PREFACE

This is the **One Hundred Thirty-Seventh Issue** of the Current Awareness Bulletin started by Delhi Technological University, Central Library. The bulletin aims to compile, preserve, and disseminate information published by the faculty, students, and alumni for mutual benefit. It also aims to propagate the intellectual contribution of Delhi Technological University (DTU) as a whole to the academia.

The bulletin contains information resources available in the internet in the form of articles, reports, presentations published in international journals, websites, etc. by the faculty and students of DTU. The publications of faculty and student which are not covered in this bulletin may be because of the reason that the full text either was not accessible or could not be searched by the search engine used by the library for this purpose.

The learned faculty and students are requested to provide their uncovered publications to the library either through email or in CD, etc. to make the bulletin more comprehensive.

This issue contains the information published during **May, 2023**. The arrangement of the contents is alphabetical. The full text of the article which is either subscribed by the university or available in the web is provided in this bulletin.

Central Library

CONTENTS

1. A deep face spoof detection framework using multi-level ELBPs and stacked LSTMs, ***3.Chhavi Dhimanm***, ***6.Aashania Antil***, Arnav Anand and ***8.Soham Gakhar***, Electronics and CSE, DTU

2. A logistic regression model to facilitate setting of organic waste composting policy for sustainable waste management, ***6.Majed Ibrahim Al-Sari*** and ***3.A. K. Haritash***, Environmental, DTU

3. A Passive Floating C-MOS Memristor with Analog Applications, ***6.Rahul Kumar Gupta***, ***3.Mahipal Singh Choudhry*** and Varun Saxena, Electronics, DTU

4. A Survey on Artificial Intelligence-based Cyber Security in IoT Networks, ***8.Akshit Tyagi***, ***8.Aniket Singh***, ***8.Amit Yadav*** and ***3.Pawan Singh Mehra***, CSE, DTU

5. A Survey on Blockchain for Rental Lease Management, ***8.Anushka Jain***, ***8.Aparna Gangwar***, ***8.Chandni Kumari*** and ***3.Pawan Singh Mehra***, CSE, DTU

6. A Survey on Blockchain in Financial Institutions, ***8.Anshu Tiwari***, ***8.Aryan Kanjolia***, ***8.Bhishek Kumar*** and ***3.Pawan Singh Mehra***, CSE, DTU

7. A Survey on Skin Lesion Detection and Classification using Machine Learning, ***6. Rashmi Yadav*** and ***3.Dr. Aruna Bhat***, CSE, DTU

8. Adoption of Metaverse in Healthcare Sector: An Empirical Analysis of its Enablers, Vipulesh Shardeo, Bishal Dey Sarkar, Umar Bashir Mir and ***8.1.Prerna Kaushik***, Physics, DTU

9. An Analytical Comparison of Deep Learning Frameworks for 2D Image-Based Hatha-Yoga Pose Identification, ***7.Debashree Debalaxmi***, ***3.Virender Ranga*** and ***3.Dinesh Kumar Vishwakarma***, IT, DTU

10. An empirical examination of the efect of domestic monetary policy on external commercial borrowings to India, ***3.Virender Kumar*** and Poonam, USME, DTU

11. An Improved Coot Optimization Algorithm for Optimal Power Flow in Small-Scale Power System, ***6.Udit Mittal***, ***3.Uma Nangia*** and ***3.Narender Kumar Jain***, Electrical, DTU

12. Analysis of Area-Controlerror in Automatic Generation Control, ***8.Jitesh Wadhwa***, ***8.Hayatunisha*** and ***3.Narendra Kumar***, Electrical, DTU

13. Artificial neural network-based adaptive control for nonlinear dynamical systems, ***6.Kartik Saini***, ***3.Narendra Kumar***, ***3.Bharat Bhushan*** and Rajesh Kumar, Electrical, DTU

14. Assessment of air quality benefits of vegetation in an urban-industrial region of India by integrating air monitoring with i-Tree Eco model, ***6.Mallika Vashist***, ***3.Thangamani Vijaya Kumar*** and ***3.Santosh Kumar Singh***, Environmental and Civil, DTU

15. Assessment of Solar-Biomass Hybrid Power System for Decarbonizing and Sustainable Energy Transition for Academic Building, ***6.Neelam Baghel***, ***3.Manjunath K.*** and ***3.Anil Kumar***, Mechanical and Environmental, DTU

16. Attribute-Based Encryption Scheme for Secure and Efficient Access in Blockchain, ***6.Anita Thakur***, ***3.Virender Ranga*** and ***3.Ritu Agarwal***, IT, DTU

17. Characterization of Luminescent Li3Ba2Gd3Mo8O32:Tb3+ Phosphors Prepared via Sol–Gel Method, Vijay Singh, B. R. V. Rao, Aadil Ahmad Bhat, Ch. B. Annapurna Devi, ***3.A. S. Rao*** and Ji Bong Joo, Applied Physics, DTU

18. Comparative study of luminescence in alkali-metal-based yttrium fluoride nanophosphor for biophotonic applications, , Simran Arora and ***3.A. Srinivasa Rao***, Applied Physics, DTU

19. Cosmic evolution in $f(Q, T)$ gravity: Exploring a higher-order time-dependent function of deceleration parameter with observational constraints, ***7.Madhur Khurana***, ***7.Himanshu Chaudhary***, Saadia Mumtaz, S.K.J. Pacif and G. Mustafa, Applied Physics and Applied Mathematics, DTU

20. Cross-efficiency aggregation by ordered visibility graph averaging: method, and application in portfolio selection, ***6.Reenu Kumari***, Abha Aggarwal and ***3.Anjana Gupta***, Applied Mathematics, DTU

21. Cyclic Heap Permutation Based Reconfiguration of Solar PV Array for Optimal Shade Dispersion, ***8.Viraj Jain***, ***8.Vikas Kumar***, ***8.Shlok Garg*** and ***3.Vinod Kumar Yadav***, Electrical, DTU

22. Design and simulation of solid-core octagonal photonic crystal fiber for terahertz wave propagation, ***7.Gurmeet Singh***, ***7.Shubham Sharma*** and ***3.Ajeet Kumar***, Applied Physics, DTU

23. DESIGNING OF A TWO STAGE TO ORBIT LAUNCH VEHICLE, ***8.Priyanshu Nailwal***, ***6.Prakash N. Budhaulia***, ***6.Rahul Kumar*** and ***3.Raj K. Singh***, Mechanical, DTU

24. Detection and Classification of Pulsed Doppler Radar Signals Using Deep Learning, ***8.Suhani Grover***, ***8.Sujal Gupta*** and ***3.Anup Mandpura***, Applied Physics and Electrical, DTU

25. Development of Ti3C2Tx-based novel immunosensor for cancer biomarker detection, ***6.Sweety*** and ***3.Devendra Kumar***, Applied Chemistry, DTU

26. Diurnal rail noise measurement, analysis, and evaluation of associated health impacts on residents living in the proximity of rail track area, Kranti Kumar, Arun Bhartia, ***3.Rajeev Kumar Mishra***, ***6.Ravi Pratap Singh Jadon*** and Jitendra Kumar, Environmental, DTU

27. EEG-Based Emotion Recognition Using Optimized Deep-Learning Techniques, ***Amit Kumar Dwivedi***, ***3.Om Prakash Verma*** and ***3.Sachin Taran***, Electronics, DTU

28. Emotion Recognition in Speech Using MFCC and Energy Based Ratio Features, ***6.Ravi*** and ***3.Sachin Taran***, Electronics, DTU

29. End-to-end handwritten Ge'ez multiple numerals recognition using deep learning, ***3.Ruchika Malhotra*** and ***7.Maru Tesfaye Addis***, Software and CSE, DTU

30. Energetic, exergetic, exergoeconomic, and enviroeconomic analysis of solar dish-integrated water desalination system with various nanofluids, Ravi Kant, ***3.Anil Kumar*** and Mukul Kumar Dubey, Mechanical and Environment, DTU

31. ERCU-Net: segmentation of road potholes using enhanced residual convolutional block based on U-Net for ADAS, ***6.Ruchi Tripathi***, ***3.S. Indu*** and ***3.Rohit Kumar***, Electronics, DTU

32. Experimental Investigation on Microstructure, Mechanical Behavior and Tribological analysis of Al2017/SiC/TiO_2 Composed by double stir casting route, ***8.Shlok Agarwal***, ***8.Kaustubh Kambiri*** and ***3.Roop Lal***, Mechanical, DTU

33. Exploring interacting bulk viscous model with decaying vacuum density, ***6.Vinita Khatri***, ***3.C. P. Singh*** and Milan Srivastava, Applied Mathematics, DTU

34. Fabrication and assessment of carboxymethyl guar gum-based sustainable flms for packaging application, ***6.Subodh K. Juikar*** and ***3.Sudhir G. Warkar***, Applied Chemistry, DTU

35. FDT Dr2T: a unified Dense Radiology Report Generation Transformer framework for X-ray images, ***6.Dhruv Sharma***, ***3.Chhavi Dhiman*** and ***3.Dinesh Kumar***, Electronics, DTU

36. Feature Aggregation with Latent Generative Replay for Federated Continual Learning of Socially Appropriate Robot Behaviours, Nikhil Churamani, ***8.Saksham Checker***, Hao-Tien Lewis Chiang and Hatice Gunes, CSE, DTU

37. Filter based saturated controller design for a class of nonlinear singularly perturbed systems, ***6.DIPAK PRASAD***, ***3.SUDARSHAN K VALLURU*** and MADAN MOHAN RAYGURU, Electrical, DTU

38. Flavonoids and their Therapeutic Applications in Neurological Disorders, ***8.Kanjam Manocha*** and ***3.Navneeta Bharadvaja***, Biotechnology, DTU

39. Fructose-Based Non-Isocyanate Polyurethane/Poly (Sodium Acrylate) Hydrogels: Design, Synthesis and Environmental Applications, ***6.Pooja Singh*** and ***3.Raminder Kaur***, Applied Chemistry, DTU

40. Generative Artificial Intelligence: A Systematic Review and Applications, Sandeep Singh Sengar, Affan Bin Hasan, ***3.Sanjay Kumar*** and Fiona Carroll, CSE, DTU

41. Graph-based Semi-supervised Learning for 3D Pose Estimation, ***8.Ravi Kant Sharma***, ***8.Raghav Kumar Jha*** and ***3.Shweta Meena***, Software Engineering, DTU

42. Gratitude research: Review and future agenda using bibliometric analysis of the studies published in the last 20years, ***3.Naval Garg***, USME, DTU

43. Green Emission in Thermally Stable Er3+ Doped Lead-Free Perovskite Phosphor for Solid-State Lighting and Optical Thermometry Applications, Ishant Kumar, Avinash Kumar, Sandeep Kumar, ***6.Vikas Sangwan***, and Arvind K. Gathania, Applied Physics, DTU

44. HumourHindiNet: Humour detection in Hindi web series using word embedding and convolutional neural network, AKSHI KUMAR, ***8.ABHISHEK MALLIK*** and ***3.SANJAY KUMAR***, CSE, DTU

45. Hypervisor Based Intrusion Detection Using Enhanced Radial Basis Neural Network on Cloud Environment, ***6.Naga Seshu Kumar Anumukonda***, ***3.Rajesh Kumar Yadav*** and ***3.Raghava N S***, CSE and ECE, DTU

46. Image Encryption Using Novel Chaotic System, ***3.Kriti Suneja***, ***8.Bhushan Kumar***, ***8.Kshitiz Jha*** and ***8.Lakshya Singh Chupha***, Electronics, DTU

47. Implementation of Secure Communication System using Various Chaotic Systems, ***8.S Suchit***, ***8.Piyush Goenka*** and ***3.Deva Nand***, Electronics, DTU

48. Implicit and Explicit Sarcasm Detection via Target of Offensive Language and Cognition of Logistic Tsallis Entropy Distribution in Social Networks, ***6.Himani Pokhriya*** and ***3.Goonjan Jain***, Applied Mathematics, DTU

49. Improved Performance of Oppositely Doped Core-Shell Junctionless Nanowire FET Using Gate Material Engineering, ***6.Bharti*** and ***3.Poornima Mittal***, Electronics, DTU

50. Information Visualization and Documentation for themes of Visual Culture, Nanki Nath and ***3.Ranganath M Singari***, Design, DTU

51. Machine Learning Approaches in Spatial Data Mining, ***7.1.Shalini Bhaskar Bajaj***, Ashima Narang and Priyanka Vashisth, CSE, DTU

52. Modelling student issues with MOOCs using TISM-P linkages, ***3.Shikha N. Khera*** and ***6.Himanshu Pawar***, DSM, DTU

53. Modified Six State Cryptographic Protocol with Entangled Ancilla Component States, ***6.Rashi Jain*** and ***3.Satyabrata Adhikari***, Applied Mathematics, DTU

54. Multi-armed bandit based online model selection for concept-drift adaptation, Jobin Wilson, Santanu Chaudhury and ***7.1.Brejesh Lall***, Electronics, DTU

55. MULTIBAND SUNFLOWER FRACTAL ANTENNA FOR WIRELESS ENERGY HARVESTING, ***6.Neeraj Sharma***, ***3.Asok De*** and ***3.Anukul Pandey***, Electronics, DTU

56. Multilingual Depression Detection in Online Social Media Across Eight Indian Languages, ***7.Viraj Rajderkar*** and ***3.Dr. Aruna Bhat***, CSE, DTU

57. Non-Alpha-Num: a novel architecture for generating adversarial examples for bypassing NLP-based clickbait detection mechanisms, ***6.Ashish Bajaj*** and ***3.Dinesh Kumar Vishwakarma***, IT, DTU

58. Nonlinear dynamical system approximation and adaptive control based on hybrid-feed-forward recurrent neural network: Simulation and stability analysis, ***3.R. Shobana***, Rajesh Kumar and ***3.Bhavnesh Jaint***, Electrical, DTU

59. ON ESTIMATION OF HANKEL DETERMINANTS FOR CERTAIN CLASS OF STARLIKE FUNCTIONS, ***3.S. SIVAPRASAD KUMAR*** AND ***6.NEHA VERMA***, MATHEMATICS, DTU

60. Online-Learning-Based Multi-RIS-Aided Wireless Systems, ***6.Ishaan Sharma***, ***3.Rohit Kumar*** and Sumit J. Darak, Electronics, DTU

61. On-To-Methodology: Ontology Development Methodology, ***7.Magendra Singh*** and ***3.Dr. Daya Gupta***, CSE, DTU

62. Parametric Bernstein operators based on contagion distribution, ***7.Kanita*** and ***3.Naokant Deo***, Mathematics, DTU

63. Performance evaluation of absorption cooling system for air conditioning-based novel trigeneration system using solar energy, ***6.Shobhit Mishra*** and ***3.Raj Kumar Singh***, Mechanical, DTU

64. Positional Analysis and Comparison of Different Charge Generation Layer based Blue OLEDs, ***6.Sugandha Yadav***, ***3.Poornima Mittal*** and Shubham Negi, Electronics, DTU

65. Potassium tert-butoxide promoted a direct one-pot synthesis of nitriles from aldehydes at room temperature, ***8.SAURAV KUMAR***, ***6.RITIKA KUBBA***, NITYANANDA AGASTI, ANITHA SELVARAJ and ***3.ANIL KUMAR***, Applied Chemistry, DTU

66. Power quality enhancement in single phase two level/five level converters using adaptive-RBFNN algorithm, ***6.Sudhanshu Mittal***, ***3.Alka Singh*** and ***3.Prakash Chittora***, Electrical, DTU

67. Prediction of shear stress distribution in compound channel with smooth converging floodplains, ***6.Vijay Kaushik*** and ***3.Munendra Kumar***, Civil, DTU

68. Prediction of the flow resistance in non-prismatic compound channels, ***6.Vijay Kaushik***, Bandita Naik, ***3.Munendra Kumar*** and ***3.Vijay K. Minocha***, Civil, DTU

69. Remote Sensing and Machine Learning Fusion: A Robust Framework for Land Use and Land Cover Change Detection, Kriti Tripathi and ***6.Abhishek Verma***, IT, DTU

70. Rethinking Latency-Aware DNN Design with GPU Tail Effect Analysis, Fuxun Yu, Zirui Xu, Longfei Shangguan, Di Wang, Dimitrios Stamoulis, ***8.1.Rishi Madhok***, Nikolaos Karianakis, Ang Li, ChenChen Liu, Yiran Chen and Xiang Chen, CSE, DTU

71. Retraction Note: CanarDeep: a hybrid deep neural model with mixed fusion for rumour detection in social data streams, Deepak Kumar Jain, Akshi Kumar and ***7.Akshat Shrivastava***, CSE, DTU

72. R-Peak Detection Using Wavelet Scattering Transform for Pre-Term Infant ECG Dataset, ***6.Shikha Singhal*** and ***3.Manjeet Kumar***, Electronics, DTU

73. RUHate-MM: Identification of Hate Speech and Targets using Multimodal Data from Russia-Ukraine Crisis, Surendrabikram Thapa, Farhan Ahmad Jafri, ***8.Kritesh Rauniyar***, Mehwish Nasim and Usman Naseem, CSE, DTU

74. Scalable and Cost-Efcient PoA Consensus-Based Blockchain Solution for Vaccination Record Management, ***6.Neetu Sharma*** and ***3.Rajesh Rohilla***, Electronics, DTU

75. Semi-Empirical DFT Based Investigation of Electronic and Quantum Transport Properties of Novel GS-AGNR (N) FET, ***6.Anshul*** and ***3.Rishu Chaujar***, Applied Physics, DTU

76. Skin Cancer Detection using Knowledge Distillation, ***6.Rashmi Yadav*** and ***3.Dr. Aruna Bhat***, CSE, DTU

77. Spectral studies of thermally stable Dy3+/Sm3+ co-doped Li2Ba5W3O15 phosphors for warm white LEDs, ***6.Anu***, ***6.Sheetal Kumari***, Nisha Deopa and ***3.A. S. Rao***, Applied Physics, DTU

78. SSR-GAN: super resolution-based generative adversarial networks model for flood image enhancement, ***6.Vinay Dubey*** and ***3.Rahul Katarya***, CSE, DTU

79. Stock assessment using cumulative prospect theory in DEA cross-efficiency model: A case study of the Indian stock market, ***6.Reenu Kumari***, ***3.Anjana Gupta*** and Abha Aggarwal, Mathematics, DTU

80. Sustainable building materials: A comprehensive study on eco-friendly alternatives for construction, ***6.Yonatan Ayele Abera***, Civil, DTU

81. Synthesis, analysis and characterizations of Dy3+ ions-doped CaBi2Nb2O9 phosphors for optoelectronic device applications, ***6.Sheetal Kumari***, ***7.Pooja Rohilla***, Samarthya Diwakar, Rupesh A. Talewar, Ankur Shandilya, Yasha Tayal, K. Swapna, Aman Prasad and ***3.A. S. Rao***, Applied Physics, DTU

82. Techno-Economic, Environmental, and Policy Perspectives of Carbon Capture to Fuel Technologies, ***8.Aditya Singh***, ***8.Vishesh Saini***, ***8.Sambhav Jain*** and ***3.Anunay Gour***, Environmental, DTU

83. Textual Context guided Vision Transformer with Rotated Multi-Head Attention for Sentiment Analysis, ***3.Chhavi Dhiman*** and ***6.Gaurav Kumar***, Electronics, DTU

84. The estimation of parameters of generalized cosmic Chaplygin gas and viscous modified Chaplygin gas and Accretions around Black Hole in the background of Einstein-Aether gravity, Puja Mukherjee, Ujjal Debnath, ***7.Himanshu Chaudhary*** and G. Mustafa, Mathematics, DTU

85. Toward Multimodal Complaint Severity Detection From Social Media, Apoorva Singh, Prince Jha, Souryadip Das, ***8.1.Raghav Jain*** and Sriparna Saha, Software Engineering, DTU

86. Towards Energy-Efficiency: Integrating DRL and ze-RIS for Task Offloading in UAV-MEC Environments, MUHAMMAD NAQQASH TARIQ, JINGYU WANG, SAIFULLAH MEMON, ***7.1.MOHAMMAD SIRAJ***, MAJID ALTAMIMI and MUHAMMAD AYZED MIRZA, CSE, DTU

87. Trihalomethanes monitoring and their seasonal variation in urban municipal water supply system in North India, M. A. Mazhar, S. Ahmed, ***3.G. Singh***, A. Husain and Rahisuddin, Environmental, DTU

88. Ultrafast catalytic reduction of organic pollutants using ternary zinc–copper–nickel layered double hydroxide, ***6.Jigyasa Pathak*** and ***3.Poonam Singh***, Applied Chemistry, DTU

89. Understanding the internationalization of Indian state-owned enterprises, ***3.Aakanksha Kaushik***, USME, DTU

ORIGINAL PAPER

A deep face spoof detection framework using multi-level ELBPs and stacked LSTMs

Chhavi Dhiman[1] · Aashania Antil[1] · Arnav Anand[3] · Soham Gakhar[2]

Abstract
Facial recognition technology has emerged as the most important element in many interactive AI systems due to its ease and accuracy on par with that of humans. Nevertheless, its dependable deployment is constrained by vulnerability to presentation attacks. Therefore, for facial recognition technology to be used safely in unsupervised situations, automatic detection of presentation attacks is crucial. In this context, we propose a novel deep face spoof detection framework, which employs multi-level Elliptical Local Binary Pattern (ELBP) and stacked LSTMs. The ELBP, a variant of Local Binary Patterns (LBPs), is utilized in three levels for three color spaces—RGB, HSV, and RGB + HSV—to acquire discriminating features. We evaluate our framework through extensive experiments on two publicly available and challenging datasets—CASIA-FASD, CASIA-SURF, and OULU-NPU. The experimental results demonstrate that our framework achieves better performance in terms of APCER, NPCER, ACER, EER, ROCs, and confusion matrix.

Keywords Face anti-spoofing · Texture descriptor · Multi-level features · Color space · LSTMs

1 Introduction

Face recognition is one of the most used biometrics these days. The simplicity of usage and non-intrusive data collection is primarily responsible for facial recognition's widespread adoption. Even many recent studies have reported its equivalency on the human level [1]. Therefore, face recognition for access control is becoming more popular, but its reliable implementation is constrained by its susceptibility to presentation attacks (PA), also known as spoofing. Face recognition systems could be tricked by simply showing printed pictures or videos to the biometric sensor. Printed photographs, replayed videos, and 3D masks are examples of presentation attacks [2, 3]. Thus, face anti-spoofing has become a need of the hour for creating a secure and impregnable biometric system.

In recent years, numerous techniques have been proposed to protect face authentication systems against spoofing attacks. These techniques have shown better performance against spoofing attacks. However, when exposed to real-world scenarios such as illumination variation and camera equipment, their performances dropped significantly. Most spoof attacks are performed either by displaying 2D prints or presenting video displays. Discriminative characteristics that may help identify spoofing have been identified by researchers through examination of the textures and quality of attack attempts, such as a facial texture spoofing detection approach based on the co-occurrence of adjacent local binary patterns (CoALBP) proposed by Gragnaniello et al. [4] Similarly, YCbCr and HSV color spaces were used by Boulkenafet et al. [5] to produce a uniform LBP for genuine vs. false categorization. In addition to textural details, temporal information [6, 7] contained in face liveness is also equally beneficial in capturing spoofing, and experts are leveraging this temporal information for face liveness detection. Several

works have connected recurrent neural networks [8], such as Long Short-Term Memory Networks (LSTM) [9], after spatial embeddings to capture temporal cues between sequential frames. Although binary cross-entropy supervised methods can arrive at promising performances, they fail to mine spoof patterns and may be stuck in poor generalization.

Motivated from above discussion, both textural and temporal data are leveraged in our work using ELBP and LSTMs. The work is performed in a two-step steps. Firstly, we propose the multi-level Elliptical variant of Local Binary Patterns (ELBPs) [10]-based feature representation for three color spaces RGB, HSV, and RGB + HSV. Secondly, defining a stacked LSTMs (Long Short-Term Memory) learning model with three LSTM layers to learn the wider cohesive association among pixels in different image patches.

To summarize, this paper comprises the following sections: Sect. 2 presents a brief survey of face spoof detection techniques. Section 3 outlines the proposed methodology for face anti-spoofing. Experimentation details along with a proper comparison are provided in Sect. 4. Lastly, Sect. 5 holds the conclusion.

2 Related Works

In recent years, many researchers have come up with robust and sophisticated face anti-spoofing detection approaches [11–14]. These approaches have greatly helped the security aspect of facial-based biometric systems by improving them immensely. They perform several analyses on spoofing attacks centered upon images, replay videos, and counterfeited masks. Therefore, we can categorize most of the literature on FAS as static and dynamic approaches.

2.1 Static approaches

Static approaches rely on texture-based information between real and fake facial images from the view of reflections on the surface and variation in materials. These approaches perform detection using a single frame without considering the temporal details. Therefore, these approaches are often known for good performance, minimal computation, and minimal cost. Moreover, they have a quicker response than dynamic systems. For instance, in [12], the experts used variations of LBPs (Local Binary Patterns) [15] and found their potential as textural descriptors on various attacks. Work like [11] demonstrates the usage of RI-LBPs (rotational invariant) and other similar textural descriptors as color texture features. Further, these textural details have been fused with extracted deep features using CNN. For involving the temporal features to express the facial dynamic structure for face anti-spoofing, Pereira et al. [13] introduced the LOP-TOP approach, which took three orthogonal planes into account that would intersect the center of a pixel in the XT, YT, and XY directions, where T stands for time axis. Following their probing outcomes, the multi-resolution LBP-TOP with SVM classifier got the best Half Total Error Rate (HTER) of 7.6% on the Replay Attack dataset. The contrast in the structural texture between 2 and 3D images is observed in [16] to discover the spoofing attacks centered upon the analysis of Fourier spectra, in which the reflections of light on the two surfaces cause a difference in their frequency distributions, whereas Maatta et al. [17] extract the texture of 2D images using the multi-scale local binary pattern (MLBP) that is later passed to the SVM classifier to classify spoofed and real faces. On the other hand, Tan et al. [18] use of a retina-based approach along with DoG filters for extracting the reflectance-based features from the facial images to detect spoofs. Another work [19] combined color texture details from the brightness as well as the chrominance/colored channels utilizing a color LBP descriptor. The work showed great results under the observed experimental outcomes.

2.2 Dynamic approaches

These approaches utilize the temporal details from the replay videos presented to the sensor like the motion of the head [20], lips, and other facial movements such as eye blinking. Other dynamic approaches include the user to follow some challenges to prove authenticity as a real user. For instance, Pan et al. [7] used a non-intrusive approach to track the blinking of the eyes as a measure for better face anti-spoofing. A randomized conditional field was employed to model various phases of eye blinking. Another work [6] combined the motion of the mouth and eye blinking 3D characteristics to detect spoofing attacks in facial images, whereas in [21] the proposal of a temporal stain metric calculated from the patterns of optical flow on the facial regions to perceive the precise facial features in the video footage to detect spoofs. In [22], a model is proposed to improve the macro- and microexpressions of the face for an advanced anti-spoofing detection. Their work resulted in the best execution and better generalizability with lesser complexity in accordance with their experimental analysis as well as results.

Besides the above approaches, some other works include deep neural network-based architecture [23–25] learn features spontaneously for face spoofing detection. CNN has generated very efficient and accurate results when it comes to computer vision applications such as object recognition [26], image classification [27], and semantic segmentation [28]. However, random learning of features often leads to poor performance.

Face liveness detection based on replay videos may be considered a video classification problem instead of image classification. Xu et al. [29] introduced the concept of LSTMs

in the FAS field. Later, LSTMs were combined with CNNs to improve motion cues for face presentation attack detection [30]. It is noted that learning temporal variations in CNN-based spatial features have strengthened the architecture's capability to detect the spoofs in videos. The above discussion motivated us to unify the characteristics of stacked LSTMs with novel multi-level ELBP textural details.

3 Proposed methodology

The section briefly discusses the proposed methodology based on a multi-level deep face spoof detection framework. The proposed framework includes three steps: data preprocessing, feature formation, and feature learning.

3.1 Data preprocessing

In the preprocessing phase, the frames are organized and labeled according to the corresponding dataset methodology. The frames are then resized to [299 × 299] pixels and fed into our proposed framework. The viola-jones algorithm [31] is utilized for face detection and ROI cropping. Furthermore, the input data are randomly flipped and rotated. Additionally, data augmentation techniques such as color jitter, random flipping, and rotation are applied.

3.2 Feature formation

Feature formation is performed in a twofold process. Firstly, the region of interest (ROI) of the face is analyzed in two distinct color spaces, namely RGB and HSV. RGB color space alone is not sufficient to provide all the necessary details in an image. As per expert opinion [32, 33], the complementary channels in the color model contain more fraudulent information, such as print defects, noise, and moiré effects. Moreover, luminance plays a vital role in highlighting imperfections on any surface. By incorporating HSV in conjunction with RGB, the color information can be separated from the intensity information, which is not possible in RGB alone. This separation can be beneficial in detecting spoofing attacks involving printed images or video displays as they may have different color properties compared to a live face. Additionally, the skin color information can be extracted using HSV, which is significant in face anti-spoofing systems. By utilizing both RGB and HSV color spaces in face anti-spoofing, a broader range of visual features can be captured, thereby improving the system's ability to detect fake faces.

Hence, in this paper, the HSV color space has been employed alongside RGB to better incorporate illumination from input frames. Additionally, a combination of both RGB and HSV color spaces is used to extract both color and hue-saturation values. This approach leads to better classification results compared to using each color space individually. As shown in Fig. 1, each RGB and HSV input face ROI is given as input to the Multi-Level Feature Extraction (MLFE) Module. It processes the input image in three levels L_i, $i \in [0, 2]$. At each level L_i elliptical LBP (ELBP) features are extracted. ELBP features are extended version of LBPs [34], where, for each central pixel (x_c, y_c) in the input image with a gray level value g_c, the value of the LBP is computed by contrasting the value of g_c with the gray level values of pixels at R distance within its surrounding in P neighborhood pixels that are in a circular path either clockwise or anti-clockwise direction. If the central pixel value (x_c, y_c) has a bigger gray level value than the neighboring pixel P_i, the neighbor pixel is given a value of 0 else 1 giving a P-bit binary number and for a neighborhood of eight pixels. LBP in total generates 256 different binary patterns. The $\mathrm{LBP}^{\mathbf{P,R}}$ is calculated as follows:

$$\mathrm{LBP}^{\mathrm{P,R}}(x_c, y_c) = \sum_{i=1}^{P} s(g_i^{\mathrm{P,R}} - g_c)^{i-1} \tag{1}$$

where $s(x)$ is defined as

$$s(x) = \begin{cases} 1, \, if x \geq 0 \\ 0, \, if x < 0 \end{cases} \tag{2}$$

A circular path neighborhood of pixels can be advantageous for a texture descriptor, but in certain applications, important texture details that could differentiate objects may be overlooked due to the circular configuration's presence. An ellipse, on the other hand, is more helpful in obtaining features from different directions [35]. So, for calculating the Elliptical Local Binary Patterns (ELBPs) [36] for each central pixel (x_c, y_c), we consider the neighboring pixels P that lie on an ellipse (with radii R_1 and R_2) estimated as:

$$\mathrm{ELBP}^{P,R1,R2}(x_c, y_c) = \sum_{i=1}^{P} s(g_i^{P,R1,R2} - g_c)2^{i-1} \tag{3}$$

where the ith neighboring pixel coordinates of (x_c, y_c), are calculated as:

$$anglestep = 2 \times \pi / P \tag{4}$$

$$x_i = x_c + R1 \times \cos(i-1) \times \mathrm{anglestep} \tag{5}$$

$$y_i = y_c - R2 \times \sin(i-1) \times \mathrm{anglestep} \tag{6}$$

MLFE module divides a face ROI in 4^i parts at each ith level. It results in formation of a histogram h_i at each level with dimension $[1 \times 256 \times 4^i]$, as shown in Fig. 2. At level L_0, the image is considered to compute $h_{0_{[1\times256]}}$. At level L_1, the image is divided in 4^1 sub-regions and $h_{1_{[1\times256\times4]}}$ is computed. At level L_2, the image is divided in 4^2 sub-regions and $h_{2_{[1\times256\times16]}}$ is computed.

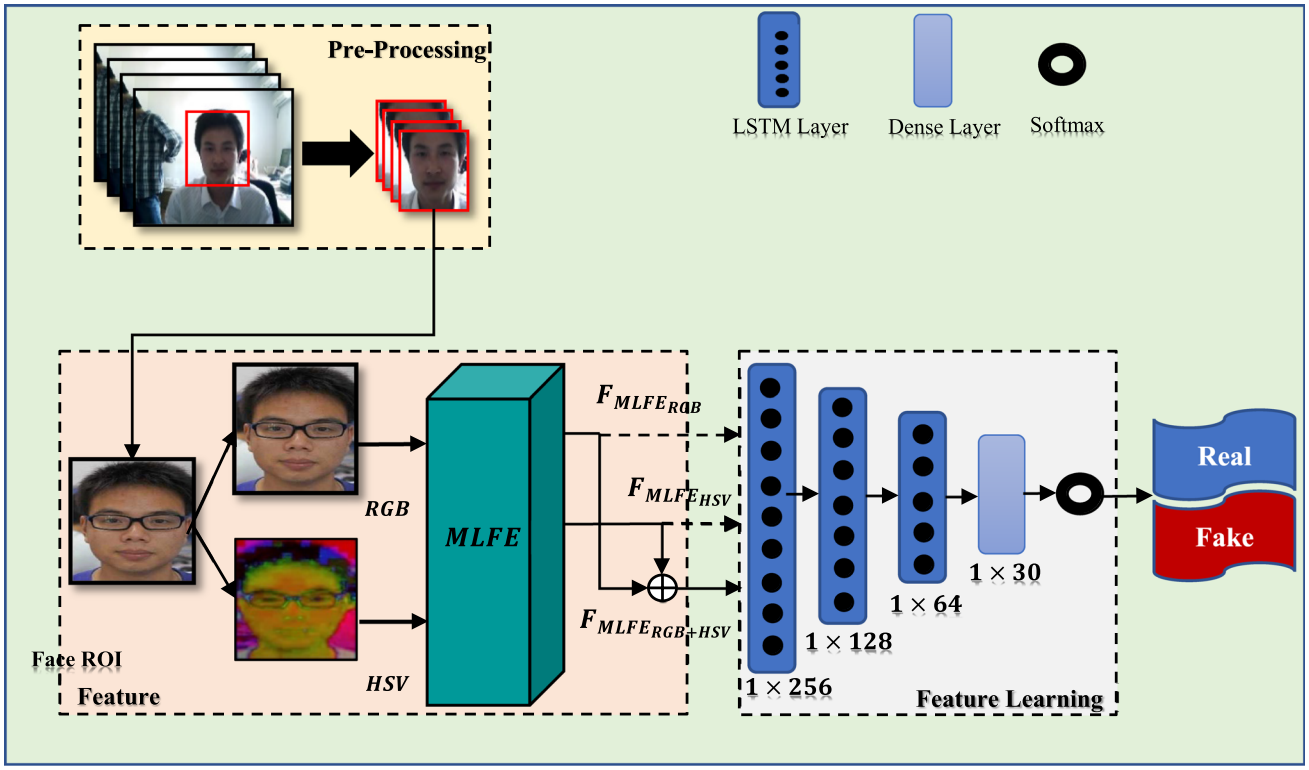

Fig. 1 Proposed deep multi-level ELBP-based anti-spoofing framework

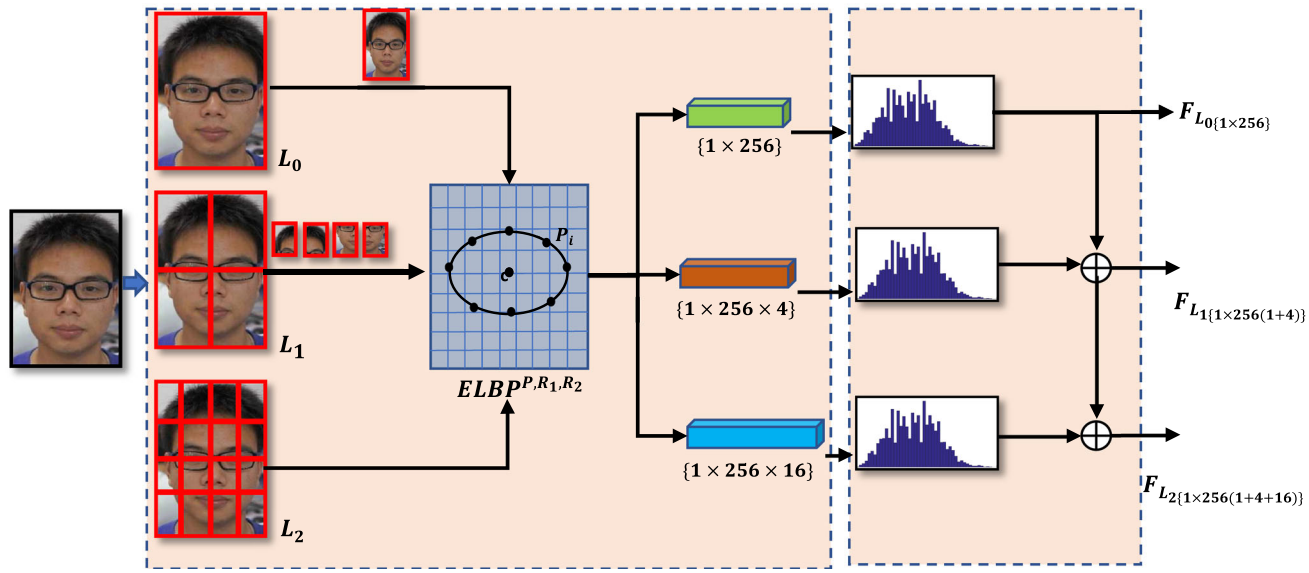

Fig. 2 Illustration of multi-level feature extraction (MLFE) from input image

3.3 Feature concatenation

From MLFE module, three multi-level feature representations are retrieved, given by F_{L_i}, $i \in [0, 2]$, as defined in Eqs. (7)–(9).

$$F_{L_0} = \{h_0\}_{[1\times256]} \tag{7}$$

$$F_{L_1} = \{h_0, h_1\}_{[1\times256(1+4)]} \tag{8}$$

$$F_{L_2} = \{h_0, h_1, h_2\}_{[1\times256(1+4+16)]} \tag{9}$$

As the number of levels increases, the feature vector size also increases. However, including higher levels decreases the performance due to increased computation cost. Thus, our framework is only limited to level-2. Algorithm 1 explains the multi-level-feature extraction (MLFE) method for levels 0, 1, and 2. The concatenation is not only limited to the feature extraction at three different levels F_{L_i}, $i \in (0, 2)$. *M*ulti-level features are further extracted for different color spaces i.e., RGB and HSV color spaces, along with third color space of HSV + RGB.

Algorithm 1 is repeated independently for each color space (RGB, HSV, and RGB + HSV images) as shown in Fig. 1. This increases the feature vector size at different levels for different color space and results in new sizes as $[1 \times 256]$ for L_0, $[1 \times 256(1 + 4)]$ for L_1, and $[1 \times 256(1+4+16)]$ for L_2. Basically, the sizes get increased by twofold as compared to a single-color space.

Finally, MLFE module generates three set of features given by $\mathrm{F}_{\mathrm{MLFE}_{\mathrm{RGB}}}$, $\mathrm{F}_{\mathrm{MLFE}_{\mathrm{HSV}}}$, $\mathrm{F}_{\mathrm{MLFE}_{\mathrm{RGB+HSV}}}$, Eqs. (10)–(12):

$$\mathrm{F}_{\mathrm{MLFE}_{\mathrm{RGB}}} = \{F_{L_0}, F_{L_1}, F_{L_2}\}_{\mathrm{RGB}} \tag{10}$$

$$\mathrm{F}_{\mathrm{MLFE}_{\mathrm{HSV}}} = \{F_{L_0}, F_{L_1}, F_{L_2}\}_{\mathrm{HSV},} \tag{11}$$

$$\mathrm{F}_{\mathrm{MLFE}_{\mathrm{RGB+HSV}}} = \{F_{L_0}, F_{L_1}, F_{L_2}\}_{\mathrm{RGB+HSV}} \tag{12}$$

Table 1 Stacked LSTM: Sequential Model parameters description; Total parameters: 512,732; Trainable parameters: 512,732

Layer	Output shape	Param#
LSTM_1	(21,950, 256, 256)	264,192
LSTM_2	(21,950, 256, 128)	197,120
LSTM_3	(21,950, 64)	49,408
Dense_1	(21,950, 30)	1950
Dense_2	(21,950, 2)	62

Unlike LBP, ELBP descriptors extract more precise spatial features from facial images as they retrieve additional directional features at various angular orientations, including extra micro-patterns. For better uniformity and orientation, we used the angle step of 45° and R_1 value to be 3 and R_2 value to be 2 for all our experiments.

3.4 Feature learning

Instead of performing direct classification based on multi-level ELBP features, the spatial distribution of multi-level ELBP features is learned through three stacked layers of the Long Short-Term Memory (LSTM) model followed by two dense layers and SoftMax Classifier, as mentioned in Table 1. The layers of LSTM units are utilized to learn the most efficient feature correlations for the spoof detection task.

Though LTSM units have been typically applied to temporal sequences, some recent works [8, 9, 37] have also utilized the memory capabilities of LSTMs in image space. In our case, we treat the output vector with size $[1 \times 256 \times n]$, where value of n changes according to the level of abstraction of features. We propose to insert 256,128, and 64 LSTM units after the MLFE module. It reduces the dimensionality of the feature vector in a structured way. Also, at the same time, memory units identify the most useful feature correlations for the task of spoof detection. The first LSTM layer is chosen to be defined with 256 units to align it with the size of the ELBP image features fed directly to it.

Algorithm 1 Computation of Multi-Level ELBP Features

Step 1: Input a frame $I(i,j)$.
Step 2: Apply Viola Jones Algorithm to extract Face ROI from the frame as $ROI(i,j)$
Step 3: Compute Multi-Level ELBP features as follows:

a) **At Level 0:** Calculate the Elliptical Local Binary Patterns (ELBPs) for each central pixel (x_c, y_c) using following formulas.

$$ELBP^{P,R1,R2}(x_c, y_c) = \sum_{i=1}^{P} s(g_i^{P,R1,R2} - g_c)2^{i-1}$$

where P is the no. of neighbouring pixels, $P \in [1,8]$ that lie on an ellipse with radii R_1 and R_2, $R_1 = 3, R_2 = 2$ and i^{th} neighboring pixel coordinates of the central coordinate (x_c, y_c), is calculated as:

$$angle\ step = 2 \times \pi/P,$$
$$x_i = x_c + R1 \times \cos(i-1) \times angle\ step$$
$$y_i = y_c - R2 \times \sin(i-1) \times angle\ step$$

And $s(x)$ is defined as $s(x) = \begin{cases} 1, & if\ x \geq 0 \\ 0, & if\ x < 0 \end{cases}$

$ELBP^{P,R1,R2}$ value for each pixel position is calculated. Obtained ELBP values for the entire image at Level 0, are quantized into 256 (2^8) evenly spaced bins generating a histogram vector h_0 of dimension $[1 \times 256]$.

b) **At Level 1:** Image is divided in four sub-regions $I_{SR1}(i,j), I_{SR2}(i,j), I_{SR3}(i,j), I_{SR4}(i,j)$. A histogram vector for each sub-region is generated, as defined in Level 0, step 3(a). Length of generated histogram at level 1, h_1, is $[1 \times 256 \times 4]$.

c) **At Level 2:** Each sub region $I_{SRi}(x,y)$, $i \in [1,4]$, is further divided into four sub regions. For each sub region a histogram vector is generated as defined in step 3(a). The Length of the histogram h_2 vector generated at level 2 is $[1 \times 256 \times 16]$.

Step 4: A combined feature vector is defined at all three levels as F_{L_i} , $i \in [0,2]$, with dimension given by $[1 \times 256]$, $[1 \times 256\ (1+4)]$, $[1 \times 256(1+4+16)]$ respectively.

4 Experiments

In this section, we evaluate our framework on two popular datasets. There will be a succinct description of these two datasets, followed by the performance analysis of the proposed method with various sought-after baseline methods.

4.1 Dataset

To demonstrate the performance of the proposed method, experiments are conducted on two challenging benchmarks datasets: CASIA-FASD, CASIA-SURF, and OULU-NPU.

CASIA-FASD. In the CASIA-FASD database, there are around 12,657 images for 50 subjects where the spoofs are generated using high-quality records of the real faces. The dataset holds around 5123 real images and 7534 fake images. The images are present in three different quality levels, i.e., low, medium, and high. The spoof images include cut photographs, distorted photograph spoofs, and video spoofs.

CASIA-SURF. CASIA-SURF is a large-scale multi-modal benchmark for face anti-spoofing. This dataset has subjects with modalities RGB, depth, and IR; however, in our approach, we will only be using the RGB images from this dataset. Therefore, we segregated all the RGB images from the dataset. It consists of 29,266 images, where 20,324 are spoofed and 8942 are genuine facial images.

OULU-NPU. The OULU-NPU dataset contains 5940 video sequences capturing real access and attempted attacks under various conditions. These sequences are carefully divided into training, development, and testing subsets. Additionally, the dataset includes four protocols designed to evaluate the effectiveness of face presentation attack (PA) detection algorithms. Protocol I examines the algorithm's ability to generalize across unseen illumination and background conditions, while Protocol II assesses the impact of attacks using unseen printers and display devices. Protocol III employs the leave-one-camera-out technique to

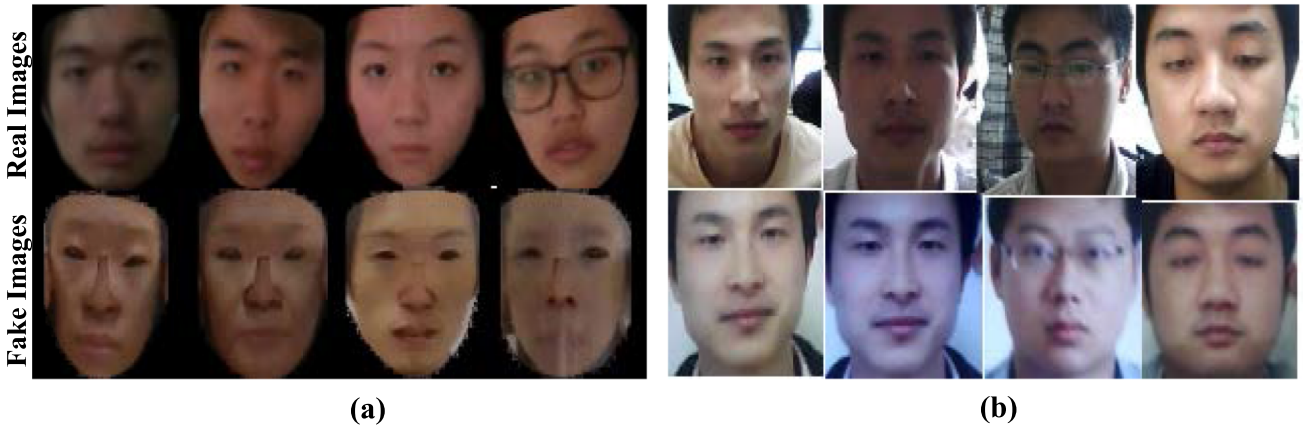

Fig. 3 Sample images **a** CASIA-SURF and **b** CASIA-FASD datasets

generalize the model across sensor variations. Finally, Protocol IV combines all three scenarios—unseen environmental setups, attacks, and sensors—posing a more challenging generalization task. This meticulous dataset design ensures a comprehensive evaluation of our proposed approach.

Figure 3 shows the sample of images from each database. We further split the images in both databases in the ratio of 75% for training and 25% for testing per Real and Fake images.

4.2 Evaluation metric

For CASIA-FASD dataset, the observed parameter is Equal Error Rate (EER), whereas CASIA-SURF dataset is analyzed in three terms, namely, Attack Presentation Classification Error Rate (APCER), Normal Presentation Classification Error Rate (NPCER), and Average Classification Error Rate (ACER) as performance evaluation metrics. EER is the point on a ROC or DET curve where the false acceptance rate equals the false rejection rate. APCER and NPCER are abbreviations for error rates that are used to gauge how well the PAD subsystem is performing. They help to assess the balance between security and convenience by measuring how well a picture is identified as either a live person or a spoof. ACER is the average of APCER and NPCER.

Besides these parameters, we have also obtained Receiver Operating Characteristic (ROC) curves obtained results in FPR and TPR values. We have also shown the Confusion Matrix in terms of True Positive (TP), False Positive (FP), True Negative (TN), and False Negative (FN) values. The mathematical formulae of the above-mentioned metrics are as follows:

$$\mathrm{FPR} = \mathrm{FP}/(\mathrm{FP} + \mathrm{TN}) \tag{13}$$

$$\mathrm{TPR} = \mathrm{TP}/(\mathrm{TP} + \mathrm{FN}) \tag{14}$$

$$\mathrm{APCER} = \mathrm{FP}/(\mathrm{TN} + \mathrm{FP}) \tag{15}$$

$$\mathrm{ACER} = (\mathrm{APCER} + \mathrm{NPCER})/2 \tag{16}$$

$$\mathrm{NPCER} = \mathrm{FN}/(\mathrm{FN} + \mathrm{TP}) \tag{17}$$

$$\mathrm{EER} = (\mathrm{FPR} + \mathrm{TPR})/2 \tag{18}$$

4.3 Training settings

We implemented the architecture using Keras and conducted the experiment on Google Colab pro, utilizing an Nvidia P100 GPU with 16 GB RAM**.** We performed horizontal flips and rotation for data augmentation. During network training, we used the Adam optimizer with a learning rate of 10e−4 and employed a batch size of 32 with random shuffling. The whole architecture was trained for 20 epochs.

4.4 Comparative analysis with other state-of-the-art

In order to demonstrate the effectiveness of our proposed architecture, we have conducted a comparison with other state-of-the-art approaches. The comparison is presented in Tables 2, 3, and 4 for the CASIA-FASD, CASIA-SURF, and OULU-NPU datasets, respectively. For the CASIA-FASD dataset, the previous works [11, 19, 23, 38, 39, 40, 33, 41] used EER as the performance measurement parameter in their experiments. Thus, Table 2 compares the performance based on EER values. The use of Local Binary Patterns (LBPs), such as LBP-TOP [40], LBP+HOOF [39], and Color LBP [19], demonstrated their efficacy in capturing texture details and learning prominent facial features for detecting spoofs. However, these methods achieved comparably high EERs. In contrast, [23] learned CNN features, and

Table 2 Comparison of the proposed method with other state-of-the-art for CASIA-FASD Dataset

Method	EER (%)
LBP-TOP [40]	10.0
LBP + Histogram of Oriented Optical Flow (HOOF) [39]	3.1
CNN [23]	7.4

Adversarial [44]	3.2
Patch CNN [45]	4.8
Antil et. al [10]	2.37
Proposed Method	**1.12 ± 0.8**

Table 3 Comparison of the proposed method with other state-of-the-art for CASIA-SURF Dataset. The values in bold highlight observed error rate is least among other state-of-the-art

Method	APCER (%)	NPCER (%)	ACER (%)
Zhang et al. [42]	1.9	0.1	1.0
Chen et al. [43]	0.92	1.74	1.33
MA-Net [46]	2.4	1.7	2.0
MF^2ShrT with T-Encoder branch [47]	1.6	1.2	1.4
Proposed Method	**0.02**	**0.019**	**0.02**

[11] integrated CNN features with RI-LBP features in the YCbCr+HSV color space resulting in an improved EER of 4.4%. Another work, [41] combined RI-LBP with SURF features and achieved comparable performance with [11], with an EER of 4.6%. However, our proposed anti-spoofing framework outperforms these previous works, achieving an EER of 1.2% by utilizing the multi-level elliptical variant of LBP features with stacked LSTMs.

For the evaluation of the CASIA-SURF dataset, we have used the parameters APCER, NPCER, and ACER. As this dataset is relatively new, only a few studies [42, 43] have utilized it for face anti-spoofing. Zhang et al. [42] used multi-modal data to learn deep features from RGB, IR, and depth frames, achieving an APCER of 1.9%, an NPCER of 0.1%, and an ACER of 1%. On the other hand, Chen et al. [43] utilized depthwise-separable attention-based deep features for anti-spoofing. Our proposed face anti-spoofing framework achieved superior performance, with an APCER of 0.02%, an NPCER of 0.018%, and an ACER of 0.02% for the CASIA-SURF dataset.

Furthermore, we conducted thorough experiments on the OULU-NPU dataset, adhering to all four prescribed protocols, and compared our method with alternative approaches, as depicted in Table 4.Across all protocols, our method consistently outperforms others, demonstrating the effectiveness of utilizing the elliptical variant of LBP-based features learned with stacked LSTM layers as a robust representation for spoof detection.

The performance of the proposed work is also observed in the form of ROC curves and a Confusion Matrix for both datasets in all three color spaces. The ROC curves (Fig. 4) obtained in RGB+HSV color space are observed to approach leftmost corners quickly with increased TP and TN and reduced FN and FP in the confusion matrix (Fig. 5).

4.5 Ablation study

To determine the effectiveness of our proposed approach, we conducted a series of ablation experiments. These experiments allowed us to choose an appropriate model demonstrate the effect of different color spaces on efficient multi-ELBP feature representation. The results of these experiments are discussed below.

4.5.1 Ablation study for MLFE

For the first set of analysis, we perform experiments on the CASIA-FASD dataset and the results are presented in Table 5. The proposed model is evaluated at different levels $\boldsymbol{L}_0$, $\boldsymbol{L}_1$, $\boldsymbol{L}_2$, using input images in the RGB, HSV, and RGB + HSV color spaces. The results in the table demonstrate that at $\boldsymbol{L}_2$ APCER, NPCER, ACER, and EER have significantly decreased in comparison with $\boldsymbol{L}_0$ and$\boldsymbol{L}_1$. Also, multi-level elliptical texture features extracted in RGB + HSV color space detect the spoofs in images with least error rate measured as APCER, NPCER, ACER, and EER. The proposed anti-spoofing framework achieves an EER of 13.8% for the RGB color space, 6.24% EER for HSV color space, and a minimum 1.12% for the combined RGB + HSV color space. It proves that multi-level detailed features extracted in RGB + HSV color space retain discriminant information resulting in enhanced performance with least EER value. The APCER and ACER metrics also support similar observations in the combined RGB + HSV color space.

Similarly, the results obtained from the CASIA-SURF dataset demonstrate that the MLFE-based features at $\boldsymbol{L}_2$ in the RGB + HSV produce the best results. This further reinforces the observation that more detailed features lead to better accuracy.

Table 4 Comparison of the proposed method with other state-of-the-art for OULU-NPU Dataset in terms of ACER (%). The values in bold highlight that observed error rates in all four protocols are least among other state-of-the-art

Method	Protocol 1	Protocol 2	Protocol 3	Protocol 4
LBP + GS-LBP [48]	15.42	11.25	16.60 ± 11.44	36.67 ± 22.56
CCoLBP [49]	12.50	14.86	14.58 ± 11.92	22.92 ± 18.06
ED-LBP + SP y[50]	32.93	5.49	15.14 ± 15.28	41.04 ± 24.53
Proposed Method	**11.6**	**5.20**	**12.3 ± 9.33**	**18.5 ± 16.55**

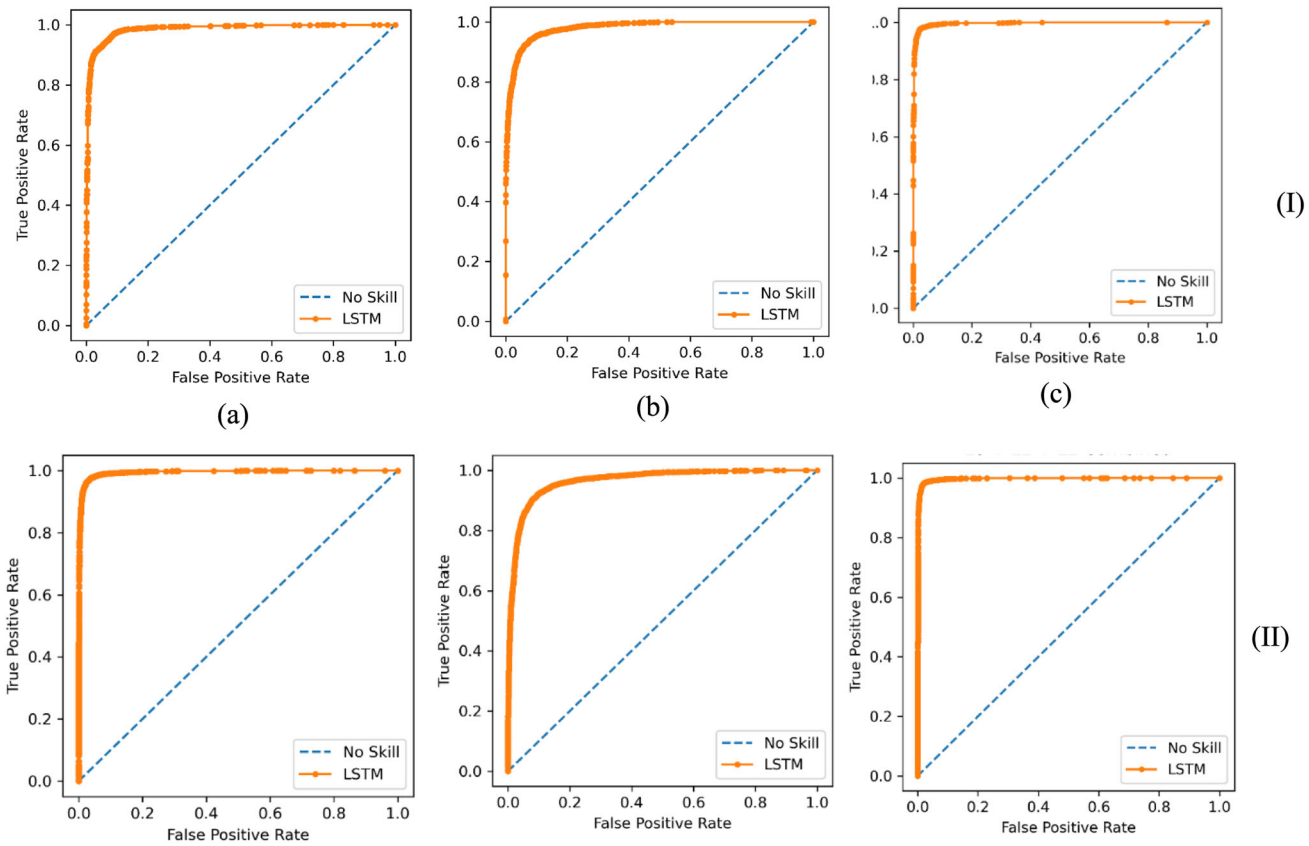

Fig. 4 Performance of proposed anti-spoofing framework in the form of ROC curves at L_2 level extracetd in **a** RGB color space, **b** HSV color space, **c** RGB + HSV color space, using LSTM learning model for (I) CASIA-FASD and (II) CASIA-SURF dataset

In terms of color spaces, it is observed in Table 6; the RGB data outperform the HSV data on the CASIA-SURF dataset with an EER of 4.1% for RGB and 9.08% for HSV. However, the results are opposite in the case of CASIA-FASD. This is due to the fact that CASIA-SURF dataset significantly holds a large set of images as compared to the CASIA-FASD dataset. Nevertheless, the combination of color space RGB+HSV is outperformed by a significant margin by getting an EER of 1.92% for both RGB and HSV color spaces on both datasets.

4.5.2 Ablation study for selection of LSTM layers

An ablation study is conducted on the CASIA-FASD dataset to demonstrate the effectiveness of using stacked LSTM layers to learn the multi-level elliptical variants of LBP face features. The experiment is evaluated for two parameters, namely, the number of stacked layers and the number of neurons in each layer. After a rigorous experimental analysis as detailed in Fig. 6, the size of LSTM layer has been chosen. The optimal results, in terms of the least EER value, are obtained for a stack of three LSTM layers with a gradual change in the number of neurons, using a downsampling factor of 2, i.e., 256, 128, and 64 neurons. As observed in Fig. 6, an increase in the number of neurons in the LSTM-3 layer leads to an increase in EER, from 1.12 to 1.83 and 2.41. Furthermore, increasing the number of neurons in LSTM-1 does not result in a great achievement in terms of a reduced value of EER.

To further analyze the impact of factors such as illumination variations and image quality on our proposed method,

we conducted an additional ablation study. Figure 7 displays a sample of illumination variation and image quality applied to the test samples to assess its effect on the architecture. For illumination variation, three different gamma values ($\gamma_1 = 1.20$, $\gamma_2 = 0.45$, and $\gamma_3 = 0.35$) were chosen; additionally, we introduced sample with different resolutions ($R_1 = \left[\frac{n}{2} \times \frac{n}{2}\right]$, $R_2 = \left[\frac{n}{4} \times \frac{n}{4}\right]$, $R_3 = \left[\frac{n}{8} \times \frac{n}{8}\right]$) to test variation in image quality. These perturbations were applied consistently across all test samples to ensure consistency in observations. The resulting observations are recorded in Table 7 for analysis. From the results presented in Table 7, it is evident that extracting Enhanced Local Binary Pattern (ELBP) features from a face image offers a certain degree of robustness against illumination variations and image quality issues. ELBP's ability to effectively capture local texture information contributes to its relative invariance to changes in illumination conditions.

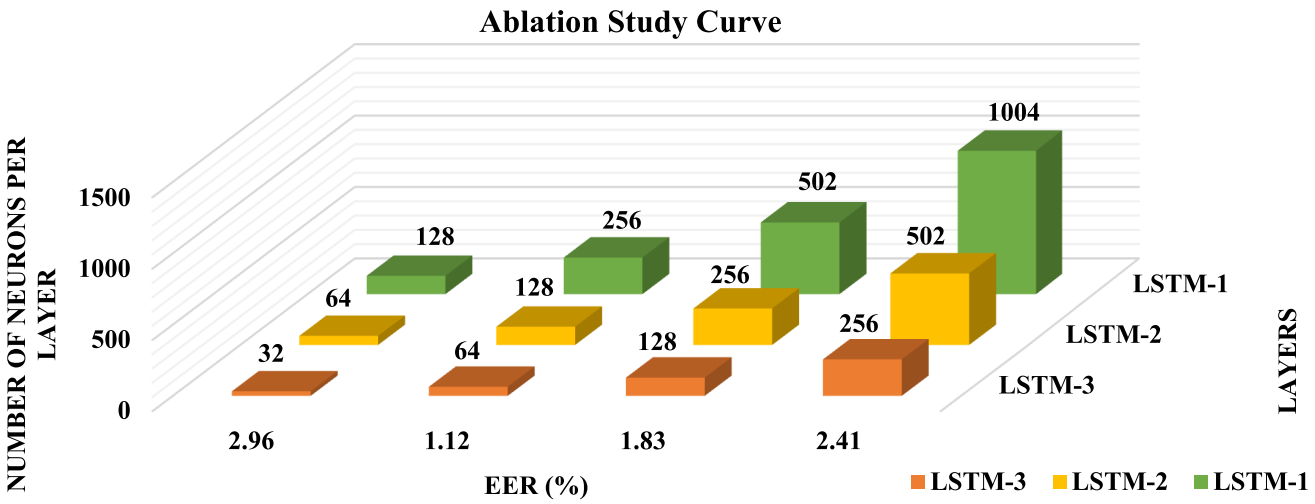

Fig. 6 Ablation study curve between number of neurons in stacked LSTM learning model with three layers and EER (%) observed in the proposed framework

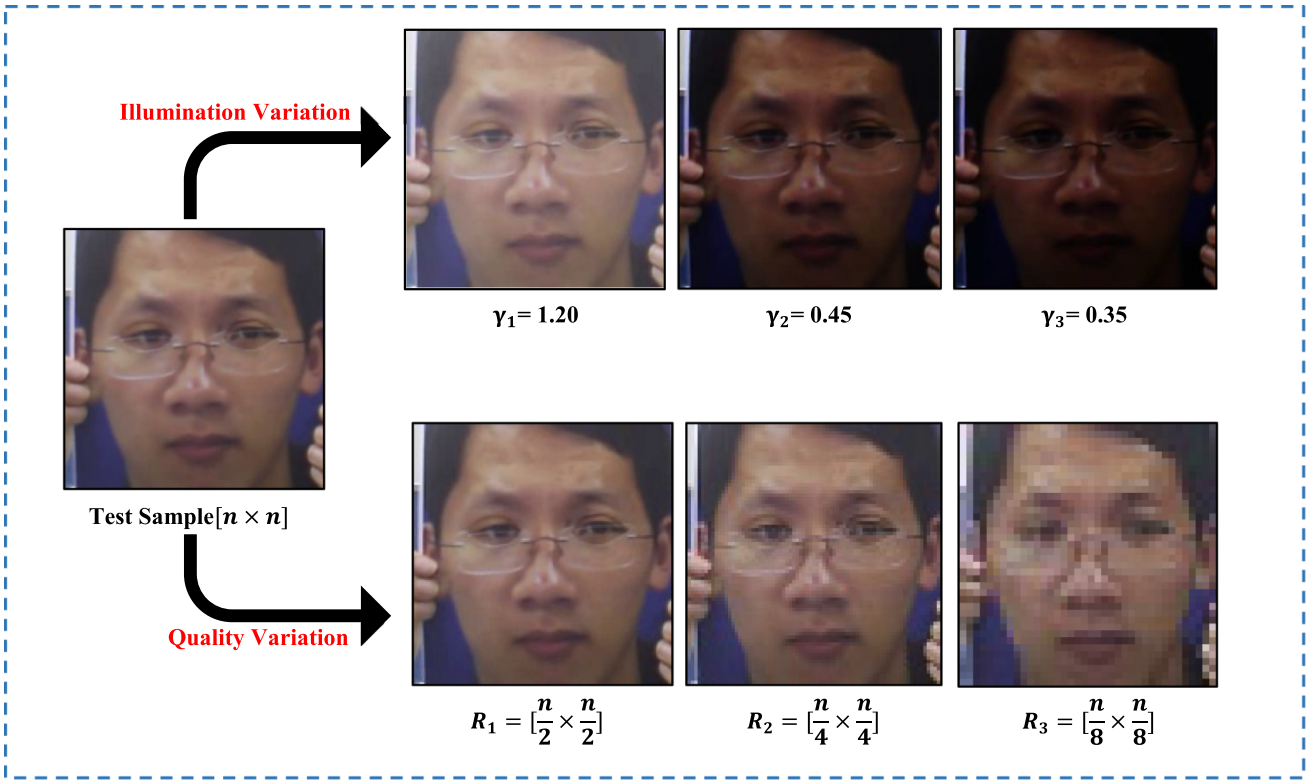

Fig. 7 Visualization of Analyzing Factors: Illumination Variation and Image Quality in CASIA-FASD Test Samples

4.6 Visualization

To gain deeper insights into the dynamics of feature enrichment within our proposed Deep Multi-level ELBP based FAS framework, we used Grad-CAM to generate visual attention maps. These maps provide valuable information about where our architecture directs its focus when analyzing faces. We present the class activation maps for test samples before the classification layer. For live faces, the architecture mainly focuses on the facial region, highlighting authentic features. In contrast, for fake faces, the attention seems scattered, indicating a lack of genuine facial characteristics. These maps provide valuable insights into the architecture's selective attention to facial regions crucial for identifying real faces. As illustrated in Fig. 8a, the architecture's emphasis

Table 7 Ablation study on CASIA-FASD (%)

Effect of impact factors on proposed architecture	Augmentation parameters	EER	NPCER	APCER	ACER
Proposed method		1.12	0.021	0.00088	0.01
Proposed Method + Illumination variation	$\gamma = 1.20$	1.11	0.021	0.0007	0.01
	$\gamma = 0.45$	1.21	0.029	0.0009	0.017
	$\gamma = 0.35$	1.24	0.031	0.0007	0.017

	$\boldsymbol{R}_2 = \frac{n}{4} \times \frac{n}{4}$	1.21	0.029	0.0009	0.017
	$\boldsymbol{R}_3 = \frac{n}{8} \times \frac{n}{8}$	1.24	0.036	0.0014	0.019

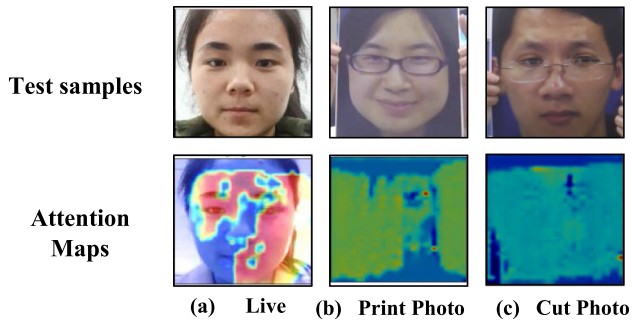

Fig. 8 Visualizing Grad-CAM attention maps for various test samples (**a**) live samples, (**b, c**) fake samples

on these areas underscores its ability to discern subtle differences between authentic and spoofed pixels. In the case of print photograph attacks, as shown in Fig. 8b, the model fails to identify any facial pixels, resulting in attention maps with uniform patterns across the frame. Similarly, for cut-out attacks, illustrated in Fig. 8c, similar activation maps are observed.

Through comprehensive ablation studies and compelling visualizations, we present robust evidence underscoring the effectiveness of our feature enhancement strategy. This comprehensive analysis not only reinforces the robustness of our approach but also sheds light on its pivotal role in advancing face anti-spoofing technology.

5 Conclusion

In this paper, we present a novel approach for detecting face spoof attacks using a Deep Face Spoof Detection Framework that combines multi-level Elliptical Local Binary Pattern (ELBP) and stacked Long Short-Term Memory (LSTM) models. Our method utilizes elliptical variants of Local Binary Patterns (LBPs) at three levels across three color spaces—RGB, HSV, and RGB + HSV, to efficiently learn distinctive features for detecting spoof attacks. By capturing both global and local features, our method achieves superior performance compared to other state-of-the-art methods. The stacked LSTM model is employed to learn the salient distribution of Multi-Level Feature Encoding (MLFE) features for both real and spoof images, generating strong decisions during the classification stage. Additionally, we conducted an ablation study to validate the selection of different parameters in the stacked LSTM model. Our results demonstrate the efficacy of our proposed approach for face spoof detection.

Abstract
Landfilling of solid waste is the common waste management (SWM) option currently in use in the southern West Bank of Palestine, which is unsustainable and causing many environmental and health problems. However, composting is an environmentally friendly waste treatment option, but of low interest due to the limited capacity of the service providers and the absence of effective waste management policies. Understanding the challenges faced by local authorities (LAs), the key stakeholders for SWM, and the factors that affect their attitude towards composting of organic waste is a major contributor to the successful setting and implementation of policies related to composting. Therefore, this study aims to assess the capacities of the LAs, the challenges faced by them, and identify the factors affecting the LAs' attitude towards organic MSW composting in southern West Bank/Palestine, Hebron and Bethlehem governorates, as a prerequisite for setting up a composting policy. For data collection, a structured questionnaire was designed, and the data was collected from all LAs that provide SWM services in the study area. The data analysis showed that 100% of the LAs are suffering from the absence of proper equipment and machinery to conduct composting (the highest challenge), while 22.6% of them are worried about farmers' acceptance of compost produced from MSW (the lowest challenge). The results also showed that LAs' perception of compost contribution to SW reduction, availability of proper place, financial capacity, community awareness, and prevalent SWM bylaws are significant predictors of LAs' attitudes toward composting. Accordingly, setting a composting policy shall consider these influencing factors to ensure the effectiveness of the policy. The results of this study are valid for similar countries and can assist decision-makers in assessing the significant influencing factors. The scientific value added by this research is that the logistic regression modelling (LRM) can be used by other countries as well, as a tool for drafting policies.

1 Introduction

Attitude and behavior and the setting of policies are among the factors that can greatly affect the performance of solid waste management (SWM) systems ((Fan et al., 2021; Yang et al., 2023). Previous studies reported inconsistent application of waste management policies in developing countries (Cetrulo et al., 2018). The lack of resources and technical capacity, lack of public participation, and awareness of waste management practices have proven to be influencing factors and main reason behind the ineffective waste management in many countries (Cetrulo et al., 2018). Understanding the barrier factors is of much importance before setting waste management policies. Trinh and Giao (2023) studied the willingness to pay the cost of electronic waste (e-waste) recycling by young consumers in Vietnam and concluded that those young consumers seriously lack knowledge about e-waste management legislation, policies, and information about the programs of collection and treatment. Budijati et al. (2023) studied the inhibiting factors for the collaboration between formal and informal sectors in handling used cell phones in Indonesia and found that collaboration was significantly hindered by insufficient organization and the absence of infrastructure. In accordance with the Asian Development Bank Institute (ADBI), the existing implications of waste management policies in developing Asia are due to the gaps in the current policies to improve the current SWM practices (ADBI, 2020). However, waste management policies are the main instrument to regulate, promote, and improve waste management practices. Therefore, overcoming the challenges in the waste management sector is a prerequisite to setting and forcing any SWM policy.

In developing countries in general, and Palestine in particular, organic waste represents the largest fraction of municipal solid waste. This waste stream is increasing following population growth and adding more pressure on the environment. It reaches 46% of the total solid waste stream in the southern part of the West Bank/Palestine as reported by the International Finance Cooperation–IFC (IFC, 2012). Improper management of the waste is the major problem behind several environmental and social impacts including surface and groundwater resources contamination (Amano et al., 2021), health risks (Vinti et al., 2023), gaseous emissions to the atmosphere and air quality degradation (Wiedinmyer et al., 2014), social disturbance due to odour release from landfills (Rana et al., 2018), and significant contributor to the climate change because of methane emissions (Sharma et al., 2019).

However, the application of advanced technologies such as green nanotechnology and advanced materials and composites, and nanostructures for improving people's lives, and environmental remediation, sustainability, renewable and clean energy production and storage can significantly contribute to environmental protection and sustainability. For example, $CoFe_2O_4@SiO_2@Dy_2Ce_2O_7$ nanocomposites can be used for removal of water contaminants (Zinatloo-Ajabshir & Salavati-Niasari, 2019), $Zn_3V_3O_8$ nanostructures can be used for electrochemical hydrogen storage (Ghodrati et al., 2019), Z-scheme heterojunction nanocomposite can be used as a photocatalyst for decomposition of nitenpyram insecticide (Hosseinzadeh et al., 2023), $Nd_2Sn_2O_7$ nanostructures produced with applying grape juice as green fuel at 500 °C can be used as photocatalyst for degrading erythrosine (Zinatloo-Ajabshir et al., 2019). Photocatalysis, which is an advanced oxidation process, is a potential environmental-friendly technology to decompose poisonous organic compounds in ambient conditions and under the irradiation of sunlight (Zinatloo-Ajabshir et al., 2024). Lanthanum zirconate ceramic microstructure could be used for electrochemical green energy sources such as hydrogen storage (Zinatloo-Ajabshir et al., 2023). In addition, innovative waste recycling technologies such as the use of machine learning for waste

separation (Fadlil et al., 2022) and recovery of carbon and fiberglass from waste composites for reuse as reinforced building materials (Nistratov et al., 2022) are major contributors to environmental sustainability. Similarly, composting is a green method for sustainable organic waste management. Composting of organic waste was reported as one of the solutions for solid waste management (SWM) in developing countries (Hettiarachchi, et al., 2018), which can eliminate contaminants and mitigate significant environmental impacts. It is a sustainable waste management option as it contributes to the circular economy and combats the depletion of resources (Kadhila et al., 2023). However, composting of organic waste faces several difficulties, especially in low-income countries. Several challenges were reported to affect the attitude towards composting including the ability of the community to participate in composting programs, availability and adequacy of resources (infrastructure, financial and technological), awareness and training of compost-production and use, market availability of the produced compost, support from the government and political leadership, knowledge of national policy and laws, society and business community contribution, and innovative methods for composting (Lalitha & Fernando, 2019).

In Palestine, SWM is within the purview of the local authorities (LA), which include municipalities, village councils (VCs), joint councils for services, planning and development (JCSPD), and joint service councils for solid waste management (JSCs-SWM). The JCSPDs are organizations formed by the VCs to provide services including SW collection to optimize these services. The JSCs-SWM are also organizations formed by the LAs to provide SW collection, transfer, and disposal. In the study area, southern West Bank (Hebron & Bethlehem governorates), the Joint Service Council for Solid Waste Management for Hebron and Bethlehem Governorates (JSC-H&B) is responsible for SW transfer and disposal, which manage SW transfer stations and the regional landfill. The interrelationship between these agencies is presented in Fig. 1. LAs (municipalities and VCs) are responsible for waste collection, which is carried out by its own waste collection vehicles (WCV) or contracted the collection service, fully or partially, to the JSCs-SWM or JCSPDs. Accordingly, these LAs are responsible for fee collection from households and pay the collection, transfer, and disposal fees to the contracting agency (JSCs-SWM or JCSPs) that pay waste transfer and disposal fees to the JSC-H&B, or pay the waste collection fees only to the contracting agency and waste transfer and disposal fees to the JSC-H&B directly. The figure presents the structure of the financial relationship between the LAs in the study area, which reflects the SW flow starting from production to disposal. Any improvement in WM through waste composting will affect this financial relationship.

However, the MoLG classifies the local authorities (municipalities only) into four groups, group "A", group "B", group "C" and group "D". This classification system is based on the local government minister's decision no. 20/4/1998. In accordance with the

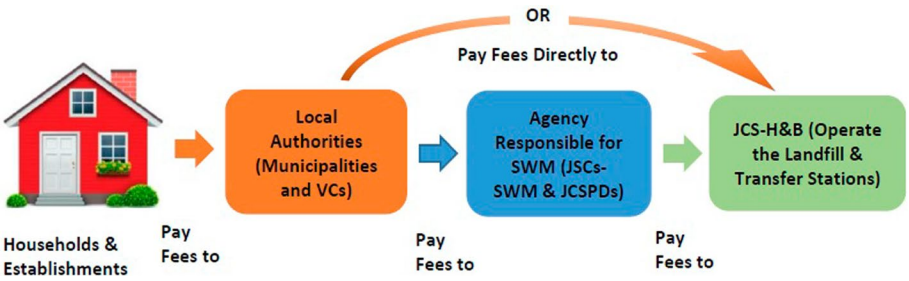

Fig. 1 The current structure of municipal SWM service in the study area

decision, large municipalities that are considered central of governorates are classified as group "A", municipalities that were established before the Palestinian Authority rolled over the West Bank and Gaza and with a population more than 15,000 are classified as group "B", municipalities of the population more than 5000 and less than 15,000 are classified as group "C", and municipalities of population less than 5000 are classified as group "D" (MoLG, 2005). The classification system doesn't provide any other information about the purpose of the classification, and the link between responsibilities and classification.

The current waste management option in the area is collection and landfilling at the engineered sanitary landfill site. The landfill is the major source of social nuisance and environmental problems due to odor emissions and leachate generation. Moreover, the lifespan of the landfill is reducing extensively due to the large quantities of SW delivered to the site, which is around 1200.0 tons daily (JSC-H&B, 2022). The extension of the landfill is currently facing several social and political constraints, which could create waste disposal problems and place the service providers under severe circumstances. Only a few sorting activities are conducted for some recyclables such as plastics, metals, and sometimes wood, but do not exceed 0.5% of the total waste stream. Pilot composting was conducted and succeeded in the production of good quality compost, but stopped because of the absence of technical and financial resources.

On the waste management policy level, the Palestinian Authority has issued the SWM bylaw in accordance with the ministers' decision no. 3 in 2019. The bylaw specified the technical requirements of SWM facilities and the obligations of all stakeholders and parties in SWM. However, waste recycling and composting were mentioned under Article 27, which encourages competent authorities to recycle solid waste and production of composting, but without targets or obligatory standards. Therefore, the bylaw remains ineffective with respect to waste recycling and composting. On the implementation level, many of the previous SW composting programs in Palestine failed. For example, the Palestinian Agricultural Relief Committee (PARK) has established three composting plants in Jericho, Jenin (Di Maria et al., 2017) and Hebron for the benefit of farmers' cooperatives. Both plants in Jericho and Hebron failed due to the high cost of operation and low participation of the local population, while the other in Jenin works during summer only (CESVI, 2019). Another two composting plants were constructed in Jericho and Ramallah (Bytillu village) in 2017 for composting agricultural waste and organic waste collected from hotels (CESVI, 2019). However, both plants stopped working in 2018. In the Gaza Strip, two composting plants have been constructed. One of them is located in the north and belongs to the Gaza and Beit Lahia municipalities, while the other is in Rafah city and was established by the Palestinian Environmental Friend (PEF) NGO, which stopped working (CESVI, 2019). The PEF then obtained funds from the United Nations Development Program (UNDP) in 2011 in coordination with Rafah municipality and constructed a sorting plant and conducted composting for the organic waste separated, but unfortunately, it stopped working in 2017 due to marketing problems (CESVI, 2019). The failure of such composting programs associated with ineffective SWM bylaw indicates a large gap between policy and practice.

On the other hand, the waste management sector was identified as one of the major sectors emitting 751.7 Gg CO_2 eq which is about 23% of total emissions as reported by the State of Palestine's Country Program for the Green Climate Fund (SPCP-GCF, 2019). The national plans and strategies aim to reduce the waste disposal at landfills by 30% and 50% by 2030 and 2040, respectively, and methane emissions by 30% in 2030 and 70% by 2040 (State of Palestine, 2021). To achieve the targets in accordance with these plans, organic waste composting is one of the appropriate options for municipal SWM, and an effective waste management policy is required. However, identifying the attitude of the local authorities towards composting and

overcoming the challenges it faces can facilitate the employment of composting to achieve the country's emissions targets. Previous studies showed that the attitudes of the LA toward organic waste composting were dissatisfactory because 63.5% of the LAs in the study area did not plan for composting (Al-Sari & Haritash, 2023). The study further identified nine factors significantly affecting their attitude including financial capacity, suitable machinery, enough refuse collection trucks for separate collection of solid waste fractions, availability of proper place for composting operations, familiarity with systems of composting, previous experience of the staff in composting, acceptance of rapid composting system, training staff members on compost production, and believing that composting of organic solid waste is within the responsibility of the LA's (Al-Sari & Haritash, 2023).

1.1 Research gap

Based on the context analysis mentioned above, there is a wide gap between the SWM policies and practice in Palestine. Although many studies have been conducted on SW recycling and composting, studies on the attitude of the LAs towards SW recycling in general and composting, in particular, are scarce. The study conducted by Al-Sari' and Haritash (2023) was based on bivariate analysis, which examines the effect of each influencing factor separately, to identify the factors influencing LAs towards composting. However, there is no study focused on using regression analysis, which examines several factors together in one model and identifies the significant ones among them.

1.2 Goal of the study

The main goal of this study is to identify the factors affecting the LAs toward composting using logistic regression analysis. In addition, it aims to assess the current capacities of the LAs and the challenges faced by them concerning organic SW management and composting. The present study bridges that gap and helps the policy-makers better understand the effect of regulating factors in implementation of a policy.

1.3 Conceptual framework

The conceptual framework and scope of this study were designed to provide answers related to the gap between the current policies and practice. Therefore, the research focused on the current situation of the LAs and provided information about their size, and cost-related issues including the cost of waste collection and disposal, number of refuse collection vehicles (RCVs), number of workers in SWM divisions, and collection rate of SW fees. These issues indicate the technical, financial, and institutional capacity of the LAs in SWM. In addition, challenges faced by LAs in organic waste management and composting were also assessed. Furthermore, it assessed the factors that affect their attitude towards the composting of organic waste and inhibit the execution of SWM policies.

2 Research methods

2.1 Research population and sample size

This research focuses on the southern part of the West Bank/Palestine, Hebron and Bethlehem governorates. The population of the study is the local authorities (municipalities, VCs, JSCs-SWM, and JCSPDs). Because the population is limited, the sample size included all the LAs that are currently providing SWM service in accordance with the list obtained from the MoLG. The list showed 85 LAs providing the service, which represents the sample size.

2.2 Survey design and data collection

A structured survey questionnaire was designed to collect the required data. The categories of the questions included information about the service provider of SWM, the quantity of SW generated, tariff, fee collection, cost of SW collection and disposal, community awareness, familiarity with SWM bylaw, compost acceptance by farmers, financial and technical capacity of the LAs to conduct composting, government support to the LAs, composting knowledge, challenges facing the LA's towards composting, and the served population which indicate the size of the LA. The data was collected via the designed survey questionnaire through direct interviews with the key staff upon direction by the LA officials. In some cases, the survey was conducted over the phone and via email at the convenience of the targeted LA. The duration of the survey was two months, which was conducted through the period extending from December 2021 to January 2022.

2.3 Data analysis

The data analysis was conducted using the statistical package for social sciences software (SPSS) version 23, and Microsoft Excel 2016. Descriptive statistics including frequencies and cross tabulation are used to assess the LAs' classifications, population, and challenges faced by them and other related issues. In addition, a binary logistic regression model (LRM) was developed to assess the factors that affect the LAs' attitude towards composting of municipal organic waste. Although the bivariate analysis can be used to assess the relationship between the dependent and independent variables, it can only assess the effect of one single variable in the absence of others, and can't predict the direction of the relationship between the dependent and independent variable. The LRM is widely used to test the effect of a combination of several explanatory variables on response variables in one model to estimate the influence of each explanatory variable in the presence of the other variables. It can identify the significance of the relationship between the dependent and the independent variables and the direction of the relationship as repeated in previous studies (Ali et al., 2012; Al-Khateeb et al., 2017; Al-Madbouh et al., 2019; Al-Sari' et al., 2012; Begum et al., 2006, 2009; Ittiravivongs, 2012). The dependent variable is the LAs' planning to compost organic SW fraction, while the independent variables are presented in Table 1. The compost selling price was not considered as an independent variable because there was no municipal solid waste composting on a commercial scale. The independent variables were selected carefully to avoid multicollinearity occurrence, which means no two independent variables have a correlation of more than 0.7 (Begum et al., 2009). The multicollinearity can cause inaccurate variances and, consequently, incorrect relationships

Table 1 Summary of the independent variables in the LRM

Variable	Description	Definition	Abbreviation in the model
X_1	Monthly SW quantity generated (tons)	1 = ≤ 20; 2 = 21–50; 3 = 51–100; 4 = 101–200; 5 = 201–400; 6 = 401–600; 7 = > 600	Mon. SW generated Qt
X_2	Household SW tariff (NIS)	1 = 10–20; 2 = 21–30; 3 = (2–3)/capita	HH SW tariff
X_3	Fee collection rate (%)	1 = ≤ 20; 2 = 20–40; 3 = 41–50; 3 = 41–60; 4 = 61–80; 5 = 81–100	Fee collection rate
X_4	Perception of composting contribution to reduction in SW	1 = Yes; 2 = Don't know; 3 = NO	Per. of compost reduce SW
X_5	Having an appropriate place for composting	1 = Yes; 2 = NO	Place availability
X_6	Having the financial capacity to conduct composting	1 = Yes; 2 = Yes, but limited capacity; 3 = NO	Financial capacity
X_7	Staff attended training on compost production	1 = Yes; 2 = No	Staff training
X_8	Staff having previous experience in composting	1 = Yes; 2 = No	Previous experience
X_9	Community awareness conducted on organic waste composting	1 = Yes; 2 = NO	Community awareness
X_{10}	Potential community participation in compost through organic SW sorting at the source	1 = Yes; 2 = Yes, but partially; 3 = NO	Pot. Comm. participation
X_{11}	Familiarity with SWM bylaw	1 = Yes; 2 = NO	Familiarity with SWM bylaw

between dependent and independent variables. The LRM used is presented in Eq. (1) as follows:

$$Log\frac{P_i}{1-P_i} = Z_i = \beta_0 + \beta_i X_i + e \tag{1}$$

where *Pi* is the LA's attitude toward organic waste composting. *Pi* = 1 if the LA attitude toward organic waste composting is positive; and Pi = 0 if not; *Xi* is the explanatory (independent) variable which is listed in Table 1; *βo* is a constant term; *βi* is a coefficient of the independent variable; *e* is the error term and *1, 2 …, n* is the number of the independent variables in the model. The sign of the coefficient *βi* determines the direction of the relationship for the dependent variable *Pi* and the independent variable *Xi*.

The model uses the maximum likelihood function to estimate the model coefficients, which is the most widely used method. The logistic regression model estimates the probability of a certain event occurring by calculating the changes in the logarithm of the dependent variable. The likelihood function, as defined in Eq. (2), expresses the values of β in terms of known and fixed values of y (β is related to P) and is derived from the probability distribution of the dependent variable so that the values of β that maximize the output of Eq. 2 are the maximum likelihood estimates (Begum et al., 2009).

$$L\left(\frac{\beta}{y}\right) = \prod_{i=1}^{N} \frac{n_i!}{y_i!(n_i - y_i)!} P_i^{y_i}(1 - P_i)^{(n_i - y_i)} \tag{2}$$

The statistical significance of each coefficient was evaluated using the Wald test (Begum et al., 2009), which is used to determine whether each independent variable in the model is significant or not.

$$W_i = \left(\frac{\beta_i}{S.E_{\beta_i}}\right)^2 \tag{3}$$

where $i = 1, 2 \ldots, n$ and $S.E$ = standard error.

The log-likelihood function, the omnibus test, Cox and Snell R^2, and Naglekerke $\check{R}^2$ were used to evaluate the suitability of the model (Al-Sari' et al., 2012). The log-likelihood function is used to measure the goodness of the data fit of the model and is defined as per Eq. (4) (Begum et al., 2009).

$$Log - likelihood = \sum_{i=1}^{n} [Y_i \ln(\hat{Y}_i) + (1 - Y_i)\ln(1 - \hat{Y}_i)] \tag{4}$$

As the model uses the observations to predict the expectations, Y_i is the actual result (the observation), and $\hat{Y}_i$ the predicted probabilities of the result (the expected), which is quoted as 2log-likelihood since it has approximately chi-squared distribution. The Omnibus test, which is a likelihood-ratio chi-squared test, provides an indication of the goodness of fit if the coefficients of the variables in the model are all jointly equal to zero. Cox and Snell R^2 and Nagelkerke $\check{R}^2$ indicate the variation proportion in the dependent variable explained by the independent variables of the model. Cox and Snell R^2 values cannot achieve a maximum value of 1, therefore Nagelkerke $\check{R}^2$ is used because it is an adjusted version of the Cox and Snell R^2 and its values are in the range from 0 to1, and is often preferred (Bewick et al., 2005).

Figure 1 depicts the methodological approach process of the research starting from the population and sample determination and ending with results presentation.

3 Results and discussion

To understand the situation of the LAs in the study area, institutional, technical, and financial indicators were analyzed to better describe the current situations and challenges faced by these LAs. Then factors of the potential effect of the attitudes of the LAs towards composting were collected in one LRM to assess its degree of effect. The following sections present these results in detail.

3.1 Classification of the LAs

The data analysis showed that 2.4% of the municipalities (2 municipalities) are classified "A", 20.0% (17 municipalities) are classified "B", and 22.4% (19 municipalities) are classified "C", while there is no official classification of VCs, JSCs-SWM, and JCSPDs which represent 55.3% (47 VCs, JSC-SWM & JCSPD) of the total LAs. The LAs and the population served in the study area are shown in Fig. 2. It is worth to mention that the classification of the LAs was based on the number of residents within the border of the LA in accordance with the MoLG rules. The classification system, as discussed in the introduction section, indicates the size of the LA but doesn't provide a link between the size and responsibilities or any other regulations. Previous studies reported that the size of the LA affects the financial performance because large LAs have more resources to generate revenues (Zamzami & Rakhman, 2023).

Figure 2 shows that communities with a population less than 5000 are fully served by VCs, 68.8% of communities with a population of 5001–10000 are served by municipalities and 31.2% of them are served by VCs, 100% of the communities with a population of 10,001–20000 are served by municipalities, 83.3% of the communities with a population of 20,001–30000 are served by municipalities and 16.7% are served by JSCs-SWM and JCSPDs, all of the communities (100%) with population of 30,001–40000 are served by municipalities, 100% of the service is provided by the JSCs-SWM and JCSPDs in the communities with population 40,001–60000, and 60% of the service is provided by municipalities in the communities with population more than 60,000 and 40% is provided by the JSCs-SWM and JCSPDs. The interrelationships between the above-mentioned actors

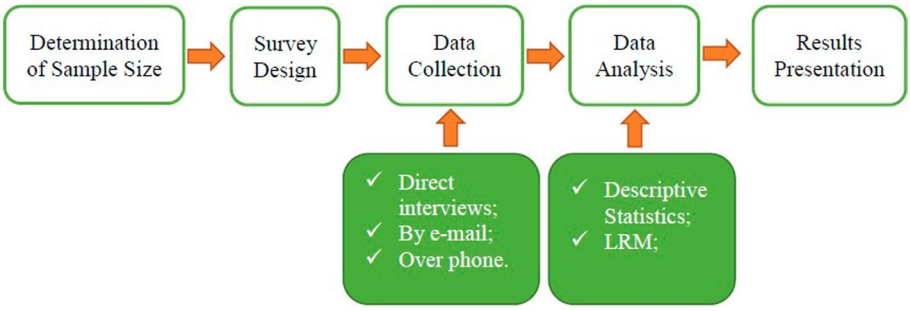

Fig. 2 Research methods process

in SWM are mainly related to the fact that all of them are authorized to provide SWM service and have the authority to contract the service or part of it in case they haven't enough capacity to cope with the waste generated in the community.

3.2 Cost-related issues of municipal SWM

SW collection and disposal cost differs from one LA to another depending on the quantity of waste generated, the number of refuse collection vehicles, and the number of workers. This is dependent on the population and the size of the LA as well. This section highlights the cost of SW collection and disposal and the elements that could influence the costs. The results reveal that the monthly waste collection cost is less than or equal to NIS 10,000.0 for 43.8% of the LAs which are of small size (i.e. the VCs). The monthly waste collection cost is between NIS 10,000.0 and 300,000.0 for the majority of the LAs (51.4%), while the cost exceeds NIS 300,000.0 for a few LAs (5.0%) as presented in Table 2. However, the monthly disposal cost for the majority (59.3%) of the LAs is less or equal to NIS 5000.0, while the disposal cost is between NIS 5000.0 and NIS 30,000.0 for 30.8% of the LAs. Few LAs (9.9%) exceed the cost of NIS 30,000.0 as disposal cost. As the organic waste fraction is the highest, the highest portion of the SW collection and disposal costs is attributed to the organic waste fraction. However, following other options in organic waste management such as composting could, to a large extent, reduce these costs. Jalalipour et al. (2024) concluded that home composting reduces SWM costs and leads to a 5% saving for the municipality of Shiraz/Iran.

Selected factors of potential influence on SWM are presented in Table 3. The results showed that 18.5% of the LAs are generating 20 tons or less of SW monthly, while 14.8% of them are generating more than 600 tons on a monthly basis. The majority of LAs (66.7%) are producing in the range of 50–600 tons of SW per month. For the refuse collection vehicles (RCVs), 67.5% of the LAs don't own RCVs because they contracted the service to the JCSPD, JSC-SWM, or nearby municipality. Around one-fourth of the LAs have one to four RCVs, and a few of them (7.2%) have five or more RCVs. However, more than one-third of the LAs don't have SW workers, which could be attributed to the fact that these are small-size LAs and are contracting the service to another service provider, and they are not conducting street sweeping because these rural areas have low density of population. LAs that have more than 20 SW workers represent 12.0% part of the total LAs in the study area, while 52.9% of them have several SW workers in the range of 1–20. The fees collection showed that 9.9% of the LAs have collection less than or equal to 20%,

Table 2 Monthly cost of SW collection and disposal against a number of LAs in the study area

Monthly cost of SW collection (NIS)	%	Monthly cost of SW disposal (NIS)	%
Less or equal to 10,000.0	43.8	Less or equal to 5000.0	59.3
10,001–30,000.0	21.3	5001.0–10,000.0	12.3
30,001–80,000.0	17.5	10,001.0–20,000.0	12.3
80,001–150,000.0	8.8	20,001.0–30,000.0	6.2
150,001.0–300,000.0	3.8	More than 30,000.0	9.9
More than 300,000.0	5.0		
Total	100.0	Total	100.0

Table 3 Factors of potential effect on SWM at the LAs

Monthly waste generation (tons)	%	RCVs	%	SW workers	%	Fee collection (%)	%
Less or equal to 20	18.5	None	67.5	None	34.9	Less or equal to 20	9.9
21–50	21.0	One	8.4	1–5	32.5	21–40	18.5
51–100	6.2	Two	8.4	6–10	12.0	41–60	25.9
101–200	17.3	Three	7.2	11–20	8.4	61–80	14.8
201–400	16.0	Four	1.2	More than 20	12.0	81–100	30.9
401–600	6.2	Five or more	7.2				
More than 600	14.8						
Total	100	Total	100	Total	100	Total	100

30.9% of them have collection in the range of 81–100%, and the rest of the LAs (60%) in the study area have collection in the range of 21–80%. In general, the fee collection rate is considered relatively low which can in turn affect the performance of the LAs and attitudes toward developing an effective SWM system. Fees are the main source of revenues for the SWM sector (Abu-Qdais et al., 2023) and failure to secure a proper budget for SWM was reported as the root cause of failure of service (Breukelman et al., 2022).

3.3 Challenges in organic SW composting

Composting of the organic municipal SW fraction can attract LAs because it can reduce the transport and disposal costs, and can prolong the life of the landfills (Folz, 1991; Muttamara et al., 1994). However, LAs could face constraints and challenges, including technical, financial, social, and legal, which can affect their decision in selecting the appropriate option. Several challenges were selected in this study as presented in Fig. 3 and the LA opinion was assessed against these challenges. The results revealed that all the LAs (100%) lack proper equipment and machinery to conduct composting; 94.3% of the LAs reported a shortage of RCVs to collect SW; 90.6% of them suffer from lack of financial resources; 86.8% of them lack knowledge and experience in composting, and the SW tariff system

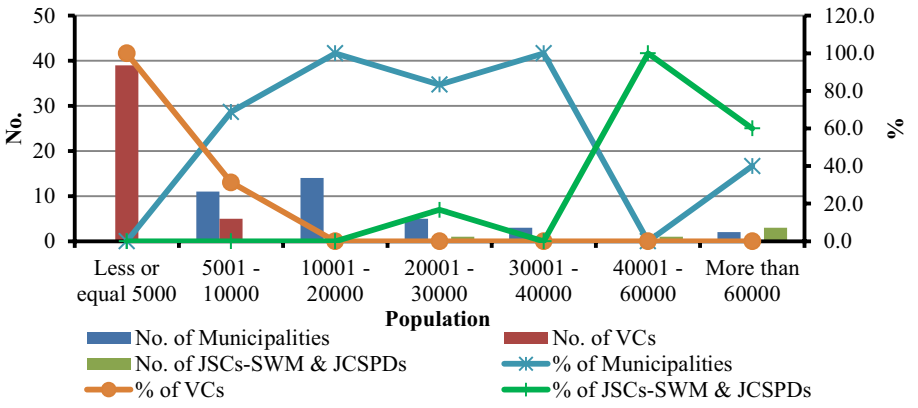

Fig. 3 LAs against the population served for waste management in the study area

was built on the cost of SW collection and disposal only, and any other associated costs with composting (cost for separate bins) were not considered; 75.5% of the LAs consider that SW sorting at the source is difficult to apply due to the lack of awareness; 73.6% of them consider a legal challenge as the compost is not forced by law; 71.7% provided that there is no incentives from the government for composting of organic waste; and 67.9% of them suffer from non-availability of a proper place to carry out composting. However, other challenges listed in Fig. 2 are of less importance in accordance with the LAs as less than 50.0% of the LAs highlighted them as challenges. Typical constraints and challenges being faced by developing countries that affect the development of effective SWM systems include a lack of financial, human, and infrastructure resources (Zhu et al., 2008). Marange et al. (2023) reported several challenges faced by the SWM council in Dangamvura/Zimbabwe which included poor engagement of the community, understaffing, political interference, and shortage of resources. Also, it has been reported that lack of infrastructure and technology, inadequate RCVs, unstandardized waste storage systems, and lack of government incentive policies are the main challenges faced by service providers in Cambodia (Pheakdey et al., 2022).

3.4 Factors affecting the attitude of LAs' towards composting of organic MSW

To evaluate the LAs' attitudes toward composting of municipal organic SW, many factors were selected. The independent variables that better explain the LAs' attitudes included in the model are monthly SW generated quantity by the LA, SW tariff on the household level, the rate of SW fee collection, LA's perception of compost contribution to SW reduction, availability of proper place (area of land) to be used for compost production, financial capacity of the LA to conduct composting, staff attended training on compost production, previous experience in compost production, awareness about compost production from organic SW, potential community participation in SW sorting, and LA's familiarity with the SWM bylaw. The LAs' attitude is estimated based on the LRM Eq. 5.

$$Logit\left(LA's\ attitude\right) = -\ 12.719 + 0.370X_1 + 0.151X_2 + 0.429X_3 + 2.044X_4 + 2.001X_5 + 2.235X_6 + 0.930X_7 + 1.704X_8 - 1.886X_9 + 1.494X_{10} - 2.697X_{11} \quad (5)$$

The results as presented in Table 4 showed that 5 out of 11 factors are significantly influencing the LAs' attitudes toward composting. The data fits the model as presented in Table 5. The significant outcomes drawn from the study showed that the attitude of LAs towards composting was negative for those who didn't perceive that composting of municipal organic SW fraction can contribute to reducing SW generation. LAs that lack a proper place to conduct composting showed a negative attitude toward organic SW composting. This finding is in agreement with Lalitha and Fernando (2019) who found that a limited area of land is a major issue for waste composting and recycling in Sri Lanka, and most of the LAs engaged in composting have failed due to lack of facilities. Al-Sari' and Haritash (2023) found that the availability of area of land to be used for compost production was a significant factor affecting the LAs' attitude toward organic waste composting. Renting an appropriate place for composting activities requires financial resources and can add more overhead on the LA's treasury, which makes it an unfavorable and non-attractive option, and results in a negative attitude towards composting.

The attitude towards organic waste composting is negative for LAs which don't have enough financial resources to cover the cost of organic waste composting. Lack of financial

resources is considered a challenge by 90.4% of the LAs as presented in Fig. 4. Financial resources are crucial for the LA's performance, and lack of financial resources can not only affect the attitude toward SW composting but also negatively affect the entire services. Choi (2021) found that financial soundness is significant for the LA's performance, and he reported that the higher the LA revenues the higher the performance level, and LAs with sufficient financial resources are more advantageous for superior performance. Zeidan et al. (2020) pointed out that budget deficit due to lack of financing is the primary obstacle that hinders the strategic plans implementation and local government units' improvements. Financial capacity was found significant factor affecting the attitude of LAs towards composting in the study area (Al-Sari' and Haritash, 2023) (Fig. 4).

In addition, the outcomes showed that LAs that have already conducted awareness in the community about compost production showed a negative attitude toward organic waste composting. LAs which conducted awareness in the community regarding composting of organic waste could have concluded that awareness without practice is not enough to change the community attitude or the awareness campaigns conducted were not enough. Conducting composting experiments for community observation in parallel with awareness could increase the citizens' understanding and knowledge about organic waste composting

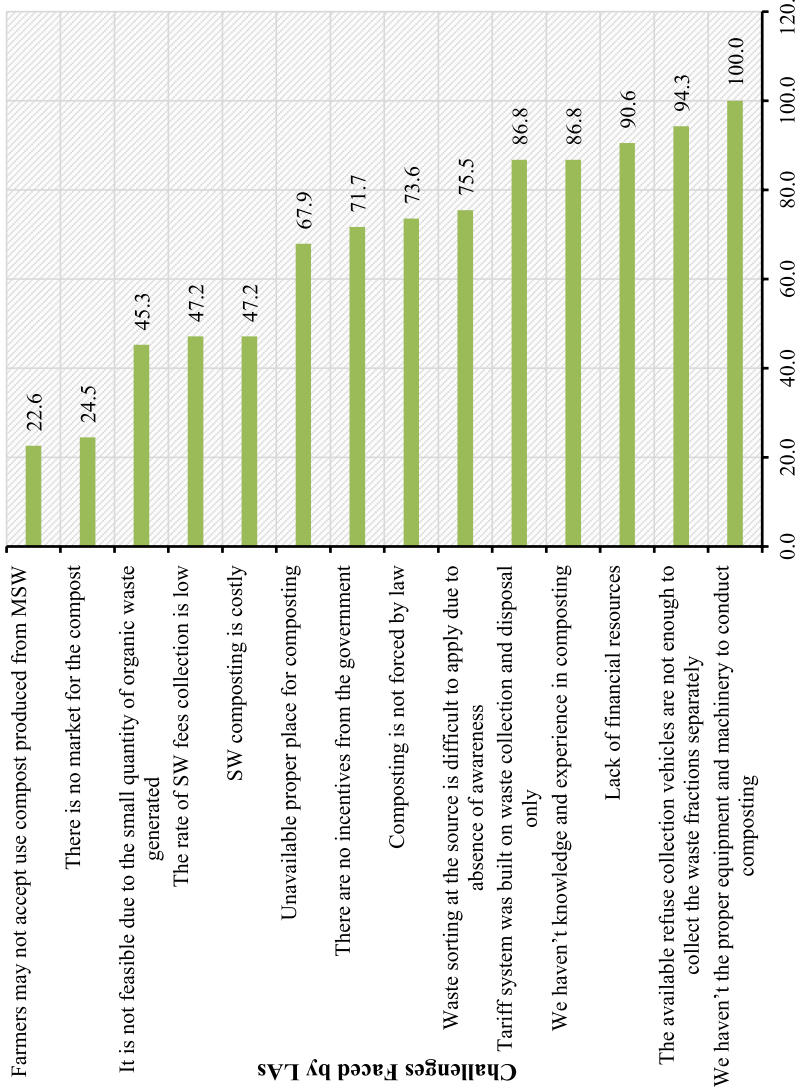

Fig. 4 Challenges faced by LAs in organic municipal SW management and composting

and knowledge, and enhance their participation. Awareness and knowledge of composting have been identified as crucial factors for community cooperation and participation in composting programs (Karkanias & Perkoulidis, 2016; Loan et al., 2019).

Moreover, the outcomes draw that LAs familiar with the SWM bylaw showed a negative attitude toward compost production from municipal organic SW. This could be attributed to the fact that composting of organic waste is not compulsory by law. SWM bylaw was issued in 2019, which encourages compost production from municipal organic SW fraction in article no. 3 and no. 27. Item 7 under article no. 3, encourages the reuse and recycling of the SW as much as possible through compost production and use in agriculture, and this use shall be in compliance with the environmental protection and health requirements. In addition, article no. 27 asks the authorities to take all necessary measures to reduce the waste stream as much as possible through reuse, recycling, and recovery (SWM bylaw, 2019). LAs who are familiar with the SWM bylaw are aware that composting of municipal organic waste fraction lies within their responsibilities, but the bylaw doesn't provide target limits as mandatory to reach, and accordingly, showed a negative attitude toward composting.

Other factors are of less importance because these had insignificant influence. The outcomes of the study showed that, first, the larger the waste quantity generated the lower the attitude toward composting. The reason could be that LA is suffering from a lack of resources such as the availability of enough area of land to conduct composting. Second, the higher the SW tariff group the lower the attitude toward SW composting. Some LAs are using the revenues to cover other services, which means that even if the tariff is high, the revenues are not used to develop the SWM system. However, some LAs have a high tariff system, but the rate of fee collection is low which means that the LA lacks the capacity to conduct composting. Other reasons could be attributed to the fact that the revenues, in some LAs, are not able to cover the cost of the service. The World Bank (2017) also reported that inter-governmental fiscal architecture in Palestine is characterized by local revenue assignments that are insufficient to cover the operational expenditure needs of local government units. Third, the higher the fee collection rate the lower the LA's attitude, which could be ascribed to the fact that LAs are using the revenues to cover other services, or the tariff, is not being able to cover the expenditures. Fourth, LAs with staff members with attained training in compost production showed positive attitudes toward organic waste composting. Training increases knowledge and plays an important role in waste processing, composting process performance, and the quality of the end product. Al-Sari' and Haritash (2023) found that staff training in compost production was a significant factor affecting the LA's attitude towards composting. Fifth, the LAs with staff members having previous experience in compost production showed positive attitudes toward composting. Previous experience enables the staff member to replicate the job successfully, thus reducing the time and effort and accelerating the processing of the waste. Staff's previous experience in compost production was found significant factor influencing the LA's attitude towards composting (Al-Sari' & Haritash, 2023). Finally, the higher the LA's expectation of community participation the higher the positive attitude toward MSW composting. The participation of the community in waste sorting at the source is of high importance because it activates the participatory bottom-up process (De Bonni et al., 2022), facilitates the composting process, and contributes to improving the quality of the compost. This in turn increases the acceptance of compost use and enhances marketing. Previous studies reported that a lack of public participation has the potential to effect attitudes towards composting (Milea, 2009).

The results of this study are compared to the results of the previous publication conducted by Al-Sari' and Haritash (2023). The previous research identified nine significant

factors while this study identified only five significant factors affecting the LAs' attitude towards composting. The comparison is presented in Table 6. The comparison showed two factors were identified were found significant by both methods of analysis, bivariate analysis and LRM. These are financial capacity and availability of place (i.e. piece of land) to be used for composting.

4 Conclusion

LAs in the study area are facing several challenges in SWM and composting. The effect of these challenges is in the range of 22.6–100% of the LAs. It is concluded that five significant factors negatively affect the attitude of LAs toward composting. These include:

1. Perception of compost contribution to SW reduction;
2. Availability of proper place to be used for composting activities,
3. Financial capacity,
4. Community awareness, and
5. Familiarity with prevalent SWM bylaws.

Identifying and overcoming the factors that affect the intention and attitude of LAs towards organic MSW composting is a cornerstone in setting a comprehensive composting policy, and developing and initiation of proper composting programs. This study suggested that a set of mitigation measures should be taken before setting and forcing composting policies to overcome the obstacles that are facing the LAs to shift their attitude towards composting from one negativity to one positivity. These measures include:

- Awareness and training on compost to improve the perception of compost contribution to waste reduction. Competent and regulatory authorities shall conduct intensive training and awareness to increase understanding and perception of the LAs about the benefits of organic waste composting especially that related to the reduction in waste generation, uses of compost, and cost-related impacts on waste management;
- Secure adequate financial resources through external funding, government support, and incentives, which can enable the LAs to cover part of the operation cost and offer a suitable place for composting activities. Also encouraging public–private partnership investment is one of the mechanisms to increase efficiency and optimization;

Table 6 Comparison of findings between Al-Sari' and Haritash (2023) and this study

Factors identified significant by Al-Sari' and Haritash (2023)	Factors identified significant by this study
Financial capacity	Financial capacity
Availability of area of land to be used for composting	Place availability
Familiarity with composting systems	Familiarity with SWM bylaw
Staff's previous experience in compost production	Community awareness
Availability of enough RCV to collect SW fractions separately	Perception of compost can reduce SW
Acceptance of the rapid composting system	
Staff training in compost	
Believe that SW composting is within the LA's responsibility	
Availability of proper machinery	

- Supporting the LAs technically and financially to conduct community awareness to ensure the cooperation of the citizens. Technical reinforcement of the LAs in waste composting is essential to enable LAs to conduct community awareness campaigns for compost promotion among the citizens who can play an important role in waste sorting at the source to facilitate organic waste composting;
- The regulatory authority shall upgrade and promote the SWM bylaw. The bylaw shall include obligatory limits and targets to achieve. These targets shall be in line with the NDCs for emission reduction, which contributes to achieving sustainable development goals (SDGs).

Taking these measures into account will assist in overcoming the influencing factors and can, to a large extent, contribute to the successful implementation of composting programs.

4.1 Applicability of the findings

Given the similarities of the LAs in the West Bank, especially for the current practices in SWM, the findings of this study could apply to the entire LAs in the West Bank and other similar LAs in the region. Policy-makers in Palestine shall consider the outcome of this study to set efficient composting policies to achieve sustainability in SWM.

4.2 Scientific value added of the study

The scientific value-added and broader importance of this research is that the LRM can be used for other SWM options as a tool to facilitate setting the related policies. It can provide the decision-makers and policy-makers with a tool to study the community situations and identify the constraints that can affect the implementation of a policy in advance, and bridge the gap in this concern.

4.3 Novelty of the research

This is the first study in Palestine that focuses on the appropriate way to set an effective composting policy through the assessment of the attitude of the key stakeholders (LAs) in SWM towards composting of organic waste. The study links policy and practice through building a mathematical model to identify the factors that affect their attitude which leads to effective drafting of the policy and better implementation.

4.4 Limitations of the study and future recommendation

This study was conducted on the LAs' located in the southern part of the West Bank/Palestine and focused on composting only. The other stakeholders of environmental protection, SWM regulatory authorities and policy-makers, and private sector companies that are working in the SWM sector, are not included in this study. Moreover, other SW recycling activities were not included. Research institutions are advised to focus future studies on other regions as well, and include other stakeholders including SWM sector regulators, policy-makers, environmental protection agencies, and the private sector. In addition, future studies can include other SW recycling fractions.

Acknowledgements The authors thank the help of different LAs in Palestine for their responses to the questionnaire survey of the study.

Funding This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Data availability The data used to support the findings of this study are available upon request from the corresponding author.

***Abstract*— A floating fully passive memristor emulator, characterized by six MOSFETs and a capacitor, has been introduced, employing the dynamic threshold MOSFET technique (DTMOS). This proposed memristor emulator circuit underwent simulation using GPDK 180nm CMOS technology in conjunction with Cadence Virtuoso Spectre software. The analysis encompassed transient behavior, hysteresis characteristics, and its nonvolatile properties. Furthermore, the manuscript includes a thorough ex- amination of process corner and temperature variations. Notably, the circuit demonstrated an impressive operating frequency of up to 10MHz. Key advantages of this proposed memristor emulator comprise its streamlined design, minimal power consumption, ability to operate at high frequencies in the MHz range, and dynamic threshold features. The circuit's layout area measures 56.725*57.15µm2. Finally, the study extends its applicability to prospective analog applications, notably in oscillators such as Colpitts chaotic and Chua's oscillators, as well as in a Schmitt trigger circuit, utilizing the proposed memristor emulator.**

Keywords— DTMOS, Memristor, hysteresis loop, nonvolatile, Schmitt trigger, chaotic, colpitts

I. INTRODUCTION

In 1971, Chua introduced a groundbreaking proposal that introduced the memristor as the fourth passive component alongside the conventional trio of resistor, capacitor, and inductor [1]. Chua's work played a pivotal role in establishing the conceptual foundation for memristors [2,3]. In 2008, Hewlett Packard (HP) marked a significant milestone by discovering the world's first nano-scale memristor [4]. Following this breakthrough, in 2010, HP achieved a major feat by successfully creating two stateful logic circuits - a NAND circuit and a material implication circuit - employing memristive switches, a category of non-volatile memristors [5]. Furthermore, volatile memristors can be used to simulate synapses for brain-inspired computing [6]. This is due to the importance of forgetting in the brain, as it is essential for adaptive computing. Without the ability to forget, every piece of information received can quickly overwhelm biological memory. As a result, emulators of volatile memristors, which have a small footprint and operate at high frequencies, have a lot of potential in brain-inspired computing..

The emulation of memristors can be broadly classified into two primary categories: analog memristor emulators [7, 8, 10–15] and digital memristor emulators [16–18]. Analog emulators make use of active components such as voltage differential transconductance amplifiers (VDTA), current conveyor transconductance amplifiers (CCTA), volt- age difference current conveyors (VDCC), differential differ- ence current conveyors (DDCC), differential voltage current conveyor transconductance amplifiers (DVCCTA), operational amplifiers (OPAMP) [10], current backward transconduc- tance amplifiers (CBTA), second-generation current conveyors (CCII), operational transconductance amplifiers (OTA), current feedback operational amplifiers (CFOA), analog multipliers, and passive elements for their implementation. However, it's essential to consider that each passive element consumes a significant amount of real estate on an integrated circuit (IC). Conversely, digital memristor emulators, which rely on field-programmable gate arrays (FPGAs) or application- specific integrated circuits (ASICs), provide several benefits, including hardware flexibility, re-configurability, and straight- forward programming and control [17]. However, it's impor- tant to note that one drawback of digital memristor emulators is their operational frequency, which is often restricted by their clock frequency.

Circuits composed solely of MOS transistors, both with and without the inclusion of external passive components [19–32], rely exclusively on the inherent capacitance of the transistors. These circuits have not used any external passive elements such as resistors, capacitors, and inductors. This approach emphasizes incorporating the most significant intrin- sic capacitances during the circuit design, resulting in high- frequency operational characteristics [26–28, 32]. These circuits also boast a compact chip footprint since intrinsic capacitors offer a higher capacitance density compared to intentionally integrated on-chip capacitors. Several researchers have introduced theoretical frameworks [33, 36], and the validation of memristor theory has been accomplished through Verilog or PSPICE coding [34, 35].

In this context, an innovative floating memristor emulator is introduced, composed of just six MOSFETs N_{1-3} and P_{1-3} and one external capacitor. Specifically, N_1 to N_3 are n- channel MOSFETs, while P_1 to P_3 are p-channel MOSFETs. Various analyses, including transient analysis, hysteresis curve examination, assessment of nonvolatile characteristics, and process corner analysis, have been conducted and presented for this memristor. Notably, this proposed memristor emulator offers several advantages, such as a simpler structure, lower power

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 27,2024 at 05:53:41 UTC from IEEE Xplore. Restrictions apply.

consumption, high-frequency operation (reaching up to 10MHz), and dynamic threshold capability. To conclude, the potential applications for this innovative memristor include analog filters, oscillators (both Colpitt and chaotic), and Schmitt triggers.

The structure of this paper can be outlined as follows: Section II is dedicated to presenting the proposed circuit and elucidating its operational principles. Subsequently, Section III offers an in-depth examination of the simulation results. The prospective applications of the emulator circuit under consideration are delineated in Section IV. Ultimately, in Section V, we summarize and provide a comprehensive assessment of the advantages and limitations of the proposed memristor emulators

II. PROPOSED MEMRISTOR EMULATOR

This study introduces a circuit, as illustrated in Fig. 1, comprising six MOSFETs and a single capacitor (C=5pF). Among these components, two MOS transistors, P_1 and N_1, are arranged as diodes, while another pair, P_2 and N_2, is configured as a resistor. Additionally, P_3 and N_3 serve as an inverter circuit, with the output of this inverter circuit providing the biasing voltage to the MOS transistor P_2. It's worth noting that this proposed circuit operates entirely in a passive mode without the need for external bias voltage.

Both transistor N_1 and transistor P_1 in the proposed circuit effectively serve as diodes. When the magnitude of the input signal rises in the positive direction, the NMOS transistor (N_1) goes into forward bias mode, while the pMOS transistor (P_1) assumes a reverse bias configuration. These transistors remain inactive until the input signal magnitude falls below 0.7V. Once the input signal surpasses the 0.7V threshold, transistor N_1 starts conducting, leading to a gradual charging of the capacitor C. Current flows through transistors N_1, N_2, N_3, and the resistor R, causing a rapid increase in the total current passing through resistor R.

Since the transistor N_1 and the transistor P_1 function as a diode in the proposed circuit. When the input signal magnitude is increasing in positive, the transistor NMOS (N_1) is in forward bias and another transistor pMOS (P_1) is reversed. Transistors will not operate until the input signal magnitude less than 0.7V. When the input signal magnitude crosses the 0.7V the transistor N_1 start conducting, and the capacitor C charges slowly. The current flows through the transistors N_{1-3}, and the resistor R. The total current across the resistor R increases tremendously.

When the input signal reaches its maximum positive voltage during the positive half cycle, transistor N_1 enters saturation. At this point, as the input signal's amplitude decreases from its maximum positive level, capacitor C begins to discharge gradually, primarily through the source of transistor N_3. As the input signal's amplitude diminishes to 0.7V, transistor N_1 ceases to active, and capacitor C continues to discharge rapidly. This discharging of the capacitor closely follows the characteristics of the input signal due to the high-resistance state. During the negative half of the input sinusoidal signal's amplitude, transistor P_1 becomes active and conducts. Consequently, capacitor C undergoes a reverse charge cycle, with a negative amplitude, facilitated by the path through P_1, N_3, and resistor R. As the negative half of the input sinusoidal signal experiences a reduction in amplitude, the capacitor commences another discharge phase. This cyclic process of charging and discharging the capacitor occurs in synchronization with every cycle of the input signal, playing a crucial role in shaping the V-I characteristics of this memristor circuit. The composition of N_1 and P_1, called diode connected load because of gate and drain of the transistors are shorted. These transistor behave as a small signal resistor and maintained the saturation region of the transistors N_1 and P_1. The proposed circuit has nonlinear behavior and presents a constricted hysteresis loop with the input signal. The W/L ratio of used MOSFETs in the composition of proposed emulator circuit in the Table I. The present emulator circuit layout has also been depicted in Fig. 2 which engages chip area of $56.725*7.15\mu m^2$.

III. Simulation Results

The memristor emulator circuit performance has been simulated using Cadence Spectre Virtuoso 180nm GPDK CMOS technology. The transient response, illustrated in Fig. 3, displays a output current with respect to the sinusoidal input signal with an amplitude of $1.5V_{pp}$. The response clearly exhibits zero crossings at $V_{in} = 0$ and Iout = 0. Fig. 4 presents the hysteresis response of the proposed memristor emulator at various frequencies (10KHz, 100KHz, 500KHz, 1MHz, and 10MHz), confirming its adherence to memristor characteristics as reported in reference [33]. Fig. 5 demonstrates the scalability behavior, with hysteresis loops observed at different capacitance values (C = 1pF , C = 2pF , and C = 5pF).the scalability means the current depends on capacitor value. The second fingerprint of memristor behavior as defined in reference [33] is portrayed in Fig. 6, highlighting the similarity in the product of frequency and capacitance for memristor characteristics. The significance of the similarity means the capacitance dependence of frequency. The non- volatile characteristics of the memristor emulator circuit is depicted in Fig. 7. Fig. 8 and Fig.9 provide a thorough analysis of process and temperature variations, further establishing the reliability of the memristor emulator.

IV. Application of Memristor Emulator

In this study, a Schmitt trigger, a Colpitts chaotic oscillator, and a Chua's oscillator circuit were introduced. Within these circuits, a resistor was substituted with the proposed memristor circuit, and the circuit's performance was carefully observed. Following the analysis, it was determined that the proposed memristor could effectively replace a resistor in these applications. The integration of this recommended memristor emulator was applied to evaluate a Schmitt trigger circuit featuring an operational amplifier, as illustrated in Fig. 10. This circuit employs positive feedback to achieve regenerative action and is commonly referred to as a regenerative comparator circuit.

The operational amplifier (Op-Amp) is biased with a voltage of ±15Vdc. A sinusoidal input signal at a frequency of 250Hz and an amplitude of 1VPP is employed, and a resistance value of R1 = 20MΩ is selected. To investigate the effect of programming pulses, a series of 1V pulses with a frequency of 1 KHz is applied to observe changes in the threshold voltage. The Schmitt trigger transient analysis can be seen in Fig. 11, and the hysteresis response is depicted in Fig. 12. Schmitt triggers are commonly used in scenarios where an Op-Amp is employed as a simple comparator.

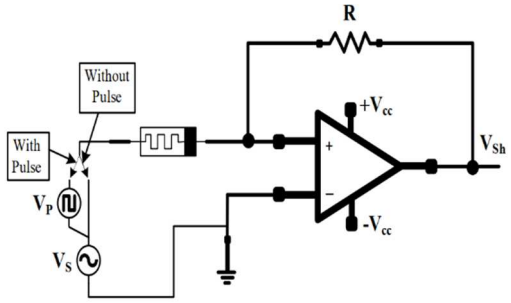

Fig. 10. Non-inverting Schmitt trigger circuit using memristor

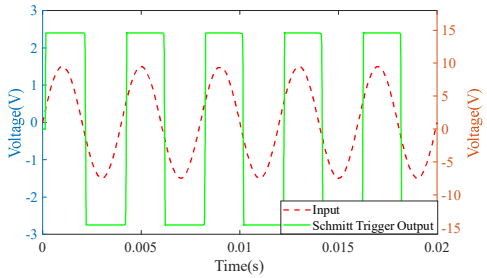

Fig. 11. Transient repsonse of Schmitt Trigger

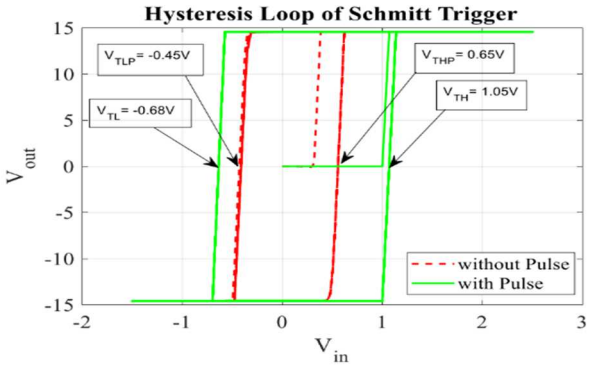

Fig. 12. Hysteresis loop for Schmitt trigger

In the context of this study, an analysis was conducted on a Colpitts oscillator circuit incorporating a memristor [37], wherein a Bipolar Junction Transistor (BJT), serving as a non-linear element, was included. The Colpitts oscillator circuit, depicted in Fig. 13, is composed of capacitors with the values of C_0 = 2µF, C_1 = 2µF, C_2 = 2µF, and C_3 = 33µF, inductor with the value of L = 10mH and Resistors with the values of R_0 = 200Ω, R_1 = 35Ω, and R2 = 1.5kΩ.

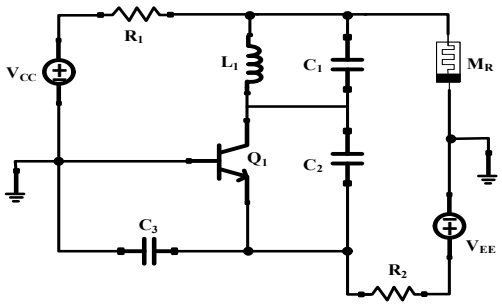

Fig. 13. Colpitts Chaotic Oscillator Circuit using memristor

The power supply is maintained at V_{CC} = 5V and V_{EE} = 5V . A spiral chaotic attractor was plotted in Figs. 14 to 15, initiated with initial values for the five state variables: $V_1(t = 0) = 0.01V$, $V_2(t = 0) = 0.01V$, $V_3(t = 0) = 0V$, $i_L(t = 0) = 0A$, and $V_0(t = 0) = 0V$. Additionally, the Chua's oscillator circuit, characterized by inductors L_0 = 70mH, L_1 = 7mH, capacitors C_0 = 1nF, C_1 = 20nF , and a resistor R_0 = 1M Ω, is illustrated in Fig. 16. The responses of Chua's oscillator have been comprehensively presented in Fig. 17 and Fig. 18.

V. CONCLUSION

In this research, an alternate approach to emulating a memristor circuit is introduced, consisting of six MOSFETs and one capacitor, devoid of any external biasing. This particular memristor circuit operates on the basis of a completely passive memristor, presenting a less intricate design compared to previously documented circuits. The results of simulations conducted on the suggested circuit

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 27,2024 at 05:53:41 UTC from IEEE Xplore. Restrictions apply.

have yielded positive out- comes. Furthermore, this study includes evaluations of process corner and temperature variations, the findings of which are detailed. The publication concludes with the demonstration of a Colpitts chaotic oscillator and Chua's oscillator circuit. Additionally, an analysis and demonstration of a Schmitt trigger circuit as a regenerative comparator circuit are presented. In conclusion, all simulated outcomes are not only satisfactory but also consistent with prior research. Due to its simplified structure, the proposed circuit holds significant promise for future applications.

ACKNOWLEDGEMENT

The authors are thankful to Delhi Technological University for providing access to the simulation tools required for the implementation of the proposed work. Author is also thankful to his supervisors for their continuous support.

***Abstract*—With the growth of network technologies and the increase in data transmission, cyber threats have become more complicated. Artificial Intelligence allows automated detection of cyber-attacks, which is important for IoT security. To achieve this, this research examines the application of deep learning and machine learning methods to DoS protection strategies for the IoT. The study uses performance metrics, and validation methods to stimulate further research on IoT security and intrusion detection systems using ensemble learning. The objective of this study was to explore and enhance the present state of knowledge regarding IoT Security, as well as to produce intrusion detection systems employing ensemble learning. We conducted a comprehensive survey of existing literature by various authors, without undertaking any original experimentation.**

Keywords—Cyber Security, Artificial Intelligence, Deep Learning , Machine Learning, IoT

I. INTRODUCTION

Today's networked world has never been so simple or efficient thanks to IoT, but there are also major cybersecurity threats. In the current era of inexpensive sensor devices and cloud computing, IoT is seen as a disruptive force that facilitates the integration of intelligent virtual interfaces with physical objects. Each layer comes with a unique security measure within its architecture [1], leaving IoT facing a complex maze of security challenges. Additionally, Internet of Things (IoT) systems are extensive and highly complex. Internet of Things attacks are among the most harmful types of attacks since they prevent individuals who have paid for a particular service from using it. Additionally, hackers these days are smarter such that they design malware and zero-day exploits that avoid detection and sometimes go undetected for quite some time. These systems consist of many components and are highly prone to attacks [2] hence, they require comprehensive security approaches. On the other hand, there exist numerous stand-alone techniques that can detect attacks as well as prevent security breaches or intrusions into these IoT systems; these include firewalls, antivirus programs, and IDSs/IPSs. Furthermore, this advantage given to adversaries by the fact that resources with security demands only need one weak point to be identified is large. To further improve the security stance of any defense responsibility, data science and machine learning can be employed to link events, identify trends, and identify abnormal behavior. With the growing prevalence of IoT devices, so too do the vulnerabilities and attack vectors that must be addressed by robust cybersecurity measures. Two general aspects of IoT security deserve special mention: malware detection and intrusion detection systems. In addition, malware threatens the integrity and secrecy of information in IoT ecosystems while the launch of intrusion may disrupt their normal operations. This comprehensive survey will focus on these key aspects by examining shallow and deep learning algorithms as well as methodologies and techniques. Additionally, this study will evaluate AI-based countermeasures' performance to understand their efficacy in protecting IoT networks. Our analysis encompasses a wide array of IoT threats and innovative AI solutions designed to mitigate these risks.

The following is a list of this survey's major contributions:

- Countermeasure Methods: Exploring shallow and deep learning algorithms.
- Performance Assessment: Evaluating AI-based countermeasures.
- Comprehensive Analysis: Analyzing IoT threats and AI solutions.

A. Types of cyber attacks

An increase in the amount of internet activity is being witnessed in every field. The quantity and type of cyberattacks also rise as a result of this development. Consequently, it is well known that cyber dangers today influence enterprises more than they did in the past. So much so that, as of late, cyberattacks are employed as a weapon [3]. Two typical cyberattacks are described here. We'll talk about the security measures for these assaults later.

1) Malware: Malware is software that, without the user's awareness, compromises or grants illegal access to networks, devices, or websites for identity theft, data breaches, and espionage. The program may act differently depending on the attacker's goals, carrying out tasks like data deletion, encryption, hijacking, and unauthorized computer activity monitoring. To determine whether computer software is malicious or not, one can apply static analysis or dynamic analysis approaches [4]. On the other hand, both methods are inadequate against zero-day attacks. These days deep learning and machine learning approaches are gradually taking their place.

2) DoS attacks: The main agenda behind a DoS attack is prohibiting a system or network so that users who rely on

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 27,2024 at 09:39:55 UTC from IEEE Xplore. Restrictions apply.

it cannot utilize it. DoS attacks achieve their target by flooding that particular system with a lot of traffic or by offering data that causes the target system to crash. DDoS attacks are those attack systems that carry out a synchronized attack against a sole target. The primary distinction is that the target is attacked from various points in contrast with just one [20]. Worldwide research is being done extensively on applying intrusion detection to resolve this issue.

B. *Intrusion detection system (IDS)*

Network IDS are required to shield a network from unauthorized or malicious activities. Three sorts of IDSs are recognized based on the type of detection employed: signature, anomaly, and specification. *For papers with more than six authors:* Add author names horizontally, moving to a third row if needed for more than 8 authors.

1) Signature-based IDS: Network traffic patterns are compared to assault-style (signatures) that have been entered in the database of a signature-based intrusion detection system. If a similar is detected, a warning is sounded. Although this system is highly accurate and has a low false alarm rate, it fails to detect new threats.

2) Specification-based network IDS: To identify malicious activity, a detailed-based network intrusion detection system (IDS) contrasts traffic patterns (parameters) to a predetermined set of guidelines and standards. A security expert manually specifies these requirements.

3) Anomaly-based IDS: Any departure from the typical network profile in network traffic is constantly monitored by a system for detecting intrusions based on anomalies. A warning is triggered to indicate the detection of an attack if the deviation is greater than the threshold. The standard attributes of networks are acquired through machine learning (ML) approaches. The capacity of an intrusion detection system that relies on anomalies to find novel threats makes it superior to signature and specification-based intrusion detection systems; nevertheless, this comes at a high false alarm rate.

II. Related Works

Numerous surveys have examined IoT security, often focusing on encryption, authentication, and access control [5]. However, in the past, some have personally explored topics such as IoT communication security and intrusion detection. However, few surveys have mentioned machine learning (ML) techniques for securing IoT through wireless sensor networks [7]. Our research stands out by delving into IoT safeguarding with special emphasis on ML and DL techniques. Misra and his colleagues [8] suggested a detailed IDS based on Learning Automata for protecting IoT networks from distributed DoS attacks. Meanwhile, Lee et al. [9] presented a DoS-based innovative IDS. Diro et al. 's team [10] introduced an IDS that uses deep learning techniques to defend against DoS attacks on IoT networks. They validated their model using NSL-KDD datasets. Furthermore, Primartha et al. [11] conducted a performance analysis on Random Forest (RF)--based IDS by considering accuracy and false alarm rate. The authors leveraged the UNSW-NB15, GPRS, and NSL-KDD datasets to train and test their model. Paper [12], worked on CPU register information, memory file system, and opcodes to classify malware into families, using SVM and K-NN models. However, the approach's limitation arises from significant variations within malware samples that are of the same family, which can decrease the model's overall accuracy. In the paper [13], the author utilized strings and PE file characteristics as features, with a larger number of malicious samples compared to benign ones. Neural networks were used for classifying malware as malicious or benign. Nonetheless, a limitation of this approach is the potential inaccuracies in labeling the training dataset.

III. DL And ML Methods In IoT Security

The ability of DL and ML algorithms to tackle complicated issues through experience-driven advancement has led to their considerable importance in real-world applications. The rise of low-computation-cost algorithms, The development of novel approaches, and the availability of large datasets are all credited with the algorithms' quick improvement. DL approaches best serve pattern analysis, which use multi-layer non-linear processing to abstract and alter the features, while ML methods usually rely on designed features. By using training data and experience, these algorithms seek to improve task performance.

Decision Trees (DT) are useful for identifying network intrusions because they provide an easy-to-understand paradigm. Support Vector Machines (SVM) help detect malware and breaches by creating hyperplanes to categorize data. To detect intrusions, Naive Bayes (NB) requires the least amount of data by computing probability for characteristics. k-Nearest Neighbors (KNN) is a common intrusion and anomaly detection algorithm that uses nearby data for categorisation. Decision trees are combined in Random Forests (RF) to provide strong predictions that help detect anomalies and illegal devices. k-Means Data may be grouped via clustering, useful for identifying Sybil assaults. Convolutional Neural Networks (CNNs) provide strong virus protection for Internet of Things devices by reducing data utilizing common parameters. Neural networks with recurrent architectures (RNNs) perform exceptionally well with sequential data, improving network traffic categorisation. Last but not least, in Internet of Things contexts, Restricted Boltzmann Machines (RBMs) are useful for anomaly and intrusion detection since they extract characteristics through unsupervised learning. These machine learning techniques offer many tools to tackle security issues in the constantly changing IoT system environment.

Table 1 outlines various Machine Learning (ML) algorithms commonly used in Intrusion Detection Systems (IDS) for enhancing security in IoT (Internet of Things) environments.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 27,2024 at 09:39:55 UTC from IEEE Xplore. Restrictions apply.

TABLE I. COMPARING ALGORITHM FOR THEIR APPLICATIONS IN IOT SECURITY

Algorithm	Basic principle	Benefits	Drawbacks	Possible Use in Security for IoT
DT	Establishes a model using decision trees (DT) from training samples, making predictions based on branches and leaves	Clear, uncomplicated, and simple technique	Needs a lot of storage, easier to understand with a few DTs	Detection of questionable traffic sources and intrusions
SVM	Forms a hyperplane to maximize the distance between sample points of different classes in feature space	Generalization capability, suitable for large feature datasets	Difficult kernel selection, complex model interpretation	Detection of intrusion, malware, smart grid attacks
NB	It applies the theory, which computes the posterior probability to predict potential for a certain feature set.	due to the Bayesian theorem, it is simple. Training dataset requirements are low.	works autonomously on features. unable to get hints from the relationship and interplay of features.	Intrusion detection in networks with issues related to dimensionality
KNN	A sample point is classified by KNN using the votes from neighboring samples.	Popular, effective for intrusion detection systems	Hard to select optimal k-value	Detection of intrusions, anomalies
RF	Combines multiple decision trees to establish a robust prediction model	Robust to overfitting, minimal feature selection, few input parameters	Impractical for large training datasets, time-consuming	Identification of abnormalities, DDoS assaults, and unapproved IoT devices
K-Means	Unsupervised clustering based on feature similarities	Suitable for data without labels, no need for labeled data	Practically less accurate and successful than supervised learning techniques.	Detection of Sybil, data anonymization
CNNs	uses equivariant representations, parameter sharing, and sparse interactions to reduce the parameters of the data.	Robust supervised DL method, scalable, improved training time complexity	High computational cost, challenging implementation on devices with restricted resources	End-to-end assurance strategy for IoT devices, malware detection
RNNs	handles sequential data by integrating a temporal layer; provides outstanding performance in several applications.	Achieves excellent performance in sequence-based threats	Gradients that disappear or explode provide a problem.	Classifying network traffic and enhancing IoT system security
RBMs	Deep generative models for unsupervised learning, extract vital features through unsupervised approach	Extraction of important features, unsupervised learning approach	High computational cost, challenging for resource-constrained devices	intrusion detection, Network anomaly detection

IV. RESULTS

The results of the study encompass an extensive evaluation of deep learning and machine learning techniques in connection to IoT security. These techniques, applied to various cyber-security focus areas, demonstrated impressive accuracy and performance. Diverse datasets, coupled with feature selection methods, were instrumental in optimizing IDS.

A. Intrusion detection systems using machine learning algorithms

Table 2 presents the performance of various intrusion detection models on different datasets. Notably, XGBoost achieved the highest accuracy of 98.69% on the NSL-KDD dataset, with precision and recall both exceeding 98%. The Grasshopper optimization algorithm with Support Vector Machine(GOA-SVM) also demonstrated strong performance on the KDDCUP99 dataset, achieving an accuracy of 98.52% with precision and recall both over 95%. These results highlight the effectiveness of these models in accurately detecting intrusions in network traffic data.

TABLE II. COMPARISON OF ML MODELS

Model	Dataset	Accuracy	Precision	Recall	F1 Score
GNB [14]	KDDCUP99	0.8328	0.90	0.83	0.85
GOA-SVM[15]	KDDCUP99	0.9852	0.9563	0.9752	0.976
GA-RF [16]	UNSW-NB15	0.928	0.616	0.630	0.623
XGBoost [17]	NSL-KDD	0.9869	0.9841	0.9911	0.9876
C4.5 [18]	NSL-KDD	0.941	0.945	0.941	0.943

B. Detection systems including intrusion using deep learning algorithms

This section explores diverse DL methods for intrusion detection. The results obtained by different authors are shown in table 3. Wang et al. [19] applied a CNN similar to LeNet-5, achieving 99.17% accuracy on CTU-13 and IXIA datasets. Staudemeyer [20] used an RNN on KDD-1999 with 100% detection rate and 2.30% FPR. Diro and Chilamkurti [22] used a DNN on NSL-KDD, reaching 99.20% accuracy, 99.27% TPR, and 0.85% FPR. Kang and Kang [23] utilized a DBN on in-vehicle networks with 97.80% accuracy. Maimó et al. [24] combined a two-stage DBN and RNN approach, achieving 81.26% precision and 99.34% recall in the first, and 68.63% precision and 70.95% recall in the second.

C. Malware detection systems using machine learning algorithm

An assessment of four distinct classification algorithms: Logistic Regression, SVM, GA-KNN, and PSO-KNN, using a provided dataset is shown in fig 1. The analysis revealed that Logistic Regression achieved the highest accuracy, standing at 99.36%, closely followed by SVM with an accuracy rate of 99.08%. Notably, GA-KNN showcased exceptional precision at 99.49%, while PSO-KNN excelled in terms of recall, reaching 99.16% [25-28].

TABLE III. OVERVIEW OF DL MODELS

Authors	Dataset	Model Description	Accuracy	TPR	FPR
Wang et al. [19]	CTU-13 & IXIA (USTC-TFC2016)	CNN (Similar to LeNet-5)	99.17%	100 %	Varies
Staudemeyer [20]	KDD-1999	RNN	100% (Detection Rate)	-	2.30%
Chawla [21]	IoT	DBN (Each hidden layer from autoencoder)	95.03%	95.40 %	-
Diro and Chilamkurti [22]	NSL-KDD	DNN (3 hidden layers)	99.20%	99.27 %	0.85%
Kang and Kang [23]	In-vehicle network (CAN packets)	Deep Belief Network (DBN) with RBMs	97.80%	-	1.60%
Maimó et al. [24]	CTU dataset	Stage 1: DBN (Two hidden layers), Stage 2: RNN	Precision: 81.26%, Recall: 99.34% (Stage 1)	Precision: 68.63 %, Recall: 70.95 % (Stage2)	-

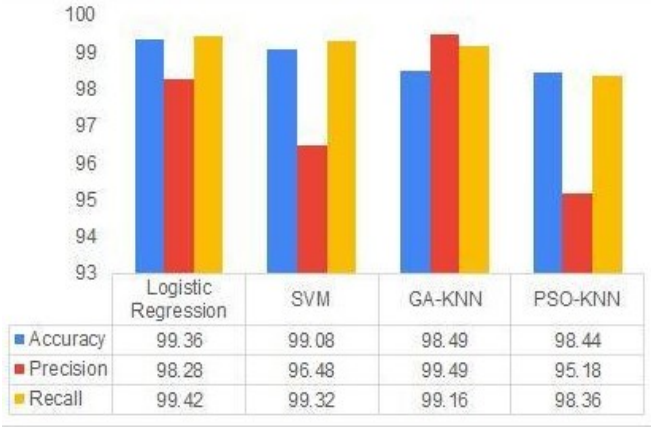

Fig. 1. Comparison of machine learning Algorithms

D. Malware detection systems using DL algorithms

Figure 2 lists the outcomes of using DL algorithms for malware identification. The analysis encompassed four key approaches: Hybrid CNN, LSTM CNN, DNN, and CNN. Notably, Hybrid CNN and LSTM CNN exhibited high accuracy rates of 99.36% and 99.08%, respectively [25]. While DNN and CNN achieved slightly lower accuracy at 90.4% and 96.6%, they demonstrated good precision and recall values [26].

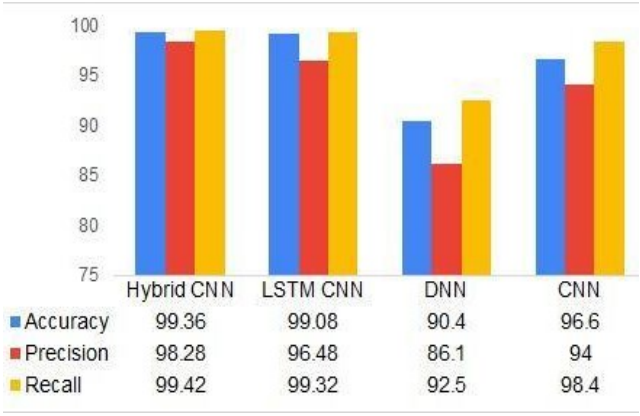

Fig. 2. Comparison of Deep learning Algorithms

V. CONCLUSION

In cybersecurity, privacy and security are essential, especially in IoT scenarios such as smart homes and hotels. This study evaluates the effectiveness of Artificial Intelligence (AI) in analyzing malware and detecting intrusions for IoT security. We analyze accuracy, methodologies, datasets, and outcomes. The research highlights AI's high performance in detecting and classifying attacks, emphasizing its value in enhancing IoT security measures.

A comprehensive survey on malware analysis and intrusion detection in IoT systems conducted from 2013 to 2023 yielded noteworthy findings. Machine learning algorithms demonstrated exceptional performance, with XGBoost emerging as the top performer in intrusion detection, achieving an AUC score of 98.76%. Deep learning techniques, including convolutional neural networks (CNNs) and recurrent neural networks (RNNs), also exhibited strong capabilities. CNNs achieved an impressive accuracy of 99.17%, while RNNs showcased a remarkable 100% detection rate with a low false positive rate. Furthermore, traditional machine learning methods like SVM and logistic regression delivered excellent classification performances, surpassing 99% accuracy. Hybrid models that combined CNNs and LSTM CNNs excelled in malware identification, reaching accuracy rates of 99.36% and 99.08%, respectively.

The study has shown that Convolutional Neural Networks (CNNs), Recurrent Neural Networks (RNNs), and Extreme Gradient Boosting (XGBoost) are all effective methods for analyzing malware and detecting intrusions in security systems for the Internet of Things.

***Abstract*—The application of blockchain technology is causing a revolution in the rental management industry by improving the security, privacy, traceability and visibility of any rental commodity. Complex tasks like commodity listings, lease agreements, payment methods, identity verification, and authentication are performed with unparalleled integrity, ultimately reducing the risk of fraud and disputes. The main objective of this survey is to review and analyse peer-reviewed literature that discusses previous works that present solutions to traditional rental lease management using blockchain technology. We start by elucidating the foundational concepts and traditional rental management industry. We then evaluated a few papers, examining the technologies used and their advantages, key focuses, and limitations. This survey aims to determine the potential of blockchain technology in improving transaction efficiency, transparency, cost reduction, and other beneficial aspects of rental management. Blockchain technology is a workable alternative to traditional rental lease management, streamlining processes, building confidence, and asserting the dynamics between landlords and tenants. This paper addresses a survey in different domains of application of blockchain technology and some suggestions for future research.**

Keywords— Blockchain, IoT, Smart Contracts, Rental lease management, Survey

I. INTRODUCTION

Blockchain technology is leading the way in this revolutionary shift that will drastically alter the rental management industry. Traditional Rental Lease Management has long served as the foundation for property rentals, yet inherent inefficiencies have plagued it, including a lack of transparency and substantial reliance on intermediaries. In this system, landlords and tenants engaged in direct negotiations, often involving the laborious process of paper-based lease agreements, where responsibilities, rental terms, and payment schedules were outlined [1,3]. However, it has been criticised for its reliance on manual paperwork, which can be time-consuming and prone to errors and communication between landlords and tenants conducted through in-person meetings, phone calls, or physical mail, leading to delays and misunderstandings. Additionally, there was a lack of transparency in the process, which led to disputes frequently arising from a lack of easily accessible records and the involvement of intermediaries like property managers and lawyers, who are essential in handling transactions, facilitating lease agreements, and resolving disputes but also increased the overall cost and complexity of the rental management process. The industry saw a revolutionary phase of digitalisation to address these issues. The rental lease management industry adopted digital records, online listing platforms, and lease management software. This change was intended to increase digital efficiency, reduce paperwork, and enhance communication. Landlords boosted productivity by simplifying property management tasks thanks to the growing popularity of property management software. Internet listing services made rental properties more visible and easier for tenants and landlords to access. Intermediaries nevertheless added to the overall complexity and expense of the rental management process despite these advancements. Incorporating blockchain technology into rental lease management marked the beginning of the next wave of change. The decentralised, immutable ledger of blockchain technology ushered in a new era of efficiency, transparency, and security. It allowed for peer-to-peer transactions between landlords and tenants, eliminating the need for middlemen. Cryptographic techniques ensured data security while reducing the risk of fraud and unauthorised access. In addition to redefining the landlord-tenant dynamic and resolving the problems with traditional RLM, this technology has also reduced expenses, boosted trust, and expedited procedures, all of which have improved the security and efficiency of the rental management process.

An in-depth analysis of the blockchain's uses, difficulties, and prospects is the goal of this survey, which focuses primarily on the technology's implications and uses in the rental management industry. The demand for innovative solutions is growing due to the long-standing issues with conventional property leasing processes, such as their inefficiencies, lack of transparency, and dependence on intermediaries. This motivation prompted us to study blockchain in the rental lease sector. As we embark on this investigation, we will examine how blockchain technology may revolutionise the rental market by empowering landlords and tenants and enabling more efficient and transparent transactions. This paper also evaluates the knowledge, opinions, and firsthand accounts of different parties on blockchain-enabled rental leasing programs in smart cities, such as landlords, tenants, and local government representatives. The survey results will provide valuable insights crucial for guiding the development and implementation of these advanced systems, ensuring that they meet smart city residents' diverse needs and expectations. This paper explores how blockchain technology can enhance rental lease administration in smart cities.

The survey aimed to determine public opinion and the effectiveness of blockchain-integrated rental leasing systems in smart cities that offer security and transparency for real estate rentals. The survey data is divided into sections in the table, each concentrating on a distinct aspect. This table's data is based on nine different research papers. This survey table aims to improve the paper's usability and accessibility by making it easier for readers to rapidly understand its key points, background, and possible discussion topics. It seeks to simplify the reading experience for the reader and make it easier for them to comprehend the document's main points in Table 1. The survey table provides an in-depth look at how the general public feels about blockchain-enabled smart city rental leasing systems. This data will significantly influence the evolution of these systems in the future. City authorities and property management organisations may make well-informed decisions to increase transparency, security, and the general efficacy of their lease management systems by gaining insight into user attitudes, measuring blockchain trust levels, and finding areas for development. More studies and action plans based on the survey results will be created to enhance and broaden the integration of blockchain technology in the smart city property rental processes. This will facilitate the continued development and expansion of the global smart city movement.

III. PRELIMINARIES

A. Blockchain

Blockchain is a decentralised digital ledger that records network transactions. A group of individuals using Satoshi Nakamoto's pseudonym created it in 2009 as a framework for the peer-to-peer electronic cash system Bitcoin [11,12]. In 1990, Nick Szabo proposed Bit Gold, which was the precursor of blockchain technology. The idea was to create a decentralised system for generating and verifying digital currencies. Various blockchain systems, including Ethereum and Hyperledger Fabric, have later implemented the technology introduced by Nick Szabo. Transparency stands as one of blockchain's primary characteristics. A transaction is accessible to every network member after it has been logged. Because of this openness, which guarantees responsibility and trust, it is practically hard to change or tamper with recorded data without the network's approval. Therefore, it is the best technology for use in accounting and trust applications, including voting systems, supply chain management, and financial transactions[14,15]. Security is another crucial element in blockchain. A consensus method, like proof of stake (pos) or proof of work (pow), connects each block to its precedent securely using unbreakable hash codes. The smart contract refers to a computer program stored in the blockchain, and it is run when specific terms are fulfilled. A smart contract state is recorded on the distributed ledger whenever it is executed. New blocks storing state changes for the state are appended to form an irreversible record representing contract state changes. Unlike traditional contracts, smart contracts eliminate the need for intermediaries like solicitors or notaries. The contract operates automatically, with the code enforcing the agreement's terms once the requirements are fulfilled. The architecture of the blockchain system was designed to create a decentralised and trustless network that is secure and transparent. A blockchain comprises a dispersed network of computers or nodes that collaborate to keep the blockchain secure from censorship and single points of failure. Blockchain consists of mainly two components:-

- A peer-to-peer network- This architecture enables direct communication and interaction between nodes, eliminating the need for a central intermediary. It distributes the blockchain ledger across all nodes, creating a decentralised and trustless system. Each node contributes computational resources to the network, such as processing power, storage capacity, and bandwidth.
- Distributed Ledger- Blockchain is a distributed ledger between a chain of connected members. The ledger is duplicated at each node, and so is transaction verification. Network nodes reach a consensus on adding a new transaction by solving a mathematical puzzle or adopting a proof of work procedure. The entry of a transaction into a ledger makes it inerasable and ensures that the ledger remains unaltered. This architecture ensures blockchain technology's security and transparency.

B. IoT in Smart Cities

IoT is one innovative technological paradigm that has gained much attention lately. The acronym for the Internet of Things is IoT. It is a network of actual physical objects, devices, cars, buildings, and other things that are embedded with network connectivity, software, and sensors to allow them to exchange and gather data over the internet. There are countless IoT applications. Through smartphones, it is possible to control smart lighting, surveillance cameras, and programmable heaters. In healthcare, wearable technology tracks vital signs and transmits information directly to medical professionals for real-time evaluation. IoT sensors are employed in agriculture, where they monitor crop health, weather changes, and soil conditions, aiding farmers in making informed decisions to enhance their harvests. The main idea behind the Internet of Things is to allow these objects to speak with centralised systems and each other via the Internet [13]. This will enable them to share and acquire information, make wise decisions, and carry out a variety of tasks without the assistance of a human. The smart-cities concept of development involves employing and applying ICTs to improve cities' sustainability, livability, and efficiency. Smart cities use data, connectivity, and the latest technologies like IoT to solve complex urban issues. Smart cities leverage collected information from various sources, including cameras, smart sensors, and other electronic devices, to optimize traffic systems, minimise energy consumption, and enhance the quality of public services, among other benefits. Residents gain from more safety, less traffic, and better mobility. The concept of smart cities aims to improve the living conditions of its population by creating more sustainable, intelligent and linked urban systems. The extensive applications of IoT in various domains make it a critical factor in advancing smart cities. The field of traffic management is one where the Internet of Things has significantly contributed to smart cities. Real-time data is gathered by IoT devices, including cameras and sensors, from roads, intersections, and moving cars that are examined to optimise traffic flow by modifying traffic signals dynamically. As a result, travel times are reduced, traffic is lessened, and urban mobility is enhanced overall. Another area where IoT is transforming urban operations is waste management. It can become more effective by keeping an eye on trash cans and streamlining collection routes. This contributes to a more sustainable and effective waste

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 20,2024 at 07:16:01 UTC from IEEE Xplore. Restrictions apply.

management system by lowering operating costs and minimising the environmental impact of needless truck trips. Regarding energy management, Internet of Things (IoT)technologies—such as smart grids—have revolutionised how cities receive and use power. It helps utilities reduce energy waste by better balancing supply and demand. This will benefit the city's economy and its commitment to environmental sustainability. Though there are clear benefits to IoT in smart cities, important issues also need to be resolved. The most pressing of these are security and privacy concerns. The vast amounts of data that IoT devices generate and exchange could be the target of hackers and cyberattacks. IoT system breaches can result in data leaks, city service interruptions, and even safety risks. These risks can be reduced by ensuring robust security policies and encryption for confidential information and citizens' privacy.

C. Rental Lease Management(RLM)

Any management system made to transform the complex process of managing rental leases of any particular commodity into an efficient and smooth process is called Rental Lease Management (RLM). It is a complete system that provides support and convenience for commodity managers, owners, and tenants. It includes management ease and provides the facility for creating and enforcing rental agreements. It makes the process of renting any commodity accessible for ordinary people as it contains all the legally binding documents that are necessary to understand the terms of leased commodity, rules that protect their rights as a landlord and tenant, information about payments and lease obligations, and the length of the tenancy agreement. A system that provides a solution for renting any commodity, from lease negotiation to the termination or reinstatement of your lease. The objective behind having any system that performs all this is to have a clearly defined lease management strategy, as it helps the landlords manage and hold a proper record of their commodities, which promotes accountability and reduces the risk of confusion and conflicts. Implementation of Rental lease management systems is revolutionised because of digital platforms and software solutions as they have secured the databases, an authentication feature provides access to rental agreements to the landlord and tenant, regular inspection of reports and financial transactions helps increase security and authenticity and decreases paperwork. RLM also performs ethical responsibility by conducting an automatic periodic check and releasing notifications promptly to reduce litigation costs and penalties. Tenants get many benefits from using RLM systems, like having access to simplified and documented rental records, which otherwise were hard to maintain access to lease-related info, pay rent electronically, and submit maintenance requests directly to RLM, improving the overall rental experience. All the above simplifications that RLM has offered to the current rental lease system make it an essential part of the leasing industry as it protects the interests of all parties involved, such as landlords, property managers, and tenants. RLM offers the entire traditional leasing process with transparency, accountability, security, and efficiency. Regarding the role of Blockchain technology in the Rental Lease Management process, it holds the potential to revolutionise the entire leasing agreement management process. Due to features like a decentralised and immutable ledger, security will ultimately decrease the probability of fraud, disputes and unauthorized lease notifications. All participants in the rental process will have instant access to the shared ledger due to the decentralised structure, which will ultimately increase trust and openness between the landlords, tenants, and managers. The transparency offered by this technology will go a long way as it reduces conflicts and improves the overall efficiency of the management system. The prime objective of Blockchain technology and smart contracts is to automate processes such as rent payments to streamline lease enforcement and eliminate the need for intermediaries such as banks and the ministry's payment processing. This will not just simplify the payment process but also help in reducing costs and associated delays. Storing money in blockchain-based smart contracts and ensuring that it will only be released when the conditions outlined in the lease are met helps us manage security deposits and users. An easy process of getting an account allows us to avoid relying on third-party resellers, reducing costs and increasing security for everyone. Also, with features like securely storing and exchanging data, including rental history, credit scores, and references, this technology can facilitate tenant screening and verification. Therefore, blockchain technology can revolutionise traditional rental management, adding improved security, transparency, and efficiency, benefiting all parties involved in the leasing process.

IV. FINDINGS AND DISCUSSIONS

The survey results revealed that blockchain technology[16-18] is integrated into rental management in various ways. Blockchain has demonstrated a noteworthy ability to augment trust and transparency within the rental sector. Using a decentralised and unchangeable ledger significantly lowers the possibility of fraud and disagreements, which promotes more confidence between landlords and tenants. Applications such as property advertisements, leasing agreements, payment processing, identification verification, and maintenance management are all covered by this transparency. Real-world case studies and applications in the rental management industry demonstrated blockchain's usefulness. These examples showed how technology may facilitate real estate transactions, reduce fraud, and enhance tenant-landlord relations. It is essential to recognise the obstacles that come with integrating blockchain technology. One significant barrier that has surfaced in the rental management sector is regulatory compliance due to the complex and often region-specific legal and regulatory systems that govern it. These regulations encompass various aspects of the rental market, including tenant rights, property standards, lease agreements, and rent control. Finding a balance between innovation and following the rules is essential for the sector's success. In addition, scalability problems were found in the blockchain ecosystem. Enormous-scale rental businesses require solutions that address the technology's limited capacity to manage enormous amounts of data and transactions. Furthermore, the rental management sector has proven challenging to change because of the industry's firmly rooted traditional practices and established intermediaries. Industry participants must be open to innovation, make the necessary infrastructural investments, and start a cultural revolution using blockchain technology. To address these issues, the survey report offers several practical suggestions. These include creating transparent regulatory frameworks, funding blockchain infrastructure and education, and encouraging industry cooperation. Stakeholders in the rental management industry

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 20,2024 at 07:16:01 UTC from IEEE Xplore. Restrictions apply.

may negotiate the revolutionary terrain and realise the full potential of blockchain technology by tackling these obstacles and putting these suggestions into practice, eventually altering the future of rental management.

V. CONCLUSION AND FUTURE DIRECTIONS

The review of blockchain technology's uses in rental management concludes by highlighting the sector's enormous potential for positive change. By examining its core ideas and valuable applications, we have shown how blockchain technology may improve trust, efficiency, and transparency in real estate rental operations. This survey study, which focuses on rental management, attempts to provide an in-depth analysis of blockchain technology and offers insights into its possible applications, challenges, and barriers. Case studies from the real world have given concrete proof of its advantages, from cutting down on conflicts and fraud to streamlining intricate processes. However, there are difficulties with this transition. Significant challenges still include industry-wide adoption, scalability issues, and regulatory compliance. Despite the apparent advantages, overcoming these obstacles requires coordinated efforts by regulators, innovators, and stakeholders. Blockchain's promise for rental management is vital. It presents the possibility of improved security, simpler operations, and redefining the relationship between property owners and tenants. So, we intend to integrate IoT and Blockchain to prevent IoT data threats. The complete potential of blockchain in rental management is yet unknown as long as the industry and technology don't stop evolving. Our survey study will prove to be a valuable tool for stakeholders and enthusiasts alike, helping them navigate the rapidly changing field of blockchain-driven rental management as the industry continues to embrace this revolutionary technology.

***Abstract*— This paper examines the transformative impact of blockchain technology in the financial sector, exploring the advantages, challenges, and future prospects of adopting blockchain and emphasising its role in enhancing efficiency and reducing transactional costs. Also, a comparative analysis is done across various blockchain technologies that are being used in the current FinTech sector. AI-powered chatbots streamline banking, while AI is implemented in blockchain for reducing operational costs, increasing scalability and AI in decentralised finance. Also, The decentralised method of operations across the FinTech sector is explored by disrupting the intermediaries across the network and the integration of UPI in regulating compliances is also discussed. Furthermore, the research highlights ongoing efforts to address scalability, interoperability, reducing security concerns, underscoring the potential for continued evolution and innovation in financial systems.**

Keywords*— *Blockchain, Financial Institutions, Consensus Algorithms, Smart Contracts, Cryptocurrency Trading, Artificial Intelligence.

I. INTRODUCTION

Increasing demand for digital usage and e-commerce has led to a significant increase in financial services, especially during the pandemic, as more individuals migrate online [1]. Blockchain turned into a complete game-changer in the domain of Fintech, as it reduces the cost of transactions, ensures security concerns, enables international payment methods and enhances regulation & auditing.

Blockchain's capacity to initiate, process, authorise, record, and report on every transaction conducted across diverse nodes has significantly impacted the realms of accounting and auditing. The advent of this groundbreaking technology has brought about a transformation in the back office, efficiently replacing the laborious tasks associated with financial audits and tax preparation.

The banking and financial sector has seen enormous developments due to the combination of blockchain and AI technologies. While AI has increased compliance and safety through autonomous verification methods, blockchain's distributed architecture has improved effectiveness and decreased transaction costs. Despite regulatory compliance and scalability challenges, the trend toward blockchain usage is nevertheless encouraging. Artificial intelligence (AI)-powered chatbots greatly streamline banking procedures by providing cheap transaction processing, detection verification, and customer service.

Future research will focus on using AI-driven solutions to enhance blockchain's scaling, connectivity, and security.

Interoperability between blockchains, artificial intelligence in decentralised banking, and enhancing security and privacy protocols are important fields. This multifaceted strategy highlights how blockchain and AI can work jointly to drive constant enhancements in financial systems. Combining blockchain technology with artificial intelligence (AI) provides more development and innovation in the financial sector as experts investigate prediction models and algorithms.[2]

Despite high-level assessments of blockchain technology, there remains a notable absence of a systematic comparison of platforms utilising blockchain technology, specifically within the financial services domain. Current research lacks a comprehensive examination of the technical implementation and applications of blockchains and distributed ledger technology across various FinTech categories in the financial services sector. While some studies have offered theoretical overviews and plans to implement in fintech platforms[4], others have explored digital finance from an operational function perspective[5].

Through our research paper we tried to delved into FinTech advancements such as analysis of various blockchain technologies and their use cases, distributed ledger[6] and the use of AI in blockchain technology. Our research's exclusive focus is to delineate blockchain-based FinTech applications, providing a dedicated exploration into this niche area.

II. EFFECTS ON FINANCIAL INSTITUTIONS

The culture of the financial world depends on centralised intermediaries, but blockchain broke the tradition by allowing a decentralised substitute. It helps reduce the efficiency and transaction costs. Centralised intermediaries boosted the unauthenticity, due to cybersecurity scams, and even steven in finances.[7]

Fundamental Banks having a feeling of threat when thinking of blockchain, some competed with markets using it. Fragile investments compressed in information technology make for cost-efficient and innovative prompts.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 20,2024 at 07:14:02 UTC from IEEE Xplore. Restrictions apply.

TABLE I. USE OF BLOCKCHAIN IN DIFFERENT FINANCIAL INSTIUTIONS

Financial Sector	Blockchain Types	Key companies/Projects	Use cases	Advantages	Challenges/Risks
Cryptocurrencies and Exchanges	Bitcoin (BTC), Ethereum (ETH)	Bitcoin: Decentralized digital currency Ethereum: Smart contracts and decentralized applications	Peer-to-peer transactions, decentralized applications, programmable contracts	Decentralization, Security, Anonymity	Regulatory Uncertainty, Volatility, Scalability Issues
Cross-Border Payments	Ripple (XRP), Stellar (XLM)	Ripple (XRP): RippleNet Stellar (XLM): Stellar Network	Facilitate fast, low-cost cross-border transactions, connecting financial institutions for efficient international transfers	Speed, Cost Efficiency, Reduced Intermediaries	Regulatory Compliance, Adoption Challenges, Network Effects
Supply Chain Finance	IBM Blockchain: Hyperledger Fabric VeChain (VET): VeChainThor Blockchain	Real-time tracking, transparency, and authentication of products in the supply chain, reducing fraud and improving traceability	Traceability, Efficiency	Integration Challenges, Standardization,	Privacy Concerns
Trade Finance	WeTrade, Marco Polo (R3 Corda)	Built on Hyperledger Fabric Marco Polo: R3 Corda	Digitizing and automating trade processes, reducing paperwork, enhancing transparency in trade finance	Efficiency, Transparency, Reduced Paperwork	Standardization, Interoperability, Legal Frameworks
Smart Contracts and Insurance	Ethereum (ETH), Chainlink (LINK), AXA	AXA: Exploring blockchain for smart contracts Chainlink (LINK): Oracle network for smart contracts	Automated and transparent insurance claims processing through smart contracts, improving efficiency and trust in insurance processes	Automation, Trust, Transparency	Legal and Regulatory Challenges, Security Concerns, Complexity
Digital Identity Verification	Evernym, Sovrin (Hyperledger Indy)	Evernym: Decentralized identity solutions Sovrin (Hyperledger Indy): Permissioned blockchain for digital identity	Secure and verifiable digital identities, improving privacy and control over personal information	Privacy, Security, User Control	Adoption Barriers, Interoperability, Regulatory Compliance
Asset Tokenization	, Polymath (POLY) Securitize	Tokenization platform Polymath (POLY): Security token issuance platform	Representing traditional assets (e.g., real estate, company shares) as digital tokens, facilitating fractional ownership and trading	Liquidity, Fractional Ownership, Accessibility	Regulatory Compliance, Market Maturity, Security Issues
AML and KYC Compliance	JPMorgan Chase, Chainalysis, Elliptic	JPMorgan Chase: Exploring blockchain for AML and KYC Chainalysis, Elliptic: Blockchain analytics for AML and compliance	Using Blockchain to improve the efficiency and accuracy of KYC and AML procedures	Efficiency, Transparency, Security	Privacy Concerns, Data Accuracy, Regulatory Frameworks

Based on the insights captured from the table, transactions across the ledgers are prioritised through bitcoin and ripple, Ethereum signifies smart contracts, IBM blockchain targets the enterprise solutions, WeTrade streamlined trading monetary aspects, Evernym emphasizes on self-sovereign identity, and Polymath specializes in security tokenization.

Each of them employs unique consensus mechanisms, security aspects and asset management across the blockchain network.

On the contrary, bitcoin uses PoW, Ripple uses a unique consensus algorithm and Ethereum transitions to PoS, WeTrade builds and hyper ledger fabric and Ethereum gets leveraged by Polymath.

These blockchain technologies diversify the needs depending upon the services they are pioneered for, they reflects varying goals in privacy, decentralisation and functioning across the network.[3]

Blockchain technology can also affect the ledger maintaining system (AIS or LMS) [8] by digitising research-studied processes, securely storing accounting data, and improving transaction efficiency. It simplifies operations, reduces settlement time, minimises fraud, and enhances regulation and liquidity.

In summary, the adoption of blockchain in banking and finance has led to significant changes in the industry, with both advantages and challenges, and its trend appears to be positive and increasing since 2008. However, there is a need to address potential limitations and Threats.

Transforming the technically advanced banking system was not easy without facing obstacles, blockchain technology to be trusted and primitive adjustments to be made for smooth involvement. [10]

III. CHALLENGES IN BLOCKCHAIN APPLICATIONS

The FinTech sector face challenges in adopting Blockchain including the uncertainties in regulating compliances, scalability issues, interoperability concerns, security and data privacy also imposes obstacles, and in order to overcome these hurdles collaborative efforts, regulatory clarity and tech advancements are required.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 20,2024 at 07:14:02 UTC from IEEE Xplore. Restrictions apply.

A. Challenges associated with using UPI and implementation of Blockchain

The culture of the financial world depends on centralized intermediaries, but blockchain broke the tradition by allowing a decentralized substitute. It helps in the efficient and transaction costs reduction. Centralized intermediaries boosted the unauthenticity, due to cybersecurity scams, and even steven in finances[3].

Traditional banking processes often involve complex and expensive intermediaries, resulting in significant cost inefficiencies. However, with the integration of UPI and blockchain technology, these inefficiencies can be minimized or even eliminated.

Blockchain eliminates the need for intermediaries by providing a decentralized and trustless network. This reduces the transaction fees and operational costs associated with traditional banking systems. Additionally, UPI enables instant and seamless transactions, further optimizing the efficiency of the banking sector.[13]

B. Regulatory Compliances

Regarding the banking sector, regulatory compliance is of utmost importance. Integrating UPI (Unified Payments Interface) with blockchain technology ensures enhanced regulatory compliance. Blockchain technology is transforming several industries, and the banking industry is no exception. The combination of blockchain technology and artificial intelligence (AI) is one of the major developments in this sector. Combining the capabilities of these two cutting-edge technologies has greatly benefited the banking industry.

Moreover, blockchain technology's automation and smart contract capabilities free up valuable resources and reduce manual errors. This not only saves time and effort but also decreases costs that were previously incurred due to human intervention. Integrating UPI with blockchain brings significant cost savings and operational efficiencies to the banking sector.[14]

Fundamental Banks having a feeling of threat when thinking of blockchain, some competed with markets using it. Fragile investments compressed in information technology make for cost-efficient and innovative prompts.

Transforming the technically advanced banking system was not easy without facing obstacles, blockchain technology to be trusted and primitive adjustments to be made for smooth involvement.

The risk factor and stabilisation made positive gains with this blockchain technology. Some information states vice-versa. Despite the benefits, there are acknowledged limits and potential threats associated with blockchain adoption in banking, such as scalability, security, energy consumption, and privacy concerns[9].

In summary, the adoption of blockchain in banking and finance has led to significant changes in the industry, with both advantages and challenges and its trend appears to be positive and increasing since 2008. However, there is a need to address potential limitations and threats.

IV. AI IN BLOCKCHAIN TECHNOLOGY

Blockchain technology is transforming several industries, and the banking industry is no exception. The combination of blockchain technology and artificial intelligence (AI) is one of the major developments in this sector. Combining the capabilities of these two cutting-edge technologies has greatly benefited the banking industry. AI in blockchain introduces intelligent algorithms that enhance the efficiency and security of transactions. It enables automated verification processes and improves fraud detection, ultimately contributing to a more reliable and transparent banking system. By leveraging AI, banks can streamline operations and provide customers with a seamless and secure banking experience.[11]

AI has significantly transformed the landscape of blockchain technology. It enhances security through real-time fraud detection and identity verification, improving transaction trust. Smart contracts are optimised and automated, and supply chain management benefits from AI's data analysis capabilities. Decentralised Autonomous Organizations (DAOs) are more efficient with AI-driven decision-making, and content filtering is enhanced. The tokenisation of assets is streamlined, and AI aids in market prediction and trading. AI-driven data analysis on the blockchain yields valuable insights. While it fosters innovation, AI integration poses challenges, like concerns about data privacy, job displacement, and ethical considerations, requiring careful navigation in the blockchain space.

Implementing Artificial Intelligence (AI) involves integrating advanced algorithms and machine learning into various sectors, offering automation, data analysis, personalisation, and predictive capabilities. There could be a lot of advantages of it, and at the same time disadvantages as well such as it is responsible for the replacement of human jobs, thus increasing unemployment, data security concerns, ethical concerns, etc. But there might be technical complexity alongwith the lack of desired resources and capital to implement it. A successful AI driven system implemented blockchain technology has to be cost efficient to be feasible and overcome it’s possible drawbacks.

V. AI DRIVEN CHATBOTS

Deep learning (DL), machine learning (ML), and natural language processing (NLP) are some of the methods used to create AI-driven chatbots. The procedures that are followed to develop it are as follows:

Collection of Data: Firstly the data is collected and it has to be preprocessed to train the chatbot to meet our requirement.

Implementing Machine Learning: ML algorithms can train the chatbot on the data that has been collected and preprocessed. One of the method is through supervised learning in which the chatbot gets trained on the labeled data, meanwhile in unsupervised learning the chatbot is trained on the clustering and topic modeling.[16]

Dialog Management: These techniques are implanted in order to manage the conversation. It involves interpreting the user’s conversation and generating possible responses.

Integration with Blockchain: After the development of the chatbot, it gets integrated with blockchain technology. This integration can be done in various ways, depending on the use case.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 20,2024 at 07:14:02 UTC from IEEE Xplore. Restrictions apply.

Secure Data Transmission and Private Environment: Implementing the Blockchain Fintech thus enhances the security of the data used to drive the chatbot, through various cryptographic algorithms used for the its encryption.

Continuous Improvement: These AI-driven chatbots ain't robust and thus it can be further enhanced through user feedbacks (reinforcement learning) thus it would improve it's user experience over the course of time.

There could be various purposes where we can use these AI-driven chatbots in blockchain technology-

Customer Support: It can be used to provide a one-on-one automated user interaction, thus providing a 24/7 facility to the user, thus decreasing the man power needs for the support system.

Transaction Processing: They can coordinate across various AI-logs available through the simultaneous network, thus emphasizing the transactions and can be used to trade assets.[19]

Identity Verification: It can be used to provide a user authentication system, allowing only the legitimate user to fetch the info, whose info is being fetched from the blockchain network which is highly encrypted on a distributive network.

Analytics: It can be used to analyze the data provided by the users and provide them with the relevant data as per the user demands.

Overall, AI-driven chatbots can be efficiently used for a better user experience, which is automated and thus cost efficient.

VI. FUTURE RESEARCH THROUGH ANALYSING BLOCKCHAIN MARKET TRENDS THROUGH AI

Security algorithm techniques can be potentially ultimate in the capital storage sectors, and there is still much ground to be covered. As we look towards the future, several areas of development and improvement can be anticipated.

- Scalability: Blockchain networks must address scalability concerns, especially when handling a massive number of transactions. Changes are constant in the tech used to improve higher-scale usage, such as sharding and layer-two solutions.
- Interoperability: Networks connected through these algorithms and blocks should be focused. Banks are exploring ways to ensure seamless communication and data sharing across multiple blockchain platforms, enabling efficient interbank transactions and collaborations.
- Security Enhancements: While blockchain is already highly secure, continuous efforts are being made to enhance its security features further. Banks are investing in cutting-edge encryption algorithms and advanced consensus mechanisms to fortify the security of their blockchain systems.
- Integration with IoT: The integration of blockchain and the IoT could be significantly proven to be beneficial for the banking sector. Enabling secure and transparent smart contract-based transactions, automate supply chain finance, and enhance data security in IoT devices.[20]

In conclusion, the above mentioned points have been proven significant in future advancements, for example the integration of UPI with blockchain technology has brought significant advancements to the banking sector. The utilization of AI in blockchain enhances efficiency and ensures regulatory compliance. The cost inefficiencies oftraditional banking systems are minimized, and the future holds even more exciting possibilities for blockchain in the banking industry. As we continue to explore the potential of blockchain technology, the banking sector is poised for a transformative journey towards a more secure, efficient, and customer-centric landscape.

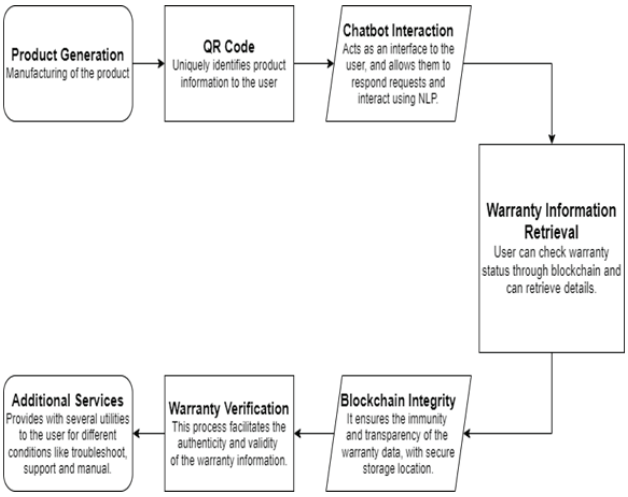

Fig. 1. This flowchart represents the sequential processes on which an AI generated chatbot works

Analyzing market trends in the context of blockchain technology with the integration of Artificial Intelligence (AI) is an evolving and highly promising field that offers both insights and challenges.

A. Current State --

Blockchain technology is responsible for revolutionizing various sectors including trading platforms, cryptography, finance, etc. The blockchain market is characterized by plethora of cryptocurrencies, decentralized applications (dApps), and diverse blockchain platforms. AI is increasingly employed to decipher complex market.

B. AI-driven tools are used for-

- Sentiment Analysis: NLP algorithms scan news, social media, and community forums to gauge market sentiment, helping investors make informed decisions.
- Predictive Analytics: Machine learning models are applied to historical data to predict token prices, market volatility, and trading patterns.
- Fraud Detection: AI assists in identifying fraudulent transactions and protecting the integrity of blockchain networks.[12]
- Smart Contract Auditing: Automated audits of smart contracts using AI to uncover vulnerabilities and ensure their reliability.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 20,2024 at 07:14:02 UTC from IEEE Xplore. Restrictions apply.

- Consistency & Loss-less Flow: AI streamlines compliance processes and helps in tracking and adhering to evolving cryptocurrency regulations.
- Market Risk Management: Further exploration of AI's role in risk management within the blockchain market, considering factors like network upgrades and forks.
- Sustainability and Green Blockchain: Investigating AI tools for assessing the environmental impact of blockchain networks and optimizing their energy consumption.
- Regulatory Technology (RegTech): AI-powered RegTech solutions to assist compliance with evolving blockchain-related regulations.

Blockchain evolving on outskirts, AI and this technology better understand the market trends and significantly increase the growth and efficient transformation. High speed upgradation and opportunities coming with unique challenges, building future updates.

Fig. 2. In the above Figure an AI generated indicator is being used to trade in cryptocurrencies

C. *Future Research Directions* --

- AI in Decentralized Finance (DeFi): Investigating the role of AI in assessing risk and improving yield optimization in the growing DeFi space, as well as addressing security concerns.
- Interoperability and Cross-Chain Analysis: Research can delve into AI solutions that facilitate interoperability between diverse blockchains and assess the broader implications of such integration on the market.
- Security and Privacy: Development of AI-based security solutions for protecting blockchain networks and enhancing privacy features.[14]

VII. CONCLUSION

This elicited research work providing an examined report of the multidimensional role of Blockchain in fin-tech sector. Blockchain impacts applications, laws, intermediation, future prospects, and other range of topics in this sector. Diving in the core of the blockchain, consisting of consensus algorithms and smart contracts, and other platforms are covered in the paper.

Furthermore, the paper emphasizes on the transitions of blockchain on accounts and audits, explaining blockchain technology enhances data transparency, auditability, and trusted access in financial data.

Artificial Intelligence combined with Blockchain for the betterment of ecosystem, projecting the collaborative capability of it.

Research also shows how the blockchain made the amendment in the culture of financial institutions, switching from centralized to decentralized intermediaries. Subsequently affecting business sectors and financial models.

Furthermore, this written work highlighted the crypto algorithmic trading world, facing different challenges and strategies to endure option trading and crypto space. Mining cryptocurrency along with the Blockchain technology and sustainable ecology of the financial accounts.

Blockchain technology on integrating with financial systems, leads to everyday evolution process. Regular reports being made for academic year and enthusiastic professionals moving towards understanding the financial sector with blockchain factor. For the future approach, influence and opportunities developing predictive models, AI impacting on decentralized assets, high-scale problems, algorithms helping in the development of Blockchain.

Financial instrumentation in upgrading the potentially collaborative blockchain approach in the further research.

The research explores how dermatologists use machine learning to quickly and accurately identify and classify skin injury. Conventional diagnosis techniques depend on visual examination, but are subjective and have different interpretations. The ability to analyze data and recognize patterns is a possible remedy for ML. The paper examines the current technology of machine learning, focusing on validation in the real world, and deals with data set variability. Although the research acknowledges the fruitfulness of deep learning (DL), the research emphasizes the benefits of traditional ML techniques regarding interpretation and processing performance. Methods for automating the analysis of skin lesions, such as feature engineering, rule-based techniques and traditional ML algorithms, have been studied. The study suggests using advanced transfer learning techniques, integrating genetic and clinical data, and refining the way artificial intelligence (AI) is explained in order to get over barriers. Intending to enhance the accessibility and correctness of skin lesion identification, the future requires collaboration between dermatology and machine learning to develop real-time diagnostic tools. By offering scalable solutions for rapid diagnosis of lesions and improved patient outcomes, this combination of medical expertise and ML capabilities has the power to revolutionize dermatology. The future of automated dermatological diagnosis is expected to be shaped by collaboration between machine learning experts and dermatologists, enabling more personalized treatment for patients.

Keywords— skin lesion, machine learning, survey, deep learning, CNN

I. INTRODUCTION

Skin injuries, from benign to malignant, are an essential component of dermatology diagnosis [3]. Accurate and prompt identification is necessary for the timely recognition and effective medicaments of skin lesions. To successfully cured some incurable diseases like skin cancer, melanoma can be cured only at primary stage [10]. The recent advancement in imaging technology have enabled high resolution skin images which gives opportunity to machine learning algorithms to step in dermatology. This work is driven by a growing tendency in the medical field to apply ML for skin lesion identification and categorization in order to enhance diagnosis. Traditional diagnosis techniques are time consuming and slow to changes in human capabilities, which motivates researchers to explore automated, effective, and unbiased evaluations by machine learning [26].

In the decade, the machine learning algorithms becomes popular and also they help in improving diagnosis [16]. Dermatologists mainly diagnose skin infections by visual examination in traditional procedures, which can lead to a variety of diagnoses and subjective interpretations. By analyzing huge amounts of data and analyzing complex patterns of identity, ML provides creative solutions to these problems [19]. High-quality dermatological imaging data sets have exponentially expanded, and the development of machine learning methods has allowed for robust and accurate models. Through methods such as DL, Convolutional Neural Networks (CNNs) [21], and learning transfer, scientists have been able to automatically recognize and catergorize skin disorders with remarkable effectiveness.

In this work, the advanced with traditional approaches for machine learning based on skin lesion identification and categorization are reviewed. It explores the traditional machine learning techniques with the recent advancement, publicly available datasets with evaluation metrics and at the end future scope and challenges are discussed.

The paper also addresses how machine learning models in dermatological applications could perform better if other modalities, such as dermoscopy and clinical data, were integrated. The integration of ML skills with medical knowledge has the possibility to transform dermatological practices as we traverse the intricacies of skin lesion detection. Machine learning has more possibilities to influence the healthcare industry by providing a scalable, dependable, and efficient solution that will help with early identification, better patient outcomes, and more efficient use of resources [9] [17].

A. Background

Skin disorders, which include a wide range of lesions and dermatological illnesses, are a major global health concern. Skin disorders are becoming more common, which highlights the

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 27,2024 at 09:41:01 UTC from IEEE Xplore. Restrictions apply.

critical need for advanced and effective diagnostic tools. The machine learning models' proven accuracy and consistency in image analysis, along with their ability to manage the increasing amount of skin image datasets, serve as further sources of incentive. Beyond just increasing productivity, the survey aims to further dermatological personalized care by customizing treatment regimens based on unique skin features. This survey attempts to shed light on the traditional as well as advanced machine learning-based skin lesion identification by combining current research trends, methodology, and findings. By doing so, it hopes to uncover gaps in the field and open up new avenues for future research that will directly affect patient care.

B. Motivation

First of all, this survey gives an encyclopedic overview of the current state-of-art methodologies which helps researchers, practitioners and dermatologists with the understanding of current research and also future advancement of the field. This survey serves as a guide for future research projects by highlighting current challenges and limitations and directing efforts towards the area of innovation and improvement. The comparative analysis of various machine learning models allows us to evaluate their strengths and weaknesses. In addition, this research helps to explore the recent practical applications of machine learning in skin lesion detection. Analysing the previous studies aids in the understanding of data diversity and quality with ethical consideration. This survey serves as a road map, shaping the direction of future research and providing a brief yet significant view of the problem.

II. Literature Survey

Skin lesion recognition and categorization has made substantial use of ML techniques and DL techniques in our study. For skin lesion identification and categorization usually, researchers go for ML and DL techniques, but there are other methods like Rule based approach like ABCD method [2], CASH method [27], three-point checklist [25], seven-point checklist [27] etc popular. The dependency of choosing any technique will dependent on the size of the dataset. In this work, we are focusing on ML techniques as they provide more interpretable results and ease of implementation compared to DL models. Additionally, these models perform better on smaller datasets, are computationally lighter and are less prone to overfitting when the data is limited. ML model involves manual feature engineering which is its limitation, whereas DL model extracts more features which results in better accuracy. Many strategies have been used, from conventional techniques to sophisticated deep learning architectures. The following are a few popular machine-learning methods for analyzing skin lesions:

A. Traditional Image Processing [22]

Color-based segmentation is a popular technique that divides skin lesions from the surrounding tissue according to unique color features. This technique helps isolate lesions by using color differences to identify regions of interest. Another important component is texture analysis, which examines the patterns of skin lesions to identify variations that may be suggestive of particular illnesses.

B. Classical Machine Learning Algorithms

The broad range of methods known as classical machine learning algorithms has been used for several purposes, such as the identification and categorization of skin lesions. Several important approaches are covered by classical ML algorithms in the context of skin lesions:

- Support Vector Machine (SVM) [16]: For binary classification, commonly engrossed for benign and malignant tumours [7] from the skin lesion, SVM is popular.
- Random Forest (RF) and Decision Tree (DT) [17] [20]: For feature selection and classification, ensemble techniques like random Forests and decision trees are used. They are flexible enough to accommodate a wide range of data kinds since they can handle both continuous and categorical information.
- K-Nearest Neighbour(KNN) [9]: In KNN technique uses closeness to classify data items according to the class their neighbours belong to. KNN can be used in skin lesion analysis to find commonalities between lesions to classify them.
- Naïve Bayes [28] : The naïve Bayes classifiers is based on using the Bayes theorem with strong assumptions about feature independence. They are easy to use and effective, particular for smaller datasets.

C. Feature Engineering [3]

It is taking statistical measurements like mean and variance or pertinent aspects like size and shape descriptors and extracting them from the photos. To differentiate benign and malignant tumours, these characteristics are essential.

D. Deep Learning Architectures

For identification and categorization, CNNs [21] shows one of the most notable DL architectures that have transformed the skin lesions. CNNs easily identify structural features from dermatological images to achieve astonishing results. In this process pretrained model through transfer learning like VGG16 [21] and ResNet [10] are included. Recurrent neural networks (RNNs) [13] are used to ensnare time related dependencies in skin lesion patterns, for sequential data processing. Interpretability is enhanced by attention mechanisms like self-attention models that focus on specific or relevant areas of images. One of the popular techniques can be used for data-augmentation is GANs which will be discussed briefly in the next section. However, this will help significantly improve the productivity and precision for diagnosis.

E. Autoencoders [26]

For the study of skin lesion, autoencoders are a key element of deep learning architectures. They are experts in feature extractions and unsupervised learning by flatting the regions of dermatological images. During encoding process, autoencoders recreate the input images by dimension and noise reduction. Additionally, they may be used for data augmentation, creating synthetic data that helps to make model

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 27,2024 at 09:41:01 UTC from IEEE Xplore. Restrictions apply.

more robust. Autoencoders are essential as they provide a productive means of extracting meaningful representations from a complicated image for skin lesion identification and categorization in a automated dermatological diagnosis.

F. Generative Adversarial Networks (GANs) [19]

GANs are highly useful for skin lesion identification and classification, when data augmentation is used. A discriminator along with generator network makeup a GAN. A discriminator network and a generator network work together to produce artificial images much like real skin lesion. GANs help dermatology by improving generalization to previously unexplored data, enhancing model training, and expanding the scope of constrained datasets. GANs deal with the problem of insufficiently labeled data by creating realistic images of artificial skin lesions. The advancement of technology significantly boosts the robustness and efficacy of algorithms for recognition and categorization of skin lesions. The ability of GANs to create realistic images similar to actual skin lesions shows that GANs can be an important utility in the creation of automated dermatological diagnostic models.

III. DATA AND EVALUATION METRICS

To further the field of skin lesion identification and categorization, it is essential to have access to a variety of carefully selected datasets. To promote research collaborations, test machine learning algorithms, and ultimately aid in the development of reliable diagnosis models for dermatological applications, several publicly available datasets have become essential. Some of them are listed in Table 1. Various measures are employed to evaluate the models' performance and determine whether they are performing better or not. We refer to these measurements as performance metrics. Some common and significant outcome measurements, which vary depending on the kind of model, are covered in the section below [8] [14].

- Accuracy: The performance of the model is evaluated based on its accuracy. It is calculated as the proportion of all occurrences to the all instances. It is represented as

$$\frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

- Precision: A model's precision indicates how accurate its positive predicts are, It is defined as the proportion of actual positive predictions to all positive predictions the model produced.

$$\frac{TP}{TP+FP} \quad (2)$$

- Sensitivity (Recall): The recall of a classification model measures how well it can find every relevant instance in a dataset. As a percentage of all false negative and true positive forecasts, it represents the percentage of true positive cases or predications.

$$\frac{TP}{TP+FN} \quad (3)$$

- Specificity: Specificity play a crucial statistic for assessing classification for binary classification. This assesses a model's capacity to accurately recognize negative examples.

$$\frac{TN}{TN+FP} \quad (4)$$

- F1 Score: The in-general performance is assessed using F1-score for the classification model. It's the precision and recall harmonic mean.

$$2 * \frac{Precision * Recall}{Precision + Recall} \quad (5)$$

$$(TP: True\ Positive, TN: True\ Negative,$$
$$FP: False\ postive, FN: False\ Negative)$$

IV. Challenges and Future Scope

Numerous obstacles affect the effectiveness and usability of the field of machine learning-based skin lesion identification and categorization. Training models that generalize across different skin conditions are hampered by limited access to balanced and diverse datasets. Even using DL algorithms, it is still a challenging task to extract information from the images of skin lesions that may utlized for clinical interpretation . Robust algorithm development is further complicated by the clinical heterogeneity in skin types, lighting settings, and presentation styles. To achieve responsible implementation in clinical settings, ethical factors like as biases in algorithm predictions and patient privacy need to be carefully considered.

To improve accuracy, this field's future scope calls on the integration of several modalities, including genetic and clinical data. The interpretability of models will increase with the development of explainable AI techniques, and feature learning can be further enhanced by continuing research into transfer learning strategies. The future landscape will need to include real-time diagnostic tools, online learning tactics, and joint machine learning and dermatologist efforts to overcome obstacles and improve skin lesion detection technologies' usability, precision, and global impact.

V. Conclusion

In conclusion, this research study clarifies the significant progress made in the use of ML in the field of dermatology to identify and categorize skin lesions. This work explores the synergistic interaction between advanced machine learning techniques and high-quality dermatological datasets, realizing the critical importance of early detection of cutaneous abnormalities. Although the study duly notes the achievements of DL, also highlights the advantages of traditional ML algorithms in terms of interpretability, processing performance, with simplified application, especially in situations where datasets are limited. Various techniques, including rule-based strategies, traditional algorithms such as RF and SVM, and feature engineering, were examined for their effectiveness in automating the analysis of skin lesions.

Looking ahead, this field's direction anticipates overcoming obstacles like the need for different datasets and ethical problems. It suggests exploring advanced transfer learning algorithms, improving explainable AI techniques, and integrating genetic and clinical data. The development of real-time diagnostic instruments and joint efforts between the fields of dermatology and machine learning are anticipated to be essential elements in enhancing the accuracy, availability, and worldwide influence of skin lesion detection technologies. Considering skin conditions diagnostics, combining medical knowledge with machine learning expertize has the potential to completely transform dermatological practices by offering scalable and effective solutions for the quick identification of lesions, better patient outcomes, and economical use of resources. The field of individualized patient care is expected to benefit greatly from the joint efforts of machine learning researchers and dermatologists, as they are anticipated to play an essential role in defining the future of automated dermatological diagnostics.

Adoption of Metaverse in Healthcare Sector: An Empirical Analysis of its Enablers

Vipulesh Shardeo, Bishal Dey Sarkar, Umar Bashir Mir, Prerna Kaushik

***Abstract*— The emergence of novel innovations has disrupted multiple service sectors, and healthcare is one such sector that has seen significant changes since the inception of Internet. The incorporation of information communication and technology (ICT) in the healthcare sector has been introduced previously; however, the recent COVID-19 pandemic has exponentially accelerated the use of ICT in the healthcare sector and the demand for contactless health services. The use of technology for online consultation, robot-assisted surgeries, training, and education are some of the common use cases of tech-driven healthcare. Metaverse, the latest innovation that is the amalgam of multiple technologies like artificial intelligence (AI), augmented reality (AR), virtual reality (VR) and robotics, holds massive potential to deliver high-quality healthcare services (HS) to the masses, eliminate bottlenecks between healthcare providers and patients and eliminate the need of in-person interaction for availing HS. This study aims to identify the factors that drive the adoption of metaverse in the healthcare industry. Following a mixed-method approach, the study combines secondary academic literature data with primary data from domain experts. A total of thirteen enablers are identified for adopting metaverse in the healthcare domain. Subsequently, a hierarchical model reflecting upon the relationship among these factors based on their significance is developed using Grey-Ordinal Priority Approach (G-OPA) and modified TISM methodology (mTISM). The proposed hierarchical model provides valuable insights into these factors' dependencies and relative importance which could empower healthcare organizations and policymakers in making informed decisions and strategic planning for an effective and efficient healthcare system.**

***Index Terms*—** Metaverse, Healthcare, Information and Communication Technology, Technology Management, modified TISM, Grey-OPA

I. Introduction

The innovations in the field of Information and Communication Technology (ICT) have transformed the way humans consume and deliver products and services. One such technology that has been in focus lately is metaverse. It is evolving rapidly and the interest in its application across domains is growing exponentially [1]. Hackl [2] defines metaverse as an evolving virtual universe in which people can create their own representation of the world based on their experiences from real world [2]. Koss [3] refers to metaverse as an immersive 3-D virtual space that enables people to connect with the other people, shop, and work in the real time. Metaverse is the amalgamation of technologies like artificial intelligence, digital twining, augmented and virtual reality that facilitate interactions between people and their digital counter parts in the virtual environments [4]. Integrating different technologies in the metaverse holds significant potential to revolutionize various sectors, including healthcare [1].

The application of digital technologies in the healthcare system is not new. Healthcare providers have adopted digital alternatives like mobile apps, and telehealth to offer various services but are primarily laggards [5], [6], [7]. Such systems were mostly for disseminating healthcare information among the stakeholders. However, metaverse has emerged as an innovative technology, and the approach to adopting it in the healthcare sector is proactive and growing. It is anticipated to transform the structure of the healthcare sector, enhancing the experience of patients and healthcare providers [8], [9]. Medical professionals are already utilizing components of metaverse for delivering HS. For example, doctors are helping patients with phobias by putting them into virtual environments where they must face their fears. Similarly, medical practitioners are also using VR to treat patients with mental diseases like social anxiety and obsessive-compulsive disorder[10]. The potential benefits of using metaverse in the healthcare sector could be ensuring anonymity, integrated health records, and providing wider reach and virtual experience. Metaverse has shifted the HS from hospitals to homes and from information-driven healthcare to experience-driven healthcare, significantly contributing to its market in the healthcare sector. As per the recent report [11], the current market for metaverse in healthcare sector is around $6 billion and is estimated to reach $71 billion by 2030. Because metaverse offers highest possibility of virtual interaction, immersive experience, duality, and the support for interoperability across platforms, it has the potential to disrupt the healthcare sector [5], [12], [13].

Despite the potential benefits of metaverse in general and healthcare in particular, there is still minuscule research in this direction. This could be because metaverse is a novel innovation still in its infancy stage. The advantages that metaverse can offer to the healthcare industry are immense and could lead to significant changes, enhancing patient engagement and experience through high levels of interaction and increasing accessibility to HS in far-flung areas [5]. Its potential applications across sectors are still being explored, and historically, the healthcare sector does not fall under early adopters of the innovations [14], [15]. However, as more people become familiar with metaverse, its adoption is expected to grow multi-fold. The success of any digital platform depends on its acceptance and use by its target audience [16]. Unlike other sectors, healthcare is a critical domain; thus, any new technology is adopted only after it has been tested, validated,

This article has been accepted for publication in IEEE Transactions on Engineering Management. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TEM.2024.3400401

and approved by the concerned authorities. The use of metaverse in healthcare has received greater emphasis, and many researchers have recommended examining how the metaverse can contribute to the healthcare sector [17], [18]. The ultimate adoption of any technology is driven by its enablers. These enablers are the factors that motivate concerned stakeholders to accept and use the technology. In the case of healthcare, enablers are the factors that could facilitate patients and healthcare providers to use metaverse for providing and receiving various HS. With this background, the study attempts to answer the following research questions:

- RQ1: What are the key enablers driving the adoption of metaverse in the healthcare sector?
- RQ2: What are the priority rankings of enablers in the context of emerging economies?
- RQ3: How are these enablers interlinked?

By answering the above questions, the study contributes to the metaverse applications and technology adoption literature in emerging economies. Precisely, the study identifies the thirteen key enablers impacting the adoption of metaverse in the healthcare sector. Further, by determining the priorities of each enabler in the context of emerging economies, the study addresses an important gap in current academic literature, contextualizing the utility of metaverse to resource-constrained geographies. Lastly, by identifying the interrelationships between enablers, the study highlights the complex dynamics of metaverse technology and its integration with the healthcare system in the rural communities of emerging economies. This combination of identifying enablers, prioritizing them in terms of emerging economies, and investigating interrelationships across enablers provides useful information for the use of metaverse in healthcare for emerging economy rural communities.

The remainder of the paper is structured as follows: Section 2 presents the literature review on the adoption of ICT in the healthcare sector, metaverse in the healthcare sector and research gaps. Section 3 outlines the research methodologies used. The results and findings of the research are presented in Section 4, and the study's implications are discussed in the Section 5. Finally, Section 6 concludes the study and offers suggestions for future research.

II. Literature Review

The term “Metaverse” was first coined by Neal Stephenson in 1992 in his novel Snow Crash, wherein it reflects upon the integration of the internet and augmented reality technology to provide real-world experience in the digital space – virtual reality [6], [19], [20], [21]. Currently, online immersive platforms are proliferating and are expected to go beyond just reflecting the real world, which is limited by boundaries and strict rules [22]. It is believed that current devices carried to access the metaverse will be replaced by the devices worn by the users, thereby better integrating our physical world with the virtual world. Considering the potential of such futuristic technologies, tech giants are spending around 5% -20% of their R&D funds on these technologies.

Healthcare is another sector that has seen massive growth, especially after the COVID-19 pandemic. The impact of COVID-19 resulted in health expenditures experiencing the most rapid growth in the past twenty years during the year 2020. Experts believe that the metaverse could impact the healthcare sector significantly because of its potential to integrate three major technological innovations, i.e., telepresence, digital twining and blockchain [19], [23], [24]. With this background, we provide a focused literature review covering two significant dimensions of the technology adoption and healthcare sector. First, we review major developments related to the adoption of traditional ICT in healthcare, and second, we review the contributions made towards the metaverse for the healthcare sector.

A. Adoption of Information and Communication Technologies in Healthcare Sector

Healthcare is divided into several areas, each using technology differently [25]. Healthcare organizations, practice settings, and nursing units use technology differently [26], [27]. For example, in nursing ICT play an important role in maintaining real-time connectivity among healthcare professionals, patients and the management. Apart from communication, it facilitates accurate record-keeping, efficient information organization, and seamless retrieval processes. Similarly, doctors use it in research, tele-consultation, effective management and communication with other healthcare professionals[27], [28], [29]. Broadly, healthcare professionals, encompassing doctors, nurses, technicians, pharmacists, and allied practitioners, harness the power of ICT to access vital information, streamline administrative tasks, elevate patient care standards, and stay updated on novel advancements within their specialized domains [12], [28], [30]. In general, ICT facilitates better knowledge management, a phenomenon extensively investigated in diverse studies [25], [31], [32]. Earlier studies have reflected upon the enhanced use of various tools, and techniques to address multiple healthcare related issues and improve the overall quality of life [33]. However, it is still challenging to introduce new technologies in the healthcare sector considering the challenges involved. Within this context, healthcare sector has diverse set of technologies at its disposal including but not limited to metaverse, blockchain, Internet of Things, augmented reality, artificial intelligence, and robotics. The strategic integration of these technologies has the potential to transform the overall healthcare industry [34], [35], [36], [37]. The need for such transformation is further accelerated by the recent COVID-19 pandemic [38]. Organizations in the healthcare industry have quickly embraced digital solutions and cutting-edge technological tools in response to the pandemic's initial phase [12], [13], [39]. To lessen the impact of COVID-19 on people and health systems, the study conducted by Golinelli et al., [40] provides the digital solutions that have been documented in the literature. Popa et al., [41] present the use of digital twins in the healthcare sector from a socio-ethical risks perspective. Attaran [42] presents the adoption of blockchain in the healthcare sector. Dhar et al., [43] explained how adopting

This article has been accepted for publication in IEEE Transactions on Engineering Management. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TEM.2024.3400401

augmented reality in medical education will help students and enhance their performances. By adopting these cutting-edge technologies, the healthcare sector may transform and build a safe, secure, and stable digital ecosystem for the management and improvement of a better, more individualized client experience [44]. To help the general populace of their economies, developed and developing countries have recently started to implement digital transformation in the healthcare sector. Nnaji and Tsai [45], [46] discusses various barriers in the adoption of these technologies, including whether the technology is safe, how it will be used, and how it will affect patients and healthcare professionals. Due to worries about the expense and a lack of knowledge with the technology, many hospitals take their time implementing new technologies [47], [48]. There are several barriers, such as the fact that much medical personnel do not know how to use the technology or how it will impact their daily work [37]. Because their current systems are so convenient and easy to use, users are reluctant to adopt new technology [28], [33]. Also, the security or efficacy of new technologies may raise concerns in clinics and hospitals. Awad et al., [49] stated that adopting new technology is a gradual and ultimately beneficial process. While the practicality of ICT adoption has improved, it remains imperative to identify the underlying reasons for low adoption rates and actively work towards resolving these challenges.

B. Metaverse in Healthcare Sector

The metaverse can be seen as the immersive follow-up to the text-and-picture-based Internet of today. The metaverse promises to deliver online interactions that are more immersive and dynamic, a seamless fusion of both the digital and physical worlds, by utilizing cutting-edge technology [50]. Technologies like artificial intelligence, augmented and virtual reality, blockchain, and 6G network constitute advanced technological innovations within the metaverse, exerting significant impact on the healthcare sector. Huynh stated that the adoption of these technologies' exposes people to the novel, much less expensive therapy delivery methods, improving patient outcomes [19]. According to Park & Kim [4], the healthcare system in the realm of the metaverse offers recreational, immersive, and interactive experiences that are tailored to each patient's needs .Metaverse is a universe that uses the internet to create an alternative reality experience, recreating patients 'emotions and gestures while encompassing the social and economic structures of the virtual and real worlds. Petrigna & Musumeci [51] explain how healthcare professionals could adopt the metaverse for disease diagnosis and effective planning. The recent pandemic has generated the need for remote HS and metaverse has the potential to provide a greater experience than the classical videoconferencing-based telemedicine systems [15]. Further, Huh [52] emphasized that Medical education and training could be revolutionized by the metaverse. Instead of distributing conceptual understanding, using AR creates a favourable setting for explaining actual techniques. Many academicians have investigated the possibility of the metaverse in various domains like, the study conducted by Yang [18] explored the application of metaverse in medical IoT using AR/VR. Bhattacharya [24] highlighted the potential of Healthcare 5.0 for renders personalized care, virtual clinics, wellness monitoring, telesurgery, telemedicine etc. Thomason [53] addressed the metaverse's potential role in enriching and revolutionizing healthcare regarding wellness, monetization, clinical care, education, and collaborative working. In another study, Krishnan [33] studied the application of metaverse in healthcare from a service provider's perspective and highlighted its relevance in conducting training, education and offering consultation in a more realistic environment. However, the study concludes that it is difficult to prove that there will be significant improvements in healthcare by using metaverse. Yang et al., [54] highlighted the role of intelligent healthcare systems, where many examples of data science and AI applications in healthcare have been studied in the context of hospital management in the metaverse. The analysis of the examples reveals challenges in the metaverse applications in healthcare sector. This dimension of metaverse adoption is important, as emphasized in multiple studies. According to Henz [55]adopting the metaverse at a large scale could reduce human interaction and increase human-to-technology interactions in the future. This could seriously affect users' well-being, leading to depression and loneliness [56]. Also, the cost associated with the adoption and access of metaverse technology pose additional challenges. Prior studies [38], [57], [58] have reflected upon the digital divide as the potential implication of metaverse adoption because of the economic inequalities present in the society, thus compromising on the wellbeing-related benefits offered through metaverse. To ensure the safe and effective usage of metaverse, various researchers have emphasized on the need to explore metaverse technology from consumers' perspectives [12], [38], [56], [59] and the motivations that drive its adoption in healthcare sector [5], [20], [56], [57], [58]. With this background, the study attempts to explore the key factors behind the adoption of the metaverse in the healthcare sector, with a primary emphasis on patient-doctor interactions in emerging economies. Emerging economies have unique characteristics in terms of literacy rate, socio-economic wellbeing, and technology adoption and contribute 85% to the global population [60]. Most of these countries suffer from inadequate healthcare infrastructure [61]. Metaverse could bridge this gap and enable better healthcare facilities to these most vulnerable populations.

C. Research Gaps

Metaverse has emerged as a significant technology and it is anticipated that the adoption of metaverse in the healthcare sector will enhance the healthcare system in developed economies for multiple purposes including disease prevention, treatment, promoting healthcare programs, training, and education [14], [55]. Yet, there is a perceived lack of effectiveness in the adoption of metaverse in the healthcare sector for the developing economies[20]. In literature, many studies have identified the factors/critical success factors for metaverse adoption [62], [63], [64], [65]. These studies have explored the barriers or enablers and provided typologies or taxonomies without taking interdependencies specific to healthcare into the consideration. To the best of our knowledge, we did not find any study specifically focused on identifying the key enablers in adopting metaverse technology in the healthcare sector by considering domain experts—most of the existing research papers in this area are related to the issues and challenges faced during the implementation phase. However,

This article has been accepted for publication in IEEE Transactions on Engineering Management. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TEM.2024.3400401

few research papers specifically developed a comprehensive framework for identifying and studying the key enablers for metaverse adoption. Additionally, prior studies have looked mainly at the technological aspects of metaverse adoption in the healthcare sector which is only one aspect of the adoption [66], [67]. Adopting novel technologies and digital platforms depends on the combination of tech and non-tech factors [16]. There is no consensus on how to classify the factors that make the adoption of the metaverse possible [5]. Further, comprehensive studies exploring the adoption of metaverse in delivering HS in the developing economies is largely missing. In this sense, an academic gap exists in identifying and analyzing the key enablers of metaverse adoption in healthcare sector in the context of emerging economies. Academic gaps must be addressed before the full potential of metaverse technology in the healthcare sector can be realized. In comparison with the prior studies, this study presents a managerial perspective on the adoption of metaverse in the healthcare industry in the context of developing economies. Because potential adopters lack access to adequate information to make informed judgements, these research gaps are impeding the widespread implementation of metaverse technologies in the healthcare sector. The study develops precise research questions to bridge the research gaps, as mentioned in section 1.

III. Research Methodology

The main objective of this research is to identify and prioritize the enablers that facilitate the adoption of metaverse technology in the healthcare sector and investigate how these enablers are interrelated. The study develops a methodological framework to fulfil this objective by integrating various theories and methodologies like Critical Success Factor Theory, Grey-OPA and modified-TISM. This study initially identified multiple enablers from the available literature on metaverse adoption, specifically in healthcare sector. Further, selected enablers have been finalized with the consultation of domain-related experts and by adopting the critical success factor theory. Furthermore, G-OPA is utilized to assess finalized enablers to obtain their importance weights. Here, OPA is preferred over other MCDM techniques for its efficiency and reliability [68]. Uncertainty is common in healthcare, especially with cutting-edge technologies like the metaverse. Integrating grey system theory can resolve this ambiguity, allowing for a more precise analysis despite scant or confusing data. This makes it more preferable than other soft computing methods [69]. The importance weights obtained by G-OPA are then used to rank the enablers based on their importance for metaverse adoption—the next sub-objective deals with investigating interrelationships among these enablers. Modified Total Interpretive Structural Modelling is used to meet this. The m-TISM is preferred over other similar methods like ISM, DEMATEL, etc. because (i) it involves simultaneous transitivity check, which reduces the requirement of pairwise comparisons, and (ii) it provides an interpretation matrix of interrelationships of enablers. The methodological flowchart representing the research flow is presented in Fig. 1. The brief details, including the steps for adopted methodologies, are explained in subsequent sub-sections.

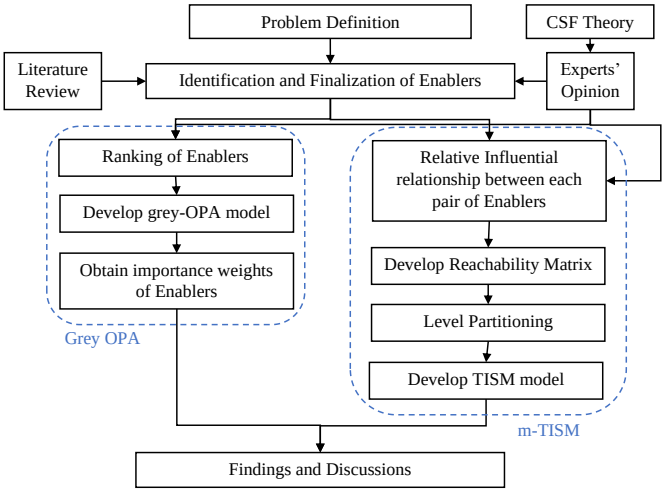

Fig. 1. Methodological Flowchart

A. *Critical Success Factor Theory & Selection of Experts*

Critical Success Factors (CSFs) were first discussed by Rockart [70] as part of his investigation into the function of information systems in organizations. His contributions set the groundwork for comprehension of the idea of critical success factors and their function in the management of businesses. Rockart [71], [72] has recommended a two-step method for interviews to pinpoint the success factors. In a series of open interviews, experts are initially questioned about the factors they believe will contribute most to the entity's success. Based on these, a preliminary list of criteria is developed, and in a future round, they are rated according to an essential factor.

This study used the CSF theory to identify the enablers that could facilitate the adoption of metaverse in the healthcare sector. Enablers are identified through a two-step process.

TABLE I
EXPERTS' PROFILE

Expert No.	Designation	Educational Qualification	Age	Gender	Field of Expertise	Work Exp.
Expert 1	Sr. Manager	Post Graduate	42 Yr	Male	Innovation Management	13 Yr
Expert 2	Medical Officer	Post Graduate	41 Yr	Male	Healthcare Services	17 Yr
Expert 3	Sr. Medical Officer	Post Graduate	47 Yr	Female	Healthcare Services	19 Yr
Expert 4	Doctor	Post Graduate	36 Yr	Female	Healthcare Services	11 Yr
Expert 5	Surgeon	Post Graduate	46 Yr	Male	Healthcare Services	18 Yr

This article has been accepted for publication in IEEE Transactions on Engineering Management. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TEM.2024.3400401

Initially, the authors compiled a preliminary list of enablers from the literature. Subsequently, the list of enablers was shared with the experts to finalize them. The experts chosen for this study are professionals in the Indian context of technology management, HS, and innovation management. India, with 1.4 billion people, is the most populous country in the world. Around 65% of its population living in rural areas [61], [73], highlights the country's unique demographic and geographic diversity making it a compelling case for investigating the phenomena of metaverse in healthcare. Additionally, hospitals in rural India are often not equipped with state-of-the-art medical equipment, suffer from a lack of sufficient clinical expertise among local doctors and necessitate rural patients to visit major hospitals located outside rural areas for better treatment [74], [75], [76], [77]. Metaverse could be a timely solution to address these issues and improve the overall quality of the healthcare system in India [78]. Moreover, experts also believe that addressing any issue in India means addressing it for over 40% of the global population [79].

To ensure that their perspectives are sufficient, the experts chosen for this study are above mid-level executives[80]. Initially, 15 experts have been consulted. Out of them, seven experts confirmed their participation in this study. The experts consulted in this study are mostly from technology management (28.6%), HS (57.1%) and innovation management (14.3%) domains. The experts' profile is presented in TABLE I. Further, the enablers were explained to the experts, who were then tasked with evaluating whether or not their interpretations of the enablers were consistent and relevant to adopting metaverse in the healthcare sector in light of their knowledge and experience. The experts gathered afterward for a brainstorming session to reach a consensus and compiled the final set of significant enablers that are important for the implementation of the metaverse in the healthcare sector.

B. Grey Ordinal Priority Approach

Ataei et al. [68] proposed Ordinal Priority Approach as a MCDM technique to solve complex decision-making problems. OPA is favoured over other MCDM techniques such as, ANP, AHP, BWM, etc. due to providing flexibility to the decision makers [68]. OPA does not require pairwise comparisons, normalization or decision matrices. Also, it allows decision-makers to either rank the factors/elements same rank or can be kept blank, if decision-maker is unsure about it. This further provides flexibility and better efficiency in decision-making process. However, few decision-making problems are bit complex and contains subjective opinion of the decision-makers. To cater this, we have integrated the grey numbers with OPA as done by Mahmoudi [81]. The steps of G-OPA are as follows:

Step 1: Determine the factors. The first step begins with the identification of factors (enablers in our case) to be analysed. In this study, enablers of metaverse adoption in healthcare sector have been extracted from the literature survey which is presented in TABLE III.

Step 2: Assessment of the factors. Once the factors are identified, the experts are asked to rank those factors using linguistic terms as mentioned in TABLE II.

Step 3: Develop the model. The next step relates to model building. In order to obtain grey weights of each factor, linear programming model can be built as follows:

$$Max \otimes Z$$
$$s.t.$$

TABLE II
GREY NUMBERS AND ITS CORRESPONDING LINGUISTIC TERMS (SOURCE: [82])

Linguistic Variables	Grey Numbers	Rank
Very Low Importance (VLI)	(6.5, 7.5)	7
Low Importance (LI)	(5.5, 6.5)	6
Medium Low Importance (MLI)	(4.5, 5.5)	5
Medium Importance (MI)	(3.5, 4.5)	4
Medium High Importance (MHI)	(2.5, 3.5)	3
High Importance (HI)	(1.5, 2.5)	2
Very High Importance (VHI)	(0.5, 1.5)	1

$$\otimes Z \leq \otimes e\left(\otimes j\left(\otimes W_{ej}^{r} - \otimes W_{ej}^{r+1}\right)\right) \quad \forall e, j \text{ and } r \qquad (1)$$
$$\otimes Z \leq \otimes e\left(\otimes j\left(\otimes W_{ej}^{m}\right)\right) \quad \forall e \text{ and } j$$
$$\sum_{e=1}^{E}\sum_{j=1}^{J} \otimes W_{ej} = [0.8, 1.2]$$

Where, $\otimes Z$ is unrestricted in sign; $\otimes e$ & $\otimes j$ are the grey ranks of the experts and enablers, respectively.

Step 4: Obtaining the crisp weights. Solving equation (1), the grey weights of the enablers can be obtained. Further, obtained grey weights can be converted to crisp weights using equation (2) as follows:

$$C_j = \frac{1}{2}\left(\overline{\otimes}\, j + \underline{\otimes}\, j\right) \qquad (2)$$

C. Modified Total Interpretive Structural Modelling

MCDM approaches are being utilized more frequently to settle new conflicts and analyze different scenarios in light of many competing evaluation criteria. It is regarded as a decision-supporting and operational assessment technique that is best suited for complex problems with many viewpoints, different interests, competing aims, and high levels of decision-making uncertainty. Some of the common MCDM techniques includes AHP, ANP, TISM, SMART, TOPSIS, ERA, DEA etc [72], [82], [83], [84], [85]. Recently, Sushil [86] developed a new MCDM technique and termed it as a modified TISM (m-TISM). The Total Interpretive Structural Modelling approach, which is used to create a hierarchical model of identified factors of interest [72], [87], [88], is extended using this technique. Although TISM could have been used, m-TISM was chosen because it enables simultaneous transitivity checks, unlike traditional TISM where transitivity is checked sequentially [89]. M-TISM not only accelerates the entire process but also

This article has been accepted for publication in IEEE Transactions on Engineering Management. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TEM.2024.3400401

reduces the risk of errors originating from redundant pairwise comparisons, as seen in the case of TISM [90]. In order to make it easier to develop a hierarchical model of the modified TISM technique addresses three fundamental concerns linked to "what," "why," and "how." Regarding the final hierarchical model, there is no significant difference between the model developed using traditional TISM and m-TISM. When contrasting m-TISM with other research methodologies, the "Systematic Literature Review (SLR)" can offer pertinent literature in the field of study and assist in gathering various constructs for study, but it is unable to produce a systematic hierarchy of the model of those constructs. The SLR also falls short in giving guidance and an explanation of how the components that were detected are linked. Literature shows that researchers have used m-TISM in various domains. For an instance, Rajan & Dhir [91] has used m-TISM for technology management in organizations [91]. Meena & Dhir [92] uses m-TISM for studying the factors of automotive industry in India. Shardeo [93] has integrated m-TISM with fuzzy-ANP method for analyzing the critical success factors of blockchain adoption in transportation domain. Further, Sharma, [94] has used m-TISM for studying the impact of artificial intelligence on tourist firms and Sindhwani [95] has used m-TISM in the domain of logistics 4.0[95]. The steps of m-TISM are as follows:

Step 1: *Identify the factors and the nature of their relationships.* The first step begins with the identification of factors (enablers in our case). In our study, 13 enablers have been identified which is presented in TABLE II. Furthermore, we are interested in exploring the influential relationship of enablers.

Step 2: *Pairwise comparison.* The pairwise comparison of factors is used to investigate the link between the factors. In this phase, respondents are requested to compare the two factors and highlight their relationship, as well as provide justification. For example, if the first component effects the second, the expert will record the link as 1 – 2. Similarly, the process continues until all pairs of factors will be compared. Unlike TISM, the modified TISM questionnaire checks transitivity with logic checks, reducing the number of pairwise comparisons.

Step 3: *Develop the reachability matrix*. The following step is the development of a reachability matrix. For instance, the influential relationship between the two factors is represented by 1; otherwise, it is represented by 0. If a relationship is transitive, it will be represented as 1*. Similarly, the entire reachability matrix is developed.

Step 4: *Level Partitioning.* To begin the level partitioning procedure, reachability, antecedent, and intersection sets must be defined. All row-wise factors that have value 1 or 1*must be included in the reachability set. In contrast, the column-wise factors with the value 1 or 1* should be included in the antecedent set. The intersection set includes the factors that are common in reachability and the antecedent set. If the intersection set of any factor equals the reachability set of that factor, that factor is assigned the level, and the factors of that level's intersection set are excluded from the rest of the matrix for further iterations. The process is repeated until all of the factors have been assigned a level.

Step 5: *To develop the digraph using the final reachability matrix:* The digraph includes nodes representing the enablers and directed links representing the direction of the relationship among the enablers. Each enabler in the digraph is assigned a level obtained in the previous step. Important relationships are only shown in the final digraph with black lines and indirect relationships with a dotted line.\

Step 6: *Develop the TISM model.* The final step is building the TISM model. In this step, the factor(s) from the last level are considered to be the fundamental factor(s) upon which the model is built. The reachability matrix, on the other hand, can be used to determine the relationships between the factors.

IV. Results

This section consists of the findings from an analysis of the enablers of metaverse adoption in the healthcare sector. The final sub-section contains discussions of the findings of the analysis.

A. Identifying and finalizing the enablers

Initially, various articles in the field of technology adoption in the healthcare sector were assessed, as shown in section 2.1. An initial list of enablers has been compiled based on a review of the literature. The list has also been shared with the experts (TABLE I) for feedback. Following an agreement with domain experts, 13 enablers were finalized. TABLE III presents the final list of enablers of metaverse adoption in the healthcare sector.

TABLE III
LIST OF ENABLERS OF METAVERSE ADOPTION IN HEALTHCARE SECTOR

Description	Source
E1: Ability to link metaverse with existing IT systems that deal with other patient related information like steps walked, diet etc.	[14], [96]
E2: Ability to provide virtual presence with real-like experience.	[6], [21]
E3: Ease with which people can use a metaverse system for HS.	[9]
E4: People are comfortable in adopting digital innovations.	[14], [97]
E5: Ability to tailor patient profile based on his/her needs.	[50], [51]
E6: Impact of individuals or groups on users' attitudes, beliefs toward use of metaverse based healthcare.	[17], [98]
E7: Users' data are confidential, & users have clear control over it.	[5], [99]
E8: Cost to avail HS via metaverse returns the value out of it.	[66], [98]
E9: Capacity to process and analyze large amounts of complex data.	[50],[100]
E10: Rules/regulations/recommendations/laws specific to use of metaverse for healthcare.	[14], [66]
E11: Reward given for using metaverse based healthcare system.	[66],[101]
E12: Hardware & software for operational metaverse system.	[14], [66]
E13: Ability to get treatment without disclosing real identity. For example, STD and other diseases.	[102]

B. Determining importance weights of enablers

The first objective of this study was to identify the potential enablers of metaverse adoption in healthcare sector. To achieve this, literature review is conducted as mentioned in section 2.1. and list of enablers has been finalized after consultation with the experts. As mentioned earlier, the experts chosen for this study are mostly healthcare professionals and technologists. Due to complexities involved in MCDM problems, too much sample size may lead to high inconsistency [103], [104]. As a result, the sample size of seven respondents is taken in this study which meets the sample size requirements of MCDM problems [105], [106]. The finalized list of enablers along with its brief description is presented in TABLE III. Furthermore, in order to achieve the second objective i.e., to obtain the importance weights of the enablers, grey OPA is employed. The brief description of steps of grey OPA is explained in section 3.1. Following the steps of grey OPA, the experts are asked to rank the enablers based on its importance using linguistic variables mentioned in TABLE II. The experts' opinion regarding the ranking of enablers on the basis of its importance is presented in TABLE IV. After collecting the data from all experts, the inputs were converted into corresponding grey numbers. For an instance, if an expert ranked Enabler 1 as "Medium High Important" then the corresponding grey number assigned is {2.5, 3.5}. Similarly, the experts' inputs have been converted into grey numbers. Then using equation (1), grey OPA model is developed as a linear programming (LP) model. The LP model is run on Python using *gekko* package. This resulted in an optimal solution of upper and lower grey values of importance weights of enablers. Further, the upper and lower grey values of importance weights assigned by each expert is summed up to obtain aggregated grey weights of enablers. Then, using equation (2), the crisp weights of the enablers are obtained. The importance weights and ranks of enablers of metaverse adoption in healthcare sector is presented in TABLE V. It can be seen from the TABLE IV, "Telepresence (E2)", "Anonymization (E13" AND, "Familiarization (E4)" are found to be three most important enablers. Whereas, "High-powered Analytics (E9)" is found relatively least important. This might be due to entrance of multiple high-powered technologies which further shifted the users' attention towards its ease of use than its powering capabilities. The importance weights of the enablers are also presented through Fig. 2.

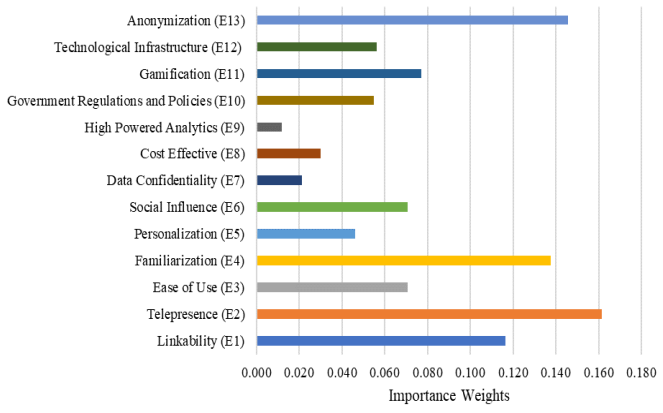

Fig. 2. Enablers and its ranking based on importance weights

TABLE IV
EXPERTS' OPINION REGARDING RANKING OF ENABLERS

Enablers	Experts						
	E1	E2	E3	E4	E5	E6	E7
Linkability (E1)	MI	VHI	HI	MHI	HI	HI	MI
Telepresence (E2)	VHI	VHI	HI	HI	VHI	MHI	MI
Ease of Use (E3)	MHI	MHI	MHI	MI	MLI	MHI	HI
Familiarization (E4)	HI	HI	VHI	HI	VHI	MLI	HI
Personalization (E5)	MI	MI	VLI	MHI	MI	MLI	MI
Social Influence (E6)	HI	MI	MLI	HI	MI	MHI	MLI
Data Confidentiality (E7)	LI	LI	MLI	MLI	MI	LI	VLI
Cost Effective (E8)	MLI	MLI	HI	LI	MI	VLI	LI
High Powered Analytics (E9)	VLI	VLI	LI	MLI	VLI	MLI	LI
Government Regulations and Policies (E10)	HI	HI	MLI	MHI	MI	LI	MI
Gamification (E11)	HI	MHI	MLI	MHI	MHI	HI	HI
Technological Infrastructure (E12)	MLI	MHI	MI	MHI	HI	MHI	MI
Anonymization (E13)	VHI	VHI	MI	HI	MHI	MI	VHI

TABLE V
IMPORTANCE WEIGHTS OF IDENTIFIED ENABLERS

Enablers	Importance Weights	Rank
Linkability (E1)	0.116	4
Telepresence (E2)	0.162	1
Ease of Use (E3)	0.071	7
Familiarization (E4)	0.137	3
Personalization (E5)	0.046	10
Social Influence (E6)	0.071	6
Data Confidentiality (E7)	0.021	12
Cost Effective (E8)	0.030	11
High Powered Analytics (E9)	0.012	13
Government Regulations and Policies (E10)	0.055	9
Gamification (E11)	0.077	5
Technological Infrastructure (E12)	0.056	8
Anonymization (E13)	0.146	2

C. Interaction among enablers

The subsequent objective of the study was to highlight the interaction of the enablers. To accomplish this objective, we employed m-TISM to develop the interpretive structural model. The same experts were consulted for collecting data for the m-TISM exercise. The pairwise comparison of enablers was conducted based on group discussion and maintaining consensus among them. As recommended by Creswell and Poth, [107] the sample size requirement for qualitative study should be 5 to 25 which supports the consideration of 7 experts in this study. It can also be justified further by prior studies used fewer sample sizes to conduct TISM analysis [106], [108]. Further, the experts were asked to mark their opinion on the influence of one enabler on another, along with justification. Based on the data collected, a reachability matrix is created that contains the concurrent transitive relationships, i.e., the strength of m-TISM, as mentioned in Section 3.2. Appendix I shows the reachability matrix with simultaneous transitive links.

This article has been accepted for publication in IEEE Transactions on Engineering Management. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TEM.2024.3400401

Furthermore, the reachability set and antecedent set are constructed depending on the enablers that appear in the reachability matrix's columns and rows, respectively. The intersection set is then produced, which contains the enablers that are common by the reachability set and the antecedent set. If the intersection set equals the reachability set, the level is partitioned, and the enablers from the Intersection set are deleted from the table for the following iteration. Similarly, the process is repeated until all enablers are assigned to different levels. Appendix II depicts the iteration-wise level partitioning. As can be seen, level partitioning takes 7 iterations, resulting in 7 levels. The TISM model can be constructed based on the level assigned to the enablers. Fig. 3. depicts the TISM model of metaverse enablers in the healthcare sector.

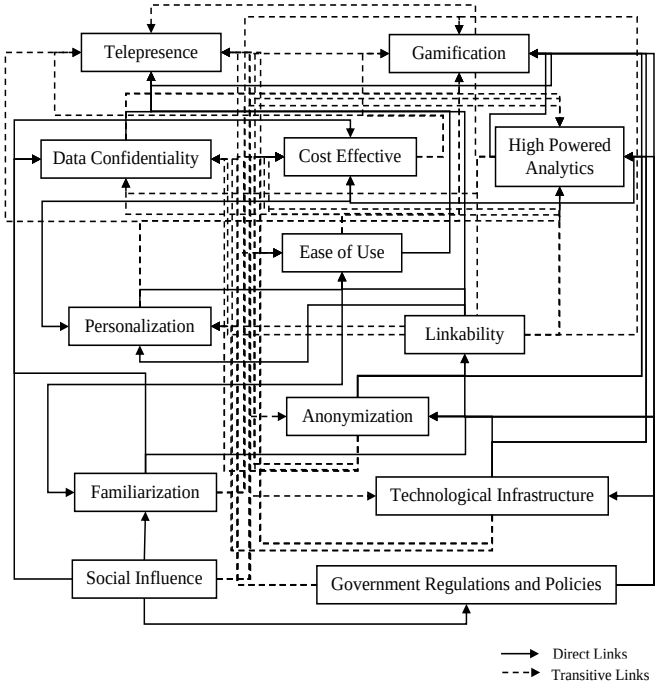

Fig. 3. Interpretive Structural Model of the Enablers

As shown in Fig. 3., the enablers "Social Influence" and "Government Regulations and Policies" are positioned at the bottom level and constitute the foundation for metaverse adoption in the healthcare sector. These two enablers have significant influence over other enablers and are critical to elevating metaverse adoption in the healthcare sector. Similarly, the model depicts the influential interrelationship of the enablers. The interpretations of the interrelationships among enablers are presented in TABLE VI. It is worth noting that the mTISM model focuses on influential relationships, whereas the G-OPA analysis reported in the preceding section underlined the importance of enablers in terms of priority weights perceived by experts. The following section provides a more extensive discussion of the importance and influence of enablers.

D. Discussions

The study aimed to explore the enablers contributing to adopting a metaverse in healthcare. Metaverse is still in its infancy stage, and it is still unclear how this technology will unfold in the future. However, researchers, business leaders and technology giants have shown their confidence and expressed keen interest in the metaverse technology and its potential applications across sectors. Broadly, the metaverse can be used in healthcare system for multiple purposes including disease prevention, treatment, promoting healthcare programs, training, education, sharing research to name a few. Thus, it becomes necessary to examine the enablers so that we can better understand the impact and their role in adopting metaverse in healthcare.

The findings showed that thirteen enablers comprise technology-related factors like telepresence, anonymization, ease of use, linkability, infrastructure, personalization, and non-technology-related factors, including social influence, familiarization, government regulations and policies, among others. Furthermore, the first aspect we focused upon is to assess the importance of enablers of metaverse adoption in healthcare sector. The results of Grey-OPA analysis indicated that the “Telepresence (E2)” is the most important enabler for metaverse adoption. Telepresence enables users to stay connected, making physical distance irrelevant. Thus, it would be relevant in contagious diseases or pandemic situations like COVID-19 outbreak[66]. However, it has been argued that telepresence could also possess socio-ethical issues due to lack of physical presence. “Anonymization (E13)” is identified as second most important enabler for metaverse adoption. Anonymization enables patients to receive medical services without disclosing their real identity. In the offline space, ensuring patients' anonymity is extremely difficult and still not considered a priority. It is one of the primary reasons many patients suffering from different life-threatening diseases, avoid consulting doctors, especially in rural areas [105]. Adopting metaverse can support the anonymity of the patients, enabling socially conscious patients to consider virtual consultation and result in building trust among patients and healthcare providers thus promotes the responsible use of data in the metaverse. Technology adoption, in general, people with sufficient knowledge about innovations are interested in experiencing them and thus seek to use such systems, leading to increased trust in the technologies. Likewise, the successful adoption of any new technology requires education, training, and awareness. By conducting training programs, workshops, and demonstrations, healthcare organizations can familiarize their staff with the metaverse, its benefits, and potential use cases. Such efforts can help overcome scepticism, reduce resistance to change, and promote the adoption of metaverse solutions in healthcare sector.

TABLE VI: INTERPRETIVE MATRIX FOR THE ENABLERS

	E1	E2	E3	E4	E5	E6	E7	E8	E9	E10	E11	E12	E13
E1	-	It enhances telepresence through expanded interaction	Seamless connections simplify user navigation	-	It offers personalized experiences through user profiles	-	It increases the risk of unauthorized access	It may necessitate extra infrastructure investment	Interlinked data enables powerful analytics	-	Seamless interaction across linked platforms enhances gamification	-	-
E2	-	-	-	-	-	-	-	-	-	-	Enhances the likelihood of telepresence and vice-versa	-	-
E3	-	Simpler systems reduce cognitive load, boosting user focus and enhancing telepresence	-	Familiar people would find the system easy and vice-versa	-	-	Ease of use fosters user familiarity, reinforcing data privacy awareness.	It drives data confidentiality awareness, demanding stronger security measures and higher costs	It raises security concerns, potentially limiting investment in high-powered analytics	-	It requires higher investment, potentially impacting effective gamification	-	-
E4	-	Reduces cognitive load, boosting telepresence by focusing users on the virtual environment	People would find the system easy and vice-versa	-	-	-	Digital civilized people are likely to be aware of data confidentiality	It with data privacy practices would impact cost considerations.	User familiarity streamlines data collection and cleaning, improving analytics quality	-	Familiar users confidently embrace gamification, fostering deeper engagement.	-	It enables awareness to anonymization and increase its likelihood
E5	-	It boosts telepresence through user interaction, deepening immersion in the VE.	It simplifies platform usage by tailoring services to user preferences	-	-	-	-	Improved experience leads to long-term cost-effectiveness	It enhances user experience but could raise costs	-	Customized rewards and challenges amplify user engagement based on preferences	-	-
E6	-	It can enhance the feeling of telepresence	It ensures virtual platform familiarity, improving ease of use.	It raises tech awareness, fostering familiarity	-	-	Conscious society would enforce data confidentiality	Privacy-conscious society demands stricter data confidentiality, affecting cost	It impacts high-powered analytics by restricting data access	It shapes societal norms	It indirectly impacts gamification design	Influences government policies and regulations	It encourages users to willingly engage
E7	-	Data confidentiality in telepresence builds trust, enhancing virtual security	-	-	-	-	-	It requires robust security measures, which leads to cost-effectiveness.	It demands strong security, raising costs for high-powered analytics	-	It limits analytics, impacting gamification	-	-
E8	-	Cost-effective solutions may compromise data confidentiality.	-	-	Cost-cutting may limit system's personalization features	-	Cost-effectiveness can weaken security, risking data confidentiality	-	It requires costly computational resources	-	Cost focus may limit high-powered analytics, hindering gamification	-	-
E9	-	It enhances telepresence with personalized experiences	-	-	It drives personalized user experiences	-	Trading insights for cost cuts can compromise data confidentiality.	It requires costly computational resources	-	-	High-powered analytics enable personalized interactions.	-	-
E10	It impacts platform linkage, affecting connectivity	It enhances telepresence by fostering user trust	It promotes user-centric design for user-friendly technology	It shapes tech norms, influencing public platform familiarity	It impacts personalization by setting boundaries for data	It shapes societal norms, influenced by public pressure	It mandates data security, enhancing user data confidentiality	Regulated data analytics may require specialized tools	It would drive the type of analytics allowed on users' data	-	Regulated gamification builds user confidence, attracting users	It establishes infrastructure standards	Policies on anonymization demand suitable infrastructure
E11	-	It increases telepresence by increasing user engagement	-	-	-	-	-	-	-	-	-	-	-
E12	It ensures seamless connections	It underpins engaging gamification	It facilitates seamless user interaction towards easy use	-	It enables user data analysis, facilitating personalized experiences	-	It ensures confidentiality	It impacts high-powered analytics	Technological support would be decisive for type of analytics offered	-	It is required to develop gamification process	-	Enabling anonymization feature in the system
E13	It restricts the system to link with other platforms	It enhances user engagement and telepresence satisfaction	It requires additional steps, impacting ease of use	-	It hinders personalization by obscuring user data	-	Ensuring data confidentiality becomes easier	It reduces the value gained from high-powered analytics,	Limited user details, could hinder in deriving analytics	-	Lack of personalized rewards limit the yield of gamification.	-	-

Among others, another significant advantage of metaverse is its ability to link with other emerging technologies such as IoT, AR/VR, Blockchain, to name a few. This ability is termed as "Linkability (E1)". It reduces the friction in the system for both healthcare providers and patients. In the healthcare sector, linkability can facilitate seamless integration of patient records, medical devices, and other data sources, enabling comprehensive and holistic care. Linkability, from the perspective of patients, provides a means for sharing data between platforms and institutions without any additional effort and aids in the accumulation and diffusion of knowledge, therefore contributing to the convenience of the healthcare system. As a result, it can further enhance care coordination, improve efficiency, and enable better clinical decision-making. Since metaverse leads to the convergence of virtual and physical worlds, which presents both opportunities as well as challenges that must be addressed properly. It has been argued that the metaverse adoption would be slower due to clinical trials before using it as a realistic component [99]. Among others, the major challenge highlighted by the literature is "Data Confidentiality (E7)". As metaverse relies on digital interactions and the exchange of personal health information. In such a case, it makes patients worrisome regarding confidentiality of their data thus, ensuring robust data privacy and security measures is essential[14], [101] . Implementing strong encryption, authentication protocols, and secure data

storage systems can be helpful in building trust and confidence among healthcare providers and patients. Another way to address such issues is to clearly communicate with the patients regarding the control of sharing the data to third parties. Additionally, the "Government Regulations and Policies (E10)" should also address such issues including patient privacy, data protection, ethical considerations, and professional guidelines. Establishing clear regulations and policies will provide a solid foundation for the responsible and ethical use of the metaverse in healthcare. Moreover, government-approved and endorsed platforms enhance the credibility and legitimacy of the overall healthcare system. The influence of "Government Regulations and Policies (E10)" can be seen from the Fig. 3. where it acts as a foundational enabler directly impacting other significant enablers and this result is also in accordance with the study by Petrigna & Musumeci [51].

Healthcare professionals and patients need intuitive and user-friendly interfaces that make it easy to navigate and interact within the metaverse. Complex or cumbersome user experiences can create barriers to adoption, as users may feel overwhelmed or discouraged. The Ease of Use (E3) can drive the likelihood of individuals to embrace it and integrate it into their daily workflows or health management routines. At the same time, its negative experience may discourage people from using metaverse for HS. Therefore, metaverse solutions should prioritize simplicity, accessibility, and seamless user experiences. Providing comprehensive tutorials, clear instructions, and responsive technical support can help users overcome initial challenges and feel confident in utilizing metaverse technologies for healthcare purposes. Implementing a reward strategy is another aspect of the adoption that is not directly linked to the metaverse technology but is related to the adoption policy followed. The ability to reward users upon using a system is termed as "Gamification (E11)" and could be instrumental in adopting the system, especially at the initial stages, wherein fewer people are aware of the platform or are reluctant to try the new system. It can make the metaverse more engaging, interactive, and enjoyable for both healthcare professionals and patients [101]. Along with the gamification, Social Influence (E6) i.e., the impact of society on users' attitudes and beliefs toward using metaverse-based healthcare could also drive the adoption. This result is in accordance with the study by Arpaci et al. [98]. Tech-friendly community reflects a higher trust level in the system, which has a ripple effect on others who are natives. People often get motivated by their local natives more as compared to others, where the trust level is not that strong. The model shown in Fig. 3. also demonstrated the influencing power of social influence. Peer testimonials, success stories, and recommendations from trusted sources can create a sense of social proof and credibility, reducing uncertainties and increasing the willingness to try metaverse solutions. Healthcare organizations can leverage social influence through targeted marketing campaigns, user testimonials, and community-building efforts to accelerate metaverse adoption in the healthcare sector.

The metaverse generates vast amounts of data, ranging from patient interactions and virtual simulations to real-time monitoring and diagnostics. High-powered analytics (E9) can process and analyse this data to extract valuable insights. Analytics-driven metaverse applications can assist healthcare professionals in making data-informed decisions, optimizing treatment plans, and improving patient outcomes [109]. This further enhance the effectiveness and impact of the metaverse in healthcare. However, high-powered analytics, such as AI and machine learning, heavily rely on advanced technological infrastructure. Technological infrastructure (E8), core for working metaverse-based healthcare systems, amalgamates state-of-the-art hardware and software components. Analysing vast amounts of data, running complex algorithms, and generating real-time insights require High-speed internet connectivity, continuous supply of electricity, substantial computing power and storage capabilities. It would be expensive to have required technological infrastructure for healthcare organizations. These enablers are interrelated and assuring such technological infrastructure could be expensive for short-term but provides greater return [14]. For instance, through data-driven insights, healthcare organizations can make informed decisions that improve operational efficiency, reduce costs, and enhance patient care. Thus, Cost-Effective (E8) solutions enable healthcare organizations to acquire the required infrastructure at affordable prices, making metaverse adoption financially viable and accessible. Moreover, the government policies should also incorporate subsidies or tax-rebates for setting up technological infrastructure resulting in faster adoption rate of metaverse.

Summarily, the enablers discussed above drive the adoption of the metaverse in the healthcare sector by leveraging technological infrastructure, enhancing collaboration and communication. As a result, it would potentially empower telemedicine and remote care, medical training and education, patients' experience, accelerating research and development, ensuring data privacy and security. No matter how novel an innovation is, it will ultimately fail if it is not easy for people to use. It is also worth noting that, like any other technology, the metaverse can lead to addiction. This may result in one of the most well-known psychological and behavioural maladaptation, Fear of Missing Out (FOMO). Alternatively, a lack of physical presence may contribute to socio-ethical difficulties. Providing HS via metaverse must be easy and safe for both healthcare providers and consumers for its successful adoption. At the end, we observed that adoption of metaverse in the healthcare sector is dependent on the intertwining of tech and non-tech factors. The enablers collectively contribute to improved healthcare delivery, research, and patient outcomes through the transformative potential of the metaverse.

V. Implications of the Study

This section emphasizes on the explanation of the value delivered from this study from theoretical and managerial perspective.

A. Theoretical implications

The healthcare industry is anticipating a similar paradigm shift from metaverse as ICT did. Therefore, the implementation of the metaverse requires scientists and researchers in the healthcare sector to find relevant research issues from various perspective, prioritizing the specific needs and neglected populations within emerging economies. This includes infrastructure limitations, access to quality HS, and lack of trained practitioners.

The healthcare industry has access to numerous interesting new opportunities because of the metaverse. The impact of the metaverse on the healthcare sector is still a subject of many interesting research issues. Prior studies have looked at the technological aspects of metaverse adoption in the healthcare sector [97], [110]. In comparison with the prior studies, this study provides the viewpoint on the adoption of metaverse in the healthcare sector, particularly for neglected populations in emerging economies from the management perspective. As a result, the current study emerges promising in bridging important research gaps in the context of technology adoption in emerging economies. The study used CSF theory to extract the enablers and mixed-method approach to analyse those enablers that drive metaverse adoption in the healthcare industry in emerging economies. These enablers contribute to the existing knowledge of the factors for IT-enabled healthcare delivery, primarily emphasising virtual healthcare. The application of CSF theory not only aids in understanding the factors contributing to the adoption of metaverse technologies but also offers practical implications for organizational success. By identifying and addressing these key enablers, healthcare organizations can streamline their adoption processes, optimize resource allocation, and ultimately enhance their operational efficiency and effectiveness. The hierarchical model developed for the study seems affirm in terms of providing a foundation for future studies to comprehend the connections between various enablers. The outcomes of this study further highlight the dynamic nature of enablers of technology adoption in healthcare and why these enablers need to evolve for continued success in embracing innovations like metaverse. Additionally, the enablers investigated in this study can serve as the foundational variables to develop research hypotheses or develop questionnaire to further explore the domain.

B. Managerial Implications

Businesses have several hurdles to satisfy their customers in the current economic environment. The healthcare sector is no exception. The adoption of innovative technology like metaverse may catalyse improved customer experience. Our research reveals several critical enablers, such as telepresence, personalization, anonymization, government regulations and linkability, among others, that could impact the use of metaverse in healthcare and aid healthcare providers and policymakers to leverage metaverse to address rural healthcare challenges especially of emerging economies, ultimately leading towards healthy societies. One of the main takeaways for managers is to recognize the significance of telepresence in addressing healthcare challenges faced in rural communities. It has emerged as the most significant enabler in adopting metaverse in providing HS to rural communities of emerging economies. Telepresence facilitates the core HS through remote monitoring, virtual consultation, education, medical training and virtual environments for medical research. Managers must prioritize anonymization in the adoption of metaverse. As it enables patients to receive medical services without disclosing their real identity. In the offline space, ensuring patients' anonymity is extremely difficult and still not considered a priority. It is one of the primary reasons many patients suffering from different life-threatening diseases, avoid consulting doctors, especially in rural areas. Anonymization is important, especially in cases where patients suffer from health issues considered undesirable in society, like HIV, abortion, Psychiatric consultation etc. From a managerial perspective, Technology adoption, in general, is high among tech-savvy people who make themselves familiar with innovations and are often among early adopters. Although familiarization is not something metaverse as technology provides, it has emerged as the third most important enabler in adopting metaverse in healthcare.

Another key implication of this study is the need to recognize the importance of linkability. It reduces the friction in the system for both healthcare providers and consumers through effective use of knowledge management. Manual record-keeping of consultations and prescriptions from different healthcare departments poses a substantial challenge in rural healthcare settings, where the literacy rate is usually low, and people have limited resources at their disposal to live a healthy life. Seamless integration of the metaverse system with existing systems enables healthcare institutions to adopt the metaverse with minimal changes in the existing working system, removing the burden of manual record-keeping from the patients. Additionally, the government should promote the seamless integration and encourage best practices throughout the healthcare sector. Managers should focus on technological infrastructure, as it is the core for working metaverse-based healthcare systems. High-speed internet connectivity, continuous supply of electricity, immersive technologies like AR/VR, interoperability and data security and privacy play an important role in building a robust technological infrastructure for a metaverse-based healthcare system that could solve many problems in rural areas of emerging economies and safeguard them from any potential exploitations. Moreover, a collaborative regulation system comprising healthcare organizations and governments should be in place to increase customer trustworthiness. Further, decision-makers should set up an effective strategy, which is essential if you want to use the metaverse to revolutionize the entire healthcare sector. Overall, the proposed model would help practitioners and policymakers in better metaverse adoption decision making.

VI. Conclusion

Metaverse has potential to transform the existing healthcare practices through its variety of affordances. However, its adoption in healthcare sector is still in its initial stage and thus requires thorough examination of its potential challenges and opportunities. In line with this, the present study examined enablers of metaverse adoption in healthcare sector. The study adopted integrated theories and methodologies combining critical success factor theory, grey-OPA and modified TISM to meet the research objectives. The integrated methodology aided in investigating the significance and important relationships of the enablers. Chosen enablers from the literature review, based on CSF theory, were presented to experts for feedback and finalization. Grey-OPA was employed to determine priority weights, and the enablers were subsequently ranked accordingly. The mTISM was utilized to examine interconnections between the finalized enablers. This resulted in a hierarchical model that represented the connections between the enablers. In terms of importance from the practitioners' perspective, the study identified thirteen significant enablers with Telepresence (E2), Anonymization (E13) and Familiarization (E3) as the topmost important enablers for successful adoption of metaverse while High Powered Analytics (E9), Data Confidentiality (E7) and Cost (E8) are perceived to have comparatively lower impact on the adoption. Based on the TSIM analysis, Government Regulations and Policies (E10) and Social Influence (E6) are identified as leading drivers and play a crucial role in the adoption as depicted in the m-TISM model which highlighted that these two enablers are building blocks of the hierarchical model. As a result, healthcare organizations should focus on social influence to accelerate metaverse adoption in the healthcare sector through focused marketing campaigns, user testimonials, and community-building efforts. The research contributes significantly to the literature by presenting a hierarchical model for metaverse adoption in the healthcare sector.

The present study has few limitations too. To begin with, the present study involved seven experts in total from an Indian healthcare and technology innovation set up. Although, the experts were carefully chosen but the lack of first-hand experience and the limited understanding about the metaverse technology could not be ruled out and thus could limit the generalizability of the findings. Additionally, the scope of the current study is limited to the adoption of metaverse in healthcare sector, primarily focusing on the doctor-patient relationship. Second, the study did not cover the ethical issues, or the challenges involved with the metaverse which could have significant impact on adoption of metaverse. Lastly, the inputs from the potential consumers of the healthcare sector i.e., patients have not been covered in this study. These limitations could be addressed by the researchers building on the findings of this study. Precisely, future research is needed to understand the metaverse adoption exclusively from the patient's perspective by keeping ethical practices at the centre. Additionally, the stakeholders' rights, and legal concerns regarding metaverse adoption in the healthcare sector should also be investigated.

Appendix

Appendix I: Reachability Matrix with Transitive Links

	E1	E2	E3	E4	E5	E6	E7	E8	E9	E10	E11	E12	E13
E1	1	1	1	0	1	0	1*	1*	1*	0	1*	0	0
E2	0	1	0	0	0	0	0	0	0	0	1	0	0

***Abstract*— The comprehensive practice of yoga seeks to improve one's mental, bodily, and spiritual well-being. Among the many forms of yoga, hatha yoga is a conventional style that uses physical postures and breath exercises to balance the body and mind. We can reap its greatest health benefits by adopting the ideal postures and adhering to the recommended techniques and sequencing. However, adopting improper postures while practising yoga can result in a number of health issues such as short-term chronic issues or acute muscle discomfort. Therefore, there is a need for scientific evaluation of yoga posture recognition in order to help people practise yoga effectively. To support self-learning, we'll provide a model for classifying poses using posture detection in this paper. Here we have taken a 2D image dataset of 20 famous hathayoga poses and we comparatively evaluated the performance of several cutting-edge deep learning architectures and DenseNet201 yields the highest accuracy of 90.4%.**

Keywords*— Pose recognition, yoga, deep learning, computer vision.

I. INTRODUCTION

With yoga's worldwide popularity growing at an exponential rate, an auto-assisted model that can support and promote properly taught and self-guided yoga practises is urgently needed. The identification of the individual body parts moving in a certain direction to create the desired position is the focus of this issue statement. Yoga positions that are incorrect or incorrect can cause more harm than good because they can result in injuries like muscle pulls, stiff necks, ankle sprains, etc.

Numerous attempts have been made to circumvent these limitations. Software that acts as an AI system trainer has been created using computer vision and data science methods. The benefits of the stance are explained by this model. It also conveys information regarding the performance's correctness. With the aid of this programme, one can practise yoga independently of a trainer. A large number of image datasets including 20 hatha yoga pose features ('Trikonasana', 'ardha matsyendrasana', 'adho mukha svanasana', 'bakasana', 'dhanurasana', 'bhujangasana', 'kapotasana', 'matsyasana', 'paschimottanasana', 'salabhasana', 'savasana', 'setu bandha sarvangasana', 'tadasana', 'uttanasana', 'balasana', 'vajrasana', 'virabhadrasana i', 'virabhadrasana ii', 'virasana', 'vriksasana') have been developed. With the use of computer vision techniques and the tf-position algorithm, these datasets have made it possible to extract important posture information. The precision and effectiveness of the system are increased by harvesting data points, such as coordinates and joint angles, and using them as features for deep learning models. Several deep learning models have been rigorously tested in order to validate the correctness of the model. Through this iterative process, the system's performance and dependability are improved, guaranteeing that practitioners may rely on its direction for the best possible and secure yoga experience.

II. RELATED WORK

The literature contains a large number of papers pertaining to the yoga expert system and posture classification. Of these, Microsoft Kinect is used for pose detection in the majority of the work, and other data mining techniques including SVM, Random Forest, Decision Trees and other Deep Learning frameworks based on CNN. Using a Kinect camera in [1], a self-training technique was created for yoga posture identification. A total of 300 films with five yoga practitioners executing 12 different positions five times each were gathered. Initially, the body map was taken from the movies and the body contour was retrieved. Next, a fast skeletonization method using a star skeleton was employed to derive a human stance descriptor. There was a 99.33% accuracy rate in the system. Edwin et al. [2] have suggested a yoga recognition system that uses Kinect v2 and Ada-boost classification to recognize six asanas with an accuracy score of 94.78%. However, the method takes more processing time for more complicated models. They used a camera that is based on a depth sensor, which is frequently out of reach for customers. A system that could recognize and adjust yoga positions by comparing the practitioner video with the reference video using the SURF algorithm was presented by Fazil et al. [3].

Using Mask RCNN, the researchers turned the dataset into keypoints. A CNN & LSTM model produced the best accuracy of 0.9996. The Yoga-82 dataset was used by Verma et al. [4] to perform keypoint recognition. The dataset originally included a variety of yoga forms that were gathered from the internet. The postures were manually cleaned and grouped into a superclass hierarchy. For

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 09,2024 at 06:51:33 UTC from IEEE Xplore. Restrictions apply.

network learning, this hierarchical annotation offered rich data that included pose details, spine effects, and body positions. Three hierarchical layers, containing 6, 20, and 82 classes at each level, were used to structure their dataset. DenseNet-201 performed remarkably well, attaining 74.91% top-1 classification accuracy. Kothari [5] conducted a thorough investigation on the classification of yoga postures using deep learning algorithms and human pose estimate. They used OpenPose to pre-process the "Yoga Vid Collected" dataset in order to extract posture keypoints. A comparison of deep learning and machine learning techniques for estimating yoga poses was carried out as part of the study. In terms of misclassifications, the hybrid CNN-LSTM model outperformed the SVM and standalone CNN models, showing the fewest errors with validation accuracy of 0.9987.

In [6], the researchers developed a computer-aided system that recognizes yoga poses and offers feedback for correction. They used the hybrid model using the same video dataset, which consisted of six yoga positions performed by fifteen people divided as 60% for training set, 20% for testing set, and last 20% for validation sets. Their approach obtained an exceptional 0.9941 frame-by-frame validation accuracy. Agrawal et al. [7] present a YOGI dataset of around 5500 pictures. Using the "tf-posture," the angles and joints from these image frames were extracted. These characteristics were then input into a number of machine learning models. At 99.04%, the random-forest classifier had the best accuracy. Long et. al. [8] used a dataset gathered from eight volunteers to develop a yoga coaching system that made use of 6 transfer learning models. They divided the dataset into train, validation, and test sets at a ratio of 3:1:1 in order to train their model. They also used strategies for data augmentation on the dataset. The best model was determined to be the TL-MobileNet-DA model as evidenced by its 98.43% total accuracy

Shubham et al. (2022) [9] suggested a CNN-based approach for classifying yoga poses in a different research. They used the MediaPipe library in their study to pinpoint important spots and make a skeletal diagram. The researchers downloaded a dataset from Kaggle that was made accessible to the public, and they obtained the greatest accuracy of 97.09%. A deep learning-based yoga pose estimation method was presented in[10] . It uses 12 identified joints compressed into 13 vectors to evaluate posture accuracy and extracts 18 keypoints. According to their analysis, the MLP classifier had an impressive testing accuracy of 0.9958. Aman et al. [11] presented the three-stage Y-PN-MSSD paradigm for yoga posture recognition. First, it uses an open-source dataset with seven postures and records the poses of four users to collect data. During training, it then connects key body components to extract characteristics. This model allows for 99.88% accuracy in real-time monitoring of users in yoga poses. However, implementation still faces difficulties because of problems like occlusion and uneven illumination.

Using a variety of datasets, these studies illustrate the several methods and strategies used in the categorization of yoga poses. Out of a wide range of categories, the majority of study has been conducted on the five most popular hatha yoga postures (‘Tree’,’Warrior-2’,’Plank’,’Goddess’ and ’Downdog’), which are relatively limited in number. It is necessary to expand the number of categories while retaining high precision and accuracy.

III. Proposed Approach

The process of creating a yoga posture identification system includes gathering a variety of picture datasets, preprocessing information, choosing models that have already been trained, fine-tuning, assessing performance, optimizing hyperparameters, deploying the best model as shown in fig 1.

A. Dataset Collection

There is a publicly accessible dataset for 107 yoga poses in Kaggle [12] from which we have taken 20 different hatha yoga poses each containing 50 to 90 images. There are 1248 photos in our compiling color image dataset. The dataset includes images of several people executing different yoga positions from various perspectives. Path, pixel values, and the associated label (asana index) are kept for every picture.

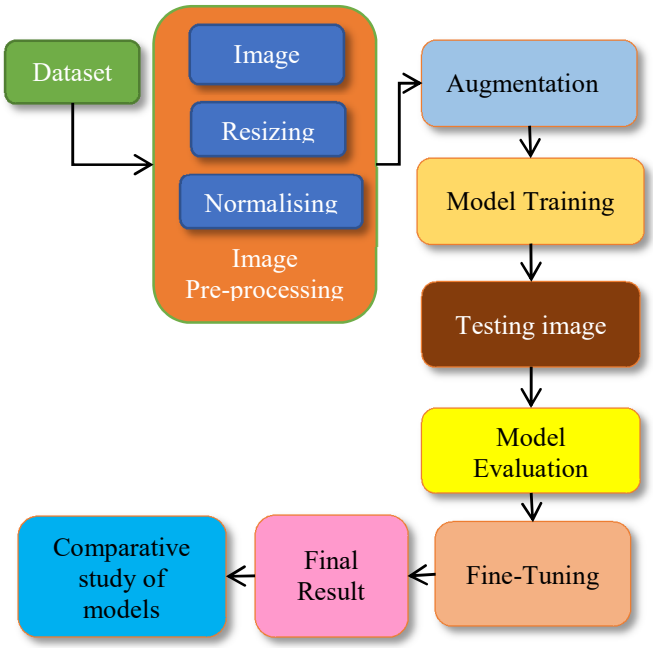

Fig. 1 Workflow

B. Data Processing and Augmentation

To guarantee consistency, images are loaded using OpenCV (cv2) and scaled to a standard size of 224x224 pixels. Each picture is given a label according to the asana to which it belongs, and the target variable is created by one-hot encoding these labels. To create a random sequence for the photos and labels, the dataset is shuffled. Then input data is normalized using the standard normalization values [-1, 1]. Then we created training and testing sets from the dataset. Around 80% of the time is usually spent on training and 20% on testing. Data augmentation is carried out using Keras' ImageDataGenerator. Techniques for augmentation include rotating, moving, zooming, and flipping both horizontally and vertically. Data augmentation exposes the model to different picture modifications, which improves its ability to generalize.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 09,2024 at 06:51:33 UTC from IEEE Xplore. Restrictions apply.

C. Model Architecture and Training

Pre-learned weights from models trained on massive datasets such as ImageNet were used in transfer learning. As a result, the models were able to use information gleaned from generic picture attributes. Feature extraction is the process of extracting hierarchical features from input photos by means of the convolutional layers of pre-trained models. In order to decrease spatial dimensions and concentrate on important features, Global Average Pooling (GAP) layers were added. To build a custom classifier for yoga pose classification, dense layers with suitable activation functions, dropout, and batch normalization were included. Models were assembled using appropriate evaluation metrics (accuracy), loss functions (categorical crossentropy), and optimizers (e.g., Adam). Models were first trained using the yoga pose dataset for a predetermined number of epochs, early stopping to avoid overfitting. The best performing model was captured.

D. Model Evaluation and Fine-Tuning

We assessed the performance of every model on a different test set. For quantitative analysis, we created accuracy, confusion matrices, and classification reports. We also found out which pose is the most accurately detected for each model. To determine convergence, overfitting, and generalization abilities, we compared metrics from training and testing. Next, in order to improve alignment with the dataset, we unfroze and fine-tuned certain layers. Model architecture and performance play a role in the selection of the layers. After making adjustments, we recompile the models and keep practicing for more epochs.

E. Comparative Study

Taking into account training speeds, convergence patterns, and final metrics, a comparative analysis allowed for a more nuanced understanding of each model's performance. This rigorous process resulted in the selection of the best-performing model, whose weights were saved for later deployment and which had the highest testing accuracy.

IV. Experimental Analysis

A. Model Architecture

Residual learning was first shown by ResNet50, a 50-layer deep convolutional neural network. Deep networks may be trained by using shortcut connections to overcome the vanishing gradient problem. The skip connections, or shortcuts, in ResNet50 allow the model to learn identity mappings, improving the training and optimization of deeper networks. The model has 48 convolutional layers, completely connected layers, and global average pooling.

VGG16 and VGG19's combined architecture, which has max-pooling and 13 convolutional layers, has a similar topology. For classification, both models employ 3x3 filters and stack fully linked layers at the end. VGG19 is marginally more difficult than VGG16 because it features an additional completely linked layer. VGG16 has three fully connected layers, each with 4096 units. For efficient feature learning, the design places a strong emphasis on max-pooling and tiny filters.

EfficientNetB0 makes use of squeeze-and-excitation modules, depthwise separable convolutions, EfficientNet blocks with inverted residuals, and stem convolutions. For the representation of global features, global average pooling is employed first, and then a dense layer is utilized for classification logits. This architecture is adaptable for computer vision jobs because it strikes a compromise between performance and efficiency.

Depth-wise separable convolution layers are present in MobileNet. A pointwise convolution comes after a depthwise convolution, offering an effective substitute for conventional convolutions. In order to reduce computational complexity, depthwise separable convolutions seek to record spatial and channel-wise dependence independently.

The Inception module, which combines convolutions of various kernel sizes, is used by InceptionV3. The 1x1, 3x3, and 5x5 convolutions included in each module allow the model to collect information at different sizes. The training gradient flow is improved with auxiliary classifiers, and factorized convolutions lower computing costs.

The convolutional blocks in Xception's architecture are detachable according to depth. These blocks enable the model to capture spatial relationships more effectively by substituting depthwise separable convolutions for ordinary convolutions. The hierarchical application of the depthwise separable convolutions highlights the need of precise spatial information.

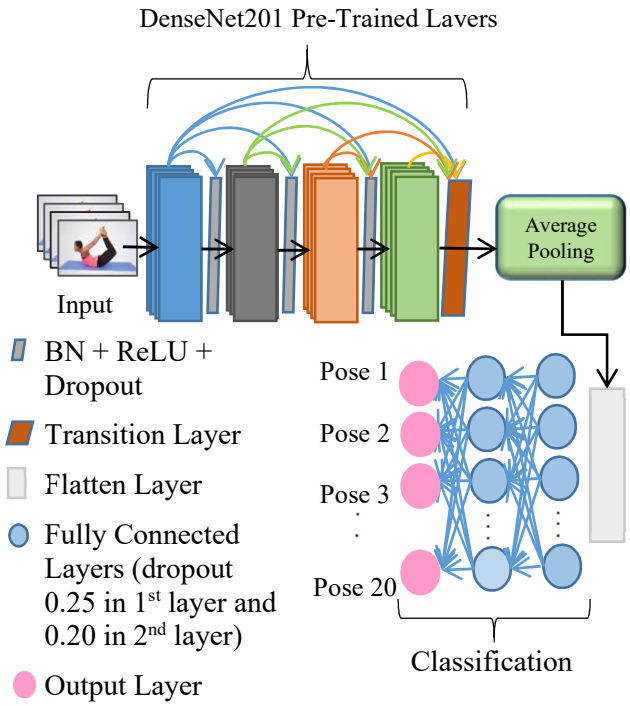

Fig. 2 Densenet201 Customized Model

DenseNet121 uses four dense blocks with skip connections that are densely linked convolutional blocks. By tweaking the DenseNet201 (fig 2) architecture, adding more layers for fine-tuning, and freezing the top layers, the model is modified for yoga posture categorization. These extra layers consist of batch normalization, dropout layers (at 25% and 20% rates), dense layers with ReLU activation (1024 and 512 units), and so on. The twenty yoga positions

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 09,2024 at 06:51:33 UTC from IEEE Xplore. Restrictions apply.

are represented by the output layer with softmax activation. During fine-tuning, certain layers are unfrozen in order to capture pose-specific characteristics. The loss function used in the model's compilation is categorical cross-entropy, and the Adam optimizer (lr: 0.001).

B. Requirements and Specification

Python version 3.7 was used throughout the careful execution of each experiment. Nine different deep learning models were trained on the HATHAYOGA dataset, which consists of 20 different classes that correspond to different yoga positions. These models require the following hardware specifications: Tesla T4, 2 x vCPU, 32GB RAM, and a K80 GPU from Google Colab Pro.

C. Result

Table 1 Benchmark accuracies of the models

Model Name	Testing Accuracy		
	Before fine-tuning	After fine-tuning	
		Top-1	Top-5
ResNet50	72.0%	84.4%	96.8%
VGG16	62.4%	80.0%	96.2%
VGG19	57.6%	82.4%	97.6%
EfficientNetB0	74.4%	86.8%	**98.4%**
MobileNetV2	66.4%	80.0%	95.6%
InceptionV3	54.4%	80.8%	96.0%
Xception	60.4%	81.2%	94.8%
DenseNet121	74.0%	85.2%	97.6%
DenseNet201	79.2%	**90.4%**	97.2%

Table 2 Precision, Recall, F1-Score of the models

DL Model	Precision	Recall	F1-Score
ResNet50	0.86	0.84	0.84
VGG16	0.82	0.80	0.80
VGG19	0.84	0.83	0.82
EfficientNetB0	0.88	0.87	0.87
MobileNetV2	0.82	0.80	0.79
InceptionV3	0.82	0.82	0.80
Xception	0.82	0.81	0.81
DenseNet121	0.86	0.85	0.85
DenseNet201	0.92	0.90	0.90

We carried out a thorough analysis of many deep learning models for yoga position identification in our study. Table 1's accuracy results demonstrated DenseNet201's better performance, with the model attaining the maximum accuracy of 90.4% for top-1 classification out of all the models. Among the best performers, EfficientNetB0 stood out with a 98.4% accuracy rate for top-5 categorization. Table 2 presents information on each model's F1 score, precision, and recall.

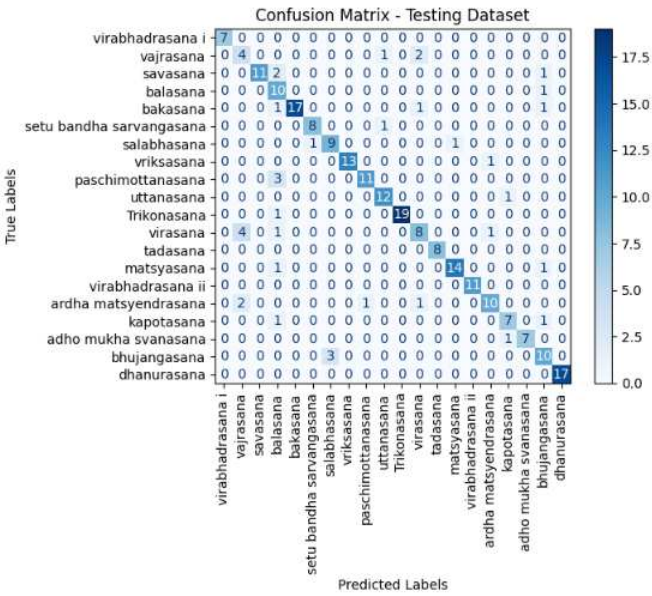

Figure 3 Confusion Matrix of DenseNet201 model

Subsequent investigation concentrated on DenseNet201, our selected model, for which we provided a thorough confusion matrix in Figure 3 and AUC-ROC curve in Figure 4. We have added Table 3 to give a more detailed picture of posture-specific accuracy using DenseNet201 architecture. The poses known as 'Virabhadrasana i', 'Salabhasana', 'Vriksasana', 'Uttanasana', 'Trikonasana', 'Matsyasana', 'Virabhadrasana ii' and 'Adho mukha svanasana' have been discovered most accurately detected with accuracy measuring 100%.

Table 3 Pose-wise accuracy of DenseNet201 Model

Pose	Accuracy
Virabhadrasana i	100.0%
Vajrasana	81.82%
Savasana	50.0%
Balasana	91.66%
Bakasana	88.88%
Setu bandha sarvangasana	76.47%
Salabhasana	100.0%
Vriksasana	100.00%
Paschimottanasana	77.77%
Uttanasana	100.00%
Trikonasana	100.0%
Virasana	88.88%
Tadasana	91.66%
Matsyasana	100.00%
Virabhadrasana ii	100.0%
Ardha matsyendrasana	88.88%
Kapotasana	86.67%
Adho mukha svanasana	100.00%
Bhujangasana	88.23%
Dhanurasana	80.00%

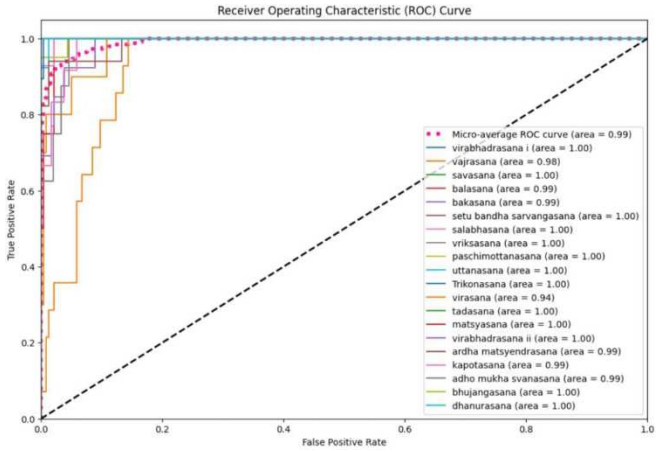

Fig. 4 AUC-ROC Curve for DenseNet201 Model

Fig. 5 Actual vs Predicted pose of some test images

In figure 5, some test images of different yoga poses are taken and their true vs predicted labels are shown.

V. Conclusion

In summary, for the purpose of classifying yoga postures, we exhaustively investigated many cutting edge deep learning architectures. The models' strengths varied according to the findings; DenseNet201 and DenseNet121 performed better than the others, while EfficientNet and MobileNet showed efficiency in terms of processing resources. These findings emphasize the trade-offs between accuracy and computing economy and offer vital insights for choosing suitable models in practical circumstances. Our work provides a baseline and important direction for further research in the area of yoga position categorization.

A. Future work

Future study should prioritize the investigation of real-time applications and deployment of the established yoga posture identification algorithm. This will enable its incorporation into user-friendly platforms or mobile applications that may offer immediate feedback during yoga practice. Furthermore, conducting an examination of the model's efficacy on a wide range of datasets, which include a more extensive array of yoga postures and practitioners with different degrees of expertise, would improve its capacity to apply to different situations and its overall strength.To enhance the model, it is necessary to tackle obstacles such occlusion and fluctuations in lighting conditions, in order to enhance its capacity to adapt to real-world situations. Incorporating user input and preferences may enhance the yoga training experience by making it more customized and effective. Finally, by examining the possible combination of biomechanical knowledge and health measurements[13], [14], the model's usefulness may be enhanced as it would be able to offer personalized suggestions to individuals according to their physical ability and wellness objectives.

ORIGINAL PAPER

An empirical examination of the effect of domestic monetary policy on external commercial borrowings to India

Virender Kumar[1] · **Poonam**[2]

Received: 13 October 2023 / Accepted: 20 March 2024

Abstract
This paper empirically examines the effect of domestic monetary policy shock on external commercial borrowings (ECBs) to India for the period 2000:Q2 to 2019:Q4. The impact of domestic monetary policy shock on ECBs is assessed using two variables: interest rate differential and domestic money supply growth. The paper employs a structural VAR model and utilizes impulse response functions and forecast error variance decomposition analysis to derive empirical results. The empirical results based on impulse response functions indicate that the interest rate differential has a positively significant effect on external commercial borrowings to India, while the effect of domestic money supply growth is found to be negative. The forecast error variance decomposition analysis indicates that the interest rate differential explains about 14.6% and domestic money supply growth explains about 2% of the total variation in external commercial borrowings, implying that domestic monetary policy variables together explain about 16.6% of the total variation in ECBs to India. The results suggest that the central bank, through monetary policy interventions, can influence and manage the flow of external commercial borrowings to India. Furthermore, the study finds that the exchange rate, domestic industrial activity, domestic output growth, domestic country's creditworthiness, and domestic macroeconomic instability are other significant determinants of external commercial borrowings.

1 Introduction

India is a major emerging economy that needs a constant flow of external funds to support its investment requirements. External commercial borrowings (ECBs) by domestic corporates are an important source of external funds to India. ECBs comprise commercial loans in the form of bank loans, suppliers' credit, buyers' credit, securitized instruments such as floating rate notes, securitized commercial borrowings, and fixed rate bonds from non-resident lenders. One of the major advantages of ECBs is that they provide an additional source of funds for Indian corporates to expand their existing capacity and finance new investment ventures, thereby contributing to the country's economic growth (Sur et al., 2019; Verma & Prakash, 2011). However, due to their significant share in India's total external debt,[1] ECBs have sparked concerns about debt repayments, raising fears of widespread crisis and threatening financial stability, particularly in the event of external shocks (Pradhan & Hiremath, 2019). Moreover, volatility in ECB flows, as observed in Fig. 1, has the potential to disrupt India's balance of payments position and create significant fluctuations in the foreign exchange market. Maran (2023) discusses the need for macroprudential policies to address such financial risks.

Figure 1 illustrates the considerable volatility in net ECB flows to India over the years. Despite the volatility, the total outstanding stock of ECBs in India has consistently grown. ECBs constitute a substantial proportion of India's total external debt and this proportion has been continuously increasing over the years, increasing from 13.7% in 1991–92 to 20.3% in 1990–00, 27.8% in 2007–08, 33.5% in 2013–14 and further to 37.9% in 2018–19 (Table 1). Given the volatility and the growing significance of ECBs in India, it is essential to understand what determines ECB flows in general and how a domestic monetary policy shock affects such flows, in particular, to help domestic policymakers, including the central bank, formulate appropriate policies to manage them. Hence, the current study aims to empirically examine the effect of the domestic monetary policy shock and other domestic factors on ECB flows to India.

In this study, the impact of the domestic monetary policy shock on external commercial borrowings to India is explored using two variables: interest rate differential and domestic money supply growth. The empirical analysis is conducted through the application of the structural VAR model. This methodology allows for an examination of the dynamic behaviour of external commercial borrowings in response to a domestic monetary policy shock, and it also helps determine the relative contribution of the domestic monetary policy shock in explaining external commercial borrowings to India.

[1] Approximately 30% of the total external debt to India over the period 1990–91 to 2018–19 is in the form of external commercial borrowings by domestic corporations, with the share further rising to around 35% in recent years. Refer to Table 1.

2018–19	543,135	205,804	37.9

The existing studies on ECB flows to India (Dev, 2014; Misra et al., 2022; Patnaik et al., 2016; Sur et al., 2019; Pradhan & Hiremath, 2019; Pradhan & Hiremath, 2020; Singh, 2007; Singh, 2009) have mainly focused on analysing the trends and determinants of ECBs. The role of domestic monetary policy in affecting ECB flows to India is not well researched in the literature. By examining the role of the domestic monetary policy shock and a wider set of other domestic factors in influencing ECB flows to India, this study makes an effort to bridge this gap. Furthermore, by employing the structural VAR model, the current study is able to determine how much proportion of the total variation in ECBs to India

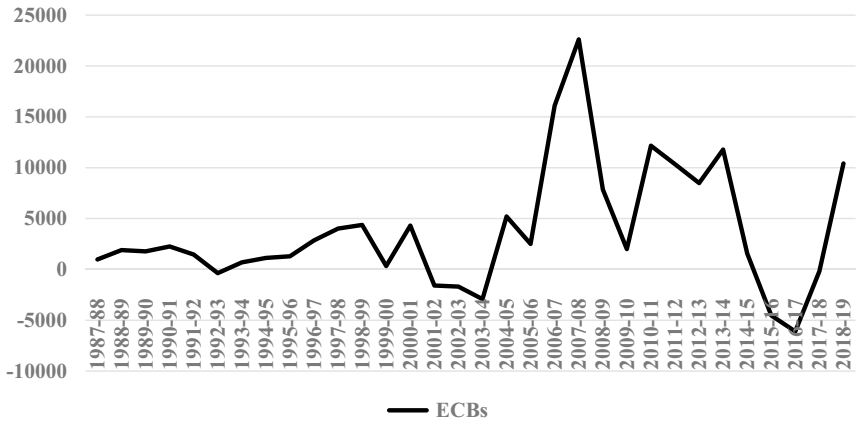

Fig. 1 Net External Commercial Borrowings to India, US$ Million. Source: Reserve Bank of India (RBI)

is explained by the domestic monetary policy shock, something that previous research has not explored.

The following section discusses the trends in external commercial borrowings to India and how it relates with domestic monetary policy shocks. Section 3 reviews the existing literature and discusses the theoretical outline. Section 4 details the empirical model, data, and methodology. Section 5 presents and examines the empirical results. At last, Sect. 6 concludes.

2 Trends in external commercial borrowings to India and how it relates to domestic monetary policy shocks

External commercial borrowings are an additional source of funds for Indian corporates to expand their existing capacity and finance new investment ventures, taking into account interest rate differential between domestic and global markets as well as associated market risks (Verma & Prakash, 2011). The ECB policy in India has been designed to provide Indian corporates with flexibility in borrowings while maintaining judicious limits for total external borrowings, subject to conditions on maturity, cost, and end-use restrictions. Unlike FPI and FDI flows, ECB flows in India are modulated based on the overall cycle of capital flows, through the use of price-based measures (such as linking interest costs to LIBOR) and administrative measures (such as end-use restrictions for ECBs).

The use of ECBs began in the 1970s but remained modest due to the dominance of external aid from multilateral and bilateral entities. In the 1980s, as external aid started to decline and the trade deficit widened, the importance of ECBs in meeting India's foreign exchange and investment requirements increased. The bulk of the increase in ECB flows was observed during the second half of the 1980s when there was a significant surge in demand for foreign currency due to a widening trade

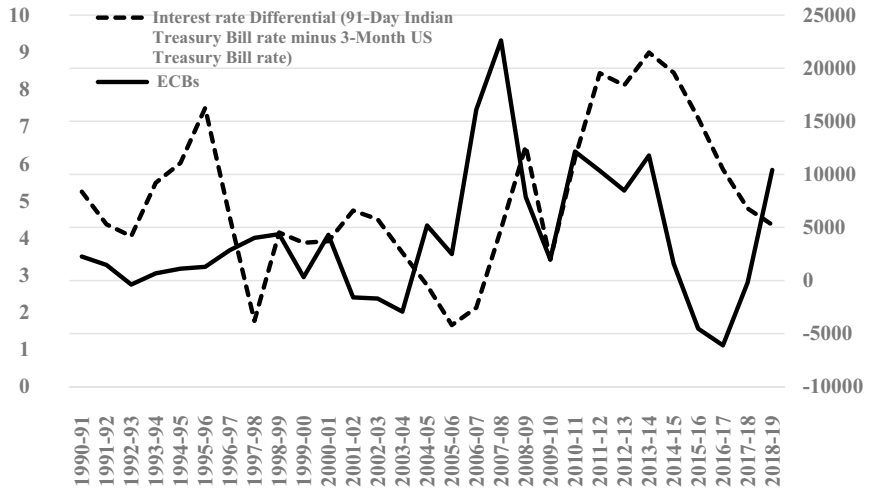

Fig. 2 Trends in net external commercial borrowings to India and interest rate differential (91-Day Indian Treasury Bill rate minus 3-Month US Treasury Bill rate). Source: Reserve Bank of India and Federal Reserve

deficit caused by higher oil prices, increased import demand, and a sharp depreciation of the domestic currency against the dollar. This led to a substantial rise in India's external liability by 1990, which eventually culminated into the balance of payment crisis of 1991. Following the crisis, external commercial borrowings dried up in response to a fall in India's credit rating. The Indian government also adopted a conservative ECB policy to address the external debt situation, imposing an annual ceiling on additional external borrowings, particularly on short-term debt, and placing restrictions on the end-use of ECBs. ECBs were mainly permitted for importing capital goods, with priority given to the infrastructure sector.

Figure 2 shows the trends in Net ECB flows and domestic monetary policy shocks, as represented by the change in 91-Day Indian Treasury Bill rate relative to 3-Month US Treasury Bill rate, i.e., the interest rate differential. We observe that net ECB flows to India exhibited a declining trend in the initial years of liberalization from 1990–91 to 1992–1993, accompanied by a decrease in the interest rate differential. However, net ECB flows began to rise thereafter and continued to do so till 1998–99. This continuous rise in ECBs was the result of improved credit ratings, enhanced domestic demand, and the liberalization of ECB policy with respect to maturity, amount and eligible borrowers in the mid-1990s. As shown in Fig. 2, the interest rate differential also experienced an upward trend during this period till 1995–96, suggesting that, if allowed, domestic corporates tend to borrow more from external sources when borrowing costs in the domestic country are higher relative to the foreign country. The turbulence in global financial markets triggered by the East Asian crisis, economic sanctions on India due to Pokhran nuclear test, global slowdown in the early 2000s, highly volatile credit markets, and lower investor confidence, interrupted developments in India's capital account, leading to fluctuations and a decline in ECB flows until 2003–04. Figure 2 shows that this period was also

Table 2 Net external commercial borrowings to India, US$ Million. Source: Reserve Bank of India

Year	ECBs	Year	ECBs
1987–88	976	2003–04	– 2925
1988–89	1894	2004–05	5194
1989–90	1777	2005–06	2508
1990–91	2254	2006–07	16,103
1991–92	1462	2007–08	22,610
1992–93	– 366	2008–09	7861
1993–94	686	2009–10	2000
1994–95	1124	2010–11	12,160
1995–96	1284	2011–12	10,344
1996–97	2856	2012–13	8485
1997–98	4010	2013–14	11,777
1998–99	4367	2014–15	1570
1999–00	333	2015–16	– 4529
2000–01	4303	2016–17	– 6102
2001–02	– 1585	2017–18	– 183
2002–03	– 1692	2018–19	10,416

characterized by a declining trend in the interest rate differential, which may mean that, ceteris paribus, domestic corporates tend to borrow less from external sources when borrowing costs in the domestic country fall relative to the foreign country.

The period from 2004–05 to 2007–08 proved to be golden years for global capital flows as well as for domestic GDP expansion, reflected in an increased net flow of ECBs from $5194 million in 2004–05 to an all-time peak of $22,610 million in 2007–08 (Table 2). The period witnessed an important policy change in the form of the issuance of a new set of policy guidelines on ECBs on January 31, 2004. The objective was to establish "more transparent and simplified policies and procedures" on external commercial borrowings. As shown in Fig. 2, this period was also marked by an upward trend in the interest rate differential up to 2008–09 as the central bank followed a contractionary monetary policy to control speculation and inflation, making borrowings from external sources cheaper. Encouraged by cheaper international liquidity, simplified policies and procedures, increasing domestic demand, and a favorable exchange rate, many Indian firms increasingly raised funds through ECBs during this period.

There was a sharp reversal in net ECB flows in 2008–09 due to the global financial crisis whose impact was felt all over the world. Net ECBs fell in 2009–10 as well. Although ECB flows recovered strongly in 2010–11, they continued to fluctuate around that level until 2013–14 before following a downward trend for the next three years, reaching their lowest point in 2016–17. The interest rate differential also exhibited a similar pattern during 2008–09 to 2016–17. The following year, 2017–18, also witnessed a net outflow of external commercial borrowings. Nevertheless, due to reform measures taken by the government, further liberalization of the ECB policy, and the huge demand for cheaper funds by Indian corporates to support their expansion, there was a sharp recovery in net ECB flows in 2018–19.

Overall, it can be stated that ECB flows to India have demonstrated substantial volatility, particularly in the aftermath of the 2008–09 financial crisis. Additionally, as shown in Fig. 2, a rise in ECB flows has often been associated with monetary policy shocks causing an increase in the interest rate differential, whereas a fall in ECB flows has been associated with monetary policy shocks causing a decrease in the interest rate differential. Hence, to explore this further, it is necessary to examine the effect of domestic monetary policy shocks on ECB flows empirically.

3 Review of literature

3.1 Empirical literature

One of the initial studies focusing on analysing external commercial borrowings to India in the post-liberalization period was conducted by Singh (2007). Using Johansen co-integration and VECM mechanisms, the study revealed that long-term external borrowings by Indian corporates were influenced by the pace of domestic real activity, interest rate differentials, and credit conditions. In terms of magnitude, it was the real variable, i.e. domestic real activity, that had the greatest impact in attracting ECB flows to India compared to price variables such as interest rate differential. Singh (2009) also concluded that external commercial borrowings to India were primarily driven by domestic real economic activity, interest rate differential, and credit constraints in the global market. The study found a strong co-movement between overseas borrowings and domestic real activity. It also observed that during normal periods, ECBs were predominantly driven by domestic real demand shocks, while during the periods of crisis, global credit shocks played a more significant role in affecting ECBs.

Verma and Prakash (2011) employed the Granger causality and Johansen co-integration methods to examine the impact of interest rate differential and other potential determinants on ECB flows to India. The co-integration analysis revealed a positive and statistically significant impact of interest rate differentials on ECBs. The granger causality test also indicated that ECB flows were granger caused by interest rate differential. The study further identified domestic currency appreciation, improvement in the current account balance, and domestic industrial activity as the other important factors attracting ECB flows to India. Dev (2014) also applied the Johansen co-integration and Granger causality to investigate the ECB flows to India and its relationship with imports, exports, interest rate differential, exchange rate, the index of industrial production, and foreign investment. The study found a significant long-term positive relationship between ECBs and the index of industrial production, exchange rates, and interest rate differentials. The granger causality test indicated a unidirectional causality running from these variables to ECB flows. Through variance composition analysis, the study observed that most of the variation in ECB flows was caused by interest rate differential, followed by the index of industrial production. On similar lines, Sur et al. (2019) analysed the determinants of ECB flows to India using Johansen cointegration and vector error correction techniques and revealed that both domestic and external factors played a role in ECB

inflows to India. The study highlighted that regulatory changes related to the capital account had the most significant impact on ECB flows. Additionally, the study identified exchange rates, India's sovereign rating, interest rate differential, and international credit conditions as other significant determinants of ECB flows to India.

Parnaik et. al (2016) talked about existing regulations, reviewed the outcomes and discussed areas of concern and recent policy changes related to foreign currency borrowings by Indian firms. They concluded that in an emerging country with incomplete markets and a managed floating exchange rate, there are systemic risks associated with foreign currency borrowings if left unhedged by large firms, hence emphasizing for a new policy framework. Pradhan and Hiremath (2019) also talked about the risks and financial stability concerns associated with foreign currency borrowings by Indian firms and recommended implementing a targeted policy approach that includes a focus on the domestic bond market, effective hedging mechanisms, and appropriate regulatory decisions regarding the cap and level of ECBs. Misra et al. (2022) also emphasized on hedging against risks associated with foreign currency borrowings and suggested firms to employ hedging strategies to cover a predefined minimum portion of their currency risk while obtaining funds via ECBs. Pradhan and Hiremath (2020) investigated reasons for external borrowings by Indian firms using a dynamic panel regression approach and concluded that both macroeconomic and firm specific factors are important in explaining external borrowings by Indian firms. Thus, we note that existing studies have mainly focused on analysing the trends and determinants of ECBs. None of the studies has specifically focused on determining the impact of domestic monetary policy shock on ECB flows to India, particularly when we want to know how much of the total variation in ECB flows to India is explained by the domestic monetary policy shock.

3.2 Literature on theoretical linkage between domestic monetary policy and ECBs

According to the open market portfolio balance theory (Branson, 1972; Kouri & Porter, 1974; Mckinnon & Oates, 1966), international debt flows such as external commercial borrowings respond to interest rate differential. Therefore, an Indian company's decision to borrow from the foreign market as compared to the domestic market primarily depends on the interest rate differential between the domestic and foreign markets.

The higher the interest rate differential, the greater the incentive for domestic firms to access low-cost funds from the international market. Singh (2007), Verma and Prakash (2011), Dev (2014) and Sur et al. (2019) have empirically observed the positive association between interest rate differential and ECB flows to India. Therefore, a domestic monetary policy shock (measured through shocks in domestic money supply growth and interest rate differential) is expected to have a significant influence on external commercial borrowings. While the interest rate differential is expected to positively impact ECB flows, domestic money supply growth, by inversely influencing the interest rate differential, is likely to have a negative impact.

However, ECB flows are also likely to be influenced by other domestic and external variables (Dev, 2014; Singh, 2007, 2009; Sur et al., 2019; Verma & Prakash, 2011). It is important to control for these variables while investigating the role of the domestic monetary policy shock. Accordingly, domestic variables that we control for include domestic output growth, foreign exchange reserves to import ratio representing domestic country's creditworthiness, domestic fiscal deficit to GDP ratio representing domestic macroeconomic instability, exchange rate defined as the rupee price of a US dollar, index of industrial production representing domestic industrial activity, and the degree of openness. External variables that are controlled include foreign output growth and volatility in the global market.

4 Empirical model, data and methodology

Drawing from the theoretical idea presented in the previous section, we obtain the following empirical model for external commercial borrowings:

$$ECB_t = \lambda + \lambda_1(i_t - i_t*) + \lambda_2 Mg_t + \lambda_3 y_t + \lambda_4 rm_t + \lambda_5 (fd/y)_t + \lambda_6 ex_t + \lambda_7 IIP_t + \lambda_8 open_t + \lambda_9 y_t* + \lambda_{10} globalVol_t + \mu_t \quad (1)$$

where ECB_t: External Commercial Borrowings, $(i_t - i_t*)$: Interest Rate Differential, Mg_t: Domestic Money Supply Growth, y_t: Domestic Output Growth, rm_t: Foreign Exchange Reserves to Import ratio representing Domestic Country's Creditworthiness, $(fd/y)_t$: Domestic Fiscal Deficit to GDP ratio representing Domestic Macroeconomic Instability, ex_t: Exchange Rate defined as the Rupee price of a US Dollar, IIP_t: Index of Industrial Production representing Domestic Industrial Activity, $open_t$: Degree of Openness, y_t*: Foreign Output Growth, $globalVol_t$: Volatility in the Global Market.

The study applies the structural VAR (SVAR) model to empirically examine the effect of domestic monetary policy variables (*i-i*and Mg*) and other explanatory variables included in the empirical model on external commercial borrowings to India. Additionally, the study includes two dummy variables, specifically EUcrisis and UScrisis, to control for the effects of the Eurozone debt crisis and the US crisis on the flow of external commercial borrowings to India. Considering India's status as a small open economy, certain variables such as foreign output growth (y_t*), global market volatility ($globalVol_t$), and the aforementioned dummy variables (EUcrisis and UScrisis) are regarded as exogenous factors within the system. Degree of openness ($open_t$) is also assumed to be exogenous. *Thus, we estimate the empirical model (1) with eight endogenous variables, namely, interest rate differential (i-i*), domestic money supply growth (Mg), foreign exchange reserves to import ratio (rm), domestic fiscal deficit to GDP ratio (fd/y), domestic output growth (y), exchange rate (ex), index of industrial production (IIP) and external commercial borrowings (ECB) after controlling for all exogenous variables in the framework of Structural VAR.*[2] As discussed in the previous section, the interest rate differential

[2] Structural VAR model includes endogenous variables only.

is expected to positively impact ECB flows, i.e., $\lambda_1 > 0$, and domestic money supply growth, by inversely influencing the interest rate differential, is likely to have a negative impact, i.e., $\lambda_2 < 0$. The expected signs of coefficients associated with other endogenous explanatory variables are $\lambda_3 > 0$, $\lambda_4 > 0$, $\lambda_5 < 0$, $\lambda_6 < 0$, $\lambda_7 > 0$, which we have discussed below:

- *Domestic Output Growth (y)* Higher domestic growth indicates rapidly growing domestic economic activity and a larger market size, which creates demand for funds by local firms both for expansion and new investment ventures. It also boosts the confidence of foreign lenders by making them feel safe about their investments. Thus, domestic output growth is expected to have a positive influence on ECB flows.
- *Foreign Exchange Reserves to Import Ratio (rm)* A country with greater foreign reserves relative to its import requirements can easily repay its external liabilities and hence is considered more creditworthy. A high level of creditworthiness lowers the sovereign credit risk of the domestic country, boosts the confidence of foreign creditors, and thus allows domestic firms easier access to international debt markets. Therefore, a rise in foreign exchange reserves to import ratio is likely to attract greater ECB flows to the domestic country.
- *Domestic Fiscal Deficit to GDP Ratio (fd/y)* A higher domestic fiscal deficit to GDP ratio indicates greater macroeconomic instability in the domestic country, which increases investment risk and thereby discourages domestic corporates from expanding their existing capacity or undertaking new investment ventures. It also discourages foreign lenders from supplying more debt capital to the domestic (host) country. Therefore, the domestic fiscal deficit to GDP ratio is expected to have a negative effect on ECBs.
- *Exchange Rate (ex)* The depreciation of the domestic currency is likely to discourage external borrowings by Indian corporates. Depreciation of the rupee means a higher repayment burden in terms of rupee and a higher effective cost of external borrowings for Indian corporates. Thus, the depreciation of the rupee is expected to negatively influence ECB flows to India.
- *Index of Industrial Production (IIP)* Index of industrial production represents the level of industrial activity in the domestic country. An increasing domestic industrial activity involves an increasing need for funds to finance new investments or expansion of existing capacities, and this, in turn, induces greater external borrowings by domestic corporates. Thus, index of industrial production is expected to have a positive influence on ECB flows.
- *Degree of Openness (open)* A highly open domestic economy means greater flexibility for domestic corporates to access funds internationally at a lower cost. It also means fewer restrictions on all types of capital inflows, including debt inflows. Further, foreign lenders feel more secure about their money in an open market. Thus, a high degree of openness is likely to facilitate greater external commercial borrowings.

4.1 Model specification and empirical strategy

This study applies the structural VAR model to empirically examine the effect of domestic monetary policy shock on external commercial borrowings to India. Innovation accounting analysis under the structural VAR model (impulse response function and forecast error variance decomposition function) is utilized to derive empirical results. The impulse response function (IRF) enables tracking the dynamic path of one variable in response to one standard error shock in another variable. The forecast error variance decomposition (FEVD) function indicates the proportion of overall variation in one variable that can be attributed to shocks from other variables in the model. These two applications together assist in determining the impact and the relative contribution of domestic monetary policy shock in explaining external commercial borrowings to India.

To perform innovation analysis, we follow Han and Kim (2023), wherein we first identify the contemporaneous relation matrix (C_0).[3] This helps recover structural shocks (ε) from the reduced form shocks (e), which as per Sims (1986) and Blanchard and Watson (1986) requires imposition of at least $(n^2\text{-}n)/2$ identification restrictions on the matrix C_0 of structural VAR model.[4] In the structural VAR model, such restrictions come from the economic theory. Once C_0 suitably is restricted, the SVAR model is labelled identified, and the structural shocks (ε_t) are recovered from the reduced form shocks (e) using the following equation: $\varepsilon_t = C_0\, e_t$. Additionally, in this study, Monte Carlo Integration is employed for innovation accounting analysis. Monte Carlo Integration, a Bayesian method, is utilized to statistically determine the significance of impulse responses by computing confidence bands around them (Doan, 1990).

As discussed earlier, the empirical model has 8 endogenous variables, interest rate differential (i-i*), domestic money supply growth (Mg), foreign exchange reserves to import ratio (rm), domestic fiscal deficit to GDP ratio (fd/y), domestic output growth (y), exchange rate (ex), index of industrial production (IIP) and external commercial borrowings (ECB). The vector of variables (X) for the structural VAR model is therefore given as:

$$\mathrm{X} = [Mg, (i - i*), y, ex, (fd/y), rm, IIP, ECB]$$

With n = 8, a minimum of $(8^2–8)/2 = 28$ restrictions must be imposed on matrix C_0 in order to recover or identify the structural shocks. The required identification is achieved using the equation $\boldsymbol{\varepsilon_t = C_0\, e_t}$ by implementing the following restrictions on matrix C_0:

[3] C_0 is a matrix having ones in the diagonal, which represents contemporaneous relationships among variables (variables in vector X) included in the structural VAR model.

[4] The formal structural VAR methodology is explained in the appendix.

$$\begin{bmatrix} \varepsilon_{Mg} \\ \varepsilon_{i-i*} \\ \varepsilon_{y} \\ \varepsilon_{fd/y} \\ \varepsilon_{rm} \\ \varepsilon_{IIP} \\ \varepsilon_{ECB} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ \gamma_{21} & 1 & \gamma_{23} & \gamma_{24} & 0 & 0 & 0 & 0 \\ 0 & \gamma_{32} & 1 & \gamma_{34} & 0 & 0 & 0 & 0 \\ 0 & \gamma_{42} & \gamma_{43} & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & \gamma_{53} & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & \gamma_{63} & \gamma_{64} & 0 & 1 & 0 & 0 \\ 0 & \gamma_{72} & \gamma_{73} & 0 & 0 & 0 & 1 & 0 \\ \gamma_{81} & \gamma_{82} & \gamma_{83} & \gamma_{84} & \gamma_{85} & \gamma_{86} & \gamma_{87} & 1 \end{bmatrix} \begin{bmatrix} e_{Mg} \\ e_{i-i*} \\ e_{y} \\ e_{fd/y} \\ e_{rm} \\ e_{IIP} \\ e_{ECB} \end{bmatrix}$$

In the above specification, it is assumed that shocks to other variables in the model do not contemporaneously affect domestic money supply growth. This is because domestic money supply growth is assumed to be determined exogenously by the central bank, which consequently produces following restrictions: $\gamma_{12}=\gamma_{13}=\gamma_{14}=\gamma_{15}=\gamma_{16}=\gamma_{17}=\gamma_{18}=0$. On the contrary, shocks to all variables are assumed to have a contemporaneous impact on ECB flows to India. Hence, none of the gammas (γ's) in the eighth row are zero. The zeroes in the matrix presented above indicate the restrictions imposed based on the theoretical considerations. As there are 36 zeros, the SVAR model has a total of 36 restrictions, indicating that the model is over-identified.

4.2 Data and variables definition

The study uses quarterly data from 2000:Q2 to 2019:Q4 for the analysis.[5] The Reserve Bank of India, OECD database and the Federal Reserve Economic Data are the main data sources. The study defines external commercial borrowings (ECB) broadly as the sum of net external commercial borrowings and net short-term credit to India, both denominated in US$ million. The difference between yield on Indian Treasury Bills (91-Day) and yield on US Treasury Bills (3-Month) is taken as the interest rate differential (***i-i****). Domestic money supply growth (***Mg***) is given by rate of growth of broad money supply in India. Domestic output growth (***y***) is defined by growth rate of GDP in India. Foreign exchange reserves to import ratio (***rm***) representing domestic creditworthiness is defined as the ratio of total foreign exchange reserves and imports, both denominated in US$ million. Domestic fiscal deficit to GDP ratio (***fd/y***) representing domestic macroeconomic instability is defined as the ratio of gross fiscal deficit and GDP.

The rupee price of a US dollar is taken as the exchange rate (***ex***). Index of industrial production (***IIP***) for India is used to measure domestic industrial activity. The degree of openness (***open***) is assessed through two factors: trade openness and financial openness. Trade openness is captured by calculating the ratio of trade to GDP, while financial openness is captured using financial openness index for India by Chinn and Ito (2008). Foreign output growth (***y****) is measured through output

[5] To remove the impact of the unexpected shock associated with COVID, the study has only considered the pre-COVID period for analysis.

growth of OECD countries. The CBOE volatility index (VIX) for the United States is utilized to capture the level of volatility in global market (***globalVol***).

5 Empirical results

5.1 Unit root results

The unit root tests reveal that external commercial borrowings and the degree of financial openness are stationary variables. On the other hand, the remaining variables, namely domestic money supply growth, foreign exchange reserves to import ratio, interest rate differential, domestic fiscal deficit to GDP ratio, domestic output growth, exchange rate, index of industrial production, degree of trade openness, volatility in the global market, and foreign output growth, are found to be non-stationary,[6,7]

Typically, when estimating Structural VAR (or VAR) models, it is necessary for all variables to exhibit stationarity. However, this study has incorporated all variables in levels, even though most of them are level non-stationary. This is because the study utilizes Monte Carlo Integration for innovation analysis, as mentioned earlier. Since Monte Carlo Integration is a Bayesian technique, the presence of non-stationary variables does not influence the statistical inferences, as established by Sims and Uhlig (1991), and Kim and Roubini (2000). Consequently, all variables in the SVAR model have been incorporated in levels.

5.2 Structural VAR results

We estimate the structural VAR model at lag length two,[8,9] In Sect. 5.2.2, it was established that the structural VAR model for ECB is over-identified. To assess the validity of the imposed restrictions, we employ the likelihood ratio test of over-identifying restrictions. The outcome of the test is shown in Table 3. We observe that the likelihood ratio test does not reject the validity of the restrictions at a significance level of 1%, thus marginally confirming the validity of the imposed restrictions.

[6] The study has employed three unit root tests, KPSS, DF-GLS and PP, to check for the unit root, the results of which are available in the appendix.

[7] The descriptive statistics of all these variables has also been presented in the Appendix.

[8] Optimal lag length is chosen using the lag length criteria under VAR.

[9] Note that the structural VAR is estimated only with endogenous variables (interest rate differential, domestic money supply growth, foreign exchange reserves to import ratio, domestic fiscal deficit to GDP ratio, domestic output growth, exchange rate, index of industrial production, and external commercial borrowings) after controlling for all the exogenous variables (UScrisis dummy, foreign output growth, EUcrisis dummy, degree of openness, volatility in global market).

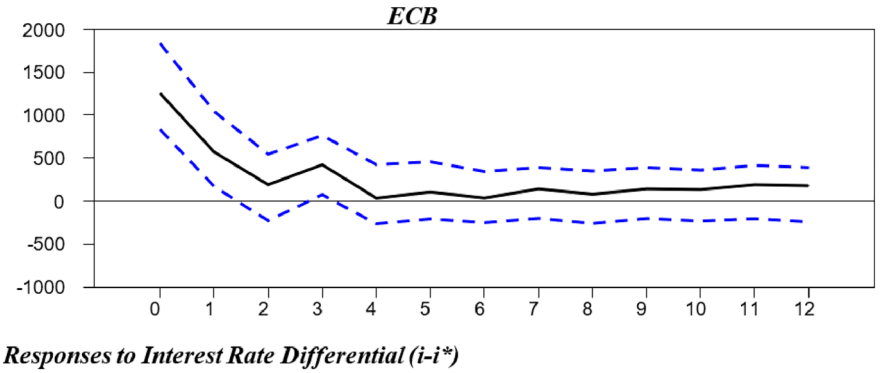

Fig. 3 Impulse response of external commercial borrowings (ECB) to one standard error shock to interest rate differential (i-i*)

5.2.1 Impulse response function

The impulse response function (IRF) is an econometric tool that traces the dynamic movement in one variable when there is a unit standard error shock in another variable. In this study, it helps trace the dynamic (over time) response of external commercial borrowings where there is one standard error shock to monetary policy variables and other variables in the SVAR model. Figure 3 shows that the impulse response of external commercial borrowings to one standard error shock to Interest rate differential. As expected, the response is positive and statistically significant[10] for up to three quarters, indicating that an increase in the interest rate differential has a positive and statistically significant influence on external commercial borrowings to India. The impulse response of external commercial borrowings to a unit standard error shock to domestic money supply growth is shown in Fig. 4. It should be noted that while the response is negligible on impact, it turns negative and statistically significant in the first quarter, which is as expected. However, the response becomes insignificant thereafter.

The results in Fig. 3 and Fig. 4 suggest that domestic monetary policy shock has a statistically significant influence on external commercial borrowings to India. In particular, interest rate differential has a positive, and the

[10] 90% confidence interval based on Monte Carlo Integration is used to check the significance of the impulse responses.

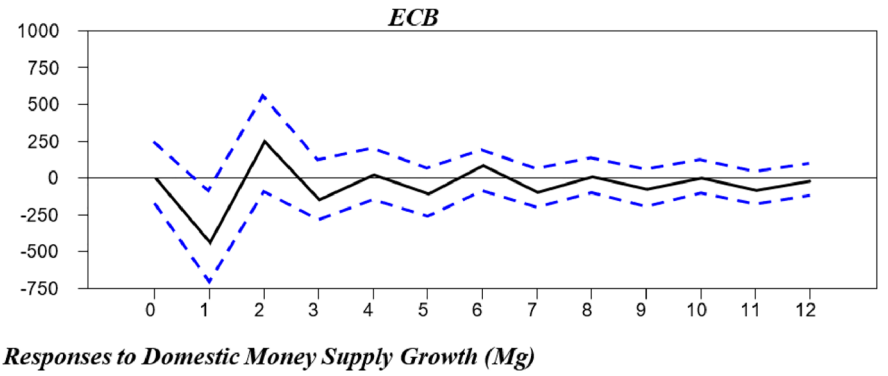

Fig. 4 Impulse response of external commercial borrowings (ECB) to one standard error shock to domestic money supply growth (Mg)

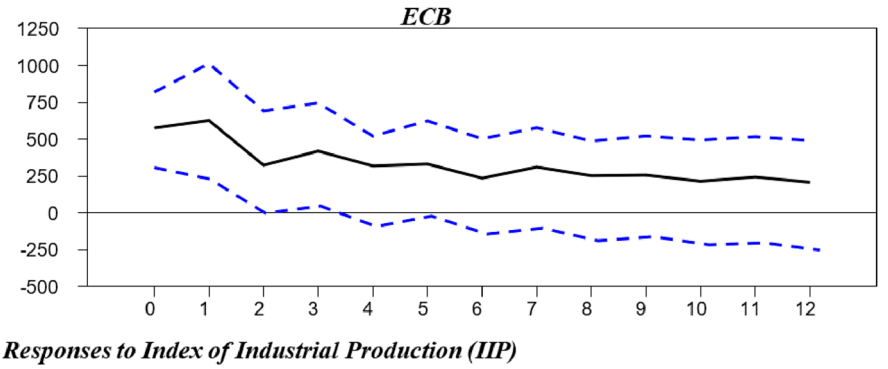

Fig. 5 Impulse response of external commercial borrowings (ECB) to one standard error shock to index of industrial production (IIP)

domestic money supply growth has a negative influence on external commercial borrowings.

The impulse response of external commercial borrowing to one standard error shock to index of industrial production representing domestic industrial activity is depicted in Fig. 5. Note that the response is positive and statistically significant for about three quarters and continues to be positive after that. This positive response indicates that an increasing domestic industrial activity induces greater external borrowings by domestic corporates to finance new investments or expand existing capacities. The response of external commercial borrowings to one standard error shock to foreign exchange reserves to import ratio representing domestic country's creditworthiness is positive and statistically significant on impact and in the first quarter (Fig. 6). We also find that the response has become persistently positive from the third quarter. This positive response indicates that a highly creditworthy country

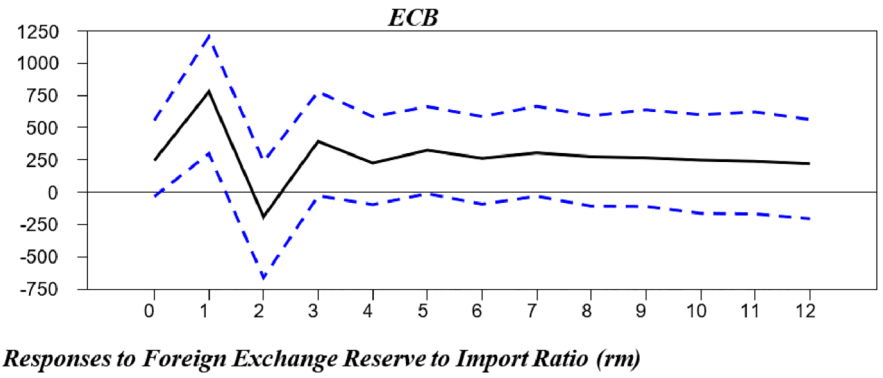

Fig. 6 Impulse response of external commercial borrowings (ECB) to one standard error shock to foreign exchange reserves to import ratio (rm)

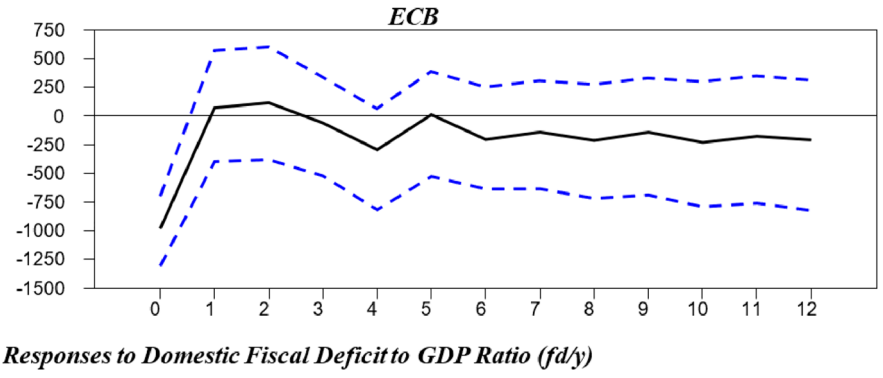

Fig. 7 Impulse response of external commercial borrowings (ECB) to one standard error shock to domestic fiscal deficit to GDP ratio (fd/y)

has easier access to international debt markets, allowing domestic corporates to raise more funds from external sources.

Figure 7 shows the impulse response of external commercial borrowings to one standard error shock to domestic fiscal deficit to GDP ratio. Note that the immediate response is highly negative and statistically significant, implying that a higher domestic fiscal deficit to GDP ratio discourages external commercial borrowings. A higher domestic fiscal deficit to GDP ratio indicates greater domestic macroeconomic instability, which increases investment risk and discourages domestic corporates from borrowing abroad to finance new investment ventures.

The impulse response of external commercial borrowings to a unit standard error shock to domestic output growth is shown in Fig. 8. We note that the response is positive and significant in initial quarters and continues to be positive even afterwards, which is in line with theory. This result indicates that an expanding domestic output provides a greater incentive for expansion and new investment ventures,

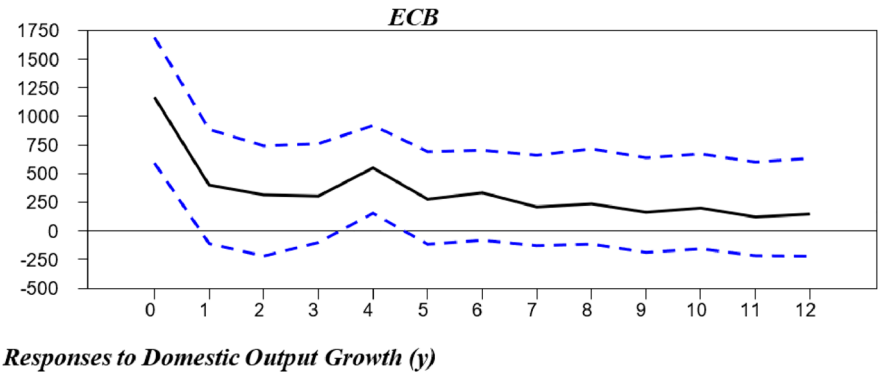

Fig. 8 Impulse response of external commercial borrowings (ECB) to one standard error shock to domestic output growth (y)

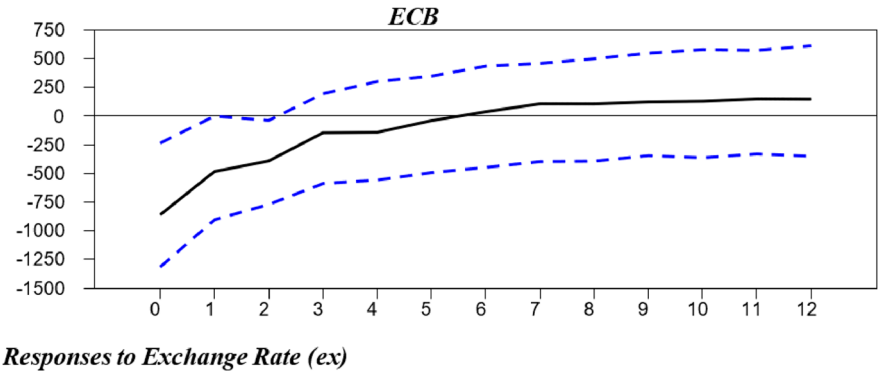

Fig. 9 Impulse response of external commercial borrowings (ECB) to one standard error shock to exchange rate (ex)

inducing domestic corporates to borrow more internationally. As expected, one standard error shock to the exchange rate, i.e., depreciation of the rupee**,** is found to have a negative and statistically significant impact on external commercial borrowings to India (Fig. 9). This result indicates that a rupee depreciation discourages external commercial borrowings by increasing the effective cost of overseas borrowings for Indian corporates.

5.2.2 Forecast error variance decomposition

The forecast error variance decomposition (FEVD) function indicates the proportion of overall variation in one variable that can be attributed to shocks from other variables in the model. In this study, it helps determine how much proportion of the total variation in ECBs to India is explained by the domestic monetary policy variables

Table 4 Forecast error variance decomposition

Period	*Mg*	*(i-i*)*	*y*	*ex*	*fd/y*	*rm*	*IIP*	*ECB*
1	1.306	15.961	10.937	6.804	5.084	0.930	3.726	55.252
2	1.955	15.036	10.823	7.556	5.258	6.412	5.912	47.048
3	2.210	15.267	10.942	8.351	4.545	6.211	5.948	46.526
4	2.215	15.137	10.297	8.269	4.144	7.064	6.345	46.529
5	2.401	15.299	10.139	8.021	4.359	7.181	6.172	46.428
6	2.386	13.367	10.520	7.866	4.128	7.621	6.228	47.884
7	2.048	13.628	10.855	7.744	4.035	7.823	6.112	47.755
8	2.046	13.858	11.014	7.683	3.942	8.198	6.033	47.226
9	2.081	14.162	11.150	7.685	3.907	8.342	5.949	46.724
10	2.075	14.474	11.118	7.747	3.859	8.501	5.886	46.340
11	2.087	14.737	10.048	7.859	3.878	8.555	5.847	46.989
12	2.076	14.948	10.948	8.146	3.907	8.592	5.817	45.566

and other variables in the SVAR model. The FEVD analysis (presented in Table 4) indicates that the interest rate differential explains about 14.6% and domestic money supply growth, on average, explains about 2% of the total variation in external commercial borrowings, implying that domestic monetary policy variables together explain about 16.6% of the total variation in ECBs to India. Other variables such as domestic industrial activity (represented by domestic IIP) explain about 5.8%, the exchange rate about 7.8%, domestic output growth about 10.7%, domestic macroeconomic instability (represented by domestic fiscal deficit to GDP ratio) about 4.2%, and domestic creditworthiness (represented by foreign exchange reserves to import ratio) about 7.1% of the total variation in external commercial borrowings to India.

5.2.3 Robustness Check

Interest Rate Differential We checked the robustness of the result using an alternative measure of interest rate differential, defined as the Call money rate minus 3-Month US dollar LIBOR. Figure 10 represents the impulse response of external commercial borrowings to one standard error shock to 'Call money rate minus LIBOR'. We note that the response is positive and significant, which verifies the results found in Fig. 3.

Exchange Rate We also checked the robustness of the result using an alternative measure of the exchange rate, the nominal effective exchange rate (NEER). Figure 11 represents the impulse response of external commercial borrowings to one standard error shock to the NEER. We note that the response is positive and significant for up to three quarters, suggesting that a shock to NEER (i.e. appreciation of the rupee) has positive impact on external commercial borrowings to India. This result is qualitatively similar to the result in Fig. 9.

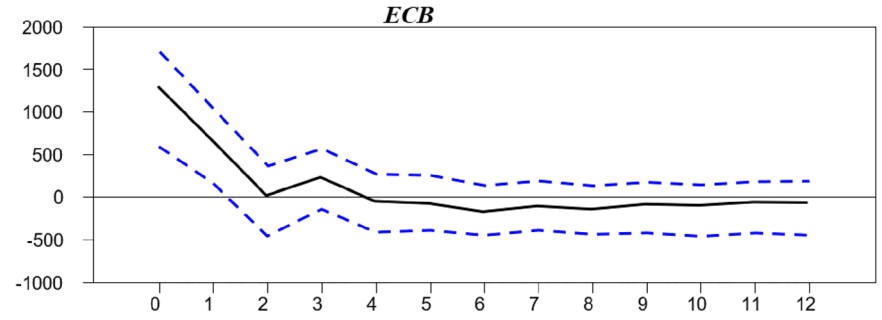

Fig. 10 Impulse response of external commercial borrowings (ECB) to one standard error shock to (call money rate minus LIBOR)

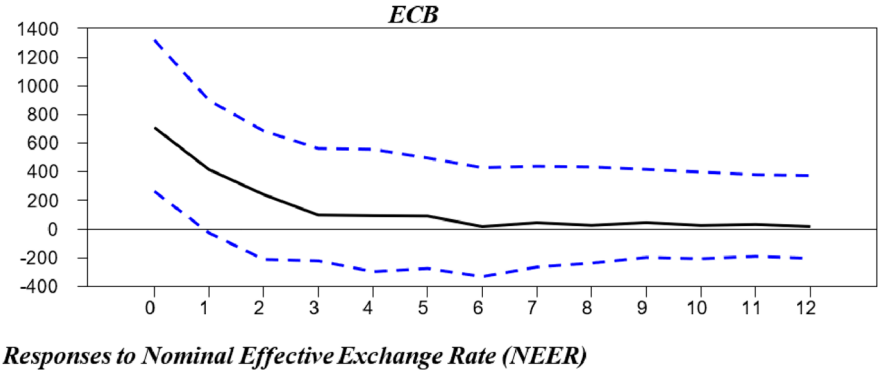

Fig. 11 Impulse response of external commercial borrowings (ECB) to one standard error shock to nominal effective exchange rate (NEER)

6 Conclusion and implication

This paper empirically examined the effect of domestic monetary policy shock on external commercial borrowings to India using the structural VAR methodology. Innovation accounting analysis under the structural VAR model (impulse response function and forecast error variance decomposition function) was utilized to derive empirical results.

The empirical results indicate that domestic monetary policy shock (measured through shocks in domestic money supply growth and interest rate differential) has a significant effect on external commercial borrowings to India, explaining about 16.6% of the total variation in ECBs to India. To be specific, the interest rate differential has a positive significant influence on external commercial borrowings (explaining about 14.6% of the total variation), and domestic money supply growth has a negative significant influence on external commercial borrowings (explaining

about 2% of the total variation). The results further indicate that the exchange rate, domestic industrial activity, domestic output growth, domestic' country creditworthiness, and domestic macroeconomic instability are the other significant determinants of external commercial borrowings to India, in the decreasing order of their importance.

The results suggest that the central bank, through monetary policy interventions, can influence and manage the flow of external commercial borrowings to India. Specifically, by implementing a contractionary monetary policy that results in a rise in interest rate differential, the central bank can persuade more ECBs, whereas by implementing an expansionary monetary policy that leads to a reduction in interest rate differential, the central bank can dissuade ECBs. The results further suggest that domestic policymakers should maintain adequate foreign exchange reserves to improve creditworthiness, follow policies to support economic and industrial growth, work on lowering macroeconomic instability, and control depreciation in the domestic currency to reduce the volatility associated with ECB flows.

***Abstract*—The economic and reliable operation of modern electricity grids relies on insights from Optimal Power Flow (OPF) studies. Implementing a robust, swift, and reliable optimization algorithm is crucial for this purpose. This paper introduces the Improved Coot Optimization Algorithm (ICOA) to address OPF challenges in small-scale power systems. Integrating Lévy flight into population initialization strategically enhances the algorithm, improving the fitness of initial Coot individuals for superior OPF outcomes. The algorithm optimizes generation costs, considering the valve-point loading (VPL) effect and technical objectives related to voltage security. Simulations on the IEEE-30 bus system demonstrate ICOA's superior performance in minimizing fuel costs, improving the voltage profile, and enhancing stability compared to existing techniques. ICOA proves to be a promising tool for small-scale power grid management, offering economic and technical benefits with fast convergence. The findings highlight ICOA as an effective approach for addressing OPF challenges in small-scale grids for the considered set of objectives.**

Keywords—optimal power flow, coot algorithm, IEEE 30-bus, voltage deviation, L-index, valve-point loading

I. Introduction

In modern eco-friendly power practices, Optimal Power Flow (OPF) solutions are crucial for efficient network operation and planning. OPF optimizes control variables to achieve goals while adhering to essential network constraints. [1]. Contemporary power system management grapples with the intricate challenge of maximizing security and reliability within a complex framework of non-convex, large-scale, and non-linear constraints. Traditional approaches (linear programming, non-linear programming, interior point method, Newton's method etc.) are ill-suited for large-scale problems due to their complex and generalized calculations and heavy reliance on initial assumption values. Moreover, due to their non-linear characteristics, these methods cannot effectively address VPL effects, as they tend to converge towards local solutions [2]. In recent times, metaheuristic approaches have gained much popularity, especially when dealing with OPF problems. This is due to the fact that progressive metaheuristic techniques and evolutionary-based methods can avoid local minima by utilizing basic concepts that mimic nature and are versatile across a range of optimization problems. Researchers have developed innovative population-based optimization algorithms (OAs) and hybrids, as reviewed in [3] and [4]. Examples include well-established techniques like Genetic Algorithm (GA) [5], Particle Swarm Optimization (PSO) [6,7], alongside newer methods like Moth Flame Optimization (MFO) [8], Improved MFO [8], Teaching-Learning-Based Optimization (TLBO) [9], Moth Swarm Algorithm (MSA) [10], Jaya Optimizer [11], Modified Sine-Cosine Algorithm (MSCA) [12], Social-Spider Algorithm (SSO) [13], Equilibrium Optimizer (EO) [14], and Enhanced EO [14]. These methods have proven effective in solving OPF, but their application to different objectives results in a variety of solutions, which can affect the overall efficacy of the optimization process. Despite achieving satisfactory outcomes, the growing intricacies of optimization tasks present continuous challenges. Furthermore, the guarantee of achieving a global optimum is not consistent across all algorithms, as highlighted by the "No Free Lunch" theorem [15]. This limitation serves as an impetus for researchers to continually seek and develop new OAs to solve the OPF problem.

This paper introduces the Improved Coot Optimization Algorithm (ICOA) as a more efficient solution for OPF problems. ICOA incorporates a Lévy Flight (LF) component to enhance the basic Coot Optimization Algorithm detailed in reference [16]. This addition ensures comprehensive search coverage, enhances convergence towards optimal solutions, and effectively avoids local minima traps. Lévy flight is applied to randomly generated candidates during population initialization, enhancing their initial fitness for a robust algorithmic start. In the present work, ICOA has been applied to solve OPF with diverse objectives. The first objective is to minimize the total production cost, characterized as a non-convex function. Additionally, we aim to address crucial aspects of power system planning and operation, focused on improving the voltage profile and enhancing voltage stability, while considering the basic quadratic fuel cost (QFC). These constitute the second and third objectives, respectively.

The organization of the paper is as follows: Section II gives an overview of related OPF works for the IEEE 30-bus test system and offers the rationale behind the proposed ICOA. Section III outlines the mathematical model and objectives of the OPF problem, accompanied by a brief overview of the ICOA algorithm, incorporating the Lévy flight element. Section IV delves into simulation results, their detailed analysis, and initiates discussions on the obtained outcomes. Section V concludes the paper by summarizing key findings.

II. Related Works

Numerous detailed studies have been conducted in the field of OPF, examining a range of objectives across different test systems. In [17], the performance of the basic COA was investigated for the first time to address the OPF problem on a small-scale test system for a certain set of objectives. In [18], modifications and hybrid versions of the Flower Pollination Algorithm (FPA) were proposed to address its slow convergence rate and low precision. Specifically, the algorithm incorporated mutation and crossover processes inspired by Differential Evolution (DE), aiming to optimize the objective of minimizing fuel cost with VPL effect as one of the OPF objectives. In [19], an improved Salp Swarm Algorithm (ISSA) was introduced to address OPF with non-

979-8-3503-8295-2/24/$31.00 ©2024 IEEE

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 22,2024 at 06:02:07 UTC from IEEE Xplore. Restrictions apply.

smooth and non-convex generator fuel cost functions. The original SSA exhibits low search capability and may converge to the local optimal solution. To address this, ISSA incorporated random mutation for enhanced population diversity. While the obtained results were promising, there was a compromise in terms of voltage profile and voltage stability. The authors in [9] implemented TLBO approach for OPF. However, this approach may tend to converge to local optima due to its reliance on the current "best" solution during the teaching phase, potentially hindering exploration of untapped areas for globally better solutions. In [20], a multi-objective Manta Ray Foraging Optimizer (IMOMRFO) was introduced, incorporating a strategy based on crowding distance for Pareto archiving. Although this method was effective in lowering fuel costs, it necessitated a trade-off with the objective of minimizing voltage deviation. In [21], the authors introduced a hybrid approach combining crisscross search with the grey wolf optimizer, named CS-GWO, and enriched it with horizontal and vertical crossover techniques. While the outcomes for fuel cost, incorporating VPL effects, were favourable, they did not extend to improvements in voltage deviation performance when considering basic QFC. In [22], an Improved Archimedes Optimization Algorithm (IAOA) was proposed with an enhanced motion strategy featuring a dimension learning-based search approach. The authors considered fuel cost along with voltage deviation as objectives and achieved competitive results. The current study introduces an Improved Coot Optimization Algorithm (ICOA) for OPF. ICOA incorporates Lévy Flight for enhanced efficiency, faster optimal solution attainment, and avoidance of local minimum traps. The algorithm is applied effectively to diverse OPF objectives on the IEEE 30-bus test system.

III. Proposed Method: Improved Coot Optimization Algorithm (ICOA)

OPF poses a challenging task owing to its intricate, non-linear nature. It aims to determine optimal values for various control variables within the power system. This involves minimizing a specified objective function while adhering to operational constraints, including network limits.

A. Components of an OPF Model

The OPF tool solves power flow equations, assigns control variable values, and identifies optimal solutions with equality and inequality constraints. Mathematically, OPF can be stated as follows:

$$\text{Minimize: } J(x,u) \tag{1}$$

$$\text{Subject to: } g(x,u) = 0 \tag{2}$$

$$\text{and } h(x,u) \le 0 \tag{3}$$

Here, x represents a state vector, holding the system's dependent variables, while u denotes a vector of independent variables serving as the control vector. Equation (1) represents the objective function targeted for minimization, while (2) and (3) depict the equality and inequality constraints, respectively, that the solution must adhere to. The representation of state variables in OPF is provided in (4) as follows:

$$x = [P_{G_1}, \mathrm{V}_{L_1} \ldots \mathrm{V}_{L_{NLB}}, \mathrm{Q}_{G_1} \ldots \mathrm{Q}_{G_{NG}}, S_{BR_1} \ldots S_{BR_{NL}}] \tag{4}$$

At the slack bus (bus 1), the generated active power is referred to as PG1. The voltage at the load bus, the amount of reactive power produced by the generator, and the flow of apparent power in the branch are denoted as VL, QG and SBR respectively. NLB represents the total load buses, NG denotes the thermal generating units, and NL signifies the power transmission branches. The control vector is expressed as shown in (5):

$$u = [P_{G_2} \ldots P_{G_{NG}}, \mathrm{V}_{G_1} \ldots \mathrm{V}_{G_{NG}}, \mathrm{Q}_{Sh_1} \ldots \mathrm{Q}_{Sh_{NC}}, \mathrm{T}_1 \ldots \mathrm{T}_{NT}] \tag{5}$$

Where, VG signifies generator bus voltage, QSh represents shunt compensator injected reactive power, and T represents the tap-changing transformer setting. The count of shunt compensator units and tap-changing transformers is represented by NC and NT, respectively.

B. Objective Functions (OFs)

This study incorporates three single-objective OPF (SOOPF) functions, comprising an economy-based OF and two technical voltage-based OFs. The latter two functions focus on enhancing voltage stability (VSE) and improving the voltage profile (VPI).

1) Fuel cost minimization including valve-point loading effects (FCVPL): The cost-related objective is a fundamental aspect of OPF, extensively studied in the literature, constituting the primary and foremost OF. The fuel cost and the generated power exhibit an approximate quadratic relationship, characterized by the basic QFC objective function expressed in (6) [23]:

$$F(P_G) = \left(\sum_{i=1}^{NG} a_i P_{G_i}^2 + b_i P_{G_i} + c_i \right) (\$ / \mathrm{h}) \tag{6}$$

Here, F (PG) is the fuel cost function for ith generator in \$/h, dependent on its real power output P_{G_i} and influenced by coefficients ai, bi and ci. However, incorporating the VPL effect refines the quadratic cost function, enhancing its precision and realism. VPL effect arises when thermal generation unit valves open during steam admission, causing sudden losses and ripples in the cost function curve. Thus, the cost function with VPL effect is described as per (7) [24]:

$$F(P_G) = \left(\sum_{i=1}^{NG} a_i P_{G_i}^2 + b_i P_{G_i} + c_i \right) + \left| e_i \times \sin(g_i (P_{G_i}^{\min} - P_{G_i})) \right| \tag{7}$$

Where, e_i and g_i represent the VPL cost coefficients for the ith unit, with $P_{G_i}^{\min}$ representing the minimum active power generation from the same unit.

2) Voltage profile improvement and basic QFC minimization (VPIFC): The second essential objective in OPF involves optimizing the voltage profile throughout the power system. This is achieved by minimizing the deviation of voltage (VD) at each load bus from its ideal value of 1.0 p.u. In most instances, the consideration of the fuel cost function is typically linked with the voltage profile improvement (VPI), as outlined in (8) [25].

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 22,2024 at 06:02:07 UTC from IEEE Xplore. Restrictions apply.

$$F_{VPIFC} = \left(\sum_{i=1}^{NG} a_i P_{G_i}^2 + b_i P_{G_i} + c_i \right) + \mu_{vp} \sum_{i=1}^{NLB} |V_i - 1.0| \quad (8)$$

Here, the weighting factor (μvp) assigned to VPI was taken as 100.

3) Voltage stability enhancement and basic QFC minimization (VSEFC): Voltage stability is essential for the consistent performance of a power system, ensuring stable voltage levels under normal operating conditions. However, voltage instability can occur due to disruptions, changes in system configuration, and heightened load demand. Lowering the L-index (voltage stability index) serves as a method to enhance voltage stability [26]. Mathematically, (9) represents a single-objective function by incorporating both basic QFC minimization and L-index reduction.

$$\left.\begin{aligned} F_{VSEFC} &= \left(\sum_{i=1}^{NG} a_i P_{G_i}^2 + b_i P_{G_i} + c_i \right) + \mu_{si} \times L \\ where, \quad L &= \max \left\{ \left| 1 - \sum_{i=1}^{NG} F_{ji} \frac{V_i}{V_j} \right| \right\} = \max(L_j) \quad \forall\ j = 1,2,....NLB \end{aligned}\right\} \quad (9)$$

Here, L_j is the local voltage stability indicator for j^{th} load bus. F_{ji} is calculated using system bus admittance sub matrices. In this study, the weighting factor μ_{si} is set to 100.

C. Operating Constraints

Addressing the OPF problem demands considering two distinct constraint categories: equality constraints and inequality constraints [19]. The equality constraints pertain to non-linear power flow equations, while the inequality constraints encompass various operational limits of power system equipment. These limits include constraints on voltage magnitudes of generator and load buses, active and reactive powers of generators, tap changer ratios, and compensating reactive power limits.

D. Basic COOT Algorithm

The ICOA is an improved version of basic COA by Naruei and Keynia in 2021 [16]. The Coot algorithm draws inspiration from collective behaviours and movement movements of a swarm of birds, known as coots, reflecting their two distinct types of behavior on water. Initially, the birds disperse with unpredictable changes in direction. Subsequently, they synchronize their movements, swimming together with similar speeds, forming a denser group as shown in Fig. 1.

E. The Proposed ICOA

The proposed modification in COA incorporates Lévy flight (LF) features to escape local optima, allowing individuals to traverse a wider solution space and increasing the probability of identifying the global optimum. In [27], it is highlighted that Lévy flight effectively escapes local minima, enhancing efficiency in solving complex problems with challenging boundaries. The three fundamental mathematical steps of ICOA are as follows:

- Initialization with LF distribution.
- Updating fitness and designating the Coot leader.
- Updating Coot positions.

Fig. 1. Coots synchronized in elegant glide over water.

Step 1 Population initialization with LF distribution

In the ICOA algorithm, the Lévy Flight mechanism is used during the initialization phase to an initial population of coots (NPOP). The algorithm initializes the population with LF distribution, which ensures that the agents are spread out across the search space and move in a stochastic manner and explore different regions of the search space. The proposed modification to the basic COA, namely ICOA, revolves around utilizing LF distribution for population initialization, as per (10).

$$CP(i_initial) = LB + Levy(\lambda) \times (UB - LB) \quad (10)$$

Here, CP(i_initial) is the initial position of the of ith coot, Levy (λ) is a random search path formulated as follows in (11).

$$Levy(\lambda) = 0.01 \cdot \frac{u}{|v|^{1/\beta}} \quad (11)$$

Here, random numbers u and v follow a Gaussian distribution, and the distribution is controlled by the power-law index β. We have chosen a value of 1.5 for β.

Step 2 Updating fitness and designating the Coot leader

The fitness function is computed for each agent's position obtained from (10). Coot leaders (N_{Leader}) are randomly chosen from the total population, while the remaining coots are designated as coot followers (N_{COOT}, where $N_{COOT} = N_{POP} - N_{Leader}$).

Step 3 Updating Coot positions

In this step, the algorithm simulates four distinct movement behaviors of coots, mimicking their actions on water.

1) Random movement: The algorithm explores diverse areas of the solution space to avoid local optima, determining the new position randomly using (12).

$$CP(i) = CP(i) + T_1 \times r2 \times \left[\{ rand(1,D).*(UB - LB) + LB \} - CP(i) \right] \quad (12)$$

Here $r2$ is chosen arbitrarily between [0-1]. D denotes the problem dimension, determined by the count of involved decision variables and T_1 is determined using (13).

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 22,2024 at 06:02:07 UTC from IEEE Xplore. Restrictions apply.

$$T_1 = 1 - \left(\frac{It}{It_\max} \right) \tag{13}$$

Here, the current iteration number is *It*, with the maximum number of iterations denoted as *It*_max.

2) Chain movement: The chain movement for a pair of coots is described as per (14).

$$CP(i) = 0.5 \times \left[CP(i-1) + CP(i) \right] \tag{14}$$

Where, $CP(i)$ denotes second coot's position when it has moved half way towards the first.

3) Update through leaders: Coot leaders guide the group, and followers adjust positions accordingly. Each follower is associated with a leader, updating its location based on the average leader position as per (15). Every coot (i) in the group aligns its position with the leader (k) and adjusts its position accordingly. The next coot position concerning its associated leader is expressed in (16).

$$k = 1 + MOD\ (i,\ N_{\text{Leader}}) \tag{15}$$

$$CP(i) = LP(k) + 2 \times r1 \times \cos(2\pi R) \times \left[LP(k) - CP(i) \right] \tag{16}$$

Here, the position of the ith coot denoted as $CP(i)$, while the position of selected leader (k) is represented by $LP(k)$. Random numbers $r1$ and R assume values chosen from the intervals [0, 1] and [-1, 1], respectively.

4) Global best position update for leaders: The leader's position is updated using (17) to approach the optimal position.

$$LP(i) = \begin{cases} (G_{Best} - LP(i)) \times T_2 \times r3 \times \cos(2\pi R) + G_{Best} & ; r4 < \frac{1}{2} \\ (G_{Best} - LP(i)) \times T_2 \times r3 \times \cos(2\pi R) - G_{Best} & ; r4 \geq \frac{1}{2} \end{cases} \tag{17}$$

Here, G_{Best} represents the position of the global optimum, with $r3$ and $r4$ being randomly selected from the interval [0-1]. T_2 is determined using (18).

$$T_2 = 2 - (It\ /\ It_\max) \tag{18}$$

For additional clarity, the utilization of the ICOA in implementing an OPF solution is illustrated in Fig. 2 through a flowchart.

IV. Results and Discussion

The effectiveness of the proposed improved Coot algorithm (ICOA) in resolving the OPF issue was assessed using the IEEE-30 bus system as a test system. Performance evaluation involved solving SOOPF problems with fuel cost (with VPL effect), total voltage deviation, and voltage stability as individual OFs defined in cases 1–3, respectively. Numerical results were then presented and compared with outcomes from other metaheuristic methods. The ICOA configuration used a population size of 40 and ran for 100 iterations on a standard laptop equipped with an Intel Core i5 processor and 8GB RAM, running MATLAB 2018a.

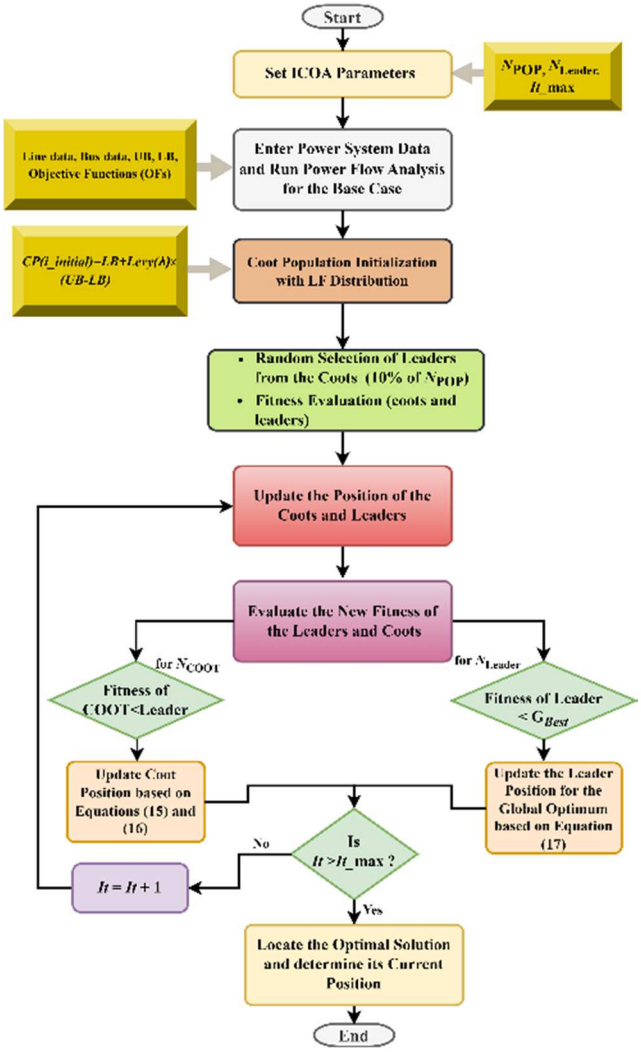

Fig. 2. Flowchart depicting the proposed ICOA for OPF.

A. IEEE 30-bus Test System

The IEEE 30-bus IEEE system represents a power grid with 6 generators, 24 load buses, and 41 connecting lines. In this configuration, bus 1 functions as the slack bus. The allowed voltage range for generator buses is defined as $0.95 \leq V_G \leq 1.1$ p.u., while load buses must maintain voltages within $0.95 \leq V_L \leq 1.05$ p.u. Tap changers operate between 0.9 and 1.1 p.u., while VAR compensators range from 0 to 0.05 p.u. Further details regarding the IEEE 30-bus test system can be found in [28].

B. Case Studies

1) Case 1- OPF for FCVPL: This case focuses on lowering fuel costs while accounting for VPL effects using ICOA, and the corresponding OF is formulated in (7). The fuel cost attributed to VPL effect decreases from 832.3648 \$/h for the basic COA to 832.1201 \$/h with ICOA. In this case, except for IMFO and PSO, the proposed method reduces fuel costs by 0.0074%, 0.0319%, 0.0384%, 0.0031%, and 10.62%, respectively, for EEO, MFO, GA, TLBO, and MSA. The proposed technique demonstrates better performance than other well-established metaheuristics in terms of accuracy and validation, as evidenced by the results.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 22,2024 at 06:02:07 UTC from IEEE Xplore. Restrictions apply.

The obtained total cost with VPL is compared with other algorithms implemented to solve the given case under the same conditions, as shown in Table I.

TABLE I. PERFORMANCE COMPARISON OF VARIOUS METHODS FOR CASE 1

Method	Fuel cost with VPL effect ($/h)	Total voltage deviation (p.u.)	L-index
ICOA	832.1201	0.8235	0.1265
COA	832.3648	0.8311	0.1288
EEO [14]	832.1817	0.841403	0.129291
EO [14]	832.1969	0.841403	0.126421
PSO [8]	832.1095	NR*	NR
IMFO [8]	832.1023	0.8318	0.1281
MFO [8]	832.3871	0.5417	0.1320
GA [8]	832.4400	0.7282	0.1289
TLBO [8]	832.0944	0.8637	0.1280
MSA [10]	930.7441	0.4492	0.15676

*Not Reported

Additionally, the convergence traits of ICOA and basic COA are depicted in Fig. 3, revealing better convergence of ICOA within 100 iterations, especially for small-scale OPF problems.

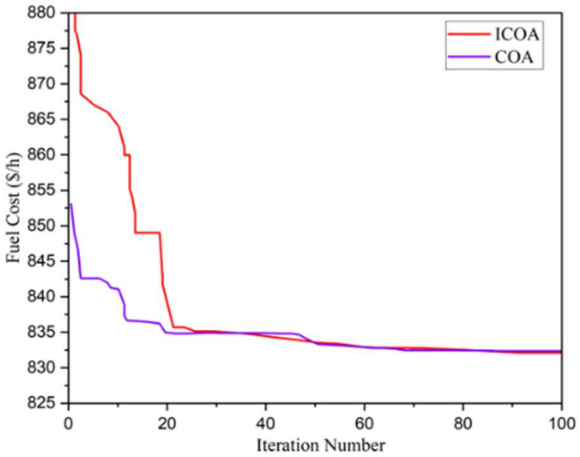

Fig. 3. Convergence plots for Case 1 by COA and proposed ICOA.

2) Case 2- OPF for VPIFC: In this case, OPF solutions are sought to simultaneously minimize the basic QFC and voltage deviation (i.e. improving voltage profile), forming a two-fold objective function as per (8). The reduction in load bus voltage deviation from 0.1126 (COA) to 0.0884 (ICOA) signifies a substantial improvement of around 21.43% compared to the basic COA. In relation to the initial case (1.1496 p.u.), the improvement reaches an impressive 92.33%. Results obtained from the proposed ICOA and well-established algorithms such as MGOA, GOA, EEO, GA, PSO, TLBO, Jaya, and MSCA for case 2 are presented in Table II, highlighting the superior solution achieved by the proposed algorithm over the others.

TABLE II. PERFORMANCE COMPARISON OF VARIOUS METHODS FOR CASE 2

Method	Total voltage deviation (p.u.)	L-index	Fuel cost (basic QFC) ($/h)
ICOA	0.0884	0.1365	803.4796
COA	0.1126	0.1369	804.3822
EEO [14]	0.089035	0.1363	864.2726
EO [14]	0.0905	0.1366	809.101
MGOA [29]	0.1107	0.1365	803.4176
GOA [29]	0.1709	0.1353	803.4488
GA [29]	0.1257	0.1379	803.9156
PSO [29]	0.1110	0.1367	803.6227
TLBO [29]	0.1087	0.1367	804.5827
Jaya [29]	0.1243	NR	840.7181

Fig. 4 depicts a bar chart illustrating load voltage deviation from 1.0 p.u., emphasizing ICOA's enhanced performance over basic COA and the base case.

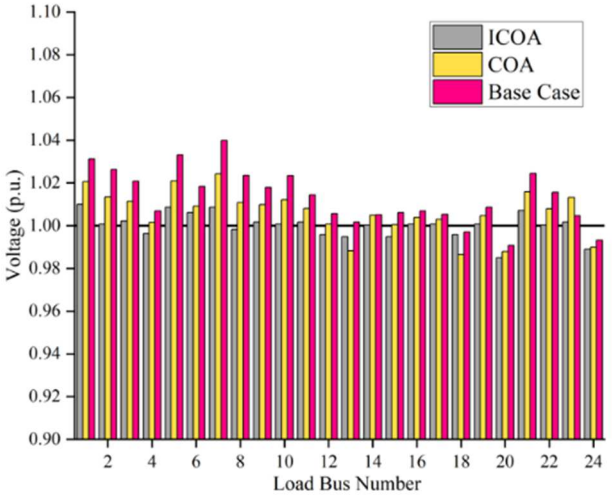

Fig. 4. Comparing voltage profiles from ICOA, COA, and base case.

3) Case 3- OPF for VSEFC: Maintaining bus voltages within operational limits is crucial for power system stability. The L-index, ranging from 0 to 1, signifies stability levels. A lower L-index signifies minimal or stable voltage loads, while an L-index near 1 suggests potential network collapse. This case aims to enhance voltage stability while simultaneously minimizing basic QFC through a two-fold objective approach. The OF related to this is defined in (9). The ICOA achieves an L-index value of 0.1243, indicating a 0.56% improvement over basic COA for the same case and a substantial 42.02% improvement over the base case value (i.e. 0.2144), as presented in Table III.

TABLE III. PERFORMANCE COMPARISON OF VARIOUS METHODS FOR CASE 3

Method	L-index	Total voltage deviation (p.u.)	Fuel cost (basic QFC) ($/h)
ICOA	0.1243	0.7532	801.912
COA	0.125	0.8162	802.661
EEO [14]	0.124236	0.980597	931.9871
EO [14]	0.124268	0.974147	887.8918
MGOA [29]	0.1255	0.8302	800.5595
GOA [29]	0.1281	0.6546	801.7874
IMFO [8]	0.1255	0.9086	800.4762
MFO [8]	0.1266	0.7789	800.9415
GA [29]	0.1266	0.7275	801.0195
PSO [29]	0.1278	0.7972	800.7512
TLBO [29]	0.1256	0.7450	800.7281
SSO [13]	0.1267	NR	NR
NISSO [13]	0.12547	NR	NR
ABC [30]	0.1379	NR	NR

Fig. 5 reveals that ICOA converges faster and achieves better solutions than the original COA.

V. Conclusion

This study effectively applies ICOA and basic COA to solve the SOOPF problem in small-scale power grids, prioritizing a well-defined set of objectives. The proposed ICOA optimizes generation costs by incorporating the VPL effect for thermal generators and includes technical objectives related to voltage stability and deviation, forming a two-fold objective function. The LF mechanism within the ICOA algorithm plays a vital role in diversifying the population by enabling particles to effectively explore the search space and prevent entrapment in local optima. Integrating LF into population initialization strategically improves the algorithm's starting point by enhancing the fitness of initial individuals, leading to better overall performance. The proposed ICOA method exhibits superior fuel cost reduction compared to existing techniques, as evidenced by results on the IEEE-30 bus system. This affirms its validity and accuracy in OPF problem-solving in small-scale power grids. Additionally, ICOA improves voltage profile and stability, ensuring feasible solutions with fast convergence, making it a promising tool for managing small-scale power grids with both economic and technical benefits.

While this paper focused on addressing SOOPF problems with constraints, there is potential for further development in future research. The proposed algorithm can be extended to handle multi-objective OPF (MOOPF) in real-world power systems with a diverse range of energy sources, including renewables and thermal generators. Additionally, there is an opportunity to explore incorporating extra objectives and constraints, addressing the complexities in present-day power systems.

***Abstract*—The Automatic Generation Control shares an objective to regulate the active power production according to the different power requirements, thus maintaining the expected energy flow and frequency in the network itself by connecting the desired control areas with power connection. A sudden change in energy can affect the magnetic currents in various motors and also cause instability in various electrical systems. In a modern and complex energy system, AGC plays an essential role and becomes an essential element in ensuring high quality energy supply to consumers, regardless of constant fluctuations in energy demand. When there are load fluctuations in the power grid, AGC plays a key role in maintaining optimal power exchange levels and grid frequencies while taking into account disturbance caused by load peaks. Therefore, to provide standard performance, the AGC system requires an intelligent efficient controller. The performance of different controllers depends on the choice of controller parameters used as well as the specific optimization algorithms.**

In literature research, the design and research of AGC has been further improved using advanced control strategies and intelligent metaheuristic strategies. Therefore, many researches have been conducted worldwide to provide many new control strategies to effectively solve the AGC problem. The centric goal of the proposed work is to study the concept of Automatic Generation Control while considering concept of area control with their respective simulations.

Keywords – Automatic Generation Control, Control Area, Area Control Error

I. INTRODUCTION

In a power system electrical energy plays a crucial role. The instability between load demand and generated power makes frequency of the system to diverge from its standard value. This will lead to unintended power transfer between various interconnected systems. The power system consists of many controlling areas and these controlling areas are being connected to each other through a transmission line. In such type of controlling areas, the generators swing (i.e., accelerate or deaccelerate) together. For maintaining the eminence of electrical power supply rather than storing it, is to maintain the frequency under different loaded conditions is defined as LFC (load frequency control). There will always be discrepancy between power demand and generation due to fluctuation in the load as shown in Fig. 1. In order to deliver reliable supply of electricity to buyers it is necessary to equalize between production of energy and demand energy. Due to environmental issues, it has become a challenging task to achieve the prerequisite levels of energy due to increase in requirement of electricity.

Modern power systems consist of several controlling areas that are interrelated to each other through a tie-line. During different time zones of a day, the change in load demand leads manual control of maintaining the precise balance to be ineffective. However, the balance among the generation and load power demand is achieved efficiently via AGC schemes. Whenever there is a sudden disturbance or the load change in any of the area it will lead to variation of frequency and if produced active power tends to become more than the required power, the generating unit's frequency starts increasing and vice versa. So, the system will always aim to maintain tie-line power and nominal frequency of a connected power system. To retain the systems tie-line power & frequency at their nominal values AGC plays a principal role in an interconnected power system. However, the speed governor alone cannot obtain the constant frequency.

II. THEORY

If there is a sudden change in the load and the load in the system starts increasing then the speed of the turbine starts dropping before the governor can alter the steam's input. The output power of electric generators within a defined area in respect to change in systems tie-line power and frequency change is regulated to maintain scheduled frequency of the system within the defined limits. For achieving the higher efficiency and to improve the quality as well stability of the electrical supply it is necessary to maintain the nominal tie-line power as well frequency deviation.

Whenever there is active power variation between load and generation this will lead to deviation in the frequency and deviation in voltage is due to imbalance reactive power in a power system. In a given power system by regulating the generation active power balance can be attained is termed as Automatic Generation Control (AGC). In a power system when there is a small load disruption, this will lead to a difference in real power and which will mainly affect the frequency deviation of the system but the level of the voltage remains unaffected as shown in Fig. 2. If there is a sudden change in reactive power this will affect the level of the bus voltage and the frequency of the system remains unaltered.

There are few objectives of an AGC system:

i. Frequency of the system should be maintained at a nominal value i.e., frequency deviation (Δf) should be reduced to zero without any delay.

ii. Change in tie-line power (ΔP_{tie}) must also be made zero as quickly as possible.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 20,2024 at 07:14:48 UTC from IEEE Xplore. Restrictions apply.

iii. In each area the optimal scheduling of generators should be done.

The active power and reactive power flow in a transmission network are independent of each other and both demands are never balanced, they keep on changing depending upon the falling or rising movement. For determining the quality of power supply, voltage & frequency are the most important factors.

By managing the output of generators, LFC is required to maintain power interchange between areas. Irrespective of the conventional approach, new methods and controllers are being executed in the investigation and design of AGC recently. So, the main purpose of AGC is:

(1) to make sure that the bus voltages, frequencies and currents are sustained at a definite value.

(2) to observe the power supply frequency and tie-line power in load sharing areas. In Table 1.1 the overall operation and controlling of the power system on time scale.

III. Load Frequency Control

Load frequency control (LFC) is a simple governing mechanism in the operation of the power system. When the demand on the output changes, a sudden imbalance occurs between the input power and the output. This difference is due to the energy stored in the rotating part of the unit.

The kinetic-energy(KE) of any unit is given by

$$K.E. = 0.5\, J\omega^2$$

Here J is the moment-of-inertia of the rotatory part and ω is the angular speed of the rotatory part.

i. If the KE decreases, angular speed reduces which leads to decrease in speed and therefore the frequency will decrease.

ii. The difference in frequency Δf is detected and it is fed back using a speed governor system to adjust the positioning of the valve which is connected to the generation unit.

iii. Re-positioning of the valve result in the balance of real power input and output. Hence, the variation of frequency depends on the balance of real-power of the system.

iv. The LFCfurthergoverns the real-powertransmissionvia the interconnectedtransmission lines by detecting the variation in flow of power from the tie lines.

IV. Automatic Load - Frequency Control (ALFC)

The main functions of ALFC are: -

a) To regulate the required MW output of the generator with reference to continuous variation in load

b) It helps to control the frequency of vast interconnected systems.

c) To keep the absolute power interchange among pool members at the predetermined data.

The loop of Automatic Load Frequency Control maintains the operation only at slow and small differences i.e., the normal variations in load and frequency. Moreover,

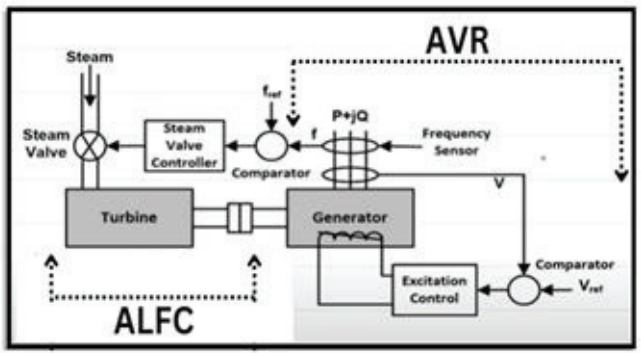

Fig. 1. Block diagram representation of load frequency and excitation control

this makes it unable to provide appropriate required balanced operation in emergency situations at the time of occurrence of large megawatts imbalance. Therefore, a more dynamic emergency control must be utilized.

V. Control Area Concept

The control area concept in power systems refers to a geographical or topological region where the electrical power generation, transmission, and consumption are coordinated and controlled as a single entity. A large power system can be divided into multiple areas of load-frequency control tied together using tie line. The issuefor the control of real power can be analysed by first interpreting the concept for a single area and then extending the solutionof a two or multi-area system.

Area Control Error - The integration control system comprises a frequency sensor and an integrator. This sensor senses the frequency error (Δf), and the resultant error signal is passed into the integrator as an input. The term used for the input to the integrator is "Area Control Error" (ACE).

VI. Area - Control Error (ACE)

A coherent area among which the generators oscillate together in reference to the variation in load or speed varying configurations in which the assumption of constant frequency is made in both static and dynamic environments can be considered as a Single Area. The isolated power system comprising a turbine, load, generator & speed governor can be a representation of single control area.

A. Area-Control-Error in single area case:

The input received by an integrator is known as ACE i.e. "Area Control Error".

The difference in area frequency is the ACE which pushes the error ofsteady state frequency to zero. Further, the production of the signal of real power command is done by an integrator which is represented as:

$$\Delta P_C = -K_I \int \Delta f\, dt = -K_I \int (ACE)\, dt$$

An APC signal is passed to the speed-changer and forces it to move where the integral gain constant is represented by KI operating the integration rate. The integral controller comprises of negative sign which reflects the production of a decrease command or negative command for attaining a positive frequency error. Similarly, the positive gain constant represented as K is responsible for controlling the integration rate and control loop's response speed. The integrator used is

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 20,2024 at 07:14:48 UTC from IEEE Xplore. Restrictions apply.

the same type of the electronic integrator which is used in analog computers.

B. *Area Control Error in two area case:*

The Area Control Error, ACE maintains the linear combination of the difference in frequency and difference in line of power for two-area category. However, to achieve the zero power of steady state tie-line (P_{TL}=0), the other loop of integral-control needs to be introduced for each area with loop of integral frequency to further integrate the incremental power signal of tie-line power and passed back to speed changer.

The ACE of Area1 and 2 are:

$$ACE1\ (S) = \Delta PTL1\ (S) + b1\Delta F1\ (S)$$

$$ACE2\ (S) = \Delta PTL2\ (S) + b2\Delta F2\ (S)$$

VII. Problem Statement

A tie line connected with a two-area system at 1000 MVA common base has following parameters:

TABLE I. Values of Parameters, Constants & Coefficients

Area	1	2
Constant of Inertia	$H_1 = 5$	$H_2 = 4$
Regulation Speed	$R_1 = 5 \times 10^{-2}$	$R_2 = 6.25 \times 10^{-2}$
Time Constant of Governor	$T_{g1} = 2 \times 10^{-1}$sec	$T_{g2} = 3 \times 10^{-1}$sec
load coefficient of sensitive frequency	$D_1 = 6 \times 10^{-1}$	$D_2 = 9 \times 10^{-1}$
Base Power	10^3MVA	10^3MVA
Time Constant of Turbine	$T_1 = 5 \times 10^{-1}$sec	$T_2 = 6 \times 10^{-1}$sec

At nominal frequency of 60 Hz, the units operate in parallel. The coefficient of synchronizing power, Ps = 2.0 per unit which is derived from initial conditions of operation. A 187.5 MW of load variation occurs in Area 1.

(a) Determine the difference in tie line flow and the new frequency of steady state.

(b) Plot the block diagram of Simulink and determine the response of frequency deviation for the above condition in part (a)

- Pm is Mechanical Power
- DPm is change in Mechanical Power
- F is Frequency
- DF is change in Frequency
- pu is per unit value
- t(s) is time in second

IX. ANALYSIS

Considering Steady State Frequency Deviation &difference in Tie Line Power

For Area 1 & Area 2 the speed regulation is calculated as:

$$\frac{1}{R_1} = \frac{1}{5 \times 10^{-2}} = 2 \times 10^{1}$$

$$\frac{1}{R_2} = \frac{1}{6.25 \times 10^{-2}} = 1.6 \times 10^{1}$$

For Area 1 and Area 2 the inertia and load iscalculated as:

$$\frac{1}{D_1 + 2H_1 s} = \frac{1}{0.6 + (2 \times 5s)} = \frac{1}{0.6 + 10s}$$

$$\frac{1}{D_2 + 2H_2 s} = \frac{1}{0.9 + (2 \times 4s)} = \frac{1}{0.9 + 8s}$$

For Area 1 the load change per unit is calculated as:

$$\Delta P_{\mathrm{LI}} = \frac{187.5}{10^3} = 18.75 \times 10^{-2}\ \text{p. u.}$$

The deviation in per unit frequency of steady state is calculated as:

$$\Delta\omega = \frac{-\Delta P_{ul}}{\left[\left(D_1 + \frac{1}{R_1}\right) + \left(D_2 + \frac{1}{R_2}\right)\right]}$$

$$= \frac{-18.75 \times 10^{-2}}{\left(\frac{1}{5 \times 10^{-2}} + 6 \times 10^{-1}\right) + \left(\frac{1}{6.25 \times 10^{-2}} + 9 \times 10^{-1}\right)}$$

$$\Delta\omega = \frac{-18.75 \times 10^{-2}}{(20 + 6 \times 10^{-1}) + (16 + 9 \times 10^{-1})}$$

$$= -5 \times 10^{-3}\text{pa}$$

Deviation in steady state frequency in Hertz is:

$$\Delta f_{\mathrm{Actual}} = \Delta f_{p.u.} \times f_{\mathrm{Base}}$$

$$\Delta f_{\mathrm{Actual}} = -5 \times 10^{-3} \times 60 = -3 \times 10^{-1}\text{Hz}$$

The steady state frequency in Hz is given by

$$f_{\mathrm{Actual}} = f_{\mathrm{original}} + \Delta f_{\mathrm{Actual}}$$

$$f_{\mathrm{Actinal}} = 60 - 3 \times 10^{-1} = 59.7\text{Hertz}$$

For each phase the mechanical power change is calculated as:

$$\Delta P_{\mathrm{m1}} = \frac{-\Delta\omega}{R_1} = \frac{-x - 5 \times 10^{-3}}{5 \times 10^{-2}} = 10^{-1}\text{pA}$$

$$\Delta P_{\mathrm{m1}} = 10^{-1} \times 10^{3} = 10^{2}\text{MW}$$

$$\Delta P_{\mathrm{m2}} = \frac{-\Delta\omega}{R_2} = \frac{-x - 5 \times 10^{-3}}{6.25 \times 10^{-2}} = 8 \times 10^{-2} p\Delta$$

$$\Delta P_{m2} = 8 \times 10^{-2} \times 10^{3} = 80\text{MW}$$

Thus, at new operating frequency of 59.7 Hz, 100MW of generation is increased by Area 1 and 80 MW by Area 2.

The total load difference in generation is observed as 180 MW, but load change is given as 187.5MW therefore, total load difference is 7.5 MW less because of the variation in area loads due to frequency drop.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 20,2024 at 07:14:48 UTC from IEEE Xplore. Restrictions apply.

For Area 1, the load change is given as:

$$\Delta\omega \times D_1 = -5 \times 10^{-3} \times 6 \times 10^{-1} = -3 \times 10^{-3} pu$$

For Area 2, the load change is given as:

$$\Delta\omega \times D_2 = -5 \times 10^{-3} \times 9 \times 10^{-1} = -4.5 \times 10^{-3} pu$$

$$\Delta\omega \times D_1 = -4.5 \times 10^{-3} \times 10^{3} = -4.5\text{MW}$$

Thus, -7.5 MW of difference in total area load is observed.

The power flow in tie line is

$$\Delta P_{12} = \Delta\omega \times \left[\frac{1}{R_2} + D_2\right]$$

$$\Delta P_{12} = -5 \times 10^{-3} \times [16 + 9 \times 10^{-1}]$$

$$\Delta P_{12} = -8.45 \times 10^{-2} \times 10^{3} = -84.5\text{MW}$$

From above calculations, 84.5 MW of power flows from Area 2 to Area 1.

And 80 MW of power is received from the increase in generation of Area 2 whereas remaining 4.5 MW of power is received from the reduction in load of area 2 due to drop in frequency.

X. Conclusion

When the load in Area 1 of the power system is modified by 187.5 MW, a common assumption is that both generators will increase their output to meet the elevated demand. However, this assumption does not align with practical scenarios. In reality, when there is a sudden change in load in any area, each area is expected to handle its own variations. In other words, the load changes should be managed by the generators within that specific area. Specifically, for a load change of 187.5 MW, the increase in mechanical power in Area 1 should precisely match this value, while the variation in mechanical power for Area 2 must remain at zero. Additionally, the variation in tie line power should also be maintained at zero. To achieve this, adjustments were made to the model to ensure that alterations in the load of one area do not impact the generation of another area. It is worth noting that despite a 187.5 MW change in load, the system frequency only recovered to 59.7 Hz, not the nominal value of 60 Hz. As a result, only 180 MW of the load has been supplied by both generators, leaving a deficit of 7.5 MW. The full 187.5 MW will be supplied once the frequency recovers to 60 Hz. Therefore, there is a need to implement control techniques to bring the frequency back to its nominal value. Regarding the flow of powerfrom the tie line, although the change in mechanical power of generator 2 is 80 MW, the simulation results indicate a tie line power flow of 84.5 MW. This apparent discrepancy is explained by 80 MW being supplied from Area 2, while an additional 4.5 MW is redirected to Area 1 due to a reduction in load caused by the frequency drop in Area 2. In summary, the tie line carries a total power flow of 84.5 MW.

XI. Future Scope

- **In-depth Analysis and Simulation of AVR**: Undertake a comprehensive study of Automatic Voltage Regulator (AVR) systems, delving into the intricacies of their operation and control mechanisms.
- **Comparative Analysis of LFC Systems**: Conduct a comparative analysis of the single area and multi-area LFC systems. This will involve evaluating their performance, stability, and response characteristics under various operating conditions.
- **Single Area AVR System Simulation**: Develop simulations for a single area AVR system, this time integrating a Proportional-Integral-Derivative (PID) controller model to enhance system control.
- **Multi Area AVR System Simulation**: Similar to the LFC systems, expand the study to include multi-area AVR systems, with a PID controller model serving as the control mechanism.
- **Comparative Analysis of AVR Systems**: Carry out a comparative study of the single area & multi-area AVR systems. Assess their performance metrics, stability margins, and response times, among other parameters

Summary

This research article presents an artificial neural network (ANN)-based indirect adaptive control method for nonlinear dynamical systems. In this article, a modified Elman recurrent neural network (MERNN) is proposed as an identifier and controller for controlling nonlinear systems. The architecture of the proposed controller is a modified form of the existing Elman recurrent neural network. The parameter training of ANN-based controllers is obtained by using the most popular optimization algorithm which is known as the back-propagation algorithm. A comparative study includes Elman, Diagonal, Jordan, feed-forward neural network (FFNN), and radial basis function network (RBFN)-based controllers to compare with the proposed MERNN controller. To determine the controller's robustness, parameter variations, and disturbance signals have been considered. The performance analysis of the proposed controller is illustrated by two simulation examples. The simulation results reveal that MERNN can not only identify the unknown dynamics of the plant but also adaptively control it compared to the others.

back-propagation, dynamic systems, indirect adaptive control, recurrent neural network

1 | INTRODUCTION

In recent years, neural networks have gained attention as an efficient global approximator. They are used to identify and control dynamical systems. Neural network technology is gaining popularity in data classification, adaptation, modeling, identification, and control.[1] The system identification procedure includes different methods. These include ANNs, fuzzy systems, and more. When system identification is achieved through the use of neural networks. They need the input–output dataset. This set can be used to approximate the unknown dynamics of the given system. They have self-learning capabilities. However, fuzzy logic systems lack self-learning. Another source must modify them. Also, fuzzy-based systems have another disadvantage. They require more mathematics to compute output than neural network models. Fuzzy-based systems generally have poor convergence speeds. Fuzzy models need more tuning and simulation than neural network models. Therefore, artificial neural network (ANN) technology is especially beneficial in the field of system identification and adaptive control. Due to the significant nonlinearity present in many systems, suitable controlling for dynamical systems by employing conventional control techniques is a challenging task.[2] However, it has been discovered that the conventionally constructed controller may not be able to meet some demanding requirements.[3,4] It is highly challenging to use conventional control methods when the mathematical model of the plant is unknown or only partially known.[5,6] The nonlinear systems have been controlled using various highly developed control techniques

 © 2024 John Wiley & Sons Ltd.

such as sliding mode control, back-stepping control, and feedback linearization control. There is a possibility that these advanced techniques may not work as expected due to their complexity.[7] The development of controllers for uncertain dynamical systems has become very effective through an adaptive control technique. Adaptive control is a method in which the response of a controller changes automatically based on changes in conditions within the process.[8] The primary benefit of the adaptive control method is that it can deliver superior performance to conventional control techniques.[9,10] There are different techniques for implementing neural network-based adaptive controllers that may be divided into two main categories: direct adaptive control and indirect adaptive control method. The direct adaptive control technique is suitable for linear systems. It uses a neural network as the controller whereas the indirect control method uses controllers designed based on a neural network model.[11,12] The indirect adaptive control technique is suitable for nonlinear dynamic systems and consists of two components, namely system identification, and control.[13,14] An ANN is one of the most widely used intelligent techniques which is capable of approximating any unknown nonlinear function to an arbitrary degree of accuracy and offering precise control instead of getting previous knowledge of the dynamics of the nonlinear systems.[15] These neural network-based adaptive controllers are capable of controlling highly nonlinear plants. The selection of the neural network to be used as a controller and the choice of the parameter learning technique to be utilized for adjusting its parameters are the fundamental problems in the field of ANN-based control.[16,17] There are several methods which are present in the literature that can be used to update parameters. The most extensive parameter optimization algorithm used to update the parameters of the identifier as well as the controller is the back-propagation optimization algorithm.[18,19] In the present study, a modification of the Elman recurrent neural network (MERNN) is constructed as an enhanced form of the original ERNN to determine the unknown dynamics of the plant. An indirect adaptive control scheme based on a MERNN is proposed to control the dynamical systems. In the suggested control structure, we employ two MERNNs as an identifier and a controller. The MERNN identifier approximates dynamical systems. It provides information on adaptability to the MERNN controller. The remaining paper is organized as follows. There are different sections in this research paper. The nonlinear dynamical system used in this article is described in detail in Section 2. The description of the proposed neural network model is discussed in Section 3. In Section 4 the identification process of the nonlinear system is explained. Section 5 describes the adaptive control scheme for dynamical systems using an ANN. The parameter update equations and control algorithm for dynamical systems are given in section 6. Results and discussion from the simulation and controllers are presented in Section 7. The robustness of controllers is tested and compared using disturbance signal and parameter variation. The conclusion is given in Section 8 and references are provided at the end.

1.1 | Literature review

In Reference 20 self-recurrent wavelet neural networks (SRWNNs) have been employed by the authors as an indirect adaptive control technique for dynamic systems. The SRWNN weights are trained using gradient descent with an adaptive learning rate (ALR). To ensure the convergence of the suggested control system, the ALR which is derived from the discrete Lyapunov stability theorem, is used. SRWNNs, which have both properties like attractor dynamics of RNN and the fast convergence of WNN, are used to identify and control nonlinear systems. But, they did not test the robustness of the proposed scheme. In Reference 21 the authors have presented diagonal recurrent neural network (DRNN)-based adaptive control for nonlinear dynamical systems. The Lyapunov stability criteria are used to build updated rules to assure stability. The robustness of the suggested control scheme is examined with parameter changes and disturbance signals. In Reference 22 this research develops an adaptive optimum tracking control technique for discrete-time nonlinear systems based on infinite horizon neural networks. As a result, the iterative adaptive dynamic programming (ADP) algorithm provides an easier way to obtain the iterative tracking control law, and neural networks are utilized to approximate the performance index function and compute the best control strategy. This proposed ADP algorithm gives optimal control and better convergence. They did not reveal the overall stability of the proposed algorithm. In Reference 23 the authors suggested a hybrid approach using feedforward neural networks to control a nonlinear dynamic system. A novel neural control approach has been created and presented. The approach is based on merging the Kohonen algorithm with the gradient descent method, the benefit of this hybrid learning algorithm is that it gives faster convergence. However, they did not examine the robustness of their suggested approach. In Reference 24 the authors have designed a novel adaptive multiple neural network controller (AMNNC) with a supervisor controller for a class of uncertain nonlinear dynamic systems. The AMNNC is a specific kind of adaptive feedback linearizing controller that approximates nonlinearity factors using multiple neural networks. The proposed control scheme (AMNNC) has better performance in comparison to the conventional adaptive neural network controller. However, they did not compare the proposed controller with different

10991115, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/acs.3823 by Delhi Technological University, Wiley Online Library on [09/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

controllers to determine the effectiveness of the scheme. In Reference 25 the dynamic surface control approach is used in radial-basis-function neural networks (NNs)-based control frameworks to solve the complexity explosion issue. By using the command filter, the command signals and derivatives have been generated without the need to perform analytical calculations. The stability of ultimate boundedness is established using the Lyapunov approach. The suggested approach delivers smoother parameter modification, more accuracy, and higher efficiency. However, the proposed scheme has not tested the effects of parameter variations and disturbance signals. In Reference 26 the authors proposed a NN-based direct adaptive control technique for nonlinear systems with unknown nonsymmetric input. A disturbance observer and NNs provide direct adaptive controllers. The proposed controlling technique has fast convergence for the uncertain nonaffine nonlinear system. However, they have not used a comparative study of different controllers. In Reference 27 the authors proposed an indirect adaptive control technique based on backstepping control to solve the stabilization issue, where an adaptive neural network approach approximates the unknown nonlinearity. In Reference 28 a novel adaptive controller with state feedback has been developed within the adaptive fuzzy back-stepping control approach to ensure that all signals in the resulting closed loop are bounded, and the state variables can be controlled to the origin. To deal with the network-induced delay, the Pade approximation has been introduced, and fuzzy logic systems have been used to estimate the unknown nonlinear characteristics of the system. The suggested controller can overcome the difficulty resulting from the delay. However, they did not test the robustness and used no comparative study. In Reference 29 Multilayer Perceptron (MLP), Elman, NARXSP, and Radial Basis Function (RBF) networks are the four neural networks employed by the authors. A benchmark nonlinear system and a DC servo motor are identified and controlled by using these neural networks. The controller is trained using the Levenberg–Marquardt technique and MATLAB's neural network toolbox. The proposed MLP network takes less time and minimum numbers of epochs to give better convergence. However, they have not tested robustness with parameter variation and disturbance signal. In Reference 30 fuzzy logic systems are used to discover unknown nonlinear dynamics before establishing an equivalent and an auxiliary system. Using the auxiliary system and the backstepping recursive design approach, an adaptive fuzzy inverse optimal scheme coupled with a meaningful objective function is developed. However, they did not use a comparative study. In Reference 31 a continuous-time recurrent neural network (CTRNN) is constructed to be utilized in the context of nonlinear model predictive control (NMPC) and using automated differentiation (AD) methods, an effective training procedure for the suggested network is created. The proposed model can reduce network training time and have better accuracy. However, they have not shown the robustness of the model. In Reference 32 a neuroadaptive stabilization scheme is proposed for the adaptive stabilization of continuous and discrete-time nonlinear systems. The neuroadaptive control is based on the universal function approximation property. The proposed technique guarantees the asymptotic stability of the closed-loop system by using the Lyapunov method. But, they haven't discussed the comparative results with different controllers.

1.2 | Motivation and contribution

The main motivation for this research is the development of an indirect adaptive controller based on a NN to control complex nonlinear dynamical systems. The suggested technique demonstrated robustness features, as it was able to deal with parameter change and disturbance signal impacts. This research study presents the following contribution:

1. A modified Elman recurrent neural network model is proposed for nonlinear system identification.
2. An indirect adaptive control scheme is used to design NN-based controllers.
3. An extensive evaluation of feed-forward, recurrent neural network-based identifiers, and controllers has been performed.
4. The back-propagation optimization method is used to optimize the parameters of the NN-based controllers.

2 | PROBLEM DESCRIPTION

Consider the following dynamical difference equation to explain the given plant.

$$y_p(k+1) = F[y_p(k), y_p(k-1), \ldots y_p(k-n+1)] + G[u_c(k), u_c(k-1), \ldots u_c(k-m+1)], \quad (1)$$

where $y_p(k+1)$ represents the plant's one step forward output value and $u_c(k)$ represents the plant's control input at kth time instant. The word n denotes the plant's order. Where F and G are accessible in terms of nonlinear or linear functions.

10991115, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/acs.3823 by Delhi Technological University, Wiley Online Library on [09/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Let the following difference equation represent the dynamics of the stable reference model.

$$y_m(k+1) = P[y_m(k), y_m(k-1), ...y_m(k-a+1)] + Q[r(k), r(k-1), ...r(k-b+1)], \tag{2}$$

where $y_m(k+1)$ reveals the reference model's single step forward output signal and $r(k)$ indicates the external input. The terms a and b are both positive, although P and Q are both differentiable functions of linear or nonlinear types. The adaptive control aim is usually described as follows: the controller parameter update equations are designed to trigger the plant output to match the reference model output.

$$\lim_{k\to\infty} \left| y_m(k+1) - y_p(k+1) \right| \leq E_c(k), \tag{3}$$

where $E_c(k) \to 0$ and $E_c(k)$ represents the MSE (mean square error). For updating the parameters of ANN-based controllers, the error between reference model output and plant output will be used. It is also necessary for the control system to compensate for parameter variations and disturbance signals. Therefore, the proposed control scheme can compensate for uncertainties by adjusting the parameters of the controllers.

3 | OVERVIEW OF ERNN AND MERNN MODEL

In this article, Figure 1 shows the structure of the Elman recurrent neural network model. The proposed modified Elman recurrent neural network (MERNN) model is shown in Figure 2 and it is an enhanced version of the standard Elman recurrent neural network (ERNN) model. The ERNN model has four layers: the first is the input layer, the second is the hidden layer, the third is the context layer, and the fourth is the output layer. The context layer gets its input from the output of the hidden layer whereas the MERNN model consists of five layers: an input layer, a hidden layer, an output layer, and two context layers. The difference between the ERNN and MERNN models is that the MERNN model has an extra context layer (between the output layer and hidden layer) and an additional self-feedback loop with unit delayed values to the output node of the output layer. $X_j(k) = \{x_1(k), x_2(k)...x_m(k)\}$ represents the m dimensional external input vector. The weight vector between the input and hidden layer is denoted by $W^I(k)$. It consists of $w_1^I(k), w_2^I(k), ...w_j^I(k)$. The

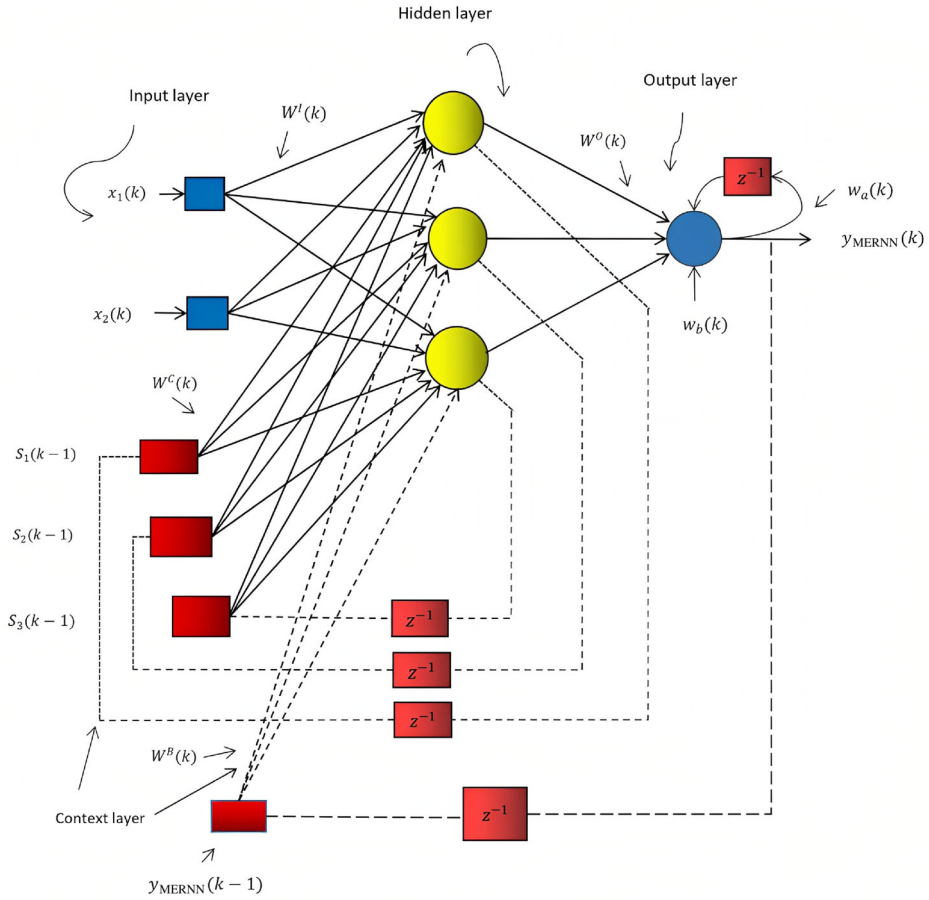

FIGURE 2 Modified Elman recurrent neural network (MERNN) model.

weight vector between the hidden layer and output layer is denoted as $W^O(k)$. This vector consists of elements $w_1^O(k)$, $w_2^O(k)$, and so on up to $w_q^O(k)$. The weight vector $W^C(k)$ contains three adjustable weights: $w_1^C(k)$, $w_2^C(k)$, and $w_3^C(k)$. It connects the first context layer to the hidden layer. In this context layer, the input is the output of the hidden layer with unit delay. In the second context layer, the input is the output of the MERNN model, which is delayed by one unit. This layer is connected to the hidden layer through the adjustable weight vector denoted as $W^B(k)$ which contains three adjustable weights: $w_1^B(k)$, $w_2^B(k)$, and $w_3^B(k)$. The MERNN model consists of an additional self-feedback loop with tunable weight $w_a(k)$ at the output node and $w_b(k)$ is the adjustable bias weight at the output node. The output of any *rth* recurrent neuron at any *kth* time instant is denoted by $S_r(k)$ and evaluated as

$$S_r(k) = V_r(k), \tag{4}$$

where $V_r(k)$ is the induced field produced by rth hidden neurons.

$$V_r(k) = \left\{ \sum_{j=1}^{m} x_j(k) w_{jr}^I(k) \right\} + \left\{ \sum_{i=1}^{h} S_i(k-1) w_{jr}^C(k) \right\} + \left\{ \sum_{j=1} w_{jr}^B(k) \times y_{\text{MERNN}}(k-1) \right\}, \tag{5}$$

where $w_{jr}^I(k)$ represents the adjustable weight between the input layer and hidden layer. w_{jr}^C and w_{jr}^B represent the adjustable weights connecting any jth input of the first context layer and second context layer to the rth hidden layer. $S_i(k-1)$ represents the previous output values of hidden neurons. $y_{\text{MERNN}}(k-1)$ represents the previous output value of the MERNN model. In this case, $T(.)$ represents the nonlinear tangent hyperbolic activation function that has both

10991115, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/acs.3823 by Delhi Technological University, Wiley Online Library on [09/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

positive as well as negative values, after nonlinear processing the output of the hidden layer is

$$T\{V_r(k)\} = \tanh\{V_r(k)\}, \tag{6}$$

$$T\{V_r(k)\} = \frac{e^{V_r(k)} - e^{-V_r(k)}}{e^{V_r(k)} + e^{-V_r(k)}}, \tag{7}$$

and the result of the output junction is

$$V_o(k) = \left\{ \sum_{q=1} w_{qr}^{O}(k) T\{V_r(k)\} \right\} + \{w_a(k) \times y_{\text{MERNN}}(k-1)\} - w_b(k), \tag{8}$$

where $w_{qr}^{O}(k)$ represents the adjustable weight parameter between rth hidden layer and qth output layer. The activation function of the output layer is linear, which is purelin $f(.)$. The outcome of the MERNN model with linear activation function is given as follows:

$$y_{\text{MERNN}}(k) = f\{V_o(k)\}. \tag{9}$$

4 | IDENTIFICATION OF NONLINEAR SYSTEM

System identification is a way of identifying or measuring the mathematical model of a system based on measurements of the system's inputs and outputs. Several controlling schemes are available if an accurate approximation mathematical model of the dynamical system is being controlled. In order to identify a system, we must first determine which model structure the given plant is related to and then approximate its order. Determining the model or category to which the presented plant belongs, as well as identifying the plant's order, is required for the identification. These nonlinear difference equations can be used to describe any of the four nonlinear dynamical plants introduced here:

$$\text{Model 1}: y_p(k+1) = F[y_p(k), y_p(k-1)....y_p(k-n+1), u_c(k), u_c(k-1)....u_c(k-m+1)]. \tag{10}$$

$$\text{Model 2}: y_p(k+1) = F[y_p(k), y_p(k-1)....y_p(k-n+1)] + G[u_c(k), u_c(k-1)....u_c(k-m+1)]. \tag{11}$$

$$\text{Model 3}: y_p(k+1) = \left[\sum_{i=0}^{n-1} a_i y_p(k-i) \right] + G[u_c(k), u_c(k-1)....u_c(k-m+1)]. \tag{12}$$

$$\text{Model 4}: y_p(k+1) = F[y_p(k), y_p(k-1)....y_p(k-n+1)] + \left[\sum_{i=0}^{m-1} b_i u_c(k-i) \right]. \tag{13}$$

All of the models described above illustrate a nonlinear system and the plant's output at $(k+1)$th is directly dependent on the present state of the plant's output and the prior state of the external inputs.

4.1 | Parallel and series-parallel identification model

Figure 3 shows the parallel identification scheme for the plant. Every dynamical plant utilized in this research is considered to be BIBO stable in the presence of a given class of input, assuming that all signals in the plants are equally BIBO stable. The series-parallel model involves feeding back the plant's output into the identification model, in contrast to the parallel model described above. The series-parallel identification scheme corresponding to a plant is shown in Figure 4.

5 | ADAPTIVE CONTROL FOR NONLINEAR DYNAMICAL SYSTEMS

Adaptive control is a technique that allows the controller's response to adjust automatically depending on changes in the process conditions. The main objective of control is to produce the expected results of the nonlinear plant, ensuring that

10991115, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/acs.3823 by Delhi Technological University, Wiley Online Library on [09/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

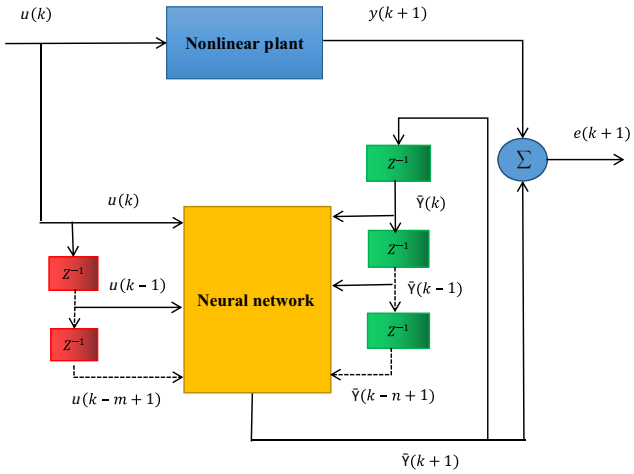

FIGURE 3 Parallel identification scheme.

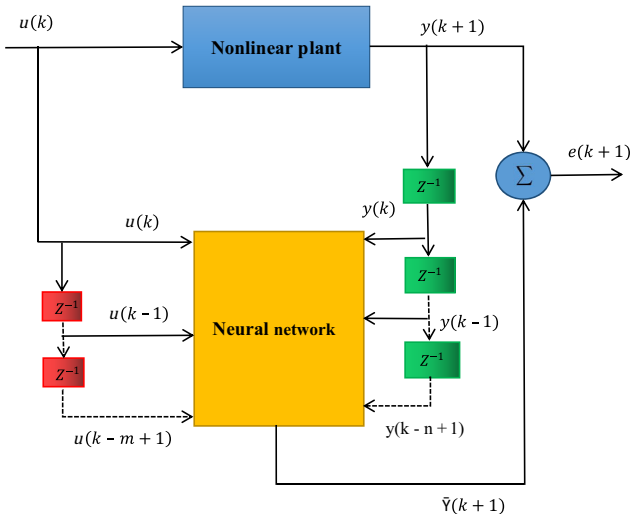

FIGURE 4 Series-parallel identification scheme.

it tracks the reference model output. There are various methods to implement adaptive control schemes, which fall into two categories.

1. Direct control
2. Indirect control

Direct control involves immediately adjusting the controller's settings at each time instant based on the difference between the plant's output and the desired reference model output. This method was limited to linear systems. Direct methods are not valid for nonlinear plants. Therefore, an indirect adaptive control approach is required to control nonlinear dynamical plants. The plant parameters are estimated, and the controller settings are computed in indirect adaptive control. In the case of indirect control, the parameter adjustment procedure demands knowledge of the mathematical model of the nonlinear plant with errors at each moment. In this article, the plant's dynamics have been considered to be unknown. Thus, in order to conduct control action in conjunction with the plant, an identification model will learn about the plant's dynamics. The indirect adaptive control technique is represented in Figure 5.

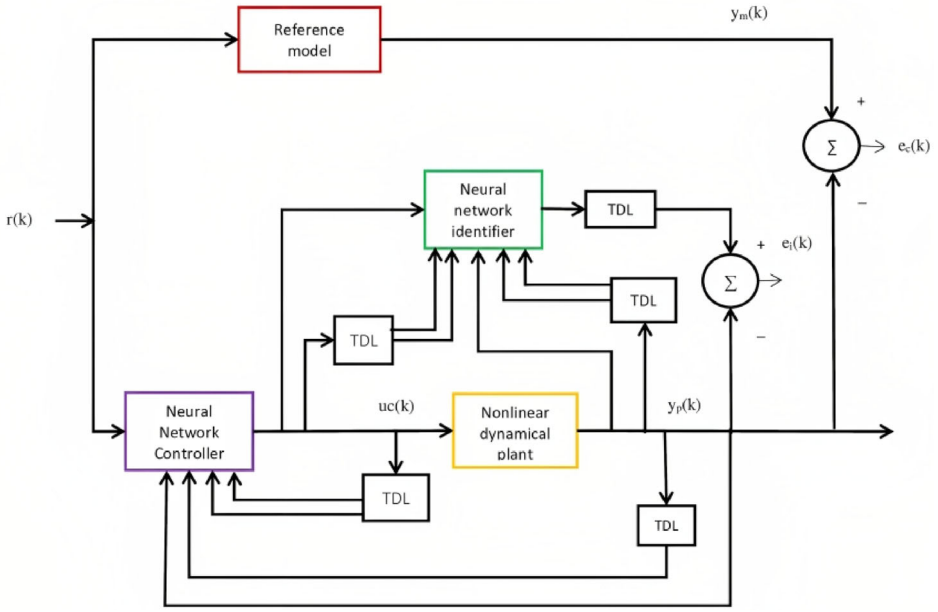

FIGURE 5 Indirect adaptive control scheme.

6 | PARAMETER OPTIMIZATION ALGORITHM

The backpropagation optimization approach is employed in this study to get the parameter update equations of the identifier and the controller.

$$E_c(k) = \frac{1}{2}e^2(k). \tag{14}$$

$$E_c(k) = \frac{1}{2}\left[y_p(k) - y_{\text{MERNN}}(k)\right]^2. \tag{15}$$

The weight update equation for each weight is obtained and described as follows:

$$w(k+1) = w(k) - \eta\frac{\partial E_c(k)}{\partial w(k)}. \tag{16}$$

Term η is known as the learning rate and lies between 0 and 1.

6.1 | Case 1: Weight update equations for identifier

The primary objective of the plant's training is to reduce identification error $e_i(k)$. The identifier's parameters between the input and hidden layer are defined by the input weight vector. The input weight vector is denoted as $W^I(k)$, consists of individual weights $w_1^I(k), w_2^I(k), \ldots w_j^I(k)$. The value of j represents the number of input nodes in the input layer. The input weight parameter update equation is described below by taking the partial derivative of an objective function $E_c(k)$ with respect to $w^I(k)$. At kth time instant, we have weight parameters: $w_1^I(k)$, $w_2^I(k)$, and $w_3^I(k)$. Each vector has three elements. $w_1^I(k)$ has elements $w_{11}^I(k)$, $w_{12}^I(k)$, and $w_{13}^I(k)$. $w_2^I(k)$ has elements $w_{21}^I(k)$, $w_{22}^I(k)$, and $w_{23}^I(k)$. $w_3^I(k)$ has elements $w_{31}^I(k)$, $w_{32}^I(k)$, and $w_{33}^I(k)$. We can write the weight update equations for all the elements of the input weight vector corresponding to input $x_j(k)$ by using Equation (16) as follows:

$$w_{11}^I(k+1) = w_{11}^I(k) - \eta\frac{\partial E_c(k)}{\partial w_{11}^I(k)}, \tag{17}$$

10991115, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/acs.3823 by Delhi Technological University, Wiley Online Library on [09/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

$$w_{12}^{I}(k+1) = w_{12}^{I}(k) - \eta \frac{\partial E_c(k)}{\partial w_{12}^{I}(k)}, \tag{18}$$

$$w_{13}^{I}(k+1) = w_{13}^{I}(k) - \eta \frac{\partial E_c(k)}{\partial w_{13}^{I}(k)}, \tag{19}$$

we can write the above equations as:

$$w_{jr}^{I}(k+1) = w_{jr}^{I}(k) - \eta \frac{\partial E_c(k)}{\partial w_{jr}^{I}(k)}. \tag{20}$$

The term $\frac{\partial E_c(k)}{\partial w_{jr}^{I}(k)}$ can be calculated as:

$$\frac{\partial E_c(k)}{\partial w_{jr}^{I}(k)} = \frac{\partial E_c(k)}{\partial y_{\mathrm{MERNN}}(k)} \times \frac{\partial y_{\mathrm{MERNN}}(k)}{\partial V_o(k)} \times \frac{\partial V_o(k)}{\partial S_r(k)} \times \frac{\partial S_r(k)}{\partial V_r(k)} \times \frac{\partial V_r(k)}{\partial w_{jr}^{I}(k)}, \tag{21}$$

$$where\ \frac{\partial E_c(k)}{\partial y_{\mathrm{MERNN}}(k)} = -e_i(k), \frac{\partial y_{\mathrm{MERNN}}(k)}{\partial V_o(k)} = 1, \frac{\partial V_o(k)}{\partial S_r(k)} = w_{qr}^{O}(k), \frac{\partial S_r(k)}{\partial V_r(k)} = \sum_{i=1}^{h}\left\{1 - S_i^2(k)\right\}\ and\ \frac{\partial V_r(k)}{\partial w_{jr}^{I}(k)} = x_j(k), \tag{22}$$

where $e_i(k)$ is the identification error. Now by using Equations (21) and (22)

$$\frac{\partial E_c(k)}{\partial w_{jr}^{I}(k)} = -e_i(k)\left\{w_{qr}^{O}(k)\right\}\left\{\sum_{i=1}^{h}\left\{1 - S_i^2(k)\right\}\right\}x_j(k), \tag{23}$$

$$w_{jr}^{I}(k+1) = w_{jr}^{I}(k) + \eta e_i(k)\left\{x_j(k)w_{qr}^{O}(k)\right\} \times \left\{\sum_{i=1}^{h}\left\{1 - S_i^2(k)\right\}\right\}, \tag{24}$$

similarly the weight update equations for weight parameter $w_{jr}^{C}(k)$ are obtained by using chain rule

$$\frac{\partial E_c(k)}{\partial w_{jr}^{C}(k)} = \frac{\partial E_c(k)}{\partial y_{\mathrm{MERNN}}(k)} \times \frac{\partial y_{\mathrm{MERNN}}(k)}{\partial V_o(k)} \times \frac{\partial V_o(k)}{\partial S_r(k)} \times \frac{\partial S_r(k)}{\partial V_r(k)} \times \frac{\partial V_r(k)}{\partial w_{jr}^{C}(k)}, \tag{25}$$

$$\frac{\partial E_c(k)}{\partial w_{jr}^{C}(k)} = -e_i(k)\left\{w_{qr}^{O}(k)\right\}\sum_{i=1}^{h}\left\{1 - S_i^2(k)\right\}S_i(k-1), \tag{26}$$

$$w_{jr}^{C}(k+1) = w_{jr}^{C}(k) + \eta e_i(k)w_{qr}^{O}(k)\left\{\sum_{i=1}^{h}\left\{1 - S_i^2(k)\right\}S_i(k-1)\right\}, \tag{27}$$

similarly the weight update equation for $w_{jr}^{B}(k)$ is:

$$\frac{\partial E_c(k)}{\partial w_{jr}^{B}(k)} = \frac{\partial E_c(k)}{\partial y_{\mathrm{MERNN}}(k)} \times \frac{\partial y_{\mathrm{MERNN}}(k)}{\partial V_o(k)} \times \frac{\partial V_o(k)}{\partial S_r(k)} \times \frac{\partial S_r(k)}{\partial V_r(k)} \times \frac{\partial V_r(k)}{\partial w_{jr}^{B}(k)}. \tag{28}$$

$$\frac{\partial E_c(k)}{\partial w_{jr}^{B}(k)} = -e_i(k)w_{qr}^{O}(k)\left\{\sum_{i=1}^{h}\left\{1 - S_i^2(k)\right\}\right\} \times y_{\mathrm{MERNN}}(k-1). \tag{29}$$

$$w_{jr}^{B}(k+1) = w_{jr}^{B}(k) + \eta e_i(k)w_{qr}^{O}(k)\left\{\sum_{i=1}^{h}\left\{1 - S_i^2(k)\right\}\right\} \times y_{\mathrm{MERNN}}(k-1). \tag{30}$$

The output parameter update equations are determined by using the chain rule

$$\frac{\partial E_c(k)}{\partial w_{qr}^{O}(k)} = \frac{\partial E_c(k)}{\partial y_{\mathrm{MERNN}}(k)} \times \frac{\partial y_{\mathrm{MERNN}}(k)}{\partial V_o(k)} \times \frac{\partial V_o(k)}{\partial w_{qr}^{O}(k)}, \tag{31}$$

10991115, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/acs.3823 by Delhi Technological University, Wiley Online Library on [09/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

$$\frac{\partial E_c(k)}{\partial w_{qr}^O(k)} = -e_i(k)\left\{\sum_{i=1}^{h} S_i(k)\right\}, \tag{32}$$

$$w_{qr}^O(k+1) = w_{qr}^O(k) + \eta e_i(k)\left\{\sum_{i=1}^{h} S_i(k)\right\}, \tag{33}$$

similarly, the weight update equation for $w_a(k)$ is given as:

$$\frac{\partial E_c(k)}{\partial w_a(k)} = \frac{\partial E_c(k)}{\partial y_{\text{MERNN}}(k)} \times \frac{\partial y_{\text{MERNN}}(k)}{\partial V_o(k)} \times \frac{\partial V_o(k)}{\partial w_a(k)}, \tag{34}$$

$$\frac{\partial E_c(k)}{\partial w_a(k)} = -e_i(k) y_{\text{MERNN}}(k), \tag{35}$$

$$w_a(k+1) = w_a(k) + \eta e_i(k)\{y_{\text{MERNN}}(k)\}, \tag{36}$$

similarly, the weight update equation for bias weight $w_b(k)$ can be written.

6.2 | Case 2: weight update equations for controller

Similarly, we can generalize the weight update equation for a controller. The parameter update equation for the input weight vector $W^I(k)$ can be calculated by using the partial derivative of an objective function $E_c(k)$ with respect to the weight vector $W^I(k) = \left\{w_1^I(k), w_2^I(k), \ldots w_j^I(k)\right\}$.

We can write weight update equations for the parameters $\left\{w_1^I(k), w_2^I(k), \ldots . w_j^I(k)\right\}$ corresponding to externally applied input $X_j(k) = \{x_1(k), x_2(k), \ldots x_m(k)\}$.

$$\frac{\partial E_c(k)}{\partial w_{jr}^I(k)} = \frac{\partial E_c(k)}{\partial y_p(k)} \times \frac{\partial y_p(k)}{\partial u_c(k)} \times \frac{\partial u_c(k)}{\partial S_r(k)} \times \frac{\partial S_r(k)}{\partial V_r(k)} \times \frac{\partial V_r(k)}{\partial w_{jr}^I(k)}. \tag{37}$$

The term $\frac{\partial y_p(k)}{\partial u_c(k)}$ is called sensitivity/jacobian of the plant and if the mathematical model of $y_p(k)$ is known, its value may be computed easily. If the plant's model is frequently unknown or just partially known then, we utilize neural network-based identifiers in parallel to the plant, and its configuration as well as the controller's parameters, are modified during online training. In that case as the training progresses, $\frac{\partial y_p(k)}{\partial u_c(k)} \approx \frac{\partial y_n(k)}{\partial u_c(k)}$, $y_n(k)$ is the identifier output. Then, the mathematical model of an identifier can approximate the dynamics of the nonlinear plant.

$$\text{where, } \frac{\partial E_c(k)}{\partial y_p(k)} = -e_c(k), \frac{\partial u_c(k)}{\partial S_r(k)} = w_{qr}^O(k), \frac{\partial S_r(k)}{\partial V_r(k)} = 1 - S_i^2(k), and \frac{\partial V_r(k)}{\partial w_{jr}^I(k)} = x_j(k), \tag{38}$$

where $e_c(k)$ is the control error. By using Equations (37) and (38) we can write

$$\frac{\partial E_c(k)}{\partial w_{jr}^I(k)} = -e_c(k)\frac{\partial y_p(k)}{\partial u_c(k)} w_{qr}^O(k) \times \left\{\sum_{i=1}^{h}\left\{1 - S_i^2(k)\right\}\right\} x_j(k), \tag{39}$$

by taking Equations (16) and (39)

$$w_{jr}^I(k+1) = w_{jr}^I(k) + \eta_c e_c(k)\frac{\partial y_p(k)}{\partial u_c(k)} w_{qr}^O(k)\left\{1 - S_i^2(k)\right\} x_j(k). \tag{40}$$

Similarly, the weight update equation for the output weight vector is determined as follows:

$$\frac{\partial E_c(k)}{\partial w_{qr}^O(k)} = \frac{\partial E_c(k)}{\partial y_p(k)} \times \frac{\partial y_p(k)}{\partial u_c(k)} \times \frac{\partial u_c(k)}{\partial w_{qr}^O(k)}. \tag{41}$$

10991115, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/acs.3823 by Delhi Technological University, Wiley Online Library on [09/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

$$\text{where,} \quad \frac{\partial E_c(k)}{\partial y_p(k)} = -e_c(k), \frac{\partial u_c(k)}{\partial w_{qr}^O(k)} = \left\{ \sum_{i=1}^{h} S_i(k) \right\}. \tag{42}$$

$$\frac{\partial E_c(k)}{\partial w_{qr}^O(k)} = -e_c(k) \frac{\partial y_p(k)}{\partial u_c(k)} \left\{ \sum_{i=1}^{h} S_i(k) \right\}. \tag{43}$$

Then,

$$w_{qr}^O(k+1) = w_{qr}^O(k) + \eta_c e_c(k) \frac{\partial y_p(k)}{\partial u_c(k)} \left\{ \sum_{i=1}^{h} S_i(k) \right\}. \tag{44}$$

7 | SIMULATION RESULTS

Two simulation examples are used to compare the performance of MERNN, ERNN, DRNN, JRNN, and feed-forward neural network (FFNN)-based controllers. Each controller contains only one hidden layer with three neurons. The initial learning rate in every example is assumed to be 0.00022.

7.1 | Example 1

Consider a nonlinear dynamical plant with dynamics defined by following the difference equation as given in Reference 17.

$$y_p(k+1) = \frac{y_p(k) y_p(k-1)[y_p(k)+2.5]}{1+y_p^2(k)+y_p^2(k-1)} + u_c(k), \tag{45}$$

where

$$F[y_p(k), y_p(k-1)] = \frac{y_p(k) y_p(k-1)[y_p(k)+2.5]}{1+y_p^2(k)+y_p^2(k-1)}, \tag{46}$$

$$r(k) = \sin\left(\frac{\pi k}{45}\right), \tag{47}$$

where $r(k)$ is the external input. The following difference equation describes the reference model.

$$y_m(k+1) = 0.6 y_m(k) + 0.2 y_m(k-1) + r(k). \tag{48}$$

The controller output error is as follows:

$$e_c(k+1) = y_m(k+1) - y_p(k+1). \tag{49}$$

The main aim of control is to determine the bounded input $u_c(k)$ by making $e_c(k+1) = 0$. Therefore,

$$y_m(k+1) = y_p(k+1). \tag{50}$$

$$y_m(k+1) = F[y_p(k), y_p(k-1)] + u_c(k). \tag{51}$$

$$u_c(k) = -F[y_p(k), y_p(k-1)] + 0.6 y_p(k) + 0.2 y_p(k-1) + r(k). \tag{52}$$

Using a neural network N, F can first be identified offline if it is unknown. Thus,

$$u_c(k) = -N[y_p(k), y_p(k-1)] + 0.6 y_p(k) + 0.2 y_p(k-1) + r(k). \tag{53}$$

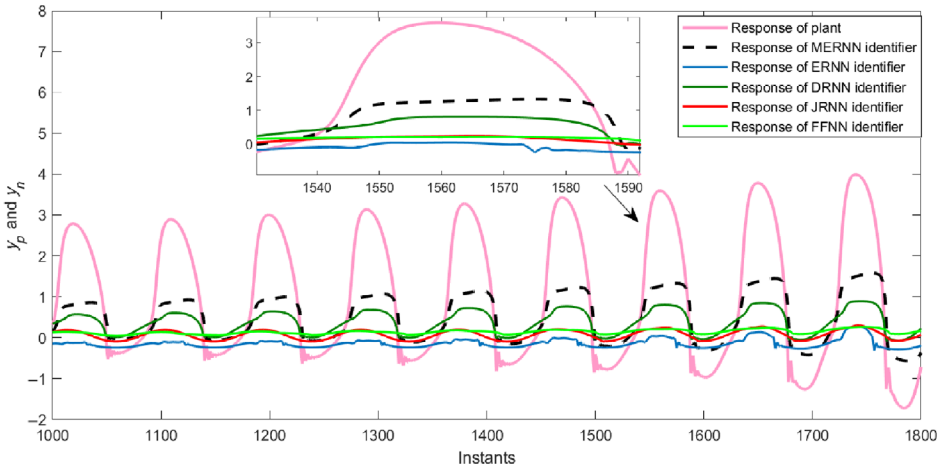

FIGURE 6 Identifier and plant output at the beginning of training [Example 1]

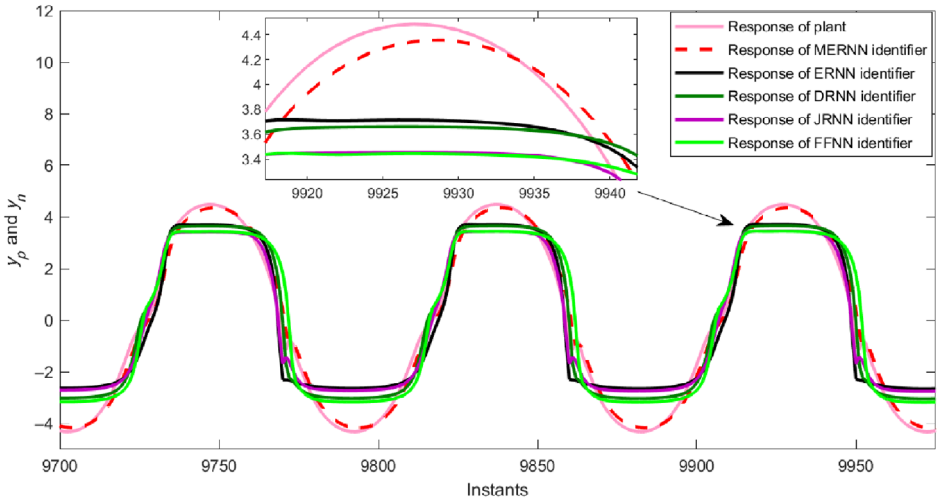

FIGURE 7 Identifier and plant output at the end of training [Example 1]

The nonlinear difference equation is

$$y_p(k+1) = F[y_p(k), y_p(k-1)] - N[[y_p(k), y_p(k-1)] + 0.6y_p(k) + 0.2y_p(k-1) + r(k). \tag{54}$$

In the given example the order of the plant is $n = 2$, which means there are $2n$ inputs to the controller. 0.00022 is the initial value of fixed learning rate η. The identifiers and plants' output at the beginning of training are shown in Figure 6. Their responses during the end phase of training are shown in Figure 7. Figure 8 shows both the controllers' response and the reference model's response at the beginning of training. In contrast, Figure 9 shows the reference model and controllers' responses at the final stage of training.

In example 1, Figures 10–14 show how parameter variation affects the output of MERNN, ERNN, DRNN, JRNN, and FFNN-based controllers. Table 1 shows the mean square error (MSE) comparison of identifiers and controllers. This comparison includes online training for the first nonlinear plant. The proposed MERNN model performs better than the ERNN, DRNN, JRNN, FFNN, and radial basis function network (RBFN) models. Table 2 compares the MSE of identifiers and controllers. It shows their MSE with online training for the second nonlinear plant. The proposed MERNN model performs better than the ERNN, DRNN, JRNN, FFNN, and RBFN models.

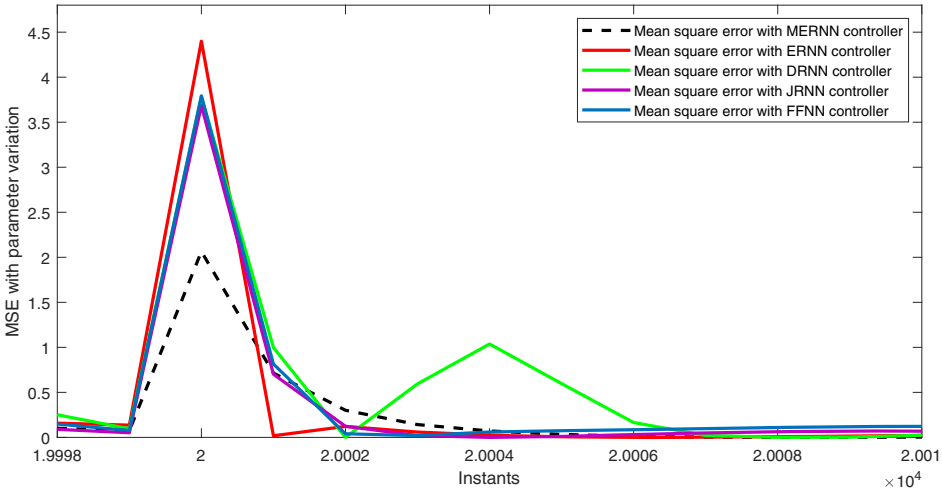

FIGURE 15 Mean squared error with parameter variation [Example 1].

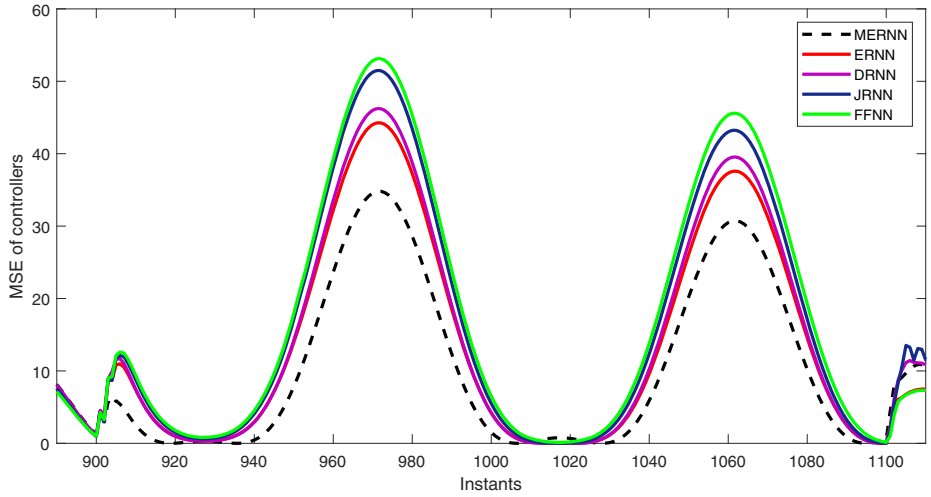

FIGURE 16 Mean squared error with disturbance signal [Example 1].

7.1.1 | Robustness testing

System robustness is defined as a system's ability to remain functioning under both uncertainties such as the disturbance signal and parameter variations. In this example, the robustness of all five controllers is analyzed and compared.

7.1.2 | Performance evaluation with parameter variation

In this case, at $k = 20{,}000$th time instant, a signal with a value of 2.5 units is applied to the controller's output to evaluate the effect of parameter variation. Figure 15 shows how parameter variation affects the MSE response of controllers. This figure shows that the increase in MSE in the proposed adaptive MERNN controller is minor at the time instant of parameter variation as compared to other controllers. MERNN-based controllers compensate for the growth in the MSE accordingly and restore it quickly to zero.

7.1.3 | Performance evaluation with disturbance signal

In the controller's output, a 1.8-unit disturbance signal is injected for values of k between 900 and 1100. The error would rise at this point; thus, if the controller is robust, this mistake must be compensated so that it can be reduced to zero

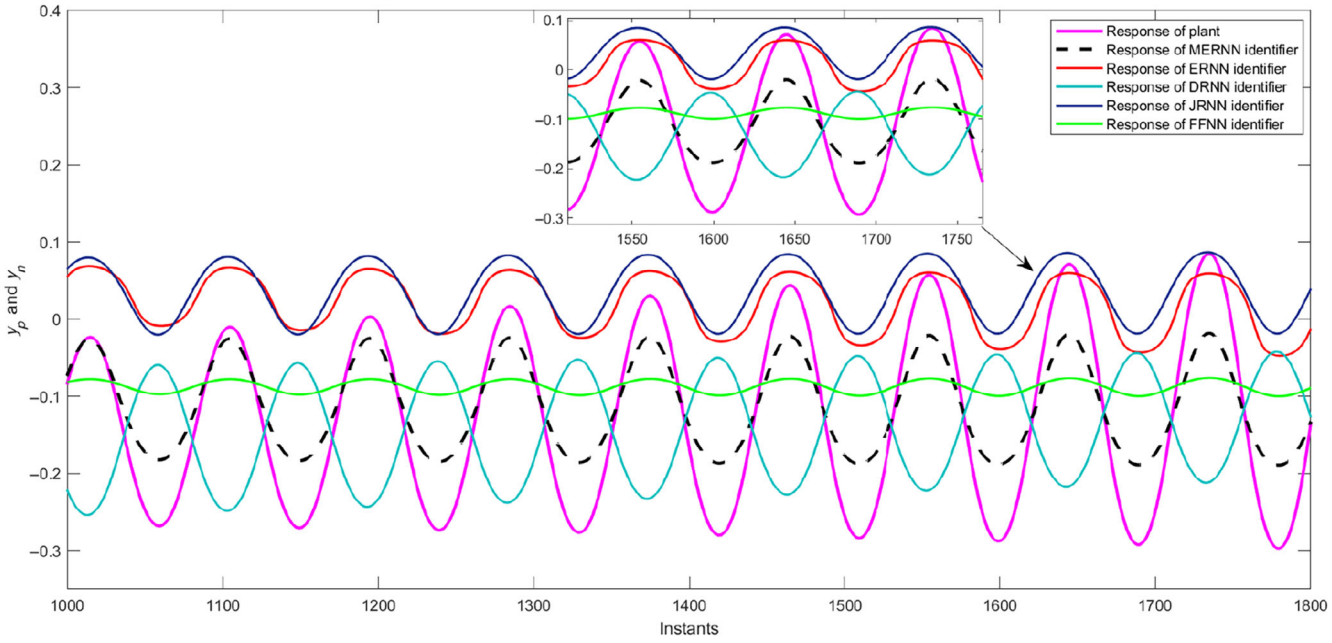

FIGURE 17 Identifier and plant output at the beginning of training [Example 2].

very quickly. Figure 16 demonstrates the instantaneous MSE plots of all the controllers affected by the disturbance signal. In comparison to the other controllers, this figure shows that the MERNN controller performs significantly better in adjusting for the impacts of the disturbance signal.

7.2 | Example 2

In this example, a nonlinear dynamical plant is considered whose dynamics are unknown, defined by the following difference equation as given in Reference 29.

$$y_p(k+1) = \frac{y_p(k)y_p(k-1)y_p(k-2)u_c(k-1)[y_p(k-2)-1]}{1+y_p^2(k-1)+y_p^2(k-2)} + \frac{u_c(k)}{1+y_p^2(k-1)+y_p^2(k-2)}, \tag{55}$$

$$r(k) = \sin\left(\frac{\pi k}{45}\right), \tag{56}$$

where $r(k)$ is the external input. The reference model equation is described as follows

$$y_m(k+1) = 0.08y_m(k) + 0.13y_m(k-1) + r(k). \tag{57}$$

If the output error $e_c(k+1)$ is defined as $e_c(k+1) = y_m(k+1) - y_p(k+1)$, the objective of control is to determine a bounded control input $u_c(k)$ by making $e_c(k+1) = 0$. In the case of a known function F, $u_c(k)$ is directly calculated based on $y_p(k)$, and its past values as $u_c(k)$.

$$u_c(k) = -F\left[y_p(k), y_p(k-1), y_p(k-2)\right] + 0.08y_p(k) + 0.13y_p(k-1) + r(k). \tag{58}$$

The function F is initially identified offline using neural network N if it is unknown. Therefore,

$$u_c(k) = -N\left[y_p(k), y_p(k-1), y_p(k-2)\right] + 0.08y_p(k) + 0.13y_p(k-1) + r(k). \tag{59}$$

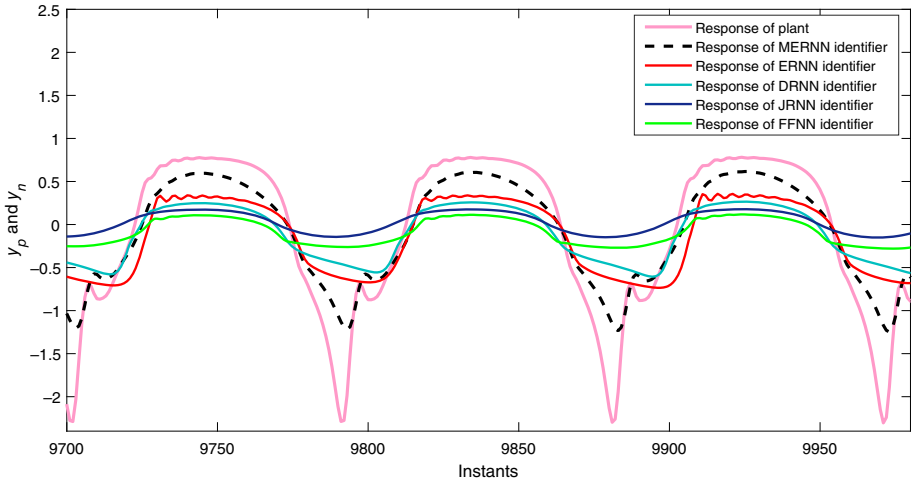

FIGURE 18 Identifier and plant output at the end of training [Example 2].

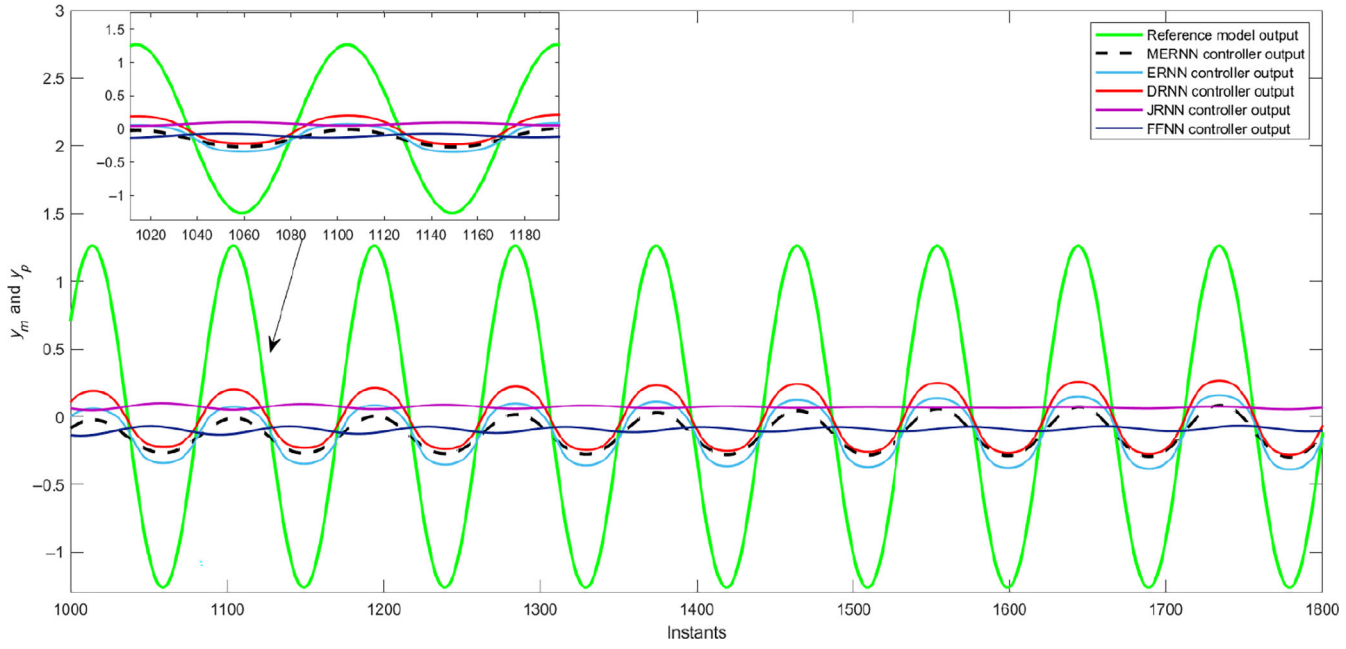

FIGURE 19 Controller and reference model output at the beginning of training [Example 2].

Then, the result of the nonlinear difference equation

$$y_p(k+1) = F\left[y_p(k), y_p(k-1), y_p(k-2)\right] - N[y_p(k), y_p(k-1), y_p(k-2)] + 0.08y_p(k) + 0.13y_p(k-1) + r(k). \quad (60)$$

Figure 17 shows the response of different identifiers. These include MERNN, ERNN, DRNN, JRNN, and FFNN with a nonlinear plant at the start of training. Whereas Figure 18 shows its response at the end of training. Figure 19 shows the NN-based controllers' response and the reference model's response at the start of controller training. Figure 20 shows the same at the end of training.

Figures 21–25 show how parameter variation affects the output of MERNN, ERNN, DRNN, JRNN, and FFNN-based controllers.

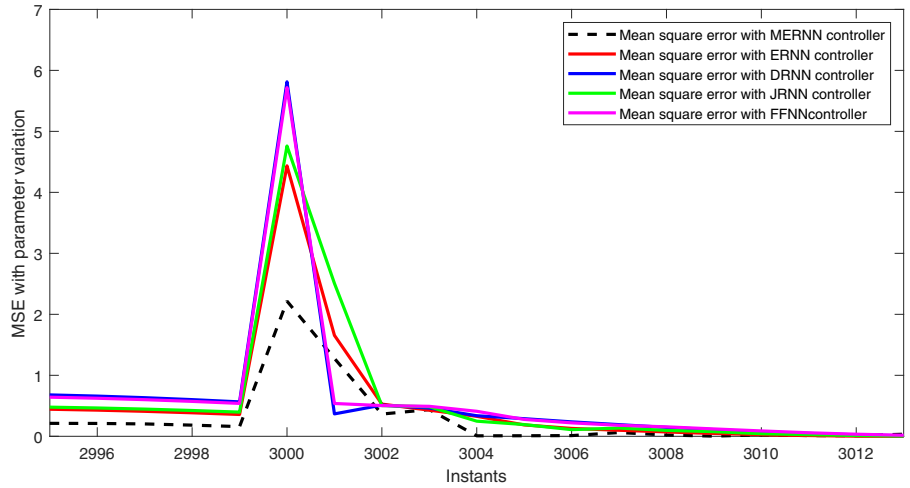

FIGURE 26 Mean square error with parameter variation [Example 2].

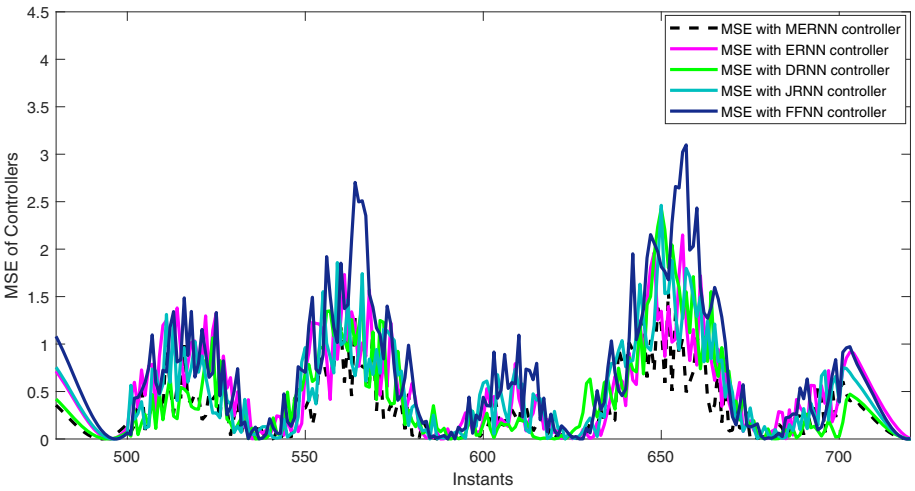

FIGURE 27 Mean square error with disturbance signal [Example 2].

7.2.1 | Performance evaluation with parameter variation

When a signal of magnitude 4.5 is applied to a controller, its performance is evaluated at the 3000th time instant. Figure 26 shows the rise in the MSE response of the controllers due to parameter variation. In this figure, the reaction of the MERNN controller shows a lesser amount of variation in comparison to the other controllers.

7.2.2 | Performance evaluation with disturbance signal

In the above example, a 1.5-unit disturbance signal is added to the controller output for k values ranging from 500 to 700. Figure 27 shows the response of instantaneous MSE of the controllers affected by the disturbance signal. From this figure, it can be noticed that the MSE response with the MERNN controller recovered more rapidly than the other controllers.

8 | CONCLUSION

This research presents a comparative study of different NN models for the identification and adaptive control of nonlinear dynamical systems. In this study, two simulation examples reveal that the identification and control of nonlinear systems

10991115, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/acs.3823 by Delhi Technological University, Wiley Online Library on [09/05/2024]. are very effective using the suggested methods. If the system dynamics are unknown, the control strategy suggested in this study is also effective. The back-propagation optimization method is applied for the training of adjustable parameters online. The performance analysis of MERNN as a controller is compared to that of ERNN, DRNN, JRNN, FNNN, and RBFN-based controllers for controlling dynamical systems and for compensating the effect of uncertainties like parameter variation and disturbance signal. According to the results, the MERNN model as an identifier and controller has the lowest mean square error and is superior to the others.

Abstract

In the last few years, urban trees have emerged as an effective nature-based solution to mitigate increasing air pollutant levels due to urbanization and industrialization. This study aims to assess the synergistic effect of urban trees on improving air quality by combining real-time $PM_{2.5}$ monitoring with the i-Tree Eco model. The monitoring was conducted during rush hours with high traffic volume and during non-rush hours, in both the tree alley and a non-tree road section within the industrial areas of the north-west region of the National Capital Territory of Delhi, India. The i-Tree Eco model was run using the diameter at breast height values of tree species present in the study area, and the $PM_{2.5}$ reduction ability of the trees was quantified. The results from both approaches indicated that urban trees can significantly reduce the traffic-fed $PM_{2.5}$ concentrations. Therefore, it is suggested that tree plantations be integrated into air pollution management strategies in urbanized regions with high traffic volumes. Although this study explores the initial link between trees and air quality in Delhi, further research incorporating local wind speed and direction measurements would provide a more comprehensive understanding of how trees influence air quality in any highly polluted urban setting.

KEYWORDS
nature-based solution, particulate matter, sustainable development goals, urban trees, vehicular emissions

1 | INTRODUCTION

Air pollution is a pressing global issue, with ≈4.2 million deaths attributed to it annually.[1] This hazard not only results in poor air quality but also elevates the risk of severe cardiovascular and respiratory disorders.[2–4] Moreover, it contributes to developing and worsening diabetes, mutagenicity, immunity, and other lifestyle-related disorders.[5–7] Beyond health concerns, poor air quality adversely affects urban wildlife, the environment, and the economy.[8] The air quality deterioration is primarily attributed to rapid urbanization, intensified industrial activities, high vehicular traffic volume, and increased population density. Elevating particulate matter (PM) emissions play a major role in the deterioration of air quality and represent a major concern in urban areas, with concentrations surging over the last decade, especially in Asia.[9] India, a South Asian country identified as one of the top five most polluted countries, particularly highlights the severity of this issue, with its megacity Delhi consistently ranking among the world's most polluted regions and recording high concentrations of $PM_{2.5}$ throughout the year.[4,10,11] Many studies have attributed these high concentrations of $PM_{2.5}$ in Delhi to vehicular emissions.[4,12] Winter conditions, including cool temperatures, shallow boundary layer heights, and frequent temperature inversions, contribute to a further escalation of already increased $PM_{2.5}$ levels by trapping pollutants within the boundary layer.[13] This

 © 2024 Wiley-VCH GmbH

necessitates potential solutions to mitigate air pollution, especially in rapidly urbanizing cities like Delhi.

Urban vegetation, comprising indoor plants, avenue trees, parks, green walls, green roofs, and other green systems, has emerged as an effective nature-based solution (NbS) to mitigate air pollution in urban areas.[14–16] It demonstrates enhanced efficiency in absorbing and catabolizing airborne pollutants compared to artificial surfaces while concurrently maintaining optimal urban environmental conditions.[17] It reduces $PM_{2.5}$ levels in the atmosphere through different mechanisms, such as deposition, dispersion, and modification. Deposition involves the 1D vertical settlement of pollutants on a uniform layer of vegetation,[18] dispersion leads to the alteration of the path and velocity of PM through the physical structure of urban trees,[19] and modification refers to the group of mechanisms which can alter of the actual properties of PM, like its size, which diminishes its adverse impacts.[20] The quantification of the reduction in $PM_{2.5}$ concentration through its dry deposition on urban vegetation is a widely studied mechanism.[20] The efficiency of trees in depositing $PM_{2.5}$ varies based on their morphology and meteorological factors such as wind speed.[21,22] A decrease in wind speed tends to increase the pollutant load owing to the poor ventilation ability and trapping effect at the leeward wall when the wind direction is perpendicular.[23,24] The intensity of this phenomenon depends on the wind direction, aspect ratio, number, distribution, and species of trees, as well as the density and porosity of vegetation. Moreover, this trapping effect mostly intensifies during winter.[25] Because of these highly varied micrometeorological conditions at the street level, it can be challenging to accurately quantify the air purification effect of urban trees. Thus, numerous studies have employed a combination of field investigations, wind tunnel studies, and numerical models to assess the influence of urban vegetation on wind flow patterns and pollution concentrations, demonstrating the potential of trees to filter out air pollutants at different locations.[26] For example, Riondato et al.[27] conducted air monitoring at vegetated and non-vegetated sites and found that the mean $PM_{2.5}$ concentration in the vegetative areas was almost half of that in the non-vegetated sites. Similarly, Zhu et al.[28] observed a 48% difference in $PM_{2.5}$ concentration in an urban park when compared to a nearby street with no vegetation in Wuhan.

The i-Tree Eco model, a user-friendly variant of the urban forest effects model, has been employed in various studies to quantify pollutants trapped by vegetation through dry deposition.[29] This model evaluates urban forest characteristics, such as species composition, leaf area, and tree health, to quantify the ecosystem services rendered by those trees. By utilizing the i-Tree Eco model's dry-deposition component, the pollution removal by trees during nonprecipitation periods and the hourly enhancements in air quality over a year can be estimated. The i-Tree Eco model can estimate pollutant removal by urban trees based on the wind tunnel parameters. It considers the urban forest as a leaf and estimates the $PM_{2.5}$ reduction across the boundary layer.[24] Several researchers worldwide have used this model to quantify the impact of trees on reducing air pollution.[30–34] However, the results obtained by the model require validation from field observations that employ high-accuracy $PM_{2.5}$ monitoring devices in multiple locations to provide high-resolution data on $PM_{2.5}$ mitigation through vegetation. For example, Su et al.[24] utilized an integrated model and mobile monitoring-based approach to quantify $PM_{2.5}$ mitigation at two different parks, one with dense vegetation and the other regarded as an open park, during the rush and non-rush hours, to calculate the PM removal. The results indicated that the park with a dense forest had a stable and stronger ability to improve air quality than open parks. The application of this integrated approach to assess the potential of urban vegetation in improving air quality remains unexplored in South Asian countries. Given the pressing environmental challenges faced by nations like India, particularly in cities like Delhi, with their poor air quality and high mortality rates, there is a critical need for NbS for air quality management, coupled with effective urban planning strategies. Therefore, the present study utilizes this approach of integrating mobile air monitoring with air quality modeling to assess the $PM_{2.5}$ deposition ability of urban vegetation in the industrial areas of the north-west district of Delhi, India, to: (a) assess the impact of urban vegetation on reducing PM levels in diverse urban settings: a tree alley (TA) and non-tree section (NTS) at different time periods, (b) evaluate the efficacy of urban trees in the reduction of air pollutants during both peak rush and non-rush hours, and (c) compare the results obtained from i-Tree Eco and those obtained from air quality monitoring. The results obtained from this study can help establish the crucial role of urban trees in mitigating both traffic-associated and background air pollution, thereby enhancing air quality within urban street canyons. Moreover, this research can serve as a baseline for emerging researchers and urban planners to conduct further research on air pollution mitigation through urban vegetation, particularly in highly polluted regions of South Asian countries.

2 | MATERIALS AND METHODS

2.1 | Site description

The urban-industrial areas investigated in this study are located in the north-west region of the National Capital Territory (NCT) of Delhi, which spans a geographical area of 1483 km^2 (28° 37′ N, 77° 12′ E). As the world's second most populous city, with 29 million population in 2018,[35] the NCT of Delhi experiences subtropical climatic conditions characterized by five well-defined seasons: winter (December–January), spring (February–March), summer (April–June), monsoon (July–September), and autumn (October–November). The weather conditions in this region feature hot summers and cold winters, with an average rainfall of 581 mm. Most of this rainfall (≈81%) occurs in July, August, and September, and the daily temperatures fluctuate between 5°C in winter and 45°C in summer.[36]

The air quality in Delhi undergoes notable fluctuations throughout the year, often surpassing the national ambient air quality standard value of 60 μg m^{-3} for 24-h mean $PM_{2.5}$ concentration. A notable spike is observed in the concentrations of $PM_{2.5}$, particularly during the winter season. This is primarily attributed to high pollutant build-up in winter due to weather conditions of a calm atmosphere, lower

18630669, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/clen.202300198 by Delhi Technological University, Wiley Online Library on [09/05/2024]. FIGURE 1 Reference map of the study areas used for the present analysis.

mixing heights due to colder temperatures, and temperature inversion that prevents the dispersion of pollutants.[37] The boundary layer is also the lowest in December, leading to the trapping of pollutants and a drastic increase in concentrations.[38] Additionally, annual Diwali celebrations involving fireworks further contribute to elevated $PM_{2.5}$ concentrations.[39] Consequently, the real-time monitoring study was conducted in December, when the most adverse air quality conditions prevailed.

The Central Pollution Control Board (CPCB) has categorized different areas of Delhi based on land use, including residential, commercial, and industrial areas. The primary sources of $PM_{2.5}$ in Delhi are vehicular emissions, construction progressions and suspended dust emissions, biomass burning, power plants, and industries.[40] The industrial areas of NCT of Delhi are hotspots of air pollutants owing to extensive industrial activities, heavy vehicular rush, commercial operations, petrol and diesel emissions, auto repair, natural gas combustion, combustion engines, and sewage sludge.[41] For this study, five different industrial areas were selected: Badli, Mangolpuri, Wazirpur, Jahangirpuri, and Lawrence-road industrial area (Figure 1). These areas were selected based on their vegetation, meteorological conditions, and anthropogenic activities. The TA and NTS chosen in each of the five industrial areas had similar characteristics. The road type chosen in each of the five areas was a street canyon, which comprised rows of buildings along both sides of the road. Two monitoring stations were set up at each site: one in the TA and the other in the NTS. Therefore, a total of 10 monitoring stations were set up for the present study. As these areas were established under proper strategic planning, vast vegetation was found with major patches of various plant species along the roadside and in various urban parks. Additionally, these five subsets of the Delhi industrial area mostly had common tree species with similar characteristics; therefore, their data sets, including the characteristics of trees, such as diameter at breast height (DBH), were pooled to obtain the final results.

These industrial areas were selected for air monitoring for several reasons:

a. Each of the streets selected for monitoring had a section with no planted trees. The other part had a TA with regularly distributed large and old trees along the road. Therefore, the presence of trees in one part of the road and their absence in another helped to compare the two sections.
b. Most trees in the five locations were planted on public property, ensuring that data for DBH for most of the local trees was measured and fed into the model.

c. Each of the streets received reasonably heavy vehicular traffic, contributing to a higher concentration of $PM_{2.5}$, owing to combustion from their engines.[42] As the rate of pollutant deposition is proportional to their concentrations,[43] the impact of trees on air quality was more evident and significant in areas with poor air quality.

2.2 | Data collection

In the present study, pollution levels were recorded using air quality detector sensors (Xiaomi Smart mi $PM_{2.5}$). These sensors feature a three-color digital indicator with a high-precision laser-sensing system and accurately detects $PM_{2.5}$. Their large screen features enlarged numbers, which make it easy to read. Furthermore, its mini-body is convenient to carry at the monitoring site and can be powered by a USB cable. The air quality monitoring was conducted for 5 days in December 2021 at 10 monitoring sites (two sites comprising a TA and NTS in each industrial area) simultaneously. The monitors were run simultaneously for ≈60–120 min during rush and low-traffic hours at each site. A total of 1070 $PM_{2.5}$ values were recorded from each area, comprising values from both the TA and NTS. The values were recorded for 5 days from 8:00 to 10:00 a.m. and 2:00 to 7:00 p.m. Data from 5:00 to 7:00 p.m. was considered to be the time when traffic intensity was at its maximum on the road and thus has been referred to as the rush hour time period. Notably, Murthy et al.[44] found that $PM_{2.5}$ concentrations in the NCT of Delhi exhibit diurnal variation, with minimum levels occurring during mid-afternoon due to increased mixing caused by solar radiation. However, the concentrations elevate during the evening hours and remain high at night. Subsequently, the data from 8:00 to 11:00 a.m. and 1:00 to 5:00 p.m. was considered to be the hours when traffic volume was relatively low and thus have been referred to as a non-rush hour time period. The readings were recorded at 5-min intervals. It was observed that during rush hours, the predominant cause of air pollution stemmed from the increased traffic volume, whereas during non-rush hours, air pollution predominantly reflected the background concentration of the areas. The monitoring was thus carried out during these two periods to investigate urban vegetation's potential in mitigating traffic-fed air pollution and background pollution. Other studies focusing on $PM_{2.5}$ concentrations in Delhi have also considered the same time period of the day for rush and non-rush hours.[39,45] Moreover, during monitoring, the observations at all sites confirmed the duration of the peak traffic hours. Preparatory monitoring was also conducted to ensure that the concentration of air pollutants was low during non-rush hours; therefore, maximum monitoring was performed during rush hours only. The five $PM_{2.5}$ values recorded in the TA (one from each site) were later averaged to obtain a single value of $PM_{2.5}$ concentration in TA for that time of the day across the five monitoring sites. The same exercise was repeated to obtain a single numerical value for $PM_{2.5}$ in the NTS for that time of the day across the five monitoring sites. The concentrations of $PM_{2.5}$ were recorded at almost the midpoint of the TA and NTS at each monitoring site. Therefore, the monitors were placed to represent the $PM_{2.5}$ concentrations in both sections of the roads, TA and NTS.

For the i-Tree Eco model calculations, individual tree species were identified and marked at each monitoring site. The values of the circumference at the base height of the 38 most common tree species across all five sites in the TA were measured using a measuring tape, which was then converted to corresponding DBH values. Subsequently, the DBH values for the same tree species were averaged to a single value. This averaging process was undertaken because the DBH values for the same tree species were consistently similar, attributable to factors such as similar tree height and age, and exposure to similar anthropogenic activities such as industrial practices and heavy vehicular traffic. This procedure was followed for all the species. Finally, 38 distinct DBH values corresponding to 38 tree species were then used as input for the i-Tree Eco model, ensuring a representative assessment of urban vegetation's impact on air quality in the industrial areas of Delhi.

2.3 | i-Tree Eco model setup

The data collection process in the study area was conducted based on the guidelines provided in the i-Tree Eco user's manual.[46] When setting up the model, the user is required to specify whether the tree data is being randomly sampled or the inventory of all trees in the study area has been completed. In the present study, all tree species in the TA were identified and recorded, along with the number of individuals of each species. The minimum requirements for running the model are entering the name of the species and the values of their DBH. The model has the option to enter additional fields such as tree address, GPS coordinates, crown height, and crown health. For this study, only the name and DBH of each tree species were entered into the model. For Delhi, the model has pre-saved air quality and weather data from two meteorological stations, namely, IGI airport monitoring station, ID: 421810-99999 (latitude, longitude: 28.56, 77.10) and Safdarjung monitoring station, ID: 421820-99999 (latitude, longitude: 28.58, 77.20). The Safdarjung monitoring station was selected as it was closer to the industrial areas of Delhi. The model was run after selecting the monitoring station and entering the names of the tree species and their DBH.

2.4 | i-Tree calculations

The i-Tree Eco model uses the following formulas to calculate the air quality improvement:[47]

Total air pollutant mass per unit tree cover is calculated as

$$M_{total} = H\,C, \tag{1}$$

where M_{total} is the total air pollutant mass per unit tree cover ($g^{-2}\,h^{-1}$), H is the urban mixing height (m), and C is the air pollutant concentration ($g^{-3}\,h^{-1}$).

The hourly improvement in air quality per unit of tree cover resulting from the dry deposition of air pollutants is further calculated

18630669, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/clen.202300198 by Delhi Technological University, Wiley Online Library on [09/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

employing M_{total} in the subsequent steps:

$$I_{unit}\,(\%) = (F/F + M_{total}) \times 100, \quad (2)$$

where F is the pollutant flux ($g^{-2}\ h^{-1}$).

Now, if the net flux is negative for $PM_{2.5}$, then

$$I_{unit} = (F/M_{total}) \times 100. \quad (3)$$

Hourly augmentation of air quality resulting from total tree cover is computed as

$$I_{total} = \{[(F\,F_c)/100\,]/[\,(F\,F_c)/100 + M_{total}]\} \times 100, \quad (4)$$

where T_c is the total tree cover in the city (%).

If $F = M_{total}$ and $T_c = 100$ for $PM_{2.5}$, the denominator in the equation will become 0, and I_{total} will become infinity.

This is avoided by using the following equation:

$$I_{total} = (I_{unit}\,T_c)/100. \quad (5)$$

3 | RESULTS

3.1 | Variation of $PM_{2.5}$ between TA and NTS

The real-time air monitoring was carried out in the winter season in December because the characteristics of the winter season are different from other seasons due to the phenomenon of temperature inversion and low mixing height, which resulted in significantly higher pollutant accumulation in this month.[48,49] The findings of the present study demonstrated the reductive effect of urban vegetation on $PM_{2.5}$. The real-time measurement data from NTS and TA was collected from 10 monitoring sites to investigate the concentration of $PM_{2.5}$ particles. From each monitoring site, 532 sample points from the NTS and 538 from TA were recorded concurrently at 5 min intervals over 5 days in December 2021. There were a few occasions when $PM_{2.5}$ concentrations were not recorded due to instrument error. During the data analysis, it was assumed that minor differences in meteorological conditions near the monitoring sites would not significantly affect $PM_{2.5}$. The $PM_{2.5}$ values from each monitoring site were then averaged to obtain the final values analyzed in this study. The concentrations of $PM_{2.5}$ were more than 60 μg m^{-3} for 93.42% of the total sample points in NTS and 93% of the total sample points in TA. Furthermore, during rush hours with high traffic volume, $PM_{2.5}$ values were >60 μg m^{-3} for 97.86% of the sample points in NTS and 92% of the total sample points in TA. Additionally, the average daily mean concentrations of $PM_{2.5}$ in Delhi exceeded the threshold limit of 25 μg m^{-3} set by WHO for all the sample points at all times.

Table 1 presents the number of individual sample points where the $PM_{2.5}$ concentrations exceeded specific thresholds: 50, 60, 100, and 150 μg m^{-3} recorded across both rush and non-rush hours, whereas Table 2 reports the individual sample points where the $PM_{2.5}$ concentrations exceeded the same $PM_{2.5}$ values during rush hours (5:00–7:00 p.m.). The 50 μg m^{-3} threshold represents a moderately elevated level of $PM_{2.5}$ in a city like Delhi. The 60 μg m^{-3} threshold aligns with the ambient air quality standard for 24-h average concentration of $PM_{2.5}$ established by CPCB in India. This regulatory standard is crucial in air quality management and is used globally as a benchmark for evaluating air pollution. Additionally, thresholds of 100 and 150 μg m^{-3} signify hazardous air quality which can lead to increased respiratory and cardiovascular risks. These elevated $PM_{2.5}$ levels are mostly prevalent during winter in Delhi, primarily due to atmospheric inversions, high traffic activity, and industrial emissions occurring concurrently. The $PM_{2.5}$ concentrations for TA ranged between 42 and 221 μg m^{-3}, whereas that for NTS ranged between 37 and 267 μg m^{-3}. Air quality was comparatively better in TA than in NTS during all hours of monitoring. The majority of the values in the NTS and TA surpassed 100 μg m^{-3}. $PM_{2.5}$ values exceeding 150 μg m^{-3} were twice as frequent in the NTS than in the TA, providing evidence for the air-purifying capabilities of urban vegetation through the higher incidence of pollutant concentrations surpassing air quality thresholds. Similar results were shown by Wu et al.[50] who suggested that the fluctuation in the distribution of urban vegetation within a region can significantly influence the quantification of total pollution removal capacity and the removal rate using a dry deposition model. Another study by Jeong et al.[19] based on practical guidelines for managing urban vegetation suggested that multi-planting street trees and central reserves have more substantial PM reduction effects and provide health benefits.

3.2 | Statistical analysis

The $PM_{2.5}$ concentrations were analyzed using the Shapiro–Wilk test, which depicted that the values were not distributed normally ($p < 0.05$). The $PM_{2.5}$ concentrations from NTS and TA were visualized using histograms, indicating that both data sets were left-skewed (Figure 2). Consequently, both distribution sets were analyzed using a nonparametric Mann–Whitney U test. The test showed that both distribution sets differed significantly ($W = 105\,211$, $p < 0.05$). The average $PM_{2.5}$ concentration at NTS was 140.05 μg m^{-3} compared to 117.34 μg m^{-3} at TA. The $PM_{2.5}$ values were high between 9:00 and 10:00 a.m., then started to decrease around 1:00 pm, and then again started to increase to the maximum levels around 5:00–7:00 p.m.

The average $PM_{2.5}$ values during hours with high traffic intensity, that is, rush hours, were 176.23 μg m^{-3} in NTS and 118.79 μg m^{-3} in TA, whereas, during non-rush hours, the average values were 122.01 μg m^{-3} in NTS and 116.63 μg m^{-3} in TA. Figure 3 depicts the average $PM_{2.5}$ concentrations in NTS and TA during rush hours. Furthermore, during rush hours, the average difference between $PM_{2.5}$ values of TA and NTS was ≈52.89 and 75.46 μg m^{-3} at 5:00 and 6:00 p.m., respectively. This translated to an increase in the air quality of 59.52% at 5:00 p.m. and 73.23% at 6:00 p.m. in the TA as compared to the NTS. Additionally, the NTS had consistently higher $PM_{2.5}$ concentrations than TA. A trendline for each data set was plotted, which

depicted an upward increase in the concentrations over time. The average difference between the two locations during rush hours was 44.59, 52.89, and 75.46 μg m^{-3} at 10:00 a.m., 5:00 p.m., and 7:00 p.m., respectively, which rendered an improvement of 27.11%, 59.52%, and 73.23% of air quality in the TA as compared to the concentrations in NTS. The average $PM_{2.5}$ values, unit, and percent difference in concentrations between NTS and TA are recorded in Table 3. The cumulative distribution function was plotted for $PM_{2.5}$ values at all times and is represented in Figure 4.

3.3 | i- Tree Eco model findings

The vegetation growing in the TA of the selected industrial areas was highly diverse in terms of morphological and physiological characteristics. The DBH of 38 commonly grown tree species was calculated after measuring the circumference at base height and fed in the i-Tree Eco model. The values of DBH ranged from 12.95 to 114.04 cm, with an average diameter of 46.22 cm. Based on the input values of DBH, the model predicted the amount of average monthly removal of $PM_{2.5}$ by vegetation in the study area (Figure 5). The results indicated that the minimum $PM_{2.5}$ removal was observed in February, which coincided with the defoliation period and consequently explains that the dry deposition model calculates the PM removal rate by both pollution concentration and leaf area index values. The maximum $PM_{2.5}$ removal took place in May, which is the full-leaf period. By utilizing the meteorological and air quality database of the i-Tree Eco from 2018, the model calculated that the vegetation of the TA was responsible for an hourly air quality improvement of 2.5% for $PM_{2.5}$ in each site (Figure 6). Moreover, the results from the model also suggested that trees can influence air quality both in negative and positive ways, as during high wind speed, the resuspension of $PM_{2.5}$ into the atmosphere can worsen the air quality.[24] However, as the wind speed in the study areas was between 0.8 and 3 m s^{-1} during monitoring in December 2021,[51] there was negligible PM resuspension, leading to lower PM concentrations during rush hours in TA.

4 | DISCUSSION

The present study combined mobile air monitoring with a model-based approach to assess the impacts of urban trees on air quality. It aimed to investigate the air filtering efficiency of vegetation in varying temporal scales and provide a more holistic assessment of the relationship between vegetation and air quality dynamics. The first method involved monitoring $PM_{2.5}$ concentrations for 5 days in December at different industrial areas of Delhi to elucidate an immediate variation in air quality due to localized factors, such as vehicular emissions and high atmospheric inversion conditions. This approach provided granularity and detailed observations about potential fluctuations in

the $PM_{2.5}$ levels influenced by the urban vegetation and the immediate effects of meteorological conditions. Conversely, the model-based approach provided the yearly trend of $PM_{2.5}$ mitigation by urban trees. This annual approach offered insights into the cumulative effects of vegetation on air quality, considering seasonal variations, changes in vegetation cover, and potential fluctuations in pollutant concentration over different seasons and environmental conditions. By employing both short- and long-term assessments, the study aimed to present a comprehensive understanding of the relationship between vegetation and air quality.

Based on the number of times the concentrations of pollutants exceeded certain air quality thresholds, the air-ameliorating properties of urban vegetation were apparent in the present study. The observed concentrations of $PM_{2.5}$ during non-rush hours were nearly the same between NTS and TA, fluctuating around 119 µg m^{-3}. These relatively similar values of $PM_{2.5}$ might represent the background pollution levels. Background concentrations occur due to contributions from all upwind source areas rather than any single source.[52] Knowledge about the concentration of background pollution can help determine a new source of pollution in an area.[53] An increase in $PM_{2.5}$ concentrations above the background levels may be due to high vehicular emissions in the monitoring locations. During rush hours, there was a sharp increase in the average $PM_{2.5}$ concentrations in both the monitoring locations, with the average concentration in TA being ≈18% less than that in NTS. Similar results have been obtained in several studies that compared the average $PM_{2.5}$ concentrations in the TA and non-tree road sections. For instance, Ozdemir et al.[54] showed that roadside $PM_{2.5}$ concentrations in Istanbul, Turkey, were significantly

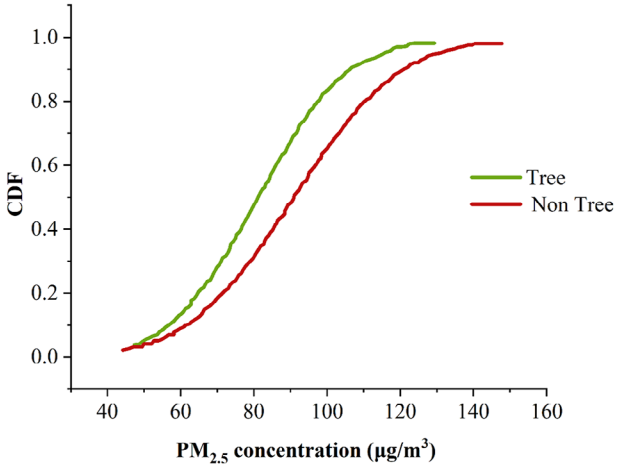

FIGURE 4 Cumulative distribution function (CDF) for $PM_{2.5}$ concentrations.

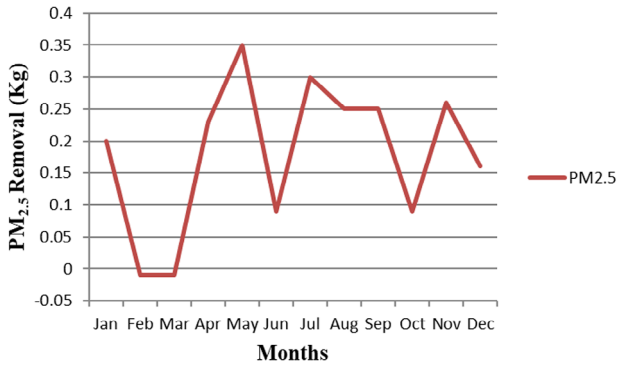

FIGURE 5 Average monthly removal of $PM_{2.5}$ by vegetation in industrial areas National Capital Territory (NCT) of Delhi.

lower in road sections with thick trees and no gaps than in road sections with no trees.

The results from i-Tree Eco revealed lower $PM_{2.5}$ removal during February and March, aligning with Delhi's defoliation period. This highlights the crucial role of leaves and their traits in pollutant removal. According to a study by Corada et al.,[55] leaf characteristics, mainly macrostructures (leaf area index and leaf area density) and microstructure (leaf shape, rigidity, and surface traits like wax and trichomes), impact PM removal. The epicuticular layer of leaves also plays a significant role by absorbing PM, with its effectiveness influenced by structure and composition. Leaves with rough surfaces retain more PM, and small leaves with complex structures and large, dense stomata efficiently accumulate PM as shown in studies by Song et al.,[56] Vashist and Singh,[57] and Chen et al.[58] The results from the model could have also been influenced by the wind speed and direction at the time of monitoring. Based on meteorological data from the DPCC website, the average daily wind speeds in the study areas ranged from 0.8 to 3 m s^{-1}, blowing in a west to north-west direction during December 2021.[48,51] A study by Nowak et al.[59] stated that around 4.5% of PM is resuspended at a wind speed of 3 m s^{-1}, which increases to ≈12% at a wind speed of 9 m s^{-1}. Although the mitigation ability of trees would have been altered due to the wind currents in the study area, there was still an evident decline in the concentration of $PM_{2.5}$ in the TA during rush hours. This observation suggests that the trees demonstrated a significant ability to filter the air in the study area during the elevated concentration levels, despite the prevailing wind direction or speed.

Additionally, as per the model findings, the urban trees present in the study area improved the air quality by 2% on an hourly basis. However, during field observations, the maximum recorded difference in air quality between the NTS and the TA was an improvement of 73.23%. This major difference between the results obtained from the model and real-time measurements can be due to the fact that the i-Tree Eco model used the air quality and meteorological data from the year 2018, and it is possible that the weather conditions and air quality during the monitoring period were significantly different, resulting in an inaccurate prediction from the model. Moreover, collecting additional data like tree height and crown size would have improved the data efficiency of the i-Tree Eco model and provided a better estimate of the role of trees in enhancing air quality. Additionally, there were further limitations linked to utilizing the i-Tree Eco model, such as the model operated on prescribed concentrations from the selected monitoring station without considering the feedback of deposition on $PM_{2.5}$ concentration and hence did not account for the effects of pollutant deposition on subsequent concentration levels. Furthermore, the model did not account for diverse interactions and processes responsive to $PM_{2.5}$ concentration changes, such as atmospheric chemistry and wet deposition. Despite these drawbacks, the model is still preferred because of its deposition-based approach, which helps gain a comprehensive depiction of vegetation through its detailed representation of trees or tree canopies. The environmental challenges faced by South Asian countries, particularly in Delhi, necessitate the

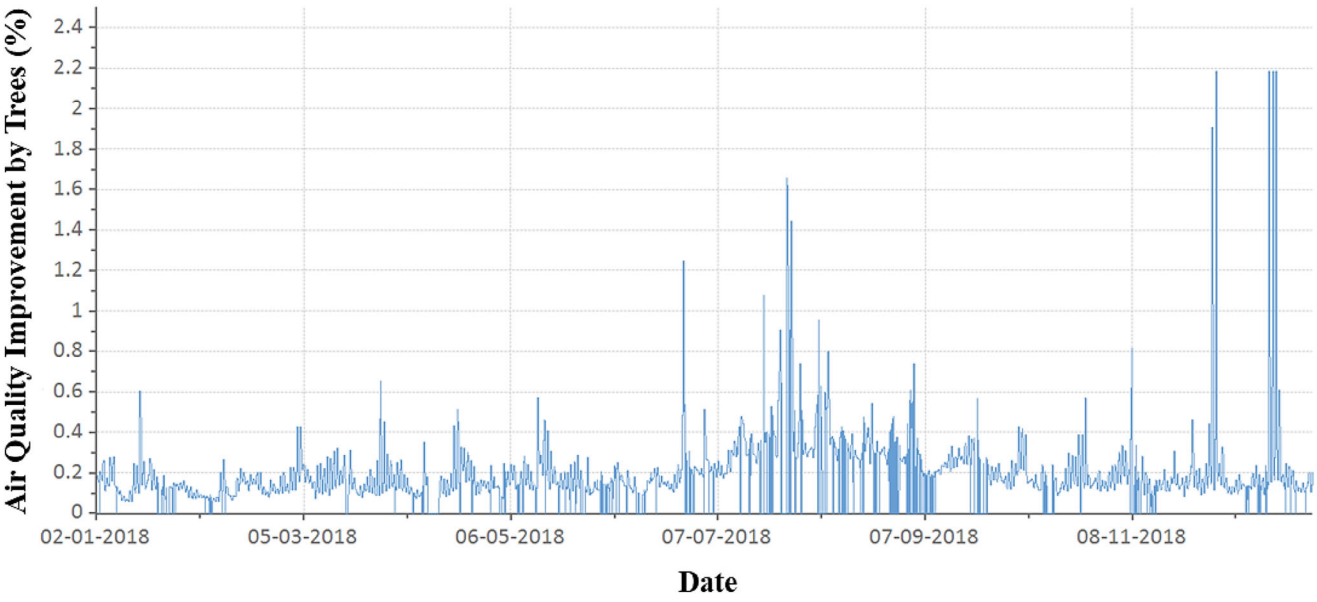

FIGURE 6 Improvement (%) of air quality by trees in industrial area National Capital Territory (NCT) of Delhi.

18630669, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/clen.202300198 by Delhi Technological University, Wiley Online Library on [09/05/2024]. implementation of NbS to address air pollution management, given their poor air quality and elevated mortality rates. The i-Tree Eco model offers quantifiable results on the potential of urban trees to mitigate air pollution, which could attract further research interest. Although this study offers a preliminary investigation into the correlation between trees and air quality in Delhi, conducting additional research that includes measurements of local wind speed and direction would provide a more comprehensive understanding of the impact of trees on air quality.

By 2030, $PM_{2.5}$ is predicted to cross an annual mean value of 74 μg m^{-3}, which is almost eight times the WHO standards/guidelines, and is expected to reduce life expectancy by more than 10 years in Delhi.[60] Several control strategies for improving the air quality have been implemented in Delhi, like Bharat stage IV vehicles, an odd-even scheme, a ban on open waste burning, and transferring entire public transportation to CNG fuel. A set of emergency measures termed a Graded Response Action Plan is also implemented in Delhi when $PM_{2.5}$ concentrations reach high levels, including reactive measures to control and reduce air pollution in the city.[61] Another project known as Clean Air for Delhi Through Interventions, Management, and Engagement has been implemented jointly by India and the United Kingdom with the aim of addressing air quality issues that affect public health in Delhi. The project has been initiated to identify a set of measures to improve present air quality by taking two future time horizons: 2030 and 2050. These options, however, have met with little success. Based on the findings of this study, it could be suggested that combining the strategy of developing vegetation strips along roads that serve as filters for air pollution from point sources along with other measures can help further reduce the concentration of $PM_{2.5}$. This is crucial because, along with improving air quality, urban green areas can help decrease stress, enhance moods, and improve social interaction, which can contribute to the prevention of cardiovascular disease, mental illnesses, and lower mortality rates.[62] Green areas can thus help address several urbanization challenges, as depicted in Figure 7, and can aid in making cities more resilient and sustainable.

Regarding the NCT of Delhi, evaluating the $PM_{2.5}$ removal capacity of urban vegetation is likely to provide a beneficial initial estimate for raising awareness in cities with elevated concentrations of $PM_{2.5}$. However, certain uncertainty exists in our study. First, the pollution removal capacity of the vegetation was only simulated during winter. As per research conducted by Abhijith et al.,[63] the dust-retaining capacity, deposition efficiency, and canopy morphology of plants would change to some extent in other seasons, which may differ from the results in winter. In another study conducted by Chaudhary and Rathore,[64] an analysis of the seasonal deposition efficiency of trees revealed that the highest dust deposition occurred during winter, followed by summer, with the lowest levels observed in the monsoon season. Second, the analysis in this study did not take into account the influence of meteorological factors such as wind speed and wind direction on the dispersion ability of trees. However, various studies have indicated that the alterations in wind direction and speed across different time intervals and heights influence the capacity of trees to capture $PM_{2.5}$.[63] Thirdly, the i-Tree Eco model ignored the resuspension process of $PM_{2.5}$. The movement of traffic can induce slight turbulence of pollutants close to the ground, facilitating the resuspension of $PM_{2.5}$; studies have identified that this process can reduce $PM_{2.5}$ levels, especially on two-way roads. Additionally, the calculation of $PM_{2.5}$ removal capacity was calculated based on the values of DBH of trees, overlooking other factors influencing the removal efficiency of tree species. This oversight could result in an underestimation of the actual deposition of pollutants. However, according to a study by Lin et al.,[65] the effect of small amounts of DBH measurement is negligible on the uncertainty of model output of i-Tree Eco at the landscape scale because the estimated degrees of input uncertainty arising from measurement errors are comparatively modest, leading to a limited influence on the uncertainty of the output.

There are several possible ways to reduce the uncertainty output of the model. One way of reducing uncertainty is by entering spatially distributed meteorological data into the model. However, that would require establishing more monitors, which can prove costly. Hence, overcoming the limitations poses a challenge, and model inputs will persistently depend on the most accurate local environmental data currently available. According to Lin et al.,[65] taking the inventory of entire street tree populations in individual tree management studies can help reduce the sampling error to zero. Furthermore, the sampling strategy can be modified from case to case depending on the area and/or the species being assessed. A significant hindrance to reducing uncertainty is the additional cost associated with reducing errors in the model inputs and sampling. Thus, although reducing uncertainty is crucial, it is essential to weigh the costs associated with it and evaluate whether the reduction is necessary. To summarize, for the reduction of uncertainty in subsequent studies, potential strategies involve the: (a) development of species-specific allometric relationships in cases where they are unavailable, (b) enhancement of the spatial accuracy of meteorological weather monitors, (c) subdivision of the study domain into subareas when multiple monitors are accessible for improved local meteorological estimates, and (d) optimization of sampling strategies to ensure representation of the urban forest diversity, balancing sampling intensities and data collection costs. The exploration of uncertainties in modeled attributes by i-Tree Eco remains a subject for further research.

To further enhance the role of urban vegetation as NbS for air quality management, certain areas need improvement. For example, introducing research briefs that extract findings and provide simple guidance to inform urban planners, multiple stakeholders, and policymakers will support the better implementation of urban planning. This can help stakeholders deliver NbS (in the form of urban vegetation) to improve air quality and public health with confidence. To ensure the selection and positioning of urban vegetation in the most efficient and effective way, the development of tools and services is necessary. Similar to the approach taken by Hewitt et al.,[14] a flowchart for decision-making in positive air quality interventions can aid management in making informed choices. Additionally, conducting a baseline study to consider all the benefits associated with urban vegetation in the early design stage can maximize its ability as an air purifier and health-promoting recreational resource. It is imperative

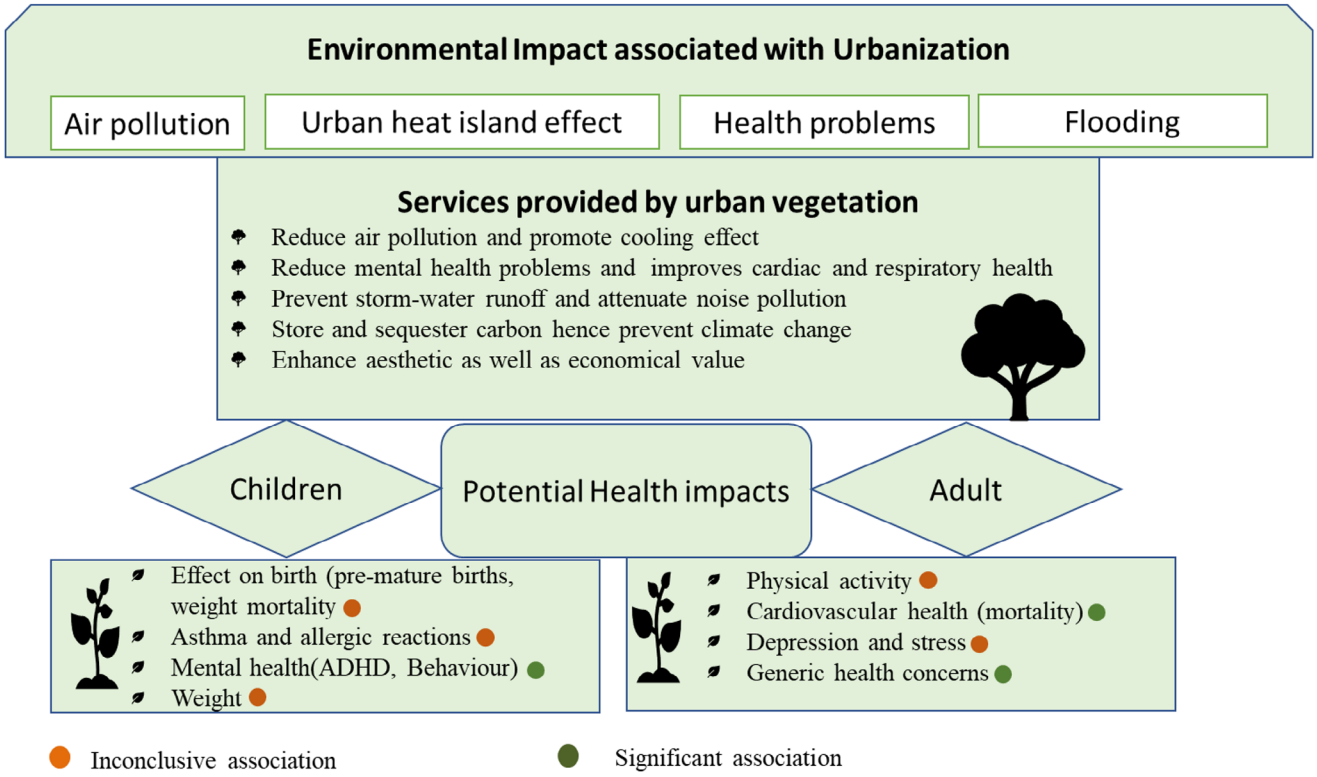

FIGURE 7 Role of urban vegetation in addressing urbanization challenge.

to continue researching the relationship between urban vegetation and air pollution to address existing scientific research gaps. Noteworthy studies by Deshmukh et al.[66] and Eisenman et al.[67] exemplify innovative research that enhances our understanding of how urban vegetation interacts with air pollutants. By documenting environmental factors that influence dispersion and plant-related variables that impact deposition, we can establish a more comprehensive evidence base to guide strategies for enhancing urban air quality. These elements, when combined, have the potential to reduce urban pollution. Furthermore, incorporating urban vegetation as an NbS into various disciplines such as economic development, educational programming, public health, and community building initiatives will enhance information exchange and facilitate the evaluation of direct and indirect health effects. Finally, it is essential to note that most studies incorporating NbS to urban problems come from high-income nations. Considering that future urban population growth is expected to occur primarily in low- and middle-income Asian and African nations, there is an urgent need to shift scientific attention to these regions.

5 | CONCLUSION

The present study focuses on quantifying the contribution of urban vegetation in reducing air pollution levels by measuring the dry deposition of PM on their leaves. This assessment has been conducted using a combination of real-time air quality monitoring and the i-Tree Eco model to evaluate the effectiveness of urban trees in mitigating air pollution in highly industrialized and polluted regions of NCT of Delhi. The findings of this study reveal that during rush hours when pollution was primarily attributed to traffic sources and vehicular emissions, the TA exhibited a significantly lower concentration of $PM_{2.5}$ compared to the NTS. However, no significant variation in $PM_{2.5}$ concentrations was observed outside of rush hours. Both the model-based approach and real-time measurements reveal that the presence of trees improves air quality. The preliminary results of this study provide valuable insights for informing national clean air strategies aimed at reducing pollutant emissions. However, conducting further research that compares additional pairs of TA and NTS across different seasons will facilitate a deeper understanding of how Delhi's trees influence air quality. The combination of real-time monitoring and modeling approaches demonstrated in this study serves the needs of various stakeholders, such as local governments, the general public, and nongovernmental organizations. Moreover, this research contributes to the paradigm shift from perceiving trees as costs and liabilities to recognizing their value and benefits, as observed through the i-Tree Eco model. This reinforces the rationale for investing in urban forests and supports decision-making processes. This study also provides evidence for integrating biodiversity in the sustainable planning of cities which can help achieve the goals outlined by the United Nations in its 2030 Agenda for Sustainable Development. Adopted in September 2015, the agenda comprises 17 Sustainable Development Goals (SDGs) aimed at enhancing global well-being through a balanced approach addressing social, environmental, and economic concerns, which strategically steer the world toward sustainability by 2030. The goal of reducing annual mean levels

18630669, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/clen.202300198 by Delhi Technological University, Wiley Online Library on [09/05/2024]. of PM in cities is addressed in Indicator 11.6.2 under SDG 11 (sustainable cities and communities), emphasizing the need to minimize PM concentration in cities due to its severe impact on public health. Additionally, the goal to integrate ecosystem and biodiversity values in government planning and policymaking of environmental issues is addressed in Target 15.9 of SDG 15 (Life on land). Therefore, urban vegetation can serve as a valuable resource for policymakers, researchers, and urban planners to develop effective strategies for managing air pollution and achieving SDG (11 and 15) aimed at urban resilience and sustainability.

AUTHOR CONTRIBUTIONS

Conceptualization; methodology; visualization; Writing—original draft; review and editing: Mallika Vashist. *Conceptualization; methodology; supervision and review*: Thangamani Vijaya Kumar. *Conceptualization; methodology; supervision; review and editing*: Santosh Kumar Singh.

ACKNOWLEDGMENTS

The authors express their gratitude to Delhi Technological University (DTU) for offering research facilities. The authors thank Mr. Harshit Chawla, a research scholar at DTU, for his valuable assistance throughout the study. The authors also thank the editor and anonymous reviewers whose valuable suggestions helped improve this manuscript.

CONFLICT OF INTEREST STATEMENT

The authors have no conflicts of interest and financial or nonfinancial interests to disclose that are relevant to the content of this article.

FUNDING INFORMATION

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

DATA AVAILABILITY STATEMENT

The data that supports the findings of this study is available from the corresponding author.

Journal Pre-proof

Abstract

A solar-biomass hybrid power system may be a feasible approach for decarbonizing and achieving a sustainable energy transition in an academic building. This cutting-edge technology generates clean, sustainable power by fusing the advantages of biomass and solar energy. The present research analyses and optimises a Hybrid Renewable Energy System (HRES) for the Department of Mechanical Engineering, Delhi Technological University (located at 28°44' N and 77°06' E). Hybrid optimization model for electric renewable (HOMER) software is employed for simulation, and analysis primarily focuses on the techno-environomic assessment of the system. HRES is designed to fulfil daily energy consumption of 588 kWh at a peak load of 65 kW. System generates 3,76,780 kWh of power every year. The cost of energy (COE) is ₹16.96 (US$ 0.207)/kWh and the gross net present cost (NPC) is ₹41,603,969.8 (US$ 5,07,737). Throughout lifetime (25 years),

biomass gasifier and solar PV contribute 23.4% and 76.6% of the total energy production. Around 161 metric tons of CO_2 is prevented from entering the atmosphere. Therefore, proposed HRES is technically consistent, dependable, economically viable, and environmentally sustainable.

Keywords:

Hybrid; Renewable energy; Feasibility analysis; Environmental sustainability; HOMER

Journal Pre-proof

1. Introduction

Energy consumption is directly proportional to the advent of manpower with the rising population, improving humanity's standard of living and the economic prosperity of emerging countries. With the rise in demand for energy, there is a subsequent need to increase and diversify energy production and energy sources (Ahmet Bozgeyik, Lutfiye Altay, 2023). Global warming is increasing greenhouse gas (GHG) emissions, and the depletion of non-renewable energy sources has raised interest in protecting the world's energy supplies (Razaghi et al., 2024). However, according to World Economic Outlook 2020, 940 million people, or 13% of the global population face shortage of grid power or other energy sources ("Access to Energy," n.d.). However, as a result of urbanization and population growth, electricity demands are increasing. Therefore, more energy is needed when the population grows, which comes from fossil fuels but also generates emissions. Utilizing cutting-edge, suitable machinery and sustainable energy sources in rural regions is a very efficient approach to reducing fossil fuel use (Mobin Korpeh, Poorya Asadbagi et al., 2023). The main issue with non-grid systems is the unpredictability of the electrical supply, which may be addressed by combining renewable and conventional technologies. Over the past ten years, research into HRESs has drawn significant attention in the Middle East, Asia, and Africa as a result of rising electricity costs, rural electrification, and rapid global climate change. Ghenai et al. investigated renewable resources in Sharjah city to find the best arrangement for meeting the city's intended power loads. In Sharjah city, a hybrid system may meet up to 14% of the entire yearly electrical demand, with photovoltaic (PV) panels contributed for 74% and a biogas generator for 26% of the total electrical demand (Ghenai and Janajreh, 2016). Kumar et al.

analyzed that in Tamil Nadu, India, there are six separate temperature zones. The best climate zone to implement this system is the arid interior (Kanyakumari) and findings of the sensitivity analysis indicate that ₹1854 (₹49/lit) was saved as NPC for the arid interior climate zone (Suresh Kumar and Manoharan, 2014). Shafiqur et al. examined actual hybrid systems worldwide in various climatic situations to discover the optimal hybrid system configurations for Saudi Arabia to enhance its current energy spectrum and found that Wind-PV HPS with battery storage is the best option (Rehman, 2021). Al-Najideen et al. analysed that 96 MWh/year of energy is consumed by Engineering Faculty at Mu'tah University. The system produces 97.02 MWh of electricity to the grid yearly through installing an on-grid solar PV system of 56.7 kW and the payback period of the system is 5.5 years (Al-Najideen and Alrwashdeh, 2017). Kavuma et al. examined the practicality of grid-connected solar PV systems in Uganda by analyzing the system performance that was already in operation. An estimated 69.52 GWh of energy was produced annually. The capacity factor varies from 13.1% to 17.5% and the performance ratio is 0.76, both within the intended ranges (Kavuma et al., 2022). Kamali et al. analysed the environmental and economic parameters of solar PV systems connected to the Malaysian electrical grid system (Kamali and Mekhilef, 2009). Goyal et al. evaluated the economic feasibility of concentrated solar power plants in Jodhpur using three distinct techniques: Solar Power Tower (SPT), Parabolic Trough Collector (PTC), and Linear Fresnel Reflector (LFR) of 50 MW and 100 MW capacity. A 50 MW Parabolic Trough Collector plant with storage has the highest NPV of ₹6940.4 million whereas the 50 MW Linear Fresnel Reflector plant without thermal storage has the lowest calculated Levelized Cost of Energy (LCOE) ₹9.27/kWh (Goyal et al., 2022). Kumar et al. analysed a 95 kW on-grid solar PV system. The maximum estimated annual specific energy generation from PVWatts is 1612.968 kWh/kWp compared to 1406.632 kWh/kWp for PVGIS. PVWatts and PVGIS both estimate capacity factors were 16.05% and 18.41%, correspondingly. An insignificant variation was perceived in the performance among PVGIS, PVWatts, and investigational data (Kumar et al., 2018). Sharma et al. did parametric analysis as well as solar photovoltaic system modelling based on varied load situations in a building to obtain performance ratio, maximum power, and improved system efficiency (Sharma et al., 2018). Wibowo et al. demonstrated that the stationary panel produces more energy, with an average final output of 3.3% and a capacity factor of 13.6% compared to 2.3% and 9.6% for PV panels with solar trackers. Due to the daily average maximum power produced between 11:00 AM and 2:00 PM, Palembang does not require solar trackers for

Journal Pre-proof

PV panels (Wibowo et al., 2021). Saha et al. evaluated the efficacy of the proposed HRES system in contrast to the conventional utility grid expansion. It was affordable, cost-effective, and environmentally safe and made for a demand of 189.26 kWh/d and a peak load of 61.78 kW, and it generates power using a solar photovoltaic and a wind turbine system. The micro-grid concept produces 1,70,872 kWh of extra energy each year (Saha et al., 2022). Al-Ghussain et al. determined the ideal size of a HRES with and without storage. The hybrid system saved the university US$ 1.37×10^6 in annual electricity costs and has a RES component of 99.59%, Demand Supply Fraction (DSF) of 98.86%, and an electricity cost of 0.1626 US$/kWh based on increasing the DSF and renewable energy percentage with a net value larger than or equal to zero (Al-Ghussain et al., 2021). Wang et al. recommended a variety of energy storage solutions used for renewable energy to address the fluctuation and unpredictability issue (Wang et al., 2022). Sen et al. highlighted the need for residential, institutional, commercial, agricultural, and small-scale industrial development. The best off-grid option is identified and evaluated against conventional grid expansion (Sen and Bhattacharyya, 2014). Koussa et al. discussed the principal advantage of photovoltaic/wind/diesel hybrid with battery storage, it enhanced the system's reliability (Saheb-Koussa et al., 2009). Zhou et al. analyzed stand-alone hybrid solar-wind power generation systems which were acknowledged as a feasible alternative to grid supply. Such hybrid power generation systems are more appropriate than systems with only one renewable energy source for electricity supply to off-grid applications (Sayed et al., 2021). Sheikh et al. explored the thermal control of a solar cell that was being cooled by a phase-change material. When phase change material is used for cooling, electrical energy efficiency rises by 4.82, 8.1, and 7.17%, respectively, while power output rises by 5.12, 8.4, and 7.29% (Sheik et al., 2022). Singh et al. estimated COE of a biomass gasifier generator set, solar PV, and fuel cell crossover energy system is 15.064 ₹/kWh, with a total net current cost of ₹51,89,003 and the suggested framework's plentiful power is 36 kWh/year with zero tariffs unmet electrical load (Singh and Baredar, 2016). Turkay et al. discussed the economics of standalone and grid-connected HRESs. Results reveal that grid-connected HRES are more likely to adapt than standalone configurations (Türkay and Telli, 2011). Decentralized green energy is becoming more feasible to supply electricity to one billion people where no admittance to the power grid (Sawle et al., 2016). While government regulations cut back on emissions of agricultural waste, solar energy prices are declining. In India, more than 70% of the population resides in isolated areas deprived of access to grid-connected power (Krishnamoorthy et al., 2020).

Journal Pre-proof

A major limitation in HRESs is a lack of a fixed optimal structure of the HRES. Simulation and modelling are based on the ease of access to traditional and non-traditional sources, existing base structures, cost of building and manufacturing, etc. As a result, proper designing of HRES needs a comprehensive survey of the planned project location and resources in addition to the renewable energy sources.

Academic institutions play an important role in demonstrating sustainable practices. Installing a solar-biomass hybrid power system demonstrates a building's dedication to sustainability and promotes similar initiatives. Reducing dependency on fossil fuels and GHG emissions can be achieved by integrating solar and biomass power. Students and researchers can analyze the integration of various renewable sources, comprehend their efficiency, and investigate breakthroughs in sustainable energy technology when an academic building has a hybrid system. Institutions can directly support decarbonization and sustainable energy transitions while also promoting research, education, and a community-wide sustainability culture by installing a solar-biomass hybrid power system in an academic building.

The literature review reveals that some techno-environomic analysis has been carried out, however, meteorological data based on an academic institute, for optimizing the HRES in Delhi, India is not present. The literature review, meanwhile, also does not mention how HRESs are prioritized in terms of energy output, NPC, COE, operational cost, and carbon emissions for an academic institute. An abundant amount of solar energy and adequate biomass is present at the site location. Hence, the main focus is to use more than one renewable energy source to provide a reliable source of power instead of the traditional form of electricity. The present work aims to tackle the proposed system's environmental assessment to ensure sustainability. Generally, research on HRESs involves a technical and economic assessment to determine the system's feasibility. The viability and sustainability of the proposed system will be thoroughly determined through technical, economic, and environmental studies.

Along with the system's technical and economic feasibility, it is also crucial to understand the extent of the positive environmental impact it can provide, which can be seen very significantly in this system. The system uses a combination of renewable energy sources like solar energy and biogas energy to provide a consistent source of power instead of the traditional form of electricity. The analysis is done using HOMER, to assess the proposed system i.e. technically consistent,

Journal Pre-proof

dependable, economically viable and environmentally sustainable. To achieve this, the system is analysed first, assessing the available resources; second choosing system parameters, third, assessing the load profile, and fourth analyzing the techno-environomic aspects of the system.

2. Methodology

In this HRES, solar PV along with a biomass gasifier generator and batteries has been used for energy storage. Figure 1 represents a schematic diagram of power generation using a PV array, biogas genset, battery and power converter. Biomass is burned or utilized after transforming it into various forms of solid, liquid, and gaseous fuels, CO_2 is emitted into the atmosphere that the biomass had recently taken from the atmosphere during its photosynthesis process. As a result, there is no net CO_2 increase (Abbasi and Abbasi, 2010). The system should have low or zero carbon emissions and be easily integrated with current technologies or grid and in the end, the cost of the system should be optimal (Azar et al., 2006).

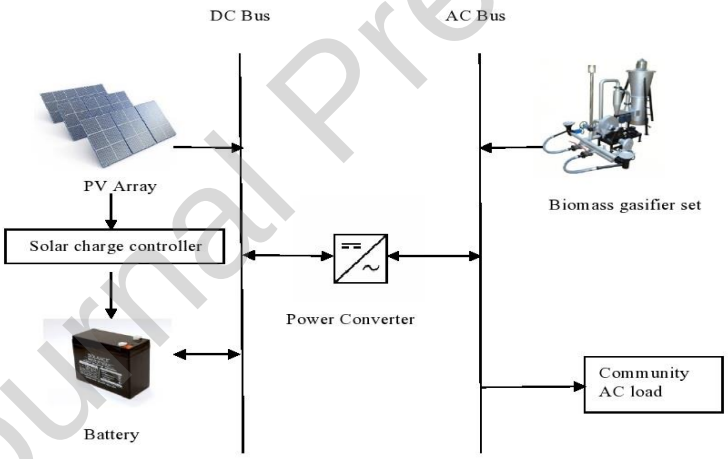

Figure 1: Hybrid renewable energy system

Proposed system is an amalgam of solar PV power sources with other power sources. The system is set to be a standalone system. It is usually advantageous in remote or inaccessible areas. Components of this system include a biomass generator set, solar PV energy generator, battery and a converter. Figure 2 shows a brief procedure to develop, simulate, and optimize the HRES using HOMER.

Journal Pre-proof

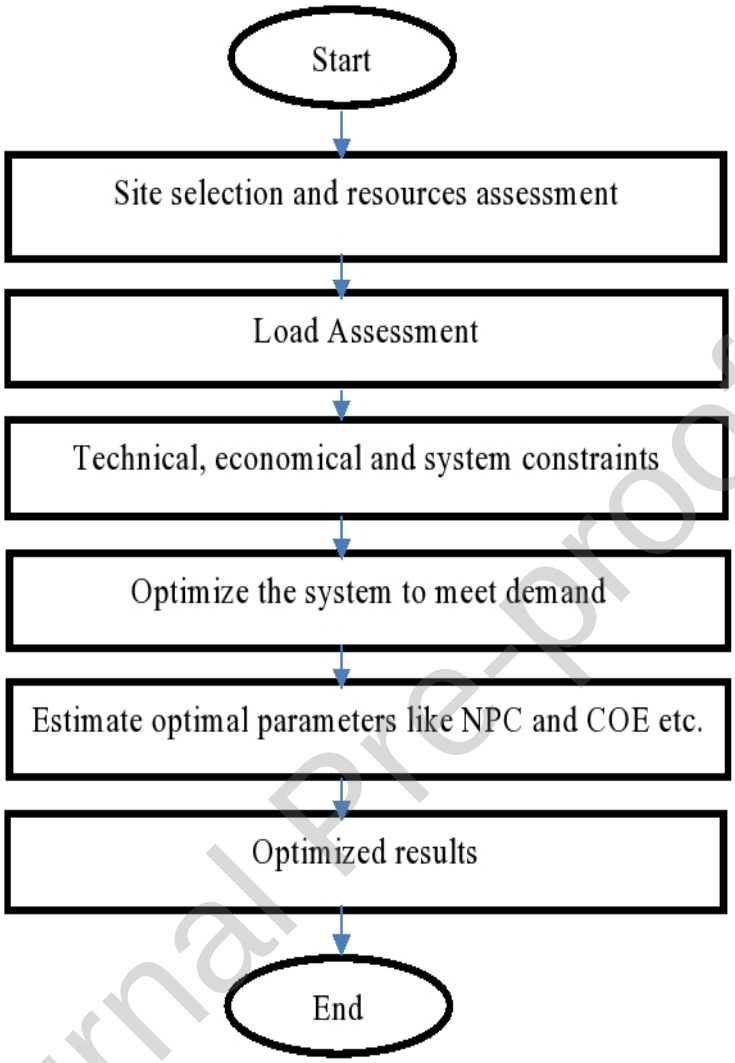

Figure 2: Flowchart to design and optimise HRES

Journal Pre-proof

2.1 Components detail

HRES comprises solar PV, biomass energy sources, a converter and a battery to store the generated power. Optimization is of utmost importance in determining the optimal system's size and cost. It can be an indication of a good ratio between the system's cost and its performance.

Solar photovoltaic system

Sunlight is converted into direct current power by solar PV cells. The cells consist of several varieties of semiconductor materials. Solar cell technology, which includes positive and negative charges, is designed with a low cost and a high conversion efficiency rate (Shaikh, 2017).

Photovoltaic system output is mainly dependent on incident solar radiation. Furthermore, the output is in terms of voltage. Hence the power generated is determined by the product of current and voltage. A 1 kW solar photovoltaic system and maintenance costs are nearly ₹1,50,000. The lifetime of this system is approximately twenty years and does not include any tracking system (Singh and Baredar, 2016).

The output of the photovoltaics in HOMER is given by Eq. (1):

$$P_{PV} = A_{PV}\, f_{PV}\, (R_T / R_{T,STC})\, (1 + a_P(T_{cell} - T_{cell,STC})) \quad (1)$$

If the option chosen is not to model the coefficient of temperature, then the simplified equation is given by Eq. (2):

$$P_{PV} = A_{PV}\, f_{PV}\, (R_T / R_{T,STC}) \quad (2)$$

PV system Output is obtained from the product of the current and voltage. Eq. (3) represents the energy distributed by the panel in the system (Kazem and Khatib, 2013).

$$P_{PV}Output = P_{NPV} \times R / R_{ref} \times (1 + K_T(T_{cell} - T_{ref}) \quad (3)$$

Biomass gasifier generator set

When an organic resource is burnt at an extremely high temperature and combined with a limited flow of air, the structure of the source breaks down into a simpler form. This organic material is heated with a limited quantity of air in a biomass gasifier to propagate incomplete combustion, producing a mix of highly combustible gases. Complete combustion of biomass resources will produce N_2, H_2O, CO_2, and excess O_2. Since incomplete combustion occurs in the gasifier, resulting gases are CO, H_2 and minimal methane gas (Farret and Simões, 2006). Collected food waste in the campus is used as biomass to produce biogas and the LHV of biogas is assumed 5.50 MJ/kg. Biogas/fossil ratio is 8.50%. The density of syngas is about 0.72 kg/m^3, then the gasification ratio is calculated at 0.70 kg/kg biomass.

The electrical efficiency of the system is defined by Eq. (4) and Eq. (5) (Singh and Baredar, 2016):

$$\eta_{elec} = (P_o - P_n) / (Input\ Biomass)_{LHV} \quad (4)$$

$$\eta_{elec} = (P_{tot}) / (Input\ Biomass)_{LHV} \quad (5)$$

Here, $P_{tot} = P_o - P_n$

Journal Pre-proof

Power converter

In this HRES, the power converter is of utmost importance. An electronic converter aims to maintain a continuous stream of power between the component's DC and AC power generated. HOMER assumes that the rectifier and inverter capacity do not exceed what the device can handle for an extended period. Instead, they are considered continuous capacities, the apparatus can resist for the required period (Farret and Simões, 2006). With research about present market rates, we anticipate the approximate capital cost to be ₹15,000, with maintenance and upkeep costs at ₹10,000. The approximate lifespan of a converter is 20 years and it maintains nearly a 90% efficiency level (Givaki et al., 2014).

Battery

A battery storage bank is used to reinforce the system. Similarly, a battery is used to keep the voltage constant over the electrical component. Common usage of the battery bank is for storing the electrical power generated in a highly effective. Its discharging capacity is unable to exceed a base breaking point. Battery bank's storage capacity (C_{Wh}) is determined by Eq. (6) (Malheiro et al., 2015):

$$C_{Wh} = (E_{tot} \times \mathrm{AD})\eta_{in} \times \eta_{batt} \times DOD_{batt} \quad (6)$$

The software performs calculations to determine the maximum amount of electricity that can be stored in the storage bank for each time step. The maximum quantity of electricity stored is used to figure out whether the storage bank can take in extra renewable energy or the extra power needed to be generated by a generator. This maximum charge power fluctuates in between steps due to the varying state of charge and previous discharge ("Homer," n.d.). The maximum amount of power that the two-tank system can withstand is provided by Eq. (7):

$$P_{batt} = (rE_1\, exp^{-r\Delta t} + Qrs\,(1 - exp^{-r\Delta t})) / (1 - exp^{-r\Delta t} + s\,(r\Delta t - 1 + exp^{-r\Delta t}) \quad (7)$$

Another limitation imposed by HOMER is the maximum charge rate. Battery storage bank power related to it is given by Eq. (8):

$$P_{batt} = (1 - exp^{-\alpha\Delta t})\,(E_{max} - E)/\Delta t \quad (8)$$

The last limitation imposed by HOMER is the maximum charge of the storage component. The

Journal Pre-proof

formula for maximum storage bank charge power for this charge current is given by Eq. (9):

$$P_{batt} = N_{batt} I_m V_n / 10 \quad (9)$$

In HOMER, the least of the previous three values is used as the maximum storage charge power after taking into account losses due to charging, leading to Eq. (10):

$$P_{batt,cmax} = MIN\,(P_{batt,cmax,kbm}, P_{batt,cmax,mcr}, P_{batt,cmax,mcc}) / \eta_{batt,c} \quad (10)$$

Capital cost ₹5,110,000 substitution cost ₹5,036,270 after 15 years and battery life is estimated to be 15 years in this project (da Silva Lima et al., 2021).

2.2 Site selection and resource assessment

Figure 3 shows the site of the study area i.e., the Department of Mechanical Engineering, Delhi Technological University, Delhi. DTU is situated in the North-West of Delhi with a 165-acre campus. It is a large campus comprising many hostels, residential buildings, educational buildings, biogas, waste plant, etc. Hence sufficient raw material is available daily to produce the required biomass. NASA Surface Meteorology used to perform irradiation at site location 28°44'N latitude and 77°06'E longitude.

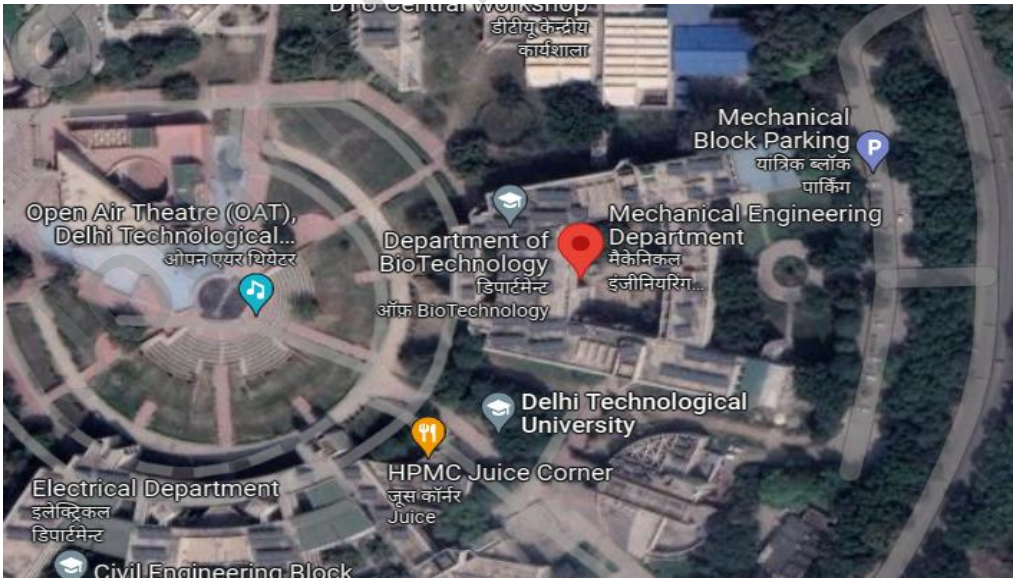

Figure 3: Location of the study area, Mechanical Engineering Department, DTU, Delhi (India)

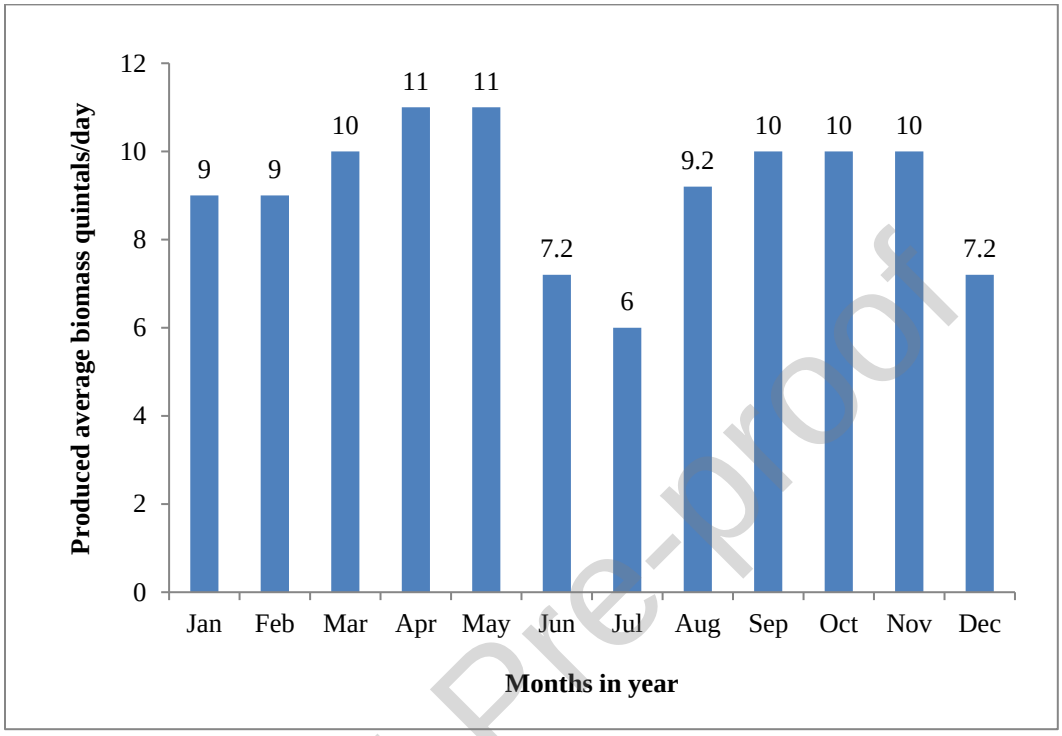
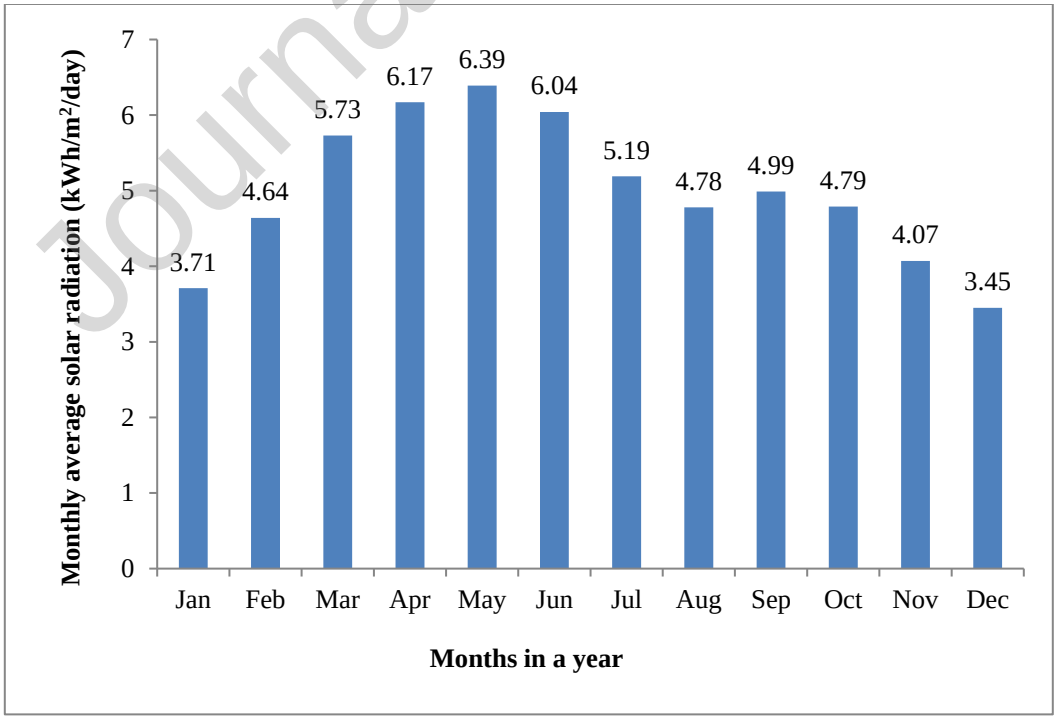
Figure 4(A) shows biomass resources available for power generation of the proposed system. The average year's biomass production amount is 9.08 quintals/day. Figure 4(B) illustrates the monthly

Pre-proof

average solar radiation. Yearly average solar power can be scaled up to 4.99 kWh/m^2 per day, which is considerable.



(A) Monthly average biomass resources

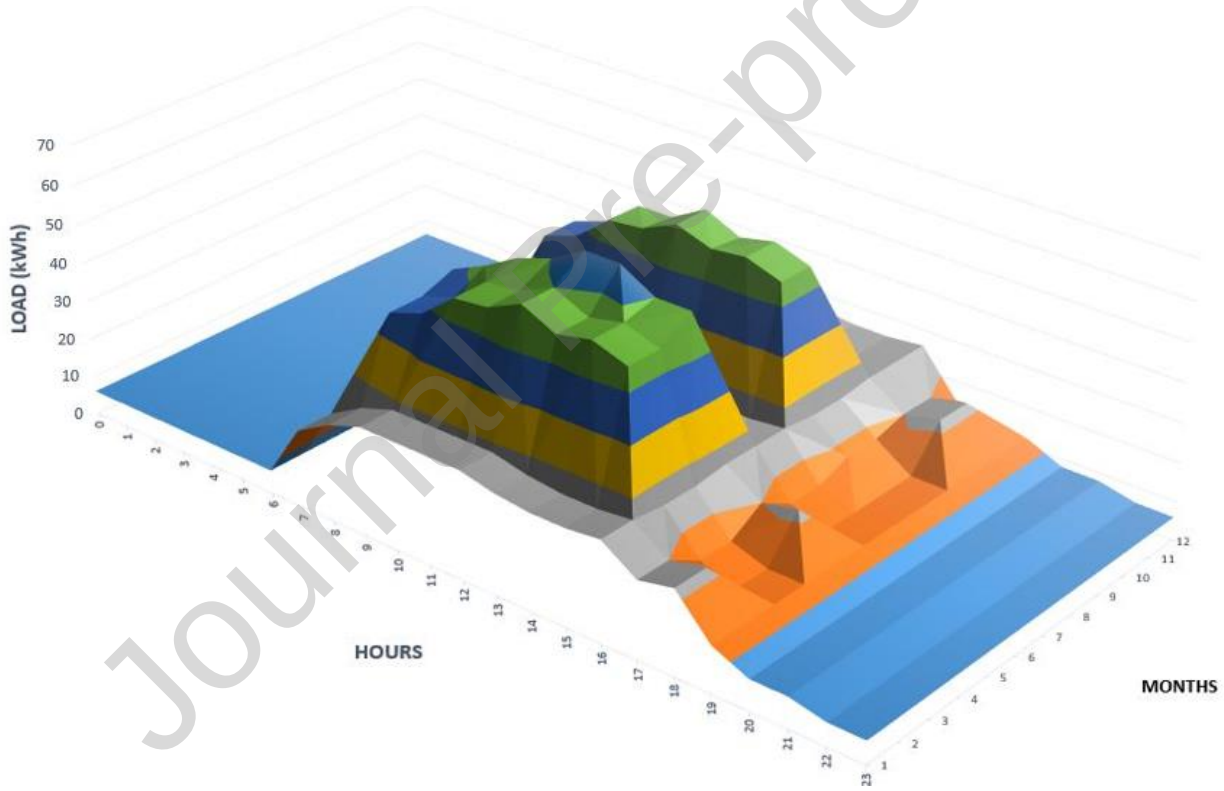


Journal Pre-proof

(B) Monthly average solar radiation

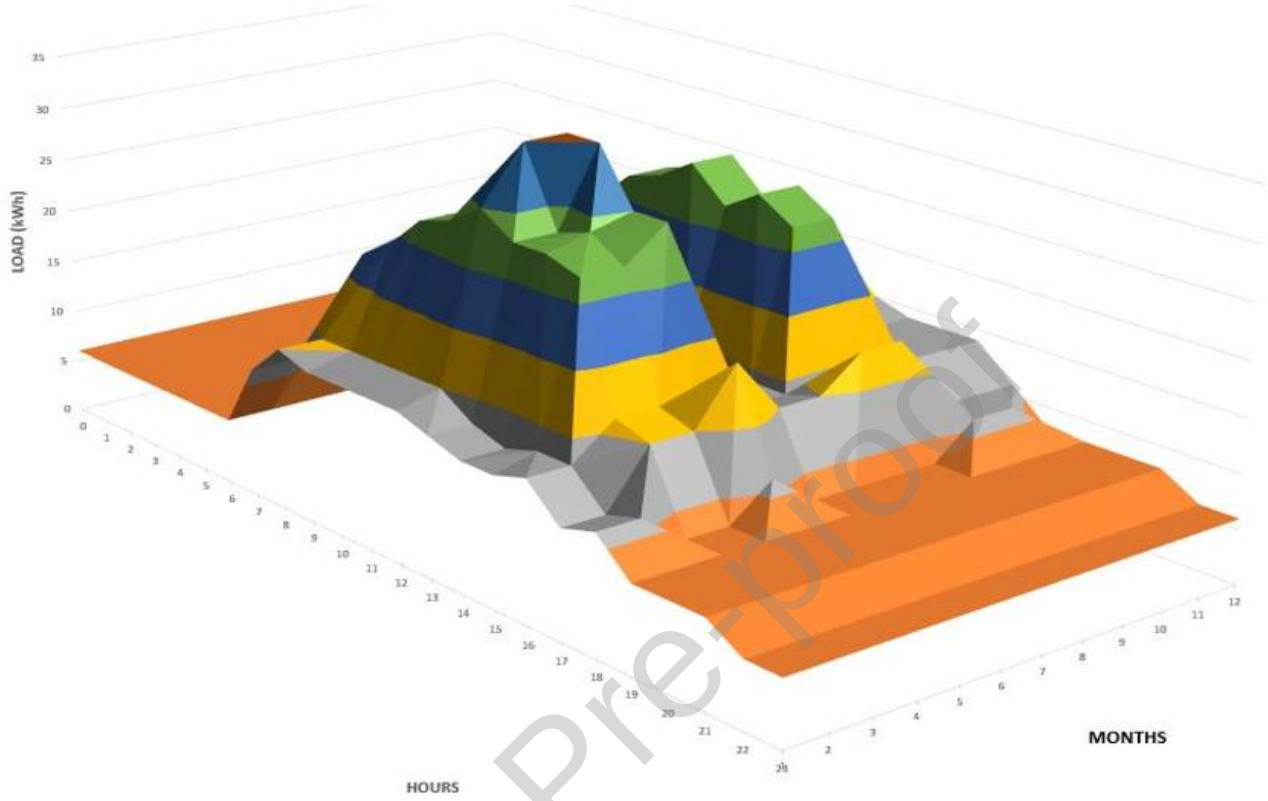
Figure 4: Renewable energy resources assessment

Figure 5(A) shows a 3D surface plot of each month of the year for the weekday load profile for the Mechanical Department, DTU, India. Figure 5(B) shows the exact data for weekends. It translates to a 65 kW peak load on weekdays and 35 kW on weekends. The average load calculated over the year amounts to 588 kWh per day. Load profiles vary based on the users, for example, homes versus commercial sites. There is the consideration that specific equipment runs continuously like refrigerators. Academic building comprises laboratory equipment and electrical appliances that contribute to their load requirement.



(A) Weekdays

Journal Pre-proof



(B) Weekends

Figure 5: Load profile for Mechanical Department, DTU, Delhi (India)

2.3 Cost analysis of the HRES

Net present cost (NPC): The net present cost of the hybrid system is the cost difference between all present costs incurred by the system over its lifetime and all present revenue collected during the project's lifetime. It is given by the Eq. (11) (Sahu et al., 2021).

$$C_{NPC} = \frac{C_{AT}}{CRF(i_r P_L)} \tag{11}$$

Levelized cost of energy (LCOE): HOMER calculates the LCOE by dividing the annualized cost of producing electricity by the total useful electric energy production, which is computed by Eq. (12) (Li et al., 2020).

$$LCOE = \frac{C_{ann,tot}}{E_{prim,AC}+E_{prim,DC}+E_{grid,sales}} \tag{12}$$

Salvage value: Salvage value is the cost of a power system component that is still operational at

Journal Pre-proof

the end of the project's lifespan. To assess the worth of each component at the conclusion of the project's life cycle, HOMER employs Eq. (13) (Bonah et al., 2022).

$$Salvage = C_{rep} \frac{R_{rem}}{R_{comp}} \quad (13)$$

Total annualized cost: As shown in Eq. (14), the annualized cost is calculated by multiplying the net present cost by the capital recovery factor (Riayatsyah et al., 2022).

$$C_{ann,tot} = CRF\ (i, R_{proj}) \times C_{NPC,tot} \quad (14)$$

The first step in this research is to decide on the site location. Decision of the site location is based on two main factors. Firstly, the given site has a significant load and is operational and relatively consistent throughout the year. Secondly, the location is easily accessible for the required data collection. Once the site location is finalized, analyze the available resources to design the system. It is done by analyzing all the naturally available resources in that particular area of Delhi, such as rain, wind, biomass, and sunlight. This particular data is sourced from the NASA meteorological website.

After that, data collection about how much energy is consumed daily in the decided location is required. This secondary data is sourced from the technicians responsible for the location. After breaking down the load profile according to weekdays and weekends and then further to summers and winters, the yearly energy required is calculated. This is done by monitoring and controlling the necessary variables. A significant review of past work in the field is done to understand the limitations faced and where the gap can be overcome.

This material is sourced from various sites, including published articles in reputed journals, reports, case studies, and government websites. These materials are chosen based on their data range, where preference and higher weightage are given to the more recent materials. After the system design, data is prepared and analysed using HOMER. Data is used to conduct three technical, economic, and environmental analyses. Results and findings are summarised, and relevant conclusions are drawn by concluding the assessment.

Tool used for Simulation: HOMER is utilized to simulate and optimize the HRES. HOMER is developed by the National Renewable Energy Laboratory (NREL) (“Homer,” n.d.). To meet thermal and electrical demands, a variety of energy sources, including photovoltaic (PV) modules,

Journal Pre-proof

wind turbines, small hydro, micro-turbines, biomass, batteries, hydrogen storage, and fuel cells, can be combined and simulated using HOMER. Studying and building these systems can be quite difficult since there are a lot of design possibilities available and uncertainty about key factors like fuel prices and load sizes. The inconsistency, seasonality, non-dispatchability, and unclear availability of renewable energy sources increase the complexity of issues. HOMER was created to deal with these problems. The main activities that HOMER performs are simulation, optimization, and sensitivity analysis and then it produces the best-optimized outcomes.

3. Results and Discussion

HOMER software is used along with the relevant parameters, inputs, and constraints to simulate the system. HOMER simulates multiple combinations and arrangements of the system and arranges the solutions based on the aggregate net present cost, and the system matches the current energy sources. The ideal arrangement of the HRES components for our proposed system is a solar photovoltaic power source, which can vary from 0 to 150 kW. The biomass gasifier generator set produces 160 kWh daily and also an idealized 600V battery and a 75 kW converter. The cost of various elements in the system is as follows: Capital Cost (CC), COE, and NPC_{total} for the HRES are ₹16.96 (US$ 0.207)/kWh, ₹32,028,543.3 (US$ 3,90,878) and ₹41,603,969.8 (US$ 5,07,737) respectively.

The yearly average load utilized is 190,116 kWh and the average energy production of the biomass gasifier and solar PV system are as follows: Solar PV system = 288,620 kWh/year and biomass gasifier generator set = 88,160 kWh/year as shown in Figure 6. The annual energy production of HRES is 376,780 kWh. Biomass gasifier supports approximately 23.4% of and solar PV approximately 76.6% of the total energy production.

Journal Pre-proof

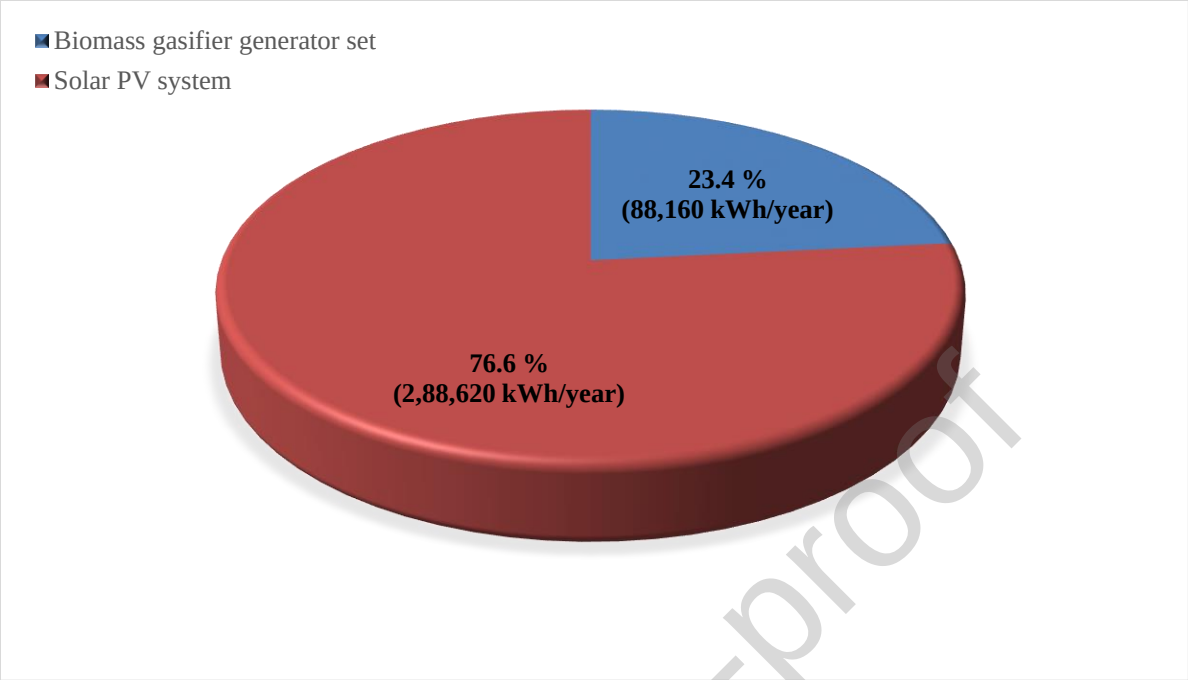


Figure 6: Average energy production from different resources

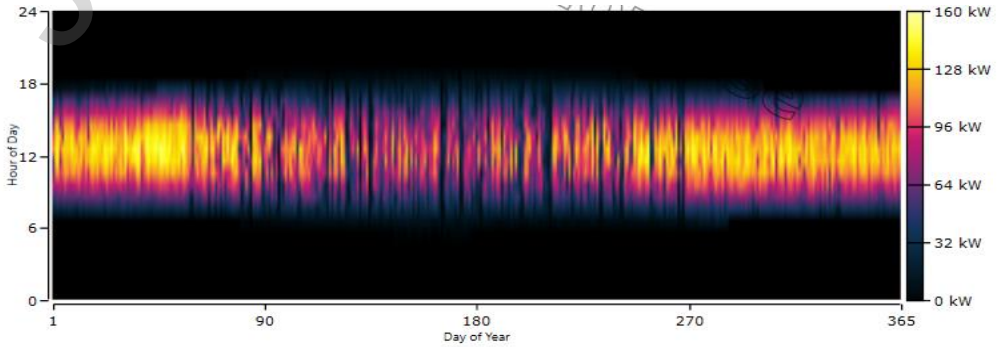
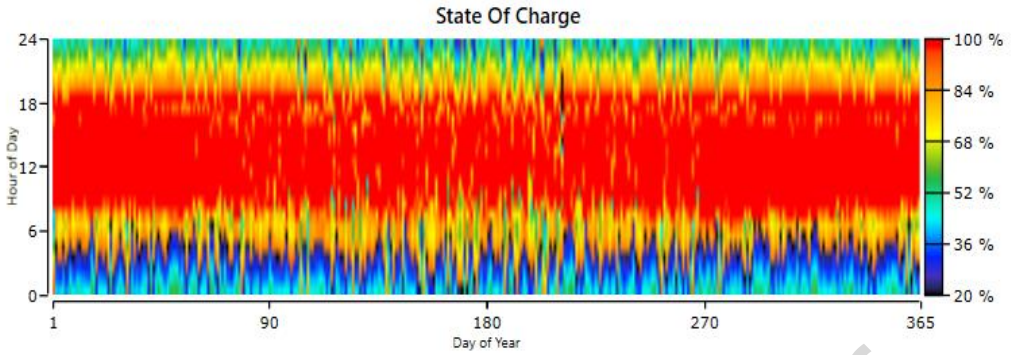
During the day, when ample solar power is accessible, there is a direct supply to the load through the solar PV system. Additionally, the biomass gasifier generator is accessible during the daytime. However, biomass gasifier works to provide a consistent supply at night when load demand is high since solar energy is not accessible. When the energy generation surpasses the energy demand, the spare energy is utilized in charging the battery. Load demand presented for the HRES of solar PV, and biomass for the Mechanical Engineering Department. In this HRES, an unmet electrical load of 48.8 kW per year is present and surplus energy of 173,147 kWh per year energy. A shortage in the capacity of 0.0375% is observed.

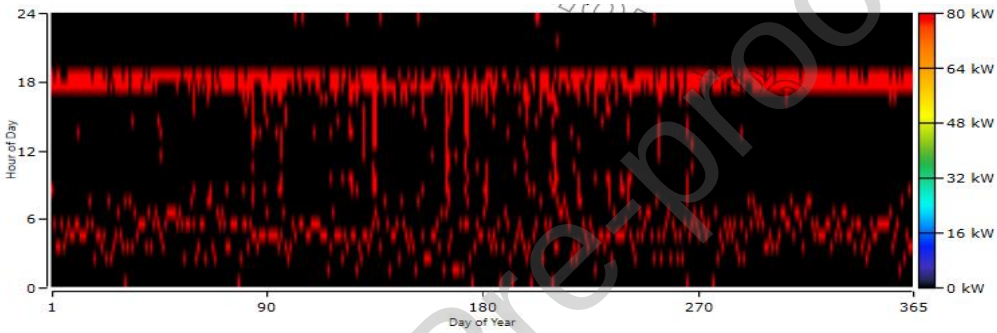


(A) Output of Solar photovoltaic system

Journal Pre-proof



(B) Battery state of charge (SOC)



(C) Biomass gasifier power generation

Figure 7: Output of different components of hybrid power generation system

Figure 7(A) shows the output of the solar PV system. PV module can produce energy in the morning even when there is not enough sunlight. However, most energy is produced between 10:00 AM to 04:00 PM i.e., 6 hours when PV modules work at full capacity. Figure 7(B) depicts the amount of charge present in the battery at a particular time. It can be deduced that the charge is always full during the daytime but constantly depletes once daylight is gone and the load is met using batteries only. The charge reduces to 15%-20% until it gets replenished in the morning. For a healthy battery life, trickle charging is suggested, and the minimum charge should never be lower than 15%. Biomass generator charges batteries and meets the load demands when PV output is unavailable. Figure 7(C) shows that the generator works at its peak during twilight and just before dawn. Figure 8 shows energy produced from PV and biogas generators every month. Throughout the system's lifetime, i.e., 25 years, biomass gasifier and solar PV contribute 23.4% and 76.6% of the total energy produced. Excess energy produced per annum is about 173,147 kWh, mainly due to the dynamic load profile, which considers the holidays and vacations in June, July and

Journal Pre-proof

December (2022) when the classes are suspended, and the halls and rooms in the academic buildings are not in that much use. It reduces the load requirements significantly. In June and July, the Northern Hemisphere is warm and sunny in summer; therefore, solar irradiation is at its fullest. Therefore, the PV at its total capacity will produce more energy than the whole Mechanical Engineering Department needs. To utilize this excess energy, the authors suggest that other departments can use this energy to power themselves, particularly during the months of vacations, rather than drawing power from the grid.

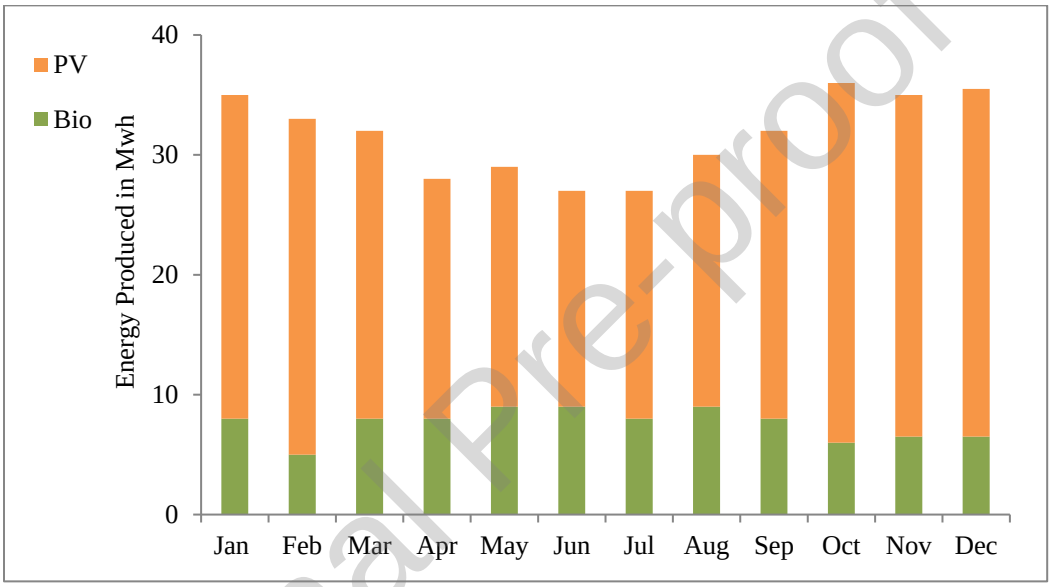


Figure 8: Monthly electricity production of HRES

The benefit of this hybrid plant does not limit itself to a lower carbon footprint compared to conventional energy generation methods. Biogas used for the gasifier comes from food waste collected on campus. Digestate is a by-product of the anaerobic digestion of food waste and can be used as fertilizer for gardening. At the same time, the biogas is extracted and utilized in power generation. In Table 1, the feedstock supplied on an average timely basis to the gasifier has been shown. In the gasifier, it has been estimated that from 1 ton of biomass, 400 kg of fertilizer is produced. Hence, with an annual food waste of 277 tons collected, around 110.8 tons of fertilizer is produced as a digest.

Journal Pre-proof

Table 1: Biomass consumption

Feedstock	Quantity	Units
Gross feedstock consumed	277	Tons
Daily average feedstock	0.759	Tons/day
Hourly average feedstock	0.0316	Tons/hour

Table 2: Yearly emissions

Pollutant	Yearly Emissions (kg/yr)
CO_2	49.90
CO	0.554
UHC	0.00
PM	0.00
SO_2	0.00
NO_X	0.346

Journal Pre-proof

HOMER calculates the analysis and consequently the results of emissions based on the following six pollutants: Carbon dioxide (CO_2), Carbon monoxide (CO), Particulate matter (PM), Unburnt hydrocarbons (UHC), Sulphur dioxide (SO_2), Nitrous oxide (NO_X). These pollutants are emitted due to electricity production by the generators, thermal energy released by the boiler and electricity consumption. HOMER simulates the gaseous emissions of both the boiler and the generator. HOMER first establishes the emissions factor, which is the weight of each pollutant in kg produced per unit of the fuel used, after which it simulates the power system. Next, it evaluates the yearly gaseous emissions of the particular pollutant from the emissions factor product and total yearly fuel consumption. The user inserts the emissions factor of 4 pollutants: CO, UHC, PM and NOx. Using this input as well as the contents of the fuel (carbon and sulphur), the software analyses to

evaluate emissions factors for the two other air pollutants, CO_2 and SO_2. HOMER also makes use of some assumptions in these calculations, which are they are as follows:

Carbon contents in the fuel which are not released as CO or UHC are treated as CO_2. The carbon ratio of the UHC produced is equivalent to that of the fuel. Sulphur contents in burnt fuel that are not released as PM are treated as SO_2 ("Homer Pro 3.15," 2022). Table 2 shows the yearly emissions that have been considered in the software for the feasibility analysis and output of the modelled HRES. According to research 1 kWh of electricity produces 0.85 kilograms of carbon dioxide annually ("Central Electricity Authority," 2022). According to the load profile, the total output of CO_2 generated by the Mechanical Engineering Department is estimated from Eq. (11).

$$190116\,\frac{\text{kWh}}{\text{year}}\,(\text{yearly average load}) \times 0.85 = 161598.6\ \text{kg}\ (\text{Output amount of } CO_2) \quad (11)$$

The total amount of CO_2 emission is calculated as 161,598.6 kg/year using Eq. (11). This shows a significant improvement of nearly 99% which is roughly 161 carbon credits per year. One carbon credit means that 1 metric tonne of CO_2 is prevented from entering the atmosphere. Similarly, 1 kWh of electricity produces approximately 7 grams/kilowatt-hour of SO_2 and 4.3 grams/kilowatt-hour of NO_x (Mittal, 2012). On the contrary, the HRES designed and analysed produces no SO_2 and only 0.346 kg/year of NOx. Hence it is a significant improvement in environmental impact and successful environmental sustainability analysis. All the feasible configurations with cost analysis for the proposed system are given in Table 3. The cost analysis of each component for a lifespan of 25 years is given in Table 4 and the Gross cost of the system is ₹41,603,935.4 (5,07,736.58US$).

Validation of the proposed system results with previous published research

In contrast to earlier research, this study has created a novel HRES configuration with different component sizes, load requirements, and renewable resource usage. Therefore, it is impossible to compare those systems precisely. However, a comparison that is established based on the systems' economic designs can be considered acceptable and appropriate. This proposed system's NPC and COE have been compared to published research findings from previous studies (Table 5).

Employment Opportunity

The design, setting up, maintenance and operation of plants lead to green employment for individuals in society. Skills required for the jobs vary from very little knowledge to high-level expertise, aiming for the community to position a post.

Improved sanitation: Adopting a hybrid project including biogas and biomass will positively

impact the waste management of society as a significant portion of the biological waste collected, that is initially discarded in landfills is now being sent to produce electricity.

Site assessment and location: Location and choice of setting up a biogas plant to be judicious and as least convenient to the area residents. Biogas plants make use of biological refuse that discards a pungent odour. The location of the biogas plant should be such that citizens feel minimal discomfort by its presence so that the plant can keep operating.

By replacing the traditional role of electricity, in academic institutions and other buildings, with green energy sources, there will be several positive impacts, most notably in the number of harmful substance emissions. Furthermore, renewable energy systems and plants can offer direct and indirect work to several people and businesses along the line of processes. HRES encourages good hygiene and sanitation since there is a significant focus on waste collection and management. It consequently reduces the waste going into dumpsites and uses it to convert it into usable energy. Therefore, all buildings and institutions can obtain their energy needs from renewable energy sources and fully optimized HRESs.

4. Conclusion

The techno-economic and environmental sustainability analysis to power the Mechanical Engineering Department at Delhi Technological University, Delhi has been done. The following remarks have been made on the basis of assessment, evaluation, and Output of HRES:

i. The cost of energy of the proposed HRES is ₹16.96 (US$0.207)/kWh, and the gross NPC is determined ₹41,603,969.8 (US$ 5,07,737).

ii. During a lifetime (25 years), biomass gasifier and solar PV contribute 23.4% and 76.6% of the total energy produced.

iii. System is optimized to meet the mean energy constraint of 588 kWh per day with a peak of 65 kW and 35 kW on weekdays and weekends, respectively.

iv. Total power generated by the system is 3,76,780 kWh per year to match the load demand of 1,90,116 kWh per year.

v. HRES has an unmet electrical load of 48.8 kW per year. A surplus of 1,73,147 kWh per year of energy is produced and a shortage of 0.0375% is observed in the capacity.

Journal Pre-proof

vi. HRES produces no SO_2 and only 0.346 kg per year of NOx, demonstrating a significant improvement in environmental effect and a successful environmental sustainability analysis and around 161 metric tonnes of CO_2 is prevented from entering the atmosphere.

The outcome of this research work highlights the future role of HRESs in meeting the load demands of educational institutions instead of relying on fossil fuel sources for power. The cost of energy is also reduced by using two renewable energy sources. It acts as a stepping-stone where energy demands can be met sufficiently by combining two or more non-conventional/renewable energy resources for power generation rather than depending on a single renewable energy source.

Recommendation for Future Scope:

i. Reduce the hazards of global warming by successfully exploiting HRES using AI-based multi-objective optimisation techniques like machine learning, artificial neural network, and deep learning models.

ii. Technological advancements in fuel cells make them economical, more dependable, and safe. Taking into account research topics such as connecting fuel cells with grid, safety concerns of storing H_2 in fuel cells, and maximum power utilisation from fuel-utilising AI-based optimisation algorithms.

Therefore there is a significant opportunity for intellectuals to further investigate proposed study areas in depth.

Nomenclature

A_{PV} = Rated capacity of the photovoltaic array

a_P = Temperature coefficient of power

α= Maximum charge rate of storage bank

DOD_{batt} = Depth of discharge of the battery

$C_{ann,tot}$ = Total annualised cost in $/year

C_{AT} = Total annualized cost

C_{NPC} = Net Present Cost

C_{rep} = Component replacement cost in $

C_{Wh} = Storage capacity

$E_{prim,AC}$ = AC primary load served in kWh/year

$E_{prim,DC}$ = DC primary load served in kWh/year

$E_{grid,sales}$ = Total grid sales in kWh/year

EL = Total energy demand

E_{tot} = Gross energy demand

E_{max}= Net capacity of the storage bank

E_1 = Available energy in storage bank-start of the time step

E_{tot}= Net amount of power in storage bank at the start of the time step

f_{PV} = Derating factor

I_m= Maximum charge current of the storage bank

N_{batt}= No. of batteries in the storage bank

P_{PV} = Energy output from photovoltaic cell

P_{NPV} = Rated power-reference

P_o = Electrical power output of the system

P_n = Power needed by system components

P_{tot} = Effective electrical energy system generated, (Input biomass) $_{LHV}$ = input biomass- lower heating value

Q = the total amount of energy in the storage at the beginning of the time step

r = The storage rate constant

R_{comp} = Component life in year

Journal Pre-proof

R_{rem} = Component remaining life in year

R_T = Incident solar radiation on the photovoltaic array in the current time step

$R_{T,STC}$ = Incident solar radiation, solar radiation under standard reference conditions

R = Solar radiation

R_{ref} = Solar radiation-reference (G_{ref} = 1000 W/m)

r = Constant (depending on storage rate)

s= Storage capacity ratio

T_{ref} = Temperature-reference conditions (Tref = 25 °C)

T_{cell} = Photovoltaic cell temperature

$T_{cell,STC}$ = Photovoltaic cell temperature under standard test conditions

Δt= Duration of the time step

V_n= Nominal voltage of the storage bank

Greek Symbol

η_{in} = Efficiency of inverter

η_{batt} = Efficiency of battery

$\eta_{batt,c}$ = Charge efficiency of the storage battery bank

Abbreviations

AD = Daily Autonomy

CC = Capital cost

COE = Cost of energy

CRF = Capital recovery factor

CUF = Capacity Utilization Factor

DSF = Demand supply fraction

Journal Pre-proof

GHG = Greenhouse gas

HRES = Hybrid renewable energy system

HOMER = Hybrid Optimization of Multiple Energy Resources

IRENA = International Renewable Energy Agency

LCOE = Levelized cost of energy

LFR = Linear Fresnel Reflector

NPC = Net present cost

NPV= Net present value

NREL = National Renewable Energy Laboratory

PTC = Parabolic Trough Collector

PV = Photovoltaic

UHC = Unburnt hydro carbon

***Abstract*— Due to the large volume of sharing and storage of sensitive information on centralized or distributed storage, there is a growing necessity for employing encryption techniques that provide promising security and access control to the sensitive data on these platforms. Access control is a fundamental aspect of information security, encompassing the mechanisms and policies governing who can access, modify, or use the data within a system. Attribute-based encryption (ABE) is a cryptographic technique that offers a fine-grained access control mechanism by associating attributes with encrypted data and secret keys. This paper suggests the proposed attribute-based encryption as a means to establish secure access control in Blockchain, thereby attaining the secrecy and freshness aspects of cryptographic protocols. The proposed scheme is simulated on SPAN AVISPA. The Security Protocol Animator SPAN functions by simulating an active intruder, enabling interactive identification and construction of potential attacks against various protocols.**

Keywords—Blockchain, Attribute-Based Encryption, Security, Access Control, AVISPA

I. INTRODUCTION

Security attacks in the Blockchain ecosystem can have profound repercussions. They can alter data, enable double spending, lead to fund theft, disrupt the network's operation, and, most significantly, erode trust in the technology. These attacks compromise the core principles of Blockchain, such as immutability, transparency, and security, making it essential for Blockchain networks to implement robust security measures to mitigate these threats and maintain their integrity. Cryptography protocols serve as a crucial defense mechanism in protecting Blockchain networks against security attacks. They play a pivotal role by encrypting data stored on the Blockchain, ensuring the confidentiality of sensitive information, and rendering it inaccessible to unauthorized parties. Additionally, cryptographic techniques are applied to secure transactions, making it extremely challenging for attackers to alter or intercept data during the transfer of assets.

In the context of cryptographic protocols, an identity-based encryption (IBE) system distinguishes individual users through distinct identity strings. Conversely, an ABE system operates by characterizing users through a collection of attributes. It utilizes a specified function based on these attributes to determine their decryption capabilities for a given ciphertext. Identity-based encryption (IBE), as pioneered by Adi Shamir in his seminal work [1], represents a cryptographic paradigm that affords individuals the capability to employ arbitrary character strings as their public keys, such as email addresses. This novel approach obviates the necessity for a distinct infrastructure for the dissemination of public keys, thereby streamlining the process of message transmission. In practical terms, it enables message senders to securely communicate with recipients solely based on the latter's identity, which can be, for instance, an email address. Shamir's motivation for developing Identity-Based Encryption (IBE) was to streamline and simplify the management of certificates in email systems.

Boneh and Franklin [2] first introduce fully functional identity-based encryption. Prior to their proposal, several IBE schemes had been put forth, but they exhibited various limitations. Some of these earlier solutions necessitated that users not collaborate or collude, while others imposed significant computational overhead on the Private Key Generator (PKG) during private key generation requests. Additionally, certain solutions called for tamper-resistant hardware, as identified by Boneh and Franklin. Nonetheless, in many cases, individuals are typically distinguished by their distinctive attributes rather than a singular unique identity. Individuals may not possess precise knowledge of the specific identities of all other individuals granted access to the data; instead, they may only possess the means to describe potential access recipients based on their descriptive credentials or attributes [3]. ABE is a form of access control in which the data owner defines access policies based on attributes, and only users with the necessary attributes can access the encrypted data. Sahai and Waters [4] introduced the notion of ABE. In an ABE framework, both a user's cryptographic keys and ciphertexts are associated with sets of descriptive attributes, and the decryption of a specific ciphertext is contingent upon the alignment of attributes between the ciphertext and the user's key.

The primary objective of this research work is to evaluate the efficacy of ABE in safeguarding sensitive data while ensuring robust security measures such as confidentiality and freshness.

A. Our Contribution

In essence, this paper contributes by proposing a novel approach to fortify access control in Blockchain through the integration of Attribute-Based Encryption. By leveraging ABE, the paper aims to elevate the security standards and responsiveness of access control mechanisms in the ever-evolving landscape of information sharing and storage. We utilized the AVISPA SPAN tool to simulate the functioning of the proposed scheme under various conditions. This simulation allows

us to thoroughly analyze the ABE's capability to protect sensitive information from intruders or attackers.

II. Related work

The advent of identity-based encryption has brought forth a distinctive approach introduced by Sahai and Waters, known as ABE [4]. Subsequently, various iterations such as KP-ABE [5] and CP-ABE [6] schemes have been introduced to advance and optimize the efficacy of ABE. A Blockchain is an ever-expanding series of blocks connected by hash values containing the ledger of validated transactions with timestamps. A Blockchain is a peer-to-peer network with each node in the network replicating and storing its copy of the data. Consequently, this distributed, decentralized approach excludes the need for truth in third parties. ABE in Blockchain can be used to enhance privacy, security, and access control in various ways such as fine-grained access control, privacy preservation, flexible access policy, key management, multi-party access, and data sharing.

Authors [7] introduced a Blockchain-centered framework integrating ABE. This scheme, beyond upholding data integrity and non-repudiation, notably safeguards the privacy of transactional data. The proposed scheme for a privacy-preserving Blockchain incorporates access control mechanisms to specifically tackle the confidentiality of shared data within the Blockchain ecosystem. Consequently, it endeavors to establish an end-to-end privacy-preserving system tailored for the Internet of Things (IoT). Authors [8] proposed an efficient and privacy-preserving traceable attribute-based encryption scheme that leverages Blockchain technology to ensure data integrity and non-repudiation. Employing pre-encryption methods, it enables swift ciphertext generation while preserving user anonymity through attribute hiding within anonymous access control structures using attribute bloom filters. This scheme allows auditing of abused secret keys, distinguishing between user and attribute authority origins, thus enhancing security. Comprehensive security and performance analyses affirm the scheme's robustness and efficiency, addressing critical issues in attribute-based encryption within distributed networks.

The primary limitation associated with ABE pertains to its computational overhead, which escalates proportionally with the intricacy of the access policy employed. Authors [9] introduced a solution that tackles the escalating computational burden in ABE by securely outsourcing decryption computation. The proposed ABE scheme introduces fairness through Blockchain and sampling techniques. Leveraging smart contracts within Blockchain ensures proxies receive rightful rewards for valid outsourced decryption results, establishing a system that upholds fairness while maintaining the confidentiality of the underlying plaintext. In the present investigation, the authors [10] have introduced a keyword-searchable ABE scheme. This innovative approach aims to enhance the security of digital certificate transfers while addressing concerns pertaining to data privacy. The findings of the study indicate that the proposed scheme demonstrates notable cost-effectiveness, characterized by a low computational cost. Furthermore, the system exhibits proficiency in attribute revocation, thereby bolstering its overall efficacy.

In the study [11], the authors introduced a novel multi-authorization attribute-based verifiable encryption scheme, leveraging Blockchain technology. The proposed scheme facilitates the validation of key accuracy distributed by numerous authorization centers, effectively resolving the challenge associated with the necessity for all authorization centers to retransmit the private key in the event of an incorrect key discovery. The study [12] introduced an innovative collaborative framework designed for secure cloud file sharing, employing a combination of Blockchain technology and ABE. The utilization of Blockchain facilitates the implementation of access control through smart contracts established between data owners and users. This decentralized scheme exhibits fault tolerance and resilience against Denial of Service (DoS) attacks, ensuring robust security measures

III. Preliminaries

Within this section, we provide a formal definition along with essential background information about cryptographic assumptions, bilinear maps, access structure, and attribute-based encryption.

A. Bilinear Maps

Considering two multiplicative cyclic groups denoted as $\mathbb{G}_0$ and $\mathbb{G}_T$, both having a prime order p. Let e be a bilinear map, e: $\mathbb{G}_0 \times \mathbb{G}_0 \rightarrow \mathbb{G}_T$ with g be a generator of $\mathbb{G}_0$ has the properties below [13]:

- Bilinearity: $\forall\ a,\ b \in \mathbb{Z}p$ and $g_1,\ g_2 \in \mathbb{G}_0$, $e(g_1^a, g_2^b) = e(g_1, g_2)^{ab}$.
- Computability: $e(g_1, g_1)$ is efficiently computable for all $g_1, g_1 \in \mathbb{G}_0$.
- Non-degeneracy: There exists $g_1, g_1 \in \mathbb{G}_0$, $e(g_1, g_1) \neq 1$.

Bilinear maps in ABE provide the mathematical framework to implement fine-grained and flexible access control policies and efficient key generation while maintaining security.

B. Security Assumption

The security of the Boneh and Franklin (in their fully functional IBE) is based on the Computational Diffie Hellman (CDH) assumption on the elliptic curve. This system can be constructed using any bilinear maps, provided that the variant of the CDH problem in $\mathbb{G}_0$ is NP-Hard.

Computational Diffie Hellman assumption states that for a probabilistic polynomial time algorithm $\mathcal{B}$, the computational challenge lies in computing $\mathbb{Z} = g^{ab}$ when provided with known tuple g^a, g^b, where $(a,b) \in \mathbb{Z}_p$ is randomly selected. The advantage ε in addressing the CDH assumption is described as:

$$|Pr[\mathcal{B}(g^a, g^b) = g^{ab}]| \geq \varepsilon$$

Another popular security assumption, Decisional Bilinear Diffie Hellman (DBDH) [4] [14] [15] describes that g is a generator of $\mathbb{G}_0$. a, b, c, z $\in \mathbb{G}_0$ are four randomly chosen elements, and let Y_1, Y_2, Y_3 are $Y_1 = g^a$, $Y_2 = g^b$, $Y_3 = g^c$, no probabilistic polynomial time algorithm $\mathcal{B}$ can distinguish from $e(g,g)^{abc}$ and $e(g,g)^z$ with advantage ε in solving:

$$Adv_{\mathcal{B}} = |Pr[\mathcal{B}(Y_1, Y_2, Y_3, e(g,g)^{abc}) = 0] - Pr[\mathcal{B}(Y_1, Y_2, Y_3, e(g,g)^z)] = 0| \geq \varepsilon$$

C. Access Structure

Access structures [16] define individuals who possess the requisite qualifications or those who lack permission to access particular data, contingent upon the authorization of specific attribute sets.

Definition: Let $\{P_{r1}, P_{r2}, \ldots, P_{rn}\}$ in access structure be a set of parties. A collection $\mathbb{A} \subseteq 2^{\{Pr1, Pr2, \ldots, Prn\}}$ is monotone $\forall$ B and C, if $B \in \mathbb{A}$, $B \subseteq C$, then $C \in \mathbb{A}$. An access structure is a collection $\mathbb{A}$ of nonempty subsets of $\{P_{r1}, P_{r2}, \ldots, P_{rn}\}$, i.e. $\mathbb{A} \subseteq 2^{\{Pr1, Pr2, \ldots, Prn\}} \setminus \{\emptyset\}$. The attributes have taken the role of the parties here.

Access Tree: Consider a tree, denoted as $\top$, representing an access structure. Within this structure, every non-leaf node within the tree signifies a threshold gate. Each gate is defined by its children node and a specific threshold value. In ABE (Figure 1), authorized users must satisfy the access policy formulated using a set of attributes to gain access to sensitive data.

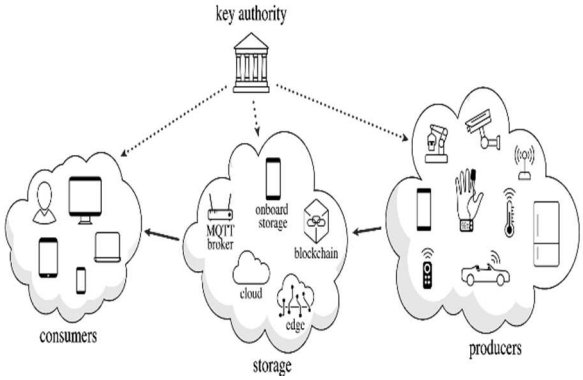

Figure 1: ABE Scheme [17]

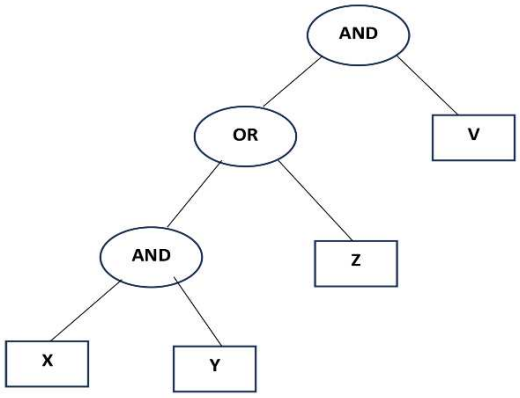

Figure 2: Access Tree

Figure 2 illustrates an access structure that gives access to those users who satisfy the access policy (((X∧Y)∨Z)∧V).

IV. System Model

Within our model (as shown in Figure 3) the encryption of the message is achieved through the implementation of the CP-ABE scheme. The proposed model consists of four key entities, namely the Data Owner, Data Consumer, Attribute Authority, and Blockchain.

Blockchain: Blockchain serves as the repository for data storage, ensuring non-repudiation, consistency, and immutability of the stored information. The data owner uploads the ciphertext on the Blockchain, also the access approach furnished by the data owner is archived, while the data user undergoes authentication in alignment with the access strategy delineated by the data owner.

Data Owner: The Data Owner assumes the role of a data sharer, storing information within the Blockchain. Utilizing an access structure, the Data Owner encrypts the message to generate ciphertext before storage.

Data Consumer: Access to the data is granted to users whose attributes align with the ciphertext access policy. Upon meeting this criterion, the user employs the decryption algorithm alongside the secret key to decrypt the file and acquire the plaintext.

Attribute Authority: The Attribute Authority releases the public parameter and formulates the master key for the system. Subsequently, the AA issues a secret key to the user, considering the user's specific attributes.

There are four major algorithms in attribute-based encryption briefly described as:

- Setup: *Setup{ λ }→PK, MSK,* In this algorithm security parameter λ is taken as input which then generates the public key *(PK),* known to everyone, and the master secret key *(MSK),* kept as secret.
- Key Generation: *KeyGen{ PK, MSK, S }→SK,* It is sometimes referred to as the attribute key generation algorithm, which takes the public key PK, set of attributes S, and master secret key MSK as input and generates the Secret Key SK.
- Encryption: *Encrypt{ PK, M, γ }→CT,* This algorithm takes the public key parameters, a message, and a set of attributes γ as the input and returns the ciphertext *CT.*
- Decryption: *Decrypt{PK, CT, SK} →M*, As stated earlier, the user acquires the decryption key that corresponds to their attribute set *S.* The user then decrypts the ciphertext using their secret key.

Security Goal

Access Control and Confidentiality: The preservation of confidentiality within the system necessitates the continuous safeguarding of message secrecy during transmission. Simultaneously, access control mechanisms guarantee that message decryption and access are exclusively granted to users whose attributes align with the access policies defined by the data owner.

Data Security: The scheme should ensure that the data is accessed by the authenticated users only and upon a user's departure from the system, their access privileges must be promptly revoked, barring any further access to the data or messages.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 09,2024 at 06:53:45 UTC from IEEE Xplore. Restrictions apply.

Collision Resistance: Collusion can occur when multiple users pool their keys together to collectively decrypt a ciphertext, even if individually they might not possess enough attributes to satisfy the access policy. Collusion tolerance aims to prevent or mitigate such attacks. Central authority can prevent collusion by managing key distribution and maintaining control over the keys.

Forward and Backward Security: Newly joined users are restricted from accessing ciphertexts shared before their enrolment to prevent access to past data. Similarly, former users are prohibited from accessing current ciphertexts and any forthcoming encrypted information. This measure ensures that only the current authorized user base can access historical and ongoing information, safeguarding the confidentiality of past, present, and future data exchanges.

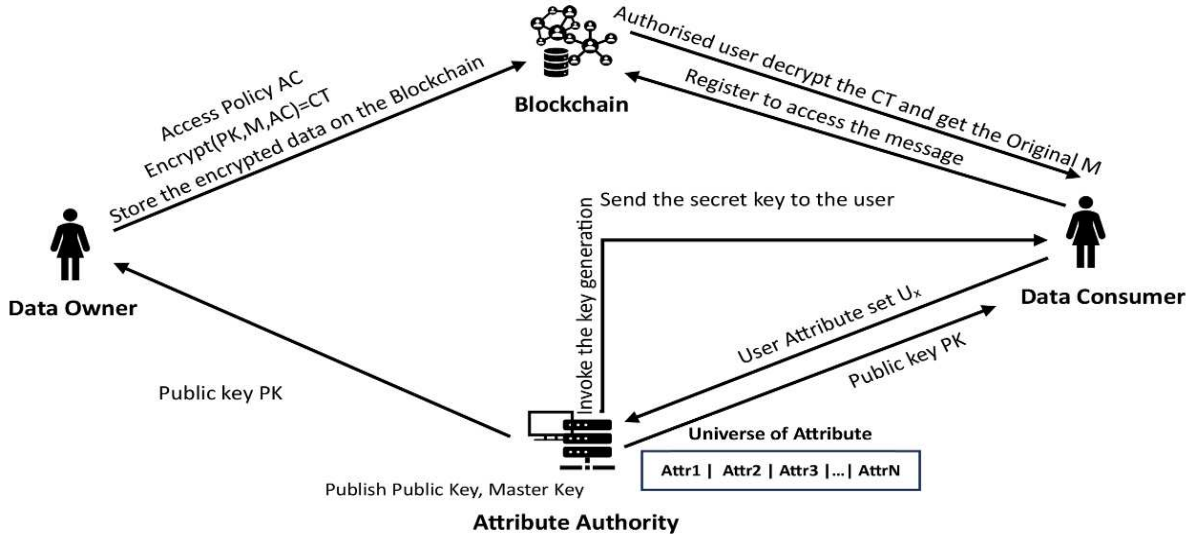

Figure 3: Work Flow of System Model

V. SIMULATION

AVISPA conducts analyses on network security protocols and software applications scripted in HLPSL.

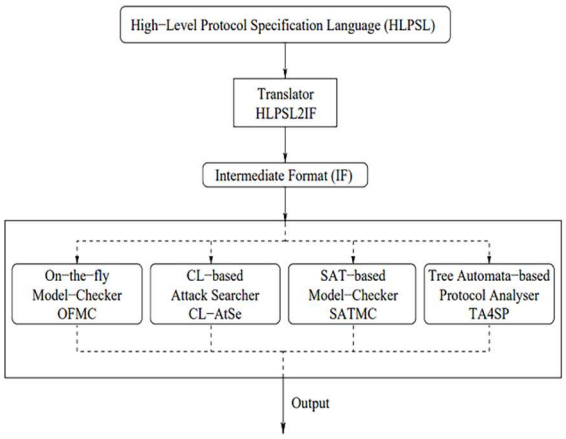

Figure 4: AVISPA Tool Architecture [18]

HLPSL encompasses fundamental roles delineating diverse entities and configurations characterizing pivotal role scenarios. The roles operate independently, gathering initial data through parameters and employing AVISPA backend parameters like CL-AtSe to verify the authenticity of the communication method with distinct characteristics.

VI. Results and Analysis

The proposed approach is replicated within the High-Level Protocol Specification Language (HLPSL), specifying the distinct roles for the data owner, data consumer, Blockchain, and attribute authority, alongside essential roles such as session, environment, and goals. This segment will offer a concise overview of the procedural sequence adopted in our implementation, along with a summary of the obtained results. Within this model, the data owner initiates attribute requests and formulates the access policy (AC).

In the context of the Attribute-Based Encryption (ABE) scheme discussed earlier, access to data or messages is restricted solely to users possessing a set of attributes aligning with the key, thereby satisfying the designated access policy. After acquiring the public key of the system(PKs) from the attribute authority, the data owner proceeds to encrypt the message, transmitting *SND(exp(exp(M,AC'),PKs'))* to the Blockchain. The operator *exp* is a special operator if a file/message has the properties *exp(exp(A,B),C)= exp(exp(A,C),B)* and *exp(exp(A,B),inv(B))=A*. The data consumer here named Alice, transmits her user identity *UID,* alongside specific attributes *Attr*, to the attribute authority. Subsequently, the attribute authority furnishes the user with a Global Identity *GID*, aimed at mitigating collusion concerns within ABE when operating beyond simulated environments.

Figure 6: Simulation results of ABE scheme for two sessions

Assigning a distinct Global Identity *GID* to each user in correspondence with their specific attributes effectively eradicates the potential for collusion between two users. The data user sends *SND(GID',PWD'),* that is Global Identity and associated password to the Blockchain. Following verification, the Blockchain securely transmits encrypted data to the authenticated data user. To realize the objective of maintaining secrecy, the declaration of *secrecy_of* includes the parameter *sec_1* allocated to the entities of both the Blockchain and the data consumer Figure 6.

HLPSL applies the Dolev-Yao threat model, and subsequently, AVISPA assesses the security protocol's viability, determining its safety or susceptibility. Within AVISPA, an active role is assumed by an intruder *i* during communication Figure 7. For formal security verification under the SPAN in AVISPA Figure 6, In this study, the widely used OFMC and CL-AtSe back-ends are employed. Results from TA4SP and SATMC backends are disregarded due to the current limitation of the HLPSL implementation, which does not recognize the *exp* operation. The protocol additionally guarantees the freshness property within the tested protocol. In the course of the protocol session, a message qualifies as fresh when it has been exclusively constructed for that particular protocol session. The study provides a secure data exchange between the owner and the consumer and has been compared with [19], showing that our scheme is safe and satisfies the secrecy, and freshness aspects of cryptographic protocol.

VII. Conclusion

In this study, our model, formulated using the HLPSL language, has been simulated within the AVISPA SPAN tool. The primary objective was to ensure the security of sensitive information exchanged between entities, Bob as the data owner and Alice as the data consumer. We analyzed the data's secrecy between the Blockchain and the data consumer in our model. Additionally, we focused on preserving data freshness across multiple sessions during model execution. In the future, our main goal will be to conduct a comprehensive examination of prospective instances of replay attacks and man-in-the-middle (MITM) attacks and also analyze the attack traces comprehensively and thoroughly with precise attention to detail.

Abstract

Luminescent $Li_3Ba_2Gd_3Mo_8O_{32}:Tb^{3+}$ phosphors were synthesized using the sol–gel method, and extensively characterized through various spectroscopic techniques, including x-ray diffraction (XRD), scanning electron microscopy (SEM), Fourier-transform infrared (FT-IR) spectroscopy, photoluminescence (PL) excitation, and emission. SEM micrographs revealed the irregular and non-uniform morphology and size of the prepared phosphors. The FT-IR spectra offered insights into the functional groups and bonding within the phosphor. The PL excitation spectra at a 545 nm emission wavelength displayed a slight shift in peak positions with a prominent peak at 283 nm, corresponding to the characteristic $4f^8 \rightarrow 4f^75d^1$ transitions of Tb^{3+} ions, while under excitation at $\lambda_{exc} = 283$ nm, PL emission spectra exhibited distinct peaks associated with $^5D_4 \rightarrow {}^7F_j$ ($j = 6, 5, 4, 3$) transitions. Notably, the transition $^5D_4 \rightarrow {}^7F_5$ at 545 nm demonstrated strong and particularly high intensity in the $Li_3Ba_2Gd_3Mo_8O_{32}:0.09Tb^{3+}$ phosphor. Photometric analysis showed the potential of this phosphor to serve as a vivid green light source for various display applications. The $Li_3Ba_2Gd_3Mo_8O_{32}:Tb^{3+}$ phosphor may be used for creating sensors for environmental monitoring. Future research could explore its biocompatibility for biomedical applications and improve its targeting and photostability.

Introduction

White light-emitting diodes (LEDs) are recognized as a fourth-generation lighting source due to their numerous advantages, which include high efficiency, extended lifespan, rapid response, safety, and environment-friendly nature.[1–4] Notably, phosphor-converted white LEDs have in recent times become commercially viable and are extensively deployed as white LEDs. Consequently, the pursuit of novel phosphor materials, specifically phosphors doped with Ln^{3+} ions and tailored for use in white LEDs has become a dynamic and vibrant area of research.[5–8]

Trivalent terbium ions (Tb^{3+}) have garnered significant attention due to their primary emission bands falling within the visible region. This emission results from transitions $^5D_4 \rightarrow {}^7F_j$ ($j = 3, 4, 5, 6$) when subjected to violet or near-ultraviolet illumination.[9] Researchers have found that the unique luminous properties and wide range of applications of Tb^{3+} -doped phosphor materials have generated significant interest across various industries.[10–12] Due to their strong green emission upon excitation, phosphors doped with $Tb^{3+}$are useful for biomedical imaging, lighting, and display technologies. To customize the emission properties and improve the functionality of Tb^{3+} -doped phosphors, researchers have investigated a variety of host matrices, such as oxides, sulfides, and fluorides. Baig et al.[13] reported that, by integrating Tb^{3+} ions into various host materials, these phosphors can be used for fluorescent labeling in biological assays, solid-state lighting, and LED color conversion. They also offer tunable emission wavelengths, improved quantum efficiency, and increased stability.[13] Garcia-Cortes et al.[14] reported Yb^{3+} -doped $Li_{0.75}Gd_{0.75}Ba_{0.5}(MoO_4)_2$ crystals

with small quantum defects, while Song et al.[15] reported the photoluminescence characterization of Nd^{3+} -doped $Li_3Ba_2Gd_3(MoO_4)_8$.

The crystal of $Li_3Ba_2Gd_3(MoO_4)_8$, which is part of the $Li_3Ba_2Ln_3(MoO_4)_8$ family (where Ln = La-Lu) is characterized by a monoclinic crystal system with the space group C2/c.[16] In this study, $Li_3Ba_2Gd_3Mo_8O_{32}$ was selected as the host material due to its outstanding luminescent properties. Lithium possesses unique characteristics that set it apart from other elements within its group, and molybdenum exhibits a range of valence states, encompassing Mo^{3+}, Mo^{4+}, Mo^{5+}, and Mo^{6+}. When molybdenum forms compounds with other elements, it gives rise to intriguing electrical and optical phenomena. Rare-earth-doped phosphors offer exceptional chemical, optical, and electronic properties that make them ideal for a wide range of applications, including luminosity and display areas.[16,17]

The uniform distribution of dopants in the phosphor matrix and precise control over their chemical composition are facilitated by the sol–gel method. Verma et al.[18] demonstrated that phosphors produced through sol–gel exhibited superior homogeneity compared to phosphors manufactured using other methods. This low-temperature processing technique allows for the preservation of the luminescence of sensitive dopants and enables the incorporation of organic additives. The sol–gel method is highly recommended for phosphor synthesis, particularly in applications that require precise control over composition, morphology, and optical properties.[19,20]

The primary objectives of this study include the examination of structural phenomena, assurance of phase purity, analysis of surface morphology, characterization of bond properties, and study of luminescent properties. Additionally, the research aims to determine the CIE chromaticity coordinates and color purity, and to provide microscopic insights into the $Li_3Ba_2Gd_3Mo_8O_{32}$:xTb^{3+} phosphor network. To achieve these goals, the investigation involves spectroscopic techniques, including x-ray diffraction (XRD; Rigaku), Fourier-transform infrared (FT-IR; Nicolet 6700; Thermo Fisher) spectroscopy, scanning electron microscopy (SEM; S-3400; Hitachi), photoluminescence (PL; RF-5301PC; Shimadzu) excitation, and emission spectroscopy, as well as photometric analysis. Future research can improve the properties of $Li_3Ba_2Gd_3Mo_8O_3$:Tb^{3+} phosphor for different sensor applications. Additional studies are needed to enhance its performance.

Materials preparation and analysis

Phosphors with the chemical formula $Li_3Ba_2Gd_3Mo_8O_{32}$:xTb^{3+} (x = 0.005–0.13 mol) were synthesized using a sol–gel procedure. Stoichiometric quantities of the following compounds were employed: $LiNO_3$ for lithium, $Ba(NO_3)_2$ for barium, $Gd(NO_3)_3{\cdot}6H_2O$ for gadolinium, $(NH_4)_6Mo_7O_{24}{\cdot}4H_2O$ for molybdenum, SiO_2 for silicon, $Tb(NO_3)_3{\cdot}xH_2O$ for terbium, and citric acid. Citric acid was added to the mixture at a molar ratio of 3.5:1 to the metal ions. The weighed compounds were homogeneously mixed with 10 mL of distilled water in a 150-mL beaker, using a magnetic stirrer. After 1 h of stirring, the transparent solution was dried in an oven at 112°C overnight. The resulting dried sol was subsequently crushed and transferred to a 50-mL porcelain crucible, which was then placed in a 400°C furnace for 2 h. The black precursors obtained were subjected to further heat treatment at 880°C for 3 h in an air atmosphere to complete the synthesis of the samples. Figure 1 shows the synthesis process.

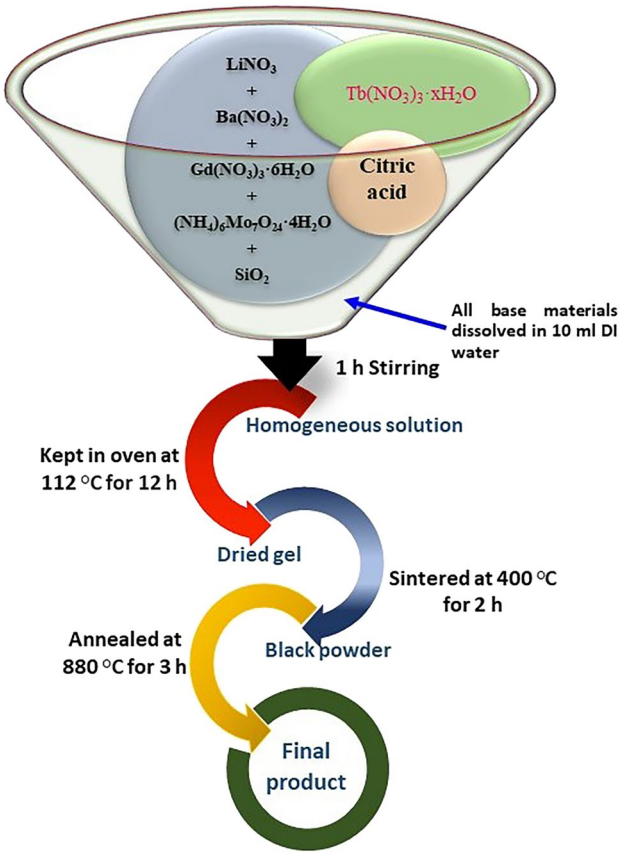

Fig. 1 The entire preparation scheme of $Li_3Ba_2Gd_3Mo_8O_{32}$:xTb^{3+}.

The phase of the prepared samples was characterized by XRD, the morphological details were investigated through SEM, the FT-IR spectra of the samples were analyzed, and the PL excitation and emission spectra were recorded.

Results and Discussion

Crystal structures and XRD examination

Figure 2a–d illustrates the standard orientation of the crystal structure of $Li_3Ba_2Gd_3Mo_8O_{32}$ and its orientation within the (011), (010), and (100) planes, which were generated using VESTA software. These observations confirm the monoclinic symmetry of $Li_3Ba_2Gd_3Mo_8O_{32}$. The structure of the $Li_3Ba_2Gd_3Mo_8O_{32}$ phosphor comprises honeycomb layers of Gd polyhedra with 8 vertices, with each layer being connected to two Mo tetrahedra featuring oxygen corners on both sides. The Li atoms are found at two distinct crystallographic positions: one-third of them occupy rare-earth sites with a coordination number of 8, while the remaining two-thirds occupy a specific position on a twofold axis with octahedral-coordinated oxygen.[21] Barium atoms possess a coordination number of 10 and are situated between the Mo and Gd polyhedral layers.

XRD pattern of the $Li_3Ba_2Gd_3Mo_8O_{32}:xTb^{3+}$ phosphors were compared with the Joint Committee on Powder Diffraction Standards (JCPDS) card 77-0830, as depicted in Fig. 3. These XRD patterns exhibit excellent agreement with all the peaks present in the reference pattern. Notably, the XRD patterns of all the prepared phosphors remain consistent across all Tb^{3+} concentrations, thereby confirming the presence of a monoclinic deformed scheelite structure in the samples with the

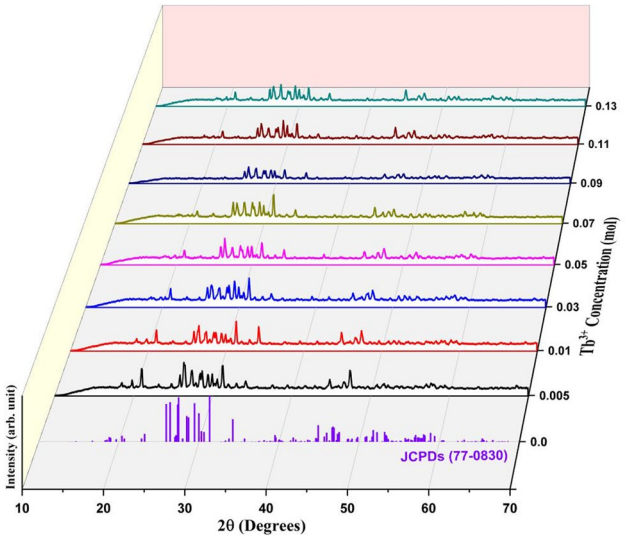

Fig. 3 XRD patterns of $Li_3Ba_2Gd_3Mo_8O_{32}:xTb^{3+}$ phosphors.

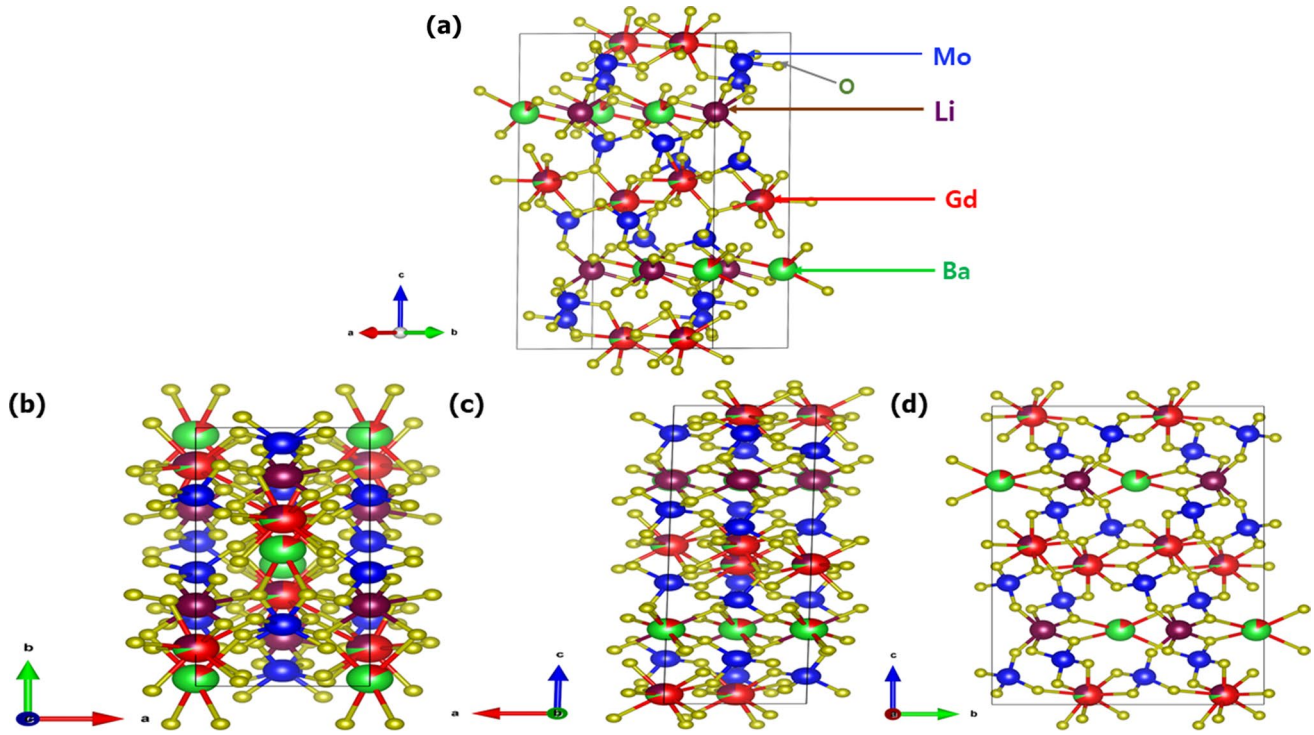

Fig. 2 $Li_3Ba_2Gd_3Mo_8O_{32}$ crystal structure: (a) standard orientation, (b–d) three different orientations of 001, 010, and 100.

C2/c space group.[22] The unit-cell parameters for the $Li_3Ba_2Gd_3Mo_8O_{32}$ single crystal were determined as follows: a = 5.341 Å, b = 12.953 Å, c = 19.367 Å, and β = 91.27 Å. By analyzing the XRD spectra, the full width at half-maximum (FWHM) values were calculated corresponding to the diffraction angles for the most intense peaks observed in all the prepared samples. Utilizing these FWHM values in the Debye–Scherrer equation,[23] the average crystallite size of the prepared samples was determined to be less than 50 nm. Table I presents the lattice strain and crystallite size.

Table I FWHM, crystallite size, and lattice strain of $Li_3Ba_2Gd_3Mo_8O_{32}$:xTb^{3+} phosphor

Morphological analysis using SEM

Figure 4a–d presents the SEM micrographs of the $Li_3Ba_2Gd_3Mo_8O_{32}$:0.09Tb^{3+} phosphors at various magnifications (×1000, ×4000, ×8000, and ×15,000). The particle size and surface morphology of phosphors are significant features that play a vital role in determining luminescence efficiency. In the present study, the particles exhibited irregular and non-uniform shapes, and their diameters range was 2–8 μm.[24] The irregular morphology observed in the SEM micrographs of the $Li_3Ba_2Gd_3Mo_8O_{32}$:0.09Tb^{3+} phosphors is likely due to the agglomeration of particles with non-uniform shapes. The agglomeration process can be influenced by various factors, such as the synthesis method, reaction conditions, and the nature of the materials involved. These conditions may lead to the formation of particles with irregular shapes and uneven surfaces. The irregular morphology observed in the $Li_3Ba_2Gd_3Mo_8O_{32}$:0.09Tb^{3+} phosphors can be attributed to the sol–gel synthetic process, in which the formation of the material occurs through the evolution of a sol, which is a colloidal suspension of small particles in a liquid, into a gel, a three-dimensional network of interconnected particles. Several factors during the sol–gel synthesis can contribute to the irregular morphology, like

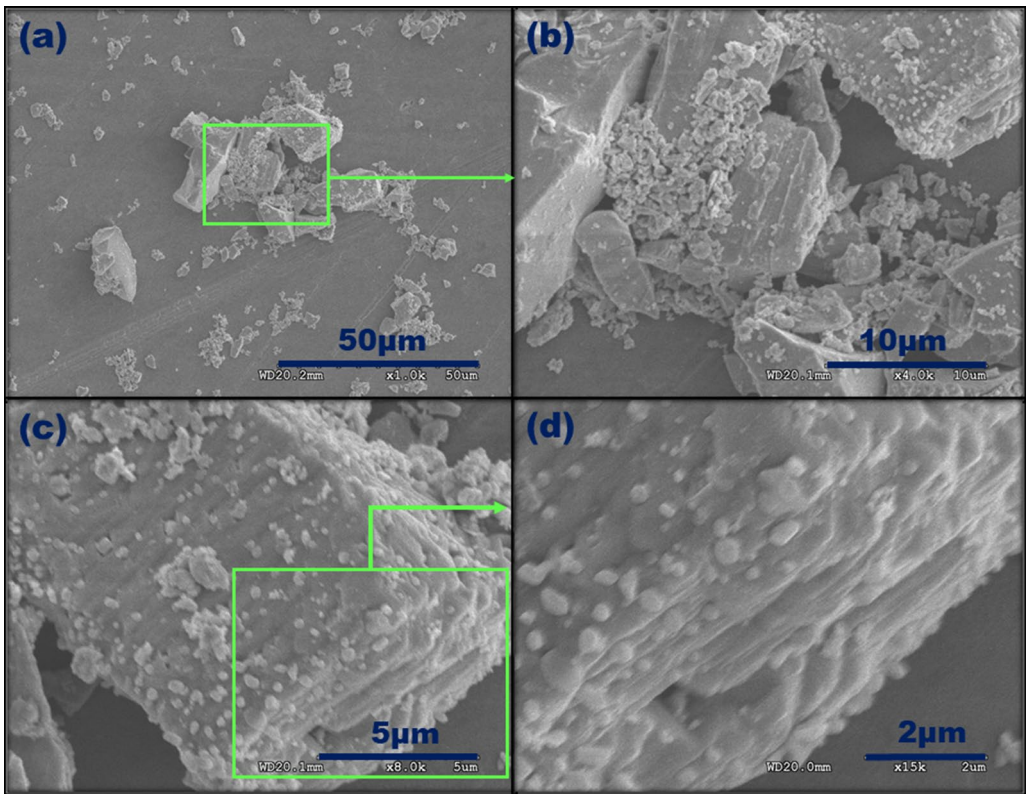

Fig. 4 Scanning electron microscopy (SEM) images, at different magnifications: (a) 1 K, (b) 4 K, (c) 8 K, and (d) 15 K of $Li_3Ba_2Gd_3Mo_8O_{32}$:0.09Tb^{3+} phosphors; (b) is the magnified view of the green zone marked in (a), and (d) is the magnified view of the green zone marked in (c) (Color figure online).

agglomeration during gelation, non-uniform drying, particle size distribution, chemical inhomogeneity, and reaction kinetics. This characteristic makes these phosphors well-suited to commercial LED fabrication, aligning with the desired particle size range of 5–10 μm.[25]

FT-IR spectral analysis

Figure 5 shows the FT-IR spectra of the $Li_3Ba_2Gd_3Mo_8O_{32}$:0.005Tb^{3+} and $Li_3Ba_2Gd_3Mo_8O_{32}$:0.09Tb^{3+} phosphors. The bands observed at 3400–3450 cm^{-1}, 1600–1650 cm^{-1}, and 1520–1500 cm^{-1} are attributed to the O-H stretching vibrations and H-O-H bending vibrations, respectively.[26–28] The presence of an asymmetric stretching band around 1400 cm^{-1} is indicative of C=O vibrations.[29] The Mo-O stretching frequency of MoO_6 octahedra is evident in the spectra, appearing in the 1000–970 cm^{-1} range.[30] Vibrations from isolated MoO_4 units may contribute to the shoulder around 890 cm^{-1}.[31] The intense absorption peaks at 840 cm^{-1} and in the 790–740 cm^{-1} range correspond to the stretching vibration of O-Mo-O in the MoO_4^{2-} tetrahedron.[30] The existence of M-O (where M is a metallic element) is confirmed by the appearance of absorption bands at 700 cm^{-1} and 630 cm^{-1}.[32,33] Vibrations involving the modification of cations concerning barium atoms are associated with absorption bands at 600 cm^{-1} or to lower bands in the range 570–530 cm^{-1}, indicative of typical metal–oxygen (M-O) lattice vibrations.[34,35] The vibration observed at 460 cm^{-1} is linked to the bending mode vibration of M-O-M, while the bending modes of Mo-O are associated with a faint absorption band around 420 cm^{-1}.[36] A comprehensive FT-IR spectral investigation confirms the formation of the prepared phosphor.

PL excitation and emission spectral analysis

The luminescent characteristics of the synthesized phosphors were investigated through PL spectra analysis. Figure 6 shows the PL excitation spectra of the $Li_3Ba_2Gd_3Mo_8O_{32}:xTb^{3+}$ phosphors that were examined within the 220 to 350-nm range (UV region), with a green light source of 545-nm wavelength ($^5D_4 \rightarrow {}^7F_5$) employed for emission. The obtained spectra reveal a single broad hump, with distinct peak positions corresponding to different doping concentrations. This observation suggests that the PL excitation transitions originate from the ground state $^7F_6$ to various excited states within the charge transfer band (CTB). A broad excitation peak is observed around 280 nm, which corresponds to the CTB.[37] The PL excitation peaks exhibit a notable shift from 279.99 to 293.48 nm with an increase in Tb^{3+} concentration from 0.005 to 0.13 mol, as depicted in Fig. 6. This shift toward longer wavelengths indicates a red shift of 13.49 nm in the CTB. Excitation intensities in the PL spectra show a linear correlation with the quantity of Tb^{3+} ions, suggesting an unaffected crystal field strength. Notably, the $Li_3Ba_2Gd_3Mo_8O_{32}$:0.09Tb^{3+} phosphor exhibits its maximum excitation intensity at 283 nm, corresponding to the spin-allowed inter-configurational $4f^8 \rightarrow 4f^75d^1$ transitions of Tb^{3+} ions within the host lattice.

The PL emission spectra of the $Li_3Ba_2Gd_3Mo_8O_{32}:xTb^{3+}$ phosphors were recorded in the range 400–650 nm under UV excitation (283 nm), as shown in Fig. 7. The PL emission spectra exhibit four distinct emission bands with

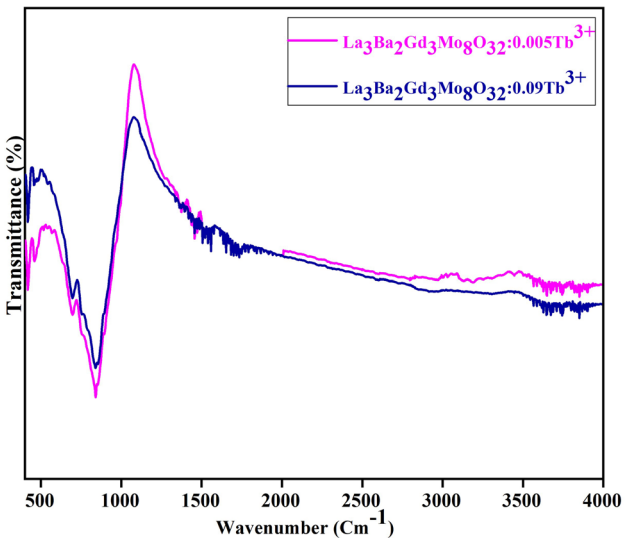

Fig. 5 FT-IR spectra of $Li_3Ba_2Gd_3Mo_8O_{32}$:0.005Tb^{3+} and $Li_3Ba_2Gd_3Mo_8O_{32}$:0.09Tb^{3+} phosphors.

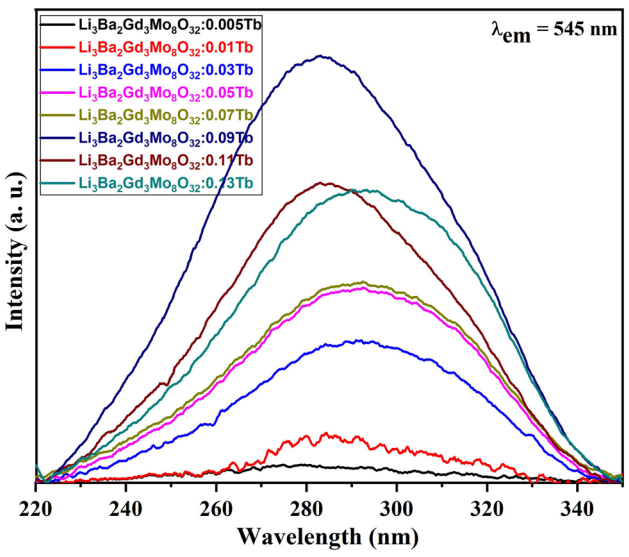

Fig. 6 Photoluminescence (PL) excitation spectra of $Li_3Ba_2Gd_3Mo_8O_{32}:xTb^{3+}$ (λ_{em} = 545 nm).

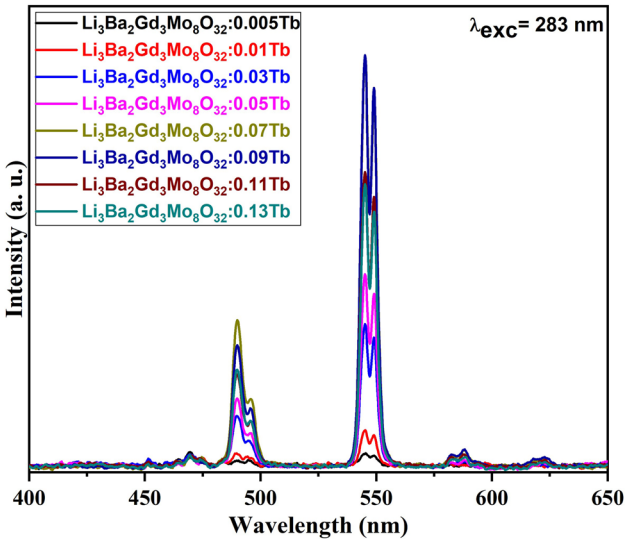

Fig. 7 Photoluminescence emission spectra of $Li_3Ba_2Gd_3Mo_8O_{32}$:xTb^{3+} (λ_{exc} = 283 nm).

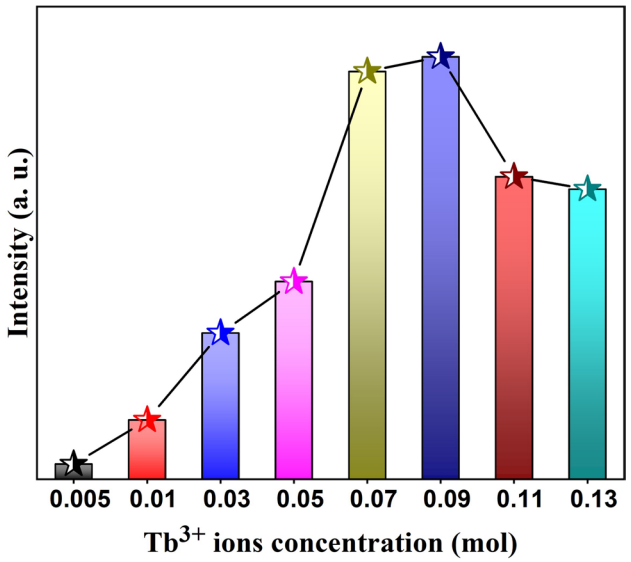

Fig. 8 Tb^{3+} concentration variation on emission intensity and increment of intensity with concentration (at 545-nm strong emission).

peaks located at 490, 545, 588, and 622 nm, corresponding to the transitions $^5D_4 \rightarrow$ ($^7F_6$, $^7F_5$, $^7F_4$, and $^7F_3$), respectively.[38] These transitions were assigned following the framework established by Carnall et al.[39]. Notably, the $^5D_4 \rightarrow {}^7F_5$ transition at 545 nm (green) is prominently intensified across all phosphors. The relationship between the emission intensity of the strong $^5D_4 \rightarrow {}^7F_5$ transition at 545 nm and the concentration of Tb^{3+} ions in the host is depicted in Fig. 8. The analysis reveals a gradual increase in emission intensity with the rising concentration of Tb^{3+} ions up to 0.09 mol, followed by a significant reduction. This observed behavior is attributed to concentration-quenching, a phenomenon arising from non-radiative energy transfer between adjacent luminescent centers (Tb^{3+} ions). In line with Blasse's theory, this quenching effect is contingent on the critical distance (R_c) between the nearest activators (Tb^{3+} ions). For the optimum phosphor composition of the $Li_3Ba_2Gd_3Mo_8O_{32}$:0.09Tb^{3+}, the critical separation R_c can be evaluated with the help of the Blasse formula[40]:

$$R_c = 2\left[\frac{3V}{4\pi x_c Z}\right]^{\frac{1}{3}} \quad (1)$$

Using $\frac{V}{Z}$= 629.1 Å^3, V = cell volume, Z = number of cations per cell, and x_c = 0.09 (optimum concentration) for the $Li_3Ba_2Gd_3Mo_8O_{32}$:0.09Tb^{3+} phosphor, R_c was calculated to be 23.73 Å.

The non-radiative relaxations between activator ions in the $Li_3Ba_2Gd_3Mo_8O_{32}$:0.09Tb^{3+} phosphor can be categorized based on the critical distance (R_c) value. In this context, the R_c for Tb^{3+} ions significantly exceed 5 Å.

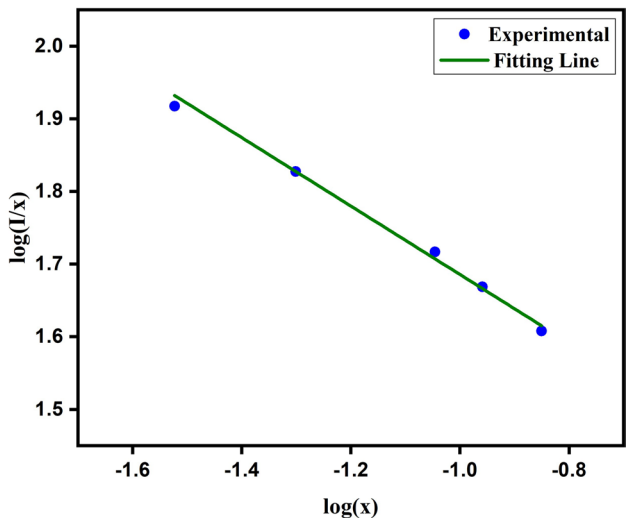

Fig. 9 log (I/x) versus log (x) plotting for $Li_3Ba_2Gd_3Mo_8O_{32}$:xTb^{3+} phosphor.

This observation supports the conclusion that electric multipole–multipole interactions are the dominant mechanism in the concentration-quenching process, as indicated by the literature.[41] The nature of multipolar interaction can be elucidated through the application of Dexter's theory.[42] According to this theory, the luminescence intensity (I) per activator concentration (x) can be expressed as:

$$\frac{I(x)}{x} = \frac{C}{[1+\beta.x^{\frac{P}{3}}]} \quad (2)$$

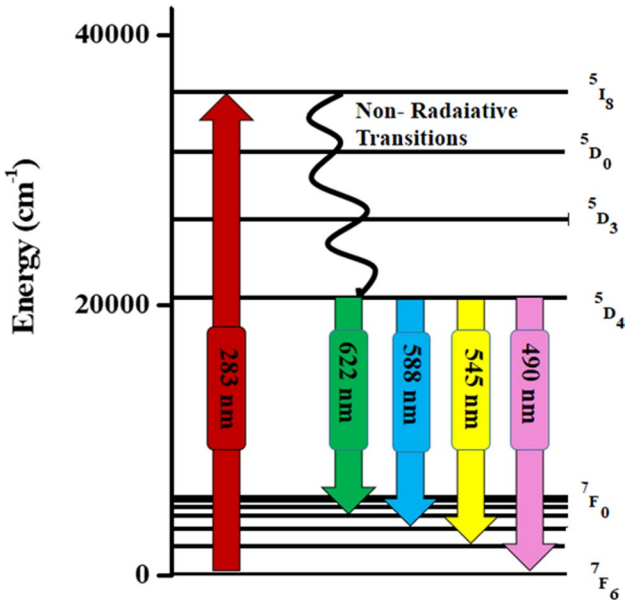

Fig. 10 Possible transition of trivalent terbium ions.

where C and β are constants for a particular host, and P is the multipolar interaction constant ($P = 6$ for dipole–dipole, $P = 8$ for dipole–quadrupole, and $P = 10$ for quadrupole–quadrupole interactions). The determination of P value involves the organization of a graph between $\log(I/x)$ and $\log(x)$, as illustrated in Fig. 9. This graph manifests as a straight line with a slope of $(-P/3)$, leading to a calculated P value close to 6 (specifically 5.9232). This outcome strongly suggests that dipole–dipole interactions are accountable for the non-radiative relaxations, thereby confirming the occurrence of concentration quenching when the Tb^{3+} ions concentration exceeds 0.09 mol in the $Li_3Ba_2Gd_3Mo_8O_{32}$ phosphors.[43] In the typical energy level diagram, depicted in Fig. 10, the excitation and emission transitions of Tb^{3+} ions in the $Li_3Ba_2Gd_3Mo_8O_{32}$ host are represented. All the samples exhibit a singular excitation transition at 283 nm, originating from the $^7F_6$ ground state to a higher energy band with a $4f^75d^1$ configuration. Additionally, four prominent non-radiative transitions occur from the $^5D_4$ level to lower energy levels $^7F_6$, $^7F_5$, $^7F_4$, and $^7F_3$ at 490 nm, 545 nm, 588 nm, and 622 nm, respectively. Figure 10 shows these crucial transitions, along with their corresponding wavelengths, in the partial energy level diagram of Tb^{3+} ions.

Photometric analysis

Photometric analysis has been utilized to discern the color emitted by the phosphors when subjected to specific lighting conditions. Figure 11 presents typical images of two phosphors: (1) $Li_3Ba_2Gd_3Mo_8O_{32}:0.005Tb^{3+}$, and (2) $Li_3Ba_2Gd_3Mo_8O_{32}:0.09Tb^{3+}$, captured under room light (Fig. 11a, a') and 254-nm UV light (Fig. 11b, b'). Both phosphor powders exhibit a white appearance under daylight. However, when exposed to UV illumination at 254 nm, the $Li_3Ba_2Gd_3Mo_8O_{32}:0.005Tb^{3+}$ phosphor appears dull-green, while the $Li_3Ba_2Gd_3Mo_8O_{32}:0.09Tb^{3+}$ phosphor emits a green hue. Photometric analysis conducted under UV excitation substantiates the green color emission of the $Li_3Ba_2Gd_3Mo_8O_{32}:0.09Tb^{3+}$ phosphor.

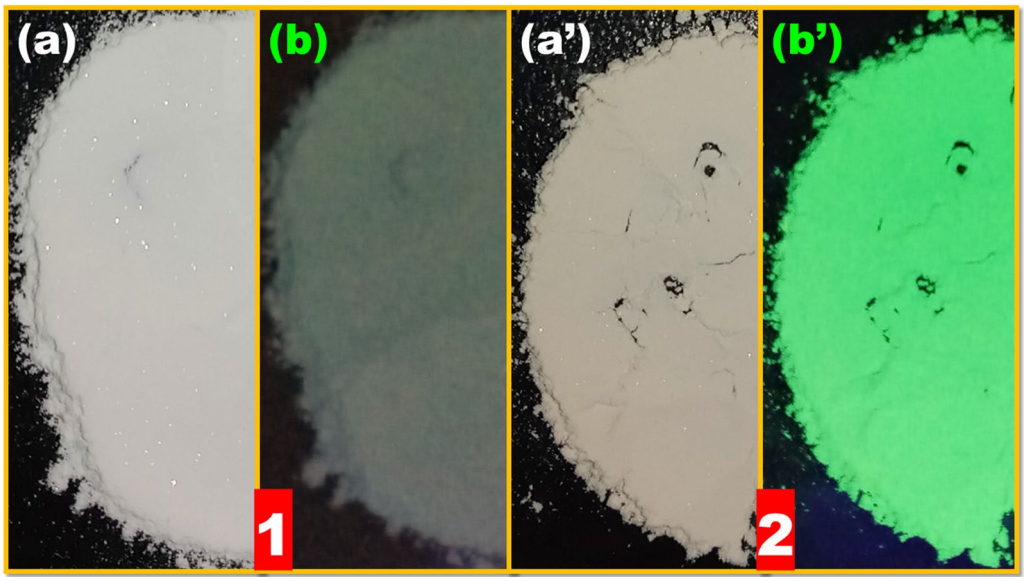

Fig. 11 Typical images of (1) $Li_3Ba_2Gd_3Mo_8O_{32}:0.005Tb^{3+}$ and (2) $Li_3Ba_2Gd_3Mo_8O_{32}:0.09Tb^{3+}$: (a, a') white powder image in direct room light and (b, b') green visible image under 254-nm ultraviolet lamp (Color figure online).

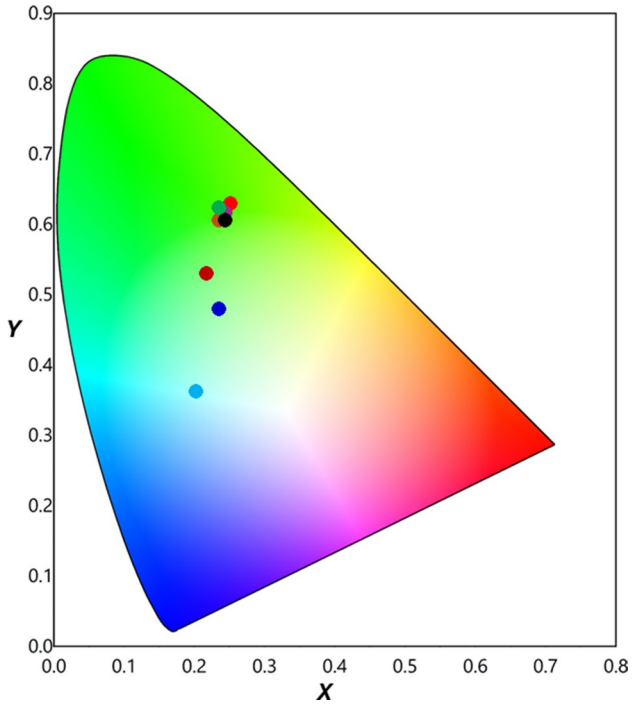

Fig. 12. CIE-chromaticity diagram for $Li_3Ba_2Gd_3Mo_8O_{32}$:xTb^{3+} phosphors (λ_{exc} = 283 nm).

The color emitted by the phosphors was predicted utilizing the Commission Internationale de l'Eclairage (CIE) chromaticity diagram, with chromaticity coordinates (*x*, *y*) derived from PL emission spectral data at an excitation wavelength of 283 nm. Table II presents these coordinates, along with the corresponding color purity percentages calculated using the established formulae.[44,45] The CIE coordinates of all prepared samples have been plotted on the CIE chromaticity diagram (Fig. 12), revealing a trend from pale blue (0.2163, 0.3756) to bright green (0.2618, 0.6358). A comparison of the estimated CIE coordinates highlights that the $Li_3Ba_2Gd_3Mo_8O_{32}$:0.09Tb^{3+} phosphor, with coordinates (0.2618, 0.6358), closely aligns with the ideal green color coordinates (0.29, 0.60), and is positioned within the bright green region. Notably, this phosphor demonstrates the highest color purity percentage (79.66%) among all the samples. Consequently, the $Li_3Ba_2Gd_3Mo_8O_{32}$:0.09Tb^{3+} phosphor emerges as a promising candidate for applications involving green light emission under UV excitation.

Conclusions

A series of $Li_3Ba_2Gd_3Mo_8O_{32}$:xTb^{3+} phosphors were successfully synthesized through the sol–gel method, resulting in a monoclinic crystal structure with the space group C2/c, as confirmed by XRD profiles. The SEM images indicated good crystallinity, with irregular and non-uniform particle shapes. The formation of the phosphors was verified through FT-IR spectra. The PL excitation spectra displayed a red shift in the $4f^8 \rightarrow 4f^75d^1$ transitions of Tb^{3+} ions, while the PL emission profiles exhibited strong emissions in the green region (545 nm) of the visible spectrum under UV excitation, specifically the $^5D_4 \rightarrow {}^7F_5$ transition. The optimal concentration of Tb^{3+} ions within the host material was determined to be 0.09 mol, beyond which concentration-quenching occurred due to dipole–dipole interactions. Photometric analyses collectively confirmed the bright green color emission of the $Li_3Ba_2Gd_3Mo_8O_{32}$:0.09Tb^{3+} phosphor. This study supports its potential for applications in green light emission technologies, including but not limited to white LEDs and solid-state lighting.

Abstract

Alkali-metal-based yttrium fluoride host ($AY_{1-x}F_4:xEu^{3+}$; A: Li/Na/K) nanophosphors were developed using co-precipitation method. Phase analysis and emission spectral behavior were established for the said nanophosphors. The highest emission observed for $NaYF_4$ doped with Eu^{3+} was then optimized to achieve maximum photoluminescence (PL) emission for varied dopant amount. The downconversion and upconversion PL studies revealed pure red emission under n-ultraviolet and infrared excitations. The CIE coordinates are observed to be lie in the red hue of the CIE diagram. The PL decay curves reported to study lifetime of the emitting state and to identify quantum efficiency using Auzel's model for the said nanophosphor. Thermal stability was also evaluated from temperature-sensitive luminescent spectra. The studies conducted on $AYF_4:.05Eu^{3+}$ (A: Li/Na/K) nanophosphors contemplates that $NaYF_4$ nanophosphors doped with Eu^{3+} ions are best suited for biophotonic applications as the later one show relatively high emission.

KEYWORDS
activation energy, downconversion, quantum efficiency, temperature-dependent PL, upconversion

1 | INTRODUCTION

There is a process to generate photons of high energy by employing photons of low energy, the process of conversion is known as upconversion (UC). The researchers are greatly attracted toward UC, as there are multifarious applications contingent on the process. The applications include solar cell converters, photocatalysis, drug delivery, in vitro/in vivo imaging, and other biophotonic applications.[1–5] Biophotonic indicates the interaction of photons with biological matter, where in appropriate organic/inorganic material comes in contact with biological matter to regulate biological activities, ultrasensitive detection, and many more.[6] Thus, biophotonic is an important tool for bioimaging, biosensors, phototherapy, laser surgery, and optogenetics. The escalating advancement in the size and structure of phosphors from micro to nanoscale has led to perspicacious encouragement for researchers to develop nanophosphors for biophotonic applications.[7,8] Nanophosphors (NP) are desirable for biophotonic applications due to their altered optical properties owing to the reduction in the size of particles from micro to nano.[9] When the size of particles encroaches in the nano range, surface to volume ratio increases, which enables more atoms at the surface to interact with biocells. Thus, the efficiency of these nanophosphors gets significantly enhanced and they become quite useful in biophotonic applications.

Generally, upconverting nanophosphors serve as excellent probe in comparison with fluorescent dyes and quantum dots, since later have certain shortcomings, such as fast photobleaching, low luminescent intensity,

 © 2024 The American Ceramic Society.

autofluorescence, loss of light due to scattering, and limited imaging length.[8,10] These pitfalls can be overcome by employing rare-earth (RE) doped NPs, since narrow and sharp f–f transitions of REs help in reducing spectral overlap of excitation and emission transitions.[11,12] In this context, alkali yttrium fluorides are identified as good near-infrared (NIR) to visible upconverter for its utilization in biophotonic applications.[13,14] Fluoride-based hosts are found suitable for nanophosphor materials as these materials have low phonon energy, which gives better luminescent efficiency and low toxicity of these materials favor their utility in biophotonic applications.[15] Typically, 980 nm laser excitation is considered as an NIR source, which makes it difficult for in vivo imaging, since water absorbs this incident radiation and makes it difficult for deep tissue imaging using 980 nm excitation. This can be over shooted if 800 nm excitation can be used instead of 980 nm excitation. Therefore, Eu^{3+} ions are chosen among various REs, as these can be excited by 800 nm and can serve as NIR to visible upconverter.[16]

In this article, AYF_4 (A: Li/Na/K) doped with Eu^{3+} ions nanophosphors ($A(Y_{1-x}Eu_x)F_4$) with low phonon energy in the range of 300–600 cm^{-1} were developed by co-precipitation route.[17,18] The structural tunability of the aforementioned nanophosphors by varying the alkali metal exhibits different luminescent properties. The structural, downconversion (DC) and UC luminescent characteristics of the said nanophosphors have been discussed in detail in the perspective of biophotonic applications.

2 | EXPERIMENT AND CHARACTERIZATION

To prepare the desired nanophosphors, the chemical precursors AF (LiF/NaF/KF), from Fisher Scientific, and yttrium acetylacetonate, from Sigma–Aldrich, were dissolved in 5 mL methanol, individually, and the solution of AF was added dropwise into the solution of yttrium acetylacetonate. The mixture was set on stirring for 10 min under room temperature and $EuCl_3{\cdot}6H_2O$ dissolved in 5 mL methanol was added dropwise into the above mixture. All the chemicals taken for the synthesis of nanophosphor were 99.9% pure. Now, the obtained solution was kept on stirring at 60°C for 5 h without any disturbance. After that, the solution gets precipitated and stirring and heating were ceased, so that it attains room temperature naturally. Then, the precipitate was centrifuged and washed five times with methanol. The obtained precipitate was kept in vacuum oven at 50°C overnight to achieve dried sample, which was grinded to carry out characterizations. The synthesis route is explained in Figure 1A.

To investigate the structure of the prepared samples, X-ray diffraction (XRD) patterns were recorded using Bruker diffractometer. Micrograph images were recorded by using scanning electron microscopy (SEM) instrument of Carl Zeiss with model no. EVO-50. Photoluminescence (PL) DC and UC studies were conducted on JASCO 8300 spectrofluorometer provided with Xenon lamp serving as irradiation source having excitation power 150 W. Decay curves were recorded using Edinburg instrument FL920 fluorescence spectrometer. The temperature-dependent photoluminescence (TDPL) measurements were made on nanophosphor by using an ocean optics spectrometer (model no. FLAME-S-XR1-ES). The powder nanophosphor was dissolved in dimethyl sulfoxide (DMSO) and polyvinylpyrrolidone (PVP) in ethanol solution.

3 | RESULTS AND DISCUSSION

3.1 | Structural analysis

Figure 1B presents XRD patterns of $AYF_4{:}.05Eu^{3+}$ (A: Li/Na/K) nanophosphor. The XRD peaks show similarity with the peaks indexed using standard JCPDS data bearing card no. 77-2042 for $NaYF_4$ cubic phase. The XRD peaks in the pattern for $LiYF_4{:}.05Eu^{3+}$ and $KYF_4{:}.05Eu^{3+}$ show some deviation along with some extra peaks, which show that mixed phase exists for these samples. The XRD peaks for $NaYF_4{:}.05Eu^{3+}$ show more resemblance with reference to the standard data suggesting the $NaYF_4$ phase has been achieved in this host. The cubic structure with space group Fm3m is formed in the synthesized nanophosphor. The XRD patterns for $NaY_{1-x}F_4{:}xEu^{3+}$ are shown in Figure S1. The average crystallite size was computed using Debye–Scherrer equation: $d = 0.9\lambda/\beta\cos\theta$, where d is crystallite size, λ is wavelength of X-rays used ($\lambda = 1.5406$ Å), and β is full width at half maximum (FWHM) corresponding to diffraction angle θ. The computed values are 2.80 and 5.75 nm for $LiYF_4$ and KYF_4 and 5.07, 4.80, 4.77, 4.67, and 4.57 nm for $NaY_{1-x}F_4{:}xEu^{3+}$ ($x = 5, 10, 15, 20$, and 25 mol%), respectively.

3.2 | Morphological studies

The as-prepared nanophosphors were taken to record SEM images in order to identify the morphology of the prepared particles. As observed from Figure 2A–C, the morphology of the prepared alkali-metal-based yttrium fluorides changes from nanospheres to nanoflakes to nanorods when alkali metal varies from lithium to potassium in the periodic table in AYF_4 host. The difference in the morphology of the prepared samples is observed to be

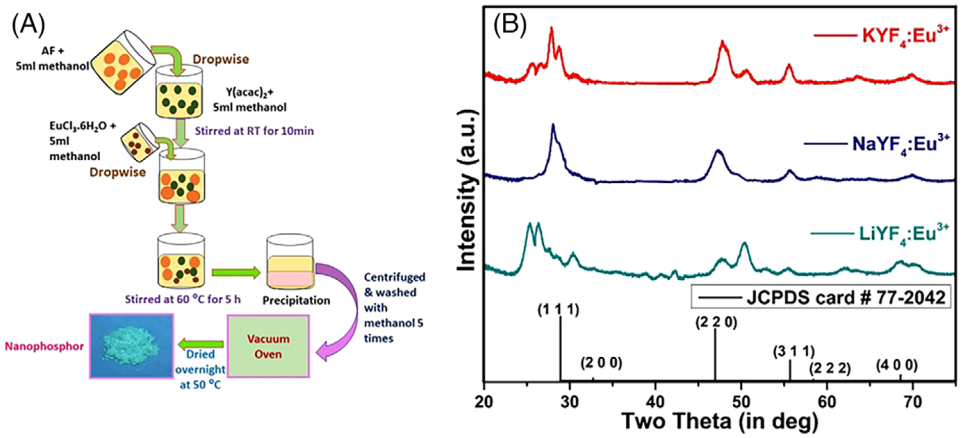

FIGURE 1 (A) Schematic illustration for synthesis of $AYF_4:Eu^{3+}$ (A: Li/Na/K) nanophosphor. (B) X-ray diffraction (XRD) patterns of $AYF_4:.05Eu^{3+}$ (A: Li/Na/K) nanophosphor.

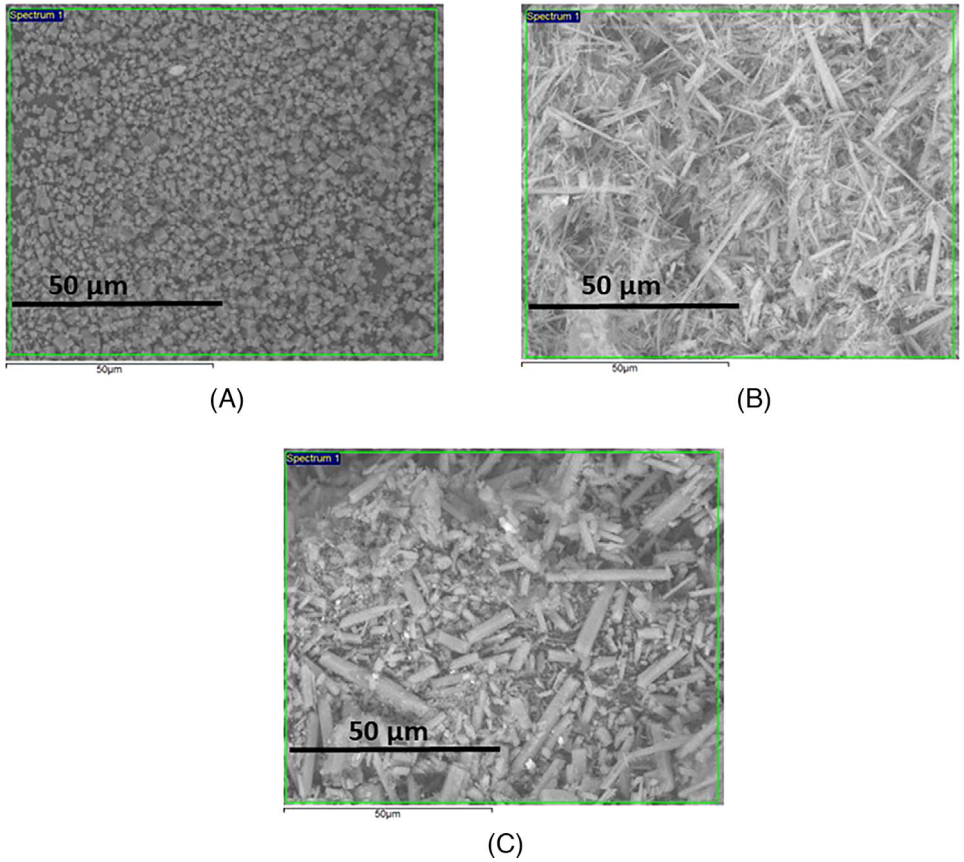

FIGURE 2 (A–C) Scanning electron microscopy (SEM) images of $AYF_4:0.05Eu^{3+}$ (A: Li/Na/K nanophosphor, respectively).

different, which might be due to different host precursor in these nanophosphors. However, the morphology observed suggested that particles are not uniformly distributed in $NaYF_4:0.05Eu^{3+}$ and $KYF_4:0.05Eu^{3+}$. Moreover, the size of the particles varies in the aforementioned host matrices, as some agglomeration is also observed, whereas the particles are uniformly distributed in $LiYF_4:0.05Eu^{3+}$ with agglomerated morphology. The size distribution of the as-prepared nanophosphor is from 100 nm to few microns as agglomeration can be seen in the prepared samples.

3.3 | X-ray photoelectron spectral analysis

X-ray photoelectron spectroscopy (XPS) is an analytical way to study properties of the sample, which are surface

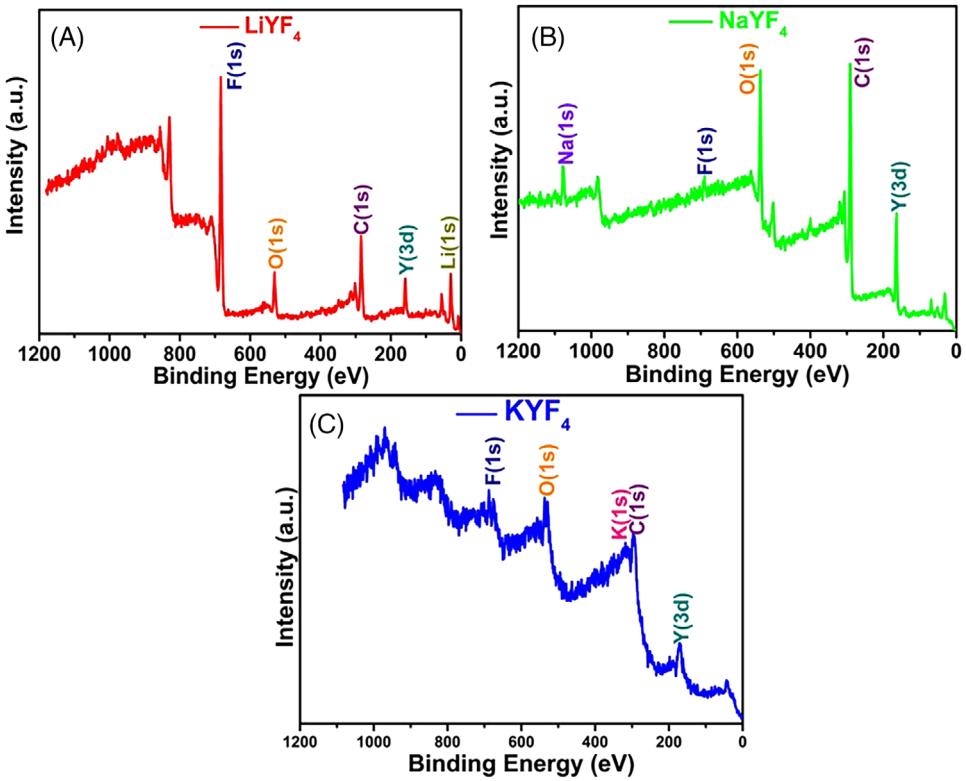

FIGURE 3 (A–C) X-ray photoelectron survey scan of AYF_4 (A: Li, Na, and K, respectively).

sensitive. It helps to identify elements, oxidation state, and binding energy of the constituent elements of the samples.[19,20] Figure 3A–C represents X-ray photoelectron survey scan of AYF_4 (A: Li, Na, K) in the range 0–1200 eV to identify elemental composition of the prepared samples, respectively. In general, fortuitous presence of carbon in 1s state is taken as reference to determine binding energy of the elements present in the host.[21] In Figure 3A, binding energy at 283 eV indicates carbon 1s peak and considered as reference for charge shift correction to identify other elements. Peaks at 55, 156, 533, and 683 eV suggest the binding energy of Li, Y, O, and F in 1s, 3d, 1s, and 1s states, respectively. The presence of oxygen in 1s state is due to the exposure of sample to air. Similarly, Figure 3B shows peak at 164, 286, 536, 686, and 1076, which indicates Y(3d), C(1s), O(1s), F(1s), and Na(1s), respectively. Figure 3C shows the presence of all the elements of KYF_4 for 166, 287, 395, 534, and 685 eV binding energy values corresponding to Y(3d), C(1s), K (1s), O(1s), and F(1s), respectively. Thus, it is well founded that the prepared samples are prepared successfully with the corresponding composition as described above.

3.4 | DC PL studies

The steady-state PL investigation of $AY_{1-x}F_4{:}xEu^{3+}$ (A: Li/Na/K) nanophosphors were conducted by observing excitation and emission spectra. Figure 4A represents the PL excitation spectrum of 5 mol% of Eu^{3+}-doped $NaYF_4$ nanophosphor from the fixed emission wavelength of Eu^{3+} ions (i.e., 613 nm). The spectrum possesses the sharp peaks related to 4f transitions of Eu^{3+} ions in the nanophosphor. The sharp excitation peaks at 380, 391, 412, and 463 nm are indexed to $^7F_0$–$^5L_7$, $^7F_0$–$^5L_6$, $^7F_0$–$^5D_3$, and $^7F_0$–$^5D_2$ transitions, respectively, as observed in 5 mol% of Eu^{3+}-doped $NaYF_4$ nanophosphor.[22] The strongest excitation at 463 nm validates the potential of the nanophosphor to get significantly excited by blue LED chips.

In order to study the intensity variation in the luminescence profile of the prepared samples, approximately the same amount of $AY_{1-x}F_4{:}xEu^{3+}$ (A: Li/Na/K) nanophosphors was taken to relate the quality of luminescence of the aforementioned nanophosphors with the replacement of alkali metals of higher order in the fluoride-based AYF_4 host. The PL emission spectra of the said nanophosphors under blue excitation are seen in Figure 4B. Usually, the transitions of RE^{3+} ions remain the same, if the host in which RE ion is doped is varied with the slight variation in their peak position. Here, in Figure 4B, almost all the transitions are common in the three emission spectral profiles with slight shift in their position. It is observed from the figure that there are four emission peaks due to transition from $^5D_0$ to $^7F_1$, $^7F_2$, $^7F_3$, and $^7F_4$ energy states.[23,24] Among these four emission lines, the one corresponding to $^5D_0$ to $^7F_1$ is magnetic dipole transition that does not

17447402, 0, Downloaded from https://ceramics.onlinelibrary.wiley.com/doi/10.1111/ijac.14805 by Delhi Technological University, Wiley Online Library on [19/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

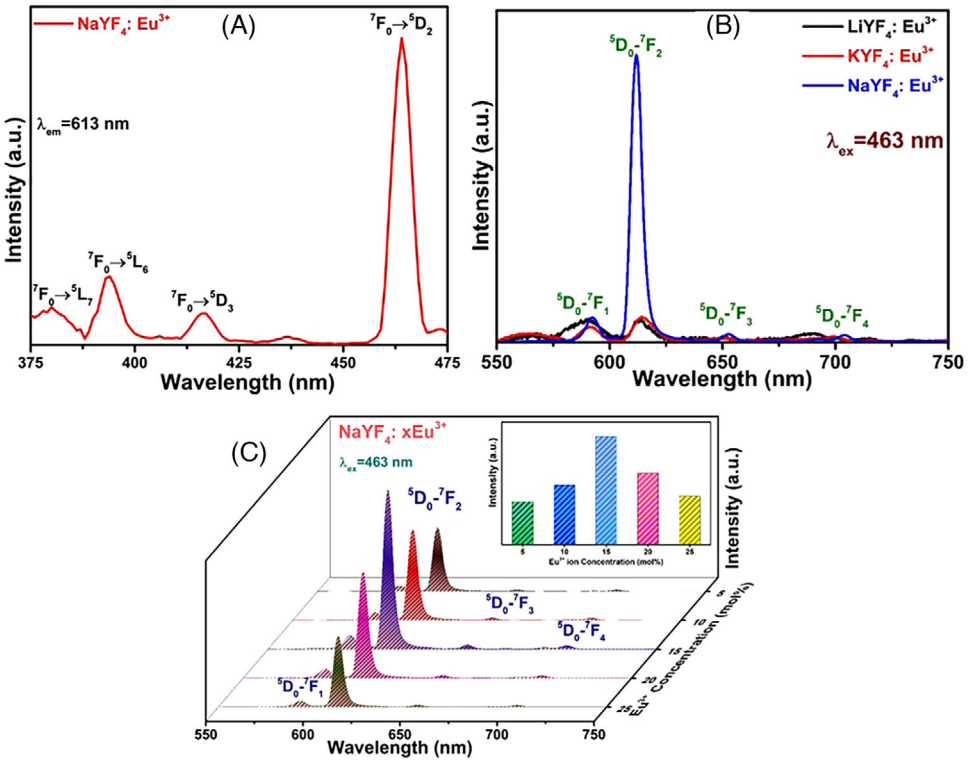

FIGURE 4 (A) Excitation spectrum of $NaYF_4$:0.05Eu^{3+} nanophosphor under 613 nm. (B) Emission spectra of AYF_4:0.05Eu^{3+} (A: Li/Na/K) nanophosphor under 463 nm. (C) Emission spectra of $NaYF_4$:xEu^{3+} (x = 0.05, 0.10, 0.15, 0.20, and 0.25 mol) nanophosphor under 463 nm. (Inset) Variation of intensity of peak at 613 nm for different concentration of Eu^{3+} ion.

get influenced by the site symmetry and the other one, the most intense one, corresponding to $^5D_0$ to $^7F_2$ is electric dipole transition that gets regulated by the site symmetry of the host crystal lattice. The f–f intra-configurational electric dipole transitions are forbidden by Laporte selection rule ($\Delta S = 0$, $\Delta L = 0$, and $\Delta J = 0, \pm 1$) and become parity allowed by mixing with opposite parity orbitals.[25–27] This induced electric dipole transition is also known as hypersensitive transition due to the dependency of this transition on the structural environment around Eu^{3+} ions. The relative dominance of transitions originating from magnetic/electric dipole dictates the site occupancy of Eu^{3+} ions in the host material. In the present analysis, all the three fluoride-based AYF_4 hosts show the dominant characteristic of electric dipole transition at 613 nm, which suggests that Eu^{3+} ions have occupied the non-inversion symmetric sites in the host crystal structure.[23,28] Furthermore, Figure 4B shows the highest emission profiles observed for sodium alkali metal in AYF_4 host, which suggested relatively more potential of Eu^{3+} ion-doped $NaYF_4$ nanophosphor in biophotonic applications. Also, the luminescence properties were studied in $NaYF_4$ nanophosphor for the different amounts of Eu^{3+} ions as emission spectral profiles recorded by keeping excitation wavelength fixed at 463 nm are presented in Figure 4C. Figure 4C shows that more doping of Eu^{3+} ions facilitates increase in emission intensity gradually from 5 to 15 mol% and then decreases for 20 and 25 mol% of Eu^{3+} ions due to increase in the non-radiative pathways. This mechanism is known as concentration quenching, where the adequately low distance between the neighboring RE ions elevates non-radiative energy transfer pathways between the ions, which consequently give reduced emission. Inset of Figure 4C discloses the emission intensity variation of electric dipole transition with concentration of Eu^{3+} ions in $NaYF_4$ nanophosphor. Hence, it is righteous to conclude that 15 mol% of Eu^{3+} ions are the optimized amount in $NaYF_4$ host prepared by co-precipitation method. Furthermore, critical distance (R_c) can be determined to identify if exchange interaction between RE ions is responsible for non-radiative transition using the formula given by Blasse as shown below[29]:

$$R_c = 2\left(\frac{3V}{4\pi X_c N}\right)^{1/3} \quad (1)$$

where N denotes occupancy number, X denotes the amount of dopant for which the luminescence intensity is maximum, and V denotes the volume of unit cell. The value of R_c is computed, which is higher than 5 Å, and validates that exchange interaction does not account for non-radiative energy transfer among RE ions.

17447402, 0, Downloaded from https://ceramics.onlinelibrary.wiley.com/doi/10.1111/ijac.14805 by Delhi Technological University, Wiley Online Library on [19/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

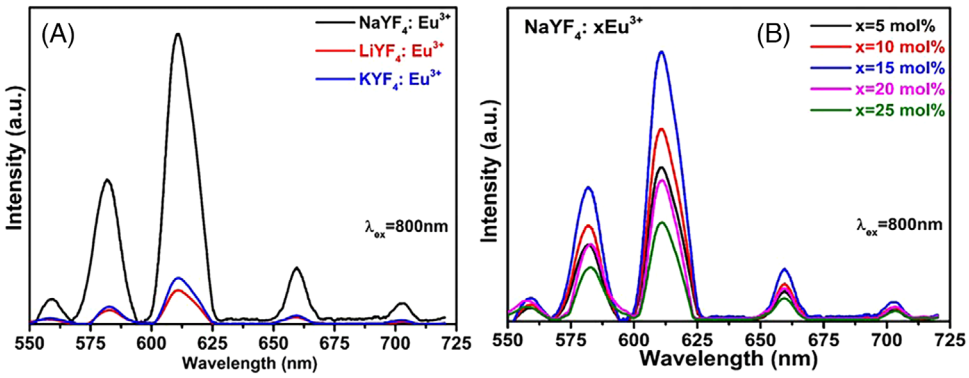

FIGURE 5 (A) Emission spectra of AYF_4:0.05Eu^{3+} (A: Li/Na/K) nanophosphor. (B) Emission spectra of $NaYF_4$:xEu^{3+} (x = 0.05, 0.10, 0.15, 0.20, and 0.25 mol) nanophosphor under 800 nm.

Consequently, the multipolar interaction between RE ions leads to non-radiative energy transfer.

In order to understand the bio-compatibility of the as-prepared nanophosphor, $NaYF_4$:Eu^{3+} was dissolved in DMSO and PVP solution (.1 g in 5 mL ethanol). It was observed that both the solutions were clear, suggesting complete solubility of the said nanophosphor. PL spectra of the two solutions were recorded and are shown in Figure S3. All the emission peaks are similar to those observed for the powder nanophosphor under 463 nm excitation. The result obtained signifies that the said nanophosphor has potential for biophotonic applications.[30,31]

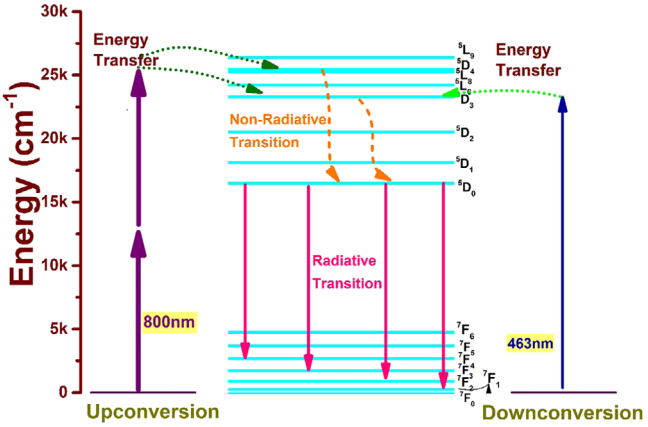

FIGURE 6 Partial energy level diagram of Eu^{3+}-doped nanophosphor representing upconversion and downconversion processes.

3.5 | UC PL studies

Figure 5A represents the UC PL spectra of AYF_4:Eu^{3+} (A: Li/Na/K) nanophosphors achieved by irradiating the samples at 800 nm. UC emission manifests similar emission peaks with some variation in the relative intensity of peaks. The distinguished emission peaks perceived at 559, 582, 611, 659, and 703 nm are arising from $^5D_0$ to $^7F_0$, $^7F_1$, $^7F_2$, $^7F_3$, and $^7F_4$ transitions, respectively.[32,33] All the emission peaks are similar with those observed in DC luminescence spectra recorded for the same samples. However, there is relative change in the intensity ratio for red (611 nm) to orange (582 nm) peak as the magnetic dipole (582 nm peak) intensity is relatively higher than the one observed in DC spectra, while the dominance of electric dipole (611 nm peak) transition is maintained in the UC spectra recorded under 800 nm. The most conceivable explanation for such a different luminescent behavior can be associated with the change in symmetries of sites around dopant ions.[34] It has been observed that the asymmetry ratio (1.839–2.019) for UC luminescence decreases when compared with asymmetry ratio (10.16–11.50) for DC luminescence.[35] Furthermore, the emission profiles of as-prepared three alkali metal-based yttrium halides are showing the similar trend of luminescence, where the lowest luminescence is observed from $LiYF_4$:Eu^{3+} and highest luminescence is observed from $NaYF_4$:Eu^{3+}, and luminescence of KYF_4:Eu^{3+} lies between $LiYF_4$:Eu^{3+} and $NaYF_4$:Eu^{3+}. While recording the emission for concentration variant of Eu^{3+} in $NaYF_4$ nanophosphor, as depicted in Figure 5B, the intensity variation follows the same trend as in DC observed above. The only difference seen in DC and UC processes is the FWHM value, which is 5.77 for the former emission and 11.25 for the latter one. The differences in FWHM between UC and DC spectra of the same sample can arise from various factors, including differences in photon energies, energy transfer mechanisms, and excited state dynamics. The concentration of Eu^{3+} ion for which the luminescence is maximum is quantified as 15 mol%, same as in case of DC luminescence of the said nanophosphor. The UC spectra observed suggested that the prepared nanophosphor can be used for biophotonic applications.

Figure 6 shows possible transitions in Eu^{3+}-doped nanophosphor for UC and DC processes. During UC

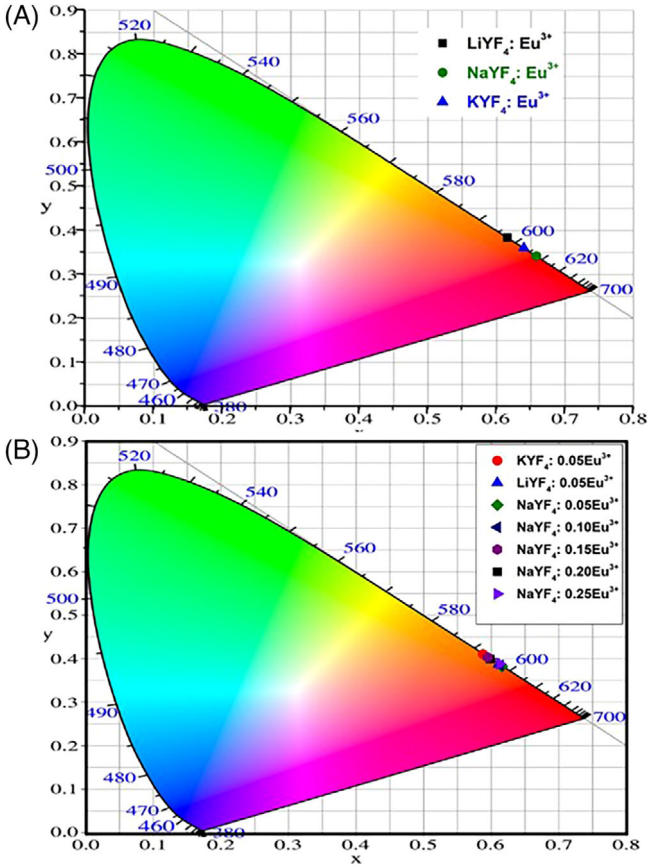

FIGURE 7 (A) CIE diagram of AYF_4:.05Eu^{3+} (A: Li/Na/K) nanophosphor under 463 nm excitation. (B) CIE diagram of $NaYF_4$:xEu^{3+} (x = .05, .10, .15, .20, and .25 mol) nanophosphor under 800 nm excitation.

process, there is no energy level corresponding to 800 nm excitation wavelength, which means that it might take up more than one photon to reach up to ^5D levels of the Eu^{3+} ions, from where after non-radiative transition, it reaches to $^5D_0$ lasing energy level.[36] It is observed from literature that $^5D_0$ level is the radiative transition level, which means that the transition from this level corresponds to radiative emission in the host. The same has been observed in the present studies. It is anticipated that during DC process, the Eu^{3+} ions got excited to $^5D_3$ level from ground state, which after non-radiative transition to $^5D_0$ level possess radiative emission lines, as discussed in the DC luminescent studies.

3.6 | Colorimetric analysis

In Figure 7A,B, the as computed CIE coordinates for the chromatic profiles for DC and UC luminescence are revealed. The CIE coordinates of AYF_4:Eu^{3+} (A: Li/Na/K) nanophosphors under blue excitation show transition in color from orange to red for Li to Na in AYF_4:Eu^{3+} (A: Li/Na/K) nanophosphors, as illustrated in Figure 7A. The CIE coordinates of $NaYF_4$:Eu^{3+} nanophosphors yield pure red color as the coordinates are close to the perimeter of the CIE diagram and for higher concentration, it is nearly the same in hue cycle. The CIE coordinates calculated for AYF_4:Eu^{3+} (A: Li/Na/K) nanophosphors and Eu^{3+} variation in $NaYF_4$ nanophosphors under 800 nm show that pure red emission is achievable for $NaYF_4$ host incorporated with Eu^{3+} ions, as exemplified in Figure 7B. Furthermore, the color purity of $NaYF_4$ host incorporated with optimized Eu^{3+} ions is evaluated using the following equation:

$$\text{Color purity} = \frac{\sqrt{(x - x_{wp})^2 + (y - y_{wp})^2}}{\sqrt{(x_d - x_{wp})^2 + (y_d - y_{wp})^2}} \times 100\% \quad (2)$$

where x and y indicate the CIE coordinates of the sample, x_{wp} and y_{wp} are the coordinates for white point, and x_d and y_d are the coordinates for dominant wavelength. The values of (x_d, y_d) for DC and UC are taken as (.661, .338) and (.618, .383), respectively, and the color purities under DC and UC are reckoned as 99.4% and 99.6%, respectively. These colorimetric analyses help to understand the ability of these nanophosphors as red emitter under DC as well as UC phenomenon, which is required for lighting and biophotonic applications, respectively.

3.7 | PL decay analysis

Figure 8A–E shows the decay curves of $NaYF_4$:xEu^{3+} (x = .05, .10, .15, .20, and .25 mol) nanophosphors under blue excitation for $^5D_0$ energy state. All the decay curves possess non-exponential behavior, which is fitted with bi-exponential equation, as mentioned elsewhere.[37] The fitted parameters were used to assess the decay lifetime values, which are estimated as 5.991, 3.008, 2.905, 2.789, and 2.597 ns for $NaYF_4$:xEu^{3+} (x = .05, .10, .15, .20, and .25 mol) nanophosphors, respectively. Figure 8F shows the lifetime values when the concentration of Eu^{3+} ions is altered. It can be noted that the lifetime values follow a declining trend with the upsurge of the amount of dopant ions. The transfer of energy that is being non-radiative in nature among the activators and concentration quenching accounts for the fall in lifetime values.[38] This result is in tune with the luminescence spectra as the luminescence decline due to energy transfer being non-radiative in nature occurs between Eu^{3+} ions. Moreover, the decrease in lifetime values suggests that there is more of non-radiative relaxation. To explore more information pertaining to declined lifetime values and to identify intrinsic lifetime of the excited energy state, Auzel's model

17447402, 0, Downloaded from https://ceramics.onlinelibrary.wiley.com/doi/10.1111/ijac.14805 by Delhi Technological University, Wiley Online Library on [19/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

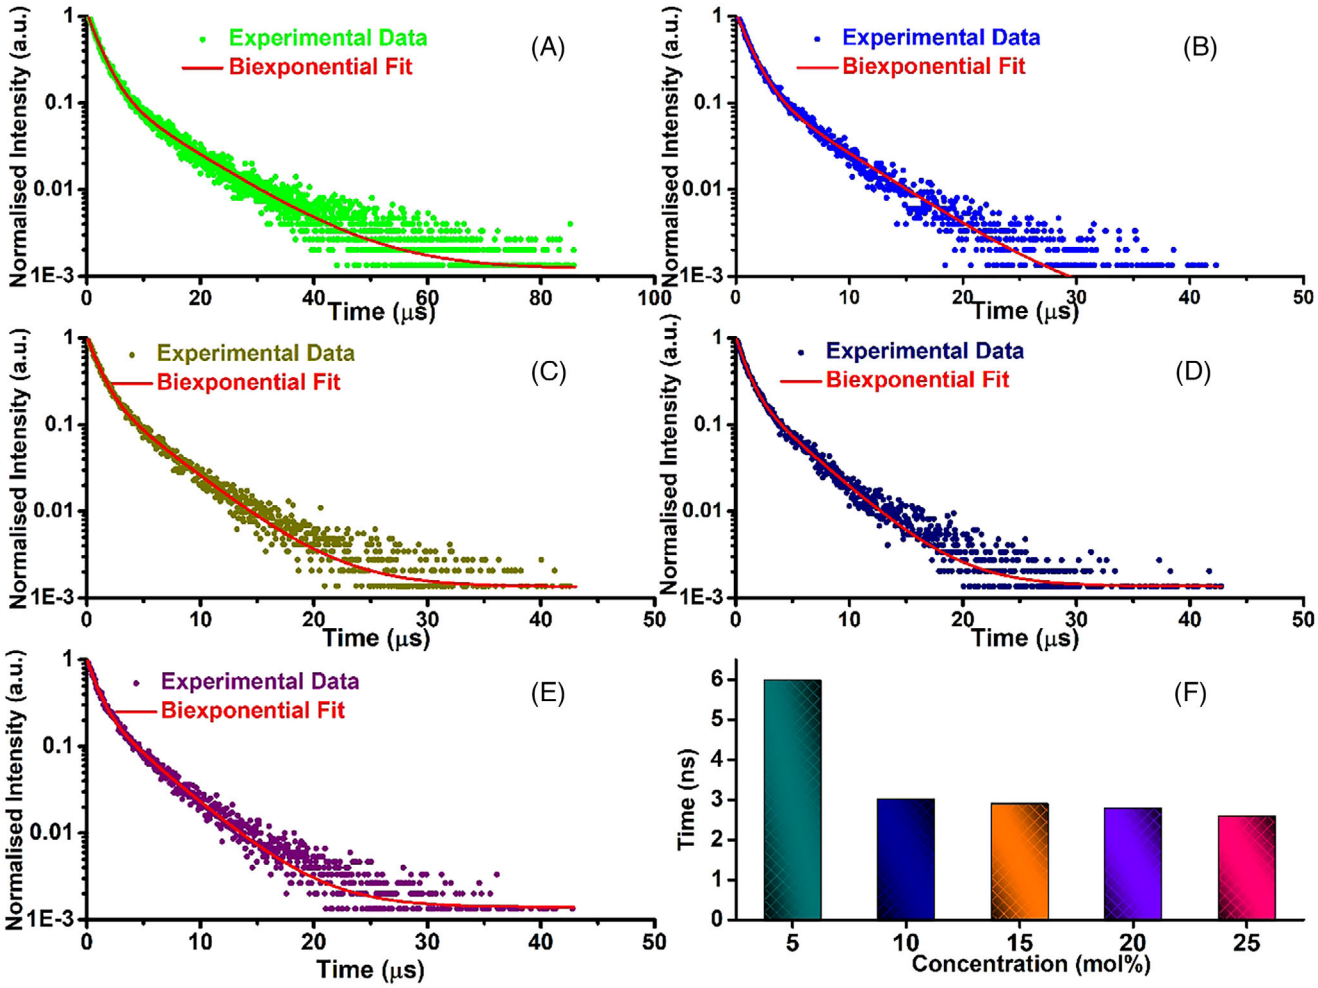

FIGURE 8 (A–E) Decay curves of $NaYF_4$:xEu^{3+} (x = .05, .10, .15, .20, and .25 mol) nanophosphor under 463 nm excitation and 613 nm emission wavelength. (F) Lifetime variation with concentration of Eu^{3+} ions.

is applied on the decay data by using the following equation[39]:

$$t_c = \frac{t_0}{1 + \frac{c}{c_0}\exp(-N/3)} \quad (3)$$

where t_c and t_0 are the lifetime values at concentration c and intrinsic value of the lifetime of the excited state, c_0 is a constant, and N denotes the phonon number. Therefore, a graph is plotted between lifetime t_c and concentration c of Eu^{3+} ions in $NaYF_4$ host nanophosphor. Figure 9 shows the data points on which Auzel's model is employed to conduct fitting. From the fitting, certain parameters were observed, including phonon number, $N = 6$, and intrinsic lifetime, $t_0 = 10.18$ ns for $^5D_0$-excited energy state. The phonon number obtained from the fitting parameters is consistent with the phonon energy of the host $NaYF_4$.[40] The intrinsic lifetime value along with experimentally observed lifetime values help to determine

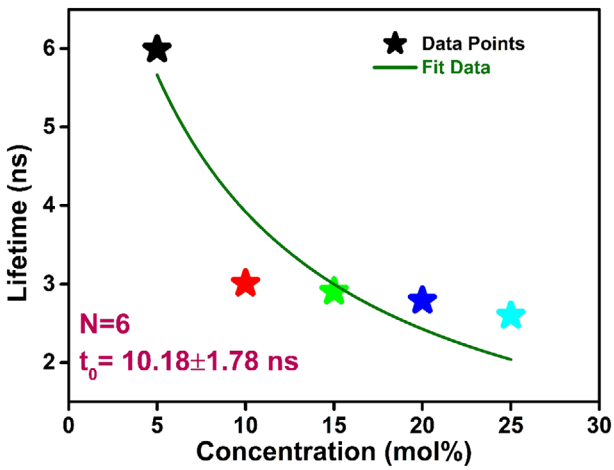

FIGURE 9 Lifetime versus concentration plot with Auzel's fit.

probability of non-radiative transitions rate (A_{NR}) and quantum efficiency of the investigated nanophosphor. The

17447402, 0, Downloaded from https://ceramics.onlinelibrary.wiley.com/doi/10.1111/ijac.14805 by Delhi Technological University, Wiley Online Library on [19/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

below mentioned equations are followed to compute A_{NR} and QE for $NaYF_4$ doped with Eu^{3+} ions:

$$\frac{1}{t_c} = \frac{1}{t_0} + A_{NR} \tag{4}$$

$$QE = \frac{t_c}{t_0} = \frac{A_R}{A_R + A_{NR}} \tag{5}$$

The computed values of non-radiative transition rates (A_{NR}) are .0446, .2100, .2218, .2362, and .2627, and quantum efficiency (QE) are 73.2, 36.7, 35.5, 34.0, and 31.7% for $NaYF_4$:xEu^{3+} (x = .05, .10, .15, .20, and .25 mol) nanophosphors, respectively. Basically, A_{NR} indicates depopulation of the excited state via non-radiative relaxation process and this value increases with increase in concentration of Eu^{3+} ions. And if A_{NR} increases with concentration, then the radiative emission transition rate gets suppressed by non-radiative transition rate, which leads to reduction in quantum efficiency. The low value of A_{NR} and good QE suggest that the prepared $NaYF_4$ host doped with Eu^{3+} ions can be an alternate for its utility in biophotonic applications.

3.8 | Judd–Ofelt parameters and quantum efficiency

The spectral transitions observed in Eu^{3+} ion-doped luminescent materials can be related with the Judd–Ofelt (J–O) intensity parameters (Ω_2, Ω_4, and Ω_6) calculated from the emission spectra. In RE ion-doped materials, certain transitions are hypersensitive whose peak position and intensity of emission strongly depend on the environment around the ion. Such hypersensitive transitions have relatively higher intensity when compared with transitions observed in emission spectrum. The J–O intensity parameters (Ω_2) dictates that the local surrounding, nature of bonding, rigidity, and viscosity are explained on the basis of Ω_4 and Ω_6. Using the emission spectra, the J–O intensity parameters are determined by employing the following equation[41]:

$$\Omega_J = \frac{S_{MD}\left(V_1^3\right)}{e^2\left(V_J^3\right)} \frac{9n^3}{n(n^2+2)^2} \frac{\int I_1(V_1)}{\langle J|U^J|J'\rangle^2 \int I_J(V_J)} \tag{6}$$

Here, S_{MD} (9.6×10^{-42} esu^2 cm^2) denotes the magnetic dipole line strength, and V_1 and V_J denote the transition frequency of $^7F_1$ and ^7F_J (J = 2, 4, and 6), Similarly, I_1 and I_J denote the corresponding intensities of the aforementioned transitions. "e" represents the elementary charge whose value is 4.803×10^{-10} esu, n denotes refractive index, which is estimated from band gap energy, as given in Supporting information, and $\langle J|U^J|J'\rangle^2$ represents the double-reduced matrix elements of the unit tensor operators, where U^J is .0032, .0023, and .0002 for J = 2, 4, and 6, respectively. The Ω_6 parameter is not evaluated as the transition $^5D_0$ to $^7F_6$ was not observed in the emission spectra. Furthermore, the spontaneous transition probability was calculated using the following equation[35,42]:

$$A_{J-J'} = \frac{64\pi^4\nu^3}{3h(2J+1)}\left(\chi_{ED}S_{ED} + \chi_{MD}S_{MD}\right) \tag{7}$$

where h is Planck's constant, ν is the transition wavenumber (cm^{-1}), S_{ED} similar to S_{MD} denotes the line strength corresponding to electric dipole transition, which can be calculated as:

$$S_{ED}(J, J') = e^2 \sum_{J = 2,4,6} \Omega_J \langle J|U^J|J'\rangle^2 \tag{8}$$

The χ_{ED} and χ_{MD} denote local field corrections for electric and magnetic dipole transitions, respectively, and can be determined using following equations:

$$\chi_{ED} = \frac{n\left(n^2+2\right)^2}{9} \tag{9}$$

$$\chi_{MD} = n^3 \tag{10}$$

The J–O intensity parameters (Ω_2 and Ω_4) and total transition probability (A) for different concentrations of Eu^{3+} ions in $NaYF_4$ host are shown in Table 1. The trend of intensity parameters ($\Omega_2 > \Omega_4$) shows an increase in covalency between Eu^{3+} ions and oxygen ligands and low site symmetry for different amounts of dopant ions as the higher value of Ω_2 suggest, whereas Ω_4 parameter indicates higher rigidity in the prepared nanophosphor.[43,44]

Also, the quantum efficiency has been calculated using the following equation[41]:

$$\eta = \frac{\tau}{\tau_r} = \frac{\frac{1}{A_r + A_{nr}}}{\frac{1}{A_r}} \tag{11}$$

where τ is the lifetime determined from decay curves and can be written as inverse of sum of radiative and non-radiative transition probabilities and τ_r is obtained from transition probability calculated above. The calculated quantum efficiency is reported in Table 1 and values are comparable with those evaluated using Auzel's model.

3.9 | TDPL investigations

It is well known that the emission color and output efficiency of the luminescent material get greatly influenced by its thermal stability. Thus, it is important to investigate the thermal stability of the nanophosphor for practical application. Also, the temperature aspects

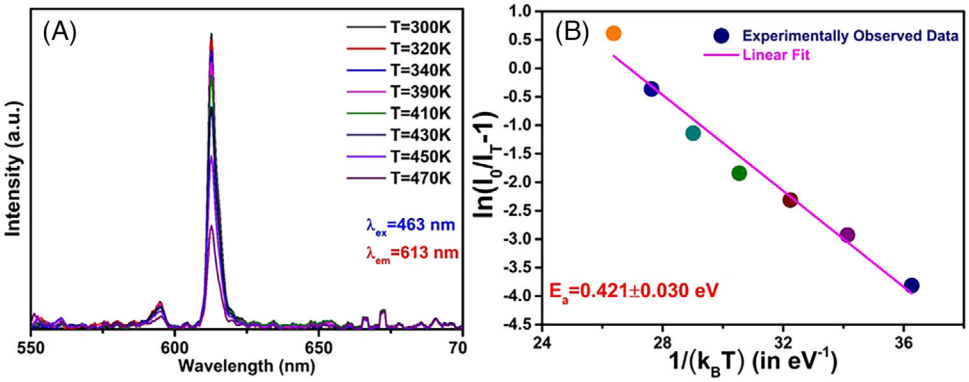

FIGURE 10 (A) Temperature-dependent photoluminescence of $NaYF_4$:.15Eu^{3+} nanophosphor monitored at 463 nm excitation. (B) Activation energy calculation for $NaYF_4$:.15Eu^{3+} nanophosphor.

of the nanophosphor for temperature sensing biophotonic applications can be understood by proclaiming temperature-dependent luminescence. The TDPL of the $NaYF_4$:.15Eu^{3+} nanophosphors were recorded by monitoring excitation wavelength at 463 nm in the temperature range of 300–470 K, as presented in Figure 10A. It is clear from Figure 10A that the emission intensity decreases to 90% at 390 K, which is the ambient operating temperature for practical applications. However, with increase in temperature, due to non-radiative phonon relaxation from upper energy levels via crossover process, the fall in emission is considerable, that is, 65% at 470 K due to thermal luminescence quenching effect. At higher temperature, there is more interaction between electron and phonon that tends to dissipate the excited state thermally and results in fall of emission at high temperature.[45] Furthermore, the well-established Arrhenius equation given below is applied on the temperature-dependent emission spectra of the said nanophosphor to investigate the thermal stability by evaluating activation energy[46,47]:

$$\ln\left(\frac{I_0}{I_T}-1\right)=\ln A-\frac{E_a}{k_BT} \tag{12}$$

where I_0 is the initial intensity at 300 K, I_T is the intensity at temperature $t = T$ K, and k_B is the Boltzmann constant. A graph is plotted between $\ln(I_0/I_T - 1)$ versus $1/k_BT$ to compute the activation energy, as illustrated in Figure 10B. The activation energy is also termed as trap depth, which is the energy required to release the captured electrons from the trap center.[48] The linear fitting of the plot gives slope as −.421 eV and negative of the slope gives activation energy as .421 eV. This value is higher than the earlier reported $Ca_{5.93-m}Sr_mBa(PO_4)_4O$:.07$Eu^{2+}$ (.276 and .292 eV for 0 and .1 value of m, respectively), $Ca_2GdZr_2Al_3O_{12}$:Mn^{4+} (.397 eV), $GdPO_4$:Eu^{3+} (.256 eV), $Ba_3Ce(PO_4)_3$:Eu^{3+} (.25 eV), $Zn_3V_2O_8$ (.14 eV), $BaSi_2O_5$:Eu^{2+} (.12 eV), and $Ca_9La_{.94}(PO_4)_5(SiO_4)F_2$:.05$Ce^{3+}$, .01$Tb^{3+}$ (.255 eV) hosts.[46,47,49–53] Hence, it can be inferred from the value of activation energy that the prepared nanophosphor exhibits good thermal stability and validate brilliance of Eu^{3+}-doped $NaYF_4$ nanophosphor for practical usage in biophotonic applications.

4 | CONCLUSIONS

Well-prepared AYF_4:.05Eu^{3+} (A: Li/Na/K) nanophosphor was compared for structural and luminescence behaviors. XPS study confirms the elemental composition of the prepared samples. It was found that $NaYF_4$:$x$$Eu^{3+}$ nanophosphor gives highest luminescence traits; therefore, $NaYF_4$:$x$$Eu^{3+}$ (x = .05, .10, .15, .20, and .25 mol) nanophosphors were prepared and detailed

17447402, 0, Downloaded from https://ceramics.onlinelibrary.wiley.com/doi/10.1111/ijac.14805 by Delhi Technological University, Wiley Online Library on [19/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

studies of luminescence properties were conducted on these nanophosphors. DC and UC studies show intense red emission under ultraviolet (n-UV) and 800 nm excitation. The PL analysis of phosphor solution in DMSO and PVP suggests the potential of the said nanophosphor for biophotonic applications. Furthermore, colorimetric studies proclaim pure red emission of the prepared nanophosphor under n-UV and infrared irradiations. Thermal analysis of $NaYF_4$:.15Eu^{3+} nanophosphor was conducted and the activation energy was observed as .421 eV, which suggests good thermal stability of the nanophosphor. The decay analysis shows bi-exponential fit for the observed data and fall in lifetime values. The fall in lifetime of the emitting state is related to the non-radiative transitions dominance over radiative transition for higher doping amount as validated by employing Auzel's model and have good quantum efficiency. The quantum efficiency was also calculated by using J–O theory and found in comparison with the values obtained from Auzel's model. Thus, Eu^{3+}-doped $NaYF_4$ nanophosphor are quite suitable for its usage in biophotonic devices.

Hubble parameter

ABSTRACT

In this research paper, we explore a well-motivated parametrization of the time-dependent deceleration parameter, characterized by a cubic form in cosmic time t, in the context of late-time cosmic acceleration. The whole analysis of our work is within the framework of $f(Q,T)$ gravity theory, where we consider the background metric as the homogeneous and isotropic one represented by the Friedmann–Lemaître–Robertson–Walker (FLRW) metric. We solve the field equations with the considered functional form of $d(t)$. In order to find some best fit values of the model parameters and validate our obtained model, we constrain the model using some recent observational datasets, including cosmic chronometer (CC), Supernovae (SNIa), Baryon Acoustic Oscillation (BAO), Cosmic Microwave Background Radiation (CMB), Gamma-ray Burst (GRB), and Quasar (Q) datasets. The joint analysis of these datasets results in tighter constraints for the model parameters, enabling us to discuss both the physical and geometrical aspects of the model. Moreover, we determine the present values of the deceleration parameter (q_0), the Hubble parameter (H_0), and the transition redshift (z_t) from deceleration to acceleration ensuring consistency with some recent results of Planck 2018. Our statistical analysis yields highly improved results, surpassing those obtained in previous investigations. Overall, this study presents valuable insights into the higher order $q(t)$ model and its implications for late-time cosmic acceleration, shedding light on the nature of the late universe.

1. Introduction

In contemporary times, one of the most significant breakthroughs is the discovery of cosmic accelerated expansion, which has been confirmed through a range of observational techniques [1,2]. This expansion is accompanied by a mysterious energy component known as "dark energy" (DE), characterized by substantial negative pressure. Despite its enigmatic nature, DE constitutes about 70% of the cosmic content and plays a crucial role in maintaining the overall energy density of the universe consistent with predictions from inflationary theory. The investigation into the dominant constituents of the universe, namely dark energy and dark matter (DM), stands as a formidable challenge in modern physics, representing nearly 95% of the universe's imperceptible composition. Dark matter, an unseen type of matter exhibiting weak interactions with electromagnetic radiation, is detectable primarily through its gravitational effects on nearby ordinary matter. The existence of DM is supported by various observable phenomena, including rotation curves and mass discrepancies.

In the absence of any substantial evidence supporting the dark sources, alternative avenues have been explored extensively. The investigation of enigmatic approaches to these exotic terms has been delineated through two distinct methods: modifying matter sources or introducing additional degrees of freedom into the gravitational action. The initial approach involves the alteration of the matter sector within the Einstein–Hilbert Lagrangian density through the incorporation of various proposals. Numerous models have been proposed to explain DE, some of which correlate with observational evidence. Among these, the

ΛCDM model is widely embraced due to its alignment with observations, although it also presents certain ambiguities such as fine-tuning and coincidence issues [3–7]. To address these limitations, alternative DE models like quintessence [8–10], phantom [11], k-essence [12–14], and Chaplygin gas [15] have been introduced, aiming to provide effective explanations for various cosmic inquiries and to explore diverse aspects of this exotic energy. Local (model-independent) H_0 values are biased to larger values than Planck ΛCDM. This disfavors Quintessence, K-essence, and any DE model in the Quintessence regime $w_{DE}(z) > -1$, while favoring phantom models, [16–20] H_0 tension is telling us new things about alternative DE models. Preceding the cosmic acceleration phase, the universe underwent a deceleration phase during its early epochs, where the impact of DE was relatively minor. It is believed that density perturbations during this period played a pivotal role in shaping cosmic structures. As a result, understanding the complete evolutionary timeline requires a cosmological model capable of describing both acceleration and deceleration phases.

The second approach involves an extension of the gravitational component in GR by introducing a DE source while keeping the matter sector unchanged. As the first category holds intriguing implications, it has not gained as much support due to certain ambiguities. In contrast, modified gravity frameworks have proven to be quite valuable due to their effective execution in the field of cosmology. Einstein formulated the concept of geometry-matter coupling whose adaptation has been integral to the development of General Relativity (GR). Several alternative theories of gravity, which incorporate additional curvature terms in the gravitational action, have been thoroughly examined in the scientific literature. Some well-known examples of these modified gravity theories encompass $f(R)$ gravity [21], Gauss–Bonnet gravity [22], $f(R,T)$ gravity [23], the scalar-tensor theory [24], $f(T)$ gravity [25], $f(T,T_G)$ gravity [26], $f(Q)$ gravity [27], etc. These alterations are rooted in the metric tensor g_{ij} being considered a dynamic variable. Interestingly, an alternative approach to GR has been gaining momentum in the scientific literature, known as $f(Q,T)$ gravity [28] appearing as an extension of symmetric teleparallel gravity, where Q and T correspond to the non-metricity and the trace of the energy–momentum tensor, respectively. This novel theory has sparked significant interest in investigating the late universe and has been the subject of different researchers in various contexts [29–32].

The Einstein field equations within the framework of General Relativity (GR) are notoriously intricate, comprising a set of nonlinear differential equations that pose significant challenges in terms of finding analytical solutions. To simplify these complexities, physicists often make certain physical assumptions, such as establishing relationships between the pressure and energy density of the universe's contents. However, when introducing components like dark energy, these equations become even more tangled. This complexity also extends to modified gravity (MG) theories, which incorporate higher-order derivative terms. To obtain tractable solutions for the field equations, whether within GR or MG theories, researchers employ a variety of techniques, including dynamical system analysis, autonomous systems, and notably, the model-independent approach. The model-independent approach, which typically involves the parametrization of any cosmological parameter, which is generally a functional form of the parameter. While the parametrization of cosmological parameters may initially appear adhoc, it proves to be a legitimate and powerful method when considering the broad spectrum of possible evolutions for the geometrical and physical parameters from a mathematical standpoint. This idea has garnered increasing interest in the realm of mathematical cosmology. This concept of cosmological parametrization has been extensively explored in the scientific literature, with comprehensive discussions by Pacif [33,34], providing valuable insights into its application and significance in cosmological studies. There are also various studies on the model-independent approach by Eric V. Linder within some cosmological contexts. Specifically, he delved into the intricate studies of cosmological parametrization, a crucial facet of his research, which aimed to comprehensively study and understand a wide range of dark energy models that play a pivotal role in understanding the universe's accelerating expansion [35–39]

Modern cosmology advocates the investigation of kinematic quantities, often referred to as "Cosmography" or "Cosmo-kinetics". This approach relies on observational data and sidesteps prior assumptions about gravity theory or specific cosmological models. Cosmography's adoption of symmetry principles offers a means to navigate debates surrounding DE, dark matter, and related topics without invoking Einstein field equations (Friedmann equations). While cosmography does not directly involve the scale factor, it allows for some inference into its evolutionary history. The foundation of modern cosmology traces back to the work by Sandage [40], who introduced fundamental cosmographic parameters. These parameters include the Hubble parameter (H_0), which dictates the rate of cosmic expansion, and the deceleration parameter (q_0), responsible for accounting for the effects of gravity that slow down the expansion rate. Despite the emergence of DE altering the cosmological landscape, the dynamics of cosmic evolution remain intimately connected to the deceleration parameter (q), defined as $q = -\frac{a\ddot{a}}{\dot{a}^2}$, where $a(t)$ represents the scale factor. A positive value of q ($\ddot{a} < 0$) indicates deceleration, while a negative value implies acceleration. The Hubble parameter characterizes the linear temporal evolution of $a(t)$, and a non-linear correction term (q_0) introduces local instabilities and chaotic behavior [41]. The deceleration parameter (q) also plays a vital role in examining the dynamics of observable galaxy numbers. Dark energy gains empirical support through various modifications to fit observational data, making its parameterization as a function of the scale factor ($a(t)$) or redshift (z) a valuable approach.

In the current paper, we have considered a parametrization of the deceleration parameter given in [42] within the classical gravity and extend the analysis in $f(Q,T)$ gravity, which is also a special case of the parametrization considered in [33]. A plethora of parametric forms for the deceleration parameter have been explored, each with its own set of limitations. While some diverge at large cosmic times, others remain well-behaved at low redshifts ($z \ll 1$) [43–81]. The adoption of parametric assumptions can occasionally lead to misinterpretations of the nature of DE, prompting an interest in non-parametric models that directly infer evolutionary mechanisms from observational data [82–86]. Nevertheless, the parameterization of q proves to be a more effective strategy for investigating the transition from cosmic deceleration to acceleration.

Highlighting the versatility and gravitational-theory independence of the parameterized q approach. In this study, we have made some analysis of the model produced by the cubic parametrization of the deceleration parameter and found tighter constraints to the model parameters involved. Additionally, we have done some cosmographic tests in order to differentiate a better-performing model when compared with cosmological data.

The paper is organized in the following manner. In Section 1, we provide an overview of the current state of modern cosmology, highlighting the various scenarios proposed to explain the late-time cosmic acceleration of the universe. We also outline the scope and objectives of the paper. In Section 2, we introduce the $f(Q,T)$ gravity framework and present the associated field equations. We derive the modified Friedmann equations within this context. In Section 3, we discuss a model-independent approach to parametrize the cosmological model. This section lays the foundation for our subsequent analyses. Section 4, focuses on characterizing the model through dynamical variables, providing insights into its behavior and evolution. In Section 5, we derive all cosmological and physical parameters in terms of redshift, enhancing our understanding of the model's evolution. Section 6 employs the Markov chain Monte Carlo (MCMC) method to constrain the model's parameters. We determine the best-fit values of model parameters by comparing them with the present Hubble rate function across different datasets. In Section 7, we validate the

model's predictions by comparing them with observational data, Section 8 delves into the kinematic cosmographic parameters, including the deceleration and jerk parameters, providing a detailed analysis of their implications within the model. Sections 9 and 10 are dedicated to the statefinder and *Om* diagnostic tests, offering further insights into the model's behavior and compatibility with observational data. In 11, we conduct a comprehensive statistical analysis to rigorously assess the model's performance and reliability. Sections 11 and 12 present the results of our study and draw conclusions based on our findings, summarizing the contributions and implications of this research.

2. Cosmological equations in $f(Q,T)$ gravity

From the modification in Einstein–Hilbert action of general relativity by introducing a function of two scalar invariants, Q and T, which are constructed from the non-metricity and the trace of the energy–momentum tensor. The action in $f(Q,T)$ is given by [87].

$$S = \int \left[\frac{1}{16\pi} f(Q,T) + \mathcal{L}_M\right] \sqrt{-g}\, d^4x \tag{1}$$

where, $g \equiv det(g_{\mu\nu})$, and $\mathcal{L}_M$ is Lagrangian density.

In Riemannian geometry, the metric tensor is always symmetric. However, for our research, we take the $f(Q,T)$ gravity, in which, we can take the non-symmetric part of the metric tensor called non-metricity. Which can be defined as

$$Q \equiv -g^{\mu\nu}(L^{\alpha}_{\beta\mu}L^{\beta}_{\nu\alpha} - L^{\alpha}_{\beta\alpha}L^{\beta}_{\mu\nu}) \tag{2}$$

where

$$L^{\alpha}_{\beta\gamma} \equiv -\frac{1}{2}g^{\alpha\lambda}(\nabla_{\gamma}g_{\beta\lambda} + \nabla_{\beta}g_{\lambda\gamma} - \nabla_{\lambda}g_{\beta\gamma}) \tag{3}$$

The trace of nonmetricity tensor is expressed as,

$$Q_{\alpha} \equiv Q_{\alpha}{}^{\mu}{}_{\mu},\ \tilde{Q}_{\alpha} \equiv Q^{\mu}_{\alpha\mu} \tag{4}$$

The trace of the energy–momentum tensor and modification in the metric tensor are respectively

$$T_{\mu\nu} = -\frac{2}{\sqrt{-g}}\frac{\delta(\sqrt{-g}\mathcal{L}_M)}{\delta g^{\mu\nu}} \tag{5}$$

$$\Theta_{\mu\nu} = g^{\alpha\beta}\frac{\delta T_{\alpha\beta}}{\delta g^{\mu\nu}} \tag{6}$$

Finding the variation of action of the field equation Eq. (1) with respect to metric tensors.

$$8\pi T_{\mu\nu} = -\frac{2}{\sqrt{-g}}\nabla_{\alpha}(f_Q\sqrt{-g}P^{\alpha}_{\mu\nu} - \frac{1}{2}f g_{\mu\nu} + f_T(T_{\mu\nu} + \Theta_{\mu\nu}) - f_Q(P_{\mu\alpha\beta}Q^{\alpha\beta}_{\nu} - 2Q^{\alpha\beta}{}_{\mu}P_{\alpha\beta\nu})) \tag{7}$$

Where super-momentum

$$P^{\alpha}_{\mu\nu} \equiv \frac{1}{4}\left[-Q^{\alpha}_{\mu\nu} + 2Q^{\alpha}_{(\mu\ \nu)} + Q^{\alpha}g_{\mu\nu} - \tilde{Q}^{\alpha}g_{\mu\nu} - \delta^{\alpha}_{(\mu}Q_{\nu)}\right] = -\frac{1}{2}L^{\alpha}_{\mu\nu} + \frac{1}{4}\left(Q^{\alpha} - \tilde{Q}^{\alpha}\right)g_{\mu\nu} - \frac{1}{4}\delta^{\alpha}_{(\mu}Q_{\nu)} \tag{8}$$

Taking the FLRW metric as follows,

$$ds^2 = -N(t)^2dt^2 + a(t)^2(dx^2 + dy^2 + dz^2), \tag{9}$$

where N(t) is the lapse function and a(t) is the scale factor. Hence, $Q = 6H^2/N^2$. We assume the value of N(t) = 1, for a standard case. Hence, $Q = 6H^2$.

To find the generalized Friedmann equations, assuming the matter content as the perfect fluid with the energy–momentum tensor $T^{\mu}_{\nu} = diag(-\rho, p, p, p)$. The tensor Θ^{μ}_{ν} becomes,

$$\Theta^{\mu}_{\nu} = \delta^{\mu}_{\nu}p - 2T^{\mu}_{\nu} = diag(2\rho + p, -p, -p, -p) \tag{10}$$

For simplicity, taking $F \equiv f_Q = dF/dt$ and $8\pi\tilde{G} \equiv f_T = dF/dt$ the Friedmann equations we derived as follows,

$$8\pi\rho = \frac{f}{2} - 6FH^2 - \frac{2\tilde{G}}{1+\tilde{G}}(\dot{F}H + F\dot{H}) \tag{11}$$

$$8\pi p = -\frac{f}{2} + 6FH^2 + 2(\dot{F}H + F\dot{H}) \tag{12}$$

From Eqs. (11) and (12), modified Einstein's field equations are derived

$$3H^2 = 8\pi\rho_{eff} = \frac{f}{4F} - \frac{4\pi}{F}[(1+\bar{G})\rho + \bar{G}p] \tag{13}$$

$$2\dot{H} + 3H^2 = -8\pi p_{eff} = \frac{f}{4F} - \frac{2\dot{F}H}{F} + \frac{4\pi}{F}\left[(1+\bar{G})\rho + (2+\bar{G})p\right] \tag{14}$$

From Eqs. (13) and (14) and the derivative of Eq. (13) we derive the continuity equation

$$\dot{\rho}_{eff} + 3H\left(\rho_{eff} + p_{eff}\right) = 0 \tag{15}$$

Although there are several forms of the function $f(Q,T)$ is considered in the literature [88], we here only confined to the linear and additive form of $f(Q,T)$ function [87,89] in the form

$$f(Q,T) = \mu Q + \nu T \tag{16}$$

where, μ and ν are the non zero model constants. Hence the first derivatives $f_Q = \mu$ and $8\pi\tilde{G} = f_T = \nu$. Solving the modified Friedmann equations and applying the barotropic equation of states $p = \omega\rho$ we can find the equation of state parameter as follows

$$\omega = \frac{3H^2(8\pi+\nu) + \dot{H}(16\pi+3\nu)}{\nu\dot{H} - 3H^2(8\pi+\nu)} \tag{17}$$

Hence the energy density equation turns out to be

$$\rho = \frac{-3H^2\mu(8\pi+\nu) + \mu\nu\dot{H}}{2(4\pi+\nu)(8\pi+\nu)} \tag{18}$$

To find the value of $\dot{H}$ we use the relation $a_0/a = 1+z$ we can define a new relation between z and t.

$$\frac{d}{dt} = \frac{dz}{dt}\frac{d}{dz} = -(1+z)H(z)\frac{d}{dz} \tag{19}$$

normalizing the equation by taking the value of the scale factor as $a_0 = a(t=t_0) = 1$, t_0 refers the present time. Hence we can write the derivation Hubble parameter with respect to time in terms of red-shift as,

$$\dot{H} = -(1+z)H(z)\frac{dH}{dz} \tag{20}$$

3. The model

The modified field equations, denoted as Eqs. (11) and (12) are two independent equations describing the dynamics of the model. These fundamental equations intertwined with three unknown variables: a, ρ, and p. This implies that, in order to completely characterize and solve this system, we are in need of an additional equation. To address this, researchers in the field have adopt a widely accepted approach *the model independent way* study of model, often considers a scheme of parameterization of a cosmological parameter. In contemporary scientific literature, this approach is gaining prominence, as it is capable of solving the field equations in a model independent way that do not affect the background physics but provide a solution in simple way. It involves making an initial assumption regarding the scale factor, which can be done either directly or by expressing it in terms of cosmological parameters and their time derivatives. This strategic choice not only simplifies the equations but also allows for a more comprehensive exploration of the model's dynamics. To aid researchers in this endeavor, a wealth of parametrizations for various cosmological parameters has been meticulously compiled and organized in Refs. [33,90]. These compilations serve as invaluable resources, facilitating the selection of appropriate parameterization schemes based on the specific characteristics and goals of a given study. There are a few intriguing models of dark energy and modified gravity based on various parametrization

schemes of some geometrical parameters [91–95]. One noteworthy aspect of this concept is its ability to reconstruct the cosmic history and also the fate, while offering solutions to certain problems of standard cosmology.

In our own investigation, we opt to employ the parameterization of the deceleration parameter to effectively close the aforementioned system of equations. This choice aligns with established practices, streamlining our analytical framework while enabling us to delve deeply into the dynamics of our model. We employ here a scheme of parametrization of higher order time-dependent deceleration parameter ($q(t)$) in the form,

$$q(t) = -1 + \frac{m}{n} - \frac{4}{n}t^3, \tag{21}$$

where $m > 0$ and $n > 0$ are two arbitrary constants. Similar form is also considered in the Ref. [42] in the context of $f(R,T)$ gravity. By using the definition of the deceleration parameter in the form of Hubble parameter, $q = \frac{d}{dt}\left(\frac{1}{H}\right) - 1$, we may obtain an explicit form of Hubble function as

$$H(t) = \frac{n}{t\left(m - t^3\right)} \tag{22a}$$

Note that this explicit form of the Hubble parameter can also be interpreted as a particular form of the parametrization given in Ref. [33] as a special case. Using the definition of the Hubble parameter in terms of scale factor will give the explicit form of scale factor as,

$$a = \beta\left(\frac{t^3}{m - t^3}\right)^{\frac{n}{3m}}, \tag{23}$$

The deceleration parameter plays a crucial role in characterizing the dynamics of the universe's expansion. It provides insights into whether the expansion is slowing down or accelerating. Specifically, when the deceleration parameter is greater than zero ($q > 0$), it signifies a phase of decelerating expansion. Conversely, when the deceleration parameter is less than zero ($q < 0$), it indicates an accelerating expansion phase. A particularly interesting point occurs when the deceleration parameter equals zero ($q = 0$), marking a significant phase transition in the expansion of the universe. This phase transition at $q = 0$ occurs at a specific time, denoted as t_{tr}, which can be calculated in this considered case as, $t_{tr} = \sqrt[3]{\frac{m-n}{4}}$. This implies, m must be greater than n. This moment represents a critical juncture in the universe's evolution, where the expansion dynamics shift fundamentally. We can observe in Eqs. (23) and (22a), for $t = m^{1/3}$, $H \longrightarrow \infty$ and $a \longrightarrow \infty$, implying the existence of a big rip singularity in this model, which is anticipated to happen in the near future, precisely at $t = t_{end} = m^{1/3}$. The universe's expansion reaches a point of extreme instability and divergence, characterized by this singularity.

4. Characterizing the model through dynamical variables

This section is dedicated to providing a comprehensive analysis of the physical behavior and properties inherent in our model. Within this context, we aim to elucidate the model's physical dynamics by examining key parameters, including energy density (ρ), pressure (p), and the equation of state parameter (ω). These parameters are essential in understanding the behavior of our model and the physical processes it encapsulates. The temporal or redshift evolution of these parameters serves as a window into the dynamic nature of our model, shedding light on various aspects of the Universe's evolution, particularly during its late stages and with regard to stability considerations.

Our discussion in this section serves as the bedrock upon which a deeper comprehension of our model is built. It lays the essential groundwork for subsequent analyses and discussions. To initiate our exploration, we leverage the field equations, denoted as Eqs. (11) and (12). These equations provide us with a means to express the energy density (ρ) and pressure (p) in specific mathematical forms. This mathematical representation is pivotal in uncovering the intricate details of our model's physical behavior and will serve as the basis for our further investigations and interpretations. The explicit expressions for ρ and p using Eqs. (23) and (22a) are found in this case as;

$$\rho(t) = \frac{-n\mu[\nu(m - 4t^3) + 3n(8\pi + \nu)]}{2(-mt + t^4)^2(4\pi + \nu)(8\pi + \nu)} \tag{24}$$

and

$$p(t) = \frac{n\mu[8\pi(-2m + 3n + 8t^3) + 3\nu(-m + n + 4t^3)]}{2(-mt + t^4)^2(4\pi + \nu)(8\pi + \nu)} \tag{25}$$

The concept of the equation of state parameter denoted as ω, holds significant importance in the realm of cosmology. It serves as a fundamental tool for characterizing the relationship between pressure (p) and energy density (ρ) within a given system. This parameter is defined as the ratio of pressure to energy density, and it plays a crucial role in describing the thermodynamic behavior of fluids within the Universe. The value of ω offers critical insights into how a substance or component reacts to variations in volume or temperature. These insights, in turn, have profound implications for the overall dynamics and fate of the Universe. In this context, we have already derived expressions for both energy density and pressure specific to our model.

Now, by employing Eqs. (24) and (25), we can deduce the expression for the equation of state parameter ω, as follows:

$$\omega(t) = \frac{8\pi(2m - 3n - 8t^3) + 3\nu(m - n - 4t^3)}{\nu(m - 4t^3) + 3n(8\pi + \nu)} \tag{26}$$

5. Deriving cosmological parameters in terms of redshift

To effectively constrain our model parameters, we need to express all the obtained cosmological variables in terms of the redshift parameter, denoted as z. To achieve this, we utilize the relationship between the redshift (z) and the scale factor (a), given by

$$1 + z = \frac{a_0}{a}, \tag{27}$$

where a_0 is the present value of the scale factor and generally normalized to be $a_0 = 1$. The $t - z$ relationship in our case can be established as;

$$t = \sqrt[3]{k_1}\left\{1 + [\zeta(1 + z)]^3\frac{m}{n}\right\}^{-\frac{1}{3}} \tag{28}$$

Now, the Hubble parameter in terms of redshift z for the Model is,

$$H(z) = H_0\left(1 + \zeta^{3\eta}\right)^{-\frac{4}{3}}(1 + z)^{-3\eta}\left\{1 + [\zeta(1 + z)]^{3\eta}\right\}^{\frac{4}{3}}, \tag{29}$$

where $\frac{m}{n} = \eta$. Now, the deceleration parameter, energy density, pressure, and the equation of state parameter can be rewritten in terms of redshift z as follows (see Box I).

To comprehensively explore the evolution of both geometric and physical parameters, as well as to rigorously assess the validity of our derived model, it becomes imperative to acquire precise values for the model parameters that play a pivotal role in our theoretical framework. Thus, we perform the data analysis in the subsequent section to derive some precise values of the model parameter. Through this data analysis, we aim to gain a deeper understanding of the dynamics governing our cosmological model and evaluate its consistency with observation too.

6. Data analysis

In this section, we conduct an extensive comparison between our proposed cosmological model and a wide range of available cosmological data. Our aim is to understand the fundamental characteristics of the model through various datasets, including the Cosmic Chronometers (CC), type Ia supernovae (SNIa), Gamma Ray Bursts (GRBs), Quasars (Q), Baryon Acoustic Oscillation (BAO) and Cosmic Microwave Background (CMB) This rigorous investigation aims to determine the optimal values of key model parameters, such as η, ζ. These

$$q(z) = -1 + \eta - \frac{4\eta}{\left\{1 + [\zeta(1+z)]^{3\eta}\right\}}, \tag{30}$$

$$p(z) = -\frac{\mu H_0^2 \left(1 + (\zeta(1+z))^{3\eta}\right)^{5/3} (16\pi + 3\nu)\eta \left(-3 + (\zeta(1+z))^{3\eta}\right) - 3(8\pi + \nu)\left(1 + (\zeta(1+z))^{3\eta}\right)}{2(4\pi + \nu)(8\pi + \nu)(1 + \zeta^2(1+z)^{3\eta})^{8/3}} \tag{31}$$

$$\rho(z) = -\frac{\left((1+z)^{-6\eta}\mu H_0^2 \left(1 + ((1+z)\zeta)^{3\eta}\right)^{5/3} \left(3(8\pi + \nu - \nu\eta) + (3(8\pi + \nu) + \nu\eta)((1+z)\zeta)^{3\eta}\right)\right)}{2(4\pi + \nu)(8\pi + \nu)\left(1 + \zeta^3\eta^8\right)^{1/3}} \tag{32}$$

$$\omega(z) = \frac{(16\pi + 3\nu)\eta\left(-3 + ((1+z)\zeta)^{3\eta}\right) - 3(8\pi + \nu)\left(1 + ((1+z)\zeta)^{3\eta}\right)}{3(8\pi + \nu - \nu\eta) + 3(8\pi + \nu) + \nu\eta((1+z)\zeta)^{3\eta}} \tag{33}$$

Box I.

datasets together describe how our model behaves in the context of the $f(Q,T)$ gravity framework. Importantly, we also account for the present-day Hubble function, denoted as H_0, which plays a crucial role in shaping our results. To obtain best fit values our cosmological model we employ a robust Bayesian statistical methodology. This method relies on likelihood functions and a well-accepted technique called Markov Chain Monte Carlo (MCMC). Within this Bayesian framework, we construct a probabilistic assessment of how likely certain combinations of model parameters are based on actual observations. Our investigation reveals hidden aspects of our cosmological model, offering valuable insights into how it deeply connects with the observable universe.

6.1. Methodology

Constraining the Hubble function through observational data involves a process known as parameter estimation or model fitting. In our case, our goal is to determine the optimal values of key model parameters, using various datasets, including Cosmic Chronometers (CC), Type Ia Supernovae (SNIa), Gamma-Ray Bursts (GRBs), Quasars (Q), Baryon Acoustic Oscillations (BAO), and the Cosmic Microwave Background (CMB). The initial step is to establish a likelihood function that measures the agreement between our model predictions and the observed data.

$$\mathcal{L}(\theta) = \exp\left(-\frac{1}{2}\sum_{i=1}^{N}\frac{(O_i - M_i(\theta))^2}{\sigma_i^2}\right) \tag{34}$$

Where O_i is the observed data point for the ith data point, $M_i(\theta)$ is the model prediction for the ith data point based on the parameters θ, and σ_i represents the uncertainty associated with the observed data point. Next, we perform Bayesian parameter estimation [96]. This requires defining prior distributions for each parameters we want to constrain, which should encapsulate any existing knowledge or constraints. If strong prior information is lacking, relatively flat priors can be used. The posterior distribution, proportional to the likelihood function multiplied by the prior distribution, is then computed as:

$$P(\theta|D) \propto \mathcal{L}(\theta) \times \pi(\theta) \tag{35}$$

In the subsequent steps, Markov Chain Monte Carlo (MCMC) is employed to explore the posterior distribution and derive parameter constraints [97]. This widely employed sampling technique generates an extensive set of samples from the posterior distribution, allowing for the extraction of key statistical measures. These measures include mean, median, standard deviation, and credible intervals for each parameter, providing optimal parameter values and their associated uncertainties. Subsequently, we rigorously evaluate our model's performance against the Cosmic Chronometers (CC) and type Ia supernovae (SNIa) datasets. Visual comparisons and quantitative metrics, such as chi-squared values or the Akaike Information Criterion (AIC), are used to assess the model's fit. The ensuing discussions delve into the implications of the derived parameter constraints, emphasizing the model's alignment with observational data. We explore potential physical interpretations and ramifications, enriching our understanding of the underlying cosmological dynamics.

6.2. Data description

6.2.1. Cosmic chronometers

In our analysis, we utilize thirty-one data points acquired through the cosmic chronometers (CC) technique for the determination of the Hubble parameter. This approach allows us to directly extract information about the Hubble function at various redshifts, extending up to $z \lesssim 2$. The selection of CC data is motivated by its reliability, as it primarily involves measurements of the age difference between two passively evolving galaxies that originated at the same time but have a slight separation in redshift. This technique enables us to compute $\Delta z/\Delta t$, making CC data preferable to methods based on absolute age determinations for galaxies [98]. Our chosen CC data points were sourced from independent [99–105]. Importantly, these references are not influenced by the Cepheid distance scale or any specific cosmological model. Nevertheless, it is worth noting that they do depend on the modeling of stellar ages, which is established using robust stellar population synthesis techniques (for more details, see [101,103,106–109] for analyses related to CC systematics). We evaluate the goodness of fit using the χ^2_{CC} estimator, which is expressed as follows:

$$\chi^2_{CC}(\Theta) = \sum_{i=1}^{31}\frac{\left(H\left(z_i,\Theta\right) - H_{\rm obs}\left(z_i\right)\right)^2}{\sigma_H^2\left(z_i\right)}, \tag{36}$$

Here, $H\left(z_i,\Theta\right)$ represents the theoretical Hubble parameter values at redshift z_i with model parameters denoted as Θ. The observational data for the Hubble parameter at z_i is given by $H_{\rm obs}\left(z_i\right)$, with an associated observational error of $\sigma_H\left(z_i\right)$.

6.2.2. Type Ia supernovae (SNIa)

Over the years, a multitude of supernova datasets has been established, including references such as [110–114]. Recently, a refreshed version of the Pantheon dataset, referred to as Pantheon+, has been introduced [115]. This updated compilation comprises 1701 data points of type Ia supernovae (SNIa), spanning the redshift interval $0.001 < z < 2.3$. SNIa observations have played a pivotal role in unveiling the phenomenon of the universe's accelerating expansion. These observations serve as crucial tools for investigating the nature of the driving component behind this expansion, owing to SNIa's status as luminous

astrophysical objects. These objects, often treated as standard candles, enable the measurement of relative distances based on their intrinsic brightness. The Pantheon+ dataset stands as a valuable resource, offering insights into the accelerating universe's characteristics. The chi-square statistic serves as a fundamental tool for comparing theoretical models with observational data. In the context of the Pantheon+ dataset, chi-square values are computed using the subsequent equation

$$\chi^2_{\text{Pantheon+}} = \vec{D}^T \cdot \mathbf{C}^{-1}_{\text{Pantheon+}} \cdot \vec{D} \tag{37}$$

Here, $\vec{D}$ represents the difference between the observed apparent magnitudes m_{Bi} of SNIa and the expected magnitudes given by the cosmological model. M represents the absolute magnitude of SNIa, and μ_{model} is the corresponding distance modulus predicted by the assumed cosmological model. The term $\mathbf{C}_{\text{Pantheon+}}$ denotes the covariance matrix provided with the Pantheon+ data, which includes both statistical and systematic uncertainties. The distance modulus is a measure of the distance to an object, defined as:

$$\mu_{\text{model}}(z_i) = 5\log_{10}\left(\frac{D_L(z_i)}{(H_0/c)\ \text{Mpc}}\right) + 25 \tag{38}$$

Here, $D_L(z)$ represents the luminosity distance, which is calculated for a flat homogeneous and isotropic FLRW universe as:

$$D_L(z) = (1+z)H_0 \int_0^z \frac{dz'}{H(z')} \tag{39}$$

The Pantheon+ dataset differs from the previous Pantheon sample as it breaks the degeneracy between the absolute magnitude M and the Hubble constant H_0. This is achieved by rewriting the vector $\vec{D}$ in terms of the distance moduli of SNIa in the Cepheid hosts. The distance moduli in the Cepheid hosts, denoted as μ_i^{Ceph}, are measured independently using Cepheid calibrators. This allows for the independent constraint of the absolute magnitude M. The modified vector $\vec{D}'$ is defined as:

$$\vec{D'}_i = \begin{cases} m_{Bi} - M - \mu_i^{\text{Ceph}} & \text{if } i \text{ is in Cepheid hosts} \\ m_{Bi} - M - \mu_{\text{model}}(z_i) & \text{otherwise} \end{cases} \tag{40}$$

With this modification, the chi-square equation for the Pantheon+ dataset can be rewritten as:

$$\chi^2_{\text{SN}} = \vec{D'}^T \cdot \mathbf{C}^{-1}_{\text{Pantheon+}} \cdot \vec{D'} \tag{41}$$

This revised formulation allows for improved constraints on the absolute magnitude M and the cosmological parameters.

We have also expanded our investigation to include a subset of 162 Gamma Ray Bursts (GRBs) [116], spanning a redshift range of $1.44 < z < 8.1$. In this context, we define the χ^2 function as:

$$\chi^2_{\text{GRB}}(\phi^{\nu}_{\text{g}}) = \mu_{\text{g}} \mathbf{C}^{-1}_{\text{g,cov}} \mu^T_{\text{g}}, \tag{42}$$

Here, μ_{g} denotes the vector encapsulating the differences between the observed and theoretical distance moduli for each individual GRB. Similarly, for our examination of 24 compact radio quasar observations [117], spanning redshifts in the range of $0.46 \leq z \leq 2.76$, we establish the χ^2 function as:

$$\chi^2_{\text{Q}}(\phi^{\nu}_{\text{q}}) = \mu_{\text{q}} \mathbf{C}^{-1}_{\text{q,cov}} \mu^T_{\text{q}}, \tag{43}$$

In this context, μ_{q} represents the vector capturing the disparities between the observed and theoretical distance moduli for each quasar.

6.2.3. Baryon acoustic oscillations

To study Baryon Acoustic Oscillations (BAO), we utilize a dataset consisting of 333 measurements [118–129]. However, considering the potential error arising from data correlations, we select a smaller dataset of 17 BAO measurements for our analysis (please see table 1 of this work [130]). This selection helps to reduce errors and improve the accuracy of our results. One of the key measurements obtained from BAO studies in the transverse direction is the quantity $D_H(z)/r_d$, where $D_H(z)$ represents the comoving angular diameter distance. It is related to the following expression [131,132]:

$$D_M = \frac{c}{H_0} S_k\left(\int_0^z \frac{dz'}{E(z')}\right), \tag{44}$$

where $S_k(x)$ is defined as:

$$S_k(x) = \begin{cases} \frac{1}{\sqrt{\Omega_k}} \sinh\left(\sqrt{\Omega_k}x\right) & \text{if} \quad \Omega_k > 0 \\ x & \text{if} \quad \Omega_k = 0 \\ \frac{1}{\sqrt{-\Omega_k}} \sin\left(\sqrt{-\Omega_k}x\right) & \text{if} \quad \Omega_k < 0. \end{cases} \tag{45}$$

Additionally, we consider the angular diameter distance $D_A = D_M/(1+z)$ and the quantity $D_V(z)/r_d$. The latter is a combination of the coordinates of the BAO peak and r_d, representing the sound horizon at the drag epoch. Furthermore, we can directly obtain "line-of-sight" or "radial" observations from the Hubble parameter using the expression:

$$D_V(z) \equiv \left[z D_H(z) D_M^2(z)\right]^{1/3}. \tag{46}$$

By studying these BAO measurements, we gain insights into the cosmological properties and evolution of the universe, while minimizing potential errors and considering relevant distance measures and observational parameters.

6.2.4. Cosmic microwave background

The CMB distant prior measurements are taken [133]. The distance priors offer useful details about the CMB power spectrum in two ways: the acoustic scale l_A characterizes the CMB temperature power spectrum in the transverse direction, causing the peak spacing to vary, and the "shift parameter" R influences the CMB temperature spectrum along the line-of-sight direction, affecting the peak heights, which are defined as follows:

$$l_A = (1+z_d)\frac{\pi D_A(z)}{r_s}, \tag{47}$$

$$R(z) = \frac{\sqrt{\Omega_m} H_0}{c}(1+z_d) D_A(z) \tag{48}$$

The observables that [133] reports are: $R_z = 1.7502 \pm 0.0046$, $l_A = 301.471 \pm 0.09$, $n_s = 0.9649 \pm 0.0043$ and r_s is an independent parameter, with an associated covariance matrix. (see table I in [133]). The points represent the inflationary observables as well as the CMB epoch expansion rate. In addition to the CMB points, we also take into account other data from the late Universe. The result is a successful test of the model in relation to the data.

The contour plots derived from various datasets, including the CC dataset, BAO dataset, SNIa dataset, and the combined dataset (CC + SNIa + GRB + Q + BAO + CMB), are presented in Fig. 1, Fig. 2, Fig. 3, and Fig. 4, respectively. To provide a comprehensive overview, we have overlaid all four figures from these diverse datasets in Fig. 5. In Table 1, we have tabulated the best-fit values of the model parameters η and ζ, along with the present-day Hubble function H_0, complete with their corresponding error bars and $q(z=0)$, $j(z=0)$, and χ^2_{min} with respect to different datasets.

7. Observational and theoretical comparisons of the hubble function and distance modulus function

After obtaining the best-fit values for our cosmological model parameters, it is crucial to compare our model with the widely accepted ΛCDM model. The ΛCDM model has consistently aligned with various observational datasets and stands as a robust framework for understanding the Universe's evolution. This comparative analysis deepens our comprehension of differences between the two models, shedding light on the implications of these disparities in cosmology. By examining deviations between our model and the ΛCDM model, we pinpoint

Table 1
We present constraints on cosmological parameters for both the standard ΛCDM and proposed models at a 95% confidence level (CL). These constraints are derived from the CC dataset, Type Ia supernovae (SNIa), and Baryon Acoustic Oscillations (BAO) datasets. Additionally, the 'JOINT' dataset combines the 'CC' dataset with data from Type Ia supernovae, gamma-ray bursts, quasars, BAO, and CMB distant prior measurements. The table includes values for $q(z=0)$, $j(z=0)$, and $\chi^2_{\rm min}$ with respect to different datasets.

Model	Dataset	H_0	η	ζ	$q(z=0)$	$j(z=0)$

the specific features that distinguish our parametrized model, such as the Universe's dynamics. This exploration provides valuable insights into our model's strengths and limitations, enriching our understanding of the cosmos. This comparison with the ΛCDM model acts as a benchmark, allowing us to assess the goodness-of-fit to observational data and gauge the alignment between our parametrized model and the established ΛCDM framework.

7.1. Comparison with the CC data points

We evaluate our model's compatibility with observational data by conducting a comparative analysis with the Cosmic Chronometers dataset, consisting of 31 data points represented by orange dots, each accompanied by error bars represented by purple dots. This comparison is illustrated in Fig. 6, where our model's predictions are depicted by the purple line. To provide a reference point, we also include the well-established ΛCDM model, represented by the black line, with cosmological parameters $\Omega_{\mathrm{m0}} = 0.3$ and $\Omega_{\Lambda} = 0.7$. The results of this analysis reveal a remarkable correspondence between our model's predictions and the observed data points, as indicated by their close alignment. This alignment underscores the ability of our model to effectively capture the inherent features and trends within the Cosmic Chronometers dataset. Consequently, our model demonstrates its capability to reproduce the expansion history of the universe, as inferred from the Hubble data.

7.2. Comparison with the type Ia supernova dataset

In this analysis, we carefully studied the $\mu(z)$ distance modulus function for our Model alongside the data from type Ia supernovae, which includes a significant 1701 data points. We also compared our Model with standard ΛCDM Model. The results of this comparison are represented in Fig. 7. The figures clearly illustrate that our model and the ΛCDM model exhibit a commendable level of agreement with the type Ia supernova dataset. This agreement indicates that these models effectively capture and replicate the observed distance measurements, signifying their consistency with empirical astronomical data.

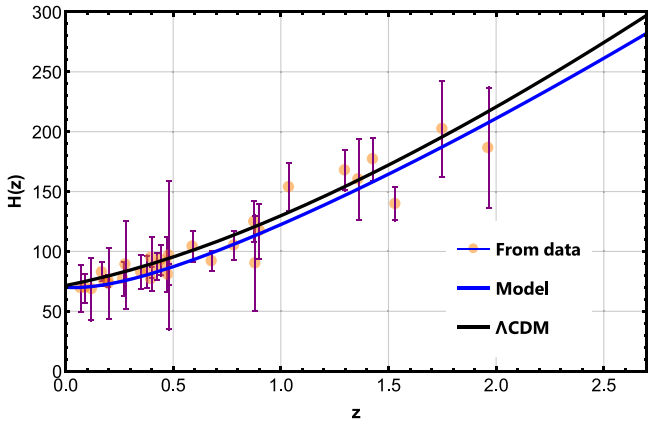

Fig. 6. Comparative analysis of our model (Blue Line) with 31 CC measurements (Orange dots) and ΛCDM model (black line). (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

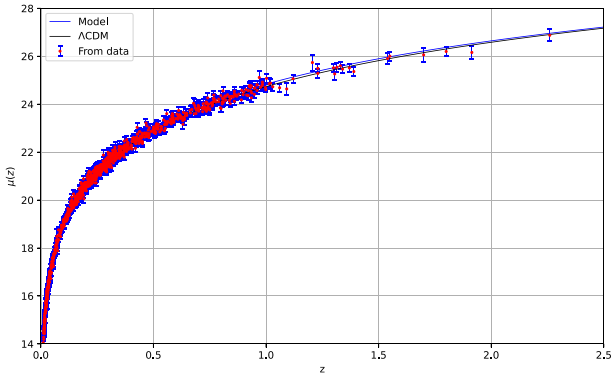

Fig. 7. Comparative analysis of our model (Blue Line) with 1701 type Ia supernova measurements (Orange dots) and ΛCDM model (black line). (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

7.3. Relative difference between model and ΛCDM

The Fig. 8 illustrates the relative difference between our Model and the standard ΛCDM model. It is evident from the Figure that our Model exhibits distinct behavior from the typical ΛCDM model, particularly noticeable start form low redshift values ($z > 0$). As the redshift increases, these disparities between our model and the ΛCDM Model become more pronounced.

8. Cosmography parameters

8.1. The deceleration parameter

The deceleration parameter [134], denoted as "q," is a fundamental cosmological parameter used in the study of the expansion dynamics of the universe. It plays a crucial role in understanding the past and future evolution of the cosmos. Introduced by Edwin Hubble in the early 20th century, this parameter provides insights into whether the expansion of the universe is slowing down or accelerating. The deceleration parameter is defined in terms of the second derivative of the scale factor of the universe, which describes how the universe's size changes with time. Mathematically, it can be expressed as:

$$q = -\frac{a\ddot{a}}{\dot{a}^2}, \tag{49}$$

where q is the deceleration parameter. $a(t)$ represents the scale factor of the universe as a function of time. $\dot{a}$ represents the first derivative of

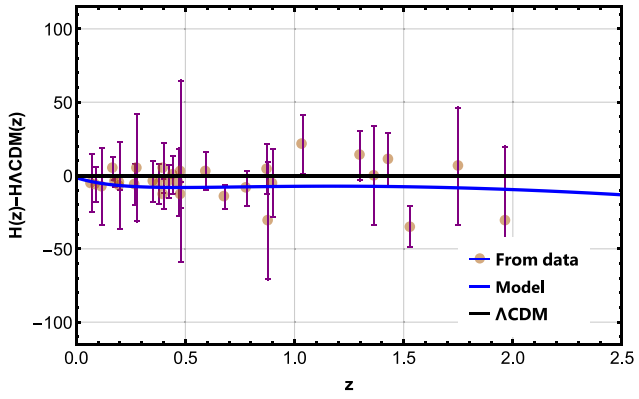

Fig. 8. Comparative analysis of our model (Blue Line) with 31 CC measurements (Orange dots) and ΛCDM model (black line). (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

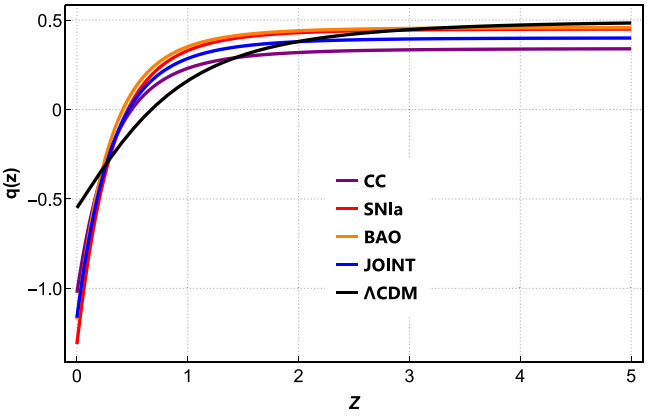

Fig. 9. Evolution of the deceleration parameter with respect to redshift across various datasets, depicted alongside the ΛCDM model represented by the black line, characterized by $\Omega_{m0} = 0.3$ and $\Omega_{\Lambda} = 0.7$.

the scale factor with respect to time. ä represents the second derivative of the scale factor with respect to time. The value of the deceleration parameter is indicative of the nature of the cosmic expansion:

1. $q > 0$ (Decelerating Universe): If the deceleration parameter is positive, it implies that the expansion of the universe is slowing down over time. In the past, this was the prevailing belief when the gravitational attraction of matter was thought to dominate the cosmic dynamics.
2. $q = 0$ (Critical Universe): A deceleration parameter of zero suggests that the expansion is proceeding at a constant rate. In this scenario, the universe's expansion is neither accelerating nor decelerating, often referred to as a "critical universe".
3. $q < 0$ (Accelerating Universe): A negative value for the deceleration parameter signifies that the universe's expansion is accelerating. This phenomenon gained significant attention in the late 20th century when the discovery of dark energy provided a compelling explanation for this observed acceleration.

In recent years, the study of the deceleration parameter has become increasingly important in cosmology, particularly in the context of understanding dark energy and the fate of the universe. It is a key parameter used in observational cosmology to probe the nature of the components of the universe, such as dark matter and dark energy, and to determine the overall geometry of the universe.

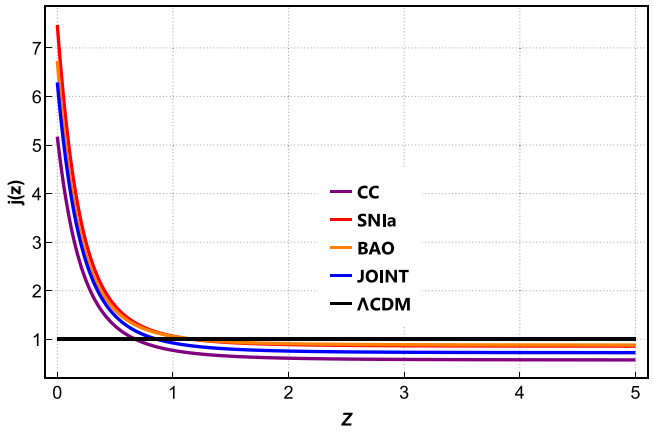

Fig. 10. Evolution of the jerk parameter with respect to redshift across various datasets, depicted alongside the ΛCDM model represented by the black line, characterized by $\Omega_{m0} = 0.3$ and $\Omega_{\Lambda} = 0.7$.

8.2. The jerk parameter

In the realm of cosmology, understanding the dynamics of the universe's expansion is of paramount importance. While the Hubble constant and the deceleration parameter have been essential tools in characterizing this expansion, a more nuanced parameter known as the "jerk parameter" has emerged as a valuable addition to our cosmological toolkit. The jerk parameter, denoted as "j," provides a deeper level of insight into the cosmic acceleration, complementing the information offered by the deceleration parameter [135]. The jerk parameter represents the third time derivative of the scale factor of the universe, building upon the concepts embodied by the Hubble parameter and the deceleration parameter. Mathematically, it can be expressed as:

$$j = \frac{1}{a}\frac{d^3a}{d\tau^3}\left[\frac{1}{a}\frac{da}{d\tau}\right]^{-3} = q(2q+1) + (1+z)\frac{dq}{dz}, \tag{50}$$

where: j is the jerk parameter, $a(t)$ represents the scale factor of the universe as a function of time, $\dot{a}$ represents the first derivative of the scale factor, ä represents the second derivative of the scale factor, $\dddot{a}$ represents the third derivative of the scale factor, z represents redshift. In the context of the Taylor expansion of the scale factor around a reference time t_0, the expansion takes the form:

$$\frac{a(t)}{a_0} = 1 + H_0(t-t_0) - \frac{1}{2}q_0H_0^2(t-t_0)^2 + \frac{1}{6}j_0H_0^3(t-t_0)^3 + O\left[(t-t_0)^4\right]. \tag{51}$$

where the subscript 0 denotes current values. Here, H_0 represents the Hubble constant at the reference time t_0, q_0 is the deceleration parameter, and j_0 is the jerk parameter at the same reference time. In contemporary cosmology, the jerk parameter has played a crucial role in refining our knowledge of the universe's evolution.

9. Statefinder diagnostic

In the field of cosmology, the study of the universe's evolution, demands a comprehensive understanding of dark energy (DE) and its influence on cosmic expansion. To analyze this cosmic dynamic without bias toward any specific DE model, cosmologists employ a valuable tool known as the statefinder diagnostic parameter. This mathematical tool, pioneered by researchers [136–139], employs higher derivatives of the cosmic scale factor to characterize the universe's expansion. Its primary purpose is to distinguish and compare different DE models effectively. What sets the statefinder diagnostic apart is its model-independent nature, enabling the exploration of various cosmological scenarios,

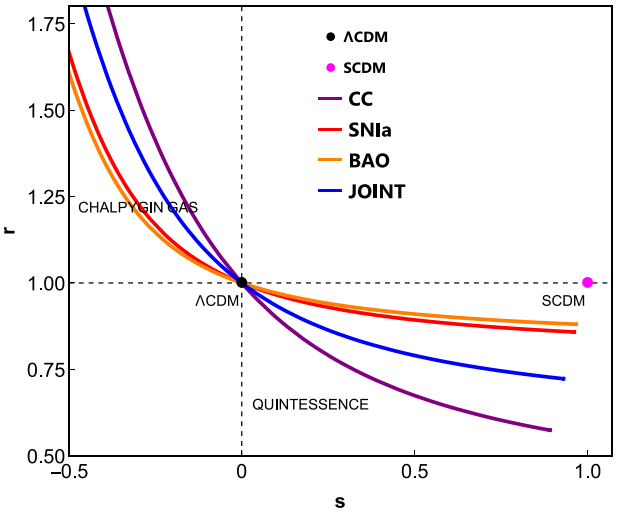

Fig. 11. Evolution of the $\{r, s\}$ profile with respect to redshift across various datasets.

including those with diverse forms of dark energy. The statefinder diagnostic is encapsulated in a parameter pair, denoted as $\{r, s\}$. These parameters are defined as follows:

$$r = \frac{\dddot{a}}{aH^3}, \quad s = \frac{r-1}{3\left(q-\frac{1}{2}\right)}. \tag{52}$$

These parameters leverage higher-order derivatives of the scale factor, the Hubble parameter H, and the deceleration parameter q to provide insights into cosmic expansion. Various possibilities in the $\{r, s\}$ and $\{q, r\}$ planes are exhibited to depict the temporal evolution of various DE models. With the assistance of the statefinder diagnostics pair. In these cases, some specific pairs typically correlate to classic DE models such as $\{r, s\} = \{1, 0\}$ represents ΛCDM model and $\{r, s\} = \{1, 1\}$ indicates standard cold dark matter Model (SCDM) in FLRW background. Also, $(-\infty, \infty)$ yields static Einstein Universe. In the $r-s$ plane, $s > 0$ and $s < 0$ define a quintessence-like model and phantom-like model of the DE, respectively. Moreover, the evolution from phantom to quintessence can be observed by deviation from $r, s = 1, 0$. On the other hand, $\{q, r\} = \{-1, 1\}$ corresponds to the ΛCDM model while $\{q, r\} = \{0.5, 1\}$ shows SCDM model. It is important to note that on a $r-s$ plane if the DE model's trajectories deviate from these standard values, the resulting model differs from the normal cosmic model.

10. Om diagnostic

In the realm of cosmology, the $Om(z)$ diagnostic [140–143] parameter plays a pivotal role in unraveling the cosmic mysteries. It is an essential tool for gauging the relative contribution of matter to the universe's total energy density, shedding light on the universe's overall geometry. ω_m, the heart of this diagnostic, tells us about the ratio of current matter density to the critical density required for a flat universe. If ω_m is less than 1, it hints at an open universe, while a value greater than 1 suggests a closed one. This parameter serves as a geometric yardstick and plays a crucial role in testing the ΛCDM model, which posits three primary components: dark matter, ordinary matter (baryonic), and enigmatic dark energy. One of the remarkable aspects of ω_m is its ability to discern different dark energy models from the standard ΛCDM model. By altering the slope of $Om(z)$, this diagnostic efficiently distinguishes between various models. A positive slope signifies a quintessence model, while a negative slope points to a phantom model. A constant slope, on the other hand, aligns with the cosmological constant. This feature allows us to explore the intricate balance among these cosmic components. Much like the statefinder

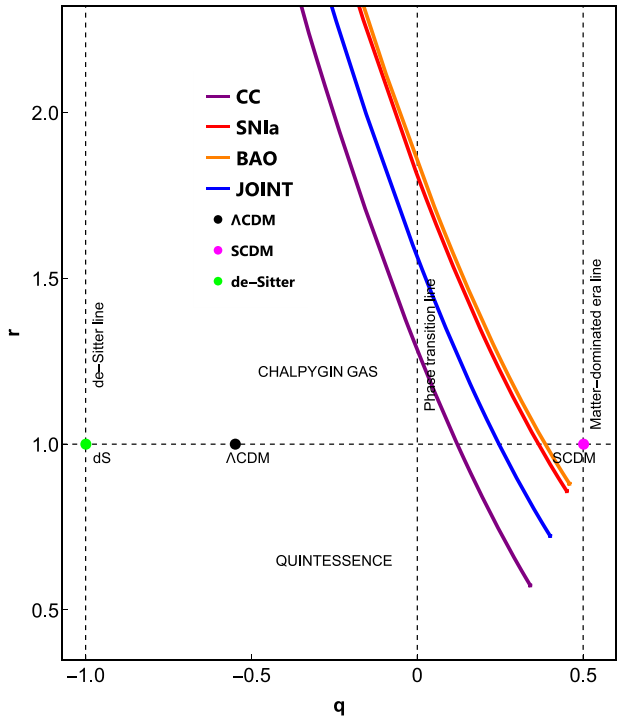

Fig. 12. Evolution of the $\{r, q\}$ profile with respect to redshift across various datasets.

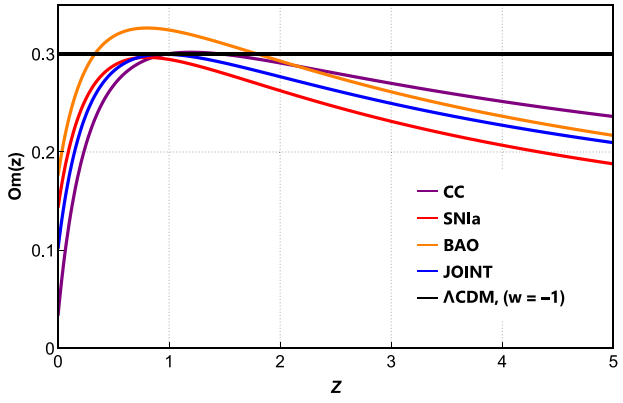

Fig. 13. Evolution of the $Om(z)$ profile with respect to redshift across various datasets.

diagnostic, $Om(z)$ serves as a powerful tool for understanding cosmic evolution, geometry, and the interplay of matter in shaping the universe's dynamics. In a flat universe, $Om(z)$ is defined as:

$$Om(z) = \frac{\left(\frac{H(z)}{H_0}\right)^2 - 1}{(1+z)^3 - 1}. \tag{53}$$

11. Physical parameters

In cosmology, physical parameters such as pressure, equations of state, and the density parameter (denoted as ρ) play crucial roles in describing the behavior and evolution of the universe. Here's a general overview of these concepts along with their associated formulas:

11.1. Pressure density p

Pressure density influences the overall behavior of the universe's expansion. The pressure associated with cosmic components, such as

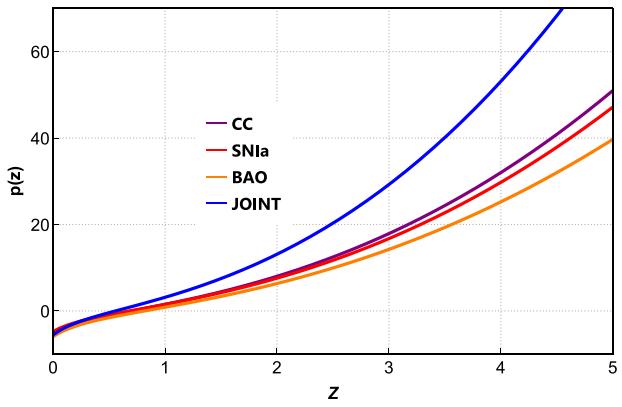

Fig. 14. Evolution of the Pressure density with respect to redshift across various datasets.

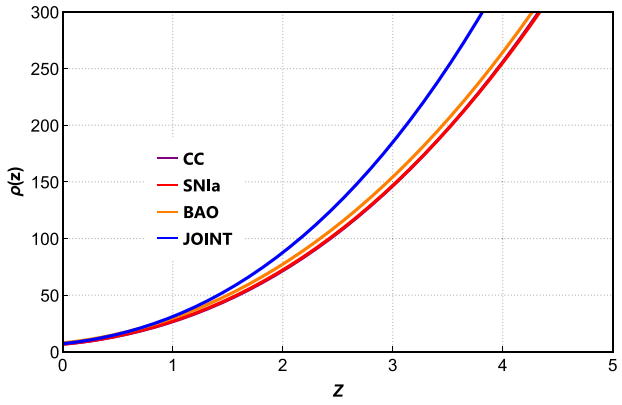

Fig. 15. Evolution of the Energy density with respect to redshift across various datasets.

matter, radiation, and dark energy, affects how they contribute to the expansion rate. Positive pressure (like that of matter) tends to slow down the expansion, while negative pressure (like that of dark energy) can accelerate it. The following Fig. 14 shows the transition from early positive values to the late negative values showing the accelerating expansion of the late universe. It is well described the early positive pressure contributes to the structure formation in the universe.

11.2. Energy density ρ

Energy density refers to the amount of energy contained within a given volume of space. In cosmology, it quantifies the total energy content of a specific cosmic component. Energy density is a crucial parameter as it determines the gravitational effects of that component on the overall cosmic dynamics. From the following Fig. 15, we can interpret the earlier high density universe to the present low values as expected.

11.3. Equation of state ω

The equation of state in cosmology establishes a relationship between the pressure (P) and energy density (ρ) of a cosmic component, effectively describing how pressure and density interrelate. In its general form, this equation is expressed as $P = \omega\rho$, where "(ω)" serves as the parameter characterizing the equation of state. Different values of "(ω)" correspond to distinct cosmic components. For instance, when $w = 0$, it corresponds to non-relativistic matter (e.g., cold dark matter). A value of $\omega = 1/3$ corresponds to radiation (e.g., photons), while $\omega \approx -1$ aligns with dark energy, exhibiting properties akin to a cosmological

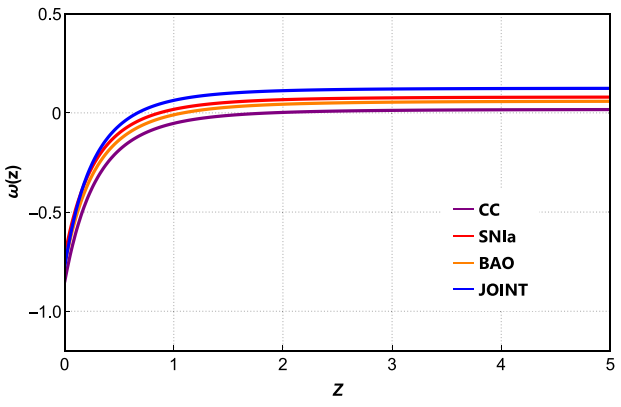

Fig. 16. Evolution of the EoS Parameter with respect to redshift across various datasets.

constant (Λ). These varying values of "(ω)" play a critical role in characterizing the behavior and properties of different cosmic components within the framework of cosmological models. The following Fig. 16 shows the evolution of the equation of state parameter in the due course of time. The universe enters into the quintessence phase in the recent past and remain in this phase in the near future too. The early positive values of ω shows the matter dominated era in the universe.

12. Statistical analysis

To determine the optimal model for our analysis, it is crucial to consider the number of free parameters associated with each model, in addition to the $\chi^2_{\rm min}$ value obtained. While choosing among the various information criteria available in the literature is not a straightforward task [144], we opt for the most commonly used ones. One of these is the Akaike Information Criterion (AIC) [144–146], defined as:

$$AIC \equiv -2\ln\mathcal{L}_{\rm max} + 2p_{\rm tot} = \chi^2_{\rm min} + 2p_{\rm tot} \tag{54}$$

Here, $p_{\rm tot}$ represents the total number of free parameters in the specific model, and $\mathcal{L}_{\rm max}$ signifies the maximum likelihood of the model being considered. Additionally, we incorporate the Bayesian Information Criterion (BIC), introduced by [144–146], which is defined as:

$$BIC \equiv -2\ln\mathcal{L}_{\rm max} + p_{\rm tot}\ln\left(N_{\rm tot}\right) \tag{55}$$

By utilizing the definitions (54) and (55), we compute the discrepancies $\triangle AIC$ and $\triangle BIC$ relative to the ΛCDM model in question. In accordance with [147], if $0 < |\triangle AIC| \leq 2$, it implies that the compared models may be viewed as compatible with each other. Conversely, if $|\triangle AIC| \geq 4$, it indicates that the model with the higher AIC value is not supported by the data. Similarly, for $0 < |\triangle BIC| \leq 2$, the model exhibiting the higher BIC value is marginally less favored by the data. In cases where $2 < |\Delta BIC| \leq 6$ ($|\triangle BIC| > 6$), the model with the higher BIC values is significantly (highly) less favored. The specific distinctions among the investigated cosmological models are detailed in 2.

In cosmology, the terms "P-value" and "L-statistic" are commonly used in statistical analyses to assess the significance of observations and test hypotheses.

- P-value (Probability Value) The P-value is a statistical measure that quantifies the evidence against a null hypothesis. It tells you the probability of observing data as extreme or more extreme than what you have, assuming that the null hypothesis is true. In cosmology, P-values are often used in the context of hypothesis testing [148–150]. For example, when analyzing cosmic microwave background (CMB) data, cosmologists may calculate P-values to assess whether the observed CMB power spectrum matches the predictions of a particular cosmological model. A low P-value suggests that the data is inconsistent with the model,

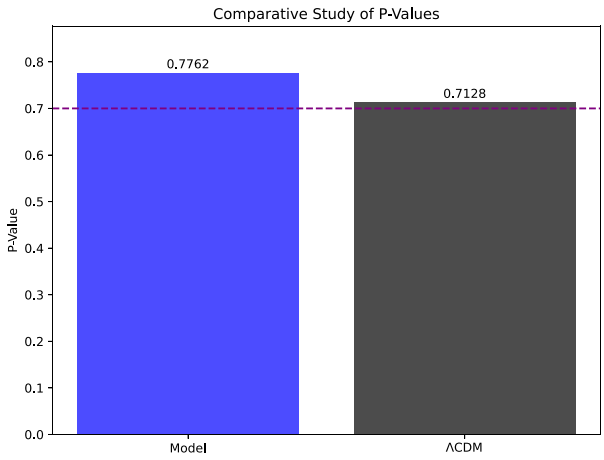

Fig. 17. The Comparative Study of P-Values of joint dataset.

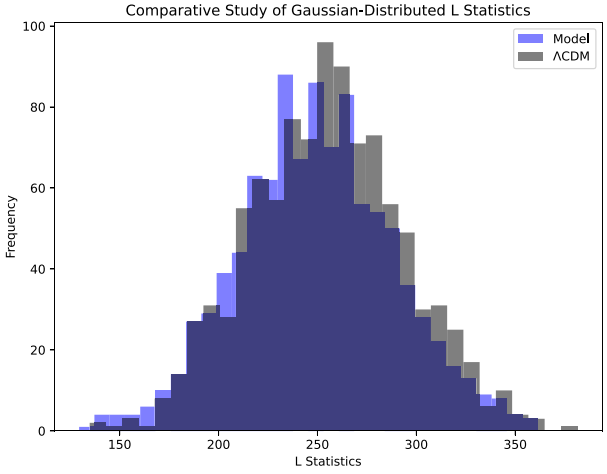

Fig. 18. The comparative histogram plot of the distribution of L statistics for both models of joint dataset.

while a high P-value suggests that the data is consistent with the model.

- L-statistic (Likelihood Statistic) The L-statistic, often referred to as the likelihood ratio [151–153], is a statistical measure used to compare the likelihood of observing data under two different hypotheses. In cosmology, the L-statistic is frequently used when comparing different cosmological models or parameter values. For instance, in Bayesian cosmological analyses, the likelihood function quantifies how well a given model explains the observed data. The L-statistic is used to compare the likelihoods of different models, and models with higher likelihoods are considered more compatible with the data.

In practical terms, when cosmologists perform statistical analyses in cosmology, they often calculate likelihoods and P-values to evaluate the goodness of fit between observational data and theoretical models. These statistical tools help cosmologists make inferences about the parameters of the universe, such as the density of dark matter, dark energy properties, and the geometry of the universe (see Fig. 17).

13. Results

13.1. Deceleration parameter

Fig. 9 represents the redshift evolution of the deceleration parameter (q) across various cosmological epochs, denoted by the redshift (z),

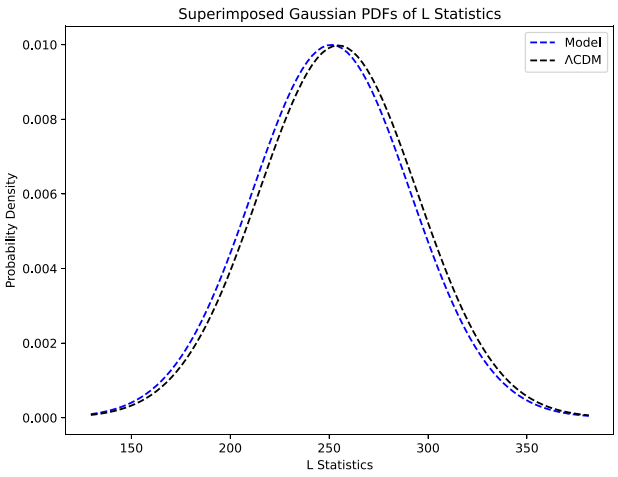

Fig. 19. The superimposed overlays of Gaussian Probability Density Functions (PDFs) on the L statistics for both models of joint dataset.

as constrained by different datasets, including Cosmic Chronometers (CC), Type Ia Supernovae (SNIa), Baryon Acoustic Oscillations (BAO), and a Joint Dataset encompassing CC + SNIa + Gamma-Ray Bursts (GRB) + Quasars (Q) + BAO and ΛCD paradigm. At high redshifts, corresponding to earlier epochs in the universe's history, the model exhibits a noteworthy convergence toward a consistent value of q across all analyzed datasets, specifically around 0.2763. As the universe evolves and redshift decreases, it undergoes a phase transition from a decelerating phase to an accelerating one. Nonetheless, the long-term behavior of the two models starkly diverges. An intriguing and noteworthy observation is that the model predicts an acceleration at half-time higher than the ΛCDM model with an approximate value of $q(0) \approx -1$, whereas the ΛCDM model predicts a value of approximately $q(0) \approx -0.5$. This deceleration parameter maintains consistency across all the datasets employed in our comprehensive analysis.

13.2. Jerk parameter

Fig. 10 illustrates the redshift-dependent behavior of the jerk parameter across the various datasets. At high redshifts, the value of j in the proposed model is across all datasets and the ΛCDM model consistently converges to approximately 1. However, important differences do exist at lower redshifts, with a very significant difference appearing at $z = 0$, where the proposed model predicts a value higher than the ΛCDM value of $j = 1$ across all datasets. Determining the current value of j through observations can be a crucial test for the proposed model cosmological model.

13.3. $\{r, s\}$ profile

The $\{r, s\}$ profile of our obtained cosmological model, as depicted in Fig. 11, reveals a fascinating cosmological evolution. At the initial stages, the model exhibits values in the range $r < 1$ and $s > 0$, which correspond to characteristics akin to the quintessence region In cosmology, quintessence is a dynamic form of dark energy with a varying energy density and negative pressure, potentially explaining the universe's accelerated expansion. Further by crossing intermediate ΛCDM fixed point $\{0, 1\}$, it transitions into a different region where $r > 1$ and $s < 0$, represent Chaplygin gas. Chaplygin gas is a cosmological model featuring exotic matter with unique properties, used to explain cosmic expansion. Remarkably, this $\{r, s\}$ profile consistently exhibits the same behavior with respect to all the datasets used in our analysis.

Table 2
Summary of $\chi^{2\ min}_{tot}$, χ^2_{red}, AIC_c, ΔAIC_c, **BIC**, Δ**BIC**, P-value and L-statistic for ΛCDM and $f(Q,T)$ model across all dataset.

Model	Dataset	$\chi^{2\ min}_{tot}$	χ^2_{red}	$\mathcal{K}_f$	AIC_c	ΔAIC_c	BIC	ΔBIC	P-value	L-statistic
ΛCDM Model	CC	15.5126	0.9053	3	21.5126	0	25.8146	0	0.560256	26.140535
	SNIa	1036.50	0.9356	3	1042.51	0	1057.43	0	0.989391	203.623840
	BAO	26.4431	0.9182	3	32.4431	0	34.9427	0	0.550075	10.811795
	Joint	1107.35	0.9645	3	1113.35	0	1128.83	0	0.712755	254.538726
Model	CC	15.6871	0.8953	3	21.6871	0.17	25.9891	0.17	0.554023	26.140535
	SNIa	1033.91	0.9298	3	1039.91	−2.59	1054.84	−2.29	0.991874	203.635102
	BAO	27.3445	0.9177	3	33.3445	0.90	35.8441	0.90	0.664331	9.446289
	Joint	1108.32	0.9634	3	1114.32	0.97	1129.80	0.97	0.776201	251.087532

13.4. $\{r, q\}$ profile

The $\{r, q\}$ profile of our derived cosmological model, as shown in Fig. 12, reveals a fascinating evolution. Initially, the model exhibits values within the region $q > 0$ and $r < 1$, which resembles characteristics commonly linked with the quintessence. As the Universe evolves, a distinctive transition occurs, leading the model into a different region characterized by $q < 0$ and $r > 1$, represented by the Chaplygin gas scenario. Notably, this $\{r, q\}$ profile consistently demonstrates the same behavior across all the datasets integrated into our analysis.

13.5. Om diagnostic

Fig. 13 illustrates the evolution of $Om(z)$ at various redshifts (z) for our model across different datasets. Notably, for the CC, SNIa, and Joint datasets, $Om(z)$ consistently remains below the current matter density parameter Ω_{m0}. This observation suggests that the model consistently resides in the phantom region throughout the entire evolution of the Universe at all redshifts. On the other hand, for the BAO dataset, $Om(z)$ consistently remains below the current matter density parameter for redshifts $z > 1.8$. This suggests that the model falls within the phantom domain. As the Universe evolves, $Om(z)$ transitions to being higher than the current matter density parameter in the redshift range of $0.34 > z > 1.8$, indicating that the model enters the quintessence domain. Finally, $Om(z)$ decreases below the current matter density parameter for redshifts $z < 0.34$, signifying that the model reverts to the phantom domain.

13.6. Physical parameters

Figs. 14, 15, and 16 provide the necessary illustration into the dynamic evolution of physical parameters, pressure (p), energy density (ρ), and the equation of state parameter (ω) at different redshifts. These figures meticulously portray how these parameters change as a function of redshift, with each curve representing a distinct set of model parameters derived from diverse datasets. The beauty of these plots lies in their ability to unveil the intricate phases of evolution exhibited by these physical parameters at different points in cosmic history. In particular, Fig. 14 unveils the transition in the pressure parameter: it shifts from being positive in the early universe to becoming increasingly negative as time progresses, hinting at the onset of late-time cosmic acceleration. However, what truly sets this observation apart from conventional cosmological models like the ΛCDM model is the intriguing revelation that the pressure does not just remain negative. Meanwhile, Fig. 15 charts the path of energy density (ρ), illustrating how it initially diminishes from its higher values in the past to its present, smaller magnitude. Fig. 16 provides a glimpse into the cosmic temperament of the Universe through the equation of state parameter. For the region $z > 1$, the model's ω falls within $0 < w < \frac{1}{3}$, aligning with the behavior expected in the Matter-dominated era, where pressure is negligible compared to energy density. As the Universe evolves and enters the epoch $z < 1$, the ω value shifts into the range $-1 < w < -\frac{1}{3}$. This shift signifies a transition to a quintessence field domain, suggesting the presence of a dynamic form of dark energy with negative pressure, contributing to the observed cosmic acceleration. We can witness the matter dominated era in the early universe to the late dark energy-dominated era in the quintessence realm.

13.7. Statistical analysis

Based on the Table 2 furnishes a detailed comparison between the $f(Q,T)$ model and the standard ΛCDM model based on various statistical indicators. Starting with $\chi^{2\ min}_{tot}$, which represents the minimum total chi-square, the $f(Q,T)$ model yields slightly higher values across all datasets compared to the ΛCDM model. This suggests that, when attempting to minimize the discrepancies between the model and observational data, ΛCDM achieves a marginally better fit. The reduced chi-square (χ^2_{red}) accounts for the number of degrees of freedom, providing a more normalized measure. Here, too, the $f(Q,T)$ model exhibits slightly higher values, indicating that ΛCDM offers a slightly improved fit when considering the complexity of the models. Moving on to information criteria, ΔAIC_c and ΔBIC are crucial for model comparison. In both metrics, positive values for the $f(Q,T)$ model signify a weaker degree of support compared to ΛCDM. Typically, ΔAIC values in the range of $(0, 2)$ suggest strong support, while values in $(4, 7)$ are less supported. Values beyond 10 indicate models without any meaningful support. Therefore, the positive ΔAIC_c values for the $f(Q,T)$ model suggest that, in terms of information criteria, ΛCDM is more strongly supported. Considering P-values and L-statistic, which provide insights into the overall goodness of fit, the $f(Q,T)$ model generally yields higher P-values and lower L-statistic values compared to ΛCDM. This implies that the $f(Q,T)$ model has a comparatively poorer fit to the observational data. Fig. 18 provides the comparative histogram distribution of L statistics for ΛCDM model and our Model. The x-axis represents the L statistics values, while the y-axis represents the frequency or count of data points within each bin. You can observe how the L statistics are distributed for both models. Look for differences in the central tendencies (peaks) and spreads (widths) of the distributions. Since our model's histogram is similar to the ΛCDM histogram, it suggests that our model is a reasonable fit for the data, Fig. 19 provides the superimposed plot overlays Gaussian Probability Density Functions (PDFs) on the L statistics for both models. The x-axis represents the L statistics values, and the y-axis represents the probability density. Again the Gaussian PDF of our model is closely aligned with the histogram of L statistics, it suggests a better match between the ΛCDM model and the data.

14. Conclusion

In this study, we conducted a comprehensive and rigorous examination of the $f(Q,T)$ cosmological model. We extend the analysis conducted in classical gravity by incorporating a parametrization of the deceleration parameter, as outlined in [42]. Our investigation encompasses the realm of $f(Q,T)$ gravity, allowing us to explore its implications and effects on the parametrization. This model was compared against a range of cosmological observations, encompassing 31 Cosmic Chronometers, 1071 type Ia supernovae measurements, 162 Gamma Ray Bursts (GRBs), 24 measurements from compact radio quasars, 17 Baryon Acoustic Oscillation (BAO) measurements, and CMB distant prior. To determine the best-fit value for the model parameters, we employed the Markov Chain Monte Carlo (MCMC) methodology, allowing us to derive the optimal fit for these parameters. Subsequently, utilizing these best-fit values, the data-fitting process yielded

exceptionally accurate outcomes for both the CC and SNIa datasets. We observed the redshift evolution of the deceleration parameter (q) across different cosmological epochs using various datasets, the model exhibits a consistent convergence toward a value of approximately 0.2763 at high redshifts, indicative of the early universe's behavior. As the universe evolves and redshift decreases, a transition from a decelerating to an accelerating phase occurs. Notably, the proposed model predicts an acceleration at a rate higher than the ΛCDM model, with an approximate value of $q(0) \approx -1$, while the ΛCDM model predicts a value of approximately $q(0) \approx -0.5$. Recent studies have provided varied estimates for the present-day deceleration parameter ($q(0)$), deviating from the standard ΛCDM model. In the cited research [154], the authors found that the value of $q(0)$ is approximately 0.05641. Similarly, in the study [77], a different estimate of $q(0) \approx 0.84331$ was derived. In the referenced research [155], $q(0) \approx -0.73$. In the study [156], the authors obtained $q(0) \approx -0.34$. In the investigation by Xu et al. [157], three models were introduced, each suggesting distinct values. In Model 1, $q(0) \approx -0.657$, in Model 2, $q(0) \approx -0.982$, and in Model 3, $q(0) \approx -0.410$. These non-standard values indicate a departure from the expected ΛCDM prediction and emphasize the growing recognition of variations in the cosmological dynamics, prompting further investigation into alternative models and theoretical frameworks. This divergence is maintained consistently across all datasets utilized in our comprehensive analysis. Moving to the jerk parameter, at high redshifts, both the proposed model and the ΛCDM model converge to a value of approximately 1 across all datasets. However, significant differences emerge at lower redshifts, particularly at $z = 0$, where the proposed model consistently predicts a higher value for j compared to the ΛCDM value of $j = 1$ across all datasets. The determination of the current value of j through observations emerges as a crucial test for validating the proposed cosmological model. This presents a crucial test for the proposed model. The analysis of the $\{r, s\}$ profile revealed a fascinating cosmological evolution. Our model exhibited characteristics resembling quintessence and Chaplygin gas phases, maintaining consistency across all datasets. The $\{r, q\}$ profile depicted a dynamic evolution, transitioning from quintessence-like behavior to a Chaplygin gas scenario. This behavior remained consistent across all datasets. The $Om(z)$ analysis indicated that our model consistently positions $Om(z)$ below Ω_{m0} for CC, SNIa, and Joint datasets, indicating a sustained presence in the phantom region. The observed transition in the BAO dataset from the phantom to quintessence domains introduces complexity to the model's dynamic evolution. The analysis of pressure (p), energy density (ρ), and the equation of state parameter (ω) across varying redshifts reveals deviations from standard cosmological models like the ΛCDM model. The EoS reveals a nuanced cosmic temperament, shifting from matter domination to quintessence, offering a unique perspective distinct from conventional models. The comparative analysis between our proposed model and the ΛCDM Model across various statistical metrics, including chi-square values, information criteria, and goodness-of-fit indicators, the results consistently favor the ΛCDM model over the $f(Q,T)$ model. The statistical analyses collectively suggest that ΛCDM provides a slightly better balance between goodness of fit and model. In conclusion, while our proposed model provides intriguing insights and predicts unique cosmic behaviors, such as super acceleration, the standard ΛCDM Model remains favored by statistical criteria. The differences observed in various cosmological parameters and profiles underscore the complexity of cosmological models and the need for ongoing research to refine our understanding of the universe's evolution. Further observations and refined datasets may shed more light on these intriguing cosmological phenomena.

In research and practice of Data Envelopment Analysis (DEA), the arithmetic average is commonly used to aggregate cross-efficiency scores. For this, each decision-making unit (DMU) contributes an equal weight, and many essential decision-making details are lost in the final aggregated cross-efficiency. We propose a novel application of the ordered visibility graph averaging (OVGA) operator for DEA cross-efficiency aggregation and apply the proposed method to study the portfolio selection problem. When solving this problem, several practical concerns, such as a budget, cardinality, buy-in requirements, and restrictions against short selling are also considered. The proposed OVGA aggregated cross-efficiency approach is explained through a numerical example, followed by the formulation of optimal portfolios based on these cross-efficiencies. The suggested method is also tested using empirical data from the Indian banking industry. The results of this study can be used to create the most acceptable portfolio in stock companies, financial institutions, and businesses in the public and private sectors.

Keywords: Data Envelopment Analysis; Decision Making Units; Aggregation method; Portfolio Optimization

1. Introduction

Portfolio selection refers to an investorâĂŹs decision to diversify their financial assets to reduce investment risk while maintaining a specific level of projected return. Portfolio selection offers guidance to an investor for allocating resources among various investment opportunities. The major breakthrough in

the field came in 1952 when Harry Markowitz published his modern portfolio theory commonly known as mean-variance portfolio theory. Markowitz (1952) mean-variance portfolio selection model is based on the trade-off between risk and return under various economic conditions. To alleviate the limitations of the mean-variance framework, various alternative risk measures have been proposed in the literature. Although variance is widely accepted as a risk measure, it has limitations. Semi-variance is another risk measure, originally introduced by Markowitz (1959), and used in the mean-semi-variance portfolio selection model in Guo and Ching (2021).

Data envelopment analysis (DEA) is a non-parametric empirical approach for evaluating the relative efficiency of decision-making units (DMUs) in the presence of multiple inputs and multiple outputs. DEA model was first introduced by Farrell (1957), and then further developed by Charnes et al. (1978) (called CCR model) and Banker et al. (1984) (called BCC model). Due to the lack of translation invariance, the CCR and BCC models cannot handle the negative data values in inputs and outputs unless the data gets transformed into positive values. The directional distance function (DDF) based DEA models have been described in the literature to handle the non-positive data values without converting them into positive ones.

One of the applications of DEA in finance is portfolio selection. Few articles in the literature have studied the problem of portfolio selection using DEA. Chen (2008) presented an application of DEA in portfolio selection. Dia (2009) introduced a four-step methodology based on DEA for portfolio selection. Chen et al. (2018) constituted fuzzy portfolio assessment models based on DEA using various risk indicators to address the uncertainty involved in the financial market. Zhou et al. (2018) offered a DEA frontier improvement technique as a rebalancing strategy for investors. Gupta et al. (2020) introduced credibilitic fuzzy portfolio selection models based on DEA. Zhu and Zhu (2023) pioneered the concept of eco-efficiency of industrial investment (EEII) in terms of energy consumption, economic benefits, and environmental impact by using a slack-based DEA model. Omid et al. (2023) introduced a two-stage multiobjective optimization problem incorporating network data envelopment analysis. Soltanifar et al. (2023) developed DEA-R models for merger analysis that can deal with negative data and apply it to the Iranian banking sector. Ghiyasi and Zhu (2020) proposed an inverse semi-oriented DEA model to assess the efficiency of Chinese commercial banks following the global financial crisis, when negative outputs were present. Amirteimoori et al. (2022) developed the chance-constrained multistage DEA model for the relative performances of supply chains. Emrouznejad et al. (2023) recently presented a review of the eco-efficiency evaluation using DEA. Recently, Lim et al. (2014) introduced a novel way of portfolio selection using the DEA cross-efficiency. They consider Markowitz's mean-variance optimization model, which identifies a portfolio consisting of DMUs with minimum variation in their cross-efficiency scores and having a desirable expected mean efficiency.

Conventional DEA approaches permit each DMU to assess its efficiency using the most favorable weights, which might lead to exaggerated weight schemes. One of the most prominent ways of dealing with limited discriminative power is the cross-efficiency assessment, which presented citesexton1986data as an expansion of DEA and further improved by Doyle and Green (1994). These authors initiated aggressive and benevolent strategies as secondary objectives to resolve the problem of nonunique optimum weights in DEA. Davtalab-Olyaie and Asgharian (2021) discussed the problem of a non-Pareto optimum solution in CE evaluation. They proposed a multiobjective program to obtain a set of Pareto-optimal CE scores. Chen et al. (2020a) highlighted the problem of non-uniqueness in CE assessments and developed a meta-frontier analysis framework to develop a novel CE assessment method. The approach presented in the paper Oukil and Amin (2015) derives the importance of each DMU from a common consensus among all DMUs, which is then reflected via a preference voting matrix. Because self and peer evaluation scores represent DMU's mutual appreciation for one another,

UNCORRECTED MANUSCRIPT

Downloaded from https://academic.oup.com/imaman/advance-article/doi/10.1093/imaman/dpae012/7671391 by Delhi Technological University user on 22 May 2024

the CE matrix is viewed as an election framework in which each DMU is both a candidate and a voter. Oukil (2020) introduced a new method based on collective weight profile (CWP) for each DMU by utilizing the preference voting system embedded within the weight matrix, which views the assessing DMUs as voters and the input/output factors as candidates. For a more detailed study of cross-efficiency innovations, limitations, and extensions, see Wu et al. (2021).

DEA cross-efficiency is helpful for portfolio selection problems since it removes the disadvantage of shifting weights in traditional DEA models. To achieve the maximum efficiency value, the DMU can give some inputs and outputs exceptionally high weights. As a result, portfolio selection that uses the traditional DEA technique is not recommended. To resolve this issue, Lim et al. (2014) proposed an MV-DEA portfolio selection method that selects a portfolio of DMUs with the least volatility in their CE scores that meets a specified anticipated return. Mashayekhi and Omrani (2016) applied the suggested MV-DEA cross-efficiency portfolio selection by assuming fuzzy returns. Recently, Amin and Hajjami (2021) examined the effect of the alternative optimal solution in portfolio selection and indicated that significant improvement in portfolio selection is obtained when alternate optimum solutions are used to obtain a cross-efficiency matrix (CEM). Chen et al. (2021) describes a portfolio selection method using fuzzy DEA cross-efficiency assessment, which considers undesirable ambiguous inputs and outputs. Deng and Fang (2019) developed a novel mean-variance-maverick DEA cross-efficiency approach based on the prospect of selecting a fuzzy portfolio. Gong et al. (2021) presented a method based on regret theory, in which they applied a fuzzy multiobjective portfolio optimization model with four objectives, namely, mean, variance, skewness, and efficiency, bounded by several realistic constraints. Essid et al. (2018) offered an innovative framework for portfolio optimization that combines the Maverick index with a DEA game cross-efficiency model.

Mehlawat et al. (2018) looked at the portfolio selection issue by adding additional facts about the non-normality of asset returns using skewness and kurtosis. The efficiency evaluation is also a critical factor to consider in the portfolio selection problem.

One of the drawbacks of the DEA cross-efficiency approach in portfolio selection is that all DMUs/stocks in the optimal portfolio are given identical weights. Amin and Hajjami (2021) suggested the development of a novel DEA cross-efficiency portfolio selection model to obtain more reasonable weights for DMUs/stocks. Although many scholars have realized the importance of aggregation methods for cross-efficiency assessment, there is still room for improvement in the existing aggregation methods and their applications in portfolio optimization problems. This paper uses the ordered visibility graph averaging (OVGA) operator to develop a cross-efficiency aggregation technique to analyze the units more thoroughly. The weights in the OVGA operator are determined by the relevance of the data in the obtained visibility graph Jiang et al. (2016). The OVGA operator is vital in aggregating CE scores since it allows values to be given varied weights depending on the importance of CE scores of different DMUs.

1.1. *Literature review*

The cross-efficiency technique, an extended form of DEA, considers both self and peer appraisal, resulting in a unique ranking of DMUs and removing the problem of artificial weight selections. Most cross-efficiency studies emphasize the cross-evaluation technique, and the arithmetic average is frequently used as a CE aggregation method in the existing research. The arithmetic average technique has certain drawbacks. First, self-evaluated efficiency does not play a sufficient role in the efficiency

UNCORRECTED MANUSCRIPT

Downloaded from https://academic.oup.com/imaman/advance-article/doi/10.1093/imaman/dpae012/7671391 by Delhi Technological University user on 22 May 2024

aggregation procedure, as each DMU has only one self-evaluated efficiency value with multiple peer-evaluated efficiency values. Second, there is no other methodology to consider the decision-maker's subjective preferences, as the arithmetic average approach provides equal weight to each efficiency score (Oukil (2019), Wang and Chin (2011)). To remedy these issues, Song et al. (2017), and Li et al. (2018) devised aggregation methods that are motivated by the Shannon entropy weight and balanced adjustment weights, respectively, which provide both a solution for the inadequacies of the average arithmetic technique and an acceptable theoretical justification for CE aggregation. Wang and Chin (2011) introduced the OWA (ordered weighted averaging) operator weight to cross-efficiency aggregation. Using weights based on the OWA operator for CE aggregation permits the decision-maker's optimism level toward the best relative efficiencies. Liu and Chen (2022) pointed out that different efficiency scores affect integration outcomes differently. The relative importance of each efficiency value is not considered in an average aggregation of cross-efficiency. Liu and Chen (2022) first applied regret theory to the CE aggregation process to understand the regret aversion behavior of DMs, which plays a crucial role in the decision-making process. To determine the regret-based aggressive and benign cross-efficiency, weight matrices are built into their study. Wu et al. (2012) suggested a common weight technique to aggregate the cross-efficiency by considering DMUs as players in a cooperative game sense and calculating their Shapley values to address these limitations. Chen et al. (2020b) developed prospect theory to represent DMs' subjective preferences in their innovative technique to aggregate CE scores based on the prospect-consensus procedure. Li et al. (2022) outlined a novel strategy for generating aggregation weights from subjective and objective viewpoints. To reflect DM preferences from a subjective standpoint, the authors established prospect theory. Their method offers reference points as intervals that can be chosen based on the DMs' decision aims and preferences. Chen et al. (2020b) introduced a novel method based on prospect consensus (APC) theory for CE aggregation. The APC method keeps as much of the cross-efficiency matrix's decision-making information as feasible and then aggregates the cross-efficiency that suits decision-making demands. Combining cumulative prospect theory, Fang and Yang (2019) proposed an ordering method for interval CE aggregation.

All the studies mentioned above have different methodologies, indicators, and characteristics, requiring deep knowledge to understand the various procedures. Additionally, the above-discussed methods require many parameters in the calculation process that can be very tedious in handling large-scale data.

1.2. *Research motivation and novelty of the proposed approach*

Although several research studies have addressed DEA cross-efficiency aggregation under various frameworks, to the best of our knowledge, there is still some room for a new aggregation method that requires only the data of the cross-efficiency matrix, we will still be able to evaluate the aggregated CE scores efficiently. Also, we find fewer studies in the literature where DEA cross-efficiency has been applied to portfolio optimization problems. The proposed study makes the following contributions:

1. Compared to the aggregated method existing in the literature (León et al. (2014), Oukil (2019), Wang and Chin (2011)), our proposed OVGA method aggregates the cross-efficiencies with unique weights and provides weightage according to the importance of the data value, while the weights depend upon different characteristics such as DMs' optimism level and orness degree value, which is uncertain; furthermore, different orness degrees provide different sets of weights, as seen in Wang and Chin (2011) and León et al. (2014).

2. Compared with different aggregating operators, the OVGA operator, fully considers the information of orders and the correlation between the values. The main advantage of OVGA is that it is

UNCORRECTED MANUSCRIPT

Downloaded from https://academic.oup.com/imaman/advance-article/doi/10.1093/imaman/dpae012/7671391 by Delhi Technological University user on 22 May 2024

completely data-driven, and the aggregated results can be produced from a series of original values.
3. We develop a new application of OVGA compared to that seen in Jiang et al. (2016, 2017) and Wang et al. (2022) in regard to DEA cross-efficiency aggregation.
4. Furthermore, compared to Deng and Fang (2019), Lim et al. (2014) and Essid et al. (2018), we integrate the MV-DEA cross-efficiency model with OVGA cross-efficiency scores and deal with the existence of an alternate optimal solution in CE for portfolio optimization problems.

1.3. *Organization of the paper*

The remainder of this paper is structured as follows. Section 2 is separated into two subsections, its subsequent subsections review the fundamental concepts of the DEA models and OVGA operator. Section 3 first presents the terminology of the OVGA operator for cross-efficiency aggregation, and then introduces the portfolio performance evaluation model. In Section 4, a numerical data set from the literature is used to demonstrate the applicability of the proposed model. Further, a case study of the Indian banking sector is taken care-off and the Managerial implications given the proposed model are also discussed here. Some concluding remarks are furnished in Section 5.

2. Preliminaries

This section presents the DEA models existing in the literature, used to investigate the efficiency and cross-efficiency of a DMU. Further, the ordered visibility graph weighted averaging (OVGWA) operator, developed by Wang et al. (2015), is also presented here. For basic definitions and notations regarding DEA models and OVGA operator, we may refer to Charnes et al. (1978) and Wang et al. (2015) respectively.

2.1. *DEA models for efficiency evaluation*

Suppose we have n *DMUs* to be evaluated with m inputs and s outputs. Let j^{th} DMU, DMU_j, $j = 1,2,\ldots,n$ uses x_{ij}, $i = 1,2,\ldots,m$ inputs and produce y_{rj}, $r = 1,2,\ldots,s$ outputs. Let DMU_k, $k = 1,2,\ldots,n$ be the DMU that is under evaluation. Let ω_{ik} $i = 1,2,\ldots,m$ and μ_{rk} $r = 1,2,\ldots,s$ be the weight given by the DMU_k, $k = 1,2,\ldots,n$ to the ith input and r^{th} outputs, respectively. The best relative self-efficiency $e^{\star}_{kk}$, under the assumption of constant return to scale, can be determined by using the following input-oriented CCR model (Charnes et al. (1978)).

Model I

$$\max e_{kk} = \sum_{r=1}^{s} \mu_{rk} y_{rk}$$

subject to,

$$\sum_{i=1}^{m} x_{ik}\omega_{ik} = 1,$$

$$\sum_{r=1}^{s} \mu_{rk} y_{rj} - \sum_{i=1}^{m} \omega_{ik} x_{ij} \leq 0, \qquad j = 1,2...n,$$

$$\omega_{ik} \geq 0,\ \mu_{rk} \geq 0, \qquad i = 1,2,\ldots,m,\ r = 1,2,\ldots,s.$$

Let $\mu^{\star}_{rk}$ $r = 1,2,\ldots,s$ and $\omega^{\star}_{ik}$ $i = 1,2,\ldots,m$ be the optimal solution of Model I, then $e^{\star}_{kk} = \sum_{r=1}^{s} \mu^{\star}_{rk} y_{rk}$ is the optimal efficiency that DMU_k can attain, which is also referred to the CCR-efficiency of DMU_k under self-evaluation. If $e^{\star}_{kk} = 1$ and all the optimal weights $\mu^{\star}_{rk}$ $r = 1,2,\ldots,s$

UNCORRECTED MANUSCRIPT

Downloaded from https://academic.oup.com/imaman/advance-article/doi/10.1093/imaman/dpae012/7671391 by Delhi Technological University user on 22 May 2024

and $\omega_{ik}^{\star}\ i=1,2,\ldots,m$ are positive, then DMU_k is CCR-efficient, otherwise, it is CCR-inefficient.

The DEA cross-efficiency assessment approach uses peer review in place of sole self-evaluation to assess efficiency. Thus, the peer evaluation of $DMU_j,\ j=1,2,\ldots,n$ by the DMU_k is defined as follows:

$$e_{kj}=\frac{\sum_{r=1}^{s}\mu_{rk}^{\star}y_{rj}}{\sum_{i=1}^{m}\omega_{ik}^{\star}x_{ij}},\quad (k=1,2,\ldots,n). \tag{2.1}$$

It should be noted that the optimal weights derived from model I are rarely unique. As a result, the cross-efficiency score defined in (2.1) will not produce a unique set of cross-efficiency values. To deal with this issue Oral et al. (2015) introduced the maximum resonated appreciative model, which was further discussed in Amin and Hajjami (2021) and Amin and Oukil (2019). In Oral et al. (2015), authors have shown that the cross-efficiency score of any DMU_j with respect to any $DMU_k,\ k=1,2,\ldots,n$ can take any value between the interval. So the minimum and the maximum cross-efficiency score of DMU_j, evaluated by $DMU_k,\ k=1,2,\ldots,n$ can be computed by those optimal weights for which the self-efficiency score value will remain unchanged. They presented the following two formulations Models II and Model III, to determine the cross-efficiency interval of DMU_j evaluated by $DMU_k,\ k=1,2,\ldots,n$.

Model II

$$\begin{aligned}
\min\quad & \hat{e}_{kj}^{L}=\sum_{r=1}^{s}\mu_{rk}y_{rj}\\
\text{subject to,}\quad & \\
& \sum_{i=1}^{m}\omega_{ik}x_{ij}=1\\
& \sum_{r=1}^{s}\mu_{rk}y_{rj}-\sum_{i=1}^{m}\omega_{ik}x_{ij}\le 0,\quad j=1,2...n,\ j\neq k\\
& \sum_{r=1}^{s}\mu_{rk}y_{rk}-e_{kk}^{\star}\sum_{i=1}^{m}\omega_{ik}x_{ik}=0,\\
& \mu_{rk},\omega_{ik}\ge 0,\qquad r=1,2,\ldots,s;\ i=1,2,\ldots,m,
\end{aligned}$$

Let $\mu_{rk}^{\star}\ r=1,2,\ldots,s$ and $\omega_{ik}^{\star}\ i=1,2,\ldots,m$ be the optimal solutions of Model II, then $\hat{e}_{kj}^{L}=\sum_{r=1}^{s}\mu_{rk}^{\star}y_{rj}$ is the optimal efficiency that DMU_j can attain when evaluated by DMU_k. We can find out the Min cross-efficiency matrix for n $DMUs$ corresponding to Model II. The n efficiency values constitute a cross-efficiency matrix, as shown in Table 1.

UNCORRECTED MANUSCRIPT

Downloaded from https://academic.oup.com/imaman/advance-article/doi/10.1093/imaman/dpae012/7671391 by Delhi Technological University user on 22 May 2024

Model III

$$\max \quad \hat{e}^U_{kj} = \sum_{r=1}^{s} \mu_{rk} y_{rj}$$

subject to,

$$\sum_{i=1}^{m} \omega_{ik} x_{ij} = 1$$

$$\sum_{r=1}^{s} \mu_{rk} y_{rj} - \sum_{i=1}^{m} \omega_{ik} x_{ij} \leq 0, \quad j = 1,2...n,\ j \neq k$$

$$\sum_{r=1}^{s} \mu_{rk} y_{rk} - e^{\star}_{kk} \sum_{i=1}^{m} \omega_{ik} x_{ik} = 0,$$

$$\mu_{rk}, \omega_{ik} \geq 0, \qquad r = 1,2,\ldots,s;\ i = 1,2,\ldots,m,$$

Let $\mu^{\star}_{rk}$, $r = 1,2,\ldots,s$ and $\omega^{\star}_{ik}$, $i = 1,2,\ldots,m$ be the optimal solutions of Model III, then $\hat{e}^U_{kj} = \sum_{r=1}^{s} \mu^{\star}_{rk} y_{rj}$ is the optimal efficiency that DMU_j can attain when evaluated by DMU_k.

TABLE 1 *Cross efficiency matrix for n DMUs corresponding to Model II*

Target DMU_K	Cross Efficiency of DMU_j					
	1	2	…	l	…	n
1	$\hat{e}^L_{11}$	$\hat{e}^L_{12}$	…	$\hat{e}^L_{1l}$	…	$\hat{e}^L_{1n}$
2	$\hat{e}^L_{21}$	$\hat{e}^L_{22}$	…	$\hat{e}^L_{2l}$	…	$\hat{e}^L_{2n}$
3	$\hat{e}^L_{31}$	$\hat{e}^L_{32}$	…	$\hat{e}^L_{3l}$	…	$\hat{e}^L_{3n}$
⋮	⋮	⋮	⋮	⋮	⋮	⋮
n	$\hat{e}^L_{n1}$	$\hat{e}^L_{n2}$	…	$\hat{e}^L_{nl}$	…	$\hat{e}^L_{nn}$
Average cross efficiency	$\frac{\sum_{k=1}^{n} \hat{e}^L_{k1}}{n}$	$\frac{\sum_{k=1}^{n} \hat{e}^L_{k2}}{n}$	…	$\frac{\sum_{k=1}^{n} \hat{e}^L_{kl}}{n}$	…	$\frac{\sum_{k=1}^{n} \hat{e}^L_{kn}}{n}$

Across all possible optimal solutions of CCR, Model II aims to determine the worst cross-efficiency score for DMU_k, and Model III aims to determine the best cross-efficiency score for DMU_k.

Remark 1 *The alternative optimal solutions of CCR model I corresponding to DMU_k are utilized to solve models II and III. It is obvious that $\hat{e}^L_{kj} < \hat{e}^U_{kj}$ only holds if the corresponding self-evaluation DEA model has different optimal solutions. In Oral et al. (2015) have stated that model III takes into consideration the issue of multiple optimal solutions from the CCR modeling the evaluation of cross-efficiency. The results can be greatly impacted by selecting the values from these intervals. One can select extreme*

UNCORRECTED MANUSCRIPT

cross-efficiency (Min cross-efficiency or Max cross-efficiency) for pessimistic and optimistic decisions. We investigate the results of the OVGA aggregated min cross-efficiency score in this work.

Similarly, we can find out the Max cross-efficiency matrix for n *DMUs* corresponding to Model III. The most popular method is averaging each row or column's efficiency in the cross-efficiency matrix with equal weights to determine a DMU's overall performance measurement. Assigning identical weights for cross-efficiency aggregation is not the best option because the self-evaluated efficiency score contributes less than peer-evaluated efficiencies do. In the next section, to follow we have the notion of the Ordered Visibility Graph Averaging operator for aggregation of efficiency of $DMU's$.

2.2. *Ordered Visibility Graph Weighted Averaging operator*

A Visibility Graph (VG) is an undirected graph of n nodes. The visibility graph method converts a time series into a graph. The associated graph derived from a time series has the following properties:

1. Connected: a node can see its nearest neighbors.
2. Undirected: the associated graph extracted from a time series
3. Invariant under affine transformations of the series data: Although rescale both horizontal and vertical axes, the visibility criterion is invariant.

Further, Wang et al. (2015) introduced an algorithm for ordered visible graphs (OVG). The VG method is to convert a time series into a graph, while the OVG maps a set of ordered data into a network.

Definition 1 (Wang et al. (2015)) *Let $O = \{o_1, o_2, \ldots, o_n\}$ represents a set of n ordered data, where, o_j is the jth largest element of the set. An ordered value o_j and its order j make up the coordinate (j, o_j) and represent a node j in the graph VG.*

Definition 2 (Wang et al. (2015)) *Two data values $(i, o_i), (j, o_j)$ have visibility, if any other value (k, o_k) is placed between them fulfills*

$$o_k < o_j + (o_i - o_j)\frac{j-k}{j-i}.$$

These argument values are connected in a network of connections by the visibility criteria. These connections are made depending on both the argument values themselves and the order in which they are presented.

The visibility criteria of OVG are similar to VG and are defined as follows:

Definition 3 (Wang et al. (2015)) *Two ordered data values $(i, o_i), (j, o_j)$ have visibility, if any other value (k, o_k) is placed between them fulfills*

$$o_k < o_j + (o_i - o_j)\frac{j-k}{j-i}.$$

Downloaded from https://academic.oup.com/imaman/advance-article/doi/10.1093/imaman/dpae012/7671391 by Delhi Technological University user on 22 May 2024

Definition 4 *Let $\{(1,o_1),(2,o_2),\ldots,(n,o_n)\}$ be the set of n ordered data values. The adjacency matrix $A=[a_{ij}]_{n\times n}$ on the basis of visibility between the node i and node j is defined as*

$$a_{ij}=\begin{cases}1 & \text{if there is visibility from node } i \text{ to node } j\ , i\neq j\\ 0 & \text{otherwise.}\end{cases}$$

Let d_i be the degree of node i, and is given by $d_i=\sum_j a_{ij}$

Definition 5 (Ordered visibility graph weighted aggregation (OVGWA) operator) *Let $\{a_1,a_2,\ldots,a_n\}$ be the set of n ordered values, where $a_i\in R$. OVGWA operator is a mapping $F: I^n\longrightarrow I$, $I\in R$, such that $F(a_1,a_2,\ldots,a_n)=w_1a_1+w_2a_2+....+w_na_n$, where a_i is the ith value and w_i is the corresponding weight of the value a_i, satisfying the conditions $w_i\in[0,1]$, $\sum_{i=1}^n w_i=1$, and is defined as follows:*

$$w_i=\frac{d_i}{\sum_{i=1}^{n} d_i},\quad i=1,2,\ldots,n,$$

where d_i is the degree of the ith node. Further the aggregated value of the ordered set $\{a_1,a_2,\ldots,a_n\}$ is $F(a_1,a_2,\ldots,a_n)=w_1a_1+w_2a_2+....+w_na_n$.

The Python program that calculates the adjacency matrix, degree, and weight of an ordered set, on the lines of Definitions 3, 4, and 5 is described as Algorithm 1 in "Appendix". To give more clarity, we consider an example considered in Wang et al. (2015).

Example 1 (Wang et al. (2015)) *Assume there are 8 ordered values, $O=\{85,75,70,70,55,50,45,40\}$. In the OVG, every node represents the corresponding element in the ordered set, in the same order.*

From Algorithm 1, the corresponding adjacency matrix A, degree, and weight of an ordered set O (depicted in Table 2) are as follows:

$$A=\begin{bmatrix}0&1&1&1&0&0&0&0\\1&0&1&1&0&0&0&0\\1&1&0&1&0&0&0&0\\1&1&1&0&1&1&1&1\\0&0&0&1&0&1&0&0\\0&0&0&1&1&0&1&0\\0&0&0&1&0&1&0&1\\0&0&0&1&0&0&1&0\end{bmatrix}$$

According to the visibility criteria and on the lines of the adjacency matrix, Fig. 1 depicts the OVG so obtained.

Further, the aggregated value of the ordered data is

$$\begin{aligned}F(85,75,70,70,55,50,45,40) &= 85\times 3/26+75\times 3/26+70\times 3/26+70\times 6/26\\ &\quad +55\times 2/26+50\times 3/26+45\times 3/26+40\times 2/26\\ &= 60.96\end{aligned}$$

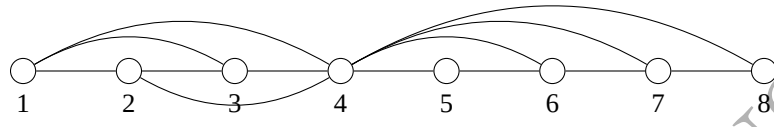
TABLE 2 *Degree and weights of ordered set O*

Nodes (i)	1	2	3	4	5	6	7	8
degree (d_i)	3	3	3	7	2	3	3	2
weight (w_i)	$\frac{3}{26}$	$\frac{3}{26}$	$\frac{3}{26}$	$\frac{6}{26}$	$\frac{2}{26}$	$\frac{3}{26}$	$\frac{3}{26}$	$\frac{2}{26}$

FIG. 1. OVG of ordered set *O*



It should be noted that if a vertex is connected to another vertex by an edge, it is visible from that vertex since the two vertices have a direct line of sight. On the other hand, if a vertex is not connected to another vertex by an edge, it means that there is an obstruction in the way and the vertex cannot be seen from that specific vertex. In a visible network, the vertex with the highest degree is the one with the greatest number of connections to other vertices. It resembles a graph's center that is visible from several other spots. This vertex is crucial to the network as a whole because it is connected to a larger number of other vertices.

3. Portfolio optimization model based on the cross-efficiency matrix: Proposed model

Lim et al. (2014) studied Markowitz (1952) portfolio selection model based on the efficiencies of their assets. Lim et al. (2014) considered return and risk aspects of Markowitz's model in terms of mean efficiencies and the co-variance between the cross-efficiency scores of all *DMU′s* respectively. Before introducing the suggested model, it is necessary to comprehend the terminology from the previous part in terms of DMU efficiency.

Definition 6 (Adjacency matrix and degree of DMU_p with respect to DMU_j corresponding to min-cross-s-efficiency) *Let $\hat{E}_j^L = \{\hat{e}_{1j}^L, \hat{e}_{2j}^L, \ldots, \hat{e}_{pj}^L, \ldots, \hat{e}_{nj}^L\}$ be the set of n ordered cross-efficiencies of a DMU_j, where $\hat{e}_{ij}^L$ is the ith largest element of the set $\hat{E}_j^L$. Let $\{(1,\hat{e}_{1j}^L),(2,\hat{e}_{2j}^L),\ldots,(p,\hat{e}_{pj}^L),\ldots,(n,\hat{e}_{nj}^L)$ be the corresponding set of n ordered data nodes. The adjacency matrix for DMU_j, denoted by $A_j^L = [a_{pq}^j]_{n\times n}$ on the basis of visibility between DMU_p, $p = 1,2,\ldots,n$ and DMU_q, $q = 1,2,\ldots,n$ becomes as follows*

$$a_{pq}^j = \begin{cases} 1, & \text{if there is visibility between the data values } (p,\hat{e}_{pj}^L) \text{ and } (q,\hat{e}_{qj}^L),\ p \neq q \\ 0, & \text{otherwise.} \end{cases}$$

Let d_p^j be the degree of DMU_p under the consideration of DMU_j, then $d_p^j = \sum_q a_{pq}^j$

Definition 7 (OVGA min-efficiency of DMU_j) *Let $\hat{E}_j^L = \{\hat{e}_{1j}^L, \hat{e}_{2j}^L, \ldots, \hat{e}_{kj}^L, \ldots, \hat{e}_{nj}^L\}$ be the set of n ordered min-cross-efficiencies of a DMU_j, where $\hat{e}_{ij}^L$ is the ith largest element of the set $\hat{E}_j^L$. Then OVGA*

Downloaded from https://academic.oup.com/imaman/advance-article/doi/10.1093/imaman/dpae012/7671391 by Delhi Technological University user on 22 May 2024

min-efficiency of DMU_j, denoted by $\tilde{e}_j^L$ is defined as

$$\tilde{e}_j^L = w_{1j}\hat{e}_{1j}^L + w_{2j}\hat{e}_{2j}^L + \ldots w_{pj}\hat{e}_{pj}^L + \ldots w_{nj}\hat{e}_{nj}^L,$$

where,

$$w_{pj} = \frac{d_p^j}{\sum_{p=1}^{n} d_p^j},\ p = 1,2,\ldots,n.$$

Definition 8 (Average of min-cross efficiency) *Let $\hat{E}_j^L = \{\hat{e}_{1j}^L, \hat{e}_{2j}^L, \ldots, \hat{e}_{kj}^L, \ldots, \hat{e}_{nj}^L\}$ be the set of n cross-efficiencies of a DMU_j, where $\hat{e}_{kj}^L$ is the min-cross-efficiency of DMU_j evaluated with respect to DMU_k. Then the average of min-cross-efficiencies of DMU_j, denoted by $\bar{e}_j$ is defined as*

$$\bar{e}_j^L = \frac{\hat{e}_{1j}^L + \hat{e}_{2j}^L + \ldots, \hat{e}_{kj}^L + \ldots \hat{e}_{nj}^L}{n}$$

Definition 9 (Adjacency matrix and degree of DMU_p with respect to DMU_j corresponding to max-cross-efficiency) *Let $\hat{E}_j^U = \{\hat{e}_{1j}^U, \hat{e}_{2j}^U, \ldots, \hat{e}_{pj}^U, \ldots, \hat{e}_{nj}^U\}$ be the set of n ordered max-cross-efficiencies of a DMU_j, where $\hat{e}_{ij}^U$ is the ith largest element of the set $\hat{E}_j^U$. Let $\{(1,\hat{e}_{1j}^U), (2,\hat{e}_{2j}^U), \ldots, (p,\hat{e}_{pj}^U), \ldots, (n,\hat{e}_{nj}^U)$ be the corresponding set of n ordered data nodes. The adjacency matrix for DMU_j, denoted by $B_j^U = [b_{pq}^j]_{n\times n}$ on the basis of visibility between DMU_p, $p = 1,2,\ldots,n$ and DMU_q, $q = 1,2,\ldots,n$ becomes as follows*

$$b_{pq}^j = \begin{cases} 1, & \text{if there is visibility between the data values} (p,\hat{e}_{pj}^U) \text{and} (q,\hat{e}_{qj}^U),\ p \neq q \\ 0, & \text{otherwise.} \end{cases}$$

Let c_p^j be the degree of DMU_p under the consideration of DMU_j, then $c_p^j = \sum_q b_{pq}^j$

Definition 10 (OVGA max-efficiency of DMU_j) *Let $\hat{E}_j^U = \{\hat{e}_{1j}^U, \hat{e}_{2j}^U, \ldots, \hat{e}_{kj}^U, \ldots, \hat{e}_{nj}^U\}$ be the set of n ordered max-cross-efficiencies of a DMU_j, where $\hat{e}_{ij}^U$ is the ith largest element of the set $\hat{E}_j^U$. Then OVGA max-efficiency of DMU_j, denoted by $\tilde{e}_j^U$ and is defined as*

$$\tilde{e}_j^U = w_{1j}\hat{e}_{1j}^U + w_{2j}\hat{e}_{2j}^U + \ldots w_{pj}\hat{e}_{pj}^U + \ldots w_{nj}\hat{e}_{nj}^U,$$

where,

$$w_{pj} = \frac{c_p^j}{\sum_{p=1}^{n} c_p^j},\ p = 1,2,\ldots,n.$$

Definition 11 (Average of max-cross efficiency) *Let $\hat{E}_j^U = \{\hat{e}_{1j}^U, \hat{e}_{2j}^U, \ldots, \hat{e}_{kj}^U, \ldots, \hat{e}_{nj}^U\}$ be the set of n cross-efficiencies of a DMU_j, where $\hat{e}_{kj}^U$ is the max-cross-efficiency of DMU_j evaluated with respect to DMU_k. Then the average of max-cross-efficiency of DMU_j, denoted by $\bar{e}_j^U$ is defined as*

$$\bar{e}_j^U = \frac{\hat{e}_{1j}^U + \hat{e}_{2j}^U + \ldots, \hat{e}_{kj}^U + \ldots \hat{e}_{nj}^U}{n}$$

UNCORRECTED MANUSCRIPT

Downloaded from https://academic.oup.com/imaman/advance-article/doi/10.1093/imaman/dpae012/7671391 by Delhi Technological University user on 22 May 2024

Remark 2 *In the visibility graph, the weight of each node is determined by the degree distribution. Thus if a node links with more nodes than others, its degree will be greater and it will be more significant. The following are the advantages of the OVGA operators over other methods for cross-efficiency aggregation:-*

1. *In the OWA method, we obtain different aggregated results for different optimism levels and it is very difficult for decision-makers to select which value to make final decisions.*
2. *Compared with the classical OWA operator, the proposed OVGA operator not only takes the information of orders but also the argument values themselves into consideration to determine the weights. The OVGA operator is inspired by the complex network theory and Newton's law of universal gravitation.*
3. *Other cross-efficiency aggregation methods, such as prospect and regret theory, require many calculation parameters that will be very difficult to handle and will be very calculative for the large-scale data set. Prospect theory cross-efficiency aggregation requires at least four parameters, including risk attitude coefficients, the concave degree of the value function within the gain/loss region, and a psychological preference value. Similarly, the regret theory cross-efficiency aggregation method utilizes the regret-rejoice function based on the regret aversion coefficient.*
4. *The primary benefit of the OVGA operator is that it is based on the idea of human intuition. In simpler terms, a vertex with the highest degree can be considered a popular person who knows many people and has a lot of influence. Their connections and interactions provide valuable insights into the relationships and dynamics of the time series data.*

Portfolio selection model corresponding to min-cross-efficiency

Let us consider a portfolio Ω constituted with n *DMUs* say DMU_i, $i = 1,2,\ldots,n$. On the same lines Lim et al. (2014), in this paper, the return and risk characteristics of Markowitz's model (Markowitz (1952)), mean and variance of the model are described by mean cross-efficiency scores and variance of its cross-efficiencies, respectively.

Let $[\hat{e}^L_{ij}]_{n\times n}$ be the min-cross-efficiency matrix on n DMUs taken under consideration for portfolio selection. Let x_i be the proportion of the total efficiency invested on DMU_i. The portfolio Ω of n *DMUs* by the OVGA operator is obtained by solving the following cross-efficiency portfolio optimization model:

Model IV

$$\min \quad V_\Omega = \sum_{i=1}^{n}\sum_{j=1}^{n} x_i x_j \tilde{\sigma}^L_{ij}$$

subject to,

$$E_\Omega = \sum_{i=1}^{n} x_i \tilde{e}^L_i \geq (1-\gamma)\tilde{E}^b_\Omega$$

$$\sum_{i=1}^{n} x_i = 1,$$

$$\textstyle\sum_{i=1}^{n} z_i = d, \quad i = 1,2,\ldots,n,$$

$$\varepsilon_i z_i \leq x_i \leq \delta_i z_i, \quad i = 1,2,\ldots,n,$$

$$x_i \in \{0,1\}, \quad i = 1,2,\ldots,n,$$

$$x_i \geq 0, \quad i = 1,2,\ldots,n,$$

UNCORRECTED MANUSCRIPT

Downloaded from https://academic.oup.com/imaman/advance-article/doi/10.1093/imaman/dpae012/7671391 by Delhi Technological University user on 22 May 2024

where, $\tilde{e}_i^L$ is the mean cross- efficiency score of DMU_i by OVGA operator, defined in Definition 7 and $\tilde{\sigma}_{ij}^L = \frac{1}{n}\sum_{k=1}^{n}(\hat{e}_{ki}^L - \tilde{e}_i^L)(\hat{e}_{kj}^L - \tilde{e}_j^L)$ is the covariance between the cross-efficiency scores of DMU_i and DMU_j. Here, γ is the trade-off parameter between mean efficiency and co-variance of their efficiency. Further, for a better selection of a DMU, the budget constraint $\sum_{i=1}^{n} x_i = 1$, cardinality constraint $\sum_{i=1}^{n} z_i = d, z_i \in \{0,1\}, \quad i = 1,2,\ldots,n,$, buy-in threshold $\varepsilon_i z_i \leq x_i \leq \delta_i z_i, \quad i = 1,2,\ldots,n,$, and no short-selling criteria $x_i \geq 0,\ i = 1,2,\ldots,n$, are also considered here. Here, E_Ω^b is the maximum OVGA efficiency achievable by the portfolio under the budget constraint, cardinality constraint, buy-in threshold, and no short-selling criteria.

Let $\tilde{E}_{\Omega^\star}$ and $\tilde{V}_{\Omega^\star}$ be the optimal mean efficiency and optimal risk corresponding to the optimal portfolio $\Omega^\star$ so obtained.

Similarly, the mean-variance cross-efficiency model for simple average efficiency as defined in Definition 8 is as follows:

Model V

$$\begin{aligned}
\min \quad & V_\Omega = \sum_{i=1}^{n}\sum_{j=1}^{n} x_i x_j \bar{\sigma}_{ij}^L \\
\text{subject to,} \quad & \\
& \sum_{i=1}^{n} x_i \bar{e}_i^L \geq (1-\gamma)\bar{E}_\Omega^b \\
& \sum_{i=1}^{n} x_i = 1 \\
& \textstyle\sum_{i=1}^{n} z_i = d, \quad i = 1,2,\ldots,n, \\
& \varepsilon_i z_i \leq x_i \leq \delta_i z_i, \quad i = 1,2,\ldots,n, \\
& z_i \in \{0,1\}, \quad i = 1,2,\ldots,n, \\
& x_i \geq 0, \quad i = 1,2,\ldots,n,
\end{aligned}$$

where, $\bar{e}_i^L$ is the mean cross efficiency score of DMU_i defined in Definition 8 and $\bar{\sigma}_{ij}^L = \frac{1}{n}\sum_{k=1}^{n}(e_{ki}^L - \bar{e}_i^L)(e_{kj}^L - \bar{e}_j^L)$ is the covariance between the cross efficiency scores of DMU_i and DMU_j. E_Ω^b is the maximum mean efficiency, achievable by the portfolio E_Ω. Further, γ is the trade-off parameter between mean efficiency and co-variance of their efficiency. Further, other constraints have the same interpretation as explained in Model IV. Let $\tilde{E}_{\Omega^\star}$ and $\tilde{V}_{\Omega^\star}$ be the optimal mean efficiency and optimal risk corresponding to the optimal portfolio $\Omega^\star$ so obtained.

Remark 3 *Now on the lines of Definitions 9, 10, and 11, we can extend Model IV and Model V to study the portfolio selection for max-cross-efficiency of DMUs.*

Remark 4 *It is imperative to bear in mind that the selection of the Minimum or Maximum cross-efficiencies, or the extraction of efficiencies from the interval between the min and max cross-efficiencies, will have a significant influence on the portfolio selection outcomes. In this work, we solely address the ideal portfolio derived from model IV. We can explore the OVGA max cross-efficiency and its impact on portfolio outcomes more thoroughly in future studies.*

UNCORRECTED MANUSCRIPT

4. Numerical Illustration

In this section, we apply our proposed method to a numerical example consisting of 22 DMUs to demonstrate the empirical effectiveness of the method. The numerical dataset is taken from Lim et al. (2014) which was further analyzed by Amin and Hajjami (2021). The input and output data for the DMUs are presented in Table 3.

TABLE 3 *Input and output data values for DMUs*

DMUs	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22
Input 1	5	6	4	8	5	8	4.4	2.6	3.4	3.6	2	3	3	2.6	4	5	6	4	7	6	8	9
Input 2	4	5	5	5	6	3	4.4	8	8	4.4	7	7	5.6	5	4	3.2	4	3.5	3	2.5	2	2
Output 1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

On solving the Model I, for DMU_1, we get $\mu_{11}^{\star} = 0.85$, $\omega_{11}^{\star} = 0.0769$, $\omega_{21}^{\star} = 0.1538$, with the optimal value of the objective function as $e_{11}^{\star} = 0.85$. Similarly on solving Model I, for other *DMUs*, the self-efficiency of respective *DMUs* can be acquired as follows:

TABLE 4 *Self-efficiency score $e_{kk}^{\star}$ of DMU_k*

k	1	2	3	4	5	6	7	8	9	10	11
$e_{kk}^{\star}$	0.85	0.69	0.84	0.61	0.69	0.80	0.85	0.82	0.71	0.94	1
k	12	13	14	15	16	17	18	19	20	21	22
$e_{kk}^{\star}$	0.80	0.88	1	0.94	0.96	0.79	1	0.85	1	1	1

For cross-efficiency interval evaluation of DMU_j, we have to solve Model II and Model III respectively for different values of k for a fixed value of j. For example if we take $k = 2$ and $j = 1$, we can find $\tilde{e}_{21}^{L}$ and $\bar{e}_{21}^{U}$. As in the cross-efficiency matrix, DMU_j is evaluated by DMU_k, so to determine the weights given by DMU_j to DMU_k to find out its aggregated efficiency by the OVGA operator, we need re-ordered minimum cross-efficiency matrix.

To get more clarity, let us calculate the weights given by DMU_1 to DMU_k, $k = 1, 2, \ldots, n$ for the OVGWA operator to get its aggregated efficiency. In a similar fashion, we can find out the weights given by other *DMUs* to DMU_k, $k = 1, 2, \ldots, n$. The set of ordered cross-efficiencies of DMU_1, $\hat{e}_{k1}^{L}$, $k =$

UNCORRECTED MANUSCRIPT

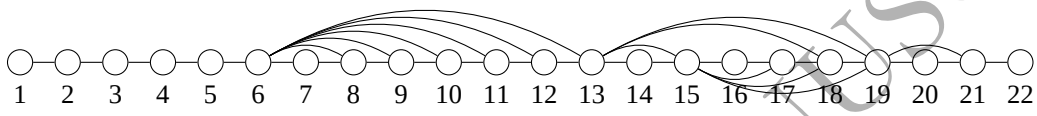
Downloaded from https://academic.oup.com/imaman/advance-article/doi/10.1093/imaman/dpae012/7671391 by Delhi Technological University user on 22 May 2024

$1,2,\ldots,22$ (as per Table 7) for DMU_1 is

$$\hat{E}_1^L = \{0.85,\ 0.85,\ 0.85,\ 0.85,\ 0.85,\ 0.85,\ 0.83,\ 0.83,\ 0.83,\ 0.83,\ 0.83,\ 0.83,\ 0.83,\ 0.76,\ 0.76,\ 0.66,\ 0.66,\ 0.66,\ 0.66,\ 0.50,\ 0.50,\ 0.40.\}\ .$$

To calculate the weights given by DMU_1 to DMU_k, $k = 1,2,\ldots,22$, for evaluating its OVGWA efficiency, the below-given Fig.1 depicts the ordered visibility graph of all $DMUs$ with respect to ordered cross efficiency set $\hat{E}_1^L$.

FIG. 2. Ordered visibility graph of ordered efficiency set $\hat{E}_1^L$



Now on lines of Definition 6, from Algorithm 1, the corresponding adjacency matrix is

$$A_1^L = \begin{bmatrix}
0&1&0&0&0&0&0&0&0&0&0&0&0&0&0&0&0&0&0&0&0&0\\

\end{bmatrix}$$

So the aggregated cross-efficiency by OVGWA operator and by simple average is $\tilde{e}_1^L = \sum_{p=1}^{22} w_p^1 \hat{e}_{p1}^L = 0.76$ and $\bar{e}_1^L = \sum_{p=1}^{22} (1/n)\hat{e}_{p1}^L = 0.75$, respectively. These values are the same as given in Table 9, and

w_p^1	$\frac{1}{68}$	$\frac{2}{68}$	$\frac{2}{68}$	$\frac{2}{68}$	$\frac{2}{68}$	$\frac{8}{68}$	$\frac{2}{68}$	$\frac{3}{68}$	$\frac{3}{68}$	$\frac{3}{68}$	$\frac{3}{68}$	$\frac{3}{68}$	$\frac{6}{68}$	$\frac{2}{68}$	$\frac{6}{68}$	$\frac{2}{68}$	$\frac{3}{68}$	$\frac{4}{68}$	$\frac{5}{68}$	$\frac{2}{68}$	$\frac{3}{68}$	$\frac{1}{68}$

in a similar manner, we can calculate the aggregated cross-efficiency scores of other DMUs. For this, we first need to solve Model II, for $k, j = 1, 2, \ldots, n$ the minimum cross-efficiency matrix is depicted in Table 9. Further, Table 7 presents the re-ordered cross-efficiency matrix. As per the requirement of the calculation Table 8 illustrates the weights given by DMU_j to DMU_p for $j, p = 1, 2, \ldots, 22$.

Portfolio selection

Here, optimal portfolios are selected in two ways:

Case I: the portfolio selection is performed with equal weights

The decision maker wishes to have an equal proportion of investment on the DMUs for the optimal portfolios. To present the advantages of the proposed portfolio selection model, we first obtain portfolios using the proposed model for different cardinality constraints i.e., d=5, d=10, and d=7. The obtained portfolio strategies are given in Table 10. To compare the portfolios obtained from the traditional method, i.e., after solving Model V, the portfolio strategies under the different cardinality constraints i.e., d=5, d=10, and d=15 are presented in Table 11. Here it is to be noted that, the portfolios obtained through the proposed model have a considerable reduction in variance (risk) and a slight reduction in mean. For example, the portfolio obtained through the proposed method, presented in Table 10 corresponding to d=5, and $\gamma = 0.1$ shows the 1.73% decrease in mean in comparison to the 33.4% decrease in variance.

Case II: Optimal portfolio selection with unequal weights

Here it is to be noted that different portfolios are generated by varying values of $d, \gamma, \varepsilon_i, \delta_i$. The optimal portfolio strategies corresponding to the proposed model i.e., after solving Model IV, are presented in Table 12, and with respect to the traditional method, i.e., after solving Model V, the optimal strategies are presented in Table 13. As discussed above, the portfolios obtained through the proposed model have a considerable reduction in variance (risk) against the slight reduction in mean. For example, the portfolio obtained through a proposed method, presented in Table 12 corresponding to $d = 5, \gamma = 0.1, \varepsilon_i = 0.03$ and $\delta = 0.4$ shows the 1.1% decrease in mean against the considerable decrease 27.5% in variance.

It is to be noted that, a bigger value of γ can also result in a more significant decrease in risk for a given expected return. The effectiveness of the proposed approach for portfolio selection is empirically supported by the acquired portfolio selection strategies. The suggested model can generate portfolios based on the investor's choices corresponding to γ.

In the subsequent section to follows, we demonstrate the benefit of the proposed method by taking a real-world application problem.

4.1. *A Case Study of the Indian Banking Sector*

We present a case study with 20 banking companies listed on the National Stock Exchange as a practical example of the suggested methodology. The data for the financial year 2021 is used here for the case study. This is just for illustrative purposes; the analysis may easily be continued for several years.

In our analysis, we have randomly selected the following twenty Banks listed in trade brains portal (https://portal.tradebrains.in).

1. SBIN (B_1)
2. AXIS (B_2)
3. PNB (B_3)
4. HDFC (B_4)
5. ICICI (B_5)
6. KOTAK (B_6)
7. FEDERAL (B_7)
8. CANARA (B_8)
9. UNION (B_9)
10. UNCO (B_{10})
11. BARODA (B_{11})
12. INDIAN (B_{12})
13. BANDHAN (B_{13})
14. MAHA (B_{14})
15. IDBI (B_{15})
16. INDIAN (B_{16})
17. CUB (B_{17})
18. DCB (B_{18})
19. DHAN (B_{19})
20. SOUTH (B_{20})

We denote the Banks by $B_k,\ k = 1,2,\ldots,20$, in order of the above listing. The description of input and output variables considered here are as follows:

Inputs:

1. Input 1: Ratio of Market price to the earning per share (I_1)
2. Input 2: Ratio of the Market price to the book value per share (I_2)

Outputs

1. Output 1: Ratio of net income to stockholders equity (O_1)
2. Output 2: percentage of a firmâĂŹs ability to generate a return from its assets (O_2)

Table 14 presents the input and output values of the 20 banking stocks and their self-evaluated DEA efficiency. Further, from Definition 7 and Definition 8, the minimum OVGWA cross-efficiency $\tilde{e}_j^L$ and the minimum average cross-efficiency $\bar{e}_j^L$ for Bank $B_j,\ j = 1,2,\ldots,20$ are also presented there. Similarly, from Definitions 9, 10 and 11, the maximum OVGWA cross-efficiency and maximum mean cross-efficiency $\tilde{e}_j^U$ and $\bar{e}_j^U$ of respective Bank's are also provided therein. We set $\varepsilon_i = 0.02$, $\delta_i = 0.6$, to

UNCORRECTED MANUSCRIPT

create portfolios with unequal weights. When we solve the proposed models IV and V for a range of d and gamma values, we found that a small increase in portfolio return (from 0.72 to 0.75) would result in a sizable increase in risk (from 0.0128 to 0.0145). The results are shown in Table15

4.2. *Managerial implications:*

The proposed two-stage methodology has significant managerial implications in the field of DEA cross-efficiency aggregation and portfolio selection in terms of their efficiency. First, the developed approach can help managers to gain a better understanding of portfolio selection. Second, the approach's results are simple to grasp for managers. It can help investors and portfolio managers to build an efficient portfolio by incorporating only the best-performing stocks. Based on the implications discussed above, the proposed approach can be used in a financial market but also in other industries to examine the impact of operational and long-term decisions on business performance. Furthermore, the problem addressed in this study is in its early stages of investigation, and further research can be conducted based on the findings of this paper. Some options are as follows:

1. A similar study can be conducted to deal with stochastic data.
2. In this study, the proposed model was applied to a problem in the banking industry. However, the same model could be used for a variety of other selection-based problems like R& D and project selection, and the stock market. The methodology applies to other asset allocation problems, mutual fund portfolio selection, multi-period portfolio problems, and other case studies.
3. Furthermore, comparative studies in different industries or countries using the model and methods from this study would be necessary to validate its claims.
4. The OVGA aggregated efficiencies can be used in the different ranking problems and the obtained results can be further compared with other aggregation methods in terms of complexity.

5. Conclusion and Future Directions

In this study, we introduce a novel portfolio selection model that can assist investors in identifying well-diversified equities based on numerous evaluation criteria. The unique primary contributions of this paper can be seen in two ways. First, the use of OVGA in cross-efficiency aggregation may be viewed as an extension and refinement of the DEA cross-efficiency aggregation approaches. Meanwhile, this is the first time, that the OVGA aggregated cross-efficiencies have been successfully applied to portfolio management. It appears to be a promising tool for assessing financial assets. It is demonstrated herein that introducing the OVGA aggregation operator into the cross-efficiency portfolio selection yields superior portfolios with reduced variance and more significant or similar projected returns; at least for this particular study. To demonstrate the value of the suggested approach, a real-time example from the Indian banking industry is used. Further, the proposed strategy can also be completed by stock selection in larger stock markets.

It is worth noting that if asset return distributions are not symmetric, using variance as a risk measure is not recommended because doing so leads to portfolio predictions that are far from the actual target. Many researchers have utilized semi-variance and semi-absolute deviation as alternative risk metrics to qualify risk in such scenarios. Additionally, the OVGA cross-efficiency aggregation model may be extended to study portfolio selection problems in the fuzzy environment. Further, this study can be extended to study the efficiency of the decision-making units having undesirable inputs and outputs.

***Abstract*—Partial shading poses a critical challenge to optimizing the performance of photovoltaic (PV) systems, affecting the attainment of maximum power output and overall system efficiency. Inadequate management of partial shading conditions (PSCs) can threaten the stability and effectiveness of PV systems. This study presents an innovative reconfiguration approach grounded in a cyclic heap permutation strategy, to alleviate the detrimental effects of Partial Shading Conditions (PSCs). Through the strategic redistribution of shading effects, the proposed reconfiguration method improves the efficiency of PV systems across a spectrum of shading scenarios. Rigorous performance evaluations, considering various shading cases and configurations, reveal the efficacy of the proposed cyclic heap permutation-based reconfiguration technique. We also highlight its versatility and adaptability across different PV array sizes and shading conditions. This study adds to continuous endeavors aimed at fortifying the resilience and improving the efficiency of solar PV systems confronted with partial shading challenges.**

***Index Terms*—solar, partial shading, photovoltaic, reconfiguration, shade dispersion**

I. Introduction

In response to the detrimental environmental impacts linked with fossil fuels, there is a growing global demand for energy sources that are both environmentally friendly and sustainable [1]. This demand is further heightened by the expansion of the world's population and the depletion of fossil fuel reserves, creating an urgent requirement for continuous and sustainable energy production. Solar power, among diverse renewable energy sources, has emerged as a viable solution to meet the rising demand for electricity.

While solar energy is acknowledged for its sustainability and cost-effectiveness, a significant challenge lies in the decrease in output resulting from variations in irradiation. These variations lead to non-uniformities and multiple peaks in the power-voltage (P-V) and current-voltage characteristics (I-V) of photovoltaic systems.

Partial shading (PS) manifests when distinct sections of a solar PV array experience disparate solar irradiance levels, often attributed to factors like cloud cover, the movement of birds, and the accumulation of dirt resulting from inadequate maintenance, among other causes [2]. The ramifications and challenges associated with partial shading conditions (PSCs) encompass several critical issues [3] [4]. Firstly, hotspot formation on solar PV modules can lead to thermal losses, potentially disrupting the overall functionality of the PV system [5]–[7]. Moreover, PSCs contribute to the ineffectiveness of conventional maximum power tracking methods, hindering the identification of the global maximum and leading to multiple peaks in the power-voltage (P-V) plot [8] [9]. This, in turn, hinders MPPT algorithms from tracking the global maxima, resulting in suboptimal power output and diminished system performance [10]. Considering the imperative to capture the maximum power output under different Photovoltaic System Conditions (PSCs), PV array reconfiguration emerges as a compelling solution. This process can be categorized into static reconfiguration, where the electrical interconnect remains unchanged, and dynamic reconfiguration, which involves alterations in the electrical interconnect [11] [12]. While the dynamic approach exhibits strong optimization capabilities, it comes with a significant cost and necessitates complex algorithms to operate at the optimum point. In contrast, the static approach necessitates a single configuration to achieve efficient shading dispersion throughout the PV array.

In tackling the difficulties presented by partial shading in photovoltaic (PV) arrays, prior research has proposed different configurations, including Series Parallel (SP) configuration, Total Cross Tied (TCT) configuration, Honey Comb (HC) configuration, and Bridge Link (BL) configuration [13] [14]. Moreover, various methods for maximizing Power Point Tracking (MPPT) have been investigated to enhance the output of solar arrays in the context of partial shading conditions [12].

This research introduces an innovative array reconfiguration technique named Cyclic Heap Permutation (CHP) as a novel solution to alleviate shading impacts on PV arrays. The performance of various PV array configurations, such as SP, BL, TCT, and HC, is assessed using a 5x5 PV array. The research

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 22,2024 at 05:57:23 UTC from IEEE Xplore. Restrictions apply.

meticulously examines the outcomes across diverse partial shading patterns through Simulink (MATLAB) simulations. The noteworthy advancements of this work are outlined as follows:

1) This work addresses the optimization challenge under partial shading conditions (PSCs). Introducing a novel cyclic heap permutation-based reconfiguration technique, the study endeavors to enhance the effectiveness of PV systems in the presence of diverse shading scenarios.
2) The outcomes of this research validate the efficacy of the proposed cyclic heap permutation-based reconfiguration technique and underscore its versatility and adaptability across various PV array sizes and shading conditions. This highlights the applicability of the proposed method in various real-world scenarios.
3) The research adds to continuous endeavors aimed at fortifying the resilience and efficiency of solar PV systems confronted with partial shading challenges. The cyclic heap permutation strategy proves to be a compelling solution for mitigating shading impacts on PV arrays, thereby improving overall system performance.

II. Modeling of PV Array

Understanding the operational characteristics of a photovoltaic cell is pivotal, and its accurate modeling is the cornerstone for achieving this comprehension. The typical design of the photovoltaic cell is illustrated in the equivalent circuit shown in Fig. 1, and this representation extends to a photovoltaic (PV) module.

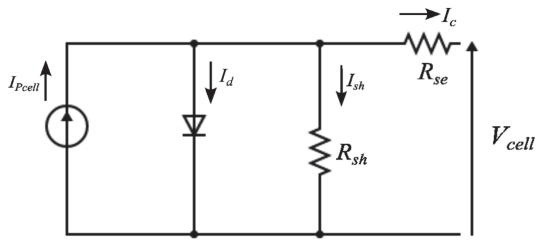

Fig. 1: Equivalent model of a Photovoltaic cell

$$I_c = I_{\text{cell}} - I_d \left[\exp\left(\frac{e(V_{\text{cell}} + R_{\text{se}} I_c)}{KBT} \right) - 1 \right] - \left[\frac{V_{\text{cell}} + R_{\text{se}} I_c}{R_{\text{sh}}} \right] \quad (1)$$

The functional characteristics of the photovoltaic (PV) cell are expressed through the mathematical formulation in Equation (1), where I_c represents the output current. I_{cell} denotes the photoelectric current generated by incoming photons, V_{cell} is the output voltage, R_{se} and R_{sh} are the series and parallel resistances across the diode, I_d is the saturation current, K is Boltzmann's constant, B is the ideality factor, and T is the module temperature in kelvin. The term e represents the fundamental charge of an electron. This equation encapsulates the intricate relationship among these parameters, defining the current-voltage characteristics of the PV cell.

III. Proposed Reconfiguration Algorithm: Cyclic Heap Permutation (CHP)

In this section, we introduce a novel reconfiguration algorithm, termed Cyclic Heap Permutation (CHP), designed for efficient and intricate matrix shuffling. The CHP algorithm draws inspiration from cyclic permutations, matrix transposition, Rubik's Cube moves, and Heap's Algorithm-based row permutations as shown in the flowchart in Fig. 3. The description of each operation performed is given below:

1) Cyclic Permutation
The foundation of the CHP algorithm lies in the cyclic permutation of elements within each row of the matrix. This step ensures the dispersion of elements originally situated in the same row across various rows in the shuffled matrix. The cyclic permutation introduces an initial level of complexity and serves as the cornerstone for subsequent transformations.
For a given matrix M of size $n \times n$, the cyclic permutation P_c is defined by:

$$P_c(p, q) = M[(p + q) \mod n][q] \quad (2)$$

where:
- $P_c(p, q)$ is the element at position (p, q) in the matrix after cyclic permutation.
- M is the original matrix.

2) Matrix Transpose
Following the cyclic permutation, the matrix undergoes a transpose operation. The transpose swaps rows and columns, further diversifying the arrangement of elements. This operation contributes to the overall intricacy of the shuffling process, promoting a more varied and layered transformation.
For a given matrix M of size $m \times n$, the transpose M^T is obtained by swapping its rows and columns:

$$M^T_{ij} = M_{ji} \quad (3)$$

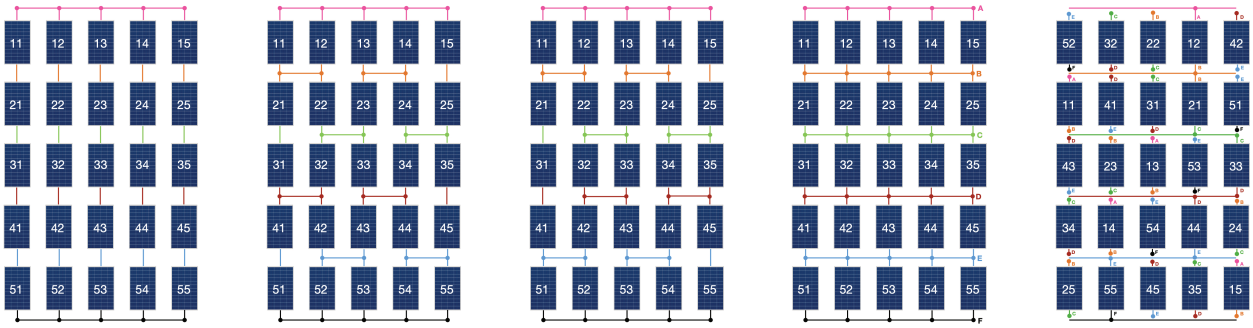
3) Rubik's Cube Move
Inspired by the movements of a Rubik's Cube, the algorithm incorporates a Rubik's Cube move to swap specific elements within each row. This step introduces a puzzle-solving aspect to the reconfiguration, creating a distinctive and dynamic arrangement of matrix elements. The Rubik's Cube move $RCM(p, q, r)$ is defined as swapping the elements at positions (p, q) and (p, r) within each row:

$$RCM(p, q, r) : M_{pq} \leftrightarrow M_{pr} \quad (4)$$

where, M_{pq} is the element at position (p, q) in the matrix, and M_{pr} is the element at position (p, r)in the matrix.

4) Heap's Algorithm for Row Permutation
To enhance the complexity of the shuffled matrix, the CHP algorithm leverages Heap's Algorithm to generate permutations of row indices. A selected permutation

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 22,2024 at 05:57:23 UTC from IEEE Xplore. Restrictions apply.



(a) SP (b) BL (c) HC (d) TCT (e) CHP

Fig. 2: PV array configurations

is applied to reorder the rows, providing additional variability to the final configuration.

Heap's Algorithm generates permutations recursively:

$$\begin{aligned} &\pi(i) \leftrightarrow \pi(n) \\ \text{if } i < n: \quad &\text{swap}(\pi(i), \pi(n)); \\ &\text{generate}(i+1); \\ &\text{swap}(\pi(i), \pi(n)) \end{aligned} \tag{5}$$

The permutation π is then applied to reorder the rows of the matrix.

The Cyclic Heap Permutation algorithm represents a holistic approach to matrix reconfiguration, incorporating diverse mathematical concepts and puzzle-solving strategies. The synergy of cyclic permutation, matrix transpose, Rubik's Cube moves, and Heap's Algorithm-based row permutations results in a versatile and efficient method for achieving complex matrix shuffling.

IV. Result and Discussion

To evaluate and compare the effectiveness of Cyclic Heap Permutation (CHP) in conjunction with other photovoltaic (PV) configurations, we conducted a comprehensive analysis using a 250W PV module from the SunPower Solar brand, characterized by an open circuit voltage V_{oc} of 50.93 V and short circuit current I_{sc} of 6.2 A, under diverse Partial Shading Conditions (PSCs). In photovoltaic (PV) arrays, various configurations are employed to optimize energy production and system reliability.

The series-parallel configuration entails linking solar panels in both series and parallel to optimize power output by balancing voltage and current. The bridge-linked configuration utilizes bridges to interconnect panels, enhancing overall system robustness and minimizing energy losses. The honeycomb configuration arranges solar modules in a hexagonal pattern, promoting the uniform distribution of sunlight and improving overall efficiency. The total cross-tied configuration connects every solar panel in the array to multiple inverters, providing redundancy and reducing the impact of shading or individual panel failures on the entire system. The configurations are shown in Fig. 2 alongside the CHP-reconfigured array.

The assessment covered four shading scenarios, each characterized by unique irradiance levels ranging from 250 W/m² to 1000 W/m². For a thorough assessment, the analysis incorporated four key metrics: quantifying Power Loss (PL), assessing Mismatch Loss (ML), identifying the Global Maximum Power Point (GMPP), and evaluating the Fill Factor (FF).

The simulations were meticulously executed using the MATLAB/Simulink framework, incorporating diverse insolation limitations while upholding a consistent temperature of 25°C. This rigorous evaluation offers valuable insights into the relative performance of CHP compared to other PV configurations under realistic shading scenarios.

A. Analysis of Shade Case 1

In the initial shading scenario, referred to as Shade Case 1 (SC1) or the short and narrow shading pattern, the 5×5 solar photovoltaic array experiences varying levels of solar irradiation. This variation is visually depicted in Fig. 4, showcasing the reconfigured PV array using the proposed Cyclic Heap Permutation (CHP) and illustrating the resultant dispersion of shading. The simulation results are presented in the P-V curve in Fig. 5, where CHP attains a peak power of 5512 watts in this shading scenario, surpassing the performance of all other configurations discussed. This exceeds the average peak power of the other four configurations by 10.3%. The PV array reconfigured using CHP demonstrates superior performance compared to alternative reconfiguration techniques in effectively mitigating the adverse effects of shading.

B. Analysis of Shade Case 2

In the second shading scenario (Shade Case 2), characterized by the short and wide shading pattern, the 5×5 solar PV array is exposed to varying solar irradiation levels. Fig. 6 illustrates the short wide shading pattern, the CHP-reconfigured PV array, and provides a visual representation of the dispersion of shading. In the P-V curve shown in Fig. 7, CHP outperforms other configurations, achieving a peak power of 4809 watts. On average, CHP achieved 30% higher

peak power compared to the other four configurations. This outcome emphasizes the effectiveness of CHP in addressing shading challenges associated with the Short Wide pattern.

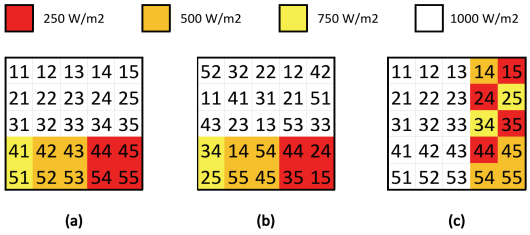

Fig. 6: Representation of Shade Case 2: (a) Shading pattern (b) Cyclic Heap Permutation (CHP) (c) Shade dispersion by CHP

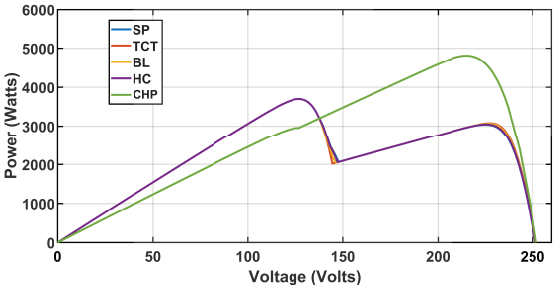

Fig. 7: Photovoltaic Performance Characteristics in the Presence of Shade Case 2

C. Analysis of Shade Case 3

In the third shading scenario (Shade Case 3), characterized as the long and wide shading pattern, the 5×5 solar PV array undergoes varying solar irradiation levels. Fig. 8 shows the long wide shading pattern along with the PV array reconfigured by CHP and the achieved effective shade dispersion. Upon examining the simulation results through the P-V curve in Fig. 9, CHP distinguishes itself by achieving a peak power of 3979 watts, surpassing the performance of

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 22,2024 at 05:57:23 UTC from IEEE Xplore. Restrictions apply.

alternative configurations. Notably, CHP's peak power exceeds the average peak power of the other four configurations by 12.11%, highlighting its adaptability in effectively addressing shading challenges associated with the Long Wide pattern.

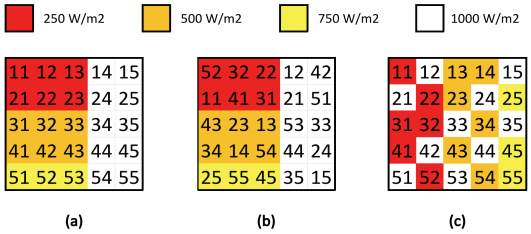

Fig. 8: Representation of Shade Case 3: (a) Shading pattern (b) Cyclic Heap Permutation (CHP) (c) Shade dispersion by CHP

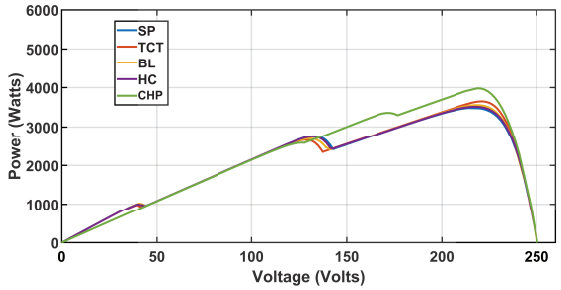

Fig. 9: Photovoltaic Performance Characteristics in the Presence of Shade Case 3

D. Analysis of Shade Case 4

In the Random Partial Shading Case (SC4), the 5×5 solar PV array encounters varied solar irradiation levels. Fig. 10 represents the shading pattern, the PV array reconfigured by CHP, and offers insights into the effective dispersion of shading. Analyzing simulation results through the P-V curve in Fig. 11, CHP once again exhibits superior performance with a peak power of 4552 watts, and an average peak power that surpasses the average peak power of the other four configurations by 32.21%, showcasing its versatility in mitigating the effects of randomly distributed shading.

E. GMPP and Power Loss

In contrast to alternative configurations, the proposed Cyclic Heap Permutation (CHP) consistently demonstrates the highest Global Maximum Power Point (GMPP) across all shading scenarios, as depicted in Fig. 12(a).

The Power Loss (PL) of the PV array is quantified by the equation:

$$PL(\%) = \frac{GMPP_{STC} - GMPP_{PSC}}{GMPP_{STC}} \times 100 \qquad (6)$$

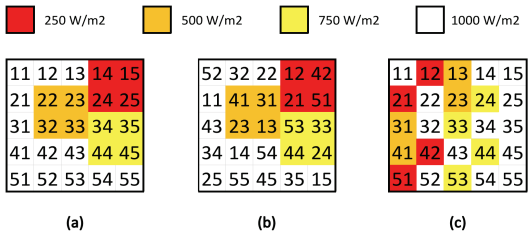

Fig. 10: Representation of Shade Case 4: (a) Shading pattern (b) Cyclic Heap Permutation (CHP) (c) Shade dispersion by CHP

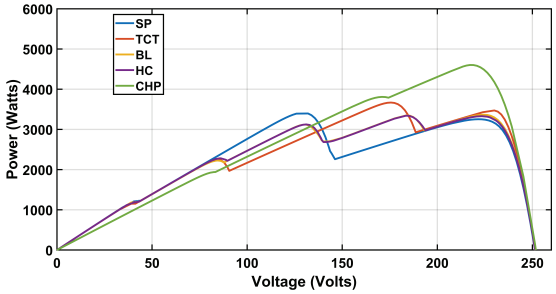

Fig. 11: Photovoltaic Performance Characteristics in the Presence of Shade Case 4

After computing and averaging the Power Loss across all shading scenarios, Table I shows that the Cyclic Heap Permutation technique proposed attains a Power Loss of 24.52%. In contrast, traditional configurations, including Bridge Link (BL) configuration, Honey Comb (HC) configuration, Series Parallel (SP) configuration, and Total-Cross-Tied (TCT) configuration, exhibit higher Power Loss values of 38.1%, 38.39%, 38.71%, and 35.6%, respectively. Fig. 12(b) depicts the comparison

F. Fill Factor and Mismatch Loss

The efficiency and performance of PV arrays are significantly impacted by critical parameters such as Fill Factor (FF) and Mismatch Loss (ML). These metrics are quantified as percentages and defined by the following equations, where $P_{max,k}$ is the maximum power that can be produced by individual modules in shading condition:

$$ML(\%) = \frac{\sum_{k=1}^{m\times n} P_{max,k} - GMPP_{PSC}}{\sum_{k=1}^{m\times n} P_{max,k}} \times 100 \qquad (7)$$

TABLE III: Fill Factor %

$$FF(\%) = \frac{P_{\text{max, PSC}}}{V_{\text{oc}} \times I_{\text{sc}}} \times 100 \tag{8}$$

Table II provides a comprehensive overview of the Mismatch Loss for all configurations under various shading scenarios. Notably, the proposed Cyclic Heap Permutation (CHP) technique demonstrates a substantial reduction in Mismatch Loss, averaging 3.36% whereas traditional configurations including Bridge Link (BL) configuration, Honey Comb (HC configuration), Series Parallel (SP) configuration, and Total-Cross-Tied (TCT) configuration exhibit higher mismatch losses of 20.79%, 21.19%, 21.56% and 17.64% respectively.

The outcomes, outlined in Table III, highlight the superior performance of the suggested CHP reconfiguration technique. On average, CHP exhibits an increment of 17.22%, 22.5%, 21.94%, and 23.16% in Fill Factor compared to TCT, HC, BL, and SP, respectively. This emphasizes the effectiveness of CHP in optimizing the array's power conversion capabilities. Fig. 12(c, d) shows the comparison of Fill Factor and Mismatch Loss in the PV configurations.

V. Conclusion

The superior performance of CHP is evident in both increased peak power output and a substantial decrease in power loss and mismatch losses, emphasizing its effectiveness in optimizing overall system performance. Additionally, the highlighted scalability of CHP enhances its practical applicability to PV systems of varying sizes, further solidifying its status as a promising and practical solution for addressing shading challenges in solar PV systems.

Abstract

A solid-core (SC) octagonal photonic crystal fiber (O-PCF) designed for operation in the terahertz regime aims to enhance its performance. The effective material loss, confinement loss, effective mode area, and nonlinear coefficient have been investigated and compared for two different media: silica glass and Teflon. The terahertz frequency range from 0.7 to 3.0 THz has been utilized to analyze all the results using a full-vectorial finite element method, with COMSOL Multiphysics software employed for the simulations. With a suitable selection of parameters, the proposed SC O-PCF demonstrates the potential to minimize losses and increase the effective mode area of the fundamental mode.

KEYWORDS

confinement loss, effective material loss, effective mode area, solid-core photonic crystal fiber, terahertz

1 | INTRODUCTION

Photonic crystal fibers (PCFs), also known as holey fibers, are made of a single material with numerous air holes in the cladding that remain periodically intact.[1] The low-index cladding around the core helps tune the dispersion slope and control confinement losses (CLs).[2] Regarding the guiding mechanism, PCFs are characterized in two ways: one has a solid core (SC) and a low index in the cladding region, which makes PCFs function like conventional fibers by guiding light through total internal reflection.[3,4] The other type is photonic band gap guidance PCF, equipped to control light guidance for any frequency band. PCFs find applications in various fields, such as PCF-based sensors, mid- and far-infrared guidance, terahertz guidance, and more.[5] The communication sector has recently evolved and undergone tremendous changes.[6] This recent transformation has brought about various applications in the terahertz (THz) region. On the electromagnetic spectrum, terahertz has a frequency range from 100 GHz to 10 THz, within which phonons, excitons, and cooper pairs are important material parameters that render the terahertz frequency a vital region.[7]

Unlike other terahertz PCFs, the benefit of the SC octagonal photonic crystal fiber (O-PCF) is that it allows operation in the fundamental mode, resulting in lower CL, a high effective mode area, and features of nonlinearity.[6] The design of O-PCF can be obtained by arranging air holes based on an isosceles triangle with a $\pi/4$ vertices angle. The arrangement of five rings can be formed, and by rotating the triangle at periods of $\pi/4$, $\pi/2$, $3\pi/4$, π, $5\pi/4$, $3\pi/2$, and $7\pi/4$, the octagonal design is achieved. If the number of rings in the cladding is decreased, radiation leakage from the core to the cladding will increase. Therefore, the rings are arranged in such a way that they can trap most of the radiation in the core and prevent any leakage into the cladding.[1] In this design, the finite element method (FEM) has been applied because, using this method, we can approach continuous functions as discrete models.[8]

In the existing PCF design, Dash et al.[9] reported on hexagonal PCF, in which at 1 THz, the CL, effective

 © 2024 Wiley Periodicals LLC.

mode area, and nonlinearity coefficient are 10^{-9}dB/cm, 5.62×10^{-6}m^2, and 3×10^{-8}rad/Wm, respectively. Kumar Paul et al.[10] reported effective material loss (EML), CL, and effective mode area of 6.6×10^{-2}/cm, 5.42×10^{-13}dB/cm, and 1.1×10^{-7}m^2, respectively. Moreover, in Islam et al.,[11] oligoporous-core (PC) PCF at 1 THz, CL, EML, and effective area are 7.24×10^{-7}/cm, 5.0×10^{-2}/cm, and 9.5×10^{-8}m^2, respectively. In 2019, Zhang et al.[12] proposed the porous core PCF. They evaluated EML, CL, and effective mode area of 0.08/cm, 3.2×10^{-13}/cm, and 1.20×10^{-7}m^2, respectively. Abdullah-Al-Shafi and Sen[13] suggested octagonal core PCF and calculated CL and effective mode area of 2.72×10^{-2}dB/m and 1.49×10^{-7}m^2, respectively. Sultana et al.[14] proposed the Zeonex-based PCF in the terahertz regime and observed EML, CL, and effective mode area as 0.05/cm, 7.79×10^{-12}/cm, and 2.0×10^{-7}m^2, respectively. Moreover, in 2020, Hossain and Sen[15] proposed optical chemical sensor-based PCF and culminated CL and effective mode area 2.70×10^{-6}dB/m and 1.25×10^{-7}m^2, respectively. The variation in the CL and EML, which is discussed above, is found to be several orders of magnitude. Such variation is expected due to novel designs presented causing tight confinement of light and less EML of background material.

In this paper, we have investigated the required parameters in the THz regime from 0.7 to 3 THz. We examined minimum losses and the maximum effective area for fused silica glass and Teflon materials. This paper is organized so that in Section 2, we introduce the geometrical structure of SC O-PCF and related parameters. Then in Section 3, required formulations are presented, and in Sections 4 and 5, numerical results and conclusions are reported.

2 | PROPOSED SC PCF DESIGN

Figure 1 illustrates the transverse cross-sectional view of the proposed SC O-PCF with the fundamental mode at 1 THz for *x*-polarization. The octagonal five-layer array of air holes is constructed in another material along the length of the fiber. In the cladding region, the air holes in the first, second, third, fourth, and fifth layers are 8, 16, 24, 32, and 40, respectively.

For comparison, two different media, namely, silica glass and Teflon, are utilized. In all five rings, the radius r remains constant. The distance between two air holes is the pitch Λ, and air filling fraction (AFF) is fixed at 0.5 which is calculated as

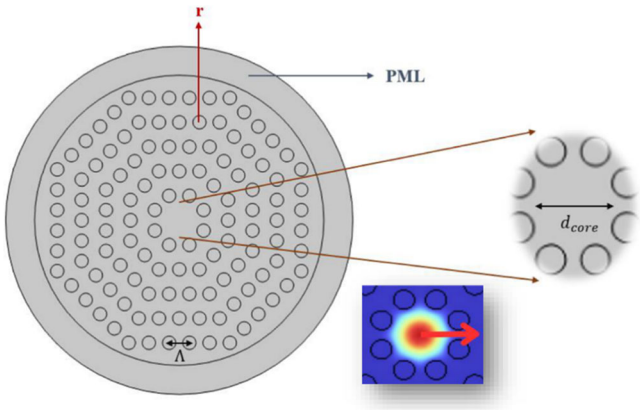

FIGURE 1 Proposed SC O-PCF with the fundamental mode at 1 THz for *x*-polarization. O-PCF, octagonal photonic crystal fiber; PML, perfectly matched layer; SC, solid core.

$$AFF = \frac{Diameter}{Pitch}. \tag{1}$$

The diameter of air holes and pitch remain constant throughout the simulation study. The perfectly matched layer (PML) is also employed to calculate the CL.

3 | FORMULATIONS

The COMSOL Multiphysics software, based on a full-vectorial FEM, evaluates the effective indices, CL, and nonlinear coefficient. Absorption loss or EML (α_{eff}) depicts the loss of the PCFs while operating at THz frequencies, and it can be calculated as[16]

$$\alpha_{eff} = \sqrt{\frac{\epsilon_0}{u_0}} \frac{\int_{mat} n_{mat}\alpha_{mat}|E|^2\,dA}{2\left|\int_{all} s_z\,dA\right|} \quad (\text{dB/cm}), \tag{2}$$

where α_{mat} is the material absorption loss, $\vec{s}_z = \frac{1}{2}(\vec{E} \times \vec{H})\hat{z}$ is the pointing vector of the z-component, here, E and H are electric and magnetic fields, n_{mat} is the effective refractive index of core material, and ϵ_o and μ_o are electric permittivity and magnetic permeability, respectively.

CL which is essential to find in terahertz applications of PCF, can be evaluated from the imaginary value of n_{eff} as

$$\begin{aligned} L\ (\text{dB/cm}) &= \frac{40\pi}{\ln(10)\lambda} Im(n_{eff}) \times 10^{-2} \\ &= 8.686 k_0 Im(n_{eff}) \times 10^{-2}, \end{aligned} \tag{3}$$

10982760, 2024, 5, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/mop.34173 by Delhi Technological University, Wiley Online Library on [09/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

where $Im(n_{eff})$ is the imaginary part of the effective mode index of that mode. And $k_0 = \frac{2\pi}{\lambda}; \lambda$ is the operating wavelength of light in meters.[17]

In high-power transmission, PCFs with a large effective mode area are used. This characteristic also suppresses the unwanted nonlinear effects. A greater effective mode area will give lesser nonlinear effects and vice versa. It is calculated using[18]

$$A_{eff} = \frac{\left[\int I(r)\,dr\right]^2}{\left[\int I^2(r)\,dr\right]}, \tag{4}$$

where $I(r) = [E(t)]^2$ is the amplitude of the transverse electric field propagating through the fiber.

The nonlinear coefficient defines the interaction of the nonlinearity of light with an optical material. It can be found by

$$\gamma = \left(\frac{2\pi}{\lambda}\right)\left(\frac{n_2}{A_{eff}}\right), \tag{5}$$

where n_2 is the nonlinear refractive index of the material.[19]

4 | NUMERICAL RESULTS

We have investigated the EML, CL, effective mode area, and nonlinear coefficient using a full-vectorial FEM in the given structure. To correlate, fused silica and Teflon of refractive indices 1.45 and 1.38, respectively, have been used.

Initially, we have chosen the fixed structural parameters, $r = 0.95\,\text{mm}$, $\Lambda = 1.9\,\text{mm}$, or $AFF = 0.5$, $cladding = 10.4\,\text{mm}$, and outer layer 20% of cladding as PML. The fundamental modes at 1 THz frequency are observed for fused silica and Teflon, which are 1.44 and 1.37, respectively. Figure 1 (inset) shows the contour plot of the field intensity of one of the fundamental modes at 1 THz.

Figure 2 shows the variation in the EML for increasing frequency when the core-cladding media is set to fused silica. The integration of the numerator of Equation (2) is performed only over the solid material region, which indents EML as a function of frequency. The loss is reported as low as 2.07×10^{-2}/cm at 0.7 THz of frequency and reached as high as 2.08×10^{-2}/cm at 3 THz. The loss in material is reaching the value of bulk material absorption loss (α_{eff}) of silica glass.

In Figure 3, the comparison of CL between silica glass and Teflon is depicted. CL is directly dependent on the frequency, and it is clarified that at a lower frequency of

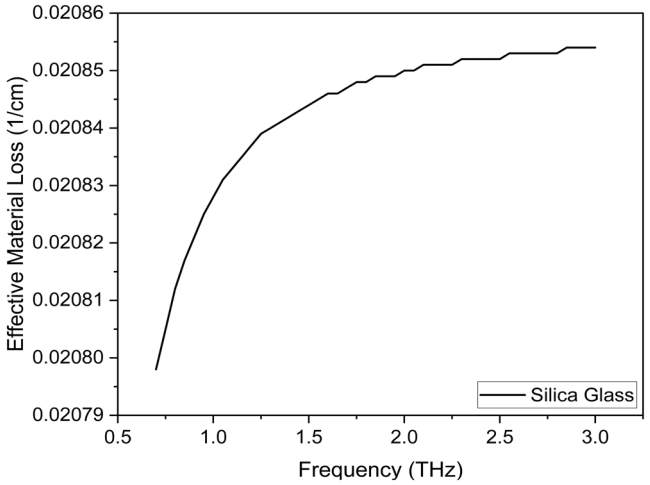

FIGURE 2 Variation of effective material loss with frequency.

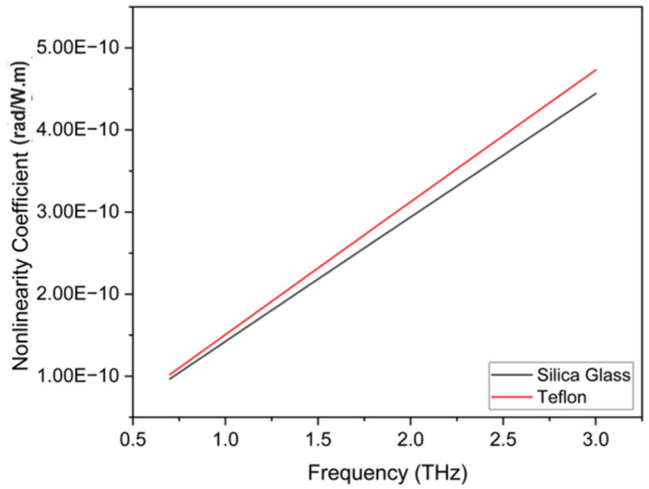

FIGURE 5 Variation of γ with frequency (silica glass and Teflon).

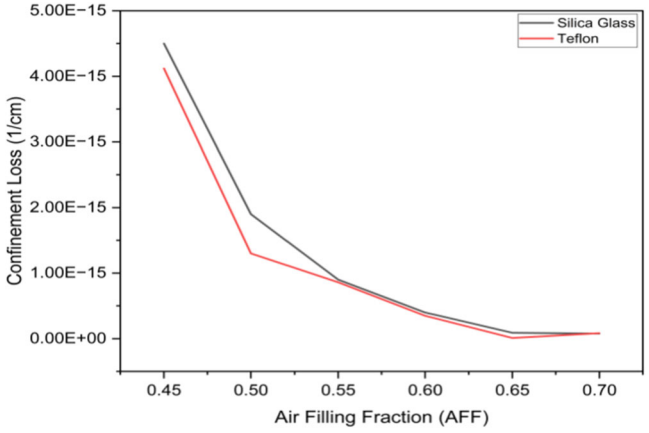

FIGURE 6 Variation of confinement loss with air filling fraction (silica glass and Teflon).

0.7 THz, it approximates 10^{-15}/cm. Subsequently, it decreases to 10^{-17}/cm for both materials in the fundamental mode. However, Teflon exhibits slightly better reliability in containing the light within the core at 1 THz frequency. This change in behavior can be attributed to a tightly packed core that prevents radiation from leaking.[20]

We have observed a significant order change between EML and CL. This behavior is primarily attributed to the core material's properties. In the case of EML, low values signify less bulk material absorption (α_{eff}) of radiation. This differs from CL, which is mainly govern by the confinement and leakage of radiation within the designed fiber.[21]

In Figure 4, large effective mode areas are obtained for lower frequencies in fundamental modes; however, it gradually decreases with an increase in frequency. Teflon shows a large effective mode area within the range [0.7, 3.0] THz among both materials. The reason for these variations is radiation confinement in the core at higher frequencies.

Theoretically, a low nonlinear coefficient will be obtained with a larger effective mode area. Figure 5 proves the theory; at lower frequencies, nonlinear coefficients are as low as 10^{-10} rad/Wm for both media, and it keeps increasing with an increase in frequency. Yet Teflon is the most effective compared to silica glass because of its high value of the nonlinear refractive index, which is 3.2×10^{-6} rad/Wm. In Figure 6, we have examined the variation in CL of silica glass and Teflon material with AFF. These findings indicate that increasing the AFF value results in lower CL within the proposed PCF. A higher AFF value brings the number of rings and air holes closer to each other, causing most of the radiation to trap within the core of the fiber and

Abbreviations: EML, effective material loss; O-PCF, octagonal photonic crystal fiber; SC, solid core.

10982760, 2024, 5, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/mop.34173 by Delhi Technological University, Wiley Online Library on [09/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

consequently reducing the CL. Specifically, it shows a decrease in CL from 4.5×10^{-15} to 7.8×10^{-17}/cm in silica glass and 4.12×10^{-15} to 8.3×10^{-17}/cm in Teflon as the AFF value increased from 0.45 to 0.7.

Table 1 compares previous results[9–15] and determined results of SC O-PCF in this paper. The proposed design shows better results in comparison to other existing models.

5 | CONCLUSION

In the proposed O-PCF, we have improved the required factors by changing the AFF in the cladding region. Making all five rings uniform plays a vital role and using materials like silica glass and Teflon reported low EML and CL due to their low material absorption loss. This paper obtains the fundamental mode of fused silica and Teflon at 1.44 and 1.37.

Both materials can reduce EML up to 2.08×10^{-2}/cm for fused silica 2.99×10^{-2}/cm for Teflon. Moreover, CLs are reduced from up to ~10^{-17}/cm for both the materials at larger frequency with the proposed design. This design will be helpful in several applications, such as telecommunication, spectroscopy, sensing, and so forth.

Delhi Technological University, Delhi, India

ABSTRACT

There is an increase in demand for cost effective and reliable launch vehicles. The commonly used and simplified vehicles are Two-Stage to Orbit (TSTO) launch vehicles which are opted for their relatively simpler design with respect to higher stage vehicles. The aim of this paper is to understand the significance and conceptual designing of a TSTO launch vehicle by studying various design parameters relating to gravity turn trajectory using a MATLAB model capable of creating a 2D simplified trajectory of the vehicle using the constraints of design and different design inputs. The designed TSTO of our consideration uses a liquid propellant engine for both the stages which has an advantage of reusability and easy manufacturing.

Keywords: Complexity, Design, Launch Vehicle, MATLAB, Physics, Reusability, Two Stage to Orbit (TSTO)

Singh, Designing of A Two Stage to Orbit Launch Vehicle, International Journal of Advanced Research in Engineering and Technology (IJARET), 14(3), 2023, pp. 1-13. https://iaeme.com/Home/issue/IJARET?Volume=14&Issue=3

1. INTRODUCTION

A TSTO launch vehicle is a type of rocket that uses two different stages in its trajectory to inject the payload into the desired orbit. In the first stage, the rocket is lifted to the atmospheric phase and the second stage, in which the uppermost stage of the vehicle is powered up with the help of its vacuum optimized engine, to inject the payload into orbit without carrying the dry mass of the first stage to space [1]. The advantage of having a two-stage launch vehicle is having lesser complexity compared to other multi-stage rockets as the minimum number of separation events minimizes the complexity, cost and risk of failure. Single stage to orbit vehicles could've been great for reusability, but they haven't been flown to orbit, so the next best option is having a two-stage vehicle.

A Reusable Launch Vehicle (RLV) is one which can have its parts recovered after flying on a space mission and reflown for the next mission. Rocket stages, boosters, or the spacecraft on top of the vehicle are the ones that are being reused, which makes it easier for the company to not constantly manufacture the same component for each launch. This reduces the cost of manufacturing, however, there is still the cost of recovery and refurbishments which is less compared to manufacturing.[2] Most common concept of RLV utilizes liquid propellant rocket engine, for its throttling capabilities.

There has been a significant rise in the number of rockets launches which led to a highly competitive market. Various space agencies have made their rockets and eventually, it has been realized that the best way to dominate this market is by having a low cost per kg of payload for orbital launch vehicles. This can be successfully achieved not just by having high performance but also the rocket can be manufactured with ease and they can be made partially reusable.

There has been a significant number of launch vehicles that employ two stages only, however, only a few are even partially reusable. Single stage to Orbit can be used in case of full reusability but as they consume more fuel they are not used. Dividing the rocket into multiple stages, each of which can be optimized to enhance performance leads to overall improved performance and a reduction in losses. Different engines can be used depending on external conditions, improving efficiency. When building multistage rockets, optimization of elements like mass distribution among stages, appropriate engine size, and propellant quantity are crucial. In this paper, we will study the Two Stage To Orbit Launch Vehicle physics and their basic conceptual designing.

2. LITERATURE REVIEW

M. A. Sharaf and L.A. Alaqal [3], and David W. Callaway [4] worked on basic gravity turn maneuver equations for the vehicle trajectory and created various results to understand the relations between various parameters. Their work has been used to understand the ascent trajectory based on gravity turn.

David Yaylalia developed simplified model to study the gravity turn maneuver in both 2D and 3D plane assuming Earth to be spherical and non-rotating.[5]

Dr Gerald M Gregorek calculated the drag force acting on the vehicle. Every component produces different values of drag for different types of drag. Due to complexity of certain type of drag, the value of drag coefficient was assumed constant for the conceptual designing phase.[6]

L. Brevault , M. Balesdent et.al: have developed dual-orbital two-stage rockets using the SABER air-breathing rocket engine and the LOx/CH4 rocket engine (for the second stage) to inject a 15-tonne payload into the Low Earth Orbit (LEO). They ran various simulations of the rocket's trajectory compiling it with various systems of the vehicle. In this work, the main focus was on the rocket trajectory.[7]

Ankit Kumar Mishra, Kshtij Gandhi et.al did an overview of a two-stage sounding rocket in their work. They emphasize the importance of multi staging and various important design parameters. The model of vehicle was developed in Open Rocket and engine was designed using Rocket Propulsion Analysis (RPA) software, which were latter analyzed in ANSYS Fluent using appropriate model of physics.[1]

Christie Alisa Maddock , Lorenzo Ricciardi et.al: have described the conceptual design and performance analysis of a partially reusable rocket for small payloads. The system was designed for a nominal mission of placing a 500 kg payload in a 600 km circular orbit with a polar orbit of 88.2 degrees. The goal of the system design was to develop an economically viable launch system with a short period of operation.

Therefore, the emphasis is on the efficient use of advanced Technology Readiness Level (TRL) technology and details on various parameters to consider when designing a spacecraft was also discussed.[9]

Byeong-Un Jo, Jaemyung Ahn have used a new method to calculate and minimize the total cost of reusable vehicles over their entire lifecycle using integrated optimization modules and cost model. The validity and effectiveness of the proposed algorithm are demonstrated through a case study on an optimal staging environment using a real reusable vehicle (Falcon 9). Case study results demonstrate that the minimum lift-off configuration achievable by conventional stage optimization does not necessarily result in the lowest life-cycle cost, justifying the usefulness of the proposed approach.[10]

3. DESIGN AND METHODOLOGIES USED

The methodology used to bring out the results was using software MATLAB for generating the results of the input equations and variable parameters and generating graphs for various dependable variables. MATLAB code was constructed with the equations and variables that need to be used to design a launch vehicle trajectory and various parameters that have a key role were used to study the physics and conceptual design of a launch vehicle. Certain key points which were needed to design the launch vehicle were Weight Distribution, Thrust parameter, Gravity Turn, and Vehicle design.

In weight distribution, we have to study the weight of the launch vehicle and optimize it in such a manner that maximum payload capacity can be achieved. Weight distribution was divided into three stages. Stage one where the structure mass and propellant mass were taken into account before the separation stage. Stage two where the structure mass and propellant mass were taken after the separation stage and the third stage was the payload meant to be injected into the orbit.

3.1. Phase of Flight

Initially, the vehicle is launched vertically from the launchpad. However, it is essential to have the vehicle inclined parallel to the local horizon. The vehicle must remain completely vertical for the initial seconds while it is still over the launchpad [11]. Once the vehicle has cleared off from the launch pad, the vehicle can initiate the gravity turn maneuver by providing a pitch kick at a specified altitude which makes the initially vertical vehicle, now inclined with some angle from vertical reference. The altitude at which the pitch kick is given and the angle at which it is given can be considered as design parameters.

This maneuver does not use the thrust of the vehicle but gravity to steer it onto its desired trajectory. Thrust is entirely used to accelerate the vehicle.

Primarily the thrust vector always points towards the direction of the velocity vector so that maximum acceleration is achieved by the rocket. Therefore, the vehicle has a very small or negligible angle of attack (hence this maneuver is also known as ‘zero lift trajectory’) that minimizes transverse aerodynamic stresses acting on the vehicle [3]. Thus, we can have lesser structure weight to improve performance.

Now due to gravity the rocket slightly rotates its orientation from vertical to horizontal. So along with the initial rest conditions of the vehicle at $t = 0$, in a gravity turn, we also have to decide two initial parameters mainly, the altitude at which gravity turns start and the angle given with respect to vertical at the start of maneuver. [5]

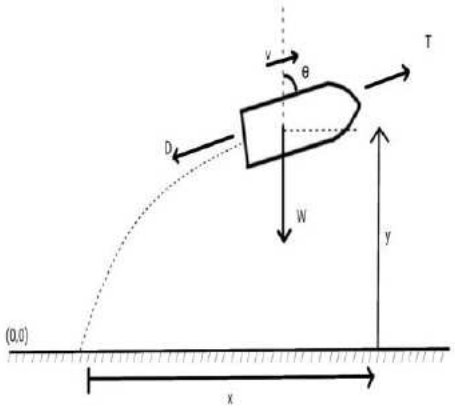

Fig: 1. Representation of parameters during gravity turn trajectory

$$\frac{dv}{dt} = \left(T - \frac{1}{2}\,\rho V^2 S C C_D\right)\frac{1}{m} - g\cos\theta \quad (1)$$

Equation (2) depicts the turn rate of the vehicle as it turns from vertical to horizontal inclination.

$$\frac{d\theta}{dt} = \frac{g\sin\theta}{V} \quad (2)$$

Equations (3) and (4) tell the velocity along horizontal and vertical direction which can provide the altitude and downrange of the vehicle at every instant.

$$\frac{dh}{dt} = v\cos\theta \quad (3)$$

$$\frac{dx}{dt} = v\sin\theta \quad (4)$$

Reduction of mass of vehicle due to propellant flow rate can be depicted in equation (5).

$$\frac{dm}{dt} = -\dot{m} * n_{engine} \quad (5)$$

h = Altitude; x = Downrange; v = velocity; m = Mass of vehicle; θ = Angle w.r.t vertical;

T = Thrust; D = Drag; g = Acceleration due to gravity; (All the parameters are at that instantaneous altitude)

ṁ = Mass flow rate from single engine;

n_{engine} = Number of engines used in the stage

After reaching a certain point during the gravity turn, the propellant in the first stage exhausts. After this, stage separation happens which removes the first stage from the vehicle and the second stage engine fires up which further pushes the payload. The altitude for stage separation should be optimally decided such that vacuum engines take the charge of operation before the sea level engine gets any more inefficient. The second stage engine which is optimized for vacuum-level performance starts operating and it will align the vehicle parallel to the local horizon. The vehicle after reaching the orbit might not necessarily have the required orbital speed to remain in the circular orbit. Thus, the vehicle is further accelerated at the fixed altitude to reach the required orbital speed.

3.2. Vehicle Dimension

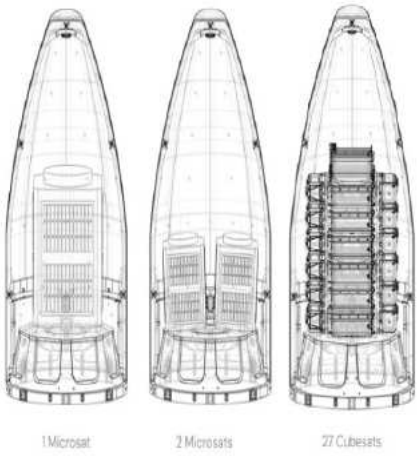

Fig: 2. Electron Rocket, Payload Configurations; Capability to put 300 kg to LEO [13]

In vehicle design, the radius of the vehicle is taken into consideration as it is important for drag calculation and the frontal area. While deciding the radius of the rockets we need to specify the payload that the vehicle has to carry with proper mounting options. The size of the payload and its weight will put constraints on the radius and payload capacity of the vehicle. The majority portion of length of vehicle can be simply obtained by converting the mass of propellants into volume

3.5. Modeling atmospheric and Gravitational effects

Various equations and assumptions we have taken to understand the conceptual design of the launch vehicle where drag is constant as 0.75. For modeling the effect of gravity, we consider Earth, spherically symmetrical and use the inverse square gravity method. [11,14]

$$\overline{Fg} = -\mu * \frac{\bar{R}}{||R^3||} \tag{6}$$

where $\mu = 3.986005 * 10^4$

For modeling the atmosphere, we used the International Standard Atmosphere (ISA). For the isothermal layer of the atmosphere, we use equations (7) & (8): [15,16]

$$\frac{P_1}{P_2} = e^{-(\frac{g_\circ}{RT})(h_2 - h_1)} \tag{7}$$

$$\frac{\rho_1}{\rho_2} = e^{-(\frac{g_\circ}{RT})(h_2 - h_1)} \tag{8}$$

For the gradient layer of the atmosphere, we use the following formulas, equations (9) & (10):

$$\frac{P}{P_1} = \left(\frac{T}{T_1}\right)^{-\left(\frac{g_\circ}{LR}\right)} \tag{9}$$

$$\frac{\rho}{\rho_1} = \left(\frac{T}{T_1}\right)^{-\left(\frac{g_\circ}{LR}+1\right)} \tag{10}$$

Were,

L = Lapse rate for the corresponding layer

g_0 = Acceleration due to gravity at ground level

R = Gas Constant

P_1, T_1, ρ_1= Pressure, Temperature, Density at the initial point of any gradient layer

3.4. Engine Parameters

For modeling the value of thrust generated by an engine, we use the basic thrust equation (11),

$$F = mv_e + (p_e - p_a)A_e \quad (11)$$

were,

P_e = Pressure at the exit of the nozzle

P_a = Pressure of the atmosphere immediately outside the nozzle

A_e = Nozzle exit area

This can be converted into another useful quantity called specific impulse. The specific impulse (I_{sp}) is the ratio of the thrust produced to the weight flow of the propellants which is used to measure the fuel efficiency of a rocket engine. [15,17]

$$I_{sp} = \frac{F}{\dot{m}g_\circ} \quad (12)$$

A rocket nozzle has optimum performance for the altitude where the exit pressure of the nozzle is equal to ambient pressure. However, since the vehicle has to ascend upwards, ambient pressure will keep reducing and thus the performance will vary with altitude. The nozzle will be designed to have optimum performance at a specific altitude and for the remaining altitude, we'll have to deal with the under-expansion of flow, which happens when ambient pressure is lower than exit pressure, and overexpansion of flow, where the ambient pressure is higher than exit pressure. The inefficiency of the nozzle is directly related to the difference between ambient and exit pressure. To have optimum performance for very low ambient pressure, we require a relatively large nozzle.

Since we have a two-stage launch vehicle, the lower-stage engines, which are referred to as sea-level engines, will have nozzles optimized for larger ambient pressure in comparison to the ones placed on the upper stage, referred to as vacuum-level engines since they operate predominantly in vacuum environments. In order to save research costs and reduce manufacturing processes, both sea level and vacuum engines are of the same design, except for the diverging section of the nozzle.

To have the engine operate optimally at a different ambient pressure, only the diverging section of the nozzle has to be changed as the dimensions of the combustion chamber and converging section are entirely similar. Sea-level engines have a small exit area, so a cluster of them can be placed but the vacuum engines are optimized for such small pressure, we cannot place the same number of engines in the upper stage. Having a multi-engine configuration and similar configuration of sea level and vacuum engine, except for a few changes due to the diverging portion, we can employ mass production of components. [18] In earlier times, larger and lesser engines were manufactured as even a single engine failure will lead to the failure of the entire mission. However, with the use of highly sophisticated computers, we can have multiple smaller engines on vehicles. Even if an engine fails, it'll be deactivated in time to safeguard the mission. Having multiple smaller engines is highly beneficial for low manufacturing costs. The specifications used in SpaceX's Falcon 9 vehicle which has 9 Merlin 1D sea level engines in octa-web arrangement and 1 Merlin 1D vacuum adapted engine. Single vacuum engine has a size comparable to that of 9 sea level engines combined.[19]

3.5. Physical Classification

To understand the effect of parameters, mission requirement is considered to deliver CubeSats of a total weight of 300 kg to 250 km. Based on the mission requirement, the diameter of the vehicle can be estimated to be 1.2 m by appropriately understanding the placement of CubeSats.

The vehicle has 2 stages and the following are the parameters set for both stages in table 1:

Table 1: Values of parameters at first stage and second stage

Parameter	First Stage	Second Stage
Structural Mass [ton]	0.9	0.3
Propellant Mass [ton]	10	2
Number of Engine	9(All sea-level engine)	1(Vacuum engine)

We consider the altitude for which pitch over maneuver initiates as 2 km and the angle provided by pitch kick as 10.2°. Till the altitude of 2 km, the vehicle accelerates upward vertically. At 2 km, a pitch kick is given to the vehicle which makes the vehicle's angle with the vertical reference line as 10.2°. This initiates the gravity turn maneuver.

The first stage has 9 sea-level engines which we can arrange in octagon arrangement. These engines are optimized for ambient pressure of 0.4 atm based on the Summerfield criterion. The vacuum engine cannot be entirely optimized for vacuum-level operation as the exit area would be significantly high [1]. Thus, we constrain the exit diameter of the vacuum level engine lower than the entire vehicle diameter and let there be slight losses due to under-expansion of flow. [20]

Using RPA software, the following parameters of engines were finalized in table 2. Since the combustion chamber assembly for both Sea-level and vacuum-optimized engines is the same, few parameters are the same. We consider the chamber pressure to be 7 MPa, the mass flow rate as 8 kg/s, and the propellant to be RP-1 + LOX. Due to the different diverging portions of both types of engines, the following parameters are separate for sea-level and vacuum-optimized engines.

Table 2: Values of different parameters obtained for sea level engine and vacuum engine

Engine Parameter	Sea Level Engine	Vacuum Engine
Thrust [kN]	24.23173	28.40706
Specific Impulse [s]	308.86886	362.08926
Exit Pressure [atm]	0.4	0.015
Exit Diameter [cm]	23.449	90.087
Exit Area [m^2]	0.0432	0.6374

4. RESULTS AND DISCUSSION

We consider the payload mass to be a part of the propellant weight in the code. Here the payload mass is targeted to be as 300kg and the propellant weight in the second stage is 2000kg, the total propellant weight as 2300 kg which the vehicle can consume till the second stage engine cut-off.

Table 3: Values of various parameters during various phases of flight

Important Phases of Flight	Time[s]	Altitude [km]	Ground Range [km]	Velocity [m/s]	Mass [kg]	Angle [degrees]
Lift-Off	0	0	0	0	13500	0
Pitch Kick	27.38	2	0	156.57	11528.64	10.2
First Stage Cut-Off	138.89	74.59	94.07	2975.91	2600	62.09
Stage Separation	138.89	74.59	94.07	2975.91	2600	62.09
Second Stage Ignites	138.89	74.59	94.07	2975.91	2600	62.09
Orbit Reached	368.81	254.51	1096.42	7041.5	760.64	90
Second Stage Cut-Off	385.54	254.51	1219.98	7752.11	626.8	90

As per the table 3, stage separation occurs at the altitude of 74.6 km, after which the vehicle attains an orbit at 254.5 km by getting parallel to the local horizon. The velocity at that point is lower than the orbital speed for that altitude by 710.6 m/s. Thus, it uses 133.84 kg of propellant further in order to attain the orbital velocity which will allow the vehicle to maintain that altitude. Figure 3 shows the entire trajectory of the vehicle and also highlights various important phases of flight.

In figure 4(right), showing variation of entire mass of vehicle at every instant, it is shown that after 385.5 seconds, the second stage vacuum engine shuts down, and the net weight of the vehicle is 626.8 kg and by removing the structural weight, the remaining weight becomes 326.8 kg which can be considered as the payload capacity to this altitude. In Figure 4 (left) shows the variation of all the 3 forces acting on the vehicle. It can be seen that the effect of gravity is always more significant than drag force. The drag force which initially increases due to increase of velocity, later starts declining due to lowering density at higher altitudes. Gravitational force is primarily reducing due to reducing weight. Thrust force sees a significant drop after stage separation due to the decrease of number of engines.

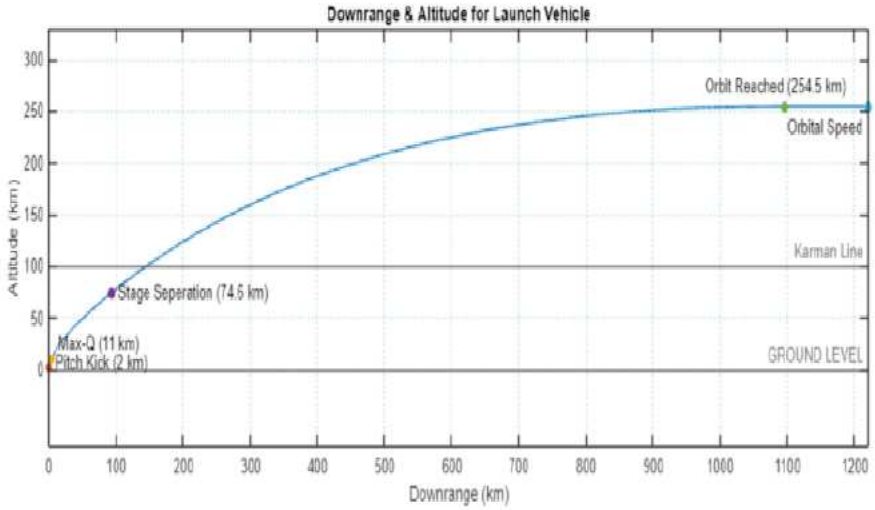

Fig: 3. Altitude vs Downrange (km)

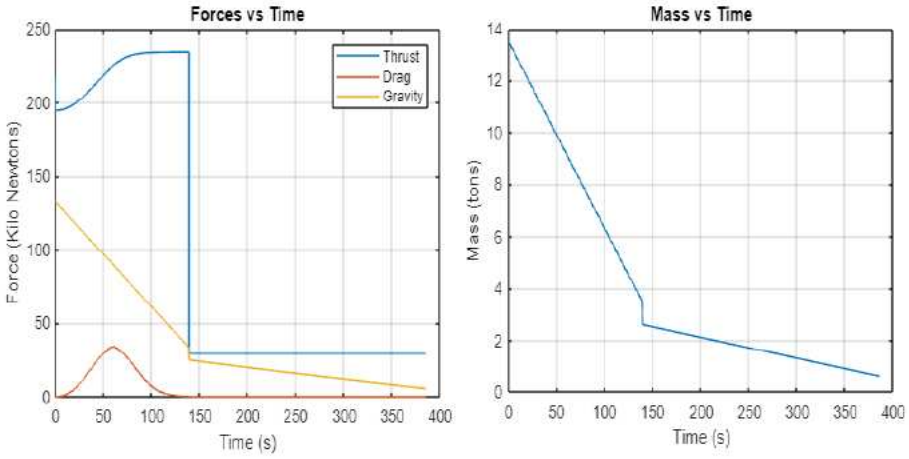

Fig: 4. Variation of forces acting on vehicle wrt time; Mass of vehicle wrt time

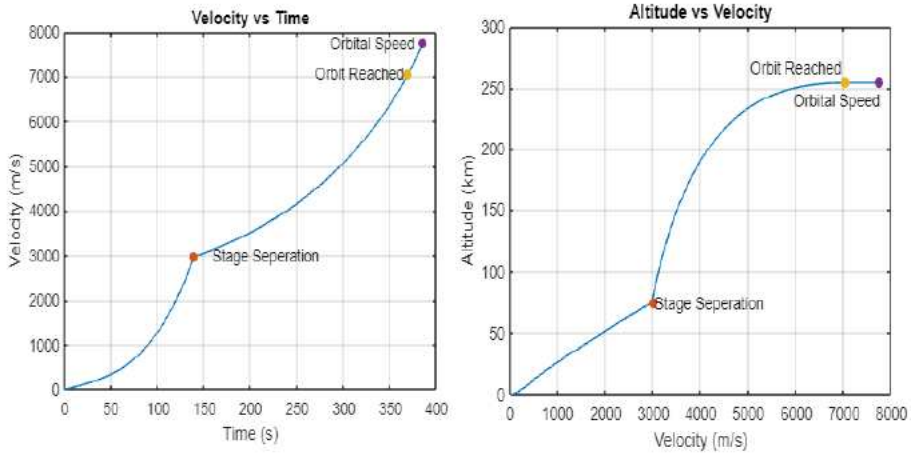

Fig: 5. Variation of velocity wrt time; Altitude achieved wrt velocity

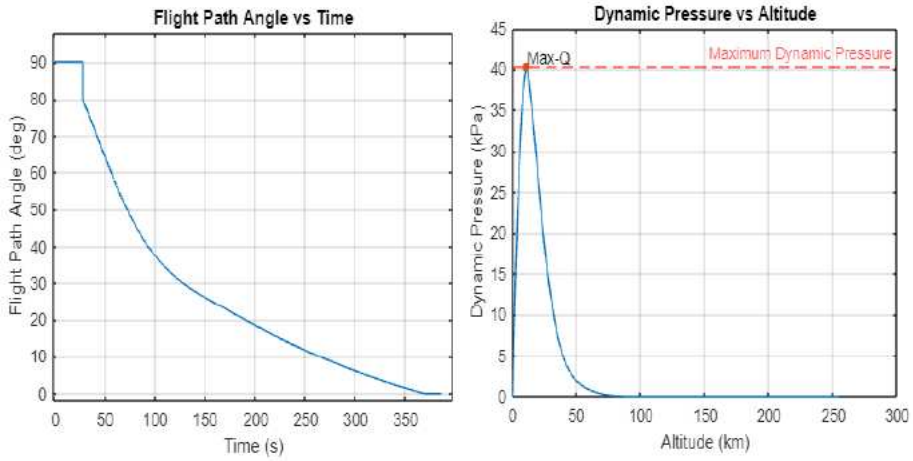

Fig: 6. Flight Path Angle vs Time; Dynamic Pressure vs Altitude

The altitude at which gravity turn initiates and the angle which is given to the vehicle with respect to vertical influences the end state of the vehicle. If the gravity turn is initiated at a higher altitude, more angle should be given to get a similar result. For example, in the table below, 2 combinations of altitude and angle were selected with comparable results.

In figure 5, variation of velocity of the vehicle has been shown with respect to the time (left) and altitude (right). In figure 6 (left), the flight path angle is 90° during the vertical lift-off phase but when pitch kick is given, it sees an instantaneous drop by a specified value. After this drop, the vehicle starts its gravity turn and reaches the value of 0° indicating that the vehicle is parallel to the local horizon.

The Max-Q point, in figure 6 (right) is attained at the altitude of 11 km which represents the phase where the vehicle experiences maximum dynamic pressure. The value of dynamic pressure for the current configuration is 40.373 kN which is very important in the design phase for structural strength and reliability of payload fairing during the first part of the trajectory.

The graph (figure 7) tells that if the angle given at pitch kick is less, while the altitude is constant, the turning of the vehicle be slower which leads to stage separation happening at a relatively higher altitude and allowing the vehicle to reach a higher orbit, though it uses relatively more fuel to reach an orbit and maintain an orbital speed. If we wish to start the pitch kick maneuver at higher altitude, the kick angle would have to be larger in value. A simple example has been highlighted in table 4 which shows that if the maneuver is initiated at 1.5 km, kick angle needed is 9.8^o to match the results of case where altitude to initiate is 1 km and angle taken as 7°.

The following plots have been created using the code which gives a deep insight into the variation of parameters during the entire phase of launch.

From these results, we can safely conclude that even if the altitude or time of pitch kick is decided arbitrarily, we can estimate the value of pitch kick accordingly depending on the final requirements of the mission.

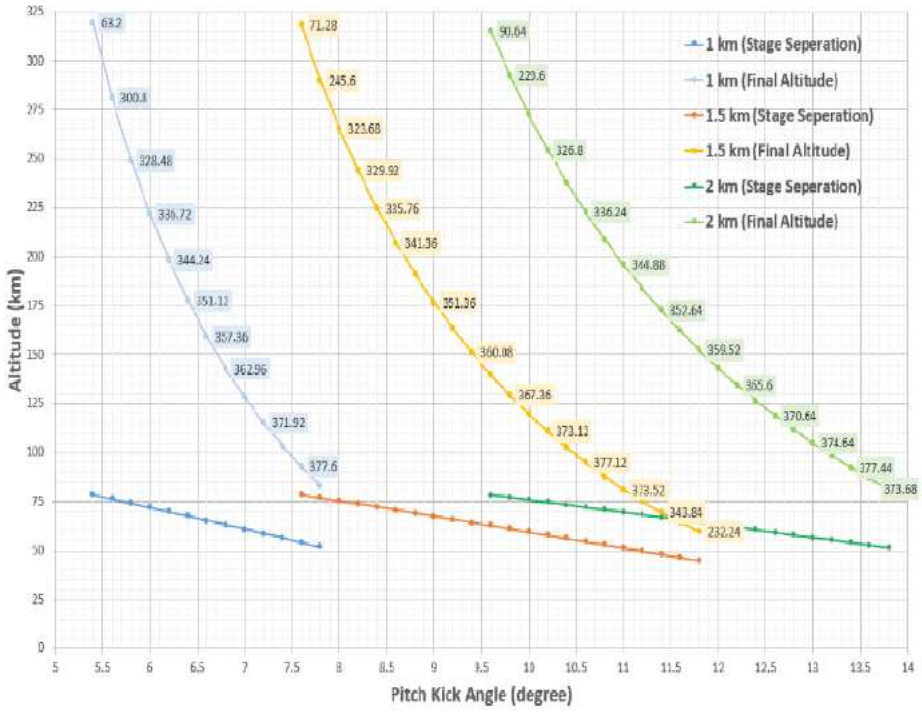

Fig: 7. Study of gravity turn parameters on the altitude of stage separation and final altitude. (Data labels correspond to the final payload mass in kg)

Table 4: Values for 2 combinations of kick angle & pitch kick altitude

Altitude for Pitch Kick [km]	Pitch Kick Angle [degrees]	Stage Separation Altitude [km]	Final Orbit Altitude [km]	Final Payload Mass [kg]
1	7	60.979	128.19	367.84
1.5	9.8	60.973	129.34	367.36

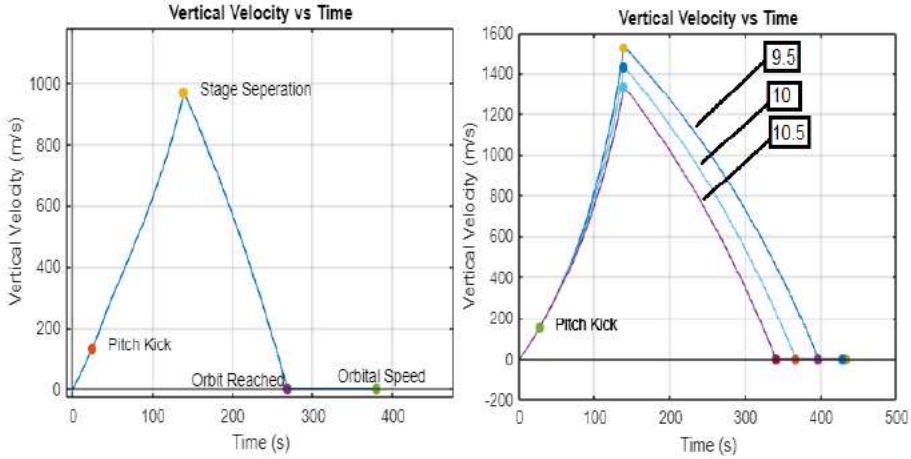

Fig: 8. Vertical Velocity vs time; Effect on change of pitch kick angle

Another parameter that we can see is vertical velocity variation with time (figure 8) which is sensitive to the kick angle. The vertical velocity increases till the sea level engine operates, and after reaching the peak, which is determined by kick angle, the value starts descending. If we create a plot for 3 different pitch kick angles, the plots are coincident till the pitch kick is reached (as for this study, the altitude for the pitch kick is the same). If the pitch angle is higher, the peak of the plot gets lower. [21]

5. CONCLUSION

In the above study we have designed the TSTO launch vehicle operating with a liquid propellant rocket engine, and the key equations which need to be kept in check while designing a vehicle. Relation between equations and various parameters were studied which plays a crucial role in deciding the design and weight of a rocket to inject a payload to desired orbit.

The paper considers various parameters and showcases their relation under a gravity turn maneuver. Important design aspects related to sea level and vacuum engines were also seen during the study and the values obtained using RPA software, were used in the MATLAB code to obtain a trajectory for the vehicle. The effect of gravity turns on the rocket with respect to the pitch kick angle and the altitude at which it is initiated was studied in the paper.

FUTURE SCOPE

The current model uses gravity turn trajectory throughout the flight for a stationary atmosphere and no effect of Earth's rotation. After testing gravity turn trajectory, we will see possibilities of using other trajectories, especially for the free-flight phase and also draw their comparison with the existing model. After understanding the basics of the parameters, the model will be further expanded to incorporate the effects of Earth's rotation, wind model, inefficiencies, optimum staging, stage separation. Another important aspect of designing any launch vehicle is to have a detailed understanding of engine design, specifically what parameters are varied while shifting from sea level engine to vacuum level engines.

***Abstract*—Pulsed Doppler radars are commonly used in military applications, especially in aircraft and missile systems, as they are able to detect and track fast-moving targets, such as enemy aircraft, while filtering out ground clutter and slower-moving objects. Classification of modulation types in airborne radar signals is essential for ensuring efficient and reliable communication, target identification, and interference rejection. This research paper presents a comprehensive study on modulation classification techniques for radar signals on an airborne module. The transmitter identity message signal is coded with pseudo-random noise codes and modulated using five modulations, namely, BASK, BFSK, BPSK, QAM and QPSK. Additionally, it is also subjected to Additive White Gaussian Noise(AWGN) and Rayleigh distribution for multipath fading in wireless transmission environments. The paper proposes a modulation recognition scheme based on multi-class classification, hierarchical feature extraction using a convolutional neural network (CNN) and residual neural network (ResNet50) architecture. The simulated result indicates that the proposed method demonstrates adaptability to modulational recognition even in low Signal-to-Noise Ratio (SNR) environments.**

***Index Terms*—Signal Detection, Modulation Classification, Continuous Wavelet Transform (CWT), Convolutional Neural Networks (CNN), Residual Neural Network, Deep Learning**

I. Introduction

Pulse Doppler radars are essential for accurately monitoring the movement and position of objects in both civilian and military domains. Radar waveform recognition is vital function required in electronic warfare systems, such as electronic intelligence (ES/ELINT), electronic protection (EP), and electronic attack (EA) systems. Pulse Doppler radar systems are designed to minimise the risk of detection by employing techniques such as low-power transmissions and frequency spread. This is particularly crucial for surveillance and reconnaissance missions where maintaining stealth is of utmost importance.

In this paper, we conduct an extensive review of the latest advancements in deep learning techniques applied to modulation recognition of pulsed Doppler radars. We begin by examining conventional methods employed in this area and subsequently delve into diverse deep-learning approaches proposed for this task. In [1], the authors used a multi-resolution convolutional neural network (CNN), feature fusion with 128x128 inputs, obtaining a recognition rate of 95.2% at SNR of -8 dB. BPSK, LFM, Costas, Frank, P1, P2, P3, P4, T1, T2, T3, and T4 are considered with varying SNR values between -10 dB and 10 dB. The radar signals are converted into time-frequency images using Fourier-based Synchrosqueezing Transform (FSST), which shows good performance even at low SNRs. Whereas in [2], CWD time–frequency transform and image binarization is used to obtain a 2-dimensional time-frequency image of the signal. The preprocessed time–frequency image is then trained using CNN and sent to the tree structure-based machine learning process optimization classifier [25]. The experimental results show that the system achieves an overall recognition rate of 94.42% when the SNR is -4 dB. In [3], LPI radar signals (LFM, BPSK, Costas, Frank, and T1–T4) are pre-processed using the Choi-Williams distribution time-frequency transform to obtain a 2-D time-frequency image. The pre-processed image is sent to the pre-training model, i.e. Inception-v3 and ResNet-152 for feature extraction with Support Vector Machine (SVM) classifiers. The overall recognition rate of the ResNet-152-SVM system reaches 97.8%, and the Inception-v3-SVM system reaches 96.2% with an SNR of -2 dB. A CNN-based architecture is proposed in [4], where all the waveforms are collected only for a single period, and the input to the CNN is a grayscale time-frequency image. To process a large number of signal samples with reduced computational cost-effectively, a sample averaging technique (SAT) is deployed. The trained CNN is employed for classifying received radar signals, achieving a commendable recognition rate of 95.8% at an SNR of -6 dB. A novel method is proposed in [5] for monostatic, bi-static, and multistatic radar systems for the detection and tracking of targets. The transmitter identity code is embedded with the LFM signal and a Pseudo Noise (PN) sequence is used to code transmitter identity, modulated using BASK. Echo signals received are identified through spectral analysis and target parameters like delay, bistatic angle, and range pertaining to a single target are estimated geometrically with reference to the transmitter separately and consecutive ranges are fused using the maximum likelihood estimation technique. In this paper, we comprehensively explore and evaluate these advanced methodologies, shedding light on the efficacy of deep learning techniques in addressing the intricate challenges of LPI radar waveform recognition.

The paper is organised as follows: Section II provides an

elaborate review of the system model. In Section III, the signal decomposition and preprocessing is discussed. The deep learning model feature extraction classification are presented in Section IV. Section V discusses the simulation result and discussion namely sample creation, deep learning model training and hyperparameter tuning. Finally, the research is concluded, and future works are stated in Section VI of the research paper.

II. System Model

Bit wise modulated message signals are transmitted through a free space channel, taking into consideration the radar position, velocity and aerial target position. A Doppler shifted frequency and time delay is induced in the signal to account for Rayleigh fading due to interferences in wireless transmission. The signal attenuation is taken into consideration in the form of transmission loss, Rayleigh fading , free channel losses, and AWGN. In a multi-static scenario, we propose a method to introduce the transmitter identity code in the transmitted signal. The transmitter identity code is modulated with an LFM signal using binary amplitude shift keying (BASK) technique. The message signal consists of a bitstream of binary data grouped into four bits.

To encrypt the pulse Doppler radar signal with an identity before transmission, we convert it into a twelve and sixteen-bit binary code using repetition of bits [5]. For example, consider an original four-bit message signal 1011. On applying repetition thrice, we convert it into twelve bits, i.e., 111000111111. While applying repetition four times, we get a sixteen-bit code i.e. 1111000011111111. A pseudorandom noise code is then used to encrypt this message signal.

Consider the pseudorandom noise codes 101101000101 and 1011010001010110. The pseudorandom noise code is XOR-ed with the 12 and 16-bit codes giving 101001000000 and 0011001000100001. The transmitted identity code is embedded with a sinusoidal carrier wave.

Resultant bits are modulated according to Binary Amplitude Shift Keying(BASK), Binary Frequency Shift Keying(BFSK), Binary Phase Shift Keying (BPSK), Quadrature Amplitude Modulation(QAM), and Quadrature Phase Shift Keying(QPSK).

The input signal is a pulsed-doppler waveform with additive white Gaussian noise (AWGN) and Rayleigh multipath fading. The signal can be expressed mathematically as:

$$s(t) = x(t) \cdot h(t) + n(t), \quad 0 \leq t \leq T \tag{1}$$

where $j = \sqrt{-1}$ is the imaginary unit, $x(t)$ is the modulated signal with the phase law $\phi(t)$, $h(t)$ denotes the Rayleigh distribution, and $n(t)$ is the additive white Gaussian noise. .

If the receiver and transmitter are in relative motion, the characteristics of the transmitted signal are negatively influenced by the Doppler effect, depending on its angle of arrival. The simulation takes into account the radar target orientation, position, and velocity as well as the electrodynamics of backscattering for every target.

In any terrestrial environment, due to multipath propagation, the received pulse doppler signal is perceived as an infinite sum of attenuated, delayed and phase-shifted versions of the transmitted signal that may interfere constructively or destructively. The signals are vulnerable to time dispersive effects of the channel and consequently, the frequency response characteristic of the received signal gets distorted by the channel, depending on the amplitude relations and delay differences. This is called delay dispersion or delay spreading.

This signal has line-of-sight (LOS) as well as non-line-of-sight (NLOS) components. When the non-line-of-sight components are large, the faded signal is approximated as a sum of complex Gaussian processes, whose probability density function follows Rayleigh distribution, given by

$$f_{\text{signal}}(r) = \frac{r}{\sigma^2} \exp\left(-\frac{r^2}{2\sigma^2}\right), \quad r \geq 0 \quad \textbf{[13]} \tag{2}$$

Where σ^2 is the variance of the in-phase and quadrature components, and r is the random variable corresponding to the signal amplitude.

It is assumed that all signals suffer nearly the same attenuation but arrive with different phases. The phase of the complex envelope of the received signal is normally assumed to be uniformly distributed in $[0, 2\pi]$.

III. Signal Decomposition and Preprocessing

In this section, the radar waveform, depicted as a time-frequency image, undergoes binarization and transformation to serve as suitable input for CNNs. The images are transformed into time series graphs, scalograms, and spectrograms to analyse the correlation between temporal and spectral characteristics.

a) Time Series Graph: Time series graphs provide a raw representation of signal amplitude variations over time, making it easy to identify patterns and anomalies.

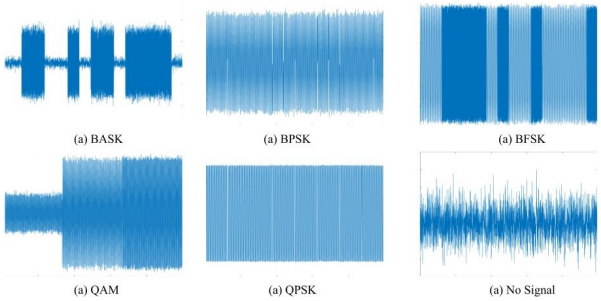

Fig. 1. Time Series Graph with different modulations

b) Scalogram: The scalogram is obtained through continuous wavelet transform (CWT) analysis. CWT is a generalised Fourier transform, designed to provide comparatively good time-frequency resolution. Wavelet functions used in the wavelet transform are chosen as

$$\psi_{k,q}(t) = 2^{k/2}\psi[2^k t - q] \tag{3}$$

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 20,2024 at 07:13:10 UTC from IEEE Xplore. Restrictions apply.

where $k = 0, 1, \ldots, K-1$ and $q = 0, 1, \ldots, 2K-1-1$.

Here, $\psi(t)$ is the mother wavelet. The parameter k introduces time scale compression of the mother wavelet by $2^0, 2^1, \ldots, 2^{K-1}$ times, and q accounts for time shifts of the compressed wavelets. The multiplier $2^{k/2}$ normalizes the square of the wavelet $\psi_{k,q}(t)$ to unity in the interval, considering that the square of the mother wavelet $\psi(t)$ is already normalized.

This enhances the effectiveness of the deep learning algorithms by extracting discriminative features from the radar data. The scalogram offers the advantage of adaptively capturing localised time-frequency features, allowing deep-learning models to learn and exploit the inherent patterns within the radar signal.

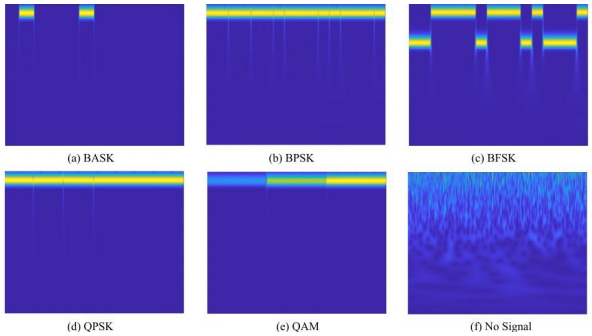

Fig. 2. Scalogram with different modulations

c) Spectrogram: The spectrogram employs a fast Fourier transform to depict the time-frequency representation of the signal. Spectrograms are effective for tasks such as target detection, classification, and anomaly detection. They provide a more intuitive representation of frequency changes over time and are particularly beneficial for capturing short-term variations in signal characteristics. This can enhance the effectiveness of deep learning models in classification, where the temporal evolution of the signal is essential for accurate training and performance.

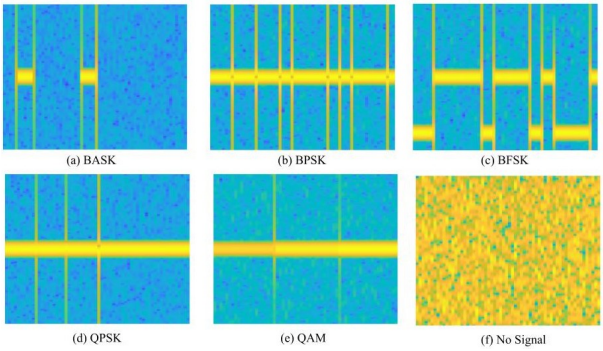

Fig. 3. Spectrogram with different modulations

IV. Deep Learning Model

In this section, we introduce a sophisticated method for improving pre-trained CNN models to enhance image analysis. Our methodology comprises two distinct sub-sections. The first section investigates image fusion to enrich input data and combines a pre-trained hierarchical CNN encoder and ResNet50 model to extract deep features at several levels of abstraction. The second subsection introduces a multi-layer dense classifier that refines decision boundaries and captures finer inter-class variations, culminating in improved classification accuracy.

A. Feature Extraction

The preprocessed images are concatenated into a single image to improve the performance of the CNN model by providing complementary information, enhancing feature learning, and reducing noise. Concatenation handles variability and generalisation, which enables multimodal learning and reduces overfitting. The papers by Zhang et al. (2017) [12], Wang et al. (2020) [14] and Wang et al. (2021) [14] provide a comprehensive overview of the use of image concatenation for deep learning and discuss the different ways in which it can be implemented.

Convolutional neural networks (CNNs) require large datasets to train, but collecting and labelling radar waveform data is time-consuming and expensive. Transfer learning with ResNet50, a pre-trained CNN model, can be used to mitigate this problem. ResNet50 has been shown to be effective for radar waveform identification in studies by [3], [14] and [24].

Extending a pre-trained model like ResNet50 with additional layers in a CNN architecture allows for a more task-specific adaptation, enabling the model to capture intricate patterns and features relevant to the targeted classification problem. Hence, three convolution layers are added after the ResNet50 model, to extract higher-level features, such as shape and texture. This makes the model more discriminative and improves the classification accuracy, thus fine-tuning our feature, for requirement-specific classification.

B. Classification

The features extracted from CNN layers are flattened and passed through dense layers. The flattening layer is used to convert the output of the CNN, which is a multidimensional tensor, into a one-dimensional vector. This vector is then passed through the dense layers, which learn to associate the features extracted by the CNN with the different categories of radar signals.

For classification, a categorical cross-entropy loss function, specifically designed for classification problems is employed. The loss function quantifies dissimilarity between the predicted probability distribution and the true probability distribution of the classes. The objective of the model is to minimise this loss function, achieved by adjusting the weights of the model through the training process.

The formula for the categorical cross-entropy loss function is as follows:

$$H(y, \hat{y}) = -\sum_{i=1}^{C} y_i \log(\hat{y}_i) \tag{4}$$

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 20,2024 at 07:13:10 UTC from IEEE Xplore. Restrictions apply.

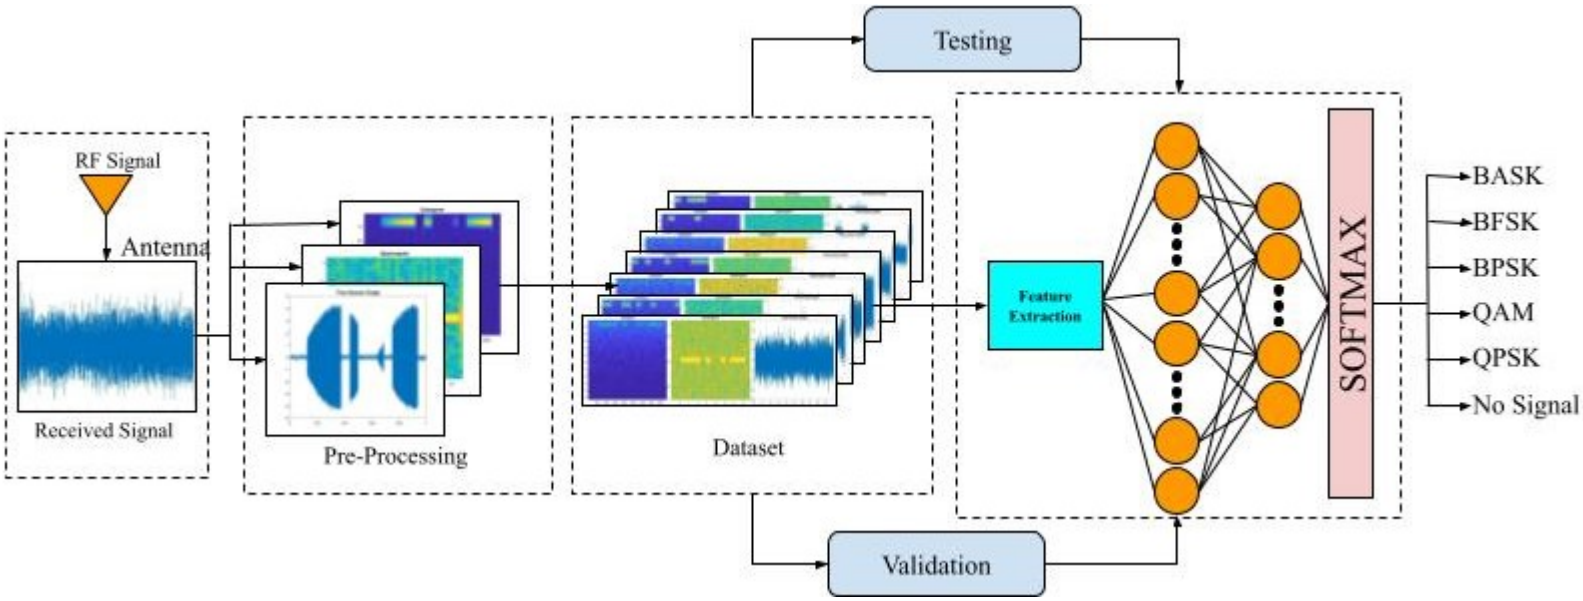

Fig. 4. Deep Learning Model

where y is the true probability distribution of the classes, $\hat{y}$ is the predicted probability distribution of the classes, C is the number of classes, and i is the index of the class.

The model attained high accuracy and demonstrated effective generalization to unseen data. In the following section, we will present the results of the simulation study conducted to evaluate the performance of the model.

V. Experimentation and Results

This section initiates an in-depth discussion of the sample creation and specific parameters selected for this paper. Subsequently, the outcomes of transfer learning on the concatenated images are explored, and hyperparameters employed for training purposes are discussed.

A. Dataset Generation

Creating training data is essential for conducting feature extraction [3] and training the classifier before the system executes classification and recognition tasks. The sample data generated is simulated on MATLAB 2022b. Within this simulation, each parameter of the signal is randomised within the designated range. Stochastic Gradient Descent (SGD) is used for optimisation of the loss calculated by the model. The specific parameters of the radar waveform are outlined in Table I.

In this paper, we simulate five modulation techniques for radar signals, namely BASK, BFSK, BPSK, QAM, and QPSK. The training and test sets are generated based on the parameter configurations of these five signal types. The data sets are created at 5 dB intervals from -20 dB to 20 dB, with every signal type producing 200 samples at each SNR. The Doppler velocity is varied from 0 to 300m/s while the range is kept between 0 to 10km. These samples are then divided into a training and test set in a ratio of 3:1 .The training set comprises

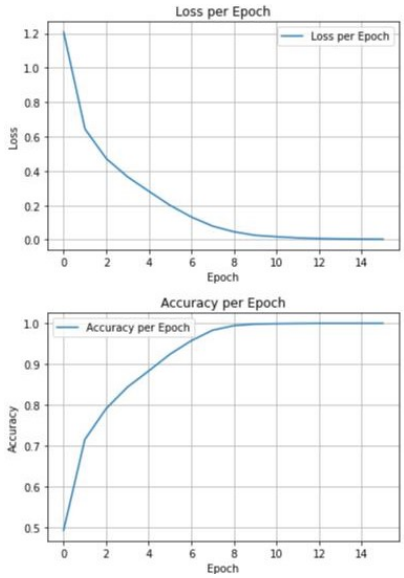

Fig. 5. Loss and Accuracy per Epoch

10,800 samples, and the test set comprises 3,600 samples. The model is constructed using Python's TensorFlow framework, and the GPU used is Nvidia P5000.

B. Deep learning model training and hyperparameter tuning

The proposed deep learning model was trained using the Adam optimizer with a learning rate of 0.0001. The model was trained for 100 epochs and stopped if the validation loss did not improve for 10 consecutive epochs. The following hyperparameters of the model were tuned using a grid search:

- Number of layers in model
- Number of neurons in each layer

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 20,2024 at 07:13:10 UTC from IEEE Xplore. Restrictions apply.

TABLE I
PARAMETERS FOR SAMPLE GENERATION

BPSK	*fc* *fs* *snr*	{*100Hz-5KHz*} [4**fc*] {*20dB, 10dB, -10dB, -20dB*}
QPSK	*fc* *fs* *snr*	{*100Hz-5KHz*} [4**fc*] {*20dB, 10dB, -10dB, -20dB*}
QAM	*fc* *fs* *snr*	{*100Hz-5KHz*} [4**fc*] {*20dB, 10dB, -10dB, -20dB*}
No Signal	*fc* *fs* *snr*	{*100Hz-5KHz*} [4**fc*] {*20dB, 10dB, -10dB, -20dB*}

- Activation function for each layer
- Dropout rate

The most effective model comprised 5 layers, with 128 neurons in each layer. The activation function for each layer was ReLU, and the dropout rate was 0.5. The model was trained on a dataset of 10,800 samples, partitioned into a training set comprising 8,100 samples and a test set comprising 2,700 samples. The model demonstrated an accuracy of 98.2% on the test set.

TABLE II
PARAMETERS FOR TRAINING CNN

Name	Parameter	Value

Early Stop	Monitoring Min. change Patience	Validation loss 0.001 15 epochs
Other	Batch Size Epochs Validation data size Test data size	16 100 15% shuffled data 15% shuffled data

VI. RESULTS

The proposed deep learning model was evaluated on a test dataset of 3600 samples. The model achieved an accuracy of 98.2%, which is significantly higher than the accuracy of the previous model (95%). The proposed model was also able to generalise well to unseen data, as evidenced by its high accuracy on the test set. The model is also relatively simple to implement, which makes it a good choice for practical applications.

TABLE III

DenseNet	*7*	*4*	*11*
Proposed Model	19	2	21

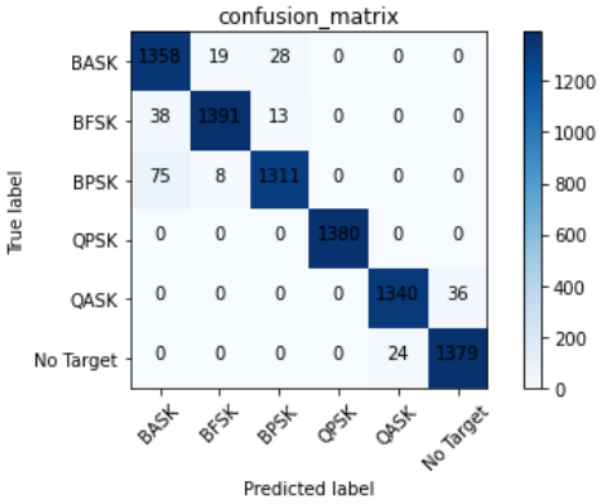

Fig. 6. Confusion Matrix of the results

A. Accuracy Comparison

The accuracy for the proposed model is calculated by the following expression:

$$Accuracy = \frac{True_p + True_n}{True_p + True_n + False_p + False_n} \quad (5)$$

Where p and n represent positive and negative respectively. Table IV displays the test dataset accuracy for both the proposed and previous models. The proposed model exhibits significantly improved test accuracy compared to existing models, indicating its enhanced capability in accurately classifying radar signals when compared to the previous model. The loss and time per epoch are also discussed in the table IV.

TABLE IV
RESULTS FOR TRAINING WITH TRANSFER LEARNING

Architecture	Test Accuracy(%)	Test Loss	Time Per Step(ms)

B. Factors Contributing to Improved Performance

The improved performance of the proposed model can be attributed to a more sophisticated CNN architecture, specifically ResNet50. This facilitates the model in capturing intricate relationships within the features extracted from radar signals. Additionally, the incorporation of a training dataset comprising 10,800 samples, surpasses the size of the dataset used in training the previous model. The extended dataset provides a more comprehensive learning opportunity, contributing to its improved performance. The model's effectiveness is further substantiated through a comparative analysis with other deep learning models designed for radar signal classification. In this evaluation, it exhibited superior accuracy, outperforming both the VGG16 and AlexNet models.

VII. Conclusion

The results of this study suggest that the proposed deep learning model is a promising approach to radar signal classification. The model is able to achieve high accuracy on a variety of radar signals, and is able to generalise well to unseen data. The model is also relatively simple to implement, making it well-suited for real-world scenarios. Importantly, the model's potential for scalability suggests its adaptability to varying complexities within radar signal datasets.

In our research, a novel method for detecting and classifying pseudo-random noise encrypted and modulated pulsed Doppler radar signals is presented. A comparison to the accuracy results in Table IV is presented in order to demonstrate the performance enhancements of the altered method. This method is applied to detect the signal from an SNR of -20 to +20 dB, with a carrier frequency of 100 Hz to 5 kHz, and classify it based on five modulation schemes.

A. Limitations and Future Work

The proposed model's training relied on signals from a controlled environment, potentially impacting its effectiveness in real-world scenarios. This is addressed by training the model on a larger dataset of radar signals generated in a real-world environment. Additionally the model will be deployed on an FPGA-based architecture for expedited signal detection and modulation recognition.

In this study, an ultrasensitive label-free electrochemical immunosensor based on $Ti_3C_2T_x$ (Mxene) with a 2D-layered morphology has been proposed for the detection of EpCAM antigen. A hydrothermal method is employed for the synthesis of $Ti_3C_2T_x$ by using a less toxic exfoliating reagent, $NaBF_4$. The bioelectrode, BSA/anti-EpCAM/$Ti_3C_2T_x$@ITO, has been fabricated by electrophoretic deposition of $Ti_3C_2T_x$ onto the ITO electrode, followed by an immobilization of EpCAM antibody. Electrochemical response studies reveal that the immunosensor shows a high sensitivity of 29.22 μA fg^{-1} ml cm^{-2} and a wide linear range from 0.1 fg/ml to 100 ng/ml, for EpCAM antigen detection. Further, the good stability of this fabricated immunosensor is an additional advantage for EpCAM antigen detection in serum samples.

KEYWORDS
electrophoretic deposition, epithelial cell adhesion molecules, immunosensor, $Ti_3C_2T_x$

1 | INTRODUCTION

In recent years, cancer has become the second leading reason of death worldwide. Early and sensitive detection of tumor markers is a great strategy for the diagnosis and prognosis of cancer patients.[1,2] Epithelial cell adhesion molecule (EpCAM) is a cell-to-cell adhesion homophilic glycoprotein antigen expressed on circulating tumor cells (CTCs).[3] An average concentration range of CTCs is identified as 1–100 CTCs per 10^7 white blood cells in 1 ml of blood.[4] EpCAM antigen contributes a significant role in the diagnosis and screening of various types of carcinomas arising from the head, neck, prostate, breast, stomach, colon, rectum, pancreas, biliary tract, and hepatic origin.[5] Mostly, immunoassay techniques are frequently used for the diagnosis of biomarkers, which are based on the specific biorecognition of antigens by antibodies.[6] Several techniques, like chemiluminescence immunoassay,[7] enzyme-linked immunosorption assay,[8] radioimmunoassay,[9] and sandwich-type immunosensor[10] have been used for the detection of tumor biomarkers. Although, these techniques give trustworthy results but have some serious limitations, such as requiring highly trained manpower, time-consuming, complex, and expensive.

Recently, biosensors have been considered the most accurate, fast, and sensitive analytical method for biomarker detection.[11] They identify cancer biomarkers by employing biorecognition elements like antibodies, DNA, RNA, etc., which transform biological signals into observable electrical signals.[12] Though numerous varieties of biosensors have been published for the identification of biomarkers.[13] Nonetheless, electrochemical biosensors have been widely used due to their ease of operation, high sensitivity, low cost, and fast response.[14–17] Electrochemical sensors that monitor the interaction of antigens and antibodies are referred to as electrochemical immunosensor. Certain biosensors have been developed in the last couple of years for the detection of epithelial cancer biomarkers.[18–20] Recently, Ying Ma et al. described an aptamer-modified quasi-ZIF-67@Au@methylene blue hybrid for highly sensitive detection of EpCAM.[21] Lina Zhu et al. proposed an electrochemical aptasensor based on CdSe/ZnS QDs for the successful detection of EpCAM.[22] In our previous work, we developed a

 © 2024 John Wiley & Sons Ltd.

biodegradable paper-based electrochemical immunosensor containing CuS/PEDOT:PSS for EpCAM antigen detection.[23] We feel that a modification with nano- or micro-materials is still required to the electrode surface that could offer better performances, such as lowering the detection threshold, increasing the signal, and better electron transport. Further, small sample volumes, fast test times, and tiny transducers are also critical components for the development of point-of-care devices (POCDs). Hence, the most important factor to improve the sensitivity of electrochemical immunosensors is based on the highly active transducer material having a large specific surface area, and numerous active sites.[23]

Different 2D-nanomaterials such as graphitic carbon nitride, graphene oxide, transition metal dichalcogenides etc., have been explored in the field of biosensing.[24,25] Recently, graphene-derived nanohybrids have been used for the fabrication of electrochemical biosensors, because of their high electrical conductivity and adsorption capacity, increased flexibility and mechanical strength, and superior immobilization of biomolecules due to the presence of oxygen-containing functional groups. However, some materials are associated with poor and unpredictable deposition onto the substrate owing to their low dispersibility, which further results in the lack of reproducibility of the biosensor.[26] Additionally, these nanomaterials have a very stable surface, which makes the modification with any functional group very difficult and possesses a major limitation of hydrophobicity.[27]

Recently, an emerging class of novel 2D materials like MXenes possessing extraordinary physiochemical properties has been explored to overcome the aforementioned limitations. MXenes have gained popularity owing to their 2D sheet-like morphology, excellent metal-like conductivity, large specific surface area, superior ability for incorporation of several functional groups, and outstanding ion intercalation behavior.[28] Also, MXenes have been chosen, because it is highly hydrophilic, biodegradable, and biocompatible; 2D-material with rich surface chemistry.[29] These materials belong to a group of transition metal carbide, nitride, or carbonitride; which are obtained by the selective etching of 'A' layers from the MAX phase.[30] Generally, the etching of 'A' layers from the MAX phase results in the surface terminations such as –OH, –F, –O, which provide a favorable microenvironment for the bioreceptor (DNA, enzymes, proteins, etc.) immobilization and help to retain their bioactivity and stability.[31] As of now, MXene-based biosensors have been developed for the detection of CEA, pesticides, phenol, nitrite, and H_2O_2.[30–36] These biosensors display promising results but limit their use to detect only a high concentration of analyte. Ti_3C_2 is one of the most extensively studied MXene, because of its unique electronic properties, excellent hydrophilicity, and high biocompatibility.[37] Therefore, it is considered a suitable candidate to detect very low concentrations of cancer biomarkers. Due to the presence of unpaired electrons on the surface of Ti_3C_2, it can be associated with different functional groups like –OH, –F, and –O, without affecting its metallic conductivity, and represented as $Ti_3C_2T_x$ (T = –OH, –F, –O).[38]

In this study, $Ti_3C_2T_x$ is being used to fabricate an immunosensor for EpCAM antigen detection. $Ti_3C_2T_x$, having robust electrochemical properties is synthesized by hydrothermal method by using a less toxic exfoliating reagent, $NaBF_4$. Electrophoretic deposition of the synthesized material is done onto the indium-tin-oxide (ITO) coated glass substrate. The 2D-layered sheets of $Ti_3C_2T_x$ could increase the active surface area of the modified electrode for the binding of biomolecules. Furthermore, the surface terminations (–OH, –F, –O) may provide biocompatible and aqueous environment for the immobilized antibody, while preserving their stability and bioactivity.[39] The constructed immunosensor, BSA/anti-EpCAM/$Ti_3C_2T_x$@ITO shows a good analytical performance with high sensitivity, quick response, and low detection limit with a broad range of EpCAM antigen detection. This biosensing approach also shows good repeatability, reproducibility, and long-term stability. To explore the applicability of this immunosensor, it is tested with artificial human serum, and data so acquired has been reported in this work.

2 | MATERIALS AND METHODS

2.1 | Materials

Epithelial cell adhesion molecule (EpCAM) antigen, N-(3-dimethyl aminopropyl)-N′-ethylcarbodiimide hydrochloride (EDC), bovine serum albumin factor-V, N-hydroxy succinimide (NHS), artificial human serum, MAX phase (Ti_3AlC_2), sodium tetrafluoro borate ($NaBF_4$), hydrochloric acid (HCl) and buffer salts of analytical grade have been procured from Sigma-Aldrich. Anti-EpCAM (antibody) was purchased from Atlas antibodies. All the solutions were prepared by using Millipore-purified deionized (DI) water.

2.2 | Synthesis of $Ti_3C_2T_x$

2D-$Ti_3C_2T_x$ was synthesized by two different methods viz. co-precipitation and hydrothermal method. In the co-precipitation method, 1 g of LiF was dissolved in 30 ml of 9 M HCl solution under stirring, and then 1 g of

10990739, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/aoc.7570 by Delhi Technological University, Wiley Online Library on [04/06/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

MAX phase was added slowly to avoid a violent reaction. This mixture was stirred for 24 h at 35 °C followed by washing with deionized water until the pH value of the supernatant reached higher than 6. Finally, it was filtered and dried under vacuum at 60 °C for 10 h.[40]

In the case of the hydrothermal method, the $Ti_3C_2T_x$ was prepared in a similar manner as reported in our previous work with a little modification.[41] Here, the reaction was carried at 160 °C for 12 h instead of a period of 16 h. It reveals that the results are good with lesser reaction time.

A comparison of both methods reveals that $Ti_3C_2T_x$ synthesized by hydrothermal method possesses a 2D-layered sheet-like structure with no traces of aluminum. This was confirmed by SEM and XRD characterization as clearly described in detail in the results and discussion (Sections 3.1 and 3.2). Hence, $Ti_3C_2T_x$ (hydrothermal) was used in all further studies in the present work.

2.3 | Electrophoretic deposition of $Ti_3C_2T_x$ onto ITO-coated glass substrate

Firstly, $Ti_3C_2T_x$ (50 μg/ml) was ultrasonicated in deionized water to make a colloidal suspension. A series of different potentials were used to optimize the smooth deposition of $Ti_3C_2T_x$ onto the pre-hydrolyzed ITO electrode. A DC potential of 10 V applied for 8 s resulted in the production of a uniform layer of $Ti_3C_2T_x$ on ITO substrate, whereas no film was obtained at a lower potential and a burning of the electrode was seen at a higher potential.

2.4 | Fabrication of $Ti_3C_2T_x$-based immunosensor

$Ti_3C_2T_x$@ITO electrode, as prepared in section 2.3, was incubated with 2 mM EDC (10 μl) and 5 mM NHS (10 μl) at room temperature for 40 min. Subsequently, 20 μl of anti-EpCAM (40 μg/ml) was dropcasted and allowed to immobilize for 12 h at 4 °C. The EDC:NHS, a crosslinker, activated the -COOH groups present in the structure of the antibody, invertibly. The activated carboxylic groups were then combined covalently with the hydroxyl groups available onto the surface of $Ti_3C_2T_x$, thereby producing an ester.[42] The anti-EpCAM/$Ti_3C_2T_x$/ITO electrodes were also treated with 1% BSA followed by washing with PBS to avoid any nonspecific binding with antigen. The fabrication of $Ti_3C_2T_x$-based immunosensor is represented schematically in Figure 1. These fabricated electrodes were stored at 4 °C prior to being used for immunosensing application.

2.5 | Design of the immunosensor

The fabrication of immunosensor is presented schematically in various steps in Figure 1. A novel 2D-layered sheet-like material, $Ti_3C_2T_x$ was prepared by hydrothermal method as depicted in step 1, Figure 1. The surface of $Ti_3C_2T_x$ is associated with different functional groups like –OH, –F, and –O providing a large electrochemically active hydrophilic platform, which further improves the analytical performance of the immunosensor. The

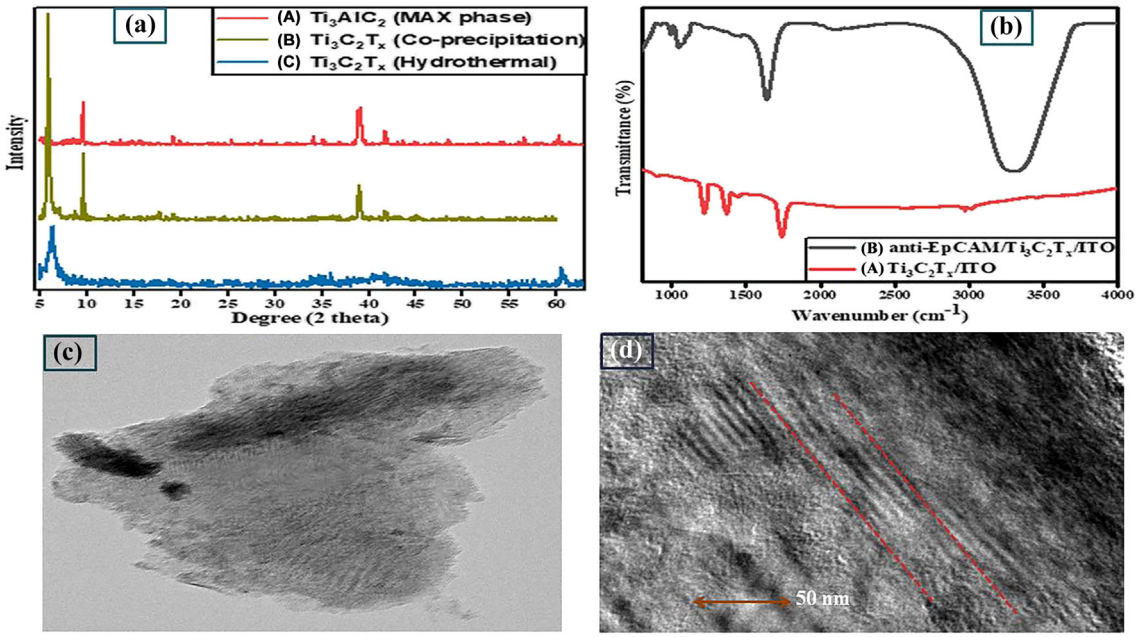

FIGURE 2 (a) XRD spectra, (b) FTIR spectra, (c) TEM image, and (d) cross-sectional image of $Ti_3C_2T_x$ (hydrothermal).

prepared $Ti_3C_2T_x$ was electrophoretically deposited onto the pre-hydrolyzed ITO electrode in the next step as shown in step 2, Figure 1. The functional groups of $Ti_3C_2T_x$ provide a compatible environment for the immobilization of biomolecules. Thus, the fabricated transducer surface was used to immobilize anti-EpCAM by using EDC-NHS as a cross-linker followed by the treatment with BSA, which is represented in steps 3 and 4 of Figure 1. It is worthwhile to mention that there is a formation of covalent bonding between the activated carboxylic groups of antibodies and the hydroxyl groups present on the surface of the transducer. Finally, the developed immunosensor, BSA/anti-EpCAM/$Ti_3C_2T_x$@ITO is utilized for the detection of EpCAM antigen, which is given in step 5, Figure 1. There is a formation of antigen–antibody complex on the surface of immunosensor, which blocks the effective surface area and results in the current decline, as shown in step 6 (Figure 1).

2.6 | Instruments

XRD data were collected by using Bruker D-8 advance monochromatic (Cu K_α) radiation X-ray diffractometer at wavelength 1.5406 A°.

Fourier transform infrared (FTIR) study has been performed by using Perkin Elmer spectrophotometer 2.

The morphological behavior of synthesized material was studied by ZEISS- scanning electron microscope (model- EVO 18) and CYRO- transmission electron microscope (model- TALOS).

The Autolab potentiostat/galvanostat (metrohm, Netherlands) has been employed for all the electrochemical and biosensing investigations. The operation of this instrument may refer to literature.[43]

3 | RESULTS AND DISCUSSION

3.1 | Chemical structure of MXene

XRD spectra of Ti_3AlC_2 (MAX phase), $Ti_3C_2T_x$ (co-precipitation), and $Ti_3C_2T_x$ (hydrothermal) are represented by curves (A), (B), and (C), respectively, in Figure 2a. The spectra of Ti_3AlC_2 (curve A) showed peaks at $2\theta = 9.63°$, 39.14°, 41.90°, and 60.29°. In curves (B) and (C), a dominant diffraction peak of Ti_3AlC_2 at $2\theta = 9.63°$ moved towards a lower angle at $2\theta = 6.36°$, showing that Ti–Al bond is interrupted and it is found in agreement with the literature report.[44] In curve (B), the presence of peaks at 9.63° and 39.14° indicate that the Al has not been etched completely from the Ti_3AlC_2 by the co-precipitation method. On the other hand, in the spectra of $Ti_3C_2T_x$ (hydrothermal), the main peak of aluminum at 39.14° is not observed (curve C), thereby suggesting that the Ti_3AlC_2 has been successfully exfoliated to $Ti_3C_2T_x$ by hydrothermal method. Furthermore, the interlayer spacing (d) is simply calculated by using Bragg's equation, i.e., $2d \sin\theta = n\lambda$. It is found that the interlayer spacing of $Ti_3C_2T_x$ (hydrothermal) increases to 13.88 Å (d-spacing of Ti_3AlC_2 is 9.18 Å), thereby confirming the etching of Al from Ti_3AlC_2.

10990739, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/aoc.7570 by Delhi Technological University, Wiley Online Library on [04/06/2024]. FIGURE 3 SEM images of (a) $Ti_3C_2T_x$ (co-precipitation), (b) $Ti_3C_2T_x$ (hydrothermal), (c) $Ti_3C_2T_x$/ITO electrode, and (d) anti-EpCAM/$Ti_3C_2T_x$/ITO electrode.

FTIR spectra of $Ti_3C_2T_x$/ITO (curve A) and anti-EpCAM/$Ti_3C_2T_x$/ITO (curve B) have been illustrated in Figure 2b. In curve A, the characteristic band at 1216 cm^{-1} is appeared due to the C–F bond stretching vibrations. The peaks at 1366 and 1738 cm^{-1} are attributed to the O–H and C=O bonds stretching vibrations, respectively.[45] On the other hand, FTIR spectra of anti-EpCAM/$Ti_3C_2T_x$/ITO (curve B), show that the characteristic band appeared at 1738 cm^{-1} due to the C=O bond stretching vibrations (curve A) has shifted to 1,638 cm^{-1}, due to formation of ester after immobilization of antibody. The characteristic peak at 1043 cm^{-1} is attributed to the C–O stretching vibrations. The broad peak observed at 3300 cm^{-1} is due to the O–H stretching vibrations.

3.2 | Morphological study of $Ti_3C_2T_x$

$Ti_3C_2T_x$ (hydrothermal) is characterized by transmission electron microscope (TEM) as shown in Figure 2c, where the micrograph represents the two-dimensional sheet-like structure of $Ti_3C_2T_x$. Figure 2d reveals a cross-sectional image of multilayered $Ti_3C_2T_x$. The red dotted lines indicate the individual layers of titanium and carbon atoms present in the structure of $Ti_3C_2T_x$.[46]

The morphology of $Ti_3C_2T_x$ prepared by two different methods was studied by scanning electron microscope (SEM). No layered sheet-like structure is visible in $Ti_3C_2T_x$ prepared by the co-precipitation method in Figure 3a. The layers appeared to be agglomerated during the synthesis process. Figure 3b presents a unique two-dimensional layered structure of $Ti_3C_2T_x$ sheet obtained by hydrothermal method. The loosely packed multilayers provide a large electroactive surface area for antibody immobilization.[47] It reveals that the $Ti_3C_2T_x$ prepared by hydrothermal method possesses better structural characteristics; hence it is used for all further characterization and electrochemical studies.

The SEM image of $Ti_3C_2T_x$/ITO electrode {Figure 3c} shows that 2D sheets of $Ti_3C_2T_x$ are well distributed onto the surface of the ITO electrode. After immobilization of anti-EpCAM onto the $Ti_3C_2T_x$/ITO electrode, the layered morphology of $Ti_3C_2T_x$ has been changed due to the covalent interactions, which further confirms that the $Ti_3C_2T_x$/ITO electrode has been covered by anti-EpCAM, as shown in Figure 3d.

The energy-dispersive X-ray (EDX) spectrum of $Ti_3C_2T_x$ is illustrated in Figure S1. The EDX peaks corresponding to Ti, C, O, F, and Cu also confirm the formation of $Ti_3C_2T_x$. However, an additional peak of Cu is due to the copper grid used during the TEM-EDX analysis.

3.3 | Electrochemical characterization of different electrodes

Electrochemical studies of fabricated electrodes were carried out by using the differential pulse voltammetry (DPV) technique in PBS (7.4 pH) having 5 mM

10990739, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/aoc.7570 by Delhi Technological University, Wiley Online Library on [04/06/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

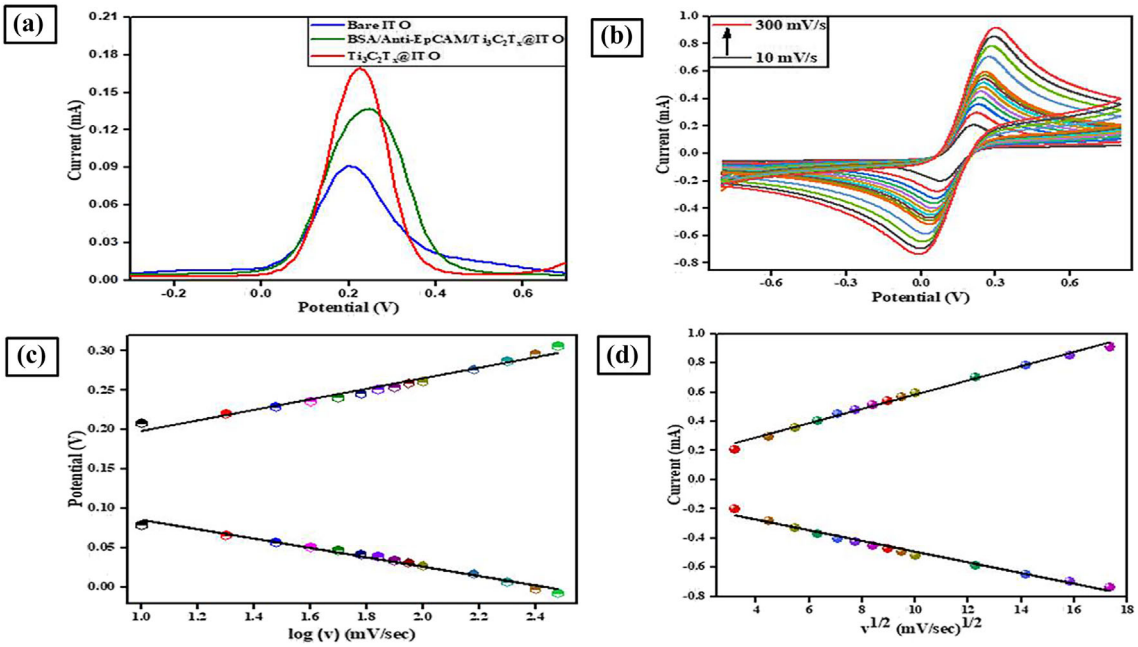

FIGURE 4 (a) DPV peaks of different fabricated electrodes. (b) CV analysis of $Ti_3C_2T_x$@ITO electrode at different scan rates (10–300 mV/sec). (c) Peak potential with log (scan rate) for $Ti_3C_2T_x$@ITO electrode. (d) Peak current with square root of scan rate for $Ti_3C_2T_x$@ITO electrode in PBS (0.2 M, pH = 7.4, NaCl = 0.9%) including $[Fe(CN)_6]^{3-/4-}$ (5 mM).

concentration of $[Fe(CN)_6]^{3-/4-}$. Figure 4a reveals that a bare hydrolyzed ITO electrode shows the least electrochemical current (0.074 mA), while the $Ti_3C_2T_x$@ITO electrode exhibits the maximum value of current (0.169 mA). This increase in current is due to the outstanding electrical conductivity of $Ti_3C_2T_x$. Further, the incorporation of $Ti_3C_2T_x$ increases the electrode's effective surface area, which facilitates fast electron transport, and hence redox peak current is increased significantly. The electrochemical current of the BSA/anti-EpCAM/$Ti_3C_2T_x$@ITO electrode decreases to 0.136 mA, due to the blockage of the conducting area of the electrode by antibody.

Figure 4b illustrates the cyclic voltammetry (CV) analysis of the $Ti_3C_2T_x$@ITO electrode by varying the scan rate (ν) from 10 to 300 mV/s. The CV plots of the ITO electrode and anti-EpCAM/$Ti_3C_2T_x$@ITO electrode are represented in Figures S2(A) and S2(B). The figures clearly show that with an increase in scan rate, the oxidation peak shifts towards a more positive value, while the reduction peak shifts towards a more negative value. It infers that there is a linear relationship between peak potentials and log (scan rate) as shown in Figure 4c, which is also denoted by the following equations (1) and (2):

$$E_{pa}\,[Ti_3C_2T_x@ITO] = 0.0668\,V\,\log(\nu) + 0.1313\,V; R^2 = 0.9720 \quad (1)$$

$$E_{pc}\,[Ti_3C_2T_x@ITO] = -0.05937\,V\,\log(\nu) + 0.1446\,V; R^2 = 0.9836 \quad (2)$$

By using the slope of the above equations, the charge transfer coefficient (α) for the $Ti_3C_2T_x$@ITO electrode is estimated to be 0.893. The heterogeneous electron transfer rate constant (K_s) is found to be 0.127 s^{-1} by using the Laviron equation.[48] Figure 4d represents a linear relationship between anodic and cathodic peak current densities against the square roots of respective scan rates. Hence, it is confirmed that the electron transfer from $Ti_3C_2T_x$@ITO electrode is a surface-controlled process as given in equations (3) and (4).

$$I_{pa}\,[Ti_3C_2T_x@ITO] = 48.90\,\mu A\,(s/mV) \times \nu^{1/2} + 934.48\,\mu A; R^2 = 0.9928 \quad (3)$$

$$I_{pc}\,[Ti_3C_2T_x@ITO] = -36.70\,\mu A\,(s/mV) \times \nu^{1/2} - 128.24\,\mu A; R^2 = 0.9836 \quad (4)$$

Furthermore, slopes of the above equations are used to calculate the effective surface area (A) by using the Randle-Sevick equation as mentioned below:

10990739, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/aoc.7570 by Delhi Technological University, Wiley Online Library on [04/06/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

$$I_p = 2.69 \times 10^5\, n^{3/2} A C D^{1/2} \nu^{1/2}$$

Where I_p is the peak current, n = no of electrons oxidized or reduced, C is the concentration of $[Fe(CN)_6]^{3-/4-}$ in mole/cm^3, D = diffusion coefficient in cm^2/s, ν =scan rate in V/s. The effective surface area (A) for ITO, $Ti_3C_2T_x$@ITO, and anti-EpCAM/$Ti_3C_2T_x$@ITO electrode is calculated as 0.22, 0.27, and 0.25 cm^2, respectively.

Also, the surface coverage (τ) of $Ti_3C_2T_x$@ITO electrode is determined as 3.57×10^{-8} mol/cm^2 with the help of equation- [$I_p = n^2F^2A\tau\nu/4RT$]; where F is the Faradays constant and R is the universal gas constant.

3.4 | Optimization of experimental parameters for efficient bioelectrode response

To check the performance of the developed immunosensor for EpCAM antigen detection, different biosensing parameters are optimized with the help of the DPV technique. The viability of the antigen and the corresponding antibody is greatly influenced by the pH of the electrolytic solution. So, the various pH values (6, 6.5, 7, 7.5, 8) were applied to the BSA/anti-EpCAM/$Ti_3C_2T_x$@ITO electrode and a resulting change in response current was measured. Figure S3(A) validates that a 6.5 pH electrolytic solution shows the highest current and hence is taken as an optimal pH for immunosensing studies. The incubation time of EpCAM antigen is another important parameter that impacts the immunosensor's performance. The value of peak current decreases as the time of incubation increases and it reaches a plateau after 8 min, signifying the end of the reaction as shown in Figure S3(B).

3.5 | Electrochemical biosensing studies

DPV is used to investigate the electrochemical performance of BSA/anti-EpCAM/$Ti_3C_2T_x$@ITO electrode for EpCAM antigen detection. The DPV response of bioelectrode after incubation of varying EpCAM antigen concentrations in PBS (6.5 pH) with 5 mM concentration of $[Fe(CN)_6]^{3-/4-}$ is shown in Figure 5a. It reveals that as the concentration of EpCAM antigen increases from 0.1 fg/ml to 100 ng/ml, the current response is found to decrease linearly. The decreasing trend in peak current occurs owing to the combination of antigen and antibody onto the bioelectrode surface that slows down the movement of electrons from the electrolytic solution to the bioelectrode. Figure 5b shows the calibration plot of the

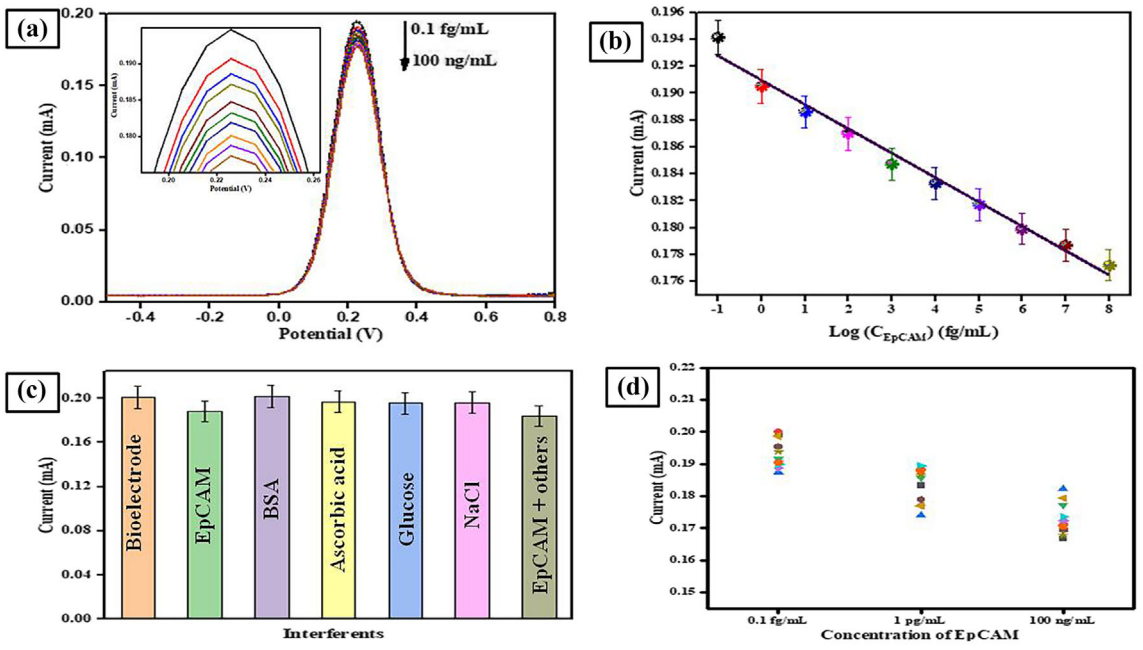

FIGURE 5 (a) Electrochemical response studies of BSA/anti-EpCAM/$Ti_3C_2T_x$@ITO electrode as a function of EpCAM antigen concentration (0.1 fg/ml to 100 ng/ml; top to bottom) in 6.5 pH PBS containing 5 mM $[Fe(CN)_6]^{3-/4-}$ using DPV technique; inset is the magnified view. (b) Plot showing linear relationship between peak current and logarithm of EpCAM antigen concentration. (c) Interference study of different analytes (1 pg/ml). (d) Repeatability of immunosensor.

TABLE 1 Comparison of recent biosensors with the proposed immunosensor for EpCAM detection.

S. No.	Materials	Detection method	Linear range of detection	Sensitivity	Limit of detection	Reference
1.	MCH, Hp1, AuE	SWV	0.1–20 ng/ml	–	20 pg/ml	[49]
2.	rGO, TiO_2	DPV	0.01–60 ng/ml	3.24 μA ml ng^{-1} cm^{-2}	6.5 pg/ml	[50]
3.	QZIF-67	SWV	0.005–100 ng/ml	–	3 pg/ml	[21]
4.	AgNPs, PVA	EM	2–2000 pg/ml	–	0.8 pg/ml	[51]
5.	CuS, PEDOT:PSS	Chronoamperometry	0.01 pg/ml to 1,000 ng/ml	104.31 μA pg^{-1} ml	0.01 pg/ml	[23]
6.	GRs–QDs	ASV	100 fg/ml – 7.5 μg/ml	–	100 fg/ml	[52]
7.	MoS_2, rGO	DPV	0.001–20 ng/ml	0.104 mA ml ng^{-1} cm^{-2}	44.22 fg/ml	[53]
8.	$Ti_3C_2T_x$	DPV	0.1 fg/ml – 100 ng/ml	29.22 μA fg^{-1} ml cm^{-2}	0.1 fg/ml	Present work

Abbreviations: AgNPs: silver nanoparticles, ASV: anodic stripping voltammetry, AuE: gold electrode, DPV: differential pulse voltammetry, EM: electrochemical microfluidic, GRs: graphene oxide nano-sheets, HP1: hairpin probe 1, MCH: 6-mercapto-1-hexanol, PVA: polyvinyl alcohol, QDs: quantum dots, QZIF-67: quasi zeolitic imidazolate framework-67, SWV: square wave voltammetry.

observed peak current against the logarithm of the concentration of EpCAM antigen (log C_{EpCAM}), which follows equation (5) as given below:

$$I_p = -1.813\,\mu A\,fg^{-1}\,ml \times \log C_{EpCAM} + 190.955\,\mu A; R^2 = 0.9809 \quad (5)$$

The aforementioned regression equation is used to calculate the sensitivity (S) and detection limit (LOD) of the BSA/anti-EpCAM/$Ti_3C_2T_x$@ITO immunosensor. The sensitivity (slope/effective surface area) of the immunosensor having LOD (0.1 fg/ml) is calculated as 29.22 μA fg^{-1} ml cm^{-2}. The recently developed EpCAM detection biosensors are being compared in the light of three parameters, namely, linear detection range, sensitivity, and limit of detection; and the data have been reported in Table 1. The immunosensor of the present work outperforms the other reported biosensors for the detection of EpCAM antigen in terms of all aforementioned parameters. The proposed immunosensor authenticates a very broad range for EpCAM antigen (0.1 fg/ml to 100 ng/ml) detection and significantly high sensitivity in comparison to other biosensors. This is mainly due to the excellent electrical conductivity, large surface area, and outstanding electrochemical properties of $Ti_3C_2T_x$.

3.6 | Immunosensor's selectivity, repeatability, reproducibility, and stability

The selectivity of the fabricated immunosensor is examined by analyzing its electrochemical response with other interfering agents like ascorbic acid, glucose, BSA, and NaCl. These analytes are the representative species of interfering organisms commonly seen in human plasma. It is observed that BSA/anti-EpCAM/$Ti_3C_2T_x$@ITO immunosensor showed a negligible change in current with an average RSD of 1.382%, even with 100 times more concentration of interfering species (1 pg/ml) as compared to EpCAM antigen (0.01 pg/ml). Furthermore, the specificity is examined by testing a mixture of all four analytes- containing EpCAM antigen, which shows a positive response for the detection of EpCAM as depicted in Figure 5c. Hence, it is inferred that the fabricated immunosensor is selective and specific for the detection of EpCAM antigen.

Reproducibility and repeatability are the crucial characteristics that demonstrate the immunosensor's analytical performance. In order to investigate repeatability, the DPV response of fabricated immunosensor has been recorded 10 times with each concentration of EpCAM antigen, viz., 0.1 fg/ml (low), 1 pg/ml (medium), and 100 ng/ml (high) as shown in Figure 5d. The RSD values for the anti-EpCAM/$Ti_3C_2T_x$@ITO immunosensor are calculated as 2.398%, 3.032%, and 2.909%, for 0.1 fg/ml, 1 pg/ml, and 100 ng/ml EpCAM antigen, respectively. The low values of relative standard deviations indicate that the fabricated immunosensor reveals good reproducibility and repeatability.

Finally, the long-term stability is measured with 10 fg/ml EpCAM antigen for 6 weeks as shown in Figure S4(A). The DPV response is recorded weekly and it is observed that the electrode retains 90% of its initial response after 5 weeks. After that, the current response remains at 77%, confirming the acceptable stability of the

TABLE 2 EpCAM antigen detection in human serum sample ($n = 3$).

S.No.	EpCAM concentration added (fg/ml)	EpCAM concentration found (fg/ml) (SD < 2.5%)	Recovery (%) (SD < 2%)	RSD (%)
1.	1	0.97	97.94	1.469
2.	10	9.91	99.16	0.597
3.	100	99.15	99.15	0.602
4.	1,000	999.40	99.94	0.038
5.	10,000	9989.00	99.89	0.077

immunosensor. It is believed that this significantly improved stability of the immunosensor is due to the excellent chemical stability of the $Ti_3C_2T_x$@ITO electrode.

3.7 | Human serum analysis

The clinical applicability of the fabricated immunosensor is explored by using artificial human serum. The human serum is diluted with PBS and spiked with EpCAM antigen (1, 10, 100, 1,000, 10,000 fg/ml). The DPV response of BSA/anti-EpCAM/$Ti_3C_2T_x$@ITO electrode incubated with different spiked concentrations is shown in Figure S4(B). The recoveries (97.93 to 99.94%) for the different serum sample analyses are reported in Table 2. Furthermore, RSD is found to be less than 1.5% suggesting that the developed immunosensor poses an excellent potential for EpCAM antigen detection.

4 | CONCLUSION

A $Ti_3C_2T_x$-based ultrasensitive electrochemical immunosensor capable of label-free detection of EpCAM antigen is reported in this study. The immunosensor shows remarkable results owing to a high specific area, superior electronic conductivity, good dispersion in the aqueous phase, and high biocompatibility of $Ti_3C_2T_x$. This immunosensor has a wide linear range from 0.1 fg/ml to 100 ng/ml and a high sensitivity of 29.22 μA fg^{-1} ml cm^{-2} for EpCAM antigen detection. Additionally, the accuracy and applicability of the immunosensor are validated by quick EpCAM detection in spiked human serum. Since the Mxene exhibits a great potential for effective immobilization of biomolecules, the suggested platform can be used for the detection of other biomarkers, which could revolutionize cancer detection.

RESEARCH

Diurnal rail noise measurement, analysis, and evaluation of associated health impacts on residents living in the proximity of rail track area

Abstract In India, railway is the major transportation mode for carrying goods and people. The tracks for the movement of the rail were initially constructed in the city for the pre-eminence and expediency of the vantage of the people. Rapid modernization and increasing population in the city crammed the area around the railway tracks. Moving rail on the tracks passing through the city is not compatible, which is creating problems for the nearby residents. In the urban and suburban regions, the railway noise has become a major problem. This study was conducted to examine the perception of the physiological and psychological effects of railway noise in the nearby areas of railway stations in Delhi, India. For this purpose, 10 sites near the railway station were selected for the study. To assess the impact of railway noise pollution on the health of humans, a questionnaire survey was conducted. The data of 344 individuals were collected through the questionnaire survey and analyzed to get the perception towards railway noise. Noise level was monitored by a Sound Level Meter (SLM) and the equivalent noise level (L_{eq}) in dB(A) was used to compute the noise pollution in three shifts, i.e., morning, noon, and evening time. Results showed that 57.65% of female and 86.11% of male respondents in the survey reported the disturbance due to railway noise. The level of noise pollution was found higher in the evening time as compared to the noon and morning period, which exceeds the limit set by the Central Pollution Control Board (CPCB) at all the monitored locations. Findings of the study show that the primary cause of the health problems is railroad noise, which is negatively impacting the health of the residents, who are living in the proximity of the rail track region. The perception survey reported that headache, sleep disturbance, irritation, and stress are common health issues among the locals residing around the railway track proximity in Delhi.

Introduction

Transportation plays a significant role in civilization, economic affluence, and interconnectivity (Mohammadi, 2009). Different transportation modes (rail, road,

Published online: 13 May 2024

air, etc.) have one consequence, i.e., generation of noise, which is influencing the living and working environment (Asdrubali & D'Alessandro, 2018; S. A. Stansfeld & Matheson, 2003). The noise generated from different kinds of transport medium, i.e., rail, road, and air, is considered a health hazard, which is majorly disturbing sleep and creating annoyance (Torija et al., 2011; Wrótny & Bohatkiewicz, 2021). Long-term exposure of the inhabitants to excessive noise is harmful to human health, having an adverse impact on numerous organs in addition to the auditory system (Petri et al., 2021; Wosniacki & Zannin, 2021). Different epidemiological and experimental studies show the determinantal effect of noise on health particularly regarding annoyance, blood pressure, and irritation (Licitra et al., 2016; Schreckenberg et al., 2012; R. Thompson et al., 2022). Few studies also have been reported in the literature showing evidence of metabolic disease and mental health hazards (Cerletti et al., 2020; Vincens & Persson Waye, 2022). Therefore, it is important to focus on lowering the impact of noise on the human population. Because each person's sensitivity to noise is unique (both subjectively and objectively), determining the detrimental effects of noise on people may be difficult. With the determination of appropriate criteria and their upper allowable values, generally recognized scientific techniques for its assessment were created (Lercher et al., 2017). In developing countries like India, the common noise sources are various construction activities, industries, and road traffic (Kumar, 2019). Due to fast infrastructure expansion, economic development, travel, and tourism, the city faces a problem of rail-induced noise pollution (Dupont, 2017). One of the greatest acceptable modes of transportation in India is the railroad. Continual, inescapable noise levels are putting a burden on the city's residents' auditory, non-auditory, and sensory systems (S. A. Stansfeld & Matheson, 2003). In recent years, due to sustainable alternative transport, rail traffic has drastically increased as a convenient way of transportation mode rather than the road and airway as it is inducing less environmental noise compared to other transport mechanisms (Perron et al., 2016). The high-speed trains are creating more noise, which may vary according to the frequency of passage (Poisson, 2015; Sarikavak & Boxall, 2019). The frequency and speed of the train were directly identified as major contributors to noise annoyance (Aasvang et al., 2008), which increases the risk of disease related to blood pressure and sleep disturbance (Zou et al., 2015). Numerous studies have demonstrated that exposure to different types of traffic noise in densely populated urban areas may adversely impact human health (Aasvang et al., 2008; Lercher et al., 2010; Maljaee et al., 2024; Sørensen et al., 2011). This environmental factor may lead to various health issues, including headache, sleep disturbance, psychiatric disorder, decreased concentration, hearing impairment, learning difficulties, stroke, hypertension, and, ultimately, a diminished overall quality of life (Guski, 2016; Lercher et al., 2008; Michaud et al., 2022; Moreno et al., 2023; Öhrström et al., 2007). Railway traffic noise constitutes a major environmental hazard, as mentioned in an extensive study conducted by Fields & Walker (1982). The study reported the assessment of the public's response towards railway noise in residential areas across Great Britain and arrived at the conclusion that "Noise is considered the most severe environmental disturbance attributable to railway operations." A study examining the community's reaction to high-speed railway noise was conducted in Tianjin, China. Residents living near various railway lines were interviewed about their annoyance and interference with daily activities due to the noise. Findings revealed that as the high-speed railway noise levels increased, so did the proportion of Chinese residents experiencing high noise annoyance and activity disruption. The length of a single noise event appeared to impact activity disturbance. Additionally, factors beyond just sound characteristics, such as noise sensitivity, satisfaction with the living environment, and housing satisfaction, significantly influenced the community's response to high-speed railway noise (Zhang & Ma, 2022). Research conducted in the railway work facility settings in Indonesia highlights the potential health and social issues that may arise from exposure to high levels of noise. Disorders, including nausea, insomnia, and masking effect, can negatively impact the well-being of individuals working or living near these areas (Damayanti et al., 2023). A field study in the UK involved interviews with participants and measurements of their exposure to vibrations from two sources of environmental vibration, specifically freight and passenger railway vibrations. By employing ordinal probit modeling with fixed thresholds to establish exposure–response relationships, it was found that individuals can differentiate between the two types of railway vibration. Moreover, the annoyance response to freight railway vibration was significantly higher than that to passenger railway vibration, even when considering

equal levels of exposure. The study also revealed that the population under investigation exhibited a community tolerance level 15dB higher for passenger railway vibration compared to freight railway vibration (Sharp et al., 2014). A questionnaire survey and on-site measurements were conducted in the railway station area of Bangladesh to assess the impact of railway noise pollution. The study discovered that various sources, including honking, trolley movement, announcements, audio speakers, and passengers shouting, contribute to the predominant noise alongside the primary noise. Additionally, the research highlights the severe health effects of noise exposure on staff, passengers, and employees in the railway station environment (Uddin et al., 2015).

A study was conducted to further understand the relationship between nocturnal railway noise exposure and its effects on cardiovascular reactivity in various age groups (Tassi et al., 2010). By comparing the cardiac responses to different types of trains, the study highlights the significance of assessing and mitigating railway noise pollution to safeguard public health and ensure a more comfortable living environment for those residing near railway stations. A socio-acoustic survey was conducted in Sweden's residential areas, examining the impact of railway and road traffic noise on human health. The study evaluated the effects of exposure to single and multiple noise sources on inhabitants' well-being. Results indicate that areas with multiple noise sources led to a significantly higher percentage of annoyed residents compared to those experiencing only one noise source at the same total sound exposure for 24 h. Consequently, researchers emphasized the importance of incorporating the combined effects of multiple noise sources in risk assessments and the development of mitigation strategies (Öhrström et al., 2007). In Tehran, the capital of Iran, a study conducted through a questionnaire survey on the residents living around the railway noise and vibrations in different districts shows that the distance from the railway affects both disaffection from noise and vibration (Maljaee et al., 2022). To aid decision-makers in assessing the financial aspects of installing new monitoring stations and evaluating existing ones, a study in Italy proposed a set of key performance indicators (KPIs) specifically tailored for noise monitoring. These KPIs were derived from those defined for general monitoring networks, ensuring compliance with current legislation. The study evaluated the performance of three noise monitoring networks in ports, offering valuable insights for improving the efficiency and effectiveness of such systems (Bolognese et al., 2023). An innovative exposure assessment strategy developed by the review of past and current cardiovascular noise effect research in Austria by a large epidemiological health survey was reported (Lercher et al., 2011). It presents the exposure–response curves, with and without interaction assessment, based on standardized re-analyses as the cardiovascular effects of noise rank second after annoyance in terms of disability-adjusted life year. A study conducted in Australia quoted that rolling contact between the rail and wheel induces vibration and consequent noise radiation along with railway noise. To promote railway transport and sustainability, it is necessary to reduce railway noise (Jiang et al., 2013).

Railway noise has generally been considered the least annoying transportation source, and, therefore, it has not achieved the same attention as road traffic and other types of transportation noise. However, recent studies suggest that nocturnal railway noise is as disturbing to sleep as road traffic noise and that railway noise has an important short-term impact on the health of the people living around railway stations and might increase the risk for different types of diseases (Lim et al., 2006; Pultznerova et al., 2018; Sørensen et al., 2011; Vincens & Persson Waye, 2022). The effects of noise pollution due to the different types of transportation medium such as road traffic and other sources are studied in India (Agarwal & Swami, 2011; Gilani & Mir, 2021; Khaiwal et al., 2016; Mishra et al., 2014) but no study has been conducted till this investigation which includes the railway transportation noise pollution as per the authors' knowledge. This makes the unique investigation to identify the effects of railway noise based on the questionnaire survey.

This study aims to bridge the gap in understanding the relationship between railway noise pollution and people's perception. By analyzing the impact of railway noise on residents residing near monitoring sites through a questionnaire survey, we aim to shed light on the pressing issue of noise pollution and its effect on overall well-being and quality of life. Given the dense population in India, the harm of noise pollution is particularly significant. As one of the most populous developing countries, India has witnessed a surge in noise pollution due to rapid urbanization (Banerjee, 2012; Firdaus & Ahmad,

2010; Jamir et al., 2014). Moreover, excessive noise pollution can disrupt daily routines and sleep patterns, leading to adverse health effects that negatively impact overall well-being (Alías & Alsina-Pagès, 2019).

The aim and objective of the proposed study are to identify and understand the railway noise pollution distribution pattern and the perception of the people residing near to rail track area. Noise distribution patterns were identified by monitoring the noise pollution in different time periods, i.e., morning, noon, and evening. It can help the higher authorities to make policies in that particular period to combat excessive noise levels. Face-to-face interviews of the participants through the questionnaire survey may give a constructive view of the various effects of railway noise on them, which may be an important factor in demitting the effect of noise. The physical and psychological consequences of the rail noise may be reduced with the dividing effective strategies, which may also bring the noise level within acceptable limits. This study may also help to make the plan for other places, which will improve the living environment of the people residing near the rail track region.

This study seeks to find a correlation between noise pollution and how it affects human mental and physical health, which has led to the following research questions: what is the railway noise distribution pattern in the morning, noon, and evening time? What is the perception of the people residing in the vicinity of the railway track? Is there any correlation between the perception of noise pollution and its various sources? Is there any relationship between the perception of noise pollution and health problems? Are there any physical and psychological consequences for the inhabitants living near monitoring sites?

To assess railway noise level patterns between morning, afternoon, and noon time period, hypothesis testing was performed and inferential analysis was carried out between (1) perception of noise pollution and various sources (railways, vehicles, industries, households, others) to know the correlation. (2) Perceived noise pollution and a number of issues (disturbance, irritation, headache, blood pressure, sleep disruption, and stress) to know the correlation. Figure 1 shows different steps of the study to achieve the above-mentioned objectives.

The rest of the article is organized as follows: "Literature survey" describes important studies conducted by various researchers related to the theme of the present paper. A description of measurement locations, noise level data collection and questionnaire survey, and study methodology adopted has been provided in "Fieldwork and methodology of the study." Detailed discussion about the results obtained from the noise level data and questionnaire survey data analysis has been presented in "Results and discussion." "Conclusion" concludes the findings of the study along with its major limitations and recommendations for possible future work.

Literature survey

Over the last 20 years, several academics have conducted extensive research on the impacts of noise pollution. An investigation carried out on Youngdeungpogu's transportation noise levels using noise prediction models in Seoul Metropolitan City, the Republic of Korea, found that many persons are susceptible to noise levels that would bother and interrupt their sleep and assessed the population exposed to vehicle noise levels. It was suggested to regulate and lower traffic noise levels in Seoul to safeguard locals from any potential negative health impacts. The European Commission has listed community noise as an environmental issue; it will become the biggest threat to the lifestyle of the people if not controlled (Ko et al., 2011). An assessment of the population exposed to noise pollution and acoustical planning mitigation analysis in a European capital city was carried out, which demonstrates that exposure exceeds the WHO-recommended guideline levels. The extent of low-frequency noise from transportation activities was examined, and it was discovered that there was a sizable low-frequency component, indicating potential health problems from exposure to noise from transportation (Douglas & Murphy, 2016; Murphy & King, 2010, 2014). Noise pollution has been referred to as a modern plague because highway, rail, and aviation traffic, which continue to be key sources of environmental noise, have grown steadily, making noise more intense and pervasive than ever before (Goines & Hagler, 2007). Possible health consequences of noise pollution are extensive, all-pervasive, long-lasting, and substantial from both a medical and societal standpoint. Health is harmed by the direct and cumulative negative

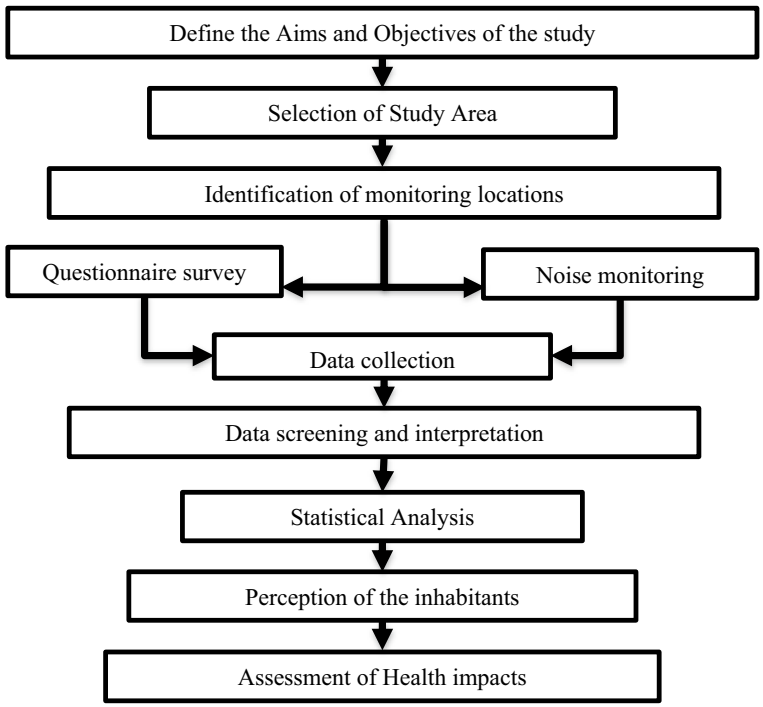

Fig. 1 Flowchart or framework for the study

impacts of noise, which also harm social, working, and learning settings. These consequences result in losses in both physical (economic) and intangible (well-being) assets. Large-scale epidemiological research has provided substantial proof that population exposure to ambient noise has a negative impact on health. As a result, environmental noise should be taken into account as both a source of annoyance and a worry for both public and environmental health (Themann & Masterson, 2019; World Health Organization, 2011). The main contributors to noise pollution in urban areas include transportation, construction equipment, manufacturing operations, and household activities. Despite the fact that this problem is continually becoming worse in emerging nations, it has not received the proper attention (Cheuk Fan, 2000; Miedema & vos, 1998) (Zannin et al., 2018). A study was conducted on a corridor used for both operational and under-construction public transportation, and discovered that while public transportation contributes less to overall noise pollution than private vehicles do, it still exceeds standards. This can be reduced by designing a noise barrier along the corridor. It is an issue that is not given enough consideration considering that individuals cannot sight, smell, or taste noise (Mishra et al., 2014). Railroads are often viewed as a practical mode of transportation, although those who live close to railroad terminals must endure high levels of train noise (Mejvald & Konopa, 2019). Train noise is issue with the environment. It is regarded as one of the primary sources of noise pollution in the vicinity of railroad stations. Negative impacts of noise on human existence will get worse in the next years and include decreased activity and performance, high blood pressure, cardiovascular disease, exhaustion, headaches, and disrupted sleep (Biswas, 2014; S. A. Stansfeld & Matheson, 2003), (Kumar, 2019). It is now well established that both wheel and rail are major radiators of sound, their exact balance depending on wheel and track design parameters. Sleepers are also seen to contribute significantly at low frequencies, and for very still rail pads may dominate the noise from the track (D. J. Thompson & Jones, 2000). Many existing techniques for acoustical properties and transportation noise still have problems with accuracy limitations. Different studies have presented methodologies and techniques for the ease of noise measurement in different kinds of acoustic environment which can help to locate the main noise sources during the pass-by of a car, but also their characterization in terms of source strength

(Ballesteros et al., 2015) such as adjusted controlled pass-by method for urban traffic noise assessment (Moreno et al., 2023), statistical pass-by method for unattended traffic noise measurement (Ascari et al., 2022), digital sensor for the measurement of outdoor noise (López et al., 2020), and deep learning, machine learning, and artificial intelligence–based algorithms for real time detection of environmental noise in different field conditions (Alías et al., 2018; Nourani et al., 2020; Renaud et al., 2023; Shah et al., 2020; Takenaka & Ozawa, 2022; Zhang & Kuehnelt, 2020). While certain literature demonstrates that gradient lifting technology models effectively predict specific targets, such as decision trees obtaining initial values for the fitting function through multiple regression (Yoon et al., 2018). This approach handles numerous input variables considered in the study. Nevertheless, calculated output values exhibit observed data information errors, which rely on loss functions like square-error, absolute-error, and negative binomial log-likelihood functions to minimize prediction discrepancies (Němec et al., 2021). The sensor network (Bolognese et al., 2023) and IoT (Liu et al., 2020) can be used for the depiction of the noise level in a specific environment over a time period in a more specific way.

A sociological study conducted in the city's neighborhoods revealed that noise irritation is a significant issue for many inhabitants. Number of persons who experience sleep disruption has been shown to be plainly unsatisfactory (Arana & García, 1998). A study conducted across four Indonesian cities, namely Bandung, Surabaya, Yogyakarta, and Semarang, revealed that noise levels at all measurement points within residential areas surpassed the prescribed noise threshold for such zones (Huboyo et al., 2022). This finding is crucial because excessive noise can negatively impact the comfort and well-being of people residing near railway tracks. Numerous studies confirm that noise exposure can harm health, leading to reduced quality of life. This is evident through its effects on hearing, sleep quality, concentration and memory, and cognitive and cardiovascular activities (Gallasch et al., 2016; Guski et al., 2016). Murphy et al. (2009) performed a study to evaluate how much road traffic noise is being exposed to locals and workers. It demonstrates that nighttime exposure to noise is more severe, also revealed that if the influence of traffic flow on residential populations is carefully considered, traffic management strategies have the potential to result in considerable reductions in the degree of noise exposure. According to Hong et al. (2011), road traffic noise masks the aero-plane (or railway) noise irritation, and the higher the level of road traffic noise, the lower the subject ranks the aviation (or railway) noise discomfort. Overall irritation of combined noise is greater than the maximum source-specific aggravation when the sound levels of the two sources are equivalent or equally bothersome, but it is equal to the maximum source-specific annoyance when one source's level is higher than the other. A study conducted by Zhang & Ma (2021) shows that the noise made by trains travelling on elevated lines regularly disturbs the daily lives of the surrounding residents. Investigations reveal that locals who live close to elevated railroads commonly complain about the noise. Another study conducted by da Paz et al. (2005) and Lakušić & Ahac (2012) shows that elevated sound levels are the primary causes of unhappiness, especially in metropolitan areas, and prolonged exposure to them can cause hearing loss due to noise. The main causes of railroad noise are loading and unloading, truck movements, braking, squeals, and whistles. As a result, at low levels of exposure to railroad noise, people are more disturbed by unusual noises, whereas at higher levels, people become accustomed to noise and pay less attention to unusual railway noise events (Licitra et al., 2016). Rylander (2004) analyzed environmental noise exposure and physiological stress reactions based on the physiological characteristics of the hearing system. Kuhnt et al. (2008) did a laboratory experiment to experimentally assess the real irritation brought on by various combinations of road and rail noise. They discovered that the 72 volunteers were subjected to several noise scenarios made up of various mixes of road and rail traffic noise. They were required to assess how irritated they felt after each loud situation. The study concluded that sleep quality decreased and reaction time increased gradually with noise levels. Disturbance in sleep due to noise may increase the risk of obesity (Oftedal et al., 2015). A survey conducted by Agarwal & Swami (2011) in Jaipur City, India, reported that 52% population was suffering from noise pollution. A study performed by Roswall et al., (2018a, b) explored the relationship between exposure to residential railway noise and the incidence of diabetes which came to no conclusion; however, it did

support the conclusion that there is a direct correlation between residential road traffic noise and diabetes incidence. Stansfeld et al. (2000) examined how noise pollution in metropolitan areas affects people's non-auditory health. In the lab, exposure to transport noise interferes with sleep, but in field trials, where adaptation takes place, it typically does not. Noise annoys people, makes it difficult to do complicated tasks, and alters social behavior. Aircraft traffic noise (1.6% threat increment per 10 dB raise in the 24-h uninterrupted level of noise; 95% CI 0.3–3.0%), road traffic sound (2.4% per 10 dB; 95% CI 1.6–3.2%), and railroad noise (3.1% per 10 dB; 95% CI 2.2–4.1%) all had statistically relevant regression exposure-risk relationships with cardiac arrest or hypertensive heart disease (Seidler et al., 2016). A study emphasized that the railway is an alternative model for the transportation of goods compared to road transportation, but due to the lack of appropriate space for loading and unloading, lack of parking space causes traffic congestion which is the primary source of noise pollution in the nearby areas of rail stations (Singh & Gupta, 2020). According to a study conducted at Chennai Central railway station by Kanakasabai et al. (2005), it was found that the noise pollution at the railway station was exceeding the permissible limits. A case study on railway noise pollution and its impacts in Bangladesh was carried out by Uddin et al. (2015) which showed that people living around railways are highly exposed to noise pollution. Bunn & Zannin (2016) executed the study to assess the noise levels generated by a railway that runs through a crowded area of a large city and to examine possible remedies that may be taken to reduce the noise levels. Three potential solutions that excluded the train horn, included acoustic barriers, and removed the railway tracks from the edge of the urban area were simulated as ways to reduce the noise pollution caused by rail traffic. Wosniacki & Zannin (2021) also presented a framework to regulate railway noise exposure in Brazil and discovered that more than 40% of the population is influenced by rail noise that is 5 dB(A) or louder than background noise, and that road traffic noise exposure levels are above WHO recommendations. Different researchers have developed numerous methods and technologies (Ascari et al., 2023; Fredianelli et al., 2022; Pallas et al., 2016) to mitigate environmental noise in a proper manner, which will be helpful in making effective noise mitigation action plans.

Fieldwork and methodology of the study

Study area and data collection

Delhi City was selected as a research area for the fulfillment of the aim and objectives of the study. Delhi is the capital of India and is surrounded by the states of Haryana and Uttar Pradesh, with an area of 1484 km^2. There are 47 railway stations in Delhi, five of which are prominent ones, which are New Delhi Railway Station, Old Delhi Railway Station, Hazrat Nizamuddin Railway Station, Anand Vihar Railway Station, and Delhi Sarai Rohilla Railway Station (Gupta & Anand, 2018). New Delhi railway station, one of the largest stations in India, is located between Ajmeri Gate and Paharganj (Government of India; Ministry of Railways; New Delhi, 2015). Continual inescapable noise levels are putting a burden on the auditory, non-auditory, and sensory systems of the residents of the city living in proximity to the railway station zone (S. A. Stansfeld & Matheson, 2003). The main objective of this study is to find out the effect of train noise, which occurs near the railway stations as shown in the framework of the research (Fig. 1). To comprehend the research locations and their surroundings/neighborhood regions better, field observations or field surveys were carried out. In this study, noise pollution monitoring was conducted only during the day in three shifts (morning, afternoon, and evening). Due to several constraints like battery backup and safety of the instrument, availability of data collection assistants, security clearance permission from Delhi police for night monitoring, and lack of sufficient funds, noise pollution levels at night could not be monitored. Therefore, in this study, health effects have been analyzed based on subjective responses collected through questionnaire surveys only. The basic elements of monitoring stations have been kept in mind during this study, considering the most popular along with different land use patterns, all the top 10 railway stations were selected out of 47 railway stations in Delhi to conduct this study as shown in Fig. 2 (A). Table 1 shows the salient features of the chosen locations. For the validation and significance, ten locations were selected

for the study keeping all the land use patterns. The noise level was monitored with the help of a class I Sound Level Meter (SLM), which had windscreen microphones confirming to international standards of IEC 61672–1:2002 (López et al., 2020). To reduce the impact of weather conditions, the devices were placed 1.5 m above ground level in open fields, close to noise sources (railway tracks), and with reflecting surfaces at a minimum distance of 3 m (Bhavan & Nagar, 2015; Wosniacki & Zannin, 2021). The primary data of noise pollution level was collected by sound level meter at each location and monitoring was conducted throughout the daytime under typical metrological conditions. For two consecutive days, at each railroad station, noise level data were recorded in three shifts (2 h/shift) of daytime at each identified location, whenever a train passed by. Figure 2 (B) shows the noise level measurement being carried out using the noise level meter at the Delhi Sarai Rohilla and Sabzi Mandi railway stations. In a similar way, noise level measurements were carried out at all the other railway stations and collected data were entered into an Excel sheet for further calculation and analysis purposes. The in situ face-to-face interview questionnaire survey was carried out with the noise level monitoring simultaneously at each selected location. In order to understand how inhabitants felt about noise pollution, a questionnaire-based study was used to measure the impact of noise on health in the neighborhood areas of the selected railway station of Delhi City. To understand the physiological and psychological effects on the inhabitants, questions were

Table 1 Salient features of the selected locations

S. no	Location	Land pattern	Latitude	Longitude
1	Delhi Shahdara (S1)	Mixed	28.6734° N	77.2922° E
2	Delhi Sarai Rohilla (S2)	Residential	28.6628° N	77.1852° E
3	Delhi Cantt (S3)	Commercial	28.6119° N	77.1157° E
4	Vivek Vihar (S4)	Industrial	28.6683° N	77.3144° E
5	Dayabasti (S5)	Mixed	28.6693° N	77.1730° E
6	Anand Vihar (S6)	Mixed	28.6471° N	77.3158° E
7	New Delhi (S7)	Commercial	28.6429° N	77.2191° E
8	Sabzi Mandi (S8)	Residential	28.6685° N	77.2004° E
9	Old Delhi (S9)	Commercial	28.6606° N	77.2271° E
10	Hazarat Nizamuddin (S10)	Mixed	28.5889° N	77.2534° E

asked about sleep disturbance, early awakenings, and subjective responses from the residents. To comprehend people's perceptions pertaining to railway noise, a questionnaire of 344 people (almost 34 respondents at each chosen railway station) was conducted. Obtained questionnaire data were further analyzed to understand the attitude of respondents towards railway noise.

Descriptive statistics

In this part of the study, the descriptive statistical analysis (Brainard et al., 2004) has been conducted to validate and correlate the observed data with noise monitoring and a questionnaire survey. The Kalmogorov-Smirnov and Shapiro–Wilk test (Nassiri et al., 2007) was conducted to determine the normality of the noise monitoring data. The data was found normal, which was further statistically analyzed with a *t*-test, to see the distribution pattern of the data (Sahoo, 2014). The hypothesis was developed to determine the relation between different time periods, i.e., morning, noon, and evening noise levels at different sites. To see the significance of the correlation between different variables, inferential statistical analysis was conducted (Maljaee et al., 2022).

Test of normality

Before applying the *t*-test, a normality test was conducted on the collected noise level data set. Noise level data were divided into three sets for morning, noon, and evening. Table 2 presents the results of the normality test.

All three data sets are evidently normal based on the results of the normality test, permitting the *t*-test to be conducted.

t-test was applied to compare the means of two samples, i.e., between morning and noon noise levels, morning and evening noise levels, and noon and evening noise levels respectively.

Hypothesis testing between morning and noon noise levels To assess railway noise level patterns between the morning and noon time period, hypothesis testing was performed.

H_0: Morning noise level = Noon noise level
H_1: Morning noise level > Noon noise level

From Table 3, *p*-value < significance level; therefore, we reject the null hypothesis. Thus, railway noise in the morning hours is more than in the noon hours.

Table 2 Test of normality

	Kolmogorov–Smirnov			Shapiro–Wilk		
	Statistic	df	Sig	Statistic	df	Sig
VAR00004	0.114	20	0.200*	0.953	20	0.416
VAR00005	0.147	20	0.200*	0.934	20	0.181
VAR00006	0.174	20	0.114	0.934	20	0.183

*This is a lower bound of true significance

Hypothesis testing between morning and evening noise levels To assess railway noise level pattern between morning and evening time period, hypothesis testing was performed.

H_0: Morning noise level = Evening noise level
H_1: Morning noise level > Evening noise level

From Table 4, p-value < significance level; therefore, we reject the null hypothesis. Thus, railway noise in the evening hours is more than in the morning hours.

Hypothesis testing between noon and evening noise levels To assess railway noise level patterns between noon and evening time period, hypothesis testing was performed.

H_0: Noon noise level = Evening noise level
H_1: Noon noise level > Evening noise level

From Table 5, p-value < significance level; therefore, we reject the null hypothesis. Thus, railway noise in the evening hours is more than the noon hours.

Analysis of variance (ANOVA)

ANOVA was performed to compare the means of three groups (i.e., morning, noon, and evening noise levels). The equation for ANOVA is given by

Table 4 *T*-test findings for the noise levels in morning and evening

	Morning	Evening
Mean	68.035	71.03
Variance	0.485553	3.381158
Observations	20	20
Hypothesized mean difference	0

P(T <= t) one-tail	2.4E−07	
t critical one-tail	1.710882	
P(T <= t) two-tail	4.8E−07	
t critical two-tail	2.063899	

$$F = \frac{variance\ between\ treatments}{variance\ within\ treatments} \tag{1}$$

$$F = \frac{MS_{Treatments}}{MS_{Error}} = \frac{SS_{Treatments}/(I-1)}{SS_{Error}/(n_T-1)} \tag{2}$$

where

F ANOVA coefficient

M mean square

I number of groups

n_T number of observations

Table 3 *T*-test findings for the noise levels in morning and noon

	Morning	Noon
Mean	68.035	66.6
Variance	0.485553	3.705263
Observations	20	20
Hypothesized mean difference	0	
Df	24	
t stat	3.134856	
P(T <= t) one-tail	0.002247	
t critical one-tail	1.710882	
P(T <= t) two-tail	0.004495	
t critical two-tail	2.063899	

Table 5 *T*-test findings for the noise levels in noon and evening

	Noon	Evening
Mean	66.6	71.03
Variance	3.705263	3.381158
Observations	20	20
Hypothesized mean difference	0	
Df	38	
t stat	−7.442267	
P(T <= t) one-tail	3.125E−09	
t critical one-tail	1.68595	
P(T <= t) two-tail	6.25E−09	
t critical two-tail	2.02439	

$$F = \frac{(Sum\ of\ variance\ within\ groups)^2/(degree\ of\ freedom\ within\ groups)}{Total\ (variance)^2/(total\ degree\ of\ freedom)} \quad (3)$$

If $F > F_{critical}$, then the groups are significantly different and if $F < F_{critical,}$ then the groups are significantly similar.

Table 6 summarizes the noise levels of all three groups, i.e., morning, noon, and evening. ANOVA results (Table 7) demonstrate that $F_{critical} < F$; therefore, all the observations of the three groups (morning, noon, and evening noise levels) are not significantly similar. Hence ANOVA results confirm the results of hypothesis testing that the railway noise levels during the evening period are higher than those in the morning and noon

Results and discussion

This section provides the output of the analysis of the questionnaire survey and the findings of the statistical correlation assessment with the different variables, which includes the discussion on the various findings and association with the previous researchers' work.

Questionnaire survey analysis

For the analysis and assessment of railway noise, the questionnaire form was designed (Lim et al., 2006). The questionnaire form was used for the data collection, which was focused on knowing the perception of the individual about the railway noise impact on human health. The questionnaire form consists of three sections (Part A, Part B, and Part C). The first part (Part A) of the questionnaire is related to personal information like age, sex, contact number, educational background, annual income, and distance from the railroad. The second part (Part B) deals with sources of noise pollution (vehicles, railways, households, industry, others), time of stay in the current house, noise pollution understanding, residential area type, etc. In the third part (Part C), the questions are related to health problems such as disturbance, headache, sleep disturbance, irritation, blood pressure, and stress. All participants were asked about the train-induced noise level of irritation like extreme, very much, moderate, slight, or not at all during their stay at home. Respondents were also asked to rate their neighborhood noise on a scale of 0 to 10 depending on how much noise bothers, disturbs, and annoys them.

Random sampling method was adopted to direct the questionnaire on various age categories, sex, educational levels, and income levels of participants, which was also used in different studies previously (Goswami & Swain, 2017; Lim et al., 2008; Tanni et al., 2015). Population characteristics of the studied area are presented in Table 8. Male participants were found more interested in participating in the survey than female participants, as reported in the previous studies also (Kumar, 2019; Mimani & Singh, 2021). No female respondent was found at Delhi Shahdara and Delhi Sarai Rohilla railway station to answer the questions. Respondents aged 15–30 and 30–45 years combined were over 70% for all areas except Delhi Shahdara, Delhi Sarai Rohilla, and Delhi Cantt railway station. Age demographics are presented in Fig. 3. More than 45% of participants did not agree to share the data regarding their annual income except at Delhi Cantt, Dayabasti, and New Delhi railway stations. Except for Delhi Cantt and Sabzi Mandi railway station, more than 60% of participants were educated to 10 + 2. The survey observed that individuals living/working less than 5 years in their present house/business area were < 29%. From Table 8, it was found that

Table 6 Summary of the railway noise level in the daytime

Groups	Minimum noise level	Maximum noise level	Average noise level	Variance
Morning	66.6	69	68.04	0.485553
Noon	64	71.3	66.6	3.705263
Evening	68.3	74	71.03	3.381158

the individuals living/working over 20 years in their current area are over 21% except for Anand Vihar railway station, which is of mixed type.

Analysis of the relationships between perception of noise pollution and its various sources

Outcomes obtained from the analysis of the correlations between the perception of noise pollution and various sources are shown in Table 9 to first identify the significance of the source. With regard to that, inferential analysis was carried out between the perception of noise pollution and various sources (railways, vehicles, industries, households, others) and it can be observed that only railways showed significant correlations with the perception related to noise. According to the results reported in previous studies, the railway is the prime source of noise pollution and significantly harms the health of the people living in proximity of the railway area (Roswall et al., 2018a,

Table 9 Correlation coefficient between perception of noise pollution and its sources

**Correlation is significant at the 0.01 level (2-tailed)

b; Seidler et al., 2016; Sørensen et al., 2021). Perception of noise pollution analyzed here with respect to the other sources shows an insignificant positive correlation except for railways at all selected locations. The degree of association between the perception of noise pollution and its sources showed a degree of significance of less than 0.001. This indicates that, as expected, there is a close relationship between the sources of noise and the effects of noise.

Analysis of the relationships between perception of noise pollution and various problems

In order to first determine the significance of the difficulties caused by noise pollution on the inhabitants based on the questionnaire survey, results from the analysis of correlations between perceptions of noise pollution and various problems are provided in Table 10. In this regard, inferential analysis was conducted between perceived noise pollution and a number of issues (disturbance, irritation, headache, blood pressure, sleep disruption, and stress), and it was found that only sleep disruption significantly correlated with perceived noise pollution. According to findings from earlier studies, railroads are the main cause of noise pollution and severely interfere with the quality of sleep of adjacent inhabitants (Reiter & Kostek, 2008; Szwarc et al., 2011). Except for sleep disturbance (SD) at all sites surveyed, the impression of noise pollution as compared to the other issues reveals a negligible positive correlation. With a corresponding *p*-value of 0.001, the degree of connection between the impression of noise pollution and its sources was 0.141. This suggests that, as would be predicted, there is a close connection between noise sources and sleep disruption.

Noise annoyance

Noise from railway traffic is the main annoyance factor for those living close to railways (Licitra et al., 2016). Expanding rail route traffic in Delhi will prompt more noise and vibration issues in the future. Two questions were asked in the survey from respondents to assess the noise annoyance in the vicinity of railway stations. First, respondents were asked to react to annoyance due to noise exposure among four categories: Slightly, Moderately, Very, Extremely, or

*Correlation is significant at the 0.05 level (2-tailed)

Not at all. Second, respondents were asked to give their opinion on a scale that ranges from zero to ten. If they were not annoyed, then respondents were asked to pick zero value and the value 10, in case they were extremely annoyed. In the first question, if a person chooses "Slightly" then it ranges from 1 to 3 on the opinion scale; if a person decides "Moderately," then it ranges from 4 to 7, and if a person selects "Very," then the value will be greater than 7 on opinion scale. Annoyance is a common issue faced by individuals for a longer period due to the high noise level. Figures 4 and 5 show the annoyance from noise exposure faced by respondents at the selected sites in the daytime and nighttime. It is evident from the figures that most of the people were annoyed due to train noise in the morning (08:00–09:00 h) and the evening (20:00–21:00) hours (Fig. 4 and 5).

Figure 6 indicates the significant sources of noise pollution in the vicinity of the railway stations. Clearly, it shows that transportation, i.e., railways, is a significant factor of noise pollution for the people living around the railroads. From the data analysis, it was found that more than 60% of noise comes from railway operations.

During the survey, participants were asked to react to the medical issues they faced because of noise pollution. They were asked to reply in three classifications: Yes, No, and Sometimes. Figure 7 shows the degree of disturbance faced by participants because of noise pollution at the selected locations. From the data, it was observed that participants were most affected by noise disturbance. The majority of respondents replied "Yes" at Delhi Shahdara, Delhi Sarai Rohilla, Delhi Cantt, Dayabasti, and Old Delhi railway stations whereas mixed responses were received at the other five locations.

Figure 8 shows the headaches from noise exposure at selected locations faced by participants. It was observed that more than 25% of people were facing headache problems near the New Delhi railway station due to railway operations and traffic. While more than 20% of people residing near Dayabasti and Anand Vihar railway stations were highly exposed to railway noise as both the stations operate an extensive number of passenger trains. Nearly 10% of people were affected near Hazarat Nizamuddin railway station. Nowadays, railway noise has become a serious

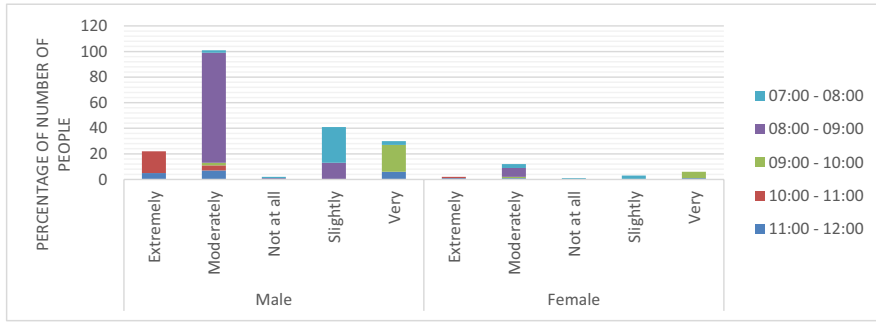

Fig. 4 People annoyed at daytime

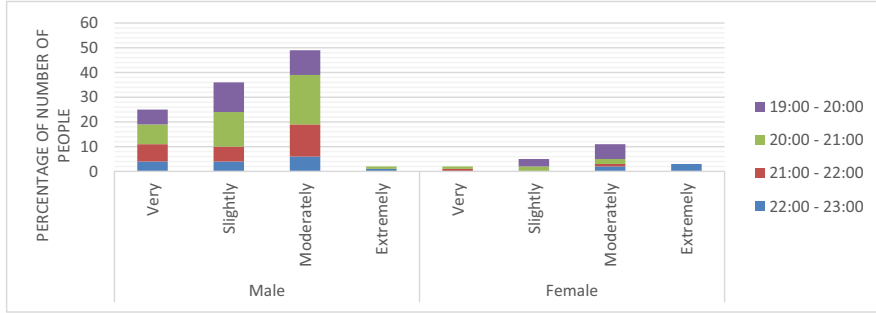

Fig. 5 People annoyed at nighttime

source of headache for people residing or working near stations.

Table 11 shows the health factors among participants due to noise exposure. The disturbance is found to be a common problem faced by participants. About 58% of male and 86% of female respondents reported disturbance issues due to noise exposure. It was found that 24%, 12%, 36%, and 16% of males answered "Yes" for Irritation, Blood Pressure, Sleep Disturbance, and Stress, respectively. Similarly, female participants replied "Yes" for Irritation, Blood Pressure, Sleep Disturbance, and Stress at 47%, 17%, 61%, and 47%, respectively. Male and female respondents replied "Yes" for headaches caused due to noise exposure at 44% and 58%, respectively. Female participants were found more affected compared to male participants.

Conclusion

The present study evaluated the railway-induced noise problem in Delhi. Several techniques were used to examine the noise levels during the train's passage. It was found that noise levels exceeded all the locations and violated the prescribed limits set by the Central Pollution Control Board. Railway noise level in the evening was found significantly higher than morning and noon time. General disturbance, headache, sleep disturbance, and irritation were the main health problems faced by the residents due to noise exposure. Results clearly show that female respondents faced railway noise–induced health problems more often as compared to male respondents. One of the possible causes of the more severe noise impact on female responders is that they spend more time at home than males do, which sensitizes them to longer periods of noise exposure. Nearly 60% of respondents agreed that railroad noise pollution is a serious problem for children. It is also clear from the self-reported questionnaire survey that perception of noise pollution shows a significant correlation with railway noise sources and majorly with sleep disturbance (SD). Face-to-face interviews were conducted with the people residing near the railway track to evaluate the level of annoyance due to railway noise. Residents faced more noise annoyance during the morning hour (08:00–09:00) and the evening hour (20:00–21:00). Residents of the selected areas suggested strict restrictions on honking and noise barrier installations along with the particular train corridor. Due to different constraints like battery back-up and safety of the instrument, availability of data collection assistants, security clearance permission from Delhi police for night monitoring, and lack of sufficient funds, noise data could not be collected during nighttime, which is one of the major limitations of this study. Another limitation of the study is the smaller number of female respondents for questionnaire survey/face-to-face interview. This is because most of the selected locations/railway stations were dominated by commercial/industrial or mixed land use pattern. Further recommendations to reduce train noise by the participants were strict control of horns blowing by trains, tree plantation, construction of under-pass, parking facility, and sound-proofing systems. Future studies may focus on the collection of more responses from more residents along with noise level data collection for a longer duration covering the entire day and nighttime so that a more precise and accurate picture of the harmful effects of noise pollution on residents can be reported.

Acknowledgements The authors would like to thank the Department of Environmental Engineering, Delhi Technological University, Delhi, for providing the noise level meter and other instruments to carry out this research work.

***Abstract*— Emotions are crucial in identifying the current mental state. Electroencephalography (EEG) signals can accurately determine the current mental state. The automatic identification and analysis of human emotions using EEG data is vital in the treatment of psychiatric diseases due to the influence that emotions have on interactions, interpretations, and decisions. However, one major problem with EEG recorders is their low spatial resolution. EEG signals are nonlinear and complicated. Advanced signal processing techniques are required to analyze and extract useful characteristics. Emotion recognition using EEG can improve human-machine interactions. A convolutional neural network (CNN) is suggested in this article for automatic feature extraction and categorization of emotions. First, EEG signals are converted into pictures by applying time-frequency representation techniques. Following this, these pictures are fed into CNN and optimized CNN models for training. The optimized CNN model produces better accuracy for classifying emotions. Deep learning (DL) techniques are popular for determining complex patterns. Deep learning methods have shown good results in EEG-based emotion identification. It can automatically extract high-level information. DL's performance depends on hyperparameters. However, optimizing the performance of a deep-learning model requires accurate hyperparameter tuning. The manual hyperparameter tuning method is tiresome, costly, computationally expensive, and time-consuming. As a result, an automated method is required to determine the best hyperparameters to maximize DL's efficacy. To automate the hyperparameter optimization process, the proposed work presents a novel framework based on Bayesian optimization. Bayesian optimization (BO) is used to automate hyperparameter selection to predict emotional states.**

Keywords—EEG, Emotion Recognition, Deep-Learning Methods, Bayesian Optimization.

I. INTRODUCTION

Emotions are physiological phenomena often resulting in motivation, personality, temperament, behavior, and feelings. The study of the link between emotions and physiological functions is becoming increasingly popular in research. Emotions have a big effect on daily activities such as work, play, and interpersonal relations. Emotions are broadly classified into two types: positive and negative, positive emotions result in good mental health[1]. Whereas, negative emotions result in poor mental and physical health and can also produce psychiatric issues.

EEG signals are utilized to identify an individual's emotional state. Human-machine interactions can be enhanced by brain-computer interfaces (BCIs) by utilizing these signals [2]-[3]. Examining useful EEG characteristics is essential for identifying emotions. Even though EEG tests usually require a large array of electrodes on the scalp (sometimes more than 30), it is rarely addressed to identify the spatial characteristics that best reflect the functional interactions among different EEG channels. Innovative research that uses multichannel EEG recordings to investigate these spatial aspects has recently come to light [4]. Investigating the complex interplay between external and psychological elements. Emotion recognition is a rapidly expanding interdisciplinary research field spanning computer engineering and neuroscience[5].

A study that combined machine learning with EEG signals discovered a strong relationship between emotional stimuli and EEG responses in a variety of models [6]. Deep-learning (DL) techniques have seen tremendous and quick progress in the last several years, attracting a lot of interest from a variety of study fields. Recurrent neural networks (RNNs) [7], CNNs [8], and deep belief networks (DBNs) [9] are a few network architectures that have been proposed for emotion recognition. These models have had a major influence on areas including speech recognition [10], image classification [11], and time-series prediction [12], [13], because of their excellent performance and computational economy.

Dynamical graph convolutional neural networks (DGCNN) trained from EEG channel relationships result in improved feature extraction and produce precise emotion classification [14]. ERACNN (emotion recognition convolution neural network) [15] is a three-layer CNN consisting of a fully connected layer, a pool, and a convolutional layer that provides accurate emotion classification results.

A two-dimensional CNN, which consists of four convolutional layers and seven fully connected layers, has an accuracy of 76.56% for arousal emotions and 80.46% for valence feelings [16]. In [17], use a CNN framework with a residual block, convolutional layer, max pooling layer, fully connected layer, and softmax layer to identify emotions. The CNN uses three convolutional layers in the residual block for EEG feature extraction, with the third layer acting as a shortcut connection. It attains a mean accuracy of 82.84% on the DEAP dataset. A CNN technique for multichannel EEG-based emotion identification is presented in [18]. The method consists of generating a 3-D feature matrix, applying three 1×1 convolutional layers as a univariate convolutional layer, adding a four-way convolution to a multivariate convolutional layer, and finishing with a fully-connected layer. On the DEAP dataset, the approach obtains an accuracy of 85.53% for valence and 85.88% for arousal.

In [19], the regional-asymmetric CNN (RACNN) has been used for EEG-based emotion identification, employing three feature extractors and achieving 95% recognition accuracy on DEAP and DREAMER datasets. Deep learning approaches have shown good accuracy, but their practical implementation is limited by the time-consuming and specialized knowledge. Thus, an automated approach is needed to replace laborious manual experimentation and expedite the creation of appropriate and effective deep-learning models. This paper suggests a method for emotion recognition using convolutional neural networks and time-frequency images. Time-domain EEG signals are converted into representations that include frequency, amplitude, and time via a scalogram, spectrogram, and smoothed pseudo-Wigner–Ville distribution. These representations serve as inputs for CNN architectures and are shown as time-frequency images. The classification task utilizes CNN and along with an optimized CNN. The optimized CNN shows better accuracy. The structure of this paper is as follows: In Section 2, explains the details of dataset and different time-frequency methods used in the work. Section 3 outlines the research methodology, detailing the processes of applying deep learning, feature extraction, and classification. Section 4, shows concluding remark.

II. THE PROPOSED METHOD

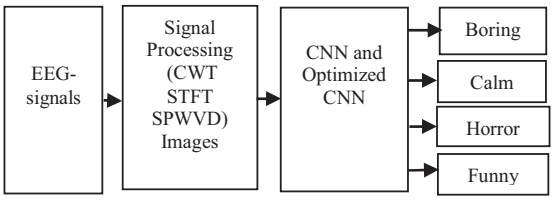

Figure 1. Block diagram of proposed work.

A. Dataset

The GAMEEMO dataset that has been utilized in this study contains recorded EEG signal data from 28 people between the ages of 20 and 27. The data were captured using a portable 14-channel EMOTIV EPOC + mobile EEG device[20]. Each participant played the games for five minutes, for a total of twenty minutes. The EEG data from four computer games: 'calm' (G2), 'boring' (G1), 'funny' (G4), or 'horror' (G3) has been used. The EEG signals were sampled at 128 Hz and subjected to band-pass filtering (0.16 Hz minimum, 43 Hz maximum). The dataset contains 1,568 EEG signals, with 38,252 samples per game (4 games × 14 channels × 28 participants). Figure 2 displays the 14-channel EEG data for the four games that were recorded from a single subject.

B. Time-Frequency Representation Continuous Wavelet Transform:

Time-Frequency Representation (TFR) is a useful technique for displaying the spectral variations of a signal over time. This article's methodology in Figure 1 makes use of the Short-Time Fourier Transform (STFT), the Continuous Wavelet Transform (CWT), and the SPWVD. It is simpler to convert EEG signals into their time-frequency representations when these transformation methods are coupled. The unique insights that each technique provides into the behavior of the signal allow for a more thorough and sophisticated study of the dynamic frequency components of the signal over time.

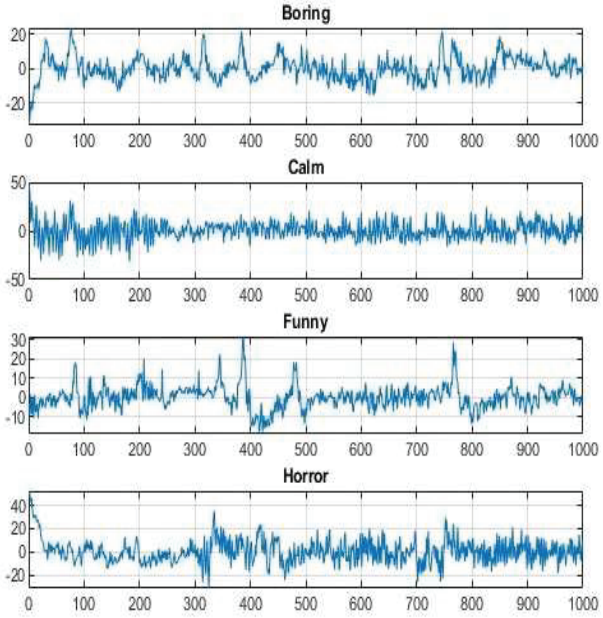

Figure 2. EEG Signals of four emotions.

C. Continuous Wavelet Transform (CWT):

A band-pass filter with finite energy and a zero mean function that oscillates within a particular frequency range is called a wavelet. There are two ways to accomplish the wavelet transform: the CWT and the discrete wavelet transform (DWT). The signal x(t)'s CWT is represented by [21].

$$W_{c,d}[x(t)] = \frac{1}{\sqrt{c}} \int_{-\infty}^{\infty} x(t) \Psi^{*}\left(\frac{t-d}{c}\right) \mathrm{dt} \quad (1)$$

Where the scaling parameter c regulates the function's spread and d represents the time shift. The scaled and shifted form of the mother wavelet ψ(t) is ψ((t − d)/c). CWT has the benefit of having adjustable window sizes. Thus, low-frequency components can be analyzed with bigger windows, and high-frequency components can be examined with smaller windows. Figure 3 shows the scalogram of EEG data during the boring game from a single participant.

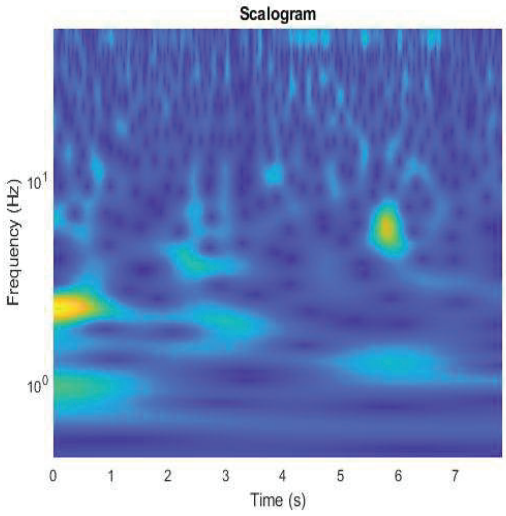

Figure 3.Scalogram of EEG data.

D. Smoothed Pseudo Wigner-Ville Distribution

SPWVD is a robust transformation method that gives complete details about the time-frequency localization of a signal's energy. SPWVD gives information on the time-domain localization of the signal and makes it easier to examine higher harmonics. Cross-term interference is efficiently minimized in SPWVD by utilizing both time and frequency windows. The formula for SPWVD is defined as [22]:

$$SPWVD(t,f) = \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} m\left(\frac{\tau}{2}\right) m^*\left(-\frac{\tau}{2}\right) \quad (2)$$

$$\text{n(t-t')}\ldots\ldots\ldots\ldots\times x(t'+\frac{\tau}{2}) x^*\left(t'-\frac{\tau}{2}\right) exp^{-j2\pi f t} dt'\, d\tau \quad (3)$$

SPWVD utilizes windows in the time (m (t)) and frequency (n (t)) domains to minimize interference. These windows are one by one adjusted for precise control over time and frequency details. The optimum between interference and time-frequency precision in conventional techniques is overcome by SPWVD, in contrast to STFT and CWT. Figure 4 shows the SPWVD of EEG data.

Figure 4. SPWVD of EEG Data.

E. Short Time Fourier Transform (STFT)

The Fourier transform in its enhanced form is known as the Short-Time Fourier transform (STFT). It evaluates the frequency variations of a signal over time. The time-domain signal is split into discrete blocks, and each block is then subjected to the Fourier transform. STFT has found several uses with EEG signals because of its ability to divide a signal into blocks [23], [24], and [25]. Several features are extracted from each time-domain signal segment by applying the Fourier transform using a window function. In symmetric band pass filtering, the frequency bands are evenly spaced in STFT. The signal x(t)'s STFT is calculated as [26]

$$X_\omega(t,f) = \int_0^T x(\tau)\omega(t-\tau) exp^{-j2\pi f\tau} \mathrm{d}\tau \quad (4)$$

The squared magnitude of the STFT defines the spectrogram. The spectrogram can be expressed mathematically as $S_\omega(t,f) = |X_\omega(t,f)|^2$, where the window function is denoted by ω(t). There must be uniformity in the length of the windows in every block. During the window's duration, a signal x(t) is taken to be almost stationary. Figure 5 shows STFT of the EEG data.

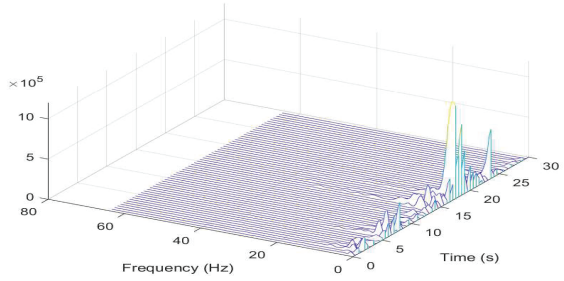

Figure 5.Spectrogram of EEG Signal.

F. Deep-Learning Hyperparameters Tuning using Bayesian optimization

Bayesian optimization is a process that combines deep learning models with optimization methods to find the best hyperparameters. In deep learning, hyperparameters are configuration parameters that must be defined before the model can be trained. These parameters were not learned from the training data. These may include batch sizes, learning rates, dropout rates, and other factors. Bayesian optimization is a probabilistic model-based optimization. It uses iterative exploration and exploitation of the hyperparameter space to determine the best set of hyperparameters. It builds a probabilistic model of the objective function of the deep learning model's performance and uses this model to guide the search for the next set of hyperparameters to evaluate. Grid search, random search, evolutionary algorithms, and gradient-based optimization techniques are some of the optimization strategies available for hyperparameter optimization. Grid search is computationally expensive. Random search is computationally efficient, but finding an optimal solution is difficult; and after every iteration, there is no guarantee of better model performance. Bayesian optimization is preferred over other methods due its advantages. Bayesian optimization requires fewer evaluations of objective functions. Bayesian optimization dynamically adjusts the sampling approach based on previous evaluations. Bayesian optimization can deal with noisy or stochastic objective functions using the surrogate model. Probabilistic surrogate models include some uncertainty, which helps with decision-making when choosing the subsequent set of evaluation hyperparameters.

III. RESULTS & DISCUSSION

In this work, the GAMEEMO dataset has been used, which has 14 channels and preprocessed EEG signals and contains 38252 samples from 28 subjects playing four distinct games. Nine segments, each measuring 3840 samples, are created from each EEG signal. To analyze the data channel-wise, firstly, the data from all 28 subjects is combined for a single epoch of the same channel, yielding a dimension for each epoch of (4×28) ×3840. Finally, signals from all nine epochs are combined, yielding a total signal dimension for each channel total signal of ((4×28×9) ×3840) or 1008×3840. A sequential transformation is required to transform the EEG signals into EEG images. The 14-channel EEG readings are analyzed individually.

The window length is automatically calculated based on time-frequency variations by applying the continuous wavelet transform (CWT) to the chosen EEG channel signals. In this work, another technique is employed to transform the 1-D EEG signal into a 2-D signal, called SPWVD. The Kaiser window is used to reduce cross-terms in the frequency and temporal domains. Selecting the right window size is important since a large window might result in a considerable increase in the size of the image, while a very small window may yield inferior resolution. As a result, a medium-sized window measuring 31 is chosen using empirical means.

To guarantee computational efficiency, the window size is kept constant at 2^n - 1, where n is the bit count. The third technique used for time-frequency analysis is STFT. It is a

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 22,2024 at 06:08:25 UTC from IEEE Xplore. Restrictions apply.

method for analyzing the temporal evolution of frequency components in a nonstationary signal. The spectrogram, or squared magnitude of the STFT, shows the spectral characteristics of the signal in a time-frequency format. A Hann window is used to window each of the 128 sample segments with an overlap length of 64. Spectrogram images are produced using a water plot. After that, the time-frequency representation is transformed into a grayscale image with dimensions of 1008 x 3840 after accounting for a scaling factor. After that, a jet128 color map is used to color the grayscale image's pixel brightness and contrast values, creating an EEG color image that is 1024 × 1024×3. The colorful photos are downsized to make them compatible with the Google Net model, which demands an input size of 224 × 224 × 3. The colorful photos are downsized to make them compatible with the Google Net model, which demands an input size of 224 × 224×3. The result of this multi-step procedure is the encoding of EEG signals as images that may be used as input into deep learning models for applications like gaming emotion recognition related to cognitive state assessments.

To train the deep-learning network, import the scalogram, spectrogram, and SPWVD images separately to create the image data store. The pictures are sorted and labeled according to their folder names using the image data store function. It reads batches of images quickly, which helps with CNN training. The images of three types of time-frequency methods are randomly split into three types: 70% of images are allocated for training, 10% of images are allocated for validation, and the rest of 10% are allocated for testing.

In deep learning, every layer in the network design is a filter that picks up basic image characteristics at the lower levels, like blobs, edges, and colors. The focus changes to more complex characteristics to differentiate between categories as one moves through the layers. A pre-trained network gives good results in the classification of images. GoogleNet is one of the most popularly used pre-trained networks. It is necessary to retrain GoogLeNet to tackle the particular EEG classification challenge, as it was initially trained to identify 1000 object categories in pictures. The network's convolutional layers extract image features, which are subsequently used to categorize the input image by the final classification layer and the final learnable layer. These two GoogLeNet layers—loss3-classifier and output—contain vital details about how to combine the extracted features into projected labels, a loss value, and class probabilities. To modify GoogLeNet for RGB picture categorization, these two layers must be replaced with new layers that are customized for the unique properties of the input.

Table 1 First seven channel validation accuracy

Deep-Learning Model	Time-Frequency Technique	First Seven Channel's validation Accuracy for classification of four gaming emotions (%)						
		AF3	AF4	F3	F4	F7	F8	FC5
Google-Net	Scalogram	60	55.4	63	64	48	60	65.5

	SPWVD	83	81	88	82	78	87	83

Table 1 and Table 2 display the validation accuracy for the classification of four different emotions. It shows that the Optimized version of GoogleNet provides better accuracy than the normal version. It can be inferred from the tables that SPWVD images give better results in terms of validation accuracy than the scalogram and STFT time-frequency images. EEG channels AF3, F3, F4, F8, O1, T8, P7, FC5, and O2 are showing better accuracy than the other channels. Table 3 displays the empirical values of hyperparameters used to train GoogleNet using time-frequency images.

The performance of GoogleNet can be improved by using optimization. Bayesian optimization algorithms have been used to choose the optimal values of the hyperparameters. The hyperparameters which has optimized is section depth, initial learning rate, momentum, regularization, and loss function. Section depth shows the number of layers within a module of neural network, adjusting section depth allows to find a balance between model complexity and efficiency. Initial Learning Rate is the parameter that determines how quickly the model learns from the data during training, variations in the initial learning rate have an impact on the stability and speed of model training. Momentum optimization expedites convergence. Increases in momentum lead to smoother and more consistent updates since the optimization method gives the previous gradients more weight. Lower momentum levels, on the other hand, lessen the impact of previous gradients, which may assist the algorithm in escaping local minima more readily but may also lead to more uncertain updates. The influence of previous gradients changes with momentum, affecting convergence stability and speed. To avoid overfitting, L2 regularization penalizes large weights. Modifying it affects how well training data fit and generalization are balanced. By calculating the difference between expected and actual values, the loss function algorithm evaluates the effectiveness of the model. Modifying the loss function has an impact on the model's learning process and how it prioritizes different training set elements, which could change the model's behavior and performance. Optimized Google is trained using the combined image data of a scalogram, spectrogram, and SPWVD from all channels. The optimized GoogleNet extracts the characteristics from the images, which are used as input to SVM classifiers for training. The trained SVM classifier tests the image data that was not used in training and testing. The classification performance is displayed using an ROC curve and confusion matrix in Figure 6 and Figure **7**. The fact that Figure 6 demonstrates that the true class and predicted class accuracy are higher than 82% indicates the dependability of the suggested model. Figure **7** shows that the AUC for the four classes is 0.9712, 0.9596, 0.9597, and 0.9625, demonstrating the clear distinction among the four classes.

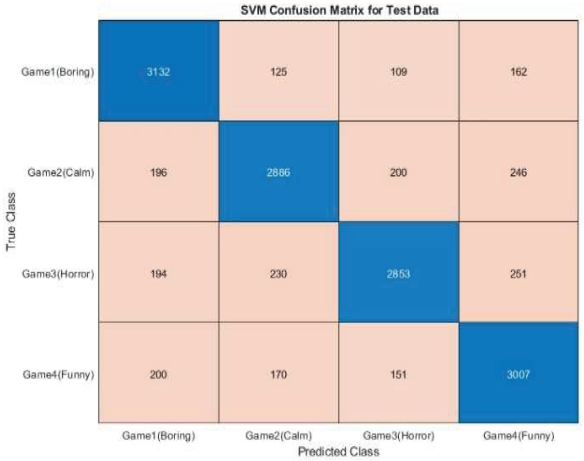

Figure 6. Confusion Matrix for Test Data.

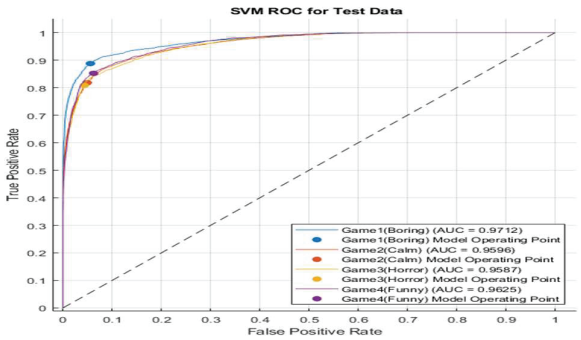

Figure 7.ROC Curve for Test Data.

Table 6 displays the results of this previous work, along with pertinent findings from similar studies that used similar statements and datasets. A multi-layer perceptron neural network (MLPNN) was used in the study of Alakus et al. [27] to classify data into four groups, with a maximum accuracy of 73.21% and 42.85% and 55% accuracy, respectively. The kNN and SVM classifiers showed relatively poorer performance. According to Alakus et al., regarding 2-class classifications, the accuracy was 81.3% with MLPNN, 72.5% with SVM, and 66% with kNN. Calculating the spectral entropy values of EEG signals across all channels was a different strategy by Alakus and Turkoglu et al. [28]. Next, a bidirectional long-short-term memory (LSTM) architecture was applied to the classification task, yielding 76.91% accuracy. For 2-class classification using SVM, kNN, and ELM classifiers, Aslam et al. [29] found high accuracies of 98.78%, 98.53%, and 98.41%, respectively. Tuncer et al.[30] used a cubic SVM classifier to achieve a channel-wise 2-class classification accuracy of 99.29%. With the use of projection dictionary learning, Su et al.[31] recorded an accuracy of 64.34% for two classes and 49.01% for four.

IV. CONCLUSION

This study investigates how well CNN-based models and various time-frequency techniques distinguish between various gaming emotions. Three conditions were investigated one showed better classification than the other two conditions. Compared to CWT and STFT methods, the SPWVD method yielded higher accuracy. This suggests that the time-frequency representation of SPWVD offers more comprehensive information than spectrogram and scalogram plots. Among other CNN-based networks, the suggested optimized CNN model demonstrated the fastest and most efficient computation but also the highest accuracy. Integration of EEG signals with additional wearable sensors is planned for future work. Better results are expected as a result of this integration, which attempts to improve classification accuracy.

***Abstract*— Emotion recognition from speech signal has emerged as a prominent research focus within the realm of human computer interaction in the last decade. Nonetheless, the existing recognition accuracy requires enhancement. To improve the recognition accuracy the proposed framework adopts a global feature extraction approach, decomposing the input speech signal into Intrinsic Mode Functions (IMFs). After that, the Mel Frequency Cepstral Coefficients (MFCC), and energy-based ratio features are extracted from each IMF. The ReliefF algorithm is employed to select pertinent features, which are subsequently tested on an optimizable ensemble classifier for evaluation. The proposed method provides 95.3% emotion recognition accuracy.**

Keywords*— Speech signal processing, Emotion recognition, Empirical mode decomposition Ratio feature, MFCC.

I. INTRODUCTION

Speech Emotion Recognition (SER) has a significant place in enhancing human-computer interaction (HCI) systems. Its contributions are found in many areas, including as audio surveillance, computer games, robotic interfaces, e-learning, and clinical research. Notably, SER can support educators by providing insights into a learner's emotional state, enabling the establishment of a classroom atmosphere that is favorable to learning, as described in [1].

Speech signal non-stationarity makes emotion recognition in speech signals a difficult task even today. For example, human listeners only successfully identify an anonymous speaker's emotions 60% of the time [1]. Additionally, the scarcity of available training data poses a significant obstacle, with most SER methods reporting accuracies ranging from 70% to 90% [2-14]. Another hurdle in SER is the development of language-independent systems, as accuracy is affected by factors such as the number of emotions, the size of the training dataset, the gender, the language, the selected feature set, and the emotion class. SER models can be optimized by selecting carefully features that efficiently capture every facet of the input signal [2]. However, the local and global features are utilized for addressing the non-stationarity of speech signals. Local features represent temporal dynamics, while global features capture statistical measures such as maximum value, standard deviation, and mean value. Further, different features based on speech quality, spectral variation, and prosodic nature of speech signal is employed in SER systems based on their applications [3]. Prosodic features analyze the rhythm and intonation of speech signals, capturing human perception through estimations of energy, length, and fundamental frequency. Meanwhile, spectral features focus on vocal cord characteristics.

For emotion classification other methods are proposed as long-term temporal contexts using recurrent Neural Networks [4], Deep Learning [5], and speech spectrogram using Neural Networks [6]. Researchers in [7-14] employ various techniques for emotion classification across various datasets. In [7], a convolutional neural network (CNN) trained on BP4D+ images and Ryerson Audio-Visual Database of Emotional Speech and Song (RAVDESS) speech signals, achieving accuracy of 77.6% and 56.2% on FAU-Aibo and RAVDESS database, respectively. Addressing challenges in speech emotion recognition (SER), researcher proposed temporal modeling framework combines bidirectional long short-term memory networks, CNN, and Capsule networks, outperforming existing systems [8]. Utilizing rational dilation wavelet transform decomposition, [9] attains a maximum accuracy of 83.3% in the categorization of two classes. Use distinct datasets for four-class emotion classification [11–13]. In [10] SER system utilizing K Nearest Neighbor (KNN) achieves an impressive 86.02% classification accuracy based on Berlin emotional database features. Using six binary classifiers, [11] suggests a multi-task learning method that yields an accuracy of 54.76%. A significant SER accuracy of 77.5% is achieved in [12] using a radial basis kernel function. Traditional approaches are also employed in [13] and [14] for developing SER models for robotic and multi-language applications, though both models exhibit unsatisfactory recognition rates.

Nevertheless, the natural non-stationarity of speech signals makes it more practical to employ nonlinear signal processing methods. Recognizing speech-based emotions accurately is still difficult due to the variability, complexity, and subtle changes in the nonlinear features of speech signal. In order to address this difficulty, the Empirical Mode Decomposition (EMD) technique was presented by Huang et al. [15], to analyze and process the input speech signal, which has the potential to display nonlinearity and non-stationarity while maintaining its inherent characteristics. SER has demonstrated success with EMD approach [16], [17],[18]. Through the use of numerous components that each capture the maximum local frequency, the EMD approach provides intrinsic mode functions (IMFs) from speech signal or time series data. These IMFs can be efficiently utilized for further processing of speech signal to identify the emotion.

In the proposed framework, the global feature extraction approach is followed. The input speech signal is decomposed into IMFs and features are computed from each IMF. In this approach two types of features are extracted, one is energy-based ratio feature and another is based on Mel frequency cepstral coefficient (MFCC). Features are selected using the

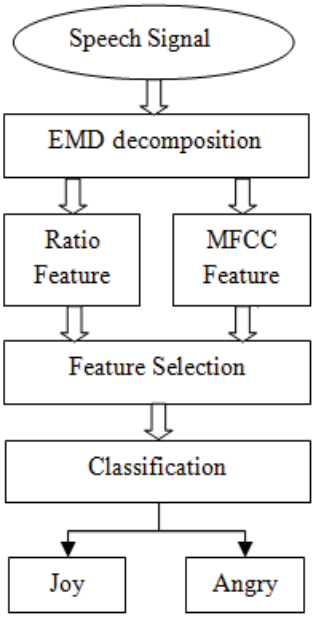

Fig. 1: Process flow of proposed SER framework

ReliefF algorithm and finally, the selected features are tested on the optimizable ensemble (OE) classifier. The obtained result is compared with the existing SER architectures in result and discussion section..

II. METHODOLOGY

The process flow of proposed SER framework is presented in Fig. 1. The detail description of each stage of Fig. 1 is discussed in subsequent sections..

A. Dataset

In the proposed framework publically available EMOVO dataset is used. This dataset, captured by three male and three female orators [19], comprises 14 sentences expressing seven distinct emotions. The dataset encompasses a total of 588 utterances. The recordings maintain a sampling frequency of 48KHz. In this experiment two emotions joy and sad are used for testing the proposed method.

B. EMD Decomposition

Before The input speech signal initially decomposed using EMD, which dissects the nonstationary signal into a amplitude and frequency modulated (AM-FM) oscillating components named as IMFs [15]. An IMF is a function that adheres to the following criteria:

1. Either the number of extrema is the same or it changes by a maximum of one.
2. Based on local extrema, the mean value of envelopes is zero.

The EMD procedure for extracting IMFs from a time series signal can be delineated through the underneath steps:

1. Determine each signal's local maximum and local minimum.
2. To obtain the envelopes $h_{max}(t)$ and $h_{min}(t)$, connect all the maxima and minima individually.
3. Compute the average value of the envelopes using (1) [15]:

$$m = \frac{h_{max}(t) + h_{min}(t)}{2} \quad (1)$$

4. Deduct m(t) from the as follows [15]:

$$q_1(t) = x(t) - m(t) \quad (2)$$

5. Verify whether $q_1(t)$ complies with the specified Intrinsic Mode Function (IMF) conditions mentioned earlier.
6. Continue from steps 2 through 5 until an IMF is obtained.

Once the initial Intrinsic Mode Function (IMF) is acquired, define $I_1(t)=q_1(t)$, representing the smallest temporal scale in $x(t)$. The subsequent IMF can be obtained by generating a residue $r_1(t) = x(t) - I_1(t)$, which is then used as the new signal in the aforementioned algorithm. The obtained residue is iterated until it becomes a monotonic function, signifying that no further IMFs can be produced. A set of narrow-band symmetric waveforms is formed by the resulting IMFs. The Fig. 2 shows the speech signal and their IMFs after decomposition. Following the decomposition, the signal $x(t)$ can be defined as [15]:

$$x(t) = \sum_{k=1}^{K} I_k(t) + r_K(t) \quad (3)$$

Where $I_k(t)$ is k_{th} IMF, K represents total number of IMF and $r_K(t)$ is the final residue.

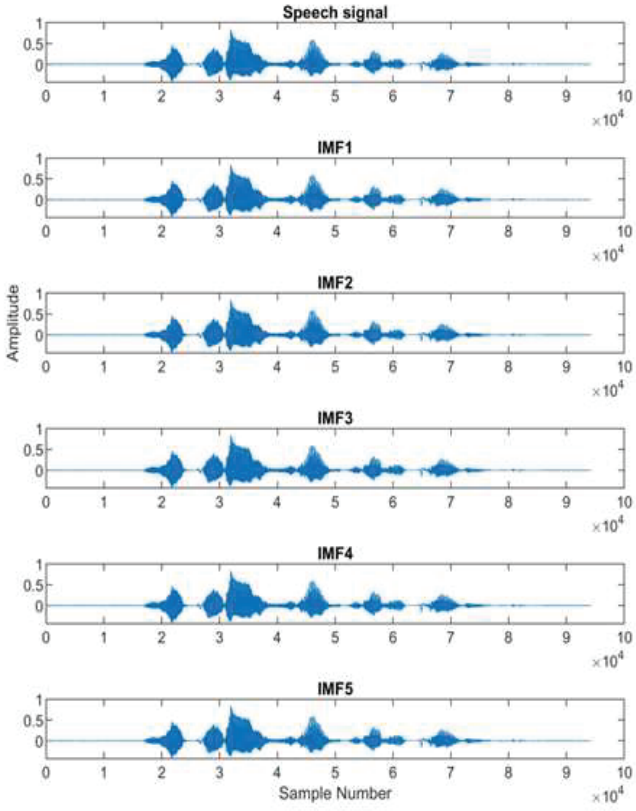

Fig. 2: Speech signal and 5 IMFs after EMD decomposition.

C. Feature Extraction

In the proposed framework ratio feature based on energy and statistical measures are calculated from MFCC coefficients. The detail descriptions are available in following sections.

a) Ratio Feature: After decomposition the energy of each IMF is calculated using (4) [21].

$$E_k = \sum_{n=1}^{N} |I_k(t)|^2 \quad (4)$$

where N is preprocessed signal length.

To obtain the ratio feature each IMF, feature energy is divided by the energy of remaining IMFs. The ratio features from IMF is calculated using (5)

$$f = {}^{E_k}/_{E_l} \qquad \text{l} = 1,2,3 \ldots \ldots \text{except k} \quad (5)$$

b) MFCC Feature: The MFCC serves as a prominent cepstral feature in the development of SER systems. Its primary purpose is to accurately depict the short-time power spectrum of a speech signal. Each preprocessed signal undergoes MFCC extraction, as outlined in Fig. 3.

D. Feature Selection and Classification

The feature selection method employs the ReliefF algorithm, a rank-based approach, to choose relevant features [22]. This algorithm randomly selects instances from both the same class and different classes. When R data instances are randomly chosen from the total n instances, the ReliefF algorithm computes the feature score for each original feature as discussed in [22].

In proposed framework optimizable ensemble classifier is used for the emotion identification. It combines multiple individual models, such as decision trees or neural networks, to enhance predictive performance by leveraging diverse perspectives [23]. Through optimization techniques like boosting or bagging, it strategically weighs and combines the strengths of each constituent model, effectively mitigating individual weaknesses. This approach promotes robustness, generalization, and improved accuracy in complex classification tasks, making it a powerful tool for heightened performance and adaptability across dataset.

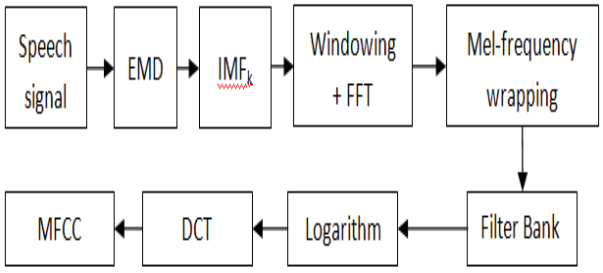

Fig 3: Schema of MFCC feature extraction.

III. RESULTS AND DISCUSSION

In this experiment publically available EMOVO database is used to train the classifier. Initially, the speech signal is decomposed into five IMFs using EMD method. After that energy based ratio feature and MFCC based statistical features are calculated. For the energy based ratio features, the energy of each IMF is calculated and obtained energy of each IMF is divided with remaining IMF energy as explained in section 2. In MFCC based features mean and variance are calculated using the first three coefficients because most of the information is lies in this region. The extracted features are optimized using ReliefF algorithm. Initially a total of 50 features are extracted. After that, top 25 features having high predictor importance weight are considered as significant feature and remaining are rejected. The predictor rank bar is shown in Fig. 4.

These selected features are utilized to train the classifier. The classifier is trained using 10 cross validation in which complete dataset is divided in 10 subsets. In which 9 subsets is utilized for the training and remaining 1 is used for testing. This process is continuing until all subsets have been utilized as the test dataset. The OE classifier is used for emotion classification and achieves an impressive 95.3% recognition accuracy. Additionally, Table 1 presents performance indicators for each emotion, such as recall, precision, and F1 score. Notably, the F1 scores show that the proposed framework exhibits a similar degree of efficacy for both emotions. Further, table 1 show how robust the framework's design is, since it constantly produces reliable outcomes for both emotional states. The precision and recall demonstrate how effectively the framework can recognize and categorize emotions. Finally, the proposed framework's effectiveness is confirmed by the high recognition accuracy and balanced F1 scores across emotions, shows its potential for use in a variety of situations where emotion classification is required. This work advances the field by establishing the framework as a reliable and strong solution for emotion recognition applications. Fig. 5 shows the region of convergence of proposed framework.

The comparison between the suggested framework and the current SER models is presented in Table 2. Earlier research showed that M. A. Jalal et al. [7] obtained 70.14% classification accuracy, R. Jannat et al. [6] obtained 66.41% and ravi et al. [9] achieves 83.3% accuracy. In contrast, the pr

Table:1 Precision, recall and F1 score of proposed framework.

Emotions	Precision %	Recall %	F1 score %
Joy	94.25	96.47	95.34
Sad	96.38	94.11	95.23

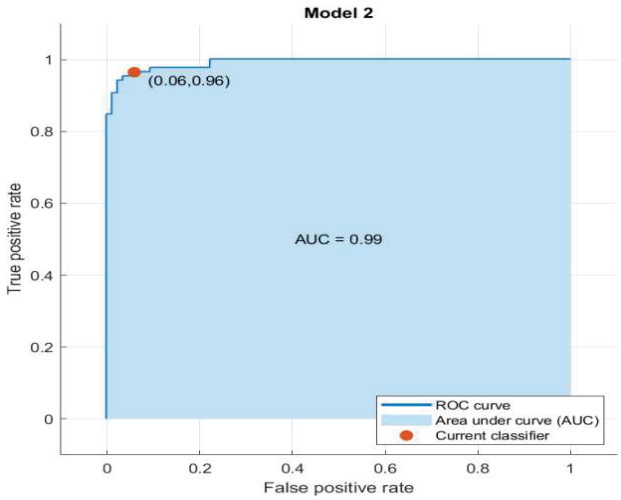

Fig. 5. Region of convergence of proposed framework.

Table: 2 Comparison of proposed framework with existing SER model.

Authors	Classified emotions	Method	Accuracy (%)
R. Jannat et al [6]	Happy, Sad	Ubiquitous computing with CNN	66.41
M. A. Jalal et al [7]	Happy, Sad	Used BLSTM, CNN and Capsule networks	70.14
Ravi et al [9]	Happy, Sad	RDWT with OE classifier	83.3
Proposed Method	Joy, Sad	EMD with OE classifier	95.3

proposed method in this study attains a significantly higher classification accuracy of 95.3%. Therefore, this research introduces a more precise approach for emotion recognition utilizing speech signals, surpassing the accuracies achieved by previous methodologies. The substantial improvement in classification accuracy underscores the effectiveness and advancement offered by the proposed method in accurately discerning emotional states from speech signals. This enhancement in performance positions the proposed method as a noteworthy contribution to the field of emotion recognition, showcasing its potential to outperform existing approaches and enhance the reliability of emotion classification systems.

IV. CONCLUSION

This study introduces features based on the EMD for analyzing speech signals associated with various emotions. Initially, EMD is used to decompose the input speech signals into IMFs. Subsequently, ratio and MFCC based features are computed from each IMF. The statistical significance of these features is evaluated using ReliefF algorithm and high rank features are selected for further processing. The energy based ratio feature shows high potential for the classification. These extracted features are employed for training and testing in OE classifiers. The classifier trained using 10 fold cross validation and achieves 95.3% accuracy for binary class. Finally the accuracy of proposed method is compared with the existing state of art. The proposed framework proved more efficient and robust compare to the other existing methods.

However, there is room for improvement in terms of SER system performance. For example, major research requires in SER system to develop a gender independent and language independent model. This enhancement can be achieved by combining several machine learning and deep learning approaches with an exploration of a novel and robust feature collection.

ABSTRACT

Ge'ez has been used in Ethiopian churches for centuries to read and interpret the Bible. As a part of the liturgy and religious ceremonies, it is also utilized in prayer and chanting. Since the language is ancient, plenty of handwritten physical documents are generated. Recognizing handwritten Ge'ez numerals poses significant challenges due to variations in handwriting styles, incomplete or overlapping strokes, noise, and distortion. This study introduces an end-to-end approach for handwritten Ge'ez multiple numeral recognition employing deep neural networks. The proposed method streamlines recognition by eliminating manual feature extraction stages. To enable end-to-end training without explicit alignment, the model uses attention mechanisms and a connectionist temporal classification-based loss function. The proposed model is evaluated on 120,000 handwritten Ge'ez multiple numeral images, which is a syntactically generated dataset. The developed recognition model achieved a character error rate (CER) of 2.81% and a word error rate (WER) of 18.13%. These results highlight the effectiveness of the approach in accurately and reliably recognizing handwritten Ge'ez multiple numerals.

Introduction

The Ge'ez language has a significant role in Ethiopian culture, functioning as an ancient Semitic language primarily used within Ethiopian churches [1]. It holds a sacred status and has been historically employed for writing Ethiopian historical accounts and religious texts, resulting in a substantial collection of Ge'ez documents found in Ethiopia. For centuries, Ge'ez has been used in Ethiopian churches for reading and interpreting the Bible. It is an integral part of liturgical practices, religious ceremonies, prayers, and chants. Due to its ancient nature, a large number of handwritten physical documents are available in the Ge'ez language. Ge'ez utilizes the Ethiopic script, which is its native alphabet [2]. The script follows a left-to-right reading and writing system similar to the Latin script.

Derived from the ancient South Arabian alphabet [1], the Ethiopic script has been used to write Ge'ez for over two thousand years and remains one of the few writing systems still in use today. Notably, Ge'ez incorporates a unique numbering system known as the Ge'ez numbering system, specifically designed for representing numerical data. Comprising a total of 20 distinct symbols as shown in Table 1, the Ge'ez numbering system employs complex shapes for each symbol, accompanied by two horizontal lines positioned above and below it. It is also important to note that the Ge'ez numeral system does not include a symbol that represents zero.

Table 1. Ge'ez numbering and English equivalent numeric symbols.

Digits*	English symbol	Numbers*	English symbol
፩	1	፲	10
፪	2	፳	20
፫	3	፴	30
፬	4	፵	40
፭	5	፶	50
፮	6	፷	60
፯	7	፸	70
፰	8	፹	80
፱	9	፺	90
		፻	100
		፼	10, 000

The Ge'ez numbering system consists of two main categories: digits and numbers. The digit's category includes symbols representing the numbers from one to nine: "፩," "፪," "፫," "፬," "፭," "፮," "፯," "፰," and "፱," where each symbol corresponds to its respective numerical value. The numbers category encompasses symbols representing multiples of ten and larger numbers. These symbols include ፲ (representing 10), ፳ (20), ፴ (30), ፵ (40), ፶ (50), ፷ (60), ፸ (70), ፹ (80), ፺ (90), ፻ (100), and ፼ (10,000). In this category, each symbol represents a specific value, and the English equivalent number appears inside the brackets. The Ge'ez numbering system can represent a wide range of numerical values by combining the 20 primary symbols. For example, the

symbol ፩ combined with other 9-digit symbols creates numbers such as ፳፩ (representing 21), ፳፪ (22), ፳፫ (23), and so on, up to ፳፱ (29).

Handwritten numeral or text recognition is a complex process that involves automatically identifying various handwritten numerals or text information [3]. While computer algorithms are employed to analyze and interpret numeral features, recognizing handwritten digits presents unique challenges in optical character recognition (OCR) and pattern recognition.

One of the main difficulties lies in the significant variations in handwritten digits exhibited in shape, size, and style [4]. These variations make it particularly challenging to develop an algorithm that can accurately recognize all possible variations. Furthermore, distinguishing between different digits can be problematic due to overlapping or incomplete strokes.

Handwritten digits are also susceptible to distortions and noise caused by factors like poor handwriting, smudges, or low-quality image documents [5–7]. So, the ability to generalize to new data makes handwritten numeral recognition more demanding than recognizing printed numerals. A variety of techniques have been explored to overcome these challenges, including pre-processing, feature extraction, and deep-learning approaches [8]. While considerable research has been conducted on pattern recognition for widely used scripts like Latin, Arabic, Urdu, Persian, and Mandarin, Ge'ez numeral recognition, which pertains to an ancient script, has not received the same level of attention in OCR research [9]. Previous works on Ge'ez script recognition have primarily been based on printed texts [10–13], and the recognition of handwritten Ge'ez scripts has remained largely unexplored due to the scarcity of datasets [3]. Although deep-learning algorithms typically require a large amount of labelled data for training [6], publicly available Ge'ez digit datasets are scarce, with the dataset prepared by Nur et al. being an exception [3]. Consequently, recognizing Ge'ez numerals poses a unique challenge in OCR.

Deep learning (DL) approaches have revolutionized pattern recognition, surpassing traditional machine-learning methods in terms of effectiveness [14]. In particular, convolutional neural networks (CNNs) have played a crucial role in image processing and pattern recognition. Building upon previous studies on Ge'ez digit recognition and handwritten text recognition [3,15], this study focused on the underexplored area of handwritten Ge'ez numeral recognition. To the best of our knowledge, this study will be the first of its kind in handwritten Ge'ez multiple-digit recognition. Our study makes the following significant contributions:

- Preparation of the dataset: To enhance the training process, we prepare synthetically generated image datasets, augmenting the available data to facilitate robust learning and recognition.
- Development of comprehensive end-to-end (E2E) learning model: The proposed model integrates automatic feature extraction, attention mechanism, bidirectional LSTM (BLSTM) based sequencing, and CTC loss functions. This comprehensive framework enables the model to automatically extract relevant features from Ge'ez numeral images, selectively focus on important regions of the input sequence, and gain a better understanding of temporal information. Additionally, it enables E2E training without the need for explicit alignment between images and labels.
- Experimental Evaluation: Leveraging the prepared dataset, we conduct different experiments, starting with hyperparameter selection, to evaluate our model's performance. The preliminary results demonstrate promising outcomes in Ge'ez handwritten numeral recognition.

Through these contributions, our study aims to advance Ge'ez handwritten numeral recognition by leveraging a comprehensive DL framework that combines CNNs, BLSTM, attention mechanisms, and CTC. This approach facilitates effective training and recognition, paving the way for improved performance in Ge'ez numeral recognition tasks.

Literature reviews

Numeral recognition has been extensively studied since the 1980s, employing various approaches ranging from traditional machine-learning techniques to deep-learning approaches [16]. Numerous published studies have explored different strategies for digit recognition, focusing on pattern recognition and feature extraction techniques. In this section, we provide an overview of the research conducted in the field of digit recognition. Some studies use traditional machine-learning approaches, while recent studies apply deep-learning and ensemble approaches.

Abdulrazzaq and Saeed compared three machine-learning recognition algorithms: Naive Bayes (NB), multilayer perceptron (MLP), and the K* algorithm [17]. They used a handwritten dataset from NIST, consisting of 48,060 samples with 128 × 128-pixel images. Pre-processing was performed, resulting in 16 × 16 feature images. The authors employed the "correlated feature selection" method and obtained 37 features for training. Their main objective was to identify the best classifier among the three algorithms, achieving high accuracy with minimal features. The K* algorithm performed better than NB and MLP, with a recognition rate of 82.36%. However, image resizing and random sample selection negatively affected recognition accuracy, leading to more misrecognized digits. The NIST

dataset presented challenges due to numerous confusing images, making it difficult to find the optimal classifier through random sampling. In a study by Boukharouba and Bennia [18] a novel feature extraction technique was proposed for recognizing Persian handwritten digits. They utilized a Freeman chain code that incorporated vertical and horizontal information. The advantage of their feature extraction approach is that it eliminates the need for normalization. They employed a support vector machine (SVM) as the classification algorithm and evaluated their model using 80,000 Persian numerals, achieving an accuracy of 98.55%.

Liu et al. [19] compared the recognition time and rate of neural networks with backpropagation (BP), support vector machines (SVM), k-nearest neighbour (KNN), and CNN. They used the MNIST handwritten dataset, which consists of 70,000 28 × 28 images for training and testing. Randomly selecting 5000 samples for training and 1000 samples for testing, the authors followed specific procedures for training the classifier, including input, pre-processing, feature selection, classifier design, and classification decision steps. For the testing phase, they repeated the input, preprocessing, feature selection, and classification decision steps to obtain recognition results. The advantages and disadvantages of the four algorithms were analyzed and reported. The simulation test results revealed that the CNN algorithm achieved the highest recognition accuracy. Abu Ghosh and Maghari [20] compared three popular neural network approaches: CNN, DBN, and DNN. Their system consisted of six steps: preprocessing, segmentation, feature extraction, classification, training, and recognition. They used the MNIST handwritten dataset and a self-created random dataset to verify their results. The random dataset contained 85 different handwritten digits from various sources. The authors evaluated the three algorithms based on accuracy and performance, considering execution time as an additional criterion. DNN outperformed the other algorithms, achieving an accuracy of 98.08%.

Ahlawat et al. [21] proposed an improved digit recognition system using the MNIST dataset and a CNN algorithm. They developed two CNN architectures: CNN_3L with three layers and CNN_4L with four layers. Their main objective was to explore various parameters of the CNN architecture using the MNIST handwritten dataset. They employed optimization algorithms, including stochastic gradient descent with momentum, Adam, Adagrad, and Adadelta, to enhance the performance and speed of the neural networks. Among these optimization parameters, the Adam optimizer achieved a detection rate of 99.89% for the CNN model with three layers, surpassing previously reported results in this field.

The authors [22] proposed recognizing Arabic handwritten characters using ensemble convolutional neural networks. They utilized adaptive gradient descent in the initial epoch for convergence and regular stochastic descent in the final epoch. The study employed K-fold and Monte Carlo cross-validation methods. With the MADbase dataset, they achieved a test accuracy of 99.47% and a classification accuracy of 99.74%. To enhance Arabic handwritten numeral recognition, Ahamed et al. [8] proposed a convolutional neural network architecture. Their CNN architecture comprised two convolutional networks with 32 filters and 5 × 5 kernels, two max-pooling networks with a 2 × 2 kernel, two dropout layers, and two fully connected layers. They conducted two activities in their study: improving a previous research model by Ashiquzzaman et al. [23] and introducing a newly proposed method. Using augmentation techniques, they expanded the initial dataset from 3000 to 72,000 images. The improved model achieved 98.95% accuracy, while the newly proposed model achieved 99.96% accuracy.

Ahlawat and Choudhary [24] proposed an automatic recognition model for handwritten digits utilizing CNN for feature extraction and SVM for output prediction. By combining CNN and SVM, they achieved a classification accuracy of 99.28% on the MNIST dataset of handwritten digits. Ali et al. [25] developed an improved method for recognizing handwritten digits using a CNN with a DeepLearning4J framework. The CNN model, consisting of three convolutional layers, one max-pooling layer, and two fully connected layers, is trained and tested on the MNIST handwritten dataset. The model achieved an overall accuracy of 99.21% when tested on a dataset of 5,130 images, with only 42 misidentifications. The computation time for training and testing was also improved. In their work [26], Yu et al. presented an improved LeNet5 digit recognition algorithm. They replaced the last two layers of LeNet5 with an SVM, utilizing SVM as the classifier and LeNet5 as the feature extractor. Yoa et al. [27] proposed a CapsNet-based recognition and separation method for fully overlapping digits. They introduced three main modifications to the original capsule network [28]: the use of a small convolution kernel, the expansion of capsule dimensions to express extracted features, and the application of dual dynamic routing. Their proposed model, called "FOD_DCNet," achieved an accuracy of 93.53%, surpassing the performance of CapsNet by 5.43%.

End-to-end learning

E2E learning is a DL or machine-learning approach that aims to simplify the process of solving a task by combining all the stages into a single model [29]. Traditionally, machine-learning pipelines involve multiple steps such as pre-processing, feature extraction, and classification. E2E learning eliminates the need for handcrafted features or intermediate representations and allows the

model to learn directly from raw input data to produce the desired output.

This approach has gained popularity with the advancement of deep-learning and neural networks [30]. DL models, such as CNN and recurrent neural networks (RNN), have demonstrated exceptional performance in various domains like computer vision, natural language processing, speech recognition, and pattern recognition.

The main advantage of E2E learning is its simplicity. By removing the need for complex feature engineering, the overall system design becomes more straightforward. Additionally, end-to-end learning models are flexible and can adapt to different domains and tasks. They automatically learn relevant features and representations from the raw data, capturing intricate patterns and dependencies [4].

However, there are some limitations to consider. E2E learning models typically require large amounts of labelled training data to generalize well, which can be time-consuming and costly to acquire. The complex representations learned by these models may also lack interpretability, making it challenging to understand the reasons behind their decisions. Furthermore, the integrated nature of E2E models can make it difficult to reuse or modify specific parts for different tasks [31].

So, we can generalize E2E learning as a powerful approach that allows a model to learn directly from raw input data to produce the desired output. It simplifies the machine-learning process, and achieves state-of-the-art results in various domains, but also requires substantial amounts of labelled data and may lack interpretability and modularity.

Studies done on handwritten Ge'ez numerals

In the realm of Ge'ez numeral recognition, limited prior studies have been conducted. Agegnehu et al. [32] applied deep learning to recognize Amharic punctuation marks and offline handwritten digits using a CNN architecture. Their dataset consisted of 5800 images collected from 100 different handwriting samples, achieving a testing accuracy of 70.04%. Furthermore, studies have also explored Ge'ez digits in contexts beyond printed and handwritten forms. Tamiru et al. [33] proposed a study on recognizing Amharic alphabetic sign language, benefiting individuals with hearing loss. Their model consisted of pre-processing, regimentation, feature extraction, and recognition stages, utilizing digital image processing and machine-learning algorithms such as SVM (98.06%) and ANN (80.86%) for classification. Abeje et al. [34] focused on Ethiopian sign language recognition using a deep convolutional neural network. Their system encompassed preprocessing, feature extraction, and classification stages, employing digital image processing techniques. The dataset used in their study was collected from hearing-impaired students.

While the majority of researchers have predominantly focused on the recognition of English numerals, the absence of publicly available Ge'ez digit datasets has deterred extensive research in this area. However, Nur et al. [3] advanced the field of Ge'ez digit recognition by developing a recognition model with improved accuracy and an experimental dataset comprising 51,952-digit images written by 524 individuals. Their proposed CNN architecture achieved a recognition accuracy of 96.21%. The authors recommended exploring multi-digit recognition using diverse deep-learning approaches for future research. Therefore, our motivation started from their recommendations.

Methodology

In this section, we present the details of our E2E handwritten Ge'ez multiple-number recognition system. The purpose of this study is to develop a recognition model that can accurately recognize handwritten multiple digits in Ge'ez numerals. The architecture of the model and the dataset used to train and evaluate the model are explained.

The dataset preparation

To address the issue of limited datasets in deep-learning studies, we recognize the significance of having a sufficiently large and diverse dataset for model training and testing. In this research, we made concerted efforts to overcome this challenge by developing an extensive dataset specifically tailored to our DL problem.

The dataset used in this study is derived from the initial handwritten dataset introduced by Nur et al. [3]. The original dataset comprises 51,952 sample preprocessed greyscale images of single digits with a dimension of 32 by 32 pixels (see Figure 1). To extend the scope of the dataset and sequentially accommodate multiple digits, we synthetically generated a new dataset having a multi-digit image from the original dataset.

Asthe dataset is synthetic, we utilize an automated multi-digit image creator algorithm to create sequential data. In achieving this, we have developed a program employing the OpenCV image creator tool, specifically using the concatenation method. The selection of digits is performed randomly. The algorithm is depicted in Table 2.

The newly generated dataset consists of 120,000 image samples with a dimension of 32 by 128 pixels (see Figure 2). Each image in this dataset contains a variable number of sequential digits. This expansion allows us to explore and evaluate the performance of the OCR model in scenarios involving multiple numerals within a single image.

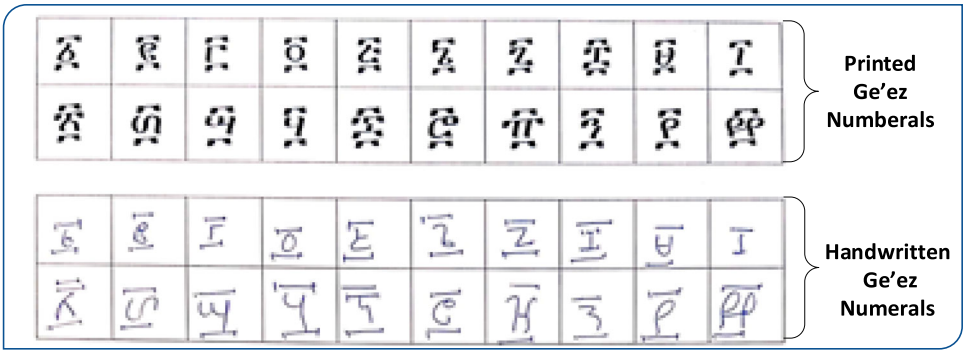

Figure 1. Sample data from the initial handwritten Ge'ez digit dataset.

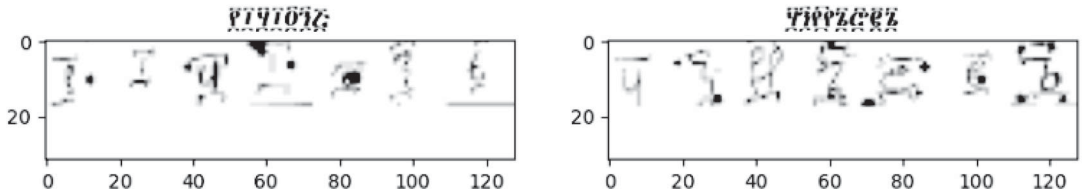

Figure 2. Sample images from synthetically generated 32 by 128 multiple numerals dataset.

Table 2. Synthetic sequential multi-digit creator algorithm.

Parameters:
n_items: Number of items per sequence
n_seqs: Total number of sequences to generate
Data:
items: Collection of available items
labels: Labels corresponding to the items
Result:
seq_labels: Array of labels for generated sequences
seq_data: Array of generated sequences
Algorithm:
1. Initialize seq_data ***as*** an ***empty list***
2. Initialize seq_labels ***as*** an ***empty list***
3. ***For*** i ***from*** 1 ***to*** n_seqs:
   a. Generate random indices ***using*** np.random.randint
   b. Retrieve random_items ***from*** items based ***on*** indices
   c. Transform ***each*** item ***in*** random_items ***as*** needed
   d. ***Convert*** transformed random_items ***to*** a numpy ***array and*** assign ***to*** seq
   e. Retrieve random_labels ***from*** labels based ***on*** random indices
   f. Append seq ***to*** seq_data
   g. Append random_labels ***to*** seq_labels
4. ***Convert*** seq_labels ***and*** seq_data ***to*** numpy arrays
5. Reshape seq_data ***to*** the desired shape
6. ***Return*** seq_labels and seq_data

By leveraging the initial dataset provided by Nur et al. [3], we were able to build upon their work and extend it to address the specific requirements of our study. The synthetic generation of the dataset provides a more diverse and challenging set of images, enabling a comprehensive evaluation of the OCR model's capabilities in handling sequential multiple digits.

Generating the sequential synthetic data follows the following algorithmic steps and the flowcharts of the steps are depicted in Figure 3.

(1) Original datasets from [3]: Random selection of images from the original dataset which has a single digit in each image.
(2) Data augmentation: Add noise, erosion, and dilatation.
(3) Pre-processing: Resize, transpose, and normalize the image
(4) Finally, generated 32 by 128-pixel image which consists of multiple handwritten Ge'ez numerals.

The proposed network architecture

The proposed recognition model consists of two main steps: feature extraction and the recognition process. These steps work together to achieve improved recognition accuracy.

Feature extraction process

In the feature extraction part, we employ seven CNN layer blocks, which automatically extract relevant features from the input image, and a SoftMax-based attention mechanism. Each CNN layer block consists of convolutional layers, max-pooling layers, and batch normalization. These components play specific roles in the feature extraction process.

Convolutional layers perform convolution operations on the input image. The convolution operation between an input image (I) and a filter/kernel (K) can be computed in Equation (1).

$$(I,K)[i,j] = \sum\sum (I[x,y] * K[i-x, j-y]) \quad (1)$$

In Equation (1), *(I,K)[i,j]* represents the value at position *[i,j]* in the resulting feature map. The double summation ($\sum\sum$) computes the element-wise multiplication and summation over the spatial dimensions. [x,y] and [i−x,−y] represent the corresponding values in the input image and filter/kernel, respectively.

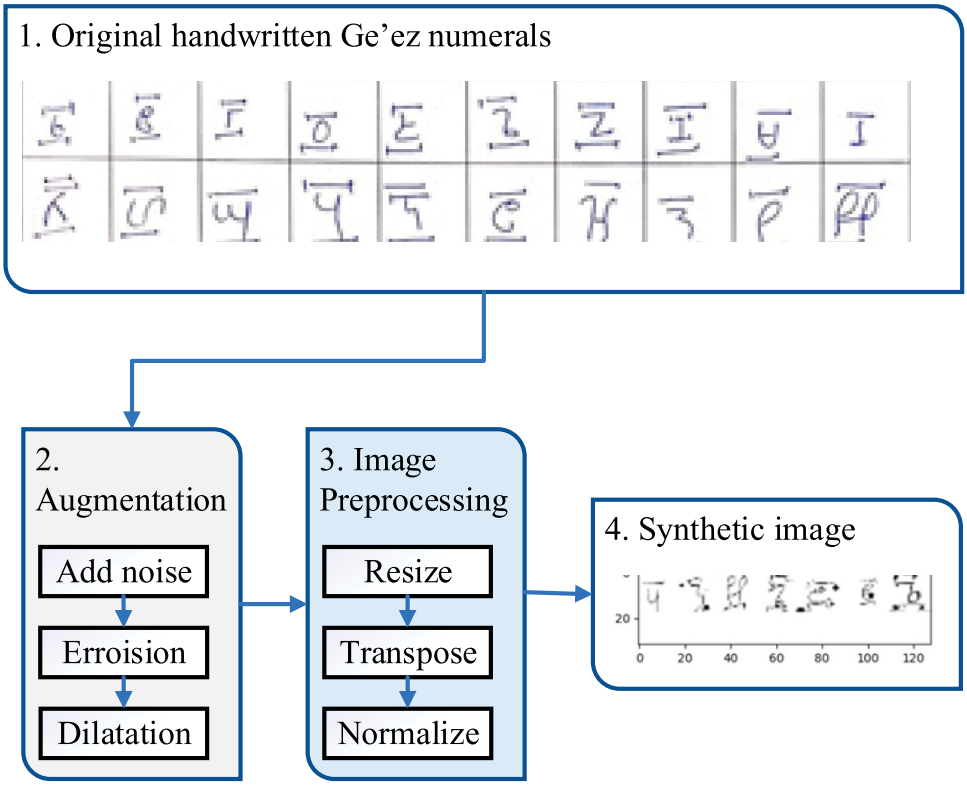

Figure 3. Experimental synthetic dataset preparation steps.

The convolutional layers are configured with parameters such as feature maps, kernel size, stride, and padding, which determine how the convolutions are applied to the input image. By applying these layers, the model can capture important patterns and structures within the image.

The max-pooling operation reduces the dimensionality of the feature maps by selecting the maximum value within each pooling region. Given a feature map (F), the max-pooling operation can be expressed in Equation (2).

$$MaxP(F)[i,j] = \max(F[x,y]) \tag{2}$$

Here, $MaxP(F)[i,j]$ represents the value at the position $[i,j]$ in the down-sampled feature map. The function $\max(F[x,y])$ returns the maximum value within the pooling region defined by coordinates $[x,y]$. This pooling operation helps to retain the most salient features while discarding unnecessary information, leading to more efficient processing and improved generalization.

Batch normalization helps normalize the feature maps by subtracting the mean and dividing by the standard deviation. Given a feature map the batch normalization operation can be represented in Equation (3).

$$BN(F)[i,j] = \frac{F[i,j] - mean(F)}{\sqrt{variance(F) + epsilon}} \tag{3}$$

where, $BN(F)[i,j]$ represents the normalized value at position (i,j) in the feature map. $mean(F)$ represents the mean of the feature map, $variance(F)$ denotes the variance, and is a small constant to avoid division by zero.

Table 3. The proposed model convolutional layer blocks along with the parameter values.

Layer blocks	Layers	Feature maps	Kernel size	Activation	Stride size
Block1	Conv1	32	(3,3)	ReLU	(1,1)
	pooling1	–	(2,2)		(2,2)
Block2	Conv2	64	(3,3)	ReLU	(1,1)
	pooling2	–	(2,2)		(2,2)
Block3	Conv3	128	(3,3)	ReLU	(1,1)
Block4	Conv4	256	(3,3)	ReLU	(1,)
	pooling4	–	(1,2)		–
Block5	Conv5	256	(3,3)	ReLU	–
	Normalization1	–	–		–
Block6	Conv6	512	(3,3)	ReLU	(1,1)
	pooling5	–	(1,2)		(1,1)
Block7	Conv7	512	(2,2)	ReLU	(1,1)

The subtraction and division operations ensure that the mean is zero and the standard deviation is one. This normalization step ensures that the recognition process is not affected by outliers or irregularities in the data. By maintaining consistent scale and distribution of the features, the model becomes more robust and reliable.

Through the combination of these CNN layer blocks, the proposed model can effectively extract meaningful features from the input image, which serves as a crucial foundation for accurate recognition. The feature extraction steps and the attribute value of each are outlined in Table 3. The attention mechanism selectively focuses on relevant parts of the feature maps. Given a set of feature maps (F) and their corresponding attention weights (W), the attention mechanism can be

computed using Equation (4).

$$A(F, W) = \sum (F[t, i] * W[t, i]) \tag{4}$$

where, $A(F, W)$ represents the attended feature vector. The summation ($\sum$) computes the element-wise multiplication and summation over the temporal (t) and spatial (i) dimensions of the feature maps. The attention weights (W) assign importance or relevance to each element in the feature maps, allowing the model to concentrate on the most informative regions. By assigning different weights to different regions, the model can allocate its attention to the most informative areas, improving recognition accuracy. This mechanism helps the model handle variations in scale, orientation, and appearance within the input image.

Recognition process

In the recognition process, two main techniques are utilized in addition to the SoftMax dense layer to further enhance the model's performance. These techniques include bidirectional RNNs and CTC.

Bidirectional RNNs are pivotal for capturing dependencies in both the forward and backward directions within a given input sequence X. This bidirectional processing occurs in two passes, and the outputs of the forward and backward RNNs at each time step are concatenated to form the final hidden state representation, as expressed by the mathematical representation in Equation (5):

$$h[t] = Con(h_f[t], h_b[t]) \tag{5}$$

where, $h[t]$ represents the hidden state at the time step t. h_f and h_b represents the outputs of the forward and backward RNNs, respectively.

The Concatenate operation fuses these two representations, enabling the model to capture contextual information from both past and future time steps. This bidirectional approach ensures a comprehensive understanding of the entire input sequence, enhancing the model's ability to discern sequential patterns and structures.

Moreover, recurrent neural networks (RNNs) have become standard in processing sequential data. In our case, RNNs maintain previous inputs within the internal network state, allowing the model to leverage past context for improved recognition accuracy.

Long Short-Term Memory (LSTM) networks, a specific type of RNN, are employed to address the challenge of learning long-term dependencies. Hochreiter and Schmidhuber [35] proposed the LSTM cell to overcome the vanishing gradient problem associated with traditional RNNs. Comprising three sigmoid activation function gates – the Input Gate, Forget Gate, and Output Gate – LSTM networks facilitate effective learning of intricate temporal dependencies. The Equations (6) to (11) outline the mathematical expressions representing the LSTM gates:

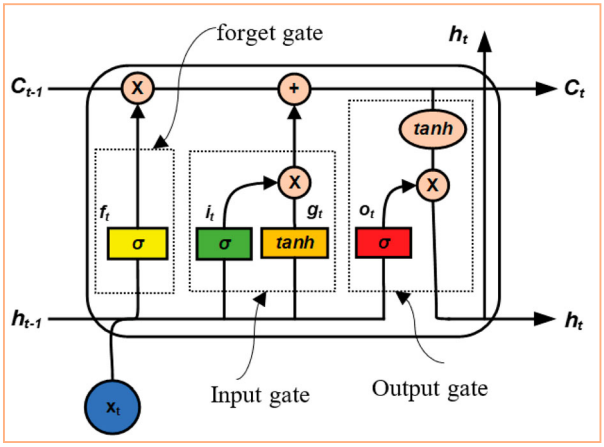

Figure 4. The LSTM gates architectures at timestamp ∼ t [12].

$$f_t = \sigma(W_f \cdot [h_{t-1}, x_t] + b_f) \tag{6}$$

$$i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i) \tag{7}$$

$$\tilde{C}_t = tanh(W_C \cdot [h_{t-1}, x_t] + b_C) \tag{8}$$

$$C_t = f_t \cdot C_{t-1} + i_t \cdot \tilde{C}_t \tag{9}$$

$$o_t = \sigma(W_o \cdot [h_{t-1}, x_t] + b_o) \tag{10}$$

$$h_t = o_t \cdot tanh(C_t) \tag{11}$$

Figure 4 providesa visual representation of the LSTM gates' architecture at a specific timestamp, enhancing the conceptual understanding of the LSTM's inner workings.

CTC loss is utilized as a loss function during training to align the predicted sequence (PS) with the ground truth (GT). Given a predicted sequence (Y_{pred}) and the GT sequence (Y_{true}), the CTC loss can be calculated here in Equation (12). Here, $p(Y_{true}|Y_{pred})$ denotes the probability of obtaining the GT sequence given the PS.

$$CTCLoss(Y_{pred}, Y_{true}) = -\log(p(Y_{true}|Y_{pred})), \tag{12}$$

The CTC loss is typically computed using dynamic programming algorithms, such as the forward–backward algorithm, to sum over all possible alignments. The negative logarithm is applied to penalize the deviation between the predicted and GT sequences. CTC enables the model to handle input sequences of variable lengths and perform E2E training. It automatically aligns the PS with the GT, accounting for possible repetitions, deletions, and insertions. This approach eliminates the need for explicit alignment information and improves the model's ability to recognize sequences accurately.

By incorporating these techniques into the feature extraction process above, the proposed model achieves superior performance in recognizing complex patterns and sequences, leading to enhanced recognition results overall. In light of the aforementioned concepts, we

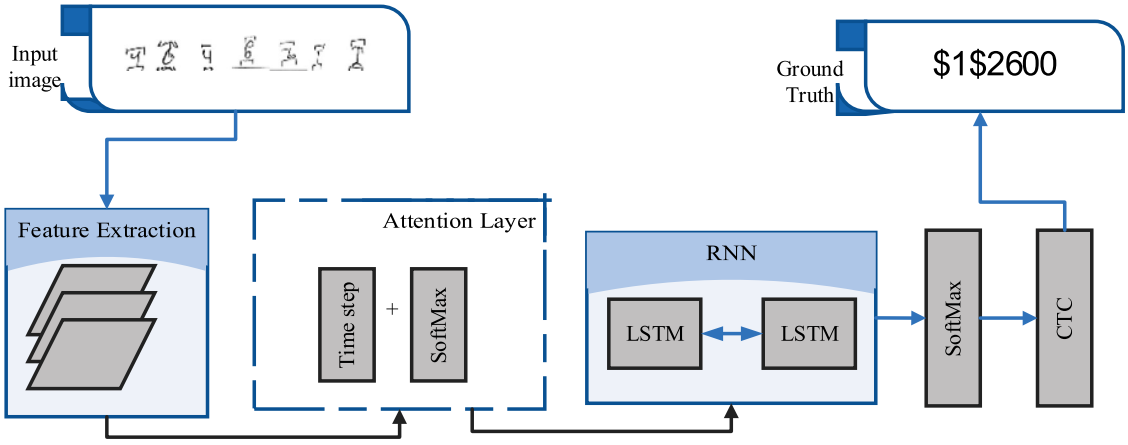

Figure 5. The proposed E2E handwritten Ge'ez multiple numerals recognition network architecture.

Table 4. The proposed model recurrent neural networks along with the parameter values.

Layer Blocks	Layers	Units	Dropouts	Activation
Bidirectional	LSTM1	128	0.25	Tanh
	LSTM2	128	0.25	Tanh
	Fully Connected	21	–	SoftMax

propose an E2E learning recognition model, as illustrated in Figure 5, specifically designed for recognizing handwritten multiple digits in Ge'ez numerals. The model architecture includes convolutional layer blocks with specific parameter values as mentioned in Table 3 to extract features from the input. Additionally, as depicted in Table 4, two layers of bidirectional LSTM cells, each with 128 hidden units, are utilized to capture long-term dependencies in sequential digit datasets. Dropout with a rate of 25% is applied to regularize the model and prevent overfitting.

Therefore, this model directly learns the mapping from input to output by optimizing the parameters of the entire model. During training, the model implicitly learns to extract relevant features or representations from the input, eliminating the need for manual feature engineering or intermediate stages.

Our proposed model's performance is evaluated using two metrics: CER and WER. CER is calculated by Equation (7).

$$CER = \left(\frac{(I + D + S)}{GT}\right) * 100, \tag{7}$$

Here, I, D, and S represent the number of character insertions, D deletions, and substitutions respectively. GT is the total number of characters in the GT text.

Similarly, WER is calculated by considering word-level errors. The formula WER can be expressed in Equation (8).

$$WER = \left(\frac{(I_w + D_w + S_w)}{N_w}\right) * 100, \tag{8}$$

where, I_w, D_w, S_w represents the number of words insertions, deletions, and substitutions respectively, and N_w is the total number of words in the ground truth.

Both CER and WER provide valuable insights into the error rates of the recognition system. By evaluating these metrics, we can measure the effectiveness of our proposed model in accurately transcribing characters and words, and identify areas where improvements may be required.

In addition to our primary evaluation metrics, CER and WER, we employed secondary evaluation metrics to provide a comprehensive analysis of the model's performance. These metrics, namely precision, recall, and F1-score, focus on the classification aspect of the model's predictions, specifically in terms of correctly predicted characters and their positions within the sequence.

To better interpret these metrics, let's define the parameters used in generating the classification report. TP (true positive) signifies the number of positive instances correctly predicted, whereas FP (false positive) denotes the number of positive instances predicted incorrectly. On the other hand, TN (true negative) indicates the number of negative instances correctly predicted, and FN (false negative) represents the number of negative instances predicted incorrectly. Equations (9), (10), and (11) are used to compute the precision (P), recall (R), and F1 score respectively.

$$P = \frac{TP}{(TP + FP)}, \tag{9}$$

$$R = \frac{TP}{(TP + FN)}, \tag{10}$$

$$F - score = \frac{2PR}{R + P}, \tag{11}$$

Precisionis also known as the positive predictive value (PPV) and it reveals the proportion of correctly identified positive instances out of all instances predicted as positive. It provides insights into the accuracy of the positive predictions made by the model. The recall represents the proportion of correctly identified

positive instances out of all actual positive instances. It measures the model's ability to capture positive instances correctly within the dataset. F1-score combines precision and recall into a single metric. It offers a balanced measure of the model's overall performance by considering both precision and recall. The F1 score allows us to assess the model's ability to achieve accurate positive predictions while capturing a sufficient number of positive instances.

By analysing these secondary evaluation metrics, including precision, recall, and F1-score, we gain a deeper understanding of the model's classification performance. These metrics provide valuable insights into the model's ability to accurately predict characters within the sequence and make informed assessments of its performance.

Results and discussion

The proposed model was implemented in Python using the Kera's framework with TensorFlow as the backend. To expedite training, the use of powerful GPUs was made accessible through Google Collaboratory, eliminating the need for expensive hardware. Collaboratory, a cloud-based service, enables remote code execution from anywhere with an internet connection. Its user-friendly interface and support for popular data science libraries make it an excellent choice for deep-learning projects.

A total of 120,000 images were used for the experiment. The dataset is first divided into three categories: training, validation, and testing. The training consists of 96,000 (80%) images, the validation comprises 12,000 (10%) images, and the testing comprises 12,000 (10%) images.

During the experimentation phase, we carefully considered and fine-tuned various network parameters to ensure optimal performance. The results reported in this study were obtained using an Adam optimizer in conjunction with a CNN that progressively increased the feature map size from 32 to 512. Additionally, a BLSTM network with two hidden layers, each consisting of 128 units, was utilized. The initial learning rate chosen for training the model was set to 0.001.

Through systematic parameter selection and experimentation, this configuration yielded favourable outcomes, which are discussed in this study. The combination of the Adam optimizer, CNN with increasing feature maps and BLSTM with two hidden layers proved effective in capturing relevant patterns within the data. Moreover, the learning rate of 0.001 facilitated a suitable balance between convergence speed and optimization accuracy.

Results

Discussions

In this experiment, the evaluation of the proposed recognition model was based on two key metrics (CER and WER) as it was described in section three of this study. The results demonstrate the model's impressive performance, with an average CER of 2.81% and a WER of 18.13% at empirically selected epoch size 30 and batch size 128. Moreover, the model showcased its capability by accurately predicting 97.18% of the digits in their entirety, while achieving coverage of 81.87% for the full-digit sequences. These outcomes are highly promising, especially considering that this study represents the first attempt at multiple Ge'ez digit recognition.

Errorsare a common occurrence in deep-learning models, and our recognition model is no exception. In Figure 6, we showcase some examples of errors in the results. In the first image sequence, the digit "፰" is mistakenly classified as "፱," while in the second sequence, the image of "፰" is incorrectly identified as "፬." The digit enclosed within the red box represents the digit that has been misrecognized. At the label parts blue represents the ground truth or correct

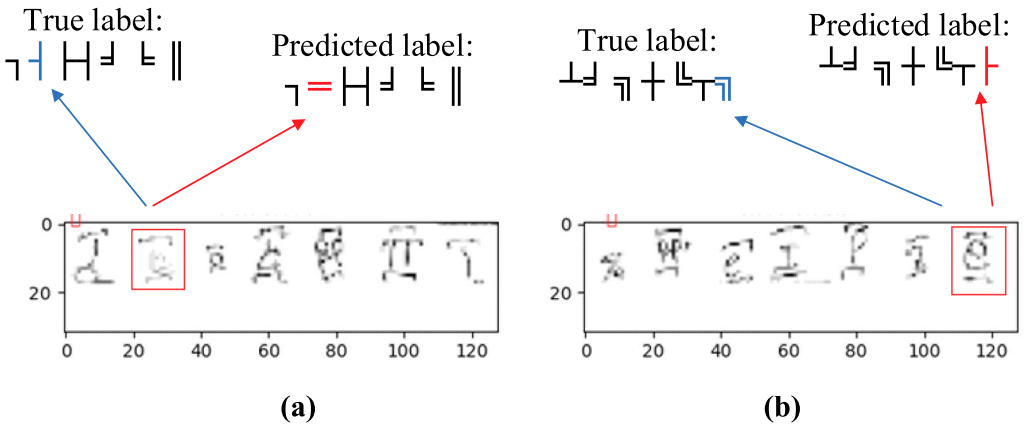

Figure 6. Sample misrecognized Ge'ez digits (a) The error that happened between the beginning and the end of the sequence. (b) The error that happens at the end of the sequence.

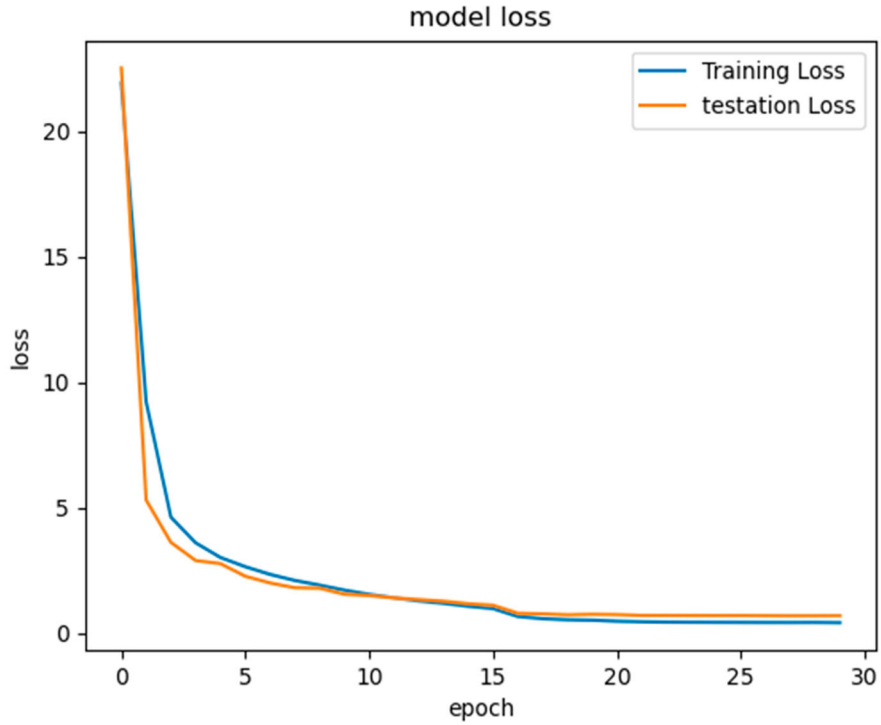

Figure 7. Training and validation loss versus epoch of the proposed multiple handwritten Ge'ez numerals model.

label for the corresponding character image and the red colour highlights the images that have been misrecognized based on the predicted label. These errors can be attributed to the close resemblance between the shapes of these digits, particularly their curved nature. The model may struggle to distinguish between them due to their visual similarities.

The training and validation loss of the proposed multiple handwritten Ge'ez numerals end-to-end learning model is also depicted in Figure 7. From this, the training and the validation graph converge on the proposed model. This convergence suggests that the model's performance on unseen data (validation set) is consistent with its performance on the training data. It is a positive sign that the model is learning effectively and is likely to perform well on new, unseen data.

The performance evaluation of the recognition model in recognizing Ge'ez numerals reveals high accuracy and effectiveness. Precision, recall, and F1 scores were used to assess the model's performance for each Ge'ez alphabet (see Table 5) The precision values ranged from 0.94 to 0.99, indicating the model's ability to accurately classify and identify the Ge'ez characters. Most of the digits achieved precision scores above 0.95, highlighting the model's accuracy in recognizing the Ge'ez numerals. Similarly, the recall values were consistently high, ranging from 0.95 to 0.99. This indicates the model's ability to effectively retrieve a significant portion of the true positive instances for each alphabet, reflecting its proficiency in capturing relevant patterns and features of the Ge'ez characters. The F1 scores, which consider both precision and recall, ranged from 0.95 to 0.99 for the different Ge'ez alphabets. These high F1 scores demonstrate the model's strong capability to achieve a balance between accurate classification and comprehensive retrieval of the Ge'ez numerals. The support column represents the number of instances for each Ge'ez alphabet in the evaluation dataset, which was well-balanced, with a similar number of instances for most characters, ranging from 5075 to 5390. Overall, the results indicate that the recognition model performed exceptionally well in recognizing the Ge'ez numerals, exhibiting high

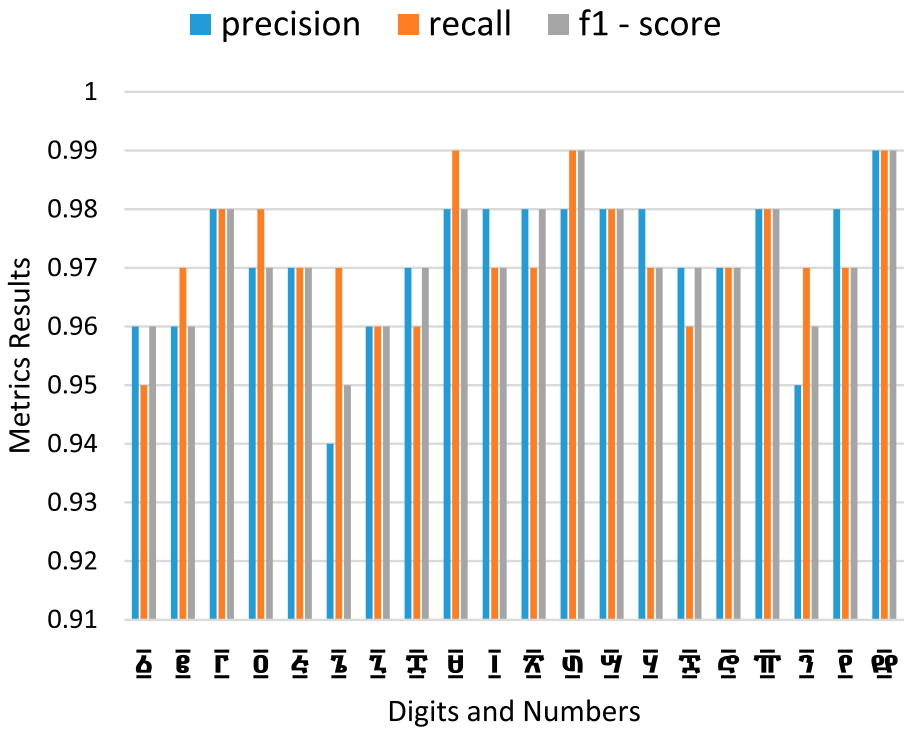

Figure 8. Precision, recall, f1-score, and support results of the proposed recognition model.

precision, recall, and F1 scores. This showcases the effectiveness of the model and its potential for various applications involving Ge'ez numeral recognition.

In terms of individual digit performance, as directed in Figure 8, the Ge'ez digit ፼ achieved the highest precision, recall, and F1-score, demonstrating exceptional accuracy and completeness in recognition. The digits ፱ and ፸ also exhibited strong performance, closely following the top-performing digit with high precision, recall, and F1 scores of 0.98. Overall, the Ge'ez digits ፼, ፱, and ፸ performed exceptionally well, exhibiting the highest precision, recall, and F1 scores. These digits consistently achieved high accuracy and retrieval rates, making them the most reliably recognized digits by the model.

Limitations. During the experiment, the proposed multiple handwritten Ge'ez numeral recognition method is not tested with real-life datasets. It is important to note that the datasets used in this experiment consisted solely of synthetic handwritten samples. As a result, the model's performance may differ when faced with real-life handwritten data, which often exhibits greater variability and complexity. Additionally, the recognition system faced challenges due to the visual similarities of the numerals. These similarities can lead to confusion and recognition errors, especially when the model is trained on a limited number of samples for certain Ge'ez numerals. The scarcity of training data for specific characters can hinder the system's ability to accurately recognize them. To address these limitations and enhance the recognition performance of the system, it is crucial to expand the training dataset by including a more diverse and representative collection of real-life handwritten samples. Increasing the number of training samples for each numeral would enable the model to learn and generalize better, improving its ability to handle the intricacies and variations present in real-life data.

Conclusion

In conclusion, this study introduces end-to-end learning model specifically designed for recognizing handwritten Ge'ez multiple numerals. By leveraging deep-learning techniques, our model automatically extracts relevant features from input images and effectively captures the sequential nature of the numerals. The integration of attention mechanisms and a CTC-based loss function allows the model to focus on crucial regions of the input, enabling end-to-end training without the need for explicit alignment between images and labels. The experimental results demonstrate a CER of 2.81% and a WER of 18.13% for the handwritten Ge'ez numeral recognition task, validating the effectiveness of our proposed approach.

Our model not only contributes to the underexplored area of OCR research for the Ge'ez script but also opens up new possibilities for Ge'ez numeral recognition. Future work can be improved by expanding the dataset to include other characters in the Ge'ez language, exploring alternate deep-learning architectures, and investigating the applicability of the approach to other languages and scripts. Continuous research and development efforts hold the potential to further improve the recognition of handwritten Ge'ez multiple numerals, benefiting various applications in pattern recognition and document processing.

To enhance the performance and reliability of our proposed method in real-life scenarios, future iterations of the recognition system should incorporate a larger and more diverse dataset. This step will address the challenges posed by real-life handwritten data and help mitigate recognition errors, ultimately improving the practical applicability of the recognition system. By continually refining and advancing our approach, we can achieve more accurate and robust recognition of handwritten Ge'ez multiple numerals, paving the way for broader adoption and utilization in various fields.

Acknowledgment

The authors would like to express our sincere gratitude to the faculty members, staff, and students of Delhi Technological University for their invaluable guidance and support throughout the completion of this manuscript. Their continuous assistance and expertise have played a crucial role in the success of this research project. The authors are also grateful for their unwavering commitment to fostering academic excellence and their contributions to our growth as researchers.

Disclosure statement

No potential conflict of interest was reported by the authors.

HIGHLIGHTS

- Solar dish collector's performance in water desalination is analyzed.
- Annual freshwater yield for SWDS is enhanced by 20.13% (Al_2O_3) and 12.56% (ZnO).
- Energy efficiency of SWDS is enhanced by 20.06 (Al_2O_3) and 12.55% (ZnO).
- Lowest cost per liter of US$0.050 is obtained for SWDS with Al_2O_3 nanofluids.
- Highest amount of net CO_2 mitigation is 72.54 tons of CO_2 for Al_2O_3 nanofluid-based SWDS.

ABSTRACT

Global demand for freshwater is increasing due to population growth and water scarcity. Traditional desalination systems are characterized by their high energy consumption, resulting in low efficiency and elevated costs. It is crucial to explore sustainable and eco-friendly desalination system to address these problems. Present study explores the impact of Al_2O_3 and ZnO nanofluids on a solar dish integrated water desalination system (SWDS). Performance evaluation includes energy, exergy, economic, exergoeconomic, and enviroeconomic perspectives. Compared to SWDS with water, annual freshwater productivity increased by 20.13% (Al_2O_3) and 12.56% (ZnO). SWDS with Al_2O_3 nanofluid exhibited the highest energy and exergy efficiency of 20.76% and 4.32%, respectively. Energetic parameters revealed a minimum energy payback time of 0.91 years and a maximum energy production factor of 27.18 for SWDS with Al_2O_3 nanofluid. The lowest cost per liter (CPL) was US$0.050 for Al_2O_3 nanofluids, while the highest CPL was US$0.0547 for ZnO nanofluid. The maximum exergoeconomic parameter was 2.50 kWh/US$ for SWDS with Al_2O_3 nanofluid. SWDS with Al_2O_3 nanofluid demonstrated the highest net CO_2 mitigation of 72.54 tonne, with corresponding carbon credits of US$2124.08 (energy) and US

$423.92 (exergy). The Al_2O_3 nanofluid-based SWDS demonstrated superior performance in energy and exergy perspective. Furthermore, Al_2O_3 nanofluid-based SWDS showed enhanced cost-effectiveness and environmental sustainability when compared to water-based SWDS.

1. Introduction

The rapid growth in world population and industrialization urges the need for potable water in various regions, especially in hot and dry regions (Yusof et al., 2022). The main challenge in the productivity of potable water is the cost and availability of water sources. The entire world is expected to face 40% water deficit by 2030. Global concerns like COVID-19, global warming, and climate change have made the situation worse. Thus, it is crucial to develop effective methods to overcome the global problem of fresh water (Modi and Gamit, 2022). Solar energy is utilized in various applications such as cooking, desalination, drying, extraction and water heating, etc. (Kant and Kumar, 2022a). Desalination is the process that is used to convert brackish water into fresh water (Kumar et al., 2021). The solar still (SS) is a promising, practical, and cost-effective solar thermal energy-based device that can meet the needs of people for freshwater water who live in water-stressed areas. However, SS must deal with the problem of lower productivity, which prevents its widespread use on a larger scale (Shatar et al., 2023). Hence, the researchers opted to use internal and external additives to enhance efficiency and productivity of solar energy systems. There are several ways to utilize solar energy effectively; one of these methods is heat transfer. The basic idea behind this technology is to achieve high temperatures by concentrating sun radiation onto a thermal receiver using concentrators. Mirrors and lenses can be used to focus solar rays. Mirrors are preferred over lenses due to lower absorptivity and cost as rays are focused by reflection. Three types of solar thermal transfer systems have been used in manufacturing fields: flat mirror concentrators, cylindrical mirror concentrators, and parabolic concentrators (Hameed et al., 2023). Parabolic dish collector is a parabolic concentrator that comprises several pieces of mirrors. It concentrates sunlight on the focused receiver. The receiver converts the reflected solar radiation into thermal energy for heating the fluid to high temperatures and allowing it to be employed in steam generation.

Various studies have been performed to design various solar concentrator systems based on their shape, configurations, physics, use of PCM and nanomaterials, and many other aspects. Hameed et al. (2023) investigated the effectiveness of solar dish integrated water desalination system using different nanofluids. The thermal performance and productivity of system were evaluated using tap water, aluminum oxide (Al_2O_3), and zinc oxide (ZnO) nanofluids. The results showed that Productivity of system was increased by 43.53% and 21.89% using Al_2O_3 nanofluid as compared to tap water and ZnO nanofluid, respectively. The thermal efficiency of the system was also increased by 9.91% using Al_2O_3 nanofluid as compared to tap water. Chaouchi et al. (2007) designed and built a small solar desalination unit equipped with solar dish and developed a theoretical model to evaluate its performance. There was a relative error of 42% in theoretical and experimental values of distillate flow rate. The results showed that design of the system required to be modified with special emphasis on the absorber. Mawire and Taole (2014) performed energy and exergy analysis of cylindrical cavity receiver for solar dish concentrator. The efficiencies and rates of exergy for the receiver were discovered to be less than the efficiencies and rates of energy. Receiver's heat loss factor and parabolic dish system's optical efficiency were determined as 4.6 W/K, and 52%, respectively for high solar radiation conditions. Alhawsawi et al. (2023) evaluated the energetic performance of the hybrid solar dish/Stirling-powered single effect distillation system (SDSPSEDS) in terms of, solar-to-electricity conversion efficiency, net electric power, distilled freshwater productivity, Stirling engine rejected heat, and overall co-generation efficiency. The modelling results showed that electrical energy produced by system was 234.7, 194.6, 159.8, and 190.0 kWh/day. However, freshwater productivity was obtained as 787.4, 657.3, 545.0, and 650.0 kg/day in June, September, January, and March, respectively.

Stefanovic et al. (2018) optimized inlet temperature and flow rate for a solar dish collector with a spiral-coil absorber in order to maximize the collector's exergetic performance. The optimal fluid temperature and flow rate were 212.3 °C, and 314.6 L/h, respectively with thermal and exergetic efficiencies of 49.83% and 21.42%. Elashmawy and Alshammari (2020) proposed a new system for harvesting water from low humid regions using a tubular solar still powered by a parabolic concentrator system. Tubular solar still was equipped with solar parabolic concentrator to evaporate the water from calcium chloride in the proposed system. System can produce 0.51 L/kg of calcium chloride. The thermal efficiency and cost of water production were 24.61% and US$0.15/L, respectively. Productivity and efficiency of proposed system were increased by 292.4% and 82.3%, respectively, while water production cost was reduced by 25%. Abulkhair et al. (2023) enhanced yield and thermal performance of conventional pyramid distiller using low-cost materials such as v-corrugated aluminum basin, paraffin wax, black cotton fabric, carbon black nanofluid, and CB nanoparticles. Moreover, thermo-economic performance of modified pyramid distiller was evaluated and compared with conventional distiller. Yield, thermal efficiency and exergy efficiency of modified distiller (addition of CB nanoparticles with paraffin wax) was improved by 76.9%, 101.5% and 109.7%, respectively as compared to conventional distiller. Dafle and Shinde (2012) designed, developed and evaluated the performance of steam generation system equipped with Scheffler reflector (16 m^2 area). Overall performance of system and maximum temperature of steam at outlet of biller was obtained as 57.41% and 107 °C, respectively.

Malwad and Tungikar (2020) performed energy analysis to determine the thermal performance of receiver with three different configurations such as bare receiver, cavity receiver and tube coil on inner wall of cavity for solar Scheffler reflector. Under identical working conditions, the energy efficiency of the receiver with the first, second, and third configurations was 57.71%, 60.93%, and 68.03%, respectively. Farooq et al. (2022) analyzed thermal performance of parabolic trough collector (PTC) for two nanofluids (Al_2O_3 and CuO) at different flow rates using computational fluid dynamics (CFD). Maximum efficiency of system was improved by 6.99% and 12.90% for CuO nanofluid as compared to Al_2O_3 nanofluid. Furthermore, Temperature distribution behaviour of absorber tube materials such as steel, copper, and aluminum was also examined. The maximum output temperature for copper was 311 K, whereas exit temperatures for steel and aluminum were 307 K and 308 K, respectively. Mohanraj et al. (2021) evaluated the performance and asses the techno feasibility analysis of heat pump water heater assisted regenerative solar still with latent heat storage. Results showed that system is capable of producing 14 kg/day fresh water and 100 L hot water for domestic use. Cost of fresh water production was obtained as 0.0547 US$/L.

India has committed to reducing the emissions intensity of its GDP by 45 percent from 2005 levels by 2030, in accordance with the revised Nationally Determined Contribution (NDC) that it submitted to the United Nations Framework Convention on Climate Change (UNFCCC) in August 2022 under the COP26 agreement. Government of India has committed to addressing climate change through several initiative and programmes such as National Action Plan on Climate Change (NAPCC) which consist of missions in specific areas of energy efficiency, solar energy, water, Himalayan ecosystem, sustainable agriculture, sustainable habitat, health, green India, and strategic knowledge for climate

change. National Solar Mission under the NAPCC is one of the key initiatives to promote sustainable growth while addressing India's energy security ("Commitments made under COP 26," n.d.).

Existing literature primarily focuses on analyzing solar concentrator systems based on receiver shape, configuration, and physics. Limited research has been conducted on the performance of water desalination systems equipped with solar dish collectors using various nanofluids. To the best of our knowledge, there is a notable gap in the literature regarding the energy, exergy, economic, and environmental analysis of solar dish integrated water desalination systems. Therefore, the primary objective of this study is to comprehensively analyze the performance of a solar dish collector integrated water desalination system, considering productivity, energy, exergy, economic, and environmental parameters. Additionally, the study explores the interplay between energy and exergy with the economic (exergo-economic), environment aspects (enviro-economic), and energy matrices to enhance our understanding of the proposed system's performance.

2. Methodology

2.1. Experimentations

2.1.1. Nanofluid preparation

Al_2O_3 and ZnO nanoparticles are employed in this study to produce nanofluids as they have lower cost compared to other nanoparticles like gold nanopowder, carbon nanotubes, and diamond nanopowder. The thermophysical properties of the Al_2O_3 and ZnO nanoparticles are depicted in Table 1.

Nanofluids were produced in Green Energy Lab, Delhi Technological University, Delhi (India) using two-step process. Al_2O_3 and ZnO nanoparticles were directly dissolved in water within a Pyrex flask with a PVC cover to prepare the nanofluid. The flask was set up inside an ultrasonic water bath in a stainless-steel basket. Water was poured into basin of ultrasonic device to a depth of about 3 cm above the mixture level in flask. Then, degas mode was switched on to remove air from the mixture. After that, the flask was sealed with the cap as it continually oscillated for 8 h for Al_2O_3 and 10 h for ZnO at 60–70 °C with a frequency and power efficiency of 37 kHz and 100%, respectively. As a result, the nanoparticles can be evenly distributed. It is important to note that no surfactants were added to the nanofluid to prevent their impact on thermophysical properties of nanofluids. Ultrasonic bath's container was covered with a cap to stop the evaporation of water during sonication.

Thermal conductivity of Al_2O_3 was improved by 10.34% by using 0.10% concentration of Al_2O_3. Hence, Al_2O_3 and ZnO nanoparticle concentration of 0.10% (w/w) was used to prepare the nanofluid. Eq. (1) was used to calculate the amount of nanoparticles required to produce 0.10% w/w concentrated nanofluid (Modi and Gamit, 2022).

$$\textit{Weight of nano particle needed}\ (g) = \frac{\textit{Concentration}(\%)}{100} \times \textit{amount of water}\ (mL) \times \textit{bulk density of nanoparticles}\ (g/mL) \quad (1)$$

Amount of water was taken as 2500 mL in Eq. (1) to determine weight of nanoparticles required. Groundwater was mixed with 0.45 g and 4.25 g of nanoparticles to produce 0.10% w/w concentrated Al_2O_3 and ZnO nanofluid, respectively.

Table 1
Thermophysical properties of nanoparticles.

S. No.	Properties	Al_2O_3	ZnO
1	Thermal Conductivity (W/mK)	40	29
2	Density (kg/m^3)	3950	5500
3	Molar mass (g/mol)	101.96	81.38
4	Specific heat (J/kg °C)	773	490
5	Bulk density (g/mL)	0.18	1.7

2.1.2. Thermal property measurement

A particular mixture of water and nanoparticles was prepared in a beaker using ultrasonication to ensure the perfect blending of samples. Afterward, the mixture was carefully transferred into a mold inside the Hot Disk Device for thermal conductivity measurement. This device had an inbuilt sensor intended specifically for thermal analysis. Mold ensured the creation of uniform flat disk for accurate measurements. The sample was placed between two surfaces of hot disk sensor in the test setup device. The temperature variation rate was carefully observed upon activation of the instrument. The thermal conductivity of each sample was then calculated using these data. Initially, thermal conductivity of underground water was 0.598 W/mK and after preparing the water nanofluid the thermal conductivity of Al_2O_3 and ZnO nanofluid was calculated as 0.657 and 0.639 W/mK, respectively. These results showed that thermal conductivity of Al_2O_3 and ZnO nanofluid was improved by 10% and 7%, respectively compared to water as depicted in Table 2.

2.1.3. Experimental setup and observations

Solar water desalination system (SWDS) is installed on rooftop of Centre for Energy and Environment, Delhi Technological University, Delhi (28.7041° N, 77.1025° E). Experiments were carried out with and without nanofluids for nine different days in May–June 2023. First experiment was conducted using underground water and other two experiments were conducted using Al_2O_3 and ZnO nanofluid. Data was recorded from 8 a.m. to 6 p.m. for every trial day. Each experiment was repeated three times to verify that results were consistent. SWDS mainly consists of four parts: solar dish collector (2.5 m^2), boiler, water tank and condenser. An iron pole is installed in concrete construction to support the solar dish reflector. Solar dish is fabricated and prepared by covering an aluminum frame structure with mirrors of glass (0.05 × 0.05 m) as reflecting surface. Solar radiation falling on surface of reflector is reflected and concentrated at the base of receiver (boiler). The stainless-steel boiler was 0.12 m in diameter and 0.28 m in height. All faces of boiler except its base are insulated with glass wool (2.5 cm) to reduce heat loss to environment. Base of the boiler is painted with thermal black coating (absorptivity 0.90) to reduce reflection losses.

A ball valve fixed to the top of boiler is used to regulate water inlet flow and outlet steam flow through boiler. At the base boiler, a brass tube with a diameter and length of 25 mm and 5 cm, respectively was welded before being rotated upward. This pipe is connected to a 25 cm long and 25 mm diameter Pyrex pipe that serves as a sight glass to show the water level inside the boiler. It is also utilized to eliminate the concentrated salts produced by raw water desalination at the end of experiment. Radiation heats the water in the boiler, turning it into steam. Flexible nylon pipe of 1.25 cm in diameter is used to connect the boiler to condenser. An automatic double-axis tracking mechanism is implemented to enhance system's efficiency. Sun was tracked using four light difference resistors (LDR sensor) and two motors. The microcontroller receives a signal from the LDR sensor, which turns the motors in the appropriate direction. First motor is used to rotate solar dish in left-right direction and other one is used to move solar dish in up-down direction. Fig. 1 depicts the SWDS schematic view. Table 3 shows a detailed explanation of SWDS.

A salty cold-water tank of 50 L is located 2 m above the ground, which is higher than the receiver height of 1.65 m and condenser height of 1 m. A ball valve is connected to bottom of tank to control head of pressure and flow of water from water tank to receiver and condenser in

Table 2
Thermal conductivity of nanofluid.

Samples	Thermal conductivity (W/mK)	Increment (%)
Under groundwater	0.598	–
Al_2O_3 nanofluid	0.657	10
ZnO nanofluid	0.639	7

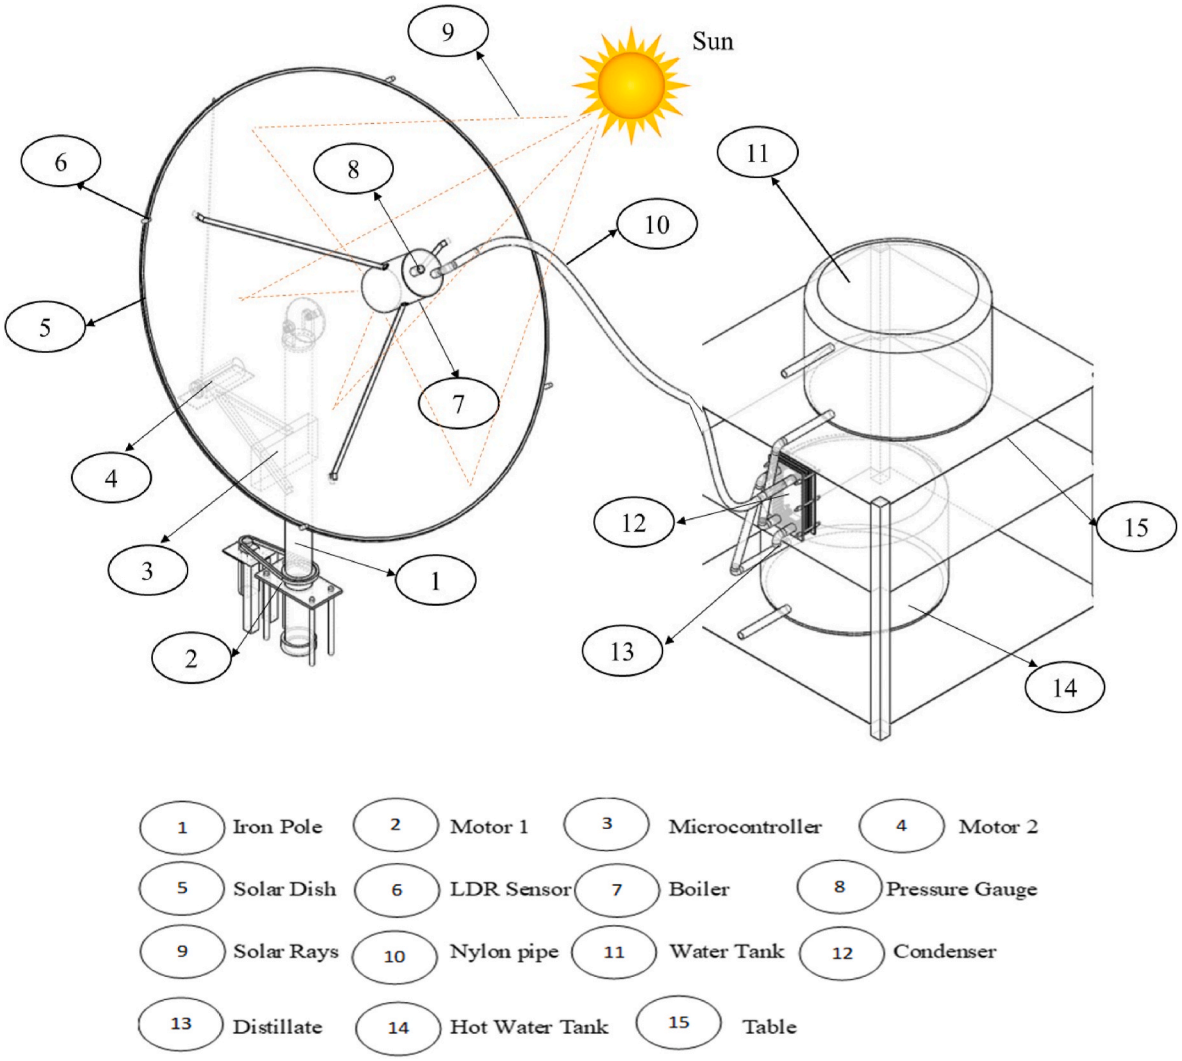

Fig. 1. Schematic of solar water desalination system.

order to maintain the desired water level and flow rate inside the receiver and condenser, respectively. PT 100 calibrated thermocouples with proper insulation are used to record the temperature at different positions of boiler and condenser. A Pressure gauge is attached to boiler to record the inside pressure. All thermocouples and pressure gauge is connected to 16-channel data logger (digital display unit). Solar radiation was recorded using solar power meter (Mico-936). Wind velocity and ambient humidity were measured by wane type anemometer (Testo-416) and thermal hygrometer (Testo-608-H1), respectively.

2.2. Uncertainty analysis

The standard uncertainty of the instruments used for observation is calculated from Eq. (2).

$$Standard\ Uncertainty = \frac{Accuracy\ of\ instrument}{\sqrt{3}} \tag{2}$$

Table 4 summarizes the instruments used in experiment along with their accuracy, range, and uncertainty. When any function Y depends on the number of input parameters or independent variables, then the uncertainty in the measured value of the function Y is given by Eq. (3) (Ahmad et al., 2023; Kumar and Sahoo, 2023):

$$U(Y) = \left[\left(\frac{\partial Y}{\partial x_1}\right)^2 u^2(x_1) + \left(\frac{\partial Y}{\partial x_2}\right)^2 u^2(x_2) + \ldots\ldots\ldots + \left(\frac{\partial Y}{\partial x_n}\right)^2 u^2(x_n)\right]^{1/2} \tag{3}$$

where, U(Y) is the uncertainty in the measured function and u(x1) … …u (x_n) is the uncertainties in the independent variables (x_1 … …x_n), affecting the function Y.

2.3. Optical design of solar dish concentrator

The purpose of this mathematical framework is to enable geometrical sizing to obtain the geometrical design parameters, such as focal length, receiver diameter, receiver position, and geometric design concentration, for various geometrical dish sizes. The optimal receiver height (H_r), rim angle ($\varnothing_r$), distance between focal point and receiver (d_f), and diameter of receiver (d) are geometrical parameters used in defining the geometry of receiver/concentrator system in proposed model.

Initially, the concentrator's focal length (f) can be calculated as a function of rim angle ($\varnothing_r$) and concentrator diameter (D) using Eq. (4) (Elashmawy, 2020; Elashmawy and Alshammari, 2020; Hameed et al., 2023).

Table 3
Detail description of SWDS.

S. No.	Components	Size (m)	Materials	Properties of Materials (Farooq et al., 2022; Modi and Gamit, 2022)
1.	Solar dish reflector Plane mirrors	Diameter = 1.8 Depth = 0.20 Aperture area = 2.5m^2 No of mirrors = 1600 (0.05 × 0.05)	Aluminum Glass	Density = 2700 kg/m^3, Thermal conductivity = 202.4 W/mK Reflectivity = 0.95
2.	Boiler	Capacity = 7 litters Height = 0.28 Diameter = 0.16 Thickness = 0.004	Stainless steel	Density = 8020 kg/m^3, Thermal conductivity = 16.27 W/mK
3.	Boiler base paint	Matt-type	Black color	Absorptivity = 0.95 Emissivity = 0.08
3.	Condenser (counter flow plate type heat exchanger)	Inlet diameter = 0.012 Outlet diameter = 0.012	Mild steel	Density = 7700 kg/m^3
4.	Insulation	Thickness = 0.025	Glass Wool	Thermal Conductivity = 0.055 W/mK

$$f = \frac{D}{4\tan\left(\frac{\varnothing_r}{2}\right)} \tag{4}$$

Rim radius is the distance between concentrator surface and receiver position and is determined (Zayed et al., 2020):

$$R_r = \frac{2f}{1 + cos\ \varnothing_r} \tag{5}$$

The spread of reflected beams from the concentrator should be taken into consideration in order to determine the aperture size of receiver for a specific concentrator diameter due to its significant impact on the optical behaviour of system. Other error sources, such as tracking drive system, sun tracking sensor, physical structure, positioning of receiver, and specular reflectance, affect the optical behaviour of the SWDS in addition to spread of reflected beam.

Eq. (6) provides the concentrator's overall optical error in terms of the SDSS's auxiliary component errors (Alhawsawi et al., 2023).

$$\sigma_t = \sqrt{(2\sigma_{str})^2 + (2\sigma_{sen})^2 + (2\sigma_{drive})^2 + (2\sigma_{ralign})^2 + (2\sigma_{mref})^2 + (2\sigma_{sun})^2} \tag{6}$$

Then, total spread of beam (Δ b,r) in a plane perpendicular to the reflected beam is as (Ranjbar et al., 2021):

$$\Delta_{b,s} = 2R_r\ \tan\left(n\frac{\sigma_t}{2}\right) \tag{7}$$

Receiver diameter (d) can be calculated by estimating beam spread projection on focal plane of receiver (Ouyang et al., 2021):

$$d = \frac{\Delta_{b,s}}{Cos(\varphi_r)} \tag{8}$$

The distance between focal point and receiver (d_f), and the focal point position (H) are calculated as (Ouyang et al., 2021):

$$d_f = \frac{d}{D}\left(f - \frac{D^2}{16f}\right) \tag{9}$$

$$H = f - d_f \tag{10}$$

The opto-geometrical solar concentration (C_{GD}) is a crucial geometric factor that has a considerable impact on the cavity receiver's energetic efficiency. It can be calculated using Eq. (11) by considering rim angle ($\varnothing_r$), solar angle (α_s), and dispersion angle (δ_{dis}) (Lashari et al., 2021).

$$C_{GD} = \left[\frac{Sin\ \varnothing_r\ Cos\left(\varnothing_r + \left(\frac{\alpha_s + \delta_{dis}}{2}\right)\right)}{Sin\left(\frac{\alpha_s + \delta_{dis}}{2}\right)}\right]^2 \tag{11}$$

The rim angle and focal length are responsible for completely defining the cross-sectional geometry of a dish reflector. In the present study, a rim angle of 45° for the parabolic dish concentrator design, as suggested by Lashari et al., 2021)(Lashari et al., 2021), has been chosen to achieve the maximum concentration ratio. The optimal receiver height (H) indicates the location of cavity receiver, where the DNI concentrates and produces highest temperatures. The receiver material, through which the heat transfer fluid passes, might be damaged by the high temperatures. Therefore, the receiver is considered to be at optimum distance (d_f) from the focal point in order to reduce receiver material overheating and provide consistent DNI. As a result, Table 5 shows optimized geometric parameters for the proposed collector/receiver system.

Table 5
Characteristics of solar dish concentrator and heat receiver.

Components	Characteristics	Values
Solar dish concentrator	Aperture diameter (D)	1.8 m
	Depth (h)	0.3 m
	Rim angle ($\varnothing_r$)	45
	Rim radius (R_r)	1.26 m
	Focal length (f)	1.08 m
	Aperture area of solar dish (A_d)	2.54 m^2
Heat receiver	Diameter (d)	0.12 m
	Optical error (σ_t)	11.34 mrad, (0.649)
	Spread of beam	1.69 m
	Distance of focal point from receiver (d_f)	0.19 m
	Optimal height of receiver (H)	0.88 m
	Receiving surface area (Ar)	0.01 m^2
	Optic geometrical concentration factor (C_{GD})	2551

Table 4
Technical specification of the instruments used in the experiments.

Instruments	Observed Parameter	Accuracy	Range	Standard Uncertainty	Uncertainty in Observed Parameter
Thermocouple (TC-KT-02)	Temperature	±0.1 °C	−20 to 200 °C	0.057 °C	±0.25 °C
Solarimeter (PMV-210)	Solar radiation	10 W/m^2	0–2000 W/m^2	5.77 W/m^2	±5.77 W/m^2
Digital Hygrometer (MEXTECH TM-1)	Ambient temperature and relative humidity	3%	5–85%	1.73%	±1.7%
Scaled Flask	Distilled Water	±10 ml	0–5000 ml	5.77 ml	±5 ml

2.4. Energy analysis

The concept of energy analysis has been developed to study and understand proposed systems in light of thermodynamics first law. This analysis calculates energy distribution across various components as well as performance of the proposed water desalination system. Solar energy incident on solar dish collector is computed as (Kant and Kumar, 2022b):

$$E_c = I_g A_c \tag{12}$$

Optical efficiency of collector is calculated as (Alhawsawi et al., 2023):

$$\eta_{optical} = \alpha\rho\tau S \tag{13}$$

Energy collected by reflector drops due to various losses such as optical losses, and scattering of rays reflected from dish surface. As a result, the energy focused on surface of receiver is computed by Eq. (14) as a function of solar irradiation (I_g), reflectivity of mirror (ρ), area of the concentrator (A_c) and shape factor (S) (Alhawsawi et al., 2023).

$$E_r = \eta_{optical} I_g A_c \tag{14}$$

Useful thermal energy output from the receiver is determined (Stefanovic et al., 2018):

$$E_u = \dot{m} C_p (T_o - T_i) \tag{15}$$

Thermal efficiency of receiver and solar collector is evaluated using Eq. (16) and Eq. (17), respectively (Stefanovic et al., 2018).

$$\eta_r = \frac{E_u}{E_r} \tag{16}$$

$$\eta_c = \frac{E_u}{E_c} \tag{17}$$

Overall thermal efficiency of SWDS is calculated as (Rani et al., 2021):

$$n_{th,o}(\%) = \frac{\sum \dot{m} L}{A_c \sum I_g(t)} \times 100 \tag{18}$$

2.5. Exergy analysis

Maximum amount of useful work obtained by system when it is in equilibrium with its environment is known as exergy. Exergy analysis is used in solar dish concentrator systems in order to reduce exergy losses and get the best design parameters. Useful exergy production is computed as (Stefanovic et al., 2018):

$$Ex_{,u} = (\dot{m} \times L)\left[1 - T_a\left(\frac{T_a}{T_w}\right)\right] \tag{19}$$

Exergy of sun is determined by Petela model (Kant and Kumar, 2022b; Stefanovic et al., 2018):

$$Ex_{,s} = I_g A_c \left[1 + \frac{1}{3}\left(\frac{T_a}{T_s}\right)^4 - \frac{4}{3}\left(\frac{T_a}{T_s}\right)\right] \tag{20}$$

Exergy efficiency of SWDS is evaluated as (Kant and Kumar, 2022b):

$$\eta_{ex}(\%) = \frac{Ex_{,u}}{Ex_{,s}} \times 100 \tag{21}$$

2.6. Energy matrices

The energy matrices are used as a decision-making tool to determine feasibility of a solar system from an energy perspective by comparing energy produced with energy consumed by system for its fabrication. Energy payback time and energy production factor are the two energy matrices that are evaluated in this study.

2.6.1. Energy payback time (EPBT)

The energy payback time (EPBT) is a period required to recuperate the energy spent (embodied energy) during the production of the SSDS components. EPBT is evaluated (Reddy et al., 2018; Sharon et al., 2020):

$$EPBT = \frac{E_{emb}}{E_{en,o}} \tag{22}$$

Thermal energy output obtained per year from distillation system can be calculated (Kumar, 2013):

$$E_{en,o} = \frac{\dot{m} L}{3600} \tag{23}$$

2.6.2. Energy production factor (EPF)

EPF predicts the performance of the system. It is computed as the amount of energy produced over life span divided by the system's embodied energy.

$$EPF = \frac{E_{en,o} \times n}{E_{emb}} \tag{24}$$

2.7. Economic analysis

The cost of freshwater produced per liter (CPL) is often determined using economic analysis. This analysis enables decision-makers to pick a system that is beneficial from both a technical and financial perspective. In order to get a clearer understanding of the feasibility of system from an energy and environmental perspective, this research additionally assesses the exergo-economic and enviro-economic factors.

The interest rate for commercial loans in India i.e 7% is used as the basis for interest rate (i) selection. Life of system (n) was taken as 30 years. The capital recovery factor (CRF) is calculated as (Shatar et al., 2023):

$$CRF = i(1+i)^n / [(1+i)^n - 1] \tag{25}$$

First annual cost of system is the product of total initial cost (TC) and CRF and is determined by Eq. (26) (Modi and Gamit, 2022).

$$FAC = TC \times (CRF) \tag{26}$$

The salvage value (S) was taken as 20% of TC and annual salvage value is determined using Eq. (28) (Modi and Gamit, 2022; Shatar et al., 2023).

$$S = 0.2 \times TC \tag{27}$$

$$ASV = SFF \times S \tag{28}$$

where, sinking fund factor is determined as:

$$SFF = i / [(1+i)^n - 1] \tag{29}$$

Annual maintenance cost was assumed as 15% of FAC and uniform annual cost (UAC) is calculated using Eq. (30) (Colakoglu and Durmayaz, 2022).

$$UAC = FAC + AMC - ASV \tag{30}$$

Cost per liter (CPL) of fresh water produced is the ratio of UAC and annual productivity (P) and is determined as (El-Sebaii and El-Naggar, 2017):

$$CPL = \frac{UAC}{P} \tag{31}$$

2.8. Exergoeconomic analysis

The relationship between energy and exergy produced by solar desalination system and overall annual cost of system is determined using the exergoeconomic analysis. Exergoeconomic parameter based

on energy approach is determined as (Shatar et al., 2023):

$$R_{en} = \frac{E_{n,o}}{UAC} \tag{32}$$

in order to maximize the exergy benefit, the exergoeconomic parameter was applied and calculated as (Abbasi et al., 2022; Fang et al., 2021a):

$$R_{ex} = \frac{E_{x,o}}{UAC} \tag{33}$$

2.9. Environmental analysis

The embodied energy method is a well-known designation for the environmental assessment framework since it is adaptable and able to compare systems easily. Embodied energy is the total amount of energy required for production of all of the materials and system parts (Vijayan et al., 2020). This kind of examination makes it possible to identify materials with high embodied energy values and subsequently swap them out for more beneficial ones. The main problem with this kind of research is a lack of knowledge of system boundaries. Materials like stainless steel, glass wool, brass, mild steel, and aluminum are used for construction of the solar distillation system. The solar distillation system is fabricated and developed using energy from coal-fired power plants. However, only solar thermal energy is used when the system is in operation, facilitating the recovery of energy used during construction of system.

The amount of carbon dioxide released and neutralized by the solar desalination system is determined by environmental analysis. This consideration is crucial to make sure that the technology being utilized does not result in increased CO_2 emissions, which would be opposed to the use of renewable technology. Additionally, this analysis displays the system's net carbon emissions, which is important for choosing carbon-neutral technology. As a result, the equations utilized to determine the CO_2 emission and mitigation are shown in the section.

2.9.1. CO_2 emissions

The coal power plant produced roughly 2 kg CO_2/kWh of CO_2 considering transmission and distribution losses (Shatar et al., 2023). Lifetime CO_2 emission, CO_2 of the solar desalination system is determined as (Kant and Kumar, 2023):

$$CO_2 \text{emissions(tons) over life span} = \frac{E_{emb} \times 2}{1000} \tag{34}$$

2.9.2. CO_2 mitigation

Environmental parameters are defined as CO_2 mitigation over the system's lifetime (tons). The computation of environmental parameters uses an energy and exergy approach. As a result, the amount of CO_2 that has been mitigated over the system's lifetime (tons) using an energy-based approach is computed as (Fang et al., 2021b; Saxena et al., 2022):

$$\varnothing_{en,CO_2} = \frac{E_{en,o} \times 2 \times n}{1000} \tag{35}$$

Exergoenvironmental parameter is the CO_2 mitigated over system life span (tons) using exergy approach and is estimated as:

$$\varnothing_{ex,CO_2} = \frac{E_{ex,o} \times 2 \times n}{1000} \tag{36}$$

2.10. Enviroeconomic analysis

The enviroeconomic approach determines annual revenue from CO_2 mitigations over life span of system. Energoenviroeconomic parameter evaluates CO_2 mitigation revenue based on energy approach and is represented as (Elbar et al., 2019; Fang et al., 2021b):

$$Z_{en,CO_2} = z_{CO_2} \times \varnothing_{en,CO_2} \tag{37}$$

Exergoenviroeconomic parameter determines and evaluates CO_2 mitigation revenue based on exergy approach and is calculated as (Singh et al., 2018):

$$Z_{ex,CO_2} = z_{CO_2} \times \varnothing_{ex,CO_2} \tag{38}$$

Carbon prices of US$14.5/tonnes of CO_2 have been used in previous studies. However, carbon credit's present value has been revised in the post-COVID era (the year 2022) as per the California Carbon Allowance, which averaged roughly US$28 per tonnes of CO_2 (Shatar et al., 2023).

3. Results and discussion

3.1. Performance of system

Experiments were performed with (Al_2O_3 and ZnO nanofluid) and without using nanofluids (groundwater) on nine different consecutive days (28/05/2023–05/06/2023). Every experiment was repeated three times and an average value of three trials was used for graphical representation. Although the experiments were conducted on different days from 8 a.m. to 6 p.m., it is important to note that there was very little variation in ambient temperature and solar radiation at every trial hour on every trial day. Thus, the data reported here only pertain to the solar radiation, and ambient temperature recorded on the first experimental day. Variation in solar radiation, ambient temperature and receiver fluid temperature with and without using nanofluids with respect time are illustrated in Fig. 2. Ambient and receiver temperatures showed a similar pattern as solar radiation. The average solar radiation and ambient temperature observed during first experiment were 808 W/m^2 and 31.5 °C respectively. The maximum receiver water temperature without nanofluid (T_w) and with Al_2O_3 (T_w- Al_2O_3) and ZnO (T_w-ZnO) nanofluids was about 114.3, 122.2 and 118.2 °C, respectively. The results showed that average receiver water temperature using Al_2O_3 (T_w-Al_2O_3) and ZnO (Tw-ZnO) nanofluids was higher than that of average receiver water temperature without using nanofluids (Tw) by 7.64% and 3.60%, respectively. This happens because water is lowest thermal conductive fluid as compared to Al_2O_3 and ZnO nanofluids. It is clear that the investigation of the receiver fluid temperature also shows the dependency on thermal conductivity of fluid.

Average hourly and cumulative yield of SWDS over the day for Al_2O_3, ZnO nanofluids and without nanofluid (groundwater) is depicted in Fig. 3. The hourly yield was initially increased to its maximum value at 15hr. and subsequently decreased. The SWDS with nanofluids produced more freshwater than SWDS without nanofluids. The maximum hourly yield of 1250 ± 6.2, 1200 ± 18.02 and 1100 ± 5 mL was obtained for Al_2O_3, ZnO nanofluids and without nanofluid, respectively at 15hr. The maximum daily cumulative yield for Al_2O_3, ZnO nanofluids and without nanofluid were obtained as 7460, 6995 and 6215 mL, respectively. Results showed that cumulative yield of SWDS with Al_2O_3,

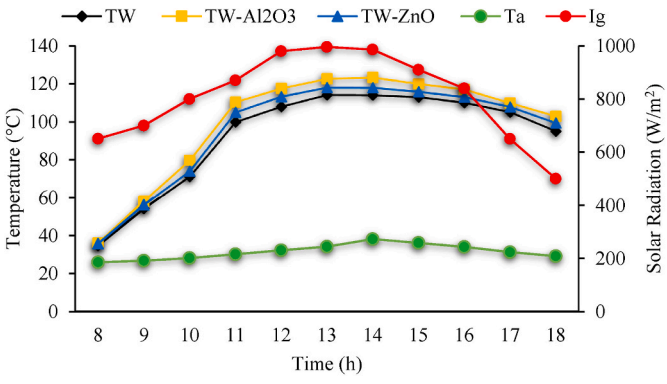

Fig. 2. Solar radiation and receiver fluid temperature with and without nanofluids versus time.

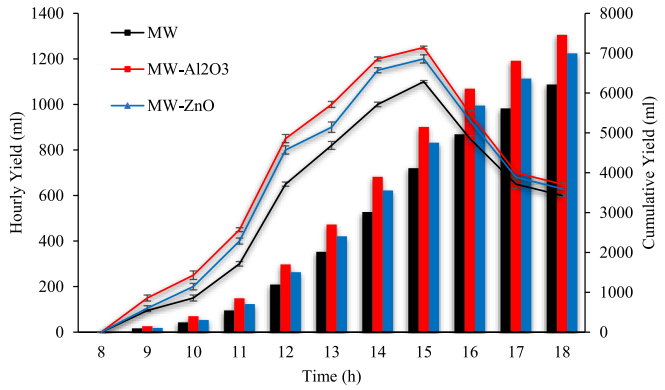

Fig. 3. Hourly and cumulative yield with and without nanofluid.

and ZnO nanofluids was 20.03% and 12.55% more than that of SWDS without nanofluids, respectively as nanofluids are more conductive than water.

Hourly efficiency for SWDS over the day for Al_2O_3, ZnO nanofluids and water is illustrated in Fig. 4. Efficiency is higher for Al_2O_3, ZnO nanofluids than that without nanofluid. Hourly efficiency was initially increased to its maximum value at 15hr and subsequently decreased. Maximum hourly efficiency of 33.95, 32.59 and 29.87% was obtained for Al_2O_3, ZnO nanofluids and water, respectively at 15hr as yield was maximum at this instant of time.

Energy and exergy efficiency of SWDS with Al_2O_3, ZnO nanofluids and water is depicted in Fig. 5. Energy efficiency of SWDS for Al_2O_3, ZnO nanofluids and water was obtained as 20.76, 19.46 and 17.29%, respectively whereas the corresponding exergy efficiency was obtained as 4.32, 4.08 and 3.52%, respectively. The energy efficiency of system for Al_2O_3, and ZnO nanofluids was 20.06 and 12.55% more than water whereas corresponding exergy efficiency was 22.72 and 15.90% more than that of water as corresponding yield was more.

3.2. Energy matrices

The embodied energy for SWDS is calculated in order to ensure that SWDS proposed in this research is both economically and energetically impressive. Table 6 shows the embodied energy values for the materials and parts of SWDS. Total embodied energy for SWDS is 1162 kWh.

Fig. 6 shows the energy payback time (EPBT) and energy production factor (EPF) of the SWDS with and without nanofluids based on energy and exergy approach. Energy payback time (EPBT) evaluation is required in order to confirm the sustainability of energy systems. Based on the findings from the several experiment days, the yield, energy, and energy output are determined for SWDS with and without nanofluids.

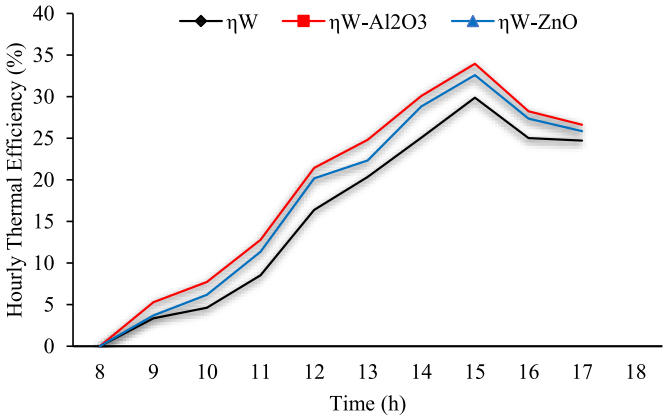

Fig. 4. Instantaneous thermal efficiency of system with and without nanofluid.

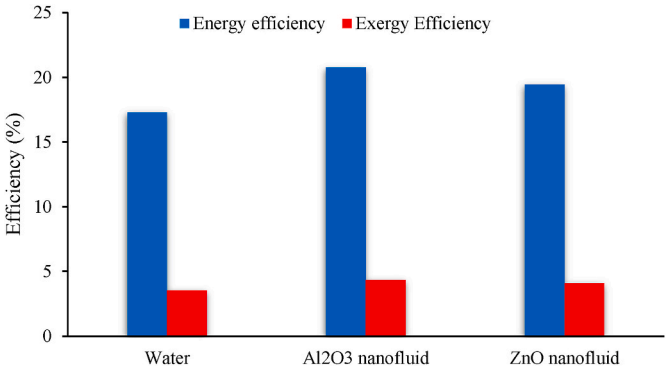

Fig. 5. Average energy and exergy efficiency of system with and without nanofluid.

The SWDS with Al_2O_3 nanofluids produced maximum energy and exergy output. The outcome demonstrates that the payback period for SWDS with Al_2O_3 nanofluids was shorter than SWDS with water and ZnO nanofluid from energetic and exergetic points of view. The EPBT values for SWDS with water, Al_2O_3 nanofluids and ZnO nanofluid based on energy approach were 1.10, 0.91 and 0.98 years, respectively. However, the corresponding values based on exergy approach were 5.69, 4.60 and 4.88 years, respectively. The energy production factor (EPF) based on energy and exergy point of view for SWDS with Al_2O_3 nanofluids was higher than SWDS with water and ZnO nanofluid. EPF values for SWDS water, Al_2O_3 nanofluids and ZnO nanofluid were 22.59, 27.18 and 25.45 based on energy approach. Whereas, based on exergy approach, the corresponding values were 4.38, 5.42 and 5.11, respectively. EPF for SWDS with Al_2O_3 nanofluids was enhanced by 20 and 6.79% than SWDS with water and ZnO nanofluid, respectively.

3.3. Economic analysis

Table 7 lists the total initial cost and various economic parameters for SWDS with and without nanofluids. The uniform annual cost was highest for SWDS with ZnO nanofluid and lowest for SWDS without using nanofluid. Cost per liter (CPL) values for SWDS without using nanofluid, with Al_2O_3 nanofluid and ZnO nanofluid were 0.051, 0.050 and 0.054 US$/L, respectively. CPL value was highest for SWDS with ZnO nanofluid and lowest for SWDS with Al_2O_3 nanofluid. CPL was enhanced by 7.25% using Zno nanofluid as compared to water. Whereas, CPL was reduced by 1.96% using Al_2O_3 nanofluid as compared to water.

3.4. Exergoeconomic analysis

Exergoeconomic analysis takes into account the financial aspects for evaluating SWDS with and without nanofluids. Table 8 illustrates the exergoeconomic evaluation's findings for the desalination system using water, Al_2O_3 nanofluid and ZnO nanofluid. It can be concluded that the SWDS with Al_2O_3 nanofluid had a higher exergoeconomic parameter value than the equivalent value of a SWDS using water. Ener-ergoeconomic parameters for SWDS without nanofluid, Al_2O_3 nanofluid and ZnO nanofluid were 12.20, 12.52 and 10.92 kWh/US$, respectively. Whereas, corresponding values of exergoeconomic parameter were 2.37, 2.50 and 2.19 kWh/US$, respectively. Exergoeconomic evaluation indicates that the incorporation of Al_2O_3 nanofluid and ZnO nanofluid is desirable. This conclusion is a result of high energy output of SWDS with nanofluids offsetting the additional cost of nanofluids.

3.5. Environmental analysis

CO_2 emissions and mitigations for SWDS with and without nano-fluids are depicted in Table 9. SWDS with Al_2O_3 nanofluid released highest CO_2 emissions over the course of its 30-year lifetime. CO_2

Table 6
Embodied energy of solar water desalination system (SWDS).

Components	Material	Energy Intensity (MJ/kg)	Weight of Components (kg)	Embodied Energy (MJ)	Embodied Energy (kWh)
Frame Structures	Mild Steel	38.8	15	582	161.66
Solar Dish	Aluminium	190	10	1900	527.76
Mirrors	Glass	25.8	5	129	35.83
Boiler	Stainless Steel	56.7	5	283.5	78.74

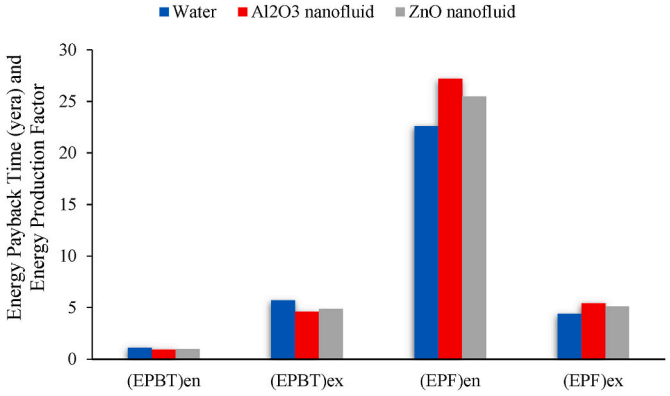

Fig. 6. Energy payback time and energy production factor for SWDS with and without nanofluid based on energy and exergy approach.

Table 7
Cost per liter values for SWDS with and without nanofluid.

Parameters (Unit)	SWDS without nanofluid	SWDS with Al_2O_3 nanofluid	SWDS with ZnO nanofluid
Total initial cost, TC (US$)	1199.85	1407.18	1510.86
Interest rate, i (%)	7	7	7
Life of system, n (Years)	30	30	30
Capital recovery factor, CRF	0.065	0.065	0.065
First annual cost, FAC (US$)	78.05	91.53	98.28
Shrinking fund factor, SFF	0.015	0.015	0.015
Annual Maintenance cost, AMC (US$)	11.7	13.73	14.74
Annual salvage value, ASV (US$)	3.611	4.23	4.54
Uniform annual cost, UAC (US$)	86.14	101.03	108.47
Annual Yield, P (L)	1676.7	2014.2	1887.3
Cost per liter, CPL (US $/L)	0.051	0.050	0.0547

Table 8
Exergoeconomic parameter for SWDS with and without nanofluid.

Parameters	Water	Al_2O_3 nanofluid	ZnO nanofluid
Annual $E_{n,o}$ (kWh)	1050.90	1264.47	1184.80
Annual $E_{x,o}$ (kWh)	204.12	252.45	237.87
Uniform annual cost, UAC (US$)	86.14	101.03	108.47
R_{en} (kWh/US$)	12.20	12.52	10.92
R_{ex} (kWh/US$)	2.37	2.50	2.19

Table 9
Environmental parameters for SWDS with and without nanofluid.

Parameters	Water	Al_2O_3 nanofluid	ZnO nanofluid
E_{emb} (kWh)	1162.70	1162.70	1162.70
Annual $E_{n,o}$ (kWh)	1050.90	1264.47	1184.80
Annual $E_{x,o}$ (kWh)	204.12	252.45	237.87
CO_2 Emissions (Tonnes)	2.33	2.33	2.33
CO_2 Mitigation (Tonnes), $\varnothing_{en},CO_2$	63.05	75.87	71.09
CO_2 Mitigation (Tonnes), $\varnothing_{ex},CO_2$	12.25	15.15	14.27
Net CO_2 Mitigation (Tonnes)	60.73	73.54	68.76
Total Carbon Credit Earned (US$)	1700.40	2059.20	1925.35

mitigations for SWDS without nanofluid, with Al_2O_3 nanofluid and ZnO nanofluid based on energetic approach were 63.05, 75.87 and 71.09, respectively. Whereas, corresponding values for CO_2 mitigations based on exergetic approach were 12.25, 15.15, and 14.27 tonnes, respectively. The amount of CO_2 mitigated by SWDS with Al_2O_3 nanofluid based on energetic approach was 20.33 and 6.27% more compared to SWDS using water and ZnO nanofluid, respectively. However, corresponding values of CO_2 mitigations based on exergetic approach were 23.67 and 6.16% more compared to SWDS using water and ZnO nanofluid, respectively. Total carbon credit earned for SWDS without nanofluid, Al_2O_3 nanofluid and ZnO nanofluid were 1700.40, 2059.20 and 1925.35 US$, respectively. It is observed that SWDS with Al_2O_3 nanofluid mitigated more CO_2 compared to water and ZnO nanofluid since yield and energy output obtained for SWDS with Al_2O_3 nanofluid was highest compared to SWDS without nanofluid and SWDS with ZnO nanofluid.

3.6. Enviroeconomic analysis

Enviroeconomic Parameters for SWDS with and without nanofluid based on energy and exergy approach are depicted in Table 10. Enviroeconomic parameters for SWDS with water, Al_2O_3 nanofluid and ZnO nanofluid based on energetic approach were 1765.4, 2124.8 and 1990.24 US$, respectively. Whereas, corresponding values of enviroeconomic parameters based on exergetic approach were 342.72, 423.92 and 399.56 US$, respectively. Highest carbon credits earned were 2124.08 and 423.92 for SWDS using Al_2O_3 nanofluid based on energetic and exergetic approaches, respectively.

Table 10
Enviroeconomic parameters for SWDS with and without nanofluid based on energy and exergy perspective.

Parameters	Water	Al_2O_3 nanofluid	ZnO nanofluid
CO_2 Mitigation (Tonnes), $\varnothing_{en},CO_2$	63.05	75.86	71.08
CO_2 Mitigation (Tonnes), $\varnothing_{ex},CO_2$	12.24	15.14	14.27
$ZCO_{2,en}$ (US$)	1765.4	2124.08	1990.24
$ZCO_{2,ex}$ (US$)	342.72	423.92	399.56

3.7. Scope of commercialization

Global demand for freshwater is increasing due to population growth and water scarcity. Conventional desalination systems are energy intensive. These techniques have a low efficiency and a high cost due to the high energy consumption. To address these problems, it is crucial to explore sustainable and eco-friendly desalination system. Hence solar dish integrated water desalination system was developed in present research work. Limited research has been conducted on the performance of water desalination systems equipped with solar dish collectors using various nanofluids. The novelty of present research work is integration of parabolic dish with automatic double-axis tracking mechanism and the use of nanofluids to enhance the productivity and efficiency of solar water desalination system. The present system is energy efficient, and environment friendly as solar energy is used as energy source. Present developed system will mitigate 2.41 tons of CO_2 per year.

Therefore, there is considerable potential to develop large-scale solar dish-integrated water desalination systems for commercial applications.

4. Conclusions

The present study investigated the performance of SWDS with and without nanofluids. A comparison was made between SWDS without using nanofluids and SWDS with different nanofluid (Al_2O_3 and ZnO) in order to determine the effects nanofluids on major parameters such as energy, exergy, freshwater productivity, energy-matrices, economic, exergoeconomic, environmental and enviroeconomic. The summarized findings of present study are listed as following:

- Annual freshwater productivity of SWDS with water, Al_2O_3 and ZnO nanofluid was 1676.7, 2014.2 and 1887.3 L, respectively.
- Annual freshwater productivity of SWDS was enhanced by 20.13% and 12.56% using Al_2O_3 and ZnO nanofluid, respectively compared to SWDS with water.
- Energy efficiency of SWDS for Al_2O_3, and ZnO nanofluids was 20.06 and 12.55% more than water whereas corresponding exergy efficiency was 22.72 and 15.90% more than that of water.
- EPBT values for SWDS with water, Al_2O_3 nanofluids and ZnO nanofluid based on energy approach were 1.10, 0.91 and 0.98 years, respectively. Whereas, based on exergy approach, the corresponding values were 5.69, 4.60 and 4.88 years, respectively.
- EPF for SWDS with Al_2O_3 nanofluids was enhanced by 20 and 6.79% than SWDS with water and ZnO nanofluids, respectively.
- Lowest CPL of US$0.050 was obtained for SWDS with Al_2O_3 nanofluids which was lower than the SWDS with water by 1.96%.
- Enerergoeconomic parameters for SWDS without nanofluid, Al_2O_3 nanofluid and ZnO nanofluid were 12.20, 12.52 and 10.92 kWh/US $, respectively. Whereas, corresponding values of exergoeconomic parameter were 2.37, 2.50 and 2.19 kWh/US$, respectively.
- Highest amount of net CO_2 mitigation was 72.54 tonnes of CO_2 for the SWDS with Al_2O_3 nanofluid.
- Enviro-economic results revealed the highest amount of carbon credit earned with SWDS using Al_2O_3 nanofluid based on energy and exergy approach was US$ 2124.08 and 423.92, respectively.

The solar water desalination system (SWDS) utilizing Al_2O_3 nanofluid demonstrated superior performance in energy and exergy output. Furthermore, the SWDS with Al_2O_3 nanofluid exhibited enhanced cost-effectiveness and environmental friendliness when compared to the SWDS employing water.

Nomenclature

A_c	Concentrator area (m^2)
E_{emb}	Embodied energy (kWh)
$E_{en,o}$	Thermal energy output (kWh)
E_r	Energy on receiver (kW)
E_u	Useful energy (kW)
Ex	Exergy (kWh)
i	Interest rate (%)
$\dot{m}$	Yield (kg/h)
n	Life of system (years)
R	Exergoeconomic parameter (kWh/US$)
S	Shape Factor
T	Temperature (°C)
φ	Environmental parameter (tonnes)
Z	Eenviroeconomic parameter (US$)

Subscript

a	Ambient
en	Energy

ex	Exergy
o	Useful
s	Sun
th	thermal

Greek letters

α	Absorbtivity of receiver
ρ	Reflectivity of concentrator
τ	Transmissivity
η	Efficiency

Abbreviations

ASV	Annual salvage value (US$)
CPL	Cost per liter (US$/L)
CRF	Capital recovery factor
EPBT	Energy payback time (years)
EPF	Energy production factor
FAC	First annual cost (US$)
SWDS	Solar dish integrated water desalination system
TC	Total initial cost (US$)
UAC	Uniform annual cost

Abstract
Potholes are one of the most common forms of road damage, and they can have a negative impact on vehicle conditions, comfort while driving, and road safety. For the Advanced Driver-Assistance System (ADAS) to ensure safe driving, accurate segmentation of road potholes is a crucial feature. The main issue with the previous state-of-the-art (SOTA) techniques is that they are not able to distinguish the visual appearance and margins of potholes close to the road areas. In order to achieve superior segmentation results and proper pothole margins, we have proposed an ERCU-Net model based on U-Net for pothole segmentation in this paper. The network consists of a novel residual convolutional block structure and employs a dropout layer in the residual convolutional block to minimize over-fitting concerns. A region-based IoU loss is proposed to reduce the regions of overlap between the anticipated segmentation and the actual segmentation. The performance of our proposed ERCU-Net model is compared with five SOTA CNNs in this paper. The result is also validated using Grad-CAM. The simulation results indicate that our proposed ERCU-Net model obtains the highest mean IoU 88.45% and the best overall pothole segmentation accuracy 98.55% in comparison to the existing state-of-the-art models.

Keywords Deep learning · Semantic segmentation · Road potholes · UNet · Advanced driver assistance system

1 Introduction

A Pothole is a depression on a road surface, which emerges as a result of the presence of both water and traffic [1]. Road users may be put in danger by the presence of potholes. In addition to being inconvenient, potholes on the road pose a safety risk because they can negatively impact driving comfort, the condition of vehicles, and traffic safety [2]. Vehicle traffic can cause the upper surface material of the road to move out and it generates small weak spots on the road. As time passes these spots worsen due to the continuous movement of vehicles over that damaged surface and cause to emergence of new potholes [3]. Road inspection is frequently done by trained maintenance personnel who drive along the roads for visual inspection of the road surface to observe and report any discovered road issues. Automatic monitoring of these tasks can improve the safety of staff and also provide an effective solution for road maintenance hazards. Furthermore, the development of ADAS systems and significant investment in autonomous driving technologies have made it possible to integrate several sensors into cars and enable multi-modal perception of the environment [4].

Among other forms of road hazards (cracks, rutting, worn markings, etc.), potholes are the most dangerous hazards on roads all around the world, causing drivers discomfort, car damage, and expensive maintenance expenditures for both public and private roadways. Vehicles are equipped with dampening systems that can lower vibrations to diminish the detrimental effects of road potholes [5]. Many efficient approaches have been put out recently using a variety of sensors, including, visual cameras [6], thermal imaging [7], RGB-D imaging [8], and Lidar [9]. In the field of visual sensors, contemporary road-pothole segmentation approaches have taken RGB images, disparity images, and depth images into consideration. The benefits and drawbacks of each modality of data are unique [10].

In recent years, pothole segmentation tasks have shown encouraging results when using deep learning-based approaches.

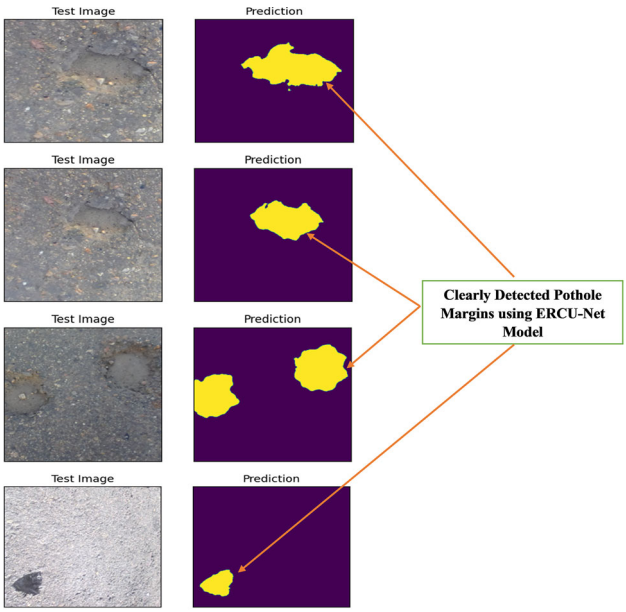

Fig. 1 Clearly visible pothole margins using proposed ERCU-Net

The fact that current techniques do not work well near pothole margins is a significant problem. We hypothesize that the causes involve just convolutional layers to take out the features. We could better protect edge information with our Enhanced Residual Convolutional block based on U-Net (ERCU-Net). We have proposed an ERCU-Net model for pothole segmentation by leveraging the advantage of residual learning with UNet. Additionally, adding residual modules in UNet boosts gradient propagation and enhances the network's capacity for generalization. Sample pothole test images with predicted output using the ERCU-Net model are shown in Fig. 1. where we can see visible pothole margins using the proposed model.

We believe that combining residual convolutional block with UNet will yield state-of-the-art results and improve the pothole segmentation impact. Our contributions can be summarized as follows:

1. We have proposed a residual convolutional block-based U-shaped encoder-decoder semantic segmentation network, replacing the convolutional block of UNet with the residual convolutional block, which led to superior segmentation effects than the original UNet.
2. In the proposed model, residual-based connections with a 1x1 convolutional block enhance the performance of the segmentation model, improve gradient flow during training, and reduce the problem of disappearing gradients, enabling the network to learn more effectively.
3. Before training the dataset, we introduced the contrast enhancement algorithm CLAHE to enhance its appearance for visual interpretation and boost the efficiency of the pothole segmentation task.
4. We have introduced a residual convolutional block for our network verified the effectiveness of different activation layers in the residual block through ablation studies and validated our result through Grad CAM.

The rest of this paper is organized as follows: A few cutting-edge existing methods for segmenting potholes are summarized in Sect. 2. The proposed model and its analysis are described in Sect. 3. In Sect. 4, the datasets, experiments, and results are thoroughly described. The conclusion and possible future directions are discussed in Sect. 5.

2 Related work

Review of pothole segmentation and detection work is presented in this section. Road pothole detection can be classified into three categories—Classical 2D image processing-based method, 3D Point cloud modeling and segmentation-based method, and machine/ deep learning-based methods [11]. 2-D image processing-based techniques are quite sensitive to environmental influences. The 3D road point cloud modeling and segmentation processes frequently interpolate a road surface point cloud into an explicit mathematical model, like a quadratic surface [12]. A 3D reconstruction-based method predicts the shape of potholes and determines their volume using stereo vision technology and it is the most accurate [13], but this method includes the high cost of pothole detection compared to alternative approaches and the difficulty of detection when a pothole is filled with water or dirt [14]. Two deep learning-based pothole detection techniques were proposed by Dhiman and Klette [15], who used stereo vision to estimate the 3-D point cloud information of the environment.

Machine/deep learning-based approaches for end-to-end road pothole detection train CNNs on annotated image data [6]. The first end-to-end single-modal CNN created for semantic segmentation was the fully convolutional network (FCN) [16]. Convolutions are created from all fully connected (FC) layers. A downsampling path and an upsampling path often make up an FCN. Convolutions, rectified linear units (ReLUs), and max pooling layers make up the converging path's usual CNN design [12]. Convolutions and concatenations are used in a series of convolutions and concatenations along the expanded path to integrate the desired visual attributes and spatial information [17]. In order to extract context information for improved segmentation efficiency, PSPNet [18], DeepLabv3+ [19], and DenseASPP [20] use a pyramid pooling module. Moreover, GSCNN [21] uses a two-branch structure made up of a shape branch and a

regular branch, which can significantly enhance the semantic predictions on the boundaries [22].

As an alternative to the single-modal networks stated above, numerous data-fusion networks have also been proposed to increase the accuracy of semantic segmentation by extracting and fusing the features from multiple visual information modalities [23, 24]. To fuse the feature maps obtained from the RGB and depth branches, for example, FuseNet [25] and depth-aware CNN [26] leverage the well-known encoder-decoder architecture but apply distinct procedures. Additionally, by combining the features acquired from RGB and thermal images, RTFNet [27] was created to enhance semantic segmentation performance. Moreover, an element-wise addition fusion approach and an encoder-decoder architecture are used. Pan et al. [28] combined multispectral images taken by an unmanned aerial vehicle to detect potholes and cracks in asphalt roads. Zhen et al. [29] have proposed a multimodal Attention Fusion network MAFNet for the segmentation of potholes. However, compared to the ground truth, in the case of MAFNet, several edges still have some incorrectly detected pixels. Gao et al. [30] proposed a new UNet based on multi-residual attention (MRA-UNet), which is used in road crack segmentation. Guo et al. [31] proposed a novel Crack Transformer (CT) model that models the long-range dependency and noisy pavement crack pixels at linear computational complexity and with high accuracy and efficiency. The model makes use of the Swin-Transformer and SegFormer with the hierarchical architecture as the Encoder and a simplified Decoder structure in SegFormer. For reliable and accurate pixel-level pavement crack identification, Guo et al. [32] suggested a Transformer-based semantic segmentation network that combines the UperNet with the attention module as the Decoder and the Swin Transformer as the Encoder. Dong et al. [33] has presented an enhanced sliding window algorithm that combines the YOLOv5 processing method for processing the two-dimensional images generated from point cloud data for automatic pavement crack detection with the random sample consensus (RANSAC) technique for directly extracting the crack information from point clouds. Zhang et al. [34] came up with a novel early warning system that combines event detection with data on the severity of foreign objects. To be more precise, the created approach can extract the track area using the upgraded railway identification method and recognize objects using the cutting-edge YOLOv5 model.

3 Proposed methodology

In the proposed ERCU-Net model residual connections are used with a shortcut path containing the 1×1 convolution with batch normalization and the activation function. The preceding feature map's depth is increased by applying the 1×1 convolution to the shortcut connectivity in the residual unit. The symmetric architecture of ERCU-Net includes expanding and contracting paths. The expanding path reconstructs spatial information, and the contracting path acquires context and learns high-level features. This symmetry makes it easier to encode and decode visual features, such as the pothole's edge, creating clearer boundaries.

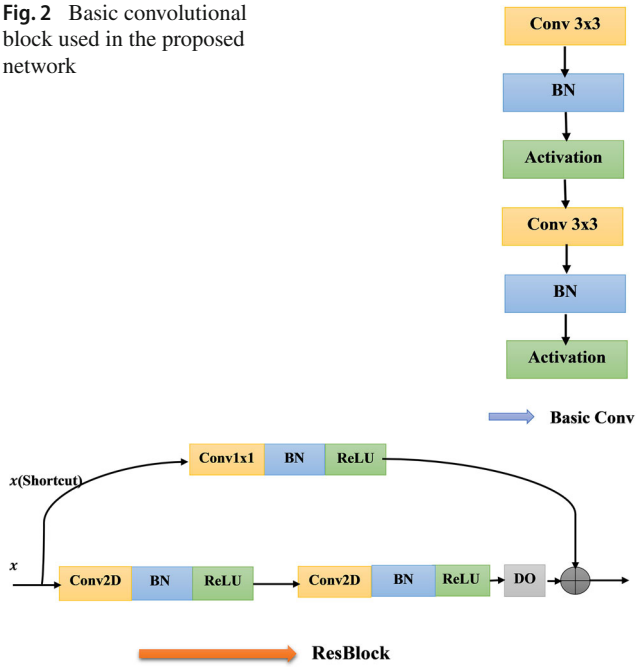

Fig. 2 Basic convolutional block used in the proposed network

Fig. 3 Proposed residual convolutional block with modified shortcut path

3.1 Proposed network architecture

The U-shaped topology of U-Net can well solve image segmentation tasks. However, due to the limitations of traditional convolution operations, U-Net cannot realize global semantic information [35]. Inspired by [36], a semantic segmentation neural network, which incorporates the benefits of residual learning and U-Net, is proposed to address the problem of correct detection of pixels at the edges of pothole areas. The proposed model employs skip connections to link the networks for the encoder and decoder. The residual convolution block uses a residual connection containing 1×1 convolution in its shortcut path, which allows the network to learn residual features and helps to improve the pothole segmentation performance by preserving more information from the input image.

Mathematically, a residual connection can be defined as follows:

$$H(x) = F(x) + x \tag{1}$$

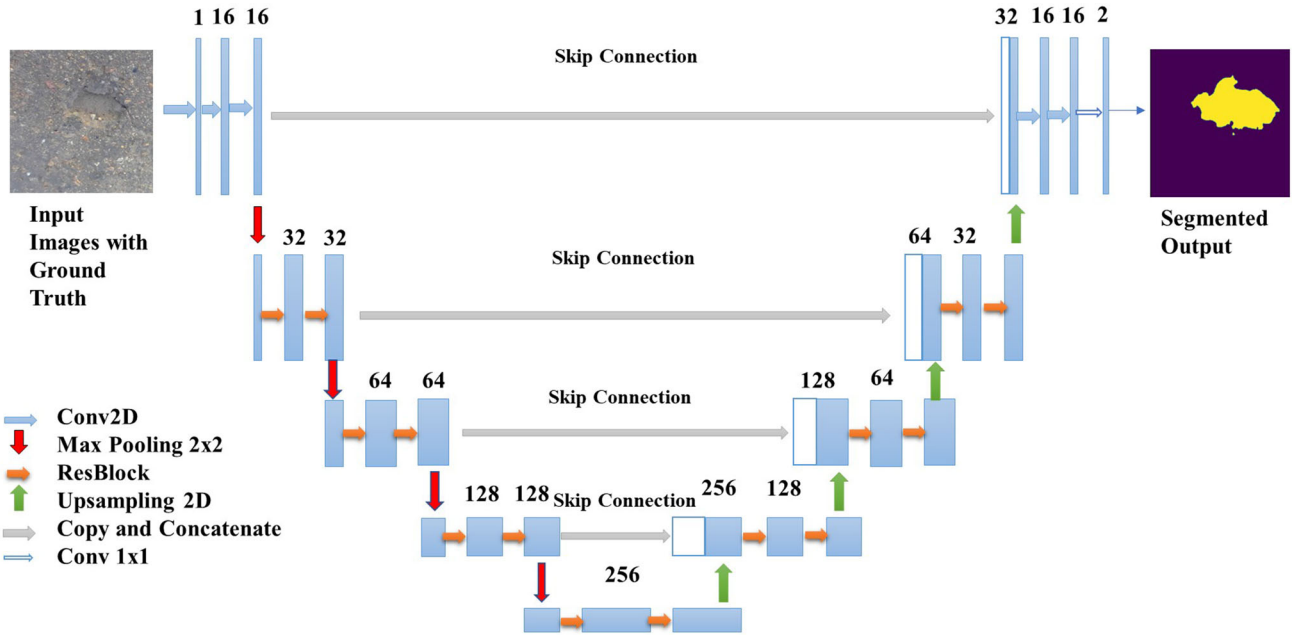

Fig. 4 Schematic of the proposed ERCU-Net architecture

where x is the input to the layer, $F(x)$ is the function of the layer, and $H(x)$ is the output of the layer. The structure of our basic convolutional block and residual convolutional block used in our proposed network is shown in Figs. 2 and 3 respectively.

The complete proposed network architecture is shown in Fig. 4. The Input RGB images of the pothole with ground truth are fed to the preprocessing block and preprocessed using the CLAHE algorithm. Certain issues, like contrast variability, feature extraction, and computing efficiency, are meant to be addressed using this algorithm. We have included pre-processed images using the CLAHE algorithm for more clarity in Fig. 5, which shows the prediction of CLAHE pre-processed images for our proposed model. After this preprocessing, patch extraction takes place, which splits the images into patches. After training, the same steps are followed during the testing stage. The overall proposed methodology is shown in Fig. 6. Skip connections and residual convolutional blocks in an ERCU-Net enable the transmission of both high-level and low-level information, as a result of testing the proposed model, we obtain a clearer pothole margin. In the proposed work we have trained three versions of the U-Net model—Simple U-Net, Attention U-Net, and Residual Attention U-Net along with the proposed ERCU-Net.

Algorithm 1 depicts the training procedure for the proposed ERCU-Net model. The algorithm iterates the training epochs, modifies the model's parameters, and evaluates the model's performance on the validation set.

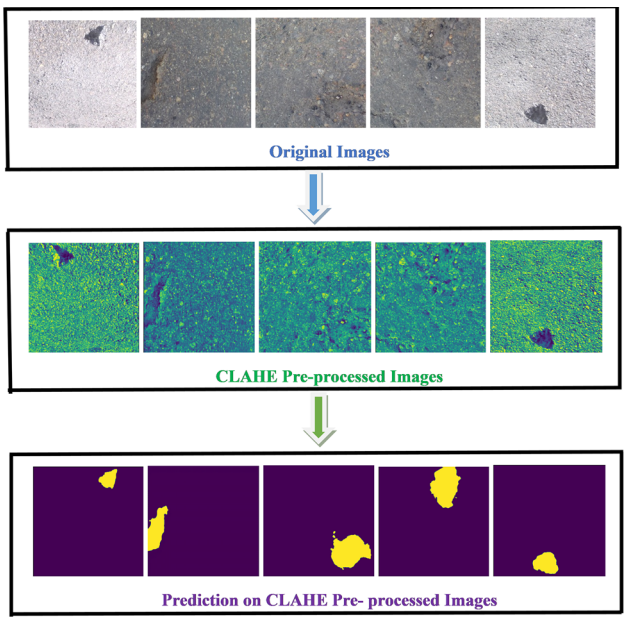

Fig. 5 Prediction on CLAHE pre-processed images

3.2 Encoder

We have utilized a modified U-Net encoder block that consists of two 3×3 convolutions applied repeatedly, each followed by a rectified linear unit (ReLU), to create a single 3×3 convolution, following this convolutional block, there is a 2×2 max pooling operation with stride 2 for input stage downsampling. The proposed residual convolutional block is used in the rest stages of the downsampling process.The $1 \times$

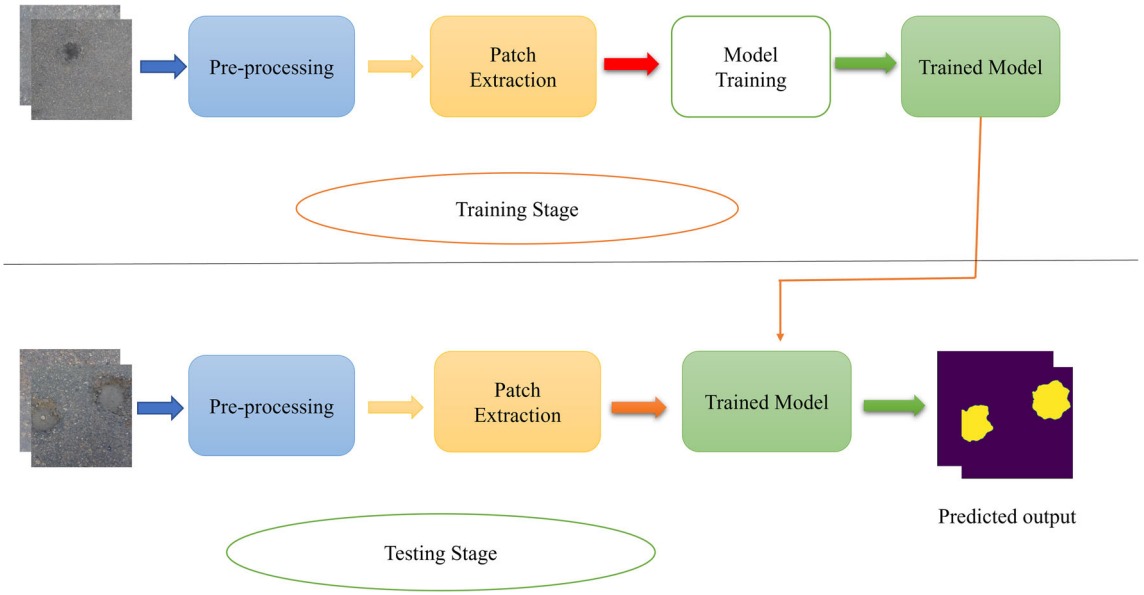

Fig. 6 Proposed methodology

Algorithm 1: Training Algorithm of ERCU-Net Model

Input: Pre-processed training dataset: $(x_i, y_i)_{i=1}^{N}$, where x_i - input image and y_i - corresponding ground truth mask for potholes
Output: Trained ERCU-Net model
Initialize ERCU-Net model
Define loss function
Choose adam optimizer with learning rate $\eta = 1e-3$
Split dataset $\leftarrow$ Train-val(70:30)
for *each training epoch* **do**
  for *each mini-batch in the training set* **do**
    Sample a mini-batch of input images (x_j) and corresponding masks (y_j)
    Perform forward pass through the ERCU-Net model to obtain predicted masks $\hat{y}_j$
    Compute the loss $\mathcal{L}_j$
    Compute the gradients $\frac{\partial \mathcal{L}_j}{\partial \text{model parameters}}$
    Update model parameters: model parameters $\leftarrow$ model parameters $- \eta \cdot \frac{\partial \mathcal{L}_j}{\partial \text{model parameters}}$
  end
  Evaluate model performance
end

1 convolution layer in the shortcut path architecture provides dimensionality reduction by lowering the number of filters while keeping crucial, feature-related information.

3.3 Decoder

The decoder has five steps. The feature map resolution doubles for every step. In terms of resolution, the output matches the input exactly. The final step adds a sigmoid layer to determine the probability of each pixel falling into the background or pothole class. The detailed configuration of the encoder and decoder blocks used in the proposed model is shown in Fig. 7.

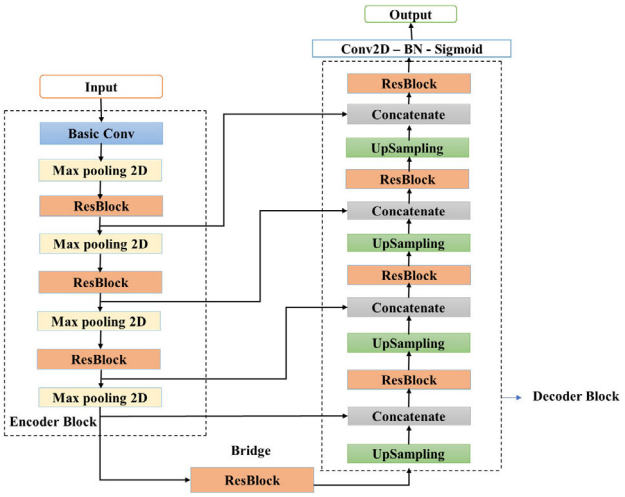

Fig. 7 Detailed configuration of encoder and decoder block

4 Experimental results and discussions

4.1 Dataset-geometric transformation augmentation

For the experiments, we employ the freely available Pothole-600 dataset [22]. In total, there are 600 RGB images of 400 x 400 resolution in the dataset.

We employ the method of [22] for dividing images, 240 RGB images are included in the training set and there are 180 images in each of the testing and validation sets. Flipping, rotating, and cropping the RGB images in the initial training set allows us to create an augmented training set. The enlarged training set has a total of 960 images, which is 4×240. The total number of RGB images for training is $240 + 960 = 1200$ [29].

4.2 Training detail

The proposed architecture was implemented with the use of the Keras framework. Our network is trained and tested using Google Colab, which has a Tesla K80 accelerator, 13 GB of RAM, and 12 GB of GDDR5 VRAM.

We used residual convolutional blocks in the ERCU-Net model and trained it from scratch. To avoid overfitting during a neural network model's training, we choose a dropout rate of 20 percent in each stage of model architecture in downsampling as well as upsampling path. With an initial learning rate of 1e−3, we train the network for 150 epochs using the adaptive moment estimation (Adam) optimization function.

4.3 Evaluation metrics

To assess the efficacy of semantic segmentation, we use two quantitative metrics: intersection over union (IoU) and accuracy. The following is how they are determined:

$$\text{Accuracy} = \frac{\text{True Positives}}{\text{True Positives} + \text{True Negatives}} \tag{2}$$

$$\text{IoU} = \frac{\text{True Positive}}{\text{True Positives} + \text{False Negatives} + \text{False Positives}} \tag{3}$$

In the ground-truth images of the dataset, there are two classes: pothole and unlabeled background (Fig. 8). The average values, which are designated as Average Accuracy and mIoU, are the mean values across the two classes [29].

4.4 Ablation analysis

4.4.1 Ablation on the effect of activation layer in residual block

In the ablation study, we tested the network with different activation layers-Softplus, Softsign, ReLU, and GeLU activation layer, in the residual convolutional block shown in Fig. 3, and discovered that using the ReLU activation layer in the residual convolutional block produces a better mean iou and accuracy than the other three. The ablation using different activation layers in the residual convolutional block is shown in Table 1.

4.4.2 Ablation study for selection of baseline

Our decision to adopt the residual-based UNet model as our baseline for the pothole segmentation problem was inspired by the model's underutilized potential in the field of pothole segmentation. The performance of various models, i.e., Simple UNet, Attention UNet, Residual Attention UNet, and ERCU-Net is examined in terms of accuracy and trainable parameters as demonstrated in Fig. 9.

The performance of various models is also examined in terms of inference speed as shown in Fig. 10.

4.5 Comparative evaluation with other cutting-edge models

We compared our proposed ERCU-Net model with SegNet [37], DeepLabv3+ [19], ESPNet [38], GSCNN [21] and MAFNet [29]. We have also made a comparison of different Unet variants on the pothole-600 dataset. The effectiveness of our proposed model is shown by contrasting the network's performance with that of other cutting-edge models. Table 2 compares the results of our model with other models that are considered to be state-of-the-art. ERCU-Net outperforms other cutting-edge models on the same dataset.

Figure 11 presents validation loss for different models on the Pothole-600 augmented dataset.

4.5.1 Qualitative demonstrations

Figure 8 presents the qualitative demonstrations. Compared to the others, our proposed ERCU-Net performs pothole segmentation with more accuracy and the best IoU score. Our network performs substantially better on pothole edges than the other networks. It improves the effectiveness of road maintenance procedures, promotes data-driven decision-making, and allows for efficient communication regarding the state of the roads and the need for repairs.

4.6 Grad-CAM visualization

Utilizing the Gradient-weighted Class Activation Mapping (Grad-CAM) technique, the heatmap is generated. The pothole regions are displayed as a heatmap by Grad-CAM, which uses the target's gradients to create the coarse localization map. The heatmap is created by utilizing the last convolution layer. Figure 12 demonstrates Grad-CAM visualization of the proposed ERCU-Net model.

5 Conclusion and future scope

In conclusion, we have proposed the use of the ERCU-Net architecture for pothole segmentation and demonstrated its effectiveness on the Pothole-600 dataset of road images. Our findings demonstrate that the ERCU-Net beats other cutting-edge techniques in terms of average accuracy and mIoU, making it a promising method for tasks requiring pothole segmentation. But there are still certain limitations in place. In situations where the training data distribution differs greatly from real-world circumstances, the model might not be able to generalize successfully. Additionally, a variety of unfavorable factors in real-world scenarios, such as different textures, patterns, marks, debris, etc., can produce background noise and clutter that hamper the segmentation of potholes and reduce the accuracy of detection. There is still scope for further research in this area. One potential direction is to investigate the real-time inference speed of the model on different datasets. Another direction is to explore multimodal fusion approaches for improving segmentation accuracy and robustness to environmental variability in pothole segmentation tasks.

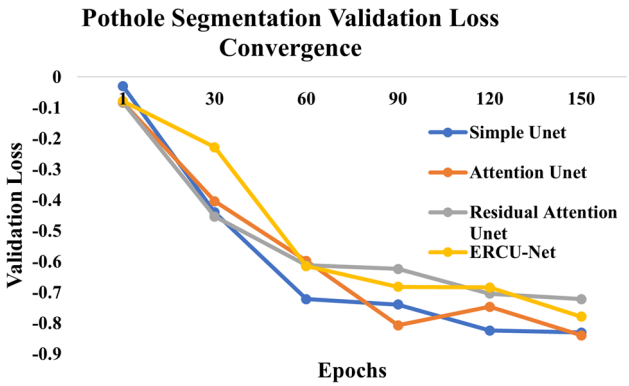

Fig. 11 Pothole segmentation validation loss convergence

Table 2 Comparative result analysis % on the pothole-600 testing dataset

Model name	Mean IoU	Average accuracy
SegNet [37]	30.71	89.35
DeepLabv3+ [19]	55.31	97.39
ESPNet [38]	49.33	96.13
GSCNN [21]	52.71	97.71
MAFNet [29]	87.29	97.62
Simple Unet	86.72	94.49
Attention Unet	86.76	97.62
Residual Attention Unet	82.63	94.54

Abstract

This study is on synthesising aluminium-based metal matrix hybrid composites with silicon carbide (SiC) and Titanium dioxide (TiO₂) reinforcements by double stir casting technique. SiC and TiO₂ were chosen for their excellent mechanical, tribological and physical properties. As limited information exists on the mechanical properties of Al2017 composites with both SiC and TiO₂. The Al/SiC/TiO₂ hybrid nanocomposites were prepared with 5 wt.% of SiC nanoparticles, 5 wt.% of TiO₂ nanoparticles, and a mixture of both at 5,5 wt.%. Microstructure analysis confirmed a uniform distribution of SiC and TiO₂ particles within the aluminium matrix. The Al2017/SiC composite exhibited a hardness of 46.33 HRB, while the Al2017/TiO₂ composite displayed a comparable hardness of 44.33 HRB. However, the combined Al2017/SiC/TiO₂ composite showed a decreased hardness of 40.33 HRB suggesting the importance of considering the composition and combination of reinforcement materials when designing metal matrix composites. The observed decrease in hardness in the Al2017/SiC/TiO₂ composite can be attributed to various factors, including the interaction and compatibility between SiC and TiO₂ particles within the aluminium matrix. Further research is required to understand the underlying mechanisms and enhance the mechanical behaviour of the Al2017 composites.

1. Introduction

It is challenging to choose the right material for a given application; lighter materials typically have lower strengths, whereas brittle materials have lesser toughness and fatigue resistance. Thus the hunt for new and better materials is ongoing due to the newest technological demands for greater energy efficiency, durability, lighter, and less expensive materials. For technological applications, it is nearly hard to find a single monolithic material with the necessary property profile.[1]

Since the early 1960s, new and improved construction materials have been sought with the advances in modern technology that have an interest in the rapid development of metal matrix composites in the aerospace and automotive sectors. Extensive research and development efforts have been made in the realm of composites as a result of the high demands placed on materials to increase overall performance. Metal matrix composites based on aluminium are often employed in the field of composites. Innovations in material processing have made it feasible to enhance wear resistance, attain high strength-to-weight ratios, increase stiffness, and maintain strength at high temperatures in order to satisfy new demands.[2]

2. Aluminium Metal Matrix Composites (AlMMCs)

A composite material is defined as a mixture of at least two materials that produces preferred qualities when compared to the properties of the component segments utilised separately. Every material has its unique chemical, physical, and mechanical qualities, as compared to metallic alloys. When compared to mass materials, composite materials' primary benefit is their excellent quality and solidity, along with their low density. This enables the finished part's weight to be reduced.[3]

Aluminium matrix composites are regarded as a novel and emerging class of materials having unique characteristics for specific applications. Advanced engineered materials, or AlMMCs, have better qualities than other traditional aluminium. Because of these characteristics, they have recently attracted considerable interest for a range of prospective applications in the automotive, aerospace, and other structural fields. In order to obtain the material with the needed qualities, extensive research and development has been done on Al-based MMCs using every conceivable alloy and various reinforcements.[4]

3. Stir Casting

In stir casting, the molten metal matrix is stirred with a stirrer. The material used to make the stirrer often has a greater melting point than the matrix temperature. Graphite stirrers are typically used in stir casting. The stirrer primarily consists of two parts: a cylindrical rod and an impeller. One end of the rod is attached to the motor shaft, and the other end is linked to the impeller. The stirrer is typically kept upright and rotates at different speeds thanks to a motor. Afterward, the molten metal is put into a die for casting. Stir casting is suited for producing composites with reinforcement volume fractions up to 30%. [5]

Such setup can be seen in Fig. 1

A major concern associated with the stir casting is segregation of reinforcement particles due to various process parameters and material properties resulting in the non-homogeneous metal distribution. The numerous process variables include things like the degree to which metal particles are moist, relative density, settling velocity, etc. The speed of the stirrer, its angle, the presence of vortices, and other factors all have an impact on how the particles are distributed inside the molten metal matrix. Where G.G. Sozhamannan et al.(2012) [6] fabricated aluminium metal composites at different processing temperatures with different holding time, which had different mechanical properties.

3.1 Double Stir-Casting Technique

There have been several reports on the use of two-step (double) stir casting to enhance cast metal matrix composites. K.K. Alaneme et al.(2012)[7] proposed that producing AMCs without using two-step stirring causes less homogeneity of the particles and greater porosity levels, which may be over the permitted limits. To promote wettability between the melt of the aluminium alloy and the SiC particles, the procedure calls for pre-treating the SiC particulates in a dry oven at 1,100°C..Additionally, to reduce the moisture content, P. Shanmughasundaram et al.(2011)[8] employed fly ash particles that had been warmed to 600℃ for two hours in a different muffle furnace. The graphite crucible was charged with aluminium, and the furnace temperature was increased to a liquidus temperature of 670℃ in order to completely melt the aluminium scraps. The melt temperature was then reduced to 620℃ in order to achieve a semi-solid condition. The crucible was filled with warmed fly ash particles and 1.5 wt% magnesium. To encourage the wetting activity between the Al matrix and the fly ash reinforcement

particles, Mg was added to the melt. After 10 minutes, the molten Al composite slurry reached a semi-solid condition and was agitated with a stirrer at a speed of 300 rpm. According to K. K. ALANEME et al. (2013)[9] research, the AA 6063/Al2O3p composites made using the two-step stir casting method used in this study had low porosity values of less than 3.6%. Although the strain to fracture and fracture toughness values of the composites declined with increasing volume percent alumina, the tensile strength, yield strength, and hardness values rose. Comparing well with other aluminium-based alumina reinforced composites described in literature, the mechanical characteristics derived from the AA 6063/Al2O3p composites created.

3.2 Material

For this study aluminium 2017 was used with compositions given below in Table 1.

Table.1. Composition of Al used as matrix material (wt. %)

Al%	Si%	Cu%	Fe%	Zn%	Mg%
92.784	0.722	4.466	0.311	0.056	0.623

Sn%	Ti%	V%	Ni%	Mn%	Cr%
0.077	0.031	0.01	0.049	0.0807	0.035

According to J. R. Davis (2001)[10], In alloys from the 2xxx class, copper serves as the main alloying element, with magnesium serving as a minor component. To achieve their ideal qualities, these alloys must undergo solution heat treatment; in this state, their mechanical properties are comparable to and occasionally even surpass those of low-carbon steel. Precipitation heat treatment, also known as ageing, is used to further improve mechanical characteristics. This process reduces elongation while increasing yield strength; it has a less significant impact on tensile strength. Screw machine products, fittings, fasteners, and machine components are the principal uses for Al2017. According to K. Mroczka et al. (2012)[11] research on the 2017A aluminium alloy under various heat treatment circumstances, the alloy should be treated at a temperature of 500°C (the allowable temperature range is between 490°C and 520°C). After 72 hours, the material had reached its maximum hardness and ultimate tensile strength due to natural ageing. After six hours, artificial ageing at 180°C results in a significant increase in hardness. The ultimate tensile strength of the material improves by 20% as a result of natural ageing (compared to the supersaturation state). Mrówka-Nowotnik Grayna et al.(2021)[12] came to the conclusion that the temperature of the solution heat treatment also influences the alloy's hardness during artificial ageing. It was discovered that as compared to natural ageing, artificial ageing enables the achievement of greater hardness levels. The hardest alloy is the alloy 2017 solution, which was heat treated at 510°C and aged at 175°C. The hardness is quite similar to the value attained during natural ageing after ageing at 120°C. It was discovered that during artificial ageing, the temperature of the solution heat treatment has no bearing on how quickly hardness increases to its maximum value.

4. Reinforcement

The reinforced metal matrix has the potential to create improved MMCs and exhibits superior characteristics when compared to base or reinforced material used alone. For micron-sized particles in general, 5 to 10% might be adequate, and for nanomaterials, even less than 5%, resulting in a significant improvement in mechanical behaviour. V.K. Sharma et al.(2012)[13] discovered that the wear resistance of manufactured composites rises as the flyash concentration increases. Composites with high flyash contents wore out 13.6% less than composites with low flyash concentrations.The sample with a medium flyash concentration (4%) had the lowest average coefficient of friction (0.12), while the sample with a high flyash level (6%) had the highest average coefficient of friction (0.161). As a result, the amount of flyash in the aluminium matrix is restricted to 4%. The addition of more reinforcement increases the coefficient of friction between the tribopairs.

4.1 SiC (Silicon Carbide)

The most widely employed reinforcement material in the development of AMMCs is silicon carbide (SiC). It also increases ultimate tensile strength while decreasing porosity. The qualities of the reinforcement vary depending on the grade of aluminium alloy used.[14]

Md. Habibur Rahmana(2014)[15] came to the conclusion that adding SiC to an Al matrix boosted the Vickers hardness and tensile strength of composites when compared to unreinforced Al. AlMMC with a SiC concentration of 20% had the highest hardness and tensile strength. The wear resistance of SiC reinforced AMCs increased as the SiC concentration in the Al matrix increased. Based on wear resistance, AMC reinforced with 20% SiC performed best. Cui Yana et al.(2008)[16] research also reveals that SiC/Al composites have a low density (2.94 g/cm^3), a high elastic modulus (220 GPa), a prominent thermal management function due to a low coefficient of thermal expansion ($8\times10^{-}$ K^{-1}) and high thermal conductivity (235 W/(mK)), and a unique preventability of resonance vibration. The multi-functional SiC/Al composites were manufactured into near-net-shape pieces using a number of established processes. Precision components for space-based optomechanical structures and airborne optoelectronic platforms have been manufactured in large quantities. Several common goods are now being tested in the field.

4.2 TiO (Titanium Dioxide)

According to Anna A. Murashkina et al.(2015)[17] research, TiO samples exhibit a mixed phase rutile-anatase crystalline structure, with the anatase component increasing linearly from 0.0 wt% for Al-TiO to 18 wt% for 1.1-Al-TiO. With increasing Al concentration, particle size decreases from 800 nm to 50 nm, and specific surface area increases from 1.7 m^2/g to 28 m^2/g. Adeolu A. Adediran et al. (2021)[18] demonstrated Simultaneous optimization of the characteristics 779.3°C, 574.2 rpm, and 22.5 min as the best stir casting parameters for temperature, speed, and duration, respectively, using Minitab 19 software. The interaction profile of the parameters according to the response surface was examined.

Contour plots for each interaction revealed distinct ranges of stirring settings for optimising each attribute.

4.3 Hybrid of SiC (Silicon Carbide)&TiO₂ (Titanium Dioxide)

Mechanical parameters of hybrid composites such as tensile strength (TS), hardness (BHN), density, and impact strength have been found to be identical to or higher than those of conventional composites. It has been said that hybrid composites provide higher flexibility and reliability in the structure of the future parts determined by the fortification mix and organization.[19]

G. Elangoa et al. (2013)[20] studied the wear behaviour of aluminium alloy LM25 reinforced with SiC particulate and further addition of TiO_2 particulate. The wear resistance and frictional properties of a hybrid metal matrix composite were investigated using a pin on disc wear tester concluding that reinforcing the metal matrix with SiC and TiO_2 minimises wear rate at room temperature.

Aluminium hybrid metal matrix nanocomposites (Al/SiC/TiO_2) were synthesised by M.R. Mattli et al. (2021)[21] using a microwave-assisted powder metallurgy procedure, and their developed microstructure and mechanical properties were examined. The Al/SiC/TiO_2 hybrid nanocomposites were prepared by reinforcing aluminium (Al) matrix with a fixed amount of silicon carbide (SiC) nanoparticles (5 wt.%) and varying concentrations of titanium dioxide (TiO_2) nanoparticles (3, 6, and 9 wt.%). The addition of TiO_2 nanoparticles increased the hardness and compressive strength of the Al/SiC/TiO_2 hybrid nanocomposites. The Al/SiC/TiO_2 hybrid nanocomposites with the highest concentration of TiO_2 nanoparticles (9 wt.%) showed the best mechanical properties.

A.D. Assi et al. (2020)[22] produced composites were reinforced with silicon carbide (SiC) and titanium dioxide (TiO_2) nanoparticles added in precise weight percentages (3, 6, 9 wt%) using a stir casting technique. All specimens were subjected to cold mechanical treatment (pressure forming) and heat-treated T6 (solution heat treatment artificial ageing). Mechanical tests were then performed on the samples. According to the SEM and X-RD data, the reinforced AA (6061) had improved in hardness, yield strength, ultimate tensile strength, and impact toughness.

S. Hariharan et al. (2020)[23] developed an aluminium-based hybrid composite material by stir casting with Al7075 as the matrix and SiC and TiO_2 as the reinforcements. Mechanical analysis of Al7075 + SiC + TiO_2 revealed greater hardness and tensile strength.

5. Experimental Procedure

Material Preparation

The Al2017 matrix alloy was used as the composites' base material. As reinforcement materials, silicon carbide (SiC) and titanium dioxide (TiO_2) particles were employed. To guarantee appropriate dispersion, the SiC and TiO_2 particles were pre-treated.

Double Stir Casting Technique

The Al2017/SiC/TiO composites were created using the double stir casting technique. The Al2017 alloy was melted in a crucible using a controlled temperature furnace. The pre-treated SiC and TiO particles were gradually added to the molten Al2017 alloy while the mixture was constantly stirred. To achieve consistent dispersion of the reinforcement particles, the stirring operation was carried out using mechanical stirrers at a predetermined speed. The stirring was done for a certain amount of time to ensure proper mixing and bonding between the matrix alloy and the reinforcing particles.

Surface Preparation

To eliminate any dirt, grease, or impurities, the surfaces of the aluminium samples were thoroughly washed with a suitable cleansing agent. To eliminate surface flaws, scratches, and oxidation, coarse grit sanding was performed with sandpaper with a grain size of 120–180.The entire surface was uniformly sanded, with special attention paid to any unusually rough or damaged areas. To further refine the surface and remove any leftover scratches or markings, fine grit sanding was performed using increasingly finer sandpapers. During the sanding operation, water or a suitable polishing fluid was employed as a lubricant to reduce heat buildup and improve surface quality. The stirring was done for a certain amount of time to ensure proper mixing and bonding between the matrix alloy and the reinforcing particles.

Mirror Polishing

Mirror finishing was performed on the smoothed surface using a high-quality aluminium polishing compound along with a clean cloth and rotatory polishing station, aluminium surface was polished in circular motions while applying light pressure and keeping a consistent speed. The polishing compound was applied uniformly throughout the whole surface, with special attention paid to any residual defects. Throughout the polishing process, the surface was inspected at regular intervals to check progress and ensure the intended outcomes. The polishing process was repeated until a mirror-like quality was obtained.

Microstructure Analysis

On polished cylindrical samples, an Olympus microscope was used for microstructure examination. This microscope provided superior optical resolution and magnification, enabling a thorough analysis of the dispersion and properties of SiC and TiO particles within the Al2017 matrix. The microscope was used to record high-resolution microstructures at various magnifications in order to gain a full understanding of the microstructural characteristics and bonding properties of the composite materials. The microstructure analysis yielded information on the distribution, shape, and bonding properties of the reinforcing particles.

Rockwell Hardness Testing

The Rockwell hardness values of the individual composite samples were determined. A Rockwell hardness testing machine with the Rockwell B scale was used. The cylindrical samples were subjected to a small load of 10 kg, followed by a main load of 100 kg. The indenter was a steel ball with a diameter of 1/16 of an inch. The cylindrical samples' polished surfaces were indented, and the related hardness values were recorded. To assure statistical reliability, each sample was indented many times.

Such setup can be seen in Fig. 2

Data Collection:

- The obtained microstructure and hardness values were recorded and documented for further analysis and interpretation.

6. Results and Discussions

The results of the experimental analysis on aluminium-based composites are presented in this section. This assessment is divided into three parts: surface analysis, hardness testing, and microstructure characterization.

These three factors were chosen because they are critical in defining the mechanical properties and performance of composites. The results of this analysis helps to understand the material's behaviour, identify any limitations, and provide a foundation for future optimization and advancement in research and applications.

6.1. Surface analysis

Surface analysis was used to evaluate the quality and characteristics of the produced samples." The results revealed that the porosity levels of the various composites varied. The TiO₂ particle-reinforced sample had the maximum porosity, followed by the hybrid composite and the SiC-reinforced sample. This finding indicates that the addition of TiO₂ particles has made achieving a fully dense structure more difficult. Porosity in composites can have a negative impact on mechanical qualities such as hardness. As a result, addressing the porosity issue is critical in order to improve the performance of composites.

On the other hand, the sample reinforced with SiC particles, demonstrated a remarkable observation after dry polishing, in which the composite was seen to shed abrasive particles. This is due to a less strong bond between the SiC particles and the aluminium matrix. However, the TiO₂ casting technique did not produce adequate results for the Al2017 alloy, indicating difficulties in obtaining uniform distribution and effective bonding of TiO₂ particles with the aluminium matrix. To improve the performance of the Al2017/TiO₂ composite, more research and optimisation of the casting parameters are required. These surface analysis findings highlight the necessity of regulating porosity and establishing strong interfacial interaction between the reinforcement particles and the matrix in hybrid composites.

6.2 Hardness

Hardness refers to a material's resistance to surface indentation. The microhardness of composites measures the strength of the interface bonding between reinforcing particles and matrix. The Rockwell hardness test was used to determine the hardness values of the produced samples. The hardness of the hybrid composite was 40.3333HRB, the hardness of the SiC-reinforced sample was 46.333 HRB, and the hardness of the TiO₂-reinforced sample was 43.333 HRB. The difference in hardness across samples reflects the effect of different reinforcements on the mechanical properties of the composites. The hybrid composite's decreased hardness seems to be related to elements such as the interaction and compatibility of SiC and TiO₂ particles within the aluminium matrix, as well as the presence of porosity. Such variation in hardness can be seen in Fig. 3

6.3 Microstructures

The microstructure study of the samples revealed distinct characteristics. The SiC sample revealed a network-like architecture with interconnected particles. It also had numerous fine black dots, which indicated the dispersion of SiC particles within the aluminium matrix. The TiO₂ sample, on the other hand, had a more homogeneous microstructure with finer grain boundaries and less apparent black spots. The microstructure of the hybrid sample was identical to that of the TiO₂ sample, indicating a homogenous distribution of TiO₂ particles inside the aluminium matrix.

The changes in microstructure across the samples can have a substantial impact on their mechanical qualities and performance. The SiC sample's linked structure may lead to improved mechanical strength and load-bearing capabilities.The highly homogeneous microstructure of the TiO₂ and hybrid samples indicates good particle dispersion and possible improvements in characteristics like wear resistance and dimensional stability. Microstructure for the following can be seen in Fig. 4.

7. Conclusion

Possible reasons for this outcome could be related to the particle distribution, particle interactions, or the effect of different reinforcement mechanisms. It is important to note that the interaction between SiC and TiO₂ particles might have influenced the overall microstructure and mechanical behaviour of the composite. The combined presence of these two types of particles may have affected their distribution and bonding within the matrix, resulting in a reduction in hardness compared to individual reinforcement additions.

Potential reasons for the observed decrease in hardness when SiC and TiO₂ are added simultaneously:

Particle Interactions

The interaction between SiC and TiO₂ particles may have led to agglomeration or clustering, resulting in uneven distribution within the matrix. This clustering could have hindered effective load transfer and

reduced the overall hardness.

Reinforcement Mechanisms

SiC and TiO₂ have different reinforcement mechanisms. SiC is known for its excellent hardness and high wear resistance, while TiO₂ is primarily used for its beneficial frictional properties. The combined addition of these particles might have influenced the dominant reinforcement mechanism, potentially leading to a compromise in hardness.

Matrix Compatibility

The Al2017 matrix may have different levels of compatibility with SiC and TiO₂. The interactions between the matrix and the two types of particles could have varied, leading to a difference in the effectiveness of reinforcement and subsequent hardness.

The addition of SiC and TiO₂ to the Al2017 matrix reduced hardness as compared to individual additions. Potential particle interactions, changes in reinforcement mechanisms, and differences in matrix compatibility can all be attributed to this drop. These findings highlight the significance of carefully evaluating the combination and interactions of different reinforcing particles when attempting to obtain the desired mechanical characteristics in composite materials.

To further enhance the understanding of the observed trend, future studies could focus on optimising the particle distribution, exploring alternative processing techniques, or investigating the effect of varying weight fractions of SiC and TiO₂ in the composite. Such research could help customise the mechanical properties of Aluminum composites for various applications.

In the present work, we study a cosmological model composed of a viscous dark matter interacting with decaying vacuum energy in a spatially flat Universe. In the first part, we find the analytical solution of different cosmological parameters by assuming the physically viable forms of bulk viscosity and decaying vacuum density with the interaction term. The second part is dedicated to constrain the free parameters of the interacting viscous model with decaying vacuum energy by employing latest observational data of *Pantheon+*, Cosmic Chronometer and $f(z)\sigma_8(z)$. We find that the interacting model just deviate very slightly from well-known concordance ΛCDM model and can alleviate effectively the current H_0 tension between local measurement by R21 and global measurement by Planck 2018, and the excess in the mass fluctuation amplitude σ_8 essentially vanish in this context. We report the Hubble constants as $H_0 = 72.150^{+0.989}_{-0.779}$, and $72.202^{+0.796}_{-0.937}$ $kms^{-1}Mpc^{-1}$, deceleration parameters as $q_0 = -0.533 \pm 0.024$, and -0.531 ± 0.024, and equation of state parameters as $w_0 = -0.689 \pm 0.016$, and -0.687 ± 0.016 for ΛCDM and interacting models, respectively. It is found that the interacting model is in good agreement with ΛCDM. Further, we discuss the amplitude of matter power spectrum σ_8 and its associated parameter S_8 using $f(z)\sigma_8(z)$ data. Finally, the information selection criterion and Bayesian inference are discussed to distinguish the interacting model with ΛCDM model.

I. INTRODUCTION

In modern cosmology, understanding of two dark components: dark energy (DE) and dark matter (DM) of the Universe is so far the most challenging research area in cosmology. The discovery of accelerated expansion in 1998 [1, 2] has motivated to comprehend the composition of these dark entities. Dark matter, which interacts only gravitationally with ordinary matter, explains the measurement of rotation curves of spiral galaxies [3]. The most important theories for DM are scalar fields [4, 5], supersymmetry models [6]. On the other hand, dark energy, which has negative pressure, is considered for the accelerated expansion of the Universe. The most interesting candidates are the cosmological constant (CC), phantom energy, quintessence, Chaplygin gas, modified theories of gravity, etc. (refer to Refs.[7–9]). The cosmological constant as DE so-called Lambda-cold-dark matter, abbreviated as ΛCDM is still the best candidate to explain the cosmological observations. However, ΛCDM model suffers with some theoretical problems [10, 11] when its origin is considered as quantum vacuum fluctuations.

Many alternative theories have been proposed beyond the ΛCDM to solve these conundrums. Some works in literature have shown that some dynamical DE models are able to resolve the problems of ΛCDM. In this respect, the cosmological models with time-varying vacuum energy are the promising models to resolve the issues. Although there is no fundamental theory to describe a time-varying vacuum, a phenomenological technique has been proposed to parametrized CC. Shapiro and Solá [12] and Solá [13] proposed a running vacuum models (RVMs) on the basis of renormalization group (RG) formalism of Quantum field theory (QFT) in curved spacetime. In the context of RVMs, it is considered that the vacuum energy density evolves slowly with the cosmic expansion. It has been illustrated that both the background and linear perturbation levels of the cosmic evolutions can be described by the RVMs. The vacuum energy is typically determined in curved space-times using renormalization group procedures, which depend on the Hubble parameter H and its time derivative and is given by the form $\rho_\Lambda(H, \dot{H}) = M_{Pl}^2\Lambda(H, \dot{H})$ [14]. In past literature, many authors [15–20] have studied the time-varying vacuum energy models. In recent years, the RVMs have been carefully confronted against many cosmological data, which receive a significant success [21–40].

On the other hand, viscous fluid cosmology is an interesting research area to understand the accelerated expansion of the Universe. It has been observed that irreversible processes in the evolution of the Universe may also be responsible for explaining the recent accelerated expansion. There are two types of viscosity: bulk and shear, however, bulk viscosity is the one that plays an important role in the evolution of the Universe as it satisfies the cosmological principle. Bulk viscous models have

* vinitakhatri_2k20phdam501@dtu.ac.in
† cpsingh@dce.ac.in (Corresponding author)
‡ milan.srivastava@sharda.ac.in

been studied using two approaches: the Eckart [41] and Israel-Stewart [42] theories. Eckart [41] proposed a non-causal theory of viscous of first order which was later modified by Landau and Lifshitz [43]. In this theory, all equilibrium states are unstable [44] and the signals can propagate through the fluids faster than the speed of light [45]. The Israel-Stewart formalism is a full causal theory of second order which avoids the casuality problem. When the relaxation time goes to zero, the causal theory reduces to the Eckart's first order theory. Despite of the causality problem, Eckart theory is widely used due to its simplicity. In both theories, the bulk viscous term is included in Einstein field equations through an effective pressure, written in the form $\bar{p} = p + \Pi$, where p is pressure of matter contents such as dust-matter, DE or relativistic species (photons and neutrinos) and Π refers the bulk viscous pressure. In Eckart theory, the bulk viscous pressure is assumed as $\Pi = -3\zeta H$, where ζ is the bulk viscous coefficient and H the Hubble parameter. Some works related to Eckart theory have studied the evolution of the Universe at late time by assuming bulk viscous coefficient with a constant [46–51] and polynomial [52–55] as functions of redshift or in terms of energy density. Some more authors [56–76] have explored the viability of a bulk viscous Universe to explain the present accelerated expansion of the Universe.

Decaying vacuum energy density (VED) models and viscous fluid models are two appealing theoretical models that have been separately studied by many authors to solve some of problems facing by standard ΛCDM model. Despite the success of decaying vacuum energy and viscous fluid models, it should be noted that they have, separately, limitations in describing the entire cosmological evolution. Recently, in Refs.[77–80] the authors have studied the cosmological model with combination of these two notions in a single cosmological setting and have investigated their cosmological implications using observational data.

The ΛCDM's problems also motivate research into new physics beyond this standard model. In standard cosmology, it is usually assumed that DM and DE do not interact with each other. However, there is no physical basis for this assumption. In this regard, a popular approach is to investigate the cosmological models where the interactions between the DM and DE take place. In this interaction theory, DM and DE are not separately conserved but they exchange energy (and /or momentum). However, the total energy (and/or momentum) is conserved. It is worth constraining the interacting models against the available wealth of precision cosmological data. This has motivated a large number of studies based on models where DM and DE share interactions, usually referred to as interacting dark energy (IDE) models. Several studies in the literature have been devoted to explore whether DM-DE interactions may help to resolve the enduring H_0 tension [81–88]. In Refs.[89–96], authors have studied the interacting viscous dark fluids for explaining the early and late time evolution of the Universe. The above cited works on bulk viscosity show that interacting viscous fluid models can be one of the possible mechanism to explain the present acceleration of the Universe.

In light of the aforementioned discussions, the main purpose of the present work is to investigate a cosmological model for a spatially flat Friedmann-Lemaître-Robertson-Walker Universe including two components: a non-perfect and interacting viscous dark matter, and decaying vacuum energy that interact with viscous dark matter in Eckart's approach. We analyze the dynamics of interacting model by constraining the free parameters by performing a Markov chain Monte Carlo (MCMC) using the latest observational data. Further, we investigate how our interacting viscous model with decaying VED affects the perturbation level. To investigate the role of this model in structure formation, we employ the perturbation equation to determine the growth of matter fluctuations. Finally, we study the evolutions of various cosmological parameters and compare the perfect fluid case that corresponds to the ΛCDM model through the model selection criteria and Bayesian evidence analysis.

The paper is organised as follows. In Sec. II, we present the general features of the proposed cosmological model for a spatially flat Friedmann-Lemaître-Robertson-Walker Universe where dissipative effects are present with interacting decaying VED. Section III deals with the analysis on Structure formation and perturbation equations. We present in Sec. IV the cosmological probes that are used to constrain the model. Section V gives the results and discussions on various cosmological parameters with the trajectories and compares the proposed model with the concordance ΛCDM using information criterion and the Bayesian inference. The main results of the work are summarized and discussed in Sec. VI. Two more solutions are also presented in Appendix.

II. INTERACTING BULK VISCOUS MODEL WITH DECAYING VED

We start with a homogeneous and isotropic Universe described by the Friedmann-Lemaître-Robertson-Walker (FLRW) metric

$$ds^2 = -dt^2 + a^2(t)\left[dr^2 + r^2(d\theta^2 + sin^2\theta d\phi^2)\right], \quad (1)$$

where $a(t)$ represents the cosmic scale factor of the Universe. The Einstein field equations with a time-varying cosmological constant term, Λ take the form

$$R_{\mu\nu} - \frac{1}{2}g_{\mu\nu}R = 8\pi G(T_{\mu\nu} + g_{\mu\nu}\rho_\Lambda) \quad (2)$$

where $R = g_{\mu\nu}R_{\mu\nu}$ is the Ricci scalar, $\rho_\Lambda = \Lambda/8\pi G$ is the energy density associated to Λ-term, so-called the vacuum energy density (VED), G is the Newton gravitational constant and $T_{\mu\nu}$ is the energy-momentum tensor of matter. It should be emphasised that we employ the geometric units $8\pi G = c = 1$.

In this paper, we propose to study the cosmological dynamics of the Universe which include the interaction between the dark matter component including dissipation through a bulk viscous coefficient and a vacuum energy density described by running coupling depending on the Hubble parameter (hereafter we refer interacting viscous $\Lambda(t)$ model). Then, the energy-momentum tensor is given by

$$T_{\mu\nu} = (\rho + \tilde{p})u_\mu u_\nu + g_{\mu\nu}\tilde{p} \tag{3}$$

where $\rho = \rho_m + \rho_\Lambda$ is the sum of total energy density of the fluid contributed from ρ_m, the energy density of DM and ρ_Λ, the energy density of vacuum, u_μ is the associated four-velocity and $\tilde{p} = p_m + \Pi + p_\Lambda$ is the sum of total pressure of fluid contributed from p_m, the equilibrium pressure, Π, the non-equilibrium pressure due to bulk viscosity and p_Λ, the pressure due to vacuum. It is assumed that deviation of any system from the local thermodynamical equilibrium is the source of bulk viscosity. In accordance with the second law of thermodynamics, the restoration of thermal equilibrium is a dissipative process that produces entropy. As a result of this entropy generation, the bulk viscous term causes an expansion in the system.

The viscous fluid in homogeneous and isotropic cosmological models is determined by its bulk viscosity. The Eckart's formalism serves as the basis for this theory[41]. It is basically obtained from the second order theory of non-equilibrium thermodynamics in the limit of vanishing relaxation time which was proposed by Israel and Stewart [42]. Inspired by the viscosity behavior in fluid mechanics, being proportional to the speed, we assume $\Pi = -3\zeta H$, where H is the Hubble parameter and ζ is the bulk viscous coefficient, which is assumed to be positive on thermodynamic grounds. Furthermore, we consider the non-relativistic matter with $p_m = 0$ to be the bulk viscous fluid. Therefore, the sum of the vacuum energy pressure, $p_\Lambda = -\rho_\Lambda$ and viscous pressure $\Pi = -3\zeta H$ are the components contributing to the total pressure. These two extra ingredients have been introduced to get a more realistic fluid description of DM and DE and also a suitable comparison with ΛCDM model.

In the presence of a non-gravitational interaction between viscous dark matter and decaying vacuum energy, which is characterized by a coupling function $Q(t)$, also known as the interacting rate, the friedmann equation and conservation equations can be written as

$$3H^2 = \rho_m + \rho_\Lambda, \tag{4}$$

$$\dot{\rho}_m + 3H\rho_m = 9\zeta H^2 + Q(t), \tag{5}$$

$$\dot{\rho}_\Lambda + 3H(\rho_\Lambda + p_\Lambda) = -Q(t), \tag{6}$$

where dot denotes derivative with respect to the cosmic time t. In Eqs.(5) and (6), $Q(t)$ denotes the interaction function providing the rate of energy transfer between viscous dark matter and decaying VED. It is to be noted that $Q(t) < 0$ gives energy transfer from viscous DM to decaying vacuum energy where as $Q(t) > 0$ gives energy transfer from decaying vacuum energy to viscous DM. Once the interaction function $Q(t)$ is specified, the background dynamics of the model can be found using (4)-(6). We can define $Q(t)$ by two ways: either by deriving the interaction function from some fundamental physics at the Lagrangian level or by assuming at phenomenological level and testing using observational data. Due to the absence of a fundamental physical theory, we will consider the second approach by assuming the interaction function as [97, 98]

$$Q = 3\alpha\rho_m H, \tag{7}$$

where the term α denotes the dimensionless coupling parameter and included in the fitting vector of free parameters which is to be constrained by the observational dataset.

For decaying VED, we assume a phenomenological application of renormalization group analysis, which can be written as [33, 40]

$$\rho_\Lambda = c_0 + 3\nu H^2, \tag{8}$$

where $c_0 = 3H_0^2(\Omega_\Lambda - \nu)$ is the additive constant and fixed by the boundary condition $\rho_\Lambda(H_0) = \rho_{\Lambda 0}$. In this scenario, ν is the dimensionless vacuum parameter and is naturally anticipated to have extremely small magnitude i.e. $|\nu| \ll 1$. Thus, the positive magnitude of ν enables the vacuum's cosmic evolution. In this instance, we will fit ν to the cosmological data set by taking it as a free parameter.

Substituting (7) into (5), we get

$$\dot{\rho}_m = 9\zeta H^2 - 3(1-\alpha)\rho_m H \tag{9}$$

From (4)-(9), we get the following Hubble evolution equation,

$$\dot{H} + \frac{3}{2}(1-\alpha)H^2 = \frac{3}{2}\frac{\zeta}{(1-\nu)}H + \frac{1}{2}\left(\frac{1-\alpha}{1-\nu}\right)c_0. \tag{10}$$

The above evolution equation (10) has H and ζ as unknown quantities. We can get the solution of H only if the functional form of ζ is specified. We consider the bulk viscous coefficient ζ as proportional to the expansion rate of the Universe, i.e., to the Hubble parameter H, which can be expressed as [48, 52, 59, 67, 99, 100]

$$\zeta = \zeta_1 H \tag{11}$$

where ζ_1 is a dimensionless constant to be estimated from the observations. Substituting this relation into (10), we get

$$\dot{H} + \frac{3}{2}\left(\frac{(1-\nu)(1-\alpha) - \zeta_1}{1-\nu}\right)H^2 - \frac{1}{2}\left(\frac{1-\alpha}{1-\nu}\right)c_0 = 0. \tag{12}$$

The preceding equation with a variable change from t to $x = \log a$ together with $c_0 = 3H_0^2(\Omega_\Lambda - \nu)$ can be written as

$$\frac{dh^2}{dx} + 3\left(\frac{(1-\nu)(1-\alpha)-\zeta_1}{1-\nu}\right)h^2 = 3\left(\frac{(\Omega_\Lambda-\nu)(1-\alpha)}{1-\nu}\right), \tag{13}$$

where $h = H/H_0$ represents the Hubble parameter which is dimensionless and $\Omega_\Lambda = \rho_\Lambda/3H_0^2$. Assuming $(1-\nu)(1-\alpha)-\zeta_1 > 0$ and employing the redshift relation to the normalised scale factor, $a = (1+z)^{-1}$, Eq.(13) gives

$$E^2(z) = \tilde{\Omega}_{m,0}(1+z)^{3\left(\frac{(1-\nu)(1-\alpha)-\zeta_1}{(1-\nu)}\right)} + \tilde{\Omega}_{\Lambda,0}, \tag{14}$$

where

$$\tilde{\Omega}_{\Lambda,0} = \frac{(\Omega_\Lambda-\nu)(1-\alpha)}{(1-\nu)(1-\alpha)-\zeta_1}, \tag{15}$$

and

$$\tilde{\Omega}_{m,0} = 1 - \frac{(\Omega_\Lambda-\nu)(1-\alpha)}{(1-\nu)(1-\alpha)-\zeta_1} = 1 - \tilde{\Omega}_{\Lambda,0}. \tag{16}$$

In Eq.(14), $E(z) = H/H_0$ is dimensionless Hubble parameter and $\Omega_{i,0}$ (i = DM,DE) represents the current value of density parameter of viscous DM and decaying vacuum energy. For $E(0) = 1$, we have $\tilde{\Omega}_{m,0} + \tilde{\Omega}_{\Lambda,0} = 1$. The scale factor of expansion can be calculated by using $H = \dot{a}/a$ and integrating the equation (14), the solution for the scale factor $a(t)$ is given by

$$a(t) = \left(\frac{\tilde{\Omega}_{m,0}}{\tilde{\Omega}_{\Lambda,0}}\right)^{\frac{(1-\nu)}{3[(1-\alpha)(1-\nu)-\zeta_1]}} \left(\sinh^{2/3}\left(\frac{t}{\tilde{t}}\right)\right)^{\frac{(1-\nu)}{(1-\alpha)(1-\nu)-\zeta_1}}, \tag{17}$$

where $\tilde{t} \equiv 2/(3H_0\sqrt{\frac{[(1-\nu)(1-\alpha)-\zeta_1](1-\alpha)(\Omega_\Lambda-\nu)}{(1-\nu)^2}})$. It can be observed from (17) that the scale factor reduces to $a(t) = (\Omega_{m,0}/\Omega_{\Lambda,0})^{1/3}\ \sinh^{2/3}(t/\tilde{t})$ for $\alpha = 0$, $\zeta_1 = 0$ and $\nu = 0$, which is the analytical solution of the scale factor for ΛCDM model. It can be observed from above equation that the scale factor varies as $a \propto t^{\frac{2(1-\nu)}{3[(1-\nu)(1-\alpha)-\zeta_1]}}$ during early times which the power-law expansion of the Universe. For late-time evolution the scale factor varies as $a \propto \exp\sqrt{\frac{(\Omega_\Lambda-\nu)}{3(1-\zeta_1-\nu)}}H_0 t$, which implies the de Sitter Universe.

To investigate the decelerated and accelerated phases of the expansion of the Universe as well as its transition during the evolution, we explore a crucial cosmological parameter, called 'deceleration parameter'. The definition of deceleration parameter q is

$$q = -\frac{\ddot{a}}{a}\frac{1}{H^2} = -\left(1 + \frac{\dot{H}}{H^2}\right). \tag{18}$$

Using (14) into (18), the deceleration parameter q in terms of redshift z is given by

$$q(z) = -1 + \frac{3}{2(1-\nu)}\left(\frac{((1-\alpha)(1-\Omega_\Lambda)-\zeta_1)(1+z)^{3\left(\frac{(1-\nu)(1-\alpha)-\zeta_1}{(1-\nu)}\right)}}{\frac{(\Omega_\Lambda-\nu)(1-\alpha)}{(1-\nu)(1-\alpha)-\zeta_1} + \left(1 - \frac{(\Omega_\Lambda-\nu)(1-\alpha)}{(1-\nu)(1-\alpha)-\zeta_1}\right)(1+z)^{3\left(\frac{(1-\nu)(1-\alpha)-\zeta_1}{(1-\nu)}\right)}}\right) \tag{19}$$

The aforementioned equation demonstrates how the redshift affects the dynamics of q . We note that the value of $q(z)$ approaches -1 in the future (negative redshift). Furthermore, we determine the present value of q for $z = 0$, denoted as (q_0), which is given by

$$q_0 = -1 + \frac{3}{2(1-\nu)}\left[(1-\alpha)(1-\Omega_\Lambda)-\zeta_1\right]. \tag{20}$$

The accelerating and decelerating phase of the Universe can be inferred from the negative and positive signs of the deceleration parameter, respectively. For $q_0 > 0$, the Universe exhibits expanding behaviour and goes through a deceleration phase. For $-1 < q_0 < 0$, represents the current state of the Universe which is the expanding and accelerating Universe.

For the sake of completion, we further calculate effective equation of state parameter w_{eff} as a function of redshift z,

$$w_{eff}(z) = -1 + \frac{1}{(1-\nu)}\left(\frac{((1-\alpha)(1-\Omega_\Lambda)-\zeta_1)(1+z)^{3\left(\frac{(1-\nu)(1-\alpha)-\zeta_1}{(1-\nu)}\right)}}{\frac{(\Omega_\Lambda-\nu)(1-\alpha)}{(1-\nu)(1-\alpha)-\zeta_1} + \left(1 - \frac{(\Omega_\Lambda-\nu)(1-\alpha)}{(1-\nu)(1-\alpha)-\zeta_1}\right)(1+z)^{3\left(\frac{(1-\nu)(1-\alpha)-\zeta_1}{(1-\nu)}\right)}}\right) \tag{21}$$

At $z = 0$, the present value of w_{eff} is determined by

$$w_{eff}(z=0) = -1 + \frac{1}{(1-\nu)}\left[(1-\alpha)(1-\Omega_\Lambda)-\zeta_1\right]. \tag{22}$$

III. GROWTH OF PERTURBATIONS IN INTERACTING MODEL

The presence of cosmological fluctuations influences the background cosmology in which the perturbations

evolve. Hence for the complete analysis of our interacting viscous $\Lambda(t)$ model we must take into account the effects on the large scale structure (LSS) formation data, which we incorporate into our observational analysis, in order to fully confront the model. As a result, we must take the matter density perturbations into consideration. Details on this portion of the analysis has been provided in many references [101, 102]. Here, we simply cite the resulting differential equation, which is entirely consistent with the analysis of [80] and references therein. For the interacting viscous $\Lambda(t)$ model, we use the standard perturbations equation for the linear matter density contrast $\delta_m \equiv \delta\rho_m/\rho_m$ as given below:

$$\delta_m'' + \left(\frac{3}{a} + \frac{H'(a)}{H(a)}\right)\delta_m' - \frac{4\pi G\rho_m}{H^2(a)}\frac{\delta_m}{a^2} = 0 \tag{23}$$

Here $()' \equiv d/da$ represents the derivative with respect to the scale factor. The aforementioned approximation to structure formation is sufficient for considering the primary consequences originate from the distinct expression of the Hubble function as compared to the ΛCDM. Thus, the preceding second-order differential equation (23) seems to be accurate. We examine the Hubble function (14) as it was determined in Section II. The smoothness of the matter perturbation in the interacting viscous $\Lambda(t)$ model is described by the equation (23).

The weighted linear growth, $f(z)\sigma_8(z)$, is typically used to compare the theoretical calculations with the structure formation data in the linear regime. Here, $\sigma_8(z)$ represents the r.m.s. mass fluctuations on $R_8 = 8h^{-1}$ Mpc at redshift z and $f(z) = d\ln\delta_m(a)/d\ln(a)$ is the growth factor. The details of the calculation are provided in coming Section-IV(C).

IV. DATA AND METHODOLOGY

In this section, we use a variety of observational data and methodology in order to constrain the model parameters of ΛCDM and interacting viscous Λ(t) models which comprise observations from: (i) Pantheon+ dataset; (ii) Hubble dataset(Cosmic Chronometers); and (iii) $f(z)\sigma_8(z)$ dataset. The following subsections provide an overview of each data set.

A. Pantheon+ dataset

We consider an updated Pantheon+ sample [103] which is the successor of the Pantheon sample. This compilation comprises of 1701 light curves gathered by 1550 type Ia supernovae (SNe), providing detailed information for cosmological analysis. In addition to the most recent SNe sightings, the Pantheon+ collection expands upon earlier SNe compilations and offers a broad range of redshifts ranging from $z = 0.00122$ to 2.2613. The Chi-squared related to the Pantheon+ dataset is given by

$$\chi^2_{Pan+} = \sum_{i=1}^{1701} \vec{D}^T C^{-1}_{Pan+}\vec{D} \tag{24}$$

where $\vec{D} = m_{Bi} - M - \mu_{model}$. Here, m_{Bi} and M are the observed peak magnitude in the rest frame of the B band and absolute B-band magnitude respectively. The theoretical distance modulus μ_{model} is defined by

$$\mu_{model}(z_i) = 5\log_{10}\left(\frac{D_L(z_i)}{1Mpc}\right) + 25, \tag{25}$$

where $D_L(z)$ represents the luminosity distance, that is described by $D_L(z) = (1+z)H_0\int_0^z \frac{dz'}{H(z')}$. In Eq. (24), C denotes the total covariance matrix which takes the form $C = D_{stat} + C_{sys}$, where the diagonal matrix D_{stat} and covariant matrix C_{sys} denote the statistical uncertainties and the systematic uncertainties.

In contrast to the Pantheon dataset, the degeneracy between the absolute magnitude M and H_0 is broken in $Pantheon+$. In order to accomplish this, the vector $\vec{D}$ in Eq. (24) is written in terms of the distance moduli of SNe in Cepheid hosts. As a result, M can have an independent constraint, which leads to the following expression:

$$\vec{D'} = \begin{cases} m_{Bi} - M - \mu_i^{Cepheid} & i \in Cepheid \\ m_{Bi} - M - \mu_{model}(z_i) & Otherwise \end{cases} \tag{26}$$

where $\mu_i^{Cepheid}$ denotes the distance modulus, determined independently using Cepheid calibrators, and corresponds to the Cepheid host of the ith SNe. Hence, we can rewrite Eq.(24) as follows:

$$\chi^2_{Pan+} = \sum_{i=1}^{1701} \vec{D'}^T C^{-1}_{Pan+}\vec{D'} \tag{27}$$

B. Cosmic chronometers

The cosmic chronometers (CC) is another observational data obtained through the differential-age method. We can find the Hubble parameter values from CC method at distinct redshifts based on the relative age of passively evolving galaxies. For our analysis, we employ a compilation of 32 data points of the Hubble parameter derived through the differential age technique [104] in the redshift range $0.07 \le z \le 1.965$ with errors. The Chi-squared function for CC is given by

$$\chi^2_{CC} = \sum_{i=1}^{32} \frac{[H(z,\theta) - H^{obs}(z_i)]^2}{\sigma^2_{H(z)}} \tag{28}$$

where $H(z)$ represents the theoretical prediction of the Hubble parameter calculated in Eq. (14) and $H^{obs}(z)$ are the observational data with errors $\sigma_{H(z)}$.

TABLE I. Flat prior used on various parameters during statistical analysis.

Parameters	Priors
H_0	$[50, 100]$
Ω_Λ	$(0, 1]$
ζ_1	$(0, 1]$
ν	$(0, 1]$
α	$(0, 1]$
σ_8	$[0.6, 1.2]$

C. $f(z)\sigma_8(z)$ data

Finally, in this work we use the recent "Gold -17" compilation consisting of 18 independent measurements of $f(z)\sigma_8(z)$. These data points are based on Redshift Space Distortion (RSD) measurements from various observations of the Large Scale Structure (LSS) and complied in Table III of Ref. [105].

The linear growth rate of matter perturbations is defined as follows:

$$f(z) = \frac{d\ln\delta_m}{d\ln a} \equiv -(1+z)\frac{\delta'_m(z)}{\delta_m(z)} \tag{29}$$

Here, (') denotes the derivative with respect to redshift. Further, in the linear regime $\sigma_8(z)$ is the redshift-dependent parameter which measures the growth of root-mean-square mass fluctuations in spheres with radius $8h^{-1}$ Mpc scales which is given as:

$$\sigma_8(z) = \sigma_8(z=0)\frac{\delta_m(z)}{\delta_m(z=0)} \tag{30}$$

Combining (29) and (30), the weighted linear growth is determined by:

$$f\sigma_8(z) = -(1+z)\frac{\sigma_8(z=0)}{\delta_m(z=0)}\frac{d\delta_m}{dz} \tag{31}$$

The Chi-squared function of $f(z)\sigma_8(z)$ can be calculated as [106]:

$$\chi^2_{f(z)\sigma_8(z)} = \sum_{i=1}^{18}\frac{[f\sigma_8(z_i) - (f\sigma_{8,i})_{ob}]^2}{\sigma_i^2} \tag{32}$$

Based on the EMCEE [107] python module, we employ the Markov Chain Monte Carlo(MCMC) statistical technique to examine the parameter space of our cosmological models and minimise the χ^2 function for both ΛCDM and interacting viscous $\Lambda(t)$ models. We consider the joint analysis by assuming the sum of all χ^2 functions:

$$\chi^2_{tot} = \chi^2_{Pan+} + \chi^2_{CC} + \chi^2_{f\sigma_8(z)}. \tag{33}$$

To perform this analysis, we choose uniform priors for the parameters of models which is listed in Table I.

TABLE II. The values of parameters for ΛCDM and interacting viscous $\Lambda(t)$ models for combination of Pantheon+, Hubble(CC) and $f(z)\sigma_8(z)$ observational datasets.

Parameter	ΛCDM	Interacting viscous $\Lambda(t)$
H_0	$72.150^{+0.989}_{-0.779}$	$72.202^{+0.796}_{-0.937}$
Ω_Λ	$0.689^{+0.016}_{-0.017}$	$0.681^{+0.014}_{-0.017}$
M	$-19.292^{+0.026}_{-0.023}$	$-19.290^{+0.024}_{-0.026}$
ζ_1	$-$	$0.010^{+0.006}_{-0.007}$
ν	$-$	$0.005^{+0.003}_{-0.003}$
α	$-$	$-0.005^{+0.003}_{-0.004}$
σ_8	$0.750^{+0.034}_{-0.031}$	$0.739^{+0.034}_{-0.030}$

q_0	$-0.533^{+0.024}_{-0.024}$	$-0.531^{+0.024}_{-0.024}$
z_{tr}	$0.643^{+0.041}_{-0.041}$	$0.647^{+0.038}_{-0.044}$
w_0	$-0.689^{+0.016}_{-0.016}$	$-0.687^{+0.016}_{-0.016}$
$t_0(Gyr)$	$13.74^{+0.019}_{-0.021}$	$13.75^{+0.023}_{-0.021}$

V. RESULT AND DISCUSSION

In this section, we present the results of our observational analysis on ΛCDM and interacting viscous $\Lambda(t)$ models, including both the constraints and cosmological parameters from the current data. In the first subsection, we will present the parameters constraints achieved by observational analysis using the data discussed in Sect.IV. In second subsection, we will implement the Bayesian inference, and in last subsection, we will examine the model comparison through information criterion.

A. Parameter constraints

The best-fit values of parameters of ΛCDM and interacting viscous $\Lambda(t)$ models using a combined $CC + f(z)\sigma_8(z) + Pan+$ data are summarized in Table II. Figures 1-3 show the 68.3% and 95.4% confidence regions and marginalized likelihood distributions for ΛCDM and interacting viscous $\Lambda(t)$ models, respectively. The GetDist code [108] is utilised to retrieve their mean values and the aforementioned Figs. 1-3. In what follows we discuss the constraints on different cosmological as well as model parameters.

It is noted that the H_0 determined by Riess et al.[109] is $73.04 \pm 1.04\ kms^{-1}Mpc^{-1}$, so-called R21 where as Planck Collaboration [110] predicts $H_0 = 67.4 \pm 0.5\ kms^{-1}Mpc^{-1}$ at 5σ confidence level. This discrepancy is recognized as "Hubble tension". For ΛCDM model we obtain $H_0 = 72.150^{+0.989}_{-0.779}\ kms^{-1}Mpc^{-1}$. This is in tension with both Planck [110] and R21 [109] results at 4.67σ and 0.65σ respectively. For interacting viscous $\Lambda(t)$ model, we obtain $H_0 = 72.202^{+0.796}_{-0.937}\ kms^{-1}Mpc^{-1}$ which is tension with both Planck and R21 results at 4.80σ and 0.86σ respectively. In other words, the H_0 measurement of interacting viscous $\Lambda(t)$ model is consistent with R21. The evolutions of $H(z)$ with redshift z are shown in

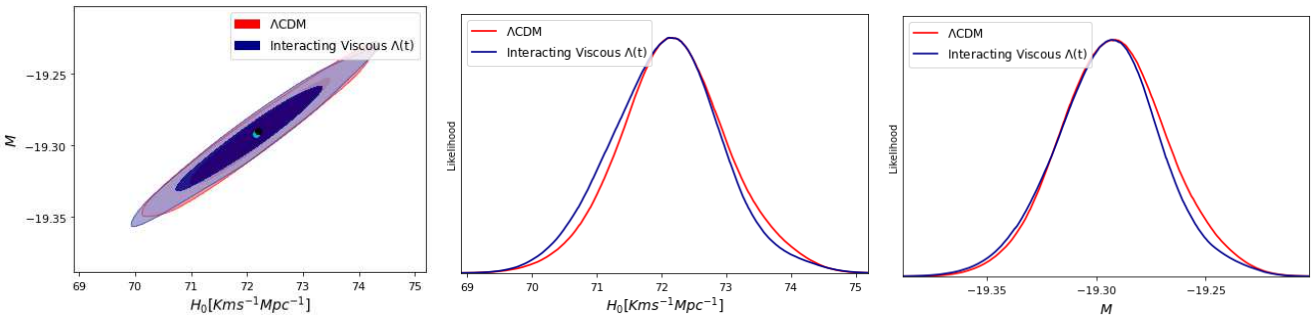

FIG. 1. The 68.3% (dark shaded) and 95.4% (light shaded) confidence contours and likelihoods for H_0 and M for the ΛCDM and interacting viscous $\Lambda(t)$ models using combined dataset. The best-fit values for these models are represented by the cyan and black dot respectively.

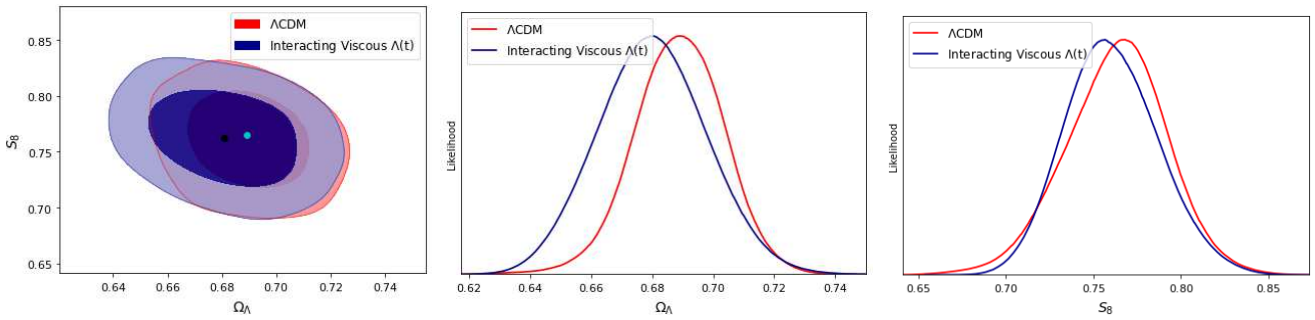

FIG. 2. The 68.3% (dark shaded) and 95.4% (light shaded) confidence contours and likelihoods for Ω_Λ and S_8 for the ΛCDM and interacting viscous $\Lambda(t)$ models using combined dataset. The best-fit values for these models are represented by the cyan and black dot respectively.

Fig.4 which predict that the trajectories cover majority of dataset with error bars of $H(z)$. This means that the interacting viscous $\Lambda(t)$ model agrees with the combination of dataset as well as ΛCDM model.

In the interacting viscous $\Lambda(t)$ model, we obtain the viscosity coefficient, ζ_1 as $0.010^{+0.006}_{-0.007}$ and ν as $0.005^{+0.003}_{-0.003}$. The coupling parameter of the interaction term, α is calculated as $-0.005^{+0.003}_{-0.004}$. The negative value of α indicates that there is a possibility of the dark matter to decay into the dark energy.

Using the best-fit values, the evolutions of deceleration parameter with redshift for ΛCDM and interacting viscous $\Lambda(t)$ models with errors are plotted in Fig.5. The trajectories show that the models have transition from decelerating phase to accelerating phase at transition redshift $z_{tr} = 0.643^{+0.041}_{-0.041}$ and $z_{tr} = 0.647^{+0.038}_{-0.044}$, respectively. The present value of deceleration parameter are found to be $q_0 = -0.533^{+0.024}_{-0.024}$ and $q_0 = -0.531^{+0.024}_{-0.024}$. These values of q_0 are within the range of the observational results, i.e., $q_0 = -0.64 \pm 0.12$ [110]. In late time of evolution, $q(z)$ approaches to -1 in both models which is the future de Sitter phase.

In Fig.6, we plot the effective EoS parameter as a function of redshift for best-fit values of ΛCDM and interacting viscous $\Lambda(t)$ models. It is observed that $w_{\rm eff} \to -1$ in the late-time in both the models, which implies that the models correspond to de Sitter phase in late-time. Using the best-fit, we get the present EoS parameters $w_{\rm eff}(z = 0) = -0.689 \pm 0.016$ and $w_{\rm eff}(z = 0) = -0.687 \pm 0.016$, respectively.

Next, we explore another tension between the theoretical prediction of the growth rate of matter perturbations with the observational growth rate data points for ΛCDM and interacting viscous $\Lambda(t)$ models. For both models the constraints on σ_8 and S_8 are given in Table II. The amplitude of the matter power spectrum (σ_8) and its associated parameter $S_8 = \sigma_8\sqrt{(1-\Omega_\Lambda)/0.3}$ may be determined using the $f(z)\sigma_8(z)$ dataset and it is further possible to calculate the σ_8/S_8 tension. The combined dataset gives $\sigma_8 = 0.750^{+0.034}_{-0.031}$ and $S_8 = 0.765^{+0.030}_{-0.030}$ in the ΛCDM model and $\sigma_8 = 0.739^{+0.034}_{-0.030}$ and $S_8 = 0.762^{+0.030}_{-0.030}$ in interacting viscous $\Lambda(t)$ model. Our results are perfectly consistent with the combined use of the SDSS and KiDS/Viking data which gives $\sigma_8 = 0.760^{+0.025}_{-0.020}$ and $S_8 = 0.766^{+0.020}_{-0.014}$ [111]. The interacting viscous $\Lambda(t)$ model is in 2.21σ tension in σ_8 and 2.11σ tension in S_8 with the corresponding values of Plank [110]. These tensions are not as large compared to H_0 tension as discussed above. The confidence contours in (S_8, Ω_Λ) and (S_8, σ_8) parameter space and corresponding likelihoods are shown in Figs. 2 and 3, which show no deviation from ΛCDM contours. This confirms that the measurement of

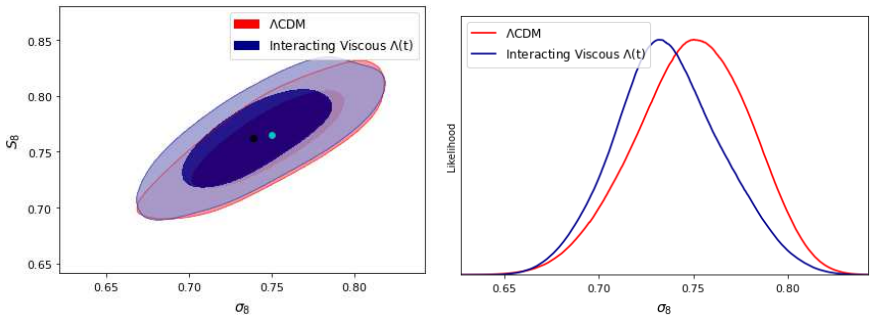

FIG. 3. The 68.3% (dark shaded) and 95.4% (light shaded) confidence contours and likelihoods for S_8 and σ_8 for the ΛCDM and interacting viscous $\Lambda(t)$ models using combined dataset. The best-fit values for these models are represented by the cyan and black dot respectively.

σ_8 and S_8 using $CC+Pan+$ with $f(z)\sigma_8(z)$ data is fully consistent with ΛCDM. The trajectories of $f(z)\sigma_8(z)$ for ΛCDM and interacting viscous $\Lambda(t)$ models are plotted in Fig.7. It can be observed that both the models are consistent with the observational data points.

Let us discuss the interacting viscous $\Lambda(t)$ model by defining a dimensionless parameter, known as jerk parameter, j. This parameter is purely kinematical and is associated with the third order derivative of the scale factor $a(t)$. It is defined as $j = \frac{\dddot{a}(t)}{aH^3}$ [112]. In terms of the deceleration parameter, it can be expressed as follows [112]:

$$j(z) = q(2q+1) + (1+z)\frac{dq}{dz}. \tag{34}$$

It can provide us the deviation of any model from the ΛCDM model. It is noted that jerk parameter always has constant value $j = 1$ for ΛCDM model. We report $j_0 = 0.992$ in interacting viscous $\Lambda(t)$ model which is quite comparable to the ΛCDM model. We plot the evolution of jerk parameter with respect to the redshift as shown in Fig.8. We observe that the trajectory of $j(z)$ deviates from ΛCDM in early phase where as it approaches to $j = 1$ as $z \to -1$. Thus, jerk parameter points us the effects of interacting viscous $\Lambda(t)$ model over the ΛCDM model.

B. Model selection

In this section, we will discuss mainly reduced Chi-square and model selection criterion to observe the compatibility of the proposed model.

Let us first calculate the reduced Chi-square, χ^2_{red}, which is defined as $\chi^2_{red} = \chi^2_{min}/dof$. Here, dof denotes the degree of freedom which is equal to the number of observational data points (N) minus the number of parameters (K). It is to be noted that we have used $N = 1751$ and $K = 3$ in ΛCDM and $K = 6$ in interacting viscous $\Lambda(t)$ model with same number of data points. Table II presents the χ^2 and χ^2_{red} of ΛCDM and interacting viscous $\Lambda(t)$ models, respectively. It is noted that

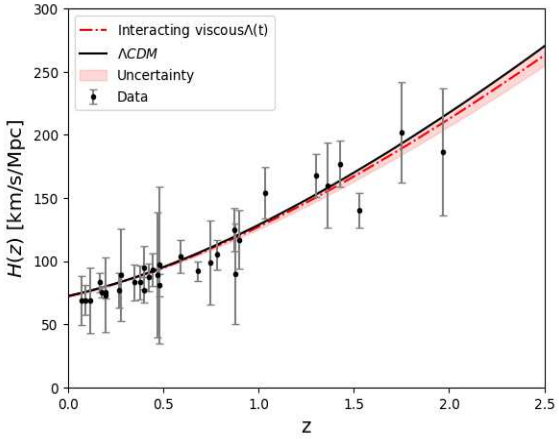

FIG. 4. The evolution of hubble function $H(z)$ with redshift z. The solid black line corresponds to the ΛCDM model and the dashed red line corresponds to the interacting viscousΛ(t) model($\zeta = \zeta_1 H$). The $H_{obs}(z)$ data are also plotted with their error bars.

a value $\chi^2_{red} < 1$ gives the best-fit with the data. We observed that both the models have the reduced χ^2 less than unity (for ΛCDM, $\chi^2_{red} = 0.447$ and for interacting viscous $\Lambda(t)$ model, it is $\chi^2_{red} = 0.448$). This shows that both the models are in very good fit with the observational data.

We discuss the another method which provides the statistical comparison of the proposed model with ΛCDM model. In this regard, there are two model selection criterion, namely, Akaike information criteria (AIC) and Bayesian information criteria (BIC). These selection criterion allow to compare models with different degree of freedom. They are defined as [113, 114]

$$AIC = \chi^2_{min} + \frac{2KN}{N-K-1}, \qquad BIC = \chi^2_{min} + K\ln N, \tag{35}$$

where N is the size of the data sample and K is the number of free parameters. In these approaches, the model with low values of AIC(BIC) is preferred by data.

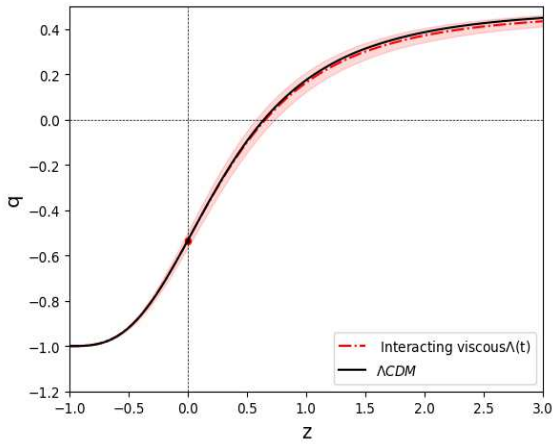

FIG. 5. The evolution of $q(z)$ with redshift z for interacting viscous$\Lambda(t)$ model and ΛCDM model using the best fit values. Present value q_0 is represented by dot.

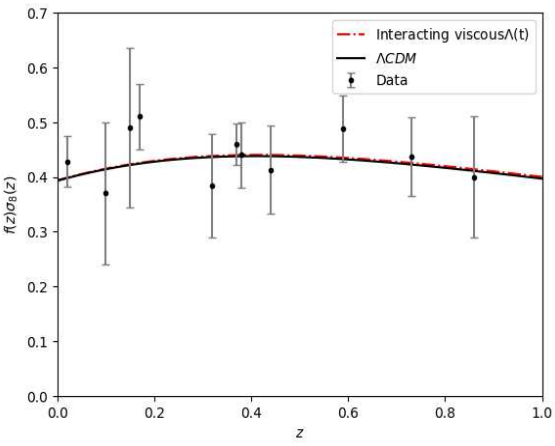

FIG. 7. The evolution of $f(z)\sigma_8(z)$ with redshift z for interacting viscous$\Lambda(t)$ model and ΛCDM model using the best fit values.

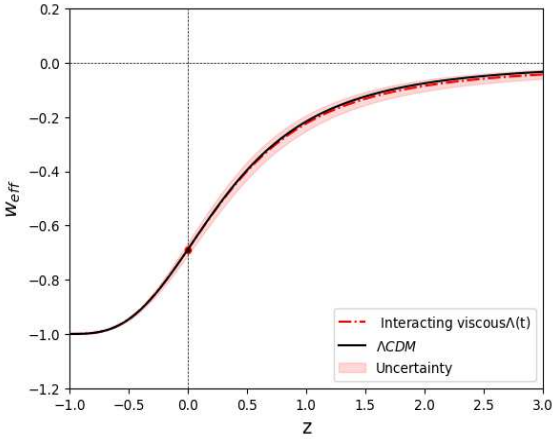

FIG. 6. The evolution of w_{eff} with redshift z for interacting viscous$\Lambda(t)$ model and ΛCDM model using the best fit values. Present value of $w_{eff}(z=0)$ is represented by dot.

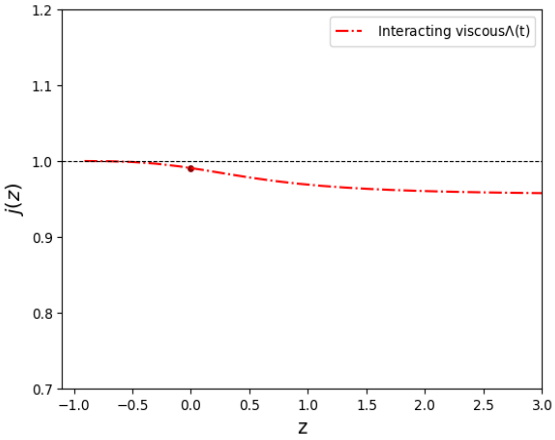

FIG. 8. The evolution of $j(z)$ with redshift z for interacting viscous$\Lambda(t)$ model the best fit values. Present value of $j_0(z=0)$ is represented by dot and the horizontal line $j=1$ represents ΛCDM model.

Considering the AIC (BIC) of ΛCDM model as reference model, denoted as $AIC_\Lambda(BIC_\Lambda)$, we compute $\Delta AIC = AIC_{model} - AIC_{\Lambda CDM}(\Delta BIC = BIC_{model} - BIC_{\Lambda CDM})$.

Following the rules described in Refs.[80, 96], let us discuss our results. Table IV displays the values of AIC (BIC) and corresponding ΔAIC (ΔBIC) for interacting viscous $\Lambda(t)$ model. According to our results, we have $\Delta AIC = 6.670$ and $\Delta BIC = 23.039$. This shows that there is "less support in favor" of the interacting viscous $\Lambda(t)$ model as far as AIC is concerned where as BIC gives "strong evidence against" the interacting viscous $\Lambda(t)$ model.

C. Bayesian Inference

The Bayesian evidence serves as the foundation for assessing a model's performance in light of the data. In Bayesian data analysis, the correlation between the data, the model or hypotheses, and the prior knowledge is characterized by the joint probability distributions. Given the observed data, the conditional probability distribution of the unknowns can be used to uniquely infer the posterior distribution using Bayes theorem. The key statistic of Bayesian model selection is the Bayesian evidence $\mathcal{E}$ [115, 116], which is employed in a model comparison problem by integrating the product of likelihood and posterior over the entire parametric space of the model.

TABLE III. "Jeffreys' scale" for evaluating the strength of evidence between two comparing models, M_i versus M_j. The right column provides the convention for denoting the different levels of evidence above these thresholds.

$\ln \mathcal{B}_{ij}$	Strength of Evidence
< 1.0	Inconclusive
1.0	Weak evidence
2.5	Moderate evidence
5.0	Strong evidence

It is defined as [117–120]

$$\mathcal{E}(D|M) = \int_M \mathcal{L}(D|\Theta, M)\mathcal{P}(D|\Theta, M)d\Theta. \tag{36}$$

On the right-hand side, Θ is a set of free parameters for the given data D, M stands for the model, the vertical bar reads as 'given', and $\mathcal{L}$ and $\mathcal{P}$ stand for likelihood and prior probability distribution function of those parameters before the data, respectively.

In cosmology, this concept has been utilized extensively [121, 122]. When comparing two models, M_i versus M_j, one is interested in the ratio of the models' evidences known as *Bayes factor*, which is given by:

$$\mathcal{B}_{ij} \equiv \frac{\mathcal{E}_i}{\mathcal{E}_j} \tag{37}$$

Here, B_{ij} indicates the support for model i over model j.

Bayes factors are typically interpreted using the Jeffreys' scale [115] which measures the strength of the evidence, given in Table III. We accomplish this by estimating the values of the logarithm of Bayes factor ($\ln \mathcal{B}$) and the Bayesian evidence ($\ln \mathcal{E}$). Using the dataset and the priors mentioned in Table I, the values of $\mathcal{E}$ and $\mathcal{B}$ are determined. We assume the ΛCDM as the reference model.

The results for the Bayesian evidence ($\ln \mathcal{E}$) and Bayes factor ($\ln \mathcal{B}$) for both ΛCDM and interacting viscous Λ(t) models examined in this work are summarized in Table IV. We find that the $\ln \mathcal{B}$ for interacting viscous Λ(t) model with respect to the ΛCDM model is obtained as 2.577 and thus the Bayesian evidence analysis shows that our model is "moderately supported" by the considered priors and dataset on Jeffreys'scale.

TABLE IV. Summary of $\ln \mathcal{E}$, $\ln \mathcal{B}$, χ^2, χ^2_{red}, AIC and BIC for the ΛCDM and interacting viscous$\Lambda(t)$ models for the following:

Values	ΛCDM	Interacting viscous$\Lambda(t)$
$\ln \mathcal{E}$	-793.120 ± 0.473	-795.697 ± 0.532
$\ln \mathcal{B}$	–	2.577
χ^2	781.708	782.344
K	3	6
N	1751	1751
χ^2_{red}	0.447	0.448
AIC	787.722	794.392
ΔAIC	–	6.670
BIC	804.112	827.152
ΔBIC	–	23.039

VI. CONCLUSION

Inspired by dissipative phenomena and decaying vacuum energy, we have discussed some cosmological consequences of an alternative mechanism of accelerating Universe based on a class of interacting viscous model with decaying vacuum energy, referred as interacting viscous $\Lambda(t)$ model. The coupling between viscous fluid and vacuum energy density has been made through a coupling parameter, Q. Within the framework of Eckart thermodynamic theory the non-equilibrium pressure, Π is proportional to the Hubble parameter H with proportionality constant ζ, i.e., $\Pi = -3\zeta(t)H$. Thus, the effective pressure is assumed as sum of barotropic pressure, bulk viscous pressure and pressure due to vacuum energy, i.e., $\bar{p} = p_m + \Pi + p_\Lambda$. In the first part of work, we have obtained some main results for the scale factor, the Hubble parameter, the deceleration parameter, jerk parameter and EoS parameter by assuming the interaction term $Q = 3\alpha\rho_m H$. Although the nature of bulk viscosity and time-varying vacuum energy density are unknown, we have assumed $\zeta = \zeta_1 H$ for bulk viscous coefficient and $\rho_\Lambda = c_0 + 3\nu H^2$ for vacuum energy density. One can expect that the viscosity is affected by the expansion rate of the Universe and varying VED from the general covariance of the effective action in QFT. We have investigated the growth perturbation of interacting viscous $\Lambda(t)$ model. In the second part of this work, we have performed the Bayesian analysis using the latest background probes such as SNe Pantheon+, cosmic chronometer and $f(z)\sigma_8(z)$. We have compared the interacting viscous $\Lambda(t)$ model with ΛCDM using the Bayesian inference and model selection criterion such as AIC and BIC. In what follows, we summarize the main points of our analysis.

The constraints on model free parameters have been reported in Table II. The best-fit value of H_0 according to a combination of Pantheon+, CC and $f(z)\sigma_8(z)$ is $H_0 = 72.202^{+0.796}_{-0.937}\ kms^{-1}Mpc^{-1}$, which is tension with both Planck and R21 results at 4.80σ and 0.86σ ,respectively. In other words, the tension in H_0 measurement is almost resolved in interacting viscous $\Lambda(t)$ model with respect to R21. The best fit values of present q and w_{eff} are $q_0 = -0.531^{+0.024}_{-0.024}$ and $w_{\rm eff}(z=0) = -0.687 \pm 0.016$, respectively. From Fig.5, it has been observed that the interacting viscous $\Lambda(t)$ model exhibits transition from an early decelerated phase to late-time accelerated phase and the transition takes place at $z_{tr} = 0.647^{+0.038}_{-0.044}$ which is close proximity $z_{tr} = 0.643^{+0.041}_{-0.041}$ to that of ΛCDM model. It has been found that the value of $\chi^2_{red} < 1$ which shows that the interacting viscous $\Lambda(t)$ model is

in very good fit with the used data points. The jerk parameter remains positive and less than one in past, and tends to unity in late-time.

We have explored the σ_8 and S_8 parameters for ΛCDM and interacting viscous $\Lambda(t)$ models using the combined data set of Pantheon+, CC and $f(z)\sigma_8(z)$. The constraints on σ_8 and S_8 in interacting viscous $\Lambda(t)$ model are $\sigma_8 = 0.739^{+0.034}_{-0.030}$ and $S_8 = 0.762^{+0.030}_{-0.030}$ which are very close to ΛCDM model as reported in Table II. The tensions of our fitting results in σ_8 and S_8 with respect to Plank results [110] are 2.21σ and 2.11σ, respectively. The evolution of $f(z)\sigma_8(z)$ has been plotted in Fig. 7 which shows that it is consistent with the observational data points.

It is noted that cosmological models are testable from the abundance of observational data as discussed above. However, an important distinction must be made between parameter fitting and model selection. As we know that the parameter fitting simply tells us how well a model fit the data. Model selection such as Bayesian inference and AIC and BIC are necessary to discriminate the proposed model with the existing model. The Bayesian inference analysis demonstrated the interacting viscous Λ(t) model is moderately supported by the considered dataset and priors. Further, there has been increasing interest in applying information criterion such as AIC and BIC for model selection. We have examined the models using AIC and BIC for a fairer comparison. We have observed that the interacting viscous $\Lambda(t)$ model has "less support" according to the selection criteria ΔAIC. On contrary, with respect to ΔBIC, interacting viscous $\Lambda(t)$ model has "strong evidence against" the model with the considered datasets.

As a concluding remark we must point out that despite its intrinsic nature of bulk viscosity and decaying vacuum energy and its interaction are not well understood yet, the work presented in this paper suggests a possible description for resolving the H_0 and σ_8 tensions in cosmology. In principle, to give a robust approach for investigating the dark energy model beyond ΛCDM, background dynamics should be considered. Taking into account such interaction between the dark components may provide an opportunity to explain the present accelerating Universe. Indeed considering the interaction between the viscous fluid and decaying vacuum energy potentially enables us to resolve tensions in cosmological parameters.

VII. APPENDIX

The main aim in this appendix is to present some more analytical solutions of the cosmological parameters of the interacting viscous model with decaying vacuum energy density based on the different choices of ζ.

Appendix A: Solution with $\zeta = \zeta_0$

It is the most simple parametric form of the bulk viscous coefficient. Many authors [50, 57, 64, 66, 71, 74, 75, 123–125] have studied the viscous cosmological models with constant bulk viscous coefficient. Using $\zeta = \zeta_0$ in Eq.(10), the Hubble evolution equation deduces the form

$$\dot{H} + \frac{3}{2}(1-\alpha)H^2 - \frac{3}{2}\frac{\zeta_0 H}{(1-\nu)}H = \frac{1}{2}\left(\frac{1-\alpha}{1-\nu}\right)c_0. \quad \text{(A1)}$$

Solving (A1) with the condition $H(t_0) = H_0$, we get

$$H = \frac{\zeta_0}{2(1-\nu)(1-\alpha)} + k\coth\left(\frac{3}{2}(1-\alpha)kt\right). \quad \text{(A2)}$$

where $k = \frac{{\zeta_0}^2 + 4(\Omega_\Lambda - \nu)(1-\nu)(1-\alpha)^2 {H_0}^2}{4(1-\nu)^2(1-\alpha)^2}$.
Integrating again with the condition $a(t_0) = 1$, we obtain the scale factor

$$a(t) = e^{\frac{\zeta_0}{2(1-\nu)(1-\alpha)}t}\left[\sinh\left(\frac{3}{2}(1-\alpha)kt\right)\right]^{\frac{2}{3(1-\alpha)}}, \quad \text{(A3)}$$

Using (A2), the deceleration parameter q and Effective EoS parameter w_{eff} are respectively given by

$$q = -1 + \frac{3}{2}\frac{(1-\alpha)k^2\csc^2 h(\frac{3}{2}(1-\alpha)kt)}{\left(\frac{\zeta_0}{2(1-\nu)(1-\alpha)} + k\coth(\frac{3}{2}(1-\alpha)kt)\right)^2}. \quad \text{(A4)}$$

$$w_{eff} = -1 + \frac{(1-\alpha)k^2\csc^2 h(\frac{3}{2}(1-\alpha)kt)}{\left(\frac{\zeta_0}{2(1-\nu)(1-\alpha)} + k\coth(\frac{3}{2}(1-\alpha)kt)\right)^2}. \quad \text{(A5)}$$

Appendix B: Solution with $\zeta = \zeta_0 + \zeta_1 H$

This form of bulk viscous coefficient has been discussed by several authors and the references therein [54, 59, 65]. For $\zeta = \zeta_0 + \zeta_1 H$, where ζ_0 and ζ_1 are constants, the Eq. (10) simplifies into

$$\dot{H} + \frac{3}{2}(1-\alpha)H^2 - \frac{3}{2}\frac{\zeta_1 H^2}{(1-\nu)} - \frac{3}{2}\frac{\zeta_0 H}{(1-\nu)} = \frac{1}{2}\left(\frac{1-\alpha}{1-\nu}\right)c_0, \quad \text{(B1)}$$

which can be integrated to calculate the Hubble function and the scale factor

$$H = \frac{\zeta_0}{2((1-\alpha)(1-\nu)-\zeta_1)} + k_1 \coth\left(\frac{3}{2}\frac{((1-\alpha)(1-\nu)-\zeta_1)}{(1-\nu)}k_1 t\right), \tag{B2}$$

$$a = e^{\frac{\zeta_0\, t}{2((1-\alpha)(1-\nu)-\zeta_1)}} \times \left[\sinh\left(\frac{3}{2}\frac{((1-\alpha)(1-\nu)-\zeta_1)}{1-\nu}k_1 t\right)\right]^{\frac{2(1-\nu)}{3((1-\alpha)(1-\nu)-\zeta_1)}}, \tag{B3}$$

where $k_1 = \frac{{\zeta_0}^2 + 4((1-\alpha)(1-\nu)-\zeta_1)((\Omega_\Lambda - \nu)(1-\alpha))H_0{}^2}{4((1-\nu)(1-\alpha)-\zeta_1)^2}$.

With this, we can calculate the deceleration parameter q and effective equation of state parameter w_{eff}, which are respectively given by

$$q = -1 + \frac{3(1-\zeta_1-\nu)\sigma_1^2 \csc^2 h(\frac{3}{2}(1-\zeta_1-\nu)\sigma_1 t)}{2\left(\frac{\zeta_0}{2(1-\zeta_1-\nu)} + \sigma_1 \coth(\frac{3}{2}(1-\zeta_1-\nu)\sigma_1 t)\right)^2} \tag{B4}$$

and

$$w_{eff} = -1 + \frac{(1-\zeta_1-\nu)\sigma_1^2 \csc^2 h(\frac{3}{2}(1-\zeta_1-\nu)\sigma_1 t)}{\left(\frac{\zeta_0}{2(1-\zeta_1-\nu)} + \sigma_1 \coth(\frac{3}{2}(1-\zeta_1-\nu)\sigma_1 t)\right)^2} \tag{B5}$$

RESEARCH

Fabrication and assessment of carboxymethyl guar gum-based sustainable films for packaging application

Subodh K. Juikar[1] · **Sudhir G. Warkar**[1]

Abstract

This study aimed towards the fabrication of biodegradable packaging films using carboxymethyl guar gum (CMG) as the base material. Various ratios of glycerol (Gly) as a plasticizer and glutaraldehyde (Glu) as a cross-linker were employed in the synthesis of these biopolymer-based films through the solution casting technique. Comprehensive characterization, such as attenuated total reflectance-Fourier transform infrared spectroscopy (ATR-FTIR), differential scanning calorimetry (DSC), thermogravimetric analysis (TGA), and scanning electron microscopy (SEM), was conducted. The films were further examined for tensile strength, percent elongation, thickness, solubility in water, gloss, haze, and transparency. The maximum tensile strength of 37.82 MPa, maximum percent elongation of 124.20%, maximum gloss of 25.52% at a 20° angle, maximum haze of 41.93%, maximum transparency of 88.53%, and a minimum water solubility of 60.42% were observed for the developed films. This reveals that CMG-based films hold promising potential as a novel biomaterial for future applications in packaging, such as edible coatings and water-soluble, biodegradable packaging films.

Keywords Biopolymer · Carboxymethyl guar gum · Glycerol · Solvent casting · Packaging film

Introduction

Packaging serves a pivotal role in safeguarding and extending the shelf life of products until they reach the end consumer. Conventional packaging relies heavily on synthetic polymers derived from petroleum, such as polyethylene (PE), polypropylene (PP), polyvinylchloride (PVC), and polystyrene (PS). These polymers are preferred for their cost-effectiveness and beneficial properties such as robust mechanical strength and effective barrier characteristics against aroma, gases, and water. Despite these benefits, the disposal and recycling of petroleum-based polymers pose significant challenges. The global annual generation of approximately 1.3 billion tons of plastic waste worsens environmental issues, underscoring the need for sustainable alternatives in packaging solutions [1, 2].

In recent years, due to the comeback of the environmental challenges posed by conventional packaging, research has shifted towards exploring the application of biopolymers for packaging purposes.

Various biopolymers due to desired properties provided by them are seen as a sustainable option for replacement of synthetic polymers for various packaging applications. The global trend of biopolymer production is expected to increase from 2.11 MT from 2020 to 2.87 MT in 2025 [3]. Biopolymers are sourced from natural materials and possess excellent biodegradability, making them more environmentally friendly [1, 2]. Biopolymers, also referred to as generation-IV packaging materials, are utilized in various forms, serving as coatings directly applied to products, as well as in the fabrication of films for items like bags, envelopes, containers, and lids. They present a promising alternative to petroleum-based synthetic polymers [2, 4–6]. Researchers are exploring a diverse range of biopolymers derived from natural resources, including polysaccharides, proteins, and lipids, as well as those synthesized from bio-derived monomers like polylactic acid, and also those synthesized by microorganisms, such as polyhydroxyalkanoates [5].

While these biopolymers exhibit excellent film-forming characteristics, their inherent brittleness and high water absorption capacity necessitate modification through the addition of plasticizers and cross-linkers for easier handling

and commercial processing. Incorporating plasticizers like glycerol enhances film flexibility by reducing intermolecular forces, and the introduction of cross-linkers, like citric acid, improves the tensile strength of the films. This research marks a significant step towards sustainable packaging alternatives, addressing the ecological impact of traditional petroleum-based polymers [5–11].

The biopolymer-based films and coatings represent a significant stride towards sustainable packaging solutions, employing materials such as alginate, chitosan, cellulose, guar gum, and starches. Notably, in our exploration of biopolymer-based materials for packaging applications, it has been observed that carboxymethyl guar gum (CMG) has yet to be used for the synthesis of biopolymer-based packaging materials. This underscores the potential novelty and unexplored possibilities in incorporating CMG into the realm of eco-friendly packaging solutions [1, 2, 7–30].

Carboxymethyl guar gum is a water-soluble biopolymer, derived through the reaction of guar gum with monochloroacetic acid in the presence of sodium hydroxide (NaOH) [31–33]. This versatile derivative finds applications across various industries, like oil recovery, paints, minerals, personal care, textiles, and food [34]. It is revealed that, due to presence of carboxyl and hydroxyl groups in the CMG backbone, it can be easily cross-linked, grafted, or blended with other polymers, leading to effective film formation [35]. This excellent film-forming property of CMG opens up various applications, particularly in areas like packaging.

The current study proposes the development of various carboxymethyl guar gum-based films via solvent casting technique, for packaging applications. The varying amounts of glycerol (plasticizer) and glutaraldehyde (cross-linker) were employed in the fabrication of films, and their impact on the film properties was further studied. The films were characterized thoroughly using TGA, SEM ATR-FTIR, and DSC techniques. Various parameters such as haze, transparency, solubility in water, gloss, tensile strength, elongation, and thickness for all the synthesized film were also examined.

Materials and methods

Carboxymethyl guar gum (CMG, M/s. Maruti Udyog, Ahmedabad, India), glycerol (Merck Life Sciences Private Ltd., India), and gluteraldehyde solution (CDH, India) were used as obtained. Double distilled water was utilized for solution preparations and washing purposes.

Fabrication of CMG-based film

The series of a total of 64 variants of CMG-based films as shown in Table 1 were fabricated by employing the different concentrations of glycerol (0 ml, 0.1 ml, 0.25 ml, 0.5 ml, 1 ml, 1.25 ml, 1.5 ml, and 2 ml) as a plasticizer and glutaraldehyde (0 ml, 0.1 ml, 0.25 ml, 0.5 ml, 1 ml, 1.25 ml, 1.5 ml, and 2 ml) as a cross-linker, via solvent casting technique. The fixed amount (1 g) of CMG was dispersed in 100 ml of distilled water at room temperature. Then, the desired volume of glycerol was added to the dispersion under stirring and heating at 70 °C on magnetic stirrer. It was then followed by the addition of glutaraldehyde to the above mixture. After 45 min, the resultant mixtures were immediately cast in an acrylic tray with dimensions (200 mm × 150 mm × 5 mm) and allowed to air dried at 25 °C for 24 h and then transferred to a hot air circulating oven maintained at 60 ± 5 °C for another 24 h. The dried films were then peeled off and stored at 25 °C. Figure 1 shows the schematic representation of the fabrication of the CMG-based films.

The same procedure was repeated for casting the films at different temperature conditions (75 °C).

Characterization and testing

Differential scanning calorimetry (DSC)

The thermal behavior of the cross-linked CMG films fabricated at two different temperatures of 70 °C and 75 °C and CMG powder were analyzed using a Perkin Elmer (model

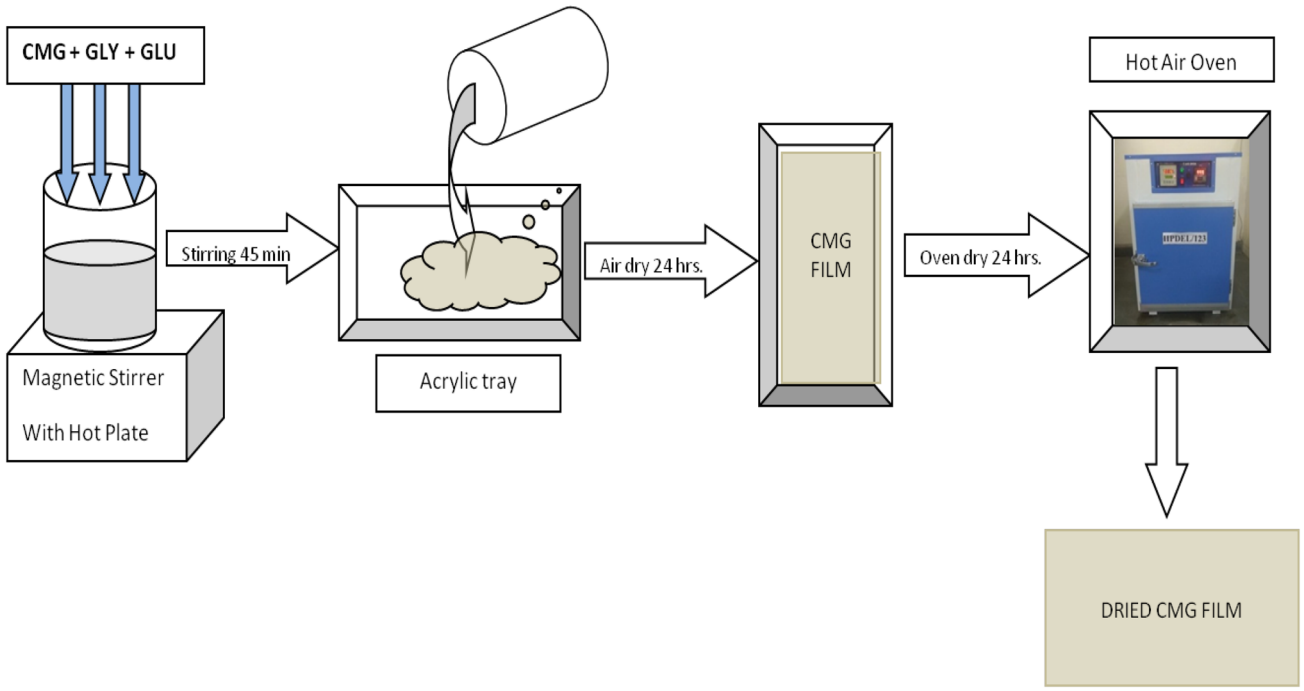

Fig. 1 Schematic representation of fabrication of the CMG-based film

no.: DSC 8000). The samples (2–3 mg) were heated at a rate of 10 °C/min, at a temperature range from 0 to 200 °C.

Thermogravimetric analysis (TGA)

TGA was done utilizing the Perkin Elmer instrument (Model No: TGA 4000). The sample (2–3 mg) was heated from a temperature range of 25 to 600 °C under a nitrogen atmosphere in a sample holder. The flow rate was maintained at 50 ml/min, and the heating rate was set at 10 °C/min. The weight change of the sample was recorded as a function of temperature.

Scanning electron microscopy (SEM)

SEM analysis was carried out using a Hitachi (model: S-3400N) at an accelerating voltage of 5 kV to examine the surface morphology of the fabricated CMG films.

Attenuated total reflectance-Fourier transform infrared spectroscopy (ATR-FTIR)

The FTIR spectrum of the films was recorded using a Shimadzu Corp. ATR-FTIR instrument (model: IR Affinity-1S). The spectra were recorded in the frequency range from 4000 to 400 cm^{-1}, at the spectral resolution of 5 cm^{-1}.

Mechanical properties

The samples were examined for tensile strength and elongation on a Universal Testing Machine (Shimadzu, Autograph AG–X 110 N) equipped with a 1-kN load cell capacity, as per the ASTM D 882–97 guidelines with minor modifications. The film dimensions were 25 mm × 150 mm, with a gauge length of 50 mm and a crosshead speed of 50 mm/min. The tensile strength was reported in MPa. The strain at the point of breakage was recorded and reported as percent elongation at break. Tests were conducted in triplicate.

Film thickness

The film thickness measurement was conducted on the Mitutoyo Japan Micrometer (Model 547-400S) as per the ASTM 6988 guideline, with a sample dimension of 50 mm × 50 mm. A total of 10 readings were randomly taken on each type of sample, and the average value is reported in microns (μ).

Solubility in water

The solubility of the film in water is referred to the percentage of soluble matter present in the film [20]. The films having dimensions of about 50 mm × 50 mm were immersed in 50 ml of double distilled water at room

temperature for 24 h. Later, the water was discarded, and the films were dried in a hot air oven set at 60 °C for 24 h. The solubility of the film was then calculated using the following Eq. (1).

$$Solubility(\%) = \frac{\text{Initial dry weight} - \text{Final dry weight}}{\text{Initial dry weight}} \times 100 \quad (1)$$

Gloss

Samples were analyzed on the Gloss meter (Model BYK Gardner) as per ASTM D 523/ASTM D2457 guidelines, at a 20° angle. A total of 10 readings were acquired for each type of sample, and the average value was reported.

Haze and transparency

The spherical haze meter, diffusion systems (M57D) was utilized for the measurement of the haze and transmittance of the film. Each sample was tested in triplicate, and the reported values signify the average percentage. The measurement was done according to the guidelines outlined in ASTM D 1003.

Results and discussions

Probable mechanism

The various 64 formulations of CMG-based films were synthesized using the different quantities of glycerol and glutaraldehyde, as outlined in Table 1. The glutaraldehyde interacts with the hydroxyl groups present in both CMG and glycerol, leading to the formation of acetyl bonds. This interaction leads to the successful development of a cross-linked CMC/Glu/Gly polymeric network. The probable mechanism underlying this process is depicted in Fig. 2 [36].

Characterization and testing

Differential scanning calorimetry (DSC)

The DSC analysis was carried out for the CMG film (Sample A-1), and CMG/Glu/Gly film (Sample E-5) fabricated at 70 °C, and 75 °C, as shown in Fig. 3. A broad peak at 91.63 °C and 97.21 °C is observed in CMG film and CMG/Glu/Gly film fabricated at 70 °C, respectively, while a sharper peak at 102.25 °C is noticed in CMG/Glu/Gly film fabricated at 75 °C. This sharp peak at 102.25 °C indicates an endothermic reaction associated with the melting of the film at a higher temperature. The difference in the peaks

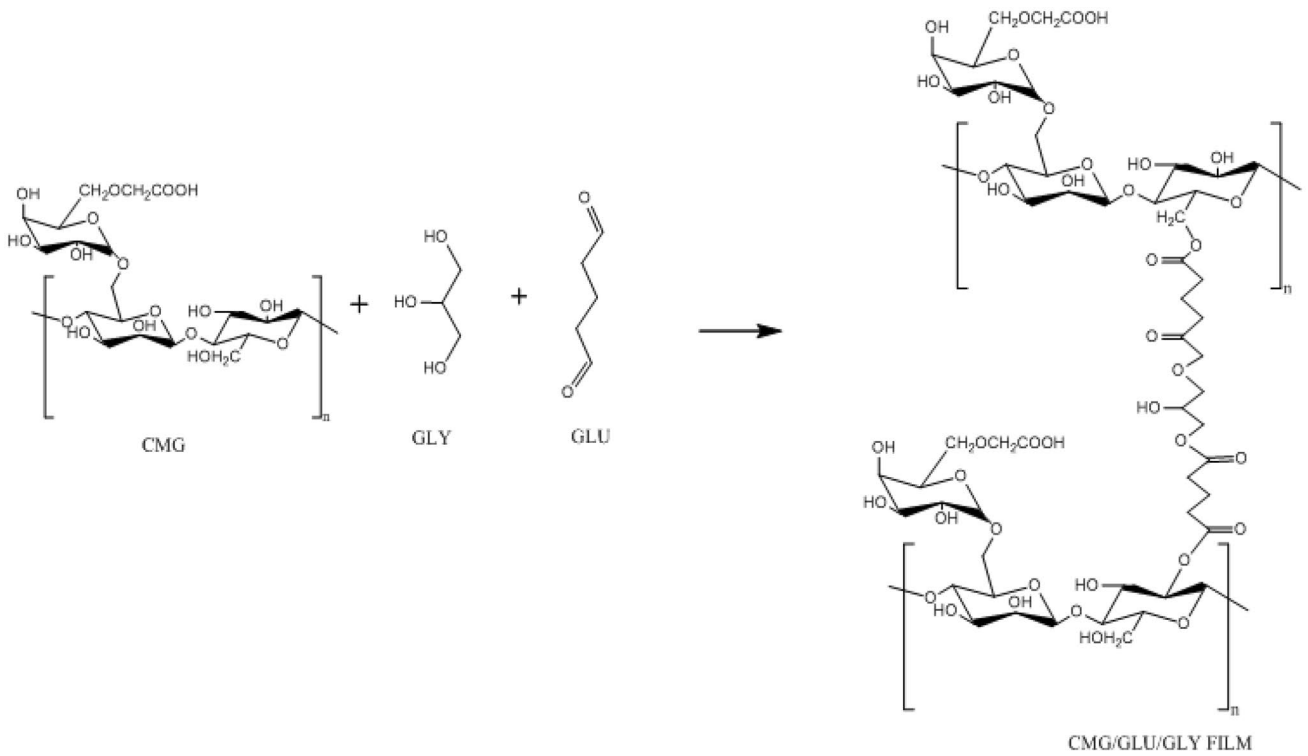

Fig. 2 Probable mechanism of CMG/Glu/Gly film formation

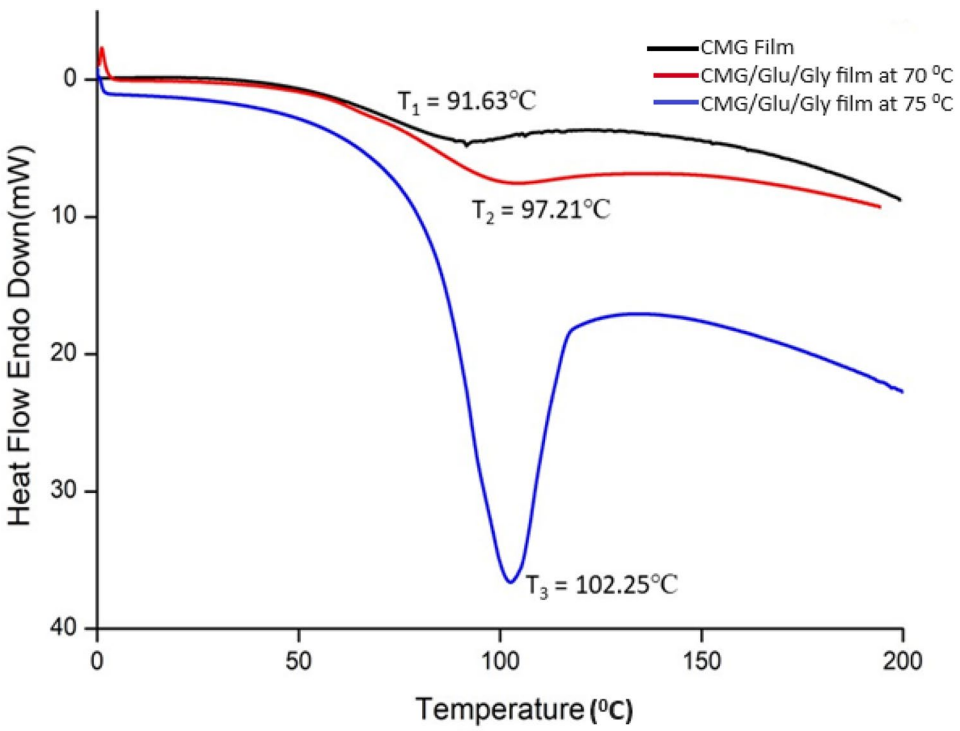

Fig. 3 DSC for CMG film and CMG/Glu/Gly films fabricated at 70 °C and 75 °C

revealed the improved cross-linking at the higher reaction temperature of 75 °C compared to the reaction temperature of 70 °C [11].

Thermogravimetric analysis (TGA)

TGA thermographs of CMG/Glu/Gly films (Sample E-5) fabricated at two different temperatures (70 °C and 75 °C) are shown in Fig. 4. The thermograms of both CMG-based films show three-stage weight loss. Initially, the same weight loss of 26% due to water evaporation from 30 to 245 °C was observed in CMG films prepared at 70 °C and 75 °C. Secondly, again, the same weight loss of 40% from 245 to 325 °C, due to the degradation of polymer backbone (-COOH and -OH group of CMG), was found in the films synthesized at reaction temperatures 70 °C and 75 °C.

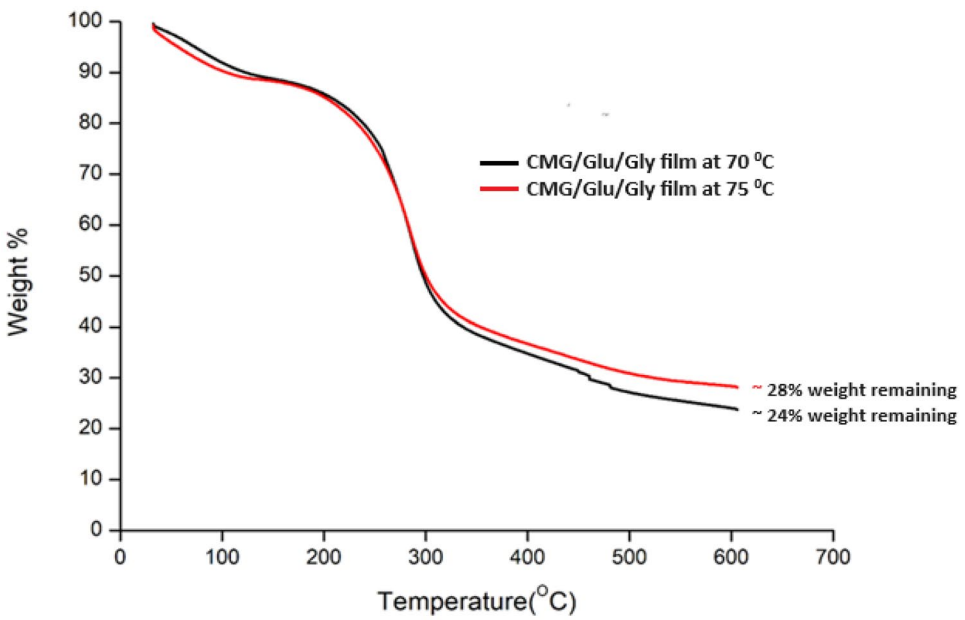

Fig. 4 TGA plot for optimized CMG/Glu/Gly films fabricated at reaction temperatures (70 °C and 75 °C)

Lastly, the weight loss of 20% and 16% from 325 to 600 °C signifies the breakage of the cross-linking present in the films fabricated at 70 °C and 75 °C, respectively [37–40].

Moreover, it was observed that up to the second stage, both films exhibited similar weight loss. However, beyond this temperature, the film produced at 70 °C shows a higher weight loss, compared to the film fabricated at 75 °C. This suggests that the film synthesized at the higher reaction temperature of 75 °C demonstrates greater stability, likely attributed to a higher degree of cross-linking. Consequently, the films synthesized at the 75 °C reaction temperature were selected for further analysis [11].

Scanning electron microscopy (SEM)

The surface morphology of the CMG (Sample A-1), CMG/Gly (Sample E-1), CMG/Glu (Sample A-5), and CMG/Glu/Gly (Sample E-5) films was analyzed by SEM. In Fig. 5A, the single-phase morphology was observed without any surface complexity, attributed to the solely presence of CMG. Figure 5B reveals the uneven surface morphology associated with the presence of cavities and air pockets resulting from the dispersion of the plasticizer within the polymer matrix. Figure 5C indicates a more uniform and denser surface, which signifies the successful cross-linking between CMG and the cross-linker. Figure 5D shows a comparatively more homogeneous surface than Fig. 5C, implying the combined effect of plasticizer and cross-linker on the overall surface morphology of the films [6].

Attenuated total reflectance-Fourier transform infrared spectroscopy (ATR-FTIR)

The ATR-FTIR spectra of the CMG (Sample A-1), CMG/Gly (Sample E-1), CMG/Glu (Sample A-5), and CMG/Glu/Gly (Sample E-5) film are shown in Fig. 6. In the FTIR spectra of the CMG film, characteristic peaks associated with O–H stretch were observed at 3300–3400 cm^{-1}, while the peak associated with C–H stretch appears at 2800–2900 cm^{-1}.

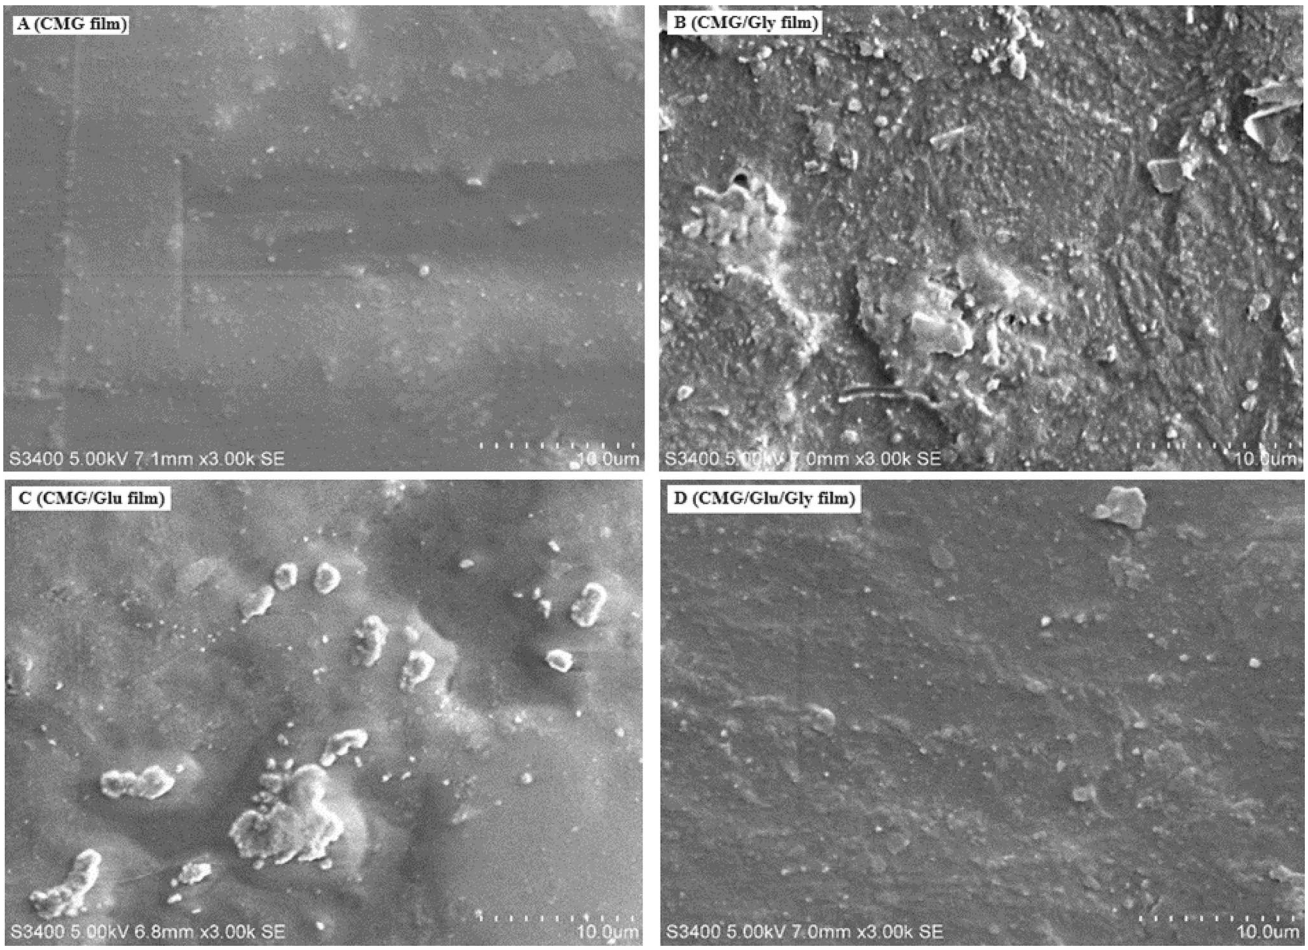

Fig. 5 SEM micrograph of **A** CMG film, **B** CMG/Gly film, **C** CMG/Glu film, and **D** CMG/Glu/Gly film, at 3000 magnifications

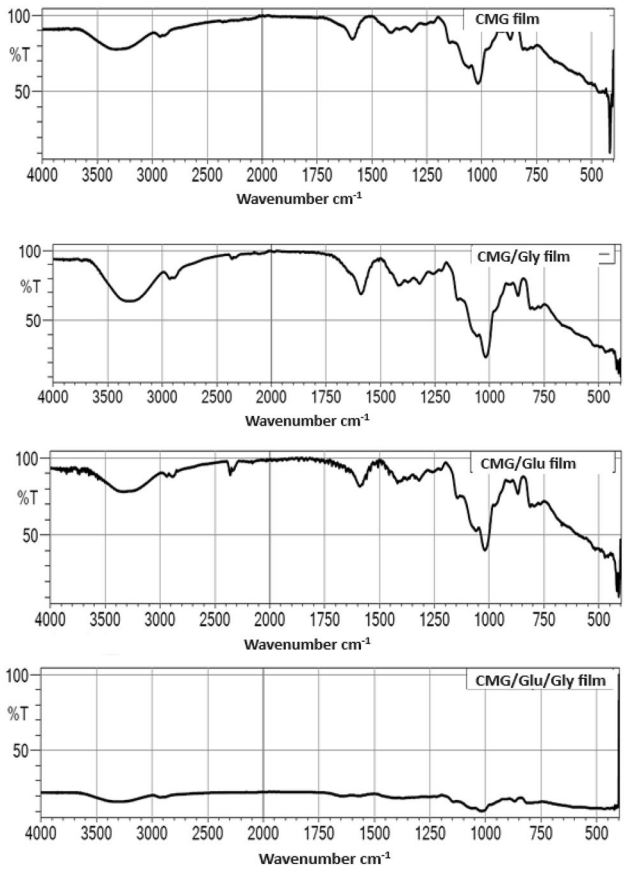

Fig. 6 FTIR spectra of CMG film, CMG/Gly film, CMG/Glu film, and CMG/Glu/Gly film

Moreover, the C = O stretch appears at 1600–1700 cm^{-1}, and the C–H bend appears at 1300–1400 cm^{-1} [41].

In FTIR spectra of CMG/Gly film, it was observed that the addition of glycerol resulted in a notable increase in the number of alcoholic hydroxyl groups. Consequently, the intensity of the peaks within the 3300–3400 cm^{-1}, corresponding to hydroxyl groups, exhibited a significant increase in amplitude [42].

In FTIR spectra of CMG/Glu film, an increase in the intensity of the peak around 2800–2900 cm^{-1} is observed, attributed to the larger number of CH_2 groups resulting upon the introduction of cross-linker (glutaraldehyde) [43].

Moreover, in the FTIR spectra of CMG/Glu/Gly film, the disappearance of peak around 2300–2400 cm^{-1}, present in CMG/Gly film and CMG/Glu film, confirms the successful formation of a cross-linked polymeric film.

Mechanical properties

All the 64 variants of CMG-based films as shown in Table 1 were tested for evaluating their mechanical properties.

The tensile strength test provides information about the mechanical strength of the material, crucial for packaging applications. The plasticizer's impact on tensile strength varies with changes in cross-linker concentration as observed in Fig. 7a. Without or with low cross-linker concentration (up to 0.25 ml), plasticizer increases film flexibility, leading to a decrease in tensile strength. For cross-linker concentrations (0.25–1 ml), tensile strength slightly increases due to glycerol's participation in cross-linking. Beyond 1-ml cross-linker, tensile strength sharply decreases, rendering the film sticky due to excess plasticizer.

Similarly, Fig. 7b illustrates the impact of cross-linker content on tensile strength. At low concentrations of cross-linker (0.1–0.25 ml), tensile strength increases slowly due to insignificant cross-linking. Beyond this range, a considerable increase in the tensile strength occurs with increased cross-linking reaching a maximum at 1.25 ml of cross-linker. Moreover, with an increase in the cross-linker content above

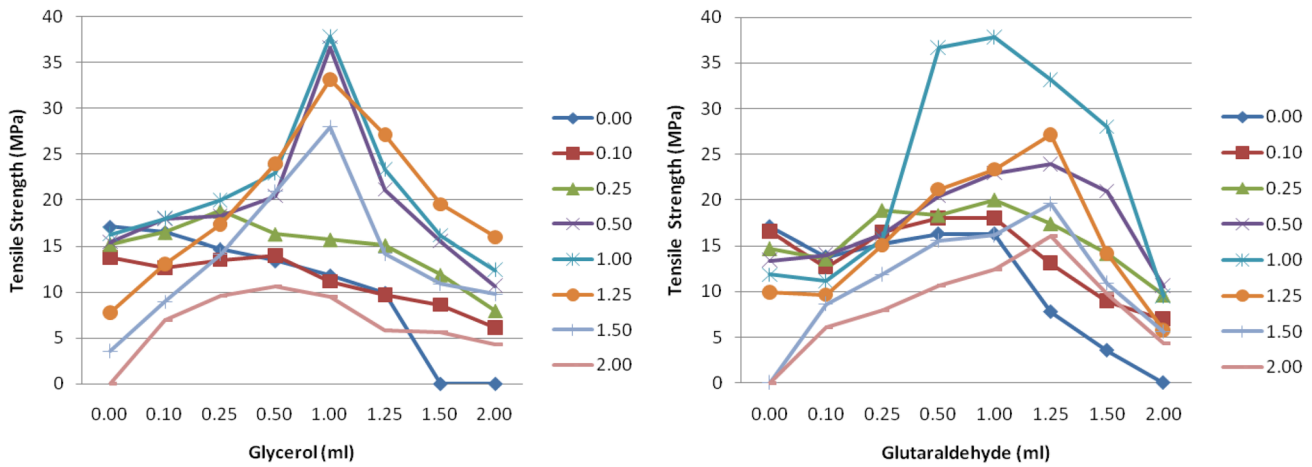

Fig. 7 Influence of **a** plasticizer and **b** cross-linker on the tensile strength of the CMG-based film

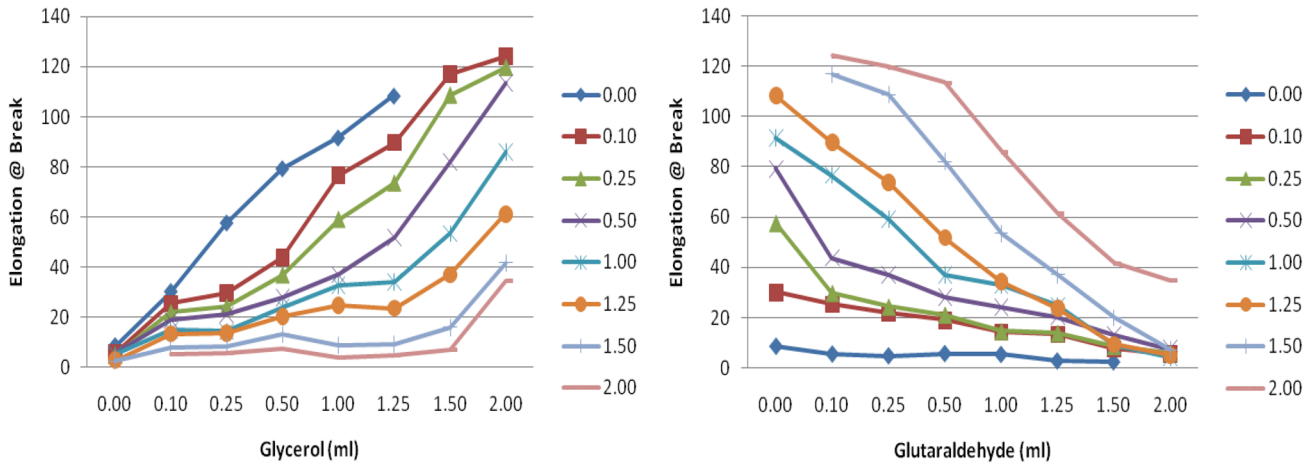

Fig. 8 Impact of **a** plasticizer and **b** cross-linker on elongation @ break of CMG-based films

1.25 ml, tensile strength decreases, possibly due to excessive cross-linker hindering available cross-linking sites. The maximum tensile strength of 37.82 MPa is observed in CMG-based film. Hence, CMG-based films can be employed for potential applications in the packaging sector [11, 42].

The elongation test provides information about the extent to which films can elongate or withstand strain before reaching the breaking point. It is an essential consideration for processes such as lamination and printing. The elongation percentage of the CMG-based films is depicted in Fig. 8. Notably, the film exhibited a maximum elongation of 124.2%. It is observed that with an increase in glycerol quantity, molecular mobility rises, leading to a decrease in intermolecular forces, resulting in an increase in film flexibility, consequently elongation increases. However, at lower glycerol quantities, where molecular mobility is limited, the plasticization effect is less significant. As seen in Fig. 8a, the addition of glycerol increases the percent elongation of the film by decreasing its brittleness due to plasticizing effect. At the lower quantity of glycerol, as the mobility of the molecules is limited, the plasticization effect is not significant but as the quantity of glycerol increases, the mobility of the molecules increases, and elongation increases due to an increase in the flexibility of the film by reducing the intermolecular forces. Similarly, with a quantity in the number of cross-linkers as shown in Fig. 8b, a decrease in the elongation at break was observed. This is due to the cross-linking effect, the films become stiffer and the flexibility of the cross-linked films decreases with an increased number of cross-links produced [11, 42, 44].

Film thickness

The average thickness of all the variants of CMG-based films as shown in Table 1 is shown in Fig. 9. The maximum

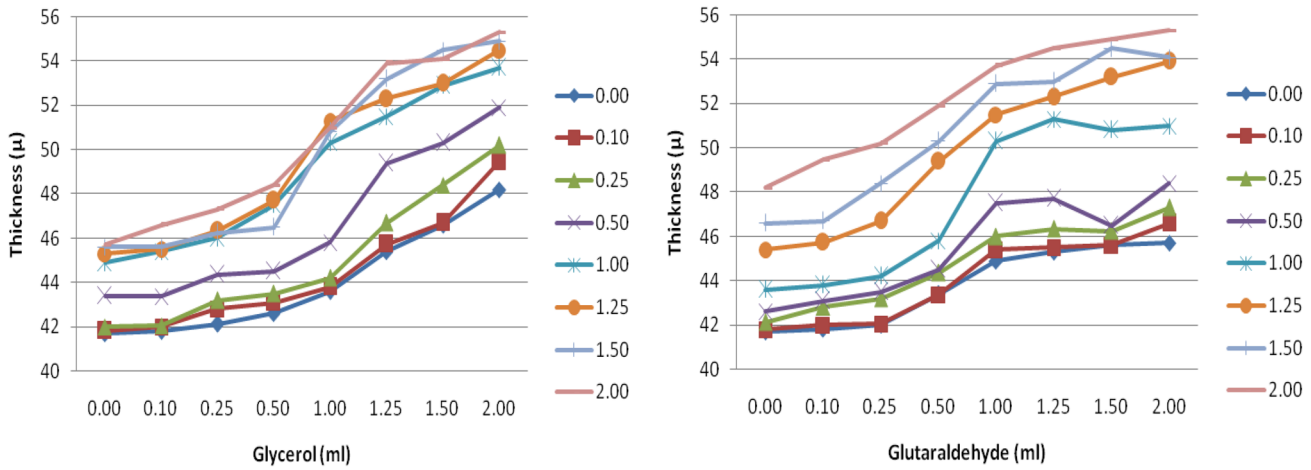

Fig. 9 Thickness of the CMG-based films as a function of **a** plasticizer and **b** cross-linker

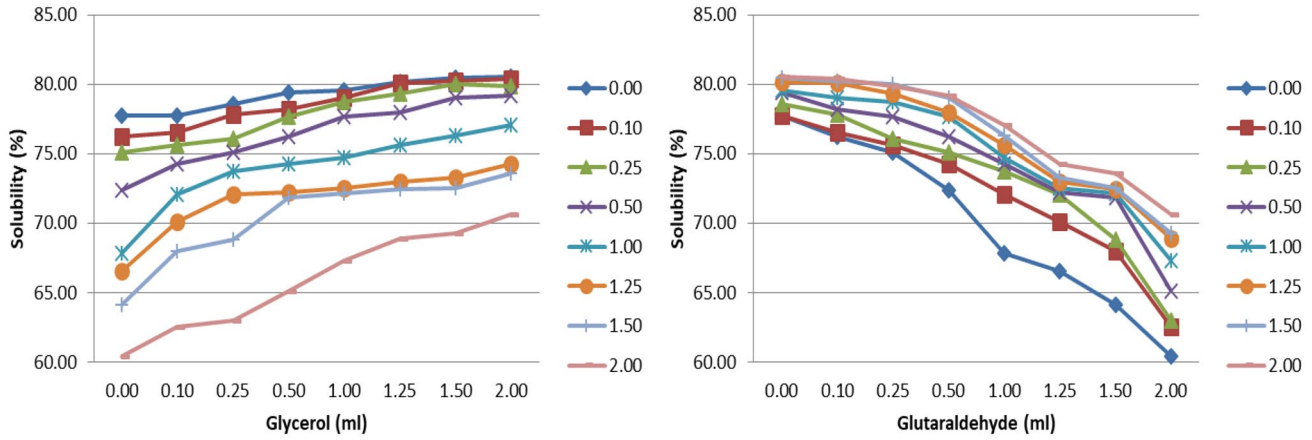

Fig. 10 Effect of **a** plasticizer and **b** cross-linker on the solubility of the CMG-based films in water

thickness of the film observed was 55.30 µ. The thickness of the film increases with the increase in the quantity of both plasticizer and cross-linker due to the distribution of intermolecular bonds leading to rearrangement providing more expanded structure due to the effect of plasticizer and in case of cross-linker due to an increase in the cross-linking which gives rise to denser film structure on cross-linking [12, 18, 45, 46].

Solubility in water

The solubility percentage of the synthesized CMG-based films as given in the Table 1 is calculated using Eq. (1), as illustrated in Fig. 10. The minimum observed solubility of the film was 60.42%. It is evident that the solubility decreases with an increase in the quantity of the cross-linker. This is attributed to higher cross-linking, which reduces hydrogen bonding in the film matrix, resulting in slower dissolution [42].

Moreover, the film's solubility increases with an increase in the plasticizer quantities due to the enhanced flexibility of the film and due to glycerol separating from the hydrogen bonding site of CMG and dissolving in water [14]. The water solubility of CMG-based films suggests potential applications in edible packaging and water-soluble packaging materials.

Gloss

The glossiness of polymeric films is an essential parameter for packaging applications. It provides information about the amount of light reflected when light is incident on the film surface from various angles. Figure 11 illustrates the gloss values of the CMG-based films as listed in Table 1, at a 20° angle with the CMG-based film displaying a maximum gloss of 25.52%. Notably, at lower quantities of concentration of plasticizer and cross-linker, the glossiness tends to increase, owing to the increased smoother surface of the

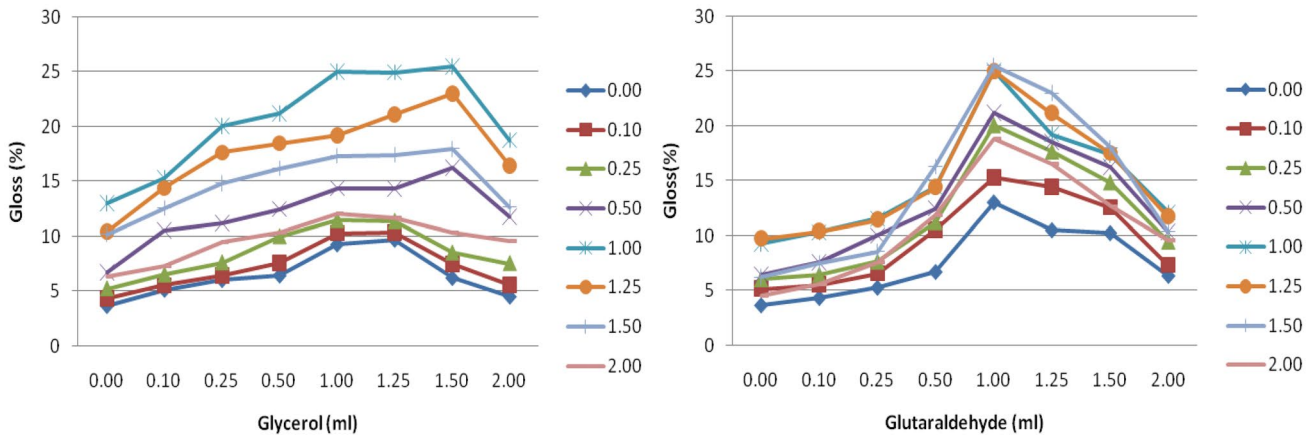

Fig. 11 Impact of **a** plasticizer and **b** cross-linker on the gloss of the CMG-based films at 20° angle

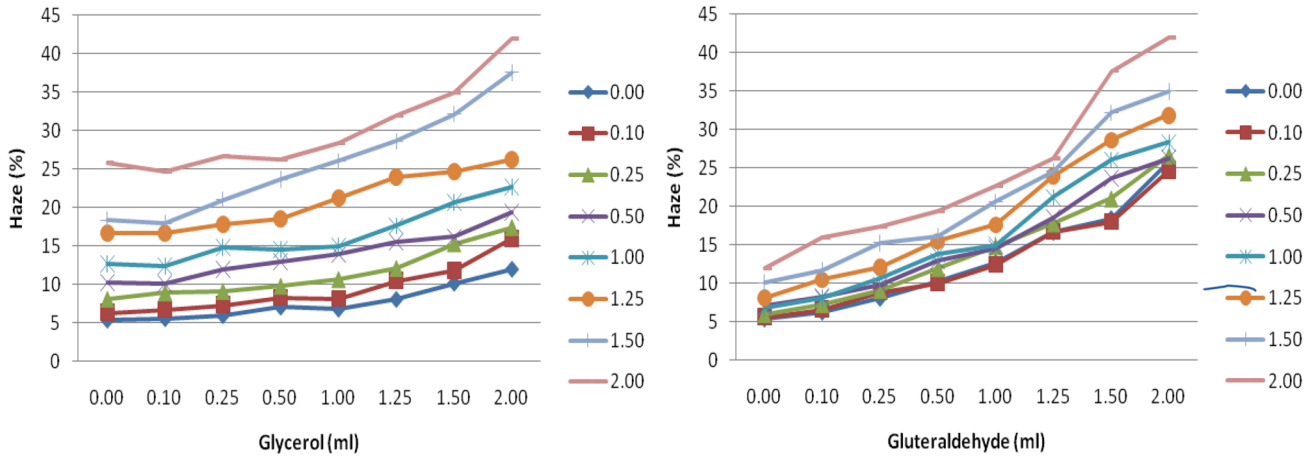

Fig. 12 Influence of **a** plasticizer and **b** cross-linker on the haze of the CMG-based films

film due to plasticization and the cross-linking. However, with the addition of high quantities of plasticizer and cross-linker, a reduction in glossiness occurs. This decrease may be attributed to the formation of rougher surfaces due to an increase in cross-linking [47].

Haze and transparency

The haze percentage of the synthesized CMG-based films given in Table 1 is presented in Fig. 12. The film exhibits a maximum haze of 41.93%. It is noteworthy that the haziness of the film increases with a rise in both the plasticizer and cross-linker content. This is due to the increase of diffusion of incident light caused by increased bulkiness at higher plasticizers and cross-linking of the film due to polymeric chain compaction to a higher cross-linking [16].

The transparency of the CMG- based films, prepared as given in Table 1, is given in Fig. 13. The transparency of any polymer plays a crucial role in its visible light barrier properties and can be correlated to its crystalline behavior. Optical transparency is inversely proportional to its crystallinity [41]. The transparency of the synthesized CMG-based films is presented in Fig. 13. The findings indicate that CMG films exhibit excellent optical transparency, with the maximum transparency observed at 88.53%.

Moreover, it is observed that as glutaraldehyde content in the film increases, the cross-linking increases, leading to a noticeable decrease in the transparency of the film. Additionally, the transparency of the film is also decreased by an increase in the quantity of plasticizer. This can be attributed to the decrease in transmittance caused change in the refractive index by the increased polymeric chain compaction [16].

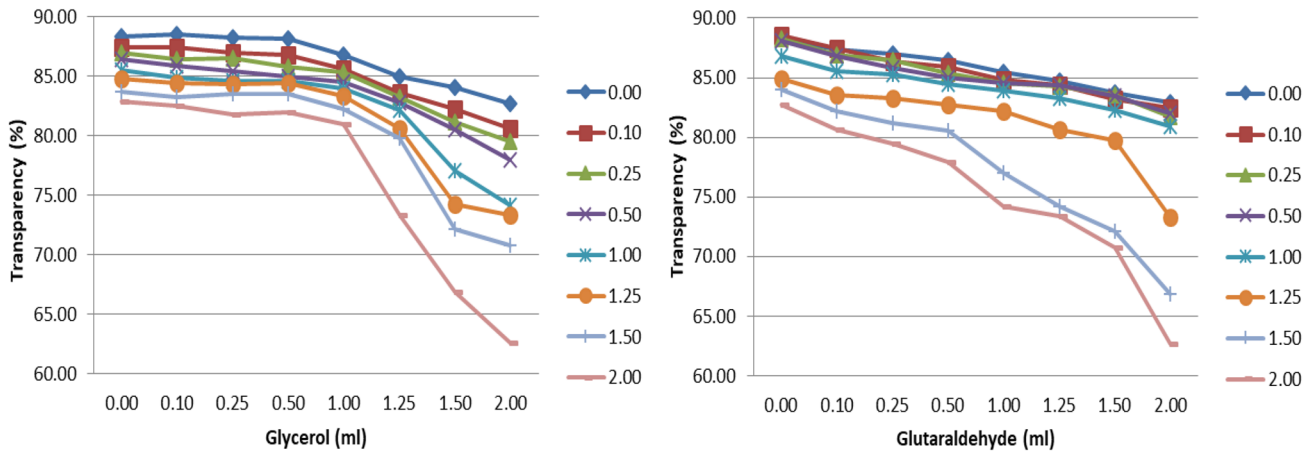

Fig. 13 Effect of **a** plasticizer and **b** cross-linker on the transparency of the films

Conclusion

In this study, films based on carboxymethyl guar gum (CMG) were successfully fabricated by utilizing glycerol as a plasticizer and glutaraldehyde as a cross linking agent using solution casting technique. The films were characterized for FTIR, DSC, and SEM. The result of the FTIR showed increase in the number of hydroxyl and CH_2 groups which confirms the cross linking of CMG with glycerol and glutaraldehyde. The DSC analysis shows that reaction temperature has significant effect on the formation of the CMG films as sharper peak at 102.25 °C when prepared at 75 °C due to better cross-linking in comparison with the blunt peak observed at 70 °C. The SEM micrographs showed improvement in improved surface in the films having both plasticizer and cross linker. Moreover, mechanical, optical, and solubility tests were also conducted on our CMG-based films. The maximum values observed for tensile strength, percent elongation, gloss at a 20° angle, haze, and transparency were 37.82 MPa, 124.20%, 25.52%, 41.93%, and 88.53%, respectively. All these properties revealed the possibility of our CMG films for packaging applications. The solubility test results indicated a minimum water solubility of 60.42% of these CMG films which highlights the potential applications of CMG-based films in areas such as edible coatings and water-soluble packaging. The maximum tensile strength value of 37.82 MPa suggests that, with further refinements, CMG-based films can compete with certain biopolymer-based films and even some commercially used synthetic polyethylene films. This study also points the CMG-based biopolymer materials as promising candidate for coatings in the packaging industry.

Abstract
Medical Image Captioning (MIC), is a developing area of artificial intelligence that combines two main research areas, computer vision and natural language processing. In order to support clinical workflows and decision-making, MIC is used in a variety of applications pertaining to diagnosis, therapy, report production, and computer-aided diagnosis. The generation of long and coherent reports highlighting correct abnormalities is a challenging task. Therefore, in this direction, this paper presents an efficient $FDT - Dr^2T$ framework for the generation of coherent radiology reports with efficient exploitation of medical content. The proposed framework leverages the fusion of texture features and deep features in the first stage by incorporating ISCM-LBP + PCA-HOG feature extraction algorithm and Convolutional Triple Attention-based Efficient XceptionNet ($C - TaXNet$). Further, fused features from the FDT module are utilized by the Dense Radiology Report Generation Transformer (Dr^2T) model with modified multi-head attention generating dense radiology reports by highlighting specific crucial abnormalities. To evaluate the performance of the proposed $FDT - Dr^2T$ extensive experiments are conducted on publicly available IU Chest X-ray dataset and the best performance of the work is observed as 0.531 BLEU@1, 0.398 BLEU@2, 0.322 BLEU@3, 0.251 BLEU@4, 0.384 CIDEr, 0.506 ROUGE-L, 0.277 METEOR. An ablation study is carried out to support the experiments. Overall, the results obtained demonstrate the efficiency and efficacy of the proposed framework.

1 Introduction

Image captioning [1] provides insights into a given image semantically and syntactically in the form of natural language sentences. This research area also finds application in the medical domain for the generation of medical reports [2]. Medical Image Captioning (MIC) [3] can assist doctors by accelerating the reporting process and reducing their workload. Figure 1 presents an example of the captioning of medical images. Medical image captioning highlights the relationships between image objects and clinical findings, which makes it a very challenging task. The generation of medical reports not only reduces the doctor's workload and accelerates clinical workflow but also aids in the efficient exploitation of medical content. Therefore, this produces faster and more accurate interpretations of findings, and offers important assistance to doctors.

Radiology and pathology medical images are widely used for the detection and treatment of different diseases [4, 5]. Generation of medical reports in multiple sentences from these images is a tedious task as this includes comprehensive examination e.g., X-ray images necessitate a detailed interpretation of visible information, including the airway, lung, cardiovascular system, and disability. Therefore, such interpretation requires the use of fundamental physiological knowledge in addition to a comprehensive comprehension of results from laboratories, electrocardiograms, and pulmonary function tests. Therefore, there has been a significant increase in interest in both clinical medicine and artificial intelligence for automatic report-generating technology.

Normal Chest with no pulmonary enema. The cardiac silhouette and mediastinum size are within normal limits. There is no focal consolidation. There are no traces of pleural effusion. There is no evidence of pneumothorax.

Fig. 1 An example of radiology report generated

Also, for a large number of radiological images manual writing of reports becomes a significant load for radiologists. Additionally, for radiologists with less experience, some anomalies in radiological images may be disregarded and not recorded in the reports [6]. Therefore, automatically generated radiography reports become a necessity to alleviate radiologists from their excessive burden and to alert novice radiologists to anomalies.

With the increase in the advancements in technology, different methods [2, 7, 8] are developed to automatically generate medical reports based on the data available. These methods generated incorrect reports for some cases with erroneous and repeated sentences. Some models [2, 9, 10] generated incoherent sentences with incorrect order of words, which were not clinically acceptable. Also, these methods failed to report some rare but important abnormalities due to ambiguities and incorrect detection of objects from radiological images. To overcome these challenges, this paper presents an efficient framework for the generation of paragraph-based reports sometimes also known as dense MIC. The proposed framework is split into two stages (as depicted in Fig. 2): (1) FDT-Image feature extraction module and (2) Dense Radiology Report Generation Transformer (Dr^2T) model for coherent medical report generation. The proposed FDT module efficiently fuses or concatenates deep features and texture features to extract effective features from the data available. The fused features obtained from the first stage are further leveraged by the transformer-based module for efficient and coherent report generation. The key contributions of the proposed work are summarized as:

- The paper presents an FDT feature extraction module that extracts salient features from medical images concatenation of deep features (Convolutional Triple Attention-based Efficient XceptionNet, $C-TaXNet$) and texture or hand-crafted features Image Segmentation-based Central Multiscale-LBP (ISCM-LBP + HOG-PCA).
- The paper also presents a Dense Radiology Report Generation Transformer (Dr^2T) with Modified-MHA which selects the best head from the structure and concatenates best-head with the multi-head representations to explore more correlations for higher-order feature representations.
- Extensive experiments are conducted on the publically available IU Chest X-ray dataset. The proposed framework provides state-of-the-art results in terms of BLEU, METEOR, CIDEr, and ROUGE-L evaluation metrics.
- An ablation study is also carried out to exhibit the effect of different feature representation methods and generate medical reports using the baseline transformer and the proposed Dr^2T.

The organization of the rest of the paper is as follows: Sect. 2 discusses previous works on medical image captioning. Section 3 provides a detailed explanation of the proposed methodology. Furthermore, Sect. 4 presents the dataset and implementation details with the results obtained. Finally, we conclude the work in Sect. 5.

2 Related works

The task of image captioning [1, 11] has gained immense popularity in the recent past. The early methods [12, 13] are based on an encoder–decoder architecture that generates single-sentence natural language descriptions of images. With the advancements made in technology, paragraph-based descriptions of images came into existence [14, 15].

MIC highlights the relationships between image objects and clinical findings. Radiologists with or without experience find writing medical reports a time-consuming and tedious task [2]. Also, the generation of error-free reports is also an intimidating challenge. In this direction, similar to image paragraph captioning few works [2, 16, 17] adopted hierarchical-RNN structures for the generation of fluent medical reports. These methods though generated fluent reports still suffer from data deviation which leads to the generation of general reports without prominent abnormalities [2, 17–19]. Also, some methods [8, 16, 20] have been proposed to alleviate data deviation.

Yuan et al. [16] fine-tuned the encoder to extract the most common medical concepts from x-ray images using radiology reports as training data. Another work [17] incorporated CNN's and LSTM in a recurrent manner to generate high-level conclusive impressions. Jing et al. [18] introduced two RNNs for writing accurate reports with normal and abnormal sentences. Further, [8] presented a hybrid model that enhanced the ability of the model by generating normal and abnormal sentences. Srinivasan et al. [21] utilized abnormality detection and a transformer with dual encoders and decoders for the generation of medical reports. Liu et al. [22] demonstrated a domain-aware automated system for creating chest X-ray radiology reports that conditionally generates sentences based on the themes that will be covered in the report. Lovelace et al. [23] developed a radiology report generation model using the transformer architecture

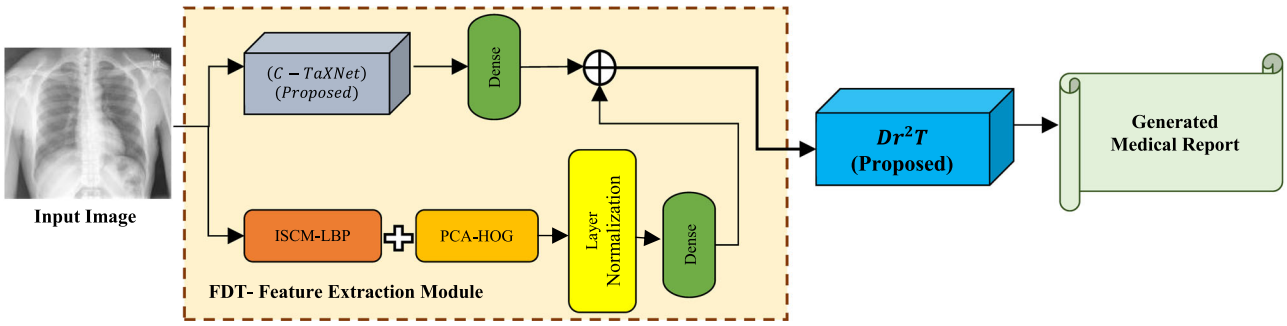

Fig. 2 Block diagram of the proposed FDT- Dr^2T framework

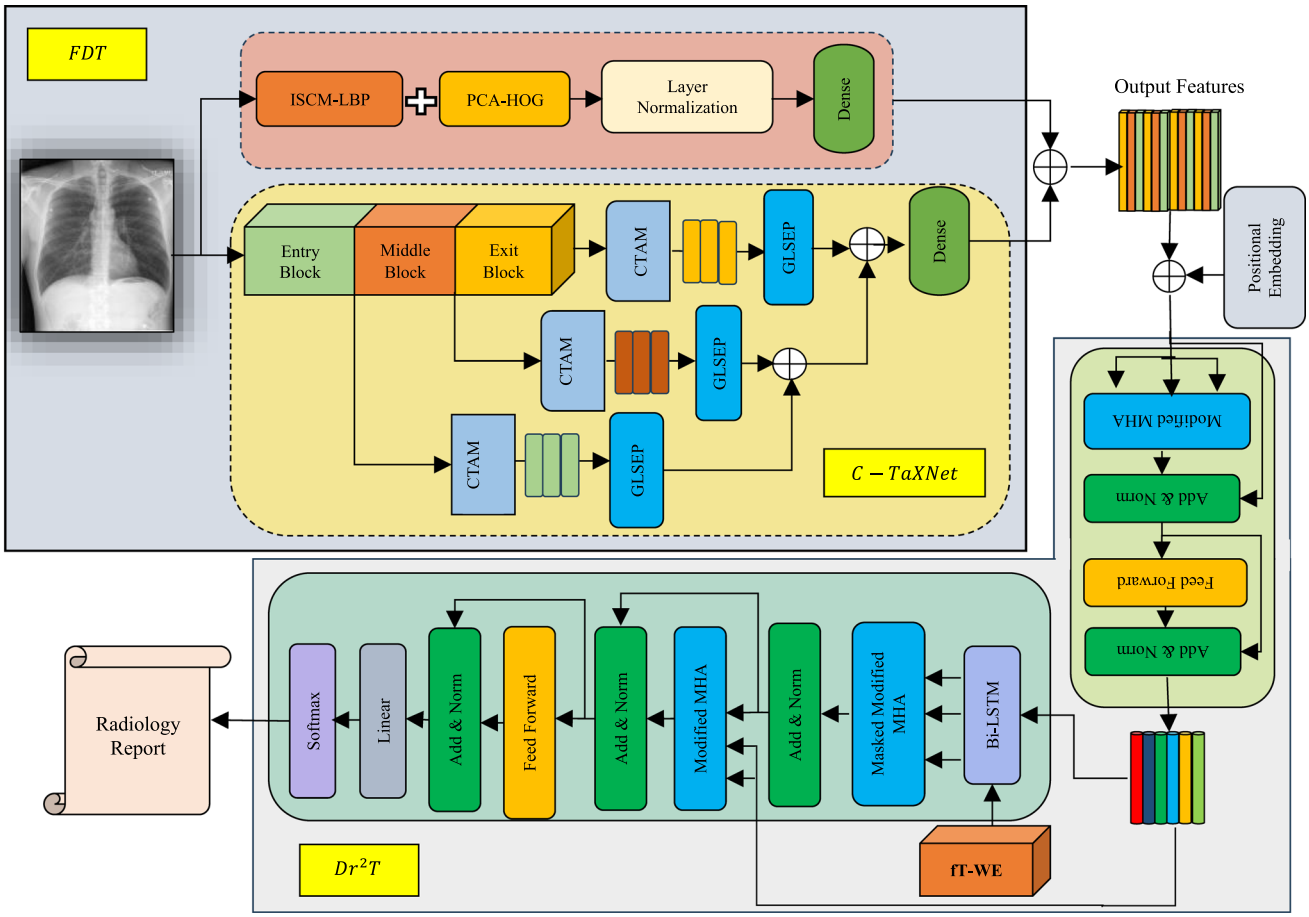

Fig. 3 Proposed FDT- Dr^2T framework

that outperforms competitor baselines in terms of both clinical coherence and standard language generation criteria. The above-mentioned methods generated incoherent sentences with incorrect order of words, which are not clinically acceptable. Also, some methods fail to describe some rare but important abnormalities due to ambiguities and incorrect detection of objects from medical images. To generate coherent and semantically and syntactically correct reports the proposed model utilized a fusion of deep and texture features for extraction of enhanced features. Further, these features are utilized by a Modified-MHA based transformer network for the generation of medical reports by considering higher-order multi-modal interactions.

3 Proposed methodology

This section provides the details for the proposed FDT- Dr^2T framework as depicted in Fig. 3.

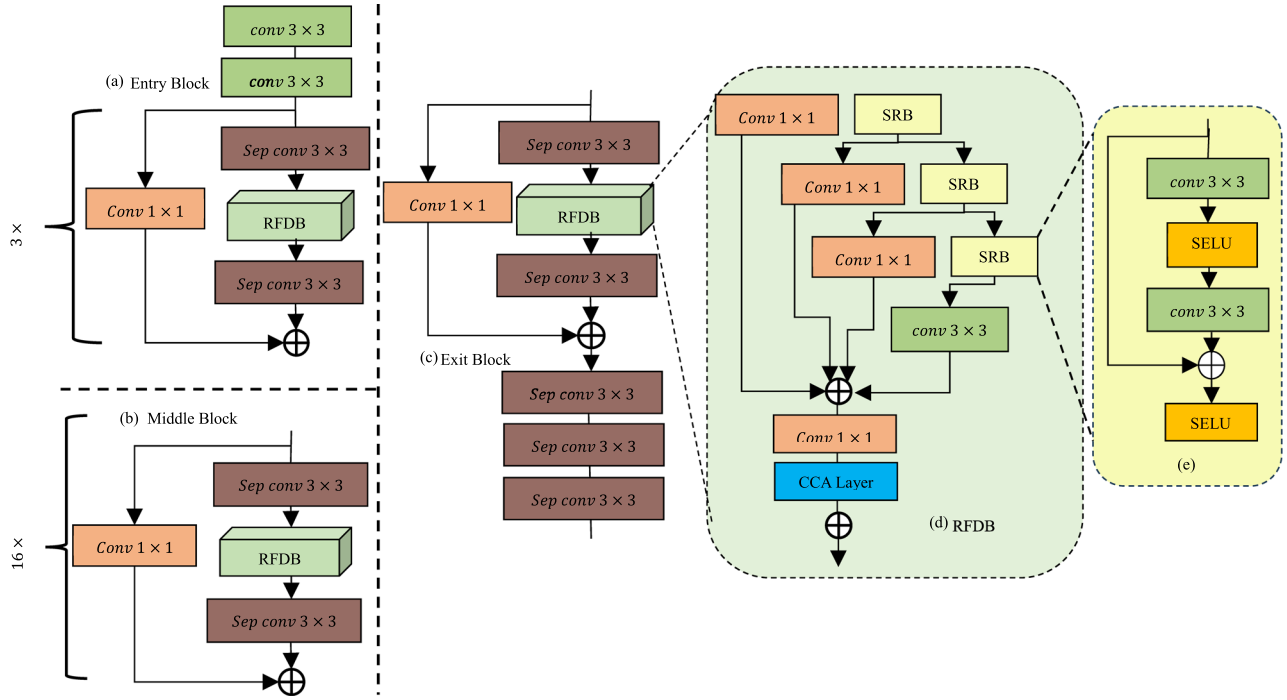

Fig. 4 Modified XceptionNet **a** entry block, **b** middle block, and **c** exit block, **d** RFDB block, **e** SRB block

3.1 FDT-image feature extraction

Medical image feature extraction aims to find the most compact and informative set of features. Deep-feature extraction incorporates a modified XceptionNet [24] module with a Residual Feature Distillation Block (RFDB) [25] and a Shallow Residual Block (SRB). Further, the proposed modified XceptionNet module also leverages a triplet attention module for the extraction of multi-level rich deep -features. Further, for the extraction of texture features, the ISCM-LBP [26] algorithm is incorporated with reduced-dimensional HOG features [27]. This helps to preserve a trade-off between model performance and parameters and ensures the appropriate level selection for the extraction of pertinent texture features.

3.1.1 Convolutional triple attention-based efficient XceptionNet ($C - TaXNet$)

The proposed $C - TaXNet$ model (Fig. 3) leverages a modified version XceptionNet module with RFDB and SRB as depicted in Fig. 4. RFDB utilizes multiple features distillation connections to learn more discriminative feature representation. For more fine-grained residual learning SRB is utilized without introducing additional parameters [28]. Further, the SRB is equipped with SELU activation function [29] described mathematically as:

$$g(x) = \begin{cases} \lambda x, & x > 0 \\ \alpha\lambda(e^x - 1), & x \leq 0 \end{cases} \tag{1}$$

where α and λ are the activation constants with approximate values of $\alpha = 1.6732$ and $\lambda = 1.0507$. Also, the proposed $C - TaXNet$ utilizes the concept of Convolutional Triple Attention Module (CTAM) [30] (almost parameter-free) that model channel attention and spatial attention [31]. The internal structure of the CTAM module is presented in Fig. 5. Consider $f_{input} \in \mathbb{R}^{C \times H \times W}$ be the feature vector of the corresponding input image which serves as an input to the Entry block of the $C - TaXNet$. The features extracted from each Xception block are made to pass through CTAM which is a three-stage architecture. For the first stage, height and channel dimension interactions are calculated by rotating the input 90° along the height dimension. The next stage calculates the interaction by rotating the input tensor to 90° anti-clockwise along W axis. For the final stage, the channels of the input tensor are reduced by using Z-pool. The Z-pool concatenates the AveragePool and MaxPool across that dimension. Mathematically, Z-pool can be represented as:

$$z - pool(x) = [MaxPool_{0d}(x) AvgPool_{0d}(x)] \tag{2}$$

where $0d$ is the zeroth dimension across which the AveragePool and MaxPool operation takes place. Further, the refined triple attended output is represented by:

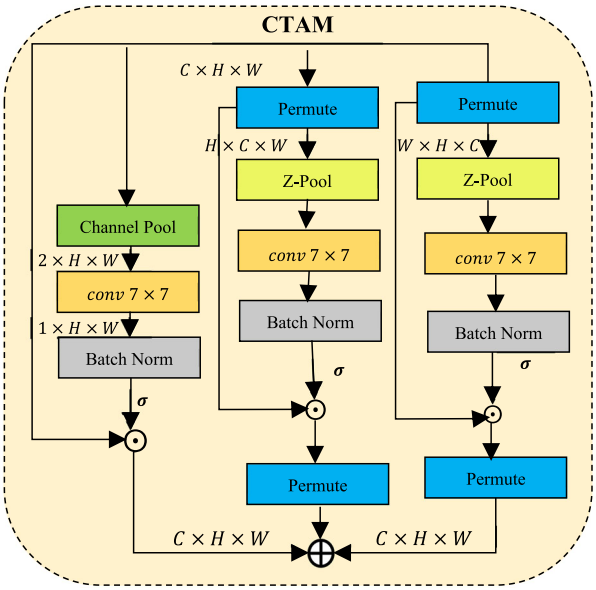

Fig. 5 Conventional triple attention module

$$y = \frac{1}{3}\left(\overline{\hat{x}_1\sigma(\varphi_1(\hat{x}_1^*))} + \overline{\hat{x}_2\sigma(\varphi_2(\hat{x}_2^*))} + x\sigma(\varphi_3(\hat{x}_3^*))\right) \tag{3}$$

In the above equation, σ represents the sigmoid activation function; φ_1, φ_2, and φ_3 represent the standard 2-D convolutional layers in three branches of triplet attention. Also, after the application of CTAM at each block of the Efficient XceptionNet we apply Global Log-Sum-Exp Pooling (GLSEP) [32] individually and concatenate the reduced features into a single vector.

3.1.2 ISCM-LBP + PCA-HOG feature extraction algorithm

This section provides the details for the hand-crafted feature extraction algorithm. Traditional LBP features [33] are sensitive to noise and incorporate center window pixels as the threshold, without any enhancement in the center pixel and considering the relationship between the center pixel and the neighborhood pixel [34]. When the central pixel intensity value is too large or too small then there might be a possibility that the detailed features are missed. Therefore, ISCM-LBP algorithm is incorporated that utilizes standard deviation to improve the resilience of the center pixel and the function of the neighborhood pixel. This further enhances the strength of the center pixel and the role of the neighborhood pixel. The specific operations are as follows:

- The 3×3 window is subdivided into sub-windows of size 3×3 to calculate the average gray value of each window

Finally, standard deviation σ is calculated for 9 windows.

$$\sigma = \sqrt{\frac{\sum_{j=1}^{9}(\tilde{\mathcal{X}}_j - \widetilde{\mathcal{X}})^2}{9}} \tag{4}$$

where $\tilde{\mathcal{X}}_j$ average gray value of each window and $\tilde{\mathcal{X}}$ is the average value of the entire window.

- For threshold value, for $\ell \leq \sigma$, the threshold q_t is the median of the nine pixels in the 3×3 window and LBP is evaluated by the formula

$$LBP(X_c, Y_c) = \sum_{P=0}^{7} 2^P \mathbb{S}(q_p - q_c) \tag{5}$$

$$\mathbb{S}(N) = \begin{cases} 1, & N \geq 0 \\ 0, & N < 0 \end{cases} \tag{6}$$

Further, if $\ell > \sigma$, let m, and n be the maximum and minimum value from the 9-pixel values. The threshold is evaluated using:

$$q_t = \frac{m + n + \tilde{q}_c}{3} \tag{7}$$

- Finally, for median M of nine pixels, ISCM-LBP features are evaluated using the formula:

$$ISCM - LBP = \sum_{P=0}^{7} 2^P \mathbb{S}(\tilde{q}_p - q_t) \tag{8}$$

$$q_t = \begin{cases} M, & \ell \leq \sigma \\ \frac{m+n+\tilde{q}_c}{3}, & \ell > \sigma \end{cases} \tag{9}$$

$$\mathbb{S}(N) = \begin{cases} 1, & \tilde{q}_p - q_t \geq 0 \\ 0, & \tilde{q}_p - q_t < 0 \end{cases} \tag{10}$$

The ISCM-LBP only extracts the texture information features and somehow neglects some edge density features from images. Therefore, we incorporate dimensionality reduction of histogram of gradient orientation i.e., PCA-HOG. This helps in the extraction of large dimensional HOG features which are reduced with the utilization of PCA mapping. Finally, the ISCM-LBP and HOG-PCA features are serially concatenated that helps to retain all the texture feature details.

Flowchart depicting the extraction process for the ISCM-LBP + PCA-HOG algorithm is presented in Fig. 6. Furthermore, the features obtained from $C - TaXNet$ and ISCM-LBP + PCA-HOG are fed to dense blocks which are the learnable feature encodings that converts the deep-features and hand-crafted features into learnable vectors $\mathbb{f}_{deep}$ and $\mathbb{f}_{hcf}$.

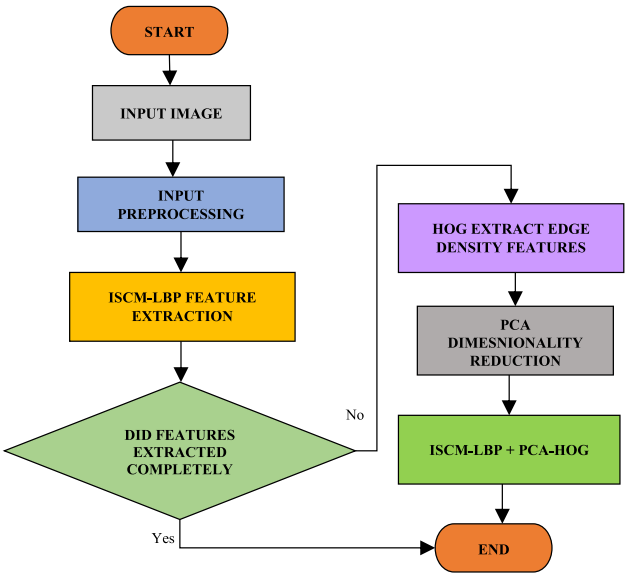

Fig. 6 Flowchart for ISCM-LBP + PCA-HOG algorithm

3.2 Dense Radiology Report Generation Transformer (Dr^2T)

The image features obtained from the FDT-Image feature extraction module are fed to the transformer-based architecture for the generation of dense medical reports. Figure 3 presents the detailed structure of the proposed Dr^2T transformer model. The traditional transformer model incorporates Multi-Head Attention (MHA) and calculates a weighted average of values based on the similarity between queries and keys. The attention scores assigned to each value determine its importance. To extract more minute details in the form of deep local features we present a modified MHA as shown in Fig. 7, which selects the best-head from the structure and concatenates the best-head and the multi-head representations to explore more correlations between the higher-order feature representations.

3.2.1 Dr^2T encoder

The encoder structure of the Dr^2T converts a set of visual attributes from the input image into a number of encodings. The encodings or embeddings obtained are represented in the form of a linear transformation of local features as keys $\hbar$, query q, and values v respectively. With this, we first calculate the multi-head self-attention scores $m\hbar_i$ using scaled-dot product attention (SPA). Mathematically,

$$mathcalligramh_i = [\hbar_1, \hbar_2 \ldots, \hbar_i] \tag{11}$$

$$SPA = softmax\left(\frac{q_i \hbar_i^T}{\sqrt{d_i}}\right) v_i \tag{12}$$

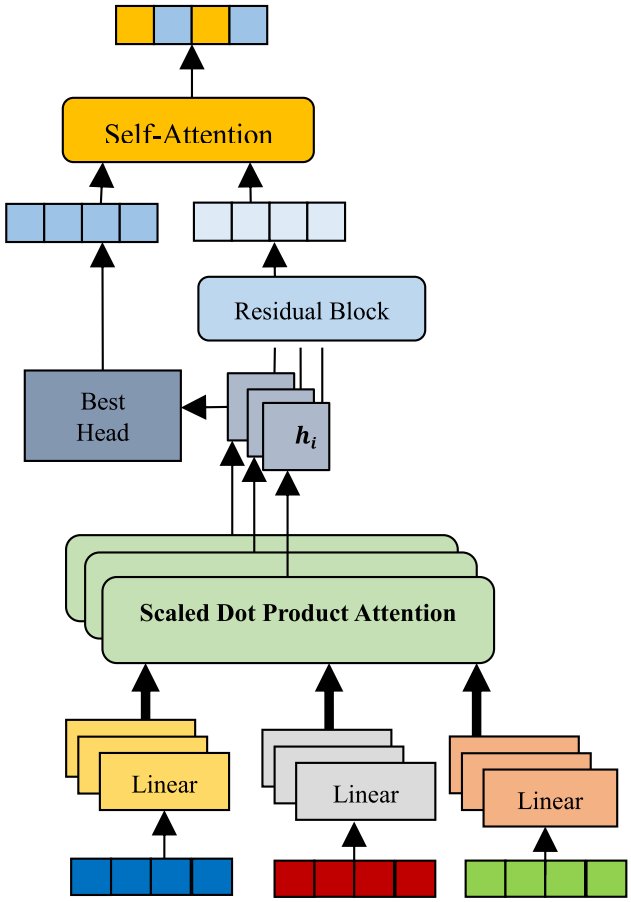

Fig. 7 Proposed modified MHA

Further, we select the best head ($m\hbar_b$) out of the calculated multi-head self-attention scores. Also, these heads $m\hbar_i$ are made to pass through to a residual block (RB) in order to avoid gradient explosion.

$$S_t = \sum RB(m\hbar_i) \tag{13}$$

The output generated from the RB and the best-selected head is fed to the self-attention network to provide a better correlation among the features obtained. The features obtained after the self-attention network is represented by:

$$\mathcal{S} = S - A(m\hbar_b, S_t) \tag{14}$$

The Modified-MHA features are added, normalized and fed to an FFN to get higher order visual features f_v as output which acts as input to Dr^2T Decoder module.

3.2.2 Dr^2T decoder

The Dr^2T decoder aims for the generation of dense medical reports either in the form of single or multiple sentences with the use of the high-level features obtained from the Dr^2T

encoder. A combination of visual features f_v and textual embeddings f_t are used to provide higher-order intra and inter-modal interactions between the image and text pairs. Also, the textual embeddings are extracted through fastText word embeddings (fT-WE) [35]. Therefore, textual and visual embeddings are concatenated via Bi-LSTM to perform multi-modal reasoning and high-level feature representation. This whole fT-WE with visual embedding (from Dr^2T encoder) and Bi-LSTM layer supports detailed encryption of visual data and provides inter-and intra-model interactions between the text and visual features.

At the decoding stage, we further integrate the Masked Modified-MHA and Modified-MHA with add and norm layers and feed-forward network layer. Finally, the medical report is generated by the generation of words through FC and softmax layers. The proposed Dr^2T model is trained by minimizing the cross-entropy loss:

$$\mathcal{L}_{XE}(\theta) = -\sum_{t=1}^{\mathcal{T}} \log(p_\theta(\omega_t^* | \mathbb{S}_{1:t-1}^*)) \tag{15}$$

where $\mathcal{T}$is the number of words in sentence; θ denotes all the parameters in the model; $\mathbb{S}_{1:t-1}^*$ is the ground truth.

4 Results and discussions

To evaluate the performance of the proposed framework, publically available dataset IU X-Ray [36] is used for the generation of paragraph-based reports. IU Chest X-Ray contains about 7470 pairs of images and reports. Each report consists of the following sections: impressions, findings, tags, comparison and indication. The report for the image includes the impression and findings only. Following standard procedure [37], images are normalized and resized to 224 × 224, making them appropriate for extracting visual features. The text data was pre-processed to produce 572 unique tags and 1915 unique words by changing all tokens to lowercase and deleting any non-alpha tokens. On average, there are 2.2 tags, 5.7 sentences, and 6.5 words per sentence attached to each image. Additionally, we discovered that the top 1000 terms account for 99.0% of all word occurrences in the dataset; as a result, we only used the top 1000 terms listed in dictionaries. Finally, we chose 500 images at random for validation and 500 images as a test. Further, to validate the effectiveness of the proposed Dr^2T we evaluated BLUE-n [38], METEOR [39], CIDEr [40], and ROUGE-L [41] scores.

4.1 Implementation details

For the first phase of the experiment, the input images are resized into 480 × 480 resolution and Adam [42] optimizer is used for training of $C-TaXNet$ and texture feature extraction module. The feature extraction FDT module is trained for 100 epochs with a learning rate of $10e-4$ and batch size of 32. For second phase, the Dr^2T model is trained for further 70 epochs with a learning rate of $1e-4$ for the encoder and decoder. We apply a linear decay scheduler with a warmup ratio of 0.01 to control the learning rate. For regularization, we set dropout to 0.1 and use a weight decay of 0.01. For the generation of paragraph, we set the dimensions of all hidden states and word embeddings as 512 and the maximum output length is set as 45. For both FDT and Dr^2T modules, we adopt a softmax cross-entropy loss.

Table 1 Comparison of the performance of the proposed $C-TaXNet$ and other Deep-feature Extraction Framework

Model	Accuracy (%)	Loss
ResNet [28]	89.64	3.547
VGGNet [43]	90.32	3.10
AlexNet [44]	89.10	3.09
Inception-V3 [45]	94.35	2.341
DenseNet [46]	94.13	2.61
XceptionNet [24]	96.80	1.928
Proposed ($C-TaXNet$)	98.74	1.29

4.2 Quantitate comparison with state-of-the-art

For the deep-feature extraction module, the proposed $C-TaXNet$ is compared with different generic networks (ResNet, VGGNet, Inception-V3, and XceptionNet) in terms of accuracy and loss. Table 1 presents the results obtained for the proposed $C-TaXNet$, it is evident that the proposed network provides significant improvements in terms of accuracy with the addition of triple attention module. Also, Fig. 8 presents the attention maps generated from the proposed $C-TaXNet$. The proposed model attends to the input image efficiently by highlighting the minute image regions that are of importance.

Table 2 presents the dimension of extracted features and feature extraction speed for the proposed ISCM-LBP + HOG-PCA algorithm. From Table 2 it is evident that with the improvement in speed of feature extraction a reduction in data redundancy is observed. The results prove that more accurate image features with strong anti-interference capabilities and minimal computing complexity are extracted by the ISCM-LBP approach. Additionally, PCA-HOG extracts the image edge features and ensures that, even at accelerated extraction speeds, the feature dimension is successfully lowered without compromising the edge features that have already been retrieved. With serial fusion of ISCM-LBP and HOG-PCA relatively complete image features with edge and

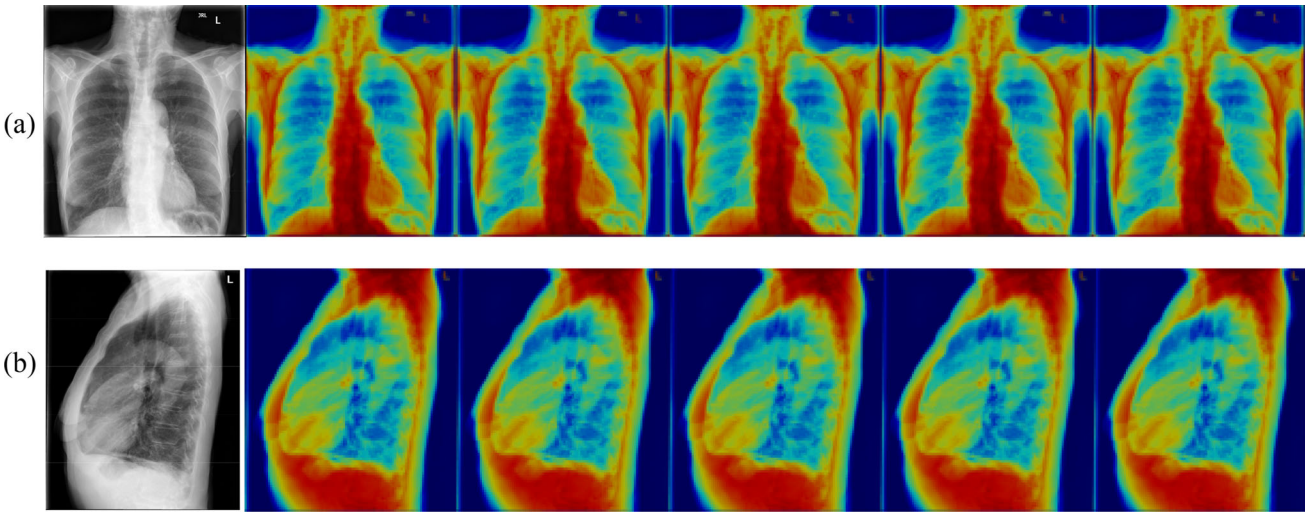

Fig.8 Attention visualization generated by the proposed $C-TaXNet$

Table 2 Comparison of the performance of different texture feature extraction algorithms

Method	Feature dimension	Feature extraction time (s)
LBP	1982	0.0121
ISCM-LBP	2770	0.0068
HOG	3221	0.0039
HOG-PCA	1026	0.0070
ISCM-LBP + HOG-PCA	2951	0.0105

texture features are obtained. Figures 9 and 10 compares different texture feature extraction algorithms on the basis of the feature dimension and time taken (s) for the extraction of features.

Table 3 reports the quantitative results obtained on the proposed FDT-DMICT. We compare our proposed approach with a wide range of state-of-the-art medical report generation methods, i.e., Variational topic inference (VTI) [37], a graph-based method [47], cross-modal memory (CMR) [48], CMAS [18], Eddie-Transformer [49], DeltaNet [50], IIHT [51], PPKED [52], Co-Att [2], RTMIC [53]. From the results reported it is evident that the $FDT-Dr^2T$ framework outperforms the recent LXMERT [54], ITHN [55], CMCA [56], ORGAN [57] state-of-the-art as well by a large margin across all evaluation metrics. Furthermore, the proposed work outperforms different hierarchical-based approaches [7, 8, 18, 20]. The proposed FDT – Dr^{2}T reports abnormalities by detecting opacity by observing the contrast, detecting hyperexpanded lungs by determining the change in size, and identifying the location of airspace disease.

4.3 Qualitative results for the proposed $FDT-Dr^2T$

Figure 11 presents the reports generated by the proposed $FDT-Dr^2T$. The figure describes the report generated corresponding to the input image and the ground truth. From the qualitative results portrayed in Fig. 11, we can infer that the proposed $FDT-Dr^2T$ framework is better at capturing abnormalities. For the third image, our framework easily detects and reports "T-spine osteophytes in the thoracic

vertebrae". Therefore, the proposed framework has a remarkable ability to accurately generate comprehensive reports for abnormal cases. Further, with this, the proposed framework provides accurate locations of the abnormalities with a well balance of normal sentences and abnormal sentences. Also, we can infer from these results that the $FDT - Dr^2T$ can efficiently alleviate the visual data deviation problem by efficiently detecting changes in the contrast, size, and disease location, which helps in the coherent generation of medical reports. Further, there were very few cases observed where the proposed framework does not generate descriptions as per the grammar rules like in Fig. 11, the generated sentence is "Pneumothorax effusion not seen".

4.4 Ablation studies

An ablation study is conducted which exhibits the effect different modules for the efficient generation of paragraph-based medical reports. This study effectively highlights the influence of baseline Transformer and Dr^2T. This study also helps to gain a better understanding of the overall behavior of the ablated models on the performance of the system. Table 4 reports the results obtained for different models i.e., (M-1 to M-6), and Fig. 12 provides the qualitative results obtained for all the ablated models. We start with the baseline transformer model [56] with Inception-V3 and LBP + HOG features for the FDT module (M-1). The results obtained with M-1 do not provide significant results. In second model i.e., M-2, we replace Inception-V3 with XceptionNet, a slight improvement is observed in B-1, B-2, METEOR, and ROUGE-L scores. Further, in M-3, the baseline transformer model is replaced with the proposed Dr^2T, and significant qualitative and quantitative results are obtained in comparison with M-1 and M-2. With baseline transformer and XceptionNet with ISCM-LBP + HOG-PCA deep and texture features module (M-4), there is no significant improvement observed with respect to M-3 in the evaluation scores. Therefore, to improve the qualitative and quantitative results we exploited the proposed $C - TaXNet$ for deep-image feature extraction with ISCM-LBP + HOG-PCA and baseline transformer i.e., M-5. To further obtain coherent medical reports with correct abnormalities we employed the proposed FDT module ($C - TaXNet$ and ISCM-LBP + HOG-PCA) and the proposed Dr^2T transformer. M-6 provides better correlations for higher-order feature representations from medical images and generates coherent reports with rare and important abnormalities.

The qualitative results obtained for different models makes it evident that a coherent report is generated with the use of proposed $FDT - Dr^2T$ highlighting the abnormalities in the report generated. Furthermore, Fig. 13 presents the influence of the proposed Dr^2T and the baseline transformer on the with respect to evaluation parameters.

5 Conclusion

This paper an efficient two-stage framework, $FDT - Dr^2T$ for generation of dense and coherent radiology or medical reports. This model efficiently learns image features from the first stage to select the highest scoring head from the structure and concatenates best-head and the multi-head representations.

to explore more correlations and provide better higher-order feature representations. Also, the proposed framework is able to detect changes in the contrast, size, and disease location of medical images which help in the coherent generation of medical reports. Furthermore, the proposed $FDT - Dr^2T$ framework imitates the working patterns of radiologists by highlighting the specific crucial abnormalities in reports.

The effectiveness of the proposed framework is analyzed on the IU-Chest X-ray dataset and provided state-of-the-art results in terms of $BLEU@N$, $METEOR$, $CIDEr$, $ROUGE-L$ evaluation metrics. To support the experimental analysis an ablation study is also carried out that exhibits the effect of different feature representation methods and generates medical reports using the baseline transformer and the proposed Dr^2T. Further, there were very few cases (around 2–3%) observed where the proposed framework does not generate descriptions to the extent expected. These cases generated sentences with missing words and some grammatical errors. This could be alleviated by utilizing fused character or word embedding models or by incorporating attention-based embedding models.

In future, the proposed framework can be utilized for other fatal diseased parts like breast and brain, etc. subject to the availability of their captioning datasets. Also, the proposed model can be utilized for the generation of radiology reports for 3D imaging data i.e. brain MRI dataset. We can incorporate different modalities of medical images for the generation of more detailed radiology reports. Furthermore, explainable AI solutions paired with examination by qualified physicians appear to be quite useful in understanding the outcomes of complex deep learning models and facilitating the evaluation process.

Feature Aggregation with Latent Generative Replay for Federated Continual Learning of Socially Appropriate Robot Behaviours

Nikhil Churamani[1,*], Saksham Checker[2], Hao-Tien Lewis Chiang[3], and Hatice Gunes[1]

***Abstract*— For widespread real-world applications, it is beneficial for robots to explore Federated Learning (FL) settings where several robots, deployed in parallel, can learn independently while also sharing their learning with each other. This work explores a simulated living room environment where robots need to learn the social appropriateness of their actions. We propose Federated Root (FedRoot), a novel weight aggregation strategy which disentangles feature learning across clients from individual task-based learning. Adapting popular FL strategies to use FedRoot instead, we present a novel FL benchmark for learning the social appropriateness of different robot actions in diverse social configurations. FedRoot-based methods offer competitive performance compared to others while offering sizeable (up to 86% for CPU usage and up to 72% for GPU usage) reduction in resource consumption. Furthermore, real-world interactions require social robots to dynamically adapt to changing environmental and task settings. To facilitate this, we propose Federated Latent Generative Replay (FedLGR), a novel Federated Continual Learning (FCL) strategy that uses FedRoot-based weight aggregation and embeds each client with a *generator* model for pseudo-rehearsal of learnt feature embeddings to mitigate forgetting in a resource-efficient manner. Our benchmark results demonstrate that FedRoot-based FCL methods outperform other methods while also offering sizeable (up to 84% for CPU usage and up to 92% for GPU usage) reduction in resource consumption, with FedLGR providing the best results across evaluations.**

I. Introduction

As advances in Artificial Intelligence (AI) gear social robots towards a ubiquitous application, they are expected to be deployed across environmental and contextual settings, interacting with several users at a time and learning different tasks [1]. Each robot, operating in its unique application settings, should be able to adapt to the dynamics of its ever-changing environment while also being sensitive to the changing preferences of the users it interacts with [2]. Such an understanding of social dynamics and norms [3] can help robots effectively navigate complex social settings while also offering enriching interaction experiences to their users. Moreover, given the vast array of potential applications [4], robots can benefit from sharing knowledge and individual experiences with one another. Under such complex and diverse application settings, there is a need to move beyond centralised platforms towards more *distributed learning paradigms*, enabling robots to keep learning *continually* while also sharing their learning with others.

Moving beyond *centralised* learning paradigms, where individual robots only gather data and send it to a central server to be aggregated and used to train a single global model for application, Federated Learning (FL) [5] (see Fig. 1; left) offers an efficient *distributed learning* paradigm where individual robots can learn *independently* from their own *unique experiences*, updating their learning models using only the data collected by them *locally*. Over time, these local updates can be *aggregated* across the centralised server, in the form of model updates that can inform training the unified global model. FL allows for a *privacy-preserving learning paradigm* where local data is never shared with a centralised server. FL solutions have been used popularly in embedded or EdgeAI devices [6] that benefit from *distributed* learning settings [7] gathering and processing their own data but sharing their learning towards training a global aggregated model [8]. More recently, FL has been explored for robotic and autonomous systems [1], [9] allowing for collaborative learning across robots, learning from each others' experience while maintaining end-user privacy.

Another challenge faced by social robots operating in dynamic human-centred environments is to effectively discern novel information from past experiences and adapt their learning models to accommodate this new knowledge [10]. As the real-world is not static and changes dynamically [11], each individual robot may learn with incremental and/or sequential streams of data where data is not *independent and identically distributed* (i.i.d). This may result in the robot forgetting past knowledge, overfitting to the current task or data. Even though FL allows for model aggregation across client robots, such forgetting locally will cause the globally aggregated model to also forget past knowledge. Continual Learning (CL) [11] can help address this problem by enabling individual robots to adapt their learning with incrementally acquired data from non-stationary or changing environments [2]. This allows robots to accumulate new information locally while preserving previously seen knowledge. Combining the principles of FL and CL, Federated Continual Learning (FCL) [1], [12] (see Fig. 1; right) allows for individual robots, learning incrementally in their unique settings, to also benefit from other robots' learning. Each robot periodically sends only their model parameters to the centralised server where the knowledge from all agents is aggregated into a unified model which is sent back.

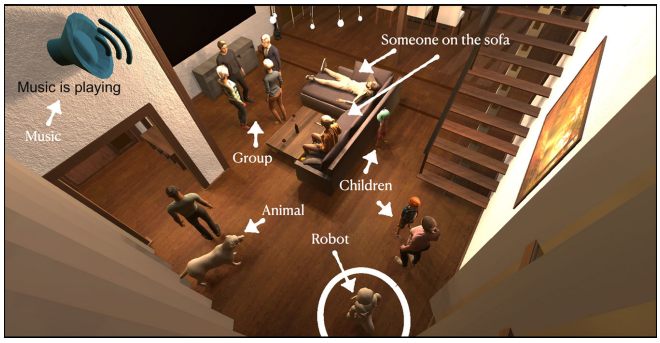

Fig. 2: MANNERS-DB: A Living Room scenario with a robot [13].

In this paper, we explore a simulated home environment with humans and animals where the robot is required to learn the social appropriateness of different tasks. We explore the MANNERS-DB dataset [13] as it has been used previously for CL-based [13] and zero-shot learning [14]. MANNERS-DB provides social-appropriateness ratings for different high-level robot actions in simulated living room settings (see Fig. 2), where the robot learns these actions in different social configurations. To simulate several robots deployed in parallel under similar living room settings, the dataset (training data) is split evenly across these robots (clients), with a shared test-set. We extend our preliminary work [15] benchmarking FL and FCL on the MANNERS-DB using the predefined $29-$d scene descriptor vectors to learning end-to-end, directly from scene renders. We propose Federated Root (FedRoot) averaging, a novel FL strategy which disentangles feature-based learning across clients from individual task-based learning. Under FedRoot, only the feature extraction layers are aggregated between *clients* however task-based learning is kept *strictly local* enhancing the resource-efficiency and privacy for FL. Adapting popular FL strategies to use FedRoot instead, we present a novel FL benchmark for learning the social appropriateness of different robot actions in diverse social configurations. Extending FedRoot to FCL settings, we propose Federated Latent Generative Replay (FedLGR), a novel FCL strategy that combines FedRoot with LGR [16] by adding a local generator model to the client for efficient pseudo-rehearsal of learnt features in order to mitigate forgetting. For successive tasks, pseudo-samples of previously seen tasks are generated and mixed with the current task's data to simulate *i.i.d* data settings. We benchmark FedLGR against popular CL adaptations of FL strategies, with and without FedRoot-based aggregation, on their ability to learn socially appropriate robot behaviours in a task-incremental manner. Both FedRoot and FedLGR reduce the memory and resource footprint of their FL and FCL counterparts, without compromising model performance.

II. Related Work

A. Socially Appropriate Robot Behaviours

Human interactions are governed by different social norms laying out expected behaviours from individuals which may be considered socially appropriate by others [17]. For social robots operating in human-centred environments, where interaction contexts and individual user preferences can vary widely, these robots must be able to comprehend and respond to the unique dynamics of each contextual setting [18]. This not only enhances their ability to navigate complex social situations but also improves the users' impressions of the robots and their acceptance in social Human-Robot Interaction (HRI) [19]. Furthermore, social robots need to *continually* learn from their interactions and adjust their behaviours accordingly [20]. Whether it is effectively navigating complex social environments [21], learning approach and positioning behaviours [22], [23] or learning task-specific behaviours [13], it is essential for robots to consider the social-appropriateness of their behaviours in order to comply with social norms [3]. With distributed deployment increasingly becoming a reality, there is a need to investigate *federated* application frameworks that allow robots to learn in their own unique environments while also informing a global learning of *generalisable* social norms and preferences [1]. This works aims to move in this direction in a more resource-efficient and privacy preserving manner.

B. Federated Learning

Distributed learning settings can be particularly desirable for social robots, to understand and learn socially appropriate behaviours, depending upon the context of the interaction, environmental factors as well as individual user preferences [1]. Federated Learning (FL) [5] enables a network of distributed client devices (such as robots) to

learn individually with locally gathered data while updating their model parameters towards aggregating a global learning model (server) that combines these updates from each individual device, over successive update rounds, and distributes this model back to individual clients. This way, each client shares their knowledge with the other clients, without sharing any local data, and gets updated with global model which combines the knowledge from other clients. Strategies such as Federated Averaging (FedAvg) [8] offer a straightforward approach for weight aggregation by collating individual client model weights and computing a weighted average in the form of the global model. However, FedAvg is sensitive to data imbalances and concepts drift challenges, especially in non-i.i.d data settings. Several improvements have been proposed on FedAvg, for instance, FedBN [24] that adapts FedAvg by keeping the parameters for all the *BatchNorm* layers 'strictly local', that is, all other model weights are aggregated across clients apart from the *BatchNorm* parameters. Similar to FedBN, FedProx [25] also proposes improvements over FedAvg by allowing for only partial aggregation of weights by adding and tracking a *proximal term* to FedAvg. FedOpt [26] offers a 'general optimisation framework' where each client uses a *client optimiser* to optimise on local data while the server updates apply a gradient-based *server optimiser* to the aggregated model weights. FedDistill [27], on the other hand, aims to improve the ability of the clients to deal with *heterogeneous* data conditions by using *knowledge distillation* [28]. Each client maintains two models: (i) a local copy of the global model and (ii) a personalised model that acts as a teacher to the student global model. The updated student model is then aggregated across clients. In this work, we adapt these methods for a regression-based task, learning to predict the social appropriateness of different robot actions.

C. Federated Continual Learning

As robots in real-world settings continually encounter novel information, under non-i.i.d conditions, their ability to remember previously learnt tasks may progressively deteriorate, resulting in forgetting [29]. Continual Learning (CL) [11], [30] strategies may enable robots to learn and adapt throughout their 'lifetime', balancing *incremental* learning of novel information with the retention of past knowledge. Federated Continual Learning (FCL) [12] combines FL and CL principles, enabling individual robots to *incrementally* learn *without forgetting* on streams of gathered data. Individual robots learn a series of local tasks while periodically updating the parameters of a global *aggregated* model that combines updates from individual clients, over successive update rounds. Several recent works [12] explore FCL for vision [31] and natural language processing [32] applications, however very little work has been done to explore its application for social robots [1]. Adapting FL approaches by adding CL-based objectives can offer straightforward solutions for FCL. For instance, regularisation-based methods such as Elastic Weight Consolidation (EWC) [33], EWCOnline [34], Synaptic Intelligence (SI) [35] or Memory Aware Synapses (MAS) [36] can be used to apply penalties on weight updates between old and new tasks to help mitigate forgetting. Rehearsal strategies such as Naive Rehearsal (NR) [37] can be used to maintain local memory buffers for each robot to store and rehearse previously seen data to preserve knowledge. Alternatively, an efficient pseudo-rehearsal of data [38] or features [16] can help mitigate forgetting by maintaining generators that model local data distributions for previously seen tasks. In this work, we augment FL with regularisation-based CL objectives for multi-label regression, predicting social appropriateness of the different robot actions under different contextual settings.

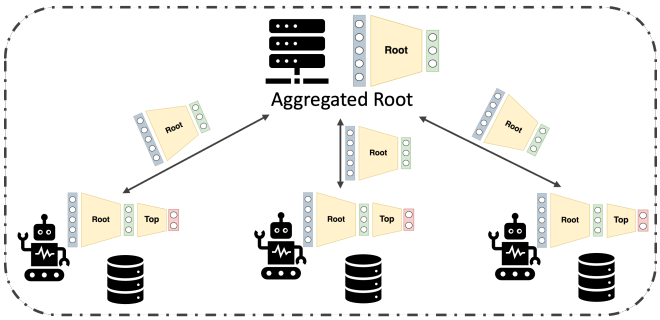

Fig. 3: **Federated Root (FedRoot)**: Local model split into (i) *Root* for feature extraction and (ii) *Top* for task-based learning. Only model *Root* is aggregated across clients while *Top* remains local.

III. Methodology

A. FedRoot: Federated Root for Feature Aggregation

With several robotic clients, deployed in parallel, FL ensures end-user privacy as data remains *strictly local* for each client and is never shared with others. Yet, as the learning models, both in terms of learnt features as well as task-based learning layers are shared with the server, there might still be 'information/data leak' [39] that may reveal how end-users interact with individual robots. Furthermore, as the robots may be equipped with Deep Neural Network (DNN)-based learning models that process high-dimensional input data, aggregating individual model weights into a global model can be computationally expensive [40]. To address the above-mentioned challenges, we propose Federated Root (FedRoot) (see Fig. 3) as a novel model aggregation FL strategy that splits client learning models into two modules:

1) Root (R): The *Root* constitutes the feature extraction layers of the learning model. For example, for Convolutional Neural Network (CNN)-based learning models, as implemented in this work, the *Conv* layers would constitute the *root* of the model that learn meaningful and relevant features from input images. For robots operating in home scenarios, as discussed here, the *root* learns efficient and descriptive scene embeddings that can help summarise each scene.

2) Top (T): The *Top* of the model, on the other hand, constitutes the task-based learning (classification or regression) Fully Connected (FC) layers. Using the *Root*-extracted features, the *top* of the model is used for task-based predictions, for example, learning to predict the social appropriateness of different robot actions.

Splitting model learning into two parts allows for robots to effectively share their learning with other clients while also protecting end-user privacy. The model is trained in an end-to-end manner, however, only the *root*, that is, the feature extraction layers, from individual client models gets aggregated across clients, over repeated aggregation rounds. This allows for the clients to improve their feature-embeddings, making them more robust, benefiting from the diversity of data settings experienced by each individual client. Yet, client-specific data as well as the task-based learning from the data, for instance end-user preferences on social appropriateness of individual robot behaviours, is kept 'strictly local'. Since FedRoot is proposed as a weight aggregation strategy, we adapt popular FL approaches (see Section II-B) to use FedRoot instead.

B. FedLGR: Federated Latent Generative Replay

Real-world application adds another complexity for robotic clients with respect to *incremental learning* where they are exposed to information in an incremental manner and have to constantly learn new tasks while preserving past knowledge [2], [29]. While replay-based CL may provide a straightforward approach for remembering past information by storing and periodically *replaying* past data [37], this may not always be possible due to memory constraints or privacy and compliance reasons. *Pseudo-rehearsal* approaches such as Deep Generative Replay (DGR) [41], on the other hand, use probabilistic or generative models that learn the inherent data statistics of previously seen data and draw *pseudo-samples* as and when needed, to be replayed to the model. These generative models, however, become hard to train as the number of tasks increases as the generator needs to learn to reconstruct high-quality discriminative pseudo-samples, adding a significant computational expense to the model. Generative feature rehearsal approaches such as Latent Generative Replay (LGR) [16] offer resource-efficient pseudo-rehearsal strategies that combine the benefits of DGR [41], with using low-dimensional latent features [42].

Under FCL learning settings clients not only need to incrementally learn on the acquired 'local data' ensuring they do not forget past knowledge, they also need to aggregate this learning in a centralised global model. To achieve this, we propose Federated Latent Generative Replay (FedLGR) (see Fig. 4) as a novel FCL strategy that applies LGR-based pseudo-rehearsal [16] under *federated learning* settings making use of FedRoot-based weight aggregation.

FedLGR uses a *scholar*-based architecture [16] that consists of three modules: (i) a *Root* to extract latent feature representations, (ii) a *Top* to learn task-discriminative information, and (iii) a *Generator* to reconstruct and rehearse *latent features*. Under FedLGR, each client locally uses LGR to *continually* and *incrementally* learn the social appropriateness of robot actions under different contextual settings. This learning is then shared with other clients by aggregating *Root* weights using FedRoot. At each time-step, the learning for each client *locally* consists of the following steps:

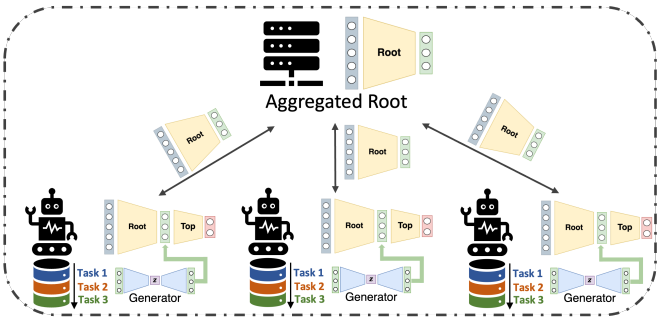

Fig. 4: **Federated Latent Generative Replay (FedLGR)**: Local model split into (i) *Root* for feature extraction, (ii) *Top* for task-based learning and (iii) *Generator* for *pseudo-rehearsal* of features. Only *Root* is aggregated across clients while *Top* and *Generator* remain local.

1) The *root* and *top* for the *scholar* are updated with the current task's data, however at different learning rates. While the *top* is trained rapidly to learn task-discriminative information, the *root* is updated *slowly* ensuring the new data does not completely *overwrite* previously seen information. This is an important step as LGR [16] is based on the assumption that if the latent-space distribution of *root*-extracted features remains relatively static between model updates, the extracted features can be effectively used to rehearse past knowledge [42].
2) For training the *generator*, the *Root*-extracted feature representations ($R(x)$) for the current task's data (x) are interleaved with *generated* features (R'_x) for all previously seen tasks. Training the *generator* on both $R(x)$ and R'_x (only $R(x)$ is used for Task 1) ensures that the updated *generator* encodes both new and old tasks. R'_x is passed to the *top* to obtain labels $T(R'_x)$.
3) Once the *generator* is updated, the *top* of the *solver* is updated using the current task data $\langle R(x), y \rangle$, interleaved with labelled *latent pseudo-samples* $\langle R'_x, T(R'_x) \rangle$ generated for previously seen tasks. The *root* is then updated *slowly* using only current task's data.

Training on each task consists of several rounds of weight aggregations, where FedRoot is used to aggregate *root* module weights across clients. The *top* and the *generator* for each client are kept 'strictly local' ensuring task-discriminative information is never shared.

IV. Experiments

A. MANNERS-DB Dataset

For our proof-of-concept evaluations on FL and FCL for learning socially appropriate robot behaviours, we explore the MANNERS-DB dataset [13] that consists of Unity-generated scenes of the Pepper robot co-inhabiting a living room (see Figure 2) with other humans and animals under different social settings. MANNERS-DB has been explored for CL-based [13] and zero-shot [14] learning, however, not for FCL. For each scene, the robot can perform 8 different actions, that is, *vacuuming, mopping, carrying warm food, carrying cold food, carrying big objects, carrying small objects, carrying drinks and cleaning/starting conversations*

either *within a circle of influence* or in the *direction of operation* (see Figure 2). Crowd-sourced annotations are provided for the social appropriateness of each of these actions for every scene ($\approx$ 1000 scenes), labelled on a 5-point Likert scale, ranging from *very inappropriate* to *very appropriate*. For both FL and FCL evaluations, the data is split into training and test splits in the ratio of $3:1$. The training data is further split amongst the different clients (2 or 10) with a shared test-set used for evaluation. For FCL evaluations, the training set of individual clients is further split into two tasks, that is, samples depicting the robot operating with an circle (**Task 1**) and in the direction of the arrow (**Task 2**). For training the models, *normalised* RGB images are used, resized to $(128\times128\times3)$ due computational restrictions of training multiple clients in parallel on GPU. Since MANNERS-DB is a relatively small dataset consisting of $\approx$ 1000 images, we evaluate the different approaches both *without* and *with* data-augmentation. We use random ($p = 0.5$) horizontal flipping and random ($p = 0.5$) rotation (up to $10°$) in either direction to augment the dataset. For a fair comparison, results are presented individually for *without* and *with* augmentation comparisons.

B. Implementation Details

For each approach, a Convolutional Neural Network (CNN)-based model is used consisting of two parts: (i) a *Conv* module that uses the popularly used MobileNet-V2 [43] backbone to extract scene features, followed by an *AdaptiveAvgPool* layer for dimensionality reduction, and (ii) an *FC* module where the $1280-$d *flattened* scene features are passed through a FC layer consisting of 32 units followed by the $8-$unit output layer. Each layer in the *FC* module is followed by *BatchNorm* layer and uses a *linear* activation with the output layer predicting the *social appropriateness* of all 8 robot actions. All models are trained using the *Adam* optimiser (β_1=0.9, β_2=0.999) with *learning rate* of lr=$1e^{-}3$. All methods are implemented using the *Flower*[1] and PyTorch Python libraries. The FL and FCL experiments are run for $2-10$ clients, attuned to a potential real-world evaluation to be conducted in the future using physical robots. For brevity, results for only 2 and 10 clients are presented. Model hyper-parameters such as the regularisation coefficients for FCL approaches are optimised using a grid-search. For without augmentation experiments, the *BatchSize* is empirically set to 16 for *two clients* and 8 for *ten clients* due to the overall low number of samples per client. When using with augmentation, *BatchSize* is set to 16. All models are trained using an Mean Squared Error (MSE) loss, computed as an average across the 8 actions. Each client agent trains on its own split of the training data but a shared test-set is used for model evaluation. We report the average MSE loss averaged across the 8 actions and all clients.

C. Evaluation Metrics

Predicting the social-appropriateness for each robot action requires transforming FL and FCL methods to use regression-based objectives, using the following metrics:

- *Root Mean Squared Error (RMSE):* We report the RMSE values which are calculated for the test-set, averaged across the 8 actions across all clients. RMSE scores are used to compare our results with the baseline provided with the MANNERS-DB dataset [13].
- *Pearson's Correlation Coefficient (PCC):* In addition to an absolute metric such as the RMSE, we also evaluate the predicted social appropriateness values relative to the ground-truth using the PCC [44] scores. PCC scores are calculated on the test-set individually for each of the 8 actions, for each client. Average scores across all actions and all clients are reported.
- *CPU Usage (s):* To evaluate the resource efficiency of FL and FCL approaches, CPU usage is reported as the CPU time (in seconds) allocated to training each client, on average. This is calculated as the CPU time utilised by each client, across all rounds of weight aggregation.
- *GPU Usage (%):* Similar to CPU usage, GPU usage is also important to evaluate the resource efficiency of the proposed methods. Since we have a single GPU simulation set-up, we report the percentage (%) of the GPU allocated per client, on average. GPU usage is also calculated using Nvidia's `nvidia-smi` tool, logged at different intervals during the training process, and *averaged* over the entire training time for each client.

both without and with data augmentation, respectively. For without data augmentation experiments with *two* and *ten clients* FedOpt and FedProx emerge as the best performing approaches, on average. The 'general optimisation framework' of FedOpt, with *Adam*-based client and server optimisers are able to efficiently aggregate learning across clients, resulting in the robust performance of the model. FedProx, on the other hand, adds a proximal term $\mu = 0.1$ (similar to [25]) to FedAvg and updates the objective for each client to minimise $F_k(\omega) + \frac{\mu}{2}||\omega - \omega^t||^2$ where F_k is the loss, ω are the local model weights to optimise and ω^t are the global parameters at time-step t. For the proposed FedRoot variants of the compared FL approaches, as task-discriminative *top* weights are kept *strictly local*, we see an overall drop in model performance. This is primarily due to the small size of the MANNERS-DB dataset which does have enough data samples for the FedRoot to optimise model performance, given only feature extracting *root* is aggregated. However, FedRoot offers *sizeable reduction* in CPU and GPU Usage per client, per aggregation round, compared to the original methods, as can be seen in Table II.

Data augmentation has a net positive impact on all models with all approaches reporting better metrics, across evaluations. With the larger amount of data available per client, we see that FedRoot-based methods improve upon their counterparts across all metrics, for the experiments with *two clients*. Similar to without augmentation experiments, using *Adam*-based client and server optimisation as well as adding a proximal term to the model learning objective results in the best performance, however here for FedRootOpt and FedRootProx, respectively. Data available per client still remains relatively low when split across *ten clients*, even when using data augmentation. Thus, despite an overall improvement compared to without augmentation results FedRoot-based approaches are still not able to match the performance of FedProx and FedOpt for *ten clients*, despite offering high resource-efficiency.

B. Federated Continual Learning Benchmark

Table IV presents the FCL results on the MANNERS-DB dataset adapting FedAvg and FedRoot-based weight aggregation strategies to use CL-based learning objectives to mitigate forgetting under incremental settings. Evaluation metrics are reported after training and testing on the data-split depicting the robot operating *within the circle of influence* **(Task 1)** and training on the data-split depicting the robot *in the direction of operation* **(Task 2)** and testing on both the splits. Similar to the FL benchmark, we compare the different FCL strategies for *two* and *ten* clients as well as without and with data augmentation. As *federated averaging* of weights struggles with learning under non-i.i.d data settings [24], extending these methods with CL-based objectives allows us to evaluate how they can objectively contribute towards maintaining model performance when learning *incrementally*.

Our results demonstrate that FedRoot-based approaches are able to outperform their FedAvg-based counterparts across most evaluations. However, similar to FL evaluations, FedRoot-based methods struggle in the scarcity of data, for instance the evaluations across *ten* clients without data augmentation, resulting in much worse loss and RMSE scores. Data augmentation has a net positive impact on model performances, especially for FedRoot-based methods. Furthermore, using FedRoot-based weight aggregation results in a sizeable (up to *84%* for CPU usage and *92%* for GPU usage) reduction in computational expense of running these methods, per client, per aggregation round (see Table III). This can be particularly beneficial for application in resource-constrained devices such as social robots. The proposed FedLGR approach performs the best across all evaluations. This is especially true when data is scarce, that is learning without using data augmentation across *two* and *ten* clients. FedLGR is able to efficiently use pseudo-rehearsal of features to maintain model performance after learning Task 2.

VI. Discussion and Conclusion

Social robots operating in dynamic real-world settings can benefit from federated learning mechanisms where, learning from and adapting towards their unique environmental and data conditions, they can also share their learning with other robots, benefiting from each others' experiences. FL-based approaches enable such a learning paradigm for robots to aggregate model updates across individual agents into a global model, while ensuring that end-user privacy is preserved. However, the resource constraints inhibit such learning settings resulting in most existing methods opting for *centralised* learning, where end-user devices only collect data for a centralised model to be trained, in isolation, for later application *in-the-wild*. The proposed Federated Root (FedRoot) weight aggregation strategy aims to address this very challenge by splitting each client's learning model into

TABLE IV: Federated Continual Learning Results for the MANNERS-DB Dataset for Two (left) and Ten (Right) Clients. **Bold** values denote best while [bracketed] denote second-best values.

aggregatable feature extraction layers, that is, model *root* and *private* task-relevant *top* layers that learn to predict the social appropriateness of different robot actions. The FL benchmark results (see Table I and Table II) highlight the competitive performance of FedRoot-based approaches with sizeable reductions in CPU and GPU usage for each client.

Furthermore, real-world applications may require robots to learn incrementally, for instance, in the form of developing novel capabilities or applying existing capabilities under novel contextual settings. In this work, we explore the latter where robots need to learn the social appropriateness of different actions depending upon the context in which they are operating, that is, operating *within the circle of influence* or *in a particular direction of operation*. We adapt the proposed FedRootAvg weight aggregation strategy and extend it by adapting popular CL-based learning objectives presenting a novel FCL benchmark on the MANNERS-DB dataset (see Table IV and Table III). In particular, the proposed Federated Latent Generative Replay (FedLGR) approach is seen to outperform other methods across all evaluations. It implements a local *generator* for efficient pseudo-rehearsal of latent features for mitigating forgetting, where the *top* learns task-relevant information. Our work contributes significantly to the fields of Federated Learning and robotics, offering promising avenues for the development of socially intelligent machines capable of learning and adapting in a decentralized and resource-efficient manner.

A. Limitations and Future Work

We present novel FL and FCL benchmarks for learning social appropriateness of high-level robot behaviours in simulated home settings. With our motivating results, we wish to conduct a user study with $2+$ robots operating in different living room settings, sharing their knowledge with each other. However, MANNERS-DB is a relatively small dataset which limits our evaluations into the generalisability of proposed approaches across a large number of clients. In future, we wish to expand the MANNERS-DB dataset to include more scenes as well as different robot embodiments such as Pepper, Nao, PR2 robots, and points-of-view (PoVs) (robot-centric and scene-centric) to extend our evaluations (both FL and FCL), under simulation, to $100+$ clients. This would result in a more generalisable evaluation for large-scale *federated* application for robots in diverse real-world settings. Additionally. it will be beneficial to explore further the scalability of FedRoot and FedLGR in more complex or dynamic environments, especially when data is scarce and data acquisition is complicated, as well as their applicability to a broader range of tasks beyond social appropriateness.

Abstract. This paper describes a novel method to design a saturated controller for a singularly perturbed systems (SPS). These systems frequently exhibit complexity and uncertainty that may have negative impacts on the performance. Further, the SPS are characterised by a substantial time scale difference between fast and slow dynamics. In order to overcome these difficulties, the singular perturbation approach is used to design a nonlinear saturated controller which has a filter and disturbance observer. A strategical approach is presented based on contraction theory to achieve convergence of all closed-loop states of the system. For the analysis and design of these systems, contraction theory offers a rigorous mathematical framework that ensures system trajectories will converge even in the presence of singular perturbation and uncertainties. The suggested approach is validate on pitch angle control of the Twin Rotor MIMO System (TRMS) to replicate the real time situations.

Keywords. Saturated control; singular perturbation; disturbance observer; contraction theory; pitch angle control.

1. Introduction

In the context of control systems,"saturated control"refers to a condition in which a system's control input or output is confined to remain within particular limitations or constraints. This might be due to physical constraints of actuators, safety concerns, or to prevent the system from responding in an unpleasant manner when control signals approach extreme values. When a system is in a saturated mode, the control signal is"clamped"or"limited"to a specific range. This has serious consequences for the system's behaviour and performance. A critical part of control system design is taking actuator constraints into account. Ignoring these boundaries may result poor performance and instability. In [1] a robust saturated controller has been designed for the attitude tracking under bounded disturbances. In this brief a saturated nonlinear controller has been designed for the pitch angle tracking control of TRMS.

Singular perturbation modelling is a method for describing the behaviour of large physical systems composed of multiple slow and rapid subsystems working on different time scales. In singularly perturbed (SP) model the derivative of some states are multiplied by a small parameter which describe the fast and slow phenomena of the system [2]. Slow and fast subsystems of two dynamical systems are connected to form a two-time scale singularly perturbed system [3]. Stochastic filtering, Model order reduction, composite control, optimal control etc utilise singularly perturbed systems [4, 5]. When the perturbation parameter is zero, a singularly perturbed system has a single root for the fast subsystem. Such systems are sometimes referred to as standard models. In contrast, fast systems have several roots or none at all in nonstandard models [6, 7]. Traditionally, controller design and stability analysis for singularly perturbed systems have been successfully accomplished using the quadratic Lyapunov function [8, 9]. To do this, the perturbation parameter is set to zero and the entire system is divided into two reduced-order models. Each reduced system's stability is examined by choosing two suitable quadratic Lyapunov functions. The convex sum of these two functions are called as Composite Lyapunov Function, is then employed to ensure system stability. Depending on the connectivity criteria met by the Lyapunov functions, the resultant stability boundaries are valid for a specific range of the perturbation parameter [10]. Many issues with the well-known SP system have been resolved: composit control design (State and Output feedback), LQG control etc [11–13].

Many physical systems are influenced by unpredictable and unavoidable environmental impacts, which are referred to as external disturbances and may also change the control variables. Therefore, the need of observers are prerequisite to reduce the impact of external disturbances. Due to presence of environmental disturbances, approximation etc the mathematical model of dynamical systems involve uncertainties. That is why it is necessary to model these uncertainties as ($\delta = 10^3 * tanh(2t)$) while designing a controller. There are many way to eliminate these uncertainties. One of the best method is to estimate the disturbances variables and remove it from the process of control design. For electro-hydraulic systems, a high-gain disturbance observer based backstepping control with position tracking error constraints have been suggested to enhance position tracking performance in the presence of disturbances [14]. Recently, in order to regulate the load following of a pressurized-water reactor (PWR) in presence of disturbances, a high-gain disturbance observer-based double closed-loop sliding mode control (HGDO-DCLSMC) method has been suggested [15].

Recently contraction theory has been proposed for the analysis of stability of the system [16].A contracting dynamical system's paths exponentially converge towards each other irrespective of their initial condition [17, 18].Every trajectory starting inside a region in the state space will converge towards each other and this region is called contracting region [19]. In reference [20] stability of nonlinear singularly perturbed system based on contraction theory has been discussed. While a contracting autonomous system implicitly guaranteed the existence of an equilibrium point, a contraction framework does not always necessitate the presence of an attractor [21]. It is simpler to manage uncertainties in the system model because the exponential convergence behavior is inherently robust to bound disturbances. These fascinating features are used in the investigation of distributed systems [22],observer design [23],networks stability [24], kalman filter [25, 26], synchronisation [27],controller design for mechanical systems [28], backstepping controller synthesis [29] etc. The results of this study are used to stabilise approximate feedback linearisable systems [30]. In this article contraction theory based methodology has been introduced for the convergence of all closed loop states. The contributions of this paper can be summarized as follows:

(1) This work proposes a novel method to design a saturated controller for a singularly perturbed system.
(2) In order to address the system complexity and external disturbances, a singular perturbation approach has been used to design a filter and a disturbance observer.
(3) A strategical approach based on contraction theory has been proposed to achieve convergence of all closed-loop states of the system.
(4) The performance of contraction theory based saturated nonlinear controller has been implemented and validated for pitch control of TRMS (Twin rotor MIMO System).

This article is arranged in the following way:

The system description is provided in section 2. The design of a saturated nonlinear controller is described in section 3. Section 4 and section 5 provide details on convergence analysis and filtered saturated controller with disturbance observer respectively, and section 6 presents the experimental outcomes for pitch angle tracking of TRMS, followed by conclusion and references.

2. System description

We consider the class of nonlinear systems which is in strict feed back form described as:

$$\begin{aligned} \dot{x_1} &= g_1 x_2 + f_1(x_1) \\ \dot{x_2} &= g_2 x_3 + f_2(x_1, x_2) \\ &\vdots \\ \dot{x_n} &= g_n u + f_n(x_1, x_2, \ldots, x_n) \end{aligned} \tag{1}$$

Equation (1) can be represented in the following form:

$$\dot{x_n} = G(x)u + F(x) \tag{2}$$

$f_i(.)$ are sufficiently smooth function and $g_i \neq 0$. The equation (2) can be converted into equation (4) by choosing z_i, α_i and α_{if}: Where,

$$\begin{aligned} & z_i = x_i - \alpha_{if}, i = 1, 2, 3...n \\ & \mu\dot{\alpha}_{if} = -\alpha_{if} + \alpha_i \\ & \alpha_{1f} = \omega_d \\ & \alpha_i = \frac{1}{g_{(i-1)}}[-f_{(i-1)}(x_1, ..x_{(i-1)}) \\ & \qquad - g_{(i-2)}z_{(i-2)} + \dot{\alpha}_{(i-1)f}], i = 2, 3, 4...n \end{aligned} \tag{3}$$

where $\mu \in (0, 1)$, ω_d is desire signal and α_{if} are obtained through the first order filter [31, 32]. The initial conditions are $\alpha_{if}(0) = \alpha_i(0)$, $g_0 = 0$. As we can see in equation (1) and (3) a nonlinear system in strict feedback form and a controller structure have been defined respectively. After applying the controller in the equation (1), equation (4) can be derived as

$$\begin{aligned} \dot{z_1} &= g_1 z_2 \\ \dot{z_i} &= -g_{(i-1)}z_{(i-1)} + g_i z_{(i+1)} \\ \dot{z_n} &= -g_{(n-1)}z_{(n-1)} \end{aligned} \tag{4}$$

This equation (4) can be written in compact form as $\dot{z} = Az$ which can be seen in equation (5).

$$\dot{z} = f(z) = Az \tag{5}$$

$$A = \begin{pmatrix} 0 & g_1 & 0 & & 0 \\ -g_1 & 0 & g_2 & & 0 \\ \ddots & \ddots & \ddots & & \ddots \\ 0 & & 0 & -g_{(n-1)} & 0 \end{pmatrix}$$

where A is a skew symmetric matrix. For a skew-symmetric matrix A, the inequality $A + A^T \leq 0$ always holds true, and the closed loop dynamics described by A is therefore stable even though marginally stable. Additionally, we have added robustifying terms to make the closed loop dynamics uniformly ultimately bounded.

By using equation (3), the equation (1) can be converted into the following form:

$$\dot{z_n} = G(z)u + F(z) \tag{6}$$

Assumption 1 A transformation $\omega = T(x)$ exists for which the equation (2) can be expressed as in the following form:

$$\dot{\omega} = A\omega + B(f(\omega) + h(\omega)u) \tag{7}$$

where A and B are in Brunovsky canonical form. $\omega \in D_\omega \subset \Re^n$. $f(\omega) : D_\omega \to \Re$, $h(\omega) : D_\omega \to \Re$ and $h(\omega) \neq 0$, $\forall \omega \in \Re^n$.

Assumption 2 The function $f(\omega)$ and $h(\omega)$ are locally Lipschitz.

Assumption 3 A smooth saturation function with the following properties ($\sigma(.) : \Re \to \Re$) exists -

(a) $\sigma(0) = 0$ and $s\sigma(s) > 0 \forall s \neq 0$
(b) $\lim_{s\to\infty} \sigma(s) = 1$, $\lim_{s\to-\infty} \sigma(s) = -1$
(c) For a finite set $D_s \subset \Re$, $\frac{\partial\sigma(s)}{\partial s} > 0 \forall s \in D_s$

Assumption 1 can transform the system (1) into a fully linearizable form. Assumption 2 gives information about existence of solution and uniqueness of solution for equation (2). And finally Assumption 3 implies that the saturation function $\sigma(s)$ is continuously differentiable and it will be an odd function such as sigmoid function, hyperbolic tangent function etc.

The aim is find an input u that ensures the closed loop trajectories of the system $\omega(t)$ closely match the states $\omega_d(t)$ of a stable system, as mentioned below:

$$\dot{\omega}_d = A_d\omega_d + B_d r \tag{8}$$

where $\omega_d = [\omega_{d1}, \omega_{d2}, ..., \omega_{dn}]' \in \Re^n$, r represents bounded reference input.

$$A_d = \begin{pmatrix} 0 & 1 & & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & & 1 \\ -a_{d1} & -a_{d2} & & -a_{dn} \end{pmatrix}$$

$$B_d = \begin{pmatrix} 0 \\ \vdots \\ 0 \\ b_d \end{pmatrix}$$

where A_d is Hurwitz for suitable a_{di}, $i = (1, 2, 3...n)$.

3. Controller design

Here, the objective is to solve the tracking problem of non-affine system by using a saturated control rule $u = \beta\sigma(\frac{v}{\beta})$, where v is a new control input.

Error dynamics can be denoted as:

$$\dot{e} = A\omega + BF(\omega, v) - A_d\omega_d - B_d r \tag{9}$$

$$\mu\dot{v} = -sign(j_g)[F(z) + G(z)\sigma(v) - \dot{\omega}_d + \sum_{i=1}^{n} tanh(z_i)] \tag{10}$$

where $e = \omega - \omega_d$ and $F(\omega, v) = f(\omega) + \beta h(\omega)\sigma(\frac{v}{\beta}), h(\omega) > 0$. Equation (7) and Equation (10) can be represented in the following forms:

$$\begin{aligned} \dot{\omega} &= A\omega + BF(\omega, v) \\ \mu\dot{v} &= g(v, z, \omega_d, r) \end{aligned} \tag{11}$$

where

$$g(.) = -sign(j_g)[F(z) + G(z)\sigma(v) - \dot{\omega}_d + \sum_{i=1}^{n} tanh(z_i)] \tag{12}$$

Equation (11) represents the time scale form of the system and the system's dynamics are in a standard singularly perturbed form (The fast dynamics consist of isolated and unique root). This fact can be observed in Theorem 1.

Theorem 1 *The ensuing closed-loop dynamics may be described in the standard singularly perturbed form if the pre-stated assumptions (1-3) continue to hold true and the dynamic controller is chosen as* $u = \beta\sigma(\frac{v}{\beta})$. *In this situation,*

$v = p(z, \omega_d, r)$ of the equation $g(v, z, \omega_d, r) = 0$ is the unique root.

Proof Reference [33, 34] presents findings that prove the existence of a distinct root for a vector field that is partially contracting. The Jacobian matrix of the vector field $g(.)$ with respect to the variable v is designated as:

$$\begin{aligned} j_g &= -\alpha(h(\omega)\frac{\partial(\sigma(v/\beta))}{\partial(v/\beta)}) \\ &= -a_v||((h(\omega)\frac{\partial(\sigma(v/\beta))}{\partial(v/\beta)}))|| \end{aligned} \tag{13}$$

The expression j_g exhibits negative definiteness within a specific bounded reason of D_ω and D_v, as indicated by equation (13). So, the equation $\mu\dot{v} = g(v, z, \omega_d, r)$ will be partially contracting in v and there will be a unique and isolated solution of $g(v, z, \omega_d, r) = 0$ [16, 34]. In other word, we can say that a mapping between the variables z, ω_d, r and control input v exist inside the domain D_ω and D_v. That's why, equation (11) is in the typical form of a singularly perturbed equation.

Corollary 1 *The error dynamics involving the slow reduced system of equations (11) is contracting in e and $(\omega_r - \omega_d) \to 0$.*

Proof Consider the root of the equation $g(v, z, \omega_d, r) = 0$ is denoted by $v = p(z, \omega_d, r)$. Hence, the reduced slow system of equations (11) will be as:

$$\dot{\omega}_r = A\omega + BF(\omega_r, p(z, \omega_d, r)) \tag{14}$$

Using $g(p(.), z, \omega_d, r) = 0$, we can write

$$\begin{aligned} u &= \beta\sigma(\frac{p(.)}{\beta}) \\ &= \frac{1}{G(z)}(-F(z) - \sum_{i=1}^{n} a_{di}\omega_{di} + \sum_{i=1}^{n} b_{di}r \\ &- \sum_{i=1}^{n} tanh(z_i)) \end{aligned} \tag{15}$$

The error dynamics can be expressed as:

$$\dot{e} = A\omega + F(\omega, p(.)) - A_d\omega_d - B_d r = A_e e \tag{16}$$

where the A_e is Hurwitz matrix and it has distinct real eigen values. A positive definite matrix M_{Ae} will exist in such a way that $\overline{A}_e = M_{Ae}A_eM_{Ae}^{-1}$ is negative definite. Here, M_{Ae} is invertible matrix. So, equation (16) is contracting in M_{Ae} and $\omega(t)$ exponentially converge to ω_d i.e. $(\omega_r - \omega_d) \to 0$ and $e(t) \to 0$ [35].

Feasible region: With a limited actuation power any unstable system may not be globally or semi globally stabilized. The tracking problem in this article can be solved inside a certain domain. From equation $u = \beta\sigma(\frac{v}{\beta})$, the dynamic inversion with a limited actuation power β is feasible, provided

$$\begin{aligned} u &= \beta\sigma(\frac{p(.)}{\beta}) \\ &= \frac{1}{G(z)}(-F(z) - \sum_{i=1}^{n} a_{di}\omega_{di} + \sum_{i=1}^{n} b_{di}r \\ &- \sum_{i=1}^{n} tanh(z_i)) \end{aligned} \tag{17}$$

The parameter, denoted as a_{di}, is adjustable, and $||\sigma(.)|| \leq 1$. Consequently, the region of attraction, represented by the finite region $(D_\omega \times D_v)$, can be approximated. Within this region, the vector fields satisfy the following condition.

$$||\frac{1}{h(\omega)}(-f(\omega) + \dot{\omega}_d)|| < \beta \tag{18}$$

4. Convergence analysis

Equations (11) is convergent in nature. This crucial information provides boundedness of closed loop system and represented in the form of lemma.

Lemma 1 *Consider a system $\dot{\omega} = f(\omega)$ which is contracting in a transformation matrix M with rate λ and assume a perturbed system $\dot{\omega}_p = f(\omega_p) + w(\omega_p, \xi)$, ξ: An external signal.*

(1) if $||w(\omega_p, \xi)|| \leq m_0$, $m_0 \in R^+$,then the following equation will be satisfied.

$$||\omega_p(t) - \omega(t)|| \leq \Gamma e^{-\lambda t}||\omega_p(0) - \omega(0)|| + \frac{\Gamma m_0}{\lambda} \tag{19}$$

where Γ represents the supremum of the condition number for M.

(2) Let us consider two positive scalars m_{on}, m_{1n} such that $||w(\omega_p, \xi)|| \leq m_{on} + m_{1n}||\omega_p||$. Also consider that, a forward bounded solution ω_b exists for the system's dynamics, $\dot{\omega} = f(\omega)$, where the inequality $m_{1n} \leq \frac{\lambda}{\Gamma}$, then

$$\dot{\omega}_p = f(\omega_p) + w(\omega_p, \xi) \tag{20}$$

is partially contracting in ω_p and

$$||\omega_p(t) - \omega(t)|| \leq \Gamma e^{-(\lambda - \Gamma m_{1n})t}||\omega_p(0) - \omega(0)|| + m_{2n} \tag{21}$$

bound can be obtained. where, $m_{2n} = \frac{\Gamma(m_{on} + m_{1n}\omega_b)}{\lambda - \Gamma m_{1n}}$.

4.1 *Convergence to Slow Manifold, $p(z, \omega_d, r)$*

Above mentioned controller in equation (10) is given in the form:

$$\mu\dot{v} = g(v, z, \omega_d, r) \tag{22}$$

Let us consider a virtual perturbed system of equation (10) in stretched time scale $\tau = \frac{t}{\mu}$,

$$\frac{dv_{ds}}{d\tau} = g(v_{ds} + p(.), z, \omega_d, r) + p'(v_{ds}, z, \omega_d, r, \mu) \tag{23}$$

where

$$\begin{aligned} p'(v_{ds}, z, \omega_d, r, \mu) &= -\mu \frac{d}{dt}(p(.)) \\ v_{ds} &= v(t) - p(z, \omega_d, r) \end{aligned} \tag{24}$$

$p'(.)$ can be evaluated as:

$$p'(v_{ds}, z, \omega_d, r, \mu) = \mu(\frac{\partial p(.)}{\partial z}\dot{z} + \frac{\partial p(.)}{\partial \omega_d}\dot{\omega_d} + \frac{\partial p(.)}{\partial r}\dot{r}) \tag{25}$$

By using the Lipschitz properties of the function $f(\omega)$, u, and $p(z, \omega_d, r)$ it can be derived that [35]:

$$||p'|| \leq m_{2a}||v_{ds}|| + m_{2b}||\omega_d|| + m_{2c}||\dot{r}|| + m_{2d} \tag{26}$$

where m_{2a}, m_{2b}, m_{2c}, m_{2d} are positive scalars. Let us consider $p'(.) = 0$ then $\frac{dv_{ds}}{d\tau}$ is partially contracting in v_{ds}. Let's assume contraction rate is $\frac{\overline{\lambda_v}}{\mu}$, M_v is transformation matrix and Ω_v is supremum of the condition number for M_v. Reference [36] ensures forward boundedness of trajectories inside the unperturbed system $\frac{dv_{ds}}{d\tau} = g(v_{ds} + p(.), z, \omega_d, r)$. It is stated in Lemma 2.

Lemma 2 *[36]: Let us assume that $\dot{\omega} = f(\omega, t)$, $\omega \in R^n$, is contracting in ω for all $t > 0$. Suppose the contraction matrix is time invariant, finite and also $||f(0, t)|| \leq a < \infty$ for all $t > 0$, then the trajectories $\omega(t)$ remain bounded and the solution $\omega(t)$ will be well defined for all $t > 0$.*

If $v_{ds} = 0$ then $v = p(.)$ which implies that the function $g(v_{ds} + p(.), z, \omega_d, r)$ die out at $v_{ds} = 0$. By using Lemma 2 we can summarize that $v_{ds}(\tau)$ of the unperturbed system $\frac{dv_{ds}}{d\tau} = g(v_{ds} + p(.), z, \omega_d, r)$ are forward bounded for all $t > 0$ and a positive number a_0 exist for which $||v_{ds}(t)|| \leq a_0$ for all $t > 0$. For equation $g(0 + p(.), z, \omega_d, r) = 0$, $v_{ds} = 0$ can act as a particular solution of $\frac{dv_{ds}}{d\tau} = g(v_{ds} + p(.), z, \omega_d, r) + p'(v_{ds}, z, \omega_d, r, \mu)$ in the absence of perturbation term.

There exist a scalar μ_m such that $m_{2a} \leq \frac{\overline{\lambda_v}}{\mu^2\Omega_v}$ for all $\mu < \mu_m$. That is why Lemma 1 can be used in equation $\frac{dv_{ds}}{d\tau} = g(v_{ds} + p(.), z, \omega_d, r) + p'(v_{ds}, z, \omega_d, r, \mu)$ to derive:

$$\begin{aligned} ||v_{ds}(t) - 0|| &\leq ||v(t) - p(z, \omega_d, r)|| \\ &\leq \Omega_v e^{-(\frac{\lambda_v}{\mu})t}||v(0) - p(z(0), \omega_d(0), r)|| + \frac{\mu\Omega_v d_2}{\lambda_v} \end{aligned} \tag{27}$$

where λ_v and d_2 can be evaluated from [36] as $\lambda_v = \overline{\lambda}_v - \mu\Omega_v m_{2a}$ and $d_2 = \mu(m_{2a}v_0 + m_{2c}||r|| + m_{2d})$. By using [36] following bound can be obtained.

$$\lim_{t\to\infty} ||v(t) - p(z, \omega_d, r)|| \leq \mu\Omega_v \frac{d_2}{\lambda_v} \tag{28}$$

4.2 *Convergence analysis of trajectories*

Equation (7) can be written in the following form with extra perturbation terms as:

$$\begin{aligned} \dot{\omega} &= A\omega + BF(\omega, p(z, \omega_d, r)) + BF(\omega, v) \\ &\quad - BF(\omega, p(z, \omega_d, r)) \end{aligned} \tag{29}$$

The first two terms $A\omega + BF(\omega, p(z, \omega_d, r))$ is same as equation (11) and that's why it is partially contracting in ω with transformation matrix M_{Ae}. By employing the Lipschitz properties of the function $F(.)$ it can be determined that there exists a Lipschitz constant denoted as L_1. This constant ensures $||BF(\omega, v) - BF(\omega, p(z, \omega_d, r))|| \leq L_1||v - p(z, \omega_d, r)||$.

The bound of equation (28) is finite inside the region of interest. That is why finite perturbation terms for all $t > 0$ in (29) can be derived. In (29) the nominal unperturbed dynamics is partially contracting, so Lemma 2 can be used to obtain forward boundedness of trajectories $\omega(t)$ $\forall t \geq 0$. By using Lemma 1 on (14) and (29), the following bounded equation can be derived:

$$\lim_{t\to\infty} ||\omega(t) - \omega_r(t)|| \leq \frac{\Omega_{ae}L_1}{\lambda_{ae}}(\frac{\mu\Omega_v d_2}{\lambda_v}) \tag{30}$$

where λ_{ae} is the minimum eigen value of $\overline{A}_e$ and Ω_{ae} is the condition number of M_{Ae}. From the equation (30), bounded steady state tracking error can be derived by using triangle inequalities.

$$\lim_{t\to\infty} ||\omega(t) - \omega_d(t)|| \leq \frac{\Omega_{ae}L_1}{\lambda_{ae}}(\frac{\mu\Omega_v d_2}{\lambda_v}) \tag{31}$$

5. Filtered saturated controller with disturbance observer

A disturbance observer with a high gain is provided to estimate the uncertain dynamics of the systems. The system uncertainties can be eliminated through disturbance observer $\delta_i(.)$ [37].

Table 1. Parametric values of TRMS

TRMS Parameters	Values
I_1 (Moment of inertia of vertical rotor)	$6.8 * 10^{-}2$ Kg m^2
T_{11}(Motor 1 denominator parameter)	1.1
T_{10} (Motor 1 denominator parameter)	1
M_g (Gravity momentum)	0.3 N-m
$B_{1\psi}$ (Friction momentum function parameter)	$6 * 10^{-}3$ N m s/rad
$B_{2\psi}$ (Friction momentum function parameter)	$1 * 10^{-}3$ N m s^2/rad
k_{gy} (Gyroscopic momentum parameter)	0.05 s/rad
a_1 (Static characteristic parameter)	0.0135
b_1 (Static characteristic parameter)	0.0924

$$\begin{aligned}
\dot{\xi}_i &= -k(\xi_i + kx_i + f_i(x_1, x_2, \ldots, x_i) + g_i x_{i+1}) \\
\dot{\xi}_n &= -k(\xi_n + kx_n + f_n(x_1, x_2, \ldots, x_n) + g_n u) \\
\hat{\delta}_i(.) &= \xi_i + kx_i \\
\hat{\delta}_n(.) &= \xi_n + kx_n
\end{aligned} \tag{32}$$

where the scalar $k > 0$ is a large positive constant, $\hat{\delta}_i(.)$ is the estimation of disturbance $\delta_i(.)$, and ξ_i is an intermediate variable. Using observer (32), the dynamics of disturbance estimator ($\hat{\delta}_i$) is given by:

$$\dot{\hat{\delta}}_i = h_i(\hat{\delta}_i, \delta_i) = -k(\hat{\delta}_i - \delta_i). \tag{33}$$

Defining a disturbance error variable $\tilde{\delta}_i = \delta_i(.) - \hat{\delta}_i(.)$, the estimation error dynamics can be written as:

$$\epsilon\dot{\tilde{\delta}}_i(.) = -\tilde{\delta}_i - \epsilon\dot{\delta}_i(.). \tag{34}$$

where $0 \leq \epsilon = 1/k \leq 1$. The boundary layer dynamics resulting from (34) can be written as:

$$\frac{\delta}{\delta\tau}(\tilde{\delta}_i) = \tilde{\delta}_i. \tag{35}$$

5.1 *Conversion to Singularly Perturbed form*

The filter based saturated control law u chosen for system (1) is based on a disturbance observer and filtering.

$$\begin{aligned}
u &= \beta\sigma(\frac{v}{\beta}) \\
\mu\dot{v} &= -sign(j_g)[F(z) + G(z)\sigma(v) - \hat{\delta}_i \\
&\quad - \dot{\omega}_d + \sum_{i=1}^{n} tanh(z_i)] \\
z_i &= x_i - \alpha_{if}, (i = 1, 2.....m) \\
\alpha_{1f} &= \omega_d, \ i \in [2, 3...m] \\
\alpha_i &= \frac{1}{g_{(i-1)}}[-f_{(i-1)}(x_1, ..x_{(i-1)}) \\
&\quad - g_{(i-2)}z_{(i-2)} + \dot{\alpha}_{(i-1)f} - \hat{\delta}_{(i-1)}], i = 2, 3, 4...n.
\end{aligned} \tag{36}$$

The closed-loop system described in equation (1) with the control law given in equation (36) can be represented as follows:

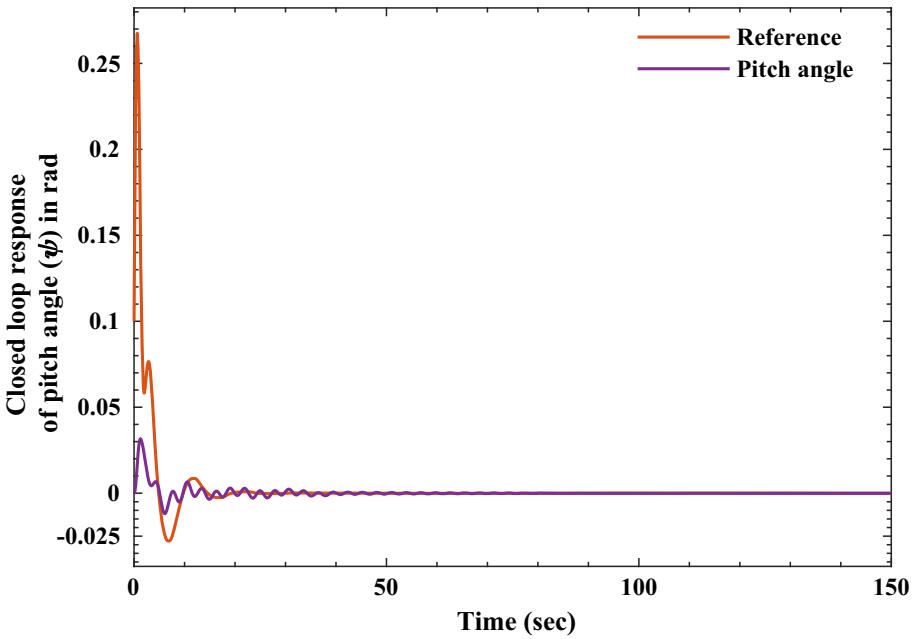

Figure 1. Closed loop response of pitch angle in rad and reference signal.

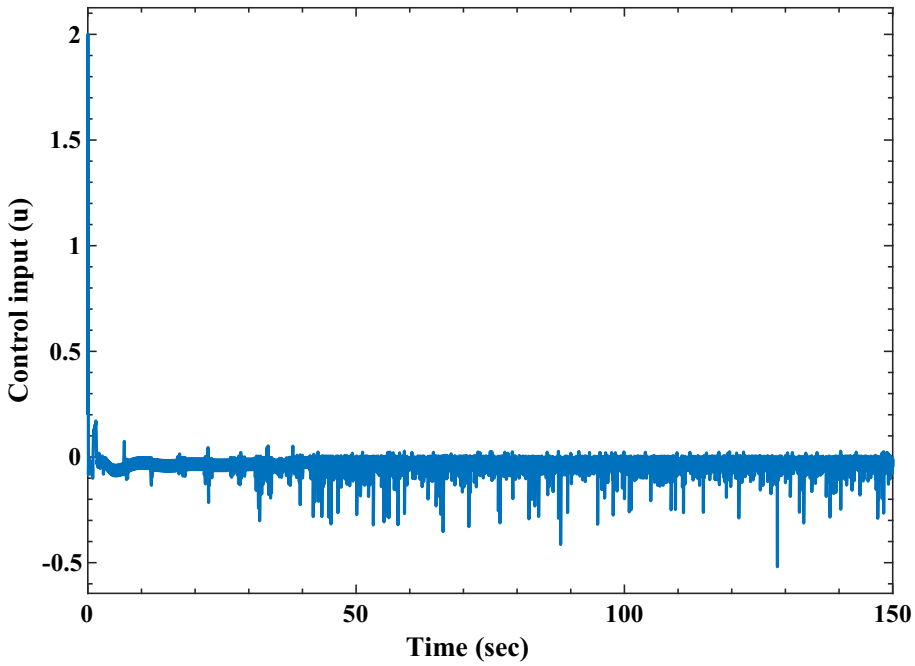

Figure 2. Closed loop control signal.

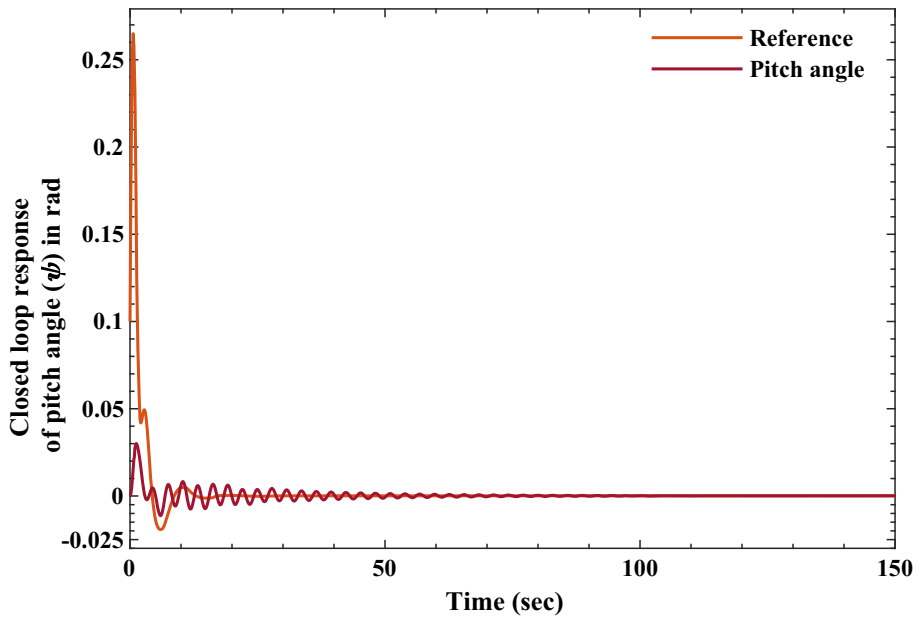

Figure 3. Closed loop response of pitch angle in rad and reference signal.

$$\begin{aligned}
\dot{z}_1 &= g_1 z_2 + g_1 \tilde{\alpha}_{2f} + \tilde{\delta}_1 \\
\dot{z}_i &= g_{(i-1)} z_{i-1} \\
&\quad + g_{(i)} z_{i+1} + g_i \tilde{\alpha}_{(i+1)f} + \tilde{\delta}_i \\
\dot{z}_n &= -g_{(n-1)} z_{n-1} + \tilde{\delta}_{(n)}.
\end{aligned} \tag{37}$$

Rewriting (37) in a compact form as (38),(39) and (40)

$$\dot{z} = f(z, \tilde{\alpha}_f, \tilde{\delta}) \tag{38}$$

$$\mu \dot{\tilde{\alpha}}_f = g(\alpha_f, \alpha_i) = -\tilde{\alpha}_f + \mu \dot{\alpha}_i \tag{39}$$

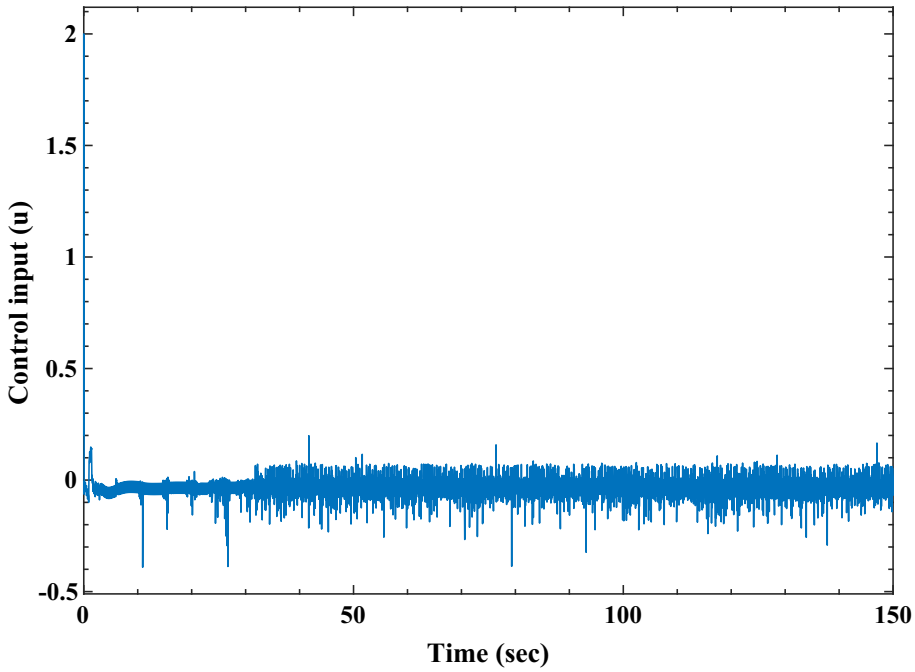

Figure 4. Closed loop control signal

$$\epsilon\dot{\tilde{\delta}} = h(\hat{\delta}, \delta_i) = -\tilde{\delta} + \epsilon\dot{\delta}_i \tag{40}$$

where $\hat{\delta} = [\hat{\delta}_1, \hat{\delta}_2, \ldots, \hat{\delta}_n]$, $\tilde{\delta} = [\tilde{\delta}_1, \tilde{\delta}_2, \ldots, \tilde{\delta}_n]$ $\delta_i = [\delta_1 \delta_2, \ldots, \delta_n]$. In equations (38)–(39), the system dynamics undergo a transformation, resulting in a singularly perturbed system with three distinct time scales. By employing the ratio $\frac{\epsilon}{\mu}$ this system can be further simplified into a two-time scale format. Assuming, without loss of generality, that $\epsilon < \mu$, indicating that the observer dynamics operates at a faster rate as compared to the filter dynamics. A suitable choice for ϵ is $\epsilon = \kappa\mu$, where $\kappa < 1$ is a small positive constant. Express the fast subsystem (39), (40) as:

$$\mu\dot{\tilde{\nu}} = W(\tilde{\nu}, \dot{\nu}, \kappa) = -\begin{bmatrix} 1 & 0 \\ 0 & \frac{1}{\kappa} \end{bmatrix}\tilde{\nu} + \mu\dot{\nu} \tag{41}$$

where $\tilde{\nu} = [\tilde{\alpha}_f^T, \tilde{\delta}^T]^T$, $\dot{\nu} = [\dot{\alpha}_i^T, \dot{\delta}_i^T]^T$ and $W(.) = [g^T(.), \frac{1}{\kappa} h^T(.)]^T$. By using Equation (41), the dynamics of the closed loop system can be described using two distinct time scales in a singularly perturbed form. Convergence of system trajectories can be analysed by using same reasoning.

6. Experimental outcomes

The TRMS serves as a benchmark in the field of aerodynamics and shares similarities with helicopter dynamics, featuring two inputs and two outputs. This system containing vertical and horizontal rotors which are actuated by two DC motors. The vertical rotor gives vertical take off and landing momentum (pitch angle ψ) and the horizontal rotor gives the steering action (yaw angle ϕ) under strong coupling. The following momentum equations [38] for the vertical take off and landing of TRMS is considered to validate the boundedness and convergence of proposed filter saturated controller:

$$I_1\ddot{\psi} = M_1 - M_{FG} - M_{B\psi} - M_G \tag{42}$$

and

$$\tau_1 = \frac{k_1}{T_{11}s + T_{10}}u \tag{43}$$

where

$M_1 = a_1\tau_1^2 + b_1\tau$, nonlinear static characteristic
$M_{FG} = M_g sin(\psi)$, gravity momentum
$M_{B\psi} = B_{1\psi}\dot{\psi} + B_{2\psi} sign(\dot{\psi})$, friction forces momentum
$M_G = K_{gy}M_1\dot{\phi}cos(\psi)$, gyroscopic momentum

The parametric values of the experimental setup of TRMS [39] is given in table 1. The actuated motor momentum is described by the equation (43). Here, u is bounded control input.

Consider, $x_1 = \psi$, $x_2 = \dot{\psi}$ and $x_3 = \tau_1$.

$$\begin{aligned} \dot{x}_1 &= g_1x_2 + f_1(x_1) \\ \dot{x}_2 &= g_2x_3 + f_2(x_1, x_2) \\ \dot{x}_3 &= g_3u + f_3(x_1, x_2, x_3) \end{aligned} \tag{44}$$

where $g_1 = 1, \quad f_1(x_1) = 0, \quad g_2 = \frac{b_1}{I_1}$, $f_2(x_1, x_2) = -\frac{1}{I_1}[M_g sinx_1 + B_{1\psi}x_2 + B_{2\psi}signx_2], \quad g_3 = \frac{1}{T_{11}}$ and $f_3(x_1, x_2, x_3) = -\frac{T_{10}}{T_{11}}x_3$

The proposed controller was tested and validated on a TRMS under two different test cases. Additionally, in both cases, a nonlinearity term $\delta = 10^3 * tanh(2t)$ has been added to the state x_2.

For the first test case, the reference parameters a_{di} of the stochastic bounded signal has been taken as $a_{d1} = 20$, $a_{d2} = 21$ and $a_{d3} = 42$ with perturbed parameter $\mu = 0.01$. It is observed from the figure 1 the closed loop state response x_1 of the TRMS tracks stochastic bounded reference signal quickly and ensure stability during disturbed environment. The required control signal to track the reference, depicted in figure 2, is designed to achieve quick stability.

The tracking performance of the designed controller has been also tested under second test case for different reference parameters such as $a_{d1} = 25$, $a_{d2} = 26$, $a_{d3} = 40$ with perturbed parameter $\mu = 0.01$. It is observed from the figure 3 the trajectory tracking of the closed loop state response x_1 of TRMS satisfactorily follows the reference signal. The required control signal to track the reference is depicted in figure 4. Finally the results reveals that the nonlinear saturated controller satisfactorily meets control design objectives.

7. Conclusion

In this paper, contraction theory based nonlinear saturated controller has been designed specifically for singular perturbations systems. The effectiveness of the designed controller has been tested on a Twin rotor MIMO System (TRMS) for tracking of pitch angle at two different unknown dynamical scenarios. The obtained outcomes suggest that the controller has the capability to provide reliable and precise control under changing conditions. One of the notable versatile strengths of this novel controller is its boundedness and convergence under all closed loop states. Its effective application and performance analysis on TRMS show that it may be used to a variety of physical systems, such as robotics platforms, inverted pendulums, and single-link manipulators etc. In summary, the designed nonlinear saturated controller exhibits encouraging outcomes when applied to TRMS for pitch angle tracking. Also, It may have great potential to tackle control issues in diverse dynamic systems.

Appendix I. Contraction and Partial Contraction

When any two of the system's trajectories, independent of their starting circumstances, converge towards one another, the system denoted by the $\dot{x} = f(x, t)$ is said to be contracting. If there is a positive definite matrix Θ within an area of the state space, then region is referred to as a contracting region. This matrix Θ is constructed in such a way that its symmetric counterpart $(\dot{\Theta} + \Theta\frac{\partial f(.)}{\partial x})\Theta^{-1}$ is negatively definite inside the region [16]. The minimum eigenvalue of the symmetric component is referred to as the contraction rate, and Θ represents the transformation matrix associated with it. A system $\dot{x} = f(x, y, t)$ is called partial contracting in x if the dynamics is contracting in x for all y [40].

Abstract

Flavonoids are a diverse class of polyphenolic compounds that occur widely in naturally occurring resources like fruits, vegetables, and plant-derived drinks which have potential therapeutic use in the treatment of several life-threatening neurological disorders. This review highlights the role of different flavonoids in various neurodegenerative disorders through their anti-inflammatory, antioxidant, and neuroprotective effects. They seem to have potential stimulatory and inhibitory effects in the mechanism of disease to either stop or delay the progression of various neurological diseases, including Parkinson's, Huntington's, Alzheimer's, and Multiple Sclerosis.

Flavonoids' role in the regulation of oxidative stress, modulation of signaling pathways as well as enhancement in neuroplasticity pose them as a possible neuroprotective agent against a disease in various clinical and models being conducted. Further, their potential to cross the blood-brain barrier and exert neural protective effect make them ideal for therapeutic roles against neurodegenerative disease.

This review highlights the mechanism of various neurodegenerative diseases, the potential of flavonoids to exert neuro-protective effects, their role in modulation of molecular pathways that can be used in combating neurodegenerative diseases, targeted course of action of flavonoids with specificity, and their future potentials in drug discovery and development.

Overall, elucidating the therapeutic potential of flavonoids in neurological disorders holds promise for developing novel therapeutic strategies aimed at improving neurological outcomes and enhancing the way of life for people affected by these debilitating conditions.

Keywords: *Flavonoid, antioxidant, neurological disorder, Parkinson's disorder, anti-inflammatory, Alzheimer's disease*

1. Introduction

Flavonoids being naturally procured secondary metabolites, consisting of polyphenolic compounds that have been observed to show therapeutic effects in cancer, cardiovascular diseases, diabetes, neurological and metabolic disorders. Flavonoids possess potential antimicrobial, antioxidant, anticancer, anti-proliferative, anti-inflammatory, and anti-apoptotic properties, and are extensively studied in lead discovery in drug discovery (Ullah et al., 2020).

They could be classified depending on their chemical structure, degree of saturation, and oxidation of carbon rings and thus further can be differentiated into different subgroups as flavanone, flavanol, flavanonols, flavans, and isoflavonoids (Panche et al., 2016a). These are produced in nature via the phenylpropanoid pathway, and their bioactivity is reliant on their route of absorption and bio-availability. The physicochemical characteristics, such as molecule size, solubility, configuration, lipophilicity, and pKa; influence the absorption of flavonoids(Youdim et al., 2003). Flavonoid glycoside or aglycan are the two types of flavonoids whose structures determine whether they are absorbed in may be in colon or small intestine. While flavonoid glycosides must first be transformed into aglycan to be absorbed, the aglycan portion of flavonoids is absorbed in the small intestine (Dabeek & Marra, 2019).

Our rapidly transforming lifestyles, high-caloric food habits, sedentary lifestyles, and stress have resulted in an increase in many metabolic diseases, cancer, and neurological disorders. Neurodegenerative conditions primarily affect people in their later years of life; a lot of people suffer from conditions such as Parkinson's disorder, Multiple Sclerosis, Huntington's disorder, and Alzheimer's disorder. The accumulation of abnormal proteins, oxidative stress, neuroinflammation, and mitochondrial dysfunction all of which have the potential to cause the degeneration of specific neurons within the brain and are some of the most significant pathophysiological bases of neurodegenerative diseases (Hamsalakshmi et al., 2022). Synaptic and cognitive dysfunction have an intrinsic relationship to major neurological disorders such as Parkinson's and Alzheimer's, which deteriorate with the loss of these neural cells and the signals that they generate.

The key causes of neurodegenerative diseases are oxidative stress and neuroinflammation. Numerous factors, including abnormal protein accumulation, disruptions in the peroxidation and imbalance in polyunsaturated fatty acid levels, and increased Ca2+ transmission across neurons, are contributors to oxidative stress. Increased oxidative stress triggers the activated interaction of numerous biochemical pathways that cause lipids, proteins, and DNA to undergo oxidative damage, which eventually results in neuronal cell death and neurodegeneration.

This overview provides of the natural flavonoids' resources, structural characteristics, processes, prospects, and potential future therapy approaches for neurological disorders. Employing a range of mechanisms that include molecular pathways and specific molecular targets linked to the pathophysiology of neurological disorders, including oxidative stress, inflammation, vascular remodeling, genetics, ionic channels, and cell proliferation, which with developments in this field would lead in drug discovery. The comprehensive mode of mechanism of several flavonoids were being highlighted against various life-threatening neurological disorders. Flavonoids' interactions with oxidative stress pathways, inflammatory mediators and several other biochemical compounds addressed its potential in having a neuroprotective effect, which either could be harnessed in drug discovery or facilitate the drug in medical treatment or side effects prevention. Further, it has been compared the selective and specific target of different flavonoids in the mechanism of a disease, and thus having a therapeutic action against the disease. The inhibitory and stimulatory effect of different flavonoids were being compared to each other, which would be crucial in knowing their course

of action. This study withstands with such comparisons that may be crucial in target selection, identification in drug discovery and development.

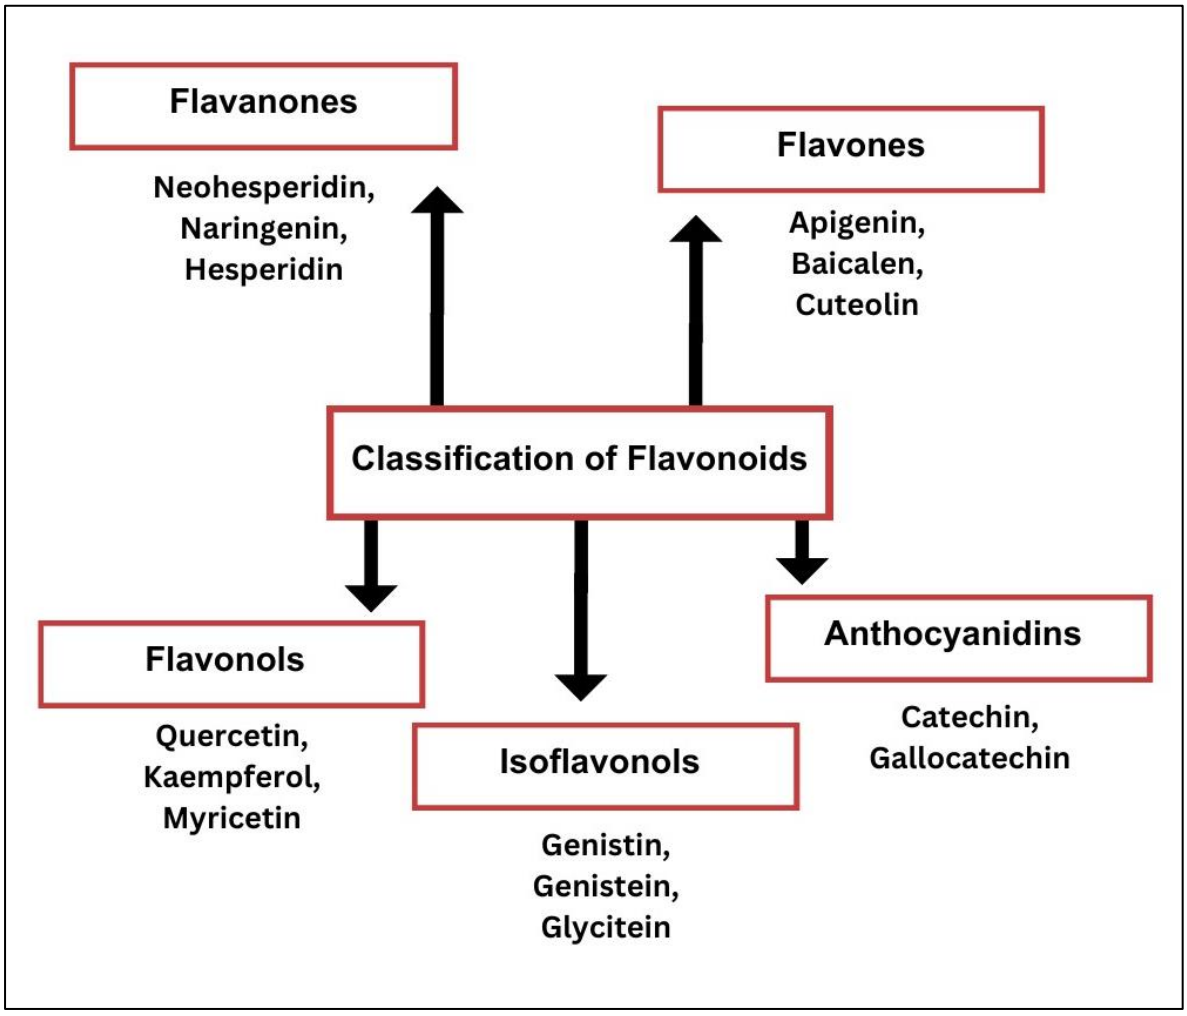

Figure 1: Classification of Flavonoids

2. Biochemical activities of Flavonoids

Plants possess substantial quantities of flavonoids, a sub class of polyphenolic compounds, especially in fruits, vegetables, grains, herbs, and beverages like tea and wine. Different characteristics of Flavonoids are:

2.1 Antioxidant Properties:

One of the most well-known characteristics of flavonoids is their potent antioxidant activity, that they scavenge free radicals and reactive oxygen species (ROS), thereby protecting cells from oxidative damage and reducing the risk of various chronic diseases, including cardiovascular diseases, cancer, and neurodegenerative disorders (Lobo et al., 2010).

2.2 Anti-inflammatory Activity:

Flavonoids possess anti-inflammatory properties, which contribute to their therapeutic potential in mitigating inflammation-associated diseases as they modulate inflammatory

pathways by inhibiting the production of pro-inflammatory cytokines, enzymes (such as cyclooxygenases and lipoxygenases), and signaling molecules involved in the inflammatory response (Rakha et al., 2022).

2.3 Neuroprotective Effects:

Flavonoids have been shown to have neuroprotective benefits in an array of neurological disorders experimental models as they protect neurons from damage caused by oxidative stress, inhibit neurological inflammation, promote neuronal survival, and enhance neuroplasticity these properties make flavonoids promising candidates for the prevention and treatment of neurodegenerative diseases like Alzheimer's and Parkinson's (Ayaz et al., 2019).

2.4 Cardioprotective Effects:

Several flavonoids have been linked to improvements for cardiovascular health. They improve endothelial function, reduce blood pressure, inhibit platelet aggregation, and lower LDL cholesterol levels, thus reducing the risk of cardiovascular diseases such as coronary artery disease and stroke (Ciumărnean et al., 2020).

2.5 Antimicrobial Activity:

Certain flavonoids exhibit antimicrobial properties, inhibiting the growth of bacteria, fungi, viruses, and parasites as they can be used as natural alternatives to conventional antimicrobial agents and may help combat microbial infections and antibiotic resistance (Vaou et al., 2021).

2.6 Potential Anti-cancer Properties:

The potential anti-cancer properties of flavonoids have sparked interest in the scientific community as they exert anti-proliferative, pro-apoptotic, and anti-angiogenic effects on cancer cells, inhibiting tumor growth metastasis, and may also be used to enhance the efficacy of conventional cancer therapies and reduce their side effects (Kopustinskiene et al., 2020).

Table 1: Different Flavonoids and its sources

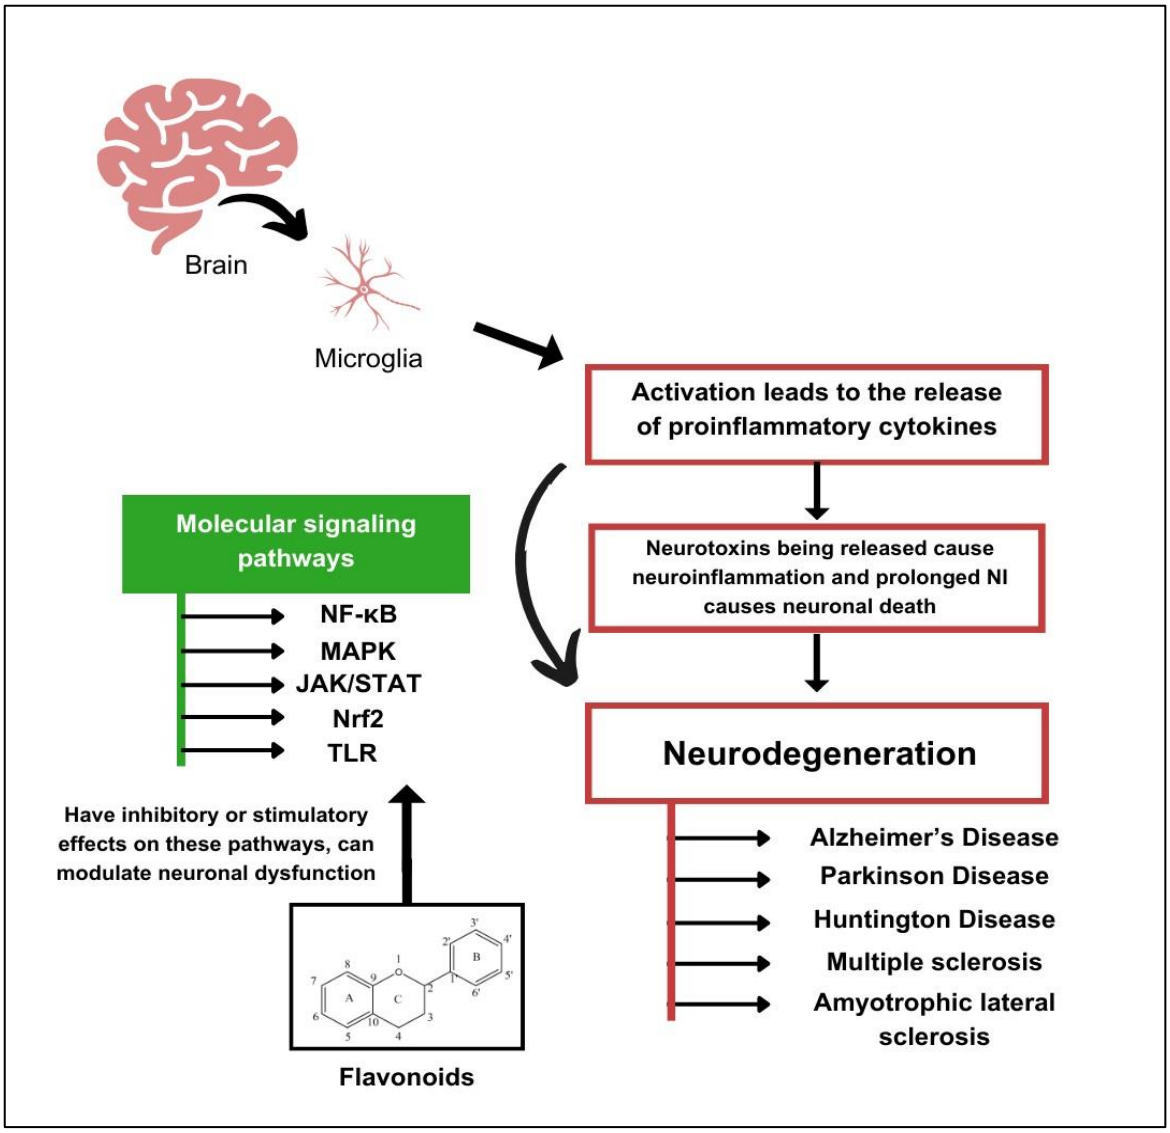

Figure 2: Schematic overview of Neurodegeneration and flavonoid actions

3. Neurological disorders and their current mechanisms

The Electron Transport Chain is usually characterized by producing reactive oxygen species in the bodies of human. Essential metabolic processes like protein phosphorylation, apoptosis, and activation of various transcriptional factors are being carried by Electron Transport Chain, but it is also responsible for lipid peroxidation that causes cell membrane damage. The potential difference exists in membrane of cells, with negative charges on the inner side and positive on the outer, the damage caused by Reactive oxygen species causes alteration in the osmotic pressure, and membrane potential thus causing cell death. The human defense system uses different mechanisms and enzymes to battle endogenous elevated Reactive oxygen species (Brunetti et al., 2013).

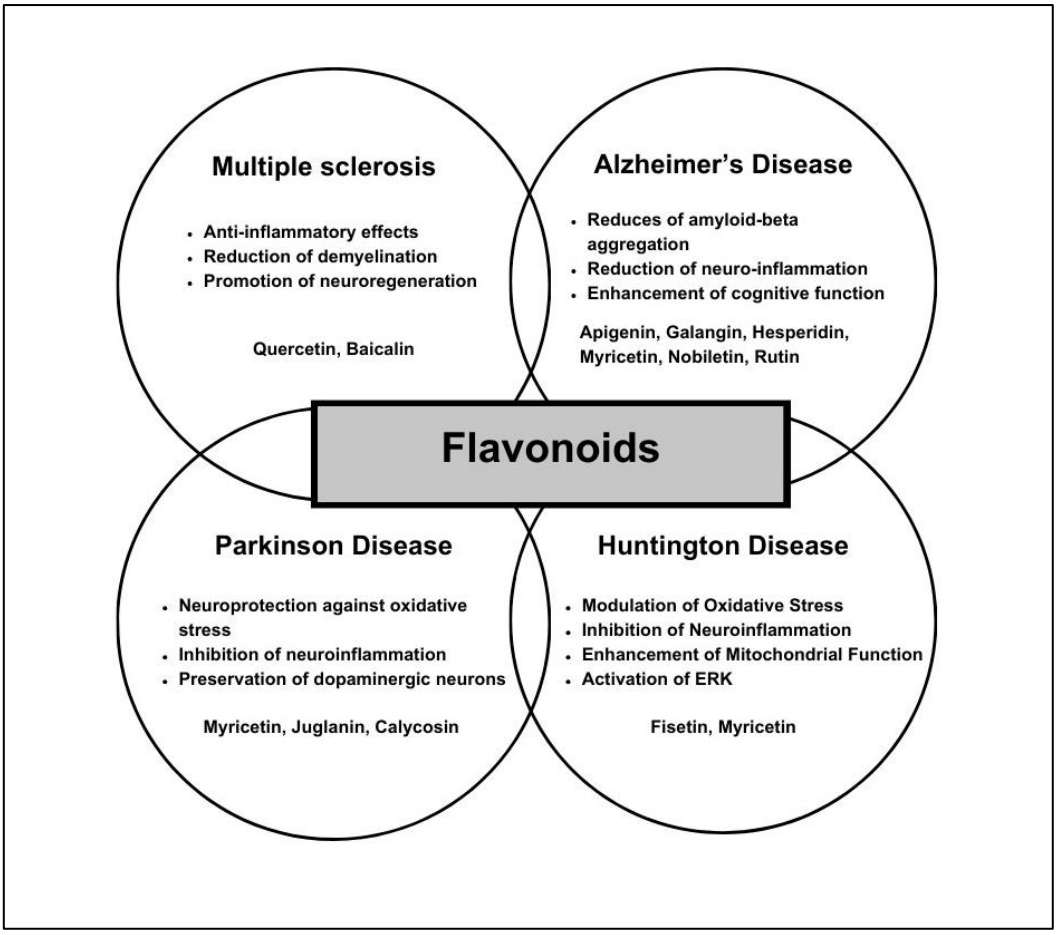

Figure 3: Main mechanism of actions of flavonoids as a neuromodulator

Neuronal interaction with microglia, astrocytes, and other Immunol signaling molecules plays a crucial role in neuroimmunol activation. Microglia are the central nervous system immune cells that usually perform sensing, housekeeping, and protective functions (Mitoma & Manto, 2019; Tchessalova et al., 2018). Microglia activation is an important factor of NI which promotes the release of pro-inflammatory cytokines resulting in progressive neuronal death (Qin et al., 2023). Neurotoxins released from microglia contrary to adverse neuroimmune function led to neurological inflammation and neuronal death and are considered to be the main cause of neurodegenerative diseases (W. Zhang et al., 2023).Neuroprotective therapies continue to be challenging in practice because neurodegeneration is caused by a variety of pathophysiological mechanisms. Thus, of this moment, there is no known cure for neurodegenerative disorders; the only available treatment focuses on symptom management.

Flavonoids appear to be potential leads, particularly for the treatment of neurological disorders. Several key molecular signaling pathways such as MAPK, CREB, Nrf2, NF-kB, JAK/STAT, and TLR are modulated by flavonoids. Inhibitory or stimulatory effects on these pathways by flavonoids significantly affect cellular functions by changing the phosphorylation state of target molecules and by modifying gene expressions (Mansuri et al., 2014; Pérez-Cano & Castell, 2016). These compounds also can modulate neuronal dysfunction through the activation of various metabolic pathways and are found to delay or prevent the onset of neurodegenerative diseases and provide neuroprotection (Makkar et al., 2020).

The antioxidant potential of flavonoids is associated with the molecular structure, and more precisely, with the location and total number of the –OH groups, the conjugation and resonance effects, the surrounding environment that modifies the thermodynamically favored antioxidant site, and the antioxidant mechanism for a compound (Zheng et al., 2019).

3.1 Alzheimer's disease

Somewhere five million individuals globally struggle with Alzheimer's disease, which makes it the most prevalent type of dementia. In Alzheimer there is the buildup of abnormal protein, increased production of amyloid beta production, and tau tangles which are responsible for causing impairment in synaptic loss, neuronal dysfunction and further leading to cognitive and memory dysfunction. The accumulation of amyloid beta leads to elevation of oxidative stress, neuroinflammation, and neurodegeneration (Williamson et al., 2018). Currently, there is no effective treatment available for the treatment and prevention of AD (Yiannopoulou & Papageorgiou, 2013). Nrf2 is a transcription factor binding to the antioxidant response element which controls oxidative response and regulates anti-inflammatory, antioxidant, and detoxifying genes (Ma, 2013). Nrf2 malfunction and its alternative localzation are common in most Neurodegenerative disorders including Amyotrophic lateral sclerosis, Alzheimer, and Parkinson. Nrf2 activation prevents our body from harmful stress by inhibiting inflammation, upregulating antioxidant defense pathways, and maintaining homeostasis (Villavicencio Tejo & Quintanilla, 2021). It was observed that Nrf2 was responsible for an array of critical roles to eliminate reactive oxygen species, preservation of redox homeostasis, and regulation of peripheral inflammatory responses thus has emerged as a promising therapeutic target and its seen flavonoids express their neuroprotective effects by inhibiting glutamate receptors and activating the Nrf2 (Moratilla-Rivera et al., 2023). However, some of the flavonoids have key potential for preventive and therapeutic effects.

3.1.1 Quercetin

Quercetin, a flavanol, possesses some pharmacological effects and has therapeutic effects. In various in vivo and in vitro models, it has been found that it protects neural cells by reducing oxidative stress and neurological inflammation. Some of the key properties that have a therapeutic effect include inhibition of amyloid beta aggregation, inhibition of tau phosphorylation, and restoration of acetylcholine levels through the inhibition of hydrolysis of acetylcholine by AChE enzyme (H. Khan et al., 2020).

3.1.2 Myricetin

Myricetin exhibits multifaceted neuroprotective effects by reducing the formation of amyloid beta 42 formations by blocking the conformational change, increasing the enzymatic activity of alpha-secretase and reducing that of beta-secretase countering the AD progression, suppressing neuroinflammation by inhibiting the activation of microglia and pro-inflammatory cytokines and mitigating oxidative stress (Taheri et al., 2020).

3.2 Parkinson’s Disorder

Parkinson's Disorder is the most common neurodegenerative disorder after Alzheimer’s disease and occurs due to the loss of dopaminergic neurons in the substantia nigra resulting in a decrease in the production of dopamine in the striatum and, subsequently, motor dysfunction (de Andrade Teles et al., 2018). The exact cause of Parkinson’s disease is unknown, but it

occurs due to the accumulation of abnormal proteins, oxidative stress, environmental toxins, and accumulation of alpha-synuclein (Dias et al., 2013; Jo et al., 2019). During neuroinflammatory diseases including Multiple sclerosis and Parkinson, it has been observed that JAK/STAT behaviour differently. JAK/STAT pathway initiates Dysregulation which generates oncological, metabolic, neurological, or other types of diseases to create disorders. The abnormalities are being regulated by JAK/STAT pathway inhibitors during the treatment of neurological disorders (Yan et al., 2018). Flavonoids possess potential in reduction of the phosphorylation of TYK2, STATs ; reduction in the translocation of nuclear STAT1 and STAT3; inhibition of COX-2 NO, iNOS, and proinflammatory cytokines such as TNF-alpha, interleukin 6 and 1beta in macrophages. Reactive oxygen species synthesis delivers the antioxidant properties of Flavonoids (S.-M. Qi et al., 2018).

3.2.1 Myricetin

Myricetin has shown some of the key neuroprotective effects that could be crucial against Parkinson's disorder are through inhibiting the activation of microglia and other proinflammatory cytokines, suppressing intracellular production of reactive oxygen species, inhibiting the formation of alpha-synuclein and destabilizing it, and re-establishing the mitochondrial transmembrane potential (Taheri et al., 2020).

3.2.2 Calycosin

Calycosin has been shown to have crucial neuroprotective effects against Parkinson's disorder by preserving and enhancing mitochondrial biogenesis, reducing oxidative stress-induced damage, and modulating and inhibiting TLR/NF-kB, and MAPK pathway (Yang et al., 2019).

3.3 Huntington’s Disease

Another neurodegenerative illness that causes involuntary movements, cognitive impairments , psychiatric disturbances, and dementia is Huntington's disease (HD). Genetically it is associated with the expansion of cytosine adenine guanine trinucleotide repeats in the Huntingtin gene (Hung et al., 2016; Velusamy et al., 2017). There is no treatment available for the management of HD (Frank, 2014).

3.3.1 Myricetin

Myricetin has been shown to interact with RNA, especially the CAG motif to inhibit the translation and destabilize the aggregates of mutant huntingtin protein, potentially reducing their cytotoxicity (E. Khan et al., 2018).

3.4 Multiple Sclerosis

In multiple sclerosis, chronic inflammation contributes to demyelination and neuronal damage. The activation of NF-kB plays a major role in many inflammatory diseases such as MS (Tak & Firestein, 2001). NF-kB is involved during functionating of the brain especially NDs (O’Neill & Kaltschmidt, 1997). Flavonoids play a significant role in providing the anti-inflammatory and antioxidant effect by hindering the NF-kB signaling pathway (Jones et al., 2012). Thus, NF-kB pathway targeting offers a novel treatment method and potential for neurodegenerative disorders.

S .No	Flavonoid	Disease	Action	References
1	*Apigenin*	Alzheimer disease	Inhibits the MAPK Pathway	(Zhao et al., 2013)

22	*Calycosin*	Parkinson Disease	Inhibits MAPK pathway	(Yang et al., 2019)

Table 2: Different Flavonoids and its therapeutic actions

4. Discussion and Future Directives

Flavonoid's ability to reach the target site (i.e. brain) in effective concentrations and exert its neuroprotective effects is hindered due to factors like low solubility, fast metabolic rate, and limited absorption in the gastrointestinal tract. Adsorption of flavonoids and delivery to specific target sites has been a challenge and needs innovative novel strategies to overcome. Delivery

systems such as nanoparticles, liposomes, or microemulsions could be used to deliver at the target site. These novel delivery systems possess the potential to improve the stability and solubility of flavonoids, improving in absorption and bioavailability of flavonoids having neuroprotective effects to cross the blood-brain barrier and reach the target site.

Complex structures and diversity in flavonoids pose challenges in understanding precise mechanisms of action and determining in optimal dosage to have therapeutic effects and metabolic activity. Flavonoids' distinct structural properties, bioactivities, and mechanisms make it difficult to find specific flavonoids that would modulate, stimulate, and interact with the abnormal proteins at the target site and cause a neuroprotective effect. This specificity and selective limitations could be overcome by conducting structure-activity relationship studies to know the peculiarities of flavonoids for their neuroprotective effects. Advanced computational tools and molecular docking technologies must be deployed in predicting the flavonoids' interactions with biological targets and pathways, these could further guide drug development efforts.

Flavonoid interactions with other medications or bio compounds are less known and could be affecting their efficacy or causing adverse effects. These potential side effects and interactions with other bio compounds are crucial to know as would have deteriorative effects on individuals having multiple diseases or some underlying health conditions. Preclinical and clinical studies could be conducted to find out the potential interaction of flavonoids with medications. Devising specialized systems to monitor the adverse effects related to flavonoid therapeutic action, to ensure timely detection and antidote for the side effects.

To summarize, flavonoids show immense promise in treating Neurological Disorders, but several limitations warrant further exploration. Firstly, leveraging tools in drug discovery, such as computer-aided design and high-throughput screening, can enhance understanding of flavonoids' safety, biochemical activity, and targeted mechanisms of action. Secondly, investigating the modifications in structure of these compounds is crucial for optimizing their efficacy. Lastly, conducting scientific clinical trials and comprehensive evaluations of potential side effects are essential to determine both the specificity and safety of flavonoids in treating Neurological Disorders. By continuing to advance our understanding, overcoming barriers, and translating research findings into clinical practice, we can harness flavonoids’ full potential in promoting brain health and combating neurological diseases.

Abstract

Conventional methods for synthesising polyurethane hydrogels encompass toxic isocyanates and organic solvents, limiting their eco-friendliness and ease of synthesis. In response, this study introduces an innovative approach to synthesising fructose-based non-isocyanate polyurethane (NIPU) hydrogel (FNHG), eliminating the need for isocyanates. Initially, fructose-based NIPU (FNPU) was synthesised using dimethyl carbonate and hexamethylene diamine under mild reaction conditions, paving the way for a greener polyurethane variant. Subsequently, a free radical polymerization technique was employed in an aqueous medium. This process allowed for the integration of poly(sodium acrylate), and N, N-methylene bisacrylamide, leading to to the development of FNHG. Remarkably short gelation time of just 30 min at 60 °C was achieved, signifying a significant advancement in the synthesis process. The synthesized NIPU-based hydrogels exhibited outstanding efficiency in the removal of crystal violet (CV) and malachite green (MG) dyes from aqueous media. With an impressive removal efficiency of 96.87% for CV and an astounding 99.8% for MG, these hydrogels demonstrated high effectiveness in remediation efforts. The study's novelty lies in both the synthesis methodology, utilising FNPU, and the exceptional efficiency exhibited by these hydrogels in eliminating diverse dyes from contaminated water. Furthermore, the structure of FNPU was confirmed using FTIR and ^{1}H NMR spectroscopy, adding robustness to our findings. This research not only presents a solution to the limitations of traditional polyurethane synthesis but also demonstrates the potential of fructose-based NIPU hydrogels (FNHG) as eco-friendly and efficient agents for water purification.

Introduction

PUs are versatile polymers with exceptional properties, making them ideal for use as engineering materials in various industrial applications ranging from lightweight construction materials, coatings in marine and aerospace industries, rollers, gaskets, seals, conveyor belts, flexible or rigid cellular foams, insulating components for energy conservation, and even as ideal candidate for biomedical industries due to their biocompatibility. However, the synthesis of PUs involves toxic isocyanates, which pose a risk to human health and the environment. Isocyanate exposure can cause health issues like dermatitis and asthma [1]. Some isocyanates have been linked to cancer, mutation, and reproductive harm [2]. In addition, their rapid hydrolysis is a challenge in humid environments. Subsequently, the one-pot one-step synthesis of PU hydrogels in water is challenging due to the rapid hydrolysis of isocyanates [3]. They are usually synthesized in bulk or organic solvents, followed by swelling in water [4]. Consequently, the development of alternative and sustainable approaches to polyurethane synthesis has become a significant area of research.

Recently, the development of non-isocyanate polyurethanes (NIPU) has gained significant consideration as a sustainable alternative to conventionally synthesized PU. NIPUs can be easily fabricated from renewable resources and do not require the use of toxic isocyanates, making them environmentally-friendly and safer for production as well as for application [5]. One of the most promising alternative approaches for the isocyanate-free synthesis of PUs proceeds via the formation of polyhydroxyurethanes via the reaction of hydroxyl group-containing precursors with cyclic carbonates, and then reacting the resulting product with diamines [6]. Nearly all these reports included the reaction of synthetic cyclic or dicyclic carbonates with aliphatic diamines (via aminolysis), but only a handful of these studies reported the use of bio-based carbonates and diamines because of the complexities in the synthesis process and poor results [7]. Unfortunately, there were still issues observed, such as harsh reaction conditions such as high temperature and the need for a catalyst, along with the use of a highly toxic reagent (epichlorohydrin) and high-pressure conditions [8]. Potential solutions to this hindrance in the synthesis of bio-based cyclic carbonates are the conversion of epoxidized vegetable oils or the utilization of glycerin carbonate intermediates. An even better strategy for the synthesis of NIPU is the use of simpler, non-cyclic dimethyl carbonate for the initial stage of carbonation, since

it is neither irritating nor mutagenic and avoids the need for ancillary steps of carbonate cyclisation [9]. NIPU materials synthesised by these sustainable routes find application in the coatings and polymer industries, similar to PU. Thermosetting coatings, UV-stable coatings, monolithic flooring, etc. could all be applied using NIPU technologies [10]. NIPUs offer distinct advantages, such as decreased toxicity and environmental impact compared to traditional PUs, yet their potential in environmental applications remains largely unexplored [11, 12]. This gap in the literature highlights the need for focused investigations into the environmental applications of NIPUs, which represent a promising area for multidisciplinary research and the formation of sustainable materials with reduced ecological impact. Among the renewable precursors explored for NIPU synthesis, fructose can emerge as a promising building block due to its abundance, biodegradability, and wide availability.

A significant portion of the population faces challenges such as malnutrition, illnesses, and, in extreme cases, fatalities, primarily due to the unavailability of safe drinking water. Water contamination stands as a pressing global challenge, posing risks to ecosystems, public health, and the environment [13–15]. The multifaceted properties of polyurethane serve as the foundation for its effectiveness in eliminating a broad range of pollutants, including oil, heavy metals, nitrates, phenols, phthalates, and dyes [16–19]. Engineered with high surface area and porosity, it effectively adsorbs pollutants such as heavy metals and dyes. Its chemical stability and robust mechanical strength ensure sustained performance when exposed to different pollutants, while the ability to customize surface chemistry enhances its affinity for specific contaminants like nitrates and phthalates [20]. These characteristics are enhanced when incorporated into hydrogels, attributed to a physically well-defined three-dimensional porous architectures and an increased surface area-to-volume ratio, thus, leading to an improved adsorption capacity [21–23]. The ability to construct a flexible network of polymer chains due to the hydrophilic nature of hydrogel adsorbents enables solutes to readily permeate the network and form stable complexes with the functional groups.

Limited research is available on the utilization of bio-based PU hydrogels for environmental applications. The first polyhydroxyurethane (PHU) hydrogels were based on a two-step process involving first the preparation of PHU in the bulk by polyaddition of a hydrophilic poly(ethylene glycol) dicyclic carbonate (PEG-diCC) to a diamine and a crosslinker; followed by their swelling in water [24]. Another example of PHU hydrogels prepared in water consisted of the aminolysis of PEG-diCC with polyethyleneimine at room temperature [25]. Fructose offers a renewable, eco-friendly source for polymer synthesis, reducing environmental impact and enabling the development of sustainable, biocompatible materials. This facile study aimed to synthesize fructose-based NIPU by using dimethyl carbonate and hexamethylene diamine solution as precursors employing mild reaction conditions, and to study their application in the fabrication of hydrogels, having potential application in dye removal. The hydrogels were prepared (with poly(sodium acrylate)e and N, N-methylene bisacrylamide) through a free radical polymerization method in an aqueous medium. In the process of hydrogel synthesis, sodium acrylate was synthesized by reacting acrylic acid (AA) with sodium hydroxide (NaOH). By harnessing the potential of fructose-based NIPUs and their hydrogels, this research offers valuable insights into the development of effective and eco-friendly solutions for dye removal and highlights the significance of NIPUs in addressing water pollution challenges.

Materials and Methods

Materials

Non-isocyanate polyurethane was synthesized by employing commercially available hexamethylene diamine (HMDA), which was obtained from Sigma Aldrich. D-Fructose, potassium persulphate (KPS), dimethyl carbonate (DMC), crystal violet dye (CV), and malachite green dye (MG) were purchased from Thermo Fisher Scientific. Acrylic acid (AA) and sodium hydroxide (NaOH) were acquired from CDH Pvt. Ltd whereas N, N'-methylene bis (acrylamide) (MBA) was procured from Merck. All chemicals and solvents used in the analytical measurement trials were of analytical grade and utilized exactly as received.

Preparation of the Fructose-Based NIPU (FNPU)

In a round bottom flask, 9.99 g of fructose ($C_6H_{12}O_6$), 6.71 g of dimethyl carbonate (CH_3OCOCH_3), and 8.33 g of water (H_2O) were added. The reaction mixture was then subjected to reflux at 80°C for 60 min. Subsequently, 1 g of a 70% solution of hexamethyl diamine (HMDA) was introduced into the reaction mixture, followed by further heating at 90°C for another 60 min. The resulting solution, upon cooling to room temperature, yielded the desired product, non-isocyanate polyurethane (NIPU), labelled as FNPU. A schematic representation and detailed reaction mechanism of the synthesis of NIPU are shown in Figs. 1 and 2, respectively.

NaOH was used to neutralise AA (2 mL), resulting in sodium acrylate (SA), which was subsequently polymerized to produce the hydrogel. Subsequently, the aqueous

solutions of each FNPU and SA were mixed and 0.05 g of MBA, and 0.05 g of KPS were added, with continuous stirring. The resulting solution was then transferred into a test tube and heated for 30 minutes in a water bath at a controlled temperature of 60 °C. The gelation process resulted in the formation of the FNHG, which was carefully removed and then further divided into tiny pellets. The hydrogel pellets were subsequently dried in an oven for 48 h at 50 °C, to remove the moisture. A schematic representation of the synthesis of NIPU-based hydrogel (FNHG) is shown in Fig. 1.

Swelling Studies

The investigation involved an examination of the swelling behaviour exhibited by synthesized hydrogels via the gravimetric approach at consistent one-hour intervals spanning 24 h in distilled water. In the initial phase, desiccated hydrogel discs were immersed in distilled water. Any surplus fluid was blotted away using filter paper [26]. Subsequently, the swollen hydrogels were extracted after a specified interval, their mass was carefully recorded and subsequently re-immersed into the distilled water. The determination of the swelling (%) was accomplished by employing the following formula (Eq. 1) [26].

$$\text{Swelling}\,(\%) = ((W_e - W_d)/W_d) \times 100 \quad (1)$$

where W_e is the weight of the swollen hydrogel at time t and W_d is the initial weight of the dried hydrogel.

pH Dependent Equilibrium Swelling Percent

Pre-weighed dried samples of the hydrogels were immersed in distilled water and buffer solutions of pH 2,4, 9 and 12 respectively. After a defined period of 24 h (equilibrium state), the hydrogel samples were carefully removed and their final weights were recorded. The equilibrium swelling percent (ES %) of the hydrogel samples was calculated using the Eq. (2) [27]. This calculation allows us to determine the extent of swelling exhibited by the hydrogel samples under specific pH conditions. A higher ES (%) value indicates greater swelling of the hydrogel, while a lower value suggests minimal swelling. By measuring ES (%) at different pH levels, pH sensitivity of the hydrogels can be determined.

$$\text{ES}\,(\%) = ((W_t - W_i)/W_i) \times 100 \quad (2)$$

- W_t is the weight of the hydrogel sample after swelling,
- W_i is the initial dry weight of the hydrogel sample.

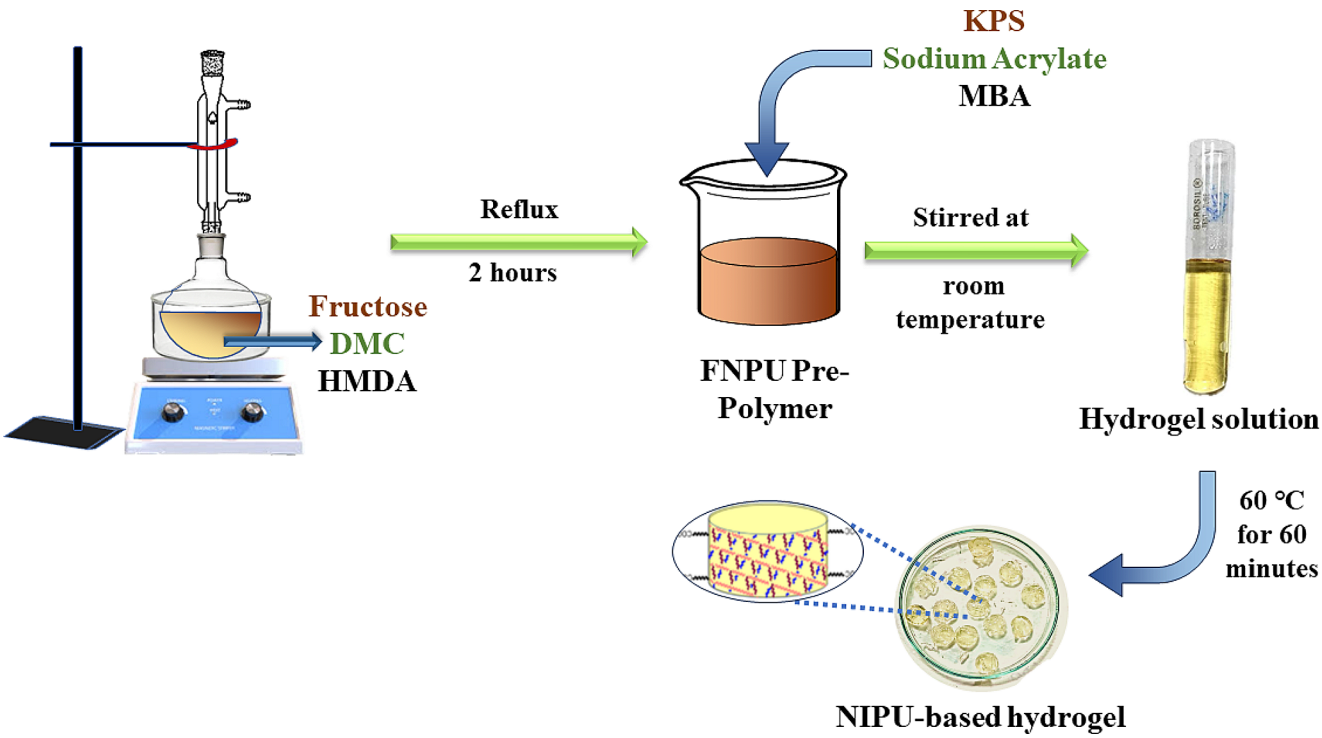

Fig. 1 Schematic diagram for the synthesis of NIPU-based hydrogel (Color figure online)

Swelling Kinetics

In order to understand the mechanism of water diffusion into the hydrogel samples, kinetic swelling studies were conducted using both the Kosmeyer-Peppas model (Eq. 3) and the Higuchi model (Eq. 4). Kosmeyer-Peppas model is particularly useful for hydrogels undergoing Fickian or non-Fickian diffusion, which is commonly observed in polymeric networks with complex structures. By fitting experimental swelling data to the Korsmeyer-Peppas model, we can determine the swelling exponent (*n*), which provides the information about the mechanism of the swelling. On contrary, the Higuchi model provides insights into the kinetics of swelling by describing the swelling as diffusion mechanism. This model helps us to understand how quickly a hydrogel reaches the equilibrium swelling, under specific conditions. The most appropriate and well-fitting model for explaining the drug release mechanism is the one that shows an R^2 value approximately equal to 1.

$$\mathrm{Log}\ (\mathrm{Swelling}\,\%) = \mathrm{Log\,K} + \mathrm{n\,Log\,t} \tag{3}$$

$$\mathrm{Swelling}\% = \mathrm{K.t}^{1/2} \tag{4}$$

where is K is rate constant and t is time.Sol-gel Analysis

The synthesised hydrogel's uncrosslinked and crosslinked fraction was determined via sol-gel analysis. A hydrogel's insoluble cross-linked portion is called a gel, while its soluble uncross-linked portion is implied by the term "sol". A sol–gel study was performed to examine the uncrosslinked portion of FNHG and control Polysodium acrylate (PSA) hydrogel. Weighed (Mi) dried hydrogels were immersed in distilled water for 24 h at room temperature. The hydrogel discs were then dried in an oven at 45 °C until a constant weight (Me) was achieved. The following equations were used to calculate the sol and gel fractions [26]:

$$\mathrm{Sol\ Fraction}\ (\%) = \frac{M_i - M\mathrm{e}}{M_e} \times 100 \tag{5}$$

$$\mathrm{Gel\ Fraction}\ (\%) = 100 - \mathrm{Sol\ Fraction} \tag{6}$$

Dye Sorption by FNHG

Batch studies were undertaken to assess the efficacy of the synthesized hydrogel FNHG in removing malachite green (MG) and crystal violet (CV) dyes at room temperature to ensure uniform experimental conditions. In each study, 0.05 g of the testing FNHG sample was put into 25 mL aqueous solution with 20 ppm of CV and MG dye solutions at room temperature for 60 min, until equilibrium was reached. The main objective of this study is to assess the dye sequestration efficiency of the synthesized hydrogel FNHG. The progression of the sorption phenomenon was precisely monitored using a UV-vis spectrophotometer at a wavelength of 617 and 582 nm for MG and CV dye, respectively. In order to assess the removal efficiency of the dyes and to ascertain the dye elimination capacity of the prepared hydrogel, the following mathematical formulation was employed:

$$\mathrm{Removal\,efficiency}\ (\%) = \frac{\mathrm{C_o} - \mathrm{C_e}}{\mathrm{C_o}}\ 100\% \tag{7}$$

where C_o refers to the initial dye concentration and C_e refers to the equilibrium dye concentration.

Instrumentation

Attenuated Total Reflectance Fourier Transform Infrared Spectroscopy (ATR-FTIR)

Examination of samples was conducted using an attenuated total reflectance (ATR) Miracle diamond crystal and a Perkin Elmer Frontier ATR-FTIR. The clamp mechanism was firmly fastened when the sample powders were positioned on the diamond eye (1.8 mm) of the ATR apparatus. For the purpose of capturing the spectra in the wave number range of 600 to 4000 cm^{-1}, each sample was scanned 32 times at a resolution of 4 cm^{-1}.

Nuclear Magnetic Resonance (NMR)

The structural analysis of FNPU was performed by employing ^{1}HNMR spectroscopy using Jeol (Model: JNM-ECZ 400 S) NMR spectrometer (at 100 MHz). Deuterated dimethyl sulfoxide was employed as a solvent to dissolve the sample for analysis.

Thermogravimetric Analysis (TGA)

The thermal stability of the NIPU and hydrogel was evaluated by thermogravimetric analysis (TGA; Perkin Elmer TGA 4000). As a purge gas, dinitrogen was used. The thermal properties in the range of 50 to 250 °C were examined at a rate of 20 °C min^{-1} in order to determine the thermal parameters of transition.

Powder X-ray Diffraction (PXRD)

PXRD was employed using a high-resolution Bruker diffractometer (D8 Discover), in conjunction with a point detector (scintillation counter), to analyze the morphology and structure of the developed samples. Cu K radiation was received via a Gobel mirror that covers the range of 2α, 5–80°, with a scan rate of 1.0 s/step and step size 0.02°, at 298 K.

Scanning Electron Microscopy (SEM)

The morphology and internal structure of the hydrogel were examined using a scanning electron microscope (Jeol JSM-6610LVmodel).

Results and Discussions

Mechanistic Pathway Followed for the Synthesis of FNPU

During the synthesis of fructose-based NIPU (FNPU), the fructose molecules act as the starting material for the formation of the polyurethane backbone. Non-cyclic dimethyl carbonate is utilised for the initial stage of carbonation [2], and then nucleophilic substitution is used to carboxymethylate the existing hydroxy groups in fructose [28]. Afterwards, the adduct is allowed to react with hexamethylene diamine to produce NIPU at ambient pressure as shown in Fig. 2.

Mechanistic Pathway Followed for the Synthesis of FNHG

The synthesized FNPU was subsequently employed as a precursor for hydrogel fabrication with SA as a co-monomer, MBA as a crosslinker, and KPS as an initiator. The various chemical interactions and reactions that occur during the synthesis process are presented in Fig. 3.

KPS serves as an initiator for the free radical polymerization of SA during the hydrogel formation. KPS dissociates in water, generating sulfate radicals ($SO_4^{\bullet -}$) through thermal decomposition. These sulfate radicals initiate the polymerization of SA monomers, leading to the formation of long polymer chains of poly(sodium acrylate) (PSA) that further crosslink to create the hydrogel matrix. PSA contains a carboxylate group (–COO–) that reacts with the hydroxyl groups present in the fructose-based NIPU backbone. This reaction involves a nucleophilic addition of the carboxylate group to the hydroxyl group, leading to the formation of ester linkages (–COO–) between the PSA and the NIPU backbone. In addition to the ester linkages formed between PSA and the NIPU backbone, MBA serves as a crosslinker attributing to the presence of two acrylamide groups that

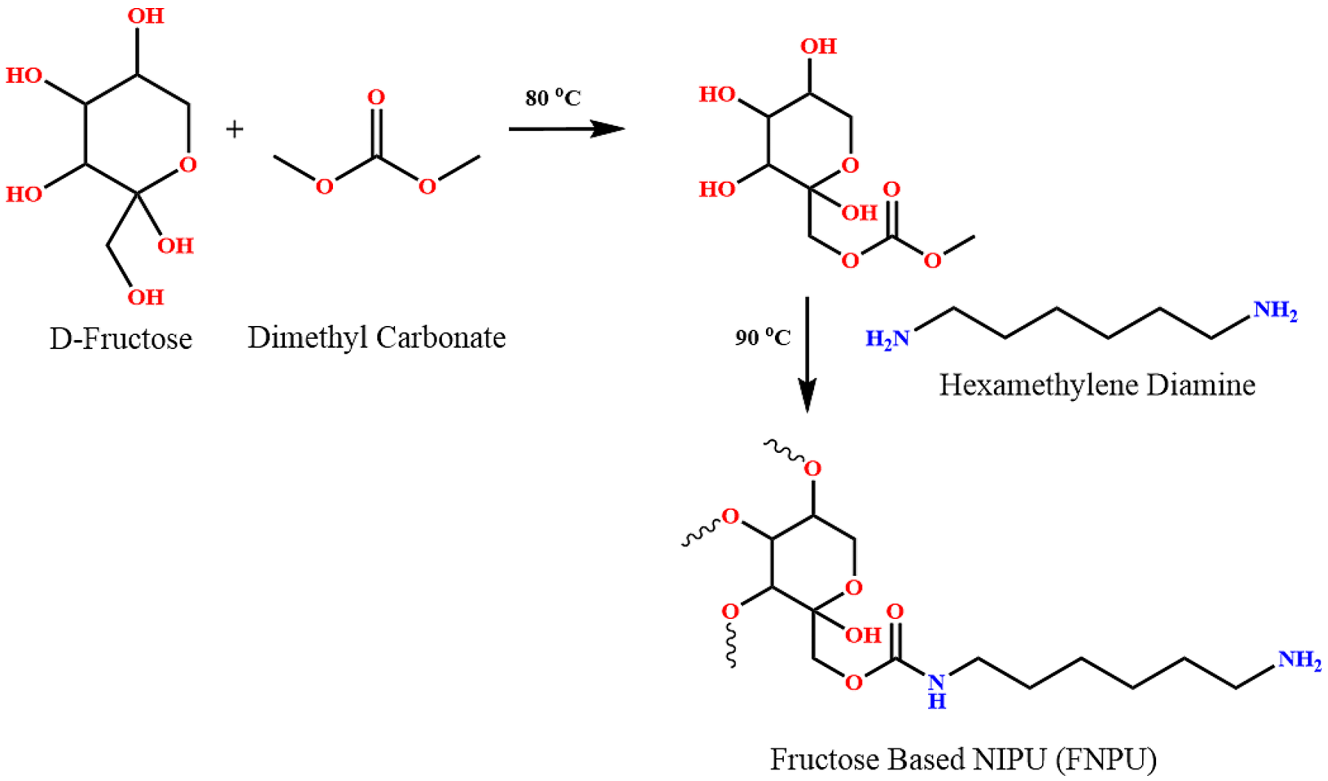

Fig. 2 Proposed mechanism for the synthesis of fructose-based NIPU (FNPU) (Color figure online)

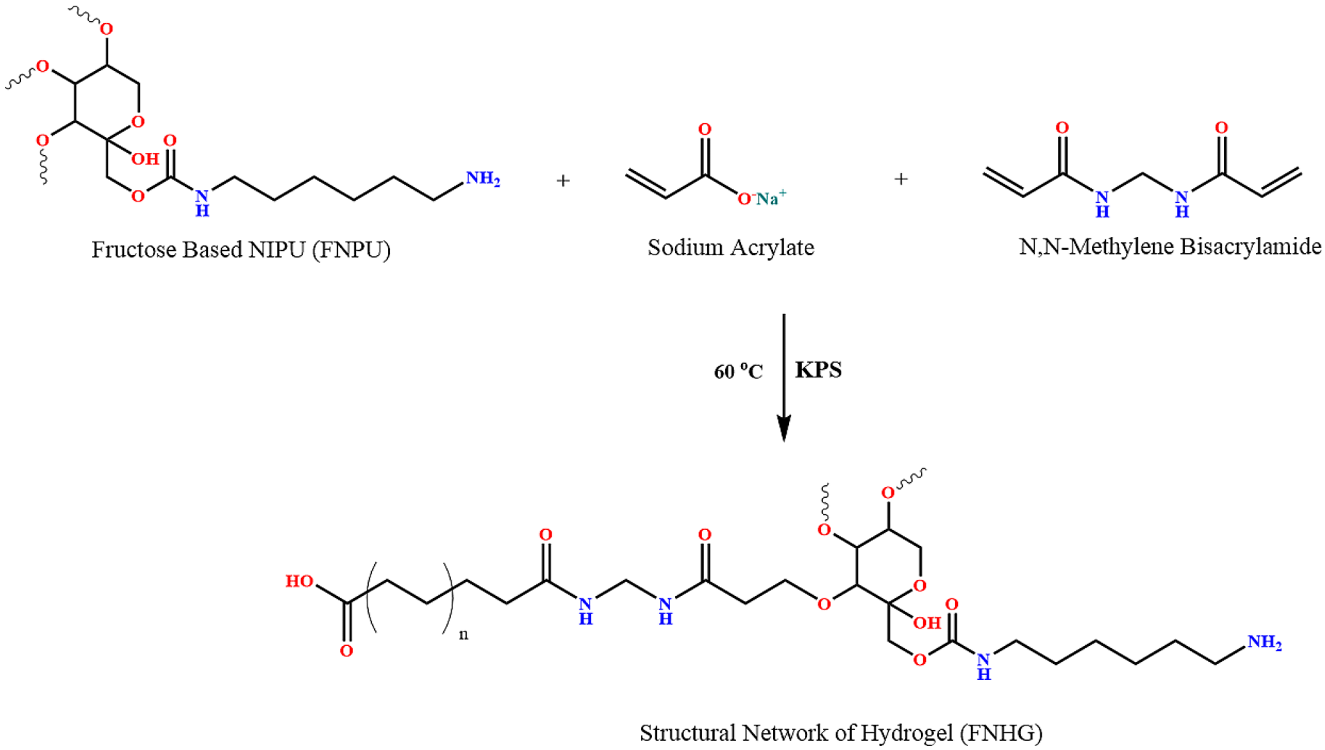

Fig. 3 Proposed mechanism for the synthesis of fructose-based NIPU hydrogels (FNHG) (Color figure online)

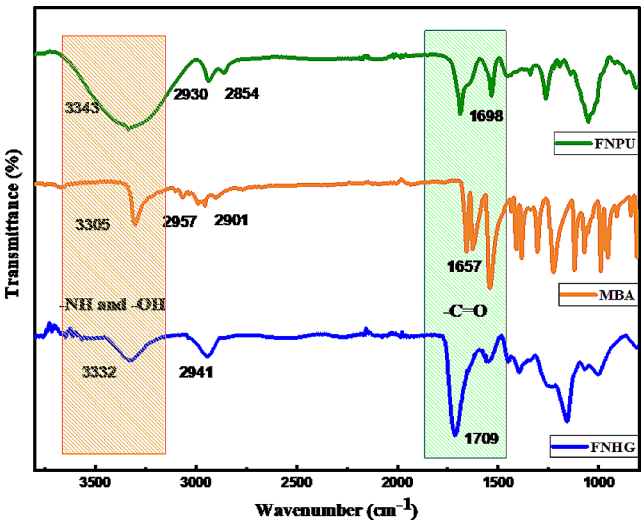

Fig. 4 FTIR spectra of FNPU, MBA, and FNHG (Color figure online)

react with the carboxylate groups present in SA. The cross-linking reaction involves the development of amide linkages (–CONH–) between the acrylamide groups of MBA and the carboxylate groups of PSA. This crosslinking reaction reinforces the three-dimensional network structure of the hydrogels, enhancing its mechanical integrity and stability.

Characterization of FNPU and FNHG

In order to study the functional group modifications occurring during the formation of FNPU, FTIR analysis was done (Fig. 4). In the case of FNPU, the broad peak at 3332 cm^{-1} is indicative of extensive hydrogen bonding, attributed to the stretching frequencies of both hydroxyl (-OH) and amine (-NH) groups. Bands around 2930–2854 cm^{-1} are associated with C-H stretching vibration in -CH_2- groups. The band around 1698 cm^{-1} confirms the presence of urethane-derived carbonyl bands of a complex nature [9]. The characteristic absorption peak at 1530 cm^{-1} correlates to bending of urethane-derived C-N-H and is typically observed in all polyurethanes [1, 9, 11, 12]. Another band at 1180–980 cm^{-1} corresponds to ether C-O-C (carbonate backbone) and alcohol C-O stretching vibrations. In contrast, the FTIR spectrum of MBA reveals a characteristic peak associated with the C-N bond at 1311 cm^{-1}. However, upon cross-linking to form FNHG, a notable shift of this peak to 1376 cm^{-1} is observed, indicating a reduction in conjugation as a consequence of the cross-linking process [26]. As a result, it can be established that the cross-linking of the FNHG has been successfully achieved. Moreover, the presence of carboxyl and urethane groups within the hydrogel matrix is evidenced by bands at 1709 cm^{-1} [9]. Additionally, the C-O ester groups of the network structure are associated with the unique absorption band at 1248 cm^{-1} [1,

10–12, 29, 30]. Thus, the FTIR spectra of FNPU, MBA, and FNHG confirm the successful synthesis of fructose-based NIPU/ PSA employing an isocyanate-free process at atmospheric pressure.

To further confirm the structure of FNPU, ^{1}HNMR studies were conducted. After dissolving a predetermined amount of FNPU (about 20 mg) in deuterated DMSO, the sample solution was transferred into an NMR tube. Once the ^{1}H NMR data acquisition was completed, characteristics peaks of urethane linkage and other entities were determined. In the NMR spectra presented in Fig. 5, peaks are observed at around 2.5 ppm and 3.4 ppm, which can be attributed to deuterated dimethyl sulfoxide (DMSO) and its water. In the NMR spectra of the synthesized compound (FNPU), several distinct peaks provide valuable insights into its molecular structure. Firstly, the peak at δ 8.12 ppm corresponds to the urethane NH group, confirming the successful formation of the urethane bond critical for enhancing mechanical strength and stability. Furthermore, Small peaks around δ 5.44 ppm are likely attributed to the anomeric proton of the glucopyranose unit. Additionally, the presence of hydroxyl (OH) groups is indicated by a visible hump around δ 3.80–3.89 ppm, contributing to the broad signal in this region. Hydroxyl groups play crucial roles in the chemistry of the synthesized compound, facilitating hydrogen bonding interactions. Furthermore, the peak at δ 3.56 ppm corresponds to the methylene group adjacent to the urethane moiety, likely belonging to the polymer backbone while peaks in the range of δ 3–4 can be attributed to the protons of the glucopyranose ring. Its chemical environment may differ from other methylene groups due to its proximity to the urethane linkage. Lastly, a cluster of peaks within the δ range of 1.21–1.49 ppm arises from the protons of methylene groups in the carbon chain of hexamethylene diamine, a common building block in polymer synthesis. The distinct chemical shifts of these methylene protons facilitate their differentiation from other methylene groups in the compound [31].

In the PXRD pattern presented in Fig. 6, the presence of a dominant peak at 20° implies that the synthesized material is segmented PU (NIPU in this case) and the broadness of the peak signifies that FNPU has a chemical structure in accordance with the previously reported studies [16, 17]. This corroborates that fructose-based NIPU has been successfully synthesized using an isocyanate-free approach at atmospheric pressure. The amorphous nature of FNPU is reduced in the process of formation of FNHG; this could be due to the introduction of other functional groups (such as acrylate entities and amide) and an increase in the number of hydroxyl groups, which may induce an ordered structure [32].

TGA was carried out to determine the thermal stability of the synthesized FNPU (Fig. 7 (a)) and FNHG (Fig. 7 (b)), in nitrogen (N_2) atmosphere across temperatures ranging from 25 to 700 °C. The TGA curve displays mass loss as a two-step process, as presented in Fig. 7 (a). The initial weight loss step between 104 and 224 °C involves the decomposition of

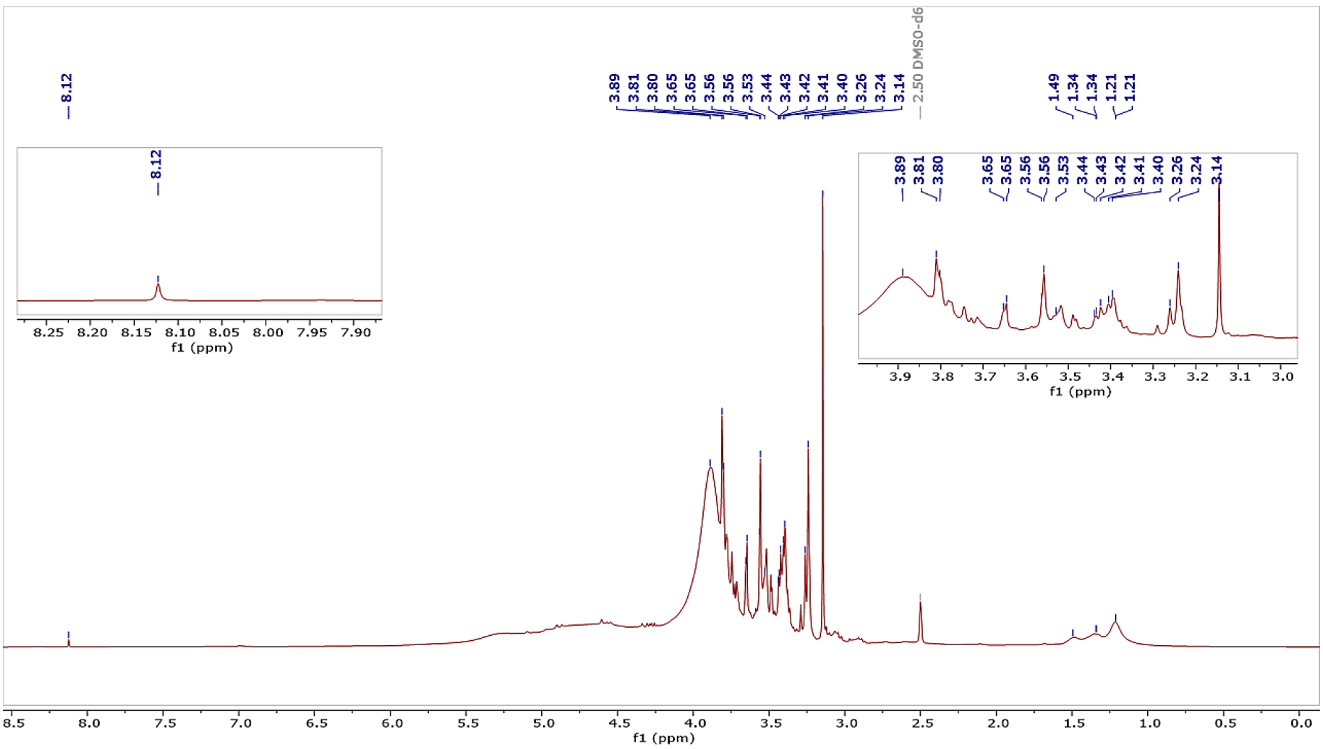

Fig. 5 ^{1}HNMR Spectra of the FNPU (Color figure online)

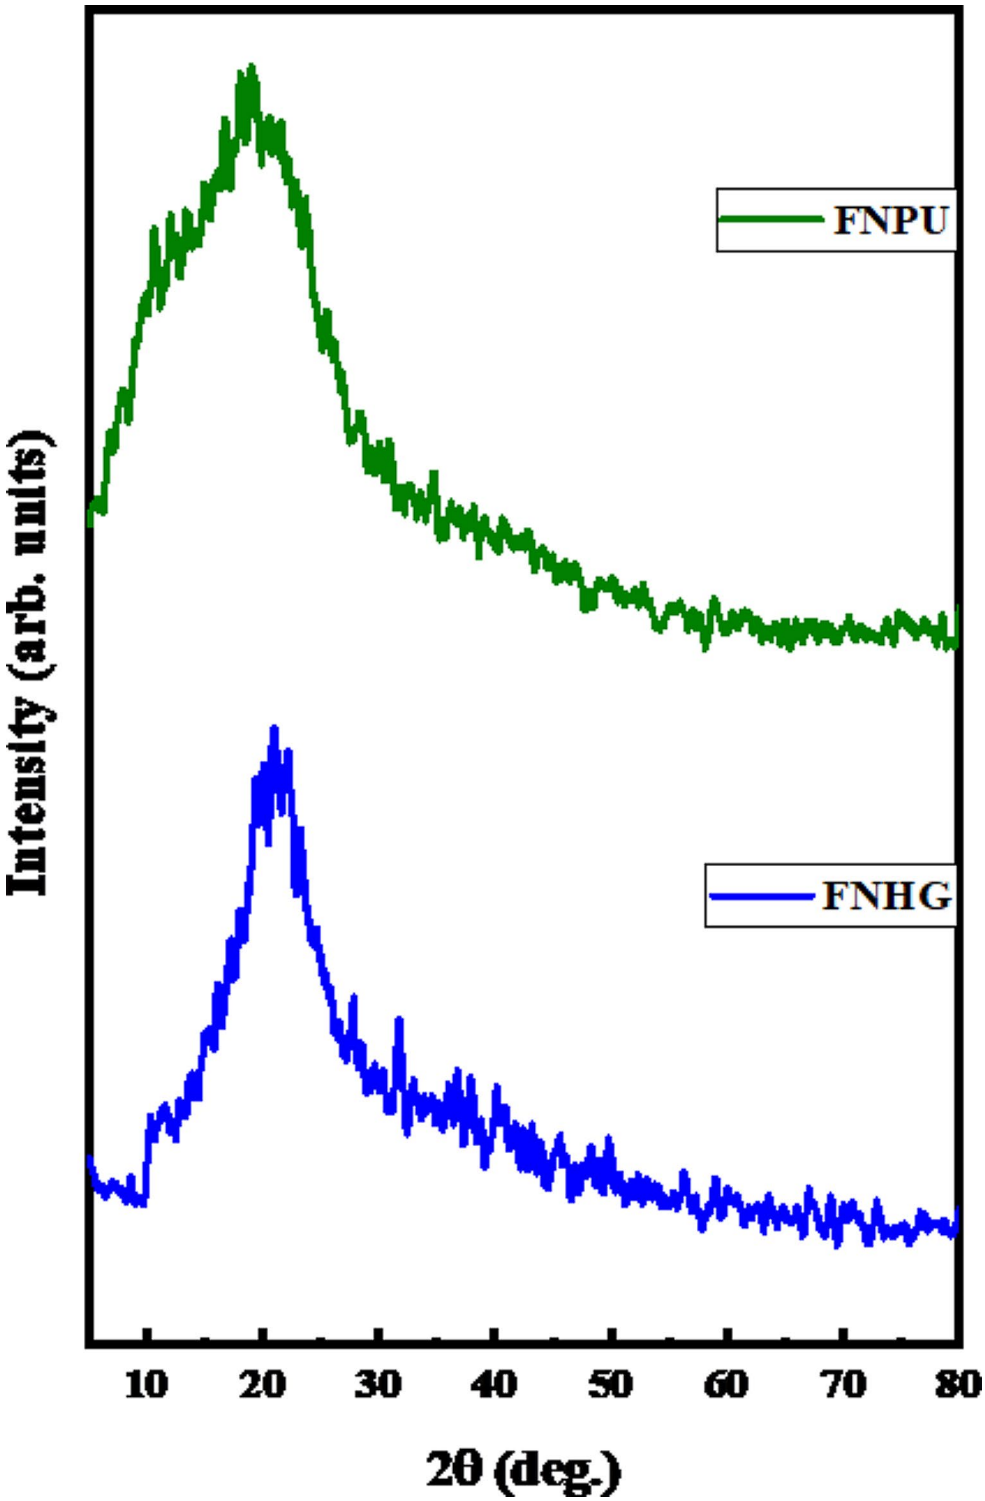

Fig. 6 PXRD pattern of FNPU and FNHG (Color figure online)

hexamine as well as the discharge of absorbed water molecules and evaporation of monomers/oligomers generated during the course of the reaction below 200 °C [24, 25]. The second weight loss step, as observed between 333 and 508 °C is a result of the collapse of the polymer backbone due to the cleavage of the urethane bond. The third and final weight loss step occurs above 500 °C and involves more than 80% mass loss, which can be credited to the possible breakdown of C–C bonds and degradation of the remnants of the pyrolysis by-products from the prior two steps.

Thermal degradation of FNHG hydrogel follows four stages of decomposition as shown in Fig. 7 (b). The first

stage occurs from 74 to 164 °C with weight loss of 1.09% indicating the vaporization of water molecules in FNHG hydrogel. The second stage indicates the loss of carboxyl and hydroxyl groups from the polymeric backbone with weight loss of 41.76% from 200 to 307 °C in FNHG hydrogel. In the third weight loss step, a weight loss of 21.92% from 333 °C to 412 °C was observed and can be attributed to the breakdown of cross-links present in FNPU hydrogel. Finally, the last weight loss of 8.03% from 412 to 508 °C can be attributed to the complete degradation of FNHG hydrogel, respectively. The FNHG hydrogel showed an enhanced thermal stability as compared to that of FNPU, thus, indicating that MBA results in the formation of a chemically cross-linked PSA and NIPU network.

The ability of FNHG to swell by retaining water in its sponge-like structure was demonstrated by a swelling study. The FNHG shows the maximum swelling of 53.20% in distilled water, as observed in Fig. 8 (a). The ES % for FNHG was evaluated in distilled water and in pH 2,4,10, and 12, as presented in Fig. 8 (b). The equilibrium swelling percent was observed maximum at pH 12 and minimum at pH 2. The ionisation characteristics of the synthesised hydrogel can be used to explain its pH-dependent swelling behaviour. At higher pH of 10 and 12, the ES % was found to have greater swelling, these values indicate that the carboxylate groups in poly(sodium acrylate) deprotonate, which increases ionisation and the electrostatic repulsion between polymer chains. The hydrogel network structure loosens as a result of this repulsion, allowing for increased water absorption and percent equilibrium swelling (PES) values. In contrast, the carboxylate groups are primarily protonated at low pH of 2 and 4 values, which results in less ionisation and reduced electrostatic repulsion between polymer chains. Overall, the ionisation state of carboxylate groups controls the pH-dependent swelling behaviour of the hydrogel. This eventually affects the hydrogel's capacity to swell by modifying the electrostatic interactions and hydrophilicity of the polymer chains [33].

The hydrogel samples showed behaviour that was in line with first-order kinetics and the Korsmeyer-Peppas model, according to the examination of the swelling kinetics data (Fig. 8c). A moderate match of the data to the Higuchi kinetics model is suggested by the derived R^2 value of 0.73582. Furthermore, the Korsmeyer-Peppas model—which takes n to be the diffusion constant and k to be the kinetic constant—was used to examine the hydrogel samples' swelling behaviour. The obtained values of R^2 (0.98019) and n (0.64034) show that the data fit the Korsmeyer-Peppas model well, implying that non-Fickian diffusion kinetics govern the hydrogel samples' swelling behaviour. It suggests that the swelling kinetics of the hydrogel may not be entirely controlled by molecular diffusion, but rather other processes like polymer chain relaxation might also be involved [26, 27].

The control (PSA hydrogel) and FNHG have an observed sol fraction of roughly 22.12% and 19.02% and a gel fraction of roughly 77.88% and 80.98% respectively. These results can be ascribed to the crosslinking density. The addition of NIPU improves the gel fraction by adding more crosslinks to the polymer matrix. These crosslinks aid in the development of a three-dimensional network, giving the hydrogel its structural stability. Low molecular weight species, oligomers, or unreacted monomers in the hydrogel formulation could be the cause of the observed sol fraction.

Figure 9 illustrates the hydrogel's surface morphology before the dye removal experiments. The SEM micrograph

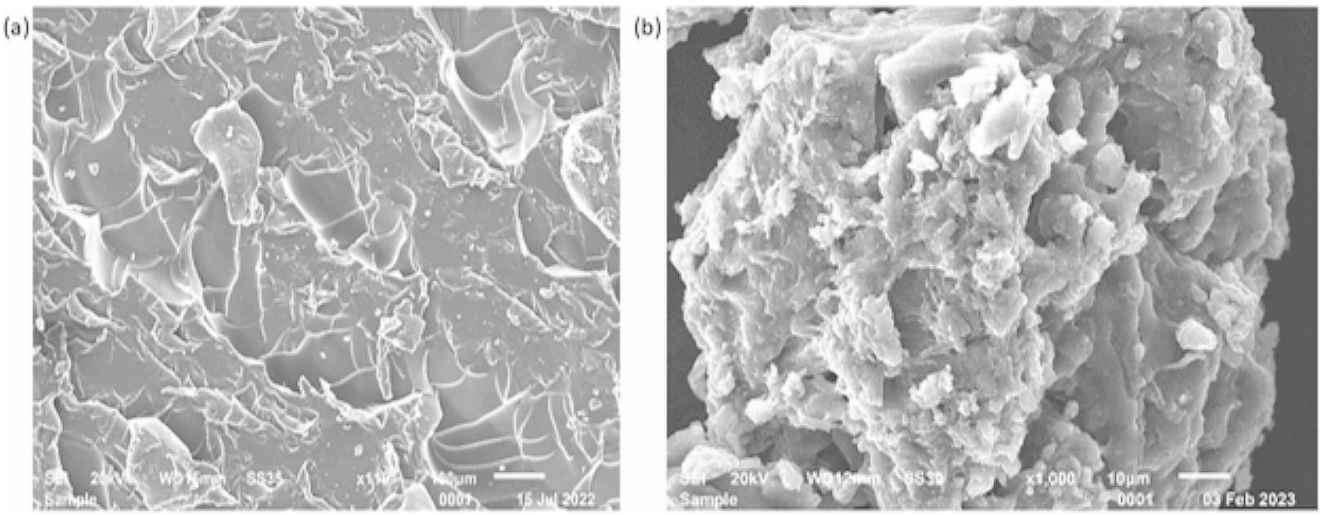

Fig. 9 SEM image of (**a**) PSA hydrogel and (**b**) FNHG

displays that FNHG hydrogel exhibits a characteristic macroporous three-dimensional structure. A closer inspection reveals that the FNHG hydrogel has a surface that is substantially rough and contains scattered pores in comparison to the controlled hydrogel (PSA hydrogel). The surface roughness of the FNHG has significantly increased with addition of NIPU due to irregularities or changes in the surface topography of the hydrogel, as seen in Fig. 9 (a) and (b) respectively. Changes in the crosslinking density and the incorporation of additional polymer chains, as a result of the integration of NIPU, are two reasons for this increase in surface roughness. The hydrogel's overall texture may be impacted by the surface imperfections resulting from the NIPU-polysodium acrylate interactions [34]. This feature of the hydrogel's surface morphology is beneficial for the effective collection and retention of dye molecules, which is a critical characteristic for its application in dye removal processes. The efficient removal of the dye molecules is greatly aided by this complex surface roughness. The existence of the pores and the uneven surface texture increases the surface area available for interactions between the dye molecules and the polymeric network [17]. As a result, this structural characteristic improves the hydrogel's ability to arrest molecules, which makes it suitable for removing dye molecules from the surrounding environment [35].

CV and MG Dye Sequestration by FNHG

The removal efficiency of the FNHG hydrogel was assessed for the sequestration of CV and MG dyes under optimum

conditions (adsorbent = 0.05 g, adsorbate solution = 25 mL, concentration of CV and MG dyes = 20 mg/L, and contact time = 60 min). During the process, a pattern was observed, as seen in Fig. 10, wherein the absorbance values for both dyes show a steady fall over time, with their levels stabilizing after 60 min. Within the first 15 min of the interaction of the dye with the synthesized hydrogel, there is an abrupt and noticeable increase in dye uptake. The initial high concentrations of the dye solutions along with the availability of readily accessible adsorption sites on the hydrogel surface are responsible for this phenomenon. The degree of removal, however, steadily slows down as time passes and the system gets closer to equilibrium, eventually achieving equilibrium at 60 min. The decline in the concentration of CV and MG solution and the gradual occupation of previously available empty sites on the sorbent material are two concurrent processes that can be attributed to this slowing down of the dye removal rate.

The removal efficiency of controlled hydrogel was found to be around 86.84% and 90.8% for CV and MG dye, respectively whereas that for FNHG it was found to be 96.87% and 99.80% for CV dye and MG dye respectively. The removal efficiency of FNHG hydrogel (Fig. 11a) is significantly higher than that of the control PSA hydrogel (Fig. 11b). These enhanced removal efficiencies of dyes via FNHG highlight the expediency of the synthesised hydrogel as an efficient material for the uptake of dyes from wastewater.

Possible Interactions Between the Synthesized Hydrogel and Cationic Dyes

It has been reported that organic and inorganic contaminants found in wastewater can be effectively removed by polyurethane foams [17–20]. However, several studies have also demonstrated that modified polyurethane-based adsorbents exhibit enhanced adsorption attributes, for example, surface area, pore size, and functional groups. These modification can be achieved through various methods, such as coating, grafting, and crosslinking; to introduce specific chemical moieties that can interact with target pollutants [36]. In this study, NIPU has been modified via crosslinking with PSA. Depending on the structure and charge of the pollutants, removal can be accomplished through a variety of interactions between the synthesized hydrogel FNHG and dye molecules, including electrostatic interactions, ion exchange, and hydrophobic interactions, etc. CV and MG dyes are water soluble and exhibit a positive charge when dissolved in aqueous solutions [37]. Negatively charged polymer entities present on the surface of hydrogel, owing to the inclusion of PSA into the matrix may have primarily facilitated the electrostatic attraction of positively charged cationic dye molecules. Leite et al. studied the inclusion of sodium dodecyl sulfate (SDS) into the PU matrix which enabled the establishment of a hydrophobic ionic pairing between the cationic dye and the anionic surfactant, displaying a strong affinity for PU [38]. Therefore, it can be suggested that PSA might be acting as a carrier to adsorb CV and MG dye molecules into the polymeric network similar to SDS. Despite the predominance of electrostatic interactions, some weaker

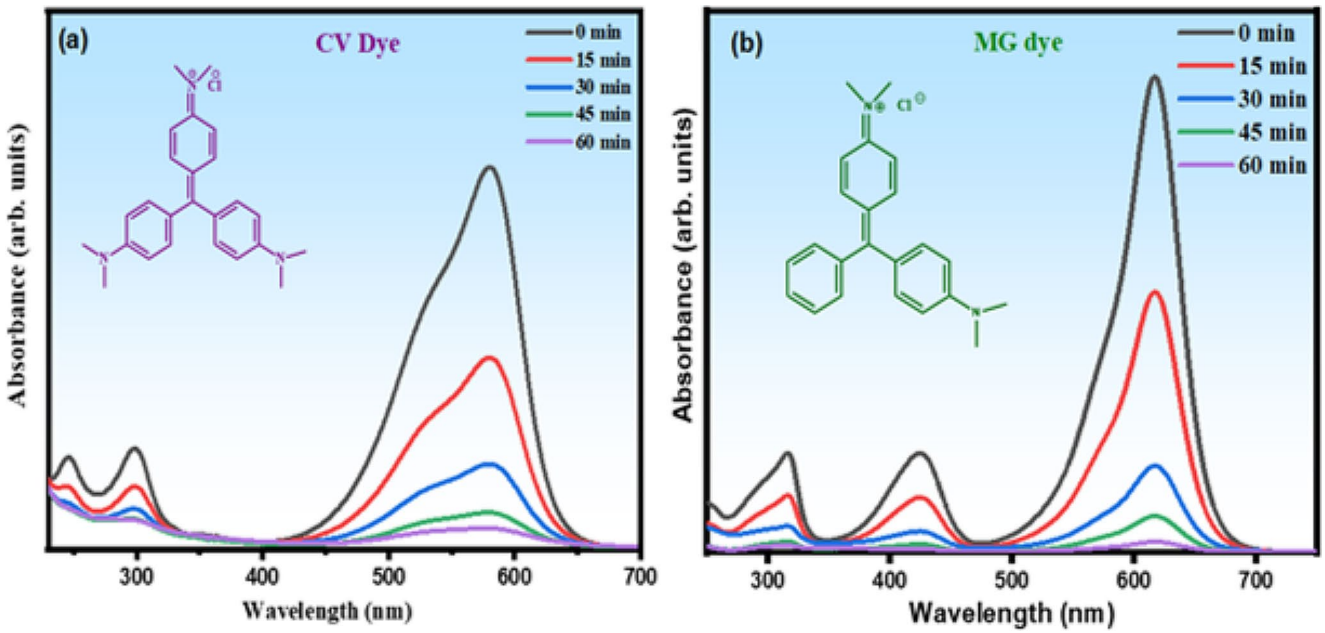

Fig. 10 Absorbance spectra of CV (**a**) and MG (**b**) dyes (Color figure online)

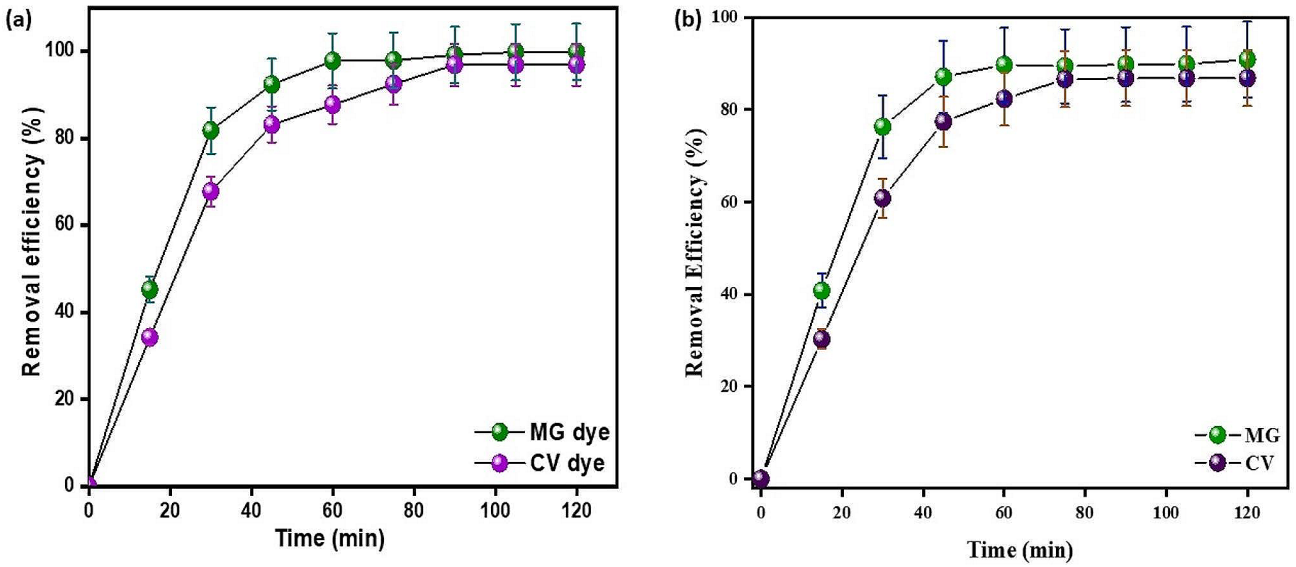

Fig. 11 Removal efficiency of CV and MG dyes (**a**) FNHG and (**b**) Control PSA Hydrogel (Color figure online)

hydrogen bonding may also occur amongst the amine groups of dye molecules and hydroxyl groups of the synthesized hydrogel [27, 39]. The interactions between CV and MG dyes with PSA polymer led to their attachment and probable adsorption onto the polymer surface. This property of PSA polymer makes it a useful carrier in the NIPU matrix for applications related to dye sequestration and material formulation.

Conclusions

The present work demonstrated the synthesis of fructose-based NIPU and then its hydrogels via a facile and novel approach. The adopted method results in the formation of hydrogel in a more ecologically friendly manner by avoiding harsh reaction conditions and by reducing gelation time to 30 minutes. The fundamental structural framework of the NIPU backbone is fructose, which was selected as a sustainable and easily accessible building element. The acquired results from FTIR and ^{1}H NMR spectroscopy confirm the formation of urethane linkages throughout the polymer matrix. The hydrogel's three-dimensional network structure is strengthened by the addition of the crosslinker MBA. Furthermore, PSA serves as a comonomer in the hydrogel formulation, facilitating the introduction of various functional groups. TGA results revealed that this structural reinforcement not only improves the hydrogel's thermal stability but also provides the mechanical resilience required for its practical applications. SEM morphology displays the presence of a rough surface providing additional surface area. The study also demonstrated that the fabricated hydrogel can act as a potential material for the sequestration of cation dyes. The NIPU-based hydrogel exhibited high removal efficiency towards CV and MG dyes i.e., 96.87% and 99.8% respectively. The novel fructose-based NIPU hydrogels have enormous potential as an effective material for dye removal from aqueous solutions.

Abstract

In recent years, the study of artificial intelligence (AI) has undergone a paradigm shift. This has been propelled by the groundbreaking capabilities of generative models both in supervised and unsupervised learning scenarios. Generative AI has shown state-of-the-art performance in solving perplexing real-world conundrums in fields such as image translation, medical diagnostics, textual imagery fusion, natural language processing, and beyond. This paper documents the systematic review and analysis of recent advancements and techniques in Generative AI with a detailed discussion of their applications including application-specific models. Indeed, the major impact that generative AI has made to date, has been in language generation with the development of large language models, in the field of image translation and several other interdisciplinary applications of generative AI. Moreover, the primary contribution of this paper lies in its coherent synthesis of the latest advancements in these areas, seamlessly weaving together contemporary breakthroughs in the field. Particularly, how it shares an exploration of the future trajectory for generative AI. In conclusion, the paper ends with a discussion of Responsible AI principles, and the necessary ethical considerations for the sustainability and growth of these generative models.

Keywords: Generative Artificial Intelligence, Generative Adversarial Networks, Diffusion, Segmentation, Variational Autoencoder, Transformers.

1 Introduction

The recent advancement in Artificial Intelligence has been mainly the result of Generative Artificial Intelligence (often referred to as Generative AI or GenAI) being introduced. Generative AI encompasses artificial intelligence systems with the ability to create text, images, or various forms of media through the utilization of generative models. These models acquire an understanding of the underlying patterns and structures within their training data, subsequently producing fresh data that share similar traits and characteristics. The motivation of this systematic review is to gather, evaluate, and synthesize existing research on a GenAI. This paper presents a systematic review that highlights key applications and variations of the architecture of Generative Artificial Intelligence models and their performance. We conducted this review to (a) understand the state-of-the-art generative AI techniques including summarizing key methodologies, algorithms, and findings across a range of studies (b) systematically review a large body of literature, which includes emerging trends, common challenges, and recurring patterns in the development and application of generative AI techniques (c) compare and contrast different generative AI approaches, such as Autoencoders, Generative Adversarial Networks, Transformers, and Diffusion models (d) explore successful applications of generative AI such as image translation, video synthesis and generation, natural language processing, knowledge graph generation, etc. (e) identify ethical challenges and propose solutions for responsible AI development.

In this research, we outline the most recent research and advancement in the field of Generative Artificial Intelligence. It details the approach used to navigate and analyze cutting-edge developments, ensuring a comprehensive and insightful review of the current landscape in Generative AI. The following criteria were applied for searching the used research papers.

Time Period: This paper presents a comprehensive overview of the advancements and applications of Generative AI, focusing on significant developments between 2018 and 2023. Additionally, it offers a concise historical perspective, tracing the evolution of foundational models from 2012 to 2018, which laid the groundwork for the current state of Generative AI techniques. This historical context enriches the understanding of the field's rapid progression and its burgeoning applications.

Keywords: This paper employs a targeted keyword search strategy, incorporating specific terms such as 'Generative Adversarial Networks', 'Transformers', 'Variational Autoencoders', and 'Diffusion Models'. This approach also includes searching for advancements in 'image translation', 'video synthesis', and various applications of Generative AI in 'natural language processing' and 'knowledge graph generation'. This methodology ensures a focused and comprehensive review of the latest developments in the field of Generative AI.

Databases: The work primarily sources relevant literature from Google Scholar, focusing on the specified timeframe. It selectively includes research that showcases advancements in generative models. This criteria ensures the inclusion of studies where developed models were rigorously tested on well-recognized datasets, and where results are communicated effectively and clearly. This approach guarantees that the paper presents a detailed and credible overview of significant developments in the field of Generative AI.

Inclusion Criteria: This work exclusively incorporates peer-reviewed papers, conference, and journal papers that are written in English. It emphasizes studies that highlight either significant advancements or innovative applications in the realm of Generative AI, ensuring that the focus remains on cutting-edge and impactful developments within this field.
Exclusion Criteria: This paper meticulously filters its sources, excluding non-peer-reviewed materials, papers not written in English, and studies that fall outside the 2012-2023 timeframe. Additionally, it deliberately omits any papers that do not directly contribute to the advancement or understanding of Generative AI, ensuring a focused and relevant academic discourse.
Evaluation Criteria: In each subsection evaluating the advancements in Generative AI techniques, the paper compares the performance of various models using standardized datasets commonly cited in the field. This comparison focuses on how different state-of-the-art models perform on these datasets, providing a clear and consistent basis for assessing the progress and effectiveness of these techniques in their respective domains.

The following is the summary of the major contributions of our work-

- **Paradigm Shift in Artificial Intelligence:** The paper discusses the paradigm shift in artificial intelligence and highlights the significant impact of generative models in the field of machine learning.
- **Historical Context:** The paper includes a section that gives a straightforward overview of how key AI models have developed from 2012 to 2018, helping to better understand how the field has grown and changed over time.
- **Real-World Uses of Generative AI:** The paper describes how Generative AI is used in different areas like image translation, diagnosing medical conditions, combining text and images, processing natural language, etc.
- **Systematic Review of Generative AI:** The work provides a comprehensive review and analysis of recent advancements in Generative AI, focusing on techniques and applications, including application-specific models. We have also provided information on relevant datasets for each used application.
- **Impact on Language and Image Translation:** The paper discusses the major impact of generative AI in language generation with large language models and in the field of image translation.
- **Responsible AI Principles:** The paper ends with a discussion on Responsible AI principles and ethical considerations necessary for the sustainability and growth of generative models.

After this introductory section, Sections 2 and 3 review the basic early architecture of Generative adversarial Networks and their variants. Section 4 deeply explores the recent applications and the advancements in Generative AI application-specific techniques. Section 5 provides the Challenges and opportunities of Generative AI. Lastly, Section 6 concludes the work and highlights the future directions of generative AI.

2 What is Generative Artificial Intelligence?

As discussed Generative Artificial Intelligence refers to artificial intelligence systems with the capability to create text, images, or other forms of media through the utilization of generative models. These models acquire an understanding of patterns and structures within their training data, subsequently generating novel data with akin characteristics. Generative Artificial Intelligence encompasses various types, each tailored for specific tasks or forms of media generation. The following are some of the more well-known types: Generative Adversarial Networks (GANs) [71], Transformer-based Models (TRMs) [133], Variational Autoencoders (VAEs) [62], and Diffusion models (DMs) [68], to name a few. The following sections will discuss these in more detail.

2.1 Generative Adversarial Networks

A generative adversarial network (GAN) is a class of machine learning framework and a prominent framework for approaching generative AI. The aspect that is novel in this generative adversarial network set-up is that it does not depend upon heavily annotated training data. Moreover, the architecture that it affords is quite unique from the conventional Deep Neural Networks [27]. Indeed, it consists of two major components named *Generator* and *Discriminator*. The main operation of the generator is to keep on generating the fake data using the noise while the purpose of the discriminator is to distinguish whether the generated image is real or fake. The discriminator is trained using the real images of the domain that the generator is trying to synthetically produce and the discriminator's sole purpose is to identify whether the output produced by the generator is fake or not. The overall system is based on the zero-sum game dynamics, the winner will remain unchanged and the loser model each time has to modify its parameters, it will keep on doing this until the discriminator is unable to detect whether the generator output is fake or not [44]. The sole purpose of this is to build a powerful generator model that generates synthetic data that looks real.

Fig. 1 demonstrates how the generator and discriminator work together. The generator aims to deceive the discriminator by providing the synthetically generated image with the objective that it is proven real. The discriminator discerns between genuine and counterfeit images and generates the output signal. This output signal then goes to both the generator and discriminator, allowing the generator to produce better synthetic output. And, in case the discriminator fails to prove the image is fake, it also uses the signal to change its weights to give better predictions. In this entire architecture, it is important to note that only the discriminator has access to the real image, synthetic image, and its own signal output while the generator only learns from the output signal of the discriminator [27].

During the initial stages of development, Generative Adversarial Network (GAN)-based models encountered significant challenges in their training process. These difficulties primarily revolved around issues like training divergence and model collapse [87]. Training divergence refers to situations where the GAN's generator and discriminator fail to achieve a stable equilibrium during training, leading to oscillations and unreliable model outputs. This problem results in inconsistent and sub-optimal generation performance, hindering the GAN's ability to produce high-quality samples. On

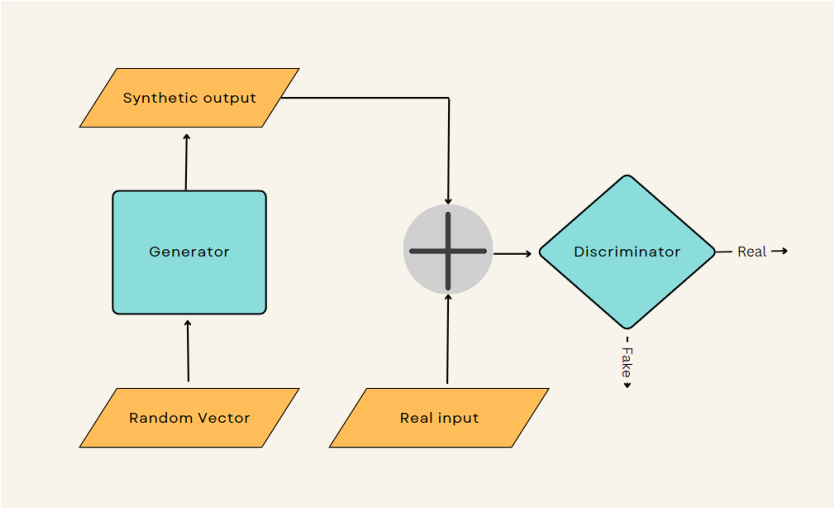

Fig. 1 GAN- Generator and discriminator working

the other hand, model collapse occurs when the GAN's generator produces limited and repetitive outputs, ignoring a large portion of the data distribution. This phenomenon causes the generator to focus on a small subset of data points, resulting in a lack of diversity and novelty in the generated samples. Addressing these challenges has been a main focus in the advancement of GAN-based models, with numerous research efforts aimed at improving stability, convergence, and diversity during the training process. As a result, substantial progress has been made, leading to the development of more robust and effective GAN architectures, which have significantly enhanced the performance and applicability of these generative models.

2.2 Transformers

Further Generative AI techniques called *Transformers* were introduced by Vaswani et al. [134]. This breakthrough architecture laid the foundation for various tasks, including machine translation and language generation, and it continues to influence subsequent neural network designs. The paper's emphasis on attention mechanisms highlighted their pivotal role in sequence-to-sequence tasks, advancing the state of the art. Transformers use both the self-attention and Multi-Head Attention mechanisms to learn the dependencies between the objects regardless of the distance between them and to learn the different relations and patterns between the input respectively. Often in Natural Language Processing, these methods are combined with positional encoding added to the input sequence to make the transformers keep track of the position of a specific word in an input sequence. Transformers are commonly used to build Generative AI Models such as Generative Pre-trained Transformers (GPT) models which are capable of generating coherent and contextually relevant text [109]. Bidirectional Encoder Representations from Transformers (BERT) and Open AI GPT are based on transformers.

2.3 Variational Autoencoders

Another model in the field of generative AI is Variational Autoencoders (VAEs), introduced by Kingma et al. [65]. As the name suggests the VAEs consist of an encoder and a decoder. The purpose of an encoder is to encode the given input in a lower dimension called *latent space* and the decoder decodes that latent output of the encoder into its original input shape. During this whole process, variation is introduced to the latent space by using the standard Gaussian distribution. The main goal is to achieve the output with a similar mean and variance as the given input after the introduction of the variance. This provides a structured way to learn meaningful representations of data and then generate new samples from that data distribution.

2.4 Diffusion Models

The Diffusion Models have been designed to improve the performance of the Simple Generative Adversarial Network, the technique was introduced by Salimans et al [115]. At a later stage, Kingma et al [64] introduced a variant of the diffusion model called Inverse Autoregressive Flow (IAF) as a building block for generative models. IAF is a type of normalizing flow. This is a type of generative model that aims to learn complex probability distributions by transforming a simple base distribution into the target distribution through a series of invertible transformations.

3 Evolution of Generative AI Models: A Look at Earlier Variants

3.1 Earlier GAN Variants

In the early stages of the introduction of Generative Artificial Intelligence models the major issue that researchers were facing was the convergence problem of generative models [87]. To avoid this problem, different approaches were adopted by the researchers to make the GAN more stable (e.g., by understanding the behavior of GAN training). In detail, Mescheder et al. [88] explained the analysis of local convergence and stability properties during the training of GAN. This involves an examination of the eigenvalues of the Jacobian matrix associated with the gradient vector field. Specifically, when the equilibrium point is characterized by solely negative real-part eigenvalues in the Jacobian, GAN training demonstrates local convergence, specifically when utilizing relatively small learning rates. However, the situation changes when the eigenvalues of the Jacobian are situated on the imaginary axis. In such cases, the local convergence of GAN training is generally compromised. Also, it is important to note that if the eigenvalues are in proximity and not directly on the imaginary axis, the training algorithm may necessitate exceedingly small learning rates to achieve convergence [88].

The study by Mescheder et al. [88] identified instances of eigenvalues near the imaginary axis in practical scenarios. This observation does not definitively address whether such proximity to the imaginary axis is a prevalent phenomenon. Furthermore, it does not conclusively establish whether these eigenvalues are the fundamental cause

behind the training instabilities that practitioners commonly encounter in their GAN training endeavors. Moreover, Nagarajan et al. [93] contributed a partial response to this query. They demonstrated that in the context of absolutely continuous data and generator distributions, these findings establish that GANs exhibit local convergence for sufficiently small learning rates. However, to emphasize, this assertion relies on the premise of absolute continuity.

Goodfellow et al. [44] presented the basic GAN architecture, other researchers also advanced more variants with some architectural differences. However, due to the potentially limiting overlap between real and generated data distributions, the Jensen-Shannon divergence presented in the objective function can become a constant value. It is this phenomenon that contributes to the challenge of the vanishing gradient, hindering effective training of GANs when employing gradient descent methods. To address the vanishing gradient problem, the Wasserstein GAN (W-GAN) was introduced [6], using the EarthMover distance instead of the Jensen-Shannon divergence to compare real and generated data distributions. W-GAN employs a critic function 'f' with a Lipschitz constraint as its discriminator, significantly improving GAN training stability. However, W-GAN may still face issues like suboptimal sample generation and occasional convergence problems in specific cases. In order to restrict the discriminative capacity of the discriminator, an alternative approach has also been introduced by [105] in the form of Loss-Sensitive GAN (LS-GAN). Both W-GAN and LS-GAN retain the fundamental GAN architecture.

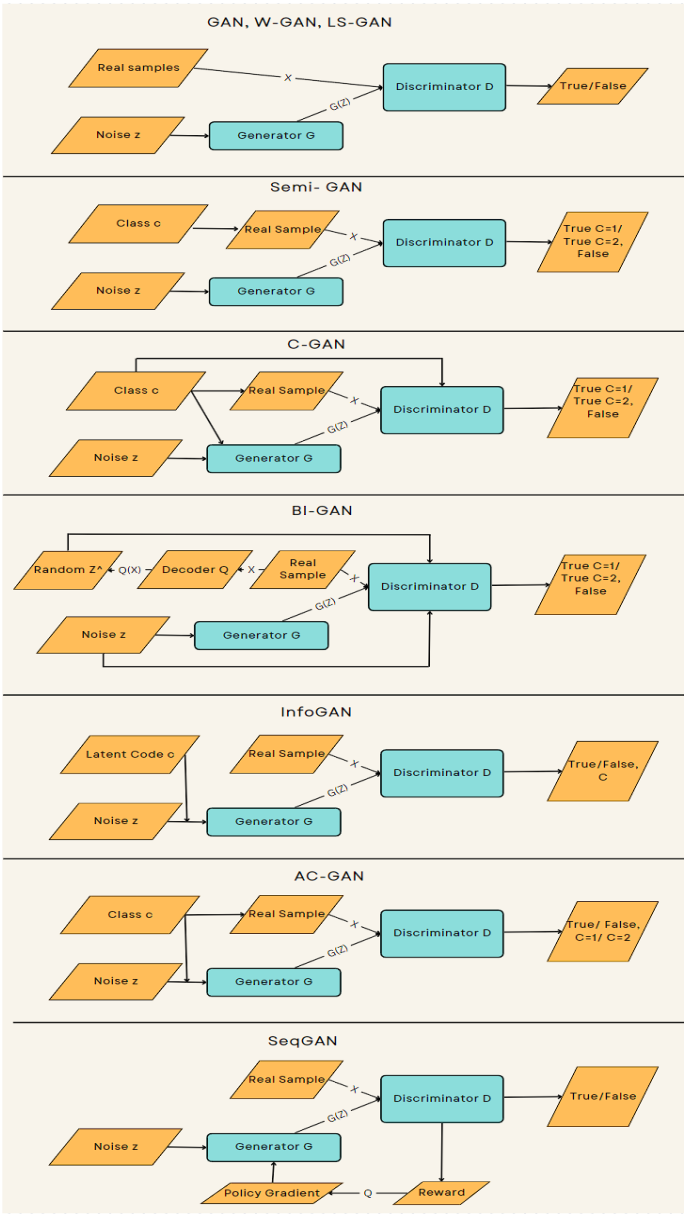

Fig. 2 Basic GANS Variants

Moreover, Qi et al. [97] introduced the Semi-GAN model, which involves the incorporation of real data labels into the discriminator's training process. Additionally, semi-GAN is an approach involving the integration of auxiliary information 'y' into both the generator 'G,' the discriminator 'D,' and the real data 'x' for the discriminator [91]. This auxiliary information can encompass labels or other supplementary data.

In the context of conventional GANs, the primary objective revolves around acquiring a generative model capable of mapping latent variable distributions to intricate real data distributions. Expanding upon this concept, Donahue et al. [33] propose Bidirectional GANs (BiGANs) to facilitate the mapping of real data to the latent variable space, thereby enabling feature learning. BiGANs extend the fundamental GAN structure by incorporating an additional decoder 'Q,' which facilitates the transformation of real data 'x' into the latent space. Consequently, this modification transforms the optimization problem into the form $\min_{G,Q} \max_D f(D, Q, G)$.

Chen et al. [21] introduce InfoGAN to capture mutual information between a subset of latent variables and observed data.

In InfoGAN, the correlation is quantified using $I(c; G(z, c))$, where c is a latent code and $G(z, c)$ is the generated output. The objective function is:

$$\min_G \max_D \{f(D, G) - \lambda I(c; G(z, c))\}$$

Here, $f(D, G)$ includes the adversarial term and penalty term $\lambda I(c; G(z, c))$. The goal is to minimize the generator's loss while maximizing the discriminator's loss with respect to mutual information.

Due to the challenge of computing $p(c|x)$, a lower bound estimation is used through variational information maximization.

Odena et al. [98] introduce the auxiliary classifier GAN (AC-GAN) approach tailored for semi-supervised synthesis. Their formulated objective function comprises two integral components: the logarithmic likelihood related to the accurate data source and the corresponding accurate class. The essence of AC-GAN lies in its capacity to seamlessly integrate label information into the generator and to adapt the discriminator's objective function accordingly. This integration yields noticeable enhancements in the generative and discriminative capabilities of the GAN framework.

In another context, Yu et al. [150] introduced SeqGAN, a pioneering framework for sequence generation using GANs. It extends GANs to handle discrete token sequences, treating the generator as a stochastic policy in reinforcement learning. SeqGAN employs policy gradient-based mechanisms to enhance sequence generation by effectively propagating errors from the discriminator. These advancements build upon the foundational work of GANs [44].

3.2 Earlier Transformer Variants

The concept of Transformers was introduced by Vaswani et al. [134]. It was a revolutionary step in the field of generative AI specifically in natural language processing and generating synthetic content. The basic concept of the Transformers was introduced in [125] by Sutskever et al as a sequence modelling technique. The basic technique of pretraining transformers was introduced and used as a state-of-the-art technique by [106]. This was used in answering different queries and also used as a chatbot to give results that are competitive and accurate. Indeed, these early Transformer Developments paved the way for State-of-the-Art NLP Chatbots.

3.3 Earlier Variational Autoencoder Variants

Variational Autoencoders [72] is one of the oldest techniques of unsupervised learning and generative modeling. The foundational work of Variational Autoencoders was done by Kingma at el in [66]. The Variational Autoencoders model combines the probabilistic modeling with the basics of Autoencoders. This concept not only learns the properties of the latent space but they also learn the probabilistic distribution of it, which gives them the ability to generate new synthetic data samples. Early variants of autoencoders also include denoising autoencoders which use denoising techniques whilst trained locally to get rid of corrupted versions of their inputs [135]. Moreover, [84] used the auto-encoders coupled with the convolutional network to solve the image recognitional problems. Without a doubt, the pioneering work of [66] has paved the way for numerous subsequent developments and applications of VAEs in a wide range of domains, including image generation, natural language processing, and more.

3.4 Earlier Diffusion Model Variants

Diffusion-based models employ a sequential diffusion process to iteratively transform simple data distributions into complex, high-dimensional ones. The Non-Linear independent component estimation (NICE) introduced the concept of invertible transformations as a foundation for generative artificial intelligence [31]. This was followed by Real NVP (Real Non-Volume Preserving), which expanded the capabilities by incorporating neural networks into the transformation process [32]. Additionally, Glow (Generative Latent Optimization) extended these ideas to high-resolution image generation, highlighting the potential of diffusion-based models in computer vision [63]. Furthermore, Diffusion Probabilistic Models (DPMs) leveraged the diffusion process to model the likelihood of data samples, making it an essential contribution to the development of diffusion-based generative models. Continuous-time flows (CTFs) diffusion models ventured into continuous-time modelling using stochastic differential equations [45]. These earlier works have laid the foundation for an exciting and rapidly evolving field of generative modelling using diffusion-based techniques.

4 Advancements in Generative AI and Their Diverse Applications

4.1 Generative AI for Image Translation

Image translation [44] is becoming a rapidly growing technology, particularly within the realm of medical applications. This innovation holds remarkable potential, not only in terms of cost-saving implications related to equipment usage but also in the facilitation of informed medical decisions.

The performance of generative AI models, particularly in the subfield of image translation, is typically assessed using specialized datasets. Among these, two notable datasets stand out: ImageNet [147], ClebA [82], and in the field of medical science: MIMIC [54], BRATS [86], FastMRI [129] and ChestX-ray [139] Each of these datasets is uniquely designed to challenge and evaluate the models' abilities to accurately and

effectively translate images, providing a comprehensive benchmark for their performance capabilities. These datasets are freely accessible to researchers for testing their models, under certain conditions. Users must properly cite the source of the dataset in their work. For datasets containing medical data, researchers are required to sign a Data Use Agreement. This agreement sets forth guidelines on the appropriate usage and security of the data and strictly prohibits any attempts to identify individual patients. This ensures that while fostering innovation and research, the datasets are used ethically and responsibly.

The utilization of AI-driven image translation yields images that are not only more polished and precise but also empower medical professionals with a heightened ability to discern critical information [146]. Yan et al. proposed a GANs-based model that uses the *Swin Transformers* in the Generator. The Swin Transformer represents a notable stride forward in the evolution of architecture. Its most remarkable enhancement entails the replacement of the conventional multiple self-attention (MSA) modules with an innovative shift window-based module while keeping the remaining layers largely unchanged. This transformer-based generator allows for the production of the output content which is the same as source images and the same information required by the target image. They tested the model using the BraTs2018 [86] and FastMRI [118] datasets. The Swin-based Transformers method attains its highest level of performance in the specific task of converting T1 mode to T2 mode images using the clinical brain MRI dataset. Moreover, they conducted evaluations using the unpaired *BraTs2018* dataset (see the results depicted in the Figure 3). These highlight that the innovative MMTrans approach stands out as the leader in terms of translation performance.

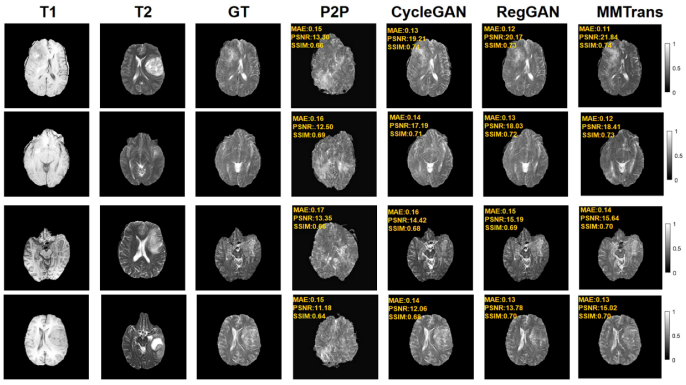

Fig. 3 qualitative outcomes obtained from various translation techniques employed to generate T2 images from T1 images within the unpaired BraTs2018 dataset, Source: [146]

Indeed, Figure 3 shows that the introduced MMTrans method performs better in translating the image when compared to other methods such as Pix2Pix [52], CycleGAN [159] and RegGAN [114]. The Image of MMTrans is closest to the Ground Truth (GT).

Furthermore, Dar et al. [28] used Conditional GANs to solve the problem of Image translation in MRI. This variant of GANs was introduced for image-image translation with the conditional label given to both generator and discriminator to instruct about what they have to forge and to predict real or fake respectively [52]. In fact, there are two types of GAN variants present for the purpose of image translation, Pix2Pix GAN is a conditional GAN [52], where the generator takes both an input image and a target condition as input and then generates an output image that adheres to the specified condition. However, for these types of GANs pixel-aligned images are required which is quite difficult to acquire [146]. Moreover, unpaired GANs do not require corresponding pairs of images for training. Instead, they focus on learning the mapping between two domains by using cycle consistency as a constraint [131].

Indeed, unpaired image translation presents a significant challenge. The objective is to ensure that translating an image from one domain to another should not compromise its fundamental characteristics (e.g., allowing for a seamless reversion back to its initial state)[159]. To address this issue, the Cyclic Generative Adversarial Network (Cyclic GAN) was developed [159]. Torbunov et al. [131] developed a Vision Transformer based GAN (UVCGAN). This works on the principle of cyclic GANs and without sacrificing the image regeneration capabilities gives better results than previous simple cyclic models. The evaluation of image-to-image translation performance commonly employs two widely accepted metrics, namely Frechet Inception Distance (FID) [46] and Kernel Inception Distance (KID) [13]. These metrics quantify the similarity between the translated images and those within the target domain, with a lower score indicative of higher similarity. UVCGAN model's superior performance is evident across most image-to-image translation tasks, as illustrated in Table 1. Operating similarly to a CycleGAN-like model, their approach consistently produces translated images that exhibit strong correlations with the input images, capturing essential aspects like hair color and facial orientations (as exemplified in Figure 4).

The high-quality result produced by UVCGAN in Figure 4 is paramount for enhancing scientific simulations. It can be observed that translations generated by ACL-GAN and Council-GAN tend to overly emphasize features that aren't pivotal for achieving the intended translation, such as non-essential attributes like hair color, background color, and length. Even in some cases, Council-GAN changed the background.

Table 1 FID and KID scores of UVCGAN and other models. Lower is better, Source:[131]

Model	Selfie to Anime		Anime to Selfie	
	FID	KID (×100)	FID	KID (×100)
ACL-GAN	99.3	3.22 ± 0.26	128.6	3.49 ± 0.33
Council-GAN	91.9	2.74 ± 0.26	126.0	2.57 ± 0.32
CycleGAN	92.1	2.72 ± 0.29	127.5	2.52 ± 0.34
U-GAT-IT	95.8	2.74 ± 0.31	108.8	1.48 ± 0.34
UVCGAN	79.0	1.35 ± 0.20	122.8	2.33 ± 0.38
Model	Male to Female		Female to Male	
	FID	KID (×100)	FID	KID (×100)
ACL-GAN	9.4	0.58 ± 0.06	19.1	1.38 ± 0.09
Council-GAN	10.4	0.74 ± 0.08	24.1	1.79 ± 0.10
CycleGAN	15.2	1.29 ± 0.11	22.2	1.74 ± 0.11
U-GAT-IT	24.1	2.20 ± 0.12	15.5	0.94 ± 0.07
UVCGAN	9.6	0.68 ± 0.07	13.9	0.91 ± 0.08
Model	Remove Glasses		Add Glasses	
	FID	KID (×100)	FID	KID (×100)
ACL-GAN	16.7	0.70 ± 0.06	20.1	1.35 ± 0.14

CycleGAN	24.2	1.87 ± 0.17	19.8	1.36 ± 0.12
U-GAT-IT	23.3	1.69 ± 0.14	19.0	1.08 ± 0.10
UVCGAN	14.4	0.68 ± 0.10	13.6	0.60 ± 0.08

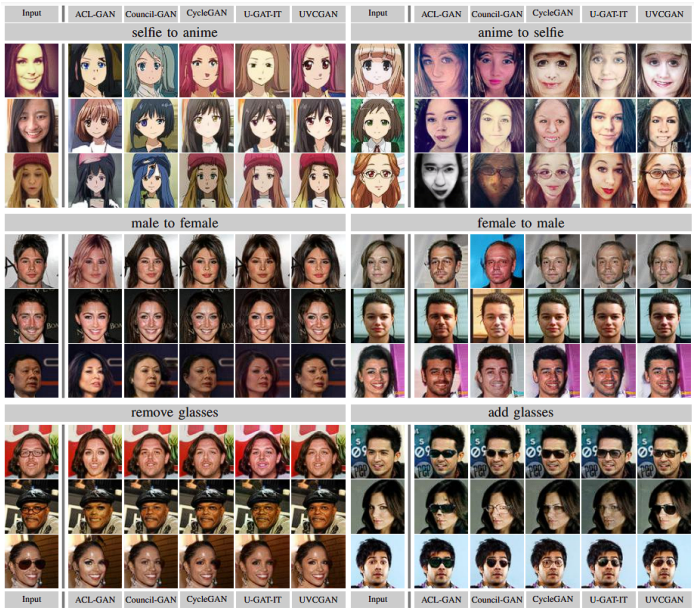

Fig. 4 unpaired UVCGAN vs Others image-to-image translation, Source: [131]

Another application under the umbrella of image translation is the Synthetic Aperture Radar (SAR) image translation [155]. Both the techniques of paired and unpaired GANs are used for this application. Indeed, the SAR-generated images are

not that visually clear but they can be captured at any time so it's a better technique when compared to optical imaging. Particularly, if it is combined with the GANs image translation methods to convert the SAR-generated image into an optical high-resolution clear image [155]. Different GANs methods of unpaired image translation such as CycleGAN [159], NICE GANs [50], Attn-CycleGAN [79] and paired GANs such as Pix2Pix [52], and Bicycle GANs [160] are used for Satellite image translation. In Wei et al. [141] the researchers presented a new technique using the generative AI that is specifically designed for the translation of unpaired SAR images to optical images. In detail, they introduced an approach known as Cross-Fusion Reasoning and Wavelet Decomposition GAN (CFRWD-GAN) [141]. The primary objective of CFRWD-GAN is twofold: to effectively retain structural intricacies and elevate the quality of high-frequency band details. This is achieved through a unique framework that integrates cross-fusion reasoning (CFR) structure, adept at preserving both high-resolution, fine-grained features and low-resolution semantic attributes throughout the entire process of feature reasoning. Additionally, to address speckle noise inherent in SAR images, the method employs discrete wavelet decomposition (WD), enabling the translation of high-frequency components. Through the convergence of these techniques, CFRWD-GAN demonstrates its capability to significantly enhance the translation process for unpaired image-to-image scenarios. The model was evaluated using Root Mean Squared Error (RMSE) [53, 117], structural similarity index (SSIM) [73, 140], peak signal-to-noise ratio (PSNR) [120, 128], learned perceptual image patch similarity (LPIPS) [119, 152] and produced a better result than the other state of art models.

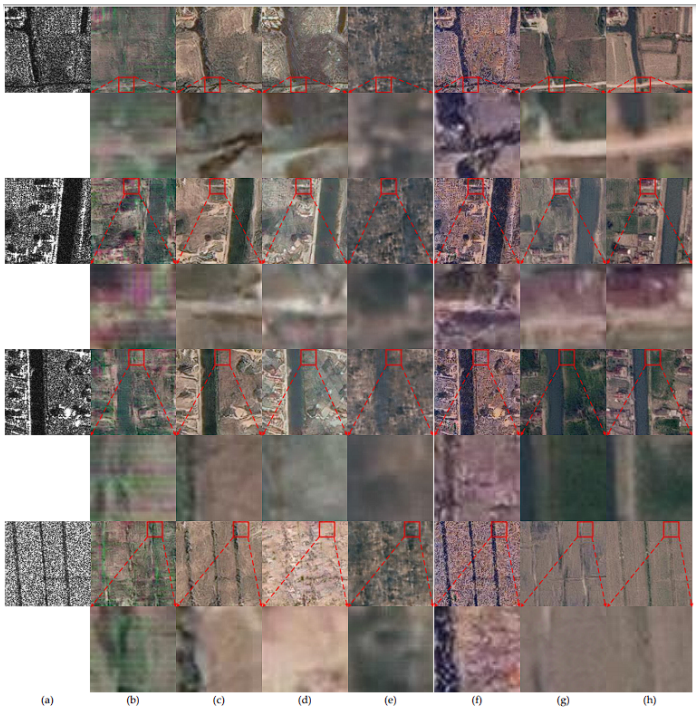

Fig. 5 Highlighted with red boxes and magnified for emphasis, the images are presented in the following order: (a) SAR images, (b) Pix2Pix, (c) CycleGAN, (d) S-cycle-GAN, (e) NICE-GAN, (f) GANILLA, (g) CFRWD-GAN, and (h) ground truth optical images., Source: [141]

The other technique for image generation and translation is Variational Autoencoders developed by Kingma et al. [66]. Furthermore, Zhu et al. [161] compared the generative capabilities of Conditional Variation Autoencoders and also compared it with the other generative techniques for image generation and translation. The main idea of this work was to find the algorithm that performs the best in balancing the diversity and realism in the generated data. The best-performing model in their work was the Bicycle GANs.

Table 2 Generative AI and Its Applications in Image Translation

Domain	Methods	References
Medical-MRI	MM-Transformers, Cyclic-GAN, Pix2Pix GAN, VAE	[1, 5, 17, 28, 30, 144, 146]
Satellite Image Translation	Cyclic-GAN, Pix2Pix GAN, NICE-GAN, Attn-CycleGAN, PSGAN	[80, 101, 155]
Facial Expression Editing	VAE, UPGPT	[22, 39, 149]
Style Transfer	VAE, GANs, DD-GAN	[9, 126, 162]
Text-to-Image Translation	TextControlGAN	[70]
Image Upscaling	GIGA-GAN	[58]

VAE was also used for the molecule generations, generating the 3-Dimensional synthetic molecule structure [151]. Jumper et al. [56] developed an architecture of a generative algorithm specifically for predicting the structure of molecules and proteins. This is the best approach till now in generative AI techniques for generating and predicting molecular architectures.

4.2 Generative AI for Video Synthesis and Generation

Generative AI has transformative applications in the field of video and animation, enabling the creation of visually stunning and dynamic content. The evaluation of video generative models often involves a set of widely recognized datasets: Voxcleb [94], HDTF [154], ClebV [142], Kinetics [59], UCF101 [123], and for specifically audio performance testing VCTK Corpus[132] and LibriSpeech [100]. These datasets are publicly available to researchers, with the stipulation that any use of these resources must include proper citation of the source.

In Hong et al. [49] the researchers introduced a GANs variant called depth-aware GAN. This model provided strong competition to the state of art models and the problem of replacing the face in a video. In detail the dataset on which they tested the built model and compared the results was called Voxcleb [94] and ClebV [142]. The model produced better results than the present state-of-the-art models for achieving talking head video face generation.

Indeed, the replacement of a face in a talking head video is the most predominant application in the video generation problem. Many advancements have been made in generative Artificial intelligence to master this application. Hong et al. [48] state that all this model needs is a target video and a 2-D picture with good pixels and facial features and it will translate the video expression features into the static picture supplied. The *DaGAN++* framework proposed by [48] comprises three key components: (a) an uncertainty-aware face depth learning network that reconstructs detailed 3D facial geometry from self-supervised face videos, without requiring camera parameters or explicit 3D annotations (b) geometry-guided facial keypoint detection, which employs the facial depth network to estimate depth maps, is used alongside RGB images for accurate facial keypoint estimation (c) a geometry-enhanced multi-layer generation process that incorporates learned motion fields, occlusion maps, and facial geometry into each layer of image generation through cross-modal geometry-guided attention. This comprehensive approach enables the synthesis of images enriched with geometry-related attributes derived from facial videos.

It is evident from Figure 6 that DaGAN++ exhibits superior capabilities. Notably, DaGAN++ excels in capturing expression-related facial movements within the driving frame, with heightened accuracy observed in regions such as the eyes and mouth. This performance enhancement can be attributed to the precise facial geometry estimation, which greatly contributes to the refinement of expression-related facial motions. Furthermore, Min et al. [90] introduce StyleTalker, an innovative audio-driven talking head generative model designed to synthesize a talking person's video using a single reference image. It features highly accurate lip synchronization, realistic head poses, and natural eye blinks synchronized to the provided audio. To achieve this, they leverage a pre-trained image generator and an image encoder to estimate latent codes for the

Fig. 6 DaGAN++ vs other state of art model on HDTF dataset [154], Source: [48]

talking head video that align faithfully with the given audio input. This achievement stems from the integration of novel components which includes a contrastive lip-sync discriminator. This ensures precise lip synchronization, a conditional sequential variational autoencoder that captures a motion space disentangled from lip movements. In more detail, it enables independent manipulation of motions and lip movements while preserving identity. In addition, it affords an auto-regressive prior enhanced with normalizing flow, facilitating the acquisition of a complex audio-to-motion multi-modal latent space. With these components in place, StyleTalker has the capacity to produce talking head videos, both in a motion-controllable manner when another motion source video is available. Also, entirely driven by audio inputs, wherein it infers real motions from the provided audio.

Fig. 7 StyleTalker vs Other models, Source: [90]

The qualitative evaluation of audio-driven talking head generation performance on VoxCeleb2 dataset in Figure 7 reveals distinct differences. In the first row (marked by a yellow box), frames corresponding to the provided audio are displayed. Conversely, the single image input (highlighted in a red box) represents a reference image of the desired target identity. When observing the generated video frames produced by the StyleTalker in comparison to those generated by other audio-driven generation

models [103, 138, 157], a notable distinction becomes evident. StyleTalker consistently produces talking head videos of exceptional quality, skillfully preserving the distinctive identity of the intended.

Advancing further, Li et al. [76] introduced Multiscale Vision Transformers (MViTv2) as a comprehensive architectural framework suitable for tasks encompassing image and video classification, along with object detection. Within this study, the researchers introduce an enhanced version of MViT, featuring decomposed relative positional embeddings and residual pooling connections. By deploying this upgraded architecture across five different scales, we meticulously assess its performance in scenarios such as ImageNet classification, COCO object detection, and Kinetics video recognition. Remarkably, MViTv2 surpasses previous benchmarks in terms of effectiveness and provided video classification accuracy of 86.1% on the Kinetics-400 dataset as shown in Table 3.

Table 3 Comparative analysis with other Models on the Kinetics-400 [59] dataset, Source: [76]

Model	**Top-1**	**Top-5**	**FLOPs×views**	**Param**
SlowFast 16×8 +NL [37]	79.8	93.9	234×3×10	59.9
X3D-XL [36]	79.1	93.9	48.4×3×10	11.0

Swin-L$^+$ in 21k [83]	84.9	96.7	2107×5×10	200.0
MViTv2-L$^+$, 40×3, in 21k [76]	**86.1**	**97.0**	2828×3×5	217.6

In the context of the Kinetics-400 dataset [59], Table 3 presents a comparison between MViTv2 and previous methodologies, encompassing both state-of-the-art Convolutional Neural Networks (CNNs) and Vision Transformers (ViTs). Upon training from the ground up, MViTv2-S and MViTv2-B models exhibit top-1 accuracy of 81.0% and 82.9% respectively, surpassing their MViTv1 [35] counterparts by +2.6% and +2.7%. Notably, earlier ViT-based models necessitate substantial pre-training on the IN-21K dataset to achieve peak accuracy on Kinetics-400 as shown in Table 3 (see last 5 rows). In contrast, MViTv2 achieves an exceptional top-1 accuracy of 86.1% when fine-tuning, the MViTv2-L model with a large spatio-temporal input size of 40×3 (time $\times$ space^2).

The rest of the reviewed applications of Generative Artificial Intelligence in the field of Video Generation are given in Table 4

Table 4 Generative AI and Its Applications in Video Generation

Domain	Methods	References
Face swapping videos	Depth Awareness GANs, DaGAN++	[48, 49]
Video/Image Classification	MViTv2	[76]
Audio-Based Facial Expression video Translation	Styletalker Sequential VAE	[90]
Simulation in Metaverses	Multi-task DT offloading model	[144]
ECG Synthesis to Improve Deep ECG Classification	SimGAN	[43]
3D human motion prediction	HP-GAN	[11]

4.3 Generative AI for Natural Language Processing

Generative AI models have demonstrated remarkable achievements across a spectrum of Natural Language Processing tasks. These encompass language comprehension, logical reasoning, and text generation.

In the domain of natural language processing, specific datasets have become standard benchmarks for evaluating state-of-the-art models in various tasks. For Named Entity Recognition, the CoNLL-2003 dataset [116] is frequently utilized. In the area of text summarization, two prominent datasets are DUC 2002 [85] and QMSUM [156]. Additionally, for Natural Language Inference (NLI) tasks across multiple languages, the XNLI dataset [24] serves as a crucial resource. All of these datasets are publicly available, providing researchers with essential tools to advance and assess the capabilities of their models in these specific NLP tasks.

Presently, a significant query the AI community poses revolves around the extent and confines of these model's capabilities [2]. Ahuja et al. [2] raise the question that most of the large language models are made and tested on only the English language. Therefore these researchers took the state-of-the-art models and trained them on other languages on certain available datasets and compared their question-answering and classificational accuracies [2]. Generative AI even has found its way into education[19, 34]. In the midst of this dynamic backdrop that challenges conventional modes of thinking, recent research endeavors investigating the implications of generative AI within the educational landscape yield valuable insights. Notably, these studies shed light on the opportunities and obstacles arising from the integration of generative AI. For instance, in a recent article [130] highlights the need for a new and creative way of teaching that effectively incorporates the progress brought by AI. They mentioned the significance of cultivating an ethical and personalized chatbot solution while augmenting digital proficiency to fully harness the manifold benefits of AI. Furthermore, the researchers advocate for the incorporation of AI literacy as an essential technological skill for navigating the complexities of the 21st century.

In the current landscape, Bozkurt [14] advocates for a significant reevaluation of the roles played by human educators and AI within the educational realm. They assert that the emergence of AI offers a unique juncture to redefine these roles. Especially, as

AI possesses the capacity to assume an increasing array of educational tasks that were traditionally the exclusive domain of human educators. This perspective underscores the importance of adopting a forward-thinking outlook that reconsiders the contributions of both technology and human educators to the educational process. Bozkurt [14] also emphasizes that generative AI's arrival presents a propitious opportunity to redefine these roles further.

The researchers further delve into the opportunities and challenges ushered in by the advent of generative AI. Generative AI, they elaborate, provides a diverse range of opportunities. These encompass personalized learning, fostering inclusive curriculum provision, and enhancing collaboration and cooperation throughout educational processes. Also, they can cater to automated assessment benefits, ensuring improved accessibility, optimizing efficiency in terms of time and effort, cultivating language skills, and enabling the round-the-clock availability of these technologies.

Generative AI can also enhance synthetic data generation, with the use of Transformers and GANs. It is clear that the understanding of data is better and now the AI is able to generate synthetic data even in the health field. For example, Frid-Adar et al. [40] used GANs to generate synthetic data for the liver lesion classification problem. The variant they used was called DCGAN. In another problem, Wang et al. [137] used the SSIM embedded-cycle GAN to count the number of people in the crowd. The dataset that they used for this problem was fully synthetically generated. It had all the weather conditions covered which made the model perform the best compared to the state-of-the-art models. Another technique of generative AI that is among the state-of-the-art techniques is BERT (Bidirectional Encoder representations from Transformers) which was introduced by the Google AI team [29]. It represents a significant advancement in pre-training techniques for NLP tasks. BERT is based on the transformer architecture and is designed to capture contextual information from both the left and right sides of a word in a sentence, hence the term 'bidirectional'. In Bert's pre-training, the model learns to predict missing words in a sentence by training on a large corpus of text. This helps BERT develop a deep understanding of syntax, semantics, and context. After pre-training, the model is fine-tuned on specific downstream tasks, such as sentiment analysis, question answering, and named entity recognition, using task-specific labelled data.

Table 5 shows the BERT model tested with the CoNLL-2003 [116] dataset for the task focusing on named entity recognition. BERTLarge demonstrates strong competitiveness with state-of-the-art techniques. The most successful approach involves concatenating token representations from the uppermost four hidden layers of the pre-trained Transformer. Remarkably, this approach lags by only 0.3 F1 behind the performance achieved by fine-tuning the complete model. This finding underscores the effectiveness of BERT for both fine-tuning and feature-based methodologies.

Another model related to Generative Natural language processing is ELMo [55]. This stands for 'Embeddings from Language Models'. ELMo utilizes a bidirectional LSTM (Long Short-Term Memory) network [47] for contextual word embeddings. In fact, ELMo embeddings have been shown to be effective in improving the performance of various NLP tasks, including sentiment analysis, question answering, and named entity recognition. The ability to capture context-specific information makes ELMo

Table 5 BERT vs others for Named Entity Recognition task on the CoNLL-2003 [116] dataset (comparison in terms of F1 Score on Validation DataSet (Dev) and Testing Dataset (Test), Source:[29]

System	Dev F1	Test F1
ELMo [55]	95.7	92.2
CVT [23]	-	92.6
CSE [3]	-	93.1
Fine-tuning approach		
BERTLARGE	96.6	92.8
BERTBASE	96.4	92.4
Feature-based approach (BERTBASE)		
Embeddings	91.0	-
Second-to-Last Hidden	95.6	-
Last Hidden	94.9	-
Weighted Sum Last Four Hidden	95.9	-
Concat Last Four Hidden	96.1	-
Weighted Sum All 12 Layers	95.5	-

embeddings particularly useful for tasks where word meanings can vary based on the surrounding context.

Another application of generative AI models used in natural language processing is malware classification. In particular, machine language malware classification is a big concern that can be solved by using generative AI. For example, Kale et al. [57] used the Bert and ELMo to train the embeddings of the models to classify the malware and the results provided remarkable improvements.

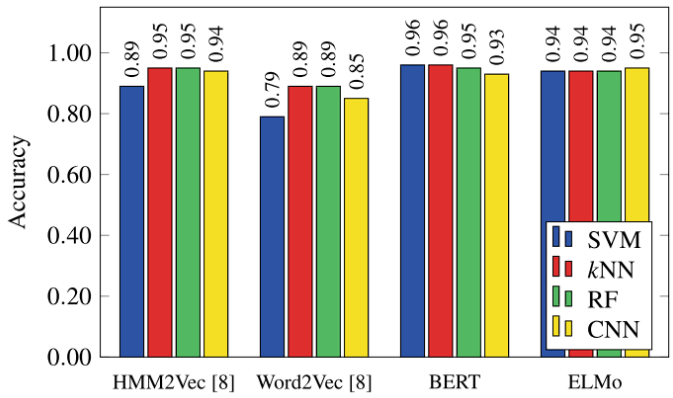

Fig. 8 HMM2Vec, Word2Vec, BERT, and ELMo based classification techniques, Source: [57]

Additionally, Figure 8 provides a summarized depiction of the optimal accuracies achieved by the classification methodologies based on HMM2Vec[20], Word2Vec[89],

BERT[29], and ELMo[102]. The graph illustrates that BERT-SVM and BERT-kNN secured the highest performance with a notable accuracy of 96%. In close pursuit HMM2Vec-kNN, HMM2Vec-RF, BERT-RF, and ELMo-CNN, achieved an accuracy of 95%. Slightly trailing behind, HMM2Vec-CNN, as well as all ELMo-based techniques, demonstrated an accuracy of 94%. Interestingly, the Word2Vec embeddings consistently yielded accuracies below 90% across all four classifiers.

A further application of Generative artificial intelligence is the text-summarization. Joshi et al. [112] introduced *Ranksum* which is an innovative technique designed for extractive text summarization of individual documents. This method hinges on the fusion of four distinct multi-dimensional sentence features, namely topic information, semantic content, significant keywords, and position. By independently acquiring sentence saliency rankings for each feature in an unsupervised manner, Ranksum subsequently amalgamates these scores through weighted fusion, yielding a comprehensive ranking of sentence significance. It is important to note that these scores are generated in a completely unsupervised manner.

Topic ranking is established through the application of probabilistic topic models, while semantic content is captured using sentence embeddings. Sentence embeddings are generated using Siamese networks to craft abstractive sentence representations, followed by a novel strategy to organize them based on their relative importance. To identify significant keywords and their associated sentence rankings within the document, a graph-based approach is employed. Additionally, a mechanism to gauge sentence novelty is formulated, relying on bigrams, trigrams, and sentence embeddings. This eliminates redundant sentences from the summary.

Table 6 Comparative analysis of RankSum with state-of-the-art algorithms conducted on the DUC 2002 [85] and QMSUM [156] dataset, Source: [112, 148]

Method	ROUGE-1	ROUGE-2	ROUGE-L
LEAD	43.6	21.0	40.2
ILP	45.4	21.3	42.8
NN-SE	47.4	23.0	–
SummaRuNNer	47.4	24.0	14.7
Egraph+coh	47.9	23.8	–
Tgraph+coh	48.1	24.3	–
URANK	48.5	21.5	–
SummCoder	51.7	27.5	44.6
HSSAS	**52.1**	24.5	**48.8**
CoRank	52.6	25.8	–
Rank-emb	49.9	24.8	45.6
Rank-topic	51.4	25.9	47.2
Rank-keyword	52.0	26.3	48.6
RankSum	**53.2**	27.9	**49.3**
PGNet on QMSUM	31.52	8.69	27.63
BART on QMSUM	32.18	8.48	28.56
HMNet on QMSUM	**36.06**	**11.36**	**31.27**
ChatGPT on QMSUM	**36.83**	**12.78**	**24.23**

Table 6 showcases the performance outcomes of the novel RankSum framework in comparison to other state-of-the-art algorithms on the DUC 2002 dataset, evaluated through ROUGE metrics. ROUGE metrics are typically used in the field of machine translation, text summarization, and other tasks where the quality of generated text needs to be evaluated automatically. The metrics involve comparing n-grams (sequences of n words) between the generated and reference texts. Common versions of ROUGE metrics include ROUGE-N (which considers overlapping n-grams), ROUGE-L (which focuses on the longest common subsequence) [78]. Ranksum achieves notable ROUGE-1, ROUGE-2, and ROUGE-L scores of 53.2, 27.9, and 49.3, respectively. Impressively, it outperforms all recent methods examined for this extractive text summarization dataset. Notably, this approach surpasses the highly accurate summarization systems, HSSAS [4] and Co-Rank, with a substantial margin of 0.6, 0.8, and 0.5 for ROUGE-1, ROUGE-2, and ROUGE-L scores respectively [112]. Additionally, the outcomes of PGnet [136], BART[75], HMNet[143], and ChatGPT[15] were assessed using the QMSUM dataset[156]. It is important to note that the current pinnacle of meeting summarization models, HMNet, achieves the most impressive performance in terms of ROUGE-L. This might be attributed to its cross-domain pretraining approach, which imparts HMNet with a heightened familiarity with the style of meeting transcripts [158]. However, it's worth highlighting that in the case of ROUGE-1 and ROUGE-2 metrics, ChatGPT emerges as the leader. ChatGPT excels due to extensive training on diverse data, enabling superior relationship comprehension in one to two grams, and boosting metric performance.

Table 7 Performance comparison among different models on all languages within the XNLI dataset, Source:[2].

Ahuja et al. [2] tested the performance of the state-of-the-art models on multilingual XNLI dataset [24] data. The results are given in Table 7, TuLRv6 - XXL achieves the highest average accuracy across all languages (88.8%). It performs exceptionally well in most languages, with accuracy scores consistently above 85%, XLM-R Large is the model that comes in second place with an average accuracy of 79.2%. While not quite as high as TuLRv6, it still maintains a strong performance across all languages and demonstrates its multilingual capabilities. With an average accuracy of 75.4%, mT5-Base takes the third spot. GPT-4-32k achieves an average accuracy of 75.4%. It exhibits consistent performance across languages, demonstrating its effectiveness in handling multilingual tasks.

Table 8: Generative AI Applications in Natural Language Processing: Major Papers and Descriptions

Paper	Field	Description	Citation
"Attention Is All You Need"	NLP / Machine Translation	Introduces the Transformer model using self-attention mechanisms for various NLP tasks, revolutionizing sequence-to-sequence models	[134]
"BART: Denoising Sequence-to-Sequence Pre-training for Natural Language Generation, Translation, and Comprehension"	NLP / Text Generation	Introduces BART, a sequence-to-sequence model pre-trained using denoising autoencoders, capable of various NLP tasks	[75]
"CTRL: A Conditional Transformer Language Model"	Language Generation	Proposes a generative model (CTRL) that can condition its output on specific attributes, enabling fine-grained control over text generation	[61]
"T5: Exploring the Limits of Transfer Learning with a Unified Text-to-Text Transformer"	NLP / Transfer Learning	Presents T5, a model that casts all NLP tasks as a text-to-text problem, achieving state-of-the-art results across diverse tasks	[111]
"GPT-2: Language Models are Unsupervised Multitask Learners"	Language Generation	Describes the GPT-2 model, a large-scale generative model that demonstrates impressive text generation capabilities across a range of tasks	[110]
"LayoutLM: Pre-training of Text and Layout for Document Image Understanding"	Document Analysis	Presents LayoutLM, a model that pre-trains on document images with associated text, improving document understanding tasks	[145]
"ERNIE: Enhanced Language Representation with Informative Entities"	NLP / Knowledge Enhancement	Introduces ERNIE, a model that enhances language representations by incorporating knowledge from knowledge bases	[153]
"DALL·E: Creating Images from Text"	NLP / Image Generation	Introduces DALL·E, a generative model capable of generating images from textual descriptions	[113]

"CLIP: Connecting Text and Images for Supervised Learning"	NLP / Vision	Proposes CLIP, a model that learns to understand images and text jointly, achieving impressive results in cross-modal tasks	[108]
"WebGPT: Browser-assisted question-answering with human feedback"	NLP, Human feedback	Introduces an approach that leverages a text-based web-browsing environment, enabling the model to access and navigate online resources. The methodology is structured in a manner that aligns with human capabilities, thus facilitating model training through imitation learning.	[95]
"GPT-4 Technical Report"	NLP/ Text Generation	GPT-4, a groundbreaking advancement, is introduced as a multimodal model with the ability to process both image and text inputs while generating text-based outputs. GPT-4's accomplishments encompass passing a simulated bar exam with a score that ranks within the top 10% of test takers.	[99]
"Let's Verify Step by Step"	Mathematical Reasoning	The introduced approach, centered around a process-supervised model, achieves a commendable success rate of 78% when addressing problems sourced from a representative subset of the MATH test set.	[77]

The landscape of Natural Language Processing (NLP) has witnessed remarkable advancements in recent years, driven primarily by the innovative applications of generative AI. The Table 8 highlights a selection of influential papers that showcase the evolution and impact of generative AI techniques within the NLP domain. These advancements have led to groundbreaking developments in various subfields of NLP, transforming the way we process and understand human language.

As evidenced by the papers presented, recent years have seen generative AI techniques reshape NLP in profound ways. These advancements not only enhance the quality and diversity of text generation but also enable more sophisticated control, cross-modal understanding, and knowledge integration. As the field continues to

evolve, it is likely that further innovations in generative AI will continue to drive NLP's progress, unlocking new frontiers of language understanding and generation across a wide array of applications.

4.4 Generative AI for Knowledge Graph Generation

Researchers and practitioners have leveraged the power of generative AI to enhance the creation and refinement of knowledge graphs—a structured representation of relationships between entities. This section explores the burgeoning landscape of generative AI applications within knowledge graph generation, highlighting pioneering research papers and their contributions to this evolving field. For evaluating models in the field of knowledge graph generation, a variety of datasets are employed, with Dbpedia [74], Cora Dataset [16] and Googles Knowledge graph [122] being among the most commonly used. However, the scope of available datasets extends beyond just these. These datasets are freely accessible, offering researchers and developers an invaluable resource to test and refine the capabilities of their knowledge graph generation models. A knowledge graph is a structured representation of information that captures relationships between entities and concepts. It goes beyond traditional databases by not only storing data but also organizing it in a way that highlights connections and context. Knowledge graphs, first introduced by Google in 2012 [124], are designed to model real-world relationships, making them a powerful tool for representing and querying complex information. Cai and Wang [18] introduced KBGAN, an innovative adversarial learning framework designed to enhance the performance of various existing knowledge graph embedding models. This approach is not dependent on the specific structures of the generator and discriminator, allowing for the incorporation of a wide range of knowledge graph embedding models as fundamental components. This enables KBGAN to significantly enhance the training dynamics and performance of existing knowledge graph embedding models. Liu et al. [81] introduce K-BERT, a novel approach that empowers language representation with knowledge graphs, enabling the incorporation of commonsense and domain-specific knowledge. The K-BERT methodology comprises two fundamental steps. Initially, knowledge from a knowledge graph (KG) is seamlessly integrated into a sentence, rendering it a knowledge-rich sentence tree. Subsequently, the utilization of soft-position and visible matrix techniques serves to regulate the extent of knowledge integration, thereby preventing any deviation from the original sentence meaning.

Despite the challenges presented by handling heterogeneous entity spans (HES) and keyphrases not seen in training (KN), the investigation yields promising outcomes across a spectrum of twelve open-domain and specific-domain natural language processing (NLP) tasks. Empirical evidence underscores the considerable efficacy of knowledge graphs, particularly in tasks that are driven by domain-specific knowledge. Moreover, K-BERT's compatibility with the model parameters of BERT offers a seamless integration of knowledge enhancement within a well-established framework.

Link prediction is a fundamental task involving the prediction of missing facts within a knowledge graph using available information. In this context, Balazevic et al. [10] introduce TuckER, a linear model that employs Tucker decomposition of the binary tensor representation of knowledge graph triples. Despite its straightforward

nature, TuckER demonstrates remarkable efficacy. It surpasses previous state-of-the-art models on widely recognized link prediction datasets, solidifying its position as a potent baseline for more sophisticated models in this domain. Moreover, Zeb et al. [121] have introduced ComplexGCN, an innovative graph convolutional network that leverages standard graph convolutional architecture(GCN) [67] to learn complex embeddings. Within the ComplexGCN framework, both node and relation features are projected into complex space through the use of learnable weights associated with neighboring nodes at each convolutional layer. To maintain the integrity of initial embedding information in the final node embeddings, a residual connection between the input and output of the convolutional stack is implemented. These researchers [121]

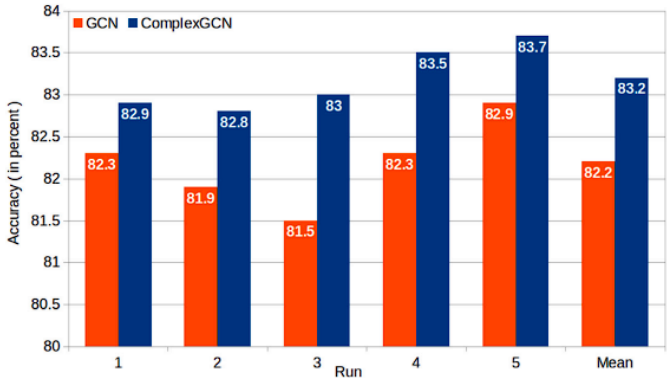

Fig. 9 GCN vs CGCN on node completion task- Cora Dataset, Source: [121]

conducted an evaluation of ComplexGCN's performance on the node classification task using the Cora dataset. This consisted of 2708 nodes categorized into 7 classes and 5429 edges representing citation links between documents. Both the standard GCN and ComplexGCN were trained on the Cora dataset for 200 epochs, with the objective of minimizing the cross-entropy loss. The training process was repeated 5 times for each model, and the results were averaged and reported in Figure 9. In terms of accuracy percentage, ComplexGCN exhibited improved performance compared to the standard GCN, achieving a 1% increase in mean accuracy.

The presented selection of papers highlights the innovative strides researchers have made in leveraging generative AI to enhance knowledge graph generation. From employing adversarial learning for improved embeddings to bridging the gap between unstructured text and structured knowledge, these papers showcase the multifaceted nature of the advancements.

4.5 Interdisciplinary Applications of Generative AI

The groundbreaking capabilities of generating synthetic data and content generation have given Generative AI the ability to be applicable in interdisciplinary fields. Further recent applications are discussed in this section. The synthetic data generation capability of generative AI is useful in mechanical fault detections. Gao et al. [42]

highlight a fault detection method that combined Finite Element Method (FEM)[26] simulations and Generative Adversarial Network (GAN) [44] to address two primary challenges. Firstly, it aimed to fill the gaps in fault samples by leveraging FEM simulations. Secondly, it sought to enhance fault detection accuracy by utilizing GAN to generate a substantial number of synthetic fault samples. Initially, FEM was employed to generate simulation signals of specific lengths to complete missing fault samples. Subsequently, GAN was utilized to create additional fault samples based on FEM simulations, resulting in a more comprehensive dataset. Finally, classifiers such as Support Vector Machines (SVM)[25], Extreme Learning Machines (ELM)[51], Decision Trees (DTree)[107], and others were employed to detect faults in cases where the faults were previously unknown.

Table 9 Comparison of Classification accuracy with and without GANs sampling, Source: [42]

Description	**FEM & AI**	**FEM, GAN & AI**
No of fault Samples	360	360
No of Synthetic Fault Samples	–	3240
Accuracy SVM (%)	84.44	86.11
Accuracy ELM (%)	89.72	91.67
Accuracy Decision Tree (%)	91.11	97.5
Average Accuracy (%)	88.42	91.76

In Table 9 the result clearly identifies the use of Generative AI to generate the synthetic samples which helps the machine learning models to achieve greater accuracy. In Feng et al. [38] a traffic generation model is developed using the Generative AI, named TrafficGen. The model outperforms the previous state-of-art techniques such as SeneGen [127] in generating the synthetic traffic scenarios. The introduced models were also able to generate the trajectory of the generated traffic and synthetic snapshots. This enabled the creation of numerous fresh traffic scenarios and the enhancement of the ones that already exist.

Music generation is also gaining popularity in the field of Generative AI, different methods such as Variational Auto Encoders, Transformers and Recurrent Neural Networks are being used in generating synthetic music, and different new approaches of music generation [60]. Another application is the Handwriting generation [41]. This proposed HiGAN+ which presented the capability to generate a wide range of authentic handwritten texts while being guided by arbitrary textual content and distinct calligraphic styles. These styles are separated from reference images or randomly drawn from a prior normal distribution. Traditional style transfer methods, which rely on pixel-level mappings, may not be suitable for HiGAN+, hence they introduce the contextual loss to notably enhance the stylistic consistency of generated images. The model performed very well in generating readable handwriting samples. In the field of software engineering, generative AI is introduced to help write better code and solve errors in the code, debugging and even writing the documentation of the work (e.g., Copilot) [92].

Emerging technologies in the realm of generative AI aim to simplify human life, yet they also underscore the imperative for responsible AI development. These innovations should prioritize ethical considerations, ensuring that their generated content aligns with societal values. The Contemporary efforts in the generative AI method development are increasingly conscious of these ethical dimensions. In a recent review, Pudari and Ernst [104] delved into Copilot and emphasized that generative AI, while valuable, won't supplant humans in the field of software engineering. This is because it struggles to grasp intricate software design principles and identify coding issues, known as 'code smells'. Instead, its role primarily revolves around aiding developers in crafting more efficient code. Researchers [8] highlight responsible AI as a comprehensive concept, mandating systematic adoption of AI principles. Besides explainability, it emphasizes fairness, accountability, and privacy in real-world AI model implementations, especially in scenarios involving sensitive information and regulatory demands for data privacy.

Apart from these discussed papers, a multitude of groundbreaking advancements are unfolding within the domain of generative AI. It is evident that in this rapidly advancing research, the previously discussed papers represent just a prominent subset of the recent developments in this field.

5 Challenges and opportunities of Generative AI

There are various domains for which we can discuss both the challenges and opportunities of Generative AI. Let's start with challenges and their proposed solutions followed by opportunities-

5.1 Challenges and their proposed solutions

Ethical Concerns:
Challenge: GenAI can be used for malicious purposes, such as the creation of deepfakes for identity theft or misinformation.
Solution: Establishing ethical governance structures, guidelines, and regulations to guide the responsible development and deployment of GenAI.
Security Concerns:
Challenge: There might be vulnerabilities in generative models that could be exploited for adversarial attacks.
Solution: The development of security measures to protect generative models from manipulation and continuous research into adversarial robustness.
Bias and Fairness:
Challenge: Generative models may amplify and perpetuate biases in the training data, leading to discriminatory and unfair outputs.
Solution: Extensive research and implementation of methods to detect and mitigate bias in training data, as well as encouraging inclusivity and diversity in datasets.
Data Privacy:
Challenge: Generative models trained on large datasets may inadvertently remember sensitive information, posing privacy risks.

Solution: Adherence to data protection regulations and implementation of privacy-preserving approaches to protect personal privacy.
Interpretability:
Challenge: Mostly, it is difficult to understand the decision-making process of generative algorithms due to their 'black boxes' nature.
Solution: Research and development of explainable AI approaches to improve interpretability and transparency and, permitting users to understand algorithm outputs.

5.2 Opportunities

Human-AI Collaboration: Collaborative work between GenAI and humans can lead to innovative solutions in design, problem-solving, and creativity.
Creative Expression: Generative AI facilitates innovative creative expressions, such as music, generative art, and literature.
Content Generation: Applications in content creation, for example- image synthesis, text generation, and video creation enhance productivity in numerous industries.
Education and Training: Generative models can be employed for simulating scenarios for training, creating interactive educational materials, and enhancing learning experiences.
Personalization: Generative algorithms can be used for personalized recommendations in entertainment, e-commerce, and other user-oriented domains.
Innovative Design: GenAI can assist in creating optimized and innovative designs in industries like architecture and product design.
Scientific Discovery: GenAI contributes to scientific investigation by simulating complex systems, predicting outcomes, and generating hypotheses.
Healthcare Applications: GenAI advances personalized medicine, drug discovery, medical imaging, and healthcare system.
Balancing the potential benefits of generative AI with the demand for responsible development and deployment is essential. Ethical considerations, transparency, and ongoing research will play major roles in maximizing the positive impact of generative AI while minimizing risks.

6 Conclusion and Future Direction

This paper offers a comprehensive systematic literature review of recent advancements in the field of generative AI. Specifically, it thoroughly explores key algorithms within the realm of Generative AI, including Diffusion Models, Transformer-based models, Generative Adversarial Networks, Variational Autoencoders, and their advancements tailored to specific applications.

Within the paper, we discuss advanced methodologies developed by various researchers, representing the current state-of-the-art achievements in the field of generative AI. A primary focus of generative AI's impact is evident in the domains of NLP and Video Translation, where advanced models have emerged with the capacity to tackle a wide array of human-centric challenges. These include tasks like question answering, code generation, language translation, image transformation, and more interdisciplinary applications. The paper highlights the recent achievements made

in these areas, shedding light on the cutting-edge advancements achieved through generative AI techniques.

Moreover, it seems evident that the future direction of generative AI will be a transformative journey. One critical avenue of exploration involves the continuous evolution of AI architectures, aiming to create models that surpass current machine and human capabilities. Additionally, the ethical dimension of AI is set to gain even more prominence, with research and development focusing on ensuring responsible AI generation, minimizing biases, and aligning with evolving ethical standards. Indeed, interdisciplinary collaborations will flourish, as generative AI is applied to complex challenges in fields like healthcare, climate science, and education, amplifying its real-world impact.

No doubt, the synergy between humans and AI will deepen, emphasizing AI's role as a collaborative partner across various domains. Advancements in NLP will persist, with an emphasis on question-answering, multilingual translation, and code generation. The domain of image, video, and multimedia processing will witness expansion, with generative AI contributing to content creation, enhancement, and interpretation. As we journey into this new and exciting future, it is also clear that we need to remain committed to responsible AI development and ethical considerations in parallel to developing these more advanced generative AI methods.

Statements and Declarations

Funding

This research received partial financial support from the Wales Innovation Network and Global Wales Small Grant Fund, Grant Number: GW-230433/414 (1.3.1b).

Conflict of interest/Competing interests

All authors declare that they have no conflict of interest.

Ethics approval

Not Required.

Data availability statement

This research paper is a systematic review that does not utilize any specific dataset for analysis. Instead, it focuses on collating and evaluating existing literature to provide a comprehensive overview of the field.

Abstract

The challenge of estimating 3D pose has been thoroughly explored and researched in computer vision due to its broad range of applications. However, due to complex structures, occlusion, frame rates, varying sizes and resolutions, this problem is highly challenging. This paper demonstrates the ability of graph neural networks (GNNs) and long short-term memory (LSTM) for 2D to 3D pose estimation in a sequence of frames. LSTM is used as a feature extractor. The bone length and joint angle play a crucial role in pose estimation. Our model uses a GNN to analyze the relationships between nearby joints and their angles and then predicts the final 3D joint positions using a multi-layer perceptron (MLP) model. A Semi-supervised learning and frame-dropping strategy approach is employed to enhance the accuracy of our model. Our model outperforms various latest advancements models, achieving an accuracy of 6.5 mm in joint localization on the HumanEva-1 and Human3.6m datasets.

1 Introduction

In the research on 3D human pose estimation from 2D pose estimation in videos, emphasis is placed on comprehending human posture and limb articulation for computer vision tasks such as augmented and virtual reality, human activity recognition, and sports analysis [1]. The use of a 2D representation of human position, deemed simpler to estimate, is common, although occlusion and foreshortening in 2D positions may introduce ambiguity. Depth information inherent in 3D poses is leveraged to eliminate uncertainty and enhance performance[2]. The challenge lies in the inherent non-uniqueness of mapping a 2D pose to 3D, as multiple projections onto a 2D plane are possible [3]. Acquiring datasets for 3D pose is challenging due to the expense and complexity of motion capture setups, unlike 2D pose datasets where key points can be manually identified [4].

Over time, various methods have been employed to address the challenge of 3D pose estimation[5]. Earlier techniques focused on extracting backdrop-independent features from photos and mapping them into 3D human poses. Recent approaches prioritize training deep convolutional neural networks (CNN) using end-to-end training for direct 3D pose estimation from input frames [6].

Two significant contributions are presented in the paper. The utilization of LSTM and GNN models for 3D pose estimation from 2D pose sequences is demonstrated [7]. A comparative analysis with other approaches, including FCN, CNN, and RNN-based methods, is conducted in terms of parameters, training accuracy, and FLOPs. Additionally, the effectiveness of a dropping frames strategy in improving model accuracy is showcased.

Furthermore, a semi-supervised learning strategy is proposed, utilizing 2D key points from a video sequence to gradually generate corresponding 3D key points [8]. The research illustrates how limited training data does not constrain the model's ability to generalize.

2 Related Works

2.1 End-to-End 3D Pose Estimation

The conversion of pixel intensities from a single picture to 3D postures is facilitated by end-to-end pose estimation algorithms. It becomes necessary for the pattern to be retained and the 3D stance deduced by deep neural networks (DNNs) [6]. Poor performance and limited generalization capabilities are observed in these networks due to the extensive requirement of heavily labeled training data and the inherent difficulty in learning. This limitation of 3D pose estimation is acknowledged [7].

2.2 3D Pose from 2D Key Points

2D-to-3D lifting techniques are employed to leverage 2D pose estimation derived from input frames or video frames. Commonly utilized for 2D pose estimation are MMPose, OpenPose, and Detectron2. Functioning as an intermediary for 3D pose estimation, 2D pose estimators serve as inputs for the deep neural network (DNN) responsible for predicting 3D key points [9]. A simple yet effective fully connected residual network for generating 3D key points from 2D key points locations was introduced by Martinez et al., utilizing only a single frame. Rather than relying on a single frame for predicting 3D pose, the utilization of videos is advocated, offering temporal information that contributes to accuracy improvement and enhances model robustness. Temporal convolutions were employed by Pavllo et al. to predict 3D pose from 2D joints using multiple frames simultaneously [10]. Some models incorporated bone length and bone directions in the loss functions to ensure temporal consistency across different frames [11]. Time-series-based models, as proposed by Hossain and Little, employed a Long Short-Term Memory (LSTM) network to predict from previous temporal information between input frames [12].

2.3 Semi-supervised Learning

The In multitask networks for action recognition and joint 2D and 3D pose estimation, supervised learning is employed. Training for 3D pose estimation involves the use of various multi-view recordings, but obtaining such recordings for unsupervised learning proves challenging [1]. The differentiation between realistic and unrealistic poses generated by the model is accomplished by GANs models, and 3D poses are discriminated by the discriminator through random projection back to 2D points [4]. Additionally, depth estimation can be utilized for the projection of different key points based on depth estimation, such as determining if the “left hand is behind the right hand [8].”

3 Preliminaries

Graph Neural Networks (GNNs) are characterized as a class of deep learning models explicitly crafted to operate on graph-structured data, wherein graphs comprise nodes (referred to as vertices) interconnected by edges (referred to as links or edges) [7]. The intricate relationships and dependencies

among the nodes in a graph are intended to be captured and modeled by GNNs. Traditional deep learning models, including convolutional neural networks (CNNs) or recurrent neural networks (RNNs), are found to be inadequately suited for processing graph data [13]. To address this limitation, GNNs consider both the local and global structure of the graph, engaging in the propagation of information between nodes and updating node representations based on the features of their neighbors [9].

The fundamental building block of a GNN is a message-passing scheme, where information is exchanged between nodes and aggregated for the purpose of updating node representations. The message-passing operation is described through the following steps:

1. *Initialization:* An initial feature vector is assigned to each of the 17 nodes in a frame *[14]*.
2. *Message Passing:* Information exchange occurs between neighboring nodes. Each node, in turn, aggregates and transforms the messages received from its neighbors to update its representation *[15]*. This step is typically performed iteratively across multiple layers to capture higher-order dependencies *[16]*.
3. *Readout:* Following the message passing step, the final node representations find application in downstream tasks, such as node classification, link prediction, or graph-level prediction *[17]*.

4 Methodology

We have described poses with exact key points opposed to the heatmap methodology used by various detectors. This allows us to use LSTM as a feature extractor for our GNN. Pose can be considered as a relational data, where one joint relates to other in a certain way which can be modelled using the GNN [18]. The poses are shifted to a common origin point and are rescaled to the same size which makes our model independent of the subject size and position in the frame. The temporal information is exploited using the LSTM network [17]. Though FCNs suffer from vanishing gradient problem, this problem can be eliminated by using residual connections in the network. These models fail to efficiently learn temporal information as already proved in various studies [19].

4.1 Model Architecture

The model architecture as shown in figure 1, is simple and consists of 3 main blocks:

1. *Feature Extraction Module:* Joint positions can be considered as a type of spatial-temporal graph. Each joint can be considered as a node which represents the current trajectory of that particular joint. As already proven, raw text or data is not rich in features and hence we require a feature extractor module [19]. The input $x \in R^{L\times17\times2}$ consists of sequence of frames, each frame has 17 (x, y) coordinates for each joint of the body. All the 17 joints are shown in figure 1. The trajectory of each joint is passed to separate LSTM models. Opposed to GRUs, LSTMs don't suffer from vanishing gradient problem [20].
2. *Relational Extraction Module:* Relational Modelling Network: The joint representations generated from the feature extractor are fed into to relational modelling module [21]. It consists of a GNN which models relationships between nearby joints.

4.2 Semi-supervised Training

In semi-supervised training, our approach capitalizes on the limited availability of labeled data by incorporating a strategy that blends supervised and unsupervised learning. The joint representations obtained from the relational modeling module are utilized to train the model on labeled data, facilitating the prediction of corresponding 3D poses from 2D key points [4]. Simultaneously, the model is exposed to unlabeled data, enabling it to discern and exploit underlying patterns and relationships present in the data without explicit annotations. This semi-supervised strategy enhances the model's ability to generalize to diverse scenarios and adapt to variations in poses that may not be fully covered by the labeled dataset [7]. Through this dual-learning paradigm, our model achieves a more robust performance, effectively leveraging both labeled and unlabeled data to enhance its overall capability in 3D pose estimation from 2D key points [23].

5 Experimental Setup

5.1 Dataset

Two datasets, Human3.6m and HumanEva-I, have been utilized for training the model. Both datasets encompass images along with corresponding 2D and 3D poses [6].

The Human3.6m dataset comprises 3.6 million images featuring associated 3D human poses. Eleven actors (comprising 6 males and 5 females) performed 17

diverse activities, including smoking, sitting, walking, using the phone, taking photographs, discussing, standing, etc [13]. Figure 3 displays selected samples from the dataset, illustrating images with corresponding 3D poses represented in stick form. Captured by four calibrated cameras operating at a 50 Hertz refresh rate [8], this dataset provides accurate 3D posed joint positions and angles using high-speed capture cameras. It involves labeling 24 body parts with precise background removal, making it a widely used dataset for pose estimation and prediction tasks.

HumanEva-I encompasses seven calibrated video sequences (four grayscale and three color), temporally synchronized with 3D body poses captured by a motion capture system [3]. The database incorporates four subjects engaged in six common actions, such as walking, jogging, gesturing, etc [2]. Participants are provided with error metrics to calculate errors in 2D and 3D poses. Figure 4 showcases selected samples from the dataset, illustrating images with corresponding 3D poses represented in box form [5].

End-to-end pose estimation involves the conversion of pixel intensities from a single picture to 3D postures [9]. This process necessitates the retention of patterns and deduction of the 3D stance by deep neural networks (DNNs) [12]. Due to the substantial requirement for heavily labeled training data and the inherent challenges in learning, these networks exhibit poor performance and limited generalization capabilities. This limitation is inherent in 3D pose estimation [4].

5.2 Loss Function

The model uses 4 loss functions:

1. Joint Loss (MPJPE Loss): This is measures of Euclidean distance between the predicted and ground truth 3D joint positions and is used in semi-supervised learning [21]. Given a set of points J with predicted positions P and ground truth positions G, the MPJPE loss is often calculated is:

$$E_{JointLoss} = \frac{1}{|J|}\sum_{j=1}^{J} || P_j - G_j ||$$

1

2. Weighted Joint Loss (WMPJPE Loss): As the subject moves away from the frame, its trajectory gets worse and it gets difficult to track its trajectory hence the WMPJPE Loss gives less weight to further subjects. This allows us to assign different importance to different joints [7].

$$E_{WeightedJointLoss} = \frac{1}{\sum_{j=1}^{J} w_j}\sum_{j=1}^{J} w_j * || P_j - G_j ||$$

2

3. Bone Angle Loss: Measure the absolute difference in lengths between predicted and ground truth bones. As the human skeleton has limited range of angular motion of joints, hence bone angle loss is used to neglect the 3D pose predictions having bone joint angle greater than maximum limit of human body [11]. Apart from this, bone angle loss combined with LSTM provides better angular accuracy to physical and dynamic joints [10]. If $\varnothing$ represents the set of bones angles, A is the set of predicted bone vectors, and B is the set of ground truth bone vectors, the bongle angle loss formulated as:

$$E_{BoneAngleLoss} = \frac{1}{|\varnothing|}\sum_{\theta \in \varnothing} \cos^{-1}\left(\frac{A_\theta * B_\theta}{||A_\theta||_2 * ||B_\theta||_2}\right)$$

3

4. Bone Length Loss: Adding a soft constraint to align the mean bone lengths of unlabeled batch subjects with those of the labeled batch is a beneficial approach for self-supervision in the context of regressing the 3D trajectory of a person [6], [13]. This method involves training everything jointly, incorporating an elastic restriction to align the average bone lengths of unlabeled predictions with the labeled counterparts [5]. If L represents the set of bones length, $L_{\varnothing p}$ is the set of predicted bone lengths, and $L_{\varnothing g}$ is the set of ground truth bone lengths, the bone length loss is:

$$E_{BondLengthLoss} = \frac{1}{|L|}\sum_{l \in L} |L_p - L_g|$$

4

$$E_{Total} = E_{JointLoss} + E_{WeightedJointLoss} + E_{BoneAngleLoss} + E_{BoneLengthLoss}$$

5

6 Results

Table 3 displays the results for both evaluation techniques for our model. The model does not depend on additional data like other techniques, and has a lowest value for average error in comparison to all other methods. Our model outperforms the earlier best result [21] under procedure 1 (Table 3) by an average of 6 mm, and an error reduction by 11%. Notably, whereas our model does not employ ground-truth boxes, [2] unlike others .

For enhancing our results on the missing frames, During training we black out frames randomly in the given dataset which helps our model to understand how much it needs to rely on past frames information [24]. Our model significantly predicts right output also for the missing frames.

Table 1. Reconstruction error is evaluated on 3.6 million human dataset, with every 64th frame used for evaluation

Next, we assess how the 2D key point detector affected the outcome. Table 3 details the model's accuracy using GT 2D poses, for the Detectron2, hourglass-network predictions, and CPN. The performance of Mask R-CNN and CPN significantly outperforms the stacked hourglass network [24]. This is brought on by a stronger feature combination and better heatmap resolution and a more varied dataset used for pre-training. Using 2D ground truth poses as training data, our method enhances results by 8.33 mm and approaches proposed by Lee et al. which are based on LSTM by 1.2mm for method 1. Thus, advancements are not attributable to a better 2D detector [1].

The smoothness of predictions is crucial for the videos which are not measured by the absolute position errors. This is evaluated using joint velocity errors termed as joint loss, which are the first derivative of joint loss of 3D posture sequences [20]. The Joint loss error produced by the single-frame is reduced by our semi-supervised approach on the transformer model by an average of 15%, resulting in noticeably smoother poses, as seen in Table 1.

Table 2 represents results on the Human-EVA dataset and the Mask R-CNN detector as a 2D key point detector for the testing purpose. Table 3 represents our model and also performs better for the small dataset [24].

Table 2. Analysis of the HumanEva-1 dataset error

Model	Parameters	FLOPs
Hossain et al. [21]	16.86M	34.0M
Our Method	1.14M	17.59M

In terms of complexity, Table 2 contrasts our model performance with the LSTM model [2]. We show the model parameters together with an estimation of FLOPs required for prediction of one frame at a time.

7 Conclusion
