In conclusion, this has provided an overview of 3D human pose estimation from 2D pose estimation[14] in videos, highlighting the challenges, techniques, and proposed solutions in this field [10]. However, there are several avenues for future research and development in this area.

Firstly, improving the accuracy and robustness of 3D pose estimation [18] algorithms remains a crucial direction. While deep learning-based models have shown promising results, there is still room for enhancing their performance, especially in challenging scenarios such as occlusions, complex poses [19], and cluttered backgrounds. Additionally, exploring novel architectures and fusion strategies that can effectively leverage both spatial and temporal information could lead to further improvements [6].

Secondly, addressing the issue of limited labeled 3D pose datasets is essential [11]. The development of methods that can leverage unlabeled or weakly labeled data to enhance the training process holds great potential. Semi-supervised and unsupervised learning techniques could be explored to make 5 better use of the vast amount of unlabeled video data available [16]. Furthermore, the integration of multimodal data sources, such as depth sensors, RGB-D cameras, and wearable devices, could offer richer information for more accurate and detailed 3D pose estimation. Leveraging additional cues, such as scene context, object interactions, or human-object relationships, could further enhance the understanding of human poses in complex environments [7], [23].

Table 3
Analysis of the effect 2D detector on the expected results

Method	P1	Method	P1
Lee et al. [19] (GT)	37.9	Our Method (D Ff)	50.9
Martinez et al. [1] (SH Ff)	63.0	Our Method (SH Fr)	53.3
Hossain & Little (GT)	42.7	Our Method (D Ff)	54.7
Martinez et at. [1] (GT)	44.9	Our Method (D Ff)	39.3
Martinez et at. [1] (SH PT)	67.8	Our Method (D Ff)	57.1
Our Method	51.9	Our Method (D Ff)	48.9

Lastly, deploying 3D pose estimation in real-time applications, such as human-computer interaction, augmented reality, and robotics, is an exciting area for future exploration [6]. Developing efficient and lightweight models that can run in real-time on resource-constrained devices would enable the integration of 3D pose estimation into a wide range of practical applications [12].

Abstract

Although there is an exponential rise in the literature on gratitude research, there is no attempt to systematically identify the historical development and recent trends in gratitude research. Gratitude has been defined diversely as an emotion, an attitude, a moral virtue, a habit, a personality trait or a coping response. As an emotion, people experience gratitude when they receive something valuable from someone else. As a trait, it is defined as a tendency to recognise and respond to goodness in others. The present study uses bibliometric analysis to review gratitude publications from the last 20 years, that is from 2001 to September 2023. WoS (Web of Science) identified 2982 publications referring to gratitude in title, abstract or keywords. It comprised 2860 articles and 122 review papers. The extracted data were analysed and visualised with the help of two analytical tools, that is the WoS analysis and VOSviewer (version 1.6.16). This study elicits the number of publications and citations from 2001 to September 2023, and most cited publications, and the most influential authors, articles, publishers, universities and countries as performance analysis. Furthermore, collaboration among countries, keyword co-occurrence and recent trend analysis are employed through science mapping. The results reveal that the major research areas of gratitude research are psychology, social sciences, business economics, psychiatry and public environmental and occupational health. The keywords co-occurrence suggest five major research clusters: evolutionary studies of gratitude, gratitude and health, gratitude and positive psychology, gratitude among children and adolescent and mediating and moderating studies of gratitude. Also, the analysis of recent 5-year studies highlights a clear trend of scientific explorations of gratitude against earlier trends of articles on philosophical and religious connotations of gratitude.

KEYWORDS
bibliometric, gratitude, VOSviewer

1 | INTRODUCTION

Gratitude has been considered a revered virtue in nearly all major religions and cultures of the world. The very notion of expressing gratitude to God through prayers and rituals permeates the teaching of the holy book 'The Bible' (Emmons & Kneezel, 2005). Gratitude is one of the pivotal moral values of Islam (Ali et al., 2019). Sixty-nine verses in the Holy Quran glorify gratitude or one of its cognates. In addition, the five rnas (auspicious duties) conceptualisation of Hinduism offer a foundation for gratitude towards ancestors, parents, friends, teachers, knowledge, God, nature and the environment (Garg, 2023). Hinduism offers one of the most comprehensive conceptualisations of gratitude, wherein Hindus worship almost everything (animals, mountains, rivers, sun, moon, soil, season, etc.) to express their gratitude for others

© 2024 Asian Association of Social Psychology and John Wiley & Sons Australia, Ltd.

(Garg, 2017). Apart from these three largest religions, other religions like Buddhism, Jainism, Judaism, etc., also favour gratitude for individual, group and societal well-being.

Although appreciated and encouraged traditionally, gratitude has captured the attention of modern scientists in the last 20 years or so. Traditionally, gratitude was a subject matter for philosophers and religious leaders. Still, a few early psychologists and sociologists, like Simmel (1950) and Heider (1958) tried to conceptualise gratitude as a construct that could be measured and studied scientifically. The fundamental scientific exploration of gratitude started with a series of articles by Robert Emmons, Michael McCullough and colleagues during the early 2000s (McCullough et al., 2001). There has been no looking back since then, and gratitude has been widely researched in various disciplines like psychology, psychiatry, business and economics, health care, clinical and therapeutic studies, etc. Today, a large body of research delineates various definitions, concepts, theories, forms, dimensions, interventions and benefits of gratitude.

The existing literature on gratitude could be understood through the following themes: (a) what is gratitude; (b) forms and dimensions of gratitude; (c) individual, social and cultural factors linked to gratitude; (d) individual and social benefits of gratitude; (e) gratitude interventions; and (f) gratitude scales. Regarding the definition of gratitude, there is no all-agreed definition and conceptualisation of gratitude (Wood et al., 2010). Gratitude has been operationalised diversely as 'emotion, an attitude, a moral virtue, a habit, a personality trait or a coping response' (Emmons & McCullough, 2003, p. 337). Rosenberg (1998) suggested that gratitude could be understood at three levels: emotion, mood and trait. As an emotion, people experience gratitude when they receive something valuable from someone else (Watkins, 2014). As an affective trait, gratitude is a 'general tendency to recognize and respond with grateful emotions to the roles of other people's benevolence in the positive experiences and outcomes that one obtains' (McCullough et al., 2002, p. 112). With the emergence of positive psychology 2.0, researchers are contemplating a new conceptualisation of gratitude: existential gratitude, which is the tendency to remain grateful or thankful even in challenging or difficult situations (Jans-Beken & Wong, 2019).

Although there is a rapid growth in the literature on gratitude research, there has been no attempt to systematically identify the historical development and recent trends in gratitude research. To the best of our knowledge and explorations, no previous researcher has reviewed and analysed the trends within the rapidly expanding domain of scientific knowledge of gratitude. Although a few scholars conducted meta-analysis and systematic reviews of gratitude studies (please see Boggiss et al., 2020; Cregg & Cheavens, 2020; Davis et al., 2016; Dickens, 2017; Renshaw & Steeves, 2016), the bibliometric analysis of gratitude researcher is still unknown. In their meta-analysis, Cregg and Cheavens (2020) investigated the impact of gratitude interventions on symptoms of anxiety and depression. In another study, Boggiss et al. (2020) analysed 19 articles to systematically analyse the impact of gratitude interventions on physical health and health behaviour. Based on 38 studies, Dickens (2017) conducted a meta-analysis of gratitude interventions. Similarly, Davis et al. (2016) and Renshaw and Steeves (2016) also conducted meta-analyses of the available literature on gratitude interventions and their impact on various specific variables. They listed down different gratitude interventions like counting your blessings, daily gratitude listing, gratitude collages, gratitude letters and visits, and introspection. There are several cultural-specific gratitude interventions also. For instance, Japanese people often express gratitude through short poems, which are referred to as 'Haiku'. Similarly, Indians express their gratefulness through different festivals and functions. For instance, Indians celebrate a 15-day festival known as '*shrad'* to articulate their gratitude for their ancestors and forefathers. Contemporary studies are exploring the beneficial effects of technology-based gratitude interventions such as telehealth services, counselling and psychotherapy platforms. Moreover, researchers are also investigating the impacts of diverse web-based interventions like daily gratitude writeups on social media, blogging, and gratitude journaling apps. It is argued that meta-analysis explains '(1) the overall strength and direction of effects or relationships, and (2) the across-study variance in the distribution of effect-size estimates and the factors that explain this variance' (Aguinis et al., 2010, p. 310). Further, meta-analyses are restricted to the examination of the direction and strength of effects and relationships among variables (Donthu et al., 2021). A systematic literature review uses systematic procedures to acquire, arrange and assess available literature. They are restricted to niche research areas like domain-based reviews, method-based reviews or intervention-based reviews.

In contrast, bibliometric analysis is appreciated and recommended for three obvious reasons. First, bibliometric analysis is not confined to the exploration of any specific domain, interventions or association between two variables. It extensively explores different facets of a phenomenon through a comprehensive evaluation of its research impact. Second, it is highly appreciated for its objectivity and ability to handle large data and files using mathematical and statistical methods (Donthu et al., 2021; Singh et al., 2020). Objectivity and a logic-driven approach differentiate bibliometric analysis from meta-analysis and systematic literature reviews. Third, it offers significant indicators of the growth and development of a field of knowledge, including

1467839x, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/ajsp.12621 by Delhi Technological University, Wiley Online Library on [09/05/2024]. growth of scholastic publications, prominent scholars, journals, institutions or countries. Accordingly, the present study uses bibliometric analysis to offer an extensive understanding of publications, citations, and authors, including their institutions and countries. It highlights how gratitude research has unfolded over the last two decades. This study also reports how gratitude research organically develops and disseminates across countries. It evaluates historical academic developments, emerging and active research areas and trends in the field of gratitude. 'It enables us to unpack the evolutionary nuances of a specific field, while shedding light on the emerging areas in that field' (Donthu et al., 2021, p. 285). As suggested earlier, the scientific studies on gratitude started in 2001 with efforts of early researchers like Robert Emmons, Michael McCullough and colleagues; thus, this study performs a bibliometric analysis of gratitude research over a period of 2001 to September 2023. It tends to answer the following research questions.

RQ1. What are the current publication and citation trends of gratitude research?

RQ2. Which are the most influential authors, articles, journals, publishers, and countries publishing extensively in the domain of gratitude?

RQ3. What are the different research areas that carry out research in the gratitude domain?

RQ4. Which themes of gratitude are contemporary researchers exploring, and which topics have scope for future research?

To answer these questions, performance analysis and science mapping (two categories of bibliometric analysis) are performed. Performance analysis highlights the most impactful and influential articles, authors, countries and journals. It also reveals trends in publications and articles. Thus, performance analysis helps in addressing the first two research questions of the study. In addition, science mapping is used to underline the network of publications based on the attributes and characteristics of the article (Donthu et al., 2021; Zupic & Čater, 2014). In the present study, two bibliometric techniques of science mapping are used. First, co-citation analysis examines the associations among cited publications, which offers an insight into the knowledge base of gratitude research accumulated over the years (Dabic et al., 2013). It addresses the third research question by revealing the major research areas that focus on exploring different facets of gratitude. Second, keyword co-occurrence analysis explores the relationship between author keywords. It addresses the fourth research questions by highlighting major research clusters and recent trends in the area of research.

2 | METHOD

2.1 | Data source, search strategy and data retrieval

The web of Science (WoS) database was used to extract data for bibliometric analysis. It has a vast collection of over 24,000 journals across 254 subject disciplines. The availability of data about publication, citation, author, affiliation, country, etc., makes WoS suitable for bibliometric analysis. Previously, scores of researchers, including Huang et al. (2022), Donthu et al. (2021) and Ohlan et al. (2022), have also relied on the WoS database for bibliometric studies. Other databases like Google scholar, PubMed, PsycInfo and Scopus were also considered but WoS database was selected for its more relevance in the present context. Google scholar does not provide a dataset in such a form suited for bibliometric analysis. The PubMed dataset predominantly comprises research in life sciences and biomedical topics. And the PsycInfo database consists of works in the field of psychology. However, gratitude studies are distributed in psychology, management, sciences, psychiatry, etc. Thus, the WoS database was preferred over Google scholar, PubMed and PsycInfo databases. Also, the WoS database was preferred over Scopus for two obvious reasons. First, WoS is an older database than Scopus. Second, WoS has 68 data field tags whereas Scopus offers 43 data field tags. Thus, WoS provides comparatively more avenues for data analysis (Singh et al., 2021). Accordingly, the WoS database was used for the present study. The word 'gratitude' was searched on WoS in the title, abstract or keywords of the publications for the year from 2002 to September 2023. Only documents of the article and review types were considered, and other document types like books, chapters, letters, etc were discarded. It resulted in a collection of 3227 publications, which were considered for analysis. The abstracts of all these publications were manually screened to check for any casual use of word gratitude in title, keywords or abstract. It leads to removal of 249 articles from the dataset. In addition, articles published in 2001 were manually included in the study. It is realised that there were four publications in the year 2001. Thus, finally 2982 publications were considered for this study. WoS allows the export of data in files with only 500 documents; thus, six files were exported.

2.2 | Data analysis and visualisation

The extracted data were analysed and visualised with the help of two analytical tools, that is the WoS analysis and VOSviewer (version 1.6.16). The WoS provides

1467839x, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/ajsp.12621 by Delhi Technological University, Wiley Online Library on [09/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

information about the most prominent authors, countries, affiliations, journals and publication years. Apart from the information provided by WoS, the VOSviewer provides visualisation facilities for country collaboration, co-authorship and keyword co-occurrence. Both performance analysis and science mapping techniques are used to analyse the exported 2982 articles. This study elicits the number of publications and citations from 2001 to September 2023, the most cited publications, and the most influential authors, articles, publishers, universities and countries as performance analysis. Also, major research areas of gratitude research are explored. Furthermore, collaboration among countries, keyword co-occurrence and recent trend analysis are employed through science mapping. Donthu et al. (2021) recommend that performance analysis and co-citation analysis reveal the knowledge foundation (past knowledge), and keyword co-occurrence analysis reveals the knowledge production (present trend of knowledge development). Accordingly, this study employs both methods to dive deep into the ocean of knowledge in gratitude research.

3 | RESULTS

3.1 | Number of publications over 2001–September 2023

WoS identified 2982 publications referring to gratitude in title, abstract or keywords. It comprised 2860 articles and 122 review papers. The first article in the period between 2001 and September 2023 was by McCullough et al.'s (2001), 'Is gratitude a moral affect?' The article conceptualises gratitude as a moral affect. It suggests three morally relevant functions of gratitude: moral barometer, moral motivator and moral reinforcer. The number of publications remained less than 100 and 200 per year until 2012 and 2016, respectively. After that, there was an exponential growth in the number of publications, reaching 432 in 2022 and subsequently 292 until September 2023. The last 5 years, that is 2018–2022, recorded 1638 publications, which were 54.92% of total publications since 2001. The number of articles has increased from 205 in 2018 to 432 in 2022; thereby, publications in gratitude showed a growth of more than 100% in the last 5 years. Figure 1 provides the year-wise growth in publication on gratitude. It clearly reflects a spurt in publication. The trend is quite obvious, as earlier studies primarily focused on conceptualisation and theoretical development. And banked upon these developments, later researchers looked upon gratitude to solve societal problems. Similarly, earlier studies conceptualised gratitude as emotion, mood, trait, etc. and developed scales and interventions to measure and augment gratitude. And, in recent years, scholars have relied on previously accumulated knowledge to explore the utility of gratitude in different fields like physical and mental health, professional organisations, societal challenges, etc.

3.2 | Most cited publications

Table 1 reports the top 10 cited publications in the field of gratitude. The most cited publication is Tangney et al.'s (2007) 'Moral emotions and moral behavior'. It is published in the *Annual Review of Psychology* and has been cited 1712 times (107 citations per year). It was a review paper that examined gratitude as a moral emotion. The most cited empirical research examined the relationship between gratitude and subjective well-being with the help of an experimental research design (Emmons & McCullough, 2003). It was the first empirical manuscript to use the 'gratitude journal' methodology. Another

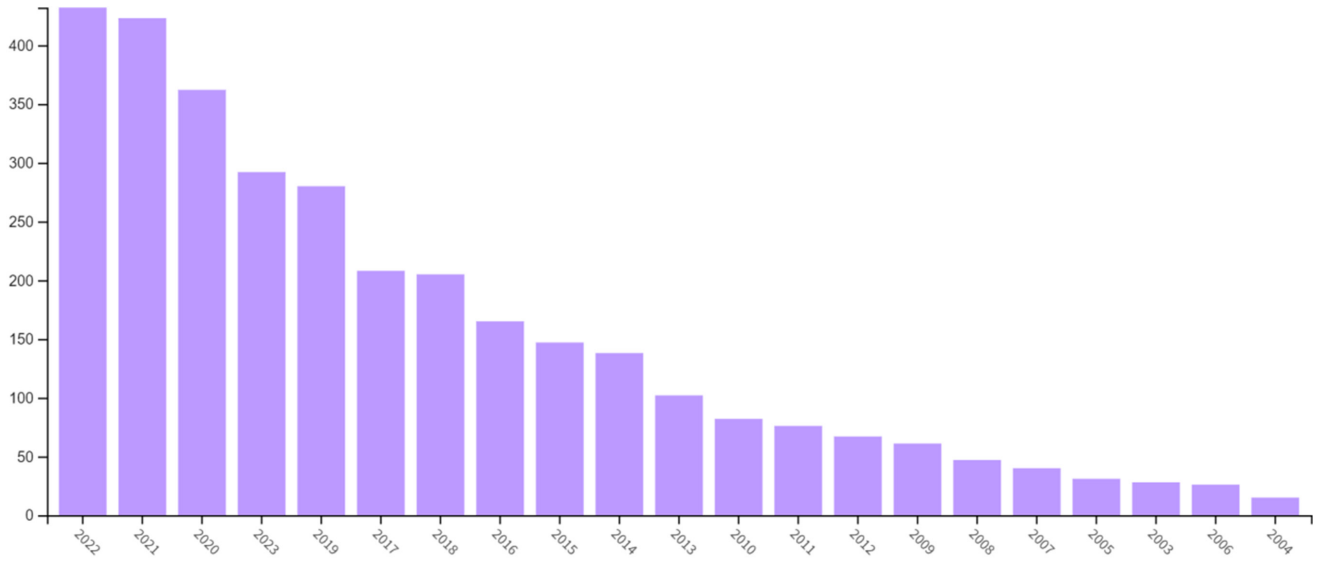

FIGURE 1 Publication trends from 2001 to 2022. *Source*: WoS database.

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

TABLE 1 Top 10 most cited publications on gratitude during 2001–September 2023.

S. No	Title	Authors	Journal	Total citations (citation per year)
1	Moral emotions and moral behaviour	Tangney et al. (2007)	*Annual Review of Psychology*	1712 (107)
2	Counting blessings versus burdens: An experimental investigation of gratitude and subjective well-being in daily life	Emmons and McCullough (2003)	*Journal of Personality and Social Psychology*	1551 (77)
3	The grateful disposition: A conceptual and empirical topography	McCullough et al. (2002)	*Journal of Personality and Social Psychology*	1542 (73)
4	What good are positive emotions in crises? A prospective study of resilience and emotions following the terrorist attacks on the United States on September 11th, 2001	Fredrickson et al. (2003)	*Journal of Personality and Social Psychology*	1511 (75)
5	Gratitude and well-being: A review and theoretical integration	Wood et al. (2010)	*Clinical Psychology Review*	934 (72)
6	Strengths of character and well-being	Park et al. (2004)	*Journal of Personality and Social Psychology*	761 (40)
7	Gratitude and prosocial behavior	Bartlett and DeSteno (2006)	*Psychological Science*	715 (39)
8	Feeling and believing: The influence of emotion on trust	Dunn and Schweitzer (2005)	*Journal of Personality and Social Psychology*	704 (42)
9	Witnessing excellence in action: the 'other-praising' emotions of elevation, gratitude, and admiration	Algoe and Haidt (2009)	*Journal of Positive Psychology*	671 (56)
10	The nature of feelings: evolutionary and neurobiological origins	Damasio and Carvalho (2013)	*Nature Reviews Neuroscience*	589 (59)

Source: WoS database.

top-cited publication investigates the role of positive emotions, including gratitude, in crisis management regarding the terrorist attacks on the United States on 11 September 2001 (Fredrickson et al., 2003). In another most-cited empirical article, Algoe and Haidt (2009) differentiated between elevation, gratitude and admiration. They suggested that gratitude motivates trust-worthy relationships with benefactors, and admiration leads to self-improvement. Interestingly, 4 of the top 10 cited publications on gratitude were published in the *Journal of Personality and Social Psychology*. In addition, all 10 top-cited articles on gratitude were published in journals related to psychology. It reflects a clear dominance of psychology-related explorations of gratitude. Also, all 10 most-cited articles and reviews were published in or before 2013. Among all types of articles published after 2013, the most cited publication focused on the multidimensional approach to well-being using the PREMA (positive emotions, engagement, relationships, meaning and accomplishment) framework (Kern et al., 2014).

3.3 | Most prolific journals and publisher

There are 1053 journals with at least one publication on gratitude. Also, there are only 20 journals with 10 or more publications. The *Journal of Positive Psychology* has published the highest number of papers on gratitude (136 publications and 4260 citations) followed by *Frontiers in Psychology* (111 publications and 1405 citations). The *Journal of Personality and Social Psychology* has only 18 publications but has the highest citation of 5027. It is interesting to note that seven out of the top 10 are psychology journals (except *Journal of Religion and Health*, *International Journal of Environmental Health and Public Health*, and *PLoS One*). It suggests a clear dominance of gratitude studies in the domain of psychology. This observation corresponds with the findings of Table 1. Another prominent area of gratitude research is 'religion and spirituality', with two journals related to religion featuring in the list. These two journals are *Journal of Religion and Health*, and *Religion*. It highlights the significance of gratitude in major religions of the world. The list also reveals gratitude studies in social areas, including social psychology, social behaviour and social indicators. Also, only one journal, *Journal of Business Research*, directly linked to business and management is there in the list. It clearly reflects the scope of future researchers. As far as publishers are concerned, Taylor and Francis (471 publications) have published the maximum number of papers on gratitude, followed by Elsevier (450 publications) and Springer Nature (443

1467839x, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/ajsp.12621 by Delhi Technological University, Wiley Online Library on [09/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

publications). Top rated journals published by Taylor and Francis are *Journal of Positive Psychology* and *Cognition and Emotion*. Tables 2 and 3 provide lists of journals and publishers with the highest number of documents on gratitude.

3.4 | Most prolific authors, universities and countries

Table 4 illustrates the list of authors with 10 or more publications on gratitude, along with their affiliation and country. Todd B. Kashdan from George Mason University (USA) has contributed a maximum number (25 publications) of papers. The author's notable contribution includes exploring the associations between gratitude and suicidal ideation, depressive symptoms, social anxiety and subjective well-being. Other top contributors in the field of gratitude are Sonja Lyubomirsky and Sara B. Algoe, with 18 publications each. Sonja Lyubomirsk majorly examined the role of gratitude in sustaining positive emotions, self-improvement, positive change and humility. Sara B. Algoe's significant contribution to the literature on gratitude is the 'find-remind-and-bind theory of gratitude'. The theory states that gratitude helps find and remind goodness in others and in relationships. And, thus, it binds one with goodness and social relations. Another notable contributor, although with 11 publications, is Philip Watkins. His notable contributions include the development and validation of the 'Gratitude Resentment and Appreciation Scale' (GRAT) and GRAT-16 short scale. His book titled 'Gratitude and the Good Life: Toward a Psychology of Appreciation' has also received much attention and appreciation throughout the world. The list also features an eminent scholar, Robert A. Emmons. However, it is disheartening to observe the non-inclusion of a few stalwarts like Michael E. McCullough. The probable reasons for such exclusion could be the non-indexing of journals in WoS, articles prior to 2001, and publications excluded from the scope of the present study like book, book chapters and proceeding articles. Out of 20, 11 top contributors are from the United States, followed by Taiwan with two publications. Table 5 reports the top 25 universities and countries in terms of the number of publications of gratitude. The top contributing country is the United States, with 1509 documents comprising 50.6% of the total publications considered in this study. Other top contributing countries are China (357 publications), England (273 publications), Australia (181 publications) and Canada (187 publications). It is also observed that citations per 1 million population are highest for Switzerland (168.89 citations per 10 million population), followed by New Zealand (118.10 citations per 10 million population), and the United States (117.10 citations per 10 million population). Also, the University of Michigan, the University of North Carolina and the University of Pennsylvania

are the top three contributing universities. The top five universities are from the United States.

3.5 | Research areas

Table 6 enlists major research areas of gratitude. Most research on gratitude has been carried out in psychology (1276 publications, 42.79% of total publications of 2982 from 2001 to September 2023). Other vital research areas include social sciences (271 publications, 9.08%), business economics (219 publications, 7.35%), psychiatry (204 publications, 6.91%) and public environmental and occupational health (207 publications, 6.98%). It suggests that although the majority of gratitude studies belong to psychology, there are gratitude researchers in other areas like social science, management, religion, philosophy, etc. too. Table 6 also reports publications in different research areas in two time frames: 2001–September 2023 and 2017–2023. It shows a decline in the research on gratitude (percentage-wise) in psychology, religion and philosophy, social science, education, and nursing from 2001–16 to 2017–23. During the same period, some research areas highlight a promising increase in research on gratitude. These areas include psychiatry, health care services, public environmental and occupational health and business economics. It suggests that contemporary researchers seem more interested in examining health and organisational utilities of gratitude. A closer look at research areas of publications of recent years suggests an increase in gratitude research in other research areas too.

TABLE 6 Top 10 research areas.

Research areas	2002–2023	%	2017–2023	%
Psychology	1276	42.79	881	40.44

3.6 | Collaboration among co-authors and countries

Figure 2 shows the networks among the top 151 authors with five or more publications from 2001 to September 2023 on gratitude. Seven author clusters were delineated with the help of VOSviewer. The top three authors with the highest linkages are Jeff C. Huffman (total link strength=35), Christopher M. Celano (total link strength=34) and Eleanor E. Beale (total link strength=27). Also, Figure 3 highlights the network among the top 38 countries with 10 or more published documents on gratitude. Again, seven country clusters were delineated with the help of VOSviewer. The top five linking countries are the United States (total link strength=336), China (total link strength=238), Australia (total link strength=94), Canada (total link strength=77) and Germany (total link

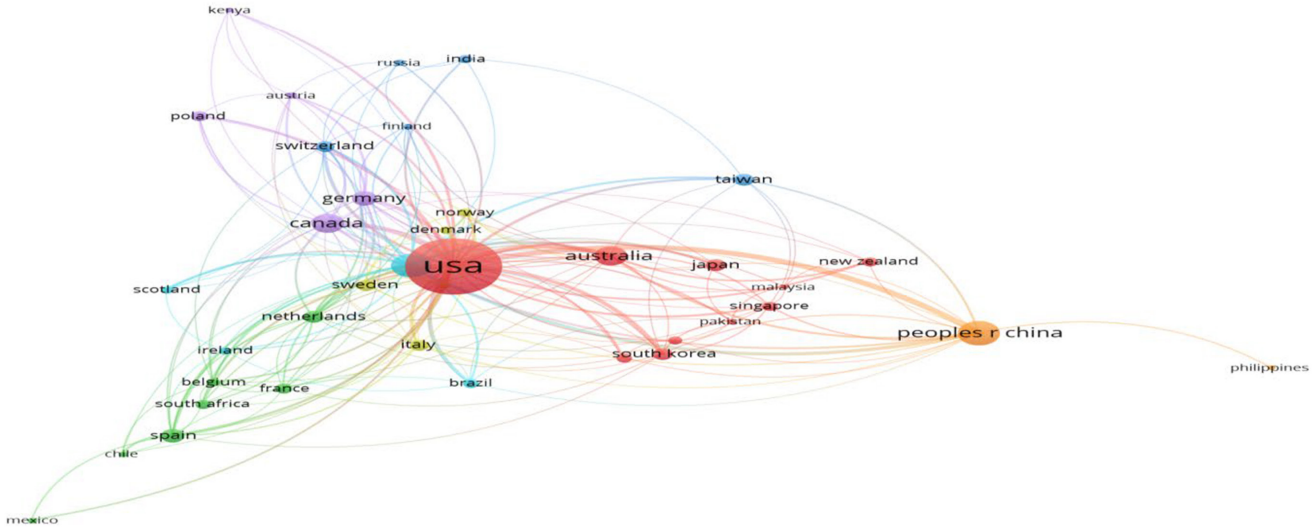

FIGURE 3 Co-authorship network among the top 50 countries with 10 or more publications. *Source*: Delineated from VOSviewer.

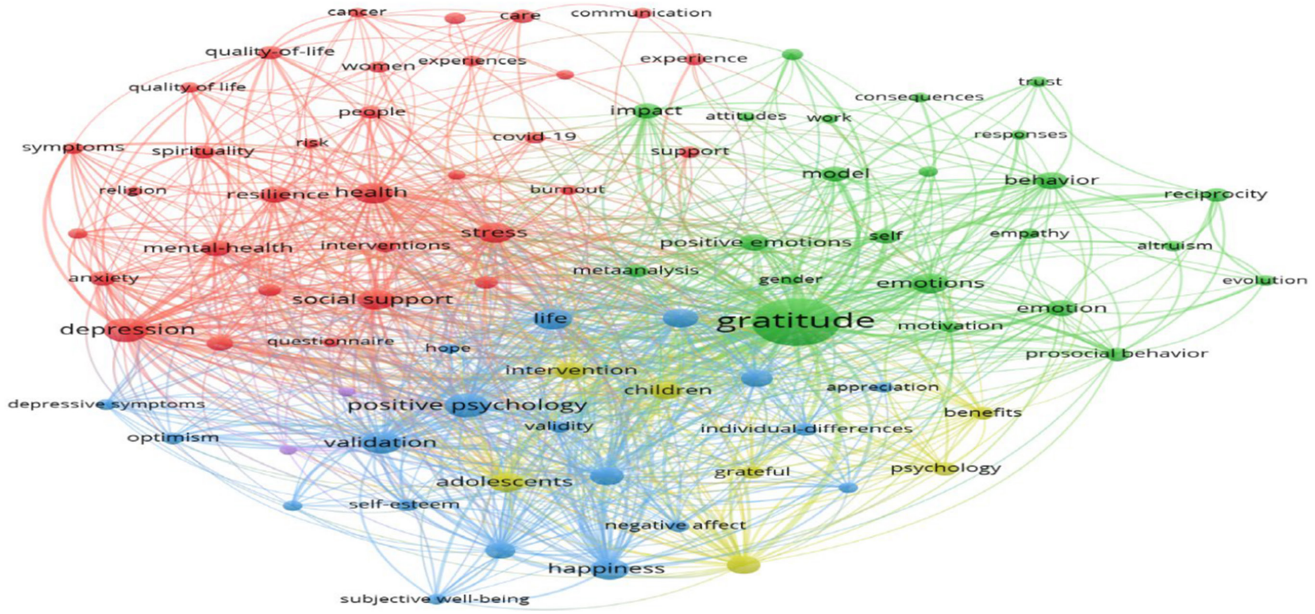

FIGURE 4 Keywords co-occurrence clusters in gratitude literature. *Note*: Five clusters are shown in different colours. The size of circles indicates the total link strength of keyword.

strength = 64). Among the two countries, the United States and China are the most networked, with link strength of 45. It is followed by the United States and Australia (link strength = 38) and the USA and Canada (link strength = 34). The most networked cluster has countries like the United States, Australia, Japan, Malaysia, New Zealand, etc.

3.7 | Keywords co-occurrence

VOSviewer was used to visualise keywords co-occurrence in the publications on gratitude. Figure 4 shows the following five keyword clusters.

3.7.1 | Cluster-1: Evolutionary studies of gratitude (in green colour)

The most prominent cluster (in green) includes keywords like positive emotion, prosocial behaviour, behaviour, attitudes, consequences, altruism, attitude, trait, work, etc. This cluster seems to inscribed early studies that conceptualised gratitude as emotion, mood, trait, attitude, habit, etc. A few notable contributors are Emmons and McCullough (2003), McCullough et al. (2002), Watkins (2014), Fredrickson (2004), Adler and Fagley (2004), Wood, Joseph, and Maltby (2009), Wood, Joseph, Lloyd, et al. (2009), etc. These studies

1467839x, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/ajsp.12621 by Delhi Technological University, Wiley Online Library on [09/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

conceptualise gratitude as an emotion (feeling that arises when one acknowledges that someone else does something good for them), a mood (more frequent and pervasive grateful emotions), a trait (tendency to recognise goodness in one's life) and an attitude (acknowledging favourable and positive aspects of life). The first cluster also discusses general and work-related consequences/impacts of gratitude. Gratitude leads to lower materialism (Polak & McCullough, 2006), higher life-satisfaction (Lambert et al., 2009), counteracts hedonic adaptation (Lyubomirsky et al., 2005), broadens one's outlook (Fredickson, 2004), develops psychological and social capital (Fredickson, 2004) and cancels out negative effects (Garland et al., 2010). Work-related benefits of gratitude include higher job performance (Grant & Wrzesniewski, 2010), job satisfaction (Garg, 2017), organisational citizenship behaviour (Andersson et al., 2007), lower work stress (Saxena et al., 2020), less chances of workplace burnout (Chan, 2011), improved leadership (Garg et al., 2020) and greater work-family enrichment.

3.7.2 | Cluster-2: Gratitude and health (in red colour)

It comprises keywords like health, stress, anxiety, mental health, burnout, covid-19, depression, cancer, symptoms, care, etc. This cluster captures vital studies that investigate the linkage between gratitude and health. Various researchers, including, Krause et al. (2014), Hill et al. (2013), and Wood, Joseph, and Maltby (2009), Wood, Joseph, Lloyd, et al. (2009) reported a positive linkage between gratitude and better physical health. Emmons and McCullough (2003) and Jackowska et al. (2016) observed better sleep among participants who kept a gratitude journal. Similarly, notable scholars like Wood et al. (2008), Froh et al. (2009), Petrocchi and Couyoumdjian (2015) and Disabato et al. (2016) reported that grateful people experience lower levels of stress, depression and anxiety. Several other studies have revealed a link between different gratitude interventions and decreased mental stress and anxiety. Studies reported decreased depression owing to the three/five good things activity (Seligman et al., 2005), gratitude journals (Kerr et al., 2014) and gratitude letters (Toepfer et al., 2011).

3.7.3 | Cluster-3: Gratitude and positive psychology (in blue colour)

The third cluster includes positive psychology, validation, happiness, appreciation, subjective well-being, self-esteem, measurement, optimism, hope, life satisfaction, etc. This cluster majorly focuses on two major subthemes: (a) development and validation of measures of gratitude; (b) relationship of gratitude with psychological constructs like hope, happiness, satisfaction, resilience, optimism, etc. It includes studies that propagates major gratitude measures like the 'Gratitude Questionnaire-6 (GQ-6)' (McCullough et al., 2002), 'Gratitude Resentment and Appreciation Test' (GRAT) (Watkins et al., 2003), 'Transpersonal Gratitude Scale' (TGS) (Hlava et al., 2014), 'Multi-Component Gratitude Measure' (MCGM) (Morgan et al., 2017) and 'Existential Gratitude Scale' (EGS) (Jans-Beken & Wong, 2019). Subsequently, these scales have been explored and validated in different cultural contexts (please see, Oğuz-Duran, 2017; Garg et al., 2021; Garg & Mehak, 2021; Hammer & Brenner, 2017; Langer et al., 2016). The third cluster also highlights that gratitude is positively associated with various psychological constructs. The direct positive relationship between gratitude and happiness has been reported by numerous researchers including, Jackowska et al. (2016), Morgan et al. (2017), McCullough et al. (2002), Watkins et al. (2003), Seligman et al. (2005), Toepfer et al. (2011) and Garland et al. (2010).

3.7.4 | Cluster-4: Gratitude among children and adolescent (in yellow)

It includes keywords like counting blessings, gratefulness, psychology, children, adolescence and intervention. This cluster seems to have special focus on gratitude studies conducted on children and adolescents. While assessing gratitude among children and adolescents, researchers firstly tried to explore whether presently available measures (developed and tested on adults) suit children and adolescents. Froh et al. (2011) concluded that the GQ-6, GRAT and GAC could be used for 14–19 year olds and the GQ-6 and GAC better suits 10–13 year olds. And, parental reports or new scales are required to measure gratitude among children below the age of 10 years. Recently, Hussong et al. (2018), in their raise grateful children project, proposed three new measures of children's gratitude: (a) parent-report daily diary; (b) a child-report scenario; (c) a behavioural task. Other studies concluded significant cultural variations in expression of gratitude among children. American and Russian children express concrete and connective gratitude, respectively (Tudge et al., 2015). Studies have reported that parents, teachers and friends' gratuitous behaviour has a significant effect on the gratitude level of children. Several studies have focused on parental role in development of gratitude among children (please see Hoy et al., 2013; Hussong et al., 2018; Rothenberg et al., 2017). There are several studies in the context of students too. For instance, Garg, Kumari, et al. (2022), Garg, Mahipalan, et al. (2022), Garg, Verma, et al. (2022) reported significant moderating effect of gratitude in the relationship of positive reframing and technostress among students. Students high on gratitude are less likely to develop cyberbullying attitude

1467839x, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/ajsp.12621 by Delhi Technological University, Wiley Online Library on [09/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(Bansal et al., 2023). Gratitude may lead to better academic performance among students (Carmona-Halty et al., 2019; Clarkson, 2020; Slåtten et al., 2021). It is reported that sense of gratefulness helps students overcome challenges in their educational journey in schools and colleges (King et al., 2023). Also, gratitude has been reported to have positive linkages with academic engagement (Cui et al., 2023; Zhen et al., 2019), learning engagement (Jin & Wang, 2019), academic self-efficacy (Yudiani et al., 2023), effective learning (Valdez et al., 2022) and academic motivation (Nawa & Yamagishi, 2021).

3.7.5 | Cluster-5: Mediating and moderating studies (in purple)

It comprises keywords like mediating roles, moderators and students. The fifth cluster includes two types of studies: (a) Gratitude studies with some other variable acting as mediating and moderating variables; (b) Gratitude studies with gratitude acting as mediator or moderator. A few mediators explored in gratitude studies are psychological needs satisfaction (Tian et al., 2016), life satisfaction (Lambert et al., 2009), perceived social support (Gabana et al., 2018), resilience (Garg, Kumari, et al., 2022), positive reframing (Garg, Verma, et al., 2022) and constructive deviance (Garg, Kumari, et al., 2022). Similarly, a few previously examined moderators are positive affect (Froh et al., 2009), personality type (Senf & Liau, 2012), spiritual climate (Garg, Mahipalan, et al., 2022) and social intelligence (Garg et al., 2020). In another set of studies, the mediating and moderating effects of gratitude are examined. Lantz et al. (2021) examined the mediating effect of gratitude amid the association of religiosity and well-being. The 10 keywords, that co-occurred most frequently with gratitude are positive psychology (total link strength = 144), depression (total link strength = 138), happiness (total link strength = 123), validation (total link strength = 120), social support (total link strength = 114), count blessing (total link strength = 113), emotions (total link strength = 107), life (total link strength = 104), stress (total link strength = 94) and health (total link strength = 92).

3.8 | Recent trends

One thousand five hundred fifty-four papers published during 2017–2023 were used to visualise the recent trends in gratitude literature using VOSviewer. Figure 5 reports four keyword clusters. The most recent cluster (in yellow) shows that current research in gratitude focuses primarily on resilience, covid-19, burnout, posttraumatic growth, symptoms and mediating role. The second cluster (in yellowish-green) reveals a trend towards examining gratitude's role in well-being. The cluster includes happiness, optimism, self-esteem, and positive affect. The third cluster (in blueish-green) reflects a growing trend towards examining the psychometric properties of gratitude. It includes validation studies, scale, reliability, fit indices, etc. And the last cluster (in blueish) indicates a recent trend of exploring gratitude in different streams and populations. It includes keywords like religion, spirituality, social support, adolescence, children, etc.

4 | DISCUSSION

The present study analysed 2982 publications on gratitude from 2001 to September 2023 to examine the current and future trends in gratitude research. The findings reveal that the last 5–6years (2018–2023)

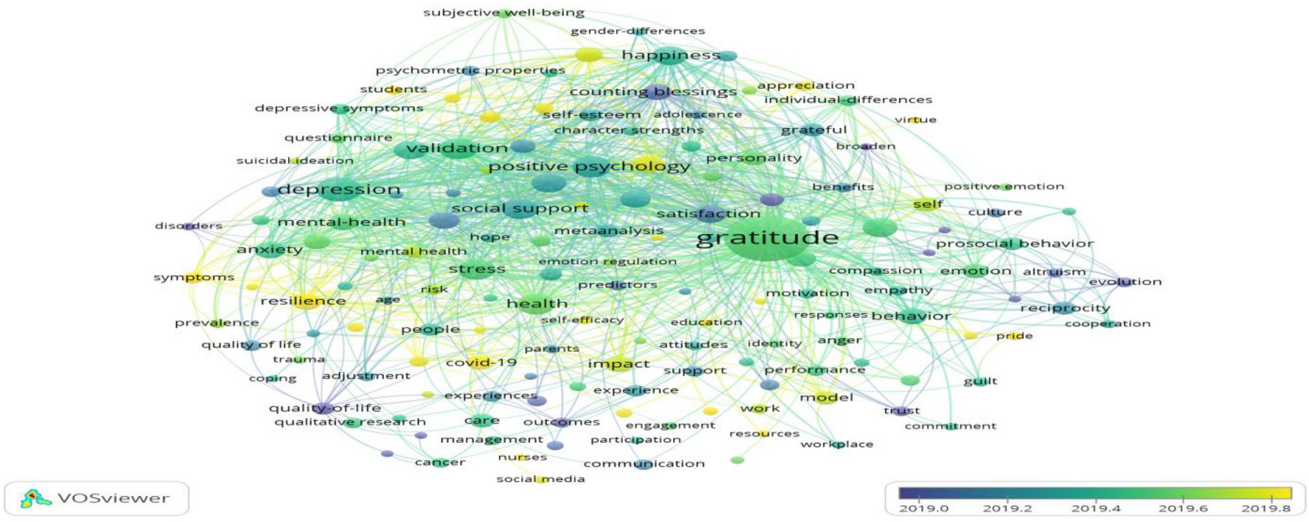

FIGURE 5 Recent trends in gratitude research. *Source*: Delineated from VOSviewer.

1467839x, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/ajsp.12621 by Delhi Technological University, Wiley Online Library on [09/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

witnessed sharp jumps in both publication and citation. It is also observed that gratitude has been widely researched in the areas of psychology, social sciences, business economics, psychiatry and the public environment. However, research area-wise trends suggest that research in traditional domains of gratitude like religion and philosophy is declining. However, there has been a spurt in scientific explorations in the research areas of psychology, psychiatry, health care services and business economics in the last 5 years. It suggests two vital recent trends in gratitude research. First, there has been a clear trend of logical and scientific explorations of gratitude in recent years. Earlier gratitude studies were more inclined towards exploring the philosophical and religious connotations of gratitude. Contemporary studies on gratitude employ scientific methods like experimental research design, quasi-experimental prototypes or sophisticated statistical tools like structural equation modelling (SEM) or partial least squares regressions (PLS).

Second, recent publications are more on exploring the utilities and benefits of gratitude in the day-to-day lives of people. Researchers in business and management have started investigating the organisational utilities of gratitude. They suggest an association between gratitude and work-family enrichment (Garg, 2022), team innovation (Li et al., 2021), workplace mistreatment (Locklear et al., 2021), customer loyalty (Audrain-Pontevia & Garnier, 2021) and employees' helping behaviour (Sawyer et al., 2022). Similarly, contemporary public health scholars are examining the role of gratitude in modern-day lifestyle disease treatment. These studies suggest a significant association of gratitude with coping during COVID-19 (Beames et al., 2021), daily hassles (Tachon et al., 2021), stress among nurses (Lee et al., 2021), mental well-being among people with substance use disorders (Leung & Tong, 2017) and the quality of life of patients with chronic schizophrenic (Kim & Jun, 2021). Similarly, there has been a shift in the subject matter of psychological studies on gratitude. Earlier studies mainly emphasised the conceptualisation of gratitude. However, current studies investigate the linkage between gratitude and other psychological constructs like resilience, a sense of coherence (Fujitani et al., 2017), forgiveness and sense of humour (Chamorro-Garrido et al., 2021), and bullying and prosocial behaviour (Oriol et al., 2021).

The recent trend analysis suggests that the most recent cluster includes keywords like resilience, covid-19, burnout and posttraumatic stress disorders. Quite plausible, positive psychology has been dominated by corona-related researchers like Jans-Beken (2021), Oliveira et al. (2021), Fishman (2020), Datu and Fincham (2022), Belkin and Kong (2021) and Day et al. (2020). A search of the word 'gratitude and covid', when searched on WoS in the title, abstract or keywords of the publications for the year from 2019 to 2021, reflects 107 articles. A few major themes of these studies are 'gratitude as a coping mechanism' (Beames et al., 2021; Gaeta et al., 2021; Jans-Beken, 2021), 'gratitude and prosocial behavior' (Mesurado et al., 2021), 'gratitude and mental well-being' (Geier & Morris, 2022), 'gratitude and stress' (Liljestrand & Martin, 2021), and 'gratitude and psychological capital' (Beames et al., 2021).

Furthermore, trend analysis also highlights that the second most recent cluster is about gratitude and well-being. A search of the word 'gratitude and well-being' when searched on WoS in the title, abstract, or keywords of the publications for the year from 2019 to 2021 reflects 336 articles. It reflects a clear inclination of contemporary researchers towards examining the role of gratitude in ensuring the well-being of practitioners. A close examination suggests that there are experimental and non-experimental studies that explore both direct and indirect associations between gratitude and well-being. The experimental studies examine the difference in the well-being of experimental and control groups (please see Chamorro-Garrido et al., 2021; Southwell & Gould, 2016). The indirect studies investigate the role of various mediating variables like interpersonal helping behaviour (Kersten et al., 2021), spirituality (Perez et al., 2021), resilience and social support (Kong et al., 2020) and cognitive and affective variables (Oriol et al., 2021).

In addition, trend analysis also suggests that the third recent cluster includes studies exploring the psychometric analysis of the gratitude scale. The development of a new scale or psychometric analysis of the existing scale is the first step towards extending the knowledge horizons of a theme in different cultures or populations (Sharma et al., 2022). Recent studies have examined the psychometric properties of existing gratitude scales like GQ-6, GRAT-16, etc., in different cultural contexts like India (Dixit & Sinha, 2021; Garg et al., 2021), France (Tachon et al., 2021), Vietnam (Tran et al., 2021), Philippines (Llenares & Almeda, 2021) and Japan (Komase et al., 2020). These studies indicate that gratitude studies are poised to flourish in new cultural contexts. Also, recent studies seek to develop new scales of gratitude in different contexts. For instance, gratitude at work scale (Cain et al., 2018; Youssef-Morgan et al., 2022), existential gratitude scale (Jans-Beken & Wong, 2019) and transpersonal gratitude scale (Hlava et al., 2014). Future researchers may explore the possibilities of developing new scales in different contexts, like the group gratitude scale, which may inquire into one's gratitude for a group rather than the individual. Similarly, new gratitude scales are being developed in different religious contexts like the Christian gratitude scale (Knabb et al., 2021) and the Islamic gratitude scale (Rusdi et al., 2021). These findings suggest that future researchers may try to develop new

1467839x, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/ajsp.12621 by Delhi Technological University, Wiley Online Library on [09/05/2024]. gratitude scales for different religious backgrounds like Hinduism, Sikhism, Persian, etc.

Further, the fourth recent cluster derived during trend analysis highlights the growth of gratitude research in specific streams and populations like adolescence, children, religion, students, health workers, working professionals, etc. For instance, there is a growing trend towards analysing gratitude in the workplace. Contemporary researchers have suggested that gratitude is positively related to lower levels of workplace materialism (Unanue et al., 2021), job satisfaction and job performance (Cortini et al., 2019), work-family enrichment (Garg, 2022) and OCBs and pro-social behaviour (Di Fabio et al., 2017; Sarkar & Garg, 2020; Saxena et al., 2020). Similarly, there is a significant rise in gratitude research among health care workers.

This study offers insights into historical and current trends in gratitude research. This bibliometric analysis of gratitude research over the last 20 years would benefit students, new researchers and academicians. Similarly, meaningful information on the most cited publications, most prolific journals, authors and countries would be helpful to one interested in any scientific investigation of gratitude. The identification of recent research topics would definitely encourage contemporary and future researchers to examine new areas of gratitude research. For instance, one of the most recent trends is the rise in studies on the development of new scales and the examination of the psychometric properties of existing scales. It is quite understandable given the culture-sensitive nature of gratitude. It would entice future researchers to develop new scales and examine the psychometric properties of existing scales in different cultural contexts. The findings of the study may also help in the development of specific gratitude interventions. For instance, the results highlight two major research clusters: gratitude and health, and gratitude among children and adolescents. Researchers and practitioners might be interested in developing gratitude interventions specifically for children and adolescents, like video games that rewards gratitude and visits to orphanages or old-age homes. Academicians are suggested to develop specific courses on gratitude. Some universities, like Delhi Technological University, India, have already started specific courses on the 'art and science of gratitude'. This study would surely help in designing better curriculum and learning outcomes. Also, educational institutions across the globe are witnessing a sharp rise in centres and courses on human values. Any such centre or course on happiness, mindfulness, compassion, or love is incomplete without an adequate understanding of the concept of gratitude. Literature and practitioners regard gratitude as a potent mechanism of happiness, mindfulness, and compassion. Furthermore, based on recent directions, the present study offers some foresight into future trends in gratitude research, which may guide future researchers in their journey.

5 | LIMITATIONS AND CONCLUSION

Despite a thorough investigation of the existing research on gratitude, this bibliometric analysis has two major limitations. Firstly, this study is based on data retrieved from the WoS database. Although search, retrieval and analysis using the WoS database have been sufficiently justified and used in previous bibliometric studies (Donthu et al., 2021; Ohlan et al., 2022), there are significant possibilities of missing out on articles on gratitude that are not indexed in the WoS database. For instance, there could be journal articles indexed in Scopus but not in the WoS database. Future research may use some other software that allows researchers to integrate data from WoS and Scopus (after avoiding duplication of articles). This consolidated data could further be subjected to bibliometric analysis. Alternatively, future research could utilise the Scopus database to refute or support the generalisability of the present study's findings. Secondly, given a very large database of 2982 articles, the present bibliometric analysis does not analyse the underpinning theories, dimensions, constructs, interventions and methodologies of the articles reviewed. A detailed analysis of each area would require a new thematic review based on the area of interest. Future researchers are encouraged to separately focus on reviewing gratitude theories, dimensions or methodologies to deep dive into a unique analysis theme. Such studies may be based on a small-scale framework- or theory-based review. For instance, a small-scale review of gratitude interventions may be beneficial.

The present study provides a comprehensive encapsulation of gratitude research using a bibliometric analysis of articles published between 2001 and September 2023. It offers a wide range of information on publications and citations over the years, the most cited articles, the most prolific authors, journals and countries, and important research areas. Most importantly, trend analysis suggests four clusters of research works, that shed light on not only the current status of gratitude research but also foresight into future directions too.

Green Emission in Thermally Stable Er^{3+} Doped Lead-Free Perovskite Phosphor for Solid-State Lighting and Optical Thermometry Applications

Ishant Kumar, Avinash Kumar, Sandeep Kumar, Vikas Sangwan, and Arvind K. Gathania

***Abstract*—$CaTiO_3$:xEr^{3+} (0.1≤x≤7 mole%) phosphor materials were meticulously prepared through the solution combustion method. Comprehensive analyses employing Powder X-ray Diffraction (PXRD), Field Emission Scanning Electron Microscopy (FESEM), and Fourier Transform Infrared Spectroscopy (FTIR) were conducted to investigate the phase, morphology, and vibrational characteristics of the synthesized phosphors. A detailed luminescence study was undertaken using photoluminescence spectroscopy, revealing distinctive 4f-4f transitions associated with Er^{3+} in both excitation and emission spectra. The application of Dexter's theory provided insights into the quenching mechanism inherent in $CaTiO_3$:Er^{3+} phosphors. Photometric studies were carried out to evaluate the suitability of the synthesized material for solid-state lighting applications. Furthermore, to assess the thermal stability of the phosphor material, the activation energy was computed. The fluorescence intensity ratio of thermally coupled energy levels of Er^{3+} ion was utilized to assess the temperature-sensing capabilities of the synthesized material. This material may be suitable for solid-state lighting and optical thermometry applications.**

***Index Terms*—Perovskite, phosphor, solid-state lighting, and optical thermometry.**

I. Introduction

LUMINESCENT materials, commonly denoted as phosphor materials, constitute inorganic compounds deliberately infused with impurities such as rare earth and transition metal ions. Solid-state lasers, optical temperature sensors, field emission displays, plasma display panels, and solid-state lighting exemplify a diverse array of applications associated with phosphors [1], [2], [3], [4], [5]. The versatility and efficacy of these materials make them integral components in a spectrum of cutting-edge technologies. From precise laser systems to highly sensitive temperature monitoring devices, and from state-of-the-art display technologies to innovative lighting solutions, the multifaceted utility of these materials underscores their significance in various industries [6], [7], [8], [9]. Conventional lighting sources, such as incandescent and fluorescent lights, constitute a significant portion of global electricity consumption, exceeding one-fourth of the total energy used worldwide. In response to this considerable challenge, material scientists have dedicated substantial efforts to replace these traditional sources with energy-efficient solid-state lighting alternatives. White light-emitting diodes (WLEDs) incorporating phosphor conversion present a particularly advantageous solution for energy conservation [10], [11]. Commercially, WLEDs are typically fabricated using an InGaN blue chip and Ce^{3+} yellow phosphor [12]. However, this production method falls short of meeting the criteria for high-quality interior illumination due to the absence of a red-light component in the overall emission. This results in an elevated correlated color temperature (CCT) of WLEDs and a correspondingly diminished color rendering index. To meet the standards of superior lighting quality, WLEDs must exhibit a lower correlated color temperature for indoor lighting applications and demonstrate an enhanced color rendering index [13], [14]. Achieving these characteristics is paramount to ensuring optimal visual comfort, color fidelity, and overall lighting performance in diverse applications ranging from commercial and residential settings to industrial environments. Consequently, researchers adopted an alternative strategy to enhance the quality of WLEDs by encapsulating a Near-Ultraviolet (NUV) blue chip with a composite of red, green, and blue phosphors [15], [16]. The identification of green, red, and blue phosphors responsive to NUV light becomes paramount in this context. Thus, our focus centres on the development of a novel green phosphor to serve as a color-mixing element for phosphor-converted WLEDs utilizing NUV chips.

Temperature constitutes a fundamental physical parameter across various domains of natural science, encompassing biological systems, industrial processes, and scientific investigations. Consequently, precise temperature monitoring assumes paramount importance in numerous aspects of life. Contact thermometers, relying on the thermal expansion of liquids and metals, serve as conventional instruments for direct temperature measurement through physical contact with the target object. Nonetheless, a limitation of these sensors lies in their inability to gauge the temperature of inaccessible entities, such as

those found in high-voltage power plants, oil refineries, coal mines, high-pressure power plants, and corrosive environments. Consequently, achieving precise temperature measurements remains a focal point for scientific researchers. To surmount the shortcomings of traditional contact thermometers, non-contact optical thermometry has garnered considerable interest among the scientific community. This attention is attributable to the fact that temperature profoundly influences fluorescence intensity, a pivotal characteristic of luminescent materials [17]. Due to its advantageous attributes, encompassing elevated sensitivity, precise spatial resolution, rapid response times, and the capability for real-time monitoring, the Fluorescence Intensity Ratio (FIR) method has garnered substantial research attention. This method is based on the examination of emissions from rare earth ion's thermally related energy levels, with a particular emphasis on the intensity ratio that varies with temperature [18], [19], [20], [21]. This feature endows it with suitability for the accurate temperature detection of typically inaccessible objects. Specifically, certain rare earth ions namely Er^{3+}, Ho^{3+}, Tm^{3+}, and Nd^{3+}- manifest pairs of thermally coupled energy levels, rendering them particularly well-suited for application in FIR based optical thermometers [22], [23], [24], [25], [26], [27]. The design and development of a phosphor material for an optical temperature sensor necessitate careful consideration of two primary factors. Firstly, the selection of an optically active ion capable of modulating its emission in response to temperature is crucial. Secondly, the choice of a host matrix assumes significance, as it profoundly influences the temperature-sensing capabilities and emission intensity of the phosphor material. In creating phosphor materials for optical temperature sensors, it's best to choose host matrices that are stable physically and chemically, have low phonon energy, and wide band gap [28]. Numerous phosphors, like $PbLa_{2-2x}Eu_{2x}W_4O_{16}$ [29] $CsPbCl_3$:Bi^{3+}, Eu^{3+} [30], $PbZrTiO_3$:Er^{3+},Yb^{3+} [31] etc. incorporate lead, a substance known for its deleterious impact on both human health and the environment due to its toxic radiation effects [32]. Considering these considerations, a collaborative endeavour has been undertaken to investigate alternative materials with environmentally sustainable attributes, serving as replacements for lead-based counterparts. The intricate oxide $CaTiO_3$ has been chosen as the host matrix in our study due to its non-toxic nature, commendable chemical and thermal stability, and relatively low phonon energy of approximately 470 cm^{-1} [33]. The orthorhombic structure of $CaTiO_3$ classifies it within the perovskite family, characterized by the generic chemical formula ABO_3. Here, B represents a cation featuring a relatively small ionic radius, exemplified by Ti^{4+}, while A denotes a cation with a larger ionic radius, exemplified by Ca^{2+}. The crystal structure of $CaTiO_3$ incorporates CaO_8 polyhedra and TiO_6 octahedra [34]. Possessing a notable band gap of 3.5 eV, $CaTiO_3$ stands out as one of the preeminent wide band gap oxides [35], [36]. Researchers have widely adopted $CaTiO_3$ as a host matrix for the formulation and advancement of rare earth-doped nano phosphors due to their distinctive attributes. These include elevated luminous efficiency, minimal phonon energy, a broadband gap, facile synthetic conditions, environmental compatibility, and robust thermal and chemical stability [37]. There has been considerable exploration of rare earth doped $CaTiO_3$ to enhance its luminescent properties, showcasing its applicability across various industrial domains [38], [39]. A key rationale for selecting Er^{3+} ions as dopants resides in their distinct energy levels, specifically $^2H_{11/2}$ and $^4S_{3/2}$, which exhibit thermal coupling and yield green light emission. This characteristic renders Er^{3+} ions particularly advantageous for applications spanning optical thermometry and the development of nano phosphors emitting green light [7].

While up conversion phosphor-based optical thermometers have been extensively scrutinized and find application in diverse fields, the competitive advantages offered by down-converting nano phosphors warrant a more comprehensive investigation for optical thermometer design. In the current study, we delve into the bifunctional attributes of $CaTiO_3$ doped with Er^{3+} ions, specifically focusing on its capabilities in temperature sensing and solid-state lighting. To the best of our knowledge, the temperature-dependent down-conversion behaviour of $CaTiO_3$:Er^{3+} has not been systematically explored. Our research is dedicated to elucidating the down-conversion characteristics of the $CaTiO_3$:Er^{3+} phosphor in relation to temperature variations, to establish its suitability as an optimal candidate for optical thermometry applications.

This study explores the dual applications of Er^{3+} doped phosphor, specifically focusing on solid-state illumination and optical thermometry. The solution combustion method was utilized to synthesize Er^{3+} doped phosphors due to its numerous benefits, including cost-effectiveness, time efficiency, and environmentally friendly nature [40]. The resulting material demonstrates commendable color purity, good thermal stability, and high sensitivity, indicating promising prospects for applications in solid-state lighting and optical thermometry.

II. Experimental

A. Phosphor Preparation

The preparation of a series of $CaTiO_3$:x Er^{3+} ($0.1 \leq x \leq 7$ mole%) phosphors using the solution combustion method involved several steps. Analytical reagent grade $Ti(OCH_2CH_2CH_2CH_3)_4$, HNO_3 (70%), $Ca(NO_3)_2 \cdot 4H_2O$, $Er(NO_3)_3 \cdot 5H_2O$, and NH_2CONH_2 were the starting materials. The synthesis process initiated with the preparation of a titanium nitrate solution. In a 100 ml beaker, 10 ml of double-distilled water and 1-2 ml of HNO_3 were added to $Ti(OCH_2CH_2CH_2CH_3)_4$. The mixture was agitated on a magnetic stirrer until a clear solution of titanium nitrate was obtained. Subsequently, stoichiometric quantities of nitrates of calcium, erbium, and urea were incorporated into the titanium nitrate solution. The resulting mixture was continuously stirred on a magnetic stirrer at an elevated temperature of approximately 80–90 °C until it transformed into a dense slurry. The obtained slurry was then subjected to a furnace heated to 500 °C to produce a fluffy powder. To enhance the crystallinity of the phosphor powder, it underwent annealing at 800 °C for a duration of 2 h. This multi-step process aimed at the preparation of high-quality phosphors for further applications.

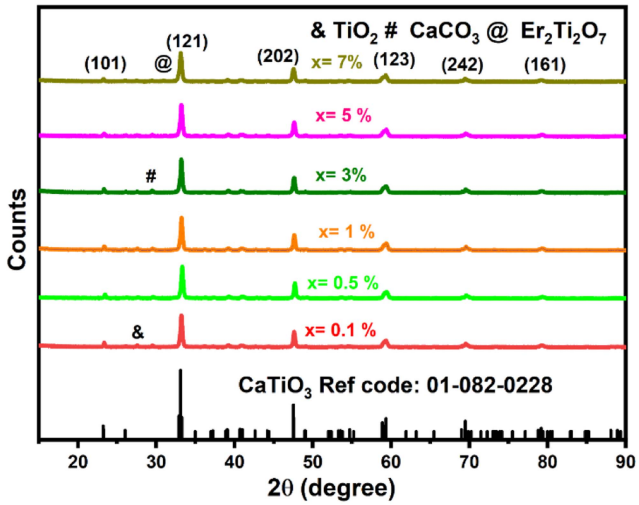

Fig. 1. PXRD patterns of $CaTiO_3$:x Er^{3+} (0.1≤x≤7 mole%).

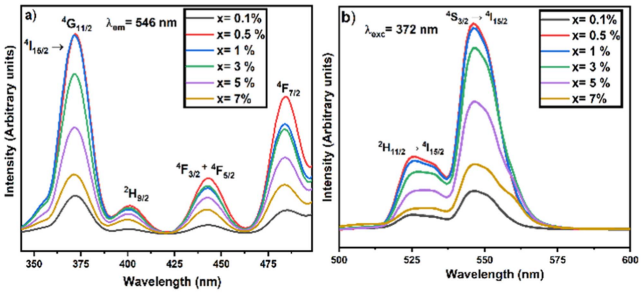

Fig. 2. (a) Excitation and (b) emission spectra of $CaTiO_3$:x Er^{3+} (0.1≤x≤7 mole%).

B. Characterization

The characterization performed in the present manuscript is same as reported in our earlier work [7], [28] and their details can be found from there.

III. Results and Discussions

A. PXRD Study

Fig. 1 presents the powder X-ray Diffraction (PXRD) pattern of $CaTiO_3$:xEr^{3+} (0.1≤x≤7 mole%) phosphor. The PXRD patterns of all the samples matches closely with the diffraction patterns of $CaTiO_3$ with ICSD (Inorganic crystal structure database) Reference Code 01-082-0228. $CaTiO_3$:xEr^{3+} (0.1≤x≤7 mole%) crystallizes into orthorhombic phase with space group Pbnm [34]. Most intense diffraction peaks of the phosphor are effectively indexed to (101), (121), (202), and (123) (242) (161). The average crystallite size was determined using Scherer's formula [41]:

$$D = \frac{K\lambda}{\beta \mathrm{Cos}\,\theta} \quad (1)$$

where 'D' represents the average crystalline size, λ is the X-ray wavelength (1.54056 Å), K is a constant, θ is the Bragg's angle, and β is the full width at half maximum (FWHM). The calculated crystallite size falls within the range of 19–22 nm. Small impurity reflections marked by ampersand (&), hash (#), and at the rate of (@) were also observed due to presence of TiO_2, $CaCO_3$ and $Er_2Ti_2O_7$ phases.

The Rietveld refinement analysis of $CaTiO_3$:xEr^{3+} (0.1≤x≤7 mole%) was performed on major phase ($CaTiO_3$) using the FULLPROF suite program. The Pseudo-Voigt function was employed to fit various parameters of the data points. Fig. S1 illustrates the Rietveld refinement of the XRD patterns of $CaTiO_3$:xEr^{3+} (0.1≤x≤7 mole%). The detailed information about the various structural parameters evaluated from the Rietveld refinement analysis of various samples is presented in Table S1.

B. FESEM Study

Fig. S2 present high-magnification Field Emission Scanning Electron Microscopy (FESEM) images, detailing the morphological characteristics of $CaTiO_3$:0.5 mole% Er^{3+}. The FESEM images depict irregularly agglomerated distorted spherical-like particles. The particle distribution, as illustrated in the histogram within Fig. S2(a), reveals a predominant particle size clustering within the range of 20-100 nm. The average particle size is 55 nm. Further insight into the elemental composition was provided by the Energy Dispersive X-ray Spectroscopy (EDS) spectra, displayed in Fig. S2(b), affirming the presence of Ca, Ti, O, and Er within the $CaTiO_3$:0.5 mole% Er^{3+} phosphors.

C. FTIR Study

The investigation into the vibrational bands of $CaTiO_3$:x Er^{3+} at varying concentrations (x = 0.1–7 mol%), was conducted through Fourier Transform Infrared (FT-IR) studies, as depicted in Fig. S3. The peaks observed at 434 cm^{-1} and broadband from 525–745 cm^{-1} correspond to the stretching vibrations of Ti–O and the bridge stretching modes of Ti–O–Ti, respectively. These spectral features reflect the structural characteristics associated with the environment surrounding the TiO_6 octahedra in the ABO_3 perovskite [42]. The shoulder peak at 875 cm^{-1} appears due to the presence of out of plane bending of CO_3^{2-} ion present in $CaCO_3$ [43], [44]. Furthermore, the band at 1442 cm^{-1} was ascribed to the asymmetric stretching vibration of the CO_3^{2-} group present in $CaCO_3$ [45], [46].

D. Room Temperature Photoluminescence Study

Photoluminescence excitation and emission spectra at room temperature were systematically recorded to analyze the impact of doping on the luminescence characteristics of $CaTiO_3$:Er^{3+}. The Photoluminescence Excitation (PLE) and Photoluminescence (PL) spectra of $CaTiO_3$:Er^{3+} are illustrated in Fig. 2(a) and (b), respectively. The PLE spectra were acquired within the range of 300–500 nm, with the emission wavelength fixed at 546 nm. In line with our previous investigations, the PLE of Er^{3+} doped $CaTiO_3$ manifested multiple narrow bands between 350 and 500 nm, corresponding to distinct 4f electronic transitions of Er^{3+} ions. Notably, sharp bands at 372, 401 nm, 442, and 484

nm denote $^4I_{15/2} \rightarrow {}^4G_{11/2}$, $^4I_{15/2} \rightarrow {}^2H_{9/2}$, $^4I_{15/2} \rightarrow {}^4F_{3/2} + {}^4F_{5/2}$, and $^4I_{15/2} \rightarrow {}^4F_{7/2}$ transitions of Er^{3+} ions, respectively [7], [47]. For the analysis of PL properties, emission spectra were recorded at 372 nm excitation for all synthesized samples. The emission spectra exhibits characteristic green emission with peaks centred at 526 nm and 546 nm, corresponding to $^2H_{11/2} \rightarrow {}^4I_{15/2}$ and $^4S_{3/2} \rightarrow {}^4I_{15/2}$ transitions [22], [48]. Notably, there was no change in peak profile with variation in doping concentration. The partial energy diagram illustrating various excitation and emission profiles are presented in Fig. S4 (a). With an increase in doping amount, there was a rise in emission intensity up to 0.5 mole percentage, attributed to the increased luminescence centres. However, beyond 0.5 mole percentage, a decline in emission intensity occurred due to concentration quenching.

When the spatial separation between activators exceeds a specific threshold, an escalation in non-radiative transitions occurs. This phenomenon is attributed to the presence of cross-relaxation channels, which act as inhibitory sites. The activation of cross-relaxation channels occurs in energy levels with comparable energy differences between them. In the context of an energy transfer process, such as A + B → C + D, cross-relaxation channels become feasible if the energy difference between A and C closely matches the energy difference between B and D. Various cross-relaxation channels may be accountable for the heightened non-radiative transitions in the synthesized phosphors, and these are detailed below [7]:

$$\text{CRC1: } {}^2H_{11/2}(\text{Er1}) + {}^4I_{15/2}(\text{Er2}) \rightarrow {}^4I_{13/2}(\text{Er1}) + {}^4I_{9/2}(\text{Er2}) \quad (2)$$

$$\text{CRC2: } {}^4S_{3/2}(\text{Er1}) + {}^4I_{15/2}(\text{Er2}) \rightarrow {}^4I_{9/2}(\text{Er1}) + {}^4I_{13/2}(\text{Er2}). \quad (3)$$

Within CRC1, the Erbium ion in the excited state $^2H_{11/2}$ undergoes relaxation to the energy state $^4I_{13/2}$, subsequently transferring the remaining energy to an adjacent Erbium ion. As depicted in Fig. S4 (b), this energy transfer through CRC1 induces stimulation of a neighbouring Erbium ion in the ground state $^4I_{15/2}$ to the excited state $^4I_{9/2}$ level. In CRC2, the Erbium ion initially in the excited state $^4S_{3/2}$ undergoes relaxation to the $^4I_{9/2}$ state and transfers the remaining energy to another Erbium ion upon being excited from the ground state $^4I_{15/2}$ to the higher state $^4I_{13/2}$. These cross-relaxation channels contribute to the increase in non-radiative transitions, and similar channels have been observed in our previous work [7], confirming their role in the concentration quenching. The influence of exchange interaction is prominent when the critical distance (R_c) between adjacent activator ions is less than 5 Å, whereas distance exceeding 5 Å lead to multipole interactions. According to Blasses, the distance between adjacent Er^{3+} ions can be determined using the equation [49]:

$$R_c = 2\left[\frac{3V}{4\pi Z X_c}\right]^{\frac{1}{3}}. \quad (4)$$

Here, R_c represents the critical distance, V denotes the unit cell volume, X_c represents the critical concentration, and Z represents the number of sites available for dopant ion occupancy per unit cell in the host lattice. For the $CaTiO_3$ host with Z equal to 4, V equal to 224.241 $Å^3$, and X_c equal to 0.005, the calculated critical distance for energy transfer is 27.78 Å. Given that this value exceeds 5 Å, it indicates the prevalence of multipole-multipole interactions in $CaTiO_3$:Er^{3+}. The determination of multipole interactions can be carried out using the Dexter formula for energy transfer [50]:

$$\frac{I}{X} = k\left[1 + l(X)^{\frac{m}{3}}\right]^{-1}. \quad (5)$$

Here, I denotes PL intensity, and k and l are arbitrary constants, while X denotes the critical concentration. The value of m signifies the type of multipolar interaction, with various constant values corresponding to different types of multipolar interactions. Specifically, for values of m = 3, 6, 8, and 10, exchange interactions, dipole-dipole, dipole-quadrupole, and quadrupole-quadrupole interactions occur, respectively. The determination of the m value involves calculating it from the slope (m/3) of the graph log(I/X) vs log(X), as illustrated in Fig. S5. The computed value of m is 5.28, closely aligning with 6. This proximity implies that dipole-dipole interactions predominate in the synthesized phosphor.

E. Photometric Analysis

The determination of CIE (Commission Internationale de L'Eclairage) coordinates for the $CaTiO_3$:x Er^{3+} (0.1≤x≤7 mole%) phosphors followed the 1931 CIE standard. The CIE diagram, corresponding to an excitation wavelength of 372 nm, is depicted in Fig. S6, with the corresponding estimated values detailed in Table S2 (The CIE coordinates for different samples are indicated numerically, corresponding to the serial numbers listed in Table S2). The CIE coordinates of the optimized phosphor, $CaTiO_3$:0.5%Er^{3+}, were found to be (0.28195, 0.70117). It has been documented that a correlated color temperature (CCT) below 5000 K is suitable for warm white light used for inside home application whereas CCT value greater than 5000 K value is suitable for outside lighting applications [51]. Furthermore, color purity, an essential parameter WLED application. The CCT and color purity values of all the samples have been evaluated using the formula described in our previous work [7] and enlisted in Table S2. The high color purity and CCT (>5000 K) value indicates that synthesized phosphor can be used as cool green emitting phosphor for outside lighting applications.

F. Decay Curve

The decay characteristics of $CaTiO_3$:0.5% Er^{3+} phosphor was analysed, as depicted in Fig. S7. Remarkably, the decay behavior of $CaTiO_3$: 0.5% Er^{3+} phosphor is effectively described by a third-order exponential decay model (Exp Dec 3). The governing equation for Exp Dec 3 is denoted as equation (6) [52]:

$$I(t) = I_0 + A_1 e^{\frac{-t}{\tau_1}} + A_2 e^{\frac{-t}{\tau_2}} + A_3 e^{\frac{-t}{\tau_3}} \quad (6)$$

Here, A_1, A_2, and A_3 are constants, while I and I_0 are luminescent intensity at time t and initial time respectively. τ_1, τ_2, and τ_3 signify decay times. For $CaTiO_3$:Er^{3+}, specific decay

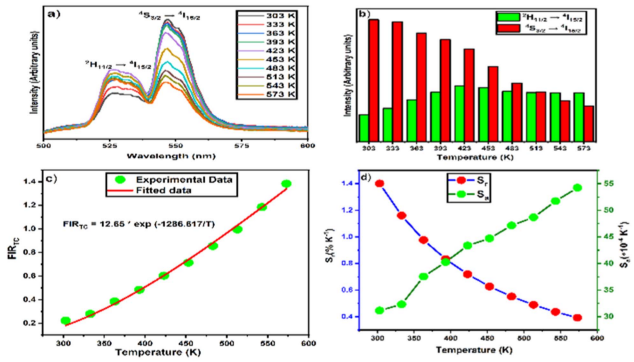

Fig. 3. Thermal evolution of (a) PL emission spectra of $CaTiO_3$: 0.5% Er^{3+} phosphor under 372 nm excitation (b) thermally coupled levels of Er^{3+} ion (c) FIR of thermally coupled levels of Er^{3+} ion and their fitting using Boltzmann's relation (d) relative and absolute sensitivity.

parameters were determined as follows: $A_1 = 0.72824$, $A_2 = 0.26383$, $A_3 = 0.33172$, $\tau_1 = 2.00036\ \mu s$, $\tau_2 = 15.39955\ \mu s$, and $\tau_2 = 76.42103\ \mu s$. The average lifetime value for the $CaTiO_3$:Er^{3+} phosphor was computed utilizing equation (7):

$$\tau_{av} = \frac{\sum A_i \tau_i^2}{\sum A_i \tau_i} \tag{7}$$

where, τ_{av}, τ_i, and A_i represent average lifetime, decay times, and constants. Through these calculations, the average lifetime was determined to be approximately 64.88 μs.

G. Thermal Stability

The influence of temperature on the PL characteristics of phosphor-based materials is a significant consideration for phosphor usage in numerous kinds of solid-state lighting applications. Usually, phosphors employed in illuminating devices necessitate excellent thermal stability as blue/UV LED chips generate temperatures of 150 °C during functioning time. Furthermore, the thermal quenching properties of the versatile phosphor are also beneficial for optical thermal sensing applications. By analyzing the emission profiles at varying temperatures, the thermal quenching features of the phosphor have been explored. The emission spectral profiles of the synthesized phosphor at 372 nm excitation as the temperature increased from 303 to 573 K, are illustrated in Fig. 3(a). The peak intensities of emission were dependent on temperature and the peak intensities associated with the transitions $^2H_{11/2} \rightarrow {}^4I_{15/2}$ and $^4S_{3/2} \rightarrow {}^4I_{15/2}$ vary with temperature. The emission peak related to the $^2H_{11/2} \rightarrow {}^4I_{15/2}$ transition at 526 nm increases with an upsurge in temperatures. Simultaneously, the emission peak at 546 nm is linked to the $^4S_{3/2} \rightarrow {}^4I_{15/2}$ transition, which diminishes with temperature. The $^2H_{11/2}$ energy level was thermally populated from the $^4S_{3/2}$ energy level via external temperature, which resulted in an intensity improvement in the $^2H_{11/2} \rightarrow {}^4I_{15/2}$ transition. This kind of variation in the PL spectral profiles occurs because of the thermally coupled and very little energy difference among the $^2H_{11/2}$ and $^4S_{3/2}$ energy levels of the dopant (Er^{3+}) ions. Furthermore, one of the most essential criteria of thermal stability for the synthesized phosphor is the activation energy, which was determined using the Arrhenius equation as shown below [53]:

$$I_T = \frac{I_0}{1 + Cexp\left(-\frac{\Delta E}{K_B T}\right)}. \tag{8}$$

The emission intensities at specific temperature T (K) and initial temperature are denoted as I_T and I_0. The Boltzmann and arbitrary constant parameters are represented as K_B and C. The activation energy of the phosphor is noted ΔE. The Arrhenius equation has been applied to assess the ΔE based on the slope of a straight line between $\ln[(I_0/I_T) - 1]$ and $1/K_BT$. The slope value was determined to be 0.279, as shown in Fig. S8. For the synthesized phosphor, ΔE is found to be 0.279 eV. Henceforth, the influence of temperature on the emission profiles of the synthesized phosphor indicates that the phosphor has excellent thermal stability.

H. Thermal Sensing

Fig. 3(a) present the thermal evolution of the emission profile of phosphor excited by 372 nm excitation within the temperature range of 303–573 K. The variation in CIE coordinates with T is negligible as depicted in Fig. S9. The emission intensity at 526 nm is observed to escalate relative to the emission at 546 nm with increasing temperature, as depicted in Fig. 3(b). This phenomenon emerges due to the thermal interconnection between two emitting levels. The relative population of these thermally coupled energy levels, separated by thermal energy (of the order of K_BT), conforms to a Boltzmann-type distribution. This distribution significantly influences the transitions between the two levels, particularly at elevated temperatures. The FIR associated with the thermally coupled levels can be described by the following expression [54]:

$$FIR_{TC} = \frac{I_{526}}{I_{546}} = A\, e^{\left(\frac{-\Delta E}{K_B T}\right)} \tag{9}$$

where I_{526} and I_{546} represent the integrated emission intensity of two thermally coupled (TC) green emitting bands, ΔE represents the energy difference between two TC levels. K_B, T, and A represent Boltzmann's constant, absolute temperature, and constant in relation to degeneracy, spontaneous radiative transition rate, and angular frequency of the respected transition. In Fig. 3(c), the experimentally determined FIR values are presented against temperature (T). The FIR data is fitted using the Boltzmann formula, and the value of $\Delta E/K_B$ is derived from the gradient of the fitted formula. Additionally, ΔE is determined to be approximately 894.25 cm^{-1}. By analysing emission spectra, the value of ΔE is found to be 696.39 cm^{-1}. The presence of non-radiative cross-relaxation channels and the overlap of two thermally coupled energy levels account for the observed subtle energy differential of 197.86 cm^{-1} [54]. In optical temperature-sensing, certain performance parameters like relative and absolute sensitivity are crucial for comparing

various optical temperatures. The absolute and relative sensitivities are defined as [55], [56]:

$$S_a = \left|\frac{d\left(FIR_{TC}\right)}{dT}\right| = \left|\frac{\Delta E}{K_B T^2} \times FIR_{TC}\right| \quad (10)$$

$$S_r = \left|\frac{1}{FIR_{TC}} \times \frac{d\left(FIR_{TC}\right)}{dT}\right| = \left|\frac{\Delta E}{K_B T^2}\right|. \quad (11)$$

The temperature-dependent behaviour of S_a and S_r is evident in Fig. 3(d), showing a steady increase with temperature. At 573 K, S_a attains its peak value, reaching 54.23 $\times$ 10^{-4}% K^{-1}. Conversely, S_r displays a consistent decreasing pattern with temperature, with its maximal value of 1.40% K^{-1} recorded at 303 K. A comparative analysis of S_a and S_r with other temperature sensing phosphors is enlisted in Table S3.

IV. Conclusion

In the current work, Er^{3+} doped $CaTiO_3$ has been successfully synthesized through solution combustion method. The obtained material underwent structural confirmation and morphology analysis via Powder X-ray Diffraction (PXRD) and Field Emission Scanning Electron Microscopy (FESEM), respectively. Additionally, Fourier Transform Infrared Spectroscopy (FTIR) was employed for vibrational characterization. Photoluminescence (PL) emission spectra were recorded at an excitation wavelength of 372 nm, revealing a distinctive green emission attributable to specific transitions. Notably, our investigation indicates a notable increase in PL emission with the initial rise in Er^{3+} concentration. However, beyond a critical concentration (x = 0.5 mol%), there is a discernible decline in emission intensity. Dexter theory elucidates that dipole-dipole interactions play a pivotal role in the observed quenching phenomenon. Calorimetric analysis of the material yields CIE coordinates, CCT, and color purity values, denoting its suitability as a green component in solid-state lighting applications. Given the thermal coupling of transitions, our study delves into potential applications, revealing the synthesized material's efficacy in optical thermometry. Maximum relative sensitivity of 1.40% K^{-1} and absolute sensitivity of 54.23 $\times$ 10^{-4}% K^{-1} were observed at temperatures of 303 K and 573 K, respectively. In summary, our findings underscore the multifunctional potential of the synthesized material. It exhibits promise for applications in both solid-state lighting and non-contact optical thermometry, establishing its viability as a bifunctional material with diverse practical implications.

HumourHindiNet: Humour detection in Hindi web series using word embedding and convolutional neural network

AKSHI KUMAR, Goldsmiths University of London, London, United Kingdom of Great Britain and Northern Ireland
ABHISHEK MALLIK, Delhi Technological University, New Delhi, India
SANJAY KUMAR*, Delhi Technological University, New Delhi, India

Humour is a crucial aspect of human speech, and it is, therefore, imperative to create a system that can offer such detection. While data regarding humour in English speech is plentiful, the same cannot be said for a low-resource language like Hindi. Through this paper, we introduce two multimodal datasets for humour detection in the Hindi web series. The dataset was collected from over 500 minutes of conversations amongst the characters of the Hindi web series *Kota–Factory* and *Panchayat*. Each dialogue is manually annotated as Humour or Non-Humour. Along with presenting a new Hindi language-based Humour detection dataset, we propose an improved framework for detecting humour in Hindi conversations. We start by preprocessing both datasets to obtain uniformity across the dialogues and datasets. The processed dialogues are then passed through the Skip-gram model for generating Hindi word embedding. The generated Hindi word embedding is then passed onto three convolutional neural network (CNN) architectures simultaneously, each having a different filter size for feature extraction. The extracted features are then passed through stacked Long Short-Term Memory (LSTM) layers for further processing and finally classifying the dialogues as Humour or Non-Humour. We conduct intensive experiments on both proposed Hindi datasets and evaluate several standard performance metrics. The performance of our proposed framework was also compared with several baselines and contemporary algorithms for Humour detection. The results demonstrate the effectiveness of our dataset to be used as a standard dataset for Humour detection in the Hindi web series. The proposed model yields an accuracy of 91.79 and 87.32 while an F1 score of 91.64 and 87.04 in percentage for the *Kota – Factory* and *Panchayat* datasets, respectively.

Additional Key Words and Phrases: Convolutional Neural Network (CNN), Hindi Web Series, Humour Detection, Long Short-Term Memory (LSTM), Low-Resource Languages, Social networks, Skip-gram Hindi Word Embedding

1 INTRODUCTION

In recent years, low-resource languages have been the epicenter of numerous research problems for Natural Language Processing (NLP) tasks such as the detection of fake news, hate speech, offensive language, sentiment analysis, emotion classification, and many others [9, 13, 15, 16, 27]. Moreover, the recent developments in language

Just Accepted

analysis have helped detection and mitigation of humour in conversations [8, 29]. Humour can be characterized as the attribute of being entertaining or comical, particularly as manifested in writing or speech. We frequently integrate humor into our discussions to elevate the conversation's quality or convey points in a more lighthearted manner. Since humor is typically conveyed through speech, it becomes imperative to devise programs capable of identifying humor in spoken language. Spoken humour is dependent on a multitude of factors, including but not limited to context, timing, and delivery [26]. Humour helps in effectively establishing communication channels and social relationships [7]. Humour detection refers to the task of detecting humour in various forms of conversation. The task of recognizing humour in conversations or day-to-day exchanges is called humour detection. Over the years, humour detection has gained great popularity in industry and academia. However, detecting humour is not a simple task due to several reasons the idiosyncrasies of humour are opposed to the dynamics of regular language. Moreover, humour is often expressed through subtle facial expressions body movements, or hand gestures that aren't easily captured. The use of sarcasm in between lines also adds to the difficulty of detecting humour in conversations. humour detection also varies as per age, gender, or ethnic background [32]. Humour detection frameworks can be used in sentiment analysis and inference [12]. With thorough analysis, they're able to interpret the conversations as humorous or not [6].

Humour detection in low-resource languages like Hindi, Urdu, Bengali, Telugu, and others is challenging due to limited data, cultural specificity, and the lack of pre-trained models. The scarcity of diverse and annotated data, coupled with the difficulty in capturing cultural nuances, poses obstacles to developing accurate and robust humour detection models for languages with fewer resources. Even though extensive work has been done in the field of humour detection. However, its application to the Indian subcontinent has still been very restricted. Amongst the various languages being spoken in India, Hindi is the most popular one, with about half a billion Hindi speakers in India alone. While there is sufficient data in the field of Humour detection for English, support for Indian languages is still required. The conventional methods used for the English language can't be used for Hindi as they differ significantly from each other across the dimensions. The methodology needed for the Hindi language is very different from the English language, from preprocessing to feature extraction to classification owing to the grammatical, syntactical, and semantical features of both languages.

The lack of availability of humour detection datasets in the Hindi language has motivated us to create a multi-modal dataset for humour detection in the Hindi web series. The datasets were collected from two popular Hindi web series. The entire scene was split into various dialogues, and then each dialogue was manually annotated as Humour or Non-Humour. The entire dataset spanned through the 1st season of both the web series and over 500 minutes of run-time. The exhaustive Hindi dataset proposed by us can be used as a benchmark dataset for Humour detection in the Hindi language or for other text classification or NLP based tasks related to the Hindi language.

In our pursuit of humour detection in the Hindi web series, we confront not only the scarcity of dedicated datasets but also the paucity of tailored word embedding techniques for the Hindi language. This research endeavors to bridge these critical gaps by proposing an innovative architecture that seamlessly integrates word embedding and convolutional neural networks to decode humour in the context of Hindi entertainment. The proposed work starts with data preprocessing, where we meticulously cleanse the raw dialogue excerpts harvested from web series transcripts. This preparatory phase meticulously rids the data of superfluous noise and extraneous special characters, establishing a foundation of data uniformity. Next, we introduce a pioneering Hindi-centric word embedding framework, cultivated through the training of a Skip-gram model on a corpus of Hindi text. This novel word embedding schema discerningly captures the nuances of Hindi language semantics and the intricate contextual intricacies embedded within the dialogues. Subsequently, we employ a trio of distinct convolutional neural network architectures, each wielding a unique filter size, to meticulously sift through the word embeddings. These parallel networks collectively unearth a rich tapestry of features, each tailored to a specific facet of the data, be it structural, semantic, or context-driven. These extracted features then embark on a transformative

Just Accepted

journey through stacked LSTM layers, where they undergo deep processing to uncover latent interdependencies among the words, a crucial step in deciphering humour's intricate timing and subtleties. These LSTM layers, serving as the final arbiter, adeptly categorize the dialogues into their respective humour or non-humour domains, encapsulating the essence of our pioneering HumourHindiNet architecture. We run intensive simulations on both datasets and evaluate several performance metrics. We compare the performance of our proposed framework with various baseline algorithms and several recently proposed Humour detection techniques. The experimental analysis reveals the utility of our proposed dataset to be used as a benchmark dataset for Humour detection in the Hindi web series. The experimental results also reveal the superiority of our proposed framework. The major contributions of this work can be summarised below.

(i) Two datasets for humour detection in the Hindi language are introduced. The dataset was collected from two popular Hindi web series, and each dialogue was manually annotated.
(ii) We perform meticulous data preprocessing techniques, involving noise reduction and special character removal, laying a strong foundation for robust analysis. These preprocessing methods are valuable not only for humour detection but also for enhancing the overall quality of other related tasks involving Hindi text.
(iii) We introduce a novel Hindi word embedding model, a custom Skip-gram model trained on a Hindi text corpus. This equips the model to capture the subtle nuances and contextual intricacies specific to the Hindi language.
(iv) The concurrent use of multiple CNNs, each with distinct filter sizes, exemplifies an innovative approach to feature extraction. This technique allows the model to extract a diverse range of features from the input data, enhancing its ability to discern humour through structural, semantic, and contextual cues.
(v) We leverage stacked LSTM layers for sequential dependency analysis, which enables our model to delve deeper into the linguistic intricacies of humour, capturing nuances such as timing and word interdependencies.

The rest of the paper is organized as follows. Section 2 discusses some recent work done in the field of Humour detection. Section 3 describes the various details of the Hindi Humour detection datasets created by us. Section 4 illustrates the various phases of our proposed framework. The experimental results obtained by us are discussed in Section 6. Section 7 presents the concluding remarks and the scope for future improvement for this work.

2 RELATED WORK

In this section, we discuss some of the recent work done in the field of Humour detection. Modeling humour is fairly difficult as compared to other text classification tasks due to several factors like idiosyncrasy and contextual dependencies [10]. Idiosyncrasy refers to the use of twisted words, hand or body gestures, or misalignment of words to get across the humour. On the other hand, contextual dependencies refer to the fact that most of the time, a punchline is based on the conversations leading up to that point. Some of the English datasets that have been proposed in the recent study are: Big Bang Theory [1], Ted Laughter [4], PTT Jokes [5], Pun of the Day [30], and 16000 One-Liners [21]. Recently, the field of humour detection has drawn a lot of attention from both the industry and the research community. Consequently, a lot of work has been done to improve the performance of the humour detection frameworks. The existing works can be broadly classified into three main categories, namely, Language analysis, Feature engineering, and machine learning-based approaches.

Language analysis-based approaches refer to the analysis of the multi-modalities of the text, audio, and video to categorize the text as humourous or non-humourous [31]. Wang et al. [28] considered not only the literal meanings of the words but also the context in which they were spoken. They proposed a framework to model the visual and acoustic patterns that appear in the spoken word segments. Moreover, they also capture the dynamic nature of humour by modifying word representations based on shifting non-verbal behaviors. Pham et al. [24] propose a method to learn joint representations for source and target modalities by using the source modality as

Just Accepted

input and injecting the target modality at runtime. This reduces disturbance when making transitions and makes the model robust. A conversational memory network to detect emotions in video conversations was proposed by Hazarika et al. [11]. They leverage historical contextual information using a deep neural network architecture. They present a multimodal approach by combining textual, audio, and video features with the vanilla-gated recurrent neural network. It helped them in modeling the past utterances of each speaker into memories. The created memories are then merged using an attention framework to capture the inter-speaker dependencies. Liang et al. [18], proposed a Recurrent Multistage Fusion Network (RMFN) model. It solves the problem of fusing the various modalities by decomposing them into various stages, with each of them focused on a subset of multimodal signals. This helps in the particular and efficient fusion of the modalities. The multi-stage fusion approach builds upon the intermediate representations of the previous stages to model the cross-modal interactions. They finally used a recurrent neural network along with the fusion approach to integrate the temporal and cross-modal interactions. Chauhan et al. [3] proposed a Multimodal Multiparty Hindi Dataset For humour recognition in conversations. It has 6,191 utterances from 13 episodes of a top-rated TV series "Shrimaan Shrimati Phir Se". The various utterances of the episodes are labeled as humour and non-humour, containing acoustic, visual, and textual modalities. They also propose several multimodal baseline algorithms to show contextual and multimodal information for humour recognition in conversations.

Feature engineering-based approaches refer to explicitly modeling features based on the task and data at hand. It usually requires domain expertise and proficiency. Various works have been done to explore the feature engineering-based approach by developing features along the lines of effective dimensions [20], distribution of part of speech [14], stylistic [23], etc. Mihalcea and Strapparava [21] defined stylistic features by working on adult slang, antonyms, and alliteration. Yang et al. [30], engineered four structural features for humour and created characteristic sets for each of the structural features. Based on experiments they concluded that incongruity and ambiguity are the best performers as compared to the other latent semantic structural features. Even though feature engineering-based approaches give good results they have a major limitation in terms of generalization. This is due to the fact that feature engineering has to be done individually for each dataset instead of the task in general.

The popularity of deep learning methods for NLP based tasks has paved the way for exploring the applications of deep learning methods in the field of humour detection. Oliveira and Rodrigo [6] presented a study for detecting humour in Yelp reviews. They used bag-of-words and word vectors as the features for the dialogues. They started the classification study with shallow methods like Random forest and linear discriminant. Then they moved on to more complex methods like deep feed-forward neural networks, recurrent neural networks, and convolutional neural networks. Bertero and Fung [2] presented the first-ever application of using long short-term memory for humour detection in dialogues of popular sitcoms. They used the canned laughter in the audio files as annotations for categorizing the dialogues as humourous or non-humourous. They use long short-term memory for modeling the punchline relation of the conversational humour while the dialogue encodings were obtained from convolutional neural networks. Bertero and Fung [1] proposed a deep learning-based approach by combining the word-level and audio-level features using a linear-chain Conditional Random Field over the convolutional neural network and recurrent neural network. They also generate a new humour detection dataset using a very popular sitcom "*The Big Bang Theory*". Chen and Soo [5], implemented a CNN based approach with extensive filter sizes, numbers, and highway networks to enhance the depth of the deep learning architecture. They also collected and constructed four datasets for conducting experiments on humour detection, with distinct joke types in both English and Chinese. Kumar et al. [17], proposed DeepHumor, an automatic humour detection model. It is an amalgamation of CNN, LSTM, and highway networks. They used CNN layers for feature extraction, and the LSTM layers were used for sequence learning. The performance of the model is enhanced using the highway network. To overcome the overfitting problem, they also add dropout layers to their architectures. They

compare the performance of their proposed model with several recently developed techniques over the Yelp user review dataset.

Table 1. Statistical details about the Hindi dataset for Humour detection created by us

Description	$Kota - Factory$	$Panchayat$
Number of Episodes	5	8
Total number of instances	2986	4145
Total number of "$Humour$" instances	1344	1713
Total number of "$Non - Humour$" instances	1642	2432

3 CREATED DATASET

In this section, we illustrate the Hindi dataset for humour detection created by us. For this purpose, we have gathered data from two popular Hindi web series, namely, $Kota - Factory$ and $Panchayat$. The data is collected from the first season of both web series. $Kota - Factory$ has 5 episodes while $Panchayat$ has 8 episodes. We have extracted utterances from different scenes from each episode and manually annotated them as "$Humour$" or "$Non - Humour$"—the various differentiators and context help in classifying the dialogues or utterances into their respective categories. The statistical details of both datasets are presented in Table 1. It gives us a clearer depiction of the empirical view of the data. Table 2 and Table 3 show the sample dialogues along with their respective categories for $Kota - Factory$ and $Panchayat$ datasets, respectively. For instance, "He founded this Jurassic park" dialogue in the "$Kota - Factory$" example refers to the coaching institute in the context of being referred to as a Jurassic park, hence it is a humour instance. While the "I'll let you know when we get there. We will not kidnap you" example from the "$Panchayat$" dataset, refers to the bus conductor saying that he'll drop the passenger at his destination and won't kidnap him. Hence, this can be considered as humour too. The exhaustive Hindi dataset proposed by us can be used as a benchmark dataset for Humour detection in the Hindi language or for other text classification or NLP-based tasks related to the Hindi language. The dataset can be accessed from here when the paper gets published HumourHindiNet dataset. The proposed datasets might be subject to some biases such as selection bias, as the choice of specific web series may limit the diversity of humour styles represented; subjectivity bias, as manual annotation of utterances, may lead to varied interpretations of comedic elements; and sampling bias, as extracting utterances from specific scenes may overlook nuanced comedic moments elsewhere in the series. By acknowledging and addressing these biases, researchers can enhance the validity and generalizability of their findings in humour detection research.

4 PROPOSED WORK

In this section, we illustrate our approach to the detection of humour in the Hindi web series by leveraging the power of word embedding and convolutional neural networks. The proposed model utilizes word embedding techniques that transform individual Hindi words into dense vectors, preserving semantic relationships and contextual nuances crucial for understanding humour. These embeddings serve as the initial input to a CNN, specifically tailored to capture complex linguistic structures inherent in comedic content. The CNN acts as a feature extractor, identifying subtle cues such as wordplay, sarcasm, and comedic timing by analyzing the input text at different levels of abstraction. Importantly, the incorporation of stacked LSTM layers further enhances the model's capability by capturing sequential dependencies and temporal context within the text. The stacked LSTM layers further enable the model to capture sequential dependencies, vital in discerning comedic timing and punchlines. This allows HumourHindiNet to recognize the sequential flow of jokes, discern comedic timing, and accurately identify punchlines, contributing to a more nuanced understanding of comedic content. By amalgamating these

techniques, HumourHindiNet offers a sophisticated and effective solution to the challenging task of humour detection in Hindi web series. Furthermore, its contributions extend beyond natural language processing, as it facilitates deeper insights into entertainment analytics, enabling better analysis and understanding of comedic elements within digital content produced in the Hindi language.

The various stages of the proposed framework are described below.

4.1 Data Preprocessing

In the data preprocessing phase, we diligently address the challenges presented by the raw transcripts extracted from the Hindi web series. These transcripts often contain a myriad of special characters, URLs, and other extraneous elements that introduce non-pertinent noise into the dialogues, potentially obstructing accurate humour detection. To mitigate this, we employ a range of text-cleaning techniques, a standard practice in Natural Language Processing, to systematically rid the data of such distractions. Given the linguistic complexities of the Hindi language, we harness the capabilities of the iNLTK library, a publicly available resource equipped with fundamental functions tailored for Natural Language Processing in Indian languages. This library aids in refining our approach to processing the obtained Hindi dialogues, ensuring linguistic subtleties are preserved. Furthermore, recognizing the pivotal role of class labels in our model's performance, we encode the dialogue labels

Just Accepted

as 2-dimensional binary arrays. In this encoding scheme, dialogues categorized as humour are represented as [1, 0], while those classified as non-humour are denoted as [0, 1]. This encoding enhances our model's processing capabilities, facilitating more efficient and precise classification of humour and non-humour dialogues in the subsequent stages of our analysis.

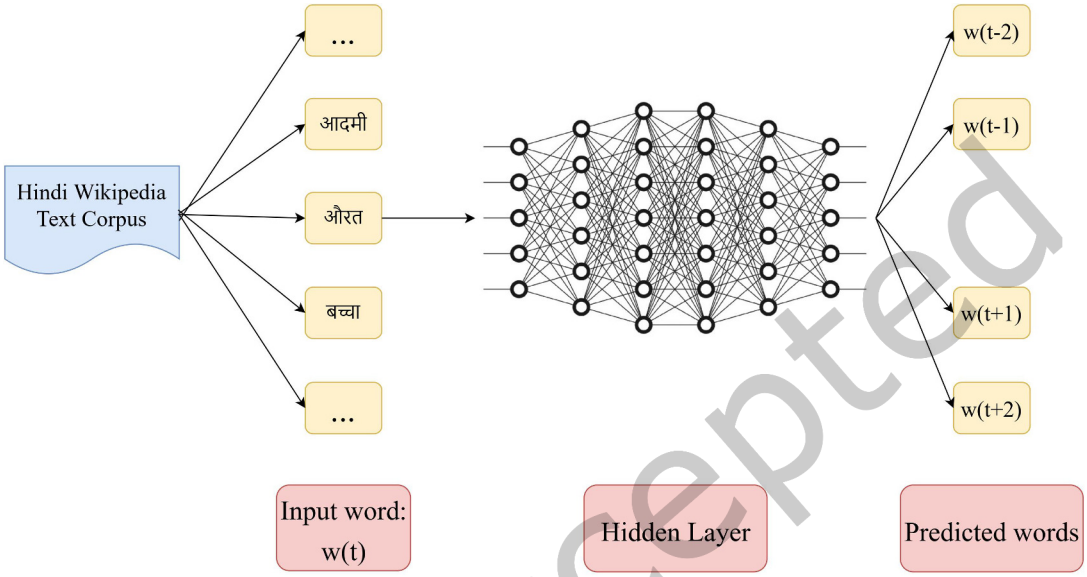

Fig. 1. Process of generating Hindi Word Embeddings using Skip-gram architecture.

Just Accepted

4.2 Skip-gram model based Hindi Word Embeddings generation

In this section, we address the need to transform the processed Hindi dialogues, obtained in the previous stage, into numerical vectors suitable for machine learning and deep learning models. Since these dialogues remain in their original Hindi form, they can't be directly utilized with such models. To bridge this gap, we employ a method commonly employed in NLP: word embeddings. While Word2Vec and Global Vectors (GloVe) are popular choices for generating word embeddings, they are primarily tailored for the English language, rendering them less effective for Hindi text.

To overcome this limitation, we embark on the creation of our Hindi-specific word embeddings. To achieve this, we employ a Skip-gram model, a technique pioneered by Mikolov et al. [22]. The Skip-gram model stands out for its ability to predict context based on a target word, a departure from the Continuous Bag of Words (CBOW) model, which predicts the target word based on context [19]. This predictive capability aligns seamlessly with our goal of humour detection, as it aids our framework in better comprehending the contextual nuances of humour or non-humour in dialogues. Our Skip-gram model is meticulously trained on the Hindi Wikipedia Corpus, a publicly accessible resource here. During training, we iteratively update the feature vectors to ensure that target words and their corresponding contexts are positioned closer to each other in the feature space. As a result, we generate feature vectors of dimension 300 for each word within the dialogues. This dimensionality strikes a balance between capturing a rich information set from the dialogue corpus while maintaining computational scalability, ultimately bolstering the effectiveness of our humour detection framework. The process of generating the Hindi word embedding using the Skip-gram architecture is shown in Figure 1

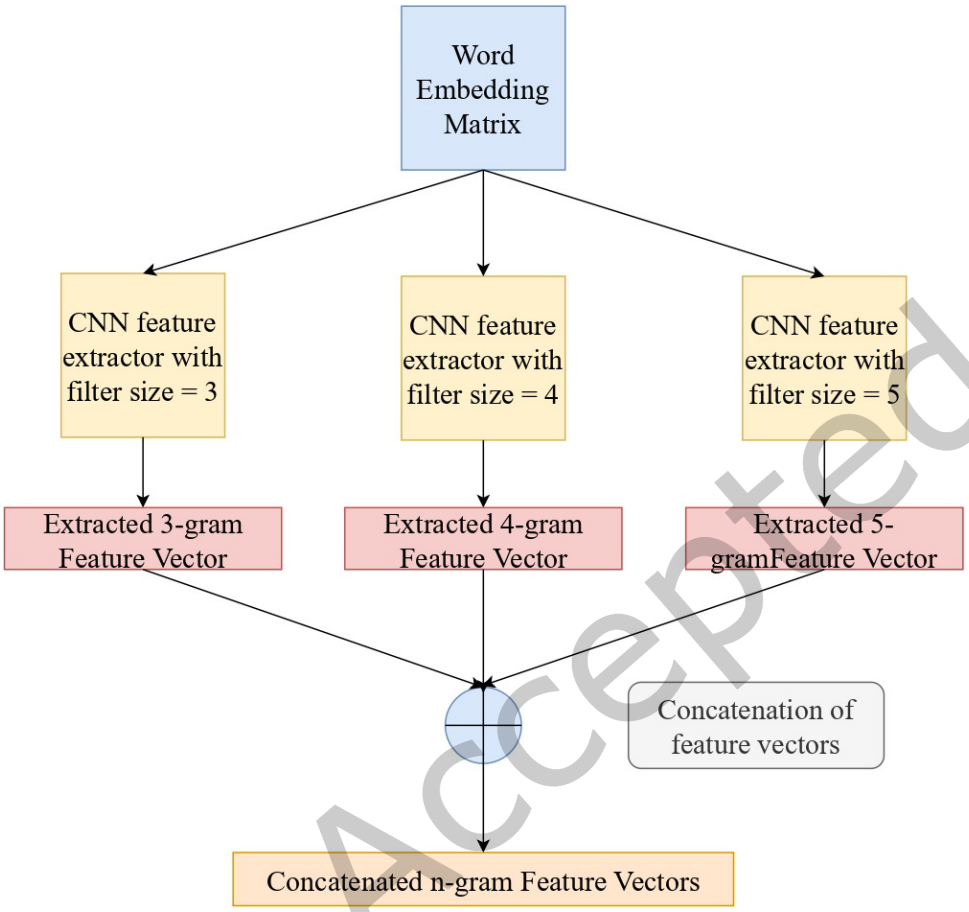

Fig. 2. Process of extracting n-gram features using CNN architecture.

Just Accepted

4.3 N-gram feature extraction using CNN

In this section of our model, we delve into the process of extracting vital features from the feature vectors acquired in the preceding stages. These feature vectors are transformed into a 2-dimensional matrix, a pivotal step in preparing them for efficient processing by a CNN. This matrix representation mimics the format of an image, aligning well with the CNN architecture, which inherently operates on 2-dimensional data.

Within our framework, we concurrently feed these 2-dimensional dialogue matrices into three distinct CNN architectures, each employing filter sizes of 3, 4, and 5. This simultaneous processing enables the extraction of n-gram features, encompassing 3-grams, 4-grams, and 5-grams, dispersed throughout the dialogues. This approach synergizes with the context-capturing prowess of the Skip-gram-based word embeddings, as the CNN-based n-gram feature extraction probes various word prefixes and suffixes to unearth intricate contextual nuances. To further harness the information gleaned from these n-gram features, we consolidate them through a concatenation layer. This amalgamation enhances feature utilization and preserves the sentence's semantic structure, judiciously situating context and target words to facilitate more precise humour detection. The process of extracting the n-gram features using parallel CNN architectures is shown in Figure 2

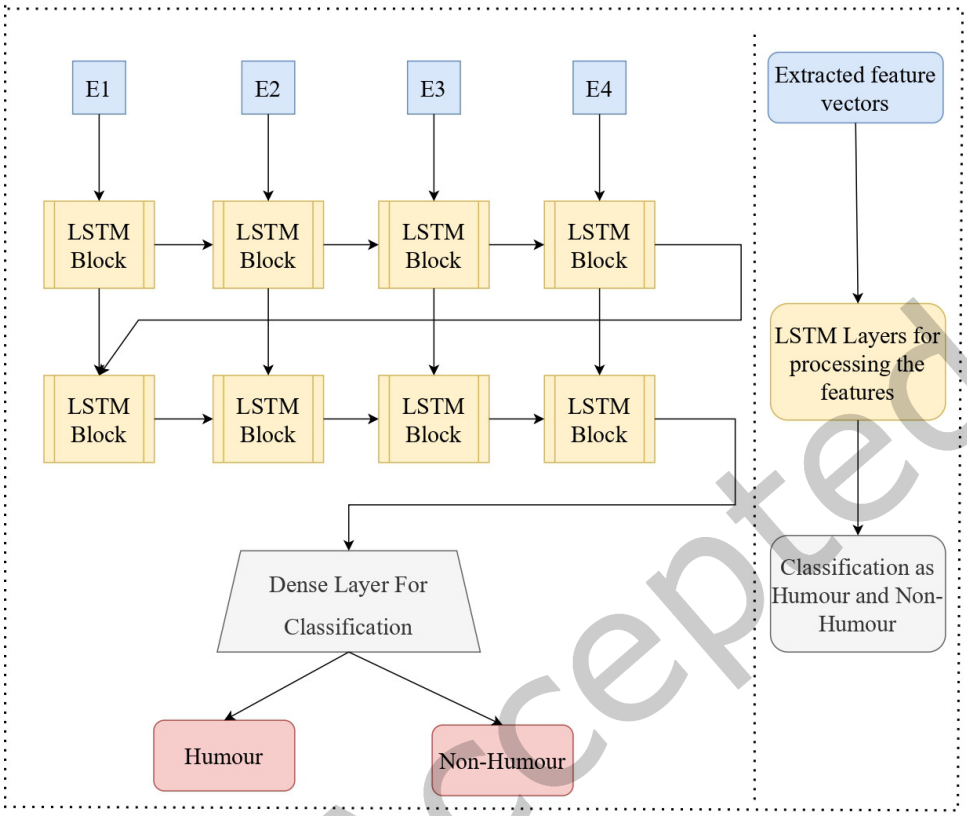

Fig. 3. Process of classification of dialogues using stacked LSTM layers

Just Accepted

4.4 Humour Classification using Stacked LSTM Layers

In this section of our model, we take the extracted features from the previous stages and subject them to the scrutiny of stacked LSTM layers. This critical phase serves as the decision-making core of our humour detection framework, where dialogues are definitively classified as either Humour or Non-Humour. LSTMs were chosen due to their well-established effectiveness in handling data holistically and their exceptional aptitude for processing sequential data while retaining contextual nuances. The recurrent nature of LSTMs, coupled with their memory cells, equips them to capture long-term dependencies without falling prey to the vanishing gradient problem. Consequently, the stacked LSTM layers represent an optimal choice for processing the extracted features. They adeptly explore these features, ferreting out hidden long-term contextual dependencies that are often pivotal in humour comprehension The processed features are then passed into a deep neural network to ultimately assign the appropriate labels of Humour or Non-Humour to the dialogues, constituting the final classification step in our approach. The process of classifying the dialogues as Humour or Non-Humour is shown in Figure 3.

5 EVALUATION METRICS

In this section, we explain the various evaluation metrics used for estimating the performance measure of our proposed algorithm are described as follows.

(i) Accuracy: Accuracy is an indicator of the share of correctly made classifications to the total number of classifications. Mathematically, it can be expressed as follows.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \tag{1}$$

(ii) Precision: Precision is an indicator of the share of positive classifications made that were actually true. Mathematically it can be expressed as follows.

$$Precision = \frac{TP}{TP + FP} \tag{2}$$

(iii) Recall: It is a performance metric, which attempts to implicate what share of actual positives were identified correctly. For a binary classification task, recall can be expressed mathematically as follows.

$$Recall = \frac{TP}{TP + FN} \tag{3}$$

(iv) F1 score: F1 score indicates the balance between precision and recall. Formally speaking, it is the harmonic mean of both precision and recall. Mathematically it is expressed as follows.

$$F1\ score = \frac{2 * (Precision) * (Recall)}{Precision + Recall} \tag{4}$$

Here, True positive (TP) - Correctly identified, True Negative (TN) - Correctly rejected, False positive (FP) - Incorrectly identified, and False negative (FN) - Incorrectly rejected.

6 EXPERIMENTAL RESULTS

In this section, we discuss the experimental analysis of the proposed work. All the experiments are conducted on both the datasets proposed in Section 3, and several standard performance metrics like Accuracy, Precision, Recall, and F1 Score are evaluated for the same as mentioned in Section 5. For conducting the experiments, we split the entire dataset into 80:20 ratios by keeping 80% of the dataset for training and 20% of the dataset for testing the performance. We evaluate the performance of several baseline machine learning algorithms on both the proposed datasets and compare it with our proposed framework. Moreover, we also compare the performance of our proposed framework with several recent humour detection frameworks.

We also evaluate the AUC values of our algorithm to understand the bias of our model. Time and space complexity analysis are also presented for our algorithm. Figure 4, shows the percentage of humour and non-humour dialogues or utterances in both the proposed datasets. From Figure 4, we see that 45% of the dialogues of the **Kota-Factory** dataset are humour while 41% of the dialogues of the *Panchayat* dataset are humour. This shows that both datasets are well-balanced in terms of the number of samples in both classes. Table 4 lists the various hyperparameters for our framework. We employ two LSTM layers and two Dense layers. We use three CNN layers having filter sizes of 3, 4, and 5. The dropouts and recurrent dropouts values used for the two LSTM layers are 0.25 and 0.20 respectively. The optimizer used to compile the model is Adam. The activation function used in the first dense layer is ReLu while that used for the second layer is Sigmoid. The loss function used to monitor the loss is Binary-crossentropy. We used 50 epochs as around 50 epochs the training loss stabilised. The batch size used is 64. We also used callbacks to train our model. The callback method used is ReduceLROnPlateau, which reduces the learning rate when the monitored metric, which in this case is validation accuracy, has stopped improving. We also use 5-fold cross-validation and L1 regularization to improve the model performance. The obtained experimental results are as follows.

6.1 Comparison with Baseline algorithms

In this section, we compare the performance of our proposed HumourHindiNet framework with several baseline machine learning and deep learning-based approaches for humour detection on both of our proposed datasets. We also use a good number of supervised and unsupervised algorithms, along with several language-based models.

Table 5. Performance comparison of our proposed HumourHindiNet framework with several baseline machine learning and deep learning algorithms on *Kota – Factory* dataset.

Methods	Accuracy	Precision	Recall	F1 Score
K-Means Clustering	67.61	64.12	76.68	69.84
KNN	75.91	78.32	72.38	75.23
Logistic Regression	78.92	75.92	85.38	80.37
Gaussian Naive Bayes	77.28	75.8	79.03	77.38
Decision Trees	80.47	78.58	83.49	80.96
Random Forest	85.22	83.3	86.77	85.0
ANN	88.59	87.34	**90.07**	88.69
CNN	73.08	73.9	71.06	72.45
RNN	83.94	87.4	79.86	83.46
GloVe	89.69	95.37	83.27	88.91
BERT	89.87	92.86	86.19	89.4
HumourHindiNet	**91.79**	**96.29**	87.41	**91.64**

The various machine learning algorithms used are K-Means Clustering, K Nearest Neighbors, Logistic Regression, Gaussian Naive Bayes, Decision Trees, and Random Forests. We use Artificial Neural Networks (ANNs), CNNs, and Recurrent Neural Networks (RNNs) as the deep learning methods. The GloVe embedding method and the Bidirectional Encoder Representations from Transformers (BERT) as the language-based models. The obtained results are presented in Table 5 for the *Kota – Factory* dataset and Table 6 for the *Panchayat* dataset. For the *Kota – Factory* dataset, we see that the unsupervised clustering algorithms are the weakest performers. However, the performance improves as we go to the supervised algorithms as can be seen by the good results achieved by Random Forest, Decision Trees, etc. Deep learning-based models like ANN and RNN are able to appropriately model the non-linear multi-dimensional relationships of the dialogues to generate even better results. Amongst all the baseline models used for the *Kota – Factory* dataset, the language-based models are the best performers. This can be attributed to the optimal language dependency modeling done by the language-based models. The best performer for the *Kota – Factory* dataset is our proposed HumourHindiNet model. For the *Panchayat* dataset, all the unsupervised and supervised machine learning models along with the deep learning models give sub-optimal results which are in close agreement with each other. The language-based models are the only models amongst the baseline algorithms to cross the 80% accuracy mark. However, they're still second to our proposed HumourHindiNet. The optimal performance of our proposed HumourHindiNet model can be attributed to the ability of our model to appropriately model the latent language dependencies along with using proper deep learning architectures for feature extraction.

6.2 Comparison with contemporary models

In this section, we compare the performance of our proposed framework with several recently proposed humour detection models. Most of the recently proposed models can be broadly categorized as follow: Language-model based, Feature engineering-based, and Deep learning based. To obtain a good sense of comparative study, we have selected a balance of algorithms from all these categories as follows. We use the deep-learning architectures of the various contemporary as it is. However, we convert the Hindi dialogues from our datasets to be compatible with the input of these models. We use our skip-gram-based model to tokenize the Hindi dialogues. For feature-engineering-based models, we generate the humour anchors for the Hindi language similar to the original work.

Just Accepted

Table 6. Performance comparison of the proposed HumourHindiNet framework with several baseline machine learning and deep learning algorithms on *Panchayat* dataset.

Methods	Accuracy	Precision	Recall	F1 Score
K-Means Clustering	76.37	73.45	81.23	77.14
KNN	75.18	80.0	69.26	74.24
Logistic Regression	75.91	77.6	71.85	74.61
Gaussian Naive Bayes	75.55	81.48	68.99	74.72
Decision Trees	78.83	81.92	75.53	78.6
Random Forest	78.01	82.4	70.72	76.11
ANN	78.56	84.03	70.33	76.57
CNN	74.09	70.95	79.44	74.95
RNN	78.92	79.52	78.22	78.86
GloVe	84.76	83.0	86.28	84.61
BERT	85.77	84.11	**87.55**	85.79
HumourHindiNet	**87.32**	**90.15**	84.14	**87.04**

Table 7. Performance comparison of our proposed HumourHindiNet framework with several recently proposed humour detection algorithms on $Kota - Factory$ dataset.

Methods	Accuracy	Precision	Recall	F1 Score
Bertero and Fung [2]	72.84	68.36	85.5	75.97
Chen and Lee [4]	78.91	76.37	82.3	79.22
Chen and Soo [5]	84.22	84.34	84.34	84.34
Yang et al. [30]	88.62	88.43	**89.22**	88.82
Oliveira and Rodrigo [6]	84.98	87.19	82.79	84.93
Kumar et al. [17]	85.76	84.10	87.54	85.79
HumourHindiNet	**91.79**	**96.29**	87.41	**91.64**

The obtained results are presented in Table 7 for the $Kota - Factory$ dataset and Table 8 for the *Panchayat* dataset. For both the datasets, we observe that the language-model based Chen and Lee [4] model is the second worst performer after the deep learning-based Bertero and Fung [2]. On the other hand, the deep learning-based models, namely, Chen and Soo [5], and Rodrigo and Rodrigo [6], are the best performers in terms of the recently proposed algorithms due to their ability to uncover and train on the various intricacies of the language and working to explore a deep understanding of the problem-specific details. The feature-engineering based Yang et al. [30], gives optimal and stable performance for both the datasets, due to its appropriate task-specific feature engineering, making it suitable for humour detection.

The proposed HumourHindiNet's superior performance can be primarily attributed to its ability to capture contextual dependencies within the dialogues, facilitated by the LSTM section of our model. Unlike traditional algorithms that may struggle to grasp the sequential nature of humour, the proposed HumourHindiNet' effectively leverages stacked LSTM layers to capture the intricate temporal relationships inherent in comedic content. This enables the model to discern not only individual humorous elements but also the overarching comedic structure within the dialogues, leading to more accurate predictions. Additionally, the utilization of appropriate preprocessing techniques ensures uniformity and well-structured dialogue across the datasets, reducing noise and enhancing the model's ability to extract relevant features. Furthermore, the CNN-based n-gram feature

Just Accepted

Table 8. Performance comparison of our proposed HumourHindiNet framework with several recently proposed humour detection algorithms on *Panchayat* dataset.

Methods	Accuracy	Precision	Recall	F1 Score

Chen and Lee [4]	84.98	82.96	88.66	85.71
Chen and Soo [5]	86.8	87.87	86.59	87.22
Yang et al. [30]	84.37	84.01	85.76	84.88
Oliveira and Rodrigo [6]	85.73	84.68	**87.72**	86.18
Kumar et al. [17]	84.76	83.01	86.27	84.68
HumourHindiNet	**87.32**	**90.15**	84.14	**87.04**

extraction mechanism employed by the proposed HumourHindiNet enables a deeper understanding of latent language dependencies, allowing the model to uncover subtle linguistic nuances that contribute to the comedic effect. By combining these advanced techniques, the proposed HumourHindiNet achieves superior performance across all performance metrics, establishing it as the top performer in humour detection for Hindi web series.

6.3 Comparison with Non-Hindi Datasets

In this section, we compare the performance of different contemporary models with our proposed model on non-Hindi specifically English datasets. We utilize several benchmark humour English datasets, namely, 16000 One-Liners [21], Pun of the Day [30], and Short Jokes Kaggle. We modify the proposed approach by replacing skip-gram based Hindi embedding with skip-gram-based English embedding using an English text corpus in Section 4.2. This helps the proposed model to generate word embedding for the English words in these datasets. The generated embedding is then fed to the "N-gram based feature extraction using CNN" module as mentioned in Section 4.3. This enables our model to adapt to non-Hindi Humour datasets. Table 9 lists the results of the

proposed model along with some contemporary models on above mentioned English datasets. The obtained results highlight HumourHindiNet's superior accuracy for these datasets, underscoring its advanced approach that combines word embeddings, CNNs, and stacked LSTM layers. This blend allows for a nuanced understanding of humor's complex linguistic and sequential nature, evident in its leading accuracy figures: 90.2% on 16000 One-Liners, 90.7% on Pun of the Day, and 91.1% on Short Jokes. Such performance not only demonstrates HumourHindiNet's adeptness at humor detection, particularly in the nuanced and culturally rich context of Hindi web series but also for English datasets.

6.4 Accuracy and Loss vs Epoch Analysis

In this section, we perform the Accuracy vs Epoch and Loss vs Epoch analysis. Figure 5 shows the Accuracy results obtained by our proposed framework for different epochs. For the $Kota - Factory$ dataset, the accuracy significantly improved from 77.2% to a remarkable peak of 91.79% throughout 50 epochs. This ascent demonstrates the model's ability to learn and capture humour patterns within the Hindi web series content. While the accuracy exhibits impressive growth early in training, it begins to plateau towards the latter epochs, suggesting that the model has captured a substantial portion of the humour-related features present in the dataset. In the case of the *Panchayat* dataset, a similar trend is observed. The accuracy starts at 63.17% and gradually climbs to a peak of 87.32% after 50 epochs. This growth indicates the model's effectiveness in discerning humour in this specific dataset. Like the $Kota - Factory$ dataset, the accuracy curve levels off in the later epochs, signaling a diminishing rate of improvement as the model has likely captured the predominant humour-related patterns within the data.

Figure 6 shows the accuracy results obtained by our proposed framework for different epochs. In terms of loss, the $Kota - Factory$ dataset exhibited a substantial decrease during training. The loss started at 1.987 and dropped consistently as the model learned. This decline reflects the model's ability to reduce the errors in its predictions. Similar to the accuracy trend, the loss curve begins to plateau towards the later epochs, indicating that the model's learning rate has slowed, and is approaching convergence. The *Panchayat* dataset showcases a comparable loss reduction over the 50 epochs. Starting at 2.255, the loss steadily diminishes as the model refines its understanding of humour within this dataset. However, similar to the $Kota - Factory$ dataset, the loss reduction rate decelerates in the later epochs, signifying that the model has captured the primary humour-related patterns in the data, and further significant loss reduction becomes challenging. In summary, both datasets exhibit notable improvements in accuracy and reductions in loss over the training period, indicating that the model is effective at humour detection. The plateauing of these trends in the later epochs suggests that the model's learning rate slows as it approaches convergence, having already captured a substantial portion of the underlying humour patterns within the respective datasets.

6.5 AUC Analysis

In this section, we evaluate the AUC values for our algorithm. Since the number of data points in our datasets is extremely less as compared to other pre-trained models, hence, the high performance of our model could be due to the inherent bias of our model. To evaluate the bias of our model, we calculate the AUC values for our model. An AUC value near 0 shows that the model has the worst distinguishing capability and it is classifying positive samples as negative and vice-versa. An AUC value of 0.5 means that the model has no distinguishing capability while a value close to 1 represents that the model can appropriately distinguish amongst the classes. Figure 7 shows the AUC values obtained by our model for the two datasets. From the figure, we can see that the obtained AUC values are well over 0.5, hence it shows that our model has great distinguishing capability and doesn't suffer from bias.

Just Accepted

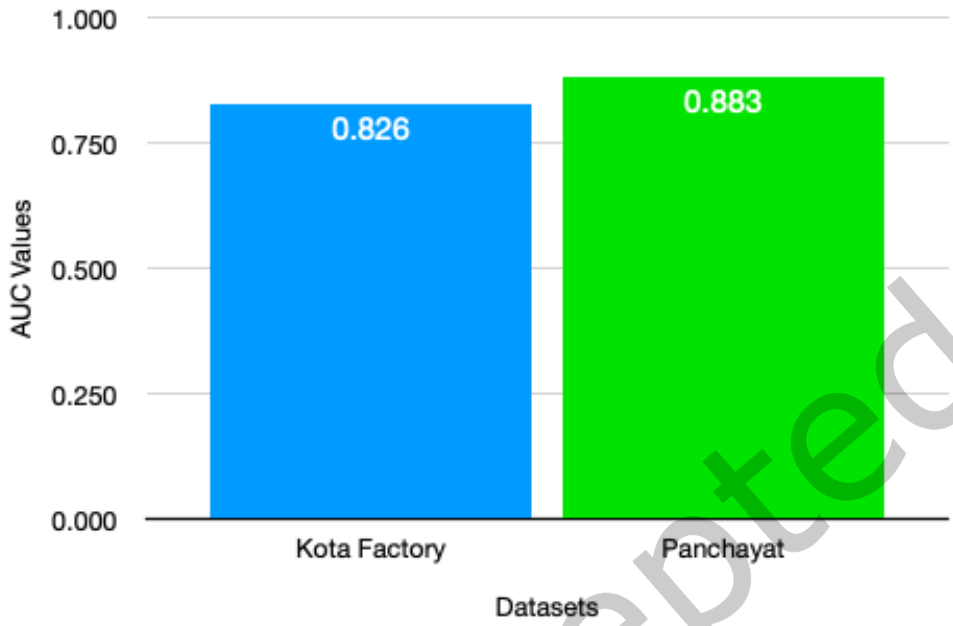

Fig. 7. The AUC values obtained by our model for the two datasets.

Just Accepted

6.6 Time Complexity

In this section, we study the time complexity of the various components of our proposed model. Our model involves various steps, namely, (i) Skip-gram model based word embedding generation, (ii) feature extraction using CNN layers, (iii) stacked LSTM layers, and (iv) a deep neural network classifier. The time complexity of the various steps is given below.

(i) Skip-gram model-based word embedding generation: Let N be the size of the entire text corpus, D be the size of the desired embeddings, and the V be the vocabulary of the unique words in the text corpus. We perform a binary search on the unique words vocabulary and we generate a D dimensional embedding for all the N words in the corpus, hence the time complexity for the skip-gram model would be $O(N \times D \times log(V))$.

(ii) Feature extraction using CNN layers: Let D be the size of the word embedding extracted in the previous step. Let D be expressed as a 2D matrix of size $n \times d$ for convolutions. Let k be the kernel size and f be the filter size. Since, we evaluate convolutions for k kernels across the entire $n \times d$, hence the time complexity becomes $O(k \times n \times d)$. Since this is repeated for the entire filter size f, hence the final time complexity comes out to be $O(f \times k \times n \times d)$.

(iii) As per the works of Raja [25], let I be the number of inputs, K be the number of outputs and H be the number of cells in the hidden layers. The time complexity for the LSTM model can then be defined as $O(4IH + 4H2 + 3H + HK)$.

(iv) Deep neural network classifier: For a deep neural network classifier, the output of every node in the input layer is multiplied by the input of every node in the first hidden layer, and the output of every node of the last hidden layer is multiplied with the input of every node of the output layer. Moreover, a similar multiplication happens across the nodes of all the layers of the hidden layers. Hence, let P be the product

of the number of layer-wise nodes in the input layer, all the hidden layers, and the output layer. Let E be the number of epochs and S be the total number of training samples. Hence, the time complexity of a deep neural network classifier is $O(E \times S \times P)$.

(v) Overall time-complexity: Combining the above four phases of our model, we arrive at an overall time complexity of $O(N \times D \times log(V) + f \times k \times n \times d + 4IH + 4H2 + 3H + HK + E \times S \times P)$

6.7 Space Complexity

In this section, we study the space complexity of the various components of our proposed model. Our model involves various steps, namely, (i) Skip-gram model based word embedding generation, (ii) feature extraction using CNN layers, (iii) stacked LSTM layers, and (iv) a deep neural network classifier. The time complexity of the various steps is given below.

(i) Skip-gram model-based word embedding generation: Let N be the size of the entire text corpus, D be the size of the desired embeddings. Since we calculate and store the embedding for every word in the text corpus, hence the space complexity for the skip-gram model would be $O(N \times D)$.

(ii) Feature extraction using CNN layers: For CNN layers, the output dimensions decrease after every layer. Hence, the largest space that we need is the output of the first layer. Let D be the size of the word embedding extracted in the previous step and let f be the filter size. The dimension of the output of the CNN layer is $((D - f)/2) + 1$. Hence the space complexity becomes $O(((D - f)/2) + 1)$. Since $f << D$, this can also be written as $O(D)$.

(iii) As per the works of Raja [25], let I be the number of inputs, and H be the number of cells in the hidden layers. The space complexity for the LSTM model can then be defined as $O(4 \times (I + H) \times H + K)$.

(iv) Deep neural network classifier: For a deep neural network classifier, the weights are stored for every neuron in every layer of the network. Let P be the product of the number of layer-wise nodes in the input layer, all the hidden layers, and the output layer. Hence, the space complexity of a deep neural network classifier is $O(P)$.

(v) Overall space-complexity: Combining the above four phases of our model, we arrive at an overall time complexity of $O(N \times D + D + 4 \times (I + H) \times H + K + P)$. Since, $D << N \times D$ and $K << 4 \times (I + H) \times H$, hence the overall space complexity can be written as $O(N \times D + 4 \times (I + H) \times H + P)$

6.8 Advantages and Limitations

The proposed approach offers several notable advantages. Firstly, it leverages word embedding techniques to enhance the contextual understanding of Hindi dialogues. This is particularly crucial for humour detection, as humour often relies on subtle contextual cues. By representing words in a dense vector space, semantic relationships are preserved, significantly improving the model's grasp of contextual humour. Secondly, the integration of convolutional neural networks, such as proposed HumourHindiNet, provides an automatic feature learning mechanism. This reduces the need for labor-intensive handcrafted feature engineering and potentially results in more robust and adaptable models. Moreover, the inclusion of stacked LSTM layers allows the model to capture sequential dependencies within dialogues, an essential aspect of humour recognition. Lastly, the research addresses a timely need in the digital age, where web series and digital content are gaining immense popularity. It contributes to the field of entertainment analytics, offering practical applications and insights into humour detection.

Despite its merits, the proposed approach does come with certain challenges. Firstly, its success hinges on the availability of suitable datasets for training and evaluation. If there's a scarcity of diverse and high-quality datasets specific to humour in Hindi web series, the model's performance could be constrained. Secondly, the

Just Accepted

computational complexity associated with deep learning models must be considered. These models demand substantial computational resources for training and inference, potentially limiting their accessibility to researchers with constrained computing power. Additionally, there's a risk of overfitting, especially if the dataset is limited or not well-regularized, which could affect the model's ability to generalize to new data. Lastly, deep learning models are often criticized for their lack of interpretability, making it challenging to understand the rationale behind specific humour detection decisions. This limitation might hinder their real-world applicability in certain contexts.

In summary, while the proposed approach holds promise for advancing humour detection in Hindi web series, it's essential to carefully address challenges related to data availability, computational resources, model complexity, and interpretability to maximize its potential impact in the field of natural language processing and entertainment analytics.

7 CONCLUSION

Humour detection is an important task in the field of NLP. However, relatively it is a difficult task as humour is often contorted in between conversations or expressed through feeble expressions or gestures that it isn't easily detectable. Moreover, it also requires good language-specific knowledge to detect humour appropriately. There is also a huge shortage of humour detection datasets in the Hindi language making it increasingly difficult to obtain good performance for detecting humour in the Hindi language. Following along these lines, in this paper, we proposed two Hindi datasets that are extracted from two recent popular web series, namely, $Kota - Factory$ and *Panchayat*. We also proposed Hindi word embedding and convolutional network-based framework, named HumourHindiNet, for humour detection in Hindi web series. We started by preprocessing the dataset to remove irrelevant data and obtain uniformity across datasets. The processed dataset is then used by our proposed Hindi language-based word embedding generation model to create word embeddings for all the dialogues in the introduced datasets. The generated word embeddings are then passed through parallelly stacked CNN layers to extract n-gram features based on varying filter sizes which range from 3 to 5. The extracted features are then passed through stacked LSTM for further processing and exploring the latent language and contextual dependencies. The final extracted features are then passed to a deep neural network architecture to make the final classifications as humour or non-humour. We conducted intensive experiments on both the proposed datasets and evaluate several standard performance metrics. We compared the performance of our proposed HumourHindiNet model with several baseline unsupervised and supervised machine learning algorithms, deep learning algorithms, and language-based models. We also compared our performance with several recently proposed language-based algorithms, feature-engineering based algorithms, and deep learning-based algorithms for humour detection. The obtained results demonstrated that our proposed HumourHindiNet model gives the best performance and proves its efficiency and efficacy for humour detection. This work can further be extended by using multi-language or multi-modal datasets. We can also work on creating humour detection datasets for other low-resource languages.

Abstract—Cloud computing has grown to be a significant component of the IT sector in the current digital economy. Despite its advantages such as reduced capital costs and operational costs, there are some constraints that limit its use. Previous research has proposed various intrusion detection systems and authentication systems, but they fail to detect intruders. Hypervisor-based intrusion detection systems have recently been developed that monitor both virtual machines (VM) and the host simultaneously. Furthermore, it has become popular because it provides a comprehensive view of the cloud environment and allows for more accurate threat detection. Considering these, we propose novel hypervisor-based intrusion detection in this work. Initially, we collect intrusion data and pre-process it. The best features are then chosen using an adaptive artificial flora algorithm (AAF), which lowers processing time and complexity. Then, the selected features are passed to the ERBNN classifier to classify the data as normal or intrusive data. For validation of the proposed method, KDDCup-99 and NSL-KDD datasets are used. The performance of the suggested technique is validated based on different metrics and the proposed system is implemented using Python.

***Keywords*—cloud computing, intrusion detection, feature selection, ERBNN, classification.**

I. INTRODUCTION

A hypervisor is a software layer used in cloud computing that allows the operation of numerous virtual machines (VMs) on one physical system [1]. Hypervisors create and manage VMs isolated from each other and from the underlying hardware. In addition to harming a single virtual machine, an attacker can harm several virtual machines and hypervisors by installing hacking tools on them [2]. The security of a system is determined by its ability to provide confidentiality, integrity and availability to its users [3]. With the growing significance of network-based computers in modern society, they are subject to more attacks and intrusions [4]. The term intrusion refers to a series of illegal actions conducted to compromise the security of a system [5]. Detecting intrusions into computer systems and networks by both internal users and external attackers is the primary objective of intrusion detection [6].
Host-based systems and network-based systems are the two conventional categories into which intrusion detection systems can be separated [7]. There are advantages and disadvantages to both host-based and network-based intrusion detection systems [8]. There is a limited effectiveness of network intrusion detection systems when it comes to detecting insider attacks because they are designed to address outsider attacks. Due to the shared multi-tenancy nature of cloud computing, these and other perimeter security controls may be less effective [9]. Many cloud users are virtually distributed across physical machines, which opens them up to attack via virtual or internal networks [10]. Despite the success of host-based intrusion detection systems, users are typically required to monitor and manage these systems themselves. When users have multiple instances running in the cloud, this approach can be challenging. In addition, host-based intrusion detection systems can be disabled by a skilled attacker once the event has been compromised [11].

II. LITERATURE SURVEY

A network-based intrusion detection system made up of ensembles of four classifiers machine learning technique was suggested by Singh and Ranga [12]. In order to obtain a consolidated final score, a voting mechanism was incorporated into the framework. Simulation and testing of the proposed model were conducted using standard datasets and simulators, namely CICIDS 2017 and CloudSim. According to the results, this model has a low rate of false positive alerts, as well as a high rate of detection, indicating that it is superior to state-of-the-art approaches for identifying intrusions in cloud environments. The accuracy of this work needs to be improved.

A cloud intrusion detection system (IDS) that employed online multivariate statistical analysis of change to identify unusual network activity was created by Aldribi et al. [13]. Using the hypervisor's collection of events as a starting point, an event-based IDS feature model is presented as part of traditional monolithic network IDS feature models. This model improves detection efficiency by taking advantage of the diverse and connected tendencies of event. To test this strategy, an updated cloud intrusion dataset with a wide range of attack routes was utilised. A Riemann rolling feature extraction strategy was utilised to empirically test this approach, and it was shown to be better to the commonly employed Riemann chunking approach.
Jin et al. [14] developed SwiftIDS, an IDS that provides satisfactory detection performance in high-speed networks for massive traffic analysis. The following methods are used by SwiftIDS to achieve these goals. In order to handle

massive traffic data, Light Gradient Boosting Machine addition, traffic data arriving at different time windows can also be analyzed with a parallel intrusion detection mechanism. By doing this, later incoming data will not be delayed by waiting for the end of the intrusion detection cycle of the first incoming data. Using offline tests, SwiftIDS achieved excellent time performance and satisfactory detection performance. Zafar and Rehman [15]proposed an improved intrusion detection system for cloud computing environments. An approach combining SVM and FCM clustering was used to develop Hypervisor Inspector. Three phases were incorporated into this model. As part of the first phase, the FCM clustering module was introduced, which allowed large datasets to be divided into smaller clusters, which in turn enabled the SVM to learn more effectively and more quickly. After the cluster values were assigned, different SVM modules were trained. Thirdly, the results of the Hypervisor Inspector were aggregated by a module called fuzzy aggregation. Various evaluation metrics were used to compare this technique with existing techniques. It has been demonstrated that this mechanism provides a high level of detection accuracy and low levels of false alarms when detecting various attacks.

According to Mendonca et al, [16] an intrusion detection system (IDS) is based on a tree-CNN hierarchical algorithm with an activation function called soft-root-sign (SRS). The model developed to detect DDoS, intrusion, brute force and web attacks reduced the training time with this model. The complexity level of this solution was analyzed. The results demonstrate that this hierarchical model can reduce execution time while improving detection accuracy by considering all analyzed attacks.

SaisindhuTheja and Shyam [17] proposed an effective system for detecting DoS attacks that used the adversarial crow search algorithm (OCSA) that combined the raven search algorithm (CSA) with adversarial based learning (OBL). Features were chosen by OCSA and classified using a Recurrent Neural Network (RNN) classifier/classifier. A RNN classifier was used to select the essential features based on the OCSA algorithm. An RNN classifier was used to classify the given data in the testing stage. An experimental evaluation of the technique demonstrated that it outperformed other conventional methods based on a benchmark data set.

III. PROPOSED METHODOLOGY

The main objective of this study is to present an innovative intrusion detection system for cloud environment. Figure 1 shows the proposed intrusion detection architecture. Initially, intrusion data is collected from the virtual machine's data collection agent (DAC) and pre-processed. After that, to conserve time and complexity of computation, the best features are chosen using an adaptive artificial flora algorithm. Finally, the selected features are passed to an Enhanced Radial Based Neural Network classifier, which classifies the data as normal or intrusive data.

A. Hypervisor based intrusion detection

In a cloud environment, hypervisor-based intrusion detection (HypIDS) is a type of intrusion detection system (LightGBM) is used as an intrusion detection algorithm. In deployed within the hypervisor. Monitoring and analyzing network traffic and detecting intrusions are carried out by hypervisor-level data and communications.The HypIDS offers comprehensive visibility into the cloud environment by simultaneously gathering data from virtual machines (VMs) and the host. It is feasible to watch and examine network interactions involving virtual machines (VM-VM), among VMs and hypervisors, and also between the cloud context and the outer (network-based) world. HypIDS is designed to detect a wide variety of intrusions, including malware infections, unauthorized access attempts, and denial of service attacks (DoS). To detect intrusions, handwriting-based rules and/or machine learning models are used. It is possible for HypIDS to take a number of actions if an intrusion is detected, including alerting the cloud administrator, blocking malicious traffic, or isolating the infected virtual machine.

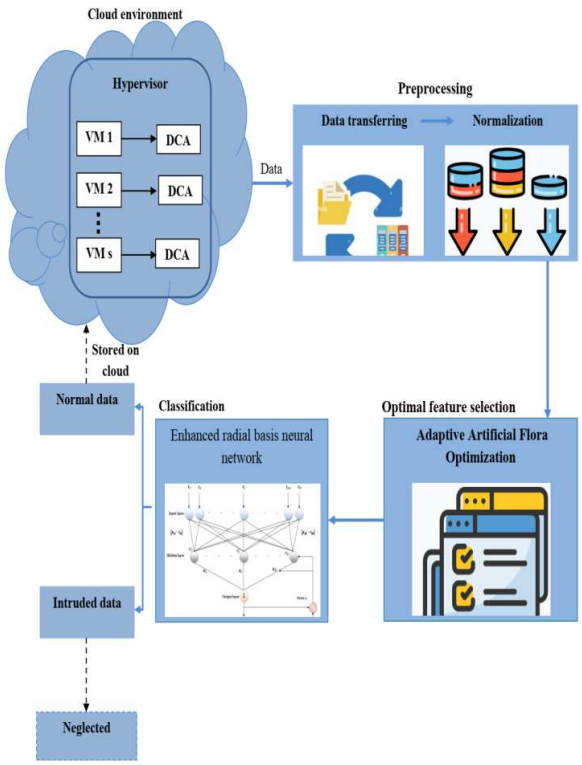

Fig.1. Overall architectural diagram for the proposed intrusion detection

B. Data pre-processing

At first, intrusion data is collected from the datasets. As part of the data collection process, the data should be pre-processed, since pre-processing is an integral part of the classification process. During the pre-processing of data, two primary stages are involved: the transfer of data and the normalization of the data. A number of non-numeric values are converted into numeric values during data transfer. There are symbolic characteristics present in all of the datasets, such as flag features and protocol features that are incompatible with classification methods (e.g., tcp, udp, etc.), as well as features related to services (e.g., telnet, ftp). As a result, each symbol must be made up of numeric values, and every class must be represented by a numeric value.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 09,2024 at 06:59:31 UTC from IEEE Xplore. Restrictions apply.

The data is normalized after it has been transferred. In order to normalize, the min-max method is used. Equation (1) is used to normalize the value of each attribute.

$$A_{new} = \frac{A_{current} - A_{\min}}{A_{\max} - A_{\min}} \quad (1)$$

$A_{\min}$ → Minimum value attribute in the corresponding column

$A_{\max}$ -> Maximum value attribute in the corresponding column

After pre-processing, the pre-processed data is sent to AAF for optimal feature selection.

C. Adaptive artificial flora (AAF) algorithm

Seeds are dispersed by plants in different ways. There are two types of seed dispersal: autochory and allochory. A plant that propagates itself is called an autochory, whereas a plant that propagates via external forces is called an allochory. The process of mechanical propagation can be considered autophagy, and the process of biological propagation can be considered allochory. Because of autochory, plants can move to an appropriate habitat. Red fruits are loculicidal when they are ripe, and their shells curl to release the seeds. When impatiens fruit bursts, the seeds are spread throughout the surrounding area. A plant migration to a distant and unspecified region is portrayed in the allegory. Anemochory, as the wind speed and direction change, determines the direction and distance of seed dispersal. As a result of these breeding methods, plant research has been widened and the risk of extinction of plants has been reduced.

The range of vegetation can expand, decrease, or be displaced due to climate change, a harsh natural environment, or competition. The individual within a plant also evolves as it migrates to a new environment. As a result, plant migration may cause changes in the distribution area of plants, as well as trigger the evolution, extinction, and regeneration of plants. By dispersing seeds and reproducing, plants locate the best place to live despite the fact that they cannot move nor have intelligence.

During plant migration and reproduction, seeds are dispersed randomly within a certain distance by the original plant. Depending on the external environment, a seed has a different probability of survival.

After ripening, a plant's seeds spread when it is placed in a suitable environment. Extreme weather can cause plants to either develop and adjust to their surroundings or go perish in the area. Plants may be able to proliferate in other regions before they die out completely in one region as a result of an analogy. Seeds can be carried by plants from one area to another where they reproduce. As a result of several generations of reproduction, plants will migrate from one area to another that is more suitable for them. Evolution, extinction, and regeneration are the mechanisms by which plants locate the optimal growing environment through migration and reproduction.

Four fundamental components are taken into account in artificial floras: the parent plant, the offspring of that plant, the plant's position, and the propagation distance. An original plant is defined as one that is prepared to yield seeds. Seeds from offspring plants cannot spread seeds at that time as they are seeds from original plants. The location of a plant is its geographical location. The propagation distance refers to the extent of a seed's spread. Behavioral patterns can be categorized into three main categories: evolution, spreading, and selection. It is possible that a plant will adapt to its environment based on its evolution behavior. The spreading behavior of seeds refers to their movement, and seeds may move by autochory or allochory. Depending on the environment, flora may either survive or go extinct. In this work, we use this AAF algorithm to select features to reduce computational complexity and time consumption.

The following describes the phases involved in the AAF algorithm's feature selection process:

1) Initialization: In order for an algorithm to be optimized, the solution initialization process must be followed.Based on the AAF algorithm, the original plants were randomly initialized with N solutions, representing the number of plants in the original plant. By using this approach, the available cells in the network are considered as candidates and initialized as follows.

$$Y_N = \{y_1, y_2, ..., y_S\}_N \quad (2)$$

Where, y_S is the solution and can be expressed as

$$Y_S = [\,Selected \quad features\,]$$

2) Fitness calculation: Fitness is calculated for each initialized solution. With this method, the classification accuracy is used to calculate each solution's fitness. The best fitness is considered to be most accurate. Equation (3) represents the fitness function.

$$Fitness = Max\,(Accuracy) \quad (3)$$

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (4)$$

3) Update the Solution: The proposed AAF algorithm optimization is based on three behaviours of plants, namely, evolutionary behaviour, spreading behaviour, and selective behaviour.

a) Evolutionary behaviour: Initially, seeds were spread out over a circle with a specific radius, or dispersal distance. The reproductive distance is calculated using the propagation distances of the mother plant and the grandfather plant.

$$d_q = d_{1q} \times rand\,(0,1) \times l_1 + d_{2q} \times rand\,(0,1) \times l_2 \quad (5)$$

In this equation, d_q represents the propagation distance between plants. Specifically, d_{1q} represents the new grandparent propagation distance, while d_{2q} represents the new parent propagation distance. l_1 and l_2 denote the learning coefficient, and rand(0,1) determines the uniformly distributed independent number in (0,1).

Equation (6) represents the propagation distance of a new grandparent.

$$d'_{1q} = d_{2q} \quad (6)$$

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 09,2024 at 06:59:31 UTC from IEEE Xplore. Restrictions apply.

The new parent propagation distance is determined by the standard difference among the locations of the offspring plant and the original plant.

$$d'_{2j} = \sqrt{\frac{\sum_{q=1}^{N} (S_{p,q} - S'_{p,q})^2}{N}} \tag{7}$$

Where, N represents the number of plants in the flora, $S_{p,q}$ represents the location of the original plants in the flora, and $S'_{p,q}$ represents the position of the offspring plants in the flora.

b) Spreading behaviour: In the flora algorithm, N solutions are generated at random, resulting in N plants in the flora. Using a matrix $S_{p,q}$ where p represents the dimension and q represents the number of plants in the flora, the position of the original plants is expressed.

$$S_{p,q} = rand(0,1) \times d \times 2 - d \tag{8}$$

In which d is the maximum range region and $rand(0,1)$ is an array of random numbers evenly distributed between (0,1).

Following is how the propagation function generates the position of the offspring plant:

$$S'_{p,q\times c} = D_{p,q\times c} + S_{p,q} \tag{9}$$

c is the maximum number of seeds that may be propagated by one plant, $S'_{p,q\times c}$ is the position of the offspring, $S_{p,q}$ is the position of the original plant, and $D_{p,q\times c}$ is a random number with Gaussian distribution and mean 0 and variance d_q. The original plant is generated according to Equation (8) if none of the offspring plants survive.

*c) Select behaviour:*The survival probability of the offspring plants is determined as follows:

$$S = \left| \sqrt{\frac{Fitness\ (S'_{p,q\times c})}{Fitness_{\max}}} \right| \times M_x^{(q\times c-1)} \tag{10}$$

Where M_x = selection probability. There must be a value between 0 and 1. It is possible that a progeny plant that is too distant from the original plant will be less fit. The exploratory efficiency of the algorithm is determined by M_x. It is important to have a large M_x for an easy problem in order to obtain a local optimal solution. In this generation of plants, $Fitness_{\max}$ represents the maximum fitness, and $Fitness(S'_{p,q\times c})$ represents the fitness of the qth solution.

4) Updation using Levy flight with AAF: Levy flight strategies are introduced to avoid the occurrence of local optima that fall easily, resulting in a loss of AAF diversity. Many optimization algorithms make use of the Levy plane, which is a stochastic strategy. This algorithm employs a random walk with a high step probability, which can increase its randomness. The AAF formula was enhanced by including Levy planes in step 3 to enhance its analytical capability:

$$Y_S = \left| \sqrt{\frac{Fitness\ (S'_{p,q\times c})}{Fitness_{\max}}} \right| \times M_x^{(q\times c-1)} \bullet Levy\ (D) \tag{11}$$

$$Levy\ (D) = 0.01 \times \frac{a \times \sigma}{|b|^{\frac{1}{\beta}}} \tag{12}$$

$$\sigma = \left(\frac{\Gamma(1+\beta) \times \sin(\frac{\pi\beta}{2})}{\Gamma(\frac{1+\beta}{2}) \times \beta \times 2^{(\frac{\beta-1}{2})}} \right)^{\frac{1}{\beta}} \tag{13}$$

The Levy plane function is denoted by *levy*, and the problem dimension is denoted by D. Here, β is a constant equal to 1.5 and random values between 0 and 1 are assigned to a and b.After the completion of the initial and second phases of the AAF, the iteration is complete. Each iteration of the algorithm updates the population using Eqs (5) and (11) until it reaches its last iteration. The best solution obtained during each iteration of the algorithm is given as output after completing the ROA processing.After feature selection, an improved radial-based neural network is used to classify intrusions.

D. Enhanced radial basis neural network (ERBNN)

Artificial neural networks that employ radial basis operations as activation functions are called enhanced radial basis neural networks (ERBFNNs). An input layer, a hidden layer having radial basis activation functions, and an output layer are the three layers that typically make up this model. In order to model the interaction among input and output data, the RBFNN model is built on expressing the hidden layer as a set of radial basis functions, frequently Gaussian functions.

The input, hidden, and output layers make up the three layers of the ERBFNN. An input layer and the jth input vector are connected $Y_j = [y_{j1}, y_{j2}, \cdots, y_{ji}, y_{jn}]$, with $i = 1,2,...,m$ and $j = 1,2,\cdots,n$. The total number of output nodes x_j, $j = 1,2,\cdots n$, is the same as the number of training input-output pair of data. Put differently, a pair of input nodes (represented by a matrix) and output nodes (represented by a vector) exist. In particular, the vectors of the jth hidden node are: $V_j = [V_{j1}, V_{j2}, \cdots, v_{jr}, \cdots, V_{jR}]$, $r = 1,2,\cdots R\ and\ j = 1,2,\cdots,n$. In this regard, W_{jr} describes the connection between the Kth hidden node and the jth output node. Figure 3 illustrates the structure of the ERBFNN. A number of input variables is indicated by M, a number of training sets is indicated by N, and a number of centers is indicated by R in Figure 2.

1) Input layer: This paper uses y_i as the ith variable in its analysis of expected performance. The input matrix for each pair of training data can be described as follows:

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 09,2024 at 06:59:31 UTC from IEEE Xplore. Restrictions apply.

$$Y = [y_{ji}]_{M\times N}, i = 1,2,3,\cdots,M,\ \ j = 1,2,3,\cdots,N. \quad (14)$$

2) Hidden layer:

T_j is defined as $[t_{j1},...,t_{jr},...,t_{jR}]$in the hidden layer. This is the jth center of the ERBFN. An Euclidean distance $\|y_{ji} - t_{jr}\|$ is calculated between input layer's i^{th} and the rth node of the hidden layer. As a result of Eq (16), the Euclidean distance can be determined. The output of the kth hidden layer can be expressed as follows by Equation (17):

$$\|y_{ji} - t_{jr}\| = \sqrt{\sum_{i=1}^{N}(y_{ji} - t_{jr})^2} \quad (15)$$

$$V_{jr} = \varphi_{jr}(\sqrt{\sum_{i=1}^{N}(y_{ji} - t_{jr})^2}) \quad (16)$$

$$\varphi(x) = E^{\frac{-x^2}{\sigma^2}} \quad (17)$$

The Gaussian distribution function $\varphi(.)$ and the smoothing parameter σ represent the Gaussian distribution function.

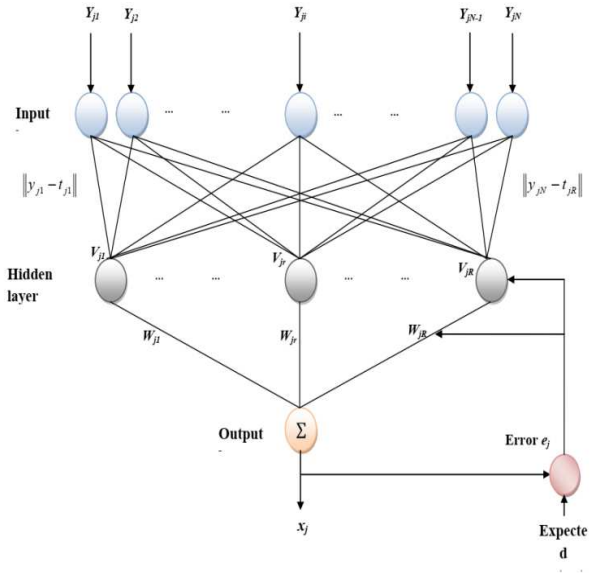

Fig. 2. An overview of the ERBFN structure based on the jth forecast.

3) Output layer: An output layer weight W_{jr} is calculated by multiplying the hidden node V_{jr} by the output node x_j.

Equation (18) describes the j^{th}output of the output layer.

$$y_j = \sum_{r=1}^{R} W_{jr} V_{jR} \quad (18)$$

IV. RESULTS AND DISCUSSION

This work proposes ERBNN-based security-aware intrusion detection. On a Windows 10 test computer with an Intel Core i5 processor and 6GB of RAM, the method is implemented in Python. The proposed work is evaluated based on accuracy, precision, recall, F-measure, specificity, detection rate, loss, error metrics, ROC curve and confusion matrix. For evaluation of the proposed method, KDDCup-99 and NSL-KDD datasets are used.

A. Metrics evaluation

An analysis of the results obtained from the presented technique is presented in this section. Here, we analyze the comparative results of the proposed and existing techniques. In order to accomplish this, we examine existing classification techniques, such as the radial basis neural network (RBNN) and the long short-term memory (LSTM).

TABLE 1. PERFORMANCE COMPARISON BETWEEN PROPOSED AND EXISTING CLASSIFICATION TECHNIQUES

Techniques	Accuracy	Precision	Recall	FMeasure
PROPOSED	97.15	97.24	97.02	97.13
RBNN	95.89	95.66	95.67	95.67
LSTM	94.06	93.91	93.82	93.86

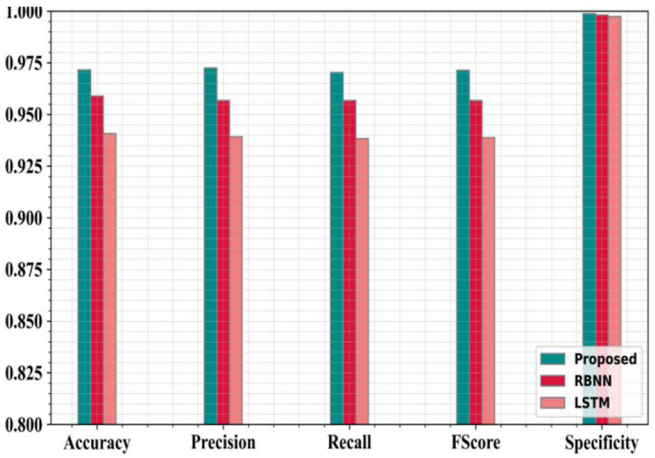

Fig. 3. Performance evaluation comparison of proposed and existing techniques

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 09,2024 at 06:59:31 UTC from IEEE Xplore. Restrictions apply.

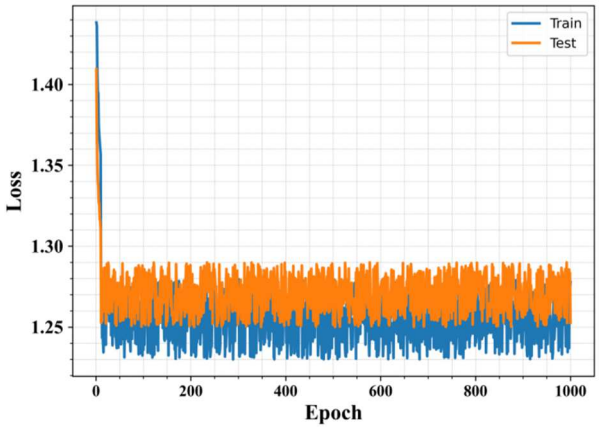

Fig. 4. Training and test validation result evaluation based on loss Vs Epoch

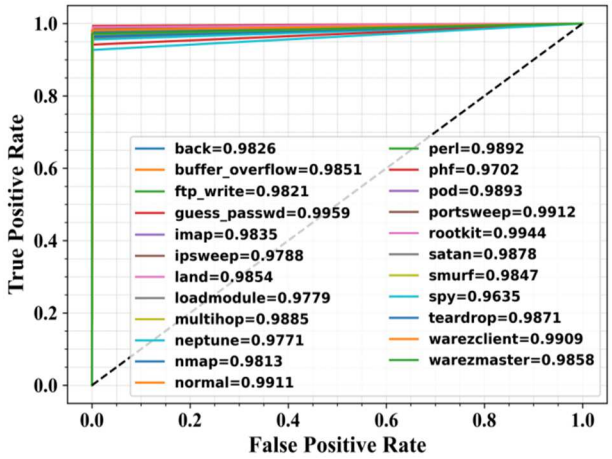

Fig. 5. The ROC curve for the proposed technique

Figure 3 shows the comparative measurement evaluation in terms of precision, accuracy, recall, F-measure and specificity. The proposed ERBNN achieves 97.15% accuracy. Our proposed ERBNN improved the accuracy by 1.26% over RBNN and 3.09% over LSTM. Our ERBNN achieves an accuracy level of 97.24%, which is 1.58% higher than RBNN and 3.33% higher than LSTM. The recall rate of the proposed technique is 97.02%, which is improved by 1.35% from RBNN and 3.2% from LSTM. The F-measure of our proposed technique is 97.13%. The proposed ERBNN improved the F-measure by 1.46% and 3.27% over the existing RBNN and LSTM techniques. Our proposed ERBNN achieves a high mark of 99.87% which is 0.06% higher than RBNN and 0.145 higher than LSTM. From Figure 4, it is demonstrated that our proposed ERBNN has the lowest test loss. Figure 5 presents the ROC curve for the proposed technique. From the above results it is proved that our proposed technique is better than the existing RBNN, LSTM.

V. CONCLUSION

The main objective of this work is to detect intrusions in a cloud-based hypervisor environment. Initially, intrusion data is collected and pre-processed. After that, an adaptive artificial flora algorithm (AAF) is used to select the optimal features to reduce computational complexity and time consumption. Then, the selected features are passed to an Enhanced Radial Based Neural Network (ERBNN) classifier to classify the data as normal or intrusive data. The performance of the proposed method is implemented in Python and the performance is analyzed based on various metrics. Our proposed task achieves 97.15%, 97.24%, 97.02%, 97.13% and 99.87% in terms of precision, accuracy, recall, F-measure and specificity, respectively.

***Abstract* – In the modern digital world, data security has become a major concern. All kinds of data are transmitted through various channels in different forms. For safeguarding this information and maintaining privacy, encryption techniques have proved very useful. In this paper, we have designed a new 3D chaotic system to be used in image encryption algorithms. The chaotic system's random and unpredictable nature make them highly suitable for encryption techniques. We have put forward a new 3D chaotic system, calculating its Lyapunov exponents, fractal dimension and performed its bifurcation analysis for successful analysis of the proposed system. A pixel-value diffusion-based encryption algorithm, using the novel chaotic system, has been performed.**

Keywords – Chaotic system, Lyapunov exponents, Image encryption, Pseudo Random Number Generator (PRNG), Pixel diffusion.

I. INTRODUCTION

Chaotic systems are a class of dynamic system which exhibit high sensitivity to initial conditions. Even a small change in the starting conditions can cause the system to diverge drastically, resulting in totally different outcomes. Chaotic systems are deterministic and can be modelled using a set of differential equations. However, they exhibit random nature because they get highly affected by small changes in input conditions. Chaos theory is a field in mathematics that showcases the pattern of nonlinear dynamic systems, showing their highly susceptible dependence on initial conditions. Some of the applications of chaos theory are random number generator [1], unmanned aerial systems [2], DC motor [3], cryptography [4], magnetic levitation oscillation [5], memristive devices [6] and many more.

To protect data from unauthorized access, the complex and unpredictable nature of the chaotic systems is used to perform encryption. In case of digital images, the pixel value or position are altered using the chaotic system due to which it appears random. Decryption of such image without the knowledge of exact chaotic parameters becomes difficult. The sensitive dependence of chaotic system makes sure that even a minute variation in chaotic parameters result in totally different decrypted image.

We have generated a new image encryption algorithm based on pixel value diffusion using the proposed new chaotic system. Pseudo random numbers are generated using the chaotic system.

There have been numerous works on using chaotic systems for image encryption. Xing-Yuan Wang et al. [7] proposed a new image encryption algorithm based on cycle shift and chaotic system. In this technique, we generate some integers which are of the same size as is the image and use these integers to scramble the plain-text image. Xiuli Chai et al. [8] proposed a chaos-based image encryption algorithm using DNA sequence operation. In this technique, a DNA matrix is used to encode the plain image. In the second step, a wave-based permutation scheme is performed on it. Hossein Movafegh Ghadirli et al. [9] discussed various encryption algorithms for color images. Li et al. [10] proposed a new algorithm for grayscale images which utilized the concepts of bit-level scrambling and multiplication diffusion for removing the correlation between pixels.

This paper is divided into five sections. The mathematical model of the new chaotic system and its dynamic properties are described in Section 2. Section 3 presents the results of simulation of chaotic system and its bifurcation analysis. Section 4 describes the applications of image encryption process using the new chaotic system. Section 5 provides the conclusion.

II. MATHEMATICAL MODEL OF THE NEW CHAOTIC SYSTEM

The newly designed 3D chaotic system is given by the following equations:

$$\dot{x} = z + a \tag{1}$$

$$\dot{y} = -x^2 - bz \tag{2}$$

$$\dot{z} = |y| + cxy \tag{3}$$

where x, y and z are the states and a, b and c are the chaotic parameters. As can be seen from the equation (1), (2) and (3), the proposed chaotic system consists of two quadratic nonlinearities and one modulus function nonlinear term.

For the system to exhibit chaotic nature, we have taken the value of chaotic parameters as:

$$(a, b, c) = (5, 2.9, 2.6) \tag{4}$$

and initial conditions as:

$$X(0) = (x(0), y(0), z(0)) = (0.2, 0.2, 0.2) \tag{5}$$

We calculated the Lyapunov exponents using the Wolf algorithm [11]. We used the conditions mentioned in (4) and (5) and run the simulation for T = seconds. The obtained Lyapunov exponents are:

$$(L1, L2, L3) = (0.0067, 0.0009, -0.0223) \tag{6}$$

From (6), we observe that of the three Lyapunov exponents two are positive which proves that the system is indeed chaotic.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 10,2024 at 04:58:55 UTC from IEEE Xplore. Restrictions apply.

The sum of the Lyapunov exponents is

$$L1 + L2 + L3 = -0.0147 \ < 0 \qquad (7)$$

The sum is less than zero indicating that the system is dissipative in nature, which again, represents its unpredictable nature.

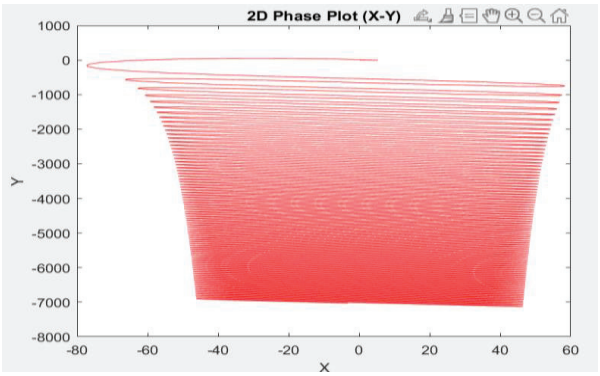
Chaotic systems exhibit fractal dimensions. The Kaplan – Yorke Fractal dimension [12] for a chaotic system is calculated as

$$D\text{xy} = 2 + \frac{L1+L2}{|L3|} \qquad (8)$$

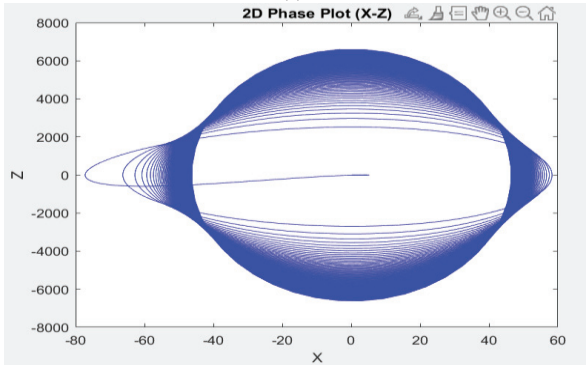
The fractal dimension of the new chaotic system comes out to be 2.3408 indicating highly chaotic nature of the system.

III. SIMULATION

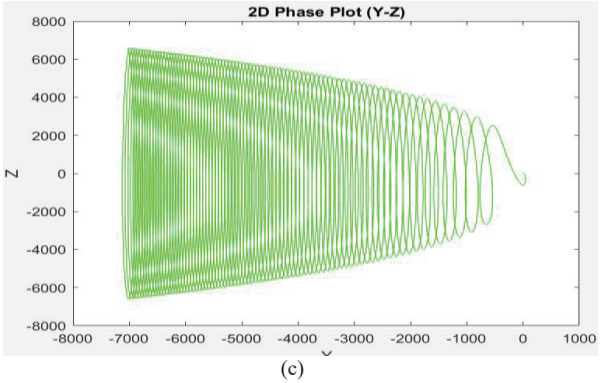
The plots obtained from the proposed chaotic system are as follows,



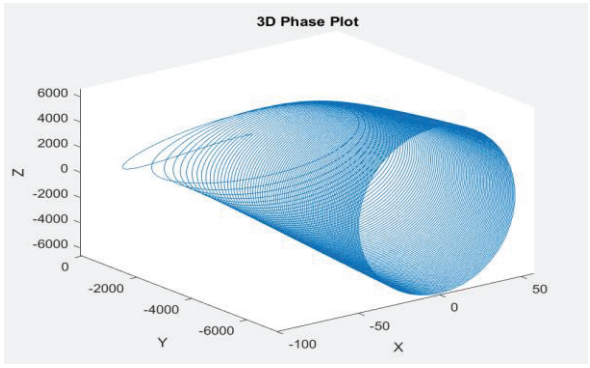
(a)



(b)



(c)



(d)

Fig. 1. (a) Phase Plot (X vs Y), (b) Phase Plot (X vs Z), (c) Phase Plot (Y vs Z), (d) Complete 3-D Phase Plot

The variation of Lyapunov exponents, can be seen in the following plot. After some initial fluctuations which was to be expected but eventually it settles down to the values mentioned previously.

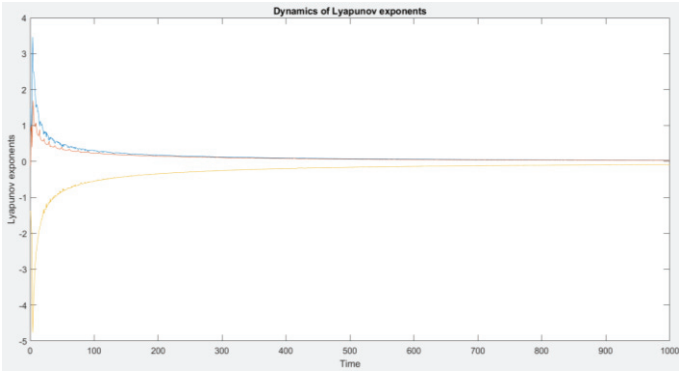


Fig. 2 Variation of Lyapunov Exponents L1, L2, L3 with time

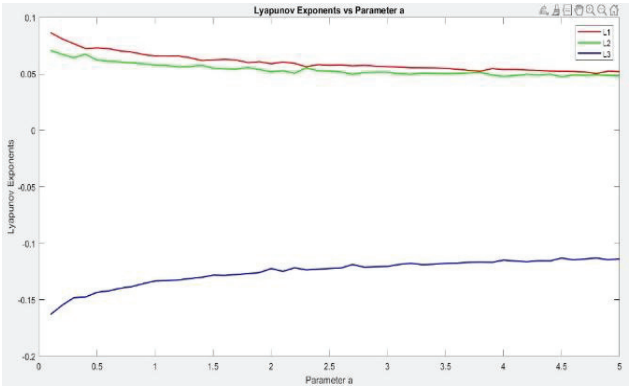
Usually, rigid chaotic systems are not preferred. Therefore, we have used 'Bifurcation Analysis' on all the three parameters to determine the ranges in which the chaotic system preserves its chaotic and unpredictable nature.



(a)

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 10,2024 at 04:58:55 UTC from IEEE Xplore. Restrictions apply.

Following this, is the image encryption done using the proposed novel chaotic system and its respective decryption.

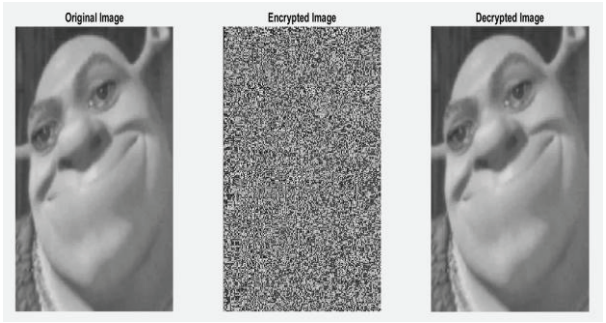

Fig. 3. Encrypted and Decrypted Image using proposed Novel Chaotic System

IV. APPLICATION

Encryption Process has been done using the Symmetric Key Block Ciphering Technique. Chaotic system's independent variable is used to make the Key for encryption. The first step includes interpretation of the image to be transmitted in the form of pixels. Following which, the data is converted into a matrix of rows and columns. In a similar manner, the Encryption Key is also reshaped to be of a matrix with same number of rows and columns as the original image matrix, so that, smooth operation of EXOR can be executed. It is to be kept in mind that this Key matrix is generated with the use of the proposed chaotic system.

EXOR operation is performed between the first column of the original image matrix taken as blocks of data and the Key matrix to get the first column of the encrypted image matrix, which in succession is then XORed with the column obtained from the EXOR operation performed between the second column of original image matrix and the second column of the Key matrix. And so on and so forth until all the columns of the encrypted matrix has been obtained according to the following equations,

$$E_1 = P_1 \oplus K_1 \tag{9}$$

$$E_2 = (P_2 \oplus K_2) \oplus R_1 \tag{10}$$

$$E_n = (P_n \oplus K_n) \oplus R_{n-1} \tag{11}$$

Decryption process can also be performed in a similar fashion with a little tuning in the equations. The same Key matrix is required to successfully decrypt the image. To get the first column of the decrypted image data, first column of the encrypted image matrix is XORed with first column of the Key matrix. Subsequently, to get the second column of the decrypted image matrix, the second column of the encrypted image matrix is XORed with its previous column and then, with the corresponding column from the key matrix. Thus, after complete decryption the original image is successfully retrieved according to the following equations,

$$D_n = E_n \oplus K_n \oplus E_{n-1} \tag{12}$$

V. CONCLUSION

Encryption performed through the proposed chaotic system showed better efficiency against unauthorized external attacks. The Lyapunov exponents L1, L2 and L3 were plotted and obtained to be 0.0067, 0.0009 and -0.0223, respectively. Also, the Fractal Dimension was evaluated to be equal to 2.3408, which was found out to be more than those of some of the more popular chaotic systems like Lorentz and Rössler Chaotic Systems. Thus, providing further unpredictability and hence, better suited for encryption techniques as a PRNG (Key Matrix).

***Abstract*—This paper conducts a comparative study among various chaotic systems, implementing a secure communication system. The chaotic communication system incorporates specific synchronization and masking schemes, contributing to achieving the objectives of secure communication. This comparative analysis aims to identify the optimal choice for this application, evaluating multiple crucial parameters integral to the design.The simulation for the design has been carried out in Xilinx Vivado using Verilog HDL.**

Keywords—Chaotic system, Synchronization, Masking, Xilinx Vivado, Verilog HDL.

I. INTRODUCTION

Since the advent of chaos theory, discovered by Edward Lorenz in 1963 [1], there have been a lot of discussions surrounding it and its applications. It has found its use in wide range of areas like stock markets, literary theory, music and electronics as well [2]. An example of its application in electronics is the Chua's circuit, which is a simple oscillator circuit exhibiting a variety of bifurcations and chaos [2].

Chaotic behavior, presents as irregular, aperiodic, uncorrelated, broad-band signals that defy prediction over extended periods [3]. These distinctive characteristics of chaotic systems, coupled with their sensitivity to initial conditions, makes them suitable for application in communication systems as well. This is also beneficial as the power spectrum of chaotic systems is similar to that of white noise. Several chaotic systems have been studied since the discovery of the Lorenz chaotic system.

A secure communication scheme that has been implemented, has been explored in detail in [4], and will be discussed briefly in the subsequent sections as well. Such a chaotic communication system was made possible through the self-synchronizing [5] capability of chaotic systems as well as a modulation scheme like the chaotic masking [6].

In this paper, we intend to find out the more suitable chaotic system by comparing their implementation in such a secure communication system. This comparison will be based on the synthesis results, timing information and the self-synchronizing ability of the respective chaotic systems.

To conduct this study, we have implemented the earlier mentioned design using five different chaotic systems, i.e., Lorenz, Rossler, Nose'-Hoover, Sprott-C and Rabinovich Chaotic systems [7-11].

The succeeding portions of the paper are organized as follows: Section II provides a brief exploration of the implemented design for communication and a comparison between chaotic systems. In Section III, the paper delves into the results derived from the conducted simulations, along with the conclusions drawn from these results. Lastly, Section IV explores potential avenues for future work related to the undertaken study.

II. METHODOLOGY

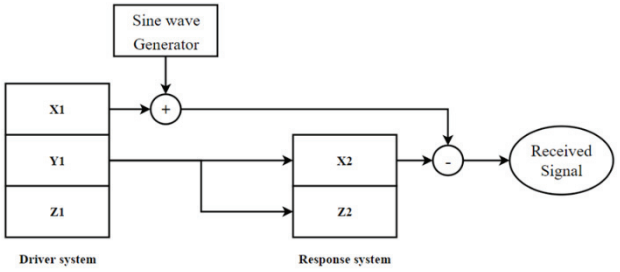

Fig. 1. Block Diagram for the Implemented Design

As shown in Fig. 1, The communication system consists of a Driver system and a Response System [4]. Both are implemented using Chaotic Systems.

The Driver system encodes the message signal, i.e., sinusoidal signal using the chaotic samples generated using the chaotic system. The Response system receives the transmitted signal and generates the same chaotic samples as the Driver to recover the original signal.

Here, the subsequent chaotic samples are generated by both Driver and Response systems by the implementation of the differential equations of the respective chaotic systems. This is done by using the Runge-Kutta 4th order method as it's an efficient method for the above purpose [12]. This approach depends on the equations that define each state within the Finite State Machine (FSM)shown in Fig 2 where, X, Y, Z represent state variables, while Fx(X, Y, Z) denotes the derivative of the state variable X. The step size, designated as h, signifies the interval between successive samples within the chaotic system. Additionally, KX1, KX2, KX3, and KX4 represent the intermediate slopes of X state variable involved in the process. Similarly, Y and Z have their intermediate slopes in the same fashion. Also, X0, Y0 and Z0 are the initial conditions.

The FSM in Fig. 2., through which the above method is being applied to generate chaotic samples in Driver and Response systems, has been implemented in Verilog HDL.

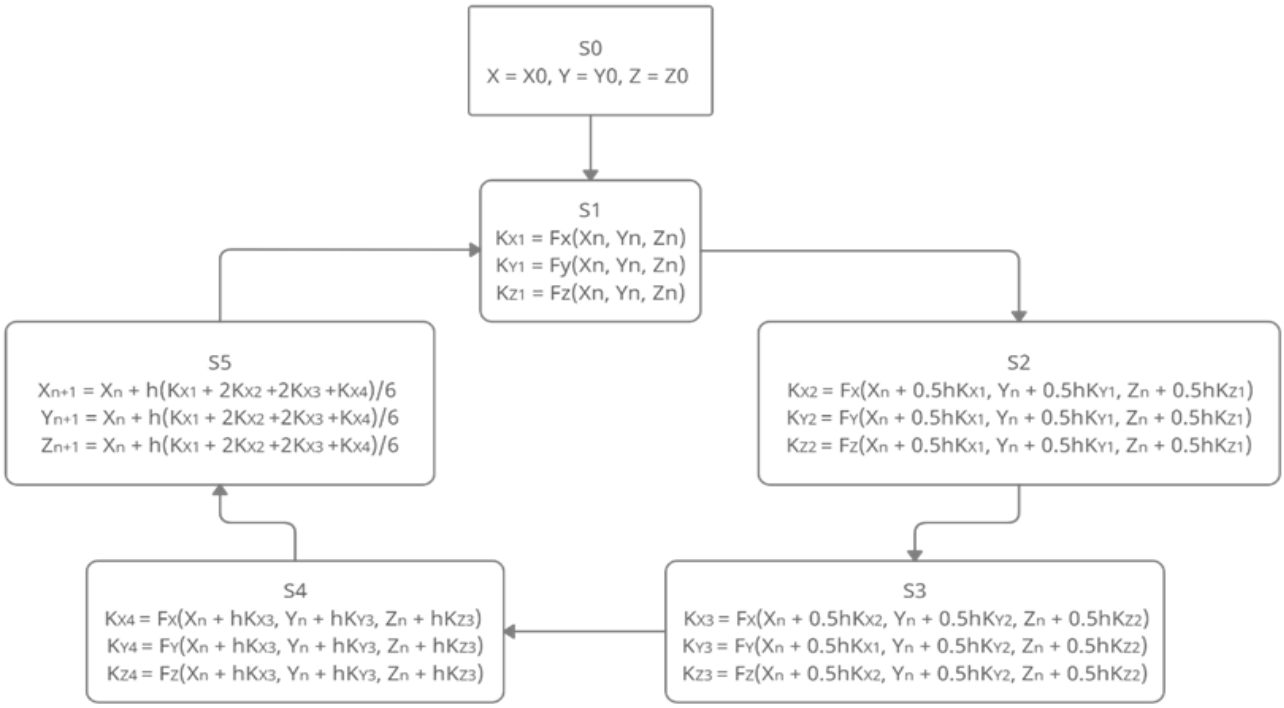

Fig. 2. Finite State Machine illustrating the implementation of a chaotic system through the RK4 method

For communication to occur, synchronization between the Driver and Response systems is essential. Both systems must be capable of generating identical chaotic samples. The synchronization method employed here is 'Complete Replacement Synchronization.' In this approach, a state variable serves as the driving signal, transmitted through the communication channel to the response system alongside the actual transmitted signal. Each sample in the driving signal replaces the corresponding state variable in the response system, ensuring it produces the same sample as the driving system.

A crucial element for ensuring a secure communication method involves implementing a modulation scheme for the encryption and decryption of a message signal. This requirement is fulfilled by employing the Chaotic Masking Scheme. In this scheme, the chaotic sample generated by the driver system is added to the sinusoidal signal intended for encryption. Subsequently, in the response system, the identical chaotic sample is subtracted from the received signal to retrieve the original sample[13]. The success of this scheme depends on the synchronization of chaotic systems at both the driver and response ends, ensuring the generated chaotic samples are identical.

III. Results and Conclusions

The design was executed by employing five distinct Chaotic Systems, each characterized by three state variables and specific variable parameters. The equations corresponding to these systems are outlined below.

1. Lorenz Chaotic System:

$$x'=a(y-x) \quad (1a)$$

$$y'=x(c-z)-z \quad (1b)$$

$$z'=xy-cz \quad (1c)$$

Where a=10, b=28, c=8/3 and initial conditions were (0,2,0).

2. Nose-Hoover Chaotic System:

$$x'=y \quad (2a)$$

$$y'=-x+yz \quad (2b)$$

$$z'=x^2-ay^2+b \quad (2c)$$

Where a=9, b=2 and initial conditions were (1,1,1).

3. Rossler system:

$$x'=-y-z \quad (3a)$$

$$y'=x+ay \quad (3b)$$

$$z'=a+z(x-c) \quad (3c)$$

Where a=0.2,b=5.7 and initial conditions were (0,0,0).

4. Spott C system:

$$x'=y \quad (4a)$$

$$y'=-x-yz \quad (4b)$$

$$x'=y2-a \quad (4c)$$

Where a=1 and initial conditions were (0,0.01,0).

5. Rabinovich system:

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 10,2024 at 04:58:01 UTC from IEEE Xplore. Restrictions apply.

$$x' = y(h+z) - ax \quad (5a)$$

$$y' = -x(h-z) - by \quad (5b)$$

$$z' = -cz + xy \quad (5c)$$

Where a=1.5, b=-0.3, c=1.67 and initial conditions were (5,5,5).

As noted in the preceding section, the application of the RK4 method is employed for implementing each chaotic system, with dependence on the step size 'h'. In this instance, the specific value assigned to 'h' is 0.0078125, and the design operates with a clock frequency of 20MHz.

The state variable Y serves as the driving signal to facilitate synchronization between the chaotic systems in both the drive and response systems. Additionally, samples derived from the state variable X execute chaotic masking on the message signal.

Communication between the Driver system and Response system was achieved successfully for all the mentioned chaotic systems and the simulation results of the design for the case of the Lorenz Chaotic system have been shown in Fig. 3. and Fig. 4. Here we can observe that the chaotic samples at both Driver and Response Systems have been generated successfully. As the Driver and Response chaotic samples are identical, we can conclude that both are synchronized successfully.

Further, it can be observed that the original message signal has been recovered. Hence secure communication has been achieved.

The design corresponding to each chaotic system has been synthesized on the xc7a200tffv1156-1 device using Xilinx Vivado, and the results have been compiled and compared in Table 1.

From Table 1., We can observe that the time taken to synchronize the Driver and Response system is the least in the case of the Lorenz Chaotic System but the Flip-Flops and DSPs utilized are at par. However, in the communication scheme employed, the synchronization time holds the utmost importance in establishing efficient communication. Due to such requirements of the design, as well as considering the trade-offs, the Lorenz Chaotic System is the preferred choice for such a secure communication system.

IV. Future Research Direction

The comparative analysis conducted herein, involving the deployment of a secure communication system as elucidated in preceding sections, offers valuable insights into the necessity of chaotic systems in communication., and the Lorenz Chaotic System stands out for its ability to achieve near-instantaneous synchronization, as demonstrated in previous sections.

Further work can be done to optimize the current design to efficiently utilize the hardware which may assist in lowering the delays as well.

Additional efforts can be directed towards implementing an enhanced synchronization scheme, potentially leading to improved security for the communication system. Exploring alternative masking schemes for the same purpose may also be considered.

***Abstract*— Social media platforms have become increasingly popular avenues for individuals to express their thoughts and emotions, especially with the advancements in computer systems and other technologies. One area of research that holds significant commercial potential is the collection and analysis of sentiments expressed in user comments, particularly in terms of their polarities. The detection, identification, and interpretation of sarcasm are of particular importance in sentiment analysis. However, automated sarcasm detection is a complex and challenging task that has not been extensively explored. This paper presents a novel approach for detecting sarcasm in social media, specifically on platforms such as Twitter and Instagram, by utilizing unsupervised mathematical optimization and probability distribution techniques. In this study, we initially employ a probabilistic distribution categorization method and a lexicon-based framework to analyze the words. Subsequently, the VADER sentiment library is utilized to ascertain the polarities of the specified sentences. By incorporating a parameter specifically designed to detect sarcasm in sentences, a sentiment score is then fed into the logistical distribution. Ultimately, we present statements that exhibit both implicit and explicit sarcasm, as well as those that contain offensive language. This proposed model serves to safeguard social media platforms against the dissemination of sarcasm, the propagation of abusive content, and instances of cyberbullying.**

Keywords—Sarcasm Detection, Logistic Distribution, Tsallis Entropy, Entropy distribution, Sentiment Analysis, Optimization.

I. INTRODUCTION

In contemporary society, individuals rely heavily on internet connectivity to access a wide range of information for personal purposes, such as obtaining relevant data, reading product reviews, acquiring knowledge, engaging in online interactions, and conducting virtual transactions. The advent of the internet has significantly enhanced the utilization of social media platforms. This is evident in the exponential growth of popular online platforms like Facebook, Twitter, LinkedIn, and others. While experts have made progress in categorizing user feedback as positive or negative, they face challenges due to the presence of sarcasm in the data, which complicates the measurement of sentiment.

Sarcasm is a rhetorical device used to mock or ridicule someone by employing a contrasting or ironic meaning [1]. Even for individuals who are adept at manipulation, identifying instances of sarcasm can be more challenging than discerning whether a situation is beneficial or detrimental [2]. The task of extracting sarcastic statements poses a complex and arduous process for computational systems. However, current techniques for sarcasm recognition have a limitation in that they primarily focus on analyzing written content responses, overlooking the valuable referential information present in comments and user data [3]. Several of the pre-defined models cannot inhibit the information contained within the text [4]. This limitation hinders the understanding of the true purpose of a sentence, as language can have a wide range of meanings. In order to address this gap in research, we have conducted a study to fill this void in knowledge. Despite the computational challenges involved, researchers are increasingly focusing on the detection of sarcasm due to its limitations in sentiment analysis [5]. This study proposes an innovative technique for detecting sarcasm in two major social media platforms, Twitter and Instagram, which are widely used for microblogging. With a large global audience, Twitter and Instagram continue to dominate the microblogging industry. This platform facilitates the sharing of ideas, perspectives, and supplementary information on a particular topic through the Twitter platform. In the present study, user attitudes and ratings expressed in comments are initially classified using the VADER sentiment analysis tool. Subsequently, the proposed approach is employed to ascertain the presence of sarcasm in statements based on the sentiment ratings and the presence of offensive language. By analyzing the tone of sarcasm and its explicit and implicit manifestations in responses, along with the occurrence of abusive language in tweets, more robust conclusions can be drawn. For the proposed study we have incorporated two datasets of online comments taken from Kaggle of Twitter and Instagram respectively.

In the course of our investigation, we have identified significant limitations in prior research endeavors and seek to address these issues through the introduction of novel methodologies. The contributions we put forth are outlined as follows:

1. The proposed algorithm, known as Logistic Distribution Learning based Sarcasm Detection using the Tsallis Entropy approach (LDL-SDTE), is a groundbreaking method that we propose. This approach leverages the lexical values and prior probabilities related to the speaker's understanding of sarcasm to effectively utilize recently acquired content. Furthermore, the incorporation of sentiment and emotion within sentences aims to enhance the classification process.
2. The suggested model aids in determining public remarks with the aim of understanding erroneous and abusive

qualities. This technique aids social media platforms in identifying harmful and abusive remarks used for digital trolling.

3. Utilizing a dynamically optimized entropy distribution strategy, we merge the sarcastic text's outcome. The result of this output combines with the algorithm's response in an appropriate and useful way to better describe implicit as well as explicit sarcasm.

This article is organized into several sections. The first section offers a concise introduction to the topic of sarcasm in sentiment analysis. The second section examines the existing literature on sentiment mining that incorporates sarcasm. The third section presents a new algorithm for detecting sarcasm. The fourth section provides a comprehensive evaluation of the proposed algorithm. Finally, the fifth section concludes the article by summarizing the key findings and offering some additional remarks.

II. Related Work

Being subjective, sarcasm recognition in text is a very difficult NLP (Natural Language Processing) topic. In a classification problem, we essentially attempt to predict whether the incoming text is sarcasm or not. Here, we discuss the primary tactics that were successfully used in order to complete this work while leveraging a range of traditional approaches with databases.

Y. Cai et al. [1] centers on the identification of sarcastic messages on Twitter. It encompasses both textual and visual elements and proposes a framework for merging hierarchical structures to serve multiple purposes. M. Bouazizi and T. O. Ohtsuki [2] introduce a classification system consisting of four categories that encompass the diverse forms of sarcasm. Additionally, they propose a pattern-based methodology (PBA) for detecting sarcasm on Twitter. H. Gregory et al. [6] aim to build upon existing research by incorporating LSTM, GRU, RoBERTa, and BERT and transformer models to investigate sarcasm in Twitter posts. Y. Liu et al. [7] aim to replicate the BERT pretraining conducted by previous studies and thoroughly assess the influence of various hyperparameters and the size of the training data. M. S. M. Prasanna et al. [8] presents an innovative method for detecting sarcasm in user reviews or opinions by analyzing text patterns at the clause level. The sentences are formulated using rules derived from a decision tree and a neuro-fuzzy system. T. Yue et al. [4] discusses the identification of the relationship between images and text and introduces a novel approach called KnowleNet. It utilizes the ConceptNet database to access relevant information and employs similarity-based semantic parallelism detection. R. A. Potamias et al. [9] present a novel approach that utilizes a transformer-based methodology, incorporating the pre-trained RoBERTa model in conjunction with a recurrent convolutional neural network, to address the challenge of analyzing figurative language in social media. K. Sundararajan and A. Palanisamy [5] gives a selection method utilizing an ensemble approach to identify the effective set of features for sarcasm detection in online comments. D. Zhang et al. [10] examine the practical applications of weakly supervised object localization and detection techniques. S. Suzuki et al. [11] present a novel approach for detecting sarcasm and emotional content in phrases, utilizing the underlying emotions conveyed by the phrases. present a novel corpus for the purpose of sarcasm detection. It includes both unbalanced and self-annotated labels. P. Goel et al. [12] seeks to address the disparity between human and machine intelligence in the identification of sarcastic behavior and patterns. It employs a combination of neural techniques, i.e., Long Short-Term Memory (LSTM), Gated Recurrent Unit (GRU), and Baseline Convolutional Neural Networks (CNN), in an ensemble model for the purpose of detecting sarcasm on the internet. M. Abulaish et al. [13] provides an overview of figurative language, encompassing both literal and non-literal structures. It explores the incorporation of humor, simile, metaphor, sarcasm, irony, and other elements within figurative language. Additionally, it delves into the utilization of these linguistic devices within language systems. R. Misra and P. Arora [3] outline the distinctive features of dataset and conduct a comparative analysis of its various attributes in relation to other established benchmark datasets in the field of sarcasm detection. Additionally, they employ a Hybrid Neural Network architecture to gain a deeper understanding of the elements that define sarcasm within a given text. T. Saha et al. [14] presents a novel approach for multimodal classification by proposing a multitask ensemble adversarial learning framework. It incorporated, bidirectional constraints to effectively capture and integrate shared semantic relationships across different modalities. O. Vitman et al. [15] capture context features, a pre-trained transformer, and CNN it employed. It possesses emotion detection and sentiment analysis tasks.

A. Problem Definition

The goal of our study is to create a multitasking method for identifying sarcasm and its numerous subtypes on social media. Each situation in this investigation comprises linked text that is categorized using a variety of techniques, involving sarcasm detection (the primary task), sentiment analysis, emotion recognition, and further sarcasm-type categorization. Depending on context, some of the expressions within these terms are to be taken both literally and sarcastically. $\{K, K_{sarc}, K_{nsarc}, D_S, E_A, L_T\}_{i=1}^{i=m}$ here $K = \{k_1, k_2, k_3, \ldots, k_n\}$ represents the collection of sentences extracted from the dataset. K_{sarc} refers to the sarcastic text in the dataset, K_{nsarc} refers to the non-sarcastic text, D_S indicates the sentiment tag, E_A represents the class of emotion analysis, and L_T to denote the type of sarcasm, whether it is implicit or apparent in nature.

III. The Proposed Methodology

Our innovative approach, known as LDL-SDTE (Logistic Distribution Learning based Sarcasm Detection using Tsallis Entropy) approach, aims to address the gap by offering an easily accessible yet effective unsupervised mathematical optimization technique for sarcasm detection. We know in the context of sarcasm detection the authorship of a comment is known. Each individual possesses a unique communication style, shaped by personal preferences, experiences, and semantic preferences. First, we harness three key aspects: the target of offensive language using the textacy Python library, the emotional scores of user comments, through Tex2emotion Python library, and the tendencies of their sentiments, as revealed by the VADER Sentiment lexicon

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 09,2024 at 07:00:37 UTC from IEEE Xplore. Restrictions apply.

tool. Our proposed algorithm seeks to extrapolate the probability of sarcasm for each user's comment, leveraging their expressed emotions and sentiment polarities.

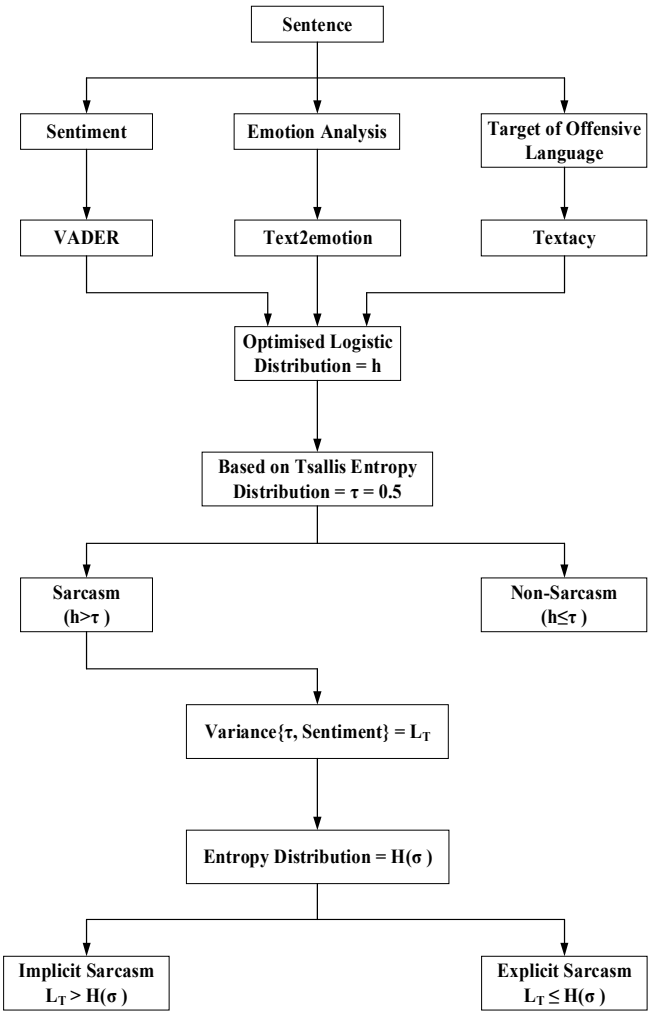

Fig. 1. Flowchart of the suggested approach

This information helps in prediction tasks related to sarcasm detection. This strategic approach aligns with the notion of treating speaker information as a form of probability calculated using Logistic distribution. It becomes an optimized probability condition, subsequently integrated into the model output with the support of Tsallis entropy and entropy distribution. Our method involves addressing a multi-classification task encompassing sarcasm, sentiment, emotion analysis, and sarcasm type. With the help of these metrics, helps in enriching the model's predictive capabilities. The schematic representation of this approach is depicted in Fig. 1.

A. Emotion analysis of text

Emotion The fundamental component of our strategy is the capture of emotions from texts. It is facilitated by the utilization of the "Tex2emotion" Python library. Using this library, we can identify emotions that are expressed in statements and provide matching ratings, enabling us to comprehend the true emotional context more thoroughly. In this first step of our system, texts are processed to provide a more precise summary of emotions. Let's refer to a series of sentences where each expression represents a distinct feeling. We do an evaluation of the emotional scores termed *emotive score analysis* denoted as δ_E, for each unique feeling. Five emotions are present in our library: surprise, fear, anger, sadness, and happiness. We derive two emotions i.e., Positive Emotion which involves an average score of $\frac{Surprise+Happy}{2}$ and Negative Emotion which involves a mean score of $\frac{Angry+Fear}{2}$, $\frac{Sad+Fear}{2}$ and $\frac{Sad+Angry}{2}$.

B. Sentiment analysis

The VADER sentiment, a sentiment lexicon analyzer relies on Natural Language Processing (NLP). Both positive and negative components are used to determine the mood of the provided text. The strength of the contrasts is also shown by the text's compound rating. The *sentiment compound score* from S_T is then imported. The suggested framework for sarcasm recognition uses the standard deviation of the compound score, designated as α_S.

C. Target of Offensive Language

Through the aid of the target of offensive language obtained using keyword extraction method i.e., textacy a Natural Language Processing (NLP) python library. The targeted offensive word is marked by the highest score value it gives to the proposed framework for sarcasm identification

D. Proposed model (LDL-SDTE) for sarcasm detection

The Logistic Distribution, which represents the likelihood distribution of a variable is autonomous of the entire distribution model. It is sinusoidal or S-shaped, with an ongoing range of possibilities. It is used in numerous applications, such as analysis of data, transport costs, and enhancing dynamics models. It has here undertaken three parameters depicted by (1).

$$h(k_i;\ \delta_E, \alpha_{S_i}) = \frac{e^{-\frac{(k-\delta_E)}{\alpha_{S_i}}}}{\alpha_{S_i}\left(1+e^{-\frac{(k-\delta_E)}{\alpha_{S_i}}}\right)^2} \quad (1)$$

Here, h is termed as the final score of the defined distribution called on the basis of which sarcasm detection is to be done. The basic parameters in this study involve k, δ_E, α_s and τ which is sentence *sentiment compound score*, average of *emotive score analysis*, standard deviation of sentiment compound score, and sarcasm *threshold value* respectively. It can be inferred that the situational intuitive emotive qualities of these factors are what detectors for sarcasm rely on. The sarcasm *threshold value* calculated is on the basis of the Tsallis entropy distribution comes up with a value of 0.5 with a fixed score.

The statement was deduced to be a sarcastic label i.e., K_{sarc} if the *final score* 'h' is greater than 0.5 and non-sarcastic if the *final score* 'h' is less than equal to 0.5. Equation (2) depicts a numerical elaboration of it.

$$K_{sarc} \rightarrow h > \tau = 0.5;\ K_{nsarc} \rightarrow h \leq \tau = 0.5 \quad (2)$$

The sarcasm *threshold value* denoted as τ in (3) is calculated on the basis of using the Tsallis entropy structure such as with $q = 3.7$ as a fixed value metric in it.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 09,2024 at 07:00:37 UTC from IEEE Xplore. Restrictions apply.

$$\tau_q(K) = \frac{1}{1-q}\left(1 - \sum_i \left(P(h_i)\right)^q\right) = 0.5 \quad (3)$$

Algorithm for sarcasm detection using LDL-SDTE

Input: δ_E (average emotive analysis score), α_S (Standard deviation of sentiment compound score), k (sentiment compound score), τ (sarcasm threshold score)

Output: sarcasm (K_{sarc}) and non-sarcasm (K_{nsarc})

1. Calculate the sentiment and compound score of sentences K using the VADER sentiment library
2. Using Tex2emotion library to obtain emotion analysis score
3. Calculate the Logistic distribution based on the given parameters
   p1 = $e^{-\frac{(k-\delta_E)}{\alpha_S}}$
   p2 = $\left(1 + e^{-\frac{(k-\delta_E)}{\alpha_S}}\right)^2$
   p3 = α_S
4. Define h :
   $h = \frac{p1}{p2 \times p3}$
   return h
5. Calculate the Logistic distribution score
   h = calculate_logistic_distribution (k; δ_E, α_S)
6. Compare the calculated score with the threshold τ to determine sarcasm
   if $h > \tau$:
   return "K_{sarc}" (sarcasm)
   else:
   return "K_{nsarc}" (non-sarcasm)
   End

where K resembles the total number of sentences over the dataset and h_i denoted as normalized average sentiment sarcasm *final score*. The Algorithm gives the perfect visualization of the proposed methodology of sarcasm detection with the help of sentiment, emotion analysis, and target of offensive words in the text within it.

E. Implicit and explicit sarcasm analysis

The analysis of sarcastic sentences is further assessed to give its nature. Implicit sarcasm deals with an indirect kind of intended mockery. Explicit sarcasm deals with direct implied intended mockery of another person. Applying the statistical measure i.e., calculating variance of final score and average of positive and negative sentiments of each sentence. Another defined parameter is the sarcasm type threshold value denoted as σ whose value is fixed at 0.7. This is calculated using another entropy distribution system as depicted in (4). Here, $p(\sigma_i)$ is the conditional probability of the variance score. Based on this structure if $L_T(\sigma) > H(\sigma) \rightarrow$ Implicit sarcasm else it is explicit sarcasm.

$$H(\sigma) = -\left(\sum_i \left(p(\sigma_i)\log\left(p(\sigma_i)\right)\right)\right) = 0.7 \quad (4)$$

IV. Results and Discussion

The proposed model has been compared with the existing state-of-the-art methods on Dataset-1 and 2 respectively. These methods are Bi-LSTM [1], Pattern Based Approach (PBA) [2], RoBERTa+XLNet [6], BERT [7], Neuro-Fuzzy Set (NFS) [8], KnowleNet [4], RCNN+RoBERTa [9] and Ensemble Neuro Fuzzy Method (ENFM) [5] are used to analyze performance evaluation on the two datasets.

A. Dataset Description

The authors created and assessed two datasets of online comments from Twitter [16], News headlines [3], and Reddit [17] datasets for sarcasm detection and other multitasking functions. Dataset-1 involves an aggregate of 7,776 comments, with 3,618 sarcastic and 4,158 non-sarcastic remarks. Dataset-2 encompasses 6,237 records, with 2,698 sarcastic and 3,539 non-sarcastic headlines.

B. Performance Indicators

In order to evaluate the effectiveness of our model's use of the confusion matrix, which includes True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN) values, while other indicators utilize such as Accuracy (A), Precision (P), Recall (R), and F1 score (F1), refer to (5)–(9). It acts as the entity's primary criteria for tasks associated with classification.

$$A = \frac{TP+TN}{TP+TN+FP+FN} \quad (5)$$

$$R = \frac{TP}{TP+FN} \quad (6)$$

$$P = \frac{TP}{TP+FP} \quad (7)$$

$$F1 = \frac{2 \times P \times R}{P+R} \quad (8)$$

$$MCC = \frac{(TP \times TN) - (FP \times FN)}{\sqrt{(\mathrm{TP+FP}) \times (\mathrm{TP+FN}) \times (\mathrm{TN+FP}) \times (\mathrm{TN+FN})}} \quad (9)$$

For Dataset-1 and 2, the simulation model received an accuracy score of 95.57 and 95.23, respectively. These findings outperform those of earlier research on recognizing sarcasm. The analysis table also compares the Matthews Correlation Coefficient (MCC) on Dataset-1 and Dataset-2, as well as accuracy, precision, recall, and F1 score. On two different datasets, we evaluated our proposed approach alongside other predetermined models, and we thoroughly compared our results to state-of-the-art methods. The results shown in TABLE I and II convincingly show how well our suggested strategy performs. Particularly, with rates of 91.44 and 90.63, respectively, the correctness of Matthews Correlation Coefficient (MCC) scores demonstrates considerable gains over the two sets of data.

TABLE III. CONFUSION MATRIX OF SARCASM DETECTION ON DATASET-1 AND 2 RESPECTIVELY

Proposed Method	No. of sentences	TP	TN	FP	FN
Identifying sarcasm on Dataset-1	7776	3599	3833	325	19
Identifying sarcasm on Dataset-2	6237	2662	3278	261	36

When our proposed algorithm is compared to BERT and transformer-based methods like RCNN+RoBERTa and KnowleNet, its effectiveness becomes very clear. Our strategy successfully beats existing well-known techniques across a range of measures. Our paradigm is strengthened even more by the inclusion of a speaker vocabulary as well as sentiment and emotion embeddings. Notably, none of these improvements result in a negative rise in processing time. The revised situation best highlights our advantages. In essence, our work revolves around the proposition of an unsupervised mathematical optimization methodology for textual sarcasm detection. The confusion matrix for Dataset-1 and 2 is shown in TABLE III. This confusion matrix lists the samples of sarcasm and non-sarcasm that are present in datasets. These improvements substantially enhance the functionality of current models while having little to no effect on computing speed.

A linear trendline for the suggested framework on Dataset-1 and 2 is shown in Fig. 2 and 3 as the best-fit straight line for the linear analysis of the data. A straight trendline shows that the accuracy, precision, recall, and F1 score for the proposed technique on both datasets are all increasing gradually. Across two datasets with accuracy scores of 0.9557 and 0.9523, respectively, it consistently rose over the prior level. This shows the ability of the dashed line's fit to the data is good given the monotonic increase in the methodology's initial settings.

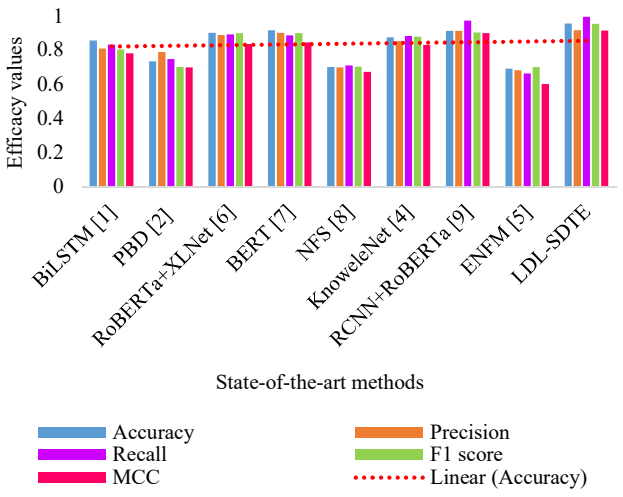

Fig. 2. Comparison graph of proposed model (LDL-SDTE) with the predefined models on the Dataset-1

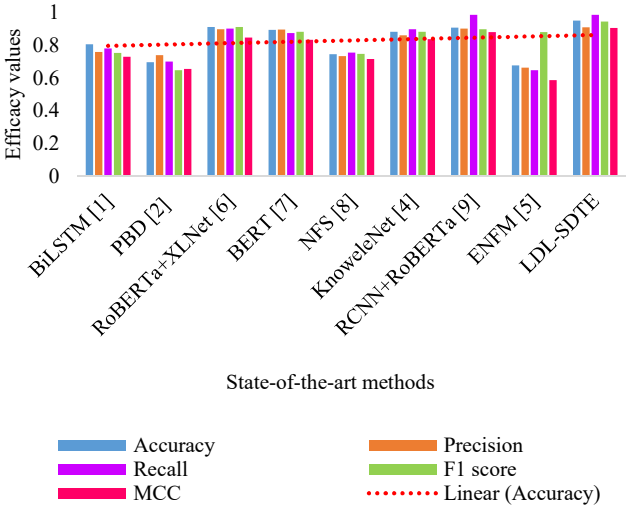

Fig. 3. Comparison graph of proposed model (LDL-SDTE) with the predefined models on the Dataset-2

The statistical validation of the proposed model is confirmed by consistent accuracies observed across a sample of datasets. The validity of the results is assessed using a z-test proportion, as depicted in Fig. 4. This indicates that the proposed model, LDL-SDTE, consistently achieves accurate results when applied to various datasets. The time complexity of the algorithm can be approximated as $O(n)$, where 'n' represents the number of sentences being processed for sentiment and emotion analysis. Concluding, we affirm that the time complexity of the proposed model primarily depends on the number of sentences, 'n' that are being analyzed for sentiment and emotion helps in sarcasm detection.

V. CONCLUSION AND FUTURE WORK

This paper proposed a novel algorithm, called LDL-SDTE, which is designed to detect sentiment, emotion, sarcasm, and offensive language in online comments on social networking sites. The model is formulated to identify and categorize instances of subjective emotional sarcasm that include foul language it. To improve sarcasm detection performance, the proposed algorithm involves optimized mathematical formulations. The results of the proposed model LDL-SDTE demonstrate the superiority of the algorithm compared to other existing models. This highlights its enhanced detection capabilities and nuanced categorization. For future research in the enhancement of the proposed model performance, we explore the integration of word embeddings and the use of ensemble language models. These defined refinements have the potential to improve the algorithm's effectiveness and contribute to its ongoing development for future applications.

***Abstract*— The impact of work function variation on Dual Material Gate Oppositely Doped Core-Shell Junctionless Nanowire FET (DMG-ODCS-JLNWFET) is explored in this paper. The variation in surface potential, electric field, band energy, drain current (I_D), leakage current (I_{OFF}), subthreshold slope (SS), transconductance (g_m), and switching ratio (I_{ON}/I_{OFF}) are analyzed. The performance of DMG-ODCS-JLNWFET is also compared with Single Material Gate (SMG) ODCS-JLNWFET. The results demonstrate that the proposed device shows significant advancements, boasting improvements of 18.9%, 73.7%, 26.8%, and 10.8% in I_D, I_{OFF}, g_m, and SS respectively when compared to SMG-ODCS-JLNWFET. These noteworthy enhancements underscore the device's exceptional suitability for both analog and digital applications within the confines of nano-scale dimensions.**

Keywords— Core-Shell (CS), Dual material Gate (DMG), Nanowire FET (NWFET), Work function.

I. INTRODUCTION

The notable Short Channel Effects (SCEs) observed at scaled dimensions are a consequence of ineffective gate control and physical restrictions in achieving ultra-scaled dimensions. This has surpassed the capabilities of traditional planar Field Effect Transistors (FET), prompting researchers to redirect their attention towards multiple-gate 3-D topologies, particularly Nanowires FET (NWFET), as the prospective foundation for technologies [1]. However, it faces major hurdles in achieving an ultra-sharp doping gradient at the junction during fabrication [2]. Considerable research efforts have been dedicated to exploring flexible organic devices, primarily due to their cost-effective fabrication process and their capacity to operate effectively at lower temperatures. Despite these advantages, the reliability of organic devices poses a notable challenge, making them less suitable for applications requiring high-speed analog and digital functionalities [3], [4].

Junctionless Nanowire FET (JLNWFET) has emerged as a noteworthy alternative exhibiting a low thermal budget during the manufacturing process due to a lack of p-n junctions [5]. Furthermore, to achieve better electrostatic control of gate voltage over the channel, Junctionless Transistors (JLTs) have also embraced cylindrical architecture [6]. Despite several advantages, the high doping concentration inherent in JLNWFET introduces challenges, notably resulting in reduced carrier mobility, leading to low ON-state current (I_{ON}) and transconductance. Additionally, insufficient volume depletion and electron tunneling during OFF-state contribute to an increase in leakage current. The incorporation of an oppositely doped core within the Core-Shell (CS) architecture of JLNWFET helps in volume depletion in the OFF state which tends to reduce I_{OFF} [7], [8]. In 2014, Lee *et al.* [9] demonstrated the feasibility of CS-JLNWFET marking the first experimental validation of the innovative approach. Previously, multiple researchers have employed Dual Material Gate (DMG) to improve carrier mobility and mitigate the impact of SCEs by altering the channel potential and electric field distributions as compared to Single Material Gate (SMG) devices [10]-[13].

The DMG architecture comprises two gate materials, M_1 and M_2, characterized by distinct work functions Φ_{M1} and Φ_{M2}, with the condition $\Phi_{M1} > \Phi_{M2}$ [10]. To harness the benefits of DMG in conjunction with an oppositely doped core-shell structure, a novel device structure named Dual Material Gate Oppositely Doped Core-Shell (DMG-ODCS) JLNWFET is proposed in this paper. Moreover, the effect of workfunction variation of M_2 (Φ_{M2}) by keeping Φ_{M1} constant, on the performance of the DMG-ODCS-NWFET device. One challenge associated with implementing work function variation in practical device fabrication is the reliance on the DMG approach. This method utilizes a single Reactive Ion Etching (RIE) process to pattern dissimilar gate metals simultaneously, ensuring high selectivity to the ultrathin gate dielectric. An alternative method entails leveraging molybdenum (Mo) as a commonly utilized gate material, with its work function susceptible to adjustment through careful control of nitrogen implantation within the Mo substrate, offering a potential avenue for achieving desired work function variations in devices [14], [15].

This paper is systematized into four sections, commencing with Section I, which serves as the introduction. In Section II, a detailed account of the device structure parameters is presented. Section III is dedicated to presenting the results and facilitating a comprehensive discussion, which includes a comparative analysis between the proposed device and SMG-ODCS-JLNWFET. The final section, Section IV, encapsulates the conclusion drawn from the analysis and findings presented throughout the paper.

II. DEVICE STRUCTURE

The devices are simulated using the SILVACO TCAD simulator [16]. A 3-D view of the proposed DMG-ODCS-JLNWFET device is presented in Fig. 1 (a) whereas its 2-D schematic view is illustrated in Fig. 1 (b). Additionally, a 2-D cross-sectional view of SMG-ODCS-JLNWFET is depicted in Fig. 2. Table I provides the structural parameters of both devices. These parameters are chosen as per experimental work [17]. The channel thickness (t_{si}) of DMG-ODCS-JLNWFET is given as [7]

$$t_{si} = (2 \text{ X } t_{shell}) + t_{core} \quad (1)$$

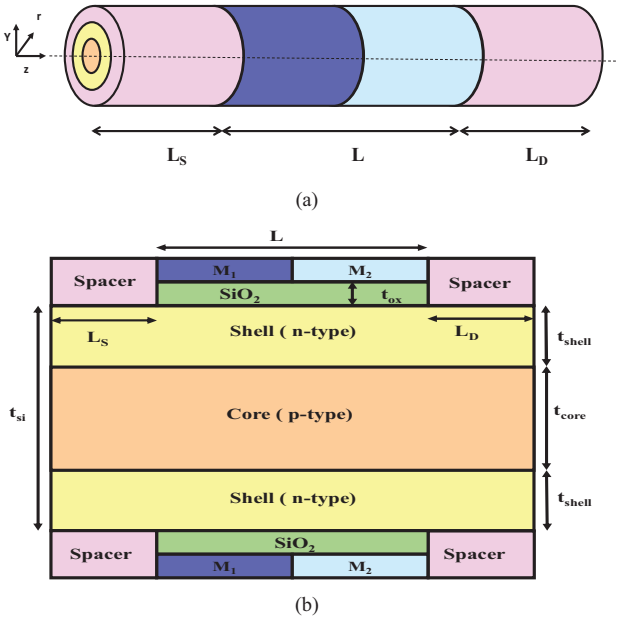

Fig. 1. (a) 3-D and (b) 2-D view of DMG-ODCS-JLNWFET.

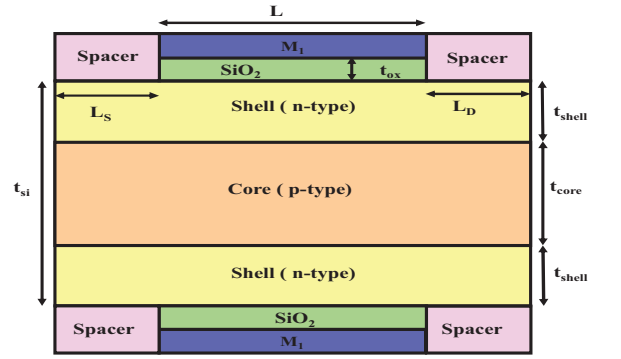

Fig. 2. 2-D cross-sectional view of SMG-ODCS-JLNWFET.

TABLE I. DEVICE PARAMETERS

Parameters	SMG-ODCS-JLNWFET	DMG-ODCS-JLNWFET	
Channel Length, L (nm)	60	L_{M1}	L_{M2}
		30	30
Channel thickness, t_{si} (nm)	20	20	
Length of S/D, L_S/L_D(nm)	1	1	
Gate work function (eV)	5.1	M_1	M_2
		5.1	4.2 - 5.0
Channel doping, N_D (cm^{-3})	1 X 10^{19}	1 X 10^{19}	
Core doping N_A, (cm^{-3})	1 X 10^{19}	1 X 10^{19}	
Gate oxide thickness, t_{ox} (nm)	25	25	

The HfO_2 serves as the spacer material. The default ATLAS TCAD models are calibrated with the experimental results documented in [18] for V_{DS} = 1 V. Fig. 3 visually represents the corresponding outcomes. These models incorporate carrier mobility models that are contingent on both the electric field and carrier concentration.

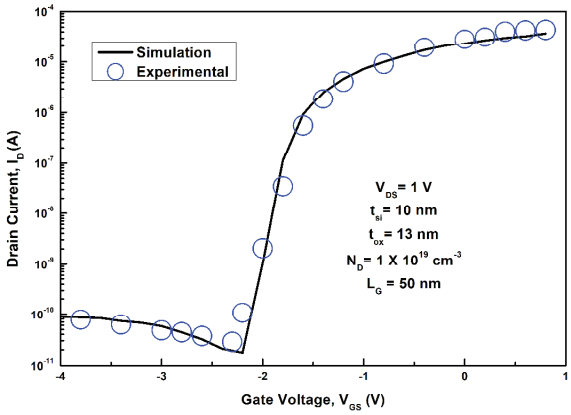

Fig. 3. Simulation models calibration with the experimental work reported in [18].

The non-local BTBT model is employed to account for electron tunneling. Additionally, the Lombardi CVT model and BGN model are activated. Gummel and Newton methods are employed to derive numerical solutions. To address recombination effects, SRH and Auger recombination models are accommodated.

III. RESULTS AND DISCUSSION

To investigate the influence of work function variation on the performance of DMG-ODCS-JLNWFET, Φ_{M1} is kept at 5.1 eV and Φ_{M2} is varied from 4.2 eV to 5.0 eV. The corresponding results are compared with SMG-ODCS-JLNWFET. The illustration of surface potential, electric field and energy band diagram is implemented by taking a horizontal cutline at 1 nm below the oxide-channel interface in the SILVACO TCAD simulator. The potential of DMG-ODCS-JLNWFET with varied Φ_{M2} and SMG-ODCS-JLNWFET along device length is demonstrated in Fig. 4. In the DMG-ODCS-JLNWFET, a noticeable enhancement in the transition at the interface of two gate materials becomes more pronounced with a decrease in Φ_{M2}. This abrupt change is caused by gate work function difference ($\delta\Phi = \Phi_{M1} - \Phi_{M2}$). The electric profile of DMG-ODCS-JLNWFET displays an additional peak, attributed to the abrupt transition in its potential profile, as depicted in Fig. 5.

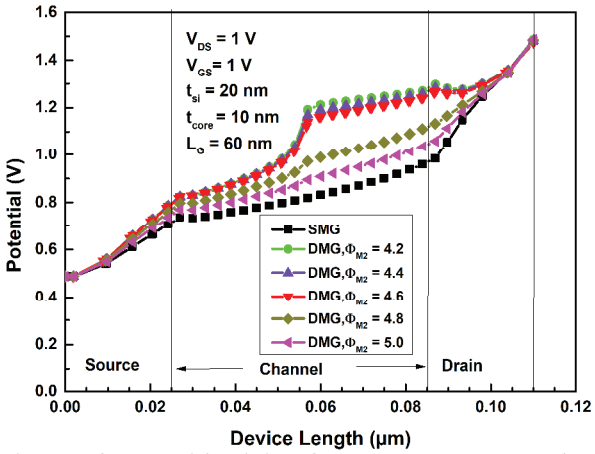

Fig. 4. Surface potential variation of DMG-ODCS-JLNWFET and SMG-ODCS-JLNWFET along device length.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 22,2024 at 05:59:42 UTC from IEEE Xplore. Restrictions apply.

Due to the potential abruptness in Fig 4, the DMG-ODCS-JLNWFET exhibits two electric field peaks at the M1 and M2 interfaces. These supplementary electric field peaks, situated near the source region, accelerate the movement of electrons within the channel, consequently boosting the drain current. As Φ_{M2} is increased up to 4.6 eV in the DMG-ODCS-JLNWFET, the electric peak near the source region experiences a rise, influencing the carrier mobility within the channel [10]. Beyond this point, the increase becomes marginal. Furthermore, the electric peak degrades with the increase of Φ_{M2} near the channel-drain region which tends to decrease the tunneling of electrons during the OFF state.

Fig 6. exhibits the influence of work function variation on the energy band diagram of DMG-ODCS-JLNWFET. The observation indicates that an increase in Φ_{M2} results in the bending of the Conduction Band (CB) and Valence Band (VB). This pronounced band bending has enhanced the tunneled width, thereby significantly reducing electron tunneling at the interface between the channel and drain. The transfer characteristic of DMG-ODCS-JLNWFET with varying Φ_{M2} and SMG-ODCS-JLNWFET is exhibited in Fig.7. It is observed that drain current (I_D) increases as Φ_{M2} decreases till 4.6 eV beyond which there is marginal enhancement due to improved carrier mobility in the channel as explained in Fig. 5.

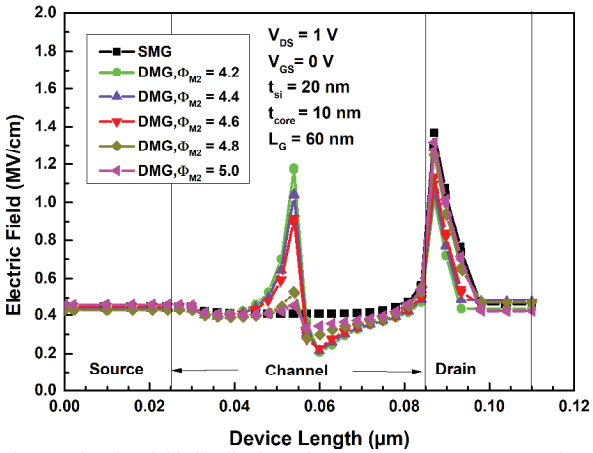

Fig. 5. Electric Field distribution of DMG-ODCS-JLNWFET and SMG-ODCS-JLNWFET along device length.

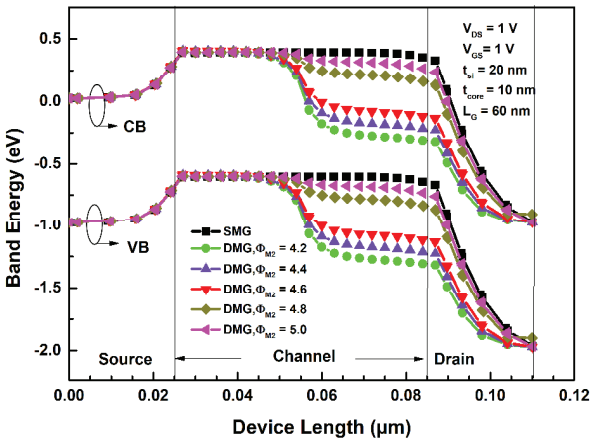

Fig. 6. Band energy profile of DMG-ODCS-JLNWFET and SMG-ODCS-JLNWFET along device length.

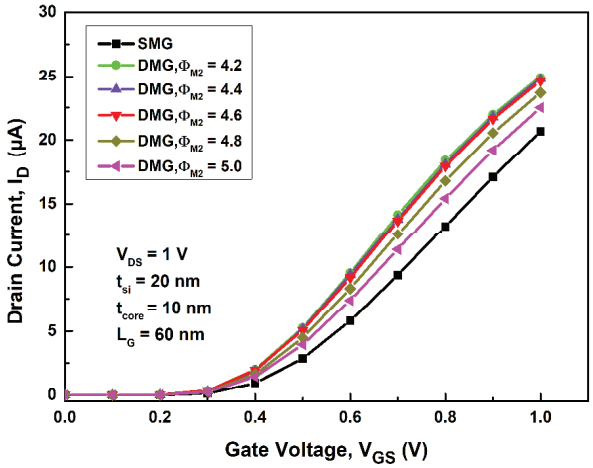

Fig. 7. Transfer characteristics of DMG-ODCS-JLNWFET and SMG-ODCS-JLNWFET with variation of Φ_{M2}.

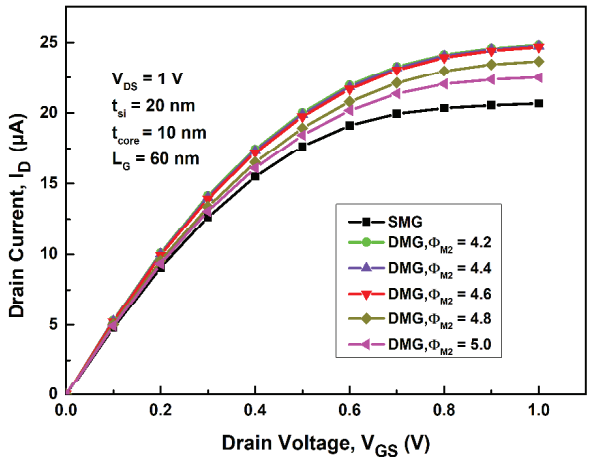

Fig. 8. Output characteristics of DMG-ODCS-JLNWFET and SMG-ODCS-JLNWFET.

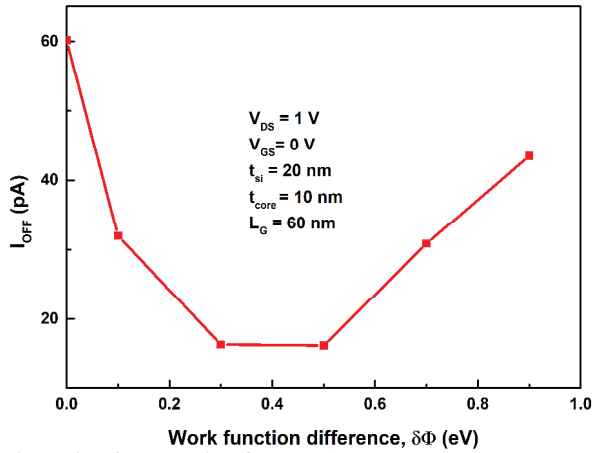

Fig. 9. Plot of I_{OFF} at various δΦ.

Furthermore, an enhancement of 20.8% in I_D is observed in DMG-ODCS-JLNWFET as compared to SMG-ODCS-JLNWFET when Φ_{M2} is varied from 5.0 eV to 4.2 eV. Fig. 8 illustrates the influence of work function variation on the output characteristics of DMG-ODCS-JLNWFET and SMG-ODCS-JLNWFET. It is perceived from the plot that I_D increases in DMG-ODCS-JLNWFET as Φ_{M2} decreases due to improved carrier mobility as compared to SMG-ODCS-JLNWFET. In Fig. 9, I_{OFF} with varying δΦ is plotted where

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 22,2024 at 05:59:42 UTC from IEEE Xplore. Restrictions apply.

$\delta\Phi$ = 0 corresponds to SMG-ODCS-JLNWFET. It is observed that I_{OFF} decreases with increasing workfunction difference due to an enhancement in tunneling width as discussed in Fig. 6. However, when the $\delta\Phi$ surpasses 0.5 eV, the increase in I_{OFF} becomes more prominent, attributed to the increased SCEs. Additionally, a notable reduction of 27.7% is evident in DMG-ODCS-JLNWFET compared to SMG-ODCS-JLNWFET when Φ_{M2} undergoes variation from 5.0 eV to 4.2 eV. The Switching Ratio (I_{ON}/I_{OFF}) as a function of $\delta\Phi$ is demonstrated in Fig. 10. This metric is crucial in evaluating the performance of electronic devices, particularly in digital applications. This is formulated as [8]

$$\frac{I_{ON}}{I_{OFF}} = \frac{I_{DS} \text{ at } V_{DS} = 1 \text{ V and } V_{GS} = 1 \text{ V}}{I_{DS} \text{ at } V_{DS} = 1 \text{ V and } V_{GS} = 0 \text{ V}} \quad (2)$$

As $\delta\Phi$ begins to rise, the I_{ON}/I_{OFF} ratio enhances due to the simultaneous reduction in I_{OFF} and enhancement in I_{ON}, as previously discussed. However, when $\delta\Phi$ exceeds 0.5 eV, there is only a marginal increase in I_D, and I_{OFF} begins to rise. Consequently, the I_{ON}/I_{OFF} ratio decreases during this phase. The dependence of the Subthreshold Slope (SS) on the work function variation is presented in Fig.11. It is referred to as [18]

$$SS = \frac{\partial V_{GS}}{\partial \log_{10}(I_D)} \quad \text{mV/decade} \quad (3)$$

SS starts to degrade when $\delta\Phi$ surpasses 0.5 eV due to the reduction of I_{OFF}. Fig. 12 illustrates the transconductance (g_m) as a function of V_{GS} of SMG-ODCS-JLNWFET and DMG-ODCS-JLNWFET at various Φ_{M2}. The ability to modulate g_m is crucial in determining the efficiency of the transistor in signal processing and amplification applications. The g_m is expressed as [12]

$$g_m = \frac{\partial I_D}{\partial V_{GS}}\Big|_{V_{DS}=\text{constant}} \quad (4)$$

The graph illustrates a 23.8% improvement in g_m of DMG-ODCS-JLNWFET as Φ_{M2} decreases to 4.2 eV as compared to SMG-ODCS-JLNWFET. This enhancement is attributed to the superior drain characteristics exhibited by DMG-ODCS-JLNWFET.

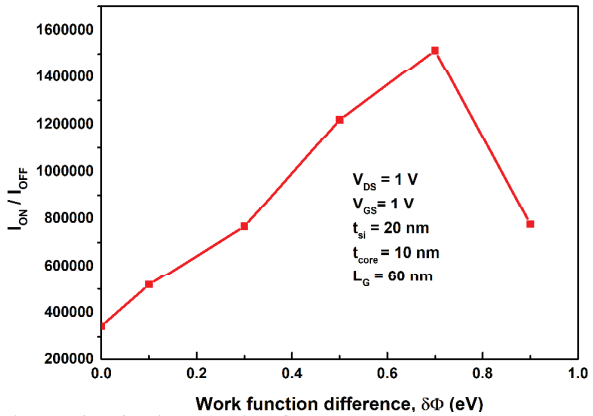

Fig. 10. Plot of I_{ON}/I_{OFF} at various $\delta\Phi$.

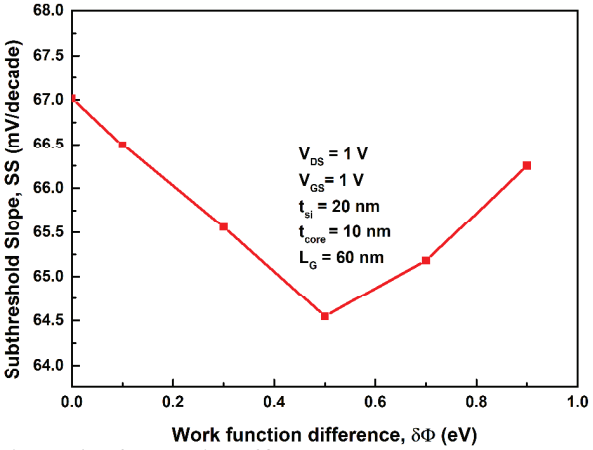

Fig. 11. Plot of SS at various of $\delta\Phi$

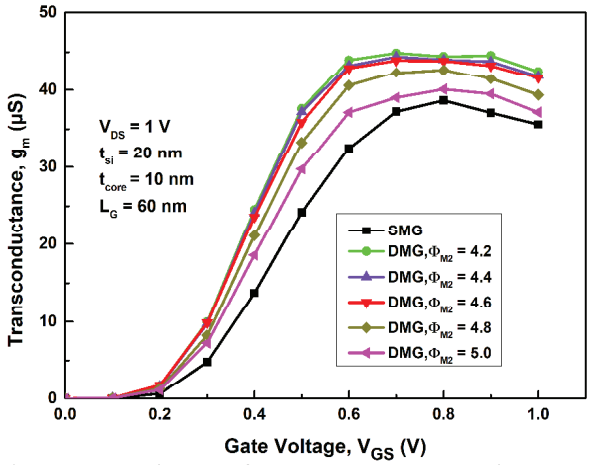

Fig. 12. Transconductance of DMG-ODCS-JLNWFET and SMG-ODCS-JLNWFET with variation of Φ_{M2}.

TABLE II. THE PERFORMANCE COMPARISON OF THE PROPOSED DEVICE WITH OTHER DEVICES

Device	L (nm)	SS (mV/dec)	I_{ON} (μA)	I_{OFF} (μA)	I_{ON}/I_{OFF}
JL-BS-Tapered FinFET [19]	14	68.65	2.15	2.08 X 10^{-9}	1.03 X 10^{9}
JGAA [20]	20	66.43	12	7.3X 10^{-7}	1.6 X 10^{6}
Cylindrical Gate-all-around JLFET [21]	30	73.25	20	3.05 X 10^{-4}	6.58 X 10^{4}
Proposed Device	60	64.8	24.5	1.68 X 10^{-5}	1.81 X 10^{6}

The aforementioned analysis underscores the superior performance of DMG-ODCS-JLNWFET in comparison to SMG-ODCS-JLNWFET across various key parameters such as I_D, I_{OFF}, I_{ON}/I_{OFF} ratio, SS, and g_m. Additionally, a comprehensive exploration of internal device characteristics, including potential, electric field, and band energy, have been presented to offer a clear insight into the underlying device physics. Notably, the extracted values of I_D, I_{ON}/I_{OFF}, I_{OFF}, SS, and g_m for DMG-ODCS-JLNWFET exhibit enhanced performance at Φ_{M1} = 5.1 eV and Φ_{M2} = 4.6 eV when compared to SMG-ODCS-JLNWFET. The performance of the proposed device in this paper is further compared with

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 22,2024 at 05:59:42 UTC from IEEE Xplore. Restrictions apply.

other reported devices as illustrated in Table II. The smaller value of SS and higher value of I_{ON} highlight the utilization of DMG-ODCS-JLNWFET for both digital and analog applications, showcasing its potential for advanced semiconductor device applications.

IV. Conclusion

This paper explored the impact of workfunction variation of DMG-ODCS-JLNWFET device, focusing on a 60 nm channel length. The results revealed that the DMG-ODCS-JLNWFET outperformed the SMG-ODCS-JLNWFET device regarding overall performance by modulating the work function of gate material. Consequently, the proposed device exhibited an improvement of 18.9%, 73.7%, 26.8% and 10.8% in I_D, I_{OFF}, SS, and g_m, respectively $\Phi_{M1} = 5.1$ eV and $\Phi_{M2} = 4.6$ eV when compared to SMG-ODCS-JLNWFET demonstrating its excellent suitability for analog and digital application in nano-scale dimensions.

ARTICLE INFO

ABSTRACT

Visual Culture envisages a trajectory of creations with information, visual styles, concepts and practices by both the makers and receivers. This paper presents the applications of popular cognitive theories during the information visualization stage followed by the graphic design students in the course of Documentation of Visual Culture at a design school in India. The baseline approach in the course has been to impart the theories and models from the fields of information visualization, cognition, history, social space and visual imagery. The course contributes a conceptual framework of 5-Pillars of Cognition: 1) What and How to Observe, 2) How to See, 3) How to Read, 4) How to Plan a Theme and 5) How to Create a Visual Language for a Visual Space/Culture. Each student applied these five pillars along with the theories of cognitive semiotics to form, reform and transform the documentation designs. The research methodologies tap the styles and trends in the context of readers' preferences, social milieus and the linked technological scenarios. Designs showcase the styles in documentations with respect to the information content, readers, social milieus, heritage scenarios and communication. The insights articulate the rationale behind preserving form-content associations in the visual culture themes.

Keywords: Cognition theories, Conceptual framework, Documentation, Visualization, Semiotics, Visual Culture

Introduction

The field of cognition with semiotics[1] is a trans-disciplinary field that integrates methods and theories developed in the disciplines of cognitive science with methods and theories developed in humanities. The aim is to provide new insights into the realm of information perception, human signification and manifestation in cultural practices. Practice is not viewed as a 'context for' but as constitutive and constituent of the cognitive process itself. It is a constitutive aspect of all forms of thinking, from the simplest to the most complex (Trasmundi and Toro, 2023; Böhme et. al., 2022; Poizat, et. al., 2022).

At a systemic scale, semiotic interactions include specific media channels, with the term 'medium' understood in its broadest sense, including bio-entities along with artefacts and technologies that can be material, and thus physically perceived by humans and animals, but also digital, which can lie beyond the scope of perception (López-Varela Azcárate, 2022). Cognition and thinking approaches utilize the use of language in communicating the surrounding social situations involving senders and receivers in the circle of information dissemination, reception and retrievals. This makes up for the fundamental premise of a two-way communication for meaning making in information studies. In context of this objective, the present paper highlights the learning experience that aimed to capture how the visual language developments based on cognitive thinking could become instrumental in crafting a visual experience of cultures, spaces and people associated in the documentation designs done by the undergraduate graphic design students, 2018 -19 at the respective national institute in India.

Visualization and cognition in everyday life helps in building a continuous experience to draw things together, decipher meanings and their essential role in developing a language that undergoes transitions over time. Taking this as a guiding light to document novel experiences of visual media in a hybrid of texts, images, and sounds became the vision for the course of Documentation of Visual Culture [DVC] in the academic year of 2018 – 2019 as full 3-week units, 6.0 credits continuous education module. The course gave design students opportunities to build and communicate the identity, processes and meaningful perspectives that unpack a range of themes of visual culture in India (Figure 1). For instance, the story of the sawantwadi wooden toys from Maharashtra, India visual documentation contains detailed process involved in the making of these special sawantwaadi wooden toys through illustrations and pictures – clicked by the student himself as part of the fieldwork done in the city of Mumbai. Inclusive from all aspects; the book emphasizes its special place and/or use by children. They get an opportunity to make theor own toys in the instructions provided in the ending sections of the documented book – using cut-outs and easy dismantling of pop-up shapes. For parents and their children as primary users, this documentation invites participatory design approach in the most playful and experiential way (Figure 1 and 2). Of all the documented books,oOnly one DVC documented publication covered a global trend in a foreign city as a theme of visual culture as part of the course (Figure 7).

Figure 1. Sawantwadi Toys theme from Maharashtra, India (left) and Chitrakaar making the Pattachitra Art with Techniques from Odisha, India (right) © 2018-19 course documentation by Author Name (hidden for peer review).

Sawantwadi is famous for its art and culture, popularly known for Ganjifa playing cards and wooden toys made from mango tree. The craft is traditionally done by the Chitari or Chitrakar community recognized by the king. These communities migrated from Karwada and settled in Sawantwadi. These families survived mainly by supplying handicrafts items to the royal families. Later other communities also adopted this craft because of its commercial success. Queen Satwasheela Devi continues the tradition even today, where many of the families are involved in Ganjifa cards and wooden toys making. The toys have been made by assembling all parts to shape solid wood. Seasoned mango wood is chiseled or carved into desired toy shape. These examples have been the practice-driven content covered in the dvc documentation by the student (Figure 1 and 2).

Figure 2. Sawantwadi Toys documented visual culture theme from Maharashtra, India (left and right), © 2018-19 course documentation by Author Name (hidden for peer review).

India is a cultural melting pot of visually rich cultural identities, events, festivals, customs, arts, crafts, practices, etc. To deconstruct with a novel lens this rich visual culture in India, the present paper presents the course of DVC and the research methodologies applied by the graphic design students developed applied learnings around visualization and cognitive semiotics.

Course Relevance

This course is important in the context of changing societal and technological scenarios. Visual approaches in everyday life has been changing frequently. In this context, documentation of special experiences around marked visual culture and the themes – that imbibes visual media in a hybrid as texts, images, analog

techniques and tactile surfaces; sound symbolisms, etc. as part of the course has been aimed to offer graduation students of graphic design to build rich, multi-perspective points of view of a range of themes as part of visual culture as a field of depth study and documentation.

Course Objectives

- To provide understanding of visual sensibility in connection to several aspects - personal, national, ethnic.
- To provide understanding of strategic analysis on cultural visual forms.
- To understand the Rhetoric of the Image.[2] Rhetoric is a creative means to design and organize discourse in order for it to be persuasive but not manipulative (D'Armenio, 2022; Greco and Mazzalli-Lurati, 2022; Barthes, 1988).
- To understand comparison with popular visual culture for attention and traditional Visual cultures.
- To understand the image making in context of everyday life experiences.

Teaching Methodology and Course Detailing

1) Instructional Process

- Lectures/ sessions included visual media-based presentations describing striking visual culture theories, models and concepts with respect to communication design, cognitive semiotics, visualization and publication designed for visual cultures. The specific aim helped teacher-learner as well as student-learners to plan and develop researched visual strategies for the creation of distinctive and reader-friendly documentations as part of the larger outcome-based education approach aided by the Bloom's taxonomy model.
- Demonstrative modes of orientating the students' batch to different and innovative ways of book binding, formats involved and the suitable fusion of printing methods have been imparted. The resulting documentations took those inputs as practice-based prompts at different stages of the ideation of final dvc documentations.

2) Student-centric approach

- The teacher-learner as well as each student-learner interacted over a series of studio-based feedback sessions by displaying parts of the dvc documents crafted by the student learners' for continuous evaluations and review feedback sessions organized three times (each time per week unit) by the teacher-learner in the total of 3 week units allotted for the course instruction.
- Honing of specific analog and digital techniques by student-learners'; alongwith participatory design approaches were a springboard for out-of-the-box ideas and final identity of the documentations designed by each student. Students' coordination of the head, the heart and the hand became unique, with respect to the strength of hand skills alongwith other soft skills of designing and representing 'content' alongwith 'form' for new meaning-making (in the context of cognitive semiotics).

Theories and Models of Cognition, Semiotics and Visualization

Generally, Cognition alongwith semiotics Semiotics has been a transdisciplinary study that comprises modes of meaning-making, applications of methods and theories from semiotics, linguistics, psychology, cognitive science, computational modeling, anthropology, philosophy and other sciences. Cognition entails complex networks of biological processes and actions that encompass perception, attention, manipulation of objects, memory mechanisms, and the formation of knowledge by means of direct experience as well as by learning from others, for which forms of communication and comprehension are also necessary. It has often been assumed that one but not both of these two types of representations underlie processing in specific domains of cognition – for instance, perception, mental imagery, and language (Kaup, et. al, 2023; Azcárate, 2022). Participatory sense-making – a cognitive act of humans during interactions with the 'medium', addresses how our intersubjective interactions enter into meaning constitution as well as co-constitution of a meaningful world. It provides an answer to the question: How do we, together, interacting with each other, constitute the meaning of the world? (Gallagher, 2023; Shapiro and Spaulding, 2021).

Within the purview of DVC course objectives that imbibed a Special Focus within the context of Visual Cultures and Visual Language Developent(s) with Communication as the raison d'être; Cognitive Semiotic Theories and Models were selectively collated, analyzed and implemented in the final print publication designs submitted for the DVC course documentations. Following are the prime theories and models applied by students in their DVC documents:

1) *Theory of the Actions of Signs and the Dialogical Model of Interspecific Communication*

Defined as the 'action of signs', semiotics has recognized the 'inter-actions' and 'intra-actions' of anything acting as a sign; present also within the framework of the 4Es -Embodied, Embedded, Enacted and Extended. The E-fields share the view, after all, that the brain-centrism of traditional cognitive science, as well as its dependence on the computer for inspiration, stands in the way of a correct understanding of cognition (Azcárate, 2023; Konderak, 2021; Shapiro and Spaulding, 2021). At a systematic scale, semiotic interactions

[2] Barthes, Roland, "The Rhetoric of the Image", from Image - Music - Text. Sei. and Trans. Stephen Heath. In: *Elements of Semiology*. New York: Hill and Wang, 1,977.32-51, (1977): 160-163.

include specific media channels, with the term 'medium' understood in its broadest sense, including bio-entities along with artifacts and technologies that can be materials, and thus physically perceived by humans and animals (Figure 3), but also digital, which can lie beyond the scope of perception.

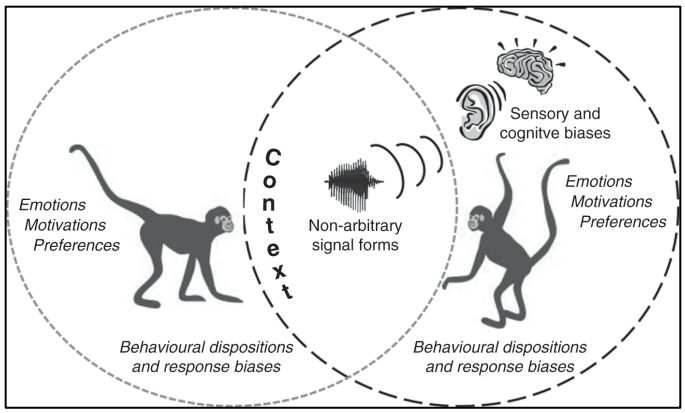

Figure 3. The Dialogical Model of Interspecific Communication © 2013 Drew Rendall and Michael J. Owren. Source: Drew Rendall and Michael J. Owren, "Communication without meaning or information: Abandoning language-based and informational constructs in animal communication theory," *Animal Communication Theory: Information and Influence,* ed. Ulrich Stegmann © Cambridge University Press 2013, pp.173, http://dx.doi.org/10.1017/CBO9781139003551.010

2) *Bio-cultural theory and the Semiotic Hierarchy model*

There has been an attempt made to define a unified bio-cultural theory of meaning and lay context of Cognitive Semiotics for developing later hierarchical models (Wiggins, 2020; Silvera-Roig, 2020; Zlatev, 2019). One of the models expresses that:

"Our conception of meaning has become increasingly fragmented, along with much else in the increasing post modernization of our worldview. The trenches run deep between different kinds of meaning theories: mentalist, behaviourist, (neural) reductionist, (social) constructivist, function- a list, formalist, and computationalist deflationist... And they are so deep that a rational debate between the different camps seems impossible. The concept is treated not only differently but incommensurably within the different disciplines."

The Semiotic Hierarchy: that each subsequent level somehow replaces the earlier one(s), for instance, a (minimal/enculturated/linguistic) self is independent of the 'underlying biological self', the organism (Mendoza-Collazos, et. al., 2021; Mendoza-Collazos, 2020). This model represents an affinity with 'layered models' of development with each higher level subsuming earlier ones (Figure 4).

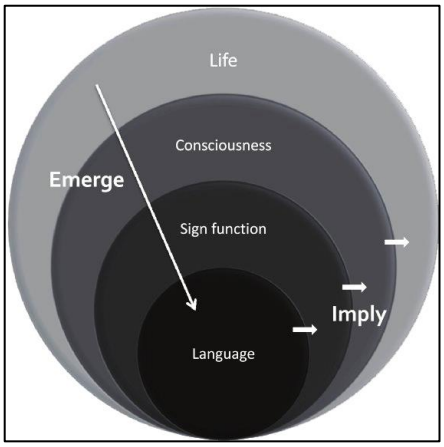

Figure 4. The Semiotic Hierarchy Model © 2009 Jordan Zlatev. Source: Jordan Zlatev, "The Semiotic Hierarchy: Life, consciousness, signs and language," *Cognitive Semiotics*, no. 4 (Spring 2009), pp. 189 https://doi.org/10.3726/81608_169

Research Methodology

Students' secondary research-based design language developments of their document designs envisaged applied learnings from two methodologies, namely: Phenomenology and Field Work. These applied learnings helped build the building blocks of a conceptual framework of reference to guide final ideations of a publication form for each documentation of visual culture per student.

Phenomenology or the systematic study of lived experience(s)

Phenomenology is grounded in certain traditions of philosophy and the humanities, and that aims to reflect on pre-reflective human experience (Manen, 2023; Mendoza-Collazos and Zlatev, 2022; Køster and Fernandez, 2021; Vasterling, 2021; Stew, 2020). In this course, the students have applied the phenomenological methods of qualitative data collections in their fieldworks on selective visual cultures - that helped them accumulate their self-experiences of the history, material culture, social spaces, visualizations and cognitions (Figure 5 and 6). Individual students and quick orientations did fieldwork and warm-up exercises were given to students (Figure 4 and 5).

A brief collection of the ways of doing fieldwork were imparted to students covers following (in a nutshell):

- How people navigate to witness a visual culture?
- How and what to observe as they navigate?
- How to design a visual language for a given space incorporating the visual culture?
- What codes govern a special visual language to communicate that visual culture?
- What discourses are happening in these spaces of special visual culture themes?
- How a public interest gets constructed around a visual culture theme?
- Why is it important to consider this public interest in final DVC documents?

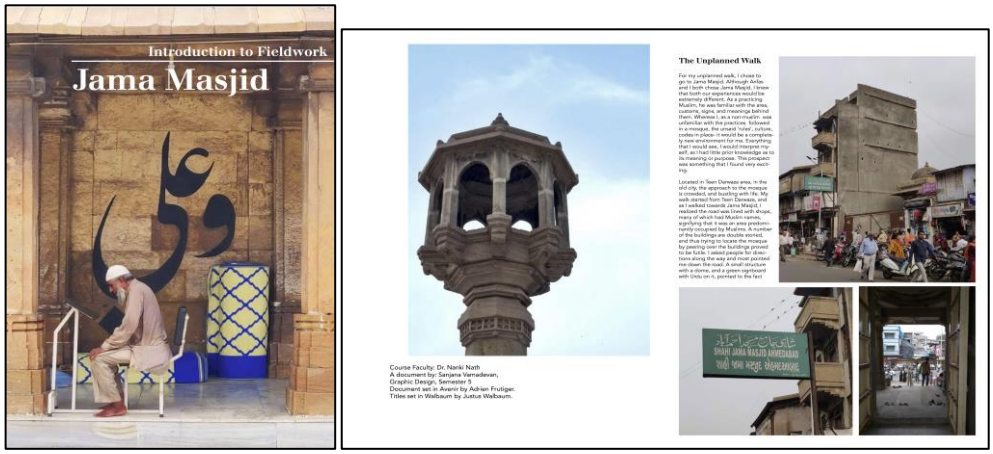

Figure 5. DVC documentation cover (left) and inside spread (right) of Jama Masjid as a visual culture theme © 2018-19 course documentation by Author Name (hidden for peer review).

Special Content Developments for DVC course

Students and the faculty instructor decided to document a range of distinct visual culture themes from the Indian land - aiming to draw things together at the intersections of bringing forth new knowledge and representation of: the People, the Environment, the Geographical Location, the tools and skills used for producing the visual material, any additional resources that are enablers in crafting special design language and communication of these themes (Figure 6). The content developments also include observations and depth analysis about how documenting the connection with larger communication goals alongwith identification of sources from everyday life, such as Cinema, Calendar, Persuasive Communication, Traditional Visual Influences, Cultural Influences, and Mythological Symbol, etc. carve out a meaning-making system of visual design elements for the final DVC documentations.

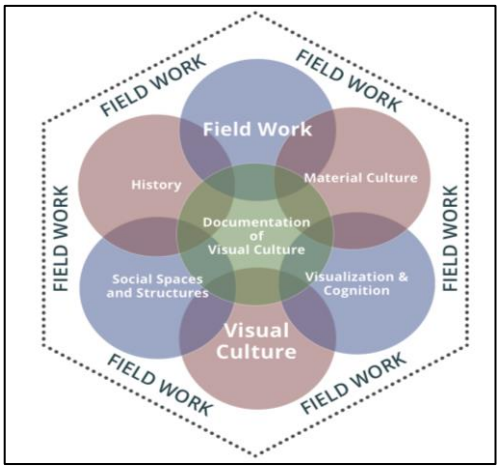

Figure 6. Information Content Mapping, Linking and Analytical approach in DVC documentations © 2018-19 course documentation by Author Name (hidden for peer review).

DVC course: the five-pillar conceptual framework

Analysing Bruno Latour's research and for course methodology to apply visualization and cognition for drawing things together to bridge Content, Form and a Visual Language Development became a pertinent series of in-classes, discourse oriented actionable tasks to ideate for the final design outcomes for each student's DVC publication cum documentations (Solberg, 2021; Wilde, 2020). The tone of voice in the descriptions below has a deliberate conversational tone of voice that has been an effort to bring forth the essence of this in-classes activity-oriented methodology. Following are the series of those activities that involved students' as well as the researcher of this paper, who as the faculty instructor implemented the method in five pillars, as follows:

1) *What and How to Observe?*

Observation is a powerful method to understand human behaviour and patterns of living. In the context of space, students were required to apply observation in following ways:

- Learn to Listen: Developing the skill of *learning to listen* would help you to go, explore, interpret and infer the space of study within the larger space.
- Temporal Discourse: Space Discourse is always temporal. It changes with time. This discourse that you record will assume different identities; and hence interpretations with time. For instance, one of the B.Des student's DVC theme of 'Revitalizing Traditional Indian Toys' involving children experiencing the space with the document design as an enabler for the temporal discourse in real-time (Figure 7).
- This publication titled, 'Khel Khoj', talks about India's rich cultural heritage of crafts in toy making; based on the books, such as 'The Joy of making Indian Toys' by Sudarshan Khanna (2002). In the context of visual culture in India, 'toys' add an innovation-based dimension of experience with the resource-scarce tools and equipments that have been utilized keeping in mind the affordability and the low-cost parameter for better access to masses. This pulsating identity associated with Indian toys as a craft heritage has been the spine to structure the publication – including 'magic toys' with respect to the Indian land. The world knows it by the name, 'Jakob's Ladder'. The ladder form becomes the structure of opening, folding, reading as well as experiencing the visual culture of magic toys as part of this interesting experiential document design done as part of the course (Figure 7).

Figure 7. Revitalizing Traditional Indian Toys visual culture theme for DVC documentations © 2018-19 course documentation by Author Name (hidden for peer review).

2) *How to See?*

Learning to See is the most essential quality that we as designers need to learn. It is because of those qualities that we will eventually learn in order to ideate designs (Peng, 2022; Vikas et. al., 2022; Cascini, 2021; Larraz-Rábanos, 2021).

- This is a blessing and a curse—once we have learned to see design, both good and bad, we cannot un-see. The downside is that the more you learn to see, the more you lose the distinct eye that you design with.
- For instance, one of the B.Des student's DVC theme of 'Documenting the city of Melbourne's Graffiti' involving the tactile and ephemeral quality as seen by the designer to become the core design identity in naming, visual language and compositional developments (Figure 8).
- Stencil City project as represented; has been a comprehensive document the depicts the unique beauty and aesthetics, modes/methods of creations, etc. as an integral part of graffiti and street art visual culture in the city of Melbourne (Figure 8). The detailing included in the documentation as field works included decoding the elements of visual aspects and cultural context that encapsulates the city's dynamic visual language. It equips the reader with graphical cues that narrate the social, economic and physical terrains of the city in an informed manner. The documentation celebrates this captivating visual culture theme of graffiti street art from

three perspectives that become chapters in the documentation, namely: a. The Fact, b. The Feel and, c. The Form. This special approach in content-form association build for the publication has been instrumental in painting a holistic picture of the graffiti scenarios in Melbourne city with technicalities and personalized travelogue section on personal interactions, observations and reflections with the graffiti painters and makers.
Developing an Eye:
Good designers try to keep their ability to see things as a customer would. You need a designer's eye to design; and a non-designer eye to feel what you designed.
"See with one eye, feel with the other." —Paul Klee

Figure 8. The Stencil City–Melbourne City's Graffiti visual culture theme for DVC documentations © 2018-19 course documentation by Author Name (hidden for peer review).

3) *How to Read?*
Learning to See is the most essential quality that we as designers need to learn. It is because of those qualities that we will eventually learn in order to ideate designs (Peng, 2022; Vikas et. al., 2022; Cascini, 2021; Larraz-Rábanos, 2021).

- In the development of design skills, theory can get in the way of practice, but only until the theory becomes practice. With practice your intuition evolves, and the better you understand what you do, the deeper your intuition. Only once you do not consciously think about the theory anymore are you achieving mastery.
- How to Read, involves that approach of graphic design that gives to the viewer a range of images or indirect meaning related to the theme/subject matter. This is largely known to be image making in graphic design; wherein, a graphic designer through images communicates direct or indirect messages (Zhang, 2022; Xu, 2022; Günay, 2021). Denotations are direct, but connotations are indirect.

For instance, one of the B.Des student's DVC theme of 'Odisha's Pattachitra' involving the insightful content for augmenting readers' interests to know the detailed product and processes involved in the making of 'chitra', that means a piece of an artwork or simply put, a painting, Pattachitra may literally translate to cloth painting (Figure 8). Derived from the Sanskrit word 'patta', that means 'cloth' or 'canvas'; and, 'chitra' that means 'a piece of an artwork' / simply put; 'a painting' – is born the 'pattachitra'. Famous as 'Cloth paintings', these pattachitras depict and celebrate the themes of ras lila, vastra haran, kaliya dalan, ten incarnations of the Lord Vishnu, nava grahas (nine planets), kanchi avijana of Lord Jagannath, panchamukhi Lord Hauman as well as the panchmukhi Lord Ganesha (Figure 9).

Figure 9. Painted Prayers –Odisha's Pattachitra visual culture theme for DVC documentations © 2018-19 course documentation by Author Name (hidden for peer review).

4) *How to Plan a Theme ?*

Brainstorm the ideas you wish to select as themes of Visual culture for your final document, as follows:

- Building an image library: Select different kinds of visual images. Some may be connotative (indirect) and others may be denotative (direct) representations of the main theme of your visual culture. Collect these by photo-documenting your space entirely. Eliminate any repetitive or incomplete pictures to do away with any confusing messages they convey.
- Construct a public interest: By including those texts from your notes, data collections, etc. that help define the identity, essence, cultural ethos and meaning of a particular visual theme for the public who would be the direct receivers.

In this context, customary practices within a space must be archived to the last detail (all micro and macro process steps). For instance, the festival of Holi imbibes a good prominence of customary practices as part of it as a visual culture in India. The larger context includes interesting associations with folklore and folk cultural practices that aim to build communities from socio-cultural as well as socio-political perspectives within the context of India.

Another instance to establish the unique significance of customary practices; when seen through the lens of rich visual cultures in India – is the dynamic Chhau dance from Bihar. The said dance form is a tradition – deeply embedded in the easter fabric of India; especially Bihar. The dance form is used to enact episodes from the epics (including Ramayana and Mahabharata), locl folklore as well as abstract forms of stories and storytelling. It's three distinct styles hail from the popular region of Seraikella, Purulia, Mayurbhanj in East India. Chhau, as a visual culture to be celebrated in the region – has been intimately connected with regional festivities; notably the spring festival Chaitra Parva. Its origin has been traced back to the indigenous forms of dance and martial practices. The vocabulary of movement includes mock combat techniques, stylized gates of birds and animals; and the movements modeled on the chores of village housewives. The effect of the dance form stand for the development of unsophisticated forms of folk dance to highly stylized forms. Chaau, symbolic of the earliest indigenous forms of dance in India – has demonstrated a living continuity with the past in order to acknowledge and preserve heritage within the silos of visual cultural practices and preservations.

While doing this as part of the fieldworks by each student, it should be kept in mind that conventions/rules define a certain cultural group's interaction and impact the related customary practice accordingly. For instance, the 'Paithani style of wearing saree from Maharashtra' is a tradition from the Western part of India as documented and designed in a coffee table book form to reach as well as touch resonance with a good section of public residing in Western India by one of the B.Des students (Figure 10). This DVC course documentation is in the form of a coffee table booklet – that visually celebrates the heritage process of wearing the iconic paithani sarees by the women of the concerned ethnic culture.

Figure 10. The Paithani: Maharashtra's pride as a visual culture theme for DVC documentations © 2018-19 course documentation by Author Name (hidden for peer review).

5) *What to create as a Visual Language for a Space/Living Culture ?*

- Message selection and communication strategies for content developments:

In last three days of the first week of the course, rigorous discussions over each visual culture theme selected by these students. They were expected to share a two -page write-up that would cover as much data and information from following perspectives. These articles that they finally submitted on the week's end became individual blueprints for their targeted visual culture documents. These write-ups covered following in a nutshell.

For each header in the content, students would pick up 3-5 keywords that will associate the purpose of your chunk to be written under that header. The text of this chunk must imbibe following:

- Cognitive underpinnings of all the observations made.
- Continuity in-text of all the observations and the sections of the space covered. The

sequence in text should ideally be linear and ordered.

- Composition of all Visual elements.
- Identity understanding and articulation of visual elements must be done with depth and sensitivity.
- Depending on your selected space, say a line as a visual element communicates a sense of alignment; or it may mean a boundary or lines in your space are facilitators of segmentation/divisions/ distributions, etc.

- Visual culture theme discussions with students:

The first two days of the second week of the course was time put in extensively to discuss with each student his/her visual culture theme selection. Larger visual culture domains got defined from the thematic information collections the students shared in these sessions. Briefly, they collected thematic information under following categories of considering 'Space as a Social means of Culture and Communication'. The criteria are as follows:

1) Space and Associations with Class
2) Space and Associations with Materials
3) Space and Associations with History
4) Space and Associations with Multicultural Artifacts
5) Space and associations with Artifacts
6) Space and Associations with a City
7) Space and Associations with an Event / Festival / Space
8) Space and Associations with a Practice
9) Space and Associations with Seeing and Reading (observations and articulations or even conjectures)
10) Space and associations with Self-Image

Insights and Discussion

Field work based research and the applied five-pillared framework for design outcomes as part of the DVC course works in this paper reveal guiding lights for future. Among them, some pertinent insights from teaching-learning perspectives can incorporate following visions for pedagogical developments around information visualization, cognition and semiotics, are as follows:

- Field works should include surveys and detailed interviews with the main stakeholders; in order to archive the processes employed by the concerned visual artists. Special story records of developing their arts, craftsmanship and entrepreneurship-based scope could be documented – for encompassing the complete circle of all the know-hows that students could experience in a better way at the grass root level.
- Ethnography, Participatory research modes of inquiry, co-creation research techniques are imparted to them as part of course and could be showcased as special chapter(s) in future documentations as part of such DVC courses. This would help them learn the importance of developing a mind and mode of operating as a design researcher.
- Students would tend to assume the role of a visual archeologist by filtering and harnessing content (text and graphics) to document varied kinds of visual cultures – in-depth through the lens of the people, the things (objects/artefacts, etc.) and the spaces in future DVC documentations. This would enhance information visualization, storage as well as retrieval in context of both socio-cultural and socio-spatial perspectives; bringing forth unknown facts and/or innovation aspects that represent the identity of a new kind of visual culture.
- Students need to understand the visual design aspects, print production aspects (selection of paper makes / quality and print production process for final outcomes). They are able to speculate a workable budget for production of their document to learn making a mini business model around their book design – and this as production content could become part of the larger information content planned as a chapter for future DVC documentations.
- Innovation in future documentations may also include explorations of outside-field digital archival methods to gather research for interesting content developments; in consideration of the recent new normal future scenarios. Such an approach could be operated in a workshop-mode for the course.
- Visualization and experiments with book design formats for future DVC documentations would add responsiveness to their designs with respect to digital modes of visual representations.

Conclusion

An in-depth and field work based research and documentation-cum-publication design courses and the applied five-pillared framework for design outcomes as part of the DVC course works in this paper reveal guiding lights for future that could incorporate following visions for pedagogical developments around 'Visualization' and 'Cognitive Semiotics'.

Visual culture may also be decoded and analyzed in a focused way with respect to the skills and craft of the makers alongwith the unique legacy testimonials in their creations that imprint the relevance of a particular visual culture ahead of its time. In the realm of preserving the heritage of the analog or special manual capabilities of such makers/artists – the form-content associations implemented in the

documentations may cater to out-of-the box approaches in research, ideation and communication aspects needed to unravel the unknown stories of a good range of visual cultures from the present and the near future scenarios. Therefore, the researcher has summarized arguments in the form of research questions that would be needed to develop pedagogy around the said DVC course, as follows:-

1) Can these documentations by students be positioned as an essential source of knowledge creation about the visual arts, design and communication design?
2) Can they be produced as 'Visual Anthologies' or tangible collection of stories of a visual culture open to anyone to read and experience those - regardless of age, experience, ethnicity, or income ?
3) What sort of visual language design approaches would be needed in these special anthologies ?

In a nutshell, the above questions earmark the potential areas of scope that may regulate discovery of new qualitative methods for information content developments and information content to form associations for experimental research. Experimentations would aid reformation and transformation of existing practices related with documentations that celebrate the essence of a particular visual culture.

ABSTRACT- This review paper surveys the integration of machine learning techniques in spatial data mining, a crucial intersection of geographic information systems and data mining. It examines the application of various machine learning algorithms such as classification, regression, clustering, and deep learning in spatial data analysis. The paper discusses challenges like data preprocessing, feature selection, and model interpretability, alongside recent advancements including spatial-temporal analysis and heterogeneous data integration. Through critical analysis of existing literature, it identifies trends, methodologies, and future research directions. Practical implications and applications across domains like urban planning, environmental monitoring, and epidemiology are explored. As a comprehensive resource, this review facilitates understanding and utilization of machine learning approaches for extracting insights from spatial data, benefiting researchers, practitioners, and policymakers alike.

KEYWORDS- Spatial data mining, machine learning, geographic information systems, classification, clustering, spatial-temporal analysis, data integration

I. INTRODUCTION

Spatial data mining is a specialized field within data mining that focuses on extracting valuable patterns, relationships, and insights from spatial datasets. These datasets contain geographic information associated with specific locations on Earth's surface, such as satellite imagery, GPS coordinates, land cover data, and environmental measurements. The integration of machine learning techniques with spatial data mining has revolutionized the field, enabling more efficient and accurate analysis of complex spatial phenomena. This introduction provides an overview of spatial data mining, discusses the importance of machine learning in this context, outlines the objectives of the review paper, and describes its structure.

A. Overview of Spatial Data Mining

Spatial data mining involves the application of data mining techniques to spatial datasets for knowledge discovery and decision-making. By analyzing spatial relationships, trends, and patterns, spatial data mining enables insights into various phenomena, such as land cover changes, urban sprawl, environmental degradation, and disease spread. Spatial data mining tasks include spatial pattern recognition, spatial clustering, predictive modeling, and anomaly detection. These tasks are crucial for addressing challenges in diverse domains, including environmental science, urban planning [2, 6, 7, 9, 12, 13], public health, agriculture, and disaster management. The integration of advanced analytical techniques, such as machine learning, enhances the effectiveness and efficiency of spatial data mining processes.

B. Importance of Machine Learning in Spatial Data Mining

Machine learning plays a vital role in spatial data mining by offering powerful tools to analyze and interpret complex spatial datasets. Traditional spatial analysis methods often struggle to handle the high dimensionality, complexity, and heterogeneity of spatial data. Machine learning algorithms, however, excel at processing large volumes of spatial data, identifying patterns, and making predictions. They can handle spatial autocorrelation, non-linearity, and complex relationships inherent in spatial datasets, enhancing the accuracy and efficiency of spatial data mining tasks. Moreover, machine learning enables the automation of spatial analysis processes, reducing human effort and time required for data interpretation. By leveraging machine learning techniques, researchers and practitioners can unlock the full potential of spatial data, leading to improved decision-making in various domains.

This review paper: (i) Provide a comprehensive overview of machine learning approaches utilized in spatial data mining; (ii) Analyze and compare the effectiveness of different machine learning algorithms in addressing various spatial data mining tasks; (iii) Explore the applications of machine learning techniques in real-world scenarios across diverse domains; (iv) Identify key challenges and limitations associated with the integration of machine learning in spatial data mining and propose potential solutions or avenues for future research; (v) Offer insights into emerging trends and future directions in the field of machine learning approaches in spatial data mining, highlighting opportunities for innovation and advancement.

The paper has been organized as follows: Section 2 discusses fundamentals of spatial data mining; section 3 focusses on machine learning techniques for spatial data mining; section 4 discusses spatial pattern recognition; section 5 gives details on predictive modelling in spatial data mining; section 6 elaborates on spatial data clustering;

section 7 mentions anomaly detection and outlier analysis; section 8 discusses challenges and future directions, and last section gives conclusions.

II. FUNDAMENTALS OF SPATIAL DATA MINING

Spatial data mining is a specialized field within data mining that deals with extracting valuable insights and patterns from spatial datasets. This section explores the definition and scope of spatial data mining, key concepts, techniques, and challenges inherent in spatial data analysis.

A. Definition and Scope of Spatial data Mining

Spatial data mining involves the application of data mining techniques to spatial datasets, which contain geographic information associated with specific locations on Earth's surface. The scope of spatial data mining extends across various domains, including environmental science, urban planning [2, 6, 7, 9, 12, 13], public health, agriculture, and disaster management. By analyzing spatial relationships, trends, and patterns, spatial data mining enables insights into various phenomena, such as land cover changes, urban sprawl, environmental degradation, and disease spread.

B. Key Concepts in Spatial Data Mining

In spatial data mining, the key concepts are spatial data representation, spatial autocorrelation, spatial clustering, spatial regression, and spatial pattern recognition. Spatial data can be represented in different formats, including raster and vector. Raster data represent spatial information as a grid of cells, while vector data represent spatial features as points, lines, and polygons. Spatial autocorrelation refers to the degree of correlation between spatially adjacent observations within a dataset. It indicates the extent to which similar values or attributes cluster together in space. Spatial clustering involves grouping spatial objects or locations based on their spatial proximity or similarity. This task aims to identify spatially coherent groups of features or phenomena within a dataset. Spatial regression is a statistical technique used to model the relationship between a dependent variable and one or more independent variables, while accounting for spatial dependencies. Spatial pattern recognition involves identifying and categorizing spatial features or structures within a dataset. It aims to detect and analyze spatial patterns such as clusters, hotspots, trends, and anomalies.

C. Challenges in Spatial data Mining

Challenges in spatial data mining include data heterogeneity, scalability, spatial autocorrelation, interpretability, and domain-specific considerations. Spatial datasets often comprise heterogeneous data types, formats, and resolutions. Integrating and analyzing diverse data sources require specialized techniques for data preprocessing, transformation, and fusion. Spatial datasets can be massive in size, posing challenges in terms of scalability and computational efficiency. Analyzing large-scale spatial data requires scalable algorithms and parallel processing techniques. Spatial data often exhibit spatial autocorrelation, meaning that nearby locations tend to have similar values or attributes. Ignoring spatial autocorrelation can bias statistical analysis results and lead to inaccurate interpretations of spatial patterns and relationships. Interpreting spatial data mining results and understanding the underlying spatial patterns can be challenging, particularly with complex machine learning models. Ensuring the interpretability and explainability of spatial data mining methods is crucial for gaining insights and informing decision-making processes. Spatial data mining tasks often involve domain-specific considerations and constraints, such as environmental regulations, land use policies, and socio-economic factors. Integrating domain knowledge and expertise into spatial data mining workflows is essential for producing meaningful and actionable results.

In summary, understanding the fundamentals of spatial data mining, including key concepts, techniques, and challenges, is essential for effectively analyzing spatial datasets and extracting valuable insights for decision-making in various domains. By addressing challenges such as data heterogeneity, scalability, spatial autocorrelation, interpretability, and domain-specific considerations, researchers and practitioners can unlock the full potential of spatial data mining and derive actionable insights from complex spatial datasets.

III. MACHINE LEARNING TECHNIQUES FOR SPATIAL DATA MINING

Machine learning techniques have revolutionized spatial data mining by providing powerful tools to analyze complex spatial datasets and extract valuable insights. This section provides an overview of machine learning in spatial data mining, covering supervised and unsupervised learning techniques, as well as deep learning approaches.

A. Overview of Machine Learning in Spatial Data Mining

Machine learning encompasses a diverse set of algorithms and techniques that enable computers to learn from data and make predictions or decisions without being explicitly programmed. In the context of spatial data mining, machine learning algorithms can analyze spatial datasets to identify patterns, relationships, and anomalies, facilitating decision-making processes across various domains.

B. Supervised Learning Techniques

Supervised learning involves training a model on a labeled dataset, where the input data is paired with corresponding output labels. Supervised learning techniques are commonly used for regression and classification tasks in spatial data mining. (a) Regression Models: Regression models aim to predict a continuous target variable based on one or more input features. Examples of regression techniques used in spatial data mining include linear regression, polynomial regression, and geographically weighted regression; (b) Support Vector Machines (SVM): SVM is a powerful supervised learning algorithm used for classification and regression tasks. It works by finding the optimal hyperplane that separates different classes or predicts continuous outcomes while maximizing the margin between data points; (c) Decision Trees: Decision trees are tree-like structures where each internal node represents a decision based on a feature, and each leaf node represents the outcome or prediction. Decision trees are intuitive and easy to interpret, making them suitable for spatial data mining tasks such as land cover classification and vegetation mapping; (d) Random Forests**:** Random

forests [15] are an ensemble learning technique that combines multiple decision trees to improve predictive performance and reduce overfitting. Random forests are robust and versatile, making them well-suited for spatial data mining tasks with high-dimensional and noisy datasets; (e) Neural Networks: Neural networks [28] are a class of machine learning models inspired by the structure and function of the human brain. They consist of interconnected layers of neurons that process input data and produce output predictions. Neural networks, including feedforward neural networks, convolutional neural networks (CNNs), and recurrent neural networks (RNNs), are increasingly used in spatial data mining for tasks such as image classification, time-series analysis, and spatial prediction.

C. Unsupervised Learning Techniques

Unsupervised learning involves training a model on an unlabeled dataset to find hidden patterns or structure in the data. Unsupervised learning techniques are commonly used for clustering and dimensionality reduction tasks in spatial data mining. (a) Clustering Algorithms: Clustering algorithms group similar data points together based on their distance or similarity measures. Common clustering algorithms used in spatial data mining include k-means clustering, DBSCAN (Density-Based Spatial Clustering of Applications with Noise), and hierarchical clustering. These algorithms are used for tasks such as hotspot detection, land use classification, and urban growth analysis; (b) Dimensionality Reduction: Dimensionality reduction techniques aim to reduce the number of features or variables in a dataset while preserving its essential information. Principal Component Analysis (PCA) and t-distributed Stochastic Neighbor Embedding (t-SNE) are popular dimensionality reduction techniques used in spatial data mining to visualize high-dimensional data, identify important features, and improve computational efficiency.

D. Deep Learning Approaches

Deep learning is a subset of machine learning that utilizes artificial neural networks with multiple layers of abstraction to learn complex patterns from data. Deep learning approaches have gained popularity in spatial data mining due to their ability to handle large-scale, high-dimensional spatial datasets and extract hierarchical representations of spatial features. (a) Convolutional Neural Networks (CNNs): CNNs are a class of deep neural networks designed for processing spatial data, such as images and grids. CNNs use convolutional layers to automatically learn spatial hierarchies of features from raw input data, making them well-suited for tasks such as image classification, object detection, and land cover mapping; (b) Recurrent Neural Networks (RNNs): RNNs are a class of neural networks designed for processing sequential data with temporal dependencies. RNNs are commonly used in spatial data mining for tasks such as time-series analysis, trajectory prediction, and spatial sequence modelling; (c) Graph Neural Networks (GNNs): GNNs are a class of neural networks designed for processing graph-structured data, such as social networks, transportation networks, and spatial networks. GNNs leverage graph convolutional layers to learn spatial dependencies and relational patterns from graph-structured data, enabling tasks such as spatial reasoning, graph-based clustering, and network analysis in spatial data mining.

In summary, machine learning techniques, including supervised and unsupervised learning algorithms, as well as deep learning approaches, have revolutionized spatial data mining by enabling the analysis of complex spatial datasets and extraction of valuable insights for decision-making across various domains. By leveraging machine learning techniques, researchers and practitioners can unlock the full potential of spatial data mining and address real-world challenges in environmental science, urban planning, public health, agriculture, and disaster management.

IV. SPATIAL PATTERN RECOGNITION

Spatial pattern recognition is a fundamental task in spatial data mining, aiming to identify and categorize spatial features or structures within a dataset. This section explores the application of machine learning for spatial pattern recognition, including case studies and applications such as land cover classification, object detection in satellite imagery, and urban scene understanding [2, 6, 7, 9, 12, 13].

A. Applications of Machine Learning for Spatial Pattern Recognition

Machine learning techniques play a crucial role in spatial pattern recognition by enabling the automated detection and characterization of spatial features and structures in complex datasets. Traditional spatial analysis methods often struggle to handle the high dimensionality and complexity of spatial data, making machine learning approaches particularly valuable for spatial pattern recognition tasks. Machine learning algorithms, including supervised, unsupervised, and deep learning techniques, are used for spatial pattern recognition tasks such as: (a) Classification: Classifying spatial features into predefined categories or classes based on their attributes and spatial characteristics; (b) Detection: Detecting and localizing specific objects or phenomena within spatial datasets, such as buildings, roads, vegetation, and land cover types; (c) Segmentation: Partitioning spatial datasets into homogeneous regions or segments based on their spatial and spectral properties; (d) Prediction: Forecasting future spatial patterns or trends based on historical data and spatial relationships.

These machine learning techniques leverage various types of spatial data, including satellite imagery, aerial photographs, LiDAR data, and geographic information systems (GIS) layers [19], to extract meaningful spatial patterns and structures.

B. Case Studies and Applications

Land Cover Classification: Land cover classification is a common application of spatial pattern recognition, aiming to classify different land cover types (e.g., forests, water bodies, urban areas) within a geographic region. Machine learning algorithms [18, 26], such as random forests, support vector machines (SVM), and convolutional neural networks (CNNs), are used to classify land cover types based on spectral, spatial, and temporal features extracted from satellite imagery.

C. Object Detection in Satellite Imagery

Object detection in satellite imagery [21] involves identifying and locating specific objects or features of interest within large-scale spatial datasets. Machine learning techniques, such as region-based convolutional neural networks (R-CNN), You Only Look Once (YOLO), and Single Shot Multibox Detector (SSD) [8], are commonly used for object detection tasks in satellite imagery. For instance, a study conducted by Lin et al. (2017) applied a deep learning approach based on SSD to detect and localize vehicles in high-resolution satellite images. The SSD model achieved accurate detection of vehicles in urban and rural areas, demonstrating the potential of deep learning for object detection in satellite imagery.

D. Urban Scene Understanding

Urban scene understanding involves analyzing and interpreting complex spatial patterns and structures within urban environments, such as building footprints, road networks, and land use patterns. Machine learning techniques, including deep learning approaches such as graph convolutional neural networks (GCNs), are used for urban scene understanding tasks, such as semantic segmentation, road extraction, and building footprint detection. For example, a study conducted by Chen et al. (2019) applied a graph-based deep learning approach to perform semantic segmentation of urban scenes using high-resolution aerial imagery. The GCN model effectively segmented urban scenes into semantic classes, such as buildings, roads, vegetation, and water bodies, enabling comprehensive urban scene understanding and analysis.

In summary, spatial pattern recognition is a critical task in spatial data mining, enabling the identification and characterization of spatial features and structures within complex datasets. Machine learning techniques [18, 26], including supervised, unsupervised, and deep learning approaches, play a crucial role in spatial pattern recognition, facilitating automated analysis and interpretation of spatial data across various domains. Through case studies and applications such as land cover classification, object detection in satellite imagery, and urban scene understanding, machine learning demonstrates its effectiveness in extracting meaningful spatial patterns and insights from diverse spatial datasets.

V. PREDICTIVE MODELLING IN SPATIAL DATA MINING

Predictive modeling is a fundamental aspect of spatial data mining, enabling the forecasting of future spatial patterns and phenomena based on historical data and spatial relationships. This section provides an overview of predictive modeling in spatial data mining, covering regression models for spatial prediction, time-series analysis, and forecasting, as well as ensemble learning techniques. Additionally, it explores case studies and applications of predictive modeling in environmental monitoring, public health, and urban planning [2, 6, 7, 9, 12, 13].

A. Overview of Predictive Modeling in Spatial Data Mining

Predictive modeling in spatial data mining involves developing mathematical models that can predict spatial patterns, trends, and events based on input variables and spatial relationships. These models utilize historical data to learn patterns and relationships and then apply them to new spatial datasets to make predictions. Regression models [29], time-series analysis techniques, and ensemble learning methods are commonly used for predictive modeling in spatial data mining [1, 16]. These techniques leverage spatial data such as satellite imagery, sensor data, geographic information systems (GIS) layers, and socioeconomic variables to make spatial predictions.

- **Regression Models for Spatial Prediction**

Regression models are used to predict a continuous target variable based on one or more input features. In spatial data mining, regression models are often used for spatial prediction tasks such as land cover mapping, environmental modeling, and spatially explicit forecasting. Techniques such as linear regression, spatial autoregressive models (SAR), and geographically weighted regression (GWR) are commonly used for spatial prediction tasks. These models consider spatial dependencies between observations and incorporate spatially varying coefficients to account for spatial heterogeneity.

- **Time-Series Analysis and Forecasting**

Time-series analysis involves analyzing sequential data points collected over time to identify patterns, trends, and seasonality. In spatial data mining, time-series analysis techniques are used for forecasting spatial phenomena such as environmental variables, disease outbreaks, and urban growth. Methods such as autoregressive integrated moving average (ARIMA), exponential smoothing, and seasonal decomposition are commonly used for time-series analysis and forecasting. These techniques capture temporal dependencies and seasonality patterns in spatial data to make accurate predictions.

- **Ensemble Learning Techniques**

Ensemble learning techniques combine multiple base models to improve predictive performance and generalization ability. In spatial data mining, ensemble learning methods are used to aggregate predictions from diverse models and reduce prediction errors. Approaches such as random forests, gradient boosting machines (GBM), and ensemble neural networks are commonly used for ensemble learning in spatial data mining. These methods combine predictions from multiple regression models, decision trees, or neural networks to produce more robust and accurate predictions.

B. Case Studies and Applications

- **Environmental Monitoring**

Predictive modeling is widely used in environmental monitoring to forecast environmental variables such as air quality, water quality, and land surface temperature. For example, a study conducted by Li et al. (2018) used machine learning techniques to predict air pollution levels in urban areas based on satellite imagery and meteorological data. The predictive model accurately forecasted air pollution levels, enabling proactive

measures for pollution control and public health protection.

- **Public Health**

Predictive modeling plays a crucial role in public health for forecasting disease outbreaks, identifying high-risk areas, and guiding resource allocation for disease prevention and control. For instance, a study conducted by Yang et al. (2019) used machine learning techniques to predict the spatial spread of dengue fever in urban areas based on environmental factors and historical disease data. The predictive model identified high-risk areas for dengue fever transmission, informing targeted intervention strategies and public health interventions.

- **Urban Planning**

Predictive modeling is essential in urban planning for forecasting urban growth, land use changes, and transportation demand. For example, a study conducted by Shen et al. (2020) used machine learning techniques to predict future land use changes in urban areas based on socioeconomic variables, land cover data, and demographic trends. The predictive model provided insights into future urban development patterns, supporting informed decision-making in urban planning and land management [2, 6, 7, 9, 12, 13].

In summary, predictive modeling is a crucial aspect of spatial data mining, enabling the forecasting of future spatial patterns and phenomena based on historical data and spatial relationships. Regression models [29], time-series analysis techniques, and ensemble learning methods are commonly used for predictive modeling in spatial data mining, facilitating applications in environmental monitoring, public health, urban planning, and other domains. Through case studies and applications, predictive modeling demonstrates its effectiveness in predicting spatial phenomena and informing decision-making processes in various fields.

VI. SPATIAL DATA CLUSTERING

Spatial data clustering is a fundamental task in spatial data mining [14, 17], aiming to group spatial objects or locations based on their spatial proximity or similarity. This section explores the role of machine learning in spatial data clustering, compares different clustering algorithms, and examines case studies and applications such as land use classification, urban growth analysis, and hotspot detection.

A. Role of Machine Learning in Spatial Data Clustering

Machine learning plays a crucial role in spatial data clustering by providing automated and scalable techniques for grouping spatial objects based on their spatial characteristics. Traditional clustering algorithms often struggle to handle the high dimensionality and complexity of spatial datasets, making machine learning approaches particularly valuable for spatial data clustering tasks. Machine learning algorithms [5, 10, 22, 24, 25, 27], including both supervised and unsupervised techniques, are used for spatial data clustering: (a) Supervised Clustering: Supervised clustering techniques use labeled training data to learn clustering patterns and relationships. Examples include fuzzy clustering algorithms, self-organizing maps (SOM), and hierarchical clustering with labeled data; (b) Unsupervised Clustering: Unsupervised clustering techniques group spatial objects without using labeled training data. Common unsupervised clustering algorithms used in spatial data mining include k-means clustering, DBSCAN (Density-Based Spatial Clustering of Applications with Noise) [11], and spectral clustering. These machine learning techniques leverage spatial data such as satellite imagery, geographic information systems (GIS) layers, and sensor data to identify spatial patterns and structures in complex datasets.

B. Comparison of Clustering Algorithms

Several clustering algorithms are commonly used in spatial data mining, each with their strengths and limitations. A comparison of clustering algorithms can help researchers and practitioners choose the most suitable approach for their specific spatial data clustering [14, 17] tasks. (a) K-means Clustering: K-means clustering is a simple and widely used algorithm that partitions data into k clusters based on the mean distance between data points and cluster centroids. It is computationally efficient and works well for globular-shaped clusters but may struggle with non-linear or irregularly shaped clusters; (b) DBSCAN: DBSCAN [11] is a density-based clustering algorithm that groups spatial objects based on their density distribution. It can identify clusters of arbitrary shape and is robust to noise and outliers. However, DBSCAN requires careful parameter tuning and may struggle with datasets of varying density or clusters with different shapes and sizes; (c) Spectral Clustering: Spectral clustering is a graph-based clustering algorithm that partitions data based on the eigenvalues and eigenvectors of a similarity matrix. It can identify clusters with complex shapes and is robust to noise and outliers. However, spectral clustering may be computationally intensive and require pre-processing steps such as affinity matrix construction and eigenvector decomposition.

C. Case Studies and Applications

- **Land Use Classification**

Spatial data clustering is widely used in land use classification to identify and categorize different land cover types within a geographic area. Machine learning techniques [5, 10, 22, 24, 25, 27] such as k-means clustering, spectral clustering, and fuzzy clustering are applied to satellite imagery and remote sensing data to classify land cover types such as forests, water bodies, urban areas, and agricultural land. For example, a study conducted by Liu et al. (2019) used k-means clustering to classify land cover types in urban areas based on multispectral satellite imagery. The clustering algorithm accurately identified different land cover classes, enabling comprehensive land use mapping and analysis.

- **Urban Growth Analysis**

Spatial data clustering is essential for urban growth analysis to identify spatial patterns and trends in urban development over time. Machine learning techniques such as DBSCAN, hierarchical clustering, and self-organizing maps are used to cluster urban features such as buildings, roads, and infrastructure to analyze urban growth patterns and trajectories. For instance, a study conducted by Li et al. (2020) used hierarchical clustering to analyze urban growth patterns in rapidly developing regions based on time-series satellite imagery. The clustering algorithm identified distinct spatial clusters representing different

stages of urban development, providing insights into urban growth dynamics and land use change processes [2, 6, 7, 9, 12, 13].

- **Hotspot Detection**

Spatial data clustering is employed for hotspot detection to identify areas with unusually high or low concentrations of spatial phenomena such as disease outbreaks, crime incidents, and environmental hazards. Machine learning techniques such as DBSCAN, spatial scan statistics, and kernel density estimation are used to cluster spatial events and detect hotspots based on their spatial distributions. For example, a study conducted by Wang et al. (2018) used DBSCAN clustering to detect hotspots of dengue fever transmission based on spatially aggregated disease incidence data. The clustering algorithm identified clusters of high disease transmission risk, enabling targeted intervention strategies and public health interventions.

In summary, spatial data clustering plays a crucial role in spatial data mining by enabling the identification of spatial patterns and structures within complex datasets. Machine learning techniques such as k-means clustering, DBSCAN, and spectral clustering are commonly used for spatial data clustering tasks, facilitating applications such as land use classification, urban growth analysis, and hotspot detection. Through case studies and applications, spatial data clustering demonstrates its effectiveness in extracting meaningful spatial patterns and insights from diverse spatial datasets.

VII. ANOMALY DETECTION AND OUTLIER ANALYSIS

Anomaly detection and outlier analysis are essential tasks in spatial data mining, aiming to identify unusual patterns or data points that deviate significantly from the norm. This section explores machine learning approaches for anomaly detection, applications in various domains such as cybersecurity and environmental monitoring and provides case studies and examples.

A. Machine Learning Approaches for Anomaly Detection

Machine learning techniques [5, 10, 22, 24, 25, 27] play a crucial role in anomaly detection by providing automated and scalable methods for identifying anomalous patterns or outliers in spatial datasets. These techniques leverage statistical models, clustering algorithms, and supervised learning methods to detect deviations from expected patterns or behaviors. Common machine learning approaches for anomaly detection include:

- **Statistical Methods**

Statistical methods such as z-score, Dixon's Q-test, and Grubbs' test are used to detect anomalies based on statistical properties of the data, such as mean, standard deviation, and distribution. These methods compare observed data points to expected values and flag outliers that deviate significantly from the norm.

- **Clustering Algorithms**

Clustering algorithms such as k-means, DBSCAN, and hierarchical clustering can be used for anomaly detection by identifying clusters of normal behavior and flagging data points that do not belong to any cluster or are isolated from the rest of the data. Outliers are often defined as data points that are distant from their nearest neighbors or have low cluster membership probabilities.

- **Supervised Learning Methods**

Supervised learning methods such as support vector machines (SVM), decision trees, and random forests [15] can be trained on labeled data to distinguish between normal and anomalous patterns. These methods learn patterns of normal behavior from training data and classify new data points as either normal or anomalous based on their learned models.

- **Deep Learning Approaches**

Deep learning approaches [3, 4, 23] such as autoencoders, recurrent neural networks (RNNs), and convolutional neural networks (CNNs) are increasingly used for anomaly detection in spatial data. These methods learn hierarchical representations of spatial features and identify anomalies based on deviations from learned representations of normal behaviors.

B. Applications in Cybersecurity, Environmental Monitoring, Healthcare and Finance

Anomaly detection and outlier analysis have diverse applications across various domains, including: (a) Cybersecurity: Anomaly detection is critical for cybersecurity to identify malicious activities, intrusions, and cybersecurity threats in network traffic, system logs, and user behavior. Machine learning techniques are used to analyze network traffic patterns, detect anomalies indicative of cyberattacks, and prevent security breaches; (b) Environmental Monitoring: Anomaly detection is essential for environmental monitoring to identify abnormal patterns or events in environmental variables such as air quality, water quality, and climate data. Machine learning techniques are used to detect anomalies indicative of environmental hazards, pollution incidents, and ecological disruptions; (c) Healthcare: Anomaly detection is employed in healthcare to identify unusual patterns or deviations from normal physiological parameters in patient data such as vital signs, medical images, and electronic health records. Machine learning techniques are used to detect anomalies indicative of medical conditions, disease outbreaks, and adverse health events; (d) Finance: Anomaly detection is utilized in finance to detect fraudulent transactions, money laundering activities, and financial anomalies in transaction data, stock prices, and market behavior. Machine learning techniques are used to analyze financial data patterns, detect anomalies indicative of fraudulent activities, and mitigate financial risks.

C. Case Studies and Examples

- **Cybersecurity**

In cybersecurity, anomaly detection is used to identify suspicious network traffic patterns indicative of cyberattacks. For example, a study conducted by Gao et al. (2020) used machine learning techniques to detect distributed denial-of-service (DDoS) attacks based on anomalous network traffic patterns. The anomaly detection model accurately identified DDoS attacks and helped mitigate cybersecurity threats in real-time.

- **Environmental Monitoring**

In environmental monitoring, anomaly detection is used to identify abnormal patterns or events in environmental

variables such as air quality, water quality, and climate data. For example, a study conducted by Jia et al. (2019) used machine learning techniques to detect anomalies in water quality data collected from river monitoring stations. The anomaly detection model identified abnormal water quality events such as pollution incidents and helped improve water resource management and environmental protection efforts.

- **Healthcare**

In healthcare, anomaly detection is used to identify unusual patterns or deviations from normal physiological parameters in patient data. For example, a study conducted by Choi et al. (2021) used machine learning techniques to detect anomalies in electrocardiogram (ECG) signals indicative of cardiac arrhythmias. The anomaly detection model accurately identified abnormal ECG patterns and helped diagnose cardiovascular diseases in patients.

In summary, anomaly detection and outlier analysis are essential tasks in spatial data mining, enabling the identification of unusual patterns or data points that deviate significantly from the norm. Machine learning approaches such as statistical methods, clustering algorithms, supervised learning methods, and deep learning approaches are used for anomaly detection in various domains such as cybersecurity, environmental monitoring, healthcare, and finance. Through case studies and examples, anomaly detection demonstrates its effectiveness in identifying anomalies and mitigating risks in diverse spatial datasets.

VIII. CHALLENGES AND FUTURE DIRECTIONS

Machine learning techniques have revolutionized spatial data mining, offering powerful tools for extracting valuable insights from complex spatial datasets. However, several challenges persist, and emerging trends present new opportunities for research and development in this field. This section explores the current challenges in machine learning for spatial data mining, emerging trends and opportunities, future research directions, and ethical considerations and implications.

A. Current Challenges in Machine Learning for Spatial Data Mining

- **Data Quality and Heterogeneity**

Spatial datasets often exhibit varying levels of quality, resolution, and accuracy, posing challenges in data integration, preprocessing, and analysis. Handling data heterogeneity and ensuring data quality are crucial for accurate and reliable spatial data mining.

- **Scalability**

Analyzing large-scale spatial datasets can be computationally intensive and resource-intensive, posing challenges in terms of scalability and efficiency. Developing scalable machine learning algorithms and parallel processing techniques is essential for handling massive spatial datasets effectively.

- **Spatial Autocorrelation**

Spatial data often exhibit spatial autocorrelation, where nearby locations tend to have similar values or attributes. Ignoring spatial autocorrelation can bias analysis results and lead to inaccurate spatial predictions. Incorporating spatial dependencies into machine learning models is necessary for addressing this challenge.

- **Interpretability**

Complex machine learning models such as deep neural networks [28] often lack interpretability, making it challenging to understand and explain model predictions. Ensuring the interpretability and transparency of machine learning models is crucial for gaining trust and acceptance in spatial data mining applications.

- **Domain-specific Considerations**

Spatial data mining tasks often involve domain-specific considerations and constraints, such as environmental regulations, land use policies, and socio-economic factors. Integrating domain knowledge and expertise into machine learning workflows is essential for producing meaningful and actionable results.

B. Emerging Trends and Opportunities

- **Geospatial Deep Learning**

Deep learning approaches, such as convolutional neural networks (CNNs), recurrent neural networks (RNNs), and graph neural networks (GNNs), are increasingly applied to spatial data mining tasks. Geospatial deep learning [3, 4, 23] enables the automatic extraction of hierarchical spatial features and representations from raw spatial data, facilitating advanced analysis and prediction tasks.

- **Transfer Learning and Domain Adaptation**

Transfer learning techniques, which leverage knowledge learned from one domain to improve performance in another domain, are gaining popularity in spatial data mining. Transfer learning and domain adaptation methods enable the transfer of spatial patterns and representations learned from one geographic region to another, overcoming data scarcity and domain shift challenges.

- **Explainable AI(XAI)**

Explainable AI techniques aim to enhance the interpretability and transparency of machine learning models, enabling users to understand and trust model predictions. XAI methods such as model interpretability techniques, model-agnostic explanations, and interactive visualization tools are increasingly applied to spatial data mining tasks to facilitate decision-making and knowledge discovery.

- **Spatial-Temporal Modeling**

Spatial-temporal modeling techniques integrate spatial and temporal dimensions into machine learning models, enabling the analysis of dynamic spatial processes and phenomena over time. Spatial-temporal modeling approaches are applied to various applications such as environmental monitoring, urban planning, and transportation management, facilitating spatiotemporal prediction, forecasting, and decision-making.

C. Future Research Directions

- **Addressing Data Quality and Heterogeneity**

Future research should focus on developing robust techniques for handling data heterogeneity, ensuring data quality, and integrating heterogeneous spatial datasets from diverse sources. Methods for uncertainty quantification and error propagation in spatial data mining should also be explored.

- **Advancing Scalable and Efficient Algorithms**

Future research should aim to develop scalable machine learning algorithms and parallel processing techniques capable of handling large-scale spatial datasets efficiently. Distributed computing frameworks and cloud-based platforms can be leveraged to improve scalability and computational efficiency in spatial data mining applications.

- **Enhancing Interpretability and Transparency**

Future research should focus on enhancing the interpretability and transparency of machine learning models in spatial data mining. Developments in explainable AI techniques, model interpretability methods, and interactive visualization tools can facilitate model understanding and trust in spatial data analysis tasks.

- **Integrating Domain Knowledge and Expertise**

Future research should emphasize the integration of domain knowledge and expertise into machine learning workflows in spatial data mining. Collaborative research efforts between machine learning researchers and domain experts can lead to the development of domain-specific models, algorithms, and tools tailored to specific application domains.

D. Ethical Considerations and Implications

- **Privacy and Data Security**

Spatial data mining raises concerns about privacy and data security, particularly when dealing with sensitive or personal location-based data. Ensuring data anonymization, encryption, and secure data handling practices are essential for protecting individuals' privacy and preventing unauthorized access to spatial data.

- **Bias and Fairness**

Machine learning models used in spatial data mining may exhibit biases and unfairness, leading to discriminatory outcomes or decisions. Addressing biases and ensuring fairness in machine learning models require careful consideration of data sampling, feature selection, and model evaluation methods to mitigate bias and promote fairness in spatial data analysis tasks.

- **Transparency and Accountability**

Transparency and accountability are essential principles in spatial data mining to ensure that machine learning models are transparent, accountable, and explainable. Providing clear explanations of model predictions, documenting model development processes, and establishing mechanisms for model auditing and oversight can enhance transparency and accountability in spatial data mining applications.

- **Environmental and Societal Impact**

Spatial data mining has significant environmental and societal implications, affecting land use, natural resource management, urban planning, public health, and transportation. Ethical considerations such as environmental sustainability, social equity, and community engagement should be integrated into spatial data mining research and practice to ensure responsible and ethical use of spatial data and machine learning techniques.

In conclusion, while machine learning has greatly advanced spatial data mining, several challenges remain, and new opportunities are emerging. Addressing these challenges and embracing emerging trends will shape the future of spatial data mining, enabling researchers and practitioners to unlock the full potential of machine learning for addressing complex spatial challenges and promoting sustainable and equitable development. Moreover, ethical considerations and implications are essential to ensure that spatial data mining is conducted responsibly, ethically, and for the benefit of society.

IX. CONCLUSIONS

In this review paper, we have explored the role of machine learning approaches in spatial data mining, covering various aspects such as spatial data clustering, predictive modeling, anomaly detection, and outlier analysis. We discussed the fundamentals of spatial data mining, including spatial data representation, spatial autocorrelation, spatial clustering, spatial regression, and spatial pattern recognition. Moreover, we examined the challenges and future directions in machine learning for spatial data mining, as well as emerging trends and opportunities in the field. Machine learning techniques have shown significant potential in addressing various challenges in spatial data mining, including data heterogeneity, scalability, spatial autocorrelation, and interpretability. These techniques have been applied to a wide range of applications, including environmental monitoring, urban planning, public health, cybersecurity, and finance. Through case studies and examples, we demonstrated the effectiveness of machine learning in extracting meaningful spatial patterns and insights from diverse spatial datasets.

A. Implications for Research and Practice

The findings of this review paper have several implications for both research and practice in spatial data mining: (a) Research Implications: Researchers in spatial data mining should focus on addressing current challenges such as data heterogeneity, scalability, spatial autocorrelation, and interpretability. Future research directions include advancing scalable and efficient algorithms, enhancing model interpretability and transparency, integrating domain knowledge and expertise, and addressing ethical considerations and implications in spatial data mining; (b) Practical Implications: Practitioners in spatial data mining can leverage machine learning techniques to tackle real-world challenges and applications such as environmental monitoring, urban planning, public health, cybersecurity, and finance. By adopting state-of-the-art machine learning approaches, practitioners can extract valuable insights from spatial datasets, improve decision-making processes, and address societal and environmental challenges effectively.

In conclusion, machine learning approaches play a crucial role in spatial data mining, enabling the extraction of valuable insights from complex spatial datasets. Despite various challenges, emerging trends and opportunities in machine learning offer promising avenues for advancing research and practice in spatial data mining. By addressing current challenges, embracing emerging trends, and considering ethical implications, researchers and practitioners can harness the power of machine learning to unlock the full potential of spatial data mining for addressing societal, environmental, and economic challenges in the future.

CONFLICT OF INTERREST

The authors declare that they have no conflict of interest.

ABOUT THE AUTHORS

Dr. Shalini Bhaskar Bajaj completed her Ph.D, from IIT Delhi, M.Tech from Delhi College of Engineering, Delhi University. She has more than 20 years of experience in teaching. She has authored numerous technical research papers and book chapters in international conferences and journals of repute. Her research interests are Databases, Data Mining, Predictive Analytics, Pattern Recognition, Cloud Computing. She is member of IEEE, CSI and IAENG and fellow of Institute of Engineers (India).

Dr. Ashima Narang has completed her Btech, Mtech and PhD in the field of computer Science from various prestigious institutes of India. Her areas of expertise include Cloud Computing, Security, Software Engineering and Virtualization. She has rich teaching experience of 12 years. She has authored numerous research papers in reputed international journals and conferences and has guided students for projects from undergraduate and graduate courses. She is also an active member in the various professional bodies like IAASSE, internet society, SCIEI etc. She is the reviewer to various journals from her expertise field.

Dr. Priyanka Vashisht has received her Ph.D from ThaparUniversity, Patiala, M.Tech from Banasthali Vidyapeeth, Rajsthan. She has 20 years of teaching and industry experience. Her areas of expertise include Cloud Computing, Fog Computing and Virtualization. She has authored numerous technical research papers and book chapters in international conferences and journals of repute. She has authored a book. She has 4 patents in her name. She is member of IETE, CSI and ACM

Abstract

To date, student issues with Massive Open Online Courses (MOOCs) have only been explored in context-specific environments. Mainstream problems such as declining student motivation during a course, massive student dropout rates, accountability, user experience, etc., persist due to the permutations and combinations of these issues. Literature is replete with a deep understanding of such problems, but the causal relationships among these issues are less focused upon. We delve into these problems by studying the interrelations among student issues that cause such problems. Garnering insights from students ($N = 149$) and using Total Interpretive Structural Modelling with Polarity (TISM-P), the study has established direct and transitive relations among nine detrimental MOOC-related student issues. The results of the study depict clear positive, negative and transitive relationships between the student issues. Matrice d'Impacts croises-multipication applique' an classment (MICMAC) analysis was also used to assess the driving and dependence power of all issues that further allowed the model to trace out negative and positive pathways of influence. The model constructed in the study will provide a platform for future research to test these interconnections as independent factors affecting problems such as dropout rates, motivation, etc. Therefore, the TISM-P model could further be explored to understand the behaviour of such issues, which might have far-reaching consequences on major existing problems with MOOCs.

1 | INTRODUCTION

The speed with which Massive open online courses (MOOCs) have gained momentum in the last decade and the stupendous increase in enrolments across different platforms has legitimised the place of online learning in mainstream higher education (Jitpaisarnwattana et al., 2022). Learning from the exploits of early MOOCs offering platforms such as MITx (transforming to Edx), various countries such as China (XuetangX), India (Swayam), the UK (Future learn) and Spain (Miríadax), etc., have now developed indigenous platforms for offering MOOCs. Albeit the positive aspects and benefits of MOOCs, such as support in career progression, the gain of new knowledge, learning new skills (Goglio & Bertolini, 2021; Littlejohn et al., 2016), reaching the educationally underserved, delivering low-cost quality higher education (Abu-Shanab & Musleh, 2018), etc. MOOCs have successfully stood the rigour and test of time. Analogous to the new technology adoption graph, that is the Gartner cycle, MOOCs are now beginning to enter the phase of productivity (Corbeil et al., 2018). The spread is massive in terms of the number of student enrolments and a culmination of both global and indigenous platforms is transforming the fabric of online education (Ruipérez-Valiente et al., 2022) Undoubtedly with such a worldwide expansion and collaboration of universities and governments, MOOCs are bound to face criticism on numerous facets of their growth (Chiappe-Laverde et al., 2015; Laaser, 2023). The integration of MOOCs in higher education systems is different across all levels of global social stratification. It is very much dependent upon factors such as early usage, technology adoption rate, university and government support etc. (Wang, Hall, & Wang, 2019; Wang, Liu, & Li, 2019). Thus, the stakeholder issues with such differentiating adoption rates are bound to vary with time and place. Furthermore, being a global phenomenon, it becomes necessary to muster a comprehensive understanding of issues associated with MOOCs. Such an approach might not only shed light on the bigger picture but, can also help understand the interconnections and causal relations among said issues. In the context of education, students will always be considered crucial primary stakeholders, which invariably justifies the need for research encompassing their perceptions, thoughts and opinions, revealing both positive and negative insights. Thus, our study aims to focus on a broader understanding of student issues with MOOCs, which are still as persistent and equally disruptive as they were during the advent of the concept. It is observed that some of the issues had already been resolved in peculiar settings of time and place. However, the majority of them still pose as a hurdle in the effective integration of MOOCs in mainstream higher education systems across the world. For example, language might not be a barrier to online learning in most developed countries. Still, for underdeveloped and developing countries, English as the lingua franca might not be well accepted as the appropriate medium of instruction (Meina et al., 2021). Over the last decade, literature has consolidated and is now replete with how student issues with MOOCs lead to bigger problems in the online education system. Massive dropout rates (Borrella et al., 2022; Goopio & Cheung, 2021; Hew & Cheung, 2014); lack of student motivation and intention to adapt to new technology (Ma & Lee, 2018a); asynchronous nature of majority MOOCs (Alario-Hoyos et al., 2014); low perceived value compared to university degrees (Rosendale, 2017) and doubts regarding the credibility of such courses in the employment market (Farrow et al., 2021; Trehan et al., 2017) are some of the manifestations of these issues. A comprehensive and fair level of understanding of basic issues and their impact is ubiquitous among researchers, but studies on interrelations and causal analysis seem to remain lacking.

Our study aims to draw interconnecting lines among student issues using a total interpretive structural modelling with polarity (TISM-P) model, which is an extended and improvised arm of interpretive structural modelling (ISM) developed by J. Warfield in 1974 (Warfield, 1974). The use of ISM has been voluminous over the years, and it has successfully assisted theory building in answering the 'what' and 'how' questions whilst explaining the driver-dependence relationships among factors. What the causal relationship among factors and how it is formed is well captured by ISM, whereas TISM, as purported by Sushil (2012), emphasises answering the 'why' question (why one factor influences another?), yielding in more interpretive power to complex hierarchical models. TISM has readily gained acceptance in the last decade and researchers have extensively used it for theory building, hypothesis testing, modelling and conceptualising ill-structured mental models

and ideas from real-life scenarios. As human beings, we often tend to create mental models of problems and issues surrounding us but, with an increase in the number of influencing factors, the ability of an individual to comprehend the value of such interrelations gets fatigued. TISM helps researchers streamline that process and follows up with a hierarchical model of our cognitive connections, emphasising interpretations from direct and transitive relationships (Kumar & Barua, 2022). The applicability of TISM is increasing with time, and the scale of its horizon is expanding to various fields such as supply chain management, operations and information management, strategic performance management, sustainable supply chain development and emotional intelligence, etc. In the context of higher education TISM has been previously used to understand the challenges of management education (Mahajan et al., 2015) and to create a model of benchmarking for higher education (Yeravdekar & Behl, 2017). Talib and Rahman (2020) used the technique to model the barriers in the growth of higher education institutions (HEIs), whereas Fathi et al. (2019) focused on teamwork training in HEIs. Coming down to the latest development in the TISM technique, an element of polarity was introduced by Sushil (2018) to extend the functioning and novelty of its application; in other words, an aggregated view was presented incorporating positive and negative influence of factors over one another. The extension, that is (TISM-P), allows the individual to capture the positive and/or negative influence of one factor over the other, furnishing a better picture of the behaviour of a model or a system. The application of TISM-P is relatively new, and the literature is still in its emerging forms; hence, as our primary research aim, we look forward to applying the extended version of TISM from students' perspective, which would encourage instructors, e-learning platforms and policymakers to holistically analyse the behaviour of student issues related to MOOCs.

2 | REVIEW OF RELATED LITERATURE

2.1 | Language barrier

One of the oldest issues within the MOOC scenario is the barrier of language (Gul et al., 2018) associated with the medium of instruction and teaching pedagogy. Even though English might be considered the lingua franca, there are countries such as Brazil or China where English is not used in major fashion at universities and colleges (Liu et al., 2010). At present, all major global platforms such as Edx® or Coursera® have begun translating MOOCs with sub-scripts of other languages; however, the level of comfort among the learners is bleak. Students have highlighted their discomfort with the accent and pronunciation of foreign instructors, which makes them feel alienated at certain times (Liyanagunawardena et al., 2014). They have raised concerns over the struggle to cope with the speed, short abbreviations and tone of the language, which results in students watching the same video repeatedly to grasp the concepts (Jones, 2014), thus hampering productivity.

2.2 | Technological barriers

Massive problems arise when technology starts acting as a deterrent for something it was supposed to enhance in the first place (Rhoads, 2015). The use of technology has been well-researched in the context of MOOCs and the challenges it brings with its advancements. For students, it is a major challenge because, even though it is safe to assume that students accessing MOOCs would be competent with new technology, there might be grey areas in developing countries where students lack skills and awareness of such mediums of teaching and learning (Ma & Lee, 2018b). In one way or another other it affects students' intention to use and accept MOOCs as an aid to traditional learning methods (Henderikx et al., 2018; Zulkifli et al., 2020). The lack of appropriate technological infrastructure refrains students from getting connected with the latest advancements in education on the global level (Leontyeva, 2018). MOOCs require high-speed internet connections for buffering and downloading, but the

lack of such connectivity affects students' motivation to access e-learning platforms for learning and development purposes.

2.3 | Overload of information

Students have often complained about the overload and segmentation of information from MOOCs (Chen et al., 2011; Khalid et al., 2021). There is no standardised framework for MOOC development, and the instructors are generally free to design and prepare course information and material based on their own individual experiences and comfort. An issue of expectation mismatch becomes quite real between MOOCs and students when there is information overload on discussion forums along with hefty course readings (Chen et al., 2011). For asynchronous MOOCs, the repetition of ideas on such discussion forums is common via multiple threads of discussions, leading to the segmentation of the core message (Fischer, 2014). The issues are still not deeply researched and often neglected when addressing student issues related to MOOCs.

2.4 | Discussion forum

MOOC discussion forums are mainly in asynchronous mode, depending upon the course and service provider (Li et al., 2018). They are expected to encourage peer learning and improve commitment in a lax learning environment (Galikyan et al., 2021; Zhang et al., 2016). Teaching hundreds and thousands of students online at the same time brings challenges in all sorts of forms, shapes and figures. Students have often failed to engage in the discussion forums due to the overwhelming participation of their peers (Onah et al., 2014), thus restraining themselves from such indulgence. A feeling of alienation in such discussion forums is quite robust, and students' tendency to actively participate is dependent upon instructor-led engagements only (Bali, 2014). Little or no regard towards peer-to-peer and instructor-student associations severely affects the effectiveness of MOOCs in the long run (Naidu, 2017).

2.5 | Student support and feedback system

Feedback is crucial for every learning endeavour to become fruitful and is considered as the bedrock of all systems to function effectively. Without appropriate student support and quality feedback, students are often found to be losing interest in MOOCs (Gregori et al., 2018; Kasch et al., 2021) adding to higher attrition rates (Veletsianos, 2013). An effective student support system is crucial in improving MOOC quality and instructional design, whereas timely feedback helps to augment student interest over a period of time (Alario-Hoyos et al., 2014). The central premise is staying connected to students whilst responding to their queries in an appropriate manner which is supportive and conducive to student learning. The lack of such support systems eventually hampers MOOCs' effectiveness and students' motivation to continue with MOOCs (Gregori et al., 2018).

2.6 | Ambiguous assignments and peer assessment

Course assessments are built on multiple factors such as the type and nature of the course, the duration of the course, the complexities involved in the course and, majorly, the number of student enrolments in the MOOC (Gamage et al., 2021; Muñoz-Merino et al., 2015). Reilly et al. (2014) examined the automated essay scoring (AES) tool for grading assignments and found inefficiencies in its accuracy when compared to instructor-led grading. Peer review in itself is highly ambiguous, and it is hard to track the quality of subjective grading and interpretations.

14682273, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/hequ.12515 by Delhi Technological University, Wiley Online Library on [21/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Students often do not agree with peer-reviewed grades (Admiraal et al., 2015) and are found to skip assessments (Eriksson et al., 2016). Ambiguity in designing assessments is also a major concern for students because of misleading and unclear course expectations (Khan et al., 2017), which will lead to more dropouts in the future.

2.7 | Design and quality of MOOCs

Much has been said about how a MOOC should be designed and what quality parameters are good enough to judge upon the effectiveness of a MOOC (Quality Matters, 2014). Trying to sum up quality is a complicated process that demands the right selection of epistemological, methodological and theoretical pre-conditions (Ghislandi, 2016; Stracke & Trisolini, 2021). The quality of MOOCs could be bifurcated into concepts, that is quality assurance and quality enhancement. In the recent past, there has been an increase in the number of universities offering MOOCs as part of credit programmes (Bordoloi et al., 2020), but the awareness and adoption rates are still low in terms of the total number of universities offering credit exchange. Students have also raised concerns about the quality of MOOCs, encompassing the effectiveness of instructional design, course material and appropriateness of content since it directly influences their satisfaction levels towards a MOOC (Albelbisi & Yusop, 2019). Quality enhancement is the umbrella term for parameters concerned with MOOC instructional design, development and delivery at an institutional level (Ghislandi, 2016). Student perception about the quality of a MOOC could take various forms where instructional quality is associated with the effectiveness of teaching methods and overall course design (Fianu et al., 2018) and is a significant predictor of student satisfaction (Pilli & Admiraal, 2017). The issue with the design of MOOCs makes it harder for students to select the right type of MOOC for their academic development. Thus, designing an effective MOOC is hard and requires a balance of appropriate pedagogical approaches, understanding student motivation, investment in material resources and creating active learning environments (Wang, Hall, & Wang, 2019; Wang, Liu, & Li, 2019).

2.8 | Credibility of MOOCs certificates in job market

Studies are now beginning to emerge which are focusing on instilling the credibility of MOOC certificates in the employment market (Rivas et al., 2020). The debate around the value of a MOOC certificate in the eyes of the recruiter and a student's perceived value of that certificate in the job market is leading us to several unanswered questions (Rivas et al., 2020). The distinction is still not clear since the credibility of MOOCs in the employment market mainly affects university students, and there is an existing gap between industry-university expectations (Wells et al., 2009). Furthermore, the value of using online certifications for the upskilling of the workforce is a topic which also lacks serious investigation by researchers (Santandreu Calonge et al., 2019).

2.9 | Teaching and pedagogy

Students have often shown discomfort with the teaching approach of instructors who deliver online classes. Effective teaching reflects a holistic learning experience; instructor intervention at the stages of attraction, orientation, interaction and consolidation is deemed necessary to improve effectiveness in teaching MOOCs (Wong, 2016). Innovative use of technology is found to stimulate new approaches for online learning and student collaboration (Myers et al., 2014). Learning via a connectivist approach in the case of cMOOCs allows for cognitive connections to be made from available learning materials and peer-to-peer interactions (Mackness et al., 2013). On the other hand, xMOOCs offer a more synchronised form of learning where instructions are ordered in the mainstream fashion of a learn-test-learn repeat cycle. Instructors often get confused in selecting the right pedagogical

14682273, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/hequ.12515 by Delhi Technological University, Wiley Online Library on [21/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

approach for their course (Armellini & Padilla Rodriguez, 2016), and a lack of pedagogical innovations is leading MOOCs towards a passive medium of knowledge acquisition (Parr, 2013).

3 | METHOD

3.1 | Factor validation

Once the student issues were identified from the literature, it was deemed necessary to validate them from a group of experts from the academia and education-technology industry. Judgemental sampling was used to identify ($N=40$) such experts. The experts from the academia ($N=35$) were seasoned faculties who were running at least one MOOC on a global e-learning platform or a government-funded MOOC offering platform. In contrast, the industry experts ($N=5$) were developers of indigenous e-learning platforms. A *t* test for hypothesis testing was applied to capture the experts' opinions.

H0. Null: No significant difference exists between the observed mean and specified mean for attribute Fn.

HA. Alternate: Significant difference exists between the observed mean and specified mean for attribute Fn. ($N=9$).

A questionnaire was prepared using a 5-point Likert scale and exercised online. Whilst testing the value of 3.5 was used (Singh et al., 2019) for factor verification and the results are displayed in (Table 1).

3.2 | TISM-P application

The data for TISM-P was collected from a technical university where MOOCs are an integral part of their higher education curriculum ordinance, bearing transferable credits towards successful completion. The students selected for filling out the questionnaire were taken from a cohort of 3rd year engineering students who had completed at least one MOOC from any e-learning platform (Appendix A) as part of their credit transfer programme. The

TABLE 1 *t* test analysis of factors ($N=40$).

		Test value = 3.5

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

participants were voluntarily asked to fill out the survey because of the complexity involved in the process, and convenience sampling was used. However, due to the hybrid mode, initially, the response rate was extremely low, but upon formal request from their mentors, we were able to get hold of ($N = 149$) students who were willing to fill up the questionnaire under the authors' supervision. We used the TISM questionnaire for simultaneous transitivity checks coupled with polarity approximations to gather student responses. An online meeting was scheduled, and the students were briefed about the process in detail, and it took approximately 30 min for everyone to fill out the questionnaire. Adding polarity is an extension to the original TISM technique, and the steps involved in the advanced version are mentioned in Figure 1 and the illustrations for our research are shortly followed.

3.2.1 | Step I

The contextual definition and brief explanation of the issues were laid down after a thorough review of the associated literature. The issues identified from students' perspectives affect MOOC integration, effectiveness, dropouts and student motivation etc. in a number of ways. Table 2 offers insight into establishing the contextual relationship for paired comparisons with polarity (+ve or −ve) and for interpreting the influence of one factor over the other.

3.2.2 | Step II

A TISM-P questionnaire was developed for paired comparison and simultaneous transitivity checks (Sushil, 2017). The paired comparisons were made in the order 1,2; 2,3; 3,4…; 8,9 by individual students. To collate all responses for the reachability matrix, we followed with the work of Prasad and Suri (2011) to set up a threshold of 70% for direct comparisons and 50% for transitive comparisons. If more than 70% of the responses (direct) were 'Yes' for a particular comparison, then the response was taken as 1; otherwise, 0 in the final reachability matrix (Table 3). The process was followed similarly for transitive comparisons too. The questionnaire captures the direction of the relationship as forward ($i \rightarrow j$), backward ($j \rightarrow i$), both ($i = j$) and no relationship (0). The polarity of direct relations (+ve or −ve) was also taken into consideration at this stage.

3.2.3 | Step III

Transitivity is defined as the relation between any such three elements such that if i influence j and j influences k then i is bound to influence k. In the case of transitive relations, the polarity was justified according to the logic of polarity from the previous relationship. For example: if $i \rightarrow j$ is +ve and $j \rightarrow k$ is −ve, then $i \rightarrow k$ would become −ve (Sushil, 2018). As mentioned in the previous step, the direct pair comparisons were done by students, and afterwards, the transitivity check was performed by authors in MS-Excel®. The polarity of the relationship was specified before the creation of the transitive reachability matrix and successive comparison digraph.

3.2.4 | Step IV

To visualise direct pair comparisons and transitivity checks with polarity, a successive comparison digraph in Figure 2 is portrayed along with a transitive reachability matrix with polarity in Table 4. For easy identification and effective visualisation, the comparisons were marked on the digraph and colour-coded along with the entries of +1, −1 or 0 in the reachability matrix with polarity. Finally, all the entries in the reachability matrix (+1, −1 or 0) were converted into 1 or 0 entries as presented in Table 5 in the form of a transitive reachability matrix without polarity.

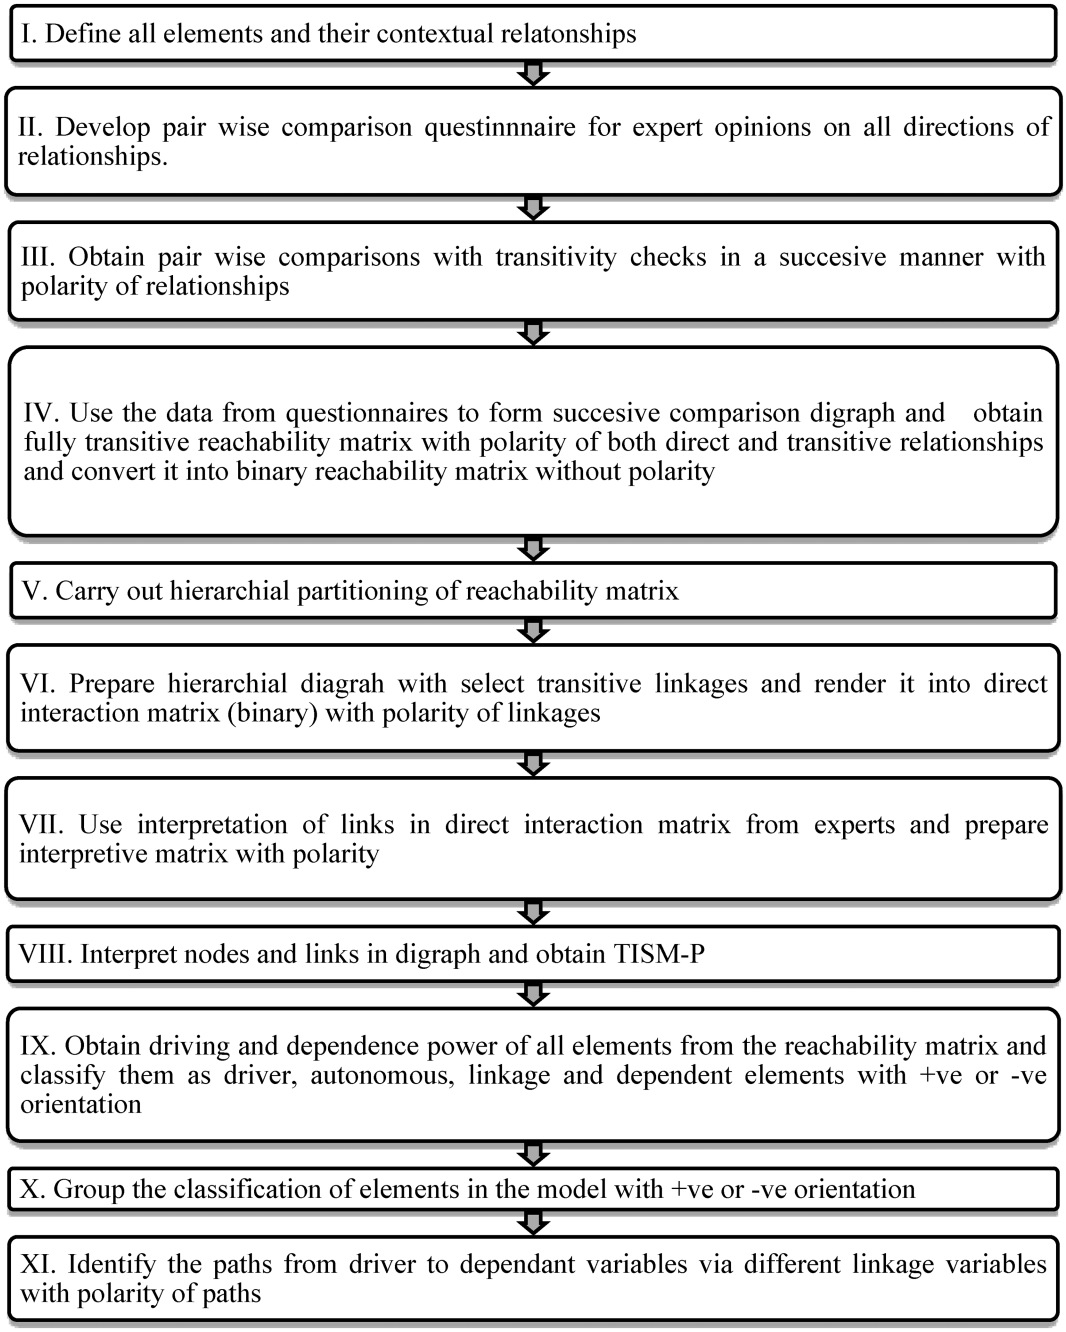

FIGURE 1 Steps involved in TISM-P adapted from Sushil (2018).

3.2.5 | Step V

The matrix from Table 5 is used as the final matrix for hierarchical partitioning. The original ISM/TISM methodology was followed to derive the reachability set, antecedent set and intersection set. The process is iterative and allows us to divide and categorise the student issues into different levels systematically. The student issues having the same reachability and antecedent set are selected for the highest level, and the rest of the levels are attained

14682273, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/hequ.12515 by Delhi Technological University, Wiley Online Library on [21/05/2024]. 7	0	0	0	0	0	1	1	1	0
8	0	0	0	0	0	0	1	1	1
9	0	0	0	0	0	0	0	1	1

after iteratively removing previous issues. The illustration of the process is given in Appendix B and the results from level partitioning of student issues are given in Table 6.

3.2.6 | Step VI

The student issues numbering '1' to '9' are arranged in a hierarchical order after level partitioning in the form of a digraph in Figure 3. It is important to note that only prominent transitive links having distinct influence are retained for the final digraph (after model validation by experts). The rest of the links were dropped out to avoid unnecessary crowding. Now, a binary interaction matrix with polarity (Table 7) is made using the final digraph from Figure 3.

3.2.7 | Step VII

Student opinions were used to convert all +1 and −1 entries from the binary matrix into an interpretive matrix in Table 8. The interpretation for each link is given. For example, language barrier (1) has a direct and negative influence on students' intention to participate in discussion forums (4), etc.

analysis is used to analyse the driver-dependence relationship among factors over one another (Figure 5). The two-dimensional graph is divided into four quadrants. The first quadrant consists of ***autonomous*** criteria, which has a low driver and dependence power; the second quadrant represents the ***dependent criteria*** which has low driving power and high dependence power; the third quadrant is made up of ***linkage criteria*** which has high driving and dependence powers, and the last quadrant represents the ***driver criteria*** which has high driving power and low dependence powers. The polarity of each student issue was interpreted from the transitive reachability matrix in Figure 4.

3.2.10 | Step X

The results from MICMAC analysis (Figure 4) are overlayed upon the TISM-P model as depicted in Figure 6. The model briefs upon the classification of student issues with MOOCs along with +ve and −ve orientation in the form of driver-dependent relationships.

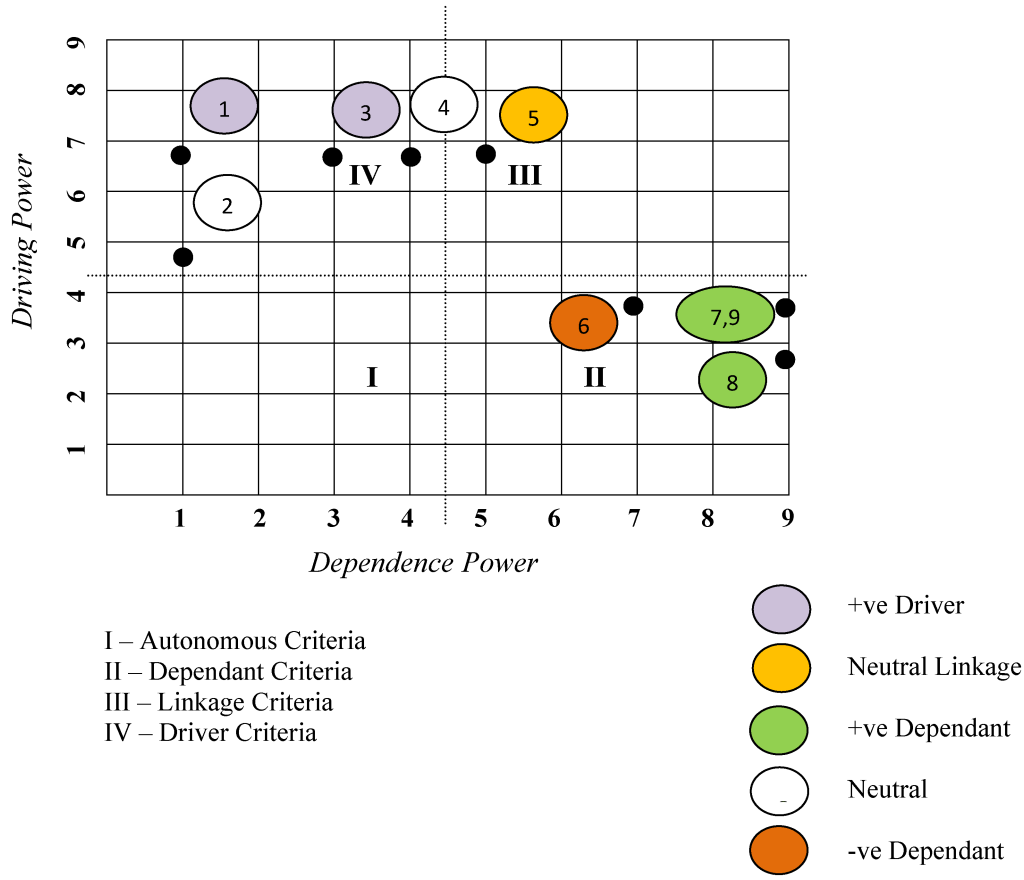

FIGURE 5 MICMAC analysis of student issues with MOOCs.

had a better idea of comprehending the nature of the work. A total of 39 linkages (Table 10) were formed in the original model and were tested for validation. It ideally depends upon the researchers' discretion to remove unnecessary transitive linkages to avoid overcrowding in the model (Agrawal, 2020; Sushil, 2018). We, however, consulted with expert opinions, and all 39 linkages were validated using hypothesis testing with a *t*-test. The final model was constructed whilst retaining the 30 most influential linkages. 39 questions were developed on a 5-point Likert scale questionnaire from strongly disagree to strongly agree for the test.

Hi0. Null: No significant difference exists between the observed mean and specified mean in respective factor linkage.

HiA. Alternate: Significant difference exists between the observed mean and specified mean in respective factor linkage.

Ms-Excel® was used to collate the responses, and a test value of 3.5 was used; results are shown in Table 10.

4 | RESULTS AND DISCUSSION

4.1 | TISM-P model

The model exhibits substantial insights into the interrelations between the student issues with MOOCs due to the effect of the positive and negative influence of factors over one another. The first factor, which is the language barrier, exhibits a direct and negative relationship with the factor discussion forum. If a country doesn't have an indigenously developed platform for offering MOOCs and English is not the medium of instruction in colleges and universities, then the students might not feel comfortable on global platforms (Ding & Shen, 2020), as was found in the case of Turkish MOOCs (Kurt, 2019). Student's ability to participate in discussion forums on global MOOC platforms might be affected due to language acting as a barrier and an issue itself. In such circumstances, students often lack the motivation to participate and might not be comfortable seeking answers to their queries. Furthermore, the language barrier was found to have a negative transitive effect on maintaining, if not increasing, the ambiguity of assignments. This effect flows through two factors, that is discussion forums and student support and feedback services. It is important to note whilst interpreting the model that not all transitive linkages will make sense in the real-world application (Sushil & Dinesh, 2022). Only those links and nodes are to be interpreted which carry substantial influence over another factor. Thus, all transitive linkages were consulted with expert opinions. Therefore, an increasing effect of language as a barrier will bring down the effectiveness of discussion forums, which in turn will increase the ambiguity of student assignments. The presence of a positive transitive link with the design and quality of a MOOC reflects the importance of recognising language as a major barrier since the link is mediated by discussion forums. A high language barrier will negatively affect a student's ability to participate in discussion forums which will eventually lower the quality of any MOOC (Sanchez-Gordon & Luján-Mora, 2020). The Technological barrier has shown a direct and negative relationship with factors 5 and 7. It is important to note that high-speed internet connections and appropriate bandwidth might not be within the reach of all current and prospective students in developing or underdeveloped countries (Ma & Lee, 2018b; Ramij & Sultana, 2020). The obstructive effects of lack of internet penetration and net neutrality are quite real in tier 2 and 3 cities in such countries (Sambuli, 2016). Students opined that technological barriers have a direct negative effect on reducing the efficiency of feedback systems. Also, the lack of appropriate bandwidth will affect students' ability to access MOOCs since they require high-speed internet connections to load videos and access supporting materials, thus lowering the overall quality. Technology as a student issue also has a positive transitive effect on maintaining the credibility of a course in the market. Increased barriers to technology will lower the quality and, thus, the credibility of the course in the market. An overload of information has a direct negative relation with discussion forums. The results are not new from our findings since, it is already well supported by literature (Chen et al., 2011; Khalid et al., 2021; Zeng et al., 2022). However, a transitive positive relation was found with the design and quality of MOOCs. An overloaded discussion forum is constrained and ineffective, which might have a negative effect on the quality of MOOCs. The negative transitive relationship with factor 6 reiterates the fact that an increase in information overload will negatively affect the discussion forum, which in turn might increase the ambiguity in assignments and negatively affect peer assessment as well. Students felt that the discussion forum had a direct and positive effect on factor 5 and a direct negative effect on factor 3. A well-regulated discussion forum could also serve as a legitimate platform to deliver effective feedback to the instructors and vice-versa (Lowenthal & Dunlap, 2020). However, it often becomes too overcrowded in the presence of multiple discussion threads, which could further increase the information overload. The negative transitive effect on factor 6 implies that effective discussion forums will support and ensure more active student feedback and help in reducing ambiguities in understanding assignments via fruitful discussions. The presence of a negative transitive effect on factor 7 tacitly expresses the fact that increased knowledge sharing helps to bank upon the basic premise of MOOCs, that is learning via a connectivist approach; thus, a

14682273, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/hequ.12515 by Delhi Technological University, Wiley Online Library on [21/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

well-regulated discussion forum would also contribute towards the better quality of MOOCs. Finally, the positive transitive relationship with factor 9 states that a well-maintained discussion forum could support instructors to garner real-time student feedback, which might be useful for improving teaching pedagogy. Student support and feedback services are crucial elements within MOOC issues and were found to have a direct positive influence in increasing the effectiveness of a discussion forum (Gamage et al., 2020). Additionally, this effect might lead to a reduction in the overload of information, thereby establishing a negative transitive relationship between factors 5 and 3. Moreover, a direct negative effect of factor 5 on 6 and a negative transitive effect on factor 7 exist. Lack of student support in MOOCs has been shown to have a negative effect on students dropping out of the course (Aldowah et al., 2020). Having an efficient support and feedback system will delimit any barriers between student-teacher interactions, thus, assisting in understanding assignments and peer assessment, further improving the quality of a MOOC. The presence of a positive transitive influence over factor 9 suggests that timely feedback from students might help teachers to make improvements in their teaching pedagogies and also adds to the completeness of a MOOC. Ambiguous assignments and peer assessment both have a direct negative effect on lowering the quality of a MOOC, which also has a positive transitive effect in lowering the credibility of such courses in the employment market. The Design and quality of MOOCs have a direct positive influence on factor 8 and a direct negative influence on factor 6. Generally, a high-quality and seasoned MOOC is famous and credible among students and in the job market as well, whereas better quality reduces ambiguity in assignments and peer assessments. Moreover, the positive transitive link with factor 9 highlights the importance of a well-designed MOOC via a direct positive relationship with credibility, that is an increase in both will serve as a driving factor for instructors to improve teaching pedagogy over a period of time (Julia & Marco, 2021). The Credibility of MOOCs in the job market has a direct positive relationship both ways forward and backwards. An increase in the credibility of a MOOC implies high-quality and effective teaching pedagogy and vice-versa. Teaching and Pedagogy have a direct positive influence on the credibility of MOOCs, and the positive transitive relationship with the quality of a MOOC reveals that an effective teaching pedagogy will improve the quality of a MOOC (Jamebozorg et al., 2022) and also gather credibility in the employment market. Finally, the positive transitive relationship with factor 6 via improved quality of a MOOC will help in reducing any ambiguities in understanding assignments.

4.2 | MICMAC analysis

No autonomous factors were identified, which communicates to us the fact that all the factors have some relationship with each other. In quadrant (II) Factors 6, 7, 8 and 9 are major dependant factors in the system. The arrangement points towards the outcome of the model and needs factors with high driving power to trigger them. The credibility of a MOOC certificate in the employment market might not be of concern to other stakeholders, but in certain education systems' where securing a job is hyper-competitive (Goglio & Bertolini, 2021; Pingle & Sharma, 2013) upskilling via MOOCs speaks for itself. Also, the teaching pedagogy and design of a MOOC are intertwined with each other and receive the maximum amount of effect from drivers. It is important to note that factor 6 has a negative dependence power due to the nature of the issue itself. The quadrant (IV) is home to four major driving factors, that is 1, 2, 3 and 4. Factors 1 and 3 are positive drivers in the system with very low dependence. Factors 2 and 4 are neutral in nature, that is they have equal amounts of positive and negative driving powers behind them. They will drive the influence but will not take a positive or negative stand. Any change in these issues will bring negative repercussions to other student issues. Finally, the third quadrant makes up the linkage criteria, which consists of factor 5 as a positive linkage. This factor is considered to be of utmost importance and volatility, that is they are highly influential and endangered at the same time. It flows both ways, that is any change in them will influence the remaining issues and the results of the model, creating a feedback effect (Mahajan et al., 2015).

14682273, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/hequ.12515 by Delhi Technological University, Wiley Online Library on [21/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The overlay of MICMAC analysis over the TISM-P model provides us with a clear picture of corresponding factor influence and flow as well. The driver factors 1 and 3 do not have any relationship with each other but are responsible for positively driving the path through the linkage factor in order to reach the dependent factors. Factors 2 and 4 are neutral in nature, that is they may influence positively or negatively the linkage factor. Factor 6 is of crucial importance because it is the sole negative dependent factor. For all direct relations, the model has to flow through the dedicated strict paths in order to influence or reach the dependent factors, but for transitive relationships, the paths could be complicated. For example, factor 4 (driver) has a positive transitive relationship with factor 9 (dependent); thus, in order to reach the outcome factor, the path could move via multiple configurations, that is 4→5→6→7→8→9; 4→5→9; 4→6→9; 4→7→9; 4→8→9. The issues interact with each other via multiple influences; thus, the nature of the path shall also have multiple inferences depending on the situation in the real world.

5 | IMPLICATIONS

The current study has key theoretical implications that could aid researchers in understanding the behaviour of student issues related to MOOCs. The study finds interrelations among student issues which interact with one another either positively or negatively depending upon the context. The model presented in the study also sheds light on the cause-and-effect relationship among student issues that can take multiple forms due to the nature of effect and transitivity. All transitive relationships could be interpreted according to the positive or negative effect that flows throughout the model. However, not examined in the current study, it is observed that the TISM-P model behaves similarly to a system dynamics causal loop model where balancing and reinforcing loops could be identified. The student issues, in this sense, are open to interpretation if examined from a systems perspective. Past research on student issues is focused on models related to factors that affect dropout rates, quality, motivation, user experience and perception (Aldowah et al., 2020; Peng & Xu, 2020; Shah et al., 2022). These studies deal with larger problems in the e-learning system but do not address the interrelationships among factors or issues. Prior literature focuses on individual issues and has studied them in depth at a micro level. The present study allows for exploration and a holistic understanding of a model dedicated to understanding interrelationships and the influence of student issues on one another.

6 | CONCLUSION AND LIMITATIONS

A MOOC must not be treated and experienced just as an online certification course but, rather, it has the potential to offer a holistic learning and development experience. High student dropout rates, lack of motivation, difficult evaluation, etc., are some major problems of online learning systems which are still difficult to address. A huge number of intrinsic and extrinsic factors exist that affect these problems and are difficult to study comprehensively. Therefore, the current study brings an extensive model of issues related to MOOCs which affect these problems. The problems arising out of the permutation and combination of these issues are well-read and explored in the literature, but a holistic understanding of major prominent issues was missing. A look into the interrelationships between these issues is achieved by exploring the causal relationships in the study. The results have highlighted the pitfalls that are ignored when we talk about student issues and their interactions among themselves. Controlling the effect of one issue has a ripple effect on other issues when viewed from a holistic perspective. A cause-and-effect relation helps to understand better the reasons behind the behaviour of a particular element in the system. Therefore, the current study carefully explores the negative or positive effects of these issues on one another. For further research, our model could be used to generate simulations and modelling exercises that can interpret the behaviour of these issues in the real world. The study is currently limited from the student's perspective. It has the potential to involve different student levels, that is High school, post-graduate and doctorate to garner multifarious perceptions about MOOC issues. In order to use the

current results effectively, it is recommended that further studies could use qualitative methods of inquiry to gather detailed information about such issues in the system.

Modified Six State Cryptographic Protocol with Entangled Ancilla Component States

Rashi Jain* and Satyabrata Adhikari†
Department of Applied Mathematics,
Delhi Technological University, Delhi-110042, India

In a realistic situation, it is very difficult to communicate securely between two distant parties without introducing any disturbances. These disturbances might occur either due to external noise or may be due to the interference of an eavesdropper sitting in between the sender and the receiver. In this work, we address the question of whether the sender and the receiver establish a secret key between them even though Eve possesses quantum power with her. This means that we probe here the existence of the possibility of the situation of generation of a secret key even if the eavesdropper is able to construct an entangled ancilla state in such a way that she can extract information from the intercepted qubit. Thus, our primary goal here is to discuss conditions for the establishment of a secret key between two distant parties in the presence of an eavesdropper. To achieve this task, we consider and modify the six-state QKD protocol in which Eve can construct the unitary transformation that may make all ancilla components entangled at the output. Then we calculate the mutual information between Alice and Bob *and* Alice and Eve, and identify the region where the secret key is generated even in the presence of Eve. We find that, in general, the mutual information of Alice and Eve depends not only on the disturbance D, but here we have shown that it also depends on the concurrence of the ancilla component states. We have further shown that it is possible to derive the disturbance-free mutual information of Alice and Eve, if Eve manipulates her entangled ancilla state in a particular manner. Thus, in this way, we are able to show that a secret key can be generated between Alice and Bob even if the disturbance is large enough. Moreover, we compare our result with Bruss's six-state QKD protocol and find that due to the occurrence of entangled ancilla states, our modified QKD protocol can generate a secret key in some region of both the cases where we consider mutual information of Alice and Eve with disturbance and disturbance free mutual information of Alice and Eve. In these cases, we find Bruss's six state QKD protocol failed to generate the secret key in the above mentioned region where the modified six-state QKD protocol is able to generate the secret key.

arXiv:2405.17046v1 [quant-ph] 27 May 2024

I. INTRODUCTION

One of the most important challenges of the information era is the ability to communicate secretly. Quantum key distribution (QKD) [1, 2] is the most advanced application of quantum mechanics [3] and information theory [4, 5], wherein a secret key is established between two trusted parties using which information can be transmitted secretly. The distribution of the secret key is the most challenging task in the field of quantum cryptography [6], as there might be an eavesdropper present between the sender and receiver, assumed to possess every possible operation acceptable by the laws of quantum mechanics [7]. The security of encrypted messages depends directly on the security of key distribution protocols. QKD uses the most powerful features and resources of quantum mechanics, such as quantum entanglement [8, 9] and quantum teleportation [10–12]. QKD protocols motivated the development of quantum cryptographic protocol variants, including quantum secret sharing [13] and quantum-secured blockchain [14].

Bennett and Brassard [15] were the first to introduce a revolutionary idea of quantum key distribution protocol, which exploits the properties of the quantum mechanics [16]. They designed a four-state quantum cryptographic protocol for secure key distribution between two distant parties. In this scheme, the sender (Alice) transmits four single qubits in a random manner to the receiver (Bob). The qubit may be prepared either in the computational bases $B_1 = \{|0\rangle, |1\rangle\}$ or in the conjugate bases $B_2 = \{|\bar{0}\rangle, |\bar{1}\rangle\}$, [17] defined as

$$\begin{aligned} |\bar{0}\rangle &= \frac{1}{\sqrt{2}}(|0\rangle + |1\rangle) \\ |\bar{1}\rangle &= \frac{1}{\sqrt{2}}(|0\rangle - |1\rangle) \end{aligned} \tag{1}$$

Bob performs measurements on one of the two bases mentioned above at random. Then, in the next step, the bases used by both, Alice and Bob are disclosed in the public channel where they compare the bit values for a randomly chosen sample of few bits from the string prepared by both sender and receiver. A secret key is said to be established using the cases in which Alice's and Bob's bases coincide. It is then important for Alice and Bob to know whether anyone in the middle may steal the information about the key. Alice and Bob can reveal the existence of the third party, i.e., the eavesdropper in the middle, by calculating the quantum bit error rate (QBER). QBER may be calculated as the ratio of the error rate to the key rate. Therefore, if the QBER is too high, Alice and Bob decide to abort the protocol. Otherwise, using either one-way [18–20] or two-way [21, 22] classical communication, they apply a classical

* rashijain_23phdam07@dtu.ac.in
† satyabrata@dtu.ac.in

post-processing protocol to distill a secret key.

The security of the standard BB84 scheme has been provided in [23], which is closer to a realistic experimental situation. Later, simple proof of security of BB84 was presented in [24–26]. A general framework of optimal eavesdropping on BB84 protocol was studied in [27] and they derived an upper bound on mutual information and described a specific type of interaction and the corresponding measurement that achieves the bound. Extending their work, in 2017, the uniqueness of optimal interaction up to rotation has been established in [28].

In 1998, D. Bruß [29] introduced a generalization of the BB84 scheme in the sense that the author uses three bases i.e. six states in her QKD protocol instead of four states used in BB84 protocol. The third set of bases may be denoted as B_3 in which the states can be defined as

$$\begin{aligned} |\bar{\bar{0}}\rangle &= \frac{1}{\sqrt{2}}(|0\rangle + i|1\rangle) \\ |\bar{\bar{1}}\rangle &= \frac{1}{\sqrt{2}}(|0\rangle - i|1\rangle) \end{aligned} \tag{2}$$

In the Bruß scheme [29], Alice transmits one of these six states to Bob, with equal probability, and in this scheme, it is assumed that all six possible states occurred at Bob's site with the same disturbance. Using the optimal mutual information between Alice and Eve, it was shown that this scheme [29] is more secure against eavesdropping in comparison to BB84 scheme [15]. In 2008, an optimal six-state eavesdropping QKD scheme [32] was proposed wherein Alice deliberately adds equal noise to the signal states before transmitting it to Bob, and they found that the six-state protocol with mixed states is more robust than the six-state protocol with pure states. The proof of security of the six-state QKD protocol has been proposed by [33, 34].

Moreover, we can also find that the security increases not only by increasing the number of non-orthogonal bases but also by increasing the level of the system. This can be easily verified from the study, where Bechmann and Peres [30] suggested the use of three-level systems rather than two-level systems for establishing a secure quantum key. Later, in 2002, Bruß and Macchiavello [31] introduced the optimal eavesdropping scheme with three-dimensional systems, and showed that it would be more secure against symmetric attacks than two-dimensional systems. One can also note that, as the number of bases increases, the security also increases, but the efficiency of key formation decreases [31]. Further, in 1999, Gisin and Wolf [35] studied a protocol in which as long as Alice and Bob share some entanglement, they can use either quantum or classical key-agreement protocols to extract a secret key.

Despite of all these studies related to QKD protocols, we observe that there is a gap in which we can think of a situation, where Eve can execute her unitary operation in such a way that she may extract the information as much as possible successfully from the intercepted qubit by allowing the small disturbance and thus omitting her presence in the protocol. Hence, this gap motivate us to study about Eve, a person in the middle, who believed to be stronger in the sense that she can use quantum resource efficiently.

The aim of this paper is two-fold. Firstly, we aim to show that the eavesdropper Eve construct the unitary transformation in such a way that it may transform her input ancilla state to the different ancilla component states at the output, which are entangled. With the help of this construction, our purpose is to show that the mutual information of Alice and Eve may depend not only on the disturbance but also on the concurrence of the entangled ancilla component states. Secondly, our aim is to show that the generation of the secret key also depends on the entanglement of ancilla component states.

The rest of the paper is organized as follows: In Section II, we will discuss in detail the unitary transformation constructed by Eve that may generate the entangled ancilla component states at the output of the transformation. In section III, we derive the mutual information of Alice and Eve and show that it depends on the concurrence of the entangled ancilla component states. Moreover, we also derive the mutual information of Alice and Bob, which solely depends on the disturbance D. In section IV, we discuss the generation of the secret key in the following two cases: (i) when the mutual information of Alice and Eve depends on the disturbance D caused by Eve's interference and (ii) when it is independent of the same. Finally, we conclude in section V.

II. CONSTRUCTION OF A UNITARY TRANSFORMATION

In a six state QKD protocol, the sender (Alice) has to send her qubit prepared in any one of the basis chosen from $\{B_1, B_2, B_3\}$ to the receiver (Bob). But before reaching to Bob, the eavesdropper (Eve) intercepts the qubit with the following motivations: (i) Eve would like to extract as much information as possible from the qubit sent by Alice so that she would know about the secret key shared between Alice and Bob (ii) While extracting the information from the intercepting qubit, she also has to keep in mind that the disturbance will be the same irrespective of the basis $\{B_1, B_2, B_3\}$ chosen for the preparation of Alice's qubit.

Thus, to achieve her motivations, Eve has to apply a suitable unitary transformation on the intercepted qubit. Therefore, it is crucial to consider all the above points while constructing the unitary transformation. The unitary transformation U constructed by Eve may be defined as

$$\begin{aligned} U|0\rangle|X\rangle &= \sqrt{F}|0\rangle|\phi_0\rangle + \sqrt{D}|1\rangle|\psi_0\rangle \\ U|1\rangle|X\rangle &= \sqrt{F}|1\rangle|\phi_1\rangle + \sqrt{D}|0\rangle|\psi_1\rangle \end{aligned} \tag{3}$$

where $|X\rangle$ denote the initial normalized ancilla component state before interaction with the input qubit while

$|\phi_i\rangle$ and $|\psi_i\rangle$ $(i = 0, 1)$ refers to normalized ancilla component states after interaction. D denote the disturbance at the output when the ancillary state of Eve interacted with the input qubit. The fidelity between the input and output qubit is described by F and it is related with D as given below

$$F + D = 1 \tag{4}$$

A. Constraints to be satisfied by the ancilla component states at the output

The constraints that can be satisfied by the ancilla component states at the output might come from two assumptions: (a) the unitarity of the transformation and (b) the transformation should keep the disturbance D same for all input qubits that come from any basis under consideration.
(a) Unitarity of the transformation gives

$$\langle\phi_0|\psi_1\rangle + \langle\psi_0|\phi_1\rangle = 0 \tag{5}$$

(b) If the transformation is treating all the input states in the same way i.e. keeping the disturbance same for all input qubits generated by sender from any basis, then the following conditions hold

$$\langle\psi_0|\psi_1\rangle = 0 \tag{6}$$

$$\mathrm{Re}\langle\phi_1|\phi_0\rangle = \frac{1-2D}{1-D} \tag{7}$$

$$\langle\phi_0|\psi_0\rangle + \overline{\langle\phi_1|\psi_1\rangle} = 0 \tag{8}$$

B. Structure of the two-qubit ancilla component states

We are now in a position to determine the structure of the two-qubit ancilla component states generated at the output when the initial ancilla component states of Eve interact with the qubit sent by the sender, Alice. The specific form of the ancilla component states may be obtained by using the constraints given in (6-8).

1. *Specific form of $|\psi_0\rangle$ and $|\psi_1\rangle$*

To start with, let us first choose the ancilla component state $|\psi_0\rangle$ and $|\psi_1\rangle$ in such a way that (6) holds. To fulfill the requirement, we may choose

$$|\psi_0\rangle = \frac{|00\rangle - \tau_1|11\rangle}{\sqrt{1+\tau_1^2}} \tag{9}$$

and

$$|\psi_1\rangle = \frac{\tau_1|00\rangle + |11\rangle}{\sqrt{1+\tau_1^2}} \tag{10}$$

where $0 \le \tau_1 \le 1$.
Defining in this way (9-10), we can say that the ancilla component states $|\psi_0\rangle$ and $|\psi_1\rangle$ represents non-maximally entangled states. They are product states when $\tau_1 = 0$, while maximally entangled states when $\tau_1 = 1$. To quantify the amount of entanglement in the states $|\psi_0\rangle$ and $|\psi_1\rangle$, we can make use of concurrence [37]. The concurrence C_{ψ_0} and C_{ψ_1} of the state $|\psi_0\rangle$ and $|\psi_1\rangle$ respectively may be given as

$$C_{\psi_0} = C_{\psi_1} = \frac{2\tau_1}{1+\tau_1^2} \tag{11}$$

From (11), we can express τ_1^2 in terms of C_{ψ_0} as

$$\tau_1^2 = \frac{2 - C_{\psi_0}^2 - 2\sqrt{1-C_{\psi_0}^2}}{C_{\psi_0}^2} \tag{12}$$

The proof of (12) is given in Appendix-A.
We should note here that when $\tau_1 = 0$, the transformation (3) reduces to the transformation prescribed by Bruss [29]. Here, we may also stress that when $0 < \tau_1 \le 1$, the transformation may shed new light on the distribution of the secret key between the sender and the receiver. We will show that the formation of a secret key is possible, although the modified transformation may increase the efficiency of Eve with respect to the stealing of information.

2. *Specific form of $|\phi_0\rangle$ and $|\phi_1\rangle$*

Let us now move on to the ancilla component states $|\phi_0\rangle$ and $|\phi_1\rangle$, which can be expressed initially in the general form of two-qubit pure states in the computational basis $\{|00\rangle, |01\rangle, |10\rangle, |11\rangle\}$ as

$$|\phi_0\rangle = \alpha_{\phi_0}|00\rangle + \beta_{\phi_0}|01\rangle + \gamma_{\phi_0}|10\rangle + \delta_{\phi_0}|11\rangle \quad \text{with } |\alpha_{\phi_0}|^2 + |\beta_{\phi_0}|^2 + |\gamma_{\phi_0}|^2 + |\delta_{\phi_0}|^2 = 1 \tag{13}$$

and

$$|\phi_1\rangle = \alpha_{\phi_1}|00\rangle + \beta_{\phi_1}|01\rangle + \gamma_{\phi_1}|10\rangle + \delta_{\phi_1}|11\rangle \quad \text{with } |\alpha_{\phi_1}|^2 + |\beta_{\phi_1}|^2 + |\gamma_{\phi_1}|^2 + |\delta_{\phi_1}|^2 = 1 \tag{14}$$

Now, our task is to determine the parameters $\alpha_{\phi_i}, \beta_{\phi_i}, \gamma_{\phi_i}$ and δ_{ϕ_i} $(i = 0, 1)$, for which the constraints (5-8) are satisfied. Simplifying the constraints (5-8) for the states $|\phi_0\rangle$ and $|\phi_1\rangle$, we get (Appendix B)

$$\alpha_{\phi_0} = \alpha_{\phi_1} = 0 \tag{15}$$

$$\delta_{\phi_0} = \delta_{\phi_1} = 0 \tag{16}$$

Therefore, the ancilla component states $|\phi_0\rangle$ and $|\phi_1\rangle$ given in (13) and (14) reduces to

$$|\chi_0\rangle = \beta_{\phi_0}|01\rangle + \gamma_{\phi_0}|10\rangle, \ |\beta_{\phi_0}|^2 + |\gamma_{\phi_0}|^2 = 1 \tag{17}$$

$$|\chi_1\rangle = \beta_{\phi_1}|01\rangle + \gamma_{\phi_1}|10\rangle,\ |\beta_{\phi_1}|^2 + |\gamma_{\phi_1}|^2 = 1 \tag{18}$$

It may be easily seen that the ancilla component states $|\chi_0\rangle$ and $|\chi_1\rangle$ are entangled unless the parameters $|\beta_{\phi_0}|$ or $|\gamma_{\phi_0}|$ and $|\beta_{\phi_1}|$ or $|\gamma_{\phi_1}|$ vanishes. If they are entangled, then the amount of entanglement can be calculated by concurrence, and it is given by

$$\begin{aligned} C_{\chi_0} &= 2|\mathrm{Re}(\beta_{\phi_0}\gamma^*_{\phi_0})| \\ &= 2|b_1 g_1 + b_2 g_2| \end{aligned} \tag{19}$$

where $\beta_{\phi_0} = b_1 + ib_2$ and $\gamma_{\phi_0} = g_1 + ig_2$.
If we now choose the parameters b_1, b_2, g_1 and g_2 in such a way that $b_1 g_2 = b_2 g_1$ then the equation (19) reduces to

$$C^2_{\chi_0} = 4\Big(|\beta_{\phi_0}|^2(1 - |\beta_{\phi_0}|^2)\Big) \tag{20}$$

Solving (20), we can obtain the value of $|\beta_{\phi_0}|^2$ in terms of the concurrence C_{χ_0} as

$$|\beta_{\phi_0}|^2 = \frac{1 \pm \sqrt{1 - C^2_{\chi_0}}}{2}, 0 \le C_{\chi_0} \le 1 \tag{21}$$

One of the two values of $|\beta_{\phi_0}|^2$ can be considered from (21) and then the ranges of $|\beta_{\phi_0}|^2$ can be found out, which are discussed below:
(i) If

$$|\beta_{\phi_0}|^2 = \frac{1 - \sqrt{1 - C^2_{\chi_0}}}{2} \tag{22}$$

then we can find that $|\beta_{\phi_0}|^2$ is lying in $[0, \frac{1}{2}]$. We may also observe that $|\beta_{\phi_0}|^2$ is an increasing function of C_{χ_0}.
(ii) If

$$|\beta_{\phi_0}|^2 = \frac{1 + \sqrt{1 - C^2_{\chi_0}}}{2} \tag{23}$$

then $|\beta_{\phi_0}|^2 \in [\frac{1}{2}, 1]$. In this case, we find that $|\beta_{\phi_0}|^2$ is a decreasing function of C_{χ_0}.
In a similar fashion, the concurrence of the ancilla component state $|\chi_1\rangle$ can be denoted by C_{χ_1}, which is given by

$$C^2_{\chi_1} = 4\Big(|\beta_{\phi_1}|^2(1 - |\beta_{\phi_1}|^2)\Big) \tag{24}$$

Therefore, $|\beta_{\phi_1}|^2$ can be expressed in terms of the concurrence C_{χ_1} as

$$|\beta_{\phi_1}|^2 = \frac{1 \pm \sqrt{1 - C^2_{\chi_1}}}{2}, 0 \le C_{\chi_1} \le 1 \tag{25}$$

Following the similar discussion above, we can have

$$\begin{aligned} &(i)\ \text{ If }\ |\beta_{\phi_1}|^2 = \frac{1 - \sqrt{1 - C^2_{\chi_1}}}{2}\ \text{ then }\ |\beta_{\phi_1}|^2 \in \left[0, \frac{1}{2}\right] \\ &(ii)\ \text{ If }\ |\beta_{\phi_1}|^2 = \frac{1 + \sqrt{1 - C^2_{\chi_1}}}{2}\ \text{ then }\ |\beta_{\phi_1}|^2 \in \left[\frac{1}{2}, 1\right] \end{aligned} \tag{26}$$

III. MUTUAL INFORMATION

Mutual information can be defined as the relative entropy between the joint distribution and the product of the marginal distributions. If $p(x, y)$ denote the joint probability mass function of the random variables X and Y and if $p(x)$ and $p(y)$ denote the marginal probability mass functions then the mutual information may be defined mathematically as [4, 38]

$$I^{XY} = \sum_x \sum_y p(x, y) \log_2 \frac{p(x, y)}{p(x)p(y)} \tag{27}$$

Mutual information I^{XY} may also be interpreted as how much information we can extract about the random variable X by performing a measurement on other random variable Y.
Therefore, our interest in this section would be to know how well Eve will use her entangled ancilla component states to extract information from the intercepted qubit, which was sent by the sender, Alice.

A. Mutual information of Alice and Eve

Let Alice prepares a two-qubit maximally entangled state of the form

$$|\psi^{(B_1)}\rangle = \frac{1}{\sqrt{2}}(|00\rangle + |11\rangle) \tag{28}$$

Here, we should note that it is not necessary that Alice prepare the qubit in only computational basis $B_1 = \{|0\rangle, |1\rangle\}$ but she may use the basis $B_2 = \{\frac{|0\rangle+|1\rangle}{\sqrt{2}}, \frac{|0\rangle-|1\rangle}{\sqrt{2}}\}$ or $B_3 = \{\frac{|0\rangle+i|1\rangle}{\sqrt{2}}, \frac{|0\rangle-i|1\rangle}{\sqrt{2}}\}$ also. Using the bases B_2 and B_3, the two-qubit maximally entangled state can be re-expressed as

$$|\psi^{(B_2)}\rangle = \frac{1}{\sqrt{2}}\Big[(|0\rangle + |1\rangle)(|0\rangle + |1\rangle) + (|0\rangle - |1\rangle)(|0\rangle - |1\rangle)\Big] \tag{29}$$

$$|\psi^{(B_3)}\rangle = \frac{1}{\sqrt{2}}\Big[(|0\rangle + i|1\rangle)(|0\rangle + i|1\rangle) + (|0\rangle - i|1\rangle)(|0\rangle - i|1\rangle)\Big] \tag{30}$$

She then transmits one of the qubits to Bob, but in the midway, Eve intercepts the qubit, and the intercepted qubit undergoes the transformation (3). Eve does not know the fact that in which basis, Alice has prepared her qubits. But Eve's transformation will act on the qubit in the same way irrespective of the basis chosen by the sender, Alice, to prepare the state. This means that the disturbance created by Eve's transformation will be same irrespective of the chosen basis.
When the intercepted qubit interacts with Eve's ancilla

component state, the four-qubit state at Eve's site is given by

$$|\chi\rangle_{AEE_1E_2} = \frac{1}{\sqrt{2}}\Big(\sqrt{F}|00\rangle_{AE}|\phi_0\rangle_{E_1E_2} + \sqrt{D}|01\rangle_{AE}|\psi_0\rangle_{E_1E_2} + \sqrt{F}|11\rangle_{AE}|\phi_1\rangle_{E_1E_2} + \sqrt{D}|10\rangle_{AE}|\psi_1\rangle_{E_1E_2}\Big) \tag{31}$$

where the first qubit possessed by Alice, the second qubit is in Eve's possession and the remaining two-qubits are from Eve's ancilla component state.
Now, tracing out the two ancilla qubits E_1 and E_2, the reduced state shared between Alice and Eve is given by

$$\begin{aligned}\rho_{AE} = \frac{1}{2}[&\left(F|\beta_{\phi_0}|^2+\eta\right)|00\rangle\langle 00| + \sqrt{F\eta}\left(\beta_{\phi_0}+\gamma^*_{\phi_1}\right)|00\rangle\langle 11| \\ &+ \left(F|\gamma_{\phi_0}|^2+\eta\tau_1^2\right)|01\rangle\langle 01| + \sqrt{F\eta}\tau_1^2\left(\gamma_{\phi_0}-\beta^*_{\phi_1}\right)|01\rangle\langle 10| \\ &+\sqrt{F\eta}\tau_1^2\left(\beta_{\phi_1}+\gamma^*_{\phi_1}\right)|10\rangle\langle 01| + \left(F|\beta_{\phi_1}|^2+\eta\tau_1^2\right)|10\rangle\langle 10| \\ &+\sqrt{F\eta}\left(\gamma_{\phi_1}+\beta^*_{\phi_0}\right)|11\rangle\langle 00| + \left(F|\gamma_{\phi_1}|^2+\eta\right)|11\rangle\langle 11|]\end{aligned} \tag{32}$$

where $\eta = \frac{D}{1+\tau_1^2}$.
The mutual information of Alice and Eve is given by

$$\begin{aligned}I^{AE}(|\beta_{\phi_0}|^2,|\beta_{\phi_1}|^2,\tau_1,D) = F(|\beta_{\phi_0}|^2+|\beta_{\phi_1}|^2)+D- \\ \left(F(|\beta_{\phi_0}|^2+|\beta_{\phi_1}|^2)+D\right)\log_2\left(F(|\beta_{\phi_0}|^2+|\beta_{\phi_1}|^2)+D\right) \\ +\epsilon\left[F|\beta_{\phi_0}|^2+\eta, F|\beta_{\phi_1}|^2+\eta\tau_1^2\right]\end{aligned} \tag{33}$$

where the parameters $|\beta_{\phi_0}|^2$, $|\beta_{\phi_1}|^2$ are defined in (22), (23) and (26) and the function $\epsilon[a,b]$ may be defined as

$$\epsilon[a,b] = a\log a + b\log b - (a+b)\log(a+b) \tag{34}$$

Therefore, the mutual information between Alice and Eve may be re-expressed in terms of the concurrences C_{χ_0} and C_{χ_1} as

$$(i)\quad I_1^{AE}(C_{\chi_0},C_{\chi_1},\tau_1,D) = F\left(\frac{1-\sqrt{1-C_{\chi_0}^2}}{2}+\frac{1-\sqrt{1-C_{\chi_1}^2}}{2}\right)+D+\epsilon\left[F\left(\frac{1-\sqrt{1-C_{\chi_0}^2}}{2}\right)+\eta, F\left(\frac{1-\sqrt{1-C_{\chi_1}^2}}{2}\right)+\eta\tau_1^2\right],$$
$$|\beta_{\phi_0}|^2\in\left[0,\frac{1}{2}\right], |\beta_{\phi_1}|^2\in\left[0,\frac{1}{2}\right] \tag{35}$$

$$(ii)\quad I_2^{AE}(C_{\chi_0},C_{\chi_1},\tau_1,D) = F\left(\frac{1-\sqrt{1-C_{\chi_0}^2}}{2}+\frac{1+\sqrt{1-C_{\chi_1}^2}}{2}\right)+D+\epsilon\left[F\left(\frac{1-\sqrt{1-C_{\chi_0}^2}}{2}\right)+\eta, F\left(\frac{1+\sqrt{1-C_{\chi_1}^2}}{2}\right)+\eta\tau_1^2\right],$$
$$|\beta_{\phi_0}|^2\in\left[0,\frac{1}{2}\right], |\beta_{\phi_1}|^2\in\left[\frac{1}{2},1\right] \tag{36}$$

$$(iii)\quad I_3^{AE}(C_{\chi_0},C_{\chi_1},\tau_1,D) = F\left(\frac{1+\sqrt{1-C_{\chi_0}^2}}{2}+\frac{1-\sqrt{1-C_{\chi_1}^2}}{2}\right)+D+\epsilon\left[F\left(\frac{1+\sqrt{1-C_{\chi_0}^2}}{2}\right)+\eta, F\left(\frac{1-\sqrt{1-C_{\chi_1}^2}}{2}\right)+\eta\tau_1^2\right],$$
$$|\beta_{\phi_0}|^2\in\left[\frac{1}{2},1\right], |\beta_{\phi_1}|^2\in\left[0,\frac{1}{2}\right] \tag{37}$$

$$(iv)\quad I_4^{AE}(C_{\chi_0},C_{\chi_1},\tau_1,D) = F\left(\frac{1+\sqrt{1-C_{\chi_0}^2}}{2}+\frac{1+\sqrt{1+C_{\chi_1}^2}}{2}\right)+D+\epsilon\left[F\left(\frac{1+\sqrt{1-C_{\chi_0}^2}}{2}\right)+\eta, F\left(\frac{1+\sqrt{1-C_{\chi_1}^2}}{2}\right)+\eta\tau_1^2\right]$$
$$|\beta_{\phi_0}|^2\in\left[\frac{1}{2},1\right], |\beta_{\phi_1}|^2\in\left[\frac{1}{2},1\right] \tag{38}$$

B. Mutual information of Alice and Bob

Eve extract the information from the intercepted qubit by using her ancilla component states in such a way that it keeps the disturbance same for all the intercepted qubit irrespective of the bases in which Alice has prepared the qubit. After eavesdropping, Eve sent the intercepted qubit to Bob so that Alice and Bob does not reveal her presence in the intermediate place. After receiving the qubit, the shared state between Alice and Bob is given by

$$\rho_{AB} = \begin{pmatrix} \frac{1-D}{2} & 0 & 0 & \frac{1-2D}{4} \\ 0 & \frac{D}{2} & 0 & 0 \\ 0 & 0 & \frac{D}{2} & 0 \\ \frac{1-2D}{4} & 0 & 0 & \frac{1-D}{2} \end{pmatrix} \tag{39}$$

Therefore, the mutual information of Alice and Bob is given by

$$I^{AB}(D) = 1 + D\log_2 D + (1-D)\log_2(1-D) \quad (40)$$

IV. GENERATION OF SECRET KEY IN SIX STATE MODIFIED QKD PROTOCOL

In this section, we will provide a detailed analysis of when the secret key will be generated in the quantum key distribution protocol in spite of the presence of an eavesdropper with entangled ancilla component states. It is known that the two parties can share a secret key if the mutual information of A and B is strictly greater than the mutual information of A and E [36]. To analyze it in detail, we divide the whole fact into two parts: In the first part, we will investigate the generation of the secret key when the mutual information of Alice and Eve depends on the disturbance D, and in the second part, we probe when mutual information of Alice and Eve is independent of D.

A. Relationship between $I^{AE}(C_{\psi_0}, C_{\chi_0}, D)$ and the concurrences C_{ψ_0} and C_{χ_0} of the ancilla component states

Eve can enhance the amount of extracted information from the intercepted qubit if she chooses the parameter $|\beta_{\phi_0}|^2$ and $|\beta_{\phi_1}|^2$ in (33) in the following way:

$$|\beta_{\phi_0}|^2 + |\beta_{\phi_1}|^2 = 1 \quad (41)$$

Therefore, using (4) and (41), the mutual information $I^{AE}(|\beta_{\phi_0}|^2, |\beta_{\phi_1}|^2, \tau_1, D)$ given in (33) reduces to

$$\begin{aligned} I^{AE}(|\beta_{\phi_0}|^2, \tau_1, D) = 1 &+ \left[(1-D)|\beta_{\phi_0}|^2 + \eta\right] \times \\ &\log_2\left[(1-D)|\beta_{\phi_0}|^2 + \eta\right] + \\ &\left[(1-D)(1-|\beta_{\phi_0}|^2) + \eta\tau_1^2\right] \times \\ &\log_2\left[(1-D)(1-|\beta_{\phi_0}|^2) + \eta\tau_1^2\right] \end{aligned} \quad (42)$$

The analysis of the generation of secret key can be studied in the following two cases:

Case-I: When $|\beta_{\phi_0}|^2 \in [0, \frac{1}{2}]$.
In this case, the relationship between $|\beta_{\phi_0}|^2$ and the concurrence $C_{\chi_0}^2$ of the ancilla component state $|\chi_0\rangle$ is given by using (12) and (22), the expression of $I^{AE}(|\beta_{\phi_0}|^2, \tau_1^2, D)$ given in (42) reduces to

$$\begin{aligned} I^{AE}(C_{\psi_0}, C_{\chi_0}, D) = 1 &+ \frac{1}{2}\left((1-\sqrt{1-C_{\chi_0}^2}) + \frac{D\left(C_{\psi_0}^2 - (1-\sqrt{1-C_{\chi_0}^2})(1-\sqrt{1-C_{\psi_0}^2})\right)}{1-\sqrt{1-C_{\psi_0}^2}}\right) \\ &\log_2\left[\frac{1}{2}\left((1-\sqrt{1-C_{\chi_0}^2}) + \frac{D\left(C_{\psi_0}^2 - (1-\sqrt{1-C_{\chi_0}^2})(1-\sqrt{1-C_{\psi_0}^2})\right)}{1-\sqrt{1-C_{\psi_0}^2}}\right)\right] + \\ &\frac{1}{2}\left((1+\sqrt{1-C_{\chi_0}^2}) + \frac{D\left(2-C_{\psi_0}^2 - 2\sqrt{1-C_{\psi_0}^2} - \left(1+\sqrt{1-C_{\chi_0}^2}\right)\left(1-\sqrt{1-C_{\psi_0}^2}\right)\right)}{1-\sqrt{1-C_{\psi_0}^2}}\right) \\ &\log_2\left[\frac{1}{2}\left((1+\sqrt{1-C_{\chi_0}^2}) + \frac{D\left(2-C_{\psi_0}^2 - 2\sqrt{1-C_{\psi_0}^2} - \left(1+\sqrt{1-C_{\chi_0}^2}\right)\left(1-\sqrt{1-C_{\psi_0}^2}\right)\right)}{1-\sqrt{1-C_{\psi_0}^2}}\right)\right] \end{aligned} \quad (43)$$

It may be observed that if we vary the parameters C_{χ_0} and C_{ψ_0} in between zero and unity and if D is lying between zero and a value which is very close to 0.5, then we get

$$I^{AB}(D) - I^{AE}(C_{\psi_0}, C_{\chi_0}, D) > 0, \quad (44)$$

Thus, equation (44) represents the fact that, in this case, a secret key can be generated. But, there exists a critical value of D, which is lying in [0.4999999.0.5) and for the concurrence $C_{\psi_0} \in (0, 0.009]$, for which a secret key cannot be generated. This can be verified if we choose the values of the concurrences C_{χ_0} and C_{ψ_0} in such a way that $C_{\chi_0} = C_{\psi_0}$. In this particular case, $I^{AE}(C_{\psi_0}, C_{\chi_0}, D)$ given in (43) can be re-expressed as

$$I^{AE}(C_{\psi_0},D) = 1+\frac{1}{2}\left(1-(1-2D)\sqrt{1-C_{\psi_0}^2}\right)\log_2\left[\frac{1}{2}\left(1-(1-2D)\sqrt{1-C_{\psi_0}^2}\right)\right]+$$
$$\frac{1}{2}\left(1+(1-2D)\sqrt{1-C_{\psi_0}^2}\right)\log_2\left[\frac{1}{2}\left(1+(1-2D)\sqrt{1-C_{\psi_0}^2}\right)\right] \quad (45)$$

Now, in the above expression (45), if we choose the values of the parameter C_{ψ_0} from 0.1 to 0.9 with a step length of 0.1 and varying D in the interval (0,0.5) then the plot of $I^{AB}(D) - I^{AE}(C_{\psi_0}, D)$ versus D may be shown in the Fig.1.

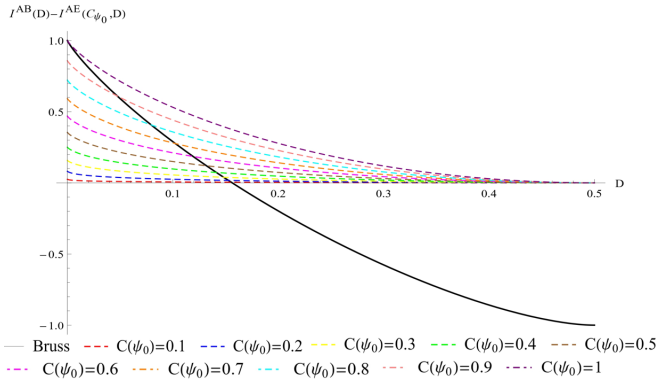

FIG. 1. Secret key generation for the six-state modified QKD protocol with each ancilla component state as entangled states compared to the six-state protocol adopted by [29]. The D-axis represents the amount of disturbance $D \in (0, 0.5)$ in the system as a result of Eve's interference and the $I^{AB}(D) - I^{AE}(C_{\psi_0}, D)$ axis represents the possibility for generation of the secret key between Alice and Bob in Eve's presence.

The following insights can be drawn from the graph (FIG.1) obtained above:
(i) As the concurrence C_{ψ_0} increases from 0 to 1, the value of $I^{AB}(D) - I^{AE}(C_{\psi_0}, D)$ increases as the disturbance D increases from 0 to 0.5.
(ii) After a certain value of disturbance D, the key is not generated for the model proposed by [29]. However, it can be easily seen that almost all the curves in our case lie in the upper half of the D-axis, implying that the secret key can be generated as $I^{AB}(D) - I^{AE}(C_{\psi_0}, D) > 0$ for all values of $C_{\psi_0} \in (0.009, 1]$ and for the values of D lying in $(0, 0.4999999)$. The secret key cannot be generated when $D \in [0.4999999, 0.5)$ and $C_{\psi_0} \in (0, 0.009]$.

Case-II: When $|\beta_{\phi_0}|^2 \in [\frac{1}{2}, 1]$.
Using (12) and (23), we find that the expression given in (42) will be independent of D, and it will be studied in detail in the next subsection.

B. Relationship between the concurrence C_{ψ_0} of the ancilla component states and D independent mutual information

Here, we discuss the case when there is no effect of D on the mutual information of Alice and Eve. That is, mutual information remains the same for whatever disturbance induced by Eve on the intercepted qubit while extracting information from it. In this scenario, mutual information depends only on the entanglement of the ancilla component states.
Recalling (42), let's re-express it in the following way

$$I^{AE}(|\beta_{\phi_0}|^2, \tau_1^2, D) = 1 + \left[(1-D)|\beta_{\phi_0}|^2 + \eta\right] \times \log_2\left[(1-D)|\beta_{\phi_0}|^2 + \eta\right] + \left[(1-D)|\beta_{\phi_1}|^2 + \eta\tau_1^2\right] \times \log_2\left[(1-D)|\beta_{\phi_1}|^2 + \eta\tau_1^2\right] \quad (46)$$

If we now choose the parameters $|\beta_{\phi_0}|^2$ and $|\beta_{\phi_1}|^2$ in such a way that

$$|\beta_{\phi_0}|^2 = \frac{1}{1+\tau_1^2}, |\beta_{\phi_1}|^2 = \frac{\tau_1^2}{1+\tau_1^2} \quad (47)$$

then (41) holds and the mutual information of Alice and Eve will now become independent of D, and it may be given as

$$I^{AE}(|\beta_{\phi_0}|^2, |\beta_{\phi_1}|^2) = 1 + |\beta_{\phi_0}|^2 \log_2 |\beta_{\phi_0}|^2 + |\beta_{\phi_1}|^2 \log_2 |\beta_{\phi_1}|^2 \quad (48)$$

Now, our task is to express $I^{AE}(|\beta_{\phi_0}|^2, |\beta_{\phi_1}|^2)$ in terms of the concurrences C_{ψ_0} and C_{χ_0}. Since $|\beta_{\phi_0}|^2$ and $|\beta_{\phi_1}|^2$ can take two values in terms of concurrences so we need to analyze the relations given in (47).
If possible let $|\beta_{\phi_0}|^2 = \frac{1-\sqrt{1-C_{\chi_0}^2}}{2}$. Then (12) and (47) gives

$$\left(1-\sqrt{1-C_{\chi_0}^2}\right)\left(1-\sqrt{1-C_{\psi_0}^2}\right) = C_{\psi_0}^2$$
$$\implies \left(\sqrt{1-C_{\psi_0}^2}-1\right)\left(\sqrt{1-C_{\psi_0}^2}+\sqrt{1-C_{\chi_0}^2}\right) = 0 \quad (49)$$

Since $0 < C_{\psi_0} \leq 1$ and $0 \leq C_{\chi_0} < 1$ so (49) is not possible and we arrive at a contradiction. Thus, $|\beta_{\phi_0}|^2 \neq \frac{1-\sqrt{1-C_{\chi_0}^2}}{2}$, Hence, $|\beta_{\phi_0}|^2$ does not belong to $[0, 0.5)$.
It can be shown that if $|\beta_{\phi_0}|^2 = \frac{1+\sqrt{1-C_{\chi_0}^2}}{2}$ then

$$C_{\psi_0} = C_{\chi_0} \quad (50)$$

holds.
If $C_{\chi_0} = 1$, then $I^{AE}(\frac{1}{2}, \frac{1}{2}) = 0$. So $C_{\chi_0} \neq 1$. Therefore, alternatively, we can say that the equation (50) holds when $|\beta_{\phi_0}|^2 \in (0.5, 1]$.
Similarly, we can also prove that if $|\beta_{\phi_1}|^2 \in [0, 0.5)$ then

$$C_{\psi_0} = C_{\chi_1} \tag{51}$$

holds.
Moreover, one can easily verify that $|\beta_{\phi_1}|^2$ cannot belong to $(0.5, 1]$.
Therefore, if $|\beta_{\phi_0}|^2 \in (0.5, 1]$ and $|\beta_{\phi_1}|^2 \in [0, 0.5)$, then we have

$$C_{\psi_0} = C_{\chi_0} = C_{\chi_1} \tag{52}$$

Hence, using (48) and (52), the expression for $I^{AE}(|\beta_{\phi_0}|^2, |\beta_{\phi_1}|^2)$ can be re-expressed as

$$\begin{aligned} I^{AE}(C_{\psi_0}) =& 1 + \frac{1+\sqrt{1-C_{\psi_0}^2}}{2} \log_2 \frac{1+\sqrt{1-C_{\psi_0}^2}}{2} \\ &+ \frac{1-\sqrt{1-C_{\psi_0}^2}}{2} \log_2 \frac{1-\sqrt{1-C_{\psi_0}^2}}{2} \end{aligned}$$

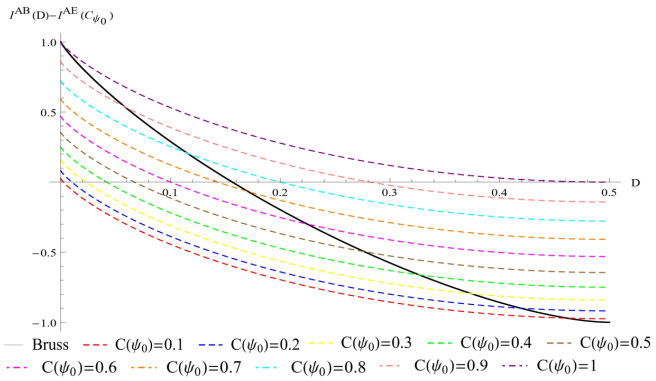

FIG. 2. The figure represents that in the modified six-state QKD protocol, the secret key is generated when the curves are lying above $D-$ axis in $(D, I^{AB}(D) - I^{AE}(C_{\psi_0}))$-plane and the secret key is not generated when the curves lying below the $D-$ axis. The different curves in the graph are drawn for different values of the concurrence of the ancilla component states. The black curve represents when the secret key is generated or is not generated in Bruss's six-state QKD protocol.

The following insights may be drawn from the graph (FIG.2) obtained above:
(i) As the value of concurrence C_{ψ_0} increases from 0 to 1, the value of $I^{AB}(D) - I^{AE}(C_{\psi_0})$ increases for increasing value of the disturbance D from 0 to 1.
(ii) Unlike the model proposed by [29], the secret key may not be generated after a certain value of disturbance D, depending upon $C_{\psi_0} \in (0, 1]$. However, one may find that the secret key may only be generated in the full range of D when the ancilla component state $|\psi_0\rangle$ is maximally entangled state.

V. CONCLUSION

To summarize, we have studied a six-state QKD protocol by modifying the unitary transformation prescribed in Bruss's work [29]. The modified unitary operation might be able to generate entangled ancilla component states at the output, and it might give extra power to the eavesdropper, Eve, to gain knowledge about the key that would be generated between two distant partners, Alice and Bob. The amount of entanglement in ancilla component states is measured by the concurrence. We have shown that the mutual information of Alice and Eve not only depends on the disturbance produced while extracting the information but also on the concurrence of the ancilla component state and we denote it by $I^{AE}(C_{\chi_0}, C_{\chi_1}, \tau_1, D)$. Moreover, we have identified the region where the inequality $I^{AB}(D) > I^{AE}(C_{\chi_0}, C_{\chi_1}, \tau_1, D)$ holds i.e., we have identified the region where the secret key may be generated in spite of the presence of Eve. To analyze this study, we divided the modified protocol into two parts. Firstly, we investigate the case where mutual information of Alice and Eve depends upon both disturbance D and concurrence of the entangled ancilla component states. We find that as concurrence increases, the value of $I^{AB}(D) - I^{AE}(C_{\psi_0}, C_{\chi_0}, D)$ will be positive and increases as the disturbance increases. Further, we noticed in the proposal proposed by [29] that the secret key is not generated after a certain value of disturbance D, i.e. when $D > 0.1565$, but in our case, the secret key is generated up to a critical value D_c of D, i.e. the secret key is generated when $0 < D_c < 0.4999999$, otherwise the secret key is not generated, i.e., when $0.4999999 \leq D_c < 0.5$. In the second case, we find that there exists a relationship between the concurrences of the ancilla component states for which the mutual information of Alice and Eve is independent of D. In this scenario, the value of $I^{AB}(D) - I^{AE}(C_{\psi_0})$ increases for increasing values of concurrence and the disturbance D respectively. One may also find that in this case, the secret key is not generated by following Bruss's six-state QKD protocol when the disturbance $D > 0.1565$ but in our modified six-state QKD protocol, the secret key is generated even for $D > 0.1565$ but the concurrence of the ancilla component state is adjusted between $(0.74, 1)$. The key is generated in the whole domain of D if the ancilla component $|\psi_0\rangle$ is a maximally entangled state. To conclude, we feel that it would be interesting to study the same when Alice prepares her state as a mixed state instead of a pure state.

Appendix A: Derivation of the expression of τ_1^2

Recalling (11) and squaring both sides, we get

$$(1+\tau_1^2)^2 C_{\psi_0}^2 = 4\tau_1^2 \tag{A1}$$

Simplifying and expressing τ_1^2 in terms of the concurrence C_{ψ_0}, we get

$$\tau_1^2 = \frac{2 - C_{\psi_0}^2 \pm 2\sqrt{1-C_{\psi_0}^2}}{C_{\psi_0}^2} \tag{A2}$$

Now, we will prove that

$$\tau_1^2 = \frac{2 - C_{\psi_0}^2 - 2\sqrt{1-C_{\psi_0}^2}}{C_{\psi_0}^2} \tag{A3}$$

holds.

Proof: If possible, let

$$\tau_1^2 = \frac{2 - C_{\psi_0}^2 + 2\sqrt{1-C_{\psi_0}^2}}{C_{\psi_0}^2} \tag{A4}$$

Since $0 < \tau_1^2 < 1$, so we have

$$0 < \frac{2 - C_{\psi_0}^2 + 2\sqrt{1-C_{\psi_0}^2}}{C_{\psi_0}^2} < 1 \tag{A5}$$

We may observe that LHS inequality is always true but simplifying the RHS inequality, we get

$$\sqrt{1-C_{\psi_0}^2}\left(\sqrt{1-C_{\psi_0}^2}+1\right) < 0 \tag{A6}$$

We arrive at a contradiction because $0 \leq C_{\psi_0} \leq 1$. Thus, we have

$$\tau_1^2 = \frac{2 - C_{\psi_0}^2 - 2\sqrt{1 - C_{\psi_0}^2}}{C_{\psi_0}^2} \tag{A7}$$

Hence proved.

Appendix B: Detailed calculation to derive the specific form of $|\phi_0\rangle$ and $|\phi_1\rangle$

To start with, let us consider the general form of initially considered pure two-qubit ancilla component state $|\phi_0\rangle$ and $|\phi_1\rangle$ in the computational basis $\{|00\rangle, |01\rangle, |10\rangle, |11\rangle\}$ as

$$\begin{aligned} |\phi_0\rangle =& \alpha_{\phi_0}|00\rangle + \beta_{\phi_0}|01\rangle + \gamma_{\phi_0}|10\rangle + \delta_{\phi_0}|11\rangle, \\ \text{with } & |\alpha_{\phi_0}|^2 + |\beta_{\phi_0}|^2 + |\gamma_{\phi_0}|^2 + |\delta_{\phi_0}|^2 = 1 \end{aligned} \tag{B1}$$

and

$$\begin{aligned} |\phi_1\rangle =& \alpha_{\phi_1}|00\rangle + \beta_{\phi_1}|01\rangle + \gamma_{\phi_1}|10\rangle + \delta_{\phi_1}|11\rangle \\ \text{with } & |\alpha_{\phi_1}|^2 + |\beta_{\phi_1}|^2 + |\gamma_{\phi_1}|^2 + |\delta_{\phi_1}|^2 = 1 \end{aligned} \tag{B2}$$

Further, we choose the states $|\psi_0\rangle$ and $|\psi_1\rangle$ in such a way that (6), i.e., $\langle\psi_0|\psi_1\rangle = 0$ is satisfied. Therefore, we can consider the following form of the states

$$|\psi_0\rangle = \frac{|00\rangle - \tau_1|11\rangle}{\sqrt{1+\tau_1^2}} \tag{B3}$$

and

$$|\psi_1\rangle = \frac{\tau_1|00\rangle + |11\rangle}{\sqrt{1+\tau_1^2}} \tag{B4}$$

where $0 < \tau_1 \leq 1$.
Let us now calculate the disturbance made by Eve if Alice prepares the state in the basis B_1:

$$\langle 0|\rho_B|0\rangle = 1 - D \tag{B5}$$
$$\langle 1|\rho_B|1\rangle = 1 - D \tag{B6}$$

where, $\rho_B = \mathrm{Tr}_{AE_1E_2}(\rho_{ABE_1E_2})$ represents the state sent by Alice to Bob which is intercepted by Eve.
In the same way, if Alice prepares the state in the bases B_2 or B_3 and keeping in mind the restrictions that make the disturbance same for all the states in the three non-orthogonal bases $\{B_1, B_2, B_3\}$, then for $0 < \tau_1 \leq 1$, we have

$$(\alpha_{\phi_0} + \alpha_{\phi_1}^*)(1 - \tau_1) + (\delta_{\phi_0} + \delta_{\phi_1}^*)(1 + \tau_1) = 0 \tag{B7}$$
$$(\alpha_{\phi_0} + \alpha_{\phi_1}^*)(1 + \tau_1) + (\delta_{\phi_0} + \delta_{\phi_1}^*)(1 - \tau_1) = 0 \tag{B8}$$

Solving (B7-B8), we obtain

$$\delta_{\phi_0} + \delta_{\phi_1}^* = 0 \tag{B9}$$
$$\alpha_{\phi_0} + \alpha_{\phi_1}^* = 0 \tag{B10}$$

Recalling (5) and (8), and using (B1-B4), we get

$$\begin{aligned} \tau_1(\alpha_{\phi_0}^* - \delta_{\phi_1}) + \delta_{\phi_0}^* + \alpha_{\phi_1} = 0 \\ \tau_1(\alpha_{\phi_1} - \delta_{\phi_0}^*) + \delta_{\phi_1} + \alpha_{\phi_0^*} = 0 \end{aligned} \tag{B11}$$

To make (B11) independent of τ_1, we have

$$\alpha_{\phi_0}^* - \delta_{\phi_1} = 0 \tag{B12}$$
$$\alpha_{\phi_1} - \delta_{\phi_0}^* = 0 \tag{B13}$$

Using (B12-B13), equation (B11) reduces to

$$\delta_{\phi_0}^* + \alpha_{\phi_1} = 0 \tag{B14}$$
$$\delta_{\phi_1} + \alpha_{\phi_0}^* = 0 \tag{B15}$$

Solving (B12) & (B15) and (B13) & (B14), we get

$$\alpha_{\phi_0} = \delta_{\phi_0} = \alpha_{\phi_1} = \delta_{\phi_1} = 0 \tag{B16}$$

Using (B16), equation (B1) and (B2) reduces to

$$|\chi_0\rangle = \beta_{\phi_0}|01\rangle + \gamma_{\phi_0}|10\rangle,\ |\beta_{\phi_0}|^2 + |\gamma_{\phi_0}|^2 = 1$$
$$|\chi_1\rangle = \beta_{\phi_1}|01\rangle + \gamma_{\phi_1}|10\rangle,\ |\beta_{\phi_1}|^2 + |\gamma_{\phi_1}|^2 = 1$$

Abstract

Ensemble methods are among the most effective concept-drift adaptation techniques due to their high learning performance and flexibility. However, they are computationally expensive and pose a challenge in applications involving high-speed data streams. In this paper, we present a computationally efficient heterogeneous classifier ensemble entitled OMS-MAB which uses online model selection for concept-drift adaptation by posing it as a non-stationary multi-armed bandit (MAB) problem. We use a MAB to select a single *adaptive learner* within the ensemble for learning and prediction while systematically exploring promising alternatives. Each ensemble member is made drift resistant using explicit drift detection and is represented as an arm of the MAB. An exploration factor ϵ controls the trade-off between predictive performance and computational resource requirements, eliminating the need to continuously train and evaluate all the ensemble members. A rigorous evaluation on 20 benchmark datasets and 9 algorithms indicates that the accuracy of OMS-MAB is statistically at par with state-of-the-art (SOTA) ensembles. Moreover, it offers a significant reduction in execution time and model size in comparison to several SOTA ensemble methods, making it a promising ensemble for resource constrained stream-mining problems.

1 | INTRODUCTION

With rapid advances in the Internet of Things (IoT), computing infrastructure and communication networks, data is increasingly generated, organized, and consumed as streams. In several real-world applications such as weather forecasting, e-commerce recommendations, and early warning systems, the underlying data generation process evolves over time causing *concept-drift*. Concept-drift means that the underlying data distribution of a stream changes over time in unforeseen ways (Lu et al., 2018). Offline storage and batch processing techniques would be ineffective in this context due to large data volume, fast arrival rate, dynamically changing data distribution, and computational resource constraints. Unlike learning techniques which assume data to be independent and identically distributed (i.i.d.), specialized algorithms that rapidly adapt to concept-drift to provide fast predictions and model updates while operating within the computational resource constraints are essential in this context (Alippi et al., 2013).

Ensemble learning is a very effective concept-drift adaptation strategy for data stream mining (Gomes, Barddal, et al., 2017). Depending on their composition, ensembles could be classified as heterogeneous or homogeneous. While the former employs different classifier types as base learners, the latter uses a single classifier type for all its members (Neto & Canuto, 2021). Ensembles adapt to concept-drift by adding new members, removing obsolete members, training multiple base models, and updating model combination rules. Though ensembles provide

 © 2024 John Wiley & Sons Ltd.

high predictive performance, computational efficiency is not their strong trait (Elwell & Polikar, 2011). This limits their usage in high-speed data stream mining (Alippi et al., 2013), motivating the need for computationally efficient ensembles with competitive predictive performance.

Diversity among members is a key factor for the effectiveness of ensembles. One approach to ensure diversity is to construct a heterogeneous ensemble with base models belonging to different model families (van Rijn et al., 2018). This eliminates the need to manually select the most appropriate base learner for a stream. Furthermore, heterogeneous ensembles often use much fewer members to provide comparable predictive performance to that of homogeneous ensembles with hundreds of members (Luong et al., 2021). Moreover, studies comparing batch-incremental and instance-incremental learning indicate equivalence in their overall performance, with instance-incremental methods requiring fewer computational resources (Read, Bifet, Pfahringer, & Holmes, 2012). For the aforementioned reasons, our proposal focuses on heterogeneous ensembles which are instance-incremental.

As data streams evolve, the predictive performance of models varies over time. Thus, a classifier that best models a certain stream segment may not be the best for a different segment of the same stream (van Rijn et al., 2014). By adaptively choosing the model best suited for each stream segment, heterogeneous ensembles could increase their predictive performance and adapt to concept-drift (Rossi et al., 2014; van Rijn et al., 2018). To this end, works such as Heterogeneous Dynamic Weighted Majority (HDWM) (Idrees et al., 2020), HEterogeneous Ensemble Selection (HEES) (Luong et al., 2021) and Best Last (BLAST) (van Rijn et al., 2018) present ensembles that simultaneously train multiple heterogeneous classifiers and use online model selection to adaptively choose a subset to make predictions. Despite being less resource intensive compared to homogeneous ensembles, the complexity of their model selection mechanism and the need to simultaneously train all the ensemble members introduce significant computational overheads. Moreover, meta-learning based heterogeneous ensembles such as (van Rijn et al., 2014) and (Rossi et al., 2014) which rely on periodic algorithm selection provide marginal performance improvements while requiring extraction of computationally expensive meta-features (van Rijn et al., 2018).

While multi-armed bandits (MAB) are well studied in the context of multivariate testing (Burtini et al., 2015), its utility as a computationally efficient online model selection framework for classification on streaming data affected by concept-drift is under-explored. Moreover, most studies on online model selection focus on choosing a subset of ensemble members that are best suited for making predictions (Idrees et al., 2020; Luong et al., 2021; van Rijn et al., 2018). Identifying which ensemble members are to be used for both learning and prediction at a time instant significantly reduces computational resource requirements as it eliminates the need to continuously train and evaluate all ensemble members. However, environment non-stationarity makes this non-trivial. Furthermore, despite several studies on enhancing the predictive performance of heterogeneous ensembles for data stream mining, little work has been dedicated to improving their computational efficiency. The above aspects motivate the present study.

In this paper, we present a heterogeneous ensemble named OMS-MAB (Online Model Selection Multi-Armed Bandit) which uses a non-stationary MAB for online model selection to adapt to concept-drift. Our algorithm operates at two levels. At the inner-level, a pool of diverse instance-incremental *adaptive learners* (ALs) each equipped with a drift detector is maintained to solve the original decision problem. At the outer level, a MAB selects the adaptive learner (AL) best suited for an instance based on past experience, while systematically exploring promising alternatives. The MAB switches between *exploration* to identify the current best AL and *exploitation* to train and evaluate the best AL. This significantly reduces computational resource requirements as only a single AL is trained and evaluated during *exploitation*, independent of the total number of ALs within the ensemble. Though all ALs undergo training and evaluation during *exploration*, the extent of exploration is controlled using the exploration factor ϵ. Furthermore, MAB based model selection is computationally lightweight compared to approaches requiring costly meta-feature extraction or complex ensemble selection. Moreover, explicit drift detection at the inner-level periodically resets ensemble members, preventing their unbounded growth in size and complexity. In summary, OMS-MAB addresses 3 challenges posed by several state-of-the-art (SOTA) instance-incremental ensembles: high computational cost, model selection complexity, and unbounded model growth. While computational efficiency is attained by adaptively training a single ensemble member for most parts of the stream, model selection is simplified using a non-stationary MAB. Furthermore, each ensemble member is equipped with a drift-detector and a backup learner to prevent their unbounded growth. Our experiments on OMS-MAB covering 20 benchmark streams and 9 classification algorithms indicate that its predictive performance is statistically at par with SOTA ensembles, while with a significant reduction in execution time and model size, making it attractive for resource constrained environments.

This paper makes three contributions:

1. It poses online model selection in non-stationary environments as a bandit problem and uses a non-stationary MAB to adaptively choose the classifier member best suited for learning and prediction from time to time. To the best of our knowledge, our proposal is the first to approach concept-drift adaptation in a classification setting as a bandit based online ensemble selection problem.
2. It combines MAB based online model selection and ALs with explicit drift detection for computational efficiency. Unlike popular instance-incremental ensembles like (Bifet, Holmes, & Pfahringer, 2010), (Frías-Blanco et al., 2016), and (van Rijn et al., 2018) that continuously train all ensemble members, our approach optimizes computational needs by adaptively identifying a single member for training by using a MAB, while preventing unbounded model growth using drift-detectors.

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

3. Complexity analysis and empirical evaluation of the proposed approach indicates that it is faster and consumes less computational resources compared to several SOTA ensembles, while providing statistically equivalent predictive performance.

The rest of the paper is organized as follows. In Section 2, we review the related work. Our proposed method is described in Section 3. In Section 4 and Section 5 we present the experimental methodology and results respectively. Finally, Section 6 concludes the paper.

2 | RELATED WORKS

2.1 | Online ensemble selection

Several heterogeneous ensembles simultaneously train multiple classifiers and choose a subset to make predictions. BLAST simultaneously trains a group of heterogeneous classifiers, while using an online performance estimation framework to dynamically select a single classifier for prediction on each test instance (van Rijn et al., 2018). While window-based and fading factor-based performance estimation have been proposed, empirical evaluations favor the fading factor-based variant. Since the performance of BLAST depends on the number of base learners and their diversity, it becomes computationally expensive for large ensembles as each member needs to be trained and evaluated continuously. Moreover, the absence of explicit drift detection may result in unbounded growth in model size and complexity.

HDWM algorithm adaptively switches between different types of base classifiers within an ensemble to increase predictive performance (Idrees et al., 2020). It uses both an active and passive approach to handle concept-drift, while using seed learners from different model families to ensure ensemble diversity. Weaker learners are temporarily removed from the ensemble when their weights drop below a threshold. Although HDWM reduces the manual effort required to select base classifiers for ensembles, its performance is lower compared to some of the SOTA homogeneous ensembles (Luong et al., 2021).

HEterogeneous Ensemble Selection (HEES) identifies a competent subset of base classifiers with high predictive performance and high confidence, for making predictions (Luong et al., 2021). The predictive performance of classifiers is estimated from their prequential accuracy whereas confidence estimation uses adaptive reliability thresholds. HEES uses ADWIN (Bifet & Gavalda, 2007) to track the performance of each base classifier and resets the respective classifier whenever a change is detected. Despite the competitive performance of HEES, computational resources for training and evaluation of multiple classifiers will still be incurred.

Diversity Pool (DP) algorithm maintains a pool of classifiers and selects a single representative member for making predictions. If a single member cannot be confidently chosen for prediction, the pool is used as a weighted majority vote ensemble (Chiu & Minku, 2018). New models are introduced into the pool once concept-drift is detected, enabling each pool member to hold the knowledge corresponding to a concept. It uses a diversity metric to maximize the difference between pool members for allowing the reuse of relevant past knowledge when recurring concepts are encountered. Though the adaptation strategy of DP enables handling recurring concepts well, it is not designed for handling diverse drift types.

Dynamic Ensemble Selection for Drift Detection (DESDD) (Albuquerque et al., 2019) creates a population of classifier ensembles each with a different level of diversity and dynamically selects a single classifier ensemble for making predictions based on global prequential accuracy. It uses explicit drift detection to reset the population of classifiers upon encountering concept-drift. Though DESDD provides competitive accuracy, its computational complexity is very high as the entire population of classifier ensembles are trained and evaluated continuously.

2.2 | Meta-learning based adaptive ensembles

Few heterogeneous ensembles use meta-learning to identify learning algorithms best suited for a specific window of instances within data streams (Rossi et al., 2014; van Rijn et al., 2014). MetaStream periodically chooses among regression algorithms based on meta-features extracted from past and incoming data windows (Rossi et al., 2014). A meta-classifier is regularly induced to map meta-features to the actual performance of regression algorithms, for predicting the best algorithm in the subsequent window.

Meta-learning based algorithm selection for data stream classification was first proposed in (van Rijn et al., 2014). Their approach determines the best classifier among several candidates for predicting the next window of instances by considering data characteristics of the previous window and meta-knowledge from streams processed previously. Limitations of the above approaches include determining the optimal window size over which meta-features need to be extracted, and the methods inherently being batch-incremental which limits their applicability on high-speed instance-incremental streams (Luong et al., 2021). Furthermore, meta-feature extraction introduces additional computational overheads (van Rijn et al., 2018).

Fast Adaptive Stacking of Ensembles (FASE) (Frías-Blanco et al., 2016) uses an adaptive meta-learner to combine the predictions of base classifiers within the ensemble for countering concept-drift. Base classifiers themselves are adaptive learners that track the error rate of the induced classifier using the Hoeffding-based Drift Detection Method (HDDM) (Frias-Blanco et al., 2014). Upon encountering a warning level, an alternate classifier is trained by the adaptive learner. In case the warning is followed by a drift detection, the adaptive learner replaces the original classifier with the alternate classifier. Each adaptive learner has at most two classifiers whose predictions are combined by weighted voting to generate a single prediction. The meta-level adaptive learner combines the predictions of all base-level adaptive learners in the ensemble to make the final prediction. Though FASE provides competitive accuracy, computational complexity due to its three-level ensemble structure will still be incurred.

2.3 | Multi-armed bandits

MAB provides a framework for trade-off among exploring the environment to discover profitable actions and exploiting the existing knowledge from past experience, to maximize cumulative rewards (Garivier & Moulines, 2008; Sutton & Barto, 2018). At each time step t, an agent pulls an arm $I_t \in \{1,\ldots,K\}$ according to a policy π learned from the sequence of past arm pulls and the associated rewards, to receive a reward $R_t(I_t)$. In the case of a stationary MAB, rewards $\{R_t(i)\}_{t\geq 1}$ associated with each arm $i \in \{1,\ldots,K\}$ is assumed to be i.i.d., with $\mu(i)$ as the expected reward corresponding to arm i. The optimal policy π^* is the one which always pulls the best arm $i^* \in \{1,\ldots,K\}$ with the largest expected reward.

$$\mu(*) = \max_{1\leq i\leq K} \mu(i), \quad i^* = \arg\max_{1\leq i\leq K} \mu(i) \tag{1}$$

The agent improves its policy π by minimizing cumulative *regret*, which is the expected difference between the total rewards obtained if the agent would have followed the optimal policy π^* and the total rewards that was obtained by following the policy π (Garivier & Moulines, 2008).

The expected regret after T time steps would be:

$$\mathbb{E}_\pi\left[\sum_{t=1}^{T}\{\mu(*)-\mu(I_t)\}\right] = \sum_{i\neq i^*}\{\mu(*)-\mu(i)\}\mathbb{E}_\pi[N_T(i)], \tag{2}$$

where $N_T(i)$ is the number of times the arm i was pulled in T time steps and $\mathbb{E}_\pi$ is the expectation under policy π. Popular strategies for solving stationary MABs include ϵ-greedy action selection, Upper Confidence Bound (UCB) and Thompson sampling (Burtini et al., 2015; Sutton & Barto, 2018). In the $\epsilon-$greedy approach, the agent selects an arm $i \in \{1,\ldots,K\}$ at random for $0 \leq \epsilon \leq 1$ fraction of the time, and the arm i^* with the highest estimated action value $Q(i^*)$ otherwise.

For non-stationary MABs, the underlying reward distributions evolve, resulting in the best arm getting changed from time to time. Specialized algorithms such as Discounted UCB, Sliding-Window UCB, Exp3.R, and Kalman Filtered Bandits have been proposed for this more challenging setting (Burtini et al., 2015). However, a simple solution to handle non-stationarity is to allow a decay of the rewards such that the contribution of long-past rewards fades away while the effect of recent rewards reflect in the action value estimation (Burtini et al., 2015; Sutton & Barto, 2018). This can be incorporated into the incremental update rule for action value estimation of ϵ-greedy algorithm by using a constant step-size parameter as per the Equation (3).

$$Q_{t+1}(i) = Q_t(i) + \alpha[R_t(i) - Q_t(i)] \tag{3}$$

Here $Q_t(i)$ is the estimated action value for arm i at time step t, $R_t(i)$ is the reward obtained by pulling arm i at time step t, and $\alpha \in (0,1]$ is the step-size parameter.

3 | PROPOSED METHOD

We introduce OMS-MAB, a heterogeneous ensemble that uses online model selection for concept-drift adaptation. Our framework has a two-level learning architecture as presented in Figure 1. At the inner level, a pool of diverse instance-incremental ALs is maintained for solving the original decision problem. Each AL is a *Drift detection method classifier* (Gama et al., 2004) which induces a main classifier for prediction and uses HDDM_A-test (Frias-Blanco et al., 2014) to decide if an alternate classifier needs to be trained. The alternate classifier replaces the main classifier

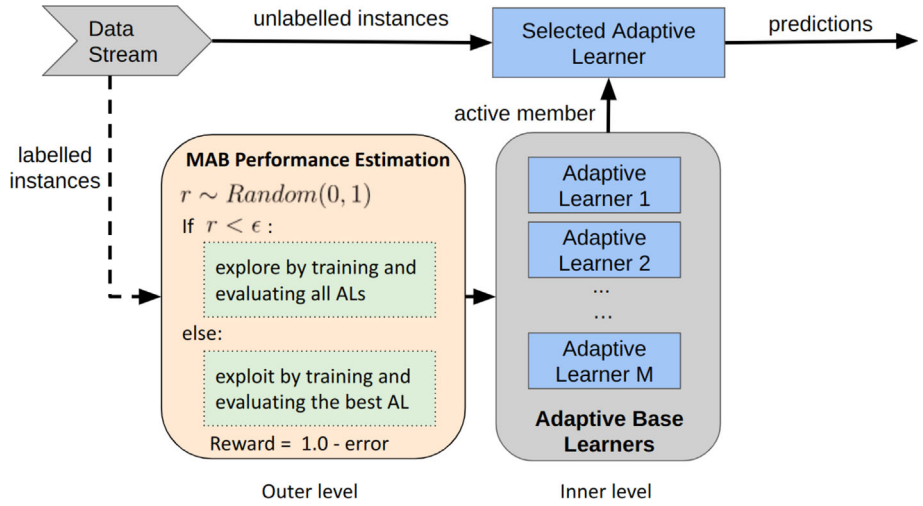

FIGURE 1 OMS-MAB ensemble architecture. A pool of heterogeneous ALs each with a builtin HDDM_A drift detector is maintained to solve the original prediction problem. A non-stationary MAB periodically selects the best AL for training and prediction based on past experience, while systematically exploring promising alternatives.

TABLE 1 Summary of notations.

Notations	Description
S	Data stream
x_t, y_t	x_t is the data instance and y_t is the corresponding data label at time t
M	Number of ALs in the ensemble
Ψ_i	Ensemble member at the index position i
$\hat{y}_t^i$	Prediction of Ψ_i for the unlabelled instance x_t
L_t^i	Loss of the ith ensemble member at time t
R_t^i	Reward for the ith ensemble member at time t
P_t^j	Performance estimate for the jth ensemble member at time t
θ	Fading factor
Ψ	Ensemble with M heterogeneous learners
ϵ	Exploration factor of the MAB
L	Loss function
t	A specific time step

once concept-drift is detected. Any instance-incremental classifier, irrespective of being stand-alone or ensemble-based, could be used to construct an AL. Outer level MAB identifies a single inner level AL best suited for an instance. It tracks the competency of each AL by translating inner level prediction errors into rewards and uses a non-stationary MAB with $\epsilon-$greedy action selection for a cost-effective but accurate performance estimation of ALs. Greedy action selection is used to choose a single best AL for prediction on a particular instance (behavior policy), whereas exploration required to identify and train the best AL is controlled by $\epsilon-$greedy action selection (exploration policy).

Let S be a data stream consisting of a sequence of instances $\{x_1,x_2,...x_t...\}$ where $x_t \in \mathbb{R}^d$ denotes the instance arriving at time step t, represented as a d-dimensional feature vector. The true label corresponding to x_t is denoted by $y_t \in \{y_1,y_2...y_K\}$, which belongs to a classification problem having a finite set of known class labels. We assume y_t to arrive subsequently, after which the pair (x_t,y_t) is available for incremental learning. These assumptions pertain to one of the common operational settings studied in data stream mining (Albuquerque et al., 2019; Luong et al., 2021) and are relevant for applications such as electricity price movement prediction (Harries et al., 1999) and weather prediction (Elwell & Polikar, 2011).

OMS-MAB maintains a pool of M ALs forming a heterogeneous ensemble $\Psi = \{\Psi_1,\Psi_2,..\Psi_M\}$. The outer level MAB models each ensemble member Ψ_j as an arm and adaptively selects a single *active member* Ψ_i best suited for an instance to make predictions. At each training time step, the MAB chooses among *exploration* to identify the current best AL within Ψ and *exploitation* to train and evaluate the best AL. In case of

14680394, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/exsy.13626 by Delhi Technological University, Wiley Online Library on [19/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

exploitation, the *active member* $\Psi_i \in \Psi$ makes a prediction $\hat{y}_t^i$ for the unlabelled instance x_t. Once y_t becomes available, the corresponding loss $L_t^i = L\left(\hat{y}_t^i, y_t\right)$ is used to generate a reward $R_t^i = 1 - L_t^i$, and (x_t, y_t) is used to update Ψ_i. The reward R_t^i acts as a feedback signal for the MAB decision to use Ψ_i as the *active member* at t. On the other hand, *exploration* involves evaluating and training all ensemble members $\Psi_j \in \Psi$ to derive rewards R_t^j corresponding to their respective predictions, to update performance estimates for all arms. Though this approach is different from that of general bandit algorithms which evaluate a single arm during exploration, it provides faster estimation of expected rewards for all arms due to their simultaneous evaluation. As our prediction procedure follows a greedy policy, the above exploration strategy results in better predictions since the best performing AL can be quickly identified by the MAB. Moreover, the computational overhead associated with evaluating all arms as opposed to a single arm during *exploration* is relatively low in this case, as arms represent instance-incremental learners which are fast to train and evaluate. Our complete learning procedure is presented in Algorithm 1. Table 1 summarizes the notations used.

OMS-MAB optimistically initializes performance estimates P_t^j associated with each ensemble member Ψ_j as 1 and randomly selects a member Ψ_i as the *active member* upon initialization. The MAB treats P_t^j as the action value estimate corresponding to the jth arm at time t. Optimistic initialization ensures frequent evaluation of each ensemble member in the early stages of the stream, until they are proven to be suboptimal. Ensemble members require training and evaluation for sufficient time steps for reliable performance estimation, a prerequisite for the MAB to correctly identify the best AL for a particular instance. To this end, an ϵ-greedy exploration policy is used. A small value for ϵ (e.g., 0.01) results in inaccurate performance estimates for ALs, whereas large values introduce the computational overhead of evaluating and training all the ensemble members during the associated larger exploration. Thus, ϵ provides a trade-off between model accuracy and computational resource requirements, a desirable property for high-speed stream mining algorithms operating in resource constrained environments. The values for ϵ range from 0 to 1.

Each AL monitors the error rate of the main classifier using the HDDM_A-test. If the error rate of an AL begins to increase, a concept-drift is anticipated and a warning is triggered. In the warning phase, the corresponding AL trains an alternate classifier. In case the warning escalates to an out-of-control level, concept-drift is detected and the main classifier is replaced with the alternate classifier. This procedure is based on (Gama et al., 2004) and is summarized in Figure 2. Each AL can have two classifiers at most whose predictions are combined using weighted voting as described in (Frías-Blanco et al., 2016). We use HDDM_A for drift detection as it is a SOTA method with mathematical guarantees on the rate of false positives and false negatives while processing each instance with a constant space and time complexity (Frias-Blanco et al., 2014; Frías-Blanco et al., 2016). Though any instance-incremental classifier can be used to construct ALs, standalone learners such as Hoeffding Tree (HT) (Domingos & Hulten, 2000), Extremely Fast Decision Tree (EFDT) (Manapragada et al., 2018), NaiveBayes (NB) (John & Langley, 1995) and Perceptron (Rosenblatt, 1958) are preferable as they provide reasonable accuracy at a lower computational cost. Though the learning strategy of ALs causes periodic model resets which prevent historical knowledge reuse during recurring concepts, it provides computational savings by avoiding unbounded growth of model size and complexity.

While evaluating an AL Ψ_j, either during *exploration* or *exploitation*, the loss L_t^j associated with each prediction $\hat{y}_t^j$ is used to calculate the reward $R_t^j = 1 - L_t^j$. We make use of the zero/one loss function as proposed in (van Rijn et al., 2018). This translates to obtaining a reward of 1 for correct predictions and 0 otherwise. Performance estimate P_t^j of the corresponding AL Ψ_j at time t is updated using the Equation (4). We observe that Equation (4) takes the form of Equation (3) which represents the update rule for action value estimation in non-stationary contexts by decaying rewards. However, it is to be noted that the fading factor $\theta = 1 - \alpha$, where α is the step size. Thus, the MAB ensures that accurate performance estimates of each member is maintained by combining their historical performance with recent accuracy using the fading factor θ. The values for θ range from 0 to 1.

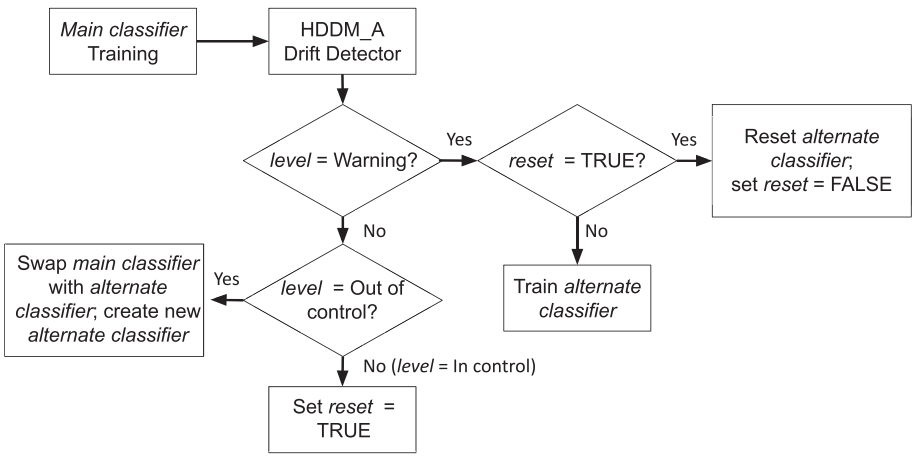

FIGURE 2 Learning procedure for adaptive learners within OMS-MAB.

ALGORITHM 1 OMS-MAB training

Input:

Set of adaptive learners Ψ, fading factor θ, loss function L

exploration factor ϵ, data stream S

Output:

active member index $i \in \{1,2,...|\Psi|\}$

1: Initialize all adaptive learners in Ψ

2: $P_t^j \leftarrow 1 \quad \forall j \in \{1,2,...|\Psi|\}, t = 1$

3: $active_member \leftarrow random.uniform(1,|\Psi|)$

4: **for all** training samples $(x_t, y_t) \in S$ **do**

5: $r \sim random.uniform(0,1)$

6: **if** $r < \epsilon$ **then** //exploration move

7: **for all** $j \in \{1,2,...|\Psi|\}$ **do**

8: $\hat{y}_t^j \leftarrow$ predicted label of x_t by Ψ_j

9: $R_t^j \leftarrow \left(1 - L\left(\hat{y}_t^j, y_t\right)\right)$

10: $P_t^j \leftarrow \theta^* P_{t-1}^j + (1-\theta)^* R_t^j$ //update estimates

11: update Ψ_j with (x_t, y_t) using procedure in Figure 2

12: **end for**

13: **else** //exploitation move

14: $i \leftarrow active_member$

15: $\hat{y}_t^i \leftarrow$ predicted label of x_t by Ψ_i

16: $R_t^i \leftarrow \left(1 - L\left(\hat{y}_t^i, y_t\right)\right)$

17: $P_t^i \leftarrow \theta^* P_{t-1}^i + (1-\theta)^* R_t^i$ //update estimates

18: update Ψ_i with (x_t, y_t) using procedure in Figure 2

19: **end if**

20: $active_member \leftarrow \underset{1 \le j \le |\Psi|}{\arg\max} P(j)$ //greedy selection

21: **end for**

22: **return** *active_member*

$$P_t^j = \theta^* P_{t-1}^j + (1-\theta)^* R_t^j \tag{4}$$

The prediction procedure of OMS-MAB is straightforward. The MAB uses a greedy behavior policy to choose the *active member* which makes the prediction at each time step. As the MAB decision relies on the action value estimates derived using the exploration policy, the AL best suited for the current instance is automatically selected to be the *active member* as the stream progresses. The prediction corresponding to each unlabelled sample x_t is made by the *active member* at that time instance.

We note that unlike ensembles such as BLAST which uses a passive approach for drift adaptation, OMS-MAB uses both an active and passive strategy to handle concept-drift, enabling it to effectively deal with both gradual and abrupt drift. Our passive strategy involves using the best performing AL for prediction at each instant, while eliminating the need to continuously train and evaluate all ensemble members. On the other hand, the active strategy uses explicit drift detection within each AL to keep them up to date with the latest concept. Moreover, as ensemble members are trained from limited samples based on MAB's stochastic decisions, explicit drift detection is essential to quickly discard obsolete knowledge. The two-level architecture of OMS-MAB enables both scalability and adaptability in handling large volume-high speed data streams affected by diverse drift types. From a scalability perspective, OMS-MAB capitalizes on the inherent diversity among heterogeneous learners within the ensemble, eliminating the need for computationally expensive techniques like online bagging for diversity generation. Moreover, the MAB framework further enhances computational efficiency, as only a single ensemble member is adaptively trained for most parts of the stream, independent of the total ensemble size. This makes OMS-MAB well-suited for large data volumes. On the adaptability front, explicit drift detection and backup learners in OMS-MAB facilitate swift adaptation to streams with both abrupt and gradual drifts, even at high speeds. Though explicit drift detection discards obsolete knowledge, choosing a lower ϵ results in members getting trained only on a subset of samples. This enables OMS-MAB to reuse historical knowledge during recurring drift, in case some of the members are not already reset.

3.1 | Space and time complexity

We analyze the space and time complexity of OMS-MAB and compare it with BLAST, a popular heterogeneous ensemble that trains all member classifiers continuously while deterministically using the best performer at each time step to make predictions.

3.1.1 | Space complexity

OMS-MAB maintains M ALs at the inner-level and a MAB at the outer-level. Let $S(N)$ be the space required by a base classifier within an AL to store a model learned from N samples. We note that $S(N)$ depends on the base classifier. For instance, $S(N) = O(ldvc)$ for HT where l represents the number of leaves, and $S(N) = O(ndvc)$ for EFDT where n denotes the number of nodes (Manapragada et al., 2018). In both cases, d denotes the number of attributes, v the values per attribute, and c the number of classes per instance.

The space complexity of OMS-MAB depends on the total number of classifiers within the ensemble. In the worst case when all ALs are in the *warning* phase, each AL maintains a *main classifier* and an *alternate classifier*, resulting in a total of $2M$ classifiers within the ensemble. With an exploration factor of ϵ, $2M$ classifiers will be trained on $(\epsilon.N)$ samples, whereas 2 classifiers corresponding to the *active_member* will be trained on $((1-\epsilon).N)$ samples. Outer-level MAB maintains performance estimates for each AL, resulting in a space complexity of $O(M)$. On similar lines, HDDM_A detectors within each AL result in a space complexity of $O(M)$ as their individual complexity is $O(1)$ (Frias-Blanco et al., 2014). Thus, the final space complexity of OMS-MAB comes out to be $O(2M.S(\epsilon.N) + 2.S((1-\epsilon).N) + 2M)$.

On the other hand, space complexity for BLAST which trains all ensemble members wherein each member is a standalone classifier as opposed to an AL would be $O(M.S(N) + M)$. We observe that as N grows large while ϵ being set to a small value, the gain in space complexity for OMS-MAB becomes more pronounced. Furthermore, our empirical study reconfirms this analysis as indicated by the lower model size growth rate for OMS-MAB when compared to BLAST, in Figure 7. Moreover, the average model size across datasets is much lower for OMS-MAB when compared to BLAST, as captured in Table 6. For practical large-scale data stream mining applications, this translates to lower memory requirements suitable for resource constrained settings.

3.1.2 | Time complexity

Let $O(T_t)$ be the time complexity to train a base classifier on an instance and $O(T_c)$ be the time complexity for a base classifier to classify an instance. T_t and T_c depend on the base classifier. For instance, $T_t = O(dvc)$ for HT, where d is the number of attributes, v the values per attribute and c the number of classes per instance (Manapragada et al., 2018).

The time complexity of OMS-MAB with M ALs depends on the total number of standalone classifiers within the ensemble, which could be up to $2M$ in the worst case, as explained in the space complexity analysis. We consider OMS-MAB being trained on N samples. With exploration factor ϵ, $2M$ classifiers are trained on $(\epsilon.N)$ samples, whereas 2 classifiers corresponding to the *active_member* are trained on $((1-\epsilon).N)$ samples. Performance estimation updates of ALs (Algorithm 1, steps 10 and 17) and *active_member* selection (Algorithm 1, step 20) by the MAB results in a time complexity of $O(2M)$. Similarly, HDDM_A detectors within ALs contribute to a time complexity of $O(M)$ as their individual time complexity is $O(1)$ (Frias-Blanco et al., 2014). Since each training step of OMS-MAB involves the evaluation and training of ALs, its overall training time complexity is $O((2M.\epsilon.N.(T_t + T_c)) + (2.(1-\epsilon).N.(T_t + T_c)) + 3M)$. In the case of prediction, only the *active_member* classifies an instance, resulting in a time complexity of $O(N.T_c)$.

On the other hand, the training time complexity for BLAST would be $O((M.N.(T_t + T_c)) + 2M)$, wherein all ensemble members are trained and evaluated on all samples. As the prediction procedure is the same as that of OMS-MAB, its prediction time complexity is $O(N.T_c)$ itself. The gain in time complexity for OMS-MAB becomes evident as N grows large while ϵ being set to a small value. Our experiments reconfirm the lower execution time growth rate for OMS-MAB in comparison to BLAST, as visualized in Figure 6. Moreover, the average total execution time across datasets is much lower for OMS-MAB when compared to BLAST, as captured in Table 5. For practical large-scale data stream mining applications, this translates to faster model updates and decisioning.

4 | EXPERIMENTAL METHODOLOGY

Our experiments evaluate the effectiveness of OMS-MAB in concept-drift adaptation using MAB based online model selection. For a rigorous evaluation, we select 10 synthetic and 10 real-world datasets pertaining to binary and multi-class problems from diverse domains affected by a variety of drift types. We compare our method with SOTA homogeneous, heterogeneous, and pool based ensembles. We perform 10 runs for all algorithms using different random seeds in all experiments to account for randomness and study the average results. Non-parametric Friedman

14680394, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/exsy.13626 by Delhi Technological University, Wiley Online Library on [19/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

test is used to verify if a statistically significant difference exists among the algorithms based on their performance. In cases where such differences exist, post-hoc Nemenyi test is used to determine which ensembles perform significantly better than others. For comparing multiple algorithms based on their performance across different datasets, the aforementioned tests are considered to be SOTA (Demšar, 2006; van Rijn et al., 2018). We use implementations of these tests from the autorank package (Herbold, 2020).

OMS-MAB is implemented in java, on top of the *Massive Online Analysis* (MOA) (Bifet, Holmes, Pfahringer, Kranen, et al., 2010) framework. Implementations of DP and FASE as released by their respective authors were used. For all other algorithms, their implementations within MOA 21.07.0 was used. Hyperparameters of all algorithms are set to their default values within MOA unless specified otherwise. Experiments were conducted on an Ubuntu 16.04 machine with a 10-core Intel(R) Xeon(R) CPU E5-2687W v3, 3.10GHz processor and 64 GB of RAM.

Our comparisons primarily focus on instance-incremental algorithms due to their merits presented in Section 1. Overall, we compare OMS-MAB with the following 9 algorithms belonging to 3 categories:

- *Homogeneous ensembles*: We include FASE and Adaptive Random Forest (ARF) (Gomes, Bifet, et al., 2017) as they are among the SOTA methods (de Barros & de Carvalho Santos, 2019; Gomes, Bifet, et al., 2017). Leveraging Bagging (LevBag) (Bifet, Holmes, & Pfahringer, 2010) with HT as the base learner is also considered based on its competitive performance (de Barros & de Carvalho Santos, 2019; Read, Bifet, Pfahringer, & Holmes, 2012). OzaBag (OBag), Online Boosting (OBoost), and DWM are also included considering their popularity and usage in several contemporary studies (Idrees et al., 2020; Zhao et al., 2020). Learn++.NSE (Elwell & Polikar, 2011) is considered as it is a highly acclaimed batch-incremental ensemble. The number of component classifiers is set to 10 for all the algorithms that require it. FASE, LevBag, OBag, OBoost, DWM and Learn++.NSE use HT as the base learner, whereas ARF uses its built in ARFHoeffdingTree as the base learner. As the ensemble time of Learn++.NSE increases exponentially with the number of base classifiers (Chen et al., 2021), we use its pruning enabled version within MOA for execution efficiency.
- *Heterogeneous ensembles*: We include BLAST, as it is a SOTA technique based on online algorithm selection (Luong et al., 2021). Fading factor based variant of BLAST is used, due to its merits reported by the authors (van Rijn et al., 2018). We choose NB, HT, EFDT, Perceptron (Percp), HoeffdingAdaptiveTree (HAT) (Bifet & Gavalda, 2009) and ASHoeffdingTree (ASHT) (van Rijn et al., 2018) as base learners to ensure diversity. The fading factor was set to 0.99.
- *Pool based ensembles*: We include DP due to its competitive performance and unique ability to handle recurring drifts. We use Hoeffding Tree with Naive Bayes (HTNB) at the leaves as the base learner and an ensemble size of 10, which is the default configuration for DP.

For a consistent evaluation, OMS-MAB is configured with the same base learners and fading factor ($\theta = 0.99$) as in the case of BLAST. Our choice for θ is based on the fading factor variational study presented in (van Rijn et al., 2018). The best value for ϵ is dependent on the stream. However, to identify a meaningful default value, initial experiments were conducted on 6 synthetic streams[1] by varying ϵ and measuring the corresponding average predictive performance and computational cost across these streams. It was observed that $\epsilon = 0.25$ provided reasonable accuracy at a low computational cost. Consequently, 0.25 was selected as the default value for ϵ to ensure sufficient exploration at a reasonable computational cost. The effect of other values of ϵ and its impact on model performance under different scenarios is studied in Section 5.4. Table 2 summarizes the hyperparameter configuration of the proposed and benchmark methods. All other hyperparameter values for all algorithms are set to their defaults in MOA.

TABLE 2 Hyperparameter configuration summary of the proposed and benchmark methods.

Method	Description
ARF	*ensembleSize* = 10
BLAST	*alpha* = 0.99, *baseClassifiers* = {*NB*, *HT*, *EFDT*, *Percp*, *HAT*, *ASHT*}
DP	*maxPoolSize* = 10 (default)
DWM	*baseLearner* = *HT*
FASE	*ensembleSize* = 10, *metaLearner* = *AdaptiveClassifier*(*HT*), *baseLearner* = *AdaptiveClassifier*(*HT*)
LevBag	*ensembleSize* = 10, *baseLearner* = *HT*
Learn++.NSE	*ensembleSize* = 10, *baseLearner* = *HT*, *pruningStrategy* = *ERROR*
OBag	*baseLearner* = *HT*, *ensembleSize* = 10

4.1 | Predictive performance

We use classification accuracy as the evaluation metric for comparing the predictive performance of algorithms. Prequential evaluation is used in all experiments wherein a model first makes a prediction on an instance before using it for learning (Lu et al., 2018). A fading factor of 0.999 was used to decay the effect of past performance towards the current accuracy, and sampling was performed for prequential accuracy at every 500th example (Chiu & Minku, 2020).

Algorithms are ranked based on their average prequential accuracy on each dataset such that higher predictive performance is indicated by lower ranks. The average rank corresponding to each algorithm across datasets is reported as an overall indicator of its predictive performance. Additionally, we report the average prequential accuracy across datasets corresponding to each algorithm. Both mean and standard deviation of average prequential accuracy from 10 runs are reported for all algorithms on all datasets. However, for deterministic algorithms such as DP, DWM, Learn++.NSE and BLAST, the standard deviation is zero. Furthermore, the statistical significance of accuracy differences among algorithms is also analyzed.

4.2 | Overall execution time

Since OMS-MAB targets learning problems involving high-speed data streams with potentially infinite samples, it is critical to ensure that training and prediction time requirements are minimal. To this end, we study the total execution time which is the sum of the time required to train the model and the time taken by the model to make predictions. Total execution time provides an insight into the computational complexity of the model, wherein lower values are preferable. We analyze the execution time growth with increase in the number of instances processed, to better understand the runtime complexity of algorithms. Also, we report the average value for total execution time across datasets for each algorithm. Further, statistical significance of timing differences among top performing algorithms in terms of accuracy across all the datasets considered is also analyzed.

4.3 | Memory requirements

To analyze the memory requirements of algorithms, we report the size of classifier models in megabytes (MB). To gain more insights, the average size of classifiers across datasets for each algorithm is analyzed. The variation in model size as the stream progresses is also studied for a deeper understanding of the memory consumption patterns of algorithms. Additionally, statistical significance of model size differences among top performing algorithms in terms of accuracy across all the datasets considered is also reported.

4.4 | Hyperparameter relevance

The overall performance of OMS-MAB depends on the hyperparameter ϵ which provides a trade-off among model accuracy and computational resource requirements. To select a meaningful value for ϵ, we analyze the effect of systematically varying ϵ on the model performance. To this end, we vary ϵ among {0.01, 0.1, 0.25, 0.5, 1.0}. This gradual variation from minimal to complete exploration allows us to closely study the aforementioned trade-off. Corresponding to each value of ϵ, we report average values for accuracy, total execution time, and model size of OMS-MAB from 10 runs on each dataset, to account for MAB stochasticity.

4.5 | Relationship between model complexity and model accuracy

Complexity analysis of OMS-MAB in Section 3.1 indicates that two factors influence its complexity: the ensemble size (M), and the exploration factor (ϵ). We vary M among {2, 3, 4, 5, 6} and ϵ among {0.01, 0.1, 0.25, 0.5, 1.0} to examine the relationship between model complexity and model accuracy. For a consistent evaluation, we keep the order of learners within the ensemble as fixed across experiments: {NB, HT, EFDT, Percp, HAT, and ASHT}, and include the first M learners in the ensemble corresponding to each size M. For each combination of M and ϵ, we run OMS-MAB ten times on each dataset, calculate the average accuracy across the datasets for each run, and then visualize the mean and standard deviation of average accuracies across the ten runs as a heatmap. This helps to analyze the interplay between model complexity and accuracy.

4.6 | Datasets

Table 3 presents a summary of the datasets used in our experiments, out of which 10 are generated synthetically and 10 are real-world. These are commonly used benchmarks in data stream mining literature. Synthetic streams are generated using SEA (Street & Kim, 2001), LED (Brzezinski & Stefanowski, 2013), Tree (Brzezinski & Stefanowski, 2013), Hyperplane (Hulten et al., 2001), Agrawal (Aggarwal et al., 2003) and RBF (Brzezinski & Stefanowski, 2013) generators available in MOA framework. MOA commands for generating all the synthetic datasets considered in our study are available at https://github.com/jobinwilson/syntheticData. For further details on the datasets considered in our experiments, we refer the reader to (Brzezinski & Stefanowski, 2013) for LED_M, TREE_F, HYP_S and HYP_F; to (Chiu & Minku, 2018) for AGR_GR and AGR_AR; to (Xu et al., 2017) for RBF_F and RBF_IN; to (MOA, datasets 2019) for Forest Covertype (Covtype), Electricity (Elec), Poker-Hand (Poker), Airlines Dataset (Airlines); to (Stream Data Mining Repository 2021) for Sensor Stream (Sensor), Powersupply Stream (Power), Kddcup99 (KDD99); to (Losing et al., 2016) for Rialto; to (Elwell & Polikar, 2011) for Weather and to Luong et al. (2021) for Adult. For the datasets Covtype, Elec and Weather, their normalized versions were used. For the Sensor dataset, we used the first 200000 instances in all experiments.

5 | EXPERIMENTAL RESULTS

5.1 | Predictive performance

The prequential accuracy of all algorithms considered is presented in Table 4. The best results are in bold. We observe that the predictive performance of algorithms varies across datasets, justifying the usage of model selection to enhance predictive performance. Though a single top performing algorithm is missing, we see that LevBag, FASE, and BLAST are the top performers based on their average rank, as observed in similar studies (de Barros & de Carvalho Santos, 2019; van Rijn et al., 2018). In terms of average accuracy across datasets, OMS-MAB is close to the aforementioned top performers. Moreover, it falls in the top tier and immediately follows BLAST, outperforming ARF and DWM in terms of average rank. Statistical analysis was conducted for 10 populations (algorithms) with 20 paired samples (datasets). Friedman test with family-wise significance level $\alpha = 0.05$ indicates the existence of statistically significant differences among the performance of algorithms. *Critical difference*

(CD) came out to be 3.03. As depicted in Figure 3a, post-hoc Nemenyi test indicates that OMS-MAB is among the top tier performers, and there is no statistically significant accuracy difference among LevBag, FASE, BLAST, OMS-MAB, ARF, and DWM. In the figure, algorithms with statistically equivalent predictive performance are connected using a horizontal line.

Accurate estimation of the predictive performance of each inner-level AL is essential for OMS-MAB to intelligently switch the *active member*, enabling it to use the current best performing AL to make predictions. In Figure 4, we present the performance estimates of OMS-MAB corresponding to all inner-level ALs, along with the MAB's choice of the *active member* for each time step. This visualization helps to verify if the MAB is able to correctly identify the best ALs for the respective stream segments. To account for randomness in data streams and MAB stochasticity, performance estimates are visualized from 10 independent runs of the model, enclosed by its 95% confidence interval. On the other hand, *active member* selection of the MAB is visualized from the first run. Key observations from these visualizations are the following:

- In the case of *HYP_S* dataset, OMS-MAB correctly identifies Perceptron based AL as the best performer as depicted in Figure 4a,b, despite the drift being incremental and slow. We observe that the MAB switches among multiple ALs during the early parts of the stream as performance estimates of ALs are not well separated in that region. However, as the stream progresses, the MAB is more confident on Perceptron and correctly switches to it for most parts of the stream.
- In the case of *AGR_AR* dataset, OMS-MAB identifies Perceptron based AL to be a poor performer throughout the stream and correctly eliminates it from the choices for *active member* selection. It is interesting to observe that the MAB switches among ALs based on HT, EFDT and ASHT as the *active member* for most parts of the stream due to their high performance, as depicted in Figure 4c,d. Furthermore, this observation confirms that a single AL need not be the best performer throughout a stream, and adaptively switching among ALs is a useful strategy for concept-drift adaptation.
- In the case of *Rialto* dataset, OMS-MAB correctly selects EFDT based AL as the best performer for most parts of the stream. However, the MAB switches among multiple ALs in a few parts of the stream as the performance estimates of ALs are not well separated in those regions. This behavior is illustrated in Figure 4e,f.

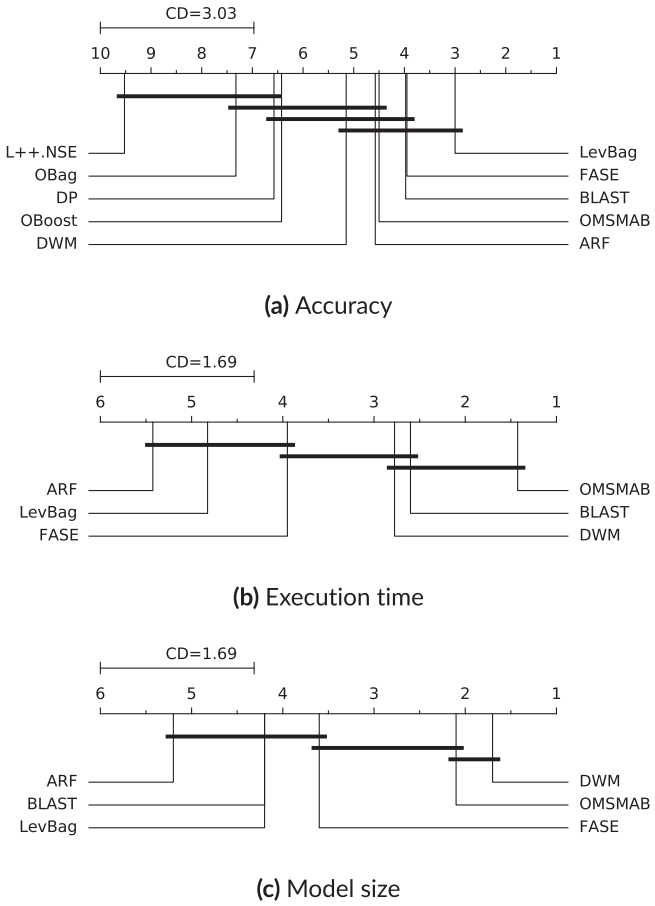

FIGURE 3 Results of Nemenyi post-hoc tests (95% confidence level).

The temporal variation in prequential accuracy of top tier algorithms on select datasets is visualized in Figure 5 to study their adaptability under diverse drift conditions. This enables us to verify that the proposed MAB based adaptation procedure allows OMS-MAB to quickly recover its predictive performance subsequent to experiencing a concept-drift. Below are the main observations:

- In the case of *LED_M* dataset having both abrupt and gradual drifts, models such as BLAST that slowly discard obsolete knowledge through implicit adaptation are outperformed by FASE and OMS-MAB. This can be attributed to the HDDM_A based explicit drift detection and backup learners associated with the latter models that enable maintaining up-to-date knowledge, allowing effective handling of both abrupt and gradual drifts. However, the superior performance of BLAST in comparison to homogeneous ensembles like LevBag and ARF indicates that heterogeneous learning is a beneficial diversity generation strategy for this stream. OMS-MAB exploits both explicit drift adaptation and heterogeneity while performing the second best on this stream, immediately following FASE.
- For *HYP_S* dataset with incremental and slow drifts, models like BLAST which use implicit adaptation to concept-drift by preserving relatively longer-term concept memory outshine models such as FASE, LevBag, and ARF. This can be attributed to the latter models rapidly eliminating outdated knowledge through explicit drift detection. While OMS-MAB also uses explicit detection, MAB based selective training prevents all members from getting updated with all samples, increasing the probability of knowledge retention. Furthermore, Figure 4a,b indicate superior performance of Perceptron based learners on this stream in comparison to Tree based learners. This is beneficial to ensembles like OMS-MAB and BLAST which maintain a pool of heterogeneous learners, allowing selection of the optimal learner matching the stream characteristics from time to time for prediction. Overall, OMS-MAB performs second best on this stream, immediately following BLAST.
- In the case of *RBF_F* dataset with incremental and fast drifts, superior performance of models like LevBag, ARF and FASE with explicit drift detection in comparison to implicit adaptation models like BLAST indicates the importance of quickly discarding obsolete knowledge. Prequential accuracy plot for this stream indicates that performance of BLAST drops significantly during drift in comparison to models equipped with explicit drift detection. OMS-MAB works reasonably well on this stream because on one hand it uses explicit drift detection to discard obsolete knowledge. On the other hand, MAB's ability to periodically select the best learner for prediction from a diverse pool of learners enables it to enjoy the benefits of heterogeneous ensembles like BLAST.

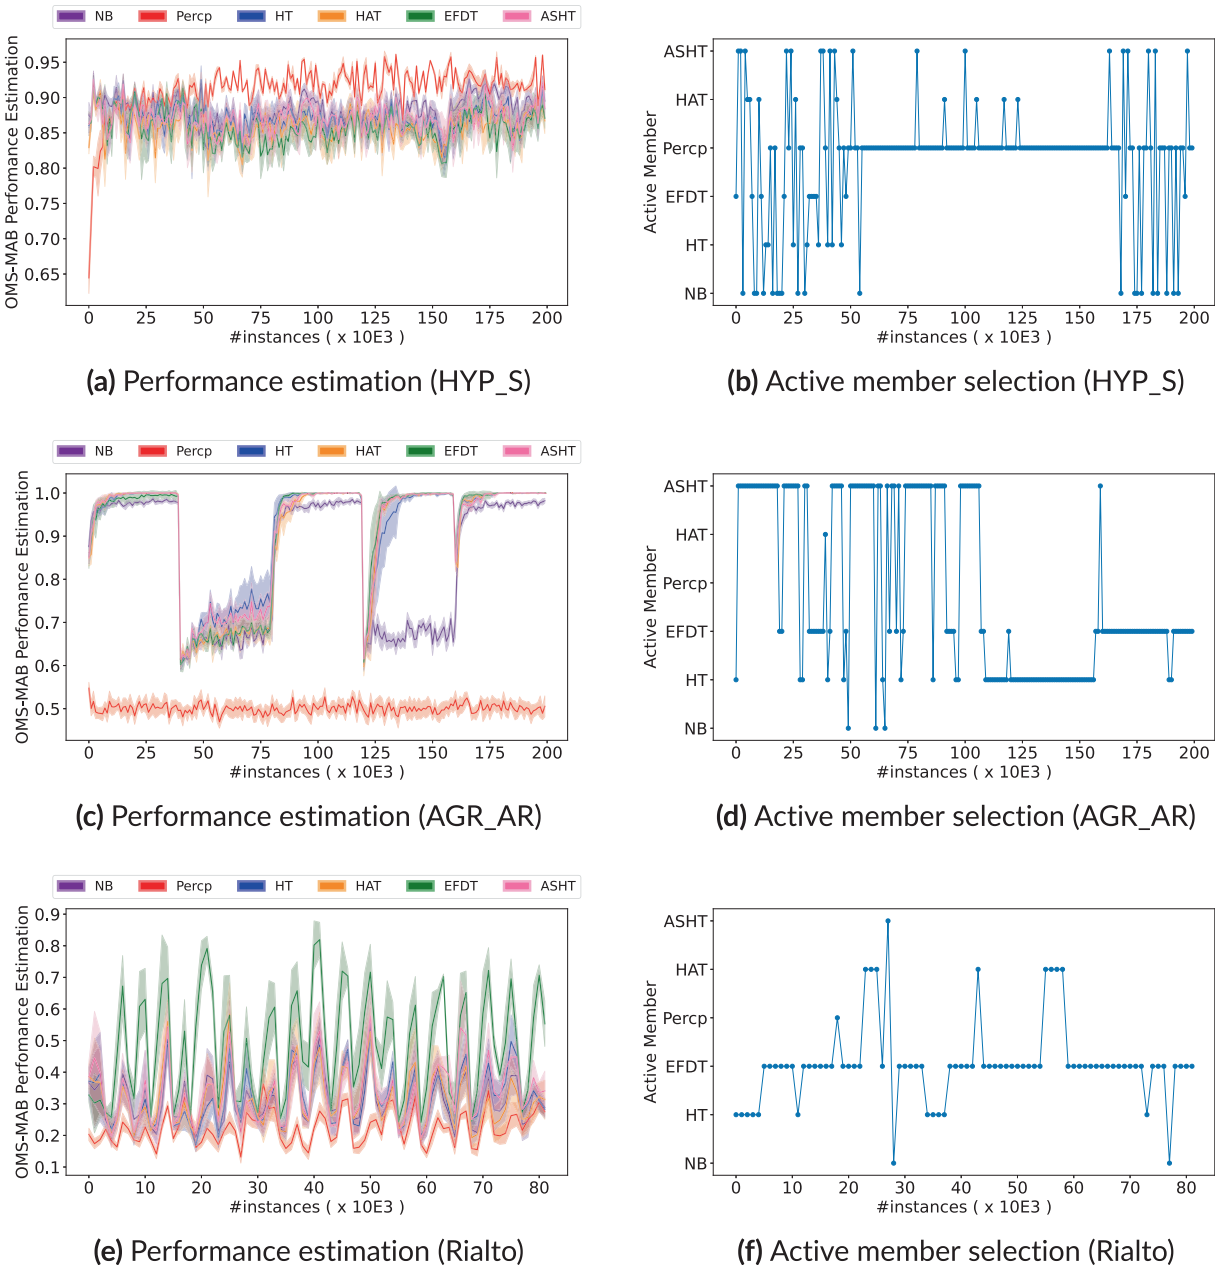

FIGURE 4 Performance estimation and active member selection of OMS-MAB.

- For *AGR_GR* dataset with gradual and recurring drifts, models such as LevBag, ARF and FASE which discard historical knowledge using explicit drift detection is outperformed by models like BLAST which uses implicit adaptation to slowly forget obsolete concepts. The adaptation strategy of former models focuses on exploiting short-term concept memory, preventing historical knowledge reuse during recurring drifts. Though OMS-MAB uses explicit drift detection to discard knowledge, lower values of ϵ ensure that members are trained on limited samples, enabling historical knowledge reuse in scenarios where they are not already reset. Moreover, OMS-MAB's strategy of alternating between *exploration* involving updates to all ensemble members and *exploitation* which solely updates the best performer results in all members getting partially trained on the latest concept at any point of time. This allows the MAB to activate suitable members from time-to-time, enabling faster adaptation. The aforementioned factors enable OMS-MAB to perform reasonably well on this stream.

It is interesting to observe that OMS-MAB exhibits a drift adaptation behavior that is comparable to other top tier ensembles that were part of our experiments. On one hand, this could be attributed to explicit drift detection and backup learners allowing obsolete knowledge to be discarded fast. On the other hand, MAB's ability to systematically estimate the performance of each AL enables selecting the most appropriate ensemble member from time to time for prediction and training, allowing adaptation to diverse drift types. However, it is to be noted that OMS-MAB improves

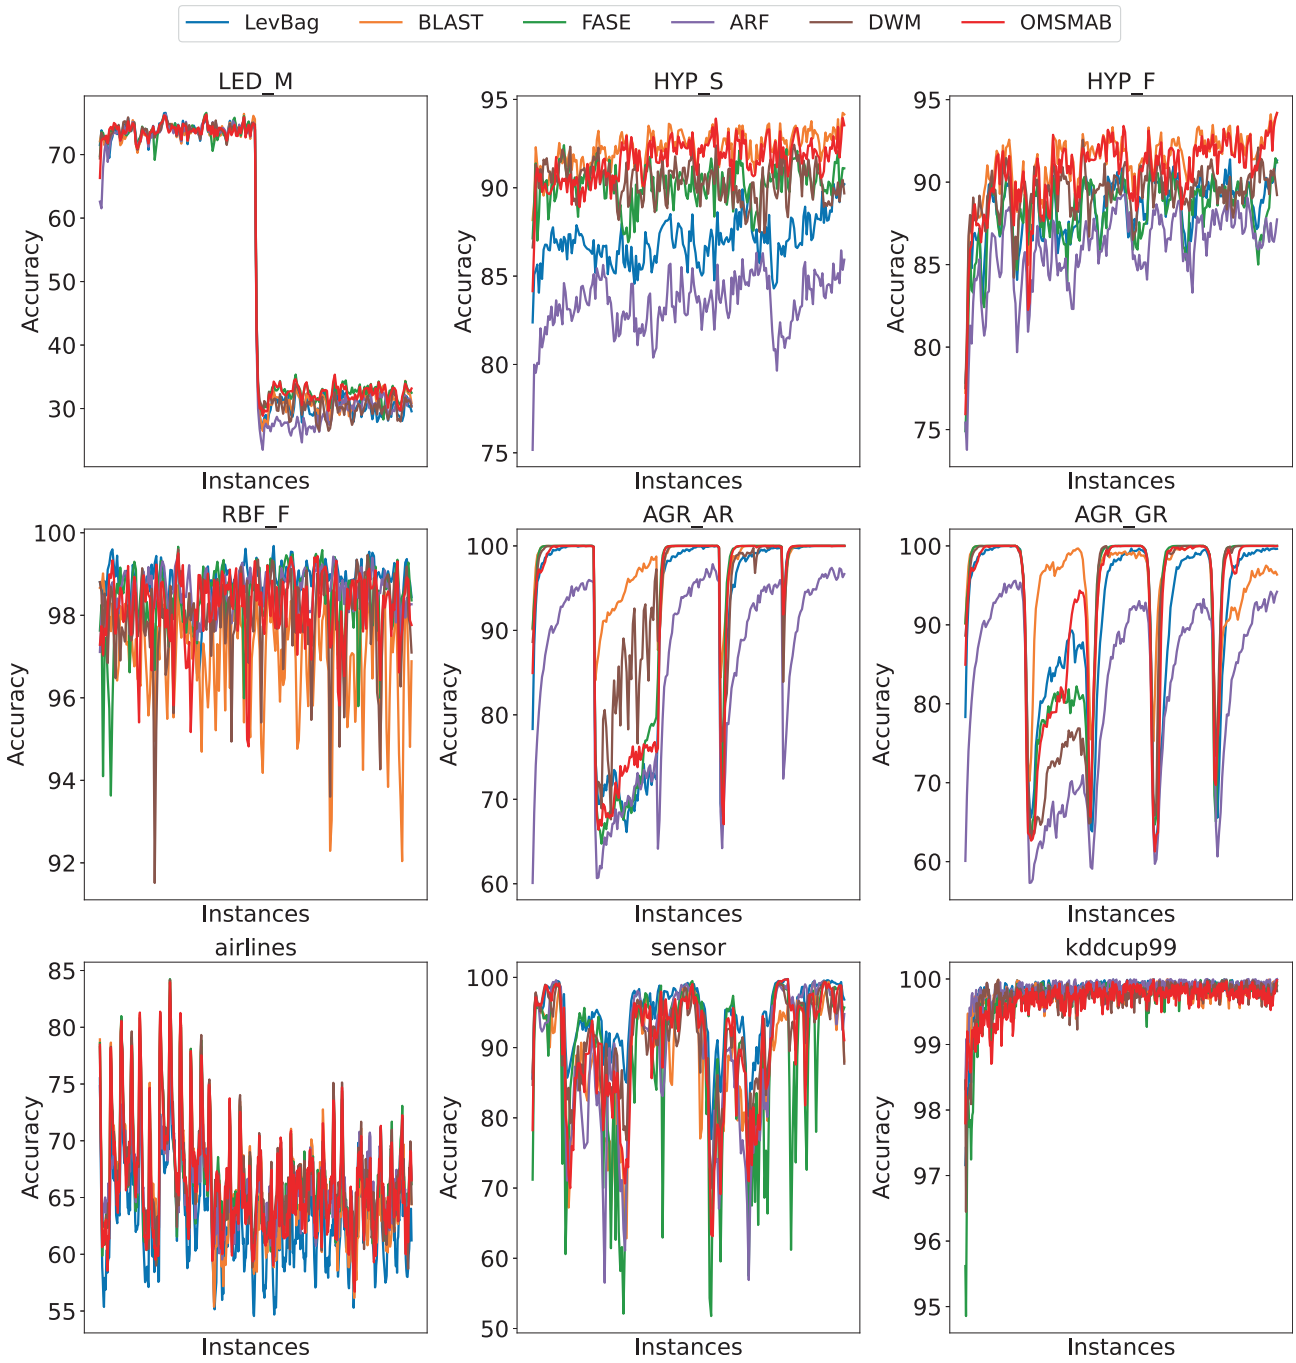

FIGURE 5 Prequential accuracy comparison of top tier ensembles on different datasets covering various drift types and speeds.

computational efficiency by selectively training promising ensemble members. Consequently, all ensemble members do not get trained on all samples, thereby obtaining a slightly lower predictive performance compared to ensembles that unconditionally train all members on all samples. Nonetheless, the exploration factor ϵ provides a tradeoff between computational resource requirements and predictive performance.

5.2 | Overall execution time

Table 5 presents total execution time along with the corresponding average values across datasets for all algorithms compared. The best results are in bold. To understand the computational efficiency provided by OMS-MAB, statistical analysis was conducted using 6 populations (top performing ensemble algorithms) with 20 paired samples (datasets). Friedman test with family-wise significance level $\alpha = 0.05$ indicates the existence

Bold indicates total execution time and model size.

of statistically significant differences among the total execution time of top performing algorithms in terms of accuracy. *Critical difference* (CD) observed was 1.69. As depicted in Figure 3b, post-hoc Nemenyi test indicates that OMS-MAB, BLAST and DWM are the top tier performers in terms of execution time, and there is no statistically significant timing differences among them. In the figure, algorithms with statistically equivalent timing requirements are connected using a horizontal line. We observe that algorithms such as LevBag, ARF and FASE which are in the top accuracy league belong to the bottom tier when it comes to execution time, making them less attractive for high-speed stream mining. Furthermore, in terms of average rank for total execution time across datasets, OMS-MAB outperforms all the top performing ensembles considered.

Figure 6 compares the execution time growth of OMS-MAB with that of the top performing ensembles in terms of accuracy, to closely understand the differences in their runtime complexity. We observe that execution time growth for OMS-MAB is the least among all the top performing ensembles considered, indicative of its time efficiency. This gain is attributed to two factors. Firstly, our MAB based adaptation eliminates the need to continuously train and evaluate all ensemble members. Secondly, periodic reset of ALs upon encountering concept-drift prevents their unbounded growth, allowing faster learning and evaluation.

5.3 | Memory requirements

Table 6 presents the model size corresponding to all algorithms considered, along with their averages across datasets. The best results are in bold. To study the memory efficiency of ensembles based on their model size, statistical analysis was conducted using 6 populations (top performing ensemble algorithms) with 20 paired samples (datasets).

Friedman test with family-wise significance level $\alpha = 0.05$ indicates the existence of statistically significant differences among model size of algorithms. *Critical difference* (CD) observed was 1.69. As depicted in Figure 3c, post-hoc Nemenyi test indicates that DWM and OMS-MAB are the top tier performers in terms of memory efficiency, and no statistically significant differences exist between them based on model size. We observe that SOTA homogeneous ensembles such as ARF and LevBag are memory intensive. On the other hand, OMS-MAB immediately follows DWM in terms of average rank for model size across datasets, making it attractive in terms of memory savings. Figure 7 compares the memory growth pattern of OMS-MAB with that of the top performing ensembles in terms of accuracy. We observe that memory growth for OMS-MAB is

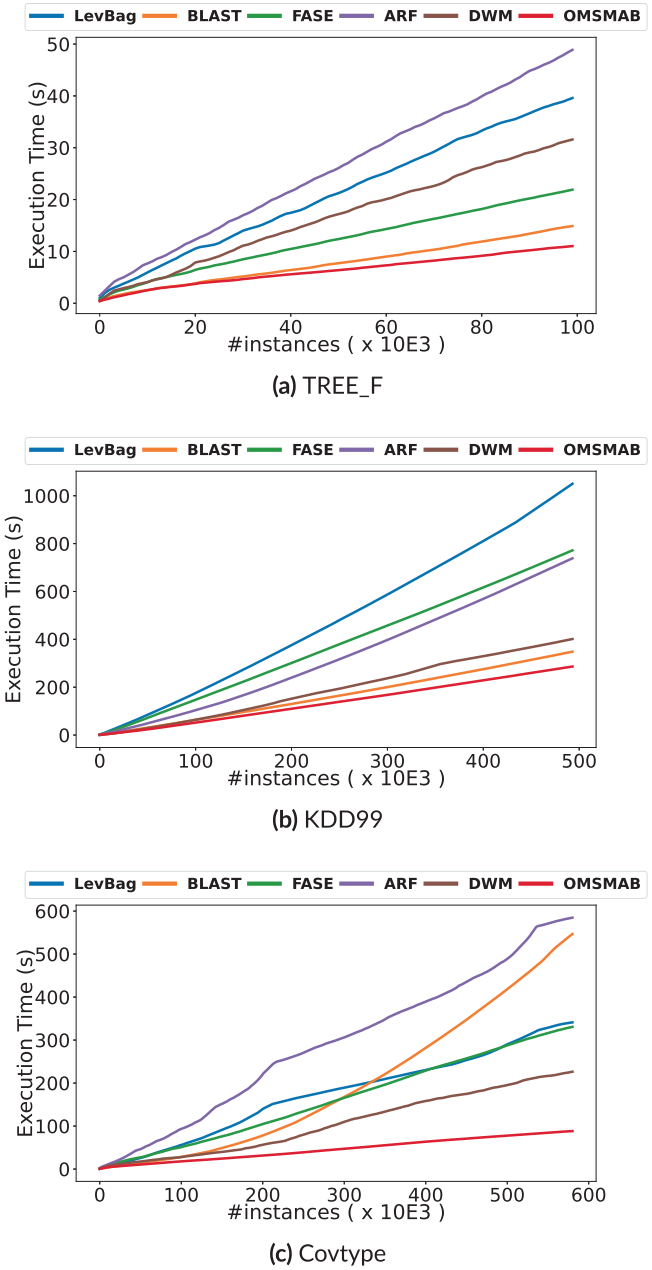

FIGURE 6 Execution time growth comparison (in seconds) across algorithms.

the least among all the top performing ensembles considered, indicative of its memory efficiency. As in the case of execution time, this gain is attributed to our adaptation strategy which eliminates the need to continuously train and evaluate all ensemble members, as well as the periodic reset of ALs upon encountering drift.

5.4 | Hyperparameter relevance

We study the effect of varying ϵ on the performance of OMS-MAB, as outlined in Section 4.4. Table 7 presents accuracy, total execution time and model size along with the corresponding average values across datasets for each ϵ. The best results are in bold. We observe that as ϵ increases, accuracy improves in most cases as expected. This is because a higher exploration rate results in more training and evaluation of all ALs, making the MAB more confident about their performance estimates and consequently improving its behavior policy. Though setting $\epsilon = 1$ is an extreme case of this scenario, it causes the drift detector to detect all drifts with high probability. This results in the corresponding AL getting reset, discarding its historical knowledge. On the other hand, lower ϵ values result in ALs getting trained on limited samples, allowing them to

reuse historical knowledge in case if they are not already reset. For instance, in the case of AGR_AR dataset which is affected by recurring drift, intermediate values for ϵ results in better accuracy.

We observe that execution time increases with larger values of ϵ as expected, since a larger exploration factor results in the training and evaluation of all ALs on a larger set of samples, increasing the computational complexity. On similar lines, lower values of ϵ results in lower model size in most cases, as all ALs except the *active member* gets trained on fewer samples in this case. Moreover, periodic reset of ALs due to explicit drift detection is observed to restrict their unbounded growth, as indicated by the non-monotonic variation in model size with gradual increase in ϵ for some of the datasets such as *Rialto* and *Airlines*. Figure 8 visualizes the overall trend in performance variation of OMS-MAB across datasets as we gradually vary the exploration factor from minimal to complete exploration.

We note that though the best value for ϵ is stream dependent, choosing a value that is neither too small nor too large is desirable for OMS-MAB to provide optimal predictive and timing performance. It is observed that selecting $\epsilon = 0.25$ provides a reasonable trade-off between model accuracy and computational resource requirements, which is aligned with our initial experiments as discussed in Section 4.

5.5 | Relationship between model complexity and model accuracy

In this study, we assess the effect of model complexity on the accuracy of OMS-MAB, as described in Section 4.5. Figure 9 visualizes the overall trend in accuracy variation of OMS-MAB across datasets as the model complexity is gradually varied. At a broad level, we observe that accuracy increases with model complexity, as indicated by the darker shades as we move to the bottom-right of the heatmap. On one hand, an increase in ϵ is expected to improve ensemble accuracy due to the training and evaluation of all members on a larger set of samples as discussed in Section 5.4. On the other hand, an increase in M introduces more learners to the ensemble, which likely improves the accuracy subject to them being sufficiently diverse (van Rijn et al., 2018). It is interesting to note that average accuracy values along the principal diagonal of the heatmap are monotonically increasing, as both M and ϵ increase along that axis. We note that for a fixed ensemble size, average accuracy increases with ϵ in most cases, as observed in Section 5.4. It is observed that up to the ensemble size of 4, accuracy increases monotonically with M for a given ϵ.

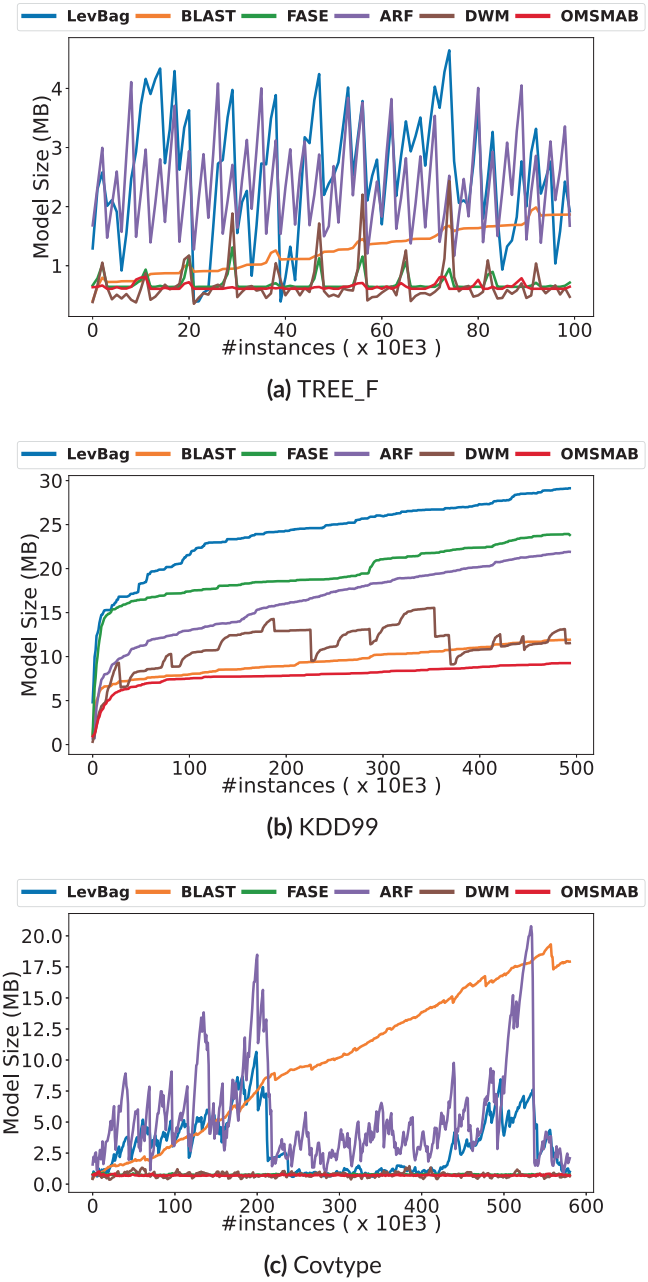

FIGURE 7 Model size growth comparison (in MBs) across algorithms.

Subsequently, it stagnates or even slightly decreases. This observation can be attributed to the ensemble diversity aspect, as the fifth and sixth members being added are respectively HAT and ASHT, both belonging to the Tree family as discussed in Section 4.5. Since the ensemble already has HT and EFDT as members representing the Tree family, introducing additional ALs from the same family will not significantly increase the diversity. In summary, a trade-off exists between model complexity and accuracy. However, it is critical to ensure sufficient diversity among members of the heterogeneous pool for superior predictive performance.

5.6 | Limitations and future research directions

Presently OMS-MAB is focused on standard non-stationary learning problems and does not address the more complex aspects of concept-drift adaptation like class-imbalance learning (CIL) (Cano & Krawczyk, 2022) and multilabel classification (MLC) (Alberghini et al., 2022). Moreover, we assume an online setting wherein labels are available for incremental learning immediately after prediction. However, several real-world streaming

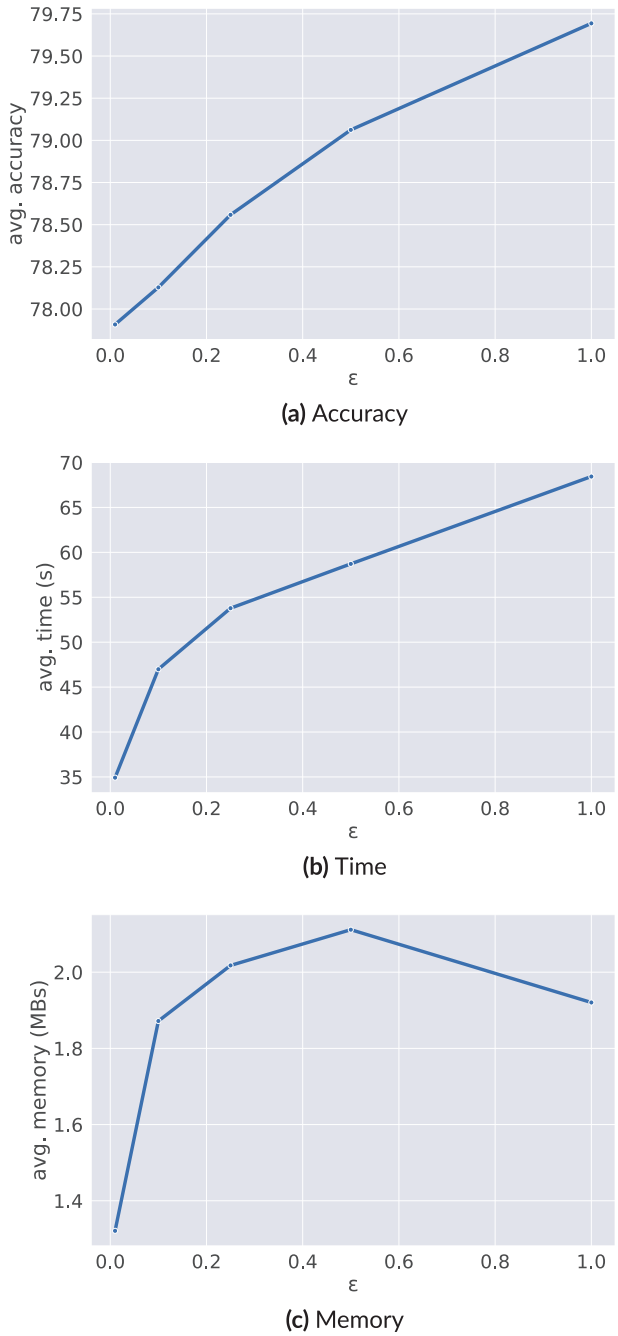

FIGURE 8 Variation in average performance of OMS-MAB across datasets with ϵ.

problems violate this assumption, as labels corresponding to previous instances arrive after a delay period (delayed setting) (Plasse & Adams, 2016). In this section, we discuss these aspects further and suggest potential approaches to extend OMS-MAB to such scenarios, along with future research directions.

CIL involves dealing with extremely skewed class distributions, with considerable underrepresentation of some classes (Cano & Krawczyk, 2022). Traditional classifiers are usually biased towards majority classes, resulting in poor predictions for minority classes which are typically more significant (Aguiar et al., 2023). Concept-drift makes CIL considerably harder as the imbalance ratio evolves with the stream, with classes possibly switching roles (Cano & Krawczyk, 2022). CIL is crucial in real-world applications such as medical data mining, social media analytics, and recommender systems with changing user preferences (Cano & Krawczyk, 2022). In contrast, MLC involves simultaneously mapping each data instance to multiple labels instead of a single class (Alberghini et al., 2022). MLC problems necessitate more intricate label and data representations to capture the interrelationships among instances and their labels, as well as among the labels themselves. Several real-world applications that involve text categorization, bioinformatics, and scene classification with objects mapped to multiple semantic meanings are well aligned to

14680394, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/exsy.13626 by Delhi Technological University, Wiley Online Library on [19/05/2024]. FIGURE 9 Variation in average accuracy across datasets with model complexity of OMS-MAB.

this setting (Zhu et al., 2023). Finally, handling delayed labels is an important aspect in streaming classification with practical applications such as malware classification, credit scoring for loans, and tweet labeling (Gomes et al., 2022). In such applications, the true class of some previously observed feature vector becomes available only after a delay, which could be fixed or varying.

Ensemble approaches have proven their effectiveness in CIL (Aguiar et al., 2023) and MLC (Zhu et al., 2023) problems in non-stationary data streams. Moreover, recent works highlight the use of different diversity induction strategies such as feature subspaces and bagging to build robustness in CIL (Cano & Krawczyk, 2022) and MLC (Alberghini et al., 2022). Due to its built-in diversity from heterogeneity and the instance-level diversity added by the MAB-based selective training process, OMS-MAB is a good candidate to be extended to tackle CIL and MLC.

According to the insights from (Cano & Krawczyk, 2022), one approach to extend OMS-MAB towards CIL is to maintain a per-class sliding window of instances globally for a balanced class representation by automatically downsampling majority classes. This sliding window can be used to periodically warm-start backup learners within ALs with a balanced class distribution, reducing majority class bias and managing evolving imbalance ratios. In order to extend OMS-MAB to MLC, we suggest capitalizing on the strengths of existing standalone MLC classifiers by employing them as ensemble base learners. Any standalone MLC classifier such as MLSAkNN (Roseberry et al., 2021), Multilabel Hoeffding Tree (Read, Bifet, Holmes, & Pfahringer, 2012), or i-SOUP Tree (Osojnik et al., 2017) could be suitable base learners in this context. To extend OMS-MAB to delayed label setting, we borrow from (Hu & Kantardzic, 2017) and propose keeping a fixed-size reservoir of labeled samples. The reservoir is updated with incoming data based on instance and label arrival times, while discarding excessively delayed samples which potentially represent obsolete concepts. Ensemble members could utilize this reservoir for periodic training and evaluation, ensuring access to relevant labeled data despite labeling delays. Furthermore, it is worth considering semi-supervised learning approaches in this context (Gomes et al., 2022).

In terms of additional future research directions, our approach can be extended to periodically select a best performing subset of members for training and prediction as opposed to choosing a single best performing member during ensemble selection. Individual predictions of the chosen subset can be combined using a voting scheme to obtain higher predictive performance while maintaining computational efficiency. Further, the approach can be generalized to support both homogeneous and heterogeneous ensembles. Finally, extending our approach to regression problems affected by concept-drift would be another interesting avenue.

6 | CONCLUSION

In this paper, we introduced a heterogeneous ensemble algorithm named OMS-MAB which uses both an active and passive strategy for concept-drift adaptation. A non-stationary MAB is used to select a single AL best suited for learning and prediction on an instance, from a pool of heterogeneous learners. The trade-off between predictive performance and computational resource requirements is controlled by an exploration factor ϵ. Our proposal provides competitive predictive performance compared to SOTA concept-drift ensembles at a significantly lower computational cost, by eliminating the need for continuous training and evaluation of all ensemble members. The above advantages make OMS-MAB a promising heterogeneous ensemble for mining high-speed data streams while operating in resource constrained environments.

***Abstract*— This study presents a novel multiband fractal antenna design in the shape of a sunflower, specifically intended for wireless energy harvesting applications. The proposed antenna operates efficiently across four distinct frequency bands: 3.9 GHz to 4.1 GHz, 4.55 GHz to 4.66 GHz, 4.8 GHz to 5.05 GHz, and 7.3 GHz to 7.85 GHz. Each frequency band offers a respective bandwidth of 120 MHz, 110 GHz, 250 MHz, and 550 MHz. The antenna under consideration exhibits a peak gain of 5.1 dBi, 2.3 dBi, 2.2 dBi, and 4.9 dBi at frequencies of 4.1 GHz, 4.6 GHz, 4.9 GHz, and 7.45 GHz correspondingly. The antenna being presented exhibits high gain and multiband features, rendering it well-suited for RF energy harvesting applications. Specifically, it can effectively target the mid 5G band, WLAN, and 5G extended mid band, taking use of the available power in the surrounding environment. Subsequently, the acquired energy might be employed for the purpose of supplying power to low-power electronic sensors.**

***Keywords*— Multiband, Return Loss (RL), Fractal antenna, radio frequency energy harvesting, Gain.**

I. INTRODUCTION

Microstrip antennas are frequently employed in satellite and mobile applications due to their advantageous characteristics, including their lightweight nature, compact dimensions, cost-effectiveness, and ease of fabrication. Fractal-shaped antennas possess appealing characteristics that arise from their geometric aspects [1].

The term "fractal" was initially introduced by B. Mandelbrot, who is widely recognised as the progenitor of fractal geometry. The term "fractus" originates from the Latin language, specifically derived from the word "fractus," denoting a state of irregularity or fragmentation [2]. The aforementioned word was employed to characterise a novel assemblage of objects that surpass squares, circles, or triangles in terms of complexity, and are rigorously delineated within the framework of Euclidean geometry. Nevertheless, Euclidean geometry fails to adequately represent various everyday phenomena, including clouds, blood arteries, and irregular patterns like coastlines [3].

In addition to B. Mandelbrot, some esteemed mathematicians have made significant contributions to the discipline of fractal geometry. These include W. Sierpinski, D. Hilbert, N. F. H. von Koch, H. Minkowski, and G. Peano, and G. F. L. P. Cantor. The fractals served as a source of inspiration for the antenna engineering community, prompting them to investigate the potential utilisation of these geometries as antennas [4]–[9]. The current publications provide a historical context of their survives and introduce antenna influenced by the fractals.

In [10], the authors present a unique design that utilised the Fibonacci sequence and created a defective ground structure (DGS) in the lower part of the antenna. This particular design enables the antenna to operate effectively throughout the C-Band frequency range.

According to the source cited as [11], The ultimate configuration of the antenna is achieved by many iterations. This amalgamation results in a unique hybrid structure that possesses a small physical size, excellent flexibility, and improved impedance bandwidth. The antenna is at 2.45 GHz. The constructed prototype of the antenna has demonstrated a satisfactory level of concordance between the numerical and experimental findings. The achieved performance includes a peak gain of 2.06 decibels relative to an isotropic radiator (dBi) and provides 75 % of efficiency.

The antenna design aims to achieve mechanical robustness as proposed in [12]. The proposed methodology entails the process of etching Moore's curve onto a standard rectangular patch, followed by enclosing it within a rectangle loop that incorporates a defective ground structure. The antenna under consideration demonstrates dual-band characteristics, with a bandwidth that spans from 1.38 to 1.8 GHz and 2.25 to 4.88 GHz, encompassing the WMTS, ISM, and Personal Communication bands. Additionally, it partially covers a section of the UWB band. The antenna possesses two operational bands, each providing a fractional bandwidth of 38.5% and 73.7% correspondingly.

The present study introduces a newly developed monopole antenna element [13]. The compact nature of this device allows for its utilisation in portable devices with twin antennas that operate within the 2.4 GHz frequency range. This enables the achievement of antenna diversity across various combining schemes. The computing demands of the finite element simulations used to estimate the concert of the verified shapes were found to be higher compared to the moment method counterparts.

The present study introduces a novel design for a microstrip antenna with circular polarisation (CP), as described in reference [14]. The parameter studies of the Iterative Fourier Domain Gradient Sensing (IFDGS) method are presented in order to demonstrate the methodology for achieving coherent population (CP) radiation. The CP antenna is constructed and assessed using the third iterative IFDGS. The obtained experimental data confirms the accuracy of the simulated results and demonstrates a high level of agreement.

Energy harvesting systems encompass the process of converting pre-existing energy sources found in the environment, such as solar energy, wind energy, thermal energy, and electromagnetic energy, into a useful form [15]. The electromagnetic energy density is observed to be progressively growing as a result of the ongoing advancements in communication technologies [16]. RF energy harvesting (RFEH) has emerged as a viable approach for the purpose of energy recycling. The utilisation of this acquired energy will prove advantageous in the charging of diverse electronic devices in scenarios where a conventional connected power source is challenging to establish, such as in rural regions, submerged environments, and aerial settings [17]-[19]. Energy harvesting technology has the potential to serve as a viable alternative to batteries, primarily due to its limited lifespan, high cost, requirement for frequent replacement, and environmental impact [20]. Recycled energy possesses environmentally friendly attributes, exhibits an extended availability period, and obviates the need for system replacement.

The antenna under consideration has been designed and simulated utilising CST MW Studio 2020. The antenna under consideration is designed on a substrate made of FR-4 material, which has a dielectric constant of 4.4 and a substrate height of 1.6 mm. The subsequent part introduces a proposed multiband high gain antenna and presents a comprehensive analysis of its outcomes. In Section 3, the conclusion is provided and thereafter addressed.

II. Antenna Design

The subsequent section introduces the sunflower-shaped multiband fractal antenna. The proposed antenna underwent a design and simulation process at multiple stages. The resulting output, including return loss, gain, and 3D radiation patterns, were examined and compared. Figure 1 depicts the initial stage (Stage 1) of the projected antenna, wherein the dimensions of the larger and smaller sections are 3 mm and 1.8 mm, respectively, measured from the centre. The thickness of the strips in this stage is 0.5 mm. Figure 2 displays Stage 2, when nine entities of identical kind are replicated, each possessing a radius of 5 mm. Figure 3 illustrates Stage 3, wherein nine entities from Stage 2 are replicated at a radius of 10 mm, resulting in a configuration resembling that of a sunflower. Consequently, this particular antenna is referred to as a sunflower-shaped antenna. Figure 4 illustrates Stage 4, whereby nine entities are arranged in a repetitive pattern. One entity is positioned at the centre, while the remaining eight entities are evenly distributed over a radius of 15 mm. Notably, the central entity is scaled to be 1.5 times larger than the outside entities. The ultimate antenna is seen in Figure 5.

The antenna has been built and simulated for stages 2, 3, and 4. The comparison of return loss for various stages is illustrated in Figure 6. The minimum required RL for stage 2 is -6 dB. The stage 3 fractal antenna exhibits resonance throughout the frequency range of 6.78 GHz to 6.97 GHz, with a minimum return loss (RL) of -19 dB occurring at 6.87 GHz. The stage 4 fractal antenna, seen in Figure 5, has operational capabilities throughout the 3.9 GHz to 4.1 GHz, 4.55 GHz to 4.66 GHz, 4.8 GHz to 5.05 GHz, and 7.3 GHz to 7.85 GHz. This antenna offers a bandwidth of 120 MHz, 110 GHz, 250 MHz, and 550 MHz, respectively. Additionally, it achieves a minimum return loss (RL) of -34.4 dB at 7.44 GHz. The suggested antenna exhibits multiband features that make it well-suited for RF energy harvesting applications. Specifically, it is designed to efficiently capture RF energy in the mid 5G band, WLAN, and 5G extended mid band, taking advantage of the available power in the surrounding environment.

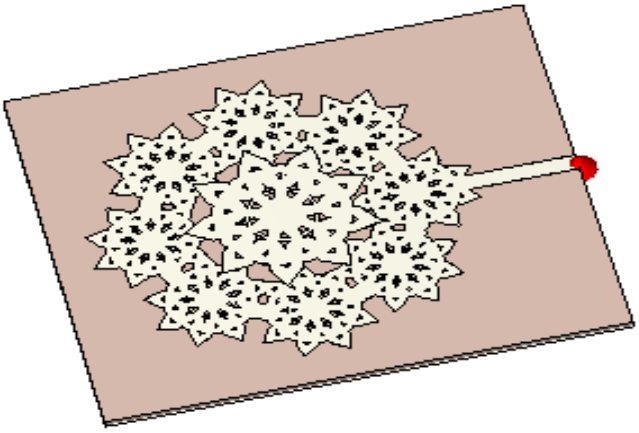

Fig. 5. Planned antenna

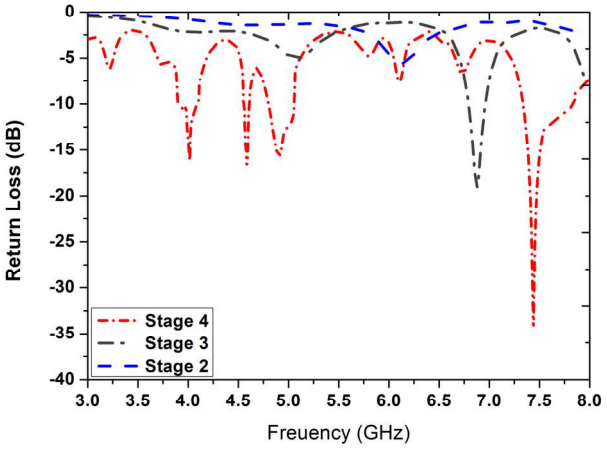

Fig. 6. RL Comparison of various stages of fractal antenna

Figure 6, 7, 8, and 9 depict the gain variation of the antenna under consideration at 4.1 GHz, 4.6 GHz, 4.9 GHz, and 7.45 GHz correspondingly. The antenna under consideration exhibits a peak gain of 5.1 dBi, 2.3 dBi, 2.2 dBi, and 4.9 dBi at 4.1 GHz, 4.6 GHz, 4.9 GHz, and 7.45 GHz correspondingly. The three-dimensional radiation pattern (RP) of the antenna under consideration is depicted in Figures 11, 12, 13, and 14. The greatest directivity achieved at 4.1 GHz, 4.6 GHz, 4.9 GHz, and 7.45 GHz is measured to be 6.1 dBi, 6.45 dBi, 8.34 dBi, and 10.1 dBi, respectively. The antenna that has been proposed exhibits multiband and high gain properties, making it suitable for many wireless applications. The proposed antenna exhibits potential for utilisation in RF energy harvesting applications, as it is capable of efficiently harvesting power from several frequency bands.

III. Conclusion

A multiband fractal antenna in the form of a sunflower, with a specific focus on its suitability for wireless energy harvesting purposes is presented. The antenna under consideration has the capability to operate on four discrete frequency ranges: 3.9 GHz to 4.1 GHz, 4.55 GHz to 4.66 GHz, 4.8 GHz to 5.05 GHz, and 7.3 GHz to 7.85 GHz. The bandwidths of each frequency band are 120 MHz, 110 GHz, 250 MHz, and 550 MHz, respectively. The antenna being examined demonstrates a maximum gain of 5.1 decibels isotropic (dBi) at a frequency of 4.1 gigahertz (GHz), 2.3 dBi at 4.6 GHz, 2.2 dBi at 4.9 GHz, and 4.9 dBi at 7.45 GHz, respectively. The antenna being presented demonstrates a high gain and the ability to operate over multiple frequency bands, making it highly suitable for applications involving the collection of RF energy. In particular, it possesses the capability to efficiently focus on the mid 5G band, WLAN, and 5G extended mid band, while harnessing the existing power within the surrounding environment. Following this, the obtained energy could be utilised for the objective of providing power to electronic sensors with low power requirements.

2024 3rd International Conference for Innovation in Technology (INOCON) | 979-8-3503-8193-1/24/$31.00 ©2024 IEEE | DOI: 10.1109/INOCON60754.2024.10511869

***Abstract*—Depression, a prevalent mental health concern, manifests itself on social media, providing opportunities for early detection. This study aims to fill the gap in research for low-resource Indian languages by proposing a comprehensive approach to depression detection across eight languages. By utilizing the Long Short-Term Memory and the Gated Recurrent Unit models, we provide an ensemble model that improves overall performance. Our translation-based dataset solves data restrictions related to language. Drawing insights from various studies, the literature review delves into the complexities of analyzing mental health on social media. We translate these insights into practical applications through model implementation and preprocessing techniques. The LSTM and GRU models, enriched with pre-trained FastText embeddings, demonstrate competitive accuracy. The ensemble model, amalgamating their outputs, exhibits robustness in depression detection. Nevertheless, certain limitations persist, including concerns related to dataset representativeness and the nuances of informal social media language. Our study concludes with a roadmap for future research, emphasizing the need to expand datasets, develop language-specific models, and explore advanced architectures. This research contributes to a nuanced understanding of depression detection in linguistically and culturally diverse contexts, building upon insights gained from the literature review and model implementations across various Indian languages.**

***Index Terms*—Depression Detection, Social Media Analysis, Multilingual Sentiment Analysis, Indian Languages, LSTM and GRU Models, Ensemble Learning, Translation Approach, Text Preprocessing, Mental Health Detection, Low-Resource Languages, Social Media Data Mining, Cross-Lingual Sentiment Analysis, Word Embeddings, Natural Language Processing**

I. Introduction

Understanding human psychology is a complex yet crucial process, especially when extracting insights from text-based data. Analyzing emotions, opinions, and judgment formation is key, with social media platforms like Facebook, Twitter, and Reddit playing a pivotal role in contemporary expression [1]. Psychology's influence spans mental health, product reviews, customer satisfaction, and business decisions. Online reviews impact product perception, offering insights for improvement [2]. This paper focuses on major depressive disorder, prevalent globally, and explores Twitter as a valuable source for mental health data [4] [9]. Social media, including Twitter, Facebook, Instagram, and Reddit, provides rich datasets for psychological classification tasks, fostering concise expression and discussions on various topics [9]. The study investigates the connection between artificial intelligence (AI) and psychology, using machine learning classifiers to detect depression on Twitter. Preprocessed datasets are subjected to four different analyses: logistic regression, decision trees, K-nearest neighbor, support vector machines, and long short-term memory. The enhanced performance of LSTM with imbalanced datasets is highlighted.

The methodology, results, and a discussion follow, contributing insights to the psychology-AI nexus. Social media platforms, especially Twitter, offer crucial psychological insights due to character limits and diverse discussion groups on topics, including mental health. Psychological analysis of social media data extracts meaningful insights from platforms like Twitter, Facebook, Instagram, and Reddit. Twitter's character limit encourages concise expression, making it valuable for understanding user psychology. Focusing on major depressive disorder in mental health research, this paper highlights symptoms, emphasizing Twitter's role as a space for users to share thoughts and feelings concisely [4] [9]. The study's core is applying machine learning classifiers to analyze social media data for depression detection. The comparative analysis showcases LSTM's effectiveness, particularly with imbalanced datasets, contributing to the intersection of psychology and AI. The structure of this work is as follows: The literature is reviewed in Section 2, the criteria for identifying depression are covered in Section 3, the approach and five machine learning classifiers are covered in Section 4, and the experimental results are presented in Section 5. Concluding remarks and research directions are provided in Section 6.

II. Literature review

The exploration of mental health through social media has been a subject of substantial research, employing various approaches across different languages and

platforms.

Reputable studies, such as [1] have examined real-time detection on Thai Twitter. The PHQ-9 questionnaire, demographic information, and Twitter IDs were utilized in the study to categorize participants as Moderately Depressed, Slightly Depressed, and Normal. F-measure, accuracy, precision, and

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 10,2024 at 04:58:28 UTC from IEEE Xplore. Restrictions apply.

recall were used to gauge the job's complexity using models including Decision Tree, Random Forest, Naïve Bayes, and Deep Learning. PySpark and other statistical tools improved the research.

[2] examined datasets from Reddit and Twitter in research done in the English language. With the use of sophisticated models like LSTM, Bi-LSTM, and BERT, this study was able to get remarkable accuracy rates of 94%, 96%, and 98%, respectively. It was emphasized how crucial word embedding methods are to accurately expressing textual data. Multimodal analysis had a role in another aspect of Twitter mental health detection in [3] This study relied on self-declared tweets for classification, highlighting the difficulties of varied user expressions, with over 11 million tweets from depressed users and 16 million from non-depressed users. [4] concentrated on Weibo in Chinese, extending beyond Western platforms. In order to get insight into language-specific difficulties, users were categorized according to the presence or lack of explicit terms connected to depression for depressed users and these keywords for non-depressed users.

[5] examined sentiment in 1.6 million tweets using well-established datasets, highlighting the need of nuanced sentiment interpretation in the context of sentiment analysis methodologies.

[6] examined Twitter and Reddit for cross-language comparisons, using explicit self-declaration as the classification criterion. The two language-specific approaches, [9] and [8]examined Bengali sentiment analysis on social media platforms such as Facebook and Twitter.

[10] showcased the difficulties of multilingual analysis by utilizing the source of articles for labeling, while also examining Japanese mood. [11]examined Arabic tweets and labeled them based on depressive and melancholic phrases. To sum up, the literature review highlights the complexity of comprehending mental health through social media by presenting a diverse range of approaches, languages, and platforms.The diverse strategies employed contribute to a nuanced understanding of sentiment and user expressions across different linguistic and cultural contexts. Comparative Analysis of Depression Detection Models Recent studies have explored the effectiveness of various depression detection models across different languages and social media platforms. Diverse machine learning techniques were employed to analyze user-generated content and identify depressive sentiments. Here, we provide an overview of several studies and their outcomes: Bengali Depression Detection Models

Finding the Severity of Depression Through Bengali Social Media Posts on Mental Health: 86% accuracy was attained with a BiGRU model. Depression Analysis using Gated Recurrent Neural Network (GRU) on Bangla Social Media Data: 75.7% accuracy was attained using GRU. Multilingual Tweet Analysis Multilabel Classification for Emotion Analysis of Multilingual Tweets: Gujarati: Accuracy of 84% using Linear SVC. Hindi: Accuracy of 78% using Linear SVC. Hindi Depression Recognition Models

CNN-BiLSTM was utilized to identify emotions in code-mixed social media in Hinglish (Hindi+English), having an accuracy of 83.21%.

BERT was utilized to recognize emotions in data containing mixed English and Hindi codes, using a six transformer technique.

Sentiment Analysis in Malayalam Deep Learning-Mixed Malayalam-English Text Analytics on Social Media: 76.33% accuracy was attained using GRU. Sentiment Analysis of Dravidian Languages

Benchmarking multi-task learning reveals that Tamil has a precision of 74.4% when using BERT regarding Offensive Language Identification.

Malayalam: 64.7% precision with BERT. Sentiment Analysis in Multiple South Indian Languages (Malayalam, Tamil, Kannada) Deep Learning Based Sentiment Analysis: Malayalam: Accuracy of 84.28% using LSTM. Tamil: Accuracy of 52.93% using LSTM. Kannada: Accuracy of 57.45% using LSTM. These comparative insights highlight the diversity in model performances across languages, emphasizing the need for language-specific and culturally sensitive approaches in social media-based mental health research.

III. Model Architecture

A. Long Short-Term Memory (LSTM) Model

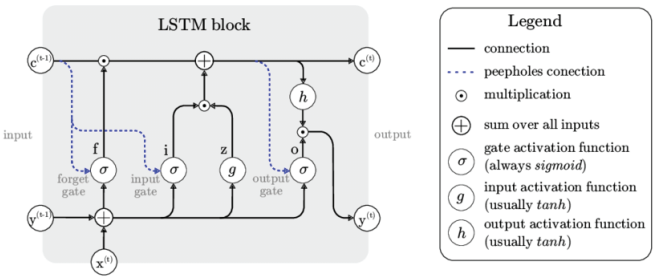

Fig. 1. LSTM Architecture [21]

The LSTM model is a type of recurrent neural network (RNN) designed to address the vanishing gradient problem, enabling the capture of long-range dependencies in sequential data. The architecture consists of memory cells, input gates, output gates, and forget gates. Given an input sequence $X = (x_1, x_2, ..., x_t)$, the LSTM computations at time t are defined in equations 1-6:

B. Gated Recurrent Unit (GRU) Model

The GRU is another type of RNN designed for simpler computations and faster training. It comprises a reset gate, an update gate, and a candidate hidden state. Given an input sequence $X = (x_1, x_2, ..., x_t)$, the GRU computations at time t are defined in equations 7-10:

C. Ensemble Model

The ensemble model combines the predictions of the LSTM and GRU models to enhance overall performance. Given individual predictions P_{LSTM} and P_{GRU} from the LSTM and

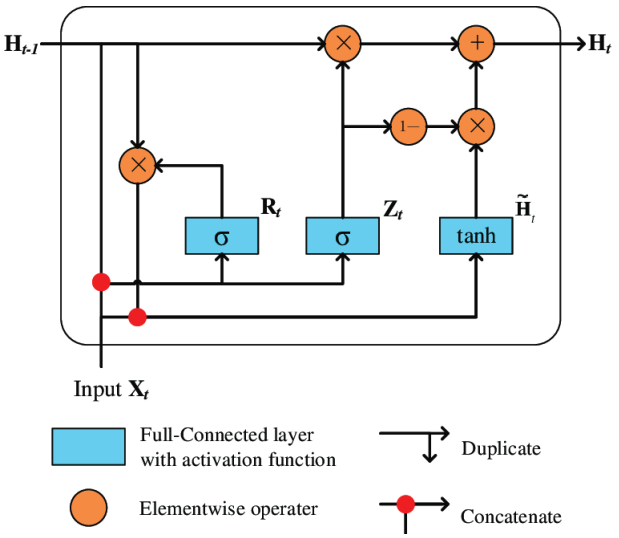

Fig. 2. GRU Architecture [22]

$$f_t = \sigma(W_f \cdot [h_{t-1}, x_t] + b_f) \tag{1}$$

$$i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i) \tag{2}$$

$$\tilde{C}_t = \tanh(W_C \cdot [h_{t-1}, x_t] + b_C) \tag{3}$$

$$C_t = f_t \cdot C_{t-1} + i_t \cdot \tilde{C}_t \tag{4}$$

$$o_t = \sigma(W_o \cdot [h_{t-1}, x_t] + b_o) \tag{5}$$

$$h_t = o_t \cdot \tanh(C_t) \tag{6}$$

Fig. 3. Equations describing LSTM model

GRU models, respectively, the ensemble prediction P_{Ensemble} is computed as shown in the equation 11:

The ensemble model benefits from the diverse representations learned by LSTM and GRU, providing a more robust and accurate prediction for the task of depression detection in social media data.

IV. Methodology

A. Dataset

1. Collection of Depressive and Non-Depressive Tweets The dataset used in this study came from Kaggle and is made up of tweets that Google Translate has translated into a number of different languages. Two subsets were created: depressive tweets, containing content indicative of depression, and non-depressive tweets, representing normal Twitter discourse. The creation of a balanced dataset ensures a representative training environment for sentiment analysis models. 2. Data Preprocessing Steps To enhance the dataset's quality and facilitate

$$r_t = \sigma(W_r \cdot [h_{t-1}, x_t] + b_r) \tag{7}$$

$$z_t = \sigma(W_z \cdot [h_{t-1}, x_t] + b_z) \tag{8}$$

$$\tilde{h}_t = \tanh(W \cdot [r_t \cdot h_{t-1}, x_t] + b) \tag{9}$$

$$h_t = (1 - z_t) \cdot h_{t-1} + z_t \cdot \tilde{h}_t \tag{10}$$

Fig. 4. Equations describing GRU model

$$P_{\text{Ensemble}} = \frac{P_{\text{LSTM}} + P_{\text{GRU}}}{2} \tag{11}$$

Fig. 5. Equation describing ensemble model

effective model training, several preprocessing steps were employed. These steps included the removal of noise and irrelevant information, text normalization, and the creation of labeled datasets for depressive and non-depressive tweets.

B. Preprocessing Techniques

1. Text Cleaning and Normalization:

Text cleaning involved the removal of special characters, URLs, and unnecessary symbols. Additionally, text normalization techniques, such as converting text to lowercase, were applied to maintain uniformity in the dataset. The preprocessing aimed to ensure that the input data for the models is consistent and free from irrelevant artifacts.

2. Tokenization and Word Analysis:

Tokenization, performed using the Keras Tokenizer, involved breaking down the cleaned text into individual tokens. This step aids in creating a vocabulary for the models. Furthermore, an analysis of words and their frequencies was conducted to understand the composition of both depressive and non-depressive tweets.

3. Word Cloud Visualization: The most common terms in the depressing tweets were shown visually in a word cloud created with the WordCloud software. This visualization contributes to a qualitative comprehension of the dataset by helping to discover important phrases linked to depression.

C. LSTM and GRU Models

1. Word Embedding with Pre-trained FastText Vectors:

Word embedding for the LSTM and GRU models was done with pre-trained FastText vectors. These vectors improve the input text's representation by capturing the semantic connections between words. Using FastText makes it easier to comprehend linguistic subtleties by making one more aware of the context.

2. Training and Model Architecture:

Both LSTM and GRU models were constructed using specific architectures that included embedding layers, recurrent layers (LSTM/GRU), and a dense output layer. The models

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 10,2024 at 04:58:28 UTC from IEEE Xplore. Restrictions apply.

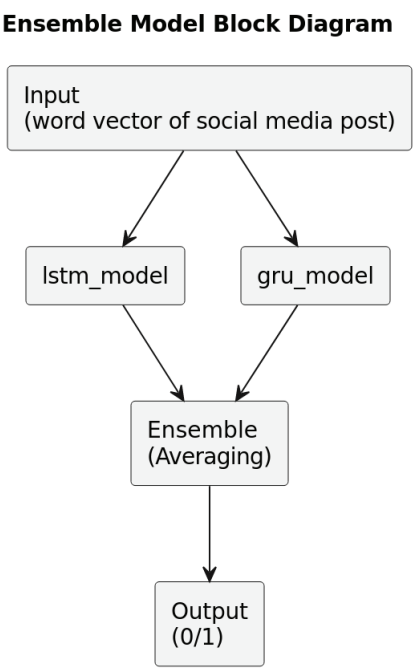

Fig. 6. Ensemble Architecture

have been trained using the preprocessed data to find hidden trends in the data, enabling sentiment analysis.

3. Early Stopping and Optimization Strategies:

To prevent overfitting and enhance training efficiency, early stopping mechanisms were implemented. Additionally, optimization strategies, such as dropout and regularization, were applied to fine-tune the models. These measures aimed to improve the generalization ability of the LSTM and GRU models. The technique described here offers a thorough rundown of the procedures used for gathering datasets, preparing them, and applying baseline and deep learning methods to evaluate sentiment on multilingual Twitter data.

V. Results and Discussion

In our comprehensive research of sentiment analysis across several Indian languages, we give an in-depth examination of the model's performance metrics, including precision, recall, accuracy, and F1 score. Our approach, leveraging a translation methodology for the creation of language-specific databases, adds a layer of complexity and sophistication to the study. The subsequent table encapsulates nuanced performance metrics for each language.

Gujarati: With an F1 score of 0.90280, recall of 0.89615, accuracy of 0.91669, precision of 0.91058, and robust performance, our sentiment analysis model performed well in Gujarati. This shows how effective our translation-based dataset construction is, since it outperforms the accuracy standard established by [15]

Kannada: Our model showed excellent recall (0.89360), accuracy (0.92232), precision (0.92664), and F1 score (0.90753) in Kannada. The accuracy and recall measures demonstrated the flexibility of our technique to the subtleties of Kannada sentiment expression, outperforming previous models.

Hindi: We obtained an accuracy of 0.92513, precision of 0.92843, recall of 0.89936, and an F1 score of 0.91181 for our Hindi sentiment analysis model. These outcomes demonstrated the model's efficacy in identifying emotion subtleties in Hindi social media content, surpassing the F1 score published in [16]

Bengali: With an accuracy of 0.91922, precision of 0.91842, recall of 0.89437, and an F1 score of 0.90492, our model performed exceptionally well in Bengali. These data show how effective our sentiment analysis model is when applied to Bengali social media material, surpassing the performance of current standards.

Telugu: With an F1 score of 0.90416, accuracy of 0.91866, precision of 0.93089, recall of 0.88704, and other notable outcomes, our sentiment analysis model performed quite well in Telugu. The model's overall usefulness is bolstered by its high accuracy, which demonstrates its ability to reliably recognize both positive and negative attitudes in Telugu text.

Marathi: With an accuracy of 0.91247, precision of 0.91511, recall of 0.88310, and an F1 score of 0.89649, our model performed admirably in Marathi. The model's 30 ability to keep recall and accuracy in check indicates its dependability when it comes to sentiment analysis of Marathi social media material.

Malayalam: We obtained an accuracy of 0.91388, precision of 0.90700, recall of 0.89309, and F1 score of 0.89952 using our sentiment analysis model for Malayalam. These findings demonstrate the efficacy of our technique in sentiment analysis of code-mixed Malayalam-English text, surpassing the F1 scores published in [18]

Tamil: With an accuracy of 0.91416, precision of 0.91904, recall of 0.88777, and an F1 score of 0.90065, our model performed competitively in Tamil. As demonstrated by the F1 scores obtained in [19] these outcomes demonstrate the adaptability of our sentiment analysis model in the context of the Tamil language. These language-specific discussions underscore the adaptability and efficacy of our sentiment analysis model across diverse linguistic landscapes, providing valuable insights into the nuances of sentiment expression in Indian languages on social media. The integration of a translation approach for dataset creation contributes to the model's success in capturing sentiment variations across different languages.

VI. Limitations

Despite the promising results obtained, our study has certain limitations. First off, the caliber and representativeness of the training data have a major impact on how well the models function. While we expanded the dataset to include many Indian languages using a translation technique, the effectiveness of this strategy could differ depending on the language, which might affect the generality of the model. Moreover, the ensemble model, while designed to enhance overall performance, is not immune to the individual limitations of the LSTM and GRU modelsThe quality of the data and the subtle differences

Tamil	0.91416	0.91904	0.88777	0.90065

TABLE II
COMPARATIVE ANALYSIS

Paper	Language	Accuracy	Precision	Recall	F1 Score	Model
[12]	Bengali	0.86	0.85	0.86	0.86	BiGRU
[13]	Bengali	0.757	-	-	-	GRU
[14]	Bengali	90.3	0.694	0.547	0.562	BiGRU
[15]	Gujarati	-	-	0.84	-	Linear SVC
[16]	Hindi	-	-	0.78	-	Linear SVC
[16]	Hindi	0.8321	0.8323	0.8321	0.8319	CNN-BiLSTM
[17]	Hindi	0.7143	-	-	-	BERT
[18]	Malayalam	0.7633	0.7607	0.7633	0.7617	GRU
[19]	Tamil	-	0.744	0.645	0.625	BERT
[20]	Malayalam	-	0.647	0.69	0.668	BERT
[20]	Malayalam	0.8428	0.6303	0.6304	0.627	LSTM
[20]	Tamil	0.5293	0.4232	0.5272	0.441	LSTM
[20]	Kannada	0.5745	0.5062	0.5455	0.5193	LSTM

in vocabulary between the languages determine how effective each model is. There are inherent difficulties with using social media data to identify mental health issues. These platforms' texts are frequently informal, context-dependent, and noisy, all of which affect how accurate the models are. Additionally, the diverse linguistic landscape of Indian languages introduces complexities that may not be fully addressed in our current approach.

VII. CONCLUSION

In conclusion, our research explores the detection of depression in social media across eight Indian languages, addressing the paucity of work in low-resource Indian languages. We have implemented LSTM and GRU models, leveraging their ability to capture sequential dependencies, and proposed an ensemble model to amalgamate their strengths. The translation approach has been employed to overcome data limitations in each language. Our findings indicate promising results, with competitive accuracy and precision scores across languages. The ensemble model, combining the strengths of LSTM and GRU, demonstrates robustness in depression detection.

VIII. FUTURE SCOPE

The current study opens avenues for future research in several directions. Firstly, continuous efforts should be directed towards expanding the dataset, encompassing a more diverse range of social media posts to enhance model generalization. Moreover, fine-tuning models on language-specific linguistic characteristics could further improve performance. To address the challenge of limited work in low-resource Indian languages, future research should focus on developing dedicated models for these languages, considering the linguistic intricacies unique to each. Contextual data, user demographics, and temporal features incorporated into the models may offer a more comprehensive knowledge of how mental health is expressed on social media. Furthermore, investigating sophisticated deep learning architectures and utilizing multimodal data sources might potentially enhance the precision and subtlety of depression detection algorithms.

REGULAR CONTRIBUTION

Non-Alpha-Num: a novel architecture for generating adversarial examples for bypassing NLP-based clickbait detection mechanisms

Ashish Bajaj[1] · **Dinesh Kumar Vishwakarma**[1]

Accepted: 23 April 2024
© The Author(s), under exclusive licence to Springer-Verlag GmbH Germany, part of Springer Nature 2024

Abstract
The vast majority of online media rely heavily on the revenues generated by their readers' views, and due to the abundance of such outlets, they must compete for reader attention. It is a common practise for publishers to employ attention-grabbing headlines as a means to entice users to visit their websites. These headlines, commonly referred to as clickbaits, strategically leverage the curiosity gap experienced by users, enticing them to click on hyperlinks that frequently fail to meet their expectations. Therefore, the identification of clickbaits is a significant NLP application. Previous studies have demonstrated that language models can effectively detect clickbaits. Deep learning models have attained great success in text-based assignments, but these are vulnerable to adversarial modifications. These attacks involve making undetectable alterations to a small number of words or characters in order to create a deceptive text that misleads the machine into making incorrect predictions. The present work introduces "*Non-Alpha-Num*", a newly proposed textual adversarial assault that functions in a black box setting, operating at the character level. The primary goal is to manipulate a certain NLP model in a manner that the alterations made to the input data are undetectable by human observers. A series of comprehensive tests were conducted to evaluate the efficacy of the suggested attack approach on several widely-used models, including Word-CNN, BERT, DistilBERT, ALBERTA, RoBERTa, and XLNet. These models were fine-tuned using the clickbait dataset, which is commonly employed for clickbait detection purposes. The empirical evidence suggests that the attack model being offered routinely achieves much higher attack success rates (ASR) and produces high-quality adversarial instances in comparison to traditional adversarial manipulations. The findings suggest that the clickbait detection system has the potential to be circumvented, which might have significant implications for current policy efforts.

1 Introduction

Throughout the preceding decennium, Machine Learning models exhibited remarkable efficacy across a range of tasks, including regression, classification, and decision-making. The susceptibility of these models to adversarial instances, which are genuine inputs that have been modified by subtle perturbations, has been noted. Recent studies have made significant advancements in the creation of hostile pictures, which have the capability to undermine the effectiveness of computer vision algorithms [1]. There exists a scarcity of research on adversarial scenarios within several NLP applications, including but not limited to sentiment analysis [2], topic categorization, machine translation, hate content identification, and false news detection [3]. Due to its efficacy in the realm of visual perception, adversarial learning has emerged as a relatively new subject of heightened interest, warranting more investigation.

The focus of previous research on adversarial examples has predominantly been on the domain of vision, mainly due to the discrete nature of text data and the challenges associated with optimisation. Moreover, it is worth noting that the perturbations introduced in the image domain often possess the ability to appear almost imperceptible to the

human visual system. As a result, this can give rise to disparities between the way humans perceive visual stimuli and the performance of state-of-the-art computational models [1]. The manipulation of a single word within the context of a text can significantly impact the meaning of a statement, with even minor changes being readily identifiable. The field of natural language processing (NLP) encompasses a diverse array of applications, spanning various domains such as machine translation, sentiment analysis, and question answering. However, despite its broad scope, there has been a limited amount of research conducted on adversarial cases within NLP. Adversarial learning has emerged as a promising technique in the field of image analysis. Its effectiveness has garnered significant interest and attention in recent years. Consequently, there is a growing need to delve deeper into this relatively new and valuable research area. Multiple studies have examined the security of current machine learning models and have proposed different attack strategies, including *causative* and *exploratory* attacks, as suggested by various research findings [4]. Exploratory attacks involve the manipulation of testing instances, known as adversarial examples, with the intention of deceiving a targeted classifier. On the other hand, causative attacks focus on modifying the training data with the intention of misleading the classification algorithm [5].

The generation of adversarial instances involve the application of two distinct adversarial environments. The concept of a "*black-box setup*" refers to a specific design approach for creating adversarial examples. In this setup, the malignant is intentionally kept unconscious of both the model being targeted & the specific training data used to train the classifier. This lack of knowledge about the inner workings of the classifier and the data it has been trained on adds an additional layer of complexity to the adversarial example creation process. In contrast, the adversary possesses complete knowledge about the classifier and training data within a "*white-box*" setting [6]. To be considered a natural language attacking system, the system must meet certain criteria. These criteria include successfully deceiving the target models and adhering to the 3 key conditions which maintain practicality. (1) Semantic similarity refers to requirement that the generated instance should possess the identical meaning as the genuine example, as assessed by human evaluators. (2) The inclusion of adversary examples should prioritise their naturalness and grammatical correctness. (3) The Integrity of Individual Predictions: Examining the Stability of Predictions Made by Humans.

The investigation into the resilience of transformer-based "clickbait-detection" is a significant area of study, particularly due to the increasing use of adversarial techniques. These techniques involve malicious users making slight modifications to deceive the classifiers and generate inaccurate outcomes. The concept of perceptual distinctiveness refers to the ability to differentiate between what should be perceived in the surrounding environment and what is actually perceived. The architecture of deceiving deep learning-based clickbait detection mechanisms is shown in Fig. 1. In addition, it is imperative to investigate and evaluate the susceptibilities of these classifiers when subjected to various adversarial attack strategies, with the aim of providing potential expedient that can be implemented to mitigate these assaults. The research studies indicate that the identified susceptibilities have the potential to manipulate the perception of classifiers, resulting in a reversal or cancellation of their intended functionality. This poses a significant risk when these vulnerabilities are exploited in applications that rely on the same classifier.

1.1 Importance of the study

The advent of social media platforms, such as Facebook and Twitter, has facilitated global connectivity and the exchange of ideas among individuals worldwide. By engaging in such actions, individuals have inadvertently opened avenues for cyber assailants and online harassers to disseminate false information, engage in offensive behaviour, cyberbully users, and incite conflicts through social media platforms and public online forums. Clickbaiting may be seen as a marketing tactic employed to attract readers by exploiting their curiosity or interest, particularly when there is a lack of compelling or captivating content. Clickbaiting is often perceived as lacking integrity. Digital marketing organisations are implementing methods to mitigate the prevalence of clickbait postings in users' timelines through the utilisation of clickbait detecting techniques. Despite the notable advancements made by deep learning systems in recognising clickbait language, they still exhibit susceptibility to adversarial settings. Adversarial machine learning refers to the intentional manipulation of input data by introducing tiny perturbations, with the objective of causing intended paradigm may have a glitch, resulting in the generation of inaccurate results. The diagram illustrating the architecture for adversarial machine learning may be observed in Fig. 5. Therefore, the effectiveness of the model may be undermined. The present work investigates the adversarial limitations inherent in sophisticated deep learning algorithms. This study is of potential significance to those who often utilise existing and advanced deep learning frameworks for analytical & commercial activities.

This finding will provide motivation for the next generation of scholars to not just focus on the improvement of model accuracy scores, nevertheless, to focus on developing resilient architectures that can survive malicious manipulations, which are already seen as a substantial security concern.

1.2 Motive of the investigation

The domain of adversarial machine learning has witnessed significant growth in recent years. The current body exists of a substantial body of scholarly work about the adversary interpretation of textual modelling but is still limited, indicating a scarcity of research in this area. In contemporary literature, Fig. 2 provides a visual representation of the prevalence of adversarial examples.

Threats are being extensively investigated in numerous studies, specifically focusing on the field of computer vision. Nevertheless, there's a shortage of scholarly articles about the domain of textual analysis. Adversarial attacks have garnered significant attention in the realm of research, particularly in the domain of image manipulation. Therefore, in this study, we analyse prominent research papers in the field of NLP to ascertain the datasets employed within the textual context. Table 1 showcases the specifications of the extensively employed datasets that have been utilised in various studies pertaining to adversarial attacks [7].

Figure 3 illustrates the distribution of percentages for the NLP assignments. A significant majority, over 50%, of databases are specifically allocated for the purpose of categorising textual data. This activity has considerable importance within the realm of NLP [7]. Clickbait intended to deceive readers by promoting misleading claims. However, it can also serve more nefarious purposes, such as engaging in phishing activities to get personal information or, in more severe cases, acting as a platform for hosting malware. Due to the aforementioned factors, the matter of clickbait assumes a significant magnitude and needs prompt attention and resolution. The initial stage involves the identification of bait and non-clickbait content through the utilisation of

deep learning algorithms. Because of a pressing need, this study used a clickbait dataset to show how fragile clickbait identification is when there are attackers around. As a result, the authors decided to do a thorough testing study of how deep learning models for clickbait detection can be attacked. Currently, there's a dearth of empirical research about the resilience of various deep neural network algorithms against adversarial assaults. This study adds something new to the field because it questions how stable existing cutting-edge deep learning models are that are often used in NLP tasks. Individuals who use these models and want to better comprehend their flaws will find this information useful.

This study employs cutting-edge techniques to attack and investigate vulnerabilities in Clickbait detection. The objective is to conduct experiments with adversarial attacks to recognize and compute the weaknesses of clickbait detectors. Therefore, the purpose of this paper is to address the following research question: How susceptible is the detection of clickbait to adversarial attacks?

1.2.1 The key *findings* of the intended research are outlined below

- "'*Non-Alpha-Num*" a novel textual adversarial attack architecture is developed that generates undetectable adversarial texts against cutting-edge text categorization systems in black-box settings. Extensive experimentation demonstrates the ease with which an adversary can deceive Deep Learning-based clickbait detection mechanisms. Such adversarial instances raise numerous concerns and significantly diminish the utility of classification systems for detecting clickbaits.
- To find the perturbation technique (attack method) that has the most significant effect on deep learning models that were trained on the clickbait dataset. Among the models are the well-known Word-CNN and five potent transformer models: BERT, DistilBERT, ALBERT, RoBERTa, and XLNet.
- This study also aims to compare and analyze the performance of deep learning-based clickbait detectors in order

to ascertain the framework that demonstrates the highest sensitivity & resilience under all adversarial scenarios.

1.2.2 Organization

The present study is structured in the following manner: Sect. 2 of this paper provides an overview of the background information and past publications that are relevant to the topic being discussed. Section 3 presents the recommended methodology for evaluating clickbait detection mechanisms in hostile circumstances. The design of our experimental settings is outlined in Sect. 4, while Sect. 5 presents the experimental outcomes. In Sect. 6, an analysis of the experimental data is presented. Following that, Sect. 7 offers a comprehensive analysis of the findings. Section 8 of the paper provides a comprehensive summary of the study's findings, along with suggestions for future investigations and a discussion of the limitations inherent in the present research.

2 Related work

This section provides an overview of the problem of clickbait detection and its use in many contexts. Subsequently, the paper delves into the contextual framework of adversarial machine learning in NLP, specifically focusing on the manipulation of text through elementary perturbations in order to deceive machine algorithms. In addition to the aforementioned points, this section also presents a compilation of previously established advanced attack tactics in the field of NLP.

2.1 Clickbait detection

Due to the widespread dissemination of information on the internet, individuals are currently exposed to a constant influx of advertising and news headlines that appear on nearly every webpage they visit. Given the widespread availability of the internet, websites and news providers are engaged in a perpetual competition to attract and retain a significant viewership [8]. Consequently, there exists a significant burden on individuals to generate more captivating, attention-grabbing, and thought-provoking titles for articles, irrespective of their veracity. As a consequence, there has been an observable increase in sensationalist "news" headings in recent years, which lack substantive information about the subject but are designed to captivate readers. The word "clickbait" pertains to deceptive hyperlinks accompanied with exaggerated headlines, designed to captivate the audience's interest and encourage them to click on the hyperlink [9]. In a general context, clickbait headlines may be categorised based on two primary factors:

(1) their tendency to deceive readers regarding the actual substance of the article.
(2) their use of the "curiosity gap" by withholding complete information about the article's contents [10]. In a more concise manner, the material contained in these headlines either generates curiosity in the reader regarding the remaining content of the article or explores subjects that are not covered inside the article's main body.
(3) Also, clickbaits are utilised by those involved in fraudulent operations, including phishing and smishing, with the intention of acquiring personal information or facilitating the dissemination of malware [11].

The initial step in resolving this issue involves differentiating clickbait headlines from authentic headline links. On the surface, clickbait headlines can be difficult to identify because they are designed to deceive the user. However, there are key semantic characteristics that can be used to identify clickbait headlines. AI tools based on machine learning algorithms can systematically detect and block clickbaits. Clickbait identification has been a subject of significant accomplishment through the use of classical machine learning methods [12]. The utilization of deep learning methods has led to advancements in model sophistication and intelligence, as demonstrated by the notable example of transformer models [13]. The models have attracted considerable attention as a result of their outstanding confidence ratings in the field of text categorization [14]. The present work utilized highly efficient classification models that are rooted in deep learning techniques. This study highlights the need to assess clickbait detectors based on deep learning techniques before their use in decision support systems, through the utilization of adversarial assaults.

2.2 Preliminaries of adversarial machine learning in NLP

This section provides an introductory understanding of adversarial instances, encompassing formulaic descriptions, interpretations, and the categorization of such cases.

Deep neural networks (DNNs) are a type of artificial neural network that are composed of the function $\boldsymbol{F}$, which represents a typical Deep Neural Network (DNN), can be defined as $\boldsymbol{F}$:$\mathbf{X} \rightarrow \mathbf{Y}$. This function maps elements from the input set $\mathbf{X}$ to corresponding labels in the label set $\mathbf{Y}$. The set $\mathbf{Y}$ consists of $\boldsymbol{k}$ classes, denoted as $\{1, 2, \ldots, k\}$. In the case of a given sample $\boldsymbol{x}$ belonging to the set $\mathbf{X}$, it is observed that the classification function $\boldsymbol{F}$ accurately assigns the true label $\boldsymbol{y}$ to $\boldsymbol{x}$, denoted as $\boldsymbol{F}(\boldsymbol{x}) = \boldsymbol{y}$.

Adversarial examples refer to a phenomenon in machine learning where slight modifications or perturbations are made to input data. The objective of the attacker is to introduce a slight perturbation $\boldsymbol{\varepsilon}$ into the input variable $\boldsymbol{x}$ in order to generate an adversarial example $\boldsymbol{x}'$. This adversarial example is designed to have a different output label $\boldsymbol{y}'$ (where $\boldsymbol{y}$ is not equal to $\boldsymbol{y}'$) when evaluated by the target model $\boldsymbol{F}$. Simultaneously, it is imperative for $\boldsymbol{x}'$ to deceive $\boldsymbol{F}$ while also maintaining imperceptibility to human observers [15]. In order to ensure that the generated $\boldsymbol{x}'$ remains imperceptible, various metrics such as semantic similarity are utilised to accomplish this objective, specifically by ensuring that the norm of $\boldsymbol{\varepsilon}$ is less than $\boldsymbol{\delta}$. Here, $\boldsymbol{\delta}$ serves as a threshold to restrict the magnitude of perturbations.

Robustness The concept of robustness refers to the ability of a system or process to maintain its functionality and when it comes to defending against adversarial examples, it is crucial for a robust deep neural network (DNN) model to possess the ability to withstand adversarial attacks [16]. This means that the model should be able to maintain accurate predictions even when faced with imperceptible additive malicious manipulations [3]. Therefore, it is hypothesised that in a robust deep neural network (DNN) model, the anticipated outcome of the adversarial example $\boldsymbol{x}'$ should be $\boldsymbol{y}$ instead of $\boldsymbol{y}'$, denoted as $\boldsymbol{F}(\mathbf{x}') = \boldsymbol{y}$. In order to improve the resilience of models, it is crucial to implement defence mechanisms that effectively address a broad spectrum of $\boldsymbol{\varepsilon}$.

2.2.1 Categorization of adversarial examples

This section provides a detailed explanation of the hierarchy of adversarial examples in Natural Language Processing, as depicted in Fig. 4.

Attacker's range A wide range of attack techniques have been proposed, including *causative* and *exploratory* attacks, in order to explore potential vulnerabilities in these models. Exploratory attacks, also referred to as test time evasion attacks, involve the generation of adversarial examples with the intention of evading a specific classifier. These malicious testing instances are designed to exploit vulnerabilities in the classifier's decision-making process. On the other hand, causative attacks focus on manipulating the training data to deceive the classifier. By altering the training data, these attacks aim to mislead the classifier during its learning process [17]. The focus of this article is solely on the topic of test time evasion, specifically examining attacks that exploit classification models as a potential security vulnerability.

Attack precision Adversarial assaults can be categorised into *Targeted* and *Non-targeted* attacks based on the intentions of adversaries. In the context of the targeted assault, the adversarial example $\boldsymbol{x}'$ is intentionally classified into a predetermined precise class $\boldsymbol{t}$, which represents the desired target for the adversary [18]. The primary mechanism of this approach is centred around augmenting the confidence score associated with class $\boldsymbol{t}$. In the context of non-targeted attack the primary objective of the adversary is to deceive the model without precisely aiming for a particular desired result. The outcome $\boldsymbol{y}'$ has the potential to belong to any class, with the exception of $\boldsymbol{y}$. In contrast to a targeted assault, a non-targeted attack functions by diminishing the confidence score associated with the right class $\boldsymbol{y}$.

Attacker's expertise Adversarial assaults can occur with expertise of attacker which includes *white-box*, *black-box*, and *grey-box* circumstances [4]. The white-box scenario gives adversaries complete target model access. Adversaries may create ideal adversarial instances by using target model knowledge, such as architectures, parameters, and training data. In the black-box scenario, adversaries cannot determine the target models [19]. Black-box attacks use transferability of hostile instances or recurrent inquiries for optimization. Since attackers can only access model parameters, adversaries in the grey-box only partially comprehend the model. Grey-box assaults assume the target model is available throughout training, unlike the other two kinds.

Perturbation granularity Text-based adversarial assaults can be categorised as *char-level*, *word-level*, *sentence-level*, or *hybrid-level* based on the perturbation granularity used to generate samples. Char-level assaults include altering several characters in words to create instances that deceive detectors. The majority of updates are misspellings and simple operations such as insertion, swap, and deletion. Attacks at the word level disturb words. Attackers create hostile instances by altering words through substitution, replacement, or deletion. Sentence-level assaults insert or rewrite sentences while retaining their meaning [20]. Hybrid-level assaults use many perturbation attacks to obtain high success rates and imperceptibility [4].

2.2.2 Constituents of textual adversarial attack

A schematic representation of generating an adversarial assault within the textual domain is depicted in Fig. 5.

Morris et al. [21] outline four components of the procedure for generating adversarial natural language instances. (1) A *sequential search* technique performs an exhaustive investigation to determine the optimal perturbations [22]. (2) A *transformation module* is used to transform a given text input, denoted $\boldsymbol{x}$, into a modified version, $\boldsymbol{x}'$. Numerous techniques, such as synonym substitutions, random character insertion, etc. are utilized to accomplish this disruption which are imperceptible to human observation. (3) A set of *constraints* is used to exclude unwanted changes to $\boldsymbol{x}'$, ensuring that the modified $\boldsymbol{x}'$ retains the semantics and fluency of the original $\boldsymbol{x}$. (4) The *objective function* is to identify an adversarial example that generates a distinct predicted label from the actual label.

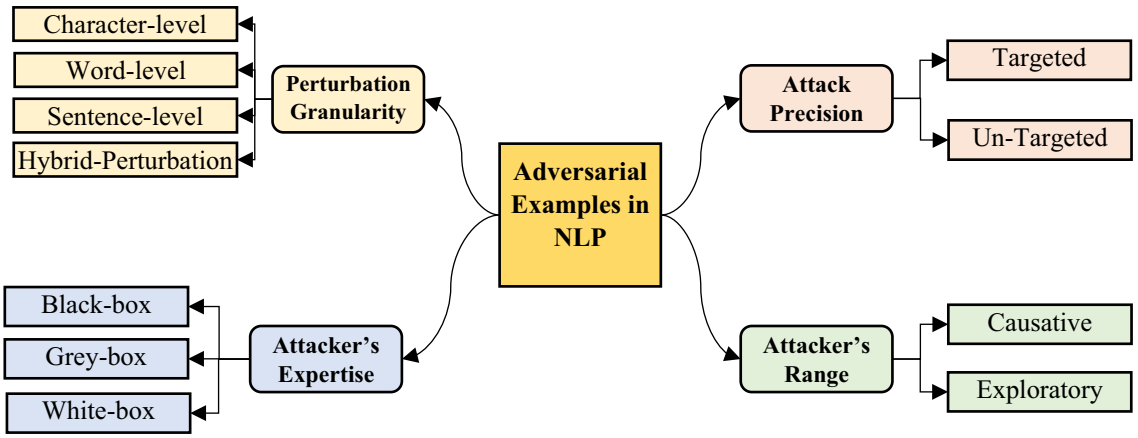

Fig. 4 Taxonomy of adversarial attacks in NLP

Fig. 5 Adversarial example generation

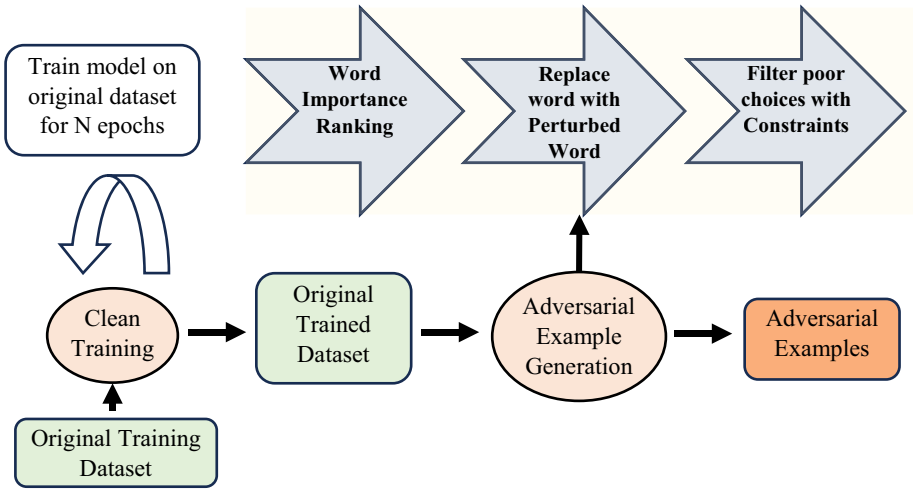

Table 2 complies with the parameters outlined in Sects. 2.2.1 and 2.2.2 by presenting notable textual adversarial assault methods across six disciplines. It comprises of the Attacker's expertise, perturbation granularity, Attack precision, searching technique, transformation used & set of constraints chosen for their attack approach, which demonstrates the uniqueness of every assault methodology outlined in the current body of academic work.

Based on current attack constraints, this study introduces "*Non-Alpha-Num*", a powerful adversarial NLP assault. This attack method creates adversarial instances by altering textual input at the character level. The assault approach aims to deceive a target NLP model when the disruption meets specific language requirements. (e.g., grammatical and semantic similarity constraints). Black-box attacks are more realistic as attackers lack knowledge of trained models or input feature representations. This analysis focuses on a black-box situation. The new strategy for clickbait identification in NLP tasks beats baseline attack techniques by improving attack success rates. The introduced approach will be explained in the subsequent section.

3 Proposed methodology

This section presents a comprehensive analysis of the proposed *'Non-Alpha-Num'* adversarial attack framework. The first segment of this section provides an overview of the problem. The subsequent section provides an overview of the attack's architecture, which comprises four distinct modules. These modules will be further elucidated. Furthermore, as an integral component of the second approach, the present investigation undertook a comparative analysis and evaluation of various neural clickbait classifiers to determine their vulnerability to adversarial perturbations. Additionally, the study aimed to identify the classifier that exhibits greater resistance to such perturbations.

3.1 Problem definition

In the context of text classification, an adversary seeks to create an adversarial document, denoted as $\boldsymbol{x}_{adv}$, from a legitimate document, denoted as $\boldsymbol{x}$, which belongs to the feature space $\mathbf{X}$. The pre-trained text classification model, denoted

Table 2 Comparing standard adversarial attack strategies with the proposed approach

Attack	Transformation	Search method	Constraints	Attack precision	Attacker's expertise	Perturbation granularity	Limitation of the work
TextFooler [23]	Word replaced with counter-fitted GLOVE Word embedding	Greedy—WIR (random)	word embedding similarity, BERT Score, POS consistency	UT	Black-box	Word-level	This type of attack is easily defended against by robust adversarial training that employs lexical alternatives to the words in a text input
TextBugger [24]	Swapping, deleting, substituting, inserting for characters	Greedy—WIR	USE similarity, POS consistency	T, UT	Black-box	Char-level	At times the modifications to the input sequence become visible
PWWS [25]	WordNet-based similar word swapping	Greedy—WIR (saliency)	USE similarity, POS consistency	UT	White-box	Word-level	An adversary must have access to the model's parameters in a white box technique
PSO [26]	How-Net word swapping	PSO	Leven-shtein edit-distance	UT	White-box	Word-level	The search technique utilises a method that requires a significant amount of time to find possible disruptions
Pruthi et al. [27]	Inserting, keyboard-char swapping, deleting, adjacent char swapping	Greedy search	USE similarity, word embedding similarity, POS consistency	T, UT	Black-box	Char-level	By utilising an orthography and grammar checker, it becomes very achievable to prevent any modifications produced to legitimate input

Table 2 (continued)

Attack	Transformation	Search method	Constraints	Attack precision	Attacker's expertise	Perturbation granularity	Limitation of the work
Kuleshov et al. [28]	Word replaced with counter-fitted GLOVE word embedding	Greedy—WIR (random)	USE similarity, word embedding similarity, POS consistency	UT	White-box	Word-level	In order to employ a white box approach, the adversary is required to possess access to the model, the feature set of inputs, and the model parameters
IGA [29]	Word replaced with counter-fitted GLOVE word embedding	Genetic algorithm	BERT Score, POS consistency	T, UT	White-box	Word-level	The modifications applied to the input may often be easily discerned by humans
DWB [30]	Deleting, substituting, inserting, adjacent char swapping	Greedy—WIR (random)	Leven-shtein edit-distance	T, UT	Black-box	Char-level	The adjustments made to genuine input may be readily avoided by employing a spelling and grammar checker
Checklist [31]	Word swap changing location of word, swapping contracting, changing name word swap extending, changing number	Greedy search	Repeat word Modification, POS consistency	UT	Black-box	Word-level	The assault strategy is less successful, and the number of alterations to input sequences is significantly more substantial
BAE [32]	BERT masked token prediction	Greedy—WIR (random)	USE similarity, POS consistency	UT	Black-box	Word-level	Resilience is lacking since word-level perturbations may be easily discovered by utilizing numerous detection procedures

Table 2 (continued)

Attack	Transformation	Search method	Constraints	Attack precision	Attacker's expertise	Perturbation granularity	Limitation of the work
A2T [33]	Word replaced with counter-fitted GLOVE word embedding	Greedy—WIR (gradient-based)	word embedding similarity, BERT Score, POS consistency	UT	White-box	Word-level	Token replacements can be complex and out-of-context at certain times, but are nevertheless readily identifiable by humans
Iyyer et al. as $\boldsymbol{F}$, is responsible for mapping the features in $\mathbf{X}$ to a set of classes, denoted as $\mathbf{Y}$. The ground truth label of the legitimate document $\boldsymbol{x}$ is represented as $\boldsymbol{y}$, where $\boldsymbol{y}$ belongs to the set of classes $\mathbf{Y}$. The objective of the adversary is to generate an adversarial document $\boldsymbol{x}_{adv}$ such that when it is passed through the text classification model $\boldsymbol{F}$, the predicted label, denoted as $\boldsymbol{y'}$, is different from the ground truth label $\boldsymbol{y}$. In order to ensure utility-preserving alteration, the adversary must satisfy the condition $\boldsymbol{Sim(x, x_{adv}) \geq \varepsilon}$ for a domain-specific similarity function $\boldsymbol{S : X \times X \rightarrow R_+}$, where $\boldsymbol{\varepsilon \in R}$ represents the bound that captures the notion of utility-preserving alteration. In the context of text classification tasks, researchers often utilize $\boldsymbol{Sim}$ as a means to capture the semantic similarity between $\boldsymbol{x}$ and $\boldsymbol{x}_{adv}$.

3.2 Attack design

The process of generating textual adversarial examples is structured as a system consisting of four key components: an objective function, a set of restraints, a modification mechanism, and a searching technique which are discussed in depth in this section [21]. The aim of this system is to search for a perturbation from $\boldsymbol{x}$ to $\boldsymbol{x}_{adv}$ that can deceive a predictive NLP model. This perturbation should be able to achieve a specific objective, such as causing the model to predict an incorrect classification label. Additionally, it must adhere to a predefined set of limitations. The searching technique aims to identify a series of transformations that lead to a successful perturbation. The Proposed adversarial attack architecture is depicted in Fig. 6.

3.2.1 Modification function

The input undergoes a transformation process, resulting in the generation of several potential perturbations. If $\mathbf{X}$ is represented as a vector ($\boldsymbol{x}_1$, …,$\boldsymbol{x_i}$, …, $\boldsymbol{x_n}$), substituting $\boldsymbol{x_i}$ with a modified version of $\boldsymbol{x_i'}$ will lead to a perturbed text. The focus of this work is to examine the substitution of significant words with character-level perturbed terms. The Non-Alpha-Num adversarial attack involves the random insertion of non-alphanumeric characters from a list that contain (!"#$%&'() * + , − . /:; < = > ? @ [\] ^‘ {|}) into the most significant words. Subsequently, the words that have been perturbed are substituted with their original counterparts. The aforementioned selections are made based on their ability to maintain the semantic closeness of the phrase as seen by human observers, despite the fact that neural text classifiers tokenize them in a different manner. Non-Alpha-numeric characters are also referred to as punctuation. Punctuation insertion might be a viable attack vector since grammar checkers struggle to identify punctuation while also not significantly impacting the content of the statement. Deep learning models perform poorly when punctuation is removed because punctuation includes crucial information that models require to function properly. Furthermore, punctuation can include antagonistic downstream information that undesirable users might use.

One crucial point in these perturbations is that words are symbolic entities, and Deep Learning frameworks that depends on learning-based approaches often employ a dictionary to represent a finite collection of potential words. The size of the average word dictionary is considerably less compared to the potential combinations of characters of a comparable length. In the context of English words, it may be seen that the total number of potential combinations is around $26^{\boldsymbol{n}}$, where n signifies the word length. This implies that premeditatedly perturbed important tokens allow for their effortless conversion into "unknown" words, which are not recognized by the dictionary. In deep learning modelling, any words that are not recognized or known will be allocated to the “unknown” embedding vector [24]. The investigation from the study provides compelling evidence that the use of random punctuation insertion is a straightforward method can significantly manipulate the behaviour of text categorization models, leading to erroneous outcomes.

3.2.2 Searching technique

The search mechanism is responsible for identifying the most optimal perturbations based on the modification function. The score is allocated to the optimal collection of altered words. The task entails the utilization of the beam search technique [22]. This algorithm employs a heuristic scoring function, as described in Eq. (1). In this function, for a given text $\boldsymbol{x}$, all potential perturbed texts $\boldsymbol{x'}$ are formed by substituting each word $\boldsymbol{x_i}$, and then scored.

$$Score(\boldsymbol{x'}) = 1 - \boldsymbol{F}_{\boldsymbol{y}}(\boldsymbol{x'}) \tag{1}$$

The function $F_y(\boldsymbol{x})$ represents the projected probability of class $\boldsymbol{y}$ by the model, whereas $\boldsymbol{y}$ represents the actual output of the original text $\boldsymbol{x}$. The highest-ranking $\boldsymbol{b}$ texts are retained, with $\boldsymbol{b}$ being referred to as the “beam width”. The iterative process continues by applying additional perturbations to each of the top $\boldsymbol{b} = 8$ perturbed texts, resulting in the generation of the subsequent set of candidate texts. The computational complexity of this operation is $\boldsymbol{O(b*W^2*T)}$, where $\boldsymbol{W}$ is the number of words in the input. The variable $\boldsymbol{T}$ denotes the maximum number of modification options that are accessible for a given input.

3.2.3 Set of restraints

A collection of linguistic restrictions is utilized to ensure that $\boldsymbol{x}$ and perturbed $\boldsymbol{x'}$ exhibit similarity in terms of both

meaning and fluency, rendering x' a viable prospective adversarial example. The search space should be designed in a way that ensures the proximity of x and x' in the semantic embedding space. We employed the Universal Sentence Encoder (USE) in this work to assess the semantic similarity of textual occurrences by utilizing cosine similarity [36]. The cosine similarity between two n-dimensional vectors, represented as m and n, is defined by Eq. (2). The word embedding vectors e_{x_i} and $e_{x_{i'}}$ must satisfy a specified minimal threshold, in Non-Alpha-Num attack, the value of the threshold is taken as $\tau = 0.6$.

$$\tau = Cosine\ similarity(m, n) = \frac{m \cdot n}{||m| \cdot |n||} = \frac{\sum_{i=1}^{k} m_i \times n_i}{\sqrt{\sum_{i=1}^{k} m_i^2} \times \sqrt{\sum_{i=1}^{k} n_i^2}} \quad (2)$$

The notation $T(x) = x'$ is employed to represent transformations that perturb x to x'. Additionally, it is assumed that the j**-th** constraints are represented as Boolean functions $C_j(x, x')$, which indicate whether x' satisfies the constraint C_j. Next, the search space S can be formally defined using mathematical notation as shown in Eq. (3).

$$Sim(x) = \{T(x) | C_j(x, T(x)) \forall j \in [m]\} \quad (3)$$

The objective of the algorithm for searching is to identify an element x' that belongs to the set $Sim(x)$ and is capable of deceiving the victim model. Additionally, in the set of restraints, the Language Tool [37] is employed to minimize the occurrence of grammatical mistakes while ensuring uniformity in part-of-speech usage. Specifically, the alternative term selected should possess the identical part of speech as the original word. The support taggers offered by SpaCy, NLTK and flair aim to maintain semantic consistency between x and x'.

3.2.4 Objective function

The effectiveness of an assault is assessed by considering the model outcomes and employing an objective function. The search strategy is explored, coupled with modifications and a specific set of restrictions, until it results in the misinterpretation of the true output [21]. The adversarial examples created by the proposed technique are illustrated in Fig. 6. Table 3 presents the algorithm employed in the suggested architecture.

3.3 Comparison of clickbait detector

In order to get a deeper comprehension of the challenges associated with clickbait detection approaches, the experiment has been bifurcated into two distinct phases. The first training of cutting-edge deep learning-based linguistic models is conducted utilizing the clickbait dataset. The baseline textual assaults and Non-Alpha-Num adversarial attacks are employed to alter the trained models in order to misclassify clickbait as non-clickbait and vice versa. Figure 7 illustrates the methodology for conducting an assault on the clickbait detector. The objective of this approach is to ascertain the relative susceptibility of different models to adversarial manipulations. The authors assert that this study represents the inaugural endeavour within the literature to juxtapose clickbait detectors in order to assess their susceptibility to hostile scenarios.

4 Experimental settings

This section provides an introduction to the dataset, victim models, attack tactics, assessment metrics, and execution details. Subsequently, in the subsequent part, we will evaluate the data and examine numerous probable factors contributing to the measured outcome.

4.1 Dataset description

This study aims to examine the impact of malicious textual examples on a widely used benchmark dataset within the domain of clickbait detection. The test set is employed for the production & assessment of the adversarial instances. Table 4 offers a concise summary of the dataset.

Clickbait [38]: The current investigation employs the clickbait dataset in order to conduct a clickbait identification task. The clickbait dataset originates from Chakraborty et al.'s paper [38]. The corpus comprises news titles extracted from a corpus of news articles annotated with two labels, namely: **0**: "*Not-Clickbait*" & **1**: "*Clickbait*". For Non-Clickbait, the headlines were taken from a repository of 18,513 Wikinews articles compiled by NewsReader, whereas for clickbait, the headlines were retrieved from 8,069 online articles of 'BuzzFeed', 'Upworthy', 'ViralNova', 'Scoopwhoop', and 'ViralStories' news portals. The average sample length of the dataset is 8.50 words, while the average length of clickbait headlines is 10 and the average length of non-clickbait headlines is 7.

Figure 8 illustrates the percentage of distribution of both clickbait and non-clickbait headlines, also it depicts the percentage of word contractions, hyperbolic words, determiners, and stop words in both clickbait and non-clickbait headlines. The data has already been pre-processed based on the methodology outlined in their paper, and it is accessible to the public via the Hugging face library. The hugging face datasets library offers an API to facilitate the acquisition of public datasets. There are a total of 16,000 samples in the dataset. In our experimental configuration, we divided the

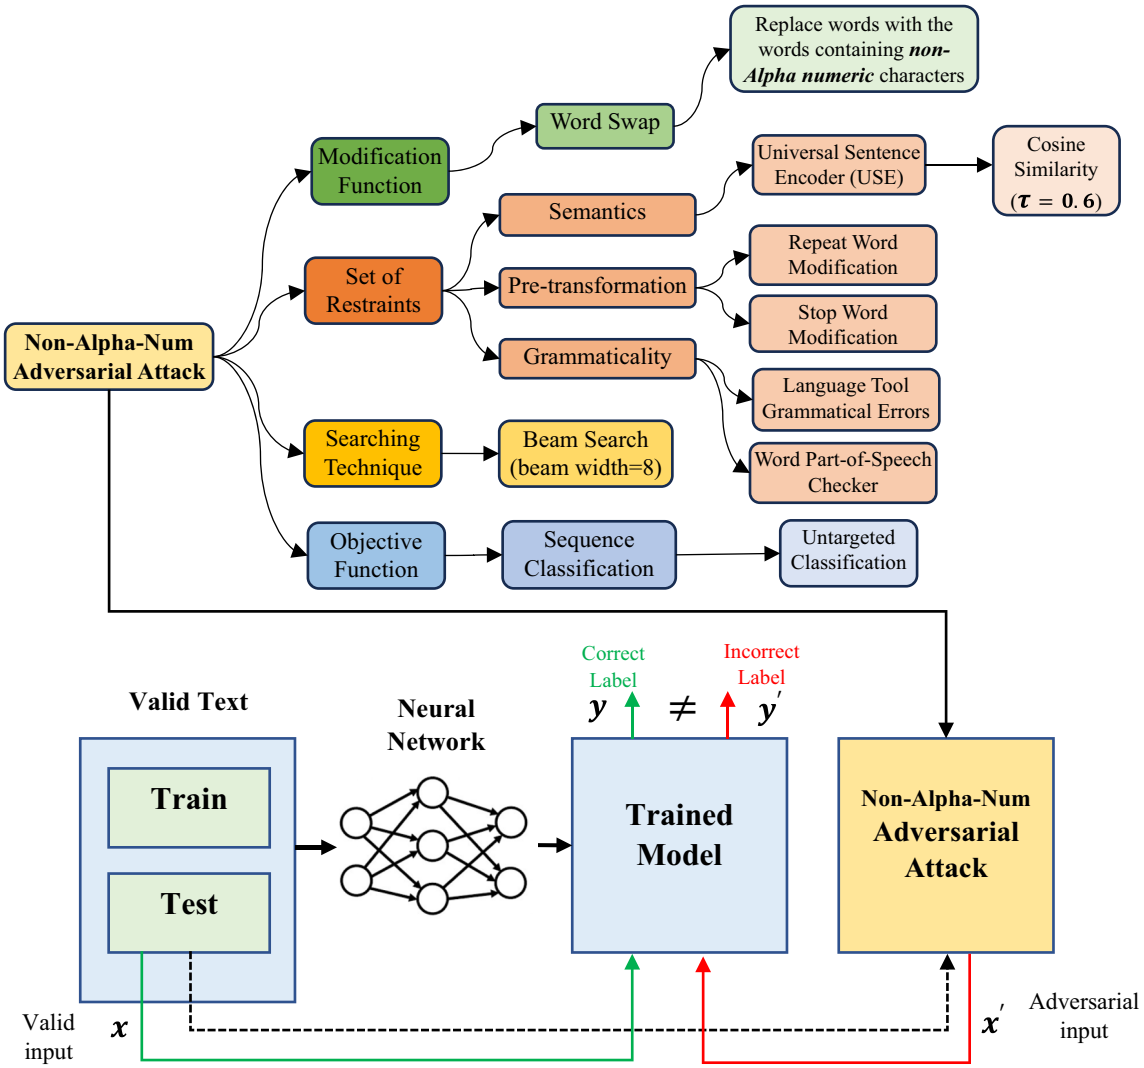

Fig. 6 Proposed adversarial attack architecture

dataset into three, namely 0.80, 0.10, and 0.10, for training, testing, and validation purposes, respectively.

4.2 Victim models

This part encompasses the depiction of the models that underwent training on the clickbait dataset, along with their respective parameter sets. The metric employed for assessing models in the context of binary classification for clickbait detection is the accuracy score. Table 5 presents the comprehensive range & corresponding description for the accuracy formula. The next section contains empirical evidence that showcases the vulnerability of each clickbait model to adversarial situations. This vulnerability is measured by a decrease in accuracy resulting from various adversarial assault strategies.

4.2.1 Description of the models

Deep neural network models demonstrate the capacity to independently acquire knowledge and identify relevant characteristics, resulting in enhanced precision and efficacy. The study employed a variety of well-known deep-learning classification methods, such as basic CNN & various transformer networks. Figure 9 presents a comprehensive representation of the models employed in this study.

Convolutional neural network (CNN) In Convolutional Neural Networks, Layers of convolution extract features through the process of screening the input information, wherein the combination of numerous filters results in the generation of outputs. subsampling or pooling is an approach utilized in CNNs to decrease the granularity of feature maps in various tiers. This process aims to improve the network's robustness against distortions and disturbances. Pooling is a

Table 3 Algorithm of the proposed attack framework

Algorithm 1: Non-Alpha-Num Adversarial Attack

Aim: Adversarial attack framework to fool neural clickbait classifier
Input: legitimate input x and its ground truth label y, classifier $F(.)$, threshold τ, semantic similarity $Sim(.)$.
Output: Generated an adversarial sequence x'

1. Initialization: $x' \Leftarrow x$
2. **for** x_i in X **do**
3. Compute score (x_i') according to **Equation (1)** — Searching Technique
4. **end for**
5. $W_{Ranked} \Leftarrow Ranking(x_1, x_2, x_3 \ldots\ldots x_n)$ in descending order
6. Remove the stop words in W_{Ranked}
7. **for** x_i in W_{Ranked} **do**
8. $x' \Leftarrow$ *Substituting x with (words with Punctuations)* — Modification
9. **if** $Sim(x, x') <= \tau$ **then** — Restraints
10. **return None**:
11. **else if** $F(x') \neq y_{true}$ **then** — Objective Function
12. Solution found **return** x'.
13. **end if**
14. **end for**
15. **return None**

technique used to decrease the dimensionality of the output produced by a certain layer in order to pass it on to the succeeding layer. The execution of categorization operations is carried out by the use of completely linked layers [39]. Convolutional Neural Networks (CNNs) have a notable capability in effectively identifying local patterns as well as patterns that are invariant to changes in position. The utilization of Convolutional Neural Networks (CNNs) has been found to be highly beneficial in the domain of text classification.

Transformer models Deep neural networks that employ transformers incorporate a self-attention mechanism to allocate various levels of importance to distinct regions of the input data. Table 6 displays a comprehensive descriptive study of many pre-trained classifiers.

4.2.2 Parameter configurations

Table 7 displays the settings of the parameters for every framework that underwent training on the clickbait dataset,

aiming to evaluate the effectiveness of adversarial attack approaches.

Table 8 displays the testing scores for the accuracy of all of the models that completed training using the clickbait dataset.

4.3 Baseline adversarial attacks

The assault strategies were employed on the testing samples of the clickbait dataset in order to produce adversarial examples. The adversarial instances are subsequently employed to incorrectly identify the authentic output of the input sentence when assigned to the pre-trained algorithms. The scope of the testing was restricted to attack approaches that have been published in reputable conferences & publications in the domains of AI and NLP. The aforementioned papers encompass a range of esteemed publications which includes ICLR, ACL, AAAI, EMNLP, IJCAI, NAACL, COLING TACL, TKDE & JMLR.

The following portion provides a succinct summary of the baselines that have been chosen to demonstrate the efficacy of the proposed approach in deceiving clickbait detection algorithms.

- A2T [33]: Yoo and Qi utilized a gradient-based method to ascertain the level of significance of words. Subsequently, a process was undertaken wherein every single word was sequentially replaced with synonyms obtained from counterfeit word embeddings.
- BAE [45]: Garg and Ramakrishnan generate samples that are adversarial with the purpose of misleading sentiment classification. The researchers proposed utilizing the BERT model for the purpose of inserting and replacing tokens inside a phrase, taking into consideration their individual levels of importance. The substitution possibilities generated by the model occasionally display antonymous or unrelated associations with the original terms, leading to a decrease in semantic consistency.
- Checklist [31]: Drawing upon the foundational principles of behavioral testing. The use of perturbations in terminology, numerical values, and places, together with contractions and expansions of the significant elements inside the sentence.

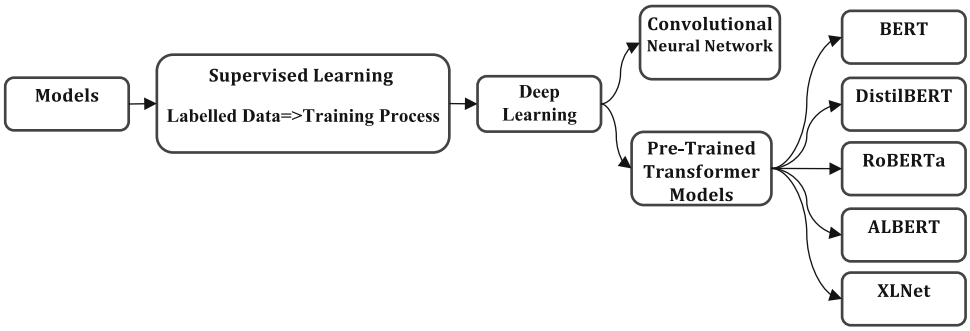

Fig. 9 Synopsis of the models employed in the investigation

Table 6 A thorough examination of the transformer variants

Model	Trained on datasets	Tuning	Description	Advantages	challenges
BERT [40]	English wikipedia & the BookCorpus	Fine-tuned on target dataset, pre-trained on specific parameters	The model under consideration is a bidirectional transformer architecture that incorporates both Masked Language Modelling (MLM) methods and Next Sentence Prediction (NSP)	1. The ability to efficiently handle and analyse context-specific data 2. Training at a Faster Pace	1. The process of categorizing is limited to a certain vocabulary 2. The total length of the input phrases is predetermined and remains constant 3. Exhibits issues pertaining to reasoning that is logical 4. The processing expense is substantial
DistilBERT [41]	English wikipedia & the BookCorpus	Fine-tuned on target dataset, pre-trained on specific parameters	The approach adopted in this study utilizes an early iteration of BERT, with a reduction in the total amount of tiers by a factor of 2. Furthermore, the implementation of adaptive masking has been carried out	1. The implementation of preliminary training has been employed to enhance the effectiveness of linguistic simulation proficiency 2. When comparing the freshly designed model to BERT, it demonstrates improved acceleration and decreased weight	1. The set-length restriction is a limitation imposed on a system or process that requires a specific length to be adhered to. This constraint ensures that the system or process operates within
ALBERT [42]	English wikipedia & the BookCorpus	Fine-tuned on target dataset, pre-trained on specific parameters	A modified version of BERT has undergone feature reduction, leading to a more lightweight version. The diminution of factors is easily accomplished by employing factorized embedding layer parameterization & cross-layer parameter allocation	1. Reduced memory utilization 2. One potential area of improvement for BERT is the enhancement of its training pace	1. Framework exhibits incompatibility for problems that involve the production of textual content 2. The text demonstrates deficiencies in logical reasoning

Table 6 (continued)

Model	Trained on datasets	Tuning	Description	Advantages	challenges
RoBERTa [43]	English wikipedia & the BookCorpus, CC-news, stories, OpenWebText	Fine-tuned on target dataset, pre-trained on specific parameters	The present study aims to replicate the BERT model by employing an enlarged training dataset and fine-tuning the hyper-parameters. Additionally, the utilization of dynamic masking is incorporated in this replication effort	1. The utilization of a larger volume of preliminary training data has been shown to enhance effectiveness 2. The performance of the model surpasses that of both XLNet and BERT	1. The attribute requires a significant number of resources 2. The current undertaking necessitates substantial computer resources and involves a lengthy processing time
XLNet [44]	English wikipedia & the BookCorpus, Giga5, ClueWeb 2012-B, Common Crawl	Fine-tuned on target dataset, pre-trained on specific parameters	It blends auto-regressive models with bi-directional context modelling to overcome BERT's drawbacks and surpass BERT on 20 tasks, frequently by a wide margin in sentiment analysis, question answering, document rating, natural language inference	Using greater amounts of initial training data improves efficacy	The absence of fictitious symbols, such as [MASK], utilized by BERT during the pretraining phase, in actual data during the finetuning phase leads to a disparity between the training and finetuning processes

- HotFlip [46]: The method involves the replacement of one token with another, using the gradients of the one-hot input vectors. The disrupted input exhibits imperceptibility to human inspection while inducing a reversal in the output, leading to inaccurate predictions.
- DeepWordBug [30]: The assault methodology described in this recipe involves the combination of four distinct forms of character disruptions, namely insertion, deletion, modification, and swapping. The authors utilize the concept of edit distance to assess the degree of resemblance between the unaltered and edited samples. This study introduces two unique scoring functions, specifically temporal and temporal tail scores, to evaluate the relevance of each word in the final model prediction. Following this, the words are sorted based on their individual scores, and a perturbation approach is then employed on the words of high relevance.
- Pruthi [27]: The authors proposed the use of a blend of character-level perturbations, such as swapping nearby characters, eliminating characters, exchanging a character with its neighboring keys on the QWERTY keyboard, and introducing new characters, as a means to produce adversarial cases.
- PWWS [25]: Ren et al. suggested defining the order of substitution candidates based on not just the classification probability but also word saliency. This enabled modeling not just the quantitative but also the qualitative aspect of the change produced by the substituted word. The substitution candidates are derived using WordNet
- PSO [26]: In their study, Zang et al. introduced a word-level adversarial assault strategy that relies on sememe substitution. The authors proposed that the challenge of choosing the best appropriate adversarial example from a set of sememe-based candidates might be seen as a multivariate combinatorial optimization problem.
- TextBugger [24]: Li et al. introduced a series of composite transformations, which encompass character deletion, swapping, substitution, and synonym substitution. In the context of the white-box setup, the identification of the most crucial words in a given sample was achieved by utilizing the Jacobian matrix of the victim classifier.
- TextFooler [23]: An attack technique with the objective of replacing the most crucial words in a given sample with a set of N synonyms. The process of selecting synonym candidates was determined by calculating the cosine similarity

Table 7 Configuration of parameters for the intended classifiers

Models	Parameter configurations
Word-CNN	For the aim of this investigation, the CNN model developed by Kim et al. [39] was used. The Word-CNN model utilizes a total of 100 filters and incorporates three different window sizes, namely 3, 4, and 5. The selected dropout rate of the framework is 0.3, and it utilizes a basis of 200-dimensional GLoVE embeddings. Afterward, a fully linked layer is utilized, which is then followed by a time-dependent max-pooling layer in order to facilitate the process of categorization. The algorithm used has achieved a test set for accuracy of 89.47% on the clickbait dataset
BERT	The "bert-base-uncased" model is subjected to a training process consisting of 10 iterations. Each iteration involves a batch size of 64, a learning rate of 2e-05, and a maximum sequence length of 128. The objective of this training is to enhance the model's performance in sequence classification specifically for the clickbait dataset. The framework underwent training by employing a cross-entropy loss mechanism. The framework attained its maximum efficacy in this assignment, as determined by the accuracy of the test set, which reached 91.55% after eight epochs
DistilBERT	The "distilbert-base-uncased" network was trained for 10 epochs using a batch size of 64, an average rate of learning of 2e-05, and an optimal sequence length of 128. This optimization was performed specifically for sequence classification on the clickbait dataset. The cross-entropy loss function was employed during the training of the model. The accuracy of the evaluation set, determined after 5 epochs, revealed that the model achieved a maximum accuracy of 90.83% on this particular job
ALBERT	We enhanced the performance of the "albert-base-v2" model for text categorization on the clickbait dataset. The model was trained for 10 epochs using a batch size of 64, a learning rate of 2e-05, and a maximum sequence length of 128 bits. The model was trained using a cross-entropy loss function. The greatest accuracy score achieved by the model in this task, as evaluated by the test set accuracy, was 91.72%
RoBERTa	The performance of the "Roberta-base" model has demonstrated enhancement in sequence classification when applied to the specific dataset utilized in our experiment. The model was executed using a maximum sequence length of 128 and a batch size of 64 for a total of 10 epochs, with a learning rate of 2e-05. The model was trained using a cross-entropy loss function, as it was a problem with categorization. The assessment of the model's performance on this particular task resulted in the highest score of 92.12% for accuracy, which was attained after 8 epochs
XLNet	The efficiency of the "xlnet-base-cased" classifier on the clickbait dataset was improved. The training process involved training the model for a total of 10 epochs. During each epoch, a batch size of 64 was used to process the data. The learning rate, which determines the step size at each iteration of the training process, was set at 2e-05. Additionally, a maximum sequence that measured 128 bits was specified to handle the input data. The training of the model was conducted with a cross-entropy loss function. The model earned a maximum accuracy score of 91.96% in this task, as determined by evaluating the test set accuracy

between word embeddings. Before finishing adversarial examples, a limitation based on part-of-speech was also enforced.

4.4 Attack assessment criteria

The effectiveness of strategies for attack has been empirically demonstrated by employing three evaluation parameters: Post Attack Accuracy, Attack Success Rate, and Average Perturbed Rate. The approach employed to evaluate and clarify the three indicators is outlined below.

- *Post attack accuracy (PAA)* The primary objective of adversarial assaults is to undermine the effectiveness of the classifiers. Performance measures, such as accuracy, are commonly employed for the evaluation of classification work. The accuracy scores have been presented both before and after the attack. The utilization of potent adversarial attacks has been found to result in a notable reduction in accuracy scores due to the efficacy of their attack techniques.
- *Attack success rate (ASR)* To analyze the effectiveness of the attack techniques, a random sample of five hundred correctly classified instances is chosen from the test set. This ensures that the evaluation is not influenced by the classifiers' classification accuracy. The source texts are subsequently subjected to attack algorithms in order to produce adversarial examples. Subsequently, the adversarial instances are forwarded to neural clickbait classifiers in order to provide the ultimate prediction. The success rate of the attack algorithm is determined by utilizing the percentage of erroneous predictions generated by these classifiers. A higher success rate indicates that the assault algorithm possesses the ability to generate more powerful adversaries, perhaps leading to the malfunctioning of

Table 8 Testing accuracy of the targeted models

	Word-CNN	BERT	DistilBERT	ALBERT	RoBERTa	XLNet
ACC	89.47%	91.55%	90.83%	91.72%	92.12%	91.96%

these clickbait classifiers. We use attack success rate ASR (ratio of successful attack samples to the total of successful and failed samples $\frac{(successful\ samples)}{successful+failed\ samples}$) to determine the effectiveness of an attack technique against the victim classifier. The successful samples refer to those that can misclassify the true prediction, whereas failed samples are unable to incorrectly categorize the genuine outcome. In an analytical context, an assault is considered effective when the algorithm $\boldsymbol{F}$ accurately classifies the initial legal input $\boldsymbol{F}(\boldsymbol{x}) = \boldsymbol{y}$, but predicts incorrectly the attacked input $\boldsymbol{F}(\boldsymbol{x} + \boldsymbol{\Delta x}) = \boldsymbol{y}'$. Therefore, the ASR may be mathematically represented as depicted in Eq. (4).

$$\text{ASR} = \frac{\boldsymbol{F}(\boldsymbol{x} + \boldsymbol{\Delta x}) = \boldsymbol{y}'}{(\boldsymbol{F}(\boldsymbol{x} + \boldsymbol{\Delta x}) = \boldsymbol{y}') + (\boldsymbol{F}(\boldsymbol{x} + \boldsymbol{\Delta x}) = \boldsymbol{y})} \tag{4}$$

In the setting of untargeted attacks, the symbol $\boldsymbol{y}'$ represents any label that differs from $\boldsymbol{y}$. The sign $\boldsymbol{\Delta x}$ is used to represent modifications made to the initial specimen. In the present context, a successful assault is defined as the ability of an adversarial sample to make inaccurate predictions with a significantly high level of confidence. In the event of an unsuccessful assault, the adversarial sample lacks the ability to cause misclassification of the true prediction. The missing statements refer to those that the model wrongly categorized throughout the training process. Our research focuses on analysing the success rates of assaults and evaluating the effectiveness of those assaults in incorrectly identifying outcomes.

- *Average perturbed rate (APR)* The average perturbation rate (APR) is another core metric employed to assess an adversarial text attack. It is defined as the ratio of the number of perturbed words to the text length as shown in Eq. (5). Less perturbation implies retention of higher levels of semantic similarity.

$$\text{APR} = \frac{Number\ of\ words\ pertured}{Total\ number\ of\ words\ in\ input\ sequence} \tag{5}$$

5 Experimental results and analysis

To comprehend the susceptibility of clickbait classifiers. The initial stage of the investigation involves employing the offered clickbait dataset to train sophisticated deep-learning models. The settings for the parameters of each model are shown in Sect. 4.2. The models that have been trained can potentially be manipulated by employing the *Non-Alpha-Num* adversarial attack strategy. After subjecting the test samples to perturbation using the technique described, the resulting drop in accuracy scores is presented in Table 9. The first measurement and recording of the accuracy of the intended models on the original test specimens is referred to as the Before-Attack Accuracy (BAA). Following this, the effectiveness of the target models is assessed by exposing them to adversarial samples created using the offered attack technique. Post-attack accuracy (PAA) refers to the score of accuracy obtained after the proposed attack has been executed. In addition, the study presents findings about the proportion of altered words in relation to the initial sentence length, denoted as Perturbation Rate (PR).

In order to assess the efficacy of the suggested attack technique in comparison to traditional attack methods against clickbait classifiers, the (ASR) metric is employed. For this, a set of 500 samples, which were accurately classified were taken from the test set. Following this, the generation of adversarial cases is achieved by the utilization of different attack methods. The current investigation entailed exposing a collection of adversarial instances to six state-of-the-art clickbait detectors. In this study, the performance of several adversarial approaches was evaluated and compared with the proposed attack, with the metric of ASR being used. This statistic can demonstrate the level of effectiveness of the assault approach. A greater ASR value signifies that a particular assault type has a higher level of effectiveness in misleading the model. Table 10 provides a concise overview of the main results obtained from the Non-Alpha-Num attack method when applied to the clickbait dataset. Additionally, it includes a comparative analysis of the effectiveness of this attack strategy with earlier attack methods.

The Non-Alpha-Num technique exhibited a notable impact on a restricted set of words, resulting in a significantly elevated rate of success in attacks. The aforementioned technique demonstrates superior performance compared to the benchmark perturbation techniques throughout all of the models. The manipulation of a restricted set of words within the data yielded a success rate of 95.8% when tested against a Word-CNN method, with an alteration rate of just under 11%. In contrast, none of the baselines were able to exceed this level of success. The mean length of the clickbait dataset sample ranges from 8 to 9 words. To execute effective assaults, the Non-Alpha-Num adversarial attack method

The findings of our proposed methodology are displayed in bold
ASR Attack success rate, *APR* Average perturbed rate

disturbed a mere percentage, namely less than 14%, of the words inside a singular sample. Research investigations have indicated that transformer representations can be deceived by the proposed attack approach, as long as the interference ratio remains under 20%. The attack approach under consideration introduced little perturbations, affecting just a small fraction of words, typically about 2–3, inside a single sample. The deception of transformer models through attacks has been seen, as long as the tampering rate stays under 20%. The ALBERT model has the highest (ASR) of 92.2% when compared to alternative attack strategies on the given dataset. The assault mechanism utilized in this work effectively deceives the DistilBERT model's predictions to a minimal extent, accomplished by introducing an average word perturbation rate of just 13.10%. Whilst being widely regarded as the leading model for a range of tasks relating to natural language processing, BERT, a sophisticated model with 110 M parameters, is vulnerable to Non-Alpha-Num adversarial attack. The results suggest that by maintaining a perturbance rate below 14.4%, the suggested methodology may successfully get an ASR of 91.6% on the clickbait dataset. Moreover, in the case of RoBERTa and XLNet, the suggested methodology demonstrates superior performance compared to previous state-of-the-art attack methodologies. This observation suggests that the suggested attack system possesses the ability to manipulate classifiers in order to provide inaccurate predictions.

In addition to the aforementioned decline in accuracy scores, we propose the concept of attack Success Rates (ASR) as a method for evaluating the efficacy of each assault, as outlined in Sect. 4.4. The assessment technique measures the proportion of successful attack samples to the total number of successful and failed samples in order to ascertain the efficacy of an attack technique against the victim classifier.

Successful samples have the potential to modify the accurate forecast, whereas failed samples do not, as outlined in Sect. 4.4. Furthermore, the Average perturbed Rates (APR) are provided, whereby the calculation entails dividing the number of disturbed words by the whole length of the text.

The application of these 2 criteria enables the assessment of different adversarial assault strategies across many models. The objective of this research is to illustrate the relative level of danger that certain attack methods pose to distinct models. Furthermore, the employment of average ASR scores assists in illustrating the classifier that has the most susceptibility to adversarial manipulations. The work also aims to analyse the vulnerability of various clickbait classifiers to various forms of adversarial interference. This study aims to assess the relative susceptibility & robustness of different models when subjected to adversarial perturbations. The success rate of each assault is assessed on each targeted paradigm in order to ascertain the relative vulnerability of each of the models as shown in Fig. 10. The mean attack success rate for each model is calculated using Eq. (6).

$$\boldsymbol{Success_{avg}} = \frac{\sum_{i=1}^{n} \frac{\boldsymbol{Successful_i}}{\boldsymbol{Successful_i + Failed_i}}}{\boldsymbol{n_{attacks}}} \tag{6}$$

The Attack Success Rate will be denoted as $\boldsymbol{Success_{avg}}$, where $\boldsymbol{Successful_i}$ represents the number of successful attacks, $\boldsymbol{Failed_i}$ represents the number of unsuccessful assaults, and $\boldsymbol{n_{attacks}}$ represents the number of attack recipes. The skipped sentences are the assertions that the machine originally mis predicted during its training. They were excluded from the computation.

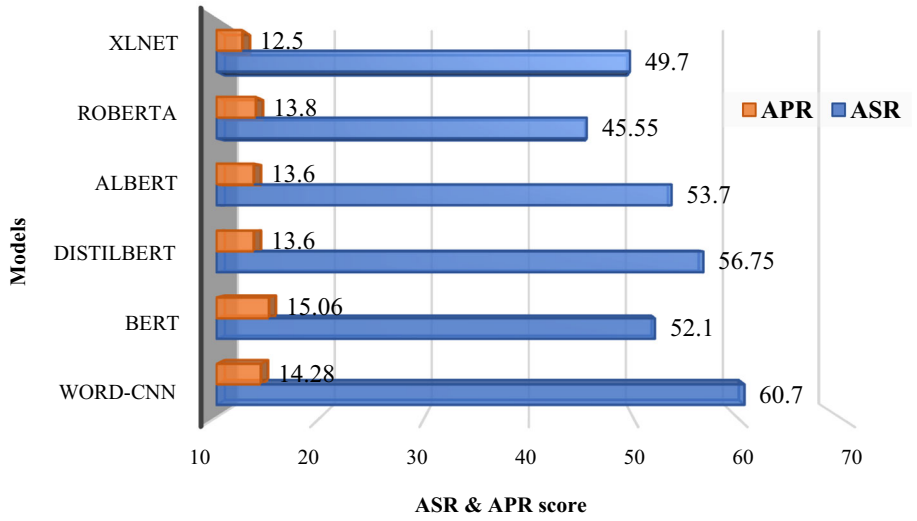
As seen in Fig. 10, subsequent examination has revealed that the Word-CNN model demonstrates the greatest vulnerability to adversarial assaults. Among transformer models, it has been observed that the RoBERTa model exhibits the least vulnerability, while the DistilBERT model is found to be the most susceptible. This observation leads to the conclusion that lighter models, such as DistilBERT [41] and ALBERT models are more prone to these attacks. This vulnerability can be attributed to the fact that the ALBERT [42] model possesses an architecture, consisting of 128 embedding layers, 768 hidden layers, and with only 12 million parameters, whereas the DistilBERT model is also a condensed variant of the BERT model. In the preliminary training stage, the BERT model experienced a process known as knowledge distillation, which led to a decrease in its overall size by 40%. Significantly, the aforementioned reduction in size was accomplished while maintaining 97% of the model's language understanding skills. However, it should be noted that the BERT base model consists of 110 million parameters, making it a computationally intensive model with a significant level of complexity. In contrast, the RoBERTa model underwent training using a significantly larger dataset and implemented a more optimized training methodology [43]. The RoBERTa model was trained using a dataset including 160GB of textual data, which is more than 10 times larger than the dataset used to train BERT. Furthermore, RoBERTa employs a dynamic masking strategy throughout its training process, which enhances the model's ability to acquire more resilient and versatile word representations. This characteristic renders RoBERTa the least susceptible among all the models. The results might be important for those who frequently utilize well-established, cutting-edge algorithms in their efforts to spot clickbait. The reader will possess the ability to determine the most appropriate model that corresponds to their particular problem. Moreover, this phenomenon acts as a motivating factor for academics to develop models that exhibit adversarial robust generalizations rather than traditional generalizations. To ascertain the comparative efficacy of assault approaches in deceiving the model with a reduced average perturbance rate. The average rate of success and alteration rate for each assault type across all models have been computed and are presented in Fig. 11. Next, we proceed to assign rankings to different assault techniques, as presented in Table 12.

The results depicted in Fig. 11 clearly demonstrate that the Non-Alpha-Num attack algorithm, which operates at the character level, exhibits the highest level of effectiveness in terms of perturbation. Following closely behind is TextBugger, another character-level perturbation attack. On the other hand, Hot-Flip emerges as the most effective word-level perturbation technique. Conversely, the attack method A2T, which employs gradient-based synonym word swap within the white-box adversarial setting, is found to be the least effective across all models, as indicated by a comprehensive evaluation of assault tactics.

The most effective attacks shown in Table 11 are char-level perturbation assaults, specifically the Non-Alpha-Num suggested attack technique and TextBugger, which is a prominent conventional attack tactic. While the majority of attacks operate at the granularity of word-level perturbations, it is worth noting that the top two assaults specifically target character-level perturbations.

6 Further investigation and analysis

A further investigation is undertaken to assess the efficacy of the Non-Alpha-Num assault methodology across several circumstances, encompassing its entire execution duration in generating an adversarial instance. The evaluation also includes an assessment of the transferability property of adversarial instances created by the proposed technique. To assess the property of transferability of our suggested approach across different classifiers, we utilize the attack success rate (ASR). ASR is calculated as the ratio of successful



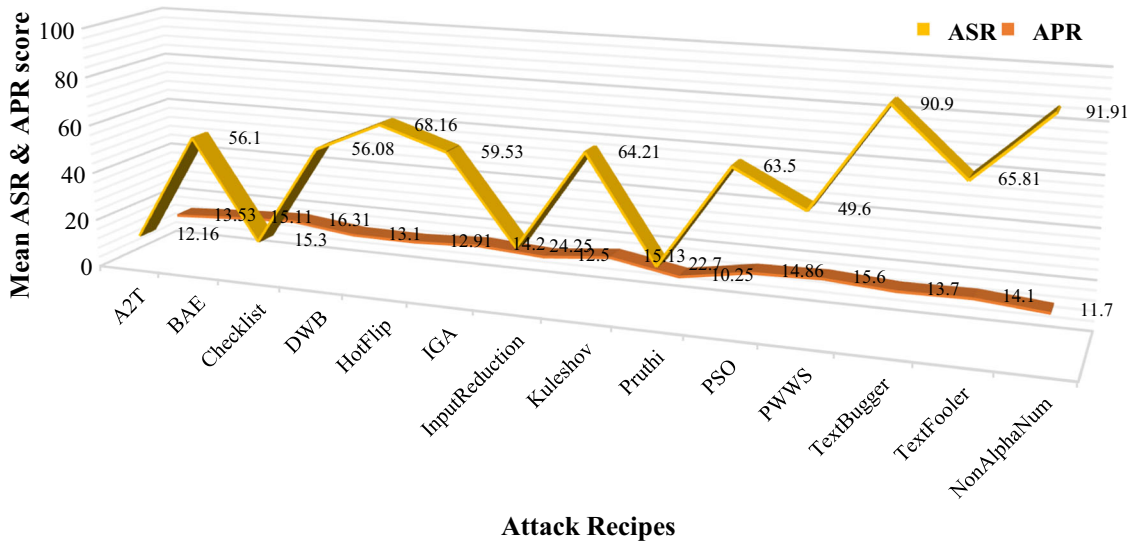


Fig. 10 Average ASR and APR scores of all classifiers

Fig. 11 Mean ASR & APR score of each attack type on all models

attack samples to the total of successful and failed samples, i.e., successful samples divided by the sum of successful and failed samples. The successful samples refer to those that can misclassify the true prediction, whereas failed samples are unable to incorrectly categorize the genuine outcome. The metric is explained in detail in Sect. 4.4. Moreover, the utility evaluation of the adversarial words generated by Non-Alpha-Num demonstrates a certain level of resemblance to the genuine text.

6.1 Execution time

A study was conducted to evaluate the computing time implications of the proposed framework. The fundamental aim of an attacker is to manipulate a model by implementing the intended attack. Figure 12 displays the probable outcomes of the average runtime required to produce a solitary adversarial example utilizing the Non-Alpha-Num assault architecture for each specific model. Analysing the research findings, it is evident from the Figure that BERT requires the longest duration in developing an adversarial example. Conversely, lighter models like ALBERT and DistilBERT exhibit less time. Furthermore, the non-transformer-based model, namely Word-CNN, demonstrates the least amount of time needed for producing an adversarial sequence.

6.2 Accountability and applicability

The attack method presented in this study generates hostile texts that exhibit a greater degree of resemblance to the source texts. Based on the findings shown in Fig. 13,

Table 11 The average ASR for each assault recipe on each classifier

Attack methodology	Mean ASR%	Mean APR%	Perturbation level
NonAlphaNum	91.91	11.7	Char-level
Textbugger [24]	90.95	13.7	Char-level
HotFlip [46]	68.16	12.91	Word-level
TextFooler [23]	65.81	14.1	Word-level
Kuleshov et al. [28]	64.21	15.13	Word-level
PSO [26]	63.5	14.86	Word-level
IGA [29]	59.53	14.2	Word-level
BAE [45]	56.10	15.11	Word-level
DWB [30]	56.08	13.1	Char-level
PWWS [25]	49.6	15.6	Word-level
Input Reduction [47]	24.25	12.5	Word-level
Pruthi et al. [27]	22.7	10.25	Char-level
Checklist [31]	15.3	16.31	Char-level
A2T [33]	12.16	13.53	Word-level

it can be inferred that the viability preservation of adversarial instances created by Non-Alpha-Num is comparatively higher in terms of its accountability and applicability. Char-level attacks refer to a range of language blunders, such as misspellings, transpositions, and random character swaps [24]. Both human individuals and spell-checking algorithms possess the ability to easily identify and recognize assaults that occur at the level of individual characters. Considering the proposed solution, the adversary can create changes through the insertion of punctuation marks that cannot be concealed by detection techniques. These transformations exhibit improved levels of imperceptibility and legibility.

6.3 Adversarial transferability

The present study aimed to investigate the property of adversarial transferability in the text by assessing the effectiveness of adversarial instances developed by one classifier in deceiving a various classifier [48, 49]. This research study involved the collection of 100 adversarial examples generated through the utilization of Non-Alpha-Num Adversarial Attack. These examples were specifically chosen as they were incorrectly classified by a designated target model. The ASR scores of these examples were subsequently evaluated against alternative target models. The results displayed in Table 12.

Table 12 demonstrate that the Word-CNN model exhibits a moderate level of transferability. In contrast, the transferability of the transformer models is comparatively lower. According to the investigation, the BERT model has been found to demonstrate superior transferability compared to other transformer models.

6.4 Explainability and interpretability

The LIME approach, as introduced by Ribeiro et al. [50], is utilized to provide localized interpretations regarding our algorithms. The LIME methodology employs a linear framework to estimate the local decision boundary for each example by fitting it to the associated data. The example was perturbed in order to get the acquired information. To evaluate the accuracy of the regional interpretations obtained from LIME, the area over perturbation curve (AOPC) is utilized as a quantitative measure. The mathematical expressions for this metric are provided in Eq. (7).

$$\mathrm{AOPC} = \frac{1}{M+1}\sum_{m=1}^{M}\frac{1}{N}\sum_{1=1}^{N}\left(X_{(0)}^{(j)}\right) - F\left(X_{(m)}^{(j)}\right) \tag{7}$$

Within the framework of this research, the notation $\boldsymbol{X}_{(0)}^{(\boldsymbol{i})}$ refers to a specific occurrence where $\boldsymbol{X}^{(j)}$ is denoted as

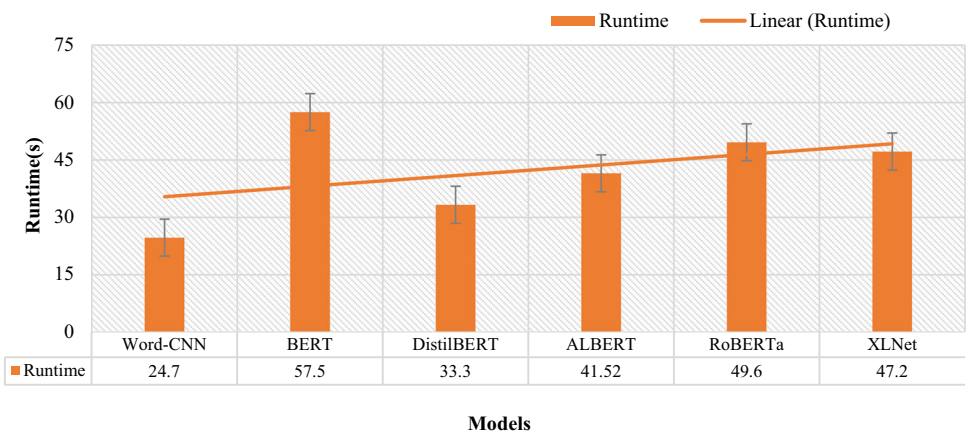

Fig. 12 Mean time to produce an adversarial sample for each model

(0) without any words being removed. On the other hand, $X^{(j)}_{(m)}$ represents an instance where the m most significant words are excluded and denoted as (m). The function $F(X)$ is employed to represent the degree of confidence of the model in relation to the predicted target label $Y^{(j)}$. The function $\mathbf{F}(\mathbf{X})$ is employed to represent the degree of confidence of the model in relation to the predicted target label $\mathbf{Y^{(j)}}$. The AOPC idea refers to the average change in the model's confidence towards the target label when the top-m most significant words, as recognized by LIME, are removed. This concept is drawn from intuitive understanding. For assessment, an arbitrary number of 500 occurrences was picked from the test set. During the explanation generation process utilizing LIME, a set of 500 altered samples is created for each instance, using the proposed attack algorithm to evaluate the explanations. The selection of $m = 10$ was made for the AOPC metric. Based on the data shown in Table 13, it

Table 12 The transferability of adversarial examples on a clickbait dataset

	Word-CNN (%)	BERT (%)	DistilBERT (%)	ALBERT (%)	RoBERTa (%)	XLNet (%)
Word-CNN	–	65.57	63.21	68.82	59.44	58.91
BERT	42.14	–	39.63	34.44	32.16	40.86
DistilBERT	48.76	45.54	–	49.75	48.91	45.09
ALBERT	52.12	49.96	51.16	–	47.72	41.66
RoBERTa	43.37	39.28	50.63	38.56	–	40.63
XLNet	42.90	42.00	48.87	49.27	48.84	–

The ASR of adversaries developed for model "p", when assessed on model "q", is represented by row "p" and column "q"

Fig. 13 Adversarial example generation using punctuation marks (non-alpha numeric characters) to evade clickbait detection mechanisms. The words enclosed in double square brackets **[[]]** have undergone alterations

Table 13 The AOPC ratings were calculated for the LIME explanations of each model. A model that has a higher AOPC score possesses greater interpretability

Models	AOPC scores
Word-CNN	0.68
BERT	0.36
DistilBERT	0.48
ALBERT	0.47
RoBERTa	0.23

is evident that the Word-CNN model achieves the greatest (AOPC) score. The analysis reveals that the AOPC scores of RoBERTa models are notably lower than those of other models, suggesting that RoBERTa may exhibit a comparatively decreased degree of explainability in comparison to all models.

7 Discussion and future work

Natural Language Processing systems that depend on textual data are susceptible to many nuanced perturbations that can alter the outcome of the neural network and extend the duration required for inference, all while keeping the visual representation of the input unaltered. The aforementioned assaults involve the utilization of random character swaps, as well as the addition, elimination, & replacement of crucial words with synonymous alternatives. This article introduces an innovative approach, employing punctuation, to deceive neural clickbait detectors. It appears that the creators of the several natural language processing algorithms currently deployed on a significant magnitude have completely overlooked these difficulties. The present work investigates the occurrence of adversarial assaults on text-based neural clickbait detectors by employing punctuation marks. The empirical results demonstrate that the Non-Alpha-Num assault outperforms traditional approaches in terms of both attack success rates as well as mean perturbations.

7.1 Future work

- *Extension to wider NLP applications* In future endeavors, we intend to broaden the reach of Non-Alpha-Num attack to encompass a diverse range of natural language processing (NLP) applications [51]. These include sentiment analysis, toxic content identification, rumor detection, as well as smishing, and phishing detection, in addition to its current focus on clickbait detection.
- *Adversarial training (defensive algorithm)* Incorporating an adversarial training methodology [52], we want to develop a framework that demonstrates resilience to adversarial disturbances specifically in the context of Non-Alpha-Num attacks. The present study provides a more comprehensive exploration of adversarial instances in the context of text categorization. Our future research endeavors to bolster these frameworks and improve the precision of classification algorithms by incorporating adversarial training methods [33]. To enhance the robustness of applications against malicious adjustments, it is recommended that all organizations engaged in the development and dissemination of natural language processing technologies integrate these precautions.
- *Extension to targeted attack* This study only concentrates on the execution of untargeted assaults, that encompass the alteration of the model's results. Nevertheless, it is important to acknowledge that Non-Alpa-Num demonstrates the capability for easy adaptation in the setting of specific assaults, whereby the framework may be coerced into generating a pre-determined classification [21]. The intentional alteration of a model with the aim of producing a specific result, sometimes known as a targeted attack, entails adjusting the objective functionality component inside the suggested approach.

7.2 Limitation of the work

The results of this investigation suggest the existence of adversarial manipulations inside the textual domain. Nevertheless, the efficacy of the modifications might be amplified by employing a more sophisticated technique, such as particle swarm optimization [26], for the purpose of identifying and altering pivotal terms. This methodology possesses the capacity to enhance the results of the suggested assault.

8 Conclusion

The primary objective of the research is to examine the susceptibility of clickbait detection algorithms to adversarial assaults. The findings unequivocally demonstrate that the identification of clickbait may be impeded by modifying the lexicon and sentence structure in algorithms used for machine learning yet retaining semantic correspondence for human assessors. The current investigation focuses on a limitation seen in deep learning models employed for the purpose of clickbait detection tasks. This study introduces Non-Alpha-Num, a unique framework that exploits a vulnerability to produce hostile text sequences with the intention of deceiving deep learning networks. Additionally, the research also conducted a comparative examination of several neural clickbait detection systems in order to ascertain the relative vulnerability of each model to adversarial perturbations, as well

as their respective levels of resilience against such perturbations. Empirical data, in a broad sense, has substantiated the viability of perturbing strategies designed for clickbait detection through the implementation of adversarial alterations. Hence, it is crucial to give precedence to the advancement of antagonistic strong generalizations to foster societal growth.

Abstract

We proposed an online identification and adaptive control framework for the nonlinear dynamical systems using a novel hybrid-feed-forward recurrent neural network (HFRNN) model. The HFRNN is a combination of a feed-forward neural network (FFNN) and a local recurrent neural network (LRNN). We aim to leverage the simplicity of FFNN and the effectiveness of RNN to capture changing dynamics accurately and design an indirect adaptive control scheme. To derive the weights update equations, we have applied the gradient-descent-based Back-Propagation (BP) technique, and the stability of the proposed learning strategy is proven using the Lyapunov stability principles. We also compared the proposed method's results with those of the Jordan network-based controller (JNC) and the local recurrent network-based controller (LRNC) in the simulation examples. The results demonstrate that our approach performs satisfactorily, even in the presence of disturbance signals.

1 | INTRODUCTION

Nonlinear control theory has gained popularity in recent times for designing nonlinear control systems. While linear control theory approaches, such as PID controllers, state space control approaches, and gain scheduling, have been used to identify and handle nonlinear dynamic systems since the late 1930s, they have many limitations (Oaks & Cook, 1976; Zhao & Guo, 2021). The linear controller design pre assumes that both the plant and the controller are linearized, which is not always the case in realtime. Second, because the linear control approaches do not follow the superposition principle, their solutions are invalid for nonlinear systems. They are stable on one range of inputs and unstable on another. Third, they exhibit chaotic behaviour at their output, and hard nonlinearities are difficult to linearized. All physical systems are subject to parameter variations, and controllers developed using linear control theory fail to account for this. This resulted in the development of nonlinear control theory methods including sliding mode control (Alanis, 2022), robust control (Qin et al., 2022), adaptive control (Swarnkar et al., 2014), and fuzzy-based control (Wang et al., 2017). Adaptive controllers, among these, have received a lot of interest from researchers. Unlike other control approaches, adaptive control generates control inputs by taking the system's slowly varying dynamics into account and driving it to follow the desired control law (Li et al., 2018; Zheng et al., 2019). As a result, even in the presence of disturbance, the controller performance is faster and better. There are two types of adaptive control approaches: direct adaptive control and indirect adaptive control. In direct adaptive control, the error between the plant and reference output is used to adjust the controller parameters. In indirect adaptive control, the controller parameters are adjusted by estimating the plant parameters. The indirect adaptive control is more prevalent than direct adaptive control. The direct adaptive control approach does not guarantee stability as the controller parameters are adjusted by calculating the error between the plant and the

reference. On the other hand, the indirect adaptive control estimates the plant's behaviour and designs a controller based on that estimated behaviour. This approach is more stable and can effectively handle time-varying systems and disturbance (Narendra & Valavani, 1979). The working of indirect adaptive control involves both identification and controller blocks. The identification block gathers knowledge about the unknown plant, while the control block generates an appropriate control signal to make the plant track the reference model. Artificial neural networks (ANNs) are increasingly used in identification-based adaptive control due to their ability to handle complex nonlinearities and self-adaptation. ANNs are suitable for modelling and control of any nonlinear system as they can approximate any nonlinear function (Akpan & Hassapis, 2011; Polycarpou & Ioannou, 1991). Additionally, they have fast processing capabilities, allowing them for real-time control. A self-recurrent wavelet neural network-based control is proposed by Yoo et al. (2007) for the control of nonlinear dynamical systems. The modified structure is trained using the gradient descent algorithm. Adaptive learning rates are used for faster convergence. The simulation result shows the effectiveness of the suggested structure. In the study by Slama et al. (2019), an indirect adaptive switch controller that switches online between PID and IAC is proposed. The adaptation laws are developed using the gradient descent method and the stability is analyzed using the Lyapunov function. The results show that the proposed controller performs better than an indirect adaptive controller, and adaptive switch controller. In the study by Ciliz (2009), an adaptive control approach combining both the direct and indirect adaptive scheme is proposed. The proposed controller convergence is proved by using the Lyapunov function and the proposed controller is found to improve the tracking accuracy of the controller. Anavatti et al. (2015) have surveyed various state-of-the-art methods in adaptive control system theory. The paper briefly discusses the various pros and cons of various techniques employed in adaptive control strategy. In the study by Cheng et al. (2021), adaptive neural control is proposed for the control of dynamic systems. Input-output linearization technique is used to convert the object's model into a multi-integrator system and for online training, the state observation technique is used. Further, in the study by Chen et al. (2016), a modified adaptive controller for the MIMO system is developed. The controller used is the backstepping control and an adaptive algorithm was developed to find the states and deal with non-symmetrical input. In the study by He et al. (2019), online adaptive control is developed with a policy iteration (PI) algorithm. The optimal control laws are developed using the Ricatti equation. In the study by Bonassi and Scattolini (2022), a gated RNN structure such as GRU and LSTM for control of a stable nonlinear system is proposed. Identification-based control was carried out and the stability was proven by using incremental input and output state stability. The results show that the proposed controller has better convergence over other controllers. Zhou, Tong, et al. (2021) have designed a neural controller with a dynamic surface control scheme to overcome the effect of uncertainties on the system. A control law is proposed and is approximated using a radial basis function neural network (RBF-NN). The stability is also analyzed using the Lyapunov function. In the study by Kumar, Srivastava, Gupta, and Mohindru (2018), a recurrent wavelet neural structure is used to identify and control nonlinear systems. The parameters are updated using the back-propagation algorithm and adaptive learning rates are designed to ensure fast convergence. In the study by Kumar et al. (2017), a diagonal recurrent neural network (DRNN) based adaptive control is proposed for identification-based control of nonlinear systems, and the Lyapunov function is used for training the algorithm. The results show better response than feed-forward networks. In the study by Kumar, Srivastava, and Gupta (2018), a comparative analysis of various FFNN and RNN-based controllers for adaptive control of nonlinear dynamic systems is carried out. Dynamic back propagation is used for updating the weights of the controller and the convergence of the structure is also analyzed. Simulation results prove that the RBFN-based controller performs better than NARX and FFNN-based controllers even in the presence of uncertainties. Perrusquía and Yu (2021) have designed an optimal controller using RNN, and learning of the structure is done using reinforcement training. The controller is designed for both continuous and discrete-time systems. The performance is analyzed for robustness. Though the results look promising, the optimal controllers require the entire knowledge of the system to be known to compute the Jacobian matrix. In the study by Truong et al. (2023), an adaptive back-stepping-based controller for a higher-order nonlinear system is proposed. An RBFNN-based time-delayed estimator (TDE) architecture is designed and controlled using a back-stepping controller. The controller model is designed off-line and tested for efficiency by comparing the model with PID based controller and the original back-stepping controller model-free approach. Kapnopoulos et al. (2024) have designed an RBF neural network-based back-stepping controller for solving the tracking problem for quad-rotor systems. Though RBFN is a memory-less structure in combination with the fuzzy controller, it is found to increase the accuracy by taking into account the unmodelled dynamics. The performance is compared with an MLP-based back-stepping controller. It is found to provide better tracking performance. In another work (Bukhari et al., 2023), the authors have analyzed the dynamic behaviour of fractional order chaotic systems with RBFN. The parameters of the system are computed with a Runge-Kutta solver and designed with RBFN for various initial conditions of the Lorentz system. Average mutual information (AMI) techniques are used to evaluate the time delay pattern and the performance of the proposed RBFN is found to be exceptionally high. In the study by Hesamian et al. (2023), an RBFN model is developed based on fuzzy responses and predictions. A squared error-based method is used to estimate the fuzzy parameters and tuning constants. The performance of the proposed Fuzzy RBFN is found to be effective in comparison to conventional fuzzy controllers. A fuzzy RBFN-based sliding mode control is used for the control of nonlinear systems of varying degrees in this work (Tavoosi, 2020). The proposed method does not require prior information about the system as the controller is simulated online. The method was found to improve the final threshold stability and yielded better performance than RBFN-based SMC. Further, the based adaptive controllers have found numerous applications in real-time. In the study by Zhou and Tan (2023), the characteristics and progress of NN-based adaptive control are tested on Nuclear power plants (NPP).The performance is compared with NNPID, self-tuning PID, and tested for efficiency with respect to disturbance. A car driving-based simulator model based on adaptive and robust control with online learning is designed by Manh et al. (2023). This RBFNN structure-based adaptive control does not require

system information. In another work (Patan & Patan, 2020), an iterative learning control of a Nonlinear system based on ANN is designed. The controller update rule is updated by iterative training and the updated rules were incorporated in the next trial process to achieve a zero error at convergence even in terms of uncertainties. The update rules are further tested in servomechanism and magnetic levitation applications. Di Ferdinando et al., 2020 have studied the Lyapunov-kravoskii theorem for global asymptotic and local exponential stability (GALES) for a nonlinear delay-free system. Point-wise dissipation rates are used. The proposed theorem is found to replace the use of the Lipschitz property of the function describing the system, thus maintaining local and global asymptotic stability. Xu et al. (2023) have studied a Lyapunov-Kravovskii function for semi-globally practical fixed-time stable systems. L'Hopital's rule is used to determine the boundness of the lyapunov-kravoskii function and the signals are bounded within the integral function range. This makes the tracking error converge into a small region around zero. Further, it is extended to adaptive control of higher-order stochastic time-delay nonlinear systems. Lale et al. (2022) have studied and proposed a Kravoskii-based stability theorem for a model-based Reinforcement training framework. The changing dynamics of the system are captured using feature extraction methods. A prime dual approach based Kravoskii theorem is used to derive the Lyapunov function. The proposed approach is found to have applications in online control of safety-critical systems such as robotic manipulators and locomotive tasks. Further in the study by Dashkovskiy and Pavlichkov (2020), a novel I_{∞} input to state stability for infinite networks is proposed. Feedback for each agent is established and an ISS-based Lyapunov function is developed for infinite networks. The Lyapunov function is further extended for the constructive design of decentralized controllers to stabilize infinitely larger networks. Zhou, Hu, et al. (2021) have discussed the various techniques that could effectively optimize the gain in the Lyapunov function. The Hamilton energy as a suitable Lyapunov function is proved against Lorentz and Chua oscillation in a chaotic state. The paper claims that the control of energy flow when done completely can control chaos in a Nonlinear system and improve stability. After reviewing the literature, we discovered significant shortcomings in the existing approaches to controlling nonlinear dynamic systems. Firstly, the feed-forward models such as MLP and RBFN are not much suited for real-time implementation as they lack dynamic memory structures. The adaptive training requires samples derived at every instant to properly control the plant. These structures cannot capture the changing dynamics of the system and must be supplied with system order in advance. Secondly, since the control applications are generally implemented in real-time, a simple control algorithm is necessary to derive the control inputs and hence the algorithm needs to be kept simple and efficient. Many of the algorithms used in the literature involve a large number of parameters, which leads to poor convergence. Lastly, while many models and approaches have been cited in the literature for the identification-based control of nonlinear dynamic systems, a benchmark approach for the control of dynamic systems is not yet available. To the best of our knowledge, there is no hybrid fusion of FFNN and RNN available in the literature. These shortcomings have motivated us to try to enhance the control approach for effective identification-based control of nonlinear dynamic systems.

The rest of the paper is organized as follows: The introduction section briefly describes the need for more controller structures and the motivation behind the work. Section 3 elaborates on the problem statement and Section 4 discusses the various architectures of the neural structure used in this work to design the controller. Section 4 discusses briefly the proposed control scheme, learning algorithm, and its convergence in the sense of Lyapunov stability. Section 5 discusses the simulation result obtained. The proposed HFRNN-based controller is tested on two benchmark nonlinear plant equations and their performance and efficiency are discussed. In section 6, the conclusion and future scope of the work are discussed.

2 | PROBLEM STATEMENT

Let's consider a plant $y_p(k)$ represented by the following difference equation as follows:

$$y_p(k+1) = f\left[y_p(k), y_p(k-1), .., y_p(k-n), u_c(k), u_c(k-1), .., u_c(k-m)\right] \tag{1}$$

where $y_p(k+1)$ denotes the one-step ahead output of plant model, n refers to the order of the plant and and m refers to the order of the controller input $u_c(k)$, f refers to the unknown differentiable nonlinear function. Let's consider a reference model with the following difference equation:

$$y_m(k+1) = \ g\left[y_m(k), y_m(k-1), .., y_m(k-n), r(k), r(k-1), .., r(k-m)\right] \tag{2}$$

where $y_m(k+1)$ refers to the one-step ahead output of the reference model, n denotes the order of the reference model and m denotes the order of external input $r(k)$, g denotes the unknown nonlinear function that is assumed differentiable. The main objective of our work is as follows: 1. To identify the unknown plant model by minimizing the error between the plant and the identified neural model. This is done by updating the identifier weight equations based on the error between the plant and the identified neural model such that

$$\lim_{k\to\infty} |\, y_p(k+1) - y_{hni}(k+1) \,| \leq \epsilon \tag{3}$$

14680394, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/exsy.13619 by Delhi Technological University, Wiley Online Library on [21/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

where $\epsilon \to 0$. 2. To make the plant follow the reference model by determining the control input $u_c(k)$. This is achieved by continuously training the ANN-based controller update equations to generate a control input $u_c(k)$ such that

$$\lim_{k\to\infty} |\, y_m(k+1) - y_p(k+1) \,| \le \epsilon \tag{4}$$

where $\epsilon \to 0$. The error between the plant and the reference model updates the controller equations.

3 | THEORETICAL FOUNDATION OF HFRNN

A brief introduction and applications of the Jordan neural network and Local recurrent neural network are discussed by many authors in the literature. For more details on the Jordan neural network, readers can refer to these references Jordan (1986), Wysocki and Lawryńczuk (2015), Huang et al. (2007) Şen et al. (2020) and for the local recurrent neural network readers can refer to these references Kumar et al. (2017), Campolucci et al. (1999), and Coban (2013). In this section, we have outlined briefly the structures of HFRNN.

3.1 | HFRNN structure

Throughout the paper, the neural architecture is referred to as HFRNN. The structure of HFRNN is depicted in Figure 1. It is the combination of both the FFNN and LRNN models. The structure is explained in brief below:

1. **Input layer:** The input layer comprises the input samples supplied to the network. Here, the present and past external input is denoted as $r(k)$ and $r(k-1)$ respectively, and the present and the delayed output of the plant are denoted as $y_p(k)$ and $y_p(k-1)$ respectively. They are considered as inputs. The input vector is denoted using the vector $x = [r(k), r(k-1), y_p(k), y_p(k-1)]$. These inputs are further passed to the feed-forward network (indicated by green lines in the figure) and recurrent network paths (indicated by orange lines in the figure) of the hidden

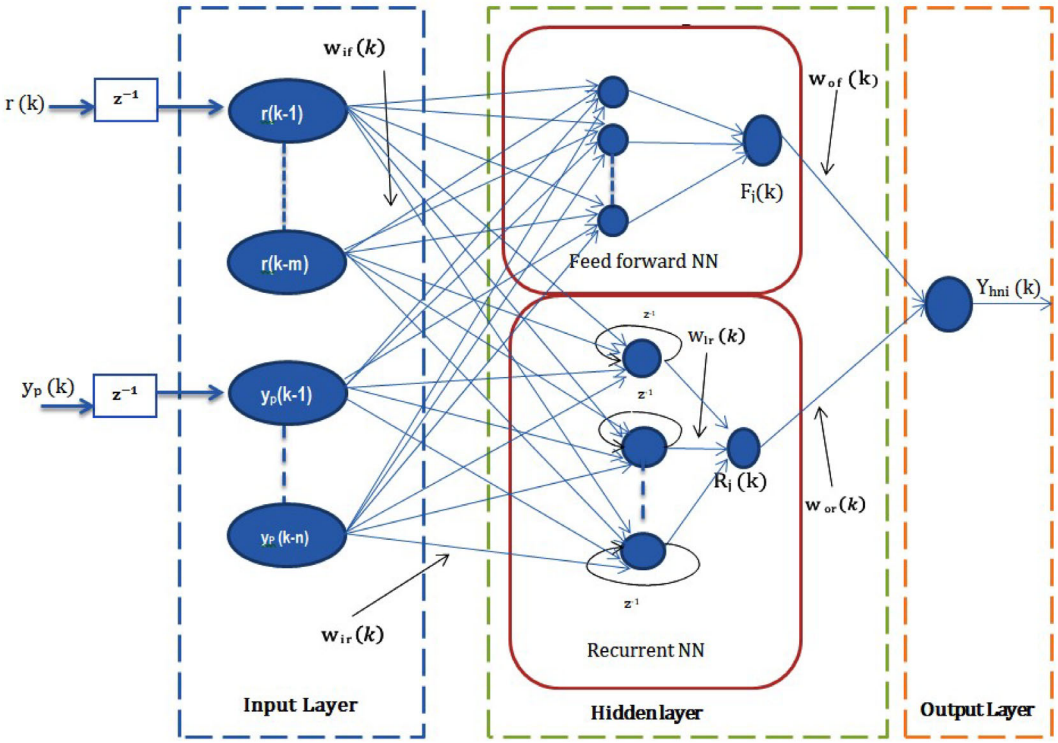

FIGURE 1 HFRNN structure.

14680394, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/exsy.13619 by Delhi Technological University, Wiley Online Library on [21/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

layer. The weight connections between the feedforward network and the input layers are denoted as $w_{if}(k)$ and that of the recurrent network and the input layer is denoted as $w_{ir}(k)$ in Figure 1.

2. **Hidden layer:** The weighted samples from the input layer enter the hidden layer and the output of the hidden layer is computed in two paths. The first path generates the induced field output of the feed-forward network and is denoted as F_j and the second path generates the induced field output of the recurrent network and is denoted as R_j. The induced field output of the feed-forward network is obtained by passing the weighted samples through a nonlinear activation function. The induced field output of the recurrent network is obtained by multiplying the weighted samples received from the input layer with the local self-hidden recurrent layer input samples. The recurrent structure being an LRNN, the past outputs of the hidden layers are fed as input to the hidden layer. Both the induced output of the hidden layers are sent to the output layer.
3. **Output layer:** The output layer computes the final hybrid network output with static and recurrent network characteristics.

The output of the induced field at any kth instant is computed below:

$$F_j(k) = f_1\left(\sum_{j=1}^{n} x(k-j)w_{if_j}(k) + b_{fx_j}w_{b_j}(k)\right), \tag{5}$$

$$R_j(k) = g_1\left(\sum_{j=1}^{m} x(k-j)w_{if_j}(k) + L(k)w_{lr}(k) + b_{fx_j}w_{b_j}(k)\right), \tag{6}$$

where f_1 and g_1 indicate the non-linear tangent hyperbolic activation function at the hidden node and b_{fx_j} denotes the associated weight of the input bias vector. The HFRNN output at any k^{th} instant is given by:

$$Y_{hni}(k) = f\left(\sum_{i=1}^{m} F_j(k)w_{of}(k) + b_{oh}w_{bh}(k) + R_j(k)w_{or}(k)\right), \tag{7}$$

where $w_{of}(k)$ and $w_{or}(k)$ denote the weights of the feed-forward and recurrent path respectively proceeding to the output layer. $w_{bh}(k)$ is the weight of the bias at the output node and b_{oh} denotes the associated weight of output bias vector. f denotes the linear activation function of the output layer.

4 | HFRNN BASED INDIRECT ADAPTIVE CONTROL SCHEME FOR NONLINEAR DYNAMICAL SYSTEMS

We will discuss the proposed HFRNN-based indirect adaptive controller scheme in this section. Figure 2 shows the block diagram of the proposed scheme. The main objective of our work is to predict the unknown controller parameters and obtain a control input to make the plant follow the reference model. The controller scheme consists of two major blocks: the identifier and the controller. We use the HFRNN-based identifier to identify the unknown plant and the HFRNN-based controller to produce the control input $u_c(k)$. We train both of these block's parameters using the backpropagation algorithm. The HFRNN-based controller takes the reference input $r(k)$, previous control input $u_c(k-1)$, and the past output of the plant $y_p(k-1)$ as inputs. The weights are updated by detecting the error between the plant and the reference model output and are applied to the HFRNN-based controller until the error is minimized. Although the plant remains generally unknown, the information about the plant is crucial for properly tuning the controller. In this case, we use an HFRNN-based identifier, to estimate the plant sensitivity for the controller. The HFRNN-based identifier takes the present control input $u_c(k)$ and previous plant output $y_p(k-1)$ as inputs. The identifier is trained using the error generated between the output of the plant and the neural identifier. The training is done online and the plant generates efficient weights and better control through simultaneous identification and control.

5 | LEARNING ALGORITHM FOR HFRNN-BASED CONTROLLER STRUCTURE

The gradient descent algorithm is used for updating the controller and identifier weight equations. $E_c(k)$ is the instantaneous error calculated between the model output and the plant output. $E_c(k)$ is given by:

14680394, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/exsy.13619 by Delhi Technological University, Wiley Online Library on [21/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

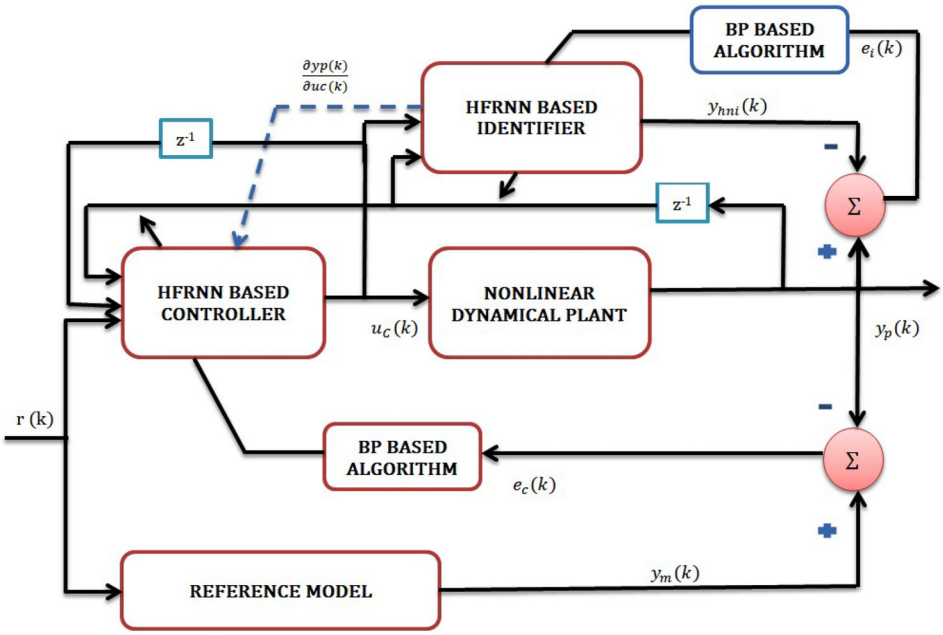

FIGURE 2 Block diagram of the proposed control scheme.

$$E_c(k) = \frac{1}{2}[e_c(k)]^2, \tag{8}$$

where, $e_c(k) = y_m(k) - y_p(k)$. Here, $y_m(k)$ and $y_p(k)$ denote the reference model output and the plant response respectively at kth instant of time. The gradient chain rule is applied by calculating the change of $E_c(k)$ with respect to every element present in the link. Starting with the calculation for updating the output recurrent weights $w_{orc}(k)$, it is obtained by differentiating $E_c(k)$ with respect to $w_{orc}(k)$ as below:

$$\frac{\partial E_c(k)}{\partial w_{orc}(k)} = \frac{\partial E_c(k)}{\partial y_p(k)} \times \frac{\partial y_p(k)}{\partial u_c(k)} \times \frac{\partial u_c(k)}{\partial w_{orc}(k)}. \tag{9}$$

The right hand side of the above equation can be written as:

$$\frac{\partial E_c(k)}{\partial w_{orc}(k)} = -e(k) \times R_j(k) \times J(k). \tag{10}$$

The weight update equation of $w_{orc}(k)$ is given by:

$$w_{orc}(k+1) = w_{orc}(k) + \eta\left(-\frac{\partial E_c(k)}{\partial w_{orc}(k)}\right). \tag{11}$$

The gradient chain rule is again applied for the calculation of output feed-forward weights $w_{ofc}(k)$. The change of $E_c(k)$ with respect to $w_{ofc}(k)$ is calculated as follows:

$$\frac{\partial E_c(k)}{\partial w_{ofc}(k)} = \frac{\partial E_c(k)}{\partial y_p(k)} \times \frac{\partial y_p(k)}{\partial u_c(k)} \times \frac{\partial u_c(k)}{\partial w_{ofc}(k)}, \tag{12}$$

where $\frac{\partial E_c(k)}{\partial y_p(k)} = -e(k)$, $\frac{\partial y_p(k)}{\partial u_c(k)} = F_j(k)$ and $\frac{\partial u_c(k)}{\partial w_{ofc}(k)} = J(k)$ so above equation can be written as follows:

$$\frac{\partial E_c(k)}{\partial w_{ofc}(k)} = -e(k) \times F_j(k) \times J(k). \tag{13}$$

The weight update equation of $w_{ofc}(k)$ is given by:

14680394, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/exsy.13619 by Delhi Technological University, Wiley Online Library on [21/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

$$w_{ofc}(k+1) = w_{ofc}(k) + \eta\left(-\frac{\partial E_c(k)}{\partial w_{ofc}(k)}\right). \tag{14}$$

Every calculation of the controller requires knowledge of the changing dynamics of the plant, and $J(k)$ computes the sensitivity of the controller. If the plant is completely unknown, it becomes very necessary to design an online identifier in parallel to the controller to automatically adapt to the changing dynamics. The proposed structure is trained online, hence requiring the weights and errors of the identifier to be updated simultaneously with the controller parameters. $E_i(k)$ is the instantaneous error calculated between the plant, $y_p(k)$ and the neural identifier, $y_{hni}(k)$. This is calculated by:

$$E_i(k) = \frac{1}{2}[e_i(k)]^2, \tag{15}$$

where, $e_i(k) = y_p(k) - y_{hni}(k)$. As the structure is trained online, the output of the controller $u_c(k)$ becomes one of the inputs of the identifier. This results in calculation of $\frac{\partial y_p(k)}{\partial u_c(k)}$. This indicates the Jacobian matrix, J(k). The sensitivity of the plant is determined through the HFRNN-based identifier block, as the plant is completely unknown to the HFRNN-based controller. This computation updates both the input recurrent $w_{irc}(k)$ and feed-forward identifier weights $w_{ifc}(k)$ with respect to $E_c(k)$. This starts with updating the hidden layer local weights of the controller $w_{hc}(k)$ with respect to $E_c(k)$.

$$\frac{\partial E_c(k)}{\partial w_{hc}(k)} = \frac{\partial E_c(k)}{\partial y_p(k)} \times \frac{\partial y_p(k)}{\partial y_{rc}(k)} \times \frac{\partial y_{rc}(k)}{\partial u_c(k)} \times \frac{\partial u_c(k)}{\partial w_{hc}(k)}. \tag{16}$$

The above equation can be written as follows:

$$\frac{\partial E_c(k)}{\partial w_{hc}(k)} = -e(k) \times \left(I - R_j^2(k)\right) \times w_{orc}(k) \times T(k), \tag{17}$$

where $T(k)$ denotes the memory of the past hidden context layer. Further, the input feed-forward layer weights of the controller $w_{ifc}(k)$ and input recurrent weights of the controller $w_{irc}(k)$ are updated as follows:

$$\frac{\partial E_c(k)}{\partial w_{ifc}(k)} = \frac{\partial E_c(k)}{\partial y_p(k)} \times \frac{\partial y_p(k)}{\partial y_{fc}(k)} \times \frac{\partial y_{fc}(k)}{\partial u_c(k)} \times \frac{\partial u_c(k)}{\partial w_{ifc}(k)}. \tag{18}$$

On substituting the values for the terms appearing on the right hand side of the above equation:

$$\frac{\partial E_c(k)}{\partial w_{ifc}(k)} = -e(k) \times w_{ofc}(k) \times \left(I - F_j^2(k)\right) \times X(k), \tag{19}$$

$$\frac{\partial E_c(k)}{\partial w_{irc}(k)} = \frac{\partial E_c(k)}{\partial y_p(k)} \times \frac{\partial y_p(k)}{\partial y_{rc}(k)} \times \frac{\partial y_{rc}(k)}{\partial u_c(k)} \times \frac{\partial u_c(k)}{\partial w_{irc}(k)}, \tag{20}$$

or

$$\frac{\partial E_c(k)}{\partial w_{irc}(k)} = -e(k) \times w_{orc}(k) \times \left(I - R_j^2(k)\right) \times X(k). \tag{21}$$

The weights $w_{ifc}(k)$ and $w_{irc}(k)$ are updated at every instant of time k using the weight update rule applied as below:

$$w_{ifc}(k+1) = w_{ifc}(k) + \eta\left(-\frac{\partial_c(k)}{\partial w_{ifc}(k)}\right), \tag{22}$$

$$w_{irc}(k+1) = w_{irc}(k) + \eta\left(-\frac{\partial E_c(k)}{\partial w_{irc}(k)}\right). \tag{23}$$

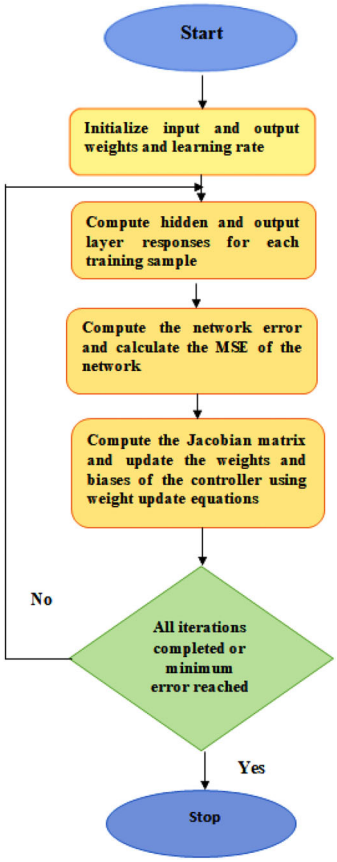

FIGURE 3 Steps followed in training HFRNN-based controller structure.

Here, η denotes the static learning rate and is taken between 0 and 1. As the training progresses, the neural network starts following the plant model, that is, $\frac{\partial y_{hni}(k)}{\partial u_c(k)} \approx \frac{\partial y_p(k)}{\partial u_c(k)}$. Once this is achieved, the identified model can accurately represent the changing dynamics of the plant. With the unknown plant identified, the HFRNN-based controller starts to learn the dynamics and hence the plant model starts to follow the reference model, that is, $\frac{\partial y_p(k)}{\partial u_c(k)} \approx \frac{\partial y_m(k)}{\partial u_c(k)}$. Figure 3 illustrates the various iterative steps followed in learning the controller algorithm.

6 | STABILITY AND CONVERGENCE

Stability is a main characteristic of a system's behaviour. Lyapunov-based stability is a stability concept that states that the system's equilibrium is maintained as long as its states remain close to the initial condition. The Lyapunov stability can be used in two ways to analyze the stability of the system. First, it is used to derive the weight update equation, which ensures that the derived equations are always stable. Second, we can declare the weight adjustment equation and then use Lyapunov stability analysis to check whether the declared equations satisfy the Lyapunov stability conditions. If they do, they will always be stable; otherwise, the stability cannot be guaranteed. In this work, we use the second approach of stability analysis. The weight update equations derived are used to check whether stability has been achieved. For this, let us consider a Lyapunov-based error function such that

$$J = min(E), \tag{24}$$

where E is the Lyapunov-based function. The system is considered to be stable if the Lyapunov-based error remains positive and minimal regardless of the system's condition.

$$\dot{V}(x) > 0 \text{ for } x > 0 \text{ and } \dot{V}(x) = 0 \text{ for } x = 0. \tag{25}$$

The rate of change of error is given by

14680394, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/exsy.13619 by Delhi Technological University, Wiley Online Library on [21/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

$$\dot{V}(k) = \left(\frac{\partial V(k)}{\partial w_{ofc}(k)} + \frac{\partial V(k)}{\partial w_{orc}(k)} + \frac{\partial V(k)}{\partial w_{hc}(k)} + \frac{\partial V(k)}{\partial w_{irc}(k)} + \frac{\partial V(k)}{\partial w_{ifc}(k)}\right) \tag{26}$$

or

$$\dot{V}(k) = \left(\frac{\partial V(k)}{\partial w_{ofc}(k)} \times \frac{dw_{ofc}(k)}{dt} + \frac{\partial V(k)}{\partial w_{orc}(k)} \times \frac{dorc(k)}{dt} + \frac{\partial V(k)}{\partial w_{hc}(k)} \times \frac{dhc(k)}{dt} + \frac{\partial E(k)}{\partial w_{irc}(k)} \times \frac{dw_{irc}(k)}{dt} + \frac{\partial E(k)}{\partial w_{ifc}(k)} \times \frac{dw_{ifc}(k)}{dt}\right). \tag{27}$$

When $\frac{dw_{ofc}(k)}{dt}$, $\frac{dw_{orc}(k)}{dt}$ $\frac{dw_{hc}(k)}{dt}$, $\frac{dw_{ifc}(k)}{dt}$, and $\frac{dw_{irc}(k)}{dt}$, is taken as $(x-y)^2$ and the weight update equations from E_q. (9) to (20), the rate of change of error becomes

$$\dot{V}(k) = \eta \times (x-y)^2 \times \left((R_j(k)J(k)) + F_j(k)J(k) + w_{orc}(k)T(k) + w_{ofc}(k)\left(1 - F_j^2(k)X(k)\right) + w_{orc}(k)\left(1 - R_j^2(k)X(k)\right)\right) \tag{28}$$

or

$$\dot{V}(k) = \eta \times (x-y)^2 \times \left(\frac{\partial V(k)}{\partial w_{orc}(k)} + \frac{\partial V(k)}{\partial w_{ofc}(k)} + \frac{\partial V(k)}{\partial w_{hc}(k)} + \frac{\partial V}{\partial w_{ifc}(k)} + \frac{\partial V}{\partial w_{irc}(k)}\right). \tag{29}$$

Now to make the system ensure stability, the term $(x-y)^2$ will always be positive and $(x-y)^2 \neq 0$. Along with this $\eta > 1$. As long as these conditions are ensured, the weight update equations ensure stability and the controller remains BIBO stable.

7 | SIMULATIONS AND DISCUSSIONS

To efficiency of the proposed HFRNN-based controller is compared with two other neural-based controllers such as the Jordan-based neural network controller (JNC), and the local recurrent-based neural network controller (LRNC) on two different nonlinear plant equations of varying degrees. All of the controllers are designed with a single hidden layer with 20 neurons and a static learning rate of 0.001. The initial weights and biases are taken randomly in the interval (0,1).

7.1 | Example 1: A nonlinear dynamic plant equation with degree 3

In this example, a plant with the following differential equation is considered as in the study by Narendra and Parthasarathy (1992).

$$y_p(k+1) = \frac{5y_p(k)y_p(k-1)}{\left(1 + y_p(k)^2 + y_p(k-1)^2 + y_p(k-2)^2\right)} + u_c(k) + 0.8u_c(k-1) + v(k). \tag{30}$$

The nonlinear plant takes the identification structure as below:
$y_p(k+1) = f\left[y_p(k), y_p(k-1), y_p(k-2), u_c(k), u_c(k-1)\right]$ Consider a reference model with the following differential equation:

$$y_m(k+1) = 0.72y_m(k) + 0.64y_m(k-1) - 0.5y_m(k-2) + r(k), \tag{31}$$

where f is the nonlinear function, $r(k)$ denotes the external reference input, $u_c(k)$ is the control input generated by the controller and $v(k)$ denotes the disturbance signal. The reference signal applied to the system is, $r(k) = sin\left(\frac{2\pi k}{25}\right)$. The disturbance applied to the system initially is $v(k) = 0$. The main objective is to obtain the control input $u_c(k)$ and make the plant follow the reference model. The inputs of the controller are $\left[y_p(k), y_p(k-1), y_p(k-2), r(k), u_c(k-1), u_c(k-2)\right]$ and that of identifier are $\left[u_c(k), y_p(k-1), y_p(k)\right]$. Figure 4 shows the open-loop response of the plant. It can be seen that, without controller action, the plant does not track the reference model. Figure 5 and Figure 6 show the response of the plant during the initial and final stages of training. It is observed initially, that the plant does not follow the reference model. But, as training progresses, the plant starts to follow the reference model and after 15000 epochs, the error minimizes and converges to a minimum value. The instantaneous MSE obtained is also shown in Figure 7.

It is evident from Figure 7 and Table 1 that the proposed controller gives good control performance even with a minimum number of parameters. On the other hand, both JNC and LRNC take time to converge to a minimum MSE.

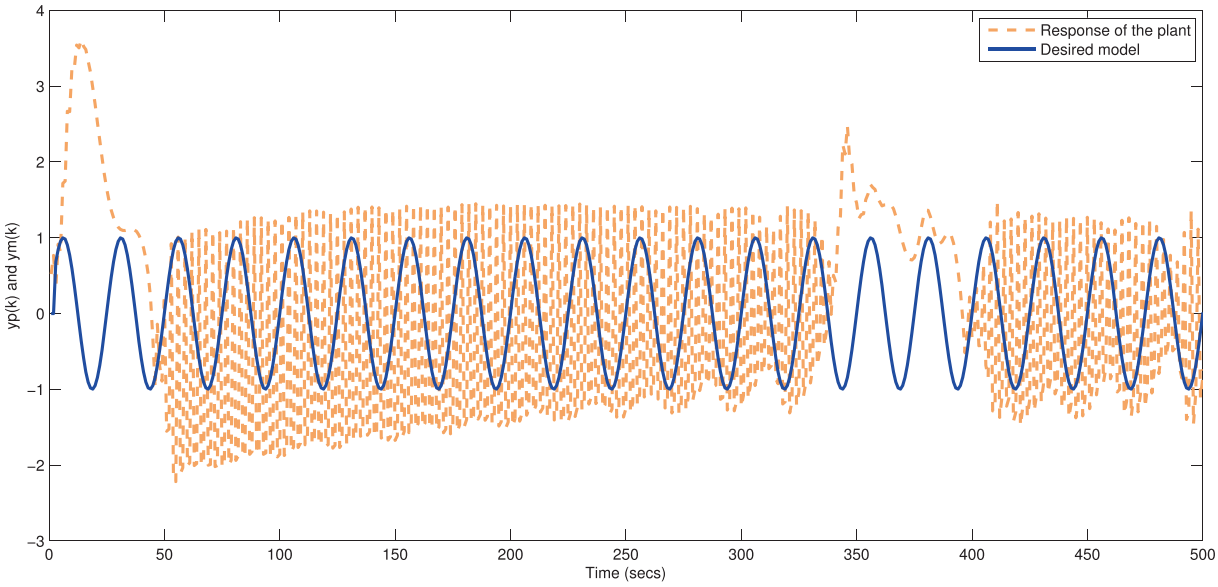

FIGURE 4 Plant's response without controller action (Example 1).

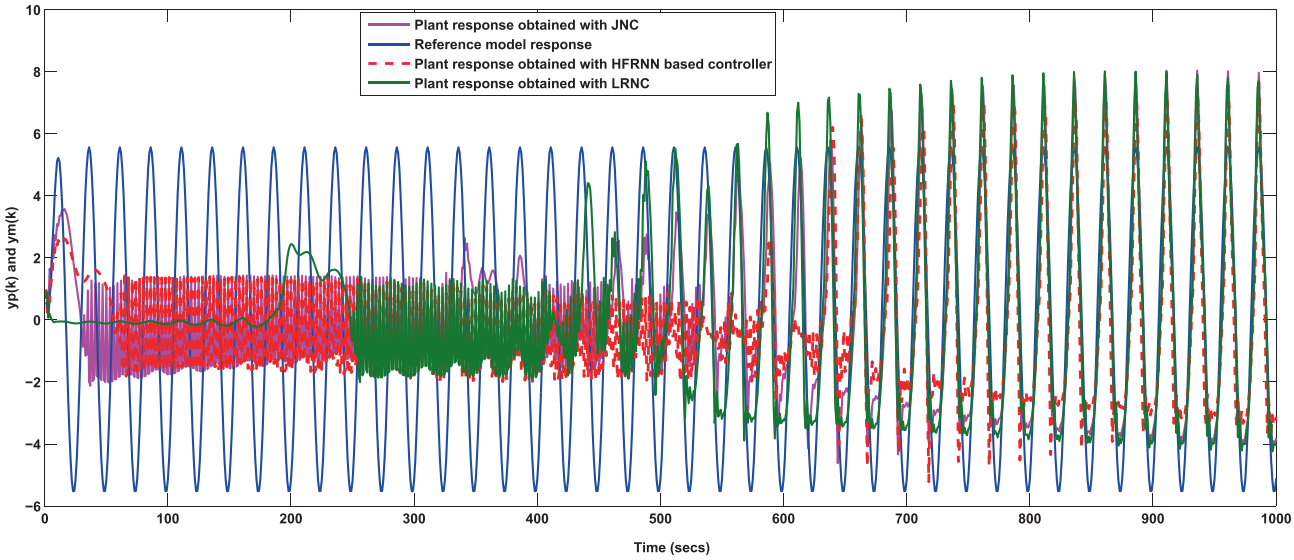

FIGURE 5 Plant response obtained during the initial training phase (Example 1).

7.2 | Disturbance testing

To examine the recovering ability of the proposed controller, a sudden disturbance signal $v(k) = sin(\frac{2\pi k}{40})$ is introduced between the time interval $9000 < k \leq 11000$. A static learning rate of 0.001 is considered, and the effect of external noise on the HFRNN-based controller, JNC, and LRNC was analyzed. Initially, the system deviated from the reference model due to the disturbance signal. But with training, the control parameters were adjusted to the changing environment and the system recovered. However, it took a little longer time. The instantaneous MSE during the disturbance signal of a based controller is found to be very small as compared to JNC and LRNC. The MSE obtained for the based controller was around 0.0653. Refer to Figure 8 for the comparison of the effect of disturbance signal over HFRNN-based controller, JNC, and LRNC.

7.3 | Recovering ability of the HFRNN based controller

The recovering ability of the proposed controller was also tested by changing the reference input. When the reference input was changed from the previous one to the new one, the network was able to capture and adapt to the new reference input. For this, a new reference input $r(k)$ was considered as below between the interval $5000 < k \leq 15000$:

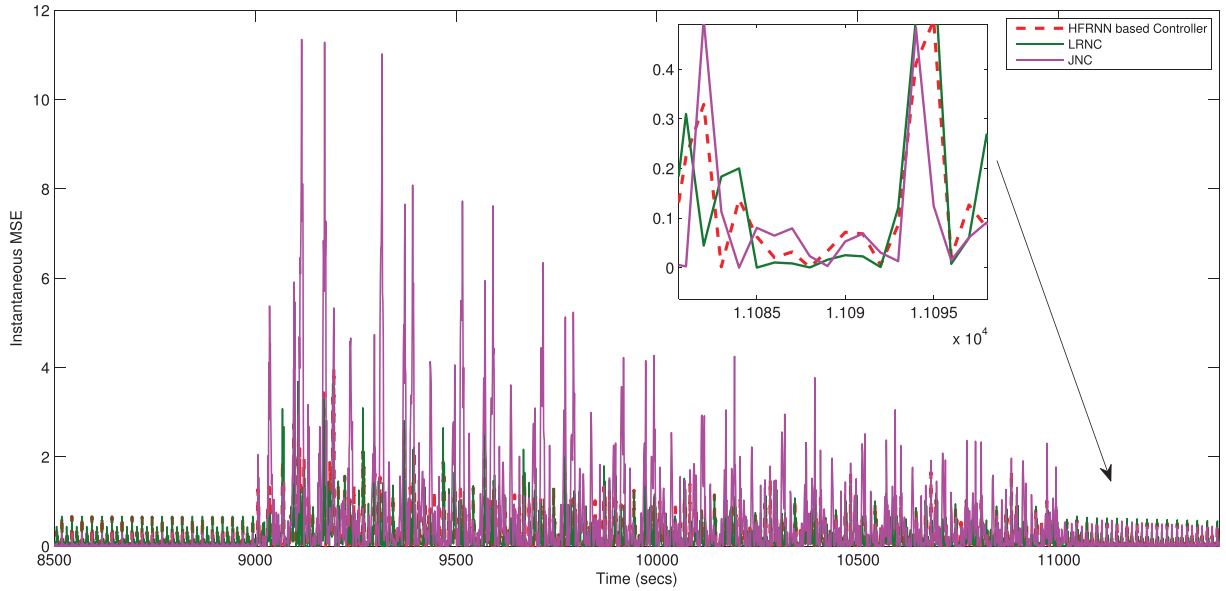

FIGURE 8 Comparison of the effect of external noise on controllers (Example 1).

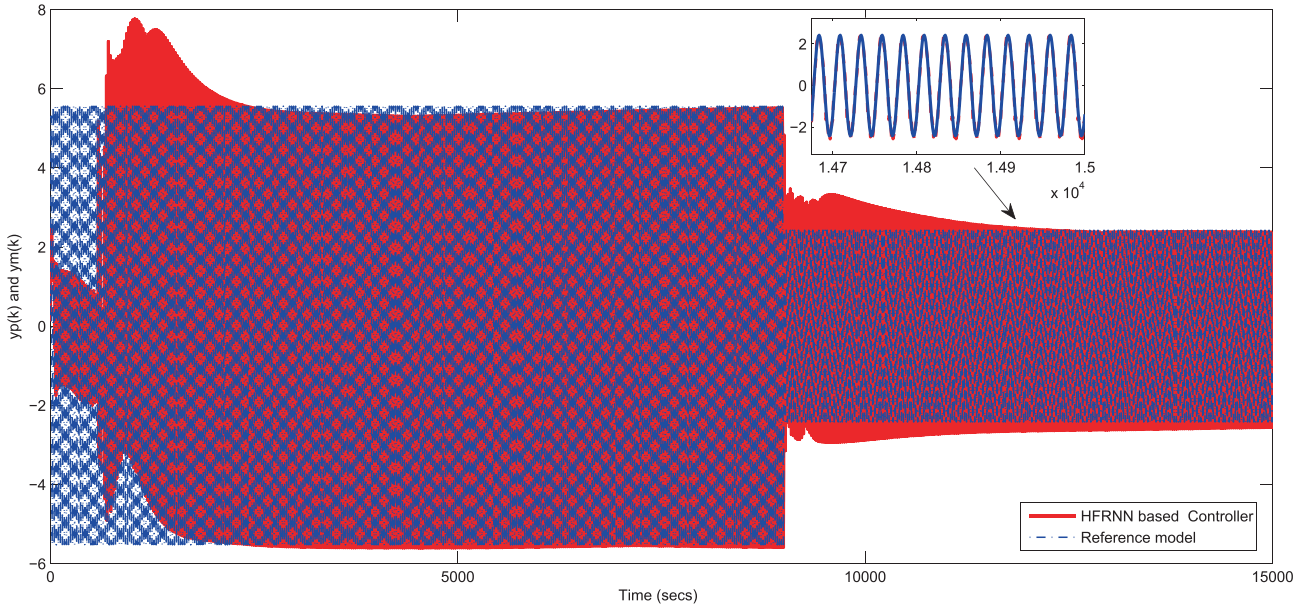

FIGURE 9 Recovering ability of HFRNN-based controller (Example 1).

When the reference input was changed after 5000 training epochs, the controller was found to show good recovering ability. Figure 9 shows the online adaptability of the controller.

7.3.1 | Testing of models with square wave as a reference signal

The controller was also supplied with a square waveform as a reference signal to test the recovery ability. The network was found to capture and adapt to a new reference input. For this, the new reference input $r(k) = square\left(\frac{\pi k}{40}\right)$ was considered. The controller showed good adaptability, with the plant slowly following the desired model. During the end of the training, the plant response resembled the desired model. The instantaneous MSE of the proposed HFRNN controller is found to be 4.7×10^{-7} and that of JNC and LRNC are found to be 4.88×10^{-8} and 6.17×10^{-7}, respectively. Figure 10 shows the responses of the controller during the final stages of training with a square waveform as a reference signal.

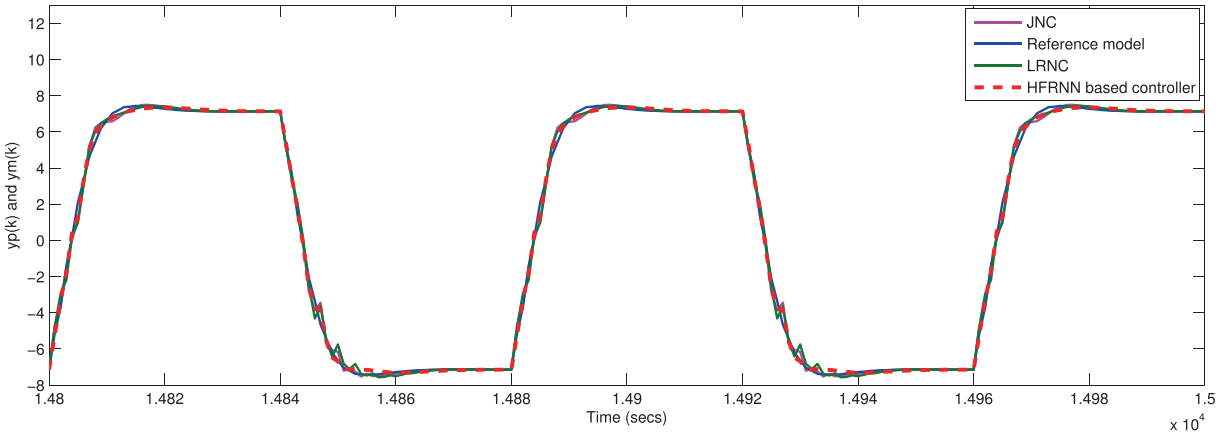

FIGURE 10 Response of controllers with a square waveform as a reference signal (Example 1).

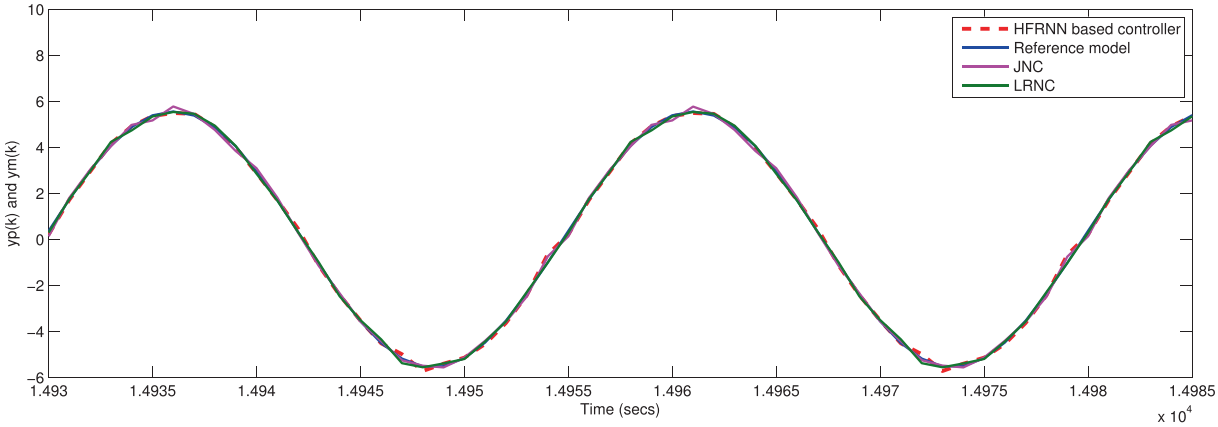

FIGURE 11 Response of controllers for different initial conditions (Example 1).

7.3.2 | Testing of models with different initial conditions

The controller was also tested by assigning a different initial condition of interval (−1, 1) for weights and biases. Initially, the plant failed to track the reference model, but with training and updates to network weights through the BP algorithm, the controller started to learn the dynamics of the plant. Towards the end of training, it is found to resemble the desired response of the plant. Figure 11 shows the response of the controller during the final stages of training. The instantaneous MSE is also shown in Figure 12. The proposed HFRNN controller is seen to provide better MSE compared to other selected JNC and LRNC controllers.

7.4 | Example 2: A nonlinear dynamic plant having degree of 2

To test the efficiency of the proposed controller, another BIBO plant with degree 2 as in the study by Narendra and Parthasarathy (1992) is considered. The plant takes the following differential equation.

$$y_p(k+1) = \frac{y_p(k)}{\left(1+y_p(k-1)^2\right)+u_c(k)^3} + v(k). \tag{33}$$

The nonlinear plant has the identification structure as below: $y_p(k+1) = f\left[y_p(k), y_p(k-1), u_c(k)\right]$ The reference model is given by the following differential equation:

14680394, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/exsy.13619 by Delhi Technological University, Wiley Online Library on [21/05/2024]. FIGURE 12 Instantaneous MSE of controllers for different initial conditions (Example 1).

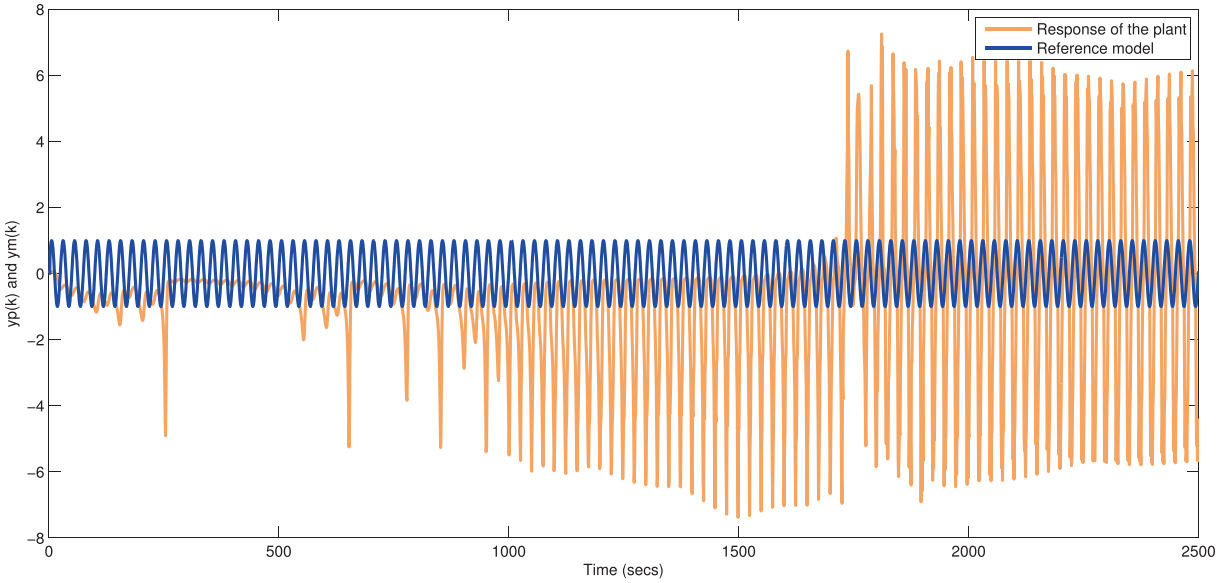

FIGURE 13 Plant's response without controller action (Example 2).

$$y_m(k+1) = 0.72y_m(k) + 0.64y_m(k-1) - 0.5y_m(k-2) + r(k), \tag{34}$$

where f is the nonlinear function, $r(k)$ denotes the external reference input, $u_c(k)$ is the control input generated by the controller and $v(k)$ denotes the disturbance signal. The reference signal applied to the system is, $r(k) = sin\left(\frac{2\pi k}{25}\right)$. The inputs of the controller are $\left[y_p(k), y_p(k-1), y_p(k-2), r(k), u_c(k-1), u_c(k-2)\right]$ and that of identifier are $\left[u_c(k), y_p(k-1), y_p(k)\right]$. The response of the plant without controller action is shown in Figure 13. The plant does not track the desired model response without controller action. With the application of the controller, the plant slowly starts to follow the desired model and after 15000 epochs the plant resembles the desired model response. Figure 14 shows the responses of the controller during the initial training phase and Figure 15 shows the responses of the controller during the final stages of training. The plant is trained online and the instantaneous MSE is also shown in Figure 16. The MSE is found to increase to the maximum during the initial

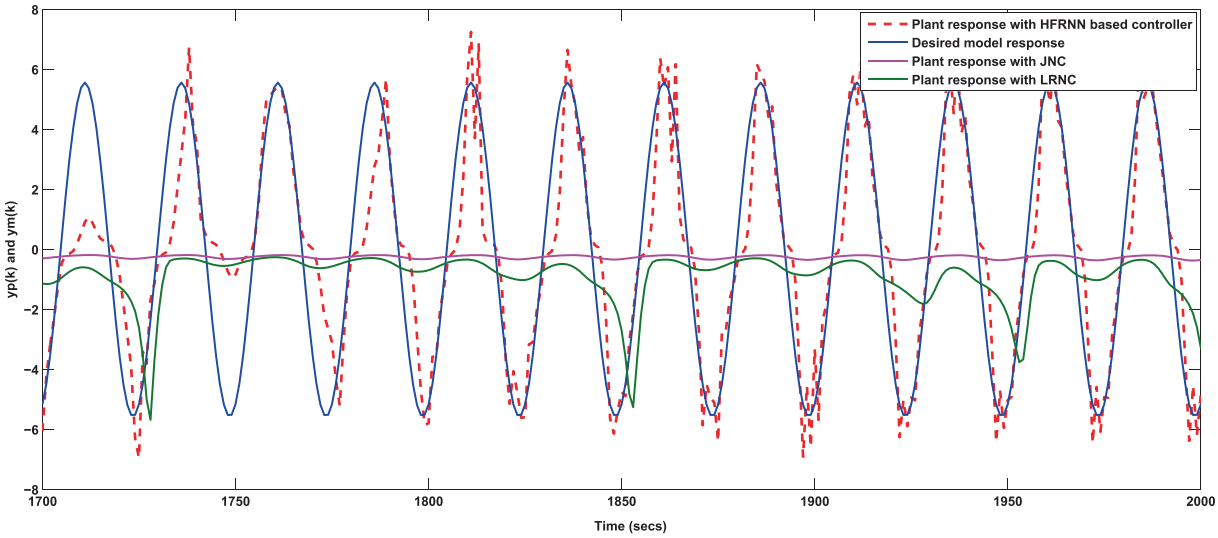

FIGURE 14 Response obtained from the plant during the initial training phase (Example 2).

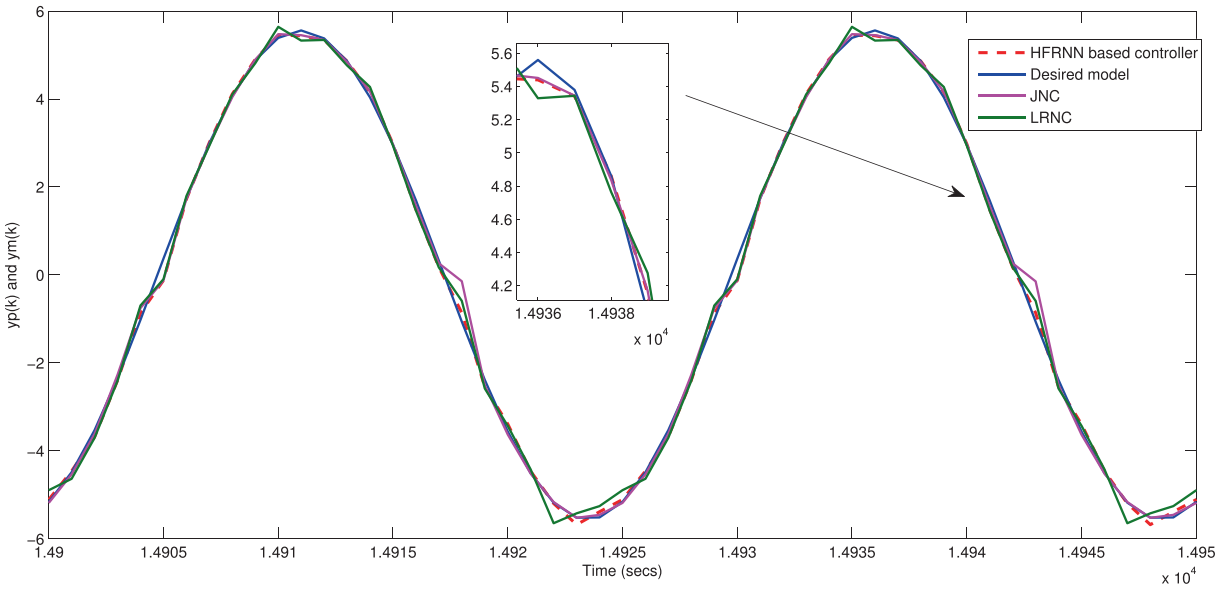

FIGURE 15 Response of controllers during the final phase of training (Example 2).

stages of training and has reached a minimum value after 15000 epochs. Figures 14 and 15 and Table 2 show that the HFRNN based controller performs better than the Jordan and the LRNN based controller scheme.

7.5 | Disturbance testing

To examine the recovering ability of the proposed controller, a sudden disturbance signal, $v(k) = sin\left(\frac{2\pi k}{40}\right)$ was added between the time interval $9000 < k \leq 11000$. A static learning rate of 0.001 was considered and the effect of external noise on HRC, JNC, and LRNC was observed. The MSE of all controllers is found to increase with the addition of external noise. This is due to the model deviating from the reference model. After a few epochs of training, the system is seen to adapt to its new changes with MSE decreasing. The instantaneous MSE of the proposed controller is found to be very small around 0.0080 as compared to JNC and LRNC. Figure 17 shows the effect of disturbance on the proposed controller, JNC, and LRNC.

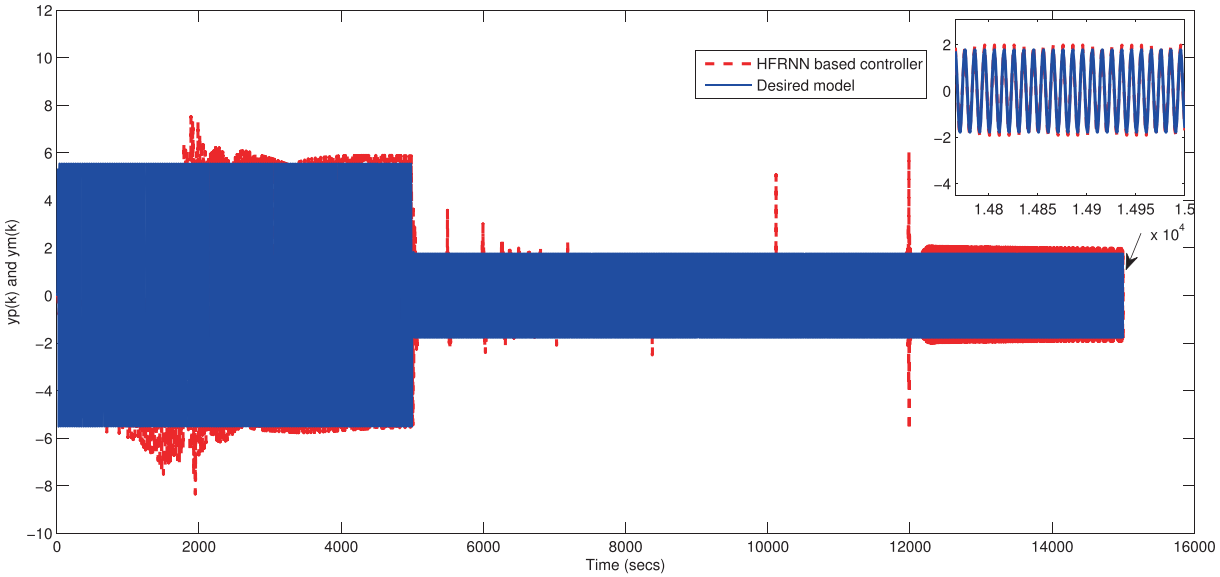

FIGURE 18 Recovering ability of HFRNN based controller (Example 2).

7.6 | Recovering ability of the HFRNN based controller

The recovering ability of the proposed controller was also tested by changing the reference input. When the reference input was changed from the previous one to the new one, the network was able to capture and adapt to the new reference input. For this, the new reference input $r(k)$ is considered as below between the interval $5000 < k \leq 15000$:

$$r(k) = \begin{cases} sin\left(\frac{2\pi k}{25}\right), & \text{for } 0 < k \leq 5000 \\ sin\left(\frac{2\pi k}{10}\right), & \text{for } 5000 < k \leq 15000 \end{cases}. \tag{35}$$

Figure 18 shows the online adaptability of the controller.

7.6.1 | Testing of models with square wave as a reference signal

The controller was also supplied with a square waveform as a reference signal to test the recovery ability. The network was found to capture and adapt to a new reference input. For this, the new reference input $r(k) = square\left(\frac{\pi k}{40}\right)$ was considered. The controller was found to show good adaptability. The plant slowly starts to follow the desired model and after 13000 epochs the plant resembles the desired model response. The instantaneous MSE of the proposed HFRNN controller is found to be 1.660×10^{-7} and that of JNC and LRNC is found to be 9.880×10^{-7} and 6.000×10^{-7}, respectively. Figure 19 shows the responses of the controller during the final stages of training with a square waveform as a reference signal.

7.6.2 | Testing of models with different initial conditions

The controller was also tested by assigning a different initial condition of interval (-1,1) for weights and biases. Initially, the plant does not track the reference model, but with training and an update of network weights through the BP algorithm, the controller starts to learn the dynamics of the plant, and slowly towards the end of training it is found to resemble the desired response of the plant. Figure 20 shows the response of the controller during the initial and final stages of training. The instantaneous MSE is also shown in Figure 21. The proposed HFRNN controller is seen to provide a better MSE as compared to other selected JNC and LRNC controllers.

From the results, it is very evident that the structure could capture the changing dynamics of the plant very efficiently. The proposed approach is order-independent and the structure is also simple as compared to other recurrent structures in the literature. All the selected

8 | CONCLUSION

In this paper, an HFRNN-based indirect adaptive control scheme for the identification-based control of nonlinear dynamic systems. The controller scheme has both identifier and controller blocks. The controller's performance is compared with the Jordan neural controller (JNC) and local recurrent neural controller (LRNC) models. The proposed model gives better MSE than JNC and LRNC for any degree of BIBO system. The proposed model can be used to control unknown plant applications as the sensitivity of the plant is identified online through the HFRNN-based identifier block. The stability and convergence of the updated equations are guaranteed by Lyapunov stability principles. The proposed model is also tested for its recovering ability and its ability to recover from disturbance. The results suggest that the proposed model can be used for real-time nonlinear applications in the future.

8.1 | Limitations and future works

The learning rate is the most important hyperparameter for every neural network. It specifies the extent of correction applied to the learning step. Our future works will focus on replacing the static learning rate with the adaptive one. This paper is also limited to the use of the BP algorithm for network learning due to its simplicity. To improve the overall performance of the learning algorithm, BP can be combined with any other new optimization technique. Our future works will also focus on creating new optimization techniques with the BP method.

ON ESTIMATION OF HANKEL DETERMINANTS FOR CERTAIN CLASS OF STARLIKE FUNCTIONS

S. SIVAPRASAD KUMAR AND NEHA VERMA

Abstract. In the present study, we consider two subclasses starlike and convex functions, denoted by $\mathcal{S}^*_{\mathcal{B}}$ and $\mathcal{C}_{\mathcal{B}}$ respectively, associated with a bean-shaped domain. Further, we estimate certain sharp initial coefficients, as well as second, third and fourth-order Hankel determinants for functions belonging to the class $\mathcal{S}^*_{\mathcal{B}}$. Additionally, we compute sharp second and third-order Hankel determinants for functions belonging to the $\mathcal{C}_{\mathcal{B}}$ class.

1. Introduction

Let $\mathcal{A}$ denote the class of normalized analytic functions defined on the open unit disk $\mathbb{D} := \{z \in \mathbb{C} : |z| < 1\}$, having the form

$$f(z) = z + \sum_{n=2}^{\infty} a_n z^n \tag{1.1}$$

and suppose $\mathcal{S}$ be a subclass of $\mathcal{A}$ comprising univalent functions. Consider $\mathcal{P}$ to be the class of analytic functions defined on $\mathbb{D}$ with a positive real part, expressed as $p(z) = 1 + \sum_{n=1}^{\infty} p_n z^n$. Suppose h and g are two analytic functions, we say h is subordinate to g, symbolically $h \prec g$, if there exists a Schwarz function w with $w(0) = 0$ and $|w(z)| \leq |z|$ such that $h(z) = g(w(z))$. A substantial body of literature exists on coefficient problems, ranging from the seminal Bieberbach's conjecture of 1916 to contemporary research (see [5]). There are two prominent subclasses of $\mathcal{S}$ consisting of starlike and convex functions, respectively denoted by $\mathcal{S}^*$ and $\mathcal{C}$. Further, in 1992, Ma and Minda [14] unfified various subclasses of $\mathcal{S}^*$ and $\mathcal{C}$ by introducing the following two classes:

$$\mathcal{S}^*(\varphi) = \left\{ f \in \mathcal{A} : \frac{zf'(z)}{f(z)} \prec \varphi(z) \right\} \tag{1.2}$$

and

$$\mathcal{C}(\varphi) = \left\{ f \in \mathcal{A} : 1 + \frac{zf''(z)}{f'(z)} \prec \varphi(z) \right\} \tag{1.3}$$

where φ is an analytic univalent function satisfying the conditions $\operatorname{Re}\varphi(z) > 0$, $\varphi(\mathbb{D})$ symmetric about the real axis and starlike with respect to $\varphi(0) = 1$ with $\varphi'(0) > 0$. Recently, many Ma-Minda classes are introduced and studied by several authors by appropriately choosing $\varphi(z)$ in (1.2). See the various Ma-Minda subclasses of starlike functions listed in the first column with the corresponding choice of $\varphi(z)$ in second column of Table 1.

The concept of Hankel determinants, introduced in 1966 (see [16]), continues to be a topic of significant interest for researchers today. The definition of the qth Hankel determinant $H_q(n)$ of

2010 *Mathematics Subject Classification.* 30C45, 30C50.

Key words and phrases. Coefficient problems, Bean-shaped domain, Starlike functions, Hankel determinants.

TABLE 1. List of sharp third order Hankel determinants

Class	$\varphi(z)$	Sharp $\lvert H_3(1)\rvert$	Reference
$\mathcal{S}^*$	$(1+z)/(1-z)$	$4/9$	[3, 7]
$\mathcal{S}^*_\varrho$	$1+ze^z$	$1/9$	[19]
$\mathcal{SL}^*$	$\sqrt{1+z}$	$1/36$	[4]
$\mathcal{S}^*_e$	e^z	$1/9$	[20]
$\mathcal{S}^*_\rho$	$1+\sinh^{-1}(z)$	$1/9$	[10]
$\mathcal{S}^*_\tau$	$1+\arctan z$	$1/9$	[9]

analytic functions $f \in \mathcal{A}$, under the assumption that $a_1 := 1$, is as follows:

$$H_q(n) = \begin{vmatrix} a_n & a_{n+1} & \dots & a_{n+q-1} \\ a_{n+1} & a_{n+2} & \dots & a_{n+q} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n+q-1} & a_{n+q} & \dots & a_{n+2q-2} \end{vmatrix}, \quad n, q \in \mathbb{N}. \tag{1.4}$$

The expressions for the second and third-order Hankel determinants for specific values of q and n, are denoted by $H_2(3)$ and $H_3(1)$, respectively, given by

$$H_2(3) := a_3a_5 - a_4^2, \tag{1.5}$$

and

$$H_3(1) := 2a_2a_3a_4 - a_3^3 - a_4^2 - a_2^2a_5 + a_3a_5. \tag{1.6}$$

Deriving a sharp bound for Hankel determinants is a formidable challenge, prompting numerous researchers to endeavor to do so for various subclasses of starlike functions, see [1, 2, 4, 6, 15] and some are listed in third column of Table 1.

Recently, Kumar and Yadav [11], by choosing $\varphi(z) = \sqrt{1+\tanh z}$, introduced and studied the Ma-Minda subclass of starlike functions $\mathcal{S}^*_{\mathcal{B}}$ associated with a bean-shaped domain, given by

$$\mathcal{S}^*_{\mathcal{B}} = \left\{ f \in \mathcal{A} : \frac{zf'(z)}{f(z)} \prec \sqrt{1+\tanh z} \right\}.$$

Motivated by it, we introduce the following convex counterpart of the above class:

$$\mathcal{C}_{\mathcal{B}} = \left\{ f \in \mathcal{A} : 1 + \frac{zf''(z)}{f'(z)} \prec \sqrt{1+\tanh z} \right\}.$$

The authors have investigated the geometric properties of the univalent function $\sqrt{1+\tanh z}$, along with some inclusion and sharp radius results involving $\mathcal{S}^*_{\mathcal{B}}$, as well as implications of first-order differential subordination. This class can be further studied to know more about the behavior of the coefficients of functions belonging to this class, second and third order differential subordination, etc. Thus, studying such subclasses of starlike and convex functions opens new avenues in the field of research. Taking this aspect in account, in our current investigation, we focus on coefficient-related problems concerning the aforementioned classes $\mathcal{S}^*_{\mathcal{B}}$ and $\mathcal{C}_{\mathcal{B}}$, which are yet not addressed in the literature. In fact, we are finding the sharp bounds of the initial coefficients, second and third-order Hankel determinants, as well as the bound of the fourth-order Hankel determinant for functions belonging to the class $\mathcal{S}^*_{\mathcal{B}}$. Additionally, we establish sharp bounds of the second and third-order Hankel determinants for functions belonging to the class $\mathcal{C}_{\mathcal{B}}$.

2. Coefficient related problems for $\mathcal{S}^*_{\mathcal{B}}$

In this section, we start by determining the sharp bounds of the initial coefficients a_i for $(i = 2, 3, 4, 5)$ followed by establishing the sharp bounds of the second and third-order Hankel determinants for functions $f \in S^*_{\mathcal{B}}$. Subsequently, we derive the bounds for a_6 and a_7 to deduce a possible bound of the fourth-order Hankel determinant for functions $f \in S^*_{\mathcal{B}}$.

2.1. **Sharp initial coefficient bounds.** Let $f \in \mathcal{S}^*_{\mathcal{B}}$, then there exists a Schwarz function $w(z)$ such that

$$\frac{zf'(z)}{f(z)} = \sqrt{1 + \tanh w(z)}. \tag{2.1}$$

Suppose that $p(z) = 1 + p_1 z + p_2 z^2 + \cdots \in \mathcal{P}$ and consider $w(z) = (p(z) - 1)/(p(z) + 1)$. Further, by substituting the expansions of $w(z)$, $p(z)$ and $f(z)$ in equation (2.1) and then comparing the coefficients, we obtain the expressions of $a_i (i = 2, 3, ..., 7)$ in terms of $p_j (j = 1, 2, ..., 5)$, given as

$$a_2 = \frac{p_1}{4}, \quad a_3 = \frac{1}{64}\Big(8p_2 - 3p_1^2\Big), \quad a_4 = \frac{1}{2304}\Big(23p_1^3 - 168p_1p_2 + 192p_3\Big), \tag{2.2}$$

$$a_5 = \frac{1}{18432}\Big(- 11p_1^4 + 528p_1^2p_2 - 576p_2^2 - 1056p_1p_3 + 1152p_4\Big), \tag{2.3}$$

$$a_6 = \frac{1}{1843200}\Big(50880p_1p_2^2 - 2367p_1^5 - 8560p_1^3p_2 + 46080p_1^2p_3 - 96000p_2p_3 - 86400p_1p_4 + 92160p_5\Big) \tag{2.4}$$

and

$$a_7 = \frac{1}{530841600}\Big(601421p_1^6 - 2365320p_1^4p_2 - 4818240p_1^2p_2^2 + 4723200p_2^3 + 26150400p_1p_2p_3 \\ - 2648640p_1^3p_3 - 11980800p_3^2 + 11577600p_1^2p_4 - 23500800p_2p_4 - 21012480p_1p_5\Big). \tag{2.5}$$

The results stated below are necessary for proving our main result.

Lemma 2.1. *[13] Let $p \in \mathcal{P}$ be of the form $1 + \sum_{n=1}^{\infty} p_n z^n$. Then*

$$|p_1^4 - 3p_1^2p_2 + p_2^2 + 2p_1p_3 - p_4| \leq 2 \tag{2.6}$$

and

$$|p_3 - 2p_1p_2 + p_1^3| \leq 2. \tag{2.7}$$

Lemma 2.2. *[14] Let $p \in \mathcal{P}$ be of the form $1 + \sum_{n=1}^{\infty} p_n z^n$. Then*

$$|p_2 - \beta p_1^2| \leq \begin{cases} 2 - 4\beta, & \beta \leq 0; \\ 2, & 0 \leq \beta \leq 1; \\ 4\beta - 2, & \beta \geq 1 \end{cases}$$

when $\beta < 0$ or $\beta > 1$, the equality holds if and only if $p(z) = (1+z)/(1-z)$ or one of its rotations. If $0 < \beta < 1$, then the inequality holds if and only if $p(z) = (1+z^2)/(1-z^2)$ or one of its rotations. If $\beta = 0$, the equality holds if and only if $p(z) = (1+\eta)(1+z)/(2(1-z))+(1-\eta)(1-z)/(2(1+z))(0 \leq \eta \leq 1)$ or one of its rotations. If $\beta = 1$, the equality holds if and only if p is the reciprocal of one of the functions such that the equality holds in case of $\beta = 0$. Though the above upper bound is sharp for $0 < \beta < 1$, still it can be improved as follows:

$$|p_2 - \beta p_1^2| + \beta|p_1|^2 \leq 2 \quad (0 < \beta \leq 1/2) \tag{2.8}$$

and

$$|p_2 - \beta p_1^2| + (1 - \beta)|p_1|^2 \leq 2 \quad (1/2 < \beta \leq 1).$$

Also, we recall that

$$\max_{0\le t\le 4}(At^2+Bt+C)=\begin{cases} C, & B\le 0, A\le \frac{-B}{4};\\ 16A+4B+C, & B\ge 0, A\ge \frac{-B}{8} \quad \text{or} \quad B\le 0, A\ge \frac{-B}{4};\\ \dfrac{4AC-B^2}{4A}, & B>0, A\le \frac{-B}{8}. \end{cases} \tag{2.9}$$

Theorem 2.3. *If $f\in\mathcal{S}^*_{\mathcal{B}}$, then (i) $|a_2|\le 1/2$, (ii) $|a_3|\le 1/4$, (iii) $|a_4|\le 1/6$ and (iv) $|a_5|\le 847/3216\simeq 0.263371\cdots$. These bounds are sharp.*

Proof. (*i*) Since $|p_n|\le 2$ for $n\ge 1$, therefore, from (2.2), $|a_2|\le 1/2$.
(*ii*) For a_3, we use the inequality $|p_2-\mu p_1^2|\le 2\max\{1,|2\mu-1|\}$ given by Ma and Minda [14], which yields $|a_3|\le 1/4$.
(*iii*) For a_4, (2.1) is re-written as:

$$zf'(z)=\sqrt{1+\tanh(w(z))}f(z). \tag{2.10}$$

On substituting $f(z)=z+\sum_{n=2}^{n=\infty}a_nz^n$ and $w(z)=\sum_{k=1}^{\infty}w_kz^k$ in (2.10) and comparing the coefficients of z^4, we get

$$6a_4=\left(w_3+\frac{1}{4}w_1w_2-\frac{13}{48}w_1^3\right).$$

Now using [17, Lemma 2, p.128], we deduce that $|6a_4|\le 1$ and hence the result follows.
(*iv*) From (2.3), we get the expression of a_5 as

$$\begin{aligned} a_5&=\frac{1}{16}\bigg(-\frac{11}{1152}p_1^4+\frac{11}{24}p_1^2p_2-\frac{p_2^2}{2}-\frac{11}{12}p_1p_3+p_4\bigg)\\ &=\frac{1}{16}\bigg(-\frac{1}{2}P+\frac{1}{12}p_1Q-\frac{7}{8}p_1^2R+\frac{1}{2}p_4\bigg), \end{aligned}$$

which further gives

$$|a_5|\le\frac{1}{16}\left(\frac{1}{2}|P|+\frac{1}{12}|p_1||Q|+\frac{7}{8}|p_1|^2|R|+\frac{1}{2}|p_4|\right),$$

where $P=p_1^4-3p_1^2p_2+p_2^2+2p_1p_3-p_4$, $Q=p_3-2p_1p_2+p_1^3$ and $R=p_2-(67/144)p_1^2$. Moreover, using the bounds of $|P|\le 2$ from (2.6), $|Q|\le 2$ from (2.7) and $|R|\le 2$ from (2.8), respectively, we obtain

$$|a_5|\le\frac{1}{16}\left(\frac{7}{3}+\frac{7}{4}|p_1|^2-\frac{469}{1152}|p_1|^4\right).$$

Now, we obtain $|7|p_1|^2/4-469|p_1|^4/1152|\le 126/67$ using (2.9) by taking $A=-469/1152$, $B=7/4$ and $C=0$, which leads to the desired estimate for $|a_5|$. The sharpness of the result can be witnessed when $p_1=p_4=2$, $p_2=(737+\sqrt{963326})/402$ and $p_3=-2$. The function

$$f_n(z)=z\exp\left(\int_0^z\frac{\sqrt{1+\tanh(t^{n-1})}-1}{t}dt\right)$$

acts as the extremal function for the initial coefficients a_n for $n=2,3$ and 4. ∎

The formula for p_j $(j=2,3,4)$, which is included in the Lemma 2.4 below, plays a vital role in establishing the sharp bounds for Hankel determinants and forms the foundation for our main results.

Lemma 2.4. *[12, 13] Let $p\in\mathcal{P}$ has the form $1+\sum_{n=1}^{\infty}p_nz^n$. Then for some γ, η and ρ such that $|\gamma|\le 1$, $|\eta|\le 1$ and $|\rho|\le 1$, we have*

$$2p_2=p_1^2+\gamma(4-p_1^2), \tag{2.11}$$

$$4p_3 = p_1^3 + 2p_1(4-p_1^2)\gamma - p_1(4-p_1^2)\gamma^2 + 2(4-p_1^2)(1-|\gamma|^2)\eta, \tag{2.12}$$

and

$$8p_4 = p_1^4 + (4-p_1^2)\gamma(p_1^2(\gamma^2-3\gamma+3)+4\gamma) - 4(4-p_1^2)(1-|\gamma|^2)(p_1(\gamma-1)\eta + \bar{\gamma}\eta^2 - (1-|\eta|^2)\rho). \tag{2.13}$$

2.2. **Sharp Hankel determinants for $\mathcal{S}^*_{\mathcal{B}}$.** The following theorem presents the sharp bound for $|H_3(1)|$ for functions belonging to the class $\mathcal{S}^*_{\mathcal{B}}$.

Theorem 2.5. *Let $f \in \mathcal{S}^*_{\mathcal{B}}$, then*

$$|H_3(1)| \leq 1/36. \tag{2.14}$$

This result is sharp.

Proof. Since the class $\mathcal{P}$ is invariant under rotation, we can take $p_1 =: p$ belongs to the interval [0,2]. Substitute the values of $a_i (i = 2, 3, 4, 5)$ in (1.6) from (2.2) and (2.3). We get

$$H_3(1) = \frac{1}{21233664}\bigg(-3511p^6 - 5160p^4p_2 - 14400p^2p_2^2 - 124416p_2^3 + 56256p^3p_3 + 216576pp_2p_3 - 147456p_3^2 - 145152p^2p_4 + 165888p_2p_4\bigg).$$

After simplifying the calculations using (2.11)-(2.13), we obtain

$$H_3(1) = \frac{1}{21233664}\bigg(\beta_1(p,\gamma) + \beta_2(p,\gamma)\eta + \beta_3(p,\gamma)\eta^2 + \beta_4(p,\gamma,\eta)\rho\bigg),$$

for $\gamma, \eta, \rho \in \mathbb{D}$. Here

$$\begin{aligned}
\beta_1(p,\gamma) :&= -1099p^6 - 1872\gamma^2p^2(4-p^2)^2 - 20736\gamma^3(4-p^2)^2 - 5760\gamma^3p^2(4-p^2)^2 + 1152\gamma^4p^2(4-p^2)^2 \\
&\quad + 3084\gamma p^4(4-p^2) + 624p^4\gamma^2(4-p^2) - 7776p^4\gamma^3(4-p^2) - 31104\gamma^2p^2(4-p^2),\\
\beta_2(p,\gamma) :&= 96(1-|\gamma|^2)(4-p^2)(149p^3 + 324\gamma p^3 + 228p\gamma(4-p^2) - 48p\gamma^2(4-p^2)),\\
\beta_3(p,\gamma) :&= 1152(1-|\gamma|^2)(4-p^2)(-32(4-p^2) - 4|\gamma|^2(4-p^2) + 27p^2\bar{\gamma}),\\
\beta_4(p,\gamma,\eta) :&= 10368(1-|\gamma|^2)(4-p^2)(1-|\eta|^2)(4(4-p^2)\gamma - 3p^2).
\end{aligned}$$

By choosing $x = |\gamma|$, $y = |\eta|$ and utilizing the fact that $|\rho| \leq 1$, the above expression reduces to the following:

$$|H_3(1)| \leq \frac{1}{21233664}\bigg(|\beta_1(p,\gamma)| + |\beta_2(p,\gamma)|y + |\beta_3(p,\gamma)|y^2 + |\beta_4(p,\gamma,\eta)|\bigg) \leq A(p,x,y),$$

where

$$A(p,x,y) = \frac{1}{21233664}\bigg(a_1(p,x) + a_2(p,x)y + a_3(p,x)y^2 + a_4(p,x)(1-y^2)\bigg), \tag{2.15}$$

with

$$\begin{aligned}
a_1(p,x) :&= 1099p^6 + 1872x^2p^2(4-p^2)^2 + 20736x^3(4-p^2)^2 + 5760x^3p^2(4-p^2)^2 + 1152x^4p^2(4-p^2)^2 \\
&\quad + 3084xp^4(4-p^2) + 624p^4x^2(4-p^2) + 7776p^4x^3(4-p^2) + 31104x^2p^2(4-p^2),\\
a_2(p,x) :&= 96(1-x^2)(4-p^2)(149p^3 + 324xp^3 + 228px(4-p^2) + 48px^2(4-p^2)),\\
a_3(p,x) :&= 1152(1-x^2)(4-p^2)(32(4-p^2) + 4x^2(4-p^2) + 27p^2x),\\
a_4(p,x) :&= 10368(1-x^2)(4-p^2)(4x(4-p^2) + 3p^2).
\end{aligned}$$

In the closed cuboid $Q : [0,2] \times [0,1] \times [0,1]$, we now maximise $A(p,x,y)$, by locating the maximum values in the interior of the six faces, on the twelve edges, and in the interior of Q.

(1) We start by taking into account every internal point of Q. Assume that $(p,x,y) \in (0,2)\times(0,1)\times(0,1)$. We calculate $\partial A/\partial y$, partially differentiate (2.15) with respect to y to identify the points of maxima in the interior of Q. We get

$$\frac{\partial A}{\partial y} = \frac{(4-p^2)(1-x^2)}{21233664}\bigg(24px(5+2x)+p^3(17+24x-12x^2)+96(8-9x+x^2)y - 12p^2(25-27x+2x^2)y\bigg).$$

Now $\partial A/\partial y = 0$ gives

$$y = y_0 := \frac{48px(19+4x)+p^3(149+96x-48x^2)}{24(1-x)(16(x-8)+p^2(59-4x))}.$$

The existence of critical points requires that y_0 belong to $(0,1)$, which is only possible when

$$300p^2+864x+24p^2x^2 > 17p^3+120px+24p^3x+48px^2-12p^3x^2 + 768+864x+24p^2x^2. \tag{2.16}$$

Now, we find the solution satisfying the inequality (2.16) for the existence of critical points using the hit and trial method. If we assume p tends to 0, then there does not exist any $x \in (0,1)$ satisfying (2.16). But, when p tends to 2, (2.16) holds for all $x < 175/648$. We also observe that there does not exist any $p \in (0,2)$ when $x \in (174/648, 1)$. Similarly, if we assume x tends to 0, then for all $p > 1.61687$, (2.16) holds. After calculations, we observe that there does not exist any $x \in (0,1)$ when $p \in (0, 1.61687)$. Thus, the domain for the solution of the equation is $(1.61687, 2)\times(0, 175/648)$. Now, we examine that $\frac{\partial A}{\partial y}|_{y=y_0} \neq 0$ in $(1.61687,2)\times(0,175/648)$. So, we conclude that the function A has no critical point in $(0,2)\times(0,1)\times(0,1)$.

(2) The interior of each of the cuboid Q's six faces is now being considered.

<u>On $p = 0$</u>

$$k_1(x,y) := \frac{16y^2-14x^2y^2-2x^4y^2-9x^3(1-2y^2)+18x(1-y^2)}{576}, \quad x,y \in (0,1). \tag{2.17}$$

Since

$$\frac{\partial k_1}{\partial y} = \frac{(1-x^2)(x+1)(8-x)y}{144} \neq 0, \quad x,y \in (0,1),$$

indicates that k_1 has no critical points in $(0,1)\times(0,1)$.

<u>On $p = 2$</u>

$$A(2,x,y) := \frac{1099}{331776} = 0.00331248, \quad x,y \in (0,1). \tag{2.18}$$

<u>On $x = 0$</u>

$$k_2(p,y) := \frac{1099p^6+(4-p^2)(14304p^3y+36864y^2(4-p^2)+31104p^2(1-y^2)}{21233664} \tag{2.19}$$

with $p \in (0,2)$ and $y \in (0,1)$. To determine the points of maxima, we solve $\partial k_2/\partial p = 0$ and $\partial k_2/\partial y = 0$. After solving $\partial k_2/\partial y = 0$, we get

$$y = \frac{149p^3}{24(59p^2-128)} (=: y_p). \tag{2.20}$$

In order to have $y_p \in (0,1)$ for the given range of y, $p_0 := p > \approx 1.61687$ is required. Based on calculations, $\partial k_2/\partial p = 0$ gives

$$p(41472-20736p^2+1099p^4+28608py-11920p^3y-139776y^2+45312p^2y^2) = 0. \tag{2.21}$$

After substituting (2.20) in (2.21), we have

$$75497472p - 107347968p^3 + 50314752p^5 - 8246384p^7 + 133989p^9 = 0. \tag{2.22}$$

A numerical calculation suggests that $p \approx 1.24748 \in (0,2)$ is the solution of (2.22). So, we conclude that k_2 does not have any critical point in $(0,2)\times(0,1)$.

On $x = 1$

$$A(p,1,y) = k_3(p,y) := \frac{331776 + 99072p^2 - 34704p^4 - 1601p^6}{21233664}, \quad p \in (0,2). \tag{2.23}$$

While computing $\partial k_3/\partial p = 0$, $p_0 := p \approx 1.14405$ comes out to be the critical point. Undergoing simple calculations, k_3 achieves its maximum value ≈ 0.0187629 at p_0.

On $y = 0$

$$k_4(p,x) := \frac{1}{21233664}\bigg(-1601p^6 - 331776(-1-2x+2x^3) + 2304p^2(97 - 144x - 54x^2 + 144x^3) - 144p^4(457 - 288x - 216x^2 + 288x^3)\bigg).$$

After further calculations such as,

$$\frac{\partial k_4}{\partial x} = \frac{(4-p^2)}{1024}\bigg(8 - 24x^2 + p^2(-2-3x+6x^2)\bigg)$$

and

$$\frac{\partial k_4}{\partial p} = \frac{1}{3538944}\bigg(-1601p^5 + 768p(97 - 144x - 54x^2 + 144x^3) - 96p^3(457 - 288x - 216x^2 + 288x^3)\bigg),$$

we observe that only real solutions (p,x) of the system of equations $\partial k_4/\partial x = 0$ and $\partial k_4/\partial p = 0$ are $(2, 1.74724)$, $(2, -1.74724)$, $(-1.36584, -0.835809)$, $(1.36584, -0.835809)$, $(2, -1.74724)$ and $(-0.854598, 0.524203)$. Thus, no solution exists in $(0,2)\times(0,1)$, resulting in no critical points.

On $y = 1$

$$k_5(p,x) := \frac{1}{21233664}\bigg\{1099p^6 + 31104p^2(4-p^2) + 11484p^4(4-p^2) + 20736(4-p^2)^2 + 8784p^2(4-p^2)^2 - 1152(4-p^2)(1-x^2)\bigg(-16(8+x^2) + p^2(32 - 27x + 4x^2)\bigg) + 96(4-p^2)(1-x^2)\bigg(48px(19+4x) + p^3(149 + 96x - 48x^2)\bigg)\bigg\}.$$

Simple calculations leads to

$$\frac{\partial k_5}{\partial x} = \frac{(4-p^2)}{110592}\bigg(-192x(7+2x^2) + 6p^2(27 + 56x - 81x^2 + 16x^3) + 24p(19 + 8x - 57x^2 - 16x^3) + p^3(48 - 197x - 144x^2 + 96x^3)\bigg)$$

and

$$\frac{\partial k_5}{\partial p} = \frac{1}{3538944}\Big(-1601p^5 - 3072x(-19 - 4x + 19x^2 + 4x^3) + 768p(-85 + 54x + 112x^2 - 54x^3 + 16x^4) - 96p^3(-15 + 216x + 224x^2 - 216x^3 + 32x^4) - 80p^4(149 + 96x - 197x^2 - 96x^3 + 48x^4) + 192p^2(149 - 132x - 245x^2 + 132x^3 + 96x^4)\Big).$$

We note that the only real solutions (p, x) of the system of equations $\partial k_5/\partial x = 0$ and $\partial k_5/\partial p = 0$ are $(-5.5858, 2.7083)$, $(2, -2.2645)$, $(-2, 0.357662)$, $(-1.98983, 0.350993)$, $(0.932759, -1.56488)$ and $(-1.03049, -0.27789)$. Thus, no solution exists in $(0, 2) \times (0, 1)$, resulting in no critical points.

(3) We next examine the maxima attained by $A(p, x, y)$ on the edges of the cuboid Q. From (2.19), we have $A(p, 0, 0) = e_1(p) := (124416p^2 - 31104p^4 + 1099p^6)/21233664$. It is easy to observe that $e_1'(p) = 0$ whenever $p = \delta_0 := 0$ and $p = \delta_1 := 1.50801 \in [0, 2]$ as its points of minima and maxima respectively. Hence,

$$A(p, 0, 0) \leq 0.00635802, \quad p \in [0, 2].$$

Now considering (2.19) at $y = 1$, we get $A(p, 0, 1) = e_2(p) := (589824 - 294912p^2 + 57216p^3 + 36864p^4 - 14304p^5 + 1099p^6)/21233664$. It is easy to observe that $e_2'(p) < 0$ in $[0, 2]$ and hence $p = 0$ serves as the point of maxima. So,

$$A(p, 0, 1) \leq \frac{1}{36} \approx 0.0277778, \quad p \in [0, 2].$$

Through computations, (2.19) shows that $A(0, 0, y)$ attains its maxima at $y = 1$. This implies that

$$A(0, 0, y) \leq \frac{1}{36}, \quad y \in [0, 1].$$

Since, (2.23) does not involve x, we have $A(p, 1, 1) = A(p, 1, 0) = e_3(p) := (331776 + 99072p^2 - 34704p^4 - 1601p^6)/21233664$. Now, $e_3'(p) = 33024p - 23136p^3 - 1601p^5 = 0$ when $p = \delta_2 := 0$ and $p = \delta_3 := 1.14405$ in the interval $[0, 2]$ with δ_2 and δ_3 as points of minima and maxima, respectively. Hence

$$A(p, 1, 1) = A(p, 1, 0) \leq 0.0187629, \quad p \in [0, 2].$$

After considering $p = 0$ in (2.23), we get, $A(0, 1, y) = 1/64$. The equation (2.18) has no variables. So, on the edges, the maximum value of $M(p, x, y)$ is

$$A(2, 1, y) = A(2, 0, y) = A(2, x, 0) = A(2, x, 1) = \frac{1099}{331776}, \quad x, y \in [0, 1].$$

Using (2.17), we obtain $A(0, x, 1) = e_4(x) := (16 - 14x^2 + 9x^3 - 2x^4)/576$. Upon calculations, we see that $e_4(x)$ is a decreasing function in $[0, 1]$ and attains its maxima at $x = 0$. Thus

$$A(0, x, 1) \leq \frac{1}{36}, \quad x \in [0, 1].$$

Again utilizing (2.17), we get $A(0, x, 0) = e_5(x) := x(2 - x^2)/64$. On further calculations, we get $e_5'(x) = 0$ for $x = \delta_4 := \sqrt{2/3}$. Also, $e_5(x)$ is an increases in $[0, \delta_4)$ and decreases in $(\delta_4, 1]$. So, it reaches its maximum value at δ_4. Thus

$$A(0, x, 0) \leq 0.0170103, \quad x \in [0, 1].$$

Given all the cases, the inequality (2.14) holds. Let the function $f_0(z) \in \mathcal{S}^*_{\mathcal{B}}$, be defined as

$$f_0(z) = z\exp\left(\int_0^z \frac{\sqrt{1+\tanh t^3}-1}{t}dt\right) = z + \frac{z^4}{6} - \frac{z^7}{144} + \cdots, \tag{2.24}$$

with $f_0(0) = 0$ and $f_0'(0) = 1$, acts as an extremal function for the bound of $|H_3(1)|$ for $a_2 = a_3 = a_5 = 0$ and $a_4 = 1/6$. ∎

Next, we find the sharp bound of $|H_2(3)|$ for functions belonging to the class $S^*_{\mathcal{B}}$, given by

Theorem 2.6. *Let $f \in \mathcal{S}^*_{\mathcal{B}}$, then*

$$|H_2(3)| \leq \frac{1}{36}. \tag{2.25}$$

This bound is sharp.

Proof. We proceed on the similar lines as in the proof of Theorem 2.5. Assuming $p_1 =: p \in [0,2]$, we substitute the values of $a_i'(i = 3,4,5)$ from (2.2) and (2.3) into (1.5), we obtain

$$H_2(3) = \frac{1}{10616832}\bigg(-761p^6 + 408p^4p_2 - 2880p^2p_2^2 - 41472p_2^3 + 10848p^3p_3 + 52992pp_2p_3 - 73728p_3^2 - 31104p^2p_4 + 82944p_2p_4\bigg).$$

Using (2.11)-(2.13), we arrive at

$$H_2(3) = \frac{1}{5308416}\bigg(\beta_5(p,\gamma) + \beta_6(p,\gamma)\eta + \beta_7(p,\gamma)\eta^2 + \beta_8(p,\gamma,\eta)\rho\bigg),$$

where $\gamma, \eta, \rho \in \mathbb{D}$,

$$\begin{aligned}
\beta_5(p,\gamma) :&= -437p^6 - 5904\gamma^2p^2(4-p^2)^2 + 1440\gamma^3p^2(4-p^2)^2 + 576\gamma^4p^2(4-p^2)^2 \\
&\quad + 5184\gamma^2p^2(4-p^2) - 852\gamma p^4(4-p^2) - 4008p^4\gamma^2(4-p^2) + 1296p^4\gamma^3(4-p^2),\\
\beta_6(p,\gamma) :&= (1-|\gamma|^2)(4-p^2)(5424p^3 - 5184p^3\gamma - 2880p\gamma(4-p^2) - 2304p\gamma^2(4-p^2)),\\
\beta_7(p,\gamma) :&= 576(1-|\gamma|^2)(4-p^2)(-32(4-p^2) - 9p^2\bar{\gamma} - 4|\gamma|^2(4-p^2))\\
\beta_8(p,\gamma,\eta) :&= 5184(1-|\gamma|^2)(4-p^2)(1-|\eta|^2)(p^2 + 4\gamma(4-p^2)).
\end{aligned}$$

Additionally, by using the fact that $|\rho| \leq 1$ and taking $x = |\gamma|$, $y = |\eta|$, we obtain

$$|H_2(3)| \leq \frac{1}{10616832}\bigg(|\beta_5(p,\gamma)| + |\beta_6(p,\gamma)|y + |\beta_7(p,\gamma)|y^2 + |\beta_8(p,\gamma,\eta)|\bigg) \leq B(p,x,y),$$

where

$$B(p,x,y) = \frac{1}{10616832}\bigg(b_1(p,x) + b_2(p,x)y + b_3(p,x)y^2 + b_4(p,x)(1-y^2)\bigg), \tag{2.26}$$

with

$$\begin{aligned}
b_1(p,x) :&= 437p^6 + 5904p^2x^2(4-p^2)^2 + 1440p^2x^3(4-p^2)^2 + 576p^2x^4(4-p^2)^2 \\
&\quad + 5184p^2x^2(4-p^2) + 852p^4x(4-p^2) + 4008p^4x^2(4-p^2) + 1296p^4x^3(4-p^2),\\
b_2(p,x) :&= (4-p^2)(1-x^2)(5424p^3 + 5184p^3x + 2880px(4-p^2) + 2304px^2(4-p^2)),\\
b_3(p,x) :&= 576(4-p^2)(1-x^2)(32(4-p^2) + 9p^2x + 4x^2(4-p^2)),\\
b_4(p,x) :&= 5184(4-p^2)(1-x^2)(p^2 + 4x(4-p^2)).
\end{aligned}$$

At this point, we must maximise $B(p,x,y)$ in the closed cuboid $R : [0,2] \times [0,1] \times [0,1]$. By identifying the maximum values on the twelve edges, the interior of R, and the interiors of the six faces, we can prove this.

(1) We start by taking into account, every interior point of R. Assume that $(p,x,y) \in (0,2)\times(0,1)\times(0,1)$. On differentiating (2.26) with respect to y, to locate the points of maxima in the interior of R, we obtain

$$\frac{\partial B}{\partial y} = \frac{(1-x^2)}{221184}(4-p^2)\Big(48px(5+4x)+p^3(113+48x-48x^2) + 384(8-9x+x^2)y - 24p^2(41-45x+4x^2)y\Big).$$

Now $\partial B/\partial y = 0$ gives

$$y = y_1 := \frac{48px(5+4x)+p^3(113+48x-48x^2)}{24(1-x)(16(x-8)+p^2(41-4x))}.$$

Since y_1 must be a member of $(0,1)$ for critical points to exist, this is only possible if

$$48px(5+4x)+p^3(113+48x-48x^2) < 24(1-x)(16(x-8)+p^2(41-4x)). \tag{2.27}$$

Now, we find the solutions satisfying the inequality (2.27) for the existence of critical points using hit and trial method. If p tends to 0 and 2, then no $x \in (0,1)$ exists satisfying (2.27). Similarly, if take x tending to 0 and 1, then there does not exist any $p \in (0,2)$ such that (2.27) holds. So, we conclude that the function B has no critical point in $(0,2)\times(0,1)\times(0,1)$.

(2) Now, we study the interior of six faces of the cuboid R.

On $p = 0$

$$l_1(x,y) := \frac{(1-x^2)(8y^2+x^2y^2+9x(1-y^2))}{288}, \tag{2.28}$$

with $x,y \in (0,1)$. We note that, in $(0,1)\times(0,1)$, l_1 does not have any critical point. As

$$\frac{\partial l_1}{\partial y} = \frac{y(1-x^2)(x-1)(x-8)}{144} \neq 0 \quad x,y \in (0,1).$$

On $p = 2$

$$B(2,x,y) := \frac{437}{165888} = 0.00263431, \quad x,y \in (0,1). \tag{2.29}$$

On $x = 0$

$$l_2(p,y) := \frac{437p^6+(4-p^2)(5424p^3y+18432(4-p^2)y^2+5184p^2(1-y^2))}{10616832} \tag{2.30}$$

with $p \in (0,2)$ and $y \in (0,1)$. We solve $\partial l_2/\partial p$ and $\partial l_2/\partial y$ to locate the points of maxima. On solving $\partial l_2/\partial y = 0$, we obtain

$$y = \frac{113p^3}{24(41p^2-128)} =: y_p. \tag{2.31}$$

For the given range of y, we should have $y_p \in (0,1)$ but no such $p \in (0,2)$ exists.

On $x = 1$

$$B(p,1,y) = l_3(p,y) := \frac{(147456p^2-43920p^4+2201p^6)}{10616832}, \quad p \in (0,2). \tag{2.32}$$

And when computing $\partial l_3/\partial p = 0$, $p = p_0 \approx 1.40378$ turns out to be the critical point. According to elementary calculations, l_3 reaches its maximum value ≈ 0.0128915 at p_0.

On $y = 0$

$$l_4(p,x) := \frac{1}{10616832}\Big(331776x(1-x^2) + 2304p^2(9 - 72x + 41x^2 + 82x^3 + 4x^4) - 48p^4(108 - 503x + 650x^2 + 564x^3 + 96x^4) + p^6(437 - 852x + 1896x^2 + 144x^3 + 576x^4)\Big) = B(p,x,0).$$

On computations, we obtain

$$\frac{\partial l_4}{\partial x} = \frac{(4-p^2)}{884736}\Big(6912(1-3x^2) + 96p^2(-18 + 41x + 69x^2 + 8x^3) - p^4(-71 + 316x + 36x^2 + 192x^3)\Big)$$

and

$$\frac{\partial l_4}{\partial p} = \frac{1}{1769472}\Big(768p(9 - 72x + 41x^2 + 82x^3 + 4x^4) - 32p^3(108 - 503x + 650x^2 + 564x^3 + 96x^4) + p^5(437 - 852x + 1896x^2 + 144x^3 + 576x^4)\Big).$$

The common real solutions (p,x) of the system of equations, $\partial l_4/\partial x = 0$ and $\partial l_4/\partial p = 0$ are $(-2,-2.86143)$, $(-2.6516,-0.571214)$, $(-2,-0.247504)$, $(-2,-2.86143)$, $(2,0.0163426)$, $(-2,0.0163426)$, $(2.6516,-0.571214)$, $(2,-0.247504)$, $(0,0.57735)$, $(0,-0.57735)$ and $(-0.914024,0.721238)$. Thus, no solution exists in $(0,2)\times(0,1)$, resulting in no critical points.

On $y = 1$

$$l_5(p,x) := \frac{1}{10616832}\Big(9216px(5 + 4x - 5x^2 - 4x^3) + 36864(8 - 7x^2 - x^4) - 2304p^2(64 - 9x - 106x^2 - x^3 - 12x^4) - 48p^5(113 + 48x - 161x^2 - 48x^3 + 48x^4) + 192p^3(113 - 12x - 209x^2 + 12x^3 + 96x^4) + 48p^4(384 - 37x - 1094x^2 - 24x^3 - 144x^4) + p^6(437 - 852x + 1896x^2 + 144x^3 + 576x^4)\Big).$$

On computations, we get

$$\frac{\partial l_5}{\partial x} = \frac{(4-p^2)}{884736}\Big(-1536x(7 + 2x^2) + 192p(5 + 8x - 15x^2 - 16x^3) + 48p^2(9 + 156x + 3x^2 + 32x^3) + 8p^3(24 - 161x - 72x^2 + 96x^3) + p^4(71 - 316x - 36x^2 - 192x^3)\Big)$$

and

$$\frac{\partial l_5}{\partial p} = \frac{1}{1769472}\Big(1536x(5 + 4x - 5x^2 - 4x^3) - 768p(64 - 9x - 106x^2 - x^3 - 12x^4) - 40p^4(113 + 48x - 161x^2 - 48x^3 + 48x^4) + 96p^2(113 - 12x - 209x^2 + 12x^3 + 96x^4) + 32p^3(384 - 37x - 1094x^2 - 24x^3 - 144x^4) + p^5(437 - 852x + 1896x^2 + 144x^3 + 576x^4)\Big).$$

The common real solutions (p, x) of the system of equations, $\partial l_5/\partial x = 0$ and $\partial l_5/\partial p = 0$ are $(10.3578, 0.237179)$, $(2.61706, 3.83978)$, $(-2, -2.97479)$, $(2, 2.03127)$, $(-2.52708, -1.62061)$, $(-2, -0.783621)$, $(-1.37805, -1.02453)$, $(-1.77448, 0.0488452)$, $(2.00019, -0.515602)$, $(0, 0)$ and $(1.35192, -1.00909)$. Thus, no solution exists in $(0, 2) \times (0, 1)$, resulting in no critical points.

(3) Now, we calculate the maximum values achieved by $B(p, x, y)$ on the edges of the cuboid R. From (2.30), we have $B(p, 0, 0) = f_1(p) := (20736p^2 - 5184p^4 + 437p^6)/10616832$. It is easy to observe that $f_1'(p) = 0$ for $p = \delta_0 := 0$ in the interval $[0, 2]$. The maximum value of $f_1(p)$ is 0.
Now considering (2.30) at $y = 1$, we get $B(p, 0, 1) = f_2(p) := (294912 - 147456p^2 + 21696p^3 + 18432p^4 - 5424p^5 + 437p^6)/10616832$. It is easy to observe that $f_2'(p)$ is a decreasing function in $[0, 2]$ and hence $p = 0$ acts as its point of maxima. Thus

$$B(p, 0, 1) \leq \frac{1}{36} = 0.0277778, \quad p \in [0, 2].$$

Through computations, (2.30) shows that $B(0, 0, y) = y^2/36$, attains its maximum value at $y = 1$. This implies that

$$B(0, 0, y) \leq \frac{1}{36}, \quad y \in [0, 1].$$

Since, (2.32) is independent of x, we have $B(p, 1, 1) = B(p, 1, 0) = f_3(p) := (147456p^2 - 43920p^4 + 2201p^6)/10616832$. Now, $f_3'(p) = 294912p - 175680p^3 + 13206p^5 = 0$ when $p = \delta_2 := 0$ and $p = \delta_3 := 1.40378$ in the interval $[0, 2]$ with δ_2 and δ_3 as points of minima and maxima respectively. Hence

$$B(p, 1, 1) = B(p, 1, 0) \leq 0.0128915, \quad p \in [0, 2].$$

On substituting $p = 0$ in (2.32), we get, $B(0, 1, y) = 0$. The equation (2.29) is independent of the all the variables namely p, x and y. Thus the maximum value of $B(p, x, y)$ on the edges $p = 2, x = 1; p = 2, x = 0; p = 2, y = 0$ and $p = 2, y = 1$, respectively, is given by

$$B(2, 1, y) = B(2, 0, y) = B(2, x, 0) = B(2, x, 1) = \frac{437}{165888}, \quad x, y \in [0, 1].$$

From (2.30), we obtain $B(0, 0, y) = y^2/36$. A simple calculation shows that

$$B(0, 0, y) \leq \frac{1}{36}, \quad y \in [0, 1].$$

Using (2.28), we obtain $B(0, x, 1) = f_4(x) := (8 - 7x^2 - x^4)/288$. Upon calculations, we see that f_4 is a decreasing function in $[0, 1]$ and hence attains its maximum value at $x = 0$. Thus

$$B(0, x, 1) \leq \frac{1}{36}, \quad x \in [0, 1].$$

On again using (2.28), we get $B(0, x, 0) = f_5(x) := 9x(1 - x^2)/288$. On further calculations, we get $f_5'(x) = 0$ for $x = \delta_4 := 1/\sqrt{3}$. Also, $f_5(x)$ is an increasing function in $[0, \delta_4)$ and decreasing in $(\delta_4, 1]$. So, it attains its maximum value at δ_4. Thus

$$B(0, x, 0) \leq 0.0120281, \quad x \in [0, 1].$$

In view of all the cases, the inequality (2.25) holds. The function specified in (2.24) acts as an extremal function for the bounds of $|H_2(3)|$ having values $a_3 = a_5 = 0$ and $a_4 = 1/6$. ∎

2.3. **Fourth Hankel determinant.** Given that sharp bounds for third-order Hankel determinants have been attained for various subclasses of stalike functions, as shown in Table 1, determining bounds for fourth-order Hankel determinants proves to be considerably challenging, necessitating extensive computations. Consequently, there have been relatively few efforts in this direction within the existing literature, for recent advancements, we refer [8, 10, 19, 20]. Subsequently, we introduce a lemma which is required in forthcoming results.

Lemma 2.7. *[8, 18] Let* $p = 1 + \sum_{n=1}^{\infty} p_n z^n \in \mathcal{P}$. *Then*

$$|p_n| \leq 2, \quad n \geq 1,$$

$$|p_{n+k} - \nu p_n p_k| \leq \begin{cases} 2, & 0 \leq \nu \leq 1; \\ 2|2\nu - 1|, & otherwise, \end{cases}$$

and

$$|p_1^3 - \nu p_3| \leq \begin{cases} 2|\nu - 4|, & \nu \leq 4/3; \\ 2\nu\sqrt{\dfrac{\nu}{\nu - 1}}, & 4/3 < \nu. \end{cases}$$

Now, we try to estimate the bound of sixth and seventh coefficient bounds of function $f \in \mathcal{S}_{\mathcal{B}}^*$ as follows:

Lemma 2.8. *Let* $f \in \mathcal{S}_{\mathcal{B}}^*$, *then* $|a_6| \leq 0.611233$ *and* $|a_7| \leq 0.690994$.

Proof. From (2.4), we have

$$\begin{aligned} 1843200a_6 = &-2367p_1^5 - 8560p_1^3p_2 + 50880p_1p_2^2 - 86400p_1p_4 + 92160p_5 - 96000p_2p_3 \\ &+ 46080p_1^2p_3 \end{aligned}$$

or

$$\begin{aligned} 1843200|a_6| \leq &|p_1^3(-2367p_1^2 - 8560p_2)| + |p_1(50880p_2^2 - 86400p_4)| + |92160p_5 - 96000p_2p_3| \\ &+ |46080p_1^2p_3|. \end{aligned}$$

Using Lemma 2.7 and the triangle inequality, we arrive at

$$|a_6| \leq \frac{35207}{57600} \approx 0.611233. \tag{2.33}$$

Similarly,

$$\begin{aligned} 530841600a_7 = &601421p_1^6 - 2365320p_1^4p_2 + 4723200p_2^3 - 4818240p_1^2p_2^2 - 2648640p_1^3p_3 - 11980800p_3^2 \\ &+ 26150400p_1p_2p_3 - 23500800p_2p_4 + 11577600p_1^2p_4 - 21012480p_1p_5 \end{aligned}$$

or

$$\begin{aligned} 530841600|a_7| \leq &|p_1^4(601421p_1^2 - 2365320p_2)| + |p_2^2(4723200p_2 - 4818240p_1^2)| \\ &+ |p_3(2648640p_1^3 - 11980800p_3)| + |p_2(26150400p_1p_3 - 23500800p_4)| \\ &+ |p_1(11577600p_1^2p_4 - 21012480p_5)|. \end{aligned}$$

By employing Lemma 2.7 and the triangle inequality, we obtain

$$|a_7| \leq \frac{31841}{46080} \approx 0.690994. \tag{2.34}$$

∎

We derive the expression of the fourth Hankel determinant, upon substituting $q = 4$ and $n = 1$ in (1.4) as follows:

$$H_4(1) = a_7H_3(1) - a_6B_1 + a_5B_2 - a_4B_3, \tag{2.35}$$

where

$$B_1 := a_6(a_3 - a_2^2) + a_3(a_2a_5 - a_3a_4) - a_4(a_5 - a_2a_4), \tag{2.36}$$

$$B_2 := a_3(a_3a_5 - a_4^2) - a_5(a_5 - a_2a_4) + a_6(a_4 - a_2a_3), \tag{2.37}$$

and

$$B_3 := a_4(a_3a_5 - a_4^2) - a_5(a_2a_5 - a_3a_4) + a_6(a_4 - a_2a_3). \tag{2.38}$$

Next, we determine the bound of these B_i for $i = 1, 2, 3$. By substituting the values from (2.2)-(2.4) in (2.36), we get

$$\begin{aligned} 707788800B_1 = {} & 110689p_1^7 - 299496p_1^5p_2 - 855360p_1^4p3 + 269760p_1^3p_2^2 + 944640p_1p_2^3 \\ & - 1128960p_1^2p_2p_3 - 3686400p_2^2p_3 + 4608000p_1p_3^2 + 2668800p_1^3p_4 \\ & + 460800p_1p_2p_4 - 3686400p_3p_4 - 3870720p_1^2p_5 + 4423680p_2p_5 \end{aligned}$$

or

$$\begin{aligned} 707788800|B_1| \leq {} & |p_1^4(110689p_1^7 - 855360p_3)| + |p_2^2(269760p_1^3 - 3686400p_3)| + |4608000p_1p_3^2| \\ & + |p_1p_2(944640p_2^2 + 460800p_4)| + |p_1^2p_2(-299496p_1^3 - 1128960p_3)| \\ & + |p_4(2668800p_1^3 - 3686400p_3)| + |p_5(4423680p_2 - 3870720p_1^2)| \end{aligned}$$

Using Lemma 2.7 and the triangle inequality, we get

$$\begin{aligned} |B_1| &\leq \frac{1}{707788800}\left(110590464 + 255027456\sqrt{\frac{165}{744671}} + 471859200\sqrt{\frac{15}{3559}} + 117964800\sqrt{\frac{3}{53}}\right) \\ &\approx 0.244544. \end{aligned} \tag{2.39}$$

Similarly,

$$\begin{aligned} 5662310400B_2 = {} & 927648p_1^5p_3 - 149225p_1^8 + 785840p_1^6p_2 + 3939840p_1^3p_2p_3 - 2073600p_1^2p_2^3 - 8294400p_2^4 \\ & + 23316480p_1p_2^2p_3 - 2025600p_1^4p_2^2 - 11704320p_1^2p_3^2 - 29491200p_2p_3^2 + 25804800p_1p_3p_4 \\ & - 3676800p_1^4p_4 - 3225600p_1^2p_2p_4 - 29491200p_1p_2p_5 + 27648000p_2^2p_4 - 22118400p_4^2 \\ & + 6144000p_1^3p_5 + 23592960p_3p_5 \end{aligned}$$

or

$$\begin{aligned} 5662310400|B_2| \leq {} & |p_1^5(927648p_3 - 149225p_1^3)| + |p_1^3p_2(785840p_1^3 + 3939840p_3)| \\ & + |p_2^3(-2073600p_1^2 - 8294400p_2)| + |p_1p_2^2(23316480p_3 - 2025600p_1^3)| \\ & + |p_3^2(-11704320p_1^2 - 29491200p_2)| + |p_1p_4(25804800p_3 - 3676800p_1^3)| \\ & + |p_1p_2(-3225600p_1p_4 - 29491200p_5)| + |p_4(27648000p_2^2 - 22118400p_4)| \\ & + |p_5(6144000p_1^3 + 23592960p_3|. \end{aligned}$$

With the aid of Lemma 2.7 and the triangle inequality, we obtain

$$\begin{aligned} |B_2| &\leq \frac{1}{5662310400}\left(1982371840 + \frac{22263552}{149225}\sqrt{\frac{6442}{778423}} + \frac{43008}{383}\sqrt{\frac{42}{2305}} + \frac{97152}{1055}\sqrt{\frac{759}{11089}}\right) \\ &\approx 0.350099. \end{aligned} \tag{2.40}$$

and

$$\begin{aligned}305764761600B_3 &= 133166592p_1^5p_3 - 8521200p_1^8 + 126489600p_1^4p_2p_3 - 621000p_1^7p_2 + 331084800p_1^4p_2^2\\ &+ 2362245120p_1p_2^2p_3 + 6566400p_1^3p_2^3 - 199065600p_2^3p_3 + 99532800p_1p_2^4\\ &- 49766400p_1p_2^2p_4 - 1260195840p_1^3p_2p_3 - 1327104000p_2p_3^2 - 103680000p_1^2p_2^2p_3\\ &- 20260800p_1^5p_2^2 - 177638400p_1^3p_3^2 - 176947200p_3^3 + 398131200p_1^2p_3p_4\\ &- 12182400p_1^5p_4 + 331776000p_1^3p_5 + 1274019840p_3p_5 + 398131200p_2p_3p_4\\ &- 311040000p_1^4p_4 - 1194393600p_1p_3p_4 + 1492992000p_1^2p_2p_4 - 1592524800p_1p_2p_5\\ &+ 637009920p_1^2p_3^2 - 160625p_1^9 - 879206400p_1^2p_2^3 + 99532800p_1p_2p_3^2 - 298598400p_1p_4^2\end{aligned}$$

or

$$\begin{aligned}305764761600|B_3| &\le |p_1^5(133166592p_3 - 8521200p_1^3)| + |p_1^4p_2(126489600p_3 - 621000p_1^3)|\\ &+ |p_1p_2^2(331084800p_1^3 + 2362245120p_3)| + |p_2^3(6566400p_1^3 - 199065600p_3)|\\ &+ |p_1p_2^2(99532800p_2^2 - 49766400p_4)| + |p_2p_3(-1260195840p_1^3 - 1327104000p_3)|\\ &+ |p_1^2p_2^2(-103680000p_3 - 20260800p_1^3)| + |p_3^2(-177638400p_1^3 - 176947200p_3)|\\ &+ |p_1^2p_4(398131200p_3 - 12182400p_1^3)| + |p_5(331776000p_1^3 + 1274019840p_3)|\\ &+ |p_2p_4(398131200p_3 - 95385600p_1^3)| + |p_1p_4(-311040000p_1^3 - 1194393600p_3)|\\ &+ |p_1p_2(1492992000p_1p_4 - 1592524800p_5)| + |637009920p_1^2p_3^2| + |160625p_1^9|\\ &+ |879206400p_1^2p_2^3| + |99532800p_1p_2p_3^2| + |298598400p_1p_4^2|.\end{aligned}$$

Through Lemma 2.7 and the triangle inequality, we have

$$\begin{aligned}|B_3| &\le \frac{1}{305764761600}\left(210371822080 + 147726139392\sqrt{\frac{114}{32059}} + 101921587200\sqrt{\frac{6}{1489}}\right.\\ &\left. + 64762675200\sqrt{\frac{366}{23309}} + 12740198400\sqrt{\frac{6}{73}} + \frac{76441190400}{\sqrt{557}}\right)\\ &\approx 0.787068. \qquad (2.41)\end{aligned}$$

Upon substituting values from (2.33), (2.34), (2.5), (2.39)-(2.41), and Theorem 2.3 in (2.35), we obtain the following result, given by

Theorem 2.9. *Let $f \in \mathcal{S}^*_{\mathcal{B}}$, then $|H_4(1)| \le 0.169251$.*

3. Sharp Hankel Determinants for $\mathcal{C}_{\mathcal{B}}$

In this section, we determine the sharp bounds for the second and third-order Hankel determinants for functions $f \in \mathcal{C}_{\mathcal{B}}$. Below, we provide the expressions for the initial coefficients of functions $f \in \mathcal{C}_{\mathcal{B}}$ in terms of Carathéodory coefficients, serving as a foundation for subsequent calculations.

Let $f \in \mathcal{C}_{\mathcal{B}}$, then there exists a Schwarz function $w(z)$ such that

$$1 + \frac{zf''(z)}{f'(z)} = \sqrt{1 + \tanh w(z)}. \qquad (3.1)$$

Suppose that $p(z) = 1 + p_1z + p_2z^2 + \cdots \in \mathcal{P}$ and consider $w(z) = (p(z) - 1)/(p(z) + 1)$. Further, by substituting the expansions of $w(z)$, $p(z)$ and $f(z)$ in (3.1) and then comparing the coefficients,

we obtain the expressions of $a_i (i = 2, 3, ..., 7)$ in terms of $p_j (j = 1, 2, ..., 5)$, given by

$$a_2 = \frac{1}{8}p_1, \quad a_3 = \frac{1}{192}\Big(8p_2 - 3p_1^2\Big), \quad a_4 = \frac{1}{9216}\Big(23p_1^3 - 168p_1p_2 + 192p_3\Big) \tag{3.2}$$

and

$$a_5 = \frac{1}{92160}\Big(- 11p_1^4 + 528p_1^2p_2 - 576p_2^2 - 1056p_1p_3 + 1152p_4\Big). \tag{3.3}$$

The following theorem presents the sharp bound for $|H_3(1)|$ for functions belonging to the class $\mathcal{C}_{\mathcal{B}}$.

Theorem 3.1. *Let $f \in \mathcal{C}_{\mathcal{B}}$, then*

$$|H_3(1)| \leq 1/576. \tag{3.4}$$

This result is sharp.

Proof. Since the class $\mathcal{P}$ is invariant under rotation, the value of p_1 belongs to the interval [0,2]. Let $p := p_1$ and then substitute the values of $a_i (i = 2, 3, 4, 5)$ in (1.6) from (3.2) and (3.3). We get

$$H_3(1) = \frac{1}{424673280}\Big(- 3581p^6 - 11184p^4p_2 - 2880p^2p_2^2 - 141312p_2^3 + 73344p^3p_3 + 211968pp_2p_3$$
$$- 184320p_3^2 - 165888p^2p_4 + 221184p_2p_4\Big).$$

After simplifying the calculations through (2.11)-(2.13), we obtain

$$H_3(1) = \frac{1}{424673280}\Big(\beta_9(p,\gamma) + \beta_{10}(p,\gamma)\eta + \beta_{11}(p,\gamma)\eta^2 + \beta_{12}(p,\gamma,\eta)\rho\Big),$$

for $\gamma, \eta, \rho \in \mathbb{D}$. Here

$$\begin{aligned}
\beta_9(p,\gamma) :&= -1157p^6 - 5328\gamma^2p^2(4-p^2)^2 - 15360\gamma^3(4-p^2)^2 - 4224\gamma^3p^2(4-p^2)^2 + 2304\gamma^4p^2(4-p^2)^2\\
&\quad + 3144\gamma p^4(4-p^2) - 1056p^4\gamma^2(4-p^2) - 6912p^4\gamma^3(4-p^2) - 27648\gamma^2p^2(4-p^2),\\
\beta_{10}(p,\gamma) :&= 192(1-|\gamma|^2)(4-p^2)(83p^3 + 144\gamma p^3 + 84p\gamma(4-p^2) - 48p\gamma^2(4-p^2)),\\
\beta_{11}(p,\gamma) :&= 9216(1-|\gamma|^2)(4-p^2)(-5(4-p^2) - |\gamma|^2(4-p^2) + 3p^2\bar{\gamma}),\\
\beta_{12}(p,\gamma,\eta) :&= 27648(1-|\gamma|^2)(4-p^2)(1-|\eta|^2)(2(4-p^2)\gamma - p^2).
\end{aligned}$$

By choosing $x = |\gamma|$, $y = |\eta|$ and utilizing the fact that $|\rho| \leq 1$, the above expression reduces to the following:

$$|H_3(1)| \leq \frac{1}{424673280}\Big(|\beta_9(p,\gamma)| + |\beta_{10}(p,\gamma)|y + |\beta_{11}(p,\gamma)|y^2 + |\beta_{12}(p,\gamma,\eta)|\Big) \leq C(p,x,y),$$

where

$$C(p,x,y) = \frac{1}{424673280}\Big(c_1(p,x) + c_2(p,x)y + c_3(p,x)y^2 + c_4(p,x)(1-y^2)\Big), \tag{3.5}$$

with

$$\begin{aligned}
c_1(p,x) :&= 1157p^6 + 5328x^2p^2(4-p^2)^2 + 15360x^3(4-p^2)^2 + 4224x^3p^2(4-p^2)^2 + 2304x^4p^2(4-p^2)^2\\
&\quad + 3144xp^4(4-p^2) + 1056p^4x^2(4-p^2) + 6912p^4x^3(4-p^2) + 27648x^2p^2(4-p^2),\\
c_2(p,x) :&= 192(1-x^2)(4-p^2)(83p^3 + 144xp^3 + 84px(4-p^2) + 48px^2(4-p^2)),\\
c_3(p,x) :&= 9216(1-x^2)(4-p^2)(5(4-p^2) + x^2(4-p^2) + 3p^2x),\\
c_4(p,x) :&= 27648(1-x^2)(4-p^2)(2x(4-p^2) + p^2).
\end{aligned}$$

In the closed cuboid $S : [0,2] \times [0,1] \times [0,1]$, we now maximise $C(p,x,y)$, by locating the maximum values in the interior of the six faces, on the twelve edges, and in the interior of S.

(1) We start by taking into account every internal point of S. Assume that $(p,x,y) \in (0,2) \times (0,1) \times (0,1)$. We calculate $\partial C/\partial y$, partially differentiate (3.5) with respect to y to identify the points of maxima in the interior of U. We get

$$\frac{\partial C}{\partial y} = \frac{(4-p^2)(1-x^2)}{2211840}\Big(48px(7+4x) + p^3(83+60x-48x^2) - 96p^2(8-9x+x^2)y + 384(5-6x+x^2)y\Big).$$

Now $\partial C/\partial y = 0$ gives

$$y = y_0 := \frac{48px(7+4x) + p^3(83+60x-48x^2)}{96(1-x)(p^2(8-x)-4(5-x))}.$$

The existence of critical points require that y_0 belong to $(0,1)$, which is only possible when

$$83p^3 + 336px + 60p^3x + 192px^2 - 48p^3x^2 < 96(-1+x)(20-8p^2-4x+p^2x). \tag{3.6}$$

Now, we find the solution satisfying the inequality (3.6) for the existence of critical points using the hit and trial method. If we assume p tends to 0, then there does not exist any $x \in (0,1)$ satisfying (3.6). But, when p tends to 2, (3.6) holds only when $x < 61/288$. Similarly, if we assume x tends to 0, then for all $p > 1.75665$, (3.6) holds. After calculations, we observe that there does not exist any $x \in (0,1)$ when $p \in (0, 1.75665)$. Thus, the domain for the solution is $(1.75665, 2) \times (0, 61/288)$. Now, we examine that $\frac{\partial C}{\partial y}|_{y=y_0} \neq 0$ in $(1.75665, 2) \times (0, 61/288)$. So, we conclude that the function M has no critical point in $(0,2) \times (0,1) \times (0,1)$.

(2) The interior of each of the cuboid S's six faces is now being considered.

On $p = 0$

$$m_1(x,y) := \frac{20x^3 + 12(1-x^2)(5+x^2)y^2 + 72x(1-x^2)(1-y^2)}{34560}, \quad x,y \in (0,1). \tag{3.7}$$

Since

$$\frac{\partial m_1}{\partial y} = \frac{(1-x)^2(x+1)(5-x)y}{1440} \neq 0, \quad x,y \in (0,1),$$

indicates that m_1 has no critical points in $(0,1) \times (0,1)$.

On $p = 2$

$$C(2,x,y) := \frac{1157}{6635520} \approx 0.000174365, \quad x,y \in (0,1). \tag{3.8}$$

On $x = 0$

$$m_2(p,y) := \frac{1157p^6 + (4-p^2)(15936p^3y + 46080(4-p^2)y^2 + 27648p^2(1-y^2))}{424673280} \tag{3.9}$$

with $p \in (0,2)$ and $y \in (0,1)$. To determine the points of maxima, we solve $\partial m_2/\partial p = 0$ and $\partial m_2/\partial y = 0$. After solving $\partial m_2/\partial y = 0$, we get

$$y = \frac{83p^3}{384(2p^2-5)} =: y_p. \tag{3.10}$$

In order to have $y_p \in (0,1)$ for the given range of y, $p_0 := p > \approx 1.75665$ is required. Based on calculations, $\partial m_2/\partial p = 0$ gives

$$36864p - 18432p^3 + 1157p^5 + 31872p^2y - 13280p^4y - 159744py^2 + 49152p^3y^2 = 0. \tag{3.11}$$

On substituting equation (3.10) into equation (3.11), we have

$$1843200p - 2396160p^3 + 1021152p^5 - 152402p^7 + 2367p^9 = 0. \tag{3.12}$$

A numerical calculation suggests that $p \approx 1.28894 \in (0,2)$ is the solution of (3.12). So, we conclude that m_2 does not have any critical point in $(0,2)\times(0,1)$.
On $x=1$

$$C(p,1,y) = m_3(p,y) := \frac{245760 + 177408p^2 - 62688p^4 + 1901p^6}{424673280}, \quad p \in (0,2). \tag{3.13}$$

While computing $\partial m_3/\partial p = 0$, $p_0 := p \approx 1.23293$ comes out to be the critical point. After simple calculations, m_3 achieves its maximum value ≈ 0.000888358 at p_0.
On $y=0$

$$\begin{aligned} m_4(p,x) :=& \frac{1}{424673280}\Big(49152x(18-13x^2) + 2304p^2(48 - 192x + 37x^2 + 168x^3 \\ &+ 16x^4) - 96p^4(288 - 707x + 400x^2 + 480x^3 + 192x^4) \\ &+ p^6(1157 - 3144x + 4272x^2 - 2688x^3 + 2304x^4)\Big). \end{aligned}$$

After further calculations such as

$$\begin{aligned} \frac{\partial m_4}{\partial x} =& \frac{(4-p^2)}{17694720}\Big(1536(6-13x^2) - 48p^2(48 - 37x - 148x^2 - 32x^3) \\ &+ p^4(131 - 356x + 336x^2 - 384x^3)\Big) \end{aligned}$$

and

$$\begin{aligned} \frac{\partial m_4}{\partial p} =& \frac{1}{70778880}\Big(768p(48 - 192x + 37x^2 + 168x^3 + 16x^4) - 64p^3(288 - 707x \\ &+ 400x^2 + 480x^3 + 192x^4) + p^5(1157 - 3144x + 4272x^2 - 2688x^3 \\ &+ 2304x^4)\Big), \end{aligned}$$

we observe that only real solutions (p,x) of the system of equations $\partial m_4/\partial x = 0$ and $\partial m_4/\partial p = 0$ are $(3.85748, 0.257377)$, $(3.76933, 0.0851082)$, $(-3.76933, 0.0851082)$, $(2, -0.644779)$, $(-3.85748, 0.257377)$, $(-1.57205, -1.03976)$, $(-2, -0.644779)$, $(0, -0.679366)$, $(0, 0.679366)$, $(-1.12904, 0.941715)$ and $(1.57205, -1.03976)$. Thus, no solution exists in $(0,2)\times(0,1)$, resulting in no critical points.
On $y=1$

$$\begin{aligned} m_5(p,x) :=& \frac{1}{424673280}\Big\{1157p^6 + 3144p^4(4-p^2)x + 27648p^2(4-p^2)x^2 \\ &+ 1056p^4(4-p^2)x^2 + 5328p^2(4-p^2)^2x^2 + 6912p^4(4-p^2)x^3 \\ &+ 15360(4-p^2)^2x^3 + 4224p^2(4-p^2)^2x^3 + 2304p^2(4-p^2)^2x^4 \\ &- 9216(4-p^2)(1-x^2)(-4(5+x^2) + p^2(5-3x+x^2)) \\ &+ 192(4-p^2)(1-x^2)(48px(7+4x) + p^3(83 + 60x - 48x^2))\Big\}. \end{aligned}$$

After calculations,

$$\frac{\partial m_5}{\partial p} = \frac{1}{70778880}\Big(6144x(7+4x-7x^2-4x^3) - 768p(160-48x-213x^2+72x^3-48x^4) - 160p^4(83+60x-131x^2-60x^3+48x^4) + 384p^2(83-24x-179x^2 + 24x^3+96x^4) + 64p^3(480-157x-1072x^2+384x^3-288x^4) + p^5(1157-3144x+4272x^2-2688x^3+2304x^4)\Big)$$

and

$$\frac{\partial m_5}{\partial x} = \frac{(4-p^2)}{17694720}\Big(1536x(5x-8-4x^2) + 384p(7+8x-21x^2-16x^3) + 48p^2(24 + 149x-68x^2+64x^3) + 16p^3(30-131x-90x^2+96x^3) + p^4(131-356x+336x^2-384x^3)\Big),$$

we observe that only real solutions (p, x) of the system of equations $\partial m_5/\partial x = 0$ and $\partial m_5/\partial p = 0$ are $(27.1136, 0.413453)$, $(-1.50007, -6.38485)$, $(2.68178, 5.28944)$, $(2, 1.39993)$, $(-1.80124, -0.775344)$, $(-4.98296, 1.51367)$, $(-2.89665, 3.0885)$, $(2, -0.192442)$, $(0, 0)$, $(-1.74974, 0.159528)$, $(-2, 0.737618)$, $(-0.776187, 0.905316)$, $(1.6981, -0.807967)$, $(2, -1.20749)$ and $(1.5135, -0.953552)$. Thus, no solution exists in $(0, 2) \times (0, 1)$, resulting in no critical points.

(3) We next examine the maxima attained by $C(p, x, y)$ on the edges of the cuboid S.
From (3.9), we have $M(p, 0, 0) = g_1(p) := (110592p^2 - 27648p^4 + 1157p^6)/424673280$. It is easy to observe that $g_1'(p) = 0$ whenever $p = \delta_0 := 0$ and $p = \delta_1 := 1.53142 \in [0, 2]$ as its points of minima and maxima respectively. Hence,

$$C(p, 0, 0) \leq 0.0002878, \quad p \in [0, 2].$$

Now consider (3.9) at $y = 1$, we get $C(p, 0, 1) = g_2(p) := (737280 - 368640p^2 + 63744p^3 + 46080p^4 - 15936p^5 + 1157p^6)/424673280$. It is easy to observe that $g_2'(p) < 0$ in $[0, 2]$ and hence $p = 0$ serves as the point of maxima. So,

$$C(p, 0, 1) \leq \frac{1}{576} \approx 0.00173611, \quad p \in [0, 2].$$

Through computations, (3.9) shows that $C(0, 0, y) = y^2/576$ attains its maxima at $y = 1$. This implies that

$$C(0, 0, y) \leq \frac{1}{36}, \quad y \in [0, 1].$$

Since, (3.13) does not involve x, we have $C(p, 1, 1) = C(p, 1, 0) = g_3(p) := (245760 + 177408p^2 - 62688p^4 + 1901p^6)/424673280$. Now, $g_3'(p) = 354816p - 250752p^3 + 11406p^5 = 0$ when $p = \delta_2 := 0$ and $p = \delta_3 := 1.23293$ in the interval $[0, 2]$ with δ_2 and δ_3 as points of minima and maxima, respectively. Hence

$$C(p, 1, 1) = C(p, 1, 0) \leq 0.000888358, \quad p \in [0, 2].$$

After considering $p = 0$ in (3.13), we get, $C(0, 1, y) = 1/1728 \approx 0.000578704$.
The equation (3.8) has no variables. So, on the edges, the maximum value of $C(p, x, y)$ is

$$C(2, 1, y) = C(2, 0, y) = C(2, x, 0) = C(2, x, 1) = \frac{1157}{6635520}, \quad x, y \in [0, 1].$$

Using (3.7), we obtain $C(0,x,1) = g_4(x) := (15-12x^2+5x^3-3x^4)/8640$. Upon calculations, we see that $g_4(x)$ is a decreasing function in $[0,1]$ and attains its maxima at $x=0$. Hence

$$C(0,x,1) \leq \frac{1}{576}, \quad x \in [0,1].$$

Again utilizing (3.7), we get $C(0,x,0) = g_5(x) := x(18-13x^2)/8640$. On further calculations, we get $g_5'(x) = 0$ for $x = \delta_4 := \sqrt{6/13}$. Also, $g_5(x)$ increases in $[0,\delta_4)$ and decreases in $(\delta_4,1]$. So, it reaches its maximum value at δ_4. Thus

$$C(0,x,0) \leq 0.000943564, \quad x \in [0,1].$$

Given all the cases, the inequality (3.4) holds. Let the function $f_1(z) \in \mathcal{C}_{\mathcal{B}}$, be defined as

$$f_1(z) = \int_0^z \left(\exp\left(\int_0^t \frac{\sqrt{1+\tanh u^3}-1}{u} du \right) \right) dt = z + \frac{z^4}{24} - \frac{z^7}{1008} - \cdots, \tag{3.14}$$

with $f_1(0) = 0$ and $f_1'(0) = 1$, acts as an extremal function for the bound of $|H_3(1)|$ for $a_2 = a_3 = a_5 = 0$ and $a_4 = 1/24$. ∎

Theorem 3.2. *Let $f \in \mathcal{C}_{\mathcal{B}}$, then*

$$|H_2(3)| \leq \frac{1}{576}. \tag{3.15}$$

This bound is sharp.

Proof. We proceed on the similar lines as in the proof of Theorem 2.5. Assuming $p_1 =: p \in [0,2]$, we substitute the values of $a_i's (i = 3,4,5)$ from (3.2) and (3.3) in (1.5), we obtain

$$H_2(3) = \frac{1}{424673280}\Big(-1853p^6 - 1488p^4p_2 + 1728p^2p_2^2 - 110592p_2^3 + 31872p^3p_3 + 119808pp_2p_3 - 184320p_3^2 - 82944p^2p_4 + 221184p_2p_4 \Big).$$

Using (2.11)-(2.13) for simplification, we arrive at

$$H_2(3) = \frac{1}{424673280}\Big(\beta_{13}(p,\gamma) + \beta_{14}(p,\gamma)\eta + \beta_{15}(p,\gamma)\eta^2 + \beta_{16}(p,\gamma,\eta)\rho \Big),$$

where $\gamma, \eta, \rho \in \mathbb{D}$,

$$\begin{aligned}
\beta_{13}(p,\gamma) :&= -1109p^6 - 15696\gamma^2p^2(4-p^2)^2 + 3456\gamma^3p^2(4-p^2)^2 + 2304\gamma^4p^2(4-p^2)^2 \\
&\quad + 13824\gamma^2p^2(4-p^2) - 2376\gamma p^4(4-p^2) - 10272p^4\gamma^2(4-p^2) + 3456p^4\gamma^3(4-p^2), \\
\beta_{14}(p,\gamma) :&= 192(1-|\gamma|^2)(4-p^2)(71p^3 - 72p^3\gamma - 36p\gamma(4-p^2) - 48p\gamma^2(4-p^2)), \\
\beta_{15}(p,\gamma) :&= 4608(1-|\gamma|^2)(4-p^2)(-10(4-p^2) - 3p^2\bar{\gamma} - 2|\gamma|^2(4-p^2)) \\
\beta_{16}(p,\gamma,\eta) :&= 13824(1-|\gamma|^2)(4-p^2)(1-|\eta|^2)(p^2 + 4\gamma(4-p^2)).
\end{aligned}$$

Additionally, by using the fact that $|\rho| \leq 1$, and taking $x = |\gamma|$, $y = |\eta|$, we have

$$|H_2(3)| \leq \frac{1}{424673280}\Big(|\beta_{13}(p,\gamma)| + |\beta_{14}(p,\gamma)|y + |\beta_{15}(p,\gamma)|y^2 + |\beta_{16}(p,\gamma,\eta)| \Big) \leq D(p,x,y),$$

where

$$D(p,x,y) = \frac{1}{424673280}\Big(d_1(p,x) + d_2(p,x)y + d_3(p,x)y^2 + d_4(p,x)(1-y^2) \Big), \tag{3.16}$$

with

$$\begin{aligned}
d_1(p,x) :&= 1109p^6 + 15696p^2x^2(4-p^2)^2 + 3456p^2x^3(4-p^2)^2 + 2304p^2x^4(4-p^2)^2 \\
&\quad + 13824p^2x^2(4-p^2) + 2376p^4x(4-p^2) + 10272p^4x^2(4-p^2) + 3456p^4x^3(4-p^2),\\
d_2(p,x) :&= 192(4-p^2)(1-x^2)(71p^3 + 72p^3x + 36px(4-p^2) + 48px^2(4-p^2)),\\
d_3(p,x) :&= 4608(4-p^2)(1-x^2)(10(4-p^2) + 3p^2x + 2x^2(4-p^2)),\\
d_4(p,x) :&= 13824(4-p^2)(1-x^2)(p^2 + 4x(4-p^2)).
\end{aligned}$$

Now, we must maximise $D(p,x,y)$ in the closed cuboid $T : [0,2]\times[0,1]\times[0,1]$. By identifying the maximum values on the twelve edges, the interior of T, and the interiors of the six faces, we can prove this.

(1) We start by taking into account, every interior point of T. Assume that $(p,x,y) \in (0,2)\times(0,1)\times(0,1)$. We partially differentiate (3.16) with respect to y in order to locate the points of maxima in the interior of T. We obtain

$$\frac{\partial D}{\partial y} = \frac{(1-x^2)}{2211840}(4-p^2)\Big(48px(3+4x) + p^3(71+36x-48x^2) + 384(5-6x+x^2)y - 48p^2(13-15x+2x^2)y\Big).$$

Now $\partial D/\partial y = 0$ gives

$$y = y_1 := \frac{48px(3+4x) + p^3(71+36x-48x^2)}{48(1-x)(8(x-5)+p^2(13-2x))}.$$

Since y_1 must be a member of $(0,1)$ for critical points to exist, this is only possible if

$$71p^3 + px(144 + 36p^2 + 192x - 48p^2x) < 48(-40 + 13p^2 + x(48 - 15p^2 - 8x + 2p^2x)). \quad (3.17)$$

Now, we find the solutions satisfying the inequality (3.17) for the existence of critical points using hit and trial method. If p tends to 2, then (3.17) holds whenever $x < 1/144$. Also, no such $x \in (0,1)$, satisfying (3.17) when p tends to 0. Similarly, if take x tending to 0, then (3.17) holds for $p > 1.99513$ only, whereas there does not exist any $p \in (0,2)$ such that equation (3.17) holds when x tends to 1. Thus, the domain for the solution of the equation is $(1.99513, 2)\times(0, 1/144)$. Now, we examine that $\frac{\partial D}{\partial y}|_{y=y_0} \neq 0$ in $(1.99513,2)\times(0,1/144)$. So, we conclude that the function M has no critical point in $(0,2)\times(0,1)\times(0,1)$.

(2) Now, we study the interior of each of six face of the cuboid T.

On $p = 0$

$$n_1(x,y) := \frac{(1-x^2)(5y^2 + x^2y^2 + 6x(1-y^2))}{2880}, \quad (3.18)$$

with $x, y \in (0,1)$. We note that, in $(0,1)\times(0,1)$, $n_1(x,y)$ does not have any critical point. As

$$\frac{\partial n_1}{\partial y} = \frac{(1-x^2)(x-1)(x-5)y}{1440} \neq 0 \quad x,y \in (0,1).$$

On $p = 2$

$$D(2,x,y) := \frac{1109}{6635520} \approx 0.000167131, \quad x,y \in (0,1). \quad (3.19)$$

On $x = 0$

$$n_2(p,y) := \frac{1109p^6 + (4-p^2)(13632p^3y + 46080(4-p^2)y^2 + 13824p^2(1-y^2))}{42467328} \quad (3.20)$$

with $p \in (0,2)$ and $y \in (0,1)$. We solve $\partial n_2/\partial p$ and $\partial n_2/\partial y$ to locate the points of maxima. On solving $\partial n_2/\partial y = 0$, we obtain

$$y = \frac{71p^3}{48(13p^2-40)} (=: \epsilon). \tag{3.21}$$

For the given range of y, we should have $\epsilon \in (0,1)$ which is possible only when $p > p_0 :\approx 1.99513 \in (0,2)$ exists. On computations, $\partial n_2/\partial p = 0$ gives

$$18432p - 9216p^3 + 1109p^5 + 27264p^2y - 11360p^4y - 141312py^2 + 39936p^3y^2 = 0. \tag{3.22}$$

On substituting (3.21) in (3.22), we get,

$$88473600p - 101744640p^3 + 38582784p^5 - 5470944p^7 + 169065p^9 = 0. \tag{3.23}$$

The solution of (3.23) in the interval $(0,2)$ is $p \approx 1.34821$, according to a numerical calculation. In $(0,2)\times(0,1)$, n_2 does not have a critical point.

On $x = 1$

$$n_3(p,y) := D(p,1,y) = \frac{398592p^2 - 121056p^4 + 6461p^6}{424673280}, \quad p \in (0,2). \tag{3.24}$$

And when computing $\partial n_3/\partial p = 0$, $p =: p_0 \approx 1.39681$ turns out to be the critical point. According to elementary calculations, n_3 reaches its maximum value ≈ 0.000859123 at p_0.

On $y = 0$

$$\begin{aligned} n_4(p,x) :=& \frac{1}{424673280}\Big(884736x(1-x^2) + 2304p^2(24 - 192x + 109x^2 + 216x^3 + 16x^4) \\ &- 96p^4(144 - 675x + 880x^2 + 720x^3 + 192x^4) \\ &+ p^6(1109 - 2376x + 5424x^2 + 2304x^4)\Big) = D(p,x,0). \end{aligned}$$

On computations,

$$\begin{aligned} \frac{\partial n_4}{\partial x} =& \frac{(4-p^2)}{17694720}\Big(9216(1-3x^2) - 48p^2(48 - 109x - 180x^2 - 32x^3) \\ &+ p^4(99 - 452x - 384x^3)\Big) \end{aligned}$$

and

$$\begin{aligned} \frac{\partial n_4}{\partial p} =& \frac{1}{70778880}\Big(768p(24 - 192x + 109x^2 + 216x^3 + 16x^4) \\ &- 64p^3(144 - 675x + 880x^2 + 720x^3 + 192x^4) \\ &+ p^5(1109 - 2376x + 5424x^2 + 2304x^4)\Big), \end{aligned}$$

we observe that only real solutions (p,x) of the system of equations $\partial n_4/\partial x = 0$ and $\partial n_4/\partial p = 0$ are $(-2,-2.72495)$, $(-2.64507,-0.503718)$, $(-2.23927,-0.0103472)$, $(-2,-0.163482)$, $(2.23927,-0.0103472)$, $(-2.00568,-0.120347)$, $(2,-2.72495)$, $(-2,-0.0837889)$, $(0,-0.57735)$, $(2,-0.0837889)$, $(2.00568,-0.120347)$, $(2,-0.163482)$, $(2.64507,-0.503718)$ and $(-0.91207,0.721981)$. Thus, no solution exists in $(0,2)\times(0,1)$, resulting in no critical points.

On $y = 1$

$$n_5(p,x) := \frac{1}{424673280}\Big(36864px(3+4x-3x^2-4x^3)+147456(5-4x^2-x^4) \\ -2304p^2(160-24x-261x^2-48x^4)+768p^3(71-167x^2+96x^4) \\ -192p^5(71+36x-119x^2-36x^3+48x^4)-96p^4(-480+45x \\ +1408x^2+288x^4)+p^6(1109-2376x+5424x^2+2304x^4)\Big).$$

On computations,

$$\frac{\partial n_5}{\partial x} = \frac{(4-p^2)}{17694720}\Big(-6144x(2+x^2)+384p(3+8x-9x^2-16x^3) \\ +48p^2(12+197x+64x^3)+16p^3(18-119x-54x^2+96x^3) \\ +p^4(99-452x-384x^3)\Big)$$

and

$$\frac{\partial n_5}{\partial p} = \frac{1}{70778880}\Big(6144x(3+4x-3x^2-4x^3)+768p(-160+24x+261x^2+48x^4) \\ -160p^4(71+36x-119x^2-36x^3+48x^4)+384p^2(71-167x^2+96x^4) \\ +64p^3(480-45x-1408x^2-288x^4)+p^5(1109-2376x \\ +5424x^2+2304x^4)\Big),$$

we observe that only real solutions (p,x) of the system of equations $\partial n_5/\partial x = 0$ and $\partial n_5/\partial p = 0$ are $(10.6873, 0.22889)$, $(-2,-2.84595)$, $(2.70664, 2.22228)$, $(2, 2.03047)$, $(0,0)$, $(-2,-0.783981)$, $(2,-0.385354)$, $(-1.77349, 0.0460014)$, $(2,-0.64512)$, $(1.98564,-0.516895)$, $(2.00568,-0.120347)$, $(2, 0.657704)$, $(-2.33662,-1.5235)$, $(-1.03494, 0.828224)$ and $(1.36475,-1.03084)$. Thus, no solution exists in $(0,2)\times(0,1)$, resulting in no critical points.

(3) Now, we calculate the maximum values achieved by $D(p,x,y)$ on the edges of the cuboid T. From equation (3.20), we have $D(p,0,0) = h_1(p) := (55296p^2-13824p^4+1109p^6)/424673280$. It is easy to observe that $h_1'(p) = 0$ for $p = \delta_0 := 0$ and $p = 1.83094$ in the interval $[0,2]$.

$$D(p,0,0) \le 0.000169059.$$

Now considering (3.20) at $y = 1$, we get $D(p,0,1) = h_2(p) := (737280 - 368640p^2 + 54528p^3 + 46080p^4 - 13632p^5 + 1109p^6)/424673280$. It is easy to observe that $t_2'(p)$ is a decreasing function in $[0,2]$ and hence $p = 0$ acts as its point of maxima. Thus

$$D(p,0,1) \le \frac{1}{576} = 0.00173611, \quad p \in [0,2].$$

Through computations, (3.20) shows that $D(0,0,y) = y^2/576$, attains its maximum value at $y = 1$. This implies that

$$D(0,0,y) \le \frac{1}{576}, \quad y \in [0,1].$$

Since, (3.24) is independent of x, we have $D(p,1,1) = D(p,1,0) = h_3(p) := (398592p^2 - 121056p^4 + 6461p^6)/424673280$. Now, $h_3'(p) = 294912p - 175680p^3 + 13206p^5 = 0$ when

$p = \delta_2 := 0$ and $p = \delta_3 := 1.39681$ in the interval $[0, 2]$ with δ_2 and δ_3 as points of minima and maxima, respectively. Hence

$$D(p, 1, 1) = D(p, 1, 0) \leq 0.000859123, \quad p \in [0, 2].$$

On substituting $p = 0$ in (3.24), we get, $D(0, 1, y) = 0$. The equation (3.19) is independent of the all the variables namely p, x and y. Thus the maximum value of $D(p, x, y)$ on the edges $p = 2, x = 1; p = 2, x = 0; p = 2, y = 0$ and $p = 2, y = 1$, respectively, is given by

$$D(2, 1, y) = D(2, 0, y) = D(2, x, 0) = D(2, x, 1) = \frac{1109}{6635520}, \quad x, y \in [0, 1].$$

From (3.20), we obtain $D(0, 0, y) = y^2/576$. A simple calculation shows that

$$D(0, 0, y) \leq \frac{1}{576}, \quad y \in [0, 1].$$

Using (3.18), we obtain $D(0, x, 1) = h_4(x) := (5 - 4x^2 - x^4)/2880$. Upon calculations, we see that h_4 is a decreasing function in $[0, 1]$ and hence attains its maximum value at $x = 0$. Thus

$$D(0, x, 1) \leq \frac{1}{576}, \quad x \in [0, 1].$$

On again using (3.18), we get $D(0, x, 0) = h_5(x) := x(1-x^2)/480$. On further calculations, we get $t_5'(x) = 0$ for $x = \delta_4 := 1/\sqrt{3}$. Also, $h_5(x)$ is an increasing function in $[0, \delta_4)$ and decreasing in $(\delta_4, 1]$. So, it attains its maximum value at δ_4. Thus

$$D(0, x, 0) \leq 0.000801875, \quad x \in [0, 1].$$

In view of all the cases, the inequality (3.15) holds. The function specified in (3.14) acts as an extremal function for the bounds of $|H_2(3)|$ having values $a_3 = a_5 = 0$ and $a_4 = 1/24$. ∎

Online-Learning-Based Multi-RIS-Aided Wireless Systems

Ishaan Sharma, Rohit Kumar, and Sumit J. Darak, *Senior Member, IEEE*

***Abstract*—The evolution of software-defined radios and reconfigurable intelligent surfaces (RIS) has enabled on-the-fly control and reconfigurability at the physical layer parameters and radio propagation environment. In multi-RIS-aided communication, the RIS block, comprising a certain number of RIS elements from one or more RIS, is selected to achieve high throughput reliable communication between transmitter and receiver. However, selecting an RIS block when there are multiple RIS and receivers is not trivial due to the large number of candidate blocks. In this article, a novel multiarmed bandit (MAB) framework, which can learn and select the optimal RIS block using focused exploration, is proposed. We provide the theoretical regret bound for the proposed algorithm and demonstrate the gain in performance over existing state-of-the-art statistical and MAB approaches via detailed simulation results in terms of rate, ergodic capacity, outage probability, energy efficiency, and received SNR. The proposed algorithm offers 33%–85% lower latency than existing MAB algorithms on various edge platforms. Furthermore, the gain in performance and latency improves with the increase in the number and size of the RIS in the network.**

***Index Terms*—Multiarmed bandit (MAB), multi-reconfigurable intelligent surface (RIS), RIS, upper confidence bound (UCB).**

I. Introduction

AFTER an initial breakthrough in the evolution of analog radio to digital radio, there have been exciting contributions to making digital radio software-controlled and software-defined. This is followed by intelligent radio evolution in which the radio parameters, such as carrier frequency, bandwidth, number of antennas, beam directions, and various physical layer parameters can be controlled on the fly [1], [2]. One well-known example of such intelligent radio is cognitive radio, through which dynamic spectrum access has become a reality [2]. Still, there is limited control over the radio propagation environment, and it limits the performance of cellular networks, resulting in poor throughput and a large number of call drops. In the last few years, we have seen significant interest in making the radio environment smart and controllable due to its potential to improve network performance and cellular coverage [3]. Specifically, the aim is to exploit smart radio's on-the-fly configuration capabilities by controlling the transmitted signal's reflection, scattering, and refraction to improve the network performance. One potential solution is reconfigurable intelligent surfaces (RISs) comprised of multiple passive metamaterial reflecting elements [4]. By controlling the amplitude and phase of these elements via the controller, we can redirect the transmitted signal in the direction of the intended receivers [5], [6]. Various studies showed that the RIS offers higher reliability, improved throughput, and low-cost solutions by reducing the number of RF chains in massive antenna systems and enabling full-duplex communication [7], [8]. Other RIS applications include improved security [9] and target localization [10]. The challenges related to channel estimation due to many RIS elements and robust beamforming due to imperfect channel state information (CSI) were also considered in the literature [11], [12]. In beyond 5G applications, RIS was explored for improving the coverage of millimeter wave (mmWave) systems where propagation loss is significant [13]. Recent works discussed channel modeling for RIS-based communication in the Terahertz (THz) spectrum [14]. In [9], [15], and [16], machine learning and deep learning algorithms were explored to improve the performance of RIS-based communication.

Recently, few works have considered multiple RIS to improve the throughput and reliability of communication links. In [17], cooperative beamforming design for multi-RIS-aided systems was discussed along with channel modeling. They demonstrated the superiority of distributed RIS over centralized RIS. In [18], an efficient pilot transmission method was proposed to enable the receiver to separate signals arriving from different RIS, which further helps in estimating the channel state and localization. In [19], the challenge of timing synchronization between multiple RIS was addressed while the accurate configuration of multiple RIS, especially in mmWave multiantenna system, was discussed in [20]. In [21], the application of stochastic geometry aided robust beamforming approach showed improved performance of the multi-RIS-aided system in mmWave. The accurate channel estimation in an RIS-aided system is challenging. A robust transceiver design for the multi-RIS assisted multiantenna system with erroneous channel estimation was discussed in [22]. In [23], a multiple RIS-assisted multihop communication system, in which multiple RISs work in a domino pattern, was explored along with closed-form expressions for ergodic capacity and the outage probability. In [24], the need

for backhaul support for the feasibility of a multi-RIS system was highlighted. Recent works demonstrated the usefulness of a multi-RIS-aided system for indoor THz wireless communication in the presence of mobile human blockage [25] and for vehicular communication [26]. Do et al. [27] considered a multi-RIS-aided communication system and proposed two schemes for RIS selection. In the first scheme, exhaustive RIS-aided (ERA), all RIS were used, while in the second scheme, ORA scheme, single optimal RIS was used. Yang et al. [28] considered relay-aided communication systems using multiple RIS and compared the gain in outage probability. However, most of these works assume prior knowledge of perfect CSI.

To address scalability issues, prior knowledge of CSI and RIS selection, the multiarmed bandit (MAB) framework was explored in the literature [29], [30]. MAB framework-based online learning algorithms are a type of reinforcement learning in which the player needs to learn and select the optimal arm as many times as possible. Since the arm statistics are unknown, the algorithm must optimally satisfy the exploration–exploitation tradeoff. MAB algorithms are being used extensively to develop learning algorithms for decision-making due to their analytical traceability. Furthermore, they are compute and memory efficient and do not need prior training like machine learning and deep learning algorithms [31]. Popular wireless applications of MAB-based decision-making include cognitive radio networks [32], [33], Energy harvesting networks [34], mmWave communications [29], [35], massive multiantenna system [36], [37], and 5G cellular networks [38]. We focus on the stochastic setting where classical bandit algorithms like upper confidence bound (UCB) [39], KL-UCB [40], and Thompson sampling [41] are applied to networks by suitably mapping actions (channels, modulations schemes, power level, RIS) to arms and quantity interests (success rate, throughput) to rewards to obtain learning algorithms. Recently, MAB algorithms were used for the selection of RIS in cellular Internet-of-Things, unmanned aerial vehicle, and mmWave applications in [29], [30], and [42], respectively. As discussed later in Section III-B, direct application of MAB algorithm for RIS selection in multi-RIS-aided system results in the poor performance. To the best of authors' knowledge, the design of MAB algorithms for multi-RIS-aided wireless systems has not been discussed yet in the literature. The MAB problem setup for multiple receivers is not trivial. This work aims to develop a new efficient MAB algorithm for wireless systems comprised of multiple RIS and receivers. We analyze the performance of the proposed algorithm via theoretical, simulation, and experimental results on the edge platform. In Table I, we compare various state-of-the-art works in the literature, and our contributions are summarized as follows.

1) In this work, we set up the RIS selection problem in a multi-RIS-aided system with multiple receivers as an MAB framework where each arm corresponds to one or more RIS with a certain number of passive elements. The aim is to learn the optimal combination of RIS and their elements that offer higher average SNR/throughput. Since the number of RIS blocks can be significantly large, resulting in higher exploration time of the conventional MAB algorithm, we exploit the sparsity to significantly reduce the number of candidate blocks by preidentifying the blocks whose average throughput is above a given threshold. We demonstrate the gain in performance over existing state-of-the-art approaches via theoretical and simulation results.
2) We propose two MAB algorithms: focused exploration UCB (FEUCB) and Enhanced focused exploration UCB (EFEUCB) algorithms. We compare the performance with existing learning and nonlearning-based approaches in terms of various performance metrics, such as regret, rate, outage probability, ergodic capacity, energy efficiency, transmit power, and consumed power.
3) We compare the performance of the centralized RIS and distributed RIS systems and demonstrate the superiority of the distributed multi-RIS-aided system for multiple-user cases.
4) In time-slotted communication, faster RIS selection allows more time for data communication, resulting in higher throughput. To analyze this, we design and implement the proposed and existing MAB-based RIS selection algorithms on various embedded edge platforms, such as ARM Cortex A9 and ARM Cortex A53 processors augmented with single instruction multiple data (SIMD) coprocessors. We study the effect of word length on the latency, i.e., execution time, of the algorithms. We demonstrate the lower execution time of the proposed algorithms compared to the state-of-the-art MAB algorithms.

The rest of this article is organized as follows. Section II discusses the network model, followed by the details of the proposed algorithms and regret analysis in Section III. Detailed simulation results are presented in Section IV followed by experimental results on the edge platform in Section V. Finally, Section VI concludes this article.

II. NETWORK MODEL

This work considers the multi-RIS-aided system comprising one transmitter, K RIS, and N receivers. Each RIS is divided into L sub-blocks, and each sub-block consists of Z sub-λ sized passive RIS elements (Fig. 1). We consider the time-slotted communication where the transmitter must select M out of KL sub-blocks in each time slot. Thus, there are $R=\binom{\mathrm{KL}}{M}$ combinations of M sub-blocks. The combination of any M sub-blocks is referred to as a block. For the chosen block, the amplitude, $A \in [0, 1]$, and phase, $\theta \in [0, 2\pi]$, of all elements are optimally configured to establish the communication with N

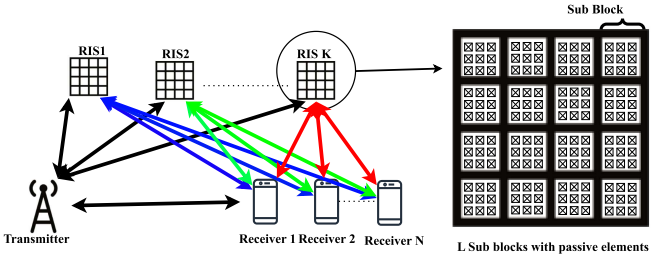

Fig. 1. Illustrations of network model for multi-RIS-aided wireless system.

receivers. We denote the block selected in the time slot, t, as $I_t \in [R] := \{1, 2, \ldots, R\}$. Note that the size of each sub-block and the number of sub-blocks per RIS are not fixed. Without loss of generality, our framework allows the transmitter to select more than one RIS in a given slot by having the sub-blocks in I_t from the same or multiple RIS.

We consider the channel model in [27], where channels associated with elements of the same RIS are assumed to be independent and identically distributed. In contrast, channels associated with different RISs are assumed to be independent but not identically distributed, and the system undergoes Nakagami-m fading. The complex channel coefficient between the transmitter and zth element of the RIS sub-block, r, is defined in the polar form as $\tilde{G}_{klz} = G_{klz}e^{j\psi_{klz}}$ where G_{klz} and ψ_{klz} denote the magnitude and phase, respectively. Similarly, the channel between the zth element of the RIS sub-block, r, and nth receiver is defined in the polar form as $\tilde{H}_{klnz} = H_{klnz}e^{j\phi_{klnz}}$ where H_{klnz} and ϕ_{klnz} denote the magnitude and phase, respectively. The channel coefficient along the direct path between the transmitter and nth receiver is $\tilde{G}_n = G_n e^{j\psi_n}$ where G_n and ψ_n denote the magnitude and phase, respectively.

For transmit symbol, x_s with power, P_s in dBm, the received signal at the nth receiver using the RIS sub-block, m, is given by [27]

$$y_n^m = \sqrt{P_s}\left(\tilde{G}_n + \sum_{z=1}^{z=Z} \tilde{G}_{klz}\alpha_{klz}e^{j\theta_{klz}}\tilde{H}_{klnz}\right)x_s + \omega_n \quad (1)$$

where α_{klnz} and θ_{klnz} are the amplitude reflection coefficient and phase-shift of the zth element of the m. ω_n denotes the additive white Gaussian noise with zero mean and variance, σ_n^2. Then, the SNR at the nth receiver, assuming optimal RIS configuration with zero phase error, is given as

$$\text{SNR}_n^m = \frac{P_s}{\sigma_n^2}\left|G_n + \sum_{z=1}^{z=Z} G_{klz}\alpha_{klz}H_{klnz}\right|^2. \quad (2)$$

For reliable communication between the transmitter and all receivers, we need to select the block, i.e., M RIS sub-blocks, which cumulatively offer an average high cumulative SNR and guarantee that the SNR at each receiver is above a certain threshold, Δ

$$I_t = \arg\max_{\substack{I_t\in[R]\\|I_t|=M}} \left[\sum_{\substack{v=i_1\\v\in[I_t]}}^{i_M}\left(\prod_{n=1}^{N} 1_{\text{SNR}_n^r>\Delta}\sum_{n=1}^{N}\text{SNR}_n^r\right)\right] \quad (3)$$

where 1_{cond} is an indicator function. Selection of all RIS results in good throughput performance but extremely high power consumption. Since SNR over each sub-block is unknown, the selection of RIS block is not trivial; hence, we need a learning framework. Due to a large number of sub-blocks and multiple receivers, one-shot learning via deep learning is not scalable [43]. The MAB algorithm is well suited for scenarios where decisions have to be made in the face of uncertainty, and the objective is to maximize accumulated rewards over time. Although such sequential learning is a promising approach, it is time-consuming, and hence, efficient algorithms are needed.

III. Proposed Work

The selection of the RIS block in a multi-RIS-aided system with multiple receivers can be set up as an MAB problem where the aim is to select the optimal block as often as possible via exploration–exploitation trade off. In this section, we discuss the selection of optimal block for multiple receiver scenarios and the drawbacks of the existing MAB algorithms. We address these challenges using the proposed algorithms.

A. MAB Framework

The standard stochastic multiplay MAB consists of a set of arms and a single player. Here, we refer to RIS sub-blocks as arms and a player as a transmitter. In each time slot, a transmitter selects a block of M RIS sub-blocks and receives a reward equal to SNR at each receiver. For each receiver, the reward is assumed to be drawn independently across time from distributions that are stationary and independent across sub-blocks. We denote the mean reward of nth receiver for block, r as SNR_n^r, and hence, total reward in time slot, t is given as

$$X^{I_t} = \sum_{\substack{v=i_1\\v\in[I_t]}}^{i_M}\left(\prod_{n=1}^{N} 1_{\text{SNR}_n^r>\Delta}\sum_{n=1}^{N}\text{SNR}_n^r\right). \quad (4)$$

The performance metric for the MAB algorithm is regret, which compares the SNR degradation due to sub-optimal block selection, and it is given as

$$R = TX^{r_*} - \mathbb{E}\left[\sum_{\substack{r=1\\r\in[R]}}^{R} X^r S^r\right] \quad (5)$$

where T is the total number of time slots, S^r is the number of times the rth block is selected by base station (BS) and r_* is the optimal block, which offers highest SNR. The expectation is with respect to the random number of selections of the block S^r. Thus, the regret can be minimized by selecting r_*, i.e., the combination of M sub-blocks with the highest SNR as often as possible in a given horizon of size T.

B. Limitations of Existing MAB Framework

In this article, we limit our discussion to the UCB-based MAB algorithm [44] and provide regret bounds. The proposed idea can be easily extended to other MAB algorithms, such as UCB variants and Thompson Sampling. In the UCB algorithm, each

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 10,2024 at 09:44:39 UTC from IEEE Xplore. Restrictions apply.

This article has been accepted for inclusion in a future issue of this journal. Content is final as presented, with the exception of pagination.

block is selected once in the beginning. After that, in each time slot ($t > R$), the block that offers the highest UCB factor is selected. The UCB factor of the block, r, in time slot t is given as

$$\text{UCB}^r(t) = \frac{\hat{X}^r(t)}{S^r(t)} + 2\sqrt{\frac{\log(t)}{S^r(t)}} \tag{6}$$

where $\hat{X}^r(t)$ denotes the accumulated SNR obtained over $S^r(t)$ time slots during which UCB selects the block, r. The expected regret of the UCB scales as $\mathcal{O}(\sum_{r\in[R]\setminus r_*} \frac{\log T}{\Delta_r})$ [45] where $\Delta_r = X^{r_*} - X^r$ for all $r \neq r_*$. For fixed T, the distribution-independent bounds are of the order $\sqrt{RT}$ [45]. It is evident that the UCB suffers from high exploration time, especially when R is large.

C. Proposed MAB Algorithms

In the Multi-RIS-aided system with N receivers, the number of RIS blocks that offer reasonably good SNRs for all receivers simultaneously is expected to be limited, and hence, we can safely assume that $\hat{R} \leq R$ where $\hat{R}$ are good RIS blocks. In such a case, we can reduce the distribution-independent upper bound to $\sqrt{\hat{R}T}$ and develop the algorithms that satisfy this bound. In the proposed algorithm, inspired from [46], we focus on quickly identifying and exploring these $\hat{R}$ blocks, and it is referred to as the FEUCB algorithm. As shown in Algorithm 1, all the blocks are selected once initially (Lines 4–5). In the rest of the time slots, we check whether at least $\hat{R}$ blocks have been explored sufficiently till time t (Line 9). If not, we will use the conventional UCB algorithm with R blocks (Line 12). Otherwise, we restrict the UCB only to the selected $\hat{R}$ blocks that have been explored sufficiently. The set of blocks that are sufficiently explored is given as

$$\mathcal{E}(t) := \left\{ r \in [R] \middle| \hat{X}^r(t) \geq 2\sqrt{\frac{\log(t)}{S^r(t)}} \right\}. \tag{7}$$

The FEUCB algorithm aims to avoid selecting RIS blocks with poor SNR into the $\hat{R}$ blocks. This is done by ensuring that each of the selected $\hat{R}$ blocks has been sampled a sufficient number of times, as shown in (7). Using Theorem 1, we show that the proposed FEUCB algorithm satisfies logarithm regret, and the scaling factor depends on $\hat{R}$ instead of R, thereby outperforming the UCB algorithm.

Theorem 1: The FEUCB algorithm guarantees that the expected regret is upper bounded as

$$\mathbb{E}[R(T)] \leq \log(T) \sum_{r\in[\hat{R}]\setminus r_*} \frac{1}{\Delta_r}. \tag{8}$$

Proof: We define the following three events.

1) $A_r(t)$: An event of good RIS block, r, being selected during the UCB phase when $\hat{R}$ blocks are sampled sufficiently (Line 10).
2) $B_r(t)$: An event of good RIS block, r, being selected during the UCB phase when $\hat{R}$ blocks are not sampled sufficiently (Line 12).
3) $C_r(t)$: An event of poor RIS block, r, being selected.

Algorithm 1: FEUCB.

1: **Input:** $R, \hat{R}, T$
2: **Initialize:** $\hat{X}^r(t) \leftarrow 0$ and $S^r \leftarrow 0$ for all r
3: **for** $t = 1, 2 \ldots T$, **do**
4: **if** $t \leq R$ **then**
5: Select block, $I_t = t$.
6: **else**
7: $UCB^r(t) \leftarrow 0$ for all r
8: Compute $\mathcal{E}(t)$ using (7).
9: **if** $|\mathcal{E}(t)| \geq \hat{R}$ **then**
10: $\forall r \in [\mathcal{E}(t)]$: Update $UCB^r(t)$ as given in (6)
11: **else**
12: $\forall r \in [R]$ Update $UCB^r(t)$ as given in (6)
13: **end if**
14: Select block, $I_t = \arg\max_{r\in[R]} UCB^r(t)$
15: **end if**
16: Transmitter configures RIS block, I_t and transmits a data frame.
17: Each receiver observes instantaneous normalized SNR, and communicates to the transmitter, which calculates X^{I_t} using (4).
18: $S^{I_t} \leftarrow S^{I_t} + 1$ and $\hat{X}^r(t) \leftarrow \hat{X}^r(t) + X^{I_t}$.
19: **end for**

Then,

$$\begin{aligned}\mathbb{E}[R(T)] = 1 &+ \sum_{r\in[\hat{R}]\setminus r_*} \Delta_r \,\mathbb{E}\left[\sum_{t=1}^{T} 1_{A_r(t)}\right] \\ &+ \sum_{r\in[\hat{R}]\setminus r_*} \Delta_r \,\mathbb{E}\left[\sum_{t=1}^{T} 1_{B_r(t)}\right] \\ &+ \sum_{r\notin[\hat{R}]} \Delta_r \,\mathbb{E}\left[\sum_{t=1}^{T} 1_{C_r(t)}\right].\end{aligned} \tag{9}$$

The first term is during the initialization phase when each block is selected once. Using Lemma 1–3, we can independently upper bound each of the three terms

$$\begin{aligned}\mathbb{E}[R(T)] = 1 &+ \sum_{r\in[\hat{R}]\setminus r_*} \left(\frac{16\log(T)+8}{\Delta_r} + 3\right) + \frac{R\Delta_{\hat{R}}\pi^2}{6} \\ &+ \sum_{r\notin[\hat{R}]} \frac{\pi^2\Delta_r}{6}.\end{aligned} \tag{10}$$

■

Since all except the second terms are independent of T, the second term dominates the regret.

Lemma 1: The regret due to event $A_r(t)$ is given as

$$\mathbb{E}\left[\sum_{t=1}^{T} 1_{A_r(t)}\right] \leq \sum_{r\in[\hat{R}]\setminus r_*} \left(\frac{16\log(T)+8}{\Delta_r^2} + 3\right). \tag{11}$$

This article has been accepted for inclusion in a future issue of this journal. Content is final as presented, with the exception of pagination.

Proof: The proof is directly based on the UCB algorithm regret analysis in [44]. ■

Lemma 2: The regret due to event $B_r(t)$ is given as

$$\sum_{r\in[\hat{R}]\setminus r_*} \Delta_r \,\mathbb{E}\left[\sum_{t=1}^{T} 1_{B_r(t)}\right] \leq \frac{R\Delta_{\hat{R}}\pi^2}{6}. \tag{12}$$

Proof: The FEUCB algorithm uses the UCB algorithm over all RIS blocks when good $\hat{R}$ blocks are not sampled sufficiently. Since UCB is based on an exploration–exploitation tradeoff, the probability of this happening for the entire horizon is finite. Thus, the probability that a good RIS block is selected when good $\hat{R}$ blocks are not sufficiently sampled is finite.Assuming $\Delta_{\hat{R}} = \max_{r\in[\hat{R}]\setminus r_*}\Delta_r$, we have

$$\sum_{r\in[\hat{R}]\setminus r_*} \Delta_r \,\mathbb{E}\left[\sum_{t=1}^{T} 1_{B_r(t)}\right] \leq \Delta_{\hat{R}} \sum_{t=1}^{T} \mathbb{E}\left[\sum_{r\in[\hat{R}]\setminus r_*} 1_{B_r(t)}\right].$$

Then,

$$\mathbb{E}\left[\sum_{r\in[\hat{R}]} 1_{B_r(t)}\right] \leq \sum_{r\notin\hat{R}} \mathbb{P}\left[\hat{X}^r(S^r(t)) \geq 2\sqrt{\frac{\log(t)}{S^r(t)}}\right].$$

Using the Chernoff bound, we have

$$\mathbb{E}\left[\sum_{r\in[\hat{R}]} 1_{B_r(t)}\right] \leq \sum_{r\notin\hat{R}} \mathbb{P}\left[\hat{X}^r(S^r(t)) - X^r \geq 2\sqrt{\frac{\log(t)}{S^r(t)}}\right] \leq \sum_{r\notin\hat{R}} t^{-2}.$$

Thus

$$\sum_{r\in[\hat{R}]\setminus r_*} \Delta_r \,\mathbb{E}\left[\sum_{t=1}^{T} 1_{B_r(t)}\right] \leq \Delta_{\hat{R}} \sum_{t=1}^{T}\sum_{r\notin\hat{R}} t^{-2} \leq \frac{R\Delta_{\hat{R}}\pi^2}{6}.$$

■

Lemma 3: The regret due to event $C_r(t)$ is given as

$$\mathbb{E}\left[\sum_{t=1}^{T} 1_{C_r(t)}\right] \leq \frac{\pi^2}{6}. \tag{13}$$

Proof: Since the poor RIS, $r \notin \hat{R}$, are not sufficiently explored by the algorithm, their regret is bounded. Let $r \notin \hat{R}$. Then, $1_{C_r(t)} = 0$ for $t \leq R$. Then

$$\mathbb{E}\left[\sum_{t=1}^{T} 1_{C_r(t)}\right] = \mathbb{E}\left[\sum_{t=R}^{T} 1_{C_r(t)}\right] \leq \mathbb{E}\left[\sum_{u=1}^{\infty} 1_{\hat{X}^r(S^r(u))\geq 2\sqrt{\frac{\log(u)}{S^r(u)}}}\right]. \tag{14}$$

Using the Chernoff bound, we have

$$\mathbb{E}\left[\sum_{u=1}^{\infty} 1_{\hat{X}^r(S^r(u))\geq 2\sqrt{\frac{\log(u)}{S^r(u)}}}\right] = \sum_{u=1}^{\infty} \mathbb{P}\left[\hat{X}^r(S^r(u)) \geq 2\sqrt{\frac{\log(u)}{S^r(u)}}\right] \leq \sum_{u=1}^{\infty} \mathbb{P}\left[\hat{X}^r(S^r(u)) - X^r \geq 2\sqrt{\frac{\log(u)}{S^r(u)}}\right]$$

Algorithm 2: EFEUCB.

1: **Input:** $R, \hat{R}, T$
2: **Initialize:** $\hat{X}^r(t) \leftarrow 0$ and $S^r \leftarrow 0$ for all r
3: **for** $t = 1, 2 \ldots T$, **do**
4: **if** $t \leq R$ **then**
5: Select block, $I_t = t$.
6: **else**
7: $UCB^r(t) \leftarrow 0$ for all r
8: Compute $\mathcal{E}(t)$ using (7).
9: **if** $|\mathcal{E}(t)| \geq \hat{R}$ **then**
10: $\forall r \in [\mathcal{E}(t)]$: Update $UCB^r(t)$ as given in (6)
11: **else**
12: $\forall r \in [R]$ Update $TCB^r(t)$ as given in (16)
13: $\forall r \in [R] s.t. TCB^r > SNR_d$, Update $UCB^r(t)$ as given in (6)
14: **end if**
15: Select block, $I_t = \arg\max_{r\in[R]} UCB^r(t)$
16: **end if**
17: Transmitter configures RIS block, I_t and transmits a data frame.
18: Each receiver observes instantaneous normalized SNR, and communicates to the transmitter, which calculates X^{I_t} using (4).
19: $S^{I_t} \leftarrow S^{I_t} + 1$ and $\hat{X}^r(t) \leftarrow \hat{X}^r(t) + X^{I_t}$.
20: **end for**

$$\leq \sum_{u=1}^{\infty} e^{-2\log(u) \leq \sum_{u=1}^{\infty} u^{-2} = \frac{\pi^2}{6}}. \tag{15}$$

■

D. Enhanced FEUCB Algorithm

In the FEUCB algorithm, the exploration is done over all R blocks until we have $\hat{R}$ sufficiently sampled blocks. Since R is large and few RIS blocks are good satisfying sparsity requirement, the performance of the FEUCB algorithm can be improved empirically by increasing the selection of good RIS blocks during the period where UCB is exploring all R blocks. The proposed empirical approach is based on a thresholding approach where the algorithm aims to identify all the RIS blocks that offer SNR above a certain desired threshold, SNR_d. Once such $\hat{R}$ blocks are identified, conventional UCB is used. As shown in Algorithm 2, the EFEUCB algorithm differs from the FEUCB algorithm on Lines 12–13, where we identify the blocks that offer SNR above a certain desired threshold, SNR_d. Such blocks are identified based on the threshold confidence bound (TCB), and it is given as

$$\text{TCB}^r(t) = \sqrt{S^r(t)}\left|\frac{\hat{X}^r(t)}{S^r(t)}\right|. \tag{16}$$

In the FEUCB algorithm, we must select $\hat{R}$ judiciously. When the selection of $\hat{R}$ is not trivial or $\hat{R}$ is large, then the performance of the FEUCB algorithm may degrade. The EFEUCB addresses this problem to a certain extent by identifying good RIS blocks using the thresholding approach, and threshold parameters can

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 10,2024 at 09:44:39 UTC from IEEE Xplore. Restrictions apply.

This article has been accepted for inclusion in a future issue of this journal. Content is final as presented, with the exception of pagination.

be selected based on prior knowledge of wireless system deployment, the number of RIS and their locations, wireless physical parameters, etc. In both algorithms, M is fixed. Future works will use an online learning approach to select the M depending on channel conditions.

Sparsity-based approaches are useful in large-scale applications where only a small fraction of options yield significant rewards. The empirical thresholding approach in EFEUCB ensures that only good RIS sub-blocks that offer SNR above a certain threshold are selected often. Due to fewer blocks, the EFEUCB algorithm is expected to converge to the optimal block faster than the FEUCB algorithm. However, the close-form expression for EFEUCB regret is challenging due to the nonlinear thresholding operation.

IV. Performance Analysis

We consider time-slotted communication, where the transmitter selects the RIS block in each time slot and transmits a certain fixed number of data packets over the selected RIS block. The aim is to select the optimal RIS block as often as possible. We compare the performance of the proposed FEUCB and EFEUCB algorithms with existing learning and nonlearning-based algorithms. In the learning-based approach, we consider UCB-based RIS selection approaches. In nonlearning-based algorithms, we consider ERA and opportunistic RIS-aided (ORA) scheme algorithms in [27]. ORA needs prior knowledge of RIS statistics since it selects the optimal RIS block in each time slot, while ERA selects all RIS simultaneously in each time slot. In addition, we consider a simple random selection approach.

We consider the number of receivers, $N = \{1, 2, 3, 4\}$, and the number of RIS, $K = \{5, 20\}$. Each RIS is divided into $L = 5$ sub-blocks. The number of elements in each sub-block is $Z = [25, 35, 45, 55, 65]$. In addition, we consider two more cases by varying the size of the sub-blocks of each RIS. We consider $K = \{5, 10\}$, with $L = \{4, 3, 5, 3, 4\}$ and $L = \{4, 3, 5, 3, 4, 2, 6, 5, 2, 3\}$ respectively. The number of elements in this case is also randomly chosen between 25 and 75. The horizon size, T, is between 10 000 and 500 000. Each result is averaged over 15 independent experiments over the selected horizon size. In each experiment, the positions of the transmitter, RIS, and receivers are selected randomly. Unless otherwise specified, the simulation parameters are set to the values mentioned in Table II. The equivalent noise power at the receiver is given as:$\sigma_n^2 = N_0 + 10\log(\text{BW}) + \text{Noise Figure[dBm]}$ where N_0 is the thermal noise power density.

The performance metrics used for comparison are regret (5), outage probability, ergodic capacity, and energy efficiency. The lower regret indicates a higher average SNR at the receivers, guaranteeing reliable communication. The outage probability is defined as the probability that the SNR of the system falls below a certain threshold. The achievable SNR can be affected by various factors, including RIS selection, channel fading, and receiver noise. Mathematically it can be expressed as

$$\text{P}_{\text{out}} = Pr(\text{SNR}_n^r < \text{SNR}_{\text{th}}) \tag{17}$$

TABLE II
Parameters

Parameters	Values

where SNR_{th}, is the minimum threshold SNR. The outage probability decreases with increased transmit power and the number of RIS elements.

Ergodic capacity refers to the maximum average rate at which the data can be transmitted reliably over a selected channel. Essentially, it represents the average capacity of a channel when both the sender and the recipient possess information on the channel state, and the channel varies randomly over time. Mathematically it can be expressed as

$$\text{EC} = \mathbb{E}[\log_2(1 + \text{SNR}_n^r)]. \tag{18}$$

The energy efficiency gauges the amount of data that can be sent for every unit of power used and can be expressed as

$$\eta = \frac{\text{BW} \times \text{Average Achievable Rate}}{\text{P}_C} \tag{19}$$

where the consumed power P_C is the sum of the circuit dissipated power at the transmitter, N receivers, and each element of the selected RIS block.

A. Regret Performance Analysis

We begin by comparing various algorithms for $K = 5$ (fewer number of RIS) and $K = 20$ (larger number of RIS), respectively, with $L = 5$ and $N = 4$. In Fig. 2(a) and (b), we compare the cumulative regret for the horizon size of 10 000. As expected, random RIS selection incurs high regret due to the

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 10,2024 at 09:44:39 UTC from IEEE Xplore. Restrictions apply.

This article has been accepted for inclusion in a future issue of this journal. Content is final as presented, with the exception of pagination.

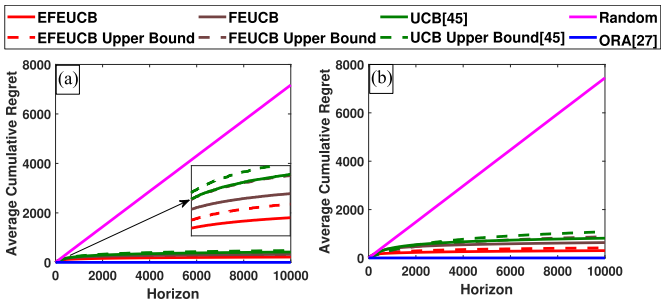

Fig. 3. Comparison of average cumulative regret for different algorithms for (a) $K = 5, L = [4, 3, 5, 3, 4]$ and (b) $K = 10, L = [4, 3, 5, 3, 4, 2, 6, 5, 2, 3]$.

frequent selection of the nonoptimal RIS blocks. The regret of the ORA scheme is zero as it has prior knowledge of the optimal RIS block. We have not included the ERA scheme for regret comparison since ERA selects all RIS blocks, while regret calculation requires selecting a single RIS block in each slot. Among learning-based UCB, FEUCB, and EFEUCB algorithms, the regret of the EFEUCB algorithm is lowest due to improved exploration, resulting in fewer selections of nonoptimal RIS blocks. It can be observed that the regret increases with the increase in K due to a large number of candidate RIS blocks, resulting in higher exploration time. However, the difference between the regret of the FEUCB/EFEUCB and UCB increases with the increase in K, which validates the superiority of the proposed focused exploration approach. The difference between FEUCB and EFEUCB increases as K increases, highlighting the impact of empirical thresholding-based enhancement in focused exploration. We have also compared the experimental regret and its desired upper bound, i.e., worst case performance. It is evident that the experimental results follow a similar trend as the theoretical results, and as expected, experimental results offer lower regret than the corresponding upper bound.

Next, we compare the regret performance for the case when all the RIS units are not identical in terms of element size and the number of sub-blocks. As shown in Fig. 3(a) and (b), the performance of the proposed algorithms is superior to the existing UCB algorithm, and EFEUCB offers improved performance as K increases.

B. Comparison of Achievable Rate, Outage Probability, and Ergodic Capacity

Next, we study the effect of the transmit power and total consumed power on the achievable rate in bits per second per Hertz (b/s/Hz). As shown in Figs. 4 and 5, different algorithms need different transmit power to achieve a given rate. For example, ERA [27] demands the lowest transmit power due to the use of all RIS, which in turn helps to improve the average SNR at the receiver. The random approach needs the highest transmit power due to the frequent selection of suboptimal RIS. All learning-based approaches need a similar transmit power as that of ORA [27], validating the successful learning and frequent selection of optimal RIS. EFEUCB offers better performance than FEUCB, which in turn offers better performance than UCB [44]. As K increases, the ERA performance improves due to increased SNR at the receiver. Furthermore, the difference between the performance of ORA and learning approaches is significant for large K, which is the penalty paid to learn optimal RIS block. As expected, focused exploration leads to a smaller penalty for EFEUCB and FEUCB than UCB.

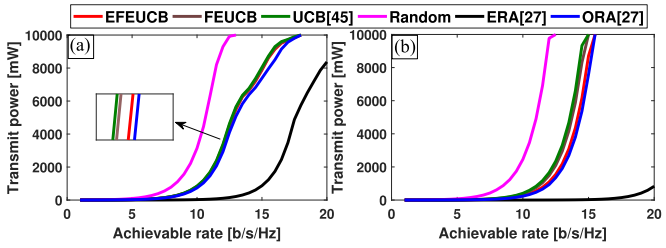

Fig. 4. Comparison of transmit power and achievable rate for different algorithms for (a) $K = 5, L = 5$, and (b) $K = 20, L = 5$.

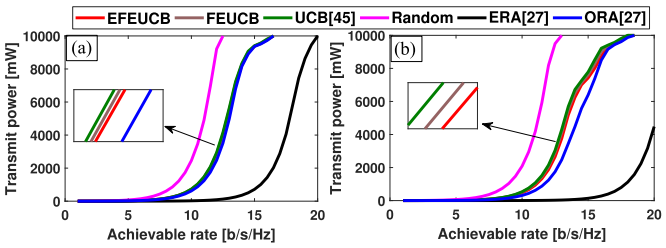

Fig. 5. Comparison of transmit power and achievable rate for different algorithms for (a) $K = 5, L = [4, 3, 5, 3, 4]$ and (b) $K = 10, L = [4, 3, 5, 3, 4, 2, 6, 5, 2, 3]$.

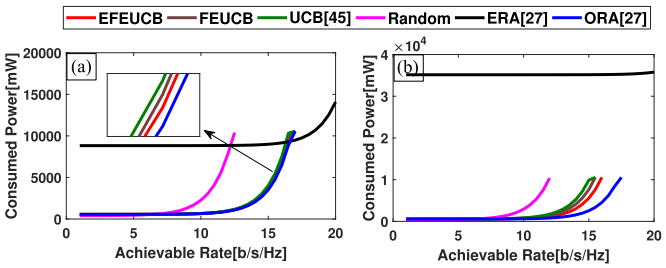

Fig. 6. Comparison of total consumed power and achievable rate for different algorithms for (a) $K = 5, L = 5$ and (b) $K = 20, L = 5$.

Next, we consider total consumed power P_C instead of transmit power in Figs. 6 and 7. As expected, ERA offers the poor performance, and the performance degrades substantially with the increase in the number of RIS. This confirms the practical challenges in the widely used ERA scheme, especially when K is large. Using the proposed learning approaches, consumed power can be reduced significantly by the appropriate selection of M.

Next, we compare the outage probability in Fig. 8(a) and (c) for different values of the transmit power. To avoid repetition of plots and discussion, the discussion is limited to $K = \{5, 20\}$ with $L = 5$. As expected, the outage probability decreases with the increase in the transmit power. The ERA scheme outperform others since it selects all RIS blocks, improving SNR at all

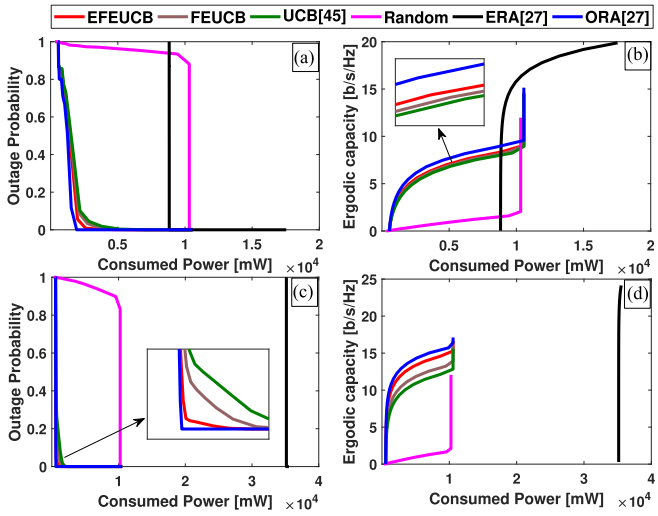

Fig. 9. Comparison of outage probability for (a) $K = 5$, and (c) $K = 20$, and ergodic capacity for (b) $K = 5$ and (d) $K = 20$ with $L = 5$ for different values of consumed power.

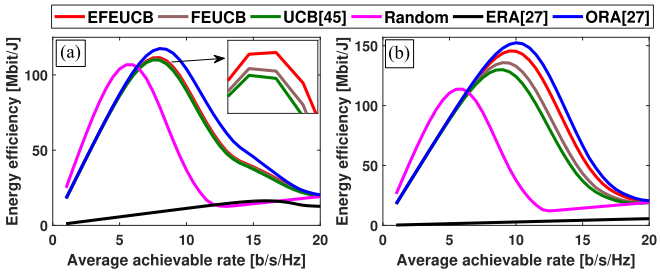

Fig. 10. Comparison of energy efficiency and average achievable rate for different algorithms for (a) $K = 5, L = 5$ and (b) $K = 20, L = 5$.

receivers. This is because the number of sub-blocks L in the ERA scheme is more as compared to the ORA scheme; hence, the total number of elements Z are more in the case of ERA scheme [27], because of which the outage probability of ERA decreases faster than that of ORA with a slight increase in transmit power. As expected, the outage probability of learning-based approaches is close to that of ORA since learning-based approaches eventually select the optimal RIS block after the initial exploration–exploitation tradeoff. The divergence at $\mathrm{P_{out}} = 10^{-2}$ is because of exploring other blocks while learning the optimal block. In Fig. 8(c), with a total of 20 RIS, ERA offers further improvement in performance as its outage probability starts decreasing at lower transmit power than in Fig. 8(a) with 5 RIS.

Similarly, in Fig. 8(b) and (d), we compare the ergodic capacity for different values of the transmit power. As expected, the ERA scheme offers the highest ergodic capacity due to the selection of all RIS elements, which allows the highest throughput for multiple users. The proposed EFEUCB offers a better outage probability among learning-based approaches. As K increases, exploration time increases; hence, the difference between the performance of ORA and learning-based approaches increases. This penalty is paid due to no prior knowledge of channel conditions and positions of RIS and receivers in the learning-based approach. Note that the difference between the performance of ERA and ORA increases with the increase in K, which validates the need for multi-RIS-aided wireless networks. In Fig. 9, we compare the outage probability and ergodic capacity for different values of consumed power. As expected, the performance of the ERA scheme is significantly poor due to the selection of all RIS, which results in high consumed power. Thus, the proposed approach addresses ERA's high consumed power drawback by learning and selecting the optimal RIS block instead of all RIS. It also outperforms UCB via focused exploration, especially when K is large.

C. Energy Efficiency Comparison

Next, we compare the energy efficiency of various algorithms for different achievable rates in Fig. 10(a) and (b). Here, we increase the transmit power to achieve the desired rate. As expected, the energy efficiency of the ERA scheme is abysmal due to the selection of all RIS elements. In contrast, the energy efficiency of ORA is highest due to the selection of optimal RIS, which results in lower consumed power. The energy efficiency of the learning-based scheme is significantly better than the ERA scheme and close to that of the ORA scheme. The difference between the energy efficiency of learning-based approaches and ORA is due to the higher transmit power needed

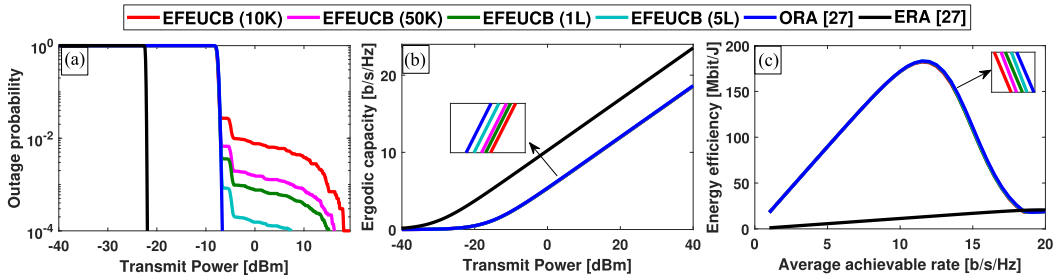

Fig. 11. Comparison of outage probability, ergodic capacity, and energy efficiency for different horizon time.

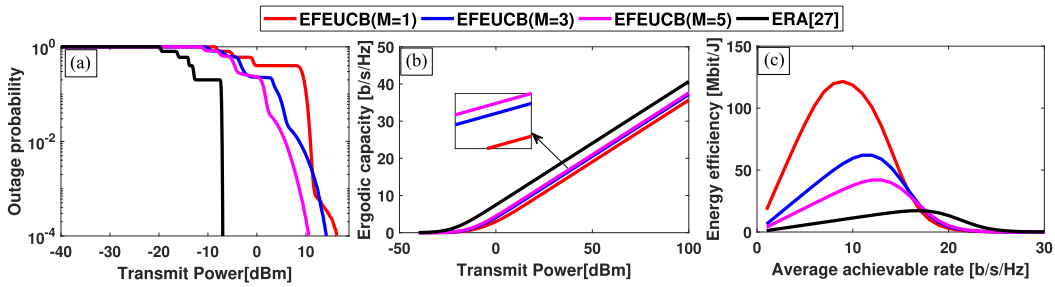

Fig. 12. Comparison of outage probability, ergodic capacity, and energy efficiency when different block sizes, M.

to meet the desired achievable rate whenever suboptimal RIS is selected due to the exploration–exploitation tradeoff. As the number of RIS increases, the energy efficiency of the proposed FEUCB and EFEUCB is better than that of UCB and random approaches, validating the superiority of the proposed focused exploration approach. The energy efficiency of the ORA and proposed learning-based algorithms decreases when the desired achievable rate goes beyond a certain value, as shown in Fig. 10. This is due to a significant increase in the desired transmit power, as shown in Fig. 4.

D. Effect of Horizon Size, T

Compared to ORA schemes, learning-based approaches do not have prior knowledge of the optimal RIS; hence, they need exploration time to learn and identify the optimal RIS block. In Fig. 11, we compare the effect of horizon size on the performance of learning algorithms. It can be observed that the difference between the learning and ORA schemes decreases with the increase in horizon time for a given K and L. This is because the penalty for selecting nonoptimal RIS during exploration time becomes insignificant as horizon time increases. This also validates the functional accuracy of the proposed learning-based approaches to identify the optimal RIS accurately and select it as many times as possible over the horizon.

E. Effect of Block Size, M

Each RIS block consists of M number of sub-blocks, and $M = 1$ corresponds to a single-RIS-aided system. We compare the effect of M on the performance of wireless systems in Fig. 12 for $M = \{1, 3, 5\}$. It can be observed that the outage probability and ergodic capacity of the EFEUCB improved with the increase in M and approaches that of ERA as M increases at the cost of poor energy efficiency. Thus, M should be carefully selected to achieve the desired tradeoff between performance and energy efficiency.

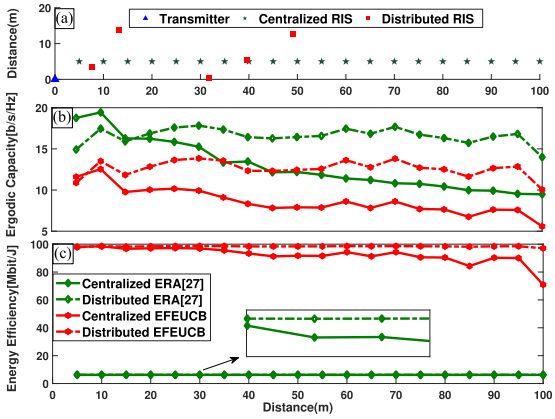

Fig. 13. Comparison between centralized and distributed RIS approaches: (a) Fixed locations of the five distributed RIS and different locations of centralized RIS. The locations of four receivers is selected randomly in each experiment. (b) Comparison of ergodic capacity for different position of centralized RIS. (b) Comparison of energy efficiency for different position of centralized RIS. The transmit power and achievable rate for energy efficiency is fixed at 20 dBm and 10 b/s/Hz, respectively.

F. Centralized Versus Distributed RIS Approach

Next, we compare the performance of the centralized and distributed RIS approaches in Fig. 13. In a centralized approach, we use a single RIS with the same number of elements as the total elements of K RIS in a distributed approach. We randomly select the position of the receivers in each experiment and average the results over multiple experiments. In Fig. 13,

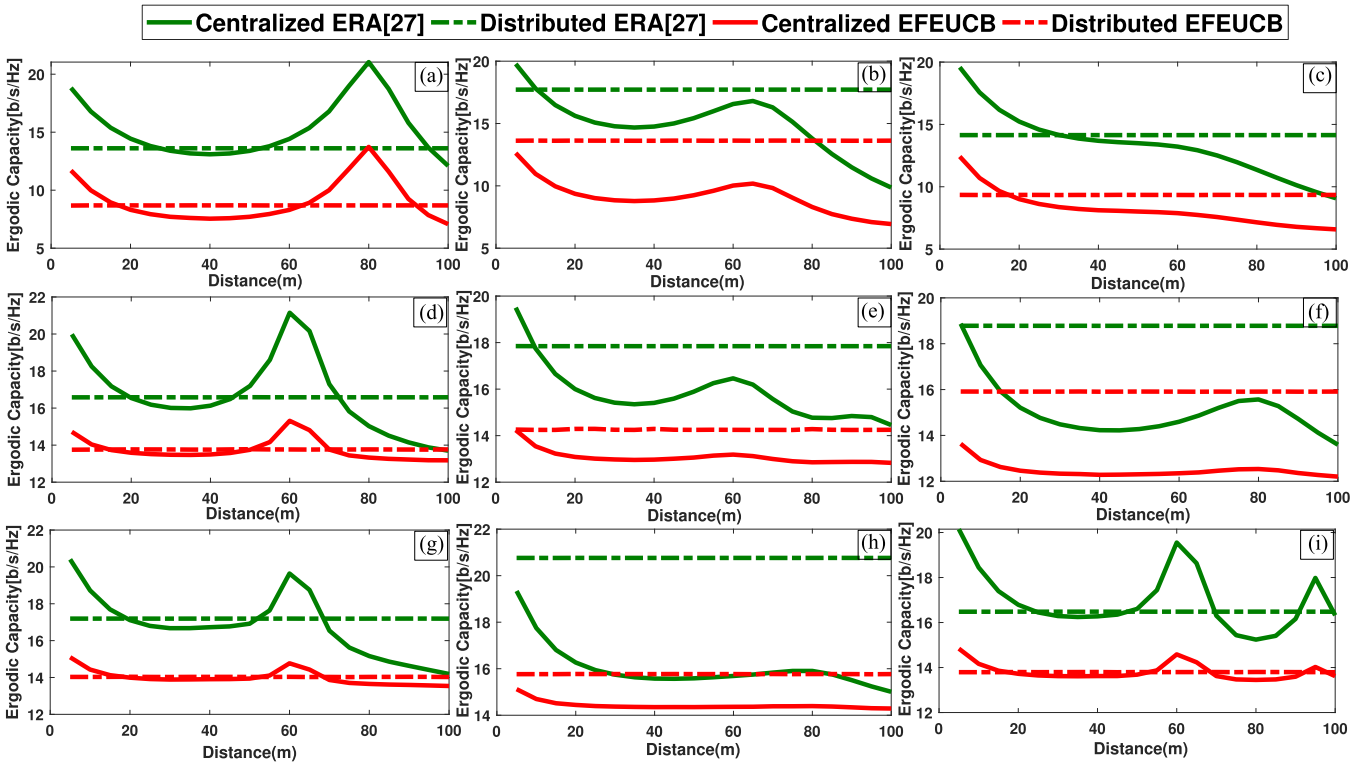

Fig. 14. Comparative results for ergodic capacity at transmit power 20 dBm, with different scenario. (a)–(c) Scenario 1 (d)–(f). Scenario 2. (g)–(i) Scenario 3.

we compare the ergodic capacity of the ERA and EFEUCB algorithms for different positions of the centralized RIS between transmitter and receiver. As expected, the distributed approach offers higher ergodic capacity than the centralized approach in both cases, thereby validating the need for a multi-RIS-aided distributed system. In Fig. 13, we also compare the energy efficiency of the centralized and distributed RIS approaches for ERA and EFEUCB algorithms. The distributed approach offers higher efficiency than the centralized one due to higher ergodic capacity.

Next, we make an in-depth comparison of the ergodic capacity of centralized and distributed approaches to analyze the effect of a number of receivers and their locations. In Table III, we consider three scenarios with 1, 2, and 4 receivers, respectively, along with the specific locations of the receivers in each case. The location of 5 distributed RIS is fixed in all scenarios. In Fig. 14(a)–(c), we compare the ergodic capacity for scenario 1 with a single receiver. The centralized RIS offers better performance than the distributed RIS in Fig. 14(a) as the receiver is near to the centralized RIS compared to any of the distributed RIS. On the other hand, the distributed approach significantly outperforms the centralized approach in Fig. 14(b) and (c) even though centralized RIS can be moved at any position between transmitter and receiver while the position of distributed RIS is fixed in advance. Similar observations can be made from various results presented in Fig. 14(d)–(i). These results validate the superiority of the distributed approach in Fig. 13, where receiver positions are selected randomly. Since the positions of receivers are not fixed in real networks, the distributed approach is more effective and practical.

V. EXECUTION TIME COMPARISON ON EDGE PLATFORMS

In the MAB algorithm deployed in wireless networks, the execution time of the algorithm should be as short as possible. In time-slotted communication, a faster MAB algorithm leads to the early selection of the RIS block, allowing the transmitter more time to transmit the actual data and achieve high throughput. In Table IV and Fig. 15, we compare the execution time of

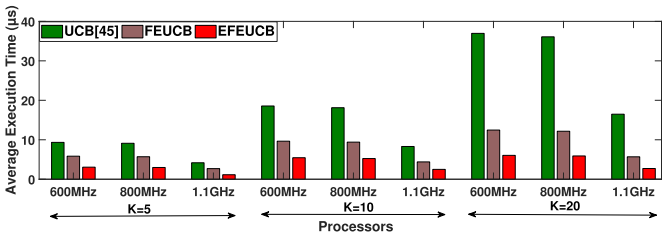

Fig. 15. Comparison of average execution time (μs) for different algorithms on different processors.

three MAB algorithms on the following three different types of processors used in edge platforms:

1) ARM Cortex A9 at 666 MHz;
2) ARM Cortex A9 at 800 MHz;
3) ARM Cortex A53 at 1.1 GHz.

We study the effect of SIMD NEON coprocessor and two different word lengths, single precision floating point (SPFL) and double precision floating point (DPFL), on the execution time. For $R = 25$ RIS sub-blocks, we can observe that FEUCB offers around 33%–39% lower execution time than UCB while EFEUCB offers around 64%–68% lower execution time than UCB. As the number of sub-blocks are increased from 25 to 50 and 100, further improvement in the performance of FEUCB and EFEUCB with respect to UCB is observed. The substantial degradation in the execution time of the UCB can be observed from Fig. 15. For 50 sub-blocks, FEUCB and EFEUCB offer around 46%–49% and 68%–71% lower execution time than UCB, respectively. This improvement is increased to 65%–66% and 80%–85% for 100 sub-blocks. The huge savings in execution time in proposed algorithms are due to the focused exploration approach, which reduces the number of computational arithmetic operations in each time slot. As expected, execution time with DPFL is slightly higher than SPFL, though we did not observe any degradation in performance with SPFL. Similarly, higher clock frequency and better processors lead to further reduced execution time, as shown in Table IV. The use of SIMD-based NEON coprocessor results in a significant reduction in execution time for all the algorithms. Further reduction in execution time can be achieved using multiple cores of these processors along with other coprocessors, such as graphic processing unit or field-programmable gate array.

VI. CONCLUSION

In this work, novel UCB-based distributed algorithms, i.e., FEUCB and EFEUCB, have been proposed to select optimal RIS sub-block. The theoretical regret analysis and the in-depth simulation results validate the effectiveness and superiority of our proposed algorithm over the existing state-of-the-art algorithms. The execution time comparison on the edge platforms demonstrates the compute and memory efficient architecture of the proposed algorithms. Future works include the hardware software codesign of the proposed algorithms and further extension in the quasi-stationary environment for vehicular applications. Furthermore, an important future direction is an efficient design of analog-front-end and antennas for directional communication over multiple RIS.

Abstract:

Ontologies are used to represent the domain knowledge. But the ontologies created by different creators are different and inconsistent. Huge difference exists between domains and currently there exists no single defined methodology for ontology development. In this work, we propose an ontology development methodology called *On-To-Methodology* that is comprehensive & generic. We elicit the domain knowledge in a structured manner and employ various documents to support the development process. We have also developed a tool that automates the development process.

Keywords: Ontology, Knowledge representation, Development methodology, Ontology design process, Ontology construction

1. Introduction

The American Heritage Dictionary defines "ontology" as "the branch of metaphysics that deals with the nature of being." Ontology, as a formal specification of a shared conceptualization [1], defines the thesaurus of the concept, relations between concepts and properties even relations between properties. Moreover, it describes axioms and individuals and relations between them, and provides sharing knowledge [2]. More specifically, it is an explicit specification of a conceptualization [3, 4].

Initial application of ontologies in computer science was that it acted as a means of providing the semantics for the semantic web i.e. web 2.0. By use of ontologies, the information retrieval could then be done based on the context (/meaning) rather than just simple string matching mechanisms.

The Ontologies created by different creators are different and inconsistent. There is a huge difference between different domains and currently there is no defined methodology for constructing Ontologies [5, 6, 7]. And inspite much being written in literature about Ontologies, the number and quality of actual, "non-toy" ontologies available on the Web today is remarkably low [7, 8].

Fernández et. al. proposed "Methontology" and defined the ontology development process and the ontology life cycle [9]. Farooq et. al. proposed "Design of Ontology in Semantic Web Engineering Process and illustrated their method with the help on a case study [10]. Gaoyun et. al. identified the reasons for the inconsistencies in ontology construction and put forward a method for Consistent Ocean Ontology Construction [7]. Zhang et. al. proposed a methodology namely MADRE and illustrated their

work by focusing on healthy housing [11]. Jia et. al. put forward "Automatic ontology construction approaches and its application on military intelligence" [12]. Chen et. al proposed Concept feature based ontology construction and maintenance which was backed up by a detailed framework [13]. A structured ontology construction by using data clustering and pattern tree mining was proposed by Yao-Tang et. al. [6].

All these proposals seem to suffer from following drawbacks [7]: (i) *Inconsistency of domain cognition*: this relates to the point that people have no consistent definition of the scope of the domain and about the contents of the domain. (ii) *Inconsistency of viewpoint*: ontologies of same scope and built by domain experts with the same background knowledge still have essential dissimilarities due to the differences in their viewpoint. (iii) *Ontology construction is affected by subjective factors*: Even in the same field with viewpoints, ontologies may be different from one another due to creators' interests, tastes, preferences, ideas, abilities etc. (iv) *Lexical inconsistency*: Conceptualization is independent from vocabulary, but ontology is language-related. Even if the language is unified, inconsistencies may still occur because the languages suffer from the problem of "polysemy" and "thesaurus".

Martin Hepp [8] classifies the ontology-related tasks into two main groups: building or contributing to the development of ontologies and committing to a particular ontology. Committing to a given ontology, explicitly or implicitly, means agreeing that it properly represents the domain's conceptual elements.

So to solve the aforesaid problems with ontology engineering, in this work, we propose a method called ***On-To-Methodology***, that is comprehensive, generic and makes it easy to commit and construct ontologies of various domains specifically transportation like bikes, cars, planes etc. We aim to produce documents similar to the documents in Software Engineering. Also, we provide a computer based tool which can automate the construction process. The proposed methodology will have following features:

- *Better domain cognition*

  As listed in above, there exists inconsistency in domain cognition. Our method handles this problem by adapting group oriented activities thus enabling experts and users to define the domain in better terms.

- *Unification of viewpoints*

  Inconsistency in viewpoints arises as different people have different perspectives and due to this contrary conclusions may be obtained. Our methodology resolves this problem by instrumenting the development process with evaluation activities after each phase of the development process. Also, the unification is achieved due to the adaptation of group oriented development activities.

- *Exhaustive documentation*

  On-To-Methodology provides an extensive and exhaustive documentation support thus making the development process more formal and helps in achieving traceability across phases. Documentation also simplifies the maintenance of the ontology by providing the backward traceability of various components of the ontology.

- *Extensive Verification & Validation*

  These two tasks of verification and validation are interleaved between various phases of the development process. This prevents introduction of bugs into the system right from the beginning of the development process and prevents faults till the maintenance phase.

We shall apply On-To-Methodology to domain of Automobile, specifically Bikes. The intended ontology of Bikes will be representation of bikes in the domain of ontology. The purpose of this ontology is to provide information on bikes based on the criteria specified by the users.

- The ontology would hold information to answer queries of customers based on single (/combination of) parameter(s) which are Make, Engine capacity, Power, Price, Fuel tank capacity, Mileage, Brake type, Weight, Wheel type, Ignition and Number of gears.
- Bike manufacturing organizations can use this ontology to identify the bike configurations that are suitable for a particular market and can also use it to analyze current sales and make future predictions. This will guide them to plan their production & inventory.
- This ontology can prove to be beneficial for bike retailers as they can use it to plan their inventory and analyze their sales.

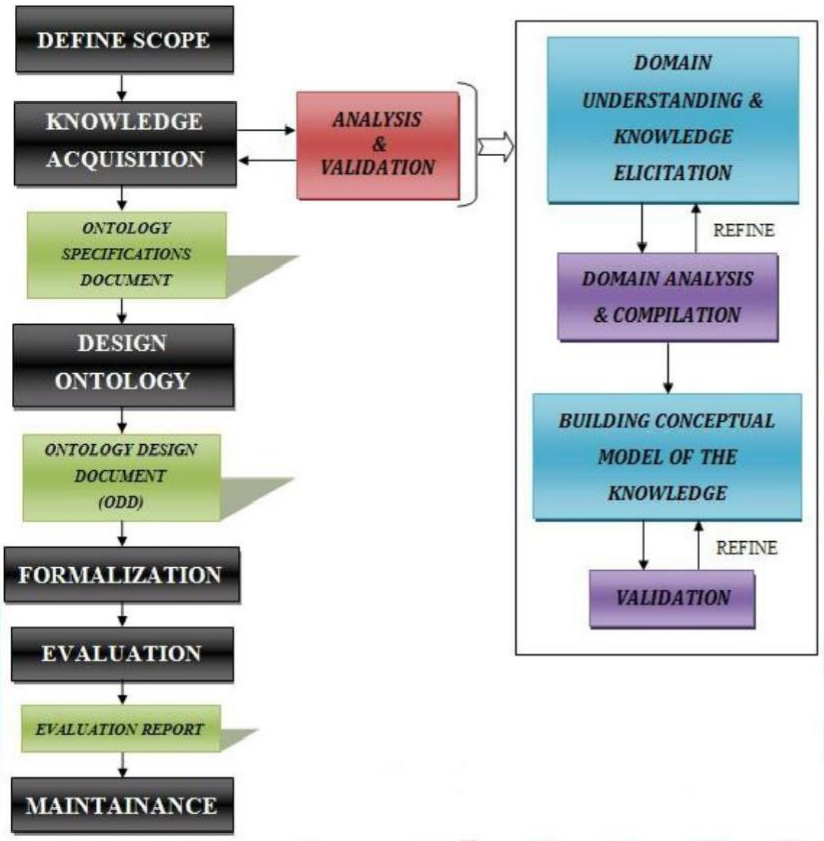
The advantage that this ontology would provide is its capability to answer the queries of the customers across a large information base of different bikes, based on multiple search criteria with complex inter-relations.

The rest of the paper is organized as follows. Section 2, proposes the methodology for ontology construction. Section 3, illustrates our methodology by constructing an Ontology of Bikes. In section 4, we evaluate the Ontology of Bikes for various competency questions and compare our approach with other existent methodologies. Section 6 concludes the thesis and proposes future work.

2. ON-TO-METHODOLOGY: Proposed methodology for ontology construction

This process is generic and extension of proposed methodology by Fernández et. al. [9] and Yao-Tang Yu et. al. [6]. The different phases in On-To-Methodology are described in Figure 1. These steps are generic and consist of four main activities namely Knowledge Acquisition, Design Ontology, Formalization and Evaluation. The output of Knowledge Acquisition is Ontology Specification document. This document is analogous to Software Requirements Specification (SRS) document IEEE standard 830. The output of Design Ontology is Ontology Design Document (ODD) and consists of logical design of the ontology being developed. The output of Evaluation is Evaluation Report. It consists of the evaluation of ontology for knowledge representation efficiency.

Fig. 1: On-To-Methodology: Ontology Development Methodology



2.1 Define Ontology Scope

The target of this phase is to establish the scope of the ontology in terms of purpose that the ontology would serve with associated advantages. It should provide an objective description of the intended users, various scenarios in which it would be used and the end users.

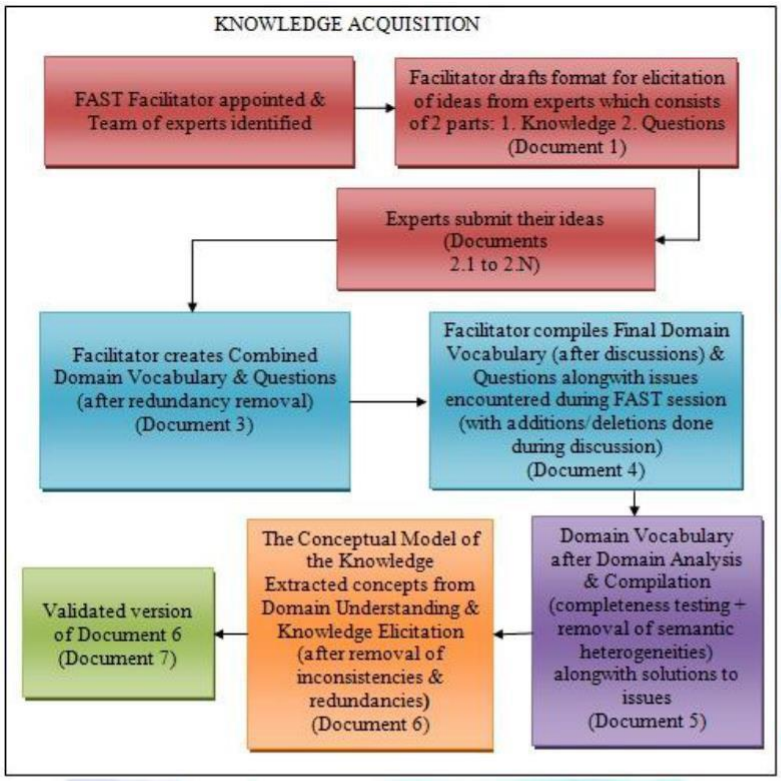
2.2 Knowledge Acquisition

This activity would require the identification of *knowledge source* from where the knowledge is to be acquired. It can include the following: Books, Experts, Figures, Tables, Files, Webpages, Other ontologies etc. The output of this phase is an *Ontology Specification Document*.

We propose the use of *FAST* (Facilitated Application Specification Technique) here. It is a team oriented Software Engineering approach for gathering of requirements. This approach encourages the creation of a joint team of domain experts and users who work together to understand the expectations and propose a set of requirements. We have adapted FAST to elicitate conceptual knowledge required to construct ontology in a formal way. We have designed various forms which are used to gather this knowledge. We identify the various stakeholders of the ontology and generate different forms to

acquire the required knowledge. Figure 2 illustrates the various forms that we have generated during the Knowledge Acquisition activity.

Fig. 2: Various forms generated during the Knowledge Acquisition



As presented in figure, in the first phase a facilitator & team of experts are identified. The facilitator controls the various activities of the FAST session and prepares an informal agenda to encourage the free flow of ideas. The facilitator drafts a form (Document 1) to elicit ideas from the experts which consists of two parts which are required to be filled by the experts. The two parts are Knowledge and Questions. This form is filled by the various experts and submitted back to the facilitator (Documents 2.1 to 2.N where N is the number of experts). The facilitator then compiles the ideas from these forms into a separate document (Document 3). The consolidated ideas are then discusses within the team and a final document i.e. document 4 is created which consists of the domain vocabulary and questions alongwith the issues encountered during the FAST session. The domain vocabulary listed in document 4 is analyzed for the given domain and thus document 5 is created after compilation. The concepts are then extracted from the Domain Understanding & Knowledge Elicitation as a result document 6 is obtained which is then validated and the final document consisting of the Conceptual model of the knowledge is obtained in the form of document 7.

We consider this activity consisting of four main tasks as described below. All these activities are carried out in a formal manner with the support of forms generated.

2.2.1 Domain Understanding & Knowledge Elicitation

In this phase, the basic elements of the ontology are identified and enumerated. The elements of ontology are Class, Relationships, Constraints, Forms, Instances, Constants, and Instance attributes. These are explained as follows [14]:

- *Class* or concepts for a domain such as location, city, travel, destination etc.
- *Relationships* are the properties between two classes such as 'isa'.
- *Constraints* are conditions that must be satisfied during the design.
- *Instance* is values for particular categories in ontology.

Here we don't categorize the domain keywords according to the above categories but the focus is on comprehensive list of constituents without worrying about redundancies or overlaps.

Competency questions are also elicitated in this phase. These questions are queries related to specific situations from real life problems that the ontology would help provide a solution. The competency questions are therefore used to evaluate the ontology thus developed.

2.2.2 Domain Analysis & Compilation

An expert for particular domain can easily examine the ontology in better way and changes suggested by expert will remove some of the inconsistencies at the earlier stage to make the design phase simpler. The expert review makes knowledge acquisition evolutionary [14].

So after drafting the basic model as described above as document 4, it is reviewed by the experts for following rules: [10]

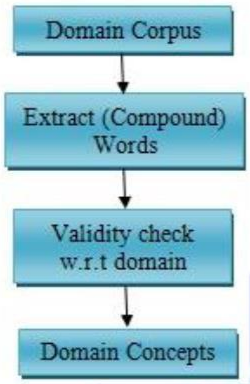
I. *Consistency rule*: various defects are analyzed for example usage of different names for a same concept.
II. C*ompleteness rule*: the defects such as omission of domain resources and the omission of relationship are diagnosed. The issues encountered during FAST sessions are also resolved here.

If any consistency or completeness check fails, it is refined by the expert and the output is called as document 5.

2.2.3 Building Conceptual Model of the Knowledge

A conceptual model is developed on the basis of the domain model which we call as the document 5. Here the knowledge is represented in form of trees and table of rules/ formulas. The inconsistencies and the redundancies are resolved. The domain vocabulary identified in the *Domain Understanding & Knowledge Elicitation* is classified as classes, sub-classes, properties, constraints and individuals. The mechanism as shown in figure 3 [15], can be employed.

Fig. 3: Framework for extracting the domain concepts



The definition of class hierarchy can be done in different ways [16] as following:

- Top-down development process begins with the definition of the concept of the field of the most common, followed by characterization of the concept.
- Bottom-up development process begins with the definition of the most specific classes, namely, class hierarchy the leaves, and then grouped into these classes more general concept.
- Combination of the two- defining more clearly the concept of the first, followed by their proper places generalization and characterization, it is the easier process.

The final result is document 6 which we call as the conceptual model of the ontology.

2.2.4 Validation

The conceptual model of the knowledge, developed in the last step is reviewed here. Expert review is again used here. An expert for particular domain will examine the ontology for the following rules and the changes suggested will be incorporated [10]:

I. *Correctness rule*: The use of incorrect relationship, aggregation & specialization of classes and cardinality of relationship are tested.
II. *Rule for Semantic heterogeneities*: Semantic heterogeneities are also determined and dissolved in this step.
III. *Constraints*: Constraints on domain and range values of each object property and datatype property are also verified in the testing activity.

The result of this activity is document 7 which is the validated version of document 6.

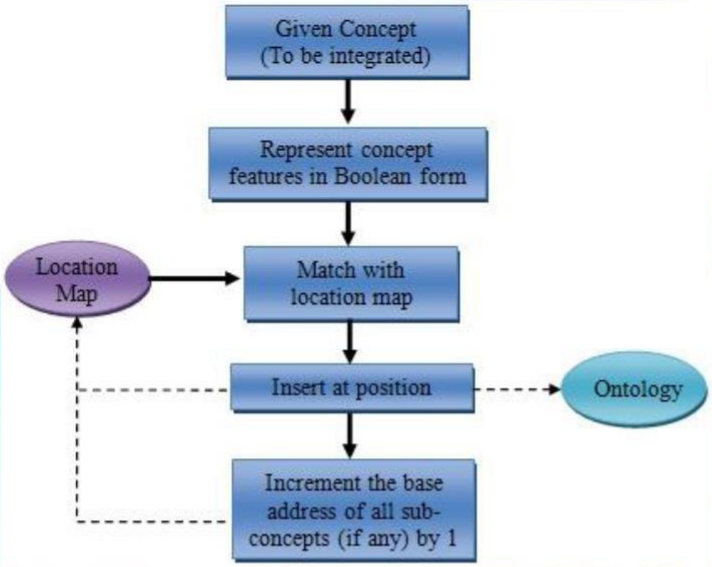
2.3 Design Ontology

This phase consists of two main tasks. One is the design where with the help of the Ontology Specification Document and the Conceptual model of the knowledge, the concepts are mapped to location in location map. In this phase the concepts in the conceptual model are structured so that knowledge can be accessed. Second task is to produce a design document called Ontology Design Document (ODD) which can be helpful in evolution of the ontology.

2.3.1 Design

This is the core task of building ontology. We have adapted an algorithm for this and apply the technique [13] as shown in figure 4 below:

Fig. 4: Addition of new concept



We have automated the above task by implementing the following algorithm:

i. Given an Ontology structure with a concept *Thing* which is super concept of all concepts.
ii. A concept with from Conceptual model of the knowledge is selected. Let it be X.
iii. All features for that concept are identified and labeled with a feature number as follows:

{X} → f^+ <feature no. from 1 to n>

iv. The concept is then represented in the Boolean form as follows: C (X): { $f^+ 1 \bullet f^+ 2 \bullet \dots \bullet f^+ n$ }

v. The concept represented in Boolean form is compared to other concepts in the location map one by one. Say the concept currently chosen from the Ontology structure be Y with address in location map as (a, b). Following cases can happen:

a. If {Y}: { $f^+ 1 \bullet f^+ 2 \bullet \dots \bullet f^+ (n-k)$ } where k<n, and we have
{X}: { $f^+ 1 \bullet f^+ 2 \bullet \dots \bullet f^+ (n-k) \bullet \dots \bullet f^+ n$ }

In this case there is match between X and Y for $f^+ 1$ to $f^+ (n-k)$. This means that X is a child of Y with $f^+ (n-k+1)$ to $f^+ n$ as additional features. Thus X is inserted in the Location map with address (a+1, xx).

b. If {Y}: { $f^+ 1 \bullet f^+ 2 \bullet \dots \bullet f^+ m$ }, and we have
{X}: { $f^+ 1 \bullet f^+ 2 \bullet \dots \bullet f^+ n$ }

If there exists a feature in Y that is not present in X, then X is not a sub-concept of Y thus it is either a brother concept of this concept or a sub-concept of some other concept.

vi. Steps ii to v are repeated for all concepts in the conceptual model and the end result is the complete ontology structure.

The following are the snapshots of our tool, fig 5(a) and fig 5(b):

Fig. 5(a): On-To-Methodology tool

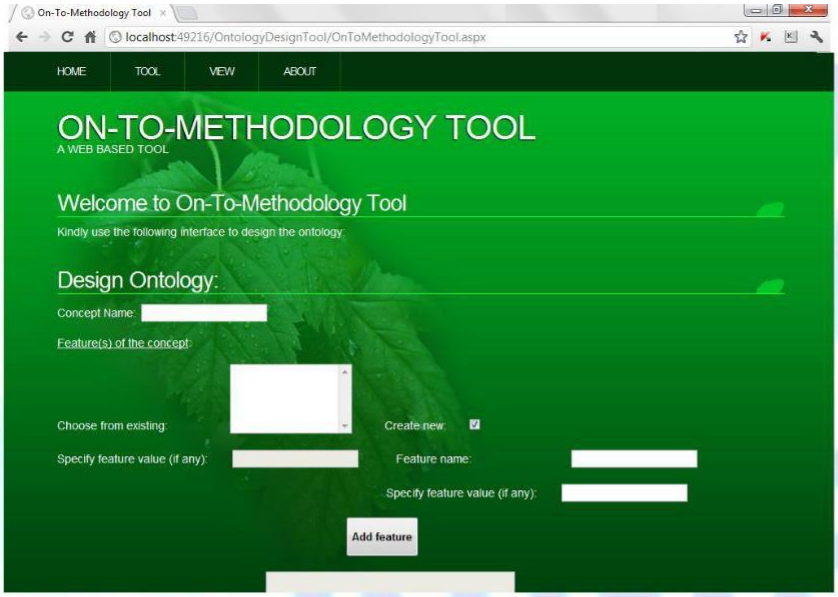


Fig. 5(b): On-To-Methodology tool

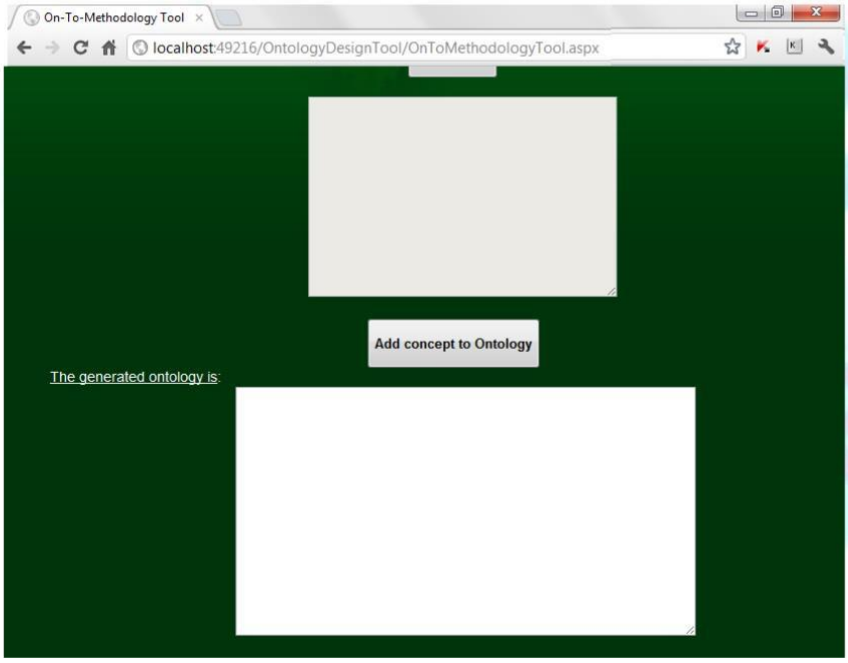


2.3.2 Ontology Design Document

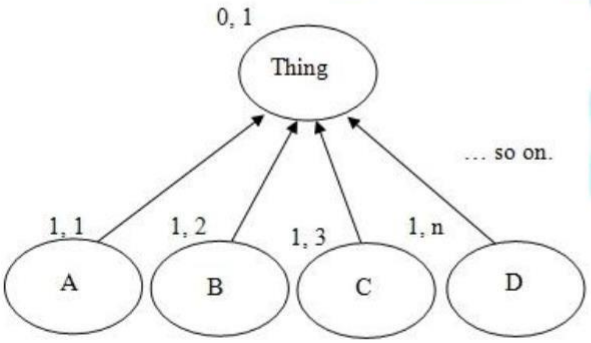
The output of this phase is the Ontology Design Document (ODD). This document is a formal record of the ontology structure and consists of the Location map alongwith the graphical representation of the ontology structure. The format for ODD is as follows [13]:

ONTOLOGY DESIGN DOCUMENT

The location map is as below:

CONCEPT ADDRESS	CONCEPT FEATURE
Thing (0, 1)	X
A (a1, a2)	f^+ 1 • f^+ 2• …
B (b1, b2)	f^+ x • f^+ y • …
…	…

The graphical representation of ontology structure is as follows:



2.4 Formalization

The main aim behind ontology development is to make the information to be understood by the machines. Thus, the ontology is finally formalized using the selected ontology languages and tools.

Semantic Web is not a single technology and it comprises of a number of components including ontology languages (RDF/RDFS, OWL etc.), editing tools (Protégé, Ontolingua etc.) and standards (WSMO, OWL-S etc.). As quoted in [14], different ontology languages provide different facilities. The most recent development in standard ontology languages is OWL from the W3C. OWL [17] makes it possible to describe concepts but it also provides new facilities. It has a richer set of operators - e.g. and, or and negation. It is based on a different logical model which makes it possible for concepts to be defined as well as described. Complex concepts can therefore be built up in definitions out of simpler

concepts. OWL ontologies may be categorized into three sub languages: OWL-Lite, OWL-DL and OWL-Full. Islam et. al. [18] have compared several editing tools as shown in Table 1 below.

Table 1: A comparison of ontology editing tools

Tools	Free	Open Source	Dot Net and Web Based	Import Languages	Export Languages	Inferencing Reasoning Tools
Protégé	√	√	×	RDF, OWL	RDF, OWL, FLogic, CLIPS	√
OntoEdit (Free)	√	×	×	DAML + OIL, RDFS	DAML + OIL, RDFS	×
Differential Ontology Editor (DOE)	√	×	×	RDFS, OWL	DAML+OIL, OIL, RDFS, OWL	×
IsaViz	√	√	×	RDF/XML, N-Triples	RDF/XML, N-Triples	√
Ontolingua	√	×	×	DAML+OIL, KIF,CLIPS	DAML+OIL, KIF, CLIPS	√
Altova Semantic Works™	×	×	×	N-triples, OWL, RDF and RDFS	N-triples, OWL, RDF and RDFS	×
WebODE	√	×	×	RDF(S), DAML+OIL, UML, OWL	CLIPS, DAML+OIL, UML, OWL	√
TopBraid Composer	×	×	×	RDBMS, OWL, RDF	OWL,RDF, XML	√
Morla	√	√	×	RDF, OWL	RDF,OWL	×
Hozo	√	√	×	RDF, OWL (subset)	OWL, RDF	×
TODE	√	×	√	RDF, OWL-Lite, N-3, RDBMS, N-Triple,	RDF, OWL-Lite, N-Triple, N-3, RDBMS	×

2.5 Evaluation

After the ontology has been drafted, it should be checked for quality and knowledge representation efficiency. If any constraints are violated then they are corrected. The ontology engineers also verify the developed ontology against the requirement document. The term 'Evaluation' encompasses both-verification & validation. Based on [11], we identify following two ways of evaluation:

- *Relation Evaluation*: Relation evaluation infers the new individual based on constructed rule set, and judges whether the relation is coincident with the professionals' knowledge. This is done using the *Reasoner* that comes inbuilt in the tool, like Fact++ in Protégé.
- *Evaluation of hierarchy*: Evaluation of hierarchy develops limits definition of created class and individual properties, makes use of ontology tool (like OntoGraf, OWLViz) to infer and create Ontology Graph automatically, and judge whether Subordination between the class and individual in the graph are coincident.

Also, in above steps, the answers to competency questions are verified by the experts. The output of this phase is the *Evaluation Report*. It consists of following:

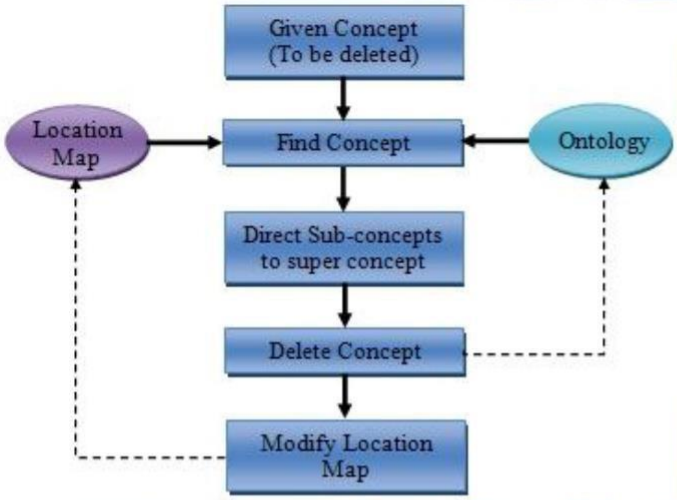
I. Evaluation of competency questions by the experts to check if the results are as per the expectation.
II. Evaluation of hierarchy using OntoGraf & OWLViz.

2.6 Maintenance

Ontologies need to adapt to the changing specifications to become more mature. This can be accomplished by adding, updating and removing concepts/ parts of the ontology. For this, following techniques can be employed:

- Addition of new concept: Technique as used in ontology design can be used.
- Deletion of a concept: Technique as shown in figure 6 can be used [13].

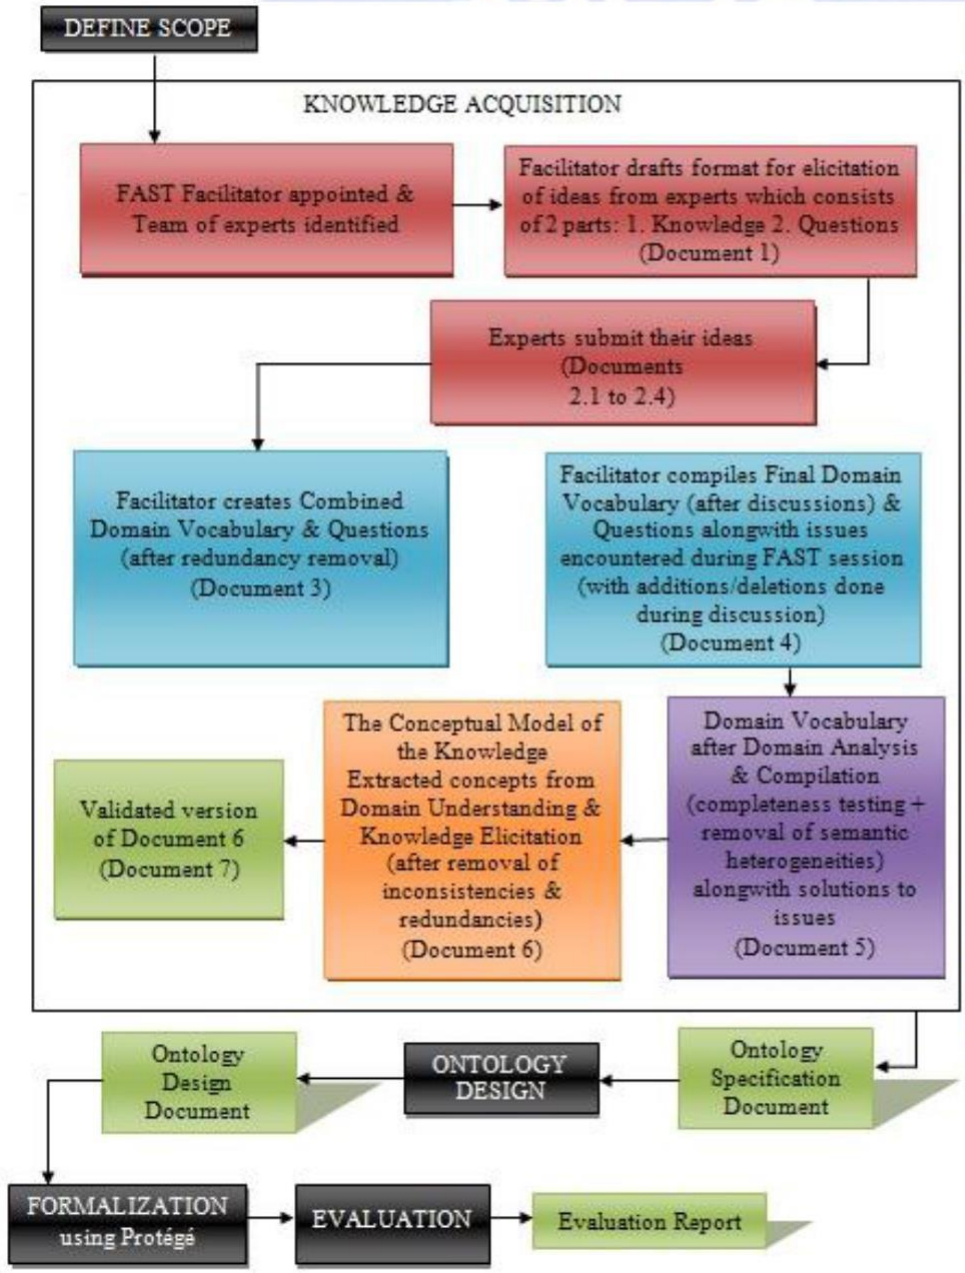
Fig. 6: Deletion of a concept



3. Case Study

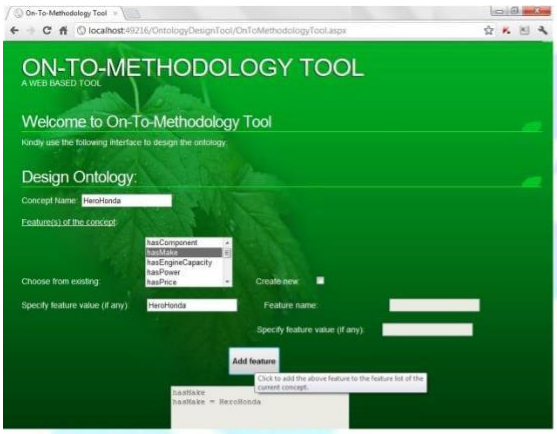
Here we illustrate our methodology by working out an Ontology of Bikes. The purpose of this ontology is to represent information related to bikes for parameters like Make, Engine capacity, Power, Price, Fuel Tank capacity, Mileage etc. Following is the workflow of the Bikes Ontology development process (figure 7):

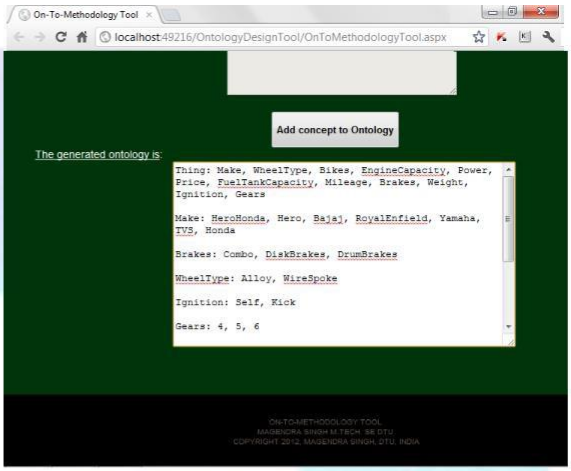
Fig. 7: Workflow of development of Ontology of Bikes



We employed our tool in the Ontology Design activity to design the ontology automatically. Following snapshots show the working of our tool in the designing process:

Fig. 8: Employment of our tool for design of Ontology of Bikes





The following is Ontology Design Document for the Ontology of Bikes.

Table 2: Final Location map

CONCEPT ADDRESS	CONCEPT FEATURE
Thing (0, 1)	X
Bikes (1, 1)	$f^+1 \bullet f^+2 \bullet f^+3 \bullet f^+4 \bullet f^+5 \bullet f^+6 \bullet f^+7 \bullet f^+8 \bullet f^+9 \bullet f^+10 \bullet f^+11 \bullet f^+12$

4. Evaluation

The developed ontology was evaluated by experts by querying it with competency questions and verifying the results. Figure 11(a) shows the following query:

" Average >=40 & price should be between Rs. 50000 & Rs. 60000, and engine capacity should be >=125"

Figure 11(b), shows the results after execution of the *Reasoner,* the results were verified by the experts and were found to be consistent.

Fig 11(a): Evaluation of competency question

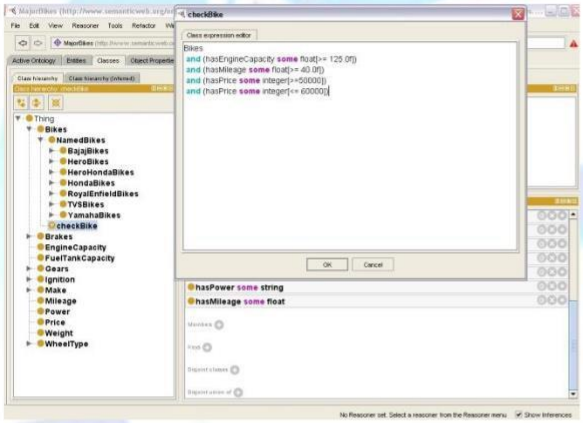

Fig 11(b): Evaluation of competency question

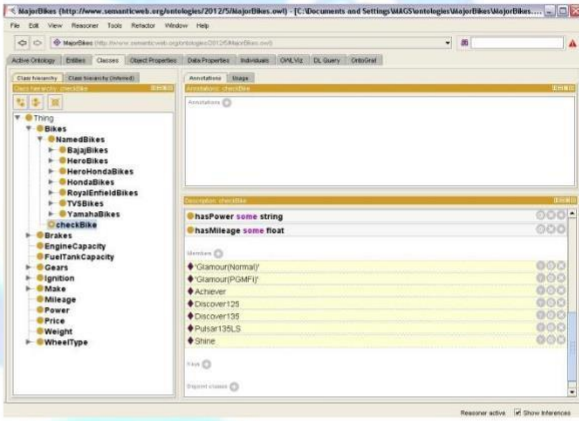

The hierarchy was also evaluated, figure 12 shows the output of OntoGraph and figure 13 shows the output of OWLViz.

5. CONCLUSION & FUTURE WORK

The work carried out in this report provides with strong base in Ontology Engineering. Here we have presented the theories and principles for construction of ontology according to various currently existent methodologies. We also noted the various issues related to the field of ontology development.

Since there exists no one methodology that can be applied in all scenarios of ontology development, our main emphasis here is on building a methodology that can be used as a standard method for ontology construction under various domains. For this we have proposed a method namely *On-To-Methodology*. Then we illustrated our methodology by working out an Ontology of bikes.

The future work entails development of a tool that will automatically generate the Conceptual model of the knowledge. Another future direction is to develop software that would

work on the ontology of Bikes that we created and has simpler graphical user interface so that it could be operated by non-technical users.

This paper proposes the extended form of the α-Bernstein operators with the Pólya–Eggenberger distribution, also known as contagion distribution, using the integral operators for $m \geq 2$. We will refer to these sequence of operators as the "Parametric-Bernstein operators based on contagion distribution" or simply the modified form of α-Bernstein operators. These operators are defined with the help of two parameters, namely, α and γ. We observe the significance of both these parameters. Subsequently, we calculate their moments and on the basis of Korovkin's approximation theorem we assert that our defined operators converge for a real valued continuous function h. We give some basic properties, study the Voronovskaya type asymptotic result and discuss the A-statistical approximation of our operators. We also use the modulus of continuity to study the rate of convergence. Alongside our primary work, we have also defined the King-type modification that preserves the operators at e_0 and e_2. Further, using modulus of continuity, we compare the properties and behavior of both the operators.

1 | INTRODUCTION

The Bernstein operators hold significant importance in approximation theory, offering a powerful framework for constructing polynomial approximations used in computer-aided design and graphics through the creation of Bézier curves. The employment of Bernstein polynomials in spline construction serves as a linchpin connecting various disciplines. Additionally, their role in probability and statistics underscores their significance in Bayesian statistics. Over the past years, several studies have been made on these operators and their applications. In the year 1923, Pólya and Eggenberger formulated a discrete probability distribution that is associated with the Pólya–Eggenberger urn scheme. This distribution, commonly referred to as the contagion distribution or the Pólya distribution, was derived using an urn model [1]. The distribution represents a straightforward procedure: An urn holds U red balls and V blue balls, and one ball is selected randomly from it. The colour of the ball is recorded and is substituted along with with X identical, same colored balls. The aforementioned procedure is iterated m times. The occurrence of obtaining a red (or blue) ball in the jth draw is represented by the random variable Y_j, which takes the value 1 (or 0) to indicate the event. The probability of observing a total of k red drawings, denoted as $k = \sum Y_j$, can be determined by the following expression:

 © 2024 John Wiley & Sons Ltd.

$$\rho_{m,k} = {}^{m}C_k \frac{\prod_{i=0}^{k-1}(U+iX)\prod_{i=0}^{m-k-1}(V+iX)}{\prod_{i=0}^{m-1}(U+V+iX)}. \tag{1.1}$$

The year 1968 saw the introduction of linear positive operators $P_m^{\langle\gamma\rangle} : C[0,1] \to C[0,1]$, defined by Stancu [2, 3], based on the above defined contagion distribution (1.1) with density function as

$$P_m^{\langle\gamma\rangle}(f;x) = \sum_{k=0}^{m} {}^{m}C_k \frac{x^{[k,-\gamma]}(1-x)^{[m-k,-\gamma]}}{1^{[m,-\gamma]}} f\left(\frac{k}{m}\right), \tag{1.2}$$

where, γ is a non-negative parameter and ${}^{m}C_k$ is the binomial coefficient.

The factorial power is determined as $a^{[n,\nu]} = a(a-\nu)(a-2\nu)\ \ldots\ (a-(n-1)\nu)$ and $a^{[0,\nu]} = 1$. This represents a polynomial of degree n.

Later on, several mathematicians gave various modifications of Bernstein operators [4–9]. Apart from the modifications of Bernstein operators, a number of studies have also been made on their Durrmeyer variant which introduces a weight function into the Bernstein basis functions [10–14]. Year 2017 was a crucial year in the field of positive linear operators as Cheng et al. [9] defined the following operators:

For each $m \geq 2$ and fixed real α,

$$\mathrm{B}_{m,\alpha}(f;x) = \sum_{k=0}^{m} f_k \left[{}^{m-2}C_k\,(1-\alpha)\,x + {}^{m-2}C_{k-2}\,(1-\alpha)\,(1-x) + {}^{m}C_k\,\alpha x(1-x)\right] x^{k-1}(1-x)^{m-k-1}, \tag{1.3}$$

where $f_k = f\left(\frac{k}{m}\right)$ and f is defined on $[0,1]$. These operators, $\mathrm{B}_{m,\alpha}(f;x)$ are named as the α-Bernstein operators.

In recent studies, several mathematicians (see the literature [15–19]) gave various modifications of α-Bernstein operators (1.3). These modifications have been analyzed in terms of their auxiliary properties and used modulus of continuity to observe the rate of convergence, analyzed the direct local approximation theorem, function of bounded variation and Voronovskaya type asymptotic result.

Now we consider another modification of the α-Bernstein operators with the help of contagion distribution as density function, defined for $m \geq 2$ as

$$\begin{aligned} \mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(h;x) = \sum_{k=0}^{m} \Bigg[& {}^{m-2}C_k\,(1-\alpha)\,\frac{x^{[k,-\gamma]}(1-x)^{[m-k-1,-\gamma]}}{1^{[m-1,-\gamma]}} \\ & - {}^{m-2}C_{k-2}\,(1-\alpha)\,\frac{x^{[k-1,-\gamma]}(1-x)^{[m-k,-\gamma]}}{1^{[m-1,-\gamma]}} \\ & + {}^{m}C_k\,\alpha\frac{x^{[k,-\gamma]}(1-x)^{[m-k,-\gamma]}}{1^{[m,-\gamma]}} \Bigg] h_k, \end{aligned} \tag{1.4}$$

where, $h_k = h\left(\frac{k}{m}\right)$.

Let us denote the polynomial inside summation as $p_{m,k}^{\langle\alpha,\gamma\rangle}(x)$, that is,

$$\begin{aligned} p_{m,k}^{\langle\alpha,\gamma\rangle}(x) = & {}^{m-2}C_k\,(1-\alpha)\,\frac{x^{[k,-\gamma]}(1-x)^{[m-k-1,-\gamma]}}{1^{[m-1,-\gamma]}} \\ & - {}^{m-2}C_{k-2}\,(1-\alpha)\,\frac{x^{[k-1,-\gamma]}(1-x)^{[m-k,-\gamma]}}{1^{[m-1,-\gamma]}} \\ & - {}^{m}C_k\,\alpha\frac{x^{[k,-\gamma]}(1-x)^{[m-k,-\gamma]}}{1^{[m,-\gamma]}}. \end{aligned}$$

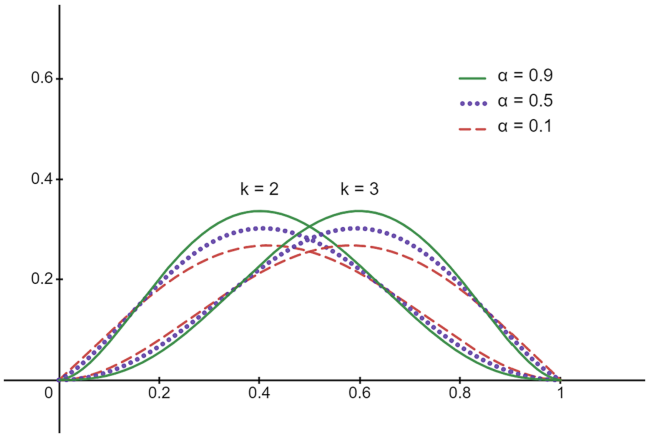

FIGURE 1 Graph of the α-Bernstein polynomial for $m = 5$, $k = 2$ and $k = 3$ and different values of α. [Colour figure can be viewed at wileyonlinelibrary.com]

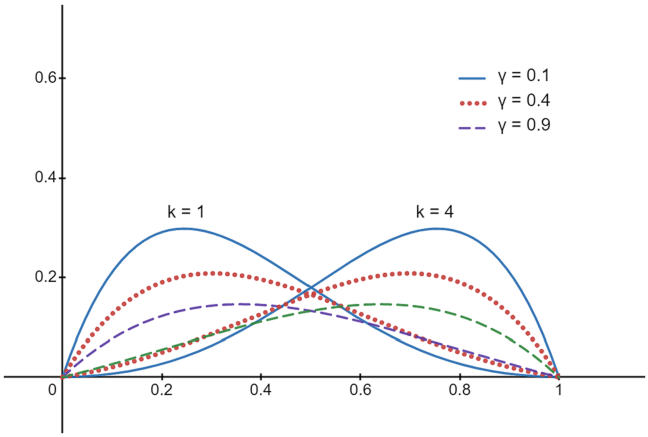

FIGURE 2 Graph of the contagion form of α-Bernstein polynomial for $m = 5$, $k = 1$ and $k = 4$, $\alpha = 0.5$ and different values of γ. [Colour figure can be viewed at wileyonlinelibrary.com]

Some basic calculations give us the alternate form of $\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(h;x)$:

$$\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(h;x) = (1-\alpha)\sum_{k=0}^{m-1} {}^{m-1}C_k \frac{x^{[k,-\gamma]}(1-x)^{[m-k-1,-\gamma]}}{1^{[m-1,-\gamma]}} g_k - \alpha \sum_{k=0}^{m} {}^{m}C_k \frac{x^{[k,-\gamma]}(1-x)^{[m-k,-\gamma]}}{1^{[m,-\gamma]}} h_k, \tag{1.5}$$

where $h_k = h\left(\frac{k}{m}\right)$, $g_k = \left(1 - \frac{k}{m-1}\right) h_k + \frac{k}{m-1} h_{k+1}$
and ${}^{m}C_k$ is the binomial coefficient.

Special cases:

1. For $\gamma = 0$ and $\alpha = 1$, the proposed operators $\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(h;x)$ transform into the classical Bernstein operators.
2. For $\alpha = 1$, the proposed operators transform into the operators (1.2), proposed by Stancu.
3. For $\gamma = 0$, we get the operators (1.3) as defined by Cheng et al. for $m \geq 2$.

From Figures 1 and 2, it is clear that like in the classical Bernstein, α-Bernstein and the Stancu-Bernstein operators, the basis polynomial, $p_{m,k}^{\langle\alpha,\gamma\rangle}(x)$ as defined with the help of operators (1.4) are also symmetric in $[0, 1]$. Contagion distribution is particularly important and applicable in various real-world scenarios where the probability of an event depends on its past occurrences.

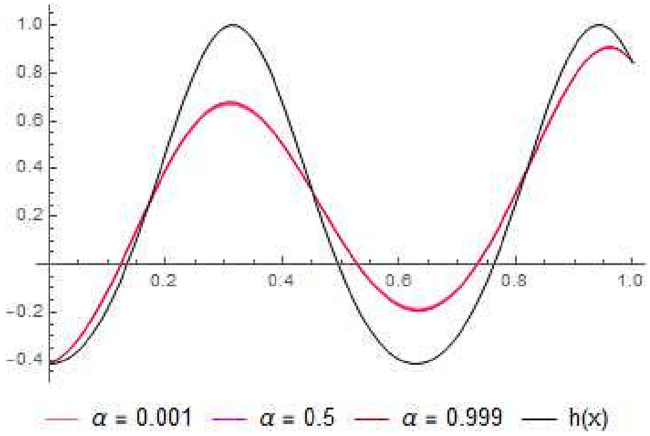

FIGURE 3 Approximation process of $\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(\cos(2\cos 5t);x)$ for $m = 30$ when $\gamma = 0.01$ is fixed and α is varying in $[0,1]$. [Colour figure can be viewed at wileyonlinelibrary.com]

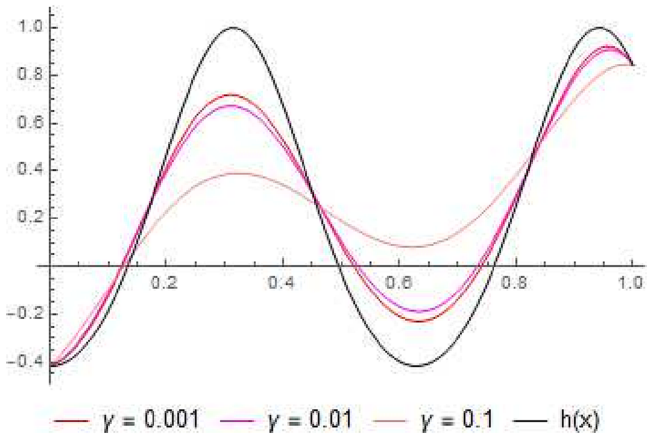

FIGURE 4 Approximation process of $\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(\cos(2\cos 5t);x)$ for $m = 30$ when $\alpha = 0.5$ is fixed and γ is varying in $[0,1]$. [Colour figure can be viewed at wileyonlinelibrary.com]

1.1 | Comparison of the parameters α and γ

This paper aims to analyze the results of approximations for the sequence of operators (1.5), which have been defined by the utilization of two parameters, namely, α and γ. Both entities are restricted to exist within the closed interval $[0,1]$. In order to gain a better understanding of the impact of these parameters on the process of approximation, an analysis is performed using a specific example, with the function $h(x) = \cos(2\cos 5x)$.

Initially, we fix the value of γ and then observe how varying α affects the results (as shown in Figure 3). Remarkably, it is observed that despite substantial variations in α, its impact on the enhancement of the approximation process is not significant. In contrast, modifying the values of γ exerts a substantial impact on the precision of the approximations made by the operators. Notably, smaller values of γ results in more precise approximations, suggesting that as m approaches ∞, γ tends to converge toward 0 (Figure 4).

Thus, we can conclude a relationship between γ and m as $\gamma = O(1/m)$. This can also be studied in the upcoming section concerning the Korovkin theorem. Nevertheless, it is worth noting that there exists potential of further research by considering simultaneous operators for $\gamma = O(1/m^a)$, where $a > 0$, or any other function $\gamma(m) \to 0$, which opens door for analysis on the convergence properties in future. Our choice of $\gamma = O(1/m)$ reduces further complexities.

Lemma 1.1. *Let $\alpha \in [0,1]$ and $\gamma = O(1/m) \in [0,1]$. Then the moments of $\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(h;x)$ are as follows:*

(i) $\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(1;x) = 1$

(ii) $\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(t;x) = x$

(iii) $\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(t^2;x) = \frac{1}{1+\gamma}\left[x^2 + \frac{m+2(1-\alpha)}{m^2}x(1-x)\right] + x\frac{\gamma}{1+\gamma}$

10991476, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/mma.10172 by Delhi Technological University, Wiley Online Library on [21/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(iv) $\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}\left(t^3;x\right)=x\left[\frac{m+6(1-\alpha)}{m^3}\right]+x\left(\frac{x+\gamma}{1+\gamma}\right)\left[\frac{3m^2+3m(1-2\alpha)-18(1-\alpha)}{m^3}\right]+x\left(\frac{x+\gamma}{1+\gamma}\right)\left(\frac{x+2\gamma}{1+2\gamma}\right)\left[\frac{m^3-3m^2-2m(2-3\alpha)+12(1-\alpha)}{m^3}\right]$

(v) $\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}\left(t^4;x\right)=x\left[\frac{m+14(1-\alpha)}{m^4}\right]+x\left(\frac{x+\gamma}{1+\gamma}\right)\left[\frac{7m^2+m(29-36\alpha)-86(1-\alpha)}{m^4}\right]+6x\left(\frac{x+\gamma}{1+\gamma}\right)\left(\frac{x+2\gamma}{1+2\gamma}\right)\left[\frac{m^3-m^2(1+2\alpha)-2m(7-8\alpha)+24(1-\alpha)}{m^4}\right]$
$+x\left(\frac{x+\gamma}{1+\gamma}\right)\left(\frac{x+2\gamma}{1+2\gamma}\right)\left(\frac{x+3\gamma}{1+3\gamma}\right)\left[\frac{m^4-6m^3-m^2(1-12\alpha)+6m(9-10\alpha)-72(1-\alpha)}{m^4}\right].$

Proof. To calculate the moments of the contagion form of α-Bernstein operators, we will use the moments of the contagion form of the classical Bernstein operators (1.2). For $h(x)=1$, we have $h_k=1=g_k$, and thus,

$$\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(1;x)=(1-\alpha)\sum_{k=0}^{m-1}{}^{m-1}C_k\frac{x^{[k,-\gamma]}(1-x)^{[m-k-1,-\gamma]}}{1^{[m-1,-\gamma]}}+\alpha\sum_{k=0}^{m}{}^{m}C_k\frac{x^{[k,-\gamma]}(1-x)^{[m-k,-\gamma]}}{1^{[m,-\gamma]}}=1.$$

Now for $h(x)=x$, $h_k=\frac{k}{m}$ and $g_k=\frac{k}{m-1}$, we have

$$\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(t;x)=(1-\alpha)\sum_{k=0}^{m-1}{}^{m-1}C_k\frac{x^{[k,-\gamma]}(1-x)^{[m-k-1,-\gamma]}}{1^{[m-1,-\gamma]}}\frac{k}{m-1}+\alpha\sum_{k=0}^{m}{}^{m}C_k\frac{x^{[k,-\gamma]}(1-x)^{[m-k,-\gamma]}}{1^{[m,-\gamma]}}\frac{k}{m}=x.$$

For $h(x)=x^2$, $h_k=\frac{k^2}{m^2}$ and $g_k=\frac{k^2}{(m-1)^2}\left[\frac{m^2-1}{m^2}\right]+\frac{k}{(m-1)m^2}$, we have

$$\begin{aligned}
\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}\left(t^2;x\right)&=(1-\alpha)\left[\sum_{k=0}^{m-1}{}^{m-1}C_k\frac{x^{[k,-\gamma]}(1-x)^{[m-k-1,-\gamma]}}{1^{[m-1,-\gamma]}}\frac{k^2}{(m-1)^2}\left(\frac{m^2-1}{m^2}\right)\right.\\
&\quad\left.+\sum_{k=0}^{m-1}{}^{m-1}C_k\frac{x^{[k,-\gamma]}(1-x)^{[m-k-1,-\gamma]}}{1^{[m-1,-\gamma]}}\frac{k}{(m-1)}\left(\frac{1}{m^2}\right)\right]\\
&\quad-\alpha\sum_{k=0}^{m}{}^{m}C_k\frac{x^{[k,-\gamma]}(1-x)^{[m-k,-\gamma]}}{1^{[m,-\gamma]}}\frac{k^2}{m^2}\\
&=(1-\alpha)\left\{\left(\frac{m^2-1}{m^2}\right)\frac{1}{1+\gamma}\left[\left(\frac{m-2}{m-1}\right)x^2+\left(\frac{(m-1)\gamma+1}{m-1}\right)x\right]+\frac{1}{m^2}x\right\}\\
&\quad-\frac{\alpha}{1+\gamma}\left[\left(\frac{m-1}{m}\right)x^2+\left(\frac{m\gamma+1}{m}\right)x\right]\\
&=\frac{x^2}{1+\gamma}\left[(1-\alpha)\left(1-\frac{1}{m}-\frac{2}{m^2}\right)+\alpha\left(1-\frac{1}{m}\right)\right]\\
&\quad-\frac{x}{1+\gamma}\left[(1-\alpha)\frac{(m+1)}{m^2}((m-1)\gamma+1)+\frac{\alpha}{m}(m\gamma+1)\right]+x\frac{(1-\alpha)}{m^2}\\
&=\frac{x^2}{1+\gamma}\left[1-\frac{1}{m}-2\frac{(1-\alpha)}{m^2}\right]+\frac{x}{1+\gamma}\left[(1-\alpha)\frac{(m+1)}{m^2}\right.\\
&\quad\left.+(1-\alpha)\gamma\frac{(m+1)(m-1)}{m^2}+\frac{\alpha}{m}+\alpha\gamma\right]+x\frac{(1-\alpha)}{m^2}\\
&=\frac{x^2}{1+\gamma}\left[1-\frac{1}{m}-2\frac{(1-\alpha)}{m^2}\right]+\frac{x}{1+\gamma}\left[\frac{1}{m}+(1-\alpha)\frac{1}{m^2}\right]\\
&\quad-x\frac{\gamma}{1+\gamma}\left[(1-\alpha)\left(1-\frac{1}{m^2}\right)+\alpha\right]+x\frac{(1-\alpha)}{m^2}\\
&=\frac{1}{1+\gamma}\left[x^2-\frac{x^2}{m}-(1-\alpha)\frac{x^2}{m^2}+\frac{x}{m}+(1-\alpha)\frac{x}{m^2}\right]-(1-\alpha)\frac{1}{1+\gamma}\frac{x^2}{m^2}+x\frac{\gamma}{1+\gamma}\\
&\quad-(1-\alpha)\frac{\gamma}{1+\gamma}\frac{x}{m^2}+x\frac{(1-\alpha)}{m^2}\\
&=\frac{1}{1+\gamma}\left[x^2+\frac{m+2(1-\alpha)}{m^2}x(1-x)\right]+x\frac{\gamma}{1+\gamma}.
\end{aligned}$$

Similarly, we can obtain the values for t^3 and t^4. □

This result brings us to a conclusion that as $m \to \infty$, $\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(e_s;x) \to e_s$, where $e_s = t^s$ for $s = 0,1,2$. From the Bohman–Korovkin theorem [20, 21], we can hence state that for a real valued continuous function h, the modified α-Bernstein operators $\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(h;x)$ converges to $h(x)$ uniformly. That is,

$$\lim_{m\to\infty} \mathcal{P}_{m,\alpha}^{\langle\gamma\rangle} h = h.$$

2 | APPROXIMATION RESULTS

Lemma 2.1. *Considering Lemma 1.1 and computing the central moments of (1.4), we obtain the following limits:*

(i) $\lim_{m\to\infty} m\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(\varphi_2(t);x) = \frac{2C}{1+\gamma}x(1-x)$

(ii) $\lim_{m\to\infty} m\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(\varphi_4(t);x) = 0,$

where $\varphi_m(t) = (t-x)^m$ *and* $C = \lim_{m\to\infty} \frac{1+m\gamma}{2}$.

Theorem 2.2. *Let* $0 \le \alpha \le 1$ *and* h *is a bounded function defined for all* $x \in [0,1]$. *Then for* $\gamma = O(1/m)$,

$$\lim_{m\to\infty} m\left[\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(h(t);x) - h(x)\right] = \frac{C}{1+\gamma}x(1-x)\,h''(x),$$

where $C = \lim_{m\to\infty} \frac{1+m\gamma}{2}$. *The theorem holds true only for those* $x \in [0,1]$ *where* $h''(x)$ *exists.*

Proof. By means of Taylor's series expansion for $k \le m$, we have

$$h(t) = h(x) + (t-x)h'(x) + \frac{1}{2}(t-x)^2h''(x) + \text{ɀ}(t-x)(t-x)^2,$$

where $\lim_{t\to x} \text{ɀ}(t-x) = 0.$. Taking $t = k/m$, we get,

$$\begin{aligned}
&m\left[\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(h(t);x) - h(x)\right] \\
&= m\sum_{k=0}^{m} p_{m,k}^{\langle\alpha,\gamma\rangle}(x)\left[\left(\frac{k}{m}-x\right)h'(x) + \frac{1}{2}\left(\frac{k}{m}-x\right)^2 h''(x) + \text{ɀ}\left(\frac{k}{m}-x\right)\left(\frac{k}{m}-x\right)^2\right] \\
&= \sum_{k=0}^{m}(k-mx)p_{m,k}^{\langle\alpha,\gamma\rangle}(x)h'(x) + \frac{1}{2m}\sum_{k=0}^{m}(k-mx)^2 p_{m,k}^{\langle\alpha,\gamma\rangle}(x)h''(x) + mR_m(x),
\end{aligned}$$

where, $R_m(x) = \sum_{k=0}^{m} \text{ɀ}\left(\frac{k}{m}-x\right)\left(\frac{k}{m}-x\right)^2 p_{m,k}^{\langle\alpha,\gamma\rangle}(x).$.

The first summation will be zero and for the second summation, we have

$$\begin{aligned}
\sum_{k=0}^{m}(k-mx)^2 p_{m,k}^{\langle\alpha,\gamma\rangle}(x) &= \sum_{k=0}^{m} k^2 p_{m,k}^{\langle\alpha,\gamma\rangle}(x) - 2mx\sum_{k=0}^{m} k p_{m,k}^{\langle\alpha,\gamma\rangle}(x) + m^2x^2\sum_{k=0}^{m} p_{m,k}^{\langle\alpha,\gamma\rangle}(x) \\
&= \frac{m^2}{1+\gamma}\left[x^2 + \frac{m+2(1-\alpha)}{m^2}x(1-x)\right] + m^2x\frac{\gamma}{1+\gamma} - 2m^2x^2 + m^2x^2 \\
&= \frac{m^2\gamma + m + 2(1-\alpha)}{1+\gamma}x(1-x).
\end{aligned}$$

10991476, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/mma.10172 by Delhi Technological University, Wiley Online Library on [21/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Hence,

$$m\left[\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(h(t);x)-h(x)\right]=\frac{x(1-x)}{2m(1+\gamma)}\left\{m^2\gamma+m+2(1-\alpha)\right\}h''(x)+mR_m(x)$$
$$=\frac{1}{1+\gamma}\left(\frac{m\gamma}{2}+\frac{1}{2}+\frac{1-\alpha}{m}\right)x(1-x)\,h''(x)+mR_m(x).$$

Now, all that is left to prove is that, $mR_m(x)\to 0$ as $m\to\infty$.
We know, for every $\varepsilon>0$, $\exists\ \delta>0$: $\varepsilon>0,\ \exists\ \delta>0:\ |\not{e}(t-x)|<\varepsilon$.
Also, since $0\leqslant|\not{e}(t-x)|\leqslant m$, therefore $\exists\ M>0$ such that $|\not{e}(t-x)|\leqslant M$ whenever $|t-x|\geqslant\delta$. Hence, we get

$$|\not{e}(t-x)|\leq\varepsilon+M\frac{(t-x)^2}{\delta^2},\qquad\text{for every } t.$$

Thus,

$$m\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}\left(\not{e}(t-x)(t-x)^2;x\right)\leq m\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}\left(\left(\varepsilon+M\frac{(t-x)^2}{\delta^2}\right)(t-x)^2;x\right)$$
$$\leq m\varepsilon\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(\varphi_2;x)+m\frac{M}{\delta^2}P_{n,\alpha}^{\langle\gamma\rangle}(\varphi_4;x).$$

Thus, we can say $\lim_{m\to\infty} m\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}\left(\not{e}(t-x)(t-x)^2;x\right)=0$.
Hence, we get

$$\lim_{m\to\infty} m\left[\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(h(t);x)-h(x)\right]=\frac{x(1-x)}{1+\gamma}\left(\lim_{m\to\infty}\frac{m\gamma}{2}+\frac{1}{2}+\frac{(1-\alpha)}{m}\right)h''(x)$$
$$=\frac{C}{1+\gamma}x(1-x)\,h''(x),$$

where $C=\lim_{m\to\infty}\frac{m\gamma+1}{2}$. □

Theorem 2.3. *Let the functions $g,h:(0,1)\to\mathbb{R}$. If $g,h\in C^2(0,1)$ then,*

$$\lim_{m\to\infty} m\left[\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(gh;x)-\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(g;x)\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(h;x)\right]=\frac{2C}{1+\gamma}x(1-x)\,g'(x)h'(x),$$

where $C=\lim_{m\to\infty}\frac{m\gamma+1}{2}$.

Proof. We consider

$$\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(gh;x)-\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(g;x)\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(h;x)$$
$$=\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(gh;x)-g(x)h(x)-\frac{1}{2}(gh)''\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(\varphi_2;x)$$
$$-h(x)\left[\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(g;x)-\frac{1}{2}g''(x)\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(\varphi_2;x)-g(x)\right]$$
$$-\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(g;x)\left[\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(h;x)-\frac{1}{2}h''(x)\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(\varphi_2;x)-h(x)\right]$$
$$-\frac{1}{2}\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(\varphi_2;x)\left[2g'(x)h'(x)+g(x)h''(x)-h''(x)\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(g;x)\right].$$

Multiplying both sides by m, taking $m\to\infty$ and using the above proven identities, we get

$$\lim_{m\to\infty} m\left[\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(gh;x)-\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(g;x)\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(h;x)\right]=\frac{2C}{1+\gamma}x(1-x)\,g'(x)h'(x),$$

where $C=\lim_{m\to\infty}\frac{m\gamma+1}{2}$. □

10991476, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/mma.10172 by Delhi Technological University, Wiley Online Library on [21/05/2024]. We have seen that for any continuous real-valued function h, $\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}h \to h$ uniformly on $[0,1]$, giving us an explicit approximation to h. Our next focus shifts on knowing how good this approximation will be. For that we calculate the error that would have occurred during the approximation process. One way to determine this is using the modulus of continuity.

Definition 2.4. The modulus of continuity, denoted by $\omega(h(\cdot);\delta)$, of a function h is defined as

$$\omega(h(t);\delta) = \sup_{\substack{|t_1-t_2|\le\delta \\ t_1,t_2\in[a,b]}} |h(t_1)-h(t_2)|,$$

where $t_1, t_2 \in [a,b]$ and $\delta > 0$.

For simplicity, we can denote $\omega(h(\cdot);\delta)$ with $\omega(\delta)$ as well.

Remark 2.5. For modulus of continuity, $\omega(\delta)$ of $h(t)$ on $[a,b]$, the following property holds: If $\upsilon > 0$, then $\omega(\upsilon\delta) \le (1+\upsilon)\,\omega(\delta)$.

Let us take into account the error bound

$$\left\|h - \mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}h\right\| = \max_{0\le x\le 1}\left|h(x) - \mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(h;x)\right|,$$

where $\|.\|$ is the uniform norm over the interval $[0,1]$. Our next attempt is to attain an upper bound to estimate the approximation error committed during the process.

Theorem 2.6. *Let* $0 \le \alpha \le 1$ *and* $\gamma = O(1/m)$. *For a bounded function* h *on* $[0,1]$, *we deduce*

$$\left\|h - \mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}h\right\| \le \frac{3}{2}\omega\left(\frac{\sqrt{m^2\gamma + m + 2(1-\alpha)}}{m\sqrt{1+\gamma}}\right),$$

where $\omega(.)$ *denotes modulus of continuity.*

Proof. From operators (1.5), we get

$$\begin{aligned}\left|h(x) - \mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(h;x)\right| &= \left|\sum_{k=0}^{m} p_{m,k}^{\langle\alpha,\gamma\rangle}(x)\left[h(x) - h\left(\frac{k}{m}\right)\right]\right| \\ &\le \sum_{k=0}^{m}\omega\left(\left|x-\frac{k}{m}\right|\right)p_{m,k}^{\langle\alpha,\gamma\rangle}(x).\end{aligned}$$

Using Schwarz's inequality, we can say

$$\begin{aligned}\sum_{k=0}^{m}\left|x-\frac{k}{m}\right|p_{m,k}^{\langle\alpha,\gamma\rangle}(x) &= \sum_{k=0}^{m}\left|x-\frac{k}{m}\right|\sqrt{p_{m,k}^{\langle\alpha,\gamma\rangle}(x)}.\sqrt{p_{m,k}^{\langle\alpha,\gamma\rangle}(x)} \\ &\le \left[\sum_{k=0}^{m}\left(x-\frac{k}{m}\right)^2 p_{m,k}^{\langle\alpha,\gamma\rangle}(x)\right]^{1/2}\left[\sum_{k=0}^{m}p_{m,k}^{\langle\alpha,\gamma\rangle}(x)\right]^{1/2} \\ &= \left[\frac{1}{1+\gamma}\left(\frac{m+2(1-\alpha)}{m^2}+\gamma\right)x(1-x)\right]^{1/2} \\ &\le \left[\frac{m^2\gamma + m + 2(1-\alpha)}{4m^2(1+\gamma)}\right]^{1/2}.\end{aligned}$$

10991476, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/mma.10172 by Delhi Technological University, Wiley Online Library on [21/05/2024]. FIGURE 5 Convergence of $\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(h;x)$ for parameters $\alpha = 0.7$ and $\gamma = 0.01$, for different values of m. [Colour figure can be viewed at wileyonlinelibrary.com]

From Remark 2.5,

$$\omega\left(\left|x-\frac{k}{m}\right|\right) = \omega\left(\frac{m\sqrt{1+\gamma}}{\sqrt{m^2\gamma+m+2(1-\alpha)}}\left|x-\frac{k}{m}\right|.\frac{\sqrt{m^2\gamma+m+2(1-\alpha)}}{m\sqrt{1+\gamma}}\right)$$
$$\leq \left[1+\frac{m\sqrt{1+\gamma}}{\sqrt{m^2\gamma+m+2(1-\alpha)}}\left|x-\frac{k}{m}\right|\right]\omega\left(\frac{\sqrt{m^2\gamma+m+2(1-\alpha)}}{m\sqrt{1+\gamma}}\right).$$

Thus, we get

$$\begin{aligned}
&\left|h(x)-\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(h;x)\right| \\
&\leq \sum_{k=0}^{m}\left[1+\frac{m\sqrt{1+\gamma}}{\sqrt{m^2\gamma+m+2(1-\alpha)}}\left|x-\frac{k}{m}\right|\right]\omega\left(\frac{\sqrt{m^2\gamma+m+2(1-\alpha)}}{m\sqrt{1+\gamma}}\right)p_{m,k}^{\langle\alpha,\gamma\rangle}(x) \\
&\leq \omega\left(\frac{\sqrt{m^2\gamma+m+2(1-\alpha)}}{m\sqrt{1+\gamma}}\right)\left[1+\frac{m\sqrt{1+\gamma}}{\sqrt{m^2\gamma+m+2(1-\alpha)}}\sum_{k=0}^{m}\left|x-\frac{k}{m}\right|p_{m,k}^{\langle\alpha,\gamma\rangle}(x)\right] \\
&\leq \frac{3}{2}\omega\left(\frac{\sqrt{m^2\gamma+m+2(1-\alpha)}}{m\sqrt{1+\gamma}}\right),
\end{aligned}$$

and thereafter, we arrive at our required result. □

Now that we have obtained an upper bound for the error function, we can also use the fact that $\lim_{\delta\to 0}\omega(\delta) = 0$ iff h is uniformly continuous on $[a,b]$ to see that our modified α-Bernstein operators, $\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}h \to h$ uniformly on the interval $[0,1]$. The following graph (Figure 5) gives us a visual representation of the approximation of our operators $\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(h;x)$ defined in (1.4) for $h(x) = (3x-1)\sin\frac{7\pi}{3}x + \frac{5}{4}$.

3 | A-STATISTICAL APPROXIMATION

In 1951, an alternative concept of convergence emerged, recognized as statistical convergence, introduced by Fast [22] and Steinhaus [23]. The term statistical convergence used henceforth is nothing but another name for "almost convergence," used by Antoni Zygmund in his book [24]. Unlike classical convergence, almost convergence accommodates divergent sequences, offering a framework to analyze and understand the behavior of sequences that do not converge in the traditional sense. One of the ways for summing sequences and series using an infinite matrix is the matrix summation method (see Braha et al. [25]). Taking an infinite matrix $A = (a_{mk})$ for $m,k \in \mathbb{N}$, a given sequence $x = \langle x_m\rangle$ can be transformed

10991476, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/mma.10172 by Delhi Technological University, Wiley Online Library on [21/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

into the sequence $\langle Ax\rangle_m$.

$$\langle Ax\rangle_m = \sum_{k=1}^{\infty} a_{mk}x_k.$$

If $\lim_{m\to\infty}\langle Ax\rangle_m = L$ and the series on the RHS, $\sum_{k=1}^{\infty} a_{mk}x_k$, converges $\forall\ m$, then the sequence $\langle x_m\rangle$ is said to be summable by the matrix A and L will be called its limit. Further, if the limit is preserved then this method is referred to as regular matrix summability method and the infinite matrix A is called a regular matrix.

Definition 3.1. For every $\varepsilon > 0$, if $\lim_m \sum_{m:|x_m-L|\geq\varepsilon} a_{mk} = 0$, then the sequence, $x = \langle x_m\rangle$ is said to be A-statistically convergent to L and is denoted by $st_A - \lim x = L$.

Lemma 3.2 (Gadjiev and Orhan [26])**.** *Let $\{\mathcal{L}_m\}$ be a sequence of linear positive operators and $A = (a_{mk})$ be a regular positive summability matrix. Then,*

$$st_A - \lim_m \|\mathcal{L}_m h - h\| = 0; h \in C([a,b])$$

iff

$$st_A - \lim_m \|\mathcal{L}_m e_r - e_r\| = 0; \quad \textit{where}\ \ e_r = t^r \textit{ for } r = 0,1,2.$$

Theorem 3.3. *Let $A = (a_{mk})$ be a regular positive summability matrix. Then for each $h \in C([0,1])$, we get*

$$st_A - \lim_{m\to\infty} \left\|\mathcal{P}^{\langle\gamma\rangle}_{m,\alpha}h - h\right\| = 0.$$

Proof. From Lemma 3.2, it is enough to prove that

$$\left\|\mathcal{P}^{\langle\gamma\rangle}_{m,\alpha}e_r - x^r\right\| = 0;$$

where, $e_r = t^r$ for $r = 0,1,2$.

Using the moments of modified α-Bernstein operator (1.4), we have

$$st_A - \lim_{m\to\infty} \left\|\mathcal{P}^{\langle\gamma\rangle}_{m,\alpha}e_0 - 1\right\| = 0$$

and

$$st_A - \lim_{m\to\infty} \left\|\mathcal{P}^{\langle\gamma\rangle}_{m,\alpha}e_1 - x\right\| = 0;$$

also,

$$\begin{aligned}
&\left\|\mathcal{P}^{\langle\gamma\rangle}_{m,\alpha}e_2 - x^2\right\| \\
&\leq \sup\left\{\left|\frac{x^2}{1+x^2}\left[\frac{(m+1)(m-2)}{m^2}\frac{1-\alpha}{1+\gamma} + \frac{m-1}{m}\frac{\alpha}{1+\gamma} - 1\right]\right|\right. \\
&\quad \left. + \left|\frac{x}{1+x^2}\left[\frac{((m-1)\gamma+1)(m+1)}{m^2}\frac{1-\alpha}{1+\gamma} + \frac{m\gamma+1}{m}\frac{\alpha}{1+\gamma} + \frac{1-\gamma}{m^2}\right]\right|\right\} \\
&= \frac{(m+1)(m-2)}{m^2}\frac{1-\alpha}{1+\gamma} + \frac{m-1}{m}\frac{\alpha}{1+\gamma} - 1 \\
&\quad - \frac{((m-1)\gamma+1)(m+1)}{m^2}\frac{1-\alpha}{1+\gamma} + \frac{m\gamma+1}{m}\frac{\alpha}{1+\gamma} + \frac{1-\gamma}{m^2} \\
&= \frac{(1-\alpha)(-1-\gamma)+(1-\gamma)(1+\gamma)}{m^2(1+\gamma)} \\
&= \frac{\alpha-\gamma}{m^2}.
\end{aligned}$$

Taking the sets $M = \{k : \left\|\mathcal{P}^{\langle\gamma\rangle}_{m,\alpha}e_2 - x^2\right\| \geq \varepsilon\}$ and $M_1 = \left\{k : \frac{\alpha-\gamma}{m^2} \geq \varepsilon\right\}$.

10991476, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/mma.10172 by Delhi Technological University, Wiley Online Library on [21/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Since $M \subseteq M_1$, therefore

$$\sum_{m\in M} a_{mk} \leq \sum_{m\in M_1} a_{mk}.$$

Thus,

$$st_A - \lim_{m\to\infty} \left\| \mathcal{P}^{\langle\gamma\rangle}_{m,\alpha} e_2 - x^2 \right\| = 0 \ \ as \ \ k \to \infty.$$

□

4 | KING-TYPE MODIFICATION

Till date many operators have been defined in approximation theory. The majority of these operators preserve e_0 and e_1. That is, for a sequence of operators $\{\mathcal{L}_m\}$, we have

$\mathcal{L}_m(e_0;x) = e_0(x)$ and $\mathcal{L}_m(e_1;x) = e_1(x)$.

The same does not hold for e_2, that is, $\mathcal{L}_m(e_2;x) \neq e_2(x)$. Rather, $\mathcal{L}_m(e_2;x)$ tends to $e_2(x)$ as m tends to infinity. The modified α-Bernstein operators (1.4) defined in this paper is an example for the same.

In 2003, King [27] gave a method to modify any sequence of operators into such a form which preserves e_0 and e_2, and for e_1 we get an expression which tends to $e_1(x)$ as m tends to infinity. Recently, Finta [28] established the unique existence of functions r_n, as defined by King, on $[0,1]$ ensuring that the associated sequence of King operators provides an approximation to every continuous function and preserves the functions e_0 and e_t, where $t \in \{2,3,\dots\}$ is fixed.

On the same grounds, we define $\tilde{\mathcal{P}}^{\langle\gamma\rangle}_{m,\alpha}(h;x)$, an alteration of $\mathcal{P}^{\langle\gamma\rangle}_{m,\alpha}(h;x)$ such that $\tilde{\mathcal{P}}^{\langle\gamma\rangle}_{m,\alpha}(1;x) = 1$, $\tilde{\mathcal{P}}^{\langle\gamma\rangle}_{m,\alpha}\left(t^2;x\right) = x^2$ and $\tilde{\mathcal{P}}^{\langle\gamma\rangle}_{m,\alpha}(t;x) = r_m(x) \to x$ as $m \to \infty$. Then by Korovkin theorem, for all continuous functions h and $x \in [0,1]$, we have

$$\lim_{m\to\infty} \widetilde{\mathcal{P}}^{\langle\gamma\rangle}_{m,\alpha}(h;x) = h(x).$$

Now, from Lemma 1.1, we have

$$\begin{aligned}
&\mathcal{P}^{\langle\gamma\rangle}_{m,\alpha}(1;x) = 1, \ \mathcal{P}^{\langle\gamma\rangle}_{m,\alpha}(t;x) = x, \ \text{ and} \\
&\mathcal{P}^{\langle\gamma\rangle}_{m,\alpha}\left(t^2;x\right) = \frac{1}{1+\gamma}\left[x^2 + \frac{m+2(1-\alpha)}{m^2}x(1-x)\right] + x\frac{\gamma}{1+\gamma} \\
&\qquad = x^2\frac{1}{1+\gamma}\left[1 - \frac{m+2(1-\alpha)}{m^2}\right] + x\frac{1}{1+\gamma}\left[\gamma + \frac{m+2(1-\alpha)}{m^2}\right] \\
&\qquad = a_m x^2 + b_m x
\end{aligned}$$

where

$$a_m = \frac{1}{1+\gamma}\left[1 - \frac{m+2(1-\alpha)}{m^2}\right] \ \text{ and } \ b_m = \frac{1}{1+\gamma}\left[\gamma + \frac{m+2(1-\alpha)}{m^2}\right].$$

We consider the modified operators as

$$\begin{aligned}
\tilde{\mathcal{P}}^{\langle\gamma\rangle}_{m,\alpha}(h;x) = (1-\alpha)\sum_{k=0}^{m-1} {}^{m-1}C_k \frac{(r_m(x))^{[k,-\gamma]}(1-r_m(x))^{[m-k-1,-\gamma]}}{1^{[m-1,-\gamma]}} g_k \\
- \alpha \sum_{k=0}^{m} {}^{m}C_k \frac{(r_m(x))^{[k,-\gamma]}(1-r_m(x))^{[m-k,-\gamma]}}{1^{[m,-\gamma]}} h_k,
\end{aligned} \tag{4.1}$$

where $h_k = h\left(\frac{k}{m}\right)$, $g_k = \left(1 - \frac{k}{m-1}\right)h_k + \frac{k}{m-1}h_{k+1}$, and

$$r_m(x) = \frac{-b_m + \sqrt{{b_m}^2 + 4a_m x^2}}{2a_m},$$

where a_m and b_m are as defined above.

10991476, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/mma.10172 by Delhi Technological University, Wiley Online Library on [21/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Lemma 4.1. *For the operators (4.1), we can prove the following identities:*

(i) $\tilde{\mathcal{P}}^{\langle\gamma\rangle}_{m,\alpha}(e_0;x) = 1$,
(ii) $\tilde{\mathcal{P}}^{\langle\gamma\rangle}_{m,\alpha}(e_1;x) = r_m(x)$,
(iii) $\tilde{\mathcal{P}}^{\langle\gamma\rangle}_{m,\alpha}(e_2;x) = x^2$,

where $e_r = t^r$ *for* $r = 0, 1, 2$.

Lemma 4.2. *From the above Lemma 4.1, we can also state*

- $\tilde{\mathcal{P}}^{\langle\gamma\rangle}_{m,\alpha}(\varphi_1(t);x) = r_m(x) - x$,
- $\tilde{\mathcal{P}}^{\langle\gamma\rangle}_{m,\alpha}(\varphi_2(t);x) = -2x\tilde{\mathcal{P}}^{\langle\gamma\rangle}_{m,\alpha}(\varphi_1;x)$,

where, $\varphi_m(t) = (t-x)^m$.

Lemma 4.3 (DeVore [29])**.** *For any sequence of linear positive operators* $\{\mathcal{L}_m\}$ *and* $h \in C[a,b]$, *we have the following relations:*

$$|\mathcal{L}_m(h;x) - h(x)| \le |h(x)|\,|1 - \mathcal{L}_m(1;x)| - \omega(h,\delta)\left[\mathcal{L}_m(1;x) + \frac{1}{\delta}(\mathcal{L}_m(1;x))^{1/2}\alpha_m(x)\right], \tag{4.2}$$

where $\omega(h,\delta)$ *is the modulus of continuity of* h *and* ${\alpha_m}^2(x) = \mathcal{L}_m\left((t-x)^2;x\right)$. *Further, if* h' *is continuous, then*

$$|\mathcal{L}_m(h;x) - h(x)| \le |h(x)|\,|1 - \mathcal{L}_m(1;x)| + \left|h'(x)\right|\,|\mathcal{L}_m((t-x);x)| - \omega\left(h',\alpha_m(x)\right)\left[1 + (\mathcal{L}_m(1;x))^{1/2}\right]\alpha_m(x). \tag{4.3}$$

Let us compare the contagion form of α-Bernstein operators (1.4) and its King-type modification (4.1), as defined above, on the basis of these relations.

Theorem 4.4. *Let* $\left\{\mathcal{P}^{\langle\gamma\rangle}_{m,\alpha}\right\}$ *and* $\left\{\tilde{\mathcal{P}}^{\langle\gamma\rangle}_{m,\alpha}\right\}$ *be the sequences of linear positive operators as defined in the above equations and* $h \in C([a,b])$. *Then for* $0 \le \alpha \le 1$ *and* $\gamma = O(1/m)$, *we have the following:*

$$\left|\mathcal{P}^{\langle\gamma\rangle}_{m,\alpha}(h;x) - h(x)\right| \le \omega(h,\delta)\left[1 + \frac{1}{\delta}\sqrt{b_m x(1-x)}\right]$$
$$\left|\tilde{\mathcal{P}}^{\langle\gamma\rangle}_{m,\alpha}(h;x) - h(x)\right| \le \omega(h,\delta)\left[1 + \frac{1}{\delta}\sqrt{2x(x - r_m(x))}\right].$$

Further, if $h \in C^2([a,b])$, *then*

$$\left|\mathcal{P}^{\langle\gamma\rangle}_{m,\alpha}(h;x) - h(x)\right| \le 2\omega\left(h',\alpha_m(x)\right)\sqrt{b_m x(1-x)}$$
$$\left|\tilde{\mathcal{P}}^{\langle\gamma\rangle}_{m,\alpha}(h;x) - h(x)\right| \le 2\sqrt{2}\omega\left(h',\alpha_m(x)\right)\sqrt{x(x - r_m(x))},$$

where $\omega(h,\delta)$ *is the modulus of continuity of* h, ${\alpha_m}^2(x)$ *is the respective second central moment of that operators and* $r_m(x)$ *and* $b_m(x)$ *are as defined above.*

Proof. Using Equation (4.2), Lemma 4.1 and Lemma 4.3, with $\varphi_m(t) = (t-x)^m$, we have

$$\begin{aligned}\left|\mathcal{P}^{\langle\gamma\rangle}_{m,\alpha}(h;x) - h(x)\right| &\le |h(x)|\left|\mathcal{P}^{\langle\gamma\rangle}_{m,\alpha}(1;x) - 1\right| \\ &\quad - \omega(h,\delta)\left[\mathcal{P}^{\langle\gamma\rangle}_{m,\alpha}(1;x) + \frac{1}{\delta}\sqrt{\mathcal{P}^{\langle\gamma\rangle}_{m,\alpha}(1;x)\,\mathcal{P}^{\langle\gamma\rangle}_{m,\alpha}(\varphi_2(t);x)}\right] \\ &= \omega(h,\delta)\left[1 + \frac{1}{\delta}\sqrt{\frac{1}{1+\gamma}\left(\frac{m+2(1-\alpha)}{m^2} + \gamma\right)x(1-x)}\right] \\ &= \omega(h,\delta)\left[1 + \frac{1}{\delta}\sqrt{b_m x(1-x)}\right],\end{aligned}$$

10991476, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/mma.10172 by Delhi Technological University, Wiley Online Library on [21/05/2024]. and

$$\begin{aligned}\left|\tilde{\mathcal{P}}_{m,\alpha}^{\langle\gamma\rangle}(h;x)-h(x)\right| &\le |h(x)|\left|\tilde{\mathcal{P}}_{m,\alpha}^{\langle\gamma\rangle}(1;x)-1\right| \\ &\quad -\omega(h,\delta)\left[\tilde{\mathcal{P}}_{m,\alpha}^{\langle\gamma\rangle}(1;x)+\frac{1}{\delta}\sqrt{\tilde{\mathcal{P}}_{m,\alpha}^{\langle\gamma\rangle}(1;x)\,\tilde{\mathcal{P}}_{m,\alpha}^{\langle\gamma\rangle}(\varphi_2(t);x)}\right] \\ &= \omega(h,\delta)\left[1+\frac{1}{\delta}\sqrt{2x(x-r_m(x))}\right].\end{aligned}$$

Now, if h' is also continuous, then we have

$$\begin{aligned}\left|\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(h;x)-h(x)\right| &\le |h(x)|\left|1-\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(1;x)\right|+\left|h'(x)\right|\left|\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(\varphi_1(t);x)\right| \\ &\quad -\omega\left(h',\alpha_m(x)\right)\left[1+\left(\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(1;x)\right)^{1/2}\right]\left(\mathcal{P}_{m,\alpha}^{\langle\gamma\rangle}(\varphi_2(t);x)\right)^{1/2} \\ &= 2\omega\left(h',\alpha_m(x)\right)\sqrt{\frac{1}{1+\gamma}\left(\frac{m+2(1-\alpha)}{m^2}+\gamma\right)x(1-x)} \\ &= 2\omega\left(h',\alpha_m(x)\right)\sqrt{b_m x(1-x)},\end{aligned}$$

and

$$\begin{aligned}\left|\tilde{\mathcal{P}}_{m,\alpha}^{\langle\gamma\rangle}(h;x)-h(x)\right| &\le |h(x)|\left|1-\tilde{\mathcal{P}}_{m,\alpha}^{\langle\gamma\rangle}(1;x)\right|+\left|h'(x)\right|\left|\tilde{\mathcal{P}}_{m,\alpha}^{\langle\gamma\rangle}(\varphi_1(t);x)\right| \\ &\quad -\omega\left(h',\alpha_m(x)\right)\left[1+\left(\tilde{\mathcal{P}}_{m,\alpha}^{\langle\gamma\rangle}(1;x)\right)^{1/2}\right]\left(\tilde{\mathcal{P}}_{m,\alpha}^{\langle\gamma\rangle}(\varphi_2(t);x)\right)^{1/2} \\ &= \left|h'(x)\right|\left|r_m(x)-x\right|+2\sqrt{2}\omega\left(h',\alpha_m(x)\right)\sqrt{x(x-r_m(x))} \\ &\le 2\sqrt{2}\omega\left(h',\alpha_m(x)\right)\sqrt{x(x-r_m(x))}.\end{aligned}$$

TECHNICAL PAPER

Performance evaluation of absorption cooling system for air conditioning-based novel trigeneration system using solar energy

Abstract

This work aims to exploit the waste heat from a basic helium Brayton cycle (HBC) driven by a solar power tower (SPT). The two subsystem heat recovery steam generator (HRSG) and vapour absorption cooling system (VACS) have been implemented to recover the waste heat, respectively, for heating to generate steam and cooling for air conditioning. A comprehensive exergy and energy analysis of this proposed trigeneration system was carried out with parametric analysis. For analysis purpose Engineering Equation Solver software has been used. It was concluded that energy and exergy efficiency and net work output of the proposed trigeneration system were observed as 44.96%, 34.15%, 14,562 kW, respectively. The heating production through the HRSG was obtained 8510 kW while the cooling production by VACS as 115.10 kW. Moreover, coefficient of performance (COP) of the VACS subsystem was observed as 0.8015. Energy and exergy efficiency of the SPT operated basic HBC using the subsystems was improved by 58.98% and 12.92%, respectively. Parametric analysis revealed that the helium turbine inlet temperature and solar heliostat field efficiency much affected the trigeneration system performance.

Keywords Performance assessment · Solar power tower · Trigeneration system · Vapour absorption cooling system · HRSG · Air conditioning

Abbreviations

CR	Central receiver
HBC	Helium Brayton cycle
SPT	Solar power tower
SHE	Solution heat exchanger
SCO_2	Supercritical CO_2
VACS	Vapour absorption cooling system
ORC	Organic Rankine cycle
IHE	Intermediate heat exchanger
HC	Helium compressor
HT	Helium turbine
COP	Coefficient of performance
CPR	Compressor pressure ratio
CIT	Compressor inlet temperature
HTIT	Helium turbine inlet temperature
DNI	Direct normal irradiation (W/m^2)
HRSG	Heat recovery steam generator

List of symbols

$\dot{EX}$	Rate of exergy (kW)
h	Specific enthalpy (kJ/kg)
$\dot{W}$	Power (kW)
N_{hel}	Number of heliostats
$\dot{Q}$	Rate of heat interaction (kW)
T	Temperature (K)
$\dot{ED}$	Exergy destruction rate (kW)
A	Area (m^2)
s	Specific entropy (kJ/kg K)
$\dot{m}$	Mass flow rate (kg/s)

Subscripts

c	Condenser
e	Exit/evaporator
g	Generator
j	Particular state
rec	Receiver
ref	Reference/reflectivity
hel	Heliostat
i	Inlet
0	Dead condition
tri	Trigeneration
co	Cogeneration

1 Introduction

Demand of energy in the world is increasing day by day. It seems to increase by 50% in near future i.e. by 2040. The generation of energy devoid of carbon dioxide is essential for sustainability and future security [1, 2]. Therefore, solar energy is the amazing source of energy that can provide carbon free and secure energy in future. The power production industry is currently showing a great deal of interest in the CSP (concentrated solar power) technology due to its high-temperature production that able to meet multi-generation purpose [3]. The supercritical carbon dioxide (sCO_2) Brayton cycle is more suitable to harvest the energy at that much high temperature due to its pressure quality. It works much higher pressure that of the steam Rankine cycle (SRC) or air Brayton cycle [4]. Also it is known that if pressure at the inlet of the compressor increased that increased the net work output necessitating a low compression pressure ratio [5]. Also sCO_2 is the affordable, environmentally safe, non-toxic, non-flammable, non-corrosive and also it is chemically stable. Due to these factors sCO_2 replaces the air and other gages in Brayton cycle. Due to the high density of sCO_2, extremely compact turbo-machinery designs are possible, which is particularly appealing for applications that recover waste heat inside of automobiles. Transcritical and supercritical CO_2 cycles have drawn more attention because of their enhanced functionality for high-temperatures waste heat recovery [6]. Currently, various power cycles use the CO_2 as the working fluid because it not only increases the efficiency of the cycle but also increases efficiencies of heat exchangers and turbines [7].

In order to convert heat into electricity, SPT facilities may use conventional Rankine cycle and closed Brayton cycles depending on the temperature of the heat source, because of sCO_2 Brayton cycle's advantageous characteristics such as its compact size and effective operation research on the subject has recently grown in popularity [8–10]. Gkountas et al. [11] discovered that by using Al_2O_3 nanofluid to enhance heat transfer, the heat exchanger's length decreased by 0.9%, which in turn decreased the pressure drop in the sCO_2 system by 14%. Chai and Tassuo [12] suggests that nickel-based alloys are used at higher temperatures, while stainless steel is considered as the best for heat exchangers material up to an operating temperature of 650 °C while analysing the helium and sCO_2 as the working fluid. After modelling the SPT system and comparing five different sCO_2 cycle designs, Al-Sulaiman and Atif [13] observed that the recompression configuration of sCO_2 Brayton was observed as the best performing cycle having highest efficiency of 52%. Additionally they observed that this advance technology is very suitable to harvest the solar heat from the CSP technology like SPT. Osorio [14] investigated various sCO_2 setups for SPT plants. They found that 21% of peak efficiency was reached at the variable seasonal situations. Using a standard sCO_2 cycle by itself was less efficient for waste recovery than combining it with an ORC or another bottoming cycle. When heated by solar energy, these coupled cycles improved in terms of sustainability, security, and environmental sensitivity.

Apart from sCO_2 fluid some researcher used the helium as the working fluid in the Brayton cycle such as Zare and Hasanzadeh [15] proposed a study in which HBC harvested the solar energy from the SPT system. They used two ORCs for utilizing the waste heat from the HBC system to enhance the thermal performance of the system. Finally they observed that the system performance increased to 30%. The working fluid for the recompression cycle in Miao et al.'s [16] optimisation study was a combination of nitrous oxide and helium, rather than sCO_2. In comparison with N_2O and CO_2, they found that the suggested method raised thermal efficiency by 5.1% and 6.5%, respectively. The optimal thermal efficiency under perfect circumstances was discovered to be 42.67%. Recently, Khan et al. [17] proposed a pre-compression configuration of the HBC for power production operated by the SPT and also transcritical cycle incorporated for waste heat recovery. They observed that HBC combined cycle produced thermal and exergy efficiency of 31.59% and 33.12%, respectively. Malik et al. [18] did the thermodynamic assessment of the Brayton cycle using the helium and mixture of helium–xenon compared the performance. They observed that compressor performance increased due to employment mixture instead of alone helium by reducing the compressor stages from 16 to 3. As a result, power plant that is working at the high-temperature xenon–helium mixture is more suitable working fluid in the turbo-machinery than that of the pure helium.

The VACS has been studied as the bottoming cycle to improve the overall performance of the plant, in addition to the combined power cycles. Recently, Zhou et al. [19] designed an SPT operated combined cycle in which the VACS is used as the bottoming cycle for the HBC's intake cooling and the HBC is used as the topping cycle. Their results show that the energy efficiency of the optimized combined cycle is 14.5% higher than that of the traditional cycle. Also, Zoghi [20] proposed a hybrid system of combined cycle driven of solar and natural gas in which they used gas turbine cycle and air Brayton cycle and ORC as the power generating cycle and to utilize the waste heat they also used HRSG and LiBr–H_2O single-effect VACS system to generate

the process heat and cooling, respectively. They found that using the HRSG and VACS, exergy and energy efficiency of the basic system enhanced by 4.43% and 13.39%, respectively. Mohtaram et al. [21] did exergy and energy analysis of the hybrid refrigerating system using the ejector transcritical CO_2 system and single-effect LiBr–H_2O VACS. They found that combined system enhances COP and exergy efficiency by 17.28% and 4.8%, respectively. Mishra and Singh [22] did a comprehensive parametric evaluation of the solar-operated combined system. The alone sCO_2 cycle and the VACS system are examples of waste heat recovery systems used for cooling applications like air conditioning. They came to the conclusion that the system's energy and exergy efficiencies were 41.89% and 72.20%, respectively. Furthermore, it was discovered that the COP of VACS for cooling and heating was approximately 0.46 and 1.43, respectively.

From the above-mentioned literature it can be concluded that it is being necessary to enhance the performance of the existing energy cycles; also very limited studies that based on helium as working fluid in the Brayton cycle for solar applications were performed. As a result, in order to close this research gap, the HRSG and VACS subsystems were added to the basic HBC system in order to maximize waste heat and improve system performance. The present study aims to achieve the following objectives:

- To develop a novel SPT-driven combined cycle implementing the HRSG and VACS subsystems
- To report the effects of the adding subsystems on total performance the basic HBC system.
- To perform the comprehensive exergy and energy analysis of the proposed novel combined system.
- To conduct a thorough parametric study of the currently under investigation combined cycle.

2 System description

Figure 1 depicts the proposed solar-operated trigeneration system. The SPT system contained the heliostats and volumetric air receiver as main components. The input and geometric parameters values of the SPT system are listed in Table 1. The volumetric air receiver is taken in this SPT plant where air is considered as the heat transfer fluid (HTF). Air is abundantly available and also obtained high temperature (about 1000 °C) [15]. Also air has no temperature stability limit as in molten salt. This proposed trigeneration system is designed and analysed at the peak load conditions that is why thermal energy storage system is not part of the present study. The topping cycle HBC is started from the state 1 where helium is compressed in the helium compressor (HC), where the temperature of compressed stream is raised. The heated stream passed through the recuperator where it takes heat from the hot flue gases which lead to rise in temperature (state 3). Then, heated helium stream passes through the intermediate heat exchanger (IHE), where it takes the heat from the SPT system by HTF. It gets the maximum temperature of 850 °C at the inlet of helium turbine (HT) (state 4). This hot stream expanded in turbine to generate the power. Expanded stream has enough pressure and temperature at state 5; then, it passes through the recuperater where its heat is utilized to heat the low-temperature stream of helium of state 2. After the recuperator it still has the sufficient amount of temperature at state 6. Therefore, to utilize this heat a subsystem HRSG is implemented to generate the medium-temperature (approximate 200 °C) and high-pressure (2000 kPa) steam for industrial processing. After the HRSG (state 7) low-temperature waste heat is available. To utilize this heat a subsystem VACS implemented to produce the cooling effect for room air conditioning. At the state 8 it goes to the precooler and then again goes to the HC.

In the VACS subsystem water is separated from the LiBr–H_2O in the generator which produces the cooling effect in evaporator passing through expansion valve (EXV) and the condenser. Generated vapour in the evaporator from the state 9 and LiBr–H_2O mixed at state 10 in the absorber and again pumped back to the generator through the solution pump. By using heat from the stream leaving the generator (state 13) to warm the mixture in state 11, the solution heat exchanger (SHE) helps the system work well.

3 Modelling of proposed system

A number of assumptions were taken into account when examining the current system: (1) every component ought to function in a stable condition. (2) It is assumed that the components' pressure loss is as indicated in Table 1. (3) There was a disregard for kinetic and potential energy. (4) Assumed and reported in Table 1 are the compressor, pump, and turbine isentropic efficiencies. The trigeneration system (HBC-HRSG-VACS) and the solar sub-system comprise the full system for thermodynamic analysis. For every component in the system, a thermodynamic model is supplied. The energy-to-exergy balance for a control volume in a steady-state process is expressed using the following equations:

$$\dot{Q}_{CV} - \dot{W}_{CV} + \sum \left(\dot{m}_i h_i\right) - \sum \left(\dot{m}_e h_e\right) = 0 \tag{1}$$

$$\dot{E}D = \dot{E}X_{in} - \dot{E}X_{out} \tag{2}$$

where $\dot{E}X_{in}$ and $\dot{E}X_{out}$ denote the rate at which exergy enters and leaves the thermodynamic system, respectively, and $\dot{E}D$ denotes the destruction in exergy within the system. The heat and work interactions from the control volume are denoted

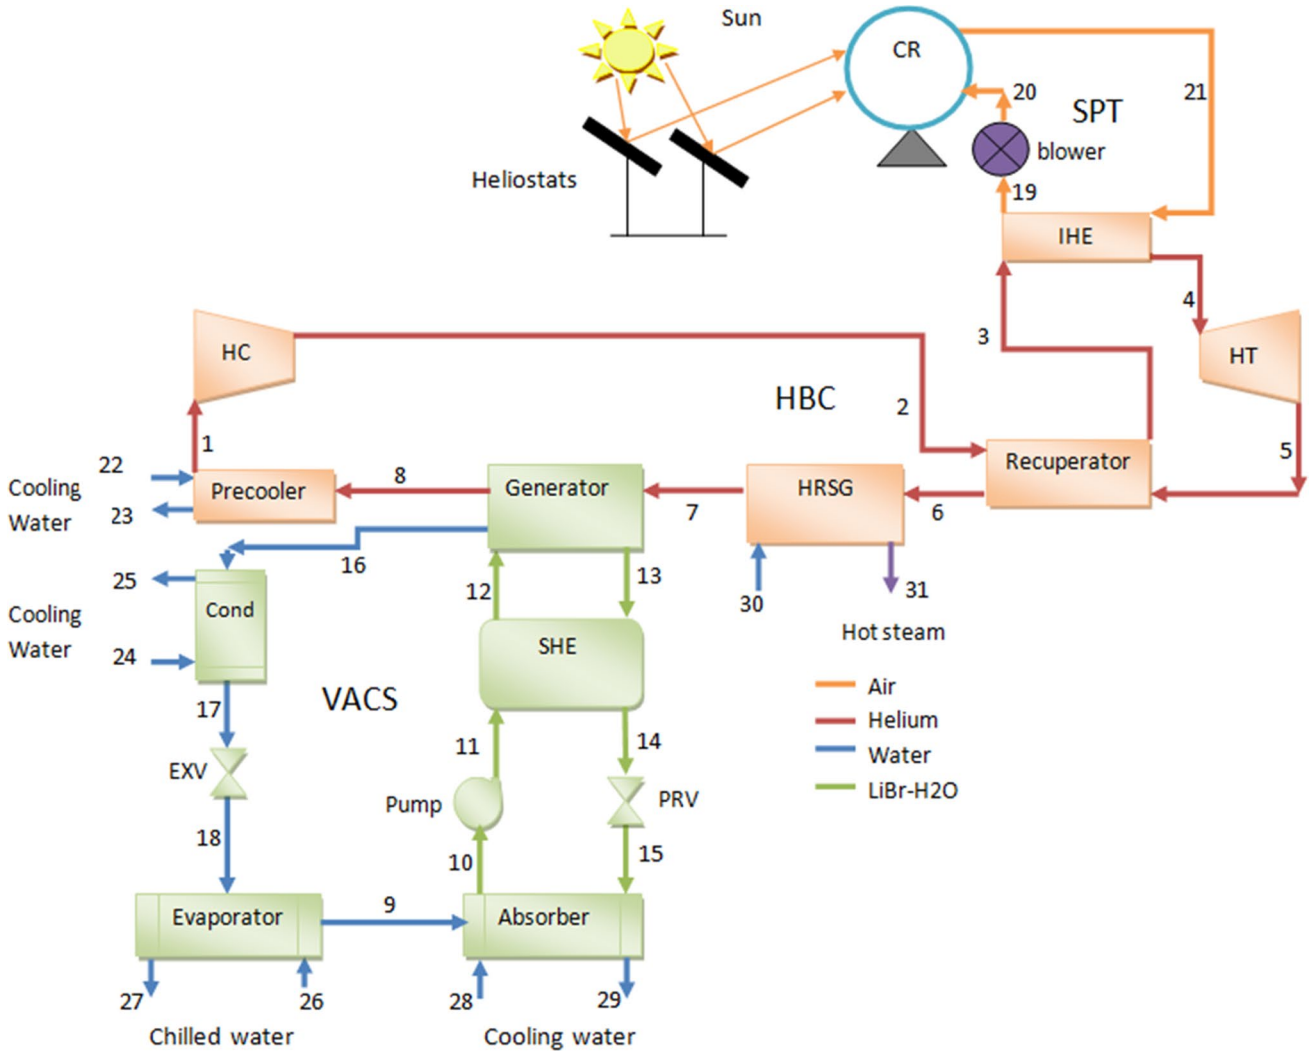

Fig. 1 Proposed SPT-based trigeneration system

by $\dot{Q}_{CV}$ and $\dot{W}_{CV}$, respectively. Without accounting for the energy associated with height, velocity, and chemical exergy (because there is no chemical concentration in the proposed system), the rate of exergy flow of a fluid stream as the physical exergy can be described as;

$$\dot{\underset{j}{\mathrm{EX}}} = \dot{m} \cdot \left[\left(h_j - h_0 \right) - T_0 \left(s_j - s_0 \right) \right] \tag{3}$$

where 'j' stands for a specific state and $\dot{\underset{j}{\mathrm{EX}}}$ represents the physical exergy at state j. The sun radiation reflects on to the thousands of heliostats through the DNI. The amount of solar radiation that actually receives by the receiver from the heliostats depends on the heliostats efficiency. Only amount of the solar energy received by the receiver, remaining amount was lost to the environment. Also the amount of the solar received depends on the geographical location i.e. amount of average DNI received. Therefore, mathematically the amount of solar thermal heat received by the receiver can be expressed as [15];

$$\dot{Q}_{\text{rec, in}} = \eta_{\text{field}} \cdot \dot{Q}_{\text{Sun}} = \eta_{\text{field}} \cdot \text{DNI} \cdot A_{\text{hel}} \cdot N_{\text{hel}} \tag{4}$$

where η_{field} is the efficiency of heliostats and expressed as [15];

$$\eta_{\text{field}} = \eta_{\cos} \cdot \eta_{s\&b} \cdot \eta_{\text{int}} \cdot \eta_{\text{att}} \cdot \eta_{\text{ref}} \tag{5}$$

where $\eta_{\text{ref}}, \eta_{\text{att}}, \eta_{\text{int}}, \eta_{\text{s\&b}}$ and$\eta_{\cos}$ denotes the efficiencies of heliostats reflectivity, atmospheric attenuation, interception efficiency, shading and blocking and cosine effect, respectively. These values have been taken directly from the operational SPT plant [15].

The receiver absorbs $\dot{Q}_{\text{rec,in}}$ amount of heat, while $\dot{Q}_{\text{rec,loss}}$ amount of heat is lost to the atmosphere due to the various modes of heat transfer. The remaining heat is transported

Table 1 Given data for base conditions

Parameters	Value
SPT system	
Heliostat field efficiency (η_{field})	0.75 [23]
Number of heliostat (N_{hel})	500 [24]
Direct normal irradiation (DNI)	850 W/m^2 [16, 24]
Heliostat reflective area (A_{hel})	9.45 × 12.84 m^2 [24]
Aperture area of receiver (A_{rec})	68.1 m^2 [24]
Efficiency of receiver (η_{rec})	0.9 [23]
HBC	
HT inlet temperature (T_4)	850 °C [16, 24]
HC isentropic efficiency (η_{HC})	0.88 [20]
Compressor pressure ratio (CPR)	2.5[25]
HT isentropic efficiency (η_{HT})	0.9[20]
HC inlet pressure (P_1)	2500 kPa [16]
Recuperator effectiveness (ε)	0.9 [16, 20]
HRSG	
Pinch point temperature difference	30 °C [21]
Steam exit pressure (P_{31})	2000 kPa [21]
VACS	
Generator temperature (T_{13})	80 °C [21]
Condenser temperature (T_{17})	35 °C [21]
Absorber temperature (T_{10})	35 °C [21]
Evaporator temperature (T_9)	6 °C [21]
SHE effectiveness $(\varepsilon_{\text{SHE}})(T_{24})(T_{25})$	0.7 [21]
Pump isentropic efficiency (η_{Pump})	0.9 [21]
Water temperature at condenser inlet	$T_{17} - 8$[21]
Water temperature at condenser outlet	$T_{17} - 3$ [21]
Chilled water temperature at evaporator outlet (T_{27})	$T_9 + 3$[21]
Water temperature at absorber inlet (T_{28})	$T_{10} - 8$[21]
Chilled water temperature at evaporator inlet (T_{26})	$T_9 + 8$[21]
Water temperature at absorber outlet (T_{29})	$T_{10} - 3$[21]
Atmospheric temperature (T_0)	25 °C [16, 25]
Atmospheric pressure (P_0)	101.3 kPa [16, 25]

to the HTF, which is air, in an amount of $\dot{Q}_{\text{rec,net}}$. Heat transport and receiver efficiency are stated as [15];

$$\eta_{\text{rec}} = \frac{\dot{Q}_{\text{rec,net}}}{\dot{Q}_{\text{rec,in}}} \tag{6}$$

$$\dot{Q}_{\text{rec,in}} = \dot{Q}_{\text{rec,net}} + \dot{Q}_{\text{rec,loss}} = \dot{m}_{\text{air}}\left(h_{30} - h_{31}\right) + \dot{Q}_{\text{rec,loss}} \tag{7}$$

when modelling the VACS subsystem, the following assumptions are taken into consideration. The system's components are considered during steady-state operations. The heat exchangers and pipes' pressure and heat loss were disregarded. LiBr–H_2O is regarded as being in equilibrium at the specific pressure and temperature in generator and absorber. Water is used to cool both the absorber and condenser. In the current analysis, saturated conditions are considered at state points 9 and 17. Table 1 lists and assumes the cooling water's pressure and temperature. Mathematical equations used for the exergy energy analysis for the each component are given in Table 2. These mathematical equations were programmed in the EES using together with the base data given in Table 1. Using the inbuilt property function in the EES the thermodynamic properties at each state were determined. Using these properties values, work and heat interaction and exergy at the each state were calculated.

3.1 The performance parameters

Net power of the proposed system $(\dot{W}_{\text{net}})$ neglecting the pump work is evaluated as:

$$\dot{W}_{\text{net}} = \dot{W}_{\text{HT}} - \dot{W}_{\text{HC}} \tag{8}$$

The COP of the VACS is defined as the ratio of cooling effect $(\dot{Q}_{\text{e}})$ at the evaporator to the heat interaction in VACS generator $(\dot{Q}_{\text{g}})$. After neglecting the pump work it can be expressed as [20];

$$\text{COP}_{\text{VACS}} = \frac{\dot{Q}_{\text{e}}}{\dot{Q}_{\text{g}}} \tag{9}$$

The energy proposed systems can be expressed as [20];

$$\eta_{\text{en, HBC}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{Sun}}} \tag{10}$$

$$\eta_{\text{en, co,h}} = \frac{\dot{W}_{\text{net}} + \dot{Q}_{\text{HRSG}}}{\dot{Q}_{\text{Sun}}} \tag{11}$$

$$\eta_{\text{en, co,c}} = \frac{\dot{W}_{\text{net}} + \dot{Q}_{\text{e}}}{\dot{Q}_{\text{Sun}}} \tag{12}$$

$$\eta_{\text{en, tri}} = \frac{\dot{W}_{\text{net}} + \dot{Q}_{\text{HRSG}} + \dot{Q}_{\text{e}}}{\dot{Q}_{\text{Sun}}} \tag{13}$$

The exergy proposed systems can be expressed as [20];

$$\eta_{\text{ex, HBC}} = \frac{\dot{W}_{\text{net}}}{\dot{Q}_{\text{Sun}} \cdot \left(1 - \frac{T_0}{T_{\text{ref,Sun}}}\right)} \tag{14}$$

Table 2 Exergy and energy balance equations for each component

Component	Energy balance equation	Exergy balance equation
Heliostat field	$\dot{Q}_{\text{rec, in}} = \eta_{\text{field}} \cdot \text{DNI} \cdot A_{\text{hel}} \cdot N_{\text{hel}}$	$\dot{Q}_{\text{Sun}} \cdot \left(1 - \frac{T_0}{T_{\text{ref,Sun}}}\right) = \dot{Q}_{\text{rec, in}} \cdot \left(1 - \frac{T_0}{T_{\text{ref,hel}}}\right) + \dot{\text{ED}}_{\text{hel}}$
Receiver	$\dot{Q}_{\text{rec, in}} = \dot{m}_{\text{air}}\left(h_{21} - h_{20}\right) + \dot{Q}_{\text{rec, loss}}$	$\dot{EX}_{20} + \dot{Q}_{\text{rec, in}} \cdot \left(1 - \frac{T_0}{T_{\text{ref,hel}}}\right) = \dot{EX}_{21} + \dot{Q}_{\text{rec, loss}} \cdot \left(1 - \frac{T_0}{T_{\text{rec}}}\right) + \dot{ED}_{\text{rec}}$
Intermediate heat exchanger	$\dot{Q}_{\text{IHE}} = \dot{m}_{\text{air}} \cdot \left(h_{21} - h_{19}\right) + \dot{m}_{\text{He}} \cdot \left(h_4 - h_3\right)$	$\dot{\text{EX}}_{21} - \dot{\text{EX}}_{19} = \dot{\text{EX}}_{4} - \dot{\text{EX}}_{3} + \dot{\text{ED}}_{\text{IHE}}$
Helium turbine	$\dot{W}_{\text{HT}} = \eta_{\text{HT}} \cdot \dot{m}_{\text{He}} \cdot \left(h_4 - h_{5\text{s}}\right)$	$\dot{\text{EX}}_{4} = \dot{\text{EX}}_{5} + \dot{W}_{\text{HT}} + \dot{\text{ED}}_{\text{HT}}$
Helium compressor	$\dot{W}_{\text{HC}} = \eta_{\text{HC}} \cdot \dot{m}_{\text{He}} \cdot \left(h_{2\text{s}} - h_1\right)$	$\dot{\text{EX}}_{1} = \dot{\text{EX}}_{2} - \dot{W}_{\text{HC}} + \dot{\text{ED}}_{\text{HC}}$
HRSG	$\dot{Q}_{\text{HRSG}} = \dot{m}_6\left(h_6 - h_7\right) = \dot{m}_{30} \cdot \left(h_{31} - h_{30}\right)$ $\Delta T_{\text{min}} = T_6 - T_{31}$	$\dot{\text{EX}}_{6} - \dot{\text{EX}}_{7} = \dot{\text{EX}}_{31} - \dot{\text{EX}}_{30} + \dot{\text{ED}}_{\text{HRSG}}$
Precooler	$\dot{m}_{\text{He}} \cdot \left(h_8 - h_1\right) = \dot{m}_{\text{water}} \cdot \left(h_{23} - h_{22}\right)$	$\dot{\text{EX}}_{8} - \dot{\text{EX}}_{1} = \dot{\text{EX}}_{22} - \dot{\text{EX}}_{23} + \dot{\text{ED}}_{\text{Preooler}}$
Recuperator	$\left(h_3 - h_2\right) = \left(h_5 - h_6\right)$ $\varepsilon_{\text{Recuperator}} = \frac{(T_3 - T_2)}{(T_5 - T_2)}$	$\dot{\text{EX}}_{5} - \dot{\text{EX}}_{6} = \dot{\text{EX}}_{3} - \dot{\text{EX}}_{2} + \dot{\text{ED}}_{\text{Recuperator}}$
Generator	$\dot{Q}_{\text{g}} = \dot{m}_{16} \cdot h_{16} + \dot{m}_{13} \cdot h_{13} - \dot{m}_{12} \cdot h_{12} \dot{m}_{12} = \dot{m}_{13} + \dot{m}_{16}$	$\dot{\text{EX}}_{13} + \dot{Q}_{\text{g}} \cdot \left(1 - \frac{T_0}{T_g}\right) = \dot{\text{EX}}_{16} + \dot{\text{EX}}_{13} + \dot{\text{ED}}_{g}$
Condenser	$\dot{Q}_c = \dot{m}_{16}\left(h_{16} - h_{17}\right) = \dot{m}_{water} \cdot \left(h_{25} - h_{24}\right)$	$\dot{\text{EX}}_{16} - \dot{\text{EX}}_{17} = \dot{Q}_{\text{c}} \cdot \left(1 - \frac{T_0}{T_c}\right) + \dot{\text{ED}}_{\text{c}}$
Expansion valve	$h_{17} = h_{18}$	$\dot{\text{EX}}_{17} - \dot{\text{EX}}_{18} = \dot{\text{ED}}_{\text{EXV}}$
Absorber	$\dot{Q}_a = \dot{m}_9 \cdot h_9 + \dot{m}_{15} \cdot h_{15} - \dot{m}_{10} \cdot h_{10}$ $\dot{m}_{10} = \dot{m}_9 + \dot{m}_{15}$ $x_{13} \cdot \dot{m}_{15} = x_{10} \cdot \dot{m}_{10}$	$\dot{\text{EX}}_{10} + \dot{Q}_a \cdot \left(1 - \frac{T_0}{T_a}\right) + \dot{\text{ED}}_{g} = \dot{\text{EX}}_{9} + \dot{\text{EX}}_{15}$
Pump	$\dot{W}_P = \dot{m}_{10}\left(h_{11} - h_{10}\right)$ $\eta_P = \frac{(h_{11\text{s}} - h_{10})}{(h_{11} - h_{10})}$	$\dot{\text{EX}}_{10} = \dot{\text{EX}}_{11} - \dot{W}_{\text{Pump}} + \dot{\text{ED}}_{\text{Pump}}$
Solution heat exchanger	$\dot{m}_{13} \cdot h_{13} - \dot{m}_{14} \cdot h_{14} = \dot{m}_{12} \cdot h_{12} - \dot{m}_{11} \cdot h_{11}$ $\varepsilon_{\text{SHE}} = \frac{(T_{13} - T_{14})}{(T_{13} - T_{11})}$	$\dot{\text{EX}}_{13} + \dot{\text{EX}}_{11} = \dot{\text{EX}}_{12} + \dot{\text{EX}}_{14} + \dot{\text{ED}}_{\text{SHE}}$
Pressure reducing valve	$h_{14} = h_{15}$	$\dot{\text{EX}}_{14} - \dot{\text{EX}}_{15} = \dot{\text{ED}}_{\text{PRV}}$
Evaporator	$\dot{Q}_{\text{e}} = \dot{m}_9\left(h_9 - h_{18}\right) = \dot{m}_{\text{chilled water}} \cdot \left(h_{26} - h_{27}\right).$	$\dot{\text{EX}}_{9} - \dot{\text{EX}}_{18} = \dot{Q}_{\text{e}} \cdot \left(1 - \frac{T_0}{T_{\text{e}}}\right) + \dot{\text{ED}}_{\text{e}}$

$$\eta_{\text{ex, co,h}} = \frac{\dot{W}_{\text{net}} + \dot{EX}_{\text{HRSG}}}{\dot{Q}_{\text{Sun}} \cdot \left(1 - \frac{T_0}{T_{\text{ref,Sun}}}\right)} \tag{15}$$

$$\eta_{\text{ex, co,c}} = \frac{\dot{W}_{\text{net}} + \dot{EX}_{\text{e}}}{\dot{Q}_{\text{Sun}} \cdot \left(1 - \frac{T_0}{T_{\text{ref,Sun}}}\right)} \tag{16}$$

$$\eta_{\text{ex, tri}} = \frac{\dot{W}_{\text{net}} + \dot{EX}_{\text{HRSG}} + \dot{EX}_{\text{e}}}{\dot{Q}_{\text{Sun}} \cdot \left(1 - \frac{T_0}{T_{\text{Sun}}}\right)} \tag{17}$$

where T_{Sun} denotes the apparent Sun's temperature and taken as 4500 K [15, 26].

4 System validation

Results of the developed models such as HBC and the VACS have been validated with the existing literature to check the correctness of the mathematical modelling procedure. The results of the alone HBC system have been validated with the existing literature Zare et al. [25]. It can be seen from Fig. 2 that very less difference in the data has been reported i.e. 0.25%. Therefore, it is acceptable. The correctness of the subsystem VACS is evaluated under the identical input conditions using research findings from the Ref. [27]. To

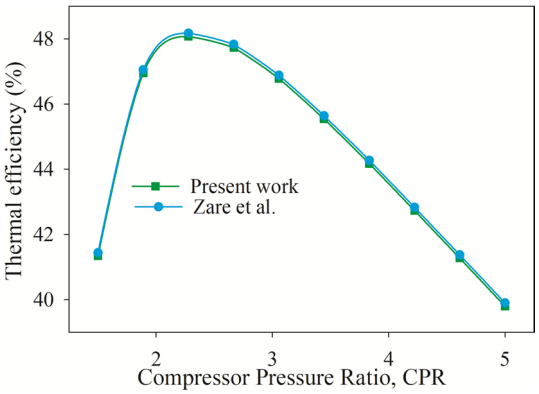

Fig. 2 Helium Brayton cycle validation

Table 3 Validation of VACS model

Results T (°C)	Present study	Ref. [27]	Deviation (%)
T_9	5.69	5.67	0.35
T_{10}	33.12	33.14	−0.06
T_{11}	33.21	33.15	0.18
T_{12}	59.25	59.25	0
T_{13}	80.87	81.39	−0.63
T_{14}	50.51	50.51	0
T_{15}	44.12	43.99	0.29
T_{16}	80.87	81.39	−0.63
T_{17}	38.42	38.4	0.05
T_{18}	5.69	5.67	0.35

conduct an adequate comparison, the produced model is appropriately modified. On temperature at all state points, the results of Ref. [27] and the results of the current model are compared. The largest difference was discovered to be − 0.63%, a negligible amount that exhibits high accuracy, according to Table 3's comparison data. The model that was developed as a result has been verified and may be trusted.

5 Results and discussion

This paper presents the novel trigeneration system using new subsystem HRSG and VACS to produce the extra process heat and cooling for the air conditioning, respectively. The results were calculated using the EES software.

5.1 Results at base conditions

First, as shown in Table 1, the trigeneration system's results were computed under the base conditions. Exergy and energy analysis parameters at the base conditions of the proposed trigeneration are indicated in Table 4. At the inlet of the HT the helium temperature is 850 °C. The power output from the trigeneration system was obtained as 14,562 kW. It was worth mentioning that exergy and energy efficiency of the trigeneration system was observed as 34.15% and 44.96%, respectively. The heating production through the HRSG was obtained 8510 kW while the cooling production by VACS as 115.10 kW. The exergy and energy efficiency of the basic HBC system was obtained as 30.24% and 28.28%, respectively, which can be improved to 34.15% and 44.96% and, respectively, by using the subsystems accordingly as can be observed in Table 4. As the exergy and energy production in the HRSG system is more than the VACS cooling system, therefore the energy and exergy efficiency of the cogeneration for heating is more than that of cooling. The energy and exergy of cogeneration for heating were observed as 44.74% and 34.14%, respectively, and corresponding values for the cogeneration for cooling were 30.26% and 28.46%, respectively. Therefore, it was observed that the improvement in the exergy and energy efficiency of the basic HBC using the subsystems is 12.92% and 58.98%, respectively. Apart from the exergy and energy efficiency of the proposed system, the COP of the VACS subsystem is found as 0.8015.

Table 4 Output results of the SPT-based trigeneration system

Parameters	Values
$\eta_{\text{en, HBC}}$	28.24%
$\eta_{\text{ex, HBC}}$	30.24%
$\eta_{\text{en, tri}}$	44.96%
$\eta_{\text{ex, tri}}$	34.15%
$\eta_{\text{en, co,h}}$	44.74%
$\eta_{\text{ex, co,h}}$	34.14%
$\eta_{\text{en, co,c}}$	28.46%
$\eta_{\text{ex, co,c}}$	30.26%
$\dot{m}_{\text{Air}}$	54.34 kg/s
$\dot{m}_{\text{Helium}}$	20.49 kg/s
$\dot{m}_{\text{Steam}}$	12.84 kg/s
$\dot{Q}_{\text{HRSG}}$	8510 kW
$\dot{Q}_{\text{e}}$	115.1 kW
$\dot{W}_{\text{net}}$	14,562 kW

The effects on the exergy destruction of the combined cycle of the subsystem were also investigated. The basic HBC, cogeneration for heating, cogeneration for cooling, and trigeneration systems are responsible for the exergy destruction values 28,911 kW, 30,064 kW, 29,089.96 kW, and 30,242.96 kW, respectively. Therefore, it can be said that implementing the both subsystems in the basic SPT operated HBC system, exergy destruction is improved by 4.6% only. Exergy destruction has additionally been determined and is presented in Table 5 for each part of the proposed trigeneration system. It was seen from the exergy analysis that

Table 5 Componentwise exergy destruction and exergy efficiency

Component	Exergy efficiency (%)	Exergy destruction (kW)
Heliostats	64.27	12,038
Solar receiver	58.28	10,713
Intermediate heat exchanger	93.01	1774
Helium turbine	96.1	1258
Recuperator	93.35	1308
HRSG	.92	1153
Precooler	27.83	499.3
Helium compressor	91.98	1320
Generator	84.25	7.027
Condenser	42.81	2.416
Expansion valve	3.071	0.3068
Evaporator	68.76	15.67
Absorber	35.98	49.69
Pump	5.23	0.11
Solution heat exchanger	60.5	51.18
Pressure reducing valve	56.87	49.68

heliostats field was responsible for highest exergy destruction. It is due to the solar irradiation that was received from the high-temperature source i.e. 4500 K. This energy has a significant irreversibility because it is received by the receiver at a temperature of about 1125 °C [15]. The energy efficiency of the heliostat was determined to be 64.27%. The IHE's helium and HTF temperatures change very little since there is not any combustion, which is the primary factor in conventional power systems' irreversibility. Consequently, if the SPT is ignored, the combined cycle has a high energy efficiency of almost 66.31%. However, the exergy efficiency of the power plant is quite low, at 34.15%, due to the significant exergy destructions in the receiver and heliostat field. The componentwise exergy destruction rate and the exergy efficiency were analysed, and results are shown in Table 5. Highest and lowest exergy destruction component of the proposed plant were heliostats and pump values 12,038 kW (39.80% of total exergy destruction) and 0.11 kW, respectively. Second highest exergy destruction component is receiver in which exergy destruction occurred as 10,713 kW contributing 35.42% of the total exergy destruction. The helium turbine has the best exergy efficiency (96.1%) of all the system's components when combined.

5.2 Parametric analysis

This section presents the results of a parametric study of the proposed system to examine the impact of the primary parameter on the output. As indicated in Table 1, other parameters were held constant while examining the impact of one variable.

5.2.1 Effect of the helium turbine inlet temperature

The exergy, energy efficiency, heating load, and net work output of the trigeneration system were continuously increased in order to improve the helium turbine inlet temperature (HTIT). The enthalpy differences within the turbine would increase as the HTIT grew, as a result net work output increases. Therefore, energy efficiency and exergy efficiency were also increased. Also the as HTIT increased, the helium gas temperature at the inlet of the HRSG was increased consequently heating production increased as can be observed in Fig. 3. Energy and exergy efficiency was increased from 42.35 to 45.67% and 26.25 to 36.29%, respectively, as HTIT increased from 600 to 950 °C. However, net work output and heating production were improved by 52.31% and 47.63%, respectively, as HTIT increased from 600 to 950 °C. On the hand, the cooling production or cooling effect did not affected by the HTIT, while COP of VACS decreased with the HTIT. Increased HTIT improved the generator

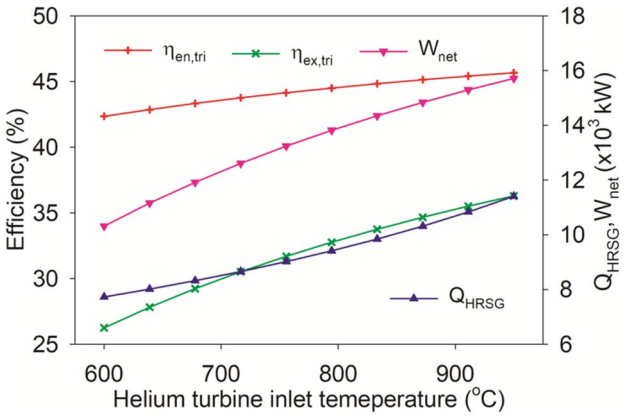

Fig. 3 Trigeneration system performance variations with HTIT

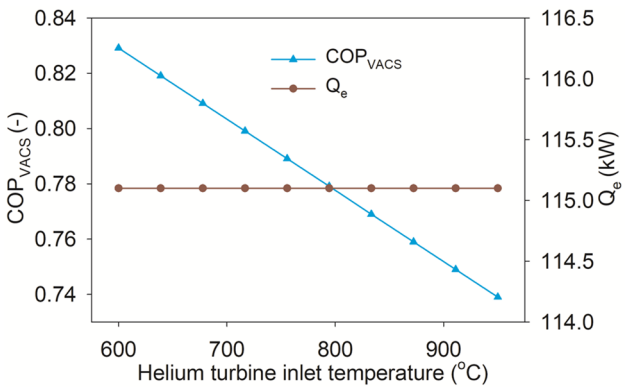

Fig. 4 COP and cooling production variation with HTIT

temperature that leads to the improvement in the generator load however no effect on the cooling production that leads to the decrement in the COP of the VACS. COP decreased by 10.86% when HTIT increased from 600 to 950 °C as revealed in Fig. 4. Therefore it can be said that the HTIT is the main critical parameters that much affected the trigeneration system performance.

5.2.2 Effect of the compressor pressure ratio

Figure 5 displays that the net power output and exergy efficiency of the trigeneration system the first increased and then decreased. They have inflation point at which they attained theirs maximum values. Therefore the optimal point is 2.278 of CPR. This pattern can be discussed by remembering the optimum CPR values: when the CPR climbed, the expansion and compression work both increased. However, in this area, the expansion work improvement rate predominated over the compression work improvement rate. Consequently, network output will increase. As a result, the combined cycle energy efficiency increases. After the CPR results' optimum values were displayed, the reverse was done. The exergy efficiency and the net work output were attained its values 34.89% and 14,610 kW, respectively, at the optimal values of CPR. However, the energy efficiency and the heating production were decreased with the CPR. Energy efficiency and the heating production decreased by 35.33% and the 59.42%, respectively, as the CPR increased from 1.5 to 5. It can be seen the improvement in the CPR values highly affected the energy efficiency and the net work output. Figure 6 displays that cooling production and COP were slightly increased with CPR. As CPR increased the output temperature at the inlet of generator decreased, it means that COP is decreased. The COP and cooling production slightly decreased by 1.05% and 8.37%, respectively.

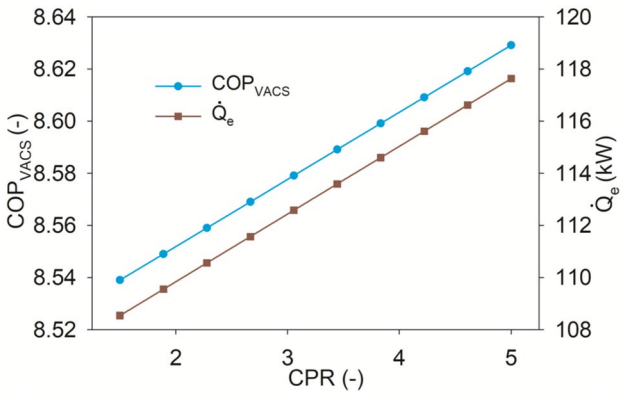

Fig. 6 COP and cooling production variation with CPR

5.2.3 Effect of the HC inlet temperature

Figure 7 shows that as the compressor inlet temperature (CIT) increased, the energy, exergy efficiency, and net work production somewhat dropped. It can be accounted for by noting that when CIT grew, across the compressor the enthalpy difference also increased, improving compressor performance. Net work output dropped as a result. Consequently, efficiencies of the trigeneration dropped with CIT. The exergy efficiency, net work output, and energy efficiency were decreased by 2.14%, 3.16%, and 0.18%, and, respectively, as CIT increased from 25 to 35 °C. However, the heating production slightly increased with the CIT. Heating production increased by 0.45% only as CIT increased from 25 to 35 °C. Therefore, heating production and energy efficiency were not much affected by CIT. On other hand the cooling production and COP were increased by the CIT. Cooling production ($\dot{Q}_e$) increased from 110.539 to 119.6291 kW as CIT increased from 25 to 35 °C as shown in Fig. 8 which is the result of the compressor removing a lot of heat from the generator side

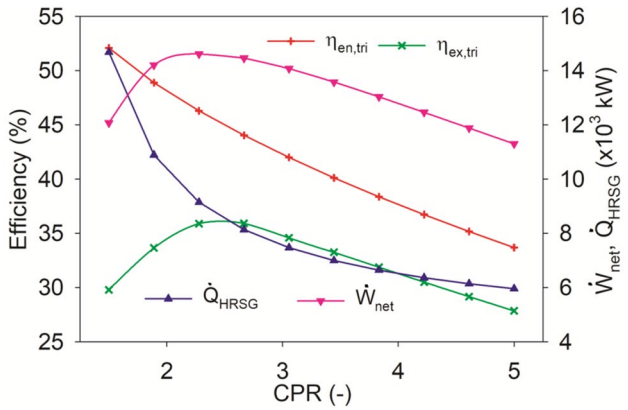

Fig. 5 Trigeneration performances variation with CPR

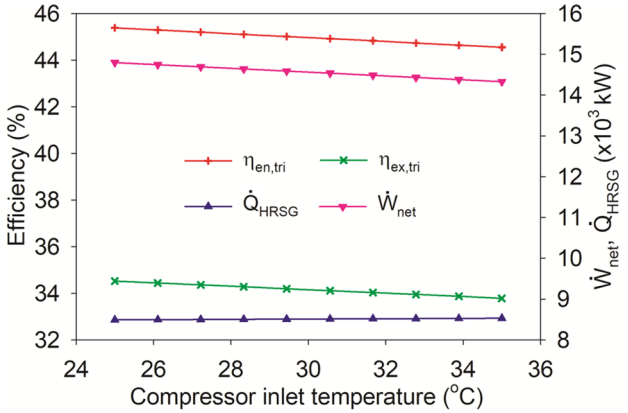

Fig. 7 Trigeneration performance variations with the CIT

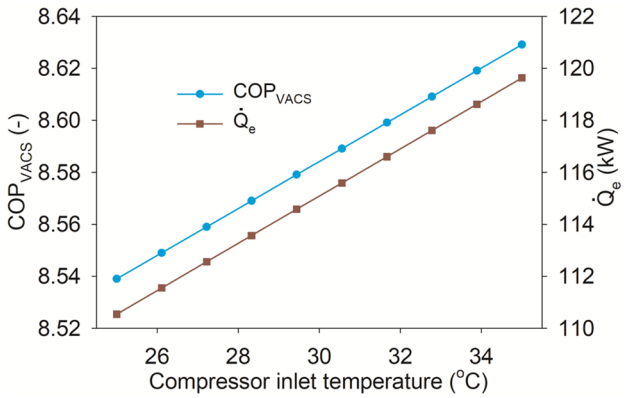

Fig. 8 COP and cooling production variation with CIT

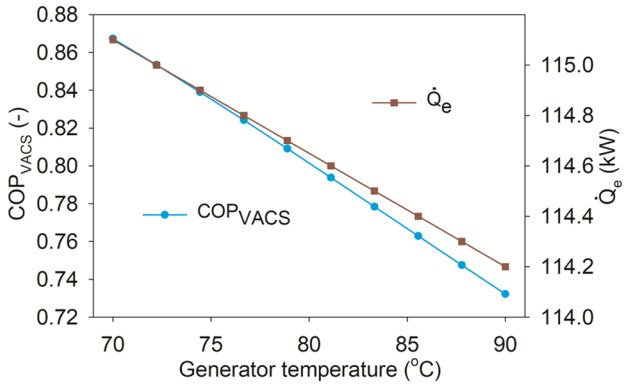

Fig. 10 COP and cooling production variation with generator temperature

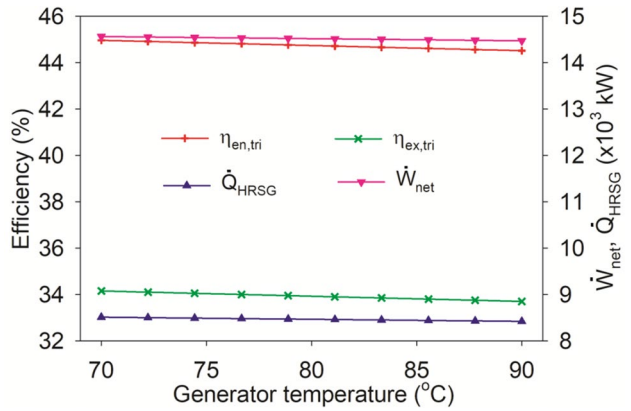

Fig. 9 Trigeneration system performance variations with generator temperature

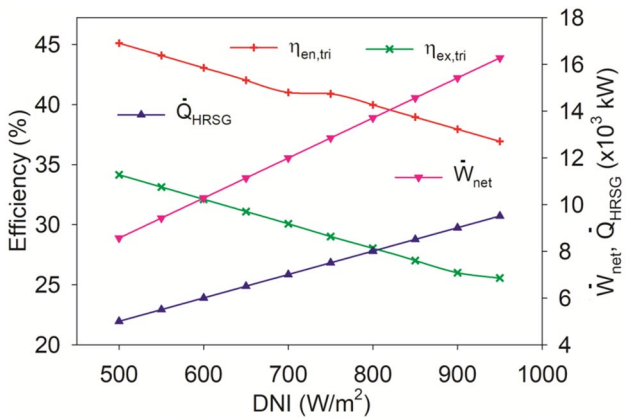

Fig. 11 Trigeneration system performance variations with the DNI

by slowing down the heat transfer from the heating coil to the generator as CIT tends to rise, which causes generator temperature to fall concurrently. Also COP rises from 8.539 to 8.6291. As the COP strongly depends on $\dot{Q}_e$, therefore reason for increasing COP is also same as discussed above for improvement in $\dot{Q}_e$.

5.2.4 Effect of the generator temperature

In this part, the effect of bottoming cycle parameters, such as VACS, on the functionality of the trigeneration system cycle, as opposed to topping cycle parameters, has also been covered. Figure 9 demonstrates that the exergy, energy efficiency of the trigeneration system, and heating output all slightly decrease from 34.15 to 33.7%, 44.96 to 44.51%, and 8510 to 8410 kW, respectively, as the generator temperature climbs from 70 to 90 °C. But as shown in Fig. 10, the COP_{VACS} falls from 0.8673 to 0.7322. The reason for the declining efficiency and COP is the rising temperature of the generator's flowing refrigerant, which can increase the average temperature of the condenser and absorber unit in the VACS and cause more heat transfer losses or energy destruction as the generator's temperature rises. As a result, cooling production drops from 115.1 to 114.2 kW and net output work slightly declines from 14,562 to 14,470 kW.

5.2.5 Effect of the solar irradiation

Figure 11 shows how changes in DNI affect the output parameters of the system. According to Eqs. (13) and (17), as DNI increases from 500 to 950 W/m^2, the receiver's outlet air temperature rises, increasing the total solar energy input. This causes a decrease in energy and exergy efficiency of 18.12% and 25.17%, respectively. However the inlet condition of the turbine improves and the net output work increases. Additionally, heating productions experience improvement from 5006 to 9511 kW,

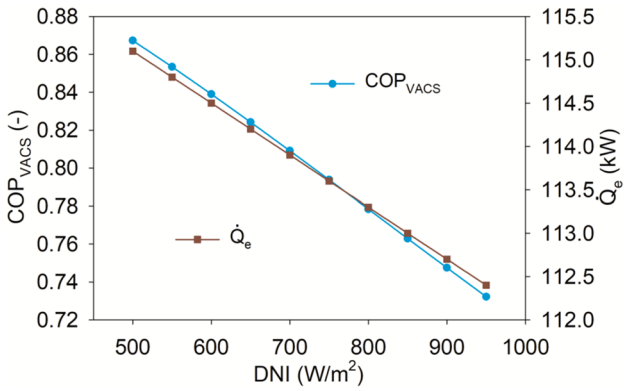

Fig. 12 COP and cooling production variation with DNI

respectively. Apart from this the COP_{VACS} and cooling production decreased with the DNI. The temperature at the generator increased that lowered the flow rate of water through evaporator as refrigerant as the DNI increased. Therefore the cooling production decreases consequently which leads to the COP_{VACS}. Cooling production and the COP_{VACS} decreased from 0.8673 to 0.7322 and 115.1 to 112.4 kW, respectively, as DNI improves from 500 to 950W/m^2, respectively, as can be observed in Fig. 12.

5.2.6 Effect of the efficiency of heliostat field

Another important factor influencing the overall cycle performance is the heliostat field efficiency. Exergy efficiency, energy efficiency, net output work, and the heating production increased with the heliostat efficiency. The performance of the under consideration trigeneration system is shown in relation to the effects of heliostat field efficiency in Fig. 13. It is evident that rising has a positive impact on system performance. For this reason, when field efficiency rises, energy

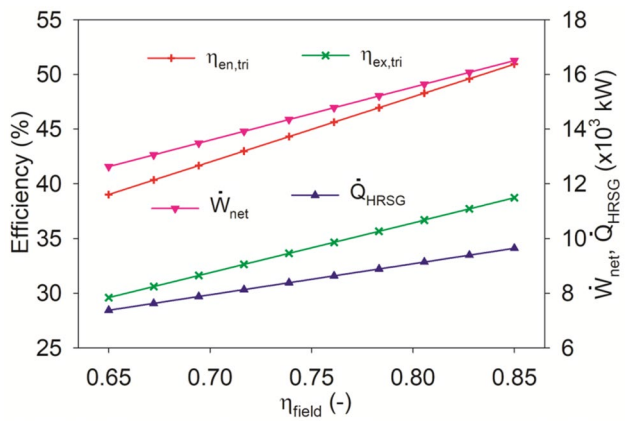

Fig. 13 Trigeneration system performance variations with heliostat field efficiency

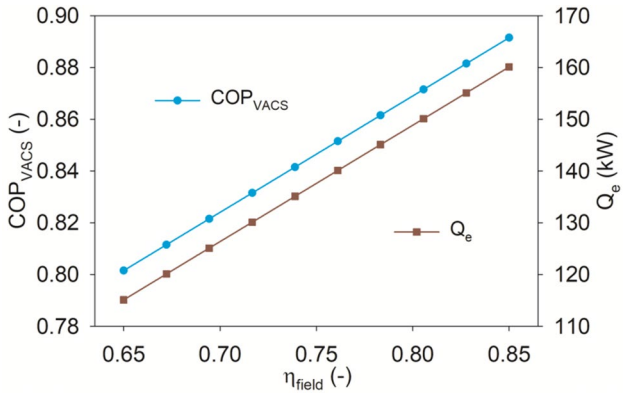

Fig. 14 COP and cooling production variation with heliostat field efficiency

loss decreases and energy transmission to the receiver improves. The much energy the receiver can absorb, the faster the flow rate of HTF and helium, which boosts power production as depicted in Fig. 13. Given the direct correlation between net output work and exergy efficiency, exergy efficiency improves along with net output work. As field efficiency improved from 0.65 to 0.85, energy efficiency, heating production, net output work, and energy efficiency grew from 29.6 to 38.71%, 39 to 50.93%, 7376 to 9645 kW, and 12,621 to 16,504 kW, respectively. Figure 14 shows that when field efficiency climbed from 0.65 to 0.85, cooling production and COP also increased, from 115.1 to 160.2 kW and 0.8015 to 0.8915, respectively.

6 Conclusions

A novel solar-operated trigeneration system has been proposed in this study where the solar energy from the SPT system is harvested using HBC in order to produce power. Additionally, to recover the waste heat from HBC the HRSG and VACS two subsystems were used to generate the heating and cooling production, respectively. Further, a comprehensive energy and exergy analysis has been conducted of the proposed trigeneration system. The following conclusions were made from this study:

- The net work output, energy, and exergy efficiency the proposed trigeneration system were observed as 14,562 kW, 34.15%, and 44.96%, respectively. The heating production through the HRSG was obtained 8510 kW while the cooling production by VACS as 115.10 kW. Additionally, COP of the VACS subsystem is found as 0.8015.

- Energy and exergy efficiency of the SPT-operated basic HBC using the subsystems is improved by 58.98% and 12.92%, respectively.
- The exergy and energy efficiency, net work output, and heating production of the proposed trigeneration system improved with the HTIT, while COP of VACS decreased and cooling production did not affected much.
- CPR and CIT much affected the proposed system's energy and exergy efficiency, net work output, and heating production however the COP and cooling production affected marginally.
- While generator temperature reduced the COP and cooling production greatly on other hand, it is marginally affected the exergy and energy efficiency, net work output, and heating production of the proposed trigeneration system.
- Solar irradiation decreased the exergy and energy efficiency and improved the net work output and heating production, while COP and cooling production marginally decreased with DNI.
- However, heliostat field efficiency has positive impact on the performance of the proposed trigeneration system.
- The cost effective analysis of the proposed novel trigeneration system is scope of the future study.

Declarations

Conflict of interest The authors confirm that they do not now have any recognized economic or interpersonal disputes that could have affected the findings of this study.

2024 2nd International Conference on Device Intelligence, Computing and Communication Technologies (DICCT) | 979-8-3503-7284-7/24/$31.00 ©2024 IEEE | DOI: 10.1109/DICCT61038.2024.10532975

***Abstract*—This paper includes three blue OLED devices which are D_1, D_2 and D_3 where D_1 is a non-CGL (charge generation layer) device, and D_2 and D_3 are CGL based devices. In all the devices, the CGL contains two materials 1,4,5,8,9,11-hexaazatriphenylene-hexacarbonitrile (HAT-CN) and 1,1-bis[(di-4-tolyamino)phenyl)]cyclohexane (TAPC) which act as electron and hole generators, respectively. As CGL provides additional charge carriers to D_2 and D_3 devices, these devices exhibit noteworthy improvement on the basis of luminescence and current. Among all the three devices, D_3 shows the best performance. The luminescence of D_3 is 2112.2 cd/m^2 which is 10 times and 1.3 times enhanced in comparison with D_1 and D_2, correspondingly. Additionally, the current of D_3 is 0.256 A which is 10 times and 1.4 times higher on comparing with D_1 and D_2, respectively. Moreover, the internal analysis of the devices is also performed using cutline and structure-based analysis to understand the in-depth performance improvements of D_1, D_2 and D_3. The reported CGL based devices are useful for bio-medical and sensor applications.**

Keywords—Luminescence, Organic LED current, charge generation layer (CGL), cutline analysis

I. INTRODUCTION

Over the past few years, full color displays with organic materials are gaining lot of attention because of their salient features like easy fabrication, light weight, wide viewing angle, better lifetime and most important flexibility. Despite having these attractive features, the OLEDs (organic light emitting diode) have made their strong presence in the display industry. On the other hands, there is need of refinement in these displays in terms of luminesces, current and lifetime. Previously, to improve these parameters various layers like EIL/HIL (electron/hole injection layer), ETL/HTL (electron/hole transport), HBL (hole blocking layer) etc. were being used widely [1-4]. These layers helped a lot for enhancing device performance to very good extent. Nevertheless, in recent times, some novel have been introduced to further improve the performance of OLED devices. These novel layers are mixed interlayers [5], spacer layers [6], and charge generation layers (CGL) [7]. To make mixed interlayers, different materials are mixed in a ratio and a single layer formed which can be used between the layers of OLED. In case of the CGL, one or two layers which are used to generate additional free electrons/holes. The CGL layers generally work as hole generator/electron generator [8-10].

In this paper, the three non-CGL and CGL based devices (D_1, D_2 & D_3) are analyzed and compared together in terms of sevral performance parameters such as luminescence and current. Herein, CGL is the mixture of two materials, one is TAPC and other is HAT-CN. TAPC plays as hole generator and HAT-CN works as electron generator. Moreover, a cutline analysis is performed here to study in-depth performance variation of all the devices. Additionally, thickness optimization of the best device is also included.

II. PARAMETERS EXTRACTION AND CHARACTERISTIC ANALYSIS OF BLUE OLED

First of all, a reference device D_1 is validated to set few boundary conditions of the modified devices D_2 and D_3 in terms of materials and thickness. The reference device represents a multi-layered blue OLED device which does not contain any charge generation layer. There are basically seven layers of cathode, ETL, EML, HTL and anode. The device contains the total length and width as 400 and 1000 μm, correspondingly. The materials and thickness of the layers are highlighted in Table I. Fig. 1 is depicting the basic structure of D_1.

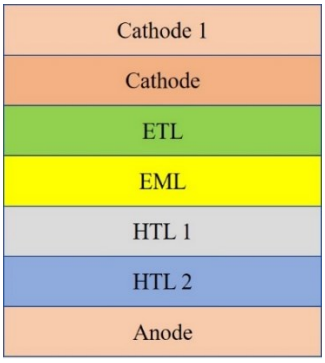

Fig. 1. Reference Blue OLED Device D_1

TABLE I. MATERIALS AND THEIR THICKNESS FOR D_1 DEVICE

Layer	Material	Thickness (nm)
Cathode1	Al	150
Cathode	LiF	1
ETL	BPhen	30
EML	DPVBi & BCzVBi	20
HTL2	NPB	60
HTL1	PEDOT:PSS	90
Anode	ITO	20

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 27,2024 at 09:41:47 UTC from IEEE Xplore. Restrictions apply.

To validate the reference device, Langevin's recombination rate model is utilized in Silvaco Atlas 2-D device simulator. The equation for the model is given below:

$$R_L(n, p) = r_l(x, y, t)(np - n_i^2) \quad (1)$$

Here, r_l, p, n and n_i are for the recombination rate coefficient, hole concentration, electron concentration and intrinsic concentration, correspondingly. Additionally, Poole- Frenkel mobility model is opted to investigate the carrier's transportation. The expression for this model is as follow:

$$\mu(E) = \mu_0 e^{\left[-\frac{\Delta}{kT}+\left(\frac{\beta}{kT}-\gamma\right)\sqrt{|E|}\right.} \quad (2)$$

where E is electric field. Moreover, μ_0 and μ are zero field mobility and field dependent mobility, consequently. Other symbols which are k, Δ, β, T and γ depict Boltzmann constant, activation energy at zero electric field, , hole Pool–Frenkel factor, effective temperature for charge carriers, and fitting parameter, correspondingly. Fig. 2 is showing the simulated structure of the reference device.

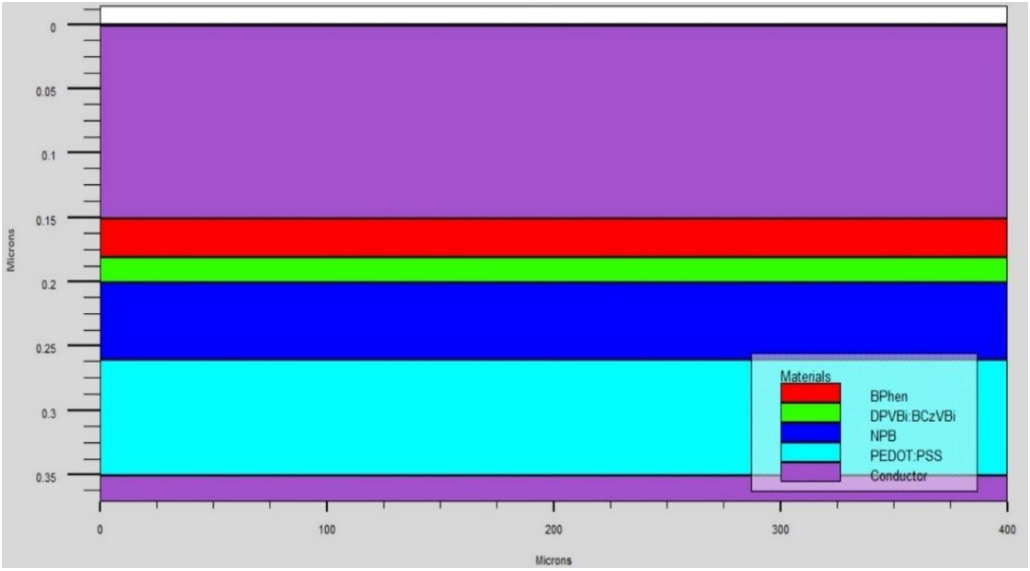

Fig. 2. Simulated Device structure of D_1

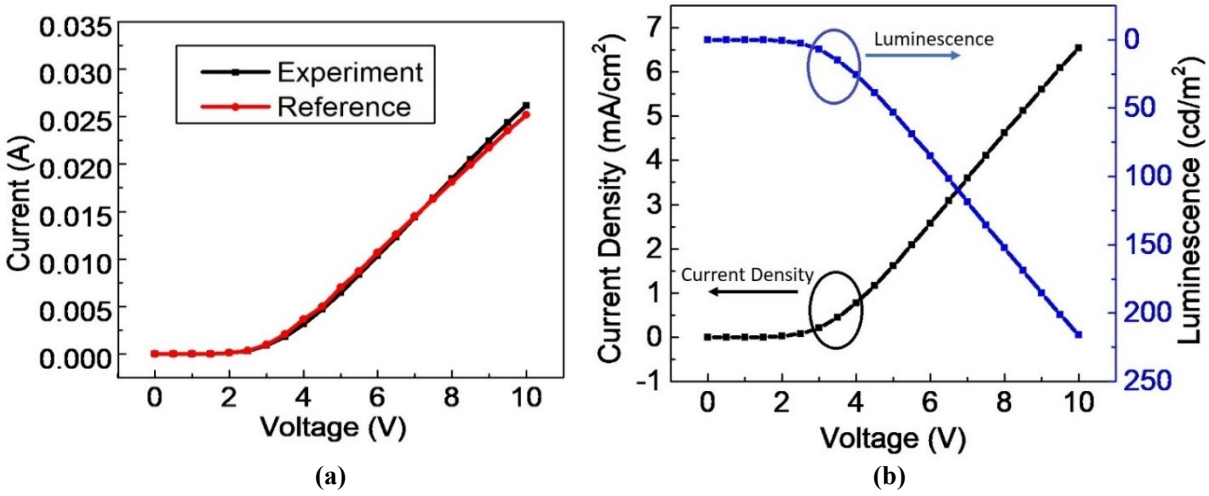

Fig. 3. (a) Experimental and Reference results of current & (b) Curves for luminescence and current density of device D_1

Fig. 3 (a) is outlining the comparison of reference and experiment data of D_1. In figure, it can be seen that experiment results are showing only less than 5% deviation in comparison with reference device as current values of the reference and experement devices are 0.025 and 0.026 A, correspondingly. Additonally, Fig. 3 (b) is illustrating the combined curve for current density and luminsecence with maximum values of 6.5 mA/cm^2 and 215 cd/m^2 and, respectively.

III. Comparison of Three Non-CGL and CGL Based Devices (D_1, D_2 & D_3)

In this section, three OLED devices D_1, D_2, and D_3 are analyzed and compared. Among these devices D_1 is the reference device which is a non-CGL device. Rest two devices D_2 and D_3 are CGL based devices which contain CGL at different positions. Herein, D_2 contains CGL just below the cathode layer and D_3 contain CGL just above the anode layer as mentioned in Fig. 4. All the devices are simulated using

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 27,2024 at 09:41:47 UTC from IEEE Xplore. Restrictions apply.

Silvaco Atlas tool. The performance of D_2 is better than D_1 as it contains CGL which is able to produce a greater number of free charge carriers. These charge carriers eventually contribute in the recombination inside the emissive layer.

Among all these devices, D_3 is providing the best results. Let us understand the reason behind this. In case of D_3, the CGL is situated bottom side near anode. Here, free electrons inside HAT-CN get attracted from anode side and on the other hand, free holes in TAPC get pulled away from anode which will travel towards EML. Also, in organic electronics hole's mobility is better as compared to mobility of electrons. Hence, hole concentration will be increased in this case more significantly in comparison with D_2 where CGL is placed near cathode side. And so, recombination rate in D_3 will be higher than D_2 for the given reasons.

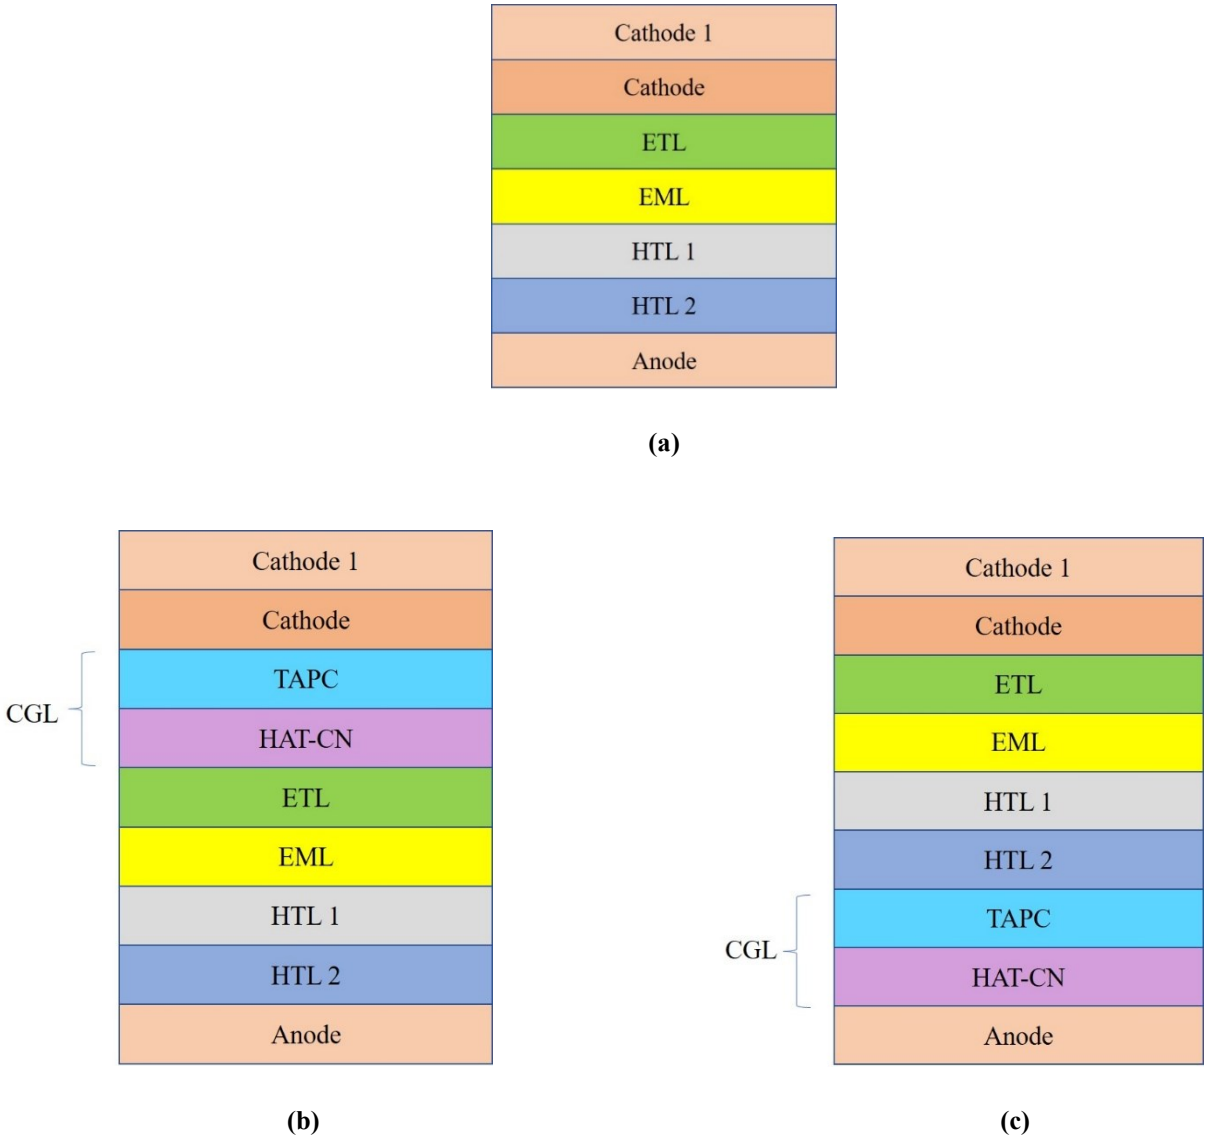

Fig. 4. (a) Reference device D_1 with no CGL, (b) Device D_2 with CGL below cathode and (c) Device D_3 with CGL above anode

TABLE II. PARAMETRIC COMPARISON OF LUMINESCENCE AND CURRENT OF VARIOUS BLUE OLEDS

Device	Current (A)	Luminescence (cd/m^2)
D_1 (Reference)	0.026	215.9
D_2	0.193	1592.3
D_3	0.256	2112.2

Table 2 is illustrating the parametric comparison on the basis of luminescence and current of all three devices. Moreover, Fig 5 (a) and (b) are representing the simulated structures of D_2 and D_3, correspondingly.

Fig. 6 is demontrating the comparison of all the three devices in terms of current and luminesence. Device D_3 is almost 10 times and 1.3 times improved in terms of current on comaring with D_1 and D_2, correspondingly. Moreover, D_3 is almost 10 and 1.4 times better in comarison with D_1 and D_2, respectively, in terms of luminescence.

IV. Internal Analysis of the Blue OLEDs Devices

In this section, the internal analysis is performed of all the mentioned device D_1, D_2 and D_3. This analysis is incorporated using two ways: 1) using cutine analysis and 2) using device structures. Both menthods are discussed in details in the below sub-sections.

A. Internal analysis using vertical cutline

Herein, a vertical cutline analysis is incorporated on the simulated structures of D_1, D_2 and D_3 by drawing a vertical cutline at 200 µm. Three parameters which are electron concentration, hole concentration and recombination rate are investigated to understand the in-depth performance of all the devices.

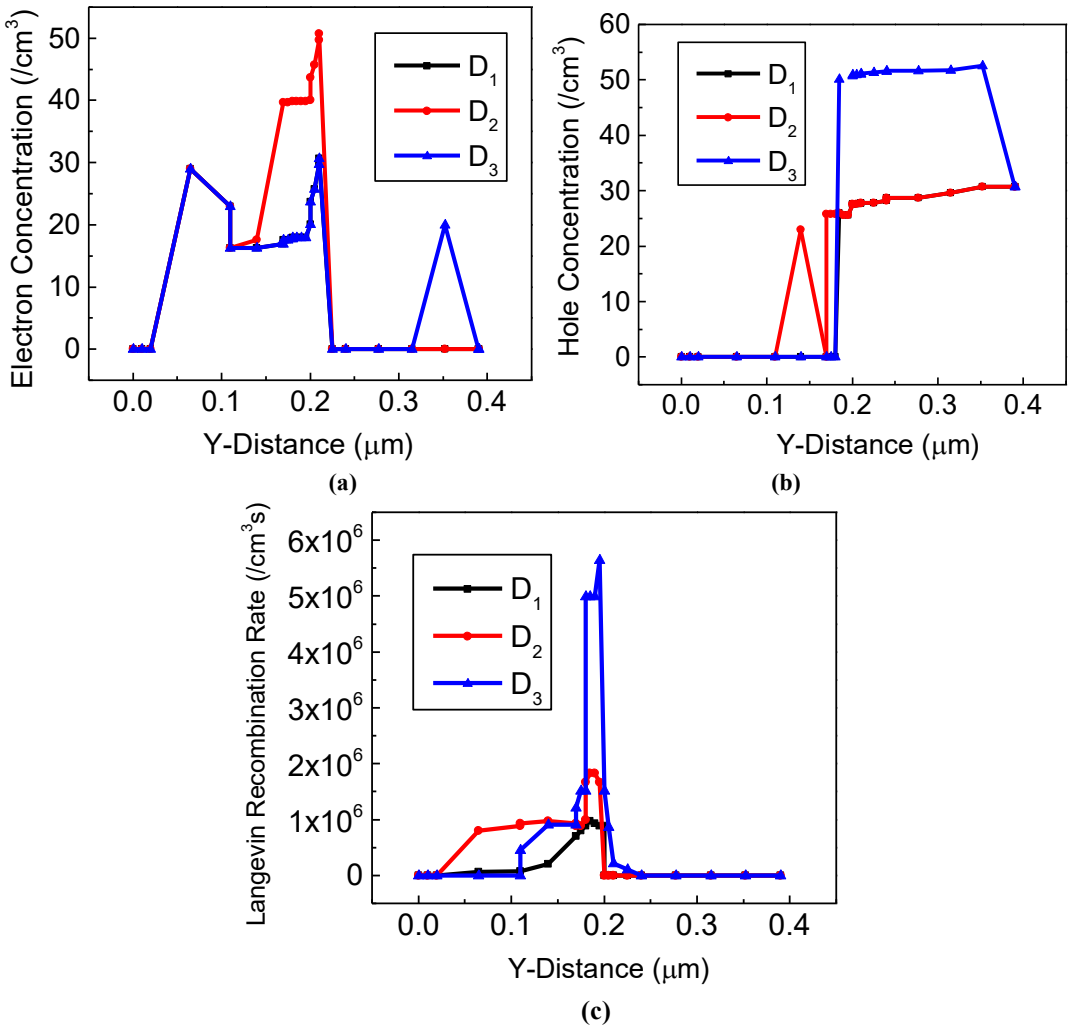

Fig. 7. Parametric comparison of D_1, D_2 and D_3 in terms of (a) Electron concentration, (b) Hole concentration and (c) Langevin recombination rate

It can be cleary observed from the Fig 7 (a) and (b) that D_3 device is outlining the best results for hole and electron concentration, respectively. This is only because of the position of CGL. In Device D_1 there is no CGL and in D_2 the CGL is placed just below the cathode layer. As discussed previously, the CGL close to anode is more benificial which is cleary visible in above figures. This increment in electrons and hole concentration directly enhances the recombination rate of device D_3 as illustrated in Fig. 7 (c). In this figure, D_3 is highlighting the maximum recombination rate among all the devices.

B. Internal Analysis using device structure

In this sub-section, the internal analysis is done using complete device structure of D_3 as shown in Fig 8. Herein, Fig. 8 (a) is demonstrating the potential distribution of device D_3. It ranges from 0 to 10 V which is in increasing fashion from cathode to anode. Moreover, Fig 8 (b) is representing the Langevin recombination rate of D_3. It can be noticed here that maximum recombination is near the emissive layer where electrons and holes recombine together and produce light.

V. Conclusion

In this paper, three devices D_1, D_2 and D_3 are analyzed and compared. Herein, D_1 is a non-CGL based device whereas, D_2 and D_3 are CGL based devices. Among all these devices, D_3 exhibits best performance. It shows the current 10 times and 1.3 times higher as compared with D_1 and D_2, correspondingly. Moreover, the luminescence of D_3 is about 1.4 and 10 times increased on comparing with D_2 and D_3, respectively. All the devices are analyzed using Silvaco Atlas tool. Furthermore, the internal analysis of the all the devices is also performed using two methods. One is cutline analysis where three parameters which are hole concentration, electron concentration and Langevin recombination rate are

compared together. For all the parameters, D_3 exhibits the best performance because of the given reasons in the previous sections. The other method is structure based internal analysis. In this method, the potential distribution and Langevin recombination rate of the D_3 is highlighted.

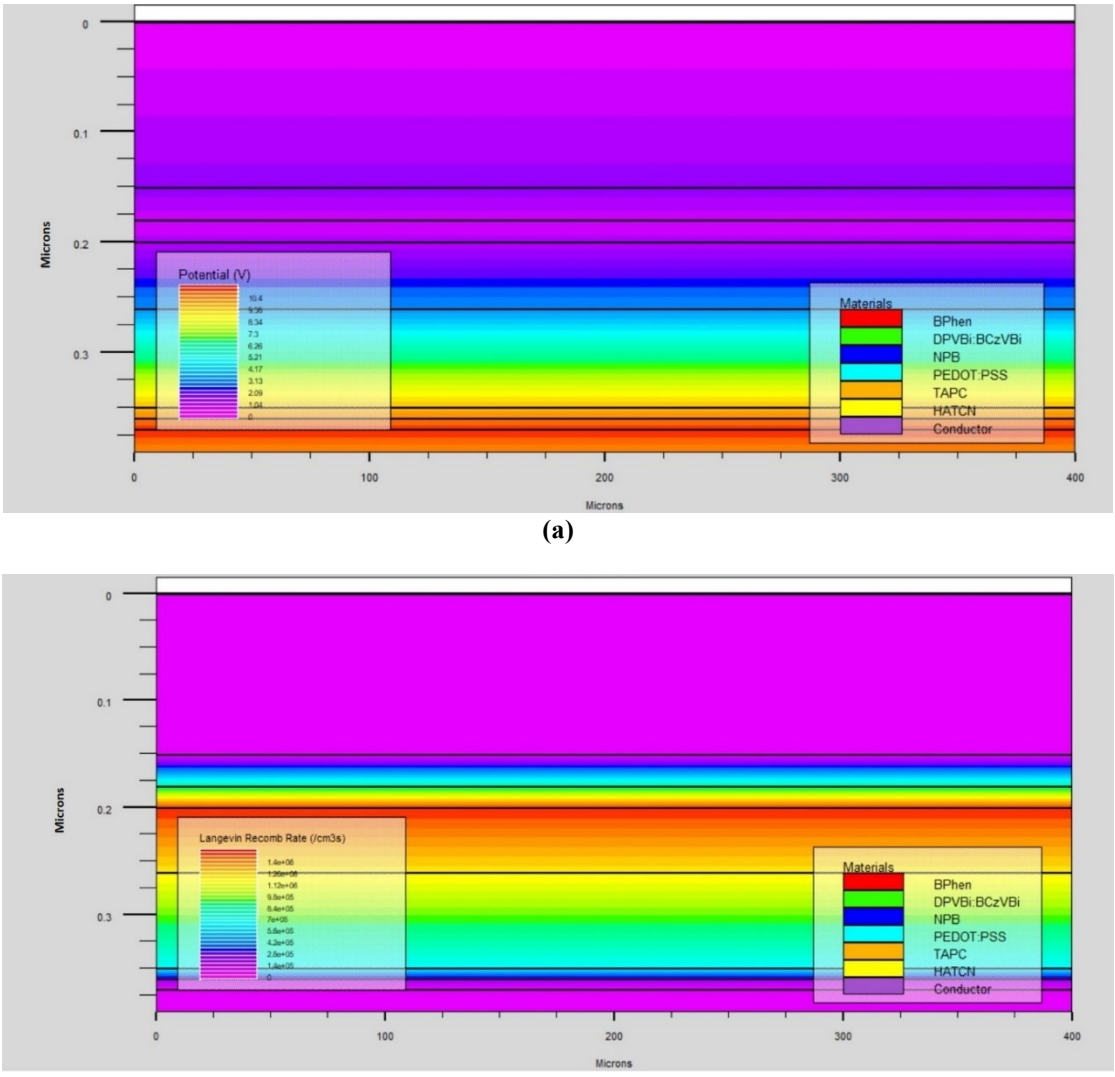

Fig. 8. Structural internal analysis of D_3 in terms of (a) Potential and (b) Recombination Rate

MS received 4 March 2024; revised 8 April 2024; accepted 9 April 2024

Abstract. Potassium *tert*-butoxide mediated a direct one-pot synthesis of diversely substituted nitriles from aldehydes *via* the sequential addition of hydroxylamine and benzoyl chloride is reported. A wide range of aromatic, heteroaromatic, and vinyl aldehydes were converted into corresponding nitriles in good to excellent yields. Room temperature reactions, transition metal-free conditions, wide functional group tolerance, simple operation, and short reaction time are the salient features of the developed methodology.

Keywords. nitrile; benzaldehyde; hydroxyl amine; benzoyl chloride; potassium *tert*-butoxide.

1. Introduction

Nitrile (cyano) is one of the key functional groups in organic synthesis.[1] Nitrile groups are found in many natural products, drugs, and bioactive molecules (Figure 1).[2] For instance, anastrozole is used against breast cancer, while verapamil and tofacitinib are used for treating high blood pressure and arthritis, respectively. On the other hand, functional group transformation of nitrile with different reagents allows easy access to primary amines, amides, carboxylic acid, ketones, etc.[3] Hence, compounds with nitrile functional group have been used as a precursor for preparing various bioactive molecules, natural products, pharmaceuticals, agrochemicals, polymers, dyes, etc.[1–4]

Considering the importance of nitrile groups in organic synthesis, numerous methods have been developed for their preparation.[5] The conventional approaches for synthesizing nitriles include Kolbe's nitrile synthesis, Sandmeyer reaction, Rosenmund-von Braun reaction, dehydration of amides, cyanide-halide exchange reactions, etc.[6] However, this approach requires complex operations, toxic metal and metal-free reagents, harsh reaction conditions, etc. In this context, the synthesis of nitriles from aldehydes received considerable attention owing to their commercial availability and inexpensiveness.[7] A diverse range of nitrogen sources has been employed in transforming aldehydes into nitriles.[5,7] However, some of the developed methods under this approach suffer due to limited substrate scope, use of strong oxidants and metal catalysts, high reaction temperature, tedious operation procedure, low yields, and poor functional group tolerances. Therefore, developing a new method for directly synthesizing nitriles from aldehydes under mild reaction conditions is still desirable.

In this context, we disclosed ^{t}BuOK-mediated one-pot synthesis of nitriles from aldehydes via the sequential addition of hydroxylamine and benzoyl chloride at room temperature. This method relies on the generation of aldoxime *in situ* from aldehyde and the sequential transformation of aldoxime into the nitrile group using benzoyl chloride and potassium *tert*-butoxide at room temperature (Scheme 1).

2. Results and discussion

In the beginning, optimization of the reaction conditions was investigated using benzaldehyde as the model substrate. Initially, benzaldehyde **1a** was

converted into benzaldoxime **I** in the presence of hydroxylamine hydrochloride and sodium acetate in methanol. The reaction was carried out at room temperature for 1 h to obtain quantitative yield aldoxime **I**. After that, the methanol was evaporated to dryness, and the crude mixture was dissolved in acetonitrile. The resulting mixture was treated with benzoyl chloride (1.1 equiv.) followed by base (1.0 equiv.). Various organic and inorganic bases, including Et_3N, DBU, DABCO, KOH, NaOH, K_2CO_3, Cs_2-CO_3, K_3PO_4, K_2HPO_4, ^{t}BuONa, and ^{t}BuOK were investigated. The desired product **2a** was not obtained with Et_3N, DABCO, KOH, NaOH, K_2CO_3, and Cs_2CO_3. However, DBU, K_3PO_4, and K_2HPO_4 gave product **2a** in 16–24% yields. On the other hand, sodium *tert*-butoxide gave the desired nitrile **2a** in 36% yield in 3 h, while 46% was obtained with potassium *tert*-butoxide in 1 h. Further, we investigated the reaction with additional equiv. of potassium *tert*-butoxide. To our delight, the desired product **2a** was obtained with a 78% yield with two equiv. of potassium *tert*-butoxide at room temperature. However, a further increase in the equiv. of potassium *tert*-butoxide did not improve the yield of the product.

The optimization study was further continued by screening acyl chlorides in the presence of potassium *tert*-butoxide (Scheme 2). The reaction provided **2a** only in 17% yield when acetyl chloride was used instead of benzoyl chloride. On the other hand, the reaction with sulfonyl chloride gave the product a 46% yield, indicating the superiority of benzoyl chloride over other acyl chlorides. The reason sulfonyl chloride gave a low yield might be due to the potassium ion coordinate with the nitrogen atom of imine and the oxygen atom of the carbonyl group, which accelerates the reaction.

After identifying optimized reaction conditions (Table 1, entry 12), the scope of the methodology was studied using different aromatic, heteroaromatic, and vinyl aldehydes 1a-v (Scheme 3). Initially, aromatic aldehydes bearing functional groups at the *para*-position were investigated to understand the electronic effects of substituents on the reaction progress.

Benzaldehydes bearing electron-donating groups such as OMe and SCH_3 (**1b** and **1c**) gave the desired products **2b** and **2c** with 77% and 80% yields, respectively. Notably, a heterocyclic compound such as morpholine functionalized benzaldehyde **1d** gave the desired product **2d** in 74% yield. On the other hand, halogens such as Br and CF_3 functionalized benzaldehydes **1e** and **1f** were successfully converted to corresponding nitriles **2e** and **2f** in 70% and 72% yields, respectively. Moreover, carboxylic esters and carboxylic acid functionalized benzaldehydes **1g** and **1h** delivered the desired products **2g** and **2h** in 66% and 64% yields, respectively. Interestingly, the strong

[a]Reactions were performed using 1.0 mmol of 1a, 1.1 equiv. of NH_2OH and 1.0 equiv. of sodium acetate in 2.0 mL of methanol at RT. Then, methanol was removed under reduced pressure. For the second step, reactions were carried out using 1.1 equiv. of BzCl and 2.0 equiv. of the base in 2.0 mL of ACN at RT. [b]Isolated yield.

electron deficient group, such as NO_2-functionalized aldehyde **1i**, gave the corresponding nitrile compound **2i** in 57% yield. On the other hand, the substrate bearing functional groups at the *meta*-position of benzaldehyde **1j** proceeded well under optimized reaction conditions to afford **2j** in 65% yields. Further, we investigated various aldehydes bearing Cl, Br, OH, and Me substituents at the *ortho*-position (**1k-r**). These substrates successfully converted into corresponding nitriles **2k-r** with 62–82% yields. Notably, 1-naphthylbenzaldehyde **1s**, cinnamaldehyde **1t**, and dimethylamino cinnamaldehyde **1u** gave desired products **2s-u** in 65–82% yields under the optimized conditions. More interestingly, the inorganic compound ferrocene carboxaldehyde **1v** was successfully converted into **2v** with a 72% yield.

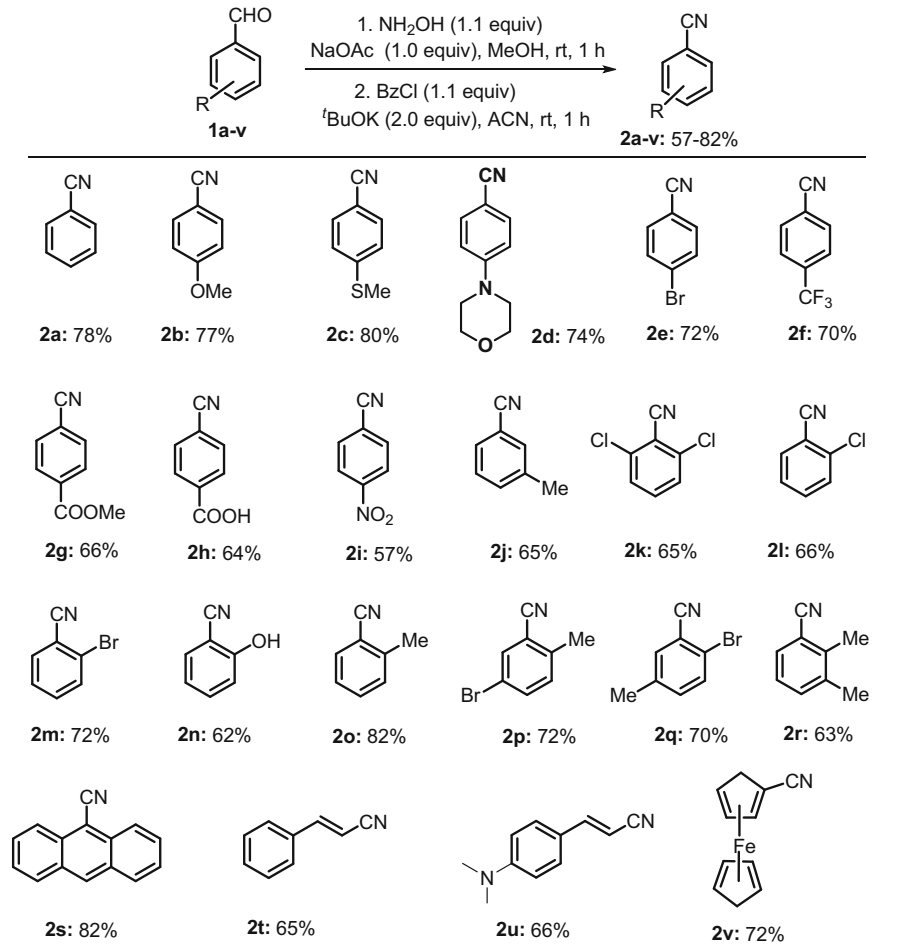
Considering the important role of heterocyclic scaffolds in medicinal and pharmaceutical chemistry, we further examined the transformation of heteroaromatic aldehydes into corresponding nitriles (Scheme 4). A range of nitrogen, sulfur, and oxygen-containing heteroaromatic aldehydes **3a-e** were smoothly converted into the corresponding nitriles **4a-e** in 75–84% yields.

To demonstrate the practicality of the protocol, a gram-scale reaction was performed using model substrate **1a** under the optimized reaction conditions (Scheme 5). The reaction proceeded very well to give the product **2a** in 76% yield.

Based on the observed results and the available literature,[5–8] a plausible mechanism for the reaction has been proposed as shown in Scheme 6. Initially, aldehyde **1** reacts with hydroxylamine to afford the aldoxime **A**. *O*-Acylation of aldoxime **A** in the presence of benzoyl chloride and ^{t}BuOK leads to the formation of compound **B.** The intermediate **B** is converted into desired compound **2** in the presence of ^{t}BuOK via an elimination reaction.

3. Conclusion

An efficient base-mediated direct synthesis of aromatic and heteroaromatic nitriles from corresponding aldehydes was reported as the starting ingredients for the



Scheme 3. Scope for substituted aromatic and vinyl aldehydes.

synthesis; aldehyde and hydroxylamine were combined with benzoyl chloride in a series of reactions. Notably, this process may be carried out at room temperature without needing transition metal catalysts, making it a practical and effective process. Various aromatic and heteroaromatic aldehydes gave the products good to excellent yields. The important features of the developed methodology include broad substrate scope, easy operation, quick reactions, tolerance of different functional groups, and room temperature reactions.

Abstract
This paper presents Adaptive Radial Basis Function Neural Network (A-RBFNN) algorithm for the control of two level and five level converters. This paper investigates the performance of five level cascaded H-bridge (CHB) multilevel converter as compared to two level converters in power distribution system to improve power quality of connected system. The CHB multilevel inverter is a popular configuration because of its wide application for high power medium voltage requirement. The power system including two level (2L) and five level (5L) converter is modeled in MATLAB environment. Experimental setup is also developed in the laboratory for hardware verification purpose and both the 2L and 5L CHB converters are integrated to single phase system as compensators. The A-RBFNN algorithm is able to regulate the DC link voltages to its rated value for two H-bridges in 5L configuration. The designed algorithm is able to compensate for PQ issues of the connected system. It is also tested under steady state and dynamic conditions. Further, A-RBFNN is used to extract individual harmonics of any desired order. Finally, comparison is presented based on the performance results of the proposed algorithm with 2L as well as 5L converters.

Keywords Two level/five level converter · Cascaded H-Bridge (CHB) · Multilevel converter (MLC) · Total harmonic distortion (THD) · Shunt active power filter (SAPF)

1 Introduction

Research in the modern power system is concentrated mainly around the negative effects of power quality events (PQEs), for providing clean and sustainable power to industry sectors and residential complexes [1]. Significant increase in non-linear loads, such as power sources for electronics devices, adjustable speed drives, uninterruptible power supplies and rectifiers increase the burden of power quality issues [2]. Reduction in harmonic content is an important prerequisite of good power quality. Harmonics are classified into two types: voltage harmonics and current harmonics [3]. Current harmonics are typically generated due to the harmonics in the voltage supply and also depend on the type of load, such as resistive, capacitive or inductive. Various topologies starting from two level inverter to multilevel inverters have been studied for improvement of power quality [4].

There is an increasing demand for highly efficient, power-dense DC–AC converters to reduce harmonics in distribution systems. The conventional two-level converter suffers from poor harmonic distortion, higher Direct Current (DC) link voltage requirement, larger dv/dt and rotor heating etc. So, due to the above mentioned issues 2L converter is not used for medium/high voltage and high power applications. In multilevel inverters, the switching stress and harmonic distortions are less in comparison to the conventional two-level converter [5]. Moreover, the voltage stress on the devices is less. Multilevel converters are being realised for high power applications as well as renewable energy integration. They are capable of providing high voltage while reducing harmonic distortions due to their unique circuit topology. Multilevel converters can generate a staircase output waveform that appears to be closer to sinusoidal and produces very low harmonics as compared to a conventional two level converter output voltage. Thus, multilevel converters have

Published online: 21 May 2024

shown to be an efficient and practical solution for reducing switching stress in high power, high voltage applications. There are mainly three types of multilevel inverters viz. Diode clamped, Flying capacitor and Cascaded H- bridge multi-level converter. Diode clamped multilevel inverter was firstly introduced in 1981 by Nabae et al. [6]. The additional clamping diodes are used in the diode clamped multilevel converter to produce AC voltage waveforms with multiple levels. Another modification in mid-1990s was developed in the form of the flying capacitor based converter as presented by Lavieville et al. along with Maynard et al. [7]. The output of this converter is half of the DC voltage input which is a disadvantage of this configuration. The third configuration which is cascaded H-bridge multilevel converter is a much simpler multilevel converter topology. The advantage of this type of multilevel converter is that it requires fewer components than diode clamped or flying capacitor converters and the modules can be combined easily with the possibility of renewable energy integration also [8].

A Shunt Active Power Filter (SAPF) is a power electronic device that is used to mitigate power quality issues caused by harmonic distortions, reactive power burden and unbalances in electrical systems. Different control algorithms can be used to address PQ issues like reactive power, harmonic unbalance, power fluctuations, etc. Among the various control algorithms, reported in literature Savitzky Golay Filter (SGF) based Phase Locked Loop controller [9] is a classical technique. New algorithms such as genetic algorithm optimized fuzzy logic [10], ANOVA kernel Kalman filter [11], adaptive normalized Huber control algorithm [12] have been recently proposed. A Phase-Locked Loop (PLL) is also required in SAPF to perform synchronization and control functions. Some PLL based algorithms are Second Order Generalized Integrator (SOGI) [13], PLL-less SRF [14], Enhanced Phase Locked Loop (EPLL) [15], Leaky Least Mean Fourth (LLMF) algorithm [16], NARLMMN algorithm [17] etc.

Neural network (NN) is a new and powerful tool for solving optimization problems. The use of neural networks has grown significantly over the past two decades due to improved computer models and development in sensor technology [18]. NN help in system identification and development of valid models which are required for system analysis. Various NN techniques are reported in literature for shunt compensation viz Hermite function-based ANN [19], Bernstein Functional Blending Neural Network [20], functional link artificial neural network controller [21], Immune RBF neural network [22], Neural Network (NN) based Improved Linear Sinusoidal Tracer (ILST) [23] etc.

An RBF neural network is an artificially generated neural network that uses the radial basis functions as activation function. RBF Neural Networks are generally applied to approximate functions, classify data, and recognize patterns. The RBF architecture has three layers with input layer, hidden layer and output layer.

In this paper, both two level (2L) and five level (5L) converter configurations are being implemented as SAPF in single phase system. A new control technique viz Adaptive Radial Basis Function Neural Network (A-RBFNN) is used in this paper. The highlights of this work are:

1. Development of an Adaptive A-RBFNN algorithm with detailed mathematical analysis.
2. The application of the developed algorithm and comparison is tested on both 2L and 5L converter topologies.
3. An application of A-RBFNN for segregation of different harmonic orders is also added.
4. Extensive steady state and dynamic results are presented for a fair comparison of two converter topologies.

2 System configuration of proposed system

Figure 1 shows the circuit diagram of the proposed system with five level cascaded H-bridge configuration. A single-phase AC source supplies power to a rectifier load having R-L branch connected at DC side. Source resistance and source inductance parameters are denoted as R_S and L_S. Two converter configurations (2L/5L CHB) are connected one by one in shunt configuration to compensate the PQ problems. The control of the proposed system requires input variables such as source voltage v_s, source current i_s, load current i_L, total dc link voltage ($V_{dc1} + V_{dc2}$). These are sensed with LEM based current and voltage sensors. These sensed voltage and current signals are fed through ADC channel of DSP (dSPACE 1104). The DSP generates the required gating pulses for SAPF. An interfacing inductor (L_C) is connected with converter to suppress the AC output ripples.

3 Description of 2-level/5-level CHB converter

The two level and five level converters being employed for harmonic mitigation and load compensation are shown in Fig. 2a, b. At the nominal frequency and voltage, the DC to AC conversion produces a two level output voltage in conventional 2L converter. However, this converter has some demerits like higher switching stresses, higher distortion and reduced efficiency. 5L-CHB converter generates sinusoidal AC with reduced harmonics as compared to conventional 2L converter [24].

A single H-bridge converter with four switches and one DC link voltage generates a three-level output voltage i.e. + V_{dc}, − V_{dc}, and 0 V [25]. This multilevel converter (MLC)

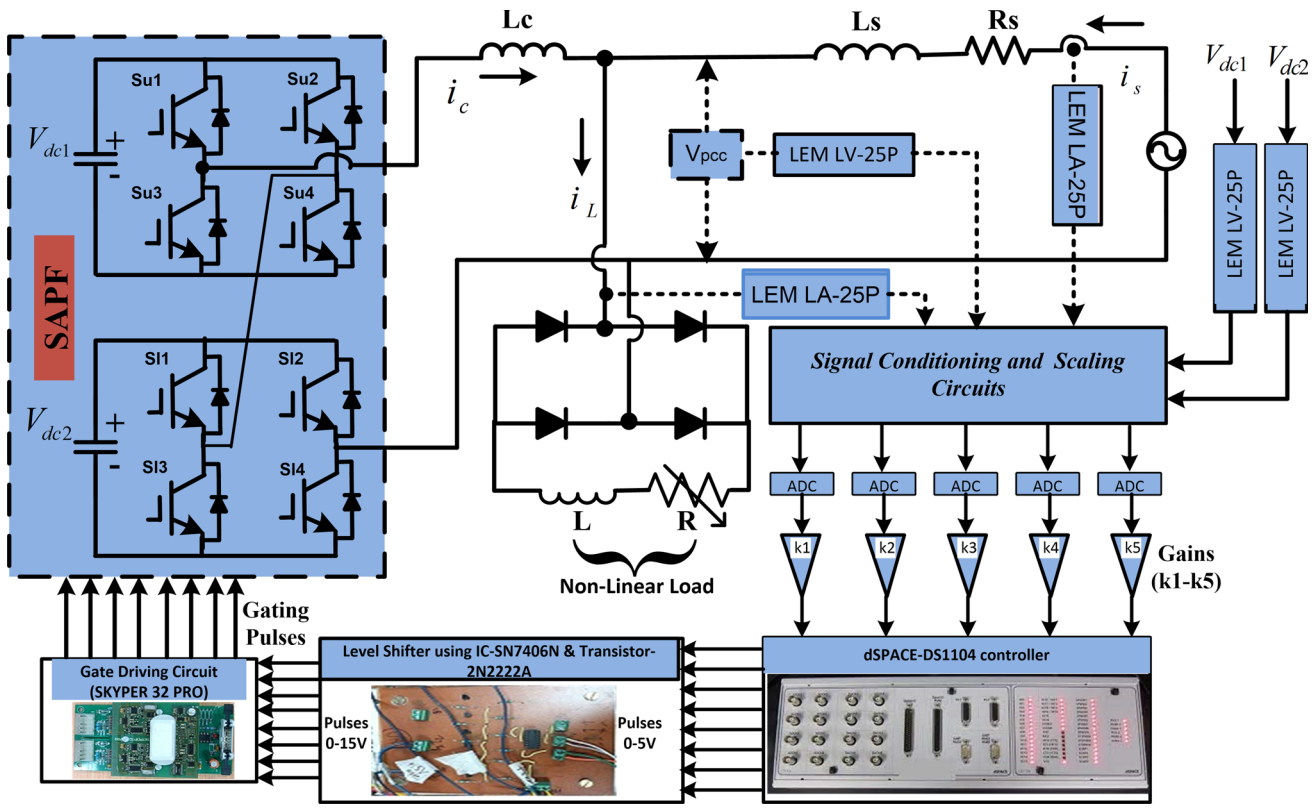

Fig. 1 System configuration of proposed system

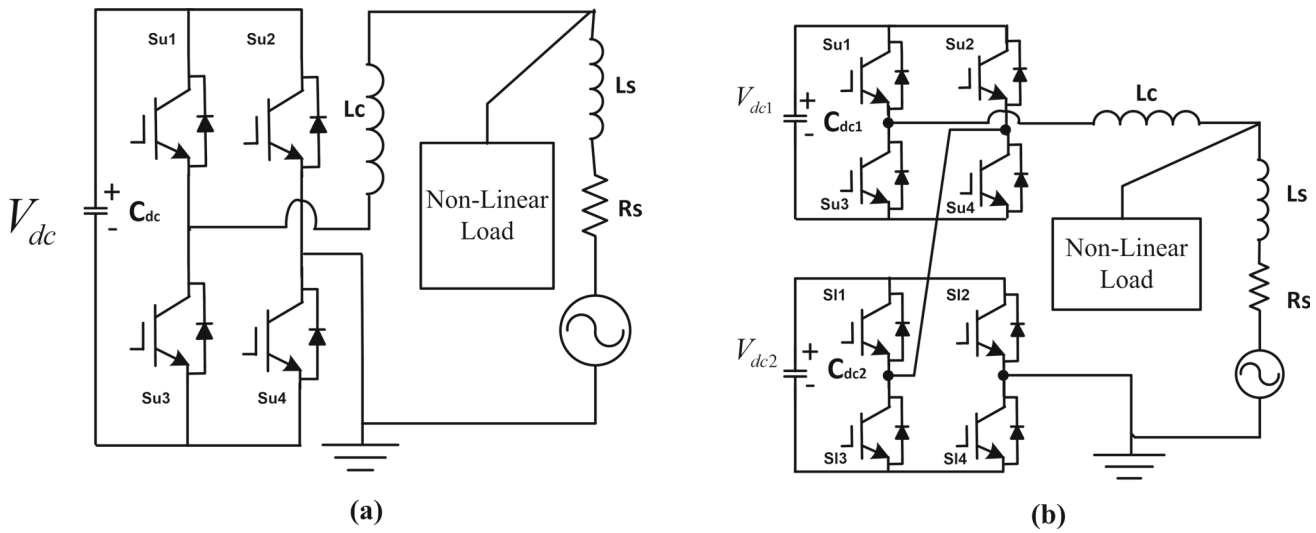

Fig. 2 **a** Two level SAPF based systems **b** Five level SAPF based systems

configuration in contrast has higher number of levels which results in stepped output voltage waveform having lesser harmonics. A full-bridge converter is also known as H-bridge cell as shown in Fig. 2a. A H-bridge circuit comprises four Insulated Gate Bipolar Transistor (IGBT) switches equipped with four freewheeling diodes.

CHB converters have been widely used in many applications such as grid interconnection due to its modular structure, high quality output waveforms and high power application in industries etc. Since the technology is advantageous to increase the converter capability as well as to improve the output voltage quality. Various phase-shifting techniques are used to reduce harmonic distortions in the output voltage waveform and bring it close to sinusoidal waveform [26].

The 5-level CHB converter consists of double H-bridge configuration each having its own DC link and IGBT switches. The number of H-bridges can be increased to increase the number of levels. However, this leads to increased power switch requirement. The design of MLC becomes complex for higher voltage steps and it is more costly and bulky also. So, in this paper, our scope is limited to 5L CHB configuration. In Fig. 2b, two H-bridges with separate DC link voltage are connected in series to generate higher voltage levels and reduced total harmonic distortion (THD) [27] in the output voltage. The 5L CHB converter is switched on so as to obtain possible voltage levels + $2V_{dc}$, + V_{dc}, 0, − V_{dc}, − $2V_{dc}$.

4 Mathematical modeling and formulation of control algorithm

In this section, Conventional Radial Basis Function Neural Network, Adaptive Radial Basis Function Neural Network and Harmonic extraction are discussed. The mathematical modeling and derivations are presented.

4.1 Conventional radial basis function neural network (C-RBFNN)

The Conventional Radial Basis Function (CRBF) Neural Network has the capability to approximate any continuous function with arbitrary accuracy if there are enough hidden neurons. The CRBF Neural Network also has the benefit of being a universal approximator, which means it can approximate any function regardless of its complexity or dimensionality. The CRBFNN structure is shown in Fig. 3a. The structure contains three layers and it is a feed-forward network. The first layer is the input layer that receives the input data, which is typically a vector of values that represent the characteristics of the data under analysis and the input signals (x) travel from this layer to the second layer. The second layer is a hidden layer made up of RBF neural units. A Gaussian function's centre is represented by each neuron in the hidden layer. Each neuron's level of activation indicates how near the input vector is to the centre point that neuron represents. The third layer is known as the output layer and it is a linear combination of activation function from the hidden layer. The weights are updated in the output layer with LMS control technique.

Neural networks are proven to have good convergence, simple structure and faster learning capability [28–30]. In Fig. 3b, the circuit diagram of CRBFNN controller is shown. The load current (i_L) is passed through activation function (f_k) to estimate the actual output (L_{OUT}) which is compared with desired output d(n) to estimate error e(n). The updated weight is calculated by LMS control technique.

Figure 3a shows, the input layer of the p_{th} node X_p = [x_1, x_2,….x_n], the centre vector of the k_{th} node g_k = [g_1, g_2,…..g_m], Euclidean distance between the input layer and RBF layer is ||dist||, bias width of kth node is b_k.

The activation function of kth node in the RBF layer is

$$f_k = \exp(-S_k^2/2b_k^2) \tag{1}$$

where,

$$S_k = \|X_p - g_k\|$$
$$f_k = \exp(-||X_p - g_k||^2/2b_k^2) \quad k = 1, 2 \ldots\ldots m,\ p = 1, 2 \ldots\ldots n \tag{2}$$

Now, L_{OUT} is the actual output of CRBFNN which is generated after the hidden layer and weight updation,

$$L_{out} = w_{p1} f_1 + w_{p2} f_2 + \ldots\ldots + w_{pm} f_m \tag{3}$$

$$L_{out} = \sum_{r=1}^{m} w_{pr} f_r \tag{4}$$

where, w_{p1}, w_{p2},……., w_{pm} are the updated weights.

In CRBFNN, the weight is updated with the help of Least Mean Square (LMS) controller and the error as shown in Eqs. (5–6).

$$w(t+1) = w(t) - \gamma \frac{\partial C(t)}{\partial w(t)} \tag{5}$$

$$e(n) = [d(n) - L_{OUT}] \tag{6}$$

where C(t) = [1/2 e^2(t)] denotes the minimum cost function and γ denotes the convergence factor having value less than 1.

4.2 Adaptive radial basis function neural network (A-RBFNN)

This neural network has been realized due to its fast self-learning ability, good generalization ability and the property of universal approximation which has been used for system control and development of nonlinear system model. Figure 3c shows the circuit diagram of A-RBFNN and it is used to extract fundamental weight of load current.

The proposed A-RBFNN technique, the dynamics of the weight is control with the help of Adaptive varying gain G as shown in Eq. (7).

$$G(n+1) = G(n) - \gamma \frac{\partial\, w_{pr}}{\partial G} \tag{7}$$

In circuit diagram of A-RBFNN as shown in Fig. 3c in which only one neuron (n = 1) is considered, the output

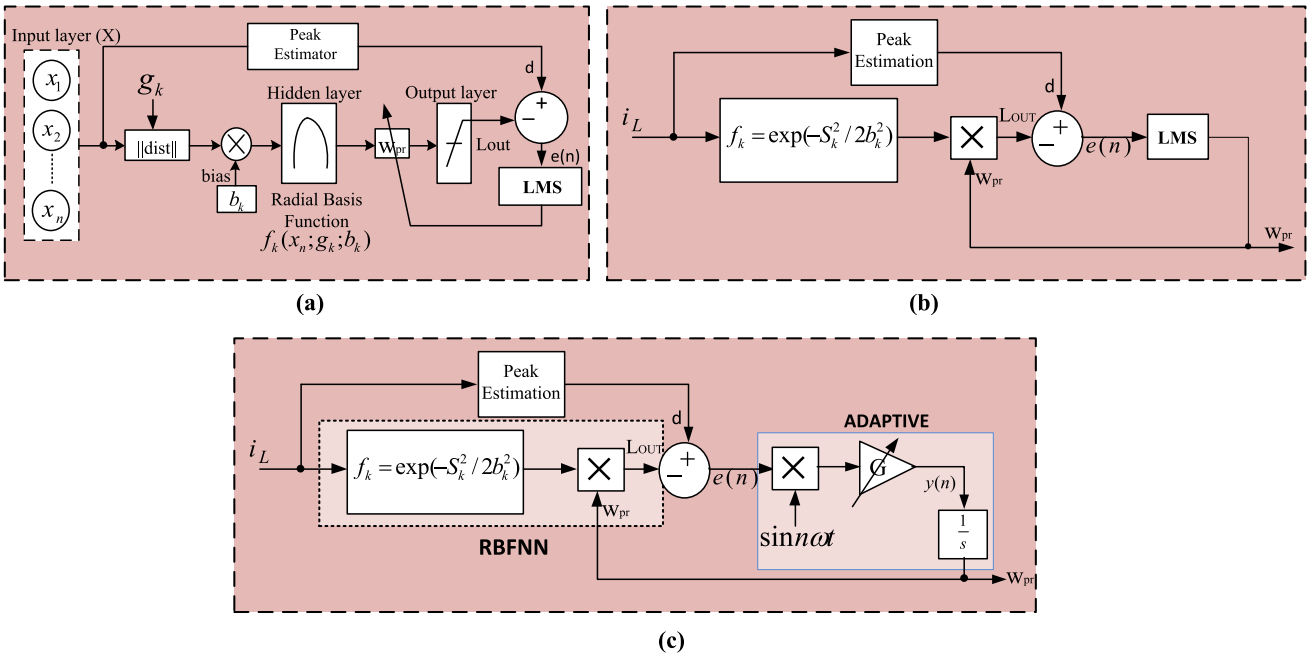

Fig. 3 **a** Structure of CRBFNN [31] **b** Circuit diagram of CRBFNN **c** Circuit diagram of A-RBFNN

'w_{pr}' is calculated as

$$w_{pr} = \int G(n)\, e\, \sin\omega t\; d\omega t \tag{8}$$

$$\therefore w_{pr} = -G(n)\, e\, \cos\omega t \tag{9}$$

The partial derivative of the cost function with respect to the weight vector is

$$\frac{\partial w_{pr}}{\partial G(n)} = -e\, \cos\omega t \tag{10}$$

Using Eqs. (7), (9) and (10)

$$G(n+1) = G(n) + \gamma\, e\, \cos\omega t \tag{11}$$

Thus, the gain varies adaptively in A-RBFNN technique until convergence is obtained.

4.3 Harmonic extraction

The distortion in current waveform is due to the harmonics injected from the nonlinear load. The circuit diagram of A-RBFNN for harmonic extraction is as shown in Fig. 3c. The load current (i_L) contains the sum of both fundamental and harmonic components, which can be represented as

$$i_L(t) = i_{Lh1} + i_{Lh2} + i_{Lh3} + i_{Lh4} + \ldots\ldots\ldots + i_{Lhn} \tag{12}$$

where i_{Lh1}, i_{Lh2}, i_{Lh3}..... i_{Lhn} denote the fundamental, 2nd, 3rd….nth order harmonic components of the load current respectively.

$$\begin{aligned} i_L(t) = {} & i_{L1}\sin(\omega t+\theta) + i_{L2}\sin(2\omega t+\theta) \\ & + i_{L3}\sin(3\omega t+\theta) + \cdots\cdots\cdots \\ & + i_{Ln}\sin(n\omega t+\theta) \end{aligned} \tag{13}$$

where ω is the angular frequency of the fundamental component; θ is the phase angle; i_{L1}, i_{L2}, i_{L3} are the peak values of the fundamental, 2nd, 3rd current components respectively. Now, the Eq. (13) can be expressed as

$$\begin{aligned} i_L(t) = {} & i_{L1}[\sin\omega t\cos\theta + \sin\theta\cos\omega t] \\ & + i_{L2}[\sin 2\omega t\cos\theta_2 + \cos 2\omega t\sin\theta_2] \\ & + \cdots\cdots + i_{Ln}[\sin n\omega t\cos\theta_n + \cos n\omega t\sin\theta n] \end{aligned} \tag{14}$$

$$\begin{aligned} i_L(t) = {} & [(i_{L1}\cos\theta)\sin\omega t + (i_{L1}\sin\theta)\cos\omega t] \\ & + [(i_{L2}\cos\theta_2)\sin 2\omega t + (i_{L2}\sin\theta_2)\cos 2\omega t] \\ & + \cdots\cdots + [(i_{Ln}\cos\theta_n)\sin n\omega t + (i_{Ln}\sin\theta_n)\cos n\omega t] \end{aligned} \tag{15}$$

The load current contains both the active and reactive components. The fundamental active load current component is $i_{Lp1} = i_{L1}\cos\theta$ and fundamental reactive load current component is $i_{Lq1} = i_{L1}\sin\theta$ and similar equations can be written for second, third and other higher order harmonics components.

Replacing $i_{L1}\cos\theta$ by w_{p1}, $i_{L1}\sin\theta$ by w_{q1}; $i_{L2}\cos\theta_2$ by w_{p2}, $i_{L2}\sin\theta_2$ by w_{q2}; and $i_{L3}\cos\theta_3$ by w_{p3}, $i_{L3}\sin\theta_3$ by w_{q3} respectively.

$$i_L(t) = [w_{p1}\sin\omega t + w_{q1}\cos\omega t] + [w_{p2}\sin 2\omega t$$

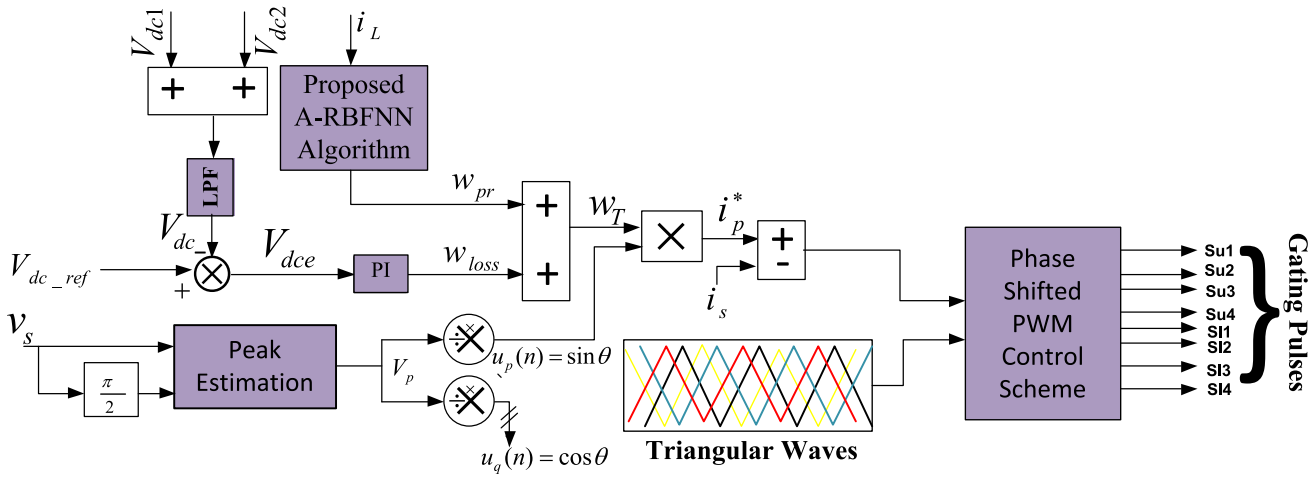

Fig. 4 Control diagram of proposed Adaptive-RBFNN based algorithm

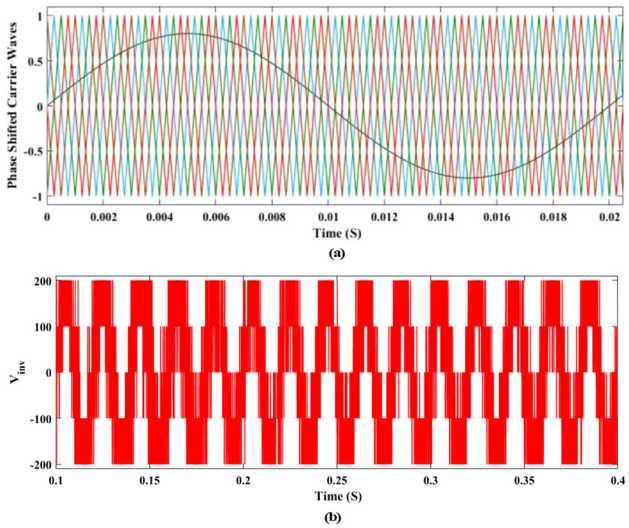

Fig. 5 Waveform showing **a** Phase Shifted-PWM techniques of 5L-CHB converter **b** five level converter voltage output of CHB

$$+ w_{q2}\cos 2\omega t] + [w_{p3}\sin 3\omega t + w_{q3}\cos 3\omega t] + \cdots\cdots\cdots + n\,terms \quad (16)$$

The reactive current components are w_{q1}, w_{q2}, w_{q3} and even harmonic component are neglected and active current component is considered to calculate reference current.

Where $w(h) = [w_{p1}, w_{p3}, w_{p5}, \ldots\ldots, w_{pn}]$ are the estimated active harmonic components of load current.

$$i_L(t) = w_{p1}\sin\omega t + w_{p3}\sin 3\omega t + w_{p5}\cos 5\omega t + \cdots\cdots\cdots + w_{pn}\cos n\omega t \quad (17)$$

To estimate w(h) the value of 'n' is updated in Fig. 3c as per harmonic order of the load current. Further; Eq. (18) can be used to calculate estimated load current upto 7th harmonics (n = 7) shown as,

Let, i_L be the actual nonlinear load current and i_{est} be an estimated current to evaluate the error signal e(h).

$$i_{est}(n) = [w_{p1}\sin\omega t + w_{p3}\sin 3\omega t + w_{p5}\sin 5\omega t + w_{p7}\sin 7\omega t] \quad (18)$$

$$e(h) = i_L - i_{est} \quad (19)$$

5 Control algorithm of the proposed system

The control diagram of proposed algorithm is shown in Fig. 4 for 5L converter topology. In this section, unit template, active weight loss component and the reference grid current calculation are discussed. The proposed algorithm is used to update the estimated weight signals output which is the fundamental component of the load current. The weight loss component is calculated by processing the DC-link voltage through the PI controller. The unit template is multiplied with the sum of the fundamental weights and the PI controller's output to produce the reference current, i_p^*.

5.1 Estimation of unit templates

In order to determine unit templates, the grid voltage (v_s) and its quadrature phase shifted component (v_j) as shown in Fig. 4, are passed through the peak estimation block. In order to calculate peak voltage (V_p) Eqs. (20–21) are used.

$$v_s = V_p\sin\omega t \quad (20)$$

$$v_j = V_p(\sin\omega t + \frac{\pi}{2}) \quad (21)$$

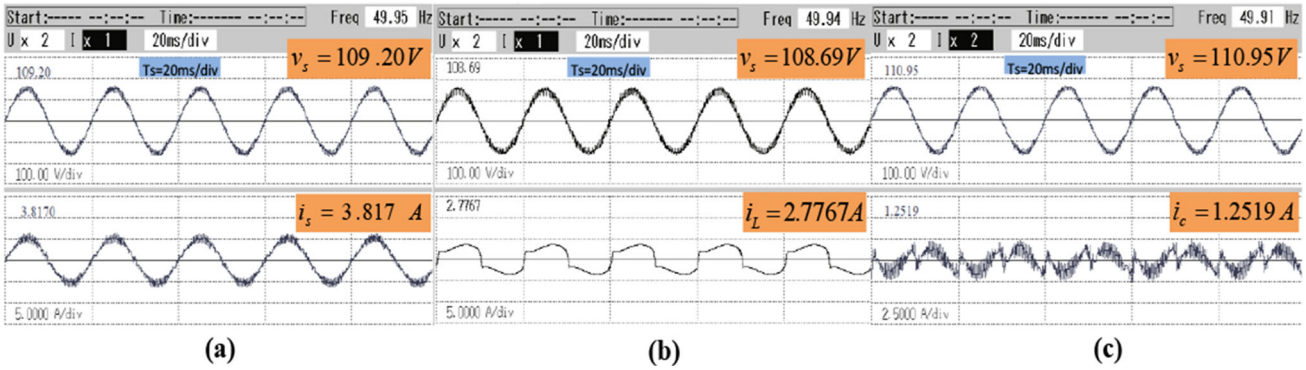

Fig. 6 Steady State experimental results for 2L converter configuration **a** Source current i_s **b** Load Current i_L **c** Compensating current i_c

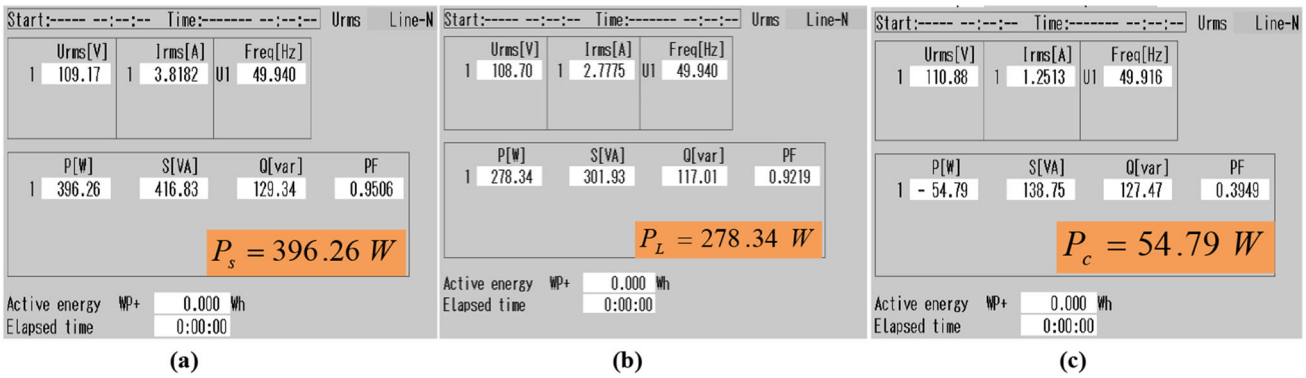

Fig. 7 **a–c** Steady State experimental results of active and reactive power for 2L converter configuration **a** source side (Ps) **b** load side (P_L) **c** compensating side (Pc)

Now, the peak voltage is computed as,

$$V_p = \sqrt{v_s^2 + v_j^2} \tag{22}$$

The unit template is computed as,

$$u(n) = \frac{v_s}{V_p} = \sin \omega t \tag{23}$$

5.2 Estimation of the active weight loss component

The DC link voltage needs to be maintained to a minimum reference value for active shunt filtering. The DC link reference voltage V_{dc_ref} and the total DC link voltage V_{dc} is compared to generate error V_{dce} as shown by Eq. (24). The Proportional Integral (PI) controller is now fed with the error V_{dce} in order to estimate the active weight loss component w_{loss} as per Eq. (25).

$$V_{dce} = V_{dc_ref} - V_{dc} \tag{24}$$

$$w_{loss} = w_{pr} + [k_P\{V_{dce}(n+1) - V_{dce}(n)\} + k_i\{V_{dce}(n+1)\}] \tag{25}$$

where k_p denotes the proportional constant gain and k_i is the integral controller gain.

For the considered system, each DC link was designed for 100 V. Hence, total DC link voltage was selected as 200 V.

5.3 Generation of grid reference current and gating pulses

The total weight w_T as shown in Eq. (26) is computed by the addition of both fundamental weight w_{pr} and active weight loss component w_{loss}. The fundamental weight w_{pr} is calculated by the proposed A-RBFNN algorithm. Now, the product of the total weight w_T and unit template u(n) is used to generate reference current i_p^* as shown in Eq. (27).

$$w_T = w_{pr} + w_{loss} \tag{26}$$

$$i_p^* = w_T * u(n) \tag{27}$$

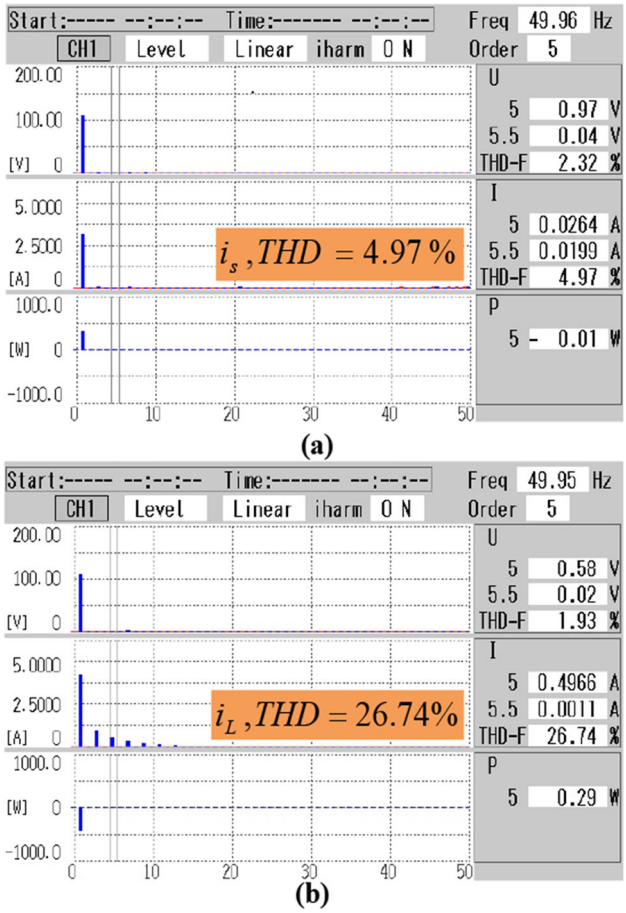

Fig. 8 Steady State experimental results for 2-level converter configuration **a** i_s, THD 4.97% **b** i_L, THD 26.74%

Eight switching pulses need to be generated so as to regulate the 5L-CHB converter. Hence, the reference current ip* is compared with triangular carrier wave of 5 kHz. Figure 5a shows the comparison of reference current signal and carrier waveform, using Phase Shifted Pulse Width Modulation (PS-PWM) technique to generate gating pulses. Here, four carrier waveforms are required in 5L CHB converter and these are compared with grid reference current (i_p*) so as to generate eight gating pulses. Figure 5b shows the obtained five level converter voltage output (V_{inv}) of CHB.

6 Experimental results

In the laboratory, single phase system incorporating 2L as well as 5L CHB converter is developed to verify the feasibility of proposed technique. The system rating is 110 V rms and 50 Hz frequency. The hardware setup for 2L converter uses two voltage sensors (LV-25P) for sensing (v_s, V_{dc}) and two current sensors (LA-25P) for sensing (i_s, i_L). The hardware setup for 5L converter features three voltage sensors (LV-25P) for sensing (v_s, V_{dc1}, V_{dc2}) and two current sensors (LA-25P) for sensing (i_s, i_L). These sensed voltage and current signals are processed by DSP (dSPACE 1104) to generate four gating pulses for 2L and eight gating pulses for 5L-CHB converter. The 2L and 5L CHB converters are controlled to inject compensating current at point of common coupling. Hardware results for steady state and dynamic states are captured using Digital Signal Oscilloscope (DSO) and Mixed Signal Oscilloscope (MSO).

6.1 Steady state results

In this section, steady state experimental results for single phase system incorporating 2-level and 5-level SAPF converters are discussed in detail.

6.1.1 Two level converters configuration

Figure 6a–c show the supply voltage (v_s) along with source current i_s, load current i_L and compensating current i_c. The load current is quite distorted while supply current is sinusoidal. The supply current is also observed to be in phase with supply voltage as shown in Fig. 6a whereas load current i_L is distorted as shown in Fig. 6b. The steady state active and reactive powers are shown in Fig. 7a–c. The active and reactive power demand of load is 278.34 W and 117.01 VAR. The grid supplies 396.26 W active and 129.34 VAR reactive power respectively. The compensator provides 54.79 W and 127.47 VAR active and reactive power respectively. The system active power demand is met by grid whereas most of the reactive power is provided by compensator. Thus, power factor at the supply end is improved from 0.92 to 0.95.

Figure 8a, b show the THD analysis of source current and load current. The THD of source current (i_s) is 4.97% in Fig. 8a and THD of i_L is 26.74% as shown in Fig. 8b. The load current is nonlinear in nature (rectifier with RL load) having high THD. The THD has been reduced by connecting SAPF at PCC and observed to be within the limits prescribed by IEEE standard.

6.1.2 Five level converter configuration

The results for the 5L converter configuration are now discussed. Figure 9a–c show the supply voltage (v_s) along with source current i_s, load current i_L and compensating current i_c. After compensation, the supply current (i_s) is observed to be in phase with supply voltage and sinusoidal as shown in Fig. 9a while the load current i_L is distorted as shown in Fig. 9b. The steady state active and reactive powers are shown in Fig. 10a–c. The active and reactive power demand of load is 287.16 W and 117.64 VAR. The grid supplies 307.79 W active and 68.72 VAR reactive power respectively. The compensator powers are 19.50 W and 120.48 VAR respectively.

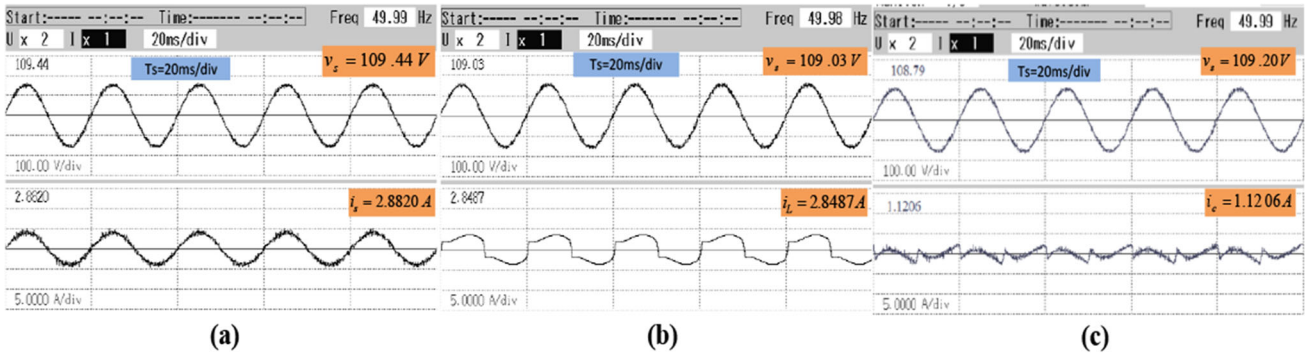

Fig. 9 Steady State experimental results for five level converter configuration **a** source current i_s **b** load Current i_L **c** compensating current i_c

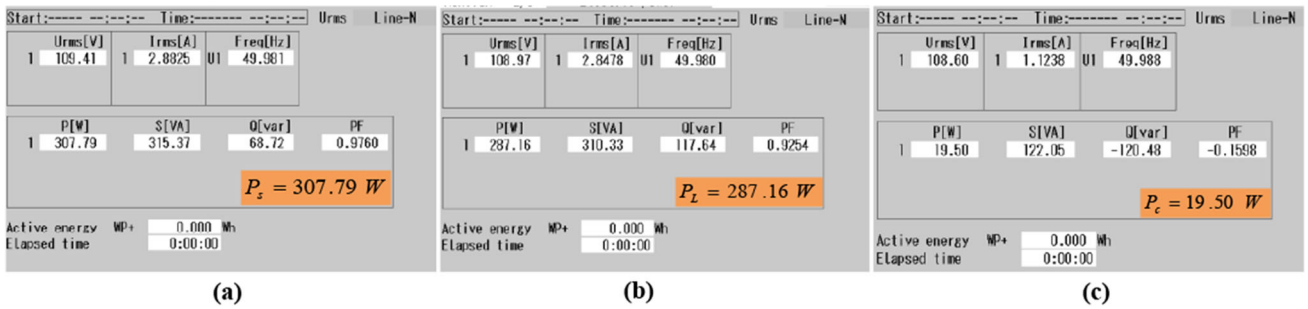

Fig. 10 **a–c** Steady State experimental results of active and reactive power for five level converter configurations **a** source side (Ps) **b** load side (P_L) **c** compensating side (Pc)

It is observed that the system active power demand is met by grid whereas most of the reactive power is provided by compensator. Thus, power factor at the supply end is improved from 0.92 to 0.97.

Figure 11a, b shows the THD analysis of source current and load current. The THD of i_s is 3.77% as shown in Fig. 11a and THD of i_L is 27.80% as shown in Fig. 11b. The load current is nonlinear (rectifier with RL load) having high THD. The source current THD has been reduced due to SAPF action and brought within prescribed IEEE standard.

6.2 Dynamic state results

In this section, the experimental results are discussed under dynamic load variations. The waveform of source voltage, source current, load current, compensating current, fundamental current, DC link voltage of first and second converter, total DC link voltage are observed under load variation for two level as well as five level converter configurations.

6.2.1 Two level converter configuration

Figure 12a, b show the waveforms of source voltage v_s, source current i_s, load current i_L, compensating current i_c and DC link voltage V_{dc}. Figure 12a shows when the load current is increased, the supply current also increases and remains sinusoidal in shape. The supply voltage and current are in same phase after compensation. In Fig. 12b, when there is a sudden increase in load, the DC link voltage dips but soon settles to its steady state value. In Fig. 12c, the waveform of v_s, i_L, w_{pr}, i_{ref} are shown. When there is an increase in load, the fundamental active weight (w) also increases and attains new steady state value quickly. Figure 12d shows waveform of i_L, w_{pr}, i_{ref}, i_s. The reference current i_{ref} also follows the change in load. Figure 12e shows the waveform of i_L, e, f_k, w_{pr}. It is observed that during, a sudden increase in load, the intermediate parameters (e, f_k, w_{pr}) also change and attain new steady state value.

6.2.2 Five level converter configurations

Figure 13a, b shows the waveforms of source voltage v_s, source current i_s, load current i_L, DC link voltage V_{dc} and

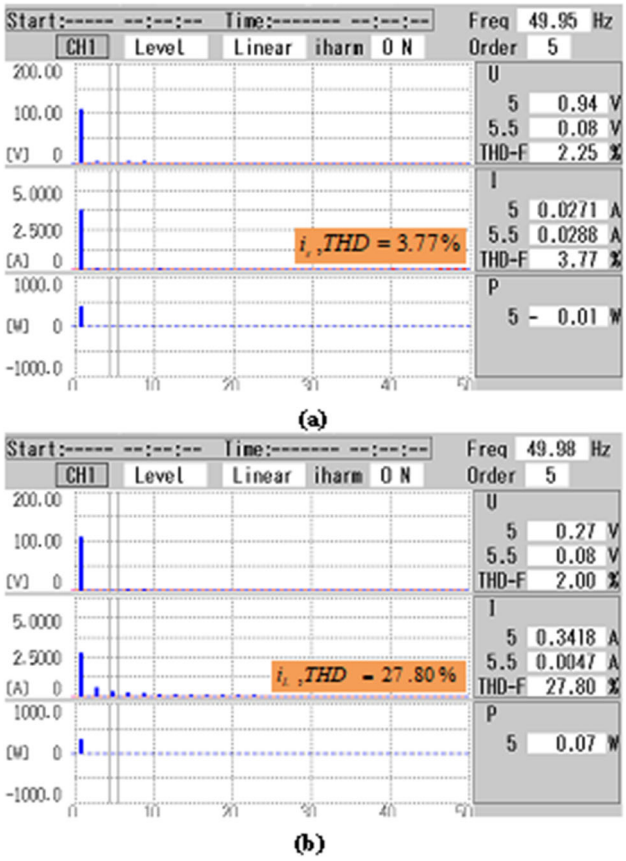

Fig. 11 Steady State experimental results for 5L converter configuration **a** i_s, THD 3.77% **b** i_L, THD 27.80%

v_s, i_s, i_L, compensating current i_c under load increase condition. The DC link voltage is well regulated to its reference value of 200 V under load dynamics as shown in Fig. 13a. Figure 13b shows, the supply voltage and current are in same phase before and after load increase. The waveform of v_s, i_L, w_{pr}, i_{ref} are shown in Fig. 13c. It is to be observed that, the load and source current both increase as expected. The reference current also changes with change in load current. In less than one cycle, the fundamental active weight also increases and reaches a new steady state value due to effective control action of A-RBFNN algorithm.

Figure 13d shows the waveforms of i_L, V_{dc1}, V_{dc2}, V_{dc}. It is observed that, there is sudden increase in load, the DC link voltage drops but soon settles to its steady state value. Figure 13e shows the intermediate signal waveforms of i_L, e, f_k, w_{pr}. It is seen that the intermediate parameters (e, f_k, w_{pr}) also change whenever there is a sudden increase in load.

Figure 14a shows the dynamic waveforms for i_L, $w_{p1}\sin\omega t$, $w_{p3}\sin 3\omega t$, $w_{p5}\sin 5\omega t$, $w_{p7}\sin 7\omega t$, i_{est}. At load increase, the fundamental, third, fifth and seventh harmonics also increases proportionally. The estimated load current i_{est} is obtained by the sum of fundamental to seventh harmonics.

Figure 14b depicts the waveform of i_L, w_{p1}, w_{p3}, w_{p5}, w_{p7}, error (e). As the load increases, the load current fundamental, third, fifth and seventh weight component also increases. The error e is calculated by the load current deducted to the sum of fundamental to seventh harmonics and observed that the error obtained is near to zero.

7 Comparison of two level and five level CHB converter

The proposed control algorithm was tested on two level and 5-level CHB converter connected as SAPF at PCC. The comparative analysis of 2L and 5L CHB converters are shown in Table 1. The topology and performance results for both 2-level and 5-level converters are thoroughly analyzed. It is concluded that 5L-CHB converter configuration shows better response in terms of THD of source current, lower switching losses and fast transient response. Although, number of IGBT switches increases from four (in 2L) to eight in 5L CHB configuration but this can be justified as the source current has much lower THD (3.77%) at similar value of load current than for 2L (4.97%). Moreover, the voltage stress on IGBT switches is less in 5L-CHB configuration. The output waveform of 5-L converter is more near too sinusoidal as compared to 2L.

8 Conclusion

In this paper, an Adaptive-RBFNN algorithm is applied to a single phase system for mitigation of power quality issues. The proposed control technique is able to estimate the magnitude of fundamental load current effectively. The control algorithm is tested with both two level and five level converter configurations along with a non-linear load. It is observed that, the performance of the hardware system with 5L converter configuration is better in terms of source current THD (3.77%), reduced voltage stress etc. The THD obtained using 2L is 4.97%. The 5L-CHB also shows faster dynamic response along with improved steady state response. A detailed comparison is also discussed in this paper. The proposed algorithm A-RBFNN is successfully implemented in this paper.

Abstract: Climate change can have a profound impact on river flooding, leading to increased frequency and severity of floods. To mitigate these effects, it is crucial to focus on enhancing early warning systems and bolstering infrastructure resilience through improved forecasting. This proactive approach enables communities to better plan for and respond to flood events, thereby minimizing the adverse consequences of climate change on river floods. During river flooding, the channels often take on a compound nature, with varying geometries along the flow length. This complexity arises from construction and agricultural activities along the floodplains, resulting in converging, diverging, or skewed compound channels. Modelling the flow in these channels requires consideration of additional momentum transfer factors. In this study, machine learning techniques, including Gene Expression Programming (GEP), Artificial Neural Networks (ANN), and Support Vector Machines (SVM), were employed. The focus was on a compound channel with converging floodplains, predicting the shear force carried by the floodplains in terms of non-dimensional flow and hydraulic parameters. The findings indicate that the proposed ANN model outperformed GEP, SVM, and other established approaches in accurately predicting floodplain shear force. This research underscores the efficacy of utilizing machine learning techniques in the examination of river hydraulics.

Keywords: Compound channel; Converging floodplains; Shear stress distribution; Non-dimensional parameters; Machine learning approaches.

INTRODUCTION

The dynamics of flow within a river are influenced by turbulence and the presence of three-dimensional objects. Consequently, selecting an appropriate modelling technique becomes a challenge when aiming to estimate various flow characteristics, including discharge, velocity, and shear stress. Mean velocities in both the main channel and floodplain fluctuate due to variations in hydraulic conditions. The determination of velocity profiles and fluid fields is contingent upon the presence of boundary shear stress. Beyond the bankfull stage, the flow within the primary channel exerts a propulsive or accelerating force on the flow across floodplains, inherently inducing a resistive or decelerating impact on the flow within the primary channel. The pioneering work on boundary shear distributions in open channels was conducted by Leighly (1932). Numerous scholars have conducted investigations on the resolution of boundary shear distributions in streams, using either direct or indirect methodologies. The analysis of shear forces at the bed helps elucidate the mechanism of bedload transfer, while the examination of shear forces at the walls offers a comprehensive perspective on variations in the channel pattern. Several researchers have conducted studies on the flow, velocity, and shear stress distribution on compound sections (Bhattacharya, 1995; Kar, 1977; Khatua et al., 2011a, b; Knight and Demetriou, 1983; Mohanty, 2013; Myers, 1987; Patra, 1999; Patra and Kar, 2000; Patra et al., 2004; Yang and Lim, 2005). Traditional channel division techniques are used for the assessment of discharge capacity in compound channels. It is postulated that the compound section is delineated by hypothetical interface planes located at the confluence of the main channel and the floodplain. The absence of shear stress in these regions suggests a lack of momentum transmission. The momentum transfer phenomena were first examined by Sellin (1964) via laboratory research. Subsequently, several researchers discovered that the uneven distribution of boundary shear stress along the perimeter of straight compound channels could be attributed to momentum transfer. As a result, they developed an empirical equation for quantifying shear stress, as evidenced by the works of Knight and Demetriou (1983), Knight and Hamed (1984), Myers (1987), Stephenson and Kolovopoulos (1990), Patra et al. (2004), and Yang and Lim (2005). In their seminal work, Knight and Hamed (1984) proposed a theoretical framework to analyse the distribution of boundary shear stress in a compound channel with homogenous characteristics. Their model specifically focused on width ratio (α) values ranging up to 4. In their work, Khatua and Patra (2007) further investigated the subject matter by conducting more experimental observations. They subsequently formulated a model that encompasses channels with width ratios (α) ranging up to 5.25. In their study, Mohanty and Khatua (2014) proposed a novel model for a channel characterized by values of α ranging from 6.67 to 11.96. Extensive investigations were conducted in laboratory flumes to study both prismatic and meandering compound channel designs. Nevertheless, a comparison between the compound section data of prismatic compound channels and non-prismatic compound channels revealed significant discrepancies in the estimation of shear force carried by floodplains. These errors can be attributed to the omission of additional mass and momentum transfer, as elucidated by Bousmar and Zech (2002), Bousmar et al. (2004), Rezaei (2006), and Rezaei and Knight (2009). The additional momentum exchange associated with this phenomenon must be considered when doing flow modelling for non-prismatic compound channels. The study conducted by Proust et al. (2006) investigated the phenomenon of asymmetric geometry,

specifically focusing on its enhanced convergence rate. An augmented convergence angle of 22° leads to heightened levels of mass transfer and head loss. The flow behaviour of skewed, two-stage converging and diverging channels was investigated by Chlebek et al. (2010). The researchers noted an elevation in head losses resulting from the transfer of mass and momentum, as well as the homogeneity of velocity on shrinking floodplains. Additionally, they discovered an augmented velocity gradient on the expanding floodplains. The observed variations in flow distribution may be attributed to alterations in the flow force between the main channel and floodplains within different subsections. Rezaei and Knight (2011) conducted a study on compound channels with floodplains that are non-prismatic. The authors examined the depth-averaged velocity, local velocity distributions, and boundary shear stress distributions at different convergence angles. The analysis of depth-averaged velocities provides insights into the impact of contractions on velocity distributions. Notably, these contractions lead to an augmentation of velocity in close proximity to the walls of the main channel. This effect is particularly pronounced in the latter portion of the convergence reach. Additionally, for cases where the relative depth is high, the lateral flow entering the main channel also contributes to these velocity variations. The study conducted by Yonesi et al. (2013) examines the influence of roughness in floodplains on the occurrence of overbank flow in compound channels with non-prismatic floodplains. Raising the depth ratio or reducing the roughness ratio effectively reduces the velocity gradient between the main channel and the floodplain at the middle and end of the divergence stretch. The rate of change in velocity, as shown by the gradient, exhibited a rise in magnitude as the angle of divergence saw an increase. The magnitude of shear stress increases with the augmentation of surface roughness on the floodplain. The researchers Naik and Khatua (2016) proposed a novel equation that allows for the estimation of the distribution of boundary shear stress by using non-dimensional geometric and flow variables.

The use of soft computing approaches has seen a growing trend in the estimation of parameters inside compound channels, as shown by the studies conducted by Zahiri and Azamathulla (2014), Najafzadeh and Zahiri (2015), and Parsaie et al. (2015, 2017). GEP has a notable advantage over other soft computing approaches due to its ability to generate simpler equations without making assumptions about the pre-existing structure of the connection. However, the current body of literature on river engineering using the GEP technique is limited, with just a few studies available (Azamathulla et al., 2013; Guven and Gunal, 2008; Guven and Aytek, 2009; Pradhan and Khatua, 2017). Wang et al. (2010) examine three techniques for modelling and predicting water level and ice jam thickness. These techniques are based on data collected from field observations of river ice jams in the Quyu Reach of the Yellow River in China. To be more precise, we compare the simulation results produced by the conventional multi-variant regression approach with those obtained from the backpropagation neural network and the support vector machine approaches. Based on the findings from simulation and field observations, it has been determined that both the backpropagation neural network approach and the support vector machine method outperform the multi-variant regression method in terms of accuracy. In this study, Khuntia et al. (2018) used an ANN methodology to forecast the distribution of wall shear stress in straight compound channels. Mohanta et al. (2021) used several AI techniques, such as MARS, GMDH-NN, and GEP, to formulate model equations for compound channels characterized by meandering patterns and relative roughness. In comparison to the GEP and MARS models, the findings indicate that the proposed GMDH-NN model exhibited a high degree of accuracy in predicting the values. In their study, Mohseni and Naseri (2022) used ANN and SVM as computational techniques to predict the water surface profile in compound channels with vegetated floodplains. Based on the obtained findings, it can be concluded that the SVM method exhibited superior performance compared to both the ANN and regression models. In their recent study, Naik et al. (2022) introduced a unique equation that utilizes GEP to forecast the water surface profile in converging compound channels by including geometric factors. In their work, Yonesi et al. (2022) investigated the modelling of discharge in compound open channels with non-prismatic floodplains (CCNPF) using soft computation models, namely MARS and GMDH. The results were afterward compared with those produced from MLPNN. The statistical error indices demonstrate that the suggested models exhibit satisfactory accuracy in estimating the flow discharge in the CCNPF. Cheng et al. (2022) conducted measurements of water temperature and environmental variables at many locations in the primary channel of the middle part of China's South-to-North Water Transfer Project. The heat balance status of this water transfer route has been analysed using the provided temperature data. A novel method has been devised using support vector machine (SVM) theory to determine the amount of heat lost or gained by flowing water in a channel during winter. This innovative technique uses the Gaussian radial basis as its kernel function. By using supervised machine learning, the analysis of observed water temperature data reveals that the air-water temperature differential and thermal conditions are the primary variables influencing the heat loss or heat absorption of a water body. In their research, Bijanvand et al. (2023) employed soft computing methodologies, including the MLPNN, GMDH, NF-GMDH, and SVM, to forecast water surface elevation in compound channels featuring converging and diverging floodplains. The SVM model demonstrated exceptional performance throughout the testing phase, as substantiated by the statistical metrics. Kaushik and Kumar (2023a) used machine learning methodologies to predict the water surface profile of a compound channel with converging floodplains in their research. The predictions were developed by considering a mix of geometric and flow factors. The findings suggest that the ANN model, when compared to GEP, SVM, and existing methods, demonstrated a notable level of precision in predicting the water surface profile. In their study, Kaushik and Kumar (2023b) used GEP as a methodology to develop an innovative equation that describes compound channels with converging floodplains. The equation is formulated using non-dimensional geometric and flow variables and was used to predict the boundary shear force transmitted by floodplains. The findings indicate that the estimated fraction of shear force borne by floodplains determined by GEP has a good degree of agreement with the actual data.

Previous research has shown that there has been little focus on investigating the impact of flow characteristics on the distribution of shear stress in non-prismatic compound channels, as well as the development of novel methods for predicting shear stress. Consequently, further investigations are being conducted at elevated flow rates on compound channels with converging floodplains that do not have a uniform cross-sectional shape. In this investigation, three non-linear machine learning techniques, namely GEP, SVM, and ANN, are employed to forecast the shear force carried by the floodplains (S_{fp}). These predictions are based on both the geometric and hydraulic characteristics of the compound channel with converging floodplains. This research aims to identify a robust methodology, namely among the proposed techniques for accurately determining the proportion of shear force distribution on the floodplain (S_{fp}) in compound channels including convergent floodplains. The calculation of

the distribution of shear force on the floodplain, as determined by different researchers using various methodologies, is estimated. The efficacy of the generated models is evaluated by analysing their performance and errors.

MATERIALS AND METHODS

Data source

The present study incorporates the works of Rezaei (2006), Naik and Khatua (2016), as well as the experimental data collected by the author. Table 1 presents data about the experimental channel dimensions of compound channels with different geometric features.

Experimental setup

The tests were conducted in the Hydraulics laboratory, which is situated under the Department of Civil Engineering at Delhi Technological University. The trials were carried out inside a masonry flume with dimensions of 12 m in length, 1.0 m in width, and 0.8 m in depth. In this study, a compound cross section was created using brick masonry, with a main channel width of 0.5 m and a depth of 0.25 m (Figure 1). Figure 1 provides a comprehensive depiction of the geometric attributes associated with a two-stage channel. The construction of the converging portion of the channel included the use of brick masonry, which was employed to achieve a converging angle denoted as $\theta = 4°$. The compound channel consists of a prismatic segment of 6 m in length, followed by a non-prismatic section spanning 3.6 m, with the remaining portion being the downstream section. The experiment included conducting the flume at six distinct flow rates. Flow properties, including the stage-discharge relationship, water surface profile, velocity distribution, and shear stress distribution, were measured for each discharge in both the prismatic section (PS) and different non-prismatic portions (NPS), as seen in Figure 2. The parts denoted as NPS1 and NPS5 represent the first and final segments of the converging component, respectively. On the other hand, NPS3 corresponds to the central region of the converging section. The NPS2 serves as an intermediary segment situated between NPS1 and NPS3. NPS4 may be regarded as the intermediary segment situated between NPS3 and NPS5.

Table 1. Experimental channel dimensions (Kaushik and Kumar 2023a).

Verified test channel	Type of channel	Angle of convergent (θ)	Longitudinal slope (S)	Cross-sectional geometry	Total channel width (B) (m)	Main channel width (b) (m)	Main channel depth (h) (m)	Converging length (L) (m)	Aspect ratio (δ)
Channel 1 Rezaei (2006)	Converging	11.31°	0.002	Rectangular	1.2	0.398	0.05	2	7.96
Channel 2 Rezaei (2006)	Converging	3.81°	0.002	Rectangular	1.2	0.398	0.05	6	7.96
Channel 3 Rezaei (2006)	Converging	1.91°	0.002	Rectangular	1.2	0.398	0.05	6	7.96
Channel 1 Naik and Khatua (2016)	Converging	5°	0.0011	Rectangular	0.9	0.5	0.1	2.28	5
Channel 2 Naik and Khatua (2016)	Converging	9°	0.0011	Rectangular	0.9	0.5	0.1	1.26	5
Channel 3 Naik and Khatua (2016)	Converging	12.38°	0.0011	Rectangular	0.9	0.5	0.1	0.84	5
Present Channel	Converging	4°	0.001	Rectangular	1.0	0.5	0.25	3.60	2

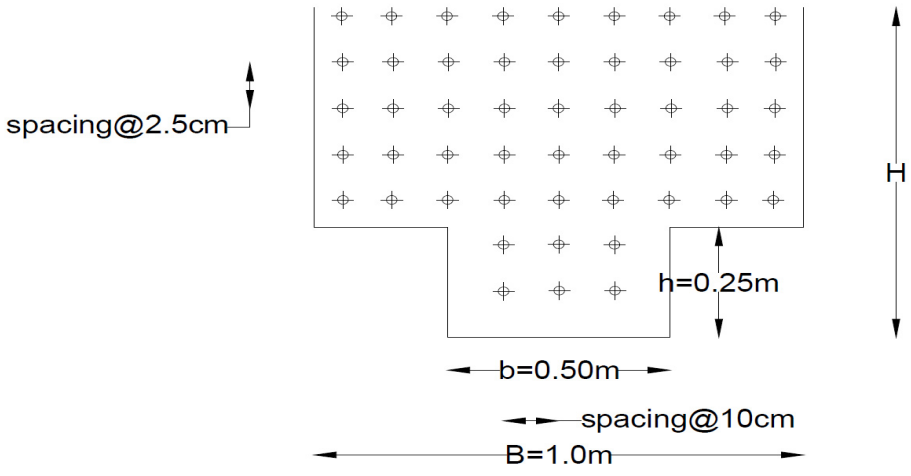

Fig. 1. Compound channel cross section.

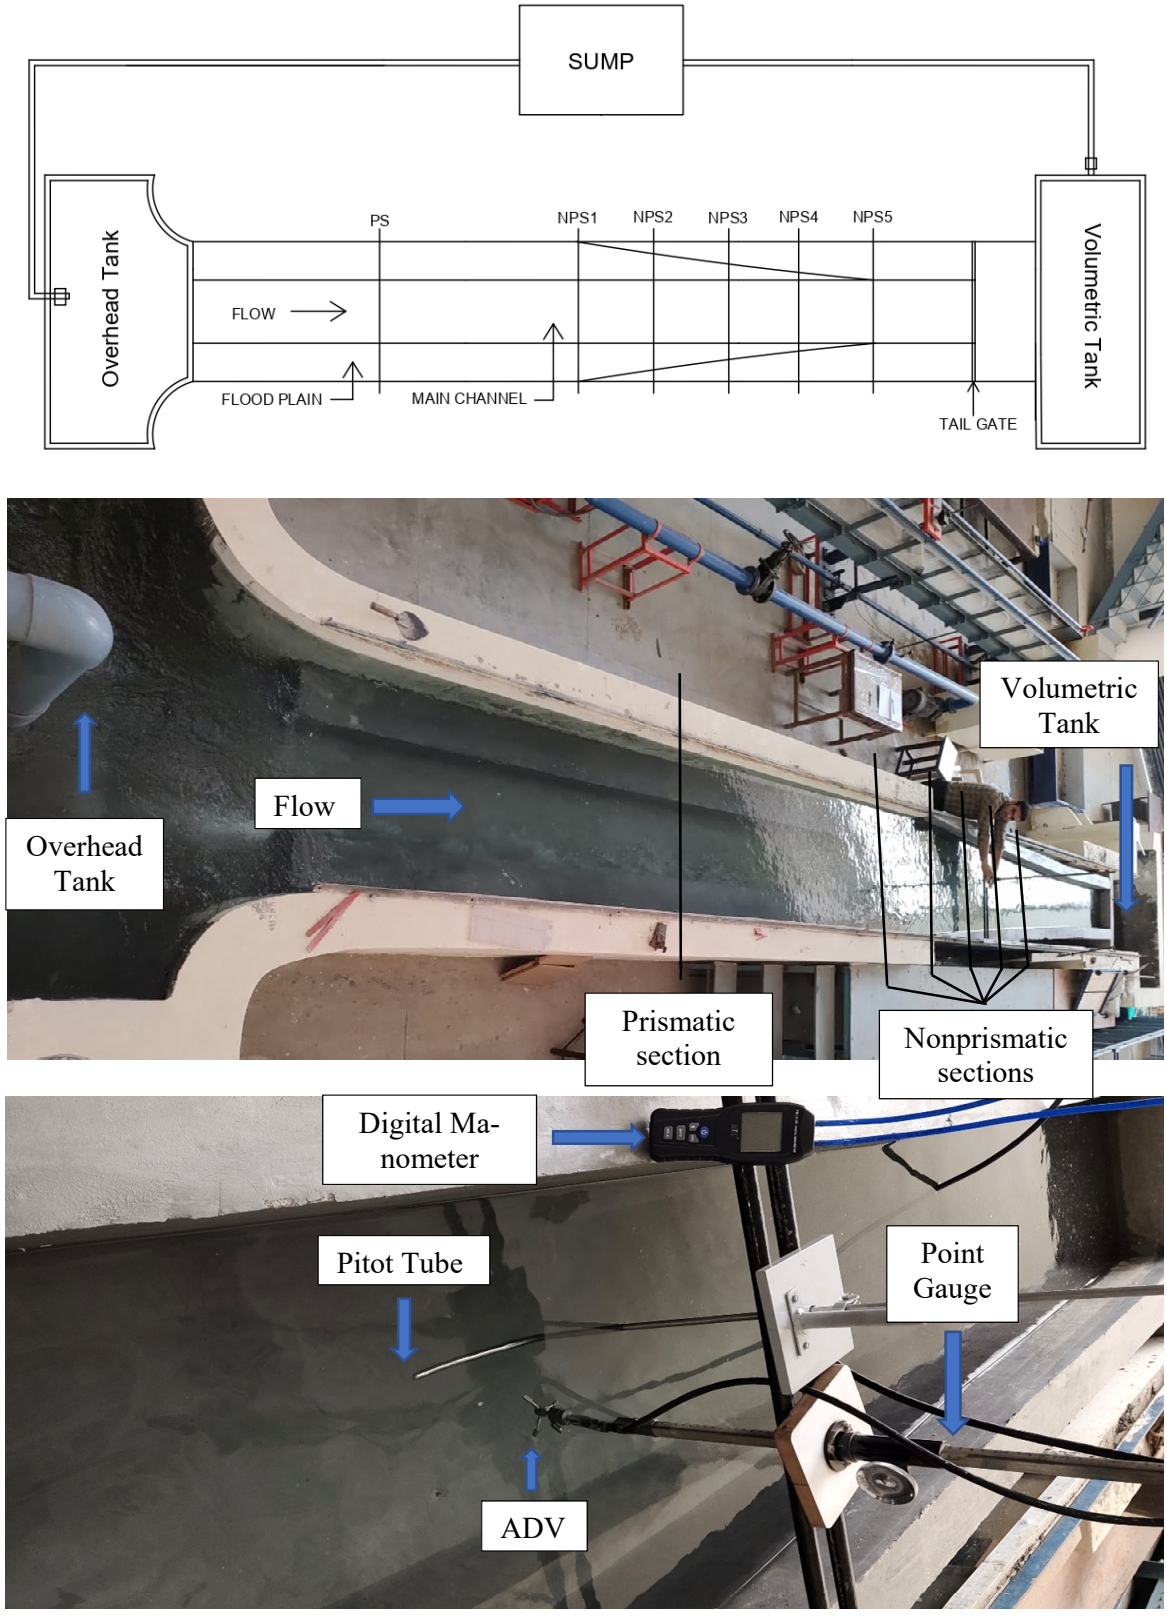

Fig. 2. Experimental setup.

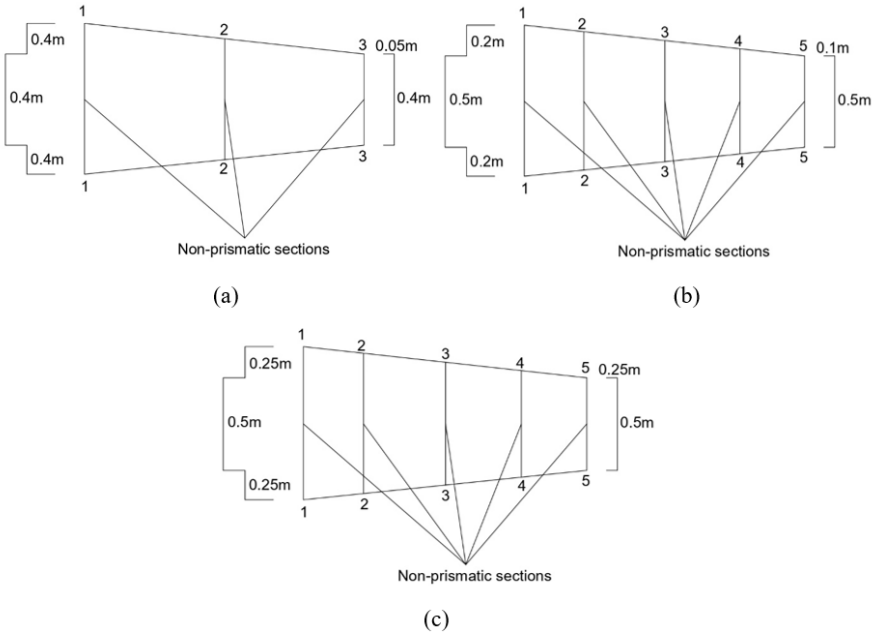

Fig. 3. Nonprismatic sections of (a) Rezaei (2006) (b) Naik and Khatua (2016) (c) Present channel.

The subcritical flow regime was seen under various circumstances in the two-stage channel, which had a longitudinal bed slope of 0.001. The estimation of Manning's n value was conducted based on data obtained from both in-bank and overbank flows in the floodplains and main channel. The water supply in the experimental channel is sourced from an underground sump and transferred to an above tank by the system. The water originating from the channel is collected inside a volumetric tank that is equipped with a v-notch. The v-notch was appropriately adjusted in order to accurately quantify the discharge emanating from the experimental channel. Subsequently, it facilitates the return of the fluid to the sump situated underneath. Figure 2 depicts the experimental configuration and the assortment of apparatus used in the investigation. Figure 3 illustrates the plan view of the non-prismatic cross-sections of Rezaei (2006), Naik and Khatua (2016), and the present channel. A tailgate was constructed at the downstream end of the flume to regulate the water surface profile and enforce a predetermined flow depth inside that section of the flume. A precision point gauge with a precision of 0.1 mm was used to measure the profile of the water surface at distances of 1.0 m and 0.3 m in the prismatic and non-prismatic sections, respectively. The researchers used an ADV to measure the mean velocity of the cross-section and the three-dimensional velocity distributions around the wetted perimeter. The measurements were taken at vertical intervals of 2.5 cm and horizontal intervals of 10 cm, as seen in the grid format presented in Figure 1. The data obtained via the use of the ADV were processed and refined using the Horizon ADV program. The measurement of lateral distributions of boundary shear stress was conducted using a Preston tube with an outer diameter of 5 mm at the identical portions where the velocity distributions were examined. The pressure differential was measured using a digital manometer. Subsequently, the calibration equations proposed by Patel (1965) were used to compute the shear stress values.

Theoretical background

Compound open channels have been the subject of investigation by several researchers, who have conducted simulations to analyse the boundary shear stress. In their seminal work, Knight and Demetriou (1983) introduced Equation (1) to describe compound channels, with values of α ranging up to 4. Knight and Hamed (1984) proposed Equation (2) as a means to include the presence of channels with non-uniform roughness in the analysis. Khatua and Patra (2007) introduced Equation (3) to represent the α within the range of 0 to 5.25. In their study, Khatua et al. (2012) derived Equation (4) to calculate the value of α, with a maximum limit of 6.67. In their study, Mohanty and Khatua (2014) introduced a new equation, denoted as Equation (5), which is applicable for values of α that are less than or equal to 12. In their study, Devi et al. (2016) developed a mathematical model, represented by Equation (6), to analyse a range of α between 3 and 12, relative flow depths between 0.10 and 0.50, and aspect ratios of the main channel between 3 and 10. Equation (7) was formulated by Naik and Khatua (2016) to describe the behaviour of converging compound channels with a width ratio of $\alpha = 1.8$ and an aspect ratio of $\delta = 5$. In their study, Kaushik and Kumar (2023b) proposed a new Equation (8) using the GEP approach to analyse compound channels with different floodplain angles.

$$S_{fp} = 48(\alpha - 0.8)^{0.289}(2\beta)^{m} \quad (1)$$

$$S_{fp} = 48(\alpha - 0.8)^{0.289}(2\beta)^{m}\{1 + 1.02\sqrt{\beta}log\gamma\} \quad (2)$$

where $m = \frac{1}{[0.75e0.38\alpha]}$

$$S_{fp} = 1.23(\beta)^{0.1833}(38ln\alpha + 3.6262)\{1 + 1.02\sqrt{\beta}log\gamma\} \quad (3)$$

$$S_{fp} = 4.1045\left(\frac{100\beta(\alpha-1)}{1+\beta(\alpha-1)}\right)^{0.6917} \quad (4)$$

$$S_{fp} = 3.3254\left(\frac{100\{\beta\alpha\delta-\beta(\delta+2s)\}}{\beta\alpha\delta+(1-\beta)(\delta+s)}\right)^{0.7467}\{1 + 1.02\sqrt{\beta}log\gamma\} \quad (5)$$

$$S_{fp} = 3.576\left\{\frac{100\beta\left(\alpha-1-\frac{2.5s}{\delta}+\frac{0.5s}{\delta^*}\right)}{\left(1+\frac{s}{\delta^*}\right)+\beta\left(\alpha-1-\frac{2s}{\delta}\right)}\right\} \quad (6)$$

$$S_{fp} = 18.505 + 62.140(\beta)^{0.631} - 24.42(X_r) + 1.38(\theta) \quad (7)$$

$$S_{fp}=\left[\left(\frac{(\alpha+\beta)\times(X_r+7.77)}{4}\right)-\left(\frac{\alpha-3.95}{2}+\frac{\alpha+0.196}{2}\right)\right]^2+\left[\frac{14.56X_r^2-38.14X_r}{\alpha^2}\right]+\tan\left[\mathrm{Max}\left((\beta+2.62),(\theta-7.23)\right)+1.50\right]^2+10.25 \quad (8)$$

However, while comparing the aforementioned equations with compound open channels that have narrowing parts, significant discrepancies are seen. Hence, the current work has examined the variation in the floodplain shear force (S_{fp}) with respect to various non-dimensional geometric and flow factors in a non-prismatic compound channel. Both the primary channel and the floodplain subsections of these compound channels have a consistent level of roughness. Manning's n values of 0.013 are assigned to all of the aforementioned smooth surfaces. In a complex channel characterized by limited floodplains, the distribution of boundary shear varies across different sections. The boundary shear force in a non-prismatic channel is believed to be influenced by various dimensionless factors, including the width ratio (α), relative depth ratio (β), aspect ratio (δ), converging angle (θ), relative distance (X_r), longitudinal slope (S_o), energy slope (S_e), discharge ratio (Q_r), Froude number (F_r), and Reynolds number (R_e). A diverse range of parameters is carefully chosen to ensure that the final model equations may be effectively applied across many channels. In order to streamline the equation for a straight compound channel, it is proposed to consider the converging angle (θ) as negligible and thereafter simplify the equation for the straight compound channel.

The equation that is necessary to be dimensionless may be expressed as:

$$S_{fp}=F(\alpha,\beta,\delta,\theta,X_r,S_o,S_e,Q_r,F_r,R_e) \quad (9)$$

SVM model

The SVR method is a frequently deployed machine learning approach utilized for regression analysis. The approach being discussed works on similar principles to SVMs used for classification but with the aim of predicting a continuous output variable based on input factors. The core principle that underlies SVR is to ascertain a function that can proficiently establish a mapping between input variables and output variables, with low error, while simultaneously adhering to a pre-established margin. The achievement of this aim necessitates the transformation of the input variables into a higher-dimensional space using a kernel function. Drucker et al. (1997) subsequently calculate the regression line that maximizes the margin while ensuring that the error remains within a preset tolerance threshold. SVR demonstrates a significant advantage in its ability to efficiently handle non-linear relationships between input and output variables. The achievement of this goal is helped by using kernel functions, such as polynomial, radial basis function, and sigmoid functions, among others. The aforementioned functions facilitate the representation of complex interdependencies among variables (Smola and Schölkopf, 2004). The use of SVR has shown to be beneficial in several fields, such as finance (Sharma et al., 2012), transportation (Yeh et al. 2010), and medical imaging (Borges et al., 2016). The careful selection and fine-tuning of the kernel function and its related parameters are crucial in achieving optimum performance. A commonly used technique for converting a linear classifier into a non-linear classifier is the application of a non-linear function to transfer the input space x onto a feature space F. A different methodology entails using a non-linear function to facilitate the process of mapping. The separating function in space F can be expressed as:

$$f(x)=w^T\varphi(x)+b \quad (10)$$

The statistical approach represented by the algebraic function f (x, w) may be described inside the subspace as follows:

$$w=\sum_{i=1}^{n}\alpha_i x_i \quad (11)$$

$$f(x,w)=\sum_{j=1}^{n}\alpha_i x_i\varphi_i(x)+b \quad (12)$$

$$f(x)=\sum_{i=1}^{n}\alpha_i x_i^T x+b \quad (13)$$

In the feature space, F, this expression takes the form:

$$f(x)=\sum_{i=1}^{n}\alpha_i\varphi(x_i)^T\varphi(x)+b \qquad 0\le\alpha_i\le C \quad (14)$$

$$k(x,x')=\varphi(x)^T\varphi(x') \quad (15)$$

$$f(x)=\sum_{i=1}^{n}\alpha_i k(x,x_i)+b \quad (16)$$

On the other hand, there is a wide array of additional kernel functions available that may be used in different contexts to improve overall performance.

Linear kernel: $k(x_i,x_j)=x_i^T x_j$

Polynomial kernel: $k(x_i,x_j)=(\gamma x_i^T x_j+r)^d,\ \gamma>0$

RBF kernel: $k(x_i,x_j)=exp(-\gamma\|x_i-x_j\|)^2,\ \gamma>0$

Sigmoid kernel: $k(x_i,x_j)=tanh(\gamma x_i^T x_j+r),\ \gamma>0$

The SVM model utilizes the parameters C, γ, r, and d. The effectiveness of the model relies on the quality of the chosen settings for its parameters, as well as the kernel parameters. The careful choice of values for the parameters C, γ, and r is of utmost importance in effectively controlling the complexity of the regression model. Nevertheless, the task of identifying the most suitable parameters is further hampered by the sophisticated complexity involved in their selection. Kernel functions are used to decrease the dimensionality of the input space and assist the process of categorization. The method of refining the SVM model involves exposing it to data sets, which is similar to the refinement process seen in other neural network models. The assessment of the proportion of shear stress borne by floodplains in a compound channel with converging floodplains was conducted using a dependable and high-caliber experimental dataset. Before constructing the SVM model, the dataset is divided into training and testing subsets using a 70:30 ratio in MATLAB R (2019). The model is then created using a cubic kernel function, which was determined to be the most optimal choice among the other kernel functions available.

ANN model

The ANN is a prominent computational approach that is now seeing significant breakthroughs in its progress. An artificial neural network is a computational model composed of linked units known as neurons or nodes, arranged in a hierarchical structure to facilitate manipulation and analysis. The ANN is structured according to the backpropagation neural network (BPNN) model and consists of three layers in a feedforward configuration. The three layers consist of a set of input neurons, denoted as I, a set of hidden neurons, denoted as m, and a set of output neurons, denoted as n. The input layer functions as the first stage for data to enter the neural network. The hidden layer, also known as the intermediate layer, receives input data from the previous layer, known as the input layer, which is largely responsible for processing the data. The second layer, referred to as the output layer, receives the processed data from the network.

The data obtained from the output is sent to external receptors. ANNs consist of interconnected layers that are sequentially linked to one another. The aforementioned relationships are often referred to as weights and weighted values, respectively. The augmentation of connectivity weights is a strategy for regulating the behaviour of specified cost functions inside an ANN (Kaushik and Kumar, 2023a).

The current study used an ANN methodology to predict the shear force borne by floodplains in a compound channel with converging floodplains. A feedforward neural network is implemented in MATLAB R (2019) using the backpropagation training algorithm with the objective of prediction. Before applying the network to any issue, the network must undergo a training phase. During this phase, the adjustment of weights and biases for each output neuron is performed in line with the training approach, with the objective of restricting the intended output of each output neuron. The training of ANNs encompasses three key components: inter-neuron weights, which dictate the significance of input sources; a sigmoid transfer function, which regulates the output level of neurons; and a collection of learning laws, which govern the adjustment of weights during the training process. During the training phase, it is common practice to use a non-linear function, often in the form of a sigmoid function (Kaushik and Kumar, 2023a):

$$F(a) = \frac{1}{1 + e^{-a}} \tag{17}$$

The result is sent to the succeeding layer of nodes for further processing. The BPNN techniques consist of four distinct steps. The aforementioned processes may be delineated as follows:

Sum the weighted input:

$$Nod_z = \sum_{i=1}^{n} (W_{xz} k_x) + \epsilon_z \tag{18}$$

Transform the weighted input:

$$Out_z = \frac{1}{1 + e^{-Nod_z}} \tag{19}$$

Sum the hidden node output:

$$Nod_y = \sum_{j=1}^{m} (W_{zy} Out_y) + \epsilon_y \tag{20}$$

Transform the weighted sum:

$$Out_y = \frac{1}{1 + e^{-Nod_y}} \tag{21}$$

The architecture of the neural network was designed with ten neurons in the input layer, ten neurons in the hidden layers, and one neuron in the output layer. Figure 4 depicts the fluctuation of neural network parameters, including the gradient, mean, and validation tests. During the training phase, the gradient and mean exhibit fluctuations at certain phases, ultimately decreasing, while the validation checks rise as the number of generations increases. This is an outcome of the optimization process, particularly gradient descent, which occurs during the training of ANNs. The repeated modifications to the weights, led by the gradient, strive to discover a collection of weights that minimizes the loss function and generates precise predictions on the training data. Figure 5 illustrates an error detected during the training, testing, and validation phases. The training error first had a rapid decline, then moved to a more consistent deceleration. After 30 generations, the network achieved convergence and demonstrated the lowest possible error value. The reduction in error seen during the training of an ANN is a direct result of the optimization process, which is led by the techniques of gradient descent and backpropagation. The parameters of the model are fine-tuned to discover the most effective setup that minimizes the error on the training data, with the ultimate objective of obtaining strong generalization performance.

GEP model

The use of GEP, a computational approach, enables the evolution of computer programs capable of solving complex problems. The first idea was introduced by Dr. Cândida Ferreira in 1992, as a component of her PhD dissertation at the University of Coimbra, situated in Portugal. The technique of the GEP is based on the basic principles of genetics and the process of natural selection. The operating mechanism of this system is the iterative development of a collection of computer programs through a sequence of mutation and selection procedures. The GEP technique encompasses the representation of individual programs as symbol sequences, which may be subjected to a range of genetic operations, such as combining and mutation. The selection of programs with higher performance on a specific task in each succeeding generation leads to an improvement in their overall fitness. The ability of GEP to effectively handle many goals simultaneously makes it an important tool in the field of optimization. The GEP has been widely used across several fields, including but not limited to data analysis, categorization, and modelling. According to Ferreira (2001), empirical data indicates that GEP has enhanced efficacy when compared to other evolutionary computation methods such as genetic programming and evolutionary strategies, particularly within certain problem areas. Furthermore, researchers have extended the GEP technique to support complex data structures such as trees and graphs. This has been achieved by the incorporation of modified genetic operators, as described by Otero et al. (2016).

The current study utilizes a modelling methodology in which the goal value is denoted as $\%S_{fp}$, while the ten independent components are regarded as input variables, as described in Equation (9). The construction of the model's structure included the use of the four basic arithmetic operators (+, −, ×, /) in combination with GeneXproTools 5.0 (2014). In general, the modelling procedure used high-calibre datasets that were randomly allocated during two discrete phases. Several models were created for the present investigation, using different ratios of training and testing datasets, program dimensions, and generations. The characteristics of the best model are shown in Table 2. The current investigation used the root-mean-squared error (RMSE) as the fitness function, which was designated as E_i. The fitness (f_i) was determined by using an equation developed from an expression tree, which took into consideration the cumulative total of mistakes with respect to the target value. The technique of addition was used as the method for joining the genetic components. Figure 6 illustrates the expression tree (ET) representing the percent shear force of the compound channel predicted from the GEP model. In the present representation, the input parameters are denoted as d0 to d9, whilst the constant values for gene one are assigned as G1c1, G1c2, and G1c6. The expression tree may be used to derive a mathematical formula that establishes a correlation between the input and output variables.

Statistical measures

Various error analysis approaches were used to evaluate the accuracy of the machine learning models. The aforementioned metrics included the coefficient of determination (R^2), mean squared error (MSE), root mean squared error (RMSE), mean absolute error (MAE), mean absolute percentage error (MAPE), scatter index (SI), coefficient of efficiency (E), and Akaike Information Criterion (AIC). The relevant equations were used to compute these measures (Kaushik and Kumar 2023a).

$$R^2 = \frac{\sum_{i=1}^{N}(a_i-\bar{a})^2\,(p_i-\bar{p})^2}{\sum_{i=1}^{N}(a_i-\bar{a})^2\ \sum_{i=1}^{N}(p_i-\bar{p})^2} \quad (23)$$

$$\text{MSE} = \frac{1}{N}\sum_{i=1}^{N}(p_i - a_i)^2 \quad (24)$$

$$\text{RMSE} = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(p_i - a_i)^2} \quad (25)$$

$$\text{MAE} = \frac{1}{N}\sum_{i=1}^{N}|p_i - a_i| \quad (26)$$

$$\text{MAPE}(\%) = \frac{1}{N}\sum_{i=1}^{N}\left(\frac{|p_i-a_i|}{a_i} \times 100\right) \quad (27)$$

$$SI = \sqrt{\frac{\sum_{i=1}^{N}[(p_i-\bar{p})-(a_i-\bar{a})]^2}{\sum_{i=1}^{N} a_i^2}} \quad (28)$$

$$E = 1 - \frac{\sum_{i=1}^{N}(p_i-a_i)^2}{\sum_{i=1}^{N}(a_i-\bar{a})^2} \quad (29)$$

$$\text{AIC} = N\log\left(\frac{1}{N}\sum_{i=1}^{N}(p_i - a_i)^2\right) + 2k \quad (30)$$

RESULTS AND DISCUSSION

The connection between bed shear stress and longitudinal distance for various relative depths (range from 0.10 to 0.60) in a compound channel with converging floodplains (θ = 4°) is shown in Figure 7. The bed shear stress shows a linear augmentation in relation to the longitudinal distance till reaching the prismatic section. Nevertheless, it is observed that there is a sudden increase in shear stress along the longitudinal distance in the initial half of the channel's converging region. Additionally, in the latter half of this section, there is an abrupt rise in bed shear caused by the convergence of the channel's geometry, resulting in accelerated flow within the channel. The bed shear stress in both the main channel and floodplains exhibits an increase in magnitude as the longitudinal distance progresses. This increase is mostly attributed to the rise in relative depth, with greater relative depths seeing a more pronounced effect. The primary driver behind this phenomenon is the transfer of momentum from the main channel to the floodplains. The boundary shear stress distributions throughout the wetted perimeter of the compound channel are depicted in Figure 8. The figure includes both prismatic and non-prismatic cross-sections and the relative flow depth β is set at 0.60. The distribution of boundary shear stress exhibits symmetry and expands progressively from section 1 to section 5. The largest value of boundary shear stress is seen near the centre of the main channel, and this value rises as the flow transitions from a prismatic portion to a non-prismatic segment. This increase in boundary shear stress may be attributed to the boundary resistance resulting from the converging shape of the channel. The magnitude of the boundary shear stress diminishes as it approaches the floodplain interface across all sections. At lower relative depths, in close proximity to the interface between the main channel and the floodplain, the boundary shear stress experiences a rapid fall, followed by a gradual decrease until reaching a minimum at both ends of the floodplain. At elevated relative flow depth, in the vicinity of the interface between the main channel and the floodplain, there is a rapid decline in shear stress. This is followed by a gradual increase towards the centre of both floodplains and subsequently a decrease towards the boundaries of the channel. This pattern arises due to the transfer of momentum from the floodplains to the main channel in the compound channel configuration.

Figure 9 displays scatter plots that compare the anticipated and actual values of $\%S_{fp}$ for each of the several machine learning algorithms. The proximity of the values to the line representing excellent agreement serves as compelling evidence for the predictive accuracy of the developed GEP, ANN, and SVM models. When comparing the three models, it can be seen that the predictions made by the ANN exhibit a higher degree of proximity to the best-fitting line in comparison to the GEP and SVM models. The ANN model demonstrates a more concentrated distribution of values along the fitted line. Hence, it can be concluded that the ANN model exhibits the highest level of agreement with the experimental data, as shown by the significant R^2 values. Figure 10 presents a comparison of the created models used to forecast the proportion of shear force carried by floodplains, using different approaches. The built models have shown remarkable proximity to the best-fitted line in comparison to earlier methodologies, indicating a robust potential for generalization. There is an absence of observable indications of the overtraining phenomena in their behaviour. Several of the suggested methodologies exhibit a clear bias toward estimating shear stress in floodplains. These models incorporate all the relevant parameters, such as discharge ratio, energy slope, Froude number, and Reynolds number, which were previously overlooked in earlier approaches. The evaluation of the GEP, ANN, and SVM models' performance was conducted using various statistical metrics, including the R^2, MSE, RMSE, MAE, MAPE, SI, E, and AIC. These metrics are presented in Table 3. The table reveals that the ANN model demonstrates superior performance in comparison to other models constructed

using SVM, GEP, and previously developed methodologies. This is evident from the highest R^2 value of 0.998, lowest MSE value of 0.375, lowest RMSE value of 0.613, lowest MAE value of 0.338, and lowest MAPE value of 0.391 associated with the ANN model. The SI serves as a standardized measure for the quantification of inaccuracy. A lower SI value is indicative of a higher level of model performance. The ANN model has a significantly reduced SI value of 0.023 in both the training and testing stages, indicating a minimum level of error. The efficiency measure, represented as E, is assigned a value of 1 when there is a complete correspondence between the model and the observed data. The interval of E extends from negative infinity to 1. The ANN model has an E value of 0.998 for both the training and testing datasets. The AIC is a widely used criterion in statistical model selection. It is used to choose the best suitable model by evaluating the statistical likelihood function. The model that has the lowest AIC value is regarded as the most optimum model. The ANN model has the lowest AIC score of -148.470 when compared to the other models proposed. The statistical study of several indices indicates that ANN exhibits superior performance compared to other machine learning techniques and established methodologies in forecasting the proportion of shear force borne by floodplains in compound channels with narrowing floodplains.

CONCLUSIONS

This work presents an evaluation of the shear stress exerted on floodplains in a compound channel with converging floodplains. The assessment is conducted using machine learning techniques, including ANN, GEP, and SVM. The suggested models have been built using 396 meticulously gathered laboratory datasets from both current and previous work. These datasets pertain to non-prismatic compound channels characterized by varying converging angles and relative depths. The suggested model has apparent sensitivity to several factors, including width ratio, relative flow depth, aspect ratio, converging angle, relative distance, longitudinal bed slope, energy slope, discharge ratio, Froude number, and Reynolds number. The bed shear stress exhibits an increasing trend as one moves along the length of the channel and with respect to the relative flow depth. Nevertheless, a rapid increase in shear stress was seen in the converging portion, particularly in the latter half of the channel, due to the interaction and transfer of momentum between the main channel and floodplains. The largest wall shear stress was observed in the central region of the primary channel, with a rise in magnitude as the flow progresses downstream within the channel. At the junction between the main channel and the floodplain, the shear stress values experience a drop as a result of the momentum shift phenomenon. This decrease is seen to be at its lowest near the extremities of the channel for lower relative depths, while it rises towards the centre of the floodplain for greater relative depths. The connection between the percent shear force and the non-dimensional geometric and hydraulic variables of a converging compound channel is nonlinear for all relative flow depths. In contrast to past methodologies, the three proposed models provide superior outcomes in relation to statistical parameters. The results indicated that, in line with the established evaluation criteria, all three models ANN, GEP, and SVM exhibited a reasonable ability to estimate the shear force carried by floodplains of a compound channel with converging floodplains. The ANN model had superior performance in comparison to other models and earlier methodologies, as shown by its greatest R^2 value and lowest values for MSE, RMSE, MAE, MAPE, SI, and AIC.

In order to mitigate the negative impacts of flooding, it is crucial to have a comprehensive understanding of the flow dynamics in both prismatic and non-prismatic sections of rivers. This understanding should include the incorporation of extra momentum transfer in flow models. Such knowledge is essential for the effective construction of flood control and diversion structures. The models proposed in this paper possess practical implications for non-prismatic rivers, such as the River Main in Northern Ireland, the Brahmaputra River in India, and other analogous river systems. The models used to predict the shear stress have some limitations, including high computational expenses, lack of interpretability, susceptibility to overfitting, and their black box character. Additionally, these models have specific drawbacks such as demanding data requirements, high processing intensity, sensitivity to parameters, restricted scalability, and being primarily designed for binary classification tasks. The computational cost of machine learning models is a crucial factor that affects their practicality, effectiveness, and capacity to handle larger datasets. Various elements contribute to the computational expense of machine learning models, including the complexity of the model, the size of the dataset, the complexity of the algorithm, the use of hardware acceleration, the tuning of hyperparameters, the application of feature engineering, the implementation of regularisation techniques, the number of model training iterations, and the need for real-time inference. Performance parameters are essential measures used to assess the efficacy and proficiency of machine learning models. These parameters provide valuable information about the performance of a model on a specific job and help in the selection and refinement of models. Several essential performance metrics are often used to evaluate machine learning models, including accuracy, precision, sensitivity, specificity, mean squared error, R-squared, and the confusion matrix. The results of this research will be valuable for informing the design of such structures, leading to a reduction in both economic and human losses.

NOMENCLATURE

The following symbols are used in this paper:
B = total width of compound channel [m]
b = width of the main channel [m]
h = height of the main channel [m]
H = flow depth [m]

α = width ratio (B/b)
β = relative flow depth [(H – h)/H]
δ^* = flow aspect ratio (b/H)
δ = main channel aspect ratio (b/h)
θ = converging angle [degree]
X_r = relative distance (x/L)
L = converging length [m]
x = distance between two consecutive sections [m]
S_o = longitudinal bed slope [radian]
S_e = energy slope [radian]
Q_r = discharge ratio (Q/Q_b)
Q = discharge at any depth [m^3/sec]
Q_b = bankfull discharge [m^3/sec]
F_r = Froude number
R_e = Reynolds number
S_{fp} = shear force carried by floodplains [percent]
a = actual values
p = predicted values
$\bar{a}$ = mean of actual values
$\bar{p}$ = mean of predicted values
N = number of datasets
k = number of variables
a = sum of weighted input value plus bias
Nod_z = sum for the zth hidden node
n = total number of input nodes
W_{xz} = connection weight between the xth input and the zth hidden node
k_z = normalized input at the xth input node
$\in_z$ = bias value at the zth hidden node
Out_z = output from the zth hidden node
Nod_y = sum of yth output node
m = total number of hidden nodes
W_{zy} = connection weights between the zth hidden node and the yth output node
$\in_y$ = bias value at the yth output node
Out_y = output at the yth output node

ABSTRACT

Achieving an accurate estimation of the flow resistance in open channel flows is crucial for resolving several critical engineering difficulties. In instances when there is excessive flow on both banks of a river, it results in the breach of the primary channel, leading to the discharge of water into the adjacent floodplain. The alteration of floodplain geometry occurs as a consequence of agricultural and developmental practises, leading to the emergence of compound channels that exhibit converging, diverging, or skewed characteristics throughout the course of the flow. The efficacy of conventional equations in accurately forecasting flow resistance is limited due to their heavy reliance on empirical approaches. As a result of this phenomenon, there persists a significant need for methodologies that possess both novelty and precision. The objective of this work is to use the support vector machine (SVM) technique for the estimation of the Manning's roughness coefficient in a compound channel with converging floodplains. Statistical indicators are used to validate the constructed models in the experimental investigation, enabling the assessment of their performance and efficacy. The findings indicate a significant correlation between the Manning's roughness coefficient predicted by SVM and both experimental data and prior research outcomes.

Key words: geometric and flow parameters, Manning's roughness coefficient, non-prismatic compound channel, statistical analysis, support vector machine

HIGHLIGHTS

- Flow resistance is crucial across various engineering contexts, such as planning irrigation systems, managing drainage networks, and constructing flood control structures.
- This study delved into assessing flow resistance in non-prismatic compound channels by employing support vector machines.
- The results indicate a strong alignment between the predicted Manning's roughness coefficient and the actual observed values.

NOTATIONS

The following symbols are used in this paper:

B	total width of compound channel
b	width of the main channel
h	height of the main channel
H	flow depth
α	width ratio (B/b)
β	relative flow depth [$(H–h)/H$]
δ	aspect ratio (b/h)
θ	converging angle
X_r	relative distance (x/L)
L	converging length
x	distance between two consecutive sections
S_o	longitudinal bed slope
S_e	energy slope
Q_r	discharge ratio (Q/Q_b)
Q	discharge at any depth
Q_b	bankfull discharge
F_r	Froude number
R_e	Reynolds number
A	flow area
P	wetted perimeter
R	hydraulic radius (A/P)
n	Manning's roughness coefficient
C	Chezy's roughness coefficient
f	Darcy–Weisbach resistance coefficient
a	actual values
p	predicted values
$\bar{a}$	mean of actual values
$\bar{p}$	mean of predicted values
N	number of datasets

INTRODUCTION

The consideration of flow resistance is of paramount importance in compound open channels, as it has a direct influence on the hydraulic behavior and overall efficiency of the channel system. Flow resistance is the phenomenon that arises as water moves inside a channel, resulting in the counteracting force against its motion. This resistance induces changes in velocity and causes a dissipation of energy. The comprehension and precise estimation of flow resistance are of utmost importance in a range of engineering applications, including the design and administration of irrigation systems, drainage networks, and flood control structures. The impact of flow resistance on water conveyance capacity is a significant aspect to consider in compound open channels. The velocity of water is substantially influenced by flow resistance, which therefore impacts the total flow rate that can be sustained by the channel. Engineers have the ability to enhance the efficiency of water distribution for irrigation or flood channeling by designing channels that optimize water conveyance via precise quantification of flow resistance. The significance of flow resistance is crucial in the determination of water surface profiles. The presence of flow resistance induces energy losses that have a direct impact on both the water surface slope and the distribution of water depths inside the channel. The precise forecasting of water surface profiles has significant importance in the fields of hydraulic design, floodplain management, and flood control operations. The comprehension of flow resistance is crucial for engineers as it enables them to develop models and simulations to analyze channel behavior. This, in turn, facilitates the accurate prediction of floods and the development of efficient strategies for flood mitigation planning. Several researchers have conducted studies on the flow, velocity, and shear stress distribution on compound sections (Kar 1977; Knight & Demetriou 1983; Myers 1987; Bhattacharya 1995; Patra 1999; Patra & Kar 2000; Patra *et al.* 2004; Yang & Lim 2005; Khatua *et al.* 2011a, 2011b; Mohanty 2013). Traditional channel division techniques are used for the assessment of discharge capacity in compound channels. It is postulated that the compound section is delineated by hypothetical interface planes located at the confluence of the main channel and the floodplain. The absence of shear

Uncorrected Proof

stress in these regions suggests a lack of momentum transmission. The momentum transfer phenomena were first examined by Sellin (1964) via laboratory research. Extensive investigations were conducted in laboratory flumes to study both prismatic and meandering compound channel designs. Nevertheless, a comparison between the compound section data of prismatic compound channels and non-prismatic compound channels revealed significant discrepancies in the estimation of shear force carried by floodplains. These errors can be attributed to the omission of additional mass and momentum transfer, as elucidated by Bousmar & Zech (2002), Bousmar *et al.* (2004), Rezaei (2006), and Rezaei & Knight (2009). The additional momentum exchange associated with this phenomenon must be considered when doing flow modeling for non-prismatic compound channels. Yang *et al.* (2005) carried out the estimation of the Manning and Darcy–Weisbach resistance coefficients in composite waterway channels. The experimental results suggest that the Darcy–Weisbach resistance coefficient for a compound channel is dependent on the Reynolds number. Bjerklie *et al.* (2005) developed equations to estimate inbank river discharge, which are constructed based on theoretical considerations and calibrated and confirmed using a comprehensive experimental database, rely on the Manning's and Chezy equations. The study conducted by Proust *et al.* (2006) investigated the phenomenon of asymmetric geometry, specifically focusing on its enhanced convergence rate. An augmented convergence angle of 22° leads to heightened levels of mass transfer and head loss. Cao *et al.* (2006) introduces novel methodologies for the computation of flow resistance and momentum flux in compound open channels. Yang *et al.* (2007) demonstrated that the methodologies used to investigate the resistance characteristics of inbank and overbank flows in compound channel consisting of a rough main channel and rough floodplains resulted in substantial errors in evaluating the composite roughness. The flow behavior of skewed, two-stage converging and diverging channels was investigated by Chlebek *et al.* (2010). The researchers noted an elevation in head losses resulting from the transfer of mass and momentum, as well as the homogeneity of velocity on shrinking floodplains. Additionally, they discovered an augmented velocity gradient on the expanding floodplains. The observed variations in flow distribution may be attributed to alterations in the flow force between the main channel and floodplains within different subsections. Rezaei & Knight (2011) conducted a study on compound channels with floodplains that are non-prismatic. The authors examined the depth-averaged velocity, local velocity distributions, and boundary shear stress distributions at different convergence angles. The analysis of depth-averaged velocities provides insights into the impact of contractions on velocity distributions. Notably, these contractions lead to an augmentation of velocity in close proximity to the walls of the main channel. This effect is particularly pronounced in the latter portion of the convergence reach. Additionally, for cases where the relative depth is high, the lateral flow entering the main channel also contributes to these velocity variations. The study conducted by Yonesi *et al.* (2013) examines the influence of roughness in floodplains on the occurrence of overbank flow in compound channels with non-prismatic floodplains. The rate of change in velocity, as shown by the gradient, exhibited a rise in magnitude as the angle of divergence saw an increase. The magnitude of shear stress increases with the augmentation of surface roughness on the floodplain. Naik *et al.* (2017) developed novel mathematical equations to predict the spatial variation of boundary shear stress in a composite channel that includes a convergent floodplain. The effective calculation of relationships for stage–discharge with decreased width ratios in compound channels with converging floodplains has been facilitated by the use of developed mathematical expressions. Das & Khatua (2018) conducted experiments on a composite stream that had symmetric geometry. This stream had sections that expanded and narrowed, resulting in zones of flood with varying depths of relative flow. The experiments were conducted to examine the resistance properties of the flow in terms of different roughness coefficients such as C, n, and f.

Creating models to estimate Manning's roughness coefficient using various methods complicates the analysis of interdependencies among components. These models become intricate and time-consuming, leading to a significant reduction in the time required for experiments and labor-intensive calculations. SVM, GEP, ANN, ANFIS, and the M5 decision tree models are commonly used for predicting flow in composite channels (Parsaie *et al.* 2017). Parsaie & Haghiabi (2017) employed analytical methods, specifically ANN and MARS, to forecast the discharge capacity of compound open channels, revealing that the MARS model outperformed the MLP model in accuracy. Mohanta *et al.* (2018) used the GMDH-NN technique to estimate Manning's n in meandering compound channels. The evaluation of GMDH-NN performance is conducted using two distinct machine learning approaches, namely SVR and MARS, using a range of statistical methodologies. The results demonstrate that the GMDH-NN model accurately predicts Manning's n in comparison to the MARS and SVR models. Khuntia *et al.* (2018) developed an ANN model using key characteristics to predict boundary shear stress distribution in straight compound channels, showcasing the effectiveness of BPNN models across diverse parameter spaces. Das

Uncorrected Proof

et al. (2020) utilized ANN and ANFIS techniques to predict discharge in compound channels with converging and diverging sections, with the ANFIS model demonstrating superior performance over the ANN model. Naik *et al.* (2022) proposed a unique equation using GEP to estimate water surface profile in converging compound channels using nondimensional variables. Yonesi *et al.* (2022) utilized soft computation models such as MARS and GMDH to model discharge in compound open channels with non-prismatic floodplains (CCNPF), showing sufficient accuracy in flow discharge estimation. The effective parameters of the Manning's n in HDPE culverts were investigated by Matin (2022) by the utilization of intelligence methodologies, including GPR and SVM. The results of the sensitivity analysis indicate that the parameters y/D and Q play a crucial role in predicting the Manning coefficient for HDPE culvert models. Bijanvand *et al.* (2023) employed soft computing models like MLPNN, GMDH, NF-GMDH, and SVM to predict water surface elevation in compound channels with converging and diverging floodplains, where SVM model demonstrated superior performance in testing. Kaushik & Kumar (2023a) utilized ANN, SVM, and GEP to forecast water surface profile in compound channels with converging floodplains, with the ANN model displaying high accuracy. Kaushik & Kumar (2023b) formulated a novel equation for compound channels with converging floodplains using GEP, estimating the boundary shear force conveyed by floodplains. Kaushik & Kumar (2023c) utilized SVM to approximate water surface profile in compound channels featuring narrowing floodplains, showing a high degree of concordance with empirical data and previous research findings.

Historically, research has been undertaken on the flow characteristics in compound channels with non-prismatic floodplains. However, there has been little focus on the flow resistance in non-prismatic compound channel with converging floodplains using creative methodologies. The current investigation focused on a compound channel including smooth converging floodplains. To estimate the flow resistance in terms of Manning's roughness coefficient using both nondimensional geometric and hydraulic parameters, a supervised learning approach known as SVM was used. The efficacy of the suggested models was evaluated using theoretical methodologies and established approaches using statistical analysis.

MATERIALS AND METHODS

Experimental setup

The tests were conducted in the Hydraulics laboratory, which is situated under the Department of Civil Engineering at Delhi Technological University. The trials were carried out inside a masonry flume with dimensions of 12 m in length, 1.0 m in width, and 0.8 m in depth. In this study, a compound cross-section was created using brick masonry, with a main channel width of 0.5 m and a depth of 0.25 m (Figure 1). Figure 1 provides a comprehensive depiction of the geometric attributes associated with a two-stage channel. The construction of the converging portion of the channel included the use of brick masonry, which was employed to achieve a converging angle denoted as $\theta = 4°$. The floodplains were made smooth with the help of trowel finish. The compound channel consists of a prismatic section (PS) of 6 m in length, followed by a non-prismatic section (NPS)

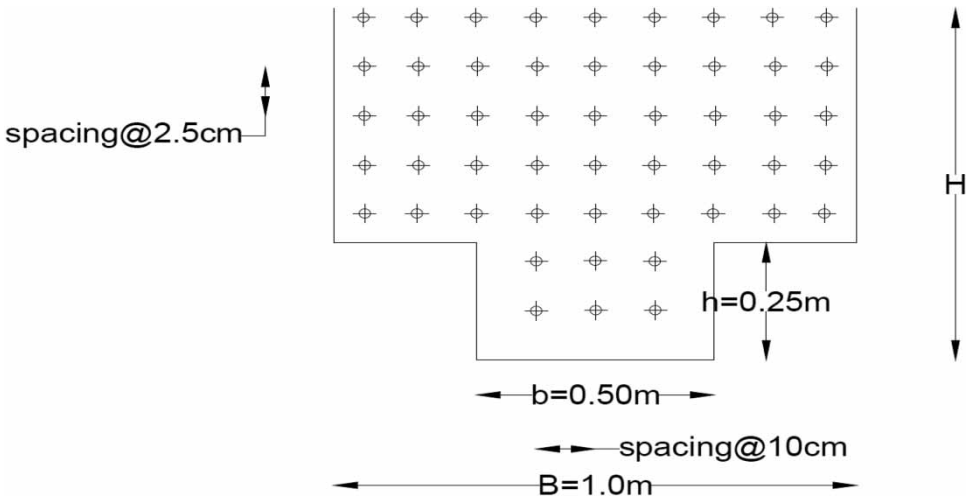

Figure 1 | Cross-section of compound channel.

spanning 3.6 m, with the remaining portion being the downstream section. The experiments were conducted at six relative flow depths ranging from 0.10 to 0.60. Flow properties, including the stage-discharge relationship, water surface profile, velocity distribution, and shear stress distribution, were measured for each discharge in both the PS and different NPS, as seen in Figure 2. The parts denoted as NPS1 and NPS5 represent the first and final segments of the converging component, respectively. On the other hand, NPS3 corresponds to the central region of the converging section. The NPS2 serves as an intermediary segment situated between NPS1 and NPS3. NPS4 may be regarded as the intermediary segment situated between NPS3 and NPS5.

Uncorrected Proof

The subcritical flow regime was seen under various circumstances in the two-stage channel, which had a longitudinal bed slope of 0.001. The estimation of Manning's n value was conducted based on data obtained from both in-bank and overbank flows in the floodplains and main channel. The water supply in the experimental channel is sourced from an underground sump and transferred to an above tank by the system. The water originating from the channel is collected inside a volumetric tank that is equipped with a v-notch. The v-notch was appropriately adjusted in order to accurately quantify the discharge emanating from the experimental channel. Subsequently, it facilitates the return of the fluid to the sump situated underneath. Figure 2 depicts the experimental configuration and the assortment of apparatus used in the investigation. A tailgate was constructed at the downstream end of the flume to regulate the water surface profile and enforce a predetermined flow depth inside that section of the flume. A precision point gauge with a precision of 0.1 mm was used to measure the profile of the water surface at distances of 1.0 and 0.3 m in the PS and NPS, respectively. The researchers used an ADV to measure the mean velocity of the cross-section and the three-dimensional velocity distributions around the wetted perimeter. The measurements were taken at vertical intervals of 2.5 cm and horizontal intervals of 10 cm, as seen in the grid format presented in Figure 1. The data obtained via the use of the ADV were processed and refined using the Horizon ADV program. The measurement of lateral distributions of boundary shear stress was conducted using a Preston tube with an outer diameter of 5 mm at the identical portions where the velocity distributions were examined. The pressure differential was measured using a digital manometer. Subsequently, the calibration equations proposed by Patel (1965) were used to compute the shear stress values.

Model development for Manning's *n*

The lateral variation of channel section roughness is observed along the wetted perimeter in a river that is experiencing flooding. The determination of the conveyance capacity of a compound channel necessitates the consideration of the composite roughness. Despite the varied structures and forms of equations, they can be categorized into distinct groups based on different criteria. These groups include the CM (Cox 1973) (as represented by Equation (1)), the EBM (Einstein & Banks 1950) (as represented by Equation (2)), and the LM (Lotter 1933) represented by Equation (3)). The Equation (4) was formulated by Das & Khatua (2018) through the utilization of multivariate analysis, with consideration of geometric and flow parameters, for a compound channel featuring converging floodplains. The composite roughness equations are

$$n = \frac{1}{A}\sum_{i=1}^{i=N} A_i n_i \tag{1}$$

$$n = \left(\frac{1}{P}\sum_{i=1}^{i=N} P_i\, n_i^{3/2}\right)^{2/3} \tag{2}$$

$$n = PR^{5/3}\left(\sum_{i=1}^{i=N}\frac{P_i\, R_i^{5/3}}{n_i}\right)^{-1} \tag{3}$$

$$n = \{0.096\{1 - 0.0131e^{0.211(\alpha)} - 0.068e^{0.3(\beta)} - 0.082(\theta)^{0.046} - 0.235e^{0.101(x)} - 0.791(R_e)^{-0.214} + ln\,(\delta^{0.0114} S_0^{0.073} F_r^{-0.167})\} \tag{4}$$

Composite roughness for compound channel with converging floodplains is calculated by the following expression:

$$n = \frac{AR^{2/3}\sqrt{S_e}}{Q} \tag{5}$$

The determination of Manning's n values is subject to various factors, among which are the width ratio, relative depth ratio, aspect ratio, converging angle, relative distance, longitudinal bed slope, energy slope, discharge ratio, Froude's number, and Reynold's number. Several parameters are utilized to facilitate the application of the model equation to various compound channels. The details of the dataset used in the present investigation are given in Table 1.

The requisite equation in a dimensionless form can be formulated as follows:

$$n = F(\alpha,\ \beta,\ \delta,\ \theta,\ X_r,\ S_o, S_e,\ Q_r,\ F_r,\ R_e) \tag{6}$$

SVM model

SVM is a highly effective and extensively used machine learning technique employed for both classification and regression purposes. This approach has notable efficacy in scenarios when the data exhibits non-linear separability, indicating that the classes cannot be distinctly partitioned by a linear or hyperplane boundary. The SVM algorithm is designed to identify the ideal hyperplane that effectively distinguishes different classes by maximizing the margin. The margin refers to the distance between the hyperplane and the closest data points from each class. SVR algorithm is a commonly employed machine learning technique utilized for the purpose of regression analysis. The method in question operates on analogous principles to those of SVMs utilized for classification purposes, albeit with the objective of forecasting a continuous output variable on the basis of input variables. The fundamental concept underlying SVR is to identify a function that can effectively map input variables to output variables, with minimal error, while also satisfying a predetermined margin. The process of attaining this objective involves the conversion of the input variables into a space of higher dimensions through the application of a kernel function. Subsequently, the regression line that optimizes the margin while maintaining the error within a predetermined tolerance level is determined (Drucker *et al.* 1997). SVR exhibits a notable benefit in its capacity to effectively manage non-linear associations between input and output variables. The attainment of this objective is facilitated through the utilization of kernel functions, including but not limited to polynomial, RBF, and sigmoid functions. These functions enable the capture of intricate relationships between variables (Smola & Schölkopf 2004). SVR has been effectively utilized in diverse domains, including finance (Sharma *et al.* 2012), transportation (Yeh *et al.* 2010), and medical imaging (Borges *et al.* 2016). It is of utmost significance to meticulously choose and adjust the kernel function and other associated parameters to attain optimal performance. One common method for transforming a linear classifier into a non-linear classifier involves the utilization of a non-linear function to map the input space x onto a feature space F. An alternative approach involves the utilization of a non-linear function for the purpose of mapping. The separating function in space f can be expressed as (Kaushik & Kumar 2023a):

$$f(x) = w^T \varphi(x) + b \tag{7}$$

Within the subspace, the statistical methodology denoted by the algebraic function $f(x, w)$ can be articulated as follows:

$$w = \sum_{i=1}^{n} \alpha_i x_i \tag{8}$$

$$f(x, w) = \sum_{j=1}^{n} \alpha_i x_i \varphi_i(x) + b \tag{9}$$

$$f(x) = \sum_{i=1}^{n} \alpha_i x_i^T x + b \tag{10}$$

In the feature space, F, this expression takes the form:

$$f(x) = \sum_{i=1}^{n} \alpha_i \varphi(x_i)^T \varphi(x) + b \qquad 0 \le \alpha_i \le C \tag{11}$$

$$k(x,\ x') = \varphi(x)^T \varphi(x') \tag{12}$$

$$f(x) = \sum_{i=1}^{n} \alpha_i k(x, x_i) + b \tag{13}$$

Conversely, there exists a diverse range of supplementary kernel functions that can be employed in various settings to enhance performance.

Linear kernel: $k(x_i, x_j) = x_i^T x_j$
Polynomial kernel: $k(x_i, x_j) = (\gamma x_i^T x_j + r)^d, \quad \gamma > 0$
RBF kernel: $k(x_i, x_j) = exp(-\gamma \|x_i - x_j\|)^2, \quad \gamma > 0$
Sigmoid kernel: $k(x_i, x_j) = tanh(\gamma x_i^T x_j + r), \quad \gamma > 0$

The SVM model employs parameters *C*, *γ*, *r*, and *d*. The *C* parameter governs the balance between optimizing the margin and minimizing the classification error on the training dataset. A lesser value of *C* leads to a broader margin, which may let some instances to be misclassified. Conversely, a bigger value of *C* aims to minimize misclassification by sacrificing margin width. The parameter *γ* is unique to the RBF kernel. It regulates the impact of specific training samples. A decrease in the gamma value results in a more refined decision boundary, characterized by a higher degree of smoothness. Conversely, an increase in the gamma value introduces more fluctuations and irregularities to the border, potentially leading to overfitting. The parameter denoted as '*d*' is exclusive to polynomial kernels. The parameter determines the order of the polynomial function used for the transformation. The attainment of advanced academic degrees has the potential to result in decision boundaries of greater complexity. However, it is important to acknowledge that this pursuit may also elevate the likelihood of overfitting. The efficacy of the SVM model is contingent upon the caliber of the selected settings for said parameters, in addition to the kernel parameters. The selection of values for the parameters *C, γ, and r* plays a crucial role in regulating the complexity of the regression model. However, the process of determining the optimal parameters is further complicated by the intricate nature of their selection. Kernel functions are utilized to reduce the dimensionality of the input space and facilitate classification. The refinement of the SVM model is achieved through its exposure to data sets, a process that is analogous to the refinement of other neural network models. The flow resistance in terms of Manning's roughness coefficient (*n*) of compound channel with converging floodplains was evaluated utilizing a reliable and high-quality experimental dataset. Prior to building the SVM model, the data are partitioned into training and testing sets using a 70:30 ratio in MATLAB R (2019). Table 2 illustrates the various models that were developed to predict roughness coefficient, utilizing distinct kernel functions and kernel scales while maintaining a consistent relationship and proportion of training and testing datasets.

Table 2 | Different models developed using SVR

Model	Preset	Kernel function	Kernel scale	Prediction speed (obs/s)	Training time (s)
M1	Linear SVM	Linear	Automatic	330	17.48
M2	Quadratic SVM	Quadratic	Automatic	370	16.30
M3	Cubic SVM	Cubic	Automatic	360	16.07
M4	Fine Gaussian SVM	Gaussian	0.79	360	15.85
M5	Medium Gaussian SVM	Gaussian	3.2	380	15.58

Statistical measures

Various error analysis approaches were used to evaluate the accuracy of the machine learning models. The aforementioned metrics included the coefficient of determination (R^2), mean squared error (MSE), root mean squared error (RMSE), mean absolute error (MAE), mean absolute percentage error (MAPE), scatter index (SI), coefficient of efficiency (*E*), and Akaike Information Criterion (AIC). The relevant equations were used to compute these measures (Kaushik & Kumar 2023a).

$$R^2 = \frac{\sum_{i=1}^{N} (a_i - \bar{a})^2 (p_i - \bar{p})^2}{\sum_{i=1}^{N} (a_i - \bar{a})^2 \sum_{i=1}^{N} (p_i - \bar{p})^2} \tag{14}$$

$$\text{MSE} = \frac{1}{N} \sum_{i=1}^{N} (p_i - a_i)^2 \tag{15}$$

by DELHI TECHNOLOGICAL UNIVERSITY (DTU) user

Uncorrected Proof

$$\text{RMSE} = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(p_i - a_i)^2} \tag{16}$$

$$\text{MAE} = \frac{1}{N}\sum_{i=1}^{N}|p_i - a_i| \tag{17}$$

$$\text{MAPE}\ (\%) = \frac{1}{N}\sum_{i=1}^{N}\left(\frac{|p_i - a_i|}{a_i} \times 100\right) \tag{18}$$

$$SI = \sqrt{\frac{\sum_{i=1}^{N}[(p_i - \bar{p}) - (a_i - \bar{a})]^2}{\sum_{i=1}^{N} a_i^2}} \tag{19}$$

$$E = 1 - \frac{\sum_{i=1}^{N}(p_i - a_i)^2}{\sum_{i=1}^{N}(a_i - \bar{a})^2} \tag{20}$$

$$AIC = N\log\left(\frac{1}{N}\sum_{i=1}^{N}(p_i - a_i)^2\right) + 2k \tag{21}$$

RESULTS AND DISCUSSION

Figure 3 depicts the longitudinal distance-dependent variation of Manning's roughness coefficient (n) in a compound channel with smooth converging floodplains for different relative flow depths. The decrease in hydraulic radius along the longitudinal distance results in a corresponding reduction in the n values within the PS, extending up to the midpoint of the converging portion. Following the midpoint of the converging section, there is a

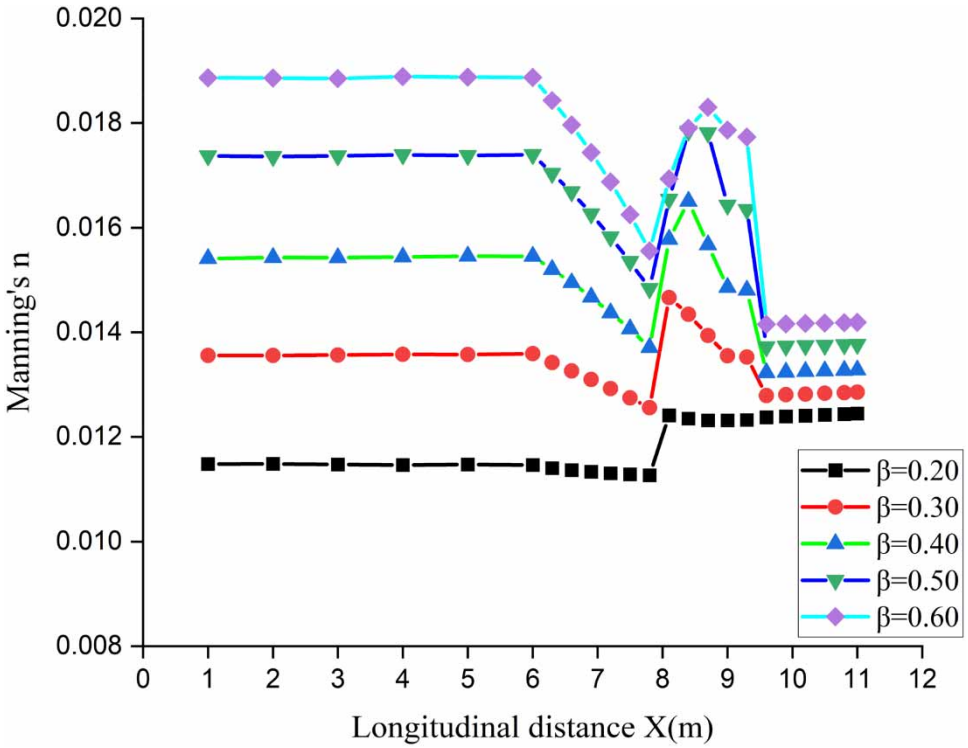

Figure 3 | Variation of Manning's n along the longitudinal distance of the non-prismatic compound channel.

by DELHI TECHNOLOGICAL UNIVERSITY (DTU) user

Uncorrected Proof

notable increase in the numerical values of n due to the convergent nature of the channel's geometry. The observed outcomes are attributed to a significant rise in the energy gradient relative to the hydraulic radius. Subsequently, the downstream section experiences a decrease in n values due to the reduction in hydraulic radius and energy slope as the flow progresses further along its length. Similar fluctuation patterns are observed in higher relative flow depths as well as in lower relative flow depths. The study reveals that a significant increase in roughness occurs primarily in the converging regions as the relative depth escalates from 0.20 to 0.60. This phenomenon can be attributed to the transfer of momentum from the main channel to the floodplains. The efficacy of the SVM methodology in generating precise forecasts is evidenced by the scatter diagrams that employ diverse models to juxtapose the projected and actual n values, as depicted in Figure 4. The SVM model exhibits

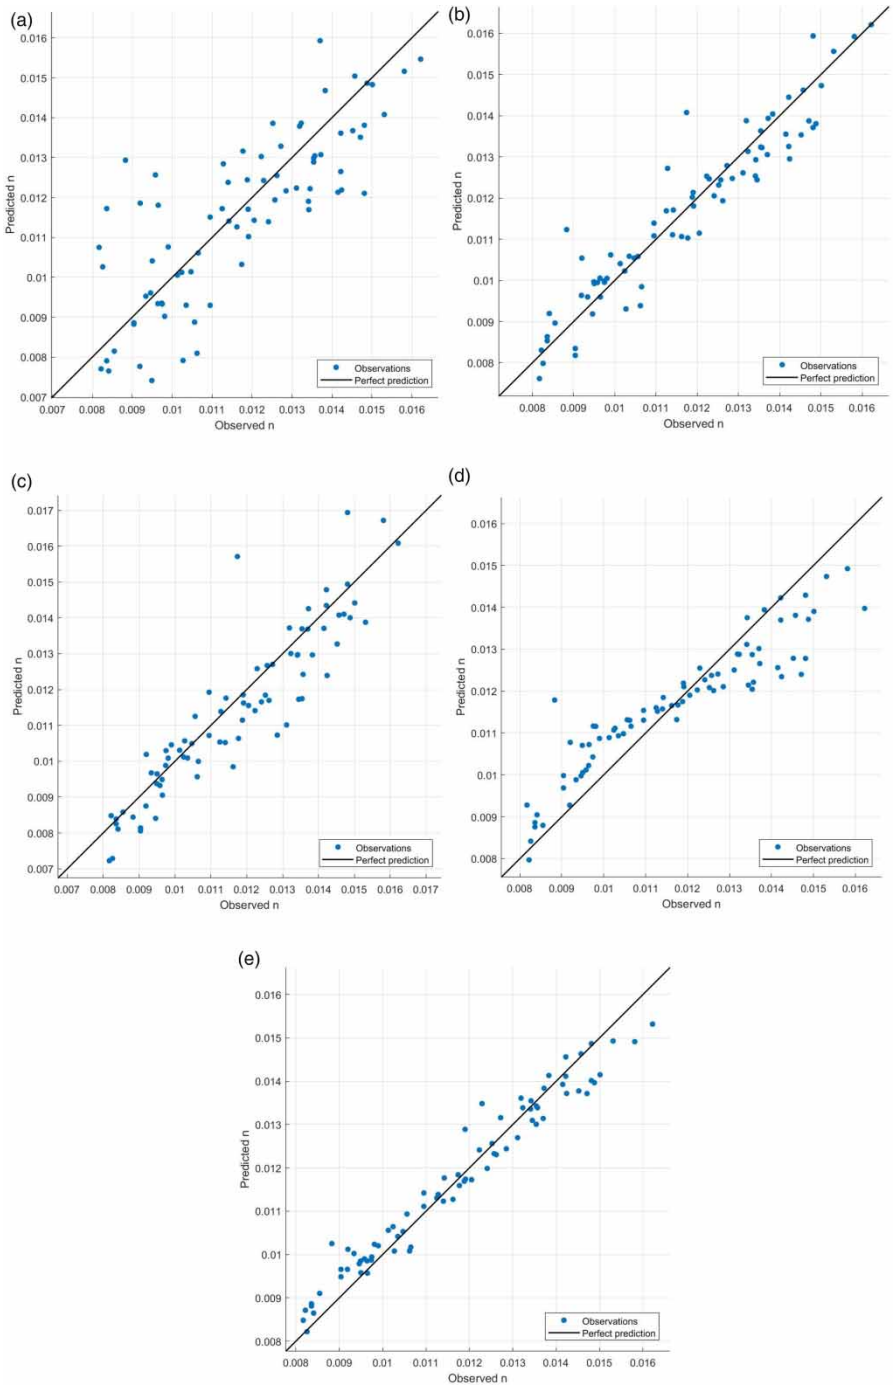

Figure 4 | Scatter plot to predict Manning's roughness coefficient (*n*) for (a) model 1; (b) model 2; (c) model 3; (d) model 4; and (e) model 5.

by DELHI TECHNOLOGICAL UNIVERSITY (DTU) user

Uncorrected Proof

significant potential, as evidenced by the notable indication of the values' proximity to the line representing exceptional concurrence. The SVM predicted values that are dispersed over the best-fitting line exhibit a superior level of concurrence with the empirical data, resulting in elevated R^2 values. According to the data presented in Figure 4(e), the SVM model five that was created using a 70:30 ratio of data in training and testing yielded predicted values of Manning's n that were more closely aligned with the best fitted line than other developed models. This suggests that the SVM model five is more accurate in its predictions.

In order to assess the effectiveness of the SVM models, statistical metrics including R^2, MSE, RMSE, MAE, MAPE, SI, E, and AIC were employed, and their corresponding numerical values are displayed in Table 3. The SVM model five has demonstrated superior predictive performance in estimating the Manning's roughness coefficient of composite waterways with converging floodplains, when compared to alternative approaches such as Das & Khatua (2018), as well as established theoretical methods including the Lotter method for composite roughness computation. This is evident from the highest R^2 value, lowest MSE value, lowest RMSE value, lowest MAE value, and lowest MAPE value. The SI serves as a standardized measure for the quantification of inaccuracy. A lower SI value is indicative of a higher level of model performance. The SVM model five has a significantly reduced SI value of 0.033 in both the training and testing stages, indicating a minimum level of error. The efficiency measure, represented as E, is assigned a value of 1 when there is a complete correspondence between the model and the observed data. The interval of E extends from negative infinity to 1. The SVM model five has an E value of 0.95 for both the training and testing datasets. The AIC is a widely used criterion in statistical model selection. It is used to choose the best suitable model by evaluating the statistical likelihood function. The model that has the lowest AIC value is regarded as the most optimum model. The SVM model five has the lowest AIC score of −510.754 when compared to the other models proposed. The statistical study of several indices indicates that SVM model five exhibits superior performance compared to other models and established methodologies in forecasting the Manning's roughness coefficient in compound channels with narrowing floodplains.

Table 3 | Statistical analysis of predicted n by various approaches

Statistical parameters	SVM model 1	SVM model 2	SVM model 3	SVM model 4	SVM model 5	Das & Khatua Method (2018)	Lotter method (1933)
R^2	0.62	0.90	0.82	0.82	0.95	0.80	0.78
MSE	1.82×10^{-6}	4.84×10^{-7}	8.82×10^{-7}	8.67×10^{-7}	2.33×10^{-7}	0.0019	0.0025

AIC	−469.873	−505.382	−472.319	−493.169	−510.754	−250.614	−105.291

CONCLUSIONS

The study employs SVM to estimate the Manning's roughness coefficient (n) in non-prismatic compound channel with smooth narrowing floodplains. The SVM models are developed using high-quality experimental datasets with varying geometrical and flow variables. The study indicates that the proposed model is influenced by a range of features, such as the width ratio, relative depth of flow, aspect ratio, angle of convergence, relative longitudinal distance, longitudinal bed slope, energy slope, discharge ratio, Froude number, and Reynolds number. In the prismatic portion, the Manning roughness coefficient decreases, and in the NPS, it decreases up to the middle. After then, a precipitous increase in the roughness value is seen. The present study aims to examine the correlation between the Manning's roughness coefficient and the nondimensional geometric and flow variables of a composite waterway with narrowing floodplains. It has been discovered that there is a connection that is not linear between each of the parameters. In comparison to previously developed techniques, the newly created model demonstrates superior performance in terms of statistical parameters for a variety of

by DELHI TECHNOLOGICAL UNIVERSITY (DTU) user

Uncorrected Proof

datasets. In line with the evaluation criteria, the SVM model five could fairly forecast the Manning's coefficient in compound channels with converging floodplains. This was shown by the fact that the technique was successful. Since it had the best R^2 and the lowest MSE, RMSE, MAE, MAPE, SI, and AIC, the SVM model developed using Gaussian kernel function demonstrated superior performance in the prediction of Manning's n in non-prismatic compound channels. The models proposed in this paper possess practical implications for non-prismatic rivers, such as the River Main in Northern Ireland, the Brahmaputra River in India, and other analogous river systems. The results of this research will be valuable for informing the design of flood control and diversion structures, leading to a reduction in both economic and human losses.

Abstract— **Determining land use and land cover (LULC) changes in an area is crucial before proceeding with any developmental or restoration plan. Traditionally, field surveys were done to mark significant changes in an area, often compared with toposheets of the region. However, this task was time-consuming and required a substantial human workforce and resources. With the advent of satellite sensor technology, the task of field surveys was minimised by a considerable percentage. The satellite imageries, capable of providing high-resolution and historical data, were analysed for land use/cover changes. The results of this study show a reduction in water bodies by a percentage of nearly 41% in a span of 28 years. Rapid industrialisation and illegal residency have contributed to an increase of 33% in built-up. Barren/fallow land shows a growth of nearly 79%, agricultural practices remain dominant in the region, whereas forest decreases 4%. Despite the time-saving capabilities, satellite imagery requires substantial processing. With the advancements in computer science and Geographical Information Systems (GIS), classification techniques came into the image, and LULC studies gave further refined and near-accurate results. The machine learning techniques, i.e. Maximum Likelihood Classification (MLC), have been used in this study to recognise its benefits in the timely analysis of a problem statement of LULC and will help review and monitor the study area.**

Keywords: Supervised classification, LULC, Hindon River basin, GIS, Maximum Likelihood Classification, ML

I. INTRODUCTION

A global scarcity of well-preserved watersheds leads to an imbalanced ecology. Riverine systems support biodiversity and serve as a crucial supply of freshwater. Nevertheless, the deterioration of watersheds and the current predicament can be attributed to unsustainable activities. The research area encompasses the Hindon River basin, which stretches over several unauthorised settlements close to the river, where the residents dispose of solid waste and sewage straight into the river. It is imperative to designate these settlements and develop a strategy for rehabilitating the inhabitants[1].

To achieve this objective, satellite imagery may be utilised to delineate the floodplain and watershed of the river. Subsequently, image analysis can be conducted to identify the distinct land use categories and track their temporal variations. Furthermore, analysing elements such as rainfall patterns, groundwater levels, and agricultural practices contributing to these changes is possible. Comprehending the connection between land use and land cover (LULC) and water resources is crucial for efficiently managing watersheds, formulating policies, considering future LULC development, and safeguarding freshwater [2]. In the monsoon season of 2023, the Hindon River basin had copious precipitation. The Hindon, often arid and devoid of life throughout the non-perennial period, experiences a resurgence of activity during the monsoon season. Due to copious rainfall this year, the river in Ghaziabad and Noida districts experienced a significant increase in water volume, resulting in the inundation of surrounding encroached areas and subsequent flooding of dwellings. As a result, the occupants were compelled to evacuate. The villages of Chajjarsi, Chotpur, Yusufpur, Kakrala, Mubarakpur, and Shafipur have witnessed the construction of several illegal residences near the river[3].

Using categorisation strategies in Land Use and Land Cover (LULC) research may assist in comprehending land and water resources more effectively, facilitating their suitable administration. Remote sensing imagery can provide a comprehensive and detailed perspective of a region, allowing for a broad overview and the ability to analyse changes over time. [4].

Artificial Intelligence (AI) and Machine Learning (ML) are robust technologies that significantly enhance the precision of such forms of analysis. Classification is a machine-learning approach that groups comparable information based on shared properties. A classification model is utilised to forecast the category of a dataset. Image classification algorithms are employed in GIS to categorise an image. Each pixel is regarded as a unit of data. Classes are allocated according to the user's requirements. Supervised classification refers to the scenario where the user provides classes or training datasets to the model before categorising the dataset. On the other hand, unsupervised classification refers to when the model first classifies the data into distinguished classes, and then the user contributes names to those classes[5].

Another form of image classification approach utilised in remote sensing is object-based categorisation. The first two strategies are widely used, whereas Object-based

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 09,2024 at 06:55:15 UTC from IEEE Xplore. Restrictions apply.

categorisation is particularly beneficial for high-resolution data.[6]

A. Study Area

The river Hindan, a notable tributary of the river Yamuna, flows through the six districts of western Uttar Pradesh: Saharanpur, Muzaffarnagar, Baghpat, Meerut, Ghaziabad, and Gautambudh Nagar. The river holds considerable historical and cultural significance and serves as the primary water source for the primarily rural inhabitants of western Uttar Pradesh. The Hindan River is located in the western region of the northern Indian state of Uttar Pradesh. Its basin extends between coordinates 77°49'51.42"E and 30°16'47.85"N to 77°29'43.5588"E and 28°24'32.2416"N. [7]

II. Related Work

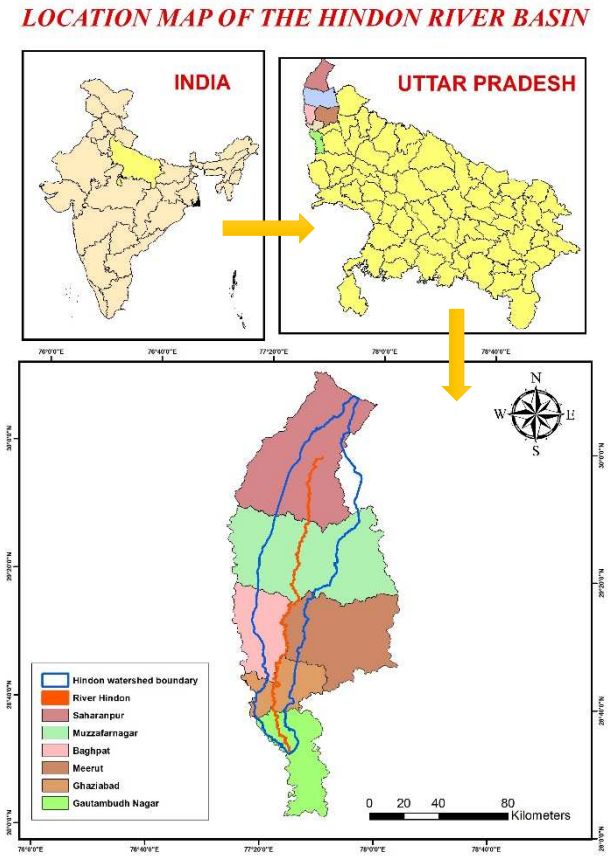

Fig. 1 Study Area

This study did an extensive literature review to detect any existing gaps. Additionally, it hoped to utilise remotely sensed data for mapping and monitoring changes in land use and land cover (LULC). The study also sought to examine the impact of these changes on the Hindon River. Furthermore, the study wanted to determine the percentage of LULC classes that have changed over the years.

A. Study on Remote Sensing Data Classification using Statistical Techniques.[8]

This study did a comprehensive literature analysis to identify any existing gaps. It then utilised remotely sensed data to accurately map and monitor land use and land cover (LULC) changes and their impact on the Hindon River. Additionally, the study quantified the proportion of LULC class changes throughout the years.

The mentioned study examined the statistical methodologies used for categorising data. Below are detailed explanations of the Minimum distance, Maximum likelihood, and Mahalnobis distance algorithms. The Maximum Likelihood is a widely used supervised classification approach in remote sensing image data. The algorithms have demonstrated favourable outcomes. Nevertheless, the correctness of the algorithm is significantly contingent upon the calibre of the generated data. These image classification techniques are effective for classifying satellite images. This work can be enhanced by combining many algorithms, which might improve the result's accuracy. Among the three methods used, Maximum likelihood classification had the highest accuracy of 92%, followed by Minimal distance with 90% and Mahalanobis distance with 86% accuracy.

B. Analysis of Supervised Maximum Likelihood Classification using Remote Sensing Image [8]

The MLC algorithm relies on Bayes' categorisation. The technology of MLC is quite sturdy. The categorisation was performed on a Landsat ETM+ remote sensing image from 2011. Ground truthing and validation have been conducted at 20 sites, including the entirety of the research region. The study also reveals that utilising MLC reduces the likelihood of misclassification. MLC assumes a normal data distribution; however, this may not always be true. Therefore, it is essential to pick the training data carefully. Additionally, the study revealed a direct correlation between the increase in image size and the corresponding increase in processing cost. The study also includes an accuracy evaluation; the algorithm attained an overall accuracy rate of 93.75%.

III. Proposed Approach

The suggested technique entails acquiring toposheets for the designated research region and satellite imageries, specifically from 2020. The initial phase is demarcating the watershed border of the river by utilising data from the Shuttle Radar Topographic Mission (SRTM) Digital Elevation Model (DEM). The SRTM provides DEM data with a spatial resolution of 30 meters. The watershed delineation was performed using the toposheet as the foundation map. The watershed covers an expanse of 5744 square kilometres. The extended configuration of the basin facilitates a gradual flow of water, resulting in a delayed discharge of all the water from the basin into the exit, which is the river Yamuna. Once the watershed has been delineated, our next objective is to conduct a classification of the satellite images of the research region[9]. The photos are from the Landsat 8 mission[10], with a temporal resolution of 16 days and a spatial resolution of 30 meters. The obtained images are timestamped as 16/05/2020.

The Hindon River spans a length of around 350 kilometres and predominantly experiences aridity. The river is heavily impacted by the disposal of solid waste, industrial effluents, and sewage discharge from residential and industrial areas along its banks. The primary tributaries include the Kali, Krishna, and Dhamola. The imagery was subjected to supervised classification to quantify the area covered by five land use classes[11]. These classes were identified and

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 09,2024 at 06:55:15 UTC from IEEE Xplore. Restrictions apply.

compared, including river/waterbody, forest, barren/fallow, built-up, and agricultural land/. The classification is performed using the maximum likelihood classification (MLC) method. The MLC is a widely utilised technique for categorising pixel data. The spectral pattern detected in the data for each pixel is used for data classification. The numerical value of each pixel is determined based on its spectral response. The bands utilized in the construction of a colour infrared mosaic for Landsat images are band 5 (near infrared), band 4 (red), and band 3 (green. Subsequently, these bands are allocated red, green, and blue to create a composite image with false colours. In a supervised technique, the user furnishes a training dataset for each class, which is then recorded as a signature file. Each class is allocated three to four distinct regions in the images corresponding to a specific land cover type. Each pixel in the image is assigned a specific grey value using three bands or channels. The grey values are subsequently matched to the signature of each land cover type in the training dataset. The particular pixel is allocated after being compared.

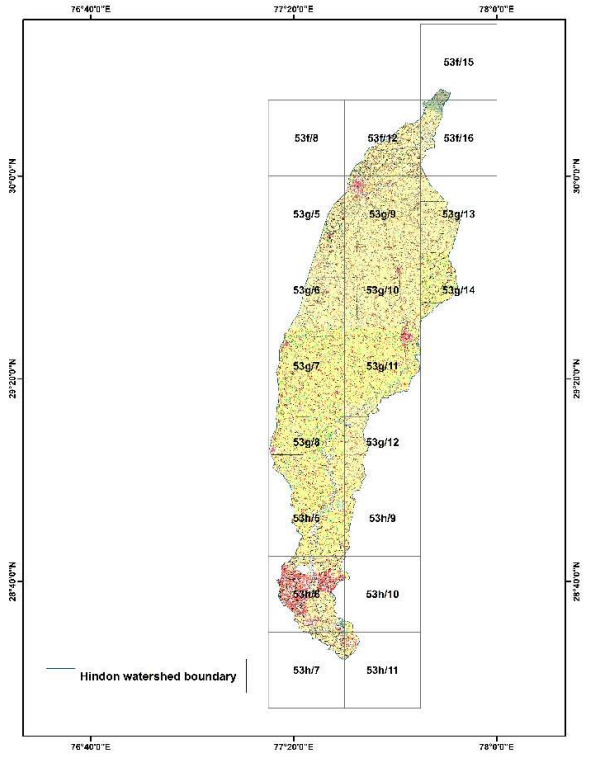

Fig. 2 Toposheets for Hindon basin

A. Satellite imagery used

Satellite imagery from the Landsat 8 mission has been obtained from earthexplore.usgs.gov. Landsat 8 was deployed on February 11, 2013, and has two sensors: the Operational Land Imager (OLI) and the Thermal Infrared Sensor (TIRS). Landsat 8, capable of capturing images in several wavelengths, offers imagery in 9 distinct bands. The bands used to create an infrared colour composite are 5 (near-infrared), 4 (red), and 3 (green). The bands possess a spatial resolution of 30 meters, and the images were obtained during the pre-monsoonal period in May 2020[12].

B. Toposheet used

Toposheets have been obtained from the official website of the Survey of India, surveyofIndia.gov.in, and they are on a scale of 1:50000. The whole research region has been covered by a total of 18 toposheets that have been procured, cropped, georeferenced and a mosaic is obtained[13].

C. Evaluation Techniques

After obtaining the satellite images, they undergo preprocessing for subsequent analysis. The topographic sheets are georeferenced and combined to create a mosaic. The desired bands of the images are then selected and assigned false colours. The study concluded that analysing land use and cover for only one year would not provide significant benefits. Therefore, it is necessary to investigate the temporal changes in the region. The toposheets are utilised for this specific objective. The land use categories were measured to facilitate a more accurate comparison study. MLC has been used to achieve an accuracy of around 92%[8]. The MLC tool, accessible in the QGIS software, has been recognised as a highly efficient classification method.

III. METHODOLOGY

The suggested technique entails acquiring toposheets for the designated research region and satellite imageries specifically from the year 2020. The initial phase is demarcating the watershed border of the river by utilizing data from the Shuttle Radar Topographic Mission (SRTM) Digital Elevation Model (DEM)and flow diagram is well illustrated in fig 3. The SRTM provides DEM data with a spatial resolution of 30 meters. The watershed delineation was performed using the toposheet as the foundation map. The watershed covers an area of 5744 square kilometers.

The extended configuration of the basin facilitates the gradual flow of water, resulting in a delayed discharge of all the water from the basin into the exit, namely River Yamuna. Once the watershed has been delineated, our next objective is

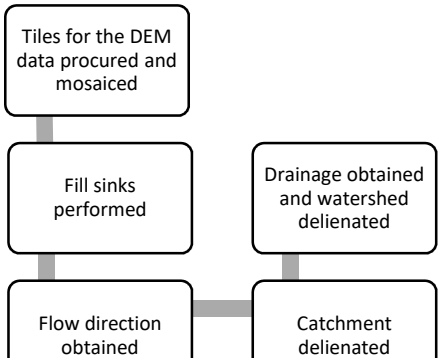

Fig. 3 Flow diagram for generation of drainage map

to conduct classification of the satellite images in the research region. The images are from the Landsat 8 mission, which has a temporal resolution of 16 days and a spatial resolution of 30 meters. The obtained images are from the date 16/05/2020. The Hindon river spans a length of around 350 kilometers and predominantly experiences aridity. The river is heavily impacted by the disposal of solid waste, industrial effluents, and sewage from residential and industrial areas located along its banks. The primary tributaries of the river include the Kali River, Krishni River, and Dhamola River. The

imagery has been classified into five distinct classes: river/waterbody, forest/plantation, barren/fallow, built up, and agricultural land/plantation.

The classification is performed using the maximum likelihood classification (MLC) method and workflow is well explained in fig 4. The MLC is a widely utilized technique for categorizing pixel data. The spectral pattern detected in the data for each pixel is utilized for data classification. The numerical value of each pixel is determined based on its spectral response. The bands utilized in the construction of a color infrared mosaic for Landsat images are band 5 (near infrared), band 4 (red), and band 3 (green). Subsequently, these bands are allocated the colors red, green, and blue, respectively, in order to create a composite image with false colors. Under a supervised method, the user furnishes a training dataset for each class, which is then recorded as a signature file. Each class is allocated three to four distinct regions in the images that correspond to a certain land cover type. Each pixel in the picture is assigned a specific gray value using three bands or channels. Subsequently, the grayscale values are compared to the signature of each land cover type in the training dataset. Upon conducting a comparison, the specific pixel is allocated to its corresponding class.

All the pixels are categorized uniformly. To categorize data, QGIS 3.28.2 has been utilized. The signature files are specified and stored in the gsg format. The maximum likelihood supervised classification method is used to classify overlapping signatures. Within the framework of MLC, the pixel is allocated to the class that possesses the highest likelihood. The MLC algorithm assumes that the likelihood of a pixel belonging to a class is equal for all classes, and that the input bands follow a normal distribution. The classification process involves computing the Spectral Euclidean distance between the target pixel's vector and the average vector for each signature class. The spectral Euclidean distance refers to the distance between two multiband raster, where the spectra of each pixel are considered as vectors [9] The algorithm is time-consuming and frequently results in misclassification of pixels that should remain unclassified. Ground truthing is a method used to confirm or validate anything.

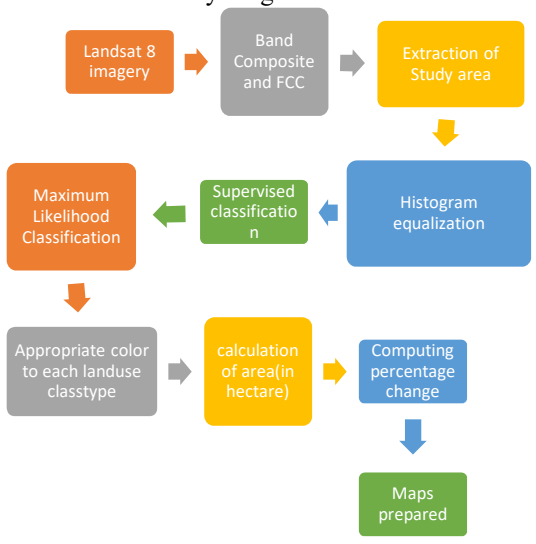

Fig. 3 Workflow for performing Maximum Likelihood Classification

IV. Result & Discussion

After the image pixels have been classified into the five classes of land cover type, each class is assigned an appropriate colour, and a map is prepared that depicts the LULC in the study area. Each class's area (in hectares) in the basin is calculated using mathematical functions.

For determining the temporal change in each class, a LULC map was prepared based on the toposheets of the study area.

Table 1 Percentage change of classes in Hindon Basin

Classes	1972	2020	Percentage change
	Area in Hectares		
Water	5204.5	3040.6	41.5%decrease
Forest	6230.8	5977.6	4% decrease
Barren	3042.9	5470.8	79.78%increase
Built up	42508.6	56931.3	33.9%increase
Agricultural	518572.9	502479.6	3.1% decrease

Subsequently another map was prepared based on satellite imagery.

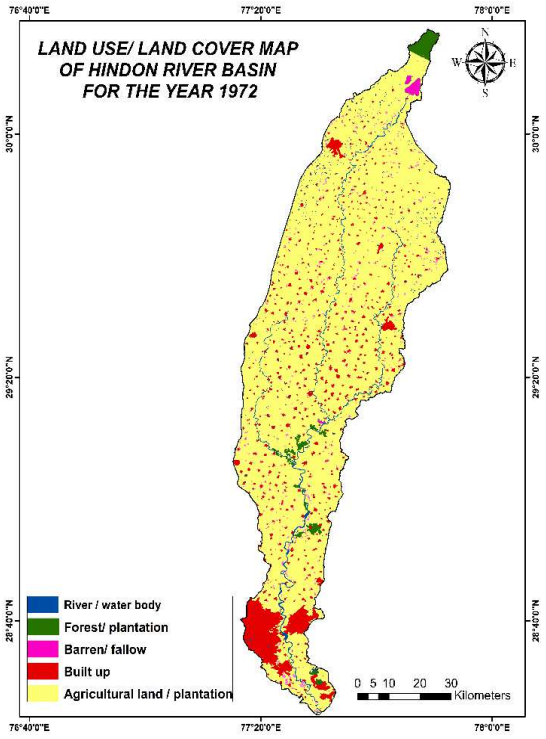

Fig. 4 LULC 1972

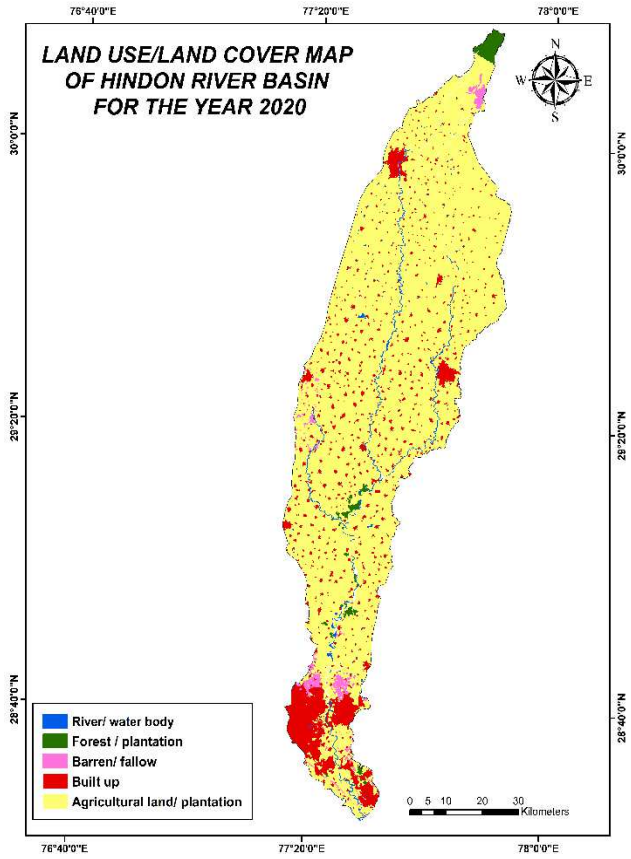

Fig. 5 LULC for 2020

A total of 18 toposheets have been downloaded and mosaiced from which the study area has been extracted. Likewise, each class's area is calculated. The difference between the values of the two data gives the percentage change in the area of each landcover type (see Table 1)

This result shows the land use and cover change over twenty-eight years. The river/water body has seen a 41.577% decrease, which indicates the deteriorating condition of the hydrological systems of the area. Agricultural practices remain prevalent in the basin. Plantation and forests see a four per cent decrease, corresponding to ignorant forestation practices. Built-up has increased by approximately 34%, given the present scenario where the basin has many industrial setups, especially in the highly populated regions of Ghaziabad and Noida. Visually, the maps prepared after classification show the population cluster in the basin and how much of the floodplain is illegally encroached upon.

V. Conclusion and Future Scope

In the wake of significant land use changes observed over the past 28 years in the study area, future endeavors should focus on implementing a continuous monitoring system for a more nuanced understanding of evolving patterns. Integrating advanced remote sensing technologies and machine learning algorithms can enhance the precision of land cover assessments. A comprehensive environmental impact assessment is imperative to discern the consequences of these changes on biodiversity and ecosystem health, guiding targeted conservation efforts. Moreover, fostering community engagement and integrating findings into regional planning will be vital for sustainable land use practices. The study's conclusion underscores the urgency of informed policy decisions to address environmental challenges and promote a balanced approach to land use in the region. Furthermore, these machine learning methodologies have achieved exceptional levels of accuracy in many categorization assignments. These models are versatile and may be used in different real-life settings as future endeavors, including sentiment categorization and hate speech detection[14], [15], [18], [19]. Furthermore, it is crucial to enhance the resilience of these models against adversarial perturbations to achieve robust generalizations in adversarial settings[16], [17].

Rethinking Latency-Aware DNN Design with GPU Tail Effect Analysis

Fuxun Yu, Zirui Xu, Longfei Shangguan, *Member, IEEE,* Di Wang, Dimitrios Stamoulis, Rishi Madhok, Nikolaos Karianakis, Ang Li, *Member, IEEE,* ChenChen Liu, *Member, IEEE,* Yiran Chen, *Fellow, IEEE,* and Xiang Chen, *Member, IEEE,*

***Abstract*—As the size of Deep Neural Networks (DNNs) continues to grow, their runtime latency also scales. While model pruning and Neural Architecture Search (NAS) can effectively reduce the computation workload, their effectiveness fails to consistently translate into runtime latency reduction. In this paper, we identify the root cause behind the mismatch between workload reduction and latency reduction is *GPU tail effect* — a classic system issue caused by resource under-utilization in the last processing wave of the GPU. We conduct detailed DNN workload characterization and demonstrate the prevalence of GPU tail effect across different DNN architectures, and meanwhile reveal that the unique deep structure and the light-weight layer workload of DNNs exacerbate the tail effect for DNN inference. We then propose a tail-awareness design space enhancement and DNN optimization algorithm to optimize existing NAS and pruning designs and achieve better runtime latency and model accuracy performance. Extensive experiments show 11%-27% latency reduction over SOTA DNN pruning and NAS methods.**

I. Introduction

Deep Neural Networks (DNNs) have achieved remarkable progress on cognitive applications [3], [16], [6] and have drawn attentions from both industry and academia on deploying DNN inference service on the cloud, edge and mobile devices [19], [39]. However, the superior performance of DNNs is largely built upon growing model volume and structure complexity. Consequently, how to run these bulky DNNs on accelerators efficiently becomes the key to meet the ever-growing user experience, *e.g.*, DNN model inference *latency*.

To relieve the computation cost and improve runtime performance, many research efforts have been made in different design perspective and implementation levels. These works include model-level optimization [11], [9], [10], compiler-level computing optimization [25], [35], [1], [30], and architecture-level optimizations [28], [27], [26]. Among these works, model-level design solutions are usually the most flexible and straightforward way, since such methods can reduce model volume and computation workload like FLOPs, which can directly translate to latency reduction. However, recent hardware-aware works questioned the effectiveness of these optimization works by revealing a widespread concept, *i.e.*, the lower amount of FLOPS does not equal to small latency during actual deployment on certain hardwares [38], [36], which underlines the importance of understanding of the hardware execution mechanisms for DNN design optimizations.

In this work, we re-examine the effectiveness of model design works for latency optimization on the general processing units (GPUs). By delving into the DNN to GPU deployment and execution mechanisms, we reveal a series of findings that current model design fails to recognize and thus lead to sub-optimal latency optimization performance. Figure 1 illustrates such an ineffective latency optimization case with a structural filter pruning example. Specifically, two layer configurations (config#1, #2) are compared, in which the config#2 conducts filter pruning and reduces partial workloads of this layer. Surprisingly, although config#2 reduces the filters, it ends up having the exact same runtime latency as config#1. In fact, as we keep pruning filters, Figure 1 (c) shows that the execution time exhibits an interesting non-linear *latency staircase* phenomenon. Why does filter pruning not always lead to latency reduction? In this paper, We identify the root cause of this phenomenon as the lack of awareness of the GPU *tail effect* — a classic parallel system issue that causes the resource under-utilization in the last processing cycle [20].

In particular, during execution on GPUs, a DNN layer's computation workload will be translated into massive parallel threads and allocated to GPU for processing on CUDA cores (Figure 1 (a)). However, due to the resource limit (*e.g.*, number of cores, maximal concurrency), the excessive parallel threads would be partitioned into multiple *waves* (Figure 1 (b)). Threads in each wave run concurrently while these multiple waves execute sequentially. Due to such an execution mechanism, although layer config#2 reduces the number of threads in the last wave, it takes the same runtime latency as config#1. Figure 1 (c) verifies the above execution analysis by showing a *latency staircase* pattern. Comparing layer config#2 to config#1, pruning certain amounts of filters brings no latency gain, but rather significantly lower down the GPU utilization and throughput due to the last partial wave.

Motivated by such an observation, **we conduct comprehensive benchmarking analysis and reveal the systematic mechanism** that causes such inefficiency in DNN inference: ***(i)*** Due to massive CUDA core parallelism, GPU presents a large *hardware-level compute granularity*. This is one major factor that causes the non-linear DNN workload to GPU runtime latency translation, and lead to the *latency staircase*

(a) DNN Design Optimization (b) GPU Execution with Tail Effect (c) GPU Inefficiencies due to Latency Staircase

Fig. 1. An Example of Ineffective Latency Optimization by Filter Pruning. Specifically, by analyzing the GPU execution mechanism, we identify that software-level DNN optimization algorithms such as pruning and NAS algorithms fail to consider the native GPU runtime and thus can easily cause *GPU tail effect* that under-utilize the GPU during runtime, which makes these methods ineffective. Therefore, we propose a tail-aware software-hardware DNN co-optimization method to achieve ultimate DNN optimization effectiveness and efficiency.

phenomenon; ***(ii)*** Most current works are non-aware of such a GPU compute granularity and their DNN optimization can easily lead to the runtime *tail effect*; ***(iii)*** Furthermore, due to common DNN's deep layer structure, such *tail effect accumulates and amplifies with hundreds of layers*, resulting in significant overall resource under-utilization.

Based on such tail effect analysis, **we rethink the current DNN design optimization and propose following insights**: ***(i)*** For DNN structure design, the observation of latency staircase implies *DNN architecture design should take GPU compute granularity into consideration*, which would help enable more efficient hardware utilization for model optimization, *e.g.*, help defining the search space in NAS solutions; ***(ii)*** For DNN structure optimization, the tail effect implies that there are *free runtime resources for potential accuracy boost*, *e.g.*, by fulfilling each layer's tail wave of workload to utilize idle SMs but without increasing the latency; ***(iii)*** For complex DNNs with hundreds of layers, accumulated tail effects within these layers implies great chances for *non-trivial latency reduction* while maintaining accuracy.

Performing the design insights above could guide both DNN pre-design and DNN post-optimizations. We demonstrate our optimization approaches regarding two common design-level solutions, neural architecture search and structural pruning: ***(i)*** For NAS solutions, we enhance the current design space with expected GPU granularity awareness. Such a GPU granularity-aware configuration discretizes previous continuous layer width design space, thus greatly reducing the search candidates and the searching complexity. Meanwhile, as the design space already avoids the tail effect, the DNN structure could also achieve better GPU runtime efficiency and thus better latency performance. ***(ii)*** For structure post-optimization like pruning, we can also leverage the GPU-aware layer design space to fine-tune the sub-optimal pruned models. Specifically, we adopt layer growing and layer pruning two operations to utilize the free resources and to eliminate the GPU tail effect. Featured with such flexibility, our structural post-optimization can achieve both accuracy lifting and latency reduction objectives, which is one major difference from previous works.

Through comprehensive evaluations, we demonstrated that our DNN design and optimization methods have exceptional latency performance and model generality with optimal accuracy. Across benchmarks, our design achieves 11%–27% latency reduction and 2.5%–4.0% accuracy improvement over state-of-the-art (SOTA) DNN structural pruning and NAS techniques.

The rest of this paper is organized as follows: Section §II provides the research preliminaries for this work. Section §III presents the observed DNN latency issue with the underlying GPU computing granularity; Section §IV then rethinks current DNN design pitfalls regarding latency-awareness; and Section §V proposes effective latency-aware DNN design insights and demonstrates different design and optimization approaches, following comprehensive evaluations in Section §VI; Section §VIII concludes this work.

II. Background and Related Work

This section introduces the background for the primary research focus of this paper. A GPU workflow overview is first given and then the state-of-the-art DNN computing latency optimization works are reviewed. Specifically, their *pros and cons* are cross-compared to highlight this work's optimization perspective and motivation.

A. GPU Computing Preliminary

GPU Architecture. We take NVIDIA's GPU architecture as the primary investigation object in this work, which also applies to other GPU products. The GPU architecture is featured with an array of *Streaming Multiprocessors* (SMs), each of which is formed by a group of CUDA Cores. For example, NVIDIA Titan-V GPU [28] has 80 SMs and can process 5120 threads

content may change prior to final publication. Citation information: DOI 10.1109/TCAD.2024.3404413

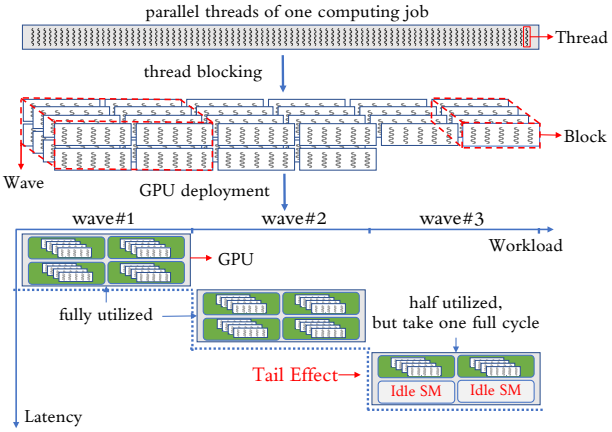

Fig. 2. GPU Execution Model. A computing workload will be split into massive threads and then split into Blocks and Waves for parallel processing. When the final wave comes unfulfilled, the GPU tail effect happens that under-utilizes the GPU resources.

simultaneously. Such a physical parallelism with massive computing units also defines the distinct GPU execution model.

GPU Execution Model. As shown in Figure 2, when a multi-thread job is deployed to a GPU, it will be first parsed into multiple logical workload partitions — ***Blocks*** with identical thread capacity. Depending on the physical capacity of the SM, the number of deployed thread blocks per SM varies.

For a large computing job, whose total workload exceeds the overall SM capacity in a GPU, the GPU needs to take multiple processing cycles. In such as case, the blocks are further clustered into logical ***Waves*** for sequential deployment. Specifically, wave describes the workload that can be concurrently processed per GPU cycle, which equals to the number of SMs $\times$ the number of blocks per SM. And the ***GPU Latency*** can be roughly estimated by the overall number of waves $\times$ the time per GPU computing cycle.

GPU Tail Effect. In practical deployment, the job workload usually will not be perfectly clustered into complete waves; in other words, the last wave could contain fewer blocks, as shown Figure 1. Nevertheless, such an incomplete tail wave will still consume a full GPU cycle, due to the GPU concurrent execution mechanisms as mentioned above, resulting in under-utilized SMs and sub-optimal runtime efficiency, namely, the GPU ***Tail Effect.***

The tail effect generally exists in parallel systems [20] and is considered a trivial issue with conventional GPU workload (*e.g.*, streaming graphic rendering), since the impact of the incomplete tail wave tail can be amortized with dozens of total wave amounts. *However, when it comes to DNN computing, particular DNN design characteristics (*e.g.*, the deep layers) will significantly exacerbate the negative impact of the tail effect with considerable latency issues.*

B. Related Works on Latency Optimization

Software Perspective — DNN Design. In early methods, the volume of the DNN model or FLOPs used to be considered as a linear factor of the workload and therefore the computing latency. Thus, early latency optimization works from the DNN design perspective are through either lightweight structure designs, such as neural architecture search (NAS) [12], [34]; or post-design model architecture tuning, such as structural DNN pruning [11], [9], [14].

However, recent works show the workload measured in FLOPs fail to consistently translate into latency due to different hardware execution mechanisms [38]. Therefore, ***latency-aware*** DNN design is expected to consider the actual hardware runtime [38]. Some recent works leverage off-line profiling of DNN models for latency estimation, such as latency-aware NAS works [10], [2].

Hardware Perspective — GPU Compiling. Currently there are also compiler optimization works that specifically target at optimizing the GPU kernel computing efficiency, such as TensorFlow-XLA and TensorRT [35]. These works tuned the low-level kernel computing primitives (*e.g.*, tiling, unrolling) for each DNN model and each target computing hardware, and thus could achieve optimal hardware efficiency, such as maximal SM utilization, memory throughput. Recently, many ML-based auto-tuning frameworks are proposed, which leverage machine learning to search scheduling factors automatically, such as TVM, TASO [1], [13], *etc.*.

It is worthy to note that these mentioned software and hardware optimizations are current mainstream, but not all. Beyond GPU compiler-level, there are also architecture-level works, such as GPU resource management and scheduling [27, 28], memory system optimizations [15], etc. However, due to their optimization cost and method generality issues, they will not be addressed in this work.

C. Pros and Cons of Different Perspectives

Latency optimizations from the software and hardware perspectives have their respective advantages and disadvantages.

From the DNN design perspective, as mentioned above, recent latency-aware DNN designs are more direct, which optimizes the profiled latency metric already, instead of indirect metrics like FLOPs [38]. However, most latency-aware optimizations treat the underlying runtime mechanism as a black box and only utilize rough look-up-table (LUT) based latency modeling [2], [36]. Although being able to approximate the end-to-end DNN inference latency, they reveal limited understanding of how varied structures perform differently on the hardware. Therefore, the searching performance can be easily limited with an improper design space configuration or insufficient sampling density[1].

Compared to that, hardware-perspective optimizations mainly focus on GPU computing efficiency and provide complementary computing speedup.

Take the TensorRT or TVM compiler for GPU as an example. In compiler-level, re-compiling the hardware-specific kernels for pruned layers can renew the shape-specific optimization (e.g., rescheduling the thread blocking/tiling settings), thus

[1]For example, most NAS works [36], [34] heuristically set or hand-pick layer width search space such as {16, 32, 64, 128, 192}, which can miss optimal layer settings in terms of GPU runtime efficiency.

content may change prior to final publication. Citation information: DOI 10.1109/TCAD.2024.3404413

reducing/removing the tail effect and achieving the optimal efficiency. However, due to the practical cost issue, the current limitation still exists even in the most popular CuDNN/TensorRT lib since TensorRT only develops a static kernel base with around 100+ kernel optimization templates [22], [21] in order to support all conv shapes and many of them are also legacy ones for GEMM-based MatMul kernels. Although such kernel templates take heavy hardware engineering tuning efforts, they are still heavily tuned towards and thus restricted to the most common layer shapes (like ResNet50 layer shapes, EfficientNet layer shapes), which cannot fit various pruning operations with different shapes. To remediate this inefficiency, pytorch and TensorRT also have a "cudnn_benchmark" function that will exhaustively test all kernel shapes' runtime in advance and rank the relative performance with these kernel templates. However, a lot of different pruning/NAS methods' customized configuration cannot find optimal matched templates and thus tail effect problems still exist in such static kernel bases.

D. Our Design Perspective and Motivation

Targeting on optimization efficiency and generality, our work mainly rethink the software-level approaches, *i.e.*, targeting at the DNN model design. But instead of treating GPU as a black box, we incorporate its computing mechanism awareness into the DNN design by diving into the DNN model-to-GPU workload mapping during compiling for an explicit GPU computing granularity analysis, and therefore guide our latency-aware DNN model optimization. Our later proposed solution and evaluation also reveal an interesting finding: DNN designers could effectively alleviate the GPU computing inefficiency (*i.e.*, tail effect) directly from the early design stages, delivering optimal computing performance with low costs, and meanwhile achieving expected generality and feasibility.

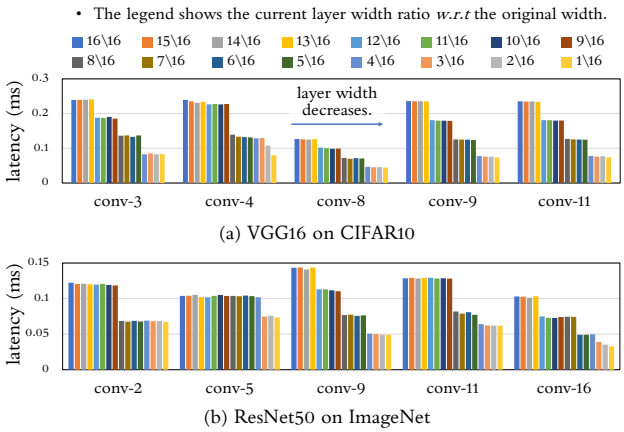
III. Revealing the GPU Computing Granularity for Runtime Latency

In this work, we first dive into the DNN latency analysis to reveal the underlying GPU computing mechanisms. A particular DNN latency issue is identified through detailed observation as the *latency staircase* phenomenon, which triggers our rethinking of the latency-aware DNN model design.

A. DNN Latency Staircase Phenomenon

We profile the inference latency of two representative DNN model settings on an NVIDIA Titan-V GPU[2]: (a) VGG16 on CIFAR10 dataset; (b) ResNet50 on ImageNet dataset. For each DNN model, we investigate the latency impact from different model volumes by gradually pruning the layer width step by step and measure the runtime latency in each layer width setting. All experiments are conducted using CUDA 10.2 and CuDNN 7.6.5 backend.

Through the analysis, we identify a distinct DNN runtime issue, *i.e.*, the ***latency staircase*** phenomenon. Specifically, Figure 3 illustrates the latency of five randomly selected



(a) VGG16 on CIFAR10

(b) ResNet50 on ImageNet

Fig. 3. DNN Runtime Latency Profiling.

DNN layers (denoted by conv-N) of VGG16 and ResNet50, respectively. For each layer's dataset, although the layer volume is gradually shrunk by filter pruning, runtime latency doesn't reduce linearly but demonstrates a "staircase" trend, are changes occurring only after a certain plateau period. Taking the left-upper corner dataset of as an example (conv-3 on VGG16), we observe that the runtime latency does not change as the layer width shrinks gradually to 13/16 (4th yellow bar from the left) *w.r.t* its original size (1st blue bar). However, the latency suddenly drops as the layer width shrinks from 13/16 further to 12/16, after which stays the latency still again until the layer width drops to 9/16 of its original size. And such a staircase dropping pattern repeats through the whole latency profiling.

Such results reveal several findings in DNN latency optimization: ***(i)*** *the layer workload reduction by conventional structural pruning cannot directly translate to GPUs' runtime latency optimization;* ***(ii)*** *such an issue is prevalent across DNN models and layer configurations;* ***(iii)*** *DNN latency optimization requires a deeper investigation of the hardware computing mechanism than a pure software perspective.*

B. Reflection of GPU Computing Granularity

Through dedicated analysis, we find that the above latency staircase is a reflection of specific GPU computing granularity due to the huge-parallelism execution mechanism. Specifically, we dive into fundamental GPU computing primitives (*e.g.*, number of GPU thread blocks B and waves W) using NVIDIA Nsight Compute [24], and reveal the DNN deployment and GPU computing mechanism.

Latency Staircase Analysis. Figure 4 shows the GPU computing changes when we vary a layer's width from 64 to 512 filters [3]. As we can see, the number of thread blocks B grows with increasing number of filters F (top figure), which is expected. Correspondingly, the number of waves also increase. However, due to the granularity mismatch (*i.e.*, one filter's workload doesn't equal to one block, and not equal to one wave.), the number of wave increase in a discrete way (step-by-step), forming the staircase growing trend and with a larger granularity (middle and bottom figure).

[2]We will show in later experiments that such phenomenon is general for both high-capacity and low-capacity GPUs like Jetson Nano.

[3]Specifically, the filter shape and input feature map sizes are set to 3×3 and 64×64×512. And we keep the batch size to 1 throughout the experiment.

This article has been accepted for publication in IEEE Transactions on Computer-Aided Design of Integrated Circuits and Systems. This is the author's version which has not been fully edi
content may change prior to final publication. Citation information: DOI 10.1109/TCAD.2024.3404413

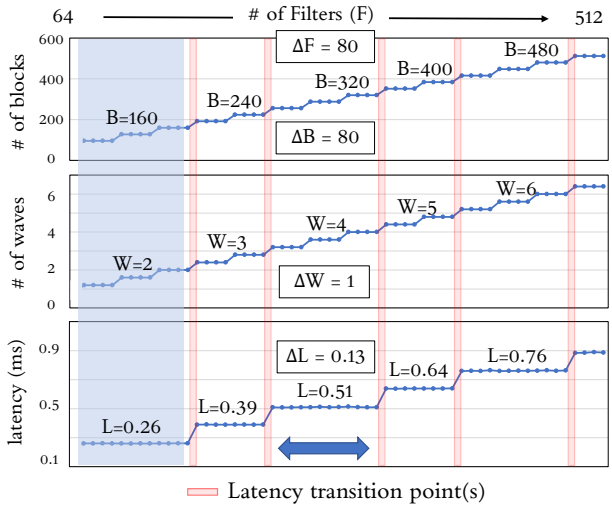

Fig. 4. GPU Computing Analysis *w.r.t.* Blocks, Waves, and Latency with Increasing DNN Layer Size.

As highlighted by the blue box in Figure 4, the number of waves W grows gradually from 1 to 2 with increasing workload. However, the latency stays still until the workload grows to above 2 waves, and then GPU consumes a new processing cycle to process the new wave of workload. We thus see a jump in the runtime latency as highlighted in the red box, *i.e.*, the latency transition point.

C. Latency Formulation with GPU Granularity

Similar staircase patterns continuously emerge with growing workloads, which reflects a GPU-specific compute granularity. We can thus model the latency staircase based on the above analysis. For a given DNN layer, its GPU runtime latency L can be represented by:

$$L = \Delta L \times \lceil \#W \rceil, \qquad \text{where } \#W = \frac{B}{S}, \tag{1}$$

where ΔL represents the latency for the GPU to finish one wave of workload, $\#W$ is the number of waves and B is the number of blocks that the overall workload being translated to. S is processing capacity of the GPU, *e.g.*, the maximal number of blocks that can be concurrently executed. $\lceil \cdot \rceil$ is the rounding-up operation that returns the least integer greater than or equal to the input (*e.g.*, $\lceil 2.1 \rceil = 3$), which reveals the impact of ***tail effect*** on the runtime latency, that is, one underutilized tail wave still leads to the latency of one full computing cycle for each DNN layer.

Eq. 1 demonstrates that the DNN execution latency on GPUs is highly dependent on a GPU-specific compute granularity, i.e., the wave W. Such a granularity is not only a hardware-level concept to describe the GPU capacity, but also an important factor for latency-aware DNN design. Without being aware of this, DNN structure design can easily generate granularity-unmatched models, thus resulting in sub-optimal GPU efficiency and DNN inference latency.

IV. Rethinking the DNN Design Pitfalls with GPU Tail Effects

The previous observation corresponds to the ***GPU tail effect*** mentioned in §II-A. As the DNN structure is usually composed of massive layers, the latency staircase and the tail effect can thus be prevalent across most DNN layers. Whereas, unlike ordinary GPU computing tasks where a single tail effect can be amortized, DNN inference with deep sequential layers incurs massive accumulated tail effects. And even worse, each tail wave may occupy a larger proportion of runtime since each layer has relatively lightweight workload.

In this section, we reveal the latency impact of the tail effect, and rethink the DNN design with GPU hardware-awareness.

A. Excessive Tail Effects within DNN Design

We characterize the workload of mainstreaming DNN models and reveal the excessive tail effects' existence in DNN structures due to two factors: ***(i)*** *Massively sequential layers*: while DNN models come in a wide variety of shapes and sizes, they all share the similar deep structure containing massive fragmented runtime units as layers. The tail-induced inefficiency in each layer thus accumulates with the feed-forward inference; ***(ii)*** *Limited per-layer workload*: While the entire DNN workload can be large, the workload of each layer is light-weight and thus requires much fewer waves to finish. amplifying the per-layer tail wave's negative impact.

Massively Sequential Layers. Figure 5 illustrates the workload of each layer (termed as Layer workload) in three different DNN models. To facilitate the presentation, we also plot the actual GPU workload in the figure, both of which are quantified by the number of waves. The gap between the layer workload and the actual GPU workload reflects the GPU under-utilization ratio. We observe these three models all contain more than 50 layers, and more importantly, the GPU under-utilization can easily occur in almost every layer of these models. During inference, such per-layer GPU under-utilization accumulates with the model execution, and thus severely undermines the GPU runtime efficiency. Beyond such lightweight models, higher under-utilization may appear in even deeper DNN models such as ResNet101 [7].

Limited per-Layer Workload. We further measure the number of waves incurred by each layer's workload in different batch size settings, and show their cumulative distribution function (CDF) in Figure 6. Here, we can observe that the majority of layers incur less than five waves for all three different models. For ResNet50, we can see over 80% of layers only introduces less than three waves from batch size=1∼4. Similarly, over 80% of layers in both MobileNet and MNasNet requires less than three GPU waves when the batch size is relatively small (*i.e.*, B=1). The maximum 80-percentile per-layer workload with batch size=4 only reaches 5-6 waves, which is far limited compared to the aforementioned same-sized GPGPU workload (30-80 waves). Due to the limited workload per layer, under-utilization in the tail wave causes more significant resource under-utilization (*e.g.*, up to 33% in a layer with three waves).

It is worthy to note that, the GPU tail effect can potentially become increasingly prominent with more light-weight DNN design (such as in the edge domain), while GPUs are becoming increasingly powerful with higher capacity even for the edge GPUs like NVIDIA Jetson [23]. *Therefore, without dedicated*

content may change prior to final publication. Citation information: DOI 10.1109/TCAD.2024.3404413

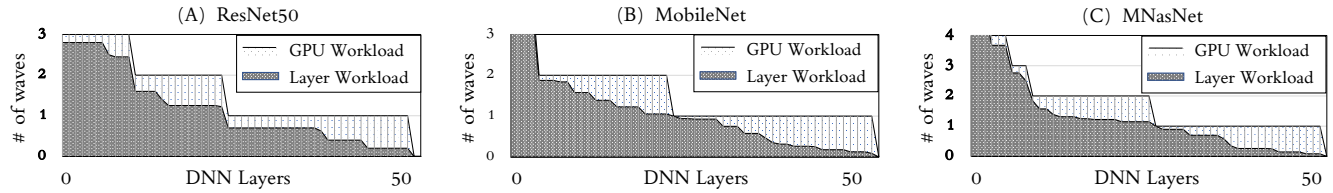

Fig. 5. The offset between the runtime GPU workload and the layer workload illustrates the GPU under-utilization caused by the tail effect (BS=1). Such under-utilized happens in each layer and thus accumulates to a non-negligible amount.

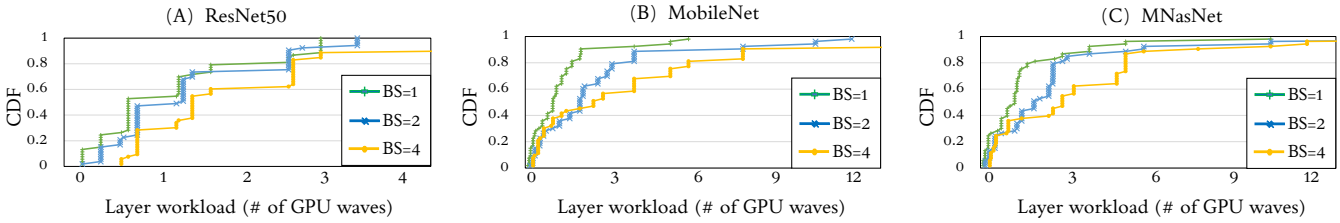

Fig. 6. The CDF of the layer workload shows that most (>90%) DNN layers consume less than 3∼9 GPU waves with varied batch sizes (BS=1∼4). In such cases, the relative influence of tail effect (affecting the last wave) is amplified.

optimization, such DNN latency sub-optimality can be exacerbated with the increased tail effects caused by mismatched GPU and DNN design granularity.

B. Pitfalls in DNN Optimization

We then demonstrate that conventional DNN optimizations such as filter pruning and architecture search (NAS) can even exacerbate the tail effect, leading to ineffective DNN optimization pitfalls.

In the beginning of Figure 1 (c), we have shown a real case of GPU runtime efficiency variation when layer workload is not matching the GPU granularity. Specifically, as the latency exhibiting a staircase pattern, the two GPU runtime metrics (GPU utilization and throughput) also show significant oscillation. The highlighted red box in Figure 1 (c) annotates a concrete example: the GPU utilization and throughput peak at the local maxima (92.63% and 12.0 TLOPS/s respectively) when the workload fully occupies the current wave, while decreases to the local minima for the lower-bound workload (74.14% and 8.6 TFLOP/s). Caused by ineffective optimization, the GPU runtime efficiency gap can reach up to 1.4×.

Such "ineffective pruning" pitfalls, that is, blindly pruning a DNN layer can lead to small runtime latency reduction but rather cause sub-optimal GPU utilization and throughput, can also be common in general pruning algorithms. For example, by reproducing the model pruning result using one of the recent SOTA pruning work [14], Figure 7 shows the runtime latency and throughput information of two resulted DNN layers. The performance result achieved by [14] is highlighted in orange. As we can observe that, without such tail awareness, two pruned layers did not achieve the optimal GPU throughput, but rather leading to the *ineffective pruning*. Especially in the first case that pruning 40% of filters doesn't lead to latency reduction, the gap between the throughput achieved by [14]'s configuration and the optimal one can reach up to 1.5×.

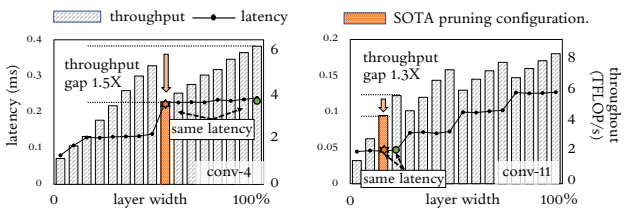

Fig. 7. The "ineffective pruning" pitfall. Without being aware of tail effect, the shown filter pruning configuration is sub-optimal, *i.e.*, 1.3×-1.5× less GPU throughput under the same latency. The DNN model is VGG16 [32] on CIFAR10 dataset as per the official open-sourced repository [15].

V. Approaching Latency-Aware DNN Design with GPU Awareness

In this section, we summarize the lessons learned from our analysis and characterization to guide DNN design on GPUs. We then demonstrate that by eliminating the GPU tail effect, we can enhance current DNN optimizations with better GPU awareness and achieve better performance.

A. DNN Design with Latency-Awareness

By understanding the GPU granularity-based latency modeling and the inefficiency caused by the tail effect, we can illustrate a series of DNN design insights:

• *Latency-aware DNN optimization on GPUs should consider a new basic unit, i.e., the GPU computing granularity (§III-B).* Previously, many DNN design and latency optimization works consider filters as the primary structural unit. However, our latency staircase analysis shows that, as one filter's workload is usually much smaller than the GPU computing granularity, workload measured by filters fails to translate to the latency consistently. By understanding this, latency-oriented DNN design could improve both their latency modeling effectiveness and design efficiency. For example, given a targeted GPU, each DNN layer's design only needs to consider a discrete design space, *i.e.*, with a step size of a certain number of filters that matches the GPU granularity.

• *For existing DNN structures, the existence of tail effects is prevailing, which exposes many opportunities for both accuracy and latency performance improvements*. The reason of prevalence is that, as the GPU platform (and other factors like compilers) can vary, the unified DNN structure design

This article has been accepted for publication in IEEE Transactions on Computer-Aided Design of Integrated Circuits and Systems. This is the author's version which has not been fully edi
content may change prior to final publication. Citation information: DOI 10.1109/TCAD.2024.3404413

can hardly avoid tail effects in all different settings. In such a case, tail effect accumulation in DNNs can incur huge inefficiency, meanwhile exposing many optimizations potentials. Specifically, the GPU resource under-utilization enables us to increase DNN workload and utilize the "free" tail resources[4] to boost accuracy while without affecting the runtime latency. In addition, as tail effect can emerge in many layers, by simultaneously pruning certain tail waves and filling up other ones, we can also obtain certain latency gains while maintain the overall DNN capacity and accuracy.

The above design insights can guide various DNN design optimization approaches. In this work, we mainly include approaches: GPU-aware NAS design space enhancement (§V-B) and lightweight DNN structure fine-tuning (§V-C).

B. GPU-aware NAS Design Space Enhancing

The first optimization we can apply is to enhance the design space of NAS methods with the proposed GPU awareness.

As discussed in related work (§II-C), previous NAS works mainly heuristically choose layer width in the design space, which may have sub-optimal GPU runtime performance. Therefore, one direct way of utilizing our GPU granularity-aware modeling is to find the optimal layer configurations and integrate into the NAS design space. The benefits are twofold: ***(i)*** our granularity-based modeling discretizes a continuous layer width design space and reduces the amount of search candidates for each layer, reducing the searching complexity; ***(ii)*** meanwhile, as each configuration already avoids the tail effect, our design space brings better GPU runtime performance without the tail effect related inefficiency.

Profiling-Guided Identification. We take a profiling strategy, *i.e.*, profiling the GPU latency staircase offline to identify the optimal design space for each layer.

Based on the layer runtime modeling in Eq. 1, the tail effect diminishes when DNN layer workload matches the GPU compute granularity, *i.e.*, the last wave of workload fully occupies the GPU. In such case, the GPU achieves optimal utilization, and the throughput also reaches local maximum in the range of current wave. Therefore, we leverage the GPU throughput T to identify the existence of tail effect in each layer and further detect its optimal layer configurations. Taking a retrospect of Figure 1 (c), we can see the throughput always peaks its local maximal (denoted by the green triangle) at the optimal layer size setting without tail effect and thus can serve as a reliable clue to track the optimal configurations. Specifically, we obtain the optimal configuration $C_i^\star$ for each layer i based on the following rule:

$$C_i^\star = \arg\max_m (T_{i,m}) \tag{2}$$

where $T_{i,m}$ denotes GPU throughput of layer i in the mth layer width configuration. We then use Eq. 2 to identify optimal configurations in different layer width intervals.

Overhead Analysis. Table I shows the offline profiling overhead on different DNN models. For each layer, we sample 16 different layer width configurations (from 1/16 to 16/16 with respect to the default layer size) and record their throughput. We observe the profiling overhead stays in the range of one to three minutes, which is generally acceptable considering the NAS overall search time.

[4]Here we mainly denote latency-wise "free". The power consumption may still show differences, which is out of scope of this work.

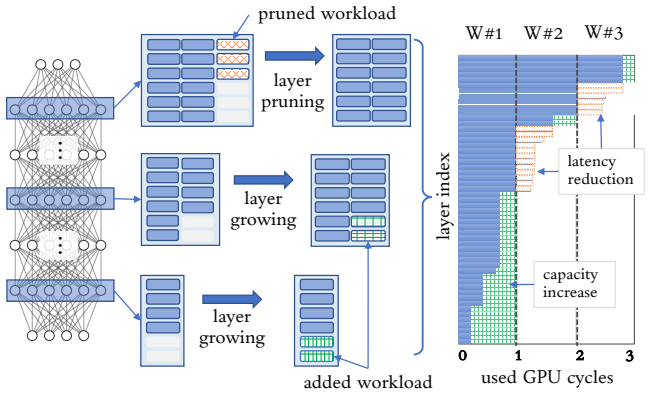

Fig. 8. We leverage two operations (*i.e.*, pruning and grafting) to eliminate the tail effect. Such two operations provide complementary latency gain and accuracy gain and facilitate the DNN accuracy-latency optimization.

C. Lightweight DNN Structure Fine-Tuning

Besides the end-to-end DNN design apporach of NAS, we can also conduct lightweight DNN structure fine-tuning to obtain the optimal pruned models in structural pruning methods.

Structure pruning without GPU awareness can generate pruned models with excessive tail effects (§IV-B). Therefore, we can leverage ***pruning*** **and** ***grafting*** two operations to eliminate the tail effect. An overview of our method is shown in Figure 8. Specifically, *layer pruning* reduces the number of filters to remove the remaining workload on the last wave and thus can effectively harvest latency gain by an entire GPU wave processing cycle. *Layer grafting* instead increases the number of filters in other laters to fill up the GPU capacity in the last wave, which can compensate the accuracy loss of layer pruning without sacrificing the latency (*i.e.*, accuracy gain). These two operations provide us flexible opportunities to match the GPU granularity and thus eliminate the tail effect. Meanwhile, they also provides DNN optimization flexibility towards two optimization targets: latency reduction and accuracy lifting, which is one major difference from traditional pruning works.

Here one challenge remains, *i.e.*, how to select two operations between layer pruning and grafting across multiple layers regarding different optimization objectives? We propose

Algorithm 1 Lightweight DNN Structure Fine-tuning.

1: **Input:** Model's initial layer configs $r[l]$, latency $L[l]$ and throughput profiling $T[l]$.
2: **Output:** New config R_{new}.
3: Identify design space C_l for each layer l by Eq. 2.
4: **for** layers $i = 1$ **to** l **do**
5: Get LG_i, PG_i estimation through profiling results.
6: Sort the layer index list [1,2...i...l] by LG_i or PG_i.
7: **while** layer index list is not empty **do**
8: Pop out layer j with argmax$_j$ $LG[l]$.
9: Prune layer j with one step in design space C_l.
10: **while** $\Sigma^l PG(R_{new}) \notin (-\tau, \tau)$ **do**
11: Pop out layer k with argmin$_k$ $LG[l]$.
12: Grow layer k with one step in design space C_l.
13: Get runtime latency evaluation L_{new} of config R_{new}.
14: **if** L_{new} achieves the target latency **then**
15: Train and evaluate the model accuracy.
16: **else**
17: Set τ *= 2 and repeat the algo. from line 9.
18: **Return** Fine-tuned config R_{new}.

a lightweight fine-tuning algorithm to flexibly balance the corresponding operations to reach different objectives.

Optimization Objectives Formulation. We first define the DNN inference accuracy and runtime latency optimization objectives. We define the latency gain LG to indicate the latency being saved, and parameter gain PG (amounts of parameters been deleted or added) to indicate the model capacity as a guidance for retaining accuracy. The two metrics could be estimated by the change in different layer widths R_i and their latency profiling L_i.

Accuracy-Oriented Optimization aims to improve the model accuracy without extra latency overhead. Therefore, it can be formulated as maximizing the parameter gain while constraining latency gain:

$$\text{Maximize} \quad \sum_i^l PG_i, \quad \text{s.t.} \quad \sum_i^l LG_i \geq 0. \tag{3}$$

Latency-Oriented Optimization aims to reduce the runtime latency without accuracy drop, *i.e.*, maximizing latency gain while maintaining parameter gain in a tolerable range (τ):

$$\text{Maximize} \quad \sum_i^l LG_i, \quad \text{s.t.} \quad \sum_i^l PG_i \in (-\tau, \tau). \tag{4}$$

Algorithm Walk-through. Without loss of generality, we take the latency-oriented optimization as an illustrate example to explain the algorithm. The accuracy-oriented optimization follows the same principle by simply switching the optimization objectives as defined in Eq. 3–4.

Step 1. Layer Candidates Identification (Line 3): Given a DNN model structure, we first identify the optimal layer configurations, *i.e.*, design space C_i by Eq. 2.

Step 2. Intra-Layer Performance Gain Estimation (Line 4–6): For each layer, we get the latency and parameter gain estimation assuming conducting layer pruning and layer growing operations by one step in the design space C_i. These performance estimation will guide the inter-layer adjustment.

Step 3. Inter-Layer Adjustment Strategy (Line 7–13): To achieve latency optimization, we maintains a bi-directional queue of layer indexes, and greedily prune layers with maximal LG_j (max latency gain) and minimal LG_k for growing (balanced capacity) . Same procedure applies to accuracy optimization by switching the objective/constrain in Line-9, 11.

Step 4. Model Structure Determination (Line 14–18): Finally, we return the new configuration if it reaches the targeted latency. Otherwise, we can adjust the constraints, *e.g.*, with larger parameter gain tolerance ($\tau* = 2$), to allow more aggressive layer pruning for latency reduction.

Algorithm Discussion. Note that different from traditional pruning-from-scratch method, our method is designed as an orthogonal pruning "post-calibration" method on top of well-searched pruning/NAS configurations, which could be easily combined with any global pruning method that finds optimal accuracy-aware pruning configurations. In fact, our pruning and grafting operations usually yiled minor pruning size calibration within one staircase as shown in Figure 8, for example, adjusting from pruning 40 filters (an accuracy-aware best pruning configuration but NOT latency-aware) to 48 filters (both latency- and accuracy-aware best setting) in a 512-filter layer. Such a practice incurs minimal accuracy change to the optimal pruning configurations. Meanwhile, with the small filter number changes, we adopt the simple but effective guidance metrics that are the parameter gain (PG) and latency gain (LG). Even though the PG indicator is not mathematically proven to be related to accuracy modeling like traditional from-scratch pruning method, it is more designed as a lower-bound indicator that our pruning post-calibration method is not hurting the model capacity (e.g., the parameter gain remains largely positive/non-negative), thus are shown to achieve fairly stable accuracy improvement and latency reduction, which we will show later in our experiments.

VI. Experimental Evaluation

In this section, we evaluate our latency-aware DNN design methodology on a series of common benchmarks. Specifically, we demonstrate our performance gain in different approaches.

Experimental Setup. We conduct experiments using the common software stack including CUDA 10.2 and CuDNN 7.6.5. For GPU hardwares, we select four GPUs from high-end (Ampere 3080Ti, Volta Titan-V, Pascal P6000) to embedded ones (Jetson Nano). The detailed specifications of these GPUs are shown in Table II, including number of SMs and CUDA cores, as well as the peak FP32 performance.

We apply our method into two common model optimization approaches, *i.e.*, *structural filter pruning* and *NAS*. For pruning, we compare with several state-of-the-art pruning methods including HRank [14], SoftPruning [8], Network Slimming [18] and Dependency Graph [5]. For NAS, we apply our model optimization method onto the EfficientNet series of structures [34], which are one type of the SOTA efficient model architectures. For model performance evaluation, we compare the model's accuracy and runtime latency. Without specific mentioning, the batch sizes for latency evaluation on CIFAR10

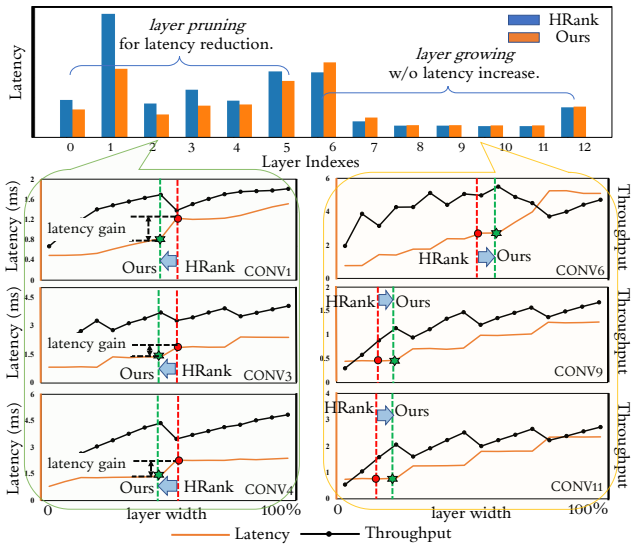

Fig. 9. Our DNN optimization illustration. We conduct layer pruning in Conv1-5 to get latency reduction, and layer growing in Conv6-12 to recover model capacity but without obvious latency increment. During this, we eliminate tail effects across layers and get latency reduction.

and ImageNet are set to 128 and 1 to observe the latency variations. Meanwhile, we also collect the GPU throughput (FLOP/s) information as a indicator to demonstrate the GPU runtime efficiency comparison.

A. Evaluation on the Pruning Approach

A Proof-of-Concept Case Study. As a proof-of-concept, we first apply our optimization to a prevalent DNN benchmark model VGG16 and compare the results with one SOTA pruning competitor HRank [14] to illustrate our algorithm mechanism. The result is shown in Figure 9.

Our results (orange bar) consistently outperform HRank (blue bar) on run-time latency reduction, as shown in Layer 0∼5. We further showcase the latency and throughput of three randomly selected layers for both layer pruning and growing operations (bottom figure). As shown in CONV-1,3,4, we successfully remove one tail latency by conducting layer pruning operation. At the same time, the GPU throughput achieves its local maximal. The layer growing actions, on the other hand, brings little to no latency overhead, as shown in CONV-6,9,11. Taking a further scrutiny on their latency results, we can see that the layer width is increased by a proper amount such that the layer's runtime latency stays similar with HRank. Overall, we can achieve **17.7%** latency reduction compared to HRank with only **0.2%** accuracy drop (93.1%→92.9%), as shown in the first two rows in Table III.

TABLE III
LATENCY OPTIMIZATION AND GPU THROUGHPUT ANALYSIS (TITAN V).

	Method	Params	#FLOPs	FLOP/s	Acc.%	Time (ns)
VGG16 (CIFAR10)	HRank [14]	1.90M	67.0M	2.41T	**93.1**	2.50E6
	Ours	2.85M	104.1M	**3.90T**	92.9	**2.05E6 (-17.7%)**
ResNet56 (CIFAR10)	HRank [14]	0.48M	65.9M	0.83T	93.6	4.20E6
	Ours-1	0.50M	79.1M	**1.00T**	**93.8**	**3.72E6 (-11.3%)**
	Ours-2	0.50M	75.1M	**0.95T**	93.5	**3.51E6 (-16.3%)**
ResNet56 (CIFAR10)	SOFT-1 [8]	0.53M	68.8M	0.88T	93.1	4.08E6
	Ours-1	0.43M	71.4M	**0.91T**	**93.2**	**3.52E6 (-13.7%)**
	SOFT-2 [8]	0.45M	53.1M	0.68T	92.3	3.64E6
	Ours-2	0.43M	66.0M	**0.79T**	**92.3**	**3.01E6 (-17.3%)**

Pruning Accuracy and GPU Throughput Analysis. We then apply our model optimization method in more pruning benchmarks and analyse both the latency and GPU throughput. The result comparisons are shown in Table III. Note that, SOFT method [8] has two pruning configurations (denoted by SOFT-1 and SOFT-2) with varied pruning degrees, which we compare separately. The latency evaluation is conducted on Titan-V.

Latency Reduction: As Table III presents, by optimizing the model structure configurations, our method achieves consistently lower latency than baseline methods (**11.3%-17.7%** latency reduction in all settings). Different from previous work that focuses on reducing workload to reduce latency, our method's latency reduction mainly comes from the higher GPU runtime efficiency, *e.g.*, GPU throughput improvement.

GPU Throughput Improvement: As Table III shows, our method shows consistently higher GPU throughput than the baselines, *i.e.*, in the (*FLOP/s*) column. For VGG16, our optimized model achieves 3.90 TFLOP/s, **1.6**× throughput than the baseline method, 2.41 TFLOP/s. For ResNet56, our models also achieve **1.2**× throughput than HRank (1.00 vs. 0.83 TFLOP/s) and SOFT-2 (0.79 vs. 0.68 TFLOP/s). Such throughput enhancement indicates the GPU runtime efficiency improvement, and shows the advantages of our configuration optimization by tail effect elimination.

Accuracy Maintenance: In addition to lower latency, our method also maintains the model accuracy change within negligible ranges (±0.2%). This is benefited by constraining the parameter gain (PG) in the algorithm. As (*Params*) column in Table III shows, our optimized models have maintained the amount of parameters either in positive range or very small negative range. By doing so, we ensure the models' capacity to be well-maintained, thus keeping the accuracy during the optimization.

Fine-Grained Comparison with SOTA Benchmarks. To further illustrate the advantages of our methods, we conduct a fine-grained analysis by applying our method on top of two state-of-the-art methods: *Network Slimming (SLIM)* [18] and *Dependency Graph (DEPG)* [5].

Specifically, given an upper bound pruning ratio for one network (e.g., 70%), we enumerate all pruning configurations below the upper bound with a specific pruning ratio step size (e.g, 5%). For each pruning ratio, we run the baseline

This article has been accepted for publication in IEEE Transactions on Computer-Aided Design of Integrated Circuits and Systems. This is the author's version which has not been fully edi
content may change prior to final publication. Citation information: DOI 10.1109/TCAD.2024.3404413

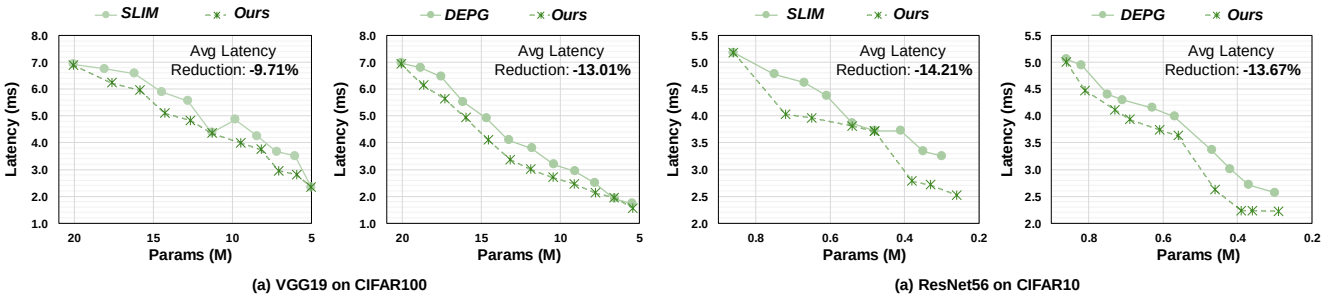

Fig. 10. We applied our fine-tuning algorithm (*Ours*) onto each pruning configuration generated by *SLIM* [18] and *DEPG* [5]. Experiments show our optimization achieves consistent latency reduction (on average 10% to 14%) on top of the baseline. Latency measured on 3080Ti with batch size = 128.

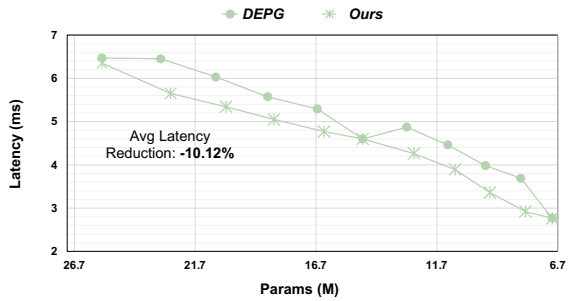

Fig. 11. We applied our fine-tuning algorithm (*Ours*) onto each pruning configuration generated by *DEPG* [5] (ResNet50 backbone on ImageNet). Experiments show our pruning optimization achieves consistent latency reduction (on average 10.12%) on top of the baseline methods. Latency measured on 3080Ti with batch size = 8.

algorithms (*SLIM*, and *DEPG*) to find the accuracy-optimized pruning configurations. Then our layer pruning and grafting Algorithm 1 is applied on top to finetune the baseline pruning configuration to remove the GPU tail effect, and thus generated a both accuracy- and latency-optimized configuration. We then compare the latency vs parameter amount plot to compare each of the baseline and our optimized results.

Figure 10 shows the detailed latency curve comparison. Latency are measured on 3080Ti GPU with batch size 128 for both CIFAR10 and CIFAR100. As we can see, most pruning configurations generated by tail-unaware baselines (*SLIM*, and *DEPG*) run with longer latencies, indicating they are far from optimal in terms of actual GPU runtime efficiency. By contrast, by slightly optimizing each layer's configuration to remove the tail effect, our fine-tuned model architecture could easily save 10%-14% average latency for nearly all pruning configurations.

To further demonstrate that our pruning and grafting algorithm only has minimal accuracy impact, we compare the model re-training performance between the baselines and our optimized model configurations. Here for simplicity, we only compare the model pruning settings that are reported in the official codebase benchmarks[5]. The results are shown in Table. IV. As we can see, ours algorithms yileds minimal accuracy variation (-0.15% to +0.02%) but achieves consistently 10% to 17.7% latency reduction.

The above experiments demonstrate the major benefits of our algorithm: ***orthogonal design***, that is, our pruning and grafting algorithm could be combined with various of different SOTA pruning algorithm logics (e.g., local-based ranking [14], [8], [18] or global-based ranking mechanisms [5], different l1-norm or other importance criteria, etc). When the SOTA algorithms generate an accuracy-oriented optimal configuration, further applying our algorithm on top will then generate a both accuracy-optimal and GPU efficiency-optimal configuration, thus achieving consistently better accuracy-latency trade-offs.

B. Evaluation on the NAS Approach

In this part, we apply our optimization method to further optimize the NAS network's performance on GPUs. Specifically, we optimize the EfficientNet [34] series of model structures to achieve better accuracy latency trade-offs. The evaluation results are shown in Table V. The latency evaluation is conducted on Titan-V and P6000 GPUs with batch size = 1 to simulate the real-time performance.

Accuracy Maximization: As Table V shows, with the similar runtime latency, our optimized EfficientNet model could achieve much better accuracy (**+3.97%**, **+2.7%**, **+2.54%**, respectively) on the challenging ImageNet dataset.

Better Latency Accuracy Trade-offs: We composedly compare the model accuracy-latency performance with original Efficient-

content may change prior to final publication. Citation information: DOI 10.1109/TCAD.2024.3404413

Nets [34], and several major types of DNN structures including ResNets, ResNeXts, InceptionNet, and Dense Net. The results are shown in Fig. 12. From the *accuracy* perspective, our optimized B0 to B3 models achieve the highest accuracies than most baselines under the same latency. From the *latency* perspective, our model B2's latency is **1.5**× less than the models which achieve the same accuracy level, *e.g.*, EfficientNet-B3 and B4. Therefore, both perspectives demonstrate the effectiveness of our method in achieving better accuracy latency trade-offs on GPUs.

Optimization Explanation: Here we explain our optimization mechanisms for the EfficientNet series of networks. When conducting EfficientNet inference on GPUs, we observe that most of layers in these models consume less than one GPU wave of workload, *i.e.*, highly under-utilizing the GPUs. The GPU throughput is only 61.9 - 109.9 GFLOP/s for B0 to B2 as shown in Table V. Such under-utilized GPU capacity allows us to conduct layer growing to reach one full wave for each layer without latency increment, thus bringing higher model capacity and model accuracy.

For implementation, EfficientNet series of networks have three scaling dimensions in their initial design: layer width (w), input resolution (r) and network depth (d) [34]. Out of the three, we balanced scale up both (w) and (r) to increase the network capacity. The depth (d) dimension, however, is kept same with the baseline model, as network layers are run sequentially and depth scaling would inevitably incur latency increase. By width and resolution growing, the optimized models have higher accuracy as well as improved GPU throughput, *e.g.*, 414.2 - 547.3 GFLOP/s, while maintaining the similar latency with baselines, as shown in Table V.

C. Generalizability across GPUs

We further extend the generalizability evaluation to different high-end GPU, P6000 and embedded GPU, Jetson Nano. The detailed GPU specifications can be found in Table II.

The overall results are shown in Table VI and Table VII. On the P6000 GPU (Table VI), our method could achieve **9.0%** to **27.2%** latency reduction than SOTA methods while maintaining similar accuracy for VGG16 and ResNet56, demonstrating the generality across different high-end GPU architectures. For Jetson Nano GPU (Table VII), although it has relatively smaller computing capacity, our method still achieves **13.3%** to **20.5%** latency reduction, demonstrating the generalizability for both high-end and embedded GPU platforms. The above results demonstrate the effectiveness and generalizability of our DNN optimization algorithm. Without any GPU-specific assumptions, our profiling-guided design could be applied to a spectrum of GPUs to enhance the DNNs' accuracy-latency trade-offs.

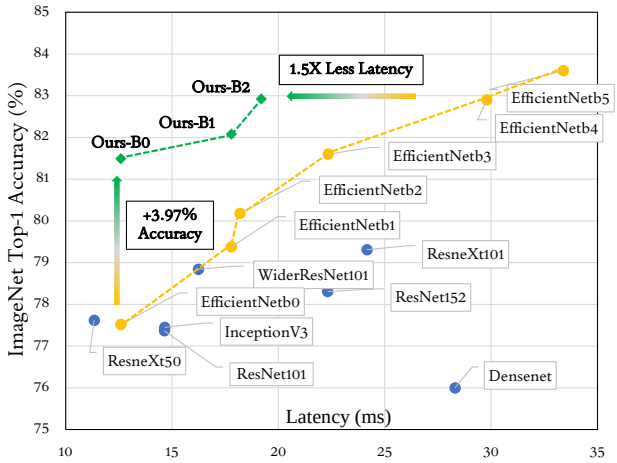

Fig. 12. ImageNet accuracy and latency comparisons. Compared to EfficientNets (yellow) and other models, our GPU-aware optimized models achieve better accuracy latency trade-offs. Evaluated platform: NVIDIA Titan-V GPU.

D. Generalizability in DNN Architectures

In this part, we conduct generalizability evaluation of DNN latency staircase in terms of different DNN hyper-parameters, including batch sizes, input resolutions and filter shapes.

Batch Size Variation: Fig. 13 shows the latency *w.r.t.* varied batch size from 1 to 256 for two CONV layers of VGG16 on ImageNet resolution. The latency staircase consistently exists for all layers with different batch sizes. Specifically, layers with larger batch size incurs a longer processing cycle for a wave, leading to a higher latency staircase.

Number of Filters Variation: Fig. 13 also shows that CONV-5 has more levels of staircase compared to CONV-3. The reason is that CONV-5 has more filters (128) than CONV-3 (64). Since the number of filters determines the number of thread blocks, more sequential GPU waves are needed with a larger number of filters, leading to more levels of staircase.

Input Resolution Variation: Similar latency evaluation is also conducted w.r.t varied input resolution from 128^2 to 1024^2 for CONV-3 and CONV-5 in Fig. 14. The latency staircase still consistently shows in both low to high resolutions.

Filter Shape Variation: In addition, we evaluate layers with different filter shapes from 1x1, 3x3, 5x5 dense filters to 3x3 depthwise filter, while keep the maximum layer workload for

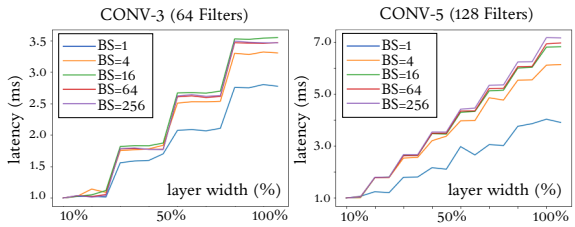

Fig. 13. Latency staircase *w.r.t* varied batch size (1 to 256 in sub-figure) and number of filters (64 to 128).

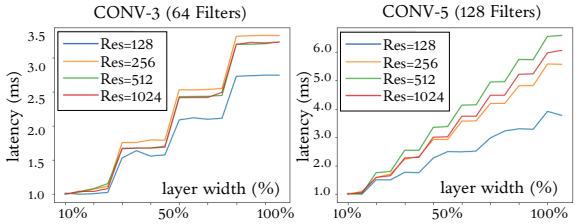

Fig. 14. Latency Staircase *w.r.t* varied input resolution.

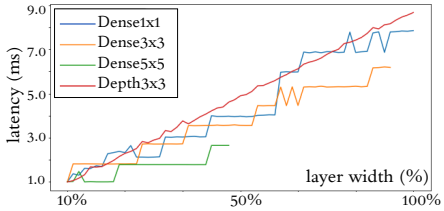

Fig. 15. Latency staircase *w.r.t* varied filter shape.

each type to be the same[6]. Fig. 15 shows the generalizability of latency staircase w.r.t. 1x1, 3x3 and 5x5 dense filters. One exception here is the depthwise 3x3 filter, whose latency results demonstrate a relatively linear pattern. The reason is that the depthwise filter is more light-weight compared to dense filters. Each GPU processing cycle for one wave of depthwise workload is thus smaller, leading to no dramatic upward edge in the latency curve. However, as depthwise filters are usually combined with 1x1 dense filters to compose depth-width layers, *e.g.*, in MobileNets [31], MnasNets [33], the latency staircase still exists for such models.

VII. Limitations and Future Works

A. Future Works for Concurrent Kernel Analysis

Our current work adopts a ***single-model*** execution assumption as stated in NN-meter [40], i.e., *the assumption that kernels run sequentially on each device, even for those ones without dataflow dependency.* This is true for most edge GPUs with limited capacity [40]. Meanwhile, we have observed the same sequential execution patterns hold for our tested architectures (e.g., VGGs, ResNets, EfficientNets) and tested server-level GPUs (e.g., Ampere 3080Ti, Volta Titan-V, Pascal P6000).

However, with the continuous CUDA feature upgrading, we do see recently some new CUDA features (such as multi-stream, multi-process service MPS [27], multi-instance MIG [26]) enable ***multiple models*** and ***concurrent kernel execution*** on the same GPU since the Ampere architecture. This will lead to complex cross-effects between several kernels such that when multiple kernels share the sane resources, the tail effect's impact can be different from current single-kernel execution. However, in the current stage, a practical limitation that we have been facing is that, up-to-now, the available CUDA profiling toolsets (NVIDIA NSight/Compute [24]) still cannot force two kernels to accurately align to co-run, thus it can be hard to analyze their concurrency states, nor profile two arbitrary kernels' concurrent execution time accurately. Multi-round end-to-end multi-model co-running and profiling can be a potential way to remediate such limitations but also require more statistical analysis.

B. Limitations for Vision Transformers

Our current work mainly focuses on convolutional neural networks including traditional VGG and ResNets, as well as the NAS-based networks like EfficientNets, which cover most of the basic convolution components for modern CNNs. Recently, vision transformer (ViT) architectures are introduced [17], [4]. ViT architecture features with a new meta-layer type, i.e., multi-head self-attention (MHSA) layer, and a new type of transformer blocks composed MHSA layers and feed-forward fully connected (FC) layers.

With the specific transformer block structure and MHSA layers, the CNN-oriented channel pruning mechanisms for CNNs are no longer suitable. Instead, ViT pruning method design and the latency analysis faces multiple major challenges that are still awaiting research and analysis: (1) ViT pruning can happen within more dimensions, e.g., image patch embedding size (E), number of head (H), query & query size (QK), value size (V) and FC layer hidden dimension (M). (2) Pruning different ViT dimensions will require corresponding dimension matching across inter-dependent layer shapes [37], [29], for example, image patch embedding size (E) will also impact all query sizes and FC layer's output sizes. With compound dimension pruning challenges and different attention computation mechanisms, our current tail effect analysis is not directly applicable onto the ViT-based architecture pruning, as shown in Figure 16. However, the fundamental parallel computing mechanism and the wave-based granularity of GPU

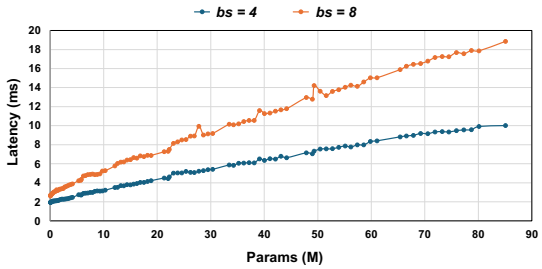

Fig. 16. We applied fine-grained pruning on VIT-Base. As we can observe, the model latency tends to be linearly correlates to the ratio of pruned num of heads, indicating the limitation of the current tail effect analysis on MHSA regarding the multi-step multi-head computation patterns, correlated FFA computation changes, etc. Latency measured on 3080Ti with batch size = 8/4.

[6]The difference between dense and depthwise filter is the dense kernel is of shape $n \times n \times 512$, while the depth-wise kernel is only $n \times n \times 1$. The latter one is mainly used in light-weight models like MobileNets [31].

content may change prior to final publication. Citation information: DOI 10.1109/TCAD.2024.3404413

architecture still remains. Therefore, we leave the compound tail-effect analysis on ViTs as future work.

VIII. Conclusion

In this work, we revisit the GPU tail effect, a classic parallel system issue, and shows it can cause significant GPU under-utilization and lower the GPU throughput for DNN inference. Detailed DNN workload characterization demonstrates the prevalence of GPU tail effect across different DNN architectures is due to the unique deep structure and the light-weight layer workload, which exacerbates the tail effect in DNN inference. We then demonstrate two user cases with simple yet effective solutions to eliminate the tail effect and enhance the DNN run-time efficiency. With effectiveness, feasibility, and generalizability well proved, our optimization methods show outstanding DNN latency accuracy trade-offs, *e.g.*, 11%–27% latency reduction over state-of-the-art (SOTA) DNN pruning and NAS approaches.

Fuxun Yu received the B.S. degree from Harbin Institute of Technology, Harbin, China, in 2017. He received his Ph.D. degree in the Department of Electrical and Computer Engineering at George Mason University under the supervision of Prof. Xiang Chen. His current research interests include high performance deep neural network computing, full-stack DNN computing optimization, deep learning security, interpretability and explainability of deep learning.

Zirui Xu received the B.S. and M.S. degree from Beijing Jiaotong University, Beijing, China, in 2014 and in 2017, respectively. He received his Ph.D. degree with the Department of Electrical and Computer Engineering at George Mason University under the supervision of Prof. Xiang Chen. His current research interests include high performance mobile computing system, neural network model optimization, and mobile intelligent application robustness and security.

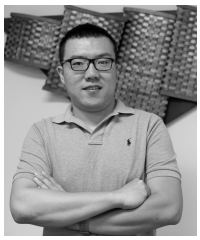
Longfei Shangguan is an assistant professor in the Computer Science Department. Before joining Pitt, he was a senior researcher at Microsoft, Redmond. Dr. Shangguan's research interests are in all aspects of IoT systems: from building novel IoT applications, solving security issues, all the way down to optimizing the network stack and designing low-power IoT hardware. His research has been recognized by a Google Research Scholar Award, MobiCom Best Paper Runner-up Award, Ubicomp Distinguished Paper Award, and an AIoTsys Young Scientist Award.

Di Wang is currently a Principal Research Manager with Microsoft. He earned his B.E. in Computer Science and Technology from Zhejiang University (2005), M.S. in Computer Systems Engineering from Technical University of Denmark (2008), and Ph.D. in Computer Science and Engineering from The Pennsylvania State University (2014). His research spans the areas of artificial intelligence, computer systems, computer architecture, and energy efficient system design and management. He has authored more than 40 peer-reviewed papers. He received 5 best paper awards and 2 best paper nominations.

Dimitrios Stamoulis is currently a Principal Research Manager at Microsoft AI, working on Neural Architecture Search (NAS) for object detection applications. He received his PhD in Electrical and Computer Engineering from Carnegie Mellon University under the supervision of Diana Marculescu. Previously, He received a MEng in ECE from McGill University, Montreal, and a Diploma in ECE from NTUA, Athens.

Rishi Madhok is currently a Senior Applied Science Manager at Microsoft and leads high-impact engineering and applied AI projects. He received his M.S. in Computer Science from Carnegie Mellon University. Before that, he received his B.S. degree from Delhi Technological University. His current research interests lie in object detection, semantic segmentation, and tracking models from aerial/satellite imagery.

Nikolaos Karianakis is currently a Principal Research Manager in Mixed Reality at Microsoft and leads high-impact engineering and applied AI projects. He received his Ph.D. in Computer Science from UCLA at the Vision Lab under the supervision of Stefano Soatto. His research spans the broader areas of Computer Vision and Machine Learning. His current focus is Computer Vision and Large Language Models for Aerial and Horizontal Imaging.



Ang Li is a tenure-track assistant professor in the Department of Electrical and Computer Engineering at University of Maryland College Park. He obtained Ph.D. from Duke University under the supervision of Professor Yiran Chen. His research interests lie in the intersection of machine learning and edge computing, with a focus on building large-scale networked and trustworthy intelligent systems to solve practical problems in a collaborative, scalable, secure, and ubiquitous manner.

ChenChen Liu received the M.S. degree from Peking University, Beijing, China, in 2013, and the Ph.D. degree from the ECE Department at the University of Pittsburgh, Pittsburgh, USA, in 2017. She is currently an Assistant Professor in the Department of Computer Science and Electrical Engineering at University of Maryland, Baltimore County. Her current research interests include brain-inspired computing system, machine learning, and emerging nonvolatile memory technologies.

Yiran Chen received B.S. (1998) and M.S. (2001) from Tsinghua University and Ph.D. (2005) from Purdue University. After five years in the industry, he joined the University of Pittsburgh in 2010 as Assistant Professor and was promoted to Associate Professor with tenure in 2014, holding Bicentennial Alumni Faculty Fellow. He is now the John Cocke Distinguished Professor of Electrical and Computer Engineering at Duke University and serving as the director of the NSF AI Institute for Edge Computing Leveraging the Next-generation Networks (Athena), the NSF Industry-University Cooperative Research Center (IUCRC) for Alternative Sustainable and Intelligent Computing (ASIC), and the co-director of Duke Center for Computational Evolutionary Intelligence (DCEI).

Xiang Chen is a Tenure-Track Associated Professor of the Department of Computer Science and Technology, the School of Computer Science, Peking University. He achieved his MS. and Ph.D. degrees with a major in Computer Engineering under the supervision of Dr. Yiran Chen at the University of Pittsburgh and finished the bachelor's degree at Northeastern University in China in 2010. After his Ph.D. graduation in 2016, he directly joined George Mason University, where he led 7 National Science Foundation (NSF) projects and achieved the NSF CAREER Award. In 2023, he joined Peking University. His research works focus on mobile and distributed computing systems, high performance intelligence computing, and related Edge, IoT, and CPS applications.

***Abstract*—Heart-related disease is one of the pre-eminent origins of mortality across the globe. Early and accurate detection of heart-related disease is essential to avoid an uncertain mishap. Peak detection is a pivotal step for the analysis of different spectral signals. The dislocation of peaks disrupts the detection accuracy of a heart-related disease. This study proposes a method for accurate R-peak detection of ECG signal. The acute R-peak detection of ECG signal is achieved using wavelet scattering transform. It eliminates the artifacts associated to signal with the help of inbuilt filters, proves reliable as it identifies the R-peaks at correct location. The wavelet scattering transform generates rational, instructive, and invariable translation representation of signals. The efficiency of the proposed method for R-peak detection is evaluated on pre-term infant ECG dataset available at physionet. The attained average accuracy and specificity for R-peak detection is 99.23% and 99.86% respectively. The proposed method outperforms the state-of-the-art methods namely continuous wavelet transform (CWT) and thresholding technique.**

Keywords— Electrocardiogram, R-peak detection, pre-term infant, wavelet scattering transform.

I. INTRODUCTION

A precise detection of R-peaks is necessary for recognition of cardiovascular diseases (CVDs) in electrocardiogram (ECG) signals. The R-peak identification is the major feature in the diagnosis of different cardiac pathologies. An electrocardiogram serves as a non-invasive tool used to detect the irregularities of heart, including the contractions in ventricular and atrial area, and supraventricular premature beats [1]. The advent of wearable ECG monitors underscores the significance of examining resilient automated R-peak detection in single-lead ECG signals. Although, several methods of R-peak detection have been proposed, it is still an important issue in terms of noise effects, alternative rhythms etc. The R-peak detection is the origin of arrhythmia recognition. Signal processing-based applications comprises of data collection, preprocessing, feature extraction, and classification models [2]. The characterization of the signal is achieved with time-varying electrical depictions that may generate from various sources. A typical ECG waveform includes the P wave, QRS complex, and T wave. The QRS complex represents the electrical depolarization of the muscles in the ventricular area of the heart [3]-[4]. The HRV assessment are generally influenced by noise level, including artifacts present in the raw signal that makes the R-peak detection complex. Noise sources [5] consists of power-line interference, baseline wandering, and electromyographic noise that affects the ECG signal in various aspects. It has been observed that R-peak detection is basically split into threshold methods, wavelet analysis method, and deep learning methods. The traditional thresholding method includes filtering the signal, increase the QRS complex, and detect the R-peak position with threshold decision. A classic threshold algorithm for R-peak detection is introduced in [6], utilizing the bandpass filter to denoise the ECG signal, then overall steps involving the first-order difference, and squaring to mention the QRS complex components. The R-peak detection using fast Fourier transform with denoising ECG signal is discussed in [7], achieved the sensitivity of 99.98%. To enhance the adaptive ability of peak detection, a weighted continuous wavelet transform is introduced in [8] that generates spectral peak characteristics in low-scale regions. In [9], a combined algorithm of biorthogonal wavelet transforms and run-length encoding is introduced for QRS complex detection achieved a low data error rate of 2×10^{-3}. Several other techniques of peak detection are illustrated in [10]-[12]. A brown exponential smoothing model [13] is implemented for an adaptive R-peak detection procedure, achieved precision and recall of 99.6% and 99.7% respectively. The challenge of noise interruption is removed with this implementation and proves well suited for noisy signals. Based on the noise suppression and peak detection, few decomposition techniques are introduced [14]-[15]. The objective of this study is to detect the R-peak of the pre-term individuals in terms of spectral analysis of the peaks illustrated using scattering transform. The purpose of the study is discussed as follows.

1) The wavelet scattering transform (WST) is proposed for R-peak detection of ECG signals.
2) Examining the wavelet analysis with scattering coefficients generated through WST.
3) The proposed method is employed on pre-term infant ECG database.

This manuscript is framed as follows. In Section I, the introduction and the related work corresponding to R-peak detection of pre-term infant ECG signal is discussed. The detailed information of proposed methodology and the database employed is exhibited in Section II. Section III outline the steps involved in implementing the proposed methodology. In Section IV, the results and discussions are presented. The conclusion is discussed in Section V

II. METHODOLOGY

A. Wavelet Scattering Transform

The WST generates systematic, revealing, and translation-invariant presentation of ECG signals. It exhibits resilience to disruptions and preserves class discriminability, making it highly effective for feature extraction [16]-[17]. The method consists of three-layered iterative signal transformation involving wavelet convolution, modulation, and denoising. The features are extracted using monotonous wavelet decomposition, local averaging, and complex modulus operations. Specifically, the high and low frequency components of respective signal are detected by the wavelet filter and the scaling function respectively. At each

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 27,2024 at 05:52:04 UTC from IEEE Xplore. Restrictions apply.

decomposition level, the characteristics associated with low frequency are improved. The balanced frequency characteristics are determined through local averaging following an assessment of the modulus of high-frequency signal coefficients. Through local averaging, the high-frequency data might be lost that can be restored utilizing the high-frequency wavelet transform [18]. Ultimately, after arranging the signal through various scattering routes, the stability is sustained between invariability and bias.

Assume the inspection of ECG signal is presented by $x(t)$. The low pass filter, $\phi_f(t)$ reflects the local translation invariant specifications of x at given scale T. The grouped wavelet indices $\mathbb{W}\mathbb{i}$, shows an octave frequency resolution q. The high pass filter bank is given by $\{\psi_f\}_{f\in\mathbb{W}\mathbb{i}}$ evaluated by widen the wavelet ψ. The convolution $(x * \phi_f(t))$ develops a confined translation invariant characteristic of x, exhibiting the information loss of high frequency. Those high frequencies can be retrieved through wavelet modulus transform and discussed in following steps.

Step1: $|W_1|x = \{C_o x(t), |x * \phi_{f_1}(t)|\}_{f_1\in\mathbb{W}1}$

The first order scattering coefficients after evaluating the mean of wavelet modulus coefficients with ϕ_f is

Step2: $C_1 x(t) = \{|x * \psi_{f_1}| * \phi_f(t)\}_{f_1\in\mathbb{W}1}$

The information can be recovered by calculating mean, where low frequency unit is shown by $C_1 x(t)$ of the high frequency coefficients $|x * \psi_{f_1}|$, can be released by

Step3: $|W_2||x * \psi_{f_1}| = \{C_1 x(t), ||x * \psi_{f_1}| * \psi_{f_1}(t)|\}_{f_2\in\mathbb{W}2}$

Second order scattering coefficients is defined as

Step4: $C_2 x(t) = \{||x * \psi_{f_1}| * \psi_{f_2}| * \phi_f(t)\}_{f_i\in\mathbb{W}i}, i = 1,2$

Reiterating the process, the wavelet modulus convolution is given as

Step5: $V_m x(t) = \{|| |x * \psi_{f_1}| * \dots | * \psi_{f_m}|\}_{f_i\in\mathbb{W}i}, i = 1,2,\dots,m$

By averaging of $V_m y(t)$ with ϕ_f, m-th order scattering coefficients is calculated

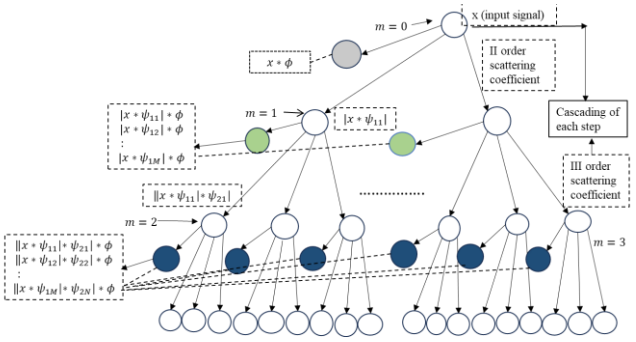

Fig1. The structure of wavelet scattering transform

Step7: $C_m x(t) = \{|| |x * \psi_{f_1}| * \dots | * \psi_{f_m}| * \phi_f(t)\}_{f_i\in\mathbb{W}i}$, $i = 1,2,\dots,m$

The scattering matrix is formed by the sum of scattering coefficients of all orders to verify the input signal characteristics, where the maximum decomposition order is presented by n, $Cx(t) = \{C_m x(t)\}_{0\le m\le n'}$

The wavelet scattering noticed the small variations in time span and dimensions of non-stationary signal which are tough to evaluate but reflects the heart condition [19]. Thus, WST is imposed to produce the robust arrangement of ECG which reduces the differences in one category of arrhythmia during the discriminability maintenance between different categories of arrhythmia. The implementation of WST for feature extraction is introduced in [20]. The formation of WST with scattering order at different layers is structured in Fig 1.

B. Dataset

The data of ten preterm infant is considered with postconceptional age of $29\frac{3}{7}$ to $34\frac{2}{7}$ weeks (average: $31\frac{1}{7}$ weeks) and weights of 843 gm to 2100 gm (average: 1468 gm) [21], available at physionet which is freely accessible [22]. A three-lead ECG signal was recorded for $20-70$ hrs per infant of sampling frequency 500 Hz. A compound ECG signal was registered at 250Hz for infant 1 and 5 in the absence of an ECG channel. The remaining recordings are performed at 500Hz. The whole information of pre-term infant database is summarized in Table1.

Table 1. Summary of pre-term infant ECG database at physionet

Infants	Age (weeks)	Weight (kg)	Duration (hrs)	Mean [SD]	Sampling freq
Inf_1	29 3/7	1.20	45.6	155	250
Inf_2	30 5/7	1.76	43.8	131	500
Inf_3	30 5/7	1.71	43.7	131	500
Inf_4	30 1/7	0.84	46.8	167	500

Inf_6	30 1/7	1.14	48.6	137	500
Inf_7	30 1/7	1.11	20.3	162	500
Inf_8	32 3/7	2.10	24.6	141	500
Inf_9	30 4/7	1.23	70.3	150	500
Inf_10	34 2/7	1.90	45.1	156	500

III. PROPOSED METHOD

Initially, the ECG signal is extracted from pre-term infant database consisting information of ten infants for different age groups. The extracted signal is normalized for precise and acute processing, to keep the different levels of signal in an appropriate range. The wavelet scattering transform (WST) is implemented on the normalized data, generating coherent, informative, and translation-invariant representation of ECG signals. The benefit of implementing the WST is to utilize the in-built filters. Thus, an extra step of preprocessing is removed by employing this technique. The technique works on both low and high frequency signal at different levels with scattering coefficients. The 2D time-frequency scalogram is generated using WST, represents the amplitude and location of peaks. The energy intensity can be estimated through the formation of peaks, which also separates the noise signal from the original signal. The scattering matrix is generated after combining all scattering coefficients obtained at each level from WST. The matrix obtained after combination is investigated through average of samples at different scales.

An automatic selection of scales corresponding to maximum energy intensity is performed. Thus, the maximum wavelet analysis at a selected scale is achieved that helps to notice the R-peak of the ECG signal. The overall flow involved in R-peak detection of ECG signal utilizing WST is presented in Fig. 2, consists of data acquisition, preprocessing using WST, and R-peak detection using wavelet analysis.

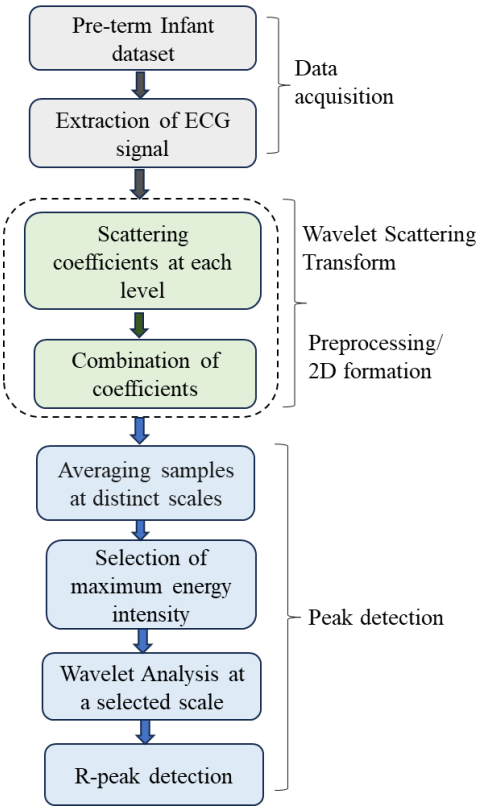

Fig 2. The proposed methodology for peak detection using WST

IV. RESULTS AND DISCUSSIONS

The simulations are executed on MATLAB 2021a using GPU: NVIDIA GEFORCE RTX 3070, processor: 11th Gen Intel(R) Core (TM) i7-11370H@3.30GHz, and memory of 128 GB with software: Win 10 64-bit operating system.

Initially, the ECG records are fetched from pre-term infant database for R-peak detection. The input signal, Inf_1 consisting 2500 samples is normalized an applied to the WST. The scalogram generated from WST conveys the spectral analysis of the respective signal. It represents the energy intensity of the specified peaks through which the R-peak detection of ECG signal is achieved. From WST, a resultant scattering coefficient matrix is produced which is analyzed at different samples. Finally, the averaging of these sample value reflects the selected time-scale. Thereafter, localized the R-peaks in the given range of samples. The results obtained through implementation of WST is illustrated in Fig. 3, represents the normalized ECG signal, the obtained 2D scalogram representation, the combined form of scattering coefficients, and the detected R-peaks of ECG signal with signal, noise, and wavelet analysis levels using blue, black, and green color respectively. The implementation of WST is made upon Inf_3 and the results obtained are discussed in Fig. 4. In Fig. 4, it is seen that the input signal of ten peaks of sample length 2300 is processed and after wavelet analysis, the number of R-peaks detected reduced to nine, shows the dislocation of peak to other scale. A random selection of samples is made and correspondingly, the detection accuracy of R-peaks is calculated using WST implementation, discussed in Table 2. The evaluation parameters named as accuracy and specificity are calculated and compared with the existing techniques for R-peak detection.

Accuracy (Acc.): It may be defined as the correctly identification of R-peaks to the total number of peaks in the ECG signal.

$$Acc. = \left(\frac{tp + tn}{tp + tn + fn + fp}\right) \times 100$$

Specificity (Spec.): It is defined as the ratio of the true negatives to all negative results obtained. It specifies how correctly the model identify the occurrences of negative class.

$$Spec. = \left(\frac{tn}{tn + fp}\right) \times 100$$

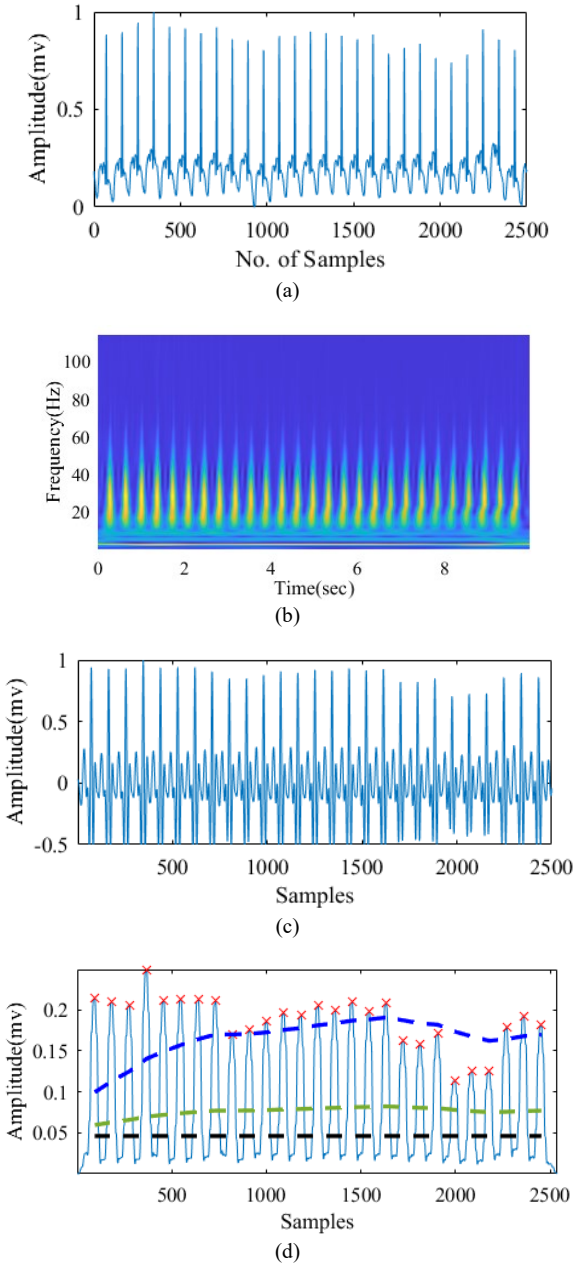

Fig 3. (a) ECG signal of infant *Inf_1* (b) Scalogram generated through WST (c) result obtained through different combinations of WST coefficients (d) R-peak detection using maximum wavelet analysis: black shows the noise level, green reflects the wavelet analysis, blue shows the signal level.

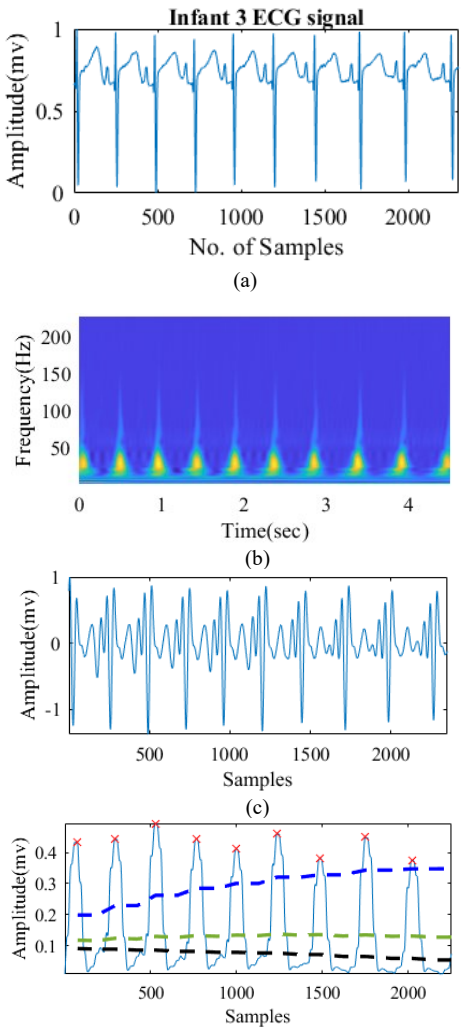

Fig 4. (a) ECG signal of infant *Inf_3* (b) Scalogram obtained through WST (c) Result obtained through different combinations of WST coefficients (d) R-peak detection using maximum wavelet analysis.

Table 2. The summary of detection accuracy at different samples of infants.

Infants	Samples	Total no. of Peaks given	Detected Peaks using WST	Detection accuracy (%)
Inf_1	3600	27	27	100
Inf_2	2500	23	23	100
Inf_2_17	4000	28	28	100
Inf_3	2300	10	9	90.0
Inf_4	1800	15	15	100
Inf_5	1300	12	12	100
Inf_5_9	3200	24	24	100
Inf_6	1000	8	8	100
Inf_7	1000	9	9	100
Inf_8	1200	11	11	100
Inf_8_11	1400	12	12	100
Inf_9	1700	16	16	100
Inf_10	2200	21	21	100

The proposed method is compared with existing methods to assess performance in terms of accuracy and specificity. Other methods such as continuous wavelet transform performed well but somehow lags in computational time which is an important parameter while handling a diseased subject. Few existing methods are compared with proposed method discussed in Table 3.

Table 3. Summary of comparing the proposed method with existing methods for R-peak detection using ECG signals.

The R-peak detection on the same database (pre-term infant database) is not available. Hence, discussed the R-peak detection with other databases in Table 3.

V. CONCLUSION & FUTURE SCOPE

The R-peak detection of ECG signal is a crucial step in diagnosing an arrhythmia disease. The dislocation of peaks from their original position disrupts the heart status, correspondingly decrease the detection accuracy of the respective disease. In this manuscript, executed an R-peak detection algorithm based on the wavelet scattering transform. The core of this framework is to detect the peak status on the basis of sample and scale group. The proposed method deals with the coefficients generated though WST, where wavelet analysis is utilized to detect the level of the obtained peaks. The verification of detected R-peaks of ECG signal with the original number of peaks is performed using a combined form of scattering coefficients, which is being averaged over different samples. The proposed methodology was tested on the preterm infant dataset and achieved an average accuracy and specificity of 99.23%, 99.86%. The computed average computational time of proposed method is 13 seconds. In future, peak detection can be processed utilizing the WST on real-time dataset.

ABSTRACT

During the conflict between Ukraine and Russia, hate speech targeted toward specific groups was widespread on different social media platforms. With most social platforms allowing multimodal content, the use of multimodal content to express hate speech is widespread on the Internet. Although there has been considerable research in detecting hate speech within unimodal content, the investigation into multimodal content remains insufficient. The limited availability of annotated multimodal datasets further restricts our ability to explore new methods to interpret and identify hate speech and its targets. The availability of annotated datasets for hate speech detection during political events, such as invasions, are even limited. To fill this gap, we introduce a comprehensive multimodal dataset consisting of 20,675 posts related to the Russia-Ukraine crisis, which were manually annotated as either 'Hate Speech' or 'No Hate Speech'. Additionally, we categorize the hate speech data into three targets: 'Individual', 'Organization', and 'Community'. Our benchmarked evaluations show that there is still room for improvement in accurately identifying hate speech and its targets. We hope that the availability of this dataset and the evaluations performed on it will encourage the development of new methods for identifying hate speech and its targets during political events like invasions and wars. The dataset and resources are made available at https://github.com/Farhan-jafri/Russia-Ukraine.

1 INTRODUCTION

Social media platforms have revolutionized the way people communicate and express their opinions. This has been a double-edged sword, as while social media platforms have strengthened unique opinions and promoted freedom of speech, they have also served as a fertile ground for cyberbullying, hate speech, and offensive language [22]. The unmatched broadcasting ability of social media platforms has made the dissemination of false information or hate speech a major social concern. As a result, several tools are being developed to help users identify harmful or deceptive content, including everything from sexualization and pornography to hate speech and disinformation [14]. Most of the research is focused on developing sophisticated machine learning algorithms to automatically detect and remove harmful content from their platforms. These algorithms use a variety of features, such as linguistic cues, social context, and user behavior, to identify and flag potentially harmful content [13]. In addition to automated tools, social media platforms are also developing policies and guidelines to govern user behavior and content creation Bhandari et al. [3]. These policies and guidelines are designed to promote responsible and respectful communication on social media platforms, while also protecting users from harmful content. The worldwide prevalence and growing significance of tweets have led to increasing studies on tweets. Several studies have been conducted to investigate the use of hate speech and other forms of offensive language on Twitter, with the aim of identifying strategies to curb their prevalence. Most of the research in tweets today focuses on a few key categories, such as ethnicity, sex, and religion. There are also several types of assaults where the target is mocked and dehumanized [20] that need a good focus of research.

On 24 February 2022, Russia launched a full-scale invasion of Ukraine by land, sea, and air, leading to a polarized response from the international community, with some supporting the invasion and others opposing it [38]. This led to widespread condemnation of

(a) No Hate **(b) Hate** **(c) Tar: Individual** **(d) Tar: Organization** **(e) Tar: Community**

Figure 1: Examples of tweets during Russia-Ukraine Crisis: *Task A*: Hate speech detection - Figure (a - 'No Hate' and b - 'Hate') and *Task B*: Target (Tar) detection - Figure (c - 'Individual', d - 'Organization', and e - 'Community')

the war and sanctions imposed on Russia. As a result, social media became a hub of activity as people expressed their opinions on the humanitarian and economic crisis caused by the invasion. Despite respectful discourse and discussion, there was also a significant amount of hateful content (as shown in Figure 1) targeting various groups of people [5].

Hate speech can have severe consequences for society, and the microblogging and social media platforms put in a significant effort to manage it, mostly through human moderators [21]. However, in political events such as invasions, the volume of hate speech can become overwhelming for human moderators to flag and regulate effectively [3, 31]. Therefore, there is a pressing need for an automated system to identify and manage such content [37]. Thus, to tackle this challenge, we propose a new dataset and benchmark them with multiple state-of-the-art algorithms. Our main contributions are as follows:

- We create and release a new large-scale dataset called **RUHate-MM**, which contains 20,675 manually annotated tweets to identify hate speech and their targets during the Russia and Ukraine crisis.
- We conduct a preliminary analysis of the data. We have set benchmarks with several state-of-the-art textual, visual, and multimodal models.
- Our experiments analysis shows that to address issues of hate speech, an integration of multimodal inputs is important.

The structure of our manuscript is as follows. Section 2 offers an overview of related work. In Section 3, we introduce the dataset, along with annotation guidelines, and present a comprehensive statistical analysis. Section 4 provides detailed information on the experimental methodology. Moving on to Section 5, we present the results and conduct a thorough analysis. Finally, Section 6 serves as the conclusion of the study.

2 RELATED WORKS

In previous studies, different aspects of mischief, such as offensiveness, false news, and hateful tweets, have been investigated separately [22]. Waseem and Hovy [36] annotated 16K tweets-dataset to classify a given tweet as sexist, racist, or neither. The aspect-based annotation is useful for understanding the theme of hate speech. Fortuna et al. [8] introduced a dataset comprising 5,668 tweets that were meticulously annotated across 81 categories of hate speech in the Portuguese language. Concurrently, Pereira-Kohatsu et al. [24] curated a dataset consisting of 6,000 Spanish tweets specifically addressing hate speech. Additionally, they provided an unlabeled corpus containing a substantial 2 million tweets. Recognizing the profound impact of political events on societal perspectives, it becomes imperative to construct datasets that encapsulate a pertinent political context. Kumar and Pranesh [15] addressed this need by presenting TweetBLM, a dataset intricately linked to the Black Lives Matter (BLM) movement. This dataset underwent manual annotation for the identification of hate speech. In a similar vein, Grimminger and Klinger [9] contributed to the landscape by introducing a dataset focused on the 2020 US elections. Their dataset comprised 3,000 tweets, each categorized based on its political stance toward a candidate. Moreover, the tweets were further classified into offensive and non-offensive categories, providing a nuanced understanding of the political discourse surrounding the election.

These studies hold a high importance in studying and understanding hate speech, bullying, and different related tasks. However, these studies focus on unimodal textual data. It is evident that textual data alone cannot provide the information a post wants to convey [2]. Nowadays, most social networks support multimodal content, and therefore it has become extremely important to tackle multimodal hate speech. Kiela et al. [14] proposed multimodal data for detecting hate speech in multimodal memes. Apart from telling if a meme is harmful or not, it is extremely important to identify who is being targeted in the memes. Annotating targets in addition to hate speech can provide valuable insights and help in understanding the nature and scope of hate speech. Sharma et al. [28] developed a meme dataset that contained 3,552 memes about US politics. The annotations of the memes in the dataset include information on whether or not the meme is harmful and the specific group, organization, community, or general public that it targets. The authors also propose DISARM, a multimodal neural architecture for detecting harmful targeting in memes. Similarly, Pramanick et al. [25] presented HarMeme, which is the dataset of 3,544 memes related to the COVID-19 pandemic. The annotation was done for the harm level as well as targets.

Despite the importance of political events, limited work has been done to address hate speech during these events such as the

Russia-Ukraine conflict. Hasan et al. [10] assembled a dataset comprising 10,861 Bengali comments discussing the Russia-Ukraine crisis on YouTube news channels. These comments were systematically categorized into three groups: 'Pro-Ukraine,' 'Pro Russia,' and 'Neutral.' In a parallel effort, Toraman et al. [33] meticulously curated a dataset featuring 5,284 English and 5,064 Turkish tweets. These tweets centered around contemporary issues such as the Russia-Ukraine war, COVID-19, and Refugees, with a specific focus on analyzing the spread of misinformation within the tweeted content. These efforts are important efforts in understanding Russia-Ukraine war sentiments. However, these datasets contain text-only information. The current social media users tend to use image along with text in their tweets. Such posts can propagate hate more easily as they can be more visually appealing than text-only tweets. To address this problem, Thapa et al. [32] presented a data set related to the detection of hate speech during the Russia-Ukraine crisis. They annotated 5,680 text-image pairs related to the crisis which were collected from Twitter. However, the authors only address the problem of hate speech detection but detection of intended targets of hate speech is also an important task which has received limited research interest. Apart from this, authors only annotate around 5,000 tweets which is a small dataset.

The significance of political events, coupled with the harmful consequences of hate speech, underscores the need for the development of hate speech detection tools for such contexts. Hate speech detection and target detection during political events such as the Russia-Ukraine war are necessary to understand the dynamics of hate speech, protect vulnerable groups, develop targeted interventions, and understand and assess the impact of hate speech on society. Furthermore, such analyses hold significant potential for enhancing the understanding of hate speech within the context of wargames, where the dynamics of conflict and the role of information warfare are increasingly complex. Table 1 shows a detailed comparison of previous work in the literature. As seen in the table, our study fills the gap of studying multimodal hate speech and related targets during political events such as the Russia-Ukraine war. To this end, we investigate hateful posts related to the Russia-Ukraine crisis and address two main tasks: (i) Task A: Detecting hateful posts – determining if a post is hateful or not. (ii) Task B: Identification of targets of hateful posts – identifying whether a given hateful post targets an individual, an organization, or a community.

3 DATASET

3.1 Data Collection

The development of the events started when Russia started to attack Ukraine on 22 February 2022. Since we were interested in the tweets around this event, we started to crawl tweets from 22 February 2022 to 28 March 2022 using Twitter API[1]. We collected the tweets with certain list of keywords namely *ukraine*, *putin*, *russia*, *zelensky*, *kyiv*, *kiev*, *kremlin*, *ukrainian*, *nato*, *russian*, *soviet*, *moscow*, *kharkiv*, and *donbas*. The tweets for keywords *kharkiv*, and *donbas* were collected from 1 March 2022 whereas, for all other keywords, tweets were collected starting from 22 February 2022. The tweets revolving around the Russia-Ukraine crisis had these keywords mentioned very frequently. The keywords *kharkiv*, and *donbas* were collected from 1 March 2022 as the crisis in those regions started later than 22 February 2023. To filter the data and ensure we collect appropriate data for our study, We included tweets in the dataset that contained media and were written in English. We eliminated tweets that had media in the form of videos or animations. Similarly, If the annotators do not find the tweet to be relevant, it was labeled as 'Non-Informative,' and such tweets were later dropped. The criteria for filtering tweets are given in section 3.2. The resulting dataset comprises 20,675 labeled tweets, each containing an image and text along with annotations. All tweets had unique tweet IDs and hence there are no duplicate data.

[1]https://developer.twitter.com/en/docs/twitter-api

3.2 Selection of image-text tweets

The tweet (image-text) selection procedure was quite straightforward. The dataset contained a collection of images that included aspects of hate, such as making derogatory comments about specific individuals, targeting a company, and raising issues relevant to the country. The dataset also contained cartoon photos that made fun of politicians, nations, and organizations. Images that were just text-oriented or blurry were not taken into consideration. We were focusing on the English language so the images that majorly included text in other languages such as Russian or Ukrainian were discarded. More concretely, the criteria for dropping data are as follows:

- The tweet contains non-textual elements such as videos, gifs, or audio recordings which do not provide any relevant information about the Russia-Ukraine conflict. We have only considered image as a media.
- The tweet does not have any context. The image and text do not contain any relevant information about the Russia-Ukraine conflict.
- The tweet has a language other than English. Since the tweets revolve around the Russia-Ukraine conflict, there were tweets in Russian and Ukrainian language as well.
- The tweet has a blurry image from which no relevant information can be gained. Such tweets are discarded on a case-by-case basis.
- The tweet contains only a link to an external website or a picture that does not provide any relevant information about the Russia-Ukraine conflict.
- The tweet has more than one image. For the purpose of creating this multimodal dataset, we take tweets with only one image as media to create a text-image pair from a given tweet.

Figure 2 shows some of the images that are filtered. In Figure 2 (a), it can be seen that the text is in the Russian language. Similarly, Figure 2 (b) has a blurred image, and hence no information can be obtained from the tweet. We hence discard such tweets.

3.3 Data Annotation:

Annotation of data was done in two folds, first, as Task A, we annotated the data for binary classes viz. 'Hate' vs 'Non-Hate'. In the second fold, as task B, we annotated the hate speech for target

Table 1: Summary of related datasets in the literature

Figure 2: Examples of discarded tweet images

labels. For the target labels, we annotated data into three labels viz. 'Community', 'Organization', and 'Individual'. As the name suggests, the class 'Hate' pertains to tweets that are offensive and contains hateful content such as personal attacks, homophobic abuse, racial abuse, or attack on the minority. The 'Non-Hate' class has tweets that report the events objectively and have no offensive or hateful content. Further details on annotation are discussed in Section 3.4. Similarly, for the annotation of targets, we defined targets as the following:

- **Community**: A community is a group of individuals who share common interests, beliefs, or characteristics and interact with one another. It can be defined as a social unit that shares a sense of identity, purpose, and values.
- **Organization**: An organization is a structured group of individuals, created to achieve a specific goal or set of goals. Examples of organizations are 'Republican Party', 'NATO', 'United Nations', etc.
- **Individual**: It refers to a person as an autonomous entity. In the context of our dataset, some of the most frequently noted individuals are 'Putin', 'Trump', 'Biden', etc.

Our team of annotators consisted of four individuals, both male and female, with diverse educational qualifications, including undergraduate, MS, and Ph.D. degrees, as well as researchers with experience in NLP and data collection. All the annotators had at least 10 years of formal English education and were familiar with Russia-Ukraine crisis. This diversity in qualifications helped to ensure clear instructions and maintain a high standard of annotations. The use of diverse annotators is an important aspect of data annotation in order to minimize potential biases [34]. In our study, the diversity in the annotator's background was intended to mitigate any potential bias in the annotation process. The manual annotation process was time-consuming and required significant effort from the annotators, but it helped to ensure a high level of accuracy in the annotations. The use of clear guidelines and regular quality checks were also employed to maintain consistency and reliability in the annotation process.

Three-Phase Annotation: Given the difficulty of labeling tweets that have both text and images, we implemented a 3-phase annotation process as explained in Section 3.4.1.

3.4 Annotation Schema

Clear-cut annotations are crucial in order to ensure that the dataset is labeled consistently and accurately. This is important as the results of any analysis or model development will be based on the labeled data. If the annotations are inconsistent or inaccurate, it can

lead to inaccurate or unreliable results. Clear-cut annotations also ensure that the dataset is representative of the underlying phenomenon being studied and that any conclusions drawn from the data are valid. Thus, we follow a 3-phase annotation. To quantitatively assess the inter-annotator agreement, we have used Cohen's Kappa (κ) (for agreement between two annotators) and Fleiss' Kappa (for agreement between multiple annotators) as our inter-rater agreement measure. We collectively refer to them as Kappa in further sections.

3.4.1 ***3-Phase Annotation***. For annotation of the data, an instruction set was created. The instructions were revised iteratively until all the annotators were clear about the instructions. To ensure that the annotation instructions are clear, we follow a three-phase annotation. The first phase involved a pilot run to make sure everyone understood the annotation. The second phase ensured that the revised instructions after the first phase were clear enough. The third phase eliminated the conflicts in the annotation.

- **Pilot Run:** As the first phase of the annotations, we run a pilot annotation for 50 tweets to ensure that everyone understood the annotation instructions. This is important as the task of labeling tweets can be challenging and it is important that everyone has the same understanding of what constitutes hate speech. There was some confusion among the annotators. Some annotators demanded annotation to be clear and we revised the instructions. The annotation instructions were then revised to address all the confusion.
- **Revised Instructions:** The second phase of annotation of 200 tweets by all four annotators was done to ensure that the instructions revised after the first stage were clear enough. During this phase, the annotators were given the revised instructions and asked to annotate the tweets. This phase was important to confirm that the revised instructions were clear and that the annotators were able to consistently identify hate speech.
- **Conflict Resolution:** The third phase was a group discussion of conflicts in the second phase of annotation, during which the annotators discussed any discrepancies in their annotations and reached a consensus. This phase was important as it helped to resolve any disagreements and ensure that all the tweets were labeled consistently. The group discussion also helped to make the instructions more apparent and provided an opportunity to identify any further ambiguities or inconsistencies in the instructions.

  The annotation guidelines is given in detail in Appendix A.1.

3.5 Inter-Annotator Agreement and Statistics:

To calculate the inter-annotator agreement, we have used Kappa (κ). Kappa is a statistical measure of inter-rater agreement for categorical items. It is a more robust measure of inter-rater agreement than simple percent agreement calculation, as it takes into account the agreement that can be expected by chance [35]. It is used to measure the level of agreement between two or more annotators on a categorical item. The coefficient ranges from -1 to 1, with values close to 1 indicating strong agreement and values close to -1 indicating strong disagreement. A value of 0 represents chance agreement. It's a widely used measure in social science and medical research. For our annotations, the inter-annotator agreement, Fleiss' Kappa for the **Task A** i.e. 2-class annotation of 'Hate' vs 'Non-Hate' ($\kappa_{2-Class}$) is 0.74. Similarly, Fleiss' Kappa for **Task B** i.e. 3-class target annotation ($\kappa_{3-Class}$) is 0.69. The value of Cohen's Kappa among different annotators for different stages of annotation is given in Table 2.

Table 2: Cohen's Kappa (κ) for annotation during different Phases by four annotators

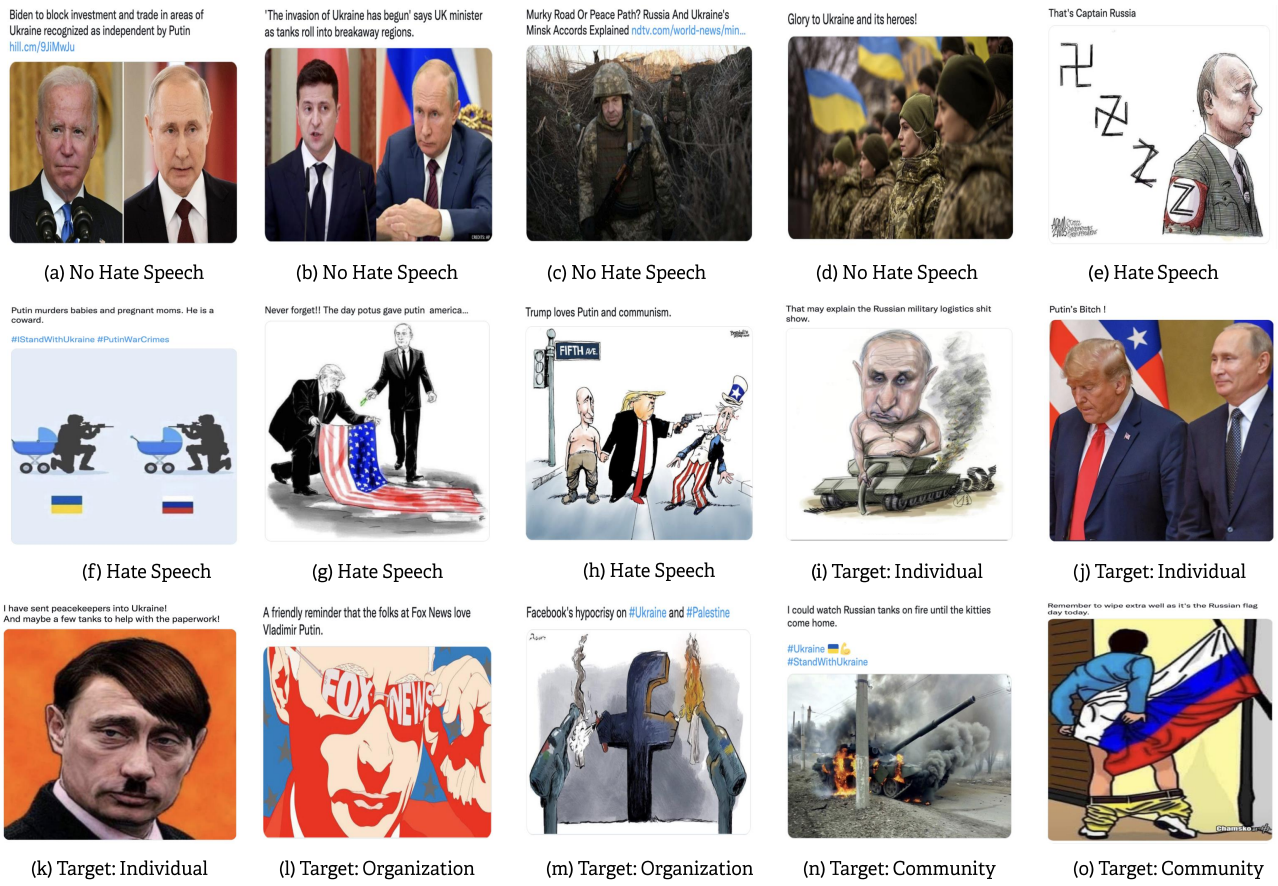
Phase	Annotators	$\kappa_{2-class}$	$\kappa_{3-class}$
Pilot Annotation	α_1 and α_2	0.49	0.53
	α_1 and α_3	0.50	0.51
	α_1 and α_4	0.55	0.56
	α_2 and α_3	0.47	0.52
	α_2 and α_4	0.57	0.60
	α_3 and α_4	0.50	0.49
Final Annotation	α_1 and α_2	0.76	0.74
	α_1 and α_3	0.78	0.76
	α_1 and α_4	0.79	0.76
	α_2 and α_3	0.80	0.73
	α_2 and α_4	0.73	0.71
	α_3 and α_4	0.81	0.73

3.6 Dataset Statistics

Our new multi-modal dataset, RUHate-MM includes 20,675 tweets, with 4,222 (20.33%) tweets being labeled as 'hate speech' label whereas 16,543 (79.67%) tweets are labeled as 'no hate' label (Table 3). The dataset statistics represent a true distribution in a real-world scenario where many posts are neutral, and only some are related to hate speech. The hate speech tweets were further annotated into three broad categories of targets. The targets are individuals, organizations, and communities. Among 4,222 hate speech tweets, 2,402 targeted individuals, 918 of them targeted organizations whereas the remaining 902 posts targeted specific communities. The statistics of data are shown in table 3. It also provides the average number of characters and words per tweet for each of the categories. These statistics can be used to gain an understanding of the overall composition and size of the dataset. The values in parentheses are calculated after preprocessing of text, which includes cleaning and normalizing the text data. Further details of text preprocessing can be found in Section 4.3. It can further be observed that the average character counts for hate and non-hate speech is somewhat distinctive. Figure 1 shows examples of annotated tweets whereas Figure 3 shows some more examples of targeted hate speech.

3.7 Exploratory Data Analysis

Table 4 presents the top 10 most frequent words in each class of the dataset along with their TF-IDF scores. TF-IDF (term frequency-inverse document frequency) is a statistical measure that is used to



(a) No Hate Speech (b) No Hate Speech (c) No Hate Speech (d) No Hate Speech (e) Hate Speech

(f) Hate Speech (g) Hate Speech (h) Hate Speech (i) Target: Individual (j) Target: Individual

(k) Target: Individual (l) Target: Organization (m) Target: Organization (n) Target: Community (o) Target: Community

Figure 3: A few examples from our dataset. The tweets are annotated as hate and non-hate for *Task A*. Hate tweets are further annotated into targets (Tar) as an individual, organization, and community for *Task B*

Table 3: Dataset Statistics for RUHate-MM. The values in parentheses in average characters per tweet (Avg. Char) and average words per tweet (Avg. words) are calculated after preprocessing of text.

Problem	Labels	Tweets	Avg. Char	Avg. words
Hate Speech	Hate	4,222	54.56 (46.46)	9.94 (9.63)
	Non-Hate	16,543	56.14 (51.63)	10.22 (10.12)
Targets	Individual	2,402	53.80 (45.62)	9.87 (9.57)
	Organization	918	56.85 (48.31)	10.14 (9.84)
	Community	902	54.23 (46.79)	9.92 (9.58)

evaluate the importance of a word in a document or a collection of documents. The fundamental principle behind TF-IDF involves assigning weights to words based on their frequency within a document and their rarity across the entire corpus. The TF-IDF score for a word in a document is calculated as the product of its term frequency (TF) and inverse document frequency (IDF) scores. Words with higher TF-IDF scores are deemed more significant and relevant to the document in which they appear. This significance arises from their frequency within the document and their scarcity across the broader collection of documents.

Analyzing the presented table 4, it becomes evident that certain prominent personalities, such as Putin, Trump, Biden, etc., are consistently targeted more frequently in individual categories. TF-IDF aids in highlighting these key terms by emphasizing their importance within specific documents while considering their rarity across the entire dataset. This approach enables a more nuanced understanding of the distinctive features and themes associated with each class, shedding light on the salient words that contribute significantly to the characterization of each category.

4 EXPERIMENTAL SETUP

In this section, we describe our experimental setup and baselines.

4.1 Experimental Settings

We used the pre-trained models for each baseline and used the F1-score as the evaluation metric. We train all the models using Tensorflow and Pytorch on a Tesla T4 or Tesla V100 GPU, with 32

Table 4: Top-10 most frequent words in each class. The TF-IDF scores are given for each words.

All Posts		Hate Speech Posts		HS: Target Individual		HS: Target Organization		HS: Target Community

GB dedicated memory. For the unimodal text models, we import all the pre-trained models of transformers from the hugging-face library. Similarly, for the visual models, we import all the pre-trained models from the PyTorch Image Models library (timm) [23]. All the models we experimented with used Adam optimizer [4]. The hyper-parameters that can be supplemental to reproduce the experiments are given in Table 5.

4.2 Baselines

We established baselines using various techniques, including both unimodal and multimodal methods.

Unimodal Models: We used the following unimodal methods:

- **Textual Unimodal:** For textual models, we used Bidirectional Encoder Representations from Transformers (BERT) [7], DistilBERT (a distilled version of BERT) [27], optimized variant of BERT, i.e., RoBERTa [18] and Albert (A Lite BERT for Self-supervised Learning of Language Representations) [16].
- **Visual Unimodal:** For the image-based unimodal baseline methods, we used 4 pretrained methods viz. DenseNet [12], Visformer [6], Improved Multiscale Vision Transformers for Classification and Detection (MVITV2) [17] and VGG19 [29].

Multimodal Models: We employed 3 multimodal models that have been widely used in earlier research involving hate speech classification. The first is a combination of ResNet [11] and BERT, where we first trained ResNet and BERT on text and image data respectively, and then merged their representations using a linear layer. We also implemented the state-of-the-art model CLIP (Contrastive Language-Image Pre-training) in our study, which has shown remarkable performance in a wide range of vision-and-language tasks [26]. We also utilized ViLBERT (Visual-Linguistic BERT) in our study, which is a pre-trained transformer-based model that is specifically designed to handle vision-and-language tasks [19].

4.3 Text Preprocessing

Text preprocessing is important in any Natural Language Processing (NLP) task [1, 30]. In order to prepare the tweet text for further analysis, a preprocessing step was conducted to remove various non-alphanumeric elements, including but not limited to special characters, hyperlinks, mentions, and emojis. Special characters, such as punctuation marks and other symbols, were removed as they can add noise to the data and potentially impact the accuracy of subsequent analysis. Hyperlinks and mentions, which reference external web pages or other users respectively, were removed as they are not relevant to the content of the tweet itself and can also introduce noise into the data. Emojis, while commonly used in social media, were also removed as they are not part of the standard character set used in most natural language processing techniques, and thus could cause errors or inaccuracies in downstream analysis. Overall, the preprocessing step serves to clean and standardize the text data for further analysis, while ensuring that only relevant and meaningful content is retained.

5 RESULTS AND ANALYSIS

In this section, we report the performance of various models on both tasks viz. hate speech classification and target classification.

5.1 Unimodal Baseline Results

Table 6 summarizes the performance of different unimodal algorithms on our dataset in terms of $F1_{HateSpeech}$ (f1-score in hate speech detection) and $F1_{Target}$ (f1-score in target identification). The results for the unimodal textual models (BERT, DistilBERT, ROBERTa, and Albert) demonstrate competitive performance in hate speech detection, with F1 scores ranging from 0.749 to 0.798. Among these, BERT exhibits the highest F1 score, indicating its effectiveness in identifying hate speech instances.

In target identification, the unimodal textual models also showcase notable performance, with $F1_{Target}$ scores ranging from 0.644 to 0.679. BERT again emerges as the leading model in target identification.

For unimodal visual models (DenseNet-161, Visformer_small, MVITV2_base, and VGG19), the results in hate speech detection (ranging from 0.758 to 0.774) and target identification (ranging from 0.598 to 0.628) demonstrate a competitive performance across the board. DenseNet-161 achieves the highest F1-score in both hate speech detection and target identification among the visual models.

Table 5: Implementation Details of the Experiments

Modality	Models	Batch Size	Epochs	Learning Rate	Parameters	Image Encoder	Text Encoder
Textual	BERT	16	3	5×10^{-5}	110M	-	bert-base-uncased
	DistilBERT	16	3	5×10^{-5}	67M	-	distilbert-base-uncased
	RoBERTa	16	3	5×10^{-5}	125M	-	roberta-base
	ALBERT	16	3	5×10^{-5}	12M	-	albert-base-v2
Visual	DenseNet-161	16	5	10^{-5}	26.5M	densenet161	-
	Visformer_small	16	5	10^{-5}	39.5M	visformer_small	-
	MVITV2_base	16	5	10^{-5}	50.7M	mvitv2_base	-
	VGG19	16	5	10^{-5}	139.6M	vgg19	-
Multimodal	ResNet + BERT	16	5	10^{-3}	172M	ResNet-152	Bert-base-uncased
	CLIP	4	6	10^{-3}	63M	ViT-Large-Patch14	
	ViLBERT-CC	16	5	10^{-3}	112M	FasterRCNN	Bert-base-uncased

5.2 Multimodal Baseline Results

The performance of multimodal algorithms on our dataset is presented in Table 6, focusing on $F1_{HateSpeech}$ and $F1_{Target}$. The multimodal models, combining ResNet with BERT, CLIP, and ViLBERT-CC, exhibit enhanced performance compared to unimodal models.

In hate speech detection, the multimodal models achieve higher $F1_{HateSpeech}$ scores compared to their unimodal counterparts. Particularly, ViLBERT-CC stands out with the highest $F1_{HateSpeech}$ score of 0.848, indicating its superior ability in identifying hate speech instances when leveraging both textual and visual modalities.

Similarly, in target identification, multimodal models outperform unimodal models, emphasizing the effectiveness of leveraging both textual and visual information. ViLBERT-CC leads in $F1_{Target}$ with a score of 0.741, demonstrating its proficiency in identifying diverse targets within hate speech instances.

These results underscore the advantages of multimodal approaches, showcasing improved performance in hate speech detection and target identification compared to unimodal models on our dataset. The combination of textual and visual information proves to be a promising avenue for advancing the field of hate speech detection during politically charged events.

Table 6: Performance of different unimodal and multimodal algorithms on our dataset

Modality	Model	$F1_{HateSpeech}$	$F1_{Target}$
Unimodal Textual	BERT	0.798	0.679
	DistilBert	0.787	0.668
	ROBERTa	0.780	0.668
	Albert	0.749	0.644
Unimodal Visual	DenseNet-161	0.768	0.628
	Visformer_small	0.762	0.611
	MVITV2_base	0.774	0.625
	VGG19	0.758	0.598
Multimodal	ResNet + BERT	0.806	0.700
	CLIP	0.826	0.719
	ViLBERT-CC	0.848	0.741

5.3 Analysis

Multimodal models, leveraging both textual and visual information, consistently outperform unimodal models in hate speech detection and target identification. ViLBERT-CC particularly shines, showcasing superior performance and emphasizing the synergistic benefits of combining both modalities. This suggests a promising avenue for future research, highlighting the potential of multimodal approaches in enhancing the discernment of hate speech instances and the identification of diverse targets during complex socio-political events.

The benchmarked evaluations reveal areas for improvement in accurately identifying hate speech and its targets, indicating the intricate nature of the dataset. This opens avenues for refining existing models and developing novel approaches to address the unique challenges presented by hate speech during geopolitical crises. The release of our multimodal dataset contributes a valuable resource to the research community, fostering further exploration and innovation in hate speech detection. The dataset's annotations, particularly the categorization of hate speech targets, offer a nuanced understanding of the manifestations of hate speech during the Russia-Ukraine crisis.

6 CONCLUSION

This paper introduces a new multi-modal dataset for identifying hateful content on social media, consisting of 20,675 text-image pairs collected from Twitter, labeled for hate speech and their targets. The experimental analysis of the presented dataset has shown that understanding both text and image modalities is crucial for detecting hateful content. In future work, we plan to develop new multi-modal models specifically for hate-speech detection, with the goal of gaining a deeper understanding of the relationship between text and images. Another potential area of research could be expanding the dataset to include more languages and different types of social media platforms. Additionally, it would be interesting to explore the hate speech detection possibilities for more specific or nuanced targets.

A APPENDIX

A.1 Annotation Guidelines

A.1.1 Hate Speech. A post (text or image or both) that contains hateful content such as a personal attack, homophobic abuse, racial abuse, or attack on minorities.

- **Targeted language:** Hate speech during political events often targets specific groups based on their political beliefs or affiliations. This can include language that demeans, degrades, or dehumanizes a particular political group or individual.

- **Hostility and aggression:** Hate speech during political events often expresses hostility or aggression towards a particular political group or individual. This can include language that promotes or glorifies violence or hatred against a particular political group or individual.
- **Use of memes and images:** Hate speech during political events often uses memes and images to disseminate harmful messages that are intended to demean, degrade or dehumanize a particular political group or individual.

Further, it is important to note that sarcasm and political satire can be used to express hate speech, and they can be difficult to identify. Sarcasm and satire can be used to mask hate speech, making it more subtle and harder to detect. Sarcasm can be used to express hate speech in a way that is less obvious and less likely to be flagged as hate speech. Satire can also be used to express hate speech in a way that is intended to be humorous or satirical but can still be harmful. Annotators were trained to identify sarcasm and satire in tweets and understand the context in which it is used. They were also trained to differentiate between sarcasm and satire which is intended to be humorous or satirical and sarcasm and satire which is used to express hate speech. Annotation guidelines included clear examples of sarcasm and satire and how they can be used to express hate speech.

A.1.2 No Hate Speech. A post (text or image or both) reports the events or others' opinions objectively and contains no offensive or hateful content. To make guidelines clear, the following were discussed as the significant characteristics of non-hate speech.

- **Constructive criticism:** Non-hate speech during political events often includes constructive criticism of political figures, policies or parties. It can also include criticism of political events and happenings.
- **Factual and informative:** Non-hate speech on Twitter during political events often includes factual and informative content, it can be news, updates, and analysis of the political events.
- **Respectful and civil:** Non-hate speech during political events is respectful and civil in nature, it doesn't use derogatory language or hate speech symbols.
- **Lack of hostility:** Non-hate speech during political events does not express hostility or aggression towards a particular political group or individual.
- **Lack of misinformation or fake news:** Non-hate speech during political events does not spread misinformation or fake news, it is based on facts and credible sources.
- **Lack of targeting specific group:** Non-hate speech during political events does not target specific groups of people based on their political beliefs or affiliations.
- **Lack of sarcasm and/or political satire intended for hate:** Non-hate speech during political events does not use sarcasm or political satire to express hate speech.

A.1.3 Conflict Resolution Between Organization and Community Targets. Organization refers to a group of people who come together for a specific purpose, such as a business, non-profit, or government agency. An organization can have a clear leadership structure, a specific goal or mission, and a defined membership. Community refers to a group of people who share a common bond, such as geographic location, culture, or interest. A community can be more loosely defined than an organization, and it may not have a clear leadership structure or defined membership.

The guidelines for delineating organization and community are given below:

Community Targets:

- The tweet references a specific group of people based on their shared characteristics, such as race, ethnicity, national origin, religion, sexual orientation, gender identity, or disability with an intention of demeaning.
- The tweet references a specific geographic location or culture or specific interest or shared activity as the basis for the targeted group with an intention of demeaning it.

Organization Targets:

- The tweet specifically mentions the name of an organization or a business.
- The tweet references a specific goal or mission of the organization. The tweet references a specific set of actions or decisions made by the organization.
- The tweet references a specific leadership structure or hierarchy within the organization.

The annotation guidelines were exhaustive and the annotators regularly communicated the problems in annotations to each other. Some resolutions in annotation were made through meetings and annotation sessions. Annotators were able to distinguish between tweets that target an organization and tweets that target a community by analyzing the language used in the tweets and understanding the context in which the tweets were written.

A.2 Limitations

In this paper, we present a large-scale multimodal dataset for hate speech detection and target identification. We also present baselines for detecting hate speech and identifying targets using this dataset. However, there are several limitations to our work that should be acknowledged. First, our dataset is limited to tweets from a specific time period surrounding a political event, and may not be representative of hate speech in other contexts. Additionally, our dataset is based on tweets from a single microblogging platform, and it is not clear how well our approach would generalize to other platforms or modalities. Second, our annotation scheme for targets is based on broad categories (Individuals, Organizations, and Communities), and may not capture more specific or nuanced targets. Furthermore, the annotation process is subjective, and different annotators may have different opinions on whether certain tweets should be considered hate speech or not. Third, the baselines we provide are based on a limited set of features, and it is possible that other features or architectures could lead to improved performance. Finally, it's important to note that hate speech detection and target identification technologies can raise ethical concerns, such as the potential for misuse, bias, and invasion of privacy. These ethical concerns should be considered and addressed in the development and deployment of such technology.

Scalable and Cost-Efficient PoA Consensus-Based Blockchain Solution for Vaccination Record Management

Neetu Sharma[1] · **Rajesh Rohilla**[1]

Accepted: 17 April 2024

Abstract
The integrity of vaccination records is essential for protecting the public from deadly diseases. Currently, vaccination records are scattered across various health organizations' custody in a centralized manner, making them vulnerable to invalid alteration or even complete loss. The benefits of blockchain include immutability, integrity, availability, and transparency, which ensure that trustworthy vaccination records are easily accessible. This research aims to create a scalable and cost-effective proof of authority (PoA) consensus-based blockchain solution for vaccination record management. It can be beneficial to ensure that accurate records are available for scheduled vaccinations, medication, migration, education, or employment. Scalability, limited functionality, high execution costs, resource consumption, and store-house costs are all issues with current blockchain-based vaccination systems. By verifying the hash of vaccination certificates on the Ethereum blockchain, the suggested system preserves the accuracy of vaccination records. Vaccination records are stored off-chain through the interplanetary le system (IPFS) based on patient preference for scalability, availability, and store-house cost savings. Furthermore, the Proof of Work (PoW) consensus engine used by the current blockchain-based systems is extremely energy-intensive. The PoA consensus process employed by the suggested system was economical. Through the remix IDE, smart contracts with extra features and access controls are successfully implemented. The performance of the contracts is assessed by examining the execution costs of various transaction sizes. We presented a security analysis for detecting vulnerabilities using the Mythril tool. Additionally, we assessed the data availability using patient preference and IPFS-network parameters for optimal results.

1 Introduction

Vaccinations are a basic necessity for ensuring public protection against infectious diseases. They need to be mandated by the government [1] as a crucial solution for protection against communicable diseases [2], saving lives and economies during pandemics [3]. Vaccines stimulate the production of antibodies, safeguarding individuals from contagious illnesses [4]. This secured and immunized public contributes to broader herd immunity by preventing disease transmission to those who are not fully vaccinated.

Vaccination can also serve as an immunity passport for medical consultations, migration, education, employment, etc. [5], safeguarding public health. The digitization of vaccination records has addressed the practical challenge of patients maintaining hard copies obtained from various sources. However, it has introduced a new challenge of securing sensitive health information. Mismanagement of vaccination data can lead to delayed or erroneous treatment, impacting public health. Integrating various healthcare sector members who operate independently is a significant challenge. Traditional healthcare systems maintain vaccination records in centralized systems susceptible to single point failures and various attacks like DDoS, ransomware, etc. The lack of security, integrity, and interoperability in centralized systems leads to record blocking and breaches, eroding public trust in healthcare providers. Innovative strategies are needed to track and validate vaccination records by all authorized members and securely share data to combat pandemics and threats, as evidenced by the importance of reliable systems highlighted by COVID-19 [6]. Distributed technologies, such as blockchain, have emerged for data handling across multiple nodes [7], finding success in the business community, particularly in cryptocurrency and token markets [8]. Blockchain, when integrated with artificial intelligence, has the potential to create an innovative business environment [9], benefiting drug supply chains and drug discovery processes [10, 11]. Unlike centralized systems, blockchain ensures distributed control, preventing data alteration [12, 13]. Optimizing storage pressure is essential to leveraging blockchain's benefits in securing sensitive vaccination records and data from smart devices [14]. Additionally, governance policies are necessary for sustainable blockchain implementation [15].

1.1 Motivation

One of the most significant issues facing the healthcare industry is health data breaches [16], wherein hackers use stolen data for fraud. Over the past ten years, a significant number of incidents involving healthcare data breaches have occurred [17]. Protecting patient information is crucial for improving health.

Blockchain presents a promising solution to challenges in existing centralized systems, yet its application in vaccination management remains immature. Few COVID-specific prototype systems exist, with limited smart contract functionality, scalability, high execution costs, and storage cost issues. Additionally, existing blockchain-based systems employ a PoW consensus engine that consumes excessive energy. Establishing a proper information security policy to govern data shared with stakeholders is imperative, achieved by incorporating access controls as security provisions within the contract. This work focuses on PoA-based blockchain for lifelong patient vaccination record management, aiming to enhance smart contract functionalities to encompass the entire vaccination process at minimal execution fees. To address scalability, availability, and storage costs, we opt to store only the vaccination record hash in the Ethereum blockchain, with actual data stored in off-chain storage based on patient preference.

1.2 Contributions

We propose a decentralized model for managing patients' lifetime vaccination records. Utilizing the Ethereum blockchain enhances decentralization and network security, with the vaccination certificate hash stored to ensure integrity. A smart contract with additional functionality and access control checks is created at a low execution cost. This contract also handles complaints against health organizations to ensure smooth governance of the vaccination process on the blockchain network. Storage costs are optimized based on patient preference and IPFS-network parameters. Our key contributions include:

- Proposing a scalable and cost-efficient proof-of-authority (PoA) consensus-based blockchain solution for managing patients' lifetime vaccination records.
- Storing vaccination records off-chain in IPFS-based on patient preference for scalability, availability, and reduced storage costs.
- Developing a vaccination smart contract with additional functionality, successfully deployed over Remix IDE, with performance evaluated through analysis of execution costs with different transaction sizes.
- Utilizing the PoA consensus engine to reduce energy waste in mining vaccination data simultaneously by all network nodes and to expedite validation.
- Evaluating data availability based on IPFS-network parameters and patient preference, along with analyzing network parameters to optimize storage costs.
- Conducting a comparative analysis demonstrating that the proposed blockchain-based scheme outperforms existing schemes across various performance metrics.

1.3 Organization

The rest of the paper proceeds as follows: Sect. 2 introduces blockchain technology and its consensus mechanisms. Section 3 presents existing work related to blockchain-based data management systems, followed by Sect. 4, which discusses preliminaries and possible solutions for blockchain scalability. Section 5 provides an overview of the proposed work, including architecture, information flow, smart contracts, and patient preferences regarding data availability. Experimental results and discussion are offered in Sect. 6, analyzing data availability, execution cost, energy efficiency, and discussing comparative analysis in terms of different metrics. Finally, Sect. 7 concludes the paper.

2 Blockchain Technology

A blockchain is a decentralized computer network based on cryptography [18], with blockchain nodes serving to store copies of transactions and maintain the network [19]. Its primary use is secure transaction recording and sharing across multiple nodes, fostering trust. Satoshi Nakamoto founded blockchain technology [20, 21], with the bitcoin blockchain being its first application in 2008 for cryptocurrency transactions [22]. Following bitcoin's success, researchers have developed various blockchain-based frameworks for cryptocurrencies [23, 24], extending its applications beyond cryptocurrency to reinforce smart home security [25, 26], manage evidence in digital forensic investigations [27], copyright management [28], transparent voting systems [29], and more. Blockchain's advantages, investigated widely in literature, include facilitating fair exchange [30] and addressing password

forgetting issues [31]. The increasing demand for blockchain emphasises the importance of accountability and confidentiality [32], as it prevents intruder manipulation, granting access rights only to authorized users [33]. In blockchain networks, transactions are recorded within blocks added after the consensus process, with databases always online and transparent, accessible to permitted members with internet facilities. Furthermore, blockchain eliminates intermediaries, making processes cheaper and more streamlined.

The technology's basic features include security, integrity, immutability, transparency, and transaction availability [34], enabling verification without third-party involvement and ensuring data immutability [35]. It employs asymmetric cryptography for data block security [36], with each block dependent on its previous block to complete the encryption process. Transactions undergo trust verification through broadcasting, consensus, and auditing before being attached to blocks, which are timestamped and shared across each node, ensuring decentralization and lifetime data availability. Transactions are visible to all authorized participants, preserving transparency, integrity, and trust, with records traceable to their origin. Consensus mechanisms verify transaction data, eliminating the risk of duplicate records, while smart contracts facilitate automatic transactions based on pre-set conditions.

Figure 1 illustrates a blockchain transaction, where a digitally signed transaction request is disseminated to all network nodes through the gossip protocol [37].

Blockchain employs a public–private key pair for transaction signing [38], where a private key encrypts transactions and only corresponding public keys can decrypt them. Blocks are encrypted using hashes, with each block hash dependent on the previous block hash, current block data, and nonce [39]. Mining, the process of generating a valid hash for new block creation, involves complex math to find a suitable nonce and obtain an acceptable hash to meet difficulty requirements. Any change to block data necessitates re-mining subsequent blocks. Once consensus among validator nodes is reached, a new block is added to the chain, and the transaction is executed.

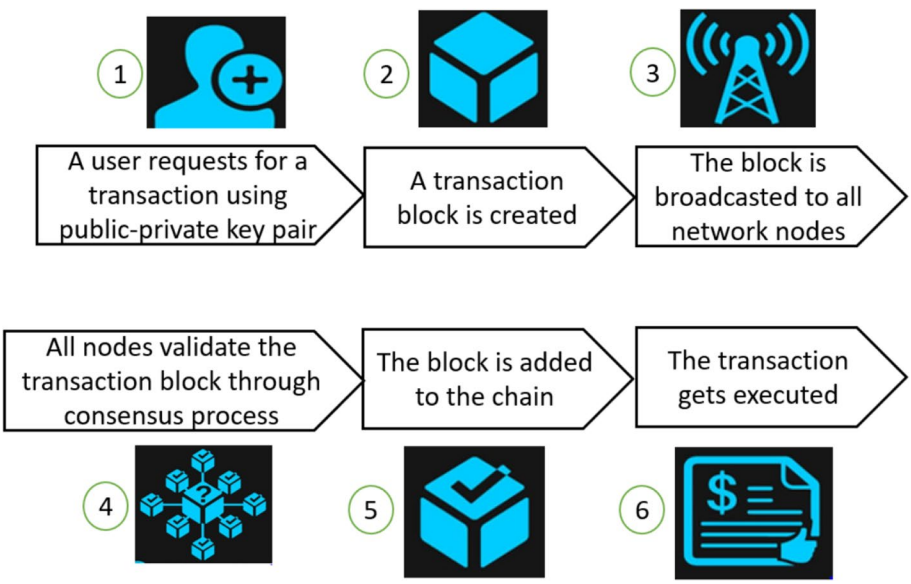

Fig.1 Blockchain transaction flow

2.1 Types of Blockchain

There are three types of blockchains: public, private, and consortium [40, 41]. A public blockchain is non-restrictive, allowing anyone to join as an authorized node to perform, verify, and record transactions. For example, bitcoin operates on a public blockchain, where individuals worldwide can become nodes. A private blockchain, on the other hand, is restrictive, with only authorized users permitted to join. The advantage of a private blockchain lies in its high transaction speed, while its weaknesses include lower security and transparency. A consortium blockchain, meanwhile, operates as a permissioned blockchain, with multiple organizations collaborating to run the blockchain platform.

2.2 Consensus in Blockchain

In the blockchain network, mathematical algorithms validate transactions and transaction blocks through consensus mechanisms, enabling communal maintenance of a sustainable ledger among members who may not trust each other. The three fundamental consensus engines are PoW, PoA, and Proof of Stake (PoS), each with its own benefits, costs, and trade-offs, with selection often contingent on application requirements. PoW, requiring complex mathematical algorithms and substantial computing power to confirm transaction blocks, offers high decentralization and security but consumes significant energy [42]. PoS mitigates energy consumption issues present in PoW, boasting low block creation time and energy usage, lower security and a monetary stake requirement for validating new blocks [43].

PoA, an enhanced version of the PoS consensus protocol, achieves consensus through authorized validators, with block sealing power limited to a set number of nodes. Validators' identities are at stake, as any faulty behavior tarnishes their reputation. In PoA consensus, with n validators, a maximum of b nodes where $b < n$ can be Byzantine to reach a consensus. PoA's cost-efficiency, throughput, and scalability make it a viable alternative to address PoW and PoS limitations, particularly suitable for applications requiring user trust in validators. The advantages of the PoA consensus protocol include: reduced energy consumption compared to other consensus schemes due to absence of block sealing competition; uniform transaction processing without dynamic transaction fees; suitability for decentralized application development; enhanced efficiency and throughput relative to other consensus models owing to its centralized reputation-based approach; and publicly shared identities of sealing nodes preventing fraudulent activities in the blockchain network, resulting in improved processing speed and reduced chances of network forks.

2.3 Comparison of PoA With PoW and PoS

PoW, a computationally intensive consensus protocol, results in slow block creation speed and fosters network forks due to block mining competition among nodes, complicating the consensus process. In contrast, PoA is energy-efficient and scalable, owing to the limited number of miner nodes in the network. PoA facilitates rapid development of decentralized networks and diminishes potential forks and network attacks. PoS, an energy-saving consensus scheme, allows nodes with higher stakes to become block sealers by locking their stakes in the network. Conversely, PoA operates as an identity-based consensus scheme for sealing new blocks, enhancing network scalability and cost-efficiency [44].

3 Related Work

This section addresses the work related to blockchain-based health data management systems, emphasizing the critical importance of medical data for healthcare [45]. The merging of digital identities from various medical records presents a significant challenge [46], with security, privacy, and authorization emerging as key concerns for real-world applications [47]. Security services are essential to ensure the secure capture, inventory, handling, transmission, and monitoring of healthcare records on the network. Blockchain has piqued the interest of investors across various sectors, including healthcare [48], offering a privacy-preserving method for the secure exchange of medical and government data [49]. While blockchain-based record management holds promise for enhancing the existing healthcare system [50], scalability remains a major research challenge [51].

Several prototypes and approaches for blockchain-based vaccination process security have been developed [1–5]. However, these prototypes lack comprehensive analysis, security, cost-efficiency, functionality to cover the entire vaccination process, and scalability. Additionally, decentralized applications aimed at supporting record-keeping for COVID-19 test reports and vaccination certificates suffer from scalability and functionality issues [5]. Previous studies have addressed security risks in cloud computing environments [52] and showcased secure sharing of Electronic Health Records (EHRs) using blockchain [53]. Moreover, applications of blockchain in information management have been reviewed [54], and proposals for cloud-supported electronic health (eHealth) systems leveraging blockchain for medical record management have been made [55].

Overall, the discussed implementations and studies emphasise the role of blockchain in ensuring the security, immutability, transparency, trust, and accessibility of recorded data, suggesting that blockchain could be the most effective tool for vaccination record management.

4 Preliminaries

4.1 Ethereum

Ethereum, founded by Vitalik Buterin in December 2013, is an open-source platform for building blockchain-based distributed applications, renowned for its execution of smart contracts [56, 57]. Smart contracts, computer programs stored on a distributed ledger, automate transactions when specific conditions are met, significantly expanding the scope of blockchain applications. The Ethereum Virtual Machine (EVM) enables machines to execute smart contracts compiled into EVM bytecode. These contracts are deployed onto the Ethereum network through contract creation transactions. Ethereum transactions comprise the following components:

- From: A 20-byte address of the transaction sender.
- To: A 20-byte address of the transaction recipient.
- Value: The amount (in wei) sent from sender to recipient.
- Data: Transaction inputs.
- Gas: A unit measuring the fee required for transaction execution.
- Gas Price: The amount of ether per unit of gas the sender is willing to pay for transaction execution.
- Gas Limit: The maximum gas set by the sender for the transaction.

4.2 Blockchain Scalability

Currently, blockchain faces scalability issues that limit its usability across various applications. Scalability refers to the limited capability of a highly distributed network to handle a large number of transactions and update ledgers within a short period of time. Transaction per second (TPS) can be calculated using the mathematical formula:

$$\text{Transactions per second} = \text{Transactions Per Block} / \text{Block Generation Time} \quad (1)$$

The above equation highlights that to increase transaction speed, the number of transactions per block should be high and the block generation time should be low. However, block generation time is typically fixed by blockchain platforms to maintain network stability. The number of transactions per block can be calculated using the formula:

$$\text{Transactions per block} = \text{Block Size} / \text{Average Transaction Size} \quad (2)$$

This equation demonstrates that increasing transactions per block can be achieved by either increasing the block size or decreasing the average transaction size. However, increasing block sizes may disrupt the harmony of the blockchain network by splitting the community. To expedite transaction validation, transactions can be partitioned and distributed across the network through sharding.

Traditional cryptocurrency-based Proof of Work (PoW) is an energy-inefficient consensus engine [58, 59]. Hence, throughput can be enhanced by adopting a more efficient consensus algorithm, such as switching from PoW to Proof of Authority (PoA). PoA boosts transaction speed, reduces energy waste by validators, and mitigates the risk of 51% attacks.

Blockchain systems often struggle to achieve scalability, decentralization, and security simultaneously. While Ethereum blockchains are secure and decentralized, they exhibit slow transaction speeds. On-chain scaling, which involves increasing block size and optimizing consensus mechanisms, may compromise decentralization and security. Therefore, improving the storage efficiency of smart contracts is crucial to enhance overall throughput [60], possibly achieved through the creation of lightweight blockchains [61].

4.3 Interplanatery File System

IPFS is a peer-to-peer file-sharing system designed for off-chain storage, enabling Off-Chain scaling without reliance on a blockchain network. It functions as a protocol for secure peer-to-peer data storage, encrypting all data files stored on IPFS with cryptographically generated hash values. This approach diminishes the computational overhead associated with mining large data files. IPFS empowers users to store and share data files within the network using content addresses rather than location addresses.

5 Proposed Work

5.1 Overview

In today's world, frequent relocations often result in individuals missing one or more vaccination records, either due to misplaced physical copies or poorly managed online records.

When such records are needed for scheduled vaccinations, illness management, migration, education, or employment purposes, individuals typically attempt to retrieve them from the relevant health organizations. However, current health organizations often maintain data in a centralized manner, leaving it vulnerable to alteration or loss due to cyber-attacks. The process of transferring vaccination data from hospitals often involves multiple hospital-to-patient communications, leading to delays that can be costly during times of illness. Moreover, individuals receive various vaccines throughout their lifetime, including Hepatitis B, Rotavirus, Haemophilus Influenzae type b, Poliovirus, Diphtheria, Tetanus, Pertussis, Pneumococcal, Meningococcal, Influenza, Measles, Mumps, Rubella, Varicella, Hepatitis A, Human Papillomavirus, Covaxin, Covishield, etc. The scattered nature of vaccination records complicates their management and retrieval. Centralizing different hospitals onto a single system is not a viable solution, as the database would be under the control of a single administrator and susceptible to tampering or loss. Therefore, there is a pressing need for the health ministry to initiate a decentralized system for maintaining immutable and trustworthy vaccination records accessible to any requesting entity throughout an individual's life.

Figure 2 illustrates the typical and proposed usecase scenario.

When a person moves out of town or country and urgently requires their past vaccination record for reasons such as illness, scheduled vaccinations, or applying for education or employment, the traditional process involves several steps:

1. The person, lacking some records, contacts the previous health organization where vaccinations were administered.
2. The health organization first authenticates and validates the person's request.
3. Subsequently, the organization takes time to issue a duplicate copy of the vaccination certificate to the person, with no guarantee of its integrity.
4. The person then submits the received record to the local health organization, academic institution, or employer, often resulting in delayed submission.

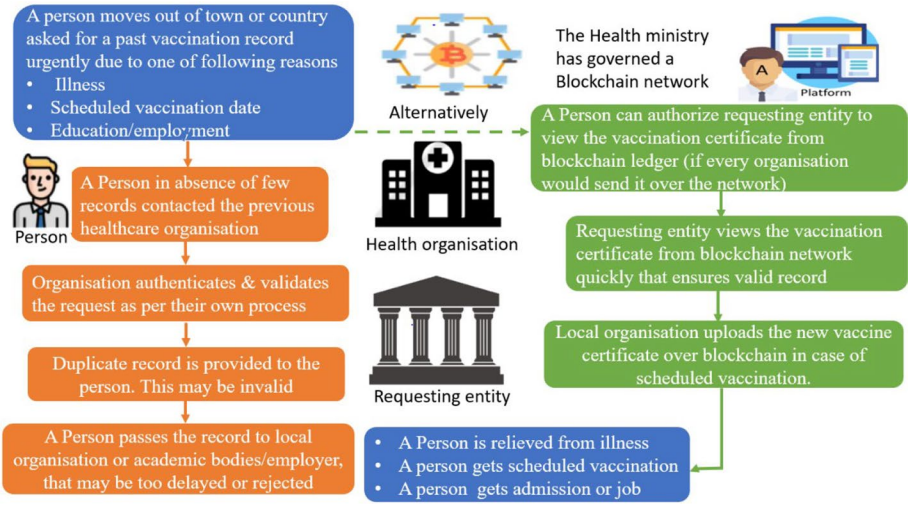

Fig.2 Typical and proposed usecase scenarios

In contrast, the proposed scenario streamlines the process:

1. The person can authorize the viewing of their vaccination record over a blockchain network by the requesting entities. This could become feasible if the health ministry mandates the uploading of vaccination records onto the blockchain network for all health organizations.
2. The requesting entity swiftly accesses the authenticated vaccination records from the blockchain network.
3. By verifying the valid vaccination certificate, the local organization can promptly provide the necessary treatment or vaccinations.
4. Additionally, the local organization uploads the vaccination record onto the blockchain network.
5. As a result, the person can easily address their illness, receive vaccinations, gain admission, or secure employment without encountering any obstacles.

5.2 System Architecture

A blockchain-based vaccination system enables users to update and retrieve vaccination records from any location and at any time. The objective is to guarantee the availability of accurate records for scheduled vaccinations or in cases of illness, thereby safeguarding patients against diseases. The proposed model for vaccination record management operates without the need for a central authority, yet it ensures accessibility of records to all requesting entities. The architecture of the proposed system, depicted in Fig. 3, consists of the following layers:

- Users layer comprises the Health Ministry, health organizations, patients, and requesting entities that initiate transactions on the blockchain network. The Health Ministry serves as the administrator, overseeing the entire network. Patients can authorize requesting entities to view their vaccination certificate using their patient ID and vaccination ID.
- The application layer serves as the frontend of the application. In the proposed model, this user interface facilitates interaction with the blockchain-IPFS network, enabling users to upload and retrieve transactions. Upon completion of a transaction, the sender receives a transaction receipt containing transaction details through this interface.
- The interface layer consists of APIs used to communicate with the blockchain and obtain required results, such as data retrieval or addition.
- The smart contract layer constitutes the logic of the network, ensuring adherence to all rules and regulations governing the blockchain network.
- The Decentralized Network and Storage layer comprise the Ethereum blockchain and IPFS. The Ethereum blockchain forms the foundation of the blockchain network, consisting of blocks (ledgers) that hold transaction data. The Ethereum blockchain network functions to broadcast uploaded transactions to all peer nodes, create new transaction blocks, mine transaction blocks, validate blocks by all authorized nodes, and append blocks into the ledger. The PoA consensus mechanism is utilized for mining purposes. Transaction hashes are stored in the blockchain, while complete transactions are stored on off-chain storage. Each transaction sender runs both a blockchain node and an IPFS node, with the API server serving as middleware. When publishing off-chain data, this middleware stores the original data in IPFS, then creates a blockchain transaction containing that data's hash. The middleware extracts the hash from the blockchain, then uses it to fetch the complete content from IPFS. The local IPFS node automatically

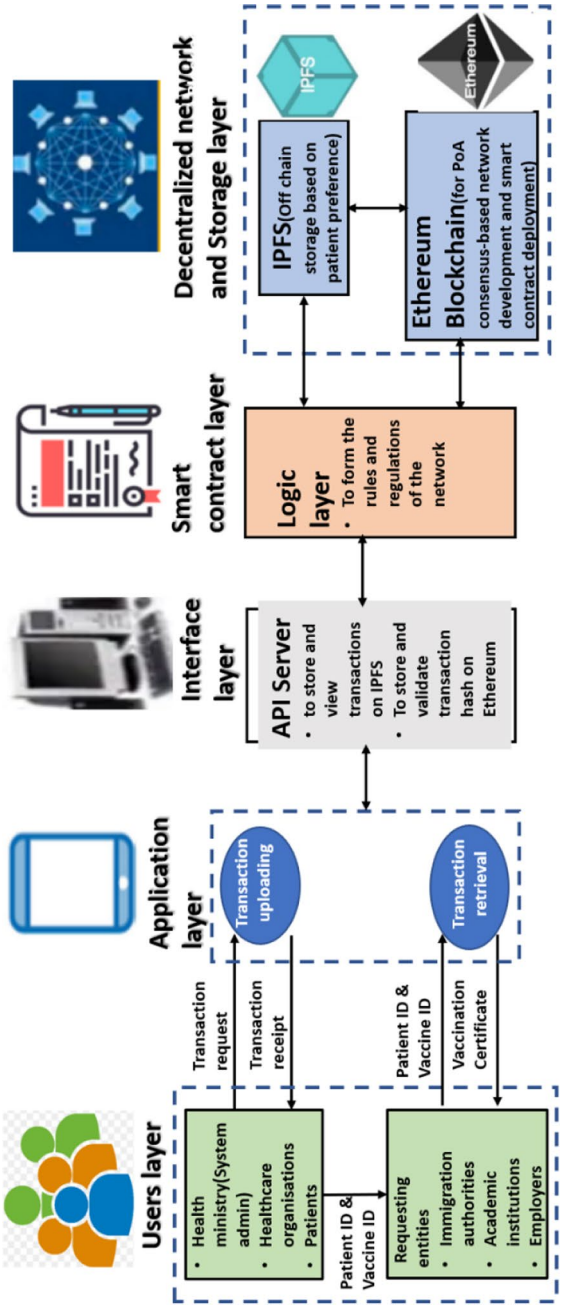

Fig. 3 Architecture of proposed decentralised vaccination system

verifies the retrieved content against the hash to ensure it hasn't been altered. IPFS is employed with the blockchain for scalability, and the patient preference feature is utilized to reduce storage costs.

5.3 Information Flow

The use-case diagram for all parties involved in the proposed system is depicted in Fig. 4. Initially, the Health Ministry adds health organizations with vaccination facilities. Patients can invoke registration requests on the network. Health organizations can register new patients in response to registration requests. Patients can view all health organization details, including addresses, available vaccines, and date-time slots. After reviewing organization details, patients add a vaccination request to any suitable health organization to schedule an appointment.

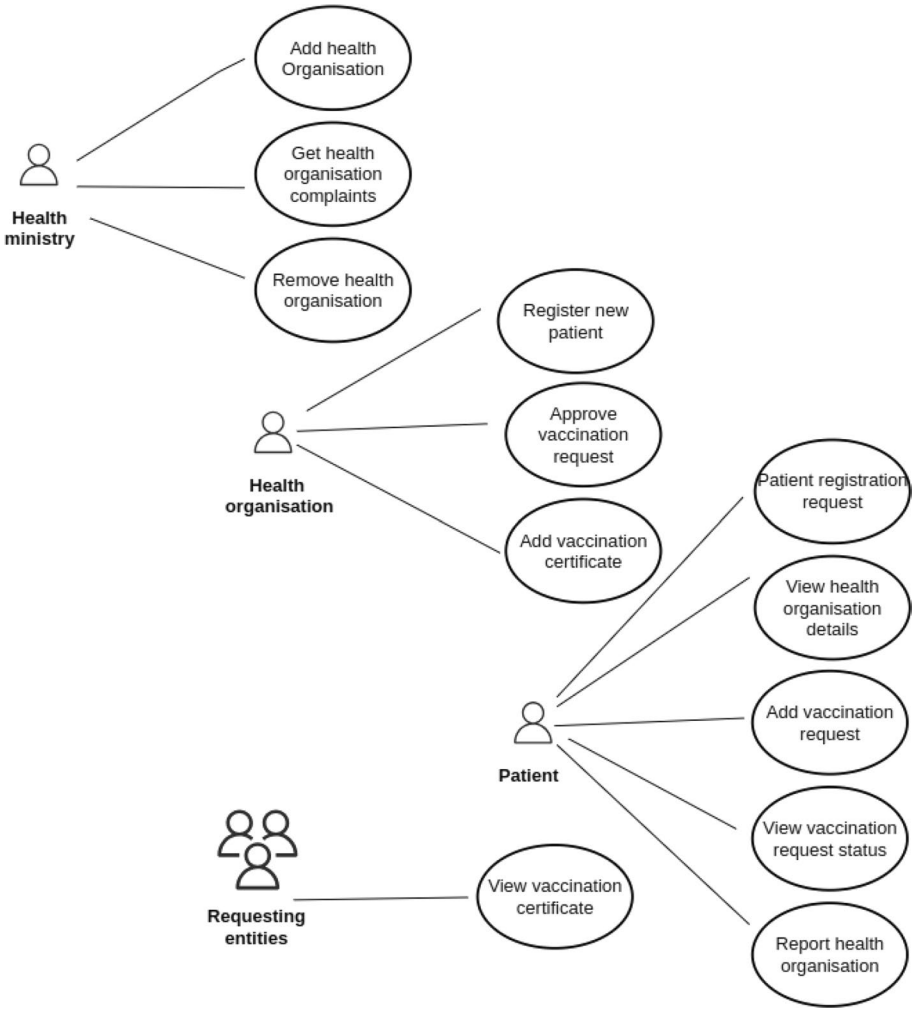

Fig. 4 Use-case diagram of proposed vaccination system

The health organization accepts the vaccination request by adding an approved status. Patients can then view the transaction request status and visit the health organization physically for vaccination. After the vaccination process, the health organization adds the vaccination certificate, which is accessible to any authorized requesting entity. Patients can report complaints against health organizations in cases of issues during the vaccination process. The Health Ministry can fetch reported complaints against any organization and remove health organizations if complaints exceed a predefined value. The Ethereum blockchain includes a smart contract for various functionalities.

Algorithm 1 Smart contract functionality of health ministry.

```
function addHealthOrganisation(Organisation ID, Address, Registration number, Available Vaccines slots)
    if msg.sender == Health ministry then
        if Organisation ID does not exist then
            Add health organisation to the Health organisation asset
        else
            Invalid transaction
        end if
    end if
end function
function getHealthOrganisationComplaints(Organisation ID)
    if Organisation ID exist then
        return Complaints reported against health organisation
    else
        Invalid Organisation ID
    end if
end function
function removeHealthOrganisation(Organisation ID)
    if Organisation ID exist then
        if Complaint reported > 1/3(Vaccination count of organisation) then
            remove health organisation
        else
            Invalid Organisation ID
        end if
    end if
end function
```

Figure 5 presents the workflow diagram, and algorithm 1 illustrates the smart contract functionality of the Health Ministry. Only the Health Ministry has the authority to perform the following functions:

- addHealthOrganisation(): Used to add health organizations, containing organization ID, address, registration number, and available vaccines with date and time slots.
- getHealthOrganisationComplaints(): Retrieves complaints reported against health organizations, containing organization ID.
- removeHealthOrganisation(): Removes health organizations if complaints are reported by more than one-third of vaccinated patients, containing the organization ID field.

Algorithm 2 outlines the smart contract functionality, and Fig. 6 presents the workflow diagram of a health organization. These organizations possess access control to invoke the following functions:

- registerNewPatient(): This function enables the health organization to register a new patient. Any health organization can initiate the registration of a new patient. It includes fields for patient ID, Aadhaar number, age, and data availability choice.
- approveVaccinationRequest(): This function is utilized to endorse vaccination requests. The health organization adds the "approved status" to the request, encompassing patient ID, date-time, requested vaccination, and status.
- 3. addVaccinationCertificate(): This function facilitates the addition of a vaccination certificate and increments the vaccination count. It includes fields for organization ID, vaccination ID, patient ID, and vaccination certificate.

Algorithm 2 Smart contract functionality of health organisation.

```
function registerNewPatient(Patient Name, Aadhaar Number, Age, Data Availability choice)
    if Patient ID does not exist then
        Add patient to the Registered patient asset
    else
        Invalid transaction
    end if
end function
function ApproveVaccinationRequest(patient name, Date Time, Requested vaccination, status)
    if Patient ID exist then
        Approve vaccination request by adding "approved" status
    else
        Invalid transaction
    end if
end function
function AddVaccinationCertificate(Organisation ID, Vaccination ID, patient ID, Vaccination certificate)
    if patient ID and vaccination ID exist then
        add vaccination certificate and increment vaccination count of organisation
    else
        Invalid transaction
    end if
end function
```

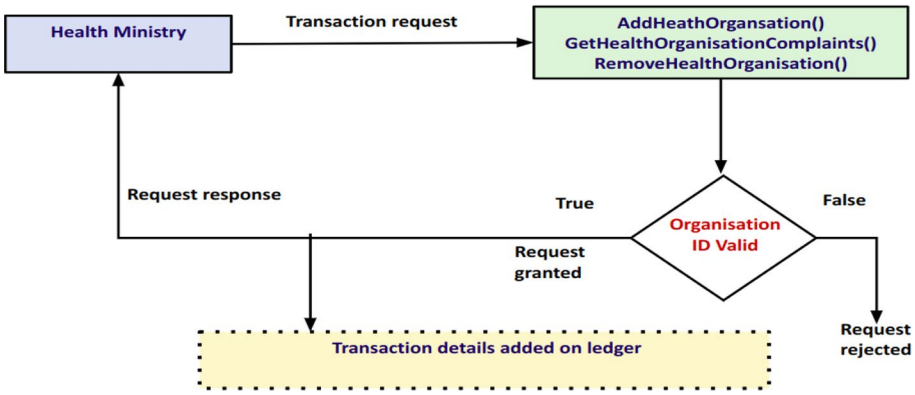

Fig. 5 Workflow diagram for health ministry functions

Figure 7 presents the workflow diagram, and algorithm 3 illustrates the smart contract functionality of a patient. Patients are the only ones with access control to perform the following actions:

Algorithm 3 Smart contract functionality of patient.

```
function patientRegistrationRequest(Patient ID, Aadhaar Number, Age, Data Availability choice)
    if Patient ID does not exist then
        Add patient to the registration request asset
    else
        Invalid transaction
    end if
end function
function ViewhealthorganisationOrganisation ID)
    if Organisation ID exist then
        return Health organisation details
    else
        Invalid Organisation ID
    end if
end function
function addVaccinationRequest(patient ID, Date Time, Requested vaccination, Organisation ID)
    if patient ID exist then
        add vaccination request to the vaccination request asset
    else
        Invalid transaction
    end if
end function
function viewVaccinationRequestStatus(Patient ID)
    if Patient ID exist then
        return Vaccination request status
    else
        Invalid Patient ID
    end if
end function
function ReportHealthOrganisation(Organisation ID)
    if Organisation ID exist then
        Increment complaint reported
    else
        Invalid transaction
    end if
end function
```

- patientRegistrationRequest(): This function allows the patient (or the parent in the case of a child patient) to submit a registration request. It includes fields for patient ID, Aadhaar number, age, and data availability choice.
- viewHealthOrganisationDetails(): This function is utilized to access health organization details, containing the organization ID field.
- addVaccinationRequest(): This function facilitates the submission of a vaccination request, encompassing fields for patient ID, date-time, requested vaccination, and organization ID.
- ViewHealthOrganisationStatus(): This function enables the patient to view the status of vaccination requests, containing the organization ID field.

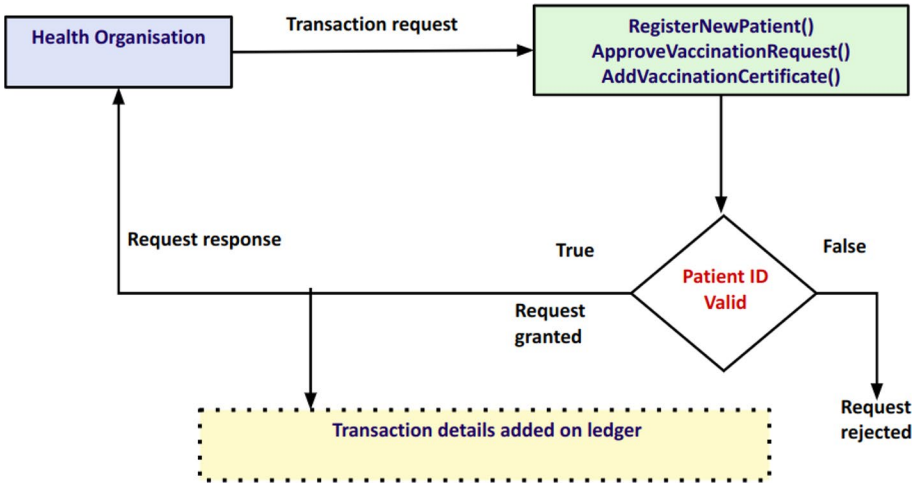

Fig. 6 Workflow diagram for health organisation functions

- reportHealthOrganisation(): This function is utilized to lodge a complaint against a health organization by incrementing the reported complaints. It includes the organization ID field.

Figure 8 presents the workflow diagram and algorithm 4 outlines the smart contract functionality of a requesting entity. Any requesting entity with a valid patient ID and vaccination ID can invoke the following function:

- View Vaccination Certificate(): This function allows any requesting entity to view the vaccination certificate. It includes fields for patient ID and vaccination ID.

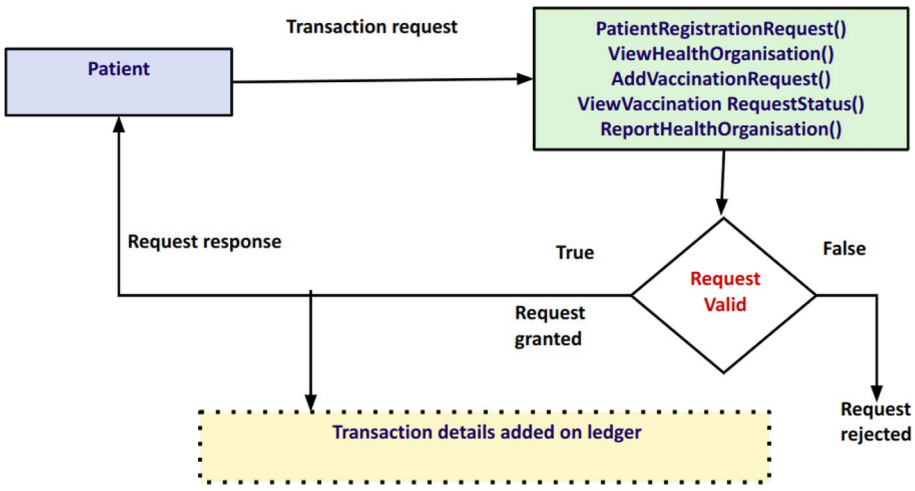

Fig. 7 Workflow diagram for patient functions

Algorithm 4 Smart contract functionality of requesting entity..

```
1: function viewVaccinationCertificate(Patient ID, vaccination ID)
2:     if Patient ID and vaccination ID exist then
3:         return Vaccination certificate
4:     else
5:         Invalid Patient ID and vaccination ID
6:     end if
7: end function
```

5.4 Patient Preferences of Data Availability

In the proposed system, patients specify their preferences for vaccination data availability as HIGH, MODERATE, or LOW in the transaction request. Based on these preferences, the system stores the data at the desired number of nodes in off-chain storage. The HIGH data availability preference may increase the probability of data availability at the cost of a larger storage size, while the low data availability preference may reduce the storage size at the cost of the risk of data unavailability. Therefore, we have devised a mechanism to assess the probability of data availability with specified patient preferences. In this section, Table 1 lists the notations used in the paper and their descriptions.

In this mechanism, the involved network parameters of the off-chain storage IPFS are denoted as TN, TDN, TIAN, and IADN. TN represents the total number of nodes, TDN represents the total number of data nodes, TIAN represents the total number of inactive nodes, and IADN represents the number of inactive-data nodes. Initially, we calculate the possible ways to obtain inactive data nodes from the total inactive nodes, active data nodes from all active nodes, and total data nodes from all nodes. This yields the probability of data unavailability as:

$$^{\mathbf{TIAN}}\mathbf{C}_{\mathbf{IADN}} * ^{\mathbf{TN-TIAN}}\mathbf{C}_{\mathbf{TDN-IADN}} / ^{\mathbf{TN}}\mathbf{C}_{\mathbf{TDN}} \tag{3}$$

Thus, the probability of data availability can be calculated as:

$$\mathbf{P} = \mathbf{1} - [(^{\mathbf{TIAN}}\mathbf{C}_{\mathbf{IADN}} * ^{\mathbf{TN-TIAN}}\mathbf{C}_{\mathbf{TDN-IADN}}) / ^{\mathbf{TN}}\mathbf{C}_{\mathbf{TDN}}] \tag{4}$$

For example, if TN = 100, TDN = 90, IAN = 10, and IADN = 0, this gives a probability of data availability (P) equal to 1.

6 Experimental Results & Discussion

To assess the performance of the proposed framework, we conducted experiments using an Intel Core i5, 8th generation CPU running on the Ubuntu 64-bit operating system with 12.00 GB of RAM. We utilized the Ethereum Geth environment to create the blockchain network and developed the smart contract in the Solidity programming

language. The smart contract of the proposed design was deployed and tested on the Remix IDE. The set of APIs to communicate with the blockchain was written in Node.js, while the algorithms to compute the IPFS-network parameters and probability of data availability were implemented in JavaScript.

6.1 Computation of IPFS-Network Parameters

In this section, we calculate the IPFS-network parameters, as shown in Algorithm 5. Initially, the data availability preferences of patients are retrieved from the ledger. This algorithm performs the following functions:

- getTotalDataNodes(): This function takes the patient preference of data availability and the total number of nodes as input and returns the total number of data nodes as output. If the input preference is high, the total number of data nodes would be 90% of all nodes. If the input preference is moderate, the total number of data nodes would be 75% of all nodes. If the input preference is low, the total number of data nodes would be 50% of all nodes.
- getTotalInactiveNodes(): This function takes the total number of nodes and the percentage of inactive nodes in all nodes as input and returns the total number of inactive nodes as output.
- getInactiveDataNodes(): This function takes the total number of nodes and the percentage of inactive data nodes in all nodes as input and returns the total number of inactive nodes as output.

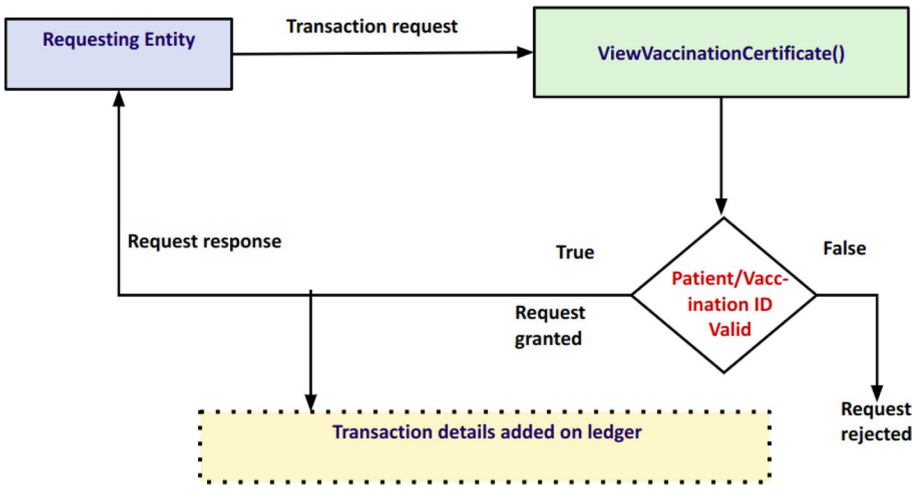

Fig. 8 Workflow diagram for requesting entity function

Algorithm 5 Computation of IPES-network parameters.

```
INPUT:Patient preferences PPDA, Total number of nodes TN, Total number of inactive
nodes in % TIAN%, Number of inactive-data nodes in % IADN%.
OUTPUT:Total number of data nodes TDN, Total number of inactive nodes TIAN,
Number of inactive-data nodes IADN
function getTotalDataNodes(PPDA, TN)
    if PPDA == "HIGH" then
        TDN% = 90
        TDN= TDN%*TN/100
        return TDN
    else if PPDA == "MODERATE" then
        TDN% = 75
        TDN= TDN%*TN/100
        return TDN
    else if PPDA == "LOW" then
        TDN% = 50
        TDN= TDN%*TN/100
        return TDN
    else
        TDN% = 50
        TDN= TDN%*TN/100
        return TDN
    end if
end function
function getTotalInactiveNodes(TN,TIAN%)
    TIAN= TIAN%*TN/100
    return TIAN
end function
function getInactiveDataNodes(TN,IADN%)
    IADN= IADN%*TN/100
    return IADN
end function
```

6.2 Computation of Probability of Data Availability

In this section, we compute the probabilities of data availability using Algorithm 6.

Table 1 Used notations with their descriptions

Symbol	Description
TN	Total nodes
TDN	Total data nodes
TIAN	Total inactive nodes
IADN	Inactive data nodes
(TN,TDN,TIAN,IADN)	IPFS-network parameters
Q	The potential methods for determining the total number of inactive nodes
R	Approaches that could be used to determine the number of active-data nodes from the total active nodes

P	Data availability probability

Algorithm 6 Computation of probability of data availability.

```
1: INPUT: Set of IPFS-network parameters(TN, TDN, TIAN, IADN)
2: OUTPUT: Probability of data availability P
3: function getProbabilityofDataAvailability(TN, TDN, TIAN, IADN)
4:     Q= combination(TIAN,IADN)
5:     R= combination((TN-TIAN), (TDN-IADN))
6:     S = combination(TN, TDN)
7:     P = (Q*R)/S
8:     return P
9: end function
```

This algorithm performs the following functions:

- getProbabilityofDataAvailability(): This function takes the set of IPFS-network parameters (TN, TDN, IAN, IADN) as input and returns the probability of data availability as output. This function determines the total number of data nodes, the total number of inactive nodes, the number of inactive data nodes, possible ways to obtain inactive data nodes from total inactive nodes, active data nodes from total active nodes, and total data nodes from total nodes, and finally the probability of data availability.

6.3 Data Availability Analysis

Patients have specified their data availability preferences as HIGH, MODERATE, and LOW. Based on these preferences, the system stores the data at the desired number of network nodes in off-chain storage. If the preference is high, data is shared among 90% of the total number of network nodes. If the preference is moderate, data is maintained at 75% of the total number of network nodes. If the preference is low, data is maintained at 50% of the total number of network nodes.

The probability of data availability can be calculated using Eq. 4 for different patient preferences. We have calculated the probability of data availability for each patient preference by considering the total number of nodes, the total number of inactive nodes (TIAN%) as a percentage of all nodes, and the number of inactive-data nodes (IADN%) as a percentage of all nodes. In our investigation, TN is kept at 100, while TDN can be 90%, 75%, or 50%, according to patient preference. The IAN values are taken as 10%, 20%, and 30%, and the IADN values are taken as 0%, 1%, 2%, 3%, 4%, and 5%. Initially, we investigated the probability of data availability for different patient preferences at 10% inactive nodes and 0–5% inactive-data nodes. Figure 9 illustrates the data availability probability with different user preferences at 10% inactive nodes.

Next, we explored the probability of data availability with 20% inactive nodes and 0–5% inactive data nodes. Figure 10 illustrates the data availability probability with various user preferences at 20% inactive nodes.

Finally, we investigated the probability of data availability for different patient preferences with 30% inactive nodes and 0–5% inactive-data nodes. Figure 11 illustrates the data availability probability with different user preferences at 30% inactive nodes.

The obtained results indicate that relatively better data availability is achieved when IADN ranges from 0 to 3%. Specifically, this lies between 0.9999 and 1.0000 at 10% inactive nodes, between 0.9933 and 0.9999 at 20% inactive nodes, and between 0.9932 and 0.9999 for high data availability choice. Similarly, for moderate data availability choice,

optimal results are obtained at IADN = 0–3%, with probabilities ranging from 0.9935 to 0.9999 at 10% inactive nodes, from 0.9864 to 0.9929 at 20% inactive nodes, and from 0.9848 to 0.9919 at 30% inactive nodes. Likewise, for low data availability choice, optimal results are again achieved at IADN = 0–3%, with probabilities ranging from 0.9934 to 0.9869 at 10% inactive nodes, from 0.8553 to 0.9721 at 20% inactive nodes, and from 0.8427 to 0.9613 at 30% inactive nodes. The probability of data availability exceeds 90% when the inactive-data nodes constitute up to 3% of all nodes at 10% down nodes. Thus, we conclude that the optimal probability of data availability can be achieved at low storage cost by ensuring that the number of inactive data nodes does not exceed 3% of the total network nodes.

6.4 Execution Cost Analysis

We developed the proposed Ethereum smart contract in the Solidity programming language. The smart contract of the proposed design was compiled and deployed in the Remix environment for testing. Figures 12 and 13 illustrates the Remix IDE interface representing the smart contract deployment read and write transactions.

We presented the logs triggered upon executing the smart contract function on the Remix ID environment in Fig. 14 and the execution cost analysis for different transaction sizes in Fig. 15. The maximum execution cost in the contract transaction is 4,291,404 gas, while all transaction functions have low costs. Additionally, during the testing phase, we endeavored to decrease execution fees by implementing various checks in the smart contract. These checks revert invalid transactions to avoid unnecessary execution fees resulting from the wastage of computational power. To enhance scalability and reduce costs, vaccination records are stored off-chain through IPFS based on patient preference. Furthermore, execution costs can be further reduced by consolidating multiple transactions into a single transaction.

6.5 Energy Efficiency Analysis

For the development of the blockchain network, we established 1 boot node and 4 peer nodes representing the users (Health Ministry, health organization, patient, requesting entity) in the Ethereum Geth environment. The boot node's role is to connect all the peers. The PoA consensus mechanism is employed for mining in the proposed system. Using the Puppeth tool, only one admin node representing the Health Ministry has been authorized to mine blocks. Since the mining process is not performed by all peers, it reduces energy wastage. Figure 11 illustrates the block sealing and block importing process.

It is evident from this figure that node1 can successfully seal a new block by committing new mining work. Since only node1 has the authority to seal a new block, when node2 or any other node attempts to commit new mining work, block sealing fails with the error message "Unauthorised signer." In our scheme, only one node out of four nodes consumes energy in mining a new block. Hence, our proposed PoA consensus-based system reduces energy consumption in sealing new blocks by a factor of 4 compared to the same system designed using the PoW consensus engine.

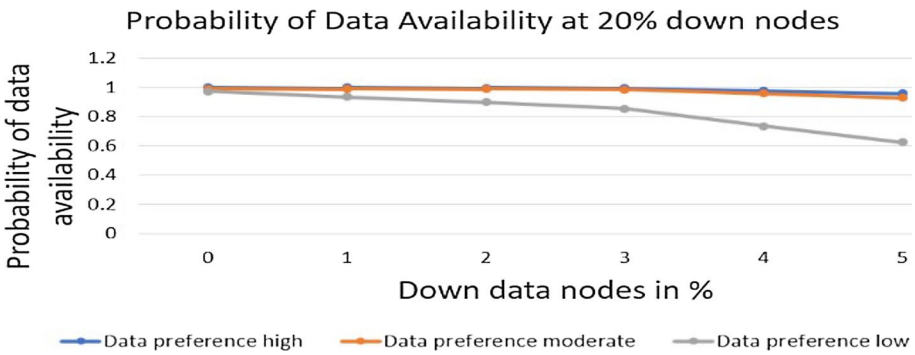

Fig. 10 Analysis of data probability at 20% inactive nodes

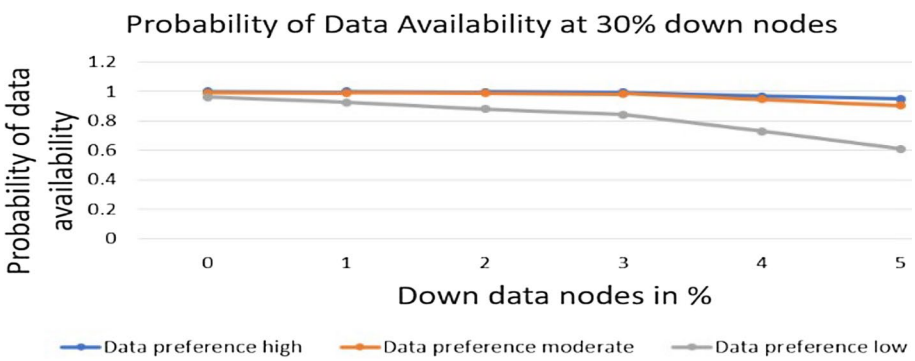

Fig. 11 Analysis of data probability at 30% inactive nodes

6.6 Comparative Analysis

A comparison of the proposed blockchain-based vaccination system with related work in terms of different metrics is presented in Table 2. Limited work related to blockchain-based

vaccination systems exists, with most authors focusing on COVID vaccination records and COVID vaccine supply schemes.

Limited work related to blockchain-based vaccination systems exists, with most authors focusing on COVID vaccination records and COVID vaccine supply schemes. In this work, we propose a blockchain-based scalable and optimal vaccination record management model that differs from prior blockchain-based models in the literature. It is not limited to COVID-19 vaccination but aims to create vaccination records for a patient's entire life, from childhood to death. Some authors have implemented their systems on the Hyperledger platform, while others have used the Ethereum platform. Our proposed system is deployed over the Ethereum private network. Furthermore, the smart contract functionalities used in our proposed system cover the entire vaccination process, which was missing in existing papers. Additionally, during the smart contract testing phase, we attempted to reduce execution fees by introducing various checks. These checks revert invalid transactions to avoid unnecessary execution fees due to the wastage of computational power. Execution costs were not evaluated in most existing works and were not analyzed for reduction. Our proposed system is energy-efficient compared to existing systems as it is based on the PoA consensus mechanism. Scalability is a major issue in the adoption of blockchain technology, and most existing works have not addressed it. In our proposed work, we attempt to provide an optimal solution. Off-chain storage, IPFS, has the potential to improve scalability, which was not widely used in existing works but is utilized in our proposed scheme. We introduced a patient preference option in our proposed system to make it cost-effective. Moreover, we analyzed the IPFS-network parameters to achieve optimal data availability at a low storage cost.

6.7 Security Analysis

The possible vulnerabilities or attacks that an intruder could perform to steal data are:

- DDOS: A malicious attempt to stop a targeted server, service, or network from operating normally by flooding it with traffic from several sources is known as a Distributed Denial of Service (DDoS) attack.
- Ransomware: A form of malware attack where the attacker encrypts and locks the victim's critical files and data, then demands money in exchange for the key to unlock and decrypt the information.
- Man-in-the-Middle (MITM) Attack: An attacker can obtain records by listening in on user communications with the system, changing messages, or taking the identity of a real user.
- Vulnerabilities in Smart Contracts: Although smart contracts are unchangeable once they are implemented, they can have flaws like reentrancy bugs or integer overflow/underflow vulnerabilities that could be used by hackers to alter data or take off funds.
- Phishing Attacks: Cybercriminals may utilize phishing tactics to deceive users into disclosing their private keys or login credentials. This information could then be exploited to obtain unauthorized access to the system.

Leveraging the benefits of blockchain, including immutability, integrity, availability, and transparency, the research has aimed to establish a scalable and cost-effective proof of authority (PoA) consensus-based blockchain solution for vaccination record management. Such a system holds promise for ensuring the availability of accurate records for scheduled vaccinations, medication, migration, education, or employment purposes. The immutable and decentralized nature of the proposed blockchain-based system prevents data theft. Because the recorded data is encrypted, dispersed among several nodes, and tamper-proof, it is very difficult for adversaries to access or change the data. Furthermore, safe data sharing is ensured by cryptographic methods like digital signatures and public-key encryption. The integrity and authenticity of vaccination records are confirmed by the Ethereum blockchain's verification of vaccination certificate hashes (Fig. 16).

Table 2 Comparison of the proposed vaccination scheme with prior works

Qualitative metrics	[1]	[2]	[3]	[4]	[5]	Proposed work

Cost analysis	×	×	✓	×	×	✓
Cost efficient	×	×	×	×	×	✓
Scalability	×	×	✓	×	×	✓
Data availability analysis	×	×	×	×	×	✓

×: Unavailable, ✓: Available

The security level of the proposed system against online data theft is relatively high due to various features that are listed below:

- The Ethereum blockchain's verification of vaccination certificate hashes protects records from unauthorized changes and tampering by ensuring their authenticity and integrity.
- By decentralizing data storage and lowering the possibility of single-point vulnerabilities, the off-chain storage of vaccination records via IPFS in accordance with patient preferences adds an additional layer of security.
- The system uses a Proof of Authority (PoA) consensus process, which is less vulnerable to attacks and more secure than the energy-intensive Proof of Work (PoW) consensus mechanism.
- Remix IDE-implemented smart contracts with extra features and access controls provide fine-grained control over transaction authorization and data access, reducing the possibility of unauthorized data access or manipulation.
- Frequent execution cost assessment and smart contract performance evaluation aid in the detection of anomalies or suspicious activity, enabling the early identification and mitigation of possible security threats.
- Network parameter analysis, including IPFS-network parameters and patient preferences, minimizes storage costs, minimizes attack surfaces, and minimises possibility to data theft.

We have adopted various strategies to mitigate potential vulnerabilities and enhance the security of the proposed smart contracts. We have analysed the smart contract to identify, validate and address all vulnerabilities. We have fixed all input data to prevent vulnerabilities such as integer overflow/underflow, buffer overflow, and other types of injection attacks. We have used standard libraries and implemented mechanisms such as function modifiers, access control, and permission checks to ensure that only authorized parties can invoke critical functions and perform state-changing operations. We have made the smart contract simple, modular and avoided unnecessary functionality that could introduce potential security risks.

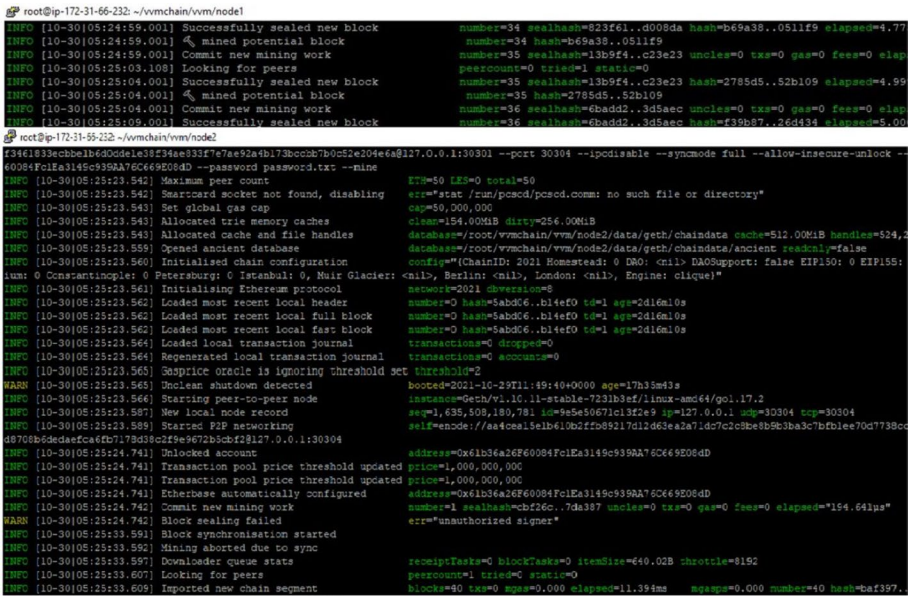

Fig. 16 New block sealing at node 1 and node 2

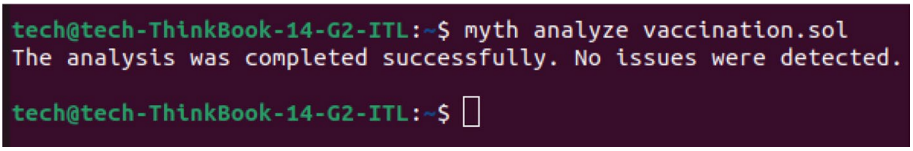

Fig. 17 Analysis report of smart contract vulnerabilities utilizing the mythril tool

We have performed the security analysis for potential vulnerabilities within the smart contracts of our proposed vaccination record management solution. Our model ensures trust, data integrity, availability, non-repudiation, and resilience against cyber-attacks. Although the Ethereum blockchain offers robustness, it remains susceptible to security threats such as network attacks. Network attackers exploit communication weaknesses through DDoS and Sybil attacks. MyThril is a tool renowned for its adeptness in identifying smart contract vulnerabilities like reentrancy bugs or integer overflow/underflow. Our analysis relies on threat analysis, dynamic symbolic execution, and control flow verification to scrutinize EVM bytecode for flaws. The audit of our smart contract yielded reassuring results, as depicted in Fig. 17. This analysis affirms the credibility of our system by providing concrete evidence of its security and demonstrating its robustness and effectiveness in managing vaccination records securely and efficiently.

7 Conclusions

This study proposes a PoA consensus-based blockchain solution for vaccination record management, which differs from prior blockchain-based models in the literature. It is not limited to COVID-19 vaccination records but aims to maintain vaccination records throughout a patient's life. This system enables healthcare organizations to upload vaccination records and allows requesting entities to easily view trustworthy vaccination records at any time. Hence, the proposed system will be beneficial in protecting the public from diseases and in situations where vaccination records are needed for non-medical purposes such as education or employment. Existing prototype systems suffer from limited smart contract functionality, scalability issues, high execution costs, and storage cost problems. Additionally, prior systems have used a PoW consensus engine, which is very energy-consuming, whereas our proposed system is based on PoA. The smart contract functionalities used in our proposed system cover the entire vaccination process with various checks to reduce execution fees. For scalability, availability, and storage cost reduction, vaccination records are stored off-chain through IPFS based on patient preference. All functionalities of the developed smart contract were successfully tested using the Remix IDE environment. We evaluated the performance of the deployed smart contract by analyzing execution costs with different transaction sizes. Moreover, we evaluated data availability based on IPFS-network parameters and patient preference. Furthermore, we analyzed network parameters to achieve optimal data availability at a low storage cost. Comparative analysis shows that our proposed blockchain-based vaccination system outperforms existing systems in terms of different metrics. Further, we presented a security analysis for detecting vulnerabilities using the Mythril tool and proved that our proposed smart contract is threat free.

Author Contributions The complete manuscript was written by Neetu Sharma. The first draft of the manuscript included the conception, design, and methodology of the work, which was reviewed several times. Then the design was implemented to produce the final manuscript. Rajesh Rohilla reviewed and approved the final manuscript.

Funding No sources of funding were received for the preparation of this article.

Availability of Data and Material Not applicable to this article as no datasets were analyzed during the current study.

Declarations

Conflict of interest Neetu Sharma and Rajesh Rohilla declare that they have no conflicts of interest.

Code Availability The authors built all code, and the software application that supports the execution of the code is openly available.

Semi-Empirical DFT Based Investigation of Electronic and Quantum Transport Properties of Novel GS-AGNR (N) FET

Anshul, *Student Member, IEEE*, and Rishu Chaujar, *Senior Member, IEEE*

***Abstract*—In this article, the electronic and quantum transport properties for the bulk configuration of armchair graphene nanoribbons (AGNRs) with varied number of carbon atoms along AGNR width (N) are investigated. The semi-empirical (SE) Density Functional Theory (DFT) approach is used to calculate the band structure, density of states (DOS), and transmission spectrum for the bulk configuration of AGNR. Further, the AGNRs are used in channel material to analyze the performance of field-effect transistors with Gate Stack (GS) architecture. The result shows that the bandgap value is higher for AGNR (N = 4) with a value of 1.98 eV compared to another bulk configuration of AGNRs. In addition to this, AGNR (N = 4) also shows an improved transmission spectrum. Moreover, the transmission spectrum at varied input voltages and projected local density of states (PLDOS) are also analyzed to study the performance of the proposed devices. The parameters mentioned above give a unique idea for evaluating the performance in terms of resonance peaks and electronic structure for device configurations. The off current (I_{off}) is remarkably reduced, and the switching ratio (I_{on}/I_{off}) is significantly improved in GS-AGNR (N = 4) FET compared with other device configurations. Owing to the enhanced switching, this paper highlights GS-AGNR (N = 4) FET as a suitable candidate for low-power applications such as low-power sensors, wireless communication, and medical devices.**

***Index Terms*—Atomic-scale, density functional theory (DFT) analysis, GS-AGNR (N) FET, quantum transport properties.**

I. Introduction

TO INCREASE the functionality of electronic gadgets; the new technology tries to shrink more components on integrated chips (IC). The co-founder of Intel, Gordon Moore, in 1965 predicted that the number of electronic devices would double every 18 months, i.e., the size of the devices would be reduced [1]. The scaling down in ICs will bring significant hurdles in the electronic industry. The majority of electronic devices are built using silicon technology, which has been widely used in the semiconductor industry. According to the International Roadmap for Devices and Systems (IRDS), transistor channel lengths will reach 5 nm by 2021 [2]. However, as the physical limits of silicon transistors are being approached, there is a growing demand for alternative materials and device architectures that can offer superior performance, energy efficiency, and scalability [3]. Graphene nanoribbon field-effect transistors (GNRFETs) have emerged as potential candidates for revolutionizing IC technology in this context [4]. Due to its outstanding electrical properties, graphene, a 2D carbon allotrope, has drawn much attention [5]. This unique material possesses amazing qualities, including outstanding electrical conductivity, excellent mechanical strength, great thermal conductivity, and gas impermeability [6]. As graphene possesses exceptional electrical characteristics, the absence of bandgap limits its employment in electronics. However, it is possible to create a bandgap in graphene through quantum confinement to make graphene nanoribbons (GNRs) [7]. The generally utilized edge configurations for GNRs are the zigzag and armchair edges [8]. Zigzag GNRs (ZGNR) shows a near-zero bandgap and exhibit metallic nature. In the AGNR category, there are three groups, N = 3p, N = 3p + 1, and N = 3p + 2, where N is the number of carbon atoms along AGNR width and p is a positive integer [9]. The 3p+1 and 3p groups in AGNR exhibit a direct energy gap and are semiconducting in nature, while the 3p+2 group is metallic in nature [10]. Semiconducting AGNRs are ideal materials for channels in GNRFET [10]. The materials with a high-κ dielectric constant are needed for the transistor gate oxide in order to upgrade the performance of nanoscale transistors and prevent Short-Channel Effects (SCEs) [11]. While choosing a high-κ dielectric material, a trade-off must be made between the high-κ dielectric and an appropriate bandgap for a transistor [10], [12]. There is an adverse relationship between the bandgap and dielectric constant. Implementing a high-κ dielectric layer on the AGNR channel can generate undesirably strong fringing fields at the source and drain contacts, which can cause various issues like bandgap degradation, threshold voltage instability, and mobility degradation [13]. The issues above, like bandgap degradation, threshold voltage instability, and mobility degradation, can be overcome using gate stack (GS) architecture [14]. In GS architecture, a combination of two dielectric layers has been used. Specifically, a low-dielectric layer of SiO_2 (κ = 3.9) has been sandwiched between the high-κ dielectric layer and the GNR channel. The narrow SiO_2 layer in GS stabilizes the high-κ dielectric ($LaAlO_3$) layer and AGNR substrate without

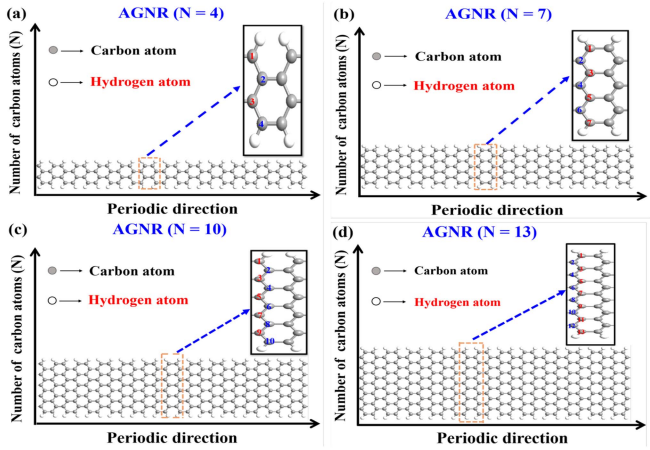

Fig. 2. (a)–(d) Optimized atomic structure of AGNR having different number of atoms used as channel material.

affecting the device's effective oxide thickness. The high-κ dielectric in GS will permit the increase in physical oxide thickness to prevent gate tunneling [15] and thus improves the carrier efficiency, reduce off current, and enhance the device performance [16]. Taking everything into consideration, we propose a Gate Stack Armchair Graphene Nanoribbon Field Effect Transistor (GS-AGNR (N) FET), where N is the number of carbon atoms along AGNR width used in the channel material of AGNR. In this research article, the authors primarily analyzed the electronic properties of AGNR having N = 4, 7, 10, and 13 using the DFT approach. These values of N belong to the 3p+1 group of AGNR because it has a better bandgap as compared to other groups. Further, the performance analysis of all device configurations is studied in terms of transmission coefficient, off current, switching ratio, and projected local density of states. All these parameters are calculated using the SE calculator with the Slater-Koster model having Density Functional Tight Binding (DFTB) parameterization.

II. Device Design and Description

The simulated architecture of the proposed device GS-AGNR FET is shown in Fig. 1. An AGNR layer of 50 Å is used as channel material considering the fact of scaling down [17]. The value of N in the AGNR varies for different types of device configurations. The optimized atomic structure for AGNR having values of N is shown in Fig. 2. From the above Fig. 2, it can be observed that the periodic direction of all widths is kept the same. The highlighted box in Fig. 2(a)–(d) shows one atom view, including the number of atoms along AGNR width. Further, the AGNR is rotated 30° to make a perfect interface with the ZGNR-type contacts, as shown in Fig. 1(b). The length of the drain and source is also taken 50 Å. A gate stacking architecture is used after a metallic gate. Step-increasing doping profile of n-type is used in all regions to make a junctionless configuration having a concentration of 3×10^{16} in the channel region and 5×10^{18} in the source and drain region. Gate potential plays an important role in calculating the electronic properties of a device, and hence, a metallic gate is employed over the dielectric layers [18]. Additional benefits of metal gates are their great thermal stability, high level of purity, and compatibility with Complementary Metal-Oxide-Semiconductor (CMOS) processing. Here, the thickness of the oxide layer (t_{ox}) is taken as 1 nm (0.50 nm $LaAlO_3$ layer + 0.50 nm SiO_2 layer). The t_{ox} is inversely related to the gate oxide capacitance (C_{ox}), i.e., reducing t_{ox} will increase the C_{ox}, which provides better control of the gate over the channel as the potential drop on gate oxide (Φ_{ox}) decreases. Further, the parameters can be co-related by a mathematical expression as follows [19]:

$$t_{ox} = \frac{\varepsilon_0 \varepsilon_r}{C_{ox}} \tag{1}$$

$$\Phi_{ox} = \frac{Q_0}{C_{ox}} \tag{2}$$

Now, putting the value of C_{ox} from (1) in (2)

$$\Phi_{ox} = \frac{Q_0 t_{ox}}{\varepsilon_0 \varepsilon_r} \tag{3}$$

where,

Φ_{ox} – gate oxide potential
Q_0 – surface charge density
t_{ox} – thickness of the oxide layer
C_{ox} – gate oxide capacitance
ε_0 – permeability coefficient
ε_r – the dielectric constant of the gate insulation

III. Simulation Methodology and Fabrication Techniques

The Atomistic Tool Kit (ATK) is used to carry out all the simulations. The semi-empirical (SE) calculator uses the Slater-Koster model with the DFTB parameter group in ATK to perform all the analyses. The Slater-Koster model is frequently used to create the tight-binding Hamiltonian matrix for a given system [20], [21]. This includes determining the matrix elements of the Hamiltonian between orbitals of atoms. The equation for the matrix elements of the tight-binding Hamiltonian in the Slater-Koster model is given as [21]:

$$H_{ij} = \sum_{\alpha\beta} t_{\alpha\beta}\left(R_{ij}\right) c_{i\alpha}^{\dagger} c_{j\beta} \tag{4}$$

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 09,2024 at 07:10:44 UTC from IEEE Xplore. Restrictions apply.

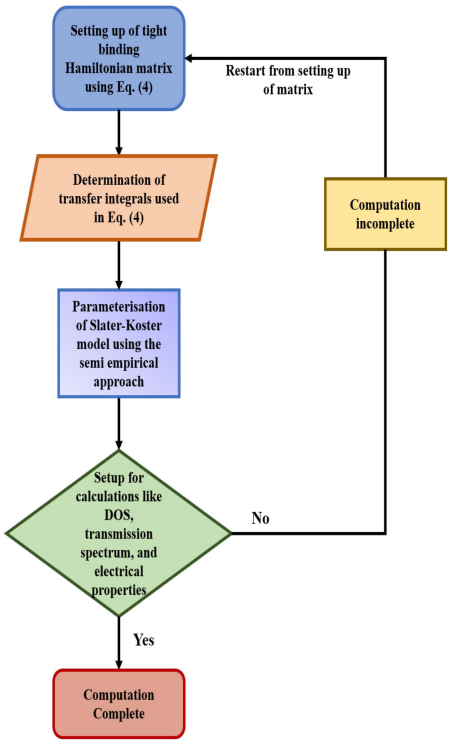

Fig. 3. Process flow chart for simulation approach.

where,

H_{ij} – matrix element of the Hamiltonian between atoms i and j

$t_{\alpha\beta}(R_{ij})$ – Slater-Koster transfer integral

$c^{\dagger}_{i\alpha}$ – creation operators for atomic orbitals

The non-equilibrium Green's function (NEGF) method without a self-consistent tight-binding function is adopted for the present study. The non-self-consistent portion of the tight-binding Hamiltonian is parametrized in SE using a two-center approximation, meaning that the matrix components are independent of the positions of the other atoms and only depend on the distance between two atoms. The Hartree potential is kept constant at 40 Ha, and the K-point sampling is taken $1\times1\times100$. The electrode temperature is kept at 300 K. Bulk configured AGNR electronic properties are calculated using the Fast Fourier Transform (FFT) Poisson solver, whereas device properties are calculated using the multi-grid type Poisson solver. Firstly, all structures are optimized using the Brenner_CH_2002 with a force tolerance of 0.05 eV/Å. Further, the electrical properties of a fully optimized structure are computed using DFT and NEGF formalisms. The process flow chart for the simulation approach is shown in Fig. 3. The step-by-step fabrication techniques for GS-GNRFET [22] is illustrated in Fig. 4.

IV. Model Calibration

The authors validated the simulation model by previously reported research findings in the literature [23]. To calibrate the simulation models, the MOSFET has been designed using

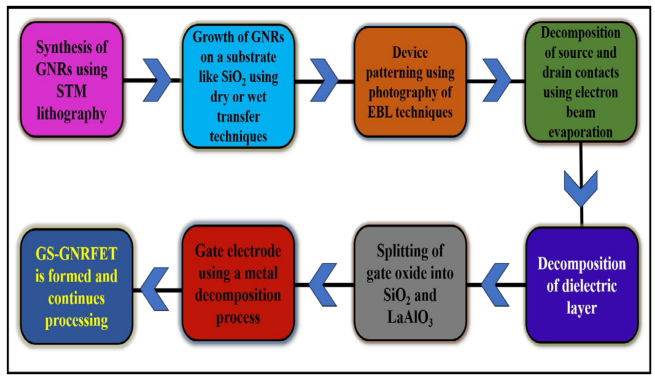

Fig. 4. Proposed fabrication flow for GS-GNRFET.

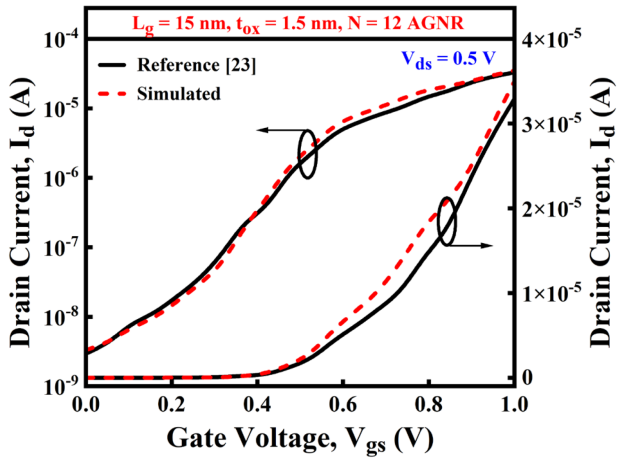

Fig. 5. Transfer characteristics calibration of simulated and reference data [23].

AGNR (N = 12) material in the entire channel region and fixed device dimensions (L_g = 15 nm, t_{ox} = 1.5 nm), the source and the drain are doped extensions of GNRs, and SiO_2 (κ = 3.9) as gate oxide as shown in reference [23]. The NEGF approach with a self-consistent tight-binding function is used to solve the Schrödinger equation to obtain device characteristics for MOSFET. Fig. 5 depicts the transfer characteristics at drain voltage, V_{ds} = 0.5 V, of the extracted data from the reference [23] and results obtained from the simulations. The left side of Fig. 5 shows the change in drain current (I_d) on the logarithmic scale with gate voltage (V_{gs}), while the right side of Fig. 5 depicts the linear change of I_d with V_{gs}. The logarithmic scale of I_d with V_{gs} depicts leakage current (I_{off}) in the device, aiding in the prediction of subthreshold slope, while the linear change of I_d with V_{gs} predicts the value of threshold voltage (V_{th}).

It can be observed from the left and right sides of Fig. 5 that the results of the simulations are consistent with previous findings. The near concordance between the simulated and reference data sets validates the choice of simulation models. Once the credibility of the simulation with the approach is established, a GS architecture is employed in the GNR-FET. The detailed simulation process of the present study for GS-AGNR (N) FET is discussed in Fig. 3.

V. Result and Discussion

In this section, the DFT analysis of AGNR with varied N belonging to the (3p+1) family is studied in terms of band structure, density of states (DOS), and transmission coefficient. Further, the AGNR is used as a channel material in GS- AGNR FET with the varied number of carbon atoms along AGNR width, and then the performance analysis of the proposed devices has been carried out using the DFT and NEGF approach.

A. DFT Investigation of Electronic Properties of AGNR With Different Values of N

The band structure and DOS for AGNR (N = 4, 7, 10, 13) is depicted in Fig. 6. The band structure is used to compute the band gap, which shows the number of energy levels that an electron can have as illustrated in Fig. 6(a), (c), (e), and (g). High symmetric k-points, or Dirac points, are plotted on the x-axis, and energy (eV) is plotted on the y-axis to represent band structures. The values of bandgap are 1.98, 1.21, 0.87, and 0.68 eV for AGNR (N = 4), AGNR (N = 7), AGNR (N = 10), and AGNR (N = 13), respectively. From the bandgap analysis, it is observed that the 3p+1 family of AGNR, i.e., N = 4, 7, 10, and 13 having values of p = 1, 2, 3, and 4, are semiconductor in nature and can be used as a channel material in FETs. It is also observed that the value of the bandgap decreased as the widths of AGNR increased. The width of AGNR is given by [24]:

$$W_{AGNR} = \frac{\sqrt{3}a_{cc}\ (N+1)}{2} \tag{5}$$

where,

W_{AGNR} – width of AGNR
acc – bond length of carbon-carbon atom in AGNR
N – number of carbon atoms along AGNR width

The width of AGNR is 1.8, 2.88, 3.96, and 4.2 nm for N = 4, 7, 10, 13 respectively. From the bandgap analysis, we observed that W_{AGNR} and bandgap have an adverse relationship. The number of unoccupied sites that are accessible for electrons to fill at a given energy level determines the DOS, as illustrated in Fig. 6(b), (d), (f), and (h). From these figures, the authors observed that there is no peak at the Fermi level in DOS. Also, in accordance with the energy states that are available, DOS exhibits similarities to band structure. The semiconducting nature of the AGNR is verified by the fact that there is no peak at the Fermi level in DOS. Further, the number of DOS peaks increases as the value of width (W_{AGNR}) increases. In AGNR (N = 4), the DOS peaks in the conduction band (CB) are observed at 1.46 eV and in the valance band (VB) at −0.68, −1.68 eV. In AGNR (N = 7), the peaks in CB are at 0.80 and 1.30 eV, while in VB, peaks are observed at −0.84 and −1.22 eV. In the case of AGNR (N = 10) and AGNR (N = 13), DOS peaks in CB are observed at 1.94 and 1.68 eV, and in VB peaks are observed at −1.74 and −1.48 eV. From the above analysis, the authors observed that as the value of N in AGNR increased, the large number of peaks shifted in CB. Further, an increase in electron energy opens more states to occupy an electron in the CB. The

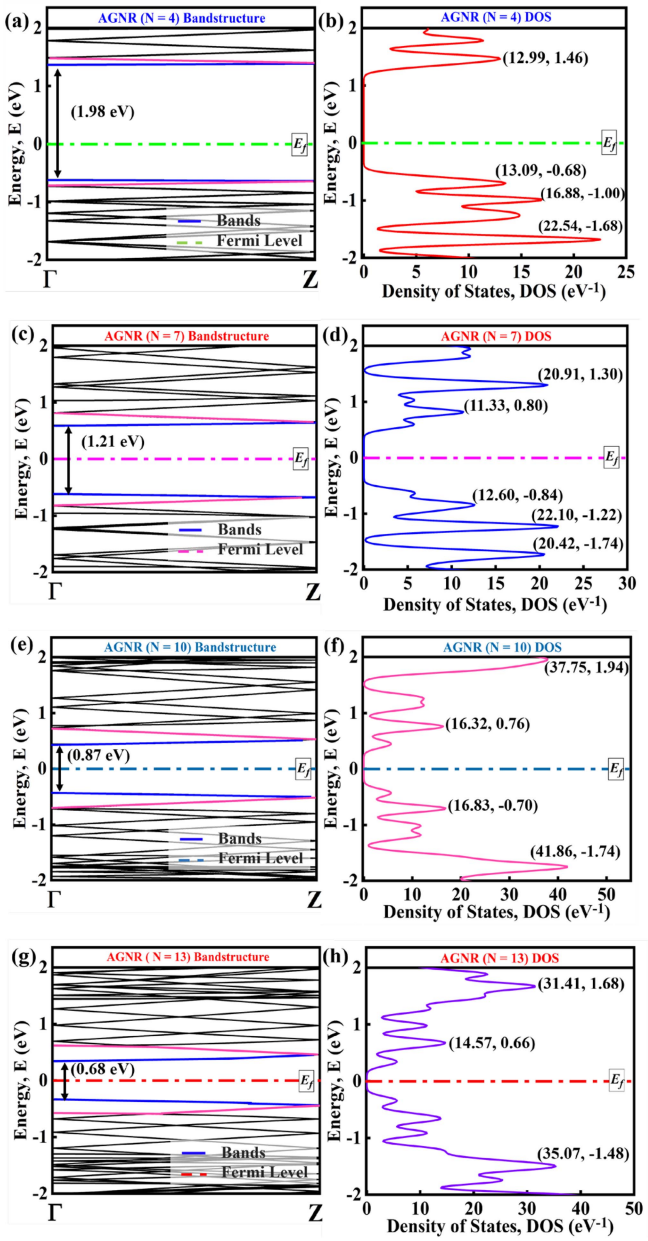

Fig. 6. Quantum transport properties for bulk configuration of AGNR with different N that are used as a channel material (a) AGNR (N = 4) band structure, (b) AGNR (N = 4) DOS, (c) AGNR (N = 7) band structure, (d) AGNR (N = 7) DOS, (e) AGNR (N = 10) band structure, (f) AGNR (N = 10) DOS, (g) AGNR (N = 13) band structure and, (h) AGNR (N = 13) DOS.

relation between DOS and energy is given by [25]:

$$D\ (E) = \frac{N\ (E)}{dE} \tag{6}$$

where,

D (E) - The density of states for the available energy range

The analysis of the transmission spectrum for diff6erent N in AGNR is illustrated in Fig. 7. The transmission spectrum of a nanoribbon (GNR) describes how the transmission of electrons changes as their energy varies while passing through the nanoribbon. This transmission is affected by the GNR structure,

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 09,2024 at 07:10:44 UTC from IEEE Xplore. Restrictions apply.

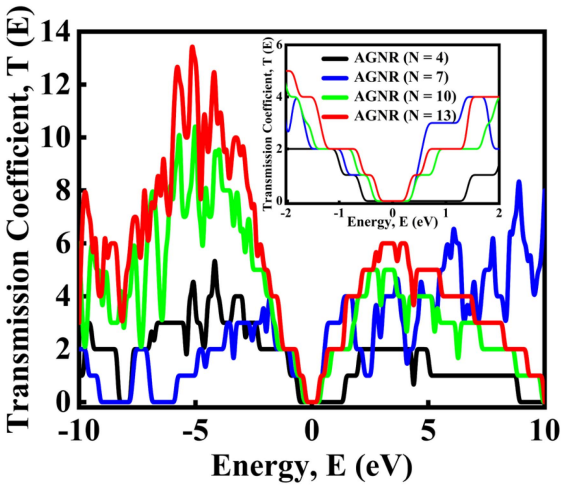

Fig. 7. Transmission spectrum for varied N in the AGNR.

which in turn depends on its width and other structural features. The energy range for the transmission coefficient is taken from -10 to $+10$ eV. It is observed from Fig. 7 that the peaks of the transmission spectrum increased as the value of N in AGNR increased. Also, no peak is observed at Fermi energy (i.e., for E = 0 eV), which points out that there is a possibility of conduction between the CB and VB. From Fig. 7, it is observed that the AGNR (N = 4) has no peaks in the energy range of - 0.5 to + 1.5 eV, which describes that an electron can easily tunnel through VB to CB. From the above discussions, the authors lead to an observation that the AGNR (N = 4) has improved transmission spectrum peaks around Fermi energy and has a better value of bandgap.

B. Performance Analysis of the Proposed Devices Using the DFT Approach

From the DFT analysis of AGNR, as discussed in Figs. 6 and 7, it is observed that the AGNR (N = 4) shows improved results in terms of band structure and transmission spectrum. Further, the transport properties for different device configurations with varying values of N in AGNR for the channel material are calculated. The authors have analyzed the impact of drain voltage (V_{ds}) on the transmission spectrum for each device configuration as depicted in Fig. 8. The transmission coefficient for a device configuration is obtained by the without self-consistent solution of the Schrodinger equation and 3-D Poisson's equations using the Slater-Koster model with NEGF method and it can be mathematically expressed as [26]:

$$T\ (E) = Trace\left[G\,(E)\,\Gamma_d\,(E)\,G^{\dagger}\,(E)\,\Gamma_s\,(E)\right] \qquad (7)$$

where,

$T(E)$ – transmission coefficient
$G(E)$ – retarded Green's function
$G^{\dagger}(E)$ – advanced Green's function
$\Gamma_L(E)$ – broadening function of the left electrode
$\Gamma_R(E)$ – broadening function of the right electrode

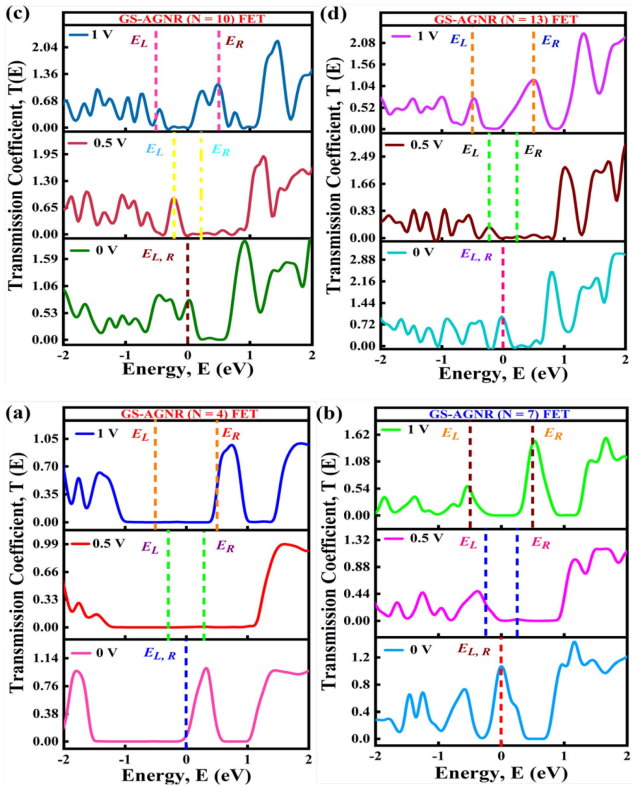

Fig. 8. Transmission spectrum at input voltages 0 V, 0.5 V, and 1 V for (a) GS-AGNR (N = 4) FET, (b) GS-AGNR (N = 7) FET, (c) GS-AGNR (N = 10) FET, (d) GS-AGNR (N = 13) FET.

The value of V_{ds} is changed from 0 to 1 V in 0.5-step increments. A new without self-consistent calculation needs to determine the associated transmission spectrum for every drain voltage. Once the transmission spectrum is calculated, it is observed that the Fermi level shift at the VB and CB edges is the primary distinction between the various spectra calculated from the parameters $\Gamma_L(E)$ and $\Gamma_R(E)$. The terms E_L and E_R in Fig. 8 denote the shift in the Fermi level corresponding to the left and right electrodes, respectively. From Fig. 8(a), it is observed that the GS-AGNR (N = 4) FET at 0 V shows a minimum resonance peak. The width and electrical characteristics of the GNR would determine the number of resonance peaks and their specific positions.

It is evident from Fig. 8(a) that the possibility of electrons tunneling for 0.5 V in GS-AGNR (N = 4) FET is greater than the other device configurations at this voltage (0.5 V). The reason can be understood by the Fermi levels shift in the left and right electrodes. The Fermi level shown in the presented work governs the range of electron transport inside a GS-AGNR (N) FET. The electron transmission inside the GNR channel increases with the value of the Fermi level range in GNR. It can be clearly observed from Fig. 8(a)–(d) that for 0.5 V, the range of Fermi level shift for both electrodes are higher in GS-AGNR (N = 4) FET as compared to the other three device configurations. Also, in Fig. 8(a) at 0.5 V, there is no peak present in the barrier of E_L and E_R, which points out the higher possibility of conductance as compared to the transmission spectrum, as shown in Fig. 8(b)–(d).

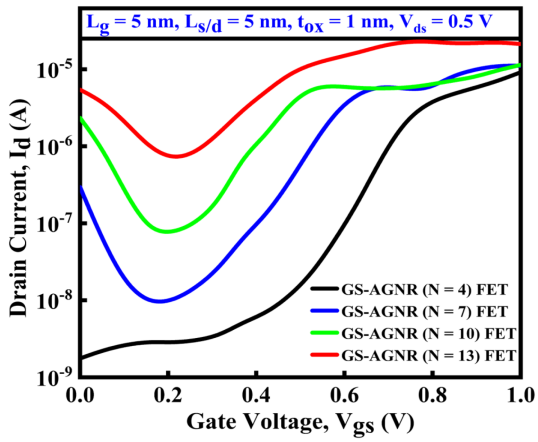

Fig. 9. Transfer characteristics of GS-AGNR (N) FETs with different values of N in the channel material.

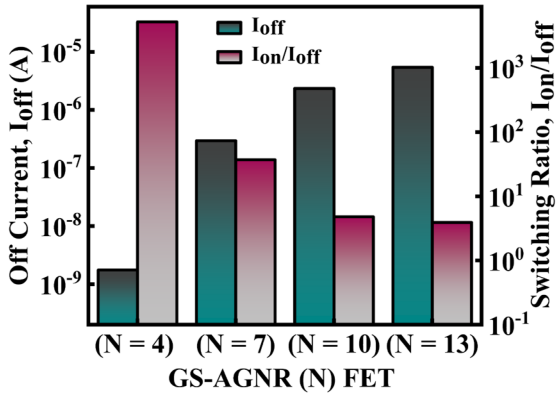

Fig. 10. Variation in off current and switching ratio for GS-AGNR FET.

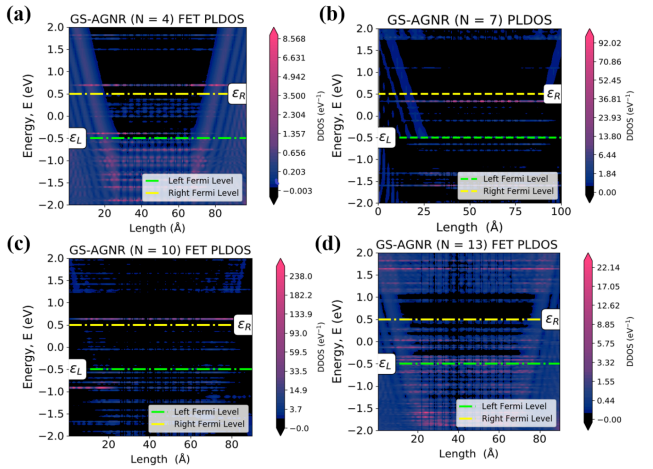

Fig. 11. Projected local density of states (PLDOS) for (a) GS-AGNR (N = 4) FET, (b) GS-AGNR (N = 7) FET, (c) GS-AGNR (N = 10) FET and, (d) GS-AGNR (N = 13) FET.

The values of T(E) at 0 V and 0 eV are 1.09 in GS-AGNR (N = 7) FET, which is higher than in other device configurations. When the drain voltages change from 0 to 1 V, it is observed that the value of T(E) decreases, and the area under the curve also decreases. In GS-AGNR (N = 10) FET and GS-AGNR (N = 13) FET, as depicted in Fig. 8(c) and (d), the values of T(E) at 0 V and 0 eV are 0.76 and 0.97. Also, as the V_{ds} change from 0 to 0.5 V, the resonance peak value decreases. Further, the authors observed that the variation of the transmission spectrum for GS-AGNR (N) FET having different values of N in channel material shows the transport of electrons and its dependence on external voltage. Moreover, the DFT analysis of GS-AGNR FET in terms of T(E) gives a unique approach to explain the device performance, which can be very useful in many applications.

The transfer characteristics of GS-AGNR (N) FETs with different values of N are shown in Fig. 9. The drain current is calculated after using the without self-consistent solution of tight-binding Hamiltonian matrix after the calculation T(E) and mathematically expressed by Landauer-Büttiker Formalism [27]:

$$I_d = \frac{2e}{h} \int_{-\infty}^{\infty} T(E) \left[f_{FD}(E - \mu_d) - f_{FD}(E - \mu_s) \right] dE \tag{8}$$

where,

I_d – drain current
f_{FD} – Fermi-Dirac distribution
μ_d – chemical potential of the drain electrode
μ_s – chemical potential of the source electrode

The (8) depicts the dependence of I_d on T (E). The GS-AGNR (N = 4) FET shows improved value of I_{off} as compared to other device configurations. The value of I_{off} changed from 1.75 nA to 5.42 μA for GS-AGNR (N = 4) FET and GS-AGNR (N = 13) FET. The narrower width of AGNR shows improved results in terms of I_{off}, switching ratio (I_{on}/I_{off}), and other parameters like transmission probability and conductance, which can be easily understood by analyzing the transmission spectrum for each device configuration. The transmission spectrum and transfer characteristics of a GNRFET are related through the electronic properties of the GNR and the operation of the FET. The discussion about the variation of transmission spectrum in terms of T(E) for different device configurations led to an observation that the transfer characteristics, as shown in Fig. 9, have been improved significantly for GS-AGNR (N = 4) FET. From the transfer characteristics, the switching ratio (I_{on}/I_{off}) and the off current (I_{off}) are calculated.

The variation in I_{off} and I_{on}/I_{off} ratio for all purposed device configurations is illustrated in Fig. 10 . The switching ratio is an important factor that determines the performance of a device [28], [29]. A high I_{on}/I_{off} ratio indicates that the device can reliably and rapidly switch between conducting (on) and non-conducting (off) states, enabling it to amplify and process electrical signals with minimal power consumption. In this present study, the GS-AGNR (N = 4) FET shows a higher switching ratio value than other device configurations. Based on the I_{on}/I_{off} parameter, the authors have observed that the GS-AGNR (N = 4) FET can be used in high-speed electronics and low-power integrated IC because of reduced off-current and better switching ratio.

Fig. 11 portrays the contour plot of the projected local density of states (PLDOS) for all device configurations. These contour

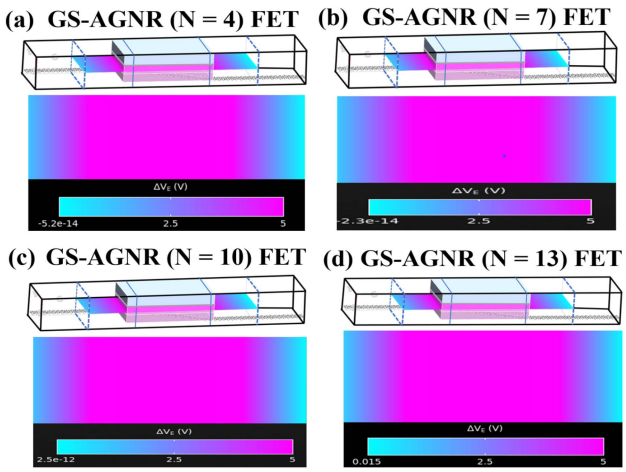

Fig. 12. Electrostatic difference potential profile for (a) GS-AGNR (N = 4) FET, (b) GS-AGNR (N = 7) FET, (c) GS-AGNR (N = 10) FET, and (d) GS-AGNR (N = 13) FET.

plots of PLDOS in GS-AGNR (N) FETs provide crucial insights into the electronic structure and behavior of these atomic-scale devices. In Fig. 11. the PLDOS is typically represented as a function of energy and position within the GNR. Each contour line in the graph corresponds to a specific energy level, and the intensity or color bar of the contour lines reflects the density of electronic states at that energy level. The magnitude of these contour lines associated with device density of states (DDOS) varies from -0.03 to 238 eV^{-1}. The contour plots of electrostatic difference potential in Fig. 12 show crucial insights into the distribution of electric charges within different device configurations. The contour plots clearly demonstrate where electric charges are concentrated and how they affect the device's overall performance. The blue color contour depicts the electronic distribution near the electrodes, whose magnitude ranges from 0.015 to -5.2×10^{-14} V, while the pink color illustrates the distribution of electric charges inside the channel. These contour plots can be used by scientists and engineers to improve the design of GNR FETs. They can fine-tune the devices having a narrower number of carbon atoms along AGNR width (like N = 4, as presented in this work) for certain uses, like high-speed computing or low-power electronics, by adjusting the charge distribution and electric field with exact atomic-level modifications.

Table I summarizes the comparison among proposed GS-AGNR(N) FETs with previously reported GNRFETs. The variation of N from 4 to 13 in GS-AGNR (N) FETs brings down the magnitude of the on current (9.14 μA to 0.21 μA) and increases the off current (1.75×10^{-3} to 5.4 μA). These variations in the on and off currents due to a varied N value in GS-AGNR(N) FETs imparts a switching ratio of 3.9 to 5.22×10^{3} corresponding to bandgap in the range of 0.68 to 1.98 eV.

VI. CONCLUSION

The Nobel prize-winning discovery of a 2D-monolayer structure in 2004 by Geim and Novoselov at Manchester University paved the path for this research. In this study, the armchair configuration of graphene with a varied number of carbon atoms along AGNR width is adopted to design GS-AGNR(N)FET. The density functional theory (DFT) assisted with a solution of 3-D Poisson's equations and a non-self-consistent solution of the Schrodinger equation using the Slater-Koster model with the NEGF method adopted for evaluating all the parameters. These parameters include band structure, the density of states, and the transmission spectrum of AGNR, which can potentially be used as channel materials. Further, the impact of V_{ds} on the transmission spectrum is analyzed for proposed device configurations. The DFT analysis of GS-AGNR FET in terms of T(E) gives a unique approach to explain the device performance, which can be very useful in many applications. The band structure and DOS for AGNR (N = 4, 7, 10, 13) concluded that the 3p+1 family of AGNR with a value of N ranging from 1 to 4 is semiconducting in nature and confirmed the potential alternative as a channel material in FETs. Moreover, the semiconducting nature of the AGNR is verified by the fact that there is no peak at the Fermi level in DOS. The value of I_{off} changed from 1.75 nA to 5.42 μA for GS-AGNR (N = 4) FET and GS-AGNR (N = 13) FET, respectively. The narrower width of AGNR shows improved results in terms of I_{off}, switching ratio, transmission probability, conductance, etc. The results of the transmission spectrum in terms of T(E) for varied input device configurations led to the conclusion that the transfer characteristics have been improved significantly for GS-AGNR (N = 4) FET. The contour plots of electrostatic difference potential show the distribution of electric charges in device configuration. In the context of GS-AGNR (N = 4) field-effect transistors, the off current (I_{off}) experiences a substantial reduction, while the switching ratio (I_{on}/I_{off}) exhibits significant improvement when

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 09,2024 at 07:10:44 UTC from IEEE Xplore. Restrictions apply.

compared with other device configurations. The electronic and quantum transport properties studied in this research provide valuable insights into performance evaluation in terms of I_{on}, I_{off}, switching ratio, and bandgap, along with resonance peaks of transmission coefficient and electronic structure. Thus, from this study, the authors conclude that the GS-AGNR (N = 4) FET has better-switching performance and can be a potential alternative to conventional FETs in low-power applications such as low-power sensors, wireless communication, and medical devices.

ACKNOWLEDGMENT

The authors extend a warm thanks to the MRL facility in the Applied Physics Department at Delhi Technological University for their assistance with this research.

***Abstract* - Skin conditions are increasingly prevalent worldwide nowadays. For this, early detection and diagnosis are effective for the treatment and prevention of skin disorders. In this research, we proposed the distilling knowledge to identify skin diseases. Our work is in two parts. Firstly, we train the deep neural network (teacher model) on large dataset which is publicly available on the Kaggle platform. While the teacher model has high accuracy, due to its computational cost it can't be used on low-power devices. So, to resolve this problem, we transfer the knowledge of the higher model i.e. teacher model to the lower model i.e. student model by the knowledge distillation (KD) technique. As the student model is simple and requires few calculations, we can deploy the model on low-power devices. We evaluate the proposed framework on the publicly available dataset representing binary classification. Our results show that the teacher model has 0.9531 training accuracy and 0.8197 validation accuracy with 0.8758 test accuracy. Adding to this, the distilled model has 0.7970 accuracy on test set.**

I. INTRODUCTION

A considerable section of the world's population is afflicted by skin illnesses, which have recently raised serious health issues. Skin disorders may have a significant pessimistic impact on a person's psychology and result in long-term health problems if they are not addressed. To be properly treated and kept from spreading, skin problems must be diagnosed and treated as soon as feasible [2]. However, current techniques for skin disease detection frequently call for expensive tools and knowledge, making them unavailable in environments with limited resources.

The discipline of computer vision has made considerable strides in recent years in creating precise and effective models for picture categorization applications. Deep neural networks (DNNs) have become an effective method for classifying images and have been used in several fields, including medical image analysis [4]. In any case, because of their high computational requests, sending DNNs on low-power gadgets like cell phones is much of the time troublesome.

One system that can be utilized to manage the above issue involves the information refining idea for sending the model to this present reality. In information refining, an easier understudy model — a more modest, less convoluted brain organization — is prepared to imitate the way of behaving of a considerably more mind-boggling educator model — a greater, more complex brain organization [5]. The understudy model is made to have more clear engineering and needs fewer estimations, making it suitable for organizations on low-power devices. Information refining has been exhibited to be a helpful system for creating exact and compelling models for picture order undertakings.

Detailed insights about how Knowledge Distillation:

- Using a process called knowledge distillation, information is moved from a huge, complicated neural network called the instructor model to a more compact, straightforward neural network called the student model. Since Hinton et al. [1] initially suggested the method, but it has been widely applied across several industries.
- The fundamental idea of KD's is to use the output of teacher model as a soft target for the training of student model. In other words, instead of focusing just on training the student model to predict class labels accurately, we trained it to duplicate the teacher's model output probabilities. The soft targets compared to hard target of class labels are more informative and beneficial for the student model as shown in Figure 1.
- Mainly for the training of the knowledge distillation, there are two steps. At the initial step, the teacher model is trained on the dataset using some loss function like cross-entropy (we are using). In the following step, the student model is trained on teacher's model soft target. This step creates the loss function by combining the standard loss function such as cross entropy, with Kullback-Leibler(KL) divergence joining teacher and student model output. The KL divergence enables the student model to learn from the output of the teacher model by measuring the difference between the two output distributions.
- The advantages of Knowledge distillation are: first it can be used to improve the accuracy of student model, especially when there is a shortage of training data. Secondly, it can reduce the computational costs of the student model by making low-power compatible devices. Thirdly, it can transfer teacher-model information to student model, allowing student model to benefit fromteacher model experience.

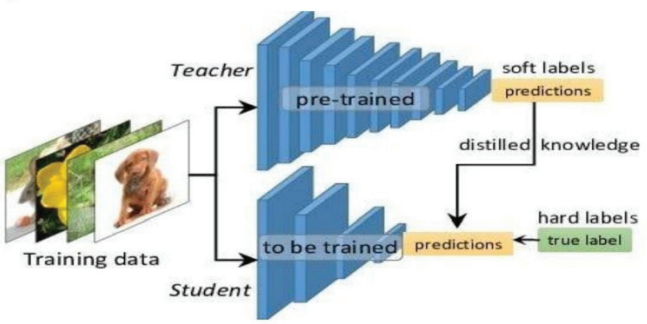

Fig. 1. Basic architecture of Knowledge Distillation [1]

In this study, we suggest a knowledge distillation-based research on skin lesion detection. The experiment consists of two steps: firstly, the training of DNN as a teacher model on Kaggle dataset images consists of benign and malignant moles. Then the knowledge of the teacher model is transferred to the student model using the above concept (KD). As the size of student model is small and requires less computational cost so, this model can be implemented on low-power devices.

II. METHODOLOGY

The proposed framework for skin disease detection using knowledge distillation consists of several steps, as described below:

A. Data Preparation and Preprocessing

For this, we utilized the Skin Cancer: Malignant vs Benign dataset [3]. Some of sample images are shown in Figure 2 The dataset is balanced mixture of malignant and benign skin moles, consisting of 3297 skin lesions images. The dataset splits into 80:20 ratio for the training and testing process. Training consists of 2637 images and the test has 660 images. All the images are labelled with binary classification labels indicating whether the image is malignant or benign. The images range in color and size some contain noises like hairs, ink marks, or rulers which are removed in preprocessing step, the preprocessed images are shown in Figure 3.

For our research, we first downloaded the dataset and organised it as per the given folders of training and testing. As mentioned above the splitting of the dataset is in 80:20 ratio.

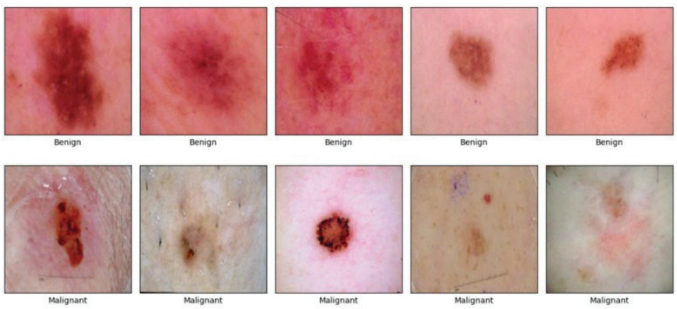

Fig. 2. Samples images from the dataset

Subsequently, the training dataset go through to data augmentation process where zoom, flips and random rotations were applied. Also, it helps to increase the training dataset and avert the model from overfitting. Data augmentation can better the generalization capability of the model.

Following data augmentation, all images are reshaped into 224*224 pixels. For training of model or neural network, it was ensured that all images were of the same dimensions and color channels. In the end, we normalize all the pixels values of each image in the dataset. With this step, the model was able to converge more quickly during training and prevent the gradient from becoming too large or too small.

Fig. 3. Preprocessed images from the dataset

B. Teacher Model Training

In the proposed framework for skin disease detection using knowledge distillation, to serve as the reference model for simple student model, we first trained a teacher model. The teacher model was designed using transfer learning with the DenseNet121 architecture as shown in Figure 4, which is already trained with the help of the ImageNet dataset. To this, we added a global average pooling layer and a dense layer with 512 units having ReLU activation function. Dropout at the rate of 0.5 was used to prevent any over-fitting in the model.

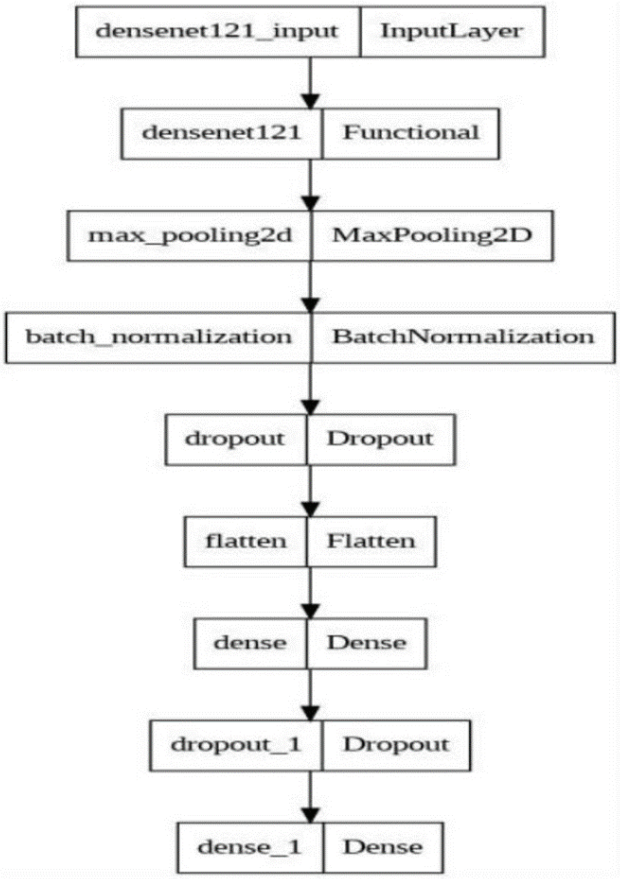

Fig. 4. DenseNet Model Architecture

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 10,2024 at 04:59:37 UTC from IEEE Xplore. Restrictions apply.

The final output layer consisted of two units with softmax activation for binary classification of malignant and benign lesions. The model was learned using the training dataset followed by validation on the validation dataset.

Categorical cross-entropy was used for calculating loss and Adam was used as optimizer with 0.001 learning rate. When the validation loss didn't reduce for one epoch, the learning rate was limited, we employed early stopping with a tolerance of three epochs and a factor of 0.5.

The teacher model was run for 20 epochs on training data and it was evaluated against the vali- dation set. When the validation loss did not decrease for one epoch, the best model was saved using the ModelCheckpoint callback, and the learning rate was decreased using the Reduce LR On Plateau callback. To compare the effectiveness of the student models' performance, the training history of the instructor model was documented and utilised as a reference.

After the teacher model was trained, it was saved to a file using the Keras save function. The model was trained for 10 epochs, and during the final epoch, the model achieved a loss of 0.1117 and an accuracy of 0.9531 on the training data. On the validation data, the model achieved a loss of 0.5543 and an accuracy of 0.8197. The graphical representation of model accuracy and loss is shown in Figure 5

With the help of Matplotib's plot, the model's training and validation accuracy and loss were plotted. The accuracy and loss were plotted over 10 epochs. The model's training accuracy and loss decreased and converged, while the validation accuracy and loss plateaued.

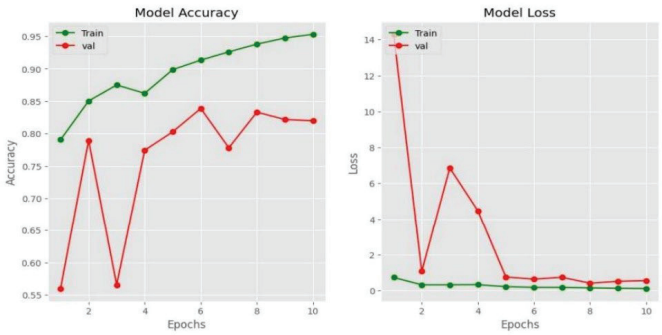

Fig. 5. Teacher model accuracy and loss

C. Student Model Training

In the student model training, a custom convolutional neural network is used. The model consists of convolution layer and max pooling layers with increasing filter size.

The input layer is defined using the Input function from Keras. The first convolutional block consists of 2 convolutional layers with 8 each layer having 8 filters and max-pooling layer following it. The second and third convolutional blocks have 16 and 32 filters respectively, with max-pooling layer after each block. The fourth convolutional block has 64 filters with a max-pooling layer following it. The fifth convolutional block has two convolutional layers with 64 filters each, along with max-pooling layers. Two dense layers with 256 and 2 units each follow the convolution blocks. To reduce over-fitting, a dropout with a rate of 0.5 is used for the second dense layer.

D. Model Distillation

The distillation process involves training the student model to predict not only the correct output labels but also the probabilities of the teacher model's predictions. This is done by minimizing the differences between the two models, as measured by the distillation loss function.

The Distiller class is initialized with the student and teacher models and allows the user to configure various parameters for the distillation process, such as the loss functions, weight coefficients, and temperature for softening probability distributions. In this particular implementation, the categorical crossentropy loss function is used for the student model's output and the KL Divergence loss function is used for the distillation loss. The temperature parameter is set to 6 and the weight coefficient alpha is set to 0.5. During the distillation process, we use the Adam optimizer with a learning rate of 1e-4 followed by beta parameters of 0.9 and 0.999 and epsilon as 1e-8. The training process consisted of 20 epochs with a batch size of 32.

During the process of training, ModelCheckpoint callback is used to save the best model data and Reduce LR On Plateau is used to lower the learning rate as and when the validation student loss plateaus.

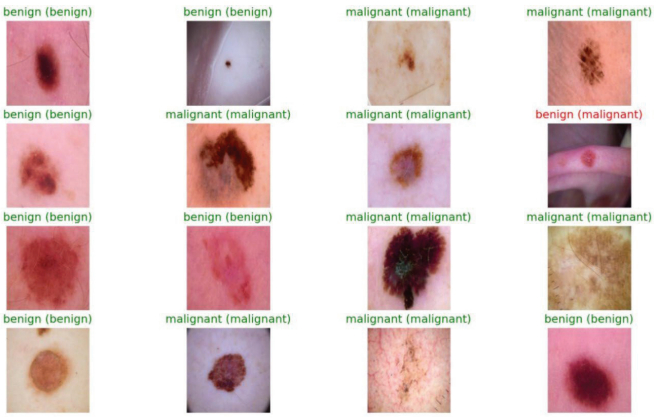

Fig. 6. Samples of predicted images and actual images

During the final epoch of the model distillation process, the training set accuracy was 0.8024, with a student loss of 0.4165 and a distillation loss of 0.0075. The validation set accuracy was 0.7837, and the validation student loss was 0.5160. These results suggest that the student model has learned to approximate the behaviour of the teacher model, but still, there is scope for improvement in validation performance. Overall, the process of knowledge distillation has proven to be effective in improving the performance of smaller student models using a larger and more complex teacher model.

III. Result and Analysis

The evaluation of the performance of the teacher model on the test set showed a promising accuracy of 0.8758 and a loss of

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 10,2024 at 04:59:37 UTC from IEEE Xplore. Restrictions apply.

0.3394, which served as the baseline for evaluating the performance of the student models trained using the knowledge distillation framework. Using the evaluate function of Keras, the student models' performance was assessed following training. The evaluation's findings revealed that the distilled student model had a 0.7970 accuracy on the test set and a 0.3858 loss. This illustrates how the knowledge distillation technique may be used to enhance student model performance.

The test set was loaded using the scikit-learn LoadFiles method, and the file names were preprocessed into arrays of photos. The trained model's performance was then assessed using the loaded test set and Keras predict function. Using matplotlib, a random selection of the test pictures, the predicted labels for those images, and the ground truth was plotted to show the predictions. For successful fore- casts, the model's predictions were highlighted in green; for wrong predictions, they were highlighted in red as shown in Figure 6.

IV. Conclusion and Future Work

Finally, it can be said that knowledge distillation has been successful in enhancing the performance of a smaller student model trained on a sizable dataset using a larger teacher model. The findings demonstrate that the student model may operate as accurately and effectively as the bigger instructor model when taught through knowledge distillation. As a result, less computationally intensive, smaller, and more effective models may be deployed.

There are various potential directions for improvement in future work. To evaluate if more performance enhancements can be made, one strategy that may be used is to experiment with various hyper-parameters and architectures. Exploring the usage of ensemble models, in which numerous smaller models are integrated to produce greater performance than a single large model, might be an- other field of research. Additionally, it might be advantageous to look into the use of various distillationmethods, like attention-based distillation, to enhance the functionality of the student models.

Overall, using knowledge distillation to deploy large models in real-world scenarios on devices with resource limitations is a promising strategy. We can make deep learning advantages available to a larger variety of applications and consumers by enabling the deployment of smaller and more effective models.

Abstract

In the current study, a series of $Li_2Ba_5W_3O_{15}$: RE^{3+} (RE=Dy, Sm) [LBW:Dy^{3+}/Sm^{3+}] phosphors were prepared using a high-temperature solid-state method. X-ray diffraction (XRD), Scanning electron microscopy (SEM) with Energy-dispersive X-ray analysis (EDX) scans showed that the crystal form was consistent with the standard LBW and comprised small irregularly shaped particles. Diffuse reflectance spectral (DRS) data was utilized to calculate the band gaps. Fluorescence study shows that LBW material doped with Dy^{3+} and Sm^{3+} yield distinct colors at 496 nm (blue) for Dy^{3+} and 582 nm (green-yellow), 612 nm (yellow), and 669 nm (red) for Sm^{3+} when excited by near-ultraviolet (n-UV) (336 nm) light. The observation of energy transfer (ET) between Dy^{3+} and Sm^{3+} ions play a role in modifying the luminescence of LBW:Dy^{3+}/Sm^{3+} co-doped phosphors. With a constant excitation wavelength (λ_{Ex}), different levels of activator doping lead to a change in the emission colors from their neutral white light to a deep orange-red region for LBW:Dy^{3+}/Sm^{3+} phosphors. The decay curves demonstrate a decrease in lifetime with an increase in the concentration of activator ions (Sm^{3+}). For D3S5 phosphor, the temperature-dependent photoluminescence (TDPL) characteristics were analysed under λ_{Ex} = 336 nm excitation. The results indicate excellent luminescence thermal stability with an activation energy of 0.16 eV at λ_{Ex} = 336 nm. With its low color-correlated temperature (CCT) and good thermal stability, the prepared phosphor sample shows potential as a solid-state emitting phosphor that can be used with UV chip stimulation for warm white LED applications.

Accepted Manuscript

1. Introduction:

Nowadays n-UV/blue light-emitting diodes (LEDs) have become increasingly popular because of their many benefits over other solid-state lighting sources, including their long lifespan, stability, high efficiency, and environmental friendliness [1–4]. Commercial LED technology was first introduced in 1960, and with the 1997 release of the InGaN blue LED, research interest in white LEDs strengthened. White light is produced by combining three primary Color combinations: the LED chips emit red, green, and blue (RGB); the $Y_3Al_5O_{12}$: Ce^{3+} (YAG:Ce^{3+}) phosphor combines blue and yellow color to provide a blue hue; and the UV or n-UV LED excitable phosphors emit a mixture of RGB hues [5]. RGB LED combinations for creating white light are less common due to their complex production and use, as well as their varied rates of deterioration and fluctuating driving current [6]. Therefore, the use of phosphor materials excitable by LED chips is encouraged to overcome these complexities. At present, YAG:Ce^{3+} phosphors, stimulated by blue LEDs, are extensively commercialised for white LEDs; however, because of insufficient red emission in the spectrum, they have a low Color rendering index (CRI) of less than 80 and a high correlated color temperature (~4500 K). Red-spectral area enhancement of YAG:Ce^{3+} can be achieved by co-doping with red-emitting ions such as Mn^{2+}, Eu^{3+}, and Sm^{3+} [7]. As an alternative, the use of RGB phosphors and UV or n-UV LED chips is becoming more common because of their high CRI values [8,9]. It is possible to produce white light with more uniformity and stable emission using this technology, since the output of the white LEDs produced depends on the quality of light emitted from phosphors [10]. Recent reports have indicated that a number of RGB phosphors, such as $KSrPO_4$:Eu^{2+} [11], $BaAl_2S_4$:Eu^{2+} [12], and $CaAlSiN_3$:Eu^{2+} [13], decrease blue emission efficiency by partially absorbing blue light. To increase the effectiveness of white LEDs, it is important to investigate novel UV or n-UV excitable phosphors [14]. Warm white lighting is great for areas like living rooms, bedrooms, and hallways as it creates a cozy and enjoyable lighting ambiance [8]. Studies have demonstrated that certain transitions of Dy^{3+}: $^4F_{9/2} \rightarrow {}^6H_{15/2}$, $^4F_{9/2} \rightarrow {}^6H_{13/2}$ [15], Sm^{3+}: $^4G_{5/2} \rightarrow {}^6H_{7/2}$, $^4G_{5/2} \rightarrow {}^6H_{9/2}$ [16], can cause Dy^{3+}/Sm^{3+} ions co-doped phosphors [17,18] or glasses [19,20] emission in the warm white light range. Now, selecting the appropriate host medium is also essential when preparing luminous materials for a variety of applications. Recent researches has focused on inorganic luminescent materials using substrates like molybdate [21,22], tungstate [23,24], phosphate [25], vanadate [26] and silicate [27] etc. Since tungstates have strong covalent interaction, high stability, and strong visible luminescence, more suitable as host materials for its potential applications in lasers, optical fibers, w-LEDs, plasma display panels, quantum electronics, phosphors, scintillators when

Accepted Manuscript

doped with suitable RE^{3+} ions [28]. Also, the alkali metal ions, for instance Li^+, Na^+, K^+, etc. improves the luminescence emission intensity and color purity of the host matrix. It is evident from literature that the presence of Li^+ ions in the host matrix improves the luminescence property as modifier in the host matrix [23]. Additionly, tungstate with alkaline-earth metal ions (i.e., Ba^{2+}, Sr^{2+}, Ca^{2+}, Mg^{2+} etc.) are a fascinating group of compounds that exhibit blue or green luminescence associated with the tetrahedral WO_4 groups [29]. These substances find extensive applications as X-ray phosphors, scintillators, laser crystals, and matrices for electron spin resonance [30]. All the aforementioned scientific patronages offered by the constituent chemical species prompted us to prepared the $Li_2Ba_5W_3O_{15}$ (LBW) host lattice co-doped with Dy^{3+} and Sm^{3+} ions and analysed for phase purity, microscopic morphology, photoluminescence (PL) properties, and temperature-dependent PL properties.

2. Synthesis and instrumentations:

2.1. Synthesis method:

Multiple techniques exist for synthesizing phosphor materials, such as high temperature solid-state method, combustion process, co-precipitation and sol-gel. However, in this particular investigation, the high-temperature solid-state method was used for synthesis purpose.

Multicomponent lithium barium tungstate phosphors, co-doped with Dy^{3+} and Sm^{3+} ($(Li_2CO_3+(5-x-y)BaCO_3+3WO_3+xDy_2O_3+ySm_2O_3$, where $x = 0.03$ and $0.01 \leq y \leq 0.07$, $\Delta y = 0.02$), were synthesized in this study. The starting materials, finely ground powders, were combined in an agate mortar, with 5 grams of each batch composition admixed till homogeneous. Subsequently, the thoroughly mixed sample was subjected to a heating process in an alumina crucible, maintaining a temperature of 1200 °C for 6 hours at a heating rate of 5°C/minute. After this, letting the mixture naturally cool to ambient temperature, the final products were reground to undergo further characterizations.

2.2. Instrumentations:

Various analytical methods were employed to examine the structural, optical, and temperature dependent characteristics of the synthesized phosphors. XRD was utilized to assess the sample structural features, employing a Bruker D-8 Advance diffractometer (accuracy ±0.01), 2θ angles ranging from 20˚ to 70˚, and a nickel (Ni) filter, with a radiation source of Cu-K_α. The surface morphology was analysed using FE-SEM with a JEOL JSM-6490 operating at a 10 kV accelerating voltage. DRS analysis was conducted using a JASCO V-770 spectrophotometer, which utilizes two different light sources, i.e., halogen and deuterium, for the UV and visible regions, with a resolution of ±0.1 nm. PL excitation (PLE) and PL emission spectra were

Accepted Manuscript

examined using a JASCO 8300 FP spectrofluorophotometer, equipped with a Xenon lamp (300 W) as the excitation source and a resolution of ±1.0 nm. Time-resolved PL (TRPL) investigations were carried out using a 150 MHz digital oscilloscope (HM 1507 Hameg Instruments). The above measurements were performed at ambient atmosphere. The thermal behavior of the optimized phosphor sample was investigated using temperature dependent PL (TDPL) study with an Ocean optics Flame-S-XR1-ES spectrometer.

3. Results and discussion:

3.1. Structural and morphological investigations

3.1.1. XRD study: structural investigations

X-ray diffraction analyses were conducted on all the powdered samples, including both un-doped LBW and co-doped LBW ($Li_2Ba_{(5-x-y)}W_3O_{15}:Dy_xSm_y$; where x = 0.03 and $0.01 \leq y \leq 0.07$, $\Delta y = 0.02$). The measurements were performed in $20^{\circ} \leq 2\theta \leq 70^{\circ}$ and the results were illustrated in **Fig. 1 (a)**. The diffraction patterns align closely with the JCPDS database file no. 01-072-1717, corresponding to LBW sample with a monoclinic structure and $P6_3mc$ space group (186). The lattice parameters were determined as: a = b = 5.760 Å, c = 23.742 Å, α = β = 90°, γ = 120°, and the volume (V) was evaluated as 682.17 $Å^3$. The host's crystal structure and the emergence of an impurity phase do not seem to be affected by increasing doping concentrations, suggesting that the activator ions (Dy^{3+} and Sm^{3+}) have been effectively integrated into the host matrix to take the position of the Ba^{2+} in the lattice structure.

Williamson-Hall (W-H) plot was utilized for the un-doped LBW sample and $Li_2Ba_{(5-x-y)}W_3O_{15}:Dy_xSm_y$ (where x = 0.03 and $0.01 \leq y \leq 0.07$, $\Delta y = 0.02$) phosphors to calculate the strain (∈) and the average crystallite size (D) [31]:

$$\beta \cos\theta = \frac{k\lambda}{D} + 4 \in \sin\theta \quad (1)$$

'K' is structure factor with a value of 0.94. '2θ' and 'β' refers to the diffraction angle full width at half maximum (FWHM) consistent to the XRD peaks, respectively and 'λ' stand for the wavelength of the Cu-K_α source. The graph (straight line) between $\beta \cos\theta$ and $4 \sin\theta$ is drawn to calculate the values of "D" and "∈", as shown by the W-H plot in **Fig. 1 (b)**.

Accepted Manuscript

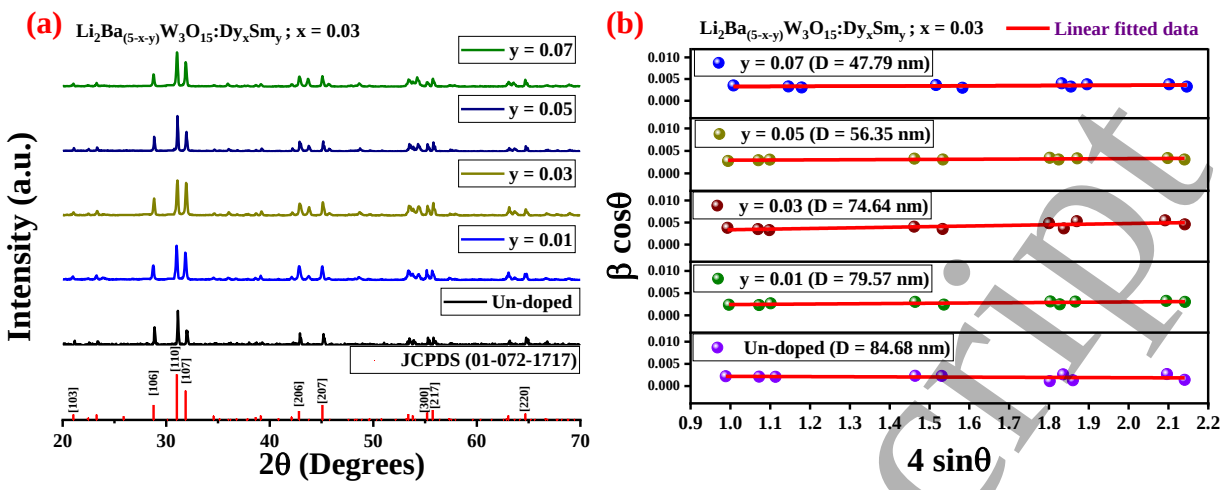

Fig. 1 (a) The XRD patterns and **(b)** A graph between $\beta_{hkl}cos\theta$ and $sin\theta$ for un-doped LBW and $Li_2Ba_{(5-x-y)}W_3O_{15}:Dy_xSm_y$ (where x = 0.03 and $0.01 \leq y \leq 0.07$, $\Delta y = 0.02$) phosphors.

3.1.2 SEM and EDX studies: morphological investigations

The surface morphology of the prepared phosphor sample was analysed using SEM and EDX. The SEM image in **Fig. 2 (a)** depicts the surface of a $Li_2Ba_{(5-x-y)}W_3O_{15}:Dy_xSm_y$ (where x = 0.03 and y = 0.05) phosphor. It is evident that there is inconsistency in both the shape and size of the particles. This variability is attributed to the agglomeration phenomenon observed in the prepared material, likely due to the high-temperature synthesis process and hand-grinding. The whole consists of irregular micron-sized particles, which play a pivotal role in enhancing the luminous intensity in solid-state lighting devices [32]. As shown in **Fig. 2 (b)**, the EDX analysis was utilized for the confirmation of the elements present in the prepared phosphor material. Clear peaks corresponding to Ba, O, W, Dy, and Sm are observed in the spectrum, validating the uniform distribution of these components in the prepared phosphors. This confirms the synthesis of LBW:Dy^{3+}/Sm^{3+} phosphors, as further illustrated in **Fig. 2 (c)-(h)**. Notably, elements with low energy, like Li, show no peaks in their EDX spectra, which is consistent with observations found in the literature [33].

Accepted Manuscript

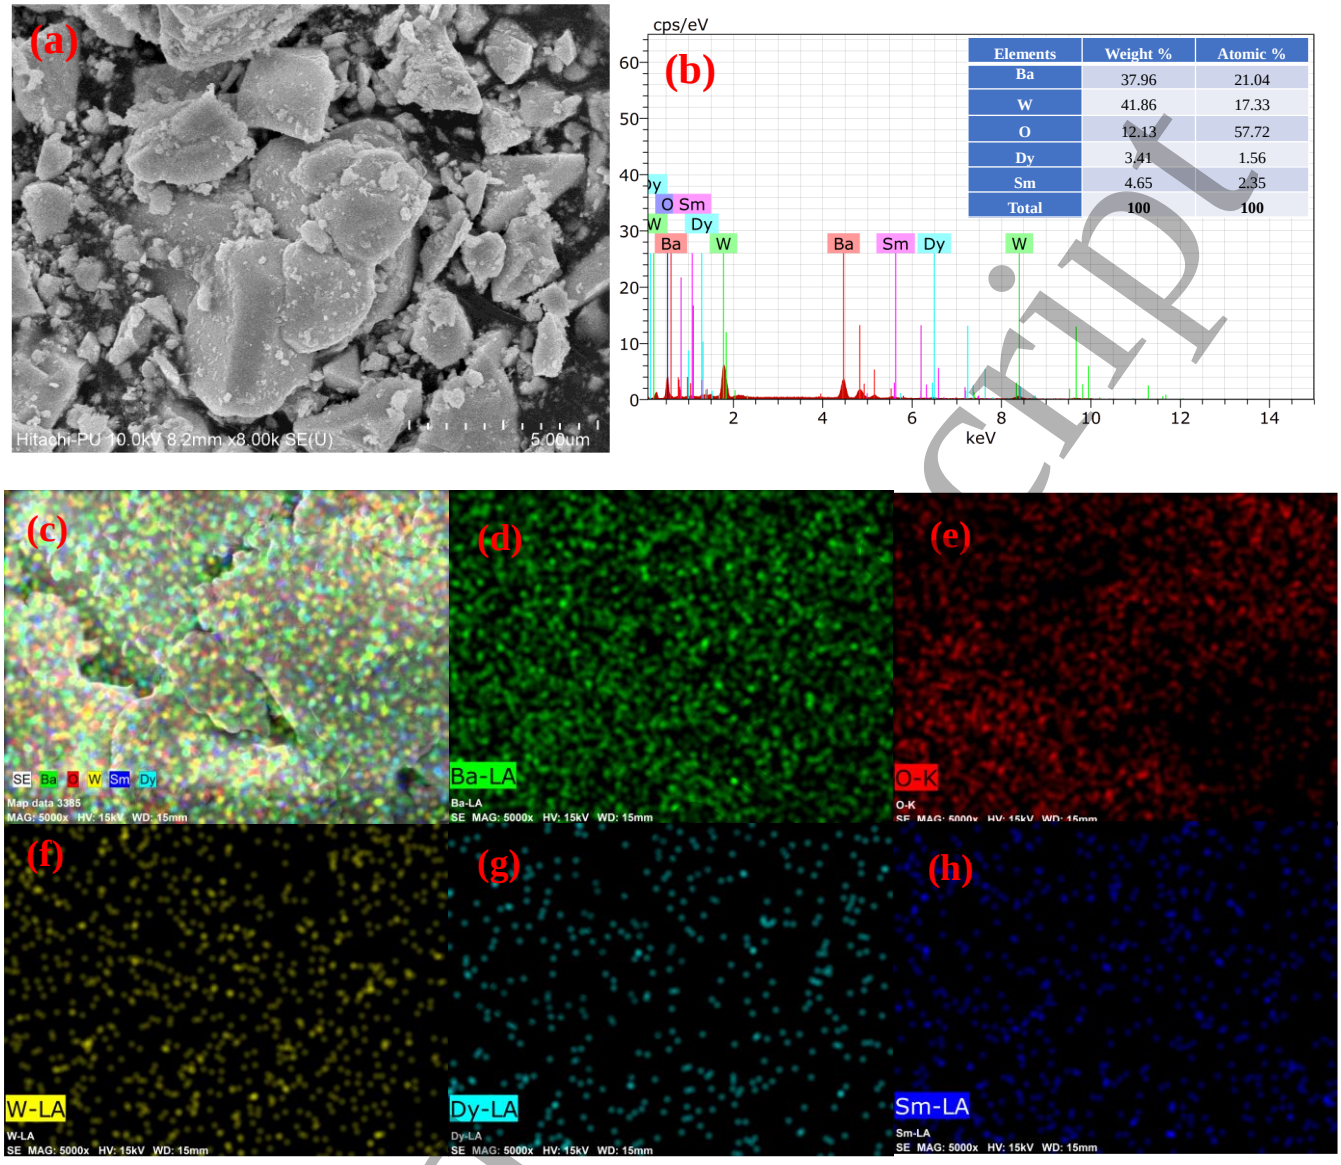

Fig. 2 (a) The SEM picture, **(b)** EDX pattern (Insert figure show the weight% and atomic% of individual atoms present in the phosphor) and **(c)-(h)** elemental distribution (Ba, W, O, Dy and Sm) of $Li_2Ba_{(5-x-y)}W_3O_{15}:Dy_xSm_y$ (where x = 0.03 and y = 0.05) phosphor.

3.2 Optical studies:

3.2.1 Study of DRS and band gap (E_g) energy evaluation

Fig. 3 represents the DRS of un-doped LBW and Dy^{3+}/Sm^{3+} ions co-doped LBW phosphors in the 200-1600 nm range. The peaks corresponding to 472, 946, 1072, 1272, 1378, 1474 and 1530 nm wavelength shows the transition from the ground state, i.e., $^6H_{5/2}$ to various excited states $^4I_{11/2}$, $^6F_{11/2}$, $^6F_{9/2}$, $^6F_{7/2}$, $^6F_{5/2}$, $^6H_{13/2}$ and $^6H_{11/2}$, related to Sm^{3+} ions [34], however, the transitions corresponding to $^6F_{3/2}$, $^6F_{5/2}$ and $^6F_{7/2}$ excited states from the ground state $^6H_{15/2}$ are represented by the remaining peaks at 736, 792 and 888 nm, were related to Dy^{3+} ions [35,36].

Accepted Manuscript

The optical absorption near the band edge is represented by the Kubelka-Munk (K-M) function, which can be utilised to address the band gap energy (E_g) [37]:

$$\alpha h\nu = A\left(h\nu - E_g\right)^{n/2} \quad (2)$$

where, the absorption coefficient, photon energy, energy band gap, and constant are represented by the symbols α, $h\nu$, E_g and A. Equation (2) uses the values n/2 = ½ for direct and 2 for indirect transitions, respectively. The function F(R) can be expressed as follows [38]:

$$F(R) = \frac{(1-R^2)}{2R} = \frac{K}{S} \quad (3)$$

which relates the ratio of the absorption coefficient (K) and scattering coefficient (S) of the sample with diffuse reflectance (R). The inset in **Fig. 3** shows the band gap value, which was determined by extrapolating the linear section of the plot between $[F(R)\,h\nu]^2$ and $h\nu$ and found to be equal to 3.74, 3.64 and 3.61 eV for the un-doped LBW, $Li_2Ba_{(5-x-y)}W_3O_{15}:Dy_xSm_y$ (where x = 0.03 and y = 0, y = 0.05) phosphors. The 4f energy level of Dy^{3+} and Sm^{3+} ions may be the cause of insignificant fall in the E_g values from 3.74 to 3.61 eV with the doping of RE^{3+} ions. Conversely, the slight decline also implies that the studied materials crystallized effectively [36].

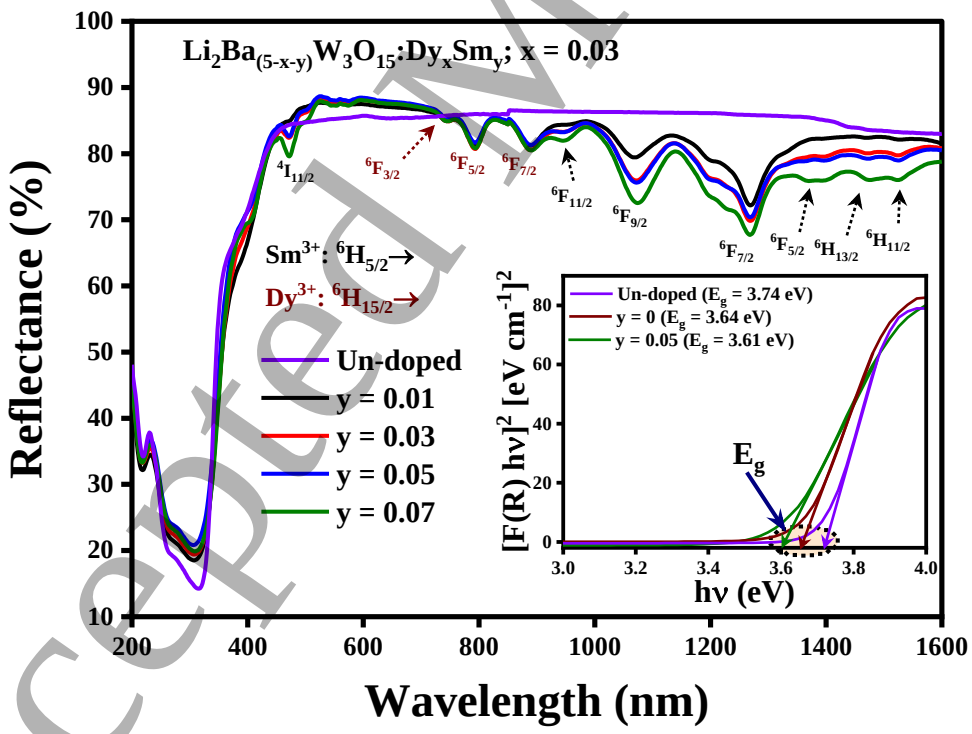

Fig. 3 DRS of the un-doped LBW, $Li_2Ba_{(5-x-y)}W_3O_{15}:Dy_xSm_y$ (where x = 0.03 and $0.01 \leq y \leq 0.07$, $\Delta y = 0.02$). [Inset shows the band gap variations of un-doped LBW, $Li_2Ba_{(5-x-y)}W_3O_{15}:Dy_xSm_y$ (where x = 0.03 and y = 0, y = 0.05) phosphors].

Accepted Manuscript

3.2.2 Study of PL excitation (PLE) and PL emission spectra

3.2.2.1 PLE and PL of LBW:Dy^{3+} phosphors

The PLE spectra of LBW phosphor doped with 3.0 mol% of Dy^{3+} ions (D3) at a PL emission wavelength (λ_{Em}) of 493 nm in the 300-460 nm spectral range is shown in **Fig. 4 (a)**. Nine PLE bands were detected at 338, 347, 357, 368, 378, 396, 425, 447 and 456 nm, corresponding to the transition from the ground state $^6H_{15/2}$ to different excited states $^6P_{3/2}$, $^6P_{7/2}$, $^4I_{13/2}$, $^6P_{5/2}$, $^4K_{17/2}$, $^4F_{7/2}$, $^4G_{11/2}$, $^4I_{15/2}$ and $4F_{9/2}$ [39,40]. $^6P_{5/2}$, the strongest excitation band, is situated at around 368 nm. Consequently, PL emission spectra were recorded, as depicted in **Fig. 4 (b)**, monitoring the excitation wavelength (λ_{Ex}) at 368 nm. The PL spectra showed three emission peaks corresponding to the transitions $^4F_{9/2}\rightarrow{}^6H_{13/2}$, $^6H_{11/2}$, and $^6H_{15/2}$. The emission intensities exhibited a gradual increase to their peak values when the concentration of Dy^{3+} ions reach to 3 mol% shown in the inset of **Fig. 4 (b)** illustrates the concentration quenching effect. The increase in the Dy^{3+} ion's concentration might lead to the non-radiative ET due to very less distance between the adjacent luminous centres [41]. Blasse suggested that the critical separation (R_c) and the ET process among adjacent dopant (Dy^{3+}) ions can be determined using the following expression [31]:

$$R_c \approx 2\left[\frac{3V}{4\Pi X_c N}\right]^{1/3} \quad (4)$$

In this case, "N", "X_c" and "V" signifies the number of atoms, optimum Dy^{3+} ions concentration and unit cell volume. The R_c was evaluated for X_c = 0.03, $N = 2$ and V = 681.182 Å^3 and found to be equal to 27.88 Å, after investigating the experimental statistics. Van Uitert claims that ET is connected to other phenomena, such as multipolar interactions, re-absorption of radiation, and energy exchange [42]. Since the current investigation's evaluated value of the essential distance between the adjacent Dy^{3+} ions was found to be greater than 5 Å [43]. Consequently, non-radiative energy transfer among Dy^{3+} ions typically happens due to electric multipole-multipole interactions, which is closely linked to the distance between them according to Dexter's theory [44,45]. The variation in photoluminescence intensity is commonly employed to explain the type of multipole interaction if the energy transfer occurs between activators of the same type. Again, the following expression can indicate a correlation among PL intensity (I) and the concentration of the activator ions (x in moles) [46];

$$\frac{I}{x} = k\,[1 + A(x)^{\frac{Q}{3}}]^{-1} \quad (5)$$

Accepted Manuscript

here, "A" is a constant, and "Q" denotes the type of interaction amid RE^{3+} ions. Q = 3 indicates the energy migration among nearest neighbour or next nearest neighbour activators. It can also take values 6, 8 and 10 for electric d-d (dipole-dipole), d-q (dipole-quadrupole), and q-q (quadrupole-quadrupole) interaction [45]. By simplifying Eq. 5, we can obtain that the relationship between $log\left(\frac{I}{x}\right)$ and $log(x)$ for LBW:Dy^{3+} phosphors under λ_{Ex} = 368 nm for λ_{Em} = 493 nm, with a slope of Q/3, well-illustrated in **Fig. 4 (c)**. Using λ_{Em} = 493 under λ_{Ex} = 368 nm, the values for the "Q" parameter are found at 5.4, which is close to 6. This indicates that the reason of ET between neighbouring Dy^{3+} ions is electric d-d interaction, which leads to concentration quenching. Additionally, the CIE chromaticity coordinates of D3 were evaluated using the PL data and lies in white region, shown in **Fig. 4 (d)**.

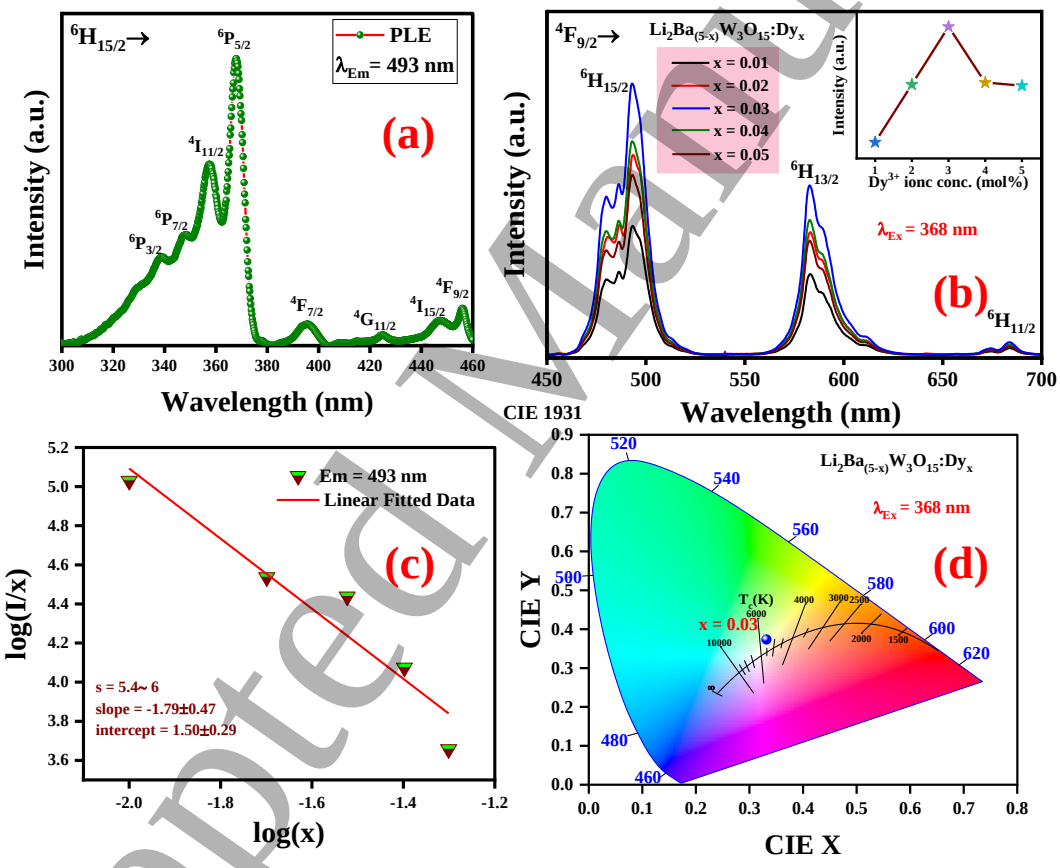

Fig. 4 (a) PLE for $Li_2Ba_{(5-x)}W_3O_{15}:Dy_x$ (x = 0.03), **(b)** PL emission spectra, **(c)** Dexter plot for LBW:xDy^{3+} ($0.01 \leq x \leq 0.05$, $\Delta x = 0.01$) phosphor and **(d)** CIE chromaticity coordinates for $Li_2Ba_{(5-x)}W_3O_{15}:Dy_x$ (x = 0.03) at λ_{Ex} =368 nm.

3.2.2.2 Effect of co-doping of Sm^{3+} ions on LBW:Dy^{3+} phosphor

Accepted Manuscript

In the pursuit of synthesising single-phase warm white phosphors, we utilized $Li_2Ba_{(5-x)}W_3O_{15}:Dy_x$ (x = 0.03) phosphors co-doped with varying concentrations of Sm^{3+} ions. Another objective of this modification was to explore the ET mechanism between the two RE^{3+} ions. In RE^{3+} ions, the down-conversion through ET involves the transfer of energy between a high-energy RE^{3+} ion and low-energy state RE^{3+} ion resulting in luminescence. It is much more probable that the ET process will go from Dy^{3+} to Sm^{3+} ions due to the higher energy state of the Dy^{3+} ions as compare to the Sm^{3+} ions. The spectrum overlap between the acceptor (Sm^{3+}) excitation and the donor (Dy^{3+}) emission is the primary requirement for the ET process analysis [47]. **Fig. 5** shows the alignment of the PL emission peak of Dy^{3+} ions at 495 nm (from $^4F_{9/2} \rightarrow {}^6H_{15/2}$) with the PLE peak of Sm^{3+} ions at 468 nm (from $^6H_{5/2} \rightarrow {}^4I_{11/2}$). These findings inspired us for further investigation into the ET process from Dy^{3+} to Sm^{3+} by combining the ideal concentration of Dy^{3+} ions with various concentration levels of Sm^{3+} ions (from 1 to 7 mol% in increments of 2 mol%).

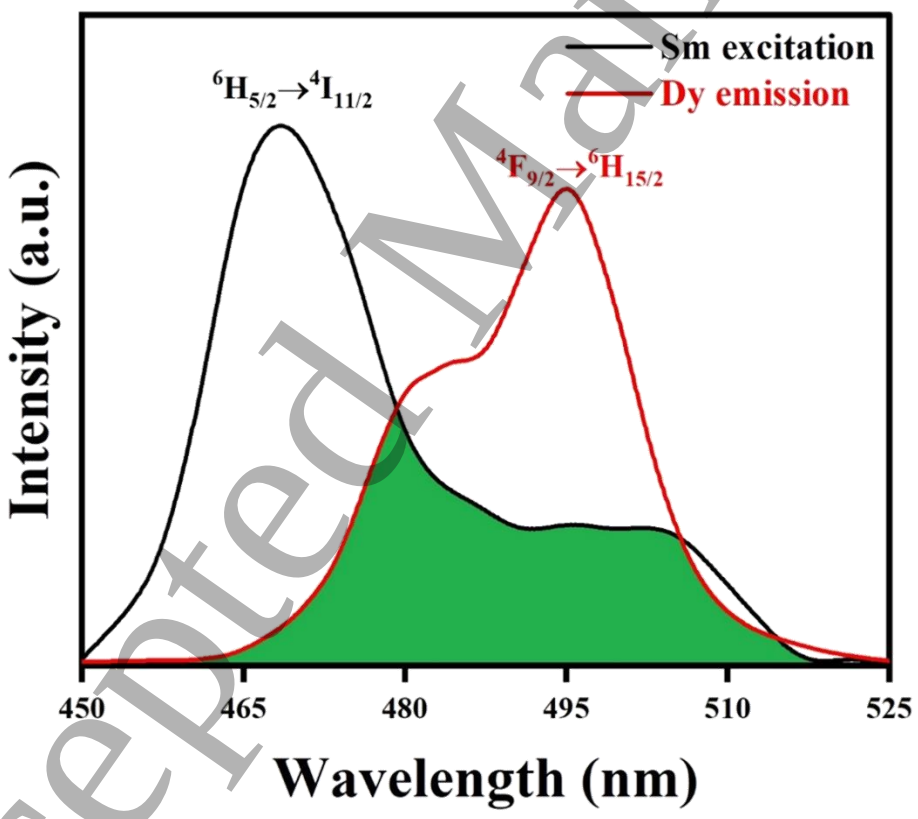

Fig. 5 The overlapped region between the Sm^{3+}excitation band and Dy^{3+} emission band.

Before commencing this investigation, the PLE spectrum of solely Dy^{3+} (3 mol% doping of Dy^{3+}-D3) and Sm^{3+} (1 mol% doping of Sm^{3+}-S1) ions doped phosphors can be observed at λ_{Ex} = 336 nm, as depicted in **Fig. 6 (a)**. **Fig. 6 (b)** displays the PL spectra of three samples

Accepted Manuscript

individually doped with 3 mol% Dy^{3+} (D3) and 1 mol% Sm^{3+} (S1) ions, as well as co-doped with 3 mol% Dy^{3+} and 1% mol Sm^{3+} (D3S1) ions. Under λ_{Ex} = 336 nm, the D3S1 samples exhibit characteristic emission peaks from both Dy^{3+} and Sm^{3+} ions. These include an emission peak at 495 nm for Dy^{3+} ions and emission peaks at 581 nm, 612 nm, and 667 nm corresponding to $^4G_{5/2} \rightarrow {}^6H_{5/2}$, $^6H_{7/2}$, and $^6H_{9/2}$ transitions for Sm^{3+} ions [32,48]. It is evident from the literature that the commercial LED has its excitation wavelength from near UV to UV region [49]. The 336 nm excitation wavelength used in the present work is near to UV region, the commercial LEDs can be used practically to excite the phosphors studied in the present work.

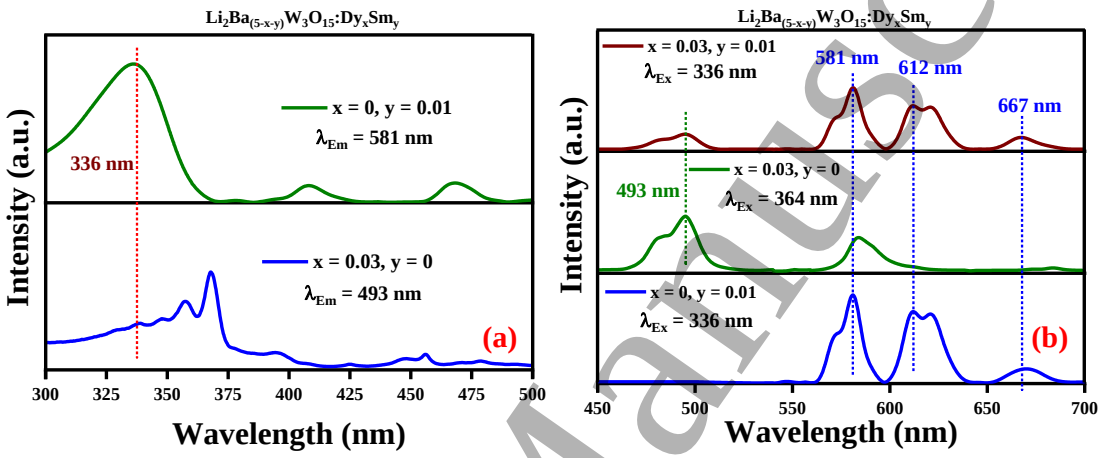

Fig. 6 (a) PLE spectrum of $Li_2Ba_{(5-x-y)}W_3O_{15}:Dy_xSm_y$ (where x = 0.03, y = 0 & x = 0, y = 0.01) phosphors, **(b)** PL spectrum of $Li_2Ba_{(5-x-y)}W_3O_{15}:Dy_xSm_y$ (where x = 0, y = 0.01, x = 0.03, y = 0 and x = 0.03, y = 0.01) phosphors.

In **Fig. 7 (a)**, the intensity of PL emission peaks of Sm^{3+} at 581, 612, and 669 nm significantly increases by about 3-4 times when doped with Dy^{3+}, as compared to single doped with Sm^{3+} ions. This suggests the effective ET from Dy^{3+} to Sm^{3+} under λ_{Ex} = 336 nm. **Fig. 7 (b)** displays the PL emission spectra of $Li_2Ba_{(5-x-y)}W_3O_{15}:Dy_xSm_y$ (where x = 0.03 and $0.01 \leq y \leq 0.07$, Δy = 0.02) phosphors. Under λ_{Ex} = 336 nm excitation, both characteristic peaks of Sm^{3+} and Dy^{3+} are simultaneously visible. Specifically, the peaks at 493 nm (blue light) and 583 nm (yellow light) correspond to the characteristic transitions of $^4F_{9/2} \rightarrow {}^6H_{15/2}$ and $^6H_{13/2}$ for Dy^{3+}, respectively. Meanwhile, the peaks at 581 nm (yellow light), 612 nm (orange-red light), and 669 nm (red light) correspond to the characteristic transitions of $^4G_{5/2} \rightarrow {}^6H_{5/2}$, $^6H_{7/2}$, and $^6H_{9/2}$ for Sm^{3+} ions.The luminous intensity of Dy^{3+} ions gradually diminish with an increase in the concentration of Sm^{3+} ions taking Dy^{3+} ions concentration constant which approves the ET between Dy^{3+} and Sm^{3+} ions. After 5 mol% doping concentration of Sm^{3+} ions, the fluorescence intensity peaks subsequently decrease due to concentration quenching.

Accepted Manuscript

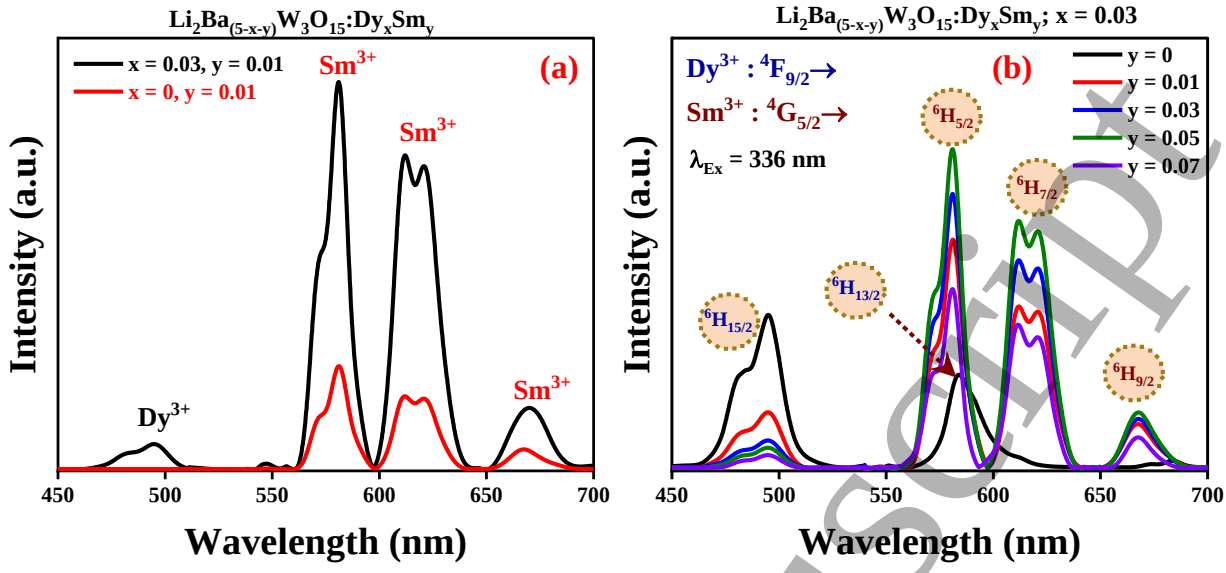

Fig. 7 (a) PL emission spectra comparison of $Li_2Ba_{(5-x-y)}W_3O_{15}:Dy_xSm_y$ (x = 0.03, y = 0.01 & x = 0, y = 0.01) under 336 nm excitation, **(b)** PL emission spectra for LBW, $Li_2Ba_{(5-x-y)}W_3O_{15}:Dy_xSm_y$ (where x = 0.03 and $0.01 \leq y \leq 0.07$, $\Delta y = 0.02$) phosphors.

3.2.2.3 Energy transfer calculation

Fig. 8 (a) illustrates the schematic representation of the ET mechanism from Dy^{3+} to Sm^{3+} within the LBW host material. The excited state of Dy^{3+} ($^4F_{9/2}$) ions is slightly higher than those of Sm^{3+} ($^4I_{19/2}$) ions, suggested that the non-radiative mechanisms are primarily responsible for the ET from Dy^{3+} to Sm^{3+} ions. These non-radiative ET mechanisms involve radiation reabsorption, exchange interaction, and electric multi-pole interaction [17]. The multipole-multipole interaction has a higher chance of causing ET amid all the interactions, in the present study. Reisfeld's approximation was utilized to identify the precise interaction mechanism that exists in the prepared Dy^{3+}/Sm^{3+} co-doped phosphor samples [17]:

$$\frac{\eta_0}{\eta} = C^{a/3} \qquad (6)$$

Here, the symbols η and η_0 represent the radiant quantum efficiencies in the presence and in the absence of the sensitizer (Sm^{3+}) ion, respectively. The type of multipolar interaction is indicated by the variable "a". For d-d, d-q and q-q interaction, a = 6, 8 and 10, respectively. C represents the total concentration of the activator (Dy^{3+}) and the sensitizer (Sm^{3+}) ions (in moles), i.e., C = (3+0), (3+1), (3+3), (3+5) and (3+7) for $Li_2Ba_{(5-x-y)}W_3O_{15}:Dy_xSm_y$ (x = 3, y = 0, 1, 3, 5 & 7), respectively. The following is the relationship between the values of radiant quantum efficiencies and the luminous intensities [47]:

Accepted Manuscript

$$\frac{I_{S0}}{I_S} \propto \frac{\eta_0}{\eta} = C^{a/3} \quad (7)$$

I_S & I_{S0} represent the PL emission peak intensities of activator (Dy^{3+}) ions in the presence and absence of sensitizer ions (Sm^{3+}), respectively. **Fig. 8 (b)** illustrates the changes in the ratio $\frac{I_{S0}}{I_S}$ as a function of $C^{a/3}$. For, a = 6, the data showed the strongest linear fit, suggesting non-radiative ET through d-d interaction. The energy levels for the dopant ions were determined by referring to Carnall's paper [34].

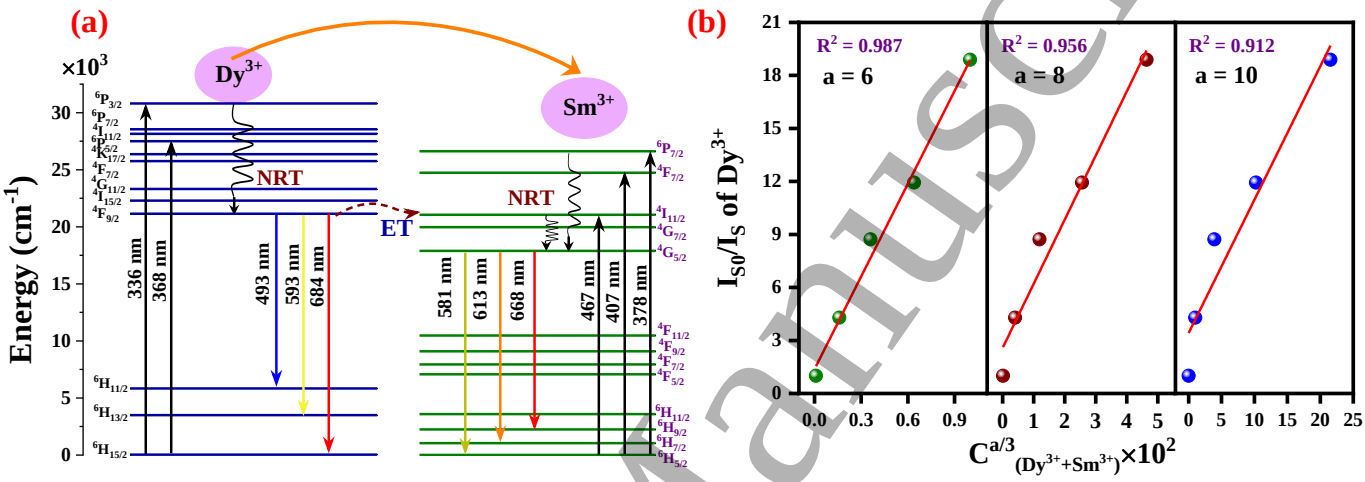

Fig. 8 (a) Schematic diagram of energy transfer from Dy^{3+} to Sm^{3+} in LBW host material, **(b)** The variation in the ratio I_{S0}/I_S as a function of $C^{a/3}$.

3.2.2.4 Study of time resolved photoluminescence (TRPL)

Fig. 9 (a) shows the decay curves of LBW, $Li_2Ba_{(5-x-y)}W_3O_{15}:Dy_xSm_y$ (where x = 0.03 and 0.01 ≤ y ≤ 0.07, Δy = 0.02) co-doped LBW phosphors when the excitation and emission wavelengths are fixed at 336 nm and 581 nm, respectively. This allows for a deeper exploration of the ET process between Dy^{3+} and Sm^{3+} ions. Single exponential fitting is not appropriate for the measured data; however, double exponential fitting provides a useful assessment method [50]*:*

$$I_t = I_0 + A_1 \exp\left(-\frac{t}{\tau_1}\right) + A_2 \exp\left(-\frac{t}{\tau_2}\right) \quad (8)$$

where, I_0 and I_t denote the intensity at initial time and at time t, respectively. The exponential component's rapid and slow lifetimes are denoted by τ_1 and τ_2, respectively. The correlative parameters that resulted after fitting are A_1 and A_2. Therefore, the following equation can be

Accepted Manuscript

used to confirm the average lifetime of the Dy^{3+}/Sm^{3+} co-doped ions in the LBW phosphor samples [41]:

$$\tau = \frac{A_1\tau_1^2 + A_2\tau_2^2}{A_1\tau_1 + A_2\tau_2} \quad (9)$$

Thus, for the as-prepared $Li_2Ba_{(5-x-y)}W_3O_{15}:Dy_xSm_y$ (where x = 0.03 and $0.01 \leq y \leq 0.07$, $\Delta y = 0.02$) co-doped phosphor samples, the computed average lifetime is 0.646 ms, 0.641 ms, 0.637 ms, and 0.624 ms, respectively. The lifetime (τ), energy transfer probability (P_{ET}), and energy transfer efficiency (ETE; η_{ET}) are plotted against the Sm^{3+} ions concentration in **Fig. 9 (b)**. As seen in **Fig. 9 (b)**, adding more Sm^{3+} ions, shortens the luminescence lifetime values, indicating the possibility of ET from $Dy^{3+} \rightarrow Sm^{3+}$. The following expression can be used to estimate the ETE based on the measured lifetime values [51]:

$$\eta_{ET} = 1 - \frac{\tau}{\tau_0} \quad (10)$$

here, τ_0 represents the lifetime for Dy^{3+} single doped sample while for Dy^{3+}/Sm^{3+} co-doped samples, the lifetime is represented by τ. When y = 0.07, the maximum η_{ET} increases to 18%. The P_{ET}, which measures the chance of ET from the donor ions to the acceptor ions, is computed using the formula given below [52]:

$$P_{ET} = \frac{1}{\tau} - \frac{1}{\tau_0} \quad (11)$$

Fig. 9 (b) shows the variation of τ, η_{ET} and P_{ET} with the concentration of Sm^{3+} ions and **Table 1** provides an overview of the above evaluated parameters.

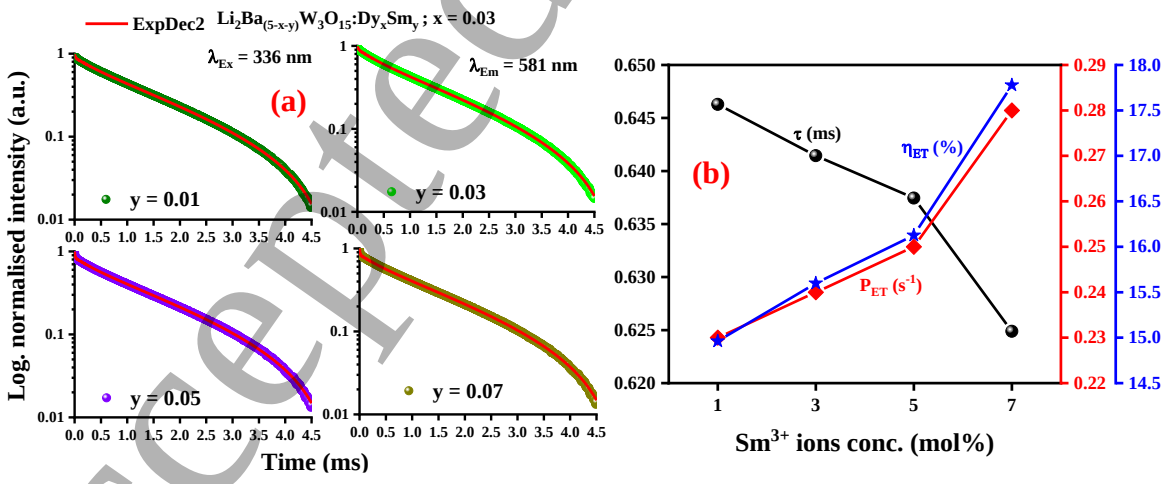

Fig. 9 (a) The decay curves of $Li_2Ba_{(5-x-y)}W_3O_{15}:Dy_xSm_y$ (where x = 0.03 and $0.01 \leq y \leq 0.07$, $\Delta y = 0.02$) phosphors at λ_{Em} = 581 nm & λ_{Ex} = 336 nm and **(b)** variation of τ_{av}, η_T and P_T with the Sm^{3+} ions concentration.

Table 1

The average value of decay lifetime (τ, ms), energy transfer efficiency (η_{ET}) and energy transfer probability (P_{ET}) of $Li_2Ba_{(5-x-y)}W_3O_{15}:Dy_xSm_y$ (where x = 0.03 and 0.01 ≤ y ≤ 0.07, Δy = 0.02) co-doped phosphors.

System Name	τ (ms)	η_{ET} (%)	P_{ET} (s^{-1})
D3S1	0.646	14.96	0.23
D3S3	0.641	15.60	0.24
D3S5	0.637	16.12	0.25
D3S7	0.624	17.78	0.28

The energy transfer efficiency can be evaluated using the emission spectra, represented in Fig. 8 (b). The following expression can be used to evaluate the $\eta_{ET(emssion)}$ using emission spectra of the as-prepared $Li_2Ba_{(5-x-y)}W_3O_{15}:Dy_xSm_y$ (where x = 0.03 and 0.01 ≤ y ≤ 0.07, Δy = 0.02) co-doped phosphors [53]:

$$\eta_{ET(emssion)} = \frac{I^{Dy^{3+}} + I^{Dy^{3+}+Sm^{3+}}}{I^{Dy^{3+}}} \quad (12)$$

here, $I^{Dy^{3+}}$ and $I^{Dy^{3+}+Sm^{3+}}$ are the luminescence intensities of $^4F_{9/2} \rightarrow {}^6H_{15/2}$ for 0.03 moles of Dy^{3+} single ions doped and Dy_xSm_y (where x = 0.03 and 0.01 ≤ y ≤ 0.07, Δy = 0.02) co-doped LBW samples. The ETE were evaluated by taking the integrated luminescence intensity data in Fig. 8 (b) into Eq. (12). The energy transfer efficiency increases with increasing Sm^{3+} ions concentration. A comparison of ETE values calculated using the emission spectra and fluorescence decay analysis has been represented in Table 2.

Table 2

A comparison of ETE values calculated using the emission spectra and fluorescence decay analysis for the as-prepared $Li_2Ba_{(5-x-y)}W_3O_{15}:Dy_xSm_y$ (where x = 0.03 and 0.01 ≤ y ≤ 0.07, Δy = 0.02) co-doped phosphors.

3.2.2.5 Evaluation of color coordinates

The chromaticity coordinate diagram for Dy^{3+} single ions doped and Dy^{3+}/Sm^{3+} ions co-doped LBW phosphors, designed by the Commission International de I 'eclairage (CIE) in 1931, evaluated using the formula given in literature [47,52] and shown in **Fig. 10 (a)**. The CIE color coordinates of white luminescent phosphor are (0.333, 0.333), which are in the white light area, based on the emission spectrum of the substance [47]. CIE of D3 sample lie in yellow-white area. When Sm^{3+} ions are co-doped with D3 phosphors, the emission gradually moves to the warm white light region. **Table 3** represents the CIE chromaticity coordinates, Correlated Color Temperature (CCT), and emission light color information for the prepared samples. The CCT values are determined using the Mc-Camy equation [54]:

$$CCT = a\eta^3 + b\eta^2 + c\eta + d \quad (13)$$

here, $a = -449$, $b = 3525, c = -6823.2$ and $d = 5520.3$ are the constants; and $\eta = \frac{x-x_e}{y-y_e}$; $x_e = 0.3320, y_e = 0.1858$, (x, y) are the CIE color coordinates of each sample.

Low CCT values imply warmer light, while high CCT values seem to be colder [41]. **Tables 3** and **Fig. 10 (a)** illustrate that the introduction of a specific quantity of Sm^{3+} doping into the D3 host leads to a notable decrease in color temperature, shifting the emission from the yellow-white sunlight region to the warmer white light region. While the D3 phosphor itself, emitting cold white light, achieves white light emission through blue and yellow light emissions, however, the absence of red light can cause prolonged discomfort such as eye strain, fatigue, and piercing sensations. Consequently, a phosphor incorporating a three-color mixture is developed to emit warm white light, thereby reducing the detrimental effects of blue light on human eyes and significantly cutting costs. Hence, the synthesized $Li_2Ba_{(5-x-y)}W_3O_{15}:Dy_xSm_y$ (where x = 0.03 and $0.01 \leq y \leq 0.07$, $\Delta y = 0.02$) co-doped phosphors, owing to its low CCT value and emission of warm white light, holds promise as potential candidate for indoor and ambient lighting applications, alleviating eye fatigue. **Table 4** shows the comparison of CCT of the optimised phosphor $Li_2Ba_{(5-x-y)}W_3O_{15}:Dy_xSm_y$ (where x = 0.03, y = 0.05) sample with previously reported literature [17,32,55,56].

Color purity (CP) is an additional significant factor in colorimetric calculations that analyse the color saturation. To assess the CP, following equation was used [48]:

$$\text{Color purity (CP)} = \frac{\sqrt{(x-x_{ee})^2+(y-y_{ee})^2}}{\sqrt{(x_d-x_{ee})^2+(y_d-y_{ee})^2}} \quad (14)$$

where, (x_{ee}, y_{ee}) is equal energy point, (x, y) is color coordinates of the prepared Dy^{3+}/Sm^{3+} co-doped LBW phosphors, and (x_d, y_d) is the dominant wavelength point. The CP values, shown in inset of **Fig. 10 (b)**, increases from 15% to nearly 80%, which are relatively high, indicate

Accepted Manuscript

the use of the prepared phosphor material as a reddish-orange emitting element in w-LEDs when excited by n-UV or blue light, presented in **Table 3**.

Table 3

The CIE chromaticity coordinates, CCT (K), emission color and CP (%) of the $Li_2Ba_{(5-x-y)}W_3O_{15}:Dy_xSm_y$ (where x = 0.03 and 0.01 ≤ y ≤ 0.07, Δy = 0.02) phosphor samples.

System Name	CIE		CCT (K)	Emission color	CP (%)

3.2.2.6 Study of temperature dependent PL

The thermal stability of the phosphor samples prepared can be well understood using thermogravimetric analysis (TGA) and the temperature-dependent photoluminescence (TD-PL) studies. We have studied the TGA of the un-doped LBW phosphor and reported it in our previous paper [50]. To complement the encouraging TGA result, the TD-PL studies have been recorded in the present work for the co-doped LBW phosphors. It is well known that, temperature has a significant effect on w-LED performance; UV/blue LED chips lose optical performance as the temperatures rises. Thus, for the optimized phosphor sample $Li_2Ba_{(5-x-y)}W_3O_{15}:Dy_xSm_y$ (where x = 0.03, y = 0.05) at λ_{Ex} = 336 nm, TDPL experiments were performed, as shown in **Fig. 11**, to investigate its thermal behavior by raising the temperature from ambient temperature to 443 K. As seen in **Fig. 11 (a)**, the PL emission peak intensity seems to be slightly decreasing as the temperature increases from 298 K to 443 K. However, the peak position remains unchanged. **Fig. 11 (b)** displays the shift of CIE chromaticity coordinates with temperature ranges from 293 K to 443 K. The CIE chromaticity coordinates are almost unchanged for $\Delta x < 0.001$ and $\Delta y < 0.006$, although the temperature rises from 298 K to 443 K.

The activation energy must be investigated in order to better understand the thermal quenching effect, and it can be estimated using the Arrhenius equation [57]:

$$I_T = \frac{I_0}{[1+c\ exp\ (-\Delta E/KT)} \quad (15)$$

where, I_0 is the emission intensity at room temperature and I_T is the emission intensity for each changing temperature [58], A is a constant and the Boltzmann constant, k, is equal to 8.62×10^{-5} eV/K. The activation energy (ΔE), can be obtained using the relationship between

Accepted Manuscript

$ln\,[(I_0/I_T)-1]$ and $1/KT$, as seen in **Fig. 11 (c)**. Consequently, following the linear fitting for these sites, ΔE was calculated to be 0.16 eV, exceeding earlier researches [55,59–62], presented in **Table 5**.

4. Conclusions

In conclusion, the high-temperature solid-state reaction technique was used to synthesize a series of Dy^{3+}/Sm^{3+} co-doped warm white LBW phosphors. The addition of dopant (Dy^{3+}/Sm^{3+}) ions in the LBW host lattice without inducing structural changes was shown by the slight shift in bandgap with the change in its concentration. Warm white light emission with a low CCT (1768 K) value can be achieved by simply changing the concentration of Sm^{3+} which makes the light emission appropriate for indoor lighting applications. Co-doping of LBW:Dy^{3+} phosphors with Sm^{3+} ions allow for the modification of luminescent colors from a neutral white to orange-red region. The concentration quenching of singly Dy^{3+} ions doped and Dy^{3+}/Sm^{3+} co-doped LBW phosphors is caused by d-d interaction, suggested by Dexter theory and Reisfeld approximation. In this study, the maximum η_{ET} was determined to be 17.78%. The optimised phosphor sample's activation energy of 0.16 eV was discovered to be higher than that of previous reported phosphors, indicating the better thermal stability of the prepared phosphor. According to our findings, the Dy^{3+}/Sm^{3+} co-doped LBW phosphor has a wide range of potential applications in warm light w-LED technological advances because of its superior solubility for RE^{3+} ions, high thermal stability, and high luminous efficiency.

ORIGINAL PAPER

SSR-GAN: super resolution-based generative adversarial networks model for flood image enhancement

Vinay Dubey[1] · **Rahul Katarya**[1]

Abstract
Floods, a common natural disaster, it affects more than half of all natural disasters, primarily due to high floods, high tides, heavy rainfall, and human activity. Distinguishing between the flooded and non-flood areas during the disaster is dependent on the quality of images collected from different sources. Since synthetic aperture radar (SAR) images can see through cloud cover and capture photos of the Earth's surface during bad weather, they are excellent for detecting floods. Image Enhancement is the approach that helps to increase the resolution of the SAR images, which helps to more accurately categorize the flooded and non-flooded areas. The quality of satellite and aerial imagery can be enhanced to recognize flooded and non-flooded areas. Our proposed approach uses a super-resolution technique to enhance the resolution of SAR images. We develop a super resolution-based generative adversarial network, or SSR-GAN (Satellite Super Resolution-based Generative adversarial network). In our approach to estimating generative models through an adversarial process, we concurrently train two different models: a generative model G and a discriminative model D. An image with low resolution is transformed into high pixel density. The peak signal-to-noise ratio (PSNR), the structural similarity index(SSIM), Multiscale Structural Similarity (MSSIM) and mean squared error (MSE) are the performance metrics used to compare the interpolation methods for enhancing resolution. In comparison to the existing approaches with our proposed model SSR-GAN, the values of PSNR, SSIM, and MSSIM are greater, and the MSE error value is lower.

Keywords Flood disaster · Generative adversarial network · Image enhancement · Super-resolution

1 Introduction

Flood catastrophes pose a significant threat to urban areas, posing a greater threat to diversity and community than other natural or man-made disasters. Vulnerable cities worldwide face extreme tides, hurricanes, river overflow, and inadequate drainage systems. Numerous cities across the globe are vulnerable to this threat, which is mostly caused by isolated areas of intense precipitation. Because they are unable to handle the floods caused by heavy precipitation and inadequate drainage systems frequently cause floods.

1.1 Problem statement

A flood occurs when the water level of the river rises above the river bank due to the flow of the river. High river levels are typically caused by river precipitation and the backwater resulting from high tides near the river's mouth [1]. Floods cause significant financial losses and require efficient detection and prediction systems. Accurate mapping using SAR photos and satellite imagery is crucial for detecting and predicting flooded areas. Detecting urban flooded areas helps cities evolve flood maps, reducing risk. Mapping flooded areas is complex due to discontinuous, shallow, and ephemeral flooding [2]. For better disaster response and conditional awareness on the ground is very essential. Nowadays Satellite imagery is crucial for disaster response, with Synthetic Aperture Radar (SAR) being a promising technique for detecting Earth's surface, even in cloudy environments, and studies have shown its effectiveness in detecting floods [3].

SAR's all-weather and night-time accessibility make it crucial for efficient disaster prevention and rescue operations, providing clear, detailed data under harsh conditions.

1.2 Major contribution

However, some progress has been made in using SAR for urban flood scenarios when utilized with high-quality data as well as creative image processing techniques [4]. There is some issue with satellite images because some satellite images have low contrast images. Blurry, noise and low contrast can cause the image to deteriorate, which Reduces the target detection ability of SAR images [5]. Research has indicated that social sensing could be a useful data source for guiding flood relief and emergency response decisions, as well as advances in science and technology that make use of innovative methods for data collection and processing [6]. To improve image quality, we propose our SSR-GAN model which utilizes a single generator, discriminator, and VGG net, in our proposed GAN model to calculate perceptual loss and structural similarity. The experimental results show that our model outperforms current methodologies in numerous image quality enhancement matrices.

- We present a new, competent super resolution-based approach for improving the quality of satellite-based flood images.
- We use generative adversarial networks GAN for super-resolution. Our model can restore fine details and enhance the visual quality of the photographs in comparison to conventional methods, which fail to provide visually realistic results.
- VGG NET is used to calculate perceptual difference, utilizing intermediate feature maps to measure perceptual loss between generated and target images, guiding image generation process optimization.
- We worked on a large-scale multi-temporal dataset for the past ten years, incorporating images before and after the event under different weather conditions.
- The comprehensive comparison performed between the proposed SSR-GAN and the state-of-art approaches shows that our model outperforms existing techniques.

The rest of the article is structured as follows. Section 2 discusses the related work. Section 3 proposed methodology is explained. The experimental findings, analyses, and dataset summary are included in Sect. 4. Finally, Sect. 5 presents the work's and conclusion.

2 Related work

The literature review examines various methodologies to enhance Synthetic Aperture Radar (SAR) images, focusing mainly on flood control and surveillance applications [7]. Speckle noise reduction is crucial for improving SAR image interpretation, target detection, and classification. Techniques such as fuzzy ARTMAP and deep neural networks enhance image quality and facilitate flood prediction [8–10]. Edge detection filters and region classification aid in identifying potential groundwater locations, while mathematical models analyze the effects of geological features on runoff and soil erosion [11, 12]. Moreover, models like MA, NSCT, and MP-CMA are prominent for SAR image enhancement, integrating speckle reduction with feature techniques such as ℓp-LSCE and GAN-FEM address noise enhancement [13]. Automatic target recognition (ATR) reduction and improved target.

feature extraction [14, 15]. Integrating artificial intelligence into change detection approaches has gained traction, particularly for identifying flood-affected regions using supervised classification methods [16, 17]. Post-event flood mapping relies on hydraulic model simulations, SAR, and optical satellite imagery [18, 19]. Innovative approaches like generative adversarial networks (GANs) with perceptual and structural loss functions are proposed for SAR image quality improvement [20]. Automated methods and machine learning models accelerate flood map creation during emergencies, leveraging tools like Google Earth Engine for satellite imagery acquisition and processing [21–23]. Unscented Kalman Filter (UKF), and Super Resolution (SR) are used to reduce noise from images [24]. Additionally, techniques such as Histogram Equalization (HE), Adaptive Histogram Equalization (AHE), and super-resolution reconstruction contribute to image enhancement [25–27]. Furthermore, for non-uniformly illuminated fundus images, GANs with illumination-guided attention are suggested, along with machine learning methods like Principal Component Analysis (PCA) and Random Forest (RF) [28, 29]. Dual-branch neural networks and compressed sensing methods aid in single-image rain removal and image compression, respectively [30, 31]. Intelligent prediction models like Deep-SIQRV for disease spread and flood index insurance algorithms are also proposed [32, 33]. Multisource remote sensing approaches and meta-heuristic feature selection techniques enhance flood forecasting accuracy [34]. Lastly, image enhancement methodologies for underwater river crab target recognition, COVID-19 patient CT scans, low-light picture enhancement, and satellite-based inference models are explored [35–39]. An overview of relevant works that are comparative is given in Table 1

Some significant research articles are given in the table above. SAR pictures are the primary source of study. The

Table 1 A summary of existing methods for SAR image quality enhancement

Ref. No	Dataset	Methodology	Description	Merit	Limitations
[8]	Land sat 8 ETM satellite images	Fuzzy ARTMAP, artificial neural network method	ARTMAP network is made of two modules (ARTb and ARTa) that provide stable identification classes	The ARTMAP approach can produce maps with the desired level of accuracy	For geological regions with a lot of variety, like mountains, the geological maps are not very accurate
[9]	Sentinel- 1A images of ganga basin	Cloud-based google earth engine (GEE) framework	The enhanced EVI and NDVI generated from satellites are used to evaluate the direct effects of floods on plant cover	Quickly determine the particular flood-affected areas and provide a quicker response	As a ratio-based index, (NDVI) and (EVI) both capture intrinsic on-linearity
[10]	Sentinel-1 (SAR satellite) and Sentinel-2 (optical satellite)	Deep neural networks, Generative adversarial networks, edge enhancement	Corresponding positions between SAR and optical pictures were determined using an image translator based on (cGANs)	The proposed methodology could effectively estimate the intersections of optical and SAR pictures	Some special land coverings and textural information are poorly transferred from SAR photos to optical images
[13]	Synthetic aperture radar images	Nonsubsampled contourlet transform, memetic algorithm	An objective enhancement criterion then tries to identify the (nearly) ideal image that uses that criterion	As the speckle noise is reduced, it can enhance the edge characteristics and contrast of SAR images	The algorithm's complexity is increasing, and operating efficiency must be improved
[14]	Synthetic aperture radar images	ℓp-regularization, low-rank, space-angle continuity,	Introduce the ℓp-LSCE, a feature-oriented algorithm to improve the target in a noisy environment	It can use the relationships between pictures to decrease speckles	The suggested 3-D image-generating model will require more processing power
[15]	Monochromatic synthetic aperture images	Generative adversarial network (GAN)	The GAN-driven focusing-enhancement approach (GAN-FEM) is used to fit an unknown out-of-focus kernel	This approach used the 2-D monochromatic imaging system's capacity for focusing enhancement for 3-D targets	The GAN-FEM also introduces some minor issues, such as the addition of energy noise toward the target scatter
[17]	Synthetic aperture radar images (sentinel-1, Sentinel-2 data)	Change detection, Supervised classification	A novel probabilistic change detection method for exposing various types of disruptions caused by excessive precipitation	The advantages of adding the SWIR channel to the visual and near-infrared indexes were only a few percentage points greater in size	Results will be improved by providing refined identification capacity at different types of deteriorations
[21]	RADARSAT-2 Synthetic Aperture Radar (SAR) images	Threshold and polarization	Flood water can be distinguished more effectively using HH polarization	This can facilitate the flood mapping process by ensuring that flood maps are distributed to the relevantly	Combining the information about the backscattering fluctuation might improve the accuracy

Table 1 (continued)

Ref. No	Dataset	Methodology	Description	Merit	Limitations
[24]	Synthetic aperture radar (SAR)	Unscented kalman filter (UKF), super resolution (SR)	A novel approach to super-resolving Satellite image utilizing the ISUKF, which can withstand multiplicative noise, is proposed	An approach to both improve resolution and reduce inherent noise, since traditional super-resolution techniques are not effective	If the transformation is linear then the unscented kalman filter will be slower than the conventional Kalman filtering

survey has highlighted the importance of SAR-based flood image improvement and has noted numerous significant findings.

Speckle noise: Speckle noise, which emerges as granular interference and can reduce image quality, frequently affects SAR photos.

Incorporating multi-temporal data: During a flood event, SAR images taken at various times might reveal important details about the flood dynamics. It would be helpful to develop algorithms that can integrate and analyze time-series SAR data.

Improved contrast enhancement methods: Poor contrast is another issue with SAR images. Novel contrast enhancement methods are required to improve the visibility of flood-related characteristics and the discrimination between flooded and non-flooded areas.

Limited image quality improvement: Traditional image enhancement approaches may struggle to adequately enhance the quality of SAR flood photos, especially in terms of noise reduction, and maintaining essential features.

3 Proposed methodology

This section outlines the fundamental ideas that are required for an exhaustive comprehension and efficient implementation of our work. The following essay gives a general introduction to generative adversarial networks, super-resolution, and image enhancement.

3.1 Super-resolution

Super-resolution (SR) is a term used to describe the process of improving the resolution and amount of detail in low-resolution pictures or videos. By using its lower-resolution counterpart, it is possible to rebuild a higher-resolution version of an image. When using satellite imagery for disaster relief, a high-resolution image is helpful for improved region categorization in multi-spectral remote sensing images [40]. It can be categorized into single-image and multi-image super-resolution techniques.

SISR is a crucial image processing technique that optimizes features and textures to improve visual perception and reconstruct high-resolution images from low-resolution ones [41]. Multi-image SR (MISR) combines numerous LR images, each of which has a unique subset of HR images. As a result, MISR can improve reconstruction accuracy compared to single-image SR (SISR) [42].

3.2 Generative adversarial networks

Generative modeling is an unsupervised machine learning task that automatically learns patterns in incoming data, enabling the model to generate new instances from the original dataset. To create new examples, we train a generator model, and we train a discriminator model to determine whether an example is genuine (coming from the domain) or fake (being generated). Generative Adversarial Networks (GANs) belong to generative models [23]. Currently, the most used data generation has been trained on the dataset. GANs consist of two networks Generator (G) and Discriminator (D). The discriminator is provided with real and generated data points that it must learn to distinguish between. The Generator has to make data points such that it becomes difficult for the discriminator to distinguish. The discriminator learns to separate the underlying distribution between real and generated points, and the Generator needs to make data points with a similar distribution to the real data points. Both the networks are trained simultaneously, thus at the end, having a Generator that captures the underlying real data distributions.

$$\min_{G}\max_{D} V(D, G) \quad \mathrm{E}_{x\sim \mathrm{Pdata}(x)}\left[\log D(x)\right] + \mathrm{E}_{z\sim \mathrm{Pz}(z)}\left[\log(1 - D(G(z)))\right] \tag{1}$$

In the above 1, Eq. 1, P_data is the real data distribution and P_z is the distribution followed by the latent variable

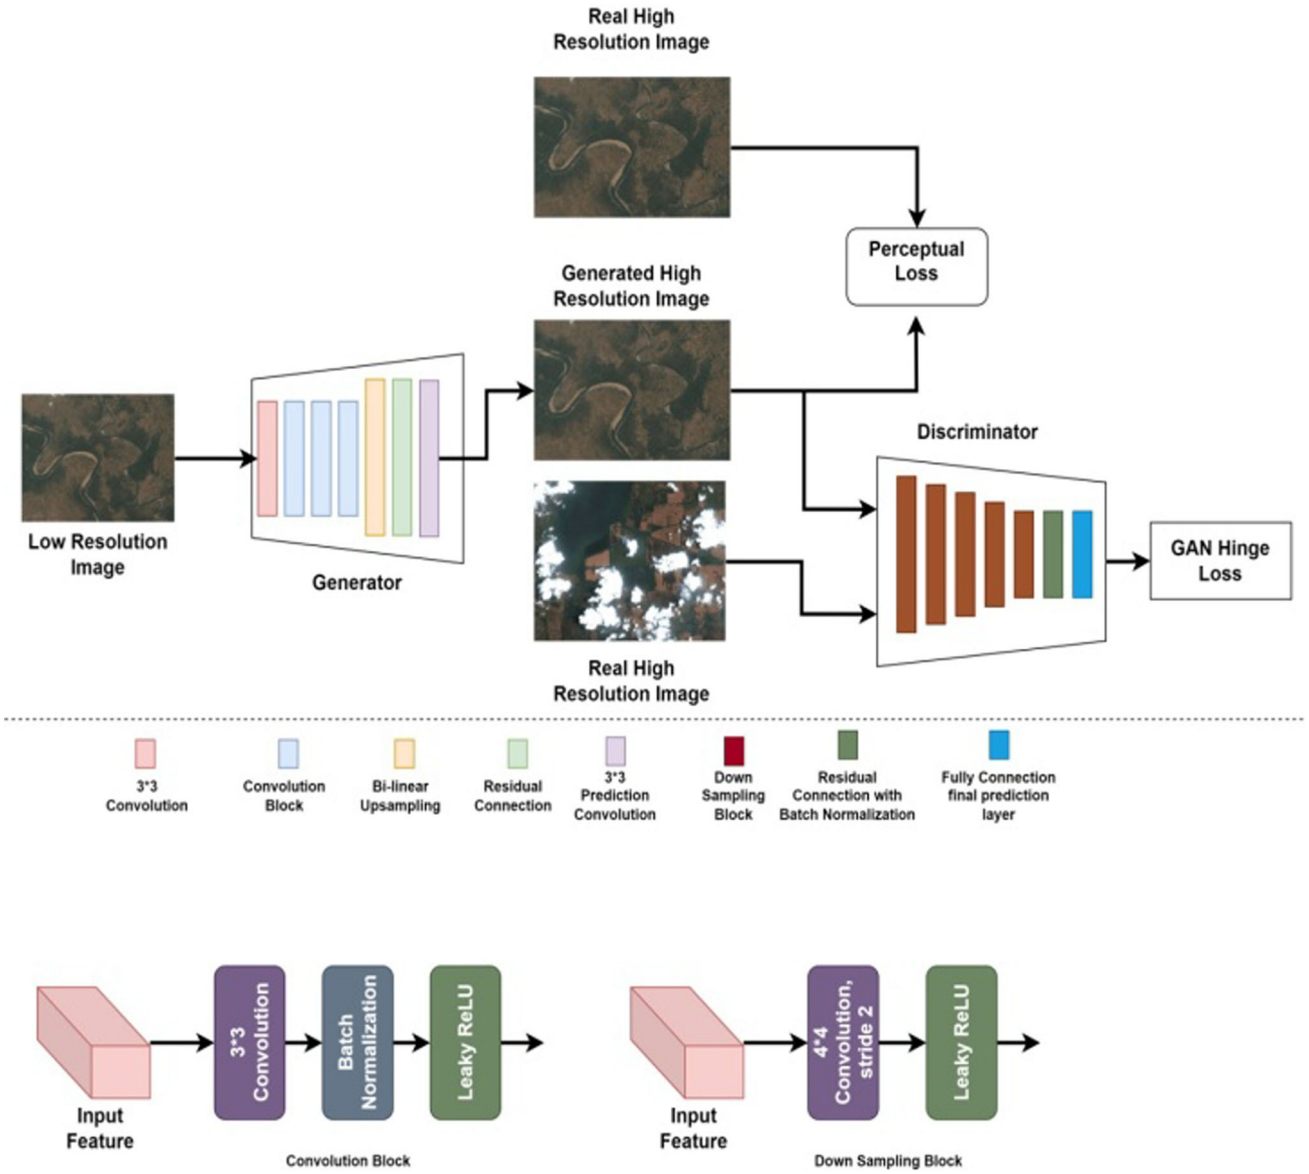

Fig. 1 The architecture of our proposed (SSR-GAN) model for SAR image enhancement

which the generator maps to generated data points mimicking the real data distribution.

3.2.1 Need of VGG net for perception loss

Perceptual loss, a loss term in picture synthesis applications, uses a convolutional neural network to preprocess input mages and calculate the similarity between input and output images. [43]. The usage of VGG16 for feature extraction for calculating perceptual differences is what connects perceptual loss and VGG16. The plan is to use the pre-trained VGG16 network and its intermediate feature maps to calculate the perceptual loss among generated and target images. The perceptual loss can be estimated and used as a guide for optimizing the picture production process by targeting pictures at different levels of VGG16. To compute the comparing the representations of features of the generated perceptual loss and get an astonishing result, multiple convolution layers from VGG-Net, a pre-trained neural.

network on a natural picture dataset was employed in the maximal effort. While we focus on additional image synthesis challenges, such as super-resolution, colorization, and other picture-building tasks [44].

3.3 Model architecture

Our model is inspired by [45] for super-resolution generations to generate high-resolution satellite data images. The

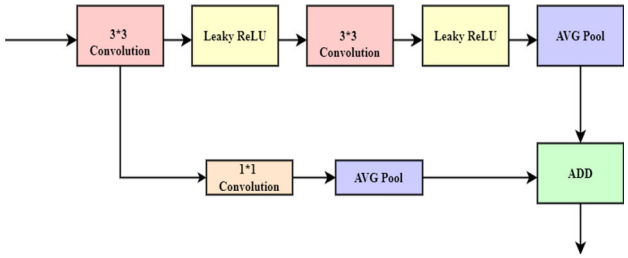

Fig. 2 Block diagram of down-sample block

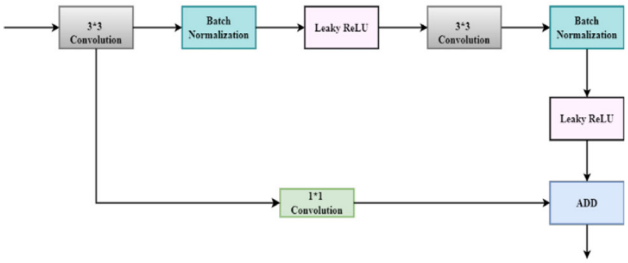

Fig. 3 Block diagram of residual block with batch normalization

block diagram of our suggested SSR-GAN model is shown in Fig. 1. Our model (SSR-GAN) consists of a Generator, Discriminator, and VGG net for preserving structure. At the time of training, we pass a low-resolution image (128*128) which is provided as input to the generator, which consists of a series of convolution and residual blocks followed by a single bilinear upsampling convolution and predict the following output using a residual block and final prediction layer. Our generator is a full convolution network that can upsample images of any resolution. The discriminator is provided with a real high resolution (256*256) and Generated high-resolution image(256*256), which the generator has to distinguish between by predicting real or fake. We also use VGG-NET for the perceptual loss using features extracted from generated high-resolution images and real-pair high-resolution images to preserve the structure of the image. Our model learns distribution to upsample locally, preserving global structure at the time of testing, using 256*256 resolution image input and 512*512 resolution output, enhancing local fine-tuning over predefined steps.

3.3.1 Loss for discriminator

$$\mathcal{L}_{Adv}^{D} = E_{x\sim p_{data}}\left[\max\left(0,\ 1 - D\left(x\right)\right)\right] + E_{\widehat{x}\sim p_G}\left[\max\left(0,\ 1D\left(x\right)\right)\right] \quad (2)$$

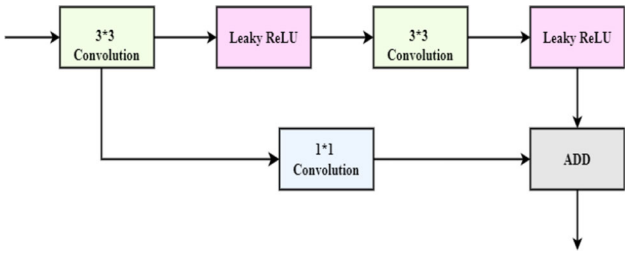

Fig. 4 Block diagram of residual block without batch normalization

In Eq. 2, p_{data} is the data distribution of high-resolution images and p_G is the Generator learned distribution to generate high-resolution images. We use Hinge Adversarial loss introduced in our model [46].

3.3.2 Loss for generator

$$\mathcal{L}_{Adv}^{G} = E_{\widehat{x}\sim p_G}[-D(\widehat{x})] \quad (3)$$

In Eq. 3, which is used to preserve the global structure of the images generated we use perceptual loss [23]. We use features extracted from the 9th layer of the Vgg-16 Network [47].

3.3.3 Perceptual loss

$$\ell_{feat}^{\varnothing,j}(\widehat{y},\ y) = \frac{1}{C_J H_J W_J}||\varnothing_j(\widehat{y}) - \varnothing_j(y)||_2^2 \quad (4)$$

In above Eq. 4,y and $\widehat{y}$ are the targeted images and synthesis images. $\varnothing_j$ represents the perceptual function that outputs the activation of the jth layer in the perceptual loss network. C_J,H_J, W_J are the dimensions of the tensor feature map [48].

The architecture of the downsample block is depicted in above Fig. 2. The discriminator's downsample block is sab-block, followed by the residual block with batch normalization.

In the above Fig. 3, the inner layered architecture of the residual block with batch normalization (BN) layer is explained. Residual block with BN is part of the generator of our proposed model. In below Fig. 4, the inner layered architecture of the residual block is explained. Residual block without BN is also part of the discriminator block of our proposed model.

4 Result and analysis

4.1 Dataset

Images with a size of 256 × 256 are used as inputs in our experiment. The experiment uses 3000 Sentinel-2 images from India over the past 20 years to construct a dataset of landscapes, including lakes, terraces, villages, and snow-capped mountains. The data is primarily prone to flooding, ensuring accurate resolution and geographic makeup.

We will be using data from the previous 20 years for various geographical locations of India because the satellite has a 12-day return cycle. The majority of the area we consider in our study is quite prone to flooding.

Algorithm 1 A detailed description of our proposed SSR-GAN model is provided below Algorithm 1.

Algorithm: Procedure for the SAR image enhancement using the proposed (SSR-GAN) model
Input: Raw (low resolution) SAR images
Output: High-resolution SAR images

Adam Optimizer: Learning Rate:= 0.0001, beta_1 = 0.5,beta_2 = 0.999
Spectral Normalization is used for all Convolution and Fully Connected layers in Discriminator and Generator

}
End
Return High-Resolution Image

4.2 Evaluation metrics

Pixel statistics are suitable for evaluating image quality using traditional measures like PSNR, SSIM, MULTI-SCALE SSIM, and MSE.

4.2.1 Peak signal-to-noise ratio

$$\mathrm{PSNR} = 20\log_{10}\left(\frac{MAX_f}{\sqrt{MSE}}\right) \tag{5}$$

4.2.2 Structural similarity index measure

$$\mathrm{SSIM}(x,\ y) = [(x,\ y)]^{\alpha}\left[c(x,\ y)\right]^{\beta}\left[s(x,\ y)\right]^{\gamma} \tag{6}$$

4.2.3 Multi-scale SSIM

$$\mathrm{MSSIM}(x,\ y) = [l_m\,(x,\ y)]^{\alpha_M}\prod_{j=1}^{M}\left[C_j\,(x,\ y)\right]^{\beta_j}.\left[S_j\,(x,\ y)\right]^{\gamma_j} \tag{7}$$

4.2.4 Mean squared error

$$\mathrm{MSE} = \frac{1}{MN}\sum_{n-1}^{M}\sum_{m-1}^{N}\left[\hat{y}(n,\ m) - y(n,\ m)\right]^2 \tag{8}$$

4.3 Analysis of results

Figure 5 provides the visual results of our proposed model and the existing approaches.

Table 2, shows the statistical measure of the existing model with our proposed model. The proposed model outperforms existing models in terms of PSNR, SSIM, MSSIM, and MSE parameters, with a low MSE value, indicating superior performance.

4.4 Analysis of result

In this section, The proposed model and traditional techniques were compared in terms of PSNR, SSIM, MSSIM, and MSE, with the original image size being (256*256) resolution.

Figure 6 displays the PSNR calculation and comparison of existing and proposed approaches, with epochs displayed on the X-axis and ratio values listed on the Y-axis.

5 Conclusion and future scope

This paper presents a GAN-based super-resolution approach for flood-based SAR image enhancement, enhancing the quality and spatial resolution of SAR images, particularly for flood management and monitoring applications. The proposed SSR-GAN model included both image quality improvement and a fake-image detection step, signifying significant development in image processing and verification. The loss is computed via VGG-NET. In comparison to other traditional approaches already in use, the proposed SSR-GAN model produces improved PSNR, SSIM, and M-SSIM scores. In comparison to previous methods, our model has a lower MSE value. We supply a (256*256) resolution image as the input, and our model predicts the outcome with an enhanced (512*512) resolution image since it has been taught to learn distribution to upsample locally while maintaining the overall structure. GAN-based SAR image enhancement has shown satisfactory outcomes and has the potential to improve the quality and interpretability of SAR images significantly. Further research in SAR analysis could lead to advancements, but challenges include large datasets and careful hyperparameter adjustment to ensure model resilience and adaptability. Furthermore, a balance between image enhancement and the preservation of important information required careful hyperparameter adjustment.

Author contributions Vinay Dubey Worked on the Conceptualization of the Idea to reach the research goals and aims, conducted a research and investigation process, and Conceived and designed the GAN-based model's methodology and creation. Rahul Katarya helps in Validation, Formal analysis of the research idea, analysis of the collected Dataset, and Preparation for the manuscript's presentation.

Abstract. Market volatility is becoming increasingly common as numerous factors are implemented in the financial system. As a result, portfolio managers and individual investors require reliable methods to assess stock performance. This study examines stock assessments using cross-efficiency evaluations in cases where negative data is present. An alternative approach to achieve this goal is to use an RDM DDF-based cross-efficiency model which oversees the negative data. We expand the RDM-based cross-efficiency analysis, which uses row and column average values to select portfolios and identify different groups for stock management. To explore the psychological factors that influence the choices made by stock market investors, we incorporate the cumulative prospect theory value for each stock as an output and the variance as an input to evaluate the overall efficiency of the assets. For the empirical analysis, our study focuses on a sample of 30 stocks listed on the Nifty-50 on India's National Stock Exchange. The results of our empirical study verify that the proposed method can serve as an effective tool for stock selection. This demonstrates how the chosen portfolio gives companies a more diversified and well-balanced approach for selecting stocks, thus improving logical decision-making.

1. Introduction

After Markowitz [14] introduced the mean-variance optimization (MVO) model in the 1950s, the financial market grew exponentially and consistently. The Mean-Variance Optimization (MVO) model represents a crucial element in modern finance, offering a balance between portfolio returns and risks, thereby quantifying portfolio performance. With rapid advancements in artificial intelligence, the MVO selection process has now been integrated into diverse methodological frameworks within contemporary investment science. In the global market, asset assessment and ranking are vital for investors. In this study, we employ data envelopment analysis (DEA) with cross-efficiency analysis in the presence of negative input-output to improve portfolio selection by enhancing the stock evaluation and management process.

DEA stands out as one of the distinguished methodologies for examining the performance of decision-making units (DMUs) that manage a variety of inputs and outputs. After the

groundbreaking research of Charnes et al. [3], who introduced non-parametric programming to approximate the production frontier, there has been a notable increase in publications concerning DEA principles and their practical implications in recent years. Pioneering studies, in this field, such as by Murthi et al. [15], were instrumental in applying DEA and crafting the DEA portfolio efficiency index (DPEI). Similarly, Chen et al. [4] introduced three distinct DEA models that incorporate various risk indicators for assessing portfolio efficiency in a possibilistic environment. Gupta et al. [7] developed an integrated approach for efficient portfolio evaluation, featuring a dynamic re-balancing strategy to empower investors in constructing optimal portfolios within a credibilistic framework. Kumar et al. [10] presented an innovative approach to multiperiod efficient portfolio selection (MPEPS), which involves a two-stage process. Additionally, Zhou et al. [26] proposed a portfolio re-balancing strategy that capitalizes on DEA frontier improvement within the mean-variance (MV) framework.

In DEA, a Decision Making Unit (DMU) evaluates itself by optimizing input and output weights to attain maximum relative efficiency. However, DEA has been criticized for its flexible weight assignment and reliance on self-assessment. To overcome this challenge, Sexton et al. [20] introduced a cross-efficiency method that integrates peer evaluation, shifting focus from self-assessment. Oukil and Amin [16] employed the concept of maximum cross-efficiency to evaluate the performance of baseball team players, presenting an alternative approach to team management. Wu [24] applied cross-efficiency to stock organization and portfolio optimization, and Lim et al. [11] introduced a novel methodology for portfolio selection on the Korean stock exchange using DEA cross-efficiency. Amin and Hajjami [1] demonstrated the effect of alternative optimal solutions in the construction of a cross-efficiency matrix (CEM) and validated that the performance of the MV portfolio selection method is enhanced. Deng and Fang [6] incorporated a DEA prospect cross-efficiency evaluation into an innovative MVM (mean-variance-maverick) framework for fuzzy portfolio selection. Amin and Oukil [2] and Sanei and Banihashemi[19] effectively applied the cross-efficiency evaluation for portfolio section.

Instead of utilizing DEA methods, researchers have also employed multi-criteria decision-making (MCDM) methods that focus on analyzing and ranking decision alternatives based on a set of criteria. Kovač and Podrug [9] provide practical perspectives on utilizing MCDM and the MPT theory for share selection and portfolio optimization. In addition, Poklepovi and Babi [17] proposed a hybrid MCDM technique to evaluate the shares of the Zagreb stock exchange. DEA offers an advantage over MCDM because MCDM relies on a uniform set of weights, whereas DEA utilizes a linear programming model to determine individual weights for each DMU, along with an enhancement in efficiency.

Cross-efficiency analysis is frequently employed in scenarios where the production frontier exhibits constant returns to scale (CRS), as occurrences of negative efficiencies are uncommon across different situations. Lim et al. [12] and Wu et al. [25] introduced two notable methods for evaluations of the cross-efficiencies in cases involving variable returns to scale (VRS) production frontier. Their primary aims are either to reduce negative efficiencies or transform them into positive values. Recognizing the limitations in prior research, Kao and Liu [8] proposed a slack-based measure model for assessing the cross-efficiency value of DMUs without eliciting negative efficiencies. Their concept provides reasonable efficiencies for only weakly efficient DMUs. Soltanifar and Sharafi [21] presented a non-radial cross-efficiency model integrated with a hybrid MCDM technique. In contrast, Lin [13] proposed an approach for cross-efficiency evaluation based on the Directional Distance Function (DDF), utilizing the Range Directional Measure (RDM) model introduced by Portela et al. [18] and duality theory within the framework of VRS technology. The model introduced by Lin [13] can handle situations with negative input-output variables and successfully addresses the issue of negative cross-efficiency. Shrivastava et al.[22] introduced a portfolio selection approach that leverages cross-efficiency, by employing the model from [13] and Cumulative Prospect Theory (CPT). They calculated the CPT value of the assets from their weekly returns using the Cumulative probability (uniform

probability) weighting function and the utility function in CPT. The CPT-based model then constructs effective portfolios by utilizing the CEM as the basis for return calculations. Chen et al. [5] explored a portfolio selection challenge that incorporated fuzzy DEA cross-efficiency evaluation, considering both undesirable fuzzy inputs and outputs.

Typically, the mean values of the CEM columns are the standard for evaluating the performance of a specific DMU. The simultaneous assessment of both the conventional cross-efficiency score (from the CEM column average) and the performance diversity score (from the CEM row average) offers a holistic method to identify stocks that outperform their peers and possess distinctive capabilities absent in others.

This study addresses the issue of robust stock selection using a cross-efficiency evaluation, that accommodates both positive and negative data. The CA and RA are used for robust portfolio selection and the identification of various types of assets. When implemented in a strategic stock selection process, this approach enables managers to pinpoint stocks/assets that not only deliver strong overall performance but also offer diverse capabilities to set them apart from other alternatives. The notable contributions of this research are as follows:

- Firstly, only a limited number of studies in the current body of literature make use of the DEA cross-efficiency model to handle negative input-output data in portfolio selection, as seen in the works of Chen et al. [5] Talluri et al.[23] and Shrivastava et al. [22], and among others.
- Additionally this study addresses asset cross-efficiency by incorporating the CPT value and return of each stock as outputs, and variance as an input. Our method combines cross-efficiency with CPT, exploring the psychological aspects that affect decision-makers when shaping portfolios. It is important to highlight that only a few studies (e.g., Shrivastava et al. [22] have employed CPT values as an output.
- Finally, in contrast to the methods employed by Talluri et al. [23], this study employs a DDF-based RDM cross-efficiency model to classify the assets. In contrast to, the classification employed by Shrivastava et al.[22], this study classifies stocks into distinct categories, to enable the inclusion of well-performing stocks with both similarity and variation in their performance. This approach offers financial experts a more comprehensive and detailed understanding of the subject.

The rest of the study comprises four sections, including the preliminary section which discusses the DEA cross-efficiency techniques to deal with negative values in input/output. The proposed work methodology is described in section 3. Next, the practical application of the proposed approach is demonstrated to highlight its validity and effectiveness in section 4. The paper concludes with Section 5, which examines the results and proposes potential avenues for future research.

2. Preliminaries

This section provides an overview of the key studies that motivated us to initiate this research. Let a group of n homogeneous DMUs be evaluated. Assume that each of these DMUs consumes m different inputs x_{ij} $(i = 1, 2, \ldots, m)$ to generate s different outputs y_{rj} $(r = 1, 2, \ldots, s)$. Specifically, j^{th} DMU consumes amount x_{ij} of input i and generates amount y_{rj} of output r. Cross-efficiency is a concept employed in ranking to tackle the issue of inconsistency among the efficiencies of a set of DMUs assessed using different weightings in DEA. The traditional cross-efficiency method relies on the CCR model and cannot handle the negative input-output data.

To address this challenge, Lin [13] introduces a VRS cross-efficiency evaluation approach based on DDF, allowing input-output variables to take on negative values in line with the approach proposed by Portela et al. [18], as outlined below:

$$\textbf{Model I} \qquad \begin{aligned} &\text{Min } \sum_{i=1}^{m} v_{ik}(x_{ik}+d_{ik}^{-}) - \sum_{r=1}^{s} \mu_{rk}(y_{rk}-d_{rk}^{+}) + \xi \\ &\text{s.t.} \\ &\sum_{i=1}^{m} v_{ik}x_{ij} - \sum_{r=1}^{s} \mu_{rk}y_{rj} + \xi \geq 0, \\ &\sum_{i=1}^{m} v_{ik}d_{ik}^{-} + \sum_{r=1}^{s} \mu_{ik}d_{rk}^{+} = 1, \quad j = 1,2,\ldots,n, \\ &v_{ik},\ \mu_{rk} \geq 0, \quad r = 1,2..s \ \ i = 1,2...m. \end{aligned}$$

where the directional vectors are computed as

$$\begin{aligned} d_{rk}^{+} &= \max_{j=1,2,\ldots,n} y_{rj} - y_{rk}, \qquad r = 1,2,\ldots,s, \\ d_{ik}^{-} &= x_{ik} - \min_{j=1,2,\ldots,n} x_{ij}, \qquad i = 1,2,\ldots,m. \end{aligned}$$

are the possible non-negative improvements for inputs and outputs. Using the weights of DMUk derived from M2, established the cross-efficiency of DMUj, in the following manner:

$$\beta_{kj} = \frac{\sum_{i=1}^{m} v_{ik}^{*}(x_{ij}+d_{ik}^{-}) - \sum_{r=1}^{s} \mu_{rk}^{*}(y_{rj}+d_{rk}^{+}) - \xi^{*}}{\sum_{i=1}^{m} v_{ik}^{*}d_{ik}^{-} + \sum_{r=1}^{s} \mu_{rk}^{*}d_{rk}^{+}}. \tag{1}$$

Thus, the cross-efficiency score of jth DMU is given by $\beta_j = \frac{1}{n}\sum_{k=1}^{n} \beta_{kj}$ which is the simple column average of the cross-efficiency matrix. Similarly, we obtain the row average cross-efficiency as $\eta_j = \frac{1}{n}\sum_{k=1}^{n} \beta_{jk}$. The self-efficiency of DMU_k will be obtained by putting $j = k$ in the equation (1) and denoted as β_{kk}^{*}. The row average cross-efficiency provides insights into the individual characteristics of each DMU. When the value of a DMU's row mean is relatively lower compared to other DMUs, it distinguishes that DMU from the rest, indicating a high level of performance diversity.

Calculation of the "Maverick index" (MI)

The cross-efficiency scores can be utilized even further by defining the extent to which there is variation between the peer appraisal and the self-appraisal efficiency of DMUs. In finance, the Maverick index serves as a valuable tool for assessing the false positives among financial assets. This measure of concordance between the two efficiencies is called the Maverick index [**?**] and it is defined as follows:

$$MI_k = \frac{\beta_{kk}^{*} - \beta_k}{\beta_k} \tag{2}$$

MI quantifies the extent of disparity between a self-evaluation score and a peer-evaluation score. A higher MI value suggests a higher likelihood of the DMU being mistakenly perceived as efficient. Conversely, a lower index value indicates a more favorable outcome.

Calculation of The "Performance Diversity Index" (PDI)
The calculation of the PDI follows a methodology similar to that of MI. To determine the performance of an evaluated DMU (stock), its basic efficiency is compared with the average cross-efficiency of all other DMUs, using the weights specific to the evaluated DMU. Consequently, all DMUs involved in the assessment procedure are subject to the same criteria. The PDI is computed as follows:

$$PDI_k = \frac{\beta^*_{kk} - \eta_k}{\eta_k}. \tag{3}$$

3. Proposed Methodology

DEA cross-efficiency is the most appropriate approach for portfolio selection because it rationalizes equities more thoroughly and analyses stocks based on efficiency rather than absolute output. As financial decision-making often involves risks and uncertainties, decision analysis should consider the behavioral aspects of decisions. From this perspective, this study introduces a resilient approach to stock management, which encompasses the following stages:
Choice of input and output variables: Input: The variance of each asset is computed to assess its associated risk, which will serve as an input in the proposed method.
Output: To account for the irrational behaviors of decision-makers (DMs) in stock selection, we incorporate the CPT value of stocks using the procedures outlined by Shrivastava et al. [22] as an output. The second output is defined as the mean return of the stocks and is computed using the following formula: $R_{jt} = \frac{C_{j(t+1)} - C_{jt}}{C_{jt}}$ where C_{jt} and $C_{j(t+1)}$are the closing price of the jth stock at time t and $t+1$ respectively.
Assessing the cross-efficiency of the stocks: Model (M2) is utilized to calculate the cross-efficiency scores for the chosen stocks. Subsequently, we determine the self-efficiency, the row average efficiency, and the column average efficiency from the obtained Cross-Efficiency Matrix (CEM).
Categorizing the Stocks: Based on the CA and RA scores obtained from M2 and equation, we categorize the stocks into the following groups: Group G1: High Column Average/High Row Average (HC/HR)
Group G2: High Column Average/Low Row Average (HC/LR)
Group G3: Low Column Average/High Row Average (LC/HR)
Group G4: Low Column Average/Low Row Average (LC/LR)
The RA value describes the unique characteristics of each stock. When a stock's row average value is comparatively lower than that of other stocks, it stands out from the rest, indicating a higher degree of performance diversity. When we depict the means of the rows and columns derived from the cross-efficiency analysis in a quadrant format, stocks in G2 exhibit superior efficiency than the other stocks, setting them apart. Stocks originally in G1 and G3 should be relocated to G2 to improve their performance. In contrast, stocks situated in G4 demonstrate subpar efficiency and fail to distinguish themselves from other stocks.

4. Empirical illustration

To demonstrate the effectiveness of the proposed DEA cross-efficiency evaluation approach addressing negative data, we employ it to analyze real data from the Indian stock market. We use data from Shrivastava et al. [22] focusing on the performance of the top 30 assets included in the Nifty 50 index. For each asset, one input variable variance, and two output variables, CPT value and long mean return are considered. For the long mean return, we consider the data from 05-03-2018 to 25-02-2019. To calculate the CPT value and variance, we select the weekly return of stocks for the period from 05-03-2018 to 02-08-2018. We select the outputs

for stock evaluation because of their direct relevance to portfolio assessment, and, importantly, their ability to account for the DM's behavioral characteristics.

To evaluate the performance of the listed stocks, the M1 model is used to evaluate the assessment of the stocks. Table 1 shows the CPT value, mean return, and variance with self-efficiency obtained by M1 of the thirty stocks.

4.1. Stock management using the proposed method

The model M1 computes the cross-efficiency of the stocks. The cross-efficiency matrix (CEM) is generated using the input and output weights from M1 and Equation (1). The resulting CEM offers unique insights pertinent to this analysis. A widely recognized use of CEM involves averaging the efficiency scores down a column and designating that average as the peer appraisal score, commonly known as the CA efficiency.

Stocks	S_1	S_1	S_3	S_4	S_5	S_6	S_7	S_8	S_9	S_{10}

Table 2: *The column and row average efficiency obtained from CEM.*

A stock with a high CA performs well because it outperforms the other units. Also, the low Row average (RA) value, indicates that the specific stock possesses distinctive capabilities and expertise that other stocks lack. The CA efficiency and RA efficiency obtained from CEM are presented in Table 2. We categorize the stocks based on their CA and RA values. Figure 1 shows the grouping of stocks based on the CA and RA scores for all 30 stocks. The data is categorized as either high or low for both CA and RA. The mean of these scores is employed to split the categories into high and low (in this instance, the average resulted in a value of 0.641). Although the classification thresholds are subjective, they can also be determined by decision makers or managers engaged in stock evaluation..

Discussion on the different groups of stocks The suggested stock classification aids investors in formulating portfolio optimization approaches. Supreme or exceptional performers are prime candidates for long-term investments because of their outstanding performance in various aspects and unique skills that contribute to building a robust and diversified stock selection, capable of meeting the current and future demands of the financial market. However, all-round good performers and niche performers exhibit differences. While the former excel overall compared to their peers, they lack the specific distinctive skills that distinguish them. Detailed descriptions of these groups are as follows.

1. All-round good-performing stocks (HC/HR): Six stocks are assigned to the HC/HR quadrant (G1). Stocks in this group are referred to as all-round good performers because they possess strengths that align with the performance of other assets. A portfolio generated with these stocks may perform well, but it may not be stable. The RA and CA efficiencies along with MI and PDI are presented in Table 3. The average MI and PDI for this portfolio are 0.0364 and 0.1739, respectively.

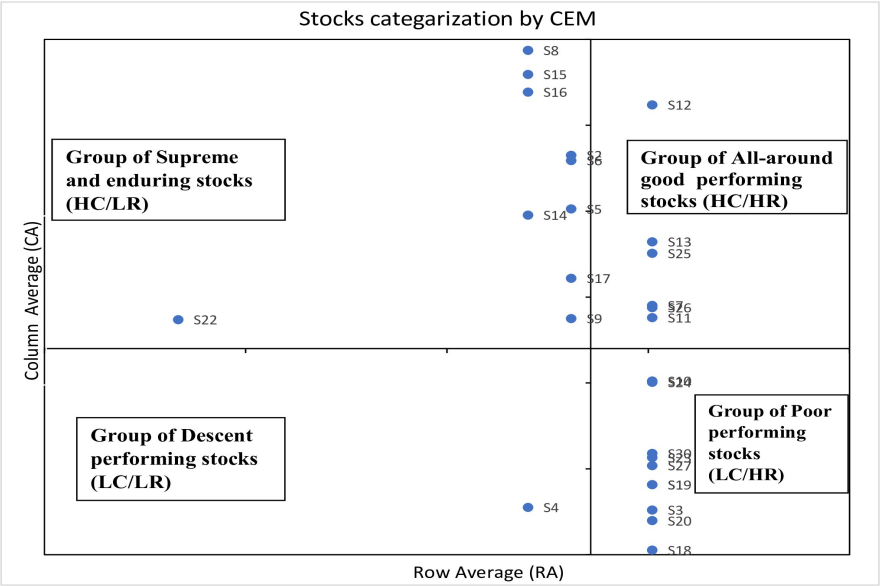

Figure 1: *Different group of stocks based on CA & RA.*

Stocks	CA	RA	MI	PDI
S_{12}	0.9237	0.6614	0.0359	0.4469
S_{13}	0.7644	0.6614	0.0587	0.2236
S_{25}	0.7510	0.6614	0.0346	0.1749
S_7	0.6902	0.6614	0.0341	0.0793
S_{26}	0.6877	0.6614	0.0337	0.0749
S_{11}	0.6759	0.6614	0.0211	0.0436
Average	0.7488	0.6614	0.0364	0.1739

Table 3: *Statistics of group HC/HR.*

2. Supreme and enduring stocks: Table 4, describes the list of stocks in the HC/LR (G2) group. The stocks within this category possess distinctive resources and strengths to set them apart or align them with the performance of other stocks. Consequently, assets from this group can be regarded as long-term stability portfolios. The portfolio obtained from this group is well-diversified with a PDI value of 0.4609.

3. Descent-performing stocks: Only stock 4 comes under the category G3. The stock in this group has unique resources that set them apart from other stocks but lack the strength to match the performance of their peers. But these are less diversified.

4. Poor performing stocks: Within the high LC/HR (G4) quadrant, there are thirteen assets, which are typically considered subpar performers. These assets lack distinctive resources or strengths that can outperform their market counterparts. Consequently, portfolios comprising assets from this group may not exhibit strong performance, and the overall diversification of such portfolios is notably low. The results are shown in Table 6.

After examining the tables, it is evident that G2 (HC/LR) assets have the best performance

with an average MI score of 0.0820 and a higher average PDI score of 0.4609. G3 and G4 have significantly lower PDI scores when assessing overall diversification with less MI. It should be

noted that the portfolio can also be chosen from a combination of the above groups of stocks or from the entire group. Similar to each category the stocks with low MI or high PDI can be selected.

To the best of our knowledge and based on our extensive literature review, there is currently no available approach to directly compare the outcomes of the method proposed in this research. Existing studies that utilize DEA cross-evaluations for portfolio selection, stocks are typically ranked in descending sequence of their cross-efficiency values, and the top n stocks are selected, where n corresponds to the number of stocks desired in portfolio. In contrast, our method involves the categorization of stocks into distinct groups based on the average values of the rows and columns in the Cross-Efficiency Matrix (CEM). Therefore, a direct comparison between these two methods is not meaningful.

5. Conclusion

We used the RDM DDF-based cross-efficiency analysis to categorize stocks with negative data. Although various approaches are available for categorizing and grouping stocks, the proposed classification methodology stands out as distinctive and holds significance in the context of portfolio construction. CA values in CEM are commonly employed in the standard practice of evaluating a unit's overall comparative performance. We established an alternative approach that involves the RA values of CEM to determine the breadth of performance diversity. These two ideas are merged to categorize financial assets into different groups, which further enables a more effective stock rationalization process that considers comparative performance and diversity of performance concurrently.

The limitations and potential future directions of this study include the Indian stock market with a restricted dataset. To enhance the significance of efficiency comparisons and benchmark selection, it would be valuable to encompass major markets in other countries. In future research, broadening the modeling scope to include ordinal and interval data values would enable the consideration of the impact of fuzzy input-output data.

Sustainable building materials: A comprehensive study on eco-friendly alternatives for construction

Yonatan Ayele Abera[1,2]

Abstract

An in-depth review of a varied range of eco-friendly options for construction is done in this thorough research on sustainable building materials. With increased worries about environmental deterioration, the building sector is increasingly focusing on long-term solutions. This research looks into a variety of materials, including bamboo, engineered wood products, recycled composites, and optimal concrete mixtures. The study underlines the importance of compressive, tensile, and flexural strengths, which are a basic feature for structural integrity. The study also gives useful insights into their practical applicability in real-world building projects by assessing the flexural strength of various materials. Furthermore, the study examines the environmental effect of these materials, taking into account characteristics such as renewability, recyclability, and energy efficiency. Laboratory tests were conducted to determine the fundamental properties of selected materials as part of the investigations. The study emphasizes the ecological advantages of adopting these sustainable alternatives through life cycle assessments and comparative studies. The research output can be served as a thorough reference for architects, engineers, and policymakers, providing a complete knowledge of sustainable building materials and their critical role in developing a greener, more resilient built environment.

Keywords

sustainable building materials, eco-friendly alternatives, construction, environmental impact, life cycle assessment, green building practices

Introduction

The building sector is important in constructing the contemporary world, but it also poses substantial environmental issues. The vast demand for building materials, as well as the resource-intensive processes involved, lead to significant carbon emissions, resource depletion, and environmental deterioration.[1] In response to these environmental issues, there is an urgent need to adopt sustainable building techniques that reduce the sector's environmental effect. One of the most important ways for accomplishing this aim is the widespread use of environmentally friendly and sustainable construction materials.[2]

This article gives a detailed analysis on sustainable building materials, with an emphasis on eco-friendly construction choices. The major goal is to offer a complete grasp of various sustainable materials, their features, environmental benefits, and prospective building applications.[3] We hope to shed light on the potential solutions available to transform the way we build and construct our built environment by a comprehensive examination of

scientific literature, experimental assessments, and life cycle evaluations.[4]

The first section of this study delves into an extensive literature review, capturing the latest advancements and developments in the realm of sustainable building materials.[5] We explore a diverse range of eco-friendly alternatives, including recycled materials, bio-based composites, and low-carbon options.[6] By delving into the production processes, material properties, and applications of each alternative, we seek to uncover the unique environmental advantages they offer and the challenges they might present in real-world applications.[7]

The second stage of the investigation comprises rigorous experimental analysis to supplement the conclusions from the literature review. We evaluate the mechanical, thermal, and durability qualities of selected sustainable materials using extensive laboratory experiments. These assessments give vital insights into the material's performance characteristics, assisting in determining its appropriateness for various building applications and informing design decisions.[8]

The third component of our research is a life cycle assessment (LCA) of sustainable construction materials.[9] The LCA investigates each material's complete life cycle, from raw material extraction to manufacture, transportation, consumption, and final disposal. We may conduct educated comparisons between eco-friendly materials and conventional alternatives by measuring environmental consequences such as carbon footprint, energy usage, and waste generation, supporting evidence-based decision-making in sustainable construction practices.[10]

The four eco-friendly materials created from diverse building wastes are rooted as sustainable construction materials, as shown in the figure below, and these materials are mostly produced from construction and demolition wastes. Tiles of various sorts and sizes can be mined from numerous sources of building byproducts (see Figure 1). Bricks and blocks are also important construction materials that may be sourced as recycled solutions from local garbage. These materials are considered sustainable construction materials because they add value to the use of recycled resources.[11]

We realize the revolutionary potential of sustainable construction materials in producing a more eco-conscious constructed environment as we go forward with this thorough research.[12] Our goal is to give architects, engineers, politicians, and industry stakeholders with a thorough grasp of the various environmentally friendly choices accessible. We hope to contribute to a greener, more robust, and peaceful future for our planet and its people by encouraging the use of sustainable materials in building.[13]

Sustainable building materials

Because of their environmental benefits and contribution to the creation of eco-friendly structures, sustainable building materials have grown in popularity in recent years. Reclaimed wood is one significant type of these materials. Reclaimed wood, which is salvaged from ancient houses, barns, or other structures, not only lessens the demand for virgin lumber but also gives character to new creations. Because of its strength and durability, it is a fantastic choice for flooring, furniture, and ornamental pieces. The building sector supports recycling and minimizes the depletion of natural forests by reusing wood that would otherwise wind up in landfills.[14]

Another important sustainable building resource is recycled metal. Steel and aluminum, for example, may be recycled endlessly without losing their quality. In green buildings, recycled metal materials are often utilized for

Figure 1. Sustainable building materials.

structural framing, roofing, and ornamental features.[15] Metal recycling eliminates the need for mining, conserves energy, and lessens the environmental effect of metal manufacturing. Furthermore, employing recycled metal reduces the carbon impact, making it a crucial choice for sustainable building methods (see Figure 2(a) and (b)).

Bamboo, a fast renewable material, has emerged as a critical component of sustainable building. Its rapid development rate, which allows it to attain maturity in a few of years, making it a very sustainable material for a variety of uses. Bamboo is an extremely flexible material that may be used for flooring, roofing, wall cladding, and even structural elements.[16] Because of its tensile strength and flexibility, it is an excellent substitute for conventional hardwoods. Furthermore, bamboo production aids in the fight against deforestation, lowers greenhouse gas emissions, and provides employment possibilities for local populations.[17]

Recycled glass is a long-lasting material that is often used in green construction projects. Crushed glass is an aggregate that may be used in concrete, glass worktops, tiles, and insulation. Incorporating recycled glass into building components not only saves natural resources but also decreases the energy necessary to manufacture new glass. The building sector helps to trash reduction initiatives and fosters a circular economy by diverting glass debris from landfills.[18]

Rammed earth construction is a centuries-old building style that has seen a resurgence in sustainable architecture. To build walls, layers of soil, chalk, lime, or gravel are compacted inside a frame. Rammed earth constructions have high thermal mass, which automatically regulates inside temperatures. This approach makes use of locally available resources, which reduces transportation emissions. Furthermore, with proper care, rammed earth

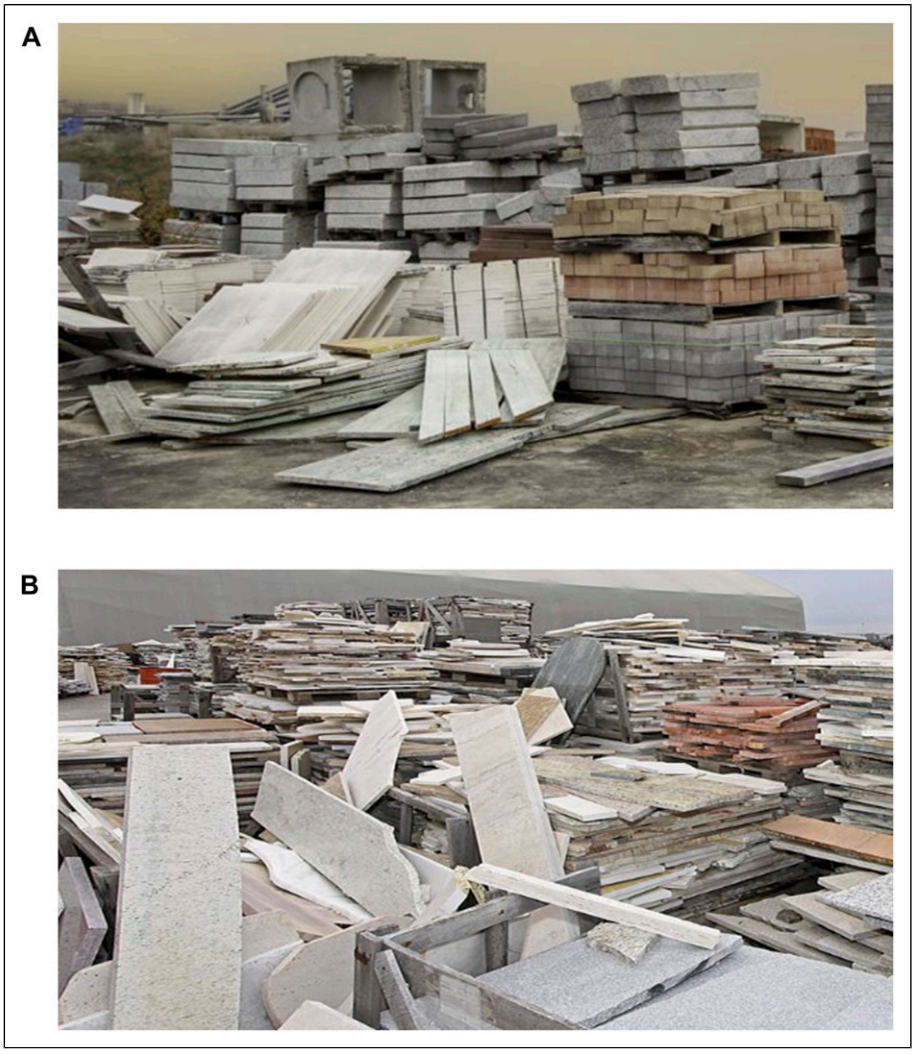

Figure 2. Sustainable building materials.

buildings have a low-carbon footprint and may survive for millennia, making them an environmentally benign alternative for sustainable construction.[4]

Hempcrete, a combination of hemp fibers, lime, and water, has gained popularity in recent years as a sustainable alternative to standard concrete. Hemp growing absorbs CO_2, making it a carbon-negative crop. Hempcrete is a lightweight, insulating, and non-toxic material that creates a healthy interior atmosphere. It also has great moisture-regulating qualities, which reduces the likelihood of mold and mildew growth.[19] The construction sector promotes sustainable agriculture and decreases dependency on energy-intensive building materials by using hempcrete into construction projects.

To summarize, the use of sustainable construction materials not only addresses environmental problems, but also helps to the production of healthier, more energy-efficient, and longer-lasting structures. The building sector encourages sustainable methods, conserves natural resources, and reduces the environmental effect of construction operations by adopting recovered wood, recycled metal, bamboo, recycled glass, rammed earth, and hempcrete.[20] As the demand for sustainable buildings grows, the development and use of these materials will be critical in crafting a greener and more sustainable future for the construction industry.

Literature review

The first section of this research focuses on completing a thorough literature assessment on sustainable construction materials. We go through recent research articles, studies, and industry publications to find a wide choice of environmentally friendly products.[21] The evaluation of literature covers recycled materials such as recycled aggregates and recovered wood, bio-based materials such as bamboo and hempcrete, and low-carbon solutions such as geopolymers and fly ash-based goods.[22] We investigate each material's manufacturing methods, features, and uses in order to comprehend its environmental benefits and limits.[23]

The pursuit of sustainable building materials has emerged as a critical component of the construction industry's attempts to solve environmental concerns and adopt more environmentally friendly methods.[5] A thorough investigation of eco-friendly alternatives for construction materials has become critical in the industry's desire to lower its ecological imprint and migrate to a greener and more sustainable built environment.[24]

Several studies have emphasized the negative environmental implications of traditional building materials, such as high carbon emissions, excessive resource usage, and trash creation.[25] As a result, academics and industry practitioners have shifted their focus to sustainable building materials, which provide potential ways to alleviate these environmental burdens.[26]

Recycled materials have received a lot of interest in recent study. Recycling aggregates from building and demolition debris has showed promise as a viable alternative to conventional aggregates, decreasing the need for massive mining and landfilling (see Figure 3). Additionally, recovered wood has developed as a sustainable solution, offering an environmentally benign alternative to virgin lumber and helping to forest conservation.[27]

Bio-based products have gained popularity due to their recyclability and minimal environmental effect. Bamboo has been a popular alternative for structural applications because of its quick growth rate and remarkable strength-to-weight ratio.[28] Moreover, hempcrete, a hemp fiber and lime combination, has shown remarkable thermal and acoustic qualities, making it an appealing choice for sustainable building insulation.[29]

Low-carbon alternatives are being intensively researched in order to reduce the carbon footprint of construction materials. Geopolymers, which are generated by the interaction of industrial byproducts such as fly ash and slag with alkaline activators, provide a cementitious alternative with much lower greenhouse gas emissions than typical Portland cement. Moreover, fly ash-based goods, which use discarded fly ash as a key constituent, have the potential to reduce environmental impacts while also contributing to the effective use of industrial byproducts.[2]

The incorporation of environmentally friendly building materials into the construction sector necessitates a thorough grasp of their qualities and prospective uses. Yet, there are still issues to address in terms of material performance, cost-effectiveness, regulatory compliance, and public acceptance. Addressing these impediments and providing evidence-based data to promote the informed selection and integration of eco-friendly options in construction methods is critical.[30]

There is a rising interest in sustainable building materials in the literature, with considerable research concentrating on material characterization, performance evaluation, and environmental analyses.[31] Many studies have been undertaken to estimate the total environmental effect of these materials, allowing for direct comparisons with traditional counterparts.

Finally, the literature illustrates the importance of promoting sustainable building materials in the construction business. This extensive research seeks to add to the current body of knowledge by conducting a detailed evaluation of eco-friendly alternatives and their potential to revolutionize the way we design our built environment.[32] This study intends to contribute to the paradigm shift toward greener and more sustainable construction methods by giving information on the environmental benefits, performance features, and prospective uses of these materials.[33]

Experimental methodology

By combining diverse research methodologies, the methodology used in this study intended to give a thorough

Figure 3. Partial views of sustainable building materials from recycled wastes.

knowledge of sustainable construction materials. To provide a multi-dimensional perspective on the viability and effect of eco-friendly alternatives in construction, the study approach included a combination of Interview for focused group, literature review, material assessment, life cycle analysis (LCA), and economic analysis.

The technique began with an exhaustive literature research to generate a solid understanding of sustainable construction principles. This entailed studying academic publications, industry reports, and case studies to identify important materials, manufacturing techniques, and applications that are environmentally benign. This literature assessment aided in the selection of resources for deeper investigation in following phases of the project.

Material evaluation followed, with an emphasis on selected sustainable construction materials. At this phase, material qualities such as strength, durability, thermal performance, and fire resistance were thoroughly examined. A comparison with traditional materials revealed technical capability and potential benefits of eco-friendly alternatives. This stage was critical in determining how these materials aligned with building needs and where they might be used most effectively.

Life cycle analysis (LCA), a thorough technique to analyze the environmental effect of materials throughout their full life cycle, was at the heart of the methodology. This included the extraction of raw materials, manufacture, transportation, usage, and end-of-life stages. Quantitative data on greenhouse gas emissions, energy consumption, and trash creation allowed for a comprehensive assessment of the environmental footprint of sustainable materials vs traditional alternatives. LCA enabled the identification of possible environmental "hotspots" and directed the evaluation of products' overall environmental advantages. The research also included economic analysis, which assessed the cost implications of using sustainable construction materials. This investigation provides insights into the economic viability of sustainable materials and their potential long-term advantages by assessing economic repercussions.

Finally, the research used a multi-dimensional approach to thoroughly investigate eco-friendly options for construction materials. This study intended to provide a comprehensive knowledge of the technical, environmental, and economic aspects of sustainable building materials by integrating a literature review, material assessment, life cycle analysis, and economic analysis. The holistic character of the technique guarantees that stakeholders may make educated decisions about the incorporation of these materials, furthering sustainable building practices in the construction sector.

Results and discussions

Experimental analysis

The second section of this study is an experimental investigation of the mechanical, thermal, and durability properties of selected sustainable construction materials. We do laboratory studies on recycled concrete, bio-based composites, and low-carbon cementitious materials samples. Compressive strength, flexural strength, and tensile strength are all mechanical tests. Thermal conductivity and heat storage capacity measures are used to assess thermal

characteristics. Weathering, chemical assault, and fire resistance are all tested for in durability testing.

The current work integrates rigorous experimental analysis to describe the mechanical, thermal, and durability features of selected eco-friendly alternatives in the quest of understanding and evaluating the feasibility of sustainable building materials. This investigation seeks to give critical data and insights to support the acceptance and integration of these materials in real-world building applications through laboratory experiments and simulations.

Data analysis and interpretation. The results of the experimental investigation are submitted to extensive statistical analysis and interpretation. This includes evaluating the material's mechanical properties, thermal properties, and durability performance using graphical representations, regression analysis, and other statistical techniques. The data are then critically reviewed to discover the sustainable building materials under consideration's strengths, limitations, and potential for development.

In the context of "Sustainable Building Materials: A Comprehensive Research on Eco-friendly Alternatives for Construction," data analysis and interpretation entail reviewing the findings of numerous tests and experiments done on various eco-friendly building materials. The goal is to use the data to develop relevant inferences and insights about the performance and appropriateness of these materials for building applications. Data analysis and interpretation are important parts of the research process because they guide the transformation of raw data into relevant insights and practical findings. This critical stage entails a methodical approach to organizing, analyzing, and identifying patterns from acquired data. To condense complicated information into understandable narratives, several methods such as statistical techniques, visualization tools, and qualitative analysis are used.

The process starts with data cleaning and preparation, which involves identifying and correcting inconsistencies, mistakes, and anomalies. Following that, statistical analysis techniques are used to discover linkages, trends, and correlations in the data. Inferential statistics allow researchers to derive inferences about larger populations based on sampling data, whereas descriptive statistics provide a picture of the data's fundamental patterns and dispersion.

In contrast, qualitative data analysis entails evaluating non-numerical data such as text, photographs, or interviews. This method uses coding and thematic analysis to uncover repeating patterns, themes, and insights that provide light on the research issue. Data visualization tools, such as graphs, charts, and maps, help both expert and non-technical audiences communicate complicated results. Graphic representations improve comprehension and emphasize crucial themes, assisting in the dissemination of study findings.

The interpretation step entails developing relevant conclusions from the data that has been studied. Researchers contextualize their findings within the framework of current literature, theory, and study aims, providing insights, explanations, and implications. This synthesis bridges the gap between empirical findings and theoretical frameworks, so contributing to field knowledge progress.

Finally, data analysis and interpretation are critical steps in the research process because they structure acquired information and translate it into insights that influence decision-making and motivate additional investigation. The rigor and precision of these processes support the legitimacy and validity of research findings, allowing researchers to make significant contributions to their respective fields.

Mechanical testing. The mechanical characteristics of sustainable building materials play an important role in determining their structural performance and appropriateness for various construction applications. The primary mechanical characteristics tested in this experimental investigation are compressive strength, tensile strength, and flexural strength. Compressive strength tests entail submitting samples to compressive stresses until they break, revealing important information about the material's load-bearing capabilities and structural integrity. Tensile strength tests assess the material's resistance to tension pressures, whereas flexural strength tests assess the material's capacity to handle bending loads. To guarantee accuracy and consistency, these tests are carried out in accordance with industry standards.

Compressive strength of sustainable building material. Compressive strength is an important feature to consider when evaluating sustainable construction materials since it determines a material's capacity to endure axial loads or pressure. Sustainable construction materials have a low environmental effect throughout their entire life cycle, from extraction and manufacture to use and disposal. These materials are intended to be resource- and energy-efficient, as well as ecologically benign. One of the primary benefits of sustainable construction materials is their ability to retain high compressive strength while utilizing environmentally responsible manufacturing procedures. This feature protects the structural integrity of buildings, reducing the need for repairs and replacements, and thereby lowering the total environmental effect. Tables 1–10

The use of high compressive strength sustainable building materials adds greatly to the construction industry's efforts to cut carbon emissions and combat climate change. Construction experts may make high-strength concrete mixes that meet or surpass typical concrete criteria by incorporating resources such as recycled aggregates, fly ash, or slag, which are byproducts of other industrial processes. These materials not only save natural

Table 1. Compressive strength of sustainable and conventional building materials.

Sample no.	Sustainable building material	Compressive strength (MPa)
1	Recycled concrete	35.2
2	Bamboo composite	48.6
3	Hempcrete	22.8
4	Geopolymer	42.1
5	Fly ash-based concrete	39.4
6	Conventional concrete	42.9

Table 2. Tensile strength of sustainable and conventional building materials.

Sample ID	Material type	Tensile strength (MPa)
1	Recycled concrete	15.2
2	Bamboo	45.6
3	Hempcrete	8.9
4	Geopolymer	25.1
5	Conventional concrete	20.3
6	Steel	550.2

Table 3. Flexural strength of sustainable building materials.

Sample ID	Material	Flexural strength (MPa)
1	Bamboo	100-150
2	Engineered wood	40-100
3	Recycled concrete	3-10
4	Hempcrete	0.2-1.0
5	Straw bale	1-2
6	Rammed earth	0.1-0.5

resources but also reduce the need for energy-intensive manufacturing procedures. As a consequence, building projects' overall carbon impact is lowered, harmonizing with global sustainability goals.

Furthermore, sustainable building materials with high compressive strength provide architects and engineers with additional design and construction freedom. This adaptability enables the creation of new and efficient structural systems, encouraging the use of smaller parts and optimal designs. These materials result in lighter and more resource-efficient structures by lowering the volume of material required without sacrificing strength. Furthermore, sustainable materials frequently have higher durability and tolerance to harsh climatic conditions, enhancing the lifespan of structures while reducing maintenance requirements. This long-lasting performance not only benefits the environment by minimizing trash, but it also benefits building owners financially by lowering life cycle expenses.

In conclusion, the compressive strength of sustainable building materials is critical to the advancement of ecologically aware construction techniques. By using high compressive strength materials into building projects, the construction industry may produce long-lasting, robust, and energy-efficient buildings, greatly contributing to the worldwide trend toward sustainable development and a greener future.

Tensile strength of sustainable building materials. Tensile strength, which determines a material's capacity to bear pulling or stretching forces without breaking or deforming, is an important attribute in sustainable construction materials. Bamboo, engineered wood products, and certain natural textiles have exceptional tensile strength in the domain of sustainable building. Bamboo, for example, is a quickly renewable material with high tensile strength, making it an excellent choice for a variety of structural applications. Because of their layered and bonded structure, engineered wood products such as laminated veneer lumber (LVL) and cross-laminated timber (CLT) have great tensile strength, offering architects and builders with sustainable alternatives to traditional lumber and steel.

Furthermore, natural fibers such as hemp and jute have high tensile strength, making them desirable components in sustainable composite materials. When these natural fibers are mixed with biopolymers or resins, they form strong and environmentally friendly composites that may be used in building components such as panels, tiles, and even structural elements. The use of these sustainable materials not only decreases reliance on traditional, energy-intensive resources, but it also dramatically reduces the carbon footprint of construction projects.

Furthermore, investigating the tensile strength of recycled materials is a critical component of sustainable construction strategies. For example, recycled steel keeps its tensile strength even after reprocessing, making it a great choice for reinforcing constructions. Similarly, recycled plastic composites have high tensile strength, making them a potential alternative to traditional building materials. By utilizing recycled materials into construction projects, the construction industry may actively contribute to waste reduction while retaining high structural integrity, so supporting the built environment's sustainability.

Table 4. Thermal conductivity of building materials.

Material	Sample size (mm)	Test method	Thermal conductivity (W/mK)
Recycled concrete	150 × 50 × 10	ASTM C518	0.075
Bamboo	100 × 40 × 8	ISO 8302	0.060
Hempcrete	120 × 45 × 9	EN 12664	0.095
Geopolymer	130 × 35 × 12	ASTM C177	0.080
Conventional concrete	180 × 60 × 15	ISO 8301	0.065

Table 5. Specific heat capacity of building materials.

Material	Sample size (mm)	Test method	Specific heat capacity (J/kg-K)
Recycled concrete	150 × 50 × 10	ASTM E1952	1000
Bamboo	100 × 40 × 8	ISO 11357	900
Hempcrete	120 × 45 × 9	EN 12524	1100
Geopolymer	130 × 35 × 12	ASTM E1269	950
Conventional concrete	180 × 60 × 15	ISO 11357	1050

Bamboo	100 × 40 × 8	ISO 175	20	0.3	Intact
Hempcrete	120 × 45 × 9	EN ISO 2812-2	40	1.2	Slight damage
Geopolymer	130 × 35 × 12	ASTM D543	25	0.8	Minimal damage
Conventional concrete	180 × 60 × 15	ISO 175	35	0.4	Intact

Table 9. Comparative analysis of sustainable building materials.

Material type	Environmental impact	Mechanical properties	Cost-effectiveness
Recycled aggregates	Low	Varies	Cost-saving
Bamboo	Low	High tensile strength	Varies
Rammed earth	Low	Good compressive strength	Cost-competitive
Straw bales	Low	Good insulation properties	Cost-competitive
Engineered wood	Low	Varies	Varies

Table 10. Comparative analysis of eco-friendly building materials.

Material	Environmental impact (kg CO2 eq/m3)	Compressive strength (MPa)	Tensile strength (MPa)	Production cost ($/m3)
Recycled aggregates	150	30	3	80
Bamboo	50	40	6	120
Rammed earth	80	25	2.5	90
Straw bales	100	15	1.5	70
Engineered wood	120	35	4	110

In conclusion, knowing and harnessing the tensile strength of sustainable building materials is critical for the construction industry's transition to environmentally friendly methods. Builders and architects can design robust and ecologically responsible structures by embracing elements such as bamboo, engineered wood products, natural fibers, and recycled materials, paving the way for a greener future in construction.

Flexural strength of sustainable building materials. Flexural strength is an important feature of sustainable construction materials, since it determines structural integrity and endurance. Unlike typical building materials, sustainable alternatives are designed to endure bending stresses while being environmentally benign. One of the key advantages of these materials is their capacity to properly distribute loads, reducing the danger of fractures and failures under stress. Wood, for example, is a renewable resource with high flexural strength, making it a popular choice for green building. Furthermore, engineered wood products such as cross-laminated timber (CLT) improve flexural strength while effectively utilizing wood, encouraging sustainable forestry methods.

Furthermore, novel sustainable materials like bamboo have a high flexural strength, making them perfect for construction applications. Bamboo's quick growth rate and renewability make it an environmentally aware choice, providing a sturdy and versatile alternative for a variety of construction components. Concrete, a frequently used building material, may also be enhanced for flexural strength in environmentally friendly methods. The environmental effect of concrete manufacturing can be greatly decreased while improving flexural performance by using recycled aggregates or supplemental cementitious materials such as fly ash and slag.

Advances in composite materials have resulted in the creation of high-performance alternatives with excellent flexural strength in the field of sustainable building. Natural fibers like jute or hemp are frequently combined with bio-based resins to create materials that are both robust and ecologically beneficial. Furthermore, recycled plastic composites made from post-consumer waste have high flexural strength, making them a viable alternative for a variety of building applications while addressing the issue of plastic pollution. The construction industry may further improve the flexural strength of sustainable materials by constantly studying and adopting novel approaches, opening the way for eco-conscious and durable structures that match the expectations of the future.

Thermal characterization. The thermal characteristics of sustainable building materials are critical in evaluating their energy efficiency and thermal insulation potential. Thermal conductivity tests reveal the material's ability to conduct heat, whereas specific heat capacity measures determine the material's ability to store thermal energy. These tests give vital information on the thermal performance of the material, assisting architects and engineers in creating energy-efficient and climate-responsive structures.

Thermal characterization is essential for comprehending the thermal characteristics and behavior of sustainable building materials. This evaluation is critical for improving

building design, assuring energy efficiency, and providing a comfortable indoor atmosphere. Thermal conductivity, specific heat capacity, and thermal diffusivity of sustainable building materials are frequently measured during thermal characterization.

Thermal conductivity. Thermal conductivity is an important attribute that governs how well a substance transmits heat. It's critical to understand how heat moves through building components like walls, roofs, and floors. Low thermal conductivity sustainable building materials may efficiently insulate buildings, lowering heat loss during colder months and minimizing heat gain during warmer months. Materials' thermal conductivity is measured in watts per meter-kelvin (W/mK) and assessed using standard test techniques such as ASTM C518 or ISO 8302.

Specific heat capacity. The quantity of heat energy required to increase the temperature of a material by one degree Celsius is measured as specific heat capacity, also known as heat capacity. Sustainable building materials with a greater specific heat capacity may store more heat energy, resulting in increased thermal inertia. Its feature aids in the regulation of temperature changes within buildings, resulting in a more stable and comfortable interior environment. Specific heat capacity is tested using methods such as ASTM E1952 or ISO 11357 and is expressed in joules per kilogram-kelvin (J/kg-K).

Thermal diffusivity. Thermal diffusivity is a metric that describes how quickly heat is transported through a material in comparison to its ability to store heat. It is a mix of thermal conductivity and specific heat capacity that determines how rapidly a material responds to temperature changes. High thermal diffusivity materials transfer and disperse heat quickly, making them ideal for applications requiring rapid thermal reaction. Typically, thermal diffusivity is determined using techniques such as laser flash analysis (ASTM E1952) or the transient plane source method (ISO 22007-2).

Thermal characterization of sustainable building materials provides designers and engineers with vital information about their thermal performance. This information aids in the selection of materials that maximize energy efficiency, improve occupant comfort, and contribute to the construction of sustainable and resilient structures. Additionally, knowing the thermal behavior of these materials is critical for the design of passive heating and cooling techniques that result in lower energy consumption and a lower carbon footprint. Incorporating thermal characterization into material selection and building design procedures is an important step toward a more sustainable and energy-efficient built environment.

Durability assessment. Durability is an important component of sustainable building materials since it directly affects service life and long-term environmental effect. To imitate real-world environmental challenges, the experimental study includes accelerated aging testing, exposure to harsh weather conditions, and chemical resistance tests. We examine the materials' robustness, resistance to degradation, and propensity for weathering and deterioration by submitting them to extreme environments. This data is critical for determining the acceptability of materials for various building applications and assuring the long-term durability of created structures.

Durability testing is an important part in determining the performance and lifetime of sustainable construction materials. It entails putting the materials to a variety of environmental pressures, such as severe environments and aging variables, in order to assess their capacity to endure these difficulties over time. The purpose of durability testing is to guarantee that the eco-friendly alternatives chosen have resilience, resistance to deterioration, and longevity, making them appropriate for use in real-world building circumstances.

The assessment of durability is a critical component in determining the long-term performance and resilience of materials, components, and structures in the context of varied environmental and operational situations. It entails systematically testing a material's capacity to endure wear, degradation, and probable deterioration over time. This evaluation is critical for assuring the lifespan of structures, lowering maintenance costs, and decreasing the environmental effect of frequent replacements.

A variety of elements are considered in the durability evaluation, including exposure to external stressors such as temperature variations, moisture, chemicals, and mechanical pressures. Accelerated aging experiments, field exposure studies, and simulation approaches are frequently used to simulate real-world situations and forecast how materials would perform in various scenarios.

Durability evaluations help in the identification of possible weaknesses, allowing for the adoption of preventative actions and informed material selection. Assessing the corrosion resistance of steel reinforcements in concrete structures, for example, helps avoid structural damage due to rust, hence increasing the construction's lifespan.

Material science, non-destructive testing, and predictive modeling advancements have broadened the scope of durability evaluation. Life cycle evaluations are also used to examine the total environmental effect of a material's performance across its lifetime.

Finally, durability testing ensures that materials and structures not only satisfy functional requirements but also provide long-term value by withstanding the rigors of their operational environment. This technique adds to the

building industry's commitment to sustainability and appropriate resource management by generating long-lasting structures that contribute to a resilient built environment.

Designers, engineers, and builders may make educated judgments about the selection and integration of sustainable building materials by completing a full durability evaluation. A thorough assessment of the material's performance under diverse situations permits the construction of long-lasting and ecologically friendly structures, therefore contributing to a more sustainable built environment.

Comparative analysis. The experimental research comprises a comparison of sustainable construction materials and conventional alternatives to give significant findings. We can make direct comparisons and evaluate the environmental benefits and performance advantages of eco-friendly alternatives by conducting parallel testing on traditional materials typically used in building.

The "Sustainable Building Materials: A Comprehensive Study on Eco-friendly Alternatives for Construction" comparative study focuses on analyzing the performance and applicability of various eco-friendly building materials as alternatives to conventional construction materials. The study's goal is to determine each material's benefits and disadvantages in terms of environmental impact, mechanical qualities, and cost-effectiveness. Recycled aggregates, bamboo, rammed earth, straw bales, and engineered wood are among the materials evaluated for the investigation (see Figure 4).

Environmental impact. In the construction industry's desire to reduce its environmental imprint, sustainable building materials have emerged as critical components. These materials have the potential to drastically reduce resource use, waste creation, and stress on natural ecosystems. The environmental effect of sustainable building materials is diverse, spanning numerous phases of their lifespan, including extraction and production, shipping, installation, usage, and final disposal.

One of the key benefits of sustainable construction materials is that they have a lower embodied energy and carbon footprint. These materials are frequently acquired locally, reducing transportation energy requirements and helping area economies. Furthermore, many sustainable building materials are sourced from renewable resources,

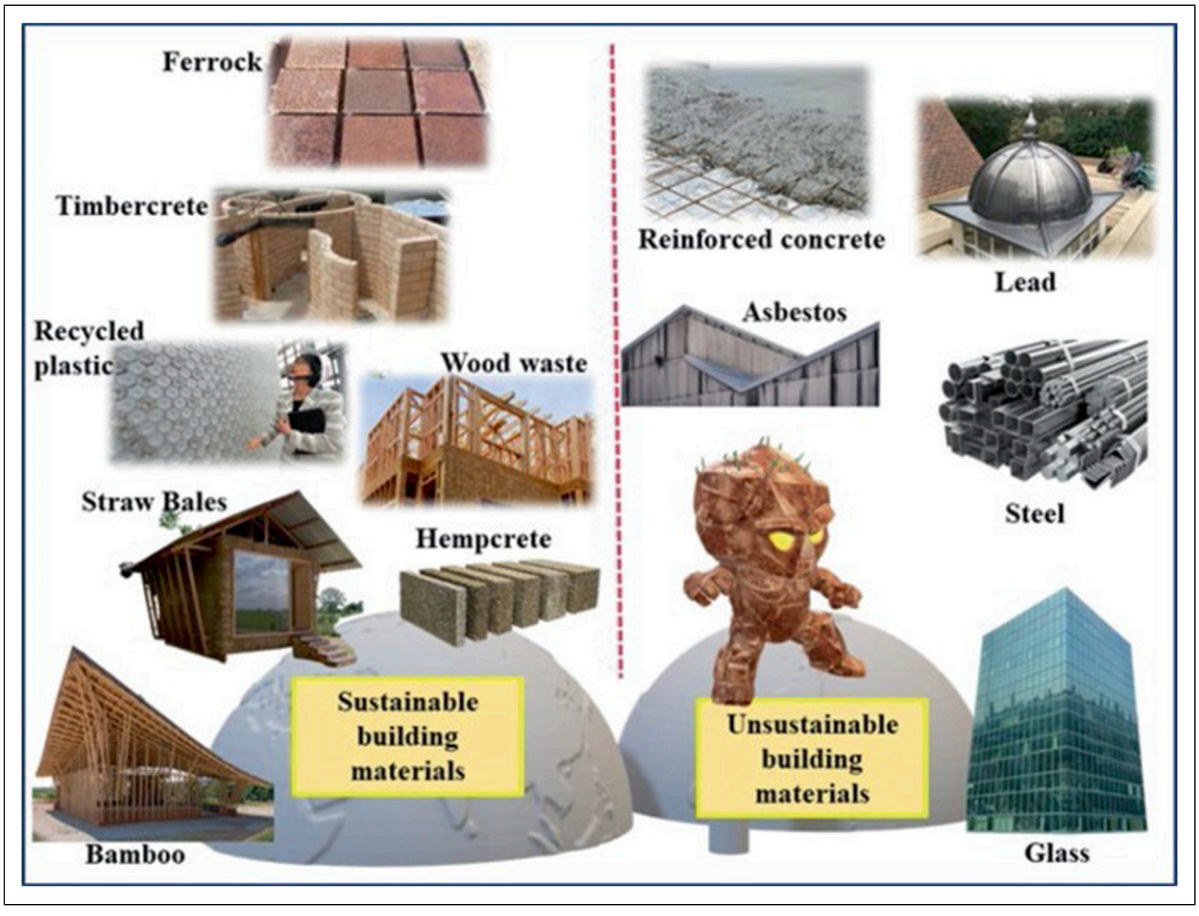

Figure 4. Comparative view of sustainable building materials and unsustainable building materials.

such as bamboo or cork, which replenish more quickly than standard building materials. The building sector may reduce its reliance on finite resources and help conserve natural ecosystems by prioritizing the use of renewable resources.

Furthermore, sustainable construction materials are built to last, decreasing the need for frequent replacements and preserving resources throughout the structure's existence. This longevity, along with recyclability, increases the usable life of the material and reduces the volume of building debris sent to landfills. For example, using recycled concrete aggregates not only diverts trash from landfills but also minimizes the environmental effect of mining virgin materials.

In terms of indoor environmental quality, sustainable materials frequently emit low levels of volatile organic compound (VOC), resulting in better indoor settings. This is especially important since poor indoor air quality can harm occupiers' health and well-being. Low-VOC paints, formaldehyde-free insulation, and non-toxic finishes assist to preserve indoor air quality and the well-being of building inhabitants.

However, it is critical to recognize that the environmental effect of sustainable construction materials varies by option. Life cycle evaluations are crucial tools for assessing a material's overall effect, taking into consideration elements such as resource extraction, production, transportation, and disposal. Furthermore, the availability and scalability of sustainable materials may differ by region, necessitating careful consideration of local context and resources.

Finally, sustainable building materials are critical in lowering the environmental effect of the construction sector. These materials contribute to a constructed environment that is not only ecologically friendly but also favorable to occupant well-being by prioritizing resource efficiency, carbon reduction, durability, and indoor air quality. The use of sustainable building materials demonstrates a conscientious commitment to a more sustainable future, helping to shape a construction sector that balances its role in urban expansion with a duty to protect the planet's natural resources.

Mechanical qualities. Sustainable building materials provide a harmonic balance of environmental responsibility and structural integrity, with mechanical qualities playing an important part in molding their feasibility for construction applications. These characteristics include a material's capacity to tolerate external pressures, stresses, and deformations while retaining overall structural performance over time. Understanding and utilizing the mechanical characteristics of sustainable building materials is critical for designing robust and long-lasting buildings that meet sustainability objectives.

Many sustainable construction materials have mechanical qualities that rival, if not outperform, their traditional equivalents. Cross-laminated timber (CLT), for example, has excellent strength-to-weight ratios, making it appropriate for load-bearing applications while lowering the requirement for energy-intensive steel and concrete. Furthermore, natural fibers like bamboo and hemp have high tensile strength, making them suitable reinforcing materials in a variety of building aspects.

Durability is an important aspect of sustainable materials, which is frequently ascribed to their capacity to withstand degradation caused by environmental variables such as moisture, temperature changes, and chemical exposure. This resilience contributes to longer service lifespans and lower maintenance requirements, which aligns with resource efficiency and waste reduction concepts.

Innovative sustainable materials, such as self-healing concrete, go beyond mechanical qualities by having the potential to mend cracks and extend their longevity on their own. This method represents the marriage of material science and structural engineering, offering increased longevity and sustainability for concrete structures.

The mechanical qualities of sustainable building materials, on the other hand, might vary greatly depending on factors such as material composition, production procedures, and quality control. Thorough testing and validation are required to verify that these materials fulfill the performance specifications of specific applications. Sustainable material standards and norms must adapt to accommodate their particular properties and promote their incorporation into mainstream construction practices.

Finally, the mechanical features of sustainable building materials support their importance in altering the construction sector. Sustainable materials provide equivalent or greater strength, durability, and resilience to traditional materials, paving the path for structurally sound and ecologically responsible construction solutions. Because of the synergy between mechanical performance and sustainable principles, these materials are positioned as significant contributors to the building industry's progress toward a more robust, efficient, and sustainable future.

Cost-effectiveness. As a more thorough understanding of sustainable construction materials' long-term cost-effectiveness emerges, the idea that they are more expensive has steadily altered. While the initial investment in sustainable materials may appear to be costlier than that of traditional counterparts, a careful examination reveals that the lifespan cost of these materials frequently produces considerable savings.

Sustainable construction materials help to save costs in a variety of ways. For starters, their durability and resistance lower maintenance and replacement costs during the life of the structure. Materials such as recycled steel, which has equivalent strength to virgin steel, can increase construction lifetime and reduce maintenance costs without sacrificing structural integrity.

Furthermore, sustainable materials usually improve energy efficiency, resulting in lower operational costs. Thermally insulated materials, such as insulated concrete forms (ICFs), for example, minimize heating and cooling needs, resulting in cheaper utility expenditures over time. Similarly, energy-efficient windows and smart building systems lead to significant energy savings.

The natural waste and resource consumption reduction inherent in sustainable materials coincides with trash disposal rules, potentially resulting in cheaper disposal costs and reducing the environmental effect associated with waste management. Furthermore, the incorporation of renewable energy systems, which is frequently enabled by sustainable construction materials, can result in energy savings that more than equal the original investment costs. As green construction approaches grow more common, economies of scale drive down the cost of green materials. Manufacturing process advancements, more competition, and rising demand have all led to a reduction of the cost gap between sustainable and conventional choices.

When analyzing the cost-effectiveness of sustainable construction materials, it is critical to include not just the initial expenses but also the overall financial impact. The financial argument for sustainable materials becomes persuasive when lifespan costs, decreased operational expenditures, higher property value, and environmental benefits are included in. The cost-effectiveness of sustainable building materials emerges as a strategic investment in both the physical environment and the future in a world more alert to the need for resource efficiency and environmental responsibility.

The comparison research reveals that each eco-friendly construction material has its own set of advantages and disadvantages. The material used is determined by project-specific considerations such as location, climate, resource availability, and desired level of sustainability. Using various sustainable materials and technologies together can provide synergistic benefits, resulting in more environmentally conscious and resilient construction methods. Further research and development in these materials will help to promote future sustainable construction solutions.

Reliability and reproducibility. The experimental analysis is carried out with a strict emphasis on reliability and repeatability. All tests are repeated numerous times to assure accuracy, and statistical averages are employed to reduce potential mistakes. The methodologies and protocols used adhere to industry norms and guidelines, guaranteeing that the experimental findings can be repeated and validated by other researchers.

Finally, the experimental analysis is an important part of this comprehensive study on sustainable construction materials. This research provides critical data to aid building industry decision-making by assessing the mechanical, thermal, and durability qualities of eco-friendly alternatives. This study intends to contribute to the adoption and implementation of sustainable building materials, promoting a more ecologically conscious and resilient built environment, through rigorous and reliable experimental methodologies.

Life cycle analysis

A quick overview. Life Cycle Assessment (LCA) is a thorough technique for assessing the environmental effect of goods, processes, or systems over the course of their entire lifespan, from raw material extraction and manufacture to use, maintenance, and final disposal. LCA considers indirect and cumulative consequences in addition to immediate ones, providing for a comprehensive knowledge of a product's environmental footprint.

LCA is a systematic way to quantifying environmental issues such as energy use, greenhouse gas emissions, water consumption, air pollution, and resource depletion. The evaluation attempts to identify possible hotspots and areas for improvement across the lifespan stages, assisting in the direction of sustainable design, decision-making, and policy formation.

Goal and scope definition, life cycle inventory analysis, life cycle impact assessment, and interpretation are the four essential steps of the process. Data on material inputs, energy consumption, and emissions are gathered and categorized throughout the life cycle inventory study. The impact assessment assesses the possible environmental impacts of these inputs and outputs and converts them into environmental indicators.

LCA provides useful information for informed decision-making in a variety of industries, including building, manufacturing, and consumer goods (see Figure 5). LCA in construction aids in the identification of materials and designs that reduce environmental effect while enhancing performance. Comparing the life cycle implications of different insulating materials, for example, might help guide decisions that lead to energy efficiency and lower emissions.

LCA has gained significance as a technique for attaining environmentally responsible practices as sustainability becomes increasingly important in numerous businesses. It allows stakeholders to examine the larger implications of their decisions, promoting a more balanced approach that adheres to the concepts of resource efficiency, circular economy, and decreased ecological impact.

To conclude, Life Cycle Assessment is a strong tool that aids informed decision-making by offering a comprehensive perspective of the environmental implications of a product or process. LCA promotes a more sustainable approach to design, manufacturing, and consumption by analyzing the full lifespan, so contributing to a more responsible and resilient global economy.

The comparative analysis emphasizes the advantages and disadvantages of various eco-friendly construction materials. Each material has distinct features that make it

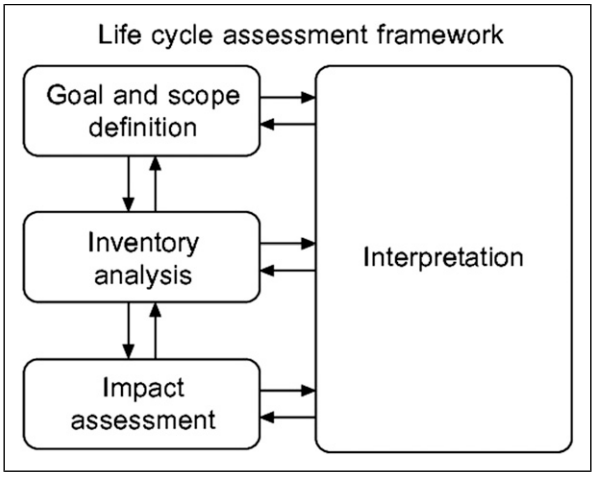

Figure 5. LCA: Sustainable building materials.

appropriate for various construction applications. Recycled aggregates are notable for their environmental advantages, while bamboo and engineered wood excel in mechanical characteristics. Rammed earth and straw bales perform admirably in terms of environmental and thermal performance. To obtain the best environmental, structural, and economic outcomes in construction projects, sustainable building materials should be chosen with specific project needs, local availability, and project goals in mind.

Bamboo has the lowest environmental effect and the highest tensile strength in this example, making it an appealing eco-friendly solution for particular applications. Recycled aggregates, on the other hand, have a reduced cost and a competitive compressive strength, making them acceptable for cost-conscious projects. Rammed earth provides an excellent combination of environmental impact and cost, whereas engineered wood has strong mechanical characteristics and a low environmental impact. Straw bales, while less expensive, have poorer strength and a bigger environmental effect than alternative materials.

The general equation for emission estimation used in this investigation is as follows

$$E = A \times EF \times (1 - ER/100) \quad (1)$$

where: E = emissions, A = activity rate, EF = emission factor, and ER = overall emission reduction efficiency, %.

This simplified table illustrates the many qualities of each eco-friendly construction material, allowing stakeholders to make educated selections based on their individual project needs, financial limits, and sustainability objectives. Additional criteria and data points may be incorporated in the comparison analysis for a more thorough assessment in real-world applications.

Policy implications and suggestions. The comprehensive study on eco-friendly options for construction materials emphasizes the critical need for policymakers, industry stakeholders, and researchers to work together to promote sustainable practices in the construction sector. This study has important policy implications that might accelerate the shift to eco-friendly construction materials and methods.

To begin, politicians should emphasize the creation and implementation of strong environmental standards and regulations for the building sector. These policies should stimulate the use of sustainable building materials by providing incentives, tax breaks, and subsidies to construction firms that utilize environmentally friendly alternatives. Governments may encourage market demand for sustainable materials by fostering a favorable policy climate, resulting in more research and development in this sector.

Furthermore, investment in research and development is critical. Governments and the commercial sector should sponsor research and development activities aimed at discovering new eco-friendly materials and upgrading current ones. Collaboration between academics, research institutes, and industry actors can lead to the development of novel materials that are both environmentally friendly and economically feasible for large-scale construction projects. Furthermore, research should focus on enhancing the durability, strength, and insulating features of sustainable materials in order to make them more appealing to builders and developers.

Furthermore, education and awareness programs should be undertaken to educate architects, engineers, contractors, and customers about the advantages of adopting environmentally friendly construction materials. Training programs and workshops may assist construction workers grasp the technical features and uses of sustainable materials. By raising knowledge, not just legislation but also educated consumer decisions may increase demand for sustainable materials. Furthermore, educational institutions should add modules on sustainable construction techniques into their curricula to ensure that the future generation of architects and engineers is well-versed in environmentally friendly solutions.

Green building certifications, such as LEED (Leadership in Energy and Environmental Design) and BREEAM (Building Research Establishment Environmental Assessment Method), can also encourage the use of environmentally friendly products. For buildings that acquire certain certifications, governments may grant tax breaks or quicker permitting processes. Policymakers may provide a competitive edge for eco-friendly construction by recognizing and rewarding sustainable building techniques, driving more stakeholders to invest in such materials and processes.

Furthermore, governments should consider encouraging cross-national research cooperation and knowledge exchange. International collaboration can help to encourage the exchange of best practices, technical developments, and effective policies relating to sustainable building materials. Countries may expedite their efforts to create more sustainable infrastructure and reduce the total environmental effect of the construction sector by learning from one another's experiences.

Finally, the study on eco-friendly construction materials gives useful insights into the policy implications required to promote sustainable practices in the construction sector. Policymakers can pave the way for a greener and more sustainable future in the construction sector by developing and enforcing stringent regulations, investing in research and innovation, launching educational initiatives, incentivizing green certifications, and fostering international collaborations. When implemented properly, these policy recommendations can stimulate broad use of eco-friendly construction materials, resulting in considerable reductions in environmental degradation and a more sustainable built environment for future generations.

Discussions

The significant research on environmentally friendly construction materials has yielded helpful insights that require serious debate and review. This part delves into important findings, potential ramifications, and opportunities for future research, highlighting the significance of sustainable building processes and the role of eco-friendly materials in shaping the construction industry's future.

One important discovery is the clear environmental benefit of sustainable building materials. The LCA analysis indicated the potential for lower greenhouse gas emissions, energy consumption, and resource depletion associated with the use of environmentally friendly alternatives. This aligns with global efforts to combat climate change and underscores the critical role that the construction industry can play in advancing environmental goals. The use of sustainable materials not only gives immediate environmental benefits, but also sets the standard for a more responsible approach to construction.

The economic research yielded mixed results, emphasizing the significance of a thorough understanding of the economic implications of sustainable materials. While some materials showed cost savings over time, others needed upfront investments, which may prevent early adoption. This stresses the importance of looking forward and accounting for concerns other than immediate building costs. Policymakers and industry stakeholders should consider innovative financing mechanisms and incentive structures to balance these constraints and promote the use of sustainable alternatives.

The debate also emphasizes the potential of technology and innovation to drive the use of sustainable construction materials. The study's focus on material characterization underlines the importance of technical feasibility in material selection. Emerging technology, such as enhanced manufacturing methods and digital tools like Building Information Modeling (BIM), offer opportunities to enhance the design, manufacture, and application of sustainable materials. Continued investment in research and development can lead to materials with higher performance qualities, allowing them to be employed in a wider range of construction projects.

However, the use of sustainable construction materials has concerns that must be carefully addressed. Barriers identified in the study included industry inertia, a lack of customer information, and potential quality disparities. To solve these difficulties, a multifaceted approach involving education, capacity building, and collaboration among many stakeholders is required. Policy and regulation are vital, as well-designed incentives and enabling structures can promote dramatic transformation in the industry.

Finally, the argument emphasizes the transformative power of environmentally friendly construction materials in creating a sustainable future. The study's findings show the interconnection of environmental, economic, and technological factors in driving the use of these materials. As the construction industry works for greater sustainability, it must adopt a comprehensive approach that includes innovation, regulatory support, and collaborative efforts to incorporate sustainable materials and practices, paving the way for a more resilient and ecologically conscious built environment.

Conclusion

In conclusion, this extensive study on eco-friendly options for construction materials provided numerous critical conclusions that highlight the necessity and promise of sustainable building methods. The examination of diverse materials' environmental, technological, and economic characteristics has offered significant insights into their feasibility and influence on the building industry.

- One of the most important conclusions is the significant environmental benefit provided by sustainable construction materials. Life cycle assessment (LCA) studies repeatedly demonstrated that these materials had lower carbon emissions, energy consumption, and resource depletion. This emphasizes their potential to greatly contribute to global sustainability goals and address the building sector's ecological footprint.
- The economic research found a complicated interaction between the initial expenses and the long-term

advantages. While some sustainable materials demonstrated significant cost advantages over their lives, others required substantial inputs. This highlights the significance of a holistic strategy that takes into account both short-term expenditures and long-term returns, emphasizing the importance of novel funding mechanisms and regulatory incentives.

- The study also highlighted the importance of technology and innovation in promoting the use of sustainable materials. Material characterization showed these materials' technical feasibility and performance characteristics, highlighting prospects for further improvement and refinement. The outcomes of the study imply that developing technologies can improve the design, manufacture, and application of sustainable materials.
- However, the study revealed certain barriers to wider adoption. Inertia in the industry, a lack of market knowledge, and possible quality variances surfaced as impediments that need focused actions. Effective legislation, incentives, and stakeholder collaboration are required to overcome these obstacles and speed the incorporation of sustainable materials into mainstream building methods.
- Finally, the study's findings highlight the critical significance of eco-friendly options in forging a more sustainable future for the construction sector. Stakeholders can work together to drive the adoption of sustainable building materials by addressing environmental concerns, economic considerations, and technological innovations, fostering a resilient and environmentally conscious built environment that meets the needs of current and future generations.

ABSTRACT

The current study focuses on the synthesis and other detailed studies on $CaBi_2Nb_2O_9$ (abbreviated CBNO) phosphor doped with Dy^{3+} ions. The aforementioned phosphors were prepared via a solid-state reaction procedure and a comprehensive analysis of the crystal structure, particle morphology, vibrational bands, luminous characteristics, decay and thermal stability of the phosphors was done. Phase identification of the synthesized material was carried out using X-ray diffraction (XRD) technique and the optical bandgap was determined using diffuse reflectance spectra (DRS). The morphological studies and particle size estimation of the phosphor material were conducted using a scanning electron microscope (SEM). Under 452 nm excitation, the photoluminescence (PL) spectra of Dy^{3+}-doped CBNO phosphor exhibit three peaks at 482, 576, and 666 nm, which correspond to the transitions $^4F_{9/2} \rightarrow {}^6H_{15/2}$, $^6H_{13/2}$, and $^6H_{11/2}$. The electric dipole–dipole interaction was the main mechanism for concentration quenching for Dy^{3+} ions. The estimated CIE chromaticity coordinates for Dy^{3+} ion-doped CBNO phosphors fall in the white region. The temperature-dependent PL (TD-PL) findings reveals that CBNO phosphors have a considerably superior thermal stability. The results of these investigations suggest that the CBNO phosphors doped with Dy^{3+} ions exhibit promising properties that could be used for prospective w-LEDs and other optoelectronic device applications.

1 Introduction

The development of a variety of inorganic phosphors appropriate for white light-emitting diodes (w-LEDs) has progressively drawn a great deal of interest to promote the area of solid-state lighting and other display related applications by virtue of their excellent luminescence, low operating voltage, and chemical and thermal durability. [1–7]. It is well known that the w-LEDs are regarded as the fourth generation of SSL and are a better alternative to conventional incandescent, and fluorescent lamps. w-LEDs have received plenty of attention and have been the subject of extensive research because of their unique benefits, which include environmental protection, short response times, high luminous efficiencies, long lifespans, reliability, and lack of mercury. Usually $Y_3Al_5O_{12}$: Ce^{3+} (YAG: Ce) phosphors, which emit yellow light, are combined with blue light from n-UV LED chips to produce commercially available w-LEDs [1, 6, 8–11]. The lack of red colour in this setup results in a low colour rendering index (CRI) and a high colour temperature (CCT). This is inefficient for general room lighting as well. Researchers are concentrating on pc-w-LEDs through tricolour (blue, green, and red) phosphors coated on n-UV chips to get greater CRI and lower CCT in order to solve this drawback [12–14]. For significant red nitride phosphors used in w-LEDs ($SrLiAl_3N_4$: Eu^{2+}, $CaAlSiN_3$: Eu^{2+}, and $Ca_2Si_5N_8$: Eu^{2+}), the synthesis requires a demanding environment, such as high pressure and high temperature. Commercial red phosphor (Y_2O_2S: Eu^{3+}) used in it, however, has several intrinsic drawbacks due to colour re-absorption and distinct degradation such as low luminous efficiency and unstable CCT respectively [15–19]. The mild synthesis environment and generally stable chemical properties of the oxide materials make them useful for a variety of applications. A single-phase white-light-emitting phosphor stimulated effectively with n-UV LED chip is widely preferred to solve the challenges mentioned above, and in the last few decades, this desire has attracted the attention of numerous research groups.

Dysprosium oxide (Dy_2O_3), one of the known rare earth ions, is crucial for emission in white region since it may be easily activated by UV or blue LED chips. Dy^{3+} exhibits blue ($^4F_{9/2} \rightarrow {}^6H_{15/2}$), yellow ($^4F_{9/2} \rightarrow {}^6H_{13/2}$) and red ($^4F_{9/2} \rightarrow {}^6H_{11/2}$) emission bands at wavelengths of 482 nm, 575 nm, and 666 nm, respectively [9, 20–24]. Also, $^4F_{9/2} \rightarrow {}^6H_{13/2}$ has a higher intensity but, it is less sensitive to the environment of the ligand. $^4F_{9/2} \rightarrow {}^6H_{15/2}$ is hypersensitive but, it is greatly impacted by the environment of the host, and $^4F_{9/2} \rightarrow {}^6H_{11/2}$ is least affected by the environment of the host. Many phosphor materials are being studied for their yellow to blue (Y/B) intensity ratio since it must be equal to one to satisfy the need for pure white light emission. Various Dy^{3+} ions-doped phosphors, including $SrAl_2O_4$ [16], $KBaY(BO_3)_2$ [15], and $SrLaAlO_4$ [17], that possess a high absorption in the n-UV range and emit white light, have already been reported.

Nowadays, a wide variety of host materials, including phosphates, silicates, borates, vanadates, fluorides, ceramics, niobates, and tungstates can be doped with RE ions. Due to its great chemical stability, good thermal stability, and eco-friendliness, niobate is regarded as a dependable host material. In general, niobium oxides have a low phonon frequency [25, 26]. The likelihood of the non-radiative transition can be efficiently lowered, that lends the phosphors their strong fluorescence [27]. The Aurivillius-type bismuth layered structure ferroelectrics (BLSFs), whose chemical formula is $(Bi_2O_2)^{2+}$ $(A_{m-1}B_mO_{3m+1})^{2-}$, have drawn a lot of interest because of their comparatively high Curie point (T_c), which translates to high thermal stability [28, 29]. CBNO is a member of the BLSF family with $m = 2$, where Ca^{2+} is present at site A and Nb^{5+} is present at site B of the pseudo-perovskite $(CaNb_2O_7)^{2-}$ blocks. CBNO has a stacking $(Bi_2O_2)^{2+}$ layer and perovskite $(CaNb_2O_7)^{2-}$ units with double NbO_6 octahedral layers [30]. It was proposed that the perovskite blocks could accommodate a wide range of cations, but the bismuth oxide layers were difficult to alter [28]. However, no research has been done on the CBNO: Dy^{3+} phosphor for fabricating white LEDs.

The main aim of this research work is to generate white light with improved luminosity. In this work, the high temperature solid-state method was used to synthesis a series of Dy^{3+} ions-doped CBNO phosphors. The structural and spectroscopic characteristics of phosphors were investigated using a variety of characterisation techniques, including XRD, UV–Vis, PL emission, decay profiles and TD-PL. FT-IR studies were employed to understand various vibrational groups present in the CBNO phosphor. From the PL emission data, the CIE chromaticity coordinates were carefully examined. As far as we are aware, there hasn't been any information published about the luminescence characteristics of Dy^{3+}-doped CBNO phosphors. The aforementioned characteristics suggest that

white light-emitting CBNO phosphor may be utilised in the fabrication of w-LEDs and other optoelectronic device applications.

2 Material preparation and instrumentation

The CBNO: x Dy^{3+} ($x = 0.01, 0.02, 0.03, 0.04,$ & 0.05 mol) ions-doped phosphors were prepared by solid-state reaction process. Starting raw materials $CaCO_3$ (Thermo fisher 98%), Bi_2CO_3 (Loba Chemie 99%), Nb_2O_5 (Loba Chemie 99.9%), Dy_2O_3 (Central Drug House 99.9%), are used. These materials were weighed with their stoichiometric ratio and ground for an hour in an agate mortar. Acetone is employed as a wetting medium. The ground powder was put in an alumina crucible, heated in a high temperature programmable muffle furnace at 1250 °C for 5.5 h, and then allowed to cool at ambient temperature. After that process, the final collected powder was reground again for 10 min to obtain the homogeneous mixture for further characterization purposes.

The chemical reaction of synthesis process can be described by the following chemical formula:

$$CaCO_3 + Nb_2O_5 + Bi_2CO_3 = CaBi_2Nb_2O_9 + \text{gases}$$

The XRD patterns of the as-titled samples were recorded using the Bruker Model D8 Advance instrument with Nickel filtered Cu-Kα radiation (1.54 Å). Using the JEOL 7610 F Plus machine, SEM records for surface morphology were taken. A Perkin-Elmer Frontier FT-IR spectrometer was employed for analysing the FT-IR spectra. A JASCO model V-923 UV–Vis-NIR spectrophotometer (± 2.0 nm resolution) was utilized to record the DRS for the as-titled phosphors. A Jasco FP-8300 spectrofluorometer with a Xenon excitation source having 1.0 nm resolution was used to study the PL excitation and emission spectra. The PL decay profiles were analysed using an Edinburgh FL920 fluorescence spectrometer. The Flame-S-XR1-ES spectrometer from Ocean Optics was utilised to study TD-PL spectra. All measurements except TD-PL were made at the room temperature. The flowchart of the steps involved in the preparation of the phosphor by the solid-state reaction method is shown in Fig. 1.

3 Results and discussion

3.1 XRD analysis

The initial assessment of the purity of the as-prepared sample was conducted using XRD. Figure 2a illustrates the XRD patterns of the undoped CBNO host material. All the diffraction peaks in the sample can be attributed to the standard data for CBNO (ICDD no. 49-0608). No signs of any other phases were detected, indicating that the obtained samples consist of a single phase. $CaBi_2Nb_2O_9$ exhibits an

$\alpha = \beta = \gamma$	90°	90°	
Cell volume, V ($Å^3$)	742.79	739.9161(3)	
GOF		2.54	

To further assess the phase purity of the synthesized samples, Rietveld refinement was employed, using CBNO as a representative. Rietveld refinement is a method that involves analyzing profile measurements of powder intensity to approximate the phosphor's structural model. The initial model was constructed based on previously reported crystallographic data for CBNO [31]. Figure 2b depicts Rietveld refinement plots for $CaBi_2Nb_2O_9$ powders, which were prepared using the solid-state reaction method and heat-treated at 1250 °C for 5.5 h. The observed XRD patterns closely match the theoretical fit results, indicating the success of the Rietveld refinement method. The refined crystallographic parameters align well with the reflection conditions, and the fit is highly satisfactory with $\chi^2 = 2.54$, confirming the phase purity of the as-prepared sample and $\chi 2$ value is less than the other reported papers [32, 33]. The smaller value of χ^2 indicates that a single phase has been formed. Table 1 provides the structural parameters of the Rietveld refinement, including crystal structure, space group, lattice parameters and goodness of fit (χ^2) [18, 34]. The term χ^2 serves as a measure of the goodness of fit (GOF), indicating how well the experimental XRD patterns align with the calculated ones. Table 2 presents the atomic coordinates and the occupancy of cations and anions in the CBNO compound [31]. Following the refinement process, crystal structures of the CBNO compound were generated using the output.cif file with the Vesta software, as depicted in Fig. 2c.

Table 2 Atomic coordinates, cation and anion occupancies of a CBNO compound

Figure 2c illustrates the crystal structure of CBNO, highlighting the arrangement of Ca^{2+}, Bi^{3+}, and Nb^{5+} atoms in their respective coordination environments. CBNO belongs to the Aurivillius-type materials, characterized by a pseudo-perovskite structure. This category was initially identified by Aurivillius in 1949. As explained in the introduction, the crystal structure of CBNO has Ca^{2+} ions occupying the A site and Nb^{5+} ions occupying the B site. The crystal structure of CBNO is composed of chains of CaO_8 octahedra that share edges and run parallel to the a-axis. According to structural data, calcium ions have a coordination number of 8, while bismuth and niobium ions have a coordination number of 6. The ionic radii for 8-coordinated Ca^{2+} and 6-coordinated Bi^{3+} are 1.12 Å and 1.03 Å, respectively. Consequently, due to their similar ionic radii and valence, it is anticipated that Dy^{3+} ion dopants, with a 6-coordinated structure and an ionic radius of 0.912 Å, will substitute for Bi^{3+} ions within the host structure.

3.2 Morphological studies

The microscopic shape and particle size of the as-prepared phosphors have also been further examined using SEM. Figure 3a, b shows the SEM pictures of the

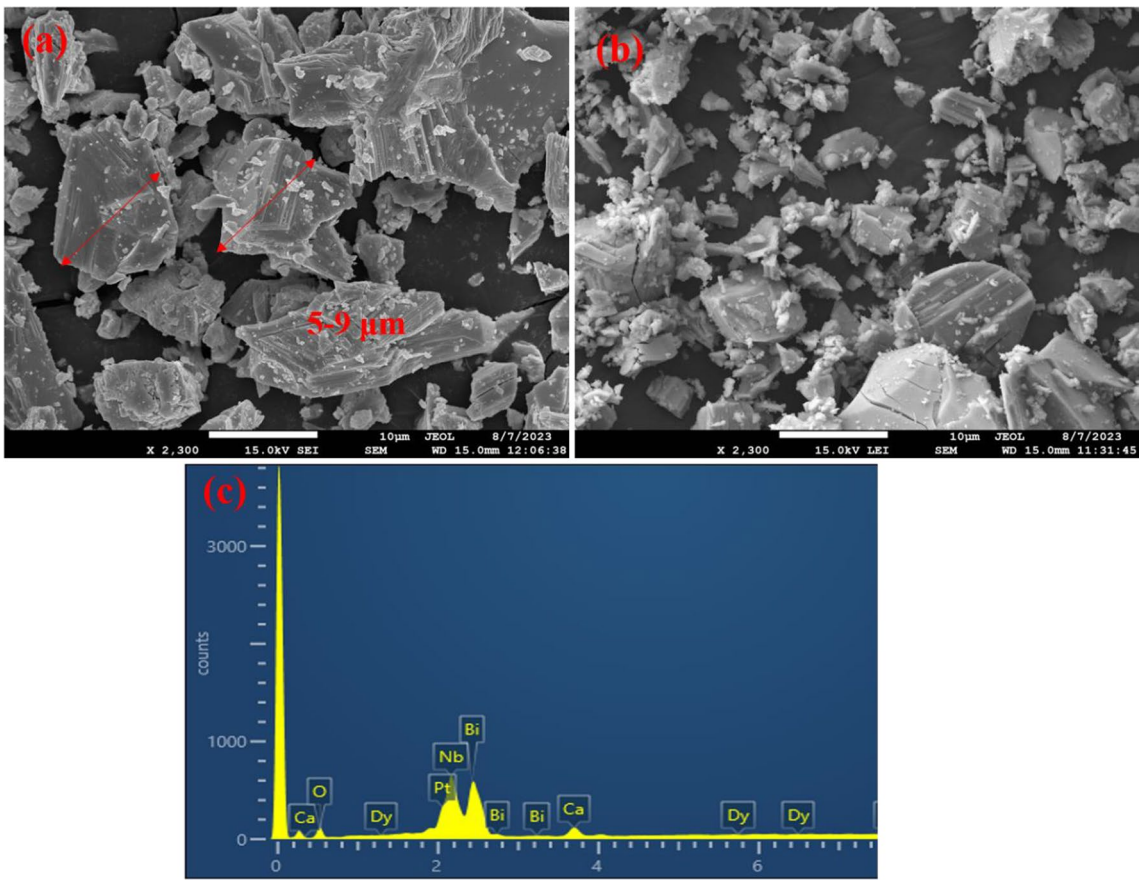

Fig. 3 **a**–**b** SEM images recorded for 0.04 mol of Dy^{3+} ions-doped CBNO phosphor, **c** corresponding EDS image

CBNO: 0.04 mol Dy^{3+}-doped phosphor. The irregular shape of the phosphor is evident in Fig. 3. Due of the high-temperature reaction and grinding procedure, the synthesised materials show agglomeration. Today's commercially available phosphor particles are typically between two 2–10 μm (μm) in size. The as-prepared phosphor samples have an average particle size in the 5–9 μm range as has been highlighted in the image. Also, the phosphor particles with size ranges in μm have been considered more convenient for use in pc w-LEDs. Energy dispersive spectrum (EDS) used to monitor the elemental composition of the as-titled phosphor is depicted in Fig. 3c. The EDS image shows that every precursor element is present in the material. The different colours, i.e. green, purple, yellow, and blue corresponding to Dy, Bi, Nb, and Ca, respectively are depicted in Fig. 4. These results demonstrate the equally distribution of the components in the as-prepared phosphors.

3.3 FT-IR analysis

Figure 5 shows the FT-IR spectrum for the CBNO: 0.04 mol Dy^{3+}-doped phosphor. FT-IR spectrum was captured to reveal information about the functional groups found in the CBNO phosphor. It contains peaks at 545, 610, 797, 1071 and 2974 cm^{-1}. The band centred at 610 cm^{-1} can be assigned to Nb–O of the NbO_6 octahedral stretching vibration [34]. The octahedral NbO_6 peak indicates single-phase formation.

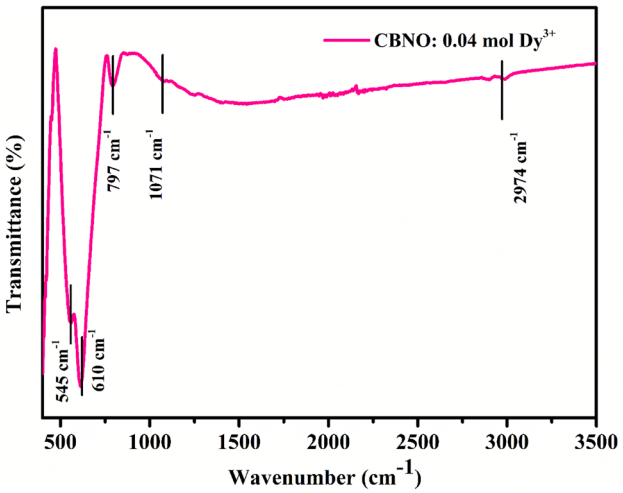

Fig. 5 FT-IR spectrum of CBNO: 0.04 mol Dy^{3+} ion-doped phosphor

The stretching vibration mode of Bi-O_3 is attributed to the shoulder peak at 545 cm^{-1} [35]. The stretching vibration mode of Nb–O_5 and the bending vibration mode of O_4–Nb–O_5 correspond to the shoulder peaks at 797 and 1071 cm^{-1}, respectively [18, 35]. The hydrogen bonding is attributed to the band was seen in the region 2700–3000 cm^{-1}.

3.4 DRS analysis

Phosphors used in w-LEDs depend significantly on the optical bandgap (Eg). Figure 6 displays the DRS

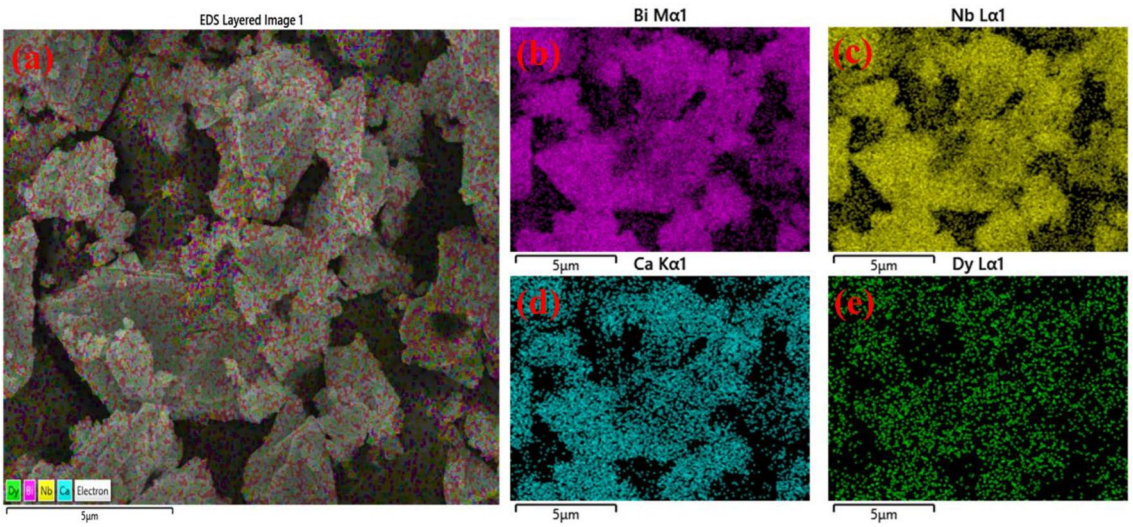

Fig. 4 **a** The total element distribution map, **b–e** shows the relative element points of various colours against a dark background; purple, yellow, blue and green, correspond to Bi, Nb, Ca, and Dy, respectively (Color figure online)

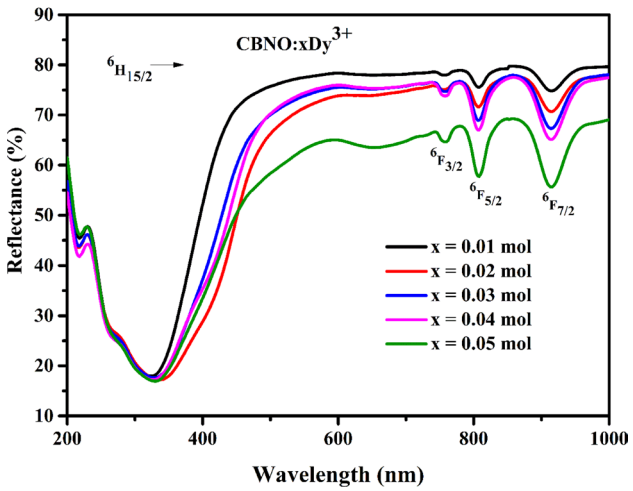

Fig. 6 DRS of CBNO: xDy^{3+} (x = 0.01, 0.02, 0.03, 0.04, & 0.05 mol) phosphors

for CBNO: x Dy^{3+} (x = 0.01, 0.02, 0.03, 0.04, & 0.05 mol) phosphors samples in the range 200–1000 nm. The charge transfer (CT) from the oxygen (2p) to the empty 4f orbital of the Dy^{3+} ion in the host can be seen by two absorption lines observed at wavelengths of 219 nm and 264 nm. The peaks observed in the spectra at 756 nm, 808 nm & 915 nm correspond to the transitions from $^6H_{15/2}$ to $^6F_{3/2}$, $^6F_{5/2}$, & $^6F_{7/2}$ respectively. Carnall et al. have validated each of the aforementioned band designations. [36].

Bandgap determination actually helps us to understand parameters like stability, lifetimes and degradation of the material. This knowledge is essential for deploying materials in various photonic, SSL and solar cell applications. Using the equation below, the E_g was estimated by transforming the DRS data into the Kubelka–Munk function [37].

$$F(R) = \frac{(1-R^2)}{2R} = \frac{\alpha}{S} \quad (1)$$

Here α stands for the absorption coefficient, R for the samples' reflectance, and S for the scattering coefficient. The Tauc equation, which determines the energy bandgap (E_g) and absorption coefficient (α), is shown below [8].

$$\alpha h\upsilon = C\left(h\upsilon - E_g\right)^n$$

Here C stands for the energy-independent constant (= 1), and hν represents the photon energy. n can have value of 2 for indirect or 1/2 for direct transition.

Since F(R) and α are directly related, the equation above can be rewritten as follows [8]:

$$F(R)h\upsilon = C\left(h\upsilon - E_g\right)^n \quad (2)$$

The optical bandgap for the Dy^{3+} ions-doped CBNO phosphors using a Tauc plot which was drawn between the $[F(R)\ h\upsilon]^2$ and hν. The E_g can be estimated by extrapolating the linear region of the plot. The direct bandgap values evaluated for CBNO: x Dy^{3+} (x = 0.01, 0.02, 0.03, 0.04, & 0.05 mol) phosphors are 4.59, 4.57, 4.56, 4.54, and 4.51 eV, respectively and shown in Fig. 7. Thus, it can be concluded that CBNO phosphor is viable host lattice because of its high bandgap and may find utility in w-LEDs applications. The E_g value slightly decreases with an increase in Dy^{3+} ion concentration, which may be due to the 4f energy level of Dy^{3+} ions [38].

3.5 PL studies

It is vital to know the proper excitation wavelength in order to analyse the PL spectra of Dy^{3+}-doped CBNO phosphor. Excitation spectrum of the as-prepared CBNO: 0.04 mol Dy^{3+}-doped phosphor measured at an emission wavelength of 576 nm in the 300–500 nm range is shown in Fig. 8. In that, PL excitation peaks were observed from the ground state $^6H_{15/2}$ to various excited states $^4M_{17/2}$, $^6P_{7/2}$, $^6P_{5/2}$, $^4F_{7/2}$, $^4G_{11/2}$, $^4I_{15/2}$ and $^4F_{9/2}$ at 311, 354, 367, 389, 428, 452 and 478 nm respectively [32, 39–41]. The strongest excitation peak was seen at a wavelength of 452 nm. Therefore, emission spectra for all of the Dy^{3+}-doped CBNO phosphors were analysed at this wavelength.

PL emission spectra for CBNO: x Dy^{3+} (x = 0.01, 0.02, 0.03, 0.04, & 0.05 mol) phosphors were recorded at 452 nm excitation in the range 470–700 nm as shown in Fig. 9. In the PL spectra, three emission peaks were seen at wavelengths of 482 nm, 576 nm, and 666 nm, corresponding to the $^4F_{9/2} \rightarrow {}^6H_{15/2}$, $^6H_{13/2}$, and $^6H_{11/2}$ transitions, respectively [9, 42]. The position of the peaks do not significantly alter with increasing Dy^{3+} ion concentration because the 5 s and 5p outer electrons shield the 4f electrons. Among three distinctive peaks, it can be seen that the emission at 576 nm dominates and is the source of yellow colour emission. As Dy^{3+} concentration rises up to 0.04 mol, the emission intensity also rises. Beyond 0.04 mol of Dy^{3+} ions, concentration quenching due to non-radiative energy transfer between

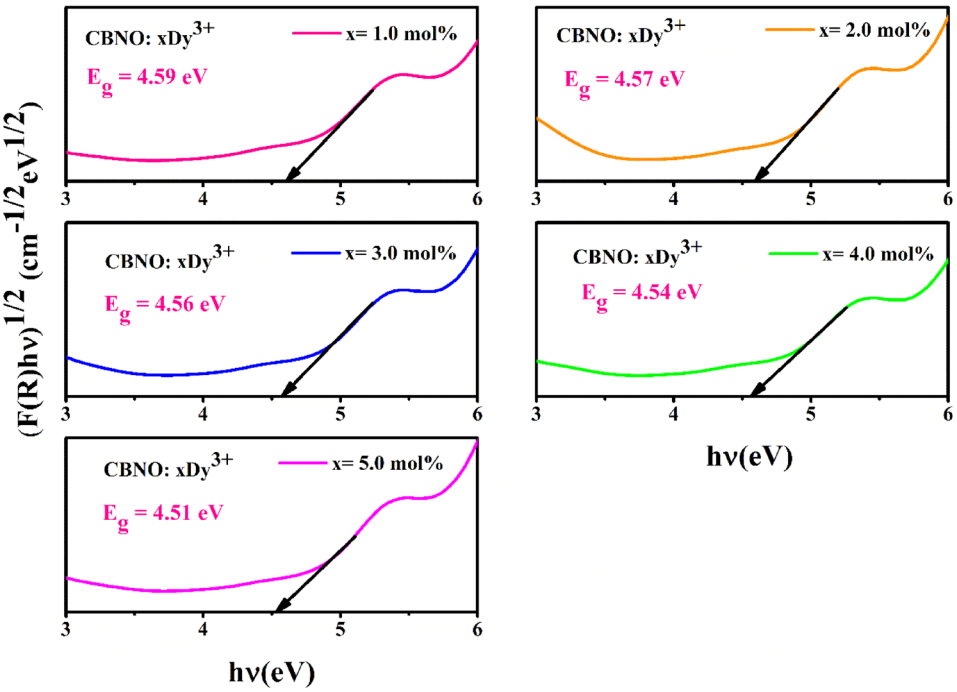

Fig. 7 Tauc plot for direct optical bandgap of CBNO phosphors at different concentrations of Dy^{3+} ions

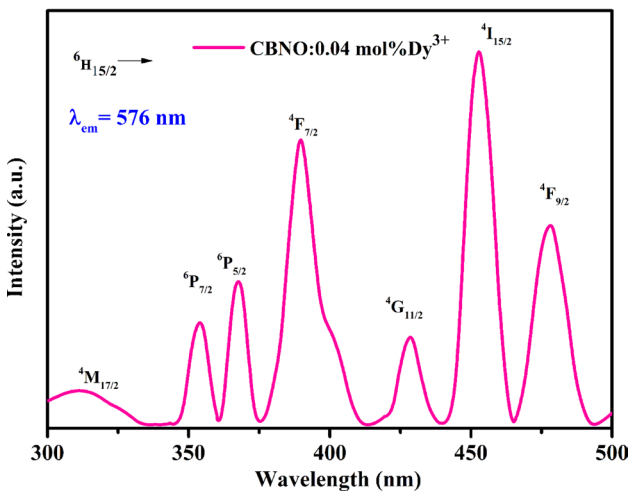

Fig. 8 Excitation spectrum of CBNO: 0.04 mol Dy3+-doped phosphor under 576 nm emission wavelength

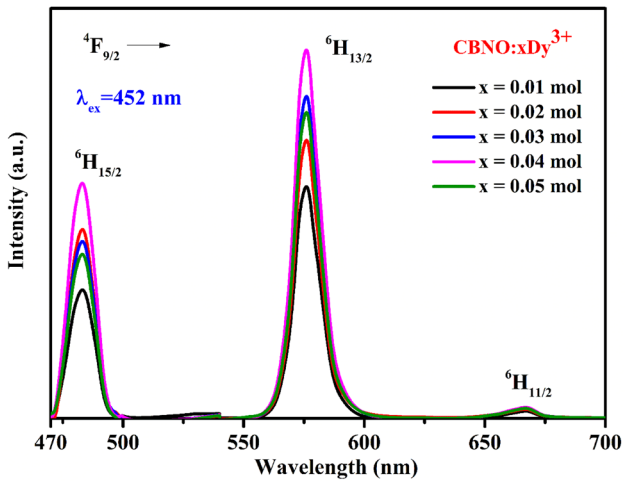

Fig. 9 PL emission spectra of CBNO: xDy^{3+} (x=0.01, 0.02, 0.03, 0.04, & 0.05 mol) at λ_{ex}=452 nm

Dy^{3+}–Dy^{3+} ions led to a drop in PL intensity. Radiation re-absorption, exchange contact, and multipole-multipole interaction between the activator ions are the reasons that cause concentration quenching.

The critical distance (R_c) is assessed to comprehend the kind of interaction that occurs between Dy^{3+} ions. Using Blasse's equation, the Rc is computed [43].

$$R_c \approx 2\left[\frac{3V}{4\pi x_c N}\right]^{1/3} \quad (3)$$

Here V stands for the unit cell volume, N is the number of cations per unit cell and x_c is the optimum concentration of the RE ions. After putting all the values, i.e. V = 748.68 Å^3, x_c = 0.04 mol, & N = 4, R_c was found to be 20.71 Å. A multipolar electric contact

between the Dy^{3+} ions arises during the energy transfer if the value of R_c is more than 5Å [44].

The type of multipolar interaction has been estimated from Dexter hypothesis, which suggests a relationship between variation in emission intensity and concentration of RE ions [45].

$$\log\left(\frac{I}{x}\right) = \log f - \frac{Q\log(x)}{3} \quad (4)$$

Here, Q stands for the type of interaction that takes place between the dopant (6, 8, or 10 denoting electric dipole–dipole (D–D), dipole-quadrupole (D–Q), and quadrupole–quadrupole (Q–Q), respectively) and A is a constant, too. The (Q/3) value is calculated using the slope of the linear fitting curve log(I/x) vs log(x), as demonstrated in Fig. 10. The computed Q value is 4.82 which is very near to 6, suggests that electric D–D interaction is the reason for concentration quenching and consequent energy transfer between Dy^{3+} ions.

Figure 11 displays the energy level diagram of the CBNO phosphor, which also covers the mechanisms for emission, excitation, energy transfer, and cross relaxation channels (CRC). The Dy^{3+} ions are first excited to higher excited levels as part of the emission mechanism, which is followed by a rapid relaxation to the metastable state $^4F_{9/2}$ level via non-radiative transfers. From the $^4F_{9/2}$ excited state, radiative transfers take place to various low energy states, such as $^6H_{15/2}$, $^6H_{13/2}$, and $^6H_{11/2}$. CRC and resonance energy transfer (RET) in the CBNO phosphor may result in concentration quenching and non-radiative energy transfer.

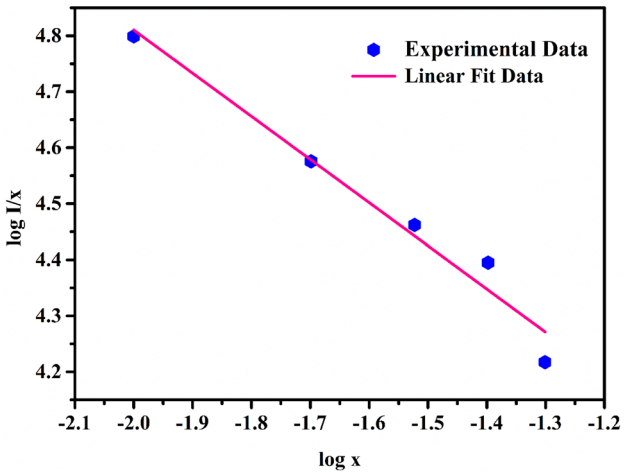

Fig. 10 Plot of log (I/x) with log(x)

3.6 CIE chromaticity coordinates

The colour of a phosphor is determined using Commission Internationale de l'Eclairclage (CIE) coordinates. The variations in the concentration of Dy^{3+} have no impact on the position of the emission peaks, but influence the intensity of the PL emission. Figure 12 displays the CIE coordinates of every Dy^{3+} ion-doped CBNO phosphor sample at λ_{ex} = 452 nm and λ_{em} = 576 nm, which are in the white area at ambient temperature. They have also been tabulated in Table 3 [17, 46, 47]. From the CIE chromaticity analysis, it can be concluded that these as prepared phosphors are acceptable for the manufacture of white LEDs.

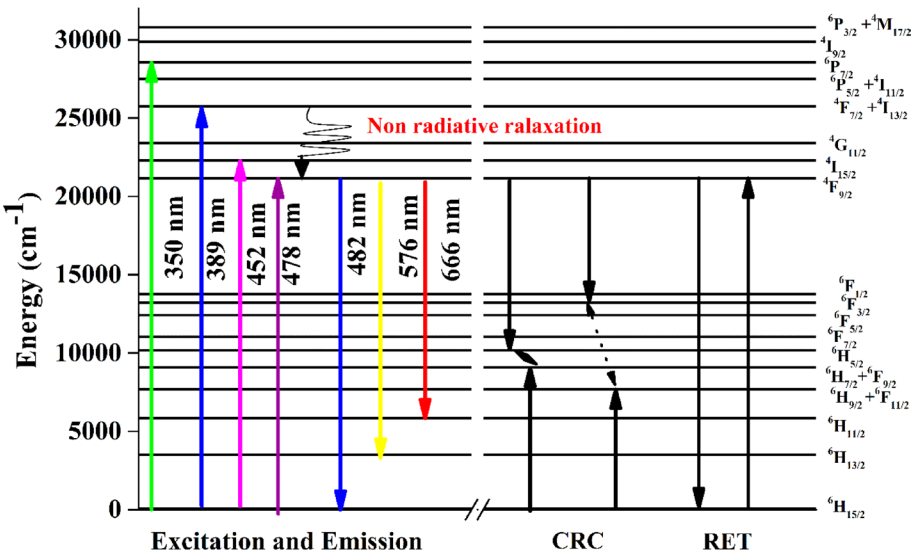

Fig. 11 Partial energy level diagram and possible cross-relaxation channels of Dy^{3+}-doped CBNO phosphor

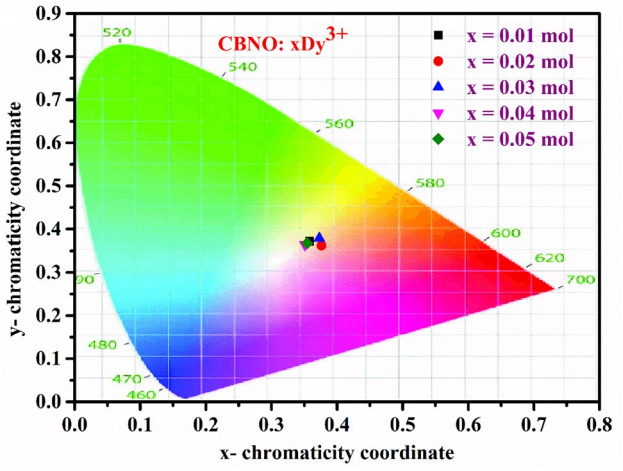

Fig. 12 CIE chromaticity coordinates for CBNO: xDy^{3+} (x = 0.01, 0.02, 0.03, 0.04, & 0.05 mol) phosphors under λex = 452 nm

Correlated colour temperature (CCT) is another significant indicator for emphasising the usage and significance of RE^{3+}-doped phosphor. CCT is the colour temperature of white light emitted by the phosphor. A low or high CCT indicates that the light being emitted is either warm or cold, respectively.

McCamy provided a formula for calculating CCT given below [9]:

$$CCT = -449n^3 + 3525n^2 - 6823.2n + 5520.3 \quad (5)$$

Here, $n = \frac{x-xe}{y-ye}$ and (x_e, y_e) refers to the colour coordinate of white illumination (x_e = 0.332, y_e = 0.186) and (x, y) stands for colour coordinates of the as-titled phosphor. Table 3 shows the CCT values of Dy^{3+}-doped CBNO phosphor at λ_{ex} = 452 nm. The calculated CCT values of the CBNO:xDy^{3+} phosphors is significantly less than 5000 K, indicating that warm white light can be created from these phosphors.

Colour purity (CP) is a significant factor in colourimetric calculations. The saturation and level of vibrant colour are described by CP. Following equation is used to evaluate the CP [48]:

$$CP = \frac{\sqrt{(x - x_{ee})^2 + (y - y_{ee})^2}}{\sqrt{(x_d - x_{ee})^2 + (y_d - y_{ee})^2}} \quad (6)$$

where (x_{ee}, y_{ee}) stand for equal energy point, (x, y) are colour coordinates of the optimized phosphor, and (x_d, y_d) denotes points of dominant wavelength. The calculated CP values for all the phosphors lie between 14 to 22%. These values are small and have been tabulated in Table 3. Owing to the low values of CP, it can be used in photonic devices as an n-UV pumped white emitting component [49].

3.7 Decay profiles

PL decay curves for CBNO: x Dy^{3+} (x = 0.01, 0.02, 0.03, 0.04, & 0.05 mol) phosphors under λ_{ex} = 452 nm and λ_{em} = 576 nm are shown in Fig. 13. The best fit to the measured decay curves is tri-exponential equation which is given below [50]:

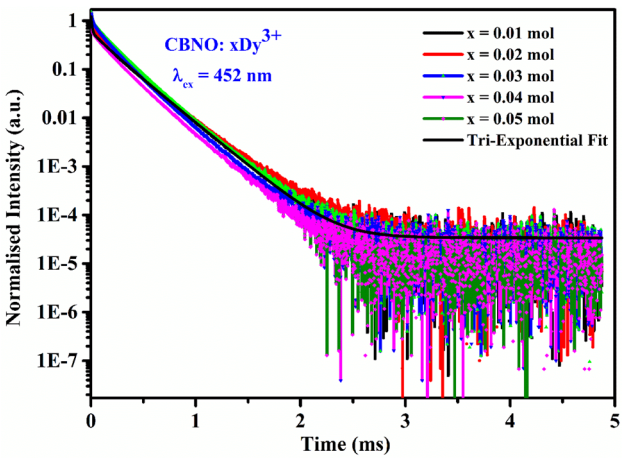

Fig. 13 PL decay profiles for CBNO: xDy^{3+} (x = 0.01, 0.02, 0.03, 0.04, & 0.05 mol) phosphors under λex = 452 nm

Table 3 CIE coordinates, CCT values & colour purity of CBNO: xDy^{3+} (x = 0.01, 0.02, 0.03, 0.04, & 0.05 mol) under 452 nm excitation wavelength

Sample ID CBNO: xDy^{3+}	CIE coordinates (x, y)	CCT values (K)	Colour purity (%)	τ_{avg} (μs)	References
x = 0.01 mol	(0.3579,0.3719)	4275.087	18.2	220.85	[17, 46, 47, 51]
x = 0.02 mol	(0.3761,0.3622)	4218.556	21.1	215.81	
x = 0.03 mol	(0.3729,0.3789)	3992.671	17.6	198.79	
x = 0.04 mol	(0.3508,0.3639)	4163.508	14.3	194.41	
x = 0.05 mol	(0.3543,0.3675)	3898.664	16.7	185.63	

$$I = I_0 + A_1 * \exp\left(-\frac{t}{\tau_1}\right) + A_2 * \exp\left(-\frac{t}{\tau_2}\right) + A_3 * \exp\left(-\frac{t}{\tau_3}\right) \quad (7)$$

where I_0 and I are the PL intensity at time $t = 0$ and time t, respectively. τ_1, τ_2 and τ_3 denote the decay lifetimes and A_1, A_2 & A_3 denote the constants for fitting. The average decay time (τ_{avg}) has been calculated with the formula given below [50, 51]

$$\tau_{avg} = \frac{A_1\tau_1^2 + A_2\tau_2^2 + A_3\tau_3^2}{A_1\tau_1 + A_2\tau_2 + A_3\tau_3} \quad (8)$$

The evaluated values of τ_{avg} have been presented in Table 3.The values of τ_{avg} decrease with the increase in doping ions demonstrating the possibility of energy transfer between Dy^{3+} ions [52]. As the doping concentration rises, the spacing between Dy^{3+} ions gets smaller. The luminescence lifetime decreases due to an increase in the nonradiative interaction between activator ions.

3.8 TD-PL studies

The TD-PL spectra of CBNO: 0.04 mol Dy^{3+}-doped phosphor were recorded under 452 nm excitation wavelength between 25 and 175ºC to study the thermal quenching behaviour and have been displayed in Fig. 14 along with the varying temperature. The PL emission intensity was seen to be decreasing with increasing temperature. At 175 ºC, the phosphor retained 48.2% of its maximal light intensity, demonstrating remarkable thermal stability.

To further assess the thermal characteristics of the sample, the activation energy (ΔE) was also measured. The value of ΔE was calculated by using the Arrhenius equation [53]

$$I_T = \frac{I_0}{1 + C\exp\left(-\frac{\Delta E}{K_B T}\right)} \quad (9)$$

Here, I_0 and I_T represent the intensity at temperature 25 ºC and the intensity at a specific temperature T and K_B denotes Boltzmann constant. The value of the activation energy (ΔE) is obtained from the slope of the of graph shown for $\ln((I_0/I_T)-1)$ versus $1/K_BT$, as depicted in Fig. 15. The calculated activation energy for CBNO: 0.04 mol Dy^{3+}-doped phosphor was 0.287 eV which is greater than other values in literature [12, 54, 55]. The high value of activation energy indicates that the as-prepared phosphor is more stable thermally. As a result, TD-PL spectra for the CBNO: 0.04 mol Dy^{3+}-doped phosphor demonstrated the excellent temperature stability [42].

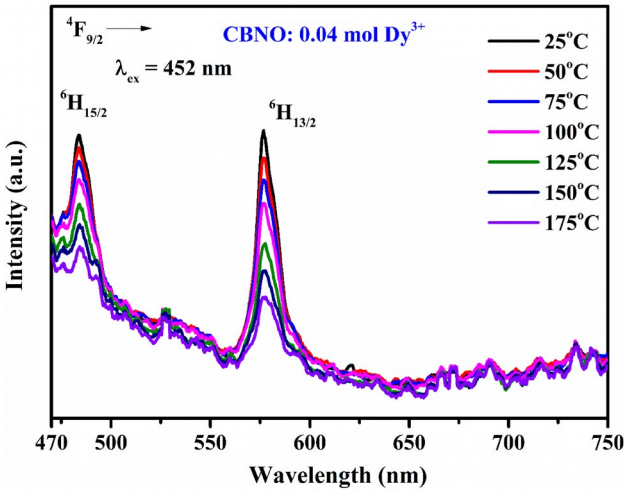

Fig. 14 TD-PL spectra for 0.04 mol Dy^{3+}-doped CBNO phosphor at 452 nm excitation wavelength from RT to 175 ºC

4 Conclusion

In conclusion, Dy^{3+}-doped CBNO phosphors were effectively synthesised using the solid-state reaction technique. The XRD analysis verifies the single phase formation of Dy^{3+}-doped CBNO phosphors. Morphological study was carried out using SEM, and the particle size was determined to be in the micrometre range. EDS indicates that all the elements were evenly distributed over the crystal's surface. FT-IR spectrum for Dy^{3+}-doped phosphor demonstrate the presence of vibrational bands. The optical bandgap of the as-titled phosphors was seen to decrease with an increase in the quantity of Dy^{3+} ions, owing to their 4f energy level. The Dy^{3+}-doped CBNO phosphors show emission peaks at wavelengths of 482, 576, and 661 nm when excited at a wavelength of 452 nm, which are attributable to distinct transitions of the Dy^{3+} ions. For CBNO phosphor, the optimal Dy^{3+} concentration was found to be 0.04 mol beyond which quenching takes place. The calculated CIE coordinates for all of the Dy^{3+} ion-doped CBNO phosphor samples at $\lambda_{ex} = 452$ nm and $\lambda_{em} = 576$ nm lie in the white region. A tri-exponential behaviour is observed in the decay curves of the as-prepared phosphors under stimulation at 452 nm.

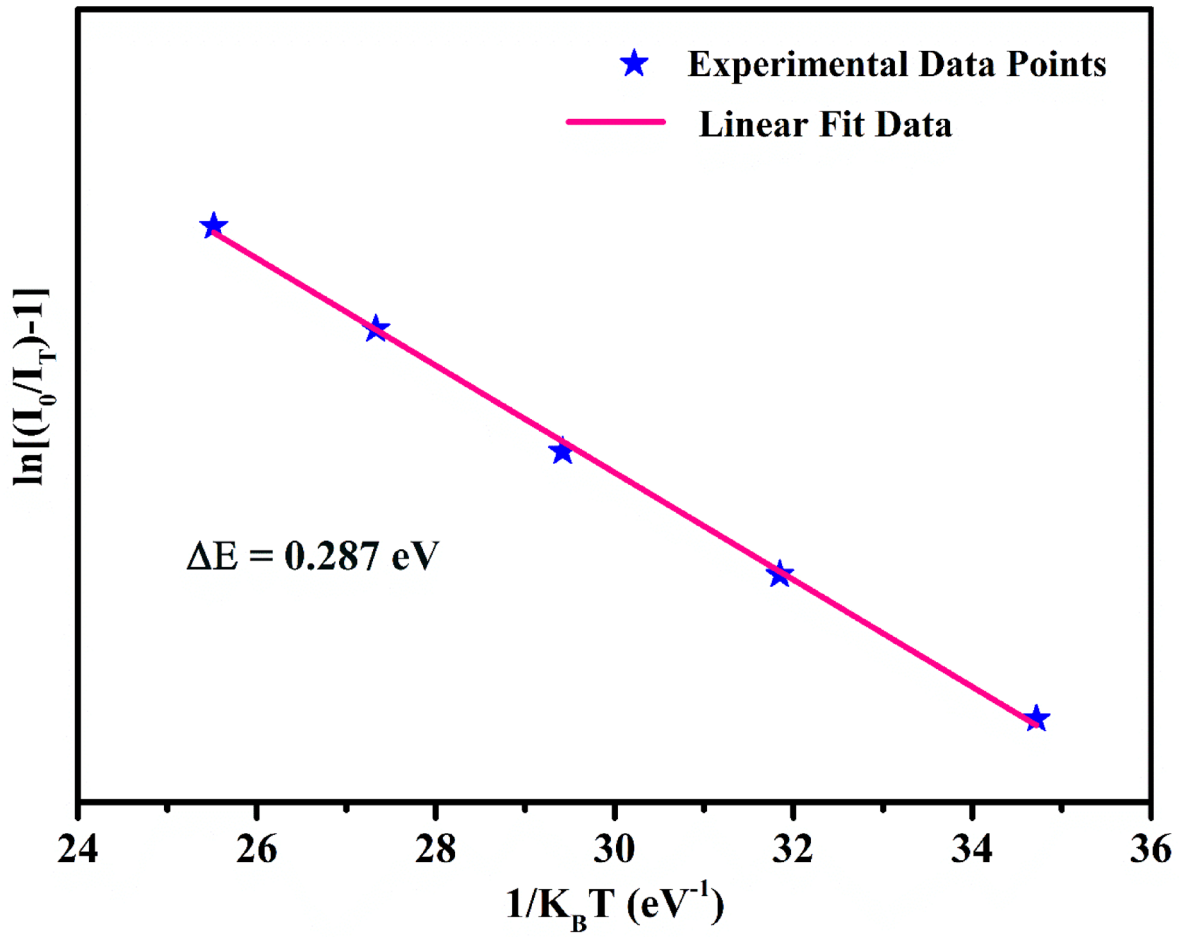

Fig. 15 Linear relationship of ln $[(I_0/I_T)-1]$ versus $1/K_BT$

The thermal stability of the phosphors was evaluated by TD-PL measurements. It was observed that a high activation energy was needed for thermal quenching in the phosphors. The experimental findings show that the CBNO phosphor doped with Dy^{3+} ions has at potential for usage in the fabrication of w-LEDs and other optoelectronic devices.

Abstract
This research paper provides a comprehensive exploration of carbon capture to fuel technologies, covering various capture methodologies and conversion processes. The analysis begins by dissecting post-combustion, pre-combustion, and direct air capture technologies, elucidating their principles, advantages, and limitations. A focus on the conversion of captured carbon into usable fuels delves into synthetic fuels and hydrogen production methods, detailing chemical processes, catalysts, and energy requirements. Moving beyond technical aspects, the paper critically analyzes the efficiency and viability of carbon capture to fuel processes, employing case studies and real-world examples to illustrate the practical application of techno-economic assessments and life cycle analyses. Economic considerations further assess implementation costs, operational expenses, and potential revenue streams, drawing insights from existing economic models and case studies. Environmental impact and benefits take center stage, evaluating potential reductions in greenhouse gas emissions, resource efficiency, and ecological considerations associated with converting captured carbon to fuel. A comparative analysis with other carbon capture applications offers a holistic perspective on the environmental footprint. The regulatory landscape is thoroughly examined, encompassing existing policies, government incentives, and international agreements influencing the development and deployment of carbon capture to fuel technologies. The research concludes with reflections on the current status, challenges, and a roadmap for future advancements, serving as a comprehensive guide for researchers, policymakers, and industry stakeholders in the pursuit of sustainable energy solutions.

Keywords: *Carbon Capture, Fuel Production, Techno-Economic Assessment, Environmental Impact, Policy and Regulation, Sustainability.*

1. Introduction
The escalating threat of climate change necessitates urgent and innovative strategies to mitigate carbon dioxide (CO2) emissions. As industries and societies grapple with the imperative to transition towards sustainable energy sources, carbon capture technologies have emerged as pivotal tools in the fight against climate change. This paper focuses on the transformative potential of carbon capture to fuel technologies, offering a nuanced exploration of their technological foundations, economic viability, environmental impact, and the intricate policy landscapes shaping their implementation.

The primary objective of this research is to comprehensively explore the intricacies of carbon capture to fuel technologies. This includes delving into various capture methodologies such as post-combustion, pre-combustion, and direct air capture, and examining their principles, advantages, and limitations. The subsequent exploration of the conversion of captured carbon into usable fuels involves an in-depth examination of synthetic fuels and hydrogen production methods, including the chemical processes,

International Research Journal on Advanced Engineering Hub (IRJAEH)

catalysts, and energy requirements involved. Beyond the technical aspects, the paper critically evaluates the efficiency and viability of carbon capture to fuel processes, using real-world case studies to illustrate the practical application of techno-economic assessments and life cycle analyses. Economic considerations further dissect the implementation costs, operational expenses, and potential revenue streams, drawing insights from existing economic models and case studies. Environmental impact and benefits take center stage in the analysis, assessing potential reductions in greenhouse gas emissions, resource efficiency, and ecological considerations associated with converting captured carbon to fuel. The paper also includes a comparative analysis with other carbon capture applications, offering a holistic perspective on the environmental footprint. Navigating the complex policy and regulatory landscape, the study examines existing frameworks, government incentives, and international agreements influencing the development and deployment of carbon capture to fuel technologies. The paper concludes by reflecting on the current status, challenges, and presenting a roadmap for future advancements, contributing to the collective knowledge base for researchers, policymakers, and industry stakeholders in the pursuit of a sustainable and low-carbon future.

2. Carbon Capture Technologies

In this segment, we are able to now not only discover the concepts, blessings, and limitations of every carbon capture technology however additionally shed light on latest trends and innovations which have fashioned the evolving landscape of carbon capture techniques.

2.1. Post-Combustion Capture

Post-combustion capture is an extensively employed technique that focuses on capturing carbon dioxide (CO2) emissions after the combustion of fossil fuels. Exhaust gases from commercial procedures or electricity plants are subjected to separation technologies, which include amine scrubbing or chemical adsorption, to isolate and seize CO2. This technique is effective for retrofitting current facilities, as it could be carried out to flue gases from numerous assets.

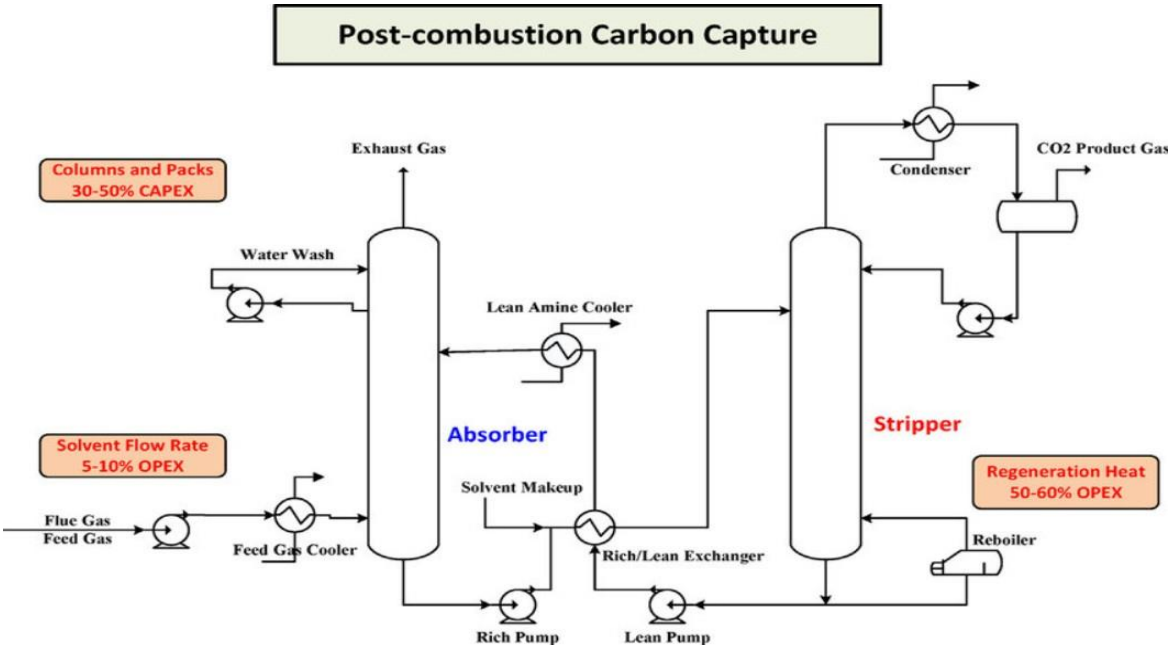

Figure 1 Post-Combustion Carbon Capture Process

International Research Journal on Advanced Engineering Hub (IRJAEH)

Vol. 02 Issue: 05 May 2024
Page No: 1387 - 1403
https://irjaeh.com
https://doi.org/10.47392/IRJAEH.2024.0192

Figure 1 A simplified representation of a post-combustion carbon capture process utilizing reactive solvents is depicted in the diagram [1].

2.1.1. Principles

Post-combustion capture by and large entails the separation of CO2 from flue gases emitted in the course of the combustion of fossil fuels. This is completed through absorption or adsorption tactics the usage of solvents or stable sorbents.

2.1.2. Advantages

Post-combustion seize is adaptable to existing business facilities, making it a viable option for retrofitting. It enables the reduction of emissions from strength flowers and business methods without large changes to existing infrastructure.

2.1.3. Limitations

The main demanding situations encompass the strength-extensive nature of the separation system and the want for large volumes of solvents or sorbents. This can result in accelerated operational prices and ability environmental effects.

2.1.4. Recent Developments

Recent advancements in post-combustion capture awareness on enhancing the performance of separation processes and developing novel solvents or sorbents with advanced overall performance and reduced environmental effect. Integration with renewable strength sources and optimization of process parameters are key areas of innovation [1].

2.2. Pre-Combustion Capture

Pre-combustion capture involves the extraction of carbon from fossil fuels before combustion occurs. Commonly applied in included gasification blended cycle (IGCC) electricity flora, this method converts fossil fuels right into a syngas, making an allowance for the separation and capture of carbon before electricity technology. The syngas, predominantly composed of hydrogen and carbon monoxide, can be applied for power production, at the same time as the captured carbon is stored or repurposed.

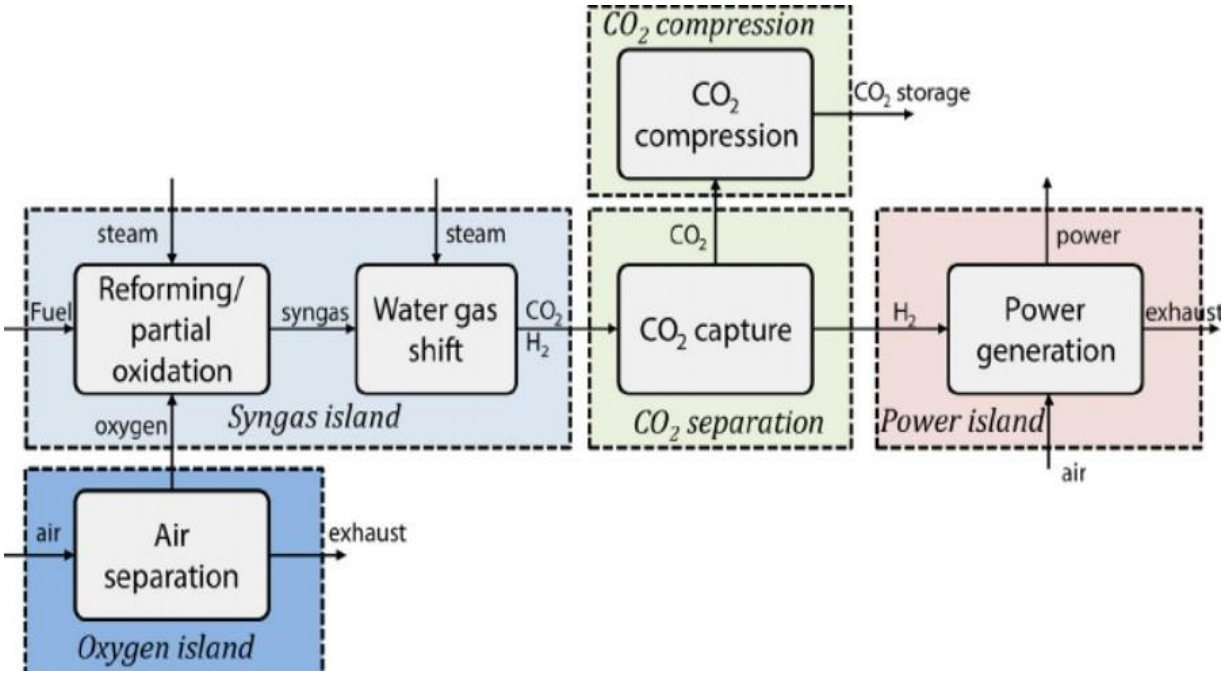

Figure 2 The Pre-Combustion Capture Process

International Research Journal on Advanced Engineering Hub (IRJAEH)
e ISSN: 2584-2137
Vol. 02 Issue: 05 May 2024
Page No: 1387 - 1403
https://irjaeh.com
https://doi.org/10.47392/IRJAEH.2024.0192

Figure 2: A diagram illustrating the pre-combustion capture process designed for power generation.

2.2.1. Principles

Pre-combustion capture involves the conversion of fossil fuels into syngas earlier than combustion. Carbon is separated from the syngas, typically through water-gasoline shift reactions or bodily separation strategies.

2.2.2. Advantages

Pre-combustion seize offers higher performance in comparison to submit-combustion strategies and enables the manufacturing of hydrogen, a precious clean electricity carrier. It is mainly suitable for new power vegetation or industrial facilities.

2.2.3. Limitations

The complexity of the gasification manner and the need for specialized systems can bring about higher capital prices. Additionally, the downstream techniques for coping with and storing captured carbon can pose technical demanding situations.

2.2.4. Recent Developments

Ongoing studies in pre-combustion capture focuses on optimizing gasification techniques, exploring alternative feedstocks, and growing superior catalysts for syngas manufacturing. Integration with hydrogen production technologies is a key region of innovation [2].

2.3. Direct Air Capture

Direct air capture is a rising generation designed to seize CO2 at once from the ambient air. Utilizing specialized sorbents or solvents, direct air seizes structures selectively bind with CO2 molecules, allowing for their separation. This approach is in particular precious for addressing emissions from dispersed sources, together with transportation and agriculture. While nonetheless in the early stages of development, direct air seizes holds promise for attaining terrible emissions and fighting climate trade on a broader scale in Figure 3.

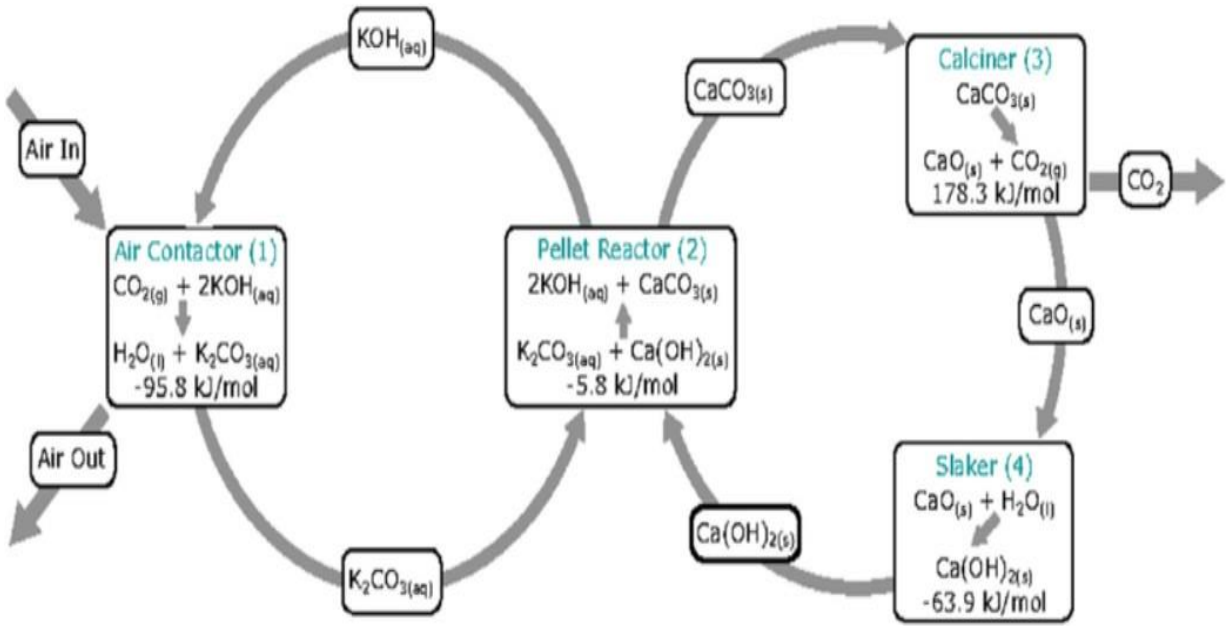

Figure 3 A Diagram Illustrating the Direct Air Capture [3]

2.3.1. Principles

Direct air capture includes the extraction of CO2 immediately from the ecosystem using sorbents or solvents. The captured CO2 can be saved underground or utilized for diverse applications.

International Research Journal on Advanced Engineering Hub (IRJAEH)
e ISSN: 2584-2137
Vol. 02 Issue: 05 May 2024
Page No: 1387 - 1403
https://irjaeh.com
https://doi.org/10.47392/IRJAEH.2024.0192

2.3.2. Advantages

Direct air seize has the ability to cope with emissions from dispersed assets and gain terrible emissions. It isn't always restrained to particular industrial facilities, offering flexibility in deployment.

2.3.3. Limitations

The technology is presently energy-in-depth, and the price of keeping tons of captured CO2 remains quite high. Scaling up direct air seize facilities to have a meaningful impact on international emissions poses logistical and economic demanding situations.

2.3.4. Recent Developments

Recent improvements in direct air seize consciousness on growing extra efficient sorbents and solvents, optimizing seize device designs, and exploring synergies with different industrial techniques. Pilot tasks and investments imply a developing hobby in advancing this technology [3]. By examining the standards, advantages, and boundaries of each carbon seize era and exploring current trends, this paper aims to provide a comprehensive review of the cutting-edge state and future potential of carbon seize methods. Each of these carbons seize technologies offers unique advantages and demanding situations, influencing their suitability for extraordinary business applications. The following sections will further discover the efficiencies, fees, and environmental concerns associated with these strategies, supplying a comprehensive expertise of the panorama of carbon seize technologies.

3. Conversion of Captured Carbon to Fuel

As we explore the conversion of captured carbon into usable fuels, it's extremely important to have a look at numerous strategies and their potential for transforming carbon emissions into valuable electricity assets. This segment will delve into various techniques, with a focal point on artificial fuels and hydrogen manufacturing.

3.1. Synthetic Fuels

Synthetic fuels, often called carbon-impartial or e-fuels, are generated through the conversion of captured carbon, typically carbon dioxide (CO2), into hydrocarbons or different electricity-rich compounds. This technique often includes the use of renewable power sources to electricity chemical reactions, ensuring a closed carbon cycle. Fischer-Tropsch synthesis and electrochemical methods are a number of the techniques employed to supply artificial fuels. This subsection will explore the ideas at the back of those strategies, emphasizing their ability to benefit in terms of energy density, compatibility with present infrastructure, and reduced dependence on fossil fuels in Figure 4[5].

Hydrogenation of CO2:

$CO^2 + 3H_2 \leftrightharpoons CH_2 + 2H_2O\ (\Delta H^0_{298} = 125\ kJ\ mol^{-1};$

The CWGS reaction:

$CO_2 + H_2 \leftrightharpoons CO + H_2O\ (\Delta H^0_{298} = 41\ kJ\ mol^{-1});$ and

The FTS reaction:

$CO + 2H_2 \leftrightharpoons -(CH_2)- + H_2O\ (\Delta H^0_{298} = -166\ kJ\ mol^{-1})$

Figure 4 Representation of Chemical Co2 Conversion into Different Fuels [5]

3.2. Hydrogen Production

The conversion of captured carbon to hydrogen represents another road for sustainable energy technology. Hydrogen is taken into consideration as a flexible and easy power provider, and its manufacturing from captured carbon can make a contribution to a decarbonized electricity panorama. Steam methane reforming (SMR) with carbon seize and garage (CCS) and electrolysis using renewable power are two essential techniques. This component will discuss the concepts, blessings, and obstacles of those methods, considering elements such as power performance, scalability, and the environmental footprint related to hydrogen manufacturing. Figure 5 A system for capturing carbon transforms carbon dioxide into both electricity and hydrogen fuel. closer to a low-carbon strength future [6].

Page No: 1387 - 1403
https://irjaeh.com
https://doi.org/10.47392/IRJAEH.2024.0192

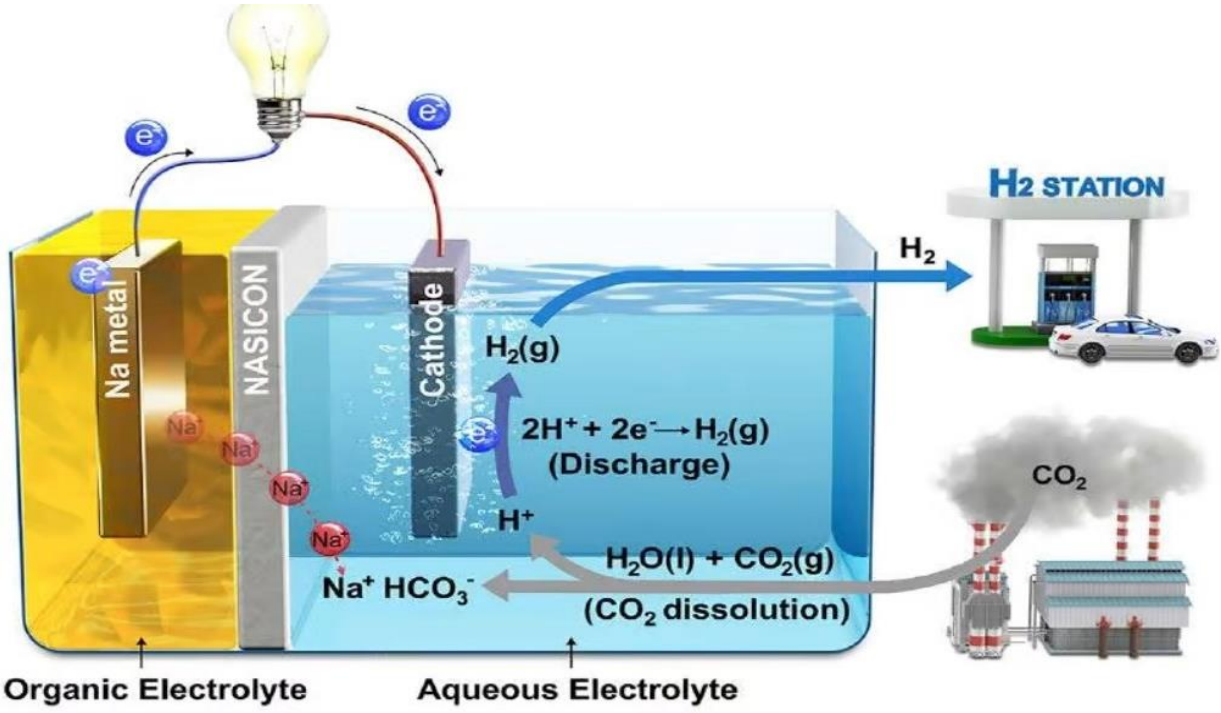

Figure 5 Carbon Transforms

By comprehensively exploring these methods, this segment aims to provide insights into the potential of changing captured carbon into fuels, addressing the growing call for sustainable electricity answers. Subsequent discussions will delve into the economic considerations, environmental influences, and actual-global applications of those conversion technologies, imparting a holistic knowledge of the position they play in the transition.

3.3. Chemical Processes and Catalysts for Conversion

The conversion of captured carbon into usable fuels involves problematic chemical strategies and often relies on catalysts to facilitate efficient reactions. Understanding those methods is critical for comparing the feasibility and effectiveness of carbon seize to fuel conversion.

3.3.1. Fischer-Tropsch Synthesis for Synthetic Fuels:

Fischer-Tropsch synthesis is a nicely-established chemical technique used inside the production of synthetic fuels. It involves the catalytic conversion of syngas (a combination of hydrogen and carbon monoxide, often derived from captured carbon) into liquid hydrocarbons. Transition metallic-primarily based catalysts, which includes iron or cobalt, play an essential position in selling the necessary reactions. This subsection will delve into the intricacies of Fischer-Tropsch synthesis, discussing reaction mechanisms, catalyst choice, and recent improvements in enhancing catalytic efficiency in Figure 5.

3.3.2. Electrolysis for Hydrogen Production

In the context of hydrogen manufacturing from captured carbon, electrolysis is a key procedure. This method includes passing an electric powered modern via water or different feedstocks containing captured carbon to cut up water molecules and generate hydrogen. Various electrolysis technologies, which include proton trade membrane (PEM) and alkaline electrolysis, employ particular catalysts like platinum or nickel to beautify response kinetics. This segment will explore the chemical concepts behind electrolysis, the function of catalysts, and current developments in electrolysis technology for efficient hydrogen production [6] in Figure 6.

https://irjaeh.com
https://doi.org/10.47392/IRJAEH.2024.0192

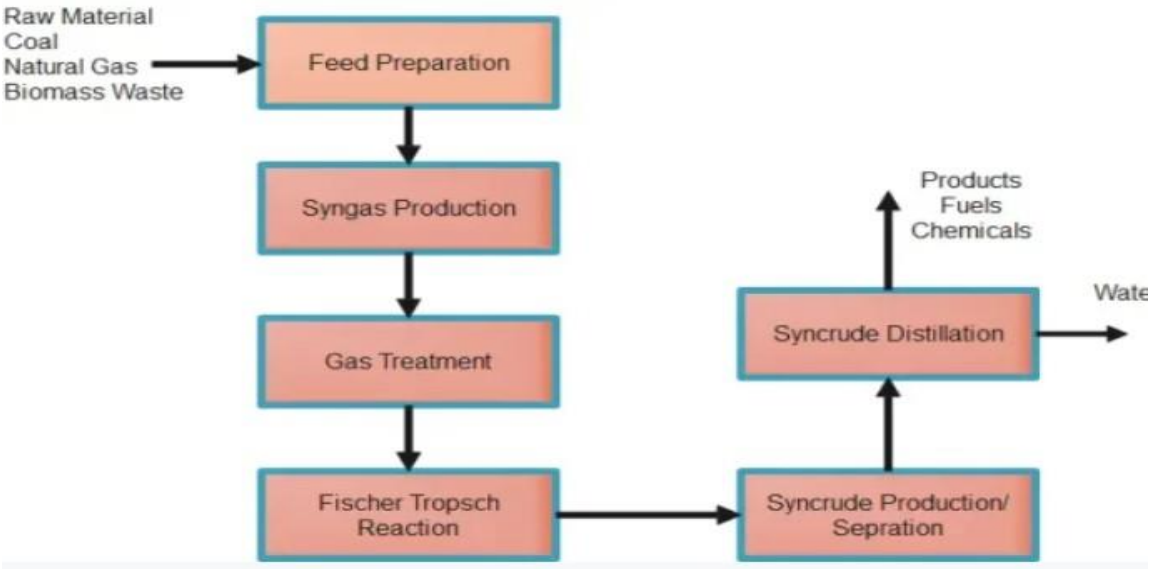

Figure 6 Steps Includes in Fischer- Tropsch [4]

3.3.3. Novel Catalysts and Emerging Technologies

Continual research efforts are centered on discovering novel catalysts and refining current ones to beautify the efficiency of carbon capture to gasoline conversion tactics. Advances in nanotechnology, catalytic substances, technological know-how, and computational modeling contribute to the identity of catalysts with stepped forward selectivity, sturdiness, and resistance to impurities. This subsection will spotlight current breakthroughs in catalyst improvement and emerging technologies that display promise in optimizing the energy efficiency and overall performance of carbon conversion methods [13].

3.4. Energy Requirements for Conversion

The conversion of captured carbon to fuels is inherently strength-extensive, and know-how the strength requirements is vital for assessing the overall sustainability of those strategies. This component will discuss the electricity inputs for diverse conversion methods, considering elements which include energy demand, thermal electricity, and standard power efficiency. It will also deal with techniques to optimize power use, integrate renewable energy assets, and beautify the overall energy balance of carbon capture to fuel conversion technology. By delving into the chemical processes, catalysts, and energy requirements related to the conversion of captured carbon to fuels, this phase aims to offer a complete information of the technical components underpinning those transformative technologies. Subsequent discussions will in addition explore the economic and environmental dimensions, supplying a holistic angle at the feasibility and ability implications of carbon seize to gasoline conversion [14].

3.5. Chemical Processes, Catalysts, and Energy Requirements

To recognize the efficiency and viability of carbon capture to fuel tactics, it's imperative to scrutinize the underlying chemical procedures, the position of catalysts, and the related power necessities. This phase will delve into the elaborate information of these factors, dropping mild on the important factors that influence the success of converting captured carbon into usable fuels.

3.5.1. Chemical Processes

The chemical methods used inside the conversion of captured carbon to fuel vary depending on the chosen technique, be it Fischer-Tropsch synthesis for synthetic fuels or steam methane reforming for

International Research Journal on Advanced Engineering Hub (IRJAEH)
e ISSN: 2584-2137
Vol. 02 Issue: 05 May 2024

https://doi.org/10.47392/IRJAEH.2024.0192

hydrogen production. A certain exam of those chemical pathways might be undertaken, elucidating the reactions, intermediates, and by means of-merchandise. Understanding the nuances of each procedure is important for evaluating their efficiency and ability for huge-scale implementation.

3.5.2. Catalysts

Catalysts play a pivotal role in facilitating and optimizing the chemical adjustments essential for converting captured carbon into fuels. This subsection will explore the styles of catalysts utilized in extraordinary techniques, ranging from heterogeneous catalysts in Fischer-Tropsch synthesis to electrocatalysts in electrolysis. The dialogue will contribute to the catalyst's impact on response fees, selectivity, and stability, presenting insights into the advancements and challenges in catalyst improvement for carbon seizure to fuel packages [7].

3.5.3. Energy Requirements

The electricity necessities of carbon capture to gasoline processes are paramount in figuring out their standard performance and environmental impact. Analyzing the strength inputs for every step, from carbon capture to gasoline synthesis, will be a focus. Consideration might be given to the assets of energy used, including renewable energy or excessive-temperature warmness, and the results for the general carbon footprint of the procedure. This scrutiny will make contributions to the assessment of the sustainability and feasibility of carbon capture to gas technology. By unraveling the intricacies of chemical methods, catalysts, and electricity needs, this section aims to offer a complete understanding of the factors influencing the efficiency and viability of converting captured carbon into fuels. Subsequent discussions will build upon this basis, addressing monetary considerations, environmental impacts, and the wider implications for sustainable power structures [15].

4. Economic Considerations

In comparing the transition from carbon capture to gasoline technologies from a monetary angle, this section will verify the financial feasibility via delving into the associated prices, potential revenue streams, and drawing insights from present economic models and case studies.

4.1. Implementation Costs

Understanding the economic viability of carbon capture to fuel technology necessitates a radical examination of implementation costs. This consists of charges related to the deployment of carbon capture structures, conversion techniques, and the essential infrastructure. Factors which include era adulthood, scale of deployment, and geographical concerns might be explored to offer a nuanced knowledge of the financial commitments involved [8].

4.2. Operational Costs

Beyond initial implementation, operational prices play a critical position in figuring out the economic feasibility of these technologies. This encompasses the everyday prices related to going for walks and maintaining carbon capture facilities, fuel conversion processes, and any ancillary systems. Analyzing those ongoing costs is important for assessing the sustainability of carbon seize to gasoline operations over the long term [9].

4.3. Revenue Streams

To balance the monetary equation, it's vital to pick out potential revenue streams associated with carbon capture to gas technologies. This ought to involve the sale of synthesized fuels, participation in carbon credit score markets, or leveraging government incentives and subsidies. The section will discover the numerous avenues via which sales can be generated, emphasizing the want for a comprehensive enterprise model to aid the monetary viability of these technologies [10].

4.4. Economic Models and Case Studies

Drawing insights from current economic fashions and case research is pivotal in providing actual-world context to the monetary concerns of carbon seize to gas technology. By examining successful projects or the ones dealing with demanding situations, this subsection will offer a comparative evaluation. Evaluation standards will encompass

International Research Journal on Advanced Engineering Hub (IRJAEH)
e ISSN: 2584-2137
Vol. 02 Issue: 05 May 2024
Page No: 1387 - 1403
https://irjaeh.com
https://doi.org/10.47392/IRJAEH.2024.0192

return on funding, payback periods, and the effect of policy frameworks on challenge economics. Such an exam will make contributions to the development of robust monetary fashions for destiny ventures. Through a radical exploration of implementation expenses, operational costs, revenue streams, and actual-world case studies, this segment pursues a comprehensive financial assessment of carbon seize to gas technology. Subsequent discussions will amplify the analysis to encompass broader environmental effects, policy considerations, and capacity avenues for destiny studies and development [8][9].

5. Environmental Impact

Assessing the environmental effect of converting captured carbon to fuel is fundamental to knowledge of the wider implications of those technologies. This segment will comprehensively evaluate both the benefits and drawbacks, thinking about elements including greenhouse fuel emissions, resource utilization, and ecological considerations.

5.1. Environmental Benefits

Greenhouse Gas Emission Reduction: One of the number one environmental advantages of carbon seize to gasoline technologies lies in their potential to lessen net greenhouse fuel emissions. By utilizing captured carbon to supply artificial fuels or hydrogen, those tactics have the potential to offset emissions from traditional fossil fuel assets.

5.2. Resource Efficiency

The conversion of captured carbon into gasoline represents a shape of recycling carbon, imparting an alternative to extracting new carbon from fossil fuels. This aid efficiency thing can make a contribution to sustainable practices and a round carbon economic system.

5.3. Air Quality Improvement

Depending on the utility, the manufacturing and utilization of synthetic fuels or hydrogen may additionally result in lower air pollutant emissions compared to traditional combustion processes, contributing to advanced neighborhood air quality [11].

5.4. Environmental Drawbacks

Energy Intensity: The strength requirements for carbon seize, conversion, and gas synthesis methods may introduce a new set of environmental demanding situations. Depending on the electricity sources utilized, these procedures should make a contribution to improved demand for power and, in flip, environmental influences associated with strength manufacturing.

5.4.1. Resource Extraction:

The extraction and processing of raw materials required for the development and maintenance of carbon seize and fuel manufacturing infrastructure may also have associated environmental costs. These can encompass land use modifications, water intake, and different ecological concerns.

5.4.2. Emissions all through Production

The manufacturing of artificial fuels or hydrogen may also entail emissions, depending on the precise conversion methods hired. Assessing the lifestyle cycle emissions is important to know the general environmental impact of those technologies [12].

5.5. Ecological Considerations

Land Use and Biodiversity: The enlargement of carbon capture to gasoline infrastructure may additionally affect land use patterns, potentially leading to habitat disruption and biodiversity loss. Careful consideration of these ecological aspects is essential in ensuring the general sustainability of such tasks.

5.6. Water Usage

Depending on the approaches involved, the water requirements for carbon capture to fuel technologies ought to pose demanding situations, mainly in regions dealing with water scarcity. An evaluation of water usage and ability impacts on neighborhood ecosystems could be addressed in this segment. By analyzing both the tremendous and bad environmental elements, this segment aims to offer a complete knowledge of the environmental impact of converting captured carbon to gasoline. Subsequent discussions will discover capacity mitigation techniques,

International Research Journal on Advanced Engineering Hub (IRJAEH)
e ISSN: 2584-2137
Vol. 02 Issue: 05 May 2024
Page No: 1387 - 1403
https://irjaeh.com
https://doi.org/10.47392/IRJAEH.2024.0192

regulatory frameworks, and the function of those technologies in broader sustainability targets.

5.7. Greenhouse Gas Reduction

Discuss the Potential Reduction in Greenhouse Gas Emissions and Other Environmental Considerations. The ability to reduce greenhouse fuel (GHG) emissions sticks out as a key environmental benefit of changing captured carbon to fuel. This subsection will delve into the specifics of how those technologies contribute to mitigating climate trade and discover additional environmental concerns.

5.7.1. GHG Emission Mitigation

The core environmental advantage of carbon seize to gas technologies lies in their ability to mitigate GHG emissions. By capturing and making use of carbon dioxide (CO2) emissions that could in any other case be launched into the surroundings from business procedures or power technology, these technologies contribute to an enormous reduction in internet GHG emissions. The discussion will complicate at the mechanisms through which this mitigation happens, considering the existence cycle of gas manufacturing and consumption Figure 7.

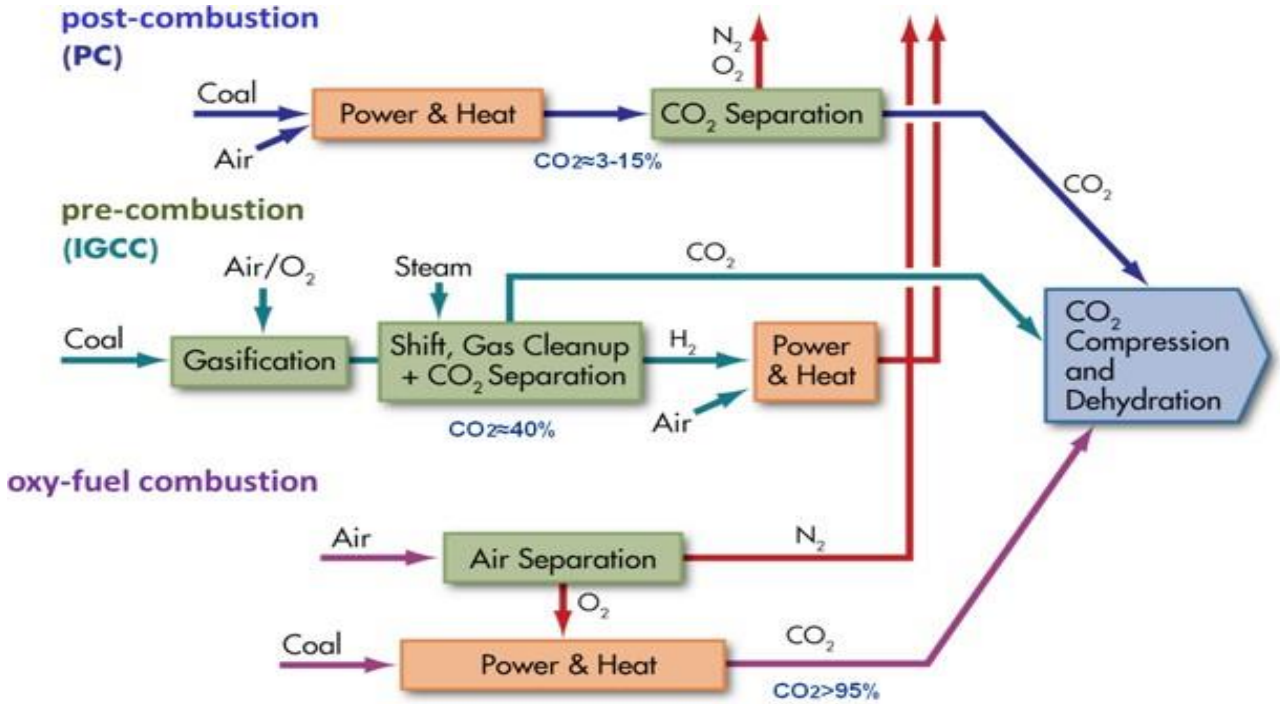

Figure 7 Greenhouse Gas Emission [12]

5.7.2. Carbon Circular Economy

Beyond emission reductions, carbon capture to fuel technologies contribute to the establishment of a carbon circular economy. This involves recycling captured carbon, minimizing reliance on fresh fossil fuel extraction. The utilization of captured CO2 to produce synthetic fuels or hydrogen fosters resource efficiency and aligns with sustainable principles.

5.7.3. Air Quality Improvement

In addition to GHG emissions, the production and use of synthetic fuels or hydrogen may lead to lower emissions of conventional air pollutants compared to traditional combustion processes. This improvement in air quality can have positive effects on human health and ecosystem well-being. The discussion will touch upon the specific pollutants affected and the potential benefits for local air quality.

International Research Journal on Advanced Engineering Hub (IRJAEH)
e ISSN: 2584-2137
Vol. 02 Issue: 05 May 2024
Page No: 1387 - 1403
https://irjaeh.com
https://doi.org/10.47392/IRJAEH.2024.0192

5.7.4. Contribution to Decentralized Energy

Carbon capture to fuel technologies can contribute to the decentralization of energy production, promoting distributed energy systems. This decentralized approach may lead to reduced environmental impacts associated with centralized energy production and distribution, such as transmission losses and infrastructure development.

5.7.5. Considerations for Other Greenhouse Gases

Beyond CO2, the discussion will touch upon considerations for other greenhouse gases, such as methane (CH4) or nitrous oxide (N2O), that may be associated with certain industrial processes. Assessing the overall impact on a broader spectrum of greenhouse gases is essential for a comprehensive understanding of the environmental benefits. By exploring these aspects, this subsection aims to provide a nuanced analysis of the potential reduction in GHG emissions and additional environmental considerations associated with converting captured carbon to fuel. Subsequent discussions will address challenges, regulatory frameworks, and the role of these technologies in advancing broader environmental sustainability goals.

6. Comparative Environmental Impact

Compare the Environmental Impact of Carbon Capture to Fuel with Other Carbon Capture Applications. To understand the relative environmental implications of carbon capture to fuel technologies, it is essential to compare them with other prevalent carbon capture applications. This section will assess how the environmental impact of converting captured carbon to fuel aligns with or differs from alternative carbon capture methods.

6.1. Comparison with Carbon Capture and Storage (CCS)

Carbon Capture and Storage (CCS) is a well-established method focused on capturing carbon dioxide (CO2) emissions from industrial processes and power plants and storing them underground. This subsection will delve into the environmental impact of CCS, emphasizing factors such as geological storage safety, potential leakage risks, and the long-term storage implications. A comparative analysis with carbon capture to fuel technologies will highlight the trade-offs and benefits associated with each approach.

6.2. Comparison with Enhanced Oil Recovery (EOR)

Enhanced Oil Recovery (EOR) involves injecting captured CO2 into depleted oil reservoirs to recover additional oil. This subsection will explore the environmental considerations associated with EOR, including the potential for induced seismicity, the long-term fate of stored CO2, and the overall sustainability of the process. A comparative assessment with carbon capture to fuel technologies will shed light on their divergent environmental impacts and associated challenges.

6.3. Comparison with Direct Air Capture (DAC)

Direct Air Capture (DAC) involves capturing CO2 directly from the ambient air. This subsection will discuss the environmental considerations of DAC, such as energy intensity, resource utilization, and the potential for negative emissions. A comparative analysis with carbon capture to fuel technologies will highlight the advantages and drawbacks of each method in the context of environmental impact.

6.4. Life Cycle Assessment (LCA)

A life cycle assessment will be employed to compare the environmental impact of carbon capture to fuel with other carbon capture applications comprehensively. This will involve evaluating the entire life cycle of each technology, from raw material extraction and manufacturing to operation and end-of-life considerations. The LCA approach will provide a holistic perspective on the environmental sustainability of different carbon capture methods.

6.5. Consideration of Co-Benefits

Apart from direct environmental impacts, this section will consider co-benefits associated with each carbon capture application. Co-benefits may include improved air quality, job creation, or

International Research Journal on Advanced Engineering Hub (IRJAEH)
e ISSN: 2584-2137
Vol. 02 Issue: 05 May 2024
Page No: 1387 - 1403
https://irjaeh.com
https://doi.org/10.47392/IRJAEH.2024.0192

positive impacts on local ecosystems. An analysis of these co-benefits will contribute to a more comprehensive understanding of the overall environmental footprint of each technology. By comparing the environmental impact of carbon capture to fuel with other carbon capture applications, this section aims to provide a nuanced assessment of their relative sustainability. Subsequent discussions will explore potential synergies, policy implications, and the broader role of these technologies in addressing climate change and environmental challenges.

7. Case Studies: Opening an Overview of CCUS Technology (CCUS)

7.1. Methanol Examples: Following TEA and LCA Guidelines for CO2 Use

As we start the journey from TEA and LCA to methanol manufacturing, this situation takes a look as it opens a sensible guide. Following the tips of the Global CO2 Initiative, the complexities of changing hydrogen and captured carbon dioxide into methanol are explored. More than just TEA or LCA, it's a treasured lesson at the realistic implementation of the guidelines and provides perception into the challenges and opportunities.

7.2. Mineralization Work Cases: Building a Sustainable Future

In the sphere of creation, this observation makes use of TEA and LCA guidelines to take a look at the mineralization system that produces carbon-containing aggregates. The record introducing the implementation of the guide no longer best explains the environmental effects, but also highlights the training discovered. They observe how carbon capture can promote sustainable construction practices and emphasizes the importance of comprehensive tests.

7.3. OME Case Study: Towards Green Transport

Focusing on Oxyethylene Dimethyl Ether (OME) as a diesel alternative exhibits realistic insights from TEA pointers. In addition to its position as a helping report, this example takes a look at highlights training learned within the search for cleaner transportation solutions. It illustrates how TEA can lead the development of coal use technologies and make them financial and environmental profitability.

7.4. TEA Target Setting Guide: Determining Carbon Use Patterns

This case takes a look at isn't just about TEA goal setting; that is a comprehensive document on the house heating sector. The examination focuses on how carbon dioxide can reduce emissions and is going past the guidelines. Lessons found out encompass the tough balance needed to set targets, a sensitive technique that includes a radical region-precise assessment and an accurate expertise of the potential influences of coal use.

7.5. SNG in Action: Unlocking the Potential of Synthetic Natural Gas

This case is well-known, shows the complexities of synthetic natural fuel (SNG) manufacturing and applies TEA steering to sensible programs. This is a helping record that offers classes found in navigating the complexities of SNG carbon seize. Beyond the specifics of the generation, it sheds mild light at the broader implications and concerns while TEA steering is implemented to various coal usage technology.

7.6. Economic Feasibility of Carbon Dioxide Utilization: Visualizing a Sustainable Chemistry Pathway

U.S. The National Renewable Energy Laboratory's records visualization device isn't always just a presentation of financial analyses. It is a dynamic aid that gives perception into the monetary viability of various chemical compounds crafted from carbon dioxide. The instructions found out increase the capacity of effective communication through visualization that offers stakeholders a clear view of the monetary possibilities of sustainable chemistry.

7.7. Techno-Economic Modeling of Electrochemical Processes: A Blueprint for Future Innovation

This document courses us via electrochemical strategies inside the discipline of CCUS technologies. This file is more than a case look at, it is an outline. In addition to introducing TEA

International Research Journal on Advanced Engineering Hub (IRJAEH)
e ISSN: 2584-2137
Vol. 02 Issue: 05 May 2024
Page No: 1387 - 1403
https://irjaeh.com
https://doi.org/10.47392/IRJAEH.2024.0192

applications, it affords steering and resources that emphasize the non-stop getting to know of techno-monetary modeling of electrochemical pathways. This is a testimony to the evolving panorama of carbon capture technologies and the want for adaptive modeling methods [16].

8. Challenges, Lessons Learned, and Future Directions

8.1. Current Challenges in the Implementation of Carbon Capture to Fuel Technologies

Implementing carbon capture to fuel technologies is not without its hurdles. This section outlines the current challenges and obstacles faced in the practical deployment of these innovative solutions.

8.1.1. Technological Maturity

Many carbons capture to fuel technologies are still in their infancy, lacking the maturity needed for large-scale deployment. The current technological landscape presents challenges related to efficiency, scalability, and reliability [14].

8.1.2. Economic Viability

The economic feasibility of these technologies remains a significant challenge. High initial costs, coupled with uncertainties in revenue streams, pose obstacles to widespread adoption. Bridging the gap between innovation and economic viability is a pressing concern [9]. Policy and Regulatory Frameworks: Inconsistent or insufficient policies and regulations can impede the implementation of carbon capture to fuel technologies. The absence of clear guidelines may hinder investment and industry commitment [13].

8.1.3. Public Acceptance

Public perception and acceptance play a crucial role in the success of any environmental technology. Addressing concerns, raising awareness, and fostering public trust are ongoing challenges in the deployment of carbon capture to fuel solutions.

8.2. Lessons Learned from Previous Initiatives

Drawing insights from past endeavors provides valuable lessons for navigating current challenges. Examining previous experiences in implementing carbon capture to fuel technologies offers a roadmap for future success.

8.2.1. Collaboration is Key

Successful initiatives often involve collaboration between government bodies, industries, and research institutions. Establishing effective partnerships can streamline the development and deployment processes. Early Stakeholder Engagement: Engaging stakeholders early in the development process is critical. Addressing concerns, incorporating feedback, and involving the community in decision-making contribute to smoother project execution. Flexibility in Technology Adoption: Recognizing the dynamic nature of technology, a flexible approach to adoption is essential. Adaptable strategies that accommodate evolving scientific and economic landscapes enhance resilience against unforeseen challenges.

8.3. Future Directions for Research and Development

To overcome current challenges and propel the implementation of carbon capture to fuel technologies, this section proposes future directions for research and development in the field.

8.3.1. Technological Advancements

Invest in research to enhance the efficiency, robustness, and scalability of carbon capture to fuel technologies. Innovations in materials, processes, and integration methods can accelerate technological maturity.

8.3.2. Economic Incentives and Policies

Advocate for the development and enhancement of supportive economic incentives and policies. Clear regulatory frameworks and financial support mechanisms can stimulate private and public investment.

8.3.3. Public Awareness Campaigns

Launch comprehensive public awareness campaigns to educate communities about the benefits and safety of carbon capture to fuel technologies. Building public support is crucial for overcoming social and regulatory challenges.

International Research Journal on Advanced Engineering Hub (IRJAEH)
e ISSN: 2584-2137
Vol. 02 Issue: 05 May 2024
Page No: 1387 - 1403
https://irjaeh.com
https://doi.org/10.47392/IRJAEH.2024.0192

8.3.4. Interdisciplinary Research Collaboration

Foster interdisciplinary collaboration between scientists, engineers, economists, and policymakers. Integrating diverse perspectives can lead to holistic solutions and expedite the development process. In navigating the challenges, learning from past experiences, and charting a course for future research, the implementation of carbon capture to fuel technologies can move closer to achieving its potential as a transformative solution in the fight against climate change.

9. Policy and Regulatory Landscape

9.1. Examination of Existing Policies and Regulations

A thorough examination of existing policies and regulations surrounding carbon capture and the production of fuels from captured carbon is crucial for understanding the current policy landscape.

9.1.1. Carbon Capture Policies

Assess the presence and effectiveness of policies specifically targeting carbon capture technologies. Identify regulatory frameworks that encourage or mandate the integration of carbon capture solutions across various industries.

9.1.2. Fuel Production Regulations

Examine regulations governing the production of fuels from captured carbon. This includes understanding standards, safety protocols, and environmental regulations applicable to synthetic fuel production. Environmental Compliance: Evaluate how existing environmental regulations address the potential environmental impacts of carbon capture to fuel technologies. Considerations may include air quality standards, water usage limits, and waste disposal guidelines.

9.2. Role of Government Incentives

Government incentives play a pivotal role in shaping the adoption and development of carbon capture to fuel technologies. This section explores the impact of such incentives on the industry.

9.2.1. Financial Support Programs

Analyze government-funded programs that provide financial support for research, development, and implementation of carbon capture to fuel technologies. Assess the effectiveness of grants, subsidies, and tax credits in stimulating industry participation.

9.2.2. Carbon Pricing Mechanisms

Investigate the role of carbon pricing mechanisms in incentivizing the adoption of carbon capture technologies. Examine how pricing signals influence investment decisions and contribute to the economic viability of carbon capture to fuel projects.

9.2.3. Technology-Specific Incentives

Identify incentives tailored to the unique characteristics of carbon capture to fuel technologies. This may include targeted funding for pilot projects, grants for technology demonstration, and rewards for achieving specific milestones in fuel production [17].

9.3. International Agreements and Collaborations

The global nature of climate change necessitates international collaboration. This section explores the role of international agreements and collaborations in promoting or hindering the advancement of carbon capture to fuel technologies.

9.3.1. Paris Agreement Commitments

Analyze how countries' commitments under the Paris Agreement influence their support for carbon capture technologies. Explore the alignment of national policies with international climate goals and targets.

9.3.2. Technology Transfer and Knowledge Sharing:

Investigate international collaborations focused on technology transfer and knowledge sharing in the field of carbon capture. Assess the impact of collaborative efforts on accelerating the global deployment of carbon capture to fuel technologies.

9.3.3. Trade Agreements

Explore how trade agreements address the exchange of carbon capture technologies and synthetic fuels between countries. Assess whether trade agreements facilitate or hinder the global

International Research Journal on Advanced Engineering Hub (IRJAEH)
e ISSN: 2584-2137
Vol. 02 Issue: 05 May 2024
Page No: 1387 - 1403
https://irjaeh.com
https://doi.org/10.47392/IRJAEH.2024.0192

adoption of these technologies in Figure 8. By comprehensively examining existing policies, government incentives, and international collaborations, this section provides insights into the regulatory environment shaping the development and deployment of carbon capture to fuel technologies. Subsequent discussions will explore potential policy improvements, global cooperation strategies, and the role of these technologies in achieving broader climate objectives.

Element	Details
Policy Path	In the near term, CCUS policy should be carbon credits or incentives based, to seed and promote the CCUS sector in India through tax and cash credits. Over time (probably beyond 2050), the policy should transition to carbon taxes, so as to enable reaching India's net zero goals by 2070. The policy should establish early stage financing and funding mechanisms for CCUS projects.
Hub & cluster business model	Regional hub & cluster models need to be established to drive economies of scale. The role of emitters, aggregators, hub operator, disposers, and conversion agents needs to be defined.
Low carbon products	Preferential procurement in Government tenders for low carbon or carbon abated products. Incentives to foster innovation for low carbon products through schemes like PLI.
Environmental and social justice	Distribution of benefits of economic value added created to communities most affected by environmental and climate change. Protection of communities and jobs, especially in sectors affected by clean energy regulations.
Accounting and regulatory framework	Regulated emission levels and allowances for different sectors. Adoption of Life Cycle Analysis (LCA) framework to take into account Scope 2 and Scope 3 emissions and drive effective carbon abatement.
Risk mitigation	Limiting the CO_2 liability, and ownership of participants across the CCUS value chain. Monitoring, Verification, and Accounting (MVA) framework and monitoring for risk management.

Figure 8 Key Elements of A CCUS Policy Framework for India [18]

Conclusion

In conclusion, the exploration of carbon capture to fuel technologies unveils a promising frontier in the pursuit of sustainable energy solutions and climate change mitigation. The diverse facets covered in this research paper, ranging from technological intricacies to policy landscapes, collectively contribute to a nuanced understanding of the challenges and opportunities inherent in this field.

Technological Advancements and Challenges: The in-depth examination of various carbon capture technologies, their conversion into fuels, and the associated chemical processes has revealed the strides made in technological innovation. Yet, the journey is not without challenges. The sector grapples with the maturation of these technologies, economic viability concerns, and the need for scalable, efficient solutions.

Economic and Environmental Considerations: Assessing the economic feasibility and environmental impact of carbon capture to fuel technologies has underscored the importance of a balanced approach. The economic landscape poses hurdles, from high implementation costs to uncertainties in revenue streams, necessitating innovative solutions. Concurrently, the environmental benefits, including the potential reduction in greenhouse gas emissions and resource efficiency, emphasize the positive role these technologies can play in addressing climate change.

Policy Dynamics and International Collaboration: The examination of the policy and regulatory landscape has shed light on the

International Research Journal on Advanced Engineering Hub (IRJAEH)
e ISSN: 2584-2137
Vol. 02 Issue: 05 May 2024
Page No: 1387 - 1403
https://irjaeh.com
https://doi.org/10.47392/IRJAEH.2024.0192

crucial role governments play through incentives and regulations. International collaborations and agreements further underscore the interconnectedness of global efforts in advancing carbon capture technologies. Striking a harmonious balance between national policies and international commitments emerges as a critical factor in fostering a conducive environment for the widespread adoption of carbon capture to fuel solutions.

Lessons Learned and Future Directions: The case studies presented, drawn from real-world applications, provide valuable insights and lessons for the future. Collaborative efforts, early stakeholder engagement, and flexibility in technology adoption have emerged as pivotal lessons. Looking ahead, a call for continued technological advancements, robust economic incentives, and increased public awareness becomes imperative to overcome current challenges and drive the industry toward maturity.

The field of carbon capture to fuel technologies stands at a crossroads, presenting both challenges and unprecedented opportunities. A concerted effort involving technological innovation, supportive policies, and international collaboration is vital to propel these technologies from theoretical promise to practical, scalable solutions. As we navigate this path, the collective commitment to a sustainable, low-carbon future remains the guiding beacon, encouraging researchers, policymakers, and industries to work collaboratively towards a resilient and cleaner energy landscape.

ABSTRACT

Social media multimodal sentiment analysis has proliferated the research attention of the research community, as it opens up various paradigms for social issues such as cyberbullying, hate speech, healthcare, politics, business analysis and many more. At the same time, it is an open problem to learn the intrinsic representation of multiple modalities in order to identify correlated patterns. In the proposed work a sentiment analysis framework is presented that defines Textual Context guided Vision Transformer with Rotated Multi-Head Attention, in order to exploit correlation between image-text pair and mine rich discriminatory features for multimodal sentiment analysis. A novel Rotated-Multi-head attention mechanism is defined that translates the visual or text embeddings in distinct feature space resulting in Adaptively Rotated Refined Embedding (ARREmb). To exhibit the performance of the proposed work, extensive experiments are carried out on three publicly available datasets-BG, Twitter and MVSA-single dataset, in terms of Precision, Recall, F1-score and accuracy. The experiments support superior performance of the proposed approach by laying out comparison with SOTA followed by ablation study.

1 INTRODUCTION

In present time, the major mode of communication is online social media platforms, which allow the common user to present their opinions or sentiments with text, images, emojis, videos etc. Sentiment analysis of content generated by common users at social platforms help to organize it and mine useful information in order to stay aligned with the exponentially growing pace of videos and images. It extends multiple solutions and advancements for various applications. It becomes essential that the performed sentiment analysis to be accurate for social good, such as identifying hate speeches made in public, misinformation propagation to harm or defame the personality of the person in the speeches, cyberbullying, mass notion about any new sensation in the market, impact of any political incident on public so on and so forth. Hence, sentiment analysis of multimodal data allows to understand the broader public consensus behind specific topics or social issues i.e., hate speech [8], cyberbullying [19], and misinformation across different online platforms, healthcare [6], politics [20], and business analysis [5] while ensuring unique reflection of the context and realities of the specific domains. Hence, multimodal sentiment analysis has emerged as a significant research problem with a potential to address a variety of societal challenges and promote positive social outcomes by leveraging insights gleaned from the integration of multiple modalities, i.e. image-text, speech-text, visual-text or video-text. Previous multimodal solutions attempted naïve fusion techniques-early fusion[10][17], late fusion [11], while utilising visual-text, speech-text, and visual-text modalities respectively in videos for sentiment score prediction. Such approaches fail to map the interactions between modalities. There exist few attempts [3] [28] that defined image and text interactions for sentiment score prediction using different attention mechanisms. With the recent proliferation in the performance of Transformer structures- BERT [10], Vision Transformers [7] for different applications, some researcher's [4][18] exploited the efficacy of transformers to learn image-text or visual-text pair interactions. Also, the fine-tuning of recent pretrained vision-language models defined with transformer-based encoders- ViLBERT [29], BLIP take much more complicated multimodal interactions into consideration, compared with late fusion or early fusion, have turned out to be a promising solution to learn complex visual-text interactions. While they offer significant advancements over BERT in terms of multimodal understanding, they also come with their own limitations, particularly in terms of model size and computational time, data dependencies, and interpretability. These limitations need to be carefully considered when choosing and deploying these models in real-world applications. Hence, multi-modal sentiment analysis is still an open challenge to present

each modality characteristics uniquely similar to human cognitive systems with practical constrains of implementations in real-time scenario. Therefore, effective text and visual interactions need to be apprehended to bridge this gap. In this direction, the proposed work deals with uniquely defining image-text interactions with a Textual Context guided Vision Transformer with Rotated Multi-Head Attention for Sentiment Analysis. The framework defines a novel adaptively rotated refined embeddings (ARREmb) that translate the text and visual embeddings in distinct feature space to distinctly perform attention on the correlated features of image and text, given by Rotated-Multi-Head Attention (R-MHA) in vision Transformer. Key contributions for the proposed framework are three folds:

- Proposes an efficient Textual Context guided Vision Transformer with Rotated Multi-Head Attention Multimodal Sentiment Analysis framework that learns the image-text corelation using textual context guided attention mechanism.
- Introduces a novel Adaptively Rotated Refined Embedding (ARREmb) representation of features-Mixed Text Embeddings (MTE) TF-IDF, POS, all-MiniLM-L12-v2 Embedding or visual embeddings. Where the amount of rotation is learnt adaptively with θ_t, θ_p, θ_{LM} parameters. The amount of rotation instils distinctness in each feature representations.
- A textual context guided VisTransformer encapsulates the visual scene region semantic features using ARREmb guided attention, that highlights relevant regions of the scene aligned with textual description for sentiment analysis.

Rest of the paper is organized as follows: Section 2 discusses recent existing state-of-the-art in three categories-fusion based approaches, attention-based approaches and transformer-based approaches. In section 2, proposed methodology is discussed in detail. In Section 4, the observed experimental results of the proposed work, are reported followed by section 5, in which conclusion of the proposed work is mentioned

2 RELATED WORKS

2.1 Fusion based approaches

In context of multimodal sentiment analysis, traditional fusion methods can be divided in three categories: early fusion, mid-level fusion and late fusion. Whereas a recent work [11] defined Multi-Model Fusion (MMF), that exploits a multichannel joint fusion model with self-attention to effectively capture the intrinsic visual and textual interactions. To model and learn end-to-end inter and intra-modality dynamics, the work [14], develops a Tensor Fusion Networks. It computes the outer product between unimodal representations. Another work [24] attempted to reduce the computational complexity of tensor-based approach by developing low-rank multimodal-fusion method yielding tensor representations. It decomposed the weights of high-dimensional fusion tensors, reducing redundant information, yet it was difficult to effectively encapsulate intermodal or specific modality dynamics. Another work [13] presented Quantum Interference (QIMF) guided Multimodal decision Fusion to address semantic gaps and model the correlation between the two modalities using density matrices. However, it has limited adaptability of feature differences and suffered with significant feature redundancy. Majumder et al. [26] defined hierarchical-fusion strategy that failed capture intramodal dynamics adequately.

2.2 Attention based approaches

The work [15] defined Attention-Based Modality-Gated Networks (AMGN)—to exploit the correlation between the modalities of images and texts and extract the discriminative features for multimodal sentiment analysis. Another work [9] developed deep multi-level attention network (DMLANet), which exploits the correlation between image and text modalities using bi-attentive visual map along the spatial and channel dimensions to magnify Convolutional neural network representation power.

Whereas, a bidirectional multi-level attention approach [23] mines complementary and comprehensive information between the image modality and text modality for joint visual-textual sentiment classification. Another work [3], utilised text guided regional attention and scene attention for attentive interactive learning of image-text features.

2.3 Transformer based approaches

These days researchers are readdressing their attention in the direction of pre-trained language models like Transformer, BERT, and ResNet as these language models present exceptional feature learning competence. A recent approach [22] defined self-adaptive representation transformer-based learning model (SRLM) using a gated network approach. Another work [4], recently, attempted transformer-based approach to exploit inner hierarchy of the documents for sentiment analysis followed by LIME analysis, while emphasizing the need for explainability of the model.

3 PROPOSED WORK

The proposed framework utilises both visual and text modality to analyse the sentiments $\{S\}$ as positive, negative, and neutral of a data given as $D \in \{V, T : S\}$, that includes visual information $\{V\}$, and its textual description $\{T\}$. Sentiment analysis problem can be defined as: For a given image and text pair $\{V_i, T_i\}$ and its associated sentiment label $\{S_i\}$; $i \in [1, n]$; n no. of samples, the objective is to learn the mapping function $\phi : (V, T) \rightarrow S$ using multimodal training sample set **{V, T: S}**. To learn the contextual semantics of the text and visuals together for efficient sentiment score prediction Multimodal Adaptive Attention based Sentiment Analysis Framework (see Figure 1) is proposed. It utilises TF-IDF embeddings, part-of-speech (POS) embeddings and all-MiniLM-L12-v2 language model-based embeddings of the given text to highlight both semantic and syntactic information in the text. The mixed text embeddings are translated in refined embedding space by adaptively rotating the embeddings by a factor of $\theta_t, \theta_p, \theta_{LM}$. This translation provides more relevant and distinct semantic and syntactic features present in the text, defined as ARREmb. Since, in Image-text pair it is important to have text aligned visual learning to ensure strong features are used for sentiment prediction. Therefore, a textual context guided vision transformer is defined, that utilises Rotary Multi-Head Attention (R-MHA). ARREmb are used for generating K and Q vectors for R-MHA block. The framework technical details are discussed in following subsections: 3.1 and 3.2.

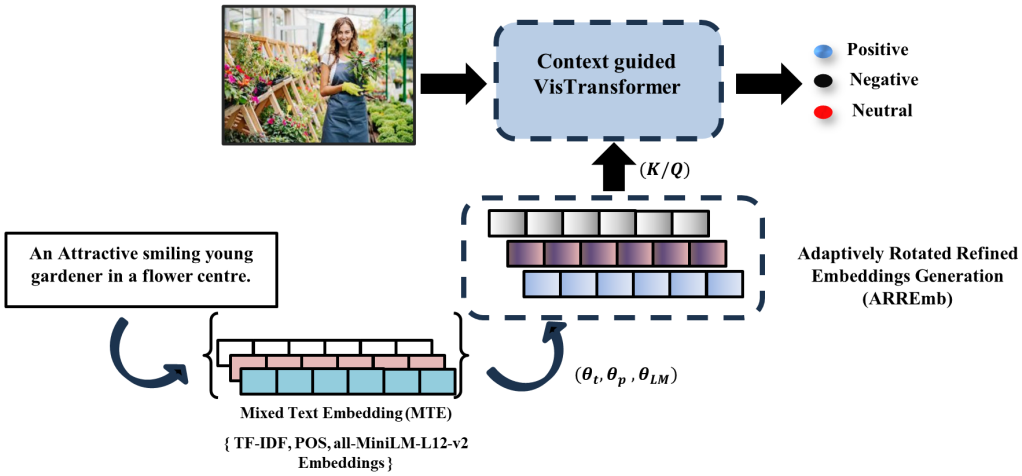

Figure 1: Proposed Multimodal Adaptive Attention based Sentiment Analysis Framework

3.1 Textual Feature Encoding

Before extracting the textual features, essential pre-processing is carried out. It includes case folding, followed by punctuation removal and stop word removal. It cleans the data and makes the features extraction more meaningful. Instead of relying on one type of textual feature representation richer textual features are learnt as a collection of word level embeddings, defined with TF-IDF and POS features- verb (VB), adverb (AVB), noun (NN), proper noun (PN) Adjectives (AD), Negation (NEG) and sentence level features, defined using all-MiniLM-L12-v2 language model. Where POS features presents structure of sentence, term frequency and inverse document frequency (TF-IDF) highlights relatively important words in a sentence, i.e. syntactic details. Language Model all-MiniLM-L12-v2 based features encrypt contextual meaning of the sentence, i.e. semantic details.

In order to refine semantic and syntactic details of textual input, mixed textual embeddings are rotated adaptively. The details are provided in following subsection.

3.1.1 Adaptively Rotated Refined Embeddings Generation (ARREmb). For the given text corpus $T = \{w_i\}, i \in no.of words(N)$, w_i represents i^{th} word in the sentence. It is translated in three types of embeddings space to ensure rich syntactic and semantic feature generation. Part-of-speech features (POS) emphasizes on word level syntactic representation of the given corpus T, such that

$$POS = \{NN, PN, VB, AVB, AD, NEG\} \tag{1}$$

where NN is a collection of set of nouns, i.e., $w_{i,k}^{NN}$, PN is a collection of set of pronouns, i.e., $w_{i,k}^{PN}$, VB is a collection of set of verbs, i.e., $w_{i,k}^{VB}$, AVB is a collection of set of adverbs, i.e., $w_{i,k}^{AVB}$, AD is a collection of set of adjectives, i.e., $w_{i,k}^{AD}$, NEG is a collection of set of negative words, i.e., $w_{i,k}^{NEG}$. Each collection is vectorized using *word-to-vec* embedding representation, given by POS_{Emb}. For sentence level T embedding to encapsulate semantic details a pre-trained all-MiniLM-L12-v2 language model is used to generate LM_{Emb}. . It maps each T_i sentence to a 384-dimensional dense vector space. Combining all three text embeddings a richer mixed text embedding is defined as shown in Eq. (3)

$$MTE = \{POS_{Emb}; TF-TDF_{Emb}; LM_{Emb}\} \tag{2}$$

The position of three embeddings in MTE is given as $m1, m2, m3$. The work [27] exhibited the impact of Rotary Position Embeddings to make the transformer learn better and converge fast. It motivated us to refine the MTE embeddings by applying rotation adaptively. Each embedding in MTE is rotated by an angle $\theta_p, \theta_t, \theta_{LM}$ respectively, learnt adaptively in such a way that in the rotated embedding space the respective embedding distinctly defines the text corpus T, resulting better text context understanding. Mathematically, embedding rotation function is defined as given in Eq. (4).

$$f_{ROT} : \{m1, m2, m3\} \rightarrow \{m1 * \theta_p, m2 * \theta_t, m3 * \theta_{LM}\} \tag{3}$$

$$ARREmb = f_{ROT}(MTE, m_i) = (W_{MTE} MTE_{mi}) e^{jm_i\theta}; \tag{4}$$

where $\theta \in \{\theta_p, \theta_t, \theta_{LM}\}; i \in [1, 3]$

Hence, f_{ROT} maps MTE to Adaptively Rotated Refined Embeddings ($ARREmb$). W_{MTE} are learnt adaptively in training phase.

3.2 Textual context guided Vision Transformer

Vision Transformers [7] learns the visual data by dividing the image in patches and performs multi-head attention layer in the encoding phase. The proposed multimodal sentiment analysis framework learns the visual analytics guided by contextual details of the text. It ensures the sentiment analysis is carried out in the alignment of both text and visual details. Hence, uniquely generated $ARREmb$ are used to guide the vision transformer with its text contextual details. The multi-head self-attention block in the vision transformer first integrates positional details with patch embeddings and converts them into queries, keys, and value representations, given as below:

$$Q_{mi} = K_{mi} = f_{ROT}(MTE, m_i) \tag{5}$$

$$V_j = f_{ROT}(\widetilde{\mu}, j); \tag{6}$$

$\forall j$:positional values of image embeddings $\widetilde{\mu}$

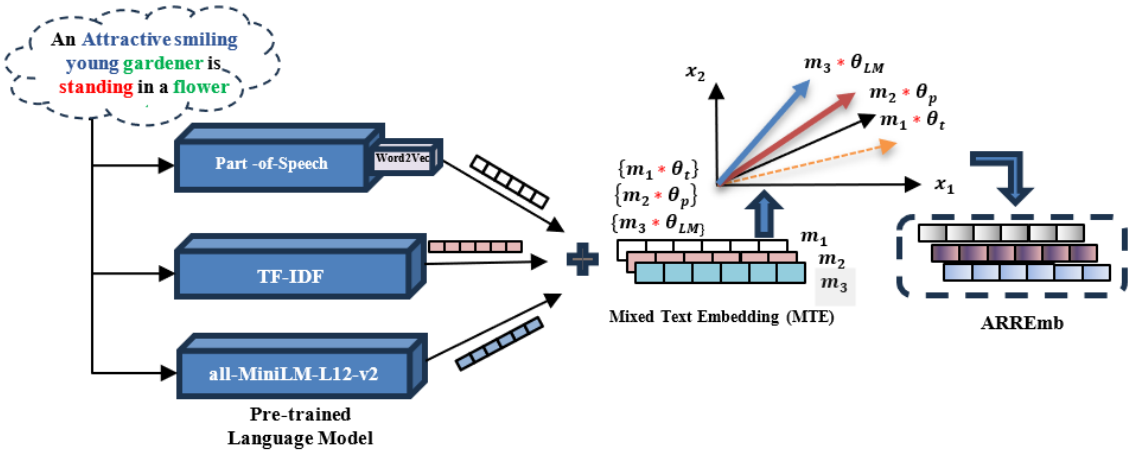

Figure 2: Illustration of Adaptively Rotated Refined Embeddings Generation (ARREmb)

$$V_j = f_{ROT}(\widetilde{\mu}, j) = (W_V, \widetilde{\mu}_j)e^{k(j_* \quad \theta_v)} \tag{7}$$

where θ_v defines adaptively learnt angle of rotation applied on values V_j.

$$ATTn_{mi,j} = \frac{e^{\frac{Q_{mi}^T K_{mi}}{\sqrt{d}}}}{\sum_{l=1}^{N} e^{Q_{mi}^T K_l}} \& O_{mi} = \sum_{j=1}^{L} ATTn_{mi,j} V_j \tag{8}$$

where $L = length\ \widetilde{\mu}$. In Eq. (9), query and key values are used to compute the attention weights $ATTn_{mi,j}$, and the output is computed as the weighted sum over the V_j value representation as O_{mi}. The positional rotated of key, query and values provide refined attention weights in the images.

4 EXPERIMENTAL RESULTS

To observe the performance of the proposed framework, experiments are conducted on three publicly available social media datasets: Getty Images dataset (BG), Twitter Dataset, Multi-View Sentiment Analysis (MVSA) dataset.

Getty Image dataset [21] is a large collection of photographs, videos, and audio from over 477 million resources. It is a user-friendly data resource that provides efficient query-based search engine. All the samples are paired with descriptive image descriptions. The dataset is named "Binary_Getty" (BG), which includes 10,098 positive images, 10,029 negative images with relevant textual explanations, and two labels.

Twitter dataset is a collection of English tweets paired with photos on twitter platform. The samples are collected using Twitter streaming Application Programming Interface (API) [1], using user-generated hashtags as keywords.Based on visual-text information, and the projected rotated sentiment polarity the tweets were manually categorized into negative, positive, and neutral sentiment polarities. The dataset contains 17,073 image-text paired tweets including 6075 positive, 5228 negative, and 5770 neutral samples.

The MVSA-Single dataset [2] includes 5129 image-text pairs extracted from Twitter. Each image-text pair is annotated with one of three polarities (neutral, negative, or positive). The contradicting textual and visual label samples have been deleted. For samples with one polarity as neutral and another as negative/positive, final polarity for the samples is considered as negative/positive. This procedure of filtering results in 4511 text-image pairs with 2683 positive, 1358 negative, and 470 neutral for MVSA-Single dataset. For experimentation the datasets are divides in train-valid-test split in 80-10-10 proportion. Since, MVSA-single dataset is imbalanced dataset, up-sampling is performed to minimize the effect of data imbalance on the smallest category. The architecture is implemented with Keras, and the experiment is performed on Google Colab pro with an Nvidia P100 GPU with 24 GB RAM. Adam optimizer is used for proposed transformer training, while learning rate is set at $10e^{-3}$ with 32 batch size for 80 epochs. Early stopping with patience value of 3 is used to control the training using binary cross-entropy loss. Xavier uniform initializer is used to set the rotation weights, i.e. $W_{MTE}, \theta_p, \theta_t, \theta_{LM}$, while defining *ARREmb*.

To measure the performance of the proposed work precision, recall, F1-score, and accuracy evaluation metrics are used.

The architecture is developed in five steps developing models Model 1 to Model 5, as described below:

- **Model 1 (Visual Data)** is a simple vision transformer pre-trained architecture with MHA. It utilises only images to predict the sentiments.
- **Model 2 (ViLBERT)** [29], the pre-trained model weights are used to learn the visual-text interactions
- **Model 3 (BLIP)** [12]: Bootstrapping Language-Image Pre-training model is used for unified vision-language understanding
- **Model 4 (Visual+MTE-Text)** is an extended version of model 1. Model 4 utilises Mixed Text Embeddings (MTE) to guide the MHA attention block in vision transformer.
- **Model 5 (Visual+ARREmb-Text)** is further extended version of Model 4. It utilises adaptively rotated refined embeddings (ARREmb) for generating K and Q vectors for textual context-based attention in vision transformer.

An ablation study is carried out, as reported in Table 1, to exhibit the effect of proposed text guided vision transformer with Rotated MHA over model 1, 2, 4 and 5. It is observed that the performance

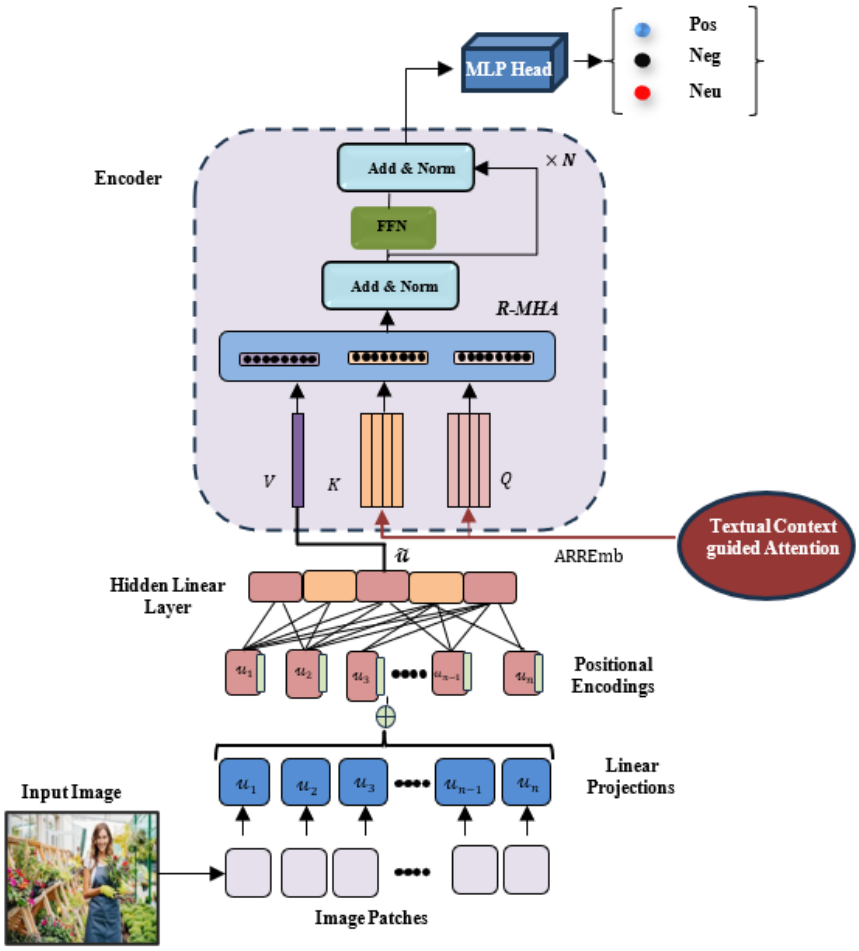

Figure 3: Textual context guided Vision Transformer architecture; R-MHA Rotated Multi-Head

is very naive, exhibiting limited sentiment prediction ability with Model 1 (only visual data). In case of Model 2 and 3, visual-language interaction is encapsulated using pretrained ViLBERT [29] with 110 epochs and BLIP [12] with 95 epochs models weights respectively. It is observed that Model 3 still performs better over Model 2, one of the reasons may be the lesser number of parameters that refrains it from overfitting the data. Whereas, In Model 4, Mixed Text Embeddings (MTE) in textual context guided Vision Transformer learns aligned visual and text interactions, reported as improved results in terms of precision, recall, F-Score and accuracy in Table 1. In case of Model 5, presented ARREmb generates K and Q vectors in multi-head attention, i.e. R-MHA, that projects the K, Q and V vectors in distinct embedding space resulting in refined attention in the visual regions and support enhanced sentiment prediction.

The observed accuracy of the proposed work for BG dataset is 99.80%, for Twitter dataset is 96.39%, and for MVSA dataset is 80.25%. The comparison of the proposed work performance is carried out, in Table 2, with following state-of-the-arts:

(i) MMF [11]: Multi-Model Fusion
(ii) DMVAN [3]: Deep Multi-View Attentive Network
(iii) HCIM [28]: Hierarchical Cross-Modality Interaction Model
(iv) AMGN [15]: Attention-Based Modality-Gated Networks
(v) DMLANet [9]: Deep Multi-Level Attentive network
(vi) HFN [16] :Hybrid Fusion Network
(vii) ITIN [12]: Image-Text Interaction Network
(viii) GLFN [25]: Global Local Fusion Neural Network

The reported results exhibit that the proposed framework that adaptively learns rotated feature embeddings followed by R-MHA outperforms MMF [11], HCIM [28], AMGN[15] with 0.02%, 6.2% and 11.6% accuracy, whereas DMVAN [3] exhibits 0.03% superior precision and equivalent accuracy for BG dataset. For Twitter dataset, multi-view attention strategy in DMVAN [3] allows it to produce marginally higher accuracy and precision over proposed work by 0.04% and 0.55% respectively. In case of MVSA-single dataset, proposed work exhibit 1.19%, 0.85%, 4.92%, 3.04%, higher accuracy from MMF [11], DMLANet [9], ITIN [12], GLFN [25]. The class wise performance of the proposed work for BG, Twitter and MVSA single dataset is presented in Figure4 respectively.

Table 1: Ablation Study Observations for BG, Twitter dataset and MVSA-single dataset Model 1: VisTranformer+ MHA; Model 2: ViLBERT Model 3: BLIP; Model 4: Text guided VisTranformer+ MHA; Model 5: Text guided VisTranformer+ R-MHA

(a) (b) (c)

Figure 4: Class wise performance of the Proposed work for (a) BG dataset, (b) Twitter dataset, and (c) MVSA single dataset

4.1 Error Analysis

The proposed work mitigates better image-text interactions over SOTA results except DMVAN [9] for BG and Twitter datasets. Whereas, for MVSA single dataset, the proposed framework observed least accuracy as 80.25% over other datasets. One of the reasons may be the annotation dispute on the image-text samples provided in MVSA single dataset, as shown in Figure5(a)-(c). In Figure 5a the caption includes negative terms 'paralyzed', 'rehab'. Whereas the sentence semantics point towards improved state of the baby, hence predicted as positive sentence. Similarly, in Figure

5b image strongly reflects positive sentiment with 'I miss you'. It is repeated two times in the caption. Whereas, the model predicts it as negative sample as the caption ends with '#depression' that echoes the negative sentiment. In Figure 5c the image stands out with neutral sentiment along with the caption, also predicted as neutral sentiment, whereas annotation of the sample is provided as positive. Further, it is found that there are 500 non-English tweets in MVSA-single dataset. Such tweets result in poor sentiment classification.

5 CONCLUSION

Like ViLBERT [29] and BLIP [12] models that learn visual-text interactions, proposed Textual Context guided Vision Transformer with Rotated Multi-Head Attention encapsulates the textual context guided visual sentiments that includes only single Vision Transformer. The proposed Rotated-MHA block projects the key (K), query (Q), and value (V) vectors in distinct embedding space, hence, defining refined attention maps. Textual context guided attention in vision transformer provides relevant text and visual mapping by detecting image regions aligned with text content. The observed results for three publicly available datasets exhibit superior performance of the proposed work, validated in terms of precision, recall, F1- score and accuracy evaluation metrics. The proposed sentiment analysis framework performance is also supported with ablation study and comparisons to other SOTA. This kind of structure may be used for general purposes to learn multi-modal interactions in an efficient way with limited computation demands, since it utilizes only single VisTransformer. Hence, it holds potential real-life applications beyond sentiment analysis such as visual question answering, visual grounding, multimodal document understanding, etc. by leveraging rich textual and visual interactions.

In this paper, we have investigated the phenomenon of accelerated cosmic expansion in the late universe and the mass accretion process of a 4-dimensional Einstein-Aether black hole. Starting with the basics of Einstein-Aether gravity theory, we have first considered the field equations and two eminent models of Chaplygin gas, viz. generalized cosmic Chaplygin gas model and viscous modified Chaplygin gas model. Then, we obtained the energy density and Hubble parameters equations for these models in terms of some dimensionless density parameters and some unknown parameters. After finding the required parameters, we proceeded with the mass accretion process. For both models, we obtained the equation of mass in terms of the redshift function and represented the change of mass of the black hole graphically with redshift. At the same time, we have made a graphical comparison between the above-mentioned models and the ΛCDM model of the universe. Eventually, we have concluded that the mass of a 4-dimensional black hole will increase along the universe's evolution in the backdrop of Einstein-Aether gravity.

I. INTRODUCTION

Our universe is such an enigma, whose most of the secrets are still hidden from us. In the last century one of such concealed mystery came into light when with the help of evidences like Chandra X-ray observations [1], Planck observations [2], Wilkinson Microwave Anisotropy Probe (WMAP) prediction [3–5], Baryon acoustic oscillation (BAO) [6, 7], observation of Ia-type supernovae [8–12], Sloan Digital Sky Survey (SDSS) [13, 14], large-scale structure theory [12, 13, 15–18] and observation of cosmic microwave background (CMB) which shows a peak while measuring angular power spectrum on degree scales [19–22] firmly indicated towards the current accelerated rate of expansion of our universe. Among all of the possibilities for such kind of accelerated expansion rate, most of the cosmologist agreed upon an exotic kind of energy named as "dark energy" which possess quite an unique type of properties such as negative pressure and positive energy density. Dark energy has several forms, like a static form commonly known as the cosmological constant [23, 24]. Then comes the ones that changes over time called as a scalar field or quintessence [25–30]. As the time progresses researchers came across many other candidates of dark energy named as phantom energy [31, 32], k-essence [33, 34], quintom [35, 36], dilaton [37], tachyon field [38–40], hessence [41], DBI-essence [42, 43] etc. Some interacting models like holographic dark energy model [44–46] and braneworld model of Universe [47] have been investigated, besides considering the theory of quantum gravity, models like the agegraphic dark energy (ADE) model and the new agegraphic dark energy (NADE) model have been introduced [48, 49].

Chaplygin gas(CG) models are another prominent candidate of dark energy, which is basically a combination of dark matter and dark energy, constructed to measure the acceleration rate of our universe. It has different types such as; pure Chaplygin gas [50–52], more general form named generalized Chaplygin gas (GCG) [53–55], modified version commonly popular as modified Chaplygin gas (MCG) [56, 57], which propagates between dust (or radiation) stage to ΛCDM stage. In 2003, a new model of CG, named as generalized cosmic Chaplygin gas (GCCG) model has been introduced [58] with some striking features like, this model can be made stable and without any unphysical behaviour, even though the vacuum fluid satisfies the condition of phantom energy. For such unique properties, this model can easily overcome the concept that the phantom energy era will finally lead us to Big-Rip as, in finite time, derivative of scale-factor with respect to time gives infinite value. The GCCG model has fewer constraints than GCG and MCG models, so it can adapt to any cosmological framework with just some appropriate choices of parameters. Thus it is more universal in nature as well as in this model black holes does not evaporate to zero masses and Big-Rip singularity can be avoided quite effortlessly. Intriguing by such flexible properties of this model several researches have been conducted on this every now and then [59–66]. Another addition to this list of dark energy models is viscous modified Chaplygin gas (VMCG) model, which have the property of bulk viscosity.Its cosmological modeling has been done in classical and loop quantum cosmology [67], the dynamical behaviour of VMCG has been studied in classical and loop quantum cosmology with the help of some recent observational data [68], the evolution of VMCG in $f(R,T)$ gravity with respect to flat FLRW universe has been studied [69], and it's interaction effects on f(R, $\mathcal{G}$, $\mathcal{T}$) gravity has been investigated [70].

Apart from this, scientists came across another very aspiring theory to explain the current accelerated expansion phase of our universe known to be the modified gravity theory, which stands on the concept that although general relativity works fine for small scales but in cases of larger cosmological distances it needs modification. This theory gives priority to the arise of cosmic acceleration due to the dynamics of modified gravity framework. It has quite a good dynamical approach regarding the alternate of ΛCDM model of the Universe. Most common type of modified gravity is basically the DGP brane-world model of gravity [71], in an alternate way we can change the law of gravity by considering the $f(R)$ theory of action in the place of usual Einstein-Hilbert action [72, 73]. Then there are some other models to explain the concept of the present time acceleration rate of our Universe [74]. This new approach opened several ways for researchers owing to which numerous researches have been carried out on this topic [75–82]. There are other forms of modified gravities including $F(T)$ gravity [83], $F(G)$ gravity [84], Hořava-Lifshitz gravity [78], Brans-Dicke gravity [85], Gauss-Bonnet gravity [81] etc.

Einstein-Aether theory is also among one of these modified gravity theories which has now been a very well known topic as it deals with the violation of Lorentz symmetry principle [76, 86–89].At first Jacobson and Mattingly developed this theory [76, 87] which later has been generalized by Zlosnik et al. [90, 91]. It works on each point of space in preferable timelike direction [92].Nature of singularities of a vacuum black hole solution has been found in this theory [93].Being verified by many observational evidences [94–97], this theory has become quite suitable for further exploration regarding it's other aspects, be it cosmological perturbations [98, 99], it's effects on the gravitational waves [100, 101], analyzing a positive energy theorem [102], finding Aetherizing Lambda by using barotropic fluid as dark energy [103] or some study related to very early universe [104]. Recently analytical static aether solutions and possible range for stability of constant density stars have been obtained [105], paving the way for researchers to study more about black holes in Einstein-Aether gravity framework. Subsequently, studies on spherically symmetric black holes in the non-reduced Einstein–Aether scenarios have been conducted [106], charged black holes in Einstein-Maxwell-aether theory have been investigated [107], n-dimensional charged black holes in Einstein–Aether gravity have been discussed in detail [108], cosmic censorship in Einstein-Aether gravity and as a result the possibility of a collapse in its dynamics leading to unstable behavior around spherical solution has been analyzed [109]. Barausse et al. have examined slowly rotating black holes in the Einstein–Aether gravity scenario, which shows that their solutions do not have any naked singularities [110]. Also, shadows of charged and slowly rotating black holes have been studied in [111]. Many other black hole related researches in Einstein–Aether gravity framework have been conducted on regular intervals [112–123].

On the other hand, in current research world, parameter constraining and observational data analysis have gain immense popularity due to it's close to reality implications. Researchers have observed the process of tallying theoretical methods with various observational databases such as cosmological supernova type Ia data, TORNY and Gold sample databases etc. measured in surveys like- GOODS ACS Treasury program, IfA Deep Survey and several other related research programs [124–127].To continue this legacy, constraining of parameter space for generalized Chaplygin gas(GCG) model taking into consideration the location of CMB radiation peak [128] and using WMAP data [129] have been performed, placement of constraints on GCG model according to type Ia supernovae (SNIa) observations have been

studied in [130]. Several other works on observational constraining of GCG model have been performed as well [131–137]. Also, applying constraining on cosmic microwave background radiation (CMBR) spectrum the range for the value of the parameter in the case of modified Chaplygin gas model has been found in [138] and parameter constraining on variable Chaplygin gas (VCG) model using gold sample database of type Ia supernova has been discussed in [139]. Cosmologists have always been keen about the concept of parameter constraining on different type of Chaplygin gas models. Hence there has been generous amount of such works in the research field of cosmology [140–156].Moving a step ahead researchers took interest on constraining of parameters in different gravities; like Brans-Dicke gravity [157–173], loop quantum cosmology [174, 175], Hořava-Lifshitz gravity [176–178], f(T) gravity [179], Chern-Simons gravity [180], Galileon gravity [181], RS II braneworld gravity [182], Einstein-Aether gravity [183] etc. Some other remarkable works on this topic has been discussed in [184–186]. Motivated by these EoS parameterizations, researchers have also extensively discussed and scrutinized the parametrization of the deceleration parameter, Hubble parameter, and a few other geometrical and physical parameters in the literature. A brief summary can be found in [187–208]. As the Universe evolves, it shifts from a deceleration phase to a late-time acceleration phase. Consequently, any cosmological model must include a transition from deceleration to acceleration to explain the Universe's evolution completely. The deceleration parameter, denoted as $q = -\frac{a\ddot{a}}{\dot{a}^2}$, where $a(t)$ represents the customary scale factor, plays a pivotal role in determining whether the Universe is undergoing acceleration ($q < 0$) or deceleration ($q > 0$). In this paper, we are particularly interested in generalized cosmic Chaplygin gas (GCCG) and viscous modified Chaplygin gas (VMCG) models, regarding which some amazing works have already been conducted in [67, 68, 144, 170, 177, 209].

Mass accretion phenomena have been quite a significant topic for researchers devoted to the studies of black holes. This concept first emerged through the work of Bondi [210]. Then Michel followed this up by considering some polytropic gases and formulating the equations of motion of spherical symmetric steady-state flow of matter to and fro some condensed objects like black holes, neutron stars, etc. [211]. This accretion process gives encouragement to the concept of existence of supermassive black holes at the center of most of the galaxies [212] and it can contribute to some of the energy portion of galaxies and quasars [213]. Accretion of phantom energy onto Schwarzschild black hole which ultimately leads to the Big Rip has been discussed in [214, 215]. Phantom energy onto black holes in oscillating or cyclic universe has been studied in [216]. One by one, accretion of modified variable Chaplygin gas and viscous generalized Chaplygin gas onto black holes [217], accretion of phantom energy onto a stringy magnetically charged black hole [218], accretion process of modified Hayward black hole as well as it's evaporation [219], dark energy accretion onto Kerr–Newman black holes [220], accretion of generalized cosmic Chaplygin gas (GCCG) and new variable modified Chaplygin gas (NVMCG) onto Schwarzschild and Kerr–Newman black holes [61], black holes in expanding universe [221] have been studied. Besides, accretion process of black holes and wormholes have been discussed simultaneously in [222] and accretion of generalized cosmic Chaplygin gas and variable modified Chaplygin gas onto Morris–Thorne wormhole have been illustrated in [223].

Afterward, many pieces of research on mass accretion process of higher dimensional black holes have been evolved in [224–229] along with there have been several remarkable works on mass accretion process of various black holes in the framework of different gravities and models of the universe [229–237]. Greatly inspired by all of these researches, we have analyzed about the generalized cosmic Chaplygin gas (GCCG) and viscous modified Chaplygin gas (VMCG) models on the backdrop of Einstein-Aether gravity. Even though we are familiar with the concept that modified gravity is an alternative to dark energy, and that is the reason for not considering any other dark energies in the case of Einstein-Aether gravity as it may itself initiate dark energy [80, 238]. However in our work we have exempted this hypothesis and consider the above mentioned dark energies from our side. In Sec.II, we have discussed the basic idea of Einstein-Aether gravity. In Sec.II A, we have considered the GCCG model of dark energy and obtained its energy density equation as well as the equation of the Hubble parameter associated with it in the form of some dimensionless density parameters. In Sec.II B we have done the same for the VMCG model of dark energy. In Sec.III, we have conducted the data analysis for the above two discussed models and elaborated the outcomes graphically. In Sec.IV, we have studied the accretion process of a 4-dimensional Einstein-Aether black hole in the case of GCCG and VMCG models of dark energy and portrayed the changes of mass of the black hole with respect to redshift function graphically first in the case of GCCG induced universe then in the case of VMCG induced universe and lastly shown the comparison of the same graphically for GCCG filled universe, VMCG filled universe and ΛCDM model of the universe side by side. Then, we discussed the results of data analysis and mass accretion process and explained the corresponding graphs in a detailed manner in Sec.V. Finally we have summarized all of our findings in the Sec.VI as a conclusion of this work.

II. BASICS OF EINSTEIN-AETHER GRAVITY:

The equation for describing the action of the Einstein-Aether gravity theory coupled with the usual Einstein-Hilbert part action is given by the following form [80, 90, 183]:

$$S = \int d^4x\sqrt{-g}\left[\frac{R}{16\pi G} + \mathbb{L}_V + \mathbb{L}\right], \tag{1}$$

where $\mathbb{L}_V$ is the Lagrangian density of the vector field and $\mathbb{L}$ represents the same for all of the other matter fields. The Lagrangian density related to the vector field is given by [80, 90, 183]:

$$\mathbb{L}_V = \frac{m^2}{16\pi G}E(K) + \frac{1}{16\pi G}\lambda(B^iB_i + 1), \tag{2}$$

$$K = m^{-2}K^{ij}_{kl}\nabla_iB^k\nabla_jB^l, \tag{3}$$

$$K^{ij}_{kl} = e_1g^{ij}g_{kl} + e_2\delta^i_k\delta^j_l + e_3\delta^i_l\delta^j_k, \tag{4}$$

Here, e_i are dimensionless constants, and m is a coupling constant with mass dimension. λ serves as a Lagrange multiplier enforcing the unit constraint for the time-like vector field. B^i represents a contravariant vector, g_{ij} is the metric tensor, and $E(K)$ denotes an arbitrary function of K. Eqn (1) yields the field equations [183]:

$$G_{_{ij}} = T^V_{ij} + 8\pi GT_{ij}, \tag{5}$$

and

$$\nabla_i(E'Q^i_j) = 2\lambda B_j, \tag{6}$$

Where,

$$E' = \frac{dE}{dK} \quad and \quad Q^i_j = 2K^{il}_{jk}\nabla_lB^k \tag{7}$$

Where, T_{ij} is given by [80, 183]:

$$T_{_{ij}} = (\rho + p)\mathfrak{u}_i\mathfrak{u}_j + pg_{_{ij}}, \tag{8}$$

which gives us the expression of energy-momentum tensor for all matter fluids. Here, p and ρ stand for all matter fluids' respective pressure and density. Also, $\mathfrak{u}_i = (1, 0, 0, 0)$ denotes the vector of fluid 4-velocity. Again, T^V_{ij} stands for the energy-momentum tensor of vector field whose expression is given as follows [80, 183]:

$$\begin{aligned} T^V_{ij} =& \frac{1}{2}\nabla_l\left[\left(Q_{(i}{}^lB_{j)} - Q^l{}_{(i}B_{j)} - Q_{(ij)}B^l\right)E'\right] \\ &- C_{(ij)}E' + \frac{1}{2}g_{ij}m^2E + \lambda B_iB_j, \end{aligned} \tag{9}$$

together with

$$C_{ij} = -e_1[(\nabla_lB_i)(\nabla^lB_j) - (\nabla_iB_l)(\nabla_jB^l)], \tag{10}$$

Here, (ij) subscript shows the symmetricity property of the indices involved. Also, $B^i = (1, 0, 0, 0)$ represents nonvanishing time-like unit vectors that follow the relation: $B^iB_i = -1$. Now, the Friedmann-Robertson-Walker (FRW) metric of the universe given by:

$$ds^2 = -dt^2 + a^2(t)\left[\frac{dr^2}{1-kr^2} + r^2\left(d\theta^2 + sin^2\theta d\phi^2\right)\right], \tag{11}$$

Here, $a(t)$ denotes the scale factor and k is called the curvature scalar, which can take values $-1, 0, 1$. Again, from the above two Eqn.(3) and Eqn.(4) we will have the following one [183]:

$$K = m^{-2}\left(e_1g^{ij}g_{kl} + e_2\delta^i_k\delta^j_l + e_3\delta^i_l\delta^j_k\right) = \frac{3\beta H^2}{m^2}, \tag{12}$$

Here, β is a constant given by the expression: $\beta = e_1 + 3e_2 + e_3$. Also, from the above Eqn.(5) we will have a modified version of Friedmann equations in the background of Einstein-Aether gravity as follows [80, 90, 183]:

$$\beta\left(-E' + \frac{E}{2K}\right)H^2 + \left(H^2 + \frac{k}{a^2}\right) = \frac{8\pi G}{3}\rho \tag{13}$$

and

$$\beta\frac{d}{dt}(HE') + \left(-2\dot{H} + \frac{2k}{a^2}\right) = 8\pi G(\rho + p), \tag{14}$$

Where, H is the Hubble parameter, given by: H ($\equiv \frac{\dot{a}}{a}$). It is quite clear from the above two Eqn.(12) and Eqn.(13) that whenever we put the L.H.S. of the first expressions of both of the Eqn.(12) and Eqn.(13) equals to zero, then we will get the general field equations for Einstein's gravity. Hence we can conclude that the first expression appears due to the Einstein-Aether gravity. Again, the conservation equation is given as follows:

$$\dot{\rho} + 3H(\rho + p) = 0 \tag{15}$$

If we consider that the matter field of our universe is an amalgamation of dark matter and dark energy. Then, the pressure and energy density will be of the forms: $\rho = \rho_{_{DM}} + \rho_{_{DE}}$ and $p = p_{_{DM}} + p_{_{DE}}$ respectively. Again, separate applications of conservation equations on dark matter and dark energy will lead us to the following equations:

$$\dot{\rho}_{_{DM}} + 3H(\rho_{_{DM}} + p_{_{DM}}) = 0 \tag{16}$$

and

$$\dot{\rho}_{_{DE}} + 3H(\rho_{_{DE}} + p_{_{DE}}) = 0. \tag{17}$$

Since dark matter has nearly no pressure so, we can take $p_{_{DM}} = 0$, also by considering the redshift equation: $(1 + z) = \frac{1}{a}$, finally the Eqn.(16) will reduces to the form, given as: $\rho_{_{DM}} = \rho_{_{DM0}}a^{-3}$ which in terms of redshift function z will be of the following form:

$$\rho_{_{DM}} = \rho_{_{DM0}}(1 + z)^3. \tag{18}$$

The term $\rho_{_{DM0}}$ gives the present energy density value of dark matter.

A. Generalized Cosmic Chaplygin Gas (GCCG) Model:

Let us consider GCCG to be a candidate of dark energy in this Einstein-Aether gravity framework.The equation of state for GCCG model is given by [58]:

$$p_{DE} = -\rho_{DE}^{-\alpha}\left[\mathcal{C} + (\rho_{DE}^{1+\alpha} - \mathcal{C})^{-\omega}\right], \tag{19}$$

Here, $\mathcal{C} = \frac{\mathcal{B}}{1+\omega} - 1$ and $-l < \omega < 0$ with l being a constant having value greater than one. Also, α and $\mathcal{B}$ are any two constants. It is quite clear from the above Eqn.(19) that whenever $\omega \to 0$, it will reduces to the equation of state for generalized Chaplygin gas(GCG). Again, whenever $\omega \to -1$, it will give us the de Sitter fluid. Now, using Eqn.(17) and Eqn.(19) together, we will have the energy density equation of GCCG as follows [59, 170]:

$$\rho_{DE} = \left\{\mathcal{C} + \left(1 + \mathcal{D}\, a^{-3(1+\alpha)(1+\omega)}\right)^{\frac{1}{1+\omega}}\right\}^{\frac{1}{1+\alpha}}, \tag{20}$$

where, $\mathcal{D}$ represents a constant. We can write the above Eqn.(20) in the following form [170]:

$$\rho_{DE} = \rho_{DE0}\left\{\mathcal{A} + (1-\mathcal{A})\left(\mathcal{A}_s + (1-\mathcal{A}_s)(1+z)^{3(1+\alpha)(1+\omega)}\right)^{\frac{1}{1+\omega}}\right\}^{\frac{1}{1+\alpha}}, \tag{21}$$

Here, $\mathcal{A}_s = \frac{1}{1+\mathcal{D}}$, $\mathcal{A} = \left(1 + \mathcal{C}^{-1}\mathcal{A}_s^{-\frac{1}{1+\omega}}\right)^{-1}$, and $\rho_{DE0}^{1+\alpha} = \mathcal{C} + \mathcal{A}_s^{-\frac{1}{1+\omega}}$. Also, z symbolizes the redshift function and ρ_{DE0} gives us the present energy density of DE. Now, we can choose different forms of the function $E(K)$ since it is a free function of K. According to [90, 239]; $E(K)$ can be taken as: $E(K) = \gamma(-K)^n$. On the other hand in [80, 238]; $E(K)$ has been taken as: $E(K) = \gamma\sqrt{-K} + \sqrt{\frac{3K}{\beta}}\ \ln(-K)$. But for easier calculation we will take $E(K)$ as [183]: $E(K) = (\frac{2}{\beta})K(1-\epsilon K)$, where ϵ is a constant. So, if we solve Eqn.(13) considering the above form of $E(K)$ then we will have the expression for Hubble parameter in terms of redshift function z as follows:

$$H^2(z) = \frac{m}{3\sqrt{3\epsilon\beta}}\left[8\pi G\rho_{DM0}(1+z)^3 - 3k(1+z)^2 + 8\pi G\rho_{DE0}\left\{\mathcal{A} + (1-\mathcal{A})\left(\mathcal{A}_s + (1-\mathcal{A}_s)(1+z)^{3(1+\alpha)(1+\omega)}\right)^{\frac{1}{1+\omega}}\right\}^{\frac{1}{1+\alpha}}\right]^{\frac{1}{2}}, \tag{22}$$

Again, if we define the dimensionless parameters in the following forms: $\Omega_{EA} = \frac{m}{3H_0\sqrt{\epsilon\beta}}$, $\Omega_{k0} = \frac{k}{H_0^2}$, $\Omega_{m0} = \frac{8\pi G\rho_{DM0}}{3H_0^2}$, $\Omega_{DE0} = \frac{8\pi G\rho_{DE0}}{3H_0^2}$, the above Eqn.(22) will reduces to the form given as follows:

$$H(z) = H_0\sqrt{\Omega_{EA}}\left[\Omega_{m0}(1+z)^3 - \Omega_{k0}(1+z)^2 + \Omega_{DE0}\left\{\mathcal{A} + (1-\mathcal{A})\left(\mathcal{A}_s + (1-\mathcal{A}_s)(1+z)^{3(1+\alpha)(1+\omega)}\right)^{\frac{1}{1+\omega}}\right\}^{\frac{1}{1+\alpha}}\right]^{\frac{1}{4}}, \tag{23}$$

Also, the above Eqn.(23) and Eqn.(13) will together leads to the following relation:

$$\sqrt{\Omega_{EA}}\ \left[\Omega_{m0} + \Omega_{DE0} - \Omega_{k0}\right]^{\frac{1}{4}} = 1. \tag{24}$$

Combining the above equations, we can obtain the following:

$$H(z) = H_0\left[\left\{\Omega_{m0}(1+z)^3 - \Omega_{k0}(1+z)^2\right\}\Omega_{EA}^2 + \left\{1 - \Omega_{EA}^2(\Omega_{m0} - \Omega_{k0})\right\}\left\{\mathcal{A} + (1-\mathcal{A})\left(\mathcal{A}_s + (1-\mathcal{A}_s)(1+z)^{3(1+\alpha)(1+\omega)}\right)^{\frac{1}{1+\omega}}\right\}^{\frac{1}{1+\alpha}}\right]^{\frac{1}{4}}. \tag{25}$$

B. Viscous Modified Chaplygin Gas (VMCG) Model:

If we appraised viscous modified Chaplygin gas (VMCG), a generalization of modified Chaplygin gas(MCG), considering the expansion process as of the cumulation of states that are out of thermal equilibrium resulting the bulk viscosity in the Einstein-Aether gravity context.The expression of pressure for VMCG is given by [56, 67, 68]:

$$p_{DE} = A\rho_{DE} - \frac{B}{\rho_{DE}^{\xi}} - 3\zeta_0\sqrt{\rho_{DE}}H, \tag{26}$$

where, A and B are constants.Also, ζ_0 stands for the positive coefficient of bulk viscosity and ξ is any positive valued constant. Substituting p_{DE} from Eqn.(26) into the Eqn.(18), we get:

$$\rho_{DE} = \left(\frac{B}{1 + A - \sqrt{3}\zeta_0} + \frac{C_1}{a^{3(1+\xi)(1+A-\sqrt{3}\zeta_0)}}\right)^{\frac{1}{1+\xi}}, \tag{27}$$

where C_1 represents the constant of integration. The above expression can be further re-written as:

$$\rho_{DE} = \rho_{DE0}\left\{B_s + (1-B_s)(1+z)^{3(1+\xi)(1+A-\sqrt{3}\zeta_0)}\right\}^{\frac{1}{1+\xi}}. \tag{28}$$

where ρ_{DE0} being the energy density value of the dark energy at the present epoch, $B_s = \frac{B}{(1+A-\sqrt{3}\zeta_0)C_1+B}$ satisfying the conditions $0 < B_s < 1$ and $1+A-\sqrt{3}\zeta_0 > 0$, and $\rho_{DE0}^{1+\xi} = \frac{(1+A-\sqrt{3}\zeta_0)C_1+B}{1+A-\sqrt{3}\zeta_0}$. From the above equations, we can obtain the following:

$$H(z) = H_0\Big[\left\{\Omega_{m0}(1+z)^3 - \Omega_{k0}(1+z)^2\right\}\Omega_{EA}^2 + \left\{1-\Omega_{EA}^2(\Omega_{m0}-\Omega_{k0})\right\}\left\{B_s + (1-B_s)(1+z)^{3(1+\xi)(1+A-\sqrt{3}\zeta_0)}\right\}^{\frac{1}{1+\xi}}\Big]^{\frac{1}{4}}. \tag{29}$$

III. METHODOLOGY

In cosmology, parameter estimation typically follows a Bayesian framework, where the goal is to compute the posterior distribution of parameters θ given observed data D. This is mathematically expressed as:

$$P(\theta \mid D) = \frac{\mathcal{L}(D \mid \theta)P(\theta)}{P(D)} \tag{30}$$

Here, $\mathcal{L}(D \mid \theta)$ represents the likelihood function, $P(\theta)$ is the prior distribution of the parameters, and $P(D)$ is the marginal likelihood. The posterior distribution is explored through the parameter space θ, often using algorithms such as Metropolis-Hastings [240]. This algorithm helps a random walker navigate the parameter space, giving preference to regions with higher likelihood values. To estimate the parameters, we determine the mean and error of the distribution by analyzing the regions where the walker frequently visits and its deviations within the parameter space. By allowing the walker to take numerous steps, we can approximate the shape of the posterior distribution. For Bayesian model selection, we calculate and compare the evidence for each model. This process typically demands significant computational resources, often utilizing nested sampling methods. However, when the posteriors resemble a Gaussian distribution, simpler tools like information criteria can offer reliable model preferences [241]. Our study explores new parameterizations for the dark energy equation of state (EoS) within both Einstein's gravity and Horava-Lifshitz gravity frameworks, determining the optimal values of the free parameters in each. Utilizing Markov Chain Monte Carlo (MCMC) analysis with the Polychord package facilitates efficient exploration of the parameter space and provides reliable estimates [242].

A. Cosmological data sets

For our Markov Chain Monte Carlo (MCMC) simulations, we utilize a diverse set of cosmological data. This includes data from Cosmic Chronometers [243–248] and Supernovae [249]

1. *Cosmic chronometers (CC)*

Cosmic chronometers are valuable tools for probing cosmic expansion, providing a model-independent method for determining the Hubble constant and the expansion rate. By analyzing the age and metallicity of nearby passive galaxies, we can estimate the expansion rate $H_{\rm CC}(z)$ at a given redshift $z_{\rm CC}$. This estimation is based on the observation that the expansion rate can be approximated by the ratio of the redshift difference to the time difference, adjusted for the redshift: $H_{\rm CC}(z) \approx -(\Delta z_{\rm CC}/\Delta t)/(1+z_{\rm CC})$. We collect cosmic chronometer data from various studies [243–248], covering the redshift range $0.07 \lesssim z \lesssim 1.97$, as compiled in [241]. These data provide direct constraints on the universe's expansion history. To evaluate how well theoretical predictions align with cosmic chronometer measurements at different redshifts, we calculate the chi-squared statistic $\chi^2_{\rm CC}$:

$$\chi^2_{\rm CC} = \sum_{i=1}^{31}\left(\frac{H(z_{\rm CC}) - H_{\rm CC}(z_{\rm CC})}{\sigma_{\rm CC}(z_{\rm CC})}\right)^2 \tag{31}$$

In this equation, $H_{\rm CC}(z_{\rm CC}) \pm \sigma_{\rm CC}(z_{\rm CC})$ represents the measured expansion rate at redshift $z_{\rm CC}$ along with its associated uncertainty. We assume that the cosmic chronometer observations are uncorrelated.

2. *Type Ia supernova (SNIa)*

We utilize the Pantheon+ compilation supernovae dataset [250] as our primary observational data source. This dataset encompasses 1701 data points collected from 1550 type Ia supernovae, spanning a redshift range of $0.001 \leq z \leq 2.3$. To assess the concordance between our theoretical model and the observed supernovae data, we

employ the χ^2 function, defined as:

$$\chi^2_{\text{Pantheon+}}(\Theta) = \mathbf{F}^T \cdot \mathbf{C}^{-1}_{\text{Pantheon+}} \cdot \mathbf{F} \tag{32}$$

Here, $\mathbf{C}_{\text{Pantheon+}}$ denotes the covariance matrix derived from the Pantheon+ dataset, accounting for both statistical and systematic uncertainties. The vector $\mathbf{F}$ comprises discrepancies between the apparent magnitudes $m_{B,i}$ and the predicted distance moduli μ_{model}, where the latter is determined by a chosen cosmological model:

$$\mu_{\text{model}}(z_i, \Theta) = 5\log_{10} D_L(z_i, \Theta) + 25 \tag{33}$$

The luminosity distance $D_L(z_i, \Theta)$ is computed as an integral of the Hubble parameter $H(z, \Theta)$ over redshift z, where Θ represents the set of cosmological parameters. Additionally, we adjust the vector $\mathbf{F}$ to accommodate the influence of Cepheid hosts on the absolute magnitude M, resulting in the modified vector $\mathbf{F}'$:

$$F'_i = \begin{cases} m_{B,i} - M - \mu_{\text{Ceph},i} & \text{if } i \text{ is in a Cepheid host} \\ m_{B,i} - M - \mu_{\text{model}}(z_i) & \text{otherwise} \end{cases} \tag{34}$$

Here, $\mu_{\text{Ceph},i}$ denotes the distance modulus associated with the Cepheid host of the i-th supernova, independently measured by Cepheid calibrators. Consequently, the modified χ^2 function is expressed as:

$$\chi^2_{\text{SNIa}} = \mathbf{F}'^T \cdot \mathbf{C}^{-1}_{\text{Pantheon+}} \cdot \mathbf{F}' \tag{35}$$

TABLE I: Summary of the MCMC Results.

IV. ACCRETIONS OF GCCG AND VMCG AROUND BLACK HOLE IN EINSTEIN-AETHER GRAVITY:

In this section, we are going to discuss about the mass accretion process of a 4-dimensional Einstein-Aether black hole.In this regard, let us consider a spherically symmetric and static black hole solution which have the following form:

$$ds^2 = -g(r)dt^2 + g^{-1}(r)dr^2 + r^2(d\Theta^2 + sin^2\Theta d\Phi^2). \tag{36}$$

The Einstein-Aether vector is given by [114]:

$$u^\mu(r) = \left(\delta(r) - \frac{\eta(r)}{g(r)}, \eta(r), 0, 0\right). \tag{37}$$

It would be in correspondence with the boundary condition that is the metric given by Eqn.(36) will reduces to that of the Minkowski metric only when as $r \to +\infty$, $u^\mu = (1, 0, 0, 0)$. Depending upon the coupling constants, we can have two types of exact black hole solutions from Einstein-Aether field of equations [92, 251, 252]. Among them the solution which is consistent with Eqn.(1) and represents a non-rotating black hole, is commonly known as first Einstein-Aether black hole solution.In this solution the metric function $g(r)$ is given as follows [107, 112, 114]:

$$g(r) = 1 - \frac{2M}{r} - \left(\frac{27e_{_{13}}}{256(1-e_{_{13}})}\right)\left(\frac{2M}{r}\right)^4, \tag{38}$$

Where, $e_{_{13}} = e_1 + e_3$ and the coupling constants satisfies the following conditions: $e_{_{14}} \equiv e_1 + e_4 = 0$, $e_{_{123}} \equiv e_1 + e_2 + e_3 \neq 0$. Also, the functions $\delta(r)$ and $\eta(r)$ of the Einstein-Aether framework are given by [114, 252]:

$$\delta(r) = \left(\frac{3\sqrt{3}}{16\sqrt{1-e_{_{13}}}}\left(\frac{2M}{r}\right)^2 + \sqrt{1 - \frac{2M}{r} + \frac{27}{256}\left(\frac{2M}{r}\right)^4}\right)^{-1}, \tag{39}$$

and

$$\eta(r) = -\frac{3\sqrt{3}}{16\sqrt{1-e_{_{13}}}}\left(\frac{2M}{r}\right)^2. \tag{40}$$

We will get the Schwarzschild black hole solution whenever $e_{_{13}} \to 0$. Now, to investigate the accretion process of the above type of black hole in Einstein-Aether gravity background, we need to assume the energy-momentum

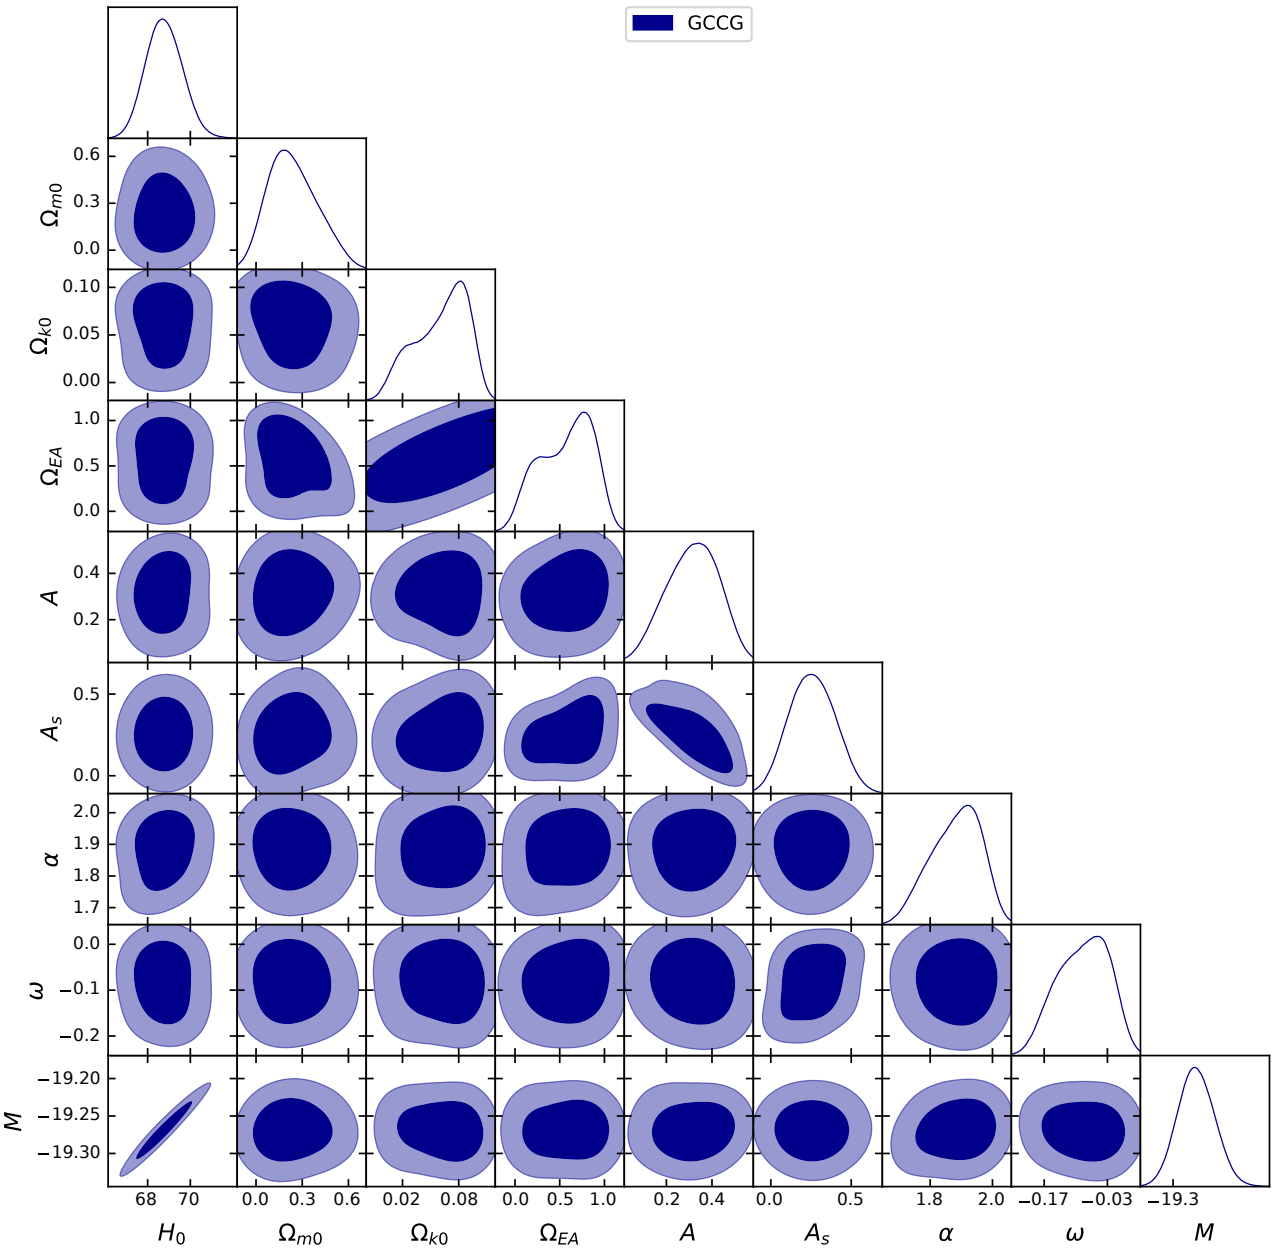

FIG. 1: The figure displays the posterior distribution for various observational data measurements using the Generalized Cosmic Chaplygin Gas Model, highlighting the 1σ and 2σ confidence levels.

tensor for the dark energy in the form of a perfect fluid whose equation of state is $p = p(\rho)$ given by:

$$T_{ij} = (\rho + p)\mathfrak{u}_i\mathfrak{u}_j + pg_{ij} \tag{41}$$

where, ρ and p are as usual the energy density and pressure of the dark energy.The fluid four-velocity vector taken as $\mathfrak{u}^i = \frac{dx^i}{ds}$ has the form $(\mathfrak{u}^0, \mathfrak{u}^1, 0, 0)$ and also satisfies the equation $\mathfrak{u}^i\mathfrak{u}_i = -1$, here only $\mathfrak{u}^0$ and $\mathfrak{u}^1$ are the two non-zero terms for this vector.Also, $\mathfrak{u} < 0$ for the fluid's inward flow towards the black hole. Considering the fact that the spherical symmetry of the black hole does not have any kind of changes due to the in-falling of dark energy fluid, we are going to advance in this accretion process. The time component of the relativistic Bernoulli's equation for the conservation of T_{ij} leads us to the following:

$$\mathfrak{u}r^2M^{-2}\left(\rho + p\right)\left(\sqrt{g(r) + \mathfrak{u}^2}\right) = I_0, \tag{42}$$

This is the first integral of motion, where I_0 stands for an integration constant having the same dimension as of the energy density. Again to obtain the second integration of motion, mostly known as the energy flux equation, we

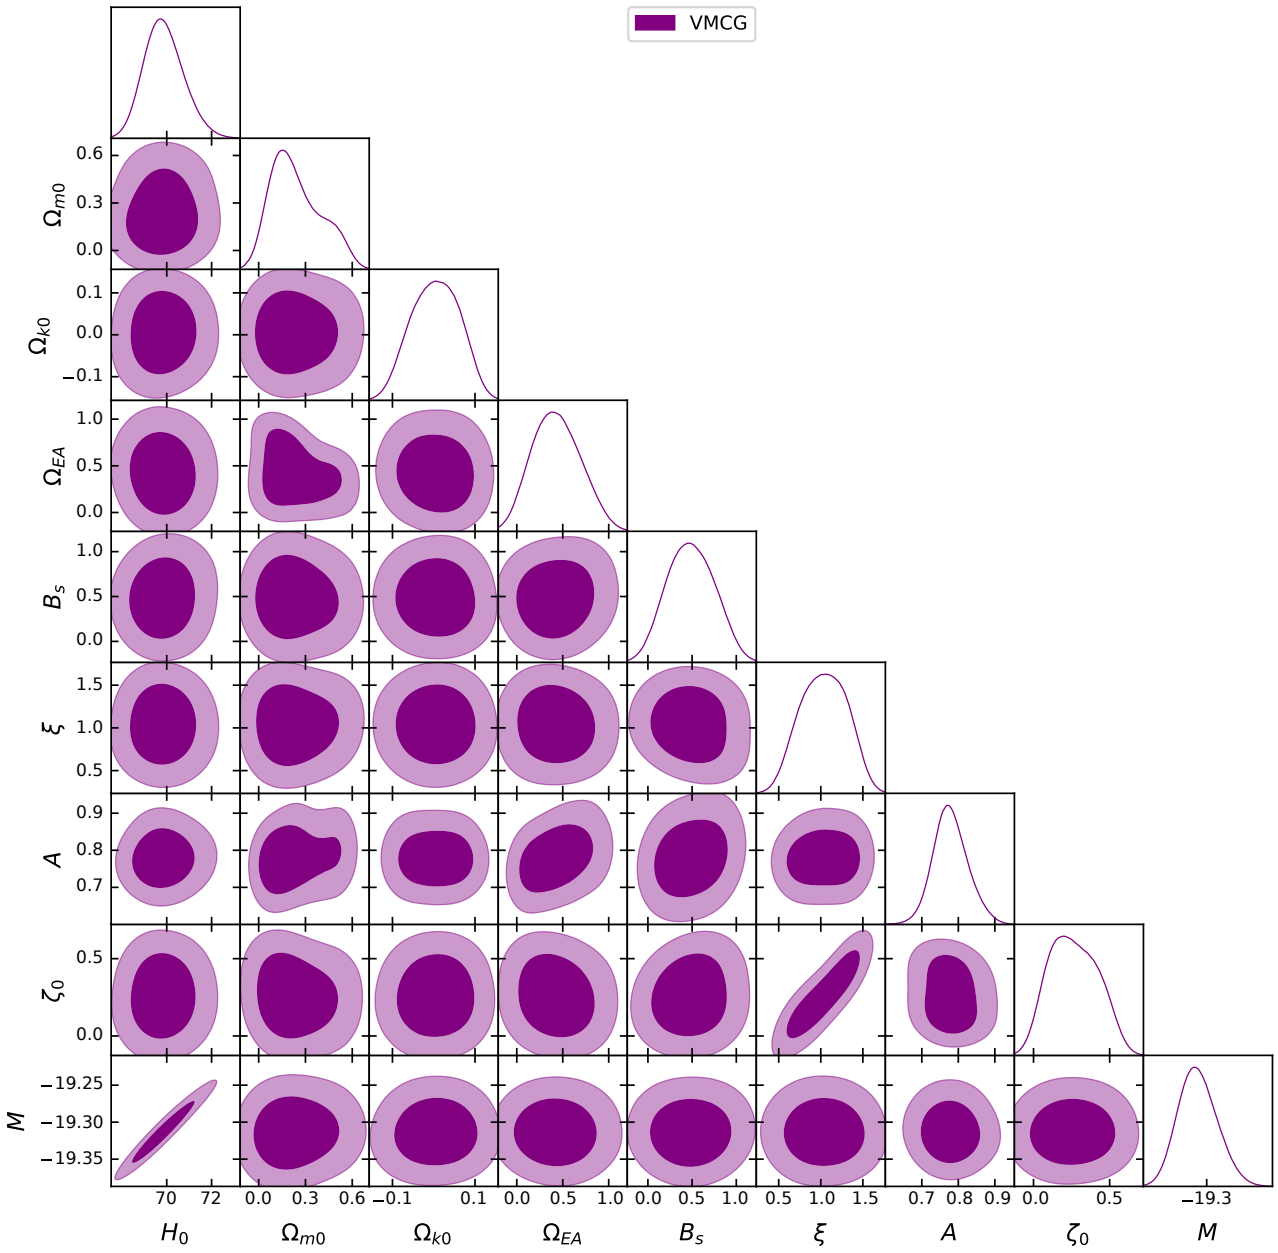

FIG. 2: The figure displays the posterior distribution for various observational data measurements using the Viscous Modified Chaplygin Gas Model

need to project T_{ij} onto $\mathfrak{u}^i = \frac{dx^i}{ds}$, which is given by the equation $\mathfrak{u}_i T^{ij}_{;j} = 0$ and can be written in simplified form as $\mathfrak{u}^i \rho_{,i} + (\rho + p)\mathfrak{u}^i_{;i} = 0$ will lead us to the following:

$$\mathfrak{u} r^2 M^{-2} exp\left[\int_{\rho_\infty}^{\rho} \frac{d\tilde{\rho}}{\tilde{\rho} + p(\tilde{\rho})}\right] = -I_1, \tag{43}$$

where I_1 is another integration constant, predominantly related to the energy flux onto the black hole, given by [214, 215, 253]. The related negative sign has been used for the convenience of the calculation. Energy densities of the black hole at horizon and infinity are given by ρ and ρ_∞, respectively. Now, by dividing the above two equations, we will have the following equation:

$$(\rho + p)\left(\sqrt{g(r) + \mathfrak{u}^2}\right) exp\left[-\int_{\rho_\infty}^{\rho} \frac{d\tilde{\rho}}{\tilde{\rho} + p(\tilde{\rho})}\right] = I_2, \tag{44}$$

Here, the constant I_2, used in the RHS of the above equation, is given by: $I_2 = -\frac{I_0}{I_1} = \rho_\infty + p(\rho_\infty)$. To compute the rate of change of mass of the black hole, i.e. $\dot{M}$ we need to integrate the flux of the dark energy over the 4-dimensional volume of the black hole [226, 254]:

$$\dot{M} = -4\pi I_0 M^2, \tag{45}$$

Now, considering the value of I_0, the above Eqn.(45) will become:

$$\dot{M} = 4\pi I_1 M^2 \left[\rho_\infty + p(\rho_\infty)\right], \tag{46}$$

From the Eqn.(46), we will get the rate of change of mass of a 4-dimensional black hole. Interestingly, for all the values of ρ and p which are in contrast with dominant energy condition, the above equation performs quite efficiently. So, in general, the above equation can be written as follows:

$$\dot{M} = 4\pi I_1 M^2 (\rho + p). \tag{47}$$

The above equation clearly implies that the changes in the mass of the black hole solely depends upon the term $\rho + p$. So, in the case of phantom energy dominance, universe will contract as $(\rho + p) < 0$ in this case. On the other hand in the case of quintessence kind of dark energy dominance, where $(\rho + p) > 0$ the universe will expand. Again, envisaging the Einstein-Aether gravity framework, we will get the following equation by using the Eqn.(13) and Eqn.(15) as follows:

$$(\rho + p) = -\frac{\dot{\rho}}{3}\left[\frac{\beta(-E' + \frac{E}{2K} + 1)}{\frac{8\pi G}{3}\rho - \frac{k}{a^2}}\right]^{\frac{1}{2}}. \tag{48}$$

Now, making use of Eqn.(48) into the Eqn.(47) and taking integration on both sides, we will obtain the required equation of mass in the following form:

$$M = \frac{M_0}{1 + \frac{4\pi I_1 M_0}{3}\int_{\rho_0}^{\rho} \frac{d\rho}{\sqrt{\frac{\left(\frac{8\pi G\rho}{3} - \frac{k}{a^2}\right)}{\beta\left(1 - E' + \frac{E}{2K}\right)}}}} \tag{49}$$

where M_0 represents the current mass of the black hole and ρ_0 represents the current energy density which can be written as $\rho_0 = \rho_{DM0} + \rho_{DE0}$.

The above equation can be written in a more simplified manner as follows:

$$M = \frac{M_0}{1 + \frac{4\pi I_1 M_0}{3}\int_{\rho_0}^{\rho} \frac{d\rho}{\sqrt{\frac{\left(\frac{8\pi G\rho}{3} - \frac{k}{a^2}\right)}{\left(\beta + \frac{15\epsilon\beta H^2}{m^2} - 1\right)}}}}. \tag{50}$$

The above Eqn.(50) is our desired equation of mass of a 4-dimensional black hole in Einstein-Aether gravity framework. Now, let us consider some Chaplygin gas models and analyzed their effects onto the mass of the Black hole during the evolution of the Universe.

A. Generalized Cosmic Chaplygin Gas (GCCG) Model:

We have already discussed this particular kind of Chaplygin gas in Sec.II A. Now, here we are going to investigate the accretion process of GCCG onto a 4-dimensional Einstein-Aether black hole. In this regard, considering Eqn.(18), Eqn.(21), Eqn.(24) and Eqn.(25) into Eqn.(50) all at once, we will get the desired equation of mass as follows:

$$M = \frac{M_0}{1 + \frac{4\pi I_1 M_0}{3}\int_{\rho_0}^{\rho} \frac{d\left(\frac{3H_0^2}{8\pi G}\left[\Omega_{m0}(1+z)^3 + \left(\Omega_{EA}^{-2} + \Omega_{k0} - \Omega_{m0}\right)\left\{\mathcal{A} + (1-\mathcal{A})\left(\mathcal{A}_s + (1-\mathcal{A}_s)(1+z)^{3(1+\alpha)(1+\omega)}\right)^{\frac{1}{1+\omega}}\right\}^{\frac{1}{1+\alpha}}\right]\right)}{\sqrt{\left(\frac{8\pi G\left(\frac{3H_0^2}{8\pi G}\left[\Omega_{m0}(1+z)^3 + \left(\Omega_{EA}^{-2} + \Omega_{k0} - \Omega_{m0}\right)\left\{\mathcal{A} + (1-\mathcal{A})\left(\mathcal{A}_s + (1-\mathcal{A}_s)(1+z)^{3(1+\alpha)(1+\omega)}\right)^{\frac{1}{1+\omega}}\right\}^{\frac{1}{1+\alpha}}\right]\right)}{3} - \frac{k}{a^2}\right)}{\left(\beta + \frac{15\epsilon\beta\left(H_0^2\left[\left\{\Omega_{m0}(1+z)^3 - \Omega_{k0}(1+z)^2\right\}\Omega_{EA}^2 + \left\{1 - \Omega_{EA}^2(\Omega_{m0} - \Omega_{k0})\right\}\left\{\mathcal{A} + (1-\mathcal{A})\left(\mathcal{A}_s + (1-\mathcal{A}_s)(1+z)^{3(1+\alpha)(1+\omega)}\right)^{\frac{1}{1+\omega}}\right\}^{\frac{1}{1+\alpha}}\right]^{\frac{1}{2}}\right)}{m^2} - 1\right)}}}. \tag{51}$$

The above Eqn.(51) stands for the equation of mass of a 4-dimensional Einstein-Aether black hole due to the ac-

cretion of GCCG. The effects of GCCG accretion onto the black hole mass M have been portrayed by the Fig.3 in terms of redshift function z, which clearly shows the increase in black hole mass with the evolution of our universe caused by the accretion of GCCG.

B. Viscous Modified Chaplygin Gas (VMCG) Model:

In Sec.II B we have briefly talked about VMCG model, hence here we are going to explore its accretion process onto a 4-dimension Einstein-Aether black hole. If we consider Eqn.(18), Eqn.(24), Eqn.(28) and Eqn.(29) altogether in Eqn.(50), we will have the desired equation of mass as follows:

$$M=\frac{M_0}{1+\frac{4\pi I_1 M_0}{3}\int_{\rho_0}^{\rho}\frac{d\left(\frac{3H_0^2}{8\pi G}\left[\Omega_{m0}(1+z)^3+\left(\Omega_{EA}^{-2}+\Omega_{k0}-\Omega_{m0}\right)\left\{B_s+(1-B_s)(1+z)^{3(1+\xi)(1+A-\sqrt{3}\zeta_0)}\right\}^{\frac{1}{1+\xi}}\right]\right)}{\sqrt{\left(\frac{8\pi G\left(\frac{3H_0^2}{8\pi G}\left[\Omega_{m0}(1+z)^3+\left(\Omega_{EA}^{-2}+\Omega_{k0}-\Omega_{m0}\right)\left\{B_s+(1-B_s)(1+z)^{3(1+\xi)(1+A-\sqrt{3}\zeta_0)}\right\}^{\frac{1}{1+\xi}}\right]\right)}{3}-\frac{k}{a^2}\right)\left(\beta+\frac{15\epsilon\beta\left(H_0^2\left[\left\{\Omega_{m0}(1+z)^3-\Omega_{k0}(1+z)^2\right\}\Omega_{EA}^2+\left\{1-\Omega_{EA}^2(\Omega_{m0}-\Omega_{k0})\right\}\left\{B_s+(1-B_s)(1+z)^{3(1+\xi)(1+A-\sqrt{3}\zeta_0)}\right\}^{\frac{1}{1+\xi}}\right]^{\frac{1}{2}}\right)}{m^2}-1\right)}}}. \tag{52}$$

The above Eqn.(52) stands for the equation of mass of a 4-dimensional Einstein-Aether black hole due to the accretion of VMCG. The effects of VMCG accretion onto the black hole mass M have been portrayed by the Fig.4 in terms of redshift function z which clearly shows the increase in black hole mass with the evolution of our universe caused by the accretion of VMCG. In Fig.5 the comparison of mass change with redshift has been depicted for GCCG model, VMCG model as well as ΛCDM model of the universe alongside eachother.

V. RESULTS

Figures 1 and 2 illustrate the 68% and 95% confidence intervals for key cosmological parameters in the Generalized Cosmic Chaplygin Gas (GCCG) Model and the Viscous Modified Chaplygin Gas (VMCG) Model, respectively. Table I summarizes the MCMC results for three cosmological models: the ΛCDM model, the GCCG Model, and the VMCG Model. All three models yield consistent H_0 values around 69.85, aligning with the findings in [255]. The ΛCDM model and the VMCG model exhibit tighter constraints compared to the GCCG model. However, the matter density parameter (Ω_{m0}) is lower than the values reported in [255] ($\Omega_{m0}=0.315\pm0.007$) for all three cases. Then we have proceeded to observe the mass accretion process, with the help of these estimated values of parameters. The outcomes have been more than satisfactory as we have obtained the mass equation of a 4-dimensional Einstein-Aether black hole in terms of some dimensionless density parameters and redshift function z. After plotting the results as black hole mass M vs redshift z graphs in Fig.3 and Fig.4, respectively, we can distinctly observe that with time, black hole mass increases for both the generalized cosmic Chaplygin gas (GCCG) model and viscous modified Chaplygin gas (VMCG) model. In Fig.5, we can observe separately the pattern of black hole mass M vs redshift z graphs in the cases of generalized cosmic Chaplygin gas (GCCG), viscous modified Chaplygin gas (VMCG) as well as ΛCDM model of the universe. All of the above-mentioned models show an increase in black hole mass with the expansion of the Universe, just as predicted in the case of the dark energy-induced Universe.

VI. CONCLUSIONS

Black Holes have always been an object of fascination for cosmologists. Several studies have been conducted on them time and again. In this study, we have investigated Einstein-Aether black holes, basically about their mass accretion process. Firstly, we have considered the non-flat FRW model of the universe, which combines dark matter and dark energy. Then in the framework of Einstein-Aether gravity, we have taken the modified Friedmann equations. Applying the conservation equation on dark matter and dark energy separately has led us to energy densities of the dark matter and dark energy, respectively. Also, for the simplicity of the calculation, we have taken $E(K)$ as a quadratic function of K. Afterward, we contemplated two different kinds of dark energy models: the generalized cosmic

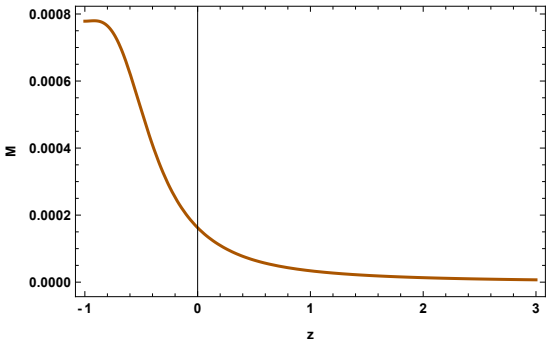

FIG. 3: The changes in BH mass M against redshift function z on the account of GCCG accretion.

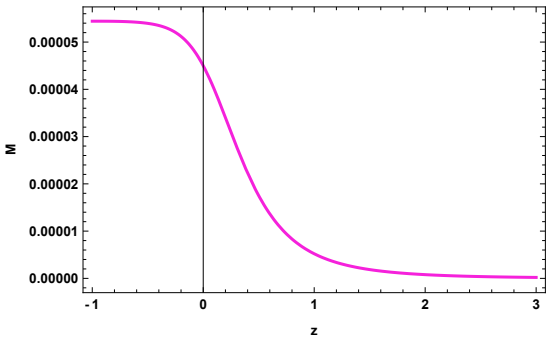

FIG. 4: The changes in BH mass M against redshift function z on the account of VMCG accretion.

Chaplygin gas (GCCG) model and the viscous modified Chaplygin gas (VMCG) model as the candidates for dark energy. In both cases, we have calculated the energy density and Hubble parameter equation in terms of some dimensionless density parameters and some unknown parameters one by one. Next, we selected 31 uncorrelated data points from Cosmic Chronometers and 1701 data points from the Type Ia Supernova dataset to obtain the best-fit values for the model parameters using MCMC. Finally, after estimating the required parameters, we analyzed the mass accretion process of a 4-dimensional Einstein-Aether black hole. Primarily we have obtained the mass equation for both the generalized cosmic Chaplygin gas (GCCG) model and viscous modified Chaplygin gas (VMCG) model one after another. Then we have picturized the result through the black hole mass M vs. redshift function z graph in Fig.3 for the case of GCCG accretion and in Fig.4 for the case of VMCG accretion respectively. Both Fig.3 and Fig.4 clearly show that the black hole mass will only grow larger with time. Again, in Fig.5, we have picturized the comparison of the black hole mass M vs. redshift function z graph for the GCCG model, VMCG model as well as ΛCDM model of the universe in the case of Einstein-Aether gravity. So, on the whole, we can conclude that with the expansion of the universe, a 4-dimensional Einstein-Aether black hole mass will increase for accretion of dark energies like generalized cosmic Chaplygin gas and viscous modified Chaplygin gas as well as in the case of ΛCDM model of the Universe.

VII. ACKNOWLEDGEMENTS

PM is thankful to IIEST, Shibpur, India, for providing Institute Fellowship (JRF).

Toward Multimodal Complaint Severity Detection From Social Media

Apoorva Singh, Prince Jha, Souryadip Das, Raghav Jain, and Sriparna Saha, *Senior Member, IEEE*

***Abstract*—The prevalence of complaints submitted online and the sheer volume of information made available by social media platforms highlight the need for automated complaint analysis tools. In linguistic studies, complaints have been classified according to how much of personal risk the complainant is willing to take. This is crucial information for understanding the motivations of complainants and how people come up with reasonable means of reparation. Few attempts have been made to use the existing multimodal complaint model, which focuses on improving the textual mode with the help of images, to find specific visual features that help identify complaints. Our aim is to find a solution to this problem. In order to detect complaints and the severity level associated with them in a multitask setting, we propose Multimodal framEwork for Complaint and Severity-level detectIon (MECSI), a novel multimodal framework that uses local and global attributes (in both modalities) and relates them to the textual context. To do this, we add severity-level annotation to the newly released CESAMARD dataset, which is a compilation of reviews and images of products listed on the Amazon website. The experimental findings confirmed the superiority of our proposed model over the state-of-the-art model and other strong rival baselines, proving the efficacy of our proposed framework.**

***Index Terms*—Multimodal complaint detection, multimodal dataset, multitask learning, severity-level classification, social media mining.**

I. Introduction

In linguistics, complaints are categorized based on emotional depth through severity levels, the level of face threat involved, and the intentions behind them [1]. Complaints serve to express dissatisfaction, seek clarification, or achieve both objectives. Recognizing and evaluating complaints and their severity levels in natural language holds crucial importance for businesses aiming to enhance customer relations by addressing and resolving issues. Additionally, it provides linguists with a broader scope for analyzing complaint speech acts across varying levels of granularity [2].

When making a purchasing decision, we pay attention to the associated texts and images in a review post. To ascertain the user's legitimate interest in the product, information from several modalities must be analyzed together. Multimodal inputs contribute to the development of effective classification models, which enable the identification of the customer's affective state and sentiment as well as the detection of genuine complaints and their associated severity levels.

Recent work on multimodal CD [3] has shown that off-the-shelf vision models, which work well on visual-linguistic tasks, do not help much when adapted to product images signifying complaints. Some challenges include: First, user-uploaded images can be chaotic, so relying solely on them without product and category context is often insufficient. Second, in product reviews, visual and textual information are sometimes uncorrelated and the entire semantics is provided in entirety. Fig. 1 illustrates two different complaint scenarios communicated via both modalities. The first image shows a low-quality page. The textual modality lacks explicit criticism. Therefore, relying solely on textual analysis does not reliably predict a violation of expectation. In one scenario, the text implies a neutral review, while the visuals suggest a negative allegation. These differing modalities in both cases highlight the importance of multiple evidence sources for detecting complaints.

Research objectives: The current study aims to achieve the following.

1) We intend to investigate how multimodal cues help identify complaints and associated severity levels from social media content.
2) We aim to understand the effect of polarity and emotion recognition (ER) tasks individually and in different combinations in the proposed framework.
3) This work aims to study multimodal complaint and severity-level prediction using local information and background knowledge (global attributes) for text and image modalities.

Contributions: The main contributions of the current work include the following.

1) We manually annotate the recently released multimodal complaint dataset, CESAMARD, with complaint severity labels for aiding fine-grained analysis of multimodal complaint severity-level prediction research.
2) We propose Multimodal framEwork for Complaint and Severity-level detectIon (MECSI), a novel multimodal framework that uses local and global attributes and relates

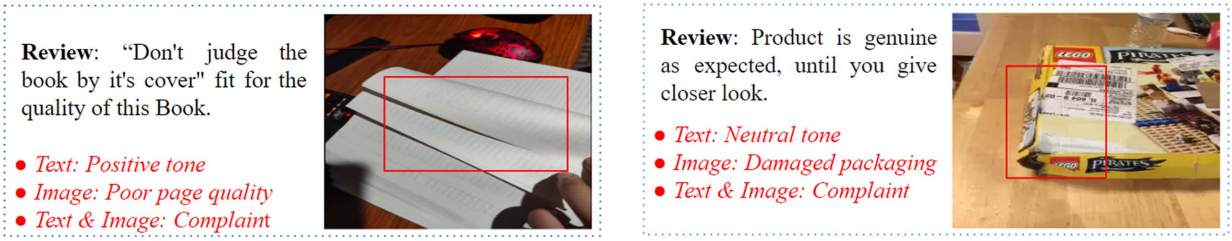

Fig. 1. Some sample instances highlight the influence of multimodal inputs in complaint detection (CD).

them to the textual context to detect complaints and associated severity-level in a multitask setting. CD and complaint severity-level classification (CS) are the main tasks and ER and polarity classification (PC) are considered additional tasks in the multitask framework.

3) We propose the benchmark model for complaint and severity-level prediction in a multimodal multitask setting.

The remainder of the manuscript follows this structure: First, we provide a concise summary of the current literature in Section II. Next, Section III delves into the details of the expanded *CESAMARD* dataset. Subsequently, in Section IV, we explain our novel multimodal multitask approach to detect complaints and severity from social media content. Section V is dedicated to discussing the experimental setup and analyzing the results. Finally, in Section VI, we present a summary and conclusion, along with a glimpse of potential future research directions.

II. Related Works

Earlier works in pragmatics interpreted complaints based on their intensity and straightforwardness [4]. Complaints were categorized into four fine-grained severity classifications, according to [1]: 1) no specific reproach; 2) disapproval; 3) accusation; and 4) blame. Prior studies in complaint diagnosis have primarily focused on distinguishing between complaints and noncomplaints. They employed various approaches including feature-based machine learning models [5], deep transformer-network-based models [6], and text-based multitask modeling techniques that incorporated polarity and emotion information for complaint mining [7], [8]. In [5], the authors used logistic regression with several different features to detect Twitter-based complaints. In a recent work on complaint mining, [9] trained multiple transformer-based networks using linguistic information to make predictions about the severity level of complaints from social media.

A. Multimodal and Multitask Learning

Recent studies such as [7], [10], [11], [12], and [13] have shown the efficacy of multitask learning where multiple related tasks are learned simultaneously by a single model. Although polarity and emotion are two separate concepts [14], they are strongly related. This is also because polarity and emotion are mostly concerned with perceptions that occur as a result of a combination of biological, psychological, and social conditions [15]. Numerous works in the literature examine the simultaneous analysis of PC and ER [10], [16], and others, along with their usage in various natural language processing tasks [17] and others. Multimodality has emerged as a major research subject in the field of emotion and polarity detection in human interactions [18], [19], [20].

B. Complaint Identification

The abundance of online information has made it increasingly difficult for companies and merchants to effectively identify and resolve complaints. This is particularly challenging when screening complaints on social networking sites, where the text fragments are often chaotic and limited by character count, and may include the use of aliases, satire, and allegations [21]. To address this, a new approach to CD has emerged that involves a multimodal approach instead of relying solely on text-based classification. Earlier research has applied methods such as semisupervised techniques, hand-crafted feature-based machine learning techniques, and deep learning models to recognize text-based complaints [5], [8], [22]. For example, logistic regression with customized features was used in [5], while a variety of neural language models supplemented by transformer networks were used in [6]. Complaints have been sorted according to the accountable department, urgency level, delivery issues, and the hazards and risks associated with the product [23], [24], [25]. Some studies have also focused on the propensity for complaints to escalate, in workplace emails, boosting ensemble models with linguistic style parameters have been employed to identify complaints [26].

Even though it has been hypothesized that multimodal sources of information (such as images along with text) might offer additional relevant data in detecting complaints, only the work by [3] has looked into this. However, while they worked to improve the textual modality, they instead used the generic ResNet-152 image classification model for the visual modality, which does not account for any of the unique characteristics of images that might be used to identify product-related complaints. As a result, we propose MECSI, a deep learning-based multimodal framework that detects complaints and correlates severity levels in a multitask setup using local and global attributes (for both modalities).

III. Corpus Description

To date, available complaint datasets have only covered textual complaints [5], [9]. We use the CESAMARD dataset[1] published in [3]. The CESAMARD dataset is a compilation

TABLE I
COMPARATIVE STUDY OF EXISTING COMPLAINT CORPORA

Dataset	Labels				
	Complaint	Severity	Polarity	Emotion	Images
Complaints [5]	✓	×	×	×	×
Complaints [9]	✓	✓	×	×	×
Complaints [7]	✓	×	✓	✓	×
CESAMARD [3]	✓	×	✓	✓	✓
CESAMARD v2 (current work)	✓	✓	✓	✓	✓

of reviews and images of products bought from Amazon.[2] The dataset contains 3962 instances, 2641 of which are noncomplaints, and 1321 of which are complaints. Since it is a publicly available, high-quality multimodal complaint dataset, we opted to use it for the current study. According to the linguistic definition provided by [27], if a given instance of a CESAMARD review contains at least one complaint speech act, the complete review is interpreted as a complaint. There are three types of polarity to consider: negative, neutral, and positive. Anger, disgust, fear, happiness, sadness, and surprise are the six key emotions used for emotion annotation based on the work of psychologist Paul Ekman. In this article, we delve into the finer details of the CESAMARD dataset's extension (*CESAMARD v2*). The expanded *CESAMARD v2* dataset is compared to other complaint datasets in Table I.

A. Task Definition

The primary objective of this work is to extend the CESAMARD dataset with severity-level annotation. We utilize the severity classes defined in the benchmark study[3] [1]. Following are the severity classes.

1) No explicit reproach: The complaint is of a neutral tone, and the reason for the complaint is not expressed explicitly.
2) Disapproval: Complaint explicitly shows negative emotions such as annoyance or discontent. The claim may imply that the complainant holds the complainee accountable without saying so.
3) Accusation: Complainant directly charges someone of wrongdoing.
4) Blame: Complainant holds someone responsible for wrongdoing.

B. Annotation

The three annotators (one doctoral and two undergraduate computer science students) with sufficient domain knowledge and experience in developing supervised corpora annotated the severity classes for each instance in the dataset. The selection process for the three students underwent a rigorous competition, allowing participation exclusively from the computer science department with expertise in natural language processing. Initially, an adept doctoral student having experience in the CD domain annotated 50 examples for each severity class, establishing gold standard references for annotation and ambiguity resolution. Students were provided with the annotation guidelines outlined in Table II. Following this, they annotated 50 samples, and based on the quality, accuracy, and semantic coherence of their annotations, three students were selected to proceed with annotating the CESAMARD dataset samples.

TABLE II
SEVERITY LEVEL ANNOTATION INSTRUCTIONS

S.No.	Annotation Guidelines
1	Severity levels classify complaints by nature rather than intensity.
2	"No explicit reproach" is an indicative approach in which the complainee is typically left out of the statement.
3	"Disapproval" conveys only an undesirable feeling or situation.
4	In "Blame," the complainer believes the complainee is directly responsible for the crime.
5	In case of ambiguity, annotators, and authors collaborate to discuss and clarify the instance.

Majority voting determined the final severity classes. In cases where the annotations differed among the three annotators, the doctoral student expert endeavored to resolve any ambiguity or uncertainty. Instances where a consensus was not reached among annotators were excluded from consideration. To measure the interrater agreement, we computed Fleiss' kappa score and achieved an agreement score of 0.67 (k) for the severity task, indicating high-quality annotations and significant agreement [28]. In the work [3], the authors state the interrater agreement scores of 0.83, 0.69, and 0.81 on the complaint, emotion, and polarity task, respectively, depicting good quality annotation. The distribution of tweets across complaint severity classes is as follows: *Accusation* (254), *Blame* (238), *Disapproval* (433), and *No explicit reproach* (396). Table III shows examples from the *CESAMARD v2* dataset.[4]

IV. METHODOLOGY

This section details the specifics of the proposed architecture. Fig. 2 depicts the proposed MECSI model's architecture.

Problem definition: We aim to detect complaints and associated severity levels from product reviews in a multimodal, multitask setting. The training data consists of R review instances, and is represented as $\{[T, I, W, c, s, e, p]_i\}_{i=1}^{N}$, where T denotes

TABLE III
FEW EXAMPLES FROM THE *CESAMARD v2* CORPUS. COMP: COMPLAINT

Title	Review	Label	Severity	Emotion	Polarity
Poor printing quality of the book	Received the book. Many pages of the book are blank, not readable due to poor printing. Disappointed!	Comp	Disapproval	Sadness	Negative
Rotten product	The package when opened was full of worms, the lentil was foul smelling. Picture attached. Coming from Tata's surprised; disappointed.	Comp	Accusation	Disgust	Negative
Defective product	Seems such as a quality defective product is being sold online... without even checking! There is a button missing in the shirt I received!!	Comp	Blame	Anger	Negative

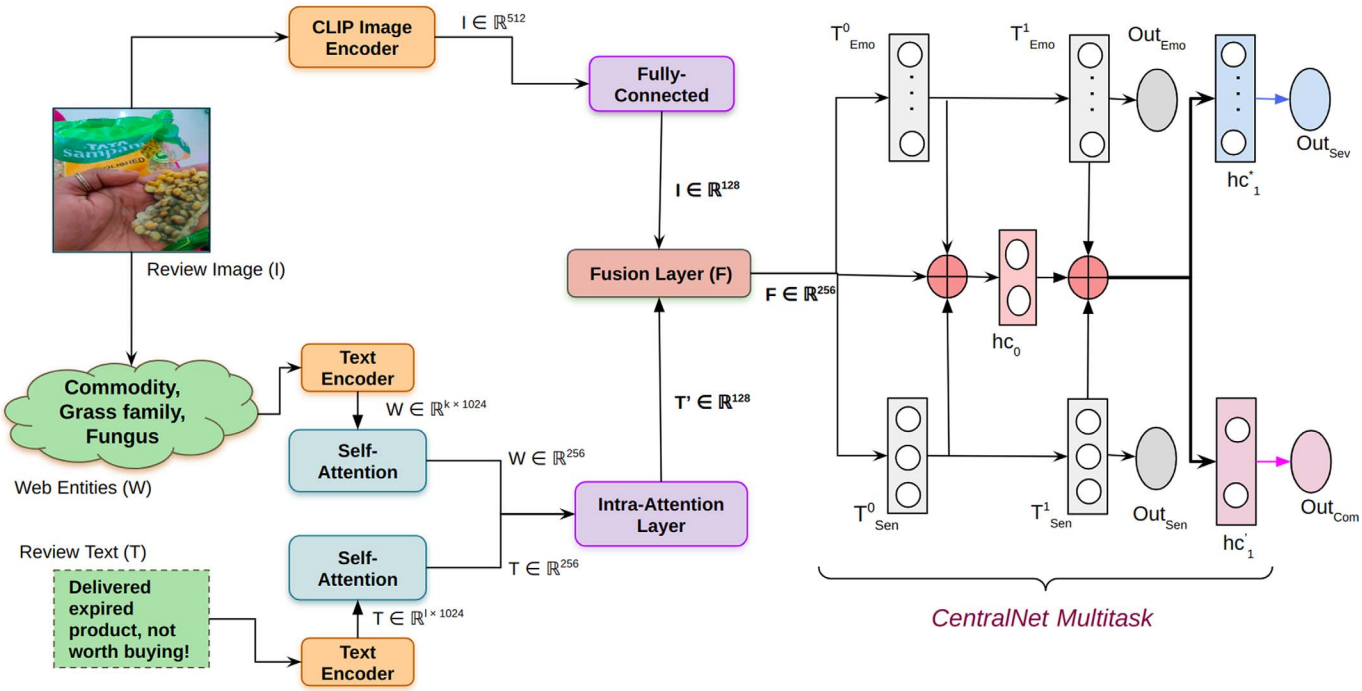

Fig. 2. Architectural diagram of the proposed model, MECSI. T^0_{Emo} is the hidden representation of Emotion task-specific network at 0th layer. T^0_{Sen} is the hidden representation of sentiment task-specific network at 0th layer.

the review text, I is the review image, and W is the web entity tag, c denotes the complaint label, s is the severity label, e is the emotion class label, and p is the polarity class label.

A. Feature Composition Module

This section discusses the feature extraction techniques used for different modules.

1) *CLIP*: For image encoding we utilize contrastive language-image pretraining (CLIP) [29], a pretrained visual-linguistic model, exploiting its encoding abilities to preserve the whole semantic. CLIP was trained using 400 million image-text pairs obtained from the Internet. CLIP provides excellent zero-shot capabilities due to the large number of images it has encountered and the natural language monitoring. We retrieved the CLIP image embedding, F_I which is a 512-dimensional vector.
2) *BERT*: For the review-text, the wordwise textual features are obtained by averaging the last four hidden states of a pretrained bidirectional encoder representations from transformers model [30]. We use *bert-large-uncased* model[5] (uncased: 12-layer, 1024-hidden, 12-heads, 110 M parameters).
3) *Web entities*: Inspired by [31], we introduce web entities[6] as a more advanced image concept for our model. The review images displayed in Fig. 3 manifest entities such as fabric, juicer, grinder-mixer, outerwear, etc., presenting contextual information corresponding to each image, aiding in complaint identification. Leveraging the Google Cloud Vision API,[7] we foreground various web entities.

[5]https://huggingface.co/bert-large-uncased
[6]Objects of interest are highlighted within rectangular bounding boxes.
[7]https://cloud.google.com/vision/docs/detecting-web

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on June 05,2024 at 06:53:02 UTC from IEEE Xplore. Restrictions apply.

This article has been accepted for inclusion in a future issue of this journal. Content is final as presented, with the exception of pagination.

Fig. 3. Identified web entities in a selection of images sourced from the *CESAMARD v2* dataset.

Let us assume that for a given review image input, the entities are denoted as $P_1, P_2, \ldots, P_k$. Each web entity is encoded using a $\text{BERT}_{\text{large}}$ encoder to create 1024-dimensional features. These features are represented as $O_f = f_1, f_2, \ldots, f_k$, where $O_f \in R^{k\times 1024}$.

B. Attention Technique

We compute attention by associating a query with key-value pairs to produce an output. This output is determined by the weighted sum of values, with weights assigned based on the compatibility function between a query and its respective key.

1) *Self attention*: We utilize self-attention across l review texts and k web entities to allocate weights to the most pertinent entities based on their relevance or importance within the given context. These weights are calculated by assessing the compatibility between each entity and every other entity in the respective set, individually for both the review texts and the web entities. Consequently, the resulting weights signify the significance of each entity relative to the others, enabling the model to prioritize the most relevant entities during processing. The resultant self-attended representations can be expressed as: $\text{SA}_i = \text{softmax}(Q_i K^T i)Vi$, where i belongs to the set of web entities, review text.
2) *Intramodality attention*: Review text is significant for some product reviews meanwhile web entities provide background context that acts as a higher-level concept regarding the review image. Hence both the modalities (text and web entity) play crucial roles in their own way. To merge both textual modalities, intramodality attention [32] has been employed. Both the self-attended representations of review text and web entities are concatenated into a vector and passed through dense layers. Finally, a sigmoid activation function is used to calculate attention scores. These attention values are the weights of each modality, and the resulting modality representations T', which is further fed into the fusion layer.

C. Fusion Layer

Both textual and visual modalities may not be equally significant for identifying the complaint. This encourages the development of a fusion network that takes into account each modality independently, similar to the work of [33].

The fusion layer takes in the textual modality $M_{T'}$ and visual modality M_I. These modalities are combined by concatenating them to create a vector V. This vector then undergoes a dense layer followed by a sigmoid activation function, computing attention scores. These scores determine the importance of each modality, and their representations are combined to form the fusion vector F. The mathematical specifics are detailed in the following equation:

$$\begin{aligned} V &= M_{T'} \bigoplus M_I \\ \text{Att}_{T'} &= \sigma(W_{T'}^T V + b_{T'}) \\ \text{Att}_I &= \sigma(W_I^T V + b_I) \\ F &= \text{Att}_{T'}.M_{T'} \bigoplus \text{Att}_I.M_I. \end{aligned} \tag{1}$$

F is then passed through CentralNet Multitask Network for the decision process.[8]

D. CentralNet Multitask

Inspired by the line of works made by [33], we introduce CentralNet Multitask. It is a neural network architecture with n independent subnetworks, where $n-1$ subnetworks are devoted to auxiliary tasks and 1 is for the main task. Complaints can be identified and their severity can be predicted at a standard layer known as the central network. The central network accumulates features learned for individual tasks by considering a weighted summation of task-specific networks and their previous layers (polarity, emotion). The multitask layers can be defined as follows:

$$h_{c_{i+1}} = \alpha_{c_i} h_{c_i} + \sum_{k=1}^{n-1} \alpha_{T_i^k} T_i^k$$

where $n-1$ denotes number of task-specific networks, α's are scalar trainable weights, h_{c_i} is the central hidden representation of the main task and T_k^i is the hidden representation of kth task-specific network at ith layer. $h_{c_{i+1}}$ is the ultimate layer, which passed to a fully connected layer accompanied by an activation function. The initial layer of CentralNet Multitask is a shared representation obtained from the fusion layer.

Loss function: The categorical-cross entropy (J_{CE}) losses are calculated for the complaint (CD), severity (CS), emotion (ER),

[8] $\{W_{T'}^T, W_I^T, b_{T'}, b_I\}$ are learnable parameters.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on June 05,2024 at 06:53:02 UTC from IEEE Xplore. Restrictions apply.

This article has been accepted for inclusion in a future issue of this journal. Content is final as presented, with the exception of pagination.

and polarity (PC) tasks. The integrated loss function $(J(\theta))$ is realized as follows:

$$J(\theta) = J_{\text{CE}}^{\text{CD}}(\theta) + J_{\text{CE}}^{\text{CS}}(\theta) + J_{\text{CE}}^{\text{ER}}(\theta) + J_{\text{CE}}^{\text{PC}}(\theta)$$

All the model parameters to be optimized are denoted by θ, which ranges from 0 to 1, and decides the per task loss-share to the total loss.

V. Experiments and Results

A. Baselines

We evaluate the proposed MECSI model with several strong baselines, divided into three classes: multimodal methods, multitask systems, and ablation models.

1) Multimodal methods: These baselines include various multimodal methods used to evaluate the visual modality, and textual and visual modality together.

a) *EfficientNet [34]:* We utilize EfficientNet for extracting visual features instead of CLIP model in the proposed framework. EfficientNet is a family of models obtained by effectively scaling up MobileNet and ResNet.

b) *ViLBERT [35]:* To acquire a visual foundation for paired visual-linguistic data, we use a collaborative technique known as vision and language BERT (ViLBERT) [35]. It has separate pathways for understanding language and visual, which communicate with one another through coattentional transformer layers. In order to work together, different modalities can share attention at separate representational levels, which is made possible by coattentional layers. Compared to the single-stream unified model, it performs better on a wider range of activities.

c) *UNITER [36]:* As one of the multimodal baselines, we additionally employ the state-of-the-art (SOTA) UNiversal Image-TExt Representation (UNITER) model [36]. UNITER is a pretrained large-scale model, which leverages its elegant self-attention mechanism built for learning contextualized representations by using transformers as the core of its model. UNITER is pretrained on four pretraining tasks relating to language modeling, masked region modeling, word-region alignment, and image-text matching, as inspired by BERT [30].

d) *VGG-19:* For the visual modality we also used a pretrained VGG-19[9] model to extract the image features. Each bounding box is clipped and resized before being passed into VGG-19, encoding it into a 4096-dimensional representation.

2) Multitask systems: The *Baseline$_1$* model (text only) is a unimodal multitask baseline developed inspired by the recent work in CD in multitask framework [7]. It is an adversarial multitask framework that uses BERT to categorize complaints, emotions, polarity, and sarcasm. By retaining the same experimental setting as in our current work, we reimplement the Baseline$_1$ model for the simultaneous learning of CD, CS, ER, and PC tasks.

3) Ablation models: To gauge the individual effects of ER and PC tasks on the primary tasks CD and CS, we create several ablation models while keeping CD and CS tasks consistent across all cases. The architecture remains unchanged except for these specific tasks.

B. Experimental Setup

We used Python-based libraries: Pytorch[10] and Tensorflow.[11] Our experiments were conducted on a hybrid cluster equipped with multiple GPUs, featuring RTX 2080Ti. We reported the weighted average F1 value along with the model accuracy. In all our experimental models, 80% of the *CESAMARD v2* dataset served as training data (10% for validation), while the remaining 20% was allocated for testing. The *K*-fold cross-validation technique, employing seven folds, was used to train the model. In the dense layers, ReLU activation was utilized to prevent overfitting, followed by dropout rates of 30%, with dropout ϵ values ranging from 20% to 50% after the dense layers. For severity, emotion, and polarity detection tasks, output layers utilized Softmax activation with 5, 6, and 3 neurons, respectively. The Sigmoid activation function was applied for complaint classification. The framework was trained with a batch size of 32 and learning rate settings of lr = 1e$-$4, where $lr\epsilon$ 1e$-$1, 1e$-$2, 1e$-$3, 1e$-$4, $\beta_1 = 0.9$, and $\beta_2 = 0.999$, utilizing the Adam optimizer.

C. Results and Discussion

The current study aims to improve CD and CS tasks using multimodal information such as texts, images, and web entities, as well as information from additional tasks (ER and PC). Consequently, we state the findings and related discussion with CD and CS as key tasks in all combinations.

Table IV depicts the classification results from the various experiments for the main tasks of CD and CS on accuracy and weighted-average F1 score metrics. As shown in Table IV, our model outperforms all the other models. Compared to baselines without web entity attributes, variants with web entity information perform well for all the multimodal baselines and the proposed MECSI$_{\text{All}}$ model. Overall the multimodal frameworks outperform the unimodal models. Moreover, the SOTA vision-text models with underlying transformer architecture such as ViLBERT and UNITER show lower performances than the MECSI (BERT + CLIP-Image, BERT + CLIP-Image + Web Entity) variants, illustrating the efficient usage of self-attention, intraattention and fusion layer in the proposed framework. In terms of tasks, MECSI$_{\text{All}}$ which includes all four tasks (CD, CS, ER, and PC), outperforms all the other variants (MECSI$_{\text{CD + CS}}$, MECSI$_{\text{CD + CS + ER}}$, MECSI$_{\text{CD + CS + PC}}$). Besides, the auxiliary task PC variant of the proposed model (MECSI$_{\text{CD + CS + PC}}$) outperforms the ER variant (MECSI$_{\text{CD + CS + ER}}$). This could be motivated by the fact that emotion, as a fine-grained task, is particularly context-dependent and therefore unable to add significantly to the multitask model by itself. It is also worth

noting that, among the three tasks (CS, ER, and SA), the CS task enhances the CI task's performance the most. We additionally notice that the text-only model achieves the best accuracy and weighted-average F1 score metrics, with 86.48% and 85.04%, respectively; this suggests that textual information is essential. In Table V, the results of the auxiliary tasks for sentiment

and emotion detection are presented. It is evident that the *[BERT + CLIP-Image]$_{All}$* baseline stands as the second-best performing model for the sentiment task, achieving an accuracy of 62.83%. For the emotion task, the *[BERT + EfficientNet]$_{All}$* model performs well, boasting an overall accuracy of 51.78%. The results shown in this work are statistically significant.[12]

1) Comparison With SOTA: We also compare our proposed approach with the existing SOTA techniques for CD and CS tasks. For multimodal CD, the SOTA approach (SOTA$_{CD}$) [3] employs an attention-based adversarial multitask model. Table IV demonstrates that the proposed approach, MECSI, along with its majority of variants surpasses the results of the SOTA$_{CD}$ model. Furthermore, for the CS task, we compare our proposed MECSI framework with the SOTA framework proposed by [9]. Kindly note the SOTA model is a text-based model for CS tasks; we chose this model for comparison as we are unaware of any other multimodal complaint severity prediction framework. SOTA$_{CS}$ utilizes an array of transformer networks with additional linguistic features. The proposed MECSI model outperforms the SOTA$_{CS}$ technique for the primary task of complaint severity prediction.

D. Error Analysis

Expressions of disapproval or accusation-related terms within reviews are seldom misclassified as noncomplaints. Here are some reasons for the proposed model's occasional failure to detect complaints and severity.

1) Disguised complaints: In scenarios where the overall sentiment appears neutral but the content is a complaint, the MECSI$_{All}$ model mistakenly categorizes the instance as noncomplaint. For instance, consider the following text: "Family fun pack! They supposedly forgot to mention its as ant family. There were live ants in it." While the actual label for this example is "complaint," the model classifies it as "noncomplaint," potentially due to the absence of explicit terms indicating disapproval.
2) Proximate severity-level errors: Reviews that belong to adjoining severity levels are similar in semantics, leading to incorrect predictions. For example, "Country of Origin is <USER>, but in product description over <USER> is mentioned <USER>. Disappointing with false details mentioned in the description." The severity level predicted is "disapproval," but the actual label is "accusation." One of the possible reasons for misclassification could be the presence of negative words such as *disappointing*, which is generally associated with the disapproval severity class.

E. Limitations

Although our approach outperforms the baselines in a variety of single-task and multitask scenarios, there are certain drawbacks to our approach, which are addressed as follows.

1) While expressing complaints, certain users employ an implied tone that includes sarcasm or irony. The proposed system, however, does not specifically detect sarcasm or irony as distinct tasks. Consequently, the approach might not effectively identify complaints that contain subtle forms of sarcasm.
2) When voicing complaints, some users prefer sharing only text-based reviews, and some just share the image of the product. In such cases, if only one modality is present, the proposed model will not be able to identify the complaint. In the current work, both modalities are needed for the model to correctly proceed further with predictions.
3) The model's training and evaluation were solely based on reviews composed in English. To extend its applicability to other languages or scenarios involving code-mixed language interactions, further training in diverse languages would be necessary.

VI. Conclusion

In this work, we have explored the tasks of complaint and severity-level detection from social media. The framework is constructed based on a multimodal multitask setting such that complaint and severity-level predictions are determined based on product reviews consisting of images and associated texts. Previous work on multimodal CD focused on enhancing the textual modality; without paying heed to specific image features, which could be beneficial in identifying complaints. We propose MECSI, a novel multimodal framework that uses local and global attributes (for both image and text) to detect complaints and associated severity-level in a multitask setting. Extensive studies were conducted to illustrate the efficacy of our proposed model.

Future research will focus on recognizing multimodal complaints on a fine-grained aspect level, in addition to finding the cause of complaints.

ABSTRACT Unmanned aerial vehicles (UAVs) play an important role within mobile edge computing (MEC) networks in improving communications for ground users during emergency situations. However, sustaining high-quality service for extended periods is challenging because of constraints on battery capacity and computing capabilities of UAVs. To address this issue, we leverage zero-energy reconfigurable intelligent surfaces (ze-RIS) within UAV-MEC networks and introduce a comprehensive strategy that combines task offloading and resource sharing. A deep reinforcement learning (DRL) driven energy efficient task offloading (DEETO) scheme is presented. The primary objective is to minimize UAV energy ingestion. DEETO aims to enhance task offloading decision mechanism, computing and communication resource allocation, while adopting hybrid task offloading mechanism with intelligent RIS phase-shift control. We begin by modeling it as a DRL problem, structuring it as a Markov decision process (MDP), and subsequently resolving it effectively through the use of the advantage actor-critic (A2C) algorithm. Our simulation results highlight the superiority of the DEETO scheme compared to alternative approaches. DEETO excelled by achieving a notable energy savings of 16.98% from the allocated energy resources, coupled with the highest task turnover rate of 94.12%, all achieved within a shorter learning time frames per second (TFPS) and yielding higher rewards.

INDEX TERMS DRL, MEC, Task offloading, UAV, ze-RIS.

I. INTRODUCTION

The mobile edge computing (MEC) networks have evolved as a very potential technological boost the quality of service (QoS) for tasks that demand significant computational power and low latency [1]. When MEC networks incorporate unmanned aerial vehicles (UAVs) into their infrastructure, they can harness the flexibility of UAV deployment [2]. This means that they can quickly expand the communication coverage and also guarantee the connectivity of the mobile users, particularly in cases of the destruction of the terrestrial communication infrastructures or a sudden influx of large numbers of users [3].

However, deploying additional UAVs in MEC networks comes with substantial costs and increased power consumption caused by the constraints in UAVs' energy and computational resources [4]. Moreover, UAV-assisted MEC systems encounter several hurdles. For instance, in urban settings, direct links between UAVs and IoT devices may encounter obstacles such as buildings, leading to significant deterioration in channel conditions. Similarly, since UAV is energy limited, it becomes critical to co-optimize UAV trajectory and computation energy to improve the overall energy efficiency. To take full advantage of UAV integration benefits in MEC and to further enhance the IoT task offloading performance, there is increasing interest in exploiting a new paradigm which is referred to as reconfigurable intelligent surfaces (RIS). RIS has emerged as an energy-efficient alternative capable of enhancing network capacity [5].

With the integration of a energy-efficient, cost-effective and high-gain metasurface, wireless propagation environ-

ment can be modified by RIS. This reconfiguration can minimize the energy consumption of the MEC networks and enhances communication capacity [6]. Recent research, such as studies in [7] through [8], has explored the applicability of RIS in MEC systems. Lately, numerous studies have delved into the theoretical exploration of leveraging RIS for network optimization. For instance, a notable work [9] focuses on integrating RIS into MEC systems to facilitate device task offloading. It seeks to enhance computational performance by maximizing the summation of computational bits. This is achieved through a joint optimization approach involving time allocation, transmit power and CPU frequency for computational offloading, while adjusting phase shifts of the RIS. The RIS beamforming and sensing mechanism for near field communications is investigated in [10]. Additionally, research by [11] delves into joint resource allocation and user grouping aided by IRS. Furthermore, [12] offers valuable insights into the resource trading mechanisms within MEC enabled UAV networks. Subsequently, in [13], the focus shifts on enhancing the total completed task-input bits within RIS-assisted MEC networks, a problem initially tackled by using an algorithm called block coordinate descending (BCD). A framework of deep learning is devised which can support the BCD algorithm and its online implementation in order to mitigate its computational complexity. Moreover, work in [14] explores the integration of wireless energy transfer (WET) into RIS-assisted MEC networks to meet both computation and energy supply demands of IoT devices.

In the context of RIS-assisted UAV networks, RIS deployment serves to mitigate blockages and improve achievable rates. In [15], the focus lies on maximizing the sum rate of users in the down-link through a joint optimization approach. This involves optimizing UAV trajectory, power control, THz sub-band allocation and RIS phase shifts. To ensure secure communication between the UAV and legitimate users, [16] employs RIS deployment to enhance legitimate transmission quality while compromising eavesdropping. To achieve the maximum average secrecy rate an iterative algorithm was proposed. Likewise, [17] explores secure transmission in UAV and RIS-assisted mmWave networks, achieving near-optimal RIS and UAV positions through exhaustive search methods. Moreover, [18] introduces a decaying deep Q-network (D-DQN) algorithm to address the dynamic stochastic environments in RIS-assisted UAV networks. This algorithm aims to minimize UAV energy consumption by optimizing RIS phase shift, power allocation, UAV trajectory and decoding order. Results of the simulation demonstrate that D-DQN algorithm effectively balances training speed acceleration, convergence to local optima, and oscillation avoidance. In [19], an active RIS-aided MEC system was the subject of attention. Acknowledging the fact that there are some tasks that cannot be partitioned, the author presented a multi-user MEC system with RIS assistance, which operates based on both binary and partial offloading policy [20]. Meanwhile, in [21], the author proposed an RIS-assisted iterative algorithm for MEC downlink communication system, aiming to minimize transmission power through alternating optimization (AO) and penalty-based optimization.

In studies [22] and [23], an innovative communication concept was introduced, featuring a UAV-based base station transmitting data to the users on ground with the simultaneous support of a reflecting and transmitting reflecting RIS (STAR-RIS). In [24], an approach was developed to enhance the energy efficacy of the system by jointly augmenting the UAV's flight trajectory in three-dimensional space and designing RIS phase shifts. Authors in [25] introduced an innovative MEC framework powered by RIS and UAV relays, specifically targeting a maximum-minimum computation capability issue.

The previously discussed networks utilizing RIS predominantly focus on two areas: RIS-assisted MEC networks, where user equipment (UE) computational capabilities benefit from access point (AP) resources, and RIS-assisted UAV architectures. This enhances the UE communication rates via UAV trajectory adaptability. However, scant attention has been given, to our knowledge, to the performance enhancement potential of RIS in UAV-enabled MEC environments. In studies [26], despite the use of a UAV-mounted RIS to aid ground user communication with an MEC server, the UAV's computational capacity remains unaddressed. Task-input data offloading by users to the MEC server via orthogonal multiple access (OMA) protocol is employed, which fails to fully exploit time and frequency resources. Subsequently, the authors in [27] introduces a non-orthogonal multiple access (NOMA) into the RIS-assisted UAV-MEC system, aiming to optimize UAV computational capacity. Simulation outcomes demonstrate the superior performance of the NOMA scheme compared to OMA. In association to it, a waveform design and detection mechanism in NOMA systems is also presented in [28]. Work presented in [29] also considered a IRS based NOMA assisted MEC mechanism for energy efficiency with queue stability option. A Lyapunov-function-based mixed integer DDPG (LMIDDPG) algorithm is proposed for centralized learning and a heterogeneous MA-LMIDDPG algorithm is proposed for distributed learning, considering system throughput, power consumption, and queue stability for computing decisions, power allocation, and phase shifts optimizations.

In an other work [30] a DDQN based resource allocation scheme, DTORA, is introduced. DTORA optimizes task offloading and resource allocation decision using double DQN algorithm. These decisions target to mitigate UAV energy consumption through optimizing computing and communication resources and RIS phase shifts. Additionally, work presented in [31] utilized another concept of RIS-equipped UAVs to facilitate MEC. A DDPG based energy-efficient solution mechanism is proposed for MEC network with RIS-equipped UAVs, considering energy conservation for ground users and UAVs. The optimization problem maximizes system energy efficiency by jointly optimizing ground user transmission power, UAV trajectory, and RIS phase shifts. The works presented in [32] explored a multi-UAV assisted

MEC system with RIS. A multi agent DRL based MA-TD3 algorithm is proposed while aiming the optimization of computation offloading, UAV trajectories, and RIS phase shifts.

Motivated by the promising features of RIS and the performance limitations encountered by UAVs operating in MEC based networks, we intend to harness RIS to enhance UAV communications within MEC based networks. The RISs offer opportunities to reduce energy expenditures, boost UAVs' channel capacity, improve transmission reliability in MEC based networks, and expand wireless coverage. However, there is a notable scarcity of research concerning RIS-assisted UAVs in the field of mobile edge computing networks. While previously discussed studies have laid the groundwork for a novel system framework that incorporates RIS-assisted UAV-MEC, limited consideration has been devoted to investigating the energy ingestion aspect of RIS-assisted UAV-MEC systems.

Besides, while the offloading users intend to use UAV's resources, but given the limited resources and UAV's energy constraints, it's infeasible for users to execute their computation tasks concurrently on the UAV. Hence, there's a need to mutually augment task offloading and resource allocation to efficiently manage UAV resources and decrease energy consumption [13], [14], [21], [24]–[26]. However, the challenge lies in the complex, non-convex nature of this joint optimization problem, making it impractical to swiftly attain the optimal solution using conventional methods. Providentially, DRL has recently emerged as a powerful instrument for tackling numerous optimization problems within wireless communication networks. DRL offers the ability to derive optimal solutions for wide-reaching, intricate, and non-convex problems without necessitating complete and precise network information [18], [20], [24], [33].

The study outlined in [20] focused on minimizing energy and delay with ze-RIS considerations, albeit limited to vehicular networks and lacking the UAV relaying mechanism. Similarly, the research in [21] solely addressed partial offloading mechanism without considering ze-RIS or UAV relaying, while also being a non-DRL solution, potentially increasing complexity overhead. Additionally, [24] exclusively explored binary offloading mechanism without incorporating ze-RIS and only focused on energy optimizations. Moreover, [29] and [30] examined partial offloading mechanisms without considering UAV relaying or ze-RIS. Both [30] and [31] only delved into binary offloading mechanisms without any association with ze-RIS, with the latter not considering delay optimizations. The work in [32] is limited to partial offloading mechanisms without a UAV relaying mechanism.

Taking these factors into account, this paper introduces a hybrid resource allocation and task offloading scheme tailored for ze-RIS-assisted UAVs operating within MEC networks. ze-RIS offers energy efficiency, making it suitable for power-constrained environments [34]. The ze-RIS and conventional passive RIS differs in their power requirements. ze-RIS operates without external power sources, relying on energy harvesting or wireless power transfer. In contrast, conventional passive RIS requires a continuous power supply. While both enhance wireless communication by reflecting and manipulating radio waves [35], [36].

The scheme formalizes the objective of minimizing energy ingesting and leverages the DRL-based A2C algorithm to efficiently address the optimization problem. A specified comparison of related studies and our work is presented in the Table 1, and the key contributions of this work are as follows:

- The proposed DRL driven energy efficient task offloading (DEETO) scheme is based on B5G technological infrastructure. It incorporates an innovative RIS-assisted UAV-MEC system that not only equips the UAV with computation capabilities but also empowers it for relay transmissions. Within the proposed framework, we conduct a comprehensive joint optimization of several critical parameters, including the allocation of the UAV's computational resources, working environment communication resource allocation, task offloading decisions, and phase shifts for the RIS. The primary objective of this optimization is to minimize the energy consumption of the UAV.
- Given the non-convex nature of the objective function, our approach involves an initial problem formulation using a Markov decision process (MDP). In this context, it's important to highlight that both of the MDP spaces, the state space and the action space are continuous. To efficiently tackle this challenge, we employ the A2C algorithm.
- Our simulation outcomes demonstrate the notable energy efficiency improvements achieved by our RIS-

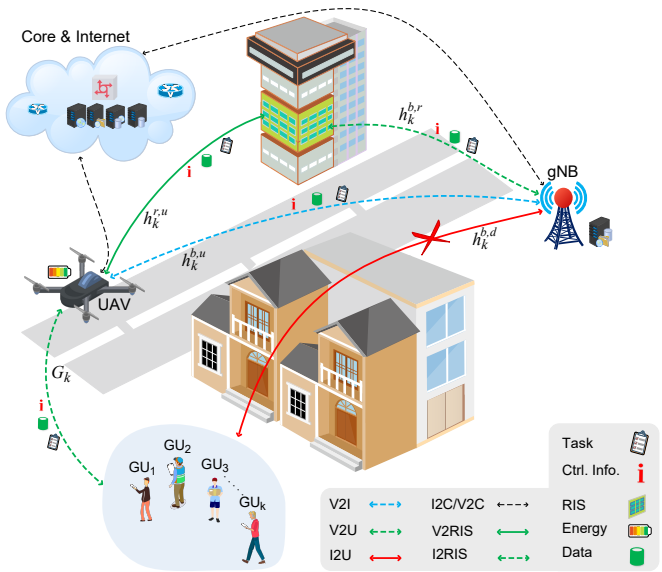

FIGURE 1: System model, demonstrating the conceptual framework.

aided UAV-MEC system, which employs the A2C algorithm. When compared to alternative benchmark schemes, our approach substantially reduces the overall energy consumption of UAVs.

II. SYSTEM AND OFFLOADING MODEL

A. SYSTEM MODEL

Recognizing the capabilities and advancements in 5G-NR communications, we have explored an RIS-enhanced UAV-MEC system, as depicted in Fig. 1. The UAV serves as a spatial base station, equipped with computational capabilities and the ability to function as a relay station. Thus, enabling the transmission of ground user's computational tasks to the next generation evolved node B (gNB) type base transceiver station (BTS). The BTS is supposed to be provided with multi CPU MEC server. We have integrated zero-energy reconfigurable intelligent surface (ze-RIS) elements into the architecture, thoughtfully positioned on the building's facade. We have followed the work proposed in [34], [35], and [36] for ze-RIS, and the zero energy device (ZED) based network configurations. The ze-RIS elements play a pivotal role in redirecting signals when needed. When users need to offload their computational tasks, they can choose between transmitting them directly to the UAV or using the UAV as a relay to send them to a distant small cell BTS for processing. The remarkable contribution of ze-RIS is its capacity to assist in signal relay from the UAV to the BTS, particularly in some situations where a direct communication is created amongst users and the BTS is hindered by physical barriers or obstructions.

Within the scheme, we have gu_m ground users, a UAV av_i, an RIS r_j equipped with k reflecting elements and a 5G small cell gNB type BTS b_l connected to MEC infrastructure. Here $i \in \mathcal{I}, j \in \mathcal{J}, k \in \mathcal{K}, l \in \mathcal{L}, m \in \mathcal{M}$ takes on values from the set $\{1, 2, \ldots, \mathcal{N}\}$, and $\mathcal{N}$ belongs to a natural number. To manage the RIS's reflection capabilities, we employ a reflection factor matrix denoted as $\Theta = \text{diag}[\theta_1(n), \theta_2(n), \ldots, \theta_k(n)]^T$, which embodies the reflecting beam-forming functionalities of the RIS. Here, $\theta_k(n)$ signifies the reflection factor of the k-th reflecting component during time slot n. The phase shift, $\phi_k(n)$, is contained within the interval $[0, 2\pi)$, and λ_k is the amplitude reflection coefficient, residing within the range $[0, 1]$. To optimize signal reflection, we typically set $\lambda_k = 1$, as previously done in [33]. We then divide total time period, T, into n distinct time periods. The variable n belongs to the set $\mathcal{N}$, and each of these time slots has a duration of δ. Users, during each of these time slots, offload their intended tasks to the in-range UAV following orthogonal frequency-division multiple access (OFDMA).

The channel gains for the ground user gu_m to UAV (gu_m–av_i link), from the UAV to BS (av_i–b_l link), UAV to RIS (av_i–r_j link), and from RIS to BS (r_j–b_l link) during time period n can be mathematically signified as $G_m(n)$, $h_m^{i,l}(n)$, $\mathbf{h}_m^{i,j}(n)$, and $\mathbf{h}_m^{j,l}(n)$, respectively. The gu_m–av_i link, av_i–b_l link, and av_i–r_j link are categorized as line-of-sight (LoS) links, and modeled using the free-space path loss model, and expressed as:

$$G_m(n) = \sqrt{\beta_0 {d_{m,i}}^{-2}(n)} \;:\; G_m(n) \in gu_m - av_i - \text{link}, \tag{1}$$

$$h_m^{i,l}(n) = \sqrt{\beta_0 {d_{i,l}}^{-2}(n)} \;:\; h_m^{i,l}(n) \in av_i - b_l - \text{link}, \tag{2}$$

$$\mathbf{h}_m^{i,j}(n) = \sqrt{\beta_0 d_{i,j}^{-2}(n)} \left[1, e^{-j\frac{2\pi}{\lambda} d\varphi_{i,j}(n)}, \ldots, e^{-j\frac{2\pi}{\lambda} d(K-1)\varphi_{i,j}(n)}\right] \;:\; \mathbf{h}_m^{i,j}(n) \in av_i - r_j - \text{link}, \tag{3}$$

In the given context, $d_{m,i}(n)$, $d_{i,l}(n)$, and $d_{i,j}(n)$ signify the distances for the gu_m–av_i, av_i–b_l, and av_i–r_j links in time slot n, respectively. The path-loss at reference distance of one meter is represented by β_0, d represents the inter RIS elements distance, and $\varphi_{i,j}(n) = (x_j - x_i)/(d_{i,j})$ denotes the cosine of the angle of arrival (AoA) of the signal. It's important to note that, for simplicity, the channel from RIS to BTS is considered to be mainly influenced by the Rician fading channel, expressed as:

$$\mathbf{h}_k^{j,l}(n) = \sqrt{\beta_0 d_{j,l}^{-2}(n)} \left[\sqrt{\frac{\beta_1}{1+\beta_1}} \mathbf{h}_{j,l}^{LoS}(n) + \sqrt{\frac{1}{\beta_1 + 1}} h_{j,l}^{NLoS}(n)\right] \;:\; \mathbf{h}_m^{j,l}(n) \in r_j - b_l - \text{link}, \tag{4}$$

$$\mathbf{h}_{j,l}^{LoS}(n) = \left[1, e^{-j\frac{2\pi}{\lambda} d\varphi_{j,l}(n)}, \ldots, e^{-j\frac{2\pi}{\lambda} d(K-1)\varphi_{j,l}(n)}\right] \tag{5}$$

where β_1 represents the Rician factor, $d_{j,l}(n)$ corresponds to the distance for the r_j–b_l link., and $\mathbf{h}_{j,l}^{LoS}(n)$ is the LOS

content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3397890

component. $\varphi_{j,l}(n) = (x_l - x_j)/(d_{j,l})$ denotes the AoD signal's cosine. For the NLoS component, $\mathbf{h}_{j,l}^{NLoS}(n)$ follows a Gaussian distribution with zero mean and unit variance, i.e., $\mathbf{h}_{j,l}^{NLoS}(n) \sim \mathcal{CN}(0,1)$.

B. OFFLOADING AND PROCESSING MODEL

In our study, we categorize the processing of user computation tasks into three specific phases. Initially, there is the task offloading from the ground users to the UAV, followed by the computation processing at the UAV, and finally, the relaying of tasks to the BTS. It is important to note that the BTS, being grounded and potentially equipped with multi-CPU MEC servers. These servers are expected to have a considerably higher computation rate compared to the UAV. Therefore, we can safely disregard the computing latency of BTS within all time slot.

1) UAV offloading

Given the constraints of finite computational power then the battery size for the ground user, the decision is made to transfer all of the computation tasks to UAV. In this context, the computation tasks of the m-th user in the n-th time slot are denoted as $t_k(n)$. Each $tk(n)$ is characterized as a 3-tuple: $tk_m(n) = \{s_m, c_m, t_m, e_m\}$, where s_m represents the task size in bits, c_m indicates the required CPU cycles for 1 bit computation, t_m, and e_m are the time and energy threshold units allocated for task completion. Since all the tasks are pre-decided to be offloaded, the transmission rate $R_m^{ofld}(n)$ of the m-th user in the n-th time slot while offloading task $tk_m(n)$ is given by:

$$R_m^{ofld}(n) = B_0 \log_2\left(1 + \frac{p_m(n)\ ||G_m(n)||^2}{\sigma^2}\right), \quad \text{and} \quad B_0 = B/m, \tag{6}$$

Here, B is the total bandwidth, distributed into m even channels as. $p_m(n)$ is the transmission power of m-th user in the n-th time slot. σ^2 denotes the power of additive Gaussian white noise. The offloading delay for the m-th user, when offloading their computation extensive tasks to the in range UAV, is calculated while following Eq. (7). Additionally, offloading a given task must follow the constraint $t_m^{ofld} < t_m$.

$$t_m^{ofld}(n) = s_m(n)/R_m^{ofld}(n). \tag{7}$$

2) UAV Computation

Since all of the user's computational tasks are transferred to UAV. The UAV dynamically determines the decisions of offloading depending on the incoming task count from the ground users. By employing a partial task offloading strategy, the UAV handles the ζ portion of the task, while the β segment is relayed to the BTS. The decision-making process involves the UAV determining the allocation of the m-th user's computation tasks, deciding how much of the task should be processed on the UAV and how much should be relayed to the BTS. These decisions adhere to the constraint $\zeta + \beta = 1$. The decision parameters ζ_m and β_m are binary in nature. In the case of adopting a partial task processing model, both of these parameters are set to 1. When exclusively UAV processing is preferred, ζ_m is set to 1, and β_m is set to 0. Conversely, when only relaying is favored, β_m is set to 1, and ζ_m is set to 0. The time t_m^{av} and energy e_m^{av} consumed in processing task $t_k(n)$ during the n-th time slot at UAV av_i can be expressed as follows:

$$t_m^{av}(n) = \Big((1-\zeta_m(n)(1-\beta_m(n))\Big)\left\{\frac{\zeta s_m(n)\ c_m(n)}{f_m^{av}(n)}\right\} \tag{8}$$

$$e_m^{av}(n) = (1 - d_m(n))\Big\{\zeta s_m(n)\ c_m(n)\ \varphi^{av}\ \left(f_m^{av}(n)\right)^2\Big\} \tag{9}$$

where $f_m^{av}(n)$ in Eq. (8) signifies the CPU resources allocated to the task t_k in n-th time slot, and φ^{av} in Eq. (9) is the UAV chip specific effective capacitance coefficient, determined by architecture of the chip.

3) UAV–BTS Relaying

For the decisions $(\zeta_m = \beta_m = 1)$ or $(\zeta_m = 0 \wedge \beta_m - 1)$ the task is to be relayed to the BTS for processing, either in parts or as a whole. Therefore, the transmission rate and time for the UAV–BTS link can be calculated while following Eq. (10), and Eq. (11), while the consumed energy for relaying can be calculated while following Eq. (12).

$$R_m^{rel} = B_0 \log_2\left(1 + \frac{p_m(n)\ ||h(n)||^2}{\sigma^2}\right), \quad \text{where}\ \ h(n) = h_m^{i,l}(n) + \mathbf{h}_m^{i,j}(n)\ \Theta \mathbf{h}_k^{j,l}(n) \tag{10}$$

$$t_m^{rel}(n) = \Big((1 - \zeta_m(n)(1 - \beta_m(n))\Big)\left\{\frac{\beta\ s_m(n)}{R_m^{rel}}\right\} \tag{11}$$

$$e_m^{rel}(n) = \Big((1-\zeta_m(n)(1-\beta_m(n))\Big)\left\{\frac{P_m^{rel}\beta\ s_m(n)}{R_m^{rel}}\right\} \tag{12}$$

III. OBJECTIVE AND SOLUTION METHODOLOGY

In this segment, we present our approach to addressing the challenge of reducing energy ingesting while enhancing the computational efficacy of the UAV based MEC network. The key objective is to fine-tune the use of computation resources, while aiming to maximize the proportion of total processed bits to the energy consumed by UAVs. In line with our goal, we can articulate the average energy ingesting and time consumed while offloading, computing, and relaying the task m is expressed in Eq. (13) and Eq. (14).

$$\mathcal{T}_m = \frac{1}{\mathcal{M}} \sum_{m=1}^{\mathcal{M}} \left(t_m^{ofld}(n) + t_m^{av}(n) + t_m^{rel}(n)\right) \tag{13}$$

$$\mathcal{E}_m = \frac{1}{\mathcal{M}} \sum_{m=1}^{\mathcal{M}} \left(e_m^{av}(n) + e_m^{rel}(n)\right) \tag{14}$$

A. DEXTERITY FACTOR

To ensure fair and impartial assessments of efficiency, we have introduced a parameter known as the dexterity factor. This factor is designed to incorporate standard benchmarks for time and energy consumption into the evaluation process. Specifically, we establish t_m^m as the average of the maximum and minimum time thresholds assigned to tasks, representing the benchmark for delay, and e_m^m as the average of the maximum and minimum energy thresholds allocated to tasks, serving as the benchmark for energy. These benchmarks, derived from the range of allowable time and energy values, provide a reference point against which the actual performance of the UAV can be compared.

In a dynamic RIS-assisted MEC network, the performance of a UAV in terms of time and energy can vary significantly across different time slots. To ensure unbiased evaluations of efficiency, we have introduced a dexterity factor. This factor is designed to incorporate standard benchmarks for time and energy consumption into the evaluation process. We define $t_m^m = \text{mean}(t_m^{max}, t_m^{min})$ as the benchmark for delay and $e_m^m = \text{mean}(e_m^{max}, e_m^{min})$ as the benchmark for energy. Here, t_m^{max} and t_m^{min} signify the maximum and minimum threshold times allocated to the tasks, while e_m^{max} and e_m^{min} signify the maximum and minimum threshold energy units allocated to the tasks, respectively. These benchmarks provide reference points against which the actual performance of the UAV can be compared, allowing for a more accurate evaluation of its efficiency. The dexterity factor is then formulated as:

$$\mathcal{D}_m = \{((t_m + t_m^m) - \mathcal{T}_m) + ((e_m + e_m^m) - \mathcal{E}_m)\} \quad (15)$$

It is worth noting that a larger value of $\mathcal{D}_m$ corresponds to a greater amount of saved energy and reduced delay. Since the dexterity factor $\mathcal{D}_m$ is associated with single task tk_m , the average dexterity factor for all M tasks can be expressed as:

$$\mathcal{D}_a = \frac{1}{\mathcal{M}} \sum_{m=1}^{\mathcal{M}} \{((t_m + t_m^m) - \mathcal{T}_m) + ((e_m + e_m^m) - \mathcal{E}_m)\} \quad (16)$$

Building upon these foundational concepts, we establish our joint objective to optimize $\mathcal{D}_m$. This encompasses decisions associated with offloading, UAV processing and execution, and the relaying mechanism.

$$\underset{\zeta,\, \beta,\, \Theta,\, P^{rel},\, f^{av}}{\text{maximize}} \quad \frac{1}{\mathcal{N}} \sum_{n=1}^{\mathcal{N}} \left(\frac{1}{\mathcal{M}} \sum_{m=1}^{\mathcal{M}} \mathcal{D}_m \right)(n),$$

s.t.

$$C1 : \mathcal{E}_m(n) \leq e_m(n), \quad (17)$$

$$C2 : \mathcal{T}_m(n) \leq t_m(n), \quad (18)$$

$$C3 : 0 \leq f_m^{av}, \text{ and}$$
$$\sum_{m=1}^{\mathcal{M}} (1 - \zeta_m(n)(1 - \beta_m(n)) f_m^{av}(n) \leq F_{max}(n), \quad (19)$$

$$C4 : 0 \leq P_m^{rel}, \text{ and}$$
$$\sum_{m=1}^{\mathcal{M}} (1 - \zeta_m(n)(1 - \beta_m(n))\, P_m^{rel}(n) \leq P_{max}^{rel}(n), \quad (20)$$

$$C5 : 0 \leq \phi_k < 2\pi, \quad (21)$$

$$C6 : \forall\, \zeta_m \in \{0, 1\}, \text{ and } \forall\, \beta_m \in \{0, 1\}. \quad (22)$$

Constraint C1 is directly associated with energy and stipulates that the energy consumed during task processing and relaying must be less than or equal to the allocated energy. Constraint C2 pertains to user experience, ensuring that the time taken for task offloading, processing, and relaying must be less than or equal to the allocated threshold time. Constraints C3 and C4 signify the limitations on UAV computation and energy resources, respectively. Constraint C5 denotes the phase shift constraints for RIS elements. Constraint C6 signifies the parameters governing task offloading decisions.

The objective of the optimization problem described in Eq. (17), i.e., to maximize the D_m, corresponds to minimize the overall energy consumption of the UAV during its operational tasks. This involves a comprehensive approach to optimizing various aspects, including the task offloading decisions ζ_m and β_m, the phase shift Θ of RIS elements, the power consumption P^{rel} during relay transmissions, and the allocation of UAV computational resources f^{av}.

Given the dynamic nature of problem Eq. (17) and its inherent involvement in a multidimensional spaciotemporal environment, employing traditional optimization approaches proves challenging due to significant difficulty and high-order complexity. To address these challenges, we have chosen to employ a DRL based methodology. This decision is driven by the adaptive and learning-centric nature of DRL, which is particularly well-suited for handling dynamic and complex optimization problems in dynamic environments.

B. MDP FORMULATION

In the scope of this paper, the UAV plays the role of an agent that actively interact with the environment, with the primary objective of collecting comprehensive state information and formulating an optimum policy to exploit the cumulative reward. The designations for the MDP components, including the state, action spaces, and reward function, are explicitly outlined as follows:

This work is licensed under a Creative Commons Attribution-NonCommercial-NoDerivatives 4.0 License. For more information, see https://creativecommons.org/licenses/by-nc-nd/4

This article has been accepted for publication in IEEE Access. This is the author's version which has not been fully edited and
content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3397890

1) State Space

The state space s_t in our MDP at the t time slot is characterized by various UAV states, including UAV position state s_u^p, UAV velocity state s_u^v, UAV energy state s_u^e, and UAV processing capacity state s_u^c. Additionally, the state space also incorporates RIS configuration state s_r, BS status state s_b, MEC workload state s_m^w, MEC capacity state s_m^c, and task-related states such as task size state s_{tk}^s, task CPU cycles requirement state s_{tk}^c, task threshold time state s_{tk}^t, and task energy threshold state s_{tk}^e. The comprehensive definition of the state space is as follows:

$$S \triangleq \{s|s = (s_u^p,\ s_u^v,\ s_u^e,\ s_u^c,\ s_r,\ s_b,\ s_m^w,\ s_m^c,\ s_{tk}^s, s_{tk}^c,\ s_{tk}^t,\ s_{tk}^e)\} \tag{23}$$

2) Action Space

The action state a_t in our MDP at t time slot encompasses UAV flight related actions including UAV speed a_u^s, UAV direction a_u^d, and UAV altitude a_u^a. Additionally, it also includes actions related to RIS phase shifts adjustments a_r, local task processing actions a_{tk}^l, task offloading decision action a_{tk}^o, and task relaying actions a_{tk}^r. In a comprehensive view, the action space can be articulated as follows:

$$A \triangleq \{a|a = (a_u^s,\ a_u^d,\ a_u^a,\ a_r,\ a_{tk}^l,\ a_{tk}^o,\ a_{tk}^r)\} \tag{24}$$

3) Reward Function

The reward function $R(s_t, a_t, s_{t+1})$ in our MDP encapsulates the goal of minimizing UAV energy consumption, ensuring task completion, and promoting efficient utilization of the ze-RIS. We have formulated the reward function as specified in Eq. (25), incorporating various factors to effectively train the DRL agent for optimal alignment with our objectives.

$$R(s_t, a_t, s_{t+1}) \triangleq \{r|r = (r_{df} + r_{ee} + r_{tc} + r_{ru})\} \tag{25}$$

The rewards r_{df}, r_{ee}, r_{tc}, and r_{ru} in Eq. (25) are directly related to the objective function. r_{df}, dexterity factor reward, this factor represents the agility and flexibility of the system in handling tasks. In the objective function, this could be associated with constraints related to task completion C2 and energy consumption C1. Maximizing r_{df} encourages the system to efficiently complete tasks while managing energy resources effectively. r_{ee}, the energy efficiency factor reward, this factor focuses on minimizing energy consumption, which directly aligns with constraint C1 in the objective function. By maximizing r_{ee}, the system aims to optimize energy usage while achieving its objectives. r_{tc}, the task completion reward, this factor is binary, indicating whether tasks are successfully completed $r_{tc} = 1$ or not $r_{tc} = 0$. In the objective function, this corresponds to the task completion constraint C2. Maximizing r_{tc} encourages the system to prioritize completing tasks efficiently. r_{ru}, the RIS utilization reward, this factor promotes the optimal utilization of RIS elements to enhance communication and energy consumption, aligning with constraints C4 and C5 in the objective function. Maximizing r_{ru} encourages the system to leverage RIS effectively to achieve its goals.

In order to train the DRL agent and guiding that towards higher rewards we have added weights with these factors as these can be observed from Eq. (26)

$$R(s_t, a_t, s_{t+1}) \triangleq \{r|r = (r_{df} + (-w_1 \cdot r_{ee}) + (w_2 \cdot r_{tc}) + (w_3 \cdot r_{ru}))\} \tag{26}$$

Here, w_1 weight is used to prioritize the importance of UAV energy consumption. The weight w_2 is associated with task completion reward, and w_3 is a measure indicating how effectively the RIS is utilized.

C. THE A2C BASED DEETO ALGORITHM

The DEETO scheme includes the collaboration among the DRL agent and the RIS-assisted MEC based UAV task offloading environment. The algorithm 1 integrates the Advantage Actor-Critic (A2C) algorithm with the UAV task offloading and relaying scenario for obtaining optimal task offloading decisions policy. The DEETO algorithm starts by initializing the policy network π_θ and the value function V_ϕ, along with the learning rate α and discount factor γ hyperparameters. Then algorithm iterates through episodes, representing sequences of interactions between the UAV and the environment. Each episode captures a series of time steps. At each time step within an episode, the algorithm the policy network π_θ samples an action a_t based on the current state s_t. Later, the sampled action a_t is executed in the environment, resulting in a reward r_t and a new state s_{t+1}. Then, based on the current state and connectivity information, the algorithm determines the communication scenario. This scenario can be a direct link $gu_m - av_i$ between the mobile user and the UAV or relay link $gu_m - av_i - b_l$ from mobile user to UAV to BS, or an RIS assisted link $gu_m - av_i - r_j - b_l$ an RIS-assisted link. Depending on the communication scenario, the state of the mobile user, BS, RIS, and UAV is updated to reflect changes in parameters such as task status, bandwidth, energy levels, delays, phase shifts, channel conditions, and resource availability. After updating, the transition tuple (s_t, a_t, r_t, s_{t+1}) is stored in a trajectory buffer for later use in policy and value function updates. Then the advantage A_t is calculated using the reward r_t and the value functions V_ϕ for the current and next states s_t and s_{t+1}, respectively. Next the policy parameters θ and value function parameters ϕ are updated using the A2C algorithm. The policy parameters are updated in the direction that increases the likelihood of selecting actions that yield higher advantages, while the value function parameters are updated to reduce the difference between the estimated value of the current state and the estimated value of the next state. After the specified number of episodes, the algorithm outputs the optimal policy π_θ and value function V_ϕ, which can then be used to make task offloading and relaying decisions in the UAV environment.

Algorithm 1 A2C assisted DEETO Algorithm

Input: Initial state s_0, policy network π_θ, value function V_ϕ, gu_m, av_i, r_j, b_l parameters
Initialize policy network π_θ and value function V_ϕ, learning rate α, discount factor γ
for each episode **do**
  Initialize environment initial state s_0
  for each time step t **do**
    Take sample offloading action $a_t \sim \pi_\theta(\cdot|s_t)$
    Execute offloading action a_t, observe reward r_t and new environment state s_{t+1}
    Determine communicating node locations and connectivity
    Select communication link ($gu_m - av_i$, $gu_m - av_i - b_l$, $gu_m - av_i - r_j - b_l$)
    if $gu_m - av_i$ **then**
      Update location, trajectory, computation and energy states of av_i
    else if $gu_m - av_i - b_l$ **then**
      Update location, trajectory, computation and energy states of av_i,
      Update b_l states
    else if $gu_m - av_i - r_j - b_l$ **then**
      Update location, trajectory, computation and energy states of av_i,
      Update phase shifts, channel conditions, energy states of r_j,
      Update b_l states
    end if
    Update gu_m, av_i, r_j, and b_l state parameters
    Update communication scenario used,
    Update energy consumed,
    Update delay incurred,
    Update available resources
    Store transition (s_t, a_t, r_t, s_{t+1}) in trajectory buffer
    Calculate advantage $A_t = r_t + \gamma V_\phi(s_{t+1}) - V_\phi(s_t)$
    Update policy parameters θ and value function parameters ϕ using A2C:

$$\theta_{\text{new}} = \theta + \alpha \nabla_\theta \log \pi_\theta(a_t|s_t) \cdot A_t$$

$$\phi_{\text{new}} = \phi + \alpha \nabla_\phi \left(0.5(V_\phi(s_{t+1}) - V_\phi(s_t))^2\right)$$

  end for
end for
Output: Optimal offloading policy π_θ and value function V_ϕ

Throughout the algorithm, mathematical notations such as π_θ, V_ϕ, α, γ, ∇_θ, and ∇_ϕ are used to represent the policy network, value function, hyperparameters, and gradients for policy and value function updates. The algorithm provides a rigorous framework for delay and energy optimizing task offloading and relaying decisions in the UAV environment.

TABLE 2: Simulation Parameters

Simulation Parameter	*Value*
CPU frequency of av_i, and MEC	2MHz–2GHz, 2GHz–5GHz
b_l antennas, RIS elements	4, 50
Maximum p_m, P_m^{rel}, β_0 and σ^2	0.5W, 1W, -50dB, and -90dBm
$av_i - r_j$ link Rician factor	10dB
$r_j - b_l$ link Rician factor	10dB
$gu_m - av_i$ link Rician factor	3dB
$r_j - b_l$ link path loss exponent	2dB
$gu_m - av_i$ link path loss exponent	3.5dB
$av_i - r_j$ link path loss exponent	2.8dB
Cellular Bandwidth	10MHz
A2C Algorithm Parameter	
Time steps	100k
Update window size per step	100
γ, GAE λ, and Learning rate	0.99,1.0, 0.0005
Value function coefficient	0.5

IV. SIMULATION SETUP, RESULTS AND DISCUSSION

In this section, we present the experimental setup and outcomes of our study on optimizing task offloading and relaying in a UAV-assisted MEC system while minimizing delays and energy consumption. The underlying subsection contains the details regarding simulation parameters, and configurations. The subsequent section contains the achieved results, discussing the DEETO algorithm's performance.

A. SIMULATION SETUP

We consider a UAV-assisted MEC based communication environment with RIS enhancement. The network is equipped with BTS having the communication range radius of 200m with ze-RISs support. Similarly, the UAV have a communication range radius of 500m. The positions of gu_m users are circularly distributed in an area around the UAV with 100m radius, randomly. We configure the channel parameters by equipping the ze-RIS with a uniform planar array (UPA), organized in an $M_x \times M_y$ grid layout. Employing the Rician fading model, our channel model encompasses both line-of-sight (LoS) and non-LoS components for the links between the $gu_m - av_i$, $av_i - b_l$, $av_i - r_j$, and $r_j - b_l$. The path loss is characterized by $PL(\alpha, d) = \beta_0(d/d_0) - \alpha$, where d represents the transmission distance, β_0 denotes the path loss at the reference distance $d_0 = 1$m, and is set to $-40dB$. The α signifies the path loss exponent. The task attributes, including size and processing time thresholds, are selected at random from predefined intervals. Task sizes vary from 1 to 50Mb, while processing thresholds range from 200 to 500ms, and 1–50 joules of energy units to process it, accordingly. Additionally, our system incorporates a sub-task feature, enabling each task to comprise a flexible number of sub-tasks, ranging from 1 to 100. The simulations were executed on a M1-MacBook, using Python 3.7, PyTorch 2.0, Spyder, and Jupyter Notebook IDEs were employed for implementation. The DRL algorithms adhered to OpenAI standards. Other simulation parametric values and hyperparameters are given in Table 2.

For thorough analysis, we conducted convergence tests on

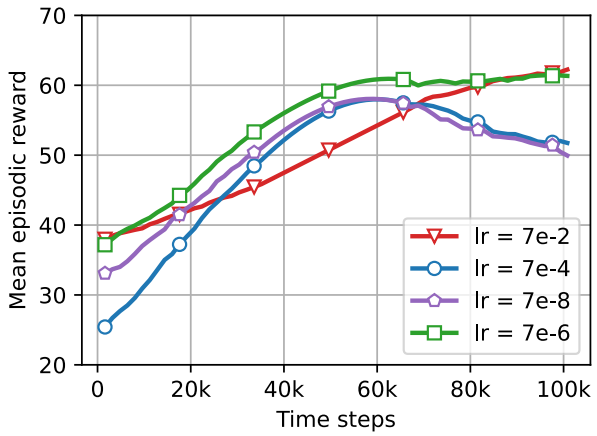

FIGURE 2: Convergence analysis of A2C based DEETO scheme for different learning rates.

the proposed DEETO scheme using various A2C DRL agent learning rates. Specifically, we evaluated the A2C algorithm's performance with learning rates set at $7e^{-2}$, $7e^{-4}$, $7e^{-6}$, and $7e^{-8}$. The convergence and reward collection analysis, depicted in Fig. 2, revealed distinct patterns. Notably, results indicated that the $7e^{-4}$ and $7e^{-8}$ learning rates achieved earlier convergence compared to $7e^{-2}$ and $7e^{-6}$, albeit experiencing declines in performance over additional time steps. While the convergence pattern for $7e^{-2}$ appeared superior to $7e^{-4}$ and $7e^{-8}$, it exhibited lower reward collection than $7e^{-6}$. Remarkably, the A2C algorithm demonstrated notable efficacy with DEETO at a learning rate of $7e^{-6}$, exhibiting enhanced convergence and higher rewards. Consequently, we have selected $7e^{-6}$ as the learning rate for subsequent experimental analyses.

B. RESULTS AND DISCUSSION

The efficiency of the DEETO scheme is systematically examined in dynamical scenarios, comparing it with other candidate DRL-based offloading techniques. we have evaluated and analyzed these schemes in terms of rewards, time frames per second (TFPS), task completion rate, energy consumption rate, and dexterity factors. Confirming an adequate comparison, all schemes are assessed using consistent simulation parameters. we have compared the DREEO scheme with the following contender schemes:

- *DEETO*: This is the proposed scheme.
- *DREEO*: This is a DRL based energy optimizing task offloading scheme. DREEO is an RIS assisted scheme, comprising hybrid task offloading scheme including binary and partial offloading mechanisms [20].
- *DTORA*: This is an RIS enabled UAV based MEC task offloading scheme. The DTORA optimizes task offloading and resource allocation decision using double DQN algorithm. These decisions target to mitigate UAV energy consumption through optimizing computing and communication resources and RIS phase shifts [30].
- *DQN*: This is an other DRL driven scheme to optimize task offloading delays and energy consumption. The DQN algorithm is adopted to optimizing task offloading decisions.

Several assessments have been made to verify and affirm the efficacy of our proposed DEETO scheme in a dynamic UAV-centric edge computing network environment. Fig. 3 provides a comprehensive comparison between DEETO and other schemes concerning rewards, a key metric in DRL-based approaches. Fig. 3(a) illustrates raw episodic rewards, while Fig. 3(b) depicts smoothed episodic rewards across time steps. Here, the DRL agent interacts with the environment, receiving rewards or penalties based on its actions. As the iteration with the environment progresses, the DRL agent adapts its policy to optimize its reward value. Favorable actions corresponding to the current environmental state yield higher rewards, whereas unfavorable actions result in reduced or negative rewards (penalties).

Besides, in the context of evaluating DRL based algorithms, apart from the comparison of rewards, time frames per seconds (TFPS) serves as a crucial performance metric. TFPS refers to the rate at which an algorithm processes the environment state steps within a given timeframe. A lower TFPS indicates that the algorithm can process each time frame more efficiently, meaning it can accomplish its tasks or decision-making processes in less time. Therefore, achieving a lower TFPS over time signifies improved performance and efficiency. Fig. 4 provides an illustration of the TFPS for all the contender approaches.

The observations indicate that the proposed DEETO scheme initially shows a higher TFPS, which gradually decreases over time and eventually converges to the lowest rate compared to all competing schemes. DEETO scheme achieves the lowest average TFPS rate of 870 among all other schemes. The DREEO scheme closely follows the characteristics of the DEETO scheme in terms of TFPS rate, yet it concludes with a slightly higher average TFPS of 910. Contrarily, the DTORA scheme starts with a higher TFPS, experiences a temporary decrease, but eventually shows an increasing trend over time, and finally converging at an average TFPS of 992. In contrast, the DQN-based scheme performs the poorest in terms of TFPS, obtaining an average TFPS rate of 1048.

The DRL characteristics shown in Fig. 3 and Fig. 4 illustrate the performance of each scheme in terms of rewards and TFPS, respectively. However, evaluating both features simultaneously unveils optimal algorithmic performance when higher rewards are achieved at lower TFPS rates collectively. It is understandable that the proposed DEETO scheme outperforms all contestant schemes while adhering to this measure. This performance gap between DEETO and other schemes can be accredited to several advantages of employing the A2C algorithm. A2C's simplicity, combining policy gradients and value-based methods, along with lower variance, renders it more robust. These attributes make it

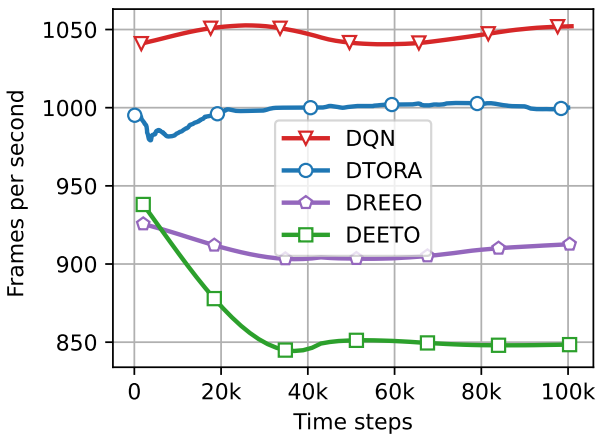

FIGURE 4: Evaluation of time frames per second across completing DRL based offloading schemes.

predominantly suitable for real-time learning scenarios, enabling firmer convergence and compliance to the dynamic communication environments.

Apart from the DRL characteristics, it is necessary to consider the interacting environmental factors in which the DRL agent operates. Therefore, to assess the effectiveness of these task offloading schemes we have analyzed the task turnover rate and energy consumption rate, as shown in Fig. 5(a) and Fig. 5(b). The analysis illustrates how accurately and effectively task offloading decisions are made, balancing task completion and energy optimization considerations. This decision involves determining whether to execute tasks locally, on the UAV, or to relay them to the edge server. For the DEETO and DREEO schemes, there exists an additional dimension of decision-making, i.e., whether task processing/offloading occurs in a binary or partial manner. Fig. 5(a) illustrates the analysis, representing that all schemes performed worthily in terms of task success and drop rates, although with slight variations. However, the DEETO scheme achieved the highest task success rate of 94.12% and the lowest drop rate of 05.87%. The DREEO scheme closely followed, achieving a 93.42% task success rate and a 06.58% drop rate. Conversely, the DTORA and DQN schemes achieved task success rates of 83.04% and 80.13%, with corresponding task drop rates of 16.96% and 19.87%, respectively.

Similarly, Fig. 5(b) depicts the percentage of energy consumed and saved during task processing and relaying. All schemes successfully conserved energy within the allocated resources while observing to delay and task completion constraints. The DREEO scheme demonstrated the highest energy savings, conserving 16.98% of the allocated energy resources. Moreover, DREEO remained a close competitor to the DEETO scheme, achieving energy savings of 12.51%. In comparison, the DTORA and DQN schemes saved 12.22% and 8.32% of the allocated energy resources, respectively.

In addition to the aforementioned analyses, we conducted a comparative investigation involving the dexterity factor across varying numbers of tasks, task threshold times, and task sizes. The dexterity factor is composed as the sum of differences between consumed time and benchmark time, as well as consumed energy and benchmark energy.

Fig. 6a illustrates the comparative performance of all offloading schemes as the number of tasks increases. It is evident that an increase in the number of tasks leads to higher delay and energy consumption. However, the dexterity factor also increases concurrently, as it represents the average sum of saved energy and time. Notably, both the DREEO and DEETO schemes exhibit a similar pattern of energy and time savings, although with differing scales. This similarity can be attributed to the shared utilization of a hybrid task offloading mechanism. However, DEETO achieves the highest average dexterity factor, reaching 239.07 against 209.79 of

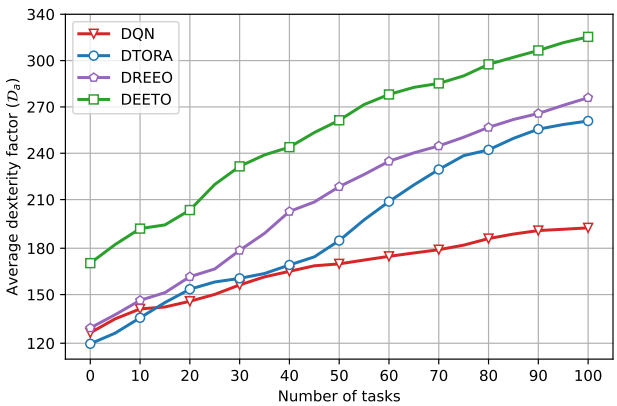
	DEETO	DREEO	DTORA	DQN
Success rate	94.12 %	93.42 %	83.04 %	80.13 %
Drop rate	05.87 %	06.58 %	16.96 %	19.87 %

(a) task rate

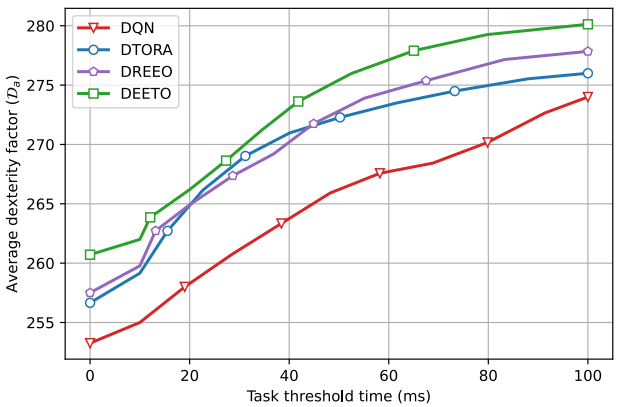
	DEETO	DREEO	DTORA	DQN
Consumed	83.02 %	87.49 %	89.78 %	91.68 %
Saved	16.98 %	12.51 %	10.22 %	08.32 %

(b) energy rate

FIGURE 5: Task completion and energy consumption of various DRL based schemes.



(a) Dexterity factor vs increasing number of tasks



(b) Dexterity factor vs increasing threshold time (t_{max})

FIGURE 6: Evaluation of dexterity factor against increasing number of tasks and the task threshold time

DREEO, 195.55 of DTORA, and 178.79 of DQN scheme. The superior decision-making mechanism of DEETO results in a higher dexterity factor, reflecting the cumulative savings in energy and time. This further validates the efficacy of relaying through ze-RIS via efficient phase shift mechanisms in reducing UAV energy consumption.

Expanding the analysis, we examined the performance of the DEETO scheme against the other schemes while increasing the threshold time, as depicted in Fig. 6b. It is evident that at lower threshold times, DEETO, DREEO, and DTORA exhibit similar performance levels, but as the threshold time increases, DEETO emerges as the superior scheme. However, the DQN scheme demonstrates the least efficiency. The proposed DEETO scheme achieved an average dexterity factor of 270.89, closely followed by DREEO with an average dexterity factor of 268.90. DTORA also closely trails DREEO with an average dexterity factor of 266.81, while the DQN scheme attained an average dexterity factor of 264.45.

The Fig. 7 illustrates the relationship of dexterity factor against increasing task size. it is obvious that as the task size increases the computation and communication over head also increases. the results show that DEETO and the DREEO schemes again has the same pattern of achieving dexterity factor, but the DEETO scheme has a smooth non linear trend as the task size increases and tends to convergence. However all the other schemes has a near linear sharp decreasing trend of dexterity factor with the increasing task size. The DEETO scheme achieved the highest average dexterity factor of 282.32, while DREEO, DTORA, and DQN achieved average dexterity factor of 277.65, 273.26, and 271.84, respectively.

The DREEO scheme emerged as the decent performer among all contender schemes due to its intelligent optimization of ze-RIS phase shifts coupled with a strategic hybrid task offloading mechanism. DREEO consistently remained a close competitor of DEETO across all evaluation results, leveraging the A2C algorithm alongside its hybrid task offloading approach, however with a random ze-RIS phase shift mechanism. In contrast, the DTORA scheme utilized the DDQN algorithm along with an intelligent RIS phase shift

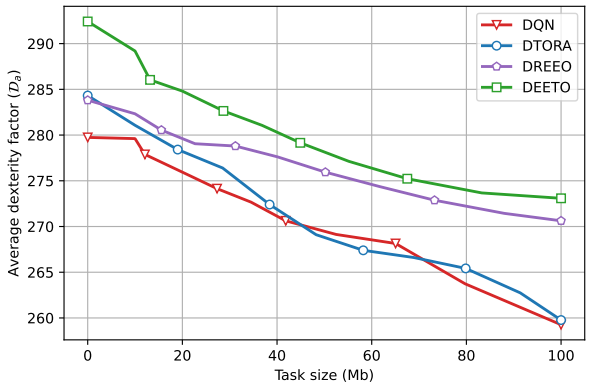

FIGURE 7: Dexterity factor vs increasing task size

mechanism but lacked a hybrid task offloading mechanism, resulting in slightly inferior performance. On the other hand, the DQN scheme, employing a deep Q-Network and employing a binary task offloading mechanism with random RIS phase shifts put it poorer scheme against all the competitor task offloading schemes.

V. CONCLUSIONS

This study addresses the challenge of sustaining high-quality communication services over extended periods in mobile edge computing (MEC) networks, particularly during emergencies, by leveraging UAVs and RIS. We introduced a comprehensive strategy that integrates ze-RIS into UAV-MEC networks, incorporating task offloading and resource allocation mechanisms. Our proposed DRL-driven energy-efficient task offloading (DEETO) scheme minimizes UAV energy consumption by optimizing task offloading decisions, UAV computing resource allocation, communication resource allocation, and RIS phase shift control, employing a hybrid task offloading mechanism. We modeled this problem as a DRL problem and structured it as an MDP and employed A2C algorithm due to its simplicity and less complexity. Simulation results demonstrate that the DREEO scheme emerged as a strong performer, utilizing intelligent ze-RIS phase shift optimization and a strategic hybrid task offloading mechanism. DEETO scheme showcased a significant energy savings of 16.98% from allocated resources, alongside the highest task turnover rate of 94.12%. Notably, DEETO scheme achieved these outcomes within shorter average learning time frames per second (TFPS) of 870 while yielding higher rewards of 57.38, underscoring its effectiveness over alternative approaches.

MUHAMMAD NAQQASH TARIQ obtained his Bachelor's degree (BEE) from The University of Faisalabad (TUF), Faisalabad in 2012, and his Master's degree in Electronics & Communication Engineering from the Beijing University of Posts and Telecommunications, Beijing, China in 2017. Currently, he is a Ph.D. candidate at the School of Information and Communication Engineering, Beijing University of Posts and Telecommunications, Beijing, China. His research interests include Unmanned Ariel vehicular communication networks, Software Defined Networking, fog and edge computing, internet of things, machine learning and deep reinforcement learning, and big data analytics.

JINGYU WANG (Senior Member, IEEE) received the Ph.D. degree from the Beijing University of Posts and Telecommunications, in 2008. He is currently a Professor with the State Key Laboratory of Networking and Switching Technology, Beijing University of Posts and Telecommunications. He has published more than 100 articles in international journals, including IEEE Communications Magazine, IEEE TRANSACTIONS ON CLOUD COMPUTING, IEEE TRANSACTIONS ON WIRELESS COMMUNICATIONS, IEEE TRANSACTIONS ON MULTIMEDIA, and IEEE TRANSACTIONS ON VEHICULAR TECHNOLOGY. His research interests include the IoV and AIoT, SDN, overlay networks, and traffic engineering.

DR. SAIFULLAH MEMON received a master's degree from Quaid-e-awam University of Engineering, Science and Technology, (QUEST) in 2015. Onward he acquired his Ph.D. degree from Beijing University of Posts and Telecommunications (BUPT), China in 2023 in the field of communication engineering. He is the author of more than 30 research articles and is currently working as an Assistant Professor at QUEST. His research interests include wireless communication, sensors, wireless body area networks (WBAN), QoS issues in sensor and ad-hoc networks, routing algorithms, and network security.

MOHAMMAD SIRAJ (Senior Member IEEE) received his Ph.D. from Universiti Technologi Malaysia. He holds Master of Engineering degree in Computer Technology and Applications from Delhi College of Engineering, Delhi, India and Bachelor of Engineering degree in Electronics and Communication Engineering from Jamia Millia Islamia, New Delhi. He has worked as a Scientist in Defense Research and Development Organization, India. Currently he is working as an Assistant Professor in Electrical Engineering, King Saud University. His research interests are Cognitive Wireless Networks, Wireless Mesh Networks, Sensor Networks, Internet of Things, Cloud Computing and Telecom Optical Networks. He has numerous peered publications in well-known international journals and Conferences. He is a Senior Member IEEE and reviewer of many well-known International Journals and Conferences.

MAJID AL TAMIMI (Member, IEEE) received the B.Sc.Eng. degree (Hons.) in electrical engineering from King Saud University, Saudi Arabia, in 2004, and the M.Sc. and Ph.D. degrees in electrical and computer engineering from the University of Waterloo, Canada, in 2010 and 2014, respectively. In 2015, he joined the Department of Electrical Engineering, King Saud University, as an Assistant Professor. He served as a TA with the Department of Electrical and Computer Engineering, University of Waterloo, in 2013, and the Department of Electrical Engineering, King Saud University, from 2004 to 2006. His current research interests include analyzing the energy cost for wireless handheld devices and cloud computing architecture, integrating mobile computing with cloud computing, and studying and designing green ICT solutions.

Abstract

This study reports the trihalomethanes generated during disinfection within the water distribution network of Delhi, India. For 12 months study period tap water samples were collected (n = 216) from the command areas of nine water treatment plants to provide a comprehensive picture of spatial and seasonal variation of trihalomethanes in the city. The mean concentrations of chloroform, bromodichloromethane, dibromochloromethane, bromoform were 34.62 ± 13.09 µg/l, 25.39 ± 11.75 µg/l, 15.83 ± 9.66 µg/l, 1.74 ± 1.51 µg/l respectively, the total trihalomethanes concentration ranged between 11.41–175.54 µg/l. Chloroform was prevalent accounting 45% in total trihalomethanes followed by bromodichloromethane, dibromochloromethane, bromoform accounting 33%, 20%, and 2% respectively. Trihalomethanes concentrations were found to be increasing during summer season and got decreased in the winter and post-monsoon season. Total trihalomethanes levels were found to be highest at Chandrawal water treatment plant command area (85.35–148.38 µg/l) and lowest at Okhla water treatment plant command area (11.41–63.38 µg/l). In many samples trihalomethanes concentrations were discovered to be higher than the allowable limit specified by Indian Standards. A strong relationship between trihalomethanes formation with total organic carbon (r = 0.934) and residual chlorine (r = 0.801) accentuate its capability for monitoring disinfection by-products in the distribution network. Results showed that considerable levels of trihalomethanes are generated in the study area, therefore the competent authorities must take the appropriate steps to regularly monitor the trihalomethanes in drinking water. The findings of this study may help to provide operators with invaluable information on drinking water quality and open up several chances to enhance water quality management.

Keywords Disinfection by-products · Chlorination · Water distribution system · Spatial variability · Seasonal variability

Introduction

For decades chlorine is being used for disinfection purpose in municipal drinking water for controlling the waterborne diseases. Chlorination kills the microorganisms and makes sure in diminishing the waterborne diseases like cholera, typhoid, infectious hepatitis, giardiasis, amoebiasis, bacillary dysentery, enteroviral diarrhoea etc. which results in decreasing death rate (Pan et al. 2014; WHO 2018; Zhang et al. 2010). Chlorine as a disinfectant has higher oxidation potential, high efficiency and low cost when compared to other disinfectants like chlorine dioxide, ozone, ultraviolet radiation, etc. It can also safeguard against regrowth of microorganism and inline biological contamination by leaky water distribution network (Elshorbagy et al. 2000; Chu et al. 2010). All forms of chlorine whether solid, liquid or gas are easily available worldwide and it is primarily used in India. Furthermore, it has previously been discovered that the reaction between chlorine and natural organic matter (NOM) during disinfection produces harmful disinfection by-products (DBPs) like trihalomethanes (THMs), haloacetic acids (HAAs), haloacetonitriles (HANs), etc., (Mazhar et al. 2020; Li et al. 2017; Richardson and Postigo 2015; States et al. 2013; Chowdhury 2013; Zamyadi et al. 2012). During chlorination process THMs and HAAs

are mostly formed DBPs. The NOM is formed by natural degradation of some organic elements and are not easily eliminated by conventional water treatment processes like coagulation further entering the water treatment system (Grenoble et al. 2007). The following can be said about how DBPs form: (Krasner 2009).

NOM + Free chlorine → THMs + HAAs + HANs + Cyanogen-Halides + Other DBPs.

Since the discovery of THMs the first group of DBPs in early 1970s (Rook 1974), the number of identified species are more than 600 till date (DeMarini 2021). A lot of species is known today still THMs and HAAs are considered as decent indicators of the DBPs formed during chlorination (Selvam et al. 2018; Richardson and Postigo 2016; Serrano et al. 2015; Zhai et al. 2014; Shah and Mitch 2012). During the past decade's researchers have found DPBs to be potential carcinogens which are of great concerned (Pan et al. 2014). Various epidemiological studies showed that DPBs are potential carcinogens to human beings and causes bladder cancer, colorectal cancer, adverse reproductive outcomes like still birth and retardation in growth (Jones et al. 2019; Quist et al. 2018; Font-Ribera et al. 2018; Barul et al. 2017; Beane Freeman et al. 2017; Kumar et al. 2014; Bove et al. 2007). Therefore, these THMs are being regulated globally by various agencies and are categorised as possible or probable carcinogens.

The measurement of total trihalomethanes (TTHMs) involves adding together four different species: chloroform (CF), bromodichloromethane (BDCM), dibromochloromethane (DBCM), and bromoform (BF). The four THMs species are considered as a group and guideline values has been set up by many organizations. Due to its carcinogenic nature various international organizations like USEPA, World Health Organization (WHO), European Union (EU) etc., establish the TTHM maximum contaminant levels (MCL) as shown in Table 1.

The presence of NOM in surface water varies at different locations due to difference in environment and different activities by humans. Therefore, the DBPs formed are spatially variable depending upon the concentration and constituents of NOM present in raw water (Brown et al. 2011; Chang et al. 2010a, b; Charisiadis et al. 2015; Delpla et al. 2018; Feungpean et al. 2015; Fooladvand et al. 2011; Guilherme and Rodriguez 2015; Valdivia-Garcia et al. 2016). Numerous studies have demonstrated its variability in relation to a number of variables, including the water supply, pH, temperature, residence time, chlorine dose, type of disinfectant, treatment plant operating parameters, concentration of bromide, applied chlorine dose, residual chlorine, etc., (Kalankesh et al. 2021; Kumari and Gupta 2015; Brown et al. 2011; Legay et al. 2011; Fooladvand et al. 2011; Chang et al. 2010a, b; Chowdhury et al. 2009; Chaib and Moschandreas 2006; Richardson et al. 2003). Owing to climate change or human caused discharges there is temporal difference in source water which are of great concern (States et al. 2013; Wang et al. 2017). The THMs formed in drinking water should be monitored effectively to protect human health. Various lab scale studies have been done resulting in higher concentration of DBPs formed (Leavey-Roback et al., 2016; Linge et al. 2017; Rodriguez and Sérodes 2001). These monitoring program would be more effective when they are studied statistically by modelling to find predictive values. Also, health risk linked with DBPs in water can be optimised by these modelling approach.

Given that chlorine is India's most common disinfectant, there is a considerable risk of THMs exposure in Delhi. The MCL for THMs was established by the Indian government in 2012 to adhere to WHO guidelines (IS:10500 2012). There have been concerns that it was crucial to quantify the THMs because very few studies in India are looking at THM levels in drinking water. The first and second objective was to analyse DBPs spatially i.e., THMs in the municipal supply system of Delhi and to examine the variation of THMs seasonally respectively. The primary goal was to utilise this database to analyse the variation of THMs spatially and seasonally. There is lack of monitoring data nationwide to explain the DBPs formation and the results obtained will help in future water

management for the populace receiving treated drinking water.

Materials and methods

Study area

Delhi is one of the important metropolitan cities located in Northern India having an area of 1483 km^2. The population of the city is 19.43 million (Census of India 2020). There are nine major water treatment plants (WTP) supplying drinking water in Delhi, namely Chandrawal WTP, Wazirabad WTP, Haiderpur WTP, Bhagirathi WTP, Bawana WTP, Nangloi WTP, Sonia Vihar WTP, Okhla WTP, Dwarka WTP abbreviated as CWTP, WWTP, HWTP, BWTP, BAWTP, NWTP, SVWTP, OWTP, DWTP respectively as shown in Fig. 1 and the command areas of the nine WTPs are referred as CCA, WCA, HCA, BCA, BACA, NCA, SVCA, OCA, DCA respectively. One minor WTP was built at Commonwealth Games Village (CGWTP). The major resource of water in Delhi is Ganga River and Yamuna River which is conventionally treated by processes i.e., coagulation, flocculation, sedimentation, filtration, followed by disinfection before supply. The atmosphere of the city is humid subtropical with high variation of temperature in summers, winters and rainy season which effects the availability of raw water.

Water sampling program and sample collection

From January 2019 to December 2019, a year-long sampling programme was implemented to cover all four seasons i.e., summer (April, May, June), monsoon (July, August September), post monsoon (October, November, December) and winter (January, February, March). Two tap water samples from the treated/processed water after chlorination were taken at the user's end at two locations (L1 and L2) as illustrated in Fig. 1 from the nine Delhi WTPs command areas, with the exception of CGWTP because of its small catchment area. Grab sampling was done at all sampling points in a 40 mL Teflon lined screw cap glass vials washed with cleansing agent, then rinsed with deionized water and dried at 400 °C for 30 min (APHA 2017). The addition of sodium thiosulfate came before sampling to quench the formation of THMs and eradicate chlorine reaction. To prevent THM volatilization the sampling vials were filled carefully eliminating air bubbles inside the sample. The samples were transferred to the laboratory after collection for extraction at

4 °C in an ice box away from light. Separate samples were collected for physicochemical parameters.

Analytical methods

The investigation procedures and equipment used in this study are shown in Table 2. A pH meter was used to measure the temperature and pH. The samples were filtered by a glass microfiber (2-µm) then Total Organic Carbon (TOC) was analysed by TOC analyzer in accordance with the 5310C Standard Method (APHA 2017) using combustion techniques. Residual chlorine (in mg/l) was determined by the N,N-diethyl-p-phenylenediamine (DPD) titrimetric method 4500-Cl-G given in Standard method (APHA 2017). Four THMs (CF, BDCM, DBCM and BF) were analysed in according to United States Environmental Protection Agency (USEPA) 551.1 Method (USEPA 1995). Samples were prepared and extracted using liquid–liquid extraction (LLE) method with n-pentane for injection according to 6232-B Standard Method (APHA 2017). The THMs concentration in aqueous samples were determined by gas chromatography coupled with mass spectrophotometer (GC–MS) system, while chromatographic separation of the analyte was carried out with a HP-5ms column, 30 m × 0.25 mm × 0.25 µm (Agilent Technologies). All chemicals were of the analytical grade from Merck (India), solvents and standards were from Sigma-Aldrich. High purity gas Helium, and de-ionized water was used in the study.

Results and discussion

Water quality parameters

The important water quality parameters measured in the command areas of nine WTPs of Delhi are shown in Table 3. All the statistical analyses were done using Microsoft Office Excel for calculating the measured parameters as mean ± standard deviation (SD). The pH measured in the samples showed very little variation in the pH values having no significant difference in the studied region. The maximum pH value in command areas of nine WTPs were found to be highest at HWTP (7.85) followed by BAWTP (7.84), CWTP (7.82), NWTP (7.81), BWTP (7.7), WWTP (7.68), SVWTP (7.66), DWTP (7.62) and lowest at OWTP (7.61). The pH measured in the distribution system was in the range of 6.65–7.85 with an average of 7.29 ± 0.23 for the study period. All the water samples revealed a normal range of pH values. In this study the temperature pattern is also

Table 3 THMs and water quality parameters concentrations in the study area

Parameter	CCA	WCA	HCA	BCA	BACA	NCA	SVCA	OCA	DCA

BDCM (µg/l)	39.87 ± 5.70	33.94 ± 6.64	30.39 ± 9.61	30.27 ± 10.07	16.14 ± 3.81	25.82 ± 6.18	30.35 ± 5.80	10.63 ± 4.32	11.09 ± 3.66
DBCM (µg/l)	26.27 ± 6.88	23.09 ± 7.06	20.95 ± 7.89	20.33 ± 8.53	9.26 ± 2.56	16.09 ± 4.63	19.06 ± 4.97	3.85 ± 1.98	3.56 ± 1.82
BF (µg/l)	3.51 ± 1.54	2.48 ± 0.94	2.14 ± 1.21	2.38 ± 1.52	0.99 ± 0.52	1.61 ± 0.84	2.38 ± 1.40	0.06 ± 0.18	0.10 ± 0.28
TTHM (µg/l)	119.53 ± 20.51	102.57 ± 21.94	94.80 ± 28.92	92.56 ± 30.26	50.65 ± 10.39	78.55 ± 17.86	92.16 ± 16.59	33.05 ± 12.58	34.34 ± 10.01

similar for all the command areas of nine WTPs. The measured temperature was in the range of 12.60–31.60 °C for the duration of the research with an average of 21.51 ± 5.95 °C.

The maximum TOC value in the command areas of nine WTPs were found to be highest at BWTP (12.92 mg/l) followed by CWTP (12.61 mg/l), HWTP (12.41 mg/l), WWTP (12.38 mg/l), SVWTP (11.41 mg/l), NWTP (9.88 mg/l), BAWTP (7.19 mg/l), OWTP (4.75 mg/l) and lowest at DWTP (4.28 mg/l). The TOC ranged between 0.57 and 12.92 mg/l with an average of 5.48 ± 2.85 mg/l for the study period. TOC concentrations at the command areas of CWTP, WWTP, HWTP, BWTP, SVWTP were found to be higher than BAWTP, NWTP, OWTP and DWTP. Variability was seen in the levels of TOC in the collected tap water reflecting some infestation of wastewater into the distribution network.

Residual chlorine works as a disinfectant in the distribution system. The maximum residual Cl value measured in nine WTPs command areas were found to be highest at BWTP (2.17 mg/l) followed by CWTP (1.83 mg/l), WWTP (1.75 mg/l), HWTP (1.74 mg/l), SVWTP (1.66 mg/l), NWTP (1.32 mg/l), BAWTP (0.97 mg/l), OWTP (0.78 mg/l) and lowest at DWTP (0.63 mg/l). The residual Cl in the water samples ranged from 0.14 to 2.17 mg/l with an average of 0.94 ± 0.43 mg/l for the study period, found to be much higher than the permissible limit, in treated water the free residual Cl ranges between 0.2 and 1 mg/l (IS:10500 2012). Free residual chlorine concentrations were found on the higher side at the command areas of CWTP, WWTP, HWTP, BWTP, NWTP, SVWTP and were found within the permissible limit only at BAWTP, OWTP and DWTP command area. This can be due to an error in estimating the post-chlorination dose or it can be due to some infestation of wastewater into the distribution network. Higher values of residual chlorine suggest more formation of trihalomethanes in the water samples.

Trihalomethanes

The command areas of nine WTPs in Delhi were found to have different concentrations of four THM species. The maximum CF value quantified in the command areas of nine WTPs were found to be highest at BWTP (66.80 µg/l) followed by CWTP (62.34 µg/l), HWTP (57.85 µg/l), SVWTP (57.45 µg/l), WWTP (56.88 µg/l), NWTP (48.68 µg/l), BAWTP (36.37 µg/l), OWTP (32.14 µg/l) and the lowest at DWTP (28.08 µg/l). The CF ranges between 7.53 and 66.80 µg/l with an average of 34.62 ± 13.09 µg/l. The maximum BDCM value quantified in the command areas of nine WTPs were found to be highest at BWTP (56.46 µg/l) followed by CWTP (49.37 µg/l), WWTP (46.26 µg/l), HWTP (45.86 µg/l), SVWTP (43.52 µg/l), NWTP (34.57 µg/l), BAWTP (25.37 µg/l), OWTP (21.37 µg/l) and lowest at DWTP (18.98 µg/l). The BDCM ranges between 3.88 and 56.46 µg/l with an average of 25.39 ± 11.75 µg/l.

The maximum DBCM value quantified in the command areas of nine WTPs were found to be highest at BWTP (45.68 µg/l) followed by WWTP (36.85 µg/l), CWTP (36.54 µg/l), HWTP (33.65 µg/l), SVWTP (28.63 µg/l), NWTP (23.59 µg/l), BAWTP (16.83 µg/l), OWTP (9.22 µg/l) and lowest at DWTP (7.19 µg/l). The DBCM ranges between 0 and 45.68 µg/l with an average of 15.83 ± 9.66 µg/l. Sometimes DBCM concentration levels were not detected (ND) in the water samples. The maximum BF value quantified in the command areas of nine WTPs were found to be highest at BWTP (6.60 µg/l) followed by CWTP (6.26 µg/l), SVWTP (5.67 µg/l), HWTP (4.68 µg/l), WWTP (3.85 µg/l), NWTP (3.68 µg/l), BAWTP (1.68 µg/l), DWTP (1.24 µg/l) and lowest at OWTP (0.65 µg/l). The BF ranges between 0 and 6.60 µg/l with an average of 1.74 ± 1.51 µg/l. BF concentrations were often below the limit of detection in these samples. When BF is present, it means that raw water contains bromide. A summary of the THM concentrations in tap water samples is shown in Table 3.

The variation of TTHMs at all the locations are shown in Fig. 2. The maximum TTHM value measured in the command areas of nine WTPs were found to be highest at BWTP (175.54 µg/l) followed by CWTP (148.38 µg/l), WWTP (142.10 µg/l), HWTP (141.21 µg/l), SVWTP (134.18 µg/l), NWTP (107.19 µg/l), BAWTP (78.93 µg/l), OWTP (63.38 µg/l) and lowest at DWTP (50.74 µg/l). The average TTHM concentration for the study period was found to be 77.58 ± 35.30 µg/l and it ranges from 11.41 µg/l to 175.54 µg/l. WHO has adopted a fractional approach to account the total toxicity of trihalomethanes and the results obtained were checked as per WHO's formula. The TTHM values were found to be higher as per WHO G.V. in the command area of CWTP, WWTP, HWTP, SVWTP and NWTP as shown in Fig. 2e. The variance in TTHM concentration may be a result of the treated water's varied TOC and residual chlorine content as well as its geographical distribution.

For the study period the average TTHM concentrations of the 24 samples taken from each of the command area of nine WTP's ranged from 85.35 to 148.38 µg/l at CWTP, 54.36 to 142.10 µg/l at WWTP, 46.42 to 141.21 µg/l at HWTP, 37.50 to 175.54 µg/l at BWTP, 33.13 to 78.93 µg/l at BAWTP, 21.48 to 107.19 µg/l at NWTP, 57.50 to 134.18 µg/l at SVWTP, 11.41 to 63.38 µg/l at OWTP and 15 to 50.74 µg/l at DWTP. The concentration of THMs measured were lower than those measured in Jharkhand, India (i.e. 231 to 484 µg/l), (Kumari and Gupta 2015). The spatial variation in the average trihalomethanes concentration for the study period is shown in Fig. 3.

Among the THMs formed, CF had the maximum concentration (45% of TTHM) trailed by BDCM (33% of TTHM), DBCM (20% of TTHM) and BF (2% of TTHM).

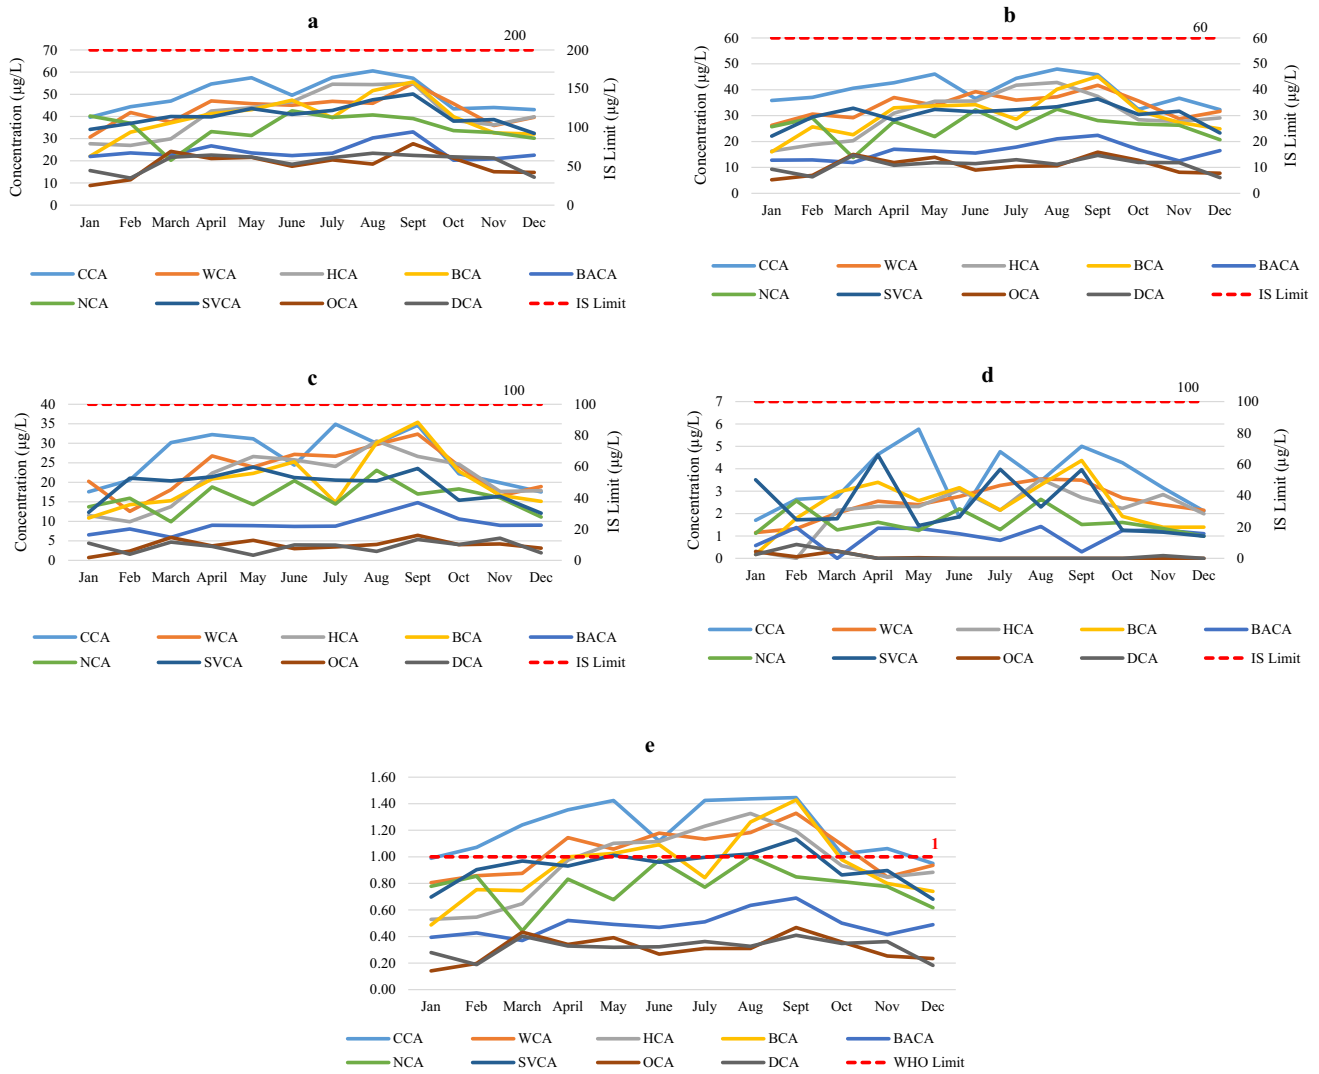

Fig. 2 THMs variation in the distribution system of Delhi **a** CF **b** BDCM **c** DBCM **d** BF **e** TTHM based on WHO's G.V

Mean speciation at all the locations is shown in Fig. 4. The order of contribution in TTHM by each THM species is CF > BDCM > DBCM > BF. Earlier findings have confirmed that the highest concentration levels among the THMs species is of CF (Domínguez-Tello et al. 2015; Uyak et al. 2014). The presence of significant levels of organic matter in the source water may be the reason chloroform typically makes up the highest share of DBPs in chlorinated drinking water. Furthermore, surface water sources are more likely than ground water sources to have greater TOC levels. The above observation is supported by the high concentration of TOC discovered in this investigation. The average THM concentrations of each species measured were mostly within the acceptable limits by Indian standards for drinking water, but they were not within the permissible limit corresponding to WHO and USEPA guidelines for Total THMs. A comparison of THMs concentrations found in drinking water detected in India and around the world is shown in Table 4.

Variation in THMs were analyzed using box and whiskers plot representing the minimum, maximum, mean and median values of THMs for the study period. The median value is shown by the lines inside the boxes, the 75th and 25th percentile values are shown by the top and bottom of the boxes, and the mean value is represented by the cross (x). Outlying points are indicated by the dot (.). The maximum and minimum values are displayed at the top and bottom

and the 75th percentile concentration of the TTHMs were 45.79 and 101.83 µg/l respectively.

Seasonal variation of THMs

THMs formation significantly varied in the four seasons and their seasonal variation in the municipal water supply system are presented in Fig. 6. The results showed the concentration of CF formed is higher than the other THM species at all locations. The maximum THMs formation was observed at CWTP command area: 142.12 µg/l in the monsoon season. The minimum THMs formation was observed in OWTP command area: 27.11 µg/l in the winter season. Higher THMs concentrations were observed in the monsoon followed by summer and post-monsoon season, while the lowest THMs concentrations were observed in winters. In summers higher temperature generally increased the THM levels and the variations were consistent with other studies reported (Delpla et al. 2018; Domínguez-Tello et al. 2015; Kalankesh et al. 2021; Uyak et al. 2014; Wang et al. 2017). During all the seasons the THMs measured in the water samples were below the MCLs in drinking water according to Indian standards (IS:10500, 2012). In summer and monsoon season the populace residing in the command area of CWTP, WWTP, HWTP, BWTP were exposed to THMs greater than 100 µg/l. Variation of TTHM were much higher at command areas of four WTP i.e., CWTP, WWTP, HWTP, BWTP in summer and monsoon. The lowest levels of TTHM were observed at command areas of OWTP and DWTP in winter and post monsoon season. The THMs measured in the water samples similarly varied at all locations as the source of water is same.

Generally, the variation in THM levels were higher in the order monsoon > summer > post-monsoon > winter. It's possible that this phenomenon is connected to high water temperatures that drop in the post-monsoon and winter months. The mean water temperature was 28.77 °C in the summer, 24.16 °C in the monsoon, 17.03 °C

in the winter, and 16.08 °C in the post-monsoon. Since high temperatures typically speed up reactions, there was a strong correlation found between water temperature and THM production (Scheili et al. 2015; Rahman et al. 2014; Chowdhury et al. 2011). The summertime had greater THM levels than the winter, according to numerous studies (Ahmed et al. 2019; Guilherme and Rodriguez 2014; Lee et al. 2013; Mercier Shanks et al. 2013; O'Driscoll et al. 2018; Sadeghi et al. 2019; Scheili et al. 2015).

THMs in the water could be detected by an organic precursor like TOC, which measures the NOM (Guilherme and Rodriguez 2014; Serrano et al. 2015; Zhou et al. 2019). The average THM levels in our study were greater in the monsoon than they were in the summer. In Delhi's subtropical monsoon climate, the monsoon brings exceptionally high rainfall (around 380.1 mm precipitation) despite the city's maximum average temperature of 28.77 °C during the summer. Water resources NOM concentration is increased by surface runoff caused by rain, raising the TOC level in drinking water. Its average concentrations in the samples were found to be 3.57 mg/l in winter, 5.81 mg/l in summer, 7.82 mg/l in monsoon and 4.73 mg/l in post-monsoon, so much greater during the monsoon. Compared to winter, the monsoon had 2.2 times greater TOC levels. Warm weather and corresponding high TOC values are likely to blame for the greater average THM concentration during the monsoon.

The monsoon season brings with it greater surface runoff, algal development, and biomass production than the winter months, which transferred more NOM and other contaminants from the regions of water catchment to the sources of raw water. Due to higher TOC and higher temperatures recorded, it is possible for bacteria to grow more quickly in the distribution system. Additionally, stronger chlorine dosages are typically used during this season to prevent infections and regulate the growth of algae, which raises the content of THMs. Furthermore, a greater residual chlorine content could potentially encourage the formation of THMs (Gallard and Von Gunten 2002). Average concentration of residual chlorine in the samples were found to be 0.79 mg/l in winter, 0.97 mg/l in summer, 1.14 mg/l in monsoon and 0.86 mg/l in post-monsoon, so markedly higher in the monsoon. Moreover, increased disinfectant dosages and organic precursors that react with chlorine may be the cause of summer and monsoon THM concentrations (Serrano et al. 2015).

Winter and the post-monsoon seasons have the minimal THM levels, It could be connected to a decreased rate of reaction that reduced THM generation. At lower temperatures, the rate at which chlorine and NOM react to generate THMs is slower (Valdivia-Garcia et al. 2016). In contrast, the average temperature in post-monsoon (16.08 °C) and in winter (17.03 °C) is notably lower than during the summer (28.77 °C). Additionally, there was significantly less rainfall in post-monsoon (about 41.6 mm precipitation) and in winter (about 58 mm precipitation). Numerous causes could be responsible for the seasonal variations in THM concentrations found in Delhi's drinking water. These discrepancies could be caused by seasonal changes in the characteristics and makeup of organic precursors, the source water's quality, the water's temperature, the quantity of chlorine supplied, and the residual chlorine (Brown et al. 2011; Pieri et al. 2014; Won et al. 2013). Determining the effect of each operational and water quality characteristic on the occurrence of THM in water distribution networks is difficult, though, due to the interconnections between parameters (Rodriguez and Sérodes 2001).

The emergence of THMs, a type of chlorinated DBP, in drinking water has highlighted the need to investigate alternative disinfectants and novel treatment methods. Other disinfectants that can be used alone or in conjunction with chlorine include ozone, chloramines, chlorine dioxide, and, more recently, ultraviolet (UV) light (Liu et al. 2021, 2020; Luo et al. 2020; Yang et al. 2013). It is necessary to consider the usage of different disinfection alternatives to chlorination, even though they can result in non-chlorinated DBPs. In general, the health risk associated with DBP exposure in drinking water can be effectively controlled by creating alternate disinfection techniques for low DBPs (Kimura et al. 2019; Mazhar et al. 2022). The removal of organic and inorganic substances before disinfection has been found to be an efficient way to reduce the likelihood for the development of chlorinated DBPs, as these substances act as precursors for DBPs (Matilainen et al. 2010). The NOM can be largely eradicated using a normal treatment by combining or replacing its components with more efficient methods such enhanced coagulation, membrane filtration, and granular activated carbon (GAC) filtering (coagulation, flocculation, sedimentation, and filtration) (Badawy et al. 2012; Mazhar et al. 2020).

To minimise the development of DBPs, models can guide decision-making for operational control during the treatment process. Examples of such controls include adjusting the pH and disinfectant dose or the hydraulic residence duration (contact time) in reservoirs (Chowdhury et al. 2009). Additionally, DBP models can be a helpful to determine where to increase the residual levels of chlorination to guarantee the eradication of bacteria and minimise the development of DBPs. To choose the sampling locations for the distribution system's water quality control, additionally, residual disinfectant models can be combined with the DBP models (Haddad et al. 2014). Considering this, appropriate management, oversight, and control procedures are needed to prevent THM development in drinking water supplies and shield people from their harmful consequences. To lower the content of THMs in water supplies, DWTP utilities must apply appropriate treatment techniques and control

Table 5 Pearson correlation between water quality parameters and THM

	pH	Temperature (°C)	TOC (mg/l)	Res. Chlorine	TTHM (µg/l)
pH	1				
Temperature (°C)	0.401	1			
TOC (mg/l)	0.259	0.343	1		
Res. chlorine (mg/l)	0.195	0.195	0.767	1	
TTHM (µg/l)	0.188	0.226	0.934	0.801	1

procedures. To lessen the production of THMs, disinfection must be done under carefully monitored circumstances. Future efforts should focus on reducing the total organic carbon content of the water supply sources. Reduced generation of DBPs might result from improved control over operational parameters (pH, disinfection contact duration, etc.). Finally, to analyse trends and supervise the water treatment and distribution system, regular THM monitoring, and regulation is necessary.

Correlation between water quality parameters and THMs

Correlation matrix was established by Pearson's correlation to evaluate the most prominent parameter accountable in THMs formation and the correlation is shown in Table 5.

From the Pearson correlation matrix, a weak relationship was obtained between total THMs formation with pH (r = 0.188) and temperature (r = 0.226). A strong relationship was obtained between THM formation with TOC (r = 0.934) and residual chlorine (r = 0.801). This indicates that pH and temperature are not much influential parameter in the formation of THM. For an increase in the amount of TOC and residual chlorine in treated water will lead to rise in THM formation. This indicates that TOC and residual chlorine will be the influential parameter in the formation of THM.

Conclusion

In this research 216 water samples from the command areas of nine WTP's of Delhi were analysed during January 2019 to December 2019 for THMs monitoring. It was observed that the treated water samples at various locations showed higher total THMs concentrations ranging from 11.41 to 175.54 µg/l. The concentration of THMs species were found to be varying between: CF (7.53–66.80 µg/l), BDCM (3.88–56.46 µg/l), DBCM (ND-45.68 µg/l) and BF (ND-6.60 µg/l). At some locations the total THM levels were higher than the permissible limits given by WHO (100 µg/l) and USEPA (80 µg/l). Water sample showed higher CF levels followed by BDCM, DBCM and BF levels. Seasonal variation of THMs showed higher concentrations in summer and monsoon and lower concentrations in winter and post-monsoon. Formation of THMs is higher because of high rate of chemical reactions in summer and higher dose of chlorination is usually practiced in monsoon. High, moderate and weak correlations were observed between water quality parameters and THMs. Seasonal variation of THMs also depends on TOC (r = 0.934) and residual chlorine (r = 0.801) which are the prominent parameter responsible for THM formation. From the results obtained it is observed that the population living in the command areas of six WTPs are consuming water with high level of THMs. The CWTP command area showed the highest level of THMs followed by WWTP command area > HWTP command area > BWTP command area > SVWTP command area > NWTP command area. Population living in command area of BWTP command area, OWTP command area and DWTP command area are consuming water with low level of THMs. The existence of THMs in water suggests the presence of other DBPs. These uncharacterized DBPs can also be reduced by controlling the formation THMs in drinking water. Due to high levels of THMs measured in this study, necessary actions are required by the concerned authorities to monitor the THM formation.

Water is the utmost essential commodity for the support of life process in animals. In recent decades, rapid industrialization and uncontrolled agricultural practices have led to increased level of toxic pollutants in groundwater, including organic pollutants (dyes, nitroarene compounds, antibiotics, etc.), inorganic pollutants (heavy metals, nanoparticles, etc.), and pesticides, posing a serious threat to human health and the environment. Although various technologies such as adsorption, photocatalysis, reverse osmosis, filtration, sedimentation, flocculation, and precipitation are available for the elimination of toxic pollutants from wastewater, issues such as their cost and efficacy limit their usage. Recently, catalysis has been found to be the most effective approach since it exhibits significant capability to eliminate almost all the pollutants and offers the benefit of simple design and low initial cost. In the present study, ternary zinc–copper–nickel layered double hydroxide (ZnCuNi-LDH) synthesized using facile acid hydrolysis method was employed as an efficacious heterogeneous catalyst for the reduction of NACs (para-nitrophenol and para-nitroaniline) and degradation of organic azo dyes (methyl orange, amaranth, and brilliant black). ZnCuNi-LDH exhibited superior catalytic activity for the reduction of all five model pollutants with reduction efficiency of more than 95% within a short time span of 5 min. Therefore, keeping in view the layered structure, high specific surface area, and remarkable catalytic performance, ZnCuNi-LDH holds immense potential for the large-scale catalytic degradation of refractory pollutants.

KEYWORDS
azo dyes, catalytic reduction, layered double hydroxide, nitroarene compounds, wastewater purification

1 | INTRODUCTION

The expulsion of refractory pollutants from water sources holds prime significance for the sustenance of ecosystems and bio-diversities, since the availability of potable water has become a burgeoning predicament because of increasing industrialization and urbanization. The contamination of water by a variety of toxic pollutants including dyes, phenolic compounds, volatile organic compounds (VOCs), drugs, and surfactants is a matter of grave concern as these pollutants exhibit toxic, carcinogenic, and mutagenic effects, thereby threatening human health and the ecosystem.[1] Nitroarene compounds (NACs) and azo dyes are among the most vicious organic pollutants that are responsible for deteriorating water quality. Their ubiquitous presence in water resources is a

 © 2024 John Wiley & Sons Ltd.

direct consequence of the uninhibited discharge of untreated effluents from paper, cosmetics pulp, printing, and textile industries. These pollutants often possess chemical and thermal stability, bioaccumulation capability, and high levels of toxicity, thereby causing severe detrimental effects on aquatic and non-aquatic ecosystems. Thus, the removal of these toxins from water sources has become an issue of serious concern so as to maintain ecological balance (Figure 1).[2]

Till today, a variety of methods such as adsorption, coagulation-flocculation, ultra- and nanofiltration, biological processes, and ion exchange have been utilized for pollutant sequestration from water bodies.[3–5] However, these techniques possess certain limitations, that is, high operating cost and low efficiency, thereby hindering their commercial usage at large scale. During the past few years, catalysis has emerged as a promising strategy for water remediation because of its easy and versatile nature, high efficacy, and economic viability.[6] Specifically, catalytic degradation of pollutants using $NaBH_4$ serves as an effective green method to break down highly stable azo dye and nitroarene molecules into smaller, safer organic moieties, thereby reducing their toxicity. Furthermore, this approach may also be used for conversion of 4-nitrophenol to 4-aminophenol that can be employed as a corrosion inhibitor, an intermediary building block for the manufacture of dyes and pigments, hair colors, drugs (analgesic-phenacetin, antipyretic-paracetamol, etc.), and in the textile and pharmaceutical industry. In addition, catalysis produces safer degradation products that are easily detectable using techniques such as absorption spectroscopy.

Despite this, the applicability of this method is still quite limited because of the time-intensive nature of the reaction, that is, thermodynamic favorability but kinetic unfeasibility. However this drawback can be overcome using several approaches, out of which the most favored one is the usage of the catalyst along with the reducing agent $NaBH_4$ that speeds up the reaction by overcoming the kinetic barrier. Previously, materials such as metal and metal hydroxide and oxide nanoparticles, carbon and carbon-based materials, polymer-based materials, and metal–organic frameworks (MOFs) have been used as co-catalysts for nitroarene reduction and dye degradation.[7–9] For instance, Ahmad et al. synthesized a composite consisting of iron oxide functionalized with Cu nanoparticles and applied it for $NaBH_4$-assisted reduction of several organic pollutants.[10]

These materials possess certain disadvantages such as agglomeration tendency, complex and expensive synthesis methods, and low catalytic efficiency, because of which the use of these materials is not favored. Also, for a material to act as a good catalyst, it should possess certain features such as high specific surface and large number of active sites.

Based on the above criteria, anionic layered materials, especially layered double hydroxides (LDHs), have emerged as breakthrough materials for catalytic applications by virtue of their high surface area, abundance of active sites, biocompatible nature, and low toxicity. LDHs

possess a unique two-dimensional layered structure with positively charged layers composed of divalent (M^{2+} = Zn, Ni, Mg, etc.) and trivalent cations (M^{3+} = Al, Fe, Sb, etc.) existing in octahedral coordination with six hydroxyl moieties, and exchangeable anions (Cl^-, NO_3^-, SO_4^{2-} etc.) and water molecules present in the interlayer region. As a result, these materials possess several exemplary physicochemical features such as structural stability and anion exchange capability along with the unique memory effect property and exhibit a myriad of electronic, magnetic, and optical properties.[11] The use of transition metals (e.g., Cu, Ni, and Co) as the intralayer cations in LDHs further augments these properties because of their special electronic structures, high surface area, and large number of active sites, which endows them with the ability to adsorb various molecules on their surface and activate them. Moreover, since transition metals can attain variable oxidation states, they can be easily paired with a variety of anionic, cationic, and neutral ligands to form homogenous (e.g., organometallic complexes) and heterogeneous catalysts (e.g., transition metal-based LDHs). Several transition metal-containing binary LDHs have been previously employed for the degradation of organic compounds, but they exhibit low catalytic activity.[12] The introduction of another transition metal in the lattice is quite desirable since it warrants improved catalytic activities because of unique geometrical and synergistic interactions between the transition metals. Therefore, transition metal-based-ternary LDHs may be considered as excellent potential candidates for catalytic applications since incorporation of additional transition metal ion in the existing lattice can help fulfill all the characteristics of good catalyst material.[13] Still, research focusing on synthesis and application of transition metal-based-ternary LDHs for $NaBH_4$-assisted reduction of NACs and azo dyes is still quite limited, owing to the difficulty in governing the oxidation states of transition metal ions. Hence, the development of facile synthesis method for transition metal-based ternary LDHs and their usage in catalytic applications is extremely desirable.

Therefore, the objective of this study was to evaluate the efficacy of ternary ZnCuNi-LDH as a catalyst for the reduction of organic pollutants. For this purpose, first, the ZnCuNi-LDH lattice was successfully synthesized using acid hydrolysis approach.[14] Later, a systematic investigation of the catalytic activity of the synthesized ZnCuNi-LDH toward the hydrogenation of 2 NACs (*p*-Nitrophenol and *p*-Nitroaniline) and reductive degradation of different azo dyes (amaranth, brilliant black, and methyl orange) was conducted. The impact of various influencing parameters (catalyst dosage, pollutant concentration) on the catalytic activity of synthesized ZnCuNi-LDH for the reduction of *p*-NP and MO was also studied. Additionally, the universality and the recyclability of ZnCuNi-LDH in the catalysis process were also assessed. The results suggested that the NACs and organic azo dyes underwent rapid and efficacious reduction when $NaBH_4$ was employed as reductant and ZnCuNi-LDH was used as the catalyst.

2 | EXPERIMENTAL SECTION

2.1 | Materials and methods

ZnCuNi-LDH was first prepared using acid hydrolysis method as reported in our previous study.[14] For the synthesis, first, 5-mL aqueous solutions of zinc acetate dihydrate (0.4664 g), copper acetate monohydrate (0.0374 g), and nickel acetate tetrahydrate (0.0466 g) were prepared separately. Afterward, copper acetate monohydrate and nickel acetate tetrahydrate solutions were added to zinc acetate dihydrate solution and then stirred for 15 min so as to obtain complete homogeneity. To initiate the acid hydrolysis process, 30% H_2O_2 solution (2.5 mL) was added to reaction solution, followed by distilled water (15 mL), and a shift in the solution color from greenish-blue to brown was observed. Reaction mixture was then ultrasonically treated for 30 min to achieve uniformity in the size of LDH particles, followed by stirring for 1 day at ambient temperature. After completion of stirring, the solution was completely dried at 60°C in oven. The schematic representation of ZnCuNi-LDH synthesis is shown in Scheme 1.

2.2 | Characterization

Crystallographic properties of the sample were studied by the use of powder X-ray diffraction (PXRD) diffractograms collected using a high-resolution Bruker diffractometer (D8 Discover) using Cu Kα radiation. Data were recorded at 298 K over the range of 2θ = 5–70° at a scan rate of 1.0 s/step and step size 0.02. The various functional groups present in synthesized material were analyzed using Fourier-transform infrared (FTIR) spectrum collected with the help of a Perkin Elmer 2000 FTIR spectrometer by the KBr disk technique. Thermal degradation behavior was evaluated by thermo gravimetric analysis (TGA) data that was recorded using the Pyris 1® thermo gravimetric analyzer in the range 50–900°C at a heating rate of 5°C min^{-1} under flowing nitrogen. SEM imaging and EDX analysis of the synthesized samples was done using a Zeiss Gemini SEM microscope. The specific surface area (S_{BET}) and average pore size distribution were

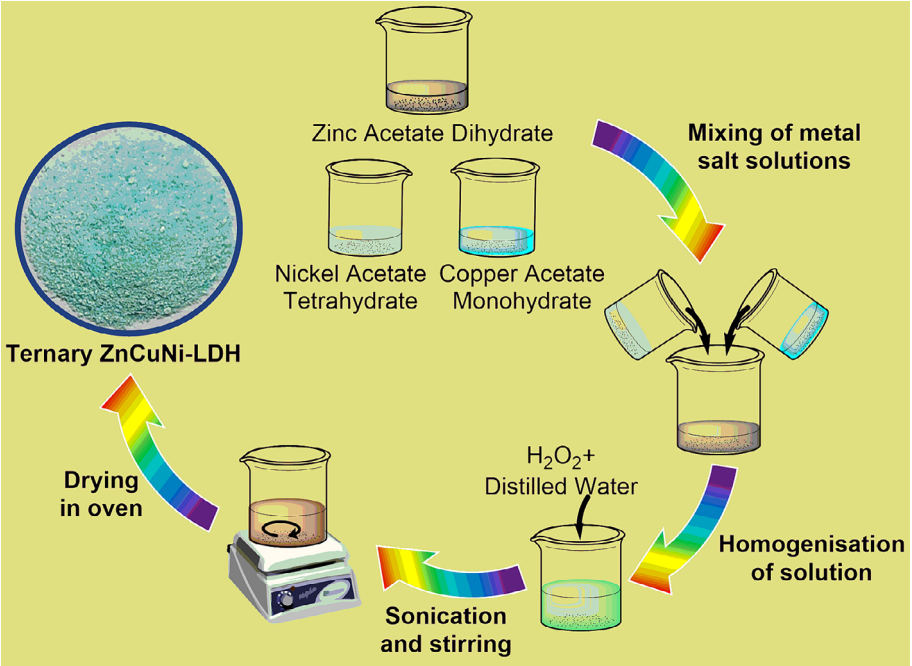

SCHEME 1 Synthesis of ternary ZnCuNi-LDH via acid hydrolysis method.

obtained by BET-BJH (Barrett–Joyner–Halenda) N_2 adsorption–desorption technique on a Quanta chrome Nova-1000 instrument at liquid nitrogen temperature 77 k.

2.3 | Evaluation of catalytic activity

2.3.1 | Catalytic hydrogenation of NACs

10 mM stock solutions of NACs and 50 mM stock solution of $NaBH_4$ were prepared with deionized water, and dilutions were made as required.

2.3.2 | *p*-Nitrophenol

The catalyst-assisted hydrogenation of *p*-nitrophenol (*p*-NP) was accomplished using the reducing agent $NaBH_4$ and ZnCuNi-LDH as the catalyst. Initiation of the reaction was done by adding freshly prepared $NaBH_4$ solution (50 mM, 10 mL) and distilled water (10 mL) to aqueous solution of *p*-NP (1 mM, 10 mL), and it was stirred well to ensure homogeneity. This was followed by the addition of ZnCuNi-LDH catalyst (5 mg) to reaction mixture at room temperature and recording the absorbance at pre-fixed time intervals using Shimadzu UV–Vis spectrophotometer. The kinetic progress of the hydrogenation was assessed by determining the variation in absorbance of reaction mixture at a wavelength of 400 nm at 1-min intervals till the peak completely disappeared and the solution became colorless.

2.3.3 | *p*-Nitroaniline

Similarly, the reduction experiment for *p*-nitroaniline was carried out by first stirring *p*-nitroaniline (*p*-NA) aqueous solution (1 mM, 10 mL) with freshly prepared $NaBH_4$ solution (50 mM, 10 mL) and distilled water (10 mL) and then followed by addition of ZnCuNi-LDH (5 mg) at room temperature. The progression of catalytic reduction was evaluated by measuring the absorbance of reduction mixture at a wavelength of 380 nm at 1-min intervals till the solution was completely decolorized.

2.3.4 | Catalytic degradation of methyl orange (MO), amaranth (Ama), and brilliant black (BB) dyes

To evaluate the decolorization ability of LDHs toward azo dyes, catalytic reduction was carried out using Ama, BB, and MO as model molecules. First, 100 mg L^{-1} stock solutions of Ama, BB, and MO dyes and 50 mM stock solution of $NaBH_4$ were prepared. For the catalytic degradation of MO dye, MO solution (100 mg L^{-1}, 10 mL) was stirred with freshly prepared $NaBH_4$ solution (50 mM, 10 mL) and distilled water (10 mL) to ensure complete mixing. Following this, ZnCuNi-LDH catalyst (5 mg) was added to the reaction mixture. The progress of reaction was assessed by measurement of the absorbance at $\lambda_{max} = 463$ nm for MO at 1-min intervals till the peak disappeared and the solution was completely decolorized. The catalytic reduction of amaranth and BB dyes

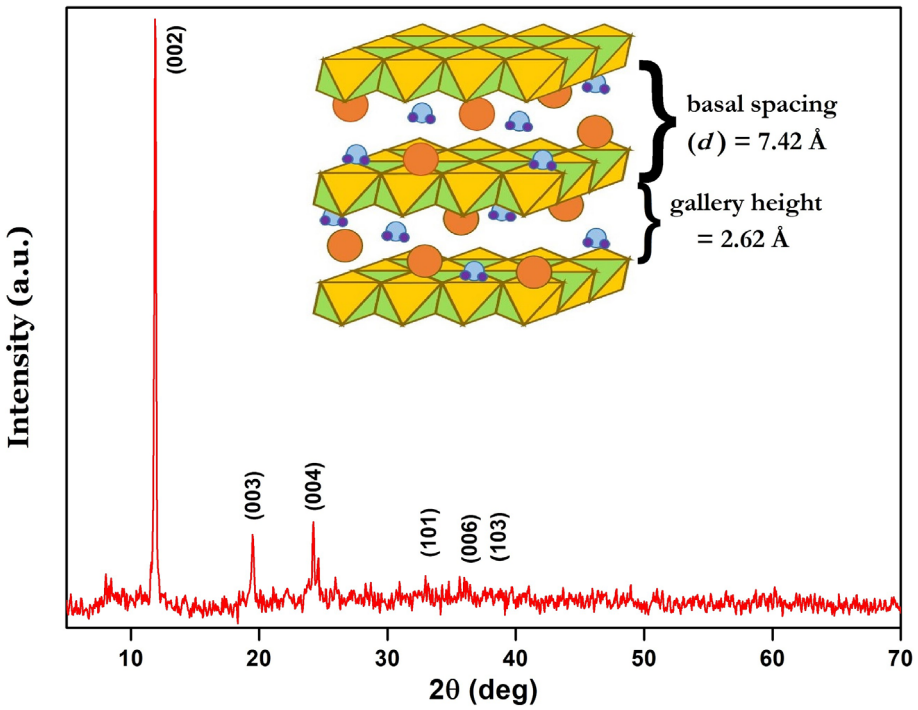

FIGURE 2 PXRD diffractogram of ternary ZnCuNi-LDH.

was studied in a similar manner. Change in absorbance was measured at $\lambda_{max} = 520$ and 490 nm for amaranth and BB, respectively.

The percentage degradation of chosen toxic moieties was calculated using the formula:

$$Percentage\ degradation = \frac{(C_O - C_f)}{C_O} \times 100 \qquad (1)$$

where C_O and C_f denote the initial and terminal concentrations of NAC and azo dyes.

The influence of various parameters such as catalyst dosage and pollutant concentration on the catalytic prowess of ZnCuNi-LDH were also assessed. Further, the universality and recyclability of ZnCuNi-LDH were also studied.

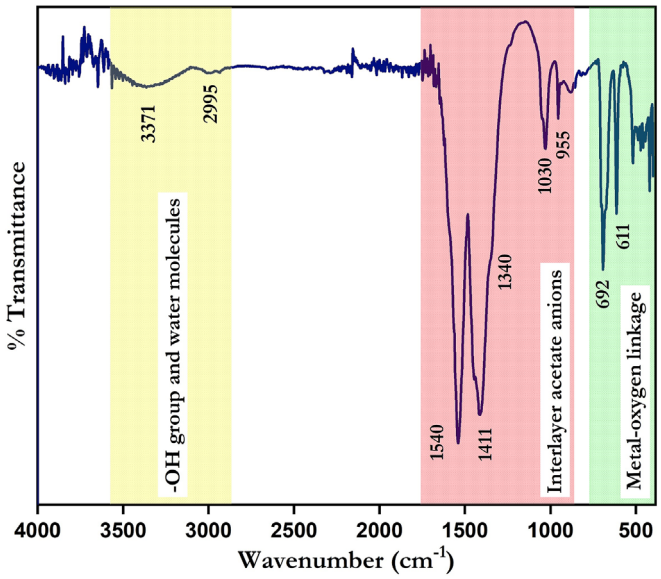

FIGURE 3 FTIR spectrum of ternary ZnCuNi-LDH.

3 | RESULTS AND DISCUSSION

3.1 | Characterization results

The PXRD diffractogram of ZnCuNi-LDH, presented in Figure 2, shows the characteristic diffraction peaks of crystalline layered materials, consisting of high-intensity reflections at low 2θ and low-intensity peaks at higher 2θ. The diffraction peaks can be indexed under hexagonal symmetry having lattice parameters $a = 3.19$ Å and $c = 14.9$ Å.[14] The sharp and symmetric nature of peaks suggests the formation of highly crystalline LDH with coherently stacked 2D layers. The d-spacing for the (002) basal plane, found to be 7.42 Å, and the gallery height, calculated to be 2.62 Å, are indicative of the monolayer alignment of acetate anions in the interlamellar region, keeping in view the thickness of brucite sheet (4.8 Å) and edge to edge length of acetate anion (3.6 Å).[15] Furthermore, d-spacing value of synthesized ZnCuNi-LDH was found to be completely different from those of zinc hydroxy acetate, copper hydroxy acetate, or nickel hydroxy acetate, thereby confirming the formation of

10990739, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/aoc.7507 by Delhi Technological University, Wiley Online Library on [21/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

lattice in pure phase with isomorphically substituted Cu and Ni cations in the LDH layers.[16–18]

The FTIR spectrum of LDH (Figure 3) exhibits a broad band at 3371 cm^{-1} that can be assigned to νO–H and interlayer water molecules, and the shoulder appearing at 3013 cm^{-1} indicates hydrogen bonded νO–H --- O. The bands at 2995, 1540, and 1411 cm^{-1} can be attributed to C–H stretching vibrations and antisymmetric and symmetric vibration modes of COO– group, respectively. Fingerprint vibration modes of acetate anions were observed at 1340, 1030, 955, 692, and 611 cm^{-1} that can be ascribed to bending/rocking modes of $–CH_3$ group, C–C stretching, and bending and rocking modes of $–CO_2$ moiety, respectively. The bands observed below 700 cm^{-1} are representative of νM–O linkage and indicate the links of metal ions of the –OH groups (O–M–O, M–O, and M–O–M) present in the LDH layers.[16]

The thermal stability and weight loss of prepared ZnCuNi-LDH were determined from the TGA thermogram presented in Figure 4. The thermal decomposition of ZnCuNi-LDH was found to be a three-tier process, including the first stage of weight loss from room temperature to 220°C, attributed to the elimination of physisorbed and interlayer water molecules, with a mass loss of 6.82%. The second stage from 220 to 385°C involves decarboxylation, dehydroxylation, and removal of interlayer acetate ions from the LDH lattice and showed the maximum mass loss of 41.73%. The final stage occurs above 385°C wherein further dehydroxylation and decarboxylation result in collapse of layered arrangement and formation of pure phase mixed metal oxide.[19] The aggregate mass loss during the thermal degradation of ZnCuNi-LDH was found to be 49.9%.

SEM imaging was conducted to identify the morphological and surface textural features of ZnCuNi-LDH. SEM micrograph (Figure 5a) clearly shows the presence of coherent lamellar orientation of LDH, corroborating the formation of layered structure of LDH. In addition, the EDX analysis was carried out to ascertain the elemental composition. The presence of Zn, Cu, Ni, C, and O elements in the EDX profile (Figure 5b) confirms the homogenous distribution of compositional elements in the synthesized heterogeneous ZnCuNi-LDH.

The specific surface area and porosity of ZnCuNi-LDH were determined using N_2 adsorption–desorption study by BET analysis. The specific surface area (S_{BET})

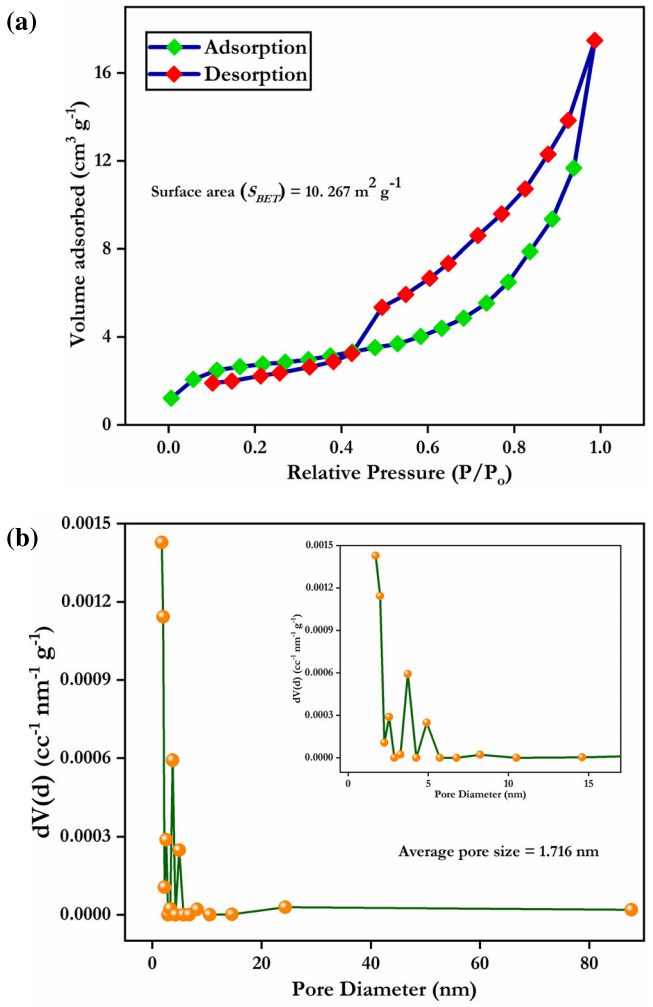

FIGURE 6 (a) N_2 adsorption–desorption isotherm and (b) corresponding pore size distribution plots with inset of enlarged view of pore size distribution between 0 and 20 nm of ternary ZnCuNi-LDH.

was found to be 10.267 m^2g^{-1}, and the pore volume was 0.004 cc g^{-1}. The average pore diameter, calculated from the N_2 desorption data using the BJH method, was found to be 1.716 nm. The shape of the isotherm in the range $0.2 < P/P_o < 0.8$ (Figure 6a) resembles the Type-IV isotherm according to IUPAC classification and indicates the presence of non-cylindrical mesopores in the synthesized LDH. Furthermore, a small amount of N_2 adsorption is observed below $P/P_o = 0.2$ and above $P/P_o = 0.8$, indicating the appearance of micropores and macropores, respectively.[20] The few macropores can be attributed to the existence of inter-particle spaces in the layered structure, usually observed in topotactic materials. The H4-type hysteresis loop also points to the existence of micropores and narrow slit-shaped mesopores in the synthesized ZnCuNi-LDH that appear because of the lamellar arrangement.[21] Additionally, the pore diameter data presented in Figure 6b demonstrate the extensive scattering of micropores and mesopores, as well as macropores throughout the synthesized product, indicating prominent non-uniformity in ZnCuNi-LDH. The presence of large number of mesopores may be a contributing factor in the high catalytic activity of ZnCuNi-LDH.

3.2 | Catalytic activity

The efficacy of synthesized ZnCuNi-LDH as a co-catalyst with $NaBH_4$ reductant for the hydrogenation/reduction of nitroarenes and azo dyes was examined using UV–Visible spectrophotometer. The progress of catalytic reduction was assessed by observing the change in absorbance values of the solution of the selected model molecule. Further, since the concentration of $NaBH_4$ (50 mM) is much greater than that of NACs (1 mM) and azo dyes (100 mg L^{-1}), the reaction rate is considered to be free of the influence of BH_4^- concentration. Hence, the hydrogenation of NACs and reduction of azo dyes was considered to follow pseudo-first-order kinetics, as presented in Equation (2).[22]

$$\ln\left(\frac{C_f}{C_O}\right) = K \tag{2}$$

where K denotes the rate constant and C_O and C_f are the initial and final concentrations of NAC and azo dyes.

Since the evaluated molecules possess distinct colors and yield peaks in the visible region, the reaction rate is evaluated in terms of comparative absorptive intensity. Therefore, using Beer–Lambert law (Equation 3)

$$A = \varepsilon Cl \tag{3}$$

Kinetics of reaction are expressed in terms of absorption by the equation[23]:

$$\ln\left(\frac{C_f}{C_O}\right) = \ln\left(\frac{A_f}{A_O}\right) = kt \tag{4}$$

where A_O and A_f are the initial and final absorbance of NAC and azo dyes.

3.2.1 | Catalytic hydrogenation of *p*-NP and *p*-NA

NACs such as *p*-NP and *p*-NA pose tremendous risk to human health and aquatic life even at trace levels because of their high toxicity and high stability. Therefore, their elimination from water is quite essential.

10990739, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/aoc.7507 by Delhi Technological University, Wiley Online Library on [21/05/2024]. FIGURE 7 (a) Molecular structure of *p*-NP, (b) UV–Vis absorption spectrum, and (c) linear fitting of pseudo-first kinetics model for the $NaBH_4$-assisted catalytic hydrogenation of *p*-NP using ZnCuNi-LDH.

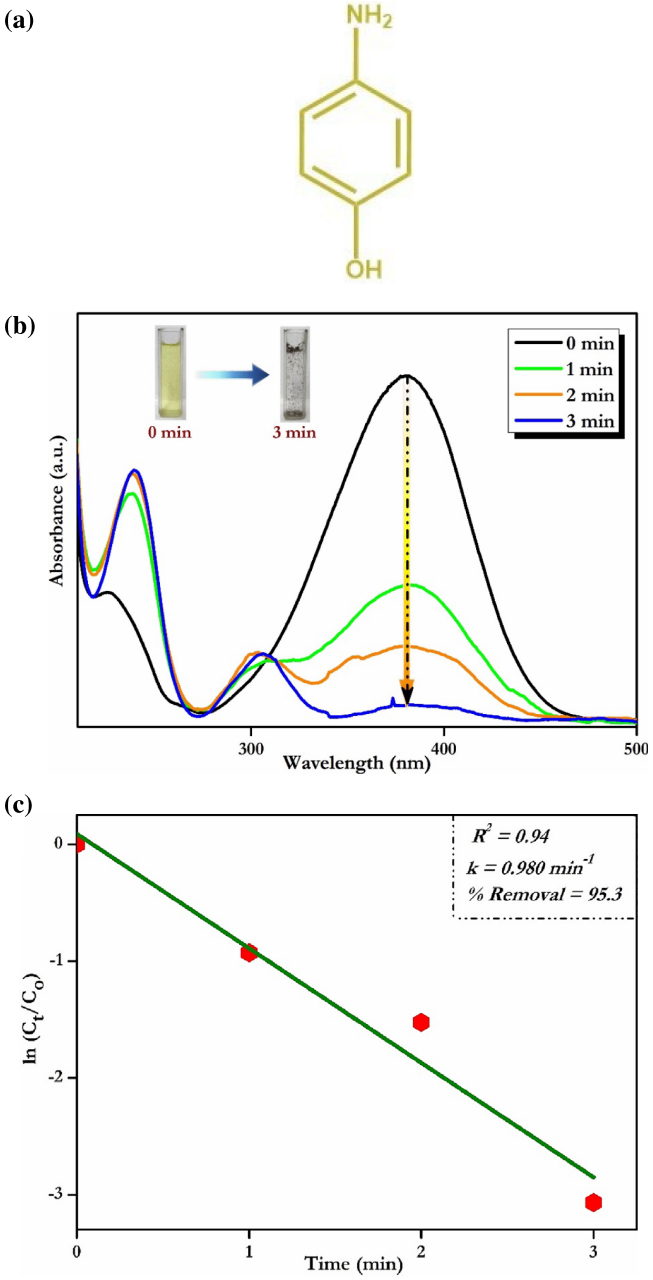

FIGURE 8 (a) Molecular structure of *p*-NA, (b) UV–Vis absorption spectrum, and (c) linear fitting of pseudo-first kinetics model for the $NaBH_4$-assisted catalytic hydrogenation of *p*-NA using ZnCuNi-LDH.

Catalytic hydrogenation using $NaBH_4$ with the assistance of a co-catalyst is an effective way to reduce these NACs to obtain safer reduction products having industrial merits. In the current study, the catalytic hydrogenation of *p*-NP and *p*-NA was studied as a model reaction.

In the case of *p*-NP (Figure 7a), the mixing of the solution of $NaBH_4$ and *p*-NP produces an absorbance peak at 400 nm as a consequence of the generation of nitrophenolate ion, as seen in Figure 7b. Then, with the addition of synthesized LDH, the intensity of peak at 400 nm begins decreasing along with the appearance of a new peak at 302 nm. The appearance of the new peak confirms the production of *p*-AP on *p*-NP reduction and is confirmed by the reduction of the peak at 400 nm. The peak disappears completely after 4 min, indicating the ultrafast hydrogenation of *p*-NP. The percentage reduction of *p*-NP was evaluated using Equation (1) and was found to be 98.8%. The rate of reaction (k_{app}) was evaluated to be 1.058 min^{-1} ($R^2 = 0.79$) in accordance with the pseudo-first-order model (Figure 7c).

10990739, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/aoc.7507 by Delhi Technological University, Wiley Online Library on [21/05/2024]. FIGURE 9 (a) Molecular structure of methyl orange, (b) UV–Vis absorption spectrum, and (c) linear fitting of pseudo-first kinetics model for the $NaBH_4$-assisted catalytic reduction of MO using ZnCuNi-LDH.

The catalyst-assisted hydrogenation of *p*-NA (Figure 8a) was evaluated in a similar manner. The plot of UV–Vis spectrum of *p*-NA (Figure 8b) shows prominent peak at 380 nm on mixing of $NaBH_4$ solution and *p*-NA solution. On the introduction of ZnCuNi-LDH to the reaction mixture, the peak intensity at 380 nm decreases rapidly before ultimately disappearing after 3 min. Meanwhile, a new peak appears at 304 nm on the addition of LDH and may be attributed to the formation of *p*-phenylenediamine. The percentage reduction of *p*-NA, calculated using Equation (1), was found to be 95.3%. Using pseudo-first-order kinetics, the rate constant of reduction (k) was calculated to be 0.98 min^{-1} ($R^2 = 0.94$) (Figure 8c).

3.2.2 | Catalytic reduction of azo dyes

Methyl orange degradation

Methyl orange, having the molecular formula $C_{14}H_{14}N_3NaO_3S$ (Figure 9a), is an anionic azo dye commonly used as a pH indicator in laboratories as well as widely used in various industries, including textile, pulp and paper, and printing, among others. In azo dyes such as MO, the appearance of color is due to the existence of the main azo (–N=N–) chromophore group. However, MO is classified as an acutely toxic compound and has been reported to be mutagenic. Excessive exposure to MO may even cause skin and eye irritation, dermal corrosion, respiratory and gastrointestinal irritation, as well as nausea, vomiting, and diarrhea. Hence, the removal of MO from water sources has received major interest.

Degradation of MO using $NaBH_4$ is an effective and thermodynamically favorable approach to achieve its degradation, but it is rendered kinetically unfavorable due to the electrostatic repulsion between BH_4^- moiety and anions of the dye molecules. Hence, $NaBH_4$ is able to only partially reduce the azo group but is unable to break the N–N bonding. The addition of ZnCuNi-LDH aids the degradation by adsorbing the active species on its surface and facilitating electron transfer between the adsorbed species. Thus, LDH can effectively act as an excellent catalytic material for the $NaBH_4$-assisted degradation of azo dyes.

The UV–Vis absorbance versus wavelength plot for the catalytic reduction of MO is presented in Figure 9b. Absorbance change was noted at $\lambda_{max} = 463$ nm for MO. No change in the peak intensity and position was observed on the addition of $NaBH_4$ alone. Then, on the addition of ZnCuNi-LDH catalyst, the intensity of the peak present at 463 nm began to decrease rapidly, whereas a new peak emerged at 250 nm, along with a visible decrease in the intensity of the color of the reaction mixture. As the reaction progressed, the peak at 463 nm kept decreasing rapidly until, eventually, it disappeared completely, and the intensity of the peak at 250 nm kept increasing. The solution was completely decolorized within the short time span of 4 min. The percentage degradation of dye was calculated using Equation (1) and was calculated to be 96.4%.

The rate constant k_{app}, obtained by linearly regressing experimental data to the pseudo-first-order model, was evaluated to be 0.797 min^{-1} ($R^2 = 0.91$) (Figure 9c). The action of $NaBH_4$ and LDH catalysts causes the cleavage of the chromophoric azo (–N=N–) group of MO, leading

10990739, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/aoc.7507 by Delhi Technological University, Wiley Online Library on [21/05/2024]. FIGURE 10 (a) Molecular structure of amaranth, (b) UV–Vis absorption spectrum, and (c) linear fitting of pseudo-first kinetics model for the $NaBH_4$-assisted catalytic reduction of amaranth using ZnCuNi-LDH.

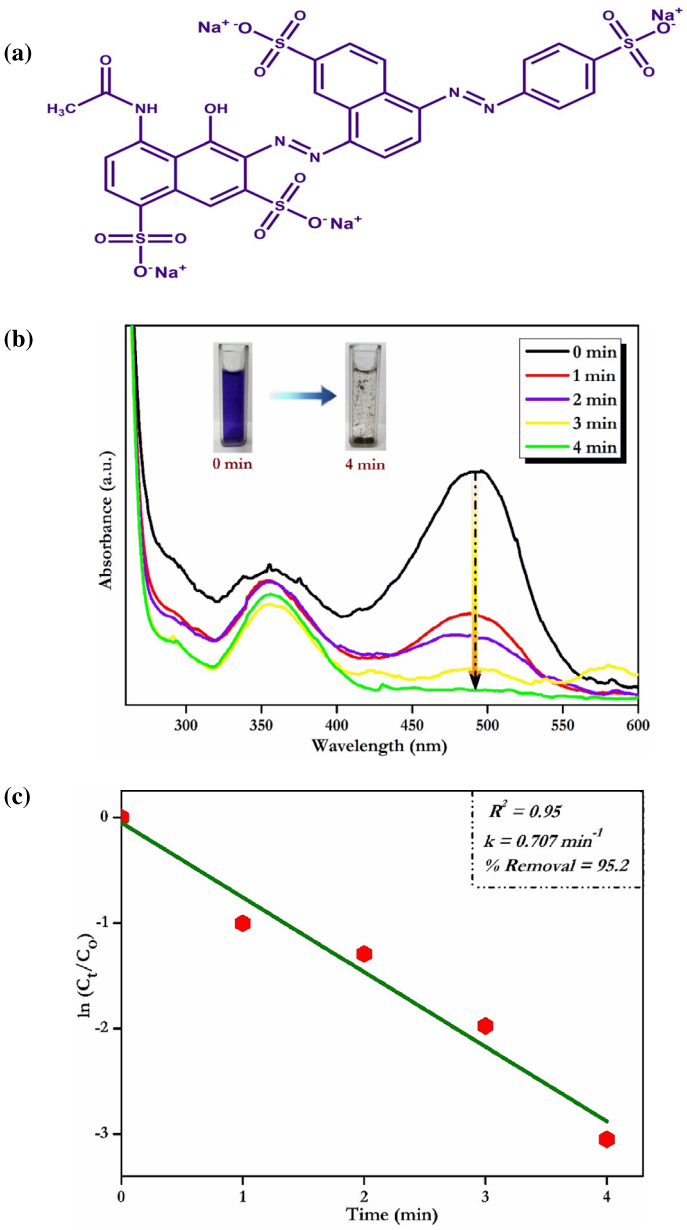

FIGURE 11 (a) Molecular structure of brilliant black BN, (b) UV–Vis absorption spectrum, and (c) linear fitting of pseudo-first kinetics model for the $NaBH_4$-assisted catalytic reduction of brilliant black BN using ZnCuNi-LDH.

to the formation of new degradation products possibly including sulfanilic acid and N,N-dimethyl-p-phenylenediamine, that exhibit absorbance peaks around 248, and 242 nm, respectively.[24,25] The emergence of a new peak at 250 nm in the recorded absorbance spectra may be attributed to these species and along with the disappearance of peak at 463 nm gives evidence for the rapid degradation of MO by LDH and $NaBH_4$, rather than adsorption of LDH.

Amaranth

Amaranth, or Acid Red 27, is an anionic mono azo dye having molecular formula $C_{20}H_{11}N_2Na_3O_{10}S_3$ (Figure 10a). This reddish-brown dye is widely used as a colorant in the food and cosmetics industry. However, its use has now been prohibited in several countries because of suspected carcinogenicity. In vivo combination of amaranth with benzoate and salicylate can cause several severe health issues, such as impaired liver functioning. Hence, the elimination of amaranth from water sources needs to be seriously addressed.

10990739, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/aoc.7507 by Delhi Technological University, Wiley Online Library on [21/05/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

To study the catalytic reduction of Ama, absorbance change was noted at $\lambda_{max} = 520$ nm. The absorbance plot of amaranth dye black solution consisted of a singular peak at 520 nm (Figure 10b). This peak does not undergo any change on the addition of $NaBH_4$, rather the emergence of a new peak is observed at 377 nm. This new peak may be attributed to the reduction of azo (–N=N–) group to –NH–NH– by $NaBH_4$. However, the appearance of peaks at both 520 and 377 nm indicates the partial reduction and no cleavage of the azo group. Further, on the addition of ZnCuNi-LDH, rapid discoloration of the solution is observed along with a rapid reduction in peak intensity at 520 nm and the appearance of a new peak at 328 nm that could possibly be attributed to the formation of naphthionic acid as a degradation product.[26] The reaction mixture was completely decolorized within 2 min, suggesting an ultrafast reduction of amaranth dye by ZnCuNi-LDH catalyst. The absorbance of the solution was recorded at 520 nm at 1-min intervals, and the percentage degradation was calculated to be 97.3%. The rate constant (k_{app}), calculated by performing linear regression analysis on the experimental data, was found to be 1.807 min^{-1} ($R^2 = 0.91$) (Figure 10c).

Brilliant black

Brilliant black BN, having molecular formula $C_{28}H_{17}N_6Na_4O_{14}S_4$ (Figure 11a), is a black-colored diazo dye that finds prevalent use in the food industry. This dye is suspected to be genotoxic and mutagenic and has been linked to worsening of asthma and DNA damage. Although $NaBH_4$-assisted catalytic reduction of several toxic azo dyes has been widely reported, virtually, no reports are available about the catalytic reduction of BB.

The λ_{max} for BB dye typically appears at 571 nm (Figure 11b) but the addition of $NaBH_4$ to BB solution causes the peak to shift from 571 to 490 nm, and this shift may be attributed to the partial cleavage of –N=N– azo bond and its reduction to –NH–NH– bond.[27] Further, on the addition of ZnCuNi-LDH, the peak at 490 nm becomes less intense, along with the appearance of a new peak at 251 nm. Complete decolorization of BB was attained within 4 min of reaction initiation. The percentage degradation efficiency of BB was calculated to be 95.2%, and the linear regression of experimental data to the pseudo-first-order model yielded a k_{app} value of 0.707 min^{-1} ($R^2 = 0.95$) (Figure 11c).

3.2.3 | Effect of influencing parameters

The performance of a catalyst is influenced by various parameters. Therefore, the effect of catalyst dosage and pollutant concentration on the catalytic activity of ZnCuNi-LDH was studied by choosing *p*-NP and MO as model pollutants.

Effect of catalyst dosage

The impact of catalyst dosage on the reduction process was investigated using three different amounts, that is, 2.5, 5, and 10 mg. The plots presented in Figure 12 exhibit the influence of ZnCuNi-LDH dosage on the reduction of *p*-NP and MO. Figure 12a–c represents the catalytic reduction of *p*-NP with 2.5-, 5-, and 10-mg LDH, whereas the reduction of MO dye by 2.5, 5, and 10 mg of LDH catalyst is presented in Figure 12d–f.

The absorption spectrum of *p*-NP presents a prominent peak at 400 nm that shows a pronounced decrease in intensity on the addition of catalyst to 1 mM *p*-NP solution. The addition of 2.5 mg catalyst led to the complete hydrogenation of *p*-NP within 6 min. An increase in dosage of ZnCuNi-LDH to 5 and 10 mg leads to a decrease in time required for the complete *p*-NP hydrogenation to 4 and 2 min, respectively. In the case of MO dye, the absorption spectrum presents an intense peak at 463 nm that decreased with the addition of catalyst to 100 mg L^{-1} MO solution. The dye solution was completely decolorized within just 7 min on the addition of 2.5 mg catalyst. An increase in ZnCuNi-LDH dosage to 5 and 10 mg promotes faster reduction, and the dye was completely decolorized within 4 and 2 min, respectively.

The observed trend may be attributed to the fact that at lower catalyst dosage, fewer active sites are available to catalyze the reduction reaction, leading to higher reaction time. An increase in dosage of ZnCuNi-LDH leads to the availability of more number of active sites for reaction, thereby leading to acceleration of the reduction process and faster culmination of reaction.[28]

Effect of pollutant concentration

The impact of pollutant concentration was studied using three concentrations for *p*-NP and MO. The plots presented in Figure 13 provide insights into the catalytic reduction process.

In the case of *p*-NP, the absorption spectrum presented in Figure 13a–c exhibits a peak at 400 nm that shows a pronounced decrease on the addition of 5 mg catalyst. Complete decolorization of 0.25 mM *p*-NP was observed within just 1 min of catalyst addition. On increasing *p*-NP concentration to 0.5 and 1.00 mM, reduction time increased to 2 and 4 min, respectively. A similar trend was observed for the reduction of MO dye, as presented in Figure 13d–f. An addition of 5 mg catalyst to 25 mg L^{-1} MO solution leads to complete reduction within 2 min. An increase in dye concentration to 50 and 100 mg L^{-1} leads to increase in reduction time to 3 and 4 min, respectively. It may be attributed to the fact that at

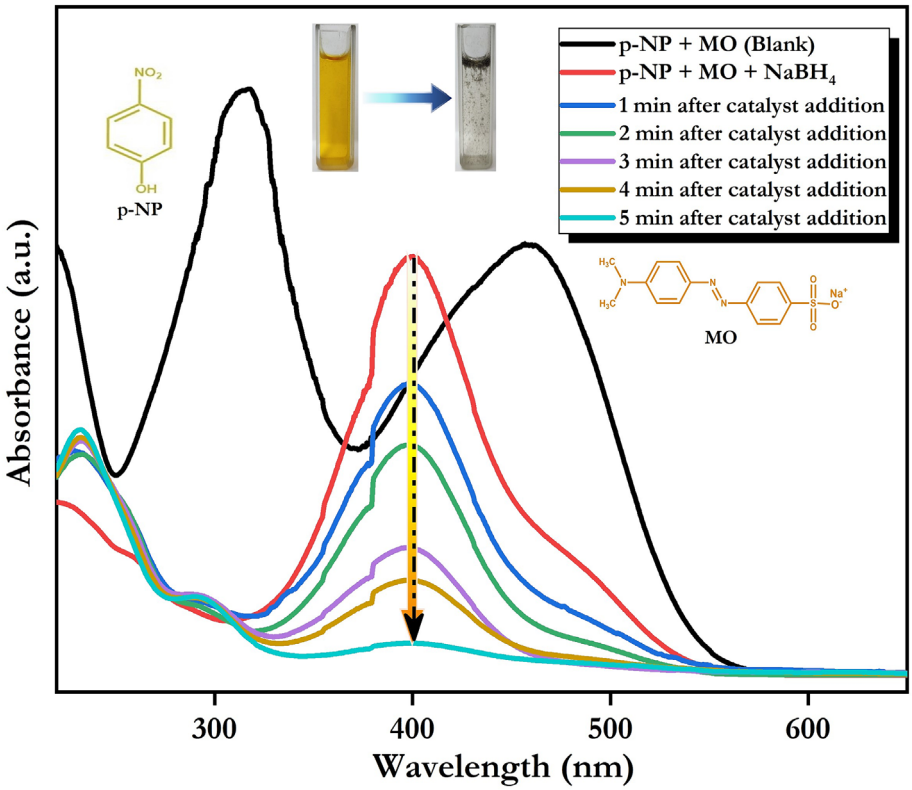

FIGURE 14 UV–Vis absorption spectrum for $NaBH_4$-assisted simultaneous reduction and degradation of *p*-NP and MO by ZnCuNi-LDH.

lower concentration, fewer number of pollutant molecules need to be catalyzed, thereby leading to faster reduction of all pollutant molecules in less time. Conversely, at higher concentrations, more number of molecules are required to be reduced, and thus, more time is expended for the complete reduction of the pollutants.[29]

3.2.4 | Universality of ZnCuNi-LDH as catalyst

The universality of a catalyst is a fundamental parameter in determining the practical and profitable usability of the material in large-scale industrial applications. An efficient catalyst must possess the ability to simultaneously reduce/degrade various types of molecules into simple and benign by-products. Therefore, in order to ascertain the catalytic prowess of synthesized ZnCuNi-LDH toward the simultaneous removal of *p*-NP and MO, 5 mL of *p*-NP solution (1 mM) was combined with 5 mL MO solution (100 mg L^{-1}), following which 10 mL freshly prepared $NaBH_4$ solution and 10 mL distilled water were added to the mixture. After the addition of ZnCuNi-LDH, the reaction mixture was stirred and the absorbance was recorded at pre-fixed time intervals.

It was observed that the absorbance spectrum of the blank mixture of *p*-NP and MO exhibits a peak at 318 nm that can be attributed to *p*-NP molecules, whereas the peak at 464 nm appears because of MO molecules. On the addition of $NaBH_4$, the peak at 318 nm disappeared and a new peak appeared at 400 nm due to the conversion of *p*-NP molecules to phenolate anions (Figure 14). The peak at 464 nm does not shift in position but only decreases in intensity and appears as a neck in the hybrid spectrum because of the closeness of the λ_{max} values of *p*-NP and MO.

Further, on the addition of ZnCuNi-LDH, the intensity of the hybrid spectrum decreased rapidly and eventually disappeared within a short span of 5 min, along with the decolorization of the reaction mixture. The rapid decolorization of the reaction mixture elucidates the fact that ZnCuNi-LDH can be successfully used as a universal catalytic material for the simultaneous reduction of NACs and anionic azo dyes.

3.3 | Plausible mechanism for catalytic activity of ZnCuNi-LDH

The surface catalytic reduction of nitro compounds and organic dyes by ZnCuNi-LDH potentially proceeds through the Langmuir-Hinshelwood mechanism, involving three steps: (1) dissociative adsorption of reactants onto LDH surface, (2) interaction between adsorbed

10990739, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/aoc.7507 by Delhi Technological University, Wiley Online Library on [21/05/2024]. FIGURE 15 Potential mechanism for the $NaBH_4$-assisted catalytic degradation of *p*-NP and MO by ZnCuNi-LDH.

moieties, and (3) desorption of reduction products from LDH surface. In aqueous medium, $NaBH_4$ breaks down into Na^+ and BH_4^- ions. BH_4^- anions further hydrolyze into BO_2^- and H_2, and these moieties are adsorbed onto LDH since they possess a high surface area (Figure 15).

For the degradation of *p*-NP and *p*-NA, H_2 is adsorbed on ZnCuNi-LDH surface, resulting in metal-hydride complex formation. The action of this complex as a hydrogen-mediator facilitates H_2 transfer to the $-NO_2$ group along with electrons. This aids in the hydrogenation of $-NO_2$ group, converting it to $-NH_2$ and resulting in the formation of p-aminophenol and p-phenylenediamine as reduction products following the hydrogenation of *p*-NP and *p*-NA respectively.

In the case of organic dyes, ZnCuNi-LDH acts as a redox catalyst and facilitates the transfer of electrons to the dye molecules. In the reaction mixture, initially, the anionic dye molecules get adsorbed onto the positively charged LDH surface via electrostatic forces of attraction. Then, because of the electron relay behavior of LDH, electrons are transferred from the electron-donating BO_2^- moiety to the electron-accepting dye molecules, leading to their reduction. Lastly, the reduction products present on LDH surface get desorbed and diffused into the solution. The synergistic interactions between the copper and nickel atoms present in the lattice may also contribute and augment the electron relay ability of the ZnCuNi-LDH, and result in the ultrafast reduction of NACs and organic dyes.

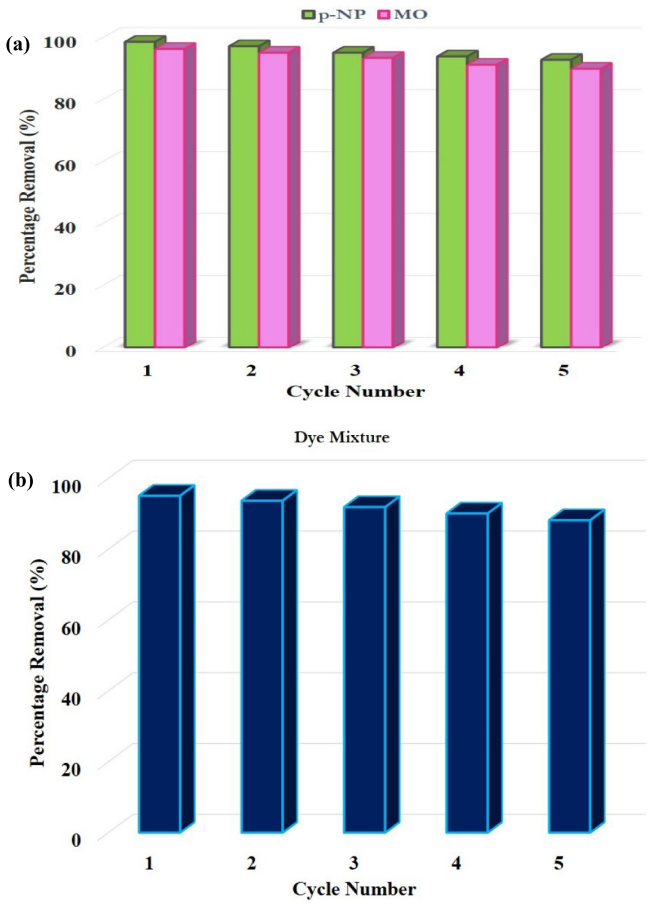

FIGURE 16 Recyclability of ZnCuNi-LDH for catalytic reduction of (a) *p*-NP and MO and (b) mixture of dyes.

TABLE 1 Comparison of rate constants of ZnCuNi-LDH with previously reported catalysts.

3.4 | Reusability and recyclability

The recyclability of heterogeneous catalysts is a significant factor that impacts their profitable commercial use. Therefore, the reusability of ZnCuNi-LDH for the reduction of *p*-NP, MO, and mixture of dyes was investigated for 5 cycles. After each reduction reaction, catalyst was recovered and washed with distilled water, dried at 60°C, and then used for subsequent catalytic cycles.

The results presented in Figure 16a indicate that ZnCuNi-LDH sustains up to 90% removal efficacy in just 4 min for the reduction of *p*-NP and MO even after 5 cycles. Moreover, ZnCuNi-LDH also exhibited excellent catalytic reduction ability of up to 88% within 5 min toward a mixture of MO, Ama, and BB dyes even after 5 cycles, as shown in Figure 16b. These results suggest that ZnCuNi-LDH is a robust catalyst that can be easily recovered and utilized for consecutive catalytic cycles without any significant decrease in catalytic performance. The slight decrease in removal efficacy may be attributed to the loss and agglomeration of catalytic material during the recovery and reuse stages.

3.5 | Comparison with reported catalysts

The comparison of the catalytic activity of ZnCuNi-LDH with previously reported catalysts toward the reduction of *p*-NP, *p*-NA, MO, and Ama is presented in Table 1. Virtually no reports were available for the catalytic reduction of BB dye. The rate constants for reactions catalyzed by ZnCuNi-LDH were found to be comparable or even better than the rate constants of most reported catalysts. Therefore, it may be concluded that ZnCuNi-LDH can act as an exemplary catalyst for the catalytic reduction of both nitroarene compounds and azo dyes. The superior catalytic activity may be attributed to the small size, high surface area, and homogeneous distribution of Zn, Cu, and Ni cations in the ZnCuNi-LDH matrix.

4 | CONCLUSION

In summary, ternary ZnCuNi-LDH was successfully synthesized through a facile acid hydrolysis route and was later used as an efficient catalyst for the rapid hydrogenation of *p*-NP and *p*-NA, as well as for the reductive degradation of MO, Ama, and BB dyes. Percentage degradation efficiency for NACs was found to be 98.8% (*p*-NP) and 95.3% (*p*-NA) respectively, whereas organic azo dyes follow the trend Ama (97.0%) > MO (96.4%) > BB dyes (95.2%). The kinetics of the reduction reactions best aligned with the pseudo-first-order model, and rate constant values (k_{app}) for the catalytic hydrogenation of *p*-NP and *p*-NA were found to be 1.058 and 0.98 min^{-1}, respectively, whereas rate constant values (k_{app}) for reductive degradation of MO, Ama, and BB were calculated to be 0.797, 1.807, and 0.707 min^{-1}, respectively. In addition, catalyst dosage and pollutant concentration were found to be important parameters that influence the catalytic performance of the synthesized lattice. It was observed that reduction time increased with increasing catalyst dosage and decreasing concentrations of the model pollutants. Furthermore, ZnCuNi-LDH rapidly decolorized a

10990739, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/aoc.7507 by Delhi Technological University, Wiley Online Library on [21/05/2024]. binary solution consisting of *p*-NP and MO, thereby exhibiting its universality as a catalyst. The synthesized catalytic material also exhibited more than 90% reduction efficiency even after five regeneration cycles. Thus, the facile synthesis, excellent catalytic activity, and recyclability reiterate the use of ternary ZnCuNi-LDH as effective catalytic materials for the degradation of NACs and azo dyes.

Understanding the internationalization of Indian state-owned enterprises

Aakanksha Kaushik

University School of Management and Entrepreneurship, Delhi Technological University, Delhi, India

ABSTRACT

The article examines the global activities of high-value Indian state-owned enterprises (SOEs) classified by the government as "Maharatnas" and "Navratnas." Using the FESPET framework, the paper assesses their performance and international presence, revealing their commitment to a public mission beyond financial gains. These SOEs prioritise social spending and often surpass regulatory environmental targets, serving as valuable assets in India and globally. Profitable SOEs demonstrate positive impacts abroad, while financially unsustainable ones fall short in contributing to the non-financial "ESPET" dimension.

Introduction

State-Owned Multinational Enterprises (SOMNEs) from developing nations have expanded globally, playing pivotal roles in their economies. International organisations now recognise their significance for both developing countries and OECD countries (IMF 2020; OECD 2020; UNCTAD 2008, 2010, 2022; World Bank 2021). UNCTAD's World Investment Report, tracking the top 100 global non-financial enterprises, consistently shows a rising share of SOMNEs – from 10% in 2013 (Kowalski et al. 2013) to 15% in 2017 (Kalotay 2018), doubling in the last decade (IMF 2020).

The (UNCTAD 2022) report shows that 43 of the top 100 non-financial multinational enterprises from developing and transition economies are state-owned. Of these 43 State-owned Enterprises (SOEs), 32 are based in China, six are in Singapore, and one enterprise each from Malaysia, Saudi Arabia, Qatar, Kuwait, and India made the list.

The limited presence of Indian SOMNEs on the list, compared to China, stems from divergent policies. India restricts SOE from overseas investments, with only energy and natural resource firms allowed to invest abroad through the automatic route.[1] In contrast, China strategically employs its SOEs, enhancing international political and economic influence (Carlos Zalaf Caseiro and Masiero 2014).

India's mixed economy model has endured economic downturns better than many other emerging economies. However, Western pushes for more liberalization and transparency risk hindering growth and social progress in emerging economies. The state-capitalist approach challenges global neoliberalism, reshaping institutional arrangements

CONTACT Aakanksha Kaushik aakanksha.kaushik@dtu.ac.in
© 2024 Informa UK Limited, trading as Taylor & Francis Group

(Nölke et al. 2022; Petry, Koddenbrock, and Nölke 2023). Indian SOEs have significantly contributed to India's development, especially in resource-based industries and manufacturing. However, they encounter challenges stemming from political interference and demonstrate comparatively lower performance in services compared to their private counterparts (Auty 1988; Bala 2006; Chatterjee 2017; Gupta and Kumar 2020; Khanna 2012; Kumar 2018)

Indian SOEs are classified as "Ratna" (meaning gem or jewel) by the Government of India based on financial, operational performance, and global presence. In descending order, the categories include Maharatna, Navratna, Mini Ratna I, and Mini Ratna II. Only Maharatna and Navratna possess the authority to invest up to 15% of their net worth abroad; others require government approval. The degree of corporatization varies between Maharatnas and Navratnas. Maharatna Companies possess increased autonomy in decision-making, particularly in areas such as investments and financial matters. The government employs Memoranda of Understanding (MoUs) as a tool to maintain control over SOEs (Clifton and Díaz-Fuentes 2019; Kumar 2018). India's approach to categorizing state-owned enterprises (SOEs) shares similarities with Norway's system. Both nations classify their SOEs based on their strategic significance and ensure that their operations align with governmental goals. However, the criteria and categories used for classification may vary between the two countries (Christensen 2023; Rygh and Benito 2022)

The Energy sector, with a focus on resource security, boasts the highest number of Maharatnas. Approximately 100 Indian SOEs have undergone internationalization, primarily through exports. While most foreign investments originate from Maharatnas and Navratnas, some Mini Ratnas also establish an international footprint. In its first section, this paper will delve into the internationalization of Indian SOEs.

The evolution of SOEs has been ongoing in India. Notably, government-owned oil and gas companies have historically prioritized fulfilling the nation's energy needs over profit generation. These entities expanded their activities from a limited scope in upstream and downstream sectors to a significant playing field. They discovered, explored, and acquired oil and gas resources in India and internationally. With heightened awareness of Global Warming and a comprehensive understanding of carbon emissions' impact, enterprises are now actively innovating and transitioning towards environmentally friendly products. Significant investments in renewable energy sources are discussed in detail in Section II. The contribution of these organizations to economic development extends beyond conventional assessments based solely on operational and financial efficiency parameters.

Moreover, these SOEs are complex entities with a rich heritage. They are constantly trying to strike a balance between the market-oriented vision and the public mission under which they were incorporated. Many SOEs in India are hybrid entities that are role models of social-value creation. It is challenging to compare private and state-owned enterprises because of the complex nature of the public mission that SOEs operate under, as noted by Sorrentino (2020).

SOEs have been assigned various roles, including Macroeconomic Stability, National Interest, Redistribution of Wealth, Model Employer, and Reduction of Externalities, as identified by Heath and Norman (2004). India Ratings and Research, a rating agency, reported that SOEs in India contributed 19.2% of gross value added (GVA) over a ten-

year period from FY2011–12 to FY20–21, with wages accounting for 39.2% (Sinha 2022). Additionally, a CRISIL study revealed that in 2020, SOEs accounted for 8% of companies engaged in Corporate Social Responsibility (CSR) expenditure, while they spent 28% of total CSR expenditure (CRISIL Foundation 2020).

For this study, the definition of SOMNE is taken from the generally accepted definition by Cuervo-Cazurra et al. (2014) in the limited literature on the subject. The study defined SOMNE as:

> . . . a legally independent firm with direct ownership by the state that has value-adding activities outside its home country. These value-added activities can be downstream activities such as production facilities or sales subsidiaries, as tend to be assumed when one thinks about a multinational company or upstream activities such as purchasing subsidiaries or design or R&D centres.

To thoroughly compare SOEs and private enterprises, Clifton and Díaz-Fuentes (2023) developed a multi-dimensional FESPET consisting of five criteria: financial, environmental, social, political, and technological. The second section evaluates the performance of SOMNEs using this framework and examines how Indian SOMNEs behave abroad.

The trend in India's Outward Foreign Direct Investment has experienced a notable evolution over the years, reflecting strategic shifts in response to changing economic landscapes and global market dynamics. A significant aspect of this evolving trend is the changing sectoral composition of Indian OFDI flows. The studies highlight a broadening diversification across sectors, with a substantial increase in the primary sector, particularly in crude petroleum and natural gas extraction. Meanwhile, the services sector has emerged as the leading contributor, surpassing manufacturing, which dominated OFDI flows in the 1990s and 2000s. There has been a shift in manufacturing from low-technology products to high-technology industries, indicating a focus on technology-intensive and knowledge-driven sectors (Joseph 2019; Pradhan 2017; Pradhan and Sauvant 2010).

The growth in OFDI, particularly in knowledge-based industries, reflects Indian firms' improved competitive capabilities. Acquisitions are becoming a preferred route for technological advancement in the liberal environment, with a focus on industries such as software, pharmaceuticals, and automotive. Indian Multinational Enterprises contribute positively to local R&D and employment in host countries, potentially shaping more competitive market structures (Pradhan and Sauvant 2010; Tiwari and Herstatt 2010)

This study is divided into two main sections. The first section delves into the internationalization of Indian SOEs. The second section analyzes the performance of the SOMNEs using the FESPET framework. The conclusion is detailed in section III.

Section I: understanding internationalisation of Indian state-owned enterprises

India's internationalization process must be understood in the context of a broad policy framework. Since 2014 in India have initiated large-scale privatization programmes through Strategic Sales[2] and Asset monetization,[3] unlike just the selling of minority shareholdings in the previous years. The policy "New Public Sector Enterprise Policy in 2021" aims for the bare minimum presence of state-owned

enterprises in the strategic sector. Moreover, the new policy has also revised and fast-tracked the closure of state-owned enterprises in the non-strategic sector. The government closed Board for Reconstruction of Public Sector Enterprises, the organization set up for the revival of loss-incurring SOEs, in November 2015. The environment is not conducive to the growth of state-owned enterprises in the country.

The profit-making enterprises are being sold off, and loss-incurring ones are being shut down in a "time-bound" manner. This impacts the performance of management and millions of employees employed in hundreds of SOEs in the country. Despite this, some enterprises remained profitable and have seen an increase in internationalization.

The number of SOEs that had earnings in foreign exchange in India is around 120 from 2011 to 2022. But for this analysis, enterprises from Hotel and Tourist Services, Aviation, Railways, Finance, and Entities for Trade promotion were excluded from the sample. These firms earned foreign earnings by operating within the country. The entities approved for closure by the government, namely Handicrafts & Handloom Exports Corporation of India Limited, Hindustan Fluorocarbons Limited, Instrumentation Limited, National Textile Corporation Limited, and Scooters India Limited, were also excluded. This has reduced the sample firms to 82 firms.

The internationalization of SOEs is measured for select state entities (Table 1) by dividing foreign revenues earned by SOEs, such as Exports of goods and services, royalties, interest, dividends and others, by the firm's total revenues. The data from 2011–2012 to 2020–21 is collected from the Public Enterprise (PE) Survey Report published annually by the Government of India and the companies' Annual Reports.

Only four years, 2011–12, 2016–17, 2019–2020, and 2020–21, are presented in Table 1 so that the broad trend in internationalization can be observed. The average internationalization of select Indian SOEs has only marginally increased by 1.5% over ten years from 2011–12 to 2021–21, with one tail test significant at 10%. The impact of the pandemic and global slowdown can be observed from 2019–20 and 2020–21 internationalization estimates, which have declined for thirty-four firms within a year. The average internationalization fell by −1.30% and was statistically significant under one tail test at a 10% significance level.

Table 2 presents the sectoral composition of the sample firms. The SOEs are internationalised across various sectors. The most significant number of SOEs are present in Heavy & medium engineering (seventeen), followed by Contract, Construction & Technology Consultancy services (fourteen), and Trading and Marketing (eleven). Most enterprises are profit-making. The highest loss-making entities belonged to the Trading and Marketing sector (three): Metals and Minerals Trading Corporation of India Limited, Project and Equipment Corporation of India Limited, and State Trading Corporation of India Limited. The government has decided to denotify the organizations from Exim transactions are considering shutting them down; therefore, they are also excluded from discussion in section II.

Fifteen of seventeen companies under the Heavy and Medium Engineering group were profit-making. All these firms have played an essential role in the country's economic development. The two loss-making SOEs are Hindustan Shipyard Limited and Rajasthan Electronics and Instruments Limited. Four companies, Bharat Earth Movers Limited, Bharat Electronics Limited, Bharat Heavy Electricals Limited, and

Table 1. Trend of Internationalisation of State-owned enterprises of India.

The Public Enterprise (PE) Survey Report published annually by the Government of India and the Annual Reports of the respective companies.

*Profitability is measured by profit after tax (PAT), and if data was unavailable for the financial year 2021–22, the latest available year value was taken.

Hindustan Aeronautics Limited, which have investments abroad, are discussed in detail in the next section. All the firms under the following main activities – Agro based, Chemicals & Pharmaceuticals, Coal, Fertilizers, Industrial and Consumer goods, other minerals & metals, Petroleum (refinery & marketing), Power Generation, Power Transmission, Transport & Logistic services, and Transport and Vehicles – are profitable.

The top three sectors in terms of internationalization are Transport and Logistics services, Other Minerals and Metals, and Crude Oil. There are only two firms under Transport and Logistics – Shipping Corporation of India Limited and Pawan Hans Limited.[4] The latter has a minuscule percentage of revenues from outside the country. The high rate of foreign exchange earnings of Shipping Corporation of India Limited is due to the nature of its business. It is the largest shipping company in India, conducting business on national and international lines.

The heavy and medium engineering sector has a higher number of international firms. Still, the share of foreign revenue compared to total revenues has remained low, consistently below 10% over the years.

The Other Minerals and Metals group has a substantial percentage of revenue in foreign exchange, which has grown over the last ten years. In 2011–12, the average percentage of internationalisation constituted 20.6%, which increased to 45.4% in 2020–21. The four companies of the group are Hindustan Copper Limited (44.93%), Indian Rare Earths Limited (47.74%), Kudremukh Iron Ore Company Limited (78.00%), National Aluminium Company Limited (56.51%), and Uranium Corporation of India Limited (0.00%). All these companies have internationalised mainly through exports. According to the 2021–22 annual report of Kudremukh Iron Ore Company Limited, the export revenue now constitutes 97.7% of its total revenue. The company deals in Iron ore, does not operate from any international location, and has operations restricted to India.

The companies under the groups Crude oil and Petroleum & Refinery Markets have acquired more foreign assets than any other listed company. The foreign investments are global, including developed and developing countries (Table 3). But the internationalisation is 24.2% because the entities cater primarily to the domestic market. The energy sector SOEs of India operate with a public mission to secure the country's energy needs. This is why the share of foreign revenue from the power generation and transmission groups is negligible in firms' total revenues. However, the power transmission group had projects in collaboration with friendly neighboring countries.

All three sample firms in the steel sector, Mishra Dhatu Nigam Limited, Rashtriya Ispat Nigam Limited, and Steel Authority of India Limited, have consistently increased internationalization. Their primary source of foreign earnings is exports. Steel Authority of India Limited's exports exceed those of Rashtriya Ispat Nigam Limited, but the latter has more revenue from abroad.

The other two sectors showing a consistent rise in internationalization are Chemicals & Pharmaceuticals and Contract, Construction & Technology Consultancy. Internationalization in Chemicals & Pharmaceuticals has increased massively in ten years. It was only 2.9% in 2011–12 and has risen to 20.8% in 2020–21. All the firms are internationalized through exports. Except for Hindustan Antibiotics Limited, all have shown a rise in foreign exchange revenues in proportion to total revenues. But there is significant variation within the group in the extent of

Table 3. Details of international markets served by the SOMNEs.

S.no.	Company	Geographical Area
1	Bharat Petroleum Corporation Limited	Oman, Russia, Australia, UAE, Brazil, Singapore, Netherlands, Indonesia, Mozambique
2	Balmer Lawrie & Company Limited	China, Kenya, Nepal, Sri Lanka, New Zealand, Qatar, Kuwait, Spain, Italy, Germany, France, Ireland, Malaysia, Australia, and Others
3	Bharat Earth Movers Limited	The major markets are Middle East countries, African countries and Southeast Asian countries. (Around 68 countries)
4	Bharat Electronics Limited	USA, France, China, Germany, Singapore, Oman Switzerland, ASEAN, Mauritius, Republic of Armenia, Sri Lanka, Sweden, Israel Kenya, Chile, Suriname, Malaysia, Nepal and Bangladesh
5	Bharat Heavy Electricals Limited	In all the continents (Around 88 Countries)
6	Coal India Limited	Mozambique
7	ENGINEERING PROJECTS (INDIA) Limited	Kuwait, Iraq, Saudi Arabia, Maldives, Thailand, Yugoslavia, Bhutan, UAE, Oman, Sri Lanka
8	Engineers India Limited	Major Market Middle East, Africa, South Asia & Central Asia.
9	Gas Authority of India Limited	Singapore, US, Russia and Mayanmar
10	Hindustan Aeronautics ltd.	USA, Mauritius, Ecuador, Israel, Mauritius, Namibia, Nepal, Russia, UK, Oman, Malaysia, Thailand, Germany, Russia, Suriname, France Vietnam
11	Hindustan Petroleum Corporation Limited	Major Markets are in Asia, the Middle East, Australia, and a few African countries.
12	Indian Oil Corporation Limited	Around 32 countries across the globe
13	IRCON International Limited	128 projects in 25 Countries, majorly from Africa, Asia and the Middle east
14	Mahanagar Telephone Nigam Limited	Mauritius and Nepal
15	Metals and Minerals Trading Corporation of India Limited	Asia, Europe, Africa, Australia, North and South America
16	National Buildings Construction Corporation Limited	Asia, Africa and the Middle east
17	National Thermal Power Corporation Limited	Asia, Africa, South America, Oceania
18	Oil & Natural Gas Corporation Limited	Asia, Africa, Europe, and South America.
19	Oil India Limited	Asia, Africa, Europe, South America, and North America
20	Power Grid Corporation of India Limited	Asia, Asia-Pacific, Europe, and Africa
21	Rail India Technical and Economic Service (RITES) Limited	Asia, Africa, Latin America, South America and the Middle East (over 55 countries)
22	Telecommunications Consultants (India) Limited	Asia, Africa, the Middle East and Europe and North America (Around 65 countries)
23	Water and Power Consultancy Services (WAPCOS) Limited	Asia, Africa, CIS, Eurasia, Europe, North America, Oceania, Pacific Islands and South America. (Around 51 countries)

internationalization. Brahmaputra Crackers & Polymer Limited's internationalization estimate is 0.43%, and on the other hand, the estimate of the step-down subsidiary of Oil & Natural Gas Corporation Limited (ONGC), ONGC Mangalore Petrochemicals Limited is 90.57%. It is a loss-making entity located in the Mangalore Special Economic Zone.

The companies under the Contract, Construction & Technology Consultancy group have offices, subsidiaries, and investments in international locations besides internationalisation through exports. But the extent of internationalisation of the group has been consistently declining over the years. From 11.3% in 2011–12, it has reduced to only 5.9%. Out of fourteen sample firms, internationalisation was facilitated for nine firms in the sector: Broadcast Engineering Consultants India Limited, Certification Engineers International Limited, Educational Consultants India Limited, IRCON International Limited, Metallurgical & Engineering Consultants (India) Limited, National Small

Industries Corporation Limited, Project & Development India Limited, Rail India Technical and Economic Service Limited, and Water and Power Consultancy Services (India) Limited.

For the sectors Fertilisers, Trading & Marketing, and Industrial and Consumer Goods, the magnitude of foreign exchange earnings has remained low and inconsistent. The decline in the Industrial and Consumer goods group is due to HLL Lifecare Limited. The proportion of foreign earnings for the group has reduced to 1.76% from a peak of 12.15% in 2016–17.

Only a few organizations invested abroad. They are not discussed in the literature; less is known about them, and lesser about their operations abroad. The next section of the study will examine the performance of such SOEs using the multidimensional framework.

Section II how Indian SOMNEs behave abroad

The SOMNEs with value-adding activities abroad were selected. The firms that internationalized through exports or royalties were excluded. As stated earlier, only Maharatna and Navaratna firms have the autonomy to invest a certain amount. But the list also includes SOEs with Mini Ratna Status. These companies are not as large (in terms of domestic and foreign assets) as oil and gas companies but are more internationalized and dependent on foreign earnings.

Eleven companies in India have been accorded Maharatna status, and nine of them are part of the sample. Only two companies, Power Finance Corporation and Steel Authority of India Limited, are not on the list. The Power Finance Corporation is a non-banking finance company that serves only Indian markets. Steel Authority of India Limited has internationalised through exports only and has no investments abroad except International Coal Ventures Private Limited, which is already being discussed in the study. The share of foreign revenue to total revenues in Steel Authority of India Limited has increased from 2.42% to 8.88% from 2011–12 to 2020–21. Of the thirteen companies under the list of Navratna companies, only six have investments or have taken projects abroad. Seven companies are Category-I Mini-Ratna companies, and one is from Category-II Mini-Ratna.

The majority of companies are from the Contract & Construction and Technology consultancy services group (six), followed by Heavy and medium Engineering (four), Petroleum (Refinery and marketing), Crude Oil (two), and telecommunication and information technology (two). The other remaining groups had one company each.

The oil and gas SOMNEs play a crucial role in managing the global exploration and production (E&P) blocks, serving as key components in the domestic hydrocarbon value chain for their respective governments. Despite having substantial foreign investments, these companies, particularly exemplified by India's ONGC, exhibit low internationalisation. UNCTAD data from 2020 reveals that ONGC's foreign assets constitute 24% of its total assets, and this ratio aligns with the proportion of foreign employees. However, the share of foreign sales in total sales is merely 3%, marking ONGC as having the lowest percentage among the top 100 non-financial multinational enterprises from developing and transition economies. In contrast, Chinese SOMNEs, notably China National Petroleum Corporation, have a different focus, with foreign investments geared towards

securing energy needs. China National Petroleum Corporation ranks 24th among the top 100 non-financial multinational enterprises, displaying a higher ratio of foreign sales (37%) and foreign assets (21%) compared to ONGC.

Table 3 provides insights into the global footprint of SOMNEs, showcasing their widespread presence in both developed and developing nations. These companies, spanning oil and gas as well as heavy and medium engineering sectors, consistently generate foreign exchange earnings across Asia, Africa, the Middle East, Russia, the USA, and Australia. Europe and America receive relatively limited attention in terms of investment flows.

The study employs a comprehensive multi-dimensional framework by Clifton and Díaz-Fuentes (2023), focusing on Financial, Environmental, Social, Political, and Technological (FESPET) criteria to evaluate the performance of Indian SOMNEs. This framework is modified for this study, and qualitative & quantitative indicators are added to the framework for the performance evaluation of the Indian SOMNEs. Under the Financial criterion, the study assesses the profitability of business activities and investigates whether these enterprises undertake riskier investments to fulfill public missions. The Environmental criterion examines the extent to which government mandates related to environmental goals are achieved both domestically and internationally. Social criteria explore the public mission of SOMNEs and their commitment to social spending, utilizing Corporate Social Responsibility (CSR) expenses in India as a proxy. The final dimension, Technology, evaluates the Research and Development (R&D) intensity of these enterprises, considering R&D expenses relative to total sales as a key variable. The study aims to provide a nuanced understanding of the performance and motives of Indian SOMNEs in the global landscape.

Financial dimension

The overall financial health of SOMNEs is assessed through profitability measure: Profit After Tax of the consolidated results of the enterprises are presented in Table 4. The data is compiled from the Public Enterprise Survey Report of the Department of Public Enterprises, Ministry of Finance, Government of India, and Companies' Annual Reports. The pandemic harmed the financial health of public and private enterprises. But most companies in the sample, like Bharat Heavy Electricals Limited, that had gone red during the pandemic, have returned to profitability from the current financial year. Therefore, firms are marked profitable if they are earning profit in the current financial year 2021–22, and an average of past years is not taken as it will be a biased estimate.

It is also important to note that the prices of petroleum and diesel have been deregulated and are market determined in India. But the rising oil prices have considerable political implications, and the government intervenes whenever necessary to insulate the economy against unprecedented rises in oil prices. The recent increase in oil prices has adversely affected the financials of state-owned oil marketing companies Bharat Petroleum Corporation Limited, Hindustan Petroleum Corporation Limited, and Indian Oil Corporation Limited. The government and the SOEs share the under-recovery. A simple measure of profitability, Profit after Tax, of the consolidated financial

Table 4. Financial performance of Indian SOMNEs in 2021–22.

Company Name	Main Activity	If, Profitable?
Bharat Earth Movers Limited	Transport and vehicles	YES
Balmer Lawrie & Company Limited	Heavy & medium engineering	YES
Bharat Electronics Limited	Heavy & medium engineering	YES*

Own compilation from Public Enterprise Survey Report of Department of Public Enterprise (DPE), Ministry of Finance (MoF), Government of India (GoI), Companies'Annual Reports.
*If the financial year 2021–22 data was unavailable, 2020–21 data was collected.

results of the enterprise is adopted to assess the financial performance of SOMNEs across sectors.

All the companies are profit-making except Mahanagar Telephone Nigam Limited (MTNL), Engineering projects India Limited and Telecommunications Consultants India Limited. The MTNL has exited the loss incurring foreign joint venture UTL in Nepal. The other investment of MTNL, the subsidiary MTML is a profit-making entity. Engineering projects India Limited has three international offices, with more than 50% of revenues from abroad before the pandemic. The Indian credit rating Agency ICRA improved it's rating because of its strong book position in 2020. After that, the company's financials worsened during the pandemic, and losses mounted in the financial year 2020–21 and became the highest in the last ten years.

Large enterprises like ONGC and Bharat Petroleum Corporation Limited have wholly owned subsidiaries that manage overseas operations. ONGC Videsh Limited is a subsidiary of ONGC and is accorded Category I, Mini-Ratna company status. Through it, ONGC owns participating interests in E&P blocks in thirty-five countries. The SOMNE also has several other investments and is a profitable entity. Bharat Petroresources Limited is a wholly owned subsidiary of Bharat Petroleum Corporation Limited, which holds participating interests in E&P blocks in five countries and has

consistently shown losses. The company will remain red until production commences in Brazil and Mozambique.

Risky investments

Investing overseas for resource-seeking is risky because it depends on host countries' energy policies. The host government can change it at any time or ban exports of resources from the country. Indian SOMNEs have invested in risky investments motivated by public missions or in geographical areas where there is unrest continuously. These investments will not be taken by many private enterprises that are governed by principles of profit maximization and market seeking. In the quest to secure energy resources, the Indian SOMNEs have invested in areas like Syria, South Sudan, Sudan, and Mozambique. The unrest is due to several factors, such as unresolved political and territorial conflicts, insurgency attacks, protests, etc.

India has diplomatic ties with the Mozambique government, and Indian SOMNEs have invested billions of US dollars in Mozambique. The country is resource-rich, but the insurgency attacks have jeopardized investments. Indian SOMNEs had to evacuate employees from Mozambique and suspend operations. Moreover, most investments in Mozambique have been financially draining for the Indian SOMNEs, either coal mining or oil and gas E&P activities.

Another example is Bharat Petro Resources JPDA (Joint Petroleum and Development Area) Limited, a wholly-owned subsidiary of Bharat Petroresources Limited, which had 20% PI in Block JPDA 06–103 in Timor Leste. The exploration activity was suspended due to arbitration proceedings between the government of Timor Leste and Australia.

Over the years, SOMNEs have gained experience and do due diligence before investing. Due to operational infeasibility, the oil and gas SOMNEs have relinquished blocks in Australia and Israel. Moreover, the oil and gas SOMNEs have strategically diversified their portfolios in different geographical areas of the World and in blocks in different production phases to mitigate risks.

The ICVL was incorporated to secure coal reserves outside India. The Joint Venture of Steel Authority of India Limited, Rashtriya Ispat Nigam Limited, National Mineral Development Corporation Limited, Coal India Limited, and National Thermal Power Corporation. Two enterprises, Coal India Limited and National Thermal Power Corporation, exited because they considered it as a financial burden. The steel companies in India continued because they needed coking coal for the furnaces, which is critical for smooth production. National Thermal Power Corporation exit was also because the company required thermal coal for operations, not coking coal. The firm could not achieve success and sophistication like oil and gas companies. The functions are restricted to Mozambique, and it has failed to acquire profitable coal reserves overseas.

Environmental dimension

The SOEs in India are not mandated to achieve targets above and beyond regulatory requirements. SOEs and private enterprises must comply with the same environmental regulations. This is the dimension where many Indian SOMNEs have outperformed. The government uses the instrument of MoU to motivate SOEs to achieve their financial and non-financial goals. The multifarious contributions of the SOEs are guided through

MoUs by the government. Sustainable development was a mandatory category to incentivize efforts by SOEs, but the weightage was only 5%. Moreover, the category was withdrawn in 2019 from MoU rating guidelines. Under the sustainable category, the SOEs were assessed on energy management, carbon management, and increased use of cleaner alternative energy sources.

The study's objective is to evaluate to what extent the SOMNEs have achieved the environmental mandate and beyond. Furthermore, the second objective is to find evidence if the practices were transferred abroad. SOMNEs' performance is evaluated on five criteria to test the research objective. The first is to check if the SOMNE has any sustainable policy or energy management system at the company level and is certified by any international organization. The Indian government encourages certification from International Organization for Standardization (ISO). Waste management is the second criterion. The criterion is more relevant for manufacturing and energy sector enterprises requiring steps for Solid Waste Management. Hazardous Waste Management, e-Waste Management, and Waste Oil Management System. Waste management can reduce illness and diseases and assist enterprises in reducing production costs. The third criterion is efforts towards environment conservation such as water conservation, energy conservation and use of renewable sources, efforts towards reduction of carbon emissions and green initiatives taken by the SOMNE. Green initiatives include plantation drives or afforestation, green innovation, or any other.

The summary of the first criterion under the environmental dimension is if the SOMNEs comply with ISO 14,001 or ISO 50,001 energy management system. ISO certification 14,001 is broad in its scope and covers all environmental aspects. ISO 50,001 only focuses on energy performance but sets specific targets, making it more difficult to achieve ISO 50,001 certification.

National Buildings Construction Corporation Limited and Water and Power Consultancy Services (India) Limited, because of their nature of business, are excluded from his criterion. All SOMNEs except MTNL are ISO14001 certified. The best practices have been transferred abroad also. The Indian SOMNE, with the largest foreign assets ONGC and its subsidiary ONGC Videsh Limited, is also ISO 14,001 certified. Very few SOMNEs comply with ISO 50,001 energy management system standards. Only Bharat Heavy Electricals Limited, Bharat Petroleum Corporation Limited, ONGC, Coal India Limited, and Power Grid Corporation of India Limited have certification.

The following criterion is regarding waste management. The waste management system is expected to be in place for all SOMNEs that have obtained ISO 14,001 certification. The percentage of recycled waste will likely differ from company to company and will depend upon the nature of the business.

As Clifton and Díaz-Fuentes (2023) noted, SOEs in the energy sector were active in this dimension. Coal India Limited reused 80.6% of discharged mined water; the remaining was retained for future use. The company has adopted several measures to ensure reclaiming of mined areas. Indian Oil has set benchmarks for the sector. The SOMNE recycles 99.5% of waste generated, 88% of wastewater, and 100% slop oil. The performance is, above all, that of public and private enterprises in India. Vedanta recycles 30.71% of wastewater, and Reliance recycles 46%. ONGC recycles 39.6% of wastewater. Bharat Petroleum Corporation Limited's all retail outlets, liquefied petroleum gas bottling plants, and Mumbai Refinery are Zero Waste to Landfills.

The ONGC's subsidiary that overlooks overseas operations, ONGC Videsh Limited, recycles wastewater more than the parent company, 67%. ONGC Videsh Limited complies with the host country's environmental regulations and has undertaken projects beyond what is required. It has also established water treatment facilities in South Sudan, Venezuela, and Russia. Bharat Petroresources Limited operates participating interests in only two blocks, domestic and overseas. It complies with the regulations of Abu Dhabi's environmental regulatory agency, the only overseas block jointly owned in Abu Dhabi.

The SOMNEs under the main activity group Heavy and Medium engineering from defence, i.e. Bharat Earth Movers Limited and Hindustan Aeronautics Limited, accomplished less than the energy companies in this segment. The products are not recycled because they are of strategic or national importance. The waste recycled was only 2% for Hindustan Aeronautics Limited. Bharat Earth Movers Limited recycled 5 to 10% of waste. The other two companies from Heavy and medium engineering companies, Bharat Electronics Limited and Bharat Heavy Electricals Limited, have excelled. Bharat Electronics Limited recycled 100% of the waste. Food waste was also used to generate biogas. Bharat Heavy Electricals Limited recycled 25% of the waste generated.

The SOMNEs that do not generally produce process wastes have also taken initiatives to process other solid wastes. Rail India Technical and Economic Service Limited and Water and Power Consultancy Services (India) Limited recycle 100% of the waste generated. The consultancy enterprises Engineers India Limited, Engineering projects India Limited, National Buildings Construction Corporation Limited, Telecommunications Consultants India Limited and Water and Power Consultancy Services (India) Limited, by business, are involved in projects related to waste management. National Buildings Construction Corporation Limited is implementing the zero-waste concept in its construction projects to manage 100% of waste at the source, which is not planned and practiced widely in India during construction.

The following criterion is efforts made by the SOMNEs for environment conservation in India and abroad. The government of India has stated the target to achieve 500 GW of green energy by 2030 and has committed to cut its carbon emissions net zero by 2070. The Indian SOEs have aligned efforts with the goal, and many SOMNEs have committed to net zero. Most energy sector SOEs have announced and committed to Net Zero. Coal India Limited is to achieve the target by as early as 2024. Bharat Petroleum Corporation Limited, Hindustan Petroleum Corporation Limited, and ONGC committed to Net Zero by 2040 and Indian Oil Corporation Limited by 2046. Engineers India Limited has committed to achieving the target by 2035. Gas Authority of India Limited and National Thermal Power Corporation are preparing their roadmap to reach net zero.

The energy sector SOEs are now foraying into green energy. ONGC plans to develop 1 GW of green energy by 2025. Similarly, other SOEs, such as Gas Authority of India Limited, Bharat Petroleum Corporation Limited, Coal India Limited, Bharat Heavy Electricals Limited, National Thermal Power Corporation Limited, and others, have invested large sums in developing the production capacities of green energy in the country. Oil and Gas companies are increasing their production of Biofuels, Natural Gas, Green Hydrogen and Compressed Biogas from Biomass waste.

Other enterprises are yet to declare net zero targets, and all play a crucial role in the transition. For example, Bharat Heavy Electricals Limited is the market leader in the nuclear and emission control business. It is also a pioneer in Engineering, Procurement

and Construction solutions for solar photovoltaic plants. The current scenario is not so green; the country meets most of its power demand from coal, which causes significant carbon emissions. To solve the immediate problem, the enterprise with National Thermal Power Corporation have devised a technology[5] that could reduce carbon emissions by 20%. Bharat Heavy Electricals Limited has commissioned the largest floating solar power plant in India at National Thermal Power Corporation. The enterprise plans to increase investments in floating solar at reservoirs of its projects because it increases the production of renewable energy and has the additional advantage of preventing water evaporation of reservoirs.

National Thermal Power Corporation has also used innovative ideas for environment conservation. The SOMNE is converting shut downed station into an eco-park. It will be constructed on the ash disposal area of Badarpur Thermal Power station. It has also fired 77,000 MT of biomass pellets, preventing nearly 45,000 acres of farm fire. Power Grid Corporation of India has minimized power transmission loss to 3%, which is at par with global standards.

All SOMNEs have contributed towards environment conservation in different ways except loss incurring MTNL. Except for MTNL, every SOMNE had rainwater harvesting at various locations and took steps to ensure groundwater recharging and recycled water. Most have Sewerage Treatment Plants, and all oil and gas companies installed state-of-the-art effluent treatment plants. Energy companies took initiatives at all levels to conserve water and reduce water consumption. Indian Oil Corporation Limited excelled and achieved a 7.17% year-on-year reduction in total water consumption. National Thermal Power Corporation was successful in reducing it by 4%.

Except for MTNL, all SOMNEs met energy requirements from alternate sources and took steps to conserve energy and reduce their carbon footprint. Bharat Earth Movers Limited and Bharat Electronics Limited outperformed in the criteria. Bharat Earth Movers Limited met 85%, and Bharat Electronics Limited met 49.55% of its energy requirement internally through green energy projects. The consultancies, by nature of business, did not have considerable investments. Still, all took steps to conserve energy, such as energy audits, rooftop solar plants, plantation drives, energy-efficient lighting, rainwater harvesting systems, and others.

The Indian SOMNEs that have excelled in this dimension also transferred their green practices abroad. Several sustainability measures were taken at Indian Oil Corporation Limited's foreign subsidiary in Sri Lanka. The many outlets in Sri Lanka are solarised, the solar facility at Trincomalee terminal reduced electricity by 5%, rainwater harvesting systems, water recycling, increased production of eco-friendly products, energy efficient lightening, etc. The SOMNE took green initiatives in Mauritius's subsidiary to increase green cover and energy-efficient lighting.

ONGC Videsh Limited took several initiatives in the host countries. In the Lower Zakum Concession region, "Project Lightening" was undertaken in Abu Dhabi. The project supplies electricity from clean energy sources to offshore platforms. The company has implemented a biodiversity project in Colombia to strengthen the ecological structure and connectivity of the forest remnants (fragmented forests) in the Moriche and Jazmin fields. Prize Petroleum International Pte Limited, a subsidiary of Hindustan Petroleum Corporation Limited, incorporated in Singapore, also promotes sustainable development and takes green initiatives.

The SOMNE consultancies, such as Engineers India Limited, by nature of business, are contributing to sustainability in the host countries. Engineers India Limited provides solutions for water management in overseas markets. The SOMNE has ongoing projects in UAE, Nigeria, and Bahrain in the segment. The enterprise also offers technological solutions for energy security, carbon-neutral technologies, and similar measures to assist enterprises across the globe in meeting their Environmental, Social, and Governance goals.

But the transfer of best green practices abroad is dependent on several factors. Indian SOMNEs from the oil and gas sector are not the operators in many investments abroad. Wherever Indian SOMNEs have managerial controls, green initiatives were taken. All SOEs are clubbed together but are a heterogeneous group, and the performance depends on the leadership. The SOMNEs that outperformed in environmental parameters in the home country have also transferred their best practices to foreign subsidiaries. The best examples are Indian Oil Corporation Limited and ONGC.

Social dimension

The market reforms such as corporatization, commercialization, and liberalization have been implemented in India. The prices across sectors are market-determined, even for petroleum products. The government intervenes only during the unprecedented rise in oil prices and freezes the selling price temporarily. The government directs CSR expenditures of SOEs through publishing guidelines. During the pandemic, the government made Health the central theme and directed CSR funds of the SOEs toward relief efforts. But the CSR expenditure mandate is the same for state and private enterprises. The data on social expenses and details of projects undertaken abroad is limited. So as a proxy, the CSR expenditures of the SOEs in India are taken as the proxy variable to test the commitment of SOMNEs towards social goals. If the SOMNEs act like private enterprises and spend more.

The government of India mandates that 2% of the average net profit of the past three years should be spent on CSR activities. The definition, by default, exempts loss-incurring enterprises from spending on social expenditures. All private and state-owned enterprises are to spend on CSR if they have a net worth of Rupees 5000 million or more, a turnover of Rupees 10,000 million or more, or a net profit of Rupees 50 million. As discussed earlier, according to the CRISIL Foundation report, in 2020, SOEs accounted for 8% of companies engaged in CSR activities, but SOEs spent 28% of total CSR expenditure. The oil companies accounted for 17% of total CSR contributions.

Table 5 presents the details of the CSR expenditures of the select SOMNEs. The CSR policy was implemented in 2014; therefore, data is available from the financial year 2014–15. If the SOMNE spends more than required in any financial year, the corresponding cell is marked "Y", implying that it spends more than required by law. If the SOMNE spends less than required in any financial year, the corresponding cell is marked "N", implying that it does not spend more than required. "NA" means Not Applicable because the firms were incurring losses and were not required by law to spend on CSR.

It can be observed from the above table that all the profit-making SOMNEs mostly spend more than required. Some of them have been spending more consistently for the

Table 5. presents the details of the CSR expenditures of the select SOMNEs.

past five years: Bharat Earth Movers Limited, Engineers India Limited, Gas Authority of India Limited, Indian Oil Corporation Limited, IRCON, National Thermal Power Corporation, ONGC, Oil India Limited, and Water and Power Consultancy Services (India) Limited. Coal India Limited was also spending consistently above the mandate, except last year. Telecommunications Consultants India Limited and Engineering projects India Limited aren't required to spend because they are incurring losses, but they did spend in the financial year 2020–21. The CSR expenditure was on health theme during the peak of the COVID-19 pandemic.

Political dimension

The study's political dimension assesses how these enterprises align their activities with government priorities and programs. The institutional and political context significantly shapes the strategies and operations of Indian SOEs. Research indicates that the extent of state control, via ownership and political ties, has a considerable impact on SOEs' decisions regarding globalization and their overall level of global engagement. This is particularly relevant in emerging economies, where changing institutional landscapes affect the dynamics between the state and SOE executives (Liang, Ren, and Sun 2015). Indian SOMNEs, while not apolitical, are closely connected to their related ministries and consistently align their actions with current government policies and priorities.

Throughout history, SOMNEs have played a crucial role in promoting national development.

SOEs operate in both strategic and non-strategic sectors, alongside private enterprises, which have grown in number over the years. The Indian government uses Memorandums of Understanding (MoUs) to direct SOMNEs towards national policies. Recent guidelines incentivize SOMNEs to procure goods from micro and small enterprises, companies owned by women and minorities, and increase Corporate Social Responsibility (CSR) expenditures while reducing imports and boosting exports. SOMNEs have also aligned their activities with the government's flagship programs, "AatmaNirbhar Bharat Abhiyan" (meaning "Self-Reliant India") and "Make in India" policies. The SOMNEs, along with the government, run campaigns to encourage indigenous manufacturers. Companies at the enterprise level have also taken similar steps.

The policy framework encourages investment within India. However, it is vital to understand why Indian SOMNEs invest abroad. Energy sector enterprises' overseas investments aim to secure the country's energy needs. Other investments can be considered efficiency-seeking, but some have political and social motives attached to them. Some investments were also made to solve market imperfections in neighboring countries. For instance, infrastructure projects undertaken by Power Grid Corporation of India in Nepal facilitated cross-border transmission of power, which is more efficient than sharing any other resource with neighboring countries.

Some SOMNEs provide consultancy services for solarization projects in 47 Least Developed Countries (LDCs) and Small Island Developing States (SIDS) under the International Solar Alliance (ISA). These SOMNEs have extensive experience implementing projects in a vast country like India. Some of the international offices established by SOMNEs are market-seeking and resemble most private entities.

Technological dimension

The final dimension on which the firms are evaluated is Technology. According to the last R&D statistics report of the government, Central Government incurred the highest share of R&D expenditures, 45.4%, 93% of which was incurred by 12 major scientific agencies. The case of India is in line with existing literature (Jamasb and Pollitt 2011; Mazzucato 2011; Sorrentino 2020); agencies do high-risk basic and applied research and are still under the state's control because privatization wasn't allowed in the strategic sector. Choudhury and Khanna (2014), in the study of 42 laboratories of the Council of Scientific and Industrial Research, argued that it internationalized and filed more foreign patents over the years for resource independence.

The R&D expenditure of business enterprises has remained low despite all direct and indirect incentives. The generous tax incentives for R&D expenses and innovation initiatives include Super Tax Deductions, Customs Tax Exemptions, GST Exemptions, Tax Holidays, and the recently introduced Patent Box Regime, but the business sector R&D expenditures remain low compared to all large economies like India (Kaushik 2022). The overly generous incentives given to private firms led to firms relabeling non-R&D costs as R&D expenses for profiteering (Kaushik 2023). At the aggregate level, SOEs' R&D expenses remained low but were high for critical sectors such as Drugs and

Pharmaceuticals, Transportation, Information Technology, Chemicals (other than fertilizer), and Defense Industries.

The variable for testing is the R&D Intensity, calculated by dividing the R&D expenses of the enterprises by the total sales of the SOE. The revenue includes both domestic and foreign earnings. The government mandates in MoU that 2% of Profit before tax should be spent on R&D expenses or innovation and initiatives. This study calculated the R&D intensity of the sample Indian SOMNEs and compared it with the R&D intensity of its respective sectors. The motive is to examine if SOMNEs spend more on innovation than other firms in the industry. As discussed before, the trend of R&D intensity is discussed in the segment. R&D Intensity is calculated by dividing the R&D expenses of the enterprises by the total sales of the SOE. The revenue includes both domestic and foreign earnings. Not all SOMNEs were in business that required R&D expenditures; only relevant ones are presented in Table 6.

The government has excluded R&D intensity in the recent MoU, leading to a decline in this area. However, some SOMNEs such as Bharat Earth Movers Limited, Bharat Heavy Electricals Limited, Bharat Petroleum Corporation Limited, Hindustan Aeronautics Limited, ONGC, National Thermal Power Corporation, Indian Oil Corporation Limited, Hindustan Petroleum Corporation Limited, and Engineers India Limited have shown an increase in R&D intensity. The top five SOMNEs with high R&D intensity are Bharat Earth Movers Limited, Bharat Heavy Electricals Limited, Coal India Limited, Engineers India Limited, and Hindustan Aeronautics Limited, with SOMNEs from the defense sector spending more on R&D. While SOMNEs can be used by the government to drive innovation, there is little evidence that they have undertaken such activities abroad.

Section III conclusion

In conclusion, the study highlights the distinctive operational approach of India's SOMNEs, showcasing their ability to sustain profitability through diversified investments, even in the face of certain risky ventures. Notably, most SOMNEs have been actively engaged in environmental conservation initiatives, barring the loss-making MTNL. The profitable entities have consistently exceeded corporate social responsibility obligations, with some surpassing mandated thresholds. Surprisingly, even the loss-making Engineering projects India Limited and MTNL have supported COVID-19 relief funds, demonstrating a commitment to societal welfare.

Despite the challenges, none of the SOMNEs resorted to employee layoffs during the pandemic, emphasizing their unique commitment to economic and social stability. While some SOMNEs exhibit high research and development intensity, there is limited evidence of these activities being outsourced internationally. This distinct operating paradigm sets SOMNEs apart from their private counterparts in India, underscoring their dual focus on creating social value and ensuring profitability.

The internationalization journey of Indian SOMNEs emerges as a global precedent, showcasing an integration of profit-oriented objectives with a public mission. The study reveals key findings, including the consistent international growth trajectory of SOMNEs, blending market-driven tactics with a broader social mission. These

Table 6. The R&D expenditures of the SOMNE.

	FY 2018–19		FY 2019–20		FY 2020–21

Public Enterprise Survey Report published by Department of Public Enterprise, Government of India.

enterprises have successfully displayed resilience and adaptability, navigating global economic fluctuations and the recent pandemic.

The history of privatization in India has seen the significant sale of profitable enterprises at substantial concessions during fiscal stress. The current government's new policy also aims to minimize its presence in SOEs. The increasing inclination of the Indian government and other national authorities towards disinvestment in all SOEs, both strategic and non-strategic, calls for a strategic reevaluation in light of these findings.

Disinvestment, often pursued to infuse capital efficiency and foster private sector participation, may inadvertently undermine the unique strengths and contributions of SOMNEs and SOEs. As this study indicates, these enterprises are significant contributors to the national economy and champions of social and environmental initiatives.

In this context, governments must consider a balanced approach that nurtures the growth and international presence of SOMNEs. Instead of disinvestment, the emphasis should be on creating an enabling environment that supports these entities in their dual mission of economic growth and social responsibility. This involves reinforcing regulatory frameworks, ensuring access to international

markets, and providing strategic support in areas like technology acquisition and sustainable practices.

For SOMNEs, the study underscores the importance of aligning internationalization strategies with global best practices in sustainability and corporate governance. This alignment maintains India's competitive edge and enhances its global reputation. The narrative of Indian SOMNEs' internationalization becomes a compelling model for other emerging economies, offering insights into leveraging state-owned enterprises for economic, social, and environmental progress. In summary, the internationalization of Indian SOMNEs is a multifaceted narrative encompassing strategic growth, societal contribution, and environmental commitment.

Notes

1. For more details, refer to the Reserve Bank of India Notification: Master Direction – Direct Investment by Residents in Joint Venture (JV)/Wholly Owned Subsidiary (WOS) Abroad https://www.rbi.org.in/Scripts/BS_ViewMasDirections.aspx?id=10637#C5 (RBI 2021)
2. Strategic Sale means the sale of large government shareholding (not necessarily major) to a strategic investor. In strategic sales, the management control is transferred to the investor, even if the strategic partner is not the major shareholder.
3. Asset monetization is leasing out of state-owned assets.
4. The government has cancelled the strategic sale of Pawan Hans after the disqualification of the winning bidder.
5. The technology is called Advanced Ultra Super Critical (AUSC) technology. It will be used to transform inefficient old power-generating units into more efficient and less polluting units.

ARTICLE INFO

ABSTRACT

In the digital age, the discipline of User Experience Design (UXD) has become increasingly important, influencing people's interactions with digital interfaces and goods. This extensive study paper delves into the many dimensions of user experience design (UXD), covering everything from its historical development and foundational ideas like usability, information architecture, visual design, and user-centered design to its significant impact on human psychology. Examining emotions, cognitive load, behaviour, trust, and satisfaction as crucial characteristics touched by UXD, it delves into the psychology of user experiences. Moreover, the research offers perceptive case studies that demonstrate how UXD concepts propel user delight and corporate success in a variety of industries. These case studies include UXD in E-Commerce, Mobile Applications, and Healthcare Technology. Design rules, emotional design, cognitive load reduction, trust enhancement, and loyalty fostering are outlined as practical implications for designers. The study also discusses the difficulties and moral issues that come with user experience design, highlighting the significance of inclusiveness, user privacy, and responsible design methods. Lastly, it explores cutting-edge themes including AI-powered personalization and the moral application of UXD to protect user privacy. This offers a forward-looking viewpoint on how UXD is changing in the digital era and emphasizes its continuing importance. Through an analysis of the convergence of design, psychology, and technology, research demonstrates how UXD influences user cognition, behaviour, and emotions, which in turn affects people and society as a whole.

Introduction

In an increasingly digital world, user experience has emerged as a crucial element in the design and development of products and services (Pucillo & Cascini, 2014). The multidisciplinary field of user experience design (UXD) blends elements of human-computer interaction, design, psychology, and technology (Luther et al., 2020) to give users intuitive and pleasurable experiences. This research paper aims to provide a comprehensive analysis of user experience design and how it affects human psychology.

In a world that is networking and changing quickly, the way individuals interact with technology (Cheng et al., 2012) is affecting the passage of time. From the smartphones we carry in our pockets to the websites and services we use on a daily basis, technology has become an essential part of our lives. In this digital world, the concept of User Experience Design (UXD) has become essential, impacting not just our interactions with technology but also our thoughts, feelings, and behaviours.

The engine of this technological revolution is user experience design. In order to provide intuitive and pleasurable user experiences, this multidisciplinary field combines design, technology, psychology, and human-computer interaction (Olson & Olson, 2003). The aim of user experience design (UXD) is to comprehend people's needs, expectations, and behaviours when they interact with digital goods and services. The objective is to make technology simple and easy to use, whether you're using a smartphone app, an online store, or a complex piece of software. Designing encounters that are both enjoyable and functional is the aim of user experience design (UXD). It involves ensuring that you feel good about yourself after using a digital product, whether that feeling is joy, satisfaction, or a sense of success.

UXD's influence, however, extends beyond usability and enjoyment on the surface. It delves into many facets of human mind. A crucial element of UXD's design is human psychology, which is the study of human cognition, emotion, and behaviour. Our in-depth knowledge of how the human mind processes information, how emotions influence our decisions, and how our cognitive capacities affect how we engage with technology has an impact on everything from website layout to mobile app colour schemes, information flow, and software interface design.

This study article aims to explore the intricate relationship that exists between user experience design and human psychology. It seeks to provide a comprehensive understanding of UXD, covering its definition, historical evolution, tenets, and important psychological ramifications. As we examine the foundations of psychology, we will discover how emotions, behaviour, and cognition are intertwined with the production of digital experiences. Along with difficulties and ethical considerations, real-world case studies, future trends in the quickly evolving field of UXD, and practical implications for designers, the paper will also cover these topics. Readers will gain a greater understanding of the significance of user experience design (UXD), which goes beyond creating intuitive interfaces to understanding and influencing human thought, emotion, and behaviour in the digital age.

1.1 Background

When developing digital or physical products and services, user demands and preferences are prioritized over those of functionality and aesthetics. This approach is known as user experience (UX) design. In today's oversaturated digital world, the quality of the user experience (Tesařová, 2022) often determines whether a digital product succeeds or fails. There is no shortage of possibilities for users. Because User Experience Design (UXD) aims to create meaningful and enjoyable experiences that deeply resonate with people, it is an indispensable component in the competitive digital world.

1.2 Research Objectives

This research paper sets out to explore the multifaceted world of User Experience Design and its profound impact on human psychology. Our main goals are as follows:

(a) Defining User Experience Design: We will provide a thorough definition of what User Experience Design comprises, considering its historical development, guiding principles, and essential ideas.

(b) Analysing the Effect on Human Psychology: We'll explore the complex ways that UXD affects psychology in humans. We will specifically look at the emotional reactions it arouses, how it affects cognitive functions, how it affects user behaviour, credibility and trust, and how it affects user happiness and loyalty.

1.3 Methodology

Our research will use a multimodal approach in order to meet its goals.

(a). Literature Review: A comprehensive analysis of the corpus of existing research on user experience design and human psychology will be carried out, utilizing academic studies, business publications, and expert judgment.

(b) Case Studies: A variety of case studies from various sectors will be looked at in order to show how UXD affects human psychology and to provide a real-world perspective.

(c) Ethical Considerations: As the ethical facets of UXD are investigated, user privacy, persuasive design, and accessibility concerns will be looked at.

2. What is User Experience Design?

User Experience Design (UXD) is a multidisciplinary area that aims to develop systems, services, or products that give users remarkable and meaningful experiences (Borriraklert & Kiattisin, 2021). It is a thorough approach to design that considers not just a product's utility and efficiency but also its emotional and psychological impact on its customers. By making interactions with digital or physical objects as simple, entertaining, and productive as possible, user experience design (UXD) aims to enhance user pleasure and engagement.

2.1 Definition of User Experience Design:

User Experience Design is he process of creating products and services with the needs, goals, and perspective of the user in mind (Vahdat, 2023). It encompasses not just a product's technical specifications and aesthetic appeal, but also the entire user experience. UXD aims to be not only user-friendly but also emotionally charged, memorable, and ultimately helpful to the user.

2.2 Historical Evolution:

The field of User Experience Design (UXD) has its origins in the Human-Computer Interaction (HCI) movement of the 1960s and 1970s, which aimed to make computer systems more user-friendly in the workplace. The phrase "user experience" was made popular by cognitive scientist and designer Don Norman during his tenure at Apple in the 1990s. Since then, processes and technologies have evolved in tandem with the rapid expansion of UXD. Furthermore, Norman's seminal book "The Design of Everyday Things," which was released in 1988, is where the idea of UX design first emerged. Because of Norman's emphasis on the intricacy of developing often-overlooked things, UX design has become the de facto standard approach to user-centered design (Norman, 2013). Figure 1. An illustration by Orange-crush demonstrates how a product's UX design makes it fun and simple to use.

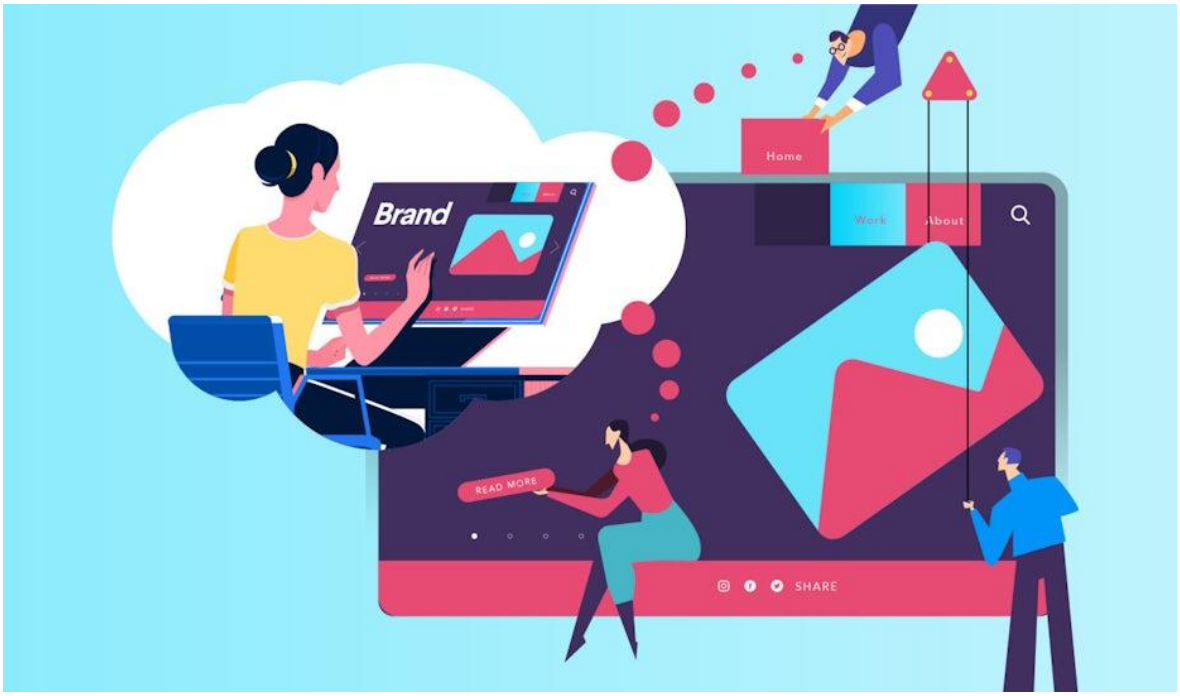

Fig 1.

2.3 Key Principles of UXD:

Any product or service must prioritize user experience. It includes all of a user's interactions with a good or service, from the beginning stage of research until the point of sale or use. It's crucial to adhere to certain standards, such simplicity, clarity, and consistency, in order to provide the best possible user experience. The following basic concepts serve as the foundation for the main tenets of user experience design (Stevens & Stevens, 2022):

Empathy: UX designers must place themselves in the shoes of their customers and consider their needs, frustrations, and motivators in order to fully comprehend and sympathize with them.

Consistency: Consumers are better able to form mental models of how a product works when design elements like layout, navigation, and vocabulary are constant. This helps to eliminate uncertainty.

Simplicity: In UXD, designing with simplicity is essential to creating intuitive, user-friendly products that give customers clear, simple instructions. A minimalist design reduces cognitive load, allowing users to execute tasks more quickly. It means getting rid of unnecessary complexity and clutter.

Feedback: By integrating feedback methods into UX design, it is possible to continuously update the design in response to user interactions and feedback, which enhances the user experience. Giving users immediate, succinct feedback on their actions helps them understand the consequences of their actions and speeds up error recovery.

Information Hierarchy: By creating a distinct information hierarchy, a page's usability and comprehension are improved by directing users' attention to the most crucial content. Information should be presented hierarchically, with the most important or often requested content being readily accessible, to ensure that visitors can find what they need fast.

Usability: A key element of UXD, usability is the degree to which tasks within a system or product can be

completed by users quickly and easily. Errors (the frequency with which users make mistakes), memorability (the ease with which users can recall how to use the product), speed (the speed at which users can pick up new skills), and satisfaction (the degree to which users are content with a product) (Rusu et al., 2015) are all included in the category of usability.

2.4 User-Centered Design:

User-Centered Design (UCD) is a fundamental aspect of UXD. Research is necessary to comprehend user behaviours, needs, and preferences. This study informs the design process, ensuring that end users are considered while developing new products and services. Common steps in UCD include brainstorming, user research, prototyping, testing, and iteration.

User-Centered Design (UCD) is an iterative design process that prioritizes understanding users and their context throughout all stages of design (Jurca et al., 2017). By including users at every stage of the design process, this method guarantees that goods are not only aesthetically beautiful but also practical and easy to use. UCD concentrates on developing products that satisfy users' requirements, goals, and input while developing special relationships with the communities they support. Through user-centered design (UCD), products are validated by end users at every level, resulting in efficient solutions that meet unique needs. Phases of the UCD process typically include gathering information about user behaviours and wants, designing solutions, testing them, and iterating designs to improve usability and satisfaction. Requirements are also specified based on user insights.

3. What is Human Psychology?

Human psychology is the scientific study of the human mind and conduct, with an emphasis on the causes and mechanisms behind people's thoughts, emotions, and behaviours (Pérez-Álvarez, 2017). It investigates many facets of human emotion, cognition, and behaviour, offering insights into the reasons behind people's decisions, responses to stimuli, and interactions with their environment. Designers need to understand human psychology in order to make products that offer outstanding user experiences.

To learn more about human behaviour, psychologists do empirical research and apply systematic approaches. To collect information and make conclusions, they could carry out surveys, observations, experiments, and clinical investigations. Studying social dynamics, societal impacts on behaviour, and individual cognitive processes are just a few of the many areas covered by psychology.

Origin and History of Psychology:

The origins of psychology can be found in the thinking of human behaviour and the secrets of the mind discovered by ancient societies such as the Greeks, Chinese, and Egyptians (lumenlearning, 2024). However, the first psychology laboratory was established in Leipzig, Germany, by German psychologist Wilhelm Wundt in 1879, which signalled the start of modern psychology as a scientific discipline in the late 19th century. This cleared the path for additional research and established psychology as an experimental and scientific field. Wundt's investigation of consciousness and his establishment of structuralism as a psychological method had a major influence on the discipline.

Influential Early Figures in Psychology

The journey of psychology's development is deeply influenced by the work of early figures who made significant contributions to the field. Among these significant forerunners are:

Wilhelm Wundt: Widely recognized as the father of psychology, Wundt's contributions paved the way for subsequent scientific investigations in the area. His self-reflective techniques aimed to reveal the composition of conscious experience.

William James: James, an American psychologist and philosopher, focused on comprehending the goals and functions of the mind through his functionalism, which shifted attention to psychology's larger picture. He is well known for writing "The Principles of Psychology," which is now regarded as a classic in the subject.

Sigmund Freud: Freud's psychoanalytic theory shed light on the complexity of human thought and behaviour by emphasizing the unconscious mind and early childhood experiences. His writings established ideas like the id, ego, and superego as well as the significance of dreams in providing insight into the unconscious.

John B. Watson: A behaviourist, Watson promoted the idea that psychology should be empirical and objective and excluded the study of mental processes in favour of an emphasis on observable behaviour. His well-known "Little Albert" experiment illustrated how classical conditioning works.

B.F. Skinner: Another significant behaviourist, Skinner developed the theory of operant conditioning, which

has real-world uses in behaviour modification and understanding. In his research, Skinner highlighted the influence of reinforcement and the environment on behaviour.
Psychology has evolved into many different schools of thought over time, such as behaviourism, psychoanalysis, functionalism, and humanistic psychology. These many viewpoints examined various facets of human psychology, ranging from analysing unconscious processes to highlighting personal development and potential to comprehending behaviour in terms of its function.

Key Elements of Psychology:
Several key elements of psychology are relevant to design:

Cognition: This component deals with mental functions like perception, memory, focus, and problem-solving. In order to build interfaces that are simple to browse and understand, designers take cognitive characteristics into account.

Emotions: It's important to comprehend how emotions affect user behavior. While unpleasant emotions can turn people away, positive emotions can improve user experiences.

Perception: When designing, designers consider how users' senses interpret and experience information. This covers haptic feedback, aural perception, and visual perception.

Motivation: In order to engage users, motivation is necessary. In order to persuade customers to perform desired actions, such finishing a purchase or signing up for a service, designers integrate motivational ideas. recognizing the needs, interests, and objectives that influence human behaviour.

Development: Studying how people evolve and change from early childhood to old age.

Social Interaction: Studying interpersonal relationships, encompassing subjects like communication, group dynamics, and social influence.

Learning and Memory: Information retention and learning are factoring that designers consider. They try to design experiences that are simple to understand and retain, reducing the need for ongoing relearning.

Decision-Making: When utilizing items, users make decisions. Reducing choice fatigue and optimizing product interfaces are two benefits of understanding decision-making processes for designers.

User Input: Obtaining user input and carrying out usability testing are crucial components of design psychology. This aids in problem identification and data-driven design enhancement.

The Importance of Psychology for Design:
A key component for designers looking to build products with exceptional user experiences is human psychology. Design heavily relies on psychology, especially when it comes to comprehending users and developing user-centered solutions (Alves, 2023). Designers may make products more intuitive and human-centered by enhancing the user experience through the integration of psychological principles into the design process. Designers that are knowledgeable about psychology are better able to relate to users, understand their wants, behaviours, and motivations, and create solutions that effectively address those needs. This information aids in the development of user interfaces that direct users toward intended actions and results, which eventually result in a satisfying user experience. Designers may use visual components to create coherent designs that consumers see as cohesive wholes by utilizing psychological ideas like Gestalt Principles (Abhishek, 2023).
Key factors that highlight the significance of psychology in design include (Lawerteh, 2022):

Human-Centered Design (HCD): HCD is a design methodology that gives users' wants and experiences first priority. Psychology aids in its implementation.

Perception and Reality: Since people interpret designs depending on contextual cues and cognitive pre-processing, it is critical for designers to comprehend the subjective nature of human perception.

Predictive Perception: In order to solve design problems and reduce human error, human cognition entails making predictions and revising mental models.

Gestalt Principles: Creating designs that are successful, logical, and in line with human experiences and expectations requires the application of Gestalt principles in design.

User-Friendly Products: By bridging the knowledge gap between design and user experience, psychology helps make goods that are easy to use, pleasurable for users, and intuitive.

Colour psychology: Colour psychology is a useful technique in design that helps elicit desired responses from users since colours have the power to inspire particular emotions and impact user behaviour.

Hick's Law: This idea stresses making options easier for consumers to understand so they can make better decisions and have less cognitive strain overall.

Mental Models: By utilizing users' pre-existing knowledge and familiarity with design patterns, designing based on their mental models improves the user experience (Nielsen & Chan, 2024).

Priming: By matching messaging to consumers' expectations, psychological concepts like priming can affect user trust and engagement with a brand or product.

Relevance of Psychology to User Experience Design

Understanding human psychology is essential for designing products and interfaces that are both efficient and user-friendly in the rapidly changing fields of technology and product design. User experience (UX) designers use psychological concepts to create intuitive, captivating experiences that ultimately satisfy the needs of the user (Kohler, 2024). The following are some significant ways that psychology and user experience design interact:

Cognitive Psychology: This branch supports interface designers in building user interfaces that match consumers' expectations and mental models. Through an understanding of human information processing, designers may create user-friendly products. Design professionals are guided in creating more intuitive user interfaces by the concepts of cognitive psychology, which include information processing, memory, and perception.

Emotional Design: Emotions have a critical influence in the user experience. Emotional design concepts are used by designers to arouse pleasant emotions in the viewer, which can improve user engagement and loyalty. Interface designers are able to produce user experiences that really connect with users when they have a thorough understanding of how people feel about visual design, information, and interactions.

Behavioural Psychology: By utilizing the concepts of operant conditioning and reinforcement, behavioural psychology principles can be utilized to promote desired user activities, such as signing up for a service or completing a purchase. In order to influence user behaviour and raise satisfaction and engagement, designers can utilize incentives and feedback (Luther et al., 2020).

User-Centered Design: User-centered design requires extensive user research and feedback gathering. The goal of design is to produce goods that satisfy the requirements, tastes, and expectations of people. Designers may better adjust product designs to customer needs by gathering insights into user behaviour and preferences through user research, questionnaires, and usability testing.

Visual Perception: Gestalt psychology, colour psychology, and typography are a few examples of concepts that designers may use to create visually appealing and functional interfaces by having a better understanding of how people see and interpret visual information. These guidelines help designers create aesthetically pleasing and intuitive user interfaces.

Decision-Making: By utilizing the concepts of behavioural economics and decision-making psychology, designers may lessen decision fatigue and simplify their designs, which will enhance user experiences. Designers can make interfaces that help users make decisions and feel less frustrated by knowing the cognitive biases that affect decision-making.

Ethical Considerations: Designers may tackle current ethical difficulties by prioritizing the well-being and autonomy of users through an understanding of user trust and privacy concerns, as well as ethical principles. Ethical concerns such data privacy, openness, and how their designs affect consumers' well-being must be considered by designers.

Understanding human cognition and behaviour is made possible by human psychology, which is the basis for many other disciplines, including user experience design. By utilizing psychological notions, designers can produce visually arresting, functionally efficient, and emotionally captivating objects. Also the history, key figures, subfields, and critical significance of psychology to user experience design is essential for navigating the intricacies of human cognition and its practical implications. These insights can be used by designers to

create products that have a strong emotional bond with users, enhancing their experiences and making a big difference in a range of industries.

Case Studies

4.1 User Experience Design in E-Commerce:

One industry where User Experience Design (UXD) is crucial is e-commerce. In this case study, we look at how good UXD may have a big impact on an online store's ability to succeed.

Background:

E-commerce platforms are online stores where customers may peruse, choose, and buy goods and services. There is a lot of rivalry in the e-commerce space, and customers have a lot of options. For this reason, offering a first-rate user experience is crucial to drawing in new business and keeping existing ones.

Key Aspects of UXD in E-Commerce:

User Interface Design: It's critical to create a visually appealing and user-friendly interface. This entails creating intuitive and aesthetically pleasing product lists, search capabilities, and navigation menus.

Product Discovery: Users may identify products that suit their tastes with the aid of efficient processes for product discovery, such as filters, sorting choices, and personalized suggestions.

Checkout Process: A crucial component of UXD is streamlining the checkout procedure to lower friction and increase conversions. This entails cutting down on the amount of steps, providing guest checkout choices, and guaranteeing safe payment processing.

Mobile Optimization: It is imperative to optimize the e-commerce platform for mobile customers, given the growing trend of using mobile devices for online purchasing. It is imperative to have responsive design, mobile-friendly navigation, and quick loading times.

Customer Reviews and Ratings: Including user-generated content can help people make wise judgments about what to buy by fostering trust. Examples of this type of content include product reviews and ratings.

Impact of Effective UXD:

Effective UXD in e-commerce can lead to several outcomes:

Increased Conversion Rates: A website that is easy to use and intuitive to navigate encourages customers to finish their transactions, which results in greater conversion rates.
Reduced Cart Abandonment: Clear pricing and an efficient checkout procedure can lower cart abandonment rates.
Enhanced User Loyalty: Happy customers are more likely to come back and make more transactions, which increases user loyalty.
Positive Word of Mouth: Happy customers can spread the word about their wonderful experiences to their friends and family, which helps with word-of-mouth advertising.
Data-Driven Improvements: By addressing user pain points and adjusting to shifting consumer preferences, ongoing UX research and data analysis enable continuous development.

4.2 User Experience Design in Mobile Applications:

Mobile apps are become a necessary component of everyday life. This case study investigates the relationship between UXD and mobile app success.

Background:

There are many different types of mobile applications, ranging from productivity and healthcare to social media and entertainment. A mobile app's usability, engagement, and user pleasure are frequently what determine its success.
Key Aspects of UXD in Mobile Applications:

User Onboarding: A smooth onboarding procedure makes it easier for users to rapidly grasp the benefits and capabilities of the app.
Navigation: Clear call-to-action buttons and intuitive menus improve user engagement and task completion.
Performance: A good user experience is influenced by quick loading times, responsive design, and effective data processing.

User Engagement Features: Notifications, gamification components, and personalization are examples of features that improve user engagement and retention.
Accessibility: It is both legally required and a user-centered design practice to make sure the software is usable by people with disabilities.

Impact of Effective UXD: Effective UXD in mobile applications can lead to:

Higher Adoption Rates: A more expansive audience is more likely to acquire an app that is easy to use and has a seamless onboarding procedure.
Increased User Retention: Enhanced user experiences, intuitive navigation, and captivating features all help to increase retention rates.
Positive Reviews and Ratings: Happy customers are more likely to give apps a high visibility and credibility in app stores by leaving positive reviews and ratings.
Monetization Opportunities: Applications with high levels of user pleasure and engagement are better suited to profit from monetization techniques like in-app purchases and subscriptions.
Brand Loyalty: A well-made app can help users stay engaged with a brand or service and strengthen their brand loyalty.

4.3 User Experience Design in Healthcare Technology:

Digital tools for healthcare include everything from telemedicine platforms to electronic health records (EHRs). We examine the impact of UXD on the healthcare technology industry in this case study.

Background:
There has been a major digital revolution in the healthcare sector, with technology being essential to patient care, diagnosis, and data management. For patients and healthcare professionals to use healthcare technology safely and effectively, effective user experience design is essential.

Key Aspects of UXD in Healthcare Technology:

Ease of Use: The technology should be simple enough for patients and healthcare professionals to use without requiring a lot of training or annoyance.
Data Security and Privacy: It is critical to guarantee patient data security and privacy. Robust security measures should be incorporated into UXD without sacrificing usability.
Accessibility: To guarantee equitable access to care, healthcare technology should be usable by people with disabilities.
Clinical Workflow Integration: Technology should not interfere with clinical workflows; rather, it should be a seamless part of them for healthcare practitioners.
Patient Engagement: Effective communication between patients and healthcare providers, adherence to treatment programs, and engagement should all be promoted via patient-facing healthcare technology.

Impact of Effective UXD: Effective UXD in healthcare technology can lead to:

Improved Patient Outcomes: Patient empowerment through effective health management can result in better health outcomes thanks to user-friendly tools.
Reduced Healthcare Errors: Clinical workflows that are integrated and intuitive can aid healthcare providers in making well-informed decisions and lowering errors.
Increased Adoption: Technology that improves patient care and fits well with their workflow is more likely to be adopted by healthcare providers.
Compliance with Regulations: Adhering to accessibility and usability guidelines guarantees adherence to healthcare laws and minimizes legal liabilities.
Enhanced Telemedicine: Effective remote healthcare delivery in the context of telemedicine depends on a good user experience.

These case studies highlight the various ways that UXD is applied in various industries and show how these applications can significantly affect user pleasure, engagement, adoption, and overall success. Because effective UXD methods and ideas can be applied to a wide range of industries, they highlight the significance of user-centered design in the digital age.

Results

Emphasizing the concrete results that User Experience Design (UXD) case studies may produce across a range of sectors is crucial. These outcomes show how UXD methods may be effectively invested in and have a major influence on user pleasure, engagement, and business success. The results highlight the revolutionary potential of user-centric design principles, from higher conversion rates and better user retention in e-commerce to

improved patient experiences and better clinical outcomes in healthcare technology. Organizations can attain tangible advantages like optimized processes, decreased attrition rates, and favourable customer feedback by placing a high priority on usability, user-friendly interfaces, and unambiguous communication. The results of UXD case studies are concisely presented in the following table, which shows Table 1 the practical applications of successful design approaches in many domains.

Case Study	**Results**
E-Commerce:	
- Increased Conversion Rates	- Streamlined checkout processes
	- Reduced cart abandonment rates
	- Higher conversion rates
- Improved User Retention	- Higher user satisfaction and loyalty
	- Increased repeat purchases
- Enhanced Mobile Experience	- Improved engagement and sales on mobile
	- Optimized mobile shopping experience
Mobile Applications:	
- Higher User Engagement	- Improved usability and navigation
	- Longer app sessions
- Reduced Churn Rate	- Enhanced onboarding experience
	- Addressed user pain points
- Positive User Reviews	- Increased app ratings and favourable reviews
	- Attracted new users
Healthcare Technology:	
- Enhanced Patient Experience	- Improved satisfaction with medical services
	- Intuitive interfaces for appointments
	- Easy access to medical records
- Better Clinical Outcomes	- Empowered patients for self-management
	- Improved health outcomes

Conclusion

The result of our research highlights how crucial User Experience Design (UXD) is to influencing digital interactions and propelling corporate success in a variety of sectors. We have examined the fundamental ideas of UXD—such as the significance of comprehending user demands, intuitive navigation, emotional involvement, and ongoing iteration—through a thorough literature analysis. Using a range of case studies in mobile apps, e-commerce, and healthcare technologies, we have direct experience with the real-world effects of good UXD techniques.

The literature review revealed that effective UXD begins with a deep understanding of user needs, behaviours, and preferences. Through the implementation of user-centric design principles and the integration of emotional engagement aspects, organizations may craft meaningful user experiences. Furthermore, UXD's iterative approach enables ongoing improvement in response to user input and changing market trends, guaranteeing that goods and services stay competitive and relevant in a constantly shifting environment (Ahsan, 2024).

Furthermore, the case studies offered specific illustrations of how UXD concepts are translated into real-world results. Effective UXD practices have a clear influence on everything from higher conversion rates and greater user retention to better clinical results and improved patient experiences. By placing a high value on user happiness, engagement, and loyalty, businesses can stand out from the competition and cultivate enduring bonds with their clientele.

It's evident that the fundamentals of UXD will continue to be vital in determining the nature of digital experiences in the future. Organizations need to stay flexible and agile as technology and user expectations change. They should embrace new trends and adjust their design strategies accordingly. Organizations may develop creative and engaging experiences that satisfy the changing needs of their users and propel economic success in an increasingly digital environment by adhering to the fundamental principles of UXD and utilizing insights from both literature and real-life case studies.

The findings emphasize how crucial it is to comprehend customer requirements, habits, and preferences when creating goods and services that appeal to consumers. Organizations may design experiences that satisfy user expectations and build loyalty and trust by emphasizing components like emotional engagement, intuitive

navigation, and usability. Furthermore, the study emphasizes how crucial it is to continuously iterate and improve UXD because user preferences and technical environments change over time. Organizations can modify their design strategies to stay competitive and satisfy the changing needs of their target audience by keeping an eye on user input and developing trends.

In conclusion, the study highlights that making an investment in UXD involves more than simply improving user interfaces; it also entails developing memorable and significant experiences that increase user pleasure, engagement, and loyalty. The fundamentals of UXD will continue to be crucial in building the digital experiences of the future as technology develops, guaranteeing that goods and services deeply connect with consumers.

***Abstract*—A novel deep-learning time-series architecture is proposed for visual servoing to control an unmanned aerial vehicle (UAV). This UAV is capable of quasi-stationary flight and is equipped with a mounted camera to track a target composed of a finite set of stationary points located in a plane. The proposed solution utilizes a time-series deep learning architecture to learn temporal data from sequential values. It then generates control cues to be sent to the flight controller, enabling the UAV to perform its tracking task. We also present an optimized implementation of the novel proposed architecture on FPGA. When it comes to implementing Neural Networks, FPGAs have demonstrated their efficiency. Specifically, our implementation is quicker than top-tier central processing units (CPUs) when it comes to carrying out the inference of the suggested model. Moreover, the proposed system also achieved improvements in terms of energy efficiency, which is important for UAV's longer endurance.**

Keywords— Visual Servoing, Deep Learning, Long Short-Term Memory, Hardware Acceleration, FPGA.

I. INTRODUCTION

Visual servoing refers to a control method for robotic maneuvers that utilizes optical data from present sensors. Its objective is to guide a robot from one point to another, through space whether specified or unspecified, by minimizing the error iteratively between its present position and the target position. There are several uses for visual servoing, such as robotic surgery and autonomous navigation [1].

Two traditional approaches to the visual servoing problem are Position-Based Visual Servoing (PBVS) and Image-Based Visual Servoing (IBVS). With an inertial frame of reference, PBVS specifies the error in Euclidean space and produces simple control laws. It does, however, entail the error-prone Perspective-n-Point problem, which necessitates accuracy-enhancing result filtering [2]. With Image-Based Visual Servoing (IBVS), visual feature extraction is used to define the inaccuracy inside the image plane. Control strategies are developed based on the image Jacobian/Interaction matrix, with its pseudo-inverse approximated. Despite their efficiency, both IBVS and PBVS are reliant on camera-specific factors, such as the intrinsic parameters of the camera and the need for precise calibration [3].

Our research introduces a novel approach to visual servoing, treating it as a time-varying neural network problem analyzed sequentially. We employ Long Short-Term Memory (LSTM) networks and generate a set of time-series data using a custom environment within the Robotic Operating System (ROS). This approach addresses the challenges of visual servoing. Similar to IBVS, we define the error in the image plane and calculate the Image Jacobian. Control is achieved using distinct computer vision algorithms.

LSTM is capable of accurately propagating initial information from previous time steps to the current process. Furthermore, research, such as [17][18], has demonstrated that Field Programmable Gate Arrays (FPGAs) exhibit great potential in efficiently implementing Recurrent Neural Network (RNN) and LSTM architectures. Therefore, to implement the developed model, programmed in Python and TensorFlow API, on the Xilinx Alveo U200, the program is configured into a hardware-friendly C++ program using the Vitis HLS tool.

The format of the paper is as follows: In Section II, deep learning techniques for visual servoing are thoroughly reviewed, along with the FPGA's potential for executing RNNs and LSTMs. Section III discusses the conventional IBVS algorithm for dataset collection, followed by the introduction of a new DLVS architecture that optimizes the neural network to accelerate RNN model inference on an FPGA. Section IV details the training setup, test results, and algorithm implementation on FPGA. Section V provides an overview of future research and concludes the study.

II. Related Works

The study referenced in [4] employed techniques that required the manual design of visual features for image representation. Control laws were determined using backpropagation of gradient descent on spatial information errors. Using this method, the camera and interaction matrix were estimated analytically or numerically. The algorithm was subsequently modified for reinforcement learning, a common technique in deep reinforcement learning, and applied to a deep learning-based architecture. The results suggested that the learned parameters of the model may not apply to tasks or surroundings that are unfamiliar to it since they are context-specific.

Another study utilized FlowNet Convolutional Neural Networks for visual servoing [5]. In order to predict optical flow, this method uses pairs of pictures as inputs and the accompanying x-y flow fields as real data. After which, the data is processed using several ConvNets and ReLU activations. Practical implementation of the architecture requires training in diverse environments and camera settings [9].

Furthermore, some recent academic articles have shown that FPGAs have enormous capability in both efficiency and energy consumption while carrying out RNNs and LSTMs. In citation [13], a speech recognition LSTM model was accelerated by an FPGA-based accelerator, resulting in a 20.18x faster speed compared to a software implementation using a single thread, and 5.41x faster than an implementation using 16 threads. The reference [15] introduces GRNN, an RNN-LSTM inference library based on GPUs that surpasses the most optimized and efficient inference library designed for multi-core server CPUs, with a latency reduction of up to 17.5×. A platform for optimizing deep RNNs and LSTM/LSTMP cells using multi-FPGAs is presented in [16] by the authors. The use of a single-layer LSTM-RNN on the FiC platform enabled the authors to speed up their system significantly. This resulted in a 31-fold increase in speed compared to an Intel CPU and a 2-fold increase compared to a GPU. Moreover, the system attained 61 times and 5 times faster processing speed than a CPU and a GPU, respectively, when a four-layer LSTM-RNN was used. When processing 8-bit numbers, it achieved a power efficiency of 12 GFLOPS/W.

III. Methodology

C. Image-Based Visual Servoing

In image-based visual servoing, similar to other vision-based control methods, the objective is to minimize the error e(t), which is defined as:

$$e(t) = s - s* \tag{1}$$

The features in the image are represented by the vector s, and their desired placements on the image plane are represented by the vector s*. The error term is derived to design the velocity controller. The spatial velocity of the UAV/Camera is denoted by $V_c = (v_c, w_c)$, where v_c is the instantaneous linear velocity and w_c is the instantaneous angular velocity. Only the linear velocities are calculated and controlled as the UAV is an underactuated system,

The relationship is established as

$$de/dt = L_s v_c \tag{2}$$

Where $L_s \in R^{k*6}$ is the interaction matrix/feature Jacobian matrix. We apply the following control law to reduce the error term exponentially.

$$v_c = -\lambda L^+_e e \tag{3}$$

In a real visual servo system, L^+_e is the approximated Moore-Penrose pseudoinverse of L_e, as their exact values cannot be precisely determined.

The following equations describe the relationship between the feature points in the image plane with coordinates $\mathbf{x} = (x, y)_{in\ pixels}$ and their projection from a 3D point of view with respect to the camera frame with coordinates $\mathbf{X} = (X, Y, Z)$ is defined by the following equations:

$$x = X/Z = (u - c_u)/f\alpha \tag{4}$$

$$y = Y/Z = (v - c_v)/f \tag{5}$$

In this context, c_u, c_v, f and α represent a set of intrinsic camera parameters. C_u and c_v are the principal coordinate points, f is the camera's focal length, and α is the pixel dimension ratio (usually equal to 1). For gathering and testing datasets, these parameters were defined in the ROS simulation environment. We determined the interaction matrix to be:

$$Lx = \begin{bmatrix} -1/Z & 0 & x/Z & xy & -(1+x^2) & y \\ 0 & -1/Z & y/Z & 1+y^2 & -xy & -x \end{bmatrix}$$

where Z represents the depth of the point from the camera.

B. Dataset Collection

Sequential deep learning models necessitate a substantial dataset for training and model inference. Due to the absence of a publicly available dataset for visual servoing applications, data for this problem statement is manually collected. This is achieved by executing IBVS control in a custom simulation environment built on ROS and Gazebo 3D simulator [6,7]. The data collection involves varying the target's (ArUco marker) location, velocity, and the UAV's altitude. The input vector comprises the error components (ex, ey) in both the x and y dimensions of the image plane, along with the UAV's altitude. Conversely, the output vector includes the UAVs' control cues, specifically the desired velocity computed using the IBVS control algorithm.

C. Proposed Architecture

Fig. 1: Proposed network architecture

The suggested architecture follows a single-phase regression approach. Here, the model's primary objective is to extract temporal information from the sequential input data (error e(t)) and use it to predict the UAV's control cues, specifically its velocity.

As illustrated in Figure 1, the input layer of the model receives the error inputs and altitude as a stacked array with a shape of (32x3). Subsequently, the LSTM layers process the input with units of 16, 64, 256, and 512 to extract key features from the input sequence. The output from the LSTM layers, with a shape of (32x512), is then passed to the encoding portion of the neural network. Here, the output is further processed with units of 256, 64, and 16 to consolidate useful information for predicting the velocity. Finally, the output layer completes the model by predicting the required output in the shape of (32x2), representing the control cues for the UAV.

The input, forget, and output gates of the LSTM layers are recurrently activated using the Sigmoid activation function during the decision-making process. Meanwhile, the memory state activation function is a customized Modified_tanh function, which helps to alleviate the vanishing gradient problems that are frequently seen in recurrent neural networks. It has been observed empirically that using asymmetric activation functions in a large neural network can lead to faster convergence during back-propagation learning. Therefore, the proposed network architecture introduces non-linearity with a modified version of the hyperbolic tangent activation function.

$$y = 5 \times ((e^{x-5} - e^{-x/5})/(e^{x/5} + e^{-x/5})) \quad (6)$$

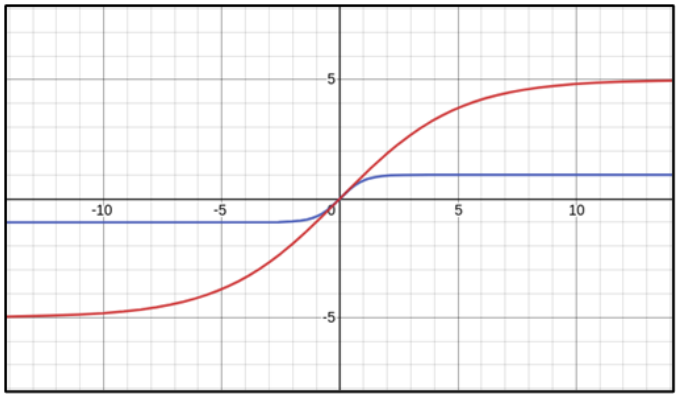

Fig 2:Plots of the activation functions: "modified_tanh" (red) and regular "tanh" (blue).

The UAV's capacity to reach higher velocities is constrained by the normal tanh activation function, which generates output values in the interval [-1, 1]. To overcome this constraint, a new modified tanh activation function is suggested, which permits the output value to lie between [-5, 5], as explained in (6). The behavior of this altered function is consistent with that of the standard tanh function, as depicted in Figure 2.

D. Neural Network Optimization

This study's ultimate objective is to expedite the inference of the RNN model on an FPGA (Xilinx Alveo U200). To reconfigure the model efficiently for the FPGA, we used the C++ functions of TensorFlow modules developed by the researchers of [12] and tailored it to use in our application. After the development of the C++ codes, they were tested against the same input data as the Python/TensorFlow model. Both of the configurations got similar outputs. Further optimization of the program was done for efficient implementation on the FPGA by pruning the model, Quantizing the weights and biases, and hardware-optimized mapping of the equations and weights.

1) Pruning

In order to reduce the computational cost of our neural network, we applied weight pruning to the LSTM layers. Specifically, we used a structured pruning approach that preserved the connectivity and structure of the LSTM layer while still reducing the number of parameters. We set a threshold for each weight value and zeroed out any weights that fell below the threshold, but we also ensured that the gates and memory cells remained intact. Through experimentation, we found that pruning up to 20% of the weights in the LSTM layers did not significantly degrade performance while reducing the number of parameters by nearly one-fifth. These results improved the computational efficiency of LSTM-based neural networks without sacrificing much accuracy.

2) Quantization

Quantization converts the weights and biases of a neural network from its original floating-point representation to a lower precision representation. This reduces the memory requirements and computational cost of the model, making it more efficient. FPGAs leverage their ability to handle numbers with arbitrary bit lengths efficiently in order to create an optimal programmable module. To achieve a high throughput rate without compromising much on the accuracy we quantized our model using Vitis-AI.

3) LSTM Hardware optimization

After obtaining the quantized values of weights and intermediate values from Vitis-AI, we allocated a register with the same bit length to store the values instead of storing them on BRAMs to reduce the latency of the model.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 09,2024 at 07:00:04 UTC from IEEE Xplore. Restrictions apply.

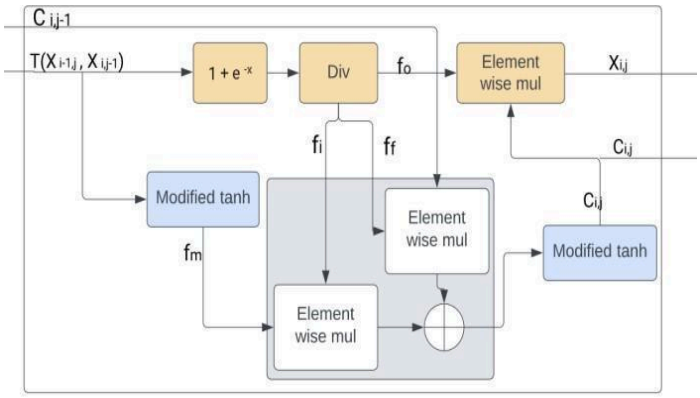

Fig. 3: Block diagram of modules implementing the basic LSTM operations

Each symbol corresponds to one of the four gates of the LSTM block, which are the input gate (f_i), forget gate (f_f), output gate (f_o), and input modulation gate (f_m). The elementwise multiplication is denoted by the usual '$\odot$' symbol. $C_{i,j}$ denotes the state or recollection of the ith layer's j^{th} time step, while b, and W and W' correspond to relevant biases and weights respectively. The dimensions of the four gates and $C_{i,j}$ at every time step are [1, Ki]. Demonstrating the employment of every term indicated in Figure 3 presents a streamlined depiction of the unit that executes the fundamental LSTM layer, featuring equations as illustrated underneath.

$$f_i = sigmoid(T(X_{i-1,j}, X_{i,j-1})) \tag{7}$$

$$f_f = sigmoid(T(X_{i-1,j}, X_{i,j-1})) \tag{8}$$

$$f_o = sigmoid(T(X_{i-1,j}, X_{i,j-1})) \tag{9}$$

$$f_m = modified\ tanh\ (T(X_{i-1,j}, X_{i,j-1})) \tag{10}$$

$$c_{i,j} = f_f \odot c_{i,j-1} + f_i \odot f_m \tag{11}$$

$$X_{i,j} = f_o \odot modified\ tanh\ (c_{i,j}) \tag{12}$$

$$T(X_{i-1,j}, X_{i,j-1}) = X_{i-1,j} \odot W + X_{i,j-1} \odot W' + b \tag{13}$$

The nomenclature utilized in this context designates the weights connecting a specific i^{th} layer and the subsequent $(i + 1)^{th}$ layer as $W_{i,i+1}$. The biases for a particular layer (layer i) are referred to as bi. The input vector for that layer is represented by Xi, and its size is [nbs, 1]. The weight matrix connecting layers i and i+1 is represented by $W_{i,i+1}$, and its size is $[K_i, K_{i+1}]$. The bias vector for layer i is represented by [nbs, 1]. Layer i has a dimension of K_i, while nbs denotes the number of input signals that will be categorized.

IV. Experimental Results

A. Training Details

The proposed architecture is developed, implemented, and trained using the TensorFlow library. In noisy issues, the adaptive momentum optimizer handles sparse gradients [11]. An internal dataset with dynamic target data and a range of elevations is used to train, infer, and validate the model. The input batch size is set to 32, representing 32 consecutive errors in x and y, along with UAV altitude values fed into the network. Training is conducted over 150 epochs on a Quadro P5000 GPU. Approximately 2.9 million parameters make up the network, crucial for collecting trainable features and predicting UAV velocities.

The architecture utilizes LSTM-based encoding and decoding to learn temporal data from 32 consecutive error values, leading to the desired outcomes. To determine the optimal length of the stacked values, experiments were conducted with 8, 16, 32, and 64 stack values. Results showed that temporal details were insufficient for training the model with 8 and 16 stacked frames. Nonetheless, the highest level of identification accuracy was attained with 32 frames. Although 64 frames performed similarly in terms of relative accuracy, handling larger stacks was necessary (Fig 4). For the model, a stack of 32 frames was selected as a result.

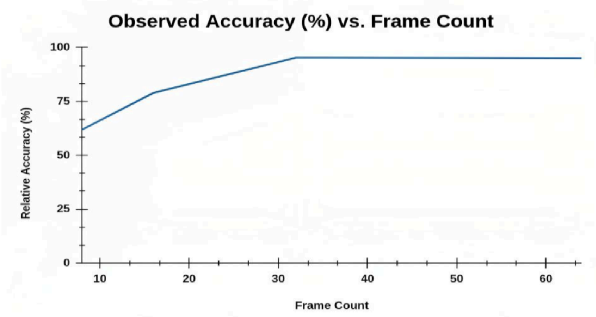

Fig. 4: The impact of input size on the performance of the proposed algorithm

B. Real-Time Testing

The method is assessed in real-world and simulation contexts. Using ROS, an open-source robotics middleware that offers a variety of software frameworks for emulating robot hardware abstractions, the algorithm is tested in simulation in a customised environment. In this arrangement, Gazebo acts as the 3D simulator. In the simulation, there is an ArUco marker placed atop a ground vehicle that serves as the tracking target, and an Iris UAV with a gimbal-stabilized camera positioned underneath. Figure 5 shows the environment used for the simulation.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 09,2024 at 07:00:04 UTC from IEEE Xplore. Restrictions apply.

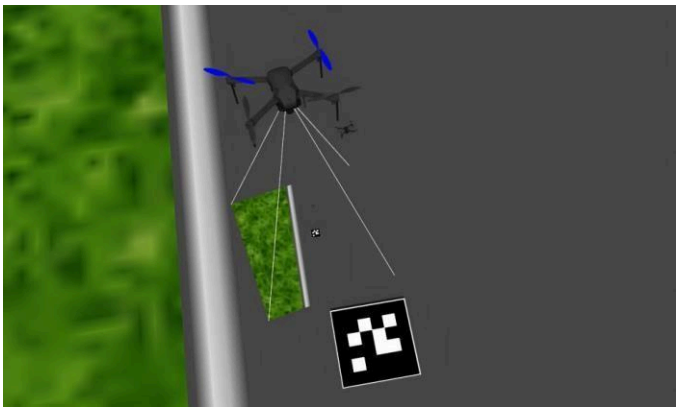

Fig. 5: ArUco marking in a frame captured by a drone in the simulation environment.

For real-world testing, depicted in Figure 6, we utilized a Tarot 650 UAV, a Pixhawk Cube flight controller, and a Jetson Nano 2.0 as the onboard computer. A Git2P camera for tracking and detection was also a part of the system; it was stabilized with a Tarot TL3T05 gimbal. The camera's frames are sent to the onboard computer (OBC) for ArUco marker detection when the program is activated. The deep learning model receives the errors and UAV height upon detection and uses those data to estimate velocities to operate the UAV. The UAV is then able to maneuver and follow the ArUco target thanks to the transmission of these output velocities as MAVLink messages to the Pixhawk flight controller.

Fig. 6: Real-life tracking of ArUco Marker using Tarot-650 UAV

C. FPGA implementation

The power consumed by the original Python/TensorFlow model executed on an Intel i9 processor is calculated using the Intel pcm-power utility to assess the efficiency of the presented system in comparison to the reference Python model. The Python program took 41 ms to be executed along with a power efficiency of 0.024 GFLOPS/W. Regarding the suggested system that employs hardware acceleration, the Xilinx Power Estimator (XPE) has indicated that the power usage on the chip when running at 200 MHZ is 12.5 watts. Based on the power consumption the power efficiency of the hardware-optimized implementation of the architecture was approximately 180 times higher energy efficient than the reference Python model with a power efficiency of 4.3 GFLOPS/W.

The resources used to implement the optimized model on the Xilinx Alveo U200 FPGA board, as shown by the Vitis HLS Tool, are presented in the table below.

Table 1: Estimated Resource utilization on Xilinx Alveo U200 FPGA

Logic Utilization (Qty)	200MHz
DSP48E	80% (5,536)
Flip Flops	34% (832,166)
Slice LUTs	42% (509,078)

V. CONCLUSION

By merging computer vision for object detection with an LSTM-based deep learning neural network for autonomous tracking, the research presents a novel method for visual servoing. The suggested method creates UAV control signals by encrypting error data that is obtained from calculating the separation between the frame center and the target ArUco marker's pixels. To train the time series model, a custom dataset was made using the Gazebo Simulator and ROS. The algorithm was validated in real-world and simulation settings. After attaining favorable outcomes, the system was refined for hardware acceleration using a top-tier Xilinx Alveo U200 FPGA.

To implement the deep learning model on the FPGA, optimized C++ functions were developed for TensorFlow modules for LSTM cells, leveraging open-source code provided by researchers [12]. Additional optimizations were incorporated into the methodology. The optimized Python program was found to be 180 times more energy-efficient in terms of GFLOPS/W compared to the original program when executed on a high-end system.

In terms of the research's future outlook, we strive to

- Implementing the program on a lighter FPGA i.e. the Xilinx Zynq 7000 SoC to replace the Jetson Nano onboard computer with higher power efficiency i.e., essential for UAV.
- Using an RL-based model to learn and estimate the control cues for target tracking with higher accuracy, efficiency, and reduced time complexity.
