SHAHBAD DAULATPUR, MAIN BAWANA ROAD
DELHI 110042

PREFACE

This is the **One Hundred Forty Eight** Issue of Current Awareness Bulletin started by Delhi Technological University, Central Library. The aim of the bulletin is to compile, preserve and disseminate information published by the faculty, students and alumni for mutual benefits. The bulletin also aims to propagate the intellectual contribution of Delhi Technological University (DTU) as a whole to the academia.

The bulletin contains information resources available in the internet in the form of articles, reports, presentations published in international journals, websites, etc. by the faculty and students of DTU. The publications of faculty and student which are not covered in this bulletin may be because of the reason that the full text either was not accessible or could not be searched by the search engine used by the library for this purpose.

The learned faculty and students are requested to provide their uncovered publications to the library either through email or in CD, etc. to make the bulletin more comprehensive.

This issue contains the information published during **April, 2025**. The arrangement of the contents is alphabetical. The full text of the article which is either subscribed by the university or available in the web is provided in this bulletin.

Central Library

CONTENTS

1. A Review on Feature Selection Techniques for Anxiety Classification from Physiological Signals, ***6.Shikha Shikha, 3.Divyashikha Sethia, 3.S. Indu,*** CSE,SE, ECE, DTU

2. A relational disaster database to document and resolve multihazard interactions, Maximillian Van Wyk de Vries, Lorenzo Nava, Ye Chen, Lisa Augustina, Louie Bell1, Joshua Nicholas, Ben Clarke, Reka Ungar, Arthur Hill, ***6.Kamini Sharma***, Julie Morin and Ekbal Hussain, Civil, DTU

3. A Study on the Viscosity of Viscoelastic Magnetic Abrasive Gel under Different Volumetric Proportions, ***3.Krovvidi Srinivas***, Mechanical Engg., DTU

4. Advancing Solar Energy through Artificial Intelligence: A Focus on Optimization and Forecasting, ***6.Nikhil Kushwaha, 3.Vinod Kumar Yadav, 3.Radheshyam Saha***, Electrical Engg., DTU

5. An Interplay Between Hypothalamic Microstructure, Systemic Metabolism and Gut Microbiome Composition in Male Rats at Hyperacute Timepoint Post TBI, Palkin Arora, ***6. Megha Kumari***, Kavita Singh, M. Memita Devi, Poonam Rana, Rajat Sandhir and Richa Trivedi, Biotech, DTU

6. AI-Driven Mental Healthcare 5.0: A Survey of Opportunities and Challenges in Leveraging Large Language Models and Generative AI, Akshi Kumar, ***8.1 Karan Gupta, 8.1 Kartik Verma, and 3.Sanjay Kumar***, CSE, DTU

7. Analysis of a Digitizer Circuit with T-Network for Low Resistance Measurement, Shiraz Sohail, ***7.1 Gopal Singh***, Tarikul Islam, Control and instrumentation, DTU

8. Analyzing Digital Image Anti-Forensics Techniques and Countermeasures, Saurabh Agarwal, ***3.Rajeev Kumar***, Abha Devi, Ki-Hyun Jung, CSE, DTU

9. Anomaly Detection for Sensor Manipulation in Matter Enabled-IoT Devices with Faulty Data Injection, ***7. Jahnvi Patel, 3.Kapil Sharma,*** IT DTU

10. Assessment of shear bond strength of triplets using different joint thicknesses and mortar types***, 3.Shilpa PAL , 7.1 Anshoo YADAV,*** & ***6. Khyati SAGGU***, Civil, DTU

11. A wideband dual polarized in-band full duplex antenna with higher order modes suppression, ***7.1 Sandeep Rana***,***8.Amit Kumar*** and Akhilesh Mohan, ECE, DTU

12. Advances in Negative Capacitance FinFET Technology: Insights into Design Innovations and Performance Enhancements, ***7.Shubhda, 3.Rishu Chaujar***, Applied Physics, DTU

13. A Novel n+ Pocket Doped L-Shaped Channel TFET for Biosensing Applications, ***8. Danishk Barwa,8. Dhruv Khanna, 8.Harshit Parihar***, & ***3.Sumit Kale***, ECE, DTU

14. Advanced Chest X-Ray Analysis via Transformer-Based Image Descriptors and Cross-Model Attention Mechanism***, 6. Lakshita Agarwal, 3.Bindu Verma***, IT DTU

15. Aggregation of Distributed Energy Resources for Optimal Operationin Local Energy Communities With Grid Constraints,***6. ShubhamGupta*** ,Vinod Kumar Yadav and ***3.MadhusudanSingh***, Electrical Engg., DTU

16. Achieving the positivity of the secret key in a BB84 like quantum key distribution protocol, ***6.Rashi Jain*** and ***3.Satyabrata Adhikar***, Applied Mathematics, DTU

17. Alzheimer's Disease Detection Using Bidirectional Empirical Mode Decomposition, Neha Garg, Amit Garg, ***3.Mahipal Singh Choudhry***, ECE, DTU

18. Bernstein type semi-exponential operators***, 6. Kanita*** and ***3.Naokant Deo***, Applied Maths, DTU

19. Building Scalable and Quantum Attack Resistant Authenticated Message Delivery System for Internet of Vehicles With Blockchain Consensus Mechanism***, 3. Rahul Singh, 3.Laxminarayan Das***, Dharminder Chaudhary, Applied Mathematics, DTU

20. Carboxymethyl Guar Gum: Bridging the Gap Between Biopolymers and Advanced Functional Materials, Vratika Verma, ***6.1 Jagram Meena***, Teena Saini, Sakshi Saini & Rajdeep Malik, Applied Chemistry, DTU

21. Conventional and Intelligent Control Schemes for Handling A Helicopter's Pitch Axis, ***3.Abhishek Chaudhary***, Electrical Engg., DTU

22. Comparative analysis of in silico tools for Drug Side effect prediction, ***6.Harshita Thakur, 3.Asmita Das***, Biotechnology, DTU

23. Coordination Frameworks for IoT-Driven Swarm Robotics Communication, Ayush Kumar Agrawal, Jayendra Kumar, ***3. Avanish Kumar***, Anumeha, Arvind R. Yadav, ECE, DTU

24. Development of intelligent hybrid controller for torque ripple minimization in electric drive system with adaptive flux estimator: An experimental case study, Surya Kant***, 3.Mini Sreejeth, 3.Madhusudan Singh***, Ambrish Devanshu, Majed A. Alotaibi, Hasmat Malik, Fausto Pedro García Márquez, Electrical Engg., DTU

25. Does ESG impact corporate performance in environmentally sensitive and non-sensitive industries? A dynamic panel approach, ***6.Prachi Jain*** and ***3.Priya Malhotra***, USME, DTU

26. Diverse Machine Learning Approaches for Early Prediction of Heart Attack, ***3.Meena Rawat***, Dhruv Shakti Singh and Rahul Boadh, Applied Science, DTU

27. Decaying vacuum energy, matter creation and cosmic acceleration, ***6 Lokesh Chander and 3.C P Singh***, Applied Mathematics, DTU

28. Design and Analysis of Substrate Integrated Folded Waveguide and Filter, Sudarshan Kumar and ***3.AsokDe***, ECE, DTU

29. Diffractive optical dermal sensor for non invasive arterial pulse wave monitoring, ***3.1. Mayank Pandey***, Sang-Woo Seo, Teaching Assistant, DTU

30. Donepezil Improves PSD95 Expression, Mitigates Neuroinflammation via PI3K/Akt/NF- κB and Mitochondrial Dysfunction in a Rodent Model of Subarachnoid Haemorrhage, Ahmed Shaney Rehman,,Ammar Tasleem, Nemat Ali, Rehan Khan, Mohd. Salman, ***3.Pravir Kumar*** and Suhel Parvez, Biotechnology, DTU

31. Enhanced Security In Matter-Enabled Iot Networks Through Anomaly Detection***, 6. Manjit Kumar***, ***3.Kapil Sharma***, IT, DTU

32. Evaluating the intensity of Typhoons over the West Pacific basin, ***6. Monu Yadav*** and ***3. Laxminarayan Das,*** Applied Mathematics, DTU

33. Enhancing the thermoelectric performance of Janus MoSSe monolayer via pressure, Anisha, Ramesh Kumar, ***3.Mukhtiyar Singh***, Sunita Srivastava, Tankeshwar Kumar, Applied Physics, DTU

34. Energy Efficient 8T SRAM Cell for Enhancing Read/Write Assist Performances with Stability, ***3.Ram Murti Rawat, 3.Vinod Kumar,*** Computer Science, DTU

35. Effect of Alfvén wave dispersion on localization and current sheet formation in solar wind near reconnection region***, 6.Ritu, 6.Jyoti, 3.Suresh C Sharma*** and R P Sharma, Applied Physics, DTU

36. Enhancing ground stability with quarry dust columns: A comparative study of ordinary and encased configurations***, 6.1 Srijan Srijan***, Civil, DTU

37. Exploring multi-material structures: An overview of arc additive Manufacturing, ***6.Dhruv Kumar, 3.Vipin and 3.Reeta Wattal***, Mechanical, DTU

38. Evaluating the intensity of Typhoons overtheWestPacificbasin, ***6. MonuYadav and 3.LaxminarayanDas***, Applied Maths, DTU

39. Exploring the dermal safety of green-synthesized Ag–TiO2 nanocomposites for topical applications, Archana Rana, Shweta Parashar, Diksha Singh, Kavita Singh, Debabrata Chanda, Anirban Pal, Ritu Srivastava and ***3.Shailesh Narain Sharma,*** Applied Physics, DTU

40. Exploring the psychometric properties of the adult hope scale in an Indian university student sample***, 6.Suhans Bansal***, Naval Garg,and Jagvinder Singh, USME, DTU

41. GRU Based Autoencoder with Maximum Overlap Discrete Wavelet Transfrmers for brain tumor detection***, 6. Bhawana Sachdeva, 3.Jeebananda Panda***, ECE, DTU

42. GMM-based Imbalanced Fractional Whale Particle Filter for Multiple Object Tracking in Surveillance Videos, ***3.Avinash Ratre***, ECE

43. Integrated wearable PPG: a multi-vital sign monitoring based on group sparse mode decomposition framework in remote health care using PPG signal, Pankaj · Pratibha Maan,· ***3.Manjeet Kumar***· Ashish Kumar,· Rama Komaragiri, ECE,DTU

44. Hybrid Anomaly Detection Framework for Matter-Enabled IoT Devices, ***6.Vaibhav Krishan, 8. Shivam Dhar, 3.Kapil Sharma***, IT, DTU

45. iHDoc: Secure NFC Mobile-based Digital Document Signatures Prototype ***7.Himanshu Sharma, 3.Divyashikha Sethia***, Computer Science, DTU

46. Incurred Changes in Water and Fat-Soluble Vitamin Profile of Alternative Ingredient Spirodela Polyrhiza Based Partial Fishmeal Substituted Aquafeed: Effect of Long Duration Variable Temperature Storage, Parul Puri1, Neha Tiwari, Vaibhav Puri, ***3.Ram Singh***, Jai Gopal Sharma, Rina Chakrabarti , Applied Chemistry, DTU

47. Linear and Nonlinear Photoluminescence in Ho3+, Yb3+ Doped CaBi2Nb2O9 Phosphor for Photonic Application***, 6.Sheetal Kumari, 6.Pooja Rohilla***, Anu, Srinibas Barik, Bhanupriya Yadav, Kaushal Kumar2, Runit Isaac***, 3. A.S.Rao***, Aman Prasad, Applied Physics, DTU

48. Literature review on SRAM cells under Stability, Energy, and Power Constraints, ***3.Ram Murti Rawat, 3.Vinod Kumar***, Computer Science, DTU

49. Longitudinal analysis of Covid-19 vaccine-related tweets in india: linking sentiment fluctuations with topic modeling***, 3.Seba Susan, 6.Anmol Bansal, 8.1Arjun Choudhry*** and ***8.1 Anubhav Sharma***, IT, DTU

50. Latch and Flip-Flop Design Using Memristors and Transmission Gates with Timer Counter Implementation, ***7.Aditya Rayer, 3.Mavulluru Ganesh and 3.Lavi Tanwar***, ECE, DTU

51. MXene coated concave shaped microchannel PCF SPR biosensor for the detection of HIV and sickle cell anaemia, ***7.Preethi Krishnan, 6.Akash Khamaru and 3.Ajeet Kumar***, Applied Physics, DTU

52. Modified Sigma-Pi neural network for dynamical system identification, ***6.Kartik Saini, 3.Narendra Kumar*** and ***3.Rajesh Kumar***, Electrical, DTU

53. Navigating the green combustion landscape: Optimizing emissions and performance in CI engines fueled by biogas and nanoparticle- doped biodiesel, S. LALHRIATPUIA, H. LALHMINGSANGA, ***6.Gulam MUSTAFA, 3.Neeraj BUDHRAJA*** and Kiran PAL, Mechanical Engg., DTU

54. Numerical Simulation on Sensitivity Modulation in Nanowire MOSFEB Detector for Biomedical Applications Amit Dasa, Anjana Bhardwaj, Kaushik Das, Shivani Yadavc***, 6.Aapurva Kaul***, Preeti Goyal, Swati Sharma, ***3.Sonam Rewari***, Binod Kumar Kanaujia & R S Gupta, ECE, DTU

55. NoCiPUF: NoC-Based Intrinsic PUF for MPSoC Authentication, ***8.1 Deepank Grover,*** Tarun Sharma, Sneha Agarwal, , Sidhartha Sankar Rout , Anushka, Madhur Kumar and Sujay Deb, ECE, DTU

56. Performance study of a retrofitted electric two-wheeler using GT-suite, ***8.1 Alpha Omar JALLOW, 8.Alphaus NKANDU , 8.Towett SAMUEL,3.Ashish Rajeshwar KULKARNI*** and ***3.Amit Pal,*** Electrical, Mechanical, DTU

57. Production of Phytase by Penicillium oxalicum in Solid State Fermentation Exhibiting Hydrolysis of Phytates and Haloperoxidase Activity, ***6.Priya,*** Bijender Singh, Ravi Kumar Goswami***, 3.Jai Gopal Sharma*** and Bhoopander Giri, Biotechnology, DTU

58. Predicting Financial Distress Using Machine Learning Techniques ***3.Pallavi Sethi, 3.Archana Singh*** and ***3.Vikas Gupta,*** USME, DSM, DTU

59. Photocatalytic degradation of crystal violet dye using phytofabricated zinc oxide nanoparticles from anthocyanin extract, ***6.Sarla Yadav, 6.Pooja Singh, 6.Gunjan Varshney, 3.Saurabh, 3.Poonam Singh, 3.Raminder Kaur***, Applied Chemistry, DTU

60. P4.0B-FAHP: prioritizing industry 4.0 barriers using fuzzy AHP—case of an Indian construction company, ***6. Ankur Tayal, 3.Saurabh Agrawal*** and ***3.Rajan Yadav***, DSM, DTU

61. ParametricAnalysisofOrganicLEDandPhoto-DiodeBased Sensor for Heart Rate Detection***, 6. SugandhaYadav, 6.PoornimaMittal***,and ShubhamNegi, ECE, DTU

62. Pointing error influence on the performance of dual-hop radio frequency/wireless optical communication system over Nakagami-m/ Fisher-Snedecor turbulence channels, ***6.Rekha Rani,*** M. Lakshmanan ***3.N. Jayanthi and 3.Anup Kumar Mandpura*** ECE, EE, DTU

63. Proposal and evaluation of a novel solar thermal driven cooling-power cogeneration system, Abdul Khaliq, ***3.Rajesh Kumar***, Tawfiq Al-Mughanam amd Khaled Zeid, Mechanical, DTU

64. Renewable Energy Systems: Engineering Solutions for a Sustainable World, ***3.Dr. Rajesh Gupta***, Mechanical, DTU

65. RankingInfluentialNodesinSocialNetworksBasedonthe Game of Thieves Algorithm, ***3.MinniJain, 8.1AdityaGupta, 8.1 AaryanArora*** and ***8.AayushPatel***, Computer Engg., DTU

66. Revocable and Privacy-Preserving CP-ABE Scheme for Secure mHealth Data Access in Blockchain, ***6.Anita Thakur***, ***6.Virender Ranga & 3.RituAgarwal,*** IT, DTU

67. Rice straw as the potential raw material for biogas production at variable temperature and feed ratio, Shubham Kumar, ***8.Sawan KAPOOR*** and ***6..Neeraj BUDHRAJA,*** Mechanical, DTU

68. SobelMNet: A Lightweight CNN based Approach for Median Filtering Detection in compressed images, ***3.Anukriti Kaushal, 3.Rajeev Kumar 3.Sanjay Kumar***, CSE

69. Substantial enhancement of the electroactive phase and dielectric properties at low loading levels of SnO 2 /MXene nanocomposite as a novel nanofiller in the PVDF matrix, ***6.Gagan Sharma, 3.Deshraj Meena***, Applied Physics, DTU

70. Stuttering Detection Using LSTM and LSTM Attention based Convolutional Neural Network, ***8.Monalisa Maity, 8.Ishita Gupta and 3.Dinesh Kumar Vishwakarma***, Applied Maths and IT, DTU

71. Space Physics of the Universe and the Evolution of π Space Quantum, ***8.1 Nishant Sahdev***, Chinmoy Bhattacharya, Biotechnology, DTU

72. Sensitivity Analysis of Dielectric Modulated Dual Gate Gallium Nitride Junctionless Accumulation Mode Nanowire FET Based Biosensor, ***6.Anupama, 3.Sonam Rewari and 3.Neeta Pandey,*** ECE, DTU

73. Stabilization and Performance Analysis of Double Link-Rotary Inverted Pendulum using LQR-I Controller***, 6.Anjali Rai, 6.Bharat Bhushan*** and ***6.Bhavnesh Jaint***, Electrical Engg., DTU

74. SS-EMERGE - self-supervised enhancement for multidimension emotion recognition using GNNs for EEG, ***6.Chirag Ahuja*** & ***3.Divyashikha Sethia,*** Computer Science, Software science, DTU

75. SobelMNet: A Lightweight CNN based Approach for Median Filtering Detection in compressed images, ***3.Anukriti Kaushal, 3.Rajeev Kumar*** and ***6.Sanjay Kumar***, Computer Science, DTU

76. Silicon slab waveguide based XOR and XNORall optical logic gates, ***6.Yash Yadav*** and ***3.Yogita Kalra***, Applied Physics, DTU

77. SDHO-KGNN:AnEffectiveKnowledge-EnhancedOptimal Graph NeuralNetwork Approach for Fraudulent Call Detection, ***6.PoojaMithoo, 3.ManojKumar,*** Computer Science, DTU

78. Temperature-dependent coupling characteristics in a silicon photonic crystal waveguide coupler, ***6.Varnam Sherawat , 3.Yogita Kalra, 3.Renuka Bokolia, 3.Ravindra Kumar Sinha***, Applied Physics, DTU

79. Tri-FusionNet: Enhancing Image Description Generation with Transformer-based Fusion Network and Dual Attention Mechanism, ***6.Lakshita Agarwal, 3.Bindu Verma***, IT, DTU

80. Towards Explainable AI: Multi-Modal Transformer for Video-based Image Description Generation, ***6.Lakshita Agarwal*** and ***3.Bindu Verma***, IT DTU

81. Towards Creating an Ecosystem of Paperless Society: Unveiling Issues and Challenges in Adoption of DigiLocker, ***3.Rajan Yadav***, DTU

82. Zn/Cu Layered Double HydroxideasaCatalyst for the Synthesis of Highly Functional ized Pyrazole Derivatives ***6. Charu Gupta, 6.Bhamini Pandey, 3.Poonam Singh and 3.Ram Singh***, Applied Chemistry, DTU

83. Urban greening for climate resilient and sustainable cities: grand challenges and opportunities, Prashant Kumar, Jeetendra Sahani , Karina Corada Perez, Ajit Ahlawat , Maria de Fatima Andrade, Maria Athanassiadou, Shi Jie Cao ,Lisa Collins , Sagnik Dey , , Silvana Di Sabatino , Christos H. Halios , Felicity Harris , Colin Horton , Luis Inostroza , Laurence Jones , Thomas Rodding Kjeldsen , Ben McCallan , Aonghus McNabola , ***3. Rajeev Kumar Mishra***

84. Vortex flow plasma reforming for hydrogen production from atomized water-methanol mixture and parameter optimization using RSM and ANN-GA***, 6.Neeraj Budhraja , 3.Amit Pa***l and ***3.R.S. Mishra***, Mechanical, DTU

Natural hazard-related disasters result in tens of thousands of deaths and billions in economic losses annually, with their frequency and intensity projected to increase due to climate change. These hazards, such as floods, landslides, and volcanic eruptions, often interact in ways that amplify their impacts, creating cascading or compounding risks. Despite these complexities, most hazard databases focus on single-hazard events, failing to capture critical interactions. To address this gap, we are developing a relational disaster database designed to systematically document and analyse multihazard interactions.

The database is designed to capture both individual hazard events and their interrelations, including causal, temporal, spatial, and amplifying interactions. It consists of two modules: a hazard characteristics and impacts module, which records essential details such as location, magnitude, and consequences, and a hazard linkages module, which documents relationships between hazards with attributes such as time lags, interaction intensity, and confidence levels. This scalable design is interoperable with existing databases like DesInventar and EM-DAT, enabling integration of existing data and automated processing and data analysis. We aim for flexibility, open access, and good metadata to ensure utility for both academic and operational (e.g,. disaster risk managers) end-users.

Complementing the database, we are developing tools for the automated generation of process-linked and coinciding multihazard groups, cumulative impact analysis, and the creation of associated visualizations. Initial database entries include case studies such as the 2023 Lhonak glacial lake outburst flood (GLOF), involving rainfall, landslides, and dam failure, and Hurricane Helene, highlighting meteorological, marine, and geological interactions. The database is currently at a prototype stage, and we welcome community input and collaboration to refine its design, expand its coverage, and ensure its long-term relevance and usability.

Figure: Concept diagram for the structure of the relational multihazard database.

***Abstract*—Anxiety disorders significantly impact individuals' quality of life and are traditionally assessed using subjective methods, which often lack accuracy. Recent advancements have enabled the use of physiological signals for anxiety classification, providing a more objective approach. However, the multidomain nature of these signals results in high-dimensional feature sets, necessitating effective feature selection. Therefore, this paper reviews various feature selection techniques—filter, wrapper, embedded, and hybrid—used in physiological-based anxiety classification, analyzing the advantages and limitations. It also highlights key challenges and suggests future research directions. Furthermore, this review introduces a proposed study utilizing a novel Corr-FGA hybrid feature selection algorithm to develop an efficient anxiety classification framework. The proposed framework achieves the highest accuracy of 88.93% using 8 features. This review aims to guide researchers in developing a robust, efficient anxiety classification model while providing insights that can help streamline feature selection and optimize machine learning model performance in real-world applications.**

***Index Terms*—Feature Selection, Physiological signals, Anxiety, Machine Learning**

I. Introduction

Anxiety disorders are among the most common mental health conditions, affecting millions worldwide. Characterized by excessive worry and fear, these disorders significantly impair daily functioning and quality of life [1]. Common subtypes include generalized anxiety disorder, social anxiety disorder, and panic disorder [1], each presenting with psychological and physiological symptoms like restlessness, muscle tension, and fatigue.

Traditional anxiety assessments rely on psychological tools such as questionnaires and clinical interviews, including the State-Trait Anxiety Inventory (STAI) and the Generalized Anxiety Disorder 7-item (GAD-7) scale [1]. These methods are inherently subjective, depending on self-reported symptoms, introducing biases and inconsistencies. Moreover, they often fail to capture physiological indicators crucial for understanding anxiety's severity.

To overcome these limitations, researchers have adopted physiological monitoring as a more objective method [2]. Physiological signals, which are regulated by the autonomic nervous system (ANS), offer valuable insights into changes associated with anxiety. Signals like electrocardiography (ECG), electrodermal activity (EDA), and electroencephalography (EEG) reflect autonomic processes, making them essential for detecting anxiety.

Furthermore, Machine Learning (ML) algorithms have gained popularity in analyzing physiological signals to automate anxiety detection. These techniques can identify complex, non-linear patterns in physiological data that traditional methods might overlook. Figure 1 shows an automated anxiety detection system that uses physiological signals and involves several technical phases, each contributing to the overall effectiveness of the system:

1) *Data Acquisition:* Researchers use wearable sensors or devices to gather physiological signals, including ECG, EEG, EDA, EMG, and RESP. These sensors allow for non-invasive, continuous monitoring, which is vital for capturing anxiety-related physiological changes in natural settings.
2) *Preprocessing:* The collected raw signals often contain noise and artifacts that must be removed to maintain data quality. Preprocessing techniques, such as filtering, normalization, and artifact removal, are applied to ensure the signals are clean and suitable for subsequent analysis.
3) *Feature Engineering:* Feature engineering involves transforming raw physiological signals into meaningful metrics. Features are extracted from different domains, such as time, frequency, and time-frequency, to capture the physiological processes comprehensively.
4) *Classification:* Researchers train machine learning models with the selected features to classify anxiety states. Algorithms like Random Forest (RF), Support Vector Machines (SVM), and Convolutional Neural Networks (CNN) are commonly employed to effectively identify anxiety-related patterns in physiological data, offering improved accuracy and robustness over traditional methods.
5) *Evaluation:* Finally, the model is evaluated to assess its effectiveness in classifying anxiety states, using metrics

such as accuracy, precision, recall, and F1-score.

Feature engineering plays a critical role in ML-based automated anxiety detection by converting raw physiological signals into meaningful features. These features are derived from domains like time and frequency to provide a comprehensive understanding of physiological changes. Nevertheless, high dimensionality can result in overfitting and increased computational complexity, making feature selection an essential step to improve performance and efficiency.

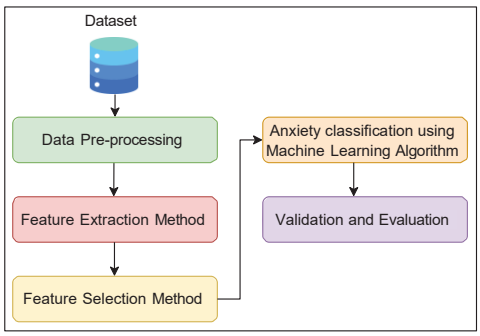

Fig. 1. Anxiety Classification Phases

Feature selection aims to identify the most informative features that contribute significantly to classification, improving model accuracy and reducing computational costs. By eliminating redundant and irrelevant features, the Feature Selection Algorithm (FSA) enhances generalizability and reduces overfitting. In recent years, numerous feature selection techniques, ranging from statistical methods like Pearson correlation and mutual information to advanced methods like wrapper-based and embedded approaches, have been explored to enhance the performance of anxiety classification models.

Despite the importance of feature selection in improving classification accuracy, to the best of our knowledge, no prior study has provided a comprehensive review of feature selection algorithms specifically for physiology-based anxiety classification. This review aims to bridge this gap by discussing the physiological signals commonly used in anxiety detection, the feature selection methods employed, and the challenges and future directions in this domain. Further, the study utilizes a spider-phobic anxiety dataset to extract ECG, EDA and RESP features. It proposes a novel Corr-FG hybrid FSA to remove irrelevant and redundant features for anxiety classification.

A. Search Process

This review focuses on advancements in feature selection techniques for anxiety classification using physiological signals, considering studies published between 2016 and 2024. Studies were gathered from several databases, including IEEE Explore, Elsevier, Springer, and Google Scholar. A total of 39 studies on physiology-based anxiety classification were identified, of which 20 specifically employed feature selection algorithms.

II. Feature Selection Techniques

Feature selection is one of the critical phases in anxiety classification methodology. It involves selecting the most informative subset of features that are crucial and valuable for classification algorithms. This process also effectively eliminates irrelevant data, reduces redundant information, and enhances learning accuracy.

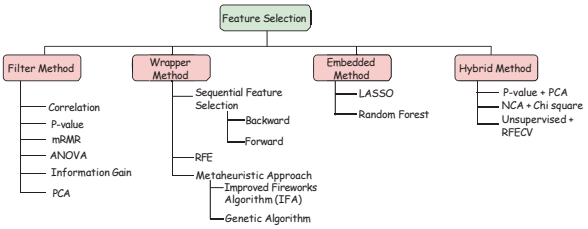

Fig. 2. Feature selection algorithms utilized in anxiety classification

This paper reviews the feature selection techniques applied in anxiety classification studies, categorizing them into three main types: filter, wrapper, and Embedded methods. Each technique serves a distinct purpose in selecting the most informative features. Table II summarizes various studies that utilized physiological signals and machine learning techniques for anxiety classification. Fig. 2 shows the list of distinct feature selection algorithms applied in anxiety classification. Further, Fig. 3 illustrates the distribution of major feature selection methods used across various physiological signals, such as EEG, ECG, EDA, EMG, and RESP, in the reviewed anxiety classification studies.

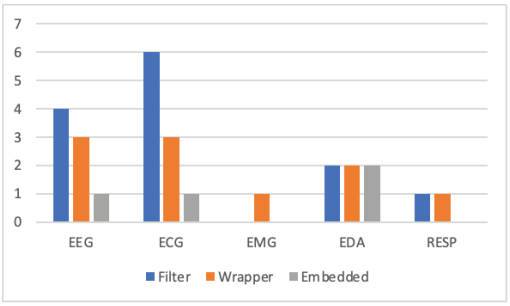

Fig. 3. The distribution of different major feature selection methods used across various physiological signals

A. Filter Methods

Filter methods assign a score to each feature and select the highest-ranked ones, operating independently of the classifier. Several studies have demonstrated the effectiveness of filter methods for anxiety classification using physiological signals. Li et al. [7] classified multiple anxiety levels using EEG, extracting 90 features and selecting 30 through correlation coefficients, resulting in 62.56% accuracy with an SVM classifier. Klados et al. [4] focused on EEG signals, extracting

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on April 08,2025 at 06:15:41 UTC from IEEE Xplore. Restrictions apply.

TABLE I
PHYSIOLOGICAL SIGNALS STRENGTH AND WEAKNESS

Physiological Signal	Definition	Strengths	Weaknesses
EEG (Electroencephalography)	Measures electrical activity in the brain	High temporal resolution; captures changes in neural activity related to anxiety	Susceptible to noise and artefacts; requires careful setup and preprocessing
EDA (Electrodermal Activity)	Measures skin conductance, reflecting sweat gland activity linked to arousal	Non-invasive; highly responsive to sympathetic nervous system activity	Sensitive to external factors like temperature and movement
ECG (Electrocardiography - HR + HRV)	Records Heart Rate (HR) and Heart Rate Variability (HRV), indicating ANS activity	Well-studied markers of anxiety; Provides information on both sympathetic and parasympathetic activity	Can be affected by factors unrelated to anxiety (e.g., physical activity)
EMG (Electromyography)	Measures muscle activity, is often used to assess tension	Useful in identifying muscle tension	Prone to movement artefacts and require calibration for accurate results
RESP (Respiration)	Measures breathing patterns, including rate and depth	Provides insights into respiratory changes associated with anxiety, such as hyperventilation	Influenced by various external and physiological factors, reducing specificity to anxiety

466 features and employing CfsSubsetEval to achieve 93.75% accuracy with a Naive Bayes classifier. Nath et al. [21] developed an anxiety detection system for older adults using wristband sensors, selecting 24 features with P-value FSA and achieving 92% accuracy with Random Forest. Tripathy et al. [15] used single-channel ECG to detect anxiety stages, selecting 187 out of 200 features with ANOVA, resulting in 79.17% accuracy with a Decision Tree.

Lastly, Daneshmand et al. [16] developed an anxiety recognition approach using EEG signals, applying mRMR to select 15 out of 28 features, which resulted in 100

B. Wrapper Methods

Wrapper methods use optimization or search algorithms in combination with machine learning to identify the most informative features, incorporating feature selection directly within the learning process. Ihmig et al. [9] used Sequential Feature Selection (SFS) to retain six out of 25 features extracted from ECG, RESP, and EDA, achieving 89.8% accuracy with Bagged Trees. Similarly, Arsalan et al. [10] employed forward selection to choose five out of ten features for anxiety detection using EEG, achieving 76.92% accuracy with an MLP classifier.

Shikha et al. [1] extracted 504 features from EEG and applied RFECV to select 318 features, resulting in 83.5% accuracy using SSAE. Muhammad et al. [13] extracted 60 features from EEG and applied RFE to reduce them to 18, achieving 94.9% accuracy with Random Forest. Wen et al. [5] employed backward feature selection to reduce 11 heart rate features to four, achieving 90.5% accuracy with an SVM classifier.

Mo et al. [18] introduced a metaheuristic approach using the Improved Fireworks Algorithm for feature selection across multiple modalities, including heart rate, respiration rate, behavioural, audio, text, and questionnaire features. This method effectively selected 19 features, achieving 97.61% accuracy with the Adaptive Boosting (ADB) classifier.

In another study, Shikha et al. [20] utilized a Genetic Algorithm for feature selection in anxiety classification. The authors investigated different sliding window sizes and achieved the highest accuracy of 98.61% using Gradient Boosting (GB) with a 1-second sliding window.

C. Embedded methods

Embedded methods incorporate feature selection within the model training process, enabling the learning algorithm to determine which features contribute the most to predictive accuracy. Salkevicius et al. [6] used an embedded feature selection approach for anxiety recognition in a virtual reality therapy system. They extracted 33 features from multimodal physiological signals and reduced the set to 10 key features using Random Forest (RF), achieving 86.3

Lee et al. [8] developed a driver anxiety detection system using EEG, PPG, EDA, and pupil size signals. They initially extracted 445 features and employed LASSO to reduce the feature set to 31, achieving 77.01% accuracy using a logistic regression classifier with frontal EEG channels.

D. Hybrid Methods

Hybrid methods integrate multiple feature selection strategies, combining filter, wrapper, or embedded approaches to leverage the strengths of each. This combination enhances feature selection performance by mitigating the limitations inherent in individual techniques. Zheng et al. [3] proposed a wearable system utilizing PPG and EEG signals. They initially extracted 32 features and applied Pearson Correlation and PCA, ultimately achieving 62.5% accuracy with KNN. Similarly, George et al. [12] used a combination of P-value and PCA to reduce an initial set of 23 features to 11, achieving 82.2% accuracy with an SVM classifier. Baygin et al. [19] combined Neighborhood Component Analysis (NCA) with the Chi-square test for feature selection, achieving 99.32% accuracy with a KNN classifier using ECG signals. In another study, Vaz et al. [14] employed an unsupervised Feature Selection Algorithm (FSA) and Recursive Feature Elimination with Cross-Validation (RFECV) to reduce 109 features from ECG, EDA, and EMG to 34, achieving 71.1% accuracy with a Logistic Regression classifier.

Rodr´ıguez-Arce et al. [2] worked with multimodal physiological signals in an academic setting, applying CfsSubsetEval,

CorrelationAttributeEval, and InfoGainAttributeEval to select 13 out of 21 features, which led to 95.56% accuracy with KNN.

III. CHALLENGES IN FEATURE SELECTION FOR ANXIETY CLASSIFICATION

Feature selection for anxiety classification using physiological signals involves numerous challenges, particularly due to the complexity of physiological data and the variability in individual responses. Some of the key challenges are as follows:

1) *Scalability Issues*: The high dimensionality of physiological data, such as multi-channel EEG or high-resolution HRV features, poses scalability challenges for feature selection, particularly for wrapper methods. These methods struggle to efficiently handle large datasets, which affects their utility for large-scale anxiety studies.
2) *Data Noise Sensitivity*: Physiological signals are inherently noisy due to factors such as movement artefacts, environmental influences, and individual variability. This noise complicates the feature selection process, making identifying consistent and reliable features for anxiety classification difficult. It is particularly problematic for anxiety detection, where subtle physiological changes are critical indicators.
3) *Generalizability*: Selected features may not always generalize well across diverse populations, especially when physiological signals vary significantly between individuals. Anxiety manifests differently among people due to various factors such as age, gender, and comorbidities, which complicates the selection of universally relevant

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on April 08,2025 at 06:15:41 UTC from IEEE Xplore. Restrictions apply.

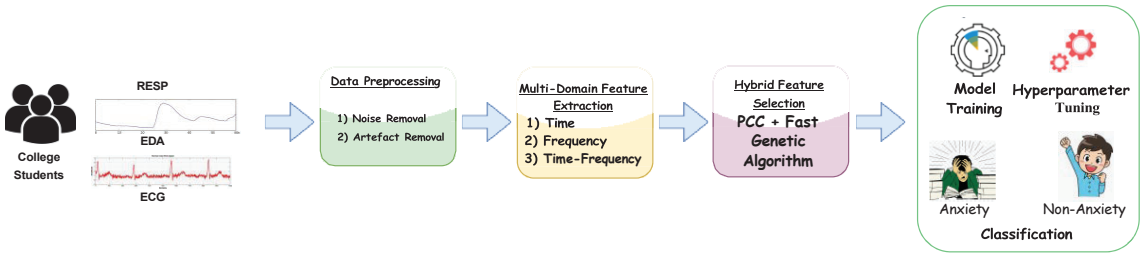

Fig. 4. Proposed anxiety classification framework using hybrid feature selection algorithm.

features.

4) *Capturing Feature Interactions*: Filter methods, while computationally efficient, cannot adequately capture intricate interactions between features, which may limit their effectiveness in anxiety classification. Physiological signals like HRV and EDA often exhibit complex relationships, and missing these interactions could lead to reduced model accuracy and reliability in detecting anxiety states.

IV. Future Directions and Solutions

Future research in physiology-based anxiety classification should address several key challenges and explore innovative directions to improve the robustness and reliability of anxiety detection models:

1) *Metaheuristic Feature Selection Algorithms:* Future research could explore the use of metaheuristic optimization techniques, such as Genetic Algorithms (GA), Particle Swarm Optimization (PSO), and Differential Evolution, to enhance feature selection. These algorithms can help navigate the complex feature space of physiological data to find optimal feature subsets while balancing accuracy and computational costs.
2) *Reinforcement Learning for Feature Selection:* Reinforcement Learning (RL) could be employed as a feature selection agent to select the most informative features in real-time adaptively. RL can improve the selection process by learning from the data and optimizing the feature subset based on classification performance, which would be especially useful in dynamic anxiety detection environments.
3) *Improving Generalizability Across Populations:* More research is needed to ensure that selected features generalize well across different populations. Various techniques, such as transfer learning and domain adaptation, could be explored to improve the model's ability to handle variability in physiological signals among diverse demographics, making the models more applicable in real-world settings.
4) *Multimodal Fusion for Robust Anxiety Detection:* Future research should improve multimodal data fusion techniques to leverage the complementary information provided by multiple physiological signals, such as EEG, EDA, and HRV. Advanced fusion methods, such as deep learning-based fusion or multi-view learning, could enhance model robustness and accuracy.
5) *Real-time Implementation and Computational Efficiency:* Developing adaptive and lightweight feature selection methods that operate in real-time is crucial for practical applications, particularly for wearable devices used in anxiety monitoring.
6) *Addressing Data Noise and Improving Signal Quality:* Future work should also focus on developing more effective preprocessing techniques to mitigate noise and artefacts in physiological signals. This could include using adaptive filtering methods or leveraging advanced signal processing techniques to improve the quality of features extracted from noisy data.

V. Proposed Architecture: Anxiety Classification based on ECG, EDA and RESP physiological signals and Machine Learning

Previous studies [2] have shown that hybrid Feature Selection Algorithms and metaheuristic algorithms [18] [20] often achieve the highest accuracies. Therefore, this review presents a framework for anxiety classification using a novel corr-FG hybrid FSA. The study utilizes a publicly available spider-phobic dataset [9], which includes physiological signals such as ECG, EDA, and RESP. Fig. 4 shows the proposed framework approach, which involves distinct phases:

1) *Data Preprocessing:* The study applies a Savitzky-Golay filter with a 40-point window and a 400 ms sigma to smooth the EDA signal and eliminate noise. For the respiration signal, the NeuroKit2 tool is utilized for cleaning and analysis.
2) *Feature Extraction:* The study extracts 31 ECG-derive Heart Rate Variability (HRV) features by identifying correct RR intervals, which represent the time between consecutive heartbeats. It also extracts 19 phasic and tonic EDA features and 11 RESP features.
3) *Feature Selection:* Feature selection is a crucial step in the anxiety classification methodology. The multidomain nature of physiological signals often results in high-dimensional feature sets. Therefore, this study proposes a hybrid feature selection algorithm. Initially it applies Correlation analysis to remove highly correlated features

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on April 08,2025 at 06:15:41 UTC from IEEE Xplore. Restrictions apply.

that do not contribute additional value. Subsequently, a Fast Genetic Algorithm (Fast GA) is utilized to further refine the feature selection by identifying the subset of features that effectively enhance classification performance. The Fast GA is optimized for quick convergence by using a reduced population size of 20 and 30 generations, which are selected based on preliminary experimentation to balance computational efficiency and accuracy.

4) *Anxiety Classification:* The selected features are input into machine learning models, including Random Forest (RF), Support Vector Machine (SVM), K Nearest Neighbour (KNN) and Decision Tree (DT). Additionally, *Grid_search* is utilized to improve the model performance further.

TABLE III
PERFORMANCE COMPARISON OF DISTINCT CLASSIFICATION ALGORITHM AFTER CORR-FG HYBRID FSA

Classifier	Accuracy (Before FSA)	F1-Score (Before FSA)	Accuracy (Corr-FG FSA)	F1-Score (Corr-FG FSA)
RF	83.53	81.48	88.93	87.01
SVM	70.18	71.85	79.55	78.68
KNN	75.78	78.35	75.37	75.36

Table III presents the performance of various classifiers using the selected features. The proposed corr-FG hybrid FSA identifies 8 out of 63 features, representing the most influential attributes for effective anxiety detection. In the classification algorithm, the RF classifier shows 5.4% improvement in accuracy, while SVM shows a 9.37% increase in accuracy after feature selection. Furthermore, KNN obtained a comparable accuracy of 75.37% using 8 features.

VI. CONCLUSION

This review highlights the significance of feature selection in physiological-based anxiety classification. Given physiological data's complexity and high dimensionality, selecting the most informative features is crucial to improving model accuracy and reducing computational load. Analyzing filter, wrapper, embedded, and hybrid approaches reveals their advantages and limitations in enhancing anxiety classification performance. Further, it proposes a novel Corr-FG hybrid FSA for anxiety classification. Future research should focus on developing adaptive and computationally efficient feature selection techniques, which can provide more robust solutions for anxiety detection. This work aims to guide researchers in advancing feature selection methodologies for more effective anxiety detection systems.

Viscoelastic medium; magnetic abrasive finishing; Nano finishing

ABSTRACT

In the present study, the Viscosity of the Viscoelastic Gel used in Magnetic Abrasive finishing is analysed based on the test conducted on the Compact Rheometer. Silicon-based Transformer oil is used as the base oil and Aluminium Stearate is used for increasing the abrasive holding capacity under very high magnetic field strength. The media prepared is commonly used for performing Nano-finishing of various metals' internal and external surfaces. The Viscosity of AP3 Grease, transformer oil and silicon oil is computed and compared using Rheometer, and the sample of viscoelastic Magnetic Abrasive media is prepared using these base oil. Six samples have been tested and the results have been analysed. The Media selected for the Viscoelastic magnetic abrasive finishing is tested after 30 days of preparation and compared its viscosity with the freshly prepared medium. The result highlighted the successful application of transformer oil and Silicon oil to prepare gel for the viscoelastic Magnetic Abrasive Finishing process.

1. Introduction

The importance of computational fluid flow has shaped the dynamics of the modern flow system and improved products and manufacturing quality. A recent example is the MAF and AFM process in which the machining operations occur due to the flow of Media inside the constrictive passage. The Media used in the Magnetic Abrasive flow Finishing is non-newtonian. The Media is a mixture of Abrasive, Gel and polymer, due to which viscosity plays a significant role in the machining operations. Many scholars have worked on the non-Newtonian fluid and contributed to the development and analysis of the non-Newtonian fluid in various aspects. Various research has been carried out for the flow governing peristaltic movement in porous walls, which acts as a reference for the non-newtonian fluid flow [1-6].

The viscoelastic Magnetic Abrasive finishing process is one of the leading solutions in the field of the nano finishing process. It consists of carbonyl particles along with abrasive and viscoelastic putty, allowing the viscoelastic putty to act along the line of the magnet. The carbonyl particles present in

* *Corresponding author.*
E-mail address: srinivaskrovvidi@dtu.ac.in

https://doi.org/10.37934/pjfd.1.1.4152

the viscoelastic putty get attracted toward the magnet. As a result, a magnetic brush is formed. The machining process occurs when this brush is rotated over the surface of the workpiece for effective machining.

A similar process may be applied when machining the internal surface of the hollow workpiece. Here the viscoelastic magnetic abrasive Media is allowed to reciprocate within the boundary of the workpiece, where the workpiece is placed co-axially along the cylindrical workpiece and the magnet is placed around it. The carbonyl particle in the media would be attracted towards the wall of the workpiece due to the magnetic field. Thus, effective machining occurs due to magnetic forces and the finishing process.

Many researchers modelled the viscoelastic Magnetic Abrasive Finishing process and studied the media's flow parameters. The researchers study the effect of Extrusion pressure, no of cycles, Abrasive mesh size, Media viscosity, abrasive, Type of Abrasive particles, Size of carbonyl particles, and Base oil for viscoelastic media and gel [7-11]. The concept of preparation of viscoelastic fluid is confined to the viscoelastic magnetic abrasive finishing and abrasive flow machining. The primary difference between the media of Abrasive Flow Machining and viscoelastic Magnetic abrasive finishing is that the media of AFM does not contain carbonyl particles, but the synthesis process remains the same [12-15].

2. Methodology

In this article, a brief discussion will be made about the linear Viscoelastic Models. Subsequently, a Viscoelastic Magnetic abrasive Medium preparation will be discussed. In total, 7 Viscoelastic Magnetic Abrasive Media have been prepared and their Viscosity has been tested using Modular Compact Rheometer (MCR 102). The graphical Results have shown the shear stress vs shear strain and shear stress vs viscosity and are also validated [16]. Based on this, a suitable Viscoelastic Magnetic Abrasive Medium has been proposed for the internal finishing of the Complex surface and the external surfaces. In the present research, the abrasive medium prepared is known as Viscoelastic Magnetic Abrasive Medium, specially prepared for performing both internal and external finishing of metallic specimens. The main problem found during the literature review is that the medium used for Magnetic abrasive finishing experiences sedimentation of the heavier particles [17,18].

In Magnetic Assisted finishing process, the Carbonyl Iron particle's density is higher than the Abrasives used. As the CIP particle settles down before and after exposure to the magnetic field, it becomes difficult to form the CIP chain under the Magnetic field. So, a Viscoelastic medium that addresses the sedimentation is prepared and experiments have been performed to find the viscosity before choosing a suitable medium. Materials with Viscoelastic properties exhibit both Viscous behaviour and Elastic behaviour. Most of the materials exhibit Viscoelasticity, both Natural and artificial. However, the dominance of Viscosity or Elasticity depends upon the individual material prepared and the operating conditions. All the Rheological materials will exhibit Viscoelastic properties. When a material is under Static loading, the Elastic behaviour dominates, whereas the Viscous behaviour dominates with Dynamic loading.

2.1 Viscosity Measurement

The Viscosity and Rheology measurement could be done using three different equipment pieces. Each piece of equipment has a specific purpose and would be used depending upon the type of loading. The types of equipment used for measuring Viscosity/Rheology are:

a) Rotational Viscometer: Used for Steady loading conditions. The probes used for this purpose are Cylindrical, Flat plates having Circular cross-sections and Conic sections. For measuring fluids with Very high viscosity, the flat plate Viscometer is usually preferred.
b) Oscillatory Rheometer (Viscometer): Used for finding the viscosity when the force Associated with it is Oscillatory or bending force.
c) Transient Condition Rheology tester: This equipment is the advanced version of the SteadyState Viscometer, in which the variation in the deformation of the specimen with time under impulsive loading would be measured.

In the present research work, Modular Compact Rheometer (MCR 102), a RotationalViscometer, is used to find the Viscosity of the Viscoelastic Magnetic Abrasive Finishing Medium, especially prepared.

The critical part associated with the Rheometer is as follows:

a) Measuring Head: Holds the rotating probe known as PP 50 measuring system.
b) MICR coupling: A part used for holding the rotating probe.
c) Flange ring: Holds the Temperature device holder.
d) Colour Display: Displays the temperature, position in mm, Normal force and status.
e) Soft keys: Used for initiating different operations of the instrument.
f) Adjustable feet: For making the platform plane.

Figure 1 shows the schematic diagram of the modular compact Rheometer and Figure 2 shows the experimental setup. Figure 2(i) shows the actual experimental setup, while Figures 2 (ii), Figure (iii) and Figure (iv) show the different types of measuring probes used for the measurement of viscosity. Plate-Plate filling and plate cone filling are used for the present work.

2.2 Viscoelastic Magnetic Abrasive Medium Preparation

In the present work, Sevensamples have been prepared, and their viscosity has been measured using MCR 102. Initially, the viscosity of the Rheological fluids used in preparing the samples was measured and based on the experimental results, the base fluid for preparing the ViscoelasticMagnetic abrasive finishing (VEMAF) Medium has been decided. Subsequently, adding the required ingredients has taken place, producing the required Viscoelasticmedium [19-21]. By adding the mixture of Carbonyl Iron Particle (CIP) of CS grade and the Silicon Carbide abrasive in predefined proportion with the Viscoelastic Medium, the requiredViscoelastic Magnetic abrasive Medium has been prepared.

Three types of Viscousfluids and AP3 grease have been considered for preparing the samples, and they are as follows:

a) Transformer Oil (white)
b) Transformer Oil (Red)
c) Silicone Oil
d) AP3 Grease

While performing the viscosity measurement experiment for the base fluids mentioned at 1 to 3 above, a Plate-Plate filling type probe was used and for the AP3 Grease Cone-Plate A filling-type probe has been used. The sample has been placed below the probe, which is initially compressed and then the probe starts rotating, which in turn induces shear stress and shear strain on the sample. The sample quantity depends upon the gap between the probe and the platform. The experimental results are shown below.

From the Graphs for Viscosity Vs Shear strain and Shear Stress vs ShearStrain for White Transformer oil, it may be noted that after initial disturbance, viscosity is almost constant and obtained an average value of 12.183 mPa-s and the Shear stress vs Shearstrain is maintaining a constant slope from point 11 in the table.

From the tabulated data and the Graphs for Viscosity Vs Shear strain and Shear Stress vs ShearStrain for Red Transformer oil, it may be noted that viscosity drops to a lower value for a strain rate of 1.2 after that, viscosity is almost constant and obtained an average value of 20.466mPa-s and the Shear stress vs Shear strain is maintaining a constant slope from the point 11 in the graph.

From the tabulated data for Silicone oil, it may be noted that the viscosity of the Silicone oil is almost constant within the experimental range and has a magnitude of 236.2 mPa-s. Also, the Shear Stress-Shear Strain curve is almost linear. Based on the results obtained above, Silicone oil and Red transformer oil have been chosen as the base Rheological fluids for making the Viscoelastic Magnetic Abrasive Medium.

Figure 3 shows the viscosity measurement results for the transformer oil red, Transformer oil White and silicone oil. The graphs were made based on tabulated data obtained from the modular compact Rheometer.

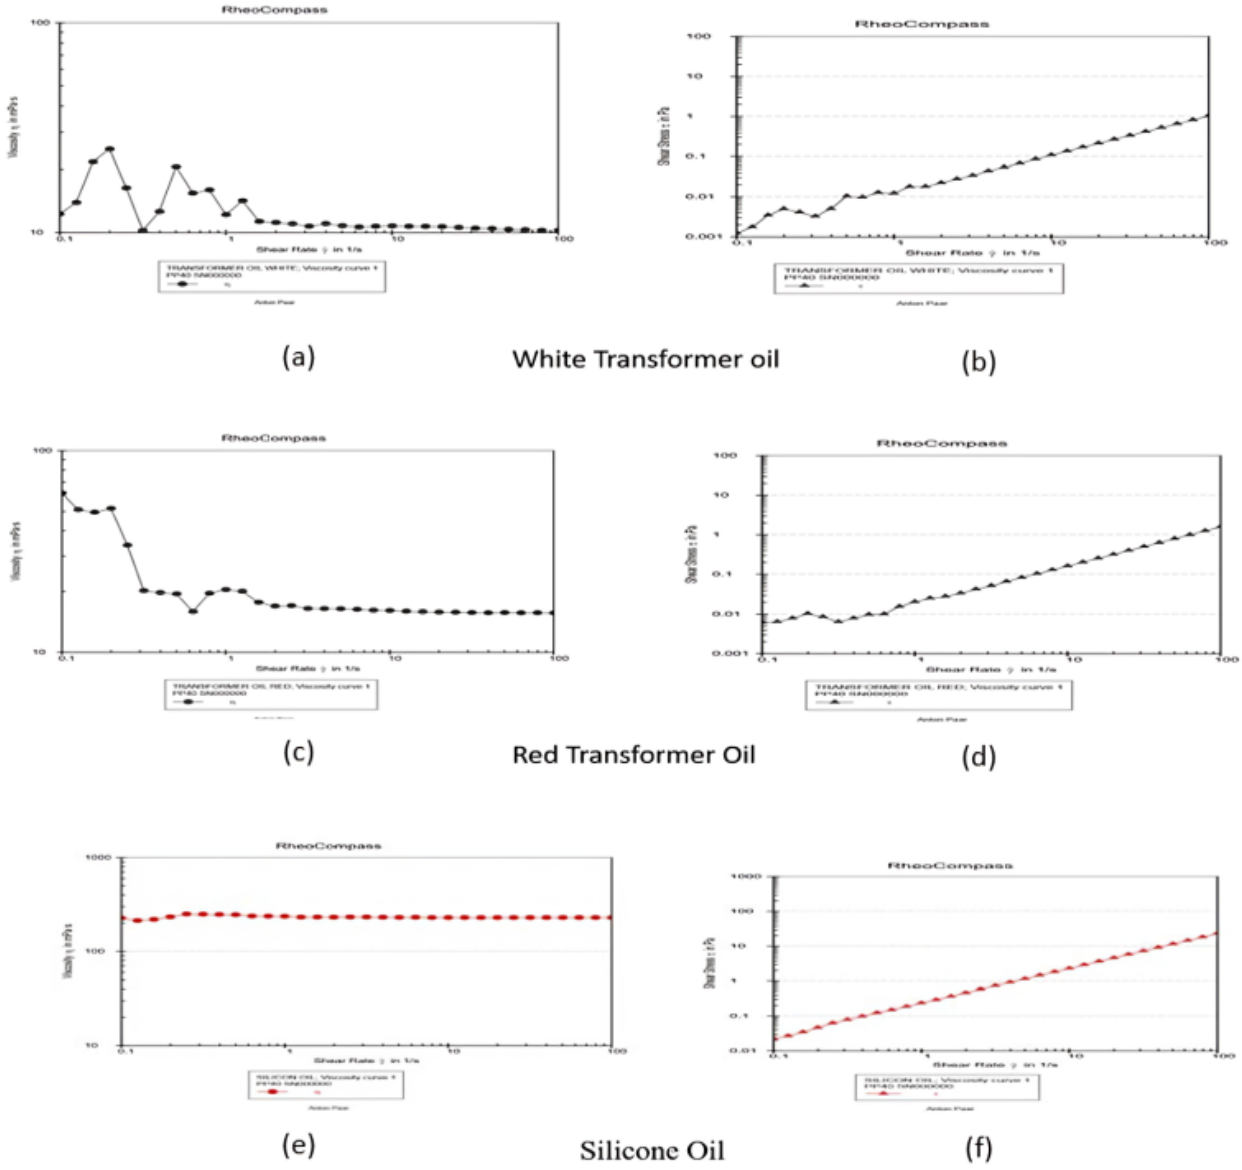

Fig. 3. Viscosity measurement for Transformer oil and the silicon oil (a) viscosity vs shear strain for white transformer oil (b) shear stress vs shear strain for white transformer oil (c) Viscosity VS shear strain for red transformer oil (d) Shear stress vs shear strain for red transformer oil (e) viscosity vs shear strain for silicon oil (f) Shear stress vs Shear strain for the silicone oil

2.3 Preparation of Silicone Oil-Based Vemaf Medium

The preparation has got the following steps.

2.3.1 Preparation of polymer

Mixing 1000 ml Silicone oil with 50 grams of Boric acid thoroughly and heating from room temperature up to 60° C makes the required polymer which would be white. Here, the cross-linking of Silicone oil's chained structure with Boric acid occurs. Figure 4(i) below shows a schematic representation of Cross-linking. Subsequently, 10 Lewis acid grams were added at 40° C of temperature, followed by adding ammonium Carbonate and heating up to boiling temperature along with Continuous stirring, bringing the final stage to the polymer, which is having pale yellow colour shown in Figure 4(ii) below. Cooling takes place in the open atmosphere. The prepared polymer will behave as a Viscous medium in the Viscoelastic Magnetic Abrasive Finishing Medium and has a marginal reduction in viscosity compared to the Silicon oil Figure 4(iv).

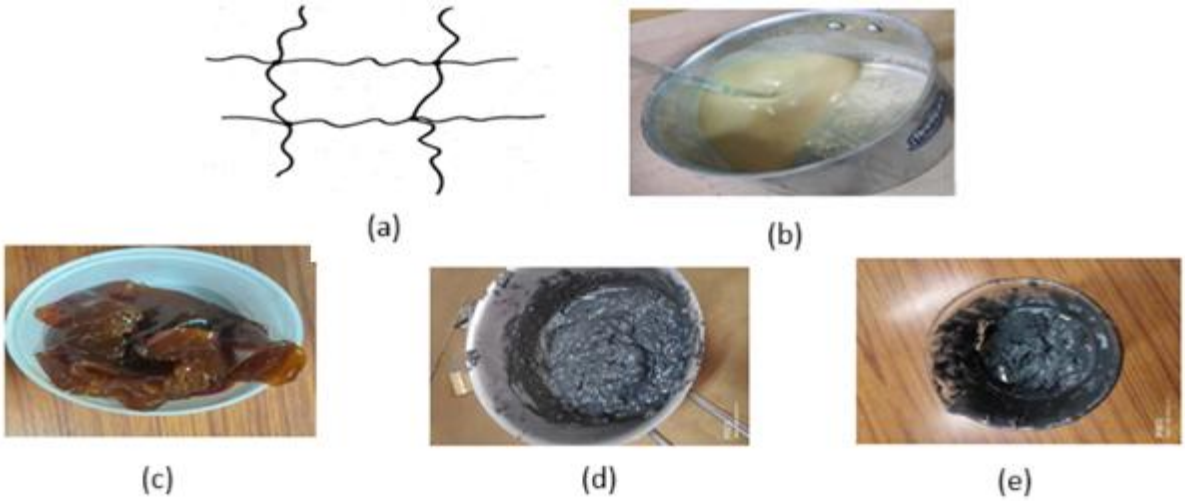

Fig. 4. (a) Cross-linking polymers (b) Prepared Polymer (c) gel (d) Silicone oil-based Magnetic Abrasive Media (e) Transformer oil-based viscoelastic magnetic abrasive based Media

2.3.2 Preparation of gel

The gel is prepared with the chemical reaction of the hydrocarbon oil and the aluminium stearate. 500 ml of the Hydrocarbon oil and 25 grams of Aluminium Stearate are mixed thoroughly and heated up to 120 degrees Celsius. The Product obtained is called the gel, having red colour and very high Viscosity [21-23].

2.3.3 Mixing of carbonyl iron particle and silicon carbide

Carbonyls Iron Particles (CIP) of CS grade and Silicon Carbide(SiC) of Abrasive Mesh Numbers 320, 400, 600 and 800 have prepared the mixture. The density of CIP is approximately 7.2 grams per cm3 and the Sic powder from the manufacturers' catalogue has a density of 2.6 grams per cm3. Carbonyl particles and Silicon Carbide have been taken in a ratio of 3:1 by weight. Separately, the mixture has been prepared for each abrasive Size. A ball mill has been used to mix CIP and the abrasive powder thoroughly.

2.3.4 Final mixing

Here, the polymer and the gel have been mixed in a ratio of 8:1 by weight Thoroughly by Gel mixing machine. Now the Polymer-Gel medium hence prepared, is mixed with CIP- Abrasive mixture in a ratio of 2:1 by weight and finally, the viscosity of the Viscoelastic Magnetic Abrasive medium has been found. This medium is used for the Internal finishing of the Spline shafts.

2.4 Preparation of Transformer Oil (Red)-Based Viscoelastic Magnetic Abrasive Medium

The following steps are followed in sequence for making the Viscoelastic Magnetic abrasive Medium.

a) 1000 ml Red transformer oil is heated till the moisture is removed. 500 ml Transformer oil is heated up to 50° C, and 50 grams of Sodium Stearate is added and thoroughly stirred until a thorough mixing occurs. This will make the medium thick compared to its initial condition.
b) Further heating up to around 150° C will saponify the mixture and it becomes further thick. The water content left is removed.
c) The remaining 500 ml transformer oil is heated up to 40O C, and Simultaneously 50 ml boric acid solution and 50 ml Sodium hydroxide solution are added and thoroughly stirred. This converts the transformer oil to highly viscous.
d) Viscous oil, both the saponified semisolid and the viscous transformer oil, were mixed thoroughly at 50° C and stirred for 60 minutes. An antioxidant solution of 1% concentration is added. This gives Viscoelastic medium.
e) Now the Carbonyl Iron Particle and SiC mixture in a 3:1 ratio by weight have been mixed Thoroughly in the ball mill.
f) Now the Viscoelastic medium and the CIP and SiC powder in 1:3 ratios by weight have been mixed and thorough stirring takes place by the Chemical stirrer. This makes the Viscoelastic Magnetic Abrasive Medium.

The Viscoelastic Magnetic Abrasive Medium prepared based on Transformer oil (Red colour) has a Viscosity of 2926.2 mPa-s (Milli Pascal-Second). This lies in the viscosity of semisolids. Also, Shear-thinning is observed as a decrease in Viscosity with Shear strain.

2.5 Preparation of Viscoelastic Magnetic Abrasive Medium Based On AP3 Grease

The Carbonyl Iron Particle and Silicone Carbide abrasive mixture have been added to the AP3 grease, and a semisolid is prepared. The viscosity of each sample is found.

2.5.1 AP3 grease-based viscoelastic magnetic abrasive medium lab sample 5

In this sample, 30 grams of AP3 Grease and 10 grams of CIP and SiC mixture is thoroughly Stirred, and the sample has been tested for viscosity using MCR 102. The viscosity obtained is 1640mPa-s. The results are given below. Graph.3.17 and Graph.3.18 show the relation between Viscosity Versus Shear strain and Shear stress versus Shear Strain.

2.5.2 AP3 grease-based viscoelastic magnetic abrasive medium lab sample 6

In this sample, 30 grams of AP3 grease and 15 grams of CIP- SiC mixture is thoroughly mixed and the sample has been tested for viscosity. The graphs show a relation between Viscosity Versus Shear strain and Shear stress versus Shear Strain.

2.5.3 AP3 grease-based viscoelastic magnetic abrasive medium lab sample 7

In this sample, 30 grams of AP3 grease and 20 grams of CIP- SiC mixture is thoroughly mixed, and the sample has been tested for viscosity.

2.5.4 AP3 grease-based viscoelastic magnetic abrasive medium lab Sample 8

In this sample, 30 grams of AP3 grease and 30 grams of CIP- SiC mixture is thoroughly mixed and the sample has been tested for viscosity.

3. Results and Discussion

All the prepared samples were tested under the Compact Rheometer and their Viscosity vs strain rate curves were obtained. Also, Graphs were plotted for the shear stress vs strain rate. Figure 5 shows the obtained graph for various samples. The Viscoelastic Magnetic Abrasive medium is 30 days old viscoelastic magnetic abrasive media, and the graph of viscosity vs strain rate for polymer and gel is also plotted in the following Figure (Figure 6). The results are shown in the graph.

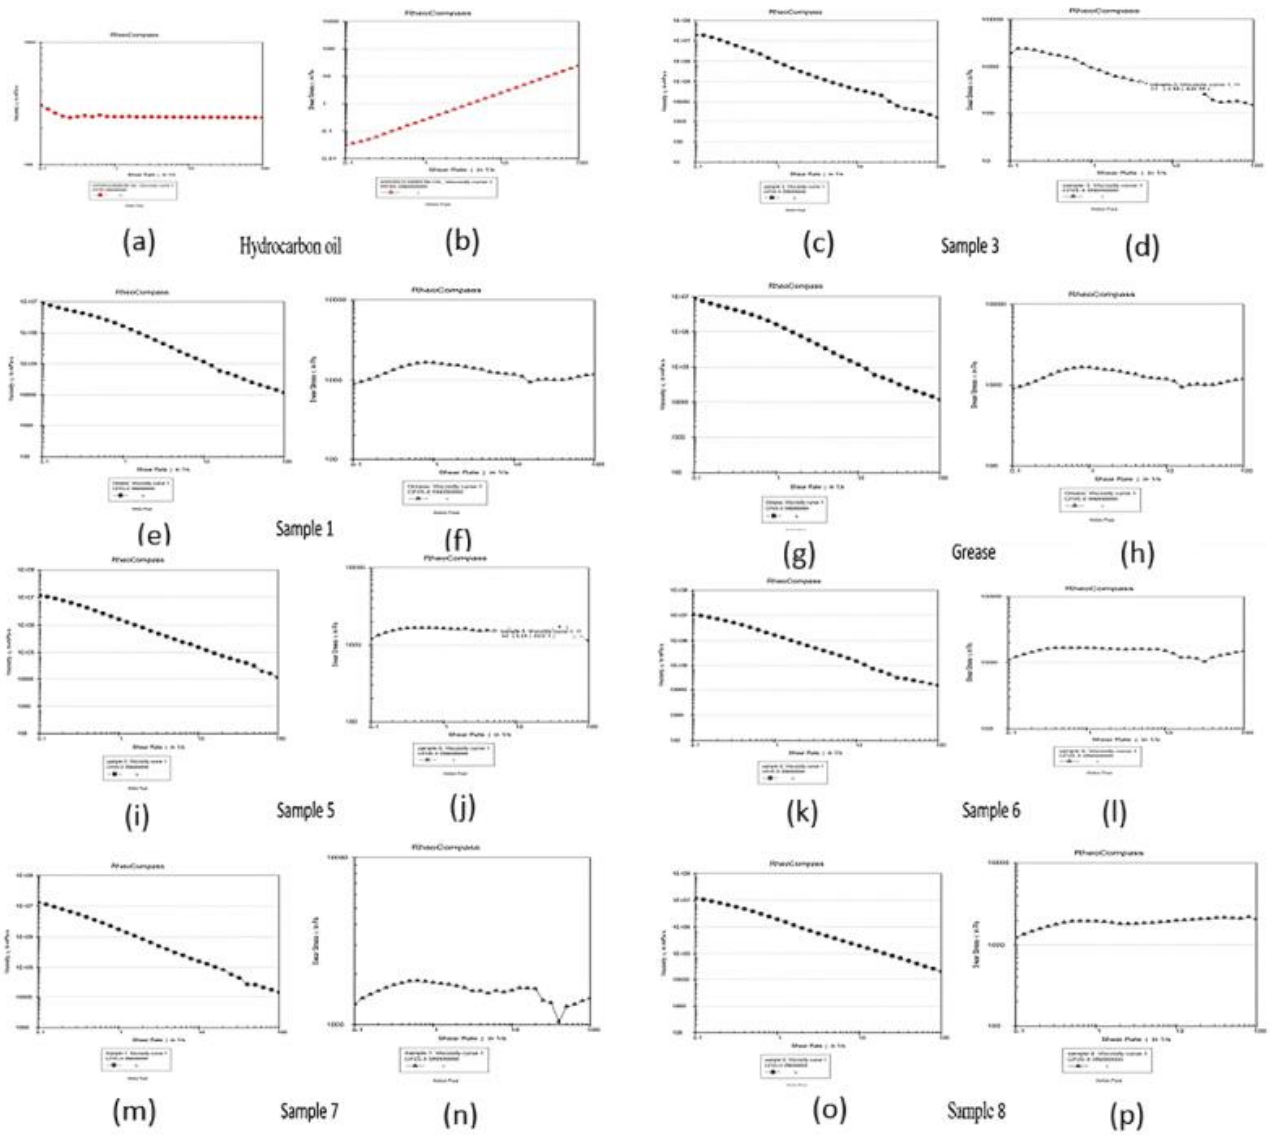

Fig. 5 Viscosity vs shear strain and shear stress vs shear strain graph for hydrocarbon oil, Sample 3, Sample 1, Grease, sample 5, Sample 6, sample 7 and sample 8. 4. Conclusions

In the present research, an attempt was made to prepare a gel for the VMAF process using different types of hydrocarbon oil as the base material. The researcher also computed the viscosity of transformer oil (Red and White), Grease, Hydrocarbon oil and silicon oil wittth the help of a Rheometer and predicted their application for the Viscoelastic Magnetic Abrasive Finishing Process. The researchers concluded the following points:

a) A total of six Viscoelastic Magnetic abrasive media have been prepared and their viscosity tested.
b) The Viscosity of the AP3 Grease-based Viscoelastic Magnetic Abrasive Media has shown an increase in the viscosity with the increase in the proportion of CIP-Abrasive Powder. However, with the increased temperatures during the finishing operations, there is a higher chance of reduction in the viscosity.
c) White transformer oil could not be used due to its instability during the initial loading period.
d) Silicone oil-based Viscoelastic Magnetic Abrasive Medium is preferred for internal Finishing. The sample also showed flow ability.
e) The viscosity of the Silicone oil has drastically increased from 954.06 mPa-s to 5688 mPas in 30 days from the date of preparation, and at this higher viscosity, this medium can't be used for finishing operation.

The viscosity of the Media is the major parameter for machining the workpiece, as the viscosity holds the abrasive particles and the polymer provides the flow to the media. The gel provides viscosity. Thus, selecting the proper base oil for the preparation of gel results in effective machining for the AFM and MAF process.

Achieving the positivity of the secret key in a BB84 like quantum key distribution protocol

Rashi Jain* and Satyabrata Adhikari†
Department of Applied Mathematics,
Delhi Technological University, Delhi-110042, India

Woodhead [Phys. Rev. A **88**, 012331 (2013)] derived the lower bound of the secret key rate for a Bennett-Brassard (BB84) like quantum key distribution protocol under collective attacks. However, this lower bound does not always assure the generation of the secret key and thus the protocol may have to be aborted sometimes. Thus, we modify the Woodhead's lower bound of the secret key rate in such a way that the secret key is always generated in a BB84 like quantum key distribution protocol. Exploiting the obtained modified lower bound of the secret key rate, we analyze two state dependent quantum cloning machines such as (i) Wootters-Zurek QCM and (ii) Modified Buzek-Hillery QCM constructed by fixing the cloning machine parameters of Buzek Hillery quantum cloning machine (QCM), which may be used by the eavesdropper to extract information from the intercepted state. We, thereafter, show that it is possible for the communicating parties to distill a secret key, even in the presence of an eavesdropper. Moreover, we also discuss the effect of the efficiency of the QCM on the generation of the secret key for a successful key distribution protocol.

arXiv:2504.16434v1 [quant-ph] 23 Apr 2025

I. INTRODUCTION

One of the most challenging problems in the modern world is to communicate securely, over an insecure channel. Quantum cryptography plays a vital role in providing security in the areas related to quantum technologies [1]. Quantum key distribution (QKD) is one of the most advanced applications of quantum cryptography. In a QKD protocol, a secure key is established between two or more trusted communicating parties following the laws of quantum mechanics. This key is then used for secure communication over a quantum channel. Various QKD protocols have been proposed since early 1980s [2, 3]. The security of the key being distributed is the utmost priority for the communicating parties. The distribution of the secret key is a challenging task as there might be some external noise or an eavesdropper present in the quantum channel, which may tamper with the key.

There are broadly two classes of QKD implementation namely, prepare-and-measure QKD and, entanglement-based approach [4]. In this paper, we will focus on the prepare-and-measure QKD scheme. In this scheme, the sender, say Alice, prepares and transmits quantum states randomly, on one of the previously decided bases to the receiver, say Bob. Upon receiving the states, Bob performs quantum measurements upon them on any one of the basis in a random manner. The state preparation basis and state measurement basis are then discussed in the public channel to assure the correctness of the key. This forms a *raw key*. Alice and Bob then chooses randomly any subset of the raw key, discuss their prepared states and calculate the error occurred in the selected subset. If the error is too high, they abort the protocol, else they continue. The remaining qubits form a *sifted key*, which can be improved by applying error correction schemes [5, 6] and privacy amplification schemes [7, 8]. In an ideal case, Bob's string is identical to Alice's string, and the key rate is considered to have no dark counts and perfect detector efficiency [9]. Although, in realistic situations, this might not be the case. An eavesdropper, say Eve, might be present in between, who is in general assumed to posses every possible power that is compatible within the laws of quantum mechanics. The most general form of attacks considered in QKD are joint attacks. An important class of joint attacks is the collective attack [10]. Eve may intercept Alice's state before reaching to Bob in the midway and she may apply an unitary transformation on it in order to know about the secret key. Since the above procedure is repeating several times so after the classical communication has been completed between Alice and Bob, Eve separately applies the same operation to each state that she intercepted from Alice. This is known as a *collective attack* [11].

The interference of Eve generate some errors in the key distribution scheme. This raises the problem of determining the number of key bits that can be securely extracted from a QKD protocol, or in other words, how much error can be tolerated by the QKD scheme such that Alice and Bob are still able to distill a key. In this regard, in 2004, Gottesman et al, proposed the achievable key rate for the BB84 protocol [2], which is given by [12]

$$r = 1 - H_2(\delta) - H_2(\delta_p) \tag{1}$$

where $H_2(\delta)$ denotes the Shannon entropy of a random variable δ, representing the fraction of the sifted key bits being sacrificed to perform error correction, and $H_2(\delta_p)$ represents the fraction of the sifted key bits being sacrificed to perform privacy amplification. Later, in 2005, Devetak and Winter proposed a lower bound on the asymptotic key rate that is secure against an adversary under collective attacks [13]. Kraus et al [14] proposed

* rashijain_23phdam07@dtu.ac.in
† satyabrata@dtu.ac.in

lower and upper bounds on the secret key using one way classical communication QKD protocols. Till date there have been many theories in the literature for the upper bound of key rate in various kinds of QKD protocols [15–18], but only a few works comprises of lower bound of secret key rates [14, 19]. Therefore, in this paper, we derive the possible lower bound, for a successful BB84 like protocol. We call BB84 like protocol is successful, if the key rate is positive. We further find the upper bound on the error rate such that the two communicating parties are able to distill a secret key, even in the presence of Eve, where she uses a quantum cloning transformation to extract information from the intercepted state from the sender, Alice.

The aim of this paper is three-fold. Firstly, we observe that the lower bound for a key rate introduced by [20] is based on Eve's fidelity and the errors introduced in the system for a BB84-like protocol. However, this lower bound does not assure the success of the protocol. Thus, our aim is to find the estimate of the lower bound possible on the secret key rate such that the protocol is completed successfully, i.e., the key is formed positively. Secondly, our aim is to find whether Eve's cloning transformation has some effect on the key rate, or the introduced errors. To study this, we find the maximum possible upper bound of the introduced errors such that the communicating parties are able to distill a secret key. Thirdly, we aim to find if there exists an upper bound on the efficiency of the QCM that may effect the generation of the secret key.

The rest of the paper is organized as follows: In Section II, we will discuss the BB84 like QKD protocol and provide the theoretical proposal for the generation of Alice's state in a laboratory, which she uses for QKD. We also clearly define the role of the eavesdropper in the QKD protocol. In Section III, we provide the estimate of the lower bound for a positive key rate. Moreover, for a given fidelity between the states resulting from the output of the QCM, we find the upper bound on the error rate upto which the protocol proves to be successful. In Section IV, we study the state dependent symmetric QCMs, such as the Wootter-Zurek QCM, and the modified Buzek-Hillery QCM. We find the upper bound on error rate, for a given fidelity and analyze the value of secret key rate, such that the protocol is successful. In Section V, we study the effect of efficiency of the QCM that may be used by Eve in a successful QKD protocol. Finally, we conclude with a brief summary in Section VI.

II. BB84 LIKE PROTOCOL

Consider the following setting of BB84 like protocol, which is similar to the BB84 protocol: Two communicating parties, namely, Alice and Bob are connected via an untrusted quantum channel and they wish to establish a secure secret key for further communication. To start with, let us suppose that Alice possesses an unbiased source that produces the two-qubit state of the following form

$$|\Phi\rangle_{AA} = |0\rangle_A \otimes |S\rangle_A + |1\rangle_A \otimes |S'\rangle_A \tag{2}$$

where $|S\rangle \equiv |\phi\rangle$ or $|\psi\rangle$ and $|S'\rangle \equiv |\phi'\rangle$ or $|\psi'\rangle$. These four quantum states, either from the "Z basis" or "X basis" (these bases may not be identical to the actual Z and X basis known in quantum mechanics) at random, with equal probability [15]. Let us further consider that the two orthogonal states in "Z basis" are $\{|\phi\rangle, |\phi'\rangle\}$, which is of the form

$$\begin{aligned} |\phi\rangle &= \alpha|0\rangle + \beta|1\rangle \\ |\phi'\rangle &= \alpha|1\rangle - \beta|0\rangle \end{aligned} \tag{3}$$

where the real numbers α and β satisfy the normalization condition $\alpha^2 + \beta^2 = 1$. The orthogonal states of the "X basis" can be given by $\{|\psi\rangle, |\psi'\rangle\}$. The density operators corresponding to these states can be given by $\rho = |\phi\rangle\langle\phi|$, $\rho' = |\phi'\rangle\langle\phi'|$, $\sigma = |\psi\rangle\langle\psi|$ and $\sigma' = |\psi'\rangle\langle\psi'|$. Alice performs measurement in the computational basis $\{|0\rangle, |1\rangle\}$ and according to the measurement outcome, she may get one of the four states $\{|\phi\rangle, |\phi'\rangle, |\psi\rangle, |\psi'\rangle\}$. Alice then sends the resulting single qubit state obtained from the measurement, to Bob. Bob chooses either "Z basis" or "X basis" at random and performs measurement on the received state, and keeps the sequence obtained in terms of bits 0 and 1 respectively. Thereafter, Alice and Bob discuss their state preparation basis and state measurement basis, respectively, through the public channel. This forms a raw key between Alice and Bob. We note here that in the variant of BB84 protocol, which is called as the BB84 like protocol, the sender Alice and the receiver Bob use only the "Z basis" results for the secret key generation. Then they select a subset of this raw key to calculate the "Z basis" bit error rate denoted by δ_z. They use the remaining data to extract the keys.

A. Generation of Alice's two-qubit state in the laboratory

In this section, we will show the procedure of the experimental generation of the two-qubit state possessed by Alice. Let us start with a pseudopure state (PPS), given by $|00\rangle$, which is experimentally generated by the process adopted by [21]. The two-qubit state possessed by Alice can be constructed by applying a sequence of various quantum gates upon the PPS state. The two-qubit state possessed by Alice is given by

$$\begin{aligned} |\Phi\rangle_{AA} &= |0\rangle_A \otimes |\phi\rangle_A + |1\rangle_A \otimes |\phi'\rangle_A \\ &= \frac{\alpha}{\sqrt{2}}(|00\rangle_{AA} + |11\rangle_{AA}) + \frac{\beta}{\sqrt{2}}(|01\rangle_{AA} - |10\rangle_{AA}) \end{aligned} \tag{4}$$

where $|0\rangle_A$ and $|1\rangle_A$ are the states of the classical registers possessed by Alice and $|\phi\rangle_A = \alpha|0\rangle_A + \beta|1\rangle_A$ and

$|\phi'\rangle_A = \alpha|1\rangle_A - \beta|0\rangle_A$ denotes the Z basis states emitted by Alice, intended for Bob.
The quantum circuits for the state construction consists of single-qubit rotation gate, controlled-NOT gates, controlled rotation (CROT) gate, followed by a single-qubit Hadamard gate. The unitary transformations applied are such that the normalization of the output state is preserved.
The single-qubit Hadamard gate for the basis $\{|0\rangle, |1\rangle\}$ is defined as

$$H = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \tag{5}$$

For the computational basis $\{|00\rangle, |01\rangle, |10\rangle, |11\rangle\}$, the ideal CNOT gate flips the target qubit (second qubit), when the control qubit (first qubit) is $|1\rangle$, which is given by

$$\mathrm{CNOT}_{12} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix} \tag{6}$$

Similarly, a controlled rotation gate (CROT-gate) is given by

$$\mathrm{CROT}_{12}^{\theta} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & \cos\frac{\theta}{2} & -\sin\frac{\theta}{2} \\ 0 & 0 & \sin\frac{\theta}{2} & \cos\frac{\theta}{2} \end{bmatrix} \tag{7}$$

where θ represents the arbitrary angle of rotation.
The experimental construction of the two-qubit state possessed by Alice is given by

$$\begin{aligned}
|00\rangle &\xrightarrow{\mathrm{U}_1^{2\theta_1}} \cos\theta_1|00\rangle + \sin\theta_1|10\rangle \\
&\xrightarrow{\mathrm{CNOT}_{12}} \cos\theta_1|00\rangle + \sin\theta_1|11\rangle \\
&\xrightarrow{\mathrm{CROT}_{12}^{2\theta_2}} \cos\theta_1|00\rangle + \sin\theta_1\cos\theta_2|11\rangle + \sin\theta_1\sin\theta_2|10\rangle \\
&\xrightarrow{\mathrm{H}_1} \frac{1}{\sqrt{2}}\Big[(\cos\theta_1 + \sin\theta_1\sin\theta_2)|00\rangle + (\sin\theta_1\cos\theta_2)|01\rangle \\
&\qquad + (\cos\theta_1 - \sin\theta_1\sin\theta_2)|10\rangle + (-\sin\theta_1\cos\theta_2)|11\rangle\Big] \\
&\xrightarrow{\mathrm{CNOT}_{12}} \frac{1}{\sqrt{2}}\Big[(\cos\theta_1 + \sin\theta_1\sin\theta_2)|00\rangle + (\sin\theta_1\cos\theta_2)|01\rangle \\
&\qquad + (-\sin\theta_1\cos\theta_2)|10\rangle + (\cos\theta_1 - \sin\theta_1\sin\theta_2)|11\rangle\Big]
\end{aligned} \tag{8}$$

The single-qubit unitary transformation $U_1^{2\theta_1}$ is a transformation that rotates the first qubit by arbitrary angle $\theta_1 \in (0, \pi/2)$. The controlled-NOT operation is applied by the implementation of CNOT_{12}, considering the first qubit as the control qubit and second qubit as the target qubit.

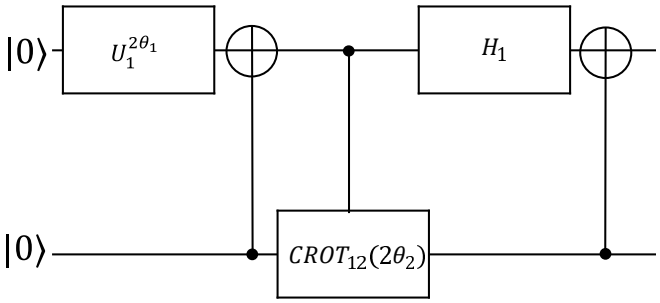

FIG. 1: Quantum circuit [21] showing the sequence of implementation of single-qubit unitary transformation, two-qubit controlled NOT gate, two-qubit controlled rotation gate and single-qubit Hadamard gate required for the construction of two-qubit state possessed by Alice, given by (11).

$\mathrm{CROT}_{12}^{2\theta_2}$ implements a controlled rotation by an arbitrary angle $\theta_2 \in [0, \pi/2)$, with the first qubit as control qubit and second qubit as the target qubit. The final state obtained is dependent upon θ_1 and θ_2.
Now, we choose the values of θ_1 and θ_2 in such a way that the coefficients of the like terms of the state given in (4) matches with the coefficients of the output state obtained in (8). Therefore, we have

$$\cos\theta_1 + \sin\theta_1\sin\theta_2 = \cos\theta_1 - \sin\theta_1\sin\theta_2 = \alpha \tag{9}$$

$$\sin\theta_1\cos\theta_2 = \beta \tag{10}$$

Here, we choose $\theta_2 = 0$, which reduces equation (8) to

$$\frac{1}{\sqrt{2}}\Big[\cos\theta_1(|00\rangle + |11\rangle) + \sin\theta_1(|01\rangle - |10\rangle)\Big] \tag{11}$$

From (11), we obtain the required values of state parameters as

$$\begin{aligned} \alpha &= \cos\theta_1 \\ \beta &= \sin\theta_1 \end{aligned} \tag{12}$$

which satisfies the normalization condition $\alpha^2 + \beta^2 = 1$, for $\theta_1 \in (0, \pi/2)$.

B. Role of eavesdropper

If we assume that a potential eavesdropper, say Eve is present in between the communicating parties, say, Alice and Bob then her role is to secretly intercept Alice's state that is being transferred to Bob. Eve's intention is to extract as much information as possible on the key exchanged between Alice and Bob. To execute her plan of stealing the information, she make use of a quantum cloning machine (QCM) to copy the intercepted state. After successfully applying $1 \longrightarrow 2$ quantum cloning transformation U, she keeps one copy with herself and

sends the other copy to Bob, in order to remain hidden in the key distribution process.
Let us consider that Eve's cloning transformation U acts on the intercepted state in the following way:

$$U(|S\rangle_{in}\langle S| \otimes |0\rangle_b\langle 0| \otimes |Q\rangle_x\langle Q|)U^\dagger, \quad S \equiv \phi \text{ or } \phi' \tag{13}$$

where $|Q\rangle_x$ denotes the QCM state vector, and the subscript "in" and "b" denote the input state and the copy mode, respectively. Eve obtains the copied state by applying a partial trace operation over the machine state vector $|Q\rangle_x$ and the input state $|S\rangle_{in}$ and keeps one of the copied state described by the density operator ρ_E or ρ'_E with herself.
Since the sender Alice and the receiver Bob have no idea about the existence of an eavesdropper in between so, Bob, after receiving the state may proceed with the protocol if the key rate $r > 0$, or they abort it and start over again if the key rate $r < 0$ [22, 23]. The key rate r depends upon the "Z basis" error rate δ_z and it may increase due to the noise present in the communication channel or the interference of the eavesdropper who is present in between the communicating parties. Thus, it would be interesting to study the effect of Eve's cloning transformation on δ_z which may lead to the failure of the protocol and thus may reveal Eve's presence in the key distribution process. Hence, our task is to explore the possible bound of the key rate where the key distribution protocol is successful, even when an eavesdropper is present in the protocol.

III. LOWER BOUND FOR A POSITIVE KEY RATE

In this section, we would like to explore the possible lower bound of the secret key rate when the key distribution protocol is successful, even in the presence of the eavesdropper. Shor and Perskill gave the lower bound on the key rate r, which is given by [24]

$$r \geq 1 - h(\delta_x) - h(\delta_z) \tag{14}$$

where δ_x and δ_z are the X and Z basis error rates, respectively. Woodhead modified the lower bound (14) on r using the cloning bound, for a variant of BB84 scheme, which is given by [20]

$$r \geq 1 - h(u) - h(\delta_z) \tag{15}$$

where $u = \frac{1}{2}(1 + F(\rho_E, \rho'_E))$ and $h(x) = -x\log_2(x) - (1-x)\log_2(1-x)$, is the binary (Shannon) entropy function [25]. The fidelity $F(\rho_E, \rho'_E)$ measures the overlapping between the output states ρ_E and ρ'_E obtained after applying the cloning transformation on the two input states $|\phi\rangle$ and $|\phi'\rangle$, respectively at Eve's site. The fidelity $F(\rho_E, \rho'_E)$ can be calculated as $F(\rho_E, \rho'_E) = ||\sqrt{\rho_E}\sqrt{\rho'_E}||_1$, where $||\cdot||_1$ denotes the trace norm.
It is interesting to note that the right hand side of (15) might be positive or negative, based on the values of $h(u)$ and $h(\delta_z)$. A key distribution protocol is considered to be successful if the key rate is positive, i.e., $1-h(u)-h(\delta_z) > 0$. Therefore, for a successful QKD protocol, we aim to find the lower bound for $1-h(u)-h(\delta_z)$ such that the key rate r is always positive.
For the sake of simplicity, let us assume that $1 - h(u) - h(\delta_z) \equiv R$. We find the lower bound of R denoted by R_{lb} such that r is always positive, i.e., $0 < R_{lb} < R < r$. Now, expressing R in terms of fidelity $F(\rho_E, \rho'_E)$ and δ_z, we get

$$R = \frac{1}{\log 2}\left[\log 2 + \left(\frac{1+F(\rho_E,\rho'_E)}{2}\right)\log\left(\frac{1+F(\rho_E,\rho'_E)}{2}\right) + \left(\frac{1-F(\rho_E,\rho'_E)}{2}\right)\log\left(\frac{1-F(\rho_E,\rho'_E)}{2}\right) + \delta_z\log\delta_z + (1-\delta_z)\log(1-\delta_z)\right] \tag{16}$$

In order to find the lower bound on R such that $0 < R_{lb} < R$, we rewrite (16) as

$$R = \frac{1}{\log 2}[a + \delta_z\log\delta_z + (1-\delta_z)\log(1-\delta_z)] \tag{17}$$

where $a = \log 2 + \left(\frac{1+F(\rho_E,\rho'_E)}{2}\right)\log\left(\frac{1+F(\rho_E,\rho'_E)}{2}\right) + \left(\frac{1-F(\rho_E,\rho'_E)}{2}\right)\log\left(\frac{1-F(\rho_E,\rho'_E)}{2}\right)$.
Let us consider the inequality

$$\frac{x}{1+x} \leq \log(1+x), \ x > -1 \tag{18}$$

We will use this inequality when $-1 < x < 0$ and by replacing x with $-\delta_z$, the inequality (18) reduces to

$$-\delta_z \leq (1-\delta_z)\log(1-\delta_z), \ 0 < \delta_z < 1 \tag{19}$$

Using the inequality (19) in the expression (17), we get

$$R \geq \frac{1}{\log 2}[a + \delta_z\log\delta_z - \delta_z] \equiv R_{lb} \tag{20}$$

Further, applying the inequality $\log\delta_z > \frac{\delta_z^2 - 1}{2.5\delta_z}$ for $\delta_z \in (0, 0.305)$, the expression of R_{lb} given in (20) further

reduces to

$$R_{lb} > \frac{1}{\log 2}\left[a + \frac{\delta_z^2 - 1}{2.5} - \delta_z\right] \tag{21}$$

For $R_{lb} > 0$, we have to find the values of fidelity $F(\rho_E, \rho'_E)$ and δ_z for which the right hand side of (21) is positive, i.e., $a + \frac{\delta_z^2 - 1}{2.5} - \delta_z > 0$ holds. Simplifying this condition, we get a quadratic equation in δ_z, which is given by

$$\delta_z^2 - 2.5\delta_z + 2.5a - 1 > 0 \tag{22}$$

Solving the inequality (22), we get

$$0 < \delta_z < \frac{2.5 - \sqrt{10.25 - 10a}}{2} \tag{23}$$

and

$$\frac{2.5 + \sqrt{10.25 - 10a}}{2} < \delta_z \tag{24}$$

Since, in general, $\delta_z \in (0, 1)$, so we eliminate (24). Therefore, the inequality (23) holds for $F(\rho_E, \rho'_E) \in (0.8281, 0.9922)$.

Substitute a in terms of $F(\rho_E, \rho'_E)$ in the inequality (23) and solving, we find that for a given $F(\rho_E, \rho'_E)$, $\delta_z \in (0, \delta_{z_1})$, where $\delta_{z_1} \in (0, 0.305)$. Therefore, the inequality $0 < R_{lb} < R$ holds when $\delta_z \in (0, \delta_{z_1})$, where $\delta_{z_1} \in (0, 0.305)$. Thus, in the given range of $F(\rho_E, \rho'_E)$ and δ_z, we find that the key rate r is always positive and hence it results into the success of the key distribution protocol.

IV. ANALYSIS OF VARIOUS SYMMETRIC QCMS

In this section, we would like to study the effect of Eve's cloning transformation on the secret key rate r. The success and failure of the protocol depend on its estimate R given in (16), which can be positive or negative, respectively. The estimated value of R depends on the type of cloning transformation used by the eavesdropper. Eve clone the input states $|\phi\rangle$ and $|\phi'\rangle$ and obtains the output states ρ_E and ρ'_E, respectively using various symmetric QCMs. The overlapping between these output states $F(\rho_E, \rho'_E)$ depends on the input state parameters α and the cloning machine parameters. We, therefore, study various types of symmetric QCMs used by the eavesdropper and derive the relationship between $F(\rho_E, \rho'_E)$, the input state parameters, and the cloning machine parameters. For the given values of the input state parameters and the cloning machine parameters, we find the values of $F(\rho_E, \rho'_E)$ and analyze the value of R for the corresponding range of δ_z given in (23). If $R_{lb} > 0$, then the secret key can be established successfully between two distant partners Alice and Bob.

A. Wootter-Zurek QCM

In 1982, Wootters and Zurek [26] analyzed the copying process of an arbitrary input state $|\phi\rangle_a$ which is a linear combination of basis states vectors $|0\rangle_a$ and $|1\rangle_a$, the subscript a denotes the original system. The cloning transformation is defined on the basis vectors $|0\rangle$ and $|1\rangle$, and is given by

$$\begin{aligned} |0\rangle_a|0\rangle_b|Q\rangle_x &\longrightarrow |0\rangle_a|0\rangle_b|Q_0\rangle_x \\ |1\rangle_a|0\rangle_b|Q\rangle_x &\longrightarrow |1\rangle_a|1\rangle_b|Q_1\rangle_x \end{aligned} \tag{25}$$

where $|Q\rangle_x$ denotes the QCM state vector and, the subscript b denotes the copy mode of the input state. The copying state vectors satisfies the conditions

$$\langle Q_0|Q_1\rangle = 0, \langle Q_i|Q_i\rangle = 1, i = 0, 1 \tag{26}$$

The WZ copying machine is input state-dependent, i.e., the quality of the copies at the output of the quantum cloner depends on the input state.

Let us assume that Eve uses WZ QCM as described by (25) to copy the intercepted state that Alice wishes to send to Bob. Therefore, the cloning transformation can be read as

$$\begin{aligned} |0\rangle_A|0\rangle_E|Q\rangle_M &\longrightarrow |0\rangle_B|0\rangle_E|Q_0\rangle_M \\ |1\rangle_A|0\rangle_E|Q\rangle_M &\longrightarrow |1\rangle_B|1\rangle_E|Q_1\rangle_M \end{aligned} \tag{27}$$

where the subscript A refers to Alice's qubit that Eve intercepts, the subscript B refers to the qubit that Eve sends to Bob after copying the intercepted state in order to remain hidden in the key distribution process, Eve's copy state is expressed in the basis state $|i\rangle_E, i = 0, 1$, and $|Q_i\rangle_M$ refers to Eve's cloning machine state vectors at the output.

Let us assume that Alice sends the state $|\phi\rangle = \alpha|0\rangle + \beta|1\rangle$ to Bob. Eve intercepts the state in the midway and applies WZ QCM given by (27) and obtains the state at the output as ρ_{BEM}. The two-qubit copy state described by the reduced density operator ρ_{BE} after applying cloning operation is given by

$$\rho_{BE} = \mathrm{Tr}_M[\rho_{BEM}] = \alpha^2|00\rangle_{BE}\langle 00| + \beta^2|11\rangle_{BE}\langle 11| \tag{28}$$

The single-qubit state ρ_E, which is in possession of Eve is given by

$$\rho_E = \mathrm{Tr}_B[\rho_{BE}] = \alpha^2|0\rangle\langle 0| + \beta^2|1\rangle\langle 1| \tag{29}$$

Further, if Alice sends the qubit $|\phi'\rangle = \alpha|1\rangle - \beta|0\rangle$, then Eve performs the same cloning operation on the intercepted qubit, which results in the two-qubit state after eliminating the machine state vector which is given by

$$\rho_{BE'} = \mathrm{Tr}_M[\rho_{BE'M}] = \beta^2|00\rangle_{BE'}\langle 00| + \alpha^2|11\rangle_{BE'}\langle 11| \tag{30}$$

Eve keeps the single-qubit state with herself and it is described by the density operator ρ'_E, which is given by

$$\rho'_E = \beta^2|0\rangle\langle 0| + \alpha^2|1\rangle\langle 1| \tag{31}$$

The overlapping between two density matrices ρ_E and ρ'_E can be described as [27]

$$F(\rho_E, \rho'_E) = \left(\sum_i \sqrt{\lambda_i(\rho_E, \rho'_E)}\right)^2 \tag{32}$$

where λ_i is the ith eigenvalue of the product of density matrices ρ_E and ρ'_E.
Therefore, the fidelity between Eve's output states ρ_E and ρ'_E when she uses WZ QCM is given by (See Appendix A.1 for calculations (A3))

$$F_{WZ}(\rho_E, \rho'_E) = 4\alpha^2(1-\alpha^2) \tag{33}$$

It can be observed that $F_{WZ}(\rho_E, \rho'_E)$ only depends upon Alice's secret state parameter α^2. It is interesting to note here that $F_{WZ}(\rho_E, \rho'_E)$ displays a symmetric behavior when α^2 is lying in the interval $(0, 0.5)$ and $(0.5, 1)$. Therefore, we will only consider the values of $\alpha^2 \in (0, 0.5)$. Further, we can find the values of α^2, for which the lower bound $R_{lb} > 0$ is satisfied i.e., the key distribution protocol is successfully completed with $R > 0$. To achieve this, we have analyzed the values of α^2 and found that when $\alpha^2 \in (0.293, 0.456)$, the fidelity $F_{WZ}(\rho_E, \rho'_E) \in (0.8281, 0.9922)$. With the help of the range of $F_{WZ}(\rho_E, \rho'_E)$, we find the corresponding range of δ_z for which $R_{lb} > 0$. This is depicted in fig 2.

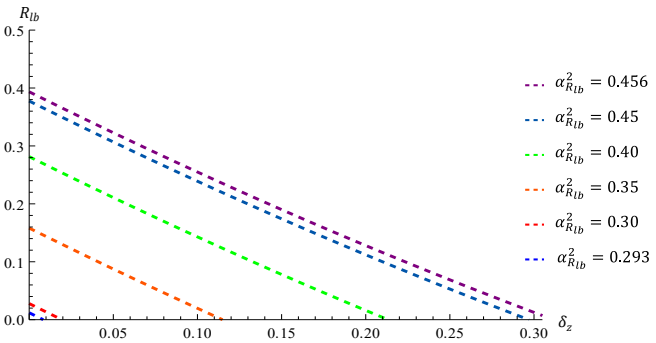

FIG. 2: The lower bound of R for a successful QKD protocol ($r > 0$) when the eavesdropper uses WZ QCM to extract information from the intercepted state is shown. The $x-$ axis represents the range of δ_z, for a given value $F_{WZ}(\rho_E, \rho'_E)$, which depends only on Alice's secret state parameter $\alpha^2 \in (0.293, 0.456)$. The $y-$ axis represents the value of lower bound R_{lb} such that $0 < R_{lb} < R$.

It can be observed from fig 2 that as Alice increases the value of her secret state parameter $\alpha^2 \in (0.293, 0.456)$, the overlapping between Eve's output states $F(\rho_E, \rho'_E)$ also increases when Eve uses WZ QCM. For an increasing $F(\rho_E, \rho'_E)$, the range of δ_z also increases significantly. This is valid because increasing fidelity implies better cloning, and therefore increase in error rate. The estimate of the lower bound of the key rate r, given by R_{lb} varies accordingly.
Since, the protocol is successful in generating the secret key for $R_{lb} > 0$, so Alice is restricted to choosing the state parameter α^2 in the interval $(0.293, 0.456)$. Otherwise, there might arise a case when Alice chooses $\alpha^2 \in (0, 0.293) \cup (0.456, 0.5)$ then R_{lb} might be negative, and thus resulting in the failure of the key distribution protocol. Therefore, the question arises that whether there exist some other cloning machine that may be used by the eavesdropper for which Alice can choose the secret parameter α^2 in the interval $(0, 1)$ with $R_{lb} > 0$ and even then Eve manages to remain hidden in the key distribution protocol?

B. Modified Buzek-Hillery symmetric QCM

In this subsection, we modified the QCM prescribed by Buzek and Hillery [28] and checked whether it fulfilled the asked question in the previous subsection. We modify the BH QCM such that it maybe used by Eve to clone Alice's intercepted qubit such that $R_{lb} > 0$ and she remains hidden in the key distribution protocol.
In 1996, Buzek and Hillery introduced the input state independent QCM, which has the property that the quality of the output state was independent of the input state. The BH quantum cloning transformation is given by

$$\begin{aligned} |0\rangle_A|0\rangle_E|Q\rangle_x \longrightarrow & |0\rangle_B|0\rangle_E|Q_0\rangle_x \\ & + [|0\rangle_B|1\rangle_E + |1\rangle_B|0\rangle_E]|Y_0\rangle_x \\ |1\rangle_A|0\rangle_E|Q\rangle_x \longrightarrow & |1\rangle_B|1\rangle_E|Q_1\rangle_x \\ & + [|0\rangle_B|1\rangle_E + |1\rangle_B|0\rangle_E]|Y_1\rangle_x \end{aligned} \tag{34}$$

The unitarity of the transformation gives

$$\langle Q_i|Q_i\rangle + 2\langle Y_i|Y_i\rangle = 1, i = 0, 1 \tag{35}$$
$$\langle Y_i|Y_j\rangle = \langle Q_i|Q_j\rangle = 0, i \neq j, i, j = 0, 1 \tag{36}$$
$$\langle Q_i|Y_i\rangle = \langle Y_i|Q_i\rangle = 0, i = 0, 1 \tag{37}$$

In addition to the above conditions, the following also holds

$$\langle Y_0|Y_0\rangle = \langle Y_1|Y_1\rangle = \xi, 0 \leq \xi \leq 1/2 \tag{38}$$
$$\langle Y_i|Q_j\rangle = \langle Q_i|Y_j\rangle = \eta/2, i \neq j, i, j = 0, 1 \tag{39}$$

where $0 \leq \eta \leq 1\sqrt{2}$. Here ξ and η denotes the cloning transformation parameters. It can be noted here that if we choose $\xi = 0$, then it implies $\eta = 0$ also, and BH cloning transformation reduces to WZ QCM. So, here we modify the BH QCM by choosing $\eta = 0$ and $\xi \neq 0$. In this case, BH QCM will become a state dependent QCM. Let us assume that Eve uses the modified QCM for cloning the intercepted state. Suppose that Alice sends

the state $|\phi\rangle = \alpha|0\rangle + \beta|1\rangle$ to Bob, which is intercepted by Eve in the mid way. If she applies the modified BH quantum cloning transformation described in (34) on the intercepted state then the combined state becomes ρ_{BEM}. The resultant single-qubit state ρ_E with Eve, after tracing out the copy qubit and the cloning machine state vector, is given by

$$\rho_E = \alpha^2 + \xi(\beta^2 - \alpha^2)|0\rangle\langle 0| + \beta^2 + \xi(\alpha^2 - \beta^2)|1\rangle\langle 1| \tag{40}$$

Similarly, if Alice sends $|\phi'\rangle = \alpha|1\rangle - \beta|0\rangle$ to Bob, then Eve may intercept it and applies the modified BH quantum cloning transformation (34) on it. In this case, the single-qubit state with Eve is given by

$$\rho'_E = \beta^2 + \xi(\alpha^2 - \beta^2)|0\rangle\langle 0| + \alpha^2 + \xi(\beta^2 - \alpha^2)|1\rangle\langle 1| \tag{41}$$

The overlap between the two mixed states described by the density operator ρ_E and ρ'_E, when Eve uses the modified BH QCM can be given by (Refer Appendix A.2 for calculations (A5))

$$F_{BH}(\rho_E, \rho'_E) = 4[\alpha^2(1-\alpha^2)(1-2\xi)^2 + \xi(1-\xi)] \tag{42}$$

It can be clearly seen here that $F_{BH}(\rho_E, \rho'_E)$ not only depends upon Alice's secret state parameter α^2, but also on the cloning machine parameter ξ.

The expression of $F_{BH}(\rho_E, \rho'_E)$ obtained in (42) lies in the interval $(0, 1]$, for $\alpha^2 \in (0, 1)$ and $\xi \in (0, 0.5]$. In this case also, we find that $F_{BH}(\rho_E, \rho'_E)$ is a symmetric function with respect to the parameter α^2. Alice choose the value of α^2 to prepare her secret state without having any idea about the cloning machine state parameter ξ, used by Eve in the construction of modified BH QCM to extract information from the intercepted state. We have shown that for a given value of $\xi \in (0, 0.455)$, there exists certain values of $\alpha^2 \in (0, 0.455)$ for which Eve manages to remain hidden in the key distribution process, and the key is distributed successfully between the sender Alice and receiver Bob.

The results in the given table I can be validated by considering the fact that as the fidelity for Eve increases, the interval of the error rate also increases due to Eve's intervention. We have shown that, it is possible to form the secret key between the sender and receiver, in spite of the increasing interval of the error rate.

TABLE I: For a given value of $\xi \in (0, 0.455)$, there exists values of Alice's secret state parameter α^2 such that the lower bound required for a successful QKD protocol, i.e., $R_{lb} > 0$ is achieved, even when Eve uses the BH QCM.

V. EFFICIENCY OF THE QCM

Alice prepares her secret states $|\phi\rangle$ or $|\phi'\rangle$ and then sends it to Bob. Eve intercepts Alice's state in the midway, before reaching to Bob. She then applies a quantum cloning transformation to extract the information from the intercepted state. After applying the quantum cloning transformation on the intercepted state $|\phi\rangle$ or $|\phi'\rangle$, the possible output is represented by the density operator ρ_E or ρ'_E, respectively.

In this section, we will study the efficiency of the QCM by calculating the Hilbert-Schmidt (HS) distance between the input (ideal) state, described by the density operator ρ_{id} or ρ'_{id} and the output state of the cloning machine, described by the density operator ρ_E or ρ'_E. We have shown that the HS distance between ρ_{id} (ρ'_{id}) and ρ_E (ρ'_E) is upper bounded by the trace distance between ρ_E and ρ'_E, by using the relationship between trace distance and the fidelity. Finally, we have analyzed the inequality between the HS distance and the trace distance to find the effect of the efficiency of the QCM on the successful key generation, i.e., $R_{lb} > 0$.

The distance between the density matrices ρ^{in} and ρ^{out} can be calculated by trace distance $D(\rho^{in}, \rho^{out})$, defined as

$$D(\rho^{in}, \rho^{out}) = \frac{1}{2}\mathrm{Tr}|\rho^{in} - \rho^{out}| = \frac{1}{2}||\rho^{in} - \rho^{out}||_1 \quad (43)$$

where $||M||_1 = \mathrm{Tr}\sqrt{M^\dagger M}$ denotes the trace norm for an arbitrary operator M. In higher dimensional systems, trace distance might require diagonalization of density matrices, and computing the diagonalized matrix can be exponentially difficult, making trace distance a less preferred choice [29]. To overcome this difficulty, an alternative measure is the Hilbert-Schmidt (HS) distance [30–32], which can be defined as

$$D_{HS}(\rho, \sigma) = \mathrm{Tr}[(\rho - \sigma)^2] = ||\rho - \sigma||_2^2 \quad (44)$$

where ρ and σ are two arbitrary quantum states. $||M||_2 = \sqrt{\mathrm{Tr}(M^\dagger M)}$ denotes the Frobenius norm which is easier to calculate both numerically and analytically. Furthermore, employing HS distance can be cost efficient as it can be efficiently computed on a quantum computer, thereby reducing the cost of the experiment [33]. It provides a direct interpretation as an information distance between quantum states [34]. The efficiency of a QCM can be analyzed using the HS distance.

A. Relation between the efficiency of the QCM and the secret key rate for a successful QKD protocol

To establish the relation between the efficiency of the QCM and the generation of the secret key, we start with the relationship between trace distance $D(\rho_E, \rho'_E)$ and fidelity $F(\rho_E, \rho'_E)$, which is given by [35]

$$D(\rho_E, \rho'_E)^2 \leq 1 - F(\rho_E, \rho'_E)^2 \quad (45)$$

In 2019, Coles et. al. proposed a strong bound between the trace distance $D(\rho, \sigma)$ and the HS distance $D_{HS}(\rho, \sigma)$ between the two density matrices ρ and σ as [36]

$$\frac{1}{2}D_{HS}(\rho, \sigma) \leq D(\rho, \sigma)^2 \quad (46)$$

Taking $\rho \equiv \rho_E$ and $\sigma \equiv \rho'_E$, the inequality (46) reduces to

$$D_{HS}(\rho_E, \rho'_E) \leq 2D(\rho_E, \rho'_E)^2 \quad (47)$$

Using the triangular inequality of the distance measure, we get

$$\begin{aligned} &D_{HS}(\rho_E, \rho'_E) \leq D_{HS}(\rho_E, \rho_{id}) + D_{HS}(\rho'_E, \rho_{id}) \\ \implies &D_{HS}(\rho_E, \rho'_E) - D_{HS}(\rho_E, \rho_{id}) \leq D_{HS}(\rho'_E, \rho_{id}) \end{aligned} \quad (48)$$

Since, $D_{HS}(\rho'_E, \rho_{id}) \geq 0$, so we impose the condition

$$D_{HS}(\rho_E, \rho_{id}) \leq D_{HS}(\rho_E, \rho'_E) \quad (49)$$

Using (47) and (49), we have

$$D_{HS}(\rho_E, \rho_{id}) \leq 2D(\rho_E, \rho'_E)^2 \quad (50)$$

Similarly, we get

$$D_{HS}(\rho'_E, \rho'_{id}) \leq 2D(\rho_E, \rho'_E)^2 \quad (51)$$

Equations (50) and (51) are the required relationships between the HS distance between ρ_E (ρ'_E) and ρ_{id} (ρ'_{id}) and the trace distance between ρ_E and ρ'_E.
We find from equation (23), that if $F(\rho_E, \rho'_E) \in (0.8281, 0.9922)$, then $0 < R_{lb} < R$, i.e., the secret key can be formed between Alice and Bob. Then for a given value of $F(\rho_E, \rho'_E) \in (0.8281, 0.9922)$, we have $\delta_z \in (0, \delta_{z_1})$, where $\delta_{z_1} \in (0, 0.305)$. Thus, for a given value of $F(\rho_E, \rho'_E) \in (0.8281, 0.9922)$, a range of $D(\rho_E, \rho'_E) \in (0, 0.56058)$ can be obtained by using the inequality given in (45). Hence, for a given value of $D(\rho_E, \rho'_E)$, an upper bound of $D_{HS}(.,.)$ can be obtained. This implies that, for a given fidelity $F(\rho_E, \rho'_E)$, we can estimate an upper bound on the efficiency of the QCM. This further suggest us that there is an upper bound of the efficiency of the QCM, beyond which QKD protocol may be aborted.

B. Analysis of the efficiency of WZ QCM and modified BH QCM and its effect on successful key generation

In the previous section, we have established the relationship between the HS distance $D_{HS}(.,.)$ and the trace distance $D(.,.)$, which is given by the inequality (50-51). In this section, we are interested in analyzing the efficiency of two particular QCMs, namely, WZ QCM and modified BH QCM, when the QKD protocol is successful.

1. Efficiency of WZ QCM in successful QKD protocol

The efficiency of WZ QCM for $R_{lb} > 0$ can be analyzed by the table (II) given below.

α^2	$F_{WZ}(\rho_E, \rho'_E)$	$D(\rho_E, \rho'_E)^2$	$D_{HS}^{WZ}(\rho_E, \rho_{id})$
0.293	0.8286	[0,0.3134)	[0,0.6268)
0.30	0.84	[0,0.2944)	[0,0.5888)
0.35	0.91	[0,0.1719)	[0,0.3438)
0.40	0.96	[0,0.0784)	[0,0.1568)
0.45	0.99	[0,0.0199)	[0,0.0398)
0.456	0.9922	[0,0.0154)	[0,0.0311)

TABLE II: Analysis of WZ QCM in Alice's secret state parameter α^2 and the HS distance $D_{HS}(\rho_{id}, \rho_E)$ between the input and the output mode.

It can be clearly observed from table II that as the fidelity $F(\rho_E, \rho'_E)$ increases from 0.8286 to 0.9922, the upper bound of HS distance between ρ_{id} (ρ'_{id}) and ρ_E (ρ'_E)

reduces rapidly. This implies that if the eavesdropper uses the WZ QCM to clone the input state $|\phi\rangle$ or $|\phi'\rangle$, then we find that the WZ QCM acts efficiently for a larger value of Alice's state parameter α^2. In this case, Eve manages to remain hidden in the QKD process in spite of generating the secret key,.

2. Efficiency of modified BH QCM in successful QKD protocol

ξ	α^2	$F_{BH}(\rho_E, \rho'_E)$	$D(\rho_E, \rho'_E)^2$	$D_{HS}^{BH}(\rho_{id}, \rho_E)$
0.1	0.241	0.8283	[0,0.3139)	[0,0.6279)
	0.30	0.8976	[0,0.1943)	[0,0.3886)
	0.35	0.9424	[0,0.1118)	[0,0.2237)
	0.40	0.9744	[0,0.0504)	[0,0.1009)

	0.25	0.9600	[0,0.0784)	[0,0.1568)
	0.30	0.9744	[0,0.0505)	[0,0.1011)
	0.35	0.9856	[0,0.0286)	[0,0.0572)
	0.39	0.9923	[0,0.0154)	[0,0.0308)
0.4	0.001	0.9602	[0,0.0781)	[0,0.1562)
	0.05	0.9676	[0,0.0637)	[0,0.1275)
	0.10	0.9744	[0,0.0505)	[0,0.1011)
	0.15	0.9804	[0,0.0388)	[0,0.0776)
	0.20	0.9856	[0,0.0286)	[0,0.0572)
	0.25	0.9900	[0,0.0199)	[0,0.0398)
	0.28	0.9923	[0,0.0154)	[0,0.0308)
0.455	0.001	0.9919	[0,0.0161)	[0,0.0321)
	0.011	0.9923	[0,0.0154)	[0,0.0308)

TABLE III: Analysis of modified BH QCM based on Eve's cloning machine's parameter ξ, Alice's secret state parameter α^2 and, the HS distance between the input state ρ_{id} and the output state ρ_E.

When Eve uses the modified BH QCM to extract information from the intercepted state, it can be noted that the fidelity $F(\rho_E, \rho'_E)$ of the modified BH QCM not only depends on Alice's state parameter α^2 but also on the cloning machine parameter ξ. Therefore, from table III we can see that for a given value of α^2, the upper bound of HS distance decreases, i.e., the efficiency of the cloning machine increases as ξ increases. This means that for a given value of α^2 and a larger value of ξ, Eve can copy the intercepted state in a better way. Therefore, though Eve can extract information using the QCM but its effect cannot be seen in the generation of secret key. Thus, Alice and Bob are able to generate the secret key as $R_{lb} > 0$, in this case, in spite of Eve's intervention in the QKD protocol.

VI. CONCLUSION

To summarize, we have analyzed the lower bound of key rate proposed by Woodhead [20] for a variant of BB84 protocol. This lower bound does not assure the success of the protocol, i.e., successful key distribution between the communicating parties. This means that if the key rate is found to be negative, the protocol is aborted. To overcome this problem, we modified the lower bound given by Woodhead in such a way that the success of the protocol is assured. For a successful key distribution scheme, we find that for a given fidelity, $F(\rho_E, \rho'_E) \in (0.8281, 0.9922)$, there exists error rate $\delta_z \in (0, \delta_{z_1})$, such that $\delta_{z_1} \in (0, 0.305)$. The modified lower bound depends only upon the overlapping between the density operators ρ_E and ρ'_E, that is obtained by Eve after applying the cloning transformation on the intercepted state $|\phi\rangle$ and $|\phi'\rangle$ respectively, and it guaranteed a successful QKD scheme. In particular, we have studied two types of state dependent QCMs, namely, WZ QCM and modified BH QCM that may be used by the eavesdropper to extract the information from the intercepted state. The modified BH QCM can be constructed by setting the cloning machine parameters η and ξ as $\eta = 0$ and $\xi \neq 0$. In both of these cases, we have shown that it is possible for Alice and Bob to distill a secret key in spite of the presence of the eavesdropper. Moreover, we use the inequality between $F(\rho_E, \rho'_E)$ and $D(\rho_E, \rho'_E)$ to determine the range of $D(\rho_E, \rho'_E)$, for a given value of $F(\rho_E, \rho'_E)$. Since the Hilbert Schmidt distances $D_{HS}(\rho_{id}, \rho_E)$ and $D_{HS}(\rho'_{id}, \rho'_E)$ represent the quality of the output of the cloning machine so we have estimated $D_{HS}(\rho_{id}, \rho_E)$ and $D_{HS}(\rho'_{id}, \rho'_E)$ in terms of $D(\rho_E, \rho'_E)$ and thereby discussed the effect of efficiency of the QCM on the generation of the secret key that is required for a successful key distribution protocol. The use of asymmetric quantum cloning transformations in the proposed methodology is still unexplored, and we leave it as an open question how our results extend in this case.

Appendix A: Fidelity between ρ and σ

In this section, we will calculate the fidelity between two density matrices ρ and σ.
The fidelity $F(\rho,\sigma)$ is given by [27]

$$F(\rho,\sigma)=\left(\sum_i\sqrt{\lambda_i(\rho\sigma)}\right)^2 \tag{A1}$$

where λ_i is the ith eigenvalue of the product $\rho\sigma$.

1. Fidelity of WZ QCM for $|\phi\rangle$ and $|\phi'\rangle$

The fidelity between the density matrices ρ_E and ρ'_E given in (29-31) maybe calculated as

$$\rho_E\rho'_E=\begin{bmatrix}\alpha^2\beta^2 & 0\\ 0 & \alpha^2\beta^2\end{bmatrix} \tag{A2}$$

The eigenvalues of $\rho_E\rho'_E$ are given by $\alpha^2\beta^2,\alpha^2\beta^2$. Therefore, substituting these values in (A1), we get

$$\begin{aligned}F_{WZ}(\rho_E,\rho'_E)&=\left(\sqrt{\alpha^2\beta^2}+\sqrt{\alpha^2\beta^2}\right)^2\\&=\left(2\sqrt{\alpha^2\beta^2}\right)^2\\&=4\alpha^2\beta^2\end{aligned} \tag{A3}$$

2. Fidelity of the modified BH QCM

The eigenvalues of the product of the density matrices ρ_E and ρ'_E obtained by Eve after applying the cloning transformation (34) and tracing out Bob's bits, can be given by $\{(\alpha^2+\xi(\beta^2-\alpha^2))(\beta^2+\xi(\alpha^2-\beta^2)),(\alpha^2+\xi(\beta^2-\alpha^2))(\beta^2+\xi(\alpha^2-\beta^2))\}$. Therefore, the fidelity

$F_{BH}(\rho_E, \rho'_E)$ is given by

$$\begin{aligned} F_{BH}(\rho_E, \rho'_E) &= \Big(\sqrt{(\alpha^2 + \xi(\beta^2 - \alpha^2))(\beta^2 + \xi(\alpha^2 - \beta^2))} \\ &\quad + \sqrt{(\alpha^2 + \xi(\beta^2 - \alpha^2))(\beta^2 + \xi(\alpha^2 - \beta^2))} \Big)^2 \\ &= 4(\alpha^2 + \xi(\beta^2 - \alpha^2))(\beta^2 + \xi(\alpha^2 - \beta^2)) \end{aligned} \tag{A4}$$

Now using the normalization condition $\beta^2 = 1 - \alpha^2$, we obtain

$$F_{BH}(\rho_E, \rho'_E) = 4\left(\alpha^2(1-\alpha^2)(1-2\xi)^2 + \xi(1-\xi)\right) \tag{A5}$$

The examination of chest X-ray images is a crucial component in detecting various thoracic illnesses. The study introduces a new image description generation model that integrates a Vision Transformer (ViT) encoder with cross-modal attention and a GPT-4-based transformer decoder. The ViT captures high-quality visual features from chest X-rays, which are fused with text data through cross-modal attention to improving the accuracy, context, and richness of image descriptions. The GPT-4 decoder transforms these fused features into accurate and relevant captions. The model was tested on the National Institutes of Health (NIH) and Indiana University (IU) Chest X-ray datasets. On the IU dataset, it got scores of 0.854 (B-1), 0.883 (CIDEr), 0.759 (METEOR), and 0.712 (ROUGE-L). On the NIH dataset, it had the best on all metrics: BLEU 1–4 (0.825, 0.788, 0.765, 0.752), CIDEr (0.857), METEOR (0.726), and ROUGE-L (0.705). This framework has the ability to enhance chest X-ray evaluation, assisting radiologists in more precise and efficient diagnosis.

1 | INTRODUCTION

Automated image description generation is an emerging technology in medical imaging that falls under the domain of computer vision. It enables the creation of textual summaries that accurately describe visual content [1]. Chest X-ray imaging is crucial for diagnosing and treating thoracic diseases and providing important information about pulmonary and cardiovascular disorders. The integration of deep learning techniques with artificial intelligence (AI) has brought a revolution in medical image analysis in recent years [2]. These technologies enhance the precision of diagnoses and promote the efficiency of radiological workflows by expediting report generation and minimizing interpretation time [3 4].

The proposed CrossViT-GPT4 architecture combines the cross-model attention mechanism of the Vision Transformer (ViT) with the language model of GPT-4. ViT captures spatial information at the pixel level, converts it into manageable sequences, and extracts comprehensive features through cross-model attention, which helps capture long-range dependencies. This integration of textual and visual data improves image description generation by enhancing sentence accuracy, contextual relevance, and detail, while offering scalability for diverse applications. The approach was tested on established chest X-ray datasets like NIH and IU, demonstrating its effectiveness. However, challenges such as computational complexity, limited annotated medical data, domain-specific terminology, clinical integration, and accuracy in analyzing flawed images remain. The proposed methodology combined ViT and cross-model attention with GPT-4, generating detailed annotations that improve the medical terminology as well as the spatial relationships with pixel-level information. It promises to outperform previous approaches towards improving diagnostic workflows and patient care.

The paper's contributions are as follows:

- The research introduces a new method, CrossViT-GPT4, that combines Vision Transformer (ViT) with cross-model attention and GPT-4 to generate detailed annotations for chest X-ray images.
- The ViT model with cross-model attention leverages contextual comprehension to integrate pertinent medical terminology and spatial relationships, whereas GPT-4 utilizes pixel-level information to generate sequences.
- The suggested model outperformed existing approaches in extensive tests conducted on benchmark datasets of the Indiana University Chest X-ray dataset and the National Institutes of Health (NIH) Chest X-ray dataset. This demonstrates the potential to enhance analysis workflows, clinical outcomes, and patient care by enabling automated production of image descriptions for better diagnosis and treatment planning.
- Ultimately, the study offers a numerical evaluation of all methods and details of the advantages and disadvantages of the proposed model.

The paper is organized as follows: Previous research in this field that is relevant is discussed in Section 2. Comprehensive information about the proposed method that is employed is provided in Section 3. The utilized datasets and the final projected descriptions and outcomes are examined in Section 4. The work's future directions and conclusion are summarised in Section 5.

2 | RELATED WORK

The primary objective of the image description model is to identify different objects and represent their relationships through accurate, semantically correct sentences. Various methods have been adapted to medical imaging tasks [5]. Sun et al.[6] proposed a feature-augmented (FA) module validated on datasets such as MS-COCO, which uses the multi-modal pre-trained CLIP model and channels attention within the encoder to enhance image description and captioning performance. Yao et al.[7] proposed a CNN-RNN framework for anatomical structure and abnormality identification in radiological imaging reports. Li et al.[8] used BERT-based models to generate radiological reports from chest X-ray images, showing the significance of contextual language understanding in medical image analysis. Shaikh et al.[9] proposed an encoder-decoder transformer model combined with a pre-trained CheXNet model, evaluated on the IU X-ray dataset, for chest X-ray report generation. The CheXReport model [10] obtains the best-reported performance on the MIMIC-CXR dataset, given the use of Swin Transformer blocks. Retrieval-based methods that incorporate deep neural networks are also presented [11]. In another work, Conditional Self Attention Memory-Driven Transformer was proposed, which outperformed all existing state-of-the-art approaches with a high BLEU score value for radiological report production by taking ResNet152 v2 for feature extraction and the self-attention memory-driven transformer for text generation [12]. Despite these developments, current models fail to integrate textual and visual information effectively and are not able to handle medical language well, which makes the descriptions less understandable and accurate. Moreover, because these models are highly sensitive to errors, misunderstandings in medical contexts could potentially affect diagnoses.

The suggested approach, CrossViT-GPT4, enhances previous research by integrating the benefits of GPT-4, which excels in contextual language modeling, with ViT and a cross-model attention technique for spatial feature extraction. This combination offers a comprehensive solution for automatically generating image descriptions in chest X-ray analysis.

3 | OVERVIEW OF THE PROPOSED WORK

The automated generation of image descriptions has received recent attention due to its intricate nature, which integrates natural language processing (NLP) with computer vision. The objective of the proposed research is to enhance the extraction of spatial and channel-wise information from images. The model is fine-tuned over multiple epochs (75) using the cross-entropy loss function and the Adam optimizer. Figure 1 represents the overall framework of the proposed approach.

Each step of the proposed model is discussed below:

3.1 | Data pre-processing

The input images (I) are initially partitioned into patches (P) of a predetermined size to prepare the input data for the encoder. The patches undergo flattening and linear projection, and each individual patch is thereafter embedded and compressed into a sequence of vectors. The data pre-processing step for the task is shown in Figure 1(a). Equation (1) denotes compressing each patch into a lower-dimensional space:

$$E_{\text{patch}} = \text{Linear}(\text{Flatten}(I_{\text{patch}})) + \text{PE} \tag{1}$$

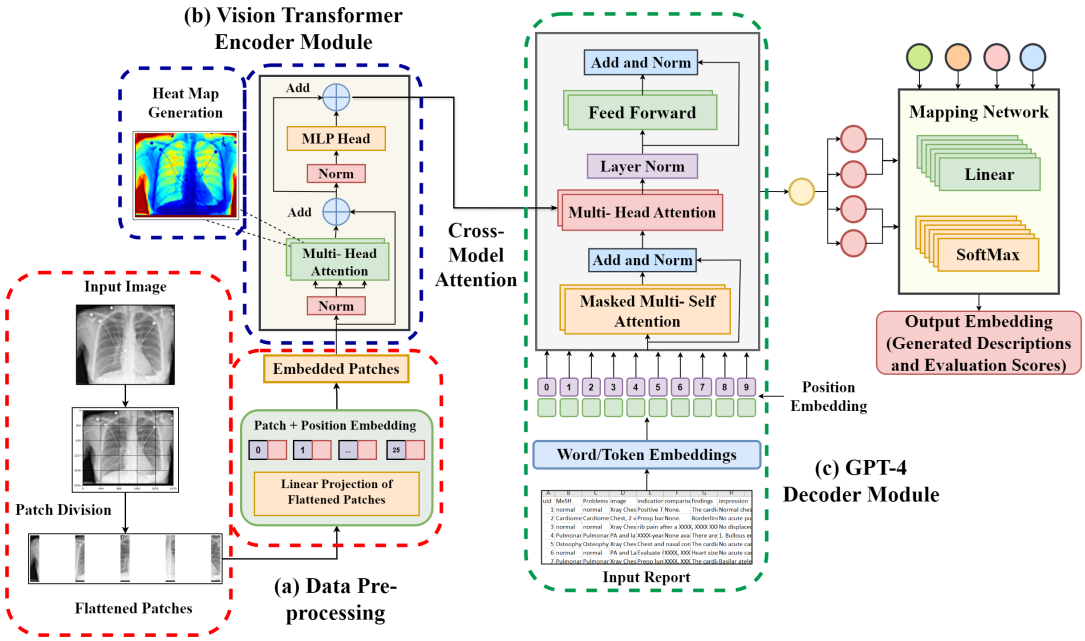

FIGURE 1 A representation of the proposed framework's structure: CrossViT-GPT4- During the initial stage, the ViT encoder utilizes cross-model attention to extract high-level visual features from the pre-processed images. GPT-4 decoder uses tokenization to extract individual words from the provided input caption file. It then utilizes the dense layers of the network to produce image descriptions.

where, I_{patch} represents the image patches, Linear denotes the linear transformation matrix used for embedding, and Flatten is the operation that flattens each patch into a vector. The positional encoding (PE) uses sine and cosine functions to include spatial information. This lets the model understand the order of events, as shown in Equations (2) and (3):

$$\text{PE}(\text{pos}, 2i) = \sin\left(\frac{\text{pos}}{10000^{(2i/\text{dim})}}\right) \tag{2}$$

$$\text{PE}(\text{pos}, 2i+1) = \cos\left(\frac{\text{pos}}{10000^{(2i/\text{dim})}}\right) \tag{3}$$

3.2 | Encoder Module of the Proposed Architecture

The encoder part efficiently collects the spatial and visual characteristics of the image, thereby preparing the model for subsequent tasks such as image labeling. The vision transformer (ViT) encoder is used to receive the sequences of tokenized patches that have been enhanced with positional data. The architectural structure for the Vision transformer encoder is illustrated in Figure 1(b). For multi-head self-attention, the attention is computed in parallel across

h heads and concatenated, as denoted in Equations (4), (5) and (6):

$$\text{Attention}(Q, K, V) = \text{Softmax}\left(\frac{QK^T}{\sqrt{d_k}}\right)V \tag{4}$$

$$\text{MultiHead}(Q, K, V) = \text{Concat}\left(\text{Head}_1, \ldots, \text{Head}_h\right)W^O \tag{5}$$

$$\text{Head}_i = \text{Attention}(QW_i^Q, KW_i^K, VW_i^V) \tag{6}$$

where, Q, K, and V represent the queries, keys, and values matrices, respectively. d_k is the dimension of the keys, W_i^Q, W_i^K, and W_i^V are projection matrices for each head and W^O is the output projection matrix. The multi-head attention module further generates heat maps to offer insights into the attention mechanism of the model, as illustrated in Figure 1(b). These heat maps aid in identifying the specific areas of the input image that impact key description elements. Additionally, the cross-model attention mechanism is used to transmit these extracted features to the GPT-4 decoder module for final mapping.

3.3 | Cross-model attention mechanism

Through cross-modal attention, which dynamically focuses on pertinent features from each modality, the proposed model is able to match visual details with textual descriptions. In image description generation, the model creates sentences by focusing on various aspects of an image and lining them up with the context that the text provides. Cross-model attention mechanism can be represented by the following Figure 2. The alignment enhances the model's

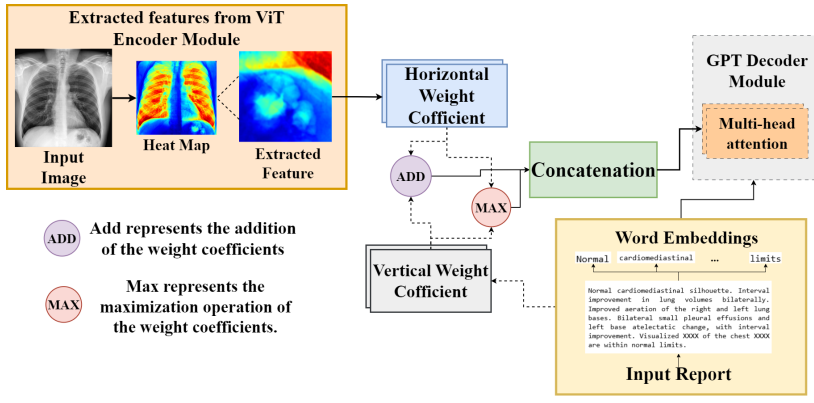

FIGURE 2 Cross-Model Attention Mechanism.

capacity to generate precise and contextually appropriate descriptions, eventually leading to a richer understanding

and more coherent outputs. The cross-modal attention mechanism is defined as Equation (7):

$$\text{CrossAttention}(Q_t, K_i, V_i) = \text{Softmax}\left(\frac{Q_t K_i^T}{\sqrt{d_t}}\right) V_i \tag{7}$$

where, Q_t represents text queries, K_i and V_i are the keys and values from the image features and d_t is the dimension of the text queries.

3.4 | Decoder Module of the Proposed Architecture

The primary architecture of the decoder is based on the GPT-4 transformer model, which is specifically designed for context-based tasks. The structure consists of layers of feed-forward and multiple self-attention neural networks. The diagram in Figure 1(c) illustrates the structural framework of GPT-4. Using self-attention mechanisms, every layer progressively enhances input embedding, enabling the model to discern distant relationships and contextual information. The self-attention within the GPT-4 decoder is given by Equation (8):

$$\text{SelfAttention}(Q_t, K_t, V_t) = \text{Softmax}\left(\frac{Q_t K_t^T}{\sqrt{d_t}}\right) V_t \tag{8}$$

where, Q_t, K_t, and V_t represent the text queries, keys, and values respectively and d_t is the dimension of the text queries. To create the next word in the sequence, the output layer predicts the probability distribution across the vocabulary using word/token embedding, representing words as vectors. Due to this methodology, GPT-4 can generate cohesive and contextually suitable information by extensively working on more substantial sentences. The final textual output is obtained by passing the combined attention outputs through a feed-forward (FF) network and then generating Logits for each token in the vocabulary as represented in Equation (9):

$$\text{Logits} = \text{FF}\left(\text{CrossAttention} + \text{SelfAttention}\right) \tag{9}$$

Linear and Softmax layers in network mapping are essential for producing the end result and predicting evaluation scores when generating image descriptions. The model can represent intricate relationships with them appropriately. Equation (10) represents the expression denoted as $\text{Linear}(W, X)$.

$$\text{Linear}(W, X) = WX + b \tag{10}$$

The weight matrix is symbolized by W, the input vector is indicated by X, and the bias vector is designated by b. Next, the updated characteristics are normalized into a probability distribution throughout the lexicon of potential words or tokens using the Softmax layer, as represented by Equation 11.

$$\text{Softmax}(\mathbf{z})_i = \frac{e^{z_i}}{\sum_j e^{z_j}}, \tag{11}$$

where, the input vector is denoted as z. The accuracy of these predictions is evaluated by comparing them to the descriptions in the reference file. The evaluation metrics used are ROUGE-L, CIDEr, METEOR, and BLEU 1-4, which assess the degree of similarities between the predicted and actual descriptions. These metrics enable the evaluation of the model's ability to effectively integrate the context and semantics of the images into the generated descriptions.

3.5 | Algorithm of the Proposed Work:

The following describes Algorithm 1 for the suggested model along with its score evaluation:

Algorithm 1: Algorithm for the proposed model, CrossViT-GPT4

Input: Images I

Output: Generated Descriptions $\text{Output}_{\text{text}}$, Evaluation Scores

Data Pre-processing:
Partition the image I into patches P, flatten and linearly project each patch;
Apply positional encoding to patches;
ViT Encoding:
Input the sequence of embedded patches E_{patch} into the ViT encoder;
Compute multi-head attention: $\text{MultiHead}(Q, K, V)$;
Cross-Modal Attention:
Compute cross-modal attention: $\text{CrossAttention}(Q_{\text{t}}, K_{\text{i}}, V_{\text{i}})$;
GPT-4 Decoding:
for *each time step t in decoding* **do**
    Compute self-attention within the text: $\text{SelfAttention}(Q_{\text{t}}, K_{\text{t}}, V_{\text{t}})$;
    Generate logits for the next token: Logits;
    Compute probability distribution and select the next token: $\text{Output}_{\text{text}} = \text{Softmax}(\text{Logits})$;
end
Evaluation:
Evaluate generated descriptions using BLEU, CIDEr, METEOR, and ROUGE-L scores;

4 | EXPERIMENTAL ANALYSIS

The experiments were performed using Google Colab Pro+, which provides high-performance resources, including 52 GB of RAM, an NVIDIA A100 GPU with 40 GB of VRAM, and a virtual CPU equivalent to an Intel Xeon processor. The framework was implemented using Keras and TensorFlow 2.12. The ViT model has 86.7 million parameters and GPT-4 has 1.76 trillion. Input images are (batch_size, 224, 224, 3), and output shapes vary by layer. The developed framework was evaluated on two benchmark datasets: the Indiana University Chest X-Ray dataset (IU X-Ray) and the NIH Chest X-ray dataset. The IU X-ray dataset consists of 3,955 XML radiologist reports and 7,471 PNG images while the NIH dataset consists of 112,120 frontal X-rays with annotations for 13 thoracic illnesses across 30,805 individuals.

4.1 | Ablation Study:

The suggested model's image description components were clarified using ablation analysis. This study investigates the capabilities of the proposed architecture, CrossViT-GPT4. In Table 1, we compare the performance of various models on two major chest X-ray datasets: the IU Chest X-Ray dataset and the NIH Chest X-Ray dataset. The results presented in the following table summarize the performance of each model across these metrics.

TABLE 1 Evaluation of Models on the IU and NIH Chest X-Ray Datasets

Dataset	Model	B-1	B-2	B-3	B-4	C	M	R-L
IU Chest X-Ray	CNN-LSTM Model	0.289	0.272	0.268	0.236	0.677	0.273	0.219
	Encoder-Decoder Transformer	0.398	0.373	0.354	0.343	0.658	0.286	0.316
	ViT+ Attention	0.283	0.258	0.236	0.205	0.574	0.194	0.188
	ViT + attention + LSTM	0.601	0.572	0.554	0.498	0.587	0.436	0.342
	ViT + GPT 2.0	0.704	0.663	0.634	0.626	0.792	0.564	0.474
	CNN + GPT 3.0	0.761	0.753	0.736	0.715	0.867	0.725	0.657
	CrossViT-GPT4 (Proposed)	**0.854**	**0.817**	**0.804**	**0.785**	**0.883**	**0.759**	**0.712**
NIH Chest X-Ray	CNN-RNN Model	0.211	0.178	0.161	0.148	0.445	0.198	0.149
	CNN-LSTM Model	0.277	0.252	0.246	0.227	0.465	0.242	0.197
	Encoder-Decoder Transformer	0.383	0.363	0.334	0.312	0.578	0.265	0.287
	ViT with Attention	0.284	0.268	0.253	0.248	0.534	0.187	0.176
	ViT with LSTM	0.438	0.425	0.409	0.387	0.589	0.436	0.386
	ViT + GPT 2.0	0.687	0.658	0.644	0.612	0.763	0.582	0.604
	CNN + GPT 3.0	0.782	0.774	0.752	0.706	0.835	0.704	0.664
	CrossViT-GPT4 (Proposed)	**0.825**	**0.806**	**0.795**	**0.772**	**0.857**	**0.726**	**0.705**

The table presents the performance comparison of different image description generation models on IU and NIH Chest X-ray datasets with respect to BLEU scores from B-1 to B-4, CIDEr (C), METEOR (M), and ROUGE-L (R-L). The proposed CrossViT-GPT4 model is seen to outperform all other models for both the datasets with respect to all metrics. It reports a BLEU score of 0.854 on B-1, 0.817 on B-2, 0.804 on B-3, and 0.785 on B-4 along with CIDEr of 0.883, METEOR of 0.759, and ROUGE-L of 0.712 on the IU Chest X-ray dataset. Correspondingly, it has a score of 0.825 on B-1, 0.806 on B-2, 0.795 on B-3, 0.772 on B-4, CIDEr of 0.857, METEOR of 0.726, and ROUGE-L of 0.705 on the NIH Chest X-ray dataset.

4.2 | Results and Analysis:

The suggested model, CrossViT-GPT4, provides an excellent approach for illustrating images in the IU and NIH chest X-ray datasets. It combines the ViT encoder and the GPT-4 decoder modules. The results for the chest X-ray datasets from IU and NIH are shown in able 2 and 3, respectively.

The tables provide a quantitative comparison between the actual data and the reports generated by the model for different test images. The results evaluate the model's capacity to forecast diseases and produce descriptions that showcase the model's precision by utilizing X-ray images for both datasets.

TABLE 2 Quantitative Results Obtained on IU Chest X-Ray Dataset

Test Image	Ground Truth Report	Disease Prediction	Predicted Report
	The heart is normal in size. The mediastinal contours are within normal limits. There is mild prominence of the superior mediastinum which is somewhat lucent and reflects mediastinal and vascular structures. No focal consolidation is seen. There is no pleural effusion.		Mediastinal contours within normal limits. Mild mediastinum somewhat lucent.
	Lateral view of the chest shows an unchanged cardiomediastinal silhouette. The cardiac silhouette remains moderately enlarged, exaggerated by epicardial fat pads. Interstitium is prominent. No focal airspace consolidation or pleural effusion. There is spine spondylosis.		Unchanged cardiomediastinal silhouette. Interstitium prominent. Spine spondylosis.

TABLE 3 Quantitative Results Obtained on NIH Chest X-Ray Dataset

Test Image	Ground Truth Report	Disease Prediction	Predicted Report
	1. The heart is normal size. 2. The mediastinum is unremarkable. 3. There is no pleural effusion, pneumothorax, or focal airspace disease. 4. There is stable irregularity of the posterior left 6th rib which represents an old fracture.		No pleural effusion, pneumothorax, or focal airspace disease
	1. The heart size and cardiomediastinal silhouette are normal. 2. There is hyperexpansion of the lungs with flattening of the hemidiaphragms. 3. There is no focal airspace opacity, pleural effusion, or pneumothorax. 4. There multilevel degenerative changes of thoracic spine.		Cardiovascular silhouette normal. No focal airspace opacity, pleural effusion, or pneumothorax.

4.3 | Comparison With Other state-of-the-art Methods:

Compared to the most advanced methodologies currently available, the proposed method demonstrates a substantial enhancement in disease prediction accuracy and report production for X-ray images. The method, CrossViT-GPT4,

effectively performs on both the IU and NIH chest X-ray datasets by utilizing a fusion model that incorporates the ViT encoder and GPT-4.0 decoder.

The study presented in Table 4 thoroughly analyzes various models used to generate image descriptions on the IU X-ray and NIH datasets. The table compares various models for generating image descriptions on the IU Chest X-Ray

TABLE 4 Comparative Analysis on IU and NIH Chest X-Ray Datasets

Model	BLEU	METEOR	CIDEr	Rouge-L
IU Chest X-Ray Dataset				
R2Gen [13]	0.470	0.187	-	0.371
R2Gen + ChexNet [14]	0.508	0.222	-	0.365
Cross-modal PROtotype driven NETwork (XPRONET) [15]	0.525	0.220	-	0.411
Contrastive attention [8]	0.492	0.193	-	0.381
Knowledge-injected U-Transformer [16]	0.525	0.242	-	0.409
AERMNet [17]	0.486	0.219	0.560	0.398
CrossViT-GPT4 (Proposed)	**0.854**	**0.759**	**0.883**	**0.712**
NIH Chest X-Ray Dataset				
Semantic Attention [18]	0.467	0.192	0.560	0.204
Co-Attention [19]	0.756	0.597	0.755	0.675
Clinical-BERT [20]	0.383	0.144	-	0.275
ChestBioX-Gen [21]	0.668	0.189	0.416	0.674
CrossViT-GPT4 (Proposed)	**0.825**	**0.726**	**0.857**	**0.705**

and NIH Chest X-Ray datasets, evaluating their performance using BLEU, METEOR, CIDEr, and Rouge-L metrics. On the IU Chest X-Ray dataset, R2Gen [13] demonstrates intermediate performance, while R2Gen + ChexNet [14] improves BLEU and METEOR scores but slightly reduces Rouge-L. Both XPRONET [15] and Knowledge-injected U-Transformer [8] achieve a BLEU score of 0.525, with the latter excelling in METEOR and Rouge-L. Contrastive Attention exhibits moderate performance, whereas AERMNet [17] provides balanced results across metrics. The proposed CrossViT-GPT4 model outperforms all these approaches, achieving significantly higher scores across all metrics: BLEU (0.854), METEOR (0.759), CIDEr (0.883), and Rouge-L (0.712). On the NIH Chest X-Ray dataset, the CrossViT-GPT4 model similarly leads with the highest scores across all metrics: BLEU (0.825), METEOR (0.726), CIDEr (0.857), and Rouge-L (0.705). In comparison, Semantic Attention [18], Co-Attention [19], ChestBioX-Gen [21], and Clinical-BERT [20] exhibit less balanced or lower performance. These results underscore the superior capability of the proposed model in generating accurate and semantically rich image descriptions across both datasets.

5 | CONCLUSION AND FUTURE DIRECTION

Combining the Vision Transformer encoder module (ViT) with cross-model attention and the Generative Pre-trained Transformers 4 (GPT 4.0) decoder module can result in an efficient framework, CrossViT-GPT4, for producing visual

descriptions. The model uses vision-based feature extraction and language modeling to thoroughly analyze and characterize complex medical images. When textual and visual components are combined, chest X-ray pathology reports can be described and explained more precisely. Transformer-based designs are scalable and adaptable, promoting medical image analysis research and innovation. Their adaptability enables them to efficiently manage diverse datasets and tasks. By enhancing medical image processing, the suggested approach may increase diagnostic precision and assist clinical decision-making platforms. Poor image quality can seriously affect model accuracy by restricting the ability to extract features and generate accurate descriptions. Future research could address this by creating reliable pre-processing methods or incorporating sophisticated denoising and super-resolution techniques to improve performance. Additional research could also increase the applicability and adaptability of the proposed method in a number of scenarios by utilizing a range of large and diverse medical imaging datasets.

***Abstract*— Because of their improved electrostatic control and lower power consumption, negative capacitance FinFETs, or NC-FinFETs, have attracted a lot of interest in improving the performance of nanoscale semiconductor devices. To improve the I_{ON}/I_{OFF} ratio, this article investigates the integration of gate oxide (GO) topologies within NC-FinFETs, focusing on buried Interfacial GO designs that enhance subthreshold properties. The impact of varying interfacial gate oxide thickness within NC-FinFET structures, embedding the IGO layer 0.6m within the channel, improves the ON-OFF current ratio, reduces substrate leakage current, and optimizes the DIBL index. We further examined the impact of dual-k spacers and selective doping to improve capacitance matching and scalability and reviewed spacers' effect on different device configurations. With HfO2 and Air as spacers, NC-FinFET gives SS values of 56.962 mV/dec and 58.830 mV/dec, with I_{on}/I_{off} ratios nearly 10^8 and 10^7, respectively. Different combinations of spacers have been explored. Air+SiO_2 reflected high SS among all combinations. This Review demonstrates how NC-FinFETs may significantly reduce subthreshold swings and maintain operational stability at high scaling levels, revolutionizing semiconductor design.**

Keywords— NC-FinFET, Buried interfacial gate oxide, Dual–k spacers, TCAD, Subthreshold swings

I. INTRODUCTION

Every two years since Moore's law was proposed in 1965, the number of transistors on a chip doubles [1]. The primary drivers behind transistors' continued downsizing are speed improvement, power consumption, and cost reduction; these factors also result in amazing conveniences and various living options. However, SCE deterioration and power consumption are problems for Moore's law nowadays. The DIBL effect reduces the threshold voltage (V_{th}) and increases the off-state current (I_{off}) by affecting the gate's capacity to control the channel. The transistor's switch-down ability, or SS, is the lowest gate voltage (Vg) needed to increase the drain (Id) current by one order of magnitude. Channel-induced SS deterioration I_{off} increases as length decreases. Additionally, punch-through brought on by the source and drain junction joining each other leads to the Rise in leakage current; the injection effect irreparably damages the hot carrier of The dielectric.

Layer carrier mobility is reduced by surface scattering; velocity Ion growth is impacted by saturation. The transistor may be blocked if the channel length is three to five times greater than the screening length. The distance across which the potential drops at the source-channel and channel-to-drain interfaces is known as the screening length, or λ [2].

In the pursuit of future node pathfinding, identifying the ferroelectric (FE) layer-induced negative capacitance (NC) effect in the gate stack of NCFETs is a viable approach. NCFETs are well-suited for applications requiring low power (LP) and high performance (HP). This discovery might improve switching behavior to sub-60 mV/decade and achieve high ON current and lower power consumption. The optimization of predominantly planar and bulk NC devices has received the most attention despite the large number of experimental and computational research on NCFETs [3]. As semiconductor technology develops, electronic device structures become smaller. Short channel effects (SCE) and decreased gate control over channel charge result from this, impairing device performance and rendering them unsuitable for scalability below 20nm [4]. Multi-gate MOSFETs, which enhance drain potential screening, are the direction semiconductor technology is taking to increase gate control. Two-gate or tri-gate FETs are recommended because of their robust behaviour against random dopant activity and reduced parasitic capacitances. FinFETs have a lower power usage, are immune to SCEs, and operate faster. Comparing planar technology to FIN patterning and the gate construction step, the advantage of interoperability with existing CMOS techniques meant tighter control over fabrication operations.

Manufacturing constraints include parasitic capacitances, Fin orientation, and FinFET device doping. Here comes the concept of negative capacitance FinFET (NC-FinFET), a field-effect transistor (FET) that integrates a negative capacitance material or structure to enhance its performance

properties. This three-dimensional transistor structure is becoming increasingly common in present-day semiconductor technology owing to its capacity to retain reasonable electrostatic control over the channel, particularly at nanoscale scaling [1]. Ferroelectric materials often serve as the negative capacitance layer in NC-FinFETs, integrated into the NCFET's transistor gate stack. An electric field can be applied to ferroelectric materials to modify their spontaneous polarization, a unique characteristic that permits them to transition between two or more stable states. According to reports, adding a spacer can improve the NC-FinFETs' gate controllability even more. The double-k spacer modifies the arrangement of spacer components and structures, improving the gate controllability and enhancing the NC-FinFET's capacitance matching. The accomplishment of <60 mV/dec in the SS has been one of the main focuses of the NCFET study.

The general numeric form of SS is given by equation (1) below [5,6]: -

$$SS = \frac{dV_{GS}}{d\log_{10} I_{DS}} \tag{1}$$

In this study, we examine the latest developments in negative capacitance FinFETs. This article aims to give readers a general understanding of NCFET's present status and working mechanism so they can decide on their future line of research with knowledge.

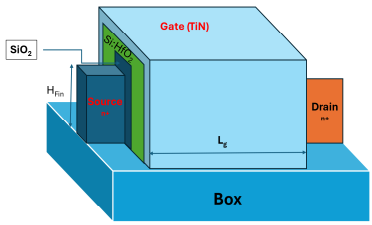

Fig 1:- 3-D structure of NC -FinFET [7].

II. Evolution of NC- FinFET

FinFET originated when the Defense Advanced Research Projects Agency (DARPA) was eager to fund research on the possibility of replacing planar transistors. The inception of the FinFET, which stands for Fin Field-Effect Transistor, can be attributed to Chenming Hu, a professor at University of California, Berkeley, in 1998 [1]. The material is designated "Fin" due to its perpendicular fin-shaped silicon substrate. As a turning point in the history of transistor scale-down, FinFETs continue to be developed; the transition from 17 nanometer N-channel FinFETs in 1998 to 3 nm gate-all-around FinFETs in 2006 is evident. Hisamoto et al. described the DELTA, the first two-gate transistor, in 1989. This delta's structure was comparable to that of the FinFET architectures. FinFETs are divided into two primary groups according to their terminal, which are shorted gate (SG)/3T (terminals) FinFETs and Independent-gate (IG)/4T FinFETs. In a shorted gate, where the front and back gates are physically separated, SG FinFETs have both gates shorted [8]. Multi-gate FETs can be seen as modifications to planar MOSFETs, offering enhanced drain potential screening from the channel by incorporating extra gates. Multi-gate devices, such as dual-gate FETs (DGFETs) or tri-gate FETs, are adopted. because they have reduced parasitic capacitances and are more resistant to random dopant behavior. The Trigate FETs have decreased fringing capacitances, albeit this comes at the expense of a more intricate production process. Silicon-on-insulator (SOI), double-gate MOSFET, ultra-thin body SOI, and tri-gate FinFET are examples of structural devices.

However, these devices have also presented significant difficulties associated with the SCEs. In order to create a more durable construction with fewer SCEs, gate all-around (GAA) technology— which enhances gate-to-channel controllability and surrounds the gate from all sides—has been put into practice. These GAA transistors' scalability extends to the 3 nm technology node [2,9]. The distance between the S-D junctions that is horizontally oriented is the channel length for a standard MOS. FinFETs, on the other hand, have a vertical channel length since the width of the device determines it. There is the concept of gate stacking which is a very crucial role in improving performance of not only NC based devices but any FET such as GS-GNR FET, Gate stacking has the effect of improving metrics like V_{th} and Scathed results showed that by reducing Ioff current and increasing device performance, gate stacking Consequently, the Ion/Ioff ratio increased [10].

In the 1970s, scientist Leon Chua was the first to discuss negative capacitance. However, it was not until a long time later that they were looked at for functional uses. Researchers first looked into NCFETs in the early 2000s when they looked into the possibility of ferroelectric materials having negative capacitance behavior when connected to a transistor. In the middle of the 2010s, several study groups showed experimental proof-of-concept NCFET devices.

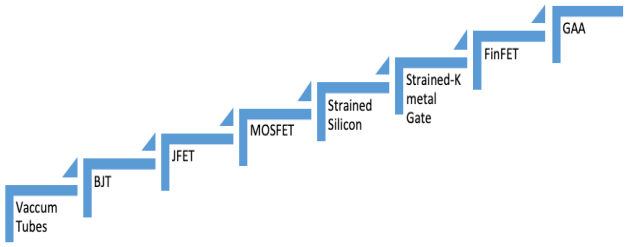

Fig 2:- Evolution of Transistors with Time [11].

The notion that it is possible to obtain a steep switch and an SS below the 60 mV/dec Boltzmann limit by integrating the NC effect in a transistor was initially put out by S. Salahuddin and S. Datta in 2008 [12]. Giovanni A. Salvatore initially experimentally shown an NC-FET in the same year. NCFET is quickly evolving for ultra-low power circuits, especially for IoTs and Deep Neural Networks. It promises to lower circuit operating voltage without affecting performance. When negative capacitance is added to FinFET architecture, performance measures like subthreshold swing, on-state current, and off-state leakage current get even better.

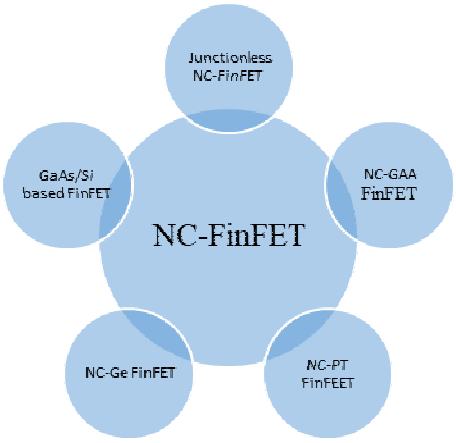

Fig 3:- Different kind of NC FinFET.

Most NCFETs are flat transistors, but NC-FinFETs have the Fin shape. FinFETs are three-dimensional transistors with a channel structure that looks like fins. Compared to flat transistors, they have better electrostatic control and less leakage current. Other devices like NC –GAA- JLFinFETs NC-PT-FinFET, which includes a negative capacitance layer with a FIN-shaped channel to improve device performances, are under research [13,14].

A. Ferroelectric materials

Even when the electric field is removed, ferroelectric materials are good at retaining their polarization. Remnant polarization (Pr) is the term used to describe the left polarization. The coercive electric field (Ec), or reverse electric field that brings Pr back to zero, is a critical property of ferroelectric materials. The usual P-E curve for ferroelectric materials is an S curve [7].

The famous Landau-Khalatnikov equation expresses the relation of polarization and electric field E of FE materials as

$$E = 2\alpha P + 4\beta P^3 + 6\gamma P^5 + \rho\frac{\partial P}{\partial t} \quad (2)$$

$$\alpha = -\frac{3\sqrt{3}}{4}\frac{E_C}{P_r} \quad (3)$$

$$\beta = \frac{3\sqrt{3}}{8}\frac{E_C}{P_r^3} \quad (4)$$

Where α,β, and γ are the material's landau coefficients and viscosity.

Traditional FE materials garnered much interest at first, used in ferroelectric memory devices in 2022, a junctionless Nanowire FET is simulated taking PZT as ferroelectric material [15] and discovered improved factors of 12.5 and 6.8 in I_{on} and $I_{on}/I_{off\ ratios}$ compared to the JL NWFET without ferroelectric materials. The drawbacks of increased deposition temperature, reduced polarization intensity, and poor compatibility with CMOS fabrication restrict their use in NC-FET devices. The discovery of 2D ferroelectric materials occurred after traditional materials, and their current mechanism of working and properties continue to elude comprehension. In NC-FETs, $CuInP_2S_6$ is a prevalent 2D ferroelectric material. The ferroelectric materials composed of Zr-doped HfO_2 (HZO) have many advantages over those discovered to date are thermally stable, compatible with contemporary semiconductor industry fabrication processes, high dielectric permittivity, broad bandgap to inhibit leakage current, scalable to thicknesses of 1 nm or less while maintaining polarization intensity [16].

B. Negative capacitance effect in Ferroelectric materials

For the NC effect, the negative differential capacitance of the Ferroelectric S' curve must coincide with other positive capacitances of the FET. Increasing drain capacitance can aid capacitance-matching as the channel is scaled down, as it softens the voltage-dependent capacitance of the FET. Consequently, the NC effect significantly mitigates SS degradation during scaling. Coupling through drain capacitance also creates negative DIBL, counteracting scaling-induced DIBL growth. The NC effect can substantially improve the short channel effect (SCE).

C. Doping in NC FinFET

The Landau parameters (α, β, γ, ρ, g) are unique to every dopant and Ferroelectric thickness and have a significant impact on the NC property of the FE layer [17]. If NC FinFET is simulated for certain dopant-based FE-HfO_2 layer, the doped-HfO_2 layer delivers a very high remnant polarization and a strong coercive electric field [18]. According to what we understand, the literature uses seven different dopants for creating a thin film-doped HfO_2 FE layer: Gadolinium (Gd) aluminium (Al), Zirconium (Zr), Yttrium (Y), strontium (Sr), Silicon (Si), and Lanthanum (La). The P_r and E_c are measured in $\mu C/cm^2$ and MV/cm, respectively. Each dopant has unique (α, β resulting in a unique NC regime, also known as the S-curve [19]. When considering uniform polarization under quasi-static analysis, α and β are the prominent parameters. The trustworthiness of the TCAD-simulated NC devices is affected by changes in the Landau parameters due to the type of dopants used. The functional dependence of the I_{ON} and I_{OFF} is observed on α and β, respectively. Furthermore, Temperature significantly affects α_0 (i.e., temperature coefficient) and exhibits a linear trend with α. As a result, the device performs worse as the temperature rises. Selecting the right Landau parameters is crucial since it influences the P-E's loop slope and span [18] which in turn affects capacitance matching intuitively and causes variance in dependability.

Table 1:- Comparison between dielectric constant of different dielectric materials.

Materials	Dielectric constant
HfO_2	25
SiO_2	3.9
TiO_2	85
Si_3N_4	7.9
sapphire	40
Ta_2O_5	25
Al_2O_3	9.1
$LaZrO_2$	40

D. *Self-heating and Interfacial Traps*

When it comes to TCAD, the NC phenomena are governed by the FE Polarization model, which is heavily impacted by the Landau parameters. This model is responsible for the realization of the NC phenomenon. It is vital to understand the TCAD configuration in order to create a realistic NC-FinFET. As a result of SHE's the effect on the lattice temperature and, consequently, the Landau parameters, one of the most important considerations is the implementation of the SHE in conjunction with the NC. One of the most significant challenges associated with the implementation of SHE in NC-FinFET is that models, specifically hydrodynamics model and FE Polarization cannot be connected inside the same simulation flow. The TCAD setup has the drift/diffusion model and the Poisson equation algorithm to include the movement of the carriers [20]. The Auger and SRH models, which are included, control carrier production and recombination. Interface traps could be acceptor traps or donor traps that impact device performance. Higher concentrations of the donor trap (Ni_t) lead to a decrease in the threshold voltage (V_{th}). However, when the (SHE) is considered, a significant shift in the threshold voltage was observed at higher Ni_t concentrations. When we consider acceptor traps, the threshold voltage (V_{th}) increases, decreasing the charge transport efficiency in conduction band (CB) and reducing the effective mobile charge. Demands an elevated gate voltage (V_{GS}). However, V_{th} decreases when the Temperature (TL) increases, leading to an increase in carrier energy above the ionization energy. Examination of trap placements near the mid-gap energy. Trapped energy locations switch between the VB and CB for acceptor and donor traps, respectively. The results indicate that accepting traps near the VB significantly impacts I_{ON}—the aging of NC-FinFETs, or EOL, with a 50-mV shift in V_{th}. Regarding stationary trap location and concentration, the influence of fluctuating ambient temperature (T_A) reflects that an increment in TA decreases the concentration of EOL. When EOL (End of life) is investigated for acceptor (Donor) traps with and without SHE, it is discovered that acceptor traps are more resistant to SHE, resulting in increased NC-FinFET sustainability and dependability [21].

III. Effects of Buried Gate Oxide

Because of their superior gate electrostatics and supremacy over short channel effects, NC-FinFETs are an important technology. A new buried oxide approach that modifies the interfacial gate oxide layer's depth is suggested for the NC-FinFET architecture. Circuit features with different buried IGO depths are revealed by the study's analysis of performance characteristics utilizing TCAD Sentaurus.

For different V_{DS}, Figures 5 illustrate the development of device's conducting mechanism, particularly the ON–OFF behavior (I_{ON}/I_{OFF} ratio). The ON–OFF ratio slightly improves when we first begin burying the IGO layer below the channel. Still, the I_{ON}/I_{OFF} characteristics noticeably increase once the maximum of the oxide enters the channel. As we alter the IGO depth in the saturation region—that is, when the oxide gets into the channel area —there is an increase in electron tunneling because the density of states rises.

The field begins to spread out toward the side gate oxides from the center as soon as the IGO's depth is increased. This is because the strong drain field is relaxed by the FE layer throughout the side gates, which lowers the substrate leakage current component and the drain side's conduction band energy (CBE). Consequently, it is discovered that When the IGO is 0.6 nm buried, the NC-FinFET offers the optimal current ratio. NC-FinFET has a favorable DIBL index because of its low NDR effect and average output conductance [22]. On the other hand, the positive DIBL index rises when buried oxide enters the channel region, but it decreases as oxide thickness increases. Because of the high permittivity of the channel, the DIBL index is improved by larger inner fringing fields. Shift in the DIBL index for the proposed NC-FinFET structure with BIGO thickness is shown in Fig 6(b) When compared to no buried IGO, the DIBL index obtained for a fully buried example of 0.6 nm has a manageable degradation where the low NDR effect causes the output conductance to be larger for the unburied case. The NDR effect is then muted when the IGO layer is buried inside the channel since there is less of a shift in the output characteristics' slope. Figure d represents SS at different thicknesses of BGO. According to recent study, NC-FinFET performance is improved by embedding the IGO within the channel, especially for low-power applications. Better ON–OFF ratio, sub-threshold performance, and controllable trade-offs in AC characteristics are the outcomes of the optimized BIGO depth (0.6 nm). This strategy may result in NC-FinFET architectures for sophisticated nanoscale devices that are more dependable and efficient.

IV. Effect of Spacers on NCFinFET

The outstanding short-channel performance of FinFETs with gate-source/drain underlaps makes them desirable for increasing device scalability. Because of undoped underlap zones, the effective length of channel in the off-state is greater than the physical gate length. But both are same in the on-state. Underlaps decrease drive current because of increased series resistance but enhance device short-channel performance. Considering doping concentrations in the source and drain regions, Super-threshold and subthreshold characteristics could be optimized. High-κ spacers can improve the fringing electric field from gate sidewalls, which will improve the performance of digital circuits, SRAM, and analogy [24]. The effect of spacers on different devices is shown in

Table 2.

A. Sidewall spacers

However, according to previously published studies, its inherent negative differential resistance (NDR) (i.e., I_{DS} drops with increasing (V_{DS}) caused by FE polarization prevents NC devices from being used in analog applications [25]. In order to address this, sidewall spacers and the gate-source/drain extension region (L_{ext}) seem to be the most popular options. To ensure improved circuit performance, sidewall spacers are placed above the extension zone to suppress the sidewall-to-sidewall capacitance of the gate and direct tunneling through the gate.

A second FE–DE stack, resembling the gate stack, is produced at the FE spacer when such high-k (FE) material is interfaced with silicon, causing the associated FE spacer's mobility to degrade. As a result of the fringing fields, charge modulation is introduced in the extension region and channel.

The direction of field lines near the FE layer is reversed as a result of the induced bound charges created by these fields, which result in negative charges on the metal gate electrode because of negative permittivity of the FE material in the Negative Capacitance area.

Table 2:- Effect of spacers on different device configurations.

DEVICE	SPACER	SPACER LENGTH	SPACER HEIGHT	SS (mV/dec)	I_{ON}/I_{OFF}	DIBL
NC FinFET [26]	HfO_2	16nm	60.9nm	56.962	1.92×10^{8}	-50.77
NC FinFET [26]	Air	16nm	60.9nm	58.830	5.27×10^{7}	-41.54
NC JL-FET [15]	Si_3N_4	10nm	-	65	$6.9\ X10^{10}$	-30
2D NCFET [27]	Air	5nm	-	63.15	1.17	-16.3
2D NCFET [27]	SiO_2	5nm	-	58.6	1.27	-54
DMG nanowire FET [28]	High k dielectric	25nm	25nm	64.8	$1.81\ X10^{6}$	-
SMG nanowire FET [28]	High k dielectric	25nm	25nm	72.3	$3.43\ X\ 10^{3}$	-
Double gate TFET [29]	SiO_2	2nm	-	21	$3.43\ X\ 10^{3}$	-
JL GAA [30]	High k dielectric	5nm	-	62.53	$1.72\ X\ 10^{9}$	-
GS-GAA FinFET [30]	High k dielectric	5nm	-	61.67	$3.87\ X\ 10^{9}$	-

Consequently, there is a Rise in the charge carriers' energy barrier, which leads to a decrease in potential in these areas less than the gate biasing applied, improving the current in the OFF state and raising the V_{TH}. This became a notable phenomenon for spacer areas due to the growth in energy barrier with the addition of (IF) inner fringing and(OF) outer fringing fields. Stacking FE–DE vertical spacers has been thoroughly examined and refined [31]. The concept is that the spacer region's FE layer aids in modulating the amount of charge. When the FE–DE stack is placed there because of its NC feature. Additionally, a comparison is made between the suggested structure and the traditional NC FinFET, which does not have a layer of ferroelectric at spacer area. It is discovered that the gate fringing fields modifies polarization of FE at the spacers, which in further modifies the charge in channel. As a result, D2 and D3 configurations of the FE–DE stack, which place Si_3N_4 at bottom and $HfZrO_2$ at the top, demonstrated enhanced performance measures such as I_{ON}, I_{OFF}, and SS [24].

B. Dual K spacers

Ferroelectric NC at the gate stacking has given Rise to a different gate control method. According to reports, adding a spacer can improve the NC-FinFETs' gate controllability even more. However, doing so will also impact the carrier flow and raise the series resistance, lowering the on-state current (I_{ON}). High-k spacers have replaced low-k spacers to address this issue since they can strengthen the on-state current while taking into account the phenomenon of fringe-induced barrier reduction. Nevertheless, high-k spacers may lead to parasitic capacitances, raising the circuit delay and total gate capacitance (C_{GG}). As is often known, the accuracy of the NC-FinFET relies on the matching capacitance between the underlying MOSFET gate capacitor (CMOS) and the ferroelectric negative capacitance (C_{FE}) [26].

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 07:34:09 UTC from IEEE Xplore. Restrictions apply.

Furthermore, substituting double-k spacers for single-k spacers increases The intricacy of matching capacitance since the two spacers have different dielectric constants. Switching current ratio and drain-induced barrier lowing all show how different single-k and double-k spacers function on FinFETs. Compared to the single-k spacers, the dual-k spacers exhibit superior capacitance matching and higher gate controllability. Therefore, compared to a single-k spacer, a double-k spacer improves intrinsic delay more. Additionally, the NC-FinFET may reach a DIBL of − 47 mV/V, an SS of 57 mV/dec, and a switching current ratio of up to 10^8 by modifying the combination of spacer materials and architectures [26].

The following double-k spacer combinations were examined in one study's NC FinFET: Air + HfO_2, Si_3N_4 + HfO_2, SiO_2 + HfO_2, Air + Si_3N_4, and Air + SiO_2. Compared to results obtained without a spacer dielectric constant, the device under test showed a considerable improvement in its I_{OFF}, IO_{FF}/I_{ON}, SS, and DIBL. The latter showed superior performance when comparing the NC-FinFETs with different spacers to those with Si_3N_4 + HfO_2. This was due to the switching properties and gate controllability being further enhanced by the increment in the low-k dielectric constant. Furthermore, the NC-FinFET output characteristic under double-k spacer It is evident that for V_{GS} = 0.5 V, the channel current of the NC-FinFET falls with a rise in V_{DS} in the saturation zone, leading to the NDR effect, irrespective of the dielectric constant of the double-k spacer [32].

The NC-FinFET's channel current intensity is not systematically affected by changes in the spacer dielectric constant. High-frequency performance can be accessed via capacitance matching (C_{GG}). The peak value of C_{GG} was significantly decreased by the addition of the low-k spacer when the high-k spacer was HfO_2. The gate voltage grew until it hit the C_{GG} peak, and the C_{GG} peak value declined continuously as the low-k spacer's dielectric constant decreased [33]. The lowest gate capacitance was observed when Air + HfO_2 was combined. The C_{GG} value in the double-k spacer structure decreases with decreasing sum of the two dielectric constants, showing an improved intrinsic delay. Therefore, the capacitance matching of NC-FinFET may benefit from a higher sum of the two dielectric constants.

The double-k spacer increases the capacitance matching of the NC-FinFET and gate controllability by varying the mix of spacer materials and architectures. By doing this, the NC-FinFET is guaranteed to be able to achieve a steeper SS, shorter intrinsic latency, reduced drain-induced barrier, and higher switching current radio. Consequently, if, the two dielectric constants added together are less than in the dual-k spacer arrangement, the better the intrinsic delay, as shown by a smaller CGG value.

dual k spacer	SiO_2+$HfO_{2\ 28.9}$	Si_3N_4+$HfO_{2\ 32.9}$	Air+HfO_{226}	Air+$SiO_{24.9}$	Air+$Si_3N_{48.9}$
SS (mV/dec	57.151	57.081	57.244	57.748	57.275
DIBL (mV/V)	-47.69	-47.69	-46.15	-44.62	-47.69
I_{ON}/I_{OFF}	1.63×10^8	1.72×10^8	1.53×10^8	9.69×10^7	1.40×10^8

Fig 7:- Parameters of the NC-FinFET with different dual-k spacers [26].

V. Conclusion

The paper explains how Negative Capacitance FinFETs (NC-FinFETs), with their improved electrostatic control and decreased subthreshold swing (SS), exhibit great potential for low-power and high-performance nanoscale applications. According to the study, NC-FinFETs can enhance device performance by reducing short-channel effects, improving the I_{ON}/I_{OFF} ratio, and facilitating scalability for low-power applications, particularly when combined with dual-k spacers and gate oxide integration. By altering the mix of spacer materials and topologies, the NC-FinFET may achieve a DIBL of -47 mV/V, an SS of 57 mV/dec, and a switching current ratio of up to 10^8.

We analysed the effect of spacers on different device parameters such as SS, I_{ON}/I_{OFF} ratio, and DIBL.We compared different combinations of low k and high k spacers from which combination of SiO_2+$HfO_{2\ \text{had a}}$ better $_{ION}/I_{OFF}$ ratio as compared to others, and the combination of Air+SiO_2 reflected high SS among all combinations. Better ON–OFF ratio, sub-threshold performance, and controllable trade-offs in AC characteristics are the outcomes of the optimized BIGO depth (0.6 nm)in NC-FinFET .The results indicate that because of their higher power efficiency and operational stability at high scaling levels, NC-FinFETs are positioned as viable solutions for future electronics and may even replace traditional devices as a result of these architectural improvements.

***Abstract*—As the need for sustainable and clean energy solutions grows, solar energy systems are becoming an increasingly important part of the solution to the world's climate problems. However, operational uncertainty and environmental unpredictability have a major impact on photovoltaic (PV) system efficiency. With an emphasis on energy forecasts, real-time changes, and system performance enhancements, this study investigates the integration of artificial intelligence (AI) for solar energy system optimization. To forecast energy generation, maximize energy storage, and improve operational efficiency, artificial intelligence (AI) approaches like Artificial Neural Networks (ANNs), Long Short-Term Memory (LSTM) networks, and hybrid AI models are used. Through AI-integrated numerical weather forecasting, the suggested AI-embedded solar energy framework reduces absolute forecasting error by 51.7%, hourly prediction variations by 9–20%, and Root Mean Square Error (RMSE) by 18–20%. IoT-enabled real-time monitoring systems and cloud-based artificial intelligence platforms allow for dynamic energy modifications in response to variations in power generation and demand. The findings show notable advancements in cost reduction, energy balancing, and predictive maintenance, guaranteeing sustainable energy supply. Additionally, forecasting powered by AI improves grid dependability and makes it easier to integrate dispersed energy sources. This study demonstrates AI's revolutionary potential to improve PV system efficiency, lower transmission losses, and lower energy expenses. Future research highlights how crucial it is to overcome privacy issues, data standardization, and ethical considerations in order to achieve broad use of AI technologies in renewable energy systems.**

Key words:* Artificial *Intelligence, Solar Energy, Optimization, Forecasting, Energy Management

I. Introduction

Solar energy, which comes from the sun, is an abundantly available renewable source with the potential to meet current and future global energy needs both through electricity generation and other technologies. Investments in solar energy can simultaneously ensure energy security and help address critical global challenges such as climate change[1]. Solar energy can be exploited close to the users and yield valuable pollution-free electricity, heat, and desalinated water[2]. However, the quality, reliability, efficiency, and sustainability of solar energy conversion and storage technologies still need to be massively improved, preferably at a reduced cost[3]. Among others, artificial intelligence has the potential to tackle these technological challenges to accelerate the improvements in solar energy systems by making forecasting, diagnosis, control, and design and optimization procedures more transparent and efficient[4][5].

A. Artificial Intelligence

Artificial intelligence (AI) refers to a branch of computer science dealing with the simulation of human intelligence in machines[6]. Many AI techniques, such as machine learning, deep learning, genetic algorithms, and expert systems, have been shown to be promising for use to enhance the assessment, operation, maintenance, design, and optimization of solar energy capture and storage systems[7]. In fact, several AI systems and tools have been developed and are actively being used to leverage insights from big data from devices, sensors, and complex human-physical systems and processes. In both the solar energy technology and AI fields, different systems have evolved over time from heuristic/manual to knowledge-based and model-based systems[6][7]. This text refers to the application of AI including solar forecasting, solar system optimization, and control in renewable solar technologies. Terminologies like solar energy, solar photovoltaic, artificial intelligence, solar forecasting, solar conversion, and energy storage are clearly defined for clarity in readers' understanding of the topic of discussion.

This research highlights the growing need for sustainable energy solutions and the optimization of photovoltaic (PV) systems amidst operational uncertainties and environmental changes. While advancements in solar energy technology are evident, existing methods face challenges with real-time forecasting and operational improvements. This study suggests incorporating artificial intelligence (AI) techniques, such as Artificial Neural Networks (ANNs) and Long Short-Term Memory (LSTM) networks, to enhance energy generation predictions, storage capabilities, and overall system performance. It also employs Internet of Things (IoT)-enabled monitoring and cloud-based AI to create a responsive, data-driven approach to energy management. The research details the integration processes of AI with PV systems, presents empirical evidence supporting the framework's effectiveness, and identifies future research directions to address privacy, data standardization, and ethical aspects in renewable energy.

II. Optimizing Solar Energy Systems With AI

Artificial intelligence (AI) plays a crucial and indispensable role in optimizing the operational and technical

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on April 08,2025 at 06:14:29 UTC from IEEE Xplore. Restrictions apply.

design of solar energy systems. The significance of AI in this field cannot be underestimated, as it offers numerous benefits and possibilities. With its ability to analyze and interpret data from solar panels, AI provides a wide range of approaches that can be employed for this purpose[8][9]. AI methods have diverse uses, including making forecasts, recognizing trends, and improving system efficiency[10]. This approach effectively harnesses solar energy and promotes environmental progress. Figure 1 flowchart outlines the process of maximizing solar energy output using AI.

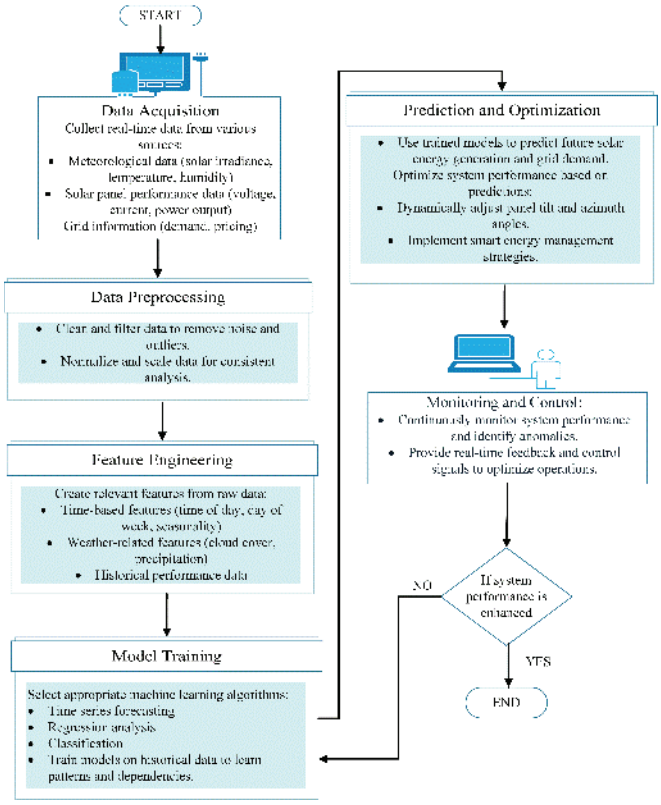

Fig. 1. Optimizing Solar Energy Systems with AI

One application case, for instance, is to optimize the direction of solar panels in order to maximize the energy output. A more complex use case is predictive maintenance for solar panels and inverters to reduce instances of having a system down and to extend its lifetime[11]. The predictive capability of AI has shown to have a good ability to forecast possible malfunctions or downtime. This will minimize the costs of downtime and unplanned maintenance.

TABLE 1 AI-DRIVEN OPTIMIZATION RESULTS FOR SOLAR ENERGY SYSTEMS

Reference	AI Technique	Performance Improvement	Forecasting Accuracy	Cost Reduction
[12][13]	ANN + LSTM	18-20% RMSE reduction	95% energy output accuracy	10-15% reduction in OPEX
[14][15]	Decision Trees (XG Boost)	12-15% improvement in prediction	92% demand-supply balance	8-12% cost savings
[16][17] [18]	Hybrid ML + Weather Models	22% reduction in absolute forecasting error	Improved seasonal energy yield	5-10% CAPEX optimization
[19]	Support Vector Machines	20% forecasting accuracy improvement	Real-time energy adjustments	Predictive maintenance savings
[13][20] [21]	Neural Network (CNN)	19% RMSE improvement	Dynamic load balancing	3-7% operational cost reduction

The table above showcases the significant advancements in solar energy optimization achieved through AI-based approaches. Neural networks, decision trees, and hybrid machine learning techniques consistently demonstrate their superiority in enhancing performance, improving forecast accuracy, and reducing costs. These findings reinforce the pivotal role of AI in driving solar energy systems toward greater efficiency and sustainability.

The value generated from the higher energy yields is more substantial than the value of capital expenditures. More research is required to quantify the savings incurred as a result of using AI predictive maintenance since this could not be quantified in the literature reviewed.

III. Improving Forecasting Accuracy With AI

Forecasting the future solar energy output is foundational for integrating solar photovoltaics (PV) into power systems and for optimizing the operational planning of solar power plants. Improving the accuracy of those forecasts is integral for the effective management of generation sources through enhanced prediction models. Due to their high computational power, artificial intelligence (AI) models using techniques such as neural networks or machine learning algorithms have been used for weather prediction to improve forecasting of solar irradiance and energy output[7][22]. AI can be used to predict solar radiation or irradiance levels following the analysis of historical weather data along with other factors that may affect this. A wide range of data can be analyzed including time series data, images, as well as spatial and geospatial data. The better the quality of the forecasting received from the available solar and energy forecasts, the better informed an energy management system operator will be to plan on building and operating distributed energy storage systems for a particular deployment scenario[6][17]. Figure 2 depicts the workflow for PV estimation for improving forecast accuracy using AI.

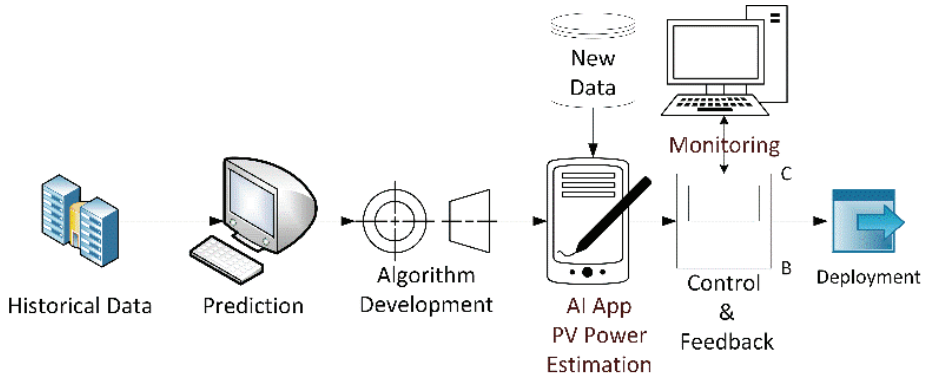

Fig. 1 Workflow for PV estimation

A. Methodology

1. Data Collection
   - Gather data from solar PV systems, weather forecasts, sensors, and historical energy generation records.
   - Integrate IoT devices for real-time monitoring.

   Inputs: (equation 1 represents multiple data sources)
   - Sensor data (temperature, irradiance, wind speed)
   - Historical energy generation data
   - Weather predictions (numerical models)

   $$D_t = \{d_1, d_2, \ldots\ldots, d_n\} \quad (1)$$

   where d_i represents each data source.
2. Data Preprocessing
   - Clean and preprocess the raw data to ensure accuracy.
   - Normalize and handle missing data.

   $$d_{norm} = \frac{d_i - \mu}{\sigma} \quad (2)$$

   where μ is the mean and σ is the standard deviation
3. AI Model Selection

- Choose appropriate AI/ML techniques for optimization:
  - Neural Networks (e.g., LSTM, ANN)
  - Decision Trees (Random Forest, XGBoost)
  - Support Vector Machines (SVM)

  Neural Network (AI Model):

  $$y = f(Wx + b) \quad (3)$$

  where W is the weight, x is the input, b is the bias, and f is the activation function.
- Selected algorithms tailored to energy forecasting and optimization.

4. Model Training and Validation
   - Train AI models using historical and real-time data.
     - Validate models using cross-validation techniques.

     Key Metrics:
     - Accuracy of energy output forecasts
     - Root Mean Square Error (RMSE)

     Error calculation metric for prediction accuracy:

     $$RMSE = \sqrt{\frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{n}} \quad (4)$$

     where y_i is the actual value and $\hat{y}_i$ is the predicted value.
5. Energy Forecasting
   - Predict energy output based on AI models.
   - Forecast demand-supply gaps to optimize energy distribution.

   $$E_{predicted}(t) = \sum_{i=1}^{n} \alpha_i f(d_{norm}(t)) \quad (5)$$

   where α_i are the model weights
6. Optimization and Control
   - Use AI models to optimize energy generation and storage.
   - Deploy rule-based controls and predictive maintenance.

   Optimization function: cost minimization with constraints:

   $$Minimize: C = \sum_{t=1}^{T}(C_{gen}(t) + C_{storage}(t)) \quad (6)$$

   Subject to: $E_{demand}(t) \leq E_{available}(t)$
7. Real-Time Monitoring and Adjustment
   - Continuously monitor performance using AI.
   - Adjust strategies dynamically for system efficiency.

   Dynamic Adjustment: Energy adjustment based on real–time data deviations:

   $$E_{adjusted}(t) = E_{predicted}(t) - \Delta E(t) \quad (7)$$

   where $\Delta E(t)$ is the deviation from the real time data.
8. Performance Analysis and Reporting
   - Analyze energy performance trends.
   - Generate insights and reports for stakeholders.

   Performance improvement: Quantified reduction error

   $$Error\ Reduction = \frac{E_{baseline} - E_{AI}}{E_{baseline}} \times 100\% \quad (8)$$

AI is used to optimize solar energy output with cost-effectiveness utilizing mathematical equations 1–8. During observations, the neural network algorithm reduced the value for the absolute error between forecasting and measurement by 51.7%. By examining hourly forecasted energy output percentages, a reduction of 9-20% was observed and an increase of 2-11% in Root Mean Square Error (RMSE). Many studies have confirmed the superiority of AI techniques in forecasting models. The latest region-based solar PV forecasts generated by incorporating numerical prediction models along with AI models predict the energy with an 18-20% reduction in RMSE.

IV. RESULTS

The results demonstrate that AI models offer substantial improvements in energy forecasting accuracy, cost efficiency, and performance optimization for solar PV systems. Figure 3 and 4 shows the current and voltage over time analysis for 24 hours of a day. Figure 5 shows the power comparison (Measured, forecast , and adjusted) for 24 hours using Neural Network AI, and figure 6 displays the cost minimization for the above time period in $. By incorporating real-time sensor data, historical datasets, and advanced weather forecasts, the AI models dynamically adapt to changing conditions.

1. Energy Forecasting Accuracy:
- The reduction in absolute error and RMSE confirms that AI models outperform traditional rule-based control methods.
- Improved predictions enable grid operators to balance supply and demand effectively.

2. Cost Minimization:
- Predictive maintenance facilitated early fault detection, reducing operational and capital costs.
    - AI systems ensured resource optimization, making solar energy more economically viable.

3. Dynamic Energy Adjustment:
- AI-enabled systems adjusted energy generation and battery storage based on real-time deviations, ensuring efficient energy use and minimizing wastage.

The combination of AI forecasting, optimization, and real-time monitoring can transform solar energy systems into highly efficient, cost-effective solutions. These results validate the potential of AI to address existing challenges in renewable energy management, promoting greater adoption of solar technologies.

V. CONCLUSION

AI remains pivotal in advancing solar energy management, offering optimization, real-time forecasting, and cost reduction. However, to harness its full potential, challenges such as protocol standardization, privacy concerns, and technical biases must be addressed. Interdisciplinary collaboration, scalable decentralized energy systems, and skill development will drive future innovations. By integrating AI into virtual power plants and ensuring ethical decision-making, the energy industry can achieve a balance between resilience, efficiency, and sustainability. AI's convergence with decentralized systems and emerging technologies promises to play a critical role in global renewable energy transitions.

TABLE II QUANTIFIED IMPROVEMENTS

Performance Metric	Baseline	AI-Optimized	Improvement
Absolute Forecasting Error	High	51.7% Lower	Significant Improvement
RMSE	100%	18-20% Reduction	Accurate Energy Prediction
Operational Cost Savings	Baseline Cost	3-35% Savings	Reduced Maintenance Costs
CAPEX for PV Systems	Baseline Expenditure	0-5% Lower	Improved Resource Planning

This study highlights the critical role of Artificial Intelligence in advancing solar energy management through optimization and forecasting. AI-enabled systems effectively predict energy output, dynamically adjust for deviations in real-time data, and optimize both generation and cost. The results demonstrate quantifiable improvements:

1. Performance Gains: Absolute error reduction by 51.7% and a notable RMSE reduction of 18%-20% in regional forecasts signify enhanced prediction accuracy.
2. Cost Minimization: Real-time optimization minimizes energy-related costs, with demonstrated savings through dynamic adjustments.
3. Dynamic Energy Adjustments: AI models ensure efficient management of deviations, balancing demand and supply seamlessly.

The simulated results revealed that AI-based energy adjustments significantly reduce baseline costs while maintaining reliable power output. Although minor deviations were observed due to simulated uncertainties, the overall performance validates the robustness of AI algorithms for energy optimization. Future research must address challenges like data standardization, ethical concerns, and scaling AI models for larger grids.

By implementing AI-driven strategies, solar plants and smart grids can efficiently manage distributed energy resources, minimize energy losses, and promote sustainable energy practices, thereby accelerating the global transition to clean energy solutions.

VI. VI. CHALLENGES

A. Key Challenges

1. Standardization of Protocols:
   - Lack of standardized communication frameworks and interoperability requirements.
   - Creates inefficiencies in integrating AI with existing energy systems.
2. Data Availability and Privacy Concerns:
   - AI systems require vast datasets for training and optimization.
   - Data acquisition is hindered due to privacy laws and fragmented ownership.
3. Bias in AI Algorithms:
   - AI decision-making processes may inherit biases embedded in training datasets.
   - This raises ethical and legal issues in energy management decisions.
4. Technical Complexity:
   - Existing frameworks for energy system simulations and demand forecasting lack advanced methodologies.
   - Integration challenges due to uncertain and evolving energy structures.
5. Interdisciplinary Research Needs:
   - Collaboration between energy experts, policymakers, and AI researchers is underdeveloped.
   - Limits progress in resilient and scalable energy system design.
6. Resilience and Adaptability:
   - Energy systems require adaptability to uncertain market conditions and external disruptions.
   - AI integration must ensure scalability and dynamic optimization.
7. Decentralized Energy Systems:
   - AI applications in distributed energy systems face incomplete data acquisition and complex operation environments.
   - Virtual technologies for optimizing energy grids are still evolving.
8. Skill and Workforce Development:
   - Energy professionals require training in AI, cloud computing, big data management, and cybersecurity.
   - Shortage of skilled personnel delays practical AI implementation.

TABLE 2 CHALLENGES AND SOLUTIONS

Challenges	Solutions
Standardization of protocols	Develop global frameworks for energy-AI interoperability.
Data availability and privacy concerns	Use federated learning, blockchain-based security, and privacy-preserving AI.
Bias in AI algorithms	Implement fairness-aware AI training methods and bias audits.
Technical complexity	Develop advanced AI simulation frameworks with predictive energy modeling.
Lack of interdisciplinary collaboration	Foster partnerships between AI experts, policymakers, and energy engineers.
Resilience and adaptability of energy systems	Build adaptive AI models for real-time energy and demand optimization.
Incomplete data for decentralized energy grids	Use synthetic datasets and real-time data from IoT sensors for training.
Skill and workforce shortage	Launch professional training programs on AI, cloud computing, and big data.

Aggregation of Distributed Energy Resources for Optimal Operation in Local Energy Communities With Grid Constraints

Shubham Gupta, Vinod Kumar Yadav, *Senior Member, IEEE*, and Madhusudan Singh, *Senior Member, IEEE*

***Abstract*—This article presents a framework to efficiently manage a sizable fleet of diverse distributed energy resources (DERs) operating within distribution systems to optimize the operations of local energy communities (LECs) and improve grid services. First, we develop aggregation modeling for DERs to evaluate cumulative flexibility that considers their preferences, spatial placement, and temporal behavior. Subsequently, we employ a hierarchical control framework (HCF) to put these aggregated flexibility of DERs for their effective dispatching. The HCF involves three key entities: an electric utility (EU) operator, community aggregators (CAs), and individual DERs. CAs harness the flexibility obtained from the aggregated DERs within their respective LECs to minimize operational costs while also considering the distribution network constraints. On the other hand, the EU operator coordinates dispatch setpoints received from CAs along with the disaggregated DERs to regulate distribution system node voltages and reduce power losses to enhance grid services. Numerical simulations conducted on a modified IEEE-123 bus radial distribution network demonstrate the efficacy of our approach in effectively managing DERs for cost-efficient operations and improving grid services.**

***Index Terms*—Aggregation model, electric vehicles (EVs), hierarchical control, load modeling, local energy communities (LECs).**

NOMENCLATURE

Variables

$P^{\text{flow}}_{ij,t}, Q^{\text{flow}}_{ij,t}$	Active, reactive branch power flow between buses i and j at time t.
$l^{\text{flow}}_{ij,t}$	Current flow (squared) between buses i and j at time t.
$\upsilon^{\text{node}}_{i,t}$	Node voltage (squared) at bus i at time t.
$E^{\text{CS}}_{i,t}$	Residual energy of CS at bus i at time t.
$P^{\text{ch,CS}}_{i,t}$	Charging power of CS at bus i at time t.
$P^{\text{dch,CS}}_{i,t}$	Discharging power of CS at bus i at time t.
$\zeta^{\text{DL}}_{i,j,t}$	State of DL j at bus i at time t.
$\zeta^{\text{DL}}_{i,j,t_0}$	State of DL j at bus i in current time slot t_0.
$P^{\text{DL}}_{i,j,t}$	Power consumed by DL j at bus i at time t.
$\zeta^{\text{task}}_{i,j,k,t}$	State of task k for DL j at bus i at time t.
$P^{\text{RE}}_{i,g,t}, Q^{\text{RE}}_{i,g,t}$	Active, reactive power supplied by RESs g at bus i at time t.

Parameters

$p^{\text{FL}}_{i,t}, q^{\text{FL}}_{i,t}$	Inflexible (fixed) active, reactive load demand at bus i at time t.
r_{ij}, x_{ij}	Resistance, reactance of a line connecting buses i and j.
$N^{a}_{i,t}, N^{d}_{i,t}$	No. of EVs arrived, departed at bus i at time t.
$E^{a,\text{EV}}_{i,n}$	Residual energy of arrived EV n at bus i.
$E^{d,\text{EV}}_{i,n}$	Desired energy at departure of EV n at bus i.
$\eta^{\text{CS}}_{\text{ch},i}, \eta^{\text{CS}}_{\text{dch},i}$	Efficiencies of the charging, discharging power of CS at bus i.
$\overline{E}^{\text{CS}}_{i,t}, \underline{E}^{\text{CS}}_{i,t}$	Upper, lower bound of the residual energy of CS at bus i at time t.
$\overline{P}^{\text{ch,CS}}_{i,t}$	Maximum charging power of CS at bus i at time t.
$\overline{P}^{\text{dch,CS}}_{i,t}$	Maximum discharging power of CS at bus i at time t.
$\overline{P}^{\text{ch,EV}}_{i,n}$	Maximum charging power of EV n at bus i.
$\overline{P}^{\text{dch,EV}}_{i,n}$	Maximum discharging power of EV n at bus i.
$\overline{E}^{\text{EV}}_{i,n,t}, \underline{E}^{\text{EV}}_{i,n,t}$	Upper, lower bound of the residual energy of EV n at bus i at time t.
$\eta^{\text{dch,EV}}_{i,n}$	Discharging power efficiency of EV n at bus i.
$\eta^{\text{ch,EV}}_{i,n}$	Charging power efficiency of EV n at bus i.
$t^{\text{EV}}_{a,n}, t^{\text{EV}}_{d,n}$	Arrival, departure time of EV n.
$\underline{E}^{\text{EV}}_{i,n}$	Minimum of residual energy of EV n at bus i.
$\overline{E}^{\text{EV}}_{i,n}$	Maximum of residual energy of EV n at bus i.
$\alpha_{i,j}, \beta_{i,j}$	Starting, ending time (operational) of DL j at bus i.
$\hat{\zeta}^{\text{DL}}_{i,j,t}$	State of DL j at bus i in previous time slot t.
$\text{Z}^{\text{DL}}_{i,j}$	No. of time slots (operational) required by DL j at bus i.
$E^{\text{DL}}_{i,j}$	Energy required by DL j at bus i.
$P^{\text{task}}_{i,j,k}$	Rated power of task k for DL j at bus i.
$\text{Z}^{\text{task}}_{i,j,k}$	No. of time slots (operational) required by DL j at bus i to finish task k.
$S^{\text{RE}}_{i,g,t}$	Apparent power capacity of RES g at bus i at time t.

$\phi_{i,g}$ Angle defining power factor of RES g at bus i.
$P^{\text{RE,fore}}_{i,g,t}$ Active power forecast for RES g at bus i at time t.

I. Introduction

A. Background

THE paradigm shift toward clean energy fundamentally relies upon electrification, leading to an escalation in power consumption and a concurrent surge in the quantity and diversity of electrical devices capable of adjusting their demand. For instance, heat pumps are gradually replacing traditional gas boilers. In parallel, the grid has witnessed a notable upswing in the adoption of electric vehicles (EVs) and renewable energy sources (RESs), prominently photovoltaic (PV) panels. Distributed energy resources (DERs) equipped with diverse technologies, such as deferrable loads (DLs), RESs, and EVs, are dynamically transforming the energy framework, steering it toward a more de-carbonized and secure configuration. Thus, recognizing and harnessing the full potential of DERs becomes indisputably paramount. However, managing a substantial array of DERs to facilitate seamless system-wide functioning and control requires a permissive regulatory framework, adaptable infrastructure, and suitable software platforms, which costs a fortune to electric utilities (EUs) [1]. As a result, many EUs are still grappling with sorting out DERs to blend into the grid, seeking to enhance both reliability and energy cost savings.

Recently, there has been a notable increase in the contribution of weather-dependent and variable RESs to the energy generation mix. This trend highlights the growing necessity for enhanced flexibility to ensure a consistent power supply that meets evolving demand patterns. Installing energy storage systems (ESs) alongside RESs has been proposed as a viable and effective strategy for enhancing the adept localization of RESs within distribution networks. However, the practical feasibility and associated costs of implementing such integrated RESs with ESs present challenges that impede their widespread adoption [2]. Consequently, EVs, which share analogous electrical characteristics with ESs, have emerged as a promising resource to facilitate the greater penetration of RESs. Moreover, the strategic temporal scheduling of spatially dispersed DLs can enhance RESs spread through significant demand flexibility. However, a collective surge in the charging of EVs and activation of DLs could lead to sudden spikes in power demand, potentially overwhelming the grid's capacity, unless measures are employed to smooth and distribute peak demand across off-peak periods [3].

As the challenges in the energy landscape are constantly evolving, it is of the utmost importance for EU operators to take a proactive approach to managing distribution networks and DERs. However, DERs can often operate invisibly and lie beyond EU operator control, which presents a challenge due to their intricate behavior. Integrating them into the broader grid operations requires digital technologies that can actively engage individuals as participants. Further, the transition to cleaner energy must be not only to gain political support for clean energy projects but also to foster local acceptance of new developments and infrastructure. Therefore, community-based initiatives are gaining traction as effective ways to create DER-enabled energy systems that are more people-centric, equitable, and resilient [4].

B. Related Literature Review and Research Gap

The growing integration of DERs undeniably enhances the flexibility of the distribution system. However, due to the relatively low individual power capacity and sheer quantities of DERs, a challenge known as the "curse of dimensionality" emerges. Thus, effectively managing each unit of DER becomes impractical within the operational framework of the distribution system [5]. As a solution, existing research suggests employing aggregated operational models at the distribution level for efficiently managing multiple small-capacity DERs [6]. Essentially, these approaches utilize the feasible limits of crucial parameters of DER to exploit flexibility. In [7], the aggregation model has been developed by an arithmetic sum of the individual feasible limits of DERs to determine cumulative flexibility, providing an outer boundary of the feasible region. However, the method has had issues producing viable solutions during the disaggregation process as it enlarged the feasible operation regions [8]. Thus, it further requires an additional problem formulation to ensure a workable solution, which results in higher information communication exchange [9]. Furthermore, methods have aimed to produce feasible disaggregation solutions, albeit increasing the computing burden [10], [11].

Moreover, [12] considers the inner-box approximation to define the feasible aggregate upper and lower power trajectories. In [13], a convex inner approximation is introduced to quantify a feeder's aggregate DER hosting capacity. However, inner aggregation methods substantially compromise the dispatching potential of DERs. As a result, it has become pivotal for future works to aggregate the viable parameter boundaries to enhance precision and practicality while still unleashing the untapped potential of DERs [14].

Recent research has explored integrating aggregators with distribution network operators to harness the collective potential of EVs and delayable loads. In [15], a methodology is outlined for efficient and secure dispatching of DERs. However, it assumes that the DERs can consume power from the grid, neglecting the possibility of bidirectional power flow. In [16], a hierarchical control framework (HCF) is introduced to optimize power flexibility within smart homes equipped with DLs, but its centralized approach raises privacy and data vulnerability concerns. In [17] and [18], an analytical expression is derived to define the dispatchable region for a large fleet of EVs. However, while these methods expand the feasible dispatchable region, they rely on relaxed complementarity constraints for EV battery modeling, which may not hold under practical conditions [19]. Moreover, the methods to assess the exact power flexibility of EVs and delayable loads are put forth in [11] and[20]. However, these models fail to account for the diverse parameters inherent to DERs. In this article, the constraints for aggregating EVs and DLs impose stringent conditions to improve accuracy.

Moreover, to fully exploit the benefits of flexibility derived from DERs, it is necessary to have a suitable control scheme in place. In the literature, various control methods [21], [22], [23], [24], [25], [26], including centralized, decentralized, hybrid, and hierarchical controls, are often applied for optimizing problems, such as voltage regulation, transmission congestion, demand response, uncertainty modeling, and reactive power dispatch, by utilizing the flexibility offered by DERs. Centralized control is frequently employed to coordinate multiple DERs effectively, owing to the increased visibility of the network [21], [22]. On the other hand, decentralized control enables for more quick

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 06:36:46 UTC from IEEE Xplore. Restrictions apply.

This article has been accepted for inclusion in a future issue of this journal. Content is final as presented, with the exception of pagination.

response times [23], [24]. Consequently, a combination of centralized and decentralized control methods is often adopted to leverage the benefits of both approaches [25]. However, the existing strategies for regulating flexibility overlook crucial aspects, such as the physical distribution of flexibility within the network, the operational limits of individual flexible resources, and grid constraints, which significantly impact the performance of the distribution system [27].

C. Contribution and Article Layout

This article puts forth the existing gap in the literature related to the effective aggregation and control of a diverse array of DERs dispersed throughout a distribution system into three key aspects: first, a lack of EVs and DLs aggregation modeling with stringent constraints to accurately assess cumulative and practical feasible flexibility. Second, the failure to consider distribution network constraints in EVs and DLs flexibility evaluation. Finally, a control scheme is absent that not only effectively coordinates among stakeholders but also ensures the preservation of their data privacy concerns and respects their preferences for self-optimization. While comparing with the existing literature, the main contributions can be summarized as follows:

1) Proposed an aggregation model aimed at assessing the collective feasible operational range for a substantial EV fleet at a charging station (CS). In contrast to [11], [17], [18], and [20], the presented approach notably enhances precision and computational efficiency in effectively managing extensive EVs with considerations for spatial placement and temporal behavior.
2) Presented an approach for DLs modeling represented by unique operational tasks, with the primary objective of facilitating time of use (ToU) price-based demand response. Unlike the existing literature [7], [11], [15], [16], and [20], the proposed model assesses the influence of a large population of DLs on the distribution system, considering their integration into the network.
3) In contrast with prior literature [8] and [20], this article proposed an HCF to facilitate the coordination of the EU operator, community aggregators (CAs), and individual DERs, thereby optimizing the deployment of DERs for cost-optimal operations within local energy communities (LECs) and improved grid services, while considering the distribution network constraints.

The rest of this article is organized as follows. Section II briefs the proposed aggregation and control framework and the branch power flow model for distribution network modeling. The model for EVs aggregation at CS and the modeling of DLs for ToU price-based demand response mechanism are discussed in Section III. The HCF optimal operation strategy for LECs and the EU operator is formulated in Section IV. Numerical results are presented in Section V. Finally, Section VI concludes this article.

II. Proposed Framework Overview and Network Modeling

This article considers the multiple LECs in the distribution system that consist of fixed (nondeferrable) loads along with

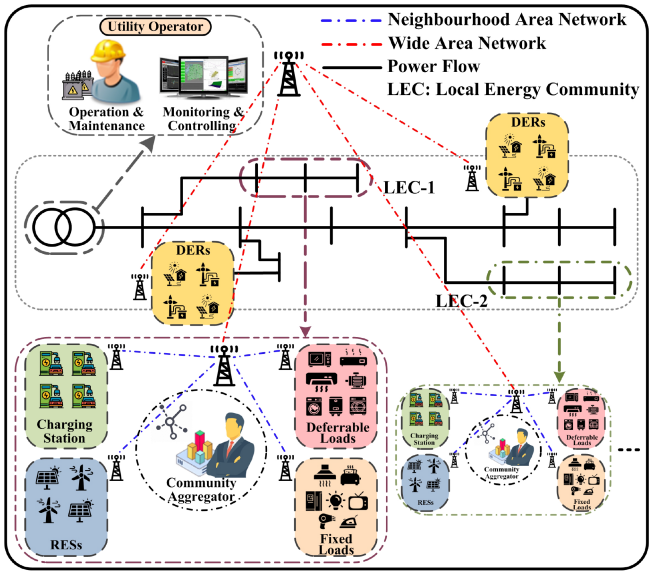

Fig. 1. Schematic of the proposed aggregation and control framework.

different DERs, such as CSs, DLs, and RESs, in the form of PV plants and wind turbine (WT) farms, as shown in Fig. 1. The proposed work assumed that the CAs manage DERs dispersed within their communities. In addition, an EU operator oversees LECs and disaggregated DERs, such as ESs integrated with PV plants and WT farms.

For simplicity, a radial distribution network (RDN) with a single feeder connected to EU modeled by a tree graph $\mathcal{G} := (\mathcal{N}, \mathcal{E})$, where $i \in \mathcal{N} := 1, 2, \ldots, n$ represents a node and $(i, j) \in \mathcal{E} \subseteq \mathcal{N} \times \mathcal{N}$ represents a distribution line connected ith to jth nodes. The relaxed branch flow model presented in [28] is employed for power flows for this network, as expressed in (1a)–(1d); where, for each node $i \in \mathcal{N}$ at tth time interval, denote $\upsilon_{i,t}^{\text{node}} = |V_{i,t}^{\text{node}}|^2$ refers to magnitude squared of node voltage. Let $s_{i,t}^{\text{FL}} = p_{i,t}^{\text{FL}} + jq_{i,t}^{\text{FL}}$ be node i net complex fixed load demand. Similarly, for each line $(i, j) \in \mathcal{E}$ at tth time interval, denote $l_{ij,t}^{\text{flow}} := |I_{ij,t}^{\text{flow}}|^2$ refers to magnitude squared of branch current flows from i node to j node. Let $S_{ij,t}^{\text{flow}} = P_{ij,t}^{\text{flow}} + jQ_{ij,t}^{\text{flow}}$ be the *sending-end* branch flow from i node to j node. A solution of (1a)–(1d) to a given s^{FL} is denoted by $x(s^{\text{FL}}) := (S^{\text{flow}}, I^{\text{flow}}, V^{\text{node}}, s_0^{\text{FL}})$, is unique for practical radial network where $|V_0| \simeq 1$ and r_{ij}, x_{ij} are small p.u. values

$$p_{j,t}^{\text{FL}} = \sum_{i:i\to j} \left(P_{ij,t}^{\text{flow}} - r_{ij} l_{ij,t}^{\text{flow}}\right) - \sum_{k:j\to k} P_{jk,t}^{\text{flow}} \tag{1a}$$

$$q_{j,t}^{\text{FL}} = \sum_{i:i\to j} \left(Q_{ij,t}^{\text{flow}} - x_{ij} l_{ij,t}^{\text{flow}}\right) - \sum_{k:j\to k} Q_{jk,t}^{\text{flow}} \tag{1b}$$

$$\upsilon_{j,t}^{\text{node}} = \upsilon_{i,t}^{\text{node}} - 2\left(r_{ij} P_{ij,t}^{\text{flow}} + x_{ij} Q_{ij,t}^{\text{flow}}\right) + \left(r_{ij}^2 + x_{ij}^2\right) l_{ij,t}^{\text{flow}} \tag{1c}$$

$$\upsilon_{i,t}^{\text{node}} l_{ij,t}^{\text{flow}} = \left(P_{ij,t}^{\text{flow}}\right)^2 + \left(Q_{ij,t}^{\text{flow}}\right)^2. \tag{1d}$$

Furthermore, the proposed control framework considers the LEC a *subnetwork* comprising DERs linked to the distribution feeder line via a single point of common coupling. Initially, the CA gathers energy demands and behavioral data from DERs

This article has been accepted for inclusion in a future issue of this journal. Content is final as presented, with the exception of pagination.

dispersed within its operational region. It then evaluates the feasible energy flexibility to facilitate effective dispatching, aiming for the optimal utilization of DERs to achieve cost-optimal operation within the LEC while considering distribution network constraints. As seen in Fig. 1, the information flow is depicted by dotted lines. Subsequently, the CA communicates these dispatch setpoints to the EU operator, who is responsible for coordination among disaggregated DERs and dispatch setpoints received from CAs, aiming to improve grid services while accounting for distribution network constraints.

III. DERs Aggregation Model

To effectively incorporate a substantial number of DERs into the overall system operation, it is imperative to establish an aggregate model that can encompass and account for their inherent flexibility. This article focuses primarily on two crucial categories of DERs, namely, EVs and DLs. This section elucidates the modeling approach employed for aggregating EV fleets at CS and for aggregating DLs to facilitate ToU price-based demand response.

A. Model for EVs Aggregation at CS

In practice, the CS can gather critical data regarding EVs upon connection, including arrival and departure time, the initial and desired energy, the maximum charging rate, and the user-defined charging duration [17]. The ebb and flow of EV arrivals and departures contribute to a dynamic fluctuation in the number of EVs present at the CS over time. Consequently, the EV fleets at the CS are aggregated into a unified entity with time-dependent power and energy constraints, effectively characterizing the operational parameters of the CS.

1) The power capacity constraints of EV aggregation

$$P_{i,t}^{\text{dch,CS}} \le \overline{P}_{i,t}^{\text{dch,CS}} - \left(\overline{P}_{i,t}^{\text{dch,CS}} / \overline{P}_{i,t}^{\text{ch,CS}}\right) P_{i,t}^{\text{ch,CS}} \tag{2a}$$

$$0 \le P_{i,t}^{\text{ch,CS}} \le \overline{P}_{i,t}^{\text{ch,CS}} \tag{2b}$$

$$0 \le P_{i,t}^{\text{dch,CS}} \le \overline{P}_{i,t}^{\text{dch,CS}} \tag{2c}$$

$$\overline{P}_{i,t}^{\text{ch,CS}} = \overline{P}_{i,t}^{\text{ch,CS}} + \overline{P}_{i,n\in N}^{\text{ch,EV}} \left(N_{i,t}^{a} - N_{i,t}^{d}\right) \tag{2d}$$

$$\overline{P}_{i,t}^{\text{dch,CS}} = \overline{P}_{i,t}^{\text{dch,CS}} + \overline{P}_{i,n\in N}^{\text{dch,EV}} \left(N_{i,t}^{a} - N_{i,t}^{d}\right) \tag{2e}$$

where (2a) is from the **Extn-LP** formulation for the battery modeling proposed in [29] and utilized for the reduction in the feasible search space. Constraints in (2b) and (2c) delineate the upper and lower bounds on the charging and discharging powers at CS at bus i at time slot t, respectively. Further, (2d) and (2e) quantify the upper boundaries of charging and discharging power at CS at bus i at time slot t, respectively.

2) The energy capacity constraints of EV aggregation

$$E_{i,t}^{\text{EV}(a,d)} = \sum_{n=1}^{N_{i,t}^{a}} E_{i,n}^{a,\text{EV}} - \sum_{n=1}^{N_{i,t}^{d}} E_{i,n}^{d,\text{EV}} \tag{3a}$$

$$E_{i,t}^{\text{CS}} = E_{i,t-1}^{\text{CS}} + \left[\eta_{\text{ch},i}^{\text{CS}} P_{i,t}^{\text{ch,CS}} - \frac{P_{i,t}^{\text{dch,CS}}}{\eta_{\text{dch},i}^{\text{CS}}}\right] \times \Delta t + E_{i,t}^{\text{EV}(a,d)} \tag{3b}$$

$$\left(\eta_{\text{ch},i}^{\text{CS}} P_{i,t}^{\text{ch,CS}}\right) \Delta t \le \left(\overline{E}_{i,t}^{\text{CS}} - E_{i,t-1}^{\text{CS}} - E_{i,t}^{\text{EV}(a,d)}\right) \tag{3c}$$

$$\left(P_{i,t}^{\text{dch,CS}}\right) \Delta t \le \left(E_{i,t-1}^{\text{CS}} + E_{i,t}^{\text{EV}(a,d)} - \underline{E}_{i,t}^{\text{CS}}\right) \eta_{\text{dch},i}^{\text{CS}} \tag{3d}$$

$$\underline{E}_{i,t}^{\text{CS}} \le E_{i,t}^{\text{CS}} \le \overline{E}_{i,t}^{\text{CS}} \tag{3e}$$

$$\underline{E}_{i,t}^{\text{CS}} = \underline{E}_{i,t-1}^{\text{CS}} + \sum_{n=1}^{N_{i,t}^{a}} \underline{E}_{i,n,t}^{\text{EV}} - \sum_{n=1}^{N_{i,t}^{d}} E_{i,n}^{d,\text{EV}} \tag{3f}$$

$$\overline{E}_{i,t}^{\text{CS}} = \overline{E}_{i,t-1}^{\text{CS}} + \sum_{n=1}^{N_{i,t}^{a}} \overline{E}_{i,n,t}^{\text{EV}} - \sum_{n=1}^{N_{i,t}^{d}} E_{i,n}^{d,\text{EV}} \tag{3g}$$

In (3a), $E_{i,t}^{\text{EV}(a,d)}$ denotes the amount of energy received from arriving EVs and subtracting the desired energy of departing EVs at bus i at time slot t. (3b) outlines the energy update rule for CS at bus i at time slot t. Notably, (3c) and (2b) results in a more stringent condition: $P_{i,t}^{\text{ch,CS}} \le \min\{\overline{P}_{i,t}^{\text{ch,CS}}, (\overline{E}_{i,t}^{\text{CS}} - E_{i,t-1}^{\text{CS}} - E_{i,t}^{\text{EV}(a,d)})\}$, that enforces a tighter upper bound on the charging power capacity, while (3d) and (2c) yields a more rigorous constraint: $P_{i,t}^{\text{dch,CS}} \le \min\{\overline{P}_{i,t}^{\text{dch,CS}}, (E_{i,t-1}^{\text{CS}} + E_{i,t}^{\text{EV}(a,d)} - \underline{E}_{i,t}^{\text{CS}})\}$, that establishes a tighter upper bound on the discharging power capacity, as in [29]. Furthermore, (3e) imposes restrictions on the energy at CS at bus i at time slot t. Constraints (3f) and (3g) calculate the lower and upper boundaries, respectively, for the net energy at CS at bus i at time slot t. Finally, constraints (3h) and (3i) shown at the bottom of this page, determine the permissible operational range for an EV n at CS at bus i at time slot t.

1) Illustrative Example: To better illustrate the proposed model and conduct a comparative analysis with previously reported aggregation models in [17] and [18], we have employed a case study involving two specific EVs. The parameters and underlying assumptions are drawn from [17] and presented in Table I. The notations $t_{a,n}^{\text{EV}}$ and $t_{d,n}^{\text{EV}}$ denote the arrival and

$$\underline{E}_{i,n,t}^{\text{EV}} = \begin{cases} 0, & t \in T \setminus \left[t_{a,n}^{\text{EV}}, t_{d,n}^{\text{EV}}\right] \\ \max\left\{\underline{E}_{i,n}^{\text{EV}}, E_{i,n}^{a,\text{EV}} - \frac{\overline{P}_{i,n,t}^{\text{dch,EV}}}{\eta_{i,n}^{\text{dch,EV}}}\left(t - t_{a,n}^{\text{EV}}\right), E_{i,n}^{d,\text{EV}} - \eta_{i,n}^{\text{ch,EV}} \overline{P}_{i,n,t}^{\text{ch,EV}}\left(t_{d,n}^{\text{EV}} - t\right)\right\}, & t_{a,n}^{\text{EV}} \le t \le t_{d,n}^{\text{EV}} \end{cases} \tag{3h}$$

$$\overline{E}_{i,n,t}^{\text{EV}} = \begin{cases} 0, & t \in T \setminus \left[t_{a,n}^{\text{EV}}, t_{d,n}^{\text{EV}}\right] \\ \min\left\{\overline{E}_{i,n}^{\text{EV}}, E_{i,n}^{a,\text{EV}} + \eta_{i,n}^{\text{ch,EV}} \overline{P}_{i,n,t}^{\text{ch,EV}}\left(t - t_{a,n}^{\text{EV}}\right), E_{i,n}^{d,\text{EV}} + \frac{\overline{P}_{i,n,t}^{\text{dch,EV}}}{\eta_{i,n}^{\text{dch,EV}}}\left(t_{d,n}^{\text{EV}} - t\right)\right\}, & t_{a,n}^{\text{EV}} \le t \le t_{d,n}^{\text{EV}}. \end{cases} \tag{3i}$$

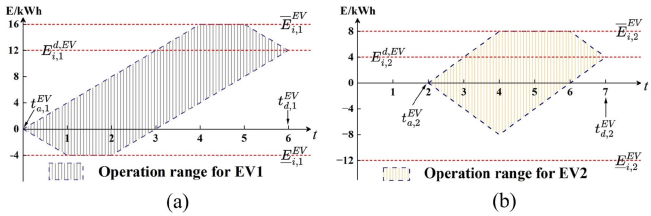
TABLE I
PARAMETERS OF EVS [17]

EV	$t^{\mathrm{EV}}_{a,n}$	$t^{\mathrm{EV}}_{d,n}$	$E^{a,\mathrm{EV}}_{i,n}$ (kWh)	$\overline{P}^{\mathrm{ch,CS}}_{i,t}$ / $\overline{P}^{\mathrm{dch,CS}}_{i,t}$ (kW)	$B^{\mathrm{EV}}_{i,n}$ (kWh)
1	0	6	4	4	20
2	2	7	12	4	20



(a) (b)

Fig. 2. Operation ranges of the individual EV1 and EV2.

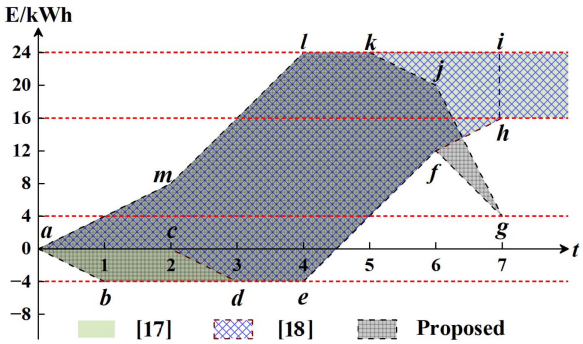


Fig. 3. Operation range for EVs aggregation (EV1 and EV2) models.

departure times of the nth EV respectively, while $E^{a,\mathrm{EV}}_{i,n}$ indicates the residual energy of EV n at bus i upon arrival, exemplified by 4 kWh for EV1 and 12 kWh for EV2. Moreover, $\overline{P}^{\mathrm{ch,CS}}_{i,t}/\overline{P}^{\mathrm{dch,CS}}_{i,t}$ signifies the maximum charging or discharging powers of the CS i at time slot t, and $B^{\mathrm{EV}}_{i,n}$ represents the maximum energy storage capacity of the EV n at bus i . Furthermore, it is assumed that the desired energy level for both EVs upon departure is set at 16 kWh.

The operational regions for EV1 and EV2 are computed utilizing (3h) and (3i), and the results are depicted in Fig. 2(a) and (b), respectively. Further, employing (3f) and (3g) from the proposed model, the energy aggregation of EV1 and EV2 at CS and a comparative evaluation against the models in [17] and [18] is shown in Fig. 3. Corresponding to the 4th interval, EV2 can discharge up to 8 kWh from its initial energy state, as depicted in Fig. 2(b). On the other hand, for the same interval, EV1 requires charging up to 4 kWh from its initial energy state, as shown in Fig. 2(a). Hence, Fig. 3, which represents the aggregation of Fig. 2(a) and (b) gives the net discharging of the CS up to 4 kWh. Furthermore, the upper aggregate energy limit of the CS starts to decline in the 5th time slot to obligate the energy desired by EV1 before it departs from CS. The reduction is further underlined in the next time slots, coinciding with the departures of EV1 from the CS in the sixth and EV2 in the seventh, consequently rendering their energy unavailable for dispatch. In contrast, prior methods exemplified in [17] and [18] exhibit different behavior, where the energy limits of EVs accumulate in subsequent time slots even after they depart from the CS.

In addition, the earlier studies, as in [17] and [18], assume that EVs may charge up to or above the stipulated desired energy, as shown in Fig. 3. This study delves into a critical inquiry: why would an EV be willing to pay for charging over their desired energy? Therefore, the proposed method restrains the upper bound to the desired energy level at the departure time of an EV, refer to Fig. 2.

B. DLs Aggregation for ToU Price-Based Demand Response

Effectively managing a range of DLs is essential in proactively mitigating the risk of sudden surges in power demand and reducing overall electricity payments in ToU pricing environments, thereby optimizing energy efficiency and economic outcomes within an LEC. To achieve this, CAs are responsible for gathering information from consumers and the electricity market, including ToU electricity prices, spatial and temporal operational characteristics, and the energy demands linked to individual household loads.

Mathematically, the modeling for DL aggregation to provide demand response is as follows:

$$\zeta^{\mathrm{DL}}_{i,j,t} = 0, \quad t \in T \setminus [\alpha_{i,j}, \beta_{i,j}] \tag{4a}$$

$$\sum_{t=\alpha_{i,j}}^{t_0-1} \hat{\zeta}^{\mathrm{DL}}_{i,j,t} + \zeta^{\mathrm{DL}}_{i,j,t_0} + \sum_{t=t_0+1}^{\beta_{i,j}} \zeta^{\mathrm{DL}}_{i,j,t} = \mathrm{Z}^{\mathrm{DL}}_{i,j} \tag{4b}$$

$$\sum_{t=\alpha_{i,j}}^{t_0-1} \hat{P}^{\mathrm{DL}}_{i,j,t} + P^{\mathrm{DL}}_{i,j,t_0} + \sum_{t=t_0+1}^{\beta_{i,j}} P^{\mathrm{DL}}_{i,j,t} = E^{\mathrm{DL}}_{i,j} \tag{4c}$$

where (4a) makes sure that an DL j at bus i must function within the predetermined operational time-frame $[\alpha_{i,j}, \beta_{i,j}]$ as specified by the consumer. Constraint (4b) describes that an DL j at bus i requires total $\mathrm{Z}^{\mathrm{DL}}_{i,j}$ time slots to complete all tasks, consequently, DL j needs to start no later than $\beta_{i,j} - \mathrm{Z}^{\mathrm{DL}}_{i,j} + 1$ and be finished no earlier than $\alpha_{i,j} + \mathrm{Z}^{\mathrm{DL}}_{i,j}$. In addition, a DL j at bus i has prespecified energy requirement $E^{\mathrm{DL}}_{i,j}$ to complete all tasks, as shown in (4c).

For a DL j at bus i that has multiple operation tasks $k = 1, 2, \ldots, N_{j,k}$ with distinct power levels and are mutually exclusive to each other are described in (5a)–(5b). However, these tasks must operate in a sequence, where the first task must finished before the second task starts, which is ensured in constraint (5c)

$$P^{\mathrm{DL}}_{i,j,t} = \sum_{k=1}^{N_{j,k}} P^{\mathrm{task}}_{i,j,k} \xi^{\mathrm{task}}_{i,j,k,t} \tag{5a}$$

$$\zeta^{\mathrm{DL}}_{i,j,t} = \sum_{k=1}^{N_{j,k}} \xi^{\mathrm{task}}_{i,j,k,t} \tag{5b}$$

$$\sum_{x=1}^{k-1} \sum_{t=\alpha_{i,j,k}}^{t_0-1} \xi^{\mathrm{task}}_{i,j,x,t} \geq \left(\sum_{x=1}^{k-1} \mathrm{Z}^{\mathrm{task}}_{i,j,k} \right) \xi^{\mathrm{task}}_{,i,j,x,t_0}. \tag{5c}$$

This article categorizes the tasks of a DL based on their operational characteristics, notably distinguishing between interruptible and deferrable tasks and noninterruptible and deferrable tasks. A graphical example in Fig. 4 demonstrates the distinction between task types, where the overall time frame for a sequential

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 06:36:46 UTC from IEEE Xplore. Restrictions apply.

This article has been accepted for inclusion in a future issue of this journal. Content is final as presented, with the exception of pagination.

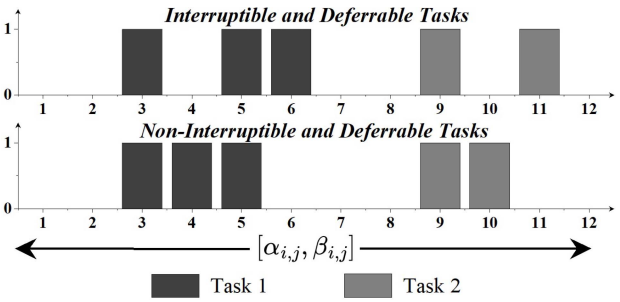

Fig. 4. Graphical example of residential DL with distinct types of tasks.

task is between 1 and 12; the total time slots required to complete task 1 is three, and task 2 is two. Moreover, it is shown that task 1 finishes before the start of task 2.

1) Interruptible and Deferrable Task: For an interruptible and deferrable task, the starting time may vary within the designated operational time frame, denoted as $[\alpha_{i,j,k}, \beta_{i,j,k}]$. Equation (6) assures that the operation of a DL can defer, with the constraint that the delay must not exceed a predetermined time threshold $[\alpha_{i,j,k} + \varphi_{i,j,k}]$, where $\varphi_{i,j,k}$ represents the acceptable duration of delay as perceived by consumers

$$\sum_{t=\alpha_{i,j,k}}^{t_0-1} \hat{\xi}^{\text{task}}_{i,j,k,t} + \xi^{\text{task}}_{i,j,k,t_0} + \sum_{t=t_0+1}^{\alpha_{i,j,k}+\varphi_{i,j,k}} \xi^{\text{task}}_{,i,j,k,t} \geq 1. \tag{6}$$

2) Noninterruptible and Deferrable Task: Deferrable characterizes the rescheduling of a task during the course of the day. Conversely, once it starts, to mitigate any potential reductions in thermal efficiency, it is imperative to complete it without interruption. Constraints (6) and (7) are employed to delineate the attributes of noninterruptible and deferrable properties

$$\sum_{t=t_0+1}^{t_0+\text{Z}^{\text{task}}_{i,j,k}} \xi^{\text{task}}_{i,j,k,t} \geq \text{Z}^{\text{task}}_{i,j,k} \left(\xi^{\text{task}}_{i,j,k,t_0+1} - \xi^{\text{task}}_{i,j,k,t_0}\right). \tag{7}$$

IV. Optimal Operation Strategy of LECs and EU Operator

This study incorporates an HCF optimal operation strategy for executing controls of DERs flexibility at both the LEC and EU levels. The primary objective of the CA is to enable the activation of DERs within an LEC based on signals from the EU operator and grid constraint considerations for optimal cost operations. In turn, the EU operator assumes to coordinate all CAs and provide dispatch setpoints to disaggregated DERs on the feeder while considering network constraints to improve the performance of the electrical grid.

A. Cost Optimal Dispatch Problem Formulation

CA solves the following problem formulation to optimize its operation cost and determine the dispatch setpoints for the available DERs within the LEC

$$\textbf{min} \quad \sum_{t\in T}\sum_{i\in\mathcal{N}} \left[\lambda^{\text{ToU}}_{\text{RL},t}\left(p^{\text{FL}}_{i,t} + \sum_{j\in\mathcal{N}^{\text{SL}}_i} P^{\text{SL}}_{i,j,t}\right)\right.$$
$$\left. + \lambda_{\text{RE},t}\left(\sum_{g\in\mathcal{G}_i} P^{\text{RE}}_{i,g,t}\right) + \lambda^{\text{ToU}}_{\text{CS},t}\left(P^{\text{ch,CS}}_{i,t} - P^{\text{dch,CS}}_{i,t}\right)\right] \tag{8a}$$

$$\text{s.t. } (1)-(7), \upsilon^{\text{node}}_i \in \left\{\underline{V}_i, \overline{V}_i\right\} \tag{8b}$$

$$\left(P^{\text{RE}}_{i,g,t}\right)^2 + \left(Q^{\text{RE}}_{i,g,t}\right)^2 \leq \left(S^{\text{RE}}_{i,g,t}\right)^2 \tag{8c}$$

$$-\phi_{i,g} P^{\text{RE}}_{i,g,t} \leq Q^{\text{RE}}_{i,g,t} \leq \phi_{i,g} P^{\text{RE}}_{i,g,t} \tag{8d}$$

$$0 \leq P^{\text{RE}}_{i,g,t} \leq P^{\text{RE,fore}}_{i,g,t}. \tag{8e}$$

The objective (8a) aims to minimize the overall operation cost, where the first term denotes the electricity payments from CA to the EU operator to supply the power required for fixed $(p^{\text{FL}}_{i,t})$ and DL $(P^{\text{SL}}_{i,j,t})$ demands. The $\lambda^{\text{ToU}}_{\text{RL},t}$ represents the standard ToU electricity rate that applies to power purchased from the EU. The second term in (8a) denotes the payments from CA to RESs for procuring power at a fixed electricity rate, $\lambda_{\text{RE},t}$. The third term in (8a), denoted as $\lambda^{\text{ToU}}_{\text{CS},t}(P^{\text{ch,CS}}_{i,t} - P^{\text{dch,CS}}_{i,t})$, refers to the cost of electricity for the net charging power demand of a CS. The constraints in (8b)–(8e) ensure the feasibility of power flow in the network and DERs power bounds. The constraint (8b) bounds voltages magnitude within specified limits, which implicitly characterize the use of voltage regulators/shunt capacitor banks. Constraints (8c) and (8d) ensure balance in active and reactive power sourced from RESs integrated inside an LEC and keep the power factor constant.

B. Problem Formulation for Coordination Between CAs and EU Operator

In this article, the EU operator aims to improve grid services by reducing voltage regulation and power loss in the distribution network while aligning with the desired dispatch setpoints from the CAs and optimizing the dispatch of disaggregated DERs. Mathematically, the problem formulation for the proposed approach is as follows:

$$\textbf{min} \quad \sum_{t\in T}\left[\sum_{i\in\mathcal{N}}\left[\gamma_{\text{vd}}\left(V^{\text{node}}_{i,t} - V_{\text{nom}}\right)^2\right]\right.$$
$$\left. + \sum_{(i,j)\in\mathcal{E}}\left[\gamma_{\text{loss}}\left(r_{ij} l^{\text{flow}}_{ij,t}\right)\right]\right] \tag{9a}$$

$$\text{s.t. } (1a)-(1d) \text{ for } \upsilon^{\text{node}}_{i,t} \in \left\{\underline{V}_i, \overline{V}_i\right\}, p^{\text{agg}}_{i,t} \tag{9b}$$

$$p^{\text{agg}}_{i,t} = -\sum_{g\in\mathcal{G}_i} P^{\text{RE}}_{i,g,t} + P^{\text{ch,CS}}_{i,t} + \sum_{j\in\mathcal{N}^{SL}_i} P^{\text{SL}}_{i,j,t} \tag{9c}$$

$$\left(P^{\text{RE,DA}}_{i,g,t}\right)^2 + \left(Q^{\text{RE,DA}}_{i,g,t}\right)^2 \leq \left(S^{\text{RE,DA}}_{i,g,t}\right)^2 \tag{9d}$$

$$-\phi_{i,g} P^{\text{RE,DA}}_{i,g,t} \leq Q^{\text{RE,DA}}_{i,g,t} \leq \phi_{i,g} P^{\text{RE,DA}}_{i,g,t} \tag{9e}$$

$$0 \leq P^{\text{RE,DA}}_{i,g,t} \leq P^{\text{RE,fore}}_{i,g,t} \tag{9f}$$

$$E^{\text{ES}}_{i,t} = E^{\text{ES}}_{i,t-1} + \left[\eta^{\text{ES}}_{\text{ch},i} P^{\text{ch,ES}}_{i,t} - \frac{P^{\text{dch,ES}}_{i,t}}{\eta^{\text{ES}}_{\text{dch},i}}\right]\Delta t \tag{9g}$$

$$(2a)-(2c), (3c)-(3e) \text{ for } E^{\text{ES}}_{i,t}, P^{\text{ch,ES}}_{i,t}, P^{\text{dch,ES}}_{i,t}. \tag{9h}$$

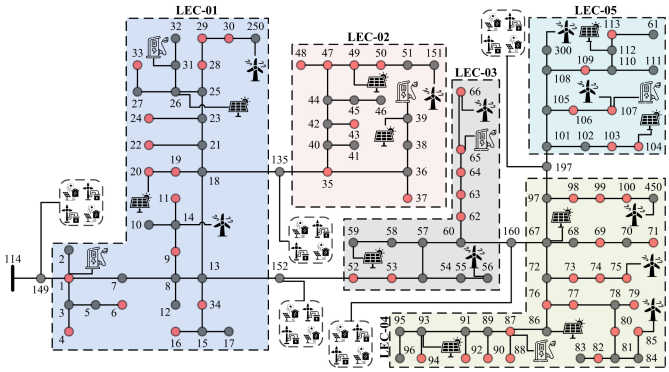

Fig. 5. Modified IEEE 123 bus RDN.

In (9a), the first term aims to enhance node voltages, and the second term minimizes the network power losses. The γ in (9a) denotes for appropriate weights given to the indices in the objective function. The constraints in (9b)–(9h) establish the feasible operations of the DERs and viable network power flow. The constraint (9b) ensures the voltage regulation within specified limits, and (9d)–(9e) regulate the reactive power of the disaggregated RESs. Notably, the EU operator refrains from altering the demand requirements specified by the CAs, thereby eliminating the need for a separate disaggregation problem formulation. Consequently, this approach offers a sequential solution that is computationally efficient and maintains optimality. Unlike during the disaggregation, which often necessitates deviations or curtailments in the preferred energy demand of CA, the proposed method effectively mitigates such suboptimality concerns.

V. Simulation Results and Discussion

The proposed problem is tested on a modified IEEE-123 bus RDN, as shown in Fig. 5. All simulations are performed in A Mathematical Programming Language environment using a KNITRO solver [30] running on an 11th Gen Intel(R) Core(TM) i5-1135G7 @ 2.40 GHz CPU processor with 8 GB RAM.

A. Description of Test System

The test system has been subdivided into five LECs, as illustrated in Fig. 5. Each LEC is equipped with CSs, and RESs in the form of PV plants and WT farms, as well as residential DLs (denoted by nodes in red) along with the fixed load demand (nodes in black). Gathering all relevant parameters for various types of DERs from a single source is considerably challenging. Therefore, the parameters of EV types and charging infrastructure, such as charging power, battery capacity, and maximum energy level, as well as the optimal configuration of CSs, including bus locations, power levels, and charging facilities for different EV types, are obtained from [31]. The power generation profiles for PV plants and WT farms during the peak summer season are adopted from [32], as they reflect real-world scenarios. Since the capacities in [32] are originally provided in megawatts, they are converted to kilowatts to align with the load demand data of the IEEE 123-bus system. For DLs, [33] is referred to define their types and operating parameters, including power level, energy requirements, and total operating time. The net demand for DLs is assumed to vary between 10% and 40% of the power demand

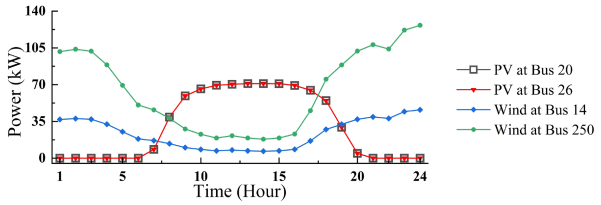

Fig. 6. Hourly power supplied by RESs in LEC-1.

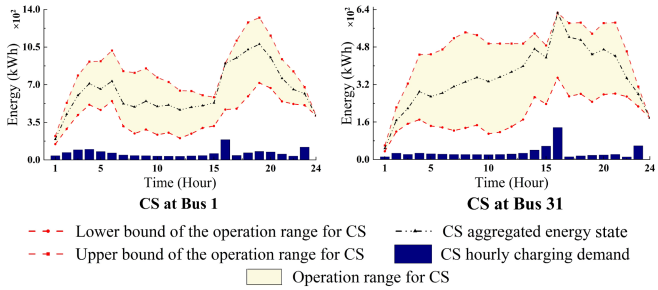

Fig. 7. Operation ranges and the aggregated energy states for CSs at Bus 1 and Bus 31 in LEC-1.

at the red nodes, which is then used to determine the number of DLs connected to each node. For the sake of simplicity, the operational status is presented on an hourly time interval. Moreover, a few DERs, i.e., RESs with integrated ESs, have been strategically placed at bus locations 135, 149, 152, 160, and 197, which are controlled by the EU operator to improve grid services.

B. Community Power Dispatch

To demonstrate the power dispatch within LECs solved by CAs, the numerical findings for the LEC-1 are provided. The LEC-1 configuration comprises PV plants, assumed to be installed at buses 20 and 26, each with an 80 kW capacity, as well as WT farms at bus 14 (80 kW) and bus 250 (220 kW). Furthermore, CSs are placed at buses 1 and 31 to facilitate 140 and 40 EVs with heterogeneous parameters, respectively, as referenced in [31]. In addition, it is assumed that a total of 252 DLs, with a net power demand of 1918.15 kW, are connected across fifteen buses, enabling them to adjust their power demands for ToU price-based demand response. Moreover, the total fixed load demand for LEC-1 is 9435.85 kW, with the hourly demand pattern considered the same for all the nodes.

Fig. 6 depicts the hourly power generation from RESs, showing a peak power output of 212.03 kW during the 18th h period. The net power supplied by the RESs over 24 h amounts to 3596.28 kW. Fig. 7 depicts the feasible operational regions, aggregate energy states, and hourly charging demand for the two CSs at buses 1 and 31. The shaded area between the upper and lower trajectories in Fig. 7 represents the available aggregate energy flexibility for the CSs to effectively meet the charging requirements of EVs. Furthermore, Fig. 8 presents the hourly maximum charging power, aggregate power dispatch for the CSs at buses 1 and 31, and the ToU electricity price derived from [34]. Notably, an observation is made regarding the reduced charging demand of the CSs during the 17th to 22nd time intervals, coinciding with elevated ToU prices, resulting in a significant reduction in operational costs.

TABLE II
DAILY OPERATIONAL DATA FOR CONSIDERED DLS

Term	Interruptible DL			Noninturruptible DL		
DL type	I	II	III	IV	V	VI
Power level (kW)	5.475	4.875	3.5	0.65/1.26	1.875	2
Required time (h)	2	2	4	1/2	2	2
Starting time (h)	8	1	1	4	8	1
Ending time (h)	20	24	24	16	20	12
Energy usage (kWh)	10.95	9.75	14	0.65/2.52	3.75	4

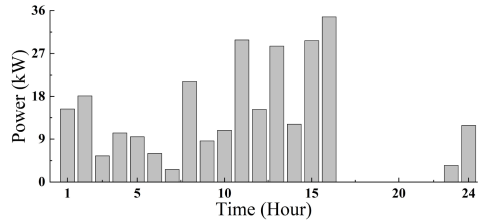

Fig. 9. Net hourly power demand by DLs at Bus 28 in LEC-1.

TABLE III
TOTAL COST OF OPERATION AND POWER DISPATCH IN LECS

Term	LEC-01	LEC-02	LEC-03	LEC-04	LEC-05
Operation cost ($)	1323.16	1105.30	743.29	1397.43	60.82
Power supplied by EU (kW)	10240.29	8390.97	5436.16	11251.65	-171.65
RES generation (kW)	3596.28	3924.36	3876.75	6912.71	5885.36
Power demand from CSs (kW)	2181.05	830.75	857.47	1216.80	811.04

This article investigates six distinct categories of DLs, three following interruptible task characteristics and the other three noninterruptible task characteristics. Table II provides detailed parametric data for each DL, where all DLs except Type IV entail a single operational task, and Type IV involves two operational tasks. In Table II, the second row outlines the power level (kW) for the task, and the third row indicates the required time (h) to complete a task. The fourth and fifth rows collectively outline the operational time frame, indicating the prescribed starting and ending times for each task. Finally, the last row indicates the total energy (kWh) needed to complete a task. The net hourly demand of DLs integrated at bus 28 is depicted in Fig. 9. Notably, there are a total of 90 DLs integrated on bus 28, evenly distributed among the six categories detailed in Table II. It is worth noting that during the high ToU electricity prices from 17th to 22nd time intervals, the power demand of DLs has been shifted to time intervals where ToU electricity prices are comparatively less.

TABLE IV
OVERALL COST AND EVS FEASIBLE ENERGY LIMITS VIOLATION COUNTS FOR THE THREE CASES

Cases	Overall cost ($)	Overall cost in %age of base: Case 1	EVs feasible energy limit violation count	Computation time (s)
Case 1	1323.16	100%	0	0.125
Case 2	1380.56	104.33%	36	0.172
Case 3	1427.14	107.86%	39	0.188

In addition, Table III summarizes the operational costs in all five LECs, along with other significant outcomes such as power supplied by the EU operator in LECs, power generation from RES situated within the LEC, and power demand from the CS in a LEC over the 24 h time horizon. It is observed that due to significant RES generation and low power demand, LEC-5 exports power to the utility, as indicated in Table III. Despite LEC-4 having the highest RES generation capacity among all LECs, it imports a substantial amount of power from the utility. This is attributed to the presence of a large number of fixed and DLs within LEC-4, resulting in 45% higher power demand than LEC-1. However, the operational cost for LEC-4 is 5.6% greater than that of LEC-1, primarily due to having 2.7 times more DL demands in LEC-4 compared to LEC-1. Similarly, although LEC-2 and LEC-3 produce almost the same amount of RES energy and have similar power demands from CSs, LEC-2 ends up operational cost of 49% more than LEC-3. The difference in operational cost comes from LEC-2 needing 4.3 times more fixed load power demand compared to DL demand, where the demand for fixed loads is lower (i.e., 3.6 times) than for DLs in LEC-3.

1) Comparative Analysis: The advantages of the proposed EVs aggregation at the CS framework are presented through the analysis of three cases for quantitative comparison. In each case, the cost-optimal dispatch problem proposed in Section IV is addressed.

1) *Case 1:* This case considers the proposed EVs aggregation framework as outlined in (2)–(3).
2) *Case 2:* For comparison with the proposed EV aggregation framework of case 1, this case does not consider EV aggregation, and instead, models EV at the individual level, as outlined in (2)–(3) except (3f)–(3i).
3) *Case 3:* For comparison with cases 1 and 2, this case does not consider EV aggregation as well as Extn-LP equations utilized to impose strict conditions on EV charging and discharging power capacity. The equations modeling EVs in this case are (2)–(3), excluding (3f)–(3i), (2a), (3c), and (3d).

Table IV reports the comparison between the three cases. The overall cost outlined in Table IV includes operational costs, and penalty costs resulting from the violation of the feasible energy limit constraints of EVs. It is assumed that the penalty cost is set at a rate of 10 ¢/kWh more than the ToU rate ($\lambda^{\text{ToU}}_{\text{CS},t}$) applied for CS during normal conditions [16]. Table IV shows that the overall cost in case 1 amounts to $1323.16 while adopting the proposed EV aggregation framework. Moreover, there is a significant increase in overall cost observed in cases 2 and 3, showing a 4.33% and 7.86% rise, respectively. As shown in the third column of Table IV, the feasible energy limits are violated 36 and 39 times in cases 2 and 3, respectively, mainly because

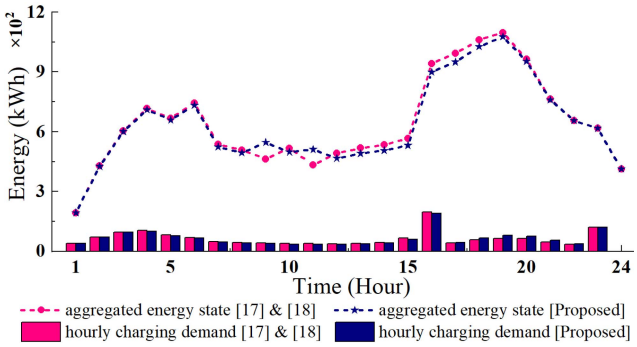

Fig. 10. Comparison of aggregated energy states and hourly charging demand at CS at Bus 1 for EV aggregation methods in [17] and [18] and the proposed method.

of not considering the EVs aggregation in case 2 and EVs aggregation as well as Ext-LP equations in case 3. Computational time (s) of the proposed EVs aggregation framework in case 1 is much less as compared to cases 2 and 3, as shown in Table IV.

2) Comparison of Proposed and Existing EV Aggregation Methods: This section presents a comparative analysis of the proposed approach and the methodologies outlined in [17] and [18] for EVs aggregation at CS. The simulation results indicate that, for both the proposed method and those in [17] and [18], the overall energy state of the CSs remains within their upper and lower flexibility boundaries, derived from the individual EV flexibility limits in each approach, as illustrated in Fig. 3. However, a closer examination of the individual energy states of departing EVs reveals that the proposed method effectively manages the desired energy levels at departure while respecting individual EV charging preferences and optimizing economic efficiency. In contrast, methods in [17] and [18] show that EVs tend to depart with energy states higher than their desired levels during low-price intervals, whereas they often leave with a lower-than-desired energy state during high-price intervals. This occurs because CSs adopt a strategy of maintaining higher energy levels during low-price periods to optimize cost-efficiency when prices rise. Consequently, EVs leaving during high-price intervals experience reduced charging, balancing out the surplus energy provided to EVs departing during low-price intervals.

For instance, during the 16th-h interval, five EVs are scheduled to depart from the CS at Bus 1. Under the proposed method, the simulated energy state is 898.72 kWh, as shown in Fig. 10. In contrast, the approaches in [17] and [18] resulted in a higher energy state of 942.2 kWh, corresponding to the upper bound of the energy state. This difference indicates that, under these strategies, departing EVs collectively received an additional 43.48 kWh beyond their intended energy levels. Over a 24-h period, EVs departing between time intervals 1 and 16 stored a total of 48.13 kWh more energy under the methods in [17] and [18] than under the proposed approach. Conversely, for EVs departing between time intervals 17 and 22, the stored energy is 48.13 kWh lower than their intended levels. This trend follows electricity pricing variations, where these methods reduce energy intake during high-price periods to maintain economic efficiency. As a result, EVs may either incur additional charging costs due to excess energy or receive a charge level lower than their desired state when electricity prices are high, meaning individual EV preferences are not fully accounted for. The proposed method, however, not only optimizes costs at a system-wide level but also integrates individual charging preferences, improving both user satisfaction and operational efficiency.

TABLE V
COMPARISON OF DIFFERENT VaR MEASURES FOR UNCERTAINTY ANALYSIS WITH CHANGE IN CONFIDENCE INTERVAL

Confidence interval	VaR (%)	CVaR (%)	MVaR (%)
0.01	0.10	0.10	0.091
0.025	0.091	0.096	0.088
0.05	0.084	0.092	0.083
0.1	0.075	0.088	0.077

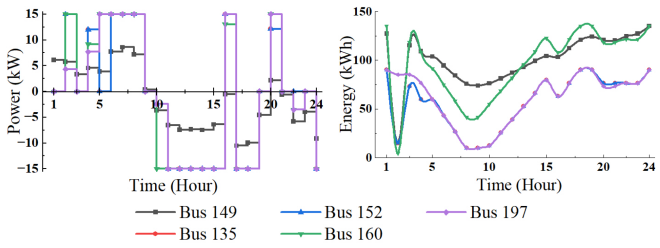

Fig. 11. Discharging power and energy states of disaggregated ESs.

3) Impact of Uncertainty on Cost Optimal Community Power Dispatch: This section investigates the impact of uncertainty in the departure times of EVs on the cost-optimal operations of CAs. The impact of this uncertainty is analyzed using risk measurement tools [35], such as value-at-risk (VaR), conditional VaR, and modified VaR. For the analysis, it is assumed that on any given day, 20% of the total EVs arriving at CSs may depart earlier than scheduled, with a standard deviation of 4 h. Based on this assumption, 100 scenarios are generated addressing the cost-optimal operation in the energy community. The mean outcome of these scenarios is 1323.75 $, with a standard deviation of 0.32 $. The VaR outcomes of the analysis are detailed in Table V, presenting measures for various values of the risk-tolerance level (i.e., 0.01, 0.025, 0.05, and 0.1). The percentage values in Table V represent the worst-case loss relative to the expected value within the given confidence interval, establishing a probabilistic threshold beyond which the operational cost is unlikely to exceed, given a specified confidence level. Notably, a lower confidence interval may lead to higher operational costs but enhances the robustness against the operational cost variation. For example, the simulation results show that the worst-case operational cost is $1323.56 for a confidence interval of 0.99. As the confidence interval decreases to 0.1, 0.01, and 0.001, the worst-case cost estimates rise to $1324.15, $1324.48, and $1324.75, respectively.

C. Dispatch Set-Points From EU Operator

This section presents the numerical results pertaining to the dispatch set-points evaluated for the disaggregated DERs within the network, aiming to improve grid services. Fig. 11 illustrates the discharge power and energy state patterns over 24 h for disaggregated ESs located at buses 149, 135, 152, 160, and 197. Notably, the results indicate that during periods of high power demand from LECs, the ESs discharge, whereas during low-demand intervals, the ESs charge to ensure demand fulfillment locally. For instance, during the 15th h, when demand is low, all ES units engage in charging, while in the 16th h, when LECs experience high demand, all ES units except the one at

TABLE VI
COMPARISON OF POWER LOSSES (KW) AND VOLTAGE DEVIATION (V^2) UNDER VARIOUS SCENARIOS

	γ_{loss} × power loss (kW)	γ_{vd} × voltage deviation (V^2)
Without DERs (No RESs and ESs)	1003.15	552.10
With RESs (No ESs)	855.49	485.46
With DERs (RESs+ESs) [Proposed]	846.68	483.87

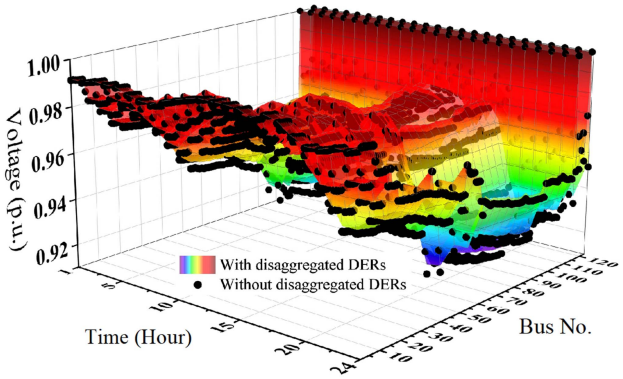

Fig. 12. Voltage profile for the system considered, with and without the dispatch of disaggregated DERs.

bus 149 switch to maximum discharging mode. Furthermore, a comparative analysis of power losses and voltage deviations in various scenarios is detailed in Table VI. It is worth mentioning that when the EU operator does not dispatch the disaggregated DERs to fulfill LECs' energy demand and when the EU operator utilizes the full potential of DERs, the net power losses are notably improved by 15.60%. Fig. 12 illustrates the bus voltage magnitudes (in pu) for the system considered with (colormap surface) and without (scatter) the dispatching disaggregated DERs, revealing a significant improvement in voltage profile. The findings reveal that effective management of disaggregated DERs in coordination with the dispatch set-points received from LECs significantly enhances grid performance.

VI. CONCLUSION AND FUTURE WORK

In conclusion, this article has focused on the development of an efficient framework for the management of a substantial fleet of DERs within the distribution system aimed at optimizing operational costs in LECs and improving grid services at the EU level. The approach first developed aggregation models to determine the cumulative energy flexibility of DERs namely EVs and DLs, followed by a hierarchical control approach for solving the optimal dispatch set-points for these DERs. In addition, a more computationally tractable linear formulation was adopted for EV and ES battery modeling. Through numerical simulations conducted on a modified IEEE-123 bus RDN, the effectiveness of the proposed method was demonstrated.

The quantitative analysis reveals that the proposed EV aggregation framework provides a more accurate and computationally efficient solution duly incorporating network constraints, which makes the framework more practically achievable, especially while managing a large fleet of EVs having spatial placement and temporal behavior. From the numerical analysis, it can be concluded that the presence of a large number of DLs within the distribution network significantly reduces operational costs in energy communities by facilitating the proposed DLs aggregation model for price-based demand response. Moreover, the effective coordination among disaggregated DERs and CAs exerts great influence on power losses and bus voltages in the distribution network. In conclusion, the proposed HCF successfully enhances the overall performance of the electrical grid.

The results of these simulations highlight the capacity of the approach to effectively manage the sizable fleet of DERs in the distribution system, delivering satisfactory outcomes in terms of economic cost and secure system operations, all while maintaining a high level of computational efficiency. The future work may be extended to analyze the proposed work with an unbalanced three-phase network model.

Shubham Gupta received the B.E. degree in electrical engineering from the College of Technology and Engineering, Udaipur, India, in 2012, the M.Tech. degree in power engineering from Guru Nanak Dev Engineering College, Ludhiana, India, in 2015. He is currently working toward the Ph.D. degree in electrical engineering with a research focus on the techno-economic analysis and optimization of distributed energy resources in modern distribution systems with the Delhi Technological University, New Delhi, India.

His research interests include electricity pricing, distributed energy resources, and energy system modeling.

Vinod Kumar Yadav (Senior Member, IEEE) received the B.Tech. degree in electrical engineering from the Institute of Engineering and Technology, Bareilly, India, in 2003, the M.Tech. degree in power system engineering from the National Institute of Technology, Jamshedpur, India, in 2005, and the Ph.D. degree in power system engineering from the Indian Institute of Technology, Roorkee, India, in 2011.

His research interests include renewable energy systems, power system planning and optimization, distributed generation, and smart grid.

Madhusudan Singh (Senior Member, IEEE) was born in Ghazipur, India, in 1968. He received the B.Sc. degree in electrical engineering from the Faculty of Technology, Dayalbagh Educational Institute, Dayalbagh, India, in 1990, the M.E. degree in control and instrumentation from the University of Allahabad, Allahabad, India, in 1992, and the Ph.D. degree in electrical engineering from the Faculty of Technology, University of Delhi, New Delhi, India, in 2006.

His research interests include modeling and analysis of electrical machines, power quality in power systems, renewable energy systems, voltage control aspects of self-excited induction generators, power electronics, and drives.

March 25, 2025

Abstract

The integration of Large Language Models (LLMs) and Generative AI into mental healthcare is reshaping diagnostic, therapeutic, and support systems, marking a transition toward AI-driven mental healthcare. This paper explores various methodologies for incorporating LLMs into mental health applications, categorizing research into key strategies such as prompt engineering, fine-tuning, emotional theory integration, AI-powered chatbots, and long-term memory architectures. Through case studies, we evaluate their effectiveness in areas like depression detection, suicide risk assessment, and AI-assisted psychological counseling, highlighting both their potential benefits and associated challenges. While LLMs enable more empathetic interactions, personalized interventions, and early risk identification, concerns remain regarding bias, misinformation, safety risks, and ethical issues related to privacy, informed consent, and AI's role in clinical decision-making. We outline critical research gaps, stressing the importance of real-world validation, standardized evaluation methods, and strong risk mitigation frameworks. This paper serves as a guide for the responsible, scalable, and ethical integration of AI in mental healthcare, ensuring these technologies enhance patient well-being while adhering to clinical and ethical standards.

Large Language Models (LLM), Mental Health, Healthcare 5.0, Generative AI, Chatbots

1 | INTRODUCTION

Millions of people around the world suffer from mental health-related issues, which underscores the urgent need for accessible, efficient, and compassionate mental healthcare. The increasing prevalence of stress, depression, suicide, and other mental health conditions poses a significant public health challenge globally Ji et al. (2022a); Sagastibeltza et al. (2023); Sharma et al. (2023b). Mental health extends beyond the absence of illness, encompassing emotional resilience, psychological well-being, and the ability to navigate life's challenges Saraceno (2002). Recognizing its fundamental role in overall health, societies increasingly prioritize mental health awareness, destigmatization, and investment in robust healthcare infrastructureBhugra et al. (2013). The evolution of Healthcare 5.0 envisions AI-driven personalized and preventive care, making scalable mental health interventions more accessible and adaptive. This has led to a growing interest in Artificial Intelligence (AI)-driven solutions, particularly Large Language Models (LLMs)

and Generative AI, which offer innovative approaches for mental health assessment, support, and intervention James (2020). Traditional psychological state assessments relied on machine learning (ML) techniques such as Support Vector Machines (SVM), Neural Networks, AdaBoost, k-nearest Neighbors (kNN), Deep Learning, Decision Trees (DT), and Clustering Shatte et al. (2019); Benfares et al. (2021). Despite demonstrating efficacy, these strategies frequently require extensive labeled data and manual feature design.

Unlike traditional methods, Generative AI and LLMs leverage a transformative approach by employing extensive pre-trained language models with self-supervised training. LLMs can engage in human-like conversations, detect subtle linguistic cues, and offer personalized emotional support Nowacki et al. (2024). Their ability to analyze textual data—ranging from social media posts to therapy transcripts—enables early detection of stress, depression, and suicide risk Frueh (2015). Figure 1 depicts the distribution of prevalent mental health concerns across diverse populations, with the most frequently discussed issues being anxiety and depression.

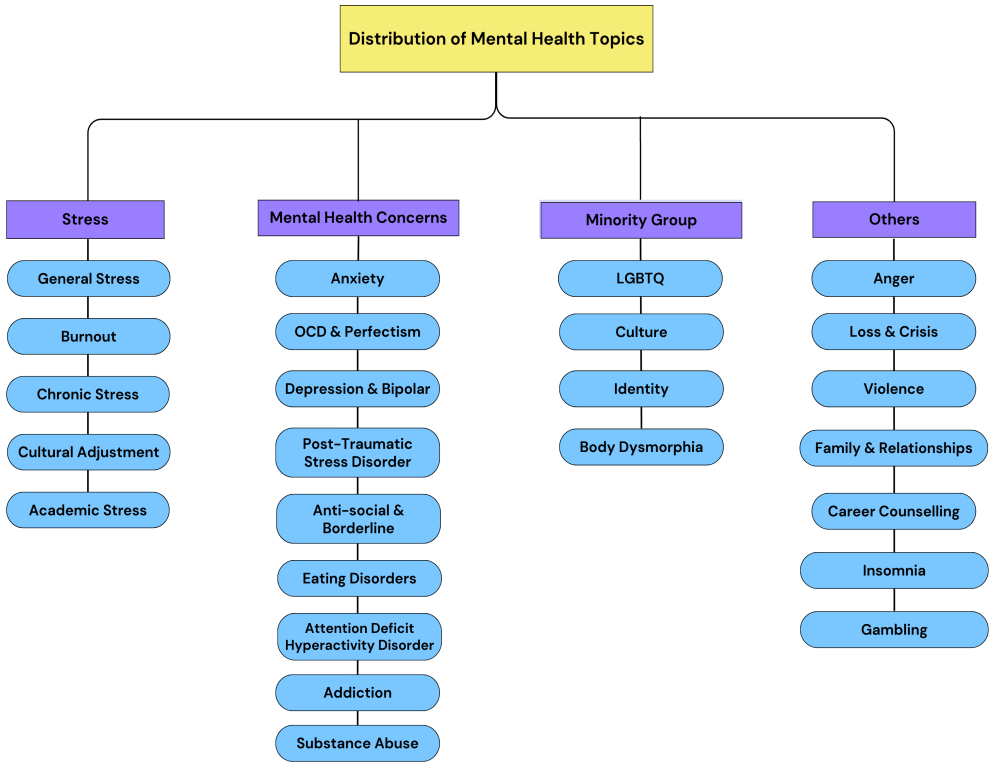

FIGURE 1 The distribution of mental health-related topics.

In addition, Generative AI enhances mental health research by synthesizing data, generating context-aware responses, and simulating therapeutic interactions. These models facilitate the creation of synthetic datasets that reflect diverse mental states, aiding in the fine-tuning of diagnostic algorithms and expanding the scope of AI-driven interventions Mandapuram et al. (2018); Lau et al. (2025). This integration presents a dynamic and adaptive framework for mental health assessment, aligned with the evolving nature of psychological conditions Naveed et al. (2023).

However, the adoption of LLMs and Generative AI in mental healthcare presents ethical, technical, and interpretability challenges Ning et al. (2024); Solaiman (2024). Issues such as bias in training data, privacy concerns, AI hallucinations, and the potential for misinformation must be critically addressed to ensure responsible deployment. This paper provides a comprehensive overview of state-of-the-art methodologies, emerging challenges, and future research directions at the intersection of LLMs, Generative AI, and mental health detection Fan et al. (2023).

The following selection criteria were adopted for the research papers:

- **Time Period**:This study examines advancements in the application of Large Language Models (LLMs) in mental health from 2019 to 2025, capturing recent breakthroughs while incorporating earlier literature to provide a comprehensive contextual overview.
- **Keywords**: A targeted keyword search was employed, including terms such as 'Large Language Models,' 'Generative AI,' 'Mental Health,' 'ChatGPT,' 'Ethics in AI,' and 'Context Learning.' This approach ensures a focused and exhaustive review of the most relevant developments in the field.
- **Inclusion Criteria**: Only peer-reviewed conference and journal papers written in English were considered. The study prioritizes the exploration of LLMs in mental health, highlighting their applications, methodologies, and ethical challenges.
- **Exclusion Criteria**: In order to maintain the study's validity, works that were published before 2019, or lacking direct relevance to the research focus were not included.

In order to have a comprehensive understanding of LLMs in the context of mental health, this research focuses on conducting a detailed analysis of their advantages, limitations, and ethical implications. This study will not only gives us insights of LLMs application in the field of mental health but will also enable us to discover techniques through which they can be implemented. The key contributions of this article in mental health are as follows.

- Categorizes research on LLM applications in mental health, covering prompt engineering, fine-tuning, emotional theory integration, AI chatbots, and long-term memory mechanisms.
- Examines depression detection, suicide risk assessment, and AI-driven psychological counseling, evaluating model performance across diverse methodologies.
- Assesses the strengths and limitations of integrating LLMs in mental health, highlighting concerns such as bias, safety risks, and reasoning failures.
- Explores privacy, informed consent, algorithmic bias, and risks of misuse, emphasizing the need for transparent and fair AI deployment.
- Identifies areas that need further exploration, including real-world clinical validation, standardized evaluation frameworks, and risk mitigation strategies.
- Provides actionable insights and recommendations to advance the ethical and effective integration of LLMs in mental healthcare.

The flow of information in this survey is structured as follows. Section 2 outlines the fundamental concepts of Large Language Models (LLMs) and their benchmarks. Section 3 pans across the current state of LLMs applied in mental health contexts. A taxonomy is proposed to categorize existing research approaches based on techniques used, including prompt engineering, fine-tuning strategies, integration of psychological theory, and conversational agents. Section 4 covers the datasets which most appear in the literature. Section 5 closely examines the ethical dimensions and practical challenges accompanying the use of LLMs for mental health purposes. Protecting personal data privacy, ensuring proper consent, avoiding misuse, and confronting algorithmic biases represent some of the complex considerations discussed. Section 6 discusses research limitations and opportunities to responsibly advance the integration of LLMs and mental healthcare. Section 7 concludes the article by summarizing the comprehensive integration of LLMs and mental health.

2 | BACKGROUND

2.1 | Large Language Models

LLMs have now become powerful AI systems, able to process and create coherent text while showing generalization across many tasks Radford et al. (2019); Brown et al. (2020). They are trained through text-based data, which helps them improve their ability to predict the next word or phrase in a sentence. Over the years, natural language processing (NLP) has advanced a lot, moving from statistical methods to neural language modeling and then evolving further from pre-trained language models (PLMs) to large language models (LLMs).

Early work on LLMs, like T5 Raffel et al. (2019) and mT5 Xue et al. (2021), mainly used transfer learning. It wasn't until GPT-3 Brown et al. (2020) came along that LLMs showed zero-shot transferability to downstream tasks without needing fine-tuning. Even though pre-trained LLMs can answer task queries based on examples and descriptions, their performance in zero-shot scenarios is still lower compared to few-shot learning situations. To improve generalization for unseen tasks, fine-tuning with task-specific data is suggested Chung et al. (2022a); Wang et al. (2022b,a). This leads to better zero-shot performance and helps minimize misaligned behavior.

LLMs demonstrate these competencies due to their extensive scale, even when no explicit training is provided to instill them. The LLM's capability to tackle diverse tasks with human-level performance is accompanied by drawbacks such as slow training and inference, substantial hardware demands, and increased operational expenses. These requirements have constrained their widespread adoption and created opportunities for the development of more efficient architectures Zeng et al. (2023); Wang et al. (2023b). Table 1 lists some of the major Large Language Models that can be employed for intervention in mental health.

TABLE 1 Basic details of Large Language Models released in recent years with varying sizes. Here parameters column corresponds to the number of trainable parameters in each LLM where M, B, and T stand for millions, Billions, and Trillions, respectively

LLM	Parameters	Focus Areas	Availability	Architecture
T5 Raffel et al. (2019)	11B, 110B	Text-to-text tasks, summarization, translation, question answering	Publicly available (API)	Encoder-decoder architecture
GPT-3 Brown et al. (2020)	175B	Text generation, translation, question answering, creative text formats	OpenAI API (paid access)	Generative Pre-trained Transformer model
mT5 Xue et al. (2021)	10B, 100B	Text-to-text tasks, multilingual translation	Publicly available (code)	Multimodal variant (mT5-XXL)
PanGu Zeng et al. (2021)	200B	Chinese language processing, text generation, translation	Limited access for research	Transformer-based architecture
ERNIE 3.0 Sun et al. (2021b)	10B	Knowledge-enhanced tasks, semantic understanding, reasoning	Publicly available (code)	Knowledge-infused model architecture
Jurassic-1 Lieber et al. (2021)	178B	Text-to-text tasks, question answering, summarization	AI21 Labs API (paid access)	Jurassic-1 Jumbo variant (355B)

Continued on next page

Table 1 – Continued from previous page

LLM	Parameters	Focus Areas	Availability	Architecture
Yuan 1.01 Wu et al. (2021)	245B	Chinese language processing, text generation, translation	Limited access for research	Transformer-based architecture
Gopher Rae et al. (2021)	280B	Text-to-text tasks, question answering, summarization	Publicly available (code)	Dense retrieval capabilities
ERNIE 3.0 Titan Wang et al. (2021)	10B	Knowledge-enhanced tasks, semantic understanding, reasoning	Publicly available (code)	Knowledge-infused model architecture
GPT-NeoX-20B Black et al. (2022)	20B	Text generation, translation, question answering	Publicly available (code)	Open-source alternative to GPT-3
OPT Zhang et al. (2022)	125M	Text-to-text tasks, efficient training	Publicly available (code)	Optimized model architecture for efficiency
AlphaCode Li et al. (2022)	530B	Code generation, competitive programming	DeepMind (limited access)	Transformer-based architecture
AlexaTM Soltan et al. (2022)	137B	Text-to-text tasks, question answering, conversational AI	Amazon Research (limited access)	Multimodal capabilities (text, audio, visual)
GPT-4 OpenAI et al. (2023)	100T / 800T (estimated)	Text generation, translation, reasoning, multimodality	Limited access (research & select partners)	Likely uses novel architectures & training techniques
FLAN-T5 Chung et al. (2022b)	137B / 540B	Multilingual tasks, translation, summarization	Google Research (limited access)	Dense retrieval capabilities
Alpaca Taori et al. (2023)	137B	Chinese language processing, text generation, translation	Limited access for research	Transformer-based architecture with domain-specific optimizations
Alpaca-LoRA Alpaca-LoRA (2023)	137B	Chinese language reasoning, factual language understanding	Limited access for research	Combines Alpaca with Long-Range Arena reasoning techniques
ChatGLM-6B Zeng et al. (2022)	6B	Conversational AI, dialogue, open-ended tasks	Tsinghua University (limited access)	Emphasis on long-term conversation coherence
BELLE-LLAMA-7B-2M Ji et al. (2023)	7B	Chinese dialogue tasks, factual language understanding	Lianjia Technology (limited access)	Focuses on improving factual accuracy and consistency in dialogue

Continued on next page

Table 1 – Continued from previous page

LLM	Parameters	Focus Areas	Availability	Architecture
Vicuna-7B-v1.1 Chiang et al. (2023)	7B	Chinese language processing, text generation, translation	Hugging Face AI (limited access)	Optimized for efficiency and runtime performance
Baichuan 2 **?**	7B, 13B	Multilingual tasks, domain-specific applications	Open-source	Trained on 2.6 trillion tokens
Command R+ Cohere (2024)	104B	Real-world challenges, retrieval augmented generation	API and direct download	Supports multiple tools for complex tasks
OpenAI o1 OpenAI (2024)	300B	Scientific problem-solving, coding, complex mathematics	API access only	Emphasizes reasoning with extensive thought process
Gemini 2.0 DeepMind (2024)	Not disclosed	Multimodal processing (text, images, audio, video)	API access only	Designed for the "agentic era" of AI
Llama 3.3 70B Instruct AI (2024)	70B	Instruction tuning, multilingual support	Open-source	Advanced language model with diverse applications
DeepSeek R1 AI (2025)	671B	Text generation, reasoning, efficient processing	Open-source adaptation available	Reinforcement learning with mixture of experts approach

2.2 | Benchmarks for LLMs

Several benchmarks have been developed to evluate the performance of Large Language Models (LLMs) across diverse tasks. Hendrycks et al. (2021) created a through evaluation test for assessing text models. Liang et al. (2023) offered a comprehensive assessment, evaluating large language models across various aspects such as language understanding and common-sense reasoning. Srivastava et al. (2023) introduced 204 challenging tasks covering various domains, with the goal of evaluating tasks beyond the capabilities of existing language models. C-EVAL estimates the developed knowledge and reasoning capabilities of foundation models in the context of the Chinese language Huang et al. (2023). Zhong et al. (2023) served as an evaluation framework named AGI-Eval to assess the performance of foundation models in human-centric standardized exams. Although these benchmarks are diverse and comprehensive, they focus majorly on general capabilities and do not specifically account for the nuances of mental health.

2.3 | Mental Health Benchmarks for LLMs

MentalLLM is designed to evaluate the capability of LLMs to assess mental health outputs through the examination of online text data Xu et al. (2023). PsyEval acknowledged that symptoms of mental disorders are nuanced, subjective, and highly personalized, it recognizes the need for expertise, empathy, and awareness of emergency response, aspects not covered in other benchmarks. This entails grasping subtle emotional states, identifying nuanced signs of mental distress, and delivering safe and empathetic interactions Jin et al. (2023). Dialogue safety focuses on understanding the safety of replies rendered by LLMs in mental health support Qiu et al. (2023). MultiMedQA Singhal et al. (2022) is specifically tailored for medical question-answering, assessing LLMs based on their clinical knowledge and

question-answering abilities. These benchmarks are devised for certain downstream tasks, offering a more specialized evaluation of LLMs.

3 | CURRENT STATE OF LLMS IN MENTAL HEALTH

This section delves into the LLMs' role in understanding, diagnosing, and providing support for mental health concerns. We provide a glance at the different model customization processes employed and developed to tackle mental healthcare problems. We provide an overview of the proposed taxonomy scheme, viz., Prompt Engineering, Chatbots, Fine-Tuning, Pre-training, Emotional & Linguistic Context, and Long-Term Memory, of segregating the current research landscape based on the method and technique used. The proposed taxonomy seeks to categorize the primary applications of LLMs into overarching groups, allowing for a comprehensive examination of each category and its potential in greater detail.

3.1 | Prompt Engineering

Prompt engineering is designing and tweaking prompts to guide LLMs in producing the right kind of responses. In mental healthcare, this process is especially important because well-crafted prompts can provide the model with the right context, helping it generate more accurate and relevant responses. To make sure the model performs well, prompts need to be carefully designed, taking into account not just technical aspects but also human interaction and ethical considerations Kamalloo et al. (2023); Liu et al. (2023a).

Xu et al. (2023) conducted a comprehensive evaluation of five Large Language Models (GPT-3.5, GPT-4, FLAN-T5, Alpaca, and Alpaca-LoRA) for mental healthcare applications, specifically evaluating their performance on six mental health prediction tasks using social media data. The authors proposed a general zero-shot prompt template that can be used to predict a variety of mental health outcomes from online text data. The proposed zero-shot prompt template was as follows:

$$Prompt_{ZS} = TextData + Prompt_{Part1-S} + Prompt_{Part2-Q} + OutputConstraint$$

where "TextData is the online text data generated by end-users. $Prompt_{Part1-S}$ provides specifications for a mental health prediction target. $Prompt_{Part2-Q}$ poses the question for LLMs to answer, and OutputConstraint controls the output of models (e.g. Only return yes or no for a binary classification task)"

The authors proposed several design strategies for $Prompt_{Part1-S}$, including:

(i) Basic: Leaving it as blank.
(ii) Context Enhancement: Providing more social media context about the TextData.
(iii) Mental Health Enhancement: Inserting a mental health concept by asking the model to act as an expert.
(iv) Context and Mental Health Enhancement: Combining both enhancement strategies by asking the model to act as a mental health expert under the social media context.

For $Prompt_{Part2-Q}$, the authors focus on two categories of mental health prediction targets:

1. Predicting critical mental states: Such as stress or depression.
2. Predicting high-stake risk actions: Such as suicide.

The authors tailored the question description for each category and investigated binary and multiclass classification

tasks. They also performed minor modifications based on specific tasks to confirm suitable questions were answered. They also suggested employing few-shot prompting across various LLMs. This technique involves furnishing the LLM with a limited set of prompt-label examples relevant to the specific task. These examples are then compiled into a few-shot prompt, which serves to guide the LLM's response generation.

The design of the prompt is straightforward as:

$$Prompt_{FS} = [SamplePrompt_{ZS} - label]_M + Prompt_{ZS}$$

where M is the number of prompt-label pairs and is capped by the input length limit of a model.

The results indicate that the success of different strategies depended on the specific LLM and the task at hand. For example, including additional context or mental health-related information in the prompt appeared to lower the performance of task-focused models such as Alpaca-LoRA and FLAN-T5. However, both smaller and larger LLMs have shown encouraging performance in mental health tasks. Notably, FLAN-T5 and GPT-4 have demonstrated performance levels that are approaching those of task-specific natural language processing (NLP) models. In the realm of improving prompt design strategies for LLMs, it is evident that these approaches generally yield effective results for dialogue-focused models. However, the effectiveness of such strategies varies based on the model's primary focus, particularly between dialogue-focused and task-solving-focused models. In particular, these strategies tend to work better for critical action prediction tasks, such as suicide prediction. Interestingly, a few-shot prompting is more effective for the smaller language models Alpaca and FLAN-T5 than for the larger language models GPT-3.5 and GPT-4. This may be because smaller models are easier to quickly adapt to a new task by seeing just a few examples. Furthermore, the provision of additional contextual information about the task and input consistently leads to performance improvements across a wide range of cases. This emphasis on contextual information is a key factor in optimizing LLM performance in various applications within the mental health domain. The influence of model architecture and trainable parameters is also notable. Dialogue-focused models equipped with larger trainable parameters, exemplified by the comparison between Alpaca and Alpaca-LoRA, as well as GPT-3.5 and Alpaca, demonstrate a heightened ability to leverage contextual or domain-specific information contained within prompts. Interestingly, GPT-4 exhibits a less pronounced effect in response to different prompts, indicating variability in the impact of model architecture on prompt utilization within the mental health context.

Similarly, in a recent study by Wang et al. (2023a), an innovative approach known as the "Dialogue Chain-of-Thought (CoT) prompting" is proposed to explore the realms of personality, emotion, and psychology within user queries in the context of mental health. This approach involves the utilization of a benchmark that encompasses Chinese and English datasets, demonstrating the consistent improvement of response quality by breaking down the response generation process into distinct reasoning steps. Furthermore, the authors introduced a detailed framework that facilitates structured and transparent reasoning in dynamic conversations. They presented two distinct modes of implementing CoT Prompting:

1. Standard CoT:
   - The authors built on conventional prompting and Chain-of-Thought (CoT) techniques by proposing 'Explicit CoT,' a method designed to improve LLM reasoning. This approach broke down the reasoning process into N-1 successive phases, with each phase producing intermediate reasoning results. In the final stage (N), the model combined the initial dialogue context with all previous intermediate results to generate the final response.
2. Explicit CoT:
   - The "Explicit CoT" method aimed to improve the reasoning abilities of LLMs by breaking down response generation into multiple sequential steps. It divided the reasoning process into N-1 consecutive steps, with each step producing intermediate reasoning results. The Nth step then combined the original dialogue context with all intermediate outputs to generate the final response.

The "Explicit CoT" approach offered several advantages. Firstly, processing intermediate outputs provided convenience, allowing for actions such as generating personalized responses by incorporating user profiles or filtering out erroneous reasoning results. Furthermore, these intermediate outputs could be retained for future use, making them valuable for various purposes. These intermediate results can also serve as criteria for selecting demonstrations under few-shot settings, a concept elaborated on in the subsequent section. In summary, the Explicit CoT technique fosters a more transparent and systematic progression of reasoning within LLMs, leading to improvements in transparency and interpretability within the dialogue generation process. The authors experiment on the following Large Language Models: for Chinese: ChatGLM-6B, BELLE-LLAMA-7B-2M, ChatGPT; for English: Flan-T5-XXL, Alpaca-7B, Vicuna-7B-v1.1, ChatGPT.

Firstly, the models demonstrated the ability to generate empathetic and supportive responses tailored to the user's psychological state which holds great promise for enhancing the quality of mental health support. By taking into account the user's emotional and psychological condition, the model can contribute to a more effective and compassionate counseling experience. This capacity to provide personalized responses can be a valuable asset in improving the overall well-being of individuals seeking mental health assistance. Secondly, the model's performance on psychology datasets can be regarded as accurate for evaluating the efficacy of language models in generating counseling responses.

3.2 | Fine-tuning

Fine-tuning of LLMs deals with customizing pre-trained models to improve their performance on specific tasks. This process starts with a model that has already been trained on a large, diverse dataset and then refines it using a more targeted dataset relevant to the specific task. By adjusting the model's parameters during fine-tuning, it becomes better at recognizing the specific nuances of that domain, thereby improving its ability to understand and generate content that aligns with the intended application Wu et al. (2023).

Researchers used fine-tuned language models to better understand and respond to mental health questions, enabling it to grasp the nuances of mental health language. Liu et al. (2023b) created a method to make AI generate longer, more relevant answers. They do this by: i) building a vocabulary specific to mental health, ii) combining this vocabulary with the AI's existing knowledge, and iii) teaching the AI how to use this combined vocabulary. By fine-tuning, the model gets better at understanding the details and nuances of mental health language and context.

To create a vocabulary that captures the subtleties of mental health data, Liu et al. (2023b) used a method that allows words to be split more flexibly. This made sure the vocabulary was tailored to the specific needs of the task. After that, the newly created vocabulary was combined with the language model's existing one while keeping the token sequence unchanged. This approach enabled the model to retain what it had already learned while also adapting to the new task. To generate meaningful text with this updated vocabulary, new token representations were formed by connecting the new tokens to sub-word units from the original vocabulary and averaging their embeddings. The performance of this adaptive vocabulary approach was assessed on the CN PsyQA and MHP Reddit datasets, comparing it against conventional tokenizers. For the analysis, reduced versions of the GPT2 and BART models were utilized as the base architecture. For the tokenization process, the authors compare different tokenizers, including gpt2-chinese-cluecorpussmall, bart-base-chinese, and chinese-LLaMA-plus-7B for the CN PsyQA dataset, and GPT2 and bart-base for the MHP Reddit dataset. These tokenizers use different vocabulary sizes and tokenization methods, such as WordPiece and BPE-dropout. To evaluate the effectiveness of the task-adaptive tokenization approach, the authors conduct both automatic evaluation and human evaluation. The automatic evaluation includes metrics such as BLEU scores and RougeL. The human evaluation involves recruiting native professionals who assess the generated responses based on fluency, coherence, and professional expression. The study further examined how varying the size of the task-specific vocabulary affected the quality of a generated text. Generation efficiency was analyzed by measuring the average time taken in centiseconds and the number of tokens produced per generation, along with the response length and token utilization rate. The experimental results demonstrated that the task-adaptive tokeniza-

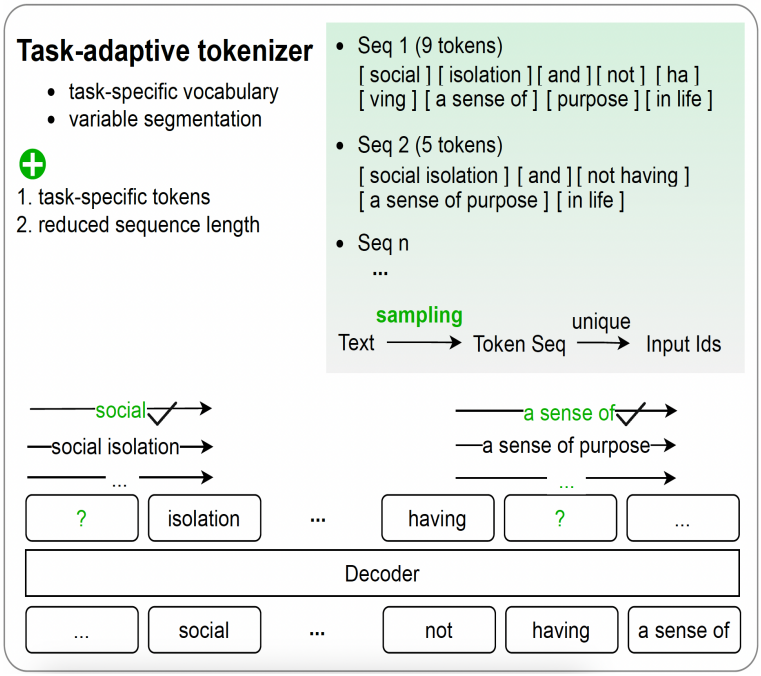

FIGURE 2 With task-adaptive tokenization, the same phrase appearing in different training instances may result in different tokenizations. For instance, Seq 1 and 2 illustrate two different token sequences of the same input using a task-adaptive tokenizer as per Liu et al.Liu et al. (2023b)

tion method enhanced the generative performance of the models when applied to mental health question-answering tasks.

Figure 2 uses an example to display the potential of task-adaptive tokenization. In terms of effectiveness, the task-adaptive tokenization approach achieves higher BLEU scores and RougeL scores compared to tokenizers from off-the-shelf pre-trained models. This indicates that the generated responses are more similar to the reference responses and have better overall quality. The human evaluation results also support the effectiveness of the task-adaptive tokenization approach.

Xu et. al Xu et al. (2023) also introduced a strategy that aligns more closely with traditional few-shot transfer learning, where the objective is to further train Large Language Models using a limited amount of domain-specific data, which bears similarity to prior research in the field of mental health Naveed et al. (2023). Our study investigates various fine-tuning techniques to enhance the performance of LLMs in mental healthcare.

- Single-dataset Fine-tuning: Consistent with previous studies in the mental health domain, they initially perform foundational fine-tuning on a single dataset, specifically the training set. This process involves adapting the LLM to the nuances of the specific dataset. Subsequently, they evaluate the fine-tuned model on both the same dataset (referred to as the test set) to assess its performance and on different datasets to determine its generalizability.
- Multi-dataset Fine-tuning: This investigation delves into the process of fine-tuning LLMs across multiple datasets simultaneously. This is accomplished by employing instruction fine-tuning, which empowers Large Language Models to handle a variety of tasks originating from different datasets. The previous models were fine-tuned for specific tasks, such as depression prediction or suicidal ideation prediction, and they became task-specific after training. In contrast, this approach fine-tunes LLMs across multiple mental health datasets with diverse instructions for different tasks within a single round of fine-tuning, equipping them to address multiple tasks

without requiring additional task-specific fine-tuning.

The analysis demonstrates that instruction-based fine-tuning enhances large language model performance in mental health prediction applications. The customized versions, Mental-Alpaca and Mental-FLAN-T5, demonstrate superior results compared to their base models, GPT variants, and the specialized MentalRoBERTa across most evaluation metrics. While both Mental-Alpaca and Mental-FLAN-T5 focus on dialogue interactions, they exhibit distinct advantages: Mental-Alpaca excels in processing natural human language, whereas Mental-FLAN-T5 shows stronger task-specific performance. Organizations with limited resources might benefit from task-oriented LLMs, while those with adequate data and computational capacity could achieve better outcomes through fine-tuning dialogue models. Models with dialogue capabilities, such as Alpaca, are particularly well-suited to mental health support applications. These findings indicate a significant potential for the creation of effective mental health assessment systems based on big language models, which could improve mental healthcare accessibility.

In a similar innovative approach, Zheng et al. (2023) leveraged the generative power of Large Language Models (LLMs) to create a vast dataset called ExTES (Extensible Emotional Support Dialogue dataset). This dataset is specifically designed to develop robust and adaptable emotional support dialogues. ExTES was developed meticulously, using ideas from psychology, past research on emotional support, and even components from creative literature to enrich and diversify the interactions. The researchers identified 36 common scenarios and arranged the dataset with psychological research as the foundation.

3.3 | Emotional & Linguistic Context

Emotions play an important role in our human experience, frequently serving as signs of problems we may be facing. By recognizing and dealing with these emotions, mental health counselors can assist clients in processing and making sense of their feelings, which can be extremely helpful. Ratican and Hutson (2023) introduced the 6DE model, a multidimensional approach to analyzing emotions. The 6DE model offers a more nuanced understanding of emotional states within text-based communication, enabling AI systems to generate appropriate emotional responses and enhance user experiences Sharma et al. (2023a). The model has six dimensions: arousal, valence, dominance, agency, fidelity, and novelty; for understanding and quantifying emotional states. By incorporating sub-dimensions within each dimension, this approach can potentially enhance the comprehension and generation of appropriate emotional responses by AI systems, leading to more effective human-AI interactions.

Garg (2024) formulated the task of determining wellness dimensions in Reddit posts as a multivariate concept extraction and classification problem. By considering multiple wellness dimensions simultaneously, the proposed approach enables a more comprehensive understanding of an individual's mental health state and the underlying causes and consequences of mental disturbance as depicted in Figure 3. Recent literature presents six different dimensions of wellness because of mental and social well-being, namely, (i) physical aspect, (ii) intellectual aspect, (iii) vocational aspect, (iv) social aspect, (v) emotional aspect, and (vi) spiritual aspect Strout and Howard (2012).

Social media content presents unique challenges for wellness dimension identification due to linguistic ambiguity and informal communication styles. The unstructured nature of social media posts, including colloquialisms, abbreviations, and non-standard expressions, creates obstacles for computational analysis. The inherent subjectivity and contextual dependence of wellness-related topics further complicate accurate identification.

To overcome these challenges, researchers suggest refining pre-trained transformer models by fine-tuning them with specialized datasets like WELLXPLAIN, which helps in better understanding the way people communicate on social media Sharma et al. (2023a). Another key approach is to develop models specifically designed to handle informal language and interpret contextual details more effectively, leading to improved accuracy. The Concept Extraction Framework (CEF) has been introduced as an automated method to identify and classify wellness-related ideas in text, making it easier to analyze mental health discussions in greater depth. LLMs, including BERT, RoBERTa, ALBERT, DeBERTa, PsychBERT, MentalBERT, and ClinicalBERT, are employed within the CEF to process and analyze text, iden-

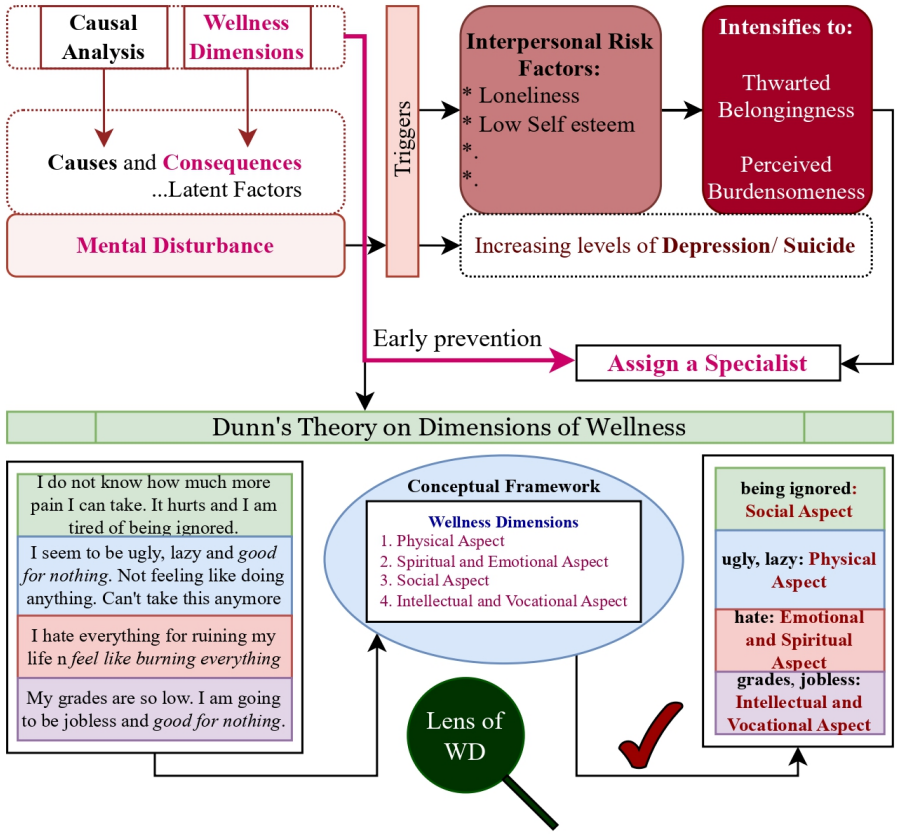

FIGURE 3 An illustration of the utility of WellXplain. The wellness dimensions in their work are grounded in Dunn's theory of wellness Garg (2024).

tifying relevant wellness dimensions and their contextual embeddings. These models, pre-trained on vast amounts of text data and fine-tuned for specific tasks, enable effective linguistic comprehension for concept extraction.

3.4 | Pre-training

Pre-training is crucial for improving LLM performance. It allows these models to get a complete understanding of language, which is particularly useful in mental health. Pre-training allows LLMs to better understand and respond to individual problems with greater accuracy and empathy. Ma et al. (2023) introduced the Psy-LLM framework that uses LLMs to answer questions in online psychological consultations. This framework aims to improve mental health support by combining pre-trained LLMs with professional QA datasets and selected psychological content. Its performance is evaluated using both intrinsic and extrinsic metrics to check how coherent and relevant its responses are. The Psy-LLM framework is built on two pre-trained models: the PanGu model and the WenZhong model.

The PanGu model is a language model with around 200 billion parameters that uses vanilla transformer layers Zeng et al. (2021). It is the first Chinese pre-training model, trained on a huge amount of unlabeled data. PanGu provides better language representations, improved initialization parameters, and effective regularization, which makes it ideal for use in the Psy-LLM framework for question-answering Zeng et al. (2021). On the other hand, the WenZhong model is built on a large pre-trained model trained using a Chinese corpus Zhang et al. (2023). Its architecture focuses on a decoder-based design. The model implemented with the WenZhong framework has 110 million parameters spread

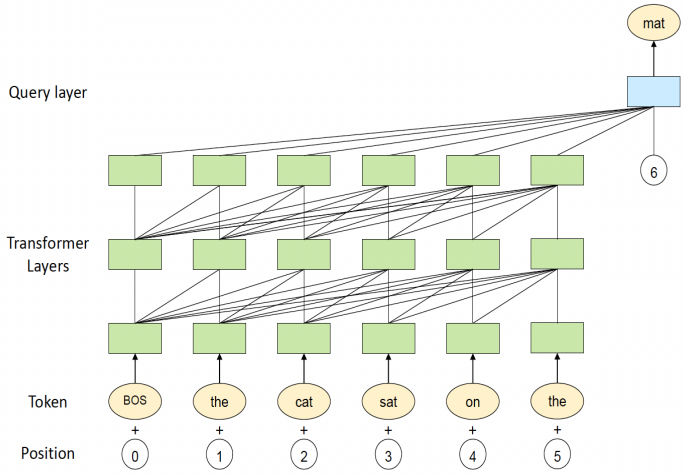

FIGURE 4 The model layers and architecture of the PanGu model as proposed in Zeng et al. (2021)

over 12 layers Zhang et al. (2023). It also benefits from being pre-trained on the Wudao Corpus, which enhances its ability to understand and generate language. This framework used two main datasets: the PsyQA dataset, which includes 22,000 mental health-related question-answer pairs and 56,000 detailed responses, and a custom dataset compiled from Chinese social media platforms such as Tianya, Zhihu, and Yixinli.

The model's performance is assessed through intrinsic and extrinsic evaluation methods. For intrinsic evaluation, metrics like perplexity, Rouge-L, distinct-1, and distinct-2 are used Zeng et al. (2021). Perplexity checks how well the model predicts the next word in a sequence, while Rouge-L measures the similarity between the generated response and the reference answer. Distinct-1 and distinct-2 focus on the diversity of the generated responses by looking at unique unigrams and bigrams. Extrinsic evaluation, on the other hand, looks at how effectively the model provides meaningful and relevant responses to users seeking psychological support. Additionally, human evaluation is carried out to gather deeper insights into the model's overall performance.

$$\text{Perplexity} = 2^{-\frac{1}{N}\sum_{i=1}^{N}\log_2 P(w_i)} \tag{1}$$

$$ROUGE\text{-}L = \frac{\text{LCS}(\text{machine-generated text, reference text})}{\text{Total number of words in reference text}} \tag{2}$$

$$\text{Distinct-1} = \frac{\text{Number of Unique Unigrams}}{\text{Total Number of Unigrams}} \tag{3}$$

$$\text{Distinct-2} = \frac{\text{Number of Unique Bigrams}}{\text{Total Number of Bigrams}} \tag{4}$$

The evaluation results show that the PanGu model performs better than the WenZhong model when it comes

to helpfulness, fluency, relevance, and logical coherence. Both intrinsic and human evaluation metrics confirm this Ma et al. (2023). Human evaluators generally find PanGu's responses to be more useful, fluent, relevant, and logically sound compared to those generated by WenZhong. One major drawback of the WenZhong model is its vulnerability to exposure bias during training Zhang et al. (2023). Exposure bias appears when samples come from the target language distribution, which leads to errors that still lack effective solutions. Moreover, repeated training of the WenZhong model seems to result in a noticeable drop in output quality.

In their study, Prystawski et. al. Prystawski et al. (2023) tested whether introducing rationales that reason about the latent variables posited by probabilistic models of language understanding could improve the capacity of large language models to choose appropriate paraphrases for metaphor. Prompts were designed with an instructional sentence followed by 10 examples. In addition, metaphors can be used in psycho-education to explain complex psychological concepts to individuals who may have limited knowledge or understanding of mental health. For example, the metaphor of a "broken record" can be used to explain rumination or repetitive negative thinking patterns. This metaphor helps individuals grasp the concept and recognize the need to break free from unhelpful thought patterns **?**. The LLMs are prompted to infer the QUD and reason about the literal state of the world to choose an appropriate paraphrase for the metaphor. Similarity prompts involve identifying the subject and object of the metaphor and reasoning about the property transferred from the object to the subject. The LLMs use this information to select an appropriate paraphrase for the metaphor.

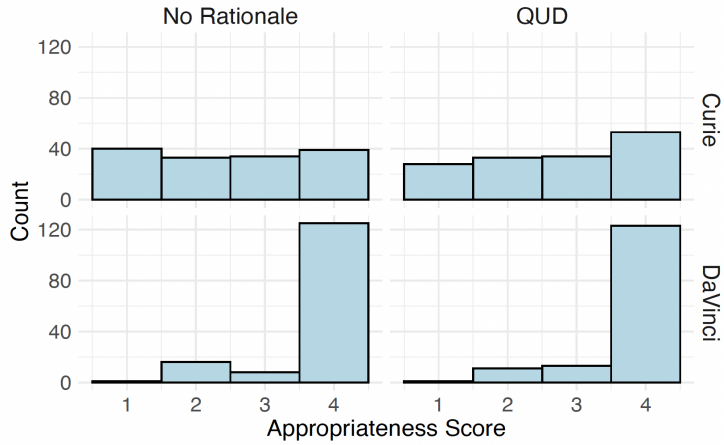

FIGURE 5 Histograms of paragraph appropriateness distributions for GPT-3 Curie (top) and DaVinci (bottom) with both no rationales (left) and QUD rationales (right) evaluated by Prystawski et al. (2023)

The dataset used for evaluation is the Katz corpus, which consists of both non-literary and literary metaphors in English. The metaphors in the corpus are of the form "[subject] is [object]" or "[subjects] are [object(s)]." The data set includes norms related to aspects such as comprehensibility, metaphor goodness, and familiarity for each metaphor, based on human ratings. Four non-metaphorical paraphrases were created for each metaphor to evaluate appropriateness. The best interpretations transferred a relevant property from the object to the subject, while the second-best transferred a less appropriate property. The third-best expression expressed a fact about the subject and the worst paraphrase expressed the opposite interpretation of the best. The main metric used for evaluating model responses was the appropriateness score of the chosen paraphrases (ranging from 1 to 4). Bayesian cumulative logistic regression and Pearson correlations were used for analysis. Ratings of psycholinguistic features of the metaphors were considered in the evaluation.

In the upper section of Figure 5, the appropriateness distributions for GPT-3 Curie are presented, comparing scenarios with and without QUD prompts. The incorporation of QUD prompts is observed to shift the appropriateness

distribution, moving it away from a rating of 1 and toward 4. Moving to the lower section of Figure 5, the complete appropriateness distributions for GPT-3 DaVinci are depicted under two conditions: without rationale prompts and with QUD rationale prompts. In both cases, the distributions predominantly favor a rating of 4, yet when QUD prompts are employed, there is a slight increase in responses rated 3 compared to those rated 2. However, it is important to note that the study primarily focuses on paraphrasing metaphors and does not extensively explore other aspects of metaphor comprehension, such as understanding the figurative meaning or interpreting the intended message. Additionally, the evaluation metrics used, such as appropriateness scores, may not capture the full complexity of metaphor understanding. Furthermore, while the study provides insights into the effectiveness of rationales in improving LLM performance, it does not thoroughly investigate the underlying mechanisms or provide a comprehensive analysis of the limitations of the approach. Future research could delve deeper into the specific cognitive processes involved in metaphor comprehension and explore alternative methods to enhance LLMs' metaphor understanding capabilities.

3.5 | Chatbots

Another approach is using chatbots in mental healthcare by implementing artificial intelligence-driven chat-based systems to provide support, guidance, and interventions for individuals facing mental health challenges. These chatbots engage with users via interactive chats to provide mental health support. This study focuses on improving the performance of this framework in the evaluation of dialogue models involved in mental support conversations. The dialogue model serves as a filter in order to decide whether to selectively utilize or ignore the expert's advice based on the context and dialogue history. Dialogue models trained include:

- Vanilla BlenderBot (2.7B): baseline BlenderBot model fine-tuned on EmpatheticDialogues, ConvAI, WizardofWiki, and BlendedSkillTalks in a multi-task style.
- BlenderBot for Mental Health: It was created by fine-tuning the BlenderBot (BB) on the original ESConv dataset. Furthermore, it integrates multi-task fine-tuning approach using both BlendedSkillTalks and ESConv with equal training weight.
- BlenderBot for Mental Health with Reasoning: This model adopts the Ask an Expert approach for mental health support systems and further, based on reasoning processes which are majorly obtained through prompts, it is fine-tuned.

Evaluation results depict that the "Ask an Expert" approach has improved the performance of dialogue models in mental support conversation. In the automatic evaluation of reasoning processes, there is a clear improvement in similarity and entailment scores from GPT-1 to DaVinci, with DaVinci outperforming other models. In the human evaluation of reasoning processes, the annotations containing reasoning information provided by the expert models are found to be valid and informative. In the evaluation of dialogue models, the models with reasoning processes outperform the baseline model in terms of providing constructive suggestions, sharing similar experiences, and being engaging and empathetic. The human evaluation results also show that davinci performed better than other models in generating high-quality dialogues.

4 | AVAILABLE DATASETS

Most of the datasets that are apt for LLMs are collected from social media posts based on the nature of the posts. Dealing with unstructured and semi-structured data from social media is one of the trickiest tasks. It involves managing missing values and cohesively presenting multi-modal information. Details of some of the widely used datasets and experimental setups are given in Table 2. The available datasets are discussed in this section.

- *CLPsych 2015 Shared task dataset*: The CLPsych dataset Coppersmith et al. (2015) consists of three modules, Depression vs. Control (DvC), PTSD vs. Control (PvC), and Depression vs. PTSD (DvP) (Post-traumatic stress disorder or PTSD, is an anxiety disorder that develops in reaction to physical injury or severe mental or emotional distress, such as military combat, violent assault, natural disaster, or other life-threatening events).
- *Reddit Self-reported Depression Diagnosis (RSDD) dataset* Yates et al. (2017): The RSDD dataset comprises Reddit posts from around 9,000 users who have self-reported a diagnosis of depression, referred to as "diagnosed users." Additionally, the dataset includes approximately 107,000 matched control users.

- *Multimodal Dictionary Learning (MDDL) dataset* Shen et al. (2017): The MDDL dataset for depression detection consists of three modules. The modules are created using tweets from 2009 to 2016, where users are labeled as depressed if their anchor tweets meet the strict pattern "(I'm/Iwas/Iam/I'vebeen) diagnosed depression."

- *Self-Reported Mental Health Diagnoses(SMHD) dataset* Cohan et al. (2018): SMHD dataset comprises Reddit posts from users who have self-reported being diagnosed with one or several of nine mental health conditions, referred to as "diagnosed users," along with matched control users. Several studies in the literature have utilized this dataset, and it focuses on multiple mental health conditions rather than solely the depression dataset.

- *eRISK* Martın-Rodilla et al. (2022): This dataset has been accessible online for experiments and analysis for a few years to support the goals of a shared task. This dataset, dedicated to early risk detection, has been provided by CLEF Lab to address the challenges associated with identifying depression, anorexia, and self-harm for a considerable period.

- *Sina Weibo* Cao et al. (2019): This dataset is extracted from the Chinese social media platform Sina Weibo comprises 3652 users exhibiting suicidal tendencies and 3677 users without any suicidal risk.

- *Suicide Risk Assessment using Reddit(SRAR)* Gaur et al. (2019): The SRAR dataset is openly accessible in the public domain and consists of 500 Redditors (anonymized), their posts, and expert-annotated labels. The research community anticipates utilizing this dataset soon to improve and advance proposed techniques.

- *Dreaddit* Turcan and McKeown (2019): Dreaddit introduces a novel text corpus designed for identifying stress in lengthy, multi-domain social media data. This dataset comprises 190,000 posts gathered from five different categories of Reddit communities.

- *GoEmotion* Demszky et al. (2020) : The GoEmotion dataset includes 58,000 meticulously curated comments sourced from Reddit, each human-annotated with one of 27 emotion categories or labeled as Neutral. It also features a filtered version derived from an inter-rater agreement, comprising a train/test/validation split.

- *The University of Maryland Reddit Suicidality Dataset (UMD-RD)* Shing et al. (2020) : The UMD-Reddit Dataset consists of two sub-directories, one containing data from 11,129 users who posted on SuicideWatch and another for 11,129 users who did not. Each user in the dataset has complete longitudinal data from the 2015 Full Reddit Submission Corpus. Academic researchers have actively utilized the UMD-Reddit dataset since 2019, accessing it through a signed agreement.

- *SDCNL dataset*: The SDCNL dataset was obtained through the Reddit API and scraped from two subreddits, namely r/SuicideWatch and r/Depression, comprising a total of 1,895 posts. Two fields were extracted from the scraped data: the original text of the post as inputs and the subreddit to which it belongs as labels. Posts originating from r/SuicideWatch are labeled as suicidal, while those from r/Depression are labeled as depressed.

- *SWMH dataset* Ji et al. (2022b): The dataset used in this study is available upon request. It comprises 5,326 suicidal posts out of 20,000 extracted posts and 594 suicidal tweets out of 10,000 extracted tweets, serving for experiments and the evaluation of the proposed classification approach for suicidal risk detection.

- *PsyQA dataset* Sun et al. (2021a): PsyQA is a Chinese dataset designed for psychological Question-Answer (QA) support. It features answers that have been provided by well-trained volunteers and professional counselors. This dataset encompasses a total of 22,346 questions and 56,063 answers, with each question being associated with one or more ground-truth responses.

5 | ETHICAL CONSIDERATIONS AND CHALLENGES

Advances in language models have led to more effective AI-driven mental health support tools. Due to its transformative capabilities, it has ensured the wide availability of mental health support for those in need. However, there is a need of a comprehensive evaluation of its ethical implications and addressing the challenges that accompany this. This section uncovers the underlying issues which generally occurs in the deployment of LLMs in the mental health field. In its initial phase, the conventional methods generally comprised of text-based services or face-to-face interactions. Hence, certain issues like long waiting times and limited access were prime concerns. With the advent of LLMs, these issues got resolved easily since it provided quick, affordable, and scalable mental health support.

In the majority of cases, to ensure fairness, it becomes necessary to address the biases that AI can generally learn from input data Bender and Friedman (2018). Thus, it becomes an issue that falls under ethical consideration. Moreover, it also raises concerns regarding professional competence and accountability.

Still, AI has limited capability While it comes to comprehending and conveying human emotions. LLMs may produce unethical and improper information, such as racist and ageist aspects, as well as other forms of bias, such as suicidal responses because they learn from uncensored online sources Bender et al. (2021). Therefore, it raises fundamental doubts about the effectiveness and fairness of LLMs. Dealing with sensitive topics like gender, religion, or other divisive concerns, the models may unwittingly feed preconceptions or come across as hostile in their responses. Hence, it is essential to carefully design and monitor AI systems to handle delicate subjects with sensitivity and fairness Ferrara (2023).

6 | LIMITATIONS AND OPPORTUNITIES

6.1 | Limitations

LLMs trained on extensive datasets carry inherent biases and errors, rendering them susceptible to generating inaccurate and misleading information. This limitation is particularly salient when addressing intricate subjects like mental health Chow et al. (2023); Holzinger et al. (2023); Rao et al. (2023); Wang et al. (2023c). Furthermore, the capability of LLMs to grasp the subtleties of human language lags behind that of humans, giving rise to potential misunderstandings and misinterpretations, which can prove detrimental in clinical contexts. Despite of their transformative capabilities, LLMs are limited by their lack of in-depth human linguistic understanding which adversely impact medical decision-making. While still in its early stages, existing studies have identified several key gaps. A key problem is the significant need to create more robust and dependable LLM systems, as current models suffer from uneven performance Wang et al. (2023c). The lack of established methods makes evaluating LLMs for mental healthcare particularly difficult. The biggest challenge in evaluating LLMs for mental health is the absence of standard methods Wang et al. (2023c). Without suitable evaluation methodologies, it is difficult to determine the effectiveness of these models. A clear, uni-

TABLE 2 Different mental health datasets and their details.

Reference	Dataset	Details	Nature
Muskan Garg Garg (2024)	WellXplain	Wellness concept extraction in Reddit posts	Custom
Glen et al. Coppersmith et al. (2015)	CLPsych	Data from Twitter users who state a diagnosis along with demographically-matched community controls	Depression, Control, and PTSD
Andrew et al. Yates et al. (2017)	RSDD	Reddit posts of users who have claimed to have been diagnosed with depression; 9210 users in depression and 1,07,274 users in control group	Depression, Control
Shen et al. Shen et al. (2017)	MDDL	300 million users and 10 billion tweets in Depression, Non-depression, and Depression candidate	Depression
Cohan et al. Cohan et al. (2018)	SMHD	Reddit dataset for multi-task mental health illness	Mental Health
Parapar et al. Martın-Rodilla et al. (2022)	eRISK	Early risk detection by CLEF lab about problems of detecting depression, anorexia and self-harm	Depression
Cao et al. Cao et al. (2019)	Sina Weibo	3,652 (3,677) users with (without) suicide risk from Sina Weibo	Suicidal Id.
Gaur et al. Gaur et al. (2019)	SRAR	Posts from 500 Redditors (anonymized) & annotated by domain expert	Suicide Risk
Turcan et al. Turcan and McKeown (2019)	Dreaddit	190K Reddit posts of 5 different categories	Stress
Demszky et al. Demszky et al. (2020)	GoEmotion	Manually annotated 58k Reddit comments for 27 emotion categories	Emotion
Shing et al. Shing et al. (2020)	UMD-RD	11,129 users who posted on r/SuicideWatch and 11,129 users who did not	Suicidal Id.
Haque et al. Haque et al. (2021)	SDCNL	Reddit dataset of 1895 posts of depression and suicide	Suicidal and Depression
Garg et al. Garg et al. (2022)	CAMS	Interpretable causal analysis of mental illness in social media (Reddit) posts	Mental Health
Zheng et al. Zheng et al. (2023)	ExTES	36 emotionally impactful scenarios that encompass a wide array of everyday life situations	Emotion
Ji et al. Ji et al. (2022b)	SWMH	Collection contains a total of 54,412 posts comprising suicide-related intention and mental disorders	Suicidal Id.
Sun et al. Sun et al. (2021a)	PsyQA	Chinese dataset of psychological health support in the form of question (22K) and answer (56K) pair	Mental Health

form method for evaluating LLMs would make it easy to grasp their strengths as well as their weaknesses. However, existing evaluation procedures remain restricted, and more accurate ways must be developed to ensure that LLMs are actually suited for clinical usage Campion et al. (2010).

Integration of LLMs into existing mental healthcare systems is a dimension that needs in-depth exploration. More research is required to understand this for seamless integration Wang et al. (2023c). The current literature focuses primarily on demonstrating LLM capabilities but lags in evaluating the associated risks and harms. Risk management should also be included, followed by techniques for content filtering, output verification, and safety constraints. Additionally, there hasn't been enough testing with actual people who need mental health support.. Studies should prioritize real-world interactions to assess the practical effectiveness of LLMs Li et al. (2023); Campion et al. (2010). Not enough studies have been conducted comparing LLMs to human mental health professionals. It's crucial to thoroughly assess the performance of LLMs in detection, counseling, and treatment Li et al. (2023). The usage of data of public online forums, which may not generalize well to clinical settings, is a critical limitation. The requirement of developing diverse and representative datasets to enhance the reliability of LLMs is also important Chhikara et al. (2023); Li et al. (2023); Xu et al. (2023). The potential of LLMs in explainable mental health analysis needs improvement. In order to promote better evaluation, the research needs to focus on enhancing transparency in LLM reasoning Ji et al. (2021). Efforts should be made to handle LLM content generation so that unethical outputs can be avoided. This involves researching techniques for content filtering, safety constraints, and output verification. The potential for overreliance on and addiction issues stemming from prolonged LLM use in mental health support requires further exploration. The mitigation strategies are also an essential domain in order to ensure responsible LLM utilization. Anthropomorphizing LLMs for mental health chatbots can lead to people becoming overly attached, which may pose risks. This warrants investigation to understand potential consequences. Evaluating LLM mental health detection on more diverse datasets, including multilingual assessments, is imperative. This expands the applicability of LLMs and improves their robustness. In conclusion, while LLMs offer promise in enhancing mental healthcare, addressing these research gaps and challenges is pivotal to ensure their safe and effective integration into clinical practice. Continued research efforts in these areas will ultimately contribute to better mental health outcomes for all.

6.2 | Opportunities

The applications of LLMs in the context of mental health encompass several key techniques which still have a lot of room for improvement. We identify a few areas where there is an opportunity to improve our LLMs.These are given below:

Real-world testing and evaluation: One fundamental aspect of LLM integration into mental healthcare involves conducting clinical trials or field studies to evaluate the effectiveness of LLM mental health chatbots when interacting with patients in real healthcare settings. Gathering feedback from both patients and clinicians is crucial for assessing the strengths and weaknesses of LLM systems. Furthermore, testing LLM detection systems retrospectively on clinical records is essential for determining the real-world accuracy of these systems.

Bias and Fairness: The potential biases in existing mental health LLM systems and data are areas of concern. Investigating these biases and developing techniques to mitigate them is critical to promote fairness in LLM training data and outputs.

Safety and Ethics: Ensuring the safety and ethical use of LLMs in mental healthcare is imperative. Tools to automatically detect and filter harmful LLM-generated text are under development, and interventions are being designed to prevent overreliance and addiction when using LLM chatbots for mental health support Ji et al. (2021).

Model Diversity: Diversifying LLM mental health systems by testing them on various cultural texts and languages is

being pursued. Adaptations to LLM architectures and training methods are being made to enhance performance on non-English data.

Clinical Efficacy: Conducting studies to determine the outcomes of LLM interventions in comparison to traditional treatment is crucial. LLMs are also being evaluated as assistive tools for clinicians to improve mental health workflows and processes.

User Assessment: Developing strategies to allow users of mental healthcare-oriented generative AI solutions to assess the performance of responses based on performance metrics such as accuracy, precision, recall, F1-score, and user satisfaction scores to help evaluate the AI's performance in specific tasks. Also, customized user feedback using a long-term memory approach can help to establish a continuous monitoring system to track the AI's performance and iteratively improve its algorithms based on user feedback and new data.

Furthermore, several specific research directions and considerations have been identified:

- Studying algorithmic biases in mental health LLMs and developing mitigation strategies Harrer (2023).
- Enhancing the interpretability of LLM-generated mental health assessments and recommendations Ji et al. (2021).
- Exploring the multimodal capabilities of LLMs, including their integration with physiological signals for mental health monitoring and companionship Wang et al. (2023c)
- Examining the integration of LLMs with professional mental health workflows Wang et al. (2023c); Srivastava et al. (2022).
- Using LLMs to augment existing therapies, thereby providing patients with personalized feedback and support between therapy sessions Sharma et al. (2021).

7 | CONCLUSION

The integration of Large Language Models (LLMs) into mental healthcare presents transformative opportunities but also introduces complex challenges that must be carefully addressed. This paper has provided a comprehensive examination of the diverse techniques employed to harness LLMs for mental health applications, shedding light on their capabilities, limitations, and ethical implications. By introducing a structured taxonomy, we conceptualized the evolving research landscape, analyzing key methodologies such as prompt engineering, fine-tuning, emotional theory integration, AI-driven chatbots, and long-term memory mechanisms. Case studies on depression detection, suicide risk prediction, and AI-assisted psychological counseling demonstrated LLMs' potential in risk assessment, emotional support, and personalized interventions. Techniques like instruction fine-tuning and domain-specific dataset curation significantly enhanced model performance, while psychologically informed prompts improved response accuracy. Conversational AI agents showed promise in fostering intuitive and engaging interactions, paving the way for AI-assisted mental health interventions. However, critical challenges remain. Bias, reasoning failures, safety risks, and inconsistencies in clinical reliability indicate that LLMs are not yet suitable for high-stakes mental health applications without rigorous oversight. The lack of real-world clinical validation, reliance on publicly available data, and long-term impacts of AI-driven mental health tools require urgent attention. Ethical concerns surrounding privacy, informed consent, and algorithmic bias must be addressed to ensure that AI augments rather than compromises mental healthcare.

This study underscores both the promise and the pitfalls of integrating Artificial Intelligence within Healthcare 5.0. To harness LLMs responsibly, developers, practitioners, ethicists, and policymakers must collaborate to establish ethical guidelines, safety mechanisms, and clinically validated AI frameworks. With prudent design, transparency, and ongoing evaluation, LLMs have the potential to enhance accessible, inclusive, and empathetic mental healthcare, shaping a future where AI serves as a responsible ally in supporting mental well-being.

***Abstract*— Alzheimer's disease is a progressively deteriorated, irreversible brain ailment that impairs memory and cognitive function. Early detection of Alzheimer's disease is crucial as it can reduce the risk factors and can provide the effective therapy to the affected person within stipulated time. In the proposed approach, bidirectional empirical mode decomposition is applied on 2-D Magnetic Resonance Images to decompose them into four Intrinsic Mode Functions. Then, using four Intrinsic Mode Functions, the Gray Level Co-occurrence Matrix has been computed. The Gray Level Co-occurrence Matrix interacts directly with the image intensity, it offers information on patterns that mutually occur. For every Intrinsic Mode Functions, 22 statistical features are obtained from these matrices. In order to improve the classification accuracy, Particle Swarm Optimization (PSO) is further utilized for extracting optimal and relevant features. The classification results for proposed method are 96.4% accuracy, 96.0 % sensitivity and 97.0 % specificity. The proposed work outperforms the existing methods for AD detection in terms of its outstanding classification results.**

Keywords—Alzheimer's disease detection, Bidirectional Empirical Mode Decomposition, Gray Level Co-occurrence Matrix, Magnetic Resonance Imaging, Particle Swarm Optimization, Feature Selection

I. INTRODUCTION

Alzheimer's disease (AD) is a fatal neurological disorder that primarily impairs older adults' memory and cognitive skills. AD is a serious health condition that spreads globally and primarily affects those over the age of 65 years [1]. Since AD cannot be cured completely at present and can only be treated to delay its progression, it is essential to precisely diagnose the patient's illness at right time. The early diagnosis of AD is essential for managing and reducing its effect. AD is triggered by the growth of tangles in the brain. These tangles are due to the accumulation of amyloid plaques and tau proteins. This process results in breaking the synaptic and neuronal connections in the brain [2]. The neuronal loss creates structural changes in the brain. These changes can be visualised through diagnostic tests like Magnetic Resonance Imaging (MRI), Positron emission tomography (PET), Diffusion Tensor Imaging (DTI). These structural changes are altered cortical thickness, enlarged ventricles, reduced grey matter tissue density, and reduced hippocampal size, shape, and volume [3]. The MR technique provides images with good resolution and high contrast. This makes MRI as the best technique to examine structural changes and grey matter density fluctuations in the brain [4]. The features obtained from MRI are more informative and relevant and thus useful for early AD detection. Researchers have presented a variety of feature extraction techniques in the literature such as Voxel Based Morphometry (VBM), Surface Based Morphometry (SBM) and Region of Interest (ROI) based methods [5]. VBM tests the white matter and grey matter density in the brain of different groups of subjects or within a same subject over time. VBM suffers from misalignment and imperfect image registration issues. SBM helps in analysing structural changes in the cortical surface of the brain. This method faces challenges while accomplishing cortical surface reconstruction. ROI based method focussed on the affected part of the brain due to AD. The accuracy of this method depends upon the expertise of the researcher [5]. This paper proposed a method which detects the structural changes and grey matter density fluctuations from the whole brain rather than a specific region. The whole-brain approaches do not need to extract any part from the brain rather they use whole brain for extracting informative features [6].

In this paper, the image is decomposed into four Intrinsic Mode Functions (IMFS) using Bidirectional Empirical Mode Decomposition (BEMD). Next, each IMF's Grey Level Co-occurrence Matrix (GLCM) is obtained, and the 22 statistical features are taken out from each IMF's GLCM. Particle Swarm Optimization (PSO) is applied for selecting significant and appropriate features from these 88 statistical features. The paper contributes in the following way:

- This work introduces a new feature extraction technique for AD classification that can be utilized to identify various AD stages by measuring the spatial pattern of structural and grey level details, which vary with AD severity.
- The proposed method uses BEMD with GLCM for feature extraction. BEMD provides multiscale decomposition of the image into IMFs, allowing for a detailed analysis of signal components at different scales. GLCM helps in finding the grey scale variation between pixels in an image by determining the spatial relationship between pixels

(i) (ii)

Fig. 1. 2-D MR slice from OASIS dataset (i) Alzheimer's Disease and (ii) Normal Control

separated by a given distance. The combined strength of BEMD and GLCM improves the classification accuracy by providing more informative features.

- The proposed method captures both local and global structural information from different parts of the brain which is very beneficial for detecting AD at different stages.

The efficacy of the proposed approach is evaluated by comparing it with three existing methods using performance measures as accuracy, sensitivity, and specificity. The paper has been divided into following sections: Section II describes the dataset and background information needed to implement the proposed work; Section III describes the results of the implementation work; and Section IV completes this paper with recommendations for future research.

II. Proposed Method And Material

A. Database

The Data used in the preparation of this article were obtained from the Alzheimer's Disease Neuroimaging Initiative (ADNI) database. The ADNI was launched in 2003 as a public-private partnership, led by Principal Investigator Michael W. Weiner, MD. Another dataset is Open Access Series of Imaging Studies (OASIS). From the OASIS [7] and ADNI collections, a total of 28 AD and 28 NC subjects are chosen, and their 3-D MR images are retrieved. The four center slices are taken out of each 3-D MR image. These 2-D MR images, or center slices, are employed in classification. There are 112 2-D MR images overall in each class. OASIS is a data warehouse where scientists may access and gather brain MRIs for their research projects. The MRI sample that is available at http://www.oasis-brains.org is shown in Fig. 1.

B. Method

The proposed approach employs BEMD for image decomposition, GLCM for extracting statistical features and PSO for selecting appropriate features. The selected features are used for AD classification. Three groups have been implemented in this work. The group 1 includes the direct application of GLCM over MR images. Total 22 statistical features have been extracted from these GLCMs matrices and have been used for classification. The second group combines BEMD and GLCM for extracting features. BEMD has been applied on 2-D MR scans to obtain four IMFs with decomposition at first level. Subsequently GLCM has been calculated for these four IMFs. Total 88 statistical features are obtained from these four IMFs with contribution of 22 features from each IMF. These features have been used for AD classification in group 2. The third group includes PSO with BEMD and GLCM. PSO selects the optimum features from these 88 features. The number of features selected by PSO are 34. These features are used for AD classification. GLCM efficiently extracts the key features from an image by giving all the information about the direction, adjacent pixel interval, and grey level changes. PSO is simple to implement and provides globally optimal solutions. PSO supports parallel computing architectures and efficiently explores the search space. All these properties make it a valuable tool for enhancing the classification performance of groups. Fig. 2 illustrates the flow of process in the proposed approach.

C. Bidirectional Empirical Mode Decomposition

BEMD [8-10] is the modified version of EMD. EMD is used for analysing nonlinear and non-stationary signals by breaking down it into Intrinsic Mode Functions (IMFs). These IMFs are obtained by iteratively sifting through the signal to extract oscillatory modes with low to high frequency ranges. Each IMF corresponds to scale or frequency component of the original signal. By decomposing MRI signals into IMFs, BEMD can capture both global and local features present in the images, providing valuable information for image interpretation and analysis. The difference in between EMD and BEMD is that EMD supports unidirectional sifting and BEMD supports bidirectional sifting. The bidirectional sifting helps in capturing temporal changes in the signal potentially and the most favourable case include complex non-stationary signal. BEMD is adaptive and data driven. BMED does not depend on predefined basis functions like wavelets for analysing the signal's underlying structure. Rather, it amends itself according to the local characteristics of the signal and thus handles the signals with varying spectral content and non-stationary dynamics effectively. BEMD offers multiple properties like multi-scale analysis, artifact removal, feature extraction, and dynamic analysis and thus becomes a valuable tool for advancing MRI research.

D. Grey Level Co-occurrence Matrix

The GLCM of an image provides all the information regarding the direction, intensity change in the grey level, and neighbouring interval between the pixels [11, 12]. GLCM is suitable for feature extraction because of this property.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 07:34:29 UTC from IEEE Xplore. Restrictions apply.

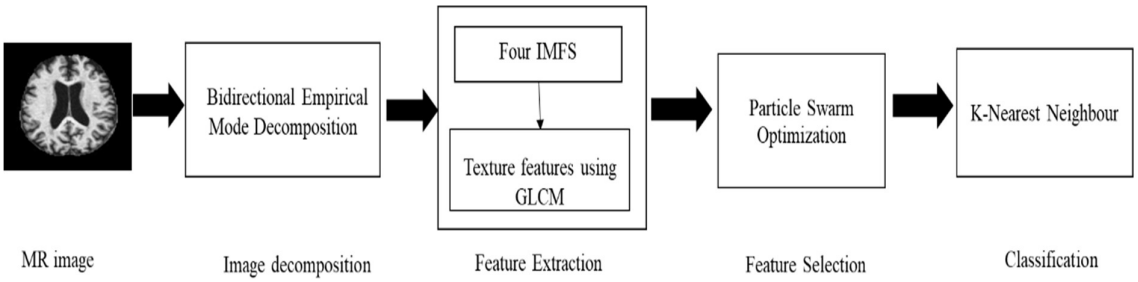

Fig. 2. Proposed Methodology

Let suppose grey scale image I_g contains N_b number of grey levels thus the GLCM ($G_{m,n}$) of image will be of order N_b. The (m,n)th value in $G_{m,n}$ indicates the frequency of distribution of two adjacent pixels with intensities 'm' and 'n'. These pixels may be at distance "d" with d=1,2 3 so on. The orientation of these pixels is at any four angles 0º, 45º, 90º,135º which is shown in Fig. 3. The 22 Haralick texture features can be computed for all four directions [13]. GLCM provides following 22 statistical features.

1. Angular second Moment: It represents uniform patterns in the image.

2 Joint Entropy: It represents the measure of randomness of joint distribution of two variables.

3.**Dissimilarity:** It defines the linear metrics of local changes in an image.

4.Contrast / Inertia: It quantifies the difference in between the highest and lowest intensity value of two adjacent pixels.

5.Homogeneity1/ Inverse difference: It indicates the uniformity of pixel values in a small region of an image.

6.Correlation: It represents how the two pixels are linearly related.

7.Homogeneity 2/ Inverse difference moment: It shows the local homogeneity of an image.

8.Autocorrelation: It measures the roughness of an image.

9.Cluster Shade: It calculates the skewness of GLCM distribution capturing the asymmetry of cluster distribution in images.

10.Cluster Prominence: It gauges variations in the pixel's local intensity. Its high value denotes the image's asymmetry.

11.Maximum probability: It indicates the instances of the most common pair of neighbouring intensity values.

12.Sum of Squares or variance: It calculates the gray intensity level dispersion around the mean value.

13.Sum Average: It calculates the mean of the total of the image's potential grey-level intensities.

14.Sum Variance: It calculates the average dispersion of the total possible grey-level image intensities around the mean value.

15.Sum Entropy: It gauges the amount of clutter in relation to the image's total grey-level intensity.

16.Difference variance: It is a measurement of the image's varying grey level spread dispersion with respect to the mean.

17.Difference entropy: It measures the clutter in relation to the image's distribution of grey-level variation.

18.Information measures of correlation (1): It calculates the texture's complexity and correlation strength.

19.Information measures of correlation (2): It computes the strength of correlation, and the complexity of texture.

20.Maximal correlation coefficient: It provides understanding of complexity of textures.

21.Inverse difference normalized (INN): It indicates the level of smoothness in local regions of an image.

22.Inverse difference moment normalized (IDN): IDN gives details about how rapidly pixel values change within the image.

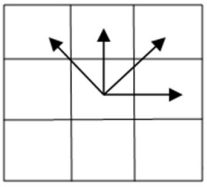

Fig. 3. GLCM with four directions

E. Particle Swarm Optimisation (PSO)

The Particle Swarm Optimization (PSO) originally presented by Kennedy and Eberhart in 1995 is a computational optimization algorithm inspired by the social behaviour of birds [14-15]. PSO shows parallel processing thus offers high convergence rate and low computation time. PSO searches for local and global optima in the search space [16]. It needs less parameters for tuning. The algorithm is inspired by the intelligence of swarm which can be seen when they search for food. Their mutual association, imparting, and learning help them for searching food. The particles in PSO can be considered as swarms. The particles in the search space have to maintain their location and velocity, and they update their location based on their own experience (personal best) and the experiences of neighbouring particles (global best). As a result, PSO effectively explores the search space, with each particle having the ability to investigate nearby areas of the solution space and being impacted by the swarm's overall best solution. After 't^{th}' iteration in search space, the position of particle p is given as

$$\mathrm{Po}_p^t = \left[\mathrm{po}_{0,p}^t, \mathrm{po}_{1,p}^t, \mathrm{po}_{2,p}^t, \mathrm{po}_{3,p}^t \dots\dots, \mathrm{po}_{N,p}^t\right] \quad (1)$$

where N is the dimensional space of the problem. Each particle is moving in search space for searching global minima as an optimum solution. The particle p moving with velocity 'Vt' at t^{th} iteration is given as

$$\mathrm{Vt}_p^t = \left[\mathrm{vt}_{0,p}^t, \mathrm{vt}_{1,p}^t, \mathrm{vt}_{2,p}^t, \mathrm{vt}_{3,p}^t \dots\dots, \mathrm{vt}_{N,p}^t\right] \quad (2)$$

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 07:34:29 UTC from IEEE Xplore. Restrictions apply.

After (t+1) [th] iteration, the position of the pth particle is given by $Po_p^{t+1} = Po_p^t + Vt_p^{t+1}$ (3)

And the velocity of particle after (t+1)[th] iteration is given by

$$Vt_p^{t+1} = w1Vt_p^t + c_1r_1\left(pbt_p^t - Po_p^t\right) + c_2r_2\left(gbt_p^t - Po_p^t\right) \quad (4)$$

In equation (4), $'pbt'$ is the best position searched by the pth particle and $'gbt'$ is the best position searched by the complete group of particles. The 'w1' represents the weight inertia constant, c1 and c2 represent the acceleration coefficients and r_1 and r_2 represent the random numbers. The values of c1, c2, w1, N and t used in implementation work are 2,2, 0.9,30 and 100 respectively. Fig. 4 illustrates the PSO convergence graph in proposed work.

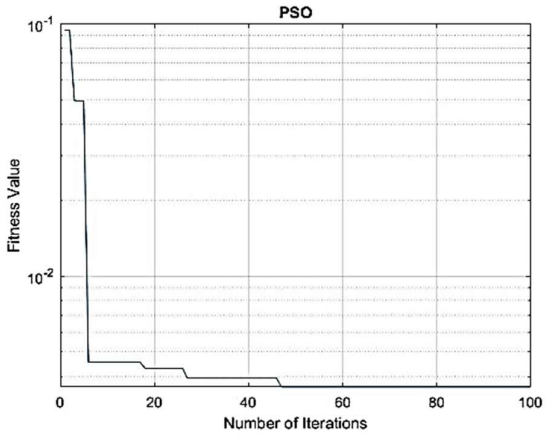

Fig. 4. Convergence Plot

III. SIMULATION RESULTS AND DISCUSSION

A. Quantitative Analysis of proposed method

The performance of the proposed work is evaluated by using parameters like Accuracy, Sensitivity and Specificity Accuracy [17] defines the proportion of rightly classified true positives and true negatives out of the total number of cases in the dataset. Sensitivity [18-19] defines the proportion of rightly classified true positives and specificity defines the proportion of rightly classified true negatives. These are mathematically formulated as

$$\text{Accuracy (Ac)} = \frac{(Tre_{pt}+Tre_{ng})}{(Tre_{ng}+Tre_{pt}+Fs_{ng}+Fs_{pt})} \quad (5)$$

$$\text{Sensitivity (Se)} = \frac{(Tre_{pt})}{(Tre_{pt}+Fs_{ng})} \quad (6)$$

$$\text{Specificity (Sp)} = \frac{(Tre_{ng})}{(Tre_{ng}+Fs_{pt})} \quad (7)$$

Where, Tre_{ng} as true negative, Tre_{pt} as true positive, Fs_{ng} as false negative and Fs_{pt} as false positive. False negative means the positive samples are detected as negative. False positive means the normal samples are detected as positives. True positive means the positive samples are detected as positives and True negative means the negative samples are detected as negatives.

B. Performance Evaluation

The proposed work provides outstanding results for AD classification. Three groups have been implemented and compared for analysing the efficiency of proposed work. The first group includes the direct implementation of GLCM on 2-D MR scans. The total 22 statistical features are obtained from matrices for all four directions at d=1.The results with this group are 92.1% using k-NN classifier. The second group includes the application of BEMD over MR scans first and then GLCM is applied. BEMD provides four IMFs and GLCM is calculated for four IMFs. The 22 statistical features are extracted from each IMF and used for AD classification. This group provides more informative features as it extracts micro and macro details from local and global parts of the brain. The classification accuracy with this group is 94.6 %. The third group includes the proposed approach which adds feature selection stage after BEMD and GLCM. The PSO has been used for feature selection process. This group provides 96.4% accuracy,96% sensitivity and 97% specificity. Table I illustrates the performance comparison between proposed work and different groups implemented in this study using OASIS dataset.

TABLE I: COMPARATIVE ANALYSIS OF DIFFERENT GROUPS

Method	Ac				Se				Sp			
	0°	45°	90°	135°	0°	45°	90°	135°	0°	45°	90°	135°
GLCM	92	92	91.5	91.5	88	91	96	93	96	93	94	90
BEMD+GLCM	94.6	94.6	94.2	94.2	92	95	97	96	97	95	91	98
BEMD+GLCM+PSO [Proposed]	95.1	96.4	96	96.4	93.2	96	97	96	97.2	96	95	96

Table II: Performance Comparison Between Proposed and Current Algorithms

Methods	OASIS Dataset (Ac/Se/Sp)	ADNI Dataset (Ac/Se/Sp)
BEMD+GLCM+PSO [Proposed]	96.4/96/97	95.1/94/96
Graph Kernel Approach [20]	92/91/93	90.2/94/87
Spiking Neural Network [21]	91/90/92	90.1/94/87
Hessian detector +LBP [22]	85.5/87/84	86.2/87/86
VGG-16[23]	86.7/85.2/87.3	85.4/86.5/84.6
Voxel-wise GM [24]	89.3/87/92	90.8/86.3/94.8

Table II lists the classification results of five existing methods [20-24] and proposed method on MATLAB 2019 with OASIS and ADNI datasets. The proposed method outperforms the current methods. The recent study [20] used graph kernel approach for extracting 3-D texture features. This method provides 92% accuracy, 91% sensitivity and 93% specificity while implementation on MATLAB with OASIS dataset. The study [21] used spiking neural network for AD classification. This study is based on deep learning including the strength of biologically inspired neurons. This method provides an accuracy, sensitivity, and specificity of 91% ,90% and 92% respectively on OASIS dataset. The study [22] combined the strength of hessian detector with Local Binary Pattern. This method gives 85.5% of accuracy,87% of sensitivity and 84% of specificity on implementation. The study [23] used deep learning model i.e. VGG-16 model for AD classification. The study [24] used voxel-based morphometry to extract grey density maps. These maps were used as features for AD classification. The results with the proposed method are 96.4% accuracy, 96% sensitivity, and 97% specificity using k-NN classifier on OASIS dataset. While on ADNI dataset, these figures are 95.1% accuracy, 94% sensitivity and 96% specificity. The proposed approach gives outstanding results for AD classification. The Receiver Operating Characteristic (ROC) graph for proposed and current methods is illustrated in Fig. 5 and Fig. 6 for OASIS and ADNI datasets, respectively.

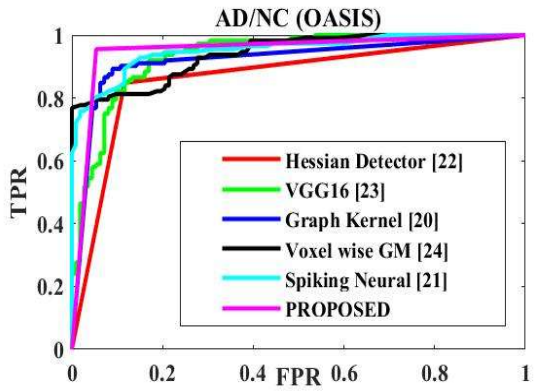

Fig. 5. ROC plot on OASIS dataset

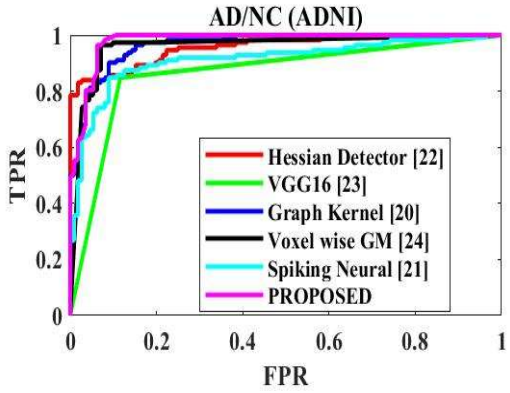

Fig. 6. ROC plot on ADNI dataset

IV. CONCLUSION

The strength of BEMD, GLCM, and PSO are combined in this study to propose a new feature extraction method for AD detection. The BEMD's ability to handle images with non-stationary characteristics and GLCM's strength in texture analysis make proposed approach strong enough to capture subtle changes in brain with different stages of AD. The experiments conducted demonstrate the ability of proposed method for capturing informative features for AD detection. The proposed approach gives 96.4% of accuracy,96.0% of sensitivity and 97% of specificity. In future this approach can be used for investigating the classification at different stages of AD. The proposed approach can be validated with different modes of decomposition and modalities with different feature selection methods.

ACKNOWLEDGEMENT

I am thankful to my guide and colleague for their valuable support. ABSTRACT

Traumatic brain injury (TBI) is an insult to the brain that impacts neuronal and non-neuronal cells/tissues. The study aimed to understand TBI-induced early changes in the brain and systemic physiology. The male rats were subjected to mild and moderate TBI, where serum and urine metabolic fingerprints of mild TBI rats showed a hypermetabolic response with increased energy metabolites, amino acids, and gut metabolites in serum and increased TCA cycle intermediates in urine. In contrast, the moderate TBI rats showed decreased lactate, pyruvate, amino acids (glycine and leucine) and gut metabolites [trimethylamine N OXIDE (TMAO), choline and acetate] in serum. The urine showed increased pyruvate, creatinine, and allantoin levels. To understand the brain's role in altered metabolic physiology, hypothalamus structure was assessed using diffusion tensor imaging (DTI) and stress levels were observed using serum corticosterone. The injured rats exhibited changes in DTI metrics in the hypothalamus, suggesting a potential disruption in the regulation of the hypothalamus-pituitary–adrenal axis (HPA) axis. These alterations were accompanied by increased TNF-α levels after moderate TBI. The injury induced allostatic overload, accompanied by impaired hypothalamic structure, and metabolic physiology also showed gut microbiome dysbiosis. The gut microbiome showed an increased Firmicutes: Bacteroidetes ratio after injury, with variable gut composition after both injuries. Therefore, the present study provides insight into an interplay between the HPA axis, metabolism, and gut microbiome following TBI. Importantly, this crosstalk between the regulatory systems was different after mild and moderate injury, highlighting the need to assess injury phenotype based on the severity.

1 | Introduction

Traumatic brain injury-induced impact or contusion to the brain leads to irreversible brain damage that is followed by secondary injury cascades within minutes to hours to months post injury. Secondary injury progresses slowly and involves complex mechanisms including axonal degeneration, metabolic perturbation, mitochondrial dysfunction, oxidative stress, inflammation, glial activation, and neuronal death (Ng and Lee 2019). Importantly, the time window from a primary

Summary

- TBI management is critical during the early time window post-traumatic event to aid in better diagnosis and treatment strategies.
- Until now, no research has comprehensively observed the changes in systemic physiology with a focus on injury severity (mild and moderate TBI).
- Therefore, the present study provides a snapshot of systemic metabolomics along with hypothalamic damage, systemic inflammation, and gut microbiome changes.

injury to the initiation of secondary injury events becomes important for the management of injury-associated disabilities. Fundamental critical care management involves various methods including mechanical ventilation, transfusion of required blood products, management of sympathetic hyperactivity, and nutritional therapy (Abdelmalik et al. 2019). Nutritional therapy is an integrated approach that optimizes systemic function and delivery of substrates to the brain. It is usually initiated as early as 24 h post injury to mitigate the effects of trauma. While nutritional supplementation suffers from issues like hyperglycemia, immunosuppression, and diminished gut integrity and function it becomes important to understand the basic metabolic and physiological mechanisms that initiate at early timepoints post injury (Kurtz and Rocha 2020).

Potential mechanisms that induce systemic alterations post TBI include the interplay of various pathways like the HPA axis and endocrine abnormalities that can further induce changes in systemic metabolism and inflammation (Tapp et al. 2019). Brain injury-induced stress can have variable effects on neurological and neurobehavioral functions. The hypothalamus plays an important role in adapting and responding to injury-associated stress and metabolic regulation under allostatic load (Zheng, Pang, et al. 2022). Our earlier study on closed head injury (CHI) has also revealed that an activated microglial population in the hypothalamic region with increased serum CORT after mild and moderate TBI is associated with a distinct metabolic and inflammatory phenotype in rats (Arora et al. 2022). While the hypothalamus is a deeply situated region, TBI-induced neuroendocrine dysfunction along with anti-hypothalamus antibodies have been observed in patients and boxers (Vijapur et al. 2020). The hypothalamus is an important region regulating energy homeostasis and metabolism in the body (Wen, Wang et al. 2019). In addition, the HPA axis is the primary responder during the states of internal and external stress to the body (Leistner and Menke 2020). While the structural changes in the hypothalamus along with its effects on HPA function are yet to be fully understood post TBI.

Since metabolites are an integral part of the biological processes and the intricate biochemical pathways that regulate the physiological system, any change in the body will reflect a unique metabolic fingerprint (Banoei et al. 2018). Metabolomics quantitatively assesses small molecules present, especially in biological fluids, including serum and urine. Since blood permeates every tissue and organ in the body, it effectively acts as a fluid network through which molecules secreted, excreted, or discarded by various tissues in response to physiological demands or stress are exchanged. Tissue damage, organ malfunctions, or pathological conditions can modify the chemical and protein composition of blood plasma or serum. Similarly, urine has been discovered to be the most convenient biological fluid for metabolic signatures related to systemic distress (Bykowski et al. 2021).

Nuclear magnetic resonance (NMR) spectroscopy is accepted as a reliable technique for metabolomic investigations due to its ability to identify novel metabolites without any chemical modification. Metabolomic fingerprinting has thus emerged as a valuable tool for identifying biomarkers and physiological indicators in various neurological conditions, including stroke, spinal cord injury (SCI), and sports-related concussions (Li and Sirko 2018). Recent studies show promise that additional research is essential to enhance our understanding of the pathophysiological processes associated with TBI severity and recovery. Extensively, TBI studies have found that the injury-associated metabolic phenotype gets repositioning or reprogramming. Injury leads to altered glucose metabolism and potentiates chronic metabolic syndrome (Li and Sirko 2018). Interestingly, a human study has also reported protective systemic lipid metabolism that can help in maintaining lipid homeostasis for optimal brain function after injury (Thomas et al. 2022). This underscores the importance of comprehending the impact of injury on systemic metabolism.

TBI-induced sympathetic activity and stress response can further progress into dysautonomia, dysbiosis, and systemic inflammation leading to gastrointestinal dysfunctions (Hanscom et al. 2021). The inflammatory shift post-injury causes gut dysmotility and increased mucosal permeability. These changes in the gut can lead to gut dysbiosis along with changes in the gut microbiome. Studies have shown that in animal models, TBI decreases smooth muscle contractility and delays gastrointestinal transit between 1 and 7 days after injury (Sun et al. 2015). Other studies have also shown microscopic changes in the intestine hours post fluid percussion injury (Feighery et al. 2008). Additionally, it has been observed that gut-derived systemic serotonin homeostasis and energy balance are disrupted post TBI (Mercado et al. 2022). Another study on TBI has also reported changes in the gut microbiome composition with altered tryptophan metabolism and microglial activation post injury day 7 and 28 (Zheng, Wang, et al. 2022). Despite this, as of now, no study has identified early changes in systemic metabolism in relation to microstructural alterations in the brain and gut microbiome after mild and moderate TBI.

Keeping in mind the above mentioned facts, the present study is aimed to assess TBI-induced changes within the early time window of 4–8 h post mild and moderate TBI. The earliest time window is considered an important phase of the injury wherein the brain is more vulnerable and susceptible to damage, with the ability of adaptive remodeling to restore homeostasis (Hoffe and Holahan 2022). The present study included metabolic phenotyping of serum and urine using ^{1}H-NMR metabolomics along with the assessment of neuronal structure that affects

10974547, 2025, 4, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/jnr.70032 by Delhi Technological University, Wiley Online Library on [06/05/2025]. metabolism (hypothalamus) using in vivo imaging. In addition, serum stress (serum CORT) and inflammation levels (IL-1β AND TNF-α) were quantified using sandwich ELISA kits. The gut microbiome composition was also observed using fecal 16S rRNA sequencing.

2 | Methods

2.1 | TBI Paradigm

2.1.1 | Animals

Twenty-four, 6–8 weeks male SD rats weighing between 200 and 250 g were obtained from the Experimental Animal Facility, INMAS. The rats were kept at a temperature of 23°C ± 1°C with a 12-h light/dark cycle (lights on 08:00 a.m.), and provided with a standard pellet diet (M/S Golden Feeds, Meharuli, Delhi, India) and water *ad libitum*. All experimental protocols performed were as per the approved guidelines by the institutional animal ethical committee (8/GO/RBi/S/99/CPCSEA/INM/IAEC/2021/02). The injury protocol and blood collection were done in the light phase, specifically between 09:00 a.m. and 01:00 p.m. (Qian et al. 2012).

2.1.2 | Injury Protocol

The animals were acclimatized for seven days and were randomly divided into three groups: Control, Mild TBI, and Moderate TBI, with each group having 8 rats. The rats were subjected to TBI by modifying Marmarou's weight drop model. Briefly, the rats for mild and moderate TBI were kept on a foam bed and were subjected to a free-falling brass rod (450 g inside an acrylic tube of 1 m held in place by an iron rod) from a height of 25 and 50 cm, respectively, above the sagittal midway (medial-lateral axis, relative to the intersection of bregma-lambda) of the brain (Arora et al. 2022). The control group received the same treatment except for the weight drop injury.

After 4–8 h post-injury, rats were subjected to MR imaging (anatomical and microstructural changes), systemic metabolomics analysis (serum and urine), and 16S rRNA sequencing for fecal microbiome composition (Figure 1). To study the difference between serum and urine metabolites, other serum markers, and DTI scalars in the control and injured groups, we assumed that there is no difference between these parameters (Ho = 0). Alternatively, if a difference was observed at $\alpha = 0.05$ and 80% power of the test with a priori effect size (f) of 1, the null hypothesis was rejected. Under these assumptions, the minimum number required for the study was 6 per group.

2.2 | In Vivo Imaging

To understand the microstructural alterations in the hypothalamus, MR imaging was performed at 4 h post-injury. Briefly, the anesthetized rats were placed on a bed with a radiofrequency array coil covering their heads. The MR imaging was done using Bruker Biospec 7.0 Tesla (Avance III) with a 30-cm horizontal bore magnet (Bruker Biospin, Ettlingen, Germany) and the imaging components included a receiver (array coil of four-channel for rat brain) and a transmitter (linear coil). Isoflurane in a mixture with oxygen was delivered to the rats with maintenance at 1%–2% isoflurane until the scan time with a flow of 0.5–1 L/min.

2.2.1 | Brain Localization

A fast low-angle single shot (FLASH) sequence was used to obtain a three-slice scout image (axial, mid-sagittal, and coronal).

2.2.2 | T2 Weighted Images

A rapid acquisition with relaxation enhancement (RARE) sequence with the following parameters: Field of view, 4 × 4 cm; Matrix size, 256 × 256; Repetition time/Echo time (TR)/(TE) = 2000/13 ms; Slice thickness, 1 mm; Number of slices = 15 was used for imaging.

2.2.3 | DTI Images

A multiple-shot spin echo EPI sequence with the following parameters: Field-of-view, 4 × 4 cm; Matrix size, 128 × 128; TR/TE, 5000 ms/34.46 ms; Number of gradient encoding directions, 46; with b, 672 s mm^{-2}; Slice thickness, 1 mm; Number of slices, 15; Number of segments, 4; number of averages = 1; Total imaging time = 12 min 55 s was used.

2.2.4 | Data Processing

Image cropping and correction of distortion were performed for all the scans. The tensor field data was diagonalized by using the

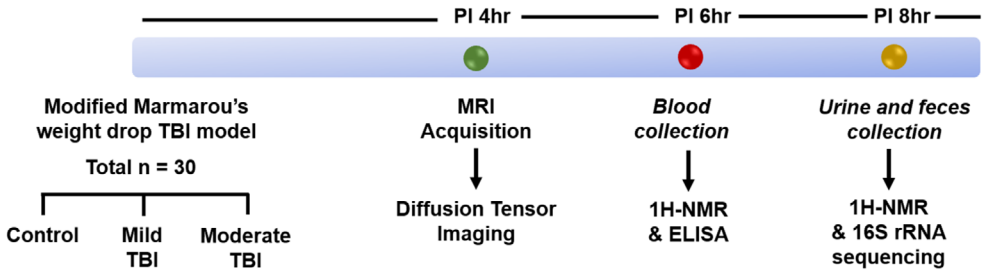

FIGURE 1 | Schematic representation of the study paradigm with the timepoint of sample collection. PI, post-injury.

10974547, 2025, 4, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/jnr.70032 by Delhi Technological University, Wiley Online Library on [06/05/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

analytic diagonalization method to obtain the eigenvalues ($\lambda 1$, $\lambda 2$, and $\lambda 3$) and the three orthonormal eigenvectors. DTI metrics including apparent diffusion coefficient (ADC), fractional anisotropy (FA), radial diffusivity (RD), and axial diffusivity (AD) for each voxel were computed using the eigenvalues. Regional FA, ADC, RD, and AD values were obtained by placing the bilateral regions of interest (ROIs; Figure 3) within the right and left sides of the hypothalamus. The size of ROIs and slices were kept constant for the analysis of each rat. For defining anatomical ROIs in the rat brain, Paxinos and Watson Rat Brain Atlas were used (Paxinos and Watson 2006). For analysis, in-house software was used, which provided the values of the DTI scalars, which were then further processed for statistical analysis (Trivedi et al. 2012).

2.3 | Sample Collection

2.3.1 | Serum

Blood (approximately 1 mL) was collected from the retro-orbital vein of each animal at 6 h post-injury in the serum vacutainers (SST Advance II BD Vacutainer) that were allowed to clot for 30 min at room temperature and then centrifuged at 2500 *g* for 15 min. The supernatant-containing serum was collected and stored at −80°C for further analysis.

2.3.2 | Urine and Feces

The rats were kept in metabolic cages as they gained consciousness for the collection of urine and fecal pellets. The samples were collected within 6–8 h post-injury and kept at −80°C for further analysis.

For NMR analysis, urine samples were centrifuged at 4722 *g* for 5 min at 4°C to remove particulate matter. The deuterated phosphate buffer solution (150 μL; 0.2 M Na_2HPO_4) (#7558-79-4, Sigma-Aldrich)/0.2 M NaH_2PO_4 (#10049-21-5, Sigma-Aldrich), pH 7.4 containing 1 mM Trimethylsilylpropanoic acid (TSP) (#7601-54-9, Eurisotop) prepared in D_2O (#7789-20-0, Sigma-Aldrich) was mixed with 450 μL of centrifuged urine to minimize variations in pH of urine samples.

2.4 | NMR Metabolomics

2.4.1 | Acquisition

Each serum (450 μL) was transferred to a 5 mm NMR tube containing 1 mM TSP in a closed capillary/insert (Wilmad, SP Industries, Buena, NJ, USA) as a reference. The urine sample (450 μL) was prepared in phosphate buffer with TSP, centrifuged, and transferred to an NMR tube. TSP in phosphate buffer acted as a chemical shift reference (0.0 ppm) and D_2O provided a signal lock. The NMR spectra were acquired at 800.20 MHz, Bruker-AV spectrometer (Bruker, Germany) at 300 K (Figure 2).

For serum NMR acquisition, water-suppressed Carr-Purcell-Meiboom-Gill (CPMG) spin echo pulse sequence [RD-90°-(τ-180°-τ) *n* acquire] with a total spin echo ($2n\tau$) of 200 ms was used to attenuate broad signals from proteins and lipoproteins. RD (relaxation delay) was 2.5 s, [RF (radio frequency) pulse], [τ (spin echo delay)], [*n* (number of loops)]. Typically, 128 scans were collected into 32 K data points over a spectral width of 12,820.51 Hz with an acquisition time of 9.29 s.

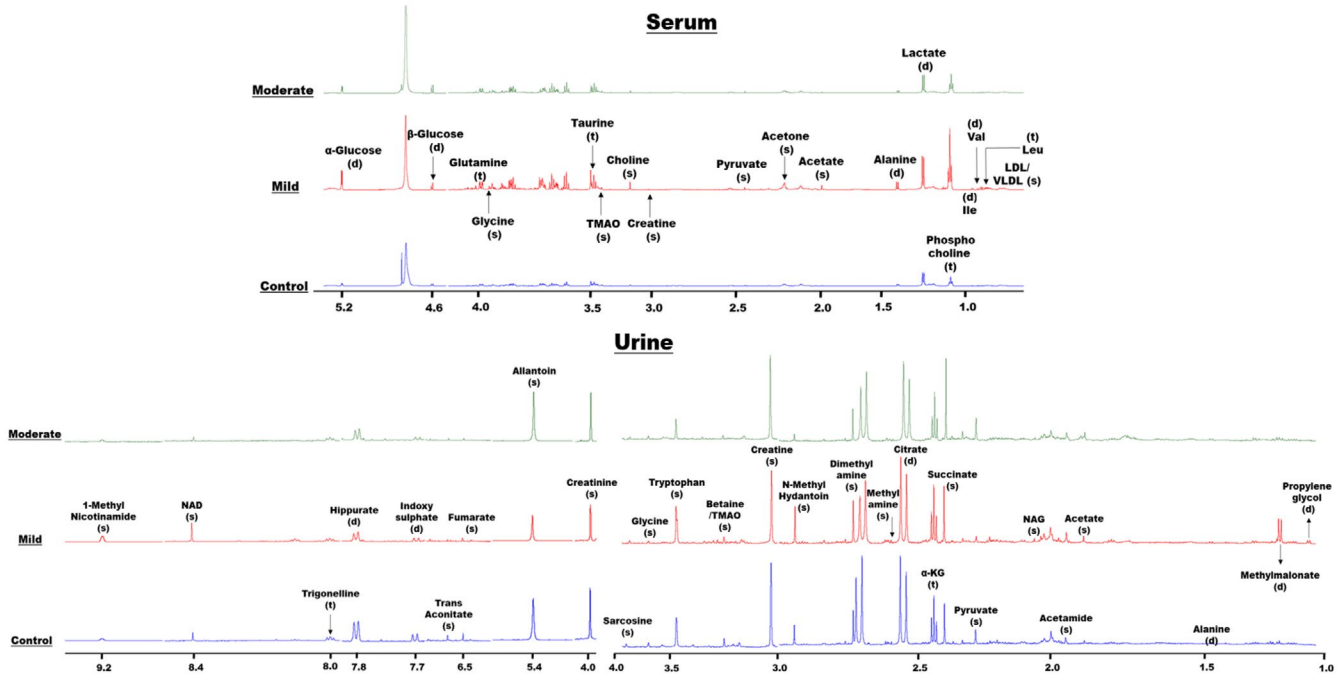

FIGURE 2 | Serum and urine spectra of ^{1}H-NMR in control, mild, and moderate groups. The spectra are labeled with the metabolites at their respective ppm. (s) Denotes singlet, (d) denotes doublet, and (t) denotes triplet. NAD, nicotinamide adenine dinucleotide; NAG, N-acetylglutamate; TMAO, trimethylamine N-oxide; α-KG, α-ketoglutarate.

10974547, 2025, 4, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/jnr.70032 by Delhi Technological University, Wiley Online Library on [06/05/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

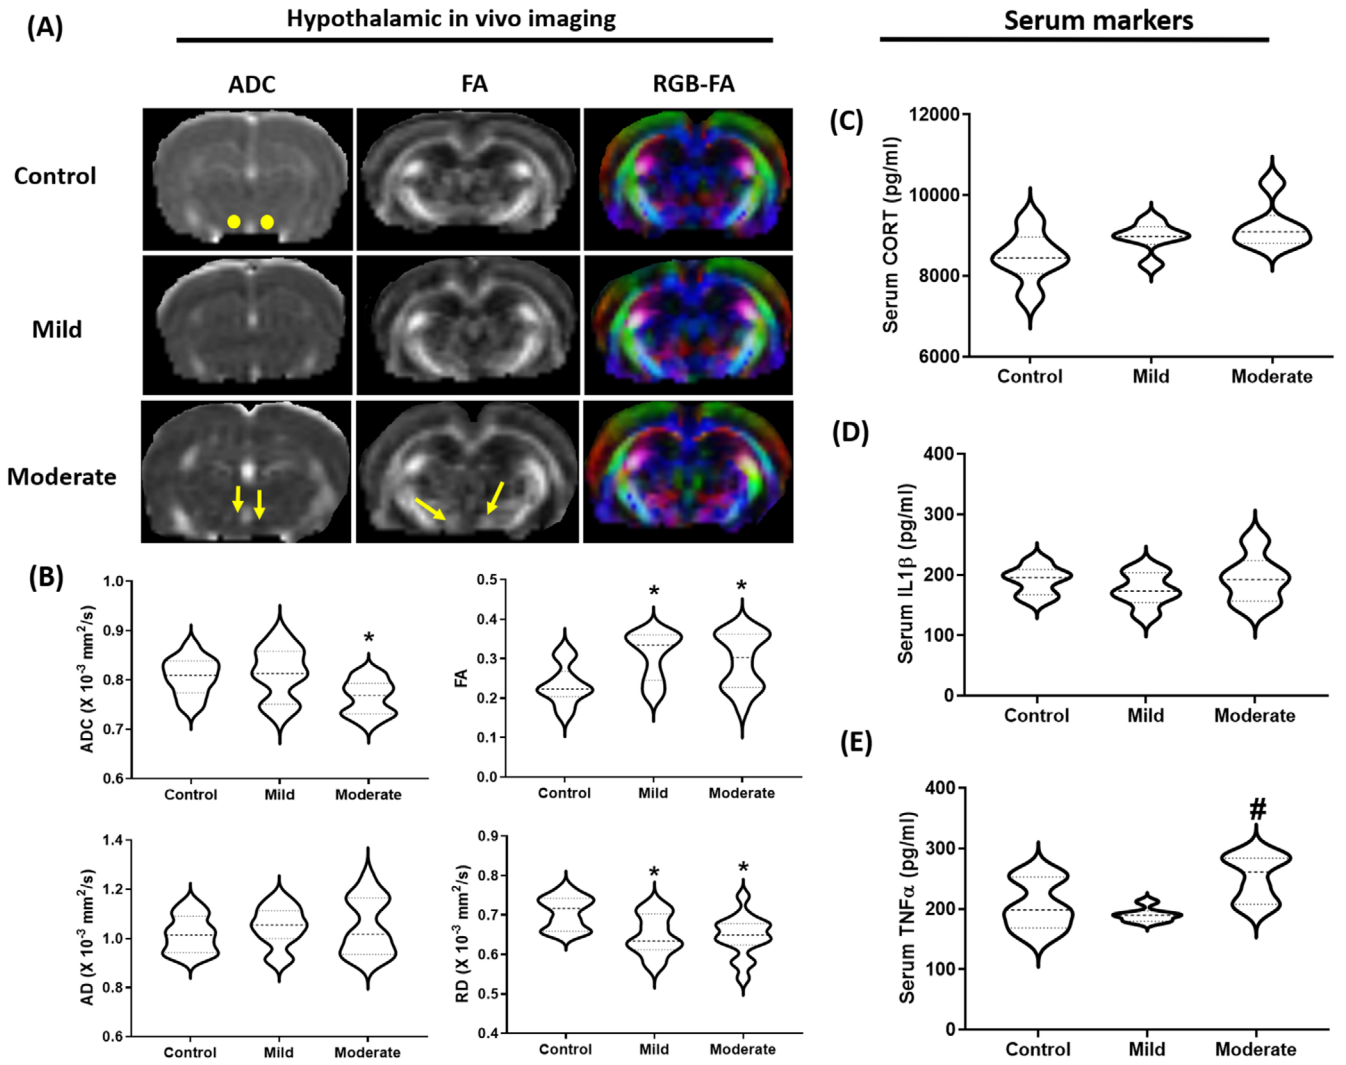

FIGURE 3 | Assessment of hypothalamic damage, systemic stress and inflammation hypothalamic apparent diffusion coefficient (ADC), fractional anisotropy (FA), and RGB-FA maps, the yellow circle shows ROI and yellow arrows depict changes in signal intensity (A) and violin plots indicating DTI scalars in all groups ($n = 7$) compared using one way ANOVA post hoc Holm's Sidak; ADC ($\times 10^{-3}\,mm^2/s$), FA, axial diffusivity (AD) ($\times 10^{-3}\,mm^2/s$) and radial diffusivity (RD) ($\times 10^{-3}\,mm^2/s$) values (B). The violin plots of serum markers of stress and inflammation in all groups ($n = 6$) were compared using one-way ANOVA post hoc Holm's Sidak; serum CORT (pg/mL) (C), serum IL-1β pg/mL (D) and serum TNF-α (pg/mL) (E) after injury. *Indicates difference versus the control group; #indicates difference versus the mild group.

For NMR acquisition of urine samples, the water signal in the samples was suppressed using a water pre-saturation pulse; Nuclear Overhauser Enhanced spectroscopy (NOESYPR1D) pulse sequence (RD-900-t-900-tm-900-acq) with relaxation delay (RD) of 5.0 s and an acquisition time of 2.5 s. 64 scans were collected into 32 K data points over a spectral width of 12,820.51 Hz.

2.4.2 | Data Processing

The serum and urine spectra were subjected to correction, including spectral phase, baseline, and chemical shift reference for each spectrum using TOPSPIN 3.7 (Bruker, Germany). Then the spectral region of 0.5–9.5 ppm was integrated, and each region was normalized with respect to the total spectral integral in TOPSPIN 3.7. The metabolites were identified using the human metabolome database (HMDB) (described in Table S1) and previous literature (Arora et al. 2022). The changes in the concentration of metabolites were compared between the control, mild, and moderate injury groups using a one-way ANOVA. The ratios were computed for serum αglucose: βglucose, lactate: pyruvate, and TMAO: choline. The relative intensity values were also analyzed in MetaboAnalyst 5.0 (https://www.metaboanalyst.ca) (Xia et al. 2009) where the data was scaled (auto-scaled and range scaled) and multivariate analysis was performed using principal component analysis (PCA) and partial least squares-discriminant analysis (PLS-DA). To identify metabolites involved in the segregation of clusters in PLS-DA, variable importance in projection (VIP) scores were used. The pathway analysis involved the selection of metabolic pathways with impact > 0.2 and $-\log 10(p) > 2$.

2.5 | Serum CORT Levels

The levels of CORT in the serum were quantified using the competitive ELISA kit (# EIACORT, Invitrogen) as described

10974547, 2025, 4, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/jnr.70032 by Delhi Technological University, Wiley Online Library on [06/05/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

previously (Arora et al. 2022). The serum samples (5 μL) were thoroughly mixed and vortexed with dissociation reagent (5 μL) and then diluted with 490 μL of 1× assay buffer from the kit. On the other hand, standards provided in the kit were serially diluted (ranging from 78.125–10,000 pg/mL) according to the manufacturers' instructions and then 50 μL were added to the well plates. The prepared serum samples and standards were then pipetted into the wells, with the addition of 1× assay buffer (75 μL), CORT conjugate (50 μL), and CORT antibody (50 μL).

The plate was kept at room temperature on a plate shaker at 400 rpm for one hour of incubation. After aspiration of the solution, the wells were washed thoroughly with 1× wash buffer from the kit for 4 times. Then, 100 μL of (3,3′, 5,5″-tetramethylbenzidine) TMB substrate was added to each well and incubated for 30 min without shaking. The reaction was terminated using a stop solution (50 μL) and end-point absorbance was read at 450 nm using a spectrophotometer (SpectraMax M2, Molecular Devices). The serum CORT levels were calculated using the standard curve and expressed in pg/mL.

2.6 | Inflammatory Markers

IL-1β (#BMS630, Invitrogen) and TNF-α (#BMS622, Invitrogen) levels were measured in serum by their respective ELISA kits. Firstly, the microwell strips were washed two times with the (1×) wash buffer. Then, diluted serum samples (50 μL) with an equal volume of sample diluents were added to the wells with (1:100) biotin-conjugate solution (50 μL) and incubated for 2 h at 25°C. For the standard curve, a serial dilution of samples ranging (TNF-α: 39.1–2500 pg/mL; IL-1β: 31.3–2000 pg/mL) was prepared and 50 μL of each was added to the wells, with (1:100) biotin-conjugate solution (50 μL) and incubated for 2 h at 25°C. After aspiration, the wells were thoroughly washed using 1× wash buffer 3–4 times. Following one hour of incubation with (1:200) streptavidin-HRP solution (100 μL), color development was observed with TMB substrate (100 μL), and the absorbance was recorded at 450 nm using a spectrophotometer (SpectraMax M2, Molecular Devices). The biotin-conjugate and HRP-streptavidin were diluted in the 1× assay buffer provided in the kit. The concentration of the cytokines was calculated using the standard curve and expressed in pg/mL.

2.7 | Fecal 16S rRNA Sequencing

2.7.1 | DNA Isolation

The genomic DNA of all the samples was isolated using DNeasy Power Soil Pro Kit (Qiagen). The purity of DNA was checked using NanoDrop 2000 (Thermofisher Scientific, Massachusetts, USA) and the integrity of DNA was evaluated on 1% (w/v) agarose (Lonza, Belgium) gel.

2.7.2 | 16S rDNA V3-V4 Metagenomics Amplification

A total volume of 12.5 ng DNA from each sample was subjected to 16S V3-V4 PCR with the primers described below. The PCR products were then loaded on a 1.5% (w/v) agarose gel along with a 100 bp ladder. Illumina adapter overhang nucleotide sequences were added to the gene-specific sequences (gene-specific sequences target the 16S V3 and V4 region).

The full-length primer sequences, using standard IUPAC nucleotide nomenclature (N = A/T/G/C, W = A/T, H = A/C/T, V = A/C/G), targeting the V3–V4 region:

16S Amplicon PCR Forward Primer: 5′TCGTCGGCAGCGTC AGATGTGTATAAGAGACAGCCTACGGGNGGCWGCAG3′ 16S Amplicon PCR Reverse Primer: 5′GTCTCGTGGGC TCG GAG ATG TGT ATA AGA GAC AGG ACT ACH VGG GTATCTAATCC3′.

After confirming the amplification on gels, 5 μL of PCR reaction were pooled for each group; control, mild, and moderate injury. The pooled PCR products were bead purified and eluted and 5 μL of eluate was subjected to another round of PCR with dual indices and adapters to generate the respective libraries as recommended by Illumina. To determine the size range of the fragments and the average library size the cleaned libraries were quantitated on a Qubit Fluorometer and appropriate dilutions were loaded on a D1000 screen tape.

2.7.3 | Data Analysis

All the analyses were performed in R version 4.2.2. The package dada2 (Callahan et al. 2016) was used to read QC, read filtering, denoising, read merging, chimera removal, and taxonomy assignment using the Silva database. A mean quality score of more than 30 was considered high quality. Multiple sequence alignment of representative sequences was done using the R package DECIPHER (Wright 2016). The bioinformatics workflow included demultiplexing of the raw sequences, which were then denoised to get the representative sequences for taxonomic classification and sequence alignment for phylogenetic studies. This data was then used for the assessment of differential abundance and diversity analysis. EdgeR, v4.2.1 (Robinson et al. 2010) an R package that uses negative binomial distribution, was used for comparative analysis. The comparisons were made based on the abundance of OTU between different sample groups.

2.8 | Statistical Analysis

All values are expressed as mean ± standard deviation (SD). The normality of the data was checked using the Shapiro–Wilk Test and then one-way analysis of variance (ANOVA) was done using pairwise comparison (Holm's Sidak) in IBM SPSS statistical software version 20 (IBM Corp., Armonk, NY, USA) and graphs were made in GraphPad version 8 (GraphPad Software Inc., California). For metabolomics data, the metabolite levels were normalized using auto and range scaling and then processed with one-way ANOVA and multivariate analysis in Metaboanalyst 5.0 (https://www.metaboanalyst.ca). (Xia et al. 2009) The fecal sequencing data analysis was performed using R software. Since the groups were pooled prior to sequencing, no statistical analysis was performed on abundance data. While EdgeR was used to find statistically significant altered genera within the groups. Values with $p < 0.05$ were considered significant. The outliers were identified

10974547, 2025, 4, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/jnr.70032 by Delhi Technological University, Wiley Online Library on [06/05/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

using adjusted box plots in R software, yielding no outliers in many cases, and if present, were not removed due to lower sample size.

3 | Results

3.1 | In Vivo Imaging Post TBI

On T2 weighted images, the hypothalamic region showed no hyperintensity and the parenchyma appeared normal after both mild and moderate TBI (Figure S1). The hypothalamic region showed changes in the DTI scalars ($n = 7$) (values including right and left hypothalamus) with a significant increase in FA [One-way ANOVA; $F_{(2, 39)} = 6.07$, $p = 0.005$] after mild ($p = 0.007$) and moderate ($p = 0.032$) injury. The RD values were significantly decreased after both injuries [One-way ANOVA; $F_{(2, 39)} = 6.54$, $p = 0.004$]; mild ($p = 0.013$) and moderate ($p = 0.007$) injury. No significant alterations were observed in AD values [One-way ANOVA; $F_{(2, 39)} = 0.54$, $p = 0.585$] after mild ($p = 0.773$) and moderate ($p = 0.744$) injury. The rats showed a significant decrease in the ADC value [One-way ANOVA; $F_{(2, 39)} = 5.02$, $p = 0.011$] in moderately injured rats ($p = 0.042$) with no change after mild injury ($p = 0.962$) (Figure 3).

3.2 | Serum CORT and Inflammatory Cytokine Levels Post TBI

Blunt impact on the brain did not significantly change the serum CORT levels ($n = 6$, each) [One-way ANOVA; $F_{(2, 15)} = 3.06$, $p = 0.077$] post mild ($p = 0.348$) and moderate ($p = 0.081$) TBI. The pro-inflammatory cytokines, IL-1β [One-way ANOVA; $F_{(2, 15)} = 0.57$, $p = 0.575$] showed no change post mild ($p = 0.789$) and moderate TBI ($p = 0.999$), while TNF-α levels were significantly upregulated [One-way ANOVA; $F_{(2, 15)} = 5.35$, $p = 0.018$] post moderate TBI ($p = 0.020$) as compared to the mild group (Figure 3).

3.3 | Metabolic Fingerprint Using ^{1}H-NMR Following TBI

Total 18 metabolites were integrated with serum ($n = 6$–7) that included metabolites from the energy metabolism (α: β glucose, lactate: pyruvate ratio, creatine), amino acids (glutamine, glycine, alanine, leucine, lysine, valine, Taurine), gut metabolism (TMAO: choline, acetate), ketone bodies (acetone), lipids (LDL/VLDL) and others (phosphocholine).

Total 27 metabolites were integrated in urine ($n = 6$–7), which included energy metabolites (fumarate, creatine, α-ketoglutarate, citrate, succinate, pyruvate, methylmalonate), amino acids (glycine, tryptophan, alanine), amino acid derivates (sarcosine, creatinine, N-acetyl glutamate (NAG)), gut (indoxyl sulfate, dimethylamine, methylamine, acetate, N-methyl hydantoin), purine metabolites (nicotinamide adenine dinucleotide (NAD), and 1-methyl nictoninamide) and others (trigonelline, hippurate, trans aconitate, allantoin, betaine, acetamide, propylene glycol).

3.3.1 | Analysis of Metabolite Alterations

The serum and urine metabolite intensities were compared using one-way ANOVA Table S2 and the heat map of the metabolites altered in both serum and urine is depicted in Figure 4.

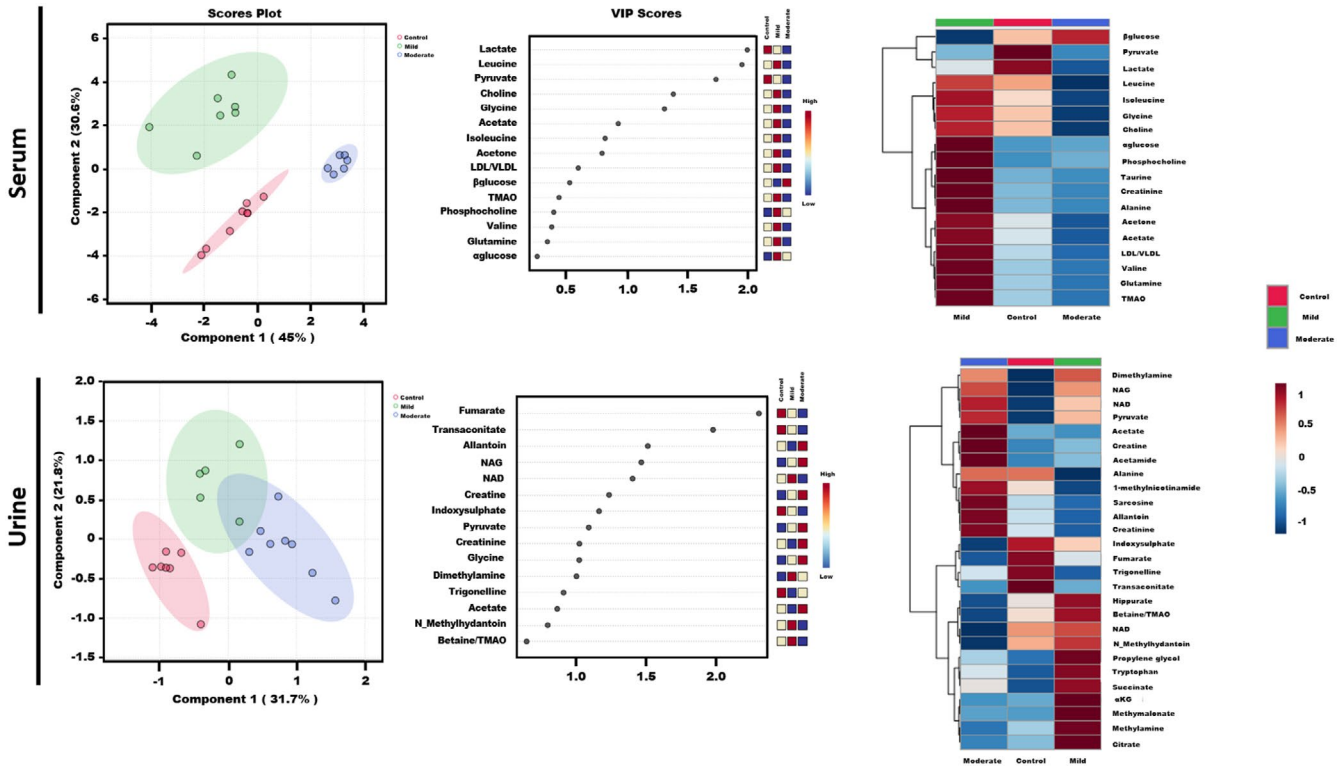

FIGURE 4 | Serum and urine metabolomics PLS-DA score plots and VIP scores of serum ($n = 6$–7) and urine ($n = 6$–7) metabolites. Metabolites with VIP > 1 were considered. The heat map shows changes in the metabolites observed in serum and urine for each group.

10974547, 2025, 4, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/jnr.70032 by Delhi Technological University, Wiley Online Library on [06/05/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The serum of mild TBI rats showed increased energy metabolites: α: β glucose ratio Table S2 and creatine intensity. The metabolic intensity of amino acids, including glutamine, alanine, valine, and taurine, was upregulated after mild TBI. The gut metabolites TMAO: choline, acetate, and ketone body (acetone) were also increased. LDL/VLDL and phosphocholine showed an increase after mild TBI. In contrast to mild injury, the serum of moderate TBI rats showed decreased lactate, pyruvate, amino acids (glycine, leucine), and gut metabolites (choline, TMAO, and acetate) Figure S2.

The urine of mild TBI rats showed an increase in energy metabolites (α-ketoglutarate, citrate, succinate, methylmalonate) accompanied by a decrease in fumarate levels. The amino acid, alanine, was decreased while the amino acid derivative, NAG, was increased. The gut metabolites, dimethylamine and methylamine, showed elevation. Trigonelline and trans aconitate decreased, while propylene glycol was increased. On the other hand, moderate TBI led to an increase in pyruvate along with a decrease in fumarate in urine. The creatinine intensity was also elevated after moderate TBI. The gut metabolites, DMA, were increased, accompanied by decreased indoxyl sulfate and N-methyl hydantoin intensities. Allantoin, an oxidative stress marker, was also increased after moderate TBI. Moderate TBI rats showed increased glycine, NAD, and NAG metabolic intensities with decreased trigonelline and trans aconitate in the urine.

3.3.2 | Multivariate Analysis

The serum PCA and PLS-DA score plots showed a complete segregation within the groups. The PLS-DA accuracy (100%) was determined by R2 (90%) and Q2 (60%). The PLS-DA score plot was calculated to identify the metabolites that had a VIP score >1 and helped in the segregation of the groups. The metabolites with VIP >1 included glycine, choline, pyruvate, leucine, and lactate.

The urine PCA score plots showed complete segregation within the groups, while the PLS-DA plot had some overlap between mild and moderate TBI groups. The accuracy (100%) was determined by R2 (90%) and Q2 (70%) values. The metabolites with VIP >1 included fumarate, trans aconitate, allantoin, NAG, NAD, creatine, Indoxyl sulfate, pyruvate, creatinine, glycine, and dimethylamine (Figure 4). The PCA plots of both serum and urine metabolites are depicted in Figure S3.

3.3.3 | Pathway Analysis

The pathway analysis was performed between control vs. mild TBI and control vs. moderate TBI groups. The selection of metabolic pathways included pathways with impact >0.2 and $-\log 10(p) >2$ (Table S3). The serum of both injuries showed changes in glycine, serine, threonine, and pyruvate metabolism. Mild TBI also resulted in changes in taurine and hypotaurine metabolism. The urine of both mild and moderate TBI rats showed an altered TCA cycle. In addition, the moderate TBI led to changes in glycine, serine, and threonine metabolism, pyruvate metabolism, and nicotinate and nicotinamide metabolism.

3.4 | Fecal Microbiome Post TBI

The gut microbiome composition analyzed using 16S rRNA sequencing showed changes following both mild and moderate TBI. The α diversity was expressed as Chao1, Ace, se.ACE, Shannon, Simpson, InvSimpson, and Fisher indexes. The β diversity was evaluated using ordination analysis. The α- diversity showed a decrease in richness within the mild TBI group, while the moderate TBI group showed no change. The β diversity has also deviated from the control group in injured rats. At the phylum level, the relative composition of Firmicutes in the control, mild, and moderate TBI groups was 38.4%, 46.8%, and 43.9%; while the Bacteroidetes composition was 58.8%, 51.7%, and 52.6%. However, the Firmicutes: Bacteroidetes ratio was increased after both mild (0.91) and moderate (0.84) injury. Other bacterial phyla including Spirochaetes, Proteobacteria, Cyanobacteria, and Epsilonbacteraeota were also altered after mild (1.4%) and moderate (3.3%) TBI, with the control group having a relative composition of 2.7%.

The percentage bacterial composition at the genus level in the pooled control group was Prevotella_9 (61.7%), Faecalibacterium (11.3%), Lactobacillus (11.0%), Ruminococcaceae_UCG-008 (6.9%) and Others (8.8%). The composition of Prevotella_9 (48.8%), Faecalibacterium (15.1%), Lactobacillus (8.7%), Ruminococcaceae_UCG-008 (19.4%), and Others (7.7%) in the mild group was altered. The bacterial composition in the moderate group included Prevotella_9 (49.8%), Faecalibacterium (14.7%), Lactobacillus (9.6%), Ruminococcaceae_UCG-008 (14.9%) and Others (11.0%) (Figure 5, Table S4). The EdgeR analysis showed significant alterations in the genus *Prevotella_9* (Bacteroidetes phylum). From the Firmicutes phylum, *Enterococcus, Blautia, Lactobacillus, Anaerovibrio, Dialister, Faecalibacterium, Subdoligranulum*, and *Treponema_2* (Spirochetes phylum) were altered. All microbes were decreased except *Lactobacillus* (Table 1).

4 | Discussion

TBI leads to bidirectional, complex, and multifaceted alteration in the systemic physiology, which has been attributed to potential mechanisms including metabolic impairment, GI tract abnormalities, and persistent inflammatory response (McDonald et al. 2020). The systemic metabolic changes are reflected in serum and urine metabolites, which can serve dual roles as signals and fuel for the gut microbiome. Conversely, metabolites originating from the gut can impact the immune, metabolic, and nervous systems (Cox et al. 2022). Therefore, to understand the TBI-induced complex interplay between the brain's metabolic regulator, hypothalamus, systemic metabolism, and gut microbiome, the present study was undertaken. The results obtained highlight an important aspect of translational studies in the diagnosis of TBI.

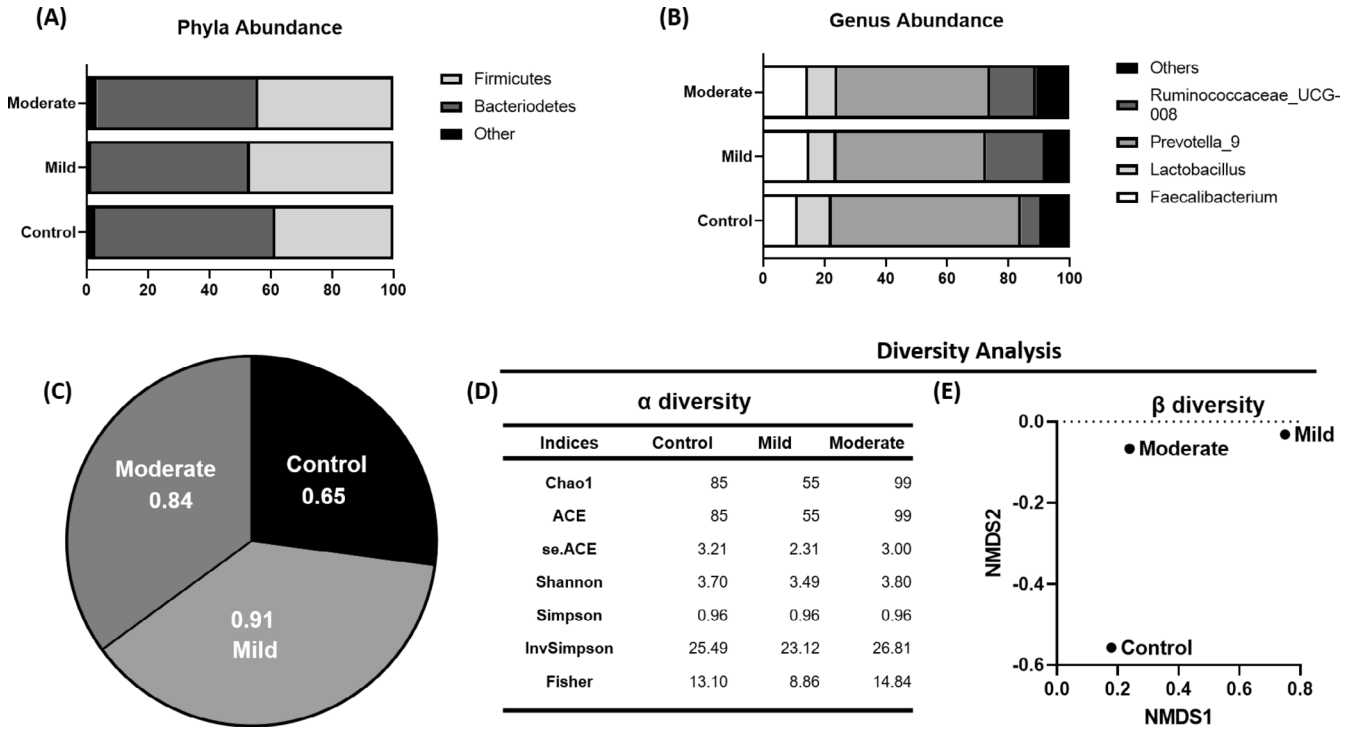

FIGURE 5 | Gut microbiome assessment the bar graph shows the relative percentage abundance of bacteria in all groups at the phylum (A) and genus level (B). The abundant phyla Firmicutes and Bacteroidetes ratio was calculated for each group shown in the pie chart (C). For diversity analysis, a table of α-diversity indices (D) and a scatter plot of β-diversity ordination values (E) in all groups. The α-diversity represents seven indices. The β-diversity was calculated using ordination analysis. All graphs shown here were not compared statistically, as the fecal samples were pooled for each group before 16S rRNA sequencing.

4.1 | Serum and Urine Metabolic Phenotypes Following TBI

Serum metabolomics yielded a variable shift in the metabolites post mild and moderate TBI. The mild TBI rats showed an increase in energy metabolites including α: β glucose ratio, (branched-chain amino acids (BCAAs), valine and leucine), glutamine, alanine and taurine, and creatine. This increase could be due to alterations in blood flow and cerebral ischemia-associated hypermetabolic conditions (Diringer et al. 2011). Increased α: β glucose ratio with glucogenic amino acids (glutamine, alanine, and valine) as a hyperacute response could be due to increased glycogen breakdown or gluconeogenesis as seen earlier in our study (Arora et al. 2022). On the other hand, increased acetone is a sign of ketosis (Manninen 2004). Therefore, both gluconeogenesis and ketosis may serve as a hyperacute injury response to maintain energy homeostasis after mild injury. Importantly, the increased taurine levels could also help in repairing tissue damage and balancing energy metabolism after TBI. As reported earlier, taurine elevation is seen after stroke and its decrease is postulated as a biomarker for stroke recovery (Wen, Li et al. 2019; Ghandforoush-Sattari et al. 2011). Glutamine has been earlier reported to promote recovery and immune modulation, resulting in an effect on the health of the intestinal lining and the balance of the gut microbiome following neuropsychiatric conditions (Kim and Kim 2017). Consequently, elevated glutamine levels in the present study suggest its immunomodulatory influence on the gut microbiome, potentially altering gut homeostasis. Corroboratively, the gut metabolites, TMAO: choline ratio, and acetate were also upregulated in mild TBI rats. Opposed to the bad effects of increased serum TMAO, the increased TMAO can also be associated with elevated glucose levels which can improve glucose tolerance (Krueger et al. 2021); (Velasquez et al. 2016). The elevation in acetate levels can be linked to the inhibition of insulin release, anti-inflammatory actions, and protein acetylation (Moffett et al. 2020). On the other hand, moderately injured TBI rats showed decreased lactate, pyruvate, leucine, glycine, TMAO, choline, and acetate intensities, indicating low levels of preferred energy substrates post injury for early response to energy requirements (Brooks and Martin 2015). The reduced BCAA is similar to the trend observed in TBI patients after severe TBI and other preclinical studies (Arora et al. 2022). While the decreased energy substrates along with glycine reduction are similar to cerebral ischemic conditions (Sidorov et al. 2019). Therefore, both injuries show unique metabolic phenotypes suggesting variable responses to the systemic effects that are dependent upon the severity of the injury.

The urine metabolic phenotype of the injured rats also suggests changes in energy metabolism, where mildly injured rats show an increase in energy metabolites: methylmalonate, α- ketoglutarate, citrate, and succinate, which suggests their increased synthesis for important functions they contribute to in the kidney, including antioxidation, immunomodulation, and gluconeogenesis, respectively. Since kidney function is directly proportional to mitochondrial activity and thereby the

Krebs cycle, the TCA intermediates have a central role in the diagnosis of kidney dysfunctions. The elevated TCA metabolites, α- ketoglutarate and succinate, have also been found in depressive disorders, making it essential to study urine metabolomics for diagnosis (Jiménez-Uribe et al. 2021). Propylene glycol was also increased after mild injury, which is an important contributor of lactate, acetate, and pyruvate (Lim et al. 2014). The amino acid alanine was decreased after mild injury. The gut metabolites dimethylamine and methylamine were elevated in the urine, while there was a decrease in the urinary trigonelline and trans-aconitate. The oxidative stress marker allantoin was also decreased in the urine of mild TBI rats. On the other hand, the urine of moderate TBI rats showed an increase in pyruvate, creatinine, allantoin, NAD, and N-methyl hydantoin, suggesting oxidative stress and impaired energy metabolism, impaired nicotinate and nicotinamide metabolism. These findings are distinctive of TBI pathology and have been reported earlier in urine samples of TBI patients (Bykowski et al. 2021). The urine of moderate TBI rats also showed a decrease in urine indoxyl sulfate, suggesting impaired gut barrier maintenance (Gisewhite et al. 2021); (Vernocchi et al. 2020). Therefore, the urine of both injuries showed an impaired TCA cycle with increased metabolites after mild injury and decreased ones after moderate injury. The gut metabolite DMA secretion was also increased after both injuries, which could be due to proteolysis from asymmetric dimethylarginine, which is involved in the L-arginine/nitric oxide pathway and is present in several cardiovascular, renal, and metabolic diseases (Tsikas 2020). Similar to DMA, elevated MA is present during CNS disturbances with increased BBB permeability leading to urinary secretion of amines (Mitchell and Zhang 2001). In conclusion, the urinary metabolic profile indicates a compromised TCA cycle following both injuries, accompanied by heightened oxidative stress and disruptions in gut and NAD metabolism after moderate injury.

4.2 | Alterations in the Hypothalamic Structure Along with Response of Serum Markers After TBI

The microstructural changes in the hypothalamus of the injured rats using DTI showed that mild TBI leads to an increase in FA and a decrease in RD values. On the other hand, moderate TBI rats showed decreased diffusivity with decreased ADC and RD values and increased FA in the hypothalamus of the rats. The increased FA is similar to the anisotropic changes seen after acute cerebral ischemia (Alegiani et al. 2017). TBI-induced hypoxic insult, intracranial pressure, and axonal injury can lead to hypothalamic damage as earlier seen in boxers, which reported autoantibodies against the hypothalamus and pituitary post-concussion (Kelestimur 2021). Similarly, a study on pediatric TBI found a decrease in the brain volume of the corpus callosum and hypothalamus (Dennis et al. 2017). The serum CORT and inflammatory cytokine levels were also quantitated, which revealed no change, except a significant increase in the TNF-α levels after moderate injury as compared to the mild group. Importantly, TBI may alter the neural pathways responsible for transmitting stress signals to the HPA axis, slowing the overall response time for CORT secretion. Additionally, the damage to the hypothalamus (as

10974547, 2025, 4, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/jnr.70032 by Delhi Technological University, Wiley Online Library on [06/05/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

also reported in the present study) can impair the communication and coordination between the hypothalamus, pituitary gland, and adrenal glands, which could have delayed the activation of CORT release. As reported earlier, physiological and psychological stressors initiate a stress response involving the sympathetic adrenal medullary (SAM) axis and the HPA axis. The SAM axis mediates the immediate stress response, while the HPA axis drives a slower, more sustained response, where stress-induced GC secretion can be delayed (Lawrence and Scofield 2024) Additionally, our earlier study has reported increased CORT from acute till chronic timepoint post mild and moderate TBI, confirming delayed but sustained CORT secretion post TBI (Arora et al. 2022).

A similar absence of elevated inflammatory markers at the hyperacute stage post both severities were observed. However, IL-1β is involved in the early response to neuroinflammation after TBI; the kinetics of IL-1β release and its detectable levels can vary depending on the time point after injury. The increase in IL-1β expression after TBI is typically observed in the acute to chronic phases, not during the hyperacute phase, which suggests that (Morganti-Kossmann et al. 2002) production of IL-1β takes time to develop after initial injury. Cytokines like IL-1β, IL-6, TNF-α, and MCP-1 are released both locally in the brain and systemically post TBI. Delayed systemic peaks in these cytokines often occur as the inflammatory response may expand from the CNS to peripheral organs, which may be dependent upon the progressive breakdown of the BBB, allowing inflammatory mediators and immune cells to cross into the systemic circulation (Alam et al. 2020) Therefore, the present results conclude hypothalamic alterations without CORT elevation and inflammation.

4.3 | Gut Microbiome Changes After TBI

It was found that Firmicutes, including short chain fatty acids (SCFAs) producing bacteria (*Faecalibacterium*, Subdoligranulum, and *Blautia*, butyrate-producing Firmicutes) were decreased. *Faecalibacterium*, a biomarker of human gut health, is reported to decrease in diabetic patients (Ferreira-Halder et al. 2017). Along with this, *Faecalibacterium* decrease is associated with pain, sleep problems, and neurological dysfunction (Taraskina et al. 2022). The decrease in *Subdoligranulum* has been found in various metabolic disorders, where its alteration is associated with microbial richness and HDL cholesterol levels (Van Hul et al. 2020). The decrease in *Blautia* strain is also similar to gut microbiome alterations observed after stroke (Sudo 2014). The increased *Lactobacillus* is similar to that seen after acute ischemic stroke, suggesting loss of good gut health (Sudo 2014). Both mild and moderate TBI groups showed altered *Enterococcus* composition, as earlier reported after TBI and stroke (Taraskina et al. 2022). The decreased *Prevotella* composition could be an adaptive response to prevent gut immune activation and maintain intestinal permeability or could be an injury-induced effect on the *Prevotella* abundance. In conclusion, the mild and moderate TBI groups showed gut microbiota changes similar to TBI and stroke pathology, with increased Firmicutes: Bacteroidetes ratio after both injuries indicating gut dysbiosis (Taraskina et al. 2022; Rosin et al. 2021).

4.4 | Interplay Between the Hypothalamus, Systemic Metabolism and Gut Microbiome

The present study directs the potential bidirectional cross-talk between the brain and systemic physiology. The hypothalamic damage was observed to be more pronounced in the moderately injured rats, with ADC significantly decreased along with RD, indicating cellular changes in the hypothalamus. Along with this, moderate rats had impaired energy metabolism, inflammation, and oxidative stress at the systemic level. Mildly injured rats, on the other hand, showed an anisotropic increase and RD decrease (due to edema) in the hypothalamus, which also initiates a cascade of metabolic changes at the systemic level, which can consequently induce several processes involved in glucose production.

At the level of the gut, it was found that Firmicutes (involved in the synthesis of SCFAs and trimethylamine (TMA), which is converted to TMAO in the liver) were altered after both injuries. Mildly injured rats showed an increased TMAO: choline ratio with an increased Firmicutes: Bacteroidetes ratio (Liu and Dai 2020). Importantly, the TMA-TMAO axis plays an important role in the systemic metabolism and gut microbiome association, as it has been found that fecal microbiota transplantation resulted in a decrease of TMA levels in feces and TMAO levels in the brain and serum after injury (Du et al. 2021). The microbiome richness (decreased α diversity and altered β diversity) after mild injury with increased TMAO production suggests an important and compensatory role of TMAO as compared to its deleterious effects reported earlier. On the contrary, the moderate TBI rats with increased Firmicutes: Bacteroidetes ratio showed decreased gut metabolism in serum (acetate, choline, and TMAO) and urine (N-methyl hydantoin and Indoxyl sulfate), oxidative stress (allantoin in urine), and altered gut metabolites (Stojanov et al. 2020). Additionally, decreased acetate levels in the serum of moderate TBI rats could potentially affect the gut microbiome composition and brain function, as it has been earlier reported that the administration of acetate improved spatial learning in the TBI-induced rats (Opeyemi et al. 2021). Thus, highlighting that moderately injured rats with more damage and decreased metabolism can further lead to impaired gut microbiome composition. Meanwhile, the mildly injured rats also showed gut dysbiosis with increased gut metabolites, indicating an important relationship between systemic metabolism and gut health.

Therefore, this study helped us to understand an integration between systemic metabolism and gut microbiome composition, where hypothalamic damage can act as an additional arm in perpetuating the injury damage leading to more devastating effects with increased severity.

5 | Limitations

1. As females exhibit higher basal and stress-induced ACTH and CORT levels (Goel et al. 2014), and the neuroprotective effects of estrogen and progesterone influence HPA axis signaling, inflammation, cerebral blood flow, and metabolism (Liu et al. 2012), the present study used male rats to avoid confounding interactions with gonadal hormones.

10974547, 2025, 4, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/jnr.70032 by Delhi Technological University, Wiley Online Library on [06/05/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

2. To better understand the interaction between CORT and the gut, a detailed morphological assessment of the intestinal lining and permeability is warranted (Leigh et al. 2023).

6 | Conclusions

The present study observed hyperacute systemic changes in mild and moderate TBI along with the underlying hypothalamic damage and gut microbiome alterations. Mild TBI showed increased glucose, amino acid, and TMAO: choline ratio. The urine metabolomics of mild-TBI rats also suggested increased levels of energy metabolites from renal gluconeogenesis. On the other hand, moderate-TBI rats showed a reduction in the energy metabolites in serum with signs of oxidative stress in urine. The rats also showed microstructural damage in the hypothalamus. The gut microbiome had an increased Firmicutes/Bacteroidetes ratio after injury, with decreased α diversity after mild TBI and altered β diversity after both injuries. Thus, the study demonstrates that both mild and moderate TBI leads to systemic metabolic alterations along with hypothalamic damage and gut dysbiosis at a hyperacute timepoint. The study holds translational significance as the animal model used closely replicates human TBI and involves different severities to understand the differential response. Additionally, the application of noninvasive techniques for hyperacute timepoint assessment could be extended to diagnostic and prognostic purposes through further investigations involving larger sample sizes. Considering the variation in the gut microbiome composition between rats and humans, additional studies are still required with the assessment of gut integrity.

Analysis of a Digitizer Circuit with T-Network for Low Resistance Measurement

Shiraz Sohail, *Senior Member, IEEE*, Gopal Singh, *Graduate Student Member, IEEE*, Tarikul Islam, *Senior Member, IEEE*

***Abstract*—An efficient interfacing circuit designed for measuring low resistance (R_X, less than 1 Ω) and generating a digital output is presented. The digitizer (resistance to digital converter, RDC) circuit utilizes a dual-slope integrator with a T-network in feedback, three single pole single throw (SPDT) switches, and a comparator. Conventional dual-slope integrators face challenges when measuring low R_X connected to the inverting terminal, as the high input current causes the op-amp to saturate. Reducing the input voltage to even 0.01 V doesn't resolve this issue. Alternatively, connecting R_X in feedback produces a low output voltage that is susceptible to inherent circuit noise, leading to significant measurement errors. Consequently, no digitizers have been developed to accurately measure R_X below 10 Ω so far. The circuit overcomes these limitations by using a T-network which enables the incoming current (I_X, 98.09 - 71.75 μA) through R_X to amplify the feedback current (I_C), hence significantly improving sensitivity which is a novel feature. During charging, lead resistance (R_L) with fixed resistance R_3 (or R_X) is measured, while during discharging, R_X and R_L are measured together. Subtracting R_L ensures accurate R_X measurement, independent of R_L, in a two-wire configuration. The circuit is experimentally tested for R_X in the range of 0.1 - 0.9 Ω (full span) in which the power dissipation ranges from 0.96 - 4.63 nW, while the measurement time varies from 1.29 - 1.51 s. The circuit yields accurate results with an average error of ± 0.68% across the full span of R_X.**

***Index Terms*—Low resistance, T-network, dual-slope integrator, digitizer, resistance to digital converter (RDC), lead resistance compensation, two-wire type.**

I. Introduction

ACCURATE measurement of low resistance holds a prime importance in characterizing various components such as ammeter shunts, inductive coils, transformer primary and secondary windings, motor armatures and field windings, sheet resistance, and more. By definition, any resistance below 1 Ω is categorized as low resistance [1]. Traditionally, three techniques are used for measurement of low resistance: (i) Ammeter and voltmeter method (ii) Potentiometer method, and (iii) Bridge method. In ammeter and voltmeter method, a recent work, which requires a DC current calibrator, a current generator for supplying currents up to 100 Ampere (A) and 1200 A, a current-reversing switch, and two nanovoltmeters make the measurement complex [2]. In potentiometric method, Dauphinee et al. used isolating potential comparator to generate the difference between the potential drops in the two resistances without making a direct differential connection to improve the measurement [3]. Further, a modified potentiometric technique which requires a high current around 40 A to operate is also presented [4]. In bridge methods, the Kelvin double bridge (KDB) is particularly popular in industry due to its high accuracy. The errors caused by the lead resistances and contact resistances of the variable jockeys are minimized by selecting high values for the outer arms (≈ 10–100 kΩ) and inner arms (≈ 100–500 Ω). The KDB is improved by interchanging the battery and the galvanometer which results in the conjugate KDB [5]. However, both of them requires the ratio of the arms to be fixed and equal, which can deviate with temperature and aging [6]. Thereafter, the Warshawsky bridge minimizes random contact resistances occurring at the junctions of Wheatstone bridge by using multiple bridge circuit and adding an auxiliary resistor pair at each bridge corner [7]. Another improvement is the automated modified Wheatstone bridge [8] which features four 1-Ω resistors in a bridge configuration with four galvanometers. It includes six lead wires, five variable shunt resistors, and a constant current source for excitation. Both [7] and [8] proposes highly complex circuit design for measurement of low R_X.

It is to be noted that all above mentioned techniques are only suitable for four wire type R_X, and require considerable time for manual bridge balancing using precision adjustable resistors. Moreover, for proper working and accurate results, several conditions for resistance values (such as lead, contact and supply series resistances) has to be fulfilled, and it also affects the accuracy and sensitivity. The bridge balance and sensitivity, both depend upon the galvanometer's sensitivity and coil resistance [9][10] as well as bridge supply voltage. Although balancing can be avoided by calibrating the bridge voltage for R_X, the finite resistance of the galvanometer still introduces an error in the measurement. Thus, a suitable correction must be applied to the measured R_X to account for the non-ideal properties of the meters involved.

The literature also includes the following recent works. In [5], a direct current comparator ratio bridge measures low resistances by comparing current ratios that equalize voltage drops. The current ratio, determined by the turns ratio, is automatically maintained by a self-balancing direct current comparator. The current injection method [11] for enhancing the Wheatstone bridge is complex, requiring a current source, a conductance meter, and a deflection meter. The cryogenic current comparator bridge described in [12] is a research

TABLE I
LITERATURE COMPARISON TABLE ON LOW RESISTANCE MEASUREMENT

Ref.	Resistance Range	Methodology Used	Components Used	Remarks
[2]	10 $\mu\Omega$ - 10 mΩ	Volt-amperiometric	DC current calibrator, current generator, switches, two nano voltmeters (nV), two digital voltmeters and two DC shunts	A calibration lab setup for high-power (500 W) shunts, requiring 1200 A, self-heating error is compensated using three Platinum thermometers, needs a cooling system with a heat exchanger, fan, pump, and oil-contact serpentine, bulky, costly, requires two 7 1/2 - digit nanovoltmeters and proper insulation, and safety measures due to high current.
[3]	1 - 10 Ω	Isolating potential comparator	Double-pole double throw chopper, condenser, galvanometer and a couple of resistors	Bulky and complex design, need manual adjustments, errors due to contact resistances and lead connections.
[4]	In the range of $\mu\Omega$	Potentiometric method	Linear differential DC amplifier, a potentiometer, a galvanometer, standard resistors	Modified conventional potentiometric method using voltage divider and differential amplifier, need of Diesselhorst compensator to nullify thermoelectric effects, requires I_X - 40 A.
[5]	In the range of 100 Ω - mΩ	Direct current comparator	Magnetic modulator, magnetic shield, two ratio windings, galvanometer and resistors	Resolution depends on number of turns which should be uniformly distributed and tightly packed, requires 10 AT (ampere turn), bulky setup and relies on manual balancing, requires I_X - 150 A.
[7]	Random contact resistances (rcr's) < 2 Ω	Wheatstone bridge	Couple of resistors representing the main wheatstone bridge, rcr's and auxiliary resistors	Manual bridge balance technique, uses multiple bridges which is complex, power dissipation - 0.01 W.
[8]	Calibrate 4-terminal 1 Ω	Modified Wheatstone bridge	Four galvanometer detectors, current source, resistors, temperature sensor and relay drivers	Need a highly sensitive and high accuracy galvanometer detectors, highly complex circuit when its automated, requires I_X - 50 mA, power dissipation - 2.5 mW.
[11]	Calibrate 4-terminal 1 Ω	Wheatstone bridge	Switches, resistors, current source and null detector	Uncertainty in reversing current direction may lead to thermoelectric effects at junctions, highly complex circuit, power dissipation - 1 mW.
[12]	1 Ω - 100 $\mu\Omega$	Cryogenic current comparator (CCC) bridge	Buffer amplifier, current source, ADC and SQUID (superconducting quantum interference device)	Type II CCC design introduces more complexity as compared to type I CCC, requires I_X - 100 A, power dissipation - 100 kW to 1 W.
[13]	10 $\mu\Omega$ - 1 Ω	Current comparator	Commercial current extender, high current source, current meter and a nano voltmeter	Nanovoltmeter need to have a stable gain and calibrated regularly, complex setup, power dissipation - 100 mW.
This work	0.1 - 0.9 Ω	Dual-slope integrator	Integrator, comparator, switches and couple of resistors	Introduction of T-network in feedback, digital output, unaffected due to lead resistance, simple circuitry, average error of $\pm$ 0.68%, requires I_X - 98.09 to 71.75 μA, power dissipation - 0.96 to 4.63 nW.

instrument that requires a low-interference constant current source and a superconducting quantum interference device (SQUID) flux sensor. In [13] describes an automated low-ohmic resistance measurement system requiring a current source, current extender, current meter, and a stable-gain nanovoltmeter in the bridge. In [14] a complex circuit involving photo isolated synchronous rectification is used to measure the contact resistance. The circuit requires current source, an amplifier, band pass filter, gain control, phase detector and finally low pass filter. Table I provides more details about these techniques regarding range, methodology, and features. The measurement techniques presented in [2], [4], [5], [12], [13] requires a high current ($\geq$ 100 A) to be injected into the R_X, and hence not suitable for low resistance measurement of ammeter shunts, inductive coils, transformer and motor windings, where a high current may damage the coil. While the other techniques in [3], [7], [8], [11], [14] use complicated circuit design, costly and sophisticated equipment make the measurement complex, time taking, expensive, and hence not suitable for general purpose, portable, day to day measurements in industry settings. Moreover, all the previously discussed techniques provide analog output, hence an analog-to-digital converter (ADC) is required for interfacing with microcontrollers for tasks such as operational control, signal processing, lead or offset compensation, and calibration.

Recently, digitizer circuits have gained significant attention due to their ability to generate a time-sequence or square wave digital output with pulse width modulation, produced through an op-amp integrator and comparator [15]. The digitizers make the measurement fast and avoid manual balancing and calculations. The digital output allows direct connection to the microcontroller digital pin for signal processing, eliminating the need for a separate ADC. As a result, it conserves analog pins, which are often limited due to costly built-in ADCs in the microcontroller. These digital interfacing circuits can be broadly classified based on their working principles as (a) dual-slope integrator [16], [17], [18] (b) sigma-delta [19], [20] (c) relaxation oscillator [21], and (d) direct interface circuit (DIC) [22], [23].

In dual-slope integrator, typically, the R_X is connected to a dual slope integrator and its output is fed to a comparator to generate a digital output. It is noteworthy that none of the digitizers previously documented in the literature have been proposed for measuring R_X below 10 Ω. The reason is that when a low value R_X is connected to the inverting terminal of the op-amp in integrator, a large current flows, causing the op-amp to saturate. Even reducing the input voltage to 0.01 V doesn't resolve the issue because the input current will be in the range of 100 mA (when keeping R_X = 0.1 Ω). Else, if R_X is connected in the feedback of op-amp, the output voltage will be very small, and prone to circuit inbuilt-noises which result in large measurement error.

To address this significant issue, [18] presents a simulation and initial investigation of an digitizer designed for measuring

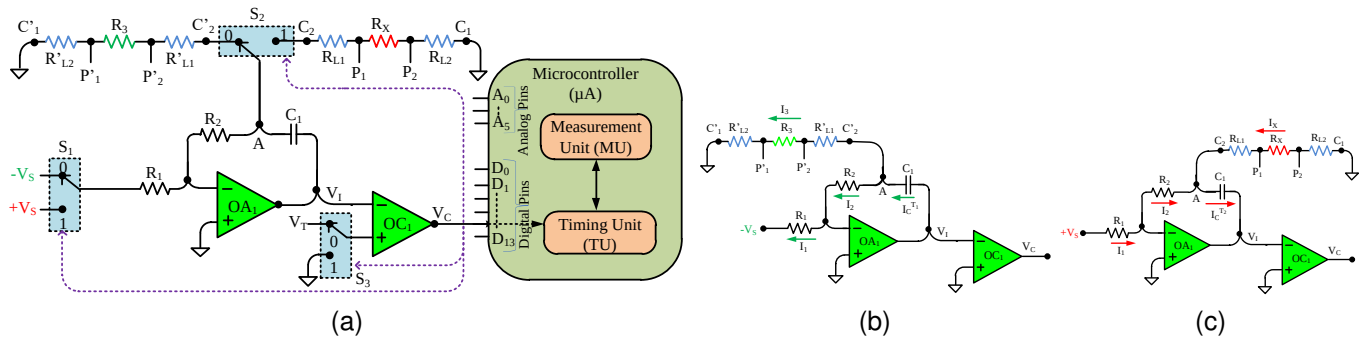

Fig. 1. (a) Proposed digitizer circuit for measurement of low resistance based on dual slope integrator with a T-network in the feedback. Simplified circuit model of the digitizer during (b) charging (T_1) interval, and (c) discharging (T_2) interval. These sub-figures show the current directions and proper labels.

R_X below 1 Ω. This study comprehensively analyzes the circuit featuring a dual-slope integrator with a T-network in its feedback loop. It also consists of three single pole double throw (SPDT) switches and a comparator. In this configuration, R_X is connected to the middle branch of the T-network, while a fixed resistor and a feedback capacitor are attached to the other two branches. Due to T-network, the incoming current (I_X) through R_X is responsible for amplifying the feedback (capacitor) current (I_C) which charges and discharges the integrating capacitor, and hence measure R_X. The I_X due to T-network enables faster R_X measurement in a two-wire configuration which is another feature of the circuit.

The proposed circuit features: 1) R_X range: 0.1 – 0.9 Ω; 2) measurement time: 1.29 – 1.51 s; 3) I_X: 98.09 – 71.75 μA; 4) power dissipation: 0.96 – 4.63 nW. In summary, the circuit offers the following novelty: 1) no manual balancing; 2) low power dissipation; 3) T-network feedback for boosted input current; 4) R_X measurement independent of R_L in two-wire configuration; 5) time-sequence digital output; 6) minimal error (± 0.68%) with good linearity (0.54% NL); and 7) no need for costly components like a waveform generator.

A. Circuit description

The proposed circuit is based on a dual-slope integrator which consists of an op-amp (OA_1) with a T-network in feedback as shown in Fig. 1. One branch of the T-network consists of a fixed resistance R_2, and the other one consists of either unknown low value R_X or fixed resistance R_3. The capacitor C_1 forms the third branch of the T-network and integrates the capacitor current (I_C). The R_2 is used to develop a fixed bias voltage (V_A = I_2R_2) so that incoming current (I_X) is a function of R_X and is equal to I_2R_2/R_X during discharging mode, and hence R_X can be measured. The R_X also includes lead resistance (R_L) since it is of two-wire type. To compensate it, a known R_3 with equally valued R_L is included in the circuit during charging, ensuring that the R_L is canceled out in the final expression of R_X.

The three single pole double throw (SPDT) switches S_1, S_2 and S_3 facilitate the charging and discharging modes of operation as per Table II. Green and red arrows represent the current paths during charging and discharging modes in Fig. 1b and 1c respectively. Initially, S_1, S_2 and S_3, all are at '0' position (refer Table II), and the equivalent circuit is shown in Fig. 1b, where $I_C^{T_1}$ splits into I_2 and I_3 at A, and exits C_1. The current flows from integrator output (V_I) to negative input (-V_S) and charges C_1, which results in gradual increase of V_I. When V_I reaches to threshold voltage (V_T) of comparator, the switches S_1, S_2 and S_3, changed to '1' position (refer Table II). The equivalent circuit is shown in Fig. 1c, where I_X and I_2 are summed as $I_C^{T_2}$ at A, and enters C_1. The current flows from the positive input (+V_S) to the V_I, and discharges C_1, due to which V_I gradually decreases to zero potential. Thus, I_C is equal to I_2 + I_3 and I_2 + I_X during charging and discharging modes respectively. The output of the integrator (V_I) is a triangular waveform which is fed to the comparator (OC_1) to compare with the threshold voltage (V_T) and generates a quasi-square waveform (V_C, pulse-type). Thus, R_X is converted into a digital waveform for direct and easy interfacing with microcontrollers. The integrator's charging (T_1) and discharging (T_2) times are measured using a timing unit (TU), and the measurement unit (MU) is used to calculate the R_X using analytical model equations. Both TU and MU are realized inside the microcontroller. The controlling signal, necessary to operate the switches is also derived from V_C.

For accurate measurement of R_X, cancelling R_L associated with R_X is crucial. Initially, S_2 connects the middle branch of the T-network to R_3 during the charging mode to calculate R_L. During discharging mode, S_2 connects the T-network to R_X to find $R_X + R_L$. Finally, R_L is subtracted from $R_X + R_L$ to measure R_X accurately. This converts the measurement scheme to a two-wire type, improving upon the typically used four-wire type [24], [25]. The switches S_1 and S_3 are used for switching the input voltages ($+V_S$ and $-V_S$) and comparator references (V_T and ground) respectively.

B. Derivation of unknown resistance R_X

Initially, switches S_1, S_2 and S_3 are set to position 0 as V_C is HIGH. In this state, the charging current ($I_C^{T_1}$) flows

This article has been accepted for publication in IEEE Transactions on Instrumentation and Measurement. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TIM.2025.3560721

from V_I back to $-V_S$ through C_1. At node A, the current $I_C^{T_1}$ splits into two paths. In first path, current I_3 passes through R_3 and R_L ($= R_{L1}^{'} + R_{L2}^{'}$) while in second path current I_1 passes through R_1, ultimately sinking to ground voltage and $-V_S$ respectively. In practice, S_1 and S_2 switches [26] have a very small on-resistance of approximately 1.25 Ω (r_1, r_2). The expressions are as follows:

$$I_1 = \frac{|V_S|}{R_1 + r_1} \tag{1}$$

$$I_C^{T_1} = I_2 + I_3 \tag{2}$$

$$I_2 = I_C^{T_1}\left(\frac{R_3 + R_L + r_2}{R_3 + R_L + R_2 + r_2}\right) = I_1 \tag{3}$$

$$I_3 = I_C^{T_1}\left(\frac{R_2}{R_3 + R_L + R_2 + r_2}\right) = \left(\frac{R_2}{R_3 + R_L + r_2}\right) I_2 \tag{4}$$

The expression for V_I is

$$V_I = \left(2I_2R_2 + \frac{I_C^{T_1}}{C_1}t\right) \tag{5}$$

The V_I is fed into OC_1 along with V_T. As long as V_I is lower than V_T, V_C stays HIGH. When V_I equals V_T, V_C goes low, signaling the end of the T_1 interval. The change in integrator's output voltage (ΔV_I) during the T_1 interval is:

$$\Delta V_I = \left(2I_2R_2 + \frac{I_C^{T_1}}{C_1}T_1\right) = V_T \tag{6}$$

The analytical expression for T_1 is:

$$T_1 = \frac{C_1\left(V_T - 2I_2R_2\right)}{I_C^{T_1}} \tag{7}$$

The TU within the microcontroller measures T_1. By using equations (1), (3), and (6), and assuming that $R_1 \gg r_1$ the expression for R_L is:

$$R_L = \frac{T_1R_2V_S}{C_1\left[R_1V_T - 2R_2V_S\right] - T_1V_S} - R_3 - r_2 \tag{8}$$

Now, with V_C LOW, all switches move to position 1, and the integrator enters the discharge mode (T_2 interval). The current I_1 starts from +V_S and gets amplified by (1+(R_X+R_L+r_2)/R_2) times at node A due to I_X. This amplified current enters C_1 and forms the discharge current ($I_C^{T_2}$) which finally sinks at V_I. Here R_L (=R_{L1}+R_{L2}) represents the lead resistance. The expressions are:

$$I_C^{T_2} = I_2 + I_X \tag{9}$$

$$I_X = I_C^{T_2}\left(\frac{R_2}{R_X + R_L + R_2 + r_2}\right) = \left(\frac{R_2}{R_X + R_L + r_2}\right) I_2 \tag{10}$$

The expression for V_I during discharge mode is

$$V_I = V_T - \left(2I_2R_2 + \frac{I_C^{T_2}}{C_1}t\right) \tag{11}$$

As long as V_I is higher than ground potential, V_C remains low. When V_I equals to ground potential, V_C goes HIGH, marking the end of the T_2 interval. At this moment, the circuit re-enters the charging mode for the next cycle, and all switches return to their previous positions; with S_1, S_2, and S_3 all moving to position 0. The change in integrator's output (ΔV_I) during the T_2 interval is:

$$\Delta V_I = \left(2I_2R_2 + \frac{I_C^{T_2}}{C_1}T_2\right) = V_T \tag{12}$$

The analytical expression for T_2 is:

$$T_2 = \frac{C_1\left(V_T - 2I_2R_2\right)}{I_C^{T_2}} \tag{13}$$

The net charge in C_1 will be zero at the end of the T_2 interval, and (6) and (12) can be equated as

$$\left(2I_2R_2 + \frac{I_C^{T_1}}{C_1}T_1\right) = \left(2I_2R_2 + \frac{I_C^{T_2}}{C_1}T_2\right) \tag{14}$$

Finally, the expression of R_X can be obtained from (1), (2), (3), (4), (9), (10) and (14) as:

$$R_X = \frac{T_2R_2\left(R_3 + R_L^{(8)} + r_2\right)}{(T_1 - T_2)\left(R_3 + R_L^{(8)} + r_2\right) + T_1R_2} - R_L^{(8)} - r_2 \tag{15}$$

The value of R_L is substituted from (8) to find R_X. Previously, digitizers [16], [17], [18], [19], [20], [21], [22], [23] did not show results for measuring low resistance (less than 10 Ω). This marks the initial effort in accurately measuring low resistance using digitizers, achieving results comparable to those of the Kelvin double bridge [1][6].

III. Analysis

A. Effect of Opamp and Comparator offset Noise

Parameters like input offset voltage (V_{OS}) and input offset current (I_{OS}) in an op-amp typically contribute to an output offset error (E_O). To analyze the errors introduced by I_{OS} and V_{OS} in the integrator (OA_1), the equivalent circuit of the proposed scheme, with V_S set to zero, is shown in Fig. 2(a-b). Additionally, the comparator (OC_1) includes an inherent input offset error denoted as V_{IO}.

To minimize the error caused by I_{OS}, a compensation resistor (R_P) is connected to the non-inverting terminal of OA_1. The selection of an appropriate R_P value is discussed in the following section. Since, S_1 on-resistance (r_1) is in series with R_1 whose value is typically 100 kΩ, so it is ignored. But, S_2 on-resistance (r_2) is in series with either R_X or R_3 whose values is less than 1 Ω, so it is considered. The $r_2^{T_1}$ and $r_2^{T_2}$ represent on-resistances of S_2 during the charging (T_1) and discharging (T_2) phases respectively, due to channel mismatches ($r_2^{T_1} \neq r_2^{T_2}$), with their absolute difference satisfying $|r_2^{T_1} - r_2^{T_2}| \leq 0.3$ Ω as per MAX4690 datasheet [26]. The error in the integrator output ($E_{01}^{'}$) due to I_{OS} during T_1 is:

$$E_{01}^{'}(t) = \frac{1}{C_1}\int_0^t I_C^{T_1}\,dt \tag{16}$$

where $I_C^{T_1} = I_B[a - (R_Pb)/R_1] - (I_{OS}/2)[a + (R_Pb)/R_1], a = 1 + [R_2/(R_4 + r_2^{T_1})], b = 1 + [R_2/(R_4 + r_2^{T_1})] + [R_1/(R_4 + r_2^{T_1})], R_4 = R_3 + R_L$ and $R_L = R_{L1}^{'} + R_{L2}^{'}$.

This article has been accepted for publication in IEEE Transactions on Instrumentation and Measurement. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TIM.2025.3560721

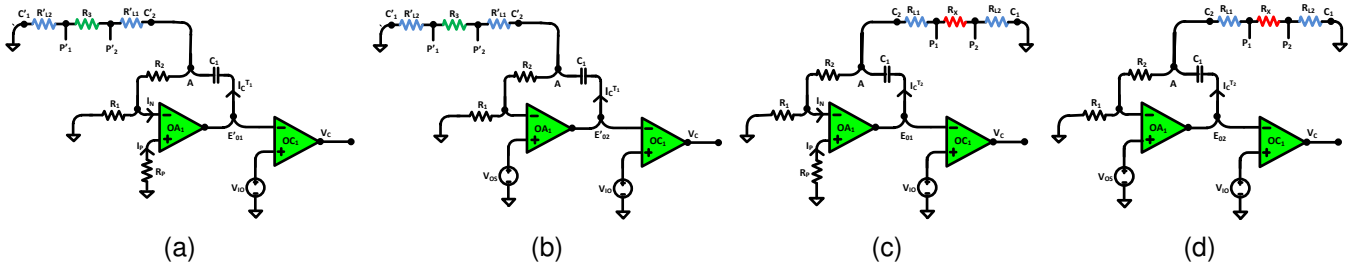

Fig. 2. The equivalent circuits for the digitizer's charging (T_1) and discharging (T_2) modes, considering offset noise. (a) Error due to I_{OS} and V_{IO} in T_1. (b) Error due to V_{OS} and V_{IO} in T_1. (c) Error due to I_{OS} and V_{IO} in T_2. (d) Error due to V_{OS} and V_{IO} in T_2.

Substituting $R_P = (aR_1/b)$ in (16), we get

$$E_{01}^{'}(t) = -\frac{aI_{OS}t}{C_1} \tag{17}$$

where I_P and I_N represent the input bias currents at the non-inverting and inverting terminals of OA_1, respectively. The input offset current (I_{OS}) is defined as $(I_P - I_N)$, while the input bias current (I_B) is given by $(I_P + I_N)/2$.

Error in integrator output ($E_{02}^{'}$) due to V_{OS} during T_1 is:

$$E_{02}^{'}(t) = \frac{1}{R_1C_1}\int_0^t (bV_{OS})dt = \frac{bV_{OS}t}{R_1C_1} \tag{18}$$

Thus, the total error in the integrator output during T_1 is

$$|E_0^{'}(t)| = |E_{01}^{'}(t)| + |E_{02}^{'}(t)| = \left[aI_{OS} + \frac{bV_{OS}}{R_1}\right]\frac{t}{C_1} \tag{19}$$

Substituting $t = T_1$ will give integrator output at the end of T_1

$$|E_0^{'}(T_1)| = \left[aI_{OS} + \frac{bV_{OS}}{R_1}\right]\frac{T_1}{C_1} \tag{20}$$

Now, the effect of V_{IO} on the output of OC_1 will be analyzed. The comparator's V_T shifts to $V_T + V_{IO}$. When the integrator output (including the offset voltage) reaches $V_T + V_{IO}$, V_C transitions from +V_{SAT} to -V_{SAT}. Thus, the voltage balance equation for finding T_1 is:

$$\begin{aligned} V_T + V_{IO} &= V_0(T_1) + |E_0^{'}(T_1)| \\ &= \frac{V_S}{R_1}\left[2R_2 + \frac{aT_1}{C_1}\right] + |E_0^{'}(T_1)| \end{aligned} \tag{21}$$

$V_O(T_1)$ expression is substituted from (5), and finally, T_1 is calculated as:

$$T_1 = \frac{[(V_T + V_{IO})\,R_1 - 2V_SR_2]\,C_1}{a\,[I_{OS}R_1 + V_S] + bV_{OS}} \tag{22}$$

Since, the typical value of I_{OS} is 0.5 pA (for TL072, [27]), it can be easily neglected. Similarly, $V_T + V_{IO}$ can also be approximated as V_T since V_{IO} (or V_{OS}) is 1 mV (for TL072, [27]), is negligible when compared to $V_T = 3V$. Additionally, $V_S + V_{OS}$ is treated as V_S. Thus, T_1 can be re-written as:

$$T_1 = \frac{[V_TR_1 - 2V_SR_2]\,C_1}{aV_S + bV_{OS}} \tag{23}$$

From (22), the expression of R_L in terms of I_{OS} and V_{OS} by considering the approximations mentioned above, can be written as:

$$\begin{aligned} R_L = &\frac{T_1\,[R_2V_S + (R_1 + R_2)\,V_{OS}]}{[V_TR_1 + V_{IO} - 2V_SR_2]\,C_1 - T_1\,[V_S + V_{OS}]} \\ &- R_3 - r_2^{T_1} \end{aligned} \tag{24}$$

After T_1 interval, all switches toggles to position 1, causing OA_1 to discharge which results in a decrease in V_I. At the same time, I_{OS} and V_{OS} slowly charge the integrator; however, their combined effect still contributes to decrease in V_I. This introduces a measurement error. Additionally, a V_{IO} appears at the non-inverting terminal of OC_1. Therefore, both error sources must be incorporated into the analytical model. The complete equivalent circuit is shown in Fig. 2(c-d) during the discharging of the integrator when V_S is set to zero. The error in integrator output (E_{01}) due to I_{OS} during T_2 is:

$$E_{01}(t) = \frac{1}{C_1}\int_0^t I_C^{T_2}dt \tag{25}$$

where $I_C^{T_2} = I_B[c-(R_Pd)/R_1]-(I_{OS}/2)[c+(R_Pd)/R_1], c = 1 + [R_2/(R_5 + r_2^{T_2})], d = 1 + [R_2/(R_5 + r_2^{T_2})] + [R_1/(R_5 + r_2^{T_2})], R_5 = R_X + R_L$ and $R_L = R_{L1} + R_{L2}$.

Substituting $R_P = (cR_1/d)$ in (25), we get

$$E_{01}(t) = -\frac{cI_{OS}t}{C_1} \tag{26}$$

Error in the integrator output (E_{02}) due to V_{OS} during T_2 is:

$$E_{02}(t) = \frac{1}{R_1C_1}\int_0^t (dV_{OS})dt = \frac{dV_{OS}t}{R_1C_1} \tag{27}$$

Thus, the total error in the integrator output during T_2 is:

$$|E_0(t)| = |E_{01}(t)| + |E_{02}(t)| = \left[cI_{OS} + \frac{dV_{OS}}{R_1}\right]\frac{t}{C_1} \tag{28}$$

Substituting $t = T_2$ will give integrator output at the end of T_2

$$|E_0(T_2)| = \left[cI_{OS} + \frac{dV_{OS}}{R_1}\right]\frac{T_2}{C_1} \tag{29}$$

During discharge mode, V_I decreases from $(V_T + V_{IO})$ to V_{IO}. At t = T_2, V_C transitions from -V_{SAT} to +V_{SAT}. Thus, the voltage balance equation for determining T_2 is:

$$\begin{aligned} &V_0(T_2) - |E_0(T_2)| \\ &= \frac{V_S}{R_1}\left[2R_2 + \frac{cT_2}{C_1}\right] - |E_0(T_2)| = V_T \end{aligned} \tag{30}$$

$V_O(T_2)$ expression is substituted from (11), and finally, T_2 is calculated as:

$$T_2 = \frac{[V_TR_1 - 2V_SR_2]\,C_1}{cV_S - dV_{OS}} \tag{31}$$

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 06:52:49 UTC from IEEE Xplore. Restrictions apply.

This article has been accepted for publication in IEEE Transactions on Instrumentation and Measurement. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TIM.2025.3560721

From (23) and (31), R_X is obtained as:

$$R_X = \frac{T_2\left(R_4 + r_2^{T_1}\right)\left[V_S R_2 - V_{OS}\left(R_1 + R_2\right)\right]}{p} - R_L^{(24)} - r_2^{T_2} \quad (32)$$

where $p = \left(R_4 + r_2^{T_1}\right)\left[V_S\left(T_1 - T_2\right) + V_{OS}\left(T_1 + T_2\right)\right] + T_1\left[R_2 V_S + V_{OS}\left(R_1 + R_2\right)\right]$.Thus, if we compare (24) with (8) for R_L, and (32) with (15) for R_X, it can be concluded that to select OA_1 with a minimal offset voltage (V_{OS}) to ensure accurate measurements.

B. Effect of Deviation of Fixed Resistance (R_1, R_2 and R_3) and Capacitance (C_1)

The deviation in the value of C_1 does not impact the measurement of R_X as it is independent of C_1 according to (15). The following analytical analysis demonstrates that deviations in the fixed resistances (R_1, R_2, and R_3) have a negligible effect on the measurement. Assuming the fixed resistors are changed to $R_1^{'}$, $R_2^{'}$, and $R_3^{'}$, which are defined as:

$$\begin{aligned} R_1^{'} &= R_1(1+\alpha) \\ R_2^{'} &= R_2(1+\beta) \\ R_3^{'} &= R_3(1+\gamma) \end{aligned}$$

where α, β and γ represents the percentage changes in R_1, R_2 and R_3 respectively due to ageing. Then (15) can be re-written as:

$$R_X^{'} = \frac{T_2 R_2^{'}\left(R_3^{'} + R_L + r_2\right)}{\left(T_1 - T_2\right)\left(R_3^{'} + R_L + r_2\right) + T_1 R_2^{'}} - R_L - r_2 \quad (33)$$

Substituing $R_1^{'}$, $R_2^{'}$, and $R_3^{'}$ in (33) we get:

$$R_X^{'} = \frac{T_2 R_2(1+\beta)\left[R_3(1+\gamma) + R_L + r_2\right]}{\left(T_1 - T_2\right)\left(R_3(1+\gamma) + R_L + r_2\right) + T_1 R_2(1+\beta)} - R_L - r_2 \quad (34)$$

From (34), we can conclude that the impact on the measurement due to deviations in the fixed resistors is negligible, as the terms associated with $(1+\alpha)$, $(1+\beta)$, and $(1+\gamma)$ can be easily neglected compared to the original terms.

C. Effect of Deviation of V_S

The measurement of R_X will remain unaffected by changes in the $\pm\, V_S$ value. However, if there is a discrepancy between $+V_S$ and $-V_S$, the following analysis will explore how this mismatch impacts the measurement of R_X. Let's assume that the input voltages are changed to V_{S1} for $-V_S$ and V_{S2} for $+V_S$, defined as follows:

$$\begin{aligned} V_{S1} &= -V_S(1+\delta) \\ V_{S2} &= +V_S(1+\sigma) \end{aligned}$$

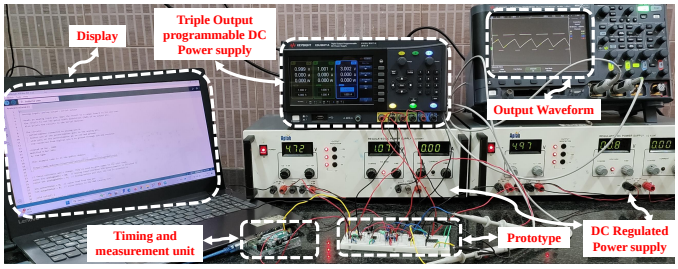

Fig. 3. Experimental setup for testing the proposed digitizer circuit with T-network for measurement of low resistance.

Here, δ and σ represent the percentage changes in $-V_S$ and $+V_S$, respectively. Thus, the charge balance in (14) can be expressed in terms of node voltage as follows:

$$\frac{V_{S1}}{\left(R_1 + r_1\right)}\left[2R_2 + \frac{T_1}{C_1}\left(1 + \frac{R_2}{R_3 + R_L + r_2}\right)\right] = \frac{V_{S2}}{\left(R_1 + r_1\right)}\left[2R_2 + \frac{T_2}{C_1}\left(1 + \frac{R_2}{R_X + R_L + r_2}\right)\right] \quad (35)$$

By substituting the values of V_{S1} and V_{S2} into (35), we obtain the following simplified expression:

$$R_X^{'} = \frac{T_2 R_2(1+\sigma)\left(R_3 + R_L + r_2\right)}{q\left(R_3 + R_L + r_2\right) + T_1 R_2\left(1+\delta\right)} - R_L - r_2 \quad (36)$$

where $q = 2R_2C_1\left(\delta - \sigma\right) - T_2\left(1+\sigma\right) + T_1\left(1+\delta\right)$. Notably, since δ and σ oppose each other, their combined impact on the measurement of R_X is minimal.

IV. Experimental Setup

A. Experimental components

The physical prototype of the dual-slope digitizer has been tested on a breadboard, and both the prototype and the experimental setup are shown in Fig. 3. The integrator (OA_1) and the comparator (OC_1) are realized using a TL072 IC [27] and a LM311 IC respectively. The SPDT switches S_1, S_2, and S_3 are realized with single pole single throw (SPST) CMOS MAX 4690 IC [26] and an inverter SN7404 IC [28]. The controlling signal for the switches is derived from the output of the comparator (V_C). The positive and negative supply (VCC and VEE) of $\pm$ 5 V are obtained from DC-regulated power supply (LQ6324T, Aplab) to OA_1, OC_1, MAX 4690 and SN7404. The values of fixed resistors R_1, R_2 and capacitor C_1 are set at 98.5 $k\Omega$, 25.5 Ω, and 27.6 μF respectively. On the other hand, R_3 is a known four-terminal low-resistance component with a value of 1.2 Ω, which is connected in circuit through its two current terminals ($C_1^{'}$ and $C_2^{'}$) only. The unknown two-terminal low value R_X ranges from 0.1 - 0.9 Ω. It is to be noted that, R_3 and R_X are connected to the circuit through R_L which is also unknown. A triple-output programmable DC power supply, precisely calibrated to an accuracy of $\pm$ 5 μV (EDU36311A, Keysight) is used to provide the input voltage (V_S) of $\pm$ 1 V and V_T of 3 V. For measuring R_X = $f(T_1, T_2)$, the timing unit is implemented using Arduino Uno ATMEGA328P. T_1 represents the time period required for V_I to gradually rise to V_T, while T_2 signifies the period for V_I to fall from V_T to ground. Initially, T_1 is used to determine R_L using (7), and subsequently R_X

TABLE III
SLOPE VARIATION IN SIMULATION FOR DIFFERENT VALUES OF R_X DURING T_1 AND T_2 INTERVALS

Value of R_X (Ω)	Rising Slope (V/s) (T_1 interval)	Falling Slope (V/s) (T_2 interval)
0.1	3.7781	6.0494
0.2	3.7807	5.7267
0.3	3.7763	5.4404
0.4	3.78	5.1741
0.5	3.7768	4.9507
0.6	3.7796	4.7382
0.7	3.7755	4.5394
0.8	3.7795	4.3665
0.9	3.7804	4.2015

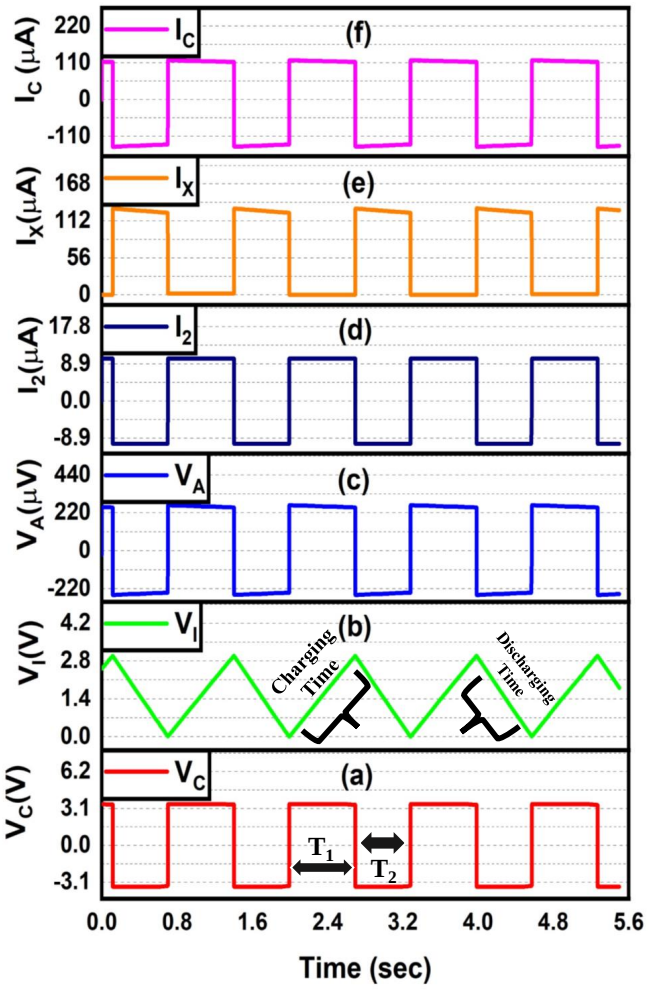

Fig. 4. Plots illustrating various branch currents (I_2, I_X, I_C) and node voltages (V_I and V_C) of the digitizer circuit for R_X = 0.5 Ω.

is calculated using (15). The circuit's performance is assessed by measuring R_X within the specified range. Additionally, a handheld LCR meter (U1733C, Keysight) is also used for verifying the measured R_X values. I_X and I_C are separately measured using a source measurement unit (SMU, B2910BL, Keysight), and a 6 1⁄2 Digit Table-top multi-meter (DM3068, Rigol) respectively.

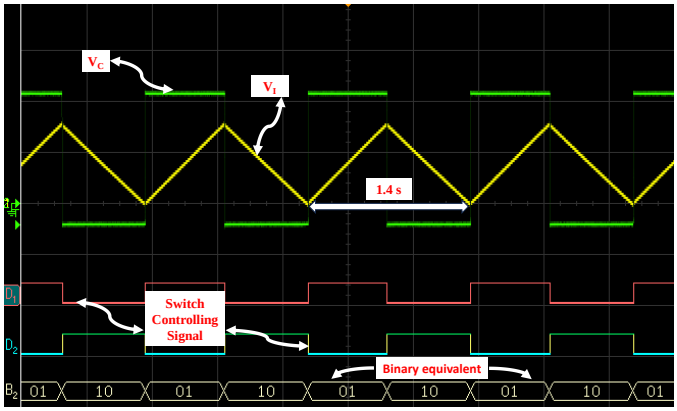

Fig. 5. The integrator (V_I) and comparator (V_C) experimental waveforms, along with control signals for switch operation are shown on mixed signal oscilloscope for R_X = 0.5 Ω.

V. RESULTS AND DISCUSSION

In the proposed digitizer, the V_S is kept at 1 V ensuring that the amplified I_C generated due to T-network remains in the operating range of OA_1, preventing it from entering into a non-linear region. The V_C is a quasi-square waveform, with its duty cycle determined by V_I and V_T. Since V_T is fixed, the time periods T_1 and T_2 primarily depend on V_I which is a triangular waveform. The V_C remains HIGH during the rising of V_I and vice-versa. As predicted in (7) and 13), T_1 remains unaffected by changes in R_X, maintaining a constant slope for V_I despite variations in R_X. In contrast, T_2 has a dependency on R_X, resulting in a different slope of V_I with variation in R_X as shown in Table III.

Fig. 4 (a-c) shows the voltage waveforms at different nodes, namely V_C, V_I, and V_A, for R_X = 0.5 Ω. The T_1 = 794.32 ms and T_2 = 605.98 ms which are measured from V_C using Arduino Uno. The V_A is a bipolar square voltage waveform with equal amplitude in both polarities. Fig. 4 (d-f) shows different current waveforms of I_2, I_X and I_C for R_X = 0.5 Ω. The nature of I_2 waveform is similar to V_A waveform as both remains constant during the charging and discharging mode irrespective of the change in R_X value. The I_X is a unipolar square nature waveform with an amplitude of 82.54 μA as switch S_2 is closed during T_2 interval. During the charging mode, $I_C^{T_1}$ is exited from C_1 and divided into two unequal halves as I_2 and I_3. Similarly, during the discharging mode, I_2 and I_X are summed at node A as $I_C^{T_2}$ and enters the C_1. Since, I_X varies with R_X, current $I_C^{T_2}$ also varies accordingly.

As, I_2 is a bipolar square waveform with equal amplitude in both polarities, its root mean square (RMS) value is equal to modulus of its peak value. For I_C, since its an bipolar unequal square waveform due to presence of I_X only during T_2, its RMS value is calculated using (37), which is given following:

$$I_C^{RMS} = \sqrt{\frac{1}{T}\left(\int_0^{T_1} {I_C^{T_1}}^2\, dt \; + \; \int_{T_1}^{T} {I_C^{T_2}}^2\, dt\right)} \qquad (37)$$

where $T = T_1 + T_2$. The values of $I_C^{T_1}$ and $I_C^{T_2}$ are obtained from (2) and (9) respectively.

The experimental waveforms of V_I, V_C, and control signals in mixed signal oscilloscope (MSOX3014G, Keysight) is

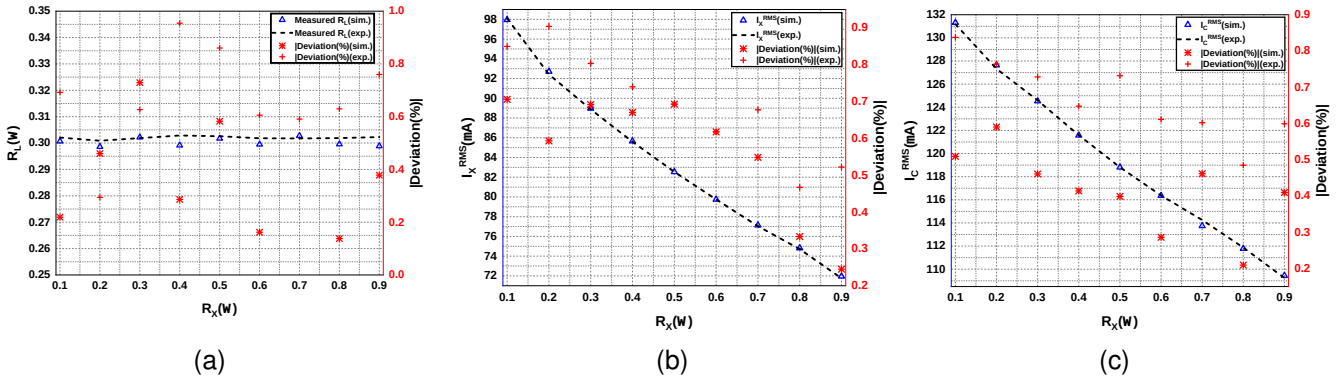

Fig. 6. Plots of parameters and branch currents for R_X varying in the range (0.1 Ω to 0.9 Ω, full span). (a) Lead resistance (R_L). (b) Incoming current (I_X^{RMS}) through R_X. (c) Capacitor current (I_C^{RMS}).

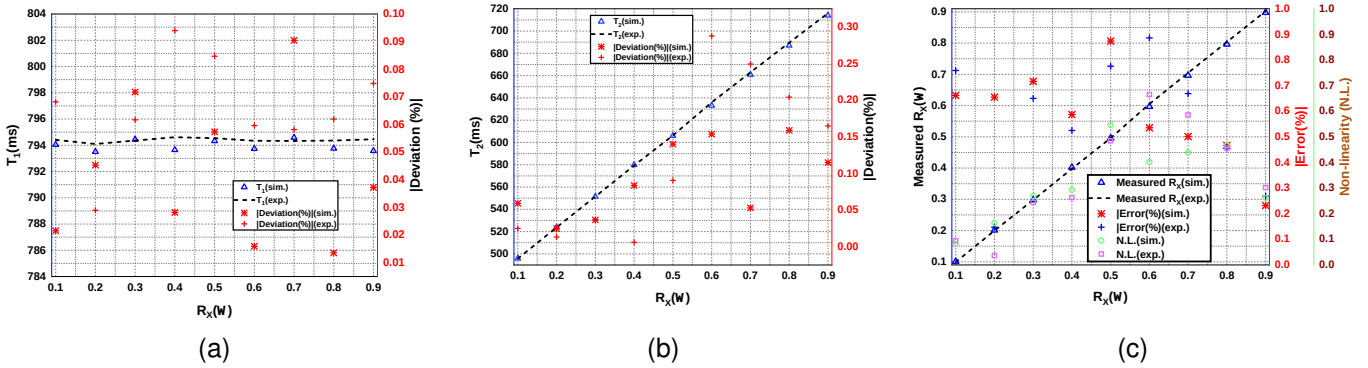

Fig. 7. Plots of different parameters of the digitizer circuit with known R_X varying for the full span. (a) Charging interval (T_1). (b) Discharging interval (T_2). (c) Measured resistance R_X. For each plot, deviation (%) is calculated from the analytical model equations (7), (13), and (15) respectively.

shown in Fig. 5 for R_X = 0.5 Ω. The T_1 and T_2 intervals measured is 794.5 ms and 606.3 ms respectively. Hence, the experimental waveform closely resembles the simulated waveforms of Fig. 4(a-b). Thereafter, when R_X varies across the entire span (0.1 Ω - 0.9 Ω), the corresponding I_X^{RMS} varies from 97.95 μA to 71.95 μA in simulation, while in experiment, it varies from 98.09 μA to 71.75 μA. Similarly, in case of I_C^{RMS}, it varies from 131.32 μA to 109.45 μA in simulation, while in experimental, it varies from 131.18 μA to 109.24 μA. The current I_2 remains constant throughout the span with a value of 10.15 μA.

Fig. 6a shows the simulation and experimental plots between R_L and R_X. The percentage deviation (%) for simulation and experimental is also depicted, and is calculated by comparing it with the analytical model (8) using formula $((\mid R_L - R_L^* \mid)/(R_L)) \times 100$ where R_L^* is the measured lead resistance. The average deviation in simulation and experimental is 0.43% and 0.67% respectively. Fig. 6b shows the simulation and experimental plots showing the relation between I_X^{RMS} and R_X as per (10). The average and maximum deviation in simulation is 0.57% and 0.71% while in experimental it is 0.7% and 0.9% respectively. Fig. 6c shows the simulation and experimental plots for the relation between I_C^{RMS} and R_X. The average and maximum deviation in simulation is 0.41% and 0.59% while in experimental it is 0.66% and 0.83% respectively. Again, (37) is used to calculate the rms value of I_C^{RMS} analytically.

The novelty of this work lies in the use of a T-network in the feedback path to measure R_X particularly when it is below 10 Ω, a task that is typically challenging with conventional dual-slope integrator based measurement techniques [15]. In conventional methods, R_X is usually placed at the input side of the op-amp integrator, and keeping it below 10 Ω, allows a large amount of current to flow, causing the op-amp to saturate. Even reducing the input voltage to 0.01 V does not resolve this, as the input current would still be in the range of 100 mA. Alternatively, connecting R_X in feedback produces a low output voltage that is susceptible to inherent circuit noise, leading to significant measurement errors. To address these challenges, a T-network is introduced. This design allows a permissible amount of current to flow through the input side of the op-amp while directing most of the current through the middle arm of the T-network. The I_X through R_X in the T-network is responsible for amplifying the I_C which charges and discharges the integrating capacitor C_1, and hence measure R_X. The I_X due to T-network enables faster R_X measurement in a two-wire configuration with accurate results.

The simulation and experimental plots of T_1 and T_2 for R_X is shown in Fig. 7a and Fig. 7b respectively. The T_1 remains almost constant while T_2 varies linearly with R_X for the full span. These plots closely align themselves with the prediction in the analytical model (7) and (13) which are also used for finding the deviation %. For T_1, the average deviation is 0.04% in simulation, and 0.06% in experimental. For T_2, the average

This article has been accepted for publication in IEEE Transactions on Instrumentation and Measurement. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TIM.2025.3560721

and maximum deviations are 0.09% and 0.15% respectively in simulation while in experiment, the average and maximum deviations are 0.11% and 0.28% respectively.

Fig. 7c shows the simulation and experimental plots of known R_X with measured R_X along with error %. The plot also shows the nonlinearity (NL) with a maximum value of 0.54% in simulation and 0.66% in experimental. In simulation, the average error % and maximum error % throughout the spam is 0.48% and 0.77% respectively while in experimental, the average error % is 0.68%. Thus, the experimental results presented in Fig. (5-7), along with the preceding discussion, demonstrate that the proposed digitizer circuit performs effectively and is well-suited for measuring low-value resistances.

VI. Conclusion

This study thoroughly examines the proposed digitizer circuit which produces digital output for measuring low resistance (R_X) in the range of 0.1 - 0.9 Ω (full span). The circuit features a dual-slope integrator with a T-network in the feedback path, three SPDT switches, and a comparator. The R_X is connected to the middle branch of the T-network, while a fixed resistor and a feedback capacitor are connected to the other two branches. The incoming current (I_X, 98.09 - 71.75 μA) in the T-network through R_X is responsible for amplifying the feedback (capacitor) current (I_C) which charges and discharges the integrating capacitor. The R_L connected to R_3 (or R_X) is measured during the integrator's charging interval. During the discharging interval, the combined resistance ($R_X + R_L$) is measured. Finally, R_L is subtracted to accurately determine R_X which is independent of R_L in a two-wire type configuration. The total measurement time ranges from 1.29 - 1.51 s, and the average error is $\pm$ 0.68% over the full span. Therefore, the proposed digitizer circuit is suitable for measuring low value resistances.

VII. Acknowledgement

The authors extend their gratitude to the Advanced I&M Laboratory of the Instrumentation and Control Engineering Department of the NIT Trichy, Tiruchirappalli, TN, India, for providing the facilities necessary for this research.

***Abstract*—With the increasing use of digital media, digital forensics has become a crucial method for ascertaining authenticity and detecting manipulations in images. However, intentional anti-forensic manipulations to hide forensic clues have made verification more difficult. The efforts to develop countermeasures against anti-forensics have contributed to the evolution toward robust techniques in the field of anti-forensics; hence, the development of anti-forensic methods and their respective countermeasures will remain continuous. This work provides a scientometric analysis, a powerful tool for the study of the growth of research output in accordance with time and citation, author, organizational, and keyword co-occurrence analysis. It enhances state-of-the-art analysis by underlining highly influential authors, organizations, and works and stipulates knowledge gaps. This would consequently provide a platform for building a community where insights and inclusiveness among researchers, industry practitioners, and policymakers would all come together to guide their strategies and decisions for innovation in this dynamic field.**

***Index Terms*—Image Forensics, Scientometric Analysis, Image Forgery, Fake Image**

I. Introduction

Mobile phones and computers have become an integral part of life. They correspondingly improve with rapid development in information and communication technology. They bear big personal data in digital format, such as photographs, videos, and messages. They are more susceptible to tampering by resorting to available multimedia tools such as Adobe Photoshop, Corel Photo-Paint, and ACDSee. The ease of accessibility with which such images are manipulated poses a severe challenge. Manipulated images may result in defamation of character or tampered evidence in courts of law. In fact, the distribution of manipulated images can also lead to social unrest or political upheaval. Thus, the authenticity and integrity of digital images are very crucial in today's digital era, pertaining to image forgery attacks like image retouching, image splicing, copy-move, etc. Because of this, two primary methods can be used for digital image forgery detection: an active approach and a passive approach. In an active approach, specific details are embedded in the image so that it can detect even the slight form of digital tampering. Examples of such can include name, date, signature, and other meta information of the image. This often requires a peculiar system to verify the authenticity of the digital image. In passive methods, duplicated objects in manipulated images are detected without using the original image watermark. Instead, the technique looks for traces left behind due to dissimilar steps involved in the image manipulation process. It can also locate the place and region where the forgery has taken place within the image. The source camera identification and alteration trace analyses are included in passive digital image forensics that verifies image manipulation. These methods take advantage of unique fingerprints left by the acquisition devices or apply signal analysis in order to disclose forgeries. However, these verifications have been complicated by the emergence of anti-forensic techniques that mask traces of manipulation. As a result of these developments, countermeasures against anti-forensics have driven further advancement of robust forensic techniques. This dynamic evolution keeps shaping anti-forensic methods and their countermeasures in the dynamic field of digital image forensics.

Sitara and Mehtre [1] discussed a survey of the anti-forensic domain through passive techniques for image and video tampering detection, along with their respective countermeasures. The authors also pointed out different limitations that have caused anti-forensic methods to grow along with digital forensics. Taneja et al. [2] presented a study related to anti-forensic attacks on JPEG compression, contrast enhancement, and median filtering. Their work presented a robust discussion on methodologies and summarized some existing state-of-the-art methods in tabular form. Al-Fehani and Al-Kuwari [3] discussed image and video forensics, including source identification, forgery detection, and problems arising from generative media. This work has stressed the attacks' liability in using the adversarial and, in turn, motivating the need for more robust methods of forgery detection. They have mentioned the generalized detection technique for forgery and the under-representation of research in GAN detection, in particular

ISBN: 979-11-88428-13-7 Copyright 2025. Global IT Research Institute (GIRI). All right reserved.

for image forensics. They have also outlined that video anti-forensics, compared to the image, is underrepresented in literature and countermeasures, too. They also talked about the legality of forensic evidence and were motivated to emphasize the justification of the authenticity of the evidence. Some problems arise from the fact that deep learning has started to replace traditional solutions in the understanding of decisions taken by classifiers, being an issue for forensic experts. Their overall review highlighted the changing nature of multimedia forensics and the need for adaptive methods in order to meet several new challenges.

Qureshi and El-Alfy [4] presented a bibliographic review about anti-forensics and relative countermeasures; the goal was to help researchers and practitioners find their place in the current panorama. This review underlines that countering AFMs is an essential task for making forensic techniques reliable against tampering with images. It points out the never-ending conflict between forensic and anti-forensic techniques, which imposes the necessity of constant development and adaptation. The authors firmly believe that new computational methods, such as the addition of dithering noise, have to be explored in order to find adequate countermeasures against emerging anti-forensic strategies. This investigation is based on the finding that the quality of images essentially defines forensic trace concealment. Moreover, they recommend the extension of anti-forensics and related countermeasures research to new fields of video, disk, and network forensics. The work raises questions concerning the reliability and trustworthiness of the existing forensic techniques, proposing a study of relationships among several picture artifact metrics for devising more secure methods. It advocates for thorough benchmark systems, embedding recent deep learning developments, and multi-sensor cameras that will improve forensic capabilities. Finally, the review discusses how cloud computing could support forensic solutions in a scalable way in the future.

More research is needed in the domain of anti-forensics. Only a few papers [1]–[4] present organized research on different anti-forensic schemes. Paper [2] discusses anti-forensic attacks on JPEG, contrast enhancement, and median filtering. It introduces image forgery, JPEG compression, contrast enhancement, and median filtering. After presenting the detailed anti-forensic methods, it shows the current state-of-the-art methodologies in a tabular form for clarity. Al-Fehani and Al-Kuwari, [3] in their work, review some of the recent works on image and video forensics that involve source identification, forgery detection, and challenges from generative media. Anti-forensics and countermeasures will be presented, focusing on the general problem of susceptibility to adversarial attacks. The review also highlights the need for more research on GAN detection, especially in the context of image forensics. Robustness in forgery detection methods is needed. It underlines a promising generalized forgery detection technique and calls for more research related to GAN detection, especially for image forensics. This paper points out that, compared to image forensics, the literature dealing with video anti-forensics and related countermeasures needs to be revised. It also considers in some depth legal issues with respect to forensic evidence and emphasizes the need for a description of the rationale for the authenticity of evidence. This movement into deep learning methods is at the price of well-understood classification decisions that might concern forensic practitioners. In general, it highlights the dynamic nature of multimedia forensics and the implication for adaptive approaches towards rising challenges. A review [4] on anti-forensics and countermeasures against digital image forensics gives an overview to help researchers and practitioners better understand the status quo in this arena. Therefore, countering AFMs is of vital importance to guarantee that forensic techniques against image tampering are reliable. It realizes the never-ending battle between forensic and anti-forensic techniques and further identifies the need for development and adaptation. It points out that new computational methodologies, such as adding noise with dithering, should be explored to counter emerging anti-forensic strategies successfully. Critical roles of image quality in masking the forensic traces are outlined in this work, and further investigation of the topic is presented. The paper also stresses the importance of extending research studies on anti-forensics and countermeasures to new emerging areas like video, disk, and network forensics, as this will contribute to the development of more secure forensic techniques. Furthermore, it suggests developing comprehensive benchmark systems, integrating deep learning advancements, and using multi-sensor cameras to improve forensic capabilities further. It finally discusses how cloud computing could enable scalable forensic solutions in the near future—surveys [1] anti-forensic techniques relating to passive image and video tampering detection, discussing countermeasures. Limitations within the current literature pertaining to tampering detection are noted, which have led to the development of anti-forensic methods, changing with digital forensics.

We previously examined key survey papers concerning antiforensics and its countermeasures. In the next section, we will delve into Scientometric Analysis.

II. Scientometric Analysis

This study will help explain productivity, seminal articles, productive authors, and organization and collaboration dynamics in the domain of anti-forensics. Scientometric analysis in research output related to anti-forensics encompasses several steps methodologically: the selection of appropriate bibliographic databases, formulating the search queries, retrieving the literature, and applying scientometric indicators quantifying the impact of research and collaboration patterns. It would naturally also involve a well-articulated search strategy to identify relevant publications, preprocessing for quality and consistency of data, computation of scientometric indicators such as counts of citations, impactful authors networks, and several visualization techniques to interpret.

A. Data Collection and Publication Trend

We have developed an exhaustive dataset of research publications from the WoS repository, one of the world-renowned databases containing exhaustive and quality research content for comprehensive analysis and synthesis of the anti-forensics field. The database includes all major indices, such as SCIE, SSCI, and BKCI-S. The search string (("antiforensic*" OR "counterforensic*" OR "anti-forensic*" OR "counter-forensic*" OR ((anti OR counter*) NEAR/3 (forensic*))) AND (JPEG OR image)) yielded 220 publications dealing with research. Manual screening for non-relevant entries brought us to the number of 210 relevant publications that deal with the area. Figure 1 describes the annual progress of anti-forensics research publications that had cropped up as early as 2006. From 2013 onwards, the domain continued to show a significant number of publications throughout the year, except for 2016.

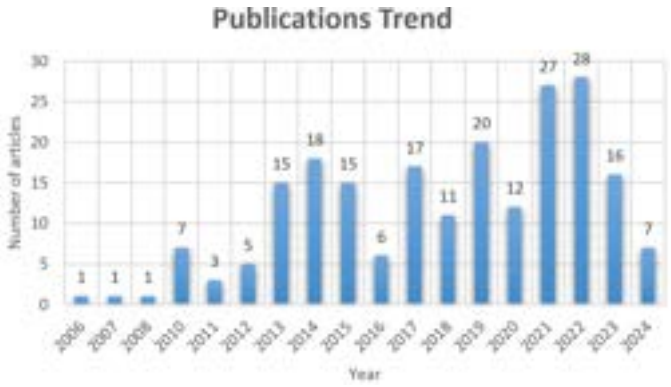

Figure 1. Yearly Publications of Anti-Forensics Research

B. Identification of Top Authors and Organizations with their country

Table I highlights the prominent researchers in the field of anti-forensics, showcasing a diverse group with significant contributions from China (four researchers), Italy (two researchers), and one each from the USA, India, Saudi Arabia, and South Korea. Barni, M. from Italy, leads the list of top contributing authors with six articles. He is followed by Stamm, MC from the USA, and Wu, JY from China, each authoring five articles.

Our analysis of the top contributing organizations, as per Table II, underscores the significant contributions of researchers from China, Italy, the USA, and India to the field of anti-forensics. Univ Maryland, Dept Elect and Comp Engn, College Pk (USA) has published the highest number of articles (8), followed by Beijing Jiaotong Univ, Inst Informat Sci, Beijing (China) with six articles, Drexel Univ, Dept Elect and Comp Engn, Philadelphia (USA) with five articles, and Sun Yat Sen Univ, Sch Informat Sci and Technol, Guangzhou (China) with four articles. Other organizations such as the Univ Siena, Dept Informat Engn and Math (Italy), TIET, Dept Elect and Commun Engn, Patiala, Punjab (India), Univ Siena, Dept Informat Engn and Math, Siena (Italy), Beihang Univ, Sch Comp Sci and Engg. (China), Shenzhen Univ, Shenzhen Key Lab Media Secur, Shenzhen (China), and Shenzhen Univ, Guangdong Key Lab Intelligent Informat Proc, Shenzhen (China) have also made significant contributions.

C. Document citation linkages

A full-scale VoS analysis was performed on the WoS corpus for research related to anti-forensics, which covered 210 published documents. This paper analyzed the citations among those documents using a full counting method that had to be at least two citations each. It identified the top ten cited documents, including their total citations, publication venues, and the years of publication. The paper spearheads the list "Do GANs Leave Artificial Fingerprints?" with 127

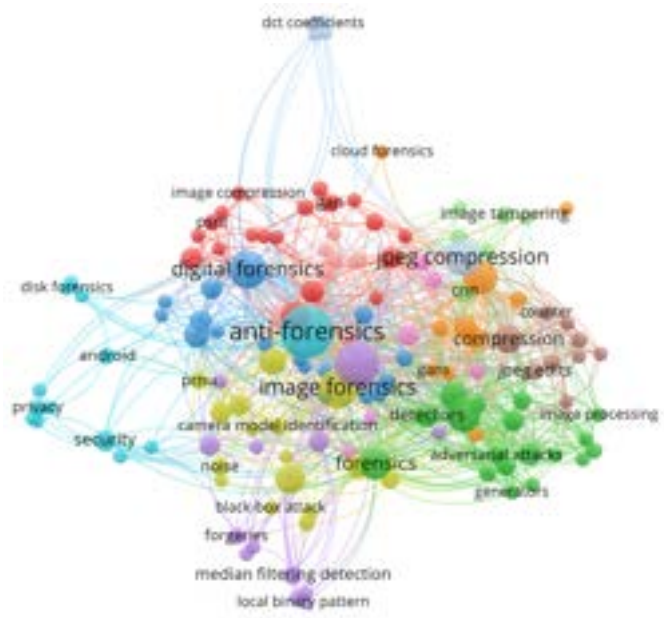

Figure 2. Keyword Co-occurrence Networks in Anti-Forensics Research

citations. Next is "Forensic Detection of Median Filtering in Digital Images" by Cao et al., which secured the second position with 107 citations. The document "Recent Progress of Fluorescent Materials for Fingermarks Detection in Forensic Science and Anti-counterfeiting" by Ansari et al. has been cited 88 times, hence placing third. The last five documents in Table III have less than 50 citations each. A key observation from this analysis is the crucial role of IEEE and conferences in promoting highly influential research work in the anti-forensics domain. The majority of high-impact papers are by IEEE, and a large fraction of them are conference papers. This underlines key works and highly influential papers that establish these publications as essential milestones in pushing the research frontier on anti-forensics.

D. Keyword Co-occurrence Networks

Figure 2 illustrates the co-occurrence networks of keywords in the anti-forensics domain based on a comprehensive analysis of the Web of Science (WoS) document corpus. The VoS search identified 649 unique keywords, with the study focusing on 140 keywords that appeared at least twice.

The co-occurrence grids are color-coded to represent different clusters:

- Cyan: The keyword "anti-forensics" forms the most significant node, frequently co-occurring with "privacy," "security," and "disk forensics."
- Blue: This network centers around "digital forensics," indicating a significant research thrust in this area.
- Yellow: Keywords related to "image forensics" dominate this cluster, highlighting its prominence in the field.
- Green: The "forensics" keyword forms the core of this cluster, encompassing a broad range of related topics.
- Smaller Clusters: These include frequent keywords such as "CNN," "cloud forensics," "forgery," "local binary pattern," and "compression," each forming distinct, smaller clusters.

The visualization provides insights into the interconnectedness and primary focus areas within the anti-forensics research landscape.

III. CONCLUSION

This scientometric analysis explains the overall growth and path of anti-forensic research, outlining the significant trends and contributions that have set a mark in the area. Growth in publication since 2006 steepens in 2013, reflecting the rising importance and complexity of digital forensics as a response against advanced challenges caused by digital manipulation. In this respect, the study identifies significant contributors from institutions worldwide, especially in the USA, China, and Italy, which are driving the research and development of new methods to respond to both established and new threats. Citation analysis has shown how keynote works, published for the most part through IEEE venues, attest to the quality of research and the pivotal role of IEEE conferences in the dissemination of critical anti-forensic studies. Keyword analysis returns a dynamic network of themes, such as "privacy," "security," and "forensics," which is necessary to understand the focus of the field and to integrate diverse research areas into effective anti-forensic strategies.

2025 International Conference on Pervasive Computational Technologies (ICPCT) | 979-8-3315-0868-5/25/$31.00 ©2025 IEEE | DOI: 10.1109/ICPCT64145.2025.10940262

***Abstract*—The security of Internet of Things (IoT) devices in Matter-enabled networks is crucial, as attacks such as sensor spoofing and data injection can lead to significant disruptions. Sensor manipulation attacks where the attackers manipulate the sensor inputs to create erroneous behavior in devices are issues of serious concern for anomaly detections. Faulty sensor data can cause devices to operate in unsafe or inefficient conditions across various applications, compromising system reliability and performance. The Isolation Forest algorithm is employed to isolate faulty data injections as outliers in sensor readings, offering a robust method for anomaly detection. The approach, therefore, focuses on the possibility of enhancing detection with greater reliability in IoT networks. The lightweight and extensible approach also assembles a process of strengthening Matter-based networks against vulnerabilities emanating from wrong control feedback.**

***Index Terms*—Matter Protocol, Internet of Things Security, Anomaly Detection, Interoperability**

I. Introduction

The expansion of the Internet of Things (IoT) has transformed industries, offering smarter solutions in areas such as home automation, healthcare, large-scale industrial systems, and smart cities. This growth, however, brings many security challenges as IoT devices generally provide open access points that can serve as gateways for various attack methods such as hacking, malware infection, phishing, and spoofing. These threats can result in unauthorized access, data manipulation, and denial of service (DoS) attacks [1], undermining the reliability of the devices and networks they operate within. In Matter-enabled IoT networks, the risk is further amplified by the mesh networking protocol [2], which facilitates communication across devices on different platforms. Matter [3], an open-source and royalty-free connectivity standard made with the intention of ensuring secure, reliable, and seamless communication between IoT devices, potentially opens new avenues for data manipulation since devices operate as relay nodes and can be exploited through vulnerabilities in the sensor systems.

Sensor spoofing attacks are a major potential threat to the security of IoT networks. Here, an unauthorized user manipulates sensor readings so as to interfere with the proper functionality of the devices. Such attacks make the systems prone to incorrect data injection, causing malfunction and posing potential safety risks to critical systems. The challenge of detecting these anomalies in real-time is crucial to maintaining the integrity of Matter-enabled networks.

To address this issue the authors have proposed the following key contributions:

- A real-time IoT network anomaly detection using an Isolation Forest algorithm-based ML security framework that secures the network.
- Provided a scalable and resource-efficient solution, making it suitable for deployment in resource-constrained IoT environments.
- Ensured the integrity of Matter-enabled networks by distinguishing legitimate sensor data from malicious alterations.

This approach not only facilitates the immediate detection and mitigation of security threats but also ensures efficient operation in resource-constrained IoT environments. It maintains data integrity, minimizes the harmful impact of data manipulation, and strengthens the resilience of Matter-enabled IoT networks. It guarantees real-time anomaly detection of sensor data that can withstand adversarial tampering, ensuring the reliability and security of the underlying network.

Section III presents a machine learning-based approach leveraging the Isolation Forest algorithm to address security challenges. It includes a pipeline diagram illustrating the data collection process and the machine learning algorithm's steps. Section IV presents the performance comparison of the proposed methodology, mentioning the highly favorable results on the limited available resources and looks into the scalability alongside the computational efficiency in diverse IoT environments. Section V provides a comprehensive discussion of the problem and the proposed solution, including limitations and potential areas for future work. Finally, a summary of the paper is offered in Section VI together with potential avenues for research in enhancing reliability and safety in IoT networks.

II. Literature Review

Anomaly detection plays a pivotal role in securing and ensuring the integrity of IoT systems, especially in the Matter-enabled devices. The Matter protocol is developed by the Connectivity Standards Alliance (CSA) [4], to provide a secure and interoperable platform for IoT devices. However, like all networked systems, Matter-enabled devices are susceptible to manipulation attacks, including faulty data injection and sensor tampering, thus reducing the integrity and system faults.

A. Vulnerabilities in IoT Networks

IoT networks, based on Matter, are usually designed in the form of a mesh topology [5], where each device communicates with multiple other devices. This decentralized communication system is vulnerable to various types of attacks. A compromised device can inject faulty data, alter sensor readings, or manipulate packets. For example, a compromised sensor could provide incorrect readings to the system, leading to abnormal system behavior. Such manipulations can lead to the inefficiencies of operations or a failure-to happen in some smart homes or within industrial systems of automation.

The risks associated with IoT networks have been extensively studied. The faults data injection attacks disrupt communication between devices, and they allow false information to be distributed through the network, causing instability in device functions. As pointed out by [6], such manipulation might stunt systems reliant on sensor data, such as with the HVAC systems, where manipulated temperature data make the equipment malfunction.

B. Security Mechanisms in Matter Protocol

To maintain reliability and safety, IoT devices employ the Matter protocol with various security measures [7]. The primary security mechanism is end-to-end encryption, which secures communication and prevents eavesdropping or data alteration. Matter also includes device authentication during commissioning to prevent unauthorized access and sabotage. Granular access control policies restrict device interaction, minimizing the risk of security breaches and unauthorized data manipulation. By ensuring only trusted devices participate, the Matter protocol reduces risks from faulty data injection and sensor manipulation. Further enhancing IoT security, combining elliptic curve cryptography (ECC) with blockchain addresses privacy and unauthorized access challenges in sensitive systems like healthcare IoT. The GAO-RF model achieved 98.4% accuracy in securely handling large amounts of private data [8]. These advancements strengthen IoT protocols like Matter, providing robust mechanisms for safeguarding sensitive information in modern ecosystems.

C. Anomaly Detection in IoT Networks

Anomaly detection is fundamental for identifying attacks such as faulty data injection and sensor manipulation in IoT systems. Various machine learning techniques [9] have long been exploited to detect such anomalies in IoT environments. The application of these techniques to faulty data detection in IoT networks shows how to detect data manipulation and some form of attacks generating network congestion induced by malicious nodes [10]. Such techniques work effectively because they identify deviations in sensor data and network behavior that indicate imminent attacks. Additionally, securing IoT devices is crucial, and recent studies have explored using honeypots, like Raspberry Pi-based systems, to detect and analyze attack patterns targeting vulnerable IoT protocols [11]. A promising approach to anomaly detection in IoT networks is the use of active learning. Various observations [12] have been made for models of active learning to improve the performance and accuracy levels of anomaly detection within resource-constrained environments by training themselves on the most informative data points. The technique is especially valuable for IoT systems, where devices produce vast amounts of sensor data, making anomaly identification in (quasi-)real-time impossible without efficient methods for data selection.

D. False Data Injection Attacks and Detection Mechanisms

False data injection attacks threaten IoT systems, especially those reliant on sensor data. These attacks inject manipulated data, causing incorrect device behavior and system failures. Several detection methods identify and mitigate their impact. Machine learning models, including supervised learning, clustering, and statistical approaches, detect data patterns deviating from normal behavior, signaling potential attacks.

The importance of detecting false data injection in IoT systems have been highlighted [13], particularly in the context of smart grids, where such attacks can significantly impact system performance. Various methods have been proposed for detecting these attacks, including anomaly detection algorithms that identify irregularities in sensor data and network traffic.

III. Proposed Methodology

A. Architecture Overview

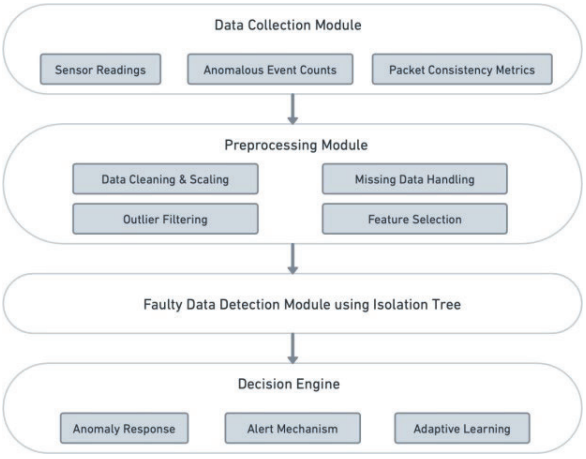

Fig. 1: Proposed Pipeline for Faulty Data Detection

Fig. 1 outlines the architecture of the IoT anomaly detection system, detailing the progression from data acquisition and

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on April 08,2025 at 06:04:49 UTC from IEEE Xplore. Restrictions apply.

preprocessing to anomaly detection and decision-making. The architectural framework comprises:

1) Data Collection Module: The data collection module receives diagnostic clusters from the devices to collect the telemetry data. The types of data collected include:

- Sensor Readings: Temperature and humidity, sensitive data are obtained to note any variation resulting from discrepancies.
- Packet Consistency Metrics: Monitoring of packet performance in ways that can reveal the signs of alteration or insertion in the transmission medium.
- Anomalous Event Counts: Number of occurrences of decision abnormalities reflected in devices, which may indicate an attempt at manipulation or the injection of bad data.

2) Preprocessing Module: The preprocessing module ensures that data collected is clean, consistent, and prepared for analysis. Key processes include:

- Data Cleaning and Scaling: Raw data from different sources such as sensor readings, packet consistency, and event counts are normalized using StandardScaler.
- Missing Data Handling: Missing data is resolved by using mean imputation techniques so as not to distort the dataset in order to analyze it.
- Outlier Filtering: Outliers are filtered using interquartile range since they distort normal patterns and improve the extent of generalization on normal behavior of devices.
- Feature Selection: Defined the feature space using sensor readings, packet integrity, response times, and event counts, focusing on detecting faulty data injection and manipulation.

3) Faulty Data Detection Module (Anomaly Detection): This module applies the Isolation Forest algorithm for identifying the perturbation of data due to malicious attacks. The detection module identifies anomalies in sensor readings, packet integrity metrics, and event counts, signaling potential manipulation, tampering, or faulty behavior. The Isolation Forest algorithm was trained with the following parameters:

- Number of Estimators: Set to 100, specifying the number of trees in the forest. This determines how thoroughly the algorithm isolates data points to detect anomalies.
- Contamination: Set to 0.10, representing the estimated proportion of anomalies in the dataset. This value helps define the threshold for distinguishing normal from anomalous data.
- Random State: Set to 42 to ensure reproducibility. Using this value ensures that the results remain consistent across different runs of the algorithm.

4) Decision Engine: The decision engine manages responses to detected anomalies:

- Anomaly Response: Devices identified as having manipulated data are flagged, triggering immediate alerts.
- Alert Mechanism: Notifications are given to an administrator or other automated systems to take measures against suspicious activities.
- Adaptive Learning: It keeps track of predictions and results so that the model refines the levels of accuracy concerning detection based on new patterns.

B. Faulty Data Detection Algorithm Using Isolation Forest

1) Algorithm Steps:

- *Input Collection:* Generated a synthetic dataset [14] comprising 10,000 records to simulate telemetry data. This dataset includes sensor readings, packet integrity metrics and anomaly counts. The diverse input ensures comprehensive analysis for detecting inconsistencies across data sources.
- *Data Preprocessing:* Normalize the features using a StandardScaler to ensure uniformity and eliminate biases caused by varying feature scales. Remove null values and outliers, reducing the dataset to 9,470 records. Split the preprocessed dataset into 80% for training, 7,576 records and 20% for testing [15], 1,894 records to ensure reliable evaluation of the model.
- *Model Training:* Train the Isolation Forest algorithm on the preprocessed synthetic dataset. This training phase establishes a baseline for normal device behavior, making it possible to identify deviations accurately.
- *Anomaly Detection:* Apply the trained model to predict faulty data injections. Data points flagged as anomalous indicate potential manipulation, facilitating targeted response actions to protect the network's integrity.
- *Alert Generation:* Generate alerts for detected anomalies, enabling rapid intervention and restoration of normal network operations.

IV. Results and Discussion

A. Results

1) Performance of the Faulty Data Detection Methodology: The anomaly detection approach demonstrated high accuracy in identifying devices with manipulated sensor data. The classification report for the test data is as follows:

Class	Precision	Recall	F1-Score
Normal (0.0)	0.99	0.99	0.99
Anomalous (1.0)	0.95	0.94	0.95

TABLE I: Performance metrics for anomaly detection.

- Precision: 95% of the devices flagged as manipulated were correctly identified.
- Recall: The method detected 94% of all instances of faulty data injection.
- F1-Score: This metric, at 95%, highlights a strong balance between precision and recall, showcasing the model's reliability.
- Accuracy: The method correctly identified 99% of the devices in the dataset.

Table 1. demonstrates that high precision minimizes false positives, avoiding unnecessary alerts, while the strong recall supports effective detection of genuine manipulation incidents.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on April 08,2025 at 06:04:49 UTC from IEEE Xplore. Restrictions apply.

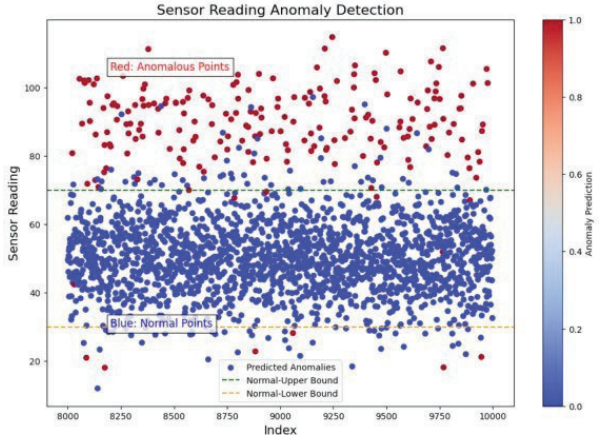

Fig. 2: Sensor Reading Anomaly Detection

Fig. 2 effectively illustrates the system's capability to differentiate between normal and anomalous sensor readings, highlighting its role in detecting deviations that could indicate potential faults, attacks, or abnormal environmental changes.

2) Feature Impact and Correlation Analysis: The correlation analysis showed that device response times had the strongest correlation (0.936) with detected manipulation events, emphasizing their critical role as an indicator of tampering. Sensor readings (0.767) also exhibited a strong positive correlation, highlighting that inconsistencies in sensor data are significant indicators of tampering. Packet integrity checks displayed a strong negative correlation (-0.838), indicating that reduced packet integrity is associated with faulty data injection scenarios.

These results imply that compromised devices tend to exhibit abnormal delays in device responses, inconsistencies in networked sensor readings, and deteriorated packet integrity metrics. These characteristics collectively point to sensor manipulation attacks or other forms of device tampering.

B. Discussion

Sensor manipulation and faulty data injection pose significant risks to Matter-enabled mesh networks, where devices may respond to false sensor readings, leading to network disruptions. Matter IoT devices, often relying on multi-hop communication, can face extensive issues when manipulated sensor data propagates throughout the network. While Matter's end-to-end encryption ensures packet contents remain secure, our findings show that faulty data injection does not require decryption of the packets. Instead, attackers manipulate sensor readings, influencing device behavior. This highlights the importance of anomaly detection that focuses on the integrity of the data rather than just the security of the packets themselves.

The authors used the Isolation Forest algorithm to detect the faulty data injections. The approach successfully identified deviations in sensor readings, learning the normal behavior of the network and flagging any anomalies. The unsupervised way is suitable for IoT, as no signature needs to be defined ahead of time, which allows adaptation. Our findings complement earlier research [16], whereby tampered sensor data were shown to compromise IoT network performance and safety of the devices. Similarly, it was discussed [17] how manipulation in one device could have network-wide repercussions in mesh networks. The studies provide endorsement for the need for robust anomaly detection systems to ensure the reliability and security of Matter-enabled IoT networks.

While Matter includes device authentication and access control to safeguard networks, these protections alone are insufficient against sensor manipulation and faulty data injection. Replay protection mechanisms help, but the intruder would still be able to inject new manipulated data in any point of the network. This aspect ultimately calls for an effective detection system.

This research underscores the effectiveness of the Isolation Forest algorithm for detecting sensor manipulation attacks in Matter-enabled IoT networks. By focusing on critical telemetry data such as sensor readings and packet integrity, the approach successfully identifies compromised devices and mitigates network disruptions. As the techniques of sensor manipulation are continually evolving, scalability, latency, and a multi-layered security approach will need to be considered for fulfilling a practical deployment of Matter IoT networks to stay ahead in these real-world scenarios.

V. Conclusion with Future Work

This paper addresses the issue of anomaly detection in sensor readings within Matter-enabled IoT networks, focusing on identifying faulty data injection and sensor manipulation. With the increasing criticality of IoT networks in various applications, real-time detection of manipulated data is essential to maintain network reliability and functionality. The proposed methodology demonstrates strong performance metrics, minimizing false positives while ensuring robust anomaly detection. These findings emphasize the importance of comprehensive sensor data monitoring to safeguard IoT networks from destabilization caused by manipulated data.

Future work will prioritize collecting high-quality telemetry data from realistic sources to enhance approach generalizability. Adaptive detection algorithms, hybrid approaches combining rule-based and machine learning techniques, and scalable, low-latency solutions will be explored to improve intrusion detection in Matter IoT environments. Cross-sensor validation and robust rate-limiting mechanisms will be integrated to mitigate the impact of faulty data injection, ensuring reliable detection across diverse application.

A Novel n+ Pocket Doped L-Shaped Channel TFET for Biosensing Applications

Danishk Barwa, Dhruv Khanna, Harshit Parihar, and Sumit Kale[z]

Department of ECE, Delhi Technological University, Delhi, 110042, India

This paper presents a novel channel-engineered Tunnel Field-Effect Transistor (TFET) featuring n+ pocket doping, specifically tailored for biosensing applications. The proposed TFET incorporates an L-shaped silicon (Si) channel with a distinctive configuration—an upright drain at the top and a lateral source at the bottom. Additionally, pocket doping is introduced at the source-channel interface, and a nano gate cavity under the dual gate for biomolecule immobilisation. The combination of pocket doping and the L-shaped channel significantly improves the performance of the TFET for biosensing. The device's performance in presence of different neutral as well as charged biomolecules has been analysed using energy band variation, surface potential, internal electric field, and transfer characteristics. The device's sensitivity and selectivity have been investigated in terms of I_{ON}, I_{ON}/I_{OFF}, threshold voltage (V_{th}), and subthreshold swing (SS) and the proposed device's performance has been compared with state-of-the-art biosensors.

Manuscript submitted February 18, 2025; revised manuscript received April 10, 2025. Published April 23, 2025.

Biosensors are miniature analytical tools that translate biological interactions into detectable electrical signals. These instruments must demonstrate high sensitivity, selectivity, rapid response, affordability, and ease of use. FET-based biosensors have earned widespread attention due to their numerous advantages, including high sensitivity, specificity, compact size, portability, fast operation, cost-effectiveness, ease of use, and suitability for large-scale analysis. The first FET-based biosensor, the Ion-Sensitive FET, was widely used for detecting charged biomolecules, but due to its inability to detect neutral biomolecules, its effectiveness is limited.[1–12]

Despite their advantages, FET-based biosensors face several challenges, such as the requirement of a minimum subthreshold slope (SS) of 60 mV decade^{-1}, vulnerability to SCEs, and a reduction in drive current due to random dopant deviations. To overcome these issues, various advanced device architectures, including IMOS,[13,14] JFET,[15,16] and Schottky Barrier MOSFET (SBMOS),[17–21] have been suggested for biosensor applications. However, these designs continue to face challenges such as low ON current (I_{ON}), issues related to doping, significant subthreshold leakage current, high SS, and increased complexity in fabrication at the nanoscale. Consequently, they demonstrate lower biomolecule detection sensitivity, higher power consumption, and slower detection speeds in label-free biosensors. In recent years, TFETs have gained attention as a promising alternative for biosensing applications.[22–31]

As a result of band-to-band tunneling (BTBT) current conduction mechanism, TFETs achieve a subthreshold slope below 60 mV decade^{-1}, making them both cost-effective and reliable. However, they also present challenges, like low ON-current and substantial ambipolar leakage, stemming from the constrained BTBT rate, which affects both analog and digital performance. Various modifications to TFET architecture and materials have been explored to mitigate these issues like Double-Gate TFETs (DG-TFETs),[32] Drain Engineered-Quasi Gate TFET(DE-QG-TFET),[33] Heterojunction TFETs (HTFETs),[34] Vertical TFETs (VTFETs),[35] and Dielectric Modulated TFETs (DM-TFETs).[9] Each of these designs has specific advantages and limitations: DG-TFETs improve electrostatic control but still suffer from low ON-current (I_{ON}), DE-QG-TFETs overcome the problem of ambipolar current but offers low ON-current (I_{ON}), HTFETs achieve higher I_{ON} using III-V materials but face fabrication challenges due to material integration issues, VTFETs increase the tunneling area, improving current drive, but require complex vertical fabrication (such as high-aspect-ratio etching, precise gate alignment, and advanced epitaxial growth techniques), DM-TFETs are highly sensitive to biomolecules but suffer from moderate I_{ON} and SS limitations. Therefore, a new device design is needed to effectively overcome these shortcomings while being a promising candidate for biosensing applications.

In this study, we propose a **novel L-shaped Channel TFET with n+ Pocket Doping** designed specifically for biosensing applications. The L-shaped channel introduces a localized electric field enhancement at the source-channel junction that facilitates band-to-band tunnelling and reduces unwanted leakage currents due to SCEs (Short Channel Effects), resulting in higher drive currents. Additionally, the n+ pocket doping at the source-channel interface plays a crucial role in improving the tunneling probability by creating a sharper potential gradient, reducing subthreshold swing (SS), and enhancing threshold voltage (V_{th}) stability. This configuration increases device sensitivity and improves charge carrier transport efficiency, making it an ideal candidate for biosensing applications. The central purpose of this research is to assess the device's performance by varying K and N_f values. Key electrical parameters, including energy band variation, surface potential, electric field distribution, and transfer characteristics, are analysed under different K and N_f conditions. Additionally, sensitivity and selectivity analysis are conducted using varied values of K and N_f.

Device Design, Calibration and Simulation

The 3D structure of the device is shown in Fig. 1. The device includes a L-shaped intrinsic channel with a drain on the top of the channel. Secondly, it has an in-built pocket at the source/intrinsic channel interface. Table I shows the parameters and specifications used for the simulation of the device. The simulations for this study were conducted using **Silvaco TCAD** for accurately modelling the tunneling mechanisms and carrier transport in the proposed TFET structure. Several models were incorporated to enhance simulation accuracy, including **bbt.nonlocal** (for nonlocal band-to-band tunneling), **bbt.forward** (forward tunneling enhancement), **qtunn.dir = 1** (enables quantum tunneling in a specific direction), **bgn** (bandgap narrowing in heavily doped regions), **consrh** (Shockley-Read-Hall recombination with constant lifetimes), and **conmob** (modelling carrier mobility under different doping and field conditions). The material used in the simulations include Silicon as the semiconductor material with a tunneling effective mass (me.tunnel) of 0.14, SiO_2 as oxide layer and oxide material with different K values to model different biomolecule interactions. The non-local BBT model is calibrated using conventional DG-TFET of K. Boucart and A. M. Ionescu.[32] The calibration has been performed which shows close agreement between reported results and our simulation, which confirms the validity of the simulations performed in this work.

Gate Metal Work Function	4.5 eV

Potential fabrication flow for the proposed device.—As illustrated in Figs. 2a–2h, the proposed device can be fabricated using a CMOS-compatible process. In Fig 2a, a thin silicon film with upper and lower oxide layers can be achieved through methods detailed in Ref. 36. Figure 2b shows the formation of the p+ source via highly precise ion implantation. A SiO_2 layer can then be developed on this structure, as illustrated in Fig. 2c. Additionally, selective etching is performed to create a vertical cavity on the right side of the device, as depicted in Fig. 2d. This process defines a seed window for the selective epitaxial growth of intrinsic silicon,[37] forming the vertical drain. Any excess silicon that extends beyond the oxide can be removed using Chemical Mechanical Polishing, as shown in Fig. 2e. The n+ drain is implemented using energized ion implantation, and pocket doping is carried out, as depicted in Fig. 2f. Furthermore, Fig. 2g illustrates the selective etching of oxides to form vertical and horizontal gate dielectrics. Finally, metallization is performed to establish the source, drain, and gate contacts, as seen in Fig. 2h,[36] followed by another selective etching step to create the cavity shown in Fig. 2i.

The biomolecules are modeled by varying the dielectric constant (K), associated to different biomolecules. When biomolecules are present in the nanogap cavity, K is greater than 1, whereas K = 1 indicates their absence. In this study, biomolecules are modeled within a nanogap cavity measuring 12.5 nm × 5 nm. The proposed device considers biomolecules with varying K values, as outlined in Table II.

Results and Discussion

This section discusses the response of the proposed biosensor device when exposed to both neutral and charged biomolecules. The

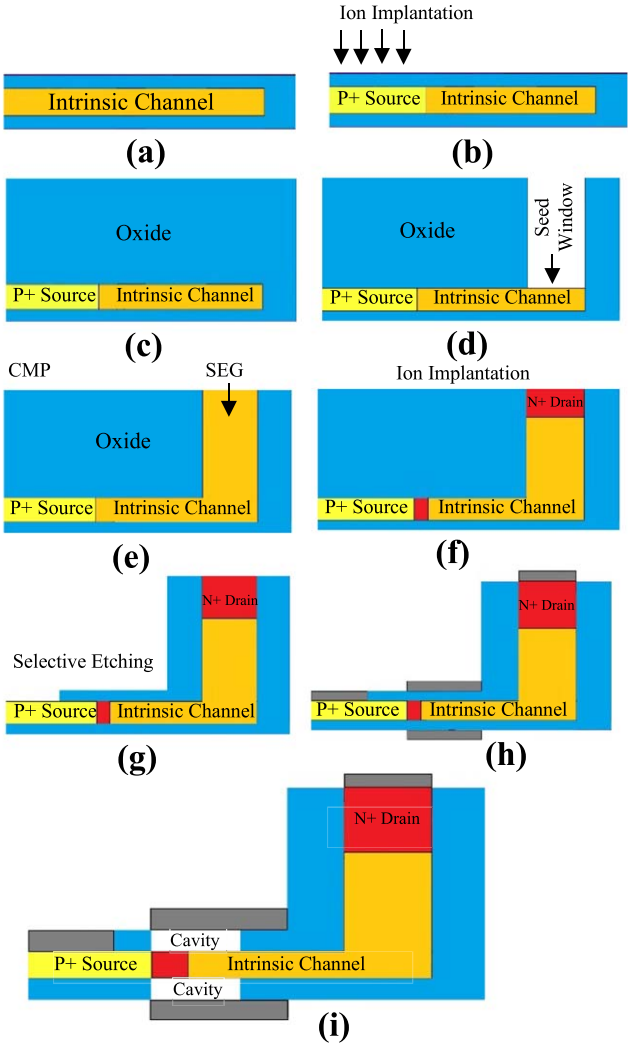

Figure 2. Key steps in the fabrication of proposed TFET.

device's performance has been evaluated by varying dielectric constant values and charge densities. For consistency, a reference value of K = 1 has been maintained throughout the analysis. Figure 3 illustrates the energy band diagram corresponding to neutral biomolecules, for different values of K. An increase in the K value from 2.63 to 12 results in a narrower tunneling width, facilitating the movement of charge carriers from the source to the drain. Consequently, this enhances carrier transport efficiency, leading to

a higher drain current, as depicted in Fig. 9. Additionally, Fig. 4 presents the energy band diagram of the proposed device under different charge density variations.

From Fig. 4, it can be observed that as the charge density becomes more negative, the tunneling width increases. Positively charged biomolecules lower the energy bands, reducing the tunneling barrier and enhancing carrier injection, leading to a lower V_{th} and increased tunneling probability. In contrast, negatively charged biomolecules raise the energy bands, increasing the tunneling barrier

and shifting Vth to a higher value, thereby reducing carrier injection. These charge-induced modulations alter the surface potential, redistributing the electric field in the gate cavity region and directly influencing tunneling efficiency and switching behavior. Figure 5 illustrates how the surface potential varies in response to neutral biomolecules. Notably, the surface potential exhibits a direct correlation with the dielectric constant (K). As illustrated in Fig. 5, the surface potential increases as the dielectric constant(K) rises.

In Fig. 6, the presence of negatively charged biomolecules lead to a decrease in surface potential as the charge density magnitude increases. Figures 7 and 8 depict variations in the electric field caused by changes in K and N_f. These variations in surface potential directly impact the electric field distribution. The electric field strengthens with an increase in the K of neutral biomolecules, whereas it weakens as the magnitude of negative charge density rises. Figures 9 and 10 present the transfer characteristics of

Sensitivity Parameters

Sensitivity is a crucial parameter for evaluating a sensor's response. A highly sensitive and fast device is essential for providing rapid analysis results. To determine the sensitivity parameter, a reference material is required. In this study, air ($K = 1$) is used as the benchmark for sensitivity calculations. The impact of various biomolecules with $K = 2.63$, 3.57, 6, 8, and 12 on the sensitivity of the proposed device structure has been analysed. This analysis involves evaluating different sensitivity parameters, including V_{th} sensitivity, I_{ON} sensitivity, SS sensitivity, and I_{ON}/I_{OFF} ratio sensitivity. These sensitivity parameters are determined using Eq. 1.

$$X_{sensitivity} = \frac{X_{air} - X_{bio}}{X_{air}} \quad [1]$$

X = Sensitivity parameter
X_{air} = Value in the absence of biomolecule ($K = 1$)
X_{bio} = Value of Sensitivity parameter in the presence of biomolecules ($K = 2.63$, 3.57, 6, 8, & 12)

Similarly, sensitivity parameters for various charge densities (N_f) can be determined using $N_f = 0$ as the reference point. Increasing the value of K increases the effective capacitance, which increases the

Electric field in the cavity region. A high electric field leads to steeper band bending and a reduction in tunnel width, which increases the tunneling rate and enhances the device's drive current. This explains why the drive current rises with an increasing K. As shown in Fig. 11, the SS decreases as K increases. This occurs because a thinner barrier enhances tunneling probability, improving switching characteristics and lowering SS. Additionally, a higher K-value strengthens the gate's control over the channel region, facilitating carrier tunneling at a lower gate voltage, which in turn reduces the threshold voltage (V_{th}). The sensitivity parameters corresponding to different K can be seen in Table III.

Similarly, Fig. 12 demonstrates that a positive charge density intensifies the electric field and reduces the tunneling width, leading to a significant increase in ON current. Conversely, a negative

charge density expands the tunneling width, thereby reducing the ON current. The SS associated with a positive charge density is lower than that with a negative charge density due to the reduced tunneling width as charge density increases. Figures 13 and 14 depict the variations in sensitivity parameters for different values of K and charge densities, respectively. In Fig. 13, the parameters are observed to increase with increasing K values. Likewise, Figure 14

shows a general rise with increasing charge density. Table IV summarizes the sensitivity parameters for various charge densities. Figures 15 and 16 illustrate the impact of channel length (L_{ch}) variation on DC parameters and sensitivity parameters, respectively. In this study, neutral biomolecules have been analysed at different channel lengths (L_{ch}). Table V presents the sensitivity parameters for the proposed device biosensors across varying channel lengths.

The influence of cavity length (L_{cavity}) variation on DC and sensitivity parameters has been analysed in Figs. 17–22, with the cavity thickness (T_{cavity}) maintained at 5 nm throughout the simulation. Figures 17 and 18 examine the impact of different cavity lengths on neutral biomolecules, revealing that sensitivity parameters improve as L_{cavity} increases.

Figures 19 and 20 illustrate the relationship between DC and sensitivity parameters and change in cavity length for biomolecules with negative charge density. Compared to neutral biomolecules, sensitivity parameters exhibit a decline. This reduction occurs because negatively charged biomolecules lower the surface potential, leading to a decrease in drain current.

Figures 21 and 22 depict the DC and sensitivity parameter trends for biomolecules with positive charge density as a function of cavity length. When positively charged biomolecules are placed within the cavity, an increase in cavity length enhances the surface potential in the cavity region, which further raises the drain current. Consequently, sensitivity parameters also improve. The sensitivity parameters for the proposed biosensor at various cavity lengths are summarized in Table VI.

The impact of varying cavity thickness, on sensitivity parameters for both charged and neutral biomolecules has been analysed in Figs. 23–28. In this study, the cavity length of 12.5 nm is taken as reference, with a K = 5. Figures 23 and 24 illustrate the relationship between cavity thickness and DC/sensitivity parameters for neutral biomolecules. Similarly, Figs. 25 and 26 present the variation in DC and sensitivity parameters for negatively charged biomolecules at different cavity

thickness values, showing that sensitivity parameters increase as cavity thickness (T_{ch}) increases. Figures 27 and 28 display the trends of DC and sensitivity parameters for positively charged biomolecules at varying cavity thicknesses. Table VII provides the sensitivity parameters of the proposed TFET biosensor at different cavity thicknesses.

The results point out that the device has High SS and V_{th} Sensitivity compared to the other existing TFET designs. The high SS and V_{th} sensitivity in our device is due to the localized electric field enhancement caused by the L-shaped channel and n+ pocket doping, which makes the device highly responsive to charge variations from biomolecules, leading to sharp changes in SS and Vth. However, the low I_{ON} sensitivity occurs because the device maintains a stable tunneling current, meaning biomolecular adsorption primarily affects the tunneling barrier without significantly altering the overall current flow. This enhances device stability, ensuring consistent performance and reducing unwanted fluctuations. This trade-off makes the sensor highly reliable for biosensing applications. Table VIII compares its sensitivity performance with earlier reported TFET-based biosensors.

Selectivity Parameters

Selectivity analysis is a technique for evaluating a biosensor's ability to accurately detect a target biomolecule while distinguishing it from other biomolecules present in the environment. The selectivity for I_{ON} and V_{th} is shown in Eqs. 2 and 3.

$$\text{Selectivity, } \Delta S, I_{on} = \frac{I_{on}(\text{target}) - I_{on}(\text{undesirable})}{I_{on}(\text{undesirable})} \quad [2]$$

$$\text{Selectivity, } \Delta S, V_{th} = \frac{V_{th}(\text{target}) - V_{th}(\text{undesirable})}{V_{th}(\text{undesirable})} \quad [3]$$

The target biomolecule in this study has a K value of 12, while other biomolecules have K values of 2.63, 3.57, 6, and 8. As the difference in the K value between the target and unwanted

Conclusions

We have successfully designed and investigated the n+ pocket doped L-shaped channel TFET for biosensing applications. A comprehensive investigation and evaluation of the device's sensitivity for charged as well as neutral biomolecules modeled by different K values and charge density has been performed in terms of I_{ON}, I_{ON}/I_{OFF}, V_{th}, and SS. In addition, the device performance has been investigated for different cavity lengths and thickness on sensitivity parameters. Results confirm that the proposed device exhibits 29% better V_{th} sensitivity and 124% better SS sensitivity in comparison with state-of-the-art devices. In addition, the proposed device exhibits high I_{ON} and V_{th} selectivity. The proposed device is a promising contender for biosensing applications.

Keywords: Masonry, Mortar Thickness, Shear Bond Strength, Triplets

Abstract. Building structures with brick masonry is the ancient form implementation and is still commonly employed worldwide, despite advances in expertise. Recent investigations are still being conducted to improve the technical and economic performance of masonry. As the mechanical characteristics of ancient masonry might vary significantly from the hypothetical one, it must be properly evaluated to quantify the well-being and usability of actual structures in the context of recuperation and/or seismic dependability valuation. Initially, small-scale assessments were performed to assess the distinct features of binder and brick separately. Investigational research of triplets made using cement and hydraulic lime-based mortars is presented in this paper. This study aimed to explore the performance variation of brick triplets utilizing two dissimilar mortar mixes cement and lime-based mortar and three mortar of 13 mm, 20 mm, and 27 mm thickness respectively. When testing was performed, the results specified that masonry units with a mortar thickness of 27 mm were more prone to shear failure and 13 mm thick specimens, regardless of the type of mortar used, were able to withstand the maximum load before failure. Cement-based mortar triplets were found to withstand 254% more load compared to lime-based mortar in the case of a 13 mm thickness.

1. Introduction

Masonry buildings continue to be a considerable part of the global constructed infrastructure. Masonry was commonly used to construct historical and aesthetic heritage including standard residential constructions in historical urban and rural areas. Masonry material cannot withstand tensile stress and is so referred to as a material that lacks tensile strength. Furthermore, because it is a diverse material, its performance is determined by the shape characteristics and the constituent materials' properties. Seismic activity can exert strong lateral forces on structures that can lead to shear deformation and failure. Therefore, the shear resistance of a structure is a critical factor in combating the effects of seismic activity. Seismic events that have hit and caused extensive damage to heavily-built areas of masonry structures in recent decades have sparked the scientific community's interest in suitable techniques to assess the seismic susceptibility of these constructions. Masonry mortar rules recommend that the mortar used in construction be frailer than the brick units to guarantee that any cracks that occur in the binder joints are readily repaired. The depth of the bed joint is another critical component influencing the overall performance of the brickwork. Several factors influence the compressive strength of mortar, including binder content, binder type, and water-cement ratio. Because of their greater binder ratio, cement-based mortars are typically regarded as stronger than lime binders. Nevertheless, compression capacity should not be the only consideration when choosing a mortar. The bond strength and flexural strength of the mortar are also important since they affect its resistance to cracking. The bond strength between the binder and brick is usually greater as compared to the tensile and compressive capacity of the binder, which means that bond failures occur at lower stress levels in mortar joints.

Despite the fact that structural engineers are creating increasingly efficient numerical techniques, "accuracy" of demonstrating findings is always reliant on the accurate documentation

of limited mechanical characteristics necessary to illustrate brickwork material. As brick, stone, and earth masonry make up a huge portion of present structures and architectural legacy in Europe and around the world, understanding their mechanical performance is critical [1]. However, assessing the mechanical properties and, as a result, the well-being and serviceableness of actual masonry is a difficult job [2], and numerous damaging and non-damaging methods are currently accessible for evaluating the integrity and excellence of resources in on-site brickwork, with the goal of providing input data for structural amplification [3]. Mortars have a considerable influence on the comprehensive performance of brickwork. The fundamental goal of binder in brickwork is to glue brickwork units together to produce an assembly that serves as an integrated component with anticipated purposeful act features [4]. An absence of connection at the boundary between mortar and brick, for example, owing to shrinkage, might allow moisture to penetrate certain regions. As a result, several methods for reinforcing unreinforced masonry buildings have been presented [5]. Liable on their form, aspect ratio, and edge conditions, masonry can suffer shear- or flexure-controlled failures. Shear failures are defined by either inclined cracks or sliding cracks, which occur as soon as a piece of the masonry sideways a bed joint moves horizontally under lateral stresses. The way brick-and-mortar interacts considerably influences the strength of URM. In general, the shear response of the interface binder-brick interface is highly reliant on moistness content, porosity, binder strength, and conditioning type [6], with saturation producing a loss of strength and stiffness [7].

When compared to other building materials, masonry exhibits anisotropic behaviour. Prior to the invention of cement, it was built with lime mortar [8]. Because of the rapid strength development of cement, the use of lime in masonry buildings quickly declined after the introduction of cement [9]. The consequence of diverse binder configurations on the structural response of brickwork is investigated in this study. To characterize masonry material, various mechanical characteristics must be correctly identified. One of these factors is the shear strength of brick triplets [10]. As a result, interfacial cohesiveness and the precise characterization of mortar qualities are critical in predicting masonry behavior under any type of activity. Cement- and lime-based mortars are explored in this study. Cement binder adds strength and longevity to brickwork, but it lacks flexibility, making it susceptible to breaking. The binder thickness of the brickwork also was treated as a changeable parameter, with considered thicknesses with the strength of the binder. In a study conducted in Korea, the behavior of factory based and handmade bricks with lime mortar is addressed and this has been determined that factory made bricks shows 15% greater compressive strength but lowers specific area by 22%. Also, handmade bricks improved shear strength. Shear stresses are mostly carried by mortar joints in masonry [11]. Similar to this work, research was conducted to analyze the physical and analytical behavior of 19th-century bricks with old aerial lime mortars after 730 days of curing. The impact of curing was checked. The results are significant in refurbishment of historic brickwork [12]. China has also been working in this domain to mechanically characterize the behavior of grey clay bricks, suggesting that though cement mortar enhances the compressive strength of the prism but it has tendency to damage grey clay bricks suggesting problem judgment as per requirement of the repair and rehabilitation [13].

This has been inferred from the literature that the standards and previous studies have been silent in understanding the impact of joint thickness of the behaviour of triplets; therefore, in present study the mortar thickness is administered. Moreover, very limited work is done considering impact of lime mortar, this study can add to the knowledge about behavior of brick masonry with lime mortar facilitating the rehabilitation and renovation work for historical structures.

2. Problem statement

The utilization of brick triplets is a widespread building tendency owing to its aesthetic appeal and structural aids. Though, the choice of mortar and thickness can pointedly govern the strength and durability of the brick triplets. In spite of the importance of these factors, there is inadequate research on the effects of diverse categories of binder and thicknesses on the features of the triplet samples. This study's aims to inspect the impact of different mortar types and thicknesses on the shear bond strength of triplets. The deductions of this work will deliver a valuable understanding of the optimal mortar and thickness combinations for brick triplets, which can enhance their performance and extend their service life.

3. Materials and Methods

This section describes the experimental evaluation, which was conducted in two phases. The first phase focused on describing the constituent ingredients, while the second phase concentrated on performing triplet tests. The constituent material samples of different types, including lime and cement were tested.Binders are constituents used in construction to keep other materials, such as aggregates, intact to make a cohesive and enduring structure. Binders show a vital role in the strength and durability of building materials since they provide the substance with its adhesive and cohesive qualities. Cement is composed of limestone, clay, and other elements that have been burned at high temperatures to make a powder that hardens when combined with water. In this experiment, 53-grade OPC as described in IS: 269-2015 was used. The properties of the binder ingredients as supplied by the supplier are highlighted in Table 1.

Lime is another frequent binder used in buildings, notably in masonry and plastering. It is created from limestone that has been burnt and slaked with water to generate a powder that hardens when exposed to air. Hydrated lime as described in IS: 1540(Part I)-1990 [14] was utilized in study. Table 1 discusses the features of the binder ingredients as given by the supplier.

Table 1. Properties of Binders

Properties	**Hydrated lime**	**OPC-53**
Chemical Composition (%)		
SiO_2	13.1	24.42
$Al2O_3$	0.7	4.85
$Fe2O_3$	2.81	3.80
CaO	66.3	66.16
MgO	0.5	1.85
K_2O	0.15	0.4
LoI	16.44	1.17
Physical Properties		
Specific Gravity	2.7	3.12
Fineness(cm^2/gm)	3800	3000
Color	White	Grey

In this study, 220 mm in length, 110 mm in width, and 75 mm deep standard-fired clay bricks were used. Before evaluating the shear bond capacity of triplets, it must be emphasized that to ensure a strong shear connection at the brick-and-mortar interface, the typology of constituent materials such as brick and mortar should be carefully examined.

Testing was done to characterize bricks by performing the following tests- Dimensions test, water absorption test, efflorescence test, and Compressive strength test in the laboratory before starting the preparation of triplets for the shear strength.

4. Tests on Specimens

4.1 Test on Bricks

(a) Dimension Tests

The experiment utilized locally available bricks for the study. However, it should be noted that not all of the bricks possess exact and precise measurements. The various brick samples are referred to as B1, B2, B3, B4, and B5. Table 2 shows the measurements of these samples.

Specimen no.	Dimensions(mm)
B_1	220x110x76
B_2	221x110x75
B_3	223x110x75
B_4	221x110x73
B_5	220x110x75

Table 2. Dimensions of Bricks

Specimens	Weight after oven-dry(M1) (Kg)	Weight after 24 hours in water(M2) (Kg)	Water absorption (%)	Avg. Water absorption (%)
B_1	2.99	3.29	10.03	11.08
B_2	3.02	3.37	11.59	
B_3	3.11	3.44	10.61	
B_4	3.13	3.46	10.54	
B_5	3.01	3.39	12.62	

Table 3. Values of water absorption

(b) Bricks Porosity Test

The experiment utilized locally available bricks for the study. However, it should be noted that not all of the bricks possess exact and precise measurements. The various brick samples are referred to as B_1, B_2, B_3, B_4, and B_5. Table 2 shows the measurements of these samples.

The standard approach defined in IS 3495:1992 Part 2 [15] was followed to measure the water absorption capacity of bricks. The samples were first dehydrated in a hot air oven at 105 to 115°C, and their dry weights were recorded (M1). Next, the bricks were deep in clean water for 24 hours, then taken out and wiped down before their wet weights were measured (M2). By subtracting the dry weight from the wet weight, the water absorption of individual bricks was found, and the average water absorption was determined. The resulting data, which provides the water absorption values for 5 samples, is listed in Table 3. To calculate the water absorption of the brick specimens, Equation (1) was utilized.

$$\text{Water Absorption (\%)} = \frac{M_2 - M_1}{M_1} \times 100 \quad (1)$$

(c) Bricks Porosity Test

The average water absorption on conducting test on the specimen was 11.08%. In accordance to the Indian standards, the average value should not surpass 20% by weight for Class B by 12.5% and 15% for higher classes. This is can be further inferred that the excessive water absorption causes structural damage like crack, warp, and corrosion of the brick. Accordingly, it is vital to monitor the properties of bricks and ensure the appropriate standards for the definite class are met.

(d) Efflorescence Test of the Bricks

The bricks were subjected to an efflorescence test, and the findings showed that the efflorescence was less than 4%. As per IS 3495:1992[16], the permissible efflorescence limit is under or equal to 10% for Class 12.5 and under or equal to 5% for higher classes.

5. Evaluating the Compression Resistance of Bricks

The compression resistance test is performed on bricks to assess its capability to endure compressive loads. The bricks are kept in between two compression plates and load is applied until the failure occurs. The results are ascertained as the maximum load that the unit can resist divided by cross-section area. The lowest strength for Class 12.5 bricks is 3.5 N/mm^2, though the minimum compressive strength for higher classes ranges from 4.5 to 7.5 N/mm^2 [17]. The importance of the strength test is to ensure that the bricks meet the essential standards and are suitable to be used in construction projects. The strength of samples was determined applying equation (2).

$$\text{Compressive Strength of Bricks (MPa)} = \frac{\mathbf{P}}{\mathbf{A}} \quad (2)$$

Where P = Peak Load at collapse (N)
A = Cross-section area (mm^2)

Figure 1 displays the strength values of individual samples. The average strength was calculated to be 22.252 MPa, which indicates that they belong to Class A as per the IS code. The test was performed on CTM after wiping the water on the surface of the bricks as the specimens were inside the water for 3 days after filling the frog on the bricks to make the surface plane so that load can be applied equally on the whole surface. Figure 2 displays the brick specimen before compressive strength test in CTM.

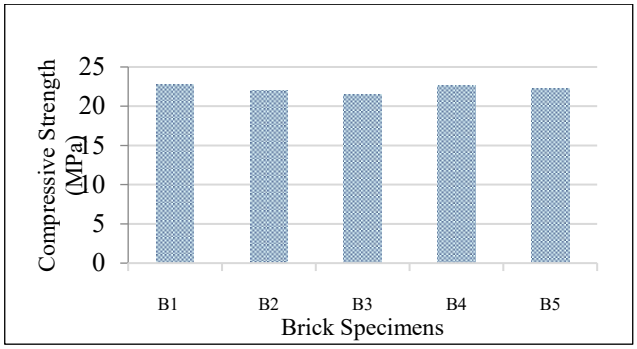

Figure 1. Crushing Strength of Brick Samples

Figure 2. Brick specimen before test

6. Test on Mortar

Mortar is a smooth paste made by mixing cement or lime, with sand. Mortars are crucial in creating a cohesive mass out of individual masonry components. For the study, lime mortars with a lime-to-sand ratio of 1:3 were chosen. This mortar was frequently used for historic masonry conservation projects because the walls' ability to naturally breathe ensures improved long-term performance. Similarly, cement is now the most efficient binder on the market, thus OPC-53 mortar was chosen because of this. The ratio of binder to aggregate in this mortar was also 1:3. River sand was used in the investigation available locally.

6.1 Mortar Compressive Strength

The mortar strength influences the maximum load limit of the brickwork, and the strength values of the mortar were computed using mortar cubes with a face area of 50 cm^2. Figure 3 depicts the test outcomes of the 28-days strength of the binder utilized in the current investigation. In comparison to lime mortar, which has a strength of 5.51MPa on average, cement mortar has a strength of 20.38MPa which is about 270% more as compared to lime mortar strength. L1, L2, L3, and C1, C2, and C3 are lime and cement mortar specimens, respectively.

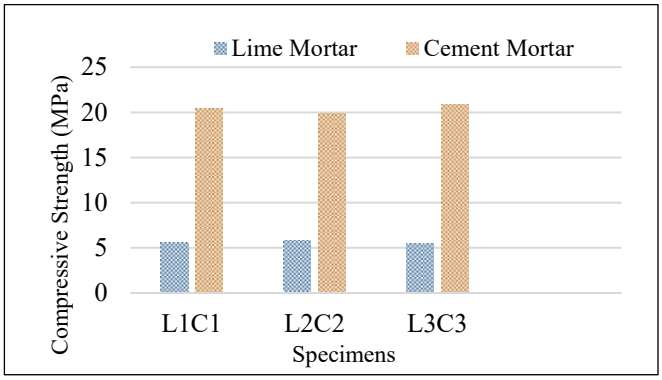

Figure 3. The individual strength of mortar cubes

Figure 4. Cement and Lime mortar triplet specimens

6.2 Triplet Specimens

This section explains the sample arrangement and testing techniques used to find the shear strength of samples. Shear capacity is one of the regulating factors in determining the capacity of brick masonry components. The shear capacity of brickwork had been calculated by experimentation by testing triplet specimens with the help of a hydraulic jack of capacity 100kN. In triplet tests, three brick assemblies are utilized to evaluate the shear bond strength. With this setup, the extreme bricks of the triplet connect against the loading edge to control movement, while the center brick is unrestrained. All of the units were submerged in water for 20 minutes before triplet casting to achieve 75% saturation. All of the samples were allowed to cure for 28 days. The failure load 'P'(N) is recorded. Equation (3) was used to compute the binding strength of a triplet.

$$\text{Shear Bond Strength} = \frac{\mathbf{P}}{\mathbf{2LB}} \quad (3)$$

Where, L= 225 mm

B = 110 mm

EN 1052-3 [18] describes the shear test, which is used to assess shear strength by evaluating specimens made up of bricks and mortar joints. Figure 4 depicts the prepared specimens with lime mortar and cement mortar respectively.

7. Results and Discussions

Two kinds of mortar were used in the current investigation, each with three distinct thicknesses, and three brick specimens were made for each thickness. Lime mortar samples were maintained in the laboratory after construction for air curing for 28 days, whereas cement mortar samples were cured in damp jute bags for 28 days.

7.1 Testing of Triplets

The masonry triplet specimens were tested using a hydraulic jack that had a maximum load capacity of 100 kilonewtons (kN).

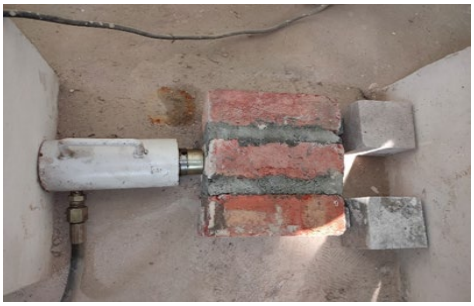

Figure 5(a). Triplet testing demonstration before testing

Figure 5(b). Triplet testing demonstration after testing

A visual representation of the testing process is presented here. A similar mode of failure was obtained in both mortars at the thicknesses of 20 mm and 27 mm as illustrated in Figure 5(b). In this kind of failure, mortar and bricks got separated from one face of bricks and at the place of the frog also mortar came out easily after applying the load. In the case of 13 mm thickness the mortar was not completely separated from the bricks in that case some mortar was on one face of the brick and some mortar was on another face of the brick and the surface of the mortar was running fracture not smooth as in previous cases. The study revealed that decreasing the strength of the mortar concluded in a decrease in the shear strength of bond values. Moreover, when comparing the different mortar thicknesses, it was observed that the 13 mm thickness showed a higher order of shear bond strength compared to the 20 mm and 27 mm thicknesses. Interestingly, the frequency of decrease of bond shear strength was found to be lower when increasing the depth of the mortar, as associated with the poor-quality binder used in brickwork structures. The results of the study indicate that the shear bond strength of brickwork is influenced to a greater extent by the strength of the mortar. While the thickness of the mortar has a relatively insignificant impact on the shear strength. Altering the thickness of the mortar layer amid the specimens can affect the stress distribution and crack propagation during testing, which can in turn influence the measured mechanical properties.

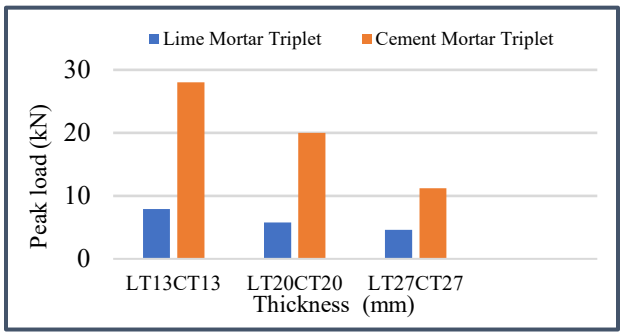

Figure 6 Relation joint thickness v/s load

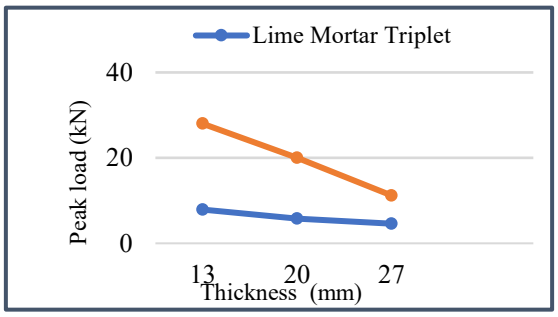

Figure 7 Relation mortar type v/s load

7.2 Mode of failure

This test can be performed using one of two distinct protocols, with or without lateral pre-compression. Figure 8 (a) and Figure 8 (b) depict the expected failure possibilities after performing this test. The first two modes (A/1 and A/2) fail owing to mortar separation from the brick, which is ascribed to poor contact between the two components (Bricks and mortar). Failure occurs in the mortar layer (B mode) when a less compressive strength mortar is used to build joints between

mortar and brick. A high-strength mortar with strong adhesive characteristics, on the other hand, would lead the specimen to fail due to the occurrence of fractures running through one or both bricks (modes C and D) [19]. In this study, mainly A/1 and A/2 were the failure mode obtained after testing in both the mortar as the compressive strength of mortar in both cases was less as compared to the strength of bricks.

7.3 Shear Bond Strength

Equation 3 demonstrates the calculation of the investigational shear bond strength, which involves dividing the maximal force that a triplet can withstand by twice the area of its cross-section [20]. Triplets with joint thicknesses of 13 mm, constructed with cement mortar or lime mortar, were found to have the highest load capacity. The 13 mm cement mortar triplet had the maximum load capacity, measuring 28.0 kN, while the 27 mm lime mortar prism had the lowest capacity, measuring 4.60 kN. Here LT13CT13, LT20CT20, and LT27CT27 show the different Lime mortar thickness and Cement mortar thickness. Table 4 display the mean peak load and shear bond strength values for cement mortar and lime mortar, respectively. For all the cases the size of specimens was the same as triplets were constructed with the help of 3 bricks.

Table 4. Shear strength of cement brick masonry and lime brick masonry

Thickness (mm)	**Specimen Size (mm)**	**Avg. Peak load (P) (kN)**	**Shear Bond Strength (MPa)**	**Avg. Peak load (P) (kN)**	**Shear Bond Strength (MPa)**
		Cement Brick Masonry		Lime Brick Masonry	
CT13±3	225*110*225	28.00	0.565	7.90	0.160
CT20±3	225*110*225	20.75	0.404	5.80	0.120
CT27±3	225*110*225	11.20	0.226	4.60	0.093

7.4 Comparative study between the difference in mortar strength and bond shear strength for different thicknesses

As the results show after testing the shear bond strength of brick triplets, the shear capacity of triplets depends on both the parameters i.e., the strength of mortar as well as the thickness of mortars. Table 6 depicts the percentage differences in strength for mortar and triplets. There exists a variation in the strength of mortar between cement mortar and lime mortar which is about 270% after 28 days of strength. This has been illustrated in many studies [21, 22]. When these mortars were used for making the brick triplets with different thicknesses and testing was performed with the help of a hydraulic jack of capacity of 100kN after 28 days of curing period.

Table 5. Comparative Study of mortar strength and triplet shear strength

Strength	**Lime Mortar (MPa)**	**Cement Mortar (MPa)**	**% Difference**
Strength of Mortar	5.51	20.38	269.87%
Shear Bond Strength (13 mm)	7.90	28.00	254.43%
Shear Bond Strength (20 mm)	5.80	20.75	257.76%
Shear Bond Strength (27 mm)	4.60	11.20	143.48%

As per the results, the strength differences in triplets are 254.43%, 257.76%, and 143.48% for 13mm, 20mm, and 27 mm thicknesses respectively. A similar comparison can also be done within

the same mortar for different thicknesses. In both the mortar the difference in shear strength in the case of 13mm and 20 mm is about 35% and in the case of 20mm and 27mm, the difference is more in the case of cement mortar as compared to lime mortar. In the case of 27mm thickness the shear strength difference is less as compared to 13mm and 20mm and in this case, the failure mode was A/1 as shown in Figure 8 (a) in both the mortars and the possible reason was the thickness itself, as the load applied mortar separated from bricks without any cracks or something like that in all three bricks.

Conclusions

This paper reports on the findings of an empirical study conducted to investigate the shear bond strength of masonry when subjected to zero normal stress conditions. The focus of this research was on the lateral load capacity of masonry triplets with different joint thicknesses, which were built utilizing cement and lime mortar as construction materials.

1. The triplets of joint thicknesses 13 mm built using cement or lime mortar had the highest lateral load capacity. The triplets constructed with cement mortar exhibited a maximum lateral capacity of 28.0 kN while the triplets of joint thickness of 27 mm with lime mortar had the lowest lateral load capacity of around 4.60 kN.
2. Cement mortar exhibited the strong shear bond between the brick unit and the mortar component. It was observed that increasing the mortar thickness to 27 mm led to a decrease in the shear bond strength of masonry triplets. Moreover, the deterioration in the shear bond strength was greater in mortars with lower compressive strength, for both cement and lime mortar, than the rate caused by augmented mortar thickness.
3. The hypothesis that the compressive strength of mortar impact load-bearing performance of masonry construction is acknowledged by this study. The results also showed that variations in the strength of the mortar have better effect on the shear bond strength of brickwork than the thickness of the mortar.

Abstract

This paper presents a wideband dual-polarized in-band full duplex antenna which can also suppress the higher order modes. A dual differential capacitive feeding scheme is proposed to increase the isolation between the co-located transmitter and receiver ports. The proposed design uses $\lambda/4$ resonators in close vicinity of the radiating patch to provide spurious-free characteristics. Further, a parasitic patch placed above the radiating patch at height "h" is used to enhance the input matching, impedance bandwidth, and gain of the proposed design. The key features of the proposed structure are its wide impedance bandwidth (∼20%), high inter-port isolation (>58 dB) throughout the entire operating frequency range (2.26–2.76 GHz), and simultaneous suppression of higher order modes which makes it a suitable candidate for modern wireless application. Finally, a prototype is fabricated and measurement results are in good agreement with simulation results.

Introduction

The rapid advancements in modern wireless technology create a scarcity in the available frequency spectrum. In-band full duplex (IBFD) system is a potential candidate to address this issue where the transmission and reception of message signals are done simultaneously using a single frequency. Theoretically, a full-duplex system can increase the spectrum efficiency two times that of a half-duplex system [1]. However, while transmitting and receiving at the same frequency, the interference caused by a strong transmitting signal on a weaker receiving signal is the main concern that needs to be minimized to make the IBFD system more efficient. To address this issue, several self-interference cancellation (SIC) techniques are reported in the literature [2]. Generally, SIC techniques are collectively implemented in RF/analog [3], digital [4], and antenna domains but an antenna system having high inter-port isolation can further decrease the need for SIC in succeeding stages. Various methods such as the use of a circulator [5], increased antenna separation [6], near field cancellation [7], and beam-forming network [8] are used for achieving high inter-port isolation. Typically, these techniques involve the use of multiple antennas or complex antenna structures, resulting in a bulky form factor or larger physical dimensions.

Considering simplicity in the design process, dual-polarized antennas are preferred for the IBFD system [9]. Several dual-polarized antenna structures are reported in the literature [10–19] which suffer from one or many of the following disadvantages:

(i) Separate radiators are used for the Transmitter (Tx) and Receiver (Rx) which results in a large footprint [13, 14].
(ii) Isolation less than 40 dB is achieved between Tx and Rx which might not be sufficient for an IBFD system [10, 15].
(iii) Impedance bandwidth of the design is limited (<6%) [11–15, 17, 19].
(iv) Peak gain of the design is limited (∼5dBi) [12, 14, 19].

Also, the higher-order modes of an antenna can cause electromagnetic interferences to the different devices of any wireless communication system. Hence, to suppress undesired higher-order modes of the antenna, several research activities have been proposed in recent times. These include exciting a circular patch with common mode signals [20], loading of shorting pins [21], deploying a pair of $\lambda/4$ resonators with capacitive feed [22], and use of multi-point differential feed [23], etc.

The above discussion clearly indicates that all the previous works are designed either for the IBFD applications or for the suppression of higher-order modes. To the best of the authors' knowledge, it is the first instant a shared radiator-based wideband IBFD antenna with enhanced

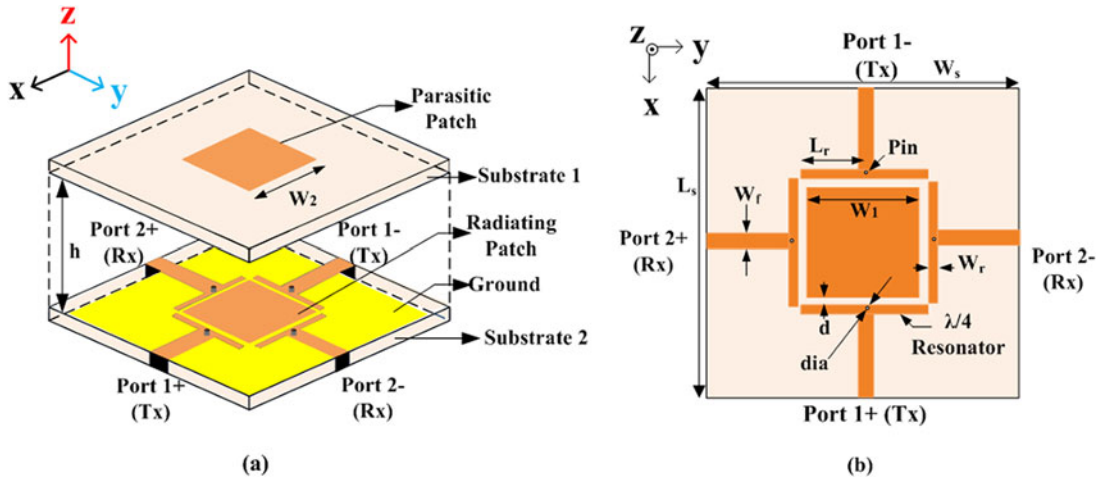

Figure 1. Proposed design with dimensions (in mm): (a) 3 d view, (b) top view of the bottom layer; $l_s = w_s = 100$, $W_1 = 37$, $W_2 = 38.2$, $l_r = 19.2$, $w_f = 4.5$, $w_r = 1.75$, $d = 1$, dia $= 0.3$, $h = 10$.

isolation is presented which can simultaneously suppress the higher-order modes. The major contributions of the proposed work are as follows:

1) To the best of the authors' knowledge, it is the first instance that dual differential capacitive feeding is proposed to implement a wideband IBFD antenna. This proposed feeding scheme has three major functions: (i) suppression of all second-order higher modes; (ii) creation of dual resonance behavior that can be transformed into wideband performance; (iii) enhancement of the inter-port isolation.

2) A mathematical model is presented to illustrate the effect of the double differential feeding on inter-port isolation.

3) To the best of the authors' knowledge, our proposed design is the first dual-polarized IBFD antenna that not only provides stellar full duplex performance (excellent inter-port isolation of greater than 58 dB over a wideband of 20% with significant peak gain of 9.1 dBi) but also suppresses all the spurious second-order higher modes. To suppress higher order modes, we have not employed any filtering circuits (LPF, BPF, BSF) that would increase the overall footprint, defected ground structures that have back radiations, or complex electronic bandgap structures.

4) The functionality of the proposed IBFD antenna is validated through the lumped equivalent circuit model. Moreover, the effectiveness of the proposed circuit model is validated through the parametric studies where the results obtained through circuit simulation closely resemble the EM simulation results.

Antenna configuration

The geometry of the proposed dual-polarized IBFD antenna is depicted in Fig. 1. It consists of two square microstrip patches which are built on Rogers RT 5880 substrate ($\varepsilon_r = 2.2$, tan $\delta = 0.0009$) of thickness 1.575 mm. The radiating patch (RP), built on substrate 2 is excited with dual differential feeding. Port 1+ and 1– are used as differential Tx ports while port 2+ and 2– are used as differential Rx ports. The feeding of RP through each differential port is done with the help of a pair of $\lambda/4$ resonators. A metallic pin having a diameter *dia* is placed at the center of the feedline which is shorted to the ground. The parasitic patch (PP) is placed above RP at a height of h on substrate 1. The ANSYS Electronics Desktop (HFSS) is used to design and optimize the structure.

Operational mechanism

Theoretically, a dual-polarized antenna where Tx and Rx have orthogonal polarization, has infinite isolation between the Tx and Rx port, a favorable condition for the IBFD system. Hence, at Stage 1, a dual-polarized square MPA is excited through direct feeding (insert-fed) at port 1 (Tx port) and port 2 (Rx port). The feeding arrangement shown in Fig. 2(a) ensures that the Tx port is orthogonally polarized with respect to the Rx port. This MPA resonates at a center frequency (f_0) of 2.5 GHz. It is evident from the S-parameters shown in Fig. 2(a) that in addition to fundamental mode TM_{10} (2.5 GHz) of this MPA, other higher order modes TM_{11} (3.55 GHz), TM_{20} (5.3 GHz) and TM_{22} (6.7 GHz) also exist.

Now, instead of direct feeding, capacitive feeding with the help of pairs of $\lambda/4$ resonators is provided to the MPA as shown in Stage 2 of Fig. 2(b). This configuration results in spurious-free characteristics as shown in Fig. 2(b). The suppression of higher-order modes is due to the presence of pairs of $\lambda/4$ resonators which are centrally loaded with a shorting pin [22].

The non-radiating $\lambda/4$ resonators along with a shorting pin exhibit resonance at discrete frequencies (nf_0, where $n = 1, 3, .. (2\,N + 1)$). The MPA is capacitively fed by $\lambda/4$ resonators, allowing energy transmission only at discrete frequencies where both the $\lambda/4$ resonators and MPA resonate simultaneously. Consequently, it is not possible to excite higher-order modes like TM_{11} and TM_{22} due to their resonance frequencies not being a multiple of f_0. For a square MPA, the resonant frequency of the TM_{11} and TM_{22} modes are $1.414\,f_0$ and $2.828\,f_0$, respectively.

In addition, the placement of a shorting pin at the center of a feedline results in the creation of an electric field null at the center plane. This configuration prevents the excitation of even order modes, such as TM_{20}, because the primary requirement to excite any even order mode is to have an electric field maximum in the central plane. Hence, this feeding mechanism shown in Stage 2 of Fig. 2(b) successfully suppresses the second-order modes which are the most critical in any communication system. In spite of good out-of-band performance, this configuration has inter-port

isolation of 20 dB as shown in Fig. 2(b) which is insufficient for an IBFD system.

Further, to increase the inter-port isolation, differential feeding is provided to Tx and Rx ports which is presented as Stage 3 of Fig. 2(c). To understand the effect of this double differential feeding on inter-port isolation in more detail, a mathematical model is developed based on the analysis proposed in [13]. To apply the differential feed at both the Tx and Rx ports, two different hybrid couplers can be utilized as shown in Fig. 3. Here, the current at Port 1(Tx) and Port 2(Rx) is represented as I_1 and I_2 respectively.

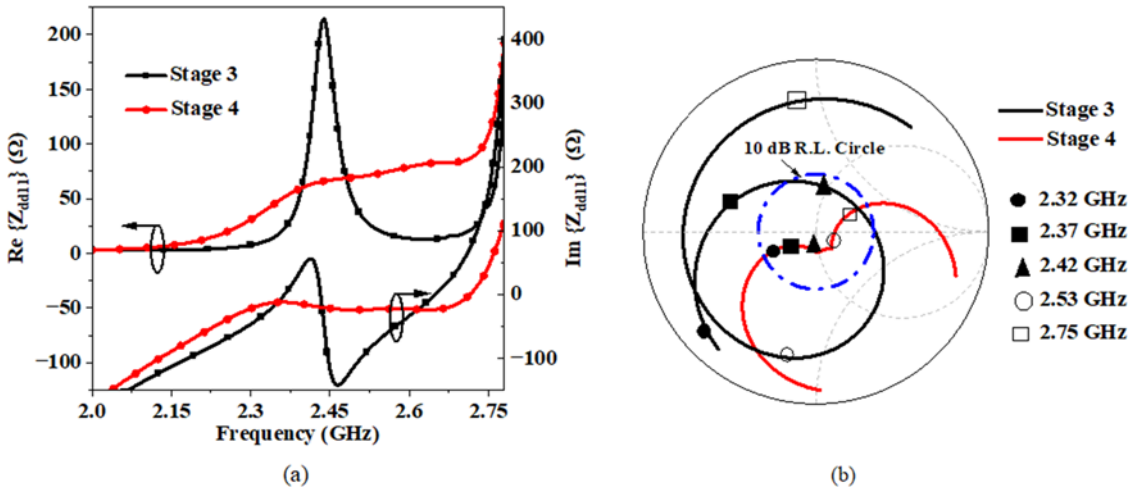

Figure 5. (a) Input impedance matching of stage 3 and stage 4 antenna, (b) Smith chart for impedance matching of stage 3 and stage 4 antenna.

Table 1. Key features of antennas of different stages

Stage	Type of feeding	Higher order modes suppression	Inter-port isolation	Impedance bandwidth
1	Insert feed	No	Very low	Narrow
2	Capacitive feed	Yes	Average	Narrow
3	Dual differential capacitive feed	Yes	Excellent	Narrow
4	Dual differential capacitive feed	Yes	Excellent	Large

Assuming the lossless hybrid coupler (H.C.), the output currents of H.C. 1 can be written as [24]

$$I_{1+} = \frac{1}{\sqrt{2}} I_1 \; and \; I_{1-} = -\frac{1}{\sqrt{2}} I_1 \tag{1}$$

As the differential port 2 is acting as a receiver port, different currents of H.C. 2 are related to each other as follows:

$$I_2 = \frac{1}{\sqrt{2}} (I_{2+} - I_{2-}) \tag{2}$$

Now, let the mutual coupling between port 2_+ (2-) and port 1_+(1-) is represented as S_{2+1+} ($S_{2\text{-}1\text{-}}$) and S_{2+1-} ($S_{2\text{-}1+}$) denotes the mutual coupling between port 2_+ (2–) and port 1_- (1+), then

$$I_{2+} = \frac{I_1}{\sqrt{2}} S_{2+1+} - \frac{1}{\sqrt{2}} I_1 \, S_{2+1-}$$

$$= \frac{I_1}{\sqrt{2}} [S_{2+1+} - S_{2+1-}] \tag{3}$$

$$I_{2-} = \frac{I_1}{\sqrt{2}} [S_{2-1+} - S_{2-1-}] \tag{4}$$

Now using eq. (2), (3) and (4), I_2 can be found as

$$I_2 = \frac{I_1}{2} [(S_{2+1+} - S_{2+1-}) - (S_{2-1+} - S_{2-1-})] \tag{5}$$

Therefore, based on Eq. (5) the relationship between the current of port 1 and 2 can be expressed as

$$\frac{I_1}{I_2} = \frac{2}{[(S_{2+1+} - S_{2+1-}) - (S_{2-1+} - S_{2-1-})]} \tag{6}$$

The proposed structure is symmetrical and considering the ideal differential operation performed by the hybrid couplers, the coupling between the orthogonally placed ports will be identical ($S_{2+1+} = S_{2+1-} = S_{2-1+} = S_{2-1-}$). Hence, it is evident from Eq. (6) that theoretically, infinite inter-port isolation is achieved using this configuration. Nevertheless, in practical use, significantly large inter-port isolation can be achieved by utilizing highly precise hybrid couplers that produce output signals with equal magnitude and out-of-phase characteristics [13].

It is important to note that double differential feeding deployed at Stage 3 is the major factor in achieving high inter-port isolation. The differential operation performed at the Tx port is responsible for suppressing any Tx-Rx leakage at Rx ports while the differential Rx ports subsequently suppress any further residual self-interference. Hence, the polarization diversity along with double differential feeding yields a high inter-port isolation better than 60 dB for the entire operating band as shown in Fig. 2(c).

The surface currents for Tx and Rx ports are shown in Fig. 4. It is evident that the surface current is oriented in the x (y) direction when differential Tx (Rx) ports are excited while the Rx (Tx) ports are terminated with a matched load. Even though high inter-port isolation is achieved at this design stage, the input matching of this stage is very poor, and impedance bandwidth ($|S_{11}| < -10\ dB$) is limited (~40 MHz).

Although the dual resonant behavior can be observed in antennas of Stage 2 and Stage 3 due to close proximity of $\lambda/4$ resonators with the RP (Fig. 2(b) and Fig. 2(c)), the input matching and impedance bandwidth are not sufficient. Therefore, a PP is placed above the RP in Stage 4 as shown in Fig. 2(d). The inclusion of PP

Capacitance of the resonator [C_{ri}, C_1, C_2, C_{p1}, C_{p2}]	Dimensions ($L \times W$) of the resonator [$\lambda/4$ resonator, RP(TM_{10}) RP (TM_{01}), PP (TM_{10}), PP (TM_{01})]
Equivalent capacitance formed by π network (C_{gi})	Gap (d) between the $\lambda/4$ resonator and RP
Inductance (L_c) and capacitance (C_c)	Mixed coupling facilitated by airgap (h) between RP and PP

has two-fold utility; first, it improves the input matching and then it also improves the impedance bandwidth. It is clear from the S-parameters shown in Fig. 2(d) that the Stage 4 antenna results in a high isolation of 65 dB over the entire operating frequency band (2.30–2.76 GHz).

To illustrate the improvement in input matching, the input impedances of Stage 3 and Stage 4 antennas are plotted in Fig. 5(a). It clearly shows that the Stage 3 antenna exhibits inadequate input matching over the desired operating band.

Now, the air gap between RP and PP facilitates the mixed coupling (electric and magnetic couplings) [23]. The effect of this mixed coupling can be observed in Fig. 5(a). This mixed coupling offers either inductive or capacitive impedance across different frequencies. Consequently, an air gap of varying height results in a substantial change in input impedance (the corresponding parametric study is shown in the Section V of this paper). Hence, with the placement of the PP above RP at an optimal height (h) of 10 mm, the imaginary part of Z_{dd11} of the Stage 4 antenna approaches zero, while the real component of Z_{dd11} is near to 50 Ω in the entire operating band. This demonstrates the significant improvement of input matching resulting from the strategic placement of PP at an optimal height of h.

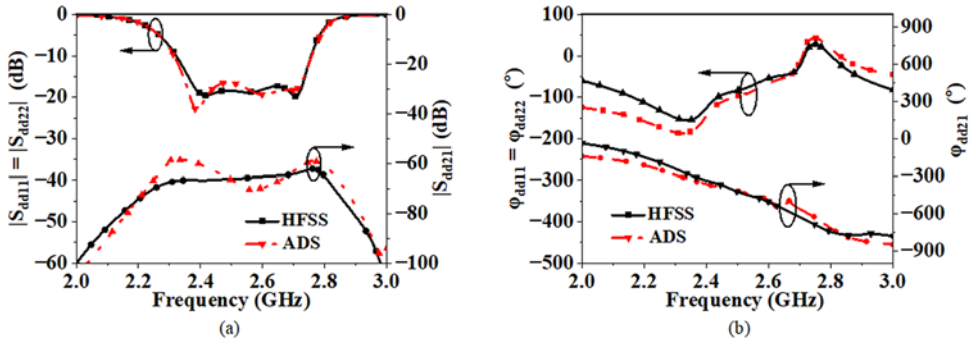

Figure 7. Comparison between EM simulation and circuit simulation of the proposed IBFD antenna: (a) magnitude plot (b) phase plot (unwrapped).

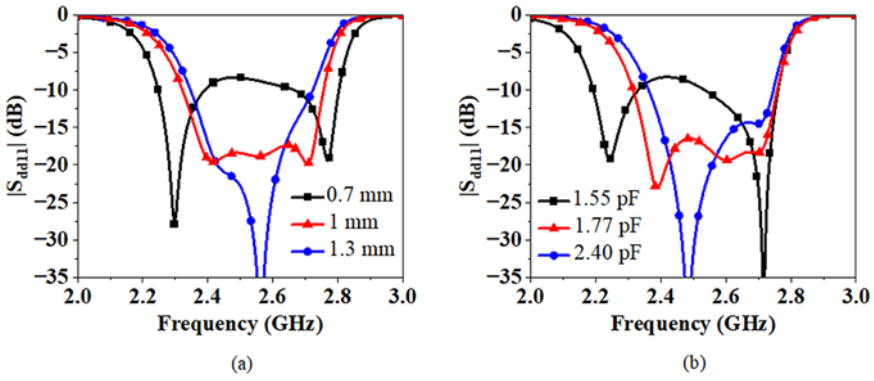

Figure 8. The effect of variations in (a) d (b) C_{g1} on the input reflection coefficient.

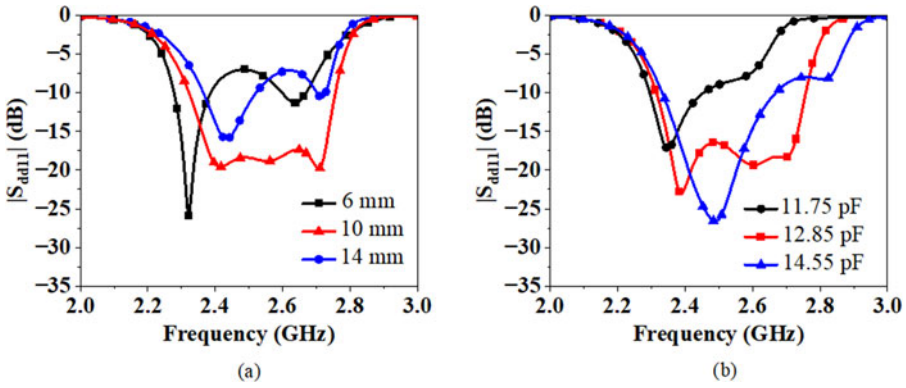

Figure 9. The effect of variations in (a) h (b) c_{c1} on the input reflection coefficient.

Additionally, the excellent input matching for the entire operating band is also reflected in the Smith Chart shown in Fig. 5(b). The impedance loop of the Stage 4 antenna evidently shifts towards the center of Smith chart which further confirms the substantial improvement in the matching performance due to PP being placed above the RP at a height of h.

Further, the judicious selection of the air gap (h) as 10 mm ($\sim$0.1 λ) facilitates the fundamental mode of PP to resonate with close proximity of the fundamental mode of RP [25]. Thus, the improved impedance bandwidth (460 MHz) is achieved because three different structures i.e. RP, PP, and $\lambda/4$ resonators are resonating in close vicinity. This Stage 4 antenna presented in Fig. 2(d) is our proposed IBFD antenna which has significantly large inter-port isolation over a wide frequency range. Also, this design successfully suppresses the higher-order modes which can be undesirable for other surrounding devices. Table 1 summarizes the key characteristics of antennas of different stages which clearly highlight the achievement of performance improvement of the proposed IBFD antenna in successive stages.

Equivalent lumped circuit model

To gain further insight into the proposed design, an equivalent lumped circuit model of the proposed dual-polarized IBFD antenna is presented in Fig. 6. The differential feeding is provided at both Tx and Rx ports through a microstrip line of characteristic impedance Z_0. The $\lambda/4$ resonator is modeled as a lossless LC circuit (L_{ri}, C_{ri}, i varying from 1 to 4). These pair of $\lambda/4$ resonators at the Tx and Rx ends are connected in parallel. At one end, these resonators are connected to shorting pins shown as L_{pin1} and L_{pin2} at the Tx and Rx ends, respectively. The gap between the feeding circuit and the RP is modeled as a π-network of three capacitances

C_{g1}, C_{g2}, C_{g3} and C_{g4}, C_{g5}, C_{g6} at Tx, and Rx ends, respectively. A combination of two parallel RLC circuits i.e. $R_1L_1C_1$ and $R_2L_2C_2$ is used to represent the RP when it is excited at differential Tx and Rx ports respectively. It is important to note that, the RP is operating under TM_{10} mode when excitation is provided at differential port 1 while the dominating mode of operation is TM_{01} when RP is excited at differential port 2. Similarly, the PP is presented as a parallel resonant circuit $R_{p1}L_{p1}C_{p1}$ and $R_{p2}L_{p2}C_{p2}$ when it is excited with differential port 1 and differential port 2, respectively. The resonant frequency (f_r) of each of the three resonators (RP, PP, and $\lambda/4$ resonators) can be calculated with the following relation:

$$f_r = \frac{1}{2\pi\sqrt{L_rC_r}} \tag{7}$$

where L_r and C_r represent the inductance and capacitance of the corresponding resonator.

Further, the mixed coupling (combination of electric and magnetic coupling) between the RP and PP is described as two parallel LC circuits (L_{C1}, C_{C1} and L_{C2}, C_{C2}). Finally, the mutual coupling between port 1 and port 2 is defined as M_{12} [26,27]. The working mechanism of various components used in the circuit model can be understood by comparing them with the actual elements utilized in the design of the IBFD antenna as tabulated in Table 2. In addition, the ADS software is utilized to design and validate the IBFD antenna equivalent circuit model. A comparison of simulated results obtained from ADS and HFSS is presented in Fig. 7, demonstrating a high level of consistency between the two.

Parametric analysis

To elucidate the impact of a few parameters on the performance of the proposed IBFD antenna, two parametric studies are performed. The first study illustrates the effect of variations in d (the gap between a pair of $\lambda/4$ resonators and RP) on the input reflection coefficient, as depicted in Fig. 8 (a). For a nominal value of d as 1 mm, all the three reflection poles due to RP, PP, and $\lambda/4$ resonators are combined to form a wideband antenna. When the value of d is increased to 1.3 mm, all the reflection poles are merged into a single reflection pole. Additionally, to validate the effectiveness of the proposed equivalent circuit model, one capacitor (C_{g1}) of the π network (the circuit equivalent of the gap (d) between a pair of $\lambda/4$ resonators and RP) is varied and its effect on input reflection coefficient is presented in Fig. 8 (b). It is evident from the Fig. 8 that both EM and circuit simulation leads to a similar conclusion. It is important to note that all parameters except d (C_{g1}) in EM (circuit) simulation are maintained constant in the aforementioned study.

Subsequently, in another parametric study, the effect of variations in the air gap (h) between RP and PP is analyzed, as shown in Fig. 9(a). It clearly demonstrates that the judicious selection of the airgap (h) as 10 mm is essential for the fundamental mode of PP to resonate with close proximity of the fundamental mode of RP which results in a good impedance matching over a wideband. Furthermore, as discussed in the previous section, the air gap between RP and PP facilitates the mixed coupling (electric and magnetic couplings) to improve the input matching. This can be further verified from the parametric variation in C_{c1} (parallel combination of C_{c1} and L_{c1} is circuit equivalent to mixed-coupling provided by the air gap between RP and PP) performed in circuit simulation as shown in Fig. 9(b). Hence, the prudent selection of air gap to obtain a good input matching over a wideband is justified with the help of EM and circuit simulation as illustrated in Fig. 9.

Results and discussion

To validate the functionality of the proposed design, a prototype is implemented using RT Duroid substrate, and the nylon screws are used to hold both substrate layers. The fabricated prototype is shown in the inset of Fig. 10(a). To provide differential signals at Tx and Rx ports, an ultra-wideband hybrid coupler proposed in [9] is used. The magnitude and phase imbalance between the two output ports of this coupler is within the limit ($\pm$0.2 dB and $\pm$2.5° respectively) over a large frequency range (1–10 GHz).

The S – parameters of the proposed dual-polarized IBFD antenna are measured using the Agilent Vector Network Analyzer [N5247A] and presented in Fig. 10. The improved out-of-band characteristic of the proposed structure can be observed in Fig. 10(a) which clearly shows that it possesses spurious free characteristics. Moreover, as shown in Fig. 10(b), the measured impedance bandwidth is ~20% (2.26–2.76 GHz) which is somewhat larger than the simulated results. Also, the measured isolation between Tx and Rx ports is better than 58 dB for the entire operating range (2.26–2.76 GHz) while in simulation it was obtained as 65 dB. The discrepancies between the simulated and measured results are due to cable losses and misalignment of the PP with respect to the driven patch.

The far-field parameters are measured in an anechoic chamber and the measured realized gain and radiation pattern are presented in Fig. 10(c) and Fig. 10(d), respectively. It is important to note that the proposed design is symmetrical with respect to Tx and Rx ports. Thus, the measured results are presented only for the differential Tx ports for brevity. The peak values of measured realized gain and radiation efficiency are 9.1 dBi and 92%, respectively. The cross-polarization better than −30 dB at boresight direction is measured at two operating frequencies 2.4 GHz and 2.65 GHz in both E and H planes. It is evident from the measured results that these are in close agreement with the simulated results.

A detailed comparison of the proposed structure with other reported dual-polarized IBFD antennas is presented in Table 3. The present design offers the largest fractional bandwidth ($|S_{11}| < -10$ dB) of 20% among all the designs listed in Table 3. Though the designs presented in [13] and [14] offer better interport isolation, these multi-radiator-based designs have very narrow bandwidths and possess lower values of peak gain. Moreover, none of the aforementioned IBFD structures provide suppression of higher-order modes. Hence, it can be concluded that the proposed shared radiator-based design provides significantly larger isolation of 58 dB over a wide bandwidth of 20% along with a large peak gain of 9.1 dBi and an excellent out-of-band performance.

Conclusion

In this paper, a wideband IBFD antenna is presented which is also capable of suppressing higher-order modes. The employability of $\lambda/4$ resonators along with PP in wideband operation. An isolation better than 58 dB between the Tx and Rx ports is achieved due to orthogonally polarized surface currents applied through a balanced feed to the Tx and Rx ports. The key attributes of the proposed design are simplicity in design, very high isolation over a large frequency band, and excellent out-of-band performance. Due to these features, the proposed design not only provides excellent performance in the ISM band but can also be scaled to higher frequency bands.

Bernstein type semi-exponential operators

Kanita and Naokant Deo

Department of Applied Mathematics, Delhi Technological University, Delhi, India

ABSTRACT

The concept of semi-exponential operators is an extension of the exponential operators in approximation theory. The analysis begins by considering the partial differential equation,

$$\frac{\partial}{\partial x}W_\beta(r,x,t) = \frac{r(t-x)}{p(x)}W_\beta(r,x,t) - \beta W_\beta(r,x,t)$$

with domain of definition Ω, for the kernel of sequence of operators

$$S_r(f;x) = \sum_{k\in\Omega} W_\beta\left(r,x,\frac{k}{r}\right) f\left(\frac{k}{r}\right)$$

while satisfying the normalization condition $\sum_{k\in\Omega} W_\beta\left(r,x,\frac{k}{r}\right) = 1$. Carrying forward this notion, we examine these operators specifically for the function $p(x) = x(1-x)$ and focus our attention on the semi-exponential Bernstein operators. Our primary focus is to explore the properties and characteristics of these Bernstein type semi-exponential operators. The paper delves into deriving a recurrence relation for the central moments of these operators, while also establishing a moment generating function for the same. Finally, we analyze the approximation of these operators using the Voronovskaya-type asymptotic result. The objective of this analysis is to characterize functions by the degree of approximation.

XXXX CLASSIFICATION

1. Introduction

In their influential study, Ismail and May were the first to propose the idea of exponential operators [1], wherein they defined the exponential-type operators,

$$S_\lambda(f(u);t) = \int_\Omega W(\lambda,t,u)f(u)\mathrm{d}u, \tag{1}$$

where Ω is the domain of definition and W is a positive function, known as the kernel of S_λ, satisfying the homogeneous partial differential equation

$$\frac{\partial}{\partial t}W(\lambda,t,u) = \frac{\lambda}{p(t)}W(\lambda,t,u)(u-t), \tag{2}$$

CONTACT Naokant Deo naokantdeo@dce.ac.in; Kanita kanitatewari@gmail.com

© 2025 Informa UK Limited, trading as Taylor & Francis Group

such that $p(t)$ is both analytic and positive over the domain Ω. The kernel $W(\lambda, t, u)$ satisfies the normalization condition

$$S_\lambda\,(1,t) = \int_\Omega W\,(\lambda,t,u)\,\mathrm{d}u = 1. \tag{3}$$

Assigning particular values to the function $p(t)$ in Equation (2), various operators can be obtained. For instance, the Bernstein polynomials can be obtained by considering the function $p(t) = t(1-t)$. Similarly, the operators of Szász-Mirakjan can be derived by the function $p(t) = t$, the Post–Widder operators by $p(t) = t^2$ and the Gauss–Weierstrass operators by $p(t) = 1$, among others.

For quite a few years following Ismail and May, no new work had been done on exponential operators up until the year 2005. It was during this time that A. Tyliba and E. Wachnicki [2] introduced the concept of semi-exponential operators and they expanded upon the findings of Ismail and May by considering a sequence of operators, denoted as V_r^β, such that $V_r^\beta(t,x) \neq x$. In Equation (2), they introduced a non-negative real parameter β and thus worked on a new homogeneous partial different equation, thus obtaining a new family of operators, known as the semi-exponential operators, defined in the following way:

$$V_r^\beta\,\big(f(t);x\big) = \int_\Omega W_\beta\,(r,x,t)\,f(t)\mathrm{d}t, \tag{4}$$

where Ω is the domain of definition. Here, we denote the kernel by $W_\beta(r,x,t)$, which satisfies:

(1) The homogeneous partial differential equation

$$\frac{\partial}{\partial x}W_\beta(r,x,t) = \frac{r}{p(x)}\,(t-x)\,W_\beta(r,x,t) - \beta W_\beta(r,x,t). \tag{5}$$

(2) The normalization condition

$$V_r^\beta\,(1,x) = \int_\Omega W_\beta\,(r,x,t)\,\mathrm{d}t = 1. \tag{6}$$

For the case $\beta = 0$, the operators V_r^β can simply be regarded as the operators of the exponential type. Recently, Herzog [3] conducted a study on the approximation properties of exponential-type operators when acting on functions from exponential weighted spaces. A range of several new semi-exponential operators were captured by Abel et al. recently [4], each corresponding to a different function $p(x)$. Further, in the past few years, numerous investigations have been carried out concerning the modification and preservation of exponential-type operators [5–14].

In all the definitions mentioned above, the domain of each operator is defined as Ω, which varies depending on the specific operator. This paper will address the case in which the polynomial function $p(x) = x(1-x)$ is considered and the function $f(k/r)$ is discretely varied over the interval $[0,\infty)$. Due to the discrete nature of the distribution, the aforementioned definitions and normalization condition will vary when summed over the discrete range of k from 0 to ∞. Solving the partial differential Equation (5) for $p(x) = x(1-x)$, and satisfying the normalization condition (6), we get the kernel of the semi-exponential Bernstein operators, $W_\beta(r,k,x)$ as follows,

$$W_\beta(r,k,x) = e^{-\beta x}x^k(1-x)^{r-k}\sum_{l=0}^{\infty}{}^{r-l}c_{k-l}\frac{\beta^l}{l!}, \tag{7}$$

where ${}^rc_k = \frac{r!}{k!(r-k)!}$ is the binomial coefficient. Solving the partial differential Equation (2) corresponding to exponential operators we get the kernel of the classical Bernstein operators, known as

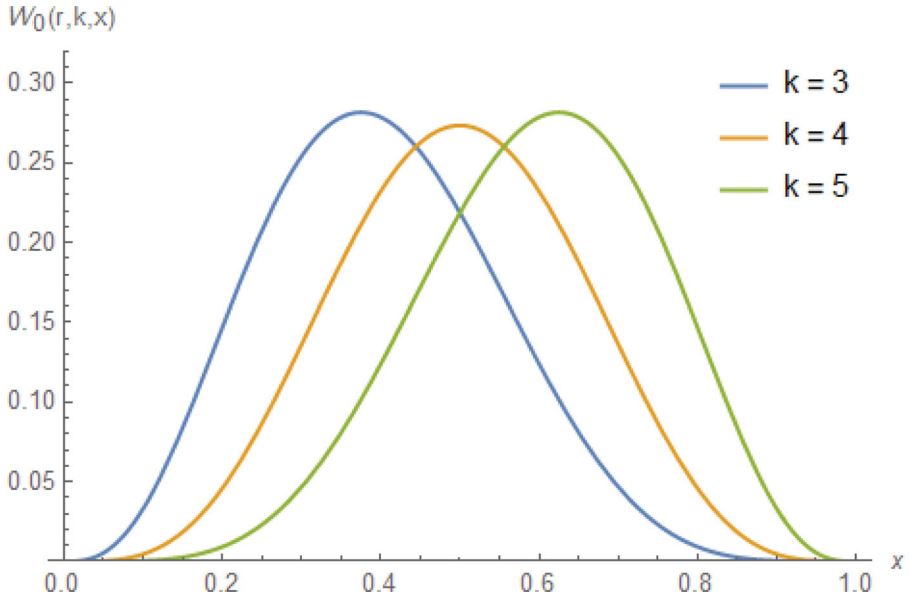

Figure 1. Graphs of the kernel of semi-exponential Bernstein operators for $r = 8$, $k = 3, 4, 5$ and $\beta = 0$.

the Bernstein polynomials, defined as $b_{r,k}(x) = {}^{r}c_k x^k (1-x)^{r-k}$. We see that the relation between the kernel of the semi-exponential Bernstein operators (7) and the kernel of the exponential Bernstein operators is given by

$$W_0(r,k,x) = b_{r,k}(x). \tag{8}$$

In this paper we focus on a whole new class of kernels $W_\beta(r,k,x)$ depending upon r and k and the parameter β, unlike the classical Bernstein polynomials $b_{r,k}(x)$ which solely depend upon r and k. To further analyze these functions and determine the effect of the parameters on $W_\beta(r,k,x)$, we graph them for different values of r, k and β.

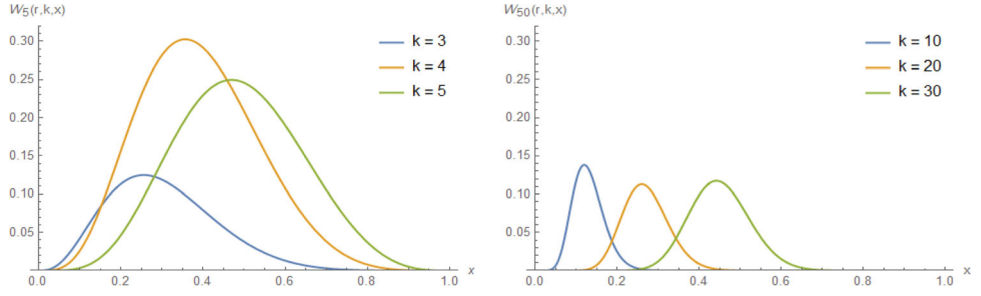
Figure 1 validates expression (8) as it is well known that the Bernstein polynomials are symmetric in the interval $[0,1]$, that is, $b_{r,k}(1-x) = b_{r,r-k}(x)$. However, from Figure 2, we can see that the kernel of the semi-exponential operators for $\beta > 0$ does not satisfy this property. Thus, we can conclude that unlike the kernels of classical Bernstein operators and its other modifications, such as the λ-Bernstein operators [15] and α-Bernstein [16], the kernel of semi-exponential operators defined by (4) for $\beta > 0$, are not symmetric over $[0,\infty]$.

Employing $W_\beta(r,k,x)$ to the definition of semi-exponential operators (4), we get the Bernstein type semi-exponential operators:

$$B_r^\beta(f;x) = e^{-\beta x}\sum_{k=0}^{\infty} x^k (1-x)^{r-k} \sum_{l=0}^{\infty} {}^{r-l}c_{k-l}\frac{\beta^l}{l!} f\left(\frac{k}{r}\right), \tag{9}$$

where ${}^{r}c_k$ is the binomial coefficient. The above operators can be demonstrated and derived as shown by Abel et al. [4] in their paper, where they introduced several new semi-exponential operators, including the semi-exponential Bernstein operators (9). Furthermore, they introduced the following alternate form of these operators (10), which is used in this paper to compute the moments and central moments of these operators,

$$B_r^\beta(f;x) = e^{-\beta x}\sum_{l=0}^{\infty} \frac{\beta^l}{l!} x^l (1-x)^{r-l} \sum_{j=0}^{\infty} {}^{r-l}c_j \left(\frac{x}{1-x}\right)^j f\left(\frac{l+j}{r}\right). \tag{10}$$



(a) Graphs of the kernel of semi-exponential Bernstein operators for $r = 8$, $k = 3, 4, 5$ and $\beta = 5$.

(b) Graphs of the kernel of semi-exponential Bernstein operators for $r = 40$, $k = 10, 20, 30$ and $\beta = 50$.

Figure 2. Graphs of the kernel of semi-exponential Bernstein operators for different values of r and k and $\beta > 0$. (a) Graphs of the kernel of semi-exponential Bernstein operators for $r = 8$, $k = 3, 4, 5$ and $\beta = 5$ and (b) Graphs of the kernel of semi-exponential Bernstein operators for $r = 40$, $k = 10, 20, 30$ and $\beta = 50$.

Based on the definition and derivation of the semi-exponential Bernstein polynomials (4), it can be stated that the operators denoted as B_r^β map a function f on $[0, \infty)$ to a function $B_r^\beta f$ defined on $[0, \frac{1}{2})$, whenever the sum is convergent.

2. Preliminaries

In the following section, we present the properties of the operators mentioned in (10), which are utilized in the subsequent sections of this paper to establish the main theorems.

Lemma 2.1: *Let $B_r^\beta(.;x)$ be the Bernstein type semi-exponential operators. Then for $x \in [0, \frac{1}{2})$ the following equalities hold:*

(i) $B_r^\beta(1;x) = 1$

(ii) $B_r^\beta(t;x) = x + \beta\frac{x(1-x)}{r}$

(iii) $B_r^\beta(t^2;x) = x^2 + \frac{x(1-x)+2\beta x^2(1-x)}{r} + \frac{\beta x(1-3x+2x^2)+\beta^2x^2(1-x)^2}{r^2}$

Proof: Applying the negative binomial expansion in (10) we get,

$$B_r^\beta(1;x) = e^{-\beta x}\sum_{l=0}^{\infty}\frac{\beta^l}{l!}x^l(1-x)^{r-l}\sum_{j=0}^{\infty}{}^{r-l}c_j\left(\frac{x}{1-x}\right)^j$$

$$= e^{-\beta x}\sum_{l=0}^{\infty}\frac{\beta^l}{l!}x^l(1-x)^{r-l}\left(1+\frac{x}{1-x}\right)^{r-l} = 1.$$

$$B_r^\beta(t;x) = e^{-\beta x}\sum_{l=0}^{\infty}\frac{\beta^l}{l!}x^l(1-x)^{r-l}\sum_{j=0}^{\infty}{}^{r-l}c_j\left(\frac{x}{1-x}\right)^j\left(\frac{l+j}{r}\right)$$

$$= e^{-\beta x}\left[\sum_{l=0}^{\infty}\frac{\beta^l}{l!}x^l(1-x)^{r-l}\sum_{j=0}^{\infty}{}^{r-l}c_j\left(\frac{x}{1-x}\right)^j\frac{l}{r}\right.$$

$$\left.+\sum_{l=0}^{\infty}\frac{\beta^l}{l!}x^l(1-x)^{r-l}\sum_{j=0}^{\infty}{}^{r-l}c_j\left(\frac{x}{1-x}\right)^j\frac{j}{r}\right]$$

$$= e^{-\beta x}\left[\sum_{l=0}^{\infty}\frac{\beta^l}{l!}x^l\frac{l}{r}+\sum_{l=0}^{\infty}\frac{\beta^l}{l!}x^l(1-x)^{r-l}\left(\frac{r-l}{r}\right)\sum_{j=0}^{\infty}{}^{r-l-1}c_j\left(\frac{x}{1-x}\right)^{j+1}\right]$$

$$= e^{-\beta x}\left[\sum_{l=0}^{\infty}\frac{\beta^l}{l!}x^l\frac{l}{r}+x\sum_{l=0}^{\infty}\frac{\beta^l}{l!}x^l\left(1-\frac{l}{r}\right)\right]$$

$$= e^{-\beta x}\left[\frac{\beta x}{r}e^{\beta x}+x\left(1-\frac{\beta x}{r}\right)e^{\beta x}\right]$$

$$= x+\frac{\beta x}{r}(1-x)$$

and

$$B_r^{\beta}\left(t^2;x\right) = e^{-\beta x}\sum_{l=0}^{\infty}\frac{\beta^l}{l!}x^l(1-x)^{r-l}\sum_{j=0}^{\infty}{}^{r-l}c_j\left(\frac{x}{1-x}\right)^j\left(\frac{l^2+2lj+j^2}{r^2}\right)$$

$$= e^{-\beta x}\left[\sum_{l=0}^{\infty}\frac{\beta^l}{l!}x^l\frac{l^2}{r^2}+2\sum_{l=0}^{\infty}\frac{\beta^l}{l!}\frac{l}{r}x^l(1-x)^{r-l}\sum_{j=0}^{\infty}{}^{r-l}c_j\frac{j}{r}\left(\frac{x}{1-x}\right)^j\right.$$

$$\left.+\sum_{l=0}^{\infty}\frac{\beta^l}{l!}x^l(1-x)^{r-l}\sum_{j=0}^{\infty}{}^{r-l}c_j\left(\frac{x}{1-x}\right)^j\left(\frac{j}{r}\right)^2\right]$$

$$= e^{-\beta x}\left[\sum_{1}+\sum_{2}+\sum_{3}\right].$$

Solving the above three summations, we will arrive at,

$$\sum_{1} = e^{\beta x}\frac{\beta x}{r^2}(1+\beta x)$$

$$\sum_{2} = e^{\beta x}\frac{2\beta x^2}{r}\left(1-\frac{1}{r}-\frac{\beta x}{r}\right)$$

$$\sum_{3} = e^{\beta x}\left(\frac{\beta^2x^4}{r^2}-\frac{\beta x^2}{r^2}-2\left(\frac{r-1}{r^2}\right)\beta x^3+\left(\frac{r-1}{r}\right)x^2+\frac{x}{r}\right).$$

Substituting these values in $B_r^{\beta}(t^2;x)$ we get the desired moment. ■

Now, let us denote the ς th central moment as,

$$\mu_{r,\varsigma}(x) = e^{-\beta x}\sum_{k=0}^{\infty}A(r,k,\beta)\,x^k(1-x)^{r-k}\left(\frac{k}{r}-x\right)^{\varsigma}, \tag{11}$$

where $A(r,k,\beta)=\sum_{l=0}^{\infty}{}^{r-l}c_{k-l}\frac{\beta^l}{l!}$.

Theorem 2.2: *Based on the aforementioned definition, a recurrence relation can be derived for the central moments of semi-exponential Bernstein operators,*

$$\begin{aligned}&\mu_{r,1}(x) = \frac{\beta}{r}x(1-x)\\ &r\mu_{r,\varsigma+1}(x) = x(1-x)\left[\mu'_{r,\varsigma}(x)+\beta\mu_{r,\varsigma}(x)+\varsigma\,\mu_{r,\varsigma-1}(x)\right];\quad \varsigma\geq 1.\end{aligned} \tag{12}$$

Theorem 2.3: *$A_\varsigma(r,x) = r^\varsigma \mu_{r,\varsigma}(x)$ is a polynomial of degree $[\frac{\varsigma}{2}]$ in r, where [.] is the greatest integer function. Also, the coefficient of r^ς in*

(i) *$A_{2\varsigma}(r,x)$ is $1\cdot 3\cdot 5\ldots(2\varsigma-1)(x(1-x))^\varsigma$, and*
(ii) *$A_{2\varsigma+1}(r,x)$ is $c_1\beta(x(1-x))^{\varsigma+1} + c_2(x(1-x))^\varsigma(1-2x)$*

where c_1, c_2 are constants and $c_1 = 1\cdot 3\cdot 5\ldots(2\varsigma+1)$.

Proof: We have $A_\varsigma(r,x) = r^\varsigma \mu_{r,\varsigma}(x)$. Therefore, we can write,

$$A_0(r,x) = 1,$$
$$A_1(r,x) = \beta x(1-x)$$

and

$$A_{\varsigma+1}(r,x) = x(1-x)\left(\frac{\mathrm{d}}{\mathrm{d}x}A_\varsigma(r,x) + \beta A_\varsigma(r,x) + r\varsigma A_\varsigma(r,x)\right), \quad \varsigma \geq 1. \tag{13}$$

By repeatedly substituting the value of $A_\varsigma(r,x)$ in Equation (13), it can be demonstrated that $A_{2\varsigma}(r,x)$ and $A_{2\varsigma+1}(r,x)$ are polynomials in r of degree ς. It follows that, the highest powered term appearing in their expression is r^ς with its coefficient as:

$$1\cdot 3\cdot 5\ldots(2\varsigma-1)(x(1-x))^\varsigma \quad \text{for } A_{2\varsigma}(r,x)$$
$$c_1\beta(x(1-x))^{\varsigma+1} + c_2(x(1-x))^\varsigma(1-2x) \quad \text{for } A_{2\varsigma+1}(r,x)$$

where c_1, c_2 are constants and $c_1 = 1\cdot 3\cdot 5\ldots(2\varsigma+1)$. ■

Remark 2.1: From Theorem 2.3 we have,

$$A_\varsigma(r,x) = O\left(r^{[\varsigma/2]}\right).$$

It follows

$$\mu_{r,\varsigma}(x) = O\left(r^{-\left[\frac{\varsigma+1}{2}\right]}\right),$$

where [.] is the greatest integer function.

One way to calculate the central moments of semi-exponential Bernstein operators is through the recurrence relation stated above in Theorem 2.2. An alternative method for calculating the central moments involves utilizing the exponential moment-generating function (MGF). Our next objective is to derive an equation for the central moment generating function of the semi-exponential operators (10).

Consider the recurrence relation (12),

$$r\mu_{r,\varsigma+1}(x) = x(1-x)\left[\mu'_{r,\varsigma}(x) + \beta\mu_{r,\varsigma}(x) + \varsigma\mu_{r,\varsigma-1}(x)\right].$$

It follows

$$\frac{r}{x(1-x)}B_r^\beta\left((t-x)^{\varsigma+1};x\right) = \frac{\mathrm{d}}{\mathrm{d}x}B_r^\beta\left((t-x)^\varsigma;x\right) + \beta B_r^\beta\left((t-x)^\varsigma;x\right) + \varsigma B_r^\beta\left((t-x)^{\varsigma-1};x\right). \tag{14}$$

Now, the exponential moment generating function of $B_r^{\beta}((t-x)^{\varsigma};x)$ is defined as,

$$\begin{aligned} G(x,z) &= B_r^{\beta}\left(e^{z(t-x)};x\right) \\ &= \sum_{\varsigma=0}^{\infty}\frac{z^{\varsigma}}{\varsigma!}B_r^{\beta}\left((t-x)^{\varsigma};x\right). \end{aligned}$$

Multiplying Equation (14) by $\frac{z^{\varsigma}}{\varsigma!}$ and taking summation over $\varsigma = 0, 1, \ldots \infty$, we get,

$$\frac{r}{x(1-x)}\sum_{\varsigma=1}^{\infty}\frac{z^{\varsigma-1}}{(\varsigma-1)!}B_r^{\beta}\left((t-x)^{\varsigma};x\right) = \frac{\partial}{\partial x}G(x,z) + \beta G(x,z) + zG(x,z).$$

It follows

$$\frac{r}{x(1-x)}\frac{\partial}{\partial z}G(x,z) = \frac{\partial}{\partial x}G(x,z) + (\beta+z)G(x,z)$$

and therefore

$$\frac{r}{x(1-x)}\frac{\partial G}{\partial z} - \frac{\partial G}{\partial x} = (\beta+z)G.$$

For the above PDE, solving the auxiliary equation: $\frac{x(1-x)}{r}\mathrm{d}z = -\mathrm{d}x = \frac{1}{(\beta+z)G}\mathrm{d}G$, we get

$$z = -r\ln\left(\frac{x}{1-x}\right) + c_1 \tag{15}$$

and

$$\begin{aligned} \ln G + c' &= -\beta x - c_1 x + r\int_{\alpha}^{x}\ln\left(\frac{\theta}{1-\theta}\right)\mathrm{d}\theta \\ &= -\beta x - c_1 x + r\int_{\theta=\alpha}^{x}\int_{\vartheta=\alpha}^{\theta}\frac{1}{\vartheta(1-\vartheta)}\mathrm{d}\vartheta\,\mathrm{d}\theta \\ &= -\beta x - c_1 x + r\int_{\vartheta=\alpha}^{x}\int_{\theta=\vartheta}^{x}\frac{1}{\vartheta(1-\vartheta)}\mathrm{d}\theta\mathrm{d}\vartheta \\ &= -\beta x - c_1 x + r\left[x\int_{\alpha}^{x}\frac{1}{\vartheta(1-\vartheta)}\mathrm{d}\vartheta - \left\{\int_{\alpha}^{x}\frac{1}{(1-\vartheta)}\right\}\mathrm{d}\vartheta\right], \end{aligned}$$

where c_1 and c' are arbitrary constants. It follows

$$G = \phi(c_1)\exp\{r\ln(1-x) - (\beta+z)x\},$$

where ϕ is an arbitrary function whose value we need to calculate. Now, by substituting the value of c_1 obtained from the first characteristic curve (15), we get

$$G(x,z) = \phi\left(z + r\ln\left(\frac{x}{1-x}\right)\right)\exp\{r\ln(1-x) - (\beta+z)x\}. \tag{16}$$

Putting the initial condition, $G(x,0) = 1$, we arrive at

$$\phi\left(r\ln\left(\frac{x}{1-x}\right)\right) = \exp\{\beta x - r\ln(1-x)\}$$

It follows

$$\phi\left(ry\right) = \exp\left\{\beta\frac{e^{y}}{1+e^{y}} - r\ln\left(1-\frac{e^{y}}{1+e^{y}}\right)\right\}$$
$$= \exp\left\{\beta\frac{e^{y}}{1+e^{y}} + r\ln\left(1+e^{y}\right)\right\}.$$

Thus

$$\phi\left(t\right) = \exp\left\{\beta\frac{e^{t/r}}{1+e^{t/r}} + r\ln\left(1+e^{t/r}\right)\right\}.$$

Substituting this value of the function ϕ in Equation (16), we arrive at the final solution, thus obtaining our moment generating function,

$$G\left(x,z\right) = \left(1-x+xe^{z/r}\right)^{r}\exp\left\{-zx + \frac{\beta x(1-x)(e^{z/r}-1)}{1-x+xe^{z/r}}\right\}. \tag{17}$$

3. Asysmptotic results

Theorem 3.1: *Let $R > 0$ and a, b be such that $0 < a, b < \infty$. Then for a sufficiently large r, we have,*

$$\left\|B_r^{\beta}\left(e^{R|t|};x\right)\right\|_{C[a,b]} < \infty,$$

$\|f\|_{C[a,b]} = \sup_{x\in[a,b]}|f(x)|$ represents the supremum norm and $C[a,b]$ is the space of all real-valued continuous functions on $[a,b]$ endowed with the supremum norm.

Proof: As per the definition of semi-exponential operators and Equation (17), we can write,

$$B_r^{\beta}\left(e^{Rt};x\right) = e^{Rx}\sum_{\varsigma=0}^{\infty}\frac{R^{\varsigma}}{\varsigma\,!}B_r^{\beta}\left((t-x)^{\varsigma};x\right)$$
$$= \left(1-x+xe^{R/r}\right)^{r}\exp\left\{\frac{\beta x(1-x)(e^{R/r}-1)}{1-x+xe^{R/r}}\right\}.$$

Taking the limit $r\to\infty$, we get

$$\lim_{r\to\infty}B_r^{\beta}\left(e^{Rt};x\right) = \lim_{r\to\infty}\left(1-x+xe^{R/r}\right)^{r} = e^{Rx}.$$

Hence, $\lim_{r\to\infty}B_r^{\beta}(e^{Rt};x) = e^{Rx}$ uniformly in $C[a,b]$. Thus, for a sufficiently large r, we get $\|B_r^{\beta}(e^{Rt};x)\|_{C[a,b]} < \infty$. And similarly, we can show that $\|B_r^{\beta}(e^{-Rt};x)\|_{C[a,b]} < \infty$.

Hence,

$$\|B_r^{\beta}(e^{R|t|};x)\|_{C[a,b]} \le \|B_r^{\beta}(e^{Rt};x)\|_{C[a,b]} + \|B_r^{\beta}(e^{-Rt};x)\|_{C[a,b]}.$$

Thus,

$$\left\|B_r^{\beta}\left(e^{R|t|};x\right)\right\|_{C[a,b]} < \infty.$$

■

Theorem 3.2: *Let $x \in (0,\infty)$. Let f be a continuous function such that $f''(x)$ exists. Then,*

$$\lim_{r\to\infty} r\left[B_r^{\beta}\left(f(t);x\right)-f(x)\right]=\beta x(1-x)f'(x)+\frac{1}{2}x(1-x)f''(x).$$

Proof: Using Taylor's expansion, we have

$$f(t)=f(x)+(t-x)f'(x)+\frac{1}{2}(t-x)^2f''(x)+\varepsilon(t,x)(t-x)^2,$$

where $\lim_{t\to x}\varepsilon(t,x)=0$. Taking $t=k/r$, we can write

$$\begin{aligned}B_r^{\beta}\left(f(t);x\right)-f(x)&=f'(x)B_r^{\beta}\left((t-x);x\right)+\frac{f''(x)}{2}B_r^{\beta}\left((t-x)^2;x\right)\\&\quad+B_r^{\beta}\left(\varepsilon(t,x)(t-x)^2;x\right)\\&=\frac{\beta x(1-x)}{r}f'(x)+\left[\frac{x(1-x)}{r}+\frac{\beta x(1-x)(1-x-x^2)}{r^2}\right]\frac{f''(x)}{2}\\&\quad+\sum_{k=0}^{\infty}W_{\beta}(r,x,k)\,\varepsilon\left(\frac{k}{r},x\right)\left(\frac{k}{r}-x\right)^2,\end{aligned}\tag{18}$$

where $\lim_{t\to x}\varepsilon(t,x)=0$.

Now, we will prove that

$$r\sum_{k=0}^{\infty}W_{\beta}(r,x,k)\,\varepsilon\left(\frac{k}{r},x\right)\left(\frac{k}{r}-x\right)^2\to 0\quad\text{as } r\to\infty.\tag{19}$$

Using Holder's inequality,

$$\begin{aligned}&r\sum_{k=0}^{\infty}W_{\beta}(r,x,k)\,\varepsilon\left(\frac{k}{r},x\right)\left(\frac{k}{r}-x\right)^2\\&\le\left(\sum_{k=0}^{\infty}W_{\beta}(r,x,k)\,\varepsilon^3\left(\frac{k}{r},x\right)\right)^{1/3}\left(r^{3/2}\sum_{k=0}^{\infty}W_{\beta}(r,x,k)\left(\frac{k}{r}-x\right)^3\right)^{2/3}.\end{aligned}$$

Since $\lim_{t\to x}\varepsilon(t,x)=0$, we get that $\sum_{k=0}^{\infty}W_{\beta}(r,x,k)\varepsilon^3(\frac{k}{r},x)\to 0$, as $r\to\infty$.

Also, from Remark 2.1, we have

$$\begin{aligned}\left(r^{3/2}\sum_{k=0}^{\infty}W_{\beta}(r,x,k)\left(\frac{k}{r}-x\right)^3\right)^{2/3}&=\left(r^{3/2}\mu_{r,3}(x)\right)^{2/3}\\&=\left(r^{3/2}O\left(\frac{1}{r^2}\right)\right)^{2/3}\\&=O\left(\frac{1}{r^{1/3}}\right)\to 0.\end{aligned}$$

It follows that the limit (19) is true. Thus, using (18) we get the conclusion. ■

4. Categorizing functions according to their level of approximation

The focus of this section is to categorize functions in a manner such that

$$\left\| B_r^{\beta}(f;x) - f(x) \right\| \leq O\left(r^{-\alpha/2}\right).$$

Definition 4.1: Let $f : \langle a,b\rangle \to \mathbb{R}$ and $h > 0$, where $\langle a,b\rangle$ stands for all possibilities of the open/closed intervals (a,b), $[a,b]$, $(a,b]$ and $[a,b)$. Then the modulus of continuity of the function f, of order one is defined as

$$\omega\left(f;h,a,b\right) = \sup_{\substack{t,t+\delta\in\langle a,b\rangle \\ |\delta|\leq h}} \left|f(t) - f(t+\delta)\right|$$

and the modulus of continuity of second order is defined as

$$\omega_2\left(f;h,a,b\right) = \sup_{\substack{t,t+2\delta,\in\langle a,b\rangle \\ |\delta|\leq h}} \left|f(t) - 2f(t+\delta) + f(t+2\delta)\right|,$$

where $\langle a,b\rangle$ collectively denotes the intervals (a,b) or $[a,b]$ or $[a,b)$ etc.

We know, $C[0,\infty)$ denotes the set of all real-valued continuous functions on $[0,\infty)$. In this section, we define the space $(C_R, \|.\|_{C_R})$ as follows:

$$C_R = \left\{ f \in C\left[0,\infty\right) : \exists M > 0 \forall t \in [0,\infty), \left|f(t)\right| \leq Me^{R|t|} \right\},$$

and

$$\left\|f\right\|_{C_R} = \sup\left\{ e^{-R|t|}\left|f(t)\right| : t \in [0,\infty) \right\}.$$

Lemma 4.2: *Suppose that ς and η are positive numbers, $R \geq 0$ and $[a,b] \subset [0,\infty)$. Then,*

$$\sum_{\mathrm{T}_r} W_{\beta}\left(r,x,\frac{k}{r}\right) e^{R\frac{k}{r}} = O\left(r^{-\varsigma}\right)$$

uniformly on $[a,b]$ as $r \to \infty$, where

$$\mathrm{T}_r = \left\{ k : \left|\frac{k}{r} - x\right| \geq \eta; k = 0,1,\ldots \right\}.$$

Proof: From the definition of T_r and Theorem 2.3, we have that

$$\sum_{\mathrm{T}_r} W_{\beta}\left(r,x,\frac{k}{r}\right) \leq r^{-4\varsigma}\eta^{-4\varsigma} A_{4\varsigma}\left(r,x\right).$$

Also, by Theorem 3.1, as $r \to \infty$, we get

$$\sum_{\mathrm{T}_r} W_{\beta}\left(r,x,\frac{k}{r}\right) e^{2R\frac{k}{r}} < \infty.$$

Thus, by Cauchy–Schwarz's inequality and Remark 2.1,

$$\sum_{\mathrm{T}_r} W_{\beta}\left(r,x,\frac{k}{r}\right) e^{R\frac{k}{r}} \leq \left(\sum_{\mathrm{T}_r} W_{\beta}\left(r,x,\frac{k}{r}\right)\right)^{1/2} \left(\sum_{\mathrm{T}_r} W_{\beta}\left(r,x,\frac{k}{r}\right) e^{2R\frac{k}{r}}\right)^{1/2}$$

$$\leq \left(r^{-4\varsigma}\eta^{-4\varsigma}A_{4\varsigma}(r,x)\right)^{1/2}\left(B_r^{\beta}(e^{2R\frac{k}{r}};x)\right)^{1/2}$$
$$= O\left(r^{-\varsigma}\right) \quad \text{as } r\to\infty.$$

This completes the proof. ■

Theorem 4.3: *Suppose that $f \in C_R$ and $0 < a < a_1 < b_1 < b < \infty$. Then, for every $\varsigma > 0$ there exists a constant K_ς, such that*

$$\left\|B_r^{\beta}(f,x)-f(x)\right\|_{C_{[a_1,b_1]}} \leq K_\varsigma\left[r^{-1/2}\omega\left(f;r^{-1/2},a,b\right)+\omega_2\left(f;r^{-1/2},a,b\right)+r^{-\varsigma}\|f\|_{C_R}\right].$$

Proof: Let $\delta > 0$. Define,

$$g_\delta(x)=\frac{1}{2\delta^2}\int_{-\delta/2}^{\delta/2}\int_{-\delta/2}^{\delta/2}\left[f(x+u+v)+f(x-u-v)\right]\mathrm{d}u\,\mathrm{d}v.$$

By the linearity of our operators B_r^{β}, it follows that

$$\begin{aligned}&\left\|B_r^{\beta}(f;x)-f(x)\right\|_{C_{[a_1,b_1]}}\\ &\leq \left\|B_r^{\beta}(f-g_\delta;x)\right\|_{C_{[a_1,b_1]}}+\left\|B_r^{\beta}(g_\delta;x)-g_\delta(x)\right\|_{C_{[a_1,b_1]}}+\|g_\delta-f\|_{C_{[a_1,b_1]}}\\ &= I_1+I_2+I_3. \end{aligned} \tag{20}$$

For I_1, we consider

$$\left|B_r^{\beta}(f;x)-B_r^{\beta}(g_\delta;x)\right|=\sum_{k=0}^{\infty}W_\beta\left(r,x,\frac{k}{r}\right)\left|f(k/r)-g_\delta(k/r)\right|.$$

Let us define,

$$\Gamma_r=\left\{k:\left|\frac{k}{r}-x\right|<\eta;k=0,1,\ldots\right\}$$

and

$$\mathrm{T}_r=\left\{k:\left|\frac{k}{r}-x\right|\geq\eta;k=0,1,\ldots\right\}.$$

Then,

$$\begin{aligned}&\left|B_r^{\beta}(f;x)-B_r^{\beta}(g_\delta;x)\right|\\ &\leq\sum_{\Gamma_r}W_\beta\left(r,x,\frac{k}{r}\right)\left|f(k/r)-g_\delta(k/r)\right|+\sum_{\mathrm{T}_r}W_\beta\left(r,x,\frac{k}{r}\right)\left|f(k/r)-g_\delta(k/r)\right|\\ &= L_1+L_2.\end{aligned}$$

For L_1, $\frac{k}{r}\in[x-\eta,x+\eta]\subset[a_1-\eta,b_1+\eta]$. Hence, we can state that

$$L_1\leq\frac{1}{2}\omega_2\left(f;\delta,a,b\right).$$

Now, since $f-g_\delta\in C_R$, it follows $|(f-g_\delta)(\frac{k}{r})|e^{-R\frac{k}{r}}\leq 4\|f\|_{C_R}$.

And thus, for a constant M, using Lemma 4.2, we can write L_2 as

$$\begin{aligned} L_2 &= \left| \sum_{\mathrm{T}_r} W_\beta \left(r, x, \frac{k}{r} \right) e^{R\frac{k}{r}} \left| f - g_\delta \right| (k/r)\, e^{-R\frac{k}{r}} \right| \\ &\leq 4Mr^{-\varsigma} \left\| f \right\|_{C_R}. \end{aligned}$$

Hence,

$$\left\| B_r^\beta (f;x) - B_r^\beta (g_\delta;x) \right\|_{C_{[a_1,b_1]}} \leq \frac{1}{2}\omega_2 \left(f;\delta,a,b \right) + 4Mr^{-\varsigma} \left\| f \right\|_{C_R},$$

which gives the following estimate of I_1:

$$I_1 \leq M_1 \left(\omega_2 \left(f;\delta,a,b \right) + r^{-\varsigma} \left\| f \right\|_{C_R} \right). \tag{21}$$

Now, to estimate I_2, we consider the first and second derivative of $g_\delta(x)$

$$\begin{aligned} {g_\delta}'(x) = \frac{1}{2\delta^2} \int_{-\delta/2}^{\delta/2} \left[f\left(x+u+\frac{\delta}{2} \right) - f\left(x+u-\frac{\delta}{2} \right) \right] \mathrm{d}u \\ - \frac{1}{2\delta^2} \int_{-\delta/2}^{\delta/2} \left[f\left(x-u+\frac{\delta}{2} \right) - f\left(x-u-\frac{\delta}{2} \right) \right] \mathrm{d}u. \end{aligned}$$

Hence, for $x \in [a_1 - \eta, b_1 + \eta]$, we have

$$\left\| {g_\delta}'(x) \right\|_{C_{[a_1-\eta,b_1+\eta]}} \leq \frac{1}{\delta}\omega \left(f;\delta,a,b \right).$$

Moreover,

$${g_\delta}''(x) = \frac{1}{\delta^2} \left[f\left(x-\delta \right) - 2f(x) + f\left(x+\delta \right) \right],$$

and

$$\left\| {g_\delta}''(x) \right\|_{C_{[a_1-\eta,b_1+\eta]}} \leq \frac{1}{\delta^2}\omega_2 \left(f;\delta,a,b \right).$$

By the definition of semi-exponential operators and Taylor's expansion, we have

$$\begin{aligned} &\left| B_r^\beta \left(g_\delta;x \right) - g_\delta \left(x \right) \right| \\ &= \left| \sum_{k=0}^{\infty} W_\beta \left(r, x, \frac{k}{r} \right) \left[g_\delta \left(k/r \right) - g_\delta \left(x \right) \right] \right| \\ &\leq \left| \sum_{k=0}^{\infty} W_\beta \left(r, x, \frac{k}{r} \right) \left(\frac{k}{r} - x \right) {g_\delta}' \left(x \right) \right| + \left| \sum_{\Gamma_r} W_\beta \left(r, x, \frac{k}{r} \right) \left(\frac{k}{r} - x \right)^2 {g_\delta}'' \left(x \right) \right| \\ &\quad + \left| \sum_{\mathrm{T}_r} W_\beta \left(r, x, \frac{k}{r} \right) \left(\frac{k}{r} - x \right)^2 {g_\delta}'' \left(x \right) \right| \\ &= S_1 + S_2 + S_3. \end{aligned}$$

For $x \in [a_1 - \eta, b_1 + \eta]$ and some constant M, we obtain,

$$S_1 = \left| g_\delta{}'(x)\, r^{-1} A_1(r,x) \right| \le \frac{M r^{-1}}{\delta} \omega\left(f;\delta,a,b\right).$$

Whereas, for $x \in [a_1, b_1]$ and some constant K,

$$S_2 = \left| g_\delta{}''(x)\, r^{-2} A_2(r,x) \right| \le \frac{K r^{-1}}{\delta^2} \omega_2\left(f;\delta,a,b\right).$$

Following Theorem 2.3 and Lemma 4.2, we can write,

$$\begin{aligned} S_3 &= \left| \sum_{\mathrm{T}_r} W_\beta\left(r,x,\frac{k}{r}\right)\left(\frac{k}{r}-x\right)^2 g_\delta{}''(x) \right| \\ &\le 4\left\|f\right\|_{C_R} \left| \left(\sum_{\mathrm{T}_r} W_\beta\left(r,x,\frac{k}{r}\right) e^{2r} \right)^{1/2} \left(r^{-4} A_4(r,x)\right)^{1/2} \right| \\ &\le L r^{-\varsigma} \left\|f\right\|_{C_R}. \end{aligned}$$

Thus, finally there exists M_2, such that

$$I_2 \le M_2 \left[\frac{r^{-1}}{\delta} \omega\left(f;\delta,a,b\right) + \frac{r^{-1}}{\delta^2} \omega_2\left(f;\delta,a,b\right) + r^{-\varsigma} \left\|f\right\|_{C_R} \right]. \tag{22}$$

To estimate I_3, let $\eta = \frac{1}{2}\min\{a_1 - a, b - b_1\}$.

Then, for $x \in [a_1 - \eta, b_1 + \eta]$, we have

$$\left| f(x) - g_\delta(x) \right| = \left| \frac{1}{2\delta^2} \int_{-\delta/2}^{\delta/2} \int_{-\delta/2}^{\delta/2} \left[f(x+u+v) - 2f(x) + f(x-u-v) \right] \mathrm{d}u\, \mathrm{d}v \right|.$$

By the limits of u and v, we have $|u+v| \le \delta$. Thus, using the definition of second order modulus of continuity,

$$\begin{aligned} \left| f(x) - g_\delta(x) \right| &\le \frac{1}{2\delta^2} \int_{-\delta/2}^{\delta/2} \int_{-\delta/2}^{\delta/2} \omega_2\left(f;\delta,a,b\right) \mathrm{d}u\, \mathrm{d}v \\ &= \frac{1}{2} \omega_2\left(f;\delta,a,b\right). \end{aligned}$$

It follows that

$$I_3 \le \frac{1}{2} \omega_2\left(f;\delta,a,b\right). \tag{23}$$

Putting $\delta = r^{-1/2}$ in estimation (21), (22), (23) and using (20) we get the conclusion. ■

Particularly, this theorem highlights that, if $\omega_2(f;h,a,b) = O(h^\alpha)$ then we can say that $\|B_r^\beta(f;x) - f(x)\|_{C[a_1,b_1]} = O(r^{-\alpha/2})$. The converse of the above statement is also true and is proved next. But first let us define the Zygmund class of functions.

Definition 4.4: Let $0 < \alpha < 2$. The Zygmund class, $Lip^*\alpha$ is defined as

$$Lip^*(\alpha;a,b) = \left\{ f : \omega_2\left(f;h,a,b\right) \le M h^\alpha \right\}.$$

Theorem 4.5: *Let $0 < a < a_1 < b_1 < b < \infty$, $0 < \alpha < 2$ and $f \in C_R$. Then the following are all equivalent statements:*

(i) $f \in Lip^*(\alpha; a_1, b_1)$
(ii) $\|B_r^\beta(f;x) - f(x)\|_{C[a_1,b_1]} = O(r^{-\alpha/2})$

Proof: We have already seen that (*i*) implies (*ii*). We are only left to prove that (*ii*) implies (*i*). Let,

$$\left\| B_r^\beta\left(f;x\right) - f(x) \right\|_{C[a_1,b_1]} \leq M_1 r^{-\alpha/2}.$$

We need to find an upper bound for the first order modulus of continuity of f.

Let $x, y \in [0,\infty)$ be such that $|y - x| \leq h$. Then,

$$\begin{aligned}
&\left|f\left(y\right) - f\left(x\right)\right| \\
&\quad \leq \left|f\left(y\right) - B_r^\beta\left(f;y\right)\right| + \left|B_r^\beta\left(f;y\right) - B_r^\beta\left(f;x\right)\right| + \left|B_r^\beta\left(f;x\right) - f\left(x\right)\right| \\
&\quad \leq 2M_1 r^{-\alpha/2} + P.
\end{aligned}$$

To calculate P, let us use the PDE (5) and examine $|(B_r^\beta)'(f;x)|$. We have

$$\begin{aligned}
\left|\left(B_r^\beta\right)'\left(f;x\right)\right| &= \left|\sum_{k=0}^{\infty} \frac{\partial}{\partial x} W_\beta\left(r,x,k/r\right) f\left(\frac{k}{r}\right)\right| \\
&= \left|\frac{r}{x(1-x)} \sum_{k=0}^{\infty} W_\beta\left(r,x,k/r\right)\left(\frac{k}{r} - x\right) f\left(\frac{k}{r}\right) - \beta \sum_{k=0}^{\infty} W_\beta\left(r,x,k/r\right) f\left(\frac{k}{r}\right)\right| \\
&\leq \left|\frac{r}{x(1-x)} \sum_{k=0}^{\infty} W_\beta\left(r,x,k/r\right)\left(\frac{k}{r} - x\right)\left(f\left(\frac{k}{r}\right) - f\left(x\right)\right)\right| \\
&\quad + \left|\frac{r}{x(1-x)} \sum_{k=0}^{\infty} W_\beta\left(r,x,k/r\right)\left(\frac{k}{r} - x\right) f\left(x\right) - \beta \sum_{k=0}^{\infty} W_\beta\left(r,x,k/r\right) f\left(\frac{k}{r}\right)\right|.
\end{aligned}$$

Also, from Theorem 2.3, we get

$$\begin{aligned}
\sum_{k=0}^{\infty} W_\beta\left(r,x,k/r\right)\left(\frac{k}{r} - x\right) f\left(x\right) &= \frac{A_1\left(r,x\right)}{r} f\left(x\right) \\
&= \frac{\beta}{r} x\left(1-x\right) f\left(x\right).
\end{aligned}$$

Using the property $\omega(\lambda\delta) \leq [1+\lambda]\omega(\delta)$, we can write

$$\omega\left(\left|\frac{k}{r} - x\right|\right) \leq \left[1 + r\left|\frac{k}{r} - x\right|\right] \omega\left(r^{-1}\right). \tag{24}$$

Thus,

$$\left|\left(B_r^\beta\right)'\left(f;x\right)\right| \leq \frac{r}{x(1-x)} \sum_{k=0}^{\infty} W_\beta\left(r,x,k/r\right)\left|\frac{k}{r} - x\right| \omega\left(f;\left|\frac{k}{r} - x\right|, a, b\right)$$

$$
\begin{aligned}
&+\left|\beta f(x)-\beta\sum_{k=0}^{\infty}W_\beta(r,x,k/r)f\left(\frac{k}{r}\right)\right|\\
&\le\frac{r}{x(1-x)}\sum_{k=0}^{\infty}W_\beta(r,x,k/r)\left|\frac{k}{r}-x\right|\omega\left(f;\left|\frac{k}{r}-x\right|,a,b\right)+\beta M_1r^{-\alpha/2}\\
&\le\frac{r}{x(1-x)}\sum_{k=0}^{\infty}W_\beta(r,x,k/r)\left|\frac{k}{r}-x\right|\left[1+r\left|\frac{k}{r}-x\right|\right]\omega\left(f;\left|\frac{1}{r}\right|,a,b\right)\\
&\quad+\beta M_1r^{-\alpha/2}\\
&\le rM_2\omega\left(f;\left|\frac{1}{r}\right|,a,b\right)\sum_{k=0}^{\infty}W_\beta(r,x,k/r)\left|\frac{k}{r}-x\right|\left[1+r\left|\frac{k}{r}-x\right|\right]\\
&\quad+\beta M_1r^{-\alpha/2}\\
&\le rM_2\omega\left(f;\left|\frac{1}{r}\right|,a,b\right)\left[A_1(r,x)+\frac{A_2(r,x)}{r}\right]+\beta M_1r^{-\alpha/2}\\
&\le M_3\left[r\omega\left(f;\left|\frac{1}{r}\right|,a,b\right)+r^{-\alpha/2}\right].
\end{aligned}
$$

Now, for $|y-x|\le h$,

$$
\begin{aligned}
P&=\left|B_r^\beta(f;y)-B_r^\beta(f;x)\right|\\
&=\left|\int_x^y B_r^{\beta'}(f;\xi)\,\mathrm{d}\xi\right|\\
&\le\int_x^y\left|B_r^{\beta'}(f;\xi)\right|\mathrm{d}\xi\\
&\le\int_x^y M_3\left[r\omega\left(f;\left|\frac{1}{r}\right|,a,b\right)+r^{-\alpha/2}\right]\mathrm{d}\xi\\
&=M_3r\omega\left(f;\left|\frac{1}{r}\right|,a,b\right)|y-x|+M_3r^{-\alpha/2}|y-x|\\
&\le M_3rh\omega\left(f;\left|\frac{1}{r}\right|,a,b\right)+M_3r^{-\alpha/2}.
\end{aligned}
$$

Hence,

$$
\begin{aligned}
\omega(f;h,a,b)&\le|f(y)-f(x)|\\
&\le M'\left[rh\omega\left(f;\left|\frac{1}{r}\right|,a,b\right)+r^{-\alpha/2}\right].
\end{aligned}
$$

Next we will prove, if $\omega(f;h,a,b)\le M'[rh\omega(f;|\frac{1}{r}|,a,b)+r^{-\alpha/2}]$ then, for $0<h\le1$ and $r>1$, we have that $f\in Lip^*(\alpha;a,b)$.

Let $K>1$ be such that $2M'<K^{1-\alpha}$. Choose $M''=\max\{\omega(f;1,a,b),2M'K^\alpha\}$ and define $h_m=K^{-m}$ for $m=1,2,\ldots$.

Using the principle of mathematical induction, we can easily show that for every positive integer m,

$$\omega(f;h_m,a,b)\le M''h_m^\alpha.$$

Now, for every $0 < h \leq 1$, there exists an integer $m > 0$ such that $h_m < h \leq h_{m-1}$.

Thus we can imply that,

$$\begin{aligned}\omega\left(f;h,a,b\right) &\leq \omega\left(f;h_{m-1},a,b\right)\\ &\leq M''h_{m-1}^{\alpha}\\ &= M''K^{\alpha}h_m^{\alpha}\\ &< M'''h^{\alpha}.\end{aligned}$$

Since,

$$\begin{aligned}\left|f\left(t\right)-2f\left(t+\delta\right)+f\left(t+2\delta\right)\right| &\leq \left|f\left(t\right)-f\left(t+\delta\right)\right|+\left|f\left(t+\delta\right)-f\left(t+2\delta\right)\right|\\ &\leq 2\omega\left(f;h,a,b\right)\\ &\leq 2M'''h^{\alpha}.\end{aligned}$$

We get,

$$\omega_2\left(f;h,a,b\right) \leq Ch^{\alpha}.$$

Thus, $f \in Lip^{*}(\alpha;a,b)$. With this, we have shown that the conclusion is true. ■

ABSTRACT

The goal of intelligent transportation systems is becoming more and more realized with the use of the Internet of Vehicles (IoV) and the rapid advancement of processing and communication technologies. Nonetheless, a lot of Internet of Vehicles applications depend on a central processing and storage unit as well as wireless transmission mediators. This may result in exorbitant expenses and delays, as well as the disclosure of real data. We suggest the Vehicle-Based Quantum-Safe Blockchain Consensus (VBQBC) algorithm as a solution to these problems and an enhancement of the effectiveness of data storage, authentic processing, and data sharing in the Internet of Vehicles. The proposed VBQBC algorithm uses a consensus algorithm and blockchain technology to assure authentic communication between cars, overcoming the shortcomings and constraints of current state-of-the-art systems. This algorithm uses ring learning with errors, and short integer solution assumptions in the construction of aggregation signatures to provide authenticity in blockchain technology. This aggregation technique reduces the size of data required for verification and improves scalability. The algorithm also incorporates a quantum-safe authentication procedure as well as a key distribution and request process, which are demonstrated when vehicles move between different zones. This allows blockchain-based systems to maintain their security, scalability, and efficiency even in the face of future cryptographic problems. The aggregation of signatures size for the proposed framework to the number of signatures to be aggregated N varies between 2^{10} (63.48 kb) and 2^{20} (131.34 kb). For aggregation of 2^{10} signatures, the proposed framework has signature size 6.3 kb, and the aggregated size of signatures is 64 kb. In simulation findings, our suggested VBQBC algorithm outperformed previous techniques in terms of authentication delay, key processing time, attack detection rate, throughput, and packet loss rate.

1 | Introduction

The concept of aggregated signatures was first introduced by Boneh et al. [1] in 2003. The aggregated signatures they proposed merge multiple signatures tied to different messages into a single signature, enabling the authentication of several message-signature pairs belonging to different users in one process. This innovation minimizes the storage space needed for signatures, reduces the network bandwidth needed for data transmission, and decreases the number of signature verification processes required. Aggregated signature technology serves not only as a method for signature compression but also as a technique for batch processing of signatures, catering to the demands for rapid data authentication in today's big data landscape,

© 2025 John Wiley & Sons Ltd.

particularly in areas like the Internet of Things, cloud computing, and blockchain technology. The aggregation of signature offers numerous possible applications, such as signing contracts, establishing trust routes, distributing certificate authorities, and utilizing blockchain technology [2, 3]. Blockchain technology brings transformative advantages to the Internet of Vehicles (IoV) by addressing critical challenges in data security, communication, and trust management within the vehicular ecosystem.

The IoV is a network where vehicles, infrastructure, and other entities interact to enable autonomous driving, efficient traffic management, and advanced vehicular services. The IoV represents a significant advancement in vehicular technology, offering numerous benefits such as enhanced safety, optimized traffic management, and improved driving experiences. The widespread adoption of (IoV) has revolutionized Intelligent Transportation Systems (ITS) in the coming years by enabling V2V (vehicle to vehicle) communication, and V2I (vehicle to infrastructure) communication. It directly addresses the increasing demand for smarter and efficient intelligent transportation system [4–7]. With the rapid growth of smart vehicles, the volume of data exchange will increase exponentially. The vast amount of data generated by IoV systems poses significant data management challenges.

Blockchain eliminates the need for centralized servers, ensuring that vehicle-related data and services are distributed across a network of nodes [8]. This technology helps to coordinate vehicle movement in smart cities by securely sharing data about traffic flow and congestion. This technology also enhances IoV by providing a secure, decentralized, and trustworthy framework for data exchange and collaboration among the participants. But, with the advent of quantum computing algorithm, traditional cryptographic schemes like RSA or ECC-based aggregate signatures algorithms are vulnerable to quantum attacks [9]. Lattice-based cryptographic techniques and aggregate signature algorithms are being explored for quantum-resistant solutions. Post-quantum cryptography, such as lattice-based algorithms, can future-proof IoV systems against quantum computing threats. Therefore, we need a quantum-safe blockchain-based distributed, scalable, flexible, and adaptable architecture to get rid of this big data exchange, and its storage. The scalability concerns include maintaining low latency in communication, managing network congestion, and ensuring reliable data transmission across the network [10].

1.1 | Motivation

The IoV envisions a highly connected ecosystem where vehicles, infrastructure, pedestrians, and other entities interact seamlessly to enhance safety, efficiency, and user experience. However, the realization of IoV comes with significant challenges related to security, privacy, scalability, and trust. Blockchain technology provides a robust solution to these issues, serving as a foundation for secure and decentralized IoV communication. The motivation for integrating blockchain technology into IoV stems from its ability to address critical challenges in security, trust, and efficiency while enabling innovative use cases like autonomous payments, and decentralized data sharing. By leveraging blockchain, IoV can realize its full potential as a secure, scalable, and collaborative transportation ecosystem. Although, there are many blockchain based solutions for IoV, but they are based on number theoretic cryptosystems. Shor's algorithm invents a significant theoretical threat to existing cryptosystems based on integer factorization and discrete logarithm. While practical quantum computer is capable of running Shor's algorithm at a threatening scale do not yet exist, the rapid advancement in quantum computing necessitates proactive measures. Transitioning to quantum-resistant cryptography and preparing infrastructure for post-quantum security are crucial steps to mitigate the potential future risks posed by quantum computing advancements. Post-quantum cryptography, such as lattice-based algorithms, can future-proof IoV systems against quantum computing threats. Moreover, there are some lattice-based quantum-safe blockchain frameworks exist, but either they are not scalable or vulnerable to well-known attacks. Therefore, we need a quantum-safe blockchain-based distributed, scalable, flexible, and adaptable architecture to get rid of this big data exchange, and its storage. The scalability concerns include maintaining low latency in communication, managing network congestion, and ensuring reliable data transmission across the network.

1.2 | Contribution

In the proposed framework, we have proposed a quantum-safe blockchain-based distributed, scalable, flexible, and adaptable architecture to get rid of this big data exchange, and its storage. This framework also solves scalability concerns include maintaining low latency in communication, managing network congestion, and ensuring reliable data transmission across the network.

- The proposed algorithm utilizes blockchain technology to provide a secure authentication scheme with low latency. In the performance section, we have given details of parameters and comparison of the proposed framework with related protocols in terms of blocks, and read latency. The proposed algorithm possesses low read latency, it deploy aggregation of signatures, which are faster than other existing ones, results approximately 60.5% faster reading time for blocks.
- The proposed aggregation technique produces single compact signature, while ensuring authenticity of communication. This technique is proven to be secure in the model "existential unforgeability under chosen-message and chosen identity attack" means if M-LWE and M-SIS assumptions are hard then proposed aggregation of signature framework is secure.
- The proposed framework uses M-LWE and M-SIS assumptions those are more standard lattice based problems and increase both security and efficiency due to simple algebraic operations (additions and multiplications). The proposed framework avoids linear compression idea that is frequently used to existing versions.
- The concept is based on zone-based architecture, and aggregation of quantum safe signatures to provide better latency, attack detection rate, and enhanced authentication in ITS. Every authentication procedure between vehicles and controllers will only be permitted in the designated zones in

15320634, 2025, 9-11, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.70071 by Delhi Technological University, Wiley Online Library on [30/04/2025]. order to minimize overhead and the number of nodes. This greatly optimizes processing time when vehicles join or depart.

- Finally, the blockchain based implementation of the proposed aggregation of signatures illustrates its practical application in IoV environment.

2 | Related Work

To address data security and efficiency issues in the Internet of Vehicles (IoV), a novel blockchain-based consensus algorithm was proposed in [11]. This solution calls for the creation of a vehicle-centered consensus mechanism. It also introduces a strategy for managing vehicle migration between regions, with the goal of reducing the overhead associated with frequent re-authentication during regional transitions. However, the proposed scheme lacks a formal security proof. Additionally, as the speed of the moving car is higher, some issues appear connected with the stability of the wireless connection, the safety and the reliability of the verification and migration steps. Some of these limitations may greatly impact the general efficiency and reliability of the solution. Due to the high speed of vehicles, constant checking with various types of roadside units is unavoidable, resulting in significant computation and communication costs. These increased demands may cause congestion in interactions between vehicles and roadside units, reducing overall system performance and efficiency. On a similar basis, Roy et al. [12] established the blockchain decentralized storage system and created BACHP-IoV, a lightweight access control protocol based on ECDSA (elliptic curve based digital signature algorithm). The effectiveness of this protocol in the security domain was later confirmed using the Real or Random Model. However, the following study did not address the security of message transmission between vehicles, leaving an unresolved issue. Yang et al. [13] presented an authentication architecture for vehicles that is flexible to multi-domain scenarios and addresses the cross-domain authentication problem. With the use of blockchain technology, it became possible to share information across many domains of management with decentralized trust. To address the issue of anonymity and traceability at the same time, the framework built an authentication solution, a pseudonym allocation mechanism based on ECDLP. A new dual-chain architecture described in [14] is used to handle vehicle authentication and message exchange in the Internet of Vehicles. It utilizes two blockchains: Car registration uses the Registration Blockchain (RBC), whereas message management prefers the Message Blockchain (MBC). The system prevents and mitigates fraud by combining the Proof of Authority (POA) and Proof of Participation (POP) consensus procedures. Nonetheless, the issue of performance enhancement for the dual-chain system was outside the purview of the study, allowing for a suggestion of an improvement. To address identity authentication difficulties in the Internet of Vehicles (IoV) using 6G technology, the scheme [15] introduced a multi-domain authentication solution with conditional privacy protection. The system splits the Blockchain-assisted multi-domain network into management and geographical domains, and it proposes an identity signature authentication approach that does not require bilinear pairing. Furthermore, Tao et al. [16] proposed a dynamic method for message verification that employs the Chinese Remainder Theorem to ensure message integrity. They also presented a blockchain approach for protecting automotive data on a large scale while maintaining privacy, as well as a smart contract enabling car traceability during postmortem investigations. Thus, the scheme's great efficiency was obtained by utilizing elliptic curve point multiplication to explain the computation burden of the RSUs. However, it failed to defend against quantum algorithm concerns, indicating that the system is not secure in the future.

But all of the above discussed frameworks are based on number-theoretic assumption like RSA/DLP which are not secure against quantum attacks. A post-quantum blockchain is a forward-looking approach to securing blockchain ecosystems against future quantum threats. It blends advanced cryptographic techniques from lattice theory, and secure hashing to create a resilient and scalable platform for decentralized applications. In [17], authors have proposed a lattice based approach to enforce anonymous authentication for VANET with vulnerable security and privacy prerequisites. Again a novel DiLSe method for safe distribution of data in IoV was introduced in [18], and it uses lattice theory for secure distribution, deep learning for content management, fault-tolerant data replication, access control, and Blockchain supported key exchange. In the same year 2023, Kaur et al. [19] introduced an authenticated architecture for transmitting sensitive data and a significant transformation using blockchain, but they lacks in blockchain testing. In the view of edge-based computing, Liu et al. [20] proposed a group-based blockchain framework. This idea is capable to provide decentralized identity based on secret information and a dynamic representation for IoV system, but it lacks the concept of shared driving. In the year 2021, Li et al. [21] proposed a post quantum secure lattice-Based aggregation of signatures, but communication cost is high, and public/private key size is bigger, consensus algorithm is missing. In [22], Wen et al. developed the first upper lattice ring signature scheme with forced revocation and proved it to possess the theoretical properties such as anonymity, unforgeability and revocability via random oracle model. This method has been used with IoV to design the first PQC secure against chosen plain text attack that solely relies on ring signatures. However, they face several challenges including high costs of computing and communication in the network environment as well as the stringent mobility and security constraints of vehicular networks. In 2024, Prajapat et al. [23] proposed a new NTRU lattice-based aggregation of signatures, but the size of signature increases during aggregation. Chen et al. [24] proposed protocol incorporates identity authentication functionality and effectively integrates the cross-domain authentication characteristics of the Blockchain. Initially, the Trusted Authority (TA) uploads the registration information of vehicles onto the Blockchain to verify the authenticity of a vehicle's identity by examining the data stored in the Blockchain. This is an authentication protocol, but it does not supports aggregation and batch verification process. Most of these methods fail to provide a decentralized nature of blockchain in authentication [19, 20, 25]. Private blockchains [19, 20, 25] have been used to solve these issues of privacy. Therefore, especially for vehicular communication, the proposed framework helps to resolve vehicular network authentication related challenges, specifically for use in autonomous vehicle-to-vehicle communication. This paper contains analysis on post-quantum blockchain [21, 23, 26–29] and attempted to implement them in authenticated vehicle-to-vehicle communication.

3 | Preliminaries

Learning with Errors (LWE) is a fundamental assumption in cryptography, and it forms the basis for many post-quantum cryptographic encryption/signature schemes, including some signature that could potentially be used for aggregate signatures in blockchain technology.

The Learning with Errors assumption is to find a secret vector $\mathbf{s}$ from noisy linear equations. Specifically, for a given matrix $\mathbf{A}$ and a vector $\mathbf{c}$, the aim is to finding $\mathbf{s}$ such that:

$$\mathbf{A} \cdot \mathbf{s} \equiv \mathbf{c} (\mathrm{mod}\, q)$$

where, $\mathbf{A}$ is a rectangular $m \times n$ matrix with entries from a finite ring $\mathbb{Z}_q$ (integers modulo prime q), $\mathbf{s}$ is an n-dimensional tuple, $\mathbf{c}$ is an m-dimensional tuple, and q is a prime modulus parameter.

- *Noise Addition*: The tuple $\mathbf{c}$ includes a noisy tuple $\mathbf{e}$ such that $\mathbf{c} = \mathbf{A} \cdot \mathbf{s} + \mathbf{e}$, where $\mathbf{e}$ is a small random vector. The noise $\mathbf{e}$ makes the assumption computationally hard to solve without knowledge of $\mathbf{s}$.
- *Hardness Assumption*: The security of LWE-based cryptosystem depends upon the assumption that it is computationally hard to distinguish $\mathbf{c}$ from uniformly random vectors in $\mathbb{Z}_q^m$, even with known matrix $\mathbf{A}$.
- *Parameter Choices*: The security of LWE depends on choosing suitable parameters m, n, and q. In general, n is dimension of $\mathbf{s}$ chosen to be larger than m is number of equations, and $q = 2^n$ is a large prime.

3.1 | Learning With Errors (LWE) Assumption

The Learning With Errors (LWE) assumption is a lattice based fundamental assumption in cryptography.

Definition 1. Let us consider parameters $n, m, q \in \mathbb{N}$, then $\mathrm{LWE}_{n,m,q}$ assumption is given n samples (a_i, b_i) where $a_i \leftarrow \mathbb{Z}_q^n$ and $b_i = \langle a_i, s \rangle + e_i \mod q$, with $s \leftarrow \mathbb{Z}_q^n$ and $e_i \leftarrow \chi$, distinguish whether $b_i \leftarrow \mathbb{Z}_q$ or $b_i \leftarrow \mathbb{Z}_q$ with non-negligible advantage.

Here, $\langle \cdot, \cdot \rangle$ denotes the general inner product, χ represents a noise distribution over $\mathbb{Z}_q$.

3.2 | Short Integer Solution (SIS) Assumption

The Short Integer Solution (SIS) assumption is another lattice based fundamental problem in cryptography.

Definition 2. Let us consider parameters $n, m, q \in \mathbb{N}$, then $\mathrm{SIS}_{n,m,q}$ assumption is given a uniformly random matrix $A \leftarrow \mathbb{Z}_q^{n \times m}$, find a non-zero vector $\mathbf{s} \in \mathbb{Z}^m$ satisfying:

- $A \cdot \mathbf{s} \equiv \mathbf{0} \pmod q$,
- $\| \mathbf{s} \| \leq \beta$,

where, $\| \cdot \|$ denotes the ℓ_2-norm and β is a parameter.

3.3 | Module Learning With Errors (M-LWE) Problem

The Module Learning With Errors (M-LWE) assumption is another variant of the Learning With Errors (LWE) assumption, which is a lattice based foundational problem in modern cryptography. Here's a description of what M-LWE involves:

Definition 3. Let us consider $k, \ell, \eta \in \mathbb{N}$, then $\mathrm{M\text{-}LWE}_{k,\ell,\eta}$ is defined for a random matrix $A \leftarrow \mathbb{R}_q^{k \times \ell}$ and a vector $t \in \mathbb{R}_q^k$, distinguish whether:

1. $t \leftarrow \mathbb{R}_q^k$, or
2. $t = \left[A | I_\ell\right] \cdot \mathbf{s}$,

where, $\mathbf{s} \leftarrow S_{\ell+k}^{\eta}$.

The distribution $S_{\ell+k}^{\eta}$ denotes vectors of length $\ell + k$ with entries from $\mathbb{Z}_q$ and a small error term from discrete Gaussian.

3.4 | Module Short Integer Solution (M-SIS) Problem

The Module Short Integer Solution (M-SIS) assumption is another fundamental problem in the field of lattice-based cryptography, closely related to the Learning With Errors (LWE) assumption. Here's a detailed description of what the M-SIS problem entails:

Definition 4. Let us consider parameters $k, \ell, b \in \mathbb{N}$, then $\mathrm{M\text{-}SIS}_{k,\ell,b}$ is defined for uniform randomly chosen matrix $A \leftarrow \mathbb{R}_q^{k \times \ell}$, find a non-zero small $\mathbf{s} \in \mathbb{R}_q^{k+\ell}$ satisfying:

- $\| \mathbf{s} \|_2 \leq b$,
- $\left[A | I_\ell\right] \cdot \mathbf{s} = \mathbf{0} \in \mathbb{R}_q^k$.

Here, I_ℓ represents the $\ell \times \ell$ identity matrix.

3.5 | Preliminaries on Aggregate Signatures

Aggregation of signatures involves the process to combine multiple signatures into a single compact signature. Here, we have discussed some mathematical notations, concepts and definitions related to aggregation of signatures:

1. *Digital Signature Algorithm*: A digital signature algorithm is a basic cryptographic method used to provide authenticity, integrity, and non-repudiation of messages or documents transferred on public channel. Here, we have discussed that how a digital signature algorithm typically works and some of its key components:
   - *Key Generation Process*: $\mathrm{Gen}(1^\kappa) \rightarrow (s\kappa, p\kappa)$, where $s\kappa$, and $p\kappa$ are private and public keys respectively.
   - *Signature Algorithm*: $\mathrm{Sign}_{s\kappa}(m) \rightarrow \sigma$, where σ is the signature on the message m using private key $s\kappa$.
   - *Verification Algorithm*: $\mathrm{Verify}_{p\kappa}(m, \sigma) \rightarrow \{\mathrm{True}, \mathrm{False}\}$, does the verification of σ for message m using public key $p\kappa$.

15320634, 2025, 9-11, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.70071 by Delhi Technological University, Wiley Online Library on [30/04/2025]. ALGORITHM 1 | Aggregation of signatures.

0: **procedure** AGGREGATE-SIGNATURE-GENERATION (Messages $\{m_1, m_2, \ldots, m_n\}$, Keys $\{sk_1, sk_2, \ldots, sk_n\}$)
1: Initializes $\sigma_{agg} \leftarrow$ Identity of the signature group
1: **for** $i = 1 \rightarrow n$ **do**
2: Computes $\sigma_i \leftarrow \text{Sign}(m_i, sk_i)$
3: $\sigma_{aggs} \leftarrow \sigma_{aggs} \oplus \sigma_i$
3: **end for**
4: **return** σ_{aggs}
4: **end procedure** = 0

2. *Aggregate Signature Algorithm*: An aggregate signature Algorithm 1 extends the above definitions to aggregate multiple signatures:
   - *Aggregate key generation*: $\text{Aggr} - \text{Gen}(1^\kappa, n) \rightarrow (s\kappa_{\text{aggr}}, p\kappa_{\text{aggr}})$, where n is the number of signers.
   - *Aggregate signing algorithm*: $\text{AggrSign}_{s\kappa_{\text{aggr}}}(m_1, \ldots, m_n) \rightarrow \sigma_{\text{aggr}}$, generates an aggregate signature σ_{aggr} for messages $m_1, \ldots, m_n$ using private key $s\kappa_{\text{aggr}}$.
   - *Aggregate verification algorithm*: $\text{AggrVerify}_{p\kappa_{\text{aggr}}}(m_1, \ldots, m_n, \sigma_{\text{aggr}}) \rightarrow \{\text{True}, \text{False}\}$, verifies σ_{aggr} for messages $m_1, \ldots, m_n$ using aggregate public key $p\kappa_{\text{aggr}}$.

3.6 | Network Model

The proposed blockchain solution comprises the following types of entities.

1. *Peer-to-Peer Communication*: The blockchain based networking operates on a peer-to-peer basis, providing decentralized functionalities. Any node can participate in the network and establish connections with other nodes.
2. *Nodes*: The nodes represent users within the network. Depending on the application, these nodes can vary in their roles.
3. *Consensus*: To reach an agreement on transactions, a consensus mechanism is executed. This ensures that decisions are transparent and safeguards against compromised activities, such as decision manipulation and Byzantine faults.

3.7 | Working of Aggregate Signature in Blockchain

An aggregation of signature algorithm is a cryptographic technique that allows multiple signers to combine multiple signatures into a single one. This aggregated signature is verified against a combined set of messages and public keys, rather than verifying each single signature individually. Aggregation of signatures in blockchain is executing multiple transaction signatures into a single compact aggregated signature. This execution process generally follows these steps:

1. *Signature Collection*: Transactions with individual signatures are collected from the network.
2. *Aggregation Algorithm*: An aggregation algorithm computes a consolidated signature (often using techniques like BLS or Schnorr aggregation) for the entire block of transactions.
3. *Verification*: The aggregated signature is included in the block header. Nodes can verify the entire block's validity using this single aggregated signature, rather than verifying each transaction individually.

4 | Proposed System Architecture

As shown in Figure 1, the proposed architecture divides vehicles into multiple divisions/zones. Each of division equipped with a designated controller to observe and supervises all of the activities occurring, including vehicle authentication, movement, and vehicle-to-vehicle internal communication with a distributed ledger powered by blockchain technology. While the vehicles are subject to restrictions on their energy consumption and computational power, the controllers in this scenario, while the Roadside Units (RSUs), are considered to have no such restrictions. The divisions have been designed to facilitate communication between various controllers, RSU-to-vehicle, vehicle-to-vehicle, and RSU-to-blockchain. Furthermore, the blockchain-enabled P2P (peer to peer) networking allows the divisions to safely interact with one another. Given the fast speeds at which vehicles are traveling, scalability has a critical issue in the authentication process [8]. As seen in Figure 1, our suggested architecture employs a structure of hierarchy to overcome this. A controller is in charge of overseeing a coverage division, which consists of several levels of modules. Identified as R, controllers engage with the public blockchain and exchange messages with one another inside a network.

Figure 2 illustrates the blockchain architecture for the vehicular network. Authentication functions, secret keys, and blockchain transaction blocks are all part of the system. All vehicle information is included in transactions, such as the vehicle ID, MAC address, zone number, and route and direction metadata. Public and private keys are created by R for each vehicle at the time of registration. The private key can be used to sign/authenticate transmitted data between vehicle in their respective divisions. The private key can also be used to migrate across divisions and communicate with other in those divisions.

4.1 | Blockchain-Based Controller

In particular, Figure 3 illustrates the internal workings of the controller and how it is connected to the cars. The ledger, denoted by L, maintains and archives the data about the cars. The duties assigned to the controller can be taken from the mechanism described in [2]. Since the vehicles can register in any zone for safe communication and migration while in motion, we gave the public blockchain some thought. As a result, it aids in protecting the vehicles' privacy [3]. The vehicles are able to connect to the network and distribute either private or public keys for the public blockchain.

The Hash functions/signatures, private keys, and public blockchain transactions are examples of the blocks that make up

15320634, 2025, 9-11, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.70071 by Delhi Technological University, Wiley Online Library on [30/04/2025]. FIGURE 1 | The proposed zone-based framework for the IoV using blockchain.

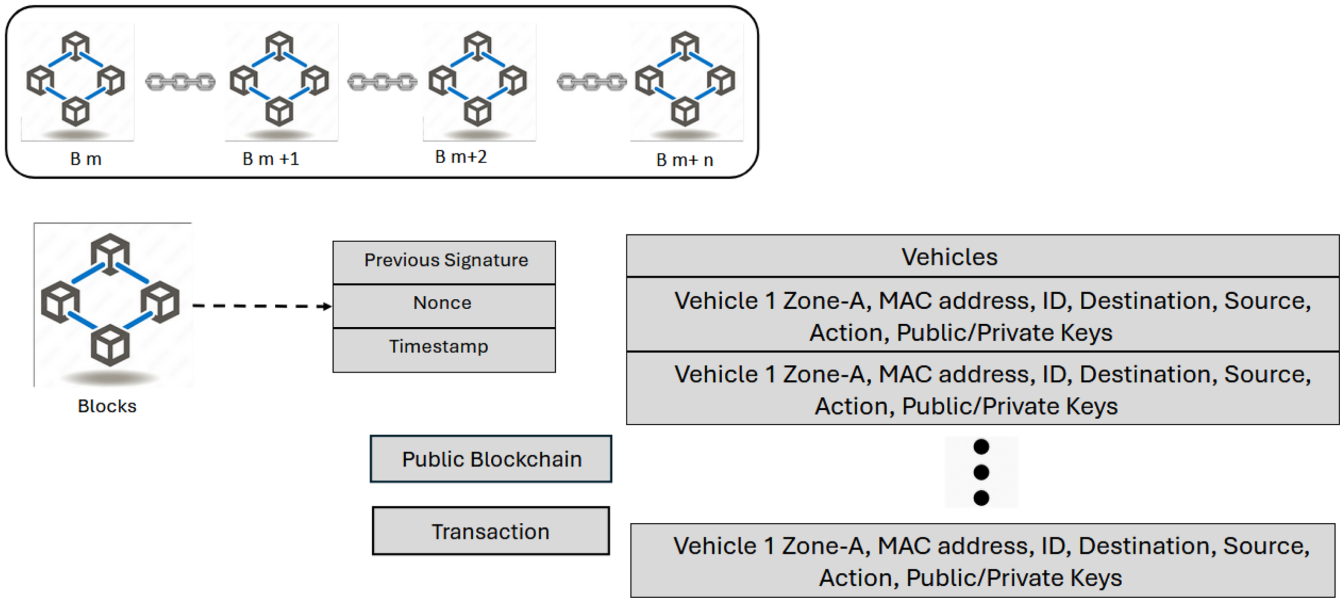

FIGURE 2 | Blockchain components and public blockchain-based communication in IoV.

the blockchain. Vehicle information, such as a car's distinct ID and MAC address obtained while driving, are contained in the transactions. On the other hand, the information is stored in a vector that the system generates and represents as V_{info}. To access their respective divisions, the vehicles can receive the public or private keys by using V_{info} and a legitimate ID. Additionally, they can use V_{info} to migrate to other vehicles the information. It is mentioned that the consensus process, a low latency, secure proof of work protocol, is responsible for managing the controllers. Due to constraints and shortcomings in the present literature, including centralized systems and problems with real-world voting, we provide a vehicle-based quantum secure blockchain consensus (VBQBC) method while maintaining the current consensus algorithm. The transactions in each division are endorsed and checked by our suggested VBQBC. Every authentication procedure between vehicles and controllers will only be permitted in the designated zones in order to minimize overhead and the number of nodes (Algorithm 2).

15320634, 2025, 9-11, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.70071 by Delhi Technological University, Wiley Online Library on [30/04/2025]. 15: Transactions in Information
16: nonce++
17: **end while**
18: Blocks (Zone(j) = Information) Mining process successful
19: Share information of Division = 0

4.2 | Secure and Authentication Process

We take into account scattered divisions/zones among the network's automobiles using blockchain technology in the safe authentication procedure. Each division is responsible for managing the blockchain process and safeguarding the cars' data transmission while they are operating. Nevertheless, there is a situation in which cars can move between zones without having to authenticate again, saving time and computing resources. As can be seen from Figure 1, in order to encrypt the data, the vehicles need to register with the controller in each division. Each vehicle is given unique keys and authenticated data in this manner. Subsequently, the controller simultaneously sends the authenticated data to all other controllers and the blockchain. Accordingly, each vehicle receives the public and private keys from the controller R. Additionally, information regarding the adversary's vehicle might be sent by the controller. By sharing this data via a shared ledger, the blockchain enables controllers in other divisions to deny the rogue cars' incoming requests.

ALGORITHM 3 | Vehicle migrations between divisions.

18: **while** Authentication==Successful **do**
19: **if** Mobility/Migration == Successful **then**
20: Authenticates in the Division
21: $Controller_j$: Information
22: Updates the Division's information
23: Migrates from current Division to requested Division
24: **else**
25: $Controller_j$: Blockchain updates
26: **end if**
27: **end while**
28: **while** Authentication == Not Successful **do**
29: Next Division CON(.) receives the data
30: Next Division CON(.) verifies the data
31: **end while** = 0

4.3 | Key Distribution and Requesting Process

Unique vehicle attributes, including position, identity, direction, and public and private keys, are identified by the authentication unit (A_U). These properties are generated by the controller unit (C_U). For security purposes, the data is added explicitly to the decentralized ledger through C_U. Every piece of data pertaining to the cars is registered and uploaded to the blockchain, where it is stored in a ledger. Other controllers must also have access to this data for estimate purposes. The private key, κ_{pri} can be used for signature on transactions between two vehicles, but the public key, κ_{pub}, is available to both vehicle and controller. The paired keys K_{pri} and K_{pub} have a mathematical relationship. Only the matching K_{pri} can be used to sign the message that can be verified using K_{pub}.

4.4 | Migration and Authentication Process

The procedure for migrating across divisions is intended for secure communication and necessitates the least amount of latency during the process of authentication, as seen in Algorithm 3. The system controller shortens the time needed

15320634, 2025, 9-11, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.70071 by Delhi Technological University, Wiley Online Library on [30/04/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

for key transfer between zones by facilitating key management inside divisions. The main goal is to optimize the transfer method by effectively managing the controllers' keys inside the divisions. By regulating the amount of time needed for key execution in vehicle authorization using the blockchain and public/private keys, the goal is to reduce the amount of third-party contact during transactions. The suggested architecture notifies the controller of the zone next to it if one of its controllers malfunctions. As a result, the cellular structure makes sure that in the zones around the malfunctioning controller, the fewest neighboring controllers are situated. The controller in charge of handling the incident will be chosen from among these nearby zones whose vehicle count is lowest.

1. *Key-Generation*: Key-generation algorithms are fundamental components of cryptographic systems, responsible for generating keys used in encryption/decryption, and signature processes. This algorithm ensures the creation of secure, random, and unique keys that are resistant to cryptographic attacks. This takes a random matrix $\overline{A}$, $s \xleftarrow{\$} S^{\eta}_{\ell+k}$, $\tau \coloneqq \overline{A}s \bmod \rho$, and generates key-pair containing $s\kappa \coloneqq s$, and $p\kappa \coloneqq \tau$ respectively.

2. *Block Generation using Sequential Aggregate Signature*: This phase considers a challenge space C, and a message space $\mathcal{M}' = \{0,1\}^{l}$, and a collision resistant hashing $H : \{0,1\}^{*} \to C$. This algorithm starts with $i = 1$, $\varrho_0 = \emptyset$ and $\sigma_0 = (0,0)$. Furthers the algorithm **SeqSigns** (Sequential Aggregate Signature) takes input $s\kappa_i, m_i, \varrho_{i-1}, \sigma_{i-1}$, and computes $\left(\tilde{\vartheta}_{i-1}, z_1, \ldots, z_{i-1}\right) \coloneqq \sigma_{i-1}$, $s_i \coloneqq s\kappa_i$, $\tau_i \coloneqq \overline{A}s_i \bmod \rho$, $\varrho_i \coloneqq \varrho_{i-1} \| (\tau_i, m_i)$. This samples $y_i \leftarrow D_{\ell+k}$, $\vartheta_i \coloneqq \overline{A}y_i \bmod \rho$, $\tilde{\vartheta}_i \coloneqq \tilde{\vartheta}_{i-1} \oplus \vartheta_i$, $c_i \coloneqq H\left(\tilde{\vartheta}_i, \varrho_i, z_{i-1}, vid_i\right)$, $z_i \coloneqq c_i \cdot s_i + y_i$, $z_i \coloneqq \text{RejSamps}\left(z_i, c_i \cdot s_i\right)$, and returns $\sigma_i \coloneqq \left(\tilde{\vartheta}_i, z_1, \ldots, z_i\right)$ see Algorithm 4.

3. *Block Verification using Sequential Aggregate Signature*: Sequential aggregate signatures are a cryptographic construct that allows multiple signatures from different signers on different messages to be combined into a single signature. This single signature can then be verified to authenticate all the messages. The primary advantage is efficiency, as it reduces the size of the overall signature and the complexity of verification. The algorithm **SeqVerify** (Sequential Aggregate Signature Verification) takes input $< \varrho_N, \sigma_N >$, and $(\tau_1, m_1) \| \ldots \| (\tau_N, m_N) \coloneqq \varrho_N$, and $\left(\tilde{\vartheta}_N, z_1, \ldots, z_N\right) \coloneqq \sigma_N$. Furthers the algorithm computes $z_0 \coloneqq 1$ if $\exists\ i$ satisfying τ_i has no inverse of any coefficient. For $i = N, \ldots, 1$, and $\| z_i \|_2 > B$, returns 0, else $\varrho_i \coloneqq (\tau_1, m_1) \| \ldots \| (\tau_i, m_i)$, $c_i \coloneqq H\left(\tilde{\vartheta}_i, \varrho_i, z_{i-1}, vid_i\right)$, $\vartheta_i \coloneqq \overline{A}z_i - c_i\tau_i \bmod \rho$, $\tilde{\vartheta}_{i-1} \coloneqq \tilde{\vartheta}_i \oplus \vartheta_i$, and if $\tilde{\vartheta}_1 = \vartheta_1$, then returns 1 and accepts the signature (see Algorithm 4).

5 | Security Analysis

Blockchain aggregation of signatures is a cryptographic technique that enables multiple signatures to be combined into a single compact signature. This can provide significant efficiency gains in blockchain technology based systems by reducing the amount of data that needs to be stored and transmitted. Here's an

ALGORITHM 4 | Description of the proposed sequential aggregation of signatures.

Cipher-Space: $C \coloneqq \left\{ c \in R : \| c \|_2 = \sqrt{\kappa} \right\}$
Message-Space: $\mathcal{M}' = \{0,1\}^{l}$

analysis of the security attributes, and mathematical correctness of blockchain aggregate signatures:

Theorem 1. *The scheme aggregation of signatures* = `Setup, Gens, SeqSigns, SeqVerifies` *as described in Algorithm 3 is mathematical correct.*

Proof. In this theorem, we have shown that, if an ith signature $\sigma_i = (\tilde{\vartheta}_i, z_1, \ldots, z_i)$ for $1 \le i < N$ is correct, then $(i+1)$ indexed signature $\sigma_{i+1} = (\tilde{\vartheta}_{i+1}, z_1, \ldots, z_{i+1})$ is also mathematical correct. The value z_{i+1} is computed correctly by signer, then it generates $\overline{A} \cdot z_{i+1} - \tau_{i+1} \cdot c_{i+1} = \vartheta_{i+1}$. Therefore, $\tilde{\vartheta}_i$ is recovered with the help of $\tilde{\vartheta}_{i+1} - \vartheta_{i+1}$ and the $\sigma_i = (\tilde{\vartheta}_i, z_1, \ldots, z_i)$ is used to do verification by the mathematical induction.

Now, let us assume $i = 1$, then it is used to generate $\| z_1 \|_\infty \le B$ and $\overline{A} \cdot z_1 = \tau_1 \cdot c_1 + \tilde{\vartheta}_1$ due to the linearity of mathematical algebra over matrices multiplication over $\mathbb{R}_q$. □

Theorem 2. *Let* $\kappa, \ell, n, \rho, \eta, \gamma, l \in \mathbb{N}$, *where* $n = 2^i$, ρ *is a prime*, p_{inv} *is the probability that* $\overline{A}$ *can find minimum one inverse of coefficient over* $\mathbb{R}_\rho$, *where* s *is uniform random sample from* $S_\eta^{\ell+\kappa}$ *and* $\overline{A} = [A | I_\kappa]$ *with* A *uniform random sample from* $\mathbb{R}_\rho^{\kappa \times \ell}$, *respectively. If the single signature is Unforgeable, then the proposed sequential aggregation in Algorithm 4, is secure.*

Proof. In cryptography, security proof often uses a series of games to show that an adversary's success probability in breaking a scheme can be reduced to an adversary breaking an underlying assumption, typically a hard problem. Here's a security proof for the proposed aggregation of signatures using a series of games G_0, G_1, G_2, G_3, and G_4, respectively. □

First, the broad concepts of the reduction $\mathcal{B}$ are outlined. You may find the full explanation of $\mathcal{B}$ in Algorithm 5. For an unforgeable game (UF-CMA game), OSeqSigns and H (resp. OSigns and H') stand for the random oracle as well as the signing oracle. After obtaining the challenge public key τ^* and the public parameter A, $\mathcal{B}$ verifies that $\tau^* \in \mathbb{R}_\rho^k$ comprises a minimum of one invertible element. In that case, $\mathcal{B}$ transfers (A, τ^*) to $\mathcal{A}$. In response to an inquiry, OSeqSigns asks OSigns to sign a uniformly selected m and programs H to produce the value c that is returned by an external random oracle H'. Since a forgery filed by $\mathcal{A}$ may subsequently utilize the same m_i, we are unable to simply pass m_i to OSigns in this case. Afterward, $\mathcal{B}$ loses the UF-CMA game since their submission of the forgery with respect to m_i will be invalid. The simulation of responses to H queries is the core element of the reduction. The forgery tuple's key list L_N includes (t_i, m_i) such that $\tau_i = \tau^*$. Afterward, in order for $(m, (\vartheta_i z_i))$ to be considered a legitimate forgery within the UF-CMA game, any arbitrary message m and the accompanying ϑ_i must be transmitted to H' by $\mathcal{B}$. It is noteworthy that z_i^{-1} is used in this extraction procedure each time $(\tilde{\vartheta}_i, \varrho_i, z_i^{-1})$ is queried from H. $\mathcal{B}$ can extract $\vartheta_i = \tilde{\vartheta}_i - \tilde{\vartheta}_{i-1}$ by using z_i^{-1} as an intuitive look-up key to retrieve the previously aggregated $\tilde{\vartheta}_{i-1}$. To be more precise, we build a number of hybrid games from the initial FH-UF-CMA game in order to arrive at the one that is employed in the final reduction $\mathcal{B}$. The probability that $G_i(\mathcal{A})$ stops when output is one, and it is indicated by $\Pr[G_i(\mathcal{A})]$.

ALGORITHM 5 | Reduction to UF-CMA VBQBC.

The UF-CMA H'.
The UF-CMA OSigns.
Consider $\tilde{\vartheta}_0 = 0$, A query to H with $\tau_1, \ldots, \tau_i$.
Process $B^{\text{OSigns},H'}(A, \vec{t}^*)$
  $Q \coloneqq \emptyset$; $M \coloneqq \emptyset$
  if t^* not having inverse **then**
    badinverse $\coloneqq$ true
  $(\sigma_N, \varrho_N) \leftarrow A^{\text{OSeqSigns},H}(A, t^*)$
  $(\tau_1, m_1) \| \ldots \| (\tau_N, m_N) \coloneqq \varrho_N$
  $(\tilde{\vartheta}_N, z_1, \ldots, z_N) \coloneqq \sigma_N$
  $I \coloneqq \{i \in [N] : \tau_i = t^* \wedge (m_i, \varrho_{i-1}) \notin Q\}$
  if SeqVerifies$(\sigma_N, \varrho_N) = 1 \wedge |I| \neq 0$ **then**
    Derives $\tilde{\vartheta}_{N-1}, \ldots, \tilde{\vartheta}_1$ **as in** SeqVerifies
    if $\exists i \in [N]$ **satisfying** $\text{ZT}[\tilde{\vartheta}_i, \varrho_i, z_{i-1}] = \perp$ **then**
      badord $\coloneqq$ true

- G_0: This game starts with initializes a blank table HT. When HT's entry is non-empty, the random oracle HH returns $HT[X]$ upon receiving the query with input X; otherwise, it returns c, assigns $HT[X] \coloneqq c$, and choose a random sample $c \in Ch$ with $\Pr\left[G_0(A)\right] = \mathrm{Adv}^{\mathrm{UF}}_{\mathrm{VBQBC}}(A)$.
- G_1: The game is pretty similar to G_0, only the difference is *OSeqSigns* implements Oracle list $HT\left[\tilde{\vartheta}_i, \varrho_i, \mathbf{z}_{i-1}\right] \coloneqq c_i$ if rejection sample phase successful, and samples uniform $c_i \in CH$ rather than making a call $c_i = H\left(\tilde{\vartheta}_i, \varrho_i, \mathbf{z}_{i-1}, vid_i\right)$ after $\tilde{\vartheta}_i$ is computed. The game gets terminated by declaring $\mathrm{bad}_{ucol} = \mathrm{true}$ if $HT\left[\tilde{\vartheta}_i, \varrho_i, \mathbf{z}_{i-1}\right]$ has been set. Thus, $|\Pr\left[G_0(A)\right] - \Pr\left[G_1(A)\right]| \leq \Pr\left[\mathrm{bad}_{ucols}\right]$.

TABLE 1 | Experiments, summaries, and metrics.

Parameters	Values
Transactions	[1; 200; 200]
Executed tests	60
Confidence-interval	82%
Price	3
Average TPS (transactions per day)	3.01296296
Average mining per transaction	1.244 s
Time for single hashing	1.42 s

TABLE 2 | Modification among three groups of blockchain.

Parameter	Transaction-1	Transaction-2	Transaction-3
Block-interval	10 min	10 min	1 min
Block-size	1 MB	1 MB	1 MB
Difficulty-adjustment-interval	2012 blocks	62 blocks	Adaptable-limit
Past-blocks	2012	62	Difficulty-adjustment

- G_2: The game is pretty similar to G_1, only the difference is simulating the responses to random oracle queries $H\left(\tilde{\vartheta}_i, \varrho_i, \mathbf{z}_{i-1}\right)$. Initialize a new empty ZT table. If $i = 1$ or $X \coloneqq \left(\tilde{\vartheta}_{i-1}, \varrho_{i-1}, \mathbf{z}_{i-2}\right)$ exists and $ZT[X] = \overline{\mathbf{A}}\mathbf{z}_{i-1} \bmod q$, extracts $\vartheta_i \coloneqq \tilde{\vartheta}_i - \tilde{\vartheta}_{i-1}$, samples random uniform $c_i \in Ch$, and assigns $ZT\left[\tilde{\vartheta}_i, \varrho_i, \mathbf{z}_{i-1}\right] \coloneqq \vartheta_i + c_i\mathbf{t}_i$. If an entry $X' \coloneqq \left(\tilde{\vartheta}_{i-1}, \varrho_{i-1}, \mathbf{z}_{i-2}\right)$ already exists and $ZT\left[X'\right] = \vartheta_i + c_i\mathbf{t}_i$, the game terminates by setting $\mathrm{bad}_{zcol} = \mathrm{true}$. Hence, $|\Pr\left[G_1(A)\right] - \Pr\left[G_2(A)\right]| \leq \Pr\left[\mathrm{bad}_{zcols}\right]$.
- G_3: The game is pretty similar to G_2, only the difference is that *OSeqSigns* and HH initializes random empty table MT and an empty set M. Upon receiving a query, *OSeqSigns* samples random message $m \in M$ and assigns m to M. After extracting ϑ_i as previously queried, H samples $m \in M$ and rejects $\mathrm{bad}_{mcols} = \mathrm{true}$ if $m \in M$ whenever it receives a query with input $\left(\tilde{\vartheta}_i, \varrho_i, \mathbf{z}_{i-1}\right)$, then $|\Pr\left[G_2(A)\right] - \Pr\left[G_3(A)\right]| \leq \Pr\left[\mathrm{bad}_{mcols}\right]$.
- G_4: The game is pretty similar to G_3, only the difference is that when $\mathcal{A}$ outputs a legal signature-history pair $\left(\varrho_N, \left(\tilde{\vartheta}_N, \mathbf{z}_1, \ldots, \mathbf{z}_N\right)\right)$, the game validates the ZT entries as follows. Let $\tilde{\vartheta}_{N-1}, \ldots, \tilde{\vartheta}_1$ be the values obtained during the *SeqVerifies* run. The game terminates by setting $\mathrm{bad}_{ords} = \mathrm{true}$ if for random chosen $i \in [N]$, the value for $ZT\left[\tilde{\vartheta}_i, \varrho_i, \mathbf{z}_{i-1}\right]$ is undefined, then $|\Pr\left[G_3(A)\right] - \Pr\left[G_4(A)\right]| \leq \Pr\left[\mathrm{bad}_{ords}\right]$.

Assuming that A wins G_4, the reduction B mentioned in Algorithm 4 is obtained in this way. Upon receiving an *OSeqSigns* query, B queries the UF-CMA game's *OSigns* with a uniformly chosen $m \in M$. B then retrieves ϑ_i and $\mathbf{z}_i$, programs HT using c_i returned by the external $H'\left(\tilde{\vartheta}_i, \tau^*, m\right)$. Therefore, $\vartheta_i^* = \tilde{\vartheta}_i^* - \tilde{\vartheta}_{i^*-1}$ is extracted by querying $H\left(\tilde{\vartheta}_i^*, \varrho_i^*, \mathbf{z}_{i^*-1}\right)$. As long as $\mathrm{bad}_{zcols} = \mathrm{bad}_{ords} = \mathrm{false}$, then queries are processed in right order.

```
# Define a simple transaction structure
class Transaction:
    def __init__(self, sender, recipient, amount, message, public_key, signature):
        self.sender = sender
        self.recipient = recipient
        self.amount = amount
        self.message = message
        self.public_key = public_key
        self.signature = signature

6 | Performance

This section illustrates a simplified implementation in Python using aggregation of signatures. Note that this is a conceptual example and might require additional cryptographic libraries and support with a blockchain framework. To integrate with blockchain, first updates the node software to handle number of transactions with aggregation of signatures, and it implements logic to create, verify, and propagate aggregation of signatures transactions. It also ensures that the block generation process handles and validates blocks containing transactions with aggregation of signatures, and implements block validation logic that verifies aggregation signatures efficiently. It depends upon the consensus mechanism (Proof of Stake, Proof of Work) integrating aggregation of signatures verification process to ensure the authenticity in the blockchain. Aggregation of signatures is a cryptographic innovation that can significantly enhance the efficiency and performance of blockchain systems. By enabling multiple signatures to be combined into a single, shorter signature, aggregate signatures can reduce the storage and bandwidth requirements of blockchain networks. This analysis covers various performance aspects of aggregate signature-based blockchains, including efficiency, scalability, authenticity, throughput, and practical implementation. Additionally, this section contains an analysis on results of existing algorithm, and the proposed algorithm. The setup details are available in the Tables 1 and 2. The Figures 4–6 contains screenshots for compiled code.

We have performed an analysis based on number of vehicles versus authentication process delay in microseconds. The authentication process delay is measured in terms of time needed

```
# Sign a message
def sign_message(private_key, message):
    message_hash = sha256(message.encode()).digest()
    signature = bls.Sign(private_key, message_hash)
    return signature

# Verify a single signature
def verify_signature(public_key, message, signature):
    message_hash = sha256(message.encode()).digest()
    return bls.Verify(public_key, message_hash, signature)

# Aggregate multiple signatures
def aggregate_signatures(signatures):
    return bls.Aggregate(signatures)
```

for authentication when a vehicle leave a division, and it joins a new division. This process needs to authenticate vehicle again while moving changing zones. In contrast, the proposed VBQBC algorithm eliminates re-authentication process of vehicles, and the consensus mechanism uses aggregation of signatures for the authenticity of transactions, and generating valid blocks to be added in the blockchain. This section also contains analysis on blockchain parameters, likewise block sizes and miners count, on the proposed algorithm bandwidths and throughput. The number of executed transactions varies with block sizes, and it is responsible for the throughput consumed by the proposed algorithm. We have done a performance analysis based on read latency versus number of blocks comparison among related, and the proposed frameworks (see Figure 7). Read latency refers to the time it takes to retrieve data from a storage system or database after a request is initiated. It is a critical performance metric in systems such as distributed databases, memory, and storage networks. In this figure, X-axis denotes number of blocks and Y-axis denotes read latency in seconds. Furthers the Figure 8 illustrates transaction latency versus number of blocks comparison among related, and the proposed frameworks. Transaction latency is the time elapsed from when a transaction is initiated to when it is confirmed and becomes part of the blockchain. In this figure, the X-axis denotes number of blocks whereas Y-axis denotes transaction latency in seconds. Both figures ensures the efficiency of the proposed framework in terms of read and transaction latency.

In the Figure 7, we have compared the proposed algorithm with other relevant algorithms in terms of blocks (denoted on X-axis) versus read latency in seconds (denoted on Y-axis). The proposed algorithm possesses low read latency, it deploy aggregation of signatures, which are faster than other existing ones, results approximately 60.5% faster reading time for blocks. In the Figure 8, we have compared the proposed algorithm with other relevant algorithms in terms of blocks (denoted on X-axis) versus transaction latency in seconds (denoted on Y-axis). Figure 9 illustrates the number of transactions occurring per second. The X-axis represents the increasing number of open transactions, while the Y-axis shows the time taken per second as the number of transactions grows. The graph indicates a noticeable decrease in time after reaching a certain threshold of transactions. Furthers, Figure 10 illustrates the analysis with respect to throughput in transactions per second denoted on Y-axis versus block sizes increase from one megabyte to 5 megabytes. This experiment is performed with varying number of miners 10, 25, 50, and 100, respectively. As the number of miners increases, then consensus execution gets expedited among number of controllers. The Table 3 contains a comparison of the suggested frameworks' computing costs against similar ones in terms of computational costs.

This section contains six algorithms for implementation. The Algorithm 6 is denotes the process for adding a new authority to the contract, Algorithm 7 plays the role of verifier for existence of authority in the contract, Algorithm 8 executes the process of taking consent from a vehicle for data sharing, Algorithm 9 verifies consents, Algorithm 10 permits to have an access vehicle data, and Algorithm 11 validates transactions and generates new block to be added to the blockchain.

ALGORITHM 6 | Adds provider.

1: **Inputs**: Authority address _provAddress, Authority-Name _name, Authority-Role _role
2: **Outputs**: None
3: **New-Authority** ← **Vehicles-Authority**(_name, _role)
4: **Authority**[_provAddress] ← **New-Authority**

ALGORITHM 7 | Checks-authority-existence.

1: **Inputs**: Authority-Address _provAdd
2: **Outputs**: **Successful** if Authority exists, **Unsuccessful** Else
3: **if** authority[_provAdds].role is non empty **then**
4: **return Successful**
5: **else**
6: **return Unsuccessful**
7: **end if** = 0

ALGORITHM 8 | Consents.

1: **Inputs**: authority-address _provAdds, Vehicle-Address _vehicleAddress
2: **Outputs**: None
3: **Vehicle-Consents**[_vehicleAddress][_provAdds] ← **true**
=0

ALGORITHM 9 | Check-vehicle-consents.

1: **Input**: Authority-address _provAdds, vehicle-address _truckAddress
2: **Output**: **True** if truck consent exists, **False** otherwise
3: **if** vehicle-Consents[_vehicle-Address][_provAdds] is **Successful then**
4: **return Successful**
5: **else**
6: **return Unsuccessful**
7: **end if** = 0

ALGORITHM 10 | Access-vehicle-data.

1: **Inputs**: Authority-address _provAdds, Vehicle-address _vehicle-Address
2: **Outputs**: Access-Vehicle-Data
3: **if** vehicleConsents[_vehicleAddress][msg.sender] is **Successful then**
4: Access-Vehicle-Data
5: **else**
6: **Outputs Error**: Vehicle consent missing for accessing data
7: **end if** = 0

ALGORITHM 11 | Proof-of-work mining.

1: **Inputs**: Previous-Block-Hashing *previousHashes*, Data block *data*
2: **Outputs**: Nonce *nonce*, Current-Hashing *currentHash*
3: *nonce* ← 0
4: *difficulty* ← 5 {Adjusting difficulty needed}
5: *prefixes* ← new strings of *difficulty* zeros
6: **while** successful **do**

7 | Conclusion

In this paper, we have presented a Vehicle-Based Quantum Secure Blockchain Consensus (VBQBC) method to address the security and effectiveness issues raised by the massive amount of data in the Internet of Vehicles (IoV). Our system is decentralized, which improves authentication while reducing the drawbacks of centralization, such as high computation costs

15320634, 2025, 9-11, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.70071 by Delhi Technological University, Wiley Online Library on [30/04/2025]. and message delay. Authentication is an important part of the Internet of Vehicles, and the VBQBC algorithm uses blockchain technology to provide authenticated communication between vehicles. Implementation of aggregate signatures in blockchain technology offers several advantages, and this technique helps in improving scalability, efficiency, and security. Aggregation of signatures allow multiple signatures to be combined into a single compact signature that leads to reduced size of transactions and blocks on the blockchain, leading to lower storage and bandwidth requirements. Simulation findings show that our VBQBC method surpasses current cutting-edge algorithms in terms of authentication latency, key processing time, and attack detection rate. Using post-quantum aggregation of signatures in blockchain technology represents a forward-thinking approach to security, particularly in the era of quantum computing.

Carboxymethyl Guar Gum: Bridging the Gap Between Biopolymers and Advanced Functional Materials

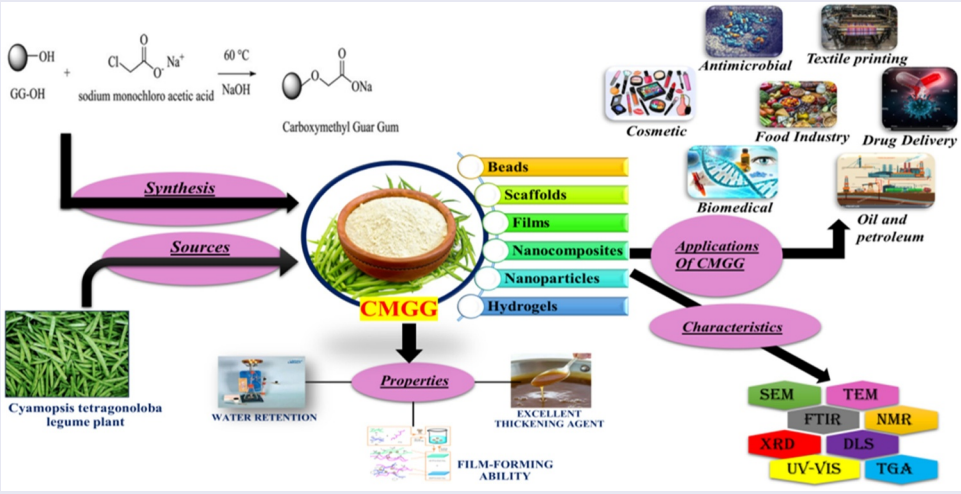
Vratika Verma, Jagram Meena, Teena Saini, Sakshi Saini, and Rajdeep Malik

Department of Chemistry, Gurukul Kangri (Deemed to be) University, Haridwar, Uttarakhand, India

ABSTRACT

Synthetic polymers pose significant environmental and biomedical challenges, including non-biodegradability, microplastic accumulation, petrochemical reliance, and hazardous additive leaching. These issues drive concerns over ecological contamination and regulatory constraints. These challenges necessitate the development of eco-friendly alternatives, with biodegradable biopolymers emerging as a promising solution. Among them, Carboxymethyl Guar Gum (CMGG) stands out for its enhanced solubility, tunable rheology, and biodegradability, making it a viable candidate for sustainable material applications. This review explores CMGG's synthesis via carboxymethylation, structural modifications, and physicochemical characterizations using FTIR, UV-visible spectroscopy, XRD, TEM, and HRTEM. CMGG demonstrates versatile applications in biomedical engineering (drug delivery, wound healing), sustainable packaging (biodegradable films, stabilizers), and industrial formulations (hydrogels, rheology modifiers). Its potential in next-generation biomaterials highlights its role in advancing sustainable material science while addressing the limitations of conventional polymers.



KEYWORDS

Biodegradable biopolymers; biomedical applications; Carboxymethyl Guar Gum (CMGG); structural characterization etc; sustainable materials

HIGHLIGHTS

- **Shift to Biopolymers**: The paper discusses the limitations of traditional polymers, emphasizing the growing scientific interest in biopolymers as safer, more sustainable alternatives.
- **Biodegradable Polymers**: It highlights the emergence of biodegradable polymers as environmentally friendly materials, focusing on their biodegradability and biocompatibility for various applications.
- **Characterization Techniques**: The review details various characterization techniques for biopolymers, including FTIR, UV-visible microscopy, XRD, TEM, and HRTEM, which are essential for understanding their properties.
- **Focus on Carboxymethyl Guar Gum (CMGG)**: A specific highlight is the in-depth exploration of Carboxymethyl Guar Gum (CMGG), its synthesis through the reaction of Guar Gum with monochloroacetic acid, and its affordability and water solubility.

- **Applications Across Industries**: Showcases CMGG's diverse applications in sectors such as biomedical, textile, food, agriculture, and construction, highlighting recent research advancements and the material's extensive potential.
- **Recent Research Insights**: The paper provides recent research developments surrounding CMGG, emphasizing its biodegradability and growing potential across various fields.

1. Introduction

The pervasive accumulation of plastic waste has emerged as a pressing global environmental crisis. Synthetic polymers, which have become integral to modern life, exhibit remarkable durability and versatility but pose significant challenges due to their non-biodegradability. The escalating demand for plastics across industries – such as packaging, healthcare, textiles, and construction – has resulted in an alarming increase in plastic waste. Marine ecosystems suffer from plastic debris accumulation, while improper disposal through landfilling and incineration releases hazardous pollutants. With plastic consumption continuing to rise and recycling methods remaining inefficient, the urgent need for sustainable materials has become more critical than ever.

Polymers, derived from the Greek words *poly* (many) and *meros* (parts), are macromolecules composed of repeating monomeric units (Illustration 1). Their diverse mechanical, thermal, and chemical properties have revolutionized industries, ranging from consumer goods to high-performance materials. Historically, natural polymers such as cellulose, starch, and proteins have been widely utilized in textiles, food preservation, and biomedical applications. However, the 20th-century advent of synthetic polymers, including polyethylene, polypropylene, and polyvinyl chloride (PVC), enabled mass production of cost-effective, lightweight, and durable materials. Despite their widespread applicability, synthetic polymers contribute significantly to environmental pollution due to their resistance to biodegradation. Unlike natural polymers, which decompose through biological processes, synthetic plastics persist in ecosystems for centuries, exacerbating land and marine pollution.

The process termed polymerization is the formation of a polymer or large molecule from single units or monomers. In the process, there should be at least two reactive or bonding sites, generally known as functionality in a substance that has to act as a monomer in the polymer formation.[1] Table 1 shows some examples of polymers and their monomeric units, showcasing their applications and structure.

The reliance on petroleum-based polymers further accelerates resource depletion and greenhouse gas emissions, intensifying the environmental burden. Addressing these challenges necessitates a shift toward biopolymers, which offer eco-friendly degradation pathways and reduced dependence on fossil-based feedstocks. The utilization of biopolymers dates back to antiquity, with early civilizations employing cellulose, starch, and proteins for structural and functional applications. Ancient Egyptians used protein-based adhesives and plant gums, while Mesoamerican cultures utilized natural rubber for toolmaking and waterproofing. The scientific characterization of biopolymers

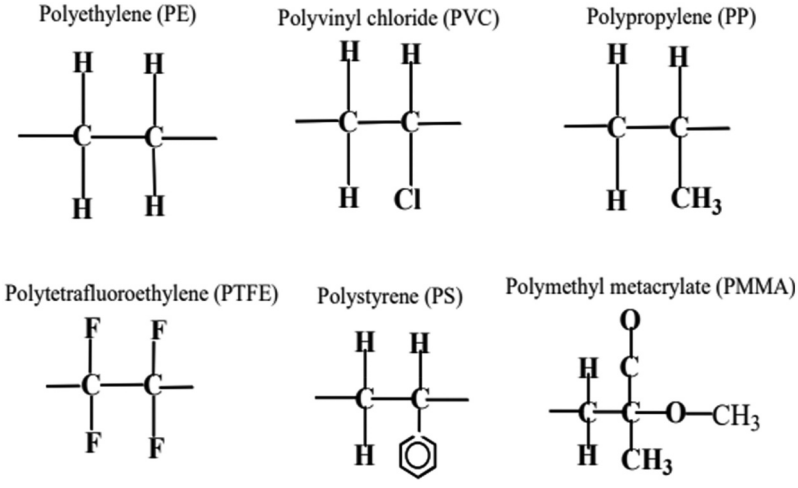

Illustration 1. Structures of the monomers of some polymers.

Table 1. Various examples of polymers along with their monomeric units are shown in the above table.

MONOMER	MONOMERIC UNIT	STRUCTURE	NAME	APPLICATIONS	REFERENCE
Styrene	 	 	Polystyrene	Pharmaceuticals, Building applications, Food and water applications	[2]
Ethylene	 	 	Polyethylene	Biomedical, pharmaceuticals, commercial, biotechnological	[3]
Propylene	 	 	Polypropylene	Packaging, housewares, consumer products	[4]
Amide	 	 	Polyamide	Textile and fiber, automotive industry, engineering plastics	[5]
Vinyl chloride	 	 	Polyvinyl chloride	Packaging, construction, plumbing, wire insulation	[6]

began in the 19th century, but large-scale industrial modifications gained traction in the mid-20th century due to the demand for sustainable alternatives to synthetic polymers. The derivatization of polysaccharides, such as carboxymethyl cellulose (CMC) and hydroxyethyl starch, expanded their functional versatility. Guar gum, a galactomannan from Cyamopsis tetragonoloba, became significant for its rheological properties, leading to derivatives like Carboxymethyl Guar Gum (CMGG), valued for its solubility and biomedical applications. Recent advancements in polymer chemistry, nanotechnology, and green synthesis have driven the development of high-performance biopolymers like polylactic acid (PLA) and polyhydroxyalkanoates (PHA), reinforcing the shift toward biodegradable and eco-friendly material solutions. **Carboxymethyl Guar Gum (CMGG)** has gained attention as a promising biodegradable alternative due to its **enhanced solubility, biocompatibility, and tunable physicochemical properties**. CMGG, a modified guar gum derivative, exhibits significant potential in diverse applications, from food and pharmaceuticals to sustainable material development. By integrating **CMGG into polymer research**, advancements in biopolymer-based materials align with green chemistry principles and environmentally conscious innovations, paving the way for sustainable alternatives to synthetic polymers. The polymers can be classified into various categories on a variety of bases, but we can say they are mainly of two types: natural polymers and synthetic Polymers (Illustration (2)).

Natural polymers, such as cellulose, starch, and proteins, have been utilized for centuries in textiles, food, and construction.[7] For instance, cellulose,[8] the most abundant natural polymer on Earth, forms the structural component of plant cell walls and has long been used in products like paper and cotton fabrics. Proteins, another class of natural polymers, play a crucial role in biological processes and are the building blocks of life, forming everything from hair and skin to enzymes that catalyze vital reactions.[9] In contrast, synthetic polymers, first developed in the early 20th century, have had an even more profound impact on industrial applications. These polymers are typically derived from petrochemical sources, such as crude oil and natural gas, and include materials like polyethylene, polypropylene, polystyrene, and polyvinyl chloride (PVC).[10,11] The development of synthetic polymers has enabled the mass production of durable, flexible, and lightweight materials, which have been instrumental in shaping the modern world. The arduous nature of these materials toward biodegradation leads to their buildup in the environment over long years.[12,13]

Every year, the approximate scale of manufacturing synthetic polymer is 140 million tons globally. Global Plastic production surged from 348 million tons to 359 million tons from 2017 to 2018 alone, as represented in Table 2.[14–16]

While synthetic polymers have undeniably transformed modern life, they also pose significant environmental challenges. Most traditional polymers, such as polyethylene, polypropylene, and PVC, are derived from nonrenewable fossil fuels and are not biodegradable.[17] As a result, plastic waste has accumulated in landfills, oceans, and natural ecosystems, leading to widespread pollution and environmental degradation. In 2015, approximately 6,300 million metric tons of plastic were produced, with 79%

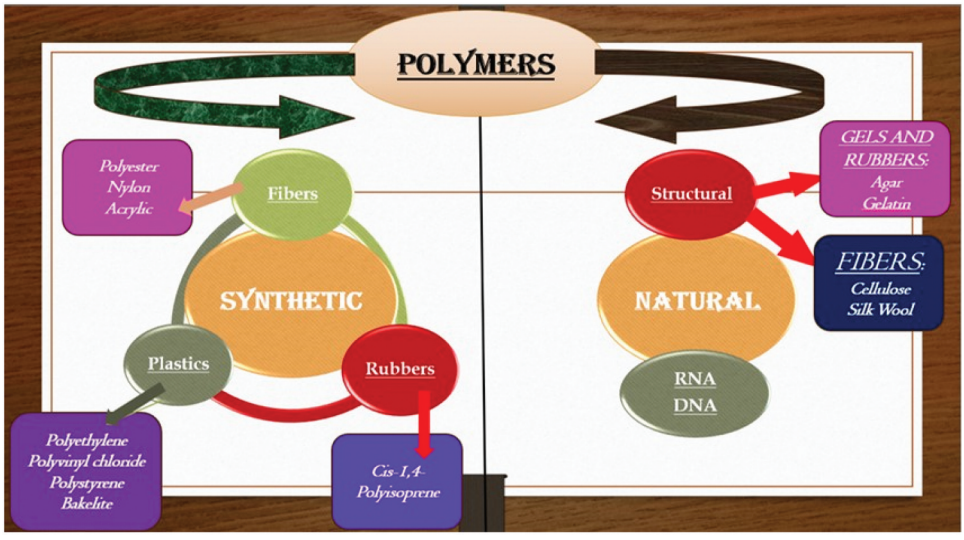

Illustration 2. Schematic representation of existence of polymers.

Table 2. Represents some major synthetic polymers produced worldwide in the year 2017 to 2018.

SYNTHETIC POLYMERS NAMES (GLOBALLY PRODUCED IN 2016)	STRUCTURE	PRODUCTION (IN MILLIONS OF TONNES)
Polystyrene		13
Polyurethane		29
Polypropylene		66
Polyvinylchloride		41
Polyethylene terephthalate		35
Polyamide		07
Polyethylene		122

accumulating in landfills, potentially reaching 12 billion tons by 2050.[18] The durability that makes polymers so valuable in products also makes them resistant to decomposition, with some plastics taking hundreds of years to break down.[20] In addressing the escalating intricacies of global environmental challenges, sustainability paradigms, advanced production methodologies, green chemistry innovations, environmentally conscious engineering, and ecosystem fortification have emerged as pivotal objectives in the design and development of future products, materials, and processes. The shift toward sustainable polymer production focuses on biodegradable starch-based composites from renewable sources. However, their weak mechanical strength and high hydrophilicity limit applications. Incorporating agro-waste cellulosic fibers enhances durability, water resistance, and biodegradability, while advanced techniques like solution casting and ultrasound-assisted extraction optimize fiber dispersion. Persistent challenges, including moisture-induced degradation, drive innovations such as hydrophobic modifications and nanoparticle integration. Future advancements aim to develop sustainable alternatives that replace conventional plastics while minimizing environmental impact.[20] Conventional petroleum-based plastics, especially single-use variants, drive environmental degradation and waste accumulation. The shift to eco-friendly alternatives meets

consumer demand while mitigating the ecological impact of traditional polymer production.[21] Noteworthy strides have been made toward a more sustainable and economically viable world, with the advancement of bio-based products, particularly biopolymers, epitomizing this progressive framework.[22]

2. Biopolymers

Biopolymers are increasingly gaining attention as sustainable alternatives to conventional synthetic polymers, primarily due to their biodegradable nature, renewability, and the reduced environmental impact they offer. As global environmental concerns such as plastic pollution, fossil fuel depletion, and climate change intensify, the need for more sustainable material solutions becomes paramount. Biopolymers, derived from natural sources like plants, animals, and microorganisms, are positioned as a key component in the transition toward greener industrial practices.[23] These materials are eco-friendly and offer diverse applications across multiple industries, including packaging, textiles, biomedical fields, and agriculture. Biopolymers are polymers produced by living organisms or synthesized from renewable biological sources.[24] They consist of long chains of repeating monomer units, similar to synthetic polymers. Still, the critical distinction is that their monomers are derived from renewable biological sources such as carbohydrates, proteins, and lipids. Biopolymers stand out from conventional polymers because they are biodegradable, meaning they can be broken down by microorganisms in natural environments, reducing the accumulation of waste. The environmental advantages of biopolymers make them increasingly vital in combating the global issue of plastic pollution, especially in landfills and oceans. Biopolymers are a class of polymers in which the prefix "bio" alludes to living. Thus, we can say "bio" suggests that the polymers are congenitally formed or synthesized from life forms such as microorganisms, plants, etc. But materials synthesized via synthetic chemistry from biological sources can also be included in this definition.[25] E.g., proteins, fats, oils, sugars, etc. Hence, in strict terms, "*biodegradation of a polymer*" can be characterized as the degradation of a polymer's chemical and physical characteristics, as well as a decrease in its molecular mass caused by microorganisms under both aerobic and anaerobic conditions, aided by abiotic variables and their chemical reactions such as photodegradation, oxidation, and hydrolysis.[26,27] Biopolymers possess diverse properties such as biodegradability, renewability, and biocompatibility. They can vary in mechanical strength, flexibility, thermal stability, and water solubility, depending on their chemical structure and origin. These properties make biopolymers ideal for applications in packaging, medicine, agriculture, and environmental sustainability, providing eco-friendly alternatives to traditional, non-degradable polymers.[28] Table 3 below gives a few examples of the applications and properties of various biopolymers along with their properties.

2.1. Classification of biopolymers

Biopolymers are classified into three major categories based on their origin and production method: natural biopolymers, synthetic biopolymers from renewable resources, and microbial biopolymers. Each category has distinct features and potential applications.[47] Natural biopolymers include cellulose, starch, and silk; synthetic biopolymers derived from renewable resources include polylactic acid and polyhydroxyalkanoates, while microbial biopolymers such as xanthan gum and alginate are produced by microorganisms.[48] Each type offers unique properties and applications that promote sustainability and eco-friendliness (Illustration 3).

2.1.1. Natural biopolymers

Natural biopolymers are derived from biological sources such as plants, animals, and microorganisms. They are typically obtained through direct extraction and modification processes.

- **Polysaccharides**: Examples include cellulose, starch, and chitin, which serve structural and storage functions in plants and arthropods, respectively.
- **Proteins**: Biopolymers such as collagen, keratin, and silk provide mechanical strength and biological functions.
- **Nucleic Acids: DNA** and **RNA** store and transmit genetic information.

2.1.2. Synthetic biopolymers from renewable resources

These biopolymers are synthesized using monomers derived from biological sources through chemical polymerization.

- **Polylactic Acid (PLA)**: Derived from corn starch or sugarcane, PLA is widely used in biodegradable packaging and medical implants.
- **Polyhydroxyalkanoates (PHAs)**: These are microbial polyesters used in biomedical applications and biodegradable plastics.

- **Polycaprolactone (PCL)**: A synthetic biodegradable polyester applied in drug delivery and tissue engineering.

2.1.3. Microbial biopolymers

Microbial biopolymers are produced by microorganisms through fermentation. These polymers have unique properties, including high viscosity and stability.

- **Xanthan Gum**: A polysaccharide produced by *Xanthomonas campestris*, widely used in food thickening and oil recovery.
- **Alginate**: Extracted from brown algae and bacteria, it is utilized in **wound dressing**, **drug delivery**, and **bioprinting**.
- **Bacterial Cellulose**: Produced by *Acetobacter xylinum*, used in **biomedical applications** and **cosmetics**.

Biopolymers are crucial to the functioning of nature. They are incredibly helpful for carrying out various tasks, including energy storage, transmitting genetic information, and building cells. All biopolymers are produced through enzymatic processes, whether in

the cytoplasm, different organelles, or compartments of the cells, at the membranes of the cytoplasm or cell wall constituents, on the surface of cells, or even extracellularly. The fabrication of a biopolymer may begin in one area of a cell and continue in another area as it takes place.[49–51] Life forms are capable of creating a wide variety of distinct polymers and in most species, these biopolymers are responsible for the majority of the dry matter in the cells. Biopolymers perform several critical and diverse tasks for cells as varied as their

Table 4. Represents several biopolymers and their nanofibers along with their characteristics, applications, and properties.

Biopolymer	Metal	Method	Applications	Characterization	Properties	References
Chitosan	Fe_2O_3	The Co-precipitation Method, Thermal decomposition method	Pharmaceuticals, biomedical,	XRD, FTIR, TEM	Surface modifications, low toxicity, super magnetic,	[55–58]

structural makeup. The functions of biopolymers are as diverse and intricate as their molecular structures. They find applications across numerous sectors, including healthcare, textiles, commercial products, cosmetics, food processing, packaging, and waste management.[52–54] Biopolymers also play critical roles in genetic information storage, catalysis of enzymatic and non-enzymatic reactions, detection of biotic and abiotic stimuli, and cellular defense mechanisms. Table 4 presents literature data on various biopolymers and their nanofibers, detailing their characteristics, properties, and applications.

2.2. Synthesis of biopolymers

The synthesis of biopolymers varies depending on the type of polymer and the source material. Below is an overview of common synthesis methods:

(1) **Enzymatic Polymerization**: Natural biopolymers such as proteins, polysaccharides, and nucleic acids are synthesized in biological systems using enzyme-mediated polymerization.[68]
(2) **Chemical Polymerization**: Synthetic biopolymers such as PLA and PHA are produced through chemical processes such as condensation polymerization and ring-opening polymerization.[69]
(3) **Microbial Fermentation**: Certain biopolymers, like xanthan gum and PHAs, are synthesized by bacteria using fermentation techniques under controlled conditions.[70]
(4) **Co-precipitation and Cross-linking Methods**: These are widely used for biopolymer-based nanocomposites, where metal nanoparticles or other reinforcing agents are incorporated to enhance their properties.[71]
(5) **Electrospinning**: A technique used for fabricating biopolymer nanofibers by applying a high-voltage electric field to polymer solutions, leading to their application in tissue engineering and drug delivery.[72]
(6) **Hydrothermal Synthesis**: This method utilizes high-temperature and high-pressure aqueous environments to synthesize biopolymer-based nanocomposites with improved thermal and mechanical properties.[73]
(7) **Sol-Gel Processing**: A wet-chemical technique for producing biopolymer-based hybrid materials, involving the transition of a system from a liquid solution into a solid gel phase, commonly used in biomaterials and coatings.[74]

2.3. Comparative analysis of biopolymers

The comparative analysis highlights the diverse origins, properties, and applications of biopolymers. Cellulose, derived from plants, is known for its high strength and biodegradability, making it ideal for paper, textiles, and pharmaceuticals.[75] Chitin, obtained from crustaceans and fungi, exhibits biocompatibility and antibacterial properties, supporting applications in wound healing and agriculture.[29] PLA, sourced from corn and sugarcane, is a thermoplastic and compostable polymer

widely used in packaging and medical implants.[21] PHAs, produced by bacteria, are highly biodegradable and versatile, finding applications in biomedical fields and bioplastics. Alginate, derived from algae and bacteria, is hydrophilic with excellent gelling properties, making it suitable for drug delivery and food stabilization.[66]

While biopolymers offer numerous advantages, including biodegradability, biocompatibility, and renewable sourcing, their widespread application faces several challenges. The primary limitations include their mechanical weakness compared to synthetic polymers, susceptibility to microbial degradation in specific environments, and often higher production costs. Additionally, many biopolymers exhibit poor thermal stability, limiting their use in high-temperature applications. Another significant concern is their inconsistent quality due to variations in natural sources, which can impact processing and end-use properties. Addressing these challenges through advanced material modifications, cross-linking techniques, and nanocomposite integration is crucial for expanding their practical applications.

Biopolymers can be classified using various criteria without strict limitations. These classifications can be based on factors such as their origin, biodegradability, thermal responsiveness, and composition, among others. Multiple factors contribute to categorizing biopolymers into distinct classes and sub-classes.[76] Illustration (4) depicts their classification based on biological degradation.

2.4. Applications of biopolymers

Biopolymers provide environmentally friendly alternatives to synthetic materials, finding use in various industries due to their versatility and sustainable properties. Their applications span biomedical devices, drug delivery systems, tissue engineering, and wound dressings, as well as food packaging, agriculture, environmental remediation, biosensing, and energy storage, including lithium-ion batteries.[14,77] These materials also contribute significantly to reducing plastic waste by replacing conventional polymers with biodegradable and renewable options. They have diverse applications across multiple industries, including pharmaceuticals, biomedical, food, agriculture, textiles, and cosmetics.[78,79] Illustration (5) highlights key applications of biopolymers across multiple industries.

Biopolymer-based nanofibers have gained attention due to their biodegradability, biocompatibility, and high surface-area-to-volume ratio. Their unique properties

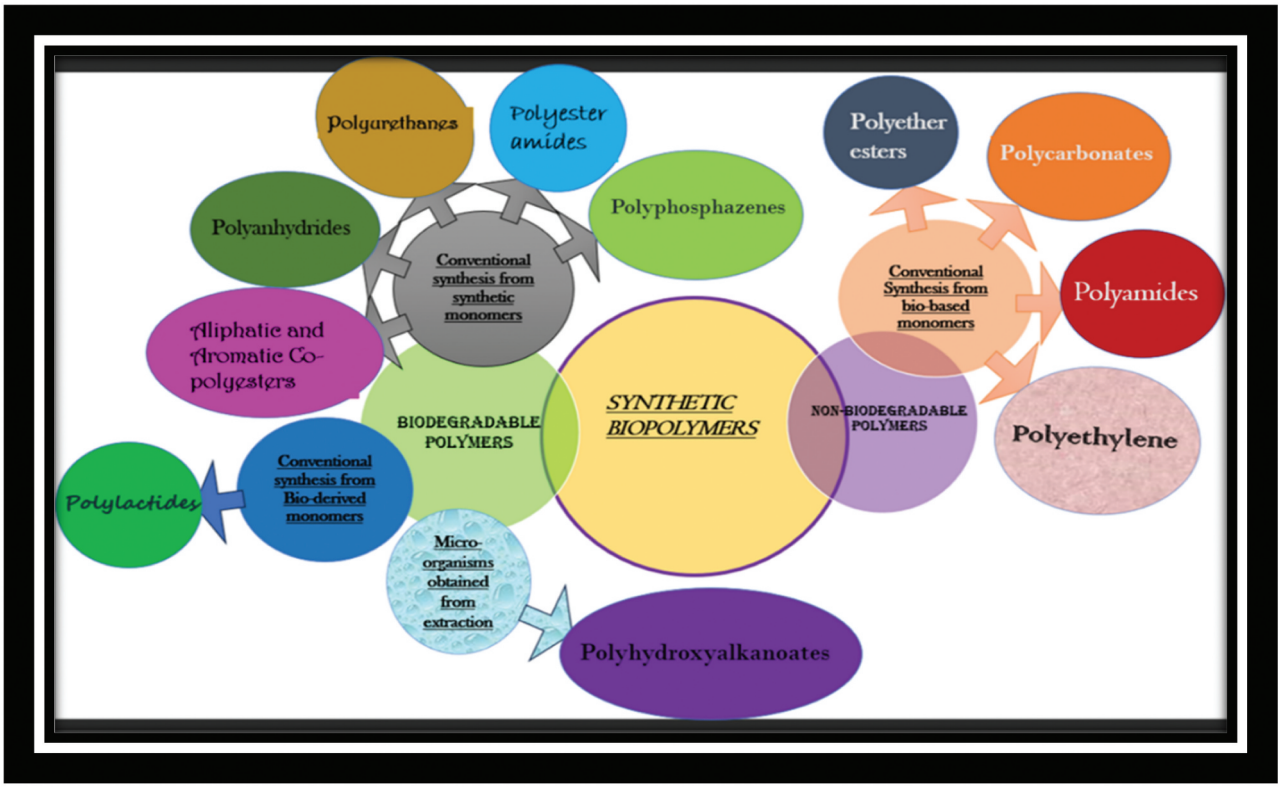

Illustration 4. classification of biopolymers based on their biodegradability.

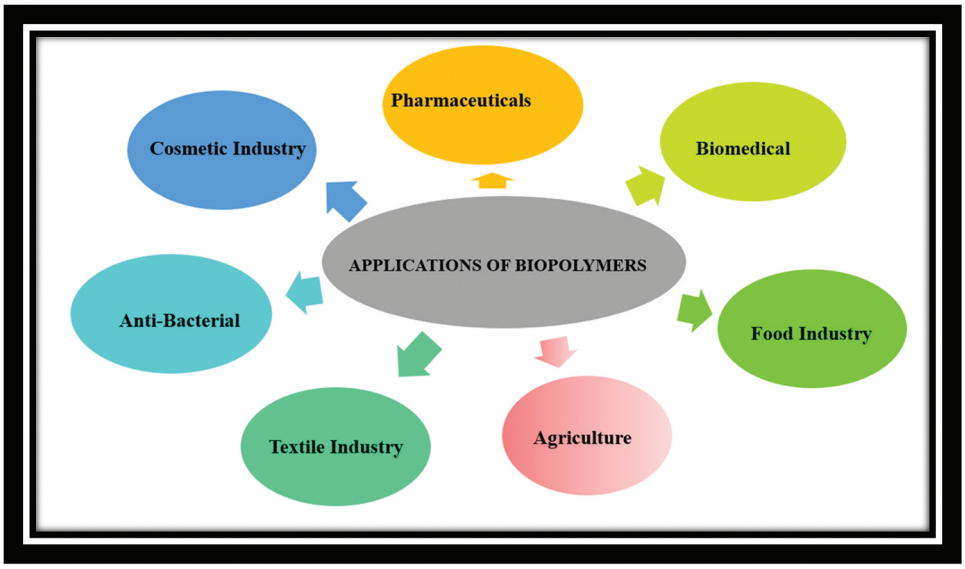

Illustration 5. Key applications of biopolymers across various industries.

make them ideal for drug delivery, wound healing, and environmental remediation. Nanofibers from cellulose, chitosan, and silk fibroin exhibit superior mechanical strength, thermal stability, and antimicrobial properties.[80] Additionally, their functionalization enhances their effectiveness in biosensing, food packaging, and filtration systems, positioning biopolymer nanofibers as promising sustainable materials.[81,82]

Guar Gum, a natural biopolymer, exemplifies these advantages with its exceptional thickening and gelling abilities. Widely used in food, pharmaceuticals, and environmental applications, Guar Gum-based nanocomposites offer enhanced mechanical strength, antibacterial properties, and stability. Table 5 presents various Guar Gum-metal nanostructures, showcasing their characteristics, properties, and applications in biomedical engineering, food packaging, and environmental remediation.

3. Guar Gum

Guar Gum is a natural biopolymer obtained from the seeds of the guar plant *(Cyamopsis tetragonoloba)*. Its molecular structure consists of a backbone of linear mannose units (β-D-mannopyranose) linked by (1→4) glycosidic bonds, with galactose units (α-D-galactopyranose) attached as side branches (Illustration (6)).[90] Typically, the ratio of mannose to galactose in Guar Gum is about 2:1, which contributes to its unique thickening and gelling properties. This structure allows Guar Gum to absorb water and form viscous solutions, making it a versatile ingredient in industries. This unique configuration contributes to its excellent thickening and gelling properties, making it a valuable additive in various industries, including food, pharmaceuticals, and cosmetics.[91] Guar Gum's ability to retain water and form viscous solutions enhances its functionality in applications such as stabilizers, emulsifiers, and binders.

Galactose and mannose (Illustration (7)) are both simple sugars (monosaccharides) that play crucial roles in various biological processes. While galactose is primarily found in lactose and is essential for cellular metabolism, mannose is involved in glycoprotein synthesis and is significant for cell signaling and recognition.[92]

Guar Gum exhibits several notable physical properties that contribute to its versatility in various applications. One of its most significant characteristics is its ability to form highly viscous solutions when hydrated, which allows it to function effectively as a thickening and stabilizing agent.[93,94] Guar gum has excellent water-absorbing and thickening properties, making it highly effective as a stabilizer and emulsifier in various industrial and food applications. Additionally, its solubility in both cold and hot water makes it particularly valuable in the food industry. The viscosity of Guar Gum solutions can be influenced by factors such as concentration, temperature, and pH, providing flexibility in formulation.[95] Furthermore, its nonionic nature allows it to interact well with other ingredients without altering their properties, making it an ideal

Table 5. Represents several nanostructures of Guar Gum along with their characteristics, applications, and properties.

Biopolymer	Metal	Method	ApplicationS	Characterization	Matrix formed	References
Guar Gum	Ag	Green Synthesis	Biomedical, Environmental	XRD, FTIR, TEM	Hydrogels	[83]
Guar Gum	ZnO NPs	Cross-linking method	Food packaging	XRD, FTIR, UV, TEM, X-ray, SEM	Hydrogel Nanocomposite film	[84]
Guar Gum	Silver NPs	In-situ Method	Food packaging, Anti-bacterial	UV/Vis, TEM, HRTEM	Nanocomposite-film	[85]
Guar Gum/ Graphene Oxide	CuO	Ex-Situ method	Waste water purification	XRD, TEM, UV, NMR	Nanocomposite powder	[86]
Guar Gum	TiO_2/ Fe_3O_4	Sol-Gel method	Photocatalytic antimicrobial activity	SEM, FTIR, UV, TEM, XRD	Nanocomposite powder	[87]
Guar Gum	Fe_3O_4	Co-precipitation and cross-linking method	Biological, Biomedical,	TEM, XRD, FTIR, VSM	Cancer treatment, hypothermia, drug delivery, catalytic	[88, 89]

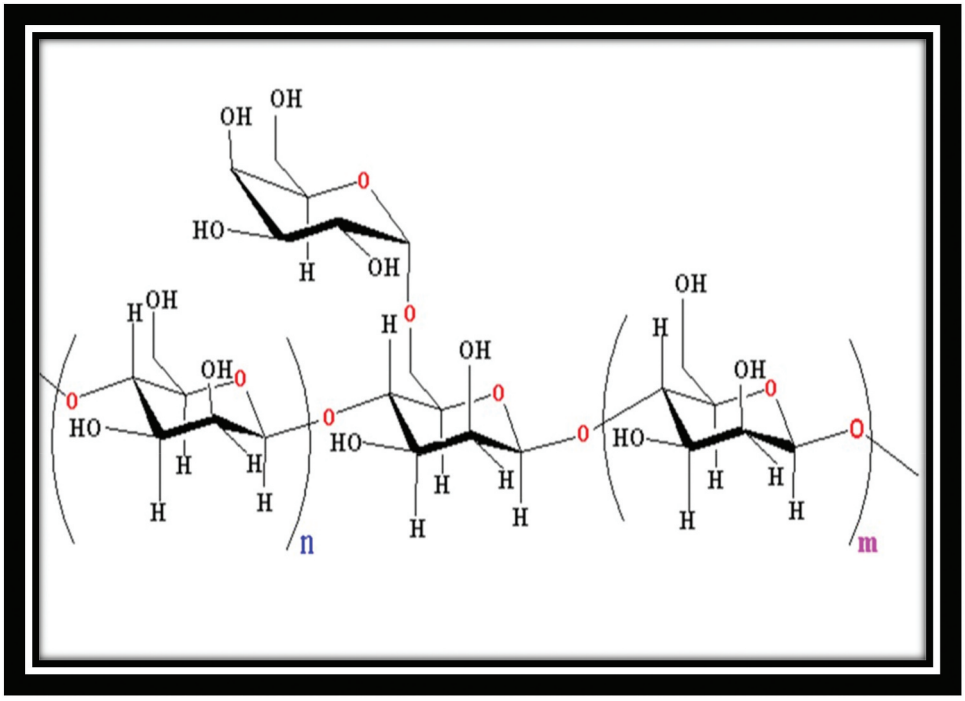

Illustration 6. chemical structure of Guar Gum.

component in pharmaceuticals, cosmetics, and various industrial applications. Guar Gum exhibits several notable physical properties that significantly contribute to its versatility across various applications. One of its most remarkable characteristics is its ability to form highly viscous solutions when hydrated, allowing it to function effectively as a thickening and stabilizing agent.[96] This biopolymer can absorb water up to ten-twenty times its weight, resulting in a gel-like consistency that enhances the texture and mouthfeel of food products. Its high water retention capacity makes it particularly useful in the food industry, where it helps to maintain moisture in baked goods, sauces, and dairy products.[97]

3.1. Properties of Guar Gum

Guar Gum is insoluble in organic solvents and forms a highly viscous solution when dissolved in cold water, especially upon heating. Its solutions exhibit notable buffering capacity and remarkable stability within a pH range of 4.0 to 10.5.[98] The exceptionally high viscosity of Guar Gum is attributed to unique intermolecular interactions, including entanglements, and its substantial hydrodynamic volume in solution.[99] Notably, an increase in temperature causes significant thinning of Guar Gum solutions, as the polymer molecules lose hydration, making it one of the most effective natural polymers.[100] Additionally, as the temperature rises, the pH decreases, and particle size reduces, facilitating faster dissolution and

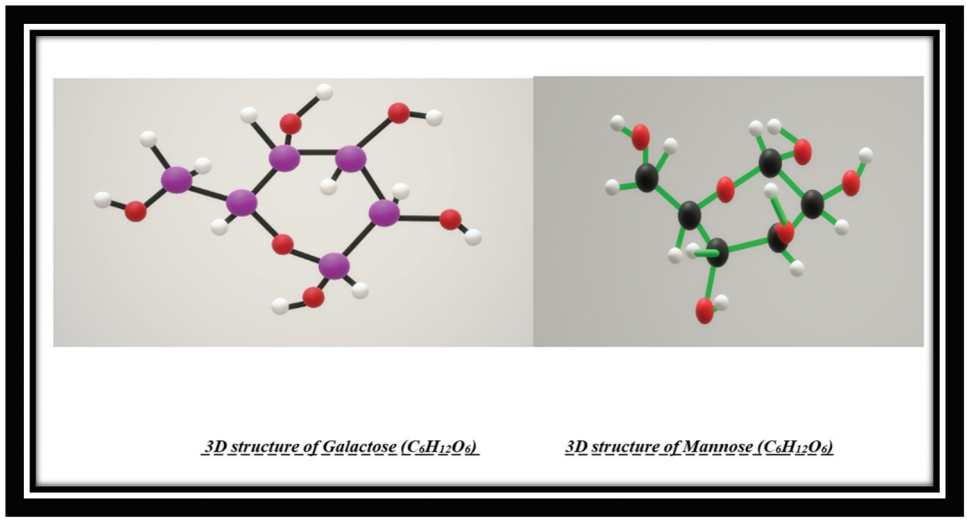

Illustration 7. chemical 3-D structure of galactose and Mannose.

viscosity development.[101] Even at minimal concentrations, Guar Gum rapidly hydrates in hot and cold water to form thick colloidal solutions, demonstrating its gel-forming capacity and excellent water-binding properties through hydrogen bonding in aqueous environments.[102]

This property is particularly valuable in the **food industry**, where Guar Gum is widely used as a thickener and stabilizer in ice creams, dairy products, and sauces, preventing ice crystal formation and improving texture. Its high viscosity also makes it a preferred **fracking agent in the oil and gas industry**, where it is employed in hydraulic fracturing fluids to enhance the efficiency of proppant transport. Additionally, in **pharmaceutical applications**, its ability to form gels and retain moisture makes it an ideal component in controlled drug delivery systems, where it modulates drug release rates. Guar Gum is biodegradable, biocompatible, and nontoxic, further enhancing its appeal for various applications. Additionally, it functions as a dispersant in organic systems and exhibits a high capacity for cross-linking and chemical modification, making it a versatile and valuable biopolymer[103] (Illustration (8)). For instance, in **cosmetic formulations**, Guar Gum is utilized in lotions and creams to improve viscosity and enhance moisture retention, contributing to better skin hydration. Moreover, its use in **wastewater treatment** as a flocculant aids in removing suspended particles, demonstrating its environmental significance.

Given its extensive industrial applications, the production and **processing of Guar Gum** play a crucial role in determining its quality, purity, and functional attributes. Various processing techniques are employed to ensure the efficient extraction and refinement of Guar Gum, optimizing its physicochemical properties for specific applications. The extraction process significantly influences its molecular weight distribution, hydration capacity, and performance in end-use formulations.

3.2. Processing of Guar Gum

India is the world's foremost producer of guar, with various mechanical techniques employed in the industry for extracting Guar Gum from guar seeds. Key methods include polishing, attrition, roasting, and sifting. Due to the varying hardness of the constituent components, the endosperm and its parts can be easily separated. Guar splits are produced following the removal of the hull and germ. After heat treatment, the hull can be effectively separated using attrition milling or various types of impact mills. Sieving facilitates the extraction of the finer fractions of the germ and hull from the endosperm. The subsequent stage involves grinding the Guar Gum into a powder. Finally, the Guar Gum is purified through a process that includes precipitation, dissolution in water, and recovery using ethanol or isopropanol. The result is purified Guar Gum, ready for various applications.[93,104]

3.3. Chemical modification of Guar Gum

Guar Gum, despite its multifaceted utility, exhibits inherent limitations that constrain its applicability across various industrial and scientific domains.[89] One of its principal shortcomings is its restricted solubility in organic solvents, thereby limiting its integration into non-aqueous systems such as pharmaceutical

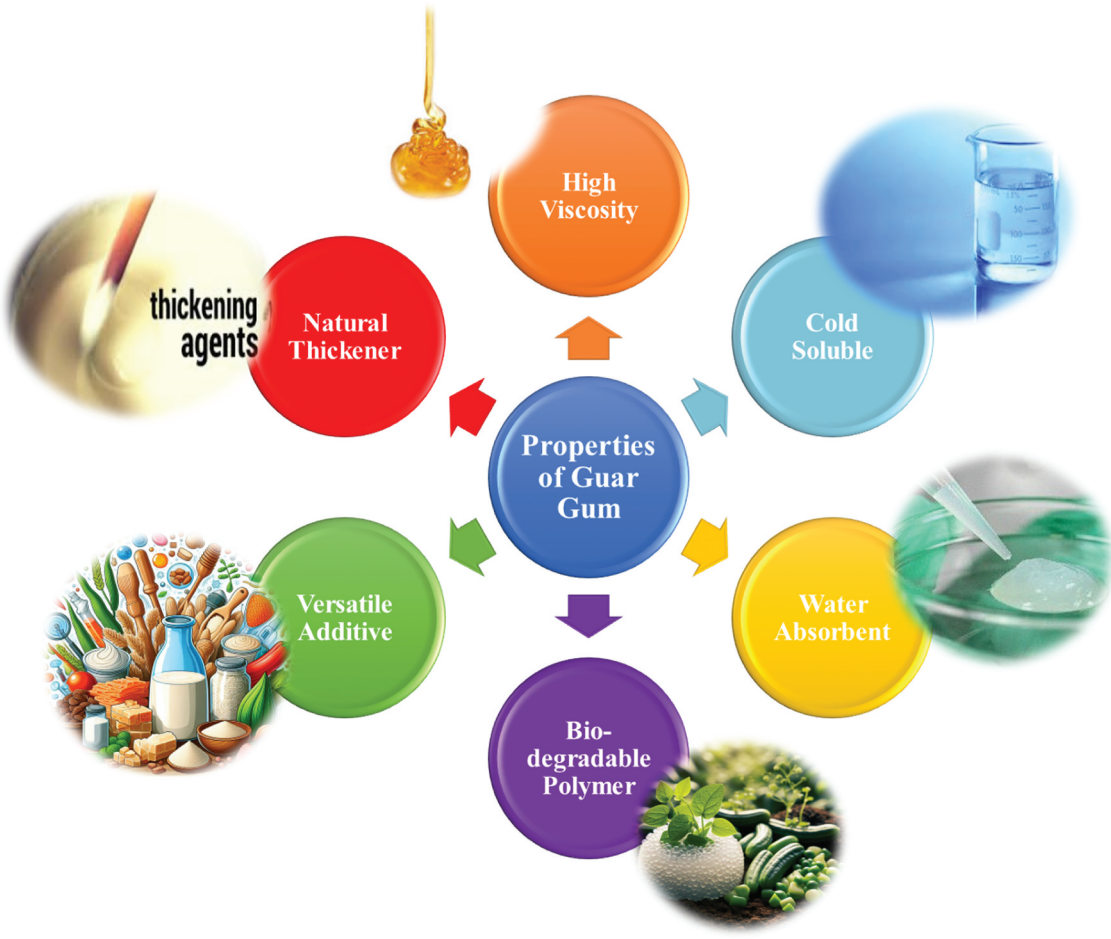

Illustration 8. properties of Guar Gum.

formulations, hydrophobic coatings, and industrial adhesives. This solubility constraint necessitates chemical modification to broaden its compatibility with diverse solvent environments. Furthermore, Guar Gum's physicochemical stability is compromised under extreme pH conditions and elevated temperatures, rendering it unsuitable for applications requiring thermal resilience, such as high-temperature food processing, enhanced oil recovery, and cosmetic formulations demanding extended stability.[105] Another critical drawback is the pronounced variability in its rheological properties, which exhibit significant sensitivity to temperature fluctuations and shear forces. This inherent instability can impede its efficacy as a viscosifier and stabilizing agent in sectors such as food technology, pharmaceuticals, and polymer composites, where precise rheological control is imperative. Additionally, Guar Gum is highly susceptible to microbial degradation, resulting in a reduced shelf life, particularly in aqueous-based formulations. This necessitates the incorporation of antimicrobial agents or molecular modifications to enhance its structural integrity and longevity. Economic volatility in the global market further exacerbates its commercial unpredictability, making cost-effective synthetic or modified biopolymeric alternatives highly desirable for industrial-scale utilization. Moreover, its ionic sensitivity predisposes it to undesirable precipitation in electrolyte-rich environments, thereby restricting its deployment in applications such as wastewater treatment, biomedical formulations, and electrolyte-based industrial processes where colloidal stability is paramount.[106,107]

To circumvent these limitations, targeted chemical modifications have been extensively explored to refine the physicochemical properties of Guar Gum, thereby augmenting its functionality and expanding its industrial viability. Modification strategies such as etherification, esterification, and oxidation facilitate substantial enhancements in solubility, stability, and application-specific performance. For instance, etherification via carboxymethylation introduces carboxymethyl functionalities into the polymer backbone, yielding carboxymethyl Guar Gum (CMGG). This derivatization markedly amplifies hydrophilicity and aqueous

Illustration 9. some examples of the applications of derivatives of Guar Gum.

solubility, thereby broadening its applicability in pharmaceutical excipients, food texturizers, and cosmetic formulations that necessitate superior dispersibility and stabilization.[108–110] Esterification, conversely, engenders the incorporation of ester moieties, conferring enhanced thermal and mechanical robustness to Guar Gum derivatives. These modifications foster the development of polymeric matrices with superior film-forming attributes, rendering them ideal candidates for biodegradable packaging materials, controlled-release systems, and advanced polymeric composites.[88] Oxidative functionalization modulates molecular weight and introduces reactive oxygen-containing groups, thereby tailoring viscosity profiles and reactivity. This structural transformation enables oxidized Guar Gum to exhibit enhanced performance in specialized applications such as drilling fluid rheology optimization, soil conditioning for sustainable agriculture, and high-performance dispersion systems.[94]

Beyond addressing the intrinsic deficiencies of native Guar Gum, these chemical modifications also facilitate its transition into biomedical and high-performance material applications. CMGG, for example, exhibits hydrogel-forming capabilities, making it a promising candidate for controlled drug delivery matrices, wound healing scaffolds, and regenerative medicine frameworks.[95] By leveraging molecular engineering approaches, chemically functionalized Guar Gum derivatives are progressively meeting the stringent performance requirements of industries such as food processing, coatings and pigments, mining, oil and gas, pulp and paper, water purification, cosmetics, and the synthesis of superabsorbent biomaterials (Illustration (9)).

Some of the derivatives of Guar Gum are listed below,

(1) Carboxymethyl Guar Gum (*CMGG*).[108]
(2) Hydroxypropyl Guar Gum (*HPGG*).[111]
(3) O-carboxymethyl- O-hydroxypropyl Guar Gum (*CMHPGG*).[112]
(4) Hydroxymethyl Guar Gum (*HMGG*).[113]
(5) Acryloyloxy Guar Gum.[114]
(6) Methacryloyl Guar Gum.[115]
(7) O-carboxymethyl- O-2 hydroxy-3- (trimethyl ammonia propyl) Guar Gum (CMHTPG).[94]

The most distinctive feature of Guar Gum and its derivatives is the presence of hydroxyl groups, which allows for the modification of their functionalization and structural formula.[116] The diverse properties and applications of Guar Gum lay the groundwork for exploring its derivative, Carboxymethyl Guar, which offers enhanced functionality and versatility in various fields.

4. Carboxymethyl Guar Gum

Carboxymethyl Guar Gum (CMGG) is a chemically modified derivative of Guar Gum, a natural polysaccharide extracted from the seeds of the guar plant (*Cyamopsis tetragonoloba*).[117] Guar Gum is widely recognized for its thickening, gelling, and stabilizing properties, which have made it a valuable ingredient in various industries, including food, pharmaceuticals, and cosmetics. However, the native form of Guar Gum has limitations in terms of solubility and functionality under specific conditions. To overcome these limitations, CMGG is synthesized through the carboxymethylation process,

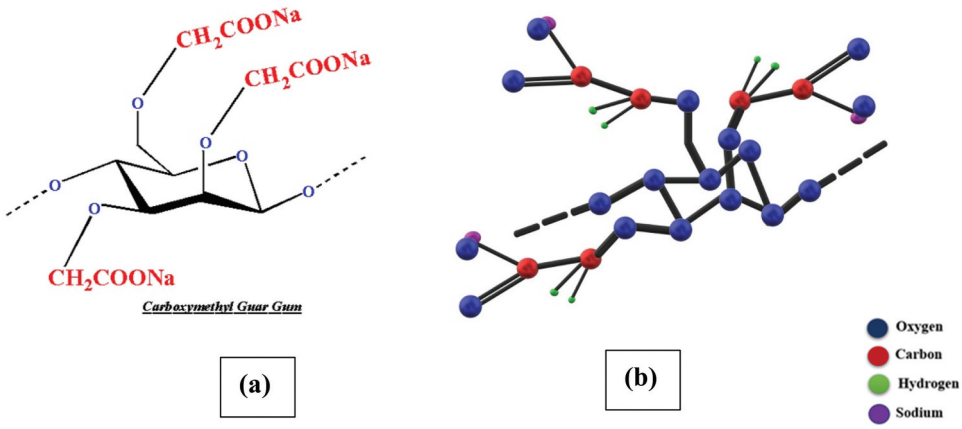

Illustration 10. (a) chemical structure of CMGG; (b) 3-D structure of CMGG.

wherein carboxymethyl groups are introduced into the Guar Gum molecule. This modification enhances the solubility of CMGG in cold water, increases its viscosity, and imparts improved stability across a broader pH range. These properties make CMGG a versatile biopolymer with a wide array of applications.[118] CMGG's unique characteristics, including its ability to form gels and films, have led to its adoption in drug delivery systems, where it acts as a controlled release agent, and in the food industry, where it serves as an effective thickener and stabilizer.[119] Additionally, its biocompatibility and nontoxic nature position CMGG as a promising candidate for biomedical applications, particularly in tissue engineering and pharmaceutical formulations.[120] As research continues to explore the potential of CMGG, its role as a functional additive in various sectors is becoming increasingly significant, driving innovation and expanding the boundaries of biopolymer applications.[121] This section delves into the synthesis, properties, applications, and prospects of Carboxymethyl Guar Gum, highlighting its importance and its contribution to advancements in material science and technology.

4.1. Introspection of chemical structure of carboxymethyl Guar Gum (CMGG)

Carboxymethyl Guar Gum (CMGG) is a chemically modified derivative of Guar Gum, characterized by the introduction of carboxymethyl groups into its polysaccharide backbone. The chemical structure of CMGG consists of a linear chain of mannose and galactose units, which are the primary components of Guar Gum[122] (Illustration 10). The carboxymethylation process occurs through the substitution of hydroxyl groups in the Guar Gum molecule with carboxymethyl groups, resulting in enhanced solubility and reactivity.[123]

This modification introduces anionic charges, allowing CMGG to interact more effectively with water molecules and other ionic species, significantly improving its functional properties.[124] One of the most notable physicochemical properties of CMGG is its solubility in water, particularly at lower temperatures. Unlike native Guar Gum, which can be less soluble in cold water and requires heat for effective hydration, CMGG exhibits a rapid dissolution process due to the presence of carboxymethyl groups.[95,121] This enhanced solubility contributes to its versatility in various applications, particularly in the food and pharmaceutical industries. Furthermore, CMGG demonstrates superior viscosity characteristics compared to native Guar Gum. The viscosity of CMGG solutions is highly dependent on concentration, temperature, and shear rate, making it an excellent thickening agent.[125] Its ability to form gels and films is another critical property that enhances its applicability in areas such as drug delivery systems and food formulation. In comparison to native Guar Gum, CMGG offers distinct advantages due to its modified structure.[100] While native Guar Gum primarily exhibits neutral behavior in aqueous solutions, the anionic nature of CMGG allows it to maintain stability over a broader pH range, making it suitable for diverse formulations. Additionally, the viscosity profile of CMGG is more favorable in terms of achieving desired textural properties in various products.[91] This adaptability makes CMGG a more effective thickening and stabilizing agent, especially in formulations that require consistency and reliability. The structural modifications and resulting physicochemical properties of Carboxymethyl Guar Gum position it as a highly functional and versatile biopolymer, surpassing the limitations of its native counterpart and paving the way for innovative applications across multiple industries.[126]

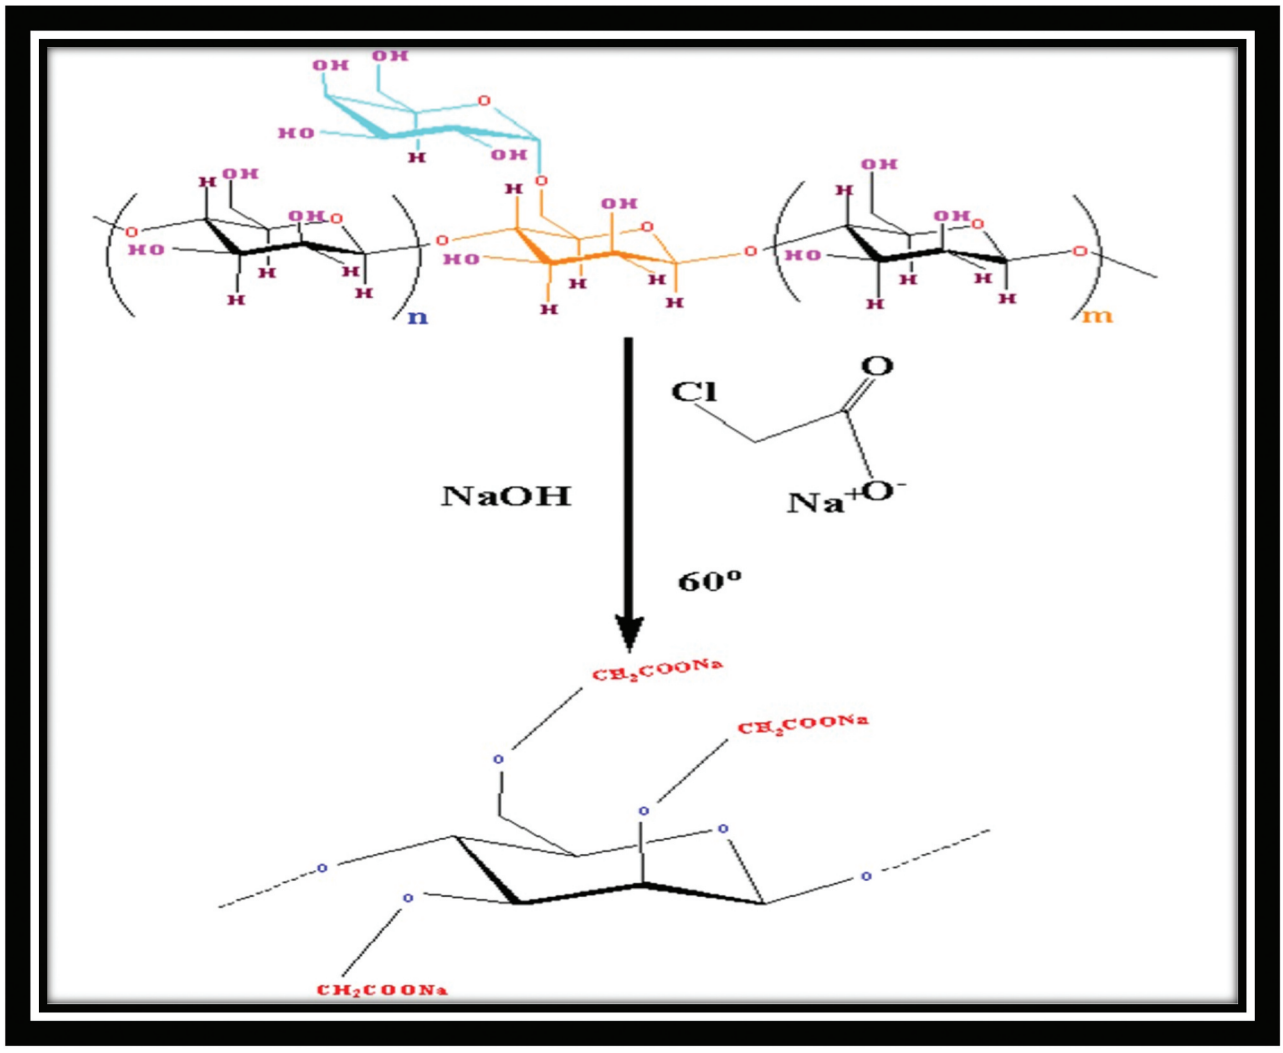

Illustration 11. synthesis of Carboxymethyl Guar Gum.

4.2. Synthesis and applications of carboxymethyl Guar Gum (CMGG)

Carboxymethyl Guar Gum (CMGG) is synthesized through an alkali-catalyzed etherification reaction, wherein Guar Gum undergoes carboxymethylation to introduce carboxymethyl groups into its molecular structure.[108] This process typically employs sodium hydroxide (NaOH) as a catalyst and monochloroacetic acid (MCA) as the carboxymethylating agent. Initially, Guar Gum is dissolved in an aqueous alkaline solution, which activates its hydroxyl groups, making them more reactive. The gradual addition of MCA facilitates the substitution of hydroxyl groups with carboxymethyl groups.[95, 108, 127, 128] The reaction is generally carried out at temperatures ranging from 30°C to 60°C for several hours (typically 4–8 hours) to ensure complete modification. Maintaining an optimal molar ratio of 1:2 (Guar Gum to MCA) and pH control is crucial for efficient etherification and achieving the desired degree of substitution[95] (Illustration (11)). Characterization techniques such as Nuclear Magnetic Resonance (NMR) spectroscopy, Fourier Transform Infrared (FTIR), Scanning Electron Microscopy (SEM), and rheological measurements confirm the successful synthesis of CMGG and its structural modifications.[123]

CMGG finds applications across diverse industries due to its biocompatibility, non-toxicity, and functional properties (Illustration (12)). In pharmaceuticals, it serves as an excipient in drug formulations, particularly for controlled-release systems that enhance therapeutic efficacy.[119] In the food industry, CMGG acts as a thickener, gelling agent, and stabilizer, improving texture and extending shelf life in products like sauces, dressings, and dairy items.[95,98] Its anionic nature ensures compatibility with various ingredients, providing stability across

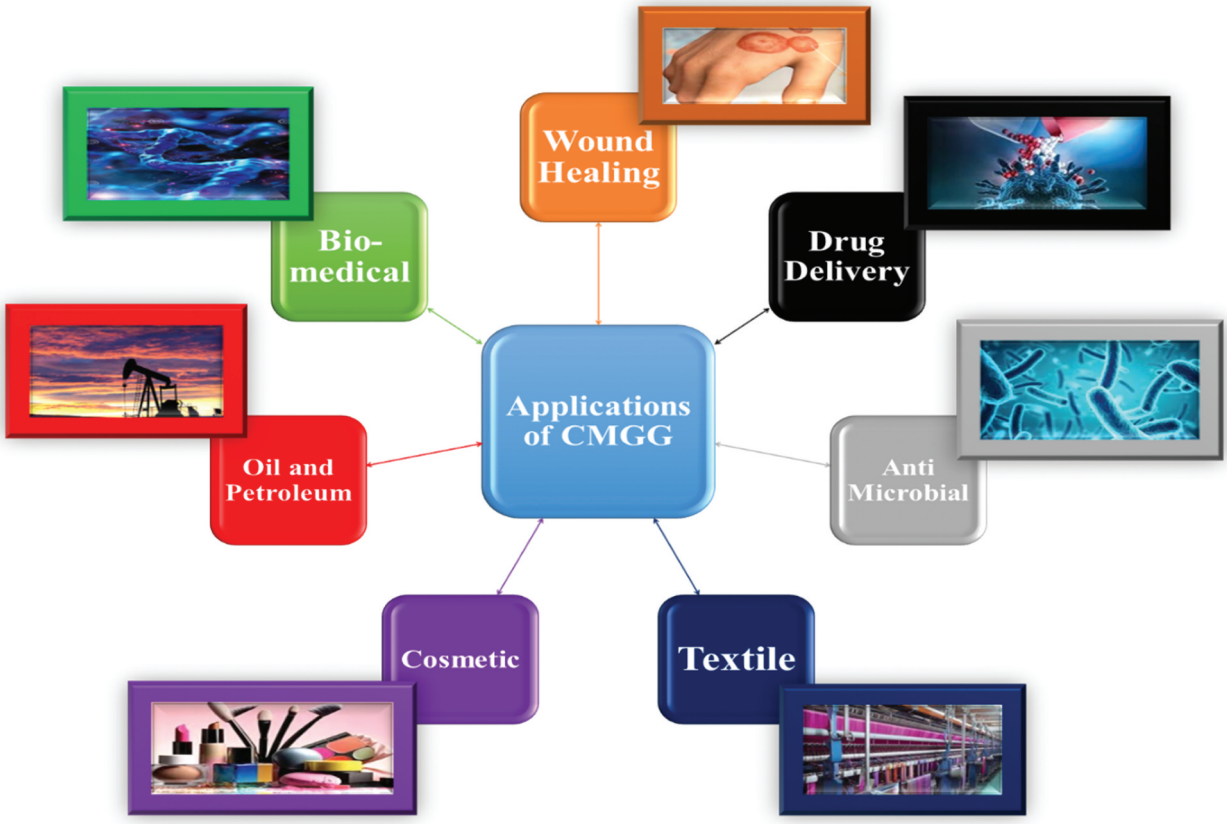

Illustration 12. applications of Carboxymethyl Guar Gum.

different pH levels. In cosmetics and personal care, CMGG contributes to emulsification and thickening in creams, lotions, and shampoos, enhancing product consistency. Industrially, it functions as a fluid loss control agent in oil drilling and as a thickener for textile printing inks, showcasing its versatility.[106]

The multifunctional capabilities of CMGG underscore its significance as an innovative biopolymer, facilitating advancements across multiple fields. Its potential in biomedical applications, including drug delivery and wound healing, highlights its relevance in healthcare. Additionally, its role in nanocomposite development, self-healing materials, and conductive applications demonstrates its versatility in material sciences. By bridging the gap between traditional biopolymers and advanced functional materials, CMGG continues to emerge as a key player in sustainable and high-performance material innovations.

4.2.1. Applications of carboxymethyl Guar Gum (CMGG) with Real-world Examples

CMGG finds applications across diverse industries due to its biocompatibility, non-toxicity, and functional properties.

- **Pharmaceutical Industry**: CMGG is widely utilized in drug formulations, particularly in controlled-release systems that enhance therapeutic efficacy. A recent study demonstrated its role in **nanoparticle-based drug carriers** for targeted cancer therapy, ensuring sustained drug release with minimal side effects.[95]
- **Food Industry**: CMGG acts as a thickener, gelling agent, and stabilizer, improving texture and extending shelf life in products like sauces, dressings, and dairy items. A case study from a leading food corporation highlighted its **use in plant-based dairy alternatives**, where it enhances creaminess and mouthfeel while maintaining stability.[118]
- **Cosmetics and Personal Care**: CMGG contributes to emulsification and thickening in creams, lotions, and shampoos. Recent formulations in **anti-aging serums** have utilized CMGG for enhanced moisture retention and prolonged hydration.[106]
- **Oil Drilling and Textile Printing**: Industrially, CMGG functions as a **fluid loss control agent in oil drilling** and as a **thickener in textile printing inks**, showcasing its versatility. A 2023 study confirmed its efficiency in reducing water loss and

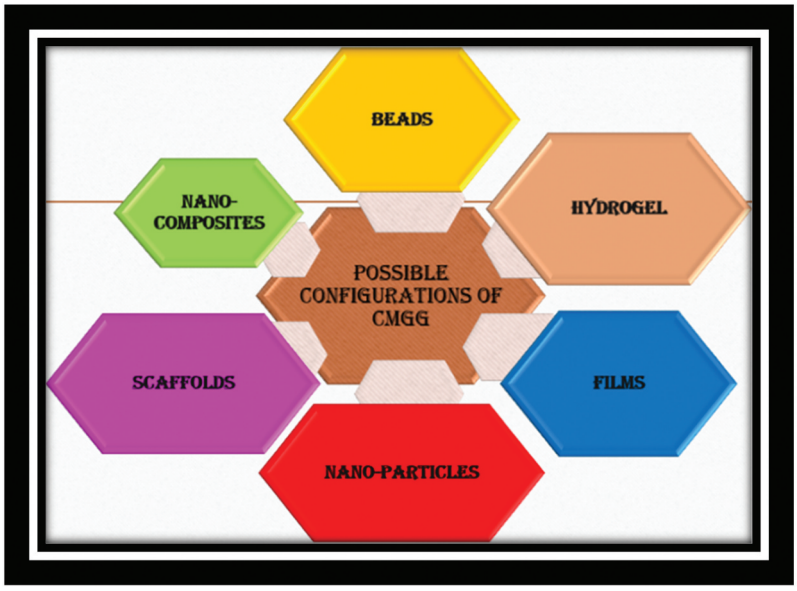

Illustration 13. configurations of Carboxymethyl Guar Gum.

improving drilling fluid viscosity under extreme conditions.

- **Biomedical Applications**: The multifunctional capabilities of CMGG make it an innovative biopolymer in healthcare. **Recent advancements in wound healing** have demonstrated the use of CMGG-based hydrogels in **accelerating tissue regeneration and minimizing infection risks** [129].
- **Nanocomposite Development and Conductive Materials**: CMGG plays a critical role in **self-healing materials and conductive applications**. A study on **CMGG-polyaniline nanocomposites** for wearable electronics showed excellent conductivity and self-repair capabilities.[130]

The ongoing advancements in CMGG research underscore its expanding potential in sustainable and high-performance material innovations. Further studies are investigating its **role in biosensors, smart hydrogels, and biodegradable packaging**, promising groundbreaking applications in various fields.

Table 6 presents various CMGG-based biopolymer-metal matrices, detailing their synthesis methods, characterizations, and applications. These composites exhibit unique properties contributing to developments in biomedical engineering, environmental remediation, and material sciences.

4.3. Characterization techniques for carboxymethyl Guar Gum (CMGG): analysis and insights

Characterization techniques play a crucial role in understanding the structural, thermal, and morphological properties of Carboxymethyl Guar Gum (CMGG). These methods help confirm successful modification, analyze molecular interactions, and assess material performance for various applications. By employing techniques such as FTIR for functional group identification, XRD for crystallinity analysis, and SEM for surface morphology evaluation, researchers can gain comprehensive insights into CMGG's properties. Table 7 summarizes key characterization techniques, detailing their purposes, advantages, and limitations.

The combination of these characterization techniques provides a comprehensive understanding of CMGG's structural, thermal, and morphological properties. By leveraging these analytical methods, researchers can validate chemical modifications, assess material stability, and optimize CMGG for various industrial and biomedical applications. These insights are crucial for tailoring CMGG-based materials to meet the specific requirements of emerging technologies. With a well-characterized profile, CMGG holds significant potential for further advancements in sustainable biopolymer research.

Table 6. Synthesized matrices of CMGG along with their characterizations and preparation methods and applications along with their significance & future impact.

Biopolymer	Matrix	Synthesis methods	Characteristics	Applications	SIZE	Significance & future impact	Reference
CMGG/STMP	Nanoparticles	Ionic Gelation	FTIR, NMR, TGA, DLS, SEM	Drug delivery(nanocarriers)	12-30nm	Enhances drug stability and controlled release, making it a potential carrier for targeted drug delivery.	[131]
CMGG	Nanoparticles	Nanoprecipitation and Sonication	FTIR, SEM, TEM, HRTM	Medical, cosmetic, biosensor, cosmetic, food supplements	12-30nm	Offers biocompatibility and enhanced surface properties, useful in diagnostics and bio-imaging applications.	[128]
CMGG/Citric Acid	Nanocomposite scaffold/ Nanocomposite films	Cross-linking	DSC, ATR-FTIR, DLS, SEM, XRD,	Wound healing		Provides a biodegradable and biocompatible scaffold for tissue regeneration and wound healing applications.	[121]
CMGG/ POLYANILINE	Nanocomposites	Chemical oxidative method	FTIR, XRD, SEM, TEM	Conductive paints	90-280nm	Introduces electrical conductivity, making it suitable for smart coatings and flexible electronics.	[132]
CMGG/PAA-Fe^{3+}	Hydrogels	In-situ radical polymerization	FTIR, UV-Vis	Self-healing in human motion detection		Exhibits self-healing properties, offering potential use in flexible and wearable sensors.	[133]
CMGG/reduced Graphene Oxide	Nanocomposites		SEM, XRD, FTIR	Wound healing		Enhances mechanical strength and antimicrobial properties for biomedical applications.	[134]
CMGG/Ni nps	Ni-polymer composite	Infusion and Reduction	UV, FTIR, XRD, TGA, SEM, TEM,	Catalytic properties and retention of magnetism		Improves catalytic efficiency and magnetic retention, applicable in wastewater treatment and energy storage.	[135]

Table 7. Summary of characterization techniques for CMGG.

Characterization technique	Purpose	Advantages	Disadvantages	References
Fourier Transform Infrared Spectroscopy (FTIR)	Identifies functional groups and confirms chemical modifications	Non-destructive, fast, requires minimal sample	Limited quantitative analysis	[136]
Nuclear Magnetic Resonance (NMR) Spectroscopy	Determines molecular structure and degree of substitution	High accuracy, provides detailed structural information	Expensive, requires specialized expertise	[137]
X-ray Diffraction (XRD)	Analyses crystallinity and phase structure	Provides information on crystal structure	Limited for amorphous materials	[138]
Scanning Electron Microscopy (SEM)	Examines surface morphology and particle size	High-resolution imaging	Requires conductive coating, vacuum environment	[139]
Transmission Electron Microscopy (TEM)	Provides detailed internal structure at the nanoscale	High magnification and resolution	Expensive, complex sample preparation	[140]
Thermogravimetric Analysis (TGA)	Measures thermal stability and decomposition profile	Provides quantitative thermal degradation data	Limited information on chemical composition	[141]
Differential Scanning Calorimetry (DSC)	Determines glass transition and melting points	Useful for studying thermal properties	Requires precise sample preparation	[142]
Dynamic Light Scattering (DLS)	Measures particle size distribution in dispersions	Rapid analysis, non-invasive	Less effective for polydisperse samples	[143]
UV-Vis Spectroscopy	Evaluate optical properties and confirm nanoparticle formation	Simple, cost-effective	Limited structural information	[144]

4.4. Possible configurations of carboxymethyl Guar Gum (CMGG)

Carboxymethyl Guar Gum (CMGG) exhibits a range of possible configurations due to the introduction of carboxymethyl groups into its Guar Gum backbone. These modifications enhance its structural flexibility, allowing for various conformations that depend on environmental conditions such as pH, ionic strength, and temperature.[105] The presence of carboxymethyl groups adds anionic charges to the polymer chain, resulting in an extended configuration in neutral or basic conditions, where electrostatic repulsion between negatively charged groups promotes chain expansion. This leads to higher solubility and increased viscosity in aqueous solutions. In acidic conditions, the anionic charges can be neutralized, allowing the polymer chains to adopt a more compact, coiled structure.[145] Additionally, the degree of substitution of carboxymethyl groups can influence the polymer's behavior, with higher substitution levels leading to more pronounced chain expansion and better interaction with water molecules. CMGG can also form cross-linked networks, particularly in the presence of divalent cations, creating gel-like structures.[146] These configurations, ranging from extended to coiled and from soluble to gelled, enable CMGG to exhibit versatile properties, making it suitable for a wide range of applications, from drug delivery to food thickening and industrial uses. The presence of both carboxyl and hydroxyl groups in the structure of Carboxymethyl Guar Gum (CMGG) attracted significant scientific interest owing to advancements in various properties. CMGG provides a broad spectrum of potential chemical reactions and improved hydrophilicity/water solubility. Carboxymethyl Guar Gum (CMGG) has amassed wide support as a potential functional base for various applications.[44,147] Equipped with increased stability and water solubility, CMGG opens the door to a wide range of additional changes. The domain of the applications of Carboxymethyl Guar Gum can therefore be expanded by blending, grafting, cross-linking, and co-polymerization owing to the presence of carboxyl and hydroxyl groups in its backbone. Fabrication and synthesis of various morphology of CMGG are possible, like scaffolds, films, beads, nanoparticles, and nanocomposites presented in Illustration (13).

Carboxymethyl Guar Gum (CMGG) exhibits remarkable versatility in its configurations, allowing it to serve a variety of functions across multiple industries. It can be processed into beads, which are commonly used in drug delivery systems to provide controlled release of therapeutic agents. Hydrogels made from CMGG offer excellent moisture retention and biocompatibility, making them ideal for applications in wound healing and tissue engineering.[145] Additionally, CMGG forms films that are utilized in biodegradable packaging and as protective layers in wound care products.[121] In the field of nanotechnology, CMGG-based nanoparticles enable targeted drug delivery and enhanced biosensing capabilities [124], [131]. Moreover, scaffolds created from CMGG play a crucial role in tissue engineering by supporting cellular growth and tissue regeneration. Lastly, CMGG can be incorporated into nanocomposites, enhancing their mechanical, thermal, and antimicrobial properties for use in environmental remediation, packaging, and biomedical applications. This adaptability makes CMGG a valuable biopolymer across a wide range of sectors. Carboxymethyl Guar Gum (CMGG) stands out as a highly adaptable biopolymer, offering enhanced properties compared to native Guar Gum through its chemical modification. Its versatility in forming beads, hydrogels, films, nanoparticles, scaffolds, and nanocomposites has expanded its

applicability across diverse fields such as pharmaceuticals, food, environmental remediation, and biomedicine.[149,150] The improved solubility, viscosity, and gelling capacity of CMGG make it an excellent choice for formulations requiring controlled release, biocompatibility, and structural integrity.[44, 95, 132] As industries increasingly seek sustainable and functional materials, CMGG's ability to enhance product performance while remaining biodegradable and nontoxic positions it as a key player in advancing innovative technologies.

5. Conclusion

Carboxymethyl Guar Gum (CMGG) has established itself as a versatile biopolymeric material with significant potential across biomedical, pharmaceutical, packaging, and environmental applications. This review has elucidated its synthesis, structural modifications, and physicochemical properties, highlighting its superiority over unmodified Guar Gum. The functionalization with carboxymethyl groups enhances aqueous solubility, rheological modifiability, and interfacial interactions, positioning CMGG as a high-performance candidate for next-generation biomaterials. Given the global imperative to transition from synthetic polymers to biodegradable alternatives, CMGG emerges as a strategic solution that aligns with contemporary sustainability paradigms. Its intrinsic biodegradability and biocompatibility mitigate environmental concerns associated with conventional polymers, thereby contributing to a reduced ecological footprint. Furthermore, its integration into advanced functional materials – such as hydrogels, nanocomposites, and bioactive films – underscores its potential in sustainable material science. However, despite its promising attributes, several challenges must be addressed to facilitate its large-scale industrial adoption. Enhancing CMGG's mechanical robustness, optimizing crosslinking strategies, and improving its processability in scalable manufacturing systems remain critical areas of research. Additionally, elucidating its long-term stability, degradation kinetics, and interactions in complex biological and environmental matrices will be pivotal for regulatory approvals and commercialization. The development of hybrid CMGG-based materials with synergistic functionalities – such as stimuli-responsiveness, self-healing capabilities, and multimodal bioactivity – could further elevate its applicability in high-performance domains. Future research should also explore eco-friendly synthesis routes and green crosslinking agents to reinforce its role in circular economy models, minimizing waste generation and microplastic pollution.

Beyond CMGG, the field of biopolymers as a whole faces similar challenges in scalability, cost-effectiveness, and functional adaptability. Despite their environmental advantages, many biopolymers exhibit limitations such as lower mechanical strength, shorter lifespan, and sensitivity to processing conditions. The development of **multifunctional biopolymeric composites**, incorporating nanoscale reinforcements and bio-based crosslinking strategies, could offer a pathway to overcome these limitations. Additionally, research efforts must focus on enhancing **biopolymer processability** using advanced fabrication techniques such as **3D printing, electrospinning, and molecular self-assembly** to create structurally refined and application-specific biomaterials.

Another crucial area of future research is **the development of fully biodegradable and recyclable biopolymeric systems** to mitigate polymeric waste accumulation. The incorporation of **bioinspired design principles**, leveraging molecular interactions seen in natural biopolymers, could lead to the next generation of high-performance sustainable materials. Furthermore, interdisciplinary collaboration between material science, nanotechnology, and biotechnology will be essential for unlocking novel functionalities in CMGG and other biopolymers, particularly in drug delivery, regenerative medicine, and environmental remediation. In essence, CMGG epitomizes the paradigm shift toward bio-based polymers that not only exhibit superior functional efficacy but also align with ecological sustainability. As advancements in polymer engineering, nanotechnology, and biomaterial science continue to accelerate, CMGG holds immense potential to redefine the landscape of sustainable materials. Bridging the gap between renewable biopolymers and technologically sophisticated functional materials, its evolution will be instrumental in fostering the next generation of environmentally benign, high-performance polymeric innovations. Likewise, continued advancements in biopolymer research will play a transformative role in **reducing dependency on petrochemical-derived materials, promoting circular economy models, and revolutionizing material applications across diverse scientific and industrial domains**

Acknowledgments

We gratefully acknowledge the invaluable contribution of our colleagues and mentors, who provided guidance and support throughout the writing of this review paper. Their insights and encouragement were instrumental in shaping our understanding and refining the content. We are also thankful to all researchers and authors whose work has been referenced in this review paper.

Disclosure statement

No potential conflict of interest was reported by the author(s).

Funding

This study did not receive financial support from any public, commercial, or non-profit funding organizations.

Notes on contributors

Vratika Verma is a dedicated researcher currently pursuing her Ph.D. at the Department of Chemistry, Gurukula Kangri University, Haridwar, Uttarakhand, under the guidance of Dr. Jagram Meena, having commenced her doctoral journey in September 2023. She completed her Master's degree from Hemvati Nandan Bahuguna Garhwal University, Srinagar (Garhwal), Uttarakhand, in 2021, which ignited her passion for research and academia. Her scholarly contributions are primarily focused on biopolymers and their integration into advanced functional materials. She has authored multiple high-impact publications, including the review paper "Carboxymethyl Guar Gum: Bridging the Gap Between Biopolymers and Advanced Functional Materials," which was recently accepted in Polymer-Plastics Technology and Materials. Additionally, her review paper "Studies on Biopolymer-Based Nanocomposites Reinforced with Metallic Nanoparticles" was published in Acta Biology Forum on July 8, 2024. Vratika has also contributed to esteemed book chapters in Industrial Chemistry and Biopolymers. Furthermore, she has co-authored two notable review papers: "A Comprehensive Scrutinization on Tamarind Kernel Powder-Based Derivatives and Nanomaterials in Modern Research" (as third author) published in Nano-Structures and Nano-Objects, and "Polyvinyl Alcohol: Recent Advances and Applications in Sustainable Materials" (as second author), published in Polymer-Plastics Technology and Materials. With a steadfast commitment to scientific innovation, her research endeavors continue to explore the frontiers of biopolymers and nanocomposites, bridging the gap between sustainable materials and technological advancements.

Dr. Jagram Meena is a Ph.D. in Biopolymer Chemistry from Delhi Technological University, Dr. Jagram Meena possesses over a decade of teaching and research experience. Currently an Assistant Professor at Gurukula Kangri University, his expertise lies in synthesizing and characterizing biopolymers, nanoparticles, and their applications in various fields. Dr. Meena's contributions extend beyond academia, as evidenced by his administrative roles and memberships in prestigious organizations. With numerous publications, conference presentations, and participation in faculty development programs, he remains dedicated to advancing knowledge in nanotechnology and biopolymer chemistry. Proficient in handling major instrumentation, Dr. Meena exemplifies a commitment to interdisciplinary research in sustainable materials.

Teena Saini is currently enrolled as a research scholar in the Department of Chemistry at Gurukula Kangri University, Haridwar (Uttarakhand). She has been working towards her Ph.D. under the supervision of Dr. Jagram Meena, since September 2023. She completed her Master's degree in organic chemistry from Hemvati Nandan Bahuguna Garhwal University, Srinagar (Garhwal), Uttarakhand in 2021. Before her doctoral studies, she gained practical experience at Patanjali Organic Research Institute Pvt. Ltd. Her current research endeavors are centered around Biopolymers.

Sakshi Saini is a research scholar in the Department of Chemistry at Gurukula Kangri University, Haridwar. She is pursuing her Ph.D. under the supervision of Dr. Jagram Meena since Sep. 2023. She has completed her Master's degree in Industrial Chemistry from Gurukula Kangri University, Haridwar,2022. During her tenure in the oil and soap industry, she honed her skills in quality assurance methodologies. She is working in Biochemistry and focuses on Natural Biopolymers. Her research interests include Nanomaterials of Biopolymers with a particular focus on Tamarind Kernel powder.

Dr. Rajdeep Malik is an accomplished assistant professor in the Department of Chemistry at Gurukula Kangri (Deemed a university student), Haridwar. With a Ph.D. in Chemistry completed in 2008, he has been dedicated to academia and research for over a decade. His expertise spans Physical Chemistry, Polymer Chemistry, Inorganic Chemistry, Electrochemistry, and Nanomaterials. Dr. Malik possesses extensive experience in handling advanced physioanalytical techniques, including UV-visible spectrophotometry, GC-MS, potentiometry, and IR spectroscopy. He has contributed significantly to scientific literature, with several research papers and conference presentations to his credit. Passionate about advancing chemical sciences, he continues to mentor students and contribute to innovative research in his field.

Data availability statement

All the data supporting this review are present with the authors and will be provided in case a request is made.

Ethical approval

All authors have agreed with the manuscript's content, and there is no financial interest in the report. We certify that the submission is original work and is not under review at any other publication.

2025 International Conference on Intelligent Control, Computing and Communications (IC3) | 979-8-3315-2749-5/25/$31.00 ©2025 IEEE | DOI: 10.1109/IC363308.2025.10956741

Abstract— In silico tools are being developed and used these days to make predictions in the field of medicine. They are being used in scientific research where they are helping to ease out the process of developing new techniques and products. Cancer research is also being benefitted from these tools. There are special algorithms developed which form basis of these in silico tools. Molecular Docking is one such tool that can be based on principles like Artificial Intelligence, Machine Learning etc. It is used to understand interactions between drugs and how do they impact the body, what makes the difference in the biologic system and how do these compounds actually cause side effects. Here is a review of Molecular Docking tools which can predict the interactions between two compounds on basis of their biding energy and other parameters. These tools will be analyzed on basis of predictions they make and on basis of this analysis, best tool will be used chosen for making adverse reaction analysis of Dabrafenib, which is an anti-cancer drug administered to melanoma patients.

Keywords — molecular docking, autoDock, swissDock, autoDock vina

I. INTRODUCTION

Bioinformatics has contributed significantly in the healthcare and disease management sectors. From identifying genes to deciphering proteins involved in any event, these in silico tools have helped scientists predict unforeseen outcomes, make generous choices and prevent unwanted impacts. Big data has reached the diagnostics as well, where the genomic sequences are analyzed for presence of mutations and other alterations leading to some diseased phenotypes. Cancer research has also been benefitted from advances in these in silico approaches. Multiple studies are being published every year which make use of these techniques and have noteworthy findings have been elucidated from these approaches. AI, ML, ANN etc have been a building block of in silico tools. They help in analyzing data, making relevant predictions and performing complex tasks involving problem solving. In context of immunology, computational vaccines and drugs are a major product of bioinformatics. With this plethora of information and easy accessibility of data and tools, it is possible for young scientists and researchers to design new beneficial compounds and medicines which are comparatively safe and effective. Use of bioinformatics tools significantly reduces the time of development and also helps in easing the process of designing and preparing a drug which otherwise takes nearly two decades just because of the time utilized in the discovery phase. Another possible way to bring bioinformatics in use is to predict the possible adverse effects of the drugs which are already in use. It has been observed that some compounds generate different response in different individuals. Such responses may make the body susceptible to unwanted reactions and may show unexpected symptoms which are often called side effects. One approach to address this issue is use of pharmacogenomic analysis to determine the what actually is causing the body of patient to respond differently. Such reactions are associated with the metabolism and how the drug is broken down in the body. The altered response is associated with different genetic makeup of certain populations which give them the altered phenotype of varying drug metabolism. These "side-effects" are dealt with by altering the dosage of the medications and such warnings are usually labelled on the packaging. Another approach is to find alternatives to those drugs which are causing side effects rendering patients more prone to illness. Cancer therapy often takes a toll on patient, both on physical and psychological aspects. There are multiple drugs and therapies which have been approved for general public use which have shown to cause the unwanted effects in the body. These effects appear due to unsupervised interactions of the administered molecules with various non target components. To address such issues, a different approach has to be used. Identifying such altered responses is possible through databases and various resources available online. Identifying the cause of those unanticipated effects is a challenging task. Computational approach to discover these non-target interactions include pathway- based methods and the chemical structure-based methods. Pathway based methods identify the various interacting molecules for a particular component. Network based tools using pictorial representations of interconnected molecules are applied for such analysis. These interactions can be used to predict the how the binding to multiple sites can lead to activation of some other pathway by influencing a completely different cascade of molecules. Structure based methods are focused on determining the actual binding energies in order to figure out how strongly do the molecules interact. These results help in validating the predicted interactions and hence proposing reasons behind the side effects. Molecular Docking [1] and QSAR [2] are major tools for making such structure-based predictions. Here are some tools and databases which can help in analyzing what are the alternate pathway, a drug is following leading to expression of a varied response in addition to the desired one. It is helpful in deriving safe and effective drugs.

A. Pathway Based Approaches

In order to obtain data pertaining to the side effect of the drug, first understand how does it actually work. For this, thorough information about the pathogenesis of disease and mechanism of action of the drug is a prerequisite. This gives a crucial understanding of the functioning of that molecule and should be retrieved through literature study. Information about anti-cancer drugs is available on National Cancer Institute. A list of approved FDA drugs is available with observed side effects and risks. These drugs can be searched in DrugBank [3] and PubChem where more information regarding the drugs can be obtained. All possible information regarding these

2025 International Conference on Intelligent Control, Computing and Communications (IC3) | 979-8-3315-2749-5/25/$31.00 ©2025 IEEE | DOI: 10.1109/IC363308.2025.10956741

therapeutic compounds is available on these databases. Next, determine the target sites. These are the sites in the entire body which have shown to interact positively with the ligand alias the drug. Databases like BindingDB [4], Therapeutic Target Database [5], PHAROS [6], DrugBank[3], SwissTarget [7], etc provide information on what targets does a particular compound interact with and what causes off-target binding that is determining the factors possibly responsible for the adverse reaction.

B. Structure Based Approaches

Molecular docking is the most favored computational approach for elucidating the interaction of two molecules. It determines the behavior of small molecules in the target binding site. Conformation and orientations of a ligand are determined and what is the best way possible for a strong binding can be elucidated from docking results. Such orientations are called poses and the best one is opted. The pose with a low energy is selected to be the best pose and it is used for future references. Molecular docking has been used in researches for drug designing and disease management. There are multiple tools and software programs for the implementation of this techniques. AutoDock [8], AMDock [9], MCDock [10], Glide [11], GOLD [12], FRED [13], CHARMM [14], ACID [15], AMBER [16], SwissDock [17,18] etc.

C. Molecular Docking

Molecular Docking has become a crucial component in drug discovery. It has now become comparatively easy to predict the possible interactions that can occur in the body using this method. Also, it has found many applications in the other areas of medicine and research. Repurposing drugs, finding better alternatives, personalized medicine etc are some of the major benefits. Interactions between proteins, protein-ligands, nucleic acids can be analyzed using docking. Various methods like Machine Learning, Deep Learning, Neural Networks have been used to design tools for performing this task. These tools are available on various platforms and can be used as standalone softwares or are subscription based. The main purpose behind using docking is to predict the binding energy of the two molecules. To do this, certain scores are provided based on the bonds provided. All the data regarding structure of the molecule is derived from Protein Data Bank (PDB). The coordinates file of PDB is converted into an actual structure by the software and the binding scores are predicted. Binding energy and RMSD values are used to predict if the participating compound can interact in vivo or not. Molecular docking usually helps in filtering out the undesirable ligands in the process of drug discovery. This is used in virtual screening to reduce the number of ligands in order to screen out the ligand which are less likely to interact with the target. As many tools are available for this process, it is crucial to determine which is handy and more favorable one to use. As molecular docking is performed at the academic level as well, it is important to know what particular tools can be used to make better predictions at a lower cost, in order to make some fruitful research. Here, we present a comparative analysis of some molecular docking tools.

D. In silico molecular docking tools

The major tools for Molecular Docking are AutoDock and AutoDock Vina [19]. They are mainly used for academic purposes. AutoDock4 is available at https://autodock.scripps.edu. It is designed to operate for protein-ligand interaction studies. It is based on Lamarckian Genetic Algorithm. A force field scoring function is used to predict the binding energy. Ligand is optimized for different conformations and each conformation is estimated and interaction energy is predicted. This keeps on improving till a satisfactory score is achieved. AutoDock Vina is an improvement over AutoDock. It is capable of making more accurate and faster predictions as compared to AutoDock. It is based on Local Search Global Optimizer. This tool finds major application in virtual screening. SwissDock (https://www.swissdock.ch/index.php) is a web server- based tool based on Dihedral Space Sampling and EADock. CHARMM energy values are estimated based on grid scores. CB Dock2 [20, 21] is available at https://cadd.labshare.cn/cb-dock2/index.php. It is a protein- ligand docking server which integrates cavity detection, docking and template fitting. It can perform blind docking and has mainly been used for drug discovery. It is based on AutoDock Vina for docking predictions and curvature- based cavity detection for active site prediction.

II. METHODS

To perform such a task, first one should have structures of drug and the receptor in the PDB format. They can be downloaded from Protein Data Bank itself or from PubChem. Along with this, a thorough literature analysis has to be performed to determine the drug targets in the body and possible reasons for the side effects of that particular drug. For performing this, Molecular Docking tools were used to determine the extent of interaction and then they are compared on basis of the output they present. Dabrafenib [22] is a BRAF inhibiting drug which is used for treatment of melanoma patients. It has been observed that it shows side effects like bone marrow depression, hyperglycemia, lymphopenia. To determine how does Dabrafenib cause these side effects, that is, where else does it bind in the body, docking has to be used. Before that, it is important what tool should be used to perform this task so that best predictions are made. Molecular Docking tools Autodock, AutoDock Vina, SwissDock, CB-Dock2 were used to perform docking analysis. Different tools make use of different methods in predicting binding. Docking was performed using these tools and results were analyze to determine a suitable tool to perform this crucial task of understanding the adverse reactions of Dabrafenib. Blind docking was performed using AutoDock to compare its results with the specific docking.

III. RESULT

Molecular Docking was performed using Autodock, AutoDock Vina, SwissDock, CB-Dock2. AutodockVina is a command line- based tool which can be used for precise docking. AutoDock can perform docking to a large extent. It can be used for both precise and blind docking but the blind docking results of AutoDock vary from the precise docking in terms of the RMSD values. CB-Dock2 and SwissDock are web server- based docking tools which predict docking poses and binding energy. They first determine the pockets and then perform docking generating comparable results. Comparative outcomes are predicted by all these tools. Also, other tools like the visualization tools, used in docking were also compared for quality and ease of use. As seen in Fig.1, RMSD values predicted by these tools are presented. It can be seen that specific docking results generated by AutoDock Vina are more precise and accurate. Fig.2 focusses on the binding energy comparison. CB- Doc2 makes one unusual prediction

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 06:43:31 UTC from IEEE Xplore. Restrictions apply.

making it less reliable to use. Though these tools make use of different parameters, but they interpret the same thing, that is the binding energy.

TABLE I. TABLE Ⅰ AUTODOCK RESULTS

Parameters→ Protein - Ligand ↓	Binding Energy (kcal/mol)	Inhibition Constant	Reference RMSD	STATISTICAL MECHANICAL ANALYSIS			
				Q	A (kcal/mol)	U (kcal/mol)	S (kcal/mol/K)
BRAF-Dabrafenib	-8.26	881.15 nM	29.73	10.13	-1372.02	-7.78	4.58
AKT-Dabrafenib	-8.02	1.32µM	20.74	10.12	-1371.18	-6.94	4.58

TABLE II. VINA RESULTS

Parameters→ Protein-Ligand↓	Binding Affinity (kcal/mol)	Distance from best mode	
		Upper bound RMSD	Lower bound RMSD
BRAF-Dabrafenib	-11.7	0.000	0.000
AKT-Dabrafenib	-13.7	0.000	0.000

TABLE III. CB-DOCK2 RESULTS

Parameters→ Protein-Ligand↓	FitDock score	Cavity volume (Å^3)	Pocket RMSD
BRAF-Dabrafenib	-12.8	1931	0.0
AKT-Dabrafenib	100.4	208	3.15

TABLE IV. SWISSDOCK RESULTS

Parameters → Docking↓	SwissParam	AC Score	RMSD	Polar Energy	Non-Polar Energy
BRAF-Dabrafenib	-8.837	-107.373731	46.4366	24.5571	-67.1287
AKT-Dabrafenib	-9.9326	-121.673935	17.5711	17.5711	-74.4133

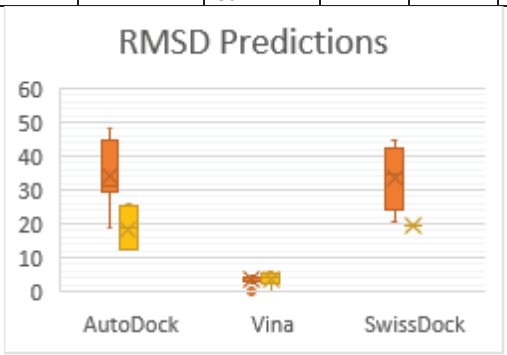

Fig. 1. Comparison of RMSD calculations by various tools

IV. DISCUSSION

To analyze Dabrafenib for its side effects [23], docking has to be performed and for that it is crucial to know which tool will be best suited for this process. For this, Autodock, AutoDock Vina, SwissDock, CB-Dock2 were used to compare and determine the best tool for academic use. Blind docking using AutoDock was compared with targeted docking. It is suggested that the active sites should be known so as to make correct predictions as AutoDock can not make satisfactory predictions in terms of binding site hence generates varying RMSD [24] results. RMSD is a comparative analysis of the poses. It is determined if the given ligand matches the actual ligand in terms of conformation. It was found that targeted docking using AutoDock Vina gave satisfactory results. Also, the binding energy analysis proved that all the four tools were able to generate correct energy relations. AutoDock provides more details in terms of bonds and interactions as compared to other tools. If the user has to visually analyze the interactions, a separate tool has to be used like PyMol, Chimera or Discovery Studio. SwissDock and CB Dock2 on the other hand provide simultaneous visualization. Correct docking sites can be visualized and interacting atoms of the receptor can be determined using both these tools. They make use of different algorithms to function. Major issue with SwissDock is it doesn't let the user decide the binding pocket and hence allows only blind docking in the freely available version. So, the RMSD values vary in the scores predicted by SwissDock. SwissParam scores and AC scores are the output of SwissDock. Attracting cavities and AutoDock Vina are the two methods by which docking was performed. The AC scores [18] are based on CHARMM force fields [25] and FACTS model. SwissParam score is approximation of binding energy and the AC scores are actual energy contributions of the interacting atoms and molecules. CB Dock2 can predict both the binding pockets and the energy functions in one go. The major fact here is that it generates on output only that is it doesn't give multiple poses as output whereas other three tools generate a list of possible poses that can be analyzed for interactions. The FitDock [21] score provided in output is energy parameter which predicts the likelihood of ligand being the match of selected receptor site. The RMSD values generated here are also comparable to that produced by other tools. All these tools when used for blind docking generate different results. PyMol, CHIMERA, Discovery Studio were analyzed to pick the best one out for publication quality images and visualization. Discovery Studio is the most suitable tools for such task as it allows a high-quality image saving, better visualization and molecule preparation. One can determine active sites in this software and this information can be used for targeted docking in any other tool. This package offers all those features making it the best pick.

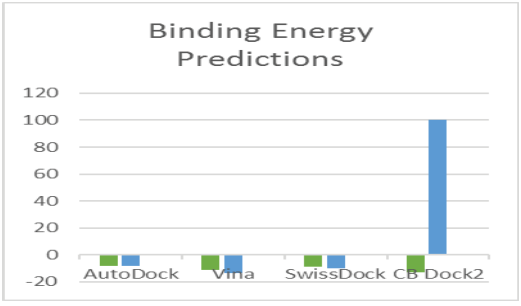

Fig. 2. Comparison of predicted binding energies

V. VCONCLUSION

Melanoma is a very aggressive form of skin cancer and the changing environmental conditions and modern living standards have led to its spread and progression. This study was attempted to understand how do the various tools work and how well are they able to predict the effect of that molecule in the body. It can be determined how does a drug work and what additional impacts does it leave on body at the molecular level. Off-target interactions can be successfully identified and can help in relating the role of Dabrafenib with

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 06:43:31 UTC from IEEE Xplore. Restrictions apply.

other underlying conditions like Hyperglycemia [26, 27] which can develop in melanoma patients. It has been found that performing blind docking can generate varying outcomes [28]. So, it is suggested to know the binding site of receptor as it generates more useful outcomes. This eliminates the use of SwissDock and CB Dock2 for Side effect analysis. AutoDock can provide sufficient results when used for targeted docking. Taking into consideration, the ease of access and usage, it is suggested that AutoDock Vina is the best choice as it saves the user from generating multiple files and the system failure which AutoDock often undergoes. Also, it can generate separate files for different poses making them easy to interpret. The results generated in Vina can be opened in a visualization softwares which can predict the structural features of binding molecules. Out of available softwares, BIOVIA Discovery Studio can be used as it generates publication quality images in just one click. Receptor and ligand both can be prepared in Discovery Studio and it can also be used for visualization. If suggesting a pipeline for side effect prediction, SIDER [29] can be used to determine side effects caused due to a particular drug, SwissTarget can be used for off-target site analysis, confirm this through literature and then docking can be performed using Vina to compare binding energies of proposed ligand and the actual ligand for that receptor. This study has opened a scope for designing safer drug candidates for melanoma which successfully target only the mutant B-RAF. Similar methods can help in discovering new molecular targets for some other drug as well and can help in deciphering new compounds with potential anti-cancer properties which are safer and easy to use.

abhishek@dtu.ac.in

***Abstract* — In this paper, a comparative study of conventional LQR controller, optimized PID controller and intelligent Fuzzy logic controller is demonstrated while achieving the desired pitch axis trajectories of a 2-DOF helicopter system. During this process, TLBO optimized PID controller is used to track down the trajectory angle of pitch axis of helicopter system and this performance is compared with inference rules of fuzzy system and a conventional LQR controller. The membership function parameters, exploration – exploitation scheme of optimization algorithm are discussed while addressing the problem of trajectory tracking. The parameter tuning and stable response of pitch axis of helicopter model is achieved on MATLAB/Simulink platform, on which the comparison is accomplished through time response analysis.**

Keywords— 2-DOF Helicopter; Optimization Control, Unmanned Aerial Vehicle; Fuzzy Logic; Pitch Trajectory: LQR.

I. INTRODUCTION

The issue of trajectory tracking control in unmanned aerial vehicles (UAVs), particularly in helicopter models, has been extensively explored in the literature for many years [1, 2]. A three-degree-of-freedom (3-DOF) helicopter's trajectory tracking can be effectively managed using a combination of two controllers: a feedforward controller for guiding the trajectory and a feedback controller for stabilizing any deviations from the intended path [1]. Experimental studies have shown that these controllers are effective in achieving precise trajectory tracking. Another approach involves dividing the dynamics of a small-scale unmanned helicopter into two subsystems—heading-heave and longitudinal-lateral movements—to focus on heading reference trajectory and inertial position tracking. Feedback loops within these subsystems are used to correct any trajectory errors [2]. Further improvements in attitude and position control have been achieved by integrating the parallel tracking and mapping method with a wireless camera, demonstrating its effectiveness in helicopter control [3]. Despite the range of control strategies available in the literature, the traditional and intelligent controller tuning remains crucial for effective axis control.

In one study, a combination of Linear Quadratic Regulator (LQR) and PID control was employed to reduce tracking errors in pitch and yaw by optimizing a quadratic function with state feedback [4]. Another study introduced a robust adaptive fuzzy controller, developed using a gradient descent algorithm, which further enhanced control accuracy [5]. To address the challenges posed by higher-order flight control actuator failures, a reorganized Fault-Tolerant Control (FTC) system was proposed [6]. Fuzzy logic, since its introduction by Professor Lotfi A. Zadeh in 1965, has become a vital tool in various fields such as pattern recognition, telecommunications, and control systems. By utilizing fuzzy set theory and mathematics, fuzzy logic systems can incorporate human knowledge and intuition through linguistic rules, making them highly effective for trajectory control in helicopter models using Gaussian-type membership functions [7, 8]. Additionally, a dual fuzzy-neural network control system was tested for an intelligent landing system in air transportation, and simulation studies confirmed its effectiveness under varying and unpredictable weather conditions [9].

Continuous monitoring of a helicopter system is essential for real-time optimization of controller parameters. Over the past decade, numerous algorithms have been developed to address this need. Computational intelligence plays a critical role in the real-time tuning of controller parameters for multivariable systems. From classical methods like the Ziegler-Nichols (ZN) method [10] to modern computational algorithms, these approaches are fundamental to optimizing nonlinear systems. Velocity control in a helicopter model is often implemented using a fuzzy-PID controller, with PID auto-tuning achieved through adjustments based on the previous control period [11]. The fuzzy-PID controller has also demonstrated its effectiveness in trajectory control, providing robust and stable responses [12]. An auto-tuned fuzzy-PID controller is designed using a twin-loop strategy [13]. The Teaching-Learning-Based Optimization (TLBO) algorithm, which mimics the learning process in a classroom, has proven to be a versatile tool in various engineering applications for finding both local and global optima [14].

This study is focused on the comparative analysis of three different controllers, used to control the pitch axis of helicopter model. These three controllers are TLBO optimized PID controller, LQR controller and intelligent fuzzy controller. Based on this, the paper is structured as follows; Section I (this section) is focused on the literature survey, Section II is about the demonstration of helicopter model. In section III, the control strategies are discussed at length. In section IV, simulation analysis of results are demonstrated. The work will be concluded with section V.

II. PITCH AXIS IN HELICOPTER

Dynamics of nonlinear equations for helicopter model, as shown in figure 1, This figure shows the physical setup available in the laboratory, which comprises a yoke, two distinct DC motors, and a helicopter-shaped body, which are acquired by using Lagrangian mechanics, are shown for the pitch axis as follows [15]:

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on April 08,2025 at 06:15:07 UTC from IEEE Xplore. Restrictions apply.

$$(J_{eq,p} + m_{heli}\, l_{cm}^2)\ddot{\theta} = K_{pp}\, V_{m,p} + K_{py}\, V_{m,y} - m_{heli} g l_{cm} \cos\theta - B_p\, \dot{\theta} - m_{heli}\, l_{cm}^2 sin\theta cos\theta \dot{\Psi}^2$$

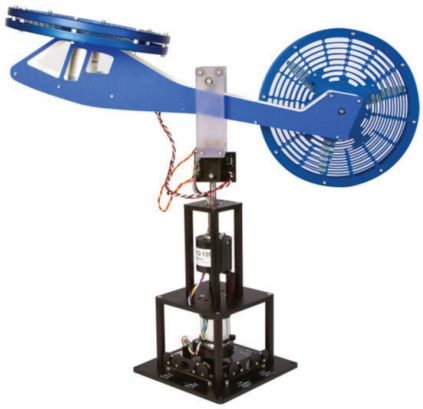

Fig. 1. Laboratory setup of 2-DOF helicopter [15]

The laboratory model showing the horizontal and vertical propellors of helicopter model, as provided by Quanser [15], is depicted in Fig. 2. The vertical motion is the responsive product of vertical propellor itself. One of the motors is designated for controlling the pitch movement, while the other is responsible for yaw movement. To measure these movements, two separate encoders are used—one for pitch and one for yaw. The helicopter system is mounted on a stationary fixed base platform.

Fig. 2. Horizontal and vertical propellors of 2-DOF helicopter [15]

The first DC motor, which operates the front propeller, adjusts the altitude of the helicopter's nose along its pitch axis, thereby controlling the pitch angle, denoted by θ. The pitch encoders are used to measure the corresponding pitch angles. Through a slip-ring mechanism, the measured angle is transmitted as signals to achieve the desired pitch and yaw angles. The nonlinear helicopter system model is subject to the following constraints:

- A pitch angle of zero indicates that the helicopter is in a horizontal position.

- When the helicopter's nose moves vertically upward, the pitch angle increases, leading to a positive pitch thrust force ($F_p > 0$) and a positive pitch angle ($\theta > 0$).

Helicopter model works with the following state space representation:

$$\dot{x} = Ax + Bu \quad (1)$$

Where, state vector x represents:

$$x = [\theta, \Psi, \dot{\theta}, \dot{\Psi}, \dot{\alpha}, \dot{\gamma}]^T \quad (2)$$

and output y is given by:

$$y = Cx + Du \quad (3)$$

III. Control Strategies

A. Fuzzy Logic Controller (FLC)

Fuzzy logic controllers encapsulate human expertise in system management by utilizing membership functions and IF-THEN fuzzy rules. This technique, allowing machines to simulate human reasoning using fuzzy logic, is referred to as a fuzzy logic controller. Fuzzy logic is particularly effective in addressing challenges related to uncertainty, imprecision, and qualitative decision-making. In fuzzy control applications, it is important to note that the control process often involves converting a range of values into a specific point or vice versa. By defining the appropriate membership functions, both inputs and outputs are fuzzified, leading to the derivation of the desired outputs.

The implementation of a fuzzy logic controller involves three fundamental steps: fuzzification, the fuzzy inference process, and defuzzification. Initially, the measured input and its derivative are processed by the fuzzy logic controller, which is connected to the 2-DOF helicopter. The output is then fed back into the input through a closed-loop feedback mechanism within the same unmanned vehicle. For system monitoring, this approach utilizes human-like reasoning to effectively manipulate, represent, and implement the fuzzy logic controller. In the context of helicopter control, a Takagi-Sugeno (T-S) fuzzy model is used, featuring two inputs and one output to manage the pitch angle error. The inputs consist of the pitch error and its derivative, while Gaussian-type membership functions are employed to ensure a smooth, continuously differentiable curve. Seven distinct linguistic variables are used for each input state variable, labeled as NS, ZE, PS, PM, NB, NM, and PB, with an associated rule base.

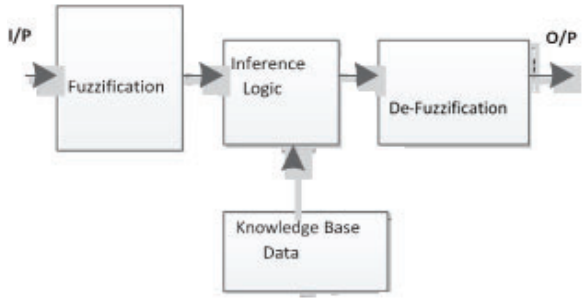

Fig. 3. FLC working Architecture

B. Proportional Integral Derivative (PID) Controller

To implement a proportional-integral-derivative (PID) controller as a cross-coupled controller on a helicopter model, the MATLAB SIMULINK platform is used once again. The error signal, e(s), is expressed as:

$$e(s) = X_d(s) - X(s) \quad (4)$$

where, X_d (s) represents the desired set points for the pitch control axisband X(s) is the actual process value. The PID controller is applied to this error signal. The set points, error signals e(s) and process values are calculated separately with PID controllers for pitch axis. TLBO algorithm is employed to optimize the parameters of PID controller. While implementing the PID controller in the frequency domain on the helicopter system, the gains $k_{d,heli}$, $k_{i,heli}$ and $k_{p,heli}$, which are the derivative, integral, and proportional gains respectively, are used to control the helicopter system, with the initial operating points given as:

$$\beta_d(s) = \left(k_{d,heli}.s + \frac{k_{i,heli}}{s} + k_{p,heli}\right)e(s) \quad (5)$$

Initial parameters of PID are calculated using ZN method [10]. Then gain parameters are updated through optimization algorithms after each iteration using describing functions.

C. Teaching Learning Based Optimization (TLBO)

TLBO algorithm works in two different phases, with 2nd phase is initiated after the end of 1st. Both phases combines up to complete one iteration in algorithm. These phase are – teaching phase and learning phase.

Teaching phase demonstrates how students in a class learn through their teacher. In this phase, the teacher's goal is to improve the average performance of the students in a specific subject based on the teacher's abilities. Mean marks of any subject (X_{mean}) and the highest marks of class ($X_{j,best,i}$) are used to calculate difference mean as:

$$Dmean_{j,k,i} = r*(X_{best} - T_f * X_{mean}) \quad (6)$$

Where i stand for iteration, k for population size, j is any subject and T_f stand for teaching factor, which is given by:-

T_f = round (1+r), where r is a random number. New solution ($X_{j,k,i}(new)$) is calculated as:

$$X_{j,k,i}(new) = X_{j,k,i}(old) + Dmean_{j,k,i} \quad (7)$$

With this, the teaching phase comes to end and learning phase starts. In learning phase, students are supposed to improve their knowledge through sharing and learning. In here, one students selects a random students from class and improves his/her knowledge through sharing. For a population size of 'n' learners/students, A and B are two randomly selected learners such that $X_{A,i}(new)$ *and* $X_{B,i}(new)$ are the updated solutions for $X_{A,i}(old)$ *and* $X_{B,i}(old)$, which are defined as:

$$X_{A,i}(new) = X_{A,i}(old) + r\,[X_{A,i}(old) - X_{B,i}(old)] \quad (8)$$

$$X_{A,i}(new) = X_{A,i}(old) + r\,[X_{B,i}(old) - X_{A,i}(old)] \quad (9)$$

Execution of above equations particularly depends upon the greedy solution conditions. Greedy solution is a criteria of deciding whether the problem is maximization type or minimization type. In pitch axis trajectory problem, aim is to reduce the error to minimum. This makes current problem as minimization problem. Hence, the greedy solution is followed considering the aim as minimization of error problem.

Time response parameters are taken as describing function for the pitch axis problem. After the completion of learning phase, first iteration comes to an end. This process continues until the minimization condition satisfies and the final gain parameters after the completion of all iteration, gives optimized results for pitch axis problem.

IV. Simulation and Results

In this study, the 2-DOF helicopter system, which was initially controlled using the default Linear Quadratic Regulator (LQR) provided by Quanser [15], is subsequently managed using two alternative strategies. The performance of the default LQR controller is graphically depicted in Figure 4. Following this, a PID controller, optimized through the Teaching-Learning-Based Optimization (TLBO) algorithm, and a fuzzy logic controller are implemented to track a predefined reference trajectory for the pitch axis. The system, commonly used as an experimental setup in laboratory research, consists of a fixed base with two separate propellers. The base facilitates movement along its center, with each propeller driven by a DC motor mounted at opposite ends of the system. The primary function of these propellers is to regulate the pitch angle's elevation trajectory. Specifically, the rear propeller controls the yaw angle, while the front propeller manages the elevation angle, thereby ensuring stable lateral motion. A key control challenge is mitigating the cross-coupling effects between the pitch and yaw movements. The real-time dynamics of this system are simulated using MATLAB software, and the results are thoroughly analyzed in this section.

The 2-DOF helicopter represents a standard MIMO (Multiple Input Multiple Output) nonlinear system, with individual controllers assigned to manage the pitch and yaw axes. For the implementation of the Fuzzy Logic Controller (FLC), the pitch axis controller is provided with two inputs: the error (e(s)), which is the difference between the desired and actual pitch angles (measured in radians), and the derivative of this error. Each controller in this setup operates with these two inputs, which are fuzzified using seven distinct Gaussian membership functions. These membership functions are distributed over closed intervals for the fuzzy logic controllers.

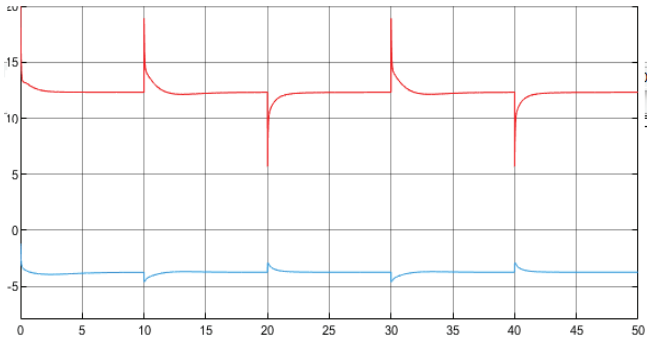

Fig. 4. Pitch angle variations (amplitude vs time) and voltage variations (volt. vs time) on 2DOF helicopter model after using LQR controller

The input and output fuzzy subsets are categorized into linguistic values: Positive Big (PB), Negative Big (NB), Positive Medium (PM), Negative Medium (NM), Positive Low (PL), Negative Low (NL), and Zero (ZE). These categories are utilized in a set of 49 fuzzy rules based on IF-THEN logic, forming a knowledge base that mimics human reasoning, which is essential for the effective operation of the FLC. The degree of membership for these fuzzy sets ranges from 0 to 1, with 0 indicating complete inconsistency and 1 representing full consistency with the fuzzy levels. The input signals for the fuzzy logic controller are the errors in pitch angle, which are the differences between the desired and actual angles. "Negative Big (NB)" represents a large negative velocity, while "Positive Big (PB)" indicates a large positive velocity. The rules function as guidelines to return to the desired position, with the proportional coefficients managed according to the membership function logic. The linguistic control strategy progressively transforms into an automated control strategy. This involves applying experimental knowledge to implement fuzzy logic rules with different membership functions for controlling the yaw and pitch angles. Variations observed in pitch angle with square reference trajectory and voltage variations observed after this control strategy are shown in figure 5. The green signal is reference trajectory and the red signal is followed output trajectory. The improved time response is visibly observed after using FLC controller as compared to default LQR controller. This nonlinear system is once again tested using a third controller for the tracing of pitch reference trajectory, further in this section.

The PID controller is further employed to manage pitch angle variations in the helicopter model, utilizing the Teaching-Learning-Based Optimization (TLBO) algorithm. Figure 6 presents the block diagram used to execute this optimization strategy. The gain parameters depicted in this figure are tuned using the TLBO algorithm and are refined after each iteration of the teaching and learning phases, as discussed in the previous section of this work. The iteration by iteration improvement in tuned gain parameters are observed and the final tuned parameter after the completion of all the iterations are taken as optimized result.

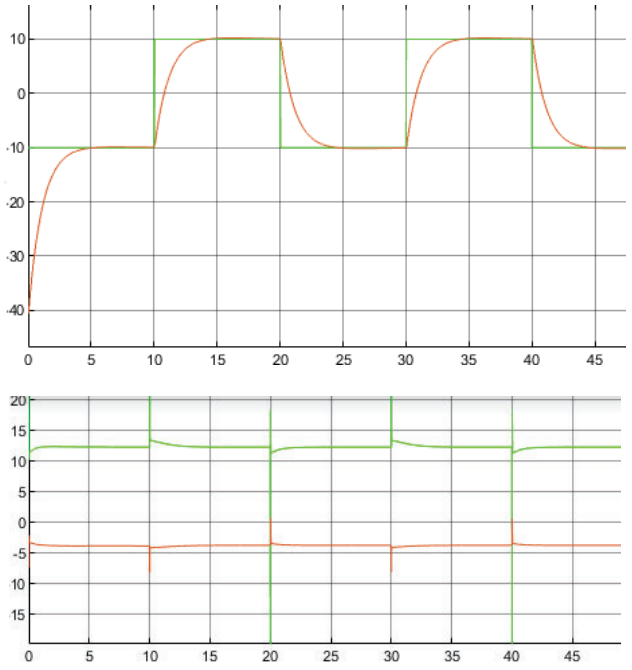

Fig. 5. Pitch angle variations (amplitude vs time) and voltage variations (volt. vs time) on 2DOF helicopter model after using FLC controller

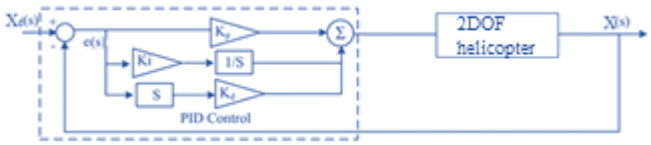

Fig. 6. Block diagram representing the implementation of PID controller on helicopter model.

The control model for the helicopter system's cross-coupled pitch axis, as shown in Figure 6, is specifically designed to ensure stable trajectory tracking. The controller's parameters are optimized using the Teaching-Learning-Based Optimization (TLBO) algorithm. In scenarios with multiple constraints, techniques like TLBO tend to provide near-optimal solutions; however, small adjustments in algorithm parameters can significantly influence their effectiveness. This consideration is particularly relevant in the present study, where TLBO is preferred over other metaheuristic algorithms due to its robustness. A key advantage of this algorithm is that its performance on the helicopter model remains independent of specific parameter settings, contributing to a more stable control environment for the 2-DOF helicopter system's cross-coupled design. The optimized performance of the helicopter model is depicted in Figure 7, where the pink line indicates the square reference trajectory, and the blue line shows the actual tracking achieved. A visual comparison highlights the improved performance compared to the default Linear Quadratic Regulator (LQR) control strategy.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on April 08,2025 at 06:15:07 UTC from IEEE Xplore. Restrictions apply.

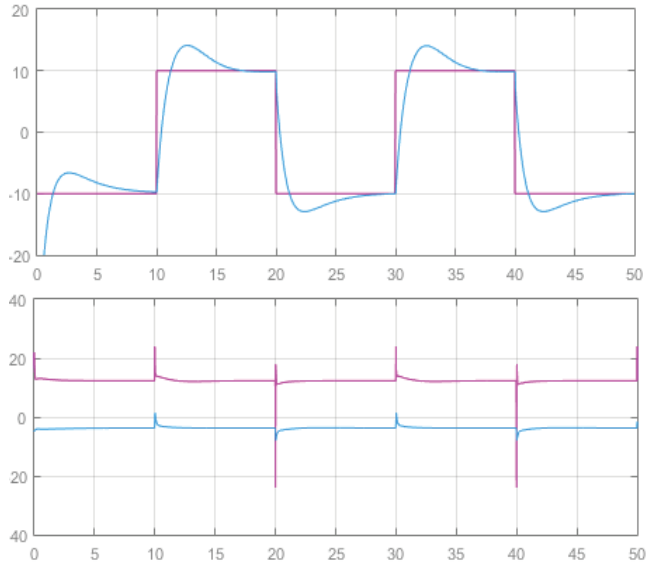

Fig. 7. Pitch angle variations (amplitude vs time) and voltage variations (volt. vs time) on 2DOF helicopter model after using TLBO-PID controller

The graphical results obtained using the three different control strategies are further analyzed to demonstrate a mathematical comparison between these techniques, as shown in Table I. Demonstration of helicopter model is conducted by implementation of conventional LQR controller, the TLBO-optimized PID controller and the fuzzy logic controller on the Simulink/MATLAB platform. Step reference trajectories are used to analyze the time response results, and the variations in pitch angle are compared across the different control schemes.

TABLE I. TIME RESPONSE ANALYSIS OF PITCH AXIS

	Settling Time (milli seconds)	**Peak Over-shoot (in %)**
LQR	4.72	8.99
TLBO-PID	3.99	4.18
FUZZY	0.95	0.5

V. CONCLUSION

Study of LQR, TLBO-optimized P-I-D and intelligent Fuzzy controllers for achieving predefined pitch axis trajectory of a helicopter model is performed. The TLBO-optimized PID controller was used to track the pitch axis trajectory and compared with the fuzzy system's inference rules and the conventional LQR controller. The membership function parameters and the optimization algorithm's exploration-exploitation scheme were discussed in the context of trajectory tracking. The parameter tuning and stable response of the pitch axis were achieved using Simulink/MATLAB and the comparison was conducted through time response analysis. Graphical and mathematical results are explaining the superiority of optimized PID control strategy and intelligent FLC control strategy over the conventional LQR control strategy and the same is explained with the help of different figures and a separate table in the different sections of this paper.

***Abstract*—The Internet of Things (IoT) has revolutionized global device interconnectivity, fostering seamless data exchange through expansive sensing networks. Similarly, swarm robotics emulates the collective behaviors observed in nature, such as bird flocks and ant colonies, aiming to adapt these principles for practical use. This paper explores the dynamics of robotic swarms operating under a centralized network model using master-slave communication. Two implementation approaches are examined: direct, small-scale interactions utilizing device MAC addresses and large-scale connectivity facilitated by an IoT-based cloud server. Our experiments employ the NodeMCU ESP8266 platform, which utilizes the IEEE 802.11 Wi-Fi standard for data handling and transfer. For cloud-based communication, we utilize the ThingSpeak server to manage data flow. This study evaluates the strengths and limitations of these approaches in fostering swarm behavior, aiming to derive strategies for enhancing the performance and coordination of swarm robotic systems.**

***Index Terms*—Centralized Communication, Collaborative Robotics, Internet of Things (IoT), Swarm Robotics, Device Interconnectivity**

I. Introduction

Effective communication is at the heart of swarm robotics, much like how a team must communicate to work toward a common goal. Think of a swarm of bees: one bee might find food, and then shares that information with the rest of the swarm so they can all act in coordination. Similarly, robots in a swarm need to exchange information to perform tasks as a unified group. Various communication methods help make this possible, including master-slave setups, mesh networks, and ring topologies. In a master-slave configuration, one robot takes the lead and directs the others, like a coach guiding a team. Mesh and ring networks, however, allow a more distributed approach, where robots communicate directly with each other. In a mesh network, messages are passed along between robots like notes in a chain, while in a ring topology, information circulates in a continuous loop, much like a game where players pass a ball around. These frameworks play a crucial role in making swarm robotics work smoothly [1]–[3].

In this study, we explore these communication frameworks on the NodeMCU ESP8266 platform, which uses Wi-Fi for both online and offline communication. In the online mode, robots connect via a router, while in offline mode, they use MAC addresses for direct interactions without relying on the internet. We specifically examine master-slave communication in both scenarios and assess mesh and ring topologies in offline settings to observe how the robots interact [4]. Additionally, we look into IoT-enabled communication through cloud servers, where robots can exchange data over the internet, allowing them to collaborate from different locations. By analyzing these frameworks, we aim to discover ways to improve the efficiency and robustness of swarm robotic systems [1]–[3].

II. Related Work

Existing models in swarm robotics, while foundational, have several limitations, particularly when it comes to scalability and communication reliability. Master-slave configurations, although effective for smaller systems, face challenges in larger swarms due to the reliance on a single master to manage all communications. As the number of robots increases, this can create bottlenecks, reducing the overall system efficiency. Similarly, mesh and ring topologies, which offer more dis-

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 07:38:24 UTC from IEEE Xplore. Restrictions apply.

tributed communication, encounter issues such as network congestion and message loss, especially when operating offline. In offline scenarios, the lack of a centralized server can result in disconnected or delayed communication, undermining the system's reliability. These limitations hinder the ability of swarm robotic systems to scale effectively in complex environments [1], [2].

Another major challenge is the dependency on centralized infrastructure, such as routers or cloud servers, to facilitate communication. This creates a vulnerability where a failure in the central server or network can disrupt the entire swarm's operation. Furthermore, many models lack adaptive mechanisms that can adjust to dynamic or changing environments, limiting the system's flexibility and resilience. As swarm robotics moves toward more autonomous and decentralized systems, addressing these issues is crucial to improving both their efficiency and robustness in real-world applications [3], [4].

III. Swarm Robotics

Swarm robotics focuses on the coordinated operation of numerous simple robots that adhere to basic interaction rules to achieve complex objectives. Inspired by social species such as ants, birds, and fish, this approach leverages collective behaviors observed in nature to address various challenges. Swarm intelligence, a paradigm rooted in algorithms mimicking self-organizing behaviors of social insects, underpins the foundation of swarm robotics. In these systems, robots engage with each other and their environment to exhibit collective behaviors. While individual robots perform simple tasks, their collective actions enable the achievement of complex goals [2], [5]–[7]. Swarm robots differ from traditional multi-robot systems through their decentralized and collective operational nature. Key characteristics distinguishing swarm robotics include scalability, fault tolerance, and adaptability, all of which make them suitable for diverse applications, which are:

1) Autonomous robots that can sense their environment and act accordingly.
2) The swarm is composed of a large number of robots working together.
3) The robots within the swarm should be uniform in design and functionality.
4) Every robot must have the ability to sense its surroundings and communicate with others.
5) Collaboration between robots is essential to accomplish tasks efficiently.

Swarm robotics is capable of performing various tasks, often tested through experimental setups. Some common tasks are listed below:

1) Aggregation: This task involves gathering all robots in a designated area within the environment.
2) Dispersion: Focuses on spreading the robots evenly across a defined space to maximize coverage.
3) Pattern Formation: The robots adjust their positions to form a specific pattern or shape.
4) Collective Movement: Ensures the synchronized movement of multiple robots as a unified group.
5) Source Search: Used for operations such as locating sounds or odors in a search area.

Other behaviors observed in swarm robotics include task allocation, collaborative object transport, and joint mapping efforts. To implement swarm robotics in real-world applications, several algorithmic approaches are applied, such as Particle Swarm Optimization (PSO), Ant Colony Optimization (ACO), and Artificial Bee Colony (ABC). These algorithms are utilized in various fields, including healthcare, smart city development, and transportation. Additionally, swarm robotics is beneficial for applications such as disaster relief, surveillance in hazardous areas, and smart management of urban systems [8]–[11].

IV. NodeMCU in Swarm Robotics

Swarm robots are typically composed of many simple units that individually perform basic tasks, but collectively carry out more complex operations. A key feature of swarm robotics is leveraging a large number of low-cost, simple robots to achieve complex behaviors. Effective communication is essential in a swarm, so each robot must be able to interact with others within the group. The NodeMCU ESP8266 is a suitable choice for this purpose, serving two primary functions: acting as the robot's microprocessor to process sensor data and control robot behavior, and enabling communication through TCP/IP protocols.

The NodeMCU ESP8266 features a Tensilica Xtensa 32-bit LX106 RISC microprocessor, capable of operating between 80 MHz and 160 MHz clock speeds. It includes 128KB of RAM and 4MB of flash memory for storing data and programs [7], [12], [13]. The ESP8266 chip, known for its low cost, supports the IEEE 802.11 Wi-Fi standard and includes a complete TCP/IP stack, enabling wireless communication between robots. Its affordability, ease of use, and communication capabilities make the NodeMCU ESP8266 an ideal choice for decentralized swarm robotics communication, even without an internet connection.

In this study, different network topologies are employed to analyze the swarm behavior of robots. Some topologies represent centralized systems, while others exhibit decentralized swarm behavior. Three network topologies are considered: a) master-slave, b) mesh, and c) ring.

The master-slave topology involves one robot acting as the master, overseeing and controlling the actions of the other robots, which function as slaves. In this configuration, the master robot monitors data from the slave robots and issues commands if any issues arise. Slave robots can only receive data from the master and cannot send instructions back. Therefore, data transfer is bidirectional, but command transfer is unidirectional [14]. If a slave robot fails, the master can replace it with another functioning robot to continue the task. Figure 1 illustrates master-slave communication between NodeMCU ESP8266 units using their MAC addresses.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 07:38:24 UTC from IEEE Xplore. Restrictions apply.

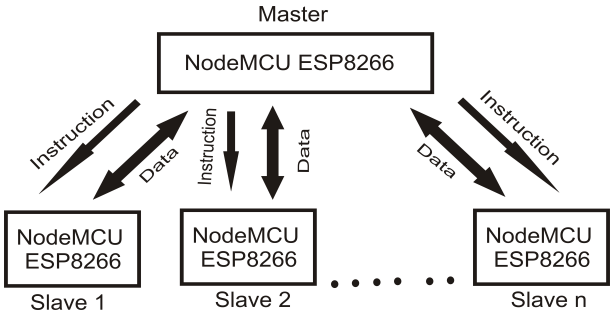

Fig. 1. Master-Slave Communication between Multiple NodeMCU ESP8266 Devices

In contrast, the mesh topology does not rely on a single robot to control the others. Each robot in a mesh network is connected to multiple other robots, allowing messages to be relayed through various paths. This architecture enhances fault tolerance, as communication can continue even if one path fails. The density of information flow depends on the number of connections between robots in the swarm. For n robots, the total number of connections in the mesh network is calculated as:

$$\text{Total connections} = \frac{n(n-1)}{2}$$

where n is the number of robots. This setup allows for more robust communication due to the multiple pathways available.

As Figure 2 shows the example of mesh communication between five NodeMCU ESP8266 and the total number connection is calculated using above formula is 10.

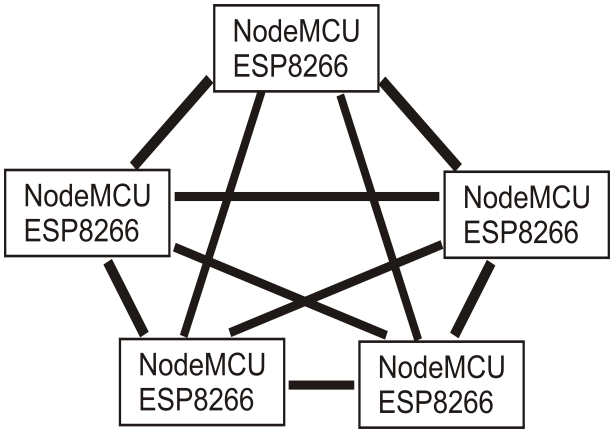

Fig. 2. Mesh Communication Between Multiple NodeMCU ESP8266 Devices

The third network configuration is the ring topology, which, like the mesh topology, does not assign control to any single robot in the swarm. In this configuration, the robots are arranged in a circular structure, where information circulates unidirectionally from one robot to the next until it reaches its destination. This setup limits the flow of information, as each robot is connected to only two others, creating a longer communication path and causing delays in transmission [15], [16]. As the number of robots increases in the swarm, the transmission time grows due to the extended route between the source and the destination. Therefore, the reliability of communication in a ring topology decreases as the swarm size increases, meaning the probability of successful message delivery diminishes. However, one advantage of using the ring topology is the ease with which a faulty robot can be replaced within the loop. Figure 3 illustrates a setup where five NodeMCU ESP8266 devices are connected in a ring configuration for communication.

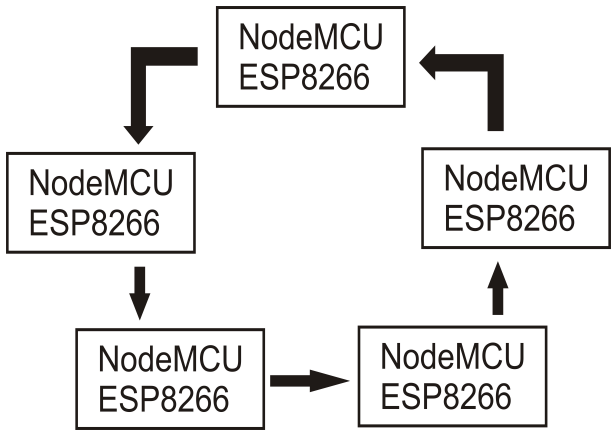

Fig. 3. Ring Communication Among Multiple NodeMCU ESP8266 Devices

As demonstrated, all three topologies—master-slave, mesh, and ring—are viable for implementing swarm behavior in robotic swarms, with the choice depending on specific needs. Both the mesh and ring configurations support decentralized communication, while the master-slave topology provides a more centralized communication structure. In each of these configurations, communication can occur without requiring internet access, utilizing the MAC addresses of the robots to facilitate message passing within the swarm.

V. Swarm Robotics with the Internet (IoT)

Over the past two decades, the Internet of Things (IoT) has seen remarkable progress, enabling widespread connectivity and computing capabilities. This transformation has positioned IoT as a crucial platform for linking devices to the internet, allowing for Machine-to-Machine (M2M) communication and data transfer through standard networking protocols such as TCP/IP. Swarm robotics is one of the key applications that benefits from M2M communication and data transfer. In many swarm robotics systems, cloud servers are utilized to provide centralized communication within the network [2], [5], [17]. The cloud infrastructure also supports computation and storage, facilitating the use of swarm intelligence algorithms that enhance communication and exhibit collective swarm behaviors.

Swarm intelligence, a subfield of artificial intelligence, focuses on creating intelligent systems that mimic the collaborative behaviors of social animals and insects. Several

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 07:38:24 UTC from IEEE Xplore. Restrictions apply.

swarm intelligence algorithms can be applied to IoT-based applications, including:

1) Ant Colony (AC) Algorithm,
2) Ant Colony Optimization (ACO) Algorithm,
3) Particle Swarm Optimization (PSO) Algorithm,
4) Artificial Bee Colony (ABC) Algorithm,
5) Bacterial Foraging Optimization Algorithm (BFOA), and others.

Swarm robotics can utilize various techniques for enabling communication between devices, one of which is the master-slave configuration. In some cases, internet connectivity is employed to establish communication. When internet-based communication and data storage are necessary, a cloud server is often used [18]. In this study, the ThingSpeak cloud server was selected to store data from both the master and slave devices. As shown in Figure 4, the slave devices can only upload data to the cloud and communicate bidirectionally with the master. In contrast, the master device has the capability to both read from and write to the cloud server, allowing it to monitor the data from the slave devices.

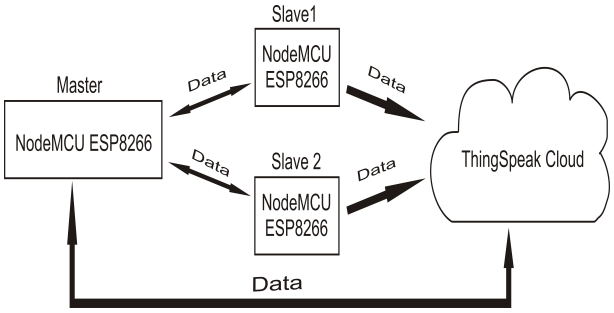

Fig. 4. Master-Slave Communication via IoT

VI. Results and Discussion

This study explored different approaches to implementing swarm behavior using NodeMCU ESP8266 devices and ultrasonic sensors. Three distinct communication topologies were used to facilitate communication within the swarm. These topologies include:

A. Communication Among Swarm Using the Master-Slave Configuration

1) Communication Without Internet: The first topology examined was the master-slave communication model. In this model, data transfer was simulated using the Arduino IDE. The results showed that both the master and slave devices successfully exchanged data without the need for internet connectivity. Communication was established using MAC addresses, as illustrated in Figure 5.

2) Communication Using Internet (IoT): For the IoT-based master-slave communication, the ThingSpeak cloud server was utilized for data storage. The master device could perform both write and read operations on the cloud server, whereas the slave devices were limited to writing data. The simulation results of data transfer between the master and slave devices are shown in Figure 6.

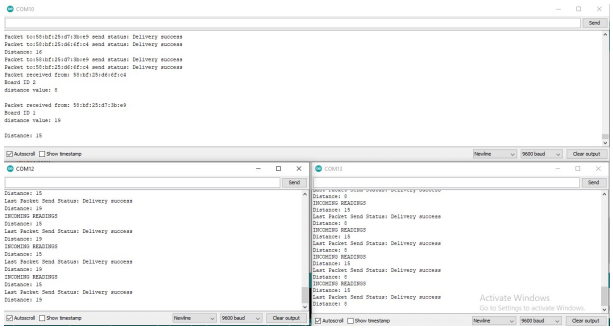

Fig. 5. Master-Slave Communication in Swarm Robotics Without Internet

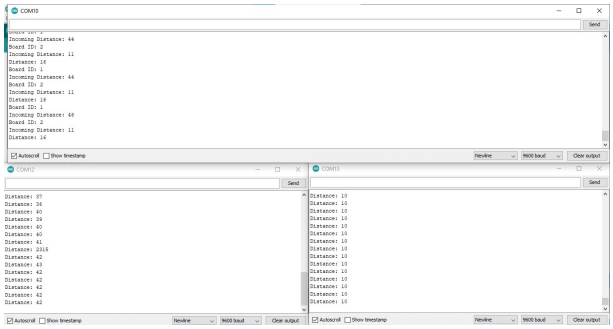

Fig. 6. Master-Slave Communication in Swarm via IoT

B. Communication Among Swarm Using Mesh Topology

The second topology implemented was the mesh network, where IoT-based communication was utilized, and the ThingSpeak cloud server was employed for data storage. The results showed that the master device could both write and read data from the cloud server, while the slave devices could only write data. Real-time data transfer among the master, $slave_1$, and $slave_2$ was observed in Figures 7, 8, and 9, respectively.

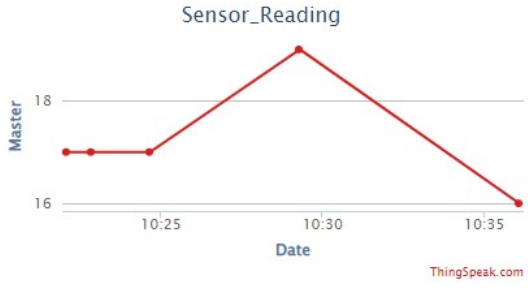

Fig. 7. Sensor Data from the Master Robot

The mesh topology allowed each device to share its ultrasonic sensor data with every other device in the swarm. The simulation results demonstrated that each device could send data to two other devices and also monitor data from these devices. Figure 10 illustrates the data transfer among all three devices.

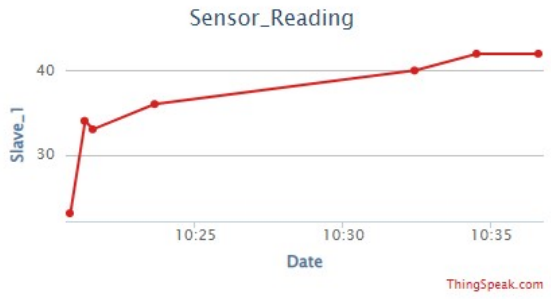

Fig. 8. Sensor Data from $Slave_1$

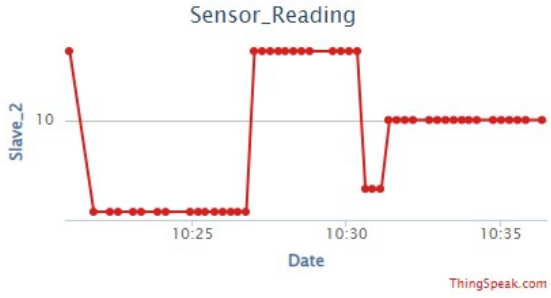

Fig. 9. Sensor Data from $Slave_2$

C. Communication Among Swarm Using Ring Topology

The final topology tested was the ring topology, where the devices were interconnected in a closed-loop. In this setup, information traveled unidirectionally from one device to the next. Each device shared data with one of its adjacent devices and received data from the next device in the loop. The results of data transfer in this configuration are shown in Figure 11.

From the simulated results, it was observed that the master-slave communication topology provided more accurate data transfer compared to the IoT-based swarm communication. The master-slave configuration allows centralized communication, where the master device has control over data exchange and operations. The mesh and ring topologies, however, allow each device to operate autonomously within the swarm.

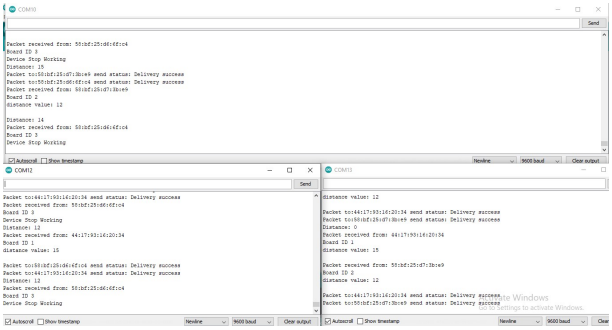

Fig. 10. Communication in the Swarm Using Mesh Topology

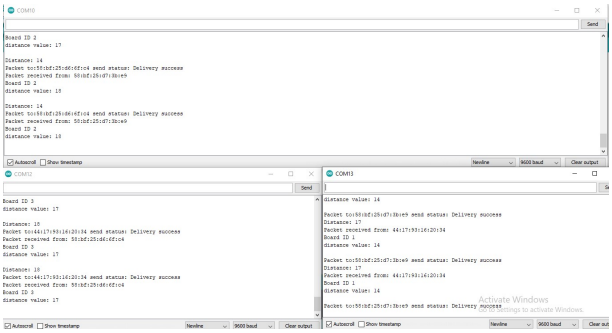

Fig. 11. Communication in the Swarm Using Ring Topology

Figures 6, 10, and 11 illustrate the results for the master-slave, mesh, and ring communication models, respectively, using NodeMCU ESP8266 devices. In the master-slave setup, the master device monitored the slaves' data and issued instructions in case of malfunction. In the mesh topology, each device exchanged data with all other devices and could instruct a malfunctioning device to be replaced. In the ring topology, each device communicated with only one adjacent device, thus managing communication in a more limited manner.

The method described in this paper demonstrates several strengths in its approach to implementing communication topologies in swarm robotics using NodeMCU ESP8266 devices and ultrasonic sensors. One major strength is the flexibility provided by the NodeMCU platform, which allows for both online and offline communication modes. This versatility is crucial for testing various topologies such as master-slave, mesh, and ring networks, each of which can be adapted to different swarm scenarios. The ability to use ultrasonic sensors for proximity detection further enhances the robots' ability to interact with their environment, facilitating more effective swarm behaviors. Additionally, the simplicity of the NodeMCU ESP8266 platform makes it accessible and cost-effective for swarm robotics research.

However, the method also has notable weaknesses. While the study explores a range of communication frameworks, the offline communication using MAC addresses can be prone to latency and data loss, particularly in larger swarms where network congestion is more likely. Moreover, relying on Wi-Fi for communication introduces potential issues with signal interference and range limitations, especially in environments with many obstacles or in expansive areas. Despite these challenges, the results provide valuable insights into the feasibility of implementing these communication methods in swarm robotics. A comparative summary of the communication methods explored is presented in Table I.

VII. Conclusion

In conclusion, this paper has explored and compared various communication topologies for swarm robotics, focusing on master-slave, mesh, and ring configurations. The findings suggest that for large-scale applications, the master-slave communication method combined with IoT proves to be the most

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 07:38:24 UTC from IEEE Xplore. Restrictions apply.

TABLE I
COMPARISON OF COMMUNICATION APPROACHES IN ROBOTIC SWARMS

Feature	Swarm Communication with Master-Slave Approach		Swarm Communication with Mesh Topology	Swarm Communication with Ring Topology
	Communication without Internet	Communication via Internet (IoT)		
Dependence on Intermediate Medium	No	Yes	No	No
Number of Devices Connected	Few	Many	Few	Few
Coverage Area	Moderate	Large	Small	Small
Device Monitoring Method	Requires physical monitoring only	Can be monitored remotely	Requires physical monitoring only	Requires physical monitoring only
Communication Medium	Uses MAC Address	Router-based	Uses MAC Address	Uses MAC Address
Malfunction Handling	Replacement is easy	Replacement is straightforward	Replacement is complex	Replacement is moderate

suitable due to its centralized nature and scalability, enabling efficient management of multiple robots. For smaller-scale setups, any of the three topologies—master-slave, mesh, or ring—can be employed, as they rely on MAC addresses for device communication. However, it was found that offline communication, without internet access, tends to yield more accurate sensor readings, as it reduces potential latency and network interference.

Both the mesh and ring topologies support decentralization, a crucial aspect of swarm behavior, enabling more flexible and autonomous coordination among robots. On the other hand, the centralized master-slave method provides better control over the swarm's actions, making it ideal for certain structured tasks. In the mesh topology, there is a risk of data collision when a device needs to be replaced, as robots communicate directly with each other. Similarly, in the ring topology, data replacement can take longer due to the sequential nature of communication, as information must pass through every device in the loop.

Future work will focus on advancing decentralized communication methods, which are vital for swarm robotics' full potential. As technology evolves, swarm robotics is poised to transform industries such as manufacturing, agriculture, and healthcare, offering solutions that are more efficient, adaptable, and autonomous.

Decaying vacuum energy, matter creation and cosmic acceleration

Lokesh Chander* and C P Singh†
Department of Applied Mathematics,
Delhi Technological University, Delhi-110042, India
(Dated: April 15, 2025)

In this paper, we discuss an interacting decaying vacuum energy and dark matter empowered by gravitationally induced matter creation model, and its impact on structure formation by analysing the growth rate perturbations. Our work is motivated by the possibility that the decaying vacuum is due to quantum field theory and dark matter originates from gravitationally induced matter creation. We delve deeper into our investigation and explore both theoretical and statistical analysis of the cosmological model to test its ability to describe the evolution of the Universe. To achieve this, we use three distinct combinations of datasets from Cosmic Chronometers, Pantheon Type Ia supernovae sample, Baryon acoustic oscillations, Cosmic Microwave Background distance priors and $f(z)\sigma_8(z)$ datapoints to constrain the model parameters. Our statistical analysis employs Markov Chain Monte Carlo (MCMC) methods. The deceleration parameter shows that the model transitions from a decelerated phase to an accelerated phase of expansion. The current Hubble parameter values are estimated to be $H_0 = 67.517 \pm 0.869$ km/s/Mpc, $H_0 = 67.534 \pm 0.874$ km/s/Mpc, and $H_0 = 67.533 \pm 0.884$ km/s/Mpc using DS1, DS2 and DS3 datasets, respectively. These values of H_0 are very close to those derived from the Planck data. The effective equation of state parameter indicates an accelerating phase, with density parameter for vacuum energy exhibiting expected values. The present value of the jerk parameter deviates slightly from the ΛCDM model. However, it approaches the standard model in late time. We analyse the stability characteristics through the selection information criteria. We also perform thermodynamic analysis by studying the evolution of entropy in the Universe for the model and find it to be in agreement with the generalised second law of thermodynamics. These findings support that the proposed model effectively describes the evolutionary features of the Universe at both theoretical and observational levels.

I. INTRODUCTION

The first observational evidence for the accelerated expansion of the Universe was confirmed through Type Ia supernovae (SNIa), rightly called 'standard candles', as these astronomical objects have an intrinsic luminosity [1, 2]. This discovery significantly changed our understanding about the Universe and caused a resurgence in modern cosmology. Subsequent datasets: Baryon Acoustic Oscillations (BAO) [3], the Hubble parameter measurements $H(z)$ [4], and Cosmic Microwave Background (CMB) anisotropies [5] have further validated this phenomenon. According to 'General Relativity' (GR), this accelerated expansion is driven by a new energy density with negative pressure, referred to as 'dark energy'(DE), which makes up around 70% of the Universe's total energy density. Accompanying this is 'dark matter'(DM), whose nature is not completely understood and together, both dark components make up for 95% of the Universe's content [6]. Understanding the origin of DE remains one of the major unsolved issues in modern cosmology as its exact nature is still unknown. The naturally arising candidate for dark energy within the framework of GR is the cosmological constant, denoted by Λ, or equivalently, the vacuum energy density associated with it, $\rho_\Lambda = \Lambda/8\pi G$ [7]. It has a negative pressure, making it the repulsive driving force that causes accelerated expansion under the condition that Λ has a value greater than zero [8].

However, the Λ-based concordance model faces theoretical challenges, most notably the cosmological constant problem and cosmic coincidence [9–13], which remain central issues in cosmology. These unresolved problems have motivated alternative approaches, such as dynamic dark energy models, where Λ evolves as a function of time, and interacting models, where dark energy interacts with other components in the cosmic fluid. In decaying vacuum energy models, Λ is not a constant; rather, it evolves over time and is thus a dynamic component $\Lambda(t)$. This approach addresses the fine-tuning problem by linking the present-day small value of Λ to its evolutionary trajectory during the Universe's history. Early studies [14–29], often motivated by phenomenological considerations, laid the theoretical foundations and proposed certain functional forms of $\Lambda(t)$. More recently, many authors [30–37] have sought to ground these models in quantum field theory (QFT). This approach also works when Λ is considered to be a relic of inflationary dynamics [38].

Besides the dynamical $\Lambda(t)$ approach, recently, a new alternative to address late-time cosmic acceleration has gained traction. It is the 'adiabatic' matter creation which is gravitationally induced, and a non-equilibrium thermodynamical process. A long time ago, Schrödinger [39] conceptualized matter creation in the microscopic realm, which was further developed by Parker [40, 41]. Since Einstein's field equations are the background equations to understand the evolution of the Universe, it was

* lokeshchander˙23phdam04@dtu.ac.in
† cpsingh@dce.ac.in

Prigogine and his collaborators [42–44] who proposed a thermodynamic framework for open systems, allowing the creation of matter via transfer of energy from the gravitational field. In this case, by assuming that DM is being produced due to a time-varying gravitational field, it is plausible for a late-time acceleration to happen in a Universe consisting of only pressureless fluids, like cold dark matter and baryons. The research work carried out by many authors [45–61] suggests that matter creation can mimic the effects of dark energy, producing negative pressure and driving accelerated expansion. These models, rooted in thermodynamics, posit that new matter gets created as the Universe expands. With the energy conservation law, we suggest that this creation comes at the expense of another component in the cosmic fluid. When combined with DE characterized by a decaying vacuum term $\Lambda(t)$, there is a naturally arising coupling between the DE and matter sector, which consists of baryons and DM. The decay of $\Lambda(t)$ thus contributes to the creation of matter. While the exact mechanism of this phenomenon cannot be deduced, the implication is clear that DE and DM are interacting entities. This idea is somewhat similar to that of an exotic fluid like the Chaplygin gas (CG), which behaves like dark matter at early redshifts and like dark energy at later times. Many models based on various forms of the CG have been studied in the literature, and this approach has been promising since it is consistent with observational data [62–64]. Moreover, there are interacting dark energy (IDE) models in which interaction between the DE and other components in the cosmic fluid is assumed, and these models have been extensively explored in the literature. Along with the class of CG models, these models can solve the coincidence problem by allowing dark energy and dark matter to evolve over time. The gradual convergence of the two densities helps to resolve the issue of their seemingly fine-tuned values at present [65–68].

The present study investigates a combined model incorporating decaying vacuum energy and matter creation, offering a unified framework to address the aforementioned challenges. Unlike traditional interacting dark energy models that require an explicitly defined coupling term, this approach inherently links the decay of $\Lambda(t)$ to the rate of matter creation, denoted by Γ, avoiding the need for arbitrary assumptions about the form of coupling. To test the viability of the proposed model, we undertake a rigorous theoretical and observational analysis. With the help of Bayesian Markov Chain Monte Carlo (MCMC) methods, the model parameters are constrained with multiple datasets, including Baryon Acoustic Oscillations (BAO), Cosmic Microwave Background (CMB) distance priors, Pantheon Supernovae Type Ia (SNIa), H(z) measurements from Cosmic Chronometers (CC), and weighted linear growth rate measurements $f(z)\sigma_8(z)$. Further, we employ statistical criteria; the reduced chi-squared test and two model selection criteria, AIC and BIC, which judge the model based on information theory and Bayesian statistics, respectively. This allows for a robust comparison with the standard ΛCDM model, highlighting the potential advantages and limitations of the proposed framework.

The paper is organized in the following way: Section II lays down the groundwork for our cosmological model combining decaying vacuum energy with matter creation, outlining the modifications to the energy-momentum tensor and the Friedmann equations. In Section III, we present analytic solutions to the field equations, focusing on the following cosmological parameters: Hubble parameter $H(z)$, deceleration parameter $q(z)$, transitional redshift $z_{\rm tr}$, and effective equation of state (EoS) parameter $w_{\rm eff}(z)$. Section IV discusses perturbations in the cosmic background with primary focus on matter perturbations and their implications for structure formation. In Section V, we discuss the observational datasets and methodology employed for constraining the model, while in Section VI, we present the results of our analysis and discuss their cosmological implications. Section VII uses the reduced chi-squared test and two model selection criteria to compare our chosen model with a reference model, the ΛCDM Model. Then we focus on the thermodynamic analysis in Section VIII, where we proceed with finding an expression for the dark matter temperature. Then we calculate the total entropy of the universe and its evolution with respect to time, to test the generalized second law (GSL) of thermodynamics. Finally, in Section IX, we summarise our findings and the scope of future research.

II. DECAYING VACUUM MODEL WITH MATTER CREATION

Let us begin with a theoretical framework characterized by a spatially isotropic and homogeneous flat Friedmann-Lemaître-Robertson-Walker line element

$$ds^2 = -dt^2 + a^2(t)\left[dr^2 + r^2\left(d\theta^2 + \sin^2\theta\, d\phi^2\right)\right], \quad (1)$$

where (r, θ, ϕ) represents spherical coordinates and $a(t)$ is the scale factor, t denotes the cosmic time. Hereafter, we assume natural units $c = \hbar = 1$.

We introduce some basic thermodynamic concept of adiabatic matter creation as proposed by Prigogine and his collaborators [42–44] in cosmological context. We consider an N particle system under adiabatic conditions, which means that the total particle number changes and is not conserved. Mathematically, we express it as $N^{\mu}_{;\mu} \neq 0$. Due to this, the energy conservation equation gets modified. The particle flux vector, which measures how the particle number changes, is taken as $N^{\mu} = nu^{\mu}$, where $n = N/V$ gives the number of particles per unit of time (particle number density), and u^{μ} is the fluid's four-velocity.

The non-conservation of the particle flux, i.e., $\nabla_{\mu} n^{\mu} = \psi$, can be written as

$$\dot{n} + 3Hn = \psi = n\Gamma, \quad (2)$$

where $\dot{a}$ denotes derivative with respect to the cosmic time, $H = \dot{a}/a$ is the Hubble parameter and Γ quantifies the rate of change of the particle number in a physical volume V consisting N number of particles. Although the physical nature of Γ is unknown, we have one constraint over Γ, i.e., $\Gamma \geq 0$. For the generalized second law of thermodynamics to be valid, this must be true. Equation (2) gives the evolution of the particle number density. As the total number of particles per comoving volume a^3 is $N = a^3 n$, therefore, the above Eq.(2) can be written as $\dot{N}/N = \Gamma$. We define the entropy flux vector as $s^\mu = n\sigma u^\mu$, where σ is the entropy per particle. The entropy must satisfy the second law of thermodynamics, $s^\mu_{;\mu} \geq 0$. Also, we consider matter creation to be an adiabatic process, i.e., we have a system in which σ remains constant.

As we are assuming the total particle number N to be variable, we have a modification of the first law of thermodynamics:

$$d(\rho V) + p\, dV - \left(\frac{h}{n}\right) d(nV) = 0, \tag{3}$$

where ρ is the energy density and p is the equilibrium pressure of the cosmic matter fluid (dark matter and baryonic matter), and $h = (\rho + p)$ is the enthalpy per unit volume. We observe there to be an extra contribution in (3), and we interpret this as a non-thermal pressure arising due to the particle production process. We call this the 'creation pressure' p_c, which is given in terms of the change in particle number with respect to volume by

$$p_c = -\frac{h}{n}\frac{d(nV)}{dV}. \tag{4}$$

The negative sign indicates that p_c can help drive the accelerated cosmic expansion era. For simplicity's sake, we assume that only dark matter particles are produced since the production of baryons is limited by the local gravity measurement-induced constraints.

From (2) and (4), along with the modified first law in (3), we obtain the following form of the creation pressure [44, 45, 61]:

$$p_c = -(\rho + p)\frac{\Gamma}{3H}. \tag{5}$$

Let us outline the fundamental equations of a general cosmological scenario. The gravitational field equations in Einstein's General Relativity are:

$$G_{\mu\nu} = \kappa \tilde{T}_{\mu\nu}, \tag{6}$$

where $G_{\mu\nu} = R_{\mu\nu} - \frac{1}{2} g_{\mu\nu} R$ is the Einstein tensor which describes the spacetime geometry and κ is the Einstein gravitational constant which in this case is, $\kappa = 8\pi G/c^4 = 1$ due to the choice of units. $\tilde{T}_{\mu\nu} \equiv T_{\mu\nu} + g_{\mu\nu}\rho_\Lambda$ is the total energy-momentum tensor, which accounts for the contribution of both matter creation and a time-dependent vacuum term. In the presence of matter creation, it is customary to associate the creation pressure, p_c in energy-momentum tensor. As a result, the usual perfect fluid energy-momentum tensor, $T_{\mu\nu}$ gets modified to

$$T_{\mu\nu} = (\rho_m + \tilde{p}_m)\, u_\mu u_\nu + g_{\mu\nu}\tilde{p}_m, \tag{7}$$

where u_μ is the four-velocity of the matter fluid, ρ_m is the matter energy density, and $\tilde{p}_m$ is the total pressure exerted by the fluid which is the sum of the isotropic pressure p_m and the creation pressure p_c. We assume matter to be dust-like, i.e. it has negligible pressure ($p_m = 0$). In this paper, we assume that the vacuum behaves like a perfect fluid, with an equation of state given by $\rho_\Lambda = -p_\Lambda$. Given these considerations, we can write the Friedmann equations as follows:

$$3H^2 = \rho_m + \rho_\Lambda, \tag{8}$$

$$2\dot{H} + 3H^2 = -(p_c + p_\Lambda), \tag{9}$$

where $H = \dot{a}/a$ gives the expansion rate and is called the Hubble parameter. The conservation of the energy-momentum tensor, $\nabla^\mu \tilde{T}_{\mu\nu} = 0$ gives

$$\dot{\rho}_m + \dot{\rho}_\Lambda + 3H\,(\rho_m + \rho_\Lambda + p_c + p_\Lambda) = 0. \tag{10}$$

Since $\rho_\Lambda = -p_\Lambda$, the equation (10) gets simplified to:

$$\dot{\rho}_m + 3H\,(\rho_m + p_c) = -\dot{\rho}_\Lambda. \tag{11}$$

From (8) and (11), we can write the evolution equation as

$$2\dot{H} + 3H^2 + p_c = \rho_\Lambda. \tag{12}$$

III. SOLUTION OF THE FIELD EQUATIONS

In this section, we find the solution of the evolution equation (12) to constrain the parameters and discuss the results accordingly. Equation (12) can be solved for H if we know ρ_Λ, and Γ which gives us p_c through Eq. (5). Parametrization of Λ has changed over time and some in particular are: $\Lambda \propto a^{-2}$ [69], $\Lambda \propto a^{-m}$ [70] and $\Lambda \propto H^2$ [71]. Although there is no correct form for the decaying VED, it is often assumed as a function of the scale factor a or the expansion rate H. The motivation for taking it as a function of H is based on a quantum field theory (QFT) approach [72, 73]. This has been proposed in the context of the renormalization group (RG) [29, 74–76]. The interesting work by Shapiro and Solà [19], further investigated by many authors [37, 77–79] motivates us to adopt the following parametrization for the vacuum energy density:

$$\rho_\Lambda = c_0 + 3\nu H^2, \tag{13}$$

where c_0 is a constant term, and ν is an independent term associated with the vacuum decay. We expect ν to

be very small ($|\nu| \ll 1$) and interpret it as a perturbation term. In the limit $\nu \to 0$, the vacuum energy density becomes a constant, i.e. it reduces to the cosmological constant. This form is well motivated from the theoretical point of view as this is related to the general form of the effective action of QFT in curved spacetime.

In the proposed model, the cosmic history is based on the rate of expansion given by H and the evolution of energy density, which can define the gravitational creation rate Γ. This is often expressed as function of the expansion rate H, i.e. $\Gamma = \Gamma(H)$. The simplest form, though, would be taking Γ as a constant; $\Gamma = \Gamma_0$ and for matter creation to take place, this would be constrained by $\Gamma_0 > 0$. A direct proportionality to H can give us another form of the creation rate. In this paper, we consider a simple form that scales directly with the Hubble parameter [47] as

$$\Gamma = 3\beta H. \tag{14}$$

The parameter β is associated with the particle production. It is important to note that the matter creation rate Γ drops to zero in the limit $\beta \to 0$, meaning that the standard model with matter conservation (no creation or annihilation) is restored. Thus, like ν, it acts as a perturbation and therefore its value is expected be small and positive.

Since we propose that our framework is interacting, we write the continuity equations for the matter and vacuum components in the following way:

$$\dot{\rho}_m + 3H(1-\beta)\rho_m = Q, \quad \dot{\rho}_\Lambda = -Q. \tag{15}$$

Here Q is the interaction term, and its expression comes directly from the vacuum decay as

$$Q = -6\nu\dot{H}H. \tag{16}$$

The sign of Q determines the direction of energy flow. In the proposed scenario, vacuum energy decaying into dark matter is plausible because it aligns with particle production. Moreover, a model where the energy flow is in the opposite direction is generally not viable, [80] and therefore, we must ensure that Q is positive. We note that $Q \propto -6\dot{H}H = -(\dot{\rho}_m + \dot{\rho}_\Lambda)$ and ν in addition to being the vacuum decay parameter also determines the strength of the interaction. For the vacuum to act as a source, we must have $Q > 0$, and since $\dot{H}$ is negative, the viability condition gives us $\nu > 0$. Additionally, from the above, we interpret matter to have an effective equation of state $w_m = -\beta$ due to the adiabatic matter creation process, which indicates a small deviation in behavior from a dust-like fluid.

Using (13) and (14) into (12), we obtain

$$\dot{H} + \frac{3}{2}(1-\beta)(1-\nu)H^2 = 3H_0^2(1-\beta)(\Omega_\Lambda - \nu), \tag{17}$$

where $c_0 = 3H_0^2(\Omega_\Lambda - \nu)$, H_0 is the value of H at present and is called the Hubble constant, and Ω_Λ is the present value of the dark energy density parameter. Equation(17) is a differential equation in H with respect to cosmic time t. Instead of using the variable t, it is more convenient to write the above equation in terms of the scale factor a or redshift z. Thus, Eq. (17) can be rewritten as

$$\frac{dH^2}{da} + \frac{3}{a}(1-\beta)(1-\nu)H^2 = \frac{3}{a}(1-\beta)(\Omega_\Lambda - \nu)H_0^2. \tag{18}$$

The solution of (18) is given by

$$H(z) = H_0\left[\left(1 - \frac{\Omega_\Lambda - \nu}{1-\nu}\right)(1+z)^{3(1-\beta)(1-\nu)} + \frac{\Omega_\Lambda - \nu}{1-\nu}\right]^{1/2}, \tag{19}$$

where $(1+z) = a_0/a(t)$. Here, a_0 represents the current cosmic scale factor value, typically assumed to be 1. The above expression gives the expansion rate in terms of the four independent model parameters H_0, Ω_Λ, ν and β. Since we have considered only matter and vacuum components to be part of the cosmic fluid, we have $\Omega_m + \Omega_\Lambda = 1$.

From (19), the *scale factor* in terms of t can be found as

$$a = \left[\sqrt{\frac{\tilde{\Omega}_m}{\tilde{\Omega}_\Lambda}}\sinh\left(\frac{3}{2}\sqrt{\tilde{\Omega}_\Lambda}(1-\beta)(1-\nu)H_0 t\right)\right]^{\frac{2}{3(1-\beta)(1-\nu)}}, \tag{20}$$

where $\tilde{\Omega}_m = 1 - \frac{\Omega_\Lambda - \nu}{1-\nu}$ and $\tilde{\Omega}_\Lambda = \frac{\Omega_\Lambda - \nu}{1-\nu}$ are the effective fractional density parameters.

To discuss the decelerating and accelerating phases of the expansion of the Universe, along with the transition, we study the cosmological parameter known as the *deceleration parameter*, q, which is defined as:

$$q = -\frac{\ddot{a}}{aH^2} = -\left(1 + \frac{\dot{H}}{H^2}\right). \tag{21}$$

The equation (19) is used for obtaining an expression for the above, and it comes out to be:

$$q(z) = -1 + \frac{3}{2}\frac{(1-\beta)(1-\nu)\tilde{\Omega}_m(1+z)^{3(1-\beta)(1-\nu)}}{\tilde{\Omega}_m(1+z)^{3(1-\beta)(1-\nu)} + \tilde{\Omega}_\Lambda}. \tag{22}$$

The value of the deceleration parameter at present time, q_0 is given by

$$q_0 = -1 + \frac{3}{2}(1-\beta)(1-\Omega_\Lambda), \tag{23}$$

In late times, as we approach the present epoch $z = 0$, the deceleration parameter transitions from a positive to a negative value. This can be probed with another quantity called the *transitional redshift*. The expression for it is given by

$$z_{\rm tr} = -1 + \left[\frac{2(\Omega_\Lambda - \nu)}{(1-\Omega_\Lambda)\left(3(1-\beta)(1-\nu) - 2\right)}\right]^{\frac{1}{3(1-\beta)(1-\nu)}}. \tag{24}$$

Another key quantity that helps us understand the dynamics and the evolution of content in the Universe is the *effective equation of state* parameter $w_{\rm eff}$. In this work, we have assumed that the decaying vacuum has an EoS parameter equal to -1. We will now compute the model's effective EoS, which includes both decaying VED and matter with dark matter creation. This is calculated by the expression,

$$w_{\rm eff} = -1 - \frac{2}{3}\frac{\dot{H}}{H^2}. \tag{25}$$

On substituting the relevant values into (25), we determine the effective EoS parameter to be as follows:

$$w_{\rm eff}(z) = -1 + \frac{(1-\beta)(1-\nu)\tilde{\Omega}_m(1+z)^{3(1-\beta)(1-\nu)}}{\tilde{\Omega}_m(1+z)^{3(1-\beta)(1-\nu)} + \tilde{\Omega}_\Lambda}, \tag{26}$$

The present value of $w_{\rm eff}$ which we denote by w_0, is given by

$$w_0 = -1 + (1-\beta)(1-\Omega_\Lambda). \tag{27}$$

IV. PERTURBATIONS IN THE COSMIC BACKGROUND

This section gives a general overview of cosmic perturbation theory in the context of a matter creation cosmology with a decaying vacuum. Studying cosmic perturbations is crucial, as they underpin the formation of large-scale structures in the Universe—such as stars, galaxies, clusters, and quasars. The reader is referred to the Refs.[81–84] for a detailed discussion on the theory of cosmological perturbations and the derivation of the perturbation equations. Here, we present only the basic equations and terms that are appropriate and relevant to our discussion.

The differential equation for the matter density contrast, defined as $\delta_m \equiv \delta\rho_m/\rho_m$, in the considered model can be approximated as follows [85]

$$\delta_m'' + \left(3 + a\frac{H'(a)}{H(a)}\right)\frac{\delta_m'}{a} - \frac{3}{2}\Omega_m(a)\frac{\delta_m}{a^2} = 0, \tag{28}$$

where 'prime' denotes differentiation with respect to the scale factor a. This second-order differential equation describes the evolution of the density contrast, as the primary effects arise from the specific form of the Hubble function.

To solve (28), we use the initial condition given in Ref.[86] as

$$\delta_{mi} = 1.5\times10^{-4} \quad \text{at} \quad a_i = 10^{-3}, \quad \text{and} \quad \delta_{mi}' = \delta_{mi}/a_i. \tag{29}$$

The expression for $\Omega_m(a)$ in terms of the model parameters can be derived through $\Omega_m(a) = 1 - \Omega_\Lambda(a)$, where

$$\Omega_\Lambda(a) = \frac{\rho_\Lambda}{3H^2} = \frac{\Omega_\Lambda - \nu}{E(a)^2} + \nu. \tag{30}$$

Here $E(a) = H(a)/H_0$ is the dimensionless Hubble parameter in terms of the scale factor $a = (1+z)^{-1}$. We substitute the required values into (28), allowing us to numerically compute the matter density contrast δ_{mi} using the initial conditions (29). Next, we consider the linear growth rate of δ_{mi}. This quantity is denoted by f, and in the linear theory, it is related to the peculiar velocity [87]. We define this as

$$f(a) = \frac{d\ln D_m(a)}{d\ln a}, \tag{31}$$

where $D_m(a) = \frac{\delta_m(a)}{\delta_m(a=1)}$ represents the linear growth function. The quantity denoted by $f\sigma_8$, called the 'weighted linear growth rate', is obtained by multiplying the linear growth rate $f(z)$, defined in (31), and $\sigma_8(z)$. Here, σ_8 is a parameter that measures the density root-mean-square fluctuation on $8h^{-1}$ Mpc scales [88, 89]. It is defined as [90]

$$\sigma_8(z) = \frac{\delta_m(z)}{\delta_m(z=0)}\sigma_8(z=0). \tag{32}$$

Using (31) and (32), the weighted linear growth rate is computed by the following relation:

$$f\sigma_8(z) = -(1+z)\frac{\sigma_8(z=0)}{\delta_m(z=0)}\frac{d\delta_m}{dz}. \tag{33}$$

V. DATA AND METHODOLOGY

In this section, we consider the well-established and most recent observational samples to constrain the model parameters. We use the Bayesian Markov Chain Monte Carlo (MCMC) method for statistical analysis, which is conducted using the *emcee* package in Python. Optimization of the best fit of parameters is done by maximization of the probability function given by

$$\mathcal{L} \propto \exp(-\chi^2/2), \tag{34}$$

where χ^2 is the chi-squared function. We enlist the χ^2 function for different data samples in the following subsections.

A. Sample of Type Ia supernovae (SNIa)

Often referred to as "standard candles," SNIa are among the most popular cosmological probes used to study the Universe's evolution. These supernovae are extremely luminous, with their peak brightness often rivalling that of their host galaxy [91]. Increasingly precise data from SNIa have solidified the original ground-breaking observations and their implications for the expansion of the universe[92–96].

The comprehensive Pantheon sample, which includes luminosity distance measurements of 1048 supernovae

across a redshift range of $0.01 < z < 2.26$, is used in this analysis. The observations allow us to constrain cosmological models using the observed distance modulus, $\mu_{\rm obs}$. The χ^2 of the SNIa dataset is defined as

$$\chi^2_{\rm SNIa} = \sum_{i=1}^{1048} \Delta\mu^T C^{-1} \Delta\mu, \tag{35}$$

where $\Delta\mu = \mu_{\rm obs} - \mu_{\rm th}$. Here, $\mu_{\rm obs}$ represents the observed distance modulus, defined as

$$\mu_{\rm obs} = m_B - M, \tag{36}$$

where m_B denotes the observed peak magnitude in the rest-frame B-band, and M gives the absolute B-band magnitude of a fiducial SNIa. We take the value of the magnitude M to be $M = -19.38$. The theoretical distance modulus, $\mu_{\rm th}$, is defined as

$$\mu_{\rm th}(z, p) = 5\log_{10}\left(\frac{D_L(z_{\rm hel}, z_{\rm cmb})}{1\ {\rm Mpc}}\right) + 25, \tag{37}$$

where p represents the parameter space, which varies across different cosmological models, and D_L is the luminosity distance, expressed as

$$D_L(z_{\rm hel}, z_{\rm cmb}) = (1 + z_{\rm hel}) r(z_{\rm cmb}). \tag{38}$$

The comoving distance $r(z)$ is calculated as

$$r(z) = cH_0^{-1} \int_0^z \frac{dz'}{E(z', p)}, \tag{39}$$

where $E(z) = H(z)/H_0$ is the dimensionless Hubble parameter, c is the speed of light in vacuum, and H_0 is the Hubble constant. The CMB-frame and heliocentric redshifts are denoted by $z_{\rm cmb}$ and $z_{\rm hel}$, respectively. The covariance matrix C used in the χ^2 calculation is given by

$$C = D_{\rm stat} + C_{\rm sys}, \tag{40}$$

where $D_{\rm stat}$ is a diagonal matrix representing statistical uncertainties, and $C_{\rm sys}$ is the covariance matrix accounting for systematic uncertainties.

B. Baryon Acoustic Oscillations

The measurement of the background expansion history of the Universe can be achieved through the standard ruler provided by the imprint of Baryon Acoustic Oscillations (BAO). The BAO method has been extensively studied and validated in numerous works [97–99], providing a critical tool for constraining cosmological models. For a comprehensive discussion, the reader is referred to these studies. We present the basic equations and terms necessary for working with BAO measuremens.

The comoving sound horizon is given by

$$r_s(z) = \frac{c}{H_0} \int_z^\infty \frac{c_s}{E(z')} dz', \tag{41}$$

where c is the speed of light in vacuum and c_s is the speed of sound, given by

$$c_s = \frac{1}{\sqrt{3(1 + R_b a)}}, \tag{42}$$

where R_b gives the baryon to photon density ratio, calculated as

$$R_b a = \frac{3\rho_b}{4\rho_\gamma}, \quad R_b = 31500\,\omega_b \left(\frac{T_{\rm CMB}}{2.7\ {\rm K}}\right)^{-4}. \tag{43}$$

Here, $\omega_b = \Omega_b h^2$ is the baryon density parameter with $h = H_0/100$, and $T_{\rm CMB}$ is the current measured value of the CMB temperature.

One crucial period in our cosmic history is the baryon drag epoch, which refers to the time when baryons decoupled from photons. The redshift at drag epoch is calculated by the fitting function:

$$z_d = \frac{1345\,\omega_m^{0.251}}{1 + 0.659\,\omega_m^{0.828}} \left(1 + b_1\,\omega_b^{b_2}\right), \tag{44}$$

where $b_1 = 0.313\,\omega_m^{-0.419}\left(1 + 0.607\,\omega_m^{0.674}\right)$ and $b_2 = 0.238\,\omega_m^{0.223}$. Here $\omega_m = \Omega_m h^2$ is the matter density parameter. By evaluating Eq. (41) at the drag epoch redshift z_d, we obtain a key quantity r_d which is a crucial term in BAO measurements. This gives the maximum distance sound waves could travel in the early Universe till the time of the last scattering (before the photon-baryon decoupling).

We use the latest BAO measurements from the Dark Energy Spectroscopic Instrument (DESI). The 12 data points used have been shown in Table I. The complete data, along with the survey details, can be found in Ref.[100, 101]. We constrain the model parameters from the BAO data using three observable within the redshift range $0.295 \le z \le 2.330$.

The first observable is the comoving angular distance $D_M(z)$ which is given by

$$D_M(z) = \int_0^z \frac{c}{H(z')}\, dz'. \tag{45}$$

Then we have the Hubble distance parameter $D_H(z)$ which is given by

$$D_H(z) = \frac{c}{H(z)}. \tag{46}$$

From the former two, we calculate the angle-average distance, which is given by

$$D_V(z) = (z D_M(z)^2 D_H(z))^{1/3}. \tag{47}$$

These quantities are normalized by the sound horizon r_d, which provides a standard ruler for measuring on large

TABLE I. Summary of tracer redshift and other observable parameters from the latest DESI BAO 2024 survey. The complete data is available at [101]

Tracer	**Redshift Range**	$z_{\mathbf{eff}}$	D_M/r_d	D_H/r_d	D_V/r_d
BGS	0.1 - 0.4	0.295	—	—	7.93 ± 0.15
LRG1	0.4 - 0.6	0.510	13.62 ± 0.25	20.98 ± 0.61	—

ELG2	1.1 - 1.6	1.317	27.79 ± 0.69	13.82 ± 0.42	—
QSO	0.8 - 2.1	1.491	—	—	26.07 ± 0.67
Lya QSO	1.77 - 4.16	2.330	39.71 ± 0.94	8.52 ± 0.17	—

scales. Thus, we calculate our theoretical values against the observed values $D_M/r_d, D_H/r_d$ and D_V/r_d obtained from the BAO measurements, which can be referred to from Table I. The χ^2 functions for the BAO data are:

$$\chi^2_{D_M/r_d} = \sum_{i=1}^{5} \frac{\left(D_M(z_i,p) - D_{M,\mathrm{obs}}(z_i)\right)^2}{\sigma^2_{D_M}(z_i)}, \tag{48}$$

$$\chi^2_{D_H/r_d} = \sum_{i=1}^{5} \frac{\left(D_H(z_i,p) - D_{H,\mathrm{obs}}(z_i)\right)^2}{\sigma^2_{D_H}(z_i)}, \tag{49}$$

$$\chi^2_{D_V/r_d} = \sum_{i=1}^{2} \frac{\left(D_V(z_i,p) - D_{V,\mathrm{obs}}(z_i)\right)^2}{\sigma^2_{D_V}(z_i)}, \tag{50}$$

where $D_M(z_i,p), D_H(z_i,p)$ and $D_V(z_i,p)$ are the theoretical values of the observable based on the model, and $D_{M,\mathrm{obs}}$, $D_{H,\mathrm{obs}}$ and $D_{V,\mathrm{obs}}$ are the observed values of the DESI BAO measurements.

Thus, the total χ^2 value for the BAO data is

$$\chi^2_{BAO} = \chi^2_{D_M/r_d} + \chi^2_{D_H/r_d} + \chi^2_{D_V/r_d}. \tag{51}$$

C. Cosmic Microwave Background

The Cosmic Microwave Background (CMB) measurements of the locations and amplitudes of peaks of acoustic oscillations give information about the distance to the surface of last scattering given by $r(z_*)$. This can be evaluated through Eq. (39) at z_*, which is the redshift at the time of recombination or last scattering. It marks the epoch when photons last scattered off free electrons before being able to freely travel through the universe, leaving behind their imprint in the form of the CMB radiation. The reader is referred to the Refs. [102, 103] for a more detailed discussion on CMB. We now proceed with the basic equations employed in the data analysis. The fitting function for recombination redshift z_* is

$$z_* = 1048\left(1 + 0.00124\,\omega_b^{-0.738}\right)\left(1 + g_1\,\omega_m^{g_2}\right), \tag{52}$$

where

$$g_1 = \frac{0.0783\,\omega_b}{1 + 39.5\,\omega_b^{0.763}}, \quad g_2 = \frac{0.560}{1 + 21.1\,\omega_b^{1.81}}. \tag{53}$$

Here ω_m and ω_b are the matter and baryon density parameters respectively. We are particularly interested in two quantities that characterize the CMB spectrum: the shift parameter and acoustic length scale.

It is observed that through the acoustic oscillations, doppler peaks are produced in the photon (radiation) spectrum. The placement of the peaks in the CMB spectrum is affected by the matter and radiation density, along with the dark energy. The shift in these peaks is probed by the shift parameter $\mathcal{R}$. The spectrum is affected in the line-of-sight direction, leading to the peak heights. We obtain $\mathcal{R}$ through the relation:

$$\mathcal{R} = \sqrt{\Omega_m} H_0 \frac{r(z_*)}{c}. \tag{54}$$

The acoustic scale l_a determines the spacing between the peaks and characterizes the CMB temperature power spectrum in the transverse direction. This is calculated by

$$l_A = \frac{\pi r(z_*)}{r_s(z_*)}. \tag{55}$$

When working with CMB, we have to consider the radiation component as in early-times it was dominant. We use the relation $\Omega_r = \Omega_m/(1+z_{\mathrm{eq}})$ to determine the radiation density, where z_{eq} is the epoch of matter-radiation equality and is given by

$$z_{\mathrm{eq}} = 2.5 \times 10^4\,\omega_m \left(\frac{T_{\mathrm{CMB}}}{2.7\,\mathrm{K}}\right)^{-4}, \tag{56}$$

where T_{CMB} represents the present-day temperature of the CMB. We adopt the best-fit value $T_{\mathrm{CMB}} = 2.7255\,\mathrm{K}$, measured by the COBE-FIRAS instrument [104]. CMB observation contribution in the constraint of cosmological parameters can be converted to CMB shift parameters for breaking degeneracy of parameters, instead of using the entire CMB power spectrum, [105, 106] This allows us to consider the data vector $\mathbf{v} = (R, l_A, \omega_b)^T$ which summarizes the Planck 2018 TT,TE,EE+lowE results [107]. The vector $\mathbf{v}$, along with the covariance matrix $C_{\mathbf{v}}$ have been reported in the Ref. [108].

The χ^2 function for the CMB data is given by:

$$\chi^2_{\mathrm{CMB}} = (\mathbf{v} - \mathbf{v}_{\mathrm{th}})^T C_{\mathbf{v}}^{-1} (\mathbf{v} - \mathbf{v}_{\mathrm{th}}), \tag{57}$$

where $\mathbf{v}_{\rm th}$ is the vector for the theoretical values of R, l_A, ω_b; and $C_{\mathbf{v}}^{-1}$ is the inverse of the covariance matrix.

D. Sample of Cosmic Chronometer (CC)

The cosmic chronometer (CC) approach provides measurements of the Hubble parameter based on the galaxy differential age method using the largest galaxies that are passively evolving [109]. In our analysis, we use 32 CC data points from different surveys that span a redshift range of $0.07 \leq z \leq 1.965$. The χ^2 function for CC data is given by

$$\chi^2_{CC} = \sum_{i=1}^{32} \frac{\left[H(z_i,p) - H_{\rm obs}(z_i)\right]^2}{\sigma_H^2(z_i)}, \tag{58}$$

where $H(z_i,p)$ represents the theoretical value of the Hubble parameter for the model parameters, $H_{\rm obs}(z_i)$ is the observed value of the Hubble parameter at redshift z_i, and $\sigma_H(z_i)$ is the associated uncertainty with $H_{\rm obs}(z_i)$.

E. $f(z)\sigma_8(z)$ Data

We introduced the background evolution of matter perturbations in Section 4 and used Eq.(33) to define the weighted linear growth rate. To provide a more comprehensive analysis of the present model in the context of perturbation evolution, we focus on the observable quantity $f(z)\sigma_8(z)$. For this purpose, we use 18 data points from the "Gold" compilation, which contains measurements of $f(z)\sigma_8(z)$ obtained from various galaxy surveys. The data has been summarized in Table III of Ref. [110].

We compare the observational data with the theoretical values calculated from our models using the χ^2 function for $f(z)\sigma_8(z)$, which is defined as

$$\chi^2_{f\sigma_8} = \sum_{i=1}^{18} \frac{\left[f\sigma_{8,\rm theo}(z_i,p) - f\sigma_{8,\rm obs}(z_i)\right]^2}{\sigma^2_{f\sigma_8}(z_i)}, \tag{59}$$

where $f\sigma_{8,\rm theo}(z_i,p)$ is the theoretical value computed using (33), and $f\sigma_{8,\rm obs}(z_i)$ represents the observed data.

Using three different combinations of the data discussed above, we employ Bayesian MCMC methods to explore the parameter space of the proposed model described in Section III, using the `emcee` Python package [111, 112]. We use the following chi-squared functions:

- **DS1**: This dataset consists of a combination of data from the observations of SNIa, BAO, and CMB. It contains 1063 independent data points. The total χ^2 function for this dataset is given by

$$\chi^2_{\rm tot} = \chi^2_{\rm SNIa} + \chi^2_{\rm BAO} + \chi^2_{\rm CMB}. \tag{60}$$

- **DS2**: The first dataset is augmented with the cosmic chronometer (CC) data containing 32 data points making the total to be 1095. In this case, the total χ^2 function is defined as

$$\chi^2_{\rm tot} = \chi^2_{\rm SNIa} + \chi^2_{\rm BAO} + \chi^2_{\rm CMB} + \chi^2_{H(z)}. \tag{61}$$

- **DS3**: We further expand DS2 by including the weighted linear growth rate data from the $f\sigma_8$ measurements. The total data points are 1113 and for this combination, the total χ^2 function becomes

$$\chi^2_{\rm tot} = \chi^2_{\rm SNIa} + \chi^2_{\rm BAO} + \chi^2_{\rm CMB} + \chi^2_{H(z)} + \chi^2_{f\sigma_8}. \tag{62}$$

VI. RESULTS AND DISCUSSION

We now discuss over the outcomes from various data sets to constrain our model with Hubble parameter, given in Eq.(19). For the parameters of the ΛCDM and the $\Lambda(t)+\Gamma$ models, Figures 1-3 display the combined $1-\sigma(68.3\%)$ and $2-\sigma(95.4\%)$ confidence level (CL) contours with marginalized likelihood distributions. Table II displays the matching parameter constraints for the datasets DS1, DS2, and DS3 that were acquired from the MCMC sampler. The best fit values of Hubble constant for $\Lambda(t)+\Gamma$ come out to be $H_0 = 67.517 \pm 0.869$ km/s/Mpc for DS1 data, $H_0 = 67.534 \pm 0.874$ km/s/Mpc for DS2 data, and $H_0 = 67.533 \pm 0.884$ km/s/Mpc for DS3 data. We know that the discrepancies in the measurement of H_0 between the Planck collaboration [113] and independent cosmological probes [114] refer to H_0 tension. The Planck collaborator estimates $H_0 = 67.27 \pm 0.06$ km/s/Mpc, whereas R22 reported $H_0 = 73.04 \pm 1.04$ km/s/Mpc which leads to a tension of 4.89σ. Our estimated values of H_0 from three the datasets show very little tension with the Planck result upon comparison. We plot the evolution of $H(z)$ for ΛCDM and decaying VED with matter creation model using 32 data points of CC as shown in Figs. 4-6. Both models are in agreement for the three datasets, as the hybrid model and the standard model coincide for nearly the whole evolution period and the model paths cover most of the CC dataset with the error bars.

In Figs. 7-9, we present the evolution of the deceleration parameter with respect to redshift. The transition redshift $z_{\rm tr}$ at which the Universe transits from a decelerating phase to an acceleration phase occurs at $z_{\rm tr} = 0.675 \pm 0.019$ with DS1, $z_{\rm tr} = 0.675 \pm 0.019$ with DS2, and at $z_{\rm tr} = 0.677 \pm 0.019$ with DS3 which doesn't vary much from the standard model but the transition happens earlier. The analysis shows that the Universe is currently in an accelerating phase of cosmic expansion, whereas it was in a decelerating phase in the past. We find the constraints of the present value of the deceleration parameter as $q_0 = -0.550 \pm 0.010$, -0.550 ± 0.010 and -0.551 ± 0.010 for DS1, DS2 and DS3 datasets, respectively. Comparing with the values of q_0 obtained for

the ΛCDM model, we see that the expansion of the Universe is accelerating at a slightly faster rate. Overall, the values of both q_0 and $z_{\rm tr}$ obtained for the model agree with the values obtained for the standard model.

In the considered cosmological scenario, the calculated values of the age of the Universe t_0 based on the parameter constraints obtained for the three datasets are 13.98 ± 0.18 Gyr, 13.98 ± 0.19 Gyr, and 13.99 ± 0.19 Gyr, respectively which when compared with the mean value for the standard model 13.79 ± 0.02 Gyr suggest a longer cosmic history however the difference is not that significant. This can be attributed to the perturbations through matter creation and vacuum decay. In this study, we have initially assumed the EoS of vacuum energy as $w_\Lambda = -1$. Therefore, we investigate the total effective EoS given by (26). The evolution of EoS is depicted in Figs. 10-12. It is obvious from the figures that $w_{\rm eff}$ has a negative value such that $w_{\rm eff} < -1/3$, which indicates an accelerating phase in the expansion. In the future, we can see that the model asymptotically approaches negative unity, i.e. $w_{\rm eff} = -1$, implying complete vacuum domination. The present values of $w_{\rm eff}$, represented by w_0, strongly favor a value around -0.700 ± 0.007 across all three datasets for the presented model which indicates the transition towards a dark energy era. The values are also consistent with those reported for the ΛCDM model.(cf. Table II)

Let us now discuss σ_8 and S_8, which are crucial for structure formation and are obtained by probing cosmological perturbations, as discussed in Section 4. The DS3 column in Table II reports the parameter constraints for these quantities. For the $\Lambda(t)+\Gamma$ model, we have $\sigma_8 = 0.762 \pm 0.028$, which is a good result considering the slight deviation with ΛCDM. We rephrase this in terms of the fitting value of the related LSS observable $S_8 = \sigma_8\sqrt{\Omega_m}/0.3$, which gives $S_8 = 0.762 \pm 0.0297$. Comparing it with $S_8 = 0.763 \pm 0.026$ of ΛCDM model for the same DS3 dataset and $S_8 = 0.737 \pm 0.036$ of weak

lensing measurement, we find that there is no residual tension left as mismatch is less than 1σ. We have also plotted $f(z)\sigma_8(z)$ data corresponding to both the standard model and our model in Fig. 13. We have used 18 data points from the $f(z)\sigma_8(z)$ Gold data along with their uncertainty measures. The curves provide a fairly good fit for the data, implying our model agrees with the observational data in the context of structure formation and cosmic perturbations.

We have found that the best-fit values of decaying pa-

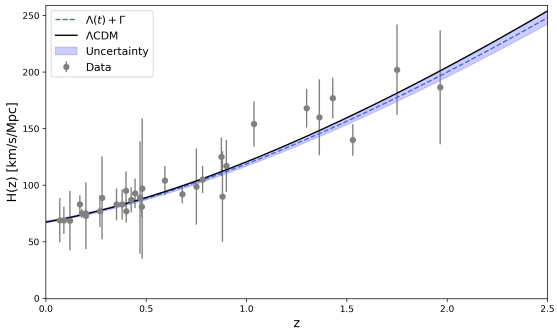

FIG. 4. Best-fit using DS1 over H(z) data for the $\Lambda(t)+\Gamma$ model (blue dotted line) and standard model (black line). The shaded band represents the uncertainty for the former. The grey points with error bar represent the 32 CC data points.

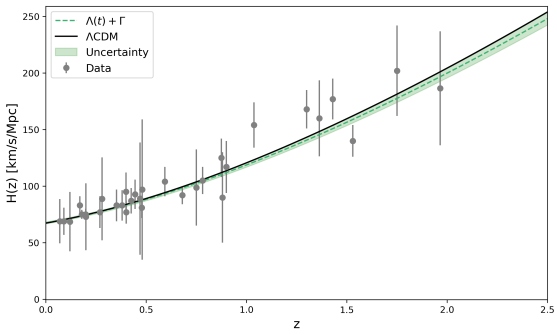

FIG. 5. Best-fit using DS2 over H(z) data for the $\Lambda(t)+\Gamma$ model (green dotted line) and standard model (black line). The shaded band represents the uncertainty for the former. The grey points with error bar represent the 32 CC data points.

rameter are $\nu = 0.00069 \pm 0.00692$, $\nu = 0.00058 \pm 0.00687$ and $\nu = 0.00067 \pm 0.00694$, and of the matter creation parameter are $\beta = 0.00109 \pm 0.00694$, $\beta = 0.00122 \pm 0.00685$ and $\beta = 0.00120 \pm 0.00694$ using DS1, DS2 and DS3 datasets, respectively. The results confirm that these parameters act as a perturbation to the ΛCDM model.

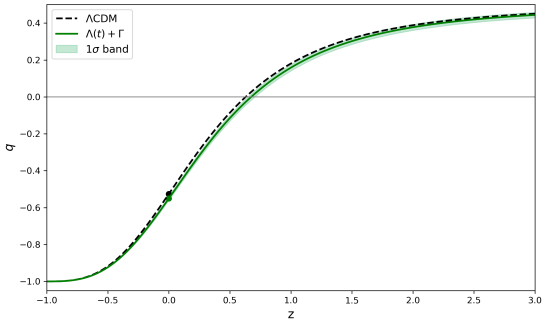

FIG. 8. The deceleration parameter versus redshift for the $\Lambda(t)+\Gamma$ model with DS2 dataset. The standard model's evolution is depicted by the dashed curve.

The values obtained for the baryon density parameter $\omega_b = \Omega_b h^2$ are also in good agreement with the Planck values across the three datasets.

Furthermore, we report the cosmographic parameter, known as the jerk parameter, which is defined by $j = \dddot{a}/aH$. It gives information about the dynamics of the DE EoS. In terms of the deceleration parameter, it is given by the expression:

$$j = q(2q+1) + (1+z)\frac{dq}{dz}. \tag{63}$$

It can be verified that for the standard model, the value of the jerk parameter is a constant, i.e. $j = 1$. This parameter is a dimensionless third derivative of the scale factor and can help us study how our model deviates from the standard model. For the proposed model, the jerk parameter (63) gives

$$j = 3(1-\beta)(1-\nu)(q+1) - 3q - 2. \tag{64}$$

We see that in the limit where the model parameters β and ν are zero, j reduces to one. In the case of the deceleration parameter, negative values imply an

accelerating expansion of the Universe. However, in the case of the jerk parameter, a positive value represents the same, and from (64), we can see that for the considered model, the value will remain positive. In Fig.14, the evolution of this parameter is shown for our model using the parameter constraints obtained for all three datasets. The figure confirms the positive nature, and we see that it remains close to but less than unity at early redshifts, eventually tending to 1 in the future. Thus, in the past, the parameter deviates from the standard model; however, in late time, it converges to a similar behaviour.

We also plot the evolution of matter density in ΛCDM and the proposed model in Fig.15 using the cosmological parameter estimates of DS1, DS2 and DS3 datasets. We consider a single case for the evolution in the case of the standard model represented by a black line. We see that in late time, the matter density tends towards zero for all the cases, resulting from the accelerated expansion causing complete vacuum domination. We also observe that because of our particular selection of the particle production rate, the creation pressure p_c, which contributes to this acceleration, has the expression $p_c = -\beta\rho_m$. The evolution of this pressure is plotted in Fig.16, which shows that it increases from negative infinity at higher redshifts and converges towards zero in late time. Thus, particle production will cease in the dark energy domination era.

VII. SELECTION CRITERIA

In this section, we are interested in determining the models that could perform better with respect to the observational data used in the analysis. We utilize three selection statistical criteria, namely, reduced chi-squared, Akaike information criteria and Bayesian information criteria, which consider the presence of an extra degree of freedom.

Table III presents the χ^2 and the reduced χ^2 values for the standard model and the presented model, respectively. The reduced χ^2, denoted by χ^2_{red}, is calculated by the formula ${\chi^2}_{red} = \chi^2/(N-d)$, where N is the total number of data points (here, it is 1063, 1095 and 1113 for DS1, DS2 and DS3, respectively), and d is the number of

free parameters ($d=3$ for ΛCDM and $d=5$ for $\Lambda(t)+\Gamma$ model for DS1 and DS2, and one additional parameter σ_8 is added to both for DS3). It is to be noted that a reduced χ^2 value less than one gives a good fit, and greater than one indicates a poor fit. From Table III, we see that the reduced χ^2 values are less than 1, indicating that our model fits well with the observational datasets and the data fits well with the current models. This is just one criterion to test the viability of our model. We will utilize two selection criteria for further analysis.

The Akaike information criteria (AIC) value is calculated as [115]

$$AIC = \chi^2_{min} + \frac{2d\,N}{N-d-1}, \tag{65}$$

where χ^2_{min} is the minimum value of the χ^2-function. Equation(65) makes it clear that the penalty for the extra number of free parameters is represented by the second term on the right hand side. In cases where d is significantly lesser than N, Eq.(65) reduces to $AIC = \chi^2_{min}+2d$. To test the proposed model M_1 against the reference model M_0, we calculate the difference in their respective AIC values as $\Delta AIC_{M_1M_0} = AIC_{M_1} - AIC_{M_0}$,

which is interpreted as the "evidence in favour" of the model M_1 as compared to the reference M_0. In this paper, the concordance model has been considered as the reference.

The value $0 \leq AIC_{M_1M_0} < 2$ indicates "strong evidence in favour" of the proposed model M_1. For $2 \leq AIC_{M_1M_0} \leq 4$, there is "averagely strong evidence in favour" of M_1. If $4 < AIC_{M_1M_0} \leq 7$, then there is "little evidence in favour", whereas for $AIC_{M_1M_0} > 7$, there is "no evidence in favour" of the proposed model.

On the other hand, the Bayesian information criterion (BIC) is defined as [116]

$$BIC = \chi^2_{min} + d\, lnN \tag{66}$$

Likewise $\Delta AIC_{M_1M_0}$, we compute $\Delta BIC_{M_1M_0}$ as $\Delta BIC_{M_1M_0} = BIC_{M_1} - BIC_{M_0}$. This gives the "evidence against the model M_1 with respect to the reference model M_0. Thus, the ranges of the values for BIC and their interpretation are different from those of AIC. The value $0 \leq BIC_{M_1M_0} < 2$ indicates "not enough evidence in favour" of the proposed model M_1. For $2 \leq BIC_{M_1M_0} < 6$, there is "evidence against" the model M_1, and for $6 \leq BIC_{M_1M_0} < 10$, we have "strong evidence against" model M_1. If $BIC_{M_1M_0} \geq 10$ then there is "overwhelmingly strong evidence" against the proposed model, and it is not the best model.

The values of $\Delta AIC_{M_1M_0}$ and $\Delta BIC_{M_1M_0}$ are shown in Table III. For the three datasets, DS1, DS2 and DS3, we obtain $\Delta AIC_{M_1M_0}$ values to be 3.73, 3.49, and 3.55, respectively, indicating averagely strong evidence in favour of our proposed model with respect to the standard model for all the datasets. The $\Delta BIC_{M_1M_0}$ values obtained for the datasets are 13.63, 13.46, and 13.54, respectively. This indicates that the evidence against our model is overwhelmingly strong and it is not the best fit for the data according to BIC.

VIII. THERMODYNAMIC ANALYSIS

In this section, we focus on the thermodynamic analysis of a universe under the proposed scenario. First we use the generalized first law of thermodynamics to obtain an expression for the dark matter temperature in terms of our model parameters. Then, we test the validity of generalized second law (GSL) of thermodynamics by computing the total entropy of the universe and its evolution w.r.t time and assess the results.

A. Dark Matter Temperature

Let us consider the modified first law of thermodynamics, given by Eq.(3). This can be rewritten as

$$d(\rho_m V) + \tilde{p}_m\, dV - \frac{(\rho_m + \tilde{p}_m)}{n} d(nV) = 0, \tag{67}$$

where $h = (\rho_m + \tilde{p}_m)$. Taking time derivative of Eq. (67), we have

$$\dot{\rho_m} = \frac{\dot{n}}{n}(\rho_m + \tilde{p}_m). \tag{68}$$

Since the temperature is defined by Gibbs equation

$$TdS = d\left(\frac{\rho_m}{n}\right) + \tilde{p}_m\, d\left(\frac{1}{n}\right) \tag{69}$$

We have $T = T(n, \rho_m)$ which gives

$$\dot{T} = \frac{\partial T}{\partial n}\dot{n} + \frac{\partial T}{\partial \rho_m}\dot{\rho_m}. \tag{70}$$

Using (68) into (70), we get

$$\dot{T} = \frac{\dot{n}}{n}\left[\frac{\partial T}{\partial n}n + \frac{\partial T}{\partial \rho_m}(\rho_m + \tilde{p}_m)\right]. \tag{71}$$

Using the integrability condition, $\partial^2 S/\partial T \partial n = \partial^2 S/\partial n \partial T$, one gets

$$\frac{\partial T}{\partial n}n + \frac{\partial T}{\partial \rho_m}(\rho_m + \tilde{p}_m) = T\frac{\partial \tilde{p}_m}{\rho_m}. \tag{72}$$

Using (72) into (71), we obtain the evolution equation for the temperature which is given by

$$\frac{\dot{T}}{T} = \frac{\dot{n}}{n}\frac{\partial \tilde{p}_m}{\partial \rho_m} = w_{\text{eff}}\frac{\dot{n}}{n}. \tag{73}$$

Using Eq.(2) in above equation, we get

$$\frac{\dot{T}}{T} = -3w_{\text{eff}}H\left(1 - \frac{\Gamma}{3H}\right), \tag{74}$$

or equivalently,

$$\frac{\dot{T}}{T} = 3\beta(1-\beta)H. \tag{75}$$

Using (20) into (75), we obtain the temperature of dark matter

$$T = T_0\left[\sqrt{\frac{\tilde{\Omega}_m}{\tilde{\Omega}_\Lambda}}\sinh\left(\frac{3}{2}\sqrt{\tilde{\Omega}_\Lambda}(1-\beta)(1-\nu)H_0 t\right)\right]^{\frac{2\beta}{(1-\nu)}}. \tag{76}$$

Using (20) into (2) we can obtain the particle number density which is given by

$$n(t) = n(t_0)\left[\sqrt{\frac{\tilde{\Omega}_m}{\tilde{\Omega}_\Lambda}}\sinh\left(\frac{3}{2}\sqrt{\tilde{\Omega}_\Lambda}(1-\beta)(1-\nu)H_0 t\right)\right]^{-\frac{2}{(1-\nu)}}. \tag{77}$$

B. Generalized Second Law of Thermodynamics

This section is devoted to examine and analyse the validity of generalized second law (GSL) of thermodynamics for the presented model. According to the GSL of thermodynamics, the total entropy of the Universe, i.e., sum of the horizon entropy and entropy of the fluid always increases with time [117]. Mathematically, we can express it as

$$\frac{d}{dt}(S_H + S_m + S_\Lambda) \geq 0, \tag{78}$$

where S_H is the entropy associated with the Hubble horizon (apparent horizon) for flat Universe, S_m is the entropy of dark matter produced by gravitationally induced matter creation and S_Λ is the entropy associated with vacuum energy. The GSL thermodynamics was first formulated for black hole by Bekestein and Hawking [117]. They stated that the black hole horizons have entropy and temperature associated with them. According to Bekenstein, the horizon entropy is proportional to the area of the horizon, which is given by

$$S_H = \frac{k_B A}{4 l_{\rm Pl}^2}, \tag{79}$$

where k_B is the Boltzmann constant, $A = 4\pi {R_H}^2$ is the area of the Hubble horizon and $l_{\rm Pl} = \sqrt{\frac{\hbar G}{c^3}}$ is the Planck length. Here, $R_H = \frac{1}{\sqrt{(H^2+\kappa a^{-2})}}$ is the radius of the Hubble horizon. In a spatially flat FLRW Universe, we have $R_H = \frac{1}{H}$. Assuming $k_B = \hbar = c = 8\pi G = 1$, the above equation can be rewritten as

$$S_H = \frac{8\pi^2}{H^2} \tag{80}$$

Therefore, the rate of change of entropy of the Hubble horizon is given by

$$\dot{S}_H = -\frac{16\pi^2}{H^3}\dot{H} \tag{81}$$

The entropy of cosmic components (matter and dark energy) inside the Hubble horizon can be calculated by the Gibb's equation [118]

$$T\, dS = d(\rho V) + p\, dV, \tag{82}$$

where $V = 4\pi/3H^3$ is volume enclosed by horizon and T is temperature associated with both matter and dark energy and due to their mutual interaction, we assume that T is equal. We assume that the system bounded by the Hubble horizon remains in equilibrium so that the temperature distribution is uniform and its value equal to the temperature of the horizon. In this case, Gibbons-Hawking temperature, $T = H/2\pi$ is a natural choice for the horizon temperature. It is evident from (82) that the vacuum energy density in the present model doesn't contribute to the entropy as $\rho_\Lambda = -p_\Lambda$. The non-zero contribution to the entropy is only due to dark matter produced by gravitationally induced matter creation, which is given by

$$S = \frac{(\rho_m + \tilde{p}_m)V}{T}, \tag{83}$$

where $\tilde{p}_m = p_m + p_c$. Substituting $V = 4\pi/3H^3$ and $T = H/2\pi$ in above equation, we get matter entropy as

$$S_m = \frac{8\pi^2}{3H^4}(\rho_m + p_c). \tag{84}$$

Using $p_c = -\beta\rho_m$, Equation (84) can be written as

$$S_m = \frac{8\pi^2(1-\beta)\rho_m}{3H^4}, \tag{85}$$

where matter energy density ρ_m is obtained from the Friedmann equation (8), which is given by

$$\rho_m = 3H_0^2(1-\nu)\tilde{\Omega}_m a^{-3(1-\beta)(1-\nu)}. \tag{86}$$

Using (80) and (85) the total entropy of the Universe, i.e., $S = S_H + S_m$ is calculated as

$$S = \frac{8\pi^2}{H^2}\left[1 + \frac{(1-\beta)\rho_m}{3H^2}\right]. \tag{87}$$

On substituting the value of ρ_m from (86), we see that the total entropy can be simplified in terms of deceleration parameter q, given in (22), as

$$S = \frac{8\pi^2}{3H^2}(5 + 2q). \tag{88}$$

Now, to check the validity of GSL, given by (78) for this model, we have the combined change in entropy for the dark fluid

$$\dot{S}_m = -\frac{8\pi^2(1-\beta)\rho_m}{H^3}\left(1 + \frac{\dot{H}}{H^2}\right). \tag{89}$$

Combining (81) and (89), and noting Eq. (21), we obtain the total change in entropy as

$$\dot{S} = \frac{8\pi^2}{H}\left[2(1+q) + \frac{(1-\beta)\rho_m}{H^2}q\right], \tag{90}$$

in which we substitute the value of ρ_m and solve further to obtain the simplified expression

$$\dot{S} = \frac{16\pi^2}{H}(1+q)^2. \tag{91}$$

In equation (91) it is noted that $\dot{S} \geq 0$ as all the terms are positive and hence the GSL is satisfied. In the asymptotic limit, the change in entropy tends to zero in late time which shows that the entropy is extremized and thus the end phase is in an equilibrium state. As $q \to -1$ in the

future, the total entropy S becomes equal to the horizon entropy S_H, given by

$$S_{\rm future} = \frac{8\pi^2}{H_0^2 \tilde{\Omega_\Lambda}} \tag{92}$$

The change in entropy, $\dot{S} \to 0$ implies that the total entropy stabilizes at the value $S_{\rm future}$ and does not increase any further, i.e. it reaches an asymptotic limit [119].

The evolution of $\dot{S}$ with respect to redshift z is shown in Fig.17 using the best-fit values obtained for DS3. Figure shows the time derivative of entropy, $\dot{S}$ remains positive throughout the cosmic evolution and tends towards zero in the future. Further, the equilibrium state may be stable or unstable according as $\ddot{S} < 0$ or $\ddot{S} > 0$ at least in the far future. We plot the evolution of $\ddot{S}$ with respect to redshift which is shown in Fig.18. It is observed that $\ddot{S} > 0$ in the early phase of evolution and made a transition to $\ddot{S} < 0$ in the recent past. Thus, a thermodynamic stable equilibrium state is achieved in late time. As $z \to -1$, $\ddot{S} \to 0$ which shows that any system satisfying the extremum of entropy and convexity condition behaves like an ordinary macroscopic system. Therefore, we can say that the evolution of the Universe is like the evolution of an ordinary macroscopic system.

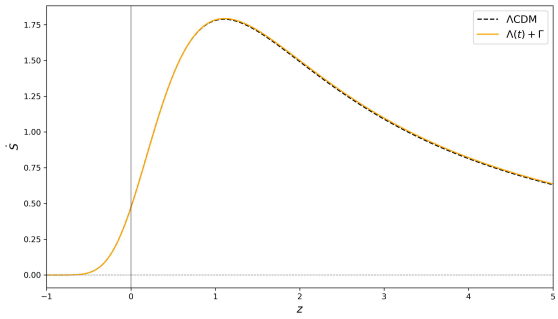

FIG. 17. Rate of change of entropy with respect to time from the best-fit values obtained for DS3. The positive value ensures that the entropy always increases. The dashed line shows the evolution for the standard model.

IX. CONCLUSION

In this work, we have studied the Universe's expansion powered by gravitationally induced 'adiabatic' matter creation and decaying vacuum in a spatially flat homogeneous and isotropic FLRW spacetime. We have demonstrated how matter creation affects the expanding Universe with a decaying vacuum, especially the late time evolution. As matter creation and varying $\Lambda(t)$ are phenomenological and have various forms in the literature, we have considered the specific forms for the vacuum energy density and matter creation rate, viz., $\rho_\Lambda = c_0 + 3\nu H^2$ and $\Gamma = 3\beta H$. Based on

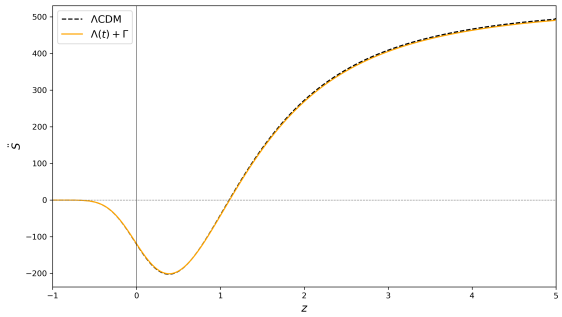

FIG. 18. Second derivative of entropy with respect to time from the best-fit values obtained from DS3 showing how the entropy accelerates with time. The dashed line shows the evolution for the standard model.

the latest observational data, the motivation was to study the dynamics of a cosmological model that has an interplay between the vacuum (dark energy) and the matter sector. The dynamical analysis confirms that the Universe's expansion is going through a cosmic acceleration phase. We have described this phenomenon using analytic solutions and observational constraints of the Hubble function and deceleration parameter. Our model's parameter constraints, which we obtained through the MCMC sampler, largely agreed with the ΛCDM model. We now present a summary of the key findings.

We have found the analytic solutions of the various cosmological parameters like $H(z), q(z), w_{\rm eff}(z)$ and $z_{\rm tr}$ and then tested them with the latest observational data. Our results show that the Universe is currently in an accelerated expansion phase, having previously been in a decelerating phase. The transition redshift $z_{\rm tr} = 0.675 \pm 0.019$ for DS1, $z_{\rm tr} = 0.675 \pm 0.019$ for DS2 and $z_{\rm tr} = 0.677 \pm 0.019$ for DS3 are consistent with ΛCDM and other recent constraints reported in the literature. The values for the effective EoS parameter for the three datasets were less than $-1/3$, which affirm the accelerating phase. Thus, the parameter constraints we obtained align with our understanding of DE in the Universe.

One thing we note is that our model favors strongly favors a value close to 0.700 ± 0.007 for the current value of the fractional density parameter Ω_Λ which is slightly higher than the values reported for the standard model and the Planck estimate 0.6889 ± 0056. The tension between the two is around 1.24σ which is not signficant. The residual tensions for the Hubble parameter constraints for our model in respect of the latest measurement of $H_0 = 73.04 \pm 1.04$ km/s/Mpc [114] for the three chosen datasets DS1, DS2, and DS3 are 4.07σ, 4.06σ, and 4.03σ respectively. We have explored cosmic perturbations and structure formation through the σ_8 and S_8 parameters, which were constrained through DS3 (Table II). The evolution of $f\sigma_8$ has been shown in

Figure 14, where theoretical curves of the weighted linear growth rate function for the ΛCDM and the $\Lambda(t) + \Gamma$ model have been plotted against the 18 $f(z)\sigma_8(z)$ data points. The curves are in agreement and consistent with the observational data. Our results align with the weak gravitational lensing observations [120] for both the standard model and the proposed model. However, there is some discrepancy between the best-fit values and the values obtained from the Planck 2018 results [121]: $\sigma_8 = 0.8102 \pm 0.0060$ and $S_8 = 0.825 \pm 0.011$.

We have also observed the evolution of the jerk parameter for our model (Figure 13), and for all three datasets, the parameter is positive and less than unity at early times. It tends towards unity in the future, mimicking the behaviour of the standard model, for which the parameter is always equal to one. The reduced χ^2 values for all three data combinations have also been calculated, and the values come out to be less than one, implying the model fits the observational data well and vice-versa. These values have been displayed in Table III. We have also used AIC and BIC selection criteria to discriminate between our chosen and the reference model, ΛCDM. According to the values of ΔAIC obtained for all three datasets, our model fits the data reasonably well, and there is averagely strong evidence in favour of it compared to the reference model. However, as per the ΔBIC values, the evidence is stacked against our model and is probably not a very good fit.

Following that, we have discussed a thermodynamic analysis for a Universe in our proposed scenario of matter creation and decaying vacuum. We found expressions for the dark matter temperature and the particle number density. We have discussed the GSL of thermodynamics for the proposed model. We have observed that the proposed model satisfies the GSL and convexity condition for the stability. We have shown these evolutions through the graphs of the first derivative of entropy $\dot{S}$ and its acceleration $\ddot{S}$ in Figs. 17 and 18, respectively.

In conclusion, the phenomenological model depicting the interaction between dark matter with matter creation and decaying vacuum dark energy, as explored in the paper, effectively describes the evolutionary features of the Universe at both background and perturbation levels. The thermodynamic features are also in accordance with established laws. Thus, exploring the interaction between dark matter empowered by matter creation and decaying vacuum stems from diverse perspectives, and holds promise for future study. This involves employing dynamical system analysis to explore deeper insights into the evolution of the Universe.

Design and Analysis of Substrate Integrated Folded Waveguide and Filter

Sudarshan Kumar[1] and Asok De[2]

[1]Maharaja Agrasen Institute of Technology, New Delhi, India; [2]Delhi Technological University, New Delhi, India

ABSTRACT
A substrate integrated folded waveguide (SIFW) and filters are proposed in this article. Analytical formulations of electric and magnetic fields, as well as cut-off frequencies, are obtained for the proposed SIFW. The dispersion characteristics of the first two fundamental modes of SIFW are considered and found to be similar to those of an ordinary substrate integrated waveguide (SIW). The SIFW is 50% narrower than the SIW. The filter is obtained by making *H*-plane slots in the central partial *H*-plane metal vane of the SIFW. The proposed SIFW filters have an application in the 26 GHz, 5 G frequency band. Both the SIFW and the SIFW filter are much smaller than their unfolded equivalents. The simulated results and the measured results match very well.

KEYWORDS
Filter; Rectangular waveguides (RWG); Substrate integrated waveguide (SIW); Substrate integrated folded waveguide (SIFW)

1. INTRODUCTION

Conventional metallic waveguides have the attractive characteristics of low insertion loss, high power handling capability, and high-quality factor, so their components have been widely employed in microwave and millimeter wave systems. However, due to their 3-dimensional design, they are challenging to fabricate and integrate with other planar components. Some researchers have proposed substrate integrated waveguide (SIW) as a solution to the difficulties in recent years. It incorporates many of the advantages of conventional rectangular waveguides (RWG) [1,2], such as simple conversion into filters and antennas and easy connection with micro-strip or coplanar circuits. Compared to micro-strip and coplanar lines, SIW's structure provides additional benefits, including low profile, high Q, low cost, high power handling capability, and light weight [3]. SIW uses metal cladding on the top and bottom of the substrate to act as the top and bottom walls, much like a RWG filled with dielectric. The metal vias on either side of the SIW serve to construct the vertical sidewalls [4,5]. However, compared with micro strip or strip line components, the width of SIW may be too large for some circuits. Therefore, a reduction in the SIW width is still required. Therefore, the concept and the geometry of a SIFW have been proposed [6–8]. Che *et al.* [1] studied SIFW and deduced the formulas for cut-off frequency, propagation constant, and gap width of the central metal vane. Trong *et al.* [9] described the variational analysis of SIFW.

Various SIW and SIFW filters are available in the literature with enhanced performance [10–16]. Greater bandwidth is achieved in these smaller-sized filters by sacrificing insertion loss. Kumar *et al.* [4] designed substrate integrated waveguide filters using the periodicity in the designed structure. Nan Song *et al.* [17] studied the tunable millimeter wave equalizer, which is mainly composed of a micro strip through line and substrate integrated folded waveguide (SIFW) resonant cavities. In [18], a SIFW filter is designed for the Wi-Fi 6E application. L. Yang *et al.* [19] designed a dual mode filter using the SIFW. The high-order modes in the SIFW cavity are employed to realize the function of filters. Fang Zhu *et al.* [20] designed a planar mode composite folded substrate integrated waveguide that enables simultaneous propagation of the $TE_{10}$and TE_{10} folded modes. Some SIFW band pass filters with good performance and compact size are reported in [21–26].

In this paper, a SIFW is designed and its electric and magnetic field components and dispersion characteristics are derived. Secondly, band pass filters are designed by making slots in the central partial *H*-plane metal vane. A FEM based simulator (Ansys HFSS) is used for the simulation of SIW, SIFW, and SIFW filters.

2. DESIGN AND ANALYSIS OF SIFW

The geometrical configuration of the SIW and the SIFW is shown in Figure 1. The SIW is designed with a dielectric substrate with a relative dielectric constant of 3.48. The height of the substrate is 0.762 mm. The width of the proposed SIW is calculated for the cut-off frequency of 10.5 GHz according to the following formula [27]. The

© 2025 IETE

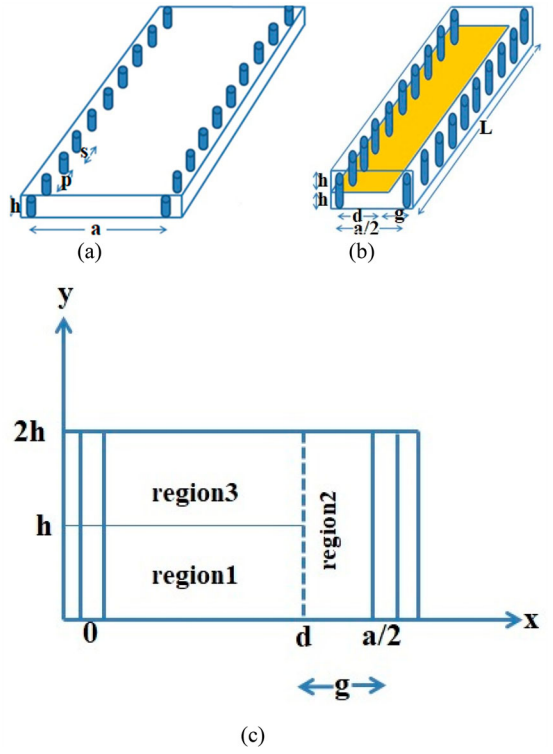

Figure 1: (a) Configuration of SIW (b) Configuration of SIFW (c) Cross section view of SIFW ($\boldsymbol{a} = 8$ mm,$\boldsymbol{s} = 0.61$ mm, $\boldsymbol{p} = 0.91$mm, $\boldsymbol{d} = 3.4$ mm,$\boldsymbol{g} = 0.6$ mm and $\boldsymbol{L} = 20$ mm)

width of the designed SIW is given by:

$$a = a_{RWG} + \frac{s^2}{0.95p} \tag{1}$$

where a is the width of the designed SIW, a_{RWG} is the width of the equivalent rectangular waveguide, s is the diameter of the vias, and p is the pitch of the vias. The calculated width of SIW is 8 mm at a cut – off frequency of 10.5 GHz. By transversely folding the SIW, the width becomes $a/2$ and the height becomes $2h$ and by inserting a partial H plane metal vane of width d, the gap spacing between the metal vane and the via is g. The thickness of the H plane metal vane is supposed to be negligible. The wave propagation direction is considered along the positive Z axis. The SIW and SIFW are both periodic devices. The unit cell of these devices comprises a dielectric substrate supported by two ground planes with two front metallic vias in SIW and an additional metal vane in SIFW. These periodic patterns have a complicated analysis. Therefore, these can be considered as regular structures to increase precision in the analysis [28,29].

The SIFW is divided into three regions labeled 1, 2, and 3 by a metal vane. As SIW only supports TE mode, the dominant mode TE_{10} and second mode TE_{20} are considered. To derive the field's components, we solve Maxwell's equation using a potential function [30].

$$E_x = -\frac{1}{\varepsilon_0\varepsilon_r}\frac{\partial F_z}{\partial y},\ E_y = \frac{1}{\varepsilon_0\varepsilon_r}\frac{\partial F_z}{\partial x},\ E_z = 0$$

$$H_x = -j\frac{1}{j\omega\mu_0\varepsilon_0\varepsilon_r}\frac{\partial^2 F_z}{\partial x\partial z},\ H_y = -j\frac{1}{j\omega\mu_0\varepsilon_0\varepsilon_r}\frac{\partial^2 F_z}{\partial y\partial z},$$
$$H_z = -j\frac{1}{j\omega\mu_0\varepsilon_0\varepsilon_r}\left(\frac{\partial^2}{\partial z^2} + k^2\right)F_z \tag{2}$$

where k is a propagation constant and $F_z(x, y, z)$ is a scalar potential function, it represents the z component of the vector potential function $\vec{F}$. The potential $\vec{F}$, and in turn F_z must satisfy Helmholtz's equation.

$$\nabla^2 F_z(x, y, z) + k^2\nabla^2 F_z(x, y, z) = 0 \tag{3a}$$

This can be reduced to

$$\frac{\partial^2 F_z}{\partial x^2} + \frac{\partial^2 F_z}{\partial y^2} + \frac{\partial^2 F_z}{\partial z^2} + k^2 F_z = 0 \tag{3b}$$

The necessary and sufficient boundary conditions for the region 1 are given by

$$E_x(0 \le x \le d, y = 0, z) = E_x(0 \le x \le d, y = h, z) = 0 \tag{4a}$$

$$E_y(x = 0, 0 \le y \le h, y = 0, z) = 0 \tag{4b}$$

and those for the region 2 are given by

$$E_x(d \le x \le a/2, y = 0, z) = E_x(d \le x \le a/2, y = b, z) = 0 \tag{5a}$$

$$E_y(x = a/2, 0 \le y \le h, z) = 0 \tag{5b}$$

The solution of the Equations (3a) or (3b) is obtained by the methods of separation of variables.

The derived electric and magnetic field components for the region 1 are as ($k_{y1} = 2m\pi/2h, m = 0, 1, 2, \ldots\ldots\ldots$),

$$E_x = \frac{k_{y1}}{\varepsilon_0\varepsilon_r}A_1\cos(k_{x1}x)\sin(k_{y1}y)e^{-jk_z z} \tag{6a}$$

$$E_y = \frac{-k_{x1}}{\varepsilon_0\varepsilon_r}A_1\sin(k_{x1}x)\cos(k_{y1}y)e^{-jk_z z} \tag{6b}$$

$$H_x = \frac{k_{x1}k_z}{\omega\mu_0\varepsilon_0\varepsilon_r}A_1\sin(k_{x1}x)\cos(k_{y1}y)e^{-jk_z z} \tag{6c}$$

$$H_y = \frac{k_{y1}k_z}{\omega\mu_0\varepsilon_0\varepsilon_r}A_1\cos(k_{x1}x)\sin(k_{y1}y)e^{-jk_z z} \tag{6d}$$

$$H_z = -j\frac{k_0^2 - k_z^2}{\omega\mu_0\varepsilon_0\varepsilon_r}A_1\cos(k_{x1}x)\cos(k_{y1}y)e^{-jk_zz} \quad (6e)$$

The derived electric and magnetic fields components for the region 2 are as ($k_{y2} = n\pi/2h, m = 0, 1, 2, \ldots\ldots\ldots$),

$$E_x = \frac{k_{y2}}{\varepsilon_0\varepsilon_r}A_2\cos\left[k_{x2}\left(\frac{a}{2} - x\right)\right]\sin(k_{y2}y)e^{-jk_zz} \quad (7a)$$

$$E_y = \frac{k_{y2}}{\varepsilon_0\varepsilon_r}A_2 sin\left[k_{x2}\left(\frac{a}{2} - x\right)\right]\cos(k_{y2}y)e^{-jk_zz} \quad (7b)$$

$$H_x = \frac{-k_{x2}k_z}{\omega\mu_0\varepsilon_0\varepsilon_r}A_2 sin\left[k_{x2}\left(\frac{a}{2} - x\right)\right]\cos(k_{y2}y)e^{-jk_zz} \quad (7c)$$

$$H_y = \frac{k_{y2}k_z}{\omega\mu_0\varepsilon_0\varepsilon_r}A_2\cos\left[k_{x2}\left(\frac{a}{2} - x\right)\right]\sin(k_{y2}y)e^{-jk_zz} \quad (7d)$$

$$H_z = -j\frac{k_0^2 - k_z^2}{\omega\mu_0\varepsilon_0\varepsilon_r}A_2\cos\left[k_{x2}\left(\frac{a}{2} - x\right)\right]\cos(k_{y2}y)e^{-jk_zz} \quad (7e)$$

The subscripts 1 and 2 define region 1 and region 2, respectively, while the wave numbers along the X and Y axis are denoted by the letters $k_x$andk_y respectively and k_z represent the wave number in the z direction as well as the propagation constant. A is an arbitrary constant of amplitude.k_0 is a free space wave number, and k is a SIFW wave number.

$$k^2 = k_{x1}^2 + \left(\frac{2m\pi}{2h}\right)^2 + k_z^2 = k_{x2}^2 + \left(\frac{n\pi}{2h}\right)^2 + k_z^2 = \omega^2\mu_0\varepsilon_0\varepsilon_r \quad (8)$$

Since the fields components E_y and H_z are continuous at $x = d$, the characteristics equation for the TE mode is derived as

$$-k_{x1}\tan(k_{x1}d) = k_{x2}\tan\left[k_{x2}\left(\frac{a}{2} - d\right)\right] \quad (9)$$

As the gap width $a/2 - d = g$, so the Equation (9) becomes

$$-k_{x1}\tan(k_{x1}d) = k_{x2}\tan(k_{x2}g) \quad (10)$$

where k_{x1} is obtained from Equations (8)–(10). The propagation constant k_z and the cut-off frequency are given by

$$k_z = \sqrt{k^2 - k_{x1}^2 - \left(\frac{2m\pi}{2h}\right)^2}, (m = 0, 1, 2, \ldots) \quad (11)$$

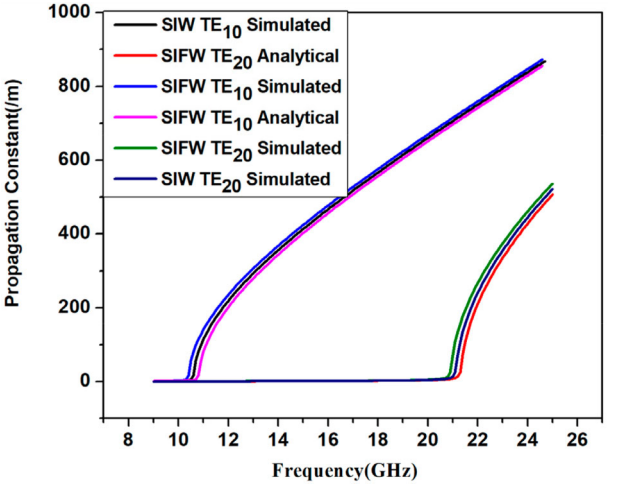

Figure 2: Dispersion characteristics of SIW and SIFW

$$f_c = \frac{c}{2\pi\sqrt{\varepsilon_r}}\sqrt{k_{x1}^2 + \left(\frac{2m\pi}{2h}\right)^2}, (m = 0, 1, 2, \ldots) \quad (12)$$

where c is the velocity of light. To validate our analytical expressions, the simulation results are compared with the analytical results of the TE_{10} and TE_{20} modes obtained from (1) to (12). The dimensions of the SIFW are $a/2 = 4$ mm,$d = 3.4$ mm and $g = 0.6$ mm. As shown in Figure 2, the simulated dispersion curves of SIW are compared with the simulated and analytical dispersion curves of SIFW.

The result shows that the cut-off frequencies and dispersion characteristics are almost the same for the modes TE_{10} and TE_{20} in both SIW and SIFW. So, at a gap width g of 0.6 mm, the propagation constants are almost equal to each other. In addition, the dispersion curves are also calculated and simulated for two different gap widths $g = 0.7$ mm and $g = 0.5$ mm. The gap width is different in these two cases, but all the other parameters are the same as in Figure 1. The results are shown in Figures 3 and 4.

Good agreement can also be observed in these two Figures 3 and 4, again representing the validity of our analysis. Table 1 shows the simulated and analytical cut-off frequencies of the TE_{10} and TE_{20} modes in SIFW. The cut-off frequencies are shown at different gap widths.

Where f_c_sim is the simulation frequency; f_c_anal is the analytical frequency and $\triangle f_c$ is the difference between the simulation and analytical frequency. The port field distribution of the TE_{10} and TE_{20} is shown in Figure 5. The field intensity is maximum in the region 2 and 3.

3. SIFW FILTER DESIGN

Figure 6 shows an isometric view of the proposed SIFW filter. Figure 7 shows the top view of a partial H-plane metal vane.

The SIFW band pass filter is a direct coupled resonator filter with a partial H plane metal vane as its basic component. The proposed SIFW filters are made up of alternating resonators and evanescent waveguide regions. The evanescent regions are constructed by inserting H plane slots into a partial H plane metal vane, and they can be represented by an admittance inverter (J inverter) circuit, as shown in Figure 8.

The jB_a and jB_b are the evanescent region reactive components and are a function of the evanescent regions length ϕ. The electrical length ϕ and normalized inverter values J are given by [29].

$$\phi = -\pi - \tan^{-1}\left(\frac{2B_b}{Y_g} + \frac{B_a}{Y_g}\right) - \tan^{-1}\frac{B_a}{Y_g} \tag{13}$$

$$J = Y_g \left| tan\left(-\frac{1}{2}\tan^{-1}\left(\frac{2B_b}{Y_g} + \frac{B_a}{Y_g}\right) + \frac{1}{2}\tan^{-1}\frac{B_a}{Y_g}\right)\right| \tag{14}$$

where Y_g, represents the wave admittance of a partial H plane SIFW filter. The normalized values of each evanescent region are obtained by (15)

$$\frac{J_{01}}{Y_g} = \sqrt{\frac{\pi\,\omega_\lambda}{2g_0g_1\omega_1}} \tag{15a}$$

$$\frac{J_{i,i+1}}{Y_g} = \frac{\pi\,\omega_\lambda}{2\omega_i}\frac{1}{\sqrt{g_i,g_{i+1}}} \tag{15b}$$

$$\frac{J_{n,n+1}}{Y_g} = \sqrt{\frac{\pi\,\omega_\lambda}{2g_n,g_{n+1}\omega_1}} \tag{15c}$$

where $g_0, g_1, g_2, \ldots\ldots g_{n+1}$ are the equal ripple low pass prototype element values, $\omega_1$is the normalized cut off frequency, $\lambda_{g0}, \lambda_{g1}, \lambda_{g2}$ is the guided wavelengths at the center frequency, lower and upper pass band edge frequencies, respectively, ω_λ is the relative band width at guided wavelength λ and n is the order of the filter. The proposed filter has specifications of 26 GHz center frequency, 0.01 dB pass band ripple, and fractional bandwidth of 4%. Simulation based SIFW design is divided into four steps. Initially, a unit cell simulation model with an evanescent region in the center and two propagating regions on both sides is investigated. In the unit cell, the dominant mode TE_{10} is considered to be propagated. For the 26 GHz center frequency, the S – parameters of the unit cell with varying widths (W_i) and depths (S_i) are produced. Second, the derived S-parameters are translated into an $ABCD$ matrix using (16). The S – parameters of the unit cell with varied widths (W_i) and depths (S_i) are calculated for the 26 GHz center frequency. Second,

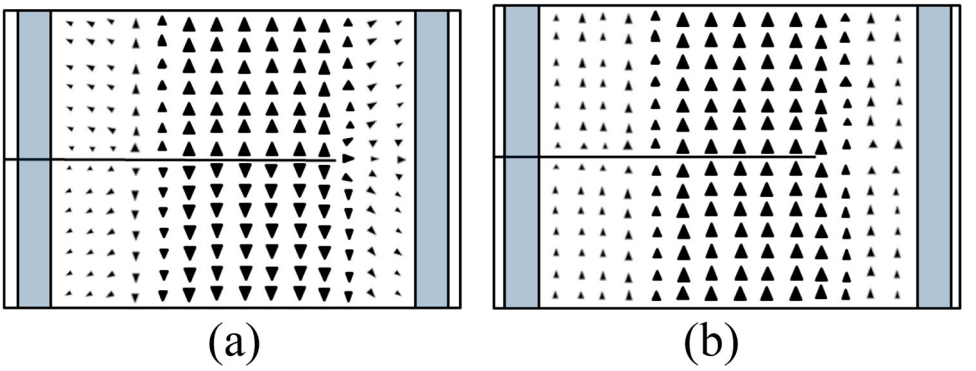

Figure 5: Electric field distribution of (a) TE_{10} and (b) TE_{20}mode

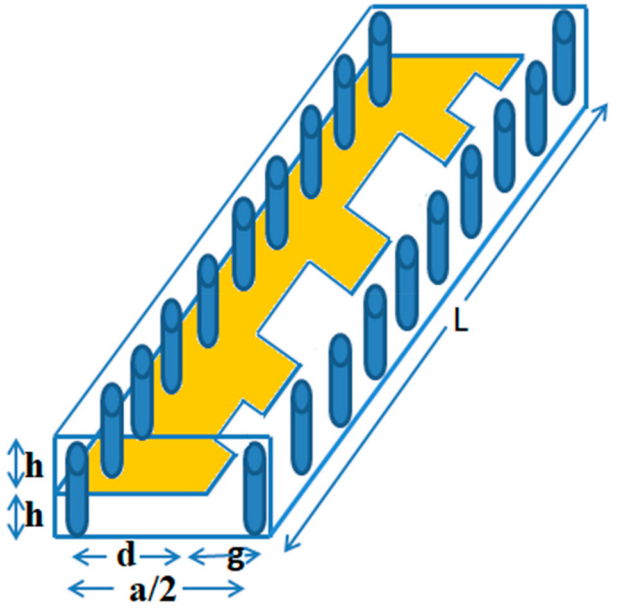

Figure 6: Isometric view proposed SIFW filter ($g = 0.6$ mm)

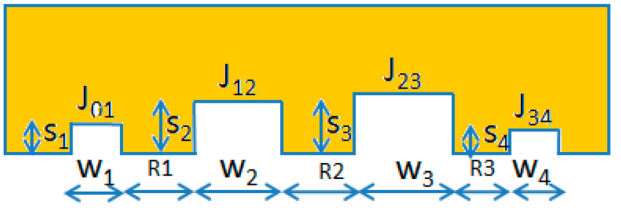

Figure 7: Top view of H plane metal vane ($S_1 = 0.4$, $S_2 = 0.8$, $S_3 = 1$, $S_4 = 0.3$, $W_1 = 2.09$, $W_2 = 3$, $W_3 = 3.74$, $W_4 = 1.8$, $R1 = 2.9$ and $R2 = 3.5$, and $R3 = 1.8$) all are in mm

the derived S parameters are used to produce an ABCD matrix (16).

$$[Overall] = \begin{bmatrix} A & B \\ C & D \end{bmatrix} \tag{16a}$$

$$A = D = \frac{1 - S_{11}^2 + S_{21}^2}{2S_{21}} \tag{16b}$$

$$B = Z_g \frac{(1 + S_{11})^2 - S_{21}^2}{2S_{21}} \tag{16c}$$

$$C = Y_g \frac{(1 - S_{11})^2 - S_{21}^2}{2S_{21}} \tag{16d}$$

where $[Overall]$ is $ABCD$ matrix of the overall unit cell and$Z_{g=}1/Y_g$. Since the unit cell is symmetric structure so it must follows $S_{11} = S_{22}, S_{12} = S_{21}$ and $A = D$. Thirdly, the evanescent region is obtained by (17).

$$[PROP][EVAN][PROP] = [Overall] \tag{17a}$$

$$[EVAN] = [PROP]^{-1}[Overall][PROP]^{-1} \tag{17b}$$

$$[EVAN] = \begin{bmatrix} A_E & B_E \\ C_E & D_E \end{bmatrix} \tag{17c}$$

where $[PROP]$, $[EVAN]$ are the propagation and evanescent region, matrixes respectively, and $[PROP]^{-1}$ is the inverse matrix of $[PROP]$. The evanescent region values can be found using (18).

$$jB_a = \frac{A_E - 1}{B_E}, jB_b = \frac{1}{B_E} \tag{18}$$

The length of the resonators are given by (19)

$$R_n = \frac{1}{K_z}\left[\pi + \frac{1}{2}(\phi_i + \phi_{i+1})\right] \tag{19}$$

where K_z is the propagation constant and is defined in (11). The slot depths S_i are also considered based on the weight binomial and the Chebyshev's coefficient of the four slots. The dimensions of the slots in the H plane metal vane are shown in Table 2.

The frequency characteristics of the proposed SIFW filters are shown in Figure 9.

For the measurement of the SIFW filter, a tapered transition and a feeding line are designed into the prototype.

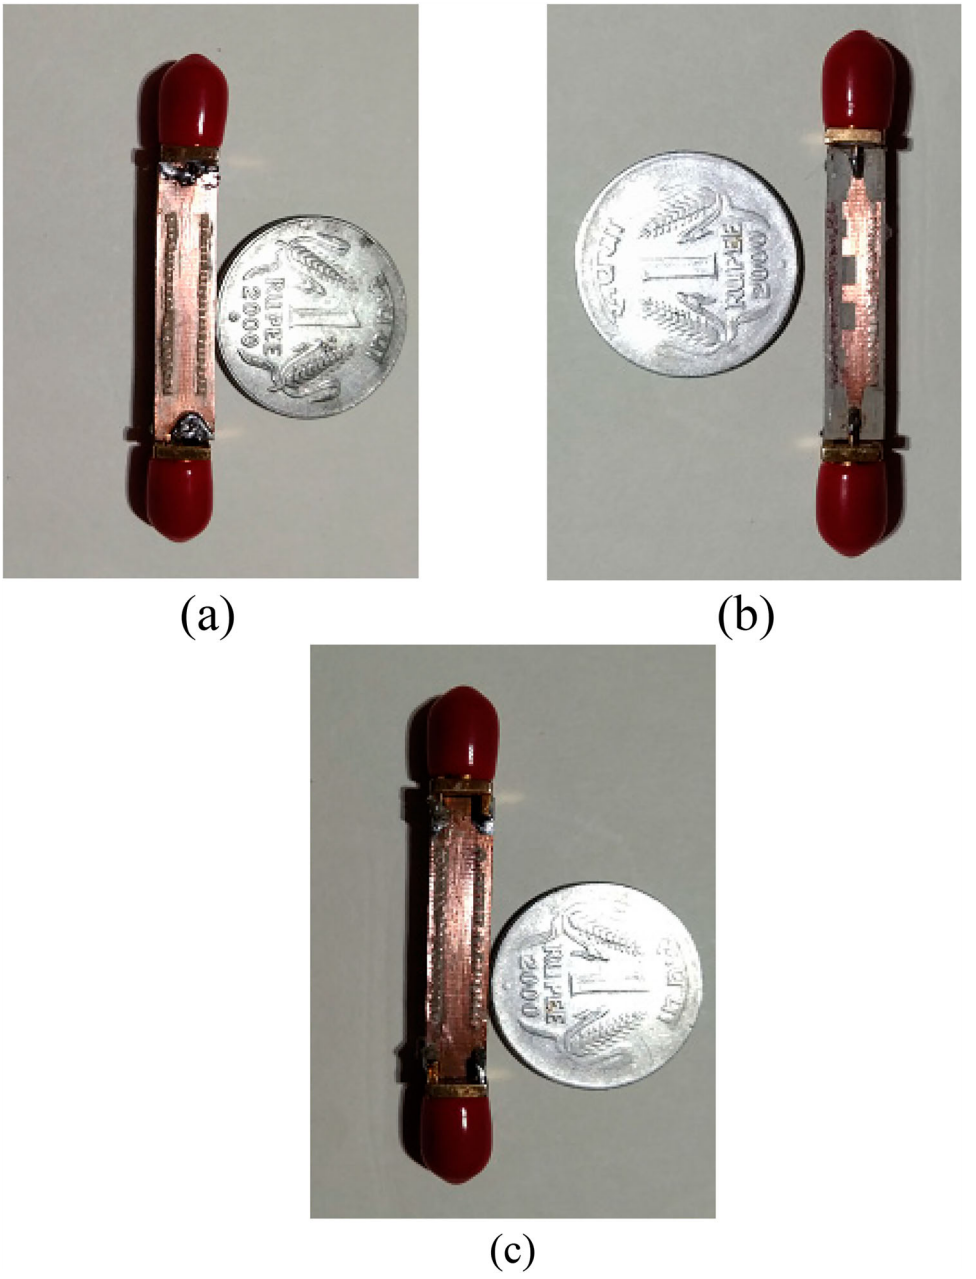

Figure 10: Designed prototype (a) Top (b) Middle (c) Bottom

A variety of transitions have been reported [31,32]. The designed prototype is shown in Figure 10.

The measurement of the designed SIFW filter is performed using an Agilent PNA-X N5247A microwave network analyzer. Calibration planes are established at the connectors where the designed prototypes are connected to the network analyzer. In our measurement setup, de-embedding was employed to isolate the parasitic effects introduced by the connectors and cabling from the actual filter characteristics. The comparison of analytical, simulated, and measured curves is depicted in Figure 9. The simulated and measured curves closely align, with any minor discrepancies attributed to fabrication errors.

The SIFW filter at 26 GHz has a 3-dB fractional bandwidth of 4% with a low insertion loss of 0.6 dB in the passband, indicating efficient signal transmission and minimal signal degradation. Insertion loss, a measure of signal attenuation through the filter, is crucial in ensuring effective signal transmission. When modifying the design to 26.5 GHz and widening the bandwidth to 7.5% using a binomial fourth-order coefficient, there's a slight increase in insertion loss to 0.8 dB, implying a bit more signal

Table 3: Performance comparison of the designed SIFW filter with various reported band pass filters

Ref. No.	Filter Type	CF(GHz)	3-dB FBW[%]	Min. RL[dB]	Min. IL[dB]	Size $\lambda_g X \lambda_g X \lambda_g$

loss in the passband. Alternatively, a Chebyshev fourth-order coefficient achieves a 7% bandwidth with a minimal insertion loss of 1.2 dB at a center frequency within the 26 GHz range. The slight increase in insertion loss with this configuration is balanced with achieving the desired center frequency and bandwidth characteristics, showcasing the trade-offs involved in filter design. The roll-off is the highest in the analytical filter and the lowest in the binomial. Table 3 describes the comparison of the proposed SIFW filter and some of the cited filters.

4. CONCLUSIONS

A partial H-plane SIFW and SIFW band pass filter have been designed in this article. The field components and cut-off frequencies have been derived and investigated. The accuracy achieved in the cut off frequency of SIW and SIFW is very high. SIFW band pass filters have been designed by making slots in the partial *H* plane metal vane. The filter has the advantages of compact size and small insertion loss. The filter has an application as a 5G, 26 GHz wireless broad band service in the K band.

Abstract

In order to ensure optimal performance of permanent magnet synchronous motors (PMSMs) across many technical applications, it is imperative to minimize torque fluctuations and reduce total harmonic distortion (THD) in stator currents. Hence, this study proposes the utilization of an adaptive flux estimator (AFE) in conjunction with an Intelligent Hybrid Controller (IHC) to mitigate the ripples and total harmonic distortion (THD). The IHC system is constructed by integrating PI and fuzzy logic controllers (FLC) in a cascade configuration, alongside a new switching unit that facilitates automatic switching between the two controllers during various operations of the PMSM. AFE estimates accurate flux which is required to achieve ripple free high dynamic performance of the PMSM drive by using a limiter to fix the flux at reference flux value of the drive. The proposed controller with AFE has achieved its originality through the refinement of membership functions located at the center of the universe of discourse (UOD) and the enhancement of the switching function. These improvements have resulted in increased sensitivity in the proximity to the reference speed. The Fuzzy Logic Controller (FLC) demonstrates superior performance when operating in a transient state, whereas the Proportional-Integral (PI) controller of the proposed system exhibits satisfactory performance under steady-state situations. The efficacy of AFE with IHC is substantiated by the simulation and experimental analysis reported in this study. A significant reduction in both total harmonics distortion (THD) and torque ripples are found.

Introduction

Alternating current (AC) motor drive systems now can use advanced control techniques due to the development of the latest technologies in power semiconductors and microprocessors.

Competing interests: The authors have declared that no competing interests exist.

In many industrial applications, it is a necessary requirement that the drive system should be more effective and precise in controlling the speed and torque over a wide range of operating speed. PMSMs are frequently employed in elevators, air compressors, and new energy vehicles due to their benefits of high efficiency, high power density, and low maintenance [1–4].

High switching frequency enhances the output current waveform's quality, but it also dramatically increases power loss and decreases system efficiency. While low switching frequency minimizes power loss and advances system effectiveness it also generates torque and current

ripple. Therefore, it is vital to strike a balance between control performance and effective operation.

Numerous traditional and reliable control methodologies have been documented in the literature for PMSMs. The motor performance is influenced by external disturbances and nonlinear changes in motor characteristics. Current vector control is the most often used control strategy for PMSM drive systems. Predictive control [5–7], sliding mode control [8,9], Adaptive control [10] etc. are used to remove the causes that affect nonlinearity of system. The two most popular methods for regulating the position and speed of PMSM drives are direct torque control (DTC) and field-oriented control (FOC) [11]. Although DTC-based drives produce high torque and flux ripples, they have a greater dynamic response. In FOC-based drives the current, speed, and position loops are independently controlled by controllers, and they offer better steady state performance. In the early days PI controllers were used to control current, speed and position in FOC-based PMSM drive but it degrades drive performance due

to complexity in tuning the controller parameters (Kp and Ki) in PI controller. FLC has the capability to remove this constraint of PI controllers [12]. There is no mathematical modelling required in designing FLC because it performs on the basis of user defined linguistic rules [13,14]. FLC is more complicated, computationally expensive, and memory intensive than PI controller. While PI controller offers better performance in steady state condition, FLC works greatly in transient condition of the drive [15–19]. So, an IHC can be constructed which

adopts the qualities of PI and FLC for improved dynamic behavior of drive. Torque ripples initiated in motor by cogging torque, armature current harmonics, the magnetic field, and so on. It affects the operational life of motor. Torque ripples can be reduced by improving motor design or employing appropriate motor control technologies. Improving the distribution of winding to increase the spatial magnetic field is a typical strategy used in motor design. The use of skewed slot and fractional slot approaches in the design of stators has proven to be effective in reducing cogging torque [20]. Control algorithms optimize the excitation current of the motor, resulting in lessened torque ripples and a smooth torque output. [21–23].

Main contribution of this paper is given as follows:

- In this paper, an AFC with IHC is realized with main objective of reducing the torque ripples of the PMSM.
- The proposed method includes cascading fuzzy logic and PI controllers, as well as a switching unit that can switch FLC in the case of transient operations and the cascaded PI controller in the case of steady state operations.
- The variation in I/O and O/P variables generate the membership functions (MFs) for FLC. The FLC's design was made novel by tuning the MFs precisely at the center to offer improved sensitivity in the vicinity of rated speed while optimizing the universe of discourse. The drive's performance can also be improved by fine-tuning the MFs to account for deviations in i/o and o/p variables. Investigation and comparison of the dynamic performance of the PI controller and the PMSM drive employing the IHC are conducted.

https://doi.org/10.1371/journal.pone.0312946.g008

This paper is arranged into five sections comprising Introduction, Principle, and modelling of PMSM through Torque Estimation, Proposed Control Scheme of PMSM Drive, simulation and experimental results followed by Conclusion.

Principle and modelling of PMSM

To provide decoupled control of stator current and rotor flux, the modelling of PMSM is derived in the α-β [24] as below.

1. Voltage and current equation of PMSM

The voltage ($v_{s\alpha}$, $v_{s\beta}$) equations in the α-β axes are represented below:

$$v_{s\alpha} = R_s i_{s\alpha} + \frac{d\psi_{s\alpha}}{dt} \tag{1}$$

$$v_{s\beta} = R_s i_{s\beta} + \frac{d\psi_{s\beta}}{dt} \tag{2}$$

Where $\mathbf{R_s}$ is the stator resistance, $\mathbf{i_{s\alpha}}$ and $\mathbf{i_{s\beta}}$ are the per phase stator currents in the α-β axes and $\psi_{s\alpha}$, $\psi_{s\beta}$ are the stator flux in the α-β axes, which is represented as

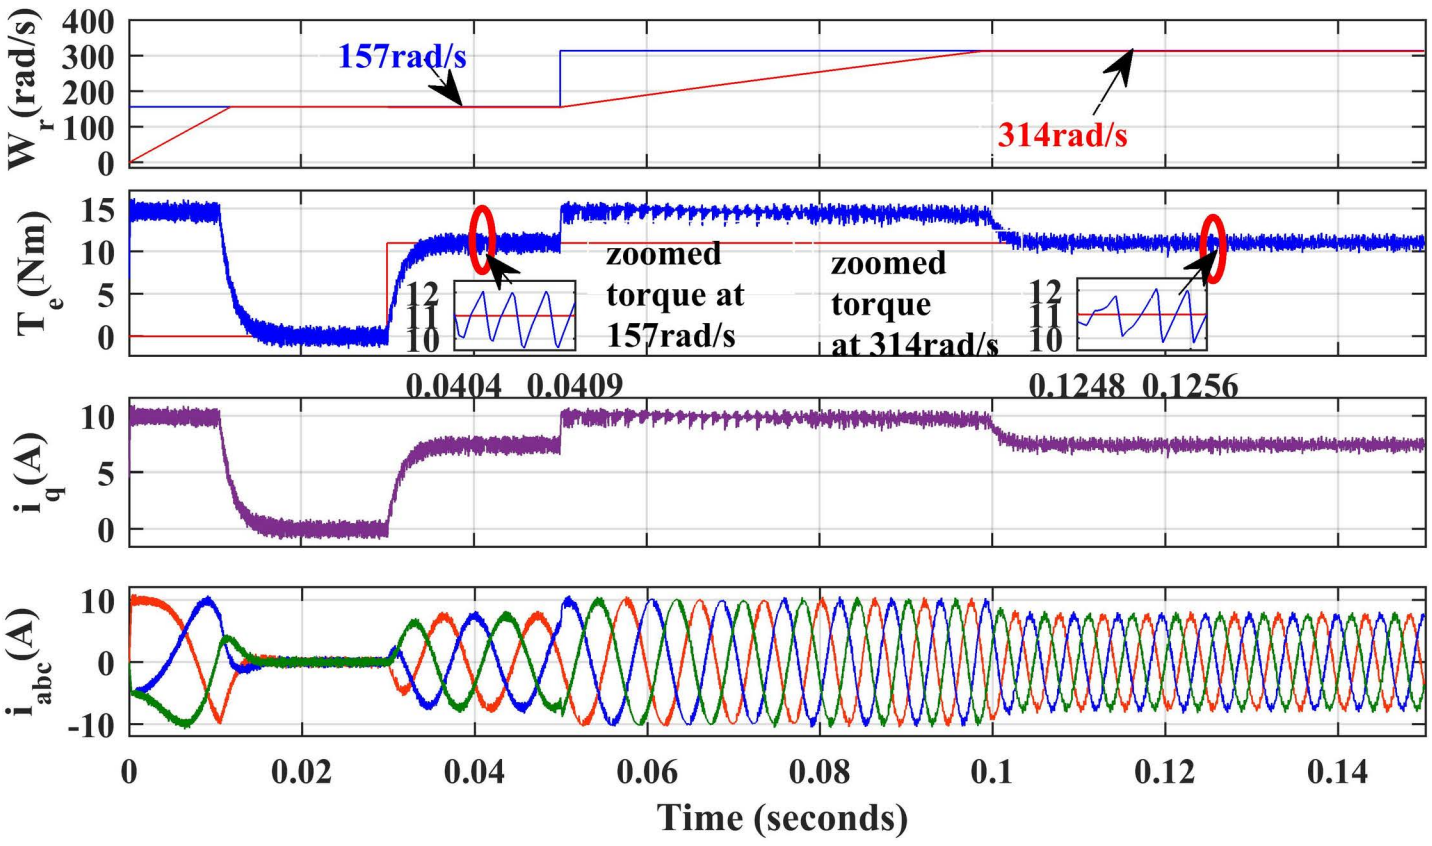

Fig 9. Simulation waveforms of W_r , T_e , i_q and i_{abc} of PMSM Drive at variable speed using PI.

https://doi.org/10.1371/journal.pone.0312946.g009

$$\psi_{s\alpha} = \int \left(v_{s\alpha} - i_{s\alpha} R_s\right) dt = \int e_{s\alpha} dt \tag{3}$$

$$\psi_{s\beta} = \int \left(v_{s\beta} - i_{s\beta} R_s\right) dt = \int e_{s\beta} dt \tag{4}$$

Where $e_{s\alpha} = \left(v_{s\alpha} - i_{s\alpha} R_s\right)$ and $e_{s\beta} = \left(v_{s\beta} - i_{s\beta} R_s\right)$

The voltage at DC link, V_{dc} and the condition of the switches of inverter may be used to depict the stator voltages in the α-β axis as:

$$v_{s\alpha} = \frac{V_{dc}}{3}\left(2S_1 - S_3 - S_5\right) \tag{5}$$

$$v_{s\beta} = \frac{V_{dc}}{3}\left[\sqrt{3}\ \left(S_3 - S_5\right)\right] \tag{6}$$

where $\mathbf{S_1}$, $\mathbf{S_3}$ and $\mathbf{S_5}$ denote the locations of the switches on a voltage source inverter (VSI), with a value of 1 for an off state and a value of 0 for a on state. The stator currents are also described as:

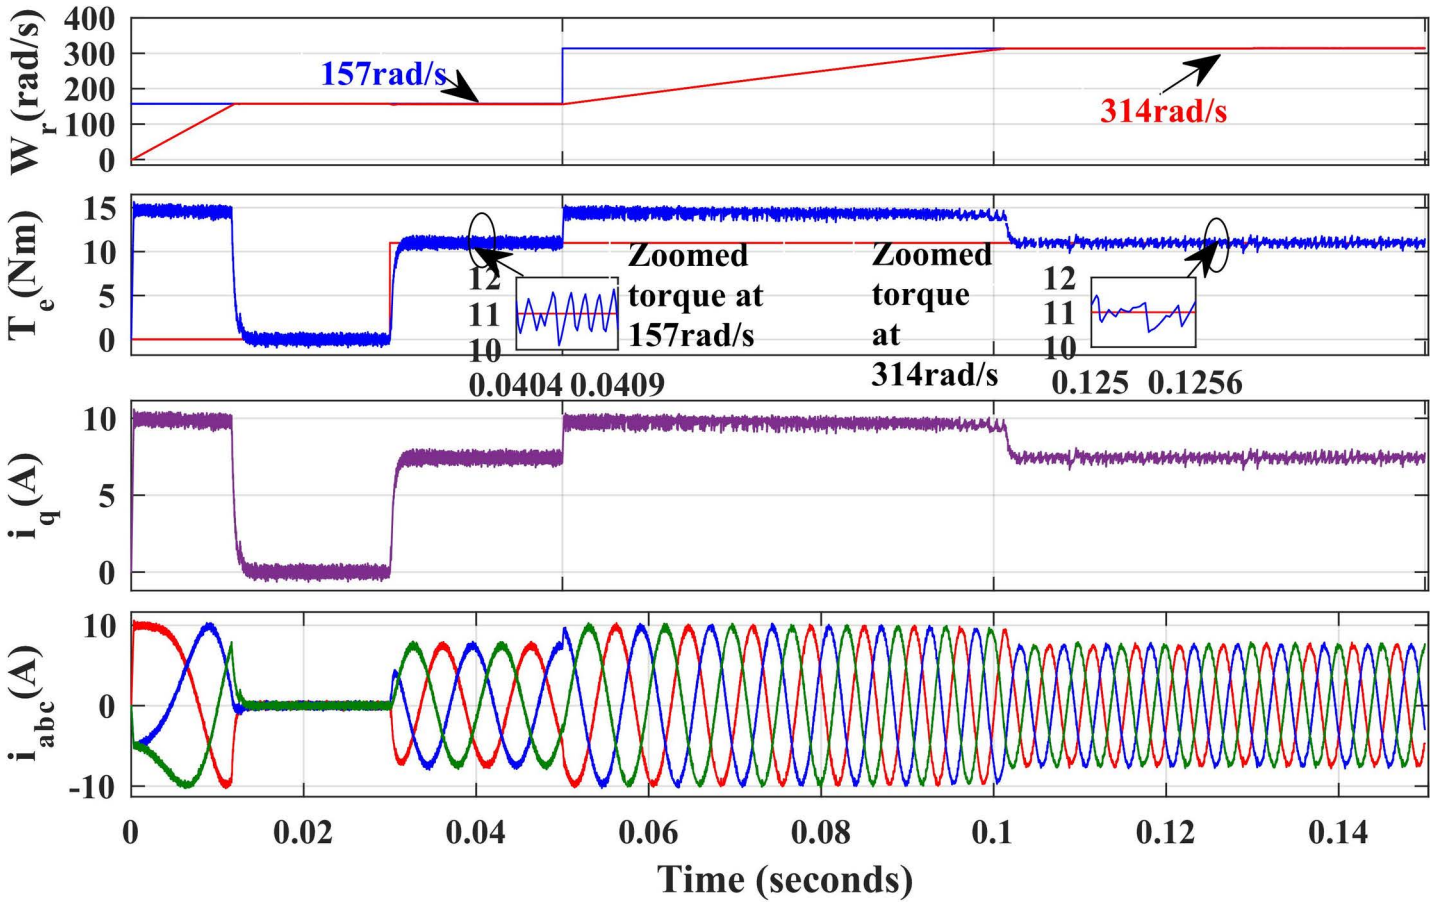

Fig 10. Simulation waveforms of W_r, T_e, i_q and i_{abc} of PMSM Drive at variable speed using IHC.

https://doi.org/10.1371/journal.pone.0312946.g010

$$i_{s\alpha} = i_a \tag{7}$$

$$i_{s\beta} = \frac{1}{\sqrt{3}}\left(i_b - i_c\right) \tag{8}$$

2. Adaptive flux estimator

Accurate flux estimation is required to achieve ripple free high dynamic performance of the PMSM drive with different control strategies such as FOC and DTC. Since the inverter is non-linear, the pure integrator used with the voltage model of the PMSM flux calculation introduces drift signal, sensors problem and many other electronics measuring instruments used while running the machine. Therefore, to overcome this problem a flux estimation technique was proposed in [25,26] for PMSM drives, but it has some limitations with it. In this method [27,28] a limiter was used to fix the flux at reference flux value of AC drive. Therefore, to achieve the variable flux levels an adaptive flux estimator is implemented in this paper as shown in Fig 1.

In this indefinite integral is substituted by a low pass filter added with the compensating feedback signal. Mathematically it can be stated as:

$$\tilde{\psi}_s = e_s \ \frac{1}{s+\omega_c} + Z_{comp} \ \frac{\omega_c}{s+\omega_c} = \tilde{\psi}_s = \psi_s^{\,1} + \psi_s^{\,2} \tag{9}$$

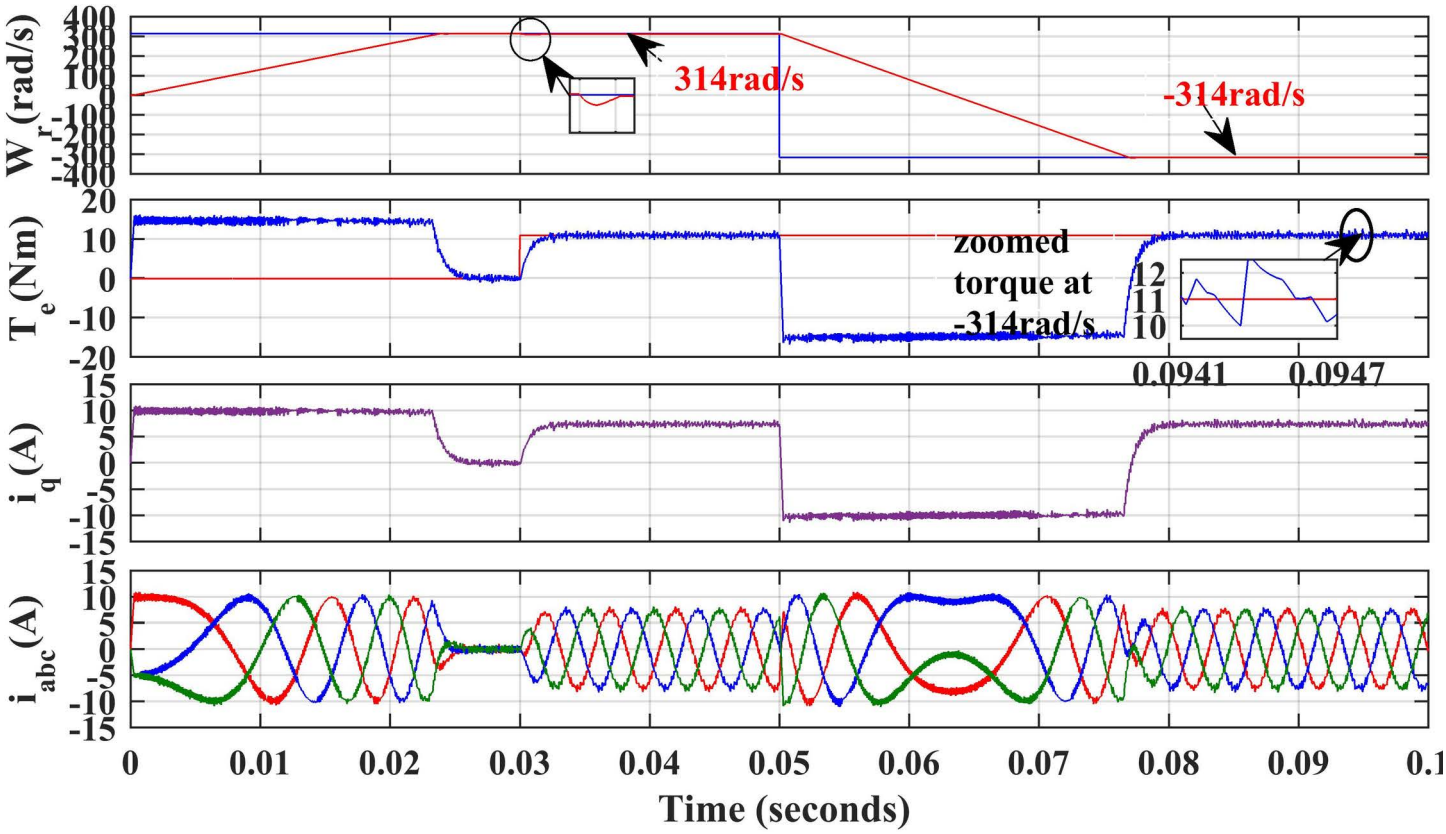

Fig 11. Simulation waveforms of W_r, T_e, i_q and i_{abc} of PMSM Drive in reverse rotation of speed using PI.

https://doi.org/10.1371/journal.pone.0312946.g011

Where, $\psi_s^1 = e_s \frac{1}{s+\omega_c}$ and $\psi_s^2 = Z_{comp} \frac{\omega_c}{s+\omega_c}$

First part of eqn. (9) is the integrator with back emf, and second part is compensating feedback flux signal to balance the output flux signal. In implemented adaptive flux estimator, motor flux and emf are in phase quadrature of each other. The two components $\Psi_{s\alpha}$ and $\Psi_{s\beta}$ of total flux Ψ_s comprised with two further components, i.e., feedback and feedforward as shown in Fig 1. Further any variations in these components lead to the phase angle deviations from 90 degrees between the flux and the emf. This deviation leads to the error which is given by the following equations:

$$|emf|.\ \cos\phi = \frac{\tilde{\psi}_{s\alpha} e_{s\alpha} + \tilde{\psi}_{s\beta} e_{s\beta}}{\left|\tilde{\psi}_s\right|} \tag{10}$$

Therefore, to eliminate this error, a detector is implemented with PI which is given by the following equation:

$$Z_{comp} = \left(k_p + \frac{k_i}{s}\right).\frac{\tilde{\psi}_{s\alpha} e_{s\alpha} + \tilde{\psi}_{s\beta} e_{s\beta}}{\left|\tilde{\psi}_s\right|} \tag{11}$$

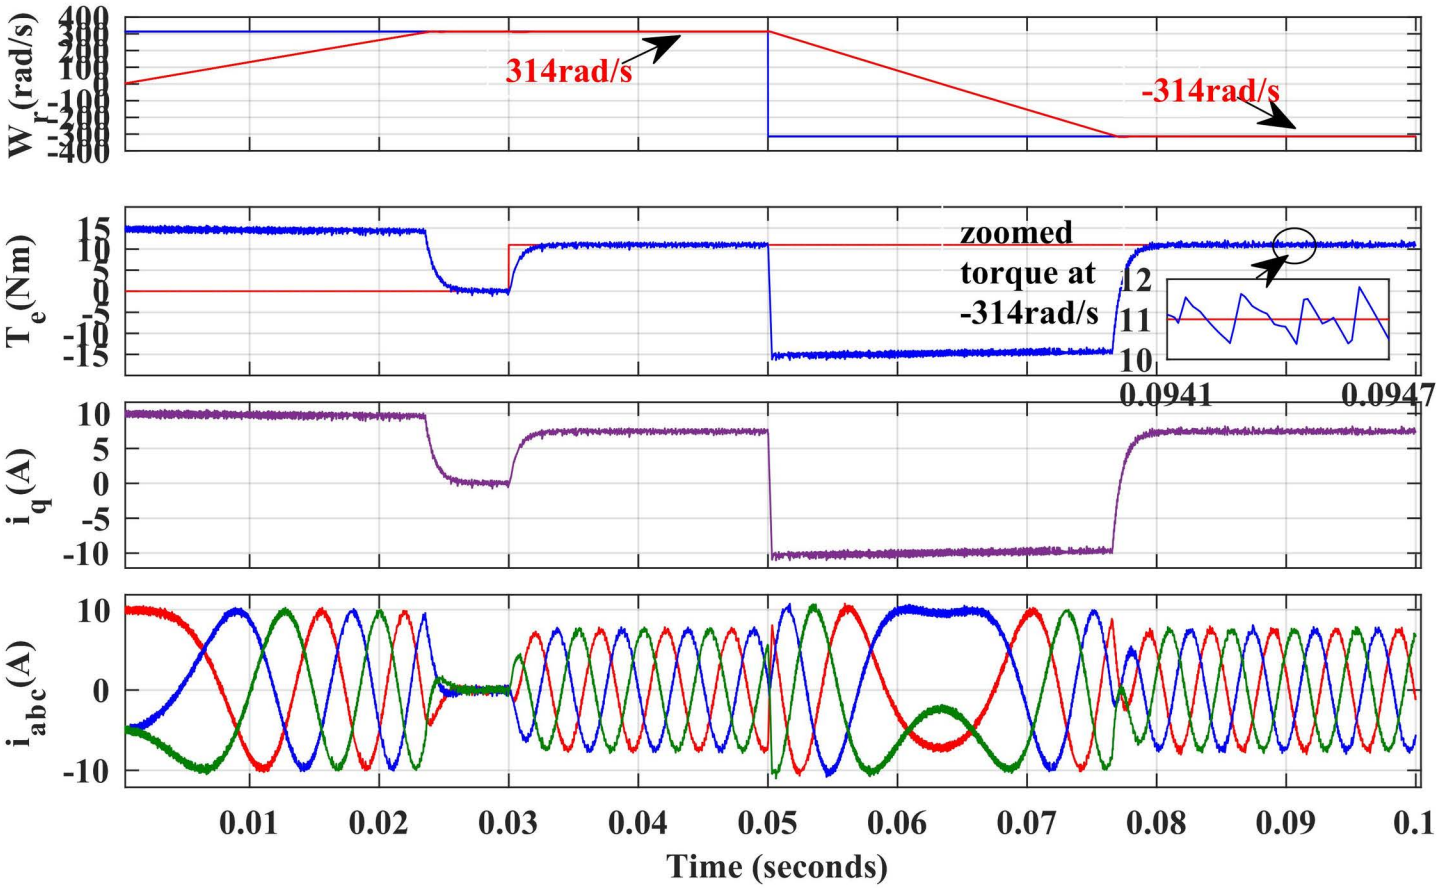

Fig 12. Simulation waveforms of W_r, T_e, i_q and i_{abc} of PMSM Drive at reverse rotation speed using IHC.

https://doi.org/10.1371/journal.pone.0312946.g012

Implementation of these methods for the operation of PMSM resulting into the lower speed, flux, and torque ripple. If the angle between the estimated flux and the and the emf is 90 degrees, then the output of the PI controller is zero.

3. Adaptive torque estimation

The estimated Torque, T_{est} is represented as given below:

$$T_{est} = \left(\frac{3}{2}\right)\left(\frac{P}{2}\right)\left(\tilde{\psi}_{s\alpha} i_{s\beta} - \tilde{\psi}_{s\beta} i_{s\alpha}\right) \tag{12}$$

'P' stands for the number of poles. Equations 1 to 12 are used to describe the torque estimator suggested here; it is seen in Fig 2.

4. PI speed and current controller

The $e_0(k)$ is output of PI controller and it is expressed as:

$$e_0(k) = K_p e(k) + K_i \int_0^k e(k) dt \tag{13}$$

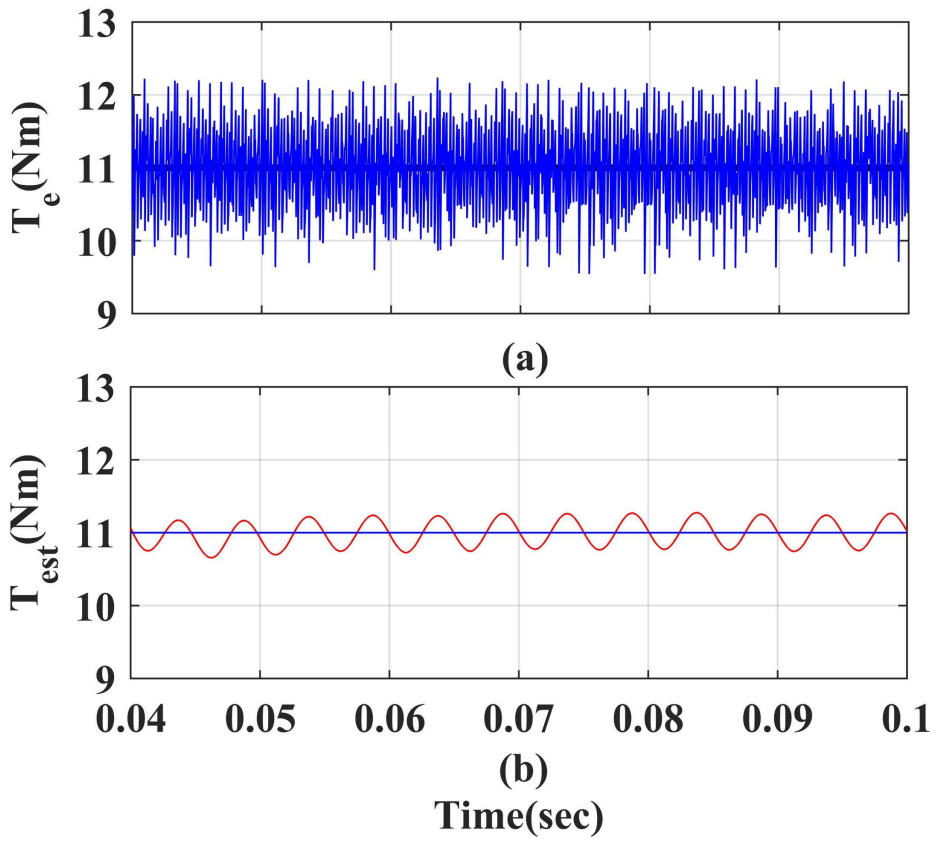

Fig 13. Measured and estimated values for the torque of the PMSM using the PI.

https://doi.org/10.1371/journal.pone.0312946.g013

Here, K_p and K_i are gains of PI, while e(k) is the error signal. By employing a PI controller, the expressions for the speed error $\omega_{r_{err}}$ that creates reference torque at the Kth instance, $T_e^*(K)$ are given.

$$\omega_{r_{err}} = \omega_r^* - \omega_r \tag{14}$$

$$T_e^*(K) = \left(K_{p\omega s} + \frac{K_{i\omega s}}{S}\right)\omega_{r_{err}}(K) \tag{15}$$

$$T_e^*(K) = \left(K_{p\omega s} + \frac{K_{i\omega s}}{S}\right)\omega_{r_{err}}(K) \tag{16}$$

Where ω_r^*, ω_r and $\omega_{r_{err}}(K)$ are the reference speed, actual speed and speed error at Kth instance respectively; $K_{p\omega s}$ and $K_{i\omega s}$ are gains of PI. The q-axis stator current, $i_q^*(K)$ is produced by the PI controller utilizing the error in torque, $T_{e_{err}}$ between the command torque, T_e^* and estimated torque, T_{est}.

$$T_{e_{err}} = T_e^* - T_{est} \tag{17}$$

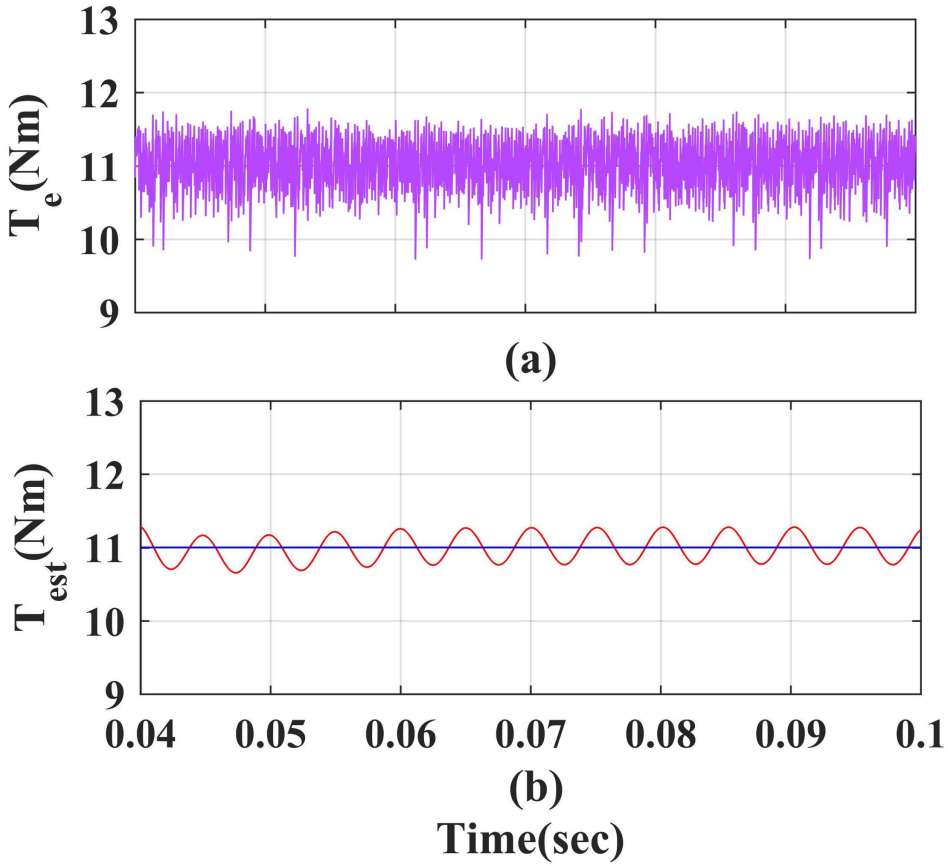

Fig 14. Measured and estimated values for the torque of the PMSM using the IHC.

https://doi.org/10.1371/journal.pone.0312946.g014

$$i_q^*(K) = \left(K_{pqs} + \frac{K_{iqs}}{S} \right) T_{e_{err}}(K) \tag{18}$$

Where K_{pqs} and K_{iqs} are defined as tuning parameter of PI controller respectively and $T_{e_{err}}(K)$ is the torque error at the Kth instance.

5. Design of intelligent hybrid controller

Soft computing approaches can be used to overcome the performance limits of traditional methods used to control the speed of PMSM drive, that rely on exact models [29,30]. The PMSM drive may experience difficulties with PI controller only to obtain the anticipated dynamic performance and when FLC is employed only then it may not be eliminating steady-state errors due to the absence of integrator. Therefore, a dual approach controller is designed which may overcome the demerits of both PI and FLC controllers. The proposed IHC compares the speed deviation with a certain fixed value. If the deviation is larger than the set value, the FLC works, and the PI controller functions as the set value is greater than the deviation. Fig 3. illustrates the controller proposed in this paper.

The IHC combines the FLC and PI controller through enhanced switching capability to utilize the PI controller during the PMSM drive's steady state and the FLC during the transient phase. It will depend on oscillations observed in the system that how will switch operate. Below is a description of the FLC algorithm created for PMSM drive speed control.

1. Determine I/O parameters.
2. Select MFs and state control rules.

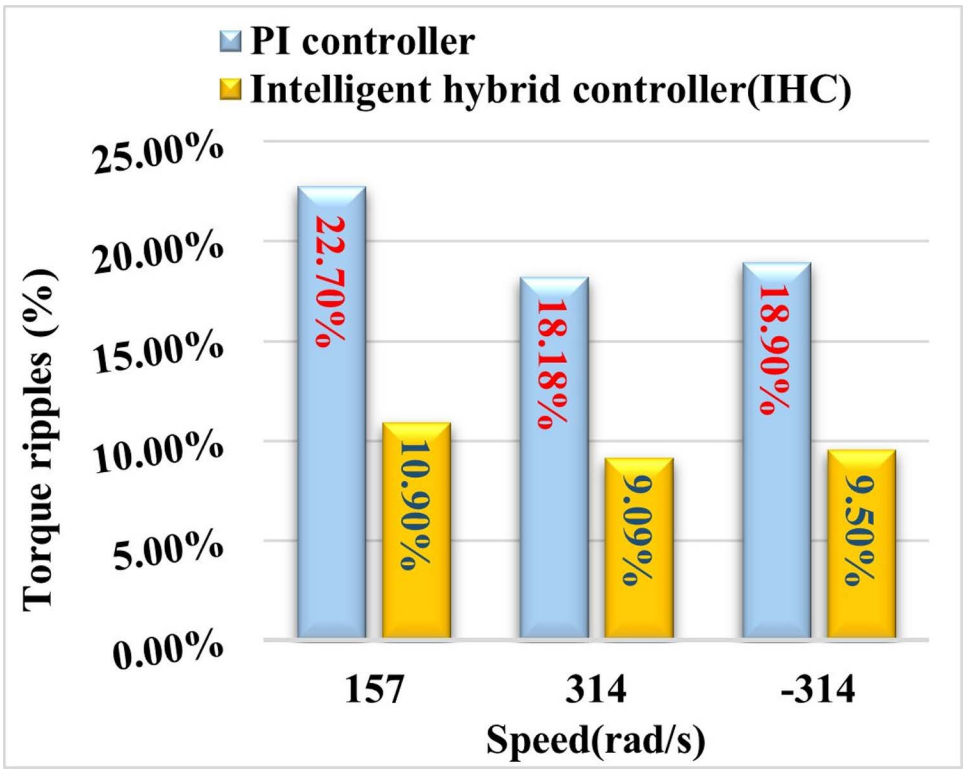

Fig 15. Torque ripples in PMSM with PI & IHC at various speeds.

https://doi.org/10.1371/journal.pone.0312946.g015

3. State probable inference with control rules and MFs.
4. Transform the fuzzy into crisp set.
5. To get the required performance, adjust the input and output gains properly.

Here input crisp variables are speed error, $\Delta\omega_r(k)$ and change in speed error, $\Delta e(k)$ which are described as:

$$\Delta\omega_r(k) = \omega_r^*(k) - \omega_r(k) \tag{19}$$

$$\Delta e(k) = \Delta\omega_r(k) - \Delta\omega_r(k-1) \tag{20}$$

Output is torque component, which is stated as

$$\Delta T_e^*(k) = \Delta T_e^*(k-1) + \mu.\Delta T_e^*(k) \tag{21}$$

where $\Delta T_e^*(k)$ is commanded value of torque at the kth sample time and μ is the gain. Fuzzyfication, rule execution, and defuzzyfication are the three main stages that make up the FLC's operation. Triangular membership functions (MFs) of I/O convert crisp variables into fuzzy variables in the first stage. The MFs for the two inputs, $\Delta e(k)$, $\Delta\omega_r(k)$ are shown in Fig 4 and Fig 5. For I/O variables, the IHC defines fifteen linguistic variables. The first input,

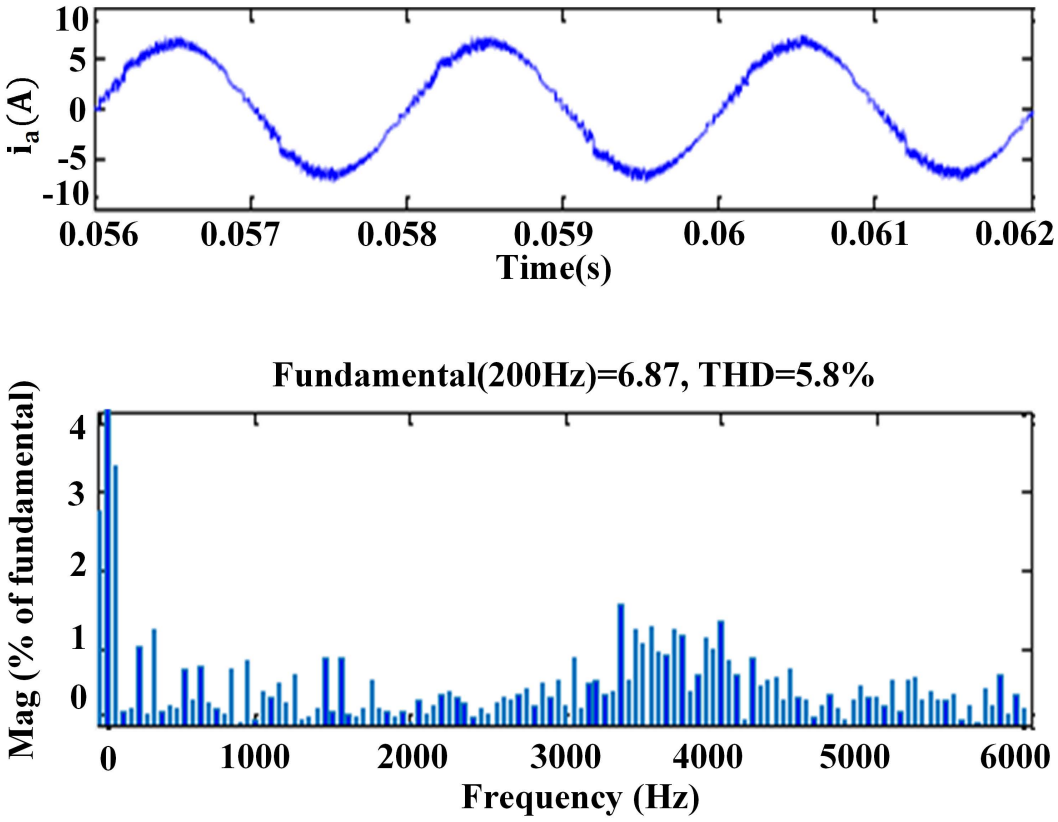

Fig 16. THD in motor current at 314r/sec with PI.

https://doi.org/10.1371/journal.pone.0312946.g016

e(k), has five linguistic variables: ***zo, nl, nm, nmh, nh.*** Likewise, the second input has ***zo, pl, pm, pmh, ph***. Thus, ***zo, pl, pm, pmh, and ph*** are the five output linguistic variables. The ***zo, nl, nm, nmh, nh, pl, pm, pmh, ph*** represents zero, negative low, negative medium, negative medium high, negative high, positive low, positive medium, positive medium high and positive high respectively.

Using fuzzy variables derived from expert knowledge, a set of control rules is constructed and put into action in the second stage. Fuzzy rules are stated as

IF $\Delta\omega_r(k)$ is 'a', $\Delta e(k)$ is 'b' THEN $\Delta T_e^*(k)$ is 'c'.

Here a, b and c are defined as fuzzy sets.

To produce computable results in fuzzy logic, fuzzy sets, and membership functions, fuzzy variables are transformed into crisp variables in the third phase, known as defuzzyfication.. Table 1 lists the fuzzy rules utilized in the IHC.

Proposed control scheme of PMSM drive

To regulate the space vectors of voltage, current, and flux, vector control uses a field-oriented technique [31,32]. High bandwidth inner loops are necessary in high performance drives in order to properly measure current, shorten the transient time, and make sure that VSI may be utilized as an amplifier [33–36]. Fig 6. demonstrates PMSM drive system with IHC.

The reference torque command is created by the IHC in the outer speed loop and contrasted with the estimated torque. The voltage at DC link, 3-phase currents (i_{abc}) and the switches positions (S1, S3 and S5) of VSI from the pulses generated by the current regulator

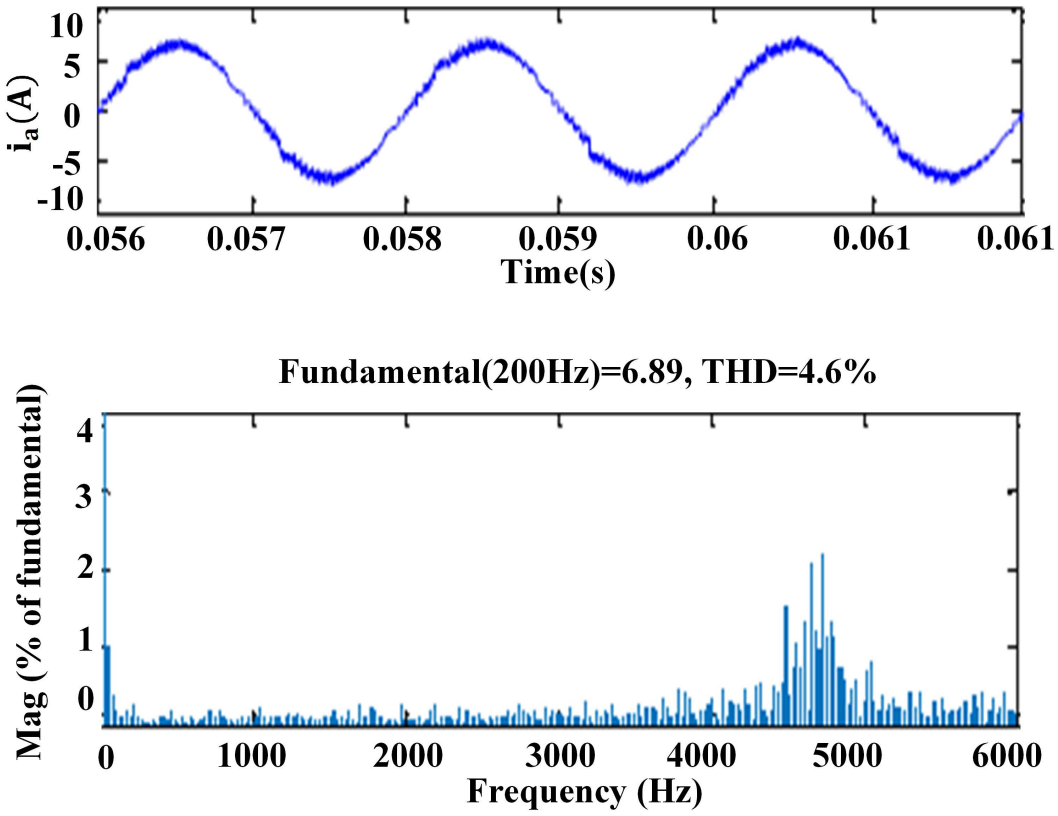

Fig 17. THD in motor current at 314r/sec with IHC.

https://doi.org/10.1371/journal.pone.0312946.g017

as stated before are used to determine the torque. The error signal obtained by comparing the estimated torque to the reference torque is given to the current controller, which produces i_q^*.

The 3-phase reference currents of stator, i_a^*, i_b^* and i_c^* are computed via Parks Transformation utilizing the rotor position from the encoder (θ), and quadrature and direct axis current, i_q^* & i_d^*.

$$i_a^* = i_q^* \cos\theta + i_d^* \sin\theta \tag{22}$$

$$i_b^* = i_q^* \cos\left(\theta - \frac{2\pi}{3}\right) + i_d^* \sin\left(\theta - \frac{2\pi}{3}\right) \tag{23}$$

$$i_c^* = i_q^* \cos\left(\theta + \frac{2\pi}{3}\right) + i_d^* \sin\left(\theta + \frac{2\pi}{3}\right) \tag{24}$$

Where $i_d^* = 0$ upto rated speed operation. Switching pulses are generated by comparing these reference currents with the triangular wave and fed to the inverter.

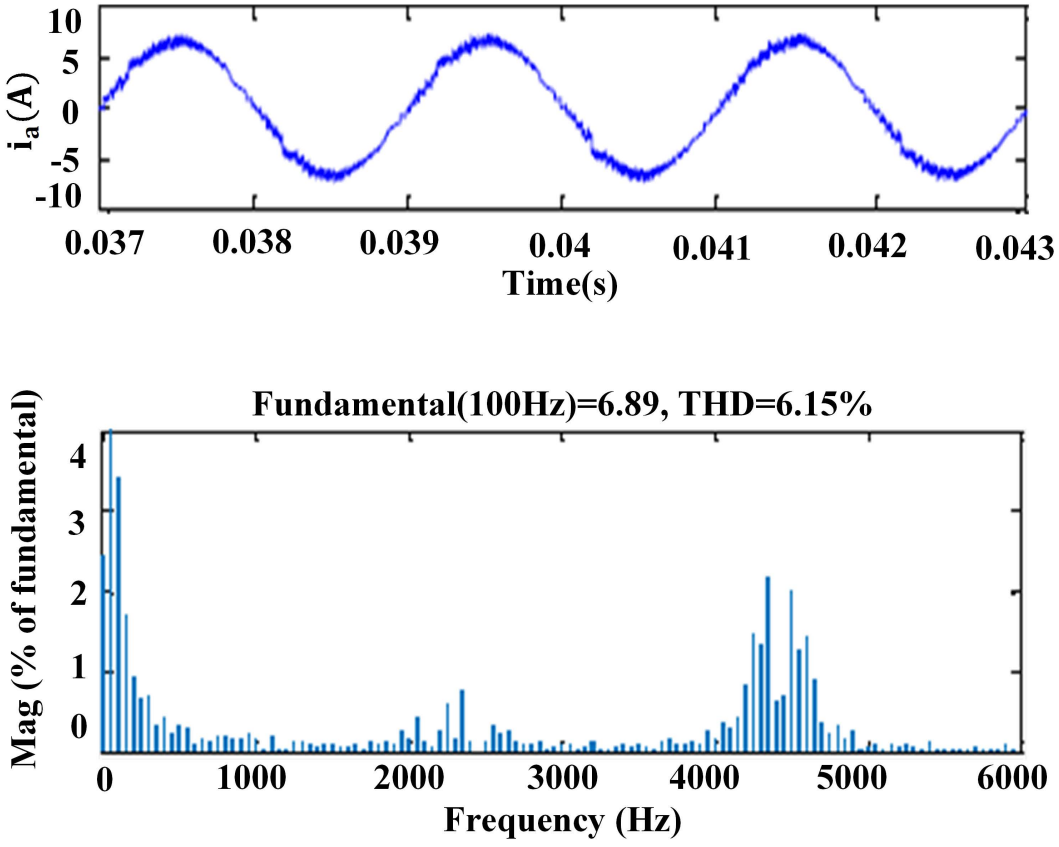

Fig 18. THD in motor current at 157r/sec with PI.

https://doi.org/10.1371/journal.pone.0312946.g018

Emulated results demonstration

In this section a simulation model of a 3.4-kW PMSM with the parameters listed in Table 2 is built in MATLAB/Simulink. The simulations are carried out to compare the proposed approach to the traditional PI control scheme and verify it at the sample time of 10μs.

1. Rated speed operation of PMSM drive

Figs 7 and 8 illustrate the simulated results of the PMSM drive's speed, torque, and stator currents when operating at 314 rad/sec, the rated speed with PI and IHC. To verify effectiveness of IHC the motor starts to rotate at speed of 314r/sec under zero load. A sudden fall is observed in speed response for very less time as load torque of 11Nm is applied at 0.03 seconds after that the drive recovers the reference speed again. It can be seen from the torque waveform in Fig 7 and Fig 8 that the IHC controller is more successful in reducing torque ripples than PI controller.

2. Drive performance with speed variation

Figs 9 and 10, illustrate the simulated results of both PI and IHC controller employed in PMSM drive at speed varying from 157r/sec to 314r/sec. At 157 r/sec, the motor is

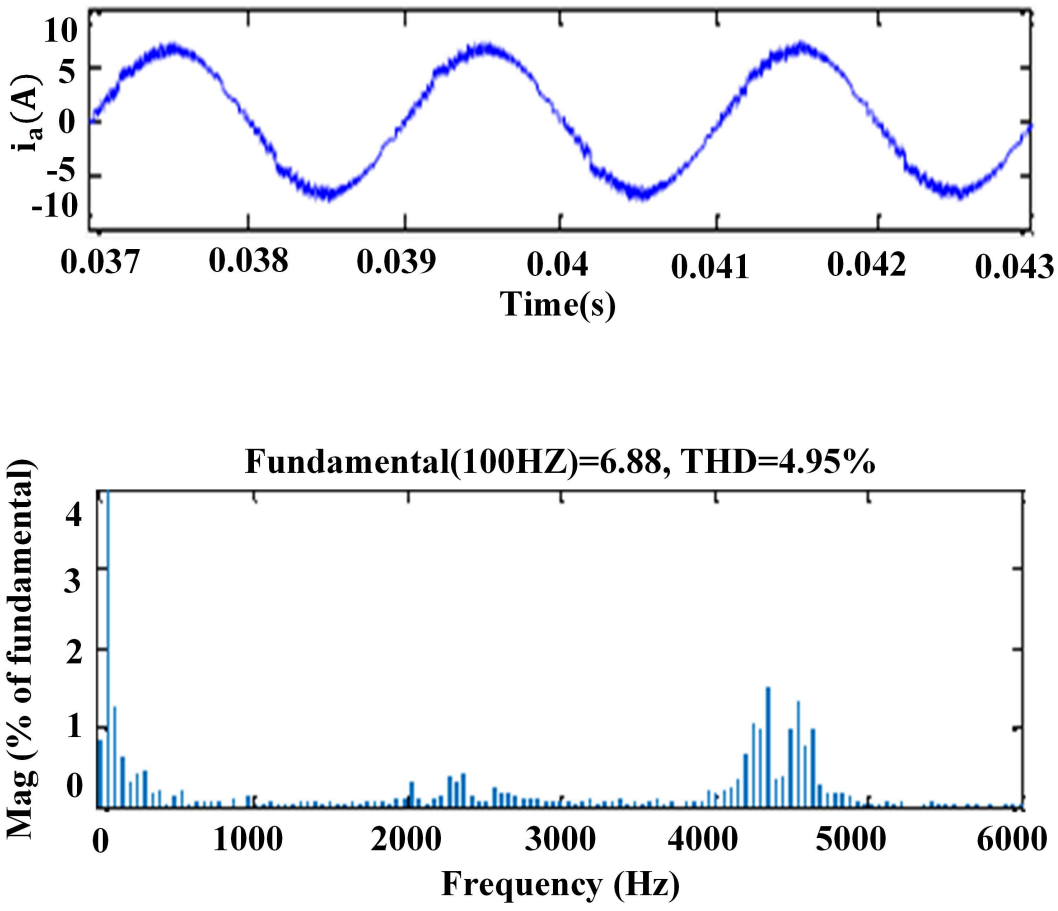

Fig 19. THD in motor current at 157r/sec with IHC.

https://doi.org/10.1371/journal.pone.0312946.g019

started at zero load torque. At 0.05s, step variation of speed is given. Initially the motor is running at no load and at 0.03 sec, 11Nm load is inserted. From the waveform given in Fig 9 and Fig 10, it is important to note that the suggested IHC outperforms the traditional PI in both steady-state and dynamic torque performance, with significantly reduction in ripples.

3. Drive performance in reverse rotation mode

Figs 11 and 12, illustrate the simulated results of both PI and IHC controller employed in PMSM drive with AFC at speed varying from 314r/sec to -314r/sec. Initially reference motor speed of rated value is given and at 0.05 sec step variation in speed 314r/sec to -314r/sec in reverse direction is applied to the motor. The motor speed and torque are observed to seamlessly track their set values. According to the torque waveform given in Fig 11 and Fig 12, there is a significant difference in torque ripples induced by both control methods. It can therefore be stated that proposed method can reduce the ripples in motor torque effectively over a conventional method.

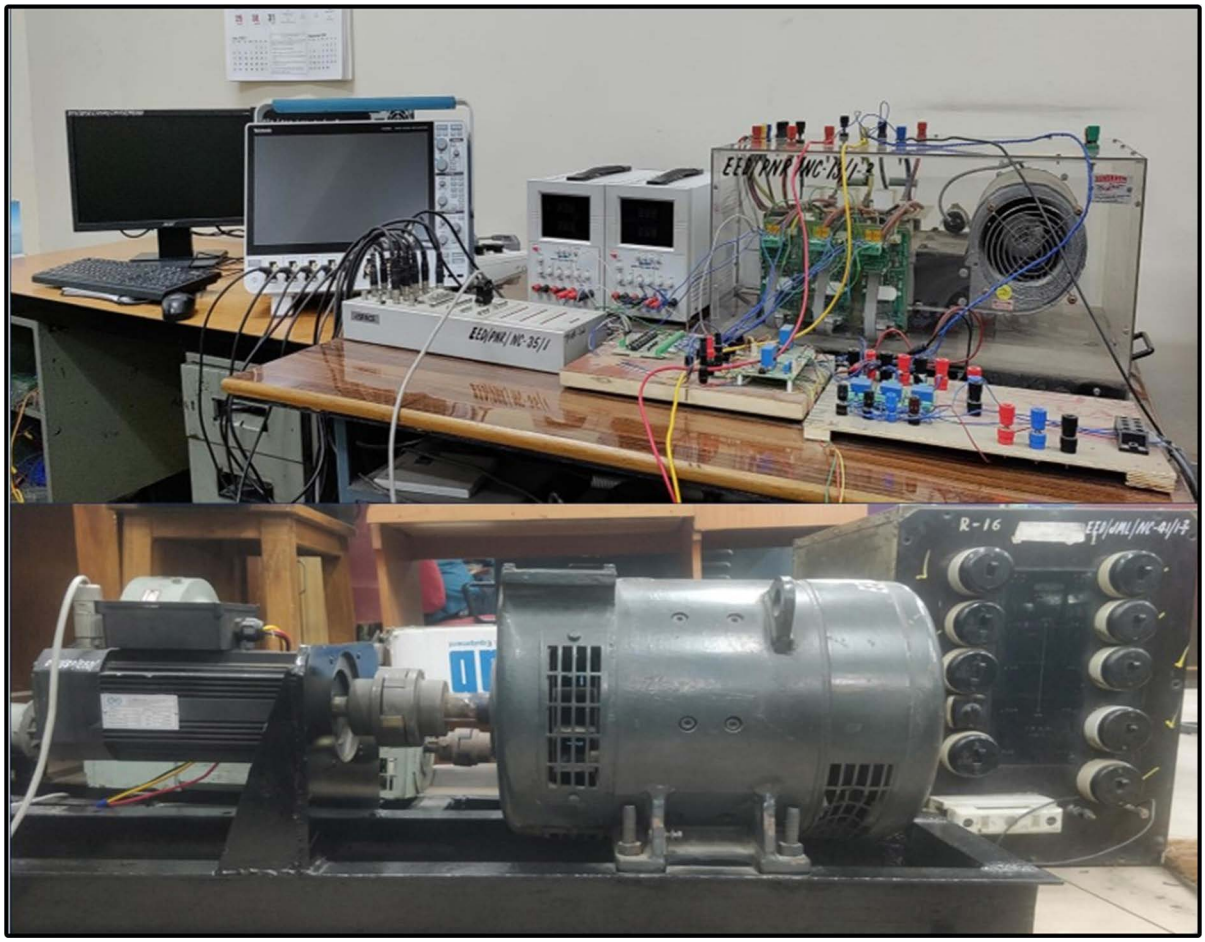

Fig 20. Experimental bench of PMSM drive.

https://doi.org/10.1371/journal.pone.0312946.g020

4. Steady state characteristics of estimated torque and measured torque

Fig 13 and Fig 14 show steady state measured value and estimated value of torque of the PMSM drive using PI and IHC with AFC. The measured value of torque (T_e) is 11Nm and estimate value of torque (T_{est}) is 10.9 Nm at rated speed. The average error between both torque values is observed to be 0.1Nm.

5. Calculation of torque ripple

Torque ripple is calculated using Equation 25 as given below:

$$\text{Torque ripple}(\%) = \frac{T_{max} - T_{min}}{T_e} \times 100 \tag{25}$$

Here T_{max}, T_{min} are maximum and minimum peak of toque which is observed from given torque waveforms. The percentage values of torque ripples running at various speeds with a PI and IHC in PMSM drive is shown in Fig 15. When employing IHC as a speed controller instead of a PI controller, ripples are seen to be minimized.

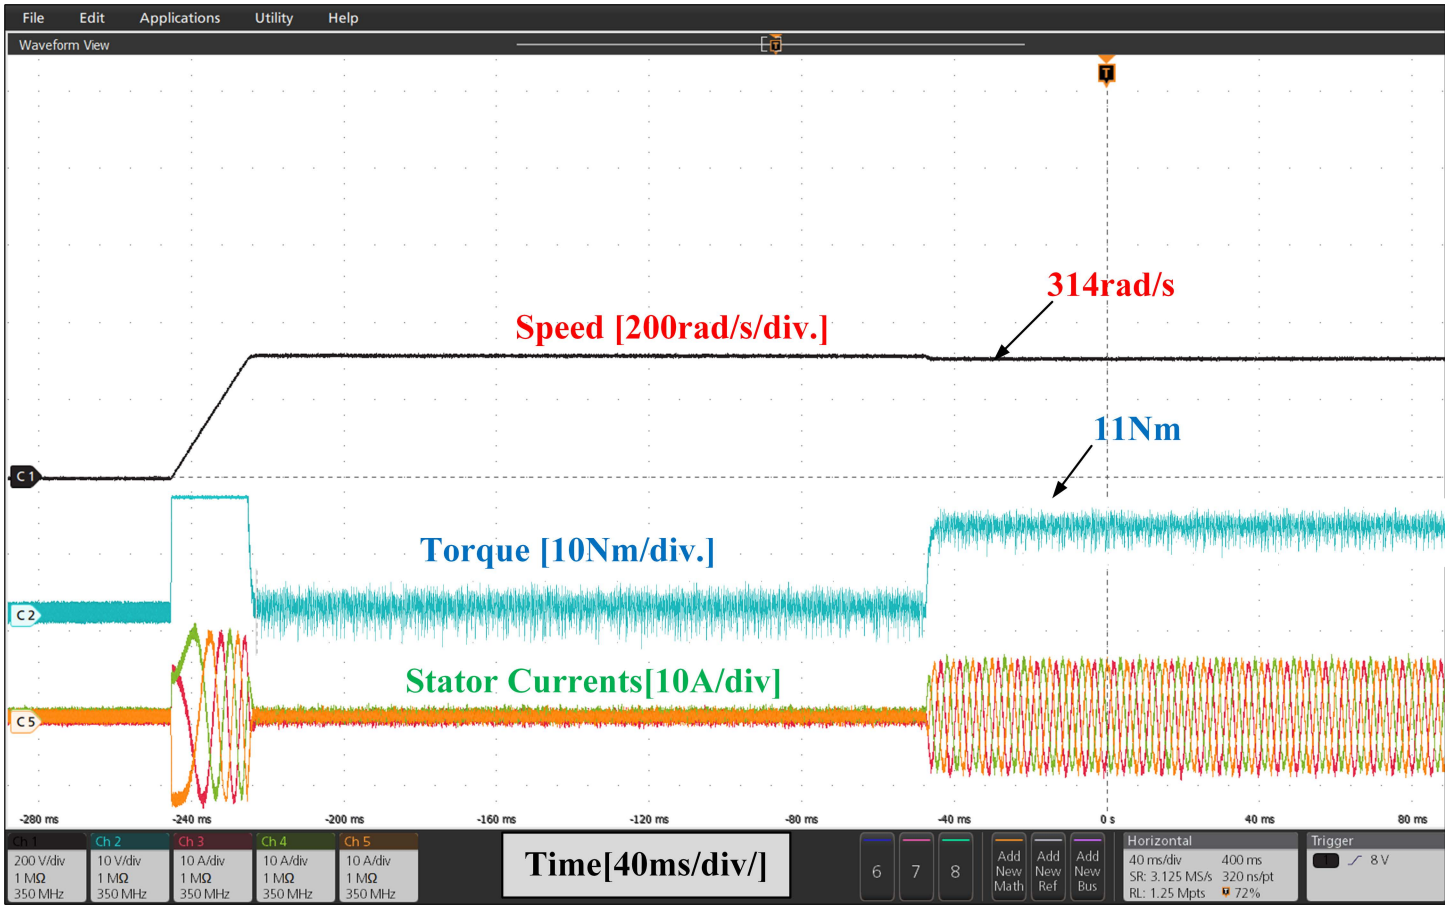

Fig 21. Experimental waveform of W_r, T_e and i_{abc} of motor running at 314r/sec using PI.

https://doi.org/10.1371/journal.pone.0312946.g021

6. THD analysis

The harmonic spectra of the stator current of PMSM with PI and IHC at 314r/sec is shown in Fig 16 and Fig 17. THD measured with PI controller is 5.8%, whereas THD measured with IHC is 4.6%. The harmonic spectra of the stator current for the drive with PI and IHC is shown in Fig 18 and Fig 19 while it is operating at half of its rated speed (157 rad/sec). THD is reported to be 4.95% with IHC and 6.15% with PI controller. The average value of switching frequency for all techniques is fixed constant at 7.5 kHz for simulation experiments. When THD is examined up to 6 kHz, it is found that the PMSM drive with Intelligent Hybrid Controller has lower THD in stator current than the PI controller.

Experimental results demonstration

An experimental setup is developed for the operation of PMSM drive shown in Fig 20. The ds1104 controller, VSI, current and voltage, driver gating circuit, and power sources are the basic components used in the experimental setup of PMSM drive. MATLAB/Simulink and dSPACE1104 are used to implement the different controllers for PMSM drives. Table 1 lists the PMSM parameters utilized for the experimental investigation. The VSI is controlled by

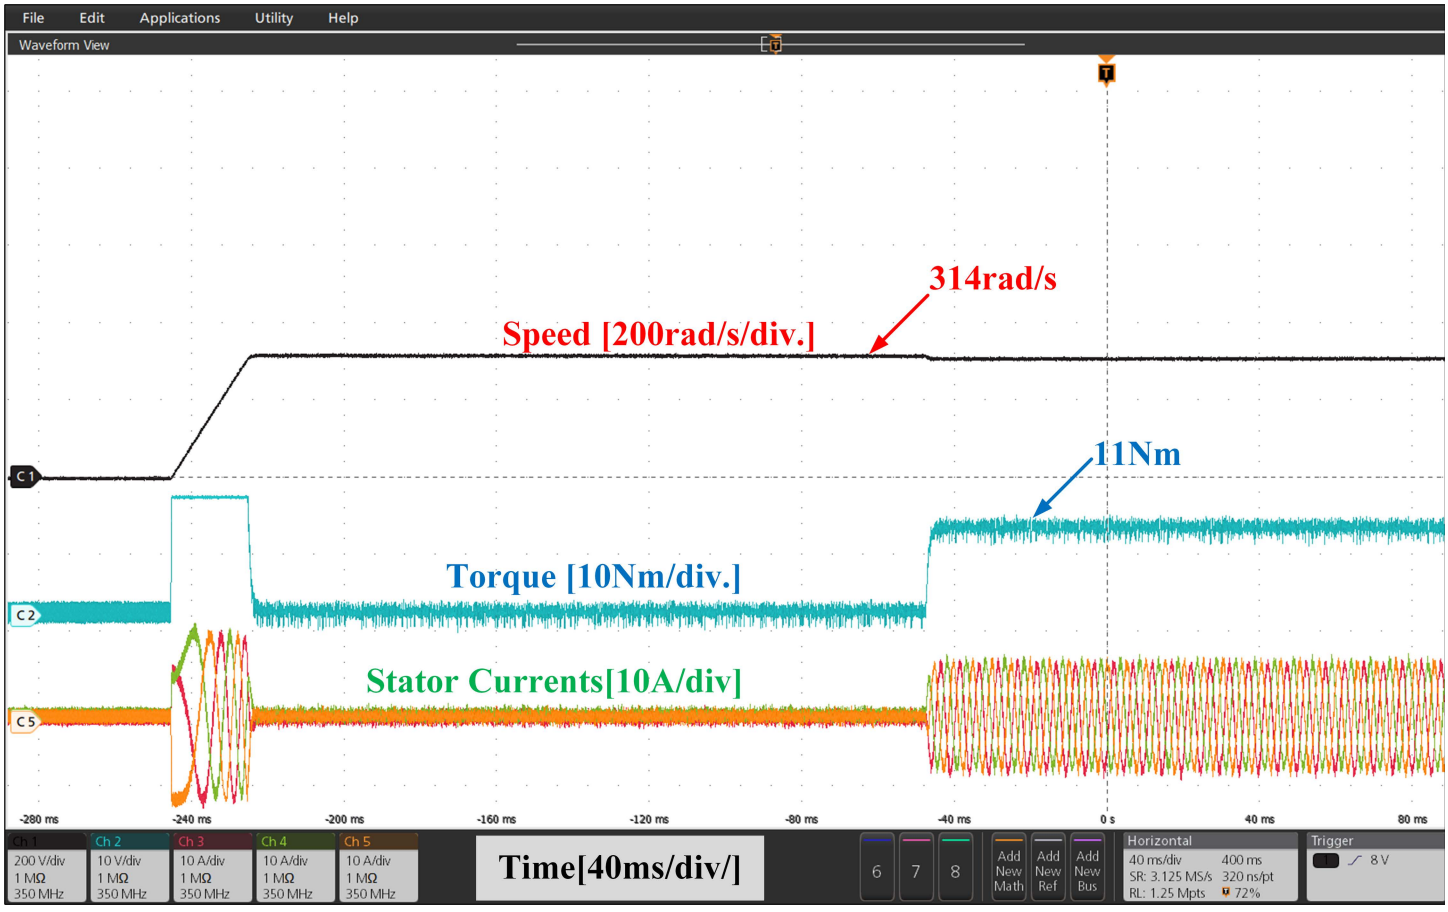

Fig 22. Experimental waveform of W_r, T_e and i_{abc} of motor running at 314r/sec using IHC.

https://doi.org/10.1371/journal.pone.0312946.g022

dS1104 controller and supplies the stator voltage for the PMSM. A DC generator is paired on the same shaft to provide electrical loading for the PMSM.

1. Experimental performance of PMSM drive

Fig 21, and Fig 22, show the experimental results of both PI and IHC employed in PMSM drive operated at 314r/sec. In starting the motor starts to rotate with full speed at zero load and easily trajectory the speed given in reference. When load of 11Nm is inserted at the shaft, a quick drop is perceived in speed curve and after few second the drive trajectories the reference speed effortlessly again. It can be seen from the torque waveform in Figs 7 and 8 that the IHC controller is more successful in reducing torque ripples than PI controller.

Fig 23 and Fig 24, illustrate the experimental results of both PI and IHC controller employed in PMSM drive at speed varying from 157r/sec to 314r/sec. At 157 r/sec, the motor is started at zero load torque. The motor is started to run at zero load condition at 157r/sec. A constant load of 11Nm is inserted to the shaft and it is perceived that the motor generates the net demanded torque without any interval. After motor reaches in steady state, a change in commanded speed from 157r/sec to 314r/sec is applied to motor. A rise in load torque is observed during the speed variation and it reaches again at rated value. The motor speed and

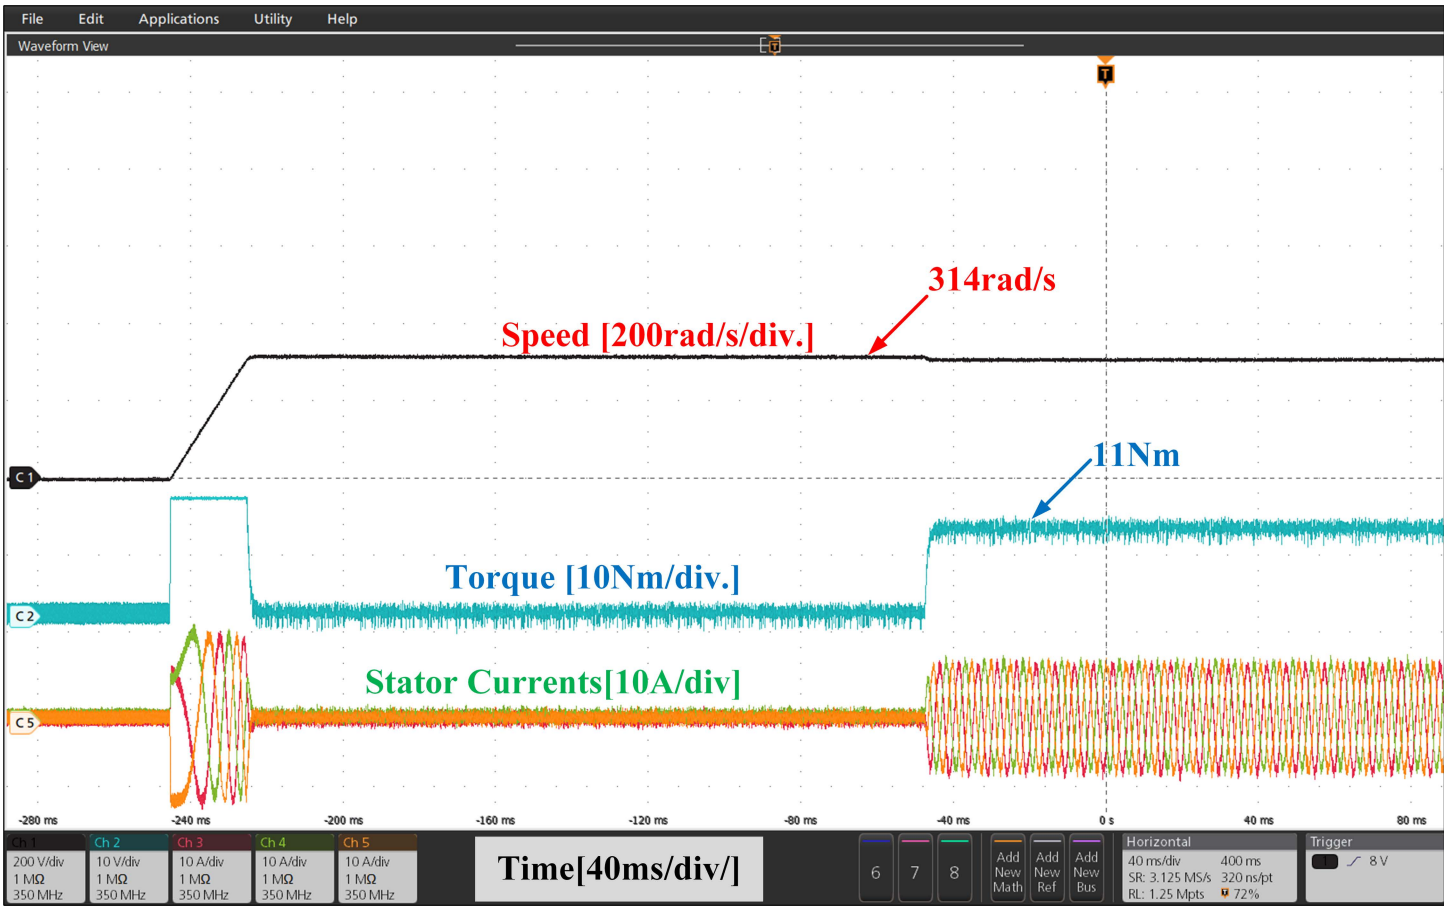

Fig 23. Experimental waveform of W_r, T_e and i_{abc} of motor with linear increase in speed using PI.

https://doi.org/10.1371/journal.pone.0312946.g023

torque are found to follow their set values. The IHC greatly reduces toque ripples, according to experimental analysis of the torque response of motor.

Fig. 25 and Fig. 26, illustrate the experimental results of both PI and IHC controller employed in PMSM drive with AFC at speed varying from 314r/sec to -314r/sec. Initially reference motor speed of rated value is given and after reaching at steady state condition a step variation in speed 314r/sec to -314r/sec in reverse direction is given to the motor. A drop in motor torque is witnessed during change in speed and it reaches again at rated value after few seconds. The motor speed and torque are observed to seamlessly track their set values. According to the torque waveform given in Figs 25 and 26, there is a significant difference in torque ripples induced by both control methods. It can therefore be stated that proposed method can reduce the ripples in motor torque effectively over a conventional method.

2. THD analysis

The harmonic spectra of the stator current of PMSM with PI and IHC at rated speed of 314r/sec is shown in Figs 27 and 28. THD measured with PI controller is 4.272%, whereas THD measured with IHC is 2.931%. The harmonic spectra of the stator current for the drive with PI and IHC is shown in Figs 29 and 30 while it is operating at half of its rated speed (157 rad/

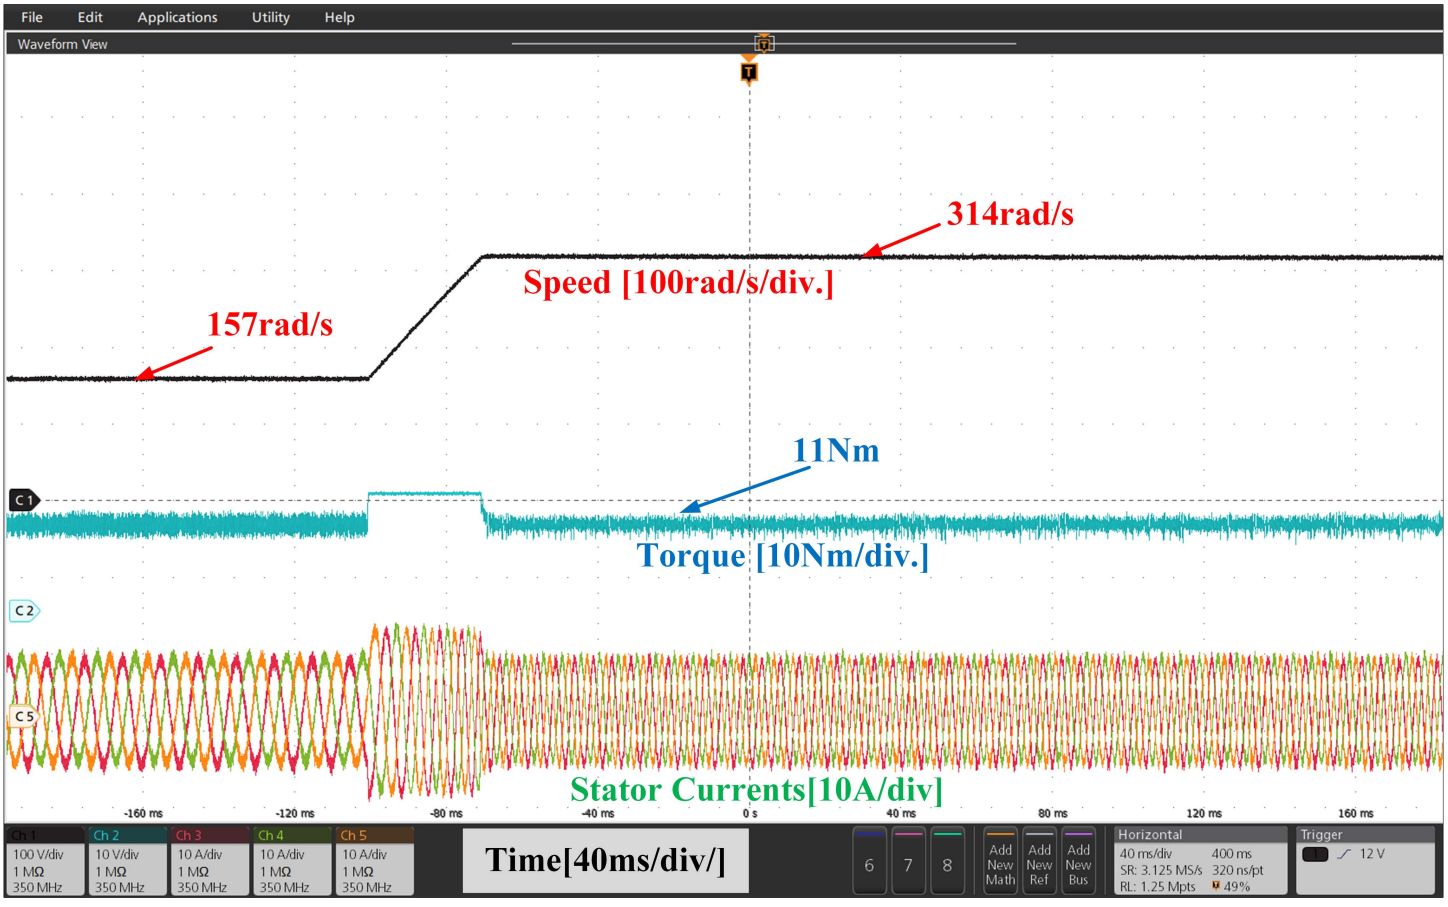

Fig 24. Experimental waveform of W_r, T_e and i_{abc} of motor with linear increase in speed using IHC.

https://doi.org/10.1371/journal.pone.0312946.g024

sec). THD is reported to be 1.848% with IHC and 3.522% with PI controller. When THD is examined by performing experiment, it is found that the PMSM drive with Intelligent Hybrid Controller has lower THD in stator current than the PI controller.

Conclusion

This study proposes an intelligent hybrid controller for Permanent Magnet Synchronous Motor (PMSM) drives, aiming to mitigate the problems arising from the independent operation of standard Proportional-Integral (PI) controller and Fuzzy Logic Controller (FLC). The proposed controller incorporates an adaptive flux and torque estimator. The controller under consideration is formulated by integrating a Proportional-Integral (PI) controller and a Fuzzy Logic Controller (FLC) in a cascaded manner, incorporating innovative switching functionalities. A unique methodology is proposed for the estimation of flux, with the aim of reducing disturbances in current, torque, and flux. In addition, comprehensive simulations and experimental findings have provided evidence that the suggested control methodology presents advantages such as decreased fluctuations in motor torque, lower total harmonic distortions in current, and enhanced overall drive performance in both steady-state and transient states across various operational scenarios, in contrast to the conventional proportional-integral (PI) controller. The torque ripples in motor are observed as 27.70%, 18.18% and

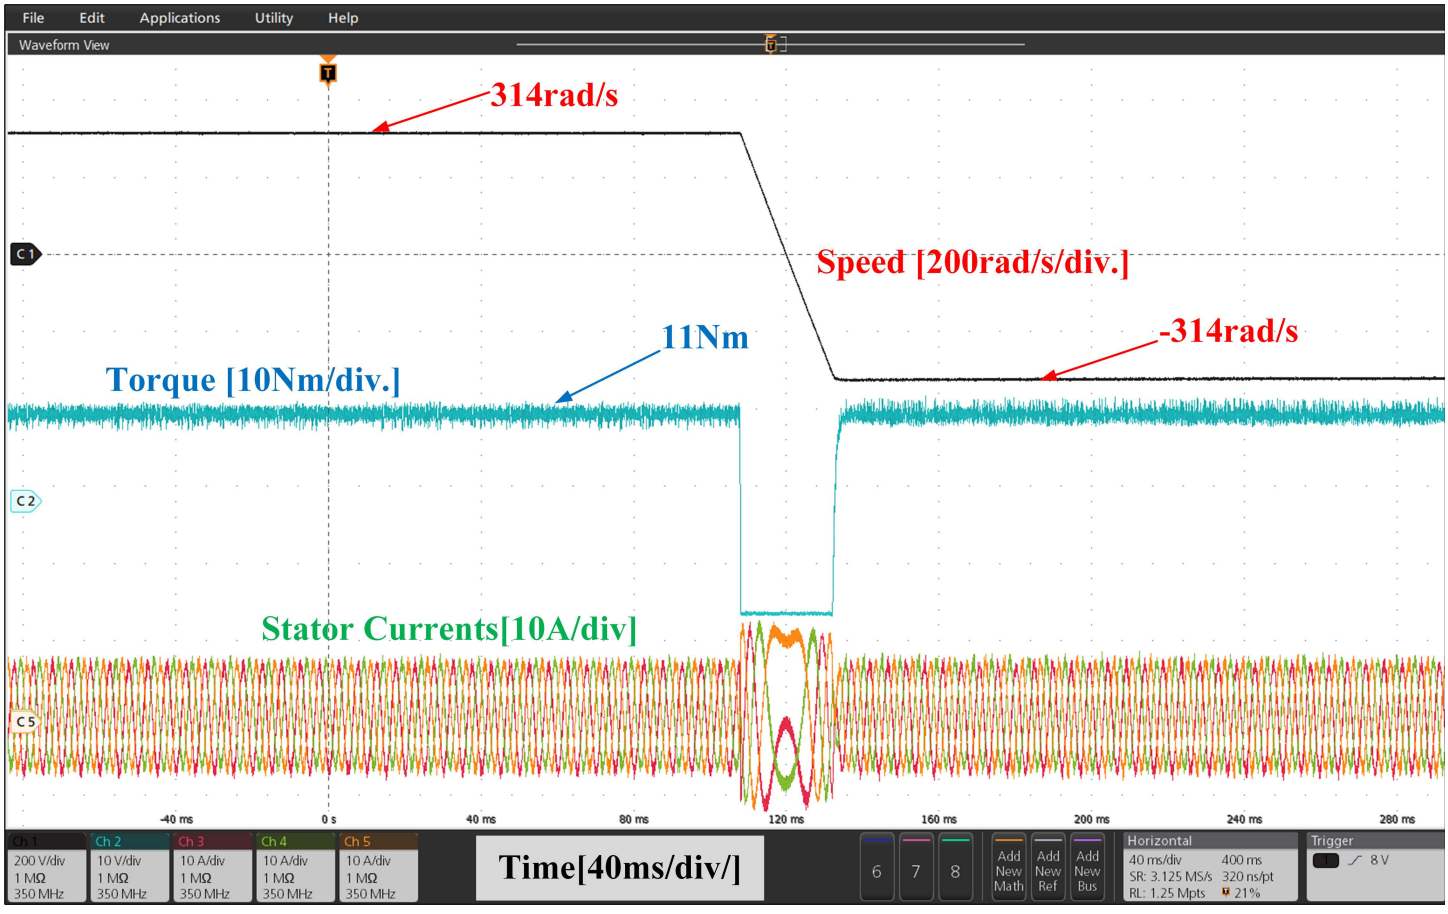

Fig 25. Experimental waveform of W_r, T_e and i_{abc} of motor with reverse rotation of speed using PI.

https://doi.org/10.1371/journal.pone.0312946.g025

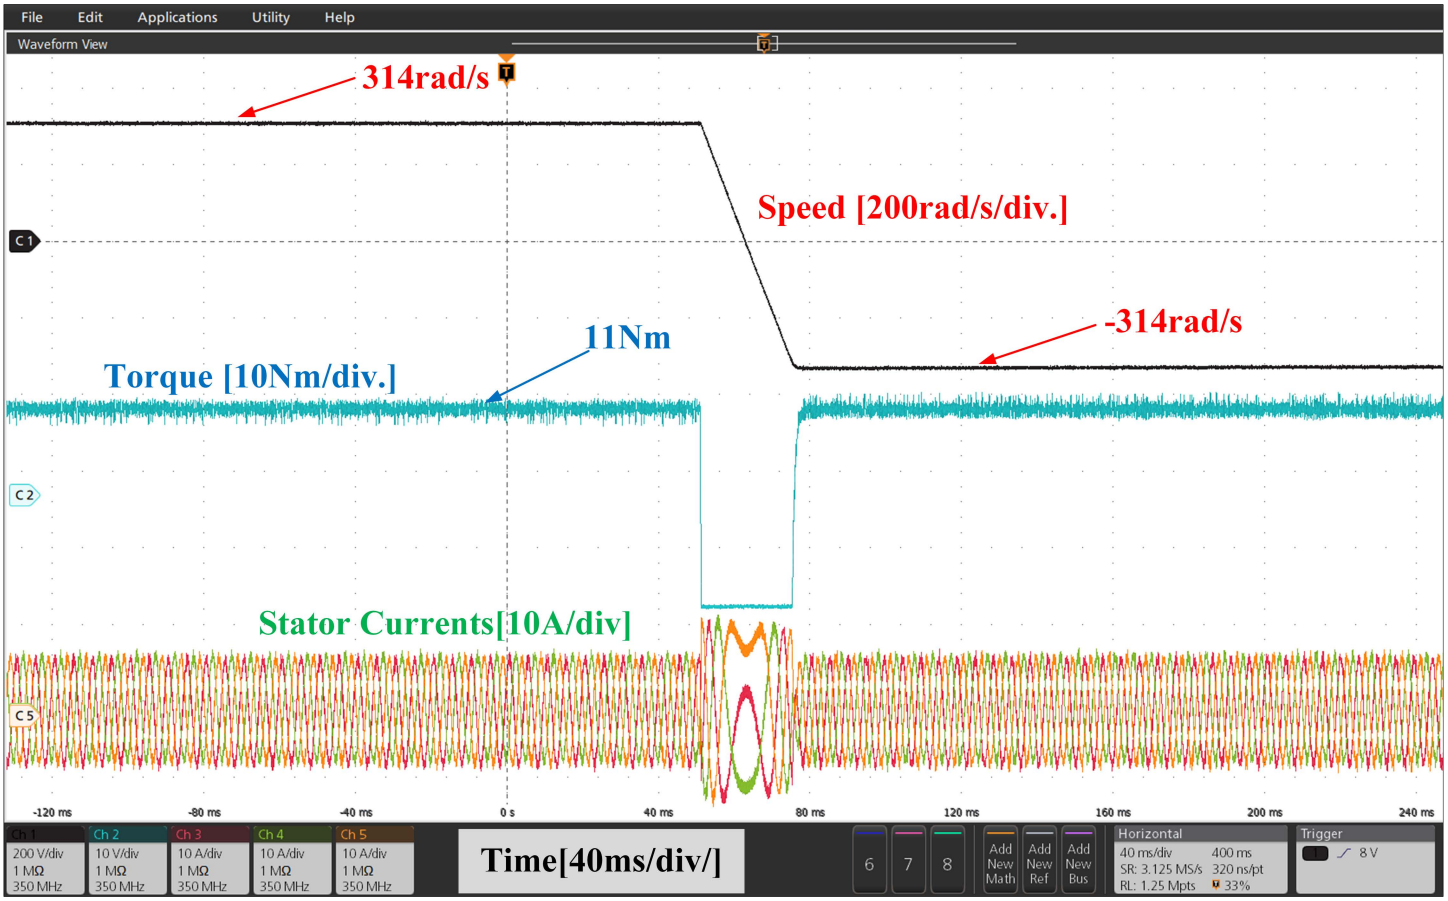

Fig 26. Experimental waveform of W_r, T_e and i_{abc} of motor with reverse rotation of speed using IHC.

https://doi.org/10.1371/journal.pone.0312946.g026

18.90% with PI controller and 10.90%, 9.09% and 9.50% with IHC controller at speed of 157 rad/s, 314 rad/s and -314 rad/s respectively. It shows that IHC can give better performance with reduced ripples in torque than PI controller. THD measured with PI controller is 5.8%, whereas THD measured with IHC is 4.6% at speed of 314 rad/s and 6.15% with PI controller, 4.95% with IHC at speed of 157 rad/s. Thus, IHC controller provides lesser THD in current than PI controller at different operating speed. In future work, the proposed method can be implemented for the electric vehicle application with some adaptive controller based on artificial intelligence.

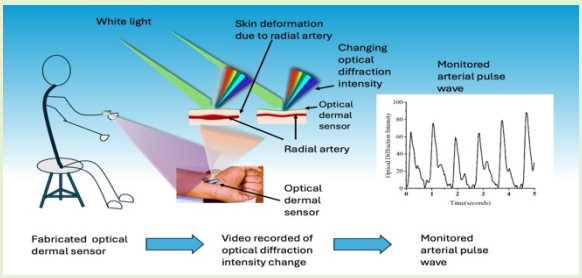
Diffractive optical dermal sensor for non-invasive arterial pulse wave monitoring

Mayank Pandey , *Sang-Woo Seo

***Abstract*— The arterial pulse wave is a crucial indicator for assessing cardiovascular health. Wearable pulse detection technology has the potential to transform daily healthcare monitoring that helps to identify cardiovascular diseases. However, the technology faces challenges due to its limited flexibility, low sensitivity, and the need for cost-effective manufacturing to enable widespread implementation. To address these issues, we introduce an innovative, non-invasive sensor made of a deformable optical grating sensor patch. This sensor allows for real-time acquisition of arterial pulse waveforms at the radial artery site. It operates by detecting strain-induced changes in the diffraction pattern that occur due to fluctuations in blood pressure. When illuminated with light, the optical grating produces a diffraction pattern that shifts in response to pulsatile blood flow. These spectral shifts are then processed and analyzed to measure changes in blood pressure, enabling real-time tracking of dynamic arterial pulse waves. With its lightweight and flexible design, along with a low-cost manufacturing approach, this sensor has the potential to be used in wearable health monitoring systems.**



***Index Terms*— Arterial pulse wave monitoring, Cardiovascular health monitoring, Optical sensor, Radial artery, Wearable pulse wave detection**

I. Introduction

THE arterial pulse wave (APW) is a vital component of human physiological signaling, carrying abundant health information that can help identify cardiovascular diseases (CVDs) [1], [2], [3]. CVDs such as ischemic heart disease and stroke, are among the leading global causes of mortality, responsible for approximately one-third of all deaths annually [4]. By 2030, this number is projected to rise to 23.6 million[5]. Despite the high mortality rates associated with CVDs[6], many of these conditions - including arteriosclerosis [7], diabetes [8], myocardial infarction[9], coronary heart disease[10], and hypertension[11] - can be prevented and treated through early diagnosis and continuous monitoring of physiological signals. While physical symptoms of CVDs are often subtle in the early stages, they can be detected through small changes in APW patterns [12]. APWs reflect the interaction between the driving force of the heart and the impedance of blood flow, serving as reliable indicators of cardiovascular health[13], [14]. These waveforms can be measured at various arterial sites, each with unique characteristics.

Recent advancements in wearable devices equipped with flexible sensors and Internet of Things technologies have enabled near-real-time monitoring of APWs. Common non-invasive techniques for measuring APWs include electrocardiography (ECG), photoplethysmography (PPG), and remote photoplethysmogrpahy (rPPG)[15], [16], [17]. However, these methods have their limitations: ECG requires forming a circuit through the heart, complicating the miniaturization of devices, while PPG is energy-intensive due to its reliance on light-emitting diodes and photodetectors. rPPG allows remote sensing but its accuracy can be affected by variations in illumination, skin tone, and other measurement conditions. Skin-contact sensors, such as piezoresistive, piezoelectric, triboelectric, capacitive, or microelectromechanical systems (MEMS), are gaining attention for transducing APWs [18], [19], [20], [21]. These sensors can effectively capture APWs, but the reliability of the signal heavily depends on the sensor's position. The radial artery, which is typically 3-4 mm in diameter and located beneath the skin, poses challenges for precise sensor placement. Even slight misplacement can compromise signal accuracy, making the process dependent on the accuracy of the placement. Although various technologies exist for measuring APWs, they face challenges related to accuracy, portability, motion sensitivity, environmental interference, and power efficiency. Emerging wearable technologies are addressing these limitations, but further research is necessary to achieve an optimal balance between precision, comfort, and practicality. Continued advancements will pave the way for reliable and

widespread use of APW monitoring systems in continuous health monitoring.

In this paper, we present a diffractive optical patch designed to detect subtle skin deformations associated with APWs. While diffractive optical detection schemes have been used for various applications, such as force measurements[22], monitoring local pressure in microfluidic devices [23] and acousto-optic sensors[24], there are few reports focused on monitoring APWs for human health. The sensor features a thin and flexible grating structure that can be applied to the radial arterial area, allowing it to visualize subtle skin deformations through variations in light intensity. The operation of the sensor is based on detecting strain-induced changes in the grating's diffraction condition caused by fluctuations in blood pressure. When illuminated with white light, the grating produces a diffraction pattern that shifts in wavelength as the pulsatile blood flow alters the diffraction conditions. These spectral shifts are analyzed to quantify changes in blood pressure waves, providing a reliable measurement of physiological conditions. This innovative design facilitates accurate detection of APWs without the need for bulky or complex sensing systems. Its lightweight and flexible structure make it particularly suitable for wearable health monitoring devices. The sensor's capability to monitor dynamic blood pressure changes in real time highlights its potential for integration into advanced healthcare systems, enabling continuous, non-invasive tracking of cardiovascular health. Moreover, the sensor can be manufactured using a cost-effective and scalable approach. These advantages promise to significantly enhance cardiovascular health monitoring by offering a reliable, accurate, and economical solution for tracking critical health metrics.

II. Design and Fabrication

Figure 1(a) presents a schematic design of the proposed sensor, which serves as a simple but sensitive device for detecting arterial pulse waves (APWs) on a target skin surface. The optical grating sensor is made from flexible polydimethylsiloxane (PDMS) elastomer. It features a deformable reflection-type grating structure coated with a metal layer to enhance its optical diffraction. The elastic properties of PDMS allow the grating to adopt a dynamic and deformable structure that responds to subtle changes in arterial pressure. Since it covers the broad skin area of radial artery, dynamic optical intensity change can be easily visualized without dedicated sensor positioning. Additionally, the unique optical sensing method operates without physical wiring, enabling remote detection of APWs and improving its application in non-invasive cardiovascular monitoring. Figure 1(b) presents image of the arterial pulse sensor on the wrist, indicating the region with vivid optical signal quality for APW measurement. Pressure waves are generated by the rhythmic contractions and expansions of the heart muscles, which propagate through the arterial vessels during the systolic and diastolic phases. These pressure waves produce the pulse observed in arteries. In the systolic phase, the arterial diameter expands (known as vasodilation) due to increased blood flow, while in the diastolic phase, the diameter reduces (referred to as vasoconstriction). These cyclic changes in arterial diameter are transmitted through soft tissues and muscles, causing surface skin pulsations that can be detected to assess the dynamics of the heart and arterial walls.

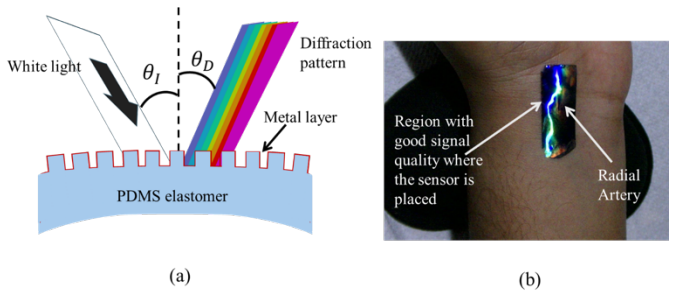

Fig. 1. (a) Schematic design of the proposed diffractive optical dermal sensor. (b) An illustration of a radial artery region where the sensor is positioned to measure APWs.

The detection mechanism of the proposed grating sensor is based on the principle of light diffraction. When incident white light interacts with the periodic structure of the grating grooves, it disperses into beams of various wavelengths. Each groove acts as a source of scattered light that interferes with light from the adjacent grooves. This interference produces alternating light and dark bands, which are characterized by constructive and destructive interference. Constructive interference occurs when light waves from adjacent grooves are in phase, resulting in bright spots that correspond to the diffraction orders. The diffraction pattern created by the grating is governed by the grating equation:

$$m\lambda = d(\sin\theta_I + \sin\theta_D)$$

Where m is the diffraction order, d is the grating period, λ is the wavelength, θ_I Is the incident angle measured from the normal of the grating, and θ_D is the diffraction angle measured from the normal of the grating. This equation shows that the diffraction angle θ_D varies depending on the wavelength λ of the light and grating period d [22], [25]. When the grating structure on the skin surface deforms in response to pulsatile blood flow, the diffraction conditions of the light are altered. As illustrated in Figure 1(b), the PDMS grating sensor is placed on the skin surface of the wrist. The arterial pressure waves periodically stretch the grating sensor, altering the diffraction conditions and causing fluctuations in the reflected light. Since the sensor is patched on a relatively broad area of the skin, the most noticeable color changes can be visualized on the specific spot area where the skin surface is highly modulated. Capturing these light spot shifts with a camera enables real-time monitoring of APWs.

Figure 2(a) illustrates the fabrication process of the PDMS grating sensor, highlighting its cost-effective production. The master mold for the PDMS grating sensor was simply generated using a low-cost DVD optical disk, which consists of two polycarbonate (PC) layers that were separated manually. Subsequently, scotch tape was employed to remove any remaining layers from the PC-grating structure. Finally, the dye layer was eliminated by immersing the structure in isopropanol and allowing it to dry in ambient air. The master mold was subsequently cut into several rectangular shapes to prepare the grating (Step 1). To prepare the PDMS grating sensor, a 10:1 weight ratio of the PDMS base (Sylgard 184 silicone elastomer) and the cross-linker was prepared and thoroughly mixed. The

PDMS mixture was then degassed in a vacuum chamber to remove air bubbles. Sensors with two different thicknesses were prepared by spinning the PDMS mixture onto the master mold at different spin speeds (Step 2 and 3). After this, the master mold with the PDMS film was placed in a vacuum chamber again to remove any residual air bubbles. It was then transferred to an oven and heated at 60°C for 4 hours to ensure complete curing of the PDMS film. Next, isopropyl alcohol was utilized as a lubricant for the careful detachment of the PDMS grating from the master mold (Step 4). The thickness of each PDMS grating film was then measured using the laser displacement system (Keyence LC-2400A, USA), which indicated a thickness of 250 µm for 300 RPM spin speed and 100 µm for 900 RPM spin speed. Finally, layers of 10nm chromium (Cr) and 50nm copper (Cu) were thermally deposited onto the fabricated grating surface (Step 5 and 6). This deposition significantly enhanced the reflective-diffraction from the PDMS grating film. Figure 2(b) shows an atomic force microscope (AFM) image of the master mold, which illustrates the grating pattern to be replicated on the PDMS film. The AFM image demonstrates the surface morphology and alignment of the fabricated grooves. The grating period and the modulation depth of the master mold were measured at 760 nm and 185 nm, respectively. Figure 2(c) presents a microscope image of the PDMS grating, with a scale bar indicating 10 µm. This confirms that the PDMS grating was successfully fabricated with the intended grating period and modulation depth, closely matching the master mold.

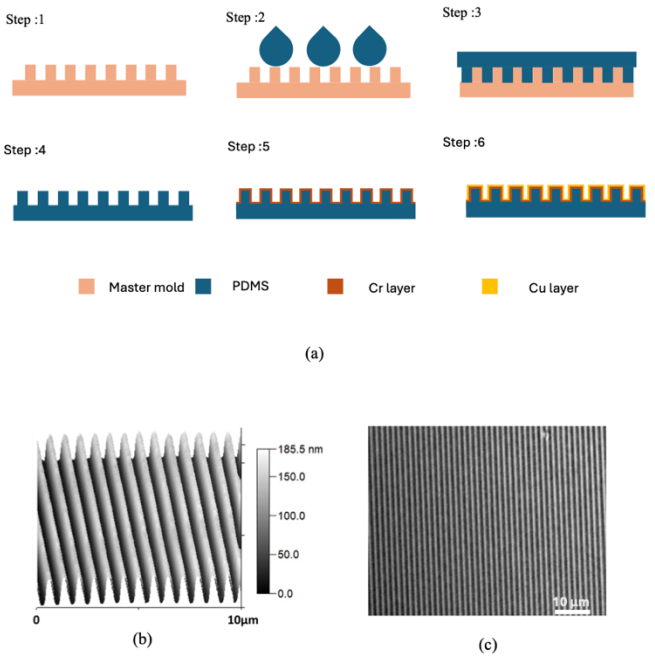

Fig. 2. (a) The sensor fabrication procedure includes Steps: 1 (Master mold), 2 (Dropping PDMS mixer on master mold), 3 (Spin-coating of PDMS mixer), 4 (Optical grating sensor after curing), and 5 and 6 (Optical grating sensor after metal deposition). (b) An AFM image of a master mold. (c) An optical microscope image of a PDMS sensor.

III. Result and Discussion

Figure 3(a) shows the structure of the PDMS grating sensor immediately after its detachment from the master mold. Figure 3(b) shows the sensor following the sequential deposition of Cr and Cu layers, which significantly improved the diffraction efficiency of the grating. Cr layer served as an adhesion layer of the subsequent Cu layer to the PDMS layer. Figure 3(d) presents a PDMS grating sensor after being placed on the person's wrist.

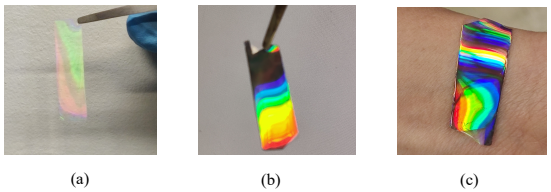

Fig.3. (a) An example of a fabricated sensor before metallization. (b) An example of a fabricated sensor after metallization. (c) An example of a fabricated sensor placed on the radial artery of a person's wrist.

Figure 4 presents a schematic representation of the experimental setup used to measure APWs on a person's wrist. A digital camera with a 10x optical zoom and the capability to record high-speed video at 200 frames per second was connected to a personal computer. The camera was then aligned to focus on the PDMS grating sensor positioned on the person's wrist. A white light source was positioned on the other side of the hand, enabling the observation of APWs with vivid optical reflection, which is illustrated in a supplemental video. This configuration effectively positioned the PDMS grating sensor on the wrist without the need for precise alignment, allowing for accurate measurements of changes in diffraction patterns caused by surface deformation related to blood pressure fluctuations. After recording a video, it was processed for data analysis using ImageJ software to display light intensity changes in multiple spot areas where vivid diffraction changes were observed. While slight movements of the subject may influence the measurement, these movements occur at a much lower frequency than typical APW signals and can be effectively subtracted from the data.

Figures 5(a) and 5(b) illustrate the two distinct wrist configurations under which APWs were monitored. It was observed that the sensor's performance was sensitive to how it was positioned on the skin surface of the wrist. Table 1 presents the measurement parameters for eight experimental sets that we have followed to measure APWs using PDMS grating sensors. These measurements aimed to evaluate the sensor's performance and analyze variations in APWs across different wrist configurations, providing valuable insights into its operational reliability. The APWs response was measured for each wrist configuration 1 and 2, and the recordings were captured for 30 seconds to observe the sensor's response for all four experimental sets. The study varied several key factors, including the sensor's thickness and the skin's surface condition. Wet state represents that the sensor is mounted with a thin layer of ultrasound gel on the skin surface. The dry state represents that the sensor is mounted without any additional layer. The natural elastic properties of PDMS make the sensor to adhere on the skin surface. These factors were tested to evaluate their impact on the detection capability.

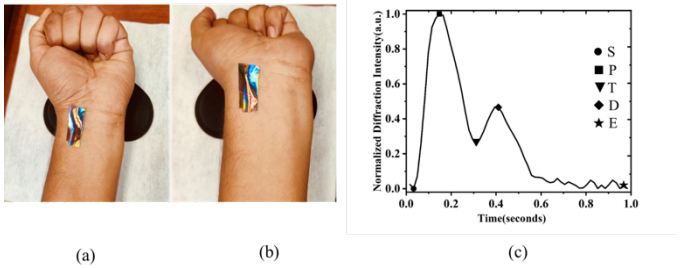

Fig. 5. (a) A sensor positioned on the radial artery indicated as a wrist configuration 1. (b) A sensor positioned on the radial artery indicated as a wrist configuration 2. (c) A measured result of APWs from a thin PDMS grating sensor including five key points: S-systolic phase onset, P-systolic phase peak (systolic pressure), T-dicrotic notch, D-diastolic phase peak, and E-diastolic phase endpoint (diastolic pressure).

Sensor Configuration	Thickness (μm)	Skin of Person's wrist	Wrist configuration
1	Thick 250 μm	Dry	1
2	Thick 250 μm	Dry	2
3	Thick 250 μm	Wet	1
4	Thick 250 μm	Wet	2
5	Thin 100 μm	Dry	1
6	Thin 100 μm	Dry	2
7	Thin 100 μm	Wet	1
8	Thin 100 μm	Wet	2

Table 1. The sensor measurement conditions.

Figure 5(c) shows an example of APW measurement using a thin PDMS grating sensor. The result consists of five key points: S-systolic phase onset, where arterial pressure begins to rise as the heart contracts; P-systolic phase peak (systolic pressure), the maximum pressure during heart contraction; T-dicrotic notch, indicating aortic valve closure and the transition to diastole; D-diastolic phase peak, reflecting stabilized pressure in early diastole; and E-diastolic phase endpoint (diastolic pressure), the lowest arterial pressure during heart relaxation[26]. The measured individual APWs represent similar artery pulse waves with early and late systolic peaks with dicrotic notches observed in other published papers[27], [28], [29], [30].

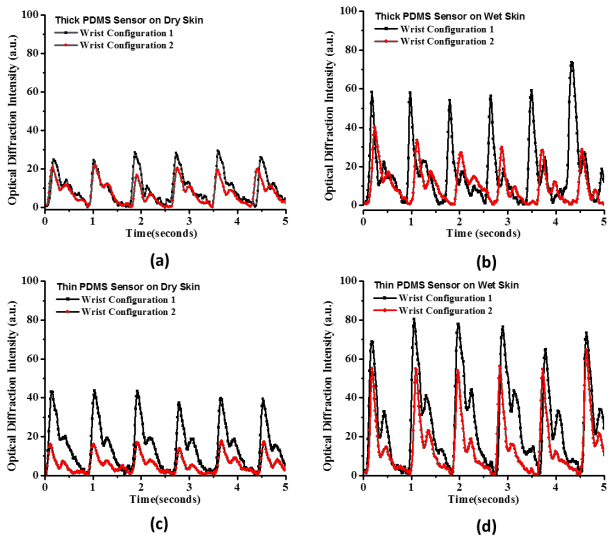

Fig. 6. Measured APWs over a 5-second duration for (a) A thick PDMS sensor placed on dry skin for wrist configuration 1 and 2, (b) A thick PDMS sensor placed on wet skin for wrist configuration 1 and 2, (c) A thin PDMS sensor placed on dry skin for wrist configuration 1 and 2, (d) A thin PDMS sensor placed on wet skin for wrist configuration 1 and 2.

Figure 6 shows the measured responses of APWs over a 5-second duration, using different wrist and sensor configurations. All measurements demonstrate the capability of the sensor to detect APWs successfully, including the five key waveform points. For example, an analysis of the systolic peaks in Figure 6(d) estimates a heart rate of around 67.4 beats per minute, which falls within the normal resting range of adults. However, the sensitivity of the sensor was affected by the measurement parameters. In general, when the wrist is in a stretched position, as seen in configuration 2, the sensor signal is lower. This can be attributed to reduced skin deformation in that configuration, which results in less deformation of the sensor itself.

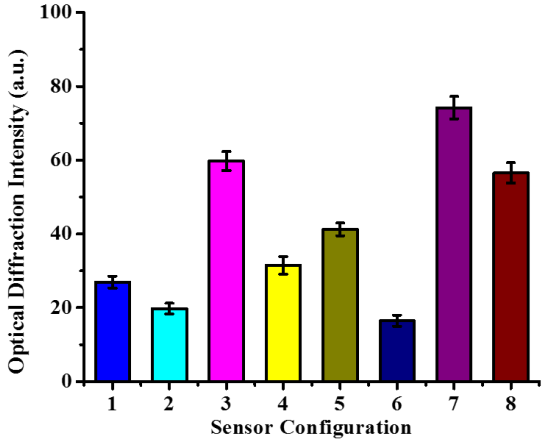

Fig. 7. Summarized measurement results for various sensor configurations.

Figure 7 shows the summarized diffraction intensity for various sensor configurations. The data were obtained from five different regions of interest (ROIs) that exhibited the most pronounced intensity changes for each measurement configuration. The average peak intensity and its standard deviation from the ROIs were extracted. Overall, thinner sensors showed greater changes in diffraction intensity compared to thicker ones, indicating that thinner sensors better followed skin deformation. Additionally, overall sensitivity improved when a thin layer of ultrasound gel was applied to the skin surface before attaching the sensor. It was also confirmed that the sensor could be used multiple times without significant signal loss when the skin was treated with the gel. However, when the sensor was used repeatedly on dry skin, the adhesive strength weakened, which occasionally affected the signal quality. For instance, under wet skin conditions, the diffraction intensity maintained within a 10 % variation over more than 10 cycles of use, provided that the grating surface of the sensor remained undamaged.

IV. Conclusion

A PDMS-based optical grating sensor was developed for non-invasive monitoring of APWs over the radial artery. The sensor was fabricated using a cost-effective soft lithography technique, incorporating a flexible PDMS elastomer with a metal coating to enhance the reflective diffraction pattern. The elasticity of the PDMS film enables the detection of subtle dynamic skin deformations caused by arterial pressure changes. Covering a relatively broad area over the radial artery, the sensor facilitates easy visualization of dynamic optical intensity changes without requiring precise positioning. Various wrist and sensor configurations have demonstrated the sensor's ability to detect APWs successfully, with optimal configurations identified for maximum sensitivity and repeated usage. Considering its low-cost fabrication process, high sensitivity, and ability to operate without complex demodulation schemes and precise positioning, the proposed sensor has significant potential for widespread adaption in general health monitoring systems for evaluating cardiovascular health.

Abstract. A significant evolution has occurred in the realm of medical sciences, attributed to advancements in computing capabilities and refining techniques, particularly in the detection of human heart diseases. Presently, heart diseases rank among the most perilous ailments worldwide, posing severe threats to human life. Prompt and precise identification of these conditions is pivotal in averting heart failure at its nascent stages, thereby enhancing patient survival rates. In addressing these challenges, machine learning algorithms emerge as efficacious and dependable tools for detecting and categorizing individuals afflicted with heart diseases versus those who remain healthy. Leveraging a variety of machine learning algorithms, we embarked on a comprehensive study aimed at identifying and predicting heart diseases, utilizing a heart disease dataset to evaluate performance metrics like sensitivity, specificity, F1-measure, and classification accuracy. Employing five classifiers including Random Forest (RF), Support Vector Machine (SVM), Naïve Bayes (NB), Logistic Regression (LR), and Decision Tree (DT), we subjected the dataset to hyperparameter tuning to enhance classifier efficacy. The proposed decision support system, based on machine learning, is poised to aid doctors in diagnosing heart patients with enhanced efficiency.

1. INTRODUCTION

A heart attack, medically known as a myocardial infarction, represents a critical cardiovascular event marked by the abrupt disruption of blood flow to a segment of the heart muscle [1]. This interruption primarily stems from the obstruction or constriction of coronary arteries, vital conduits responsible for delivering oxygenated blood to the heart. With heart attacks serving as a primary contributor to mortality on a global scale, their prevalence significantly impacts the burden of disease across [2]. Understanding the epidemiology, risk factors, symptoms, and preventive measures associated with heart attacks is crucial for the effective management and prevention of this life-threatening condition[3].

Heart attacks have a substantial impact on public health, affecting millions of individuals globally each year. As per data from the World Health Organization (WHO), cardiovascular diseases, encompassing heart attacks, contribute to roughly 17.9 million fatalities annually, positioning them as the foremost cause of death globally. Within the United States, figures from the Centers for Disease Control and Prevention (CDC) reveal a staggering occurrence rate, with an individual suffering a heart attack approximately every 40 seconds. This equates to an estimated 805,000 Americans experiencing a heart attack annually. Furthermore, heart attacks contribute to significant healthcare costs, hospitalizations, and long-term disability, placing a considerable economic burden on healthcare systems and societies.

Numerous risk factors play pivotal roles in the onset of heart attacks, comprising both modifiable and non-modifiable elements. Modifiable factors encompass lifestyle choices and behaviors that individuals can alter to reduce their risk, such as smoking, unhealthy diet, physical inactivity, and excessive alcohol consumption [4]. Non-modifiable factors, on the other hand, are inherent characteristics or conditions that individuals cannot change, including age, gender, family history of heart disease, and genetic predispositions. Understanding and addressing these risk factors are crucial steps in mitigating the likelihood of experiencing a heart attack. Men face a greater risk of heart attacks than women, although women's risk escalates following menopause [5]. Additionally, individuals with a family history of heart disease are more susceptible to experiencing heart attacks at a younger age. Modifiable risk factors encompass lifestyle behaviors and underlying medical conditions[6]. These include smoking, unhealthy diet, physical inactivity, obesity, hypertension, high cholesterol, diabetes, and chronic stress. Addressing these risk factors through lifestyle modifications and medical management is crucial for reducing the risk of heart attacks and improving overall cardiovascular health.

Heart attacks present with a variety of symptoms, ranging from mild to severe, and may differ among individuals. The predominant symptom is chest pain or discomfort, frequently characterized as pressure, tightness, squeezing, or aching in the chest [7]. Other symptoms may include shortness of breath, nausea, vomiting, indigestion, sweating, lightheadedness, palpitations, and pain or discomfort in the arms, back, neck, jaw, or stomach[8]. However, some people, particularly women, older adults, and individuals with diabetes, may experience atypical symptoms or no symptoms at all, known as silent heart attacks. Early recognition of symptoms and prompt medical intervention are crucial for preventing complications and improving outcomes[9].

Recently, Machine learning (ML) has surfaced as a promising tool. for early prediction and diagnosis of heart attacks[10]. ML algorithms possess the capability to scrutinize extensive sets of patient data, incorporating demographic details, medical records, laboratory findings, imaging results, and lifestyle variables. This comprehensive analysis enables the identification of patterns and facilitates the prediction of heart attack probabilities [11]. By leveraging predictive modeling techniques, ML algorithms can assist healthcare providers in identifying high-risk individuals, enabling targeted interventions and preventive measures to reduce the incidence of heart attacks[12].

Furthermore, ML-based risk prediction tools can be integrated into electronic health records (EHRs) and clinical decision support systems, enabling healthcare providers to assess patients' cardiovascular risk more efficiently and tailor preventive strategies accordingly[13]. By harnessing the power of ML, healthcare systems can enhance risk stratification, optimize resource allocation, and improve patient outcomes in the management of heart attacks and other cardiovascular diseases. ANFIS, FIS and mathematical modeling have been used for different type of work in health and other industries in previous studies [14-28].

2. MATERIAL AND METHODS

The subsequent subsections provide a succinct overview of the research materials and methodologies employed in this study.

15 April 2025 04:45:48

2.1 Dataset: The dataset utilized in this study originates from 1988 and comprises four distinct databases: Cleveland, Hungary, Switzerland, and Long Beach V[29].

TABLE 1: Description of Heart Diseases dataset

SN	Feature Name	Type	Description	Range of values
1	Age	Continuous	Age in Years	$29 \leq Age \leq 77$
2	Sex	Discrete	Male and Female	Male = 1 Female = 0
3	Chest Pain Type	Discrete	Atypical Angina Typical Angina Asymptomatic Nonanginal Pain	Atypical Angina = 1 Typical Angina = Asymptomatic = 3 Nonanginal pain = 4
4	Resting Blood Pressure	Continuous	In mm Hg admitted at the hospital	94mm – 200mm
5	Serum Cholesterol	Continuous	In mg/dl	120 mg/dl -564 mg/dl
6	Fasting Blood Sugar	Discrete	Fasting Blood Sugar $>$ 120 or not	True = 1 False = 0
7	Resting Electrocardiographic Results	Discrete	normal or having ST-T or hypertrophy	Normal = 0; having ST-T = 1; hypertrophy = 2
8	Maximum Heart Rate Achieved	Continuous	-	71-202
9	Exercise Induced Angina	Discrete	Yes or No	Yes = 1; No = 0
10	ST depression induced by exercise relative to rest	Continuous	-	0 – 6.2
11	Slope of the Peak Exercise ST Segment	Discrete	For upslope, Stable and downslope	For upslope = 1; Stable = 2 and downslope = 3
12	Number of Major Vessels (0-3) Colored by Fluoroscopy	Discrete	-	Four classes 0,1,2,3
13	Thallium Scan	Discrete	Normal, fixed defect and reversible defect	Normal = 3; fixed defect = 6 and reversible defect =7
14	Heart Diseases	Discrete	Binary	True = 1, False = 0

Comprising a total of 1025 records, each entry encompasses 76 attributes, inclusive of the predicted attribute. However, the emphasis of this work is on using a subset of the dataset that includes 14 features. The target output label represents two classes, distinguishing between heart patients and normal subjects. Consequently, the extracted dataset forms a 1025 × 13 features matrix. A detailed description of the 1025 instances, each with 13 features, is provided in Table 1.

2.2 Proposed Methodology: The proposed system has been designed with the primary objective of accurately classifying individuals into two categories: those afflicted with heart disease and those who are deemed healthy. The heart disease diagnosis system incorporated a range of machine learning classifiers including LR, K-NN, SVM, RF, and NB. Following this, the model underwent

15 April 2025 04:45:48

rigorous validation and performance assessment using established metrics. The methodology of the proposed system was methodically structured into five discernible stages: (1) preprocessing the dataset, (2) dividing the dataset into training and testing subsets, (3) employing cross-validation techniques, (4) utilizing machine learning classifiers, and (5) assessing classifier performance. The comprehensive approach adopted for heart disease diagnosis is encapsulated in the framework depicted in Fig. 1, signifying a structured and thorough process.

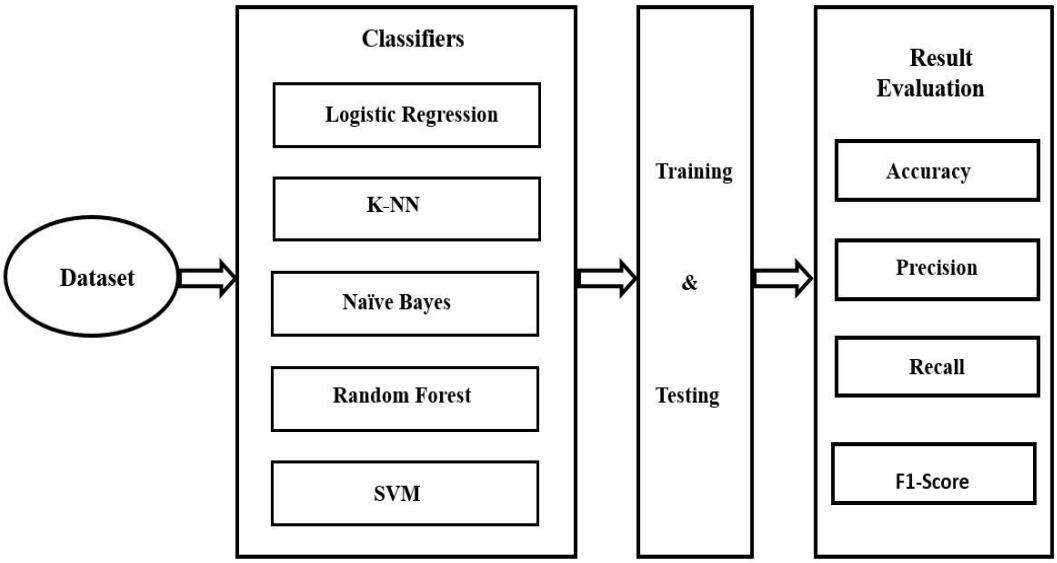

FIG.1: Proposed Methodology for the diagnosis of Heart-Diseases

2.2.1 Data preprocessing: Data preprocessing plays a crucial role in ensuring the efficient representation of data and facilitating the effective training and testing of ML classifiers. To achieve this, various preprocessing techniques, including the removal of missing values, standard scaling, and Min-Max scaling, were applied to the dataset [30]. The standard scalar technique was employed to standardize features by ensuring that each feature has a mean of 0 and variance of 1, thereby bringing all features to the same scale. Similarly, Min-Max scaling was utilized to shift the data so that all features fall within the range of 0 and 1. While missing values were observed to be absent in the dataset used for predicting heart diseases, any rows containing missing values were simply deleted from the dataset. Apart from this, all other steps of data preprocessing techniques were meticulously executed in this research endeavor.

2.2.2 Machine Learning Classifiers: ML Classifiers play a pivotal role in categorizing individuals into heart patients and healthy individuals. These classifiers leverage various classification algorithms to make predictions based on input data[31]. In this paper, several popular classification algorithms and their theoretical underpinnings are succinctly elucidated.

Logistic Regression: LR operates by modeling the relationship between one or more predictor variables and a binary outcome[32]. It employs a logistic function to depict the probability of the binary outcome. This function, commonly referred to as the sigmoid function, is defined as:

15 April 2025 04:45:48

$$h_\theta(x) = \frac{1}{1 + e^{-\theta^t x}} ;$$

Where $h_\theta(x)$ is the predicted probability of the positive class for input x,
θ is the vector of coefficients (parameters) to be estimated,
x is the vector of predictor variables,
$\theta^t x$ is the dot product of θ and x
e is the base of the natural logarithm.
During training, LR aims to estimate the parameters θ that best fit the data. This is achieved by maximizing the likelihood function, which measures the likelihood of the observed data given the parameters θ. Mathematically, it can be expressed as:

$$l(\theta) = \prod_{i=1}^{n} h_\theta\left(x^{(i)}\right)^{y^{(i)}} (1 - h_\theta(x^{(i)}))^{1-y^{(i)}}$$

Where $l(\theta)$ is the likelihood function,
$x^{(i)}$ is the ith observation (input data),
$y^{(i)}$ is the ith (binary outcome),
$h_\theta(x^{(i)})$ is the predicted probability for the ith observation.
The parameters θ are estimated by minimizing the negative log-likelihood function (or maximizing the log-likelihood function). This optimization task is commonly tackled through iterative optimization algorithms like gradient descent or Newton'os method. Once the parameters θ are estimated, Logistic Regression can make predictions on new data by applying the logistic function to calculate the predicted probabilities. A decision threshold (usually 0.5) is then applied to these probabilities to classify the observations into the positive or negative class.
Finally, the performance of the LR model is assessed through diverse metrics to assess its effectiveness in binary classification tasks, providing interpretable results and insights into the relationship between predictor variables and outcomes.

Random Forest: A RF comprises a multitude of decision trees, each trained on a random subset of both data and features. Predictions from the Random Forest are derived by consolidating the forecasts of individual trees, usually employing a majority voting mechanism for classification purposes [33]. So, the classifier employs an ensemble of decision trees to make predictions, utilizing the following mathematical equation:

$$\hat{Y} = \frac{1}{N} \left(\sum_{i=1}^{N} T_i(X)\right);$$

Where $\hat{Y}$ represents the predicted class for a given input X,
N represents the number of decision trees in the RF ensemble,
$T_i(X)$ stands for the prediction of the ith decision tree on input X.
Each decision tree is constructed based on a random sampling of the data and features, and its prediction is obtained by the majority vote of the nodes within the tree. The ultimate forecast of the Random Forest is achieved by consolidating the predictions made by all decision trees within the ensemble. By employing this ensemble methodology, the Random Forest classifier attains

15 April 2025 04:45:48

resilience and precision in its prognostications, thereby rendering it appropriate for a diverse range of classification undertakings.

Support Vector Machine: In order to group data points into discrete groups and maximize the margin between them while minimizing classification errors, the SVM classifier determines the best hyperplane [34]. It achieves this by finding the decision boundary that best separates the support vectors of each class.

$$f(x) = sign\left(\sum_{i=1}^{n} \alpha_i y_i K(x_i, x) + b\right)$$

Where $f(x)$ represents the decision function for classifying new data point x,
α_i are the Lagrange multipliers determined during the process of training,
y_i is the class label of the training data point x_i
$K(x_i, x)$ is the kernel function, which measures the resemblance between x_i and x,
B is the bias term.
In linear SVM, the kernel function $K(x_i, x)$ simplifies to the dot product of the input vectors x_i and x. However, for non-linear SVM, diverse kernel functions like polynomial or radial basis functions are utilized to transform the input data into a higher-dimensional space, enabling a linear hyperplane to segregate the classes. Throughout training, SVM endeavors to maximize the margin, defined as the distance between the hyperplane and the nearest data points (support vectors) of each class. This optimization task typically involves solving a convex quadratic programming problem using optimization techniques. Once the optimal hyperplane is established, SVM can classify new data points by assessing the decision function f(x), assigning them to the class based on the function output's sign. Through this mathematical framework, SVM achieves efficient binary classification by identifying the hyperplane that effectively separates the data points of distinct classes while maximizing the margin.

K-Nearest Neighbor: For tasks involving regression as well as classification, the non-parametric k-NN classifier is employed [35]. To function, a data point is allocated to the majority class among its k nearest neighbors in the feature space. Mathematically, the process can be represented as follows:

$$\hat{y}(x) = mode\ (y_{i1}, y_{i2}, y_{i3}, \ldots, y_{ik})$$

where $\hat{y}(x)$ denotes the predicted class for the data point.
$(y_{i1}, y_{i2}, y_{i3}, \ldots, y_{ik})$ Represents the class labels of the k nearest neighbors of x.
Mode calculates the most frequent class label among the k neighbors.
In simple terms, k-NN determines the class of a data point by considering the classes of its nearest neighbors. The value of k is a hyperparameter that needs to be specified before training. Larger values of k result in smoother decision boundaries but may lead to misclassification of data points near the boundary. Conversely, smaller values of k result in more complex decision boundaries but may be sensitive to noise in the data.

15 April 2025 04:45:48

Gaussian Naive Bayes: Based on the Bayes theorem, the NB classifier asserts that characteristics, given the class label, are conditionally independent [36]. Mathematically, the classification decision for a new data point x can be expressed as:

$$\hat{y} = \underbrace{\arg\max P(y \mid x)}_{y} = \underbrace{\arg max}_{y} \frac{P(x|y)\,P(y)}{P(x)}$$

In this equation $\hat{y}$ represents the predicted class for the new data point x.
P (y | x) represents the posterior probability of class y given the features x.
P (x | y) represents the likelihood of observing features x given class y.
P(y) represents the prior probability of class y.
P(x) represents the probability of observing features x (often considered as a constant for all classes and thus ignored in the classification decision).

2.2.3 Training and Testing: The dataset is partitioned into training and testing data sets. The training set comprises instances with known outputs, which the model utilizes to learn and later generalize its predictions to unseen data. In this study, training is conducted using 70% of the dataset. Accordingly, 717 cases out of 1025 instances in the dataset are selected as the training set, while the remaining 308 instances are allocated for testing purposes, representing 30% of the total data. To optimize model performance, a technique known as parameter tuning is employed, ensuring that each model operates at its highest potential.

3. RESULT AND DISCUSSION

In this study, we implemented the k-fold cross-validation (CV) method alongside four distinct performance evaluation metrics. The k-fold cross-validation technique involves dividing the dataset into k equal-sized segments, where k - 1 groups serve as training data for the classifiers, and the remaining portion is reserved for performance evaluation in each iteration. This validation procedure is iterated k times, with the classifier's performance gauged based on the outcomes of these k iterations. Various values of k can be chosen for CV, and for our experiment, we selected k = 10 due to its favorable performance. Throughout the 10-fold CV process, 90% of the data were utilized for training, while the remaining 10% were earmarked for testing. This iterative process was repeated 10 times for each fold, with instances randomly allocated to training and testing groups before each cycle. Subsequently, following the 10-fold process, the averages of all performance metrics were computed to comprehensively evaluate the classifier's overall performance.

3.1 Performance Evaluated by the Classifiers: Table 2 presents the performance metrics of different classifiers. The Random Forest classifier achieves an accuracy of 98.05%, with perfect precision and a high recall of 95.97%, resulting in an F1-score of 97.94%.
Similarly, the K-NN classifier demonstrates superior performance, with an accuracy of 99.02%, perfect precision, a high recall of 97.99%, and an impressive F1-score of 98.98%. In contrast, both Logistic Regression and Gaussian classifiers exhibit lower accuracy, precision, and recall values. Logistic Regression achieves an accuracy of 81.16%, with a precision of 77.24%, recall of 86.57%, and an F1-score of 81.64%. The Gaussian classifier shows comparable results, with an accuracy of 81.49%, precision of 76.44%, recall of 89.26%, and an F1-score of 82.35%.

15 April 2025 04:45:48

TABLE 2: presents the performance metrics of different classifiers

	Accuracy	Precision	Recall	F1-Score
Random Forest	**98.05**	**100**	**95.97**	**97.94**
K-NN	**99.02**	**100**	**97.99**	**98.98**
Logistic Regression	**81.16**	**77.24**	**86.57**	**81.64**
Gaussian Naïve Bayes	**81.49**	**76.44**	**89.26**	**82.35**
SVM	**97.08**	**100**	**93.96**	**96.89**

While comparing the results with the statistical graph that are shown in Fig. 2, we observe the following points:

1. Accuracy and Precision: Random Forest and K-NN classifiers demonstrate superior accuracy and precision, achieving near-perfect scores of over 98%. SVM also shows high accuracy and perfect precision, while Logistic Regression and Gaussian classifiers exhibit lower scores, indicating less reliable classification.
2. Recall: K-NN classifier achieves the highest recall, indicating its ability to effectively capture positive instances, closely followed by Random Forest. While SVM also performs well in recall, Logistic Regression and Gaussian classifiers have comparatively lower recall rates, suggesting they may miss some positive instances.
3. F1-Score: K-NN classifier achieves the highest F1-score, reflecting a balanced performance in terms of precision and recall. Random Forest also demonstrates a strong F1-score, indicating a good balance between precision and recall. On the other hand, Logistic Regression and Gaussian classifiers exhibit lower F1-scores, suggesting a trade-off between precision and recall.
4. Robustness: Random Forest and K-NN classifiers appear to be more robust, as they consistently perform well across all metrics. SVM also shows robust performance, particularly in accuracy and precision. However, Logistic Regression and Gaussian classifiers display more variability in performance, with lower scores in some metrics.
5. Model Complexity: Random Forest and K-NN classifiers are relatively simple models yet achieve high performance, making them suitable choices for various classification tasks. SVM, while more complex, also demonstrates strong performance. In contrast, Logistic Regression and Gaussian classifiers are simpler models but show comparatively weaker performance, indicating limitations in capturing complex relationships in the data.

15 April 2025 04:45:48

4. CONCLUSION

Heart disease remains a significant public health challenge, contributing to substantial morbidity, mortality, and healthcare costs worldwide. Understanding the epidemiology, risk factors, symptoms, and preventive measures associated with heart disease is essential for reducing the burden of this disease and improving cardiovascular health. Machine learning offers exciting opportunities for early prediction and diagnosis of heart attacks, empowering healthcare providers to identify high-risk individuals and implement targeted interventions to prevent adverse cardiovascular events. By leveraging ML algorithms and predictive modeling techniques, healthcare systems can enhance risk stratification, optimize resource allocation, and improve patient outcomes in the management of heart attacks and other cardiovascular diseases. Through continued research, innovation, and collaboration, ML-based approaches have the potential to revolutionize the prevention, diagnosis, and treatment of heart attacks, ultimately saving lives and improving the quality of care for individuals at risk.

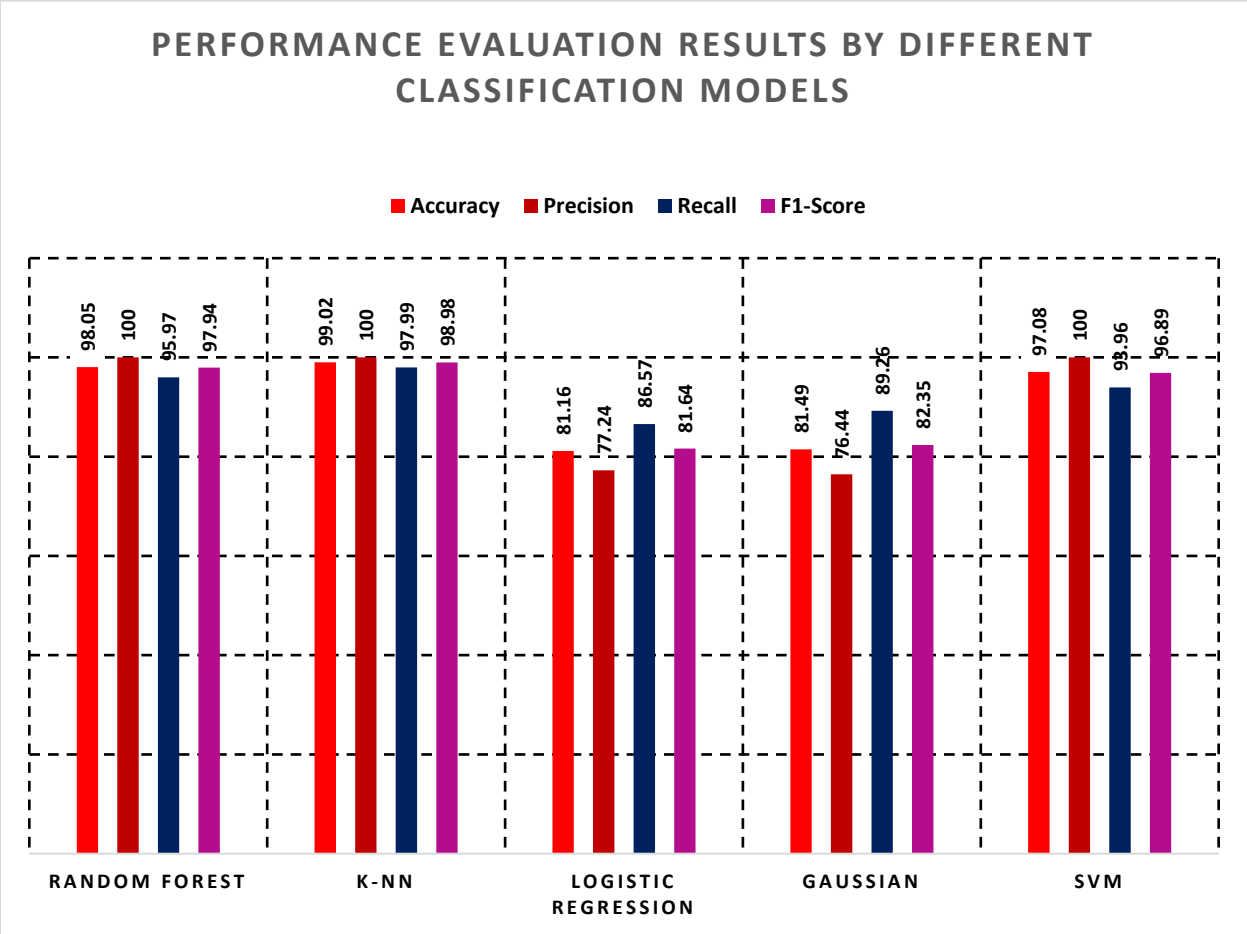

FIG.2: Performance Evaluation Results by different classification Models

The comprehensive evaluation of various classification algorithms provides invaluable insights into the diagnosis of heart diseases. With high accuracy, precision, recall, and F1-scores, the Random Forest and K-NN classifiers emerge as robust contenders, showcasing their efficacy in accurately identifying individuals with heart conditions. Their remarkable performance

15 April 2025 04:45:48

underscores their potential as reliable tools in clinical settings for early detection and intervention. Furthermore, the solid performance of the SVM classifier reaffirms its utility, particularly in scenarios where precision and accuracy are paramount. However, the comparatively lower scores of the Logistic Regression and Gaussian classifiers suggest potential limitations in their ability to discern subtle patterns within the data. Nonetheless, these findings collectively emphasize the significance of leveraging machine learning algorithms for enhancing the diagnostic process of heart diseases, ultimately contributing to improved patient outcomes and healthcare management.

Does ESG impact corporate performance in environmentally sensitive and non-sensitive industries? A dynamic panel approach

Prachi Jain and Priya Malhotra
University School of Management and Entrepreneurship (USME), Delhi Technological University, Delhi, India

Received 7 July 2024
Revised 13 January 2025
26 February 2025
Accepted 28 February 2025

Abstract

Purpose – This study explores how aggregate ESG disclosure, along with its three individual dimensions – environmental, social and corporate governance – affects corporate performance by categorizing corporations into environmental sensitivity industries (SI), characterized by business activities with significant socioenvironmental landscapes and more likely to damage social and environmental factors and non-environmental sensitivity industries (NSI) in India.

Design/methodology/approach – This research employs a system-generalized method of moments (GMM) technique to analyze 605 Indian firms listed on the National Stock Exchange (NSE) from 2015 to 2023. The methodology ensures robust and endogeneity-resistant results, reliably assessing the relationship between the variables.

Findings – The study indicates that ESG factors influence corporate outcomes differently across industries, and simply following sustainability – is somewhat naïve. In SI industries, ESG efforts show an insignificant association and implementing effective systems for corporate governance reduces profitability due to challenges and scrutiny from stakeholders. Conversely, NSI corporations benefit significantly from ESG practices, enhancing long-term value and investor appeal.

Originality/value – The research offers novelty and contributes to the existing literature by providing robust empirical evidence on the diverse impact of ESG (and its dimensions). It underscores the necessity for concerned companies, especially in emerging economies, to customize sustainable strategies that align with their unique operational contexts. The findings provide valuable insights for managers seeking to effectively manage ESG implementation and its financial effects, enhancing strategic approaches to sustainability in different industry contexts.

Keywords ESG disclosure, Environmental disclosure, Social disclosure, Corporate governance disclosure, Corporate performance, Environmental sensitivity, System-generalized method of moments (GMM), Indian firms

Paper type Research paper

1. Introduction

In recent years, sustainability has become integral to corporate strategy, emphasizing long-term viability and financial market resilience (Aras *et al.*, 2018). This shift stems from corporations' concerns about economic stability, investor confidence, and competitive advantage. Thus, sustainability has emerged as a critical factor for organizational success and growth, focusing on waste management, carbon footprint reduction, and operational efficiency (Eccles and Serafeim, 2013). This transition is fueled by growing stakeholder awareness (Maji and Lohia, 2023), prompting firms to consider environmental and social responsibility alongside profit maximization (Arianpoor *et al.*, 2023; Khandelwal *et al.*, 2023). As social and climate change gain prominence (Ge *et al.*, 2016; Quang *et al.*, 2022), they converge environmental stewardship, social responsibility, and corporate governance

performance into (ESG) principles. The ESG word, first introduced by the United Nations in 2004 through the "Who Cares Wins (n.d.)" reports, guides investors in integrating environmental, social, and governance factors into their investment decisions (United Nations, 2020).

With the growing interest, ESG reporting has become a pivotal framework for assessing corporate sustainability (Kolk and Perego, 2010; Zhou, 2022). Effective ESG management mitigates environmental degradation, social controversies, and governance scandals risk, thereby averting financial and reputational harm (Eccles *et al*., 2014). Moreover, robust ESG performance can lead to cost savings through enhanced efficiencies, reputation, financing, profitability, and lower capital costs. These advantages, however, are contingent on market conditions, regulations, and firm actions (Busch *et al*., 2016; Eccles *et al*., 2014). Hence, the influence of ESG on the performance of corporations can be complex, influenced by the company's operations and commitment to adopting eco-friendly practices (Rahman *et al*., 2023).

The relationship between ESG and corporate performance is intricate and context-dependent, yielding mixed results across past studies (Alareeni and Hamdan, 2020; Jyoti and Khanna, 2021; Rahman *et al*., 2023; Savio *et al*., 2023; Zhou *et al*., 2022). Some research reflects that ESG benefits (Rahman *et al*., 2023), while others report insignificant or negative (Almulhim and Aljughaiman, 2023; Brammer *et al*., 2005; Jain *et al*., 2019). Discrepancies arise from data selection, sample size, industries, timing, methodology, and study context (i.e. developed vs. developing countries listed or following a particular index) (Busch *et al*., 2016). Furthermore, ESG approaches and performance metrics further complicate the findings, especially in emerging markets (Orlitzky *et al*., 2003; Orlitzky and Shen, 2013). These inconsistencies underscore the need for more rigorous research on this domain (Khan, 2022; Lin *et al*., 2019).

Due to significant challenges, industries with high environmental impact, such as oil, chemicals, and mining, face increasing regulatory pressure to improve their environmental performance (Pisani *et al*., 2017). Indian firms are no exception, including those involved in environmental disasters over the past decades; notable examples include the Bhopal disaster in 1984, the world's worst industrial accident caused by methyl isocyanate gas exposure, and the 2020 Assam gas leak, which resulted in a blown out, methane leakage, subsequent fires, fatalities, and environmental damage. These incidents have heightened scrutiny of corporate sustainability. Hence, Indian firms now prioritize ESG disclosure to enhance credibility and secure stakeholder support (Braam and Peeters, 2018; Dong *et al*., 2014; Tadros and Magnan, 2019). However, such reporting is often met with skepticism, as stakeholders question the credibility of environmental claims (Cho and Patten, 2007). To address this, many companies seek external assurance from an independent third party to enhance their ecological disclosure credibility and safeguard their image and reputation by procuring voluntary external assurance services (Gillet-Monjarret, 2015; Cho *et al*., 2014).

This study categorizes firms based on environmental sensitivity. Following the definition by Halkos and Skouloudis (2016), environmentally sensitive industries comprise sectors whose business activities significantly impact the socio-environmental landscape. In line with prior studies, Gracia and Siregar (2021), Miralles-Quirós *et al*. (2018), and Yoon *et al*. (2018), we classify industries within the energy, material, and utilities sectors as environmentally sensitive industries, following the Global Industry Classification Standard (GICS). All other industries are categorized as NSI industries. Unlike prior studies that primarily focused on developed economies (Ademi and Klungseth, 2022; Hamrouni *et al*., 2019), this study diverges from and extends the literature by investigating the relationship between ESG disclosure and corporate performance in SI and NSI companies in India, a rapidly growing economy. We examine how ESG disclosures affect operating, financial, and market performance throughout 2015–2023, encompassing Indian listed firms. This study determines whether there is any difference in industries' profitability due to sustainability, highlighting the varying effects on corporate performance in SI and NSI (Arian *et al*., 2023;

Omar and Zallom, 2016). Moreover, we incorporate individual ESG dimensions — environmental, social, and corporate governance —offering nuanced insights into their distinct impacts. At this end, the following research question will be explored. How does the extent of ESG disclosure impact corporate performance (i.e. operating, financial, and Tobin's Q) in the environmentally sensitive and non-sensitive industries of Indian companies? Is there any difference in the association between ESG (and its dimensions) and corporate performance based on the environmental sensitivity of the corporation?

Notably, we focused on India for several reasons. India became one of the world's top five economies in terms of Gross domestic product (GDP) [1] and most prominent in terms of demographic footprints, overtaking China [2]. It emerged as a leading participant in sustainability discourse, driven by its unique institutional environment, cultural diversity, and evolving regulatory framework. A notable shift towards sustainable practices is evident, as Indian corporations are progressively embracing Corporate Social Responsibility (CSR) initiatives and releasing comprehensive "Business Responsibilities and Sustainability Reports (BRSR)" in 2021 as a result of regulatory requirements such as the Companies Act of 2013 and supervision from the Securities and Exchange Board of India (SEBI). With mounting scrutiny from regulators and investors, the volume of ESG research has seen significant growth, particularly in exploring the interaction of ESG factors and profitability, particularly in the Indian context (Narula *et al*., 2024; Nenavani *et al*., 2024; Sharma *et al*., 2019; Suprabha *et al*., 2024; Veeravel *et al*., 2024a, b; Yadav and Jain, 2023).

Furthermore, India's rapid economic growth and technological advancement have also intensified environmental challenges (Malik and Kashiramka, 2024). Additionally, the country's vulnerability to climate change (manifested in rising sea levels and extreme weather events) emphasizes the critical need for corporations to adopt robust environmental practices that mitigate risks and contribute to a sustainable future. Hence, Indian firms' environmental commitments are pivotal in global climate change efforts (Lu and Cheng, 2023; Zhao *et al*., 2018). Addressing social issues like poverty, inequality, and access to basic needs aligns corporate strategies with societal goals. Strong governance practices enhance accountability, attract investment, and build trust in the evolving market. Furthermore, increasing public awareness, stakeholder activism, and shifting consumer preferences have intensified the demand for ESG adoption. Moreover, India's prominence as a top investment destination in Europe and the US, driven by efforts to reduce reliance on uncertain economies, further amplifies the global significance of its sustainability practices (Narula, 2012; Palmate *et al*., 2021; Rao *et al*., 2023). India is also at the forefront of development among emerging nations [3], offering significant value as a model that can be replicated in other emerging countries. The country's evolving sustainability landscape, regulatory advancements, and corporate strategies for ESG provide actionable insights for nations with similar socioeconomics and institutional contexts.

This study makes several contributions to the existing literature. First, it addresses a critical gap by focusing on the association between ESG reporting and corporate performance in SI and NSI companies. It also conducts an industry-focused study for India, providing implications for other emerging markets. Second, it explores how environmental sensitivity influences ESG's impact on operational, financial, and market performance, providing an in-depth understanding of the orientation diversity and sensitivity in ESG practices. Third, it considers individual ESG dimensions (E, S, and G) beyond overall ESG impact, offering different perspectives. Fourth, the study's rigorous methodology uses a robust econometric approach, specifically system-GMM, to control for time effects and potential endogeneity issues, thereby enhancing the credibility and generalizability of the findings. Fifth, we employed a sample of Indian listed companies rather than relying on any specific representative index, enhancing its generalizability across- small, medium, and large enterprises. This broad sampling approach ensures that the findings are equally replicable to various companies in the securities basket, providing more comprehensive insights to managers and investors. Finally, the empirical results assist in designing legal and regulatory

frameworks for enhancing sustainability in respective industries. As a result, it suggests that ESG factors influence corporate outcomes differently across both industry types, and simply following sustainability- is somewhat naïve. Across listed businesses in SI, there is an insignificant association with strengthening the credibility of their non-financial reporting and implementing effective systems for corporate governance, reducing profitability as sensitive firms face more challenges and scrutiny from stakeholders. Meanwhile, in NSI companies, ESG practices positively and significantly enhance performance, highlighting their importance for long-term value creation and investor recognition. The varying effects of environmental, social, and governance (ESG) factors underscore the need for companies to develop customized sustainable strategies to see both SI and NSI corporations succeed economically.

2. Theoretical background and literature review

The relationship between ESG and corporate performance has garnered significant attention, with numerous meta-analyses and literature surveys examining the dynamic (Brooks and Oikonomou, 2018; Friede *et al*., 2015; Hang *et al*., 2019). For instance, Peloza (2009) and Friede *et al*. (2015) report that most research indicates positive results, attributing this to competitive advantage (Danso *et al*., 2019) by enhancing reputation (Zimon *et al*., 2022) and consumer loyalty (Orlitzky *et al*., 2003). This, in turn, is expected to boost profits (Freeman, 1984). Furthermore, Chen *et al*. (2023a, b) found that ESG substantially impacts profitability in large-scale companies and high-risk scenarios. Conversely, some studies highlight the costs and time required for sustainable practices, which may reduce profitability (Jaeger and Upadhyay, 2020; Cerciello *et al*., 2023). Others, like Franco *et al*. (2020), discover a U-shaped, indicating the complexity of ESG's impact.

2.1 Aggregating ESG and corporate performance

Despite the extensive studies, there still needs to be a consensus on the impact of ESG disclosure on firm profitability (Khandelwal *et al*., 2023; Lu and Cheng, 2023). For instance, Salehi and Arianpoor (2021) reveal a mutual relationship between financial and non-financial sustainability performance, emphasizing the need for a comprehensive approach to assessing sustainability performance across various components. Variability in empirical findings from diverse characteristics of ESG data and methodologies employed in its collection and analysis (Busch and Hoffmann, 2011; Chatterji *et al*., 2009; Stefan and Paul, 2008). Studies reveal that firms disclose their ESG commitment to meet legitimacy criteria and improve performance (Lee and Raschke, 2023). Contrary to these observations, agency cost theory posits that sustainability disclosures adversely impact the firm value due to associated costs (Giannopoulos *et al*., 2022; Hussaini *et al*., 2021; Lahouel *et al*., 2021). Nevertheless, these practices may yield positive effects in the long term (Behl *et al*., 2022).

Stakeholder theory claims that fostering positive relationships with internal and external stakeholders through corporate disclosure enhances performance, thereby ensuring long-term business sustainability (Freeman, 2010). Also, ESG practices assist in bolstering efficiency and value (Mohammad and Wasiuzzaman, 2021). Chelawat and Trivedi (2016) assess that ESG positively influences not only market value but also the operating and finances of the firms. A strong ESG score enhances reputation (Pham and Tran, 2020), lower debt cost (Gigante and Manglaviti, 2022), and improves capital access at a lower rate (Ramirez *et al*., 2022; Wong *et al*., 2021). These benefits are observed in developed economies (Gartia and Panda, 2024) due to stringent regulations and effective ESG communication. Recently, emerging economies have also moved towards mandatory regulations. For instance, Indian regulators have mandated ESG disclosures for India's top 1,000 listed companies. Complying with these requirements necessitated substantial investments, meaning firms must have adequate financial resources to support and enhance their ESG disclosures.

In India, the impact of ESG disclosures on corporate performance yields mixed results. For instance, a 2024 study by Veeravel *et al.* (2024a, b) using GMM methodology reveals that better ESG disclosures lead to superior financial performance. Anklesaria-Dalal and Thaker (2019), Chelawat and Trivedi (2016), and Sinha Ray and Goel (2023) similarly note that improved accounting and market-based outcomes for firms with strong ESG performance. However, Bansal *et al.* (2022) find benefits only when sustainability reporting exceeds a certain threshold. Gupta *et al.* (2021) emphasize the significant role of environmental sustainability across performance dimensions. In contrast, Jha and Rangarajan (2020) reported no substantial link, indicating that firms with varying sustainability measures performance are similar in economic measures. In another study, Mishra *et al.* (2024) show a significant negative of ESG disclosures on performance measures. This diverse body of literature highlights that ESG factors can vary widely depending on the specific measures and thresholds considered.

2.2 Environmental practices and corporate performance

Environmental practices have been a focal point for researchers (Pinheiro *et al.*, 2022), with their financial results have yielded contrasting results, being described as positive, negative, insignificant, U-shaped, and even reverse U-shaped (Guenther and Hoppe, 2014; Lee *et al.*, 2016; Lewandowski, 2017; Wagner, 2005). Some studies reveal that environmentally friendly activities yield superior profits (Blanco *et al.*, 2009; Molina-Azorín *et al.*, 2009; Nakao *et al.*, 2007; Schultze and Trommer, 2012). As a pioneering study, Cohen *et al.* (1997) analyzed S&P 500 constituents between 1987 and 1989 and found that environmental compliance positively affected return on assets and equity. Subsequent studies have corroborated these findings with meta-analyses, confirming a linear and positive association between corporate environmental performance and financial profitability. This positive is observed in developed countries (Campbell, 2007; Fijałkowska *et al.*, 2018) and emerging economies (Manrique and Martí-Ballester, 2017; Voinea *et al.*, 2020). The natural resource-based viewpoint is that corporate environmental practices offer a competitive advantage, resulting in better financial outcomes (Hart, 1995; Hart and Dowell, 2011; Russo and Fouts, 1997). Another strand of literature reports a negative association (Boakye *et al.*, 2021; Hasan *et al.*, 2022; Preston and O'Bannon, 1997; Wong *et al.*, 2018). For instance, Xie *et al.* (2019) found a significant negative effect of environmental commitment on profitability across nearly 7,000 firms in 74 countries. According to neoclassical theories, the costs of implementing ecological activities can outweigh the benefits, thus reducing competitiveness (Ayayi and Wijesiri, 2022; García-Sánchez and Prado-Lorenzo, 2012; Jo *et al.*, 2015; Lioui and Sharma, 2012), since environmental initiatives require time and cost.

A third tranche of the literature suggests that the relationship between environmental practices and financial profitability is more complex than simply negative and positive; some research argues for a neutral impact (Ortiz-de-Mandojana and Aragon-Correa, 2015; Zou *et al.*, 2015) while others U-shaped and inverse U-shaped effect (Boakye *et al.*, 2020; Guo and Lu, 2021). For instance, Horváthová (2012) found that the relationship between environmental practices and profitability initially appears hostile but turns positive over time. The lack of consensus partly stems from the heterogeneity of measures to capture the environmental impact. Different methodologies and contexts make it challenging to generalize findings.

2.3 Social practices and corporate performance

The relationship between CSR and firm performance continues to be a topic of significant debate (Adamkaite *et al.*, 2023), with studies offering three main perspectives: positive, negative, and non-linear. The first tranche of literature supports stakeholder theory and supports a positive association between CSR and financial performance. According to Freeman (1984), firms exist within an ecosystem of stakeholders, including employees, customers, suppliers, communities, and shareholders. Engaged stakeholders contribute to

better financial outcomes, ensuring long-term success (Mhlanga and Moloi, 2020) and sustainability (Kitchen, 2020). Conversely, another tranche posits that CSR harms financial performance (Aupperle *et al*., 1985; Graves and Waddock, 2000). A recent study using data from 15 countries (2011–2020) reveals that CSR hinders firm performance (Hsiao *et al*., 2024). This view is supported by the trade-off theory, which argues that pro-social activities impose additional costs on firms, ultimately reducing profitability (Cai *et al*., 2016; Friedman, 1970).

Research by Nollet *et al*. (2016) and Mittal *et al*. (2008) concludes that firms committed to CSR generate significantly less economic value. The agency theory further supports this view, suggesting that managers pursue social contribution for personal reputation at the expense of shareholders, leading to deterioration in firm wealth (Barnea and Rubin, 2010). Consequently, social activities are often seen as problems with the managerial agency (Benbou and Tirole, 2010; Masulis and Reza, 2013). Other studies indicate no association (Garcia-Castro *et al*., 2010; McWilliams and Siegel, 2000) or non-linear relationships (Flammer, 2015). For instance, Wagner and Schaltegger (2004) show that CSR and firm outcomes have an inverted U-shaped curve relationship based on data from the EU manufacturing industry. Similarly, Kim and Statman (2012) report that social commitment increases financial profitability only up to a certain point, after which it has a negative performance effect, aligning with this agency's view (Flammer, 2015).

2.4 Governance practices and corporate performance

This relationship has been extensively reviewed, with studies presenting various perspectives (Martínez-Ferrero and Frías-Aceituno, 2015; Nguyen *et al*., 2021; Rodriguez-Fernandez, 2016). Corporate governance arises from the separation of business ownership (principals/shareholders) and the management (agents), encompassing the rules and practices that guide firm operations and align stakeholders' interests (Cuervo, 2002). Effective corporate governance promotes sustainable development and ethical business practices (Lambertini and Tampieri, 2015; Manasakis *et al*., 2014) while mitigating sustainability-related controversies. The board of directors is critical in ensuring the firm's financial viability (Agnese *et al*., 2023).

A significant body of literature suggests a positive association between corporate governance and financial profitability. Stewardship theory posits that employees are intrinsically motivated to perform the tasks, leading to improved business track records (Davis *et al*., 1997; Muth and Donaldson, 1998). Donaldson and Preston (1995) claims that top management does not need to oversee manager's work closely, as they aim to achieve superior financial results. Alternatively, resource dependency theory supports the positive relationship, emphasizing that governance must interact with external organizations to secure essential resources for firm survival (Pfeffer and Salancik, 1978). Implementing effective management frameworks and governance structures can improve financial results and competitive advantage (Hillman *et al*., 2000). Conversely, some studies identify a negative relationship (Agrawal and Knoeber, 1996; Saidat *et al*., 2019). Cherian *et al*. (2019) find that specific corporate board characteristics negatively impact ROE. Similarly, Paniagua *et al*. (2018) analyzed 1,207 companies from 59 countries across 19 sectors (2013–2015) and observed the adverse effects of corporate governance on performance. The agency cost theory explains these results, posing that those managers may not act in the owners' best interest due to a lack of incentives (Jensen and Meckling, 1976). Although appropriate rewards can mitigate the agency problem (Grossman and Hart, 1986), they might backfire, leading managers to pursue personal goals over the firm's best interest (Brown, 2006; Krüger, 2015).

2.5 ESG disclosure and controversial environmentally sensitive firms

The variability in social or environmental disclosure content across different industries is a focal point of current research (Branco and Rodrigues, 2008; Teng *et al*., 2021). Studies by

Han *et al*. (2021) and Huang *et al*. (2024) emphasize the challenges faced by inherently more polluting industries such as thermal power generation and steel production. These sectors, characterized by significant environmental footprints, are under intense stakeholder pressure and social scrutiny, which drive them towards extensive ESG disclosure. Kuo and Chang (2021) note that firms in SI face unique challenges in ESG reporting, using Sustainable Development Goals (SDG) reporting as a strategy to mitigate negative public image. Since 2015, research has focused on ESG within specific sectors, particularly the energy industry (Horobet *et al*., 2024; Makridou *et al*., 2024). For instance, Zhao *et al*. (2017) find that high ESG can enhance the financial performance of firms in Chinese energy power. In contrast, Adamkaite *et al*. (2023) conclude that sustainability efforts do not impact the economic performance of nine Lithuanian energy companies. Similarly, Constantinescu *et al*. (2021) discover a varied connection between ESG and market values across various sectors, such as oil and gas, renewable energy, and utilities, indicating both positive and a negative link. Another study in the Indian context finds that while ESG disclosure positively affects firm performance, the relationship is moderated by industry climate sensitivity, with the effect being more substantial for less climate-sensitive industries (Maji and Lohia, 2024).

Although the global interest in ESG (Arianpoor and Salehi, 2020; Chen and Zhang, 2024; Chen *et al*., 2023a, b; Nie *et al*., 2024; Salehi *et al*., 2018; Salehi and Arianpoor, 2021; Shafeeq Nimr Al-Maliki *et al*., 2023; Zhou *et al*., 2024; Zimon *et al*., 2022), few studies have differentiated the impact between environmentally sensitive and non-sensitive industries (Naeem *et al*., 2022). Research indicates that firms in SI exhibit higher environmental performance, where they define sensitive industries as those operating in sectors marked by societal taboos, moral conflicts, and political pressure, including weapons, nuclear, biotech, gambling, alcohol, and adult entertainment. Moreover, environmentally sensitive industries encompass energy, mining, metals, construction, chemicals, pulp, and paper, known for their significant environmental impact and regulatory scrutiny (Garcia *et al*., 2017). Companies in these industries invest heavily in environmental and social management to mitigate their operational impact and face stricter regulatory frameworks and social pressures due to their substantial environmental footprints (Miralles-Quirós *et al*., 2018). However, this study defines environmentally sensitive industries as those whose business activities significantly impact socio-environmental landscapes (Halkos and Skouloudis, 2016). In line with prior studies, Gracia and Siregar (2021), Miralles-Quirós *et al*. (2018), and Yoon *et al*. (2018), we classify industries within the energy, material, and utilities sectors as environmentally sensitive industries, following the GICS. All other industries are categorized as non-environmentally sensitive industries.

Previous studies point out different firm characteristics due to the firm's affiliation with SI (Iatridis, 2013; Miralles-Quirós *et al*., 2018; Wang *et al*., 2022; Yoon *et al*., 2018). ESG disclosure in these industries may not significantly contribute to corporate sustainable growth, potentially due to the stricter regulatory scrutiny and accusation of "greenwashing" (Ren *et al*., 2022b). This scrutiny leads firms to use impression management tactics in their sustainable disclosures (Appiagyei and Donkor, 2024; Hahn and Lülfs, 2013). Xue *et al*. (2023) highlight that regardless of the disclosure regime, an adverse relationship exists between disclosures and firm value, with the effect being more pronounced in SI companies.

Numerous academic studies indicate a positive association between a firm's market value and its ESG scores (Abdi *et al*., 2022; Bissoondoyal-Bheenick *et al*., 2023; Carnini Pulino *et al*., 2022; Chouaibi *et al*., 2021). However, these findings do not account for whether a firm belongs to an SI or NSI. The link between robust corporate ESG performance and increased corporate outcomes varies in both industries, highlighting the need for further research into the nuanced impacts of ESG on corporate performance. Given the significant influence on stakeholders and regulatory frameworks, particularly in SI companies (Wichianrak *et al*., 2023). Hence, it is imperative and novel to explore the differentiated impacts of ESG on SI and

NSI corporate performance in India. To the best of our knowledge, no prior study has addressed this distinction analysis, as shown in the conceptual framework (Figure 1), which is crucial for developing targeted strategies to enhance corporate performance and sustainable growth.

3. Research design and methodology

3.1 Sample and data description

The study examines the differential impact of ESG and dimensions on corporate performance across SI and NSI industries among Indian companies listed on the NSE from 2015 to 2023. This investigation's initial period is prompted by the implementation of laws mandating the disclosure of information in 2014–15. A sample comprising 605 Indian-listed corporations, those who have headquarters in India. These corporations were selected based on the corporate metrics from Prowess databases and the availability of ESG disclosure data sourced from Refinitiv Eikon. Notably, the availability of ESG scores varies across corporations and years based on the availability of ESG data for selected companies. Consequently, sample size fluctuates annually based on the data availability of chosen companies.

To delve into the distinct industry contexts, the study classifies corporations based on the GICS classification provided by Morgan Stanley Capital International (MSCI) and Standard and Poor (S&P), which are utilized by the global community. Table 1 illustrates the sample's industry classification, ensuring a representative and unbiased portrayal of the broader economy. As shown in Panel A of Table 1, the companies represented in the sample are well-distributed across several sectors, with materials (19.67%), industrials (17.52%), and financials (15.7%) as the most prominent segments. At the same time, real estate, utilities, and information technology have the lowest concentration. Panel B classified industries into SI and NSI. The analysis explicitly defines the businesses operating in the energy, materials, and utility sectors as environmentally sensitive companies, following the framework employed by Yoon *et al*. (2018) and Gracia and Siregar (2021). The energy sectors encompass energy equipment and services and the oil, gas, and consumable fuel industries; the materials sector includes chemicals, construction materials, containers and packaging, metals and mining, and papers and forest products industries; the utility sectors include electric, gas, water, and power and renewable electric producers' industries. The categorization allows for a nuanced examination of how SI industries may interact with ESG factors in driving corporate performance.

3.2 Variable and measurement

The research has been facilitated by the utilization of pertinent empirical variables, which are elaborated upon in the subsequent description:

3.2.1 Dependent variables. Table 2 outlines the variables in this study, focusing on corporate performance, which is assessed using three key metrics: operating (indicated by ROA), financial (ROCE), and market (Tobin's Q) as defined by Narula *et al*. (2024), Veeravel *et al*. (2024a, b). Prior research has commonly utilized these metrics as outcome variables to examine the performance of corporations, employing appropriate panel data regression (Buallay, 2019; Alareeni and Hamdan, 2020; Pätäri *et al*., 2012; Choi and Wang, 2009).

We utilize ROA as a measure to evaluate operational performance; it assesses how effectively and efficiently a corporation utilizes its total assets to generate profit, thereby providing insights into its overall operational efficiency and performance (Velte, 2020; Wang and Sarkis, 2017). Additionally, ROCE is employed as an indicator of financial performance; it evaluates the firm's profitability and efficiency in utilizing its capital. It provided insights into how efficiently a firm generates returns from capital invested (Maqbool and Bakr, 2019; Veeravel *et al*., 2024a, b). Tobin's Q is employed as a measure of market performance; it is a market-based metric for assessing a company's performance and market valuation. In addition to market performance, it accounts for the long-term replacement cost of a country's assets, making it a significant indicator in sustainable investment strategies, as defined by Narula *et al*. (2024) and Veeravel *et al*. (2024a, b).

3.2.2 Independent variables. ESG scores from Refinitiv Eikon-DataStream reflect a composite measure derived from publicly available data, such as annual reports, stock market filings, corporate websites, newspapers, and CSR reports from reputable corporations across environmental, social, and corporate governance dimensions. This database objectively and transparently evaluates a company's ESG practices, accountability, and effectiveness. The scoring system evaluates companies using 186 key metrics and industry-specific criteria, generating a percentage score ranging from 0 to 100 (Bruna *et al*., 2022; Rajesh and Rajendran,

Table 2. Definitions of key variables

Symbol	Definition	Measurement	Source
Dependent Variables			
ROA	Return on Assets	Operating Performance: Earnings Before interest and tax divided by Total Assets	Prowess
ROCE	Return on Capital Employed	Financial Performance: Earnings Before interest and tax divided by Capital Employed	Prowess
TQ	Tobin's Q	(Market Capitalization + Debt)/ Total Assets	Prowess
Independent variables			
ESG	Environmental, Social, and Governance score	The aggregate score consists of parameters from Thomson Reuters	Refinitiv Eikon
ES	Environmental Score	The environmental score consists of parameters such as natural systems and ecosystems. Thomson Reuters has analyzed 57 indicators to measure the score	Refinitiv Eikon
SS	Social Score	The social score is the company's ability to increase loyalty and trust with its workforce, customers, and society. Thomson Reuters has utilized 60 indicators to measure the score	Refinitiv Eikon
GS	Governance Score	The governance score consists of parameters such as the systems and processes of a company, which are in the best interests of its shareholders. Thomson Reuters has assessed 48 indicators to measure the score	Refinitiv Eikon
Control variables			
Age	Firm Age	log of the fiscal year minus the incorporation year	Prowess
Size	Firm Size	Natural logarithm of total assets	Prowess
Growth	Firm Growth	determined by the growth rate of core business revenue	Prowess
DE	Firm Leverage	Total company debt divided by shareholder's equity	Prowess

Source(s): Authors' own work

2020; Sarkis and Cordeiro, 2001; Shakil, 2021). These scores reflect a firm's performance across ten critical E, S, and G themes. Where the E discloses the emissions, innovation, and resource usage. The S pillar includes human rights, workforce, community, and product responsibility. The G pillar covers shareholders, management, and CSR strategy. These data are calculated based on publicly available data utilizing Refinitiv's specific methodology [4].

3.2.3 Control variables. Moreover, this study incorporates control variables to enhance the study's internal validity, thus mitigating the confounding factors and bolstering the robustness of the findings, as shown in Table 2. We include the following control variables to enhance the efficiency of the measurement model. Firm age, measured as the natural logarithm of the fiscal year minus the incorporate year, reflects the influence of mature firms, which may possess more established operational structures and reputational capital, affecting their sustainability initiatives and financial performance (Doshi *et al*., 2024). The firm size, determined by the natural logarithm of total assets (Buallay, 2019; Hillman *et al*., 2000; Velte, 2017), is a key factor influencing corporate performance. Larger firms generally exhibit superior disclosure strategies compared to small companies (Veeravel *et al*., 2024a, b). Leverage, measured by debt-to-equity ratio, captures financial risk, with evidence suggesting that firms with lower debt levels tend to adopt stronger ESG practices than highly leveraged firms (Bhandari, 1988). High leverage may reduce operational efficiency by increasing interest expenses, which limits investment in growth and innovation. Moreover, it also impacts market performance, as investors may view highly leveraged firms as riskier. Another control variable is sales growth, which is calculated as annual changes in sales included to account for a firm's growth trajectory, which can impact the ability to allocate resources to sustainability initiatives (Bansal *et al*., 2021; Chen and Ibhagui, 2019).

3.3 Model specification

The interplay between ESG and corporate performance, along with relevant control variables, involves potential endogeneity issues, such as mutual influence, reverse causality, and simultaneity (Kahloul *et al*., 2022; Martínez-Ferrero and Frías-Aceituno, 2015). To navigate this, we employed the system-GMM, recommended by Arellano and Bond (1991) and refined by Arellano and Bover (1995) and Blundell and Bond (1998). This approach uses lagged variables as instruments, combining equations in first differences and levels, as shown in the given equations.

System GMM is widely used in ESG research (Agnese *et al*., 2023; Sinha Ray and Goel, 2023) due to its robust ability to mitigate econometric issues like weak instruments, size distortion, and omitted variable bias. By leveraging instruments from both level and first differenced equations, this technique effectively handles challenges in dynamic panel data, ensuring robust and precise estimates through asymptotic normality (Dwibedi *et al*., 2024).

$$ROA_{it}(SI) = \varnothing ROA_{it-1} + \beta_1 ESG_{it} + \beta_2 Age_{it} + \beta_3 Size_{it} + \beta_4 Growth_{it} + \beta_5 leverage_{it} + \varepsilon_{it}$$

$$ROCE_{it}(SI) = \varnothing ROCE_{it-1} + \beta_1 ESG_{it} + \beta_2 Age_{it} + \beta_3 Size_{it} + \beta_4 Growth_{it} + \beta_5 leverage_{it} + \varepsilon_{it}$$

$$Tobin'sQ_{it}(SI) = \varnothing TObin'sQ_{it-1} + \beta_1 ESG_{it} + \beta_2 Age_{it} + \beta_3 Size_{it} + \beta_4 Growth_{it} + \beta_5 leverage_{it} + \varepsilon_{it}$$

$$ROA_{it}(NSI) = \varnothing ROA_{it-1} + \beta_1 ESG_{it} + \beta_2 Age_{it} + \beta_3 Size_{it} + \beta_4 Growth_{it} + \beta_5 leverage_{it} + \varepsilon_{it}$$

$$ROCE_{it}(NSI) = \varnothing ROCE_{it-1} + \beta_1 ESG_{it} + \beta_2 Age_{it} + \beta_3 Size_{it} + \beta_4 Growth_{it} + \beta_5 leverage_{it} + \varepsilon_{it}$$

$$Tobin'sQ_{it}(NSI) = \varnothing Tobin'sQ_{it-1} + \beta_1 ESG_{it} + \beta_2 Age_{it} + \beta_3 Size_{it} + \beta_4 Growth_{it} + \beta_5 leverage_{it} + \varepsilon_{it}$$

ROA, ROCE, and Tobin's Q are operational, financial, and market performance indicators. Here, SI and NSI represent environmentally sensitive and non-sensitive industries. Concurrently, ESG (and E, S, and G pillars individually) scores are explanatory variables, with age, size, growth, and leverages as controls. Parameters $\varnothing and\ \beta$ represents coefficients, i denotes cross-sections, t represents time, and ε is the error term.

To ensure robustness, data were winsorized at the 1 and 99 percentiles. VIF (Variance Inflation Factor) and correlation tests have been employed to test multicollinearity, while Wooldridge and modified Wald tests addressed serial correlation and heteroscedasticity. Instrument validity was confirmed using Sargon and Hansen tests (Arellano and Bond, 1991), ensuring the reliability of the dynamic analyses.

4. Descriptive statistics and correlation matrix

Table 3 presents descriptive statistics of this study. The mean ROA is 0.111, indicating an average return on assets for the sample companies, ranging from – 16.1% to 43.3%, while ROCE averages 18.3%, surpassing the ROA return. Tobin's Q ratio averages 2.789, signifying that the market value of companies exceeds their replacement cost. The average ESG

Table 3. Descriptive statistics

disclosure is 46 out of 100, reflecting a commendable level of performance among Indian corporations, with pillar-wise averages of 39.1 (environmental), 50 (social), and 50.2 (governance), indicating a balanced and upbeat performance. Control variables include age (mean 1.494), size (4.661), growth (0.162), and leverage (0.714), offering a comprehensive overview of the sample's financial and non-financial attributes.

Table 4 presents the Pearson correlation matrix, revealing varying associations between ESG and corporate performance across both industries. ESG and performance indicators exhibit negative correlations in SI industries, whereas NSI is generally favorable. However, the correlation matrix does not provide a definitive analysis. Therefore, we employed multivariate models to investigate these dynamics further. As a preliminary diagnostic tool, we employed the Pearson correlation matrix to identify potential multicollinearity among the variables within SI and NSI companies. Multicollinearity occurs when two or more predictors in multiple regression models are highly correlated (Kennedy, 2008; Wooldridge, 2015). While the correlation matrix offers initial insights, it must comprehensively depict the relationship. We calculated and displayed the mean VIF in their respective model to address this limitation, presenting a more nuanced understanding of multicollinearity.

5. Empirical results

We examine the relationship between ESG and corporate performance among SI and NSI companies using a two-step system-GMM—Tables 5-7 present operating, financial, and market performance results, respectively. Here, Model (1) evaluates the overall ESG score, while Models (2), (3), and (4) assess individual dimensions' impact, respectively. The estimated coefficients β and corresponding t-values (in parenthesis) are reported.

One concern is the potential endogeneity issue due to reverse causality between the variables. To address endogeneity, measurement errors, and unobserved heterogeneity, we employed system-GMM, controlling for time-fixed effect. The AR tests confirm no second-order correlation (with p-value>0.05), and the Sargon and Hansen tests ($p > 0.05$) validate the instrument sets. These results ensure the robustness and unbiasedness of the models.

5.1 Impact of ESG on the operating performance across SI and NSI corporations

Table 5 delineates ESG's impact on the operating performance of corporations for SI (as shown in Panel A) and NSI (in Panel B). For SI, the results indicate that ESG has an

insignificant (−0.0228) effect (Chung *et al*., 2024). Supporting this, Yoon *et al*. (2018) suggested that firms in sensitive industries are held to higher standards to address the environmentally harmful activities associated with their operations. These standards may lead to costs for these corporations rather than benefits. For instance, mining, cement, and chemical industries with stricter sustainability practices may impose significant compliance costs. In contrast, ESG positively and significantly influences ROA ($\beta = 0.514$, p-value<0.01) across NSI firms, indicating that investing in companies with vital ESG initiatives can yield higher returns (Xu and Zhu, 2024; Veeravel *et al.*, 2024a, b). Moreover, robust ESG practices enhance corporate reputation, bolster stakeholder confidence, and improve the efficiency of operations. This observation is consistent with stakeholder theory, which posits that ethical and moral considerations are critical in organizational decisions (Freeman *et al*., 2020). Consequently, businesses that effectively manage ESG risks and capitalize on ESG opportunities exhibit superior performance (Dong *et al*., 2023; Rahman *et al*., 2023; Zhao *et al*., 2018). These findings align with numerous seminal studies documenting a favorable association between ESG and firm performance (Albitar *et al*., 2020; Rahman *et al*., 2023). This finding underscores the strategic importance of integrating ESG considerations into management to achieve sustainable financial success.

On a standalone analysis, the analysis reveals that environmental ($\beta = 0.0259$, p-value<0.05), social ($\beta = 0.0483$, p-value<0.05), and governance ($\beta = 0.0165$, p-value<0.10) exhibit significant positive impacts NSI companies. Social factors, in particular, are critical to improving outcomes, highlighting stakeholders positively evaluating social concerns (Fosu *et al*., 2024). These findings underscore the importance of societal contributions in fostering value creation and enhancing public image, thereby encouraging stakeholder investment. Conversely, in SI firms, we find that while aggregate ESG disclosure does not have a significant impact (Masongweni and Simo-Kengne, 2024), governance factors ($\beta = -0.0317$, p-value<0.05) show a negative and significant impact, contradicting stakeholder theory, aligning with the findings of Yoon *et al*. (2018). This relationship is likely due to the burden of regulatory burdens, suggesting that increased focus on sustainability can detract from corporate objectives. These industries often have stringent disclosure requirements due to their negative potential environmental impacts, which can hinder performance (Yoon *et al*., 2018). These findings highlight ESG's varied effects across different industries, shaped by regulatory demands and stakeholders' expectations.

Control variables show a negative and significant association between size and leverage with the operating performance, indicating that smaller firms are generally more profitable and higher leverage increases risk, reducing profitability, aligning with the pecking order theory, which posits that higher debt levels reduce profit margins (Gupta and Aggarwal, 2024; Malik and Kashiramka, 2024; Veeravel *et al*., 2024a, b). Conversely, growth consistently shows a positive impact across industries.

5.2 Impact of ESG on the financial performance of across SI and NSI corporations

In Table 6, Panel A represents the impact of ESG disclosure and its dimensions on the financial performance of SI companies, whereas Panel B focuses on NSI companies.

The analysis indicates that ESG positively and significantly impacts ROCE for NSI ($\beta = 0.0303$, p-value<0.10) but is insignificant for SI (−0.0228), highlighting that NSI firms benefit more from sustainability initiatives (Bocken and Geradts, 2020). In contrast, SI companies face challenges like high compliance costs, substantial investments, and short-term financial focus, diluting ESG's immediate initiatives. Like ROA, we decompose ESG performance into individual components and find that only governance disclosure significantly negatively impacts sensitive corporations ($\beta = -0.0603$, p-value<0.01). This negative valuation effect is inconsistent with the stakeholder theory. However, it aligns with the trade-off theory, which may emphasize the substantial costs and complexities of maintaining strong governance standards. In NSI, social performance ($\beta = 0.0329$, p-value<0.05) significantly impacts financial performance, enhancing productivity, brand reputation, loyalty, and ethical investors.

These factors bolster companies' financial stability and growth prospects. Whereas in the SI industries, the impact of governance disclosure is significant but negative; in other words, we can say that the firms with better governance practices would have lower market value (Yoon *et al*., 2018).

Among control variables, growth and age significantly positively affect financial performance. This indicates that firms experiencing growth and older trends perform better financially. Conversely, leverage shows a negative and significant association with ROCE, suggesting that higher debt levels reduce profitability.

5.3 Impact of ESG on the market performance across SI and NSI corporations

As shown in Table 7, results based on market factors also demonstrate a stark contrast, measured by Tobin's Q, between SI and NSI corporations. ESG factors and their dimensions do not significantly affect SI companies' market performance (Atan *et al*., 2018). The reason could be that investors and stakeholders lack confidence and trust in these corporations' ESG practices and operations in emerging markets (Naeem *et al*., 2022). Moreover, another explanation could be that investors in these industries may prioritize immediate financial returns over long-term ESG improvements, leading to an insignificant impact. For SI firms, ESG disclosure may function as a signaling and reputation mechanism, fostering sustainable growth. However, stricter environmental in recent years have complicated their effectiveness. Instead of attracting stakeholders, such disclosures risk being perceived as "greenwashing", potentially undermining their role in fostering sustainable corporate success (Ren *et al*., 2022a; Wang *et al*., 2022).

In contrast, analysis indicates a significant positive impact of ESG ($\beta = 1.612$, p-value<0.10), with environmental ($\beta = 2.066$, p-value<0.05) and social ($\beta = 1.512$, p-value<0.05) dimensions playing a pivotal role. This implies that strong ESG practices are more highly valued by investors, boosting market valuation, as reflected by Tobin's Q (Malik and Kashiramka, 2024). Improvements in environmental and social practices enhance brand reputation and customer loyalty, which are recognized and rewarded. Additionally, firm age significantly impacts sensitive industries, whereas size negatively and substantially impacts non-sensitive sectors.

5.3.1 Robustness test. To test the robustness of this research, we simultaneously regressed the individual E, S, and G scores on corporate performance metrics (ROA, ROCE, and Tobin's Q) in a unified model. This approach corroborated previous conclusions, demonstrating consistent outcomes across analytical approaches. This not only strengthens the reliability of the study but also underscores the significance of considering each ESG dimension independently when assessing its impact on outcomes in SI and NSI. Therefore, the previous findings are robust, as shown in Table 8.

6. Discussion and contribution of the study

Intriguingly, the summarized results (as shown in Table 9) suggest the differentiating impacts of ESG factors on corporate outcomes across industry types. In SI companies, ESG initiatives may insignificantly influence performance indicators in emerging economies, as firms often engage in ESG activities primarily to meet regulatory obligations and social contracts rather than to drive profitability (Naeem *et al*., 2022). Additionally, in line with recent research on sustainable practices, factors such as organizational productivity, macro policies, and technological advancements have been identified as crucial for enhancing the performance of sustainability-driven models (Bagherpasandi *et al*., 2024a, b). Consequently, companies in these industries may face a challenging balance between regulatory demands and profitability in emerging nations. Furthermore, among ESG dimensions, Governance operations, in particular, exhibit an inverse relationship, aligning with shareholder theory (Friedman, 1970) and incurring reputational expenses (Mendiratta *et al*., 2023; Nirino *et al*., 2021; Wu *et al*., 2023), high innovational costs (Liu, 2023), and regulatory burdens (Gracia and Siregar, 2021;

Jucá *et al*., 2024; Nilipour *et al*., 2020), which might be seen as a cost rather than a performance driver (Makridou *et al*., 2024). Moreover, companies with high ESG scores are not immune to reputational issues arising from scandals involving inadequate social or governance practices and environmental mishaps (Liu, 2024; Xue *et al*., 2023). However, some studies argue that environmental innovation leads to long-term cost savings (Fiore *et al*., 2017) through improved production efficiency (Hojnik and Ruzzier, 2016), productivity (Arvanitis *et al*., 2017), and lower input costs. Doran and Ryan (2012) suggest that firms are willing to incur initial expenses for green technologies, following the same Hellström (2007) asserts that short-term sacrifices can lead to long-term cost reductions. Theoretically, the negative relationship between corporate performance and aggregate ESG performance of environmentally sensitive industries supports the shareholder theory (Barnea and Rubin, 2010; Friedman, 1970) and opposes the stakeholder theory (Freeman, 1984; Wang, 2024). ESG disclosures in environmentally sensitive corporations are driven by regulatory obligations and the potential to enhance corporate reputation, with key motivations including regulatory compliance and stakeholder pressures (Khamisu *et al*., 2024).

Most importantly, research findings contrast (Miralles-Quirós *et al*., 2018), who show a more significant positive valuation effect of CSR in environmentally sensitive industries by

Table 9. Summarized results

analyzing the sample of Brazilian firms. Furthermore, the negative effect of corporate governance practice on firm valuation in environmentally sensitive industries is well aligned with the studies of Yoon *et al*. (2018) based on Korean markets. Moreover, environmental, social, and governance dimensions have a distinctive impact.

Conversely, in NSI industries, ESG practices significantly enhance performance, highlighting their importance for long-term value creation and investor recognition. This result supports stakeholder theory (Freeman, 1984), which posits that strong ESG propositions help businesses attract and retain top talent, enhance employee motivation by fostering a sense of purpose, and boost overall productivity. The study findings indicate that implementing social responsibility and environmental practices may increase the return on assets, return on capital employed, and Tobin's Q in non-sensitive industries (Rahman *et al*., 2023). The varying effects of environmental, social, and governance (ESG) factors underscore the need for companies to develop customized sustainable strategies to see both environmentally sensitive and non-sensitive sectors achieve economic success and sustainability (Jucá *et al*., 2024). Furthermore, three core pillars of ESG also show a positive impact, resulting in those businesses that adopt ESG standards gaining advantages, including better corporate reputation with stakeholders and employees, higher returns on investments, competitive advantage over industry rivals, appeal to investors and lenders, improved financial performance, and increased customer loyalty (Maji and Lohia, 2023).

6.1 Contributions to theory, practice and policy

This paper makes significant theoretical contributions. First, to the authors' best knowledge, it is the first research to classify sectors according to environmental sensitivity and investigate ESG disclosure's influence on company performance in the Indian market. We explore the

listed firms rather than taking any indices that aid in replicating the findings for all companies in the securities basket. Secondly, the study's findings support the initial hypothesis that the impact of ESG and its dimensions on corporate performance has varied based on environmental sensitivity classification.

From a policy perspective, government and regulatory bodies are crucial in promoting clean technologies through carbon taxes and environmental mandates (Costa and Ferrão, 2010). Stringent ecological measures can facilitate the implementation of advanced green technologies (Farinelli *et al*., 2005) and enhance eco-technologies development, fostering optimization and innovation within the enterprise ecosystem (Jang *et al*., 2016). As clean technologies become more cost-effective over time (Chang, 2011), they help firms comply with stringent environmental regulations, offsetting initial acquisition and installation costs (Arvanitis *et al*., 2017). In this context, Ghisetti and Quatraro (2013) posit that even firms not directly affected by environmental regulation may invest in clean technologies to signal their commitment to social and ecological responsibilities and position themselves for future market opportunities. Additionally, polluting firms that integrate the latest eco-innovations will likely lead to research and development (R&D) for clean technologies in the long run. Hence, regulators should persist in supporting and strengthening ESG initiatives by offering firms guidance, assistance, and financial grants. Ultimately, compliance and disclosure of ESG benefits society as firms contribute value to the environment and community.

The work's economic implications encourage the advancement of ESG programs; the research provides insightful recommendations for businesses in both sectors, enhancing the body of knowledge on corporate sustainability. For instance, regarding ESG strategy implementations, corporations in SI industries should move beyond mere regulatory compliance by adopting proactive sustainability initiatives, such as developing carbon management strategies, investing in renewable energy, and pursuing eco-innovation to reduce further costs and risks. Additionally, transparency and investor trust may be increased by strengthening stakeholder involvement through specialized sustainability committees and coordinating ESG reporting with global frameworks like the Global Reporting Initiatives (GRI). NSI sectors should prioritize community involvement, diversity efforts, and employee-centric projects to improve their social reputations. Industry-wide ESG disclosure reliability may be increased, and digital advancements like AI-driven sustainability reporting systems can streamline disclosure.

The study offers key managerial implications, such as prioritizing ESG performance and improving disclosure, which can enhance financial success and market valuation relative to industry peers. In SI, strategic resource allocation is pivotal to balance immediate financial returns and long-term sustainability goals. Investing in areas with strong regulatory compliance potential despite high costs ensures long-term value. Furthermore, findings suggest that allocating resources to sustainable activities deepens stakeholder engagement and ensures crisis resilience. This research also offers key investors insights. For instance, NSI companies with superior ESG performance tend to exhibit better operating efficiency, financial performance, and market valuation; incorporating ESG performance into investment decisions can yield improved returns. Lastly, the findings emphasize the significance of implementing a robust legal framework and vigilant oversight to ensure effective ESG implementation. Governance streamlining is vital in balancing oversight with corporate outcomes, while reputation management underscores the necessity of ESG investment in building stakeholder trust and market competitiveness.

7. Conclusions and future research directions

Sustainable development initiatives are gradually reshaping the corporate landscapes, mitigating the climate-damaging effects of business activities and benefiting stakeholders. Firms worldwide face unprecedented hurdles due to social disruptions and climate change, necessitating regulatory and policy measures to encourage industries to adopt better practices. Prior research has predominantly focused on developed economies (Bassen *et al*., 2006; Cheng

et al., 2014; Dhaliwal *et al*., 2014). ESG practices within emerging nations remain relatively unexplored (Baughn *et al*., 2007; Dobers and Halme, 2009), despite their significance in global activities. This motivated us to conduct this study by employing system-GMM, offering timely and significant contribution by investigating the relationship between ESG disclosure and corporate performance across four different disclosures: (1) aggregate ESG disclosure, (2) Environmental disclosure, (3) Social disclosure and (4) Corporate governance disclosure. Based on data from 605 Indian-listed companies from 2015 to 2023, categorizing companies based on environmental sensitivity. The findings indicate that ESG factors affect corporate performance differently based on environmental sensitivity. While ESG disclosure in NSI firms significantly enhances profitability, market valuation, and long-term growth. It may translate differently for SI firms as compliance-driven ESG activities might not enhance profitability, given high governance costs and regulatory burdens (Yoon *et al*., 2018). Thus, customizing ESG strategies to industry-specific contexts is necessary to balance sustainability with profitability. It further underlines the reframing of the regulatory guidelines as per the environmental sensitivity of the industries (Appiagyei and Donkor, 2024). Moreover, larger firms with more resources to meet ESG criteria can leverage ESG standards for strategic growth and reduce regulatory pressure, highlighting the need for more rigorous ESG reporting frameworks in emerging nations than in developed countries (Chen *et al*., 2023a, b).

Academically, this study contributes to the literature on the ESG-corporate performance nexus within emerging nations, i.e. India. Examining outside developed nations, this study provides critical insights into the unique regulatory, cultural, and economic characteristics, offering findings that may be relevant to other emerging nations with comparable contexts. It is worth mentioning that our study reflects the snapshot of ESG performance over time, not capturing the evolving impact of ESG disclosure. Future research directions could include (1) investigating ESG performance in other developing nations where institutional frameworks, regulatory environments, and corporate governance structure differ to gain a comprehensive understanding of global ESG dynamics, (2) extending the time frame by leveraging newly available data to explore the evolving impact of ESG disclosures, enhancing the temporal scope of the analysis.; (3) further by conducting more granular sector-specific analyses to standardize better and understand the association between ESG and corporate outcomes.

Keywords: apoptosis | donepezil | mitochondrial biogenesis | neuroinflammation | PSD 95 | spatial working memory | subarachnoid haemorrhage

ABSTRACT

Mitochondrial dysfunction is a known contributor to subarachnoid haemorrhage (SAH) induced early brain damage (EBI), leading to poor neurological outcomes. An experimental SAH model was induced in adult male Wistar rats using endovascular perforation. Donepezil, an acetylcholinesterase (AChE) inhibitor (1 or 2 mg/kg body weight), was administered intraperitoneally 4 h after SAH. The severity of cerebral cortex injury was assessed using blood clot grading, behavioral tests and H and E staining. We carried out an assessment of neuroinflammatory markers using western blotting and immunofluorescence. Additionally, we examined neuronal architecture using H and E staining, measured mitochondrial redox imbalance or ROS and membrane potential (Δψm) and analyzed mitochondrial morphology using transmission electron microscopy (TEM). Apoptotic markers and mitochondrial respiratory complexes were assessed by western blotting. Our results indicated that donepezil treatment significantly upregulated PSD95, α7-AChR, CaMKII, BDNF, CREB, and PI3K expression in cerebral cortical neurons in response to SAH. This was accompanied by improved neurological function, reduced brain edema, decreased neuronal degeneration, and increased levels of OXPHOS and ATP. In the cerebral cortex, donepezil inhibited mitochondria-associated neuronal apoptosis after SAH as revealed by increased membrane potential integrity of mitochondria, reducing the ratio of Bax to Bcl-2 and inhibiting caspase-3 activity. Additionally, donepezil upregulated synaptic proteins (PSD95), strengthening synaptic connections and supporting spatial working memory circuits via the neurotrophic factor BDNF in post-SAH rats. Our research concludes that donepezil has neuroprotective benefits by inhibiting SAH-induced mitochondrial-mediated cell death through the regulation of Drp1-mediated mitochondrial morphology changes.

Abbreviations: α7-AChR, alpha 7 nicotinic acetylcholine receptors; BBB, blood–brain barrier; BDNF, brain-derived neurotrophic factor.; DCFDA, dichlorodihydrofluorescein diacetate; DPZ, donepezil; DRP 1, dynamin-related protein 1; EBI, early brain injury; GFAP, glial fibrillary acidic protein; MMP (Δψm), mitochondrial membrane potential; OXPHOS, oxidative phosphorylation; PSD 95, post synaptic density 95 protein; ROS, reactive oxygen species; SAH, Subarachnoid haemorrhage; TEM, Transmission electron microscopy; TMRE, tetramethyl rhodamine, ethyl ester.

1 | Introduction

Subarachnoid haemorrhage (SAH) occurs when blood accumulates in the subarachnoid space as a result of an aneurysm rupture (Suarez et al. 2006). Although relatively rare, comprising only 3%–4% of all strokes, it carries major implications. Approximately 40% of those diagnosed with SAH experience fatality, while 95% of those who survive face enduring challenges such as impaired mobility (Connolly et al. 2012), altered sensory perception (Jeon et al. 2009), speech difficulties (Hütter et al. 1994), cognitive impairments (Al-Khindi et al. 2010), fluctuations in mood, and chronic fatigue (Egeto et al. 2018). The sequence of pathophysiological processes that are altered following SAH, such as inflammation, oxidative stress, apoptosis, and abnormalities in cell electrophysiology, exerts an important impact on the progression of anxiety, cognitive impairment, and long-term memory issues (Rouanet and Silva 2019; Al-Khindi et al. 2010).

Brain injury after a SAH is diverse, occurring directly as early brain injury (EBI), and also developing secondarily as delayed brain damage (Schneider et al. 2018). EBI is influenced by several factors, such as cerebral ischemia, BBB compromise, brain swelling, cellular oxidative damage, inflammatory reactions, and apoptosis (Sehba et al. 2012). Therefore, it is crucial to develop neuroprotective techniques to combat EBI to improve clinical treatment outcomes (Zhang et al. 2017). Researchers recently employed a mouse model of SAH to develop a framework for understanding the short- and long-term consequences of the disease. They performed a range of neurobehavioral tests to evaluate the functional results in mice after the circle of Willis was perforated following SAH (Regnier-Golanov et al. 2022). Nevertheless, neurocognitive assessments alone may be insufficient in detecting impairments caused by SAH (Turan et al. 2020) (Pace et al. 2018); it is necessary to use particular tests that focus on learning and memory to evaluate the effectiveness of therapy (Fanizzi et al. 2017; Chung et al. 2021).

The role of PSD 95 in post-ICH synaptic impairment and cognitive dysfunction is being studied in recent studies (Wang et al. 2019). PSD 95 is a scaffolding protein involved in the development, remodeling, and maturation of neural synapses. It is essential for the assembly of excitatory synaptic signaling complexes. It takes part in NMDAR-mediated cerebral ischemia, in which an enhancement in PSD95-NMDAR interaction intensifies the entry of Ca^{2+} and triggers signaling cascades that lead to ischemia injury and neuronal death (Loomis et al. 2020; Cui et al. 2007). Moreover, the activation of BDNF-CREB proteins in the hippocampus following SAH enhances the strengthening of synaptic connections. BDNF and CREB are crucial in synaptic plasticity, a process that is thought to be responsible for memory formation (Yang et al. 2019). Post-SAH also has a considerable impact on the validity of important proteins, including CaMKII, a key serine/threonine kinase, essential for synaptic plasticity and memory formation, emphasizing the importance of these enzymes in maintaining and improving cognitive functioning (Gao et al. 2024).

Mitochondria are vital organelles within cells that play a crucial role in energy generation within the central nervous system (CNS) (Koch et al. 2017). They regulate apoptosis, cell differentiation, and the generation of ROS (Sharma et al. 2018). Removing excess ROS is necessary to preserve the normal state of cells. On the other hand, abnormalities in mitochondrial biogenesis may result in the buildup of ROS (Xian et al. 2019; Pei et al. 2016). ROS-induced cytochrome C release from damaged mitochondria causes activation of a caspase-dependent mechanism, which in turn initiates apoptosis (Rashmi et al. 2019). While excessive fission may lead to ROS generation (Qin et al. 2019), balanced fission and fusion are necessary for optimal mitochondrial stability. It is essential to understand these mechanisms to manage CNS disorders. Mitochondrial quality is regulated by certain activities, such as mitofusion (Mfn1 and Mfn2) and mitofission (Dynamin-related protein 1, DRP1) (Meyer et al. 2017). Therefore, reducing ROS generation and neuronal death based on mitochondrial malfunction requires limiting mitochondrial fission and fusion. ROS production is linked to neuroinflammation, which is a crucial component of early brain damage (EBI) following SAH. Hemoglobin, a blood component, binds to pathogen recognition receptors (PRRs) including the fourth Toll-like receptor (TLR4) on microglia following an injury (Hanafy 2013). This attachment activates inflammatory pathways such as NF-κB, TNF-alpha, and IL-1 beta (Lin et al. 2012).

Donepezil, a second-generation acetylcholinesterase inhibitor, has been approved for the treatment of Alzheimer's disease related dementia (Birks and Harvey 2018). Additionally, it demonstrates the potential to reduce the damage caused by ischemic stroke through the stimulation of neurogenesis, angiogenesis, inhibition of inflammation, and apoptosis (Madani Neishaboori et al. 2021). Nevertheless, donepezil remains an unexplored candidate for repurposing in SAH, making it a possible drug development target. This study aimed to examine the possibility of using donepezil for SAH by evaluating its effectiveness in reducing post-SAH changes through mitochondrial-mediated Drp1 fission with cognitive impairment and short-term memory problems. We assessed the neuroprotective properties of donepezil on neurological impairments, mitochondrial oxidative stress, and histological alterations using an endovascular perforation model of SAH. It was assumed that being an acetylcholinesterase inhibitor, donepezil could be a potential candidate, for enhancing acetylcholine levels, which interacts with nicotinic receptors, specifically α7 nAChRs (Shen et al. 2010; Ongnok et al. 2021). These receptors have the potential to improve cognitive function by modulating the PSD-95 protein and the BDNF-CREB-CamkII signaling pathway. This research is the first to examine donepezil's role in promoting mitochondrial-mediated neuroprotection in a rodent SAH model, suggesting its promise as a therapeutic target for drug development.

2 | Material and Methods

2.1 | Chemicals

Donepezil (C. no. 120011-70-3) was acquired from Sigma. We purchased tetramethyl rhodamine ethyl ester [TMRE] (C. no. 115532-52-0 λex 540 nm; λem 595 nm in DMSO), 2,7-dichlorodihydrofluorescein diacetate (DCDHF-DA) (C. no. 4091-99-0, Sigma), dihydroethidium (DHE) (C. no. 38483-26-0),

14714159, 2025, 4, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/jnc.70063 by Delhi Technological University, Wiley Online Library on [01/05/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

and RIPA lysis buffer (MFCD02100484) from Sigma Aldrich and cell signaling technology. Apoptotic markers such as BAX (SC-7480 mouse monoclonal IgG2b κ Bax antibody), Bcl2 (SC-7380 mouse monoclonal IgG1 κ Bcl-2 antibody), and Caspase-3 (SC-65497 mouse monoclofnal IgG2a κ) were obtained from Santa Cruz Biotechnology. Anti-Iba1(Rabbit mAb #17198, CST) is a marker for glial cells, while anti-GFAP (Cat #14–9892-82 source Mouse monoclonal IgG1, Invitrogen) is a marker specifically for astrocytes. The proteins PSD 95 (RRID: AB_2292883), Creb (RRID: AB_331277) (CST), and Oxphos (ab110413 Rodent WB Antibody Cocktail) (Abcam) are being referred to. The chemicals ethanol (110-73-6), diethyl ether (60-29-7), EGTA (60-00-4), bovine serum albumin (BSA) (9048-46-8), and orthophosphoric acid (OPA) (7664-38-2) were purchased from Loba and SRL as standard chemicals.

2.2 | Animal and Experimental Group

Male Wistar rats weighing between 230 and 250 g and aged 8–10 weeks were utilized in this study under the guidelines set by the Institutional Animal Ethics Committee (IAEC), Jamia Hamdard, New Delhi, India (CPCSEA Registration: 173/GO/ReBi/2000/CPCSEA). Male Wistar rats (weighing 230–250 g) were purchased from in-house Centre Animal House Facility (CAHF) Jamia Hamdard University. The rats were kept in hygienic plastic cages with metal covers, with each cage housing 3–4 rats. The temperature was maintained at 25°C ± 1°C, with a 12-h cycle of light and darkness and a humidity level of 60%. The food pellets were provided ad libitum by Arshiwad Industries Pvt. Ltd., located in Punjab, India. The water used was filtered and obtained from RIOS (Merck Millipore, Billerica, MA). All experimental protocols were approved by the IAEC (Protocol no. 1742). Two hundred male rats were used in this work, and they were divided into four groups at random: (a) a sham-operated control group that underwent all procedures except for the occlusion of the right ICA; (b) a SAH surgery group; (c) a SAH + donepezil (1 mg/kg) treatment group; and (d) a SAH + donepezil (2 mg/kg) treatment group. First, we arranged the rats descendingly according to their weight. We then systematically divided them between different groups using Microsoft Excel (version 2019) to ensure a balanced distribution. All groups have a standard error mean of ±5. As a result of simple randomization, every rat has an equal chance of being assigned to any group, reducing selection bias and assuring unbiased group allocation (Kim and Shin 2014). Donepezil hydrochloride was administered intraperitoneally every 12 h, with daily doses of 1 and 2 mg/kg body weight split into two equal injections. The first dose was given on the day of surgery, followed by the second dose 12 h later on the same day. The treatment started 4 h after the surgery and lasted for 24 h (as shown in Figure 1). Out of the 148 rats with SAH examined, 46 (31.08%) did not survive (Table S1). The endovascular perforation SAH model shows high mortality due to abrupt haemorrhage causing vasospasm, reduced cerebral blood flow, impaired autoregulation, increased ICP and global ischemia, especially within 24 h (Fabiana et al. 2003). In this study, the mortality timeline showed the highest death rate within the first 24 h post-SAH, with 19 animals dying on day one, followed by 15 and 12 animals on subsequent days. This pattern suggests that the acute phase of SAH is the most critical, with mortality driven by the immediate consequences of haemorrhage and associated complications. Animals with severe deformities and epileptic seizures (approximately 16) were excluded (Figure S1). The remaining rats (36 operated as a control) were classified as having either undergone a simulated operation or experienced a reduced amount of bleeding, resulting in SAH grades below 13. The experimenter was kept blind to the allocation of treatments during the entire process.

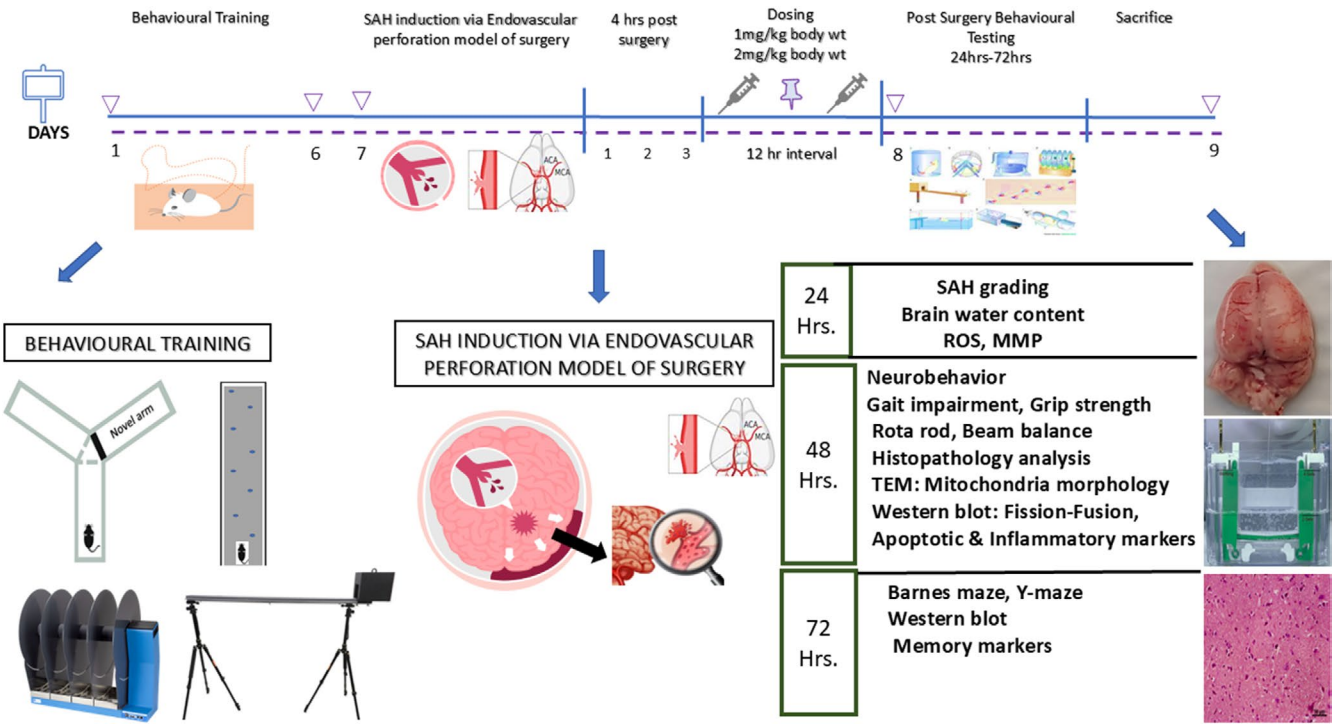

FIGURE 1 | Experimental design.

2.2.1 | SAH Model

Rats were used in the endovascular perforation model of SAH, with minor modifications made to the procedure previously described (Zhang et al. 2019). Anesthesia was administered by utilizing 4% isoflurane in a combination of 70% medical air and 30% oxygen. To sustain anesthesia during surgery, isoflurane was maintained at 1.5%. All animals were anesthetized with isoflurane (2%–3%) during surgery to guarantee total unconsciousness and painlessness. The rectal temperature was kept at 36.0°C ± 0.5°C using a warming pad. A 3- to 4-mm stump remained after the left external carotid artery was severed and ligated. After that, the external carotid artery stump was used to cannulate a sharpened 3–0 suture into the left internal carotid artery, puncturing the vessel wall where the anterior cerebral artery and middle cerebral artery split. Post-surgery, animals were monitored every 4 h for the first 24 h and twice daily thereafter for signs of pain or distress, including changes in posture, grooming, mobility, and body weight. The veterinarian quickly reassessed the animals if they showed any indications of distress. Environmental enrichment, including soft bedding and easy access to food and water, was provided to enhance recovery. Analgesics were not administered postoperatively to avoid confounding effects on neuroinflammation and neuronal recovery, which were key study outcomes. Donepezil, administered 4 h post-surgery, is known to reduce neuroinflammation and has mild analgesic properties. Nonpharmacological measures, including temperature-controlled environments, supported recovery, and human endpoints were predefined to minimize suffering (Kogure et al. 2017). Except for perforation, sham-operated rats received the same treatments. We maintained all the animals on ventilation until the anesthesia subsided.

2.2.2 | Drug Administration

Two distinct doses of Donepezil were given through intraperitoneal injection (ip), following a prior investigation (Madani Neishaboori et al. 2021). Donepezil, at a concentration of 3 mg/kg, was mixed in 1 mL of standard saline solution and delivered through an intraperitoneal injection at doses of 1 and 2 mg/kg, 4 h after SAH. Previous findings have reported on the pharmacokinetics of donepezil, where its concentration was measured in various organs, including the brain, following administration in Wistar rats (Krishna et al. 2018). Following that, donepezil was administered in doses of 1 mg/kg and 2 mg/kg at 12-h intervals to two different SAH-induced groups. The doses were not divided (as an instance, 1 mg/kg was not divided into two 0.5 mg/kg doses or 2 mg/kg into two 1 mg/kg doses). This approach aimed to assess short-term outcomes during a 24- to 72-h period.

2.2.3 | Neurological Score Evaluation

After 24 h following a subarachnoid haemorrhage (SAH), a neutral evaluator performed neurological assessments using the 6-point scale developed by Garcia et al. (Garcia et al. 1995). The evaluations included five distinct tests: the following assessments were conducted: (1) monitoring the natural activity after 5 min, (2) evaluating the voluntary movement of all limbs, (3) viewing the climbing behavior on the wire cage's wall, (4) measuring the extension of the fore limbs when the subject was held by the tail, and (5) evaluating the reflex response when both sides of the trunk were touched. The grading of each test was determined on a scale ranging from 0 to 3, taking into account the observable consequences that occurred after SAH. The scale spanned from negligible or minimum movement (0–1) to vigorous movement or performance equivalent to pre-SAH conditions (2–3), with uniform grading criteria utilized for all assessments.

2.2.4 | Neurobehavioral Assessment

To investigate whether donepezil improves the outcome of SAH, we assessed six neurobehavioral measures both before the surgery and at various time points between 24 and 72 h following the SAH procedure. After conducting a neurological assessment, we carried out grip strength, beam balance, and rotarod tests between 24 and 48 h post-SAH to evaluate motor coordination and balance. Additionally, we looked at gait impairment during this time to further assess any changes in motor function.

2.2.5 | Gait Analysis

Mendes et al. (2015) thoroughly explained the footprint method, which is also referred to as gait analysis. This method entailed submerging the fore paws and hind paws of rats in distinct nonharmful watercolor substances. Afterward, the rats traversed a distance of 1.2 m on a white paper surface, resulting in the imprinting of their paw prints. Stride length was determined by measuring the distance between successive imprints of the same paw, whereas stride width was evaluated by measuring the distance between the imprints of the left and right forelimbs or hind limbs. After a surgical procedure for SAH, gait analysis was performed at 48 h.

2.2.6 | Beam Balance

The assessment of vestibulomotor function after surgery (48 h) was conducted using a modified beam balance test, following the protocols described in the reference (Soltani et al. 2015). Animals received preoperative instruction. Each group performed five attempts on a beam measuring 160 cm in length and having a diameter of 2.5 cm. The average of three trials was calculated during the testing process. The experiment commenced with rats starting from one end of the beam and concluded upon their traversal of a distance of 1 m. The trials had a maximum duration of 60 s, during which the time spent maintaining balance was recorded. A score of 5 signifies the complete keeping of balance for 60 s, with each 12-s interval earning 1 point. Falls and traversal time were used as indicators of vestibulomotor function.

2.2.7 | Grip Strength

Evaluating grip strength is a widely used technique to determine the impact of medicines, toxins, or injuries on motor function.

14714159, 2025, 4, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/jnc.70063 by Delhi Technological University, Wiley Online Library on [01/05/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

To assess the strength of the forelimb and hind limb, grip tests were performed at 48 h after SAH. A one-meter string was securely stretched between two upright supports that were placed 50 cm above the base of the experiment. Rats were placed halfway down the string, and their performance was scored on a scale from 0 to 6. Here, 0 means one falls off within 30 s, 1 means one grips the string with one's forepaws for 30 s, and 2 is the same as 1 except one tries to climb the string. Three refers to the act of grasping the line using two front paws and either one or both hind paws; four indicates using all forepaws to grasp the string and encircling it with the tail; and five indicates a successful escape (Hall 1985).

2.2.8 | Rotarod

Before the surgical procedure, rats were subjected to a 3-day training program using a dynamic rotarod (Omni dynamic Rotor, Columbus, USA) set to maintain a consistent speed of 10 rpm (rpm). This regimen was designed to evaluate changes in motor coordination and balance following a subarachnoid haemorrhage (SAH) at 48 h. After a 1-min break between trials, a total of five trials were conducted, each lasting a maximum of 180 s. The latency to fall (measured in seconds) was recorded during each trial (Rosell et al. 2013).

2.2.9 | Barnes Maze

The Barnes maze used a 91.5-cm-wide black circle with 20 holes, each measuring 5 cm in diameter, spaced 3 cm from the circle's edge. An escape box (10.5 × 6 × 6 cm) could be placed beneath a designated hole. The rats were habituated to the starting location and escape box for 2 days. Rats were trained by placing them in the middle of the maze for 10 s, then exposing them to unpleasant stimuli to get them to enter the escape box. There were two trials and five daily sessions in each session. Rats were led to the escape box by the experimenter if needed, and trials had a maximum duration of 3 min. The final test evaluated the post-SAH rats (at 72 h) capacity to locate the escape box. Rats' travel times through any given maze were timed to determine the degree of anxiety and cognitive impairment. Odor cues were reduced by cleaning the maze with 70% ethanol in between each animal (Broadbelt et al. 2022).

2.2.10 | Y Maze

The Y-maze test quantifies the ability to remember spatial information in the short term (Sarter et al. 1988). Rats that were trained 3–6 days before, were given doses of donepezil and conducted Y-maze testing at 72 h after endovascular perforation for subarachnoid haemorrhage (SAH). The Y-maze comprises three arms that are equidistant from each other. Every rat was individually placed in one arm of the maze and given 5 min to freely explore. The researchers recorded both the spontaneous alternation and total entries. An actual alternation refers to a sequence in which consecutive entries appear in all three arms, such as ABC, CAB, and BAC. However, patterns like ABA are not included in this definition. The following formula was utilized to get the percentage of alternations: [(the number of alternations)/(the total number of arm entries-2)] × 100.

2.2.11 | SAH Grade

Rats were subjected to surgical induction of SAH and were euthanized 24 h after the surgery by cervical dislocation while under anesthesia induced with ketamine and xylazine (75 mg/kg and 10 mg/kg bt.wt.) respectively. The severity of SAH was blindly graded after euthanasia by an observer using a predetermined grading scale (24 h post-SAH). The basilar area around the circle of Willis was divided into six subsegments graded on a scale of 0–3 based on subarachnoid blood clot presence. The severity of SAH was assessed by calculating the overall score obtained from adding up the scores of each subsegment. SAH was classified as mild if the score ranged from 0 to 7, moderate if it fell between 8 and 12, and severe if it ranged from 13 to 18. Animals that had a cumulative score of eight or less were not included. Non-haemorrhaged or sham-operated animals received a score of zero. SAH grading was performed after sacrificing the animal after post-behavioral assessment.

2.2.12 | Brain Water Content

The rats were anesthetized with an intraperitoneal injection of a mixture of ketamine (75 mg/kg) and xylazine (10 mg/kg). Under anesthesia, the brains were instantly removed following decapitation. Subsequently, the brain's left and right hemispheres were separated (24 h post-SAH). The weight of the brain was promptly measured while it was still wet, and then the brain was dried at a temperature of 100°C for 48 h to ascertain its weight after it had dried out for 24 h following SAH. Brain water content % was calculated by [(wet weight − dry weight)/wet weight] × 100.

2.3 | Fluorescent Immunohistochemistry

Rats were anesthetized intraperitoneally with a mixture of ketamine (75 mg/kg bt.wt.) and xylazine (10 mg/kg bt.wt.) and subjected to transcardiac perfusion with 4% paraformaldehyde fixative for immunofluorescence staining. After the sacrifice, the brains were removed, preserved for 24 h in 4% paraformaldehyde, and then embedded in paraffin. Eight- to 10-micrometer sections were cut, xylene deparaffinized, and then dried. A solution of sodium citrate monohydrate with a concentration of 10 mM and a pH of 6.0 was utilized for antigen retrieval, and it was microwaved for 15 min. After that, 0.1% Triton X-100 was used to permeabilize the sample. After that, sections were treated for 60 min at 37°C with 5% normal donkey serum. Next, they were exposed to the primary antibody, GFAP (1:50 dilution; Invitrogen, UK), and anti-Iba1 (Cell for an overnight period at 4°C). The sections were subjected to treatment with a goat anti-rabbit Alexa Fluor 488 secondary antibody (diluted 1:500; Invitrogen, Scotland, UK) after being washed with PBS. Ultimately, antifade DAPI was applied to the slices, and a fluorescence microscope (Zeiss, Oberkochen, Germany) was used to take pictures of the ipsilateral cerebral cortical area.

14714159, 2025, 4, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/jnc.70063 by Delhi Technological University, Wiley Online Library on [01/05/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

2.4 | TEM

Samples of rats brain tissue, thin slices, or tiny cubes with a thickness of no more than 1 mm, were gathered, with an emphasis on the cerebral cortex area in order to evaluate SAH injuries (48 h post SAH). The samples were initially fixed by immersing them whole night at 4°C–5°C in a solution containing 2% glutaraldehyde in cacodylate buffer (consisting of 0.1 M sodium cacodylate and 2 mM MgCl2). Following three washes at 4°C using cacodylate buffer, the samples were then fixed for 1 h at 4°C in a 2% osmium tetroxide solution. Following fixation, the tissues were dried resin blocks were made, and ultramicrotomy was used to cut extremely thin 60 nm slices. Following their collection on metal mesh grids, these sections were dyed with uranyl lead staining. After staining, the sections were finally inspected under a TEM microscope (Talos).

2.5 | Mitochondrial and Cytosolic Fractionation

Differential centrifugation was used to separate the cytosolic and mitochondrial components (24 h post-SAH). With the aid of a glass dounce homogenizer, brain tissue was homogenized in a mitochondrial isolation solution that contained 0.07 M sucrose, 0.22 M mannitol, 10 miliMolar HEPES-KOH (pH 7.2), 0.1% fatty acid-free BSA, and 1 miliMolar EDTA. To separate intact cells and nuclei, the homogenate was centrifuged at 800 × g for 3 min at 4°C. After centrifuging the resultant supernatant for 10 min at 10 000 rcf, a loosely packed mitochondrial pellet was obtained; the cytosolic fraction was discarded. Using a discontinuous Ficoll gradient (3% layered over 6%) supplemented with 0.12 M mannitol, 0.03 M sucrose, and 25 mM EDTA, the mitochondrial fraction was further purified. After 30 min at 4°C and 10 400 × *g* of centrifugation, the mitochondrial fractions were successfully separated (Brown et al. 2004).

2.5.1 | Mitochondrial ROS and Mitochondrial MMP

Mitochondrial redox imbalance or ROS and membrane potential (MMP) were measured using BD Lyric flow cytometry (Becton Dickinson, San Jose, CA, USA). A 400 μL analytical buffer containing 250 miliMolar sucrose, 10 mM Tris base, 20 miliMolar 3-[N-morpholino] butane sulfonic acid, 100 M Pi[K], and 0.5 miliMolar Mg^{2+} was used to evaluate a 25 g sample of mitochondria. H2DCFDA (10 M) and TMRE (100 nM) were used to measure mitochondrial redox imbalance or ROS and MMP (Δψm), respectively. To measure ROS, excitation wavelengths of 495 and 540 nm were employed, while emission wavelengths of 525 and 595 nm were utilized for MMP. Fluorescence intensity was measured after mitochondrial labeling in six different sample sets, and 10 000 events were recorded in the flow cell. A logarithmic scale was used to create the scatter plot, which was then examined using FACS DIVA software.

2.5.2 | Cellular ATP Content Assay

For the assessment of cellular ATP concentration in brain tissue, a widely used ATP colorimetric assay kit from Elabscience in the USA was utilized. The brain sample was broken down into small fragments and then placed in hot distilled water at a w/v ratio of 1:9 for 10 min. Afterward, the mixture was vigorously mixed for 1 min, and the resulting liquid was used to quantify the cellular adenosine triphosphate (ATP) levels. The supernatant was acquired through centrifugation of the mixture at a speed of 10 000 rpm, following the methodology outlined in the kit's instructions.

2.6 | Western Blotting

Rats were sacrificed by cervical dislocation under anesthesia induced by intraperitoneal administration of ketamine (75 mg/kg bt.wt.) and xylazine (10 mg/kg bt.wt.). Samples of brain tissue were taken from several anesthetized groups of rats at 48–72 h after SAH surgery. The ipsilateral (left) cerebral hemisphere was suspended, homogenized, and sonicated in ice-cold RIPA (CST, USA) lysis buffer containing a protease and phosphatase inhibitor cocktail (20 mM Tris–HCl [pH 7.5], 150 mM NaCl, 1 mM Na_2EDTA, 1 mM EGTA, 1% NP-40, 1% sodium deoxycholate, 2.5 mM sodium pyrophosphate, 1 mM β-glycerophosphate, 1 mM Na_3VO_4, and 1 μg/mL leupeptin). All of the samples were then centrifuged for 30 min at 21 000*g*. The Bradford test was used to quantify the protein; 20–30 μg of protein were loaded onto 8%–15% SDS-PAGE gels, and then the gels were transferred onto 0.45 μm PVDF membranes. Additionally, after transferring the proteins onto the membrane, the membranes were blocked with 5% non-fat dry milk for 60 min at room temperature. Then, using distinct primary antibodies (Bax, Bcl2, Caspase 3, OXPHOS, TLR4, NfkB, Cytochrome C, AKT) that were acquired from multiple sources and targeted at different proteins, these membranes were incubated for an entire night. Secondary antibodies conjugated to horseradish peroxidase were added at a dilution ratio of 1:5000 for 90 min at room temperature following three rounds of PBST washing. The density of the bands was assessed using ImageJ software for densitometric measurements (version 1.50, NIH, USA) following observation using an enhanced chemiluminescence reaction.

2.7 | Histopathological Examination

H and E staining was carried out to assess neuronal degeneration using a previously established methodology. Histopathological examination started at 48 h. Rats were fixated with 4% paraformaldehyde after being anesthetized and having a transcardial perfusion of 0.9% saline. H and E was used to stain 5-μm thick coronal frozen slices for 10 min, or until the required staining intensity was reached. The stained specimens were viewed and photographed using an inverted optical microscope, and analysis was conducted using Image J software.

2.8 | Statistical Analysis

The statistical analysis was conducted using GraphPad Prism 6.0 software, developed in the United States. The data is displayed as the Mean ± SD. The statistical differences between groups were determined using ANOVA, followed by Tukey's test. A $p < 0.05$ value was deemed to be statistically significant. Based on the previously published reports and pilot study data (Uzair

14714159, 2025, 4, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/jnc.70063 by Delhi Technological University, Wiley Online Library on [01/05/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

et al. 2024; Weissgerber et al. 2015), effect sizes were calculated using G*Power analysis. An effect size of 0.299 was obtained for ANOVA, with an α error of 0.05 and a power of 95%. A sample size of $n = 3$ was used to assess the statistical significance of the data (Table S2). The data exhibited parametric characteristics, as confirmed by the non-significance of the Shapiro–Wilk test for normality (Table S3). No test for outliers was conducted and no data points were excluded from the analysis.

3 | Result

3.1 | Donepezil Administration Attenuates SAH-Induced Grading Score, Neurological Deficits, and Brain Water Content

Blood clots were primarily seen near the ventral brain stem and circle of Willis. Their severity was measured using a grading scale ranging from 1 to 18, following the onset of SAH. In this work, our attention was directed towards the specific area of the brain, that is, the right cortical region (Figure 2A,B). A statistically significant difference was seen between the SAH grades in rats and the sham-operated groups ($p < 0.0001$, F (3, 20) = 154.7; Figure 2A,B). Administration of donepezil resulted in a substantial decrease in clot formation in rats that underwent SAH (#$p < 0.05$ or ###$p < 0.001$). In terms of neurological outcomes, the induction of SAH resulted in a substantial rise in the neurological impairment score as compared to the sham-operated group ($p = 0.0676$, F (3, 32) = 37.87; Figure 2C). The administration of donepezil at the highest concentration resulted in a substantial improvement in the neurological impairment score (###$p < 0.001$). After inducing SAH, there was a significant increase in brain water content ($p = 0.0008$, F (3, 20) = 8.386; Figure 2D) and higher levels of AQP4 protein after 24 h, compared to the sham-operated group [$p = 0.0008$, F (3, 8) = 17.17; Figure 2E]. Administration of donepezil resulted in a notable decrease in brain water content (##$p < 0.01$) and AQP4 levels in the first 24 h after SAH (#$p < 0.05$ or ##$p < 0.01$).

3.2 | Donepezil Rescued Neurobehavioral Impairment Caused by SAH

To examine whether donepezil benefits SAH outcome, we analyzed six neurobehavioral measures both prior to the surgical procedure and at intervals between 24 and 72 h after SAH induction. After the neurological scoring assessment, grip strength, beam balance, and rotarod tests were performed between 24 and 48 h post-SAH surgery to evaluate motor coordination and balance. Gait impairment was also assessed during this period. Combined anxiety and memory deficits were investigated between 48 and 72 h post surgery using Barnes maze and Y-Maze tests, providing insight into cognitive recovery and spatial memory function. This sequential testing ensured a comprehensive evaluation of motor and cognitive outcomes while minimizing stress on the animals. To perform gait analysis, we recorded the footprints of the rats to quantify the stride length, which is the distance between two consecutive imprints formed by the same limb is referred to as step length, while the stride width is defined as the distance between the footprints of the left and right paws. The rats subjected to SAH showed a substantial decrease in both stride length ($p < 0.0001$, F (3, 32) = 9.858; F (3, 32) = 32.68 Figure 3A–C) and width ($p = 0.0024$, F (3, 32) = 5.935; $p = 0.0001$; F (3, 32) = 9.599; Figure 3A,D–E) when compared to the sham group. The administration of donepezil resulted in a significant improvement in these specific measures of walking (##$p < 0.01$), stride length forelimbs and hind limbs; (##$p < 0.01$ or ###$p < 0.001$, stride width forepaws and hind paws), leading to an enhanced walking pattern in rats that had experienced SAH. The results of the Rota rod test demonstrated that motor ability was considerably decreased following SAH surgery, as seen by an increased fall latency compared to rats who underwent a sham operation (F (3, 32) = 25.39, $p < 0.0001$ Figure 3F). Treatment with donepezil led to a significant improvement in motor function, resulting in a reduction in fall latency (##$p < 0.01$ or #$p < 0.05$). The beam balancing test was employed to evaluate motor coordination ($p < 0.0001$, F (3, 32) = 309.9; Figure 3G). After SAH, therapy with donepezil significantly enhanced motor coordination in a dose-responsive manner (##$p < 0.01$ or ###$p < 0.001$). The grip strength test was employed to evaluate muscular strength. The study found that SAH caused a substantial decrease in neuromuscular function, leading to a decrease in muscular strength compared to the sham-operated group ($p < 0.0001$, F (3, 32) = 17.34; Figure 3H). On the other hand, the administration of donepezil greatly improved grip strength in rats compared to the rats in the SAH group (##$p < 0.01$ or ##$p < 0.01$).

3.3 | Donepezil Upregulates Post-Synaptic Density Protein, Improving SAH-Induced Memory Deficits

In order to detect the expression of α7 nAChR, BDNF-CREB, and CamkII, a protein quantification or western blot analysis was conducted to elicit the effect of donepezil on the α7 nAChR receptor. In contrast to the Sham-operated group, the SAH rodents exhibited a substantial decrease in α7 nAChR ($p = 0.0001$, F (3, 8) = 29.77; Figure 4C,D), BDNF-CREB($p = 0.0004$, F (3, 8) = 20.83; $p = 0.0008$, F (3, 8) = 16.69 Figure 4C,G–H), and CamkII ($p = 0.0002$ F (3, 8) = 24.48; Figure 4C,F). Donepezil administration significantly enhanced the expression of these proteins (#$p < 0.05$, ##$p < 0.01$ or ###$p < 0.001$). Additionally, PSD95 expression, which declined in SAH rats compared to the Sham group ($p < 0.0001$, F (3, 12) = 159.4; $p = 0.0001$, F (3, 8) = 27.51; Figure 4–B,E) was significantly increased (###$p < 0.001$) with donepezil treatment, suggesting maintenance of post-synaptic circuits. As an additional method to confirm that donepezil improves memory deficits in rats, we used Barnes and Y maze tests to measure anxiety and working memory reductions at 72 h after SAH onset (Figure 4A–H). During the Barnes maze test, SAH rats exhibited significantly increased escape latency and entries in the target zone compared to the Sham group ($p = 0.0001$, F (3, 32) = 83.35; $p < 0.0001$, F (3, 32) = 88.29; Figure 5A–C). Treatment with donepezil dramatically decreased entry in the target zone and escape latency (##$p < 0.01$ or ###$p < 0.001$). Unlike SAH rats, Sham rats demonstrated considerable alternation and no arm preference in the Y-maze spontaneous alternation task ($p < 0.0001$, F (3, 32) = 20.14; Figure 5D,E). In SAH rats, donepezil therapy dramatically decreased arm preference and increased working memory (#$p < 0.05$ or ###$p < 0.001$). Donepezil-treated SAH rats showed improved working memory and reduced arm preference, confirming the cognitive benefits of donepezil in this model.

FIGURE 2 | Effects of donepezil on SAH grading score, neurological severity, aquaporin expression, and brain edema. (A, B) Representative images of the brain across different experimental groups. Validation of the SAH model was conducted by quantifying the blood clot in cerebral cortex near the Circle of Willis with a grading score (1–18), $n = 6–9$ rats per group. (C) Neurological severity score. (D, E) Immunoblot showing that donepezil suppressed AQP4, reduced brain water content, and improved blood–brain barrier function 24 h after SAH ($n = 3$ rats per group). Experimental data are presented as means ± SD and were analyzed using a one-way ANOVA followed by the Tukey post hoc test. $^{**}p < 0.01$, $^{***}p < 0.001$ versus sham, $^{\#}p < 0.05$, $^{\#\#}p < 0.01$, $^{\#\#\#}p < 0.001$ versus SAH.

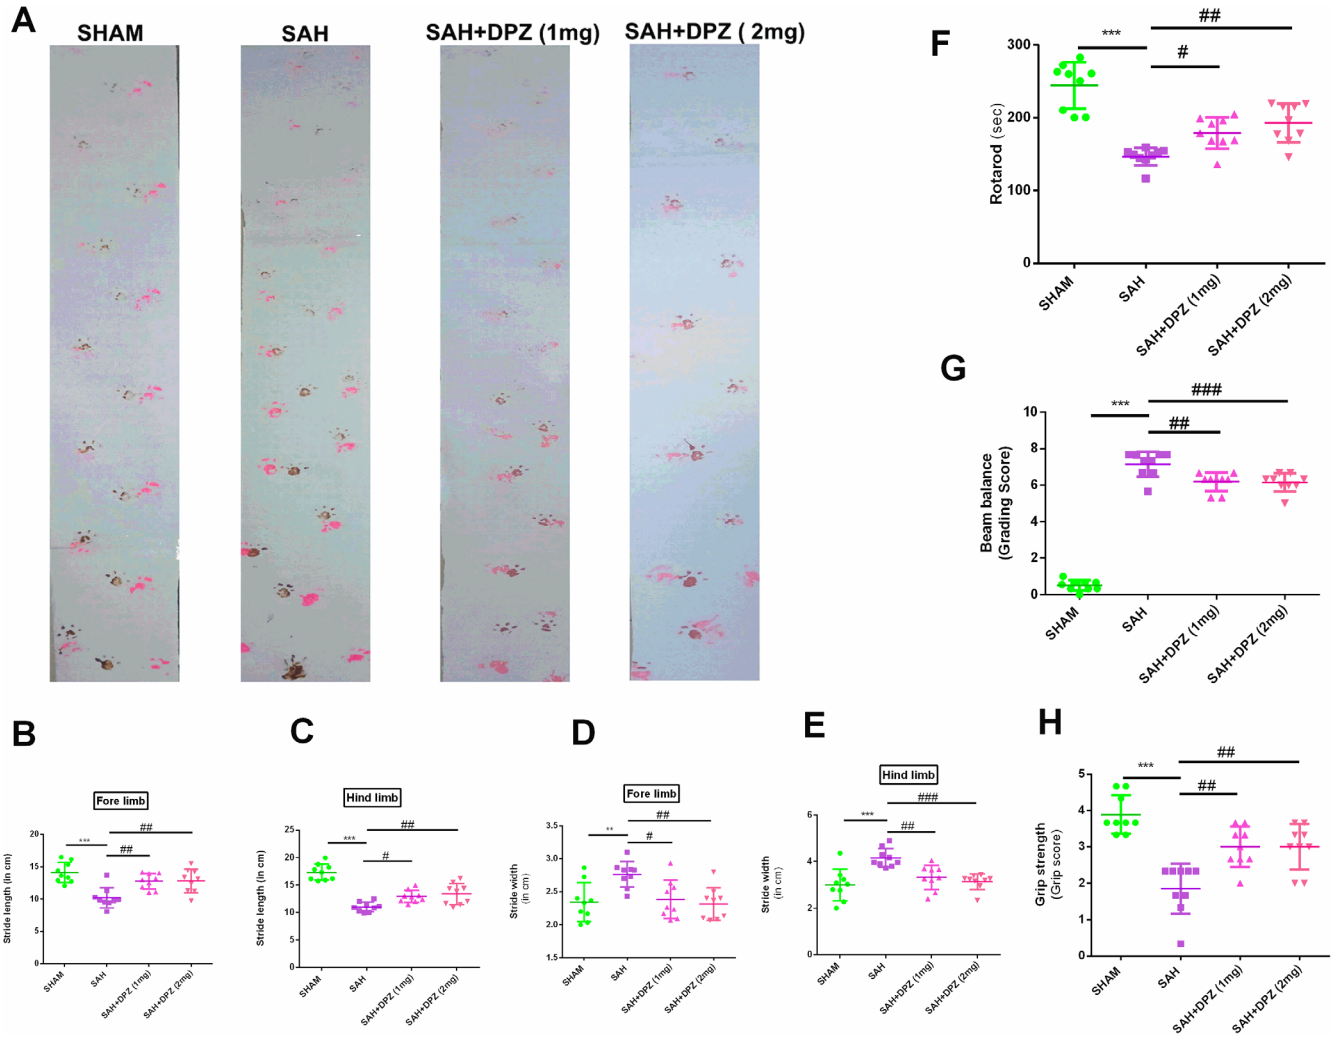

FIGURE 3 | Effect of donepezil on rats with SAH-induced short-term neurobehavioral dysfunction. (A) A diagrammatic representation of the rat's gait analysis, with the forepaws colored brown and the hind paws colored pink, illustrating the animal's foot printing pattern. Measurements include (B, C) stride length, indicating the distance between successive steps of the same paw; (D, E) stride width, the lateral distance between the left and right paws during movement; (F) rotarod performance, testing motor coordination and balance by measuring the duration the rat can stay on a rotating rod; (G) beam balance, evaluating the ability of the rat to maintain balance while walking on a narrow beam; and (H) grip strength, assessing the muscle strength of the forelimbs and hind limbs. Experimental data are presented as means ± SD ($n = 9$ rats per group) and were analyzed using a one-way ANOVA followed by the Tukey post hoc test. $^{**}p < 0.01$, $^{***}p < 0.001$ versus sham, $^{\#}p < 0.05$, $^{\#\#}p < 0.01$, $^{\#\#\#}p < 0.001$ versus SAH.

3.4 | Donepezil Regulates the TLR4/NF-κB/PI3K/AKT Pathway in Post-SAH Surgery

Inducing SAH-activated TLR4/NF-κB pathways, as indicated by increased expression, along with possible involvement of PI3K/AKT pathways in inflammation. The activation of TLR4 receptors ($p = 0.0005$, F (3, 8) = 19.44; Figure 6A,B) led to a high expression following NF-κB activation ($p = 0.0026$, F (3, 8) = 11.80; Figure 6A,C). Donepezil was assessed for its anti-inflammatory properties by examining intracellular TNF-alpha levels ($p = 0.0016$, F (3, 8) = 13.82; Figure 6A,D), as well as its antiapoptotic properties by measuring PI3K ($p = 0.0001$, F (3, 8) = 28.36; Figure 6A,E) and pAKT levels ($p < 0.0001$, F (3, 8) = 45.32; Figure 6A,F). Compared to the control group, these proteins were undetectable. Upon SAH induction in rats, the protein expression of TLR4, NF-κB, and TNF-α peaked,

FIGURE 4 | Donepezil enhances the expression of the α7 receptor along with improvements in memory markers PSD95, BDNF, CamkII, and Creb. (A–F) Representative western blot images and quantitative analyses of α7 nAChR, PSD95, BDNF, CamkII, and Creb from a time course study using samples obtained from the right hemisphere after SAH ($n = 3$ rats per group). (G, H) Representative microphotographs of immunofluorescence staining and quantification, showing the expression of PSD95 (green) in the damage neuron with DAPI (blue) between 48 and 72 h after SAH in different experimental groups ($n = 4$ rats per group). Expression was viewed at 20× magnification using a fluorescent microscope. Scale bar = 20 μm. Data are presented as means ± SD and were analyzed using a one-way ANOVA followed by the Tukey post hoc test. $^{**}p < 0.01$, $^{***}p < 0.001$ versus sham, $^{\#}p < 0.05$, $^{\#\#}p < 0.01$, $^{\#\#\#}p < 0.001$ versus SAH.

accompanied by a downregulation of PI3K/AKT protein levels. SAH rats were significantly more likely to express inflammatory proteins (TLR4, NF-B, and TNF-alpha) compared to control rats, along with decreased PI3K and pAKT levels, as shown in Figure 6A–F. Further, we observed that donepezil treatments significantly reduced levels of TLR4/NF-κB/TNF-α ($\#p < 0.05$, $\#\#p < 0.01$ or $\#\#\#p < 0.001$) and increased PI3K/pAKT levels ($\#p < 0.05$, $\#\#p < 0.01$ or $\#\#\#p < 0.001$) compared to SAH rats.

3.5 | Donepezil Ameliorates Increased GFAP and Iba-1 Expression in Post-SAH Rats

After observing signs of donepezil's ability to protect against inflammation, we confirmed this result by assessing the number of activated astrocytes and microglia in the vicinity of the clot site. At 48 h following SAH, there was a notable rise in the number of activated microglia, as identified by the iba1 antibody ($p < 0.0001$, $F(3, 12) = 132.2$; Figure 7A,B), and astrocytes, as detected by the GFAP antibody ($p < 0.0001$, $F(3, 12) = 242.3$; Figure 7C,D), in contrast to the control group. The administration of donepezil significantly decreased the expression of iba-1 and GFAP ($\#\#\#p < 0.001$) in rats having SAH.

3.6 | Effect of Post-Treatment of Donepezil on Mitochondrial ROS and MMP ($\Delta\Psi_m$) in SAH Rats

The endovascular perforation model of SAH showed a blood clot near the circle of Willis, caused by blood reperfusion injury, which increased mitochondrial ROS generation, leading to oxidative stress. To confirm ROS generation, DCFDH2 dye expression in mitochondria was measured using BDlyric. As compared to SHAM-operated animals, the SAH group had significantly higher ROS levels ($p < 0.0001$, $F(3, 20) = 72.84$; Figure 8A,B). The post-SAH rats group was treated with donepezil, and we found a significant reduction in ROS production. ROS generation was found to be the main cause of cellular membrane damage. It has been discovered that the generation of ROS decreased the Δψm and ATP production in post-SAH rats ($p = 0.0002$, $F(3, 8) = 25.41$; Figure 8C). The addition of TMRE, a fluorescent membrane potential indicator, to isolated mitochondria served as validation for the effect of ROS on mitochondrial membrane potential (Δψm). The mitochondrial membrane potential decreased with SAH injury, according to our results ($p < 0.0001$, $F(3, 20) = 73.70$; Figure 8D,E), but MMP was significantly recovered by donepezil treatment. These findings strengthen our hypothesis that donepezil works as a scavenging compound against ROS generation.

3.7 | Effect of Donepezil on Morphology and Quality Control of Mitochondria

Mitochondrial quality control is primarily regulated by the involvement of two proteins: dynamin-related GTPase (DRP1) and mitofusin1/2 (MFN1/2). To examine the impact of SAH induction on mitochondrial dynamics in rats, a western blotting analysis was conducted (Figure 9H–K). The results showed a significant increase in the translocation of Drp1 from the cytosol ($p = 0.0002$, $F(3, 8) = 24.02$; Figure 9H,I) to the mitochondria ($p = 0.0002$, F (3, 8) = 27.08 Figure 9H,J) in SAH-induced rats compared to rats who underwent a sham operation. The level of Mitofusin 2 (mfn2) was considerably reduced in the mitochondria of rats with SAH compared to the control group ($p = 0.0037$, $F(3, 8) = 10.61$; Figure 9H,K). It was shown that rats treated with donepezil inhibited the recruitment of drp1 into mitochondria and increased the level of mfn2 in mitochondria. To substantiate the hypothesis of mitochondrial dysfunction, the western blot analysis demonstrated that SAH directly impacts the stability of the electron transport chain (ETC) and mitochondrial respiratory complexes. Specifically, there was a more noticeable effect on the subunits CI ($p = 0.0051$, $F(3, 8) = 9.516$; Figure 9B,C), CII ($p = 0.0013$, $F(3, 8) = 14.78$; Figure 9B,D), and CIV ($p = 0.0025$, $F(3, 8) = 11.92$; Figure 9B,F). However, treatment with donepezil significantly mitigated the imbalance of mitochondrial respiratory complexes ($^{*}p < 0.05$, $^{**}p < 0.01$ or $\#p < 0.05$ or $\#\#p < 0.01$). To investigate the effectiveness of donepezil in protecting the brain's neurons and promoting the creation of new mitochondria, we utilized Electron microscopy to analyze any alterations in the structure of mitochondria, specifically looking for signs of fragmentation and fusion. TEM imaging in the SAH group demonstrated a notable increase in mitochondrial fragmentation and edema as compared to the sham group. Nevertheless, administration of donepezil led to a reduction in fragmentation and a boost in the framework of mitochondria in comparison to the SAH group (Figure 9A).

3.8 | Donepezil Reduces Mitochondrial-Mediated Cell Death in Post-SAH Rats

The proportion of pro- and anti-apoptotic Bcl-2 proteins is modified in response to stressful situations. Chronic stress exacerbates cellular apoptosis pathways, increasing the severity and decreasing the viability of organisms. The formation of ROS in cells can disturb the balance of ROS in mitochondria, which in turn triggers the apoptotic pathway. Following SAH, several apoptotic proteins including BCL-2, Cytochrome C, BAX, and cleaved caspase are triggered. Within 48 h following SAH, the caspase-dependent apoptotic cascade is triggered. This results

14714159, 2025, 4, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/jnc.70063 by Delhi Technological University, Wiley Online Library on [01/05/2025]. FIGURE 6 | Donepezil reduced the expression of neuroinflammatory markers and enhanced the expression of anti-apoptotic markers following SAH injury. (A) Representative western blot images. (B–F) Quantitative analyses of TLR4, NF-κβ, TNF-α, p-PI3K, pAKT ($n = 3$ rats per group). Data are presented as means ± SD and were analyzed using a one-way ANOVA followed by the Tukey post hoc test. $^{**}p < 0.01$, $^{***}p < 0.001$ versus sham, $^{\#}p < 0.05$, $^{\#\#}p < 0.01$, $^{\#\#\#}p < 0.001$ versus SAH.

in the translocation of Bax protein to the mitochondria through the mitochondrial membrane pore, causing damage to the mitochondria, and the subsequent release of Cytochrome C into the cytoplasm was verified using western blot analysis. In Figure 10A–F, the expression of BAX dramatically increases ($p = 0.0008$, F (3, 8) = 17.07 Figure 10A,C), whereas the levels of Cytochrome C significantly decrease in rats with SAH compared to animals who underwent a sham operation ($p = 0.0005$, F (3, 8) = 19.27; Figure 10D,F). The Western blot analysis revealed that donepezil caused a significant decrease in the movement of Bax protein ($p = 0.0006$, F (3, 8) = 18.18; Figure 10A,B) from cytosol to mitochondria, and also restored the expression levels of Cytochrome C in the mitochondria ($p < 0.0001$, F (3, 8) = 30.91; Figure 10D,E). To provide additional evidence for the anti-apoptotic function of donepezil, we noticed a notably increased Bax/Bcl-2 ratio ($p < 0.000$, F (3, 8) = 40.21; Figure 10G,H) and the production of activated cleaved caspase-3 ($p = 0.0003$, F (3, 8) = 22.36; Figure 10G,I) in whole cell lysates following SAH. Donepezil significantly reduced the proportion of Bax to Bcl-2 and the expression of cleaved caspase-3 in the basilar cortex following SAH.

3.9 | Donepezil Effects on Alterations in Neuron Morphology

Using hematoxylin and eosin staining, changes in the neuronal architecture of the cortex were investigated. In sham-operated mice, representative H and E pictures (Figure 11A–E) demonstrated normal neuronal morphology. SAH rats, on the other hand, showed increased vacuolated gaps, pyknotic neurons with reduced cytoplasm, and significant neuronal death. When SAH rats were compared to sham rats, the number of non-viable neurons rose considerably ($p < 0.0001$, F (3, 20) = 123.3 Figure 11A–E). When compared to SAH animals that were not treated, donepezil post-treatment significantly increased neuronal survivability and preserved the number of intact neurons ($^{\#\#\#}p < 0.001$).

4 | Discussion

Donepezil, an acetylcholinesterase inhibitor, has been demonstrated to reduce neuroinflammation and ROS generation after

14714159, 2025, 4, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/jnc.70063 by Delhi Technological University, Wiley Online Library on [01/05/2025]. Expression viewed at a 20× magnification using a fluorescent microscope. Scale bar = 20 μm.

brain haemorrhages. An FDA-approved cholinergic drug, donepezil was assessed for its therapeutic potential in subarachnoid hemorrhage (SAH). The decision to administer donepezil 4 h after SAH was based on multiple considerations. While neuroprotective drugs are often administered immediately following brain injury, we chose a 4-h window to better reflect clinical relevance, since it approximated the therapeutic timeframe available to patients following the onset of subarachnoid hemorrhage. Furthermore, donepezil's pharmacokinetics, including its ability to cross the blood–brain barrier and exert effects on acetylcholine levels and support its efficacy within this timeframe (Madani Neishaboori et al. 2021). The results of our study indicate that (a) SAH induction causes neurobehavioral deficits, particularly in the area of working memory and sensorimotor behavior. SAH rats treated with donepezil demonstrated improved functional outcomes, including working memory, postsynaptic density as well as prevention of neuroinflammation. (b) Donepezil regulates activated glial cells and astrocytes, while downregulating ROS that are responsible for improving outcomes after SAH. (c) Furthermore, donepezil enhanced the restoration of mitochondrial morphology and ultrastructure, regulated mitochondrial-mediated apoptosis and oxidative stress, preserved mitochondrial integrity, and promoted mitochondrial quality control in the brain after SAH.

Subarachnoid hemorrhage is the event where blood spreads into the subarachnoid space. This occurrence is associated with significant brain swelling and severe neurological deficits (Chen et al. 2016). The coagulation of blood cells results in the buildup of harmful compounds, leading to increased oxidative stress and subsequent neuronal apoptosis, ultimately resulting in persistent neurological impairments (Hamming et al. 2017). The formation of blood clots, which is measured using the SAH grading system, contributes to the severity of SAH in rats (Sugawara et al. 2008). Before euthanasia at either 24 or 72 h after surgery, the severity of brain edema, as evaluated by the amount of water in the brain, was found to be connected with various neurofunctional measures. These assessments included a compromise

neuroscore, test for beam balance, gait impairment, rota rod performance, and grip strength (McBride et al. 2015). A higher degree of SAH (increased brain water content) led to decreased performance in these tests. Emerging data suggests that aquaporin 4 (AQP4), a protein responsible for transporting water in the brain, plays a vital role in regulating brain edema in different brain disorders. This underscores the significance of AQP4 in the progression and treatment of brain edema after SAH (Aoki et al. 2003). Our findings demonstrated that donepezil had a positive impact on the treatment outcomes in SAH-induced rats, leading to improvements in neurobehavioral deficits and motor coordination that worsened after surgery. In addition, donepezil effectively reduces the accumulation of blood clots and the increase in AQP4 caused by SAH. Previous research investigating the effects of Donepezil on ischemic stroke has shown that donepezil improved the loss of hippocampal neurons and cognitive impairments in Wistar rats after global cerebral ischemia, which is consistent with our findings (Madani Neishaboori et al. 2021b). In addition, galantamine, another agonist of the α7-AChR receptor, demonstrated comparable enhancements in functional outcomes, as indicated by a decrease in brain water content (Dienel et al. 2021).

The endovascular perforation model of SAH developed anxiety-like behavior that was detected at 72 h. The Barnes maze and Y maze were employed to quickly evaluate anxiety levels and working memory. Healthy rats generally exhibit elevated levels of arm alternation and reduced escape latency, which is indicative of strong working memory, in contrast to SAH animals. In the SAH perforation model, mice exhibited a slight elevation in alternation compared to the Sham group, as hippocampectomized animals developed a preference for one side and performed more effectively (Deacon and Rawlins 2006). The brain undergoes essential structural and functional rearrangement after intracerebral hemorrhage (ICH) to preserve brain plasticity (Tamakoshi et al. 2016). Enhanced synaptic function,

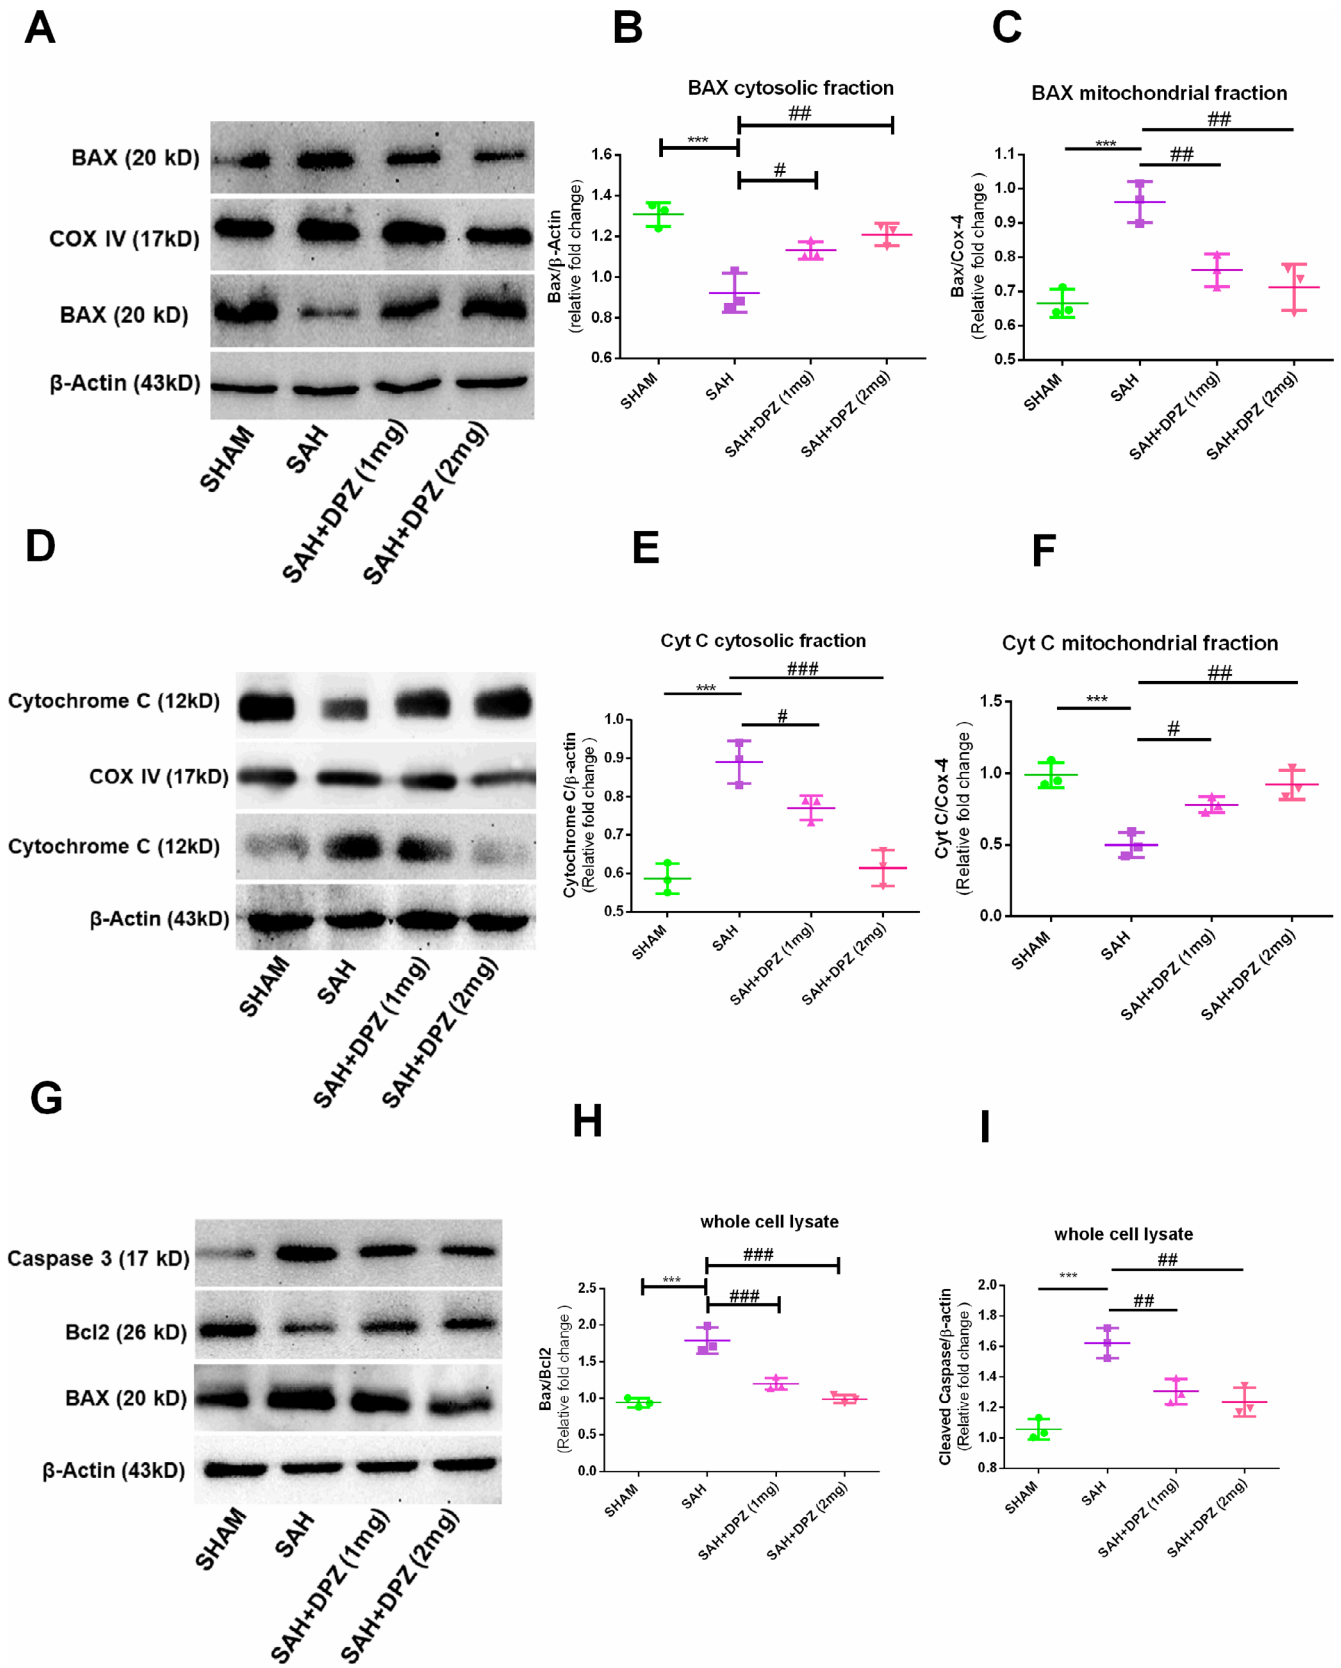

FIGURE 10 | Legend on next page.

which is linked to a higher quantity of synapses, facilitates neuron connectivity and inhibits post-ICH cognitive decline. The PSD-95 protein plays a crucial role in regulating synaptic maintenance following an ICH. Recent research suggests that PSD-95 experiences disruption following SAH surgery in rats (Shen et al. 2015). Similarly, BDNF protein together with PSD-95

enhances synaptic plasticity and promotes the activation of the CaMKII-CREB pathway in mouse neurons (Hu et al. 2011).

Our research has uncovered that donepezil can increase the expression of PSD 95 protein and enhance the function of α7 nAChR receptors. Additionally, it promotes synaptic connection by activating memory markers such as CREB/CaMKII and BDNF protein in rats with SAH. In addition, donepezil demonstrated dose-dependent enhancements in escape latency and arm alternation in post-SAH rats. Prior research has shown that α7 nAChR overexpression can enhance the expression of PSD-95 in SH-SY5Y neuronal cells (Ren et al. 2020). A previous study reported that α7-nicotinic receptor activation enhances the growth of primary cultured rat cortical neurons (Takada-Takatori et al. 2008) and improves learning and memory through an adjunctive treatment strategy combining donepezil with PNU-120596 (Callahan et al. 2013). Furthermore, it has been shown to improve spatial memory deficits caused by temporary global cerebral ischemia in gerbils by elevating the expression of CaMKII-CREB (Min et al. 2012). Stimulation of presynaptic α7 nAChRs has been demonstrated to boost CaMKII activity, resulting in heightened Ca^{2+} entry and CaM production. This, in turn, may activate the CaMKII-CaM-CREB signaling pathway, leading to neuroprotective benefits and improved learning and memory abilities in mouse models (Wang et al. 2020).

SAH induction causes oxidative stress, which is then made worse by reperfusion injury and the overproduction of ROS within the cell. Overexposure to ROS causes the release of pro-inflammatory proteins, which in turn causes neuroinflammation. After SAH surgery, this disruption triggers astrocyte and glial cell activation, a significant early brain injury (EBI) event (Lucke-Wold et al. 2016). Through the activation of TLR4 receptors, SAH triggers the release of inflammatory proteins, including TNF-α and NF-κB, as well as activating anti-apoptotic pathways including PI3K and Akt. Reperfusion, on the other

14714159, 2025, 4, Downloaded from https://onlinelibrary.wiley.com/doi/10.1111/jnc.70063 by Delhi Technological University, Wiley Online Library on [01/05/2025]. hand, decreases these anti-apoptotic proteins action (Iadecola and Anrather 2011). Our research shows that donepezil therapy reduces the expression of Iba1 and GFAP in SAH damage. In SAH rats, the production of inflammatory mediators like TLR4, phosphorylated NF-κB, and TNF-α is downregulated by this therapy.

The prior report indicated that donepezil inhibits the nuclear translocation of NF-κB in LPS-stimulated macrophage cells, which lowers the production of proinflammatory mediators (Arikawa et al. 2016). Moreover, donepezil increases the expression of PI3K/Akt, which in turn triggers the activity of antioxidant enzymes, lowering oxidative stress and reducing the damage that ROS brings to neurons (Haraguchi et al. 2017). According to our findings, donepezil can significantly increase PI3K/Akt expression in post-SAH rats, suggesting that it may be used as a therapeutic agent for SAH-induced injury.

The maturation and development of neurons depend on mitochondrial dynamics. Oxidative damage during SAH causes mitochondrial permeability transition pores (PTPs) to open, which increases the release of ROS into the cytoplasm and eventually causes mitochondrial malfunction. An excess of ROS is produced as a result of this malfunction, upsetting the equilibrium between endogenous oxidants and antioxidants as well as the Drp1-mfn2 mediated fission and fusion process (Smith et al. 2013), (Xie et al. 2018). Consequently, oxidative alteration of proteins, lipids, and DNA occurs, further increasing ROS emission. The brain produces ATP by a process known as oxidative phosphorylation, or OXPHOS. OXPHOS downregulation is frequent in neurodegenerative disorders and impairs brain function (Hroudová et al. 2014). Better ATP availability is ensured by increased oxygen consumption, and this is important for preserving essential cellular functions and averting necrosis and apoptosis (Ali et al. 2022), (Kaushik et al. 2020). Our findings show that donepezil treatment successfully restores mitochondrial morphology, upregulates OXPHOS (C-I to C-V) protein expression, including ATP synthase activity, and reduces SAH-induced damage to the ETC. Donepezil has been shown to prevent oxidative stress and deficiencies in mitochondrial bioenergetics, which aligns with our findings, protecting mitochondrial integrity and biogenesis in the post-SAH brain (Ye et al. 2015).

The normal processes of mitochondrial fission and fusion are responsible for maintaining a functional and healthy mitochondrial network. Nevertheless, abnormal mitochondrial division facilitated by Drp1 results in the excessive formation of ROS and triggers the caspase-3-dependent process of cell death. This abnormal division also enables the movement of the proapoptotic Bcl-2 family member Bax from the cytosol inside the cell to the outer membrane of the mitochondria, increasing the release of cyt c into the cytosol inside the cell and encouraging cell death in different disease types (Clerc et al. 2014; Du et al. 2019).

Donepezil has demonstrated its efficacy as an anti-apoptotic drug in specific circumstances within the human brain (Sharifipour et al. 2014). Our hypothesis strongly indicates that donepezil has an immediate protective effect on mitochondrial function by preventing the movement of Bax. This is accomplished by enhancing the integrity of the mitochondrial membrane, thus restricting the release of cyt c from the mitochondria. In addition, donepezil decreases the Bax/Bcl-2 ratio and lowers the levels of cleaved caspase-3 in the brain tissue of rats after SAH. Similarly, the therapeutic approach of donepezil seems to mitigate the significant damage to the neuronal architecture that is commonly associated with SAH. In keeping with our findings, Madani Neishaboori et al. (2021) documented that donepezil can ameliorate the damage caused by ischemic stroke through the reduction of inflammation and enhancement of mitochondrial function, neurogenesis, and angiogenesis, highlighting its potential as a therapeutic agent.

There are different limitations in our investigation. Initially, the study concentrated on the immediate effects (between 24 and 72 h) of donepezil after SAH, highlighting the need for more research on long-term survival and functional recovery. Furthermore, although the involvement of PSD-95 in synaptic density and spatial memory has been recognized, a more in-depth investigation is needed to understand its exact molecular mechanisms. Furthermore, while we investigated the neuroprotective properties of donepezil concerning mitochondrial dysfunction, neuroinflammation, and neuronal death, a more comprehensive understanding of these molecular interconnections is necessary for therapeutic applications.

5 | Conclusion

In general, our idea suggests that donepezil helps to sustain the expression of PSD95 and promotes the levels of α7-AChR and BDNF-CaMKII. As a result, this restores neurobehavioral impairments and partially preserves anxiety and spatial memory. Our work presents novel data that show how donepezil can reinstate the dynamics of mitochondria, which helps protect neurons from damage caused by SAH at intervals of 24 and 72 h. This is achieved by minimizing a process called Drp1-mediated neuronal apoptosis, decreasing neuroinflammation, and maintaining the proper functioning of mitochondria. Thus, donepezil may be a promising therapeutic approach for averting and treating SAH.

Abstract

Observations show that dispersive Alfvén waves (DAWs) play a significant role in the heating and generation of turbulence at reconnection sites. The present work investigates the nonlinear evolution of DAWs and the related turbulence with pre-existing magnetic islands in solar wind. The turbulence is driven by nonlinear interactions, including wave–wave coupling and ponderomotive force, in the presence of pre-existing magnetic islands. Using computer modeling and numerical techniques, the resulting dynamical equation is solved. Space integration is performed using a pseudo-spectral method, while time integration is carried out using a finite difference scheme. The simulation findings validate the presence of turbulence and demonstrate the spatiotemporal evolution of the DAW localized structures and current sheets. The scale sizes of the localized structures have been calculated using a semi-analytic model and it has been demonstrated that these scale sizes are dependent on the characteristics of magnetic islands and ponderomotive nonlinearity. Thermal tail formation in energetic ions has been investigated based on the power-law scaling of turbulence generation.

Keywords: magnetic reconnection, turbulence, localization, reconnection rate

1. Introduction

Many spacecraft observations have revealed the turbulent state of electromagnetic fluctuations in the solar wind regime. Additionally, the solar wind may be utilized as an endless, natural laboratory for investigating a variety of scientific phenomena occurring in plasma turbulence that are difficult to replicate in a laboratory [1–5]. Smaller scales of energy exchange are facilitated by the wave energy cascade created by the turbulence in the solar wind. This cascading of energy is thought to play a significant role in the creation of solar winds and the acceleration of high-energy particles. Solar wind turbulence exhibits $k^{-5/3}$ scaling in the inertial range, regardless of energy injection into the system or energy dissipation at small scales. Energy is dissipated until the fluctuation-scale size approaches the order of the proton inertial length (λ_i) or the ion gyro-radius (ρ_s) after being injected into this region from the energy injection region (corresponding scaling k^{-1}). This region is regarded as a large-scale region where the description of magnetohydrodynamics (MHD) may be fully described [3, 6].

When Landau damping and other phenomena start to dominate, the MHD description of turbulence becomes invalid and changes in turbulence characteristics can be observed. The spectrum also steepens in comparison with inertial scaling. Moreover, the turbulent spectrum at the kinetic scale ($k\lambda_i > 1$) can be described using two models. One possible approach is

the cascading of whistler waves or kinetic Alfvén waves [7–9]. Another approach is the localization of parallel propagating dispersive Alfvén waves (DAWs). Alfvén waves are usually non-dispersive in nature (i.e. the speed of these waves remains the same as the change in wavelength) but when the frequency of Alfvén waves becomes comparable to the ion cyclotron frequency, then the speed of Alfvén waves also depends on their wavelength, showing dispersive behavior. Many researchers have shown the dispersion of Alfvén waves with the insertion of the Hall term [10–13].

Furthermore, Alfvén waves are the most prominent phenomenon in magnetized plasmas. Specifically, nonlinear Alfvén waves have a significant impact on a range of plasma processes both in the laboratory and in space, and these processes include turbulence, reconnection and heating [14–18]. In addition to the different space phenomena, it has been determined that magnetic reconnection is essential to the dynamics of turbulence [19, 20]. An inherent plasma characteristic, also present in solar wind plasmas, is the development of magnetic islands brought about by the dynamic processes of magnetic reconnection and turbulence [21, 22]. Magnetic islands can take on different shapes, such as spherical or elongated forms. The acceleration of particles in solar wind plasmas might be significantly aided by these magnetic islands. The energy transmission between various length scales may be impacted by the influence of magnetic islands on the wave dynamics [23–25].

DAWs are widely recognized in the literature for their involvement in turbulence generation and are highly promising for magnetic reconnection [26–28]. Consequently, it is possible for turbulence and magnetic reconnection, two basic phenomena, to coexist and have an impact on one another. We examine the two phenomena (i.e. turbulence and reconnection) in the framework of DAWs, which acquire the properties of dispersion due to the wave's finite frequency correction [27–31]. The finite frequency refers to the consideration of effects that arise when the frequency of Alfvén waves is not negligibly small compared to the ion cyclotron frequency. To fully comprehend space plasma dynamics, it becomes necessary to study the relationship between turbulent dissipation and reconnection. The formation of coherent structures and current sheets has been studied by Perri *et al* [32, 33] in the dissipation range (i.e. at smaller length scales). Their findings support the presence of current sheets and localized structures at sub-proton scale sizes, where energy exchange over the dissipation range might occur via magnetic reconnection. Hence, it becomes necessary to further study whether dissipation over small length scales occurs as a result of reconnection or other factors such as instabilities which cause the generation of localized/coherent or both. The purpose of the current analysis is to explore this question given the aforementioned context. Using WIND spacecraft data at 1 AU, Voros *et al* [34] showed that turbulence generation in solar wind is due to reconnection outflows. The present study is motivated by recent observations [32, 34–36] where the Hall effect, pressure tensor and other physical conditions affect the reconnecting electric field, current sheet formation and their scale size. In this work we consider a simple model where the effect of the Hall term is studied on the localized structures and current sheet formation by numerical simulations and analytical models. Pseudo-spectral and finite difference methods are used for space integration and time domain integration, respectively [37]. For this, we consider a situation where Alfvén waves are present at the reconnection site. Various types of waves, including right- and left-handed polarized Alfvén waves, kinetic Alfvén waves, and torsional Alfvén waves, have been observed at the reconnection site [38–40], and due to the Hall effect, they become dispersive. In solar wind turbulence, right-handed waves can also survive the shift into the intermediate dispersive region at higher wavenumbers [10, 11, 13, 41]. For this reason, the main focus of the present study will be on right-handed polarized DAWs. It is also discovered that the Hall term, due to the notable rise in the reconnection rate, has a significant impact on collisionless plasmas [42–44]. The turbulence in the solar wind and its related consequences are diversified due to the wide range of frequencies and amplitudes of Alfvén waves.

The present work investigates the temporal phase of nonlinear evolution of right-handed DAWs at reconnection sites that cause current sheet formation, localization and turbulence. The objective of this study is to analyze the dynamics of DAWs, the reconnection rate and the evolution of current sheets for two cases, as follows: case I, when the Hall term (i.e. ω/ω_{ci}) is present; and case II, when the Hall term is absent (i.e. $\omega/\omega_{ci} \to 0$) in the presence of a fully developed chain of magnetic islands and ponderomotive nonlinearity. The obtained results demonstrate consistency with earlier reported observations [32, 34, 35]. Both models investigate structures and dynamics in solar wind turbulence, emphasizing the role of coherent structures such as magnetic islands and current sheets.

This paper is arranged as follows: The dynamics of DAWs and ion acoustic waves (IAWs) are covered in section 2. The numerical simulation methods and their outcomes are examined in section 3. In addition, we examine the semi-analytical model in section 4 to comprehend the fundamental physics behind the localization. Section 5 provides a summary and conclusion of the present study.

2. Formulation of wave equations

Let us consider the dynamics of a DAW having finite frequency and amplitude propagating parallel to the magnetic field. Alfvén waves are treated as non-dispersive, meaning their velocity is constant and does not depend on wavelength. However, when the wave frequency approaches a significant fraction of the ion cyclotron frequency, dispersive effects come into play. We also consider a medium having an ambient magnetic field (B_{0z}) along the z-axis and the magnetic islands present at the reconnection sites owing to the perturbation in the background magnetic field by δB_y. The dependence of the

magnetic field of the islands in the y-direction is considered to be much larger than their dependence in the x-direction, i.e. $\delta B_y \gg \delta B_x$. The total magnetic field (B) under the influence of which the DAW is propagating becomes $\vec{B} = B_{0z}\hat{k} + \delta B_y \hat{j}$. The DAW also exhibits transverse instability [45].

By using Faraday and Ampere laws, one may obtain [46]

$$\nabla^2 \vec{E} - \nabla\left(\nabla.\vec{E}\right) = \frac{1}{c^2}\frac{\partial^2 \vec{D}}{\partial t^2}, \tag{1}$$

where c is the speed of light in vacuum. Using the well-known relation of the dielectric tensor, $\tilde{\varepsilon}$, and electric field, $\vec{E}$, with $\vec{D}$, i.e. $\vec{D} = \tilde{\varepsilon}\vec{E}$, taking $\vec{\nabla}.\vec{D} = 0$, and further taking field variation as $e^{-i\omega t}$, equation (1) in its component form can be written as follows:

$$\frac{\partial^2 E_x}{\partial y^2} + \frac{\partial^2 E_x}{\partial z^2} - \frac{\partial^2 E_z}{\partial x \partial z} - \frac{\partial^2 E_y}{\partial x \partial y} = \frac{1}{c^2}\frac{\partial^2}{\partial t^2}\left(\tilde{\varepsilon}_{xx}E_x + \tilde{\varepsilon}_{xy}E_y\right) \tag{2}$$

$$\frac{\partial^2 E_y}{\partial x^2} + \frac{\partial^2 E_y}{\partial z^2} - \frac{\partial^2 E_x}{\partial y \partial x} - \frac{\partial^2 E_z}{\partial y \partial z} = \frac{1}{c^2}\frac{\partial^2}{\partial t^2}\left(\tilde{\varepsilon}_{yx}E_x + \tilde{\varepsilon}_{yy}E_y\right) \tag{3}$$

$$\frac{\partial E_z}{\partial z} = -\frac{1}{\tilde{\varepsilon}_{zz}}\left[\tilde{\varepsilon}_{xx}\frac{\partial E_x}{\partial x} + \tilde{\varepsilon}_{xy}\frac{\partial E_y}{\partial x} - \tilde{\varepsilon}_{xy}\frac{\partial E_x}{\partial y} + \tilde{\varepsilon}_{yy}\frac{\partial E_y}{\partial y}\right]. \tag{4}$$

Defining $E_- = E_x - iE_y$ and $E_+ = E_x + iE_y$ as the right and left modes of a circularly polarized wave. The following coupled wave equation can be obtained by using equations (2)–(4) as

$$\begin{aligned}
&\frac{\partial^2 E_+}{\partial z^2} + \frac{1}{2}\left(1 + \frac{\tilde{\varepsilon}_{+00}}{\varepsilon_{0zz}}\right)\left(\frac{\partial^2 E_+}{\partial x^2} + \frac{\partial^2 E_+}{\partial y^2}\right) + \frac{1}{2}\left(-1 + \frac{\tilde{\varepsilon}_{-00}}{\varepsilon_{0zz}}\right) \\
&\quad \times \left(\frac{\partial^2 E_-}{\partial x^2} + \frac{\partial^2 E_-}{\partial y^2}\right) - i\left(1 - \frac{\tilde{\varepsilon}_{-00}}{\varepsilon_{0zz}}\right) \times \frac{\partial^2 E_-}{\partial x \partial y} \\
&= \frac{\tilde{\varepsilon}_{+0}}{c^2}\frac{\partial^2}{\partial t^2}E_+ . \frac{\partial^2 E_-}{\partial z^2} + \frac{1}{2}\left(1 + \frac{\tilde{\varepsilon}_{-00}}{\varepsilon_{0zz}}\right)\left(\frac{\partial^2 E_-}{\partial x^2} + \frac{\partial^2 E_-}{\partial y^2}\right) \\
&\quad + \frac{1}{2}\left(-1 + \frac{\tilde{\varepsilon}_{+00}}{\varepsilon_{0zz}}\right)\left(\frac{\partial^2 E_+}{\partial x^2} + \frac{\partial^2 E_+}{\partial y^2}\right) - i\left(1 - \frac{\tilde{\varepsilon}_{+00}}{\varepsilon_{0zz}}\right) \\
&\quad \times \frac{\partial^2 E_+}{\partial x \partial y} = \frac{\tilde{\varepsilon}_{-0}}{c^2}\frac{\partial^2}{\partial t}E_- .
\end{aligned} \tag{5}$$

where $\tilde{\varepsilon}_{+00} = \frac{\omega_{pe}^2}{\omega_{ce}(\omega - \omega_{ci})}$ and $\tilde{\varepsilon}_{-00} = \frac{\omega_{pe}^2}{\omega_{ce}(\omega + \omega_{ci})}$ represent the linear parts of the dielectric, $\tilde{\varepsilon}_{+0} = \frac{\omega_{pe}^2}{\omega_{ce}(\omega - \omega_{ci})}\left(1 - 2\frac{\delta B_y}{B_{0z}} + \frac{\delta n}{n_0}\right)$, $\tilde{\varepsilon}_{-0} = \frac{\omega_{pe}^2}{\omega_{ce}(\omega + \omega_{ci})}\left(1 - 2\frac{\delta B_y}{B_{0z}} + \frac{\delta n}{n_0}\right)$ and $\varepsilon_{0zz} = 1 - \frac{\omega_{pe}^2}{\omega^2}$. ω_{cf} denotes the cyclotron frequency of species f (i for ion and e for electron), $\omega_{cf} = eB_{0z}/m_f c$. Further, $\omega_{pf} = \sqrt{4\pi n_0 e^2/m_f}$ is the plasma frequency and n_0 and δn represent the background density and perturbation in the background density, respectively.

Verscharen *et al* [41] observed that the right- and left-handed modes, having frequencies of the order of the ion cyclotron frequency (i.e. $\omega \approx \omega_{ci}$) or wavelengths of the order of $1/\lambda_i$ (where $\lambda_i = c/\omega_{pi}$), can co-exist in the solar wind. At higher wave numbers, left modes undergo cyclotron resonance [47, 48] and make the system complex. Only right-handed waves survive and are able to reach small wavenumbers ($k\lambda_i > 1$). Therefore, we will focus only on the right-handed mode for a better understanding of the system.

For the right-handed mode of a circularly polarized DAW, $E_+ = 0$, and using the relation $\vec{B} = \nabla \times \vec{A}$along with Faraday's law, the following equation is obtained

$$\begin{aligned}
&\frac{\partial^2 A_-}{\partial z^2} + \frac{1}{2}\left(1 + \frac{\tilde{\varepsilon}_{-00}}{\varepsilon_{0zz}}\right)\left(\frac{\partial^2 A_-}{\partial x^2} + \frac{\partial^2 A_-}{\partial y^2}\right) \\
&= \frac{1}{c^2}\frac{\omega_{pe}^2}{\omega_{ce}(\omega + \omega_{ci})}\left(1 - 2\frac{\delta A_z}{A_{0y}} + \frac{\delta n}{n_0}\right)\frac{\partial^2}{\partial t^2}A_- .
\end{aligned} \tag{6}$$

$\frac{\delta B_y}{B_{0z}} = \frac{\delta A_z}{A_{0y}}$ has been obtained by using the above given relation between magnetic field and vector potential and A_- is the magnetic vector potential of the DAW.

2.1. IAW dynamics

Consider an IAW having low frequency and propagation parallel to the magnetic field present in the background. The fundamental equations governing the dynamics of the wave are as follows:

(i) Equation of motion

$$\frac{\partial v_f}{\partial t} = \frac{q_f \vec{E}}{m_f} + \frac{q_f}{c m_f}\left(\vec{v}_f \times \vec{B}\right) + \frac{\vec{F}_f}{m_f} - \frac{T_f}{m_f}\nabla\frac{n_f}{n_0} \tag{7}$$

(ii) Equation of continuity

$$\frac{\partial n_f}{\partial t} + \nabla\left(n_f \vec{v}_f\right) = 0 \tag{8}$$

(iii) Ponderomotive force

$$\vec{F}_f = \frac{q_f}{c}\left(\vec{v}_f^{\,*} \times \vec{B}\right) - m_f\left(\vec{v}_f^{\,*}.\vec{\nabla}\right)\vec{v}_f \tag{9}$$

where n_f is the density, m_f is the mass, $\vec{v}_f$is the velocity and q_f is the charge of the species 'f' of plasma ($f = e$ for electrons and i for ions). Furthermore, in terms of the scalar potential, the electric field is defined as $\vec{E} = -\vec{\nabla}\phi$. The thermal velocity of an electron has been considered to be very much larger than the phase velocity of a wave. The scalar potential can be written as [18]

$$\phi = \frac{T_e \delta n}{e n_0} - \frac{F_{ez}}{ik_z e}. \tag{10}$$

Upon using equation (10) and the components of equation of motion, we will obtain the following form

$$\frac{\partial v_{ix}}{\partial t} = \frac{\Omega^2 \rho_s^2}{n_0}\frac{\partial n}{\partial x} - \frac{\Omega^2 k_x F_{ez}}{\omega_{ci}^2 m_i k_z} - \frac{\Omega^2 F_{ix}}{\omega_{ci}^2 m_i} - \frac{i\Omega F_{iy}}{\omega_{ci} m_i} \tag{11}$$

$$\frac{\partial v_{iz}}{\partial t} = -\frac{c_s^2}{n_0}\frac{\partial n}{\partial z} + \frac{(F_{ez} + F_{iz})}{m_i}. \tag{12}$$

Now, using equations (11) and (12), the equation of continuitytakes the following form

$$\frac{\partial^2 n}{\partial t^2} - \rho_s^2 \frac{\partial^2}{\partial t^2}\frac{\partial^2 n}{\partial x^2} - c_s^2 \frac{\partial^2 n}{\partial z^2} = \frac{\Omega^2 n_0}{\omega_{ci}^2 m_i}\frac{\partial F_{ix}}{\partial x} + \frac{i\Omega n_0}{m_i \omega_{ci}}\frac{\partial F_{iy}}{\partial x}$$

$$+\frac{\Omega^2 n_0 k_x}{\omega_{ci}^2 m_i k_z}\frac{\partial F_{ez}}{\partial x}-\frac{n_0}{m_i}\frac{\partial\left(F_{ez}+F_{iz}\right)}{\partial z}. \tag{13}$$

Here, $n=n_0+\delta n$, where n and δn represent the modified number density and modified density, respectively. Ω is the frequency of the IAW and its value is much less the frequency of the DAW. The constants are defined as follows: $c_s=\sqrt{(T_e+T_i)/m_i}$ is the ion sound speed and $\rho_s=c_s/\omega_{ci}$ is the ion acoustic gyro-radius (here, 's' in subscript refers to the sound scale or sound speed). The ponderomotive force components (i.e. F_{ix},F_{iy},F_{iz} and F_{ez}) are obtained using equation (9) and have the form:

$$F_{ix}=-\frac{e^2\omega^2}{8m_i\left(\omega^2-\omega_{ci}^2\right)^2}\left[2-\frac{\omega_{ci}}{\Omega}\left(3-\frac{\omega_{ci}^2}{\Omega^2}\right)\right]\frac{\partial|A_-|^2}{\partial x} \tag{14}$$

$$F_{iy}=-\frac{ie^2}{16m_i\left(\omega^2-\omega_{ci}^2\right)^2}\left[\left(\omega^2-\omega_{ci}^2\right)^2+\left(1+\frac{\omega_{ci}}{\omega}\right)\left(\omega^2-\omega_{ci}^2\right)\right]\times\frac{\partial|A_-|^2}{\partial z} \tag{15}$$

$$F_{iz}=-\frac{e^2}{8m_i\left(\omega^2-\omega_{ci}^2\right)}\left(1-\frac{\omega_{ci}}{\omega}\right)\frac{\partial|A_-|^2}{\partial z} \tag{16}$$

and

$$F_{ez}=-\frac{e^2}{8m_e\left(\omega^2-\omega_{ce}^2\right)}\left(1-\frac{\omega_{ce}}{\omega}\right)\frac{\partial|A_-|^2}{\partial z}. \tag{17}$$

Using ponderomotive force components (i.e. equations (14)–(17) in equation (13), this equation will take the following form $\frac{\partial^2 n}{\partial t^2}-\rho_s^2\frac{\partial^2}{\partial t^2}\frac{\partial^2 n}{\partial x^2}-c_s^2\frac{\partial^2 n}{\partial z^2}=-\frac{e^2\Omega^2}{16m_i^2\omega_{ci}^2}\left[\frac{2(1+\omega_{ce}/\omega)m_i}{(\omega^2-\omega_{ce}^2)m_e}+\frac{\omega^2}{(\omega^2-\omega_{ci}^2)^2}\left\{2-\frac{\omega_{ci}}{\omega}\left(3-\frac{\omega_{ci}^2}{\omega^2}\right)\right\}\right]\frac{\partial^2|A_-|^2}{\partial x^2}$

$$-\frac{e^2\left(1-\omega/\omega_{ci}\right)}{8m_i^2\left(\omega_{ci}^2-\omega^2\right)}\frac{\partial^2|A_-|^2}{\partial z^2}. \tag{18}$$

The above equation represents the time-dependent variation of the acoustic density perturbation for the effect of ponderomotive nonlinearity, which is determined by the DAW.

Now, by taking the steady-state approximation, density perturbation takes the form

$$\frac{\delta n}{n_0}=\exp\left(-\alpha_0|A_-|^2\right)-1 \tag{19}$$

where $\alpha_0=\frac{\omega_{pi}^2}{32\pi n_0 T(\omega_{ci}^2-\omega^2)}\left(1-\frac{\omega}{\omega_{ci}}\right)$.

Further, equation (6) is solved semi-analytically by considering the wave solution [49] as follows

$$A_-=A\left(x,y,z,t\right)\mathrm{e}^{-\mathrm{i}(\omega t-k_- z)}. \tag{20}$$

where A is the complex amplitude of the DAW and $k_-=\frac{\omega}{c}\tilde{\varepsilon}_{-00}^{1/2}$ is the wave number. Substituting equations (19) and (20) in equation (6) and further assuming $\partial_z A\ll k_+ A$, the following equation is obtained

$$\frac{2\mathrm{i}}{\omega}\frac{\partial A}{\partial t}+\frac{2\mathrm{i}}{k_-}\frac{\partial A}{\partial z}+\frac{1}{2k_-^2}\left(1+\frac{\tilde{\varepsilon}_{-00}}{\varepsilon_{0zz}}\right)\left(\frac{\partial^2 A}{\partial x^2}+\frac{\partial^2 A}{\partial y^2}\right)-2\frac{\delta A_z}{A_{0y}}A+\left(\exp\left(\alpha_0|A|^2-1\right)\right)A=0. \tag{21}$$

The dimensionless form of equation (21) can be written as follows

$$\mathrm{i}\frac{\partial A}{\partial t}+\mathrm{i}C_1\frac{\partial A}{\partial z}+C_2\left(\frac{\partial^2 A}{\partial x^2}+\frac{\partial^2 A}{\partial y^2}\right)+\left(2\frac{\delta A_z}{A_0}-\frac{\delta n}{n_0}\right)A=0 \tag{22}$$

where C_1 and C_2 are constants. They are defined as $C_1=\frac{\omega t_n}{k_- z_n}$ and $C_2=\frac{\omega t_n}{4k_-^2}\left(1+\frac{\varepsilon_{-00}}{\varepsilon_{0zz}}\right)$. $x_n=\lambda_i, n_n=n_0, z_n=\frac{2}{k_-}, t_n=\frac{2}{\omega}$ and $A_n=\left(\frac{8m_i^2\omega^2(\omega_{ci}^2-\omega^2)}{k_-^2 e^2(1-\omega/\omega_{ci})}\right)^{1/2}$ are normalization parameters.

Weak and slowly changing field fluctuations are caused by the previously existing chain of magnetic islands. Magnetic reconnection has been considered within the framework of magnetic islands. The magnetic island profile [50] is considered as

$$\frac{\delta A_z}{A_0}=-\frac{x^2}{2L^2}+0.5\cos ky. \tag{23}$$

Using equation (23) in equation (22), the dynamical equation of the DAW is obtained. This will be useful for a basic understanding of localized structures and current sheet formation under the influence of magnetic islands at the reconnection sites. Finally, we have

$$\mathrm{i}\frac{\partial A}{\partial t}+\mathrm{i}C_1\frac{\partial A}{\partial z}+C_2\left(\frac{\partial^2 A}{\partial x^2}+\frac{\partial^2 A}{\partial y^2}\right)+\left(2\left(-\frac{x^2}{2L^2}+0.5\cos ky\right)-\frac{\delta n}{n_0}\right)A=0. \tag{24}$$

Equation (24) represents the nonlinear dynamical equation of the DAW which will be solved further by numerical simulations. The dynamical equations of the DAW will be solved further by using solar wind parameters.

It should also be emphasized that the values of ion inertial length and ion gyroradius ($\rho_s=c_s/\omega_{ci}$) are approximately equal [51].

3. Numerical simulation

A modified nonlinear Schrödinger model is developed for solving equation (24). Equation (24) is solved numerically, in a 3D periodic spatial domain of size $(2\pi/\alpha_x)\times(2\pi/\alpha_y)\times(2\pi/\alpha_z)$ and grid points $(128\times128\times128)$ with step size of (5×10^{-5}). The perturbations in the wave number of the DAW are $\alpha_x=\alpha_y=\alpha_z=0.2$. The system resolution is $\Delta x=\Delta y=\Delta z=\frac{2\pi}{\alpha n'}$, where n' represents the grid points and $\alpha=0.2$ is a dimensionless quantity. A numerical methodology is employed in which time evolution is handled using the finite difference method combined with a predictor–corrector scheme, while spatial integration is performed using a pseudo-spectral method. The simplicity of the finite difference method over other approaches, including the finite element and finite volume methods, make it significantly beneficial. Finite difference methods take less time for a given grid. Computationally,

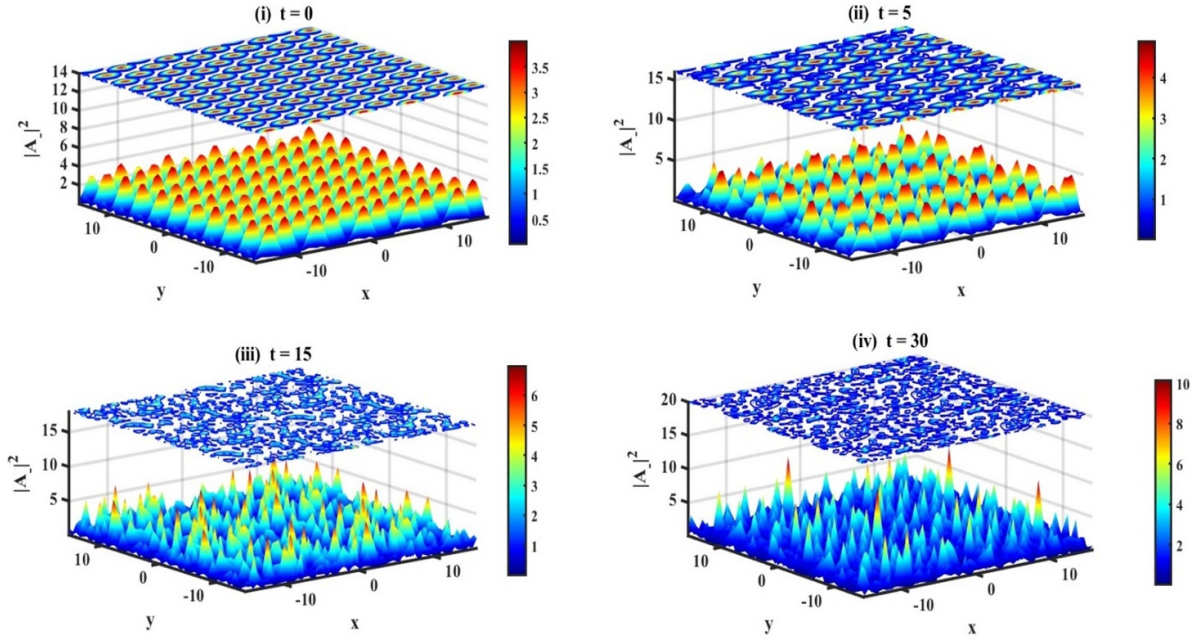

Figure 1. Representation of projection plots of localization of a DAW for different times at (i) $t = 0$, (ii) $t = 5$, (iii) $t = 15$, and (iv) $t = 30$.

this method is very accurate and efficient. The spectral convergence rate is the primary benefit of the pseudo-spectral method. The pseudo-spectral technique also yields high accuracy with rather coarse grids, which is another advantage. Initially, a simulation is run for the nonlinear Schrödinger equation and then the accuracy of the code is checked by the consistency of plasmon numbers (i.e. $N = \sum_k |A_k|^2$). We observed that during computation this quantity is constant up to six decimal places. For numerical simulation, the model equation was modified into a nonlinear Schrödinger equation, and in the present study we consider the initial condition [52] for the numerical simulation as

$$A(x,y) = \cos(2x + 2.3) + \cos(y + 4.1). \tag{25}$$

Numerical simulations are performed for solar wind at 1 AU. The typical plasma parameters of solar wind [51] we have used are as follows $T_i \approx 5.8 \times 10^5$ K, $T_e \approx 1.4 \times 10^5$ K, $n_0 \approx 3$ cm^{-3}, $B_{0z} \approx 6.2 \times 10^{-5}$ G, $\omega_{ci} \approx 0.594$ s^{-1}, $v_A \approx 7.815 \times 10^6$ cm s^{-1}, $k \approx 0.2$, $\rho_s \approx 1.298 \times 10^7$ cm, $\lambda_i \approx 1.315 \times 10^7$ cm, $\omega_{pe} \approx 9.767 \times 10^4$ s^{-1} and the other parameters are as follows: $\omega = 0.8\omega_{ci}$, $\omega_{ci} = 0.594$ sec^{-1}, $k_- = 4.531 \times 10^{-8}$ cm^{-1} and $A_n = 8.221 \times 10^{-8}$ statV cm^{-1}.

3.1. Results and discussions

Numerical simulations have been performed for equation (24). Localization plots, contour plots and current sheets have been studied for different values of time. Figure 1 represents the localized structures of DAWs at different times. The localized structures are of the order of the ion inertial length and formed as a result of a pre-existing chain of magnetic islands and density modification. The projection plots shown here depict symmetry at the early stage of time, due to the initial symmetric setup of magnetic islands and the periodic boundary conditions as given by (23) and (25), respectively, and become irregular at later period of time. The asymmetry of the structures can be taken into account, as the nonlinearity evolves over time due to changes in the background density and magnetic field. Figure 2 shows the fluctuations of the vector potential versus time.

Figure 3 (left panel) represents the contour plots of vector potentials at different times. The contour plots are utilized to depict the presence of magnetic islands at the reconnection site. It is clearly shown that the structures are modified with time showing high intensity. At the initial stage, the size of the structures is of the order of a few times the ion inertial length. As shown in figure 3 (right panel), spatial evolution of current density, i.e. $j = -\nabla^2 A_z$, has been studied over time. As current sheets are typically identified by sharp gradients in the current density, they naturally occur at the interface between regions of positive and negative current (i.e. the red and blue areas in the visualization). One can also see from figure 3 that the structures begin to deform over time and result in chaotic structures. The formation of the chaotic structures might be due to the generation of turbulence over time [32]. Figure 4 illustrates the fluctuation in density.

3.2. Quasi-steady state of the system

To observe the turbulent power spectrum, we take the quasi-steady state into account (i.e. $\partial/\partial t \approx 0$). So, equation (24) becomes

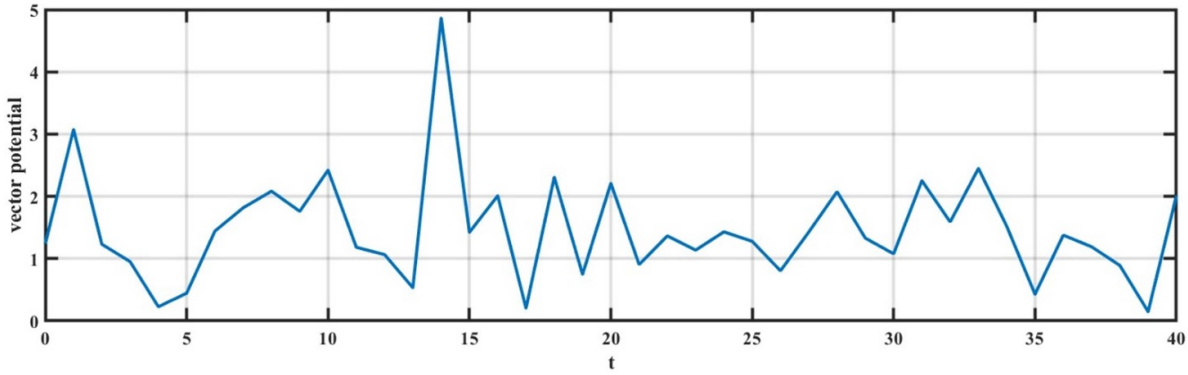

Figure 2. Representation of fluctuations in vector potential versus time (in normalized units).

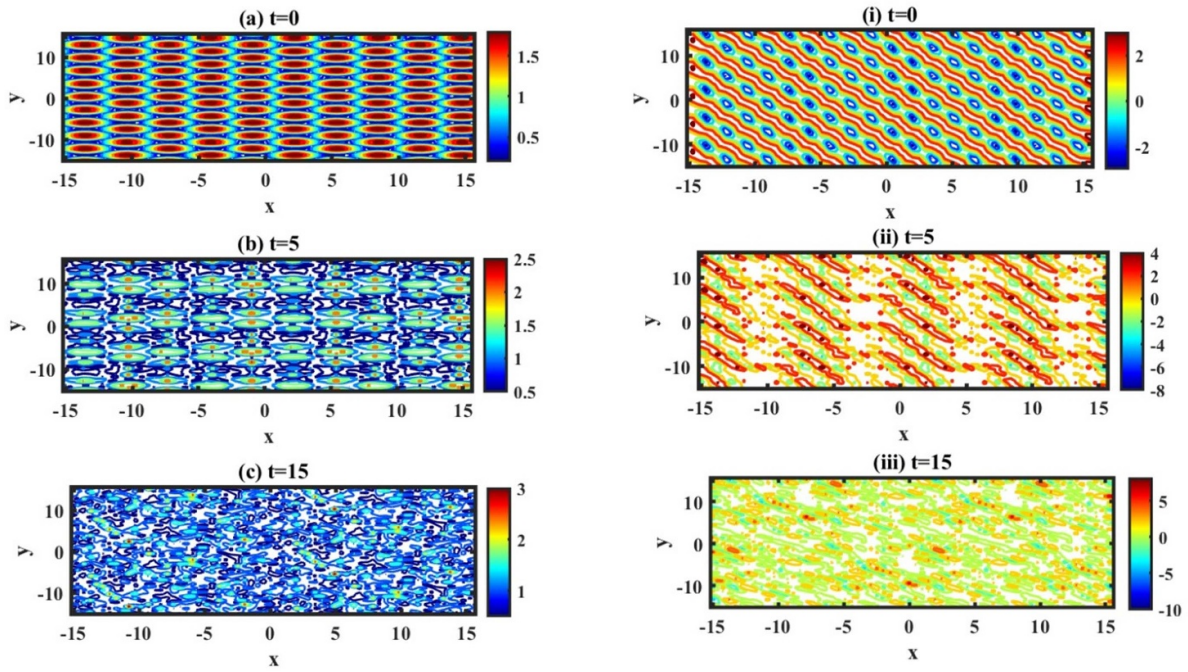

Figure 3. Representation of contour plots of vector potential in the left panel (a)–(c) and current density in the right panel (i)–(iii) of a DAW under the effect of modified density and magnetic islands in the background at different time.

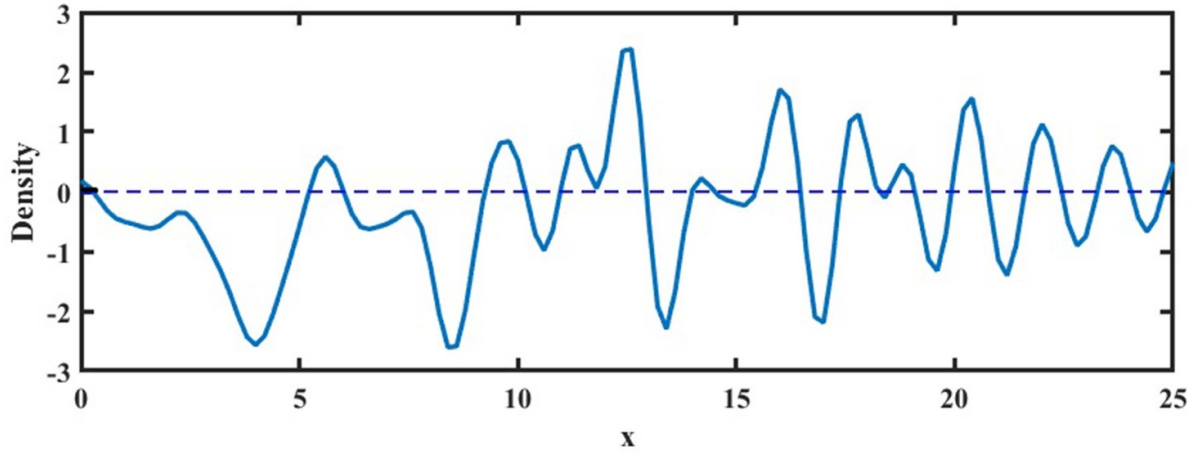

Figure 4. Representation of fluctuations in density at time, $t = 30$.

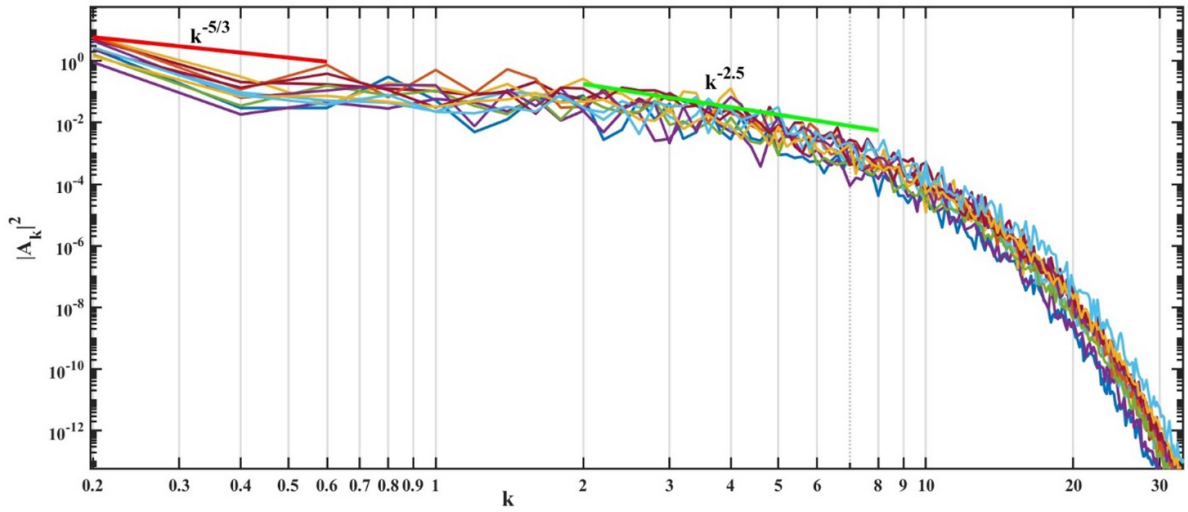

Figure 5. Plot of power spectra of the DAW, $|A_k|^2$, versus wave number between $z = 38$ to $z = 50$ in the presence of background density perturbation (ponderomotive) and magnetic islands.

$$iC_1\frac{\partial A}{\partial z} + C_2\left(\frac{\partial^2 A}{\partial x^2} + \frac{\partial^2 A}{\partial y^2}\right) + \left(2\left(-\frac{x^2}{2L^2} + 0.5\cos ky\right) - \frac{\delta n}{n_0}\right)A = 0. \quad (26)$$

To solve the above equation, the finite difference method has been used in the z-direction and the pseudo-spectral method along the x- and y-directions. Figure 5 shows the power spectra obtained by plotting the results obtained from numerical simulation with 512×512 grid points. The power spectrum is obtained by studying the distribution of energy over different length scales. The steepness of the power spectrum at small length scales $(k\lambda_i \ll 1)$ reveals the transformation of energy to smaller length scales from larger length scales $(k\lambda_i \ll 1)$. The red and green lines are used just for reference purposes.

To study the distribution of energy over different length scales power spectra has been plotted.

In the plot of power spectra field fluctuations versus wave number are plotted for finite $k_\perp$and zero $k_\parallel$ (in normalized units), when ponderomotive nonlinearity and magnetic islands are present. From the spectra, one may conclude that the transfer of energy from large length scale to small length scale represents the steepening of the power spectrum at smaller length scales. Voros *et al* [34] considered that the spectral break may be due to the Hall effect and showed the generation of turbulence due to the reconnection outflow by using WIND spacecraft data. They also reported an approximate scaling of fluctuations in the power spectral density driven by reconnection outflows to be 2.6–2.8 and 1.4–1.7 for small and large length scales, respectively. Our results show similarities to these conclusions. In the power spectra, one can clearly see the cascade of energy from large structures to small structures and in the small structures, energy dissipates and goes into the heating of plasma and acceleration of charged particles. Hence, stochastic interaction leads to energy exchange and subsequently leads to energy exchange and plasma heating.

This particular spectral index of the power spectra will encourage the formation of energetic particle thermal tails, which will accelerate the particles. By employing the Fokker–Planck equation, the recurrent interaction of charged particles with localized structures may be used to generate energy and this mechanism is also known as the second-order Fermi acceleration mechanism. Using this approach, charged particles accelerate due to their repeated collision with the magnetic clouds created by turbulence. Different mechanisms have been employed to investigate the acceleration of charged particles. In the current scenario, charged particles repeatedly interact with localized structures to obtain energy from them, which causes the particles to accelerate in a manner akin to the Fermi acceleration process. We study particle acceleration due to localized structures of the pump wave, which arise from the nonlinear coupling of waves. A quasi-linear diffusion equation [53] is employed to explain the recurring interaction of charged particles with localized structures. This equation may be obtained using the following

$$\frac{\partial g(v,t)}{\partial t} = \frac{\partial}{\partial v}\left\{D(v)\frac{\partial g(v,t)}{\partial v}\right\}. \quad (27)$$

When the ponderomotive nonlinearity set-up time is smaller than the observation time, the velocity distribution function might remain constant with respect to time. The distribution function, $g(v)$, and spectral index, μ [54, 55] in this context, are related in the following way

$$g(v) \propto v^{2-\mu}. \quad (28)$$

In this study $\mu \sim 2.5$. The spectral index promotes the enhancement of thermal tails in energetic particles, leading to their acceleration.

4. Semi-analytical model

The localized nature of DAWs is demonstrated through the temporal evolution (figure 1) of artificially imposed localized structures. Initially, the intensity is uniform, but as time progresses, localized structures form, leading to a redistribution of intensity. In some regions, the intensity becomes very high, while in others, it is negligible. In figure 2 (right panel), current sheets in the manuscript are visualized as regions with sharp gradients in the current density. In our model, magnetic islands and associated current sheets are not dynamically generated through magnetic reconnection but are instead imposed as part of the initial conditions. To understand the physics behind the localization of DAWs, a semi-analytical analysis is performed. This analysis will be helpful in understanding the effect of nonlinearity (i.e. perturbations in magnetic field and density) on current sheets, localized structures and the estimation of the size of these structures. By using the steady-state approximation in equation (21), the equation obtained is as follows:

Case I: when the Hall term (i.e. ω/ω_{ci}) is taken into account.

$$\frac{2\mathrm{i}}{k_-}\frac{\partial A}{\partial z}+\frac{1}{2k_-^2}\left(1+\frac{\tilde{\varepsilon}_{-00}}{\varepsilon_{0zz}}\right)\left(\frac{\partial^2 A}{\partial x^2}+\frac{\partial^2 A}{\partial y^2}\right)-2\left(-\frac{x^2}{2L^2}+0.5\cos ky\right)A+\left(\exp\left(\alpha_0|A_z|^2-1\right)\right)A=0. \tag{29}$$

To solve equation (29), the solution of the vector potential is considered [56] as follows

$$A\left(x,y,z\right)=A_0\left(x,y,z\right)\mathrm{e}^{\mathrm{i}k_-S(x,y,z)}. \tag{30}$$

Using the above equation in equation (29), the real and imaginary parts can be written as given by the following equations, i.e. (31) and (32), respectively,

$$2\frac{\partial S}{\partial z}-\frac{1}{2}\left(1+\frac{\tilde{\varepsilon}_{-00}}{\varepsilon_{0zz}}\right)\left(\frac{\partial^2 A_0}{\partial x^2}+\frac{\partial^2 A_0}{\partial y^2}\right)\frac{1}{k_-^2 A_0}+\frac{1}{2}\left(1+\frac{\tilde{\varepsilon}_{-00}}{\varepsilon_{0zz}}\right)\left(\left(\frac{\partial S}{\partial x}\right)^2+\left(\frac{\partial S}{\partial y}\right)^2\right)=\left(\exp\left(\alpha|A_0|^2\right)-1\right)+2\left(\frac{x^2}{2L^2}-0.5\cos ky\right) \tag{31}$$

$$\frac{\partial A_0^2}{\partial z}+\frac{A_0^2}{2}\left(1+\frac{\tilde{\varepsilon}_{-00}}{\varepsilon_{0zz}}\right)\left(\frac{\partial^2 S}{\partial x^2}+\frac{\partial^2 S}{\partial y^2}\right)+\frac{1}{2}\left(1+\frac{\tilde{\varepsilon}_{-00}}{\varepsilon_{0zz}}\right)\left(\frac{\partial A_0^2}{\partial x}\frac{\partial S}{\partial x}+\frac{\partial A_0^2}{\partial y}\frac{\partial S}{\partial y}\right)=0. \tag{32}$$

Further, the solution of the above equations is given by assuming the Gaussian profiles as follows

$$A_0^2\left(x,y,z\right)=\frac{E_{00}^2\left(x,y,z\right)}{f_1 f_2}\exp\left(-\frac{x^2}{r_{01}^2 f_1^2}-\frac{y^2}{r_{02}^2 f_2^2}\right) \tag{33}$$

$$S\left(x,y,z\right)=\beta_1\left(z\right)\frac{x^2}{2}+\beta_2\left(z\right)\frac{y^2}{2}+\phi\left(z\right). \tag{34}$$

Here, r_{01}, r_{02} represents the transverse scale size of the DAW and S represents the eikonal of the wave. In addition, $\beta_1(z)$ and $\beta_2(z)$ vary slowly with respect to z and their values are given by the following equations

$$\beta_1\left(z\right)=\frac{2}{\left(1+\frac{\tilde{\varepsilon}_{-00}}{\varepsilon_{0zz}}\right)}\frac{1}{f_1}\frac{\mathrm{d}f_1}{\mathrm{d}z}\text{ and }\beta_1\left(z\right)=\frac{2}{\left(1+\frac{\tilde{\varepsilon}_{-00}}{\varepsilon_{0zz}}\right)}\frac{1}{f_2}\frac{\mathrm{d}f_2}{\mathrm{d}z} \tag{35}$$

where f_1, f_2 represents the dimensionless beam width parameters.

Now, the beam width parameters are obtained by solving equations (33)–(35) using the approximations $x \ll r_{01}f_1$ and $y \ll r_{02}f_2$ (i.e. paraxial limits). Hence, one can obtain f_1 and $f_2$equations by comparing the coefficients of x^2 and y^2, i.e.

$$\frac{\mathrm{d}^2 f_1}{\mathrm{d}Z^2}=\frac{1}{4}\left(1+\frac{\tilde{\varepsilon}_{-00}}{\varepsilon_{0zz}}\right)^2\times\left(\frac{1}{f_1^3}-\frac{2R_{d1}^2 f_1}{\lambda_i^2\left(1+\tilde{\varepsilon}_{-00}/\varepsilon_{0zz}\right)}-\frac{2|E_{00}|^2 R_{d1}^2\alpha_0}{r_{01}^2 f_1^2 f_2\left(1+\tilde{\varepsilon}_{-00}/\varepsilon_{0zz}\right)}\times\exp\left(\frac{\alpha_0|E_{00}|^2}{f_1 f_2}\right)\right) \tag{36}$$

$$\frac{\mathrm{d}^2 f_2}{\mathrm{d}Z^2}=\frac{1}{4}\left(1+\frac{\tilde{\varepsilon}_{-00}}{\varepsilon_{0zz}}\right)^2\times\left(\frac{1}{f_2^3}-\frac{2R_{d2}^2 0.5k^2 f_2}{\lambda_i^2\left(1+\tilde{\varepsilon}_{-00}/\varepsilon_{0zz}\right)}-\frac{2|E_{00}|^2 R_{d2}^2\alpha_0}{r_{02}^2 f_1 f_2^2\left(1+\tilde{\varepsilon}_{-00}/\varepsilon_{0zz}\right)}\times\exp\left(\frac{\alpha_0|E_{00}|^2}{f_1 f_2}\right)\right). \tag{37}$$

where $R_{d1}=k_- r_{01}^2$ and $R_{d1}=k_- r_{02}^2$. We have solved equations (31) and (32) for a plane wavefront using the initial conditions $f_1=f_2=1$ at $z=0$ and $\frac{\mathrm{d}f_1}{\mathrm{d}z}=\frac{\mathrm{d}f_2}{\mathrm{d}z}=0$ at $z=0$. The last two terms of equations (36) and (37) are due to the presence of background density perturbations and magnetic islands. These two terms have the opposite sign from the first term, which is why competition continues between the first term and the last two terms. This competition causes the DAW to become localized. The converging and diverging effects are not the same in the x- and y-directions. Hence, the rate of change of f_1,f_2 along the x- and y-directions will be different and results in dissimilarity in localized structures along the x- and y-directions,

$$r_{01}=\left(\left(\lambda_i^2/2k_-^2\right)\left(1+\frac{\varepsilon_{-00}}{\varepsilon_{0zz}}\right)\right)^{1/4}=1.089\,\lambda_i \tag{38}$$

$$r_{02}=\left(\left(\lambda_i^2/k^2k_-^2\right)\left(1+\frac{\varepsilon_{-00}}{\varepsilon_{0zz}}\right)\right)^{1/4}=2.896\,\lambda_i. \tag{39}$$

The values of r_{01} and r_{02} have been obtained by taking the nonlinearity in the system due to the ponderomotive

force being zero. It should also be noted here that the size of the structures further decreases with non-zero ponderomotive nonlinearity in the system.

Case II: when $\omega/\omega_{ci} \to 0$. Taking only the x-components of the wave equation, we have

$$\frac{\partial^2 E_x}{\partial z^2} = \frac{1}{c^2}\frac{\partial^2 D}{\partial t^2}. \tag{40}$$

This equation gives $\omega = k_z v_A$, which is the dispersion relation for a non-DAW. However, if we include E_z, then

$$\frac{\partial^2 E_x}{\partial z^2} - \frac{\partial^2 E_z}{\partial x \partial z} = \frac{1}{c^2}\frac{\partial^2 D}{\partial t^2} \tag{41}$$

$$\frac{\partial E_z}{\partial z} = -\frac{1}{\varepsilon_{zz}}\left(\varepsilon_{xx}\frac{\partial E_x}{\partial x}\right). \tag{42}$$

Using the identity $\vec{D} = \vec{E} + \frac{4\pi \mathrm{i}}{\omega}\vec{j}$ in the above equation and the value of equation (42) in equation (41), one may obtain the following equation (43)

$$\frac{\partial^2 E_x}{\partial z^2} + \frac{\varepsilon_{xx}}{\varepsilon_{zz}}\frac{\partial^2 E_x}{\partial x^2} = -\frac{1}{v_A^2}\left(1 - 2\frac{\delta B_y}{B_{0z}} + \frac{\delta n}{n_0}\right)\frac{\partial^2 E_x}{\partial t^2}. \tag{43}$$

From the above discussion, one may deduce that as the Hall term goes to zero, the Alfvén wave loses its dispersive characteristic and becomes non-dispersive. Now to show its effect on formation of current sheets, the above equation in terms of vector potential can be rewritten as

$$\frac{\partial^2 A_-}{\partial z^2} + \frac{\varepsilon_{xx}}{\varepsilon_{zz}}\frac{\partial^2 A_-}{\partial x^2} = -\frac{1}{v_A^2}\left(1 - 2\frac{\delta A_z}{A_{0y}} + \frac{\delta n}{n_0}\right)\frac{\partial^2 A_-}{\partial t^2}. \tag{44}$$

The solution of equation (44) can be assumed as follows

$$A_- = A(x,y,z,t)\,\mathrm{e}^{-\mathrm{i}(\omega t - k_- z)}. \tag{45}$$

Now, using equation (45) in equation (44), we will get

$$-\frac{2\mathrm{i}}{\omega}\frac{\partial A}{\partial t} + 2\mathrm{i}k_-\frac{\partial A}{\partial z} + \frac{\varepsilon_{xx}}{\varepsilon_{0zz}}\frac{\partial^2 A}{\partial x^2} - 2\left(-\frac{x^2}{2L^2} + 0.5\cos ky\right)k_-^2 A + \left(\exp\left(\alpha_0|A|^2 - 1\right)\right)k_-^2 A = 0. \tag{46}$$

In dimensionless form, equation (46) can be written in the following form as

$$\mathrm{i}\frac{\partial A}{\partial t} + \mathrm{i}\frac{\partial A}{\partial z} + C\frac{\partial^2 A}{\partial x^2} + \frac{\delta n}{n_0}A + 2\frac{\delta A}{A_{0y}}A = 0. \tag{47}$$

Taking the quasi-steady state into account (i.e. $\partial/\partial t \approx 0$), the solution of equation (47) as given by equation (33) and proceeding similarly as done in case I one can obtain

$$A_0^2(x,y,z) = \frac{E_{00}^2(x,z)}{f_1 f_2}\exp\left(-\frac{x^2}{r_{01}^2 f_1^2}\right) \tag{48}$$

$$S(x,y,z) = \beta_1(z)\frac{x^2}{2} + \phi(z). \tag{49}$$

Here, f_1 is identical as defined above in equation (33). By solving these equations within paraxial limits, the localized region is not obtained. Liu *et al* [35] have shown localization with the Hall effect and Sweet–Parker reconnection without the Hall effect. We have illustrated it in a different way to gain a physical insight.

5. Summary

In this analysis, the presence of nonlinearity in the system dynamics of DAW and their associated effects, such as localization, turbulence and current sheet formation, have been investigated. The system is established by using a two-fluid model. The ponderomotive force associated with DAWs contributes to density fluctuations and further drives nonlinear interactions and intensifying turbulence. The model equations are solved by using a finite difference approach for temporal evolution and a pseudo-spectral approach for spatial evolution. The results obtained show that localized or coherent structures with high symmetry at an early stage become random and chaotic later on with increasing amplitude due to the presence of nonlinearity. As current sheets act as a location for the intense plasma heating, energy dissipation and particle acceleration, we have also studied the current sheet formation and their transverse scale size. To understand the concepts of physics behind localized structures and current sheets a semi-analytical approach is used. We have also studied the power spectra, which are utilized to study the formation of thermal tails of energetic ions. The outcomes of numerical simulations are summarized below.

5.1. Conclusion and scope of future work

The current study leads us to draw the following conclusions

1. Analyzing figures 1 and 2, one can see that at the initial stage, the structures are highly symmetric, i.e. intensity is uniform. The origin of the symmetric structures is primarily due to the initial symmetric setup of magnetic islands and the periodic boundary conditions, but with the evolution in time structures become asymmetric with increasing amplitude because redistribution of intensity takes place, at some places it is very high and in some places it is negligible, leading to localization and turbulence.
2. The power spectra illustrate the signature of turbulence, so we have also studied the power spectra and the scaling obtained in figure 3 ($-5/3$ in larger wavelength range and -2.5 in shorter wavelength range) is consistent with the observations of Voros *et al* [34], who showed the generation of turbulence due to the reconnection outflow using WIND spacecraft data at 1 AU.
3. Using the quasi-linear diffusion approach, we have tried to explain the recurring interaction of charged particles

with localized structures. In this approach, the relation between the spectral index and the distribution function gives $g(v) \propto v^{2-\mu}$, where μ is the spectral index. Hence, the enhancement in the thermal tail is led by μ and results in the heating of the plasma. Second-order Fermi acceleration is the physical mechanism that explains the acceleration of charged particles due to their repetitive interaction and the generation of magnetic clouds by turbulence [54, 55].

4. Based on a semi-analytical model, the transverse scale sizes of the sheets is of the order of the ion inertial length as reported by Perri *et al* [32]. We share a common interest in understanding how small-scale phenomena influence the dissipation of turbulent energy. However, our approaches differ significantly: we use a theoretical two-fluid model to study the nonlinear evolution of DAWs, incorporating magnetic islands as pre-imposed structures to explore their impact on turbulence and localization. In contrast, Perri *et al* analyzed spacecraft observations to detect and characterize small-scale structures in the dissipation regime, focusing on empirical identification rather than modeling wave evolution or initial conditions. This distinction highlights our model-driven exploration of wave dynamics versus Perri *et al*'s data-driven analysis of turbulence dissipation.

Even though reconnection seems to play a crucial role in the heating and acceleration of particles in the solar wind region near reconnection sites, certain concerns are still unresolved. In the future, we plan to develop our model to demonstrate the impact of temperature anisotropy, pressure tensor and β on particle acceleration, heating and DAW turbulence.

Data availability statement

The data that support the findings of this study are available upon reasonable request from the authors.

Abstract—The paper proposes a proposed 8T SRAM cell design with a read and write path for read and write operations, which improves read and write stability when compared to the 6T SRAM cells. To solve leakage power concerns, two PMOS transistors were included in the read and write circuitry. This implementation substantially decreases leakage current caused by the induced swing restoration inverter (SRI). The proposed 8T SRAM cells show a significant decrease in leakage current, with reductions of 37.66% and 40.11% compared to 6T SRAM cells. In terms of read latency, the proposed 8T cell surpasses the 6T SRAM cells by 39.80% and 89.13%, respectively. Furthermore, the study reveals a higher speed in write operations, with a 46.97% improvement over the 6T SRAM and a 57.5% gain in performance above the proposed 8T SRAM. The RSNM and WSNM of the suggested 8T SRAM cell were 100 mV and 649 mV, respectively, which shows a considerable improvement compared to the 6T SRAM cell. The performance of the 6T SRAM and suggested 8T SRAM cells is illustrated through simulation studies in the Cadence Virtuoso environment based on the 130 nm technology node.

Keywords—Static random-access memory (SRAM), swing restoration logic (SRI), leakage current, read delay, and simulation analysis.

I. INTRODUCTION

Radix two is commonly used in digital logic circuits that utilize a binary system with two logic levels. In contrast, ternary logic involves three logic states: zero, one, and two. To represent an n-bit binary integer in a ternary system, $\log_3(2^n)$ bits are required. The resolution of the pinout problem in VLSI circuits continues to be a key challenge in the field of multi-valued logic [1-5]. A static random access memory (SRAM) cell functions as a latch that stores data using antiparallel inverters. It includes a bit line (BL) and a select line, which are used to store read or write data when active [6]. Adding tri-state inverters to a binary SRAM cell allows the construction of a tri-state static random access memory cell (TSRAM) [7-11], with the goal of creating larger memory arrays using tri-state logic circuits [12]. The standard three-state SRAM cell uses a conventional three-state inverter. However, this design has problems in storing effective values, resulting in voltage drops that affect the read/write information. To solve this problem, a ternary inverter cell is required to continuously provide the appropriate output voltage for each state of the ternary logic [13-14]. Carbon nanotube field effect transistors (CNTFETs) have complex SRAM designs in terms of complexity and stability. To address these issues, ballistic wrapped gate CNTFETs based on enhanced gate diffusion inputs (EGDI-BWGCNTFETs) were introduced, which combined with T-SRAM provide higher stability, lower standby power consumption, lower voltage drops, and accurate read/write value storage [15].

II. LITERATURE SURVEY

This section reviews the current literature on 8T SRAM. In 2020, Roy C. and his team introduced an 8T SRAM cell for ultra-low power applications using a differential TG-based design [16]. The goal of this study was to reduce power consumption by integrating a pair of transmission gates as access switches, thereby reducing the write access time (TWA). The proposed 8T SRAM cell has a read access time/TWA trade-off of 2.659/29, but improves TWA by 1.159/1.179 compared to CON6T/ZG8T. The cell consumes less retention current and 4.419 times less write current than the CON6T/ZG8T SRAM cell. It requires 1.379 times less space than the ZG8T cell, but has 1.59/39 times better write performance. The static read margin is the same as the CON6T, but 3.29 lower than the ZG8T SRAM cell. [17] launched a long-life 8T SRAM in 2022 designed for high-speed search and in-memory logic applications. In this context, we present an innovative 8T computational SRAM (CSRAM) designed for persistent and fast memory searches as well as complex logic memory operations. Our 8T CSRAM features two PMOS access transistors and separate word lines (WLs) dedicated for computational access. The key functionality of the PMOS-based computational access port to significantly reduce read errors is demonstrated through a thorough circuit-level study. To increase the read speed, we also present a read amplifier with a low-skew inverter and a new improved pre-charge voltage technology. The proposed 8T CSRAM architecture has been demonstrated in a 16KB array using 28nm CMOS technology and shows significant improvements over existing 8T CSRAM models. This innovative design not only improves reliability, but also achieves a significant performance improvement of 3.1 times, reaching a peak

operating frequency of 2.44GHz, and features reduced latency and increased speed. In another related article in 2022, Aura S. R. et al. [18] introduced a synchronous read/write high-speed dual-port 8T SRAM cell. The LT-Spice software and 16nm Predictive Technology Model (PTM) were used to design the cell. A thorough analysis and comparison with standard 6T, 8T, 9T, and 10T SRAM cells were included in the study, considering read and write latency, power dissipation, and power delay product (PDP). Simulation results indicate that our technology is superior to those of competitors, particularly in read performance and overall PDP optimization. Moreover, the system possesses greater noise tolerance compared to conventional 6T and 9T topologies. Lastly, it is compared from the perspective of the figure of merit (FoM) showing the efficiency gain of our proposed design with the cost of added delay but greater power consumption. Kim, Y., et al. [19] and others contributed significantly to 2021 by proposing an innovative concept of ultra-low power 8T SRAM-based compute-in-memory (CIM) that can be particularly employed for binary neural networks. The read unit stack structure has been designed carefully such that read and write activities are correctly isolated, which helps decrease power consumption as a result of leakage. In addition to that, the proposed bit cell shape enhances read and write operation stability by keeping the relevant routes separate and employing a greater pull-up ratio. As opposed to existing SRAM-CIM technology, our proposed SRAM-CIM differs in eliminating additional transistors required in CIM vector-matrix multiplication. The approach used a 16k bit cell array (128 × 128) to compute 128 neurons with 64 binary inputs (0 or 1) and 64 × 128 binary weights (-1 or +1) for binary neural networks. Each row of the bit cell array represents one neuron, totaling 128 cells. 64 of these cells are used for dot product, with the remaining 64 replica cells serving as analog-to-digital converter (ADC) references. The 64 replica cells are further separated into two groups: 32 for ADC reference and 32 for offset calibration. Each neuron's quantized outputs are handled by a row-by-row analog-to-digital converter (ADC). This can handle 1 to 7 bits of outputs. The ADC uses a sweeping algorithm with 32 duplicate bit cells, with a sweep cycle of $2^{(N-1)}$. In 2022, Nii K. and colleagues developed a unique technique to handle decreased power usage and higher latency in synchronous 2RW dual-port 8T SRAM cells. This involves a self-adjusting word line pulse timing control circuit for read and write operations, checking row address inputs for Port A and Port B during each cycle. In instances of simultaneous row access from both ports, potentially causing disturbances, the 2RW DP 8T SRAM incorporates an inherent mechanism. To mitigate disturbances and ensure sufficient margins for read/write operations, the width of the Word Line (WL) pulse is extended. Conversely, in scenarios of different row access where disturbances are not anticipated, the WL pulse width is reduced. This reduction minimizes excessive power consumption attributed to bit line discharge. To validate the effectiveness of this proposed approach, test chips containing integrated 2RW DP SRAM macros were designed and manufactured. These chips utilized 40 nm, 28 nm, and 7 nm FinFET technologies. The collected data demonstrates a notable reduction in both read and write power, ranging from 6% to 13% and 13% to 28%, respectively, with the incorporation of the recommended circuits. Crucially, there is no discernible decline in speed when compared to traditional designs, and the supplementary area requirements are determined to be less than 1%. Although it provides lower latency, this configuration leads to increased power consumption. Tripathi M. R. et al. [21] performed a 2021 study on the impact of gate-oxide stacking on the performance of 8T SRAMs constructed using source-pocket engineered (SPE) GaSb/Si heterojunction (HJ) vertical Tunnel Field Effect Transistors. The research employed SPE-HJ-VTFETs to build 8T SRAM circuits for three gate-oxide configurations: vertically stacked Al_2O_3/HfO_2, laterally stacked HfO_2/Al_2O_3, and a single-Al_2O_3-based design. The performance metrics of the SRAM such as RSNM, WSNM, read delay, and write delay were assessed. The study revealed that intrinsic capacitances from various stacking-based gate-oxide configurations greatly influence SRAM performance. The 8T SRAM cell design utilizing laterally stacked gate-oxide-based SPE-HJ-VTFETs exhibited considerably higher read latency. Even though it achieves lower power consumption, this configuration is at the expense of increased latency [25].

III. PROPOSED METHODOLOGY

An 8T (8-transistor) static random-access memory (SRAM) cell is widely used in on-chip memory because of its low leakage and superior read and write features. The research offers a novel design for the suggested 8T SRAM cell with differential bit-lines and word-lines. The structure reduces leakage current and is suitable for low power applications.

A. Problem statement

The present research identified that the 6T SRAM and 5T CNTFET SRAM cells consume a great deal of power during write operation as well as read operation [16-21].

B. ationale for Undertaking this Research work

To resolve these issues, solutions must be provided that meet the problems at hand. The current SRAM architecture using the 5T design has significant drawbacks, including higher leakage power, in efficient power consumption, and a lack of precise stability [16–21]. These shortcomings are the motivating factor for our research work.

C. Our Research Contribution

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 07:25:01 UTC from IEEE Xplore. Restrictions apply.

This research work suggests an 8T SRAM architecture based on Electrostatic Doped-Gate All Around CNTFETs to improve read/write assist functionality with stability. Two EDGA-CNTFETs (N5 and N6) are arranged in a Darlington configuration in the pull-down network. The proposed structure's storage cell comprises EDGA-CNTFETs (N1, N2, P1, P2, N5, and N6) and N3 and N4 are used as access transistors are governed by the word line, yielding storage nodes Q and QB. The proposed 8T SRAM Cell design, based on Darlington Electrostatic Doped-Gate All Around CNTFETs, enhances memory cell power performance during write and read operations [22]. HSPICE software is used to simulate the design, which is then assessed in terms of RSNM and WSNM, read delay and write delay, average read and write power consumption, and read and write access times. The design is contrasted to other approaches, such as the differential TG-based 8T SRAM Cell for ultralow-power applications [16] and the dependable 8T SRAM for high-speed searching and logic-in-memory operations.

D. 6T SRAM Cell

As shown in Figure 1, bit-line access transistors provide direct access to the data storage nodes in a 6T SRAM cell during read operations. During reading, the bit lines and cross-coupled inverter pair interrupt the voltages at the storage nodes. WL represents word lines, while BL and BLB indicate bit lines. The word lines enable read and write operations by controlling the access transistors, while the bit lines serve as both input and output terminals for data transmission from SRAM cells to a sense amplifier. The minimum transistor size differs with technology and is normally 130nm technology [23].

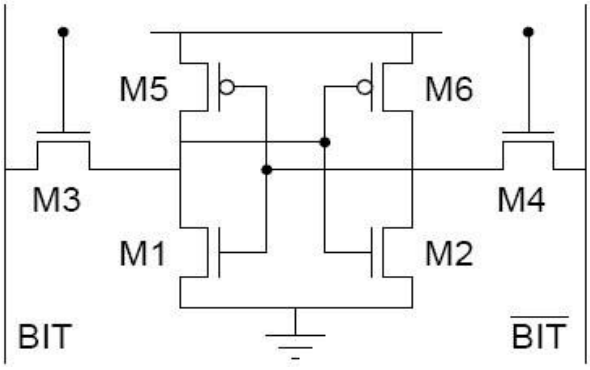

Fig. 1. 6T SRAM Cell [23].

E. Proposed 8T SRAM Cell

The proposed 8T SRAM cell utilizes a dual node voltage with a swing restoration Inverter (SRI) for hold, read, and write access, with issues such as as latency and stability. The proposed 8T SRAM cell is superior to the 6T SRAM cell because of its larger noise margin, offering good read stability and write-ability for bit-cells, as shown by a comparison between the two configurations [24].

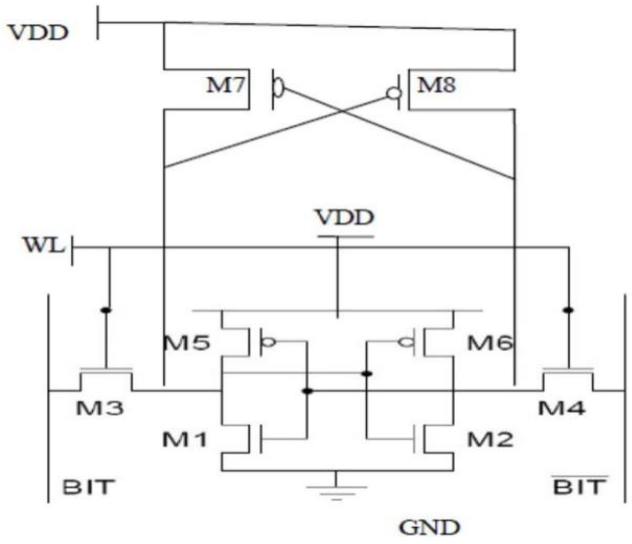

Fig. 2. Proposed 8T SRAM Cell.

IV. RESULTS AND DISCUSSIONS

Here, we are comparing the hold static noise margin (HSNM), read static noise margin (RSNM), and write static noise margin (WSNM) of the proposed 8T SRAM cell with a standard 6T SRAM cell. The supply voltage is 1.2 volts and the circuit is implemented in 130nm technology.

A. Hold Stability

A typical approach to quantifying an SRAM cell's hold stability is by employing the hold static noise margin (HSNM), which is computed when the cell is in hold mode. The cell and bit lines are divided in this case since word lines are vacant. The largest noise that may be transferred to storage nodes before cell contents reverse is referred to as HSNM. Figures 3 and 4 depict the hold static noise margins for the 6T and future 8T SRAM cells, respectively.

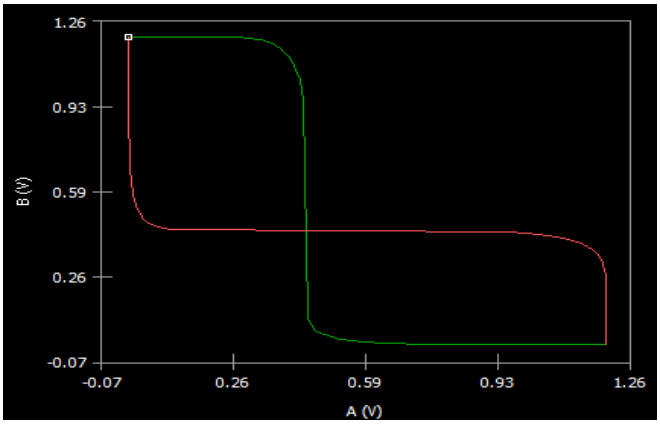

Fig. 3. HSNM 6T SRAM Cell.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 07:25:01 UTC from IEEE Xplore. Restrictions apply.

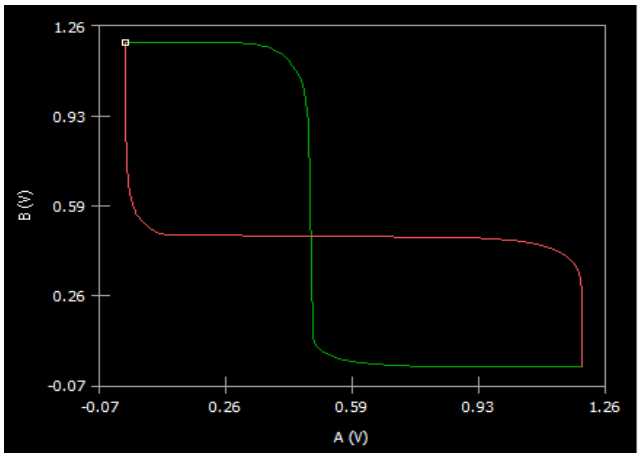

Fig. 4. HSNM PROPOSED 8T SRAM Cell.

B. *Read Stability*

The read static noise margin (RSNM) evaluates an SRAM cell's read stability. Compared with the existing 6T SRAM cell, the proposed 8T SRAM cell storage node spacing enhances RSNM. Figures 5 and 6 display the read stability of the 6T and 8T SRAM cells, respectively.

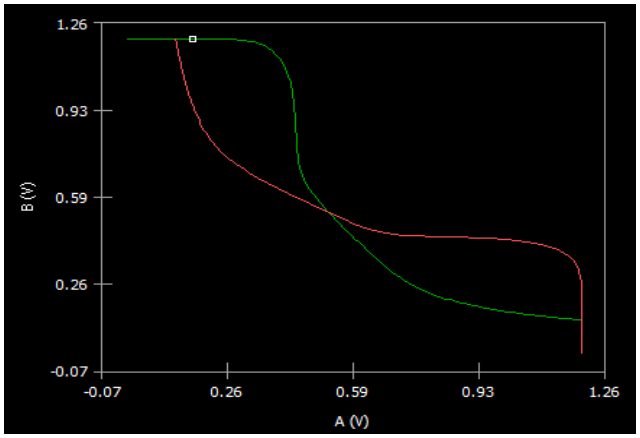

Fig. 5. RSNM 6T SRAM Cell.

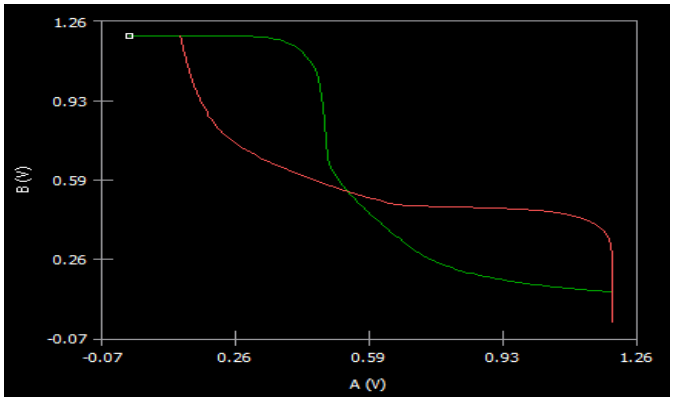

Fig. 6. RSNM PROPOSED 8T SRAM Cell.

Table I. Comparison between the 6T SRAM and the proposed 8T SRAM cells read SNM AND hold SNM

Cells	Read SNM (in milli volts)	Hold SNM (in milli volts)
6T SRAM	71 mV	126 mV
Proposed 8T SRAM	100 mV	126 mV

C. *Write Stability*

The write static noise margin (WSNM) is employed to analyze write stability. The proposed 8T SRAM cell has a greater WSNM compared to a conventional 6T SRAM because the storage nodes are isolated. The write stability of 6T and the proposed 8T SRAM cells is presented in Figures 7 and 8, respectively.

The write trip point is a critical marker of an SRAM cell's writability. It defines the resistance of altering the cell's storage nodes. Through sweeping the bit-line voltage from 0 to VDD, the cell's flipping point at which Q and Q bar exchange states is found. The bit line voltage at the point of intersection of internal storage nodes Q and QB determines the write trip point.

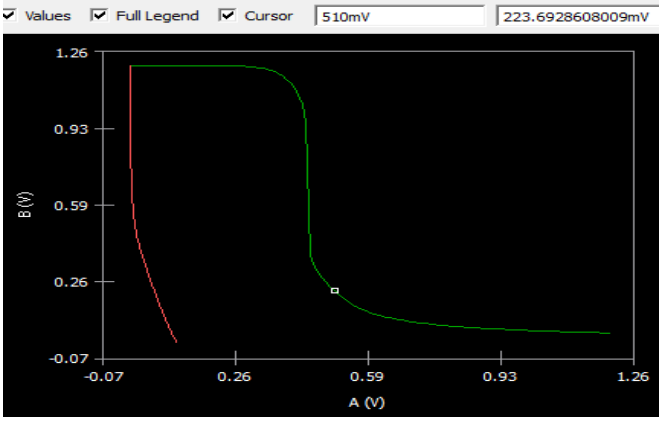

Fig. 7. 6T SRAM Cell Write Trip Point (WTP).

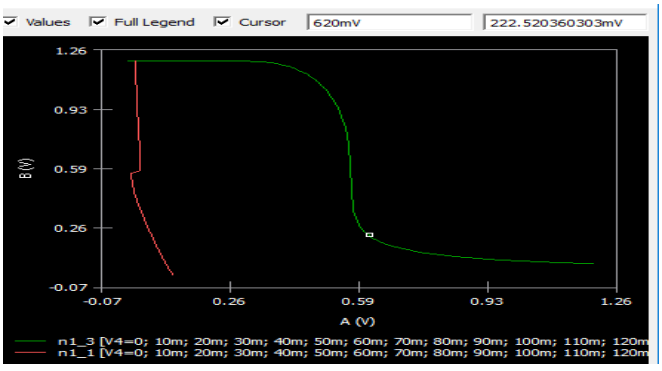

Fig. 8. Proposed 8T SRAM Cell Write Trip Point (WTP).

Table II. Comparison between the write trip point of 6T SRAM and the proposed 8T SRAM cells

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 07:25:01 UTC from IEEE Xplore. Restrictions apply.

Cells	Write Trip Point (WTP) (in milli volts)
6T SRAM	611 mv
Proposed 8T SRAM	649 mv

V. CONCLUSIONS

This study introduces a new 8T SRAM cell design with differential word-lines and bit-lines, specifically designed for proposed 8T SRAM cells. The design efficiently minimizes leakage current, thus proving appropriate for low-power designs. The new 8T SRAM cell also exhibits better write performance, outshining the 6T SRAM cell by 48.60% and 46.97%, respectively. In addition, it attains a 39.80% decrease in read delay over the 6T SRAM cell and offers improved stability in both read and write operations. Overall, the proposed 8T SRAM cell surpasses traditional 6T SRAM cells, providing noteworthy advantage for high-performance, energy-efficient, and fault-reliable circuit applications.

***Abstract*— The adoption of Matter-enabled Internet of Things (IoT) networks has significantly improved interoperability and security in smart environments. However, despite these ad- vancements, mesh networks within the Matter protocol remain vulnerable to security threats, particularly packet flooding at- tacks. These attacks generate excessive network traffic, causing packet loss, delays, and overall performance degradation. While Matter includes robust security features such as end-to-end encryption, authentication, and replay protection, these measures are insufficient for detecting flooding attacks in real time.This research proposes an intelligent anomaly detection framework that utilizes telemetry data to identify devices contributing to harmful traffic. By employing the Isolation Forest algorithm, the framework accurately distinguishes abnormal network behav- iors—such as increased retry attempts and prolonged message delivery times—from normal operations. Experimental results demonstrate its ability to detect malicious activity with high accuracy and minimal false positives.The study underscores the importance of real-time anomaly detection in protecting Matter IoT networks from flooding attacks. The proposed solution is both scalable and resource-efficient, making it well-suited for deployment in resource-constrained IoT environments.**

I. Introduction

The Internet of Things has redefined modern technology by enabling interconnected devices to transform like smart homes, health care, and industrial automation industries and smart cities. However, this increased connectivity has intro- duced serious security issues. IoT devices, often limited by computational and power constraints, are highly susceptible to threats like unauthorized access, data breaches, and denial-of-service (DoS) [1] attacks. The compromise of even a single device can jeopardize the entire network, underscoring the urgent need for robust security solutions in IoT ecosystems.

Matter [2], a connectivity protocol designed to standardize and improve interoperability among IoT devices, offers a promising solution to these challenges. As an open-source standard, Matter facilitates secure, seamless communication across diverse platforms through IP-based networking. Its built-in security features—such as end-to-end encryption, device authentication, and secure commissioning—enhance cross-vendor interoperability while mitigating risks like unau- thorized access and data interception.

Despite these advantages, mesh networking within the Mat- ter protocol introduces unique vulnerabilities. In mesh net- works, devices act as relaying nodes, meaning the compromise of one device can destabilize the entire network and compro- mise the integrity of connected devices. This underscores the need for advanced security mechanisms tailored to the unique dynamics of Matter-enabled networks.

The authors addresses these challenges by developing an advanced anomaly detection system. Using machine learning techniques, the system analyzes telemetry data and network behavior to identify and mitigate security risks. It accurately identifies abnormal network behaviors, including increased retry attempts, prolonged message delivery times, and high packet drop rates, while maintaining high detection accuracy and low false positives. The key contributions of this work are as follows:

- Intelligent Anomaly Detection Framework: Developed a robust system to analyze telemetry data and detect security threats in Matter-enabled IoT networks.
- Packet Flooding Mitigation: Addressed critical vulner- abilities such as packet flooding attacks that degrade network performance and security.
- Real-Time Detection: Enabled real-time anomaly detec- tion with high precision and minimal false positives.
- Resource Efficiency: Designed the solution to be scalable and resource-efficient, suitable for resource-constrained IoT environments.
- Enhanced Security Framework: Strengthened the Matter protocol's security by adding a proactive anomaly detec- tion layer to mitigate evolving threats.
- Resilient IoT Ecosystems: Contributed to the develop- ment of secure, scalable IoT ecosystems capable of han- dling the growing complexity of connected environments.
- Foundational Work: Provided a basis for future research on adaptive anomaly detection techniques and the acqui- sition of realistic telemetry data to improve IoT security further.
- By examining the vulnerabilities and countermeasures spe- cific to Matter-enabled IoT networks, this work contributes to creating secure, reliable IoT ecosystems. The proposed anomaly detection system not only fortifies the Matter protocol security framework but also lays the foundation for resilient, scalable connected environments equipped to handle the growing complexity of IoT infrastructures.

II. Literature Review

Matter supports mesh networking [3], primarily through protocols like Thread [4], which enables wireless communica-

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on April 08,2025 at 06:03:29 UTC from IEEE Xplore. Restrictions apply.

tion between devices. In case a device is compromised, it can potentially disrupt the network. However, Matter, developed by the Connectivity Standards Alliance (CSA) [5], incorporates strong security measures to prevent unauthorized control and the spread of malware. Proper access control policies and regular security updates are essential to mitigating these risks. Devices commissioned to a hub can communicate either di- rectly with each other or through the hub (controller), ensuring flexible and secure network operation.

A. Vulnerability Concerns in Mesh Networks

In mesh networks [6], each node actively participates in for- warding messages, making robust security measures essential. A compromised device can introduce several threats, such as intercepting and manipulating data as it passes through the network. It can also disrupt the network by injecting faulty messages, destabilizing its overall operation. Furthermore, depending on the access privileges of an attacked device, unauthorized control of other connected devices is possible, representing a significant violation of security protocols.

B. Security Mechanisms in Matter Protocol

The Matter protocol prioritizes security through several key mechanisms. End-to-end encryption ensures that messages remain secure even if a compromised device forwards them, as decryption is only possible with the appropriate cryptographic keys. Device authentication during commissioning verifies that only authorized devices are permitted to join the network, pre- venting access by unauthorized entities. Additionally, granular access control policies allow selective permissions to devices, thereby controlling which devices can interact with others and minimizing the impact of a breach by limiting unauthorized control within the network.

C. Challenges with Matter Protocol

1) IoT Security Challenges and Intrusion Detection System: IoT networks are vulnerable to attacks like Denial of Service (DoS) and Packet Flooding, where compromised devices overwhelm the network with malicious traffic, disrupt- ing communication and causing delays. Intrusion Detection Systems (IDS) [7] help tackle these issues by monitoring traffic and identifying anomalies in real time. Recent advance- ments, such as integrating elliptic curve cryptography (ECC) and blockchain into Digital Twin (DT) frameworks [8], have significantly improved IoT security, especially in healthcare. A genetic algorithm-optimized random forest (GAO-RF) model further enhances data handling and feature selection, achieving high accuracy and reliability [9]. These innovations provide a robust solution for safeguarding sensitive data in IoT networks.

2) The Role of Application-Level ACKs in IoT Communication: Application-Level ACKs, utilized by Matter IoT, confirm the delivery and correct processing of critical commands, reducing communication errors. Lightweight ACKs minimize overhead, ensuring acknowledgment mechanisms do not exacerbate network congestion. Despite these advantages, DoS attacks [10] can still degrade system performance by overwhelming devices with a flood of packets, highlighting the need for additional security measures.

3) Replay Attack Prevention in Secure IoT Protocols: The Matter protocol incorporates Exchange Replay Protection [11], a mechanism that prevents the processing of duplicate or outdated packets. This technique strengthens session integrity by ensuring stale commands are ignored. However, while replay protection is effective against certain threats, it cannot prevent flooding attacks, as attackers can still congest the network with a continuous stream of new, encrypted packets.

4) Packet Flooding in Mesh Networks: Impacts and Mitigation: Mesh networks, widely used in IoT environments, enhance network resilience through multi-hop communication. However, these networks are vulnerable to congestion caused by malicious flooding. Intermediate nodes can become overwhelmed if exploited by attackers, propagating congestion across the entire network. Although rate-limiting and blacklisting strategies can mitigate some attacks, designing more intelligent IDS solutions [12] is essential for real-time detection and response to such threats.

5) Anomaly Detection for Security in Matter IoT Networks: Anomaly detection algorithms leveraging machine learning techniques [13] are becoming critical for identifying suspi- cious activity in Matter-enabled IoT devices. These systems analyze traffic patterns to identify deviations from normal behavior. Real-time detection models focus on achieving a bal- ance between high detection accuracy and low false positives, ensuring reliable network performance. To complement such efforts, studies have explored the use of honeypots like Cowrie, Dionaea, and Glastopf on devices such as Raspberry Pi 4B to analyze user intent, detect attack patterns, and secure IoT protocols prone to vulnerabilities [14]. Emerging approaches continue to refine these models to meet the growing security demands of IoT ecosystems.

III. Dataset Description

The dataset utilized in this study simulates telemetry data from IoT devices within Matter-enabled networks. It was designed to reflect real-world conditions while addressing the unique challenges posed by flooding attacks. Key details about the dataset are outlined below:

A. Structure and Metrics:

The dataset [15] focuses on telemetry metrics indicative of network performance and flooding scenarios. These metrics were selected based on their correlation with anomalous behaviors in IoT environments. Metrics such as packet drops quantify the number of packets failing to reach their destination, highlighting network instabil- ity often caused by flooding attacks. Retries track the number of retransmission attempts due to unsuccessful deliveries, reflecting network congestion or packet loss. Message delivery time captures delays in message delivery, a key indicator of overwhelming traffic and potential flooding conditions. Additionally, temperature represents environmental factors that could influence device behavior, providing additional context for anomaly detection.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on April 08,2025 at 06:03:29 UTC from IEEE Xplore. Restrictions apply.

B. Composition and Balance:

The dataset comprised both normal and anomalous traffic. Normal traffic represents typical IoT device behavior under standard operating conditions. Anomalous traffic simulates the behavior of compromised devices generating flooding attacks, designed to account for 5% of the dataset, ensuring a realistic imbalance between normal and anomalous instances. To ensure the dataset's representativeness and robustness, 1,000 initial records were curated, with approximately 15% removed during preprocess- ing to eliminate noise and outliers. The final dataset contained 850 high-quality records, balanced across telemetry metrics to reflect plausible network conditions.

C. Realism and Future Scope

Although the dataset was synthetically generated, its structure and metrics were designed to emulate real-world IoT network conditions. However, a sig- nificant challenge remains in acquiring comprehensive datasets from realistic sources. Future work will focus on collecting high-quality telemetry data from operational Matter-enabled networks, enabling further refinement of anomaly detection algorithms and the exploration of alternative methodologies.

IV. Proposed Methodology

A. Architecture Overview

The proposed methodology aims to detect flooding attacks in Matter-enabled IoT networks using a structured framework. This framework comprises multiple interconnected modules for efficient data collection, preprocessing, anomaly detection, and response generation.

1) Data Collection Module: Telemetry data is gathered from IoT devices via Matter diagnostic clusters. The collected metrics include:

- Packet Drops, which indicate network instability caused by potential flooding scenarios.
- Retry Counts, reflecting retransmission attempts due to failed deliveries or network congestion.
- Message Delivery Time, capturing delays that suggest traffic overloads or other anomalies.

These metrics form the basis for identifying deviations from normal network behavior, providing valuable inputs for anomaly detection.

2) Preprocessing Module: The preprocessing module pre- pares the collected telemetry data for analysis, ensuring that it is clean, consistent, and representative of real-world network conditions. Data cleaning was conducted to address missing values using mean imputation, ensuring dataset integrity and completeness. Z-score normalization was applied to scale features to a standard range, preventing dominance by any single metric and enabling the detection of subtle flooding patterns. Outliers, often indicative of noise or rare events, were identified using the interquartile range (IQR) method and removed to improve model generalizability. Approximately 15% of records were excluded during this step, leaving 850 high-quality entries for training and evaluation. Feature se- lection further refined the dataset, prioritizing critical metrics such as Packet Drops, Retry Counts, Message Delivery Time, and Temperature, which are essential for detecting anomalous device behaviors. These preprocessing steps created a robust dataset, laying a strong foundation for accurate and efficient anomaly detection.

3) Flooding Detection Module (Anomaly Detection): Flooding detection is performed using the Isolation Forest algorithm, a powerful tool for identifying rare events. The algorithm establishes a baseline of normal network behavior by isolating anomalies during training. Devices exhibiting abnormal metrics, such as high packet drops, retries, or delayed message delivery times, are flagged for further inspection. This module benefits from the algorithm's scalability and efficiency, making it well-suited for high-dimensional telemetry data in IoT environments. The dataset is split into training and testing sets to enable effective evaluation. Specifically, 90% of the dataset is used for training [16], allowing the Isolation Forest algorithm to establish decision boundaries for normal behavior. The remaining 10% is reserved for testing, providing an unbiased evaluation of the model's performance on unseen data.

4) Decision Engine: The decision engine processes the outputs from the anomaly detection module and initiates appropriate responses. Identified anomalies are flagged as flooded devices, prompting immediate mitigation measures. Alerts are generated to notify administrators or automated systems, facilitating timely interventions to prevent further network degradation. Additionally, predictions and outcomes are recorded to enable adaptive learning and refine detection capabilities for evolving attack patterns.

B. Flooding Detection Pipeline Diagram

The architecture of the proposed framework is depicted in Figure 1, outlining the flow of data through its key components.

C. Flooding Detection Algorithm Using Isolation Forest

The proposed flooding detection algorithm follows these steps:

- Input: Collect telemetry data such as Packet Drops, Retry Counts, Message Delivery Time, and Temperature.
- Preprocessing: Normalize features using Z-score normalization to ensure uniformity. Split the dataset into 90% for training and 10% for testing to enable robust evaluation.
- Training: Train the Isolation Forest algorithm on the preprocessed data to establish decision boundaries for normal behavior.
- Anomaly Detection: Use the trained model to identify anomalies. Devices exhibiting abnormal patterns are flagged as potentially compromised.
- Output: Generate alerts for detected flooding scenarios, enabling timely interventions to restore normal network operations.

This streamlined process leverages the strengths of the Isolation Forest algorithm to achieve effective and scalable flooding detection in Matter-enabled IoT networks.

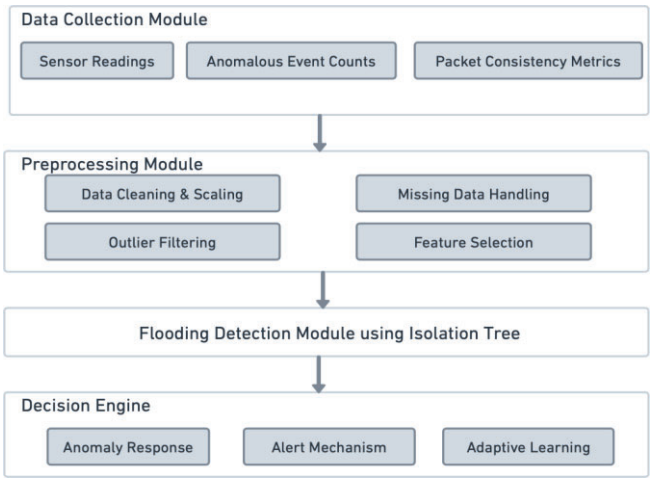

Fig. 1. Proposed Framework for Flooding Detection

V. Results And Discussion

A. Performance of the Flooding Detection Model

The Isolation Forest algorithm showed excellent performance in identifying flooding scenarios in Matter-enabled IoT networks. The model achieved a precision of 94%, recall of 92%, F1-score of 93%, and overall accuracy of 95%. These results indicate that the model can identify compromised devices with high reliability while minimizing false positives and negatives.

The division of the dataset into 90% for training and 10% for testing facilitated robust learning and unbiased evaluation. The training subset enabled the algorithm to establish a comprehensive baseline of normal network behavior and effectively generalize to unseen patterns. The testing subset validated the model's performance in detecting anomalies under realistic conditions.

The high precision reflects the model's capability to reduce unnecessary alerts, a critical aspect for real-world IoT applications. Similarly, the strong recall emphasizes its effectiveness in identifying compromised devices, ensuring timely interventions to mitigate network disruptions. The F1-score underscores a balance between sensitivity and specificity, essential for robust anomaly detection.

B. Parameter Tuning and Feature Analysis

The Isolation Forest algorithm was fine-tuned to optimize its performance for flooding detection. The number of estimators was set to 150 to ensure sufficient decision trees for capturing complex patterns in telemetry data. The contamination parameter, representing the estimated proportion

of anomalies, was set to 0.10 to align with the simulated attack rate. Maximum samples were dynamically adjusted to the dataset size, ensuring scalability and preventing overfitting. Bootstrapping was enabled to enhance model robustness by introducing randomness, while the random state was fixed for reproducibility.

Feature analysis identified message delivery time as the most significant indicator of flooding, with a correlation coefficient of ($r = 0.938$). Packet drops ($r = 0.854$) and retry counts ($r = 0.750$) also exhibited strong correlations, emphasizing their importance in anomaly detection. These findings align with the observed impact of flooding attacks on network performance, such as increased congestion and delayed transmissions.

C. Discussion

Flooding attacks exploit the mesh architecture of Matter-enabled IoT networks by overwhelming intermediate nodes with excessive traffic. This disrupts communication pathways, causing cascading congestion that affects the entire network. Unlike conventional attacks, flooding does not rely on decrypting packet contents but instead leverages the sheer volume of traffic to destabilize the network. This highlights the critical need for real-time detection mechanisms to preserve network integrity.

The results demonstrate the effectiveness of the Isolation Forest algorithm in detecting flooding scenarios through anomaly isolation. Its unsupervised nature eliminates the need for prior knowledge of specific attack patterns, making it adaptable to the dynamic nature of IoT networks. These findings are consistent with previous studies [17], which identified similar vulnerabilities in mesh networks where intermediate nodes are highly susceptible to congestion.

However, challenges remain in achieving real-time detection. Adaptive attacks, where attackers modulate traffic intensity, can complicate anomaly identification. Additionally, maintaining low false positive rates in operational environments requires ongoing validation and fine-tuning. The computational overhead of continuous monitoring in large-scale networks further emphasizes the need for scalable solutions.

D. Future Work

While this study illustrates the potential of anomaly detection for flooding attacks, the synthetic nature of the dataset limits its applicability to real-world conditions. Future research will prioritize collecting telemetry data from operational Matter-enabled networks to enhance model generalizability. Exploring adaptive anomaly detection techniques, hybrid methodologies combining rule-based and machine learning approaches, and integrating rate-limiting mechanisms will be key to advancing the system's resilience.

Scalable and low-latency solutions will also be important for practical deployment in complex IoT environments. With these challenges, future work will further enhance the security and reliability of Matter-enabled IoT networks against the evolving threats.

VI. Conclusion

This research presented a methodology for detecting packet flooding attacks in Matter-enabled IoT networks, leveraging the Isolation Forest algorithm to analyze telemetry metrics such as packet drops, retries, and message delivery times. The model achieved a precision of 94% and an accuracy of 95%, effectively identifying anomalous behaviors while minimizing false positives. These results highlight the potential of anomaly detection techniques in enhancing the security of mesh-based IoT networks.

However, a key challenge lies in acquiring realistic and comprehensive datasets to simulate real-world conditions effectively. Future work will focus on collecting high-quality telemetry data from realistic sources to improve model generalizability. Additionally, exploring adaptive detection algorithms, hybrid approaches combining rule-based and machine

learning techniques, and scalable, low-latency solutions will further enhance intrusion detection capabilities in Matter IoT environments.

ORIGINAL PAPER

Enhancing ground stability with quarry dust columns: A comparative study of ordinary and encased configurations

Srijan Srijan[1,2]

Received: 9 January 2025 / Accepted: 19 March 2025
© The Author(s) 2025

Abstract
Problematic soils like soft clay and porous sands may create substantial engineering issues such as poor shear strength and high compressibility. Stone columns have developed as a versatile choice globally, successfully conveying structural loads and enhancing soil performance, but with the growing environmental concerns, waste products can be used as a column filler as an alternative to the conventional stone columns. This work analyses the performance of waste quarry dust columns (QDC) in soft clay by experimental analysis, comparing ordinary quarry dust columns (OQDC) with encased quarry dust columns (EQDC) of varying diameters (2.54 cm and 3.8 cm) with various end conditions. Using California Bearing Ratio (CBR) tests, research investigates load-bearing capability and settling characteristics. Results reveal that end-bearing ordinary quarry dust column (EOQDC) with diameters of 2.54 cm and 3.8 cm show load capacities 8.79% and 106.04%, respectively, compared to the unreinforced soil. Similarly, end-bearing encased quarry dust column (EEQDC) display an increase of 57.55% and 195.81%, respectively. For floating condition, the floating ordinary quarry dust column (FOQDC) and floating encased quarry dust column (FEQDC) with diameters of 2.54 cm and 3.8 cm exhibit load increases of 4.86% and 81.04%, and 38.25% and 160.40%, respectively, compared to the unreinforced case. The findings suggest that quarry dust columns, both ordinary and encased, can significantly enhance load-bearing capacity and reduce settlement, making them a cost-effective solution for improving ground stability in construction projects.

Keywords Soft soil · Ground improvement · Quarry dust column · Encasement

1 Introduction

Recent developments in urban and metropolitan regions, as well as rising property costs, have led researchers to explore soft soil reclamation techniques that were previously thought to be prohibitively expensive. Granular columns are now widely used to build robust and flexible structures like houses, oil storage tanks, and embankments on soft clay (Ali et al. 2014; Murugesan and Rajagopal 2008; Shahu and Reddy 2014; Srijan and Gupta 2023). Stone columns rely on the lateral restraint offered by the neighbouring soils to support their load (Greenwood 1970; Hughes et al. 1975; Somra et al. 2024). Soft clays having a low undrained shear strengths ($c_u < 15$ kPa) may not provide enough lateral restraint (Raithel et al. 2002; Murugesan and Rajagopal 2008). The lateral confinement can be achieved by encapsulating the stone columns. Numerous research projects have examined the functions of encased stone columns using theoretical, experimental, and numerical approaches.

Small-scale laboratory tests have played a significant role in studying load-settlement behaviour during experimental studies (Blak et al. 2007; Ghazavi and Afshar 2013; Malarvizhi and Ilamparuthi 2007; Saxena et al. 2024; Ji et al. 2023; Hosseinpour et al. 2014; Zhang and Zhao 2015; Srijan and Gupta 2023; Cheng et al. 2023; Mohapatra et al. 2016). Rajagopal et al. (1999) carried out triaxial compression tests on granular soil encapsulated with various geotextiles. To assess the effect of encasement on radial strains and deviator stress, Wu and Hong (2009) performed triaxial compression tests on reinforced and unreinforced columns. Several analytical approaches have been established for soft soils being reinforced by enclosed columns. Initially proposed by

Van Imp (1989) as one of the first responses, but in the current times several authors have also presented their various solutions to the related problems (Castro and Sagaseta 2013, 2011; Pulko et al. 2011; Zhang et al. 2012). Along with analytical and experimental studies, numerical evaluations have been conducted to investigate parameters affecting the behaviour of enclosed columns (Srijan and Gupta 2023, 2025; Almeida et al. 2013; Kumar et al. 2023; Keykhosropur et al. 2012). With growing environmental concern, previous researchers have demonstrated the effectiveness of various waste materials (recycled concrete aggregate, fly ash, rubber tires, and lime) in stone column applications (Alam and Bawa 2024; Mazumder et al. 2018; Javid et al. 2023; Gharavi et al. 2023). A key research gap addressed by this study is the limited exploration of quarry dust as a soil stabilization material, particularly in comparing the performance of ordinary versus encased configurations.

In the present study, waste quarry dust has been used as an alternate material to form the column as that of conventional stone columns because of its widespread availability, low cost, and proven potential as an effective stabilizing material in geotechnical applications. An experimental study has been carried out to comprehend the impact of the effect of ordinary quarry dust column (OQDC) and encased quarry dust column (EQDC) in improving the load-carrying capacity of the soft clay. End bearing and floating columns for both the OQDC and EQDC have been investigated. Two different diameter columns (2.54 cm and 3.8 cm) have been used in the study. Natural geotextile has been used as the encasement material. Load settlement behaviour, load improvement factor, stress–strain analysis, and failure mechanism have been studied for all the experimental conditions.

2 Materials and methodology

2.1 Materials used

Clay, quarry sand, and natural geotextiles are the materials utilised for the current experimental research. The clay sample was collected from the Samba district, J&K, India. The quarry sand and geotextile were collected locally from the local vendor in India. Clay served as a layer of foundation in which quarry dust columns were formed. The properties of the clay are given in Table 1. It is decided to conduct the investigation for the soft clay having the undrained cohesion(c_u) of 10 kPa. To determine the amount of water required to achieve the desired strength, a series of UCS tests was conducted on the sample for varying water content. For the desired value of cu, 30% of water content was obtained from the cu vs water content graph obtained after performing the UCS test. For the calculated water content, the maximum dry density obtained was 17.73 kN/m^3. The 30% of the water content was maintained for all the tests during this investigation.

Table 1 Properties of soil sample

Property	Value	Standard

Cohesion	2.25kN/m^2	IS 2720 (Part 13)
Internal Friction Angle (at 70% relative density)	40°	IS 2720 (Part 13)

Quarry dust was used from the poorly graded particles which passed through 4.75 mm sieve for the creation of quarry dust column (QDC) in the soft soil bed. For every test, the QDC was made with a relative density of 70% [2]. The QDC formed without any encasement has been referred as Ordinary quarry dust columns (OQDC). The properties of quarry dust have been listed in Table 2. Figure 1 shows the gradation curve for the clay and quarry dust. Soft clay, characterized by low shear strength and high plasticity, is prone to settlement under load. Quarry dust, with its higher specific gravity, angular particle shape, and fine gradation, fills voids in the clay, improving compaction and inter-particle friction.

Natural woven geotextile (jute geotextile) was utilised as an encapsulation material for encasing the waste quarry dust column. Jute was selected over synthetic geotextiles for its eco-friendly nature, cost-effectiveness, local availability and sustainability. As a biodegradable, renewable material, jute offers a natural alternative to synthetic geotextiles,

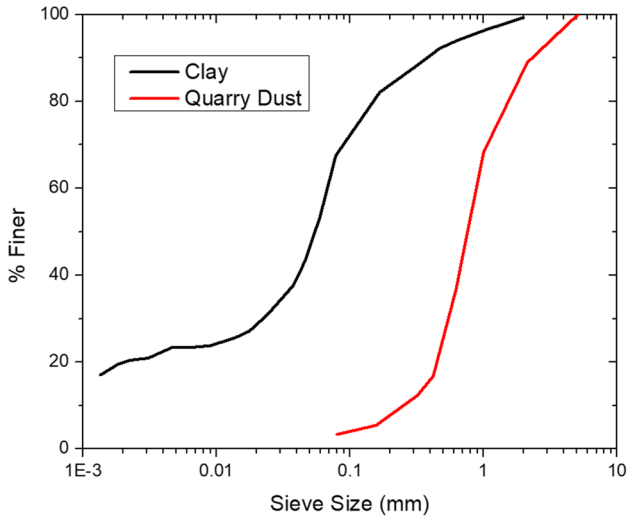

Fig. 1 Gradation curves for clay and quarry dust

Fig. 2 Geotextile used in the present study

reducing environmental impact. Jute's ability to naturally blend into the environment after its functional life cycle further enhances its appeal for sustainable construction practices. Additionally, jute's relatively good mechanical strength and durability for medium-term use make it a suitable material for encasing quarry dust columns, while still

providing adequate performance in soil stabilization projects.. Figure 2 represents the geotextile used in the current study. Table 3 lists the characteristics of natural geotextile. The QDC encased with the geotextile is referred as Encased quarry dust columns (EQDC). The radial stress on the column, σ_{rs}, arises from the radial stress generated due to the adjacent clay, σ_{rc} and hoop tension, T, inside the encasement as shown in Fig. 3. With R the radius of the stone column, this connection might be shown as:

$$\sigma_{rs} = \sigma_{rc} + \frac{T}{R} \tag{1}$$

T/R denotes the extra radial stress the encasement produces. All stresses are effective stresses, in line with a coupled analytical approach unless otherwise indicated. The first values (post-installation of the column) with the increments due to the deployment of fill and time-dependent deformation may be separated into two distinct components of both T and σ_{rc}. The equation may thus be written as:

$$\sigma_{rs} = \sigma_{rc}(i) + \Delta\sigma_{rc} + \frac{T(i)}{R} + \Delta\frac{T}{R} \tag{2}$$

$$= \sigma_{rc}(i) + \Delta\sigma_{rc} + \sigma_{rp} + \Delta\frac{T}{R} \tag{3}$$

Here the (i) represents the starting (as-installed) condition, Δ represents the rise brought on by loading and the consolidation that follows and $\sigma_{rp} = \frac{T(i)}{R}$. Usually not zero, the initial hoop tension, T(i), depends on the installation technique. Including T(i) into the modeling is essential. This equation can also be formulated as:

$$\sigma_{rs} = \sigma_{rc}(i) + \sigma_{rp} + \Delta\left(\sigma_{rc} + \frac{T}{R}\right) \tag{4}$$

$$\sigma_{rs} = \sigma_{rc}(i) + \sigma_{rp} + \Delta\sigma_{rs} \tag{5}$$

2.2 Test setup and preparation of clay bed

To prepare the soft soil bed, a CBR mould with internal diameter of 150 mm with a height of 175 mm was used. It has a 50 mm high detachable extension collar and a 10 mm thick removable perforated base plate. Grease was applied to the mould's interior surface before it was covered with a thin and smooth polythene sheet to reduce the friction acting between the mould wall and the soil. Also, it makes sure that no water was lost from the sides of the mould. To ensure consistent density and water content throughout experiments, layers of soft clay, each 25 mm thick, were placed inside the tank. To create the clay layer, a predetermined weight of dried clay was ground into a fine powdered form and thoroughly combined with water to achieve a 30% water content. The clay samples were put in the mould and were compacted by the help of a metal rammer weighing 2.6 kg with a height of fall of 310 mm in order to achieve a bulk unit weight of 17.73 kN/m^3. The entire process was repeated for each layer of the clay sample till the height of 175 mm was reached. A thick plastic covering was placed over the prepared test bed, and it was left alone for seven days. Thin-walled cylinder samplers were used to gather undisturbed soil samples from several test bed locations, and their characteristics were assessed. The average value of water content, undrained cohesion and dry density in the test bed was found as 30%, 10 kPa and 17.73 kN/m^3 respectively. The maximum coefficient variance for all the variation was found to be 1.5%.

2.3 Formation of quarry dust column

After the preparation of clay bed, a steel pipe with inner diameter of 25.4 mm and 38 mm were used to prepare a cylindrical hole at the centre of the clay bed to prepare the quarry dust column of diameter 25.4 mm and 38 mm respectively. Clay was extracted from the pipe using a helical steel auger and subsequently and smoothly finished. The excavation was done for a height of 175 mm and 132 mm for the end bearing and floating column respectively. The relative density of the quarry dust was kept at 70% and the amount needed to fill up the cylindrical hole was calculated accordingly. 70% relative density of the quarry dust was chosen because of its its ability to provide optimal soil stability, strength, workability, and drainage characteristics, making it a practical choice both for field applications and controlled experimental setups. Total amount of quarry dust was divided into 5 and 4 batches equally to fill up the height of 175 mm and 132 mm respectively. Each batch was filled up till the required depth and was compacted with a customised circular steel tamping rod having diameter 10 mm and height of 200 mm. For the construction of encased column, once the soft soil is removed the geotextile was wrapped around the pipe and inserted in the column space after which required amount of quarry dust was poured and compacted. Figure 4 represents the unreinforced, column pocket creation for ordinary QDC and encased QDC.

2.4 Test procedure

All the tests were performed on the CBR mould of diameter 150 mm and height of 175 mm. A loading frame with a 50 mm diameter cylindrical plunger is used to conduct the test. A loading machine applies load on a plunger to penetrate the soil mould gradually. The load is applied at a rate of 1.25 mm per minute of penetration. The following load penetrations were recorded: 0.5, 1, 1.5, 2, 2.5, 3, 4, 5, 7.5,

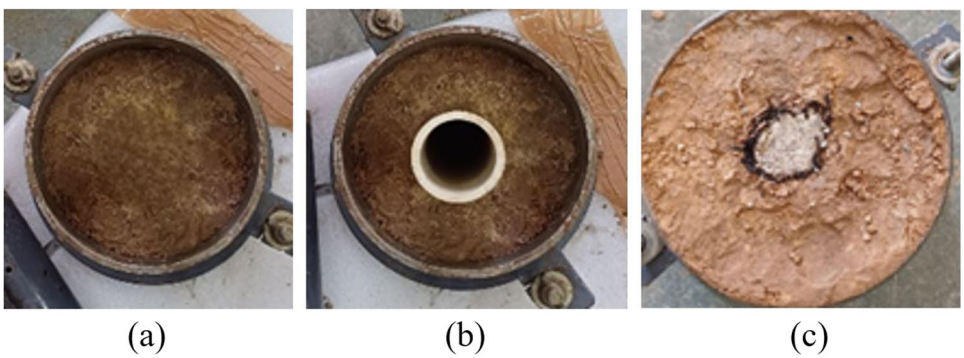

Fig. 4 **a** Unreinforced sample (**b**) Colum pocket creation for ordinary QDC (**c**) Encased QDC

10, and 12 mm. The deformation observed with help of a linear variable differential transducer (LVDT) placed over the testing plate and the mould. Loading setup is depicted in Fig. 5. Table 4 provides an overview of all the tests that were carried out.

3 Results and discussions

3.1 Settlement analysis

In the study, load at penetration of 1, 1.5, 2, 2.5, 3, 4, 5, 7.5, 10 and 12 mm were noted and compared for the load-bearing capacities of different quarry dust column configurations at 12 mm settlement. The results reveal significant variances in load capacity influenced by both kind and diameter of the QDC employed. For a comparison analysis, unreinforced soil sample were tested and at a settlement threshold of 12 mm, the unreinforced soil sample displays a load-bearing capability of 0.596 kN.

In comparison, end-bearing ordinary quarry dust columns (EOQDC) with diameters of 2.54 cm and 3.8 cm exhibit greater load capacities of 0.708 kN and 1.228 kN respectively as presented in Fig. 6. Displaying percentage increases of around 18.79% and 106.04% compared to the un-reinforced soil sample, indicating the effectiveness of increasing stone column diameter in enhancing load-bearing capacities.

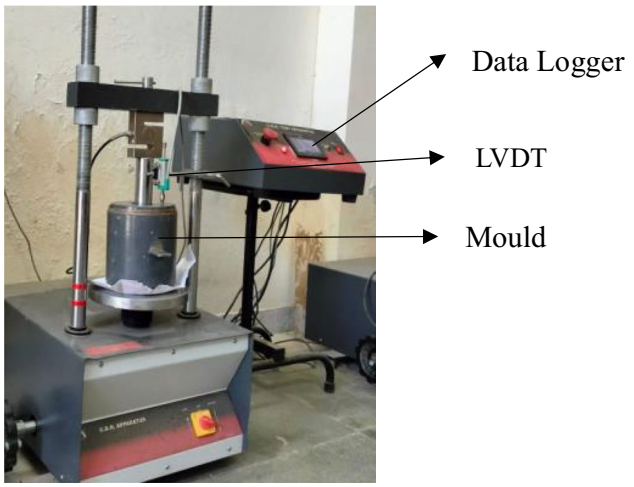

Fig. 5 Test setup

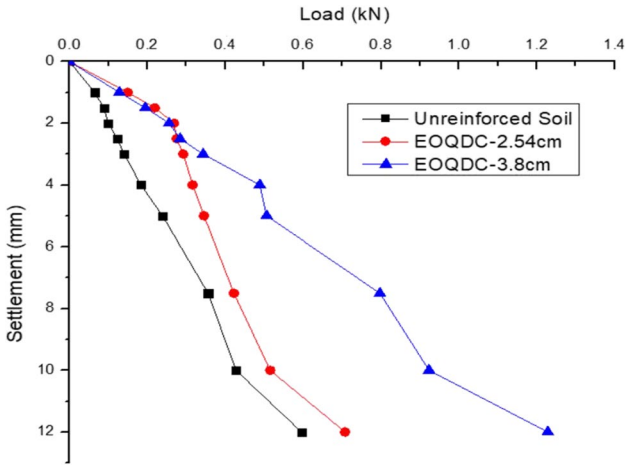

Fig. 6 Load -Settlement behaviour of EOQDC with varying diameter

Similarly, end-bearing encased quarry dust columns (EEQDC), at 2.54 cm and 3.8 cm diameters, display load capabilities of 0.939 kN and 1.763 kN, respectively as presented in Fig. 7. These capabilities show percentage increases of roughly 57.55% and 195.81% above the unreinforced soil sample, demonstrating the increased structural support given by encasement. For EOQDC, increasing the diameter 2.54 cm—3.8 cm indicate a percentage increase of around 73.45%. Similarly, EEQDC when the diameter is raised from 2.54 cm to 3.8 cm, suggesting a percentage increase of roughly 87.75%.

The floating ordinary quarry dust column (FOQDC) with a diameter of 2.54 cm and 3.8 cm results in a load carrying capability of 0.625 kN and 1.079 kN at a settlement of 12 mm (Fig. 8). The results show an increase in the capacity by 4.86% and 81.04% as compared to the unreinforced case. Floating encased quarry dust column (FEQDC) with a diameter of 2.54 cm and 3.8 cm results in a load carrying capability of 0.824 kN and 1.552 kN at a settlement of 12 mm (Fig. 9). The results show an increase in the capacity by 38.25% and 160.40% as compared to the unreinforced case. Increasing the diameter from 2.54 cm to 3.8 cm increases

Table 4 Summary of the tests performed

Reinforcement type	Detailed parameters	
	End bearing column	Floating column
Natural expansive soil	–	–
Expansive soil + OQDC	L = 17.5 cm Dia = 2.54 cm and 3.8 cm	L = 13.2 cm Dia = 2.54 cm and 3.8 cm
Expansive soil + EQDC	L = 17.5 cm Dia = 2.54 cm and 3.8 cm	L = 13.2 cm Dia = 2.54 cm and 3.8 cm

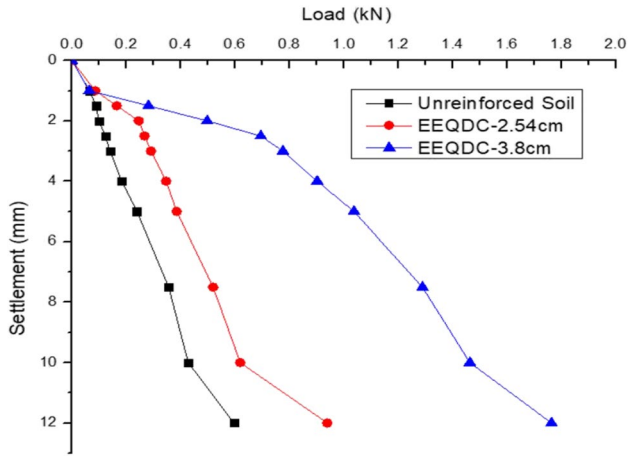

Fig. 7 Load -Settlement behaviour of EEQDC with varying diameter

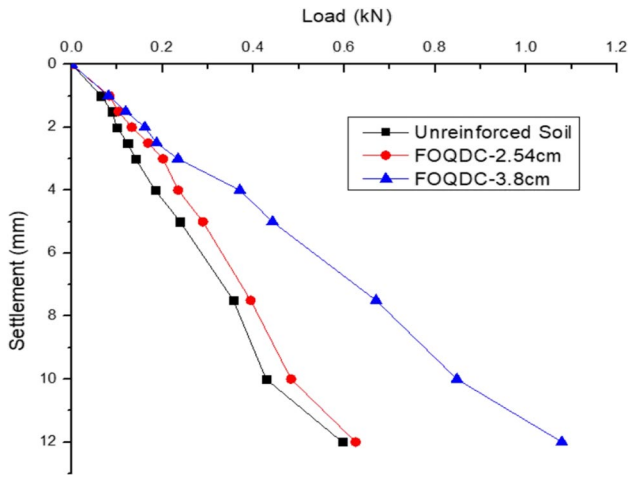

Fig. 8 Load -Settlement behaviour of FOQDC with varying diameter

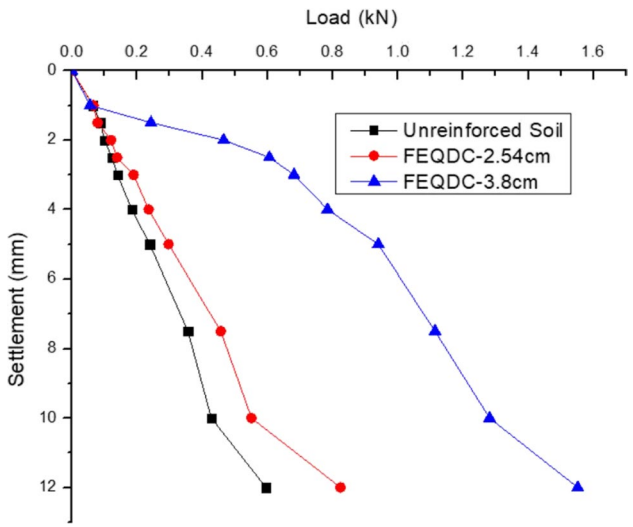

Fig. 9 Load -Settlement behaviour of FEQDC with varying diameter

the carrying capacity by 72.64% for FOQDC and by 88.35% for FEQDC.

Figure 10 presents a comparative analysis of the load-settlement characteristics between end-bearing and floating columns for varying diameter. Encasement provided a better load carrying capacity as compared to ordinary scenario for both end-bearing as well as the floating conditions. For EEQDC of 2.54 cm and 3.8 cm diameter column, an increase of 32.64% and 43.56% respectively as compared of EOQDC. While, for FEQDC of 2.54 cm and 3.8 cm, and increase of 31.84% and 43.83% respectively as compared to FOQDC. When the results were compared between end-bearing and floating end conditions, EOQDC of 2.54 cm and 3.8 cm diameter showed an increase of around 13.5% better than FOQDC. Also, EEQDC fared an increase of around 13.7% as compared to FEQDC. The increase in the load-carrying capacity of Quarry Dust Columns (QDC) with larger diameters, both in end-bearing and floating cases, is primarily due to the larger cross-sectional area that helps distribute the applied load over a greater surface. A wider column provides more contact area with the surrounding soil, improving the overall load distribution and reducing localized stress concentrations. When ordinary QDC is encased with geotextile, similar results are observed because the geotextile provides additional confinement to the quarry dust, preventing lateral bulging and enhancing the column's overall stability. The geotextile material, by offering external support, increases the strength of the column by reducing the radial expansion under load and maintaining the integrity of the quarry dust inside the column. The ultimate load carrying capability at a settlement of 12 mm of all the cases has been presented in Fig. 11.

3.2 Load improvement factor

Load Improvement Factor (LIF) is an important indicator of the degree to which quarry dust columns reduces settlement and improves the load-bearing capacity. It measures the degree to which the presence of QDC enhances stress distribution. Consequently, the ratio of the reinforced soil's load-bearing capacity to that of the unreinforced soil is known as LIF. Figure 12 represents the LIF of EOQDC and EEQDC. At 12 mm settlement LIF for 2.54 cm EOQDC and EEQDC was found as 1.188 and 1.786 respectively. Similarly, for 3.8 cm diameter column of EOQDC and EEQDC was calculated as 2.07 and 2.96 respectively. From the LIF data, it was clearly observed that encapsulating the ordinary quarry dust column improves the load carrying factor which gives additional support and helps transfer the load more effectively to the surrounding soil. Figure 13 gives the LIF of FOQDC and FEQDC for both the 2.54 cm and 3.8 cm diameter columns. At 12 mm settlement, LIF for 2.54 cm diameter column of FOQDC and FEQDC was found as 1.05 and

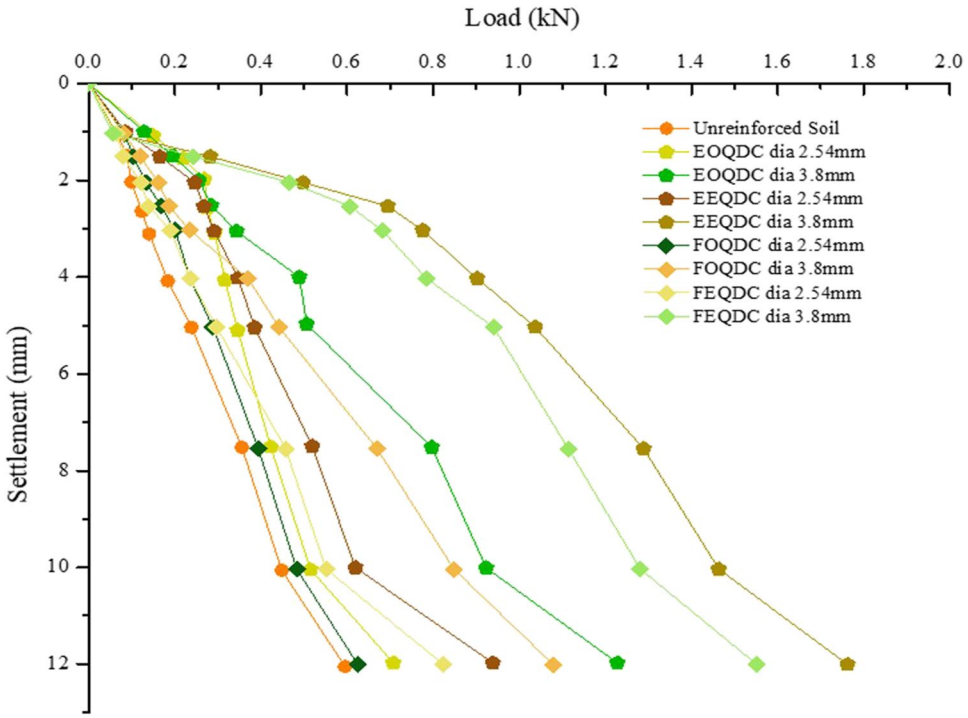

Fig. 10 Load -Settlement comparison of all the cases carried out in the current study

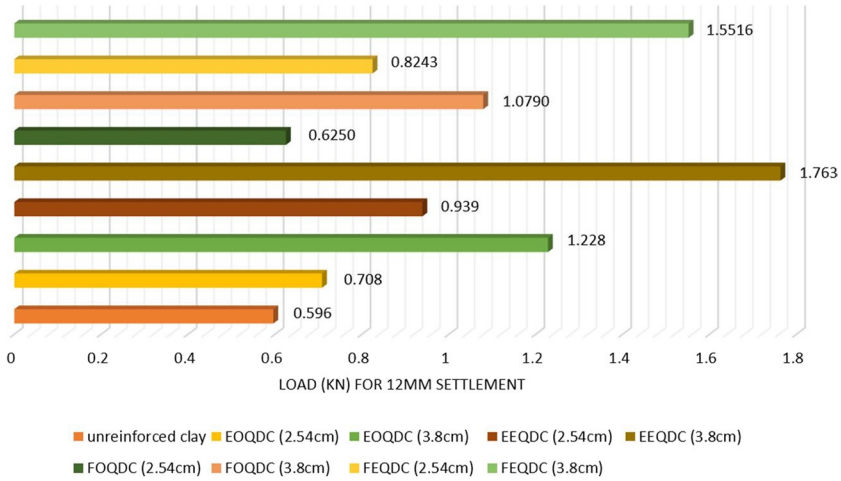

Fig. 11 Ultimate load carrying capacity at a settlement of 12 mm for all the cases

1.38 respectively. Likewise, for 3.8 cm diameter for FOQDC and FEQDC was calculated as 1.81 and 2.60 respectively.

Figure 14 represents a comparative analysis of the LIF for both end-bearing and floating case for the two different diameters of the columns for both ordinary and encased scenario. It was found that the 3.8 cm diameter column with the encasement provides the maximum value of LIF of 2.96 and thereby can be said to be carrying the maximum load bearing capability.

3.3 Stress–strain analysis

Stress responses to varying strain for soil and different quarry dust column configurations, including Ordinary and Encased Quarry Dust Columns of diameters 2.54 cm and 3.8 cm, reveals significant distinctions in their load-bearing capacities. For this analysis end bearing scenario have been presented which is depicted in Fig. 15. Ordinary QDC of 2.54 cm exhibit consistently higher stress than soil, with stress values escalating from 43.63 kPa at zero strain to 360.43 kPa at 0.0686 strain, demonstrating the reinforcement benefit of smaller diameter columns. In contrast, Ordinary QDC with a diameter of 3.8 cm while starting at a lower initial stress (20.74 kPa) experience a significant increase, reaching a peak of 625.36 kPa. This suggests that larger diameters provide better resistance to loads. Initially, encased QDC with a diameter of 2.54 cm have lower stress compared to OQDC. This is likely because of adjustments in the interaction between the encasement and the

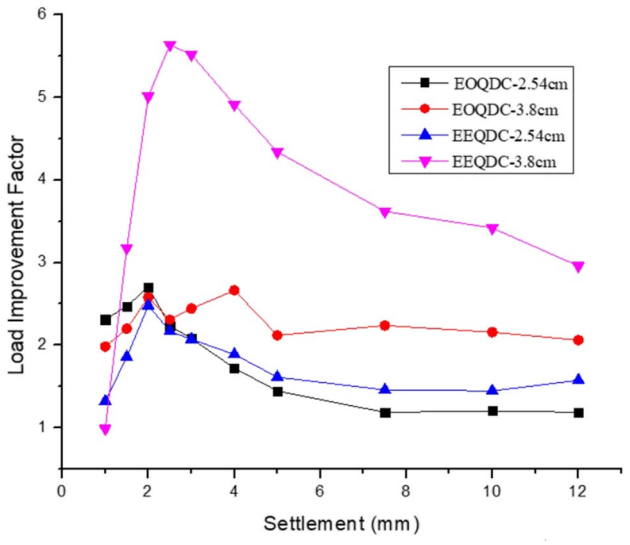

Fig. 12 LIF of end bearing conditions for both ordinary and encased scenario

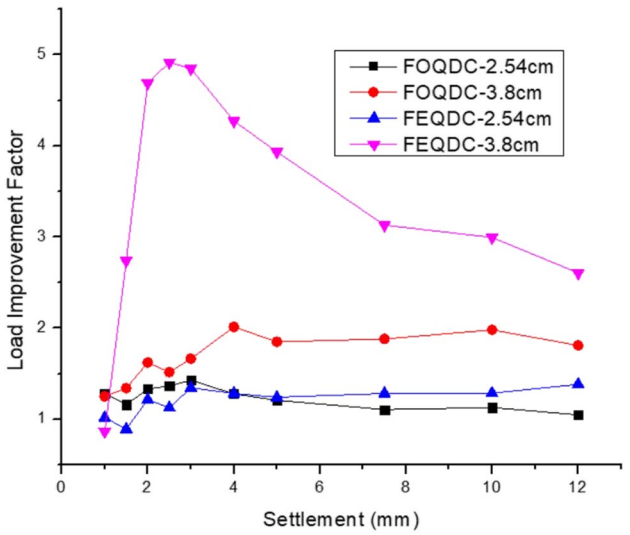

Fig. 13 LIF of floating conditions for both ordinary and encased scenario

soil. However, surpass them as strain increases, reaching 478.23 kPa at 0.0686 strain, highlighting the advantages of encasement in enhancing column stiffness and load transfer efficiency. The most significant performance is found with Encased QDC of 3.8 cm reaching an outstanding 897.87 kPa at the highest strain, underlining that the combination of bigger diameter with encasement enhances stress capacity delivering improved reinforcement against load-induced deformations primarily because of the lateral confinement maintain the column's structural integrity. This comparison underlines the utility of encasement and greater diameter

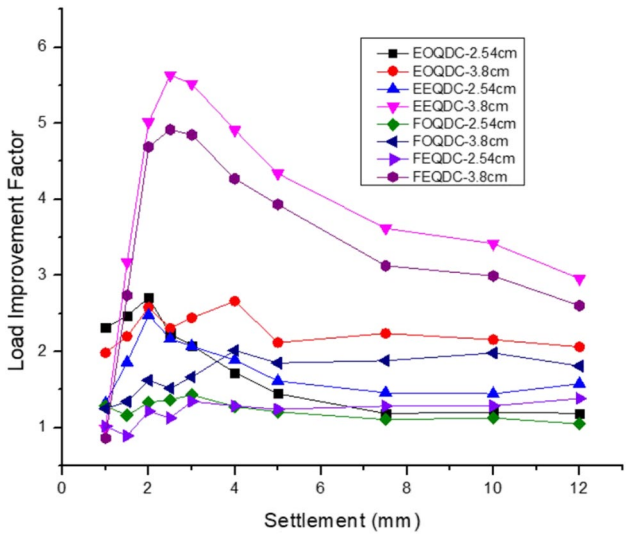

Fig. 14 Comparison of LIF for end bearing and floating conditions for both ordinary and encased scenario

in stone columns delivering improved stress performance, making them appropriate for application demanding strong ground improvement and higher load-bearing capabilities.

3.4 Failure mechanism

Quarry dust columns (QDC), both encased and ordinary, can experience various failure modes depending on their configuration (end-bearing or floating) and presence of encasement in soft clay. After testing, distorted granular piles were developed through taking out quarry dust and adding plaster of Paris into the holes. Ordinary QDCs exhibited bulging failure. This occurred from the top of the column (crest) for a distance of D to 1.5D (D being the column diameter). Encasement can mitigate this by providing lateral confinement and improving stress distribution. For the floating columns, punching failure was observed which resulted in the penetration of column up to a certain depth along with the tip yielding or bulging because of the lower shear stress to support the applied load. Failure mechanism of both the cases have been represented in Fig. 16. Encasing the floating columns also resulted in the mitigation of tip yielding or bulging along with the prevention of penetration into clays up to a certain extent.

3.5 Comparison with the existing literature

A direct comparison with some of the existing literature is not feasible due to the differences in materials used as no studies have used waste quarry dust as a soil modifier. The materials investigated in our study differ substantially from those used in many of the referenced works, and such variations may lead to

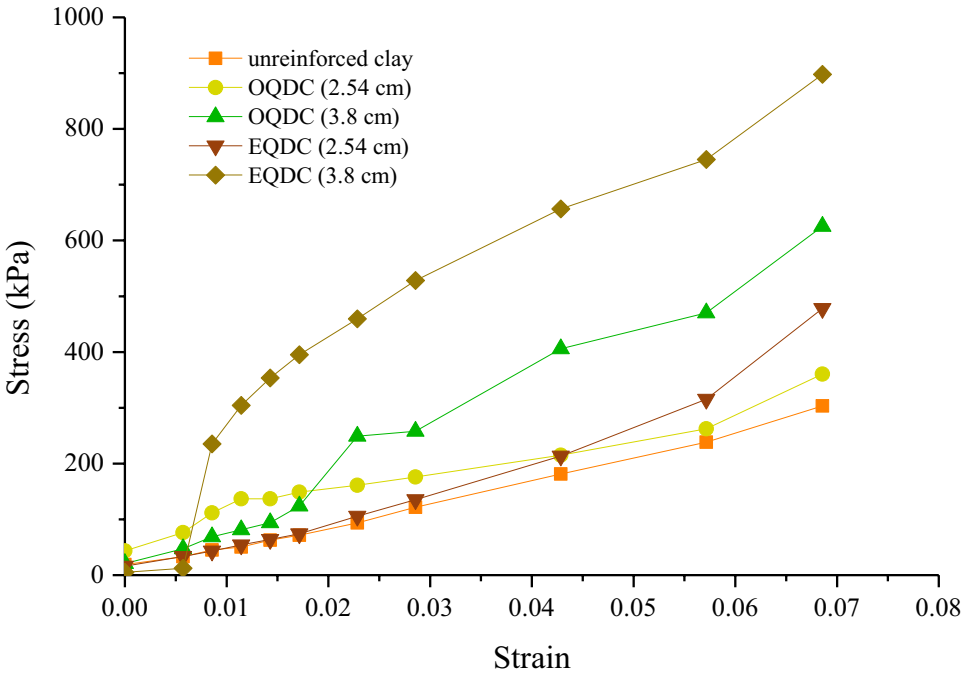

Fig. 15 Stress–Strain relationship of end bearing OQDC and EQDC for varying diameter columns

inherent differences in performance or behaviour. Despite this limitation, we have taken care to compare our results with studies that employ materials that are more similar to those used in our work. Load-Settlement behaviour has been compared for OQDC and EQDC end bearing configurations with the other studies. These studies provide a more relevant context for comparison, and the results are presented in Fig. 17. The comparison results clearly demonstrates that the general behaviour and trends in our study are consistent with those seen in the literature for similar materials. This suggests that, while material differences exist, the underlying principles and trends are widely applicable across different studies in this field.

4 Conclusion

This study investigated the efficiency of quarry dust columns (QDC) in improving the stability of soft clay soils by means of a comparison between encased quarry dust columns (EQDC) and ordinary quarry dust columns (OQDC) over various diameters (2.54 cm and 3.8 cm) for end bearing and floating scenarios. The load-bearing capacity and settling properties were assessed using California Bearing Ratio (CBR) test. The following conclusion can be observed:

1. Load-bearing capacity increased significantly in both EOQDC and EEQDC when compared to untreated soil. Larger diameter column (3.8 cm) consistently outperformed smaller ones (2.54 cm), hence increasing the diameter helps enhance performance.
2. Encased columns (EQDC) demonstrated even greater load-bearing capacities than ordinary columns (OQDC) for both end bearing and floating conditions.
3. Both OQDC and EQDC show a notable increase in SIF value compared to untreated soil and indicating better stress distribution and lower settlement. Greater SIF values came from larger diameter columns for both OQDC and EQDC. EQDC consistently showed a higher SIF than OQDC with the same diameter, emphasizing the efficacy of encasement in stress distribution. The results were observed in both end bearing and floating conditions.
4. Ordinary ODCs with a 2.54 mm diameter demonstrate higher stress levels than untreated soil. However, larger diameter ODCs (3.8 mm) show a notable increase in stress, indicating that larger diameters offer enhanced resistance to loading conditions. EQDC initially shows lower stress values compared to OQDC due to interaction between the encasement material and the surrounding soil but, as strain is increased, encased columns surpass OQDC.
5. Failure mechanism for end bearing columns were bulging, whereas floating columns fails in tip yielding/bulging and punching. Maximum bulging was noted at a depth of D-1.5D from the top of the column. Encasing the columns resulted in prevention of such failures.
6. Reinforced floating granular piles are a better alternative to unreinforced end-bearing piles.
7. Conventional stone columns made up of aggregate can be effectively replaced by the waste material like quarry dust without compromising much of its efficiency.

5 Practical consideration, limitations and future scope

To implement Quarry Dust Columns (QDC) in construction projects, start with a thorough site assessment to understand the soil properties, as these determine the suitability of QDC for soil stabilization. Soft clays and weak soils are ideal candidates for this technique. The quarry dust used should be clean and free from organic impurities; its particle size distribution and compaction characteristics should be tested to ensure effectiveness. For installation, vertical columns of quarry dust are placed at the specified intervals and depth, ensuring proper compaction for optimal stability. In the case of EQDC, the quarry dust columns are encased in jute geotextile, which helps provide additional confinement and prevent lateral spreading. Limitations of this method include the potential decay of jute over time and variable performance under extreme environmental conditions. While jute offers several advantages as an eco-friendly and cost-effective material for encasing quarry dust columns, its biodegradability and susceptibility to moisture and UV degradation can reduce its long-term effectiveness. The decay of jute over time can lead to a loss of confinement, reduced load-bearing capacity, and increased settlement, ultimately

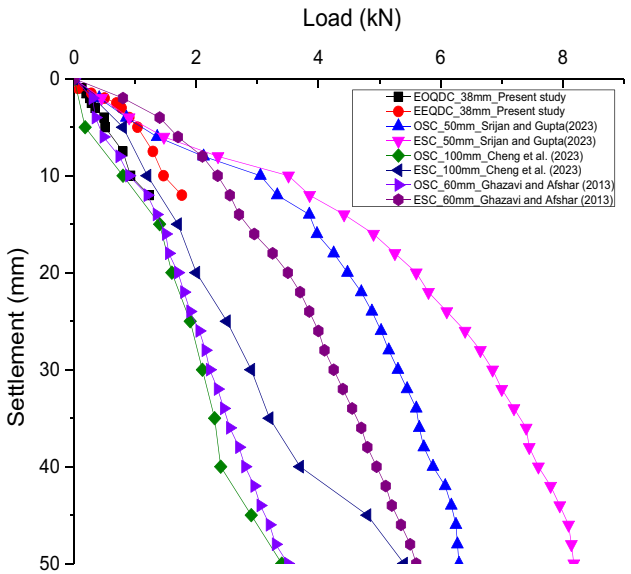

Fig. 17 Comparison of load-settlement behaviour of the present study with existing literatures

impacting the performance of the EQDC system. To further enhance the effectiveness and durability of Quarry Dust Columns (QDC), future research should explore the trategies to mitigate decay can help improve the longevity and stability of jute-encased quarry dust columnsand also the development of hybrid materials that combine the benefits of natural geotextiles, like jute, with synthetic materials, offering better long-term stability and resistance to environmental degradation.

Abstract By combining first-principles computations with the semi-classical Boltzmann transport equations, a systematic investigation of the structural, electronic and thermoelectric properties of the MoSSe Janus monolayer is conducted under pressure. The monolayer semiconducting nature is indicated by the band gap value (E_g = 1.5 eV), which may be further tuned from 0.56 to 1.67 eV by applying pressure in the -3GPa to + 2GPa range. The figure of merit (ZT) for p (n)-type carriers at 300 K in the absence of pressure is computed to be 0.67 and 0.59. The power factor has enhanced from 16.59 (27.21) Wm^{-1} K^{-2} to 227.15 (159.50) Wm^{-1} K^{-2} for *n* (*p*)-type carriers by applying an external pressure of -1 GPa to the Janus monolayer. For *n* (*p*) -type doping at 300 K, the corresponding maximum value of ZT is 0.82 (0.78), which is 39% (14%) greater for *n* (*p*) type than for pure MoSSe Janus monolayer. When the pressure is increased to + 3 GPa, the value of ZT for n-type doping is further increased to 0.73, which is 24% higher than the value for pure monolayer. It is possible for a pure Janus monolayer to undergo n-type doping under pressure due to the shifting of the conduction band minima and valence band maxima. This study presents an attractive approach for manipulating the material thermoelectric properties through external pressure application.

1 Introduction

Several factors including population growth, industrialization and technological improvement are contributing to the very rapid rise in the global energy demand. The energy needs will be met by using fossil fuels and other non-renewable resources [1], which will lead to the production of massive amounts of waste and the eventual depletion of the resources owing to intensive use. The future energy problems can be resolved by anticipating a rise in energy efficiency and a decrease in energy consumption [2].

The environmentally friendly and efficient methods of resolving this problem are the conversion of waste heat into electrical energy using thermoelectric material [3, 4]. The past three decades have seen a rise in the importance of low-dimensional materials [5], especially nanosized materials, in many scientific and technological domains. Also, the 2D materials can have nano-bio interactions which can be further used in bio medical applications [6]. This is because 2D materials are preferred to their bulk equivalent due to their distinctive and outstanding properties [7, 8].

Theoretical predictions and experimental synthesis of several 2D transition metal dichalcogenides (TMDCs) have been made [9–11]. The density of states (DOS) of the valence and conduction bands [12] in low-dimensional materials has been increased close to the Fermi level, causing an increase in power factor (σS^2) that results in good thermoelectric performance with the mathematical expression for figure of merit (ZT) as

$$ZT = \frac{S^2 \sigma T}{\kappa} \tag{1}$$

where the total thermal conductivity (electronic and lattice), Seebeck coefficient, electrical conductivity and absolute temperature (in kelvin) are represented as κ, S, σ and T [13]. All these parameters are interconnected in such a way that it is impossible to change the value of ZT by changing just one variable, as they are all dependent on one another. Thermoelectric materials have a special tendency for using the Seebeck effect to transform heat energy into electrical energy, whereas the reverse process uses the Peltier effect.

The study of the Mo-based TMDCs, such as $Mo(S/Se)_2$, $W(S/Se)_2$ and $Zr(S/Se)_2$ have been extensively investigated [14–17]. Janus monolayers are formed with two different types of chalcogenides in a single monolayer and by breaking the mirror symmetry [18–21]. Thermoelectric properties have been well investigated for Janus HfSSe, and WS-X (X = Se & Te) monolayers [22–26]. The chemical vapour deposition method was used by Zhang et al. [27] to synthesize MoSSe, making it the most suitable and deserving

[a] e-mail: ramesh85@gjust.org (corresponding author)

Published online: 08 April 2025

candidates of further development. Based on how the chalcogenides are arranged, these TMDC monolayers are split into two phases called the 2H and 1 T phases. In comparison with ZrS_2 monolayer, ZrSSe [28] monolayer has been predicted in 1 T-phase and has proven to be a promising n-type thermoelectric material. Thermoelectric performance of TMDCs materials is improved by diverse ways like doping [29, 30], applying strain [31, 32], dimension and stacking engineering [8, 33, 34], applying pressure [35], inducing defects [36] and converting the 2D materials into nanofibres can be used in tissue regeneration [37].

Thermoelectric properties of Sb_2Se_3 monolayer have been studied by H. A. R. Aliabad et al. [38] under different values of pressure. Y. Zhang et al. [39] predicted the pressure induced thermoelectric properties of SnSe crystal and found that the value of ZT has been enhanced up to 1.7 from 0.9 at 600 K under the pressure of 6 GPa. Thermoelectric average power factor has been enhanced up to 33% under the pressure of 20 GPa at 800 K temperature, and corresponding enhancement in thermoelectric performance of SnS_2 material has been studied by Y. Javed et al. [40]. D. Zou et al. [35] have studied about the tuning of electronic parameters under external pressure and gave the valuable insight on the enhanced thermoelectric performance of layer $SnSe_2$ material. In the case of $NbSe_2$, B. Hou et al. have studied atomic tracking techniques to systematically explore the thermally-driven structural evolution [41].

Keeping in mind the above literature studies on various monolayers, the present investigation deals with the study of structural, electronics and thermoelectric properties of MoSSe Janus monolayers using pressure. A systematic investigation has been performed for the structural and electronic properties. Band structure has been altered by applying the external pressure, and it has found that band gap gets tuned. Phonon dispersion curve at different pressure has been drawn and investigate that chosen monolayer at different pressure is found to be thermodynamically stable. Using the semi-classical Boltzmann transport equation, thermoelectric properties of monolayer under different pressure have been investigated. It is observed that MoSSe Janus monolayer is a promising thermoelectric material.

By demonstrating how pressure influences MoSSe's unique structural asymmetry, the research highlights the material's potential for fine-tuning of its band gap, carrier transport, and phonon interactions. This opens up a practical pathway for enhancing the performance of MoSSe in energy conversion applications, such as thermoelectric, where precise control over electronic and thermal transport properties is essential for improving efficiency.

2 Computational details

Ab-initio calculations for MoSSe Janus monolayer were carried out in framework of density functional theory (DFT) as implemented in Quantum Espresso (QE) software [42]. The Janus monolayer has been designed by replacing the one layer of sulphur (S) in MoS_2 by the layer of selenium (Se), and structure has been relaxed without using any constraint by taking a vacuum of 20 Å along the Z-direction. The Janus monolayer has been totally relaxed under the convergence criteria for energy and force up to 0.0001 eV and 0.001 eV/Å^2. As an exchange correlation functional, generalized gradient approximation (GGA) has been adopted along with Perdew-Burke-Ernzerhof (PBE) form [43]. For the core interaction, ultrasoft pseudopotentials were used and plane wave basis set with optimized energy up to 90 Ry was used for the incorporation of core and valence electrons interactions. Kinetic energy cut-off and k-mesh was converged against the total energy, for reducing the computational cost. For the self-consistent calculations, an optimized k-mesh of Monkhorst Pack of $16 \times 16 \times 1$ is sampled for Brillouin zone. The convergence tests for k-point and cut-off energy have been provided in supplementary information (#). Thermodynamical stability has been checked with the phonon dispersion curve by using the phonopy software [44]. The thermoelectric parameters such as Seebeck coefficient, electrical conductivity, and electronic thermal conductivity have been evaluated by solving the semi-classical Boltzmann transport equations (BTEs) using the interface of QE software with BoltzTraP code [45]. The well convergent transport parameters have been obtained by taking the high Monkhorst Pack of $60 \times 60 \times 1$, and these are found to be the function of relaxation time (τ). The relaxation time is determined by using the deformation potential theory [31, 32, 46]. Further, the contribution of phonon to the lattice thermal conductivity is calculated by coupling of QE with phono3py code [47]. The finite displacement of atoms was generated by making the supercell of $3 \times 3 \times 1$, to obtain the second and third order force constants. Generated supercell was sampled with $6 \times 6 \times 1$ k-points mesh and used optimized q-mesh of size $25 \times 25 \times 1$. All the above calculated parameters are further used to calculate the value of figure of merit (ZT).

3 Results and discussion

3.1 Structural properties

MoSSe Janus monolayer is made up of three layers, one layer of transition metal atom (Mo) sits between the two distinct chalcogenide types (S & Se). In addition, as illustrated in Fig. 1, it had a honeycomb lattice structure like graphene, composed of Se/S atoms in place of the S/Se atoms in MoS_2/$MoSe_2$.

Figure 1a and b shows the side and top views of the Janus monolayer, respectively, whereas Fig. 1c shows the top view. The MoSSe Janus monolayer asymmetric structure results from its two different chalcogenides, which give its exceptional properties. In

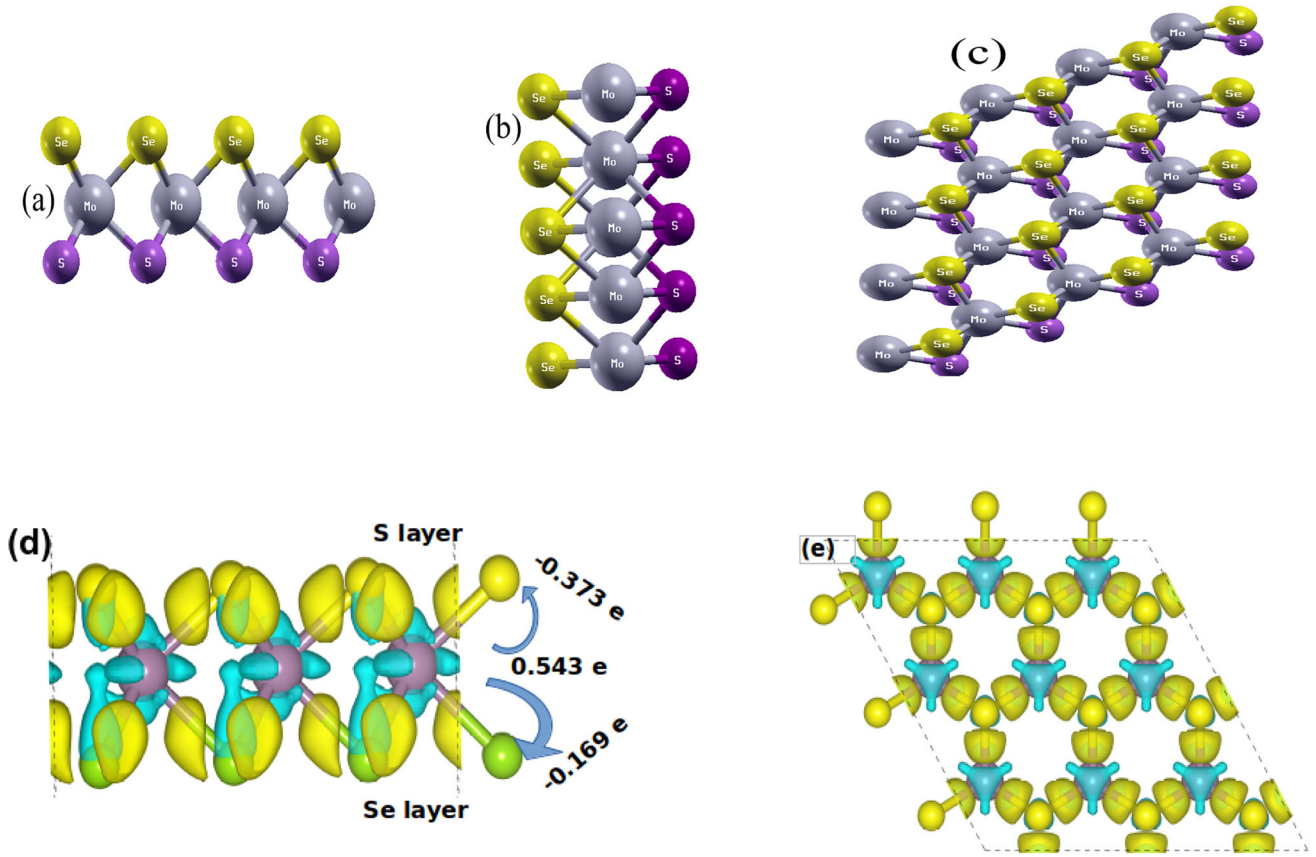

Fig. 1 Crystal structure of MoSSe Janus monolayer (**a**), (**b**) Side views and (**c**) Top view having different orientation, whereas, (**d**) Side view and (**e**) Top view of charge density difference (cdd) plots

Table 1 Lattice constant (a) of the monolayer and their literature values

Monolayer	MoS_2	MoSSe	$MoSe_2$
a (Å)	3.17 [48], 3.18 [26]	3.25 [present work, 26], 3.23 [48]	3.30 [26, 48]

this case, structural asymmetry causes reflection symmetry to break regarding the central transition metal, while MoS_2 and $MoSe_2$ retain reflection symmetry. A vacuum of 20 Å has been added along the Z-direction to prevent the interaction between the layers.

Figure 1d and e shows the side view and top view of charge density difference plots. Due to the presence of layers of different chalcogen atoms in the upper and lower environment of transition metal layer, there is breaking in the symmetry of charge carriers and electronic band structure which also affects the thermoelectric performance of material. The charge transport is not uniform across the material due to presence of different environment. Here, in Fig. 1d, there is accumulation of charge 0.373 e from Mo to S atom and 0.169 e from Mo to Se atom. Transfer of different amount of charge shows asymmetry in chemical environment in lower and upper phase.

Since the atomic radius of Se is greater than that of S, the lattice constant of MoSSe lies between the lattice constants of MoS_2 and $MoSe_2$, as shown in Table 1 [26, 48]. A very small discrepancy in lattice constant is due to computational error. Figure 2a illustrates how the lattice constant varies as a function of applied pressure (in GPa).

3.2 Electronic properties

The MoSSe Janus monolayer band structure is studied along the K–Γ–M–K–Γ high symmetry path in the first Brillouin zone.

As shown in Figs. 2a and 3, the contribution of different orbitals in the formation of bands varies with pressure i.e. the contribution of 3d orbital of Mo atom, 3p orbital of Se atom and 2p orbital of S atom varies with change in pressure. The thermoelectric properties of materials are depended on the formation of bands. That is why transport properties get tuned with pressure variation.

The electronic band structure will have a direct band gap nature with a value of 1.56 eV, where the valence band maxima (VBM) and conduction band minima (CBM) are both located at the high symmetric point K as illustrated in Fig. 4a. The obtained results are similar to the previously published research [48].

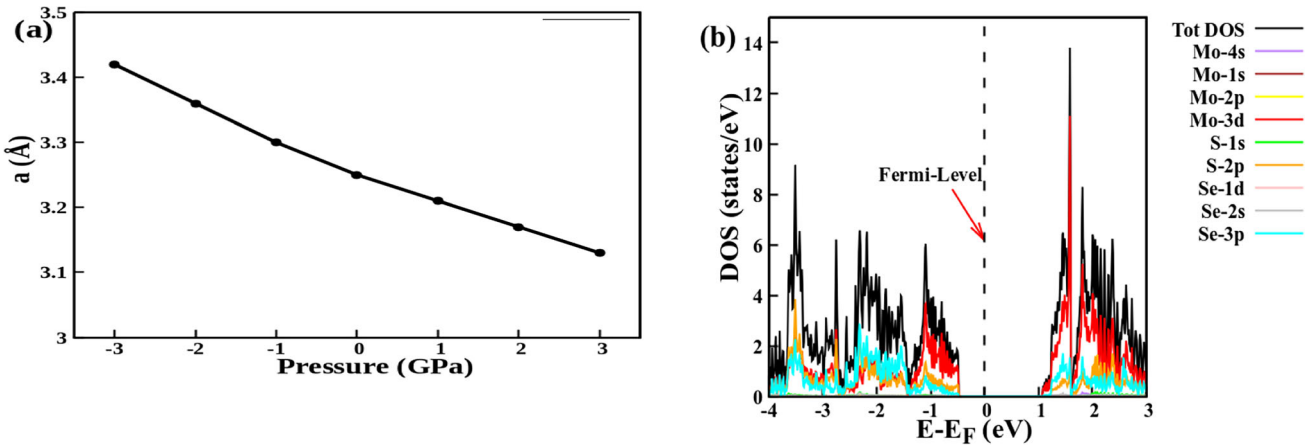

Fig. 2 **a** Variation of lattice constant with different values of pressure (GPa) and **b** Density of states corresponding to pure Janus monolayer

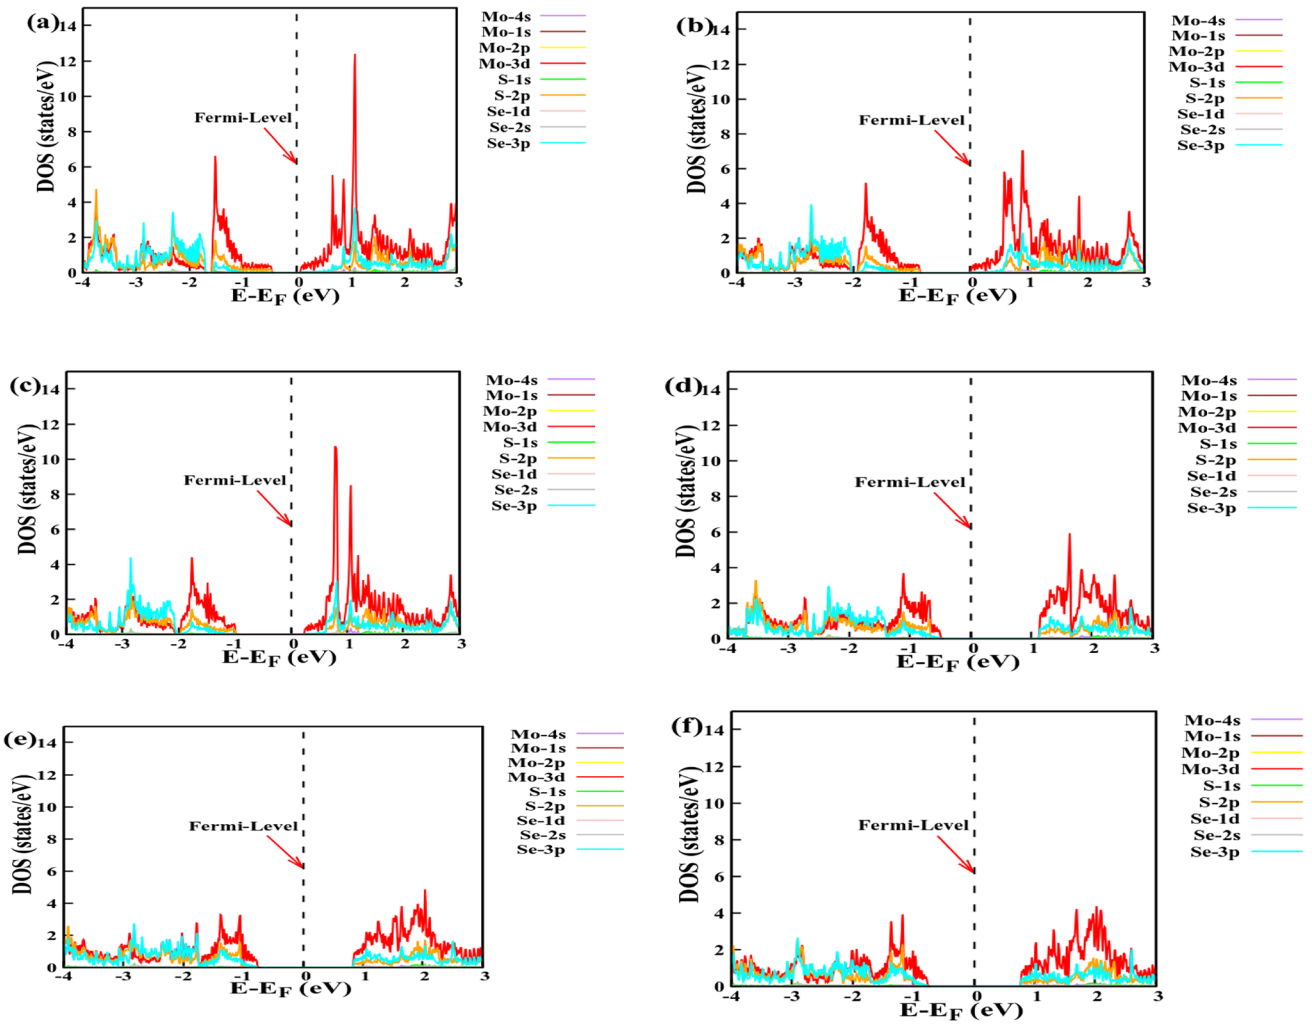

Fig. 3 The plot of projected density of states (pdos) at pressure, (**a**) −3, (**b**) −2, (**c**) -1, (**d**) 1, (**e**) 2 and (**f**) 3 GPa, respectively

The Mexican hat-like band structure at the high symmetric Γ-point in the E-K dispersion curve causes the Seebeck coefficient to increase [49, 50], which in turn yields improved thermoelectric efficiency. Pressure has been applied systematically from -3 GPa to + 3 GPa to observe the impact of pressure on the electronic band structure.

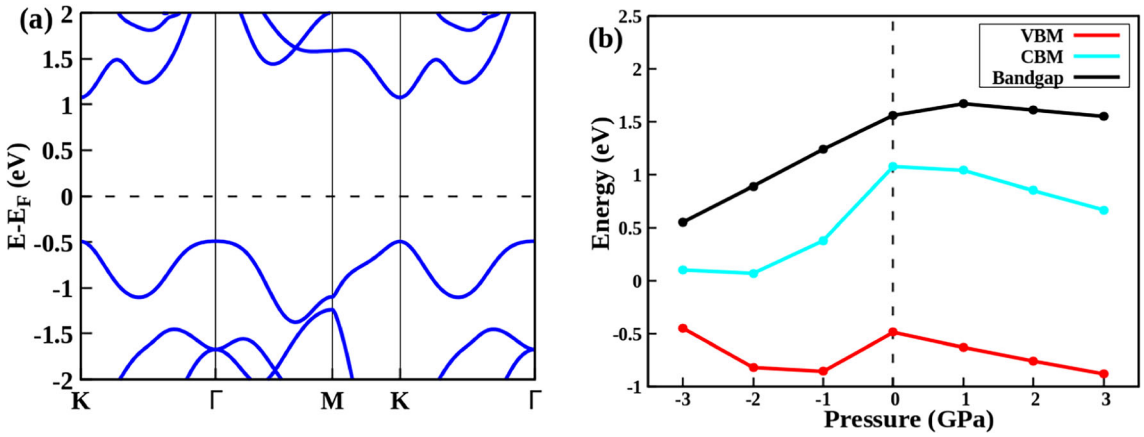

Fig. 4 **a** Electronic band structure of pure Janus monolayer and **b** Variation in bandgap with respect to external pressure

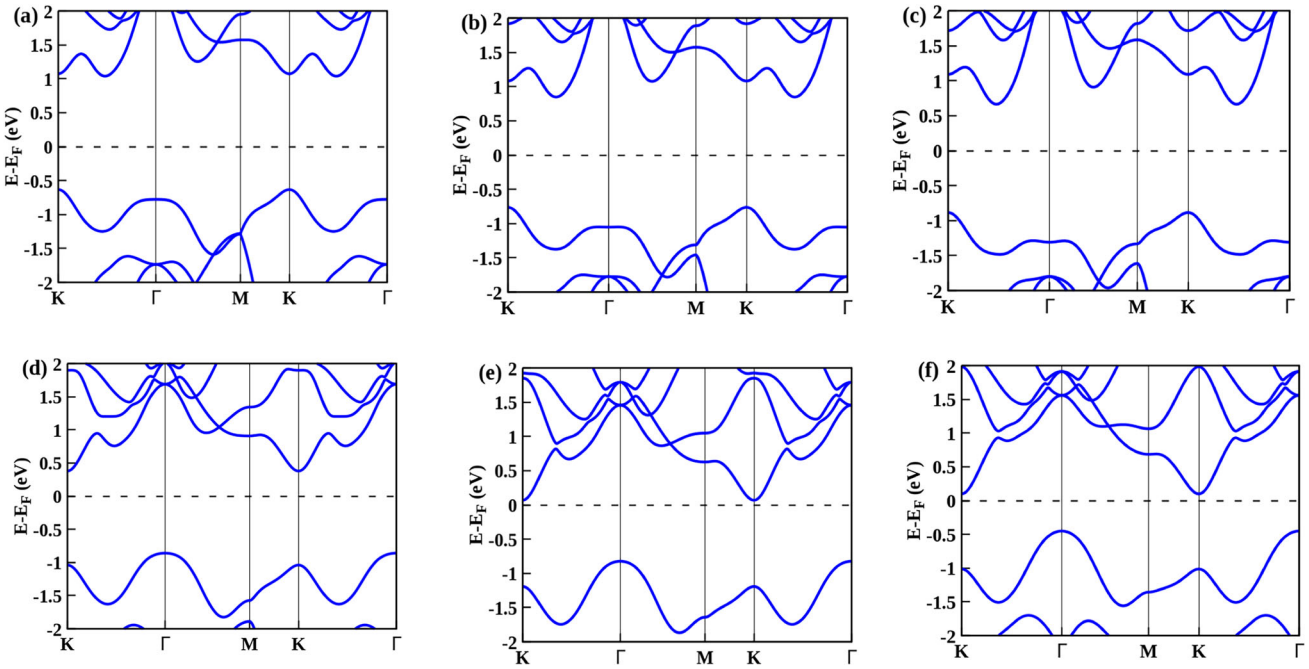

Fig. 5 Energy band structure at external pressure (**a**) + 1 GPa, (**b**) 2 GPa, (**c**) 3 GPa, (**d**) −1 GPa, (**e**) −2 GPa and (**f**) −3 GPa, respectively, of MoSSe Janus monolayer

After the confirmation of thermodynamical stability of Janus monolayer under different pressures, the effect of pressure has been studied on electronic properties. Tuning of band gap with respect to external pressure is shown in Fig. 4b, in which VBM starts to go away from Fermi level, whereas CBM starts to move toward the Fermi level. Also, the energy band dispersion curves become influenced to give indirect band gap with external pressure and no longer VBM & CBM both lies on high symmetric point K as shown in Fig. 5. The ability to manipulate MoSSe under pressure represents a significant advancement in tailoring two-dimensional materials for next-generation energy harvesting and cooling technologies.

3.3 Thermal and stability dynamics

As shown in Fig. 6a, the fully relaxed parameters are used to compute the phonon dispersion curve and high symmetric positions of the first Brillouin zone using the phonopy code to comprehend the dynamical stability.

These curves consist of nine modes, three of which are acoustic modes with lesser energy and the other six being optical modes. Each mode is made up of three atoms. The Janus monolayer is thermodynamically stable since all these modes come inside the positive frequency range. Further investigation of the material under pressure has led to the drawing of the dispersion curve under various pressures.

300	3.73	2.60	1.90	1.82	6.2	6.45	7.00
500	2.25	1.55	1.13	1.08	3.7	3.85	4.20

The Janus monolayer considered as thermodynamically stable under different pressures as shown in Fig. 7. Lattice vibrations can be used to predict heat conduction and estimates for lattice thermal conductivity have been made. The lattice thermal conductivity (κ_l) is calculated by using the linearized Boltzmann transport equations for phonons.

The lattice thermal conductivity is determined as a function of temperature, and it is decreasing because of phonon scattering dominance over phonon interactions. The plot is displayed in Fig. 6b, and the values are included in Table 2. It is exhibiting diminishing behaviour under various pressures. There is greater phonon scattering and a decreased lattice thermal conductivity because of the gap being smaller between the highest acoustical branch and optical branch. Hence, like other TMDCs Janus monolayers as WSSe [23, 51], WSTe [51] and HfSSe [25], MoSSe Janus monolayer exhibits very low lattice thermal conductivity.

3.4 Effective mass and relaxation time

Effective mass is essential for determining the thermoelectric parameters absolute value, which is determined by fitting quadratic curve to an electronic band structure. The second order curve fitting of the VBM and CBM of energy bands has yielded the effective

mass for hole (h) and electron (e) carriers. Further, the relaxation time for hole and electrons is calculated by effective mass dependent deformation potential theory [24] and formulated as.

$$\tau = \frac{\hbar^3 C_{11}}{E_\beta^2 (m_d k_B T)} \tag{2}$$

The effective mass (m*) of a charge carrier hole (electron) as defined by formula; $m^* = \hbar^2/(\partial^2 E(k)/\partial k^2)$, was calculated by fitting a quadratic polynomial to a VBM (CBM) of a monolayer band structure. Here, $\partial^2 E(k)/\partial k^2$ denotes the second order derivative of the maxima valence (minima conduction) band energy curve with respect to wave vector (k). The average effective mass m_d has been expressed by $m_d = \sqrt{m^*_{\Gamma-M} m^*_{M-K}}$, where, $m^*_{\Gamma-M}$ and m^*_{M-K} are the effective mass along Γ-M and M–K direction. We further evaluated the charge carrier's relaxation time (τ) using deformation potential theory. Elastic constant C_{11} has been evaluated by quadratic polynomial fitting of total energy difference (E- E_0) versus applied strain, where E is strained system energy and E_0 is the energy of unstrained system.

Deformation potential constant is evaluated as $E_\beta = \partial E_{edge}/\partial\delta$, where E_{edge} is the energy of VBM (CBM) for hole (electron) and δ is the applied strain and is calculated by linear fitting of curve. By using the above calculated value of m_d, C_{11} and E_β in equation [34]. By using all calculated coefficients, the relaxation time (τ) has been calculated at different temperatures as tabulated in Table 3. The absolute value of the thermoelectric parameters can be found by using the relaxation time.

4 Transport properties

4.1 Janus monolayer at 0 GPa pressure

After the investigation of structural and electronic properties, a deep understanding has been gained for the estimation of the thermoelectric properties of the Janus monolayer based on the semi-Boltzmann transport equation within the rigid band approximation.

Seebeck coefficient (S) is the measurement of bipolar conduction of charge carriers and its variation with respect to carrier concentration (n) is plotted in Fig. 8a. Negative and positive value of n refers to carriers as electrons and holes, respectively. In the same manners, negative and positive values of S represent for the n- and p-type doping. Its value obtained for n- and p-type doping is 2.52 and 2.56 mV/K, at room temperature, suggesting that the material is behaving as p-type semiconductor. Seebeck coefficient drops with temperature because of increase of bipolar effect at higher temperatures for both *p*- and *n*-type carriers. Also, its value decreases with increase in carrier concentration as followed by expression $S \propto (1/n)^{2/3}$ [26] and remains constant with the increase in carrier concentration.

The variation of electrical conductivity (σ) with respect to carrier concentration is illustrated in Fig. 8b. Intrinsic scattering of charge carriers becomes more strengthened with increase in temperature results to give the decreasing behaviour with temperature. Its value increases with increase in carrier concentration because of its direct dependency on carrier concentration (n) as $\sigma \propto n$ [52]. As mentioned in Table 3, effective mass for holes is greater than electrons cause to give higher Seebeck coefficient for p-type carriers as compared to n-type carriers and reflect to higher electrical conductivity for p-type doping [35, 53, 54].

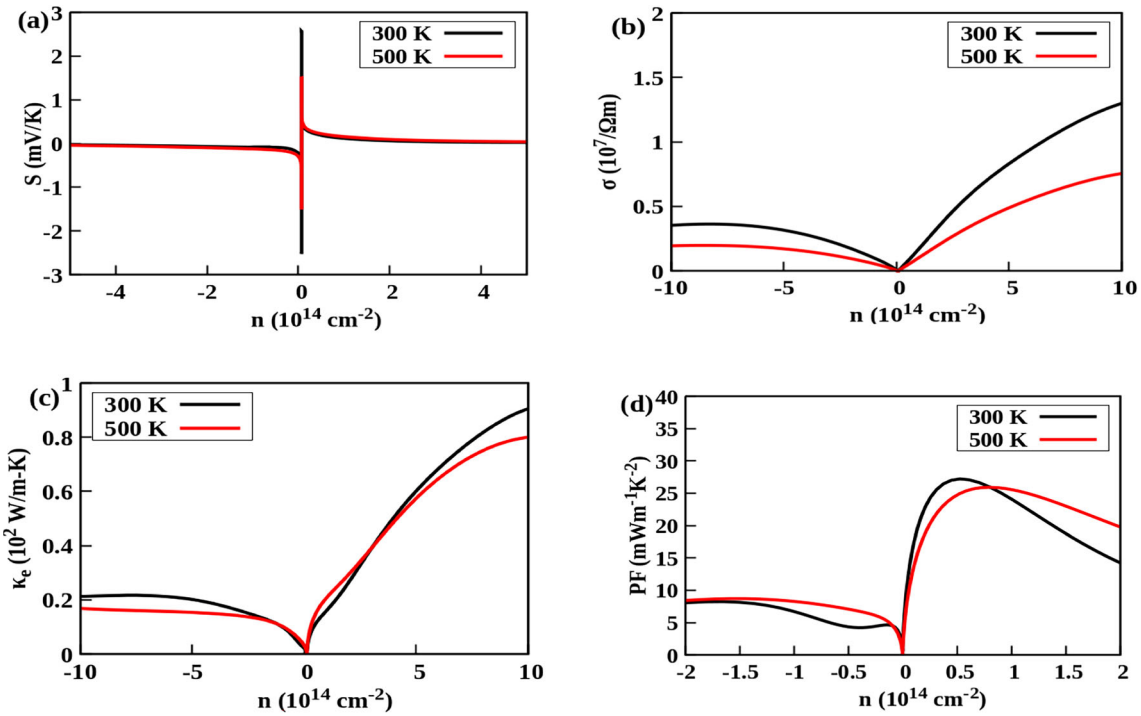

Fig. 8 Variation of **a** Seebeck coefficient, **b** Electrical conductivity (σ), **c** Electronic thermal conductivity and **d** Power factor, with respect to carrier concentration (n)

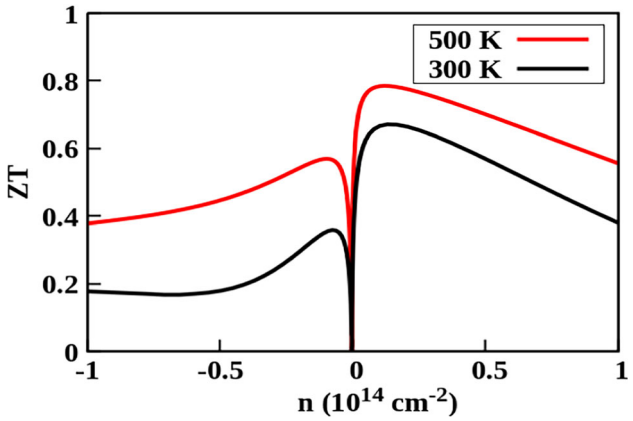

Fig. 9 Variation of figure of merit (ZT) of pure Janus monolayer with respect to carrier concentration (n), at different temperatures

The electronic thermal conductivity (κ_e) is showing similar behaviour as electrical conductivity as related by Wiedemann–Franz law [55], expressed as $\kappa_e = L\sigma T$, where for non-degenerate semiconductors, Lorentz number (L) $= 1.5 \times 10^{-8}$ $W\Omega K^{-2}$ [56]. Variation of κ_e with respect to carrier concentration and temperature is shown in Fig. 8c.

Power factor is another key related by the combined effect of Seebeck coefficient and electrical conductivity as power factor $= \sigma S^2$, and the variation with carrier concentration is shown in Fig. 8d. It has been noticed that power factor is increasing with carrier concentration and observed a significant influence of increasing temperature. Plot analysis reveals that the power factor is relatively small at low doping due to the dominance of electrical conductivity over Seebeck coefficient. It grows to its higher value with an increase in carrier concentration (n) and then begins to display a falling trend. Peak of p-type and n-type doping is suggested that p-type doping is more favourable over n-type doping, providing higher power factor for p-type doping.

The figure of merit (ZT) was calculated using the previously determined parameters and its plot with respect to carrier concentration (n) is presented in Fig. 9. The figure illustrates that the peak value of ZT is 0.67 for p-type doping which is higher than 0.59 for n-type doping. Also, it is increasing with increase in temperature.

All the above parameters are also showing that under 0 GPa pressure, material is giving enhanced thermoelectric properties for p-type doping as compared to n-type doping and the value is higher or comparable with previously reported Janus monolayers like MoSeTe [24], WSSe [23], HfSSe [25] and WSTe [25].

4.2 Janus monolayer MoSSe under pressure

The impact of external pressure on $SnSe_2$ monolayers and bilayers [35] is a source of inspiration for the development of Janus monolayers' thermoelectric properties. First, it is discovered that the VBM and CBM have been moved against the Fermi level and that external pressure has a significant impact on the electronic structure. As illustrated in Fig. 4(b), the band gap exhibits decreasing behaviour with respect to negative external pressure but first increases with pressure when exposed to positive external pressure. The transport properties are tuned, exhibiting an enhanced behaviour. As explained by Goldsmid-Sharp relation [54], $E_g = 2e|S_m|T_m$, here E_g and T_m, S stands for bandgap, temperature and the highest Seebeck coefficient, respectively; therefore, the band gap and Seebeck coefficient are manifesting similar behaviour. This causes the Seebeck coefficient for n-type doping to grow from 2520 to 2770 μVK^{-1} under positive pressure; however, it constantly falls under negative pressure, as shown in Fig. 10a.

P-type charge carriers have demonstrated a similar behaviour at room temperature. As previously explained and shown in Table 3, the effective mass of holes decreases with external pressure relative to the effective mass of electrons, which causes the Seebeck coefficient for p-type doping to decrease from n-type doping. At 0 GPa, however, the Seebeck coefficient for p-type doping was higher than that of n-type doping. It follows that for n-type doping, external pressure is more effective in enhancing the Seebeck coefficient. This causes the material to transition from being p-type doped to being n-type doped when external pressure increases.

The power factor exhibits the same trends as the Seebeck coefficient in the transition from p-type to n-type doping because it is the result of the combined action of electrical conductivity and the Seebeck coefficient. However, due to the combination of two components, where electrical conductivity predominates over Seebeck coefficient as shown in Fig. 10b, the power factor value has a different trend from the Seebeck coefficient with respect to pressure. The maximum value of power factor is 227.15 mWm^{-1} K^{-2} obtained at −1 GPa pressure for n-type doping, and its value is increased up to 154.40 mWm^{-1} K^{-2} with positive pressure for n-type doping which is much larger from pure material as given in Table 4.

Figure 10c illustrates the evaluation of the thermoelectric figure of merit (ZT), which considers the combined effect of all thermoelectric parameters and relaxation time. ZT and external pressure follow similar trends, as ZT is directly dependent on the

power factor. The maximum ZT value of 0.82 for n-type doping is reached at a pressure of −1 GPa, which is 39% higher than that of pure material.

It is proposed that hydrostatic pressure conditions can be useful to improve the thermoelectric performance of the material in a practical application, as $BiTe_2$ -based materials have found highly challenged features [57]. Two *n*- and *p*-type legs of thermoelectric material with good thermoelectric performance make up a thermoelectric module.

5 Conclusions

The theoretical investigation of structural, electronic and thermoelectric properties MoSSe Janus monolayer is systematically studied without and with pressure. Under different pressure, the bandgap of the material can be tuned and converts the material from direct to indirect semiconductor. Absence of negative frequency in phonon dispersion modes indicates the thermodynamical stability of pure monolayer and monolayer under applied pressure. Seebeck coefficient for n- and p-type doping is 2.52 and 2.56 mV/K, at room temperature, suggesting that the material behaves as a p-type semiconductor. ZT is 0.67 for p-type doping which is higher than 0.59 for n-type doping without any external pressure. Seebeck coefficient for n-type doping is firstly increased from 2520 to 2770 μVK^{-1} with positive pressure and after that decreases whereas, it is continuously decreasing with negative pressure. With the external pressure, the value of ZT is enhanced from 0.67 to 0.78 at −1 GPa for p-type carriers, whereas, for n-type charge carriers, the value of ZT increases up to 0.73 at + 3 GPa and up to 0.82 at −1GPa from 0.59, at room temperature.

Therefore, the value of ZT for n- and p-type material can be enhanced under positive and negative value of external pressure, respectively. Hence, based upon the above results, the MoSSe Janus monolayer plays the important role in thermoelectric power generators, sensors and performance wearables.

Abstract

A Typhoon is a severe weather system that can cause significant damage to human property. Accurate typhoon intensity estimation is vital for timely risk warning and hazard assessment. In this study, we proposed a novel neural network-based model to estimate the intensity of typhoons more accurately than the traditional methods. The proposed model takes inputs from three traditional methods: the automated rotational center hurricane eye retrieval algorithm, the advanced Dvorak technique, and the satellite Consensus technique. The model is trained using 147 typhoon cases, including tropical storms that formed over the West Pacific basin during 2017–24, and validated using 15 cases. The results show that the error percentage of the proposed method concerning Best track data provided by the Regional Specialized Meteorological Center (RSMC) for the West Pacific Basin is 6.806%, and the root mean square error is 5.42, which is lower than other methods. R-squared also indicates that our proposed methods show better predictive capability than other methods. As a result, there is a good chance that the proposed method for storm intensity estimation will provide a more accurate estimation than the other traditional methods.

1. Introduction

Today, Typhoons are becoming increasingly frequent worldwide due to global warming [1]. Characterized by strong winds and rainstorms, Typhoons have devastating impacts on human activity. Predicting Typhoons efficiently is challenging due to their complex physical processes. Numerous studies have been conducted on the axisymmetric structures and dynamic mechanisms of Typhoons [2, 3]. In recent years, machine learning and deep learning have significantly advanced Typhoon research, including forecasting, tracking, intensity estimation, classification, and disaster impact prediction. Currently, these fields are investigated separately, limiting the potential of data analysis tools to enhance our understanding of Typhoons. Future research should focus on incorporating more prior knowledge and gathering extensive multi-source data to improve the accuracy of Typhoon modeling.

In the field of Typhoon modeling, the research on Typhoon classification precedes the estimation of Typhoon intensity. Extensive research on Typhoon classification utilizing machine learning and deep learning has provided substantial insights that enhance Typhoon intensity prediction.

Traditional methods necessitate extensive human intervention and the manual engineering of features to estimate typhoon intensity. Intensity is correlated with other attributes of typhoons, such as the radius of maximum wind [4, 5]. Over the past three decades, the Dvorak Technique (DT) has been the most widely employed satellite image-based pattern recognition method for estimating Typhoon intensity [6]. The DT establishes a relationship between organized cloud patterns and Typhoon intensity, saving tens of thousands of lives. However, it is a subjective method, with its accuracy heavily influenced by the experience of the experts applying it. To address these limitations, several revisions have been developed, including the Objective Dvorak Technique (ODT) [7] and the Advanced Dvorak Technique (ADT) [8]. All versions of the DT technique rely on cloud features and pattern recognition to estimate Typhoon intensity [8]. Despite this, the handcrafted features inherent to these methods are often subjectively biased and may not fully capture the relationship between cloud patterns and Typhoon intensity. In 2010, [9] proposed the Automated Rotational Center Hurricane Eye

Retrieval (ARCHER) algorithm, which determines the center of rotation by analyzing spirally oriented brightness temperature gradients in Typhoon banding patterns and the gradients along the ring-shaped edge of a potential eye. The Advanced Microwave Sounding Unit (AMSU) technique, described by [10], employs temperature anomaly profiles associated with the Typhoon warm core to estimate intensity. The Satellite Consensus (SATCON) technique, as discussed by [11–13], combines estimates from various methods, including the Advanced Dvorak Technique (ADT) and AMSU, to provide state-of-the-art intensity estimations. Those traditional techniques require systematic meteorological knowledge and cannot easily adapt to diversified data.

In recent years, the application of convolutional neural networks (CNNs) to various image processing tasks has emerged as a promising approach for improving the accuracy of Typhoon intensity estimation using neural network (NN)-based models.

Goodfellow *et al* (2016) [14] is a foundational textbook that comprehensively covers deep learning concepts, including neural networks, optimization, and generative models. It serves as a key resource for researchers and practitioners in machine learning and artificial intelligence. Pradhan *et al* (2017) [15] propose a deep CNN using satellite image classification for Typhoon intensity estimation using satellite images. This model achieves improved accuracy and lower root mean square error (RMSE) compared to traditional methods like the Dvorak and deviation-angle variance techniques. Chen *et al* (2018) [16] introduce a novel dataset for Typhoon intensity estimation and propose a CNN-based model incorporating domain knowledge. Combinido *et al* (2018) [17] demonstrate that a CNN-based approach can effectively estimate Typhoon intensity from infrared satellite images, achieving an RMSE of 13.23 knots (kts). The model learns critical features like cloud organization and eye formation, comparable to traditional feature-based techniques, highlighting the potential of deep learning in meteorology. Lee *et al* (2019) [18] demonstrate that multi-dimensional CNNs using multi-spectral satellite data improve intensity estimation. The optimized 2D-CNN model achieved an RMSE of 8.32 kts, outperforming previous methods and confirming the potential of deep learning in meteorological applications. Chen *et al* (2019) [19] present a deep-learning model using CNNs for intensity estimation from satellite imagery. The optimized and smoothed CNN model demonstrates superior accuracy compared to traditional methods, achieving an RMSE of 8.39 kts and showing promise for future operational applications. Higa *et al* (2021) [20] propose a deep learning model for Typhoon intensity classification by integrating meteorological domain knowledge. By utilizing VGG-16 with fisheye-preprocessed satellite images, the model achieved a higher classification accuracy of 76.8%, outperforming previous methods. The fisheye preprocessing enhanced key Typhoon features like the eye and cloud distribution, improving interpretability. Chen *et al* (2020) [21] introduce a novel tensor-based (TCNN) for intensity estimation using multispectral satellite images. By integrating tensor decomposition and deep learning, TCNN effectively captures typhoon structures, improving intensity categorization and wind speed estimation. The proposed models, C-TCNN and T-TCNN, outperform traditional and state-of-the-art methods in accuracy and efficiency. Experimental results confirm TCNN's potential for operational meteorological applications. Zhang *et al* (2021) [22] propose a novel deep learning approach, TCICENet, for intensity classification and estimation using infrared satellite images. The model consists of cascading CNN modules, achieving an RMSE of 8.60 kt and an MAE of 6.67 kt. Varalakshmi *et al* (2023) [23] proposed a deep learning model that combines CNN architectures for feature extraction and machine learning models for regression to predict the intensity of TCs. Griffin *et al* (2024) [24] present two machine-learning methods, D-MINT and D-PRINT, utilizing infrared and microwave imagery to predict short-term intensity changes in typhoons, demonstrating improved skill over traditional methods, particularly in the North Atlantic and western North Pacific regions. Raynaud *et al* (2024) [25] introduce a CNN based on the U-Net architecture for detecting Typhoon wind structures in high-resolution numerical weather prediction (NWP) models. The model outperforms traditional heuristic methods, achieving an average intersection-over-union metric of 0.8, particularly improving detection for weaker cyclones. Additionally, it generalizes well to different domains and higher-resolution data, demonstrating its potential for operational forecasting. Yadav *et al* (2024) [4] focus on estimating the radius of maximum wind (RMW) in typhoons, a crucial parameter for assessing cyclone intensity and predicting impacts on climate and ecosystems. Using machine learning methods, they introduce an ensemble model combining random forests, gradient boosting, and NNs, enhancing precision in RMW estimation over traditional techniques.

Furthermore, several challenges persist in Typhoon modeling. One significant issue is the severe imbalance in the number of different types of Typhoons observed in nature. Most satellite images capture medium and low-intensity Typhoons, with high-intensity Typhoons relatively rare. The intensity of Typhoons spans a wide range, from 30 knots to over 150 knots. Nevertheless, Typhoon intensity estimation accuracy remains inadequate, particularly for high-intensity Typhoons, which are critically important.

Motivated by the SATCON technique, they "improve upon estimates provided by the individual members and a straight average of those estimates, and are competitive with existing traditional approaches such as the Dvorak technique."

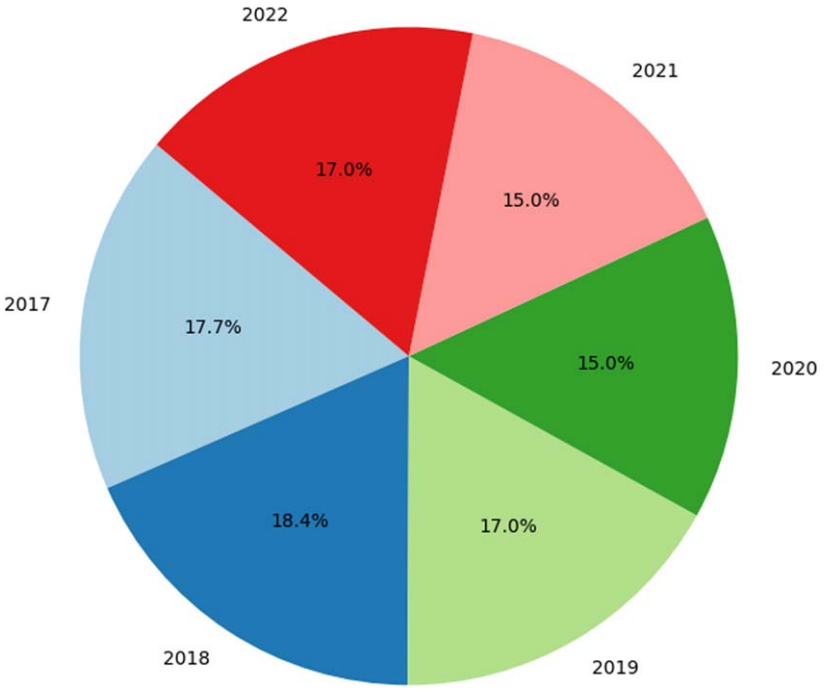

Figure 1. Representation of selected tropical storm for model training.

Using multiple techniques is crucial when single methods are not able to accurately estimate Typhoon intensity. We individually examine ADT, ARCHER, and SATCON, giving less accurate results. Using a neural network, we combine these outputs to minimize errors and maximize each method's strengths, resulting in more accurate and reliable Typhoon intensity estimates than traditional methods.

Our work aims to fill the current knowledge gap by accomplishing the following objectives:

- We propose a Neural Network model to estimate the Typhoon's Intensity.
- Comparing the accuracy of the proposed method with that of existing traditional methods (ARCHER, ADT, and SATCON) and one artificial approach (Artificial Intelligence-enhanced Dvorak Technique).

This paper is organized as follows: section 2 provides an overview of the data and research methodology, with a comprehensive discussion of the proposed method. Section 3 then compares this approach with alternative methods. Finally, section 4 concludes the paper and outlines directions for future research.

2. Data and method

2.1. Data

We collected information about each 6-hourly data point of the Typhoon's intensity from the three state-of-the-art intensity estimation models: ARCHER 'https://tropic.ssec.wisc.edu/real-time/archerOnline/cyclones/', ADT 'https://tropic.ssec.wisc.edu/misc/adt/info.html,' and SATCON 'https://tropic.ssec.wisc.edu/real-time/satcon/.' We gathered data from 162 typhoons, including tropical storms, using 147 (representation of selected cases according to yearly is shown in figure 1) for model training (table 1) and 15 (category representation of selected case is shown in figure 2) for validating (table 2) our proposed model.

The study primarily focused on the West Pacific Basin regions for training and validation. To ensure comprehensive data acquisition, the Best Track data has been collected from the official websites of the Regional Specialized Meteorological Center (RSMC) for the West Pacific Basin (https://www.jma.go.jp/jma/jma-eng/jma-center/rsmc-hp-pub-eg/RSMC_HP.htm) for 2017–2024.

We decided not to use satellite images in our study to estimate the intensity of Typhoons. Instead, we take the data from three advanced intensity estimation models: ARCHER, ADT, and SATCON. This decision was intentional, and we recognize that our approach depends on the information provided by these trusted models.

Table 1. In this study, the following typhoons were considered for training the model over the West Pacific Basin. PrM stands for pre-monsoon, PoM stands for post-monsoon, MSW stands for maximum sustained wind, and kts stands for knots.

2.2. Method

In this study, we develop a method to estimate the value of Typhoon intensity over the West Pacific basin using a machine-learning technique. We compared the results of the proposed method with the three other methods: ARCHER, ADT, and SATCON.

The brief descriptions of the current members in our model are as follows:

- **ARCHER** (**Automated Rotational Center Hurricane Eye Retrieval**): The ARCHER estimates Typhoon characteristics using the Advanced Technology Microwave Sounder (ATMS)-derived minimum sea level pressure (MSLP) anomaly, Typhoon eyewall vigor, and the inner core brightness temperature (Tb) gradient (maximum of channel 8 or 9) [26].
- **ADT** (**Advanced Dvorak technique**): The ADT is a computer method designed with great care to determine Typhoon features by studying infrared data from geostationary satellites. Operational Typhoon analysis and forecasting centers worldwide commonly use it to help determine Typhoon strength, especially in maritime areas where direct observations are impossible. The algorithm was originally developed to closely resemble the Dvorak approach, based on previous versions provided by [27]. In this conventional approach, a skilled analyst uses pattern-matching and classification techniques to estimate the characteristics of Typhoons based on satellite images. The ADT algorithm has gradually developed into a functional instrument, officially supported and upheld by NOAA/NESDIS. It has become a dependable source for delivering up-to-date, unbiased advice on Typhoon characteristics to operational Typhoon centers across the globe.
- **SATCON** (**Satellite Consensus**): The SATCON, developed by CIMSS, combines the ADT estimation acquired from Geostationary Satellites with other estimates collected during polar-orbiting satellite overpasses. This combination provides a complete assessment of Typhoon features worldwide, as outlined in research conducted by [11–13, 26, 28–30].

The input for our method is the results obtained from the three methods: ARCHER, ADT, and SATCON. The target for our method is the best track data provided by the RSMC over the West Pacific basin.

Here is the whole process of our method (flowchart presenting each step of the proposed method is shown in figure 3):

1. **Preprocessing:** The three sets of experimental values are first combined and normalized using the StandardScaler from scikit-learn [31] to ensure that all the input data are on a similar scale.

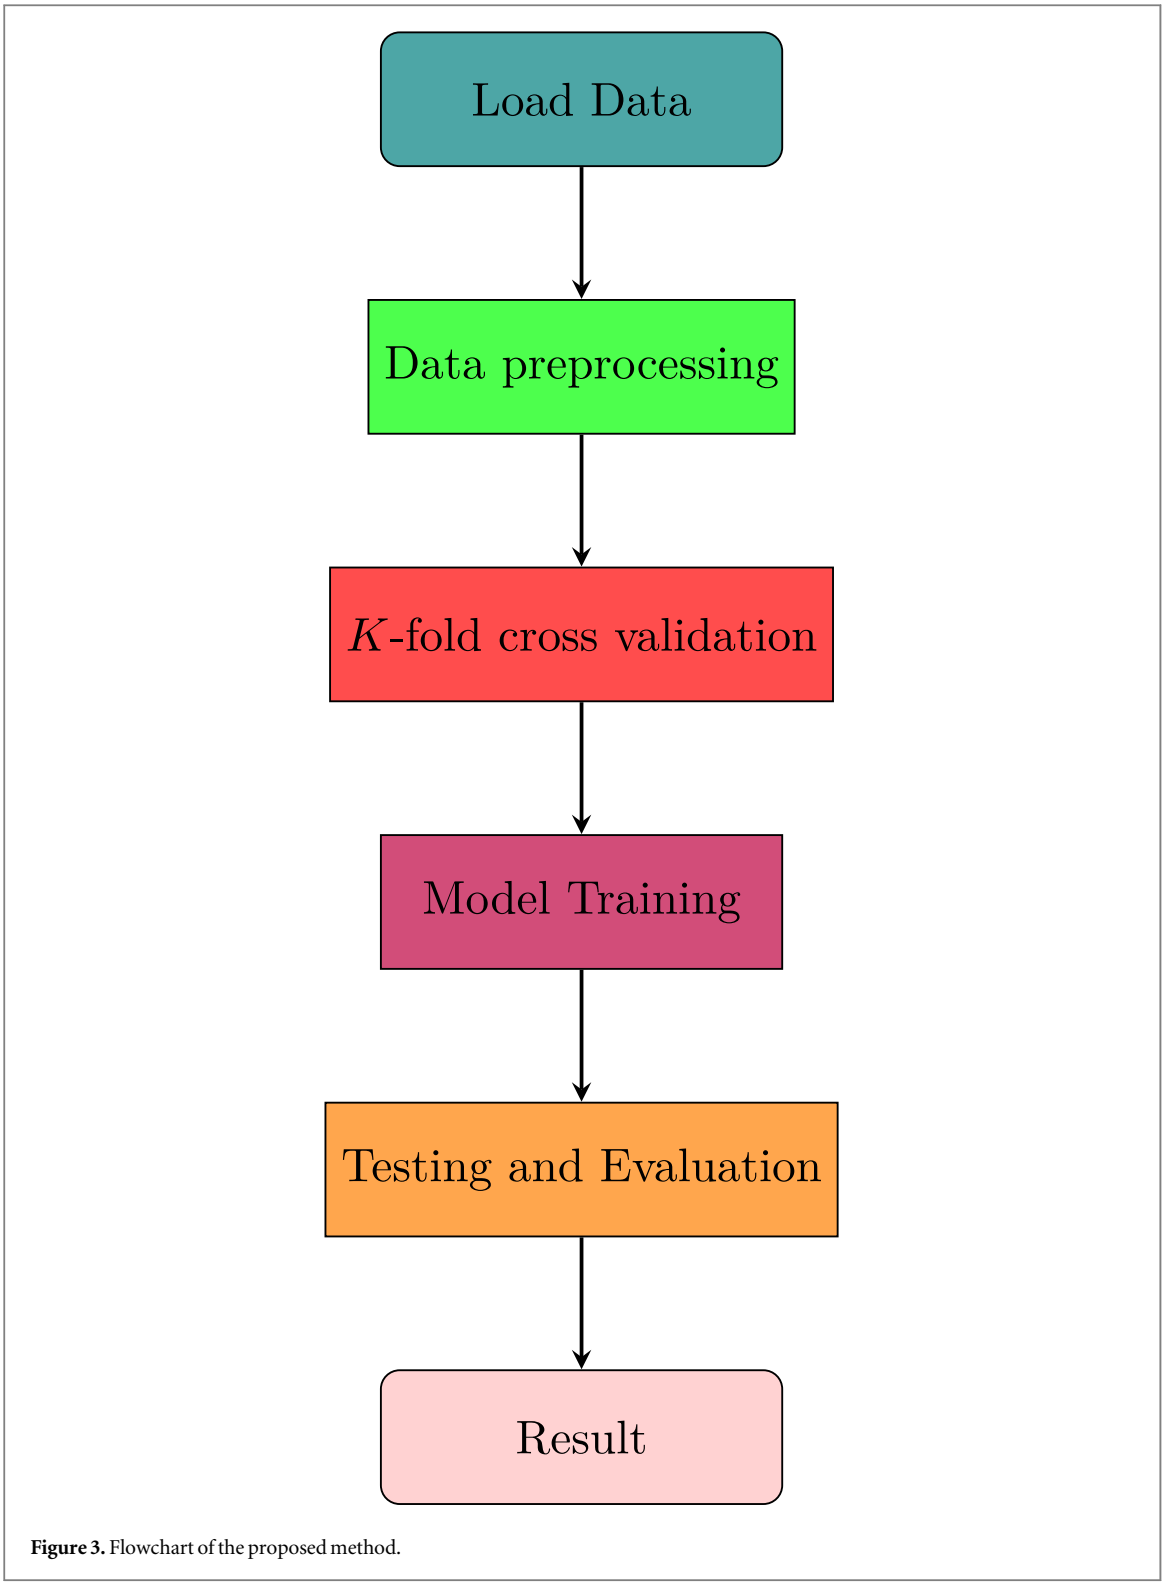

Figure 3. Flowchart of the proposed method.

2. ***k*-fold cross-validation:** *k*-fold cross-validation is a reliable method for assessing the performance of machine learning models [32]. It involves dividing the dataset into *k* equally sized folds, training the model on $k-1$ folds, and then evaluating it on the remaining fold. This procedure is repeated *k* times. [33, 34]. For example, we divided our data into five equal groups. To test a model, we use four groups for training and the remaining group to check how well the model performs We do this five times, using each group to check once.
   - Iteration 1: Use folds 2, 3, 4, and 5 to train the model, then test it on fold 1.
   - Iteration 2: Use folds 1, 3, 4, and 5 to train the model, then test it on fold 2.
   - Iteration 3: Use folds 1, 2, 4, and 5 to train the model, then test it on fold 3.

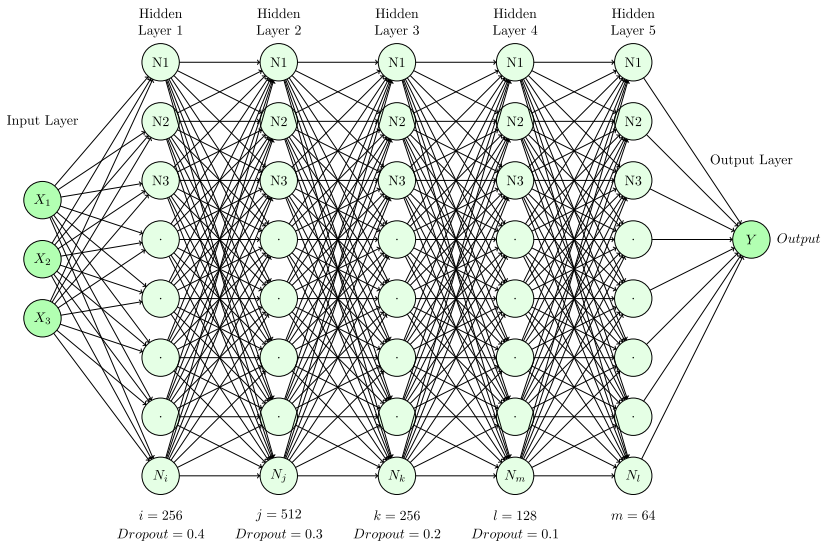

Figure 4. Architecture of the Proposed Neural Network.

Table 2. In this study, the following typhoons were considered for validating our proposed method over the West Pacific Basin.

S. No.	Typhoon Name	Season	Date	Maximum Wind Speed (knots (kts))	Classification
2024					
1	Ewiniar	PrM	25 - 30 May	70 kts	Typhoon
2	Gaemi	PrM	20 - 25 Jul.	90 kts	Very Strong Typhoon
3	Prapiron	PrM	21 - 23 Jul	55 kts	Severe Tropical Storm
2023					
1	Sanvu	PrM	20 Apr. - 21 Apr.	45 kts	Tropical Storm
2	Mawar	PrM	20 May - 31 May	115 kts	Violent Typhoon
3	Guchol	PrM	06 - 14 Jun.	80 kts	Typhoon
4	Talim	PrM	15 - 17 Jul.	60 kts	Severe Tropical Storm
5	Doksuri	PrM	21 - 28 Jul.	100 kts	Very Strong Typhoon
6	Lan	PoM	08 - 16 Aug.	90 kts	Very Strong Typhoon
7	Damrey	PoM	25 - 28 Aug.	50 kts	Severe Tropical Storm
8	Haikui	PoM	29 Aug. - 04 Sep.	85 kts	Typhoon
9	Kirogi	PoM	30 Aug. - 02 Sep.	45 kts	Tropical Storm
10	Yun-Yeung	PoM	05 - 08 Sep.	40 kts	Tropical Storm
11	Bolaven	PoM	07 - 14 Oct.	115 kts	Violent Typhoon
12	Sanba	PoM	18 - 19 Dec.	40 kts	Tropical Storm

- Iteration 4: Use folds 1, 2, 3, and 5 to train the model, then test it on fold 4.
- Iteration 5: Use folds 1, 2, 3, and 4 to train the model, then test it on fold 5.

3. **Neural Network Architecture:** The model is constructed via the Keras Sequential API (Application Programming Interface) [35]. The architecture consists of many layers, such as densely linked with LeakyReLU activation, batch normalization, and dropout layers, which help avoid overfitting. The model's architecture (figure 4) facilitates deep learning using five hidden layers of 256, 512, 256, 128, and 64 neurons.
4. **Training the Model:** The compiled model is trained using the Adam optimizer [36] with a reduced learning rate of 0.00001, optimizing the mean squared error loss function. To enhance the model's learning process, a substantial number of epochs, 10,000 in this case, are executed during the training process. The batch size is set to 128, and the training progress is tracked for analysis.
5. **Model Evaluation:** Following training, the model is evaluated using the trained neural network to predict the experimental values. The mean absolute percentage and root mean square errors are calculated to assess the model's accuracy and performance.

To assess the accuracy of our neural network model, we use four statistical techniques: t-test, error percentage, R-squared, and root mean square error. Using these techniques, we confidently assert that our neural network-based model achieves more efficiency and accuracy than the three traditional methods (ADT, ARCHER, and SATCON) and one artificial approach (Artificial Intelligence-enhanced Dvorak Technique).

The Artificial Intelligence-enhanced Dvorak Technique (AiDT) [37] represents a modern evolution of the traditional Dvorak methodology for estimating tropical cyclone intensity using geostationary satellite data. Traditional Dvorak methods relied on pattern recognition and empirical rules, but AiDT integrates machine learning to enhance objectivity and accuracy. This hybrid approach allows the extraction of intricate satellite features, such as cloud structures and thermal patterns, which are processed by advanced algorithms to improve intensity predictions.

t-test:

The t-test serves as a statistical tool to assess differences in mean values between two datasets, validating the effectiveness of our model against alternative methods. This involves comparing our model's performance metrics or predictions with existing models. By calculating the t-value and corresponding p-value, we determine the statistical significance of mean differences, establishing whether our method outperforms alternatives. This approach objectively evaluates the effectiveness and reliability of our proposed model, providing empirical evidence that supports its accuracy in predicting the desired outcome.

Error Percentage:

Error percentage, also known as error rate or relative error, measures the relative difference between predicted and actual values. It quantifies how far off the model's predictions are from the ground truth. The error percentage can be calculated as follows:

$$\text{Error percentage} = \left(\frac{|\text{Predicted Value} - \text{Actual Value}|}{\text{Actual value}} \right) \times 100$$

A lower error percentage indicates a more accurate model, which signifies that the model's predictions are closer to the actual values.

Root Mean Square Error (RMSE):

RMSE is a widely used metric to assess the accuracy of regression models. It measures the average magnitude of the errors between predicted and actual values. The RMSE is calculated as follows:

$$\text{RMSE} = \sqrt{\frac{1}{n} \times \sum (\text{Predicted Value} - \text{Actual Value})^2}$$

A lower RMSE indicates that the model's predictions are, on average, closer to the actual values. It represents the standard deviation of the model's errors.

R^2 (R-squared):

R^2 is a statistical measure representing the proportion of the variance for a dependent variable explained by an independent variable or variables in a regression model. It ranges from 0 to 1, where:

- $R^2 = 1$ indicates that the regression model predicts the dependent variable perfectly.
- $R^2 = 0$ indicates that the model does not explain any of the variability of the dependent variable around its mean.

3. Result and discussion

The NN-based model proposed for Typhoon intensity estimation has been assessed across fifteen cases. Table 2 presents information on selected Typhoons for validating, detailing their respective categories, seasons, and time periods.

3.1. Typhoon Ewiniar

Typhoon Ewiniar (2024) slammed into the Philippines in May 2024, bringing heavy rains, floods, and landslides. Thousands were displaced and sought shelter in evacuation centers. The typhoon also caused significant damage to homes, infrastructure, and agriculture

Figure 5 compares the performance of our proposed typhoon intensity estimation method to traditional approaches (ARCHER, ADT, and SATCON) and the artificial learning approach, i.e., AiDT using RSMC Tokyo's Best Track data. Table 3 summarizes the results of Typhoon Ewiniar.

For Typhoon Ewiniar, our method achieved a 4.43% error rate, outperforming ARCHER (13.97%), ADT (19.58%), SATCON (12.25%), and AiDT (15.93%). RMSE values are detailed in table 20. A t-test confirms our method's superior performance. Table 21 shows R^2 values of 0.92, 0.12, -0.26, 0.43, and 0.13 for the methods. An

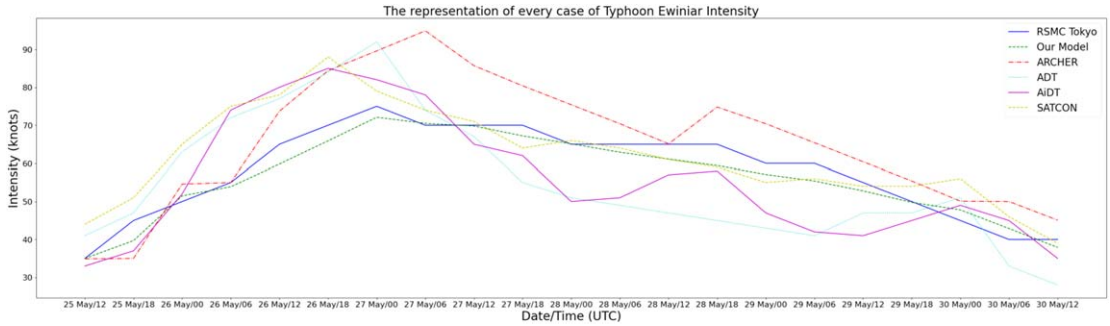

Figure 5. A graphic representation for each method's result for intensity of typhoon ewiniar.

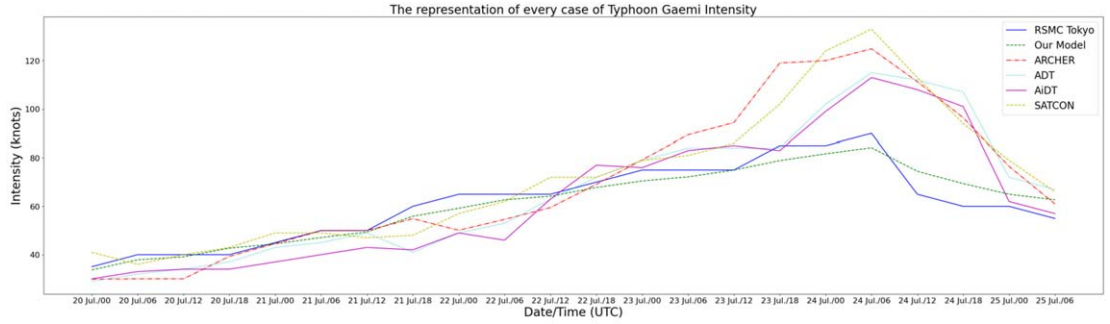

Figure 6. A graphic representation for each method's result for intensity of very strong typhoon gaemi.

R^2 of 0.92 indicates strong predictive accuracy, capturing 92% of data variability. Moderate fits are shown by R^2 values of 0.43, explaining 43% variability. However, the negative R^2 reveals poor performance, suggesting the model is less reliable than using the mean. Interpreting R^2 values in context is crucial for understanding model alignment with data patterns.

3.2. Very strong Typhoon gaemi

Very Strong Typhoon Gaemi (2024) was a powerful typhoon that affected East China, Taiwan, and the Philippines in late July 2024. It caused significant damage and casualties in these regions, including flooding, landslides, and power outages. The typhoon reached its peak intensity, with maximum sustained winds of 165 km/h. Figure 6 compares the performance of our proposed typhoon intensity estimation method with traditional methods: ARCHER, ADT, SATCON, and artificial learning approach, i.e., AiDT against RSMC Tokyo's Best Track data. Table 4 summarizes the quantitative results for Typhoon Gaemi.

For Very Strong Typhoon Gaemi, our method achieves an error rate of 5.89%, outperforming ARCHER (21.15%), ADT (19.43%), SATCON (19.36%) and AiDT (19.16%). The RMSE values are detailed in table 20. A t-test confirms our method's superiority over others.

The R^2 values (table 21) further highlight model performance: 0.91 (our method), -0.63 (ARCHER), -0.28 (ADT), 0.54 (SATCON), and −0.09 (AiDT). An R^2 of 0.91 indicates our method explains 91% of the data variation, representing a good fit. In contrast, a negative R^2 indicates poor performance, suggesting the model underperforms relative to using the mean for predictions. Evaluating R^2 values in context helps assess model alignment with data patterns.

3.3. Severe tropical storm prapiron

Severe Tropical Storm Prapiron (2024) formed in the South China Sea in July 2024. It made landfall in Hainan, China, and Vietnam, bringing heavy rain and strong winds. The storm caused flooding, landslides, and power outages in the affected areas. Figure 7 illustrates the comparative performance of the proposed intensity estimation method relative to conventional approaches (ARCHER, ADT, and SATCON) and also with the artificial approach (AiDT) using Best Track data from RSMC Tokyo. A quantitative summary of Severe Tropical Storm Prapiron is presented in table 5.

The proposed method demonstrates an error rate of 7.82%, outperforming ARCHER (23.55%), ADT (26.85%), SATCON (23.17%), and AiDT (12.97%). RMSE values, detailed in table 20, further validate the

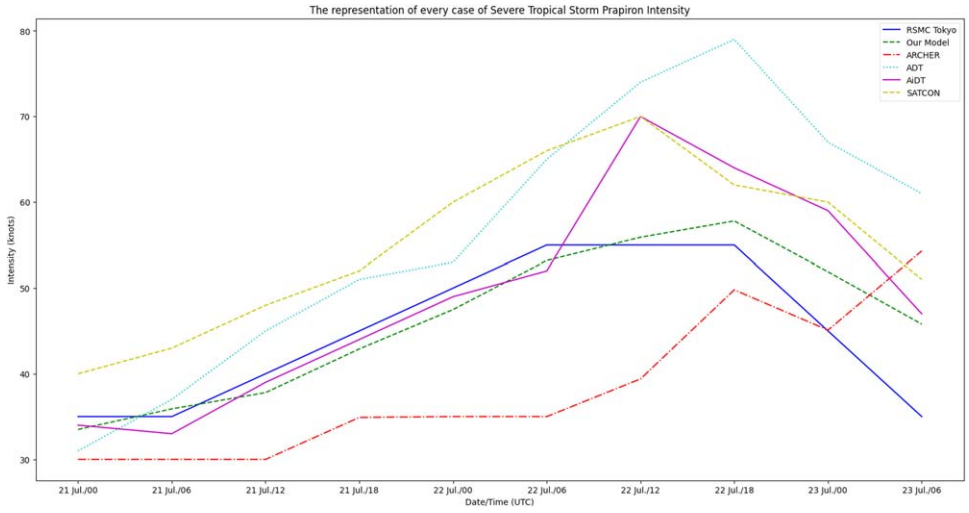

Figure 7. A graphic representation for each method's result for intensity of severe tropical storm prapiron.

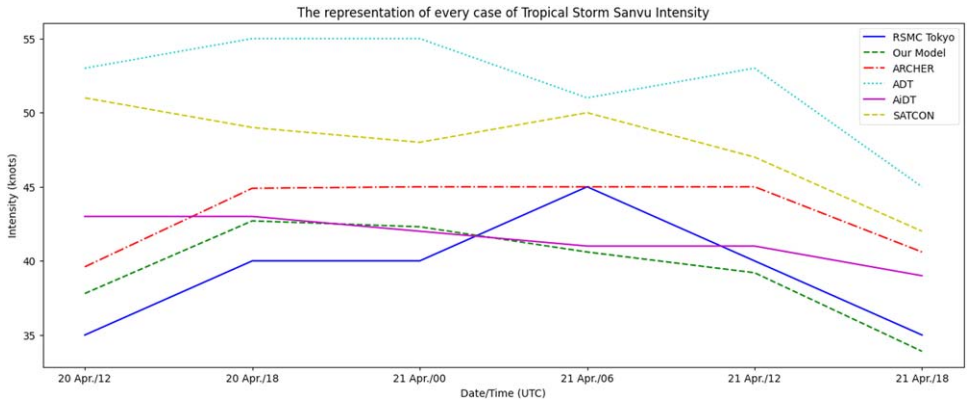

Figure 8. A graphic representation for each method's result for intensity of tropical storm sanvu.

improved accuracy. Statistical analysis via a t-test confirms the statistical significance of the proposed method's superior performance.

The R^2 values (table 21) quantify model efficacy, with the proposed method achieving 0.70, indicating that it accounts for 70% of the variability in the observed data. ARCHER, ADT, SATCON, and AiDT yield a negative R^2, reflecting the models' performance inferior to a baseline prediction using the mean. These results emphasize the better estimative capacity of our proposed method and its alignment with the observed data patterns.

3.4. Tropical storm Sanvu

Tropical Storm Sanvu was the first named storm of the 2023 Pacific typhoon season. It formed in April 2023 and remained a weak tropical storm throughout its lifespan. Sanvu did not make landfall and dissipated over open waters. Figure 8 illustrates the performance of our proposed method for estimating typhoon intensity in comparison to traditional approaches (ARCHER, ADT, and SATCON) and the artificial approach (AiDT) using Best Track data from RSMC Tokyo. Quantitative results for Tropical Storm Sanvu are summarized in table 6.

The proposed method achieves a percentage error of 5.90%, outperforming ARCHER (11.06%), ADT (33.47%), SATCON (22.80%), and AiDT (9.69%). Root Mean Square Error (RMSE) values are provided in table 20, and statistical analysis using a t-test confirms the significant improvement of the proposed method over the others. Table 21 presents the R^2 values for the models: 0.41 (proposed method), -0.78 (ARCHER0, -6.39 (SATCON), -14.23 (ADT), and -0.55 (AiDT). The R^2 value of 0.41 indicates that the proposed method explains 41% of the variance in the intensity data, representing a strong fit. In contrast, the negative R^2 value implies that it performs worse than a baseline prediction using the mean intensity, suggesting limitations in its applicability or alignment with the dataset. These results demonstrate the fitness of the proposed method in accurately modeling typhoon intensity.

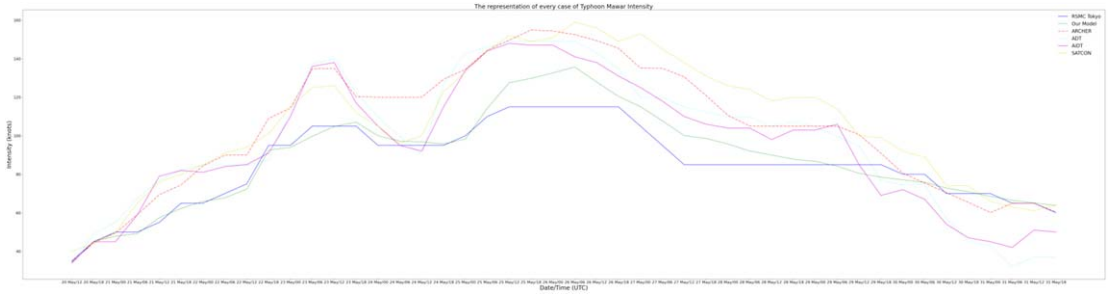

Figure 9. A graphic representation for each method's result for intensity of violent typhoon mawar.

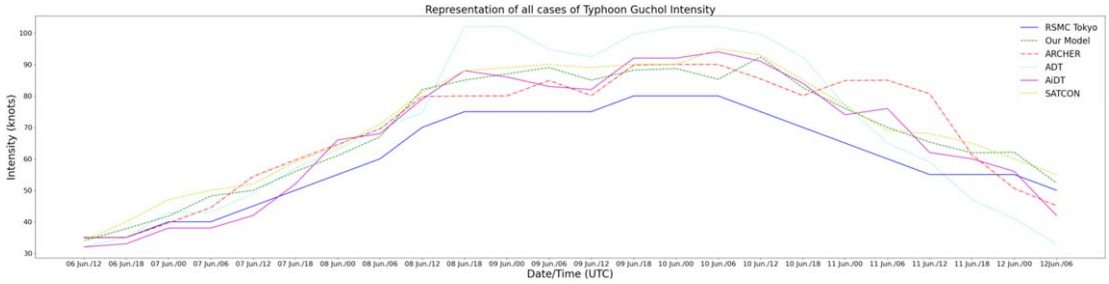

Figure 10. Graphically representation of all results of typhoon guchol.

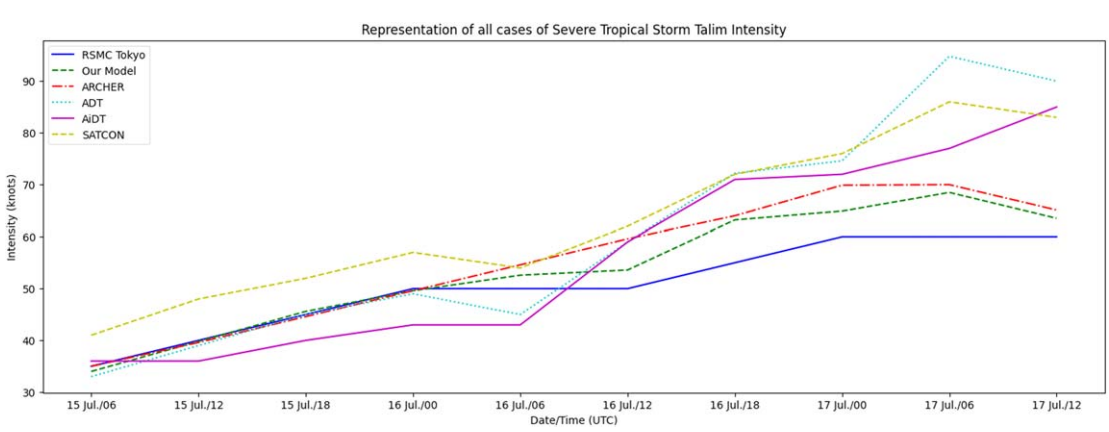

Figure 11. Graphically representation of all results of severe tropical storm talim.

3.5. Violent typhoon mawar

Violent Typhoon Mawar (2023) was one of the strongest Northern Hemisphere tropical storms on record in May and the strongest worldwide in 2023. It caused significant damage to Guam, including widespread power outages, downed trees, and coastal flooding. Figure 9 shows the comparative performance of our proposed typhoon intensity estimation method against established approaches (ARCHER, ADT, SATCON, and AiDT), benchmarked using Best Track data from RSMC Tokyo. A detailed summary of the results of Typhoon Mawar is provided in table 7.

The proposed method achieves a percentage error of 5.75%, demonstrating superior accuracy over ARCHER (18.79%), ADT (24.86%), SATCON (23.02%), and AiDT (20.17 %). Corresponding RMSE values, detailed in table 20, further emphasize this improvement. Statistical validation using a t-test confirms the proposed method's significant advantage over traditional techniques.

The R^2 values, presented in table 21, further distinguish model performance: 0.90 (proposed method), 0.05 (ARCHER), -0.21 (SATCON), 0.06 (ADT), and 0.31 (AiDT). A R^2 value of 0.90 suggests that the proposed method captures 90% of the variance in intensity, indicating a strong model fit. In contrast, ARCHER and SATCON exhibit moderate fits, explaining 5% of the variability, while SATCON's negative R^2 of -0.21 highlights

a failure to perform better than mean-based predictions. These findings underscore the efficacy of the proposed approach in capturing the underlying dynamics of typhoon intensity with higher precision and reliability.

3.6. Typhoon Guchol

Typhoon Guchol (Chedeng) in 2023 was a storm that stayed out at sea, never making landfall. It reached its peak intensity as a typhoon in the Philippine Sea but weakened before reaching the Philippines or Japan. While it brought some heavy rain to western Luzon in the Philippines due to the enhanced southwest monsoon, it caused minimal overall impact. Figure 10 shows how our proposed method for estimating Typhoon intensity is doing well as compared to other traditional methods: ARCHER, ADT, and SATCON concerning the Best track data provided by the RSMC Tokyo. Table 8 provides a quantitative summary of the results for Typhoon Guchol.

Based on Typhoon intensity data from RSMC Tokyo, with an intensity recorded at 60.62 knots, our proposed method shows an error rate of 12.97%. This is better than the error rates of other methodologies:

R^2		0.96	0.64	0.20	0.57	0.50					

ARCHER (14.46%), ADT (19.07%), and SATCON (16.74%). The RMSE values for this case are listed in table 20. Statistical analysis using a t-test indicates that our proposed method performs better than the other methods.

The R^2 values (table 21) of 0.61, 0.42, -0.09, and 0.42 provide insight into how well each model explains the variation in the data. A R^2 of 0.61 suggests a good fit, meaning the proposed method captures about 61% of the variability in the dependent variable. Similarly, a R^2 of 0.42 indicates a moderate fit, explaining 42% of the variability.

However, the negative R^2 value of -0.09 is concerning as it suggests the model performs worse than simply using the mean of the dependent variable. This could indicate that the model is not appropriate for the data or that there are fundamental issues with the model's ability to predict accurately. It's essential to interpret R^2 values in context, considering both positive and negative values to assess how well the models align with the underlying data patterns.

3.7. Severe Tropical Storm Talim

Severe Tropical Storm Talim (2023), also known as Tropical Storm Dodong in the Philippines, was a compact tropical cyclone that affected the Philippines, China, and Vietnam in July 2023. The fourth named storm of the 2023 Pacific typhoon season, Talim, originated from a weak monsoon depression east of Manila while moving towards Luzon [38].

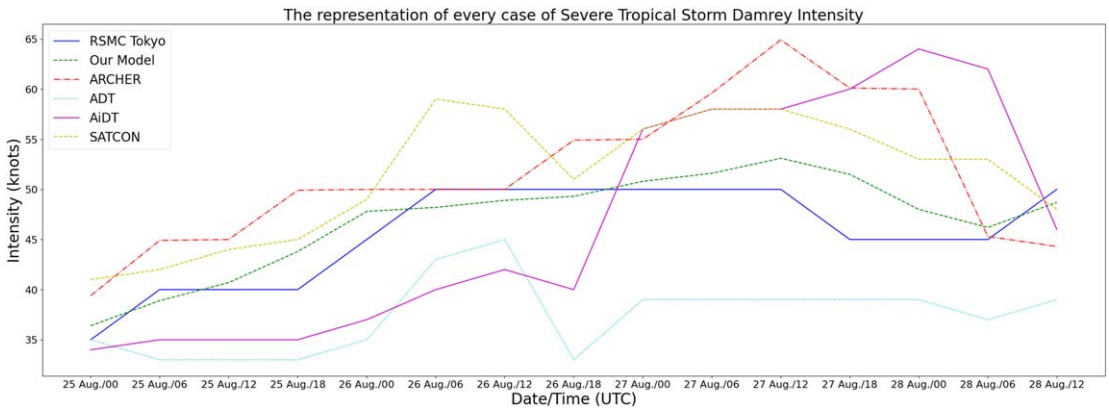

Figure 14. A graphic representation for each method's result for intensity of severe tropical storm damrey.

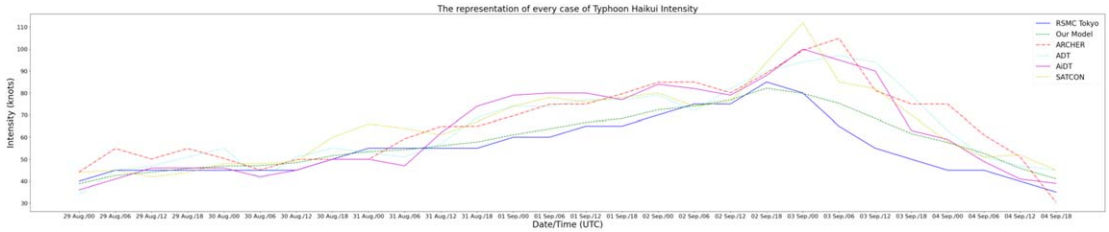

Figure 15. A graphic representation for each method's result for intensity of typhoon haikui.

The storm tracked westward near the northern edge of Luzon before emerging off the coast of Ilocos Norte. Favorable conditions allowed Talim to intensify rapidly into a Severe Tropical Storm rapidly. It maintained this intensity until shortly before landfall near Zhanjiang, Guangdong, China, on July 17th. Talim then quickly weakened and dissipated early on July 18th. Figure 11 shows how our proposed method for estimating Typhoon intensity is doing well compared to other traditional methods: ARCHER, ADT, and SATCON concerning the Best track data provided by the RSMC Tokyo. Table 9 provides a quantitative summary of Severe Tropical Storm Talim results.

Based on Typhoon intensity data from RSMC Tokyo, with an intensity recorded at 58 knots, our proposed method shows an error rate of 6.09%. This is better than the error rates of other methodologies: ARCHER (8.91%), ADT (20.18%), SATCON (23.79%), and AiDT (12.38%). The RMSE values for this case are listed in table 20. Statistical analysis using a t-test indicates that our proposed method performs better than the other methods.

The R^2 values (table 21) of 0.70, 0.37, -3.06, -2.13, and -1.28 clearly show how well each model fits the data. A R^2 of 0.70 indicates that our proposed method explains 70% of the data variability, showing it captures the underlying patterns effectively. On the other hand, a R^2 of 0.37 suggests moderate performance, explaining 37% of the variability but leaving room for improvement.

The negative R^2 values (-3.06, -2.13, and -1.28) are concerning as they imply that these models perform worse than simply using the mean of the data to predict outcomes. This indicates serious issues with these models, suggesting they are unsuitable for accurately representing the relationships within the data. These findings highlight the importance of selecting models with positive R^2 values, as they better explain and predict the observed data variability.

3.8. Very strong Typhoon doksuri

Very Strong Typhoon Doksuri, also known as Super Typhoon Egay in the Philippines. It packed a powerful punch, causing serious trouble in several places. The Philippines bore the brunt with heavy rains, floods, and strong winds, while Taiwan and China also experienced damage from fallen trees, power outages, and landslides. Figure 12 shows how our proposed method for estimating Typhoon intensity is doing well as compared to other traditional methods: ARCHER, ADT, SATCON, and AiDT concerning the Best track data provided by the RSMC Tokyo. Table 10 provides a quantitative summary of Very Strong Typhoon Doksuri results.

Based on Typhoon intensity data from RSMC Tokyo, with an intensity recorded at 72.03 knots, our proposed method shows an error rate of 13.59%. This is better than the error rates of other methodologies: ARCHER (20.29%),

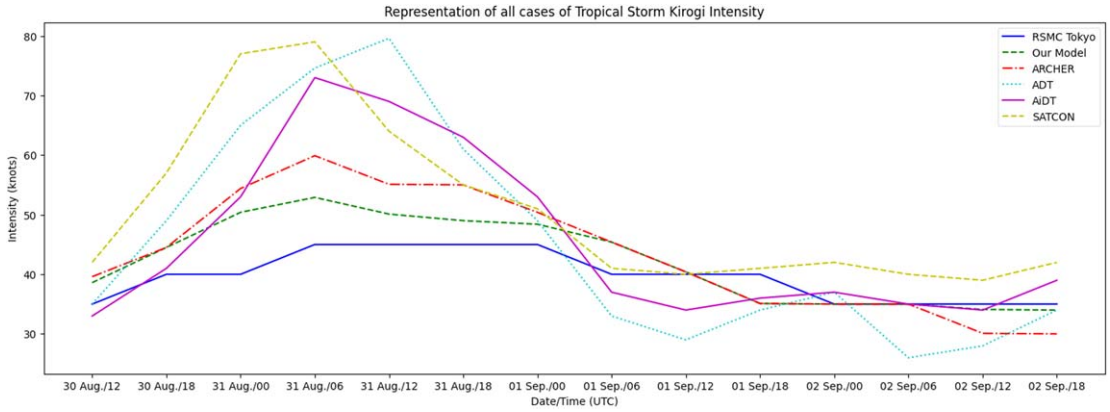

Figure 16. Graphically representation of all results of Tropical Storm Kirogi.

R^2		-0.39	-2.60	-14.60	-14.10	-7.97					

ADT (22.79%), SATCON(15.77%), and AiDT (17.77%). The RMSE values for this case are listed in table 20. Statistical analysis using a t-test indicates that our proposed method performs better than the other methods.

The R^2 values (table 21) of 0.53, 0.20, -0.10, 0.38, and 0.41 show different levels of how well the models explain the data. A R^2 of 0.53 means that our proposed method does a decent job, explaining 53% of the variability in the data. A R^2 of 0.41 and 0.38 is similar but weaker, explaining 41% and 38% of the variability.

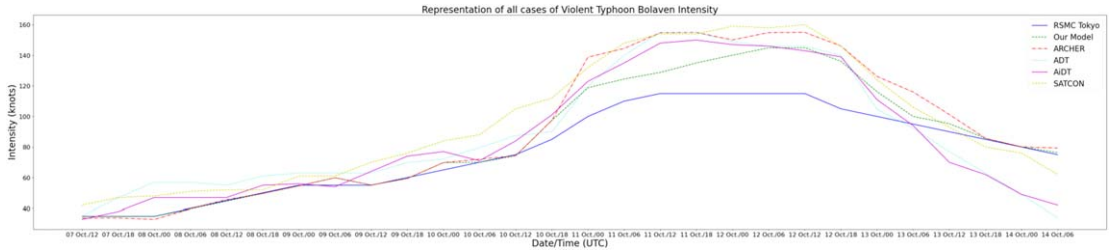

Figure 18. Graphically representation of all results of Violent Typhoon Bolaven.

R^2		0.43	-0.52	-5.04	-0.06	-0.24					

On the other hand, a R^2 of 0.20 means the model only explains 20% of the data, indicating it doesn't capture much of the underlying trend. The R^2 of -0.10 is especially bad, suggesting the model performs worse than just using the data average, indicating it is not a good fit at all.

3.9. Very strong typhoon lan

Very Strong Typhoon Lan (2023) was a powerful tropical cyclone that struck central Japan in mid-August 2023. It caused significant damage and disruption, including flooding, landslides, and power outages. The typhoon reached its peak intensity as a typhoon with sustained winds of 90 kts. Figure 13 compares the performance of the proposed typhoon intensity estimation method with ARCHER, ADT, SATCON, and AiDT, using Best Track data from RSMC Tokyo. Table 11 summarizes Typhoon Lan results.

The proposed method achieves a 3.95% error, outperforming ARCHER (11.5%), ADT (20.6%), SATCON (12.2%), and AiDT (14.4%). Table 20 highlights lower RMSE values, confirming its accuracy. A t-test statistically validates its significant improvement over other methods. Table 21 presents R^2 values: 0.96 (proposed method),

0.64 (ARCHER), 0.57 (SATCON), 0.20 (ADT), and 0.50 (AiDT). The proposed method, with 0.96 R^2, explains 96% of intensity variance, indicating a strong fit. In contrast, ARCHER, ADT, AiDT, and SATCON show weak fits and poor performance. These results emphasize the proposed method's superior precision and reliability in modeling typhoon intensity.

3.10. Severe tropical storm damrey

Severe Tropical Storm Damrey (2023) formed in the western Pacific Ocean in August 2023. It intensified into a Severe Tropical Storm before weakening again. Damrey did not make landfall and dissipated over open waters. Figure 14 compares the performance of the proposed typhoon intensity estimation method with ARCHER, ADT, SATCON, and AiDT, using Best Track data from RSMC Tokyo. Table 12 summarizes Severe Tropical Storm Damrey results.

The proposed method achieves a 4.58% error, outperforming ARCHER (14.72%), ADT (17.67%), SATCON (13.16%), and AiDT (18.63%). Table 20 highlights lower RMSE values, confirming its accuracy. A t-test statistically validates its significant improvement over other methods. Table 21 presents R^2 values: 0.71 (proposed method), -2.02 (ARCHER), -0.92 (SATCON), -2.58 (ADT), and -3.24 (AiDT). The proposed method, with 0.71 R^2, explains 71% of intensity variance, indicating a strong fit. In contrast, ARCHER, ADT, AiDT, and SATCON show weak fits and poor performance. These results emphasize the proposed method's superior precision and reliability in modeling typhoon intensity.

3.11. Typhoon haikui

Typhoon Haikui (2023) was a significant typhoon that impacted Taiwan and mainland China in September 2023. It brought strong winds, heavy rain, and flooding to both regions. The typhoon caused widespread damage, including power outages, downed trees, and landslides. Figure 15 compares the performance of our proposed typhoon intensity estimation method with ARCHER, ADT, SATCON, and AiDT, using Best Track data from RSMC Tokyo. Results for Typhoon Haikui are summarized in table 13.

The proposed method achieves a percentage error of 7.50%, outperforming ARCHER (21.20%), ADT (19.21%), SATCON (18.16%), and AiDT (16.52%). RMSE values (table 20) confirm this accuracy improvement. A t-test validates the statistical significance of the proposed method's advantage over traditional approaches.

R^2 values (table 21) highlight model performance: 0.82 (proposed method), -0.32 (ARCHER), 0.01 (SATCON), -0.17 (ADT), and -0.05 (AiDT). An R^2 of 0.82 indicates the proposed method explains 82% of intensity variance, showing a strong fit. In contrast, SATCON explains only 1%, and ARCHER, ADT, and AiDT show negative R^2, reflecting poor performance compared to mean-based predictions. These results emphasize the proposed method's precision and reliability in modeling typhoon intensity.

3.12. Tropical Strom Kirogi

Tropical Storm Kirogi (2023) formed far east of Guam in the West Pacific Ocean and moved north but remained over water, never making landfall. It reached peak intensity on August 30th with winds of 45 knots before dissipating on September 2*nd*. Figure 16 shows the estimated Typhoon intensity calculated by the proposed method; traditional methodologies like ARCHER, ADT, SATCON, and Best Track data from RSMC Tokyo. Table 14 provides a quantitative summary of the results of Tropical Storm Kirogi.

When evaluating the mean error based on Typhoon intensity data from RSMC, where the intensity is recorded at 39.6 knots, our proposed method shows an error rate of 8.89%. This is better than the error rates of other methodologies: ARCHER (14.6%), ADT (27.0%), SATCON (27.5%), and AiDT (19.03%). The RMSE values for this case are listed in table 20. Statistical analysis using a t-test indicates that our proposed method performs better than the other methods.

3.13. Tropical storm Yun-Yeung

Tropical Storm Yun-Yeung, also known as Tropical Storm Ineng in the Philippines, was a weak tropical storm that affected Japan in early September 2023. It brought heavy rainfall and strong winds to parts of Japan, leading to localized flooding and landslides. Figure 17 illustrates a performance comparison between the proposed typhoon intensity estimation method and existing approaches: ARCHER, ADT, SATCON, and AiDT—using Best Track data from RSMC Tokyo. Key findings for Tropical Storm Yun-Yeung are outlined in table 15.

With a percentage error of 1.92%, the proposed method significantly outperforms ARCHER (2.69%), ADT (12.72%), SATCON (4.35%), and AiDT (5.64%). This improvement is further supported by RMSE values presented in table 20. Statistical analysis via a t-test confirms the proposed method's superior accuracy compared to traditional models. Table 21 reports R^2 values: 0.43 (proposed method), 0.03 (ARCHER), -0.06 (SATCON), -5.04 (ADT), and -0.24 (AiDT). An R^2 of 0.43 demonstrates the proposed method accounts for 43% of intensity variance, indicating a robust model fit. In contrast, ARCHER captures only 3%, while SATCON's

Sanba	2.54	5.13	28.88	26.38	14.46

negative R^2 of -00.06 reflects poor predictive capability. These results underline the proposed approach's effectiveness in capturing typhoon intensity dynamics with enhanced precision and reliability.

3.14. Violent typhoon bolaven

Bolaven is the powerful Typhoon that formed near the Federated States of Micronesia on October 6th in the Western Pacific Ocean. It moved northwest, impacting areas like Micronesia and the Northern Mariana Islands with heavy rain and strong winds. It is absorbed by another weather system, with remnants bringing rain and wind to parts of Alaska and British Columbia. Figure 18 shows how our proposed method for estimating Typhoon intensity is doing well compared to other traditional methods: ARCHER, ADT, and SATCON concerning the Best track data provided by the RSMC Tokyo. Table 16 provides a quantitative summary of the results for Violent Typhoon Bolaven.

Based on Typhoon intensity data from RSMC Tokyo, with an intensity recorded at 87 knots, our proposed method shows an error rate of 8.27%. This is better than the error rates of other methodologies: ARCHER (14.18%), ADT (26.62%), SATCON (24.86%), and AiDT (19.10%). The RMSE values for this case are listed in table 20. Statistical analysis using a t-test indicates that our proposed method performs better than the other methods.

Our proposed method has the value of R^2 0.76 (table 21), indicating that our proposed method captures most of the data's underlying patterns. On the other hand, other methods have values of 0.36, 0.21, 0.18, and 0.45, which show weaker fits. These lower R^2 values suggest that these models do not capture much of the variability in the data, indicating a need for improvement or alternative approaches to explain the data better.

Table 20. Detail of root mean square error of all cases.

3.15. Tropical Storm Sanba

Tropical Storm Sanba (2023) was a weak tropical storm that formed in the South China Sea in October 2023. It made landfall in Hainan, China, and brought heavy rainfall to the region. Sanba caused some flooding and disruptions, but its impact was relatively minor compared to other storms in the 2023 Pacific typhoon season. Figure 19 compares the proposed typhoon intensity estimation method with ARCHER, ADT, SATCON, and AiDT, based on Best Track data from RSMC Tokyo. Results for Tropical Storm Sanba are summarized in table 17.

The proposed method shows a percentage error of 2.54%, much lower than ARCHER (5.13%), ADT (28.88%), SATCON (26.38%), and AiDT (14.46%). RMSE values in table 20 confirm its improved accuracy, supported by a t-test analysis.

R^2 values in table 21 show strong performance: 0.54 for the proposed method, compared to -2.38 (ARCHER), -35.25 (SATCON), -50.24 (ADT), and -10.74 (AiDT). An R^2 of 0.54 means the proposed method explains 54% of intensity variation, while other methods show negative R^2 shows poor performance. These results highlight the method's precision and reliability in estimating typhoon intensity.

4. Conclusion

In this paper, we develop a NN-based model to estimate Typhoon intensity, primarily focusing on the West Pacific Ocean. Our proposed method performs better than traditional methodologies, including ARCHER, ADT, and SATCON, as well as the artificial intelligence-based approach AiDT, achieving more accurate estimations of typhoon intensity.

Additionally, we evaluate the performance (table 18) of our NN model against the recently introduced convolutional neural network (CNN) model by Yadav *et al* (2024) [4], and our approach achieves improved accuracy in estimating typhoon intensity.

We substantiate the effectiveness of our proposed method through four statistical tests: the t-test, error percentage, R-squared (R^2), and root mean square error (RMSE). These tests confirm the proposed method's reduced error percentage (as shown in table 19), lower RMSE (as detailed in table 20), R^2 (as shown in table 21) says our proposed method is a good fit and captures a substantial portion of the underlying variability in the data as compared to traditional individual methodologies, thereby validating its improved accuracy and reliability over existing methods.

The implications of our proposed method are significant when estimating various aspects of Typhoons, such as the radius of maximum winds and rapid intensification. These aspects are crucial for understanding the potential impact and behavior of TCs. Our proposed method's design and capabilities remain consistent across different applications, ensuring its robustness and adaptability. The only necessary adjustments in certain scenarios would involve updating the training data and output classifications to tailor the proposed method to specific Typhoon cases.

Accurate estimation of Typhoon intensity enhances our understanding of other Typhoon characteristics and plays a vital role in disaster preparedness and mitigation. By providing more reliable intensity estimates, our proposed method can help authorities and communities minimize the loss of life and property due to Typhoons.

Evolution of Microstructure, Mechanical Properties, and Tribological Behavior of AA2024/B_4C/Al_2O_3 Nanocomposites Fabricated by Multi-pass FSP

Md Saquib Bin Reyaz, Joginder Singh, Shallender Singh Bhati, Husain Mehdi, and Subhash Mishra

Submitted: 28 November 2024 / Revised: 23 February 2025 / Accepted: 8 March 2025

The objective of this study is to enhance the microstructure, mechanical properties, and tribological performance of a 6 mm-thick AA2024 alloy through the incorporation of B_4C and Al_2O_3 nanoparticles using multi-pass friction stir processing (MPFSP). The hybrid composites are fabricated using six FSP passes at a constant spindle speed of 800 rpm and a traverse speed of 35 mm/min. The research assessed composite performance using metallography, tensile testing, hardness evaluation, wear analysis, and fractographic studies. The microstructural findings indicated that MPFSP facilitated a consistent reduction in the mean grain size, decreasing from 7.18 ± 0.26 μm after the initial pass to 2.82 ± 0.06 μm following six passes. Electron backscatter diffraction results indicated that the fraction of high-angle grain boundaries rose from 76.49 to 95.21% after one to six passes. The ultimate tensile strength of the composite rises from 469 to 507 MPa, while the yield strength increases from 327 to 360 MPa. However, the elongation decreases from 6.4 to 3.1% when subjected to one pass to six passes. The hardness of the composite increases from 155 to 189 HV, while the wear depth decreases from 83 to 59 μm when subjected to one pass to six passes. The enhanced mechanical and tribological performance of the composite is linked to grain refinement, consistent reinforcement distribution, and improved grain boundary transformations following six passes of FSP. The tensile fractured surfaces exhibited dominant ductile mode failure and the worn surface morphology showed abrasive wear, oxidation, and delamination as the primary wear mechanism caused due to thermal effects and repeated sliding cycles.

1. Introduction

One of the key challenges in materials engineering today is developing materials that can meet the demands of sustainable transportation. With the push for lightweight yet durable materials, aluminum matrix composites (AMCs) have garnered significant attention due to their combination of a light matrix and high strength, derived from the inclusion of ceramic particles, such as silicon carbide (SiC), aluminum oxide (Al_2O_3), and boron carbide (B_4C) (Ref 1, 2). These ceramic particles enhance the properties of AMCs through mechanisms such as Orowan strengthening, pinning effect, and grain refinement, which collectively hinder dislocation movement and improve the overall strength and hardness of the composite (Ref 3). The AMCs have potential applications in structural components, especially where low weight and high strength are critical. Recently, research has also been directed toward using these composites as substitutes for aluminum molds in polymer injection processes, aiming to extend the molds' operational lifespan (Ref 4). Despite these benefits, AMCs possesses some challenges in achieving uniform reinforcement distribution, interfacial reactions between matrix and reinforcements, porosity, limited ductility, and high manufacturing costs. To address these issues, researchers have explored innovative approaches (Ref 5, 6). A concept gaining traction over the past decade is the selective reinforcement of the component surface. This approach allows for the strategic placement of reinforcing particles on specific surface regions that are subject to wear, abrasion, and fatigue, without compromising the overall structure. Rather than uniformly dispersing particles throughout the material, the particles are added to the surface after the component has been initially fabricated. This targeted reinforcement can provide durability where it is most needed, while keeping the production cost and weight lower compared to traditional, fully reinforced composites (Ref 7).

Friction stir processing (FSP) has emerged as a promising method for achieving this localized surface reinforcement (Ref 8). FSP allows micro- and nanoparticles to be incorporated into the surface layer of metal matrices, creating what are known as

surface metal-matrix composites. This process involves using a specially designed FSP tool to stir the particles into a shallow groove cut on the surface of the component, distributing the reinforcing particles in a concentrated area (Ref 9, 10). The FSP technique allows for the creation of a thin surface composite layer, typically several mm deep, on a wrought Al-alloy. This layer is subsequently hardened through heat treatment, providing enhanced durability specifically in high-wear areas (Ref 11). During FSP, the stirring action and localized heating can lead to the dissolution or coarsening of the strengthening precipitates within the Al-alloy matrix, which can reduce hardness in the stirred region. The tribological properties, such as wear and erosion, are influenced by several structural factors, including atomic-scale surface adhesion, nanoscale dislocations, and microscale grain size or secondary phase dimensions. As a result, materials with similar hardness values but different microstructures may exhibit vastly different tribological behaviors, with reinforced surfaces offering increased resistance to abrasion and wear. The unique properties conferred by FSP allow for the integration of hard particles, such as B_4C, as a final surface treatment for heat-treatable Al-alloys. This reinforcement enables the surface to achieve hardness levels comparable to hardened Al-alloys, along with the added benefit of improved wear resistance (Ref 4).

FSP significantly improves the mechanical and tribological properties of aluminum matrix materials when micro- or nanoparticles are incorporated into the matrix. Generally, the matrix materials used in these studies include wrought aluminum from non-heat-treatable series like 1xxx (Ref 12, 13) and 5xxx (Ref 14, 15), and heat-treatable series such as 6xxx and 7xxx (Ref 16-18), though typically in an annealed state. However, little research has applied FSP to hardened materials like 2xxx series, where loss of hardness is seen due to thermal cycles due to intense heat of FSP. Researchers are working to retain or improve its hardness properties by incorporating reinforcing particles utilizing multi-pass friction stir processing (MPFSP). However, achieving uniform dispersion of reinforcements within the matrix by utilizing MPFSP is challenging, as multiple passes can lead to particle clustering, agglomeration, and uneven distribution due to improper material flow and inadequate stirring. Moreover, optimizing the strengthening mechanism is crucial, which involves controlling the grain size, dislocation density, and particle-matrix interface. The repeated thermal cycles during multi-pass FSP may lead to grain coarsening, reducing the overall strengthening effect. The final target is to enhance the mechanical properties of the AMC by achieving a homogeneous reinforcement distribution, refined grain structure, and strong interfacial bonding, ultimately improving strength, hardness, and wear resistance. Ghanbari et al. (Ref 19) fabricated AA2024/SiC-based AMCs, where they find that three pass FSP resulted in a uniform distribution of reinforcement particles and improved hardness properties. A same aluminum surface composite has been fabricated through MPFSP by Acuna et al. (Ref 4). They found a microhardness value of the composite that reached the base metal value, while the wear rate was reduced to 24% after three passes of FSP. Similarly, an aluminum composite of AA2024/Al_2O_2 has been formed by employing three numbers of FSP passes, and they found enhanced ultimate tensile strength (UTS), ductility, and hardness due to the refined grains, homogenous reinforcement dispersion, and enhanced matrix-reinforcement missing due to the increased number of FSP passes (Ref 20). Rana et al. (Ref 21), who developed an AA7075/B4C surface composite through FSP. The composite demonstrated a remarkable 70% increase in hardness over the base Al-alloy in its annealed state (75-80 HV), achieving hardness values close to those of T651-hardened aluminum (175 HV) without undergoing any additional hardening treatments. The aluminum-based hybrid AA7475/B4C/Al_2O_2 composite is fabricated successfully through multi-pass FSP in another study (Ref 22). The authors conducted four passes at a constant tool rotational speed of 1300 rev/min and a feed rate of 45 mm/min, using equal proportions of reinforcements. This resulted in increases in UTS, ductility, and hardness strengths of 22.79%, 69.01%, and 38.12%, respectively. The research conducted by Pranavi et al. (Ref 23) involved the mechanical characteristics of the Al5059 by incorporating B4C and Al_2O_3 particles, whereby the components were incorporated according to a different weight percentage. The investigation elucidated the enhancement in the surface hardness and UTS due to the increase in weight percentage of reinforcements, but there was decrease in elongation properties corresponding to the proportional increase in weight percentage. Moreover, the coefficient of friction was decreased with an increase in the wt.% percentage of the reinforcement particles in the fabricated composites. The wear resistance of aluminum (AA6061) matrix is also improved by incorporating hybrid Al_2O_3 and ZrO_2 reinforcements (Ref 24). Giridharan et al. (Ref 25) enhanced tensile, hardness and fatigue properties of the dissimilar steel-copper welded joints by incorporating SiO_2, GNP and biochar reinforcements via FSP. The maximum ultimate tensile strength of 225 MPa and a fatigue strength of 168 MPa were achieved with 2 wt.% GNPs, whereas the addition of 2 wt.% biochar produced the second highest strength factor. The findings indicate that biochar nanoparticles obtained from natural sources could serve as a substitute for expensive nanofillers in metal joining, achieving over 85% effectiveness compared to the costly fillers for equivalent results. Sezhian et al. (Ref 26) also improved the copper weld properties by incorporating B4C particles to the weld region via FSP. The FSP is conducted using varying weight percentages of B4C particles (ranging from 1 to 4 wt.%), resulting in welds without defects at a spindle speed of 1100 rpm, a travel speed of 30 mm/min, a plunge depth of 0.25 mm, and an axial stress of 5 KN. The findings indicated that incorporating nanoparticles (3 wt.%) into the joint achieved a highest UTS of 203 MPa, hardness of 123 HV, and a fatigue strength of 159 MPa.

Although various research works have been performed by using different reinforcements to produce aluminum-based composites via FSP, an investigation into the fabrication of AA2024/B_4C/Al_2O_2 surface composites using MPFSP is lacking. The objective of this study is to fabricate, characterize, and examine the mechanical and tribological performance of AA2024/B_4C/Al_2O_2 surface composite via MPFSP. The in-depth microstructural analysis of the fabricated composites is carried out using OM, SEM-EDS, EBSD, and XRD that delves into the dissemination of reinforced particles, grain size, grain boundary transformations, and phase structure. Furthermore, the research evaluates the influence of MPFSP on UTS, elongation, and hardness, alongside the tribological behavior of the hybrid composites. The purpose of this work is to enhance the durability and performance of aluminum matrix (AA2024-T351) by incorporating hybrid reinforcements while maintaining a lightweight structure, making them suitable for sustainable applications ranging from automotive to aerospace industries.

2. Materials and Methods

This research employed AA2024-T351 as a substrate material with dimensions of 140 × 100 × 6 mm in thickness to produce nanocomposites via FSP. The chemical composition of the base metal was demonstrated in Table 1 analyzed through spectroscopic process. The mechanical characteristics of the substrate material, derived from experimental results, are presented in Table 2. Nanoparticles such as boron carbide (B_4C) and alumina (Al_2O_3) were employed as reinforcement materials for this study. The mean grain size (MGS) of the B_4C particles was approx 13.8 μm, while the MGS of Al_2O_3 particles was approx 10.1 μm.

Nanocomposites of AA2024/B_4C/Al_2O_3 was fabricated by employing multi-pass FSP on a modified vertical milling machine (Fig. 1a) with a designed clamping fixture setup. The purpose of the specific fixture is to hold the aluminum plate in a proper. The FSP process utilized a tool with the help of profiled pin (Fig. 1b). The tool pin profile featured a taper threaded shape with a 1 mm slot on each face. Before performing MPFSP, the capping pass was performed with pin less tool to compact the hybrid reinforcement particles. To incorporate these nanoparticles into the base alloy, a groove measuring 1 mm in width and 3 mm in depth was cut using wire EDM across the central section of the 140 mm length (Fig. 1c). After compaction, six number of passes were performed by profiled pin. The taper threaded pin tool enhances the mixing of material within the tool pin's area. The FSP tool, made from high-speed H13 steel, had a shoulder diameter of 20 mm and included a square pin measuring 4.5 mm in length and 6 mm in diameter. Table 3 reveals the FSP parameters utilizing the tool rotated at 1300 rpm, a traverse speed of 45 mm/min with a tilt angle of 0° with a plunge depth of 0.12 mm. The six number of FSP passes were performed to facilitate effective mixing of reinforcements with aluminum matrix. The range of FSP factors was determined through trial experiments, experimental conditions, and literature (Ref 20, 27, 28) to ensure the fabrication of defect-free hybrid AA2024/B4C/Al_2O_2 composites. The defect free hybrid AA2024/B_4C/Al_2O_3 surface composites fabricated with MPFSP are revealed in Fig. 1(d).

After the production of composites, tensile and hardness test specimens were prepared by wire electrical discharge machining. Tensile test samples were fabricated as per ASTM E8 standard (refer to Fig. 1e). Tensile tests were conducted using a UTM machine (Tinius Olsen H50KS) with a crosshead speed of 2 mm/min. Hardness measurements of the nanocomposite were performed across the mid cross section of the specimen with a 1 mm gap between two consecutive indents (Fig. 1f) using a microhardness tester (Omnitech YOM-2010), applying a 100-gf load for 10 seconds. Dry sliding wear experiments were conducted on a rotary tribometer using a test pin with dimensions of 4.5 × 4.5 × 10 mm^3 as per ASTM G99-05 standard. The experiments were conducted for a duration of 10 min at a tracking diameter of 45 mm, a vertical burden of 40 N, and a disk rotation speed of 850 rpm. The sliding distance was 1000 m. For metallographic analysis, samples were mirror finished using standard polishing techniques, and then etched in Keller's reagent for 10 to 15 seconds. Microstructural images were captured using an optical microscope (OM) and a scanning electron microscope (SEM). Elemental distribution in the stir zones of the processed samples was analyzed using energy-dispersive spectroscopy (EDS). Phase identification within the treated regions was performed through x-ray diffraction (XRD) using CuKα radiation, covering a 2θ range of 10-90°. Grain size was determined using the line intercept method via ImageJ software, providing detailed insights into the material's phase characteristics (Ref 29).

3. Results and Discussion

3.1 Microstructural Evolution

The properties and performance of base metals and fabricated hybrid surface composites are essential to comprehend through microstructural analysis. SEM and OM generate detailed images of reinforcement particle distribution, grain structure, and surface morphology. EDS is performed to identify the elemental composition, precipitate distribution (if any), and to ensure the dispersion of hybrid reinforcements within the material. Phase analysis is conducted via XRD technique to confirm the intermetallic phases formation, their peak intensity variation with respect to diffraction angle 2θ. EBSD is performed to determine the grain orientations and the grain boundary transformations as a result of FSP. These methods collectively reveal the microstructural evolution and reinforcement distribution, confirm homogeneity and detect defects, relate microstructure to mechanical properties (including strength, hardness, and ductility), optimize fabrication FSP variables, and improve material design and application suitability.

Figure 2(a) depicts the microstructure of the base alloy (AA2024-T351) showing elongated grains oriented along the rolling direction with significant intermetallic phases dispersed in the matrix. The elongated grains contain intermetallic precipitates (Al_2CuMg) both within the grains and along their boundaries. These precipitates, ranging from 3 to 10 μm in diameter, contribute significantly to the alloy's strength and ductility through precipitation hardening (Ref 30). Figure 2(b) illustrates the interface region of the composite, highlighting the stir zone (SZ), thermomechanically affected zone (TMAZ), and the heat-affected zone (HAZ). In MPFSP, the SZ develops from intense plastic deformation and localized thermal input, leading to fine-equiaxed grains through dynamic recrystallization (DRX), in which deformed grains are constantly replaced by new, strain-free grains. The TMAZ arises from a combination of thermal and mechanical effects, while the HAZ is created by the thermal cycles produced by the rotating tool, resulting in localized heating, thermal softening, and microstructural changes without considerable plastic deforma-

Tool plunge depth, mm	0.12

tion (Ref 31). Increasing the number of FSP passes significantly influences the grain morphology and reinforcement particle distributions in AA2024/B_4C/Al_2O_2 composites, specifically increasing the number of FSP passes from one pass to six passes refines and homogenizes the grain structures and results in fragmentation and uniform dispersion of particles across the SZ. Figure 2(c), corresponding to the first pass of FSP, the microstructure reveals the presence of non-fragmented B_4C and Al_2O_2 particles, indicating that the reinforcement particles are still in their original form without significant breakdown. The distribution of these particles is likely not uniform, as the FSP has just begun to plastically deform the material, and the stirring effect has not been sufficient to homogenize the matrix. Moving to Fig. 4(d), which shows the second pass of FSP, it is observe that the composite material undergoes further refinement. The stirring effect has increased, leading to a better

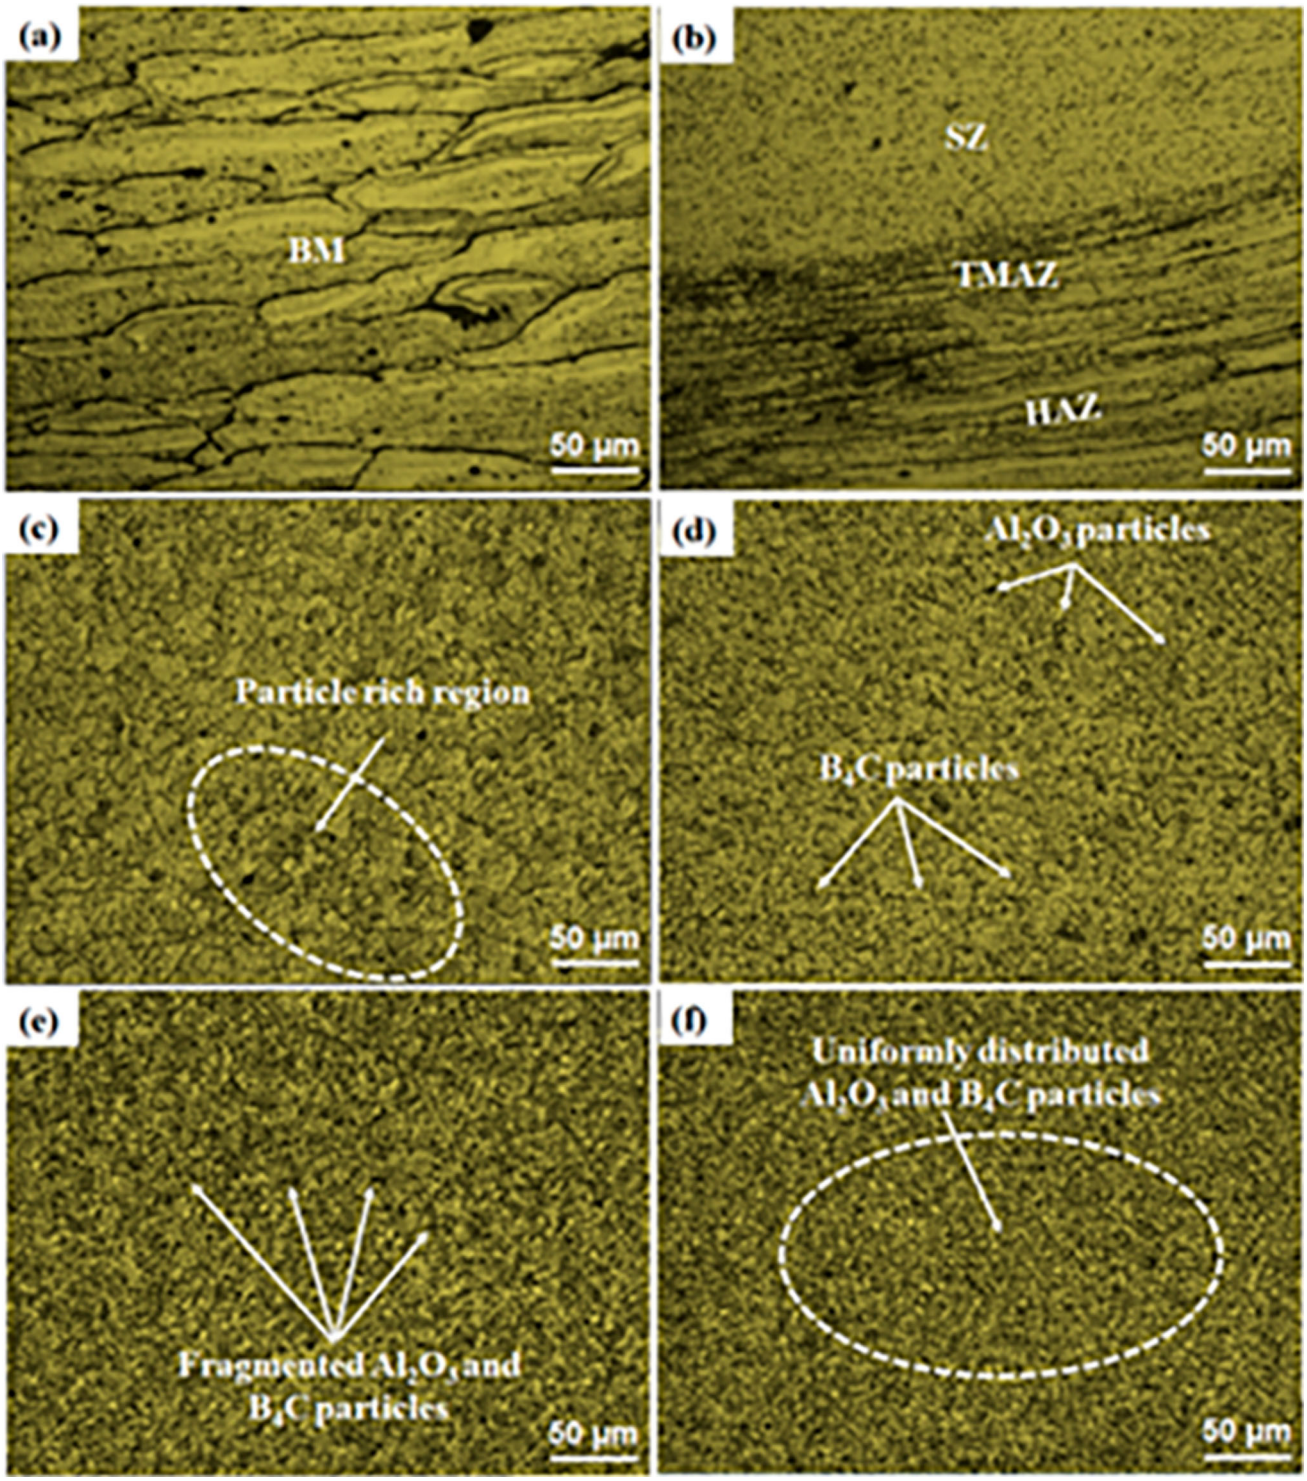

Fig. 2 OM images of the BM and AA2024/B_4C/Al_2O_3 nanocomposites for different FSP passes: (a) AA2024-T351, (b) Interface region, (c) 1 Pass, (d) 2 Pass, (e) 4 Pass, and (f) 6 Pass

mixing of the aluminum matrix and the hybrid reinforcement particles. However, compared to subsequent passes, the distribution may still not be entirely uniform, and some clusters or agglomerations of B_4C and Al_2O_3 is still persist. In Fig. 4(e), corresponding to the fourth pass of FSP, the microstructure shows significant improvement in terms of particle distribution. The stirring action from multiple passes enhances the breaking down of the reinforcement particles, resulting in a finer and more uniformly distributed particle phase. At this stage, fragmentation of B_4C and Al_2O_2 is more apparent, contributing to a more homogeneous microstructure. Figure 4(f), which depicts the microstructure after six passes of FSP, shows the most refined and uniform distribution of the B_4C and Al_2O_2 particles. The particles appear to be thoroughly dispersed throughout the matrix, with no signs of significant agglomeration. The repeated FSP passes have led to the uniform

fragmentation and incorporation of the reinforcement particles, suggesting that the material has achieved a more optimized and homogeneous microstructure for enhanced mechanical properties.

Figure 3 shows the grain size distribution the BM and hybrid composites for different FSP passes. The base AA2024-T351 alloy exhibited a mean grain size (MGS) of 65.64 ± 1.94 μm (Fig. 3a) and the MGS consistently decreases with an increasing FSP passes. The MGS starts at around 7.18 ± 0.26 μm after the first pass, around 4.46 ± 0.14 μm after the fourth pass (Fig. 3c), and reduces to 2.82 ± 0.06 μm after six passes (Fig. 3d). FSP induces severe plastic deformation and high temperatures in the material, leading to DRX. With each pass, new grains nucleate and grow, replacing the existing larger grains. Repeated passes enhance the recrystallization process, reducing the MGS (Ref 32). Each FSP pass applies mechanical deformation through the rotating tool, further breaking down the grain structure. The more deformation a material undergoes, the finer the grains tend to become as the original grains are fragmented and replaced by smaller grains (Ref 33). After six passes, the grain size seems to stabilize at about 2.8 μm signifying that the grains may attain an equilibrium size and further deformation does not dramatically diminish size. The stabilization of grain size after MPFSP is primarily governed by mechanisms such as dynamic recrystallization (DRX), Orowan strengthening, Zener pinning, and particle-stimulated nucleation (Ref 34). DRX plays a crucial role by continuously refining grains through strain-induced nucleation and growth, ultimately leading to a stable ultra-fine or nano-grained structure. Orowan strengthening occurs as dispersed second-phase particles hinder dislocation motion, maintaining grain size stability. Zener pinning further contributes by restricting grain boundary migration due to the presence of finely distributed precipitates, preventing excessive grain coarsening. Additionally, the particle-stimulated nucleation mechanism enhances grain refinement by promoting nucleation sites around dispersed particles, ensuring a balanced microstructure. The interplay of these mechanisms ensures that grain growth remains limited, leading to a stabilized fine-grained structure after multiple FSP passes.

Figure 4 illustrates the SEM images of the hybrid AA2024/B_4C/Al_2O_3 surface composites fabricated with six different passes. In Fig. 4(a), a single FSP pass notably reduces the coarse dendritic structure of the substrate alloy and transformed it into a fine equiaxed grains structure. During subsequent passes, material mixing improves, leading to a reduction in hybrid nanoparticle aggregation within the surface composite. The B_4C and Al_2O_3 nanoparticles undergo significant and progressive fragmentation following the second and fourth FSP passes (Fig. 4b and c), correlating with the decreased B_4C and Al_2O_3 nanoparticles aggregation observed as the FSP passes increase (Ref 35). The area percentage of B_4C increases with each FSP pass, directly linked to the grain refinement and precipitates fragmentation process. By the six passes, the grains become more homogenous and finer (Fig. 4d) due to DRX processes associated with the Zener–Holloman parameter (Ref 36). The MPFSP process consequently yields a refined and uniform microstructure, primarily driven by lower thermal input and accumulated strain. Compared to the one-pass FSP process, the four-pass FSP process demonstrates superior

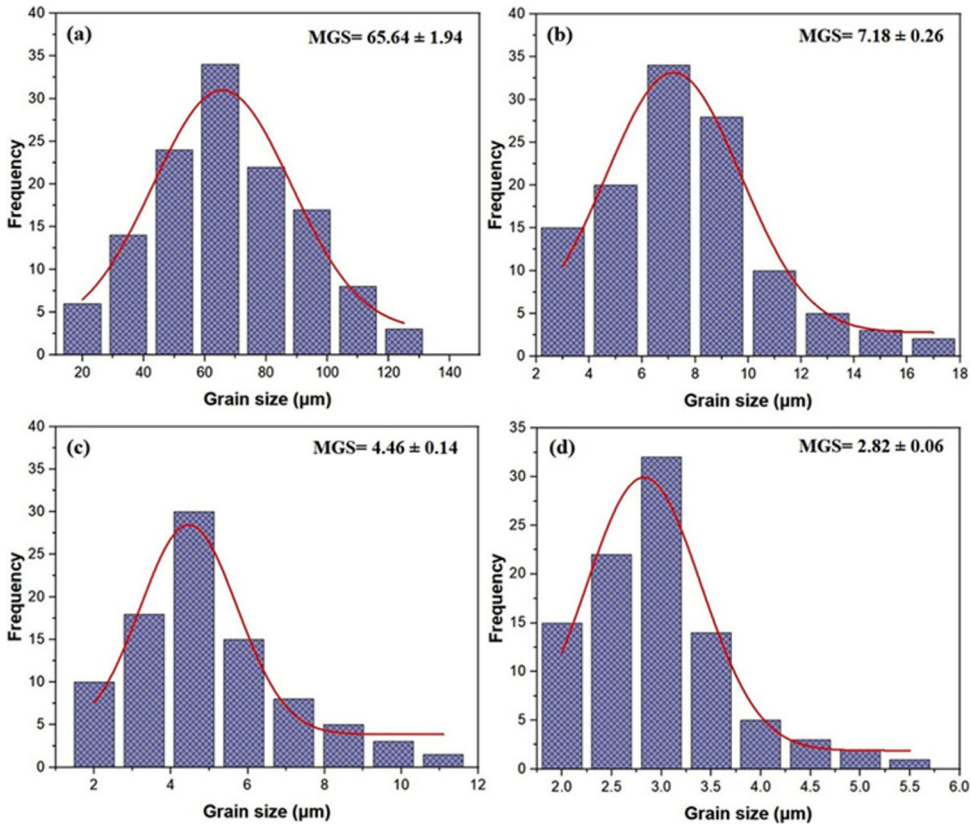

Fig. 3 Grain size distribution of the AA2024/B_4C/Al_2O_3 nanocomposites for different FSP passes: (a) BM, (b) 1 Pass, (c) 4 Pass, and (d) 6 Pass

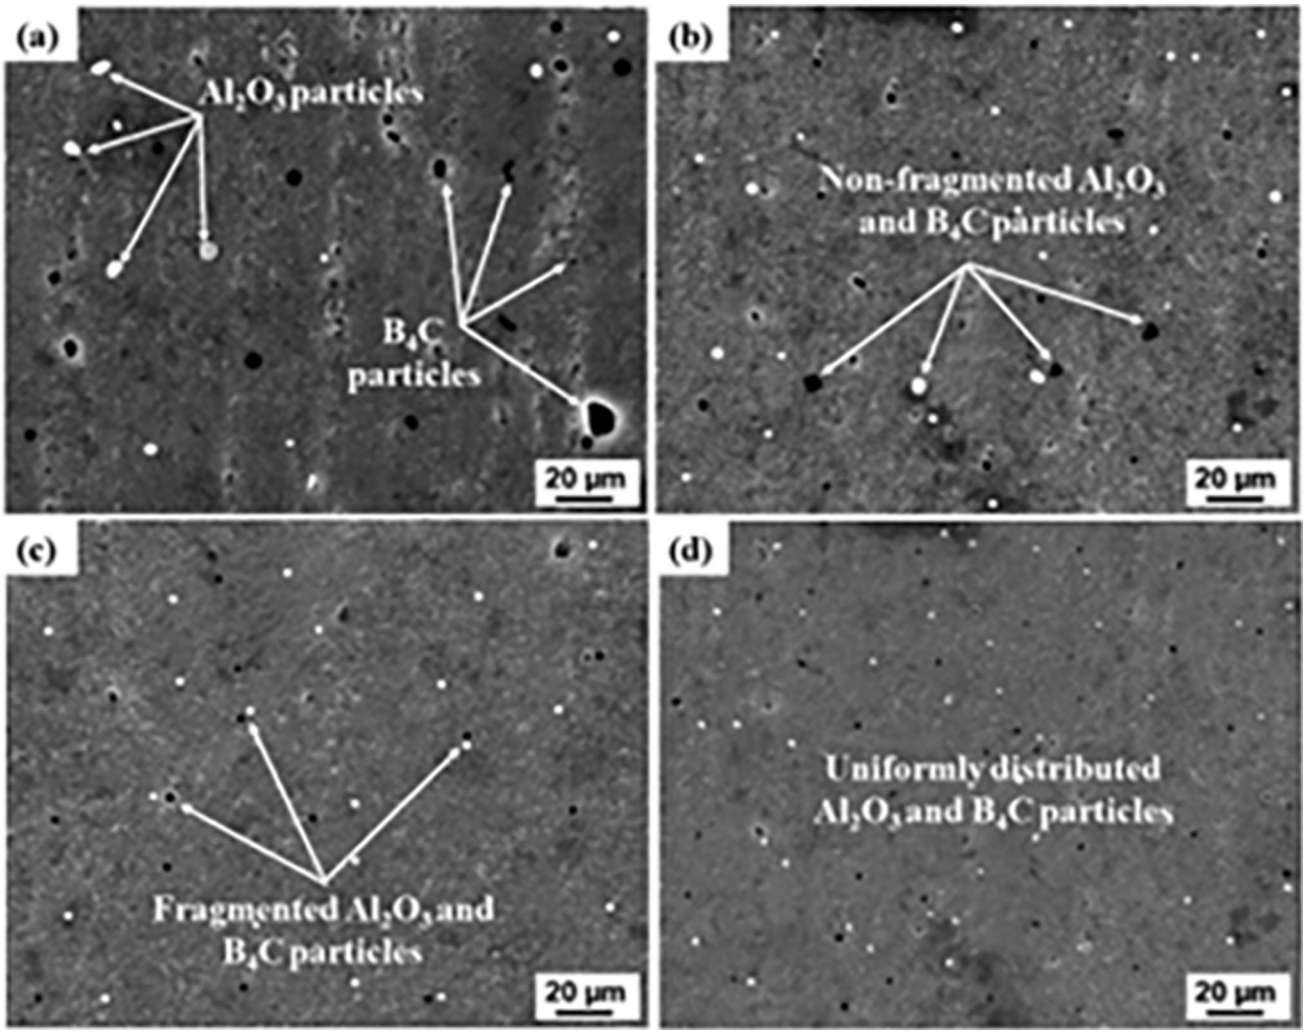

Fig. 4 SEM images of the AA2024/B_4C/Al_2O_3 nanocomposites for different FSP passes: (a) 1 Pass, (b) 2 Pass, (c) 4 Pass, and (d) 6 Pass

mechanical properties of hybrid AA2024/B_4C/Al_2O_3 surface composites (Ref 37]. Moreover, the size of B_4C and Al_2O_3 nanoparticles reduces significantly in the six-pass FSP compared to the one-, two-, and four-pass FSP processes. MPFSP leads to more uniform particle dispersion and contributes to breaking up SiC nanoparticle clusters due to cumulative strain. This process facilitates the creation of a large number of Al-B_4C-Al_2O_3 bonds and optimizes the distribution of nanoparticles, improving the pinning effect that is essential for strengthening and structural stability. Further, dislocation sources emerge during MPFSP, enhancing the DRX process and producing a refined grain structure (Ref 38). Moreover, as the FSP passes increases, B_4C and Al_2O_3 nanoparticles aggregation decreases, with single-pass FSP highlighting inadequate adhesion between highly agglomerated particles and the Al-alloy matrix. Defects such as fractures and discontinuities reduce around the agglomerated B_4C particles with additional FSP passes (Fig. 6a-d). During the plunging phase, the FSP tool applies compression to both B_4C and Al_2O_3 nanoparticles and the substrate metal matrix, causing lateral and upward particle motion that establishes a process zone (Ref 39). Notably, no separation or voids are detected between both B_4C and Al_2O_3 nanoparticles and the substrate matrix, suggesting that the six-pass FSP specimens exhibit higher UTS than those with fewer passes.

Figure 5 illustrates the elemental mapping results of the SZ for the six-pass hybrid surface composites, which include dispersed particles within the composite. The red areas indicate a high concentration of aluminum (Al-Kα), suggesting the existence of an AMCs within the composite. The gold color indicates the region with concentration of copper (Cu-Kα), blue area highlights regions with a concentration of oxygen (O-Kα), which may suggest the presence of aluminum oxides or other compounds that contain oxygen and copper in the material. The cyan regions indicate the integration of boron (B-Kα)-based reinforcements within the matrix. The green area suggests that the presence of carbon (C-Kα) could imply the existence of boron carbide reinforcements. This elemental distribution pattern demonstrates the effective mixing and integration of reinforcement particles during the FSP, resulting in a hybrid composite structure where multiple elements are distributed throughout the SZ, contributing to the material's enhanced properties through the combination of different reinforcement mechanisms. The EDS report displays the weight percentages of elements found in the single-pass FSP hybrid composite. The primary components are Al (91.98%), Cu (3.45%) and

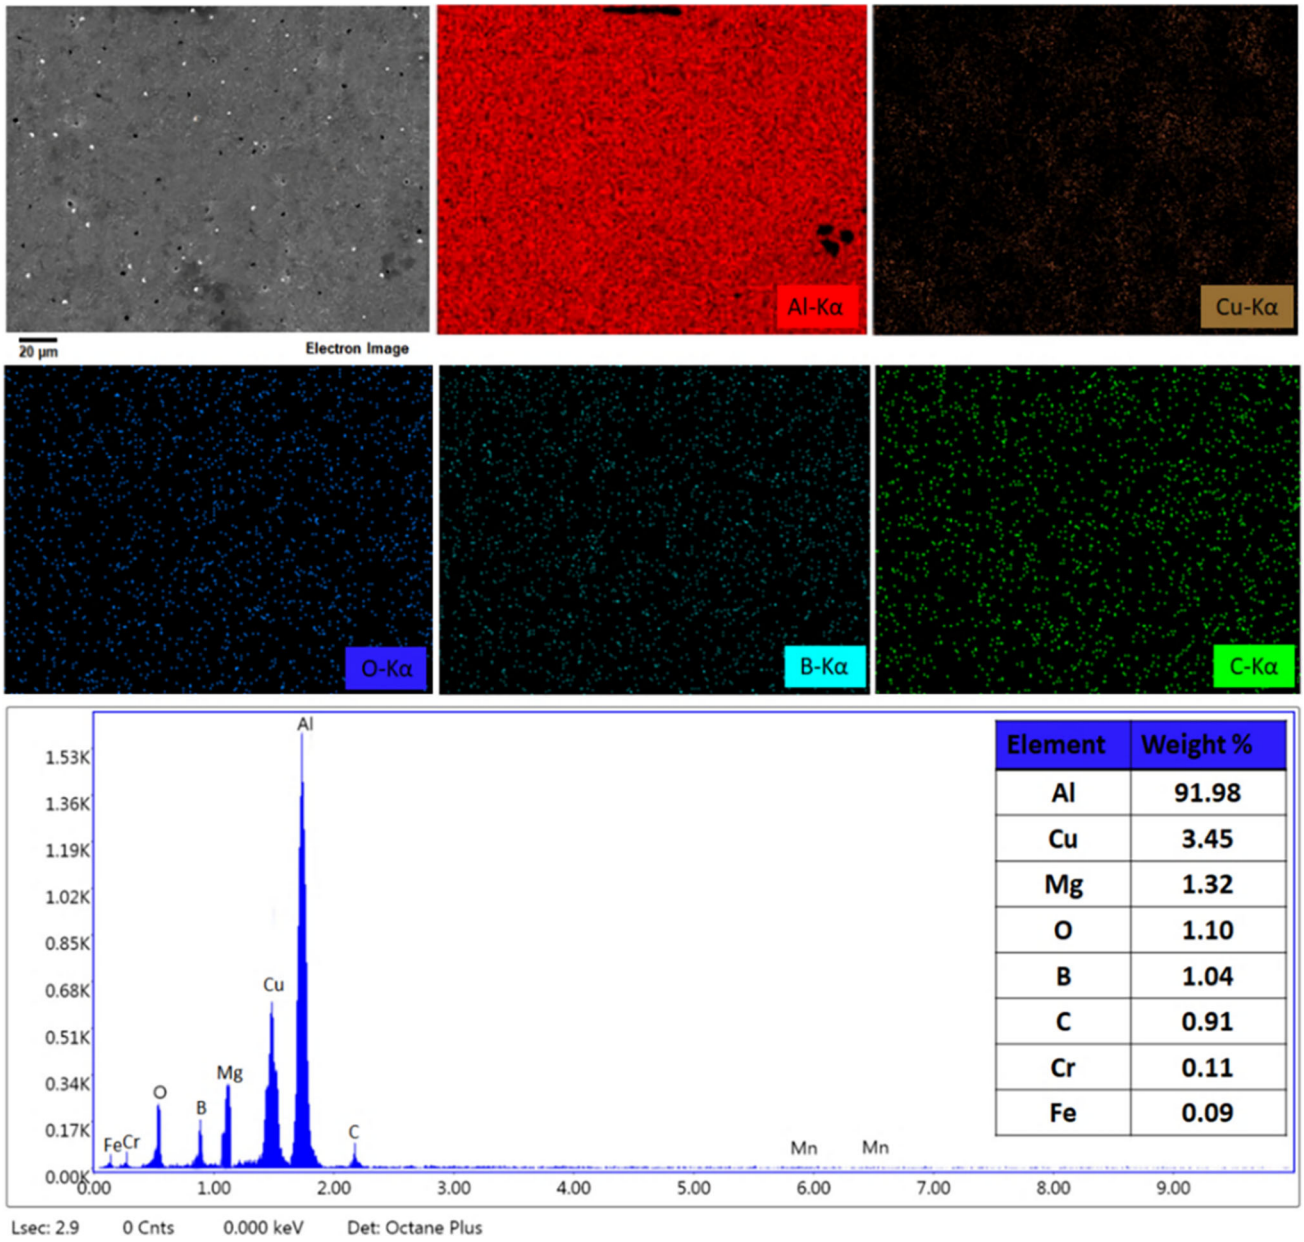

Fig. 5 Elemental mapping with EDS report of the AA7475/B_4C/Al_2O_3 nanocomposite with six pass FSP

magnesium (1.32%), indicating that the material is mainly an Al-alloy with significant amount of copper and magnesium elements may form Al_2CuMg phase. The reduced magnesium content exhibits that the Al_2CuMg phase has been reduced after MPFSP. While, reduced oxygen at 1.10%, boron at 1.04%, and carbon at 0.91% contents indicate that the multiple passes might have contributed to the reduction of aluminum oxides (Al_2O_3) and boron carbides (B_4C) or improved the dispersion of the reinforcement particles. The decrease in oxygen levels and enhanced homogenization indicate that MPFSP enhances the distribution and minimizes oxides in the composite. The results suggest that several FSP passes can improve the quality of hybrid surface composites by enhancing the uniformity of reinforcements (Ref 40).

The XRD patterns for the multi-pass hybrid AA2024/B_4C/Al_2O_3 surface composites in the stir region with Cu-Kα radiation at a wavelength of 1.518 Å are shown in Fig. 6. There are four main phases such as α-Al, Al_2CuMg, Al_2O_3 and B_4C are identified in the hybrid surface composites. No adverse reactions were identified between the Al_2O_3 and B_4C and the substrate metal matrix, demonstrating their compatibility during the MPFSP process. The phases identified in the XRD analysis are in agreement with EDS findings, which also shows the significant contents of the four alloying elements, namely Mg, Zn, B, and C. Moreover, the intensity of phases decreased with increasing FSP passes, signifying the uniform distribution and dispersion of second phase particles within the aluminum matrix, resulting in improved mechanical properties and microstructural homogeneity. This trend well aligns with findings of the previous study (Ref 41), that increasing FSP passes enhances Al_2O_3 particle dispersion and fragmentation and resulted in improved mechanical properties. These phases, when finely dispersed and exhibiting a coherent or semi-coherent interface with the surrounding matrix, can contribute

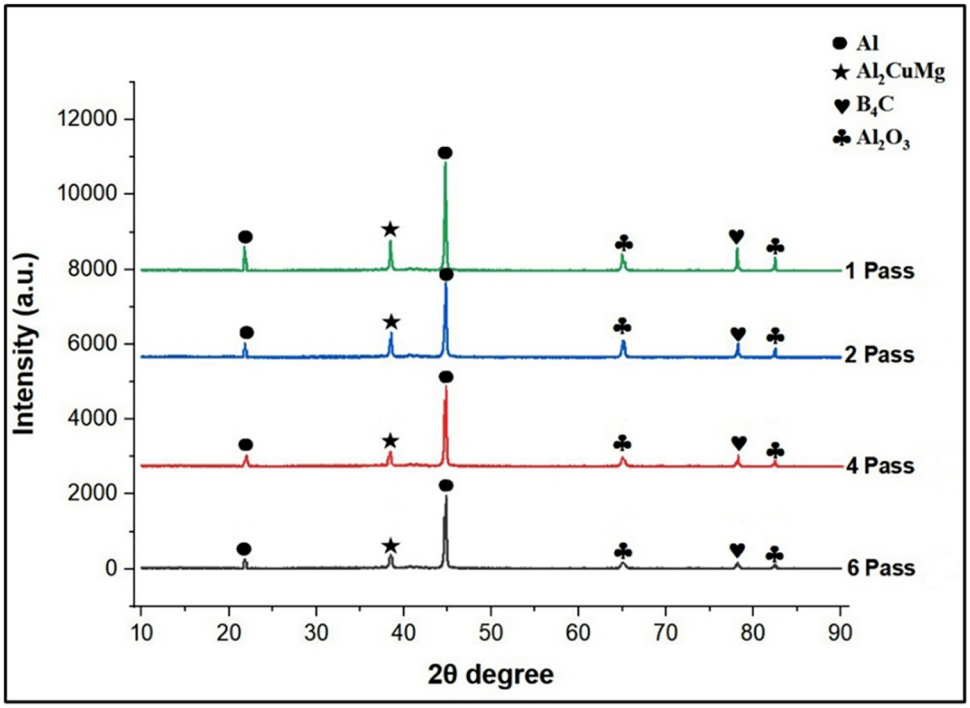

Fig. 6 XRD pattern of the AA2024/B_4C/Al_2O_3 nanocomposites for different FSP passes

to the composite's strengthening through a process known as precipitation hardening. The variations in the phase intensity of different phases can be attributed to several factors, including the heat input, plastic deformation, and material flow during FSP (Ref 42).

Figure 7 displays the EBSD images showing inverse pole figure (IPF) maps, grain boundary (GB) maps, and the distribution of low and high-angle grain boundary in the stir zone of the hybrid AA2024/B_4C/Al_2O_3 composites compared along with the base alloy. The colors in the IPF maps represent the crystallographic orientation of the grains, while the misorientation angle distributions highlight the grain boundary transformations resulting from the MPFSP. Low-angle grain boundaries (LAGBs) are defined by a misorientation angle between 2 and 15°, while high-angle grain boundaries (HAGBs) have angles greater than 15 degrees (Ref 10). Crystallographic orientation refers to the angular relationship between a grain's crystal lattice and a fixed reference frame, such as the sample surface or a standard coordinate system. It describes how individual grains are aligned in a polycrystalline material and helps in understanding texture evolution, slip systems, and grain boundary characteristics, which are crucial for evaluating material behavior due to thermomechanical process. They reveal the evolution of grain refinement, texture development, and recrystallization mechanisms. Additionally, the grain boundary transformations from LAGBs to HAGBs signify a more pronounced dynamic recrystallization process. This transformation indicates that the material has undergone significant plastic deformation, leading to the formation of new, strain-free grains with high-angle boundaries. The increased fraction of high-angle grain boundaries suggests a stronger texture (a significant number of grains have similar crystallographic orientations), which can contribute to improved mechanical properties (Ref 43). Black dots observed among the grains in the IPF map signify the existence of B_4C and Al_2O_3 particles within the stir region. In the IPF map of the composite fabricated with single pass, an equiaxed grain morphology (agreed with OM and SEM results) is observed with relatively coarser grains, as shown in Fig. 7(a), with the grains are equiaxed. The misorientation angle represents the difference in crystallographic orientation between neighboring grains. In the AA2024/B_4C/Al_2O_3 composites, the fraction of HAGBs is 76.49% for the single pass FSP (Fig. 7a) while the fraction of HAGBs is increased as the FSP pass is increased. The composite fabricated with double-pass FSP exhibited a higher fraction of HAGBs of 84.03%, as illustrated in Fig. 7(b). However, the fraction of HAGBs is 91.05% for the composite fabricated with four numbers of FSP passes (Fig. 7c), and it reaches 95.21% for the composite fabricated with six numbers of FSP passes (Fig. 7d). The composite fabricated with six FSP passes exhibited the highest grain boundary transformations with significant grain refinement. The role of Zener pinning and particle-stimulated nucleation (PSN) in grain refinement during MPFSP is significant due to the presence of second-phase particles such as B4C and Al_2O_3 reinforcements. These particles act as obstacles to grain growth through the Zener pinning effect, which restricts the migration of grain boundaries. Additionally, PSN contributes to grain refinement by providing nucleation sites for recrystallization. The IPF map of the composite after six FSP passes demonstrates that B4C and Al_2O_2 reinforcements effectively hinder grain growth, leading to the formation of ultrafine grains. The grain refinement is further supported by the occurrence of continuous DRX during FSP, which facilitates the transformation of coarse grains into finer grains. Similar observations were reported in the previous study (Ref 44), where significant grain refinement in the AMCs is achieved by the combined effect of Zener pinning and PSN. These combined mechanisms play a crucial role in achieving ultrafine grains in hybrid composites fabricated via MPFSP.

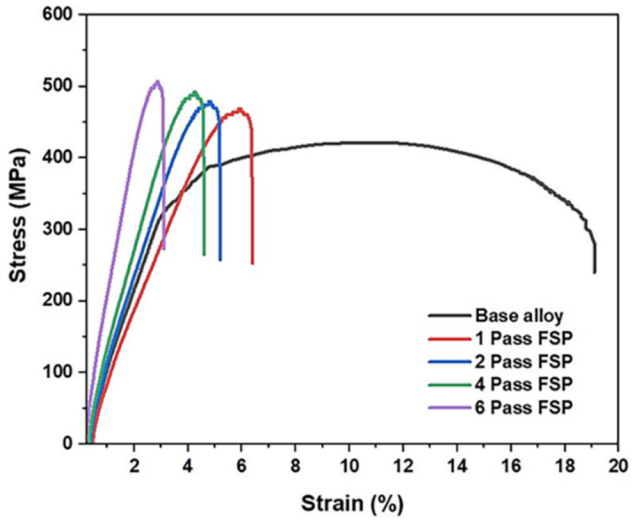

Fig. 8 Engineering stress-strain curve for different FSP passes

3.2 Tensile Properties

Tensile tests are performed to evaluate the tensile performance of the fabricated material, which is crucial in structural and industrial applications (Ref 45). The addition of B_4C and Al_2O_3 nanoparticles to the AA2024-T351 matrix is expected to enhance its strength, ductility, and toughness. Figure 8 presents the engineering stress-strain curves derived from tensile testing of hybrid nanocomposites, revealing the mechanical response of these materials after MPFSP. The data show that the UTS and YS of all samples significantly increased after MPFSP. However, these enhancements in strength were accompanied by a noticeable reduction in tensile elongation (El) as the FSP passes increased. The present findings are well agreed with prior findings (Ref 20, 46, 47), which showed that the MPFSP improved hardness, UTS, and YS while simultaneously diminishing El. The bar graphs in Fig. 9 quantitatively illustrate the changes in YS, UTS, and elongation of the hybrid nanocomposites, while Table 2 highlights that the base alloy retains the highest elongation compared to the processed composites. The mechanical behavior induced by FSP can be attributed to the synergistic effects of severe plastic deformation (SPD) heat-induced microstructural stability, and emerging strain-hardening mechanisms. SPD is a critical mechanism in enhancing material properties, particularly strength and toughness, by refining microstructures at the grain level. The process involves extensive deformation, which introduces a high density of dislocations and promotes grain refinement through dynamic recrystallization (DRX). However, the corresponding frictional and deformation heat plays a vital role in controlling the growth of these recrystallized grains. This heat, coupled with strain-induced

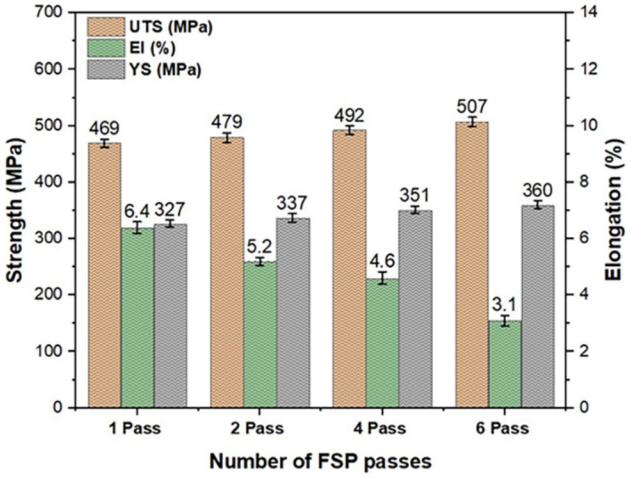

Fig. 9 Bar graphs showing UTS, yield, and elongation properties with different FSP passes

grain fragmentation, effectively inhibits excessive grain coarsening, ensuring the retention of ultra-fine or nanostructured grains that contribute to superior mechanical properties. Additionally, strain hardening mechanisms emerge as a result of this refined microstructure, where dislocation entanglement and interaction with grain boundaries enhance material strength while maintaining ductility. This effect is particularly important in overcoming the conventional strength-ductility trade-off, which typically limits the improvement of both properties simultaneously (Ref 48, 49). The fine-grain microstructure ensures improved grain boundary strengthening (Hall-Petch effect), while controlled dislocation motion facilitates strain hardening, thereby balancing strength and toughness efficiently (Ref 50). The synergy between SPD, heat-induced microstructural stability, and emerging strain-hardening mechanisms provides unique insights into the optimization of structural materials for high-performance applications. The alloy employed in this investigation is a precipitate-hardened Al-alloy. The Al_2CuMg phase is observed to nucleate along grain boundaries, as shown in Fig. 2(a). This phase behaves like secondary particles that impede dislocation motion, significantly contributing to the strength of the alloy. Furthermore, FSP promotes the formation of DRX in the Al_2CuMg phase within the aluminum matrix, along with the uniform dispersion of the reinforcement particles, namely B_4C and Al_2O_3. In this study, mechanical properties of the base alloy showed substantial improvements post-FSP, particularly after six passes. YS and UTS are increased by 16.88% and 20.42%, respectively, due to grain refinement, improved DRX, and enhanced phase distribution. On the other hand, ductility dropped markedly to 83.76% after six FSP passes, reflecting the trade-off between strength and ductility inherent in such processing techniques. The tensile test results presented in this study provide valuable insights into the nanoparticle dispersion and interfacial bonding within the composite. The improved YS and UTS observed with increasing FSP passes suggest enhanced nanoparticle dispersion and interfacial bonding. Specifically, the uniform distribution of nanoparticles and the strong bonding between the nanoparticles and the aluminum matrix contribute to the improved mechanical properties (Ref 51). The tensile test results imply that the MPFSP process effectively disperses the nanoparticles and promotes interfacial bonding, leading to enhanced composite performance.

Figure 10 shows the SEM images of the tensile fractured surface of the AA2024/B_4C/Al_2O_3 composite subjected to different passes, highlighting features such as dimples, tear ridges, facets, and micropores (Ref 50). With the increase in the number of FSP passes from one to six, the size of the dimples diminished (Fig. 10a–d), aligning with the microstructural characteristics that influence the failure modes. The fractured surface of the composite samples made with six FSP passes showed very fine and equiaxed dimples, leading to a ductile mode of failure. Fine dimples enhance the composite's strength due to the robust bonding between the materials, leading to considerable necking prior to failure and ultimately resulting in cup-cone failure (Ref 52). The cup-cone fracture demonstrates the ductile nature of failure, characterized by a fractured surface plane that is inclined at 45° to the tensile loading axis. Nonetheless, the fractured surface of the composite samples created using single-pass FSP displayed several coarse dimples along with rough cleavage facets, leading to a ductile-brittle fracture mode of failure. The transition from ductile to brittle fracture modes in the composite is affected by various factors. The existence of coarse dimples on the fractured surface of single-pass FSP composite samples points to a ductile fracture mode, whereas the presence of rough cleavage facets indicates a brittle fracture component. The failure mode characterized by ductile-brittle fracture can be linked to the interaction between the aluminum matrix and the reinforcement particles. The elements influencing this transition encompass the distribution and size of the ceramic particles, the bonding at the matrix-particle interface, and the strain rate experienced during deformation. Non-fragmented reinforcement particles may serve as stress concentrators, which can promoted brittle fracture, whereas the aluminum matrix is capable of plastic deformation, resulting in ductile fracture. All composite samples were found to fracture within the HAZ region, except the composites fabricated with a single pass, in which the failure occurs across the SZ region. In the HAZ region, localized softening takes place due to intense thermal cycles induced by MPFSP, which can result in the dissolution of precipitates, grain coarsening, and a lack of hard ceramic particles (Ref 2). The localized HAZ softening could lead to failure and diminish the tensile performance. The study reveals that MPFSP incorporating B4C and Al_2O_2 nanoparticles produces finer and more uniform microstructures, increases tensile features, and controls fracture location, thereby enhancing performance and durability of hybrid surface composites.

3.3 Hardness Distribution

The Vickers hardness distribution curves with respect to the distance from the center of hybrid AA2024/B4C/Al_2O_3 surface composites are illustrated in Fig. 11. It can be clearly observed that as the FSP passes increases from one to four, a notable increase in hardness values is observed (Ref 47). This improvement in hardness correlates with refined grain size and increased nanoparticle dispersion within the composite structure, suggesting that each additional pass leads to enhanced material properties. In particular, Vickers hardness values observed along the SZ showed a progressive increase: from 155 HV in the one-pass FSP to 164 HV in the two-pass, 172 HV in the four-pass, and finally to 189 HV in the six-pass FSP (see Fig. 13). This gradual improvement contrasts with the base metal AA2024, which had a lower average hardness of 136 HV (see Table 2). Each pass in the FSP process contributed to

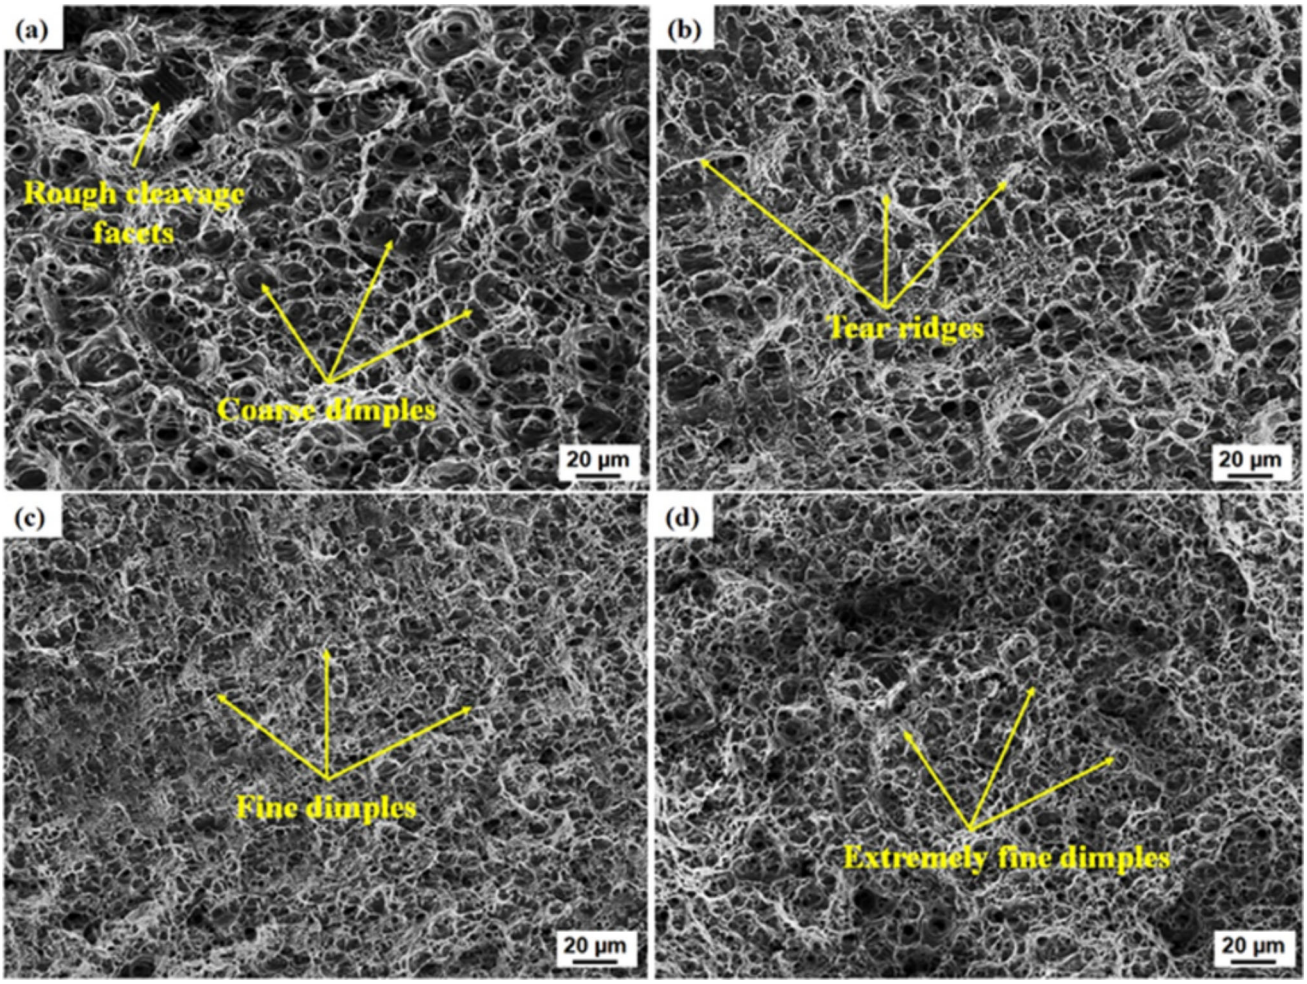

Fig. 10 SEM images of the tensile fractured surfaces of the AA2024/B_4C/Al_2O_3 nanocomposites for different FSP passes: (a) 1 Pass, (b) 2 Pass, (c) 4 Pass, and (d) 6 Pass

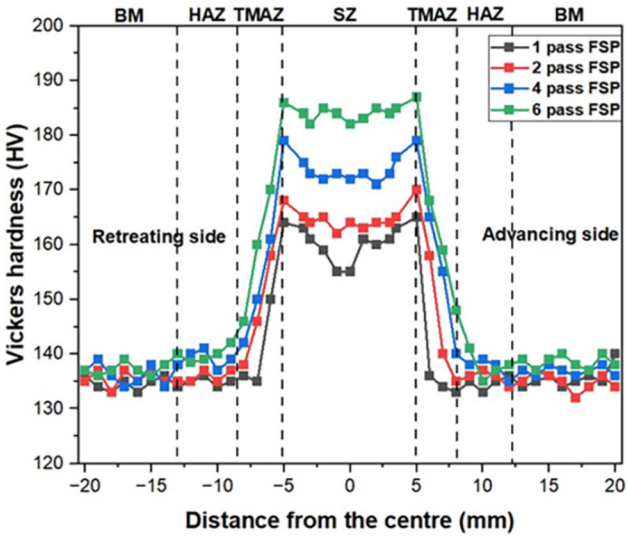

Fig. 11 Hardness distribution of the AA2024/B_4C/Al_2O_3 nanocomposites for different FSP passes

improved hardness through mechanisms like grain fragmentation, refinement of B4C and Al_2O_3 nanoparticles, and the incorporation of B4C and Al_2O_3 particles. These particles are hard, reinforcing agent, enhances composite microhardness due to its inherent structural properties. In the SZ across all MPFSP configurations, a low fluctuation in hardness reflects effective mixing and dispersion of these nanoparticles, which contributes to the uniformity of the SZ microstructure. The hardness increment seen in MPFSP with B4C and Al_2O_3 nanoparticles infill can be attributed to the grain refinement and increased dislocation density as a result of the intense plastic deformation and heat generated by the rotating FSP tool. DRX occurring during MPFSP produces very fine grains by fragmenting B4C and Al_2O_3 nanoparticles and helping migrate grain boundaries. This effect is especially pronounced in the six-pass FSP with B4C and Al_2O_3 nanoparticles, where extremely fine-grained structures emerge compared to those seen in fewer-pass FSPs or the base metal. The B4C and Al_2O_3 particles distribution, alongside the grain boundary migration, facilitates an even finer granular structure, which contributes significantly to hardness.

This refined grain structure and improved particle dispersion are further facilitated by DRX, where B4C and Al_2O_3 nanoparticles in the substrate alloy act as effective nucleation points for new grains. These nanoparticles, therefore, enable optimal formation of fine, equiaxed grains, particularly in the six-pass FSP, resulting in improved hardness properties (Ref 53, 54). This relationship is best explained by the Hall–Petch principle, where a refined grain size leads to an increase in strength and hardness by limiting dislocation movement. Consequently, with each additional FSP pass, the composite structure becomes increasingly resilient due to cumulative microstructural enhancements. The increase in microhardness within the SZ compared to the TMAZ and the HAZ can be attributed to particle size. The SZ benefits from the smallest particle size due to the consistent application of FSP, while microhardness diminishes in the TMAZ and HAZ because of precipitate behavior. Specifically, in the TMAZ, the decline in hardness is tied to the dissolution of precipitates, whereas, in the HAZ, it stems from precipitate coarsening. These changes reflect underlying transformations at the microstructural level that result in a hardness gradient across different regions of the composite. One of the notable observations is the coarsening of reinforcing precipitates in the HAZ, coupled with the dissolution of the Guinier–Preston zones, both of which contribute to a decrease in microhardness in this region (Ref 55). In contrast, MPFSP leads to a finer grain structure, superior particle dispersion, and improved reinforcement-matrix mixing within the SZ, leading to increased hardness properties.

3.4 Tribological Behavior

Figure 12 examines the changes in the coefficient of friction (COF) over sliding distances and as influenced by the number of FSP passes in AA2024/B_4C/Al_2O_3 nanocomposites. Figure 13 specifically illustrates COF fluctuations across various sliding distances, showing a clear trend where COF variability intensifies as the sliding distance increases. This effect is likely due to the fracture of oxide layers, which results from elevated temperatures generated by prolonged sliding. Shafiei et al. (Ref 56) also observed this phenomenon, noting that oxide fracture under high thermal conditions contributes to increased surface roughness,

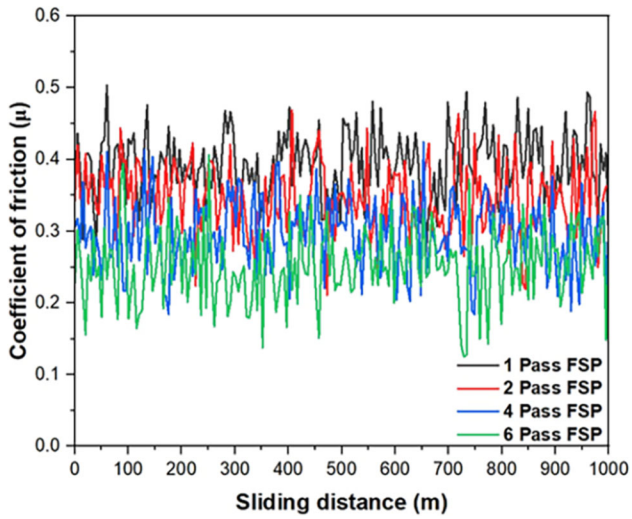

Fig. 12 Graphs showing COF versus sliding distance of the AA2024/B4C/Al_2O_3 nanocomposites for different FSP passes

signaling a shift from mild to more aggressive wear. This progression toward severe wear becomes particularly evident after a significant portion of the sliding distance has been covered. Figure 12 highlights the average COF (μ) for these nanocomposites, demonstrating a consistent decrease in COF as the FSP passes increases. This reduction in COF can be attributed to the effects of DRX and grain refinement induced by the FSP process, which causes SPD of the material. With each additional FSP pass, the grains become finer, leading to a reduction in frictional resistance. Furthermore, finer grain structures increase the hardness of the material, as described by the Hall–Petch relationship (Ref 57, 58), which states that smaller grains enhance material strength. This hardness increase, in turn, leads to a lower wear rate, a trend illustrated in Fig. 13. In Fig. 13, the wear depth is shown to be most significant in the nanocomposites subjected to only a single FSP pass. This greater wear depth indicates lower hardness and increased susceptibility to wear in single-pass samples. As the FSP passes increase, however, the wear depth diminishes substantially, which can be explained by the enhancement in hardness due to grain refinement and DRX. These findings are consistent with previous observations by Yuvaraj et al. (Ref 59), who noted that multiple FSP passes enhance the material's hardness and reduce wear depth. In nanocomposites subjected to a single FSP pass, the COF and wear rate are notably higher. The increased wear rate is due to adhesive wear mechanism involves the transfer of aluminum matrix material to the counter face, often due to the strong bonding between the composite pin and the disk surface, resulting in more material loss. This ultimately resulted in additional resistance, elevating both COF and wear rates.

Figure 15 presents SEM images depicting the worn surfaces of AA2024/B4C/Al_2O_2 nanocomposites after wear testing. The worn surfaces showed abrasive wear, oxidation, and delamination as the primary wear mechanism (Ref 4). In AMCs the abrasive wear mechanism occurs in aluminum surface composites due to the presence of hard reinforcement particles, which can act as abrasive agents and cause micro-cutting and plowing of the counter face, leading to material removal and wear. Concurrently, oxidation of the aluminum matrix and reinforcement phases takes place, forming a thin oxide layer that can delaminate under repeated sliding contact, resulting in material loss and exposure of fresh surfaces. Delamination of the oxide layer and the underlying material can also occur due to the thermal and mechanical stresses generated during sliding, leading to a complex wear mechanism that involves the degradation of both the matrix and reinforcement phases. Similar mechanisms are found in the previous studies (Ref 19, 60), where aluminum-based composites are subjected to MPFSP. The single-pass specimen in Fig. 15(a) has an oxide coating on its worn surface, possibly from frictional sliding heat. Frictional heat, especially under larger loads, raises nanocomposites' temperatures, promoting surface oxidation and oxidative wear (Ref 61). Under sliding wear, plastic deformation creates pressure and stress zones in the front and back. Deformation causes cracks below the surface to migrate outward, detaching material and forming wear debris. Oxide layer forms in some areas imply that debris interacts with the worn surface to cause oxidation wear (Ref 62). The single-pass worn surface (Fig. 15a) has wider grooves than the six-pass specimen (Fig. 15(d)), suggesting higher material loss during sliding wear. This shows that single-pass FSP has broader wear tracks than MPFSP because of decreased hardness and microstructure refinement. In contrast, Fig. 15(b) and (c) shows

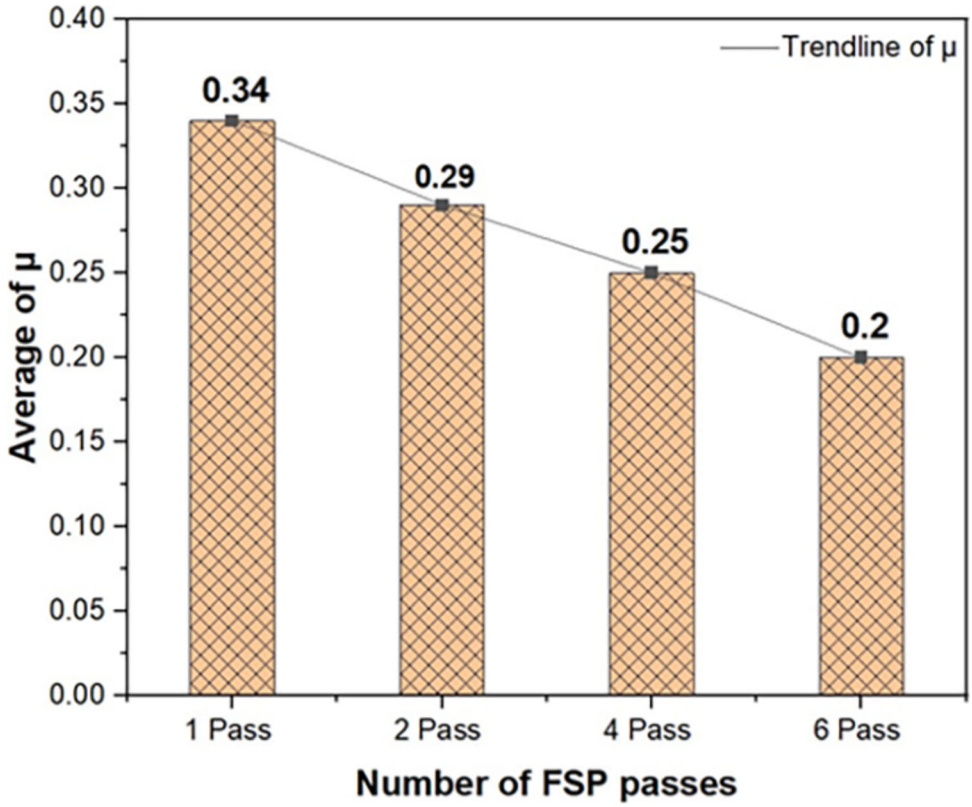

Fig. 13 Bar graph showing trendline of average coefficient of friction (μ) with FSP passes

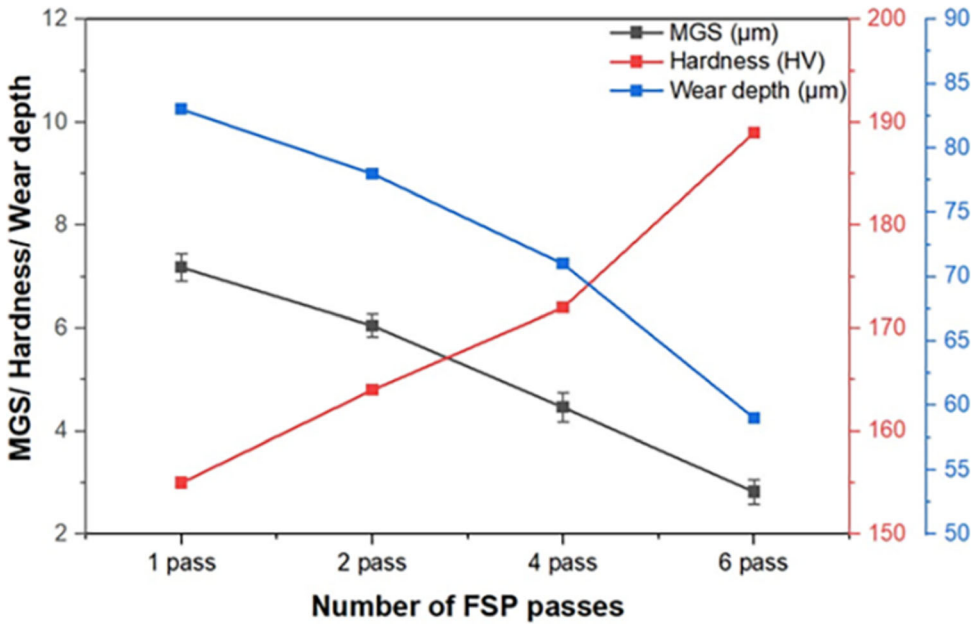

Fig. 14 Correlation between mean grain size (MGS), hardness, and wear depth with FSP passes

worn surfaces from distinct wear track sections in MPFSP specimens. More FSP passes increase wear resistance, as shown by finer wear grooves and less delamination than the single-pass sample. Figure 14(d) shows plowing and material delamination, but fewer deep wear grooves, suggesting less severe adhesive wear in multi-pass samples. In Fig. 15(d), particles distributed throughout the surface indicate oxidized areas, demonstrating oxidative wear in these nanocomposites. Comparing single-pass and six-pass FSP samples shows that more passes reduce groove depth and breadth. The six-pass sample had narrower grooves than the single-pass sample, showing less material was lost during wear testing. Hardness improvements from DRX and grain refining with repeated FSP reduce groove size and wear. Figure 16 shows elements

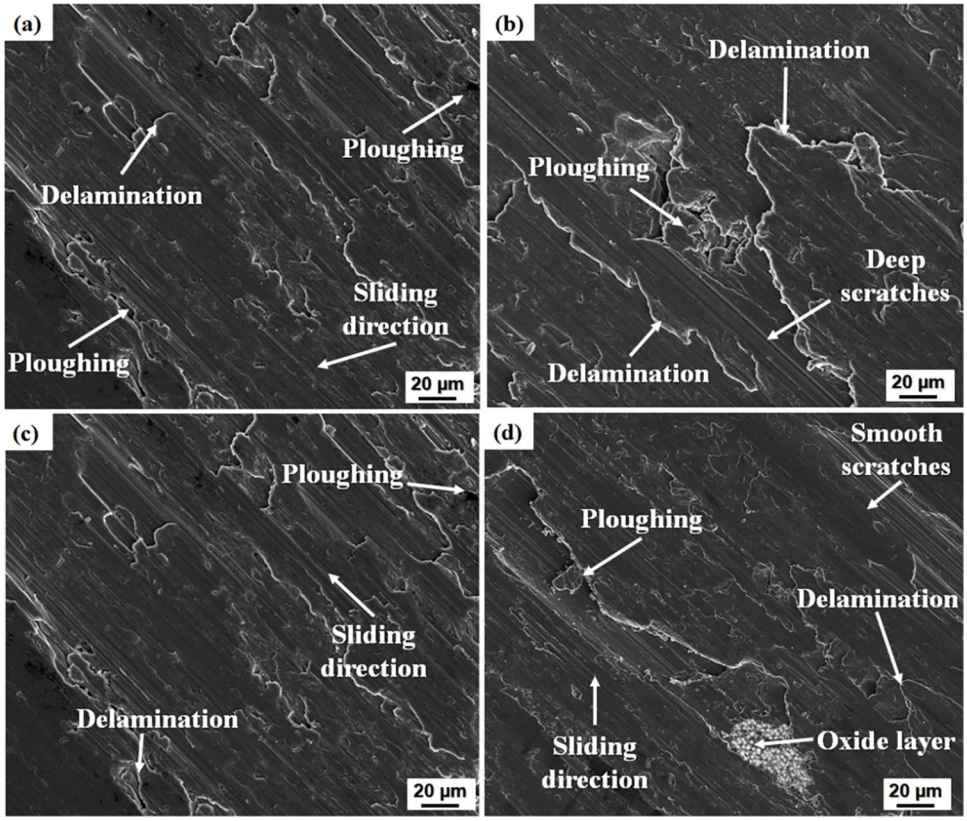

Fig. 15 SEM images of the worn-out surfaces of the AA2024/B_4C/Al_2O_3 nanocomposites for different FSP passes: (a) 1 Pass, (b) 2 Pass, (c) 4 Pass, and (d) 6 Pass

mapping of the worn-out composite surfaces manufactured at six-pass FSP, which include scattered particles. High concentrations of aluminum (Al-Kα) in red regions reflect the presence of AMCs. The gold color represents copper concentration (Cu-Kα), whereas the blue area suggests oxygen concentration (O-Kα), perhaps indicating aluminum oxides or other compounds containing oxygen and copper. In the matrix, blue patches represent the integration of boron (B-Kα)-based reinforcements. The presence of carbon (C-Kα) in the green region may indicate boron carbide reinforcements. The high Al (85.79%) in the EDS data indicates an aluminum-rich matrix. The elemental makeup includes oxygen (5.71%), boron (3.08%), carbon (2.83%), and copper (1.63%) after aluminum. The SEM picture shows a large oxide layer, which may explain the high oxygen levels. This oxide layer may improve composite wear resistance by preventing material deterioration.

The results of the present investigation are compared with prior studies (Ref 4, 20), where AA2024-based composites were fabricated through MPFSP. Compared to the findings of Moustafa (Ref 20), which reported a maximum ultimate tensile strength (UTS) of approximately 308 MPa, elongation of 2.4%, and hardness of 109 HV, with an average mean grain size (MGS) of 5.1 μm in the stir zone, the current study demonstrates a remarkable grain refinement of 82.1%, along with improvements in UTS by 64.6%, ductility by 29.16%, and hardness by 72.4%. Similarly, when compared to Acuna's study (Ref 4), which reported a maximum wear depth of 297 μm, the present research achieves a substantial reduction in wear depth by approximately 80%. The improved mechanical and tribological performance can be attributed to multiple factors (Ref 63). Firstly, the increased number of FSP passes facilitates extensive grain refinement and fragmentation of reinforcement particles due to the pinning effect, which limits grain growth by reducing the heat input during FSP. Secondly, the thermal expansion mismatch between the matrix and reinforcement particles generates a high dislocation density at the reinforcement-matrix interfaces, activating the Orowan strengthening mechanism. Lastly, the intrinsic hardness of the reinforcement phases significantly contributes to the improved overall hardness. The findings of the present study not only validate the effectiveness of the fabricated hybrid composites through employing MPFSP but also the advancement in the fidelity of AMCs to achieve superior performance.

4. Conclusions

The influence of multi-pass friction stir processing (MPFSP) on the microstructure, mechanical and tribological performance of AA2024-T351 surface composites reinforced with 50% B_4C and 50% Al_2O_3 nanoparticles was effectively investigated at a tool rotation speed of 800 rpm and a traverse speed of 35 mm/min. The findings may be summarized as follows:

- The microstructural analysis revealed that MPFSP effectively induced significant grain refinement and homogeneous distribution of reinforcement particles. Notably, the mean grain size (MGS) in the stir region decreased substantially from 7.18 ± 0.26 to 2.82 ± 0.06 μm after six passes,

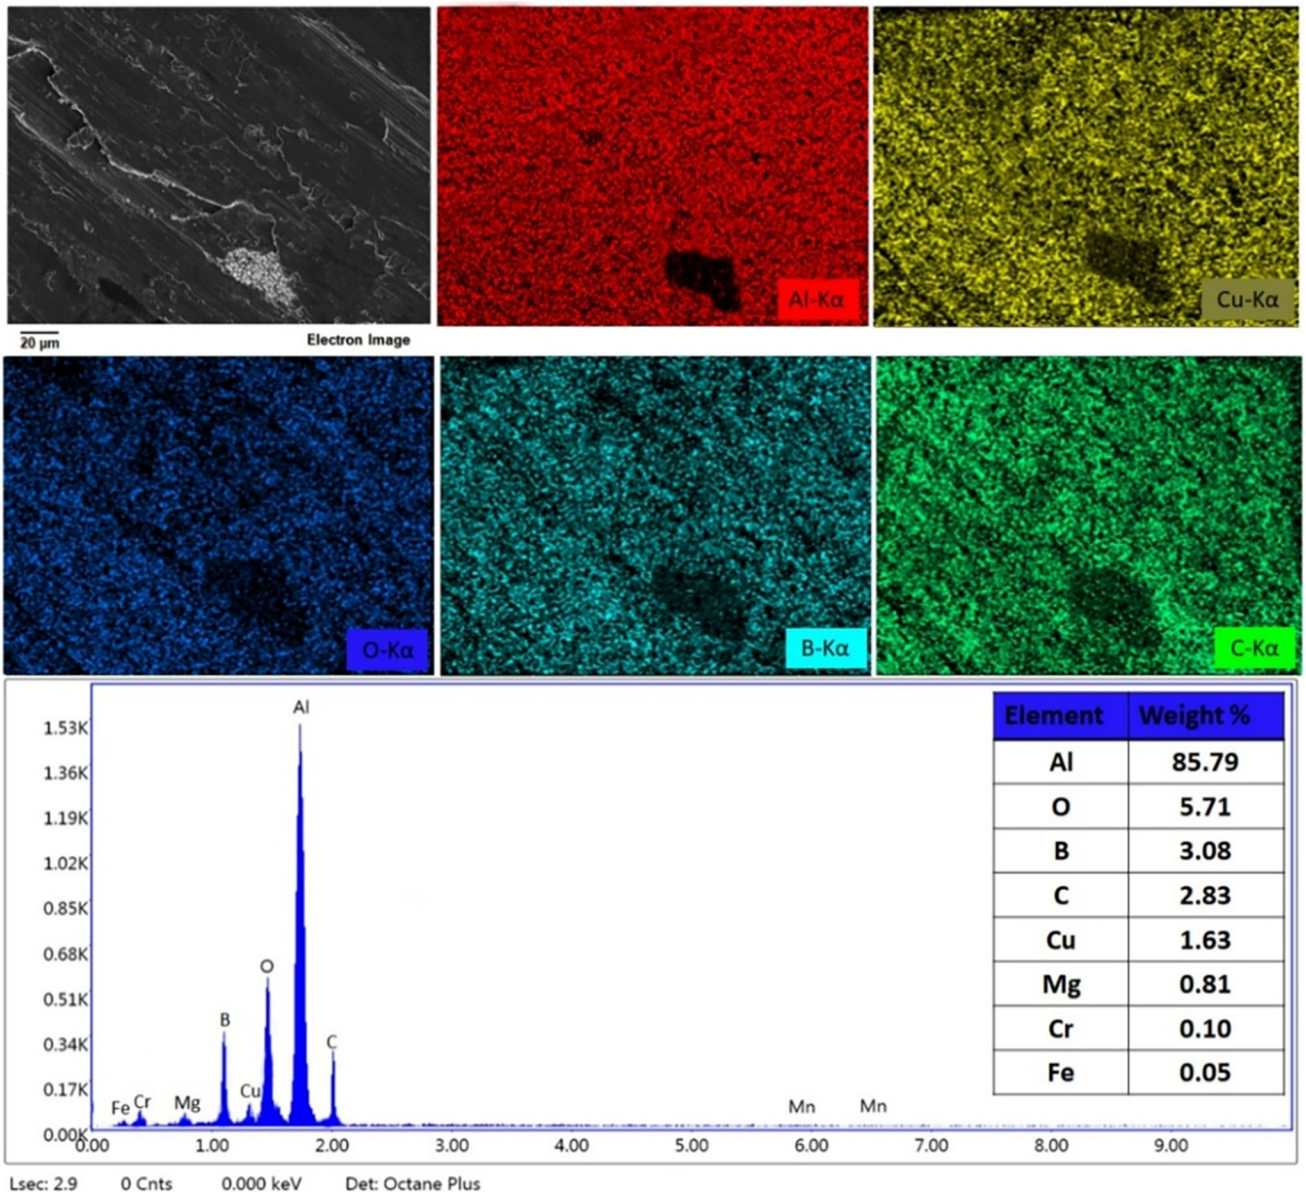

Fig. 16 Elemental mapping with EDS report of the worn-out surface of the nanocomposite with six pass FSP

compared to one pass. Furthermore, XRD results showed a consistent reduction in peak intensity of α-Al, Al_2CuMg, B_4C, and Al_2O_3 phases with increasing number of passes, indicating fragmentation of secondary phase particles.

- Electron backscatter diffraction (EBSD) results revealed a notable increase in the fraction of high-angle grain boundaries (HAGBs) from 76.49 to 95.21% after six passes of FSP. This significant rise in fraction of HAGBs effectively hindered grain boundary dislocation motion, thereby providing substantial resistance to deformation under tensile loading, ultimately yielding improved tensile performance.
- The base alloy AA2024-T351 exhibited an ultimate tensile strength (UTS) of 421 MPa, a yield strength (YS) of 307 MPa, and an elongation (El) of 19.1%. However, the hybrid composite showed significant improvements in tensile properties after MPFSP. Specifically, the UTS increased from 469 to 507 MPa, the YS increased from 327 to 360 MPa, while the El decreased from 6.4 to 3.1% after six passes of FSP, compared to one pass.
- The results demonstrated that increasing the number of FSP passes from one to six led to significant improvements in the hardness and tribological properties of the hybrid composite. Specifically, the hardness increased by 22% from 155 to 189 HV, while the coefficient of friction (COF) decreased by 41% from 0.34 to 0.20, and the wear rate decreased by 29% from 83 to 59 μm. These enhancements in surface properties can be attributed to the formation of ultrafine grain structures and the uniform dispersion of reinforcements within the matrix.
- The tensile fractured surfaces revealed a predominantly ductile mode of failure, characterized by the presence of dimples and shear lips. In contrast, the worn surface morphology exhibited a complex wear mechanism, involving abrasive wear, oxidation, and delamination, which were likely caused by the syner-

gistic effects of thermal softening and repeated sliding cycles, leading to material degradation and removal.

Acknowledgments

The authors would like to thank the CRF, Indian Institute of Technology Kharagpur, West Bengal, for facilitating the EBSD characterization and the Precision Manufacturing Lab, Delhi Technological University, Delhi, for assisting with the wear characterization of the composite samples.

Conflict of interest

On behalf of all authors, the corresponding author states that there is no conflict of interest.

Keywords: WAAM, Bi-Metallic Materials, Additive Manufacturing and Functionally Graded Materials

Abstract. Arc welding-based additive manufacturing techniques offer promising prospects for metal additive manufacturing, particularly in the economic production of large-sized components with relatively high deposition rates. This review article provides an introduction to wire arc additive manufacturing (WAAM) and offers an overview of its fundamental principles. Additionally, it delves into the fabrication of bi-metallic structures and functionally graded materials/structures using WAAM, exploring their applications across various industries.

1. Introduction

Wire Arc Additive Manufacturing (WAAM) is a promising and more popular technique for creating metal objects using additive manufacturing. The procedure employs an electric arc as the heat source and filler wires as the material for deposition, enabling the creation of medium to large-scale structures using a step-by-step layering method. The WAAM technique has proven effective in producing structures using various alloys like aluminum, nickel, titanium, and steel [1]. Weldability plays a crucial role in governing the production of metallic structures using WAAM, given its reliance on stacking successive layers of weld beads. Functional Graded Materials (FGMs) represent an innovative and evolving category of high-strength materials ideal for diverse industrial applications, enabling varied functional performances within a single part. Traditionally, FGMs are crafted through post-processing methods such as fusion welding techniques, diffusion bonding, or friction stir welding [2].

Functionally graded materials (FGMs) differ from traditional homogeneous materials in that their composition and microstructure gradually change in spatial direction, leading to continuous or discontinuous alteration of mechanical, physical, and chemical properties along single or multiple directions [3]. FGMs possess distinctive features including enhanced mechanical properties, resistance to heat shock, and corrosion. Currently, FGMs find extensive applications in aerospace, medical, optoelectronics, and energy sectors [4]. Various methods are employed to fabricate FGMs, including centrifugal casting, discharge plasma sintering, vapor deposition, and self-propagating synthesis [5]. Nonetheless, traditional deposition techniques for FGMs suffer from several drawbacks, such as limited capability to produce complex structures and insufficient efficiency. SS321 and Inconel 625 are commonly used alloys in the fabrication of bi-metallic structures for aircraft, power generation, gas turbines, high-temperature bolts, petrochemical, and marine applications. This is due to their outstanding corrosion resistance and mechanical properties, particularly at temperatures below 850°C [1]. Utilizing the WAAM process for manufacturing FGMs offers the potential to expedite the creation of new materials due to the ability to incorporate varying compositions and mechanical properties.

Additive manufacturing (AM) has experienced rapid advancement recently and is poised to play a significant role in the future [2]. Furthermore, AM techniques offer a novel approach to fabricating FGMs. In contrast to traditional subtractive manufacturing methods, AM employs innovative processing techniques to create parts using computer-aided geometric models,

constructing them layer by layer from the bottom up. AM not only enables the direct fabrication of intricate structural components but also enhances production efficiency. By altering alloy composition, process parameters, and stacking paths, AM methods can produce materials with gradients in one or multiple dimensions. Laser AM, electron beam AM, and wire arc additive manufacturing (WAAM) are among the AM technologies employed, widely utilized for producing functionally gradient metals such as aluminum and titanium alloys [3].

2. Bi-metallic structures

Utilizing the wire arc additive manufacturing (WAAM) technique to deposit two metallic wires enables the creation of bimetallic structures (BMS), which can optimize the individual properties of each metal while mitigating their respective drawbacks. The aim of manufacturing BMS is to meet the specific property requirements at designated locations within parts and to reduce costs compared to fabricating entire components using a single, high-cost material. Ahsen et al. [6, 7] fabricated a bimetallic additively manufactured structure of ER70S6, a low carbon steel and SS 316L using a GMAW based WAAM and studied the effect of heat treatment on mechanical properties. The heat treatment technique resulted in a 35% improvement in ultimate tensile strength and a 250% increase in elongation compared to the as-deposited structure. An abrupt rise in hardness was found at the interface of the manufactured bimetallic material. The interface resulting from depositions was determined to be defect-free. The analysis of the bimetallic structure's microstructure showed predominantly dendritic grains with a minor presence of equiaxed grains. The hardness test findings indicated a significant and sudden rise in the hardness value at the bimetallic interface. The samples subjected to tensile tests exhibited a ductile fracture and failed in the SS 904L region, displaying fine dimples and ripping ridges.

Wenhao et al. [8] studied the effect of deposition sequence of 316L and Inconel 625 on the microstructure and mechanical properties of the fabricated bimetallic structures. The results showed no effect of the deposition sequence on the microstructure types. The interface was bonded well but due to element diffusion and Laves phase there were cracks at the interface. It was also revealed that hardness at the interface was within the hardness range of the two used alloys. Yinbao et al. [9] studied the effects of subsequent deposited layers of aluminium alloy on the microstructure characterization of the reaction layers of the Ti-Al bimetallic structure fabricated using cold metal transfer based WAAM. $TiAl_3$,TiAl and Ti_3Al were the Ti-Al intermetallic compounds formed in the subsequent layers.

3. Functionally graded materials/structures

Functionally graded materials (FGMs) are those materials in which chemical composition and microstructure changes gradually which leads to have different properties in one or different directions. The variation in chemical compositions and microstructures throughout the structure results in variation of mechanical properties, which makes the functionally graded materials a suitable candidate for the wide range of applications like aerospace engineering, nuclear power generation, sensor, biomedical implants, optoelectronic devices, and absorption systems [10]. There are several conventional or traditional methods which has been used to manufacture functionally graded materials, but it is somewhat difficult to make with significant composition changes. Conventional methods are not suitable to manufacture FGMs with high structural strength and thus require post treatment, which makes the process costly and uneconomical [11].

Recently, Additive manufacturing has evolved as a better option to manufactured functionally graded materials with different combinations of materials, with a wide scope of eliminating disadvantages of the traditional methods. Additive manufacturing methods to manufacture FGMs include Laser AM, electron beam AM and wire arc additive manufacturing technologies. Meanwhile WAAM has the advantages of low cost, easy operation, high deposition rate and the ability to deposit large-sized components [5]. The depicted WAAM system in **Figure 1** is

Materials Research Proceedings 49 (2025) 29-38 https://doi.org/10.21741/9781644903438-4

employed for the production of functionally graded titanium-aluminide alloys. It comprises a gas tungsten arc welding (GTAW) torch and power supply, a trailing argon shielding mechanism, a double-wire feeder, and a preheating system.

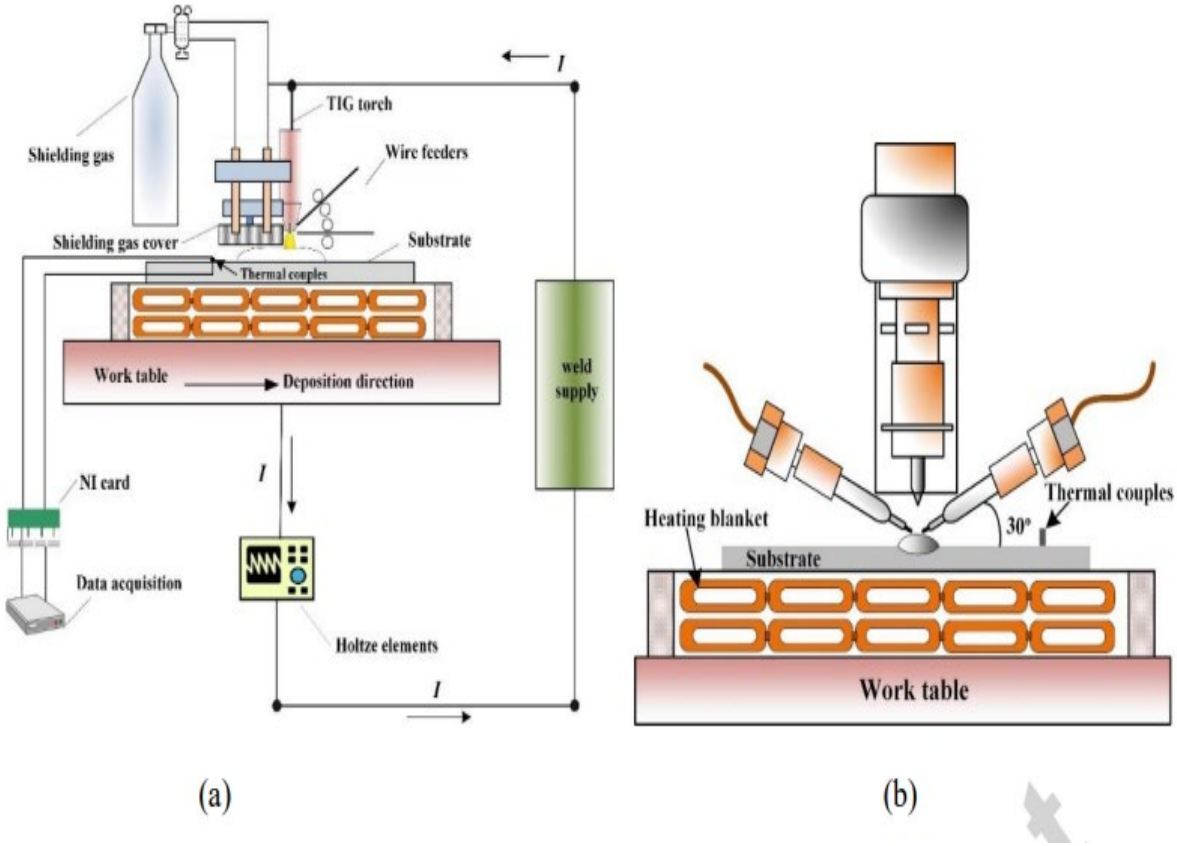

Figure 1 *Schematic diagram of* ***(a)*** *WAAM process* ***(b)*** *Double-wire feeding [5]*

3.2 Methods of fabrication of FGMs:

FGMs' processing methods are broadly categorized into two groups based on constructive processing and mass transport principles [10]. **Figure 2** depicts the various fabrications methods of FGMs. The constructive processing approach involves the deliberate development of gradients in space to build FGMs layer by layer. This approach provides the benefit of generating an infinite amount of gradients. In contrast, within the mass transport category, gradients within components are dependent on natural transport phenomena such as fluid movement, atomic diffusion, or heat conduction. Advancements in automation technology in the last twenty years have made constructive gradation procedures both technologically and economically feasible.

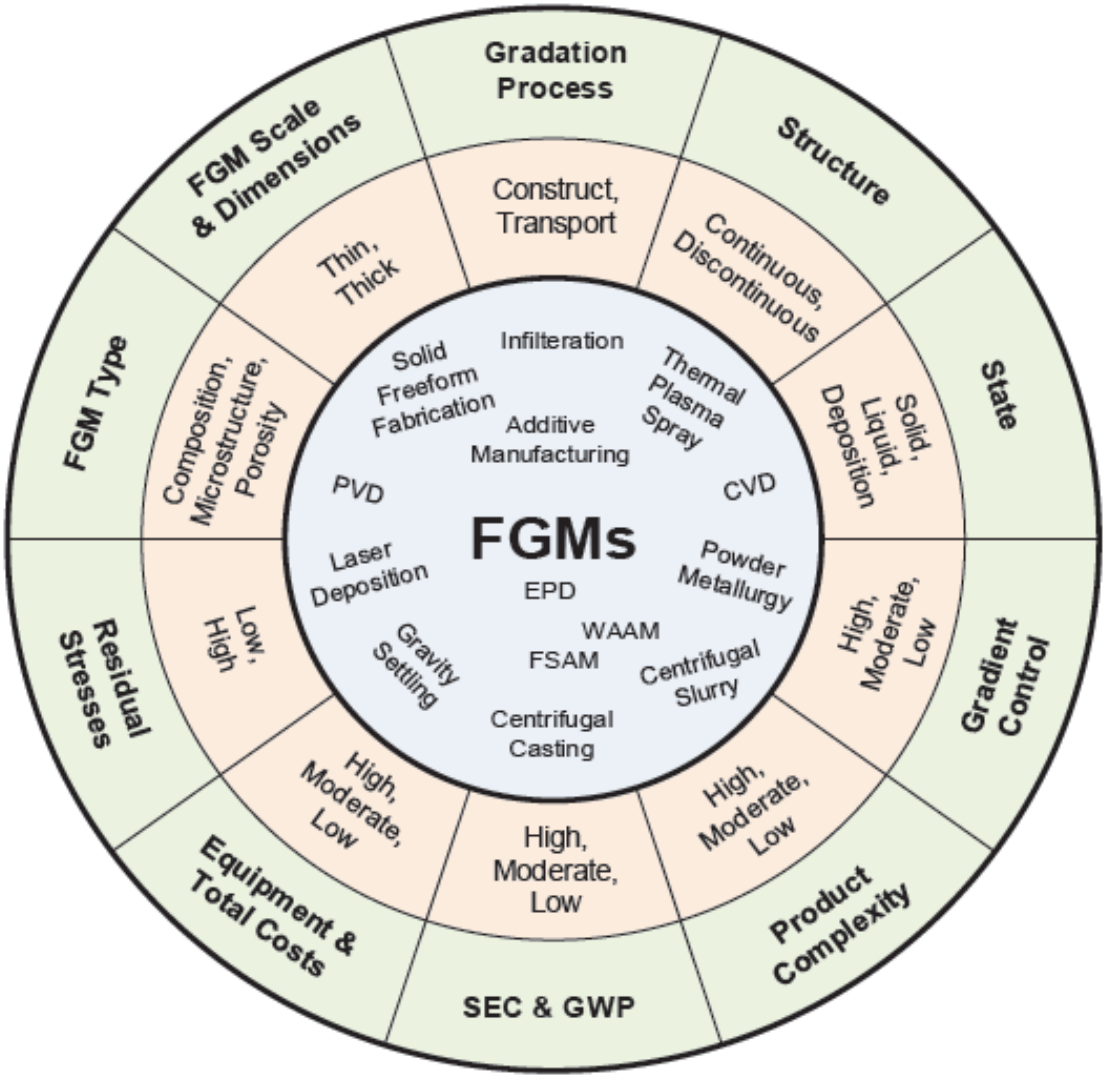

Figure 2. *Methods of fabrication of FGMs [11]*

3.2.1 Vapor deposition technique

There are several vapour deposition (VDT) methods accessible, such as plasma-enhanced CVD, sputter deposition, chemical vapour deposition (CVD), and physical vapour deposition (PVD). Vapour materials are converted to solid solids by condensation, chemical reactions, or other processes during vapour deposition [10-11]. By using these techniques, coatings that modify substrates' mechanical, electrical, thermal, optical, corrosion-resistant, and wear characteristics can be produced. Functionally graded surface coatings, which have good microstructure for thin surface coatings, are deposited using vapour deposition techniques. Although vapour deposition methods consume a lot of energy, they also produce toxic gases as a byproduct.

3.2.2 Centrifugal Casting

Centrifugal casting (CS) utilizes gravitational force by rotating the mold to produce functionally graded material, a technique designed primarily for manufacturing cylindrical parts. Liquid metal is introduced into a rotating mold and allowed to solidify while the rotation persists. The primary advantage of centrifugal casting is its ability to enhance metal density, elevate actual mechanical properties of castings by 10–15%, and ensure a uniform metallurgical structure [2, 10].

Compositional gradients are mainly achieved through variations in centrifugal force arising from differences in density between molten metal and solid particles. Literature suggests there's a limit to the type of gradient that can be produced as it occurs naturally through processes like centrifugal force and density differences.

3.2.3 Powder metallurgy

The powder metallurgy (PM) technique is utilized for producing functionally graded material and involves four fundamental steps: powder preparation, weighing and mixing of powder according to pre-designed spatial distribution, stacking and ramming of premixed powders (forming operations), and finally compacting and forming a solid mass of material (sintering) [1, 11]. Multiple techniques, including chemical processes, electrolytic deposition, grinding, pulverization, atomization, centrifugal disintegration, and solid-state reduction, are used to prepare powders. Accurate measurement of quantities and the even distribution of combined powders are critical factors in powder processing that impact the characteristics of the structure. Forming procedures include compressing powders into certain shapes, usually done at normal ambient temperature. The strength of the compressed, unsintered portion depends on its capacity to be compacted. Sintered parts are produced as a solid mass without visible particle arrangement, although there may be some porosity, which can be reduced through additional processes.

Solid freeform fabrication (SFF) is a leading technology for directly producing physical objects from computer-generated part information. Among its notable applications, fabricating functionally graded materials stands out due to its ability to represent varying material distribution in geometry and control internal component composition. SFF is an additive manufacturing process offering numerous advantages, including higher production speed, lower energy consumption, maximal material utilization, and the ability to produce intricate designs and shapes. Laser-based processes are predominantly employed in SFF for fabricating functionally graded materials.

3.2 Applications of FGMs

In the recent years, the use of functionally gradient materials (FGMs) has grown due to their numerous advantages over composite materials. As functionally graded material to have graded variation in the composition, thus the properties of FGMs changes significantly and continuously from one location to another. This variation in chemical composition resulting in mechanical properties eliminates the interface problems like stress concentrations and poor interfacial bonding.

Nowadays, FGMs have attracted great interest in many fields, especially in some extreme environments, including aerospace engineering, nuclear power generation, marine, sensor, biomedical implants, optoelectronic devices, and absorption systems [1, 11]. **Figure 3** depicts the applications of FGMs in various sectors.

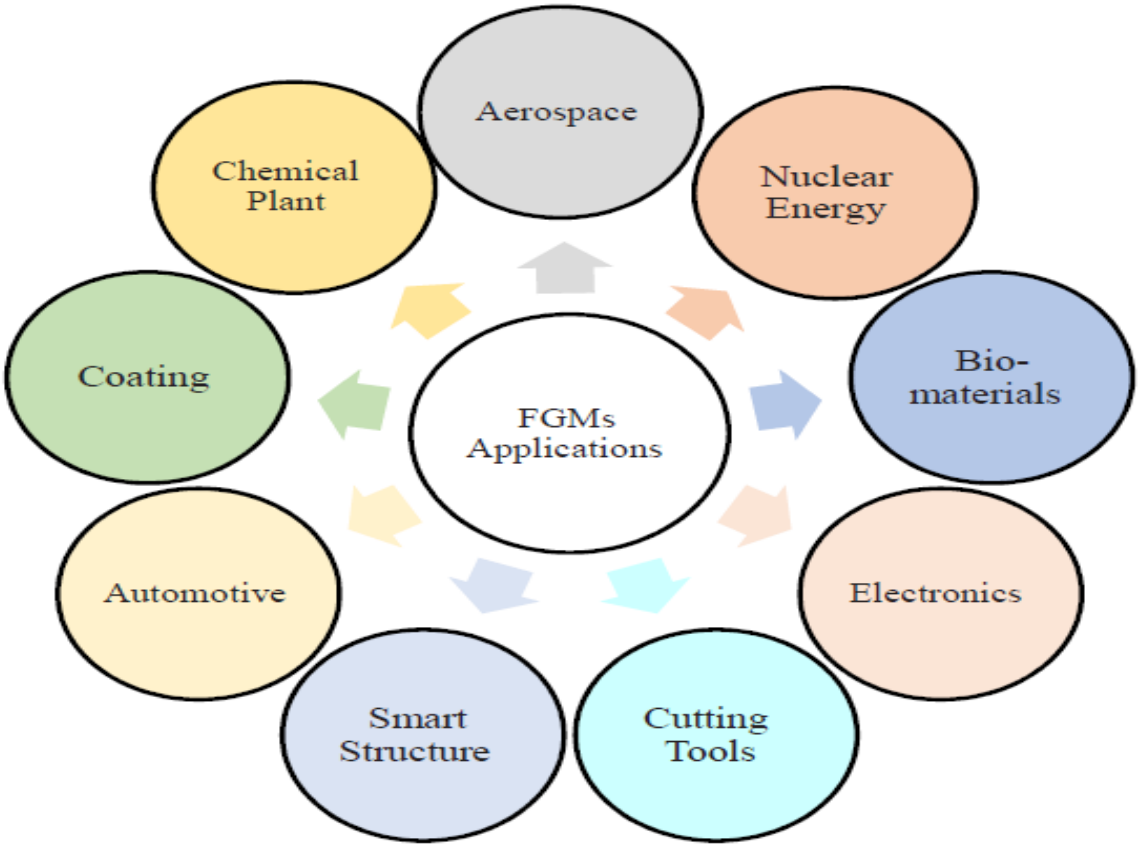

***Figure 3**. Applications of FGMs [11]*

3.2.1 Application in aerospace

Since FGMs reduce thermal tensions between exterior and interior surfaces, their true application began with spacecraft. Nevertheless, because of their many benefits, FGMs have found several additional uses. A rocket engine, the spacecraft gear structure, heat exchange plates, and some structures, like reflectors, solar panels, camera bunks, turbine wheels, turbine blade coating, nose covers, and the front edge of missiles and space shuttles, are among the most common parts of spacecraft and aircraft that currently use FGMs with gradient properties [12, 13].

The FGMs with graded characteristics provide this protection since these components are subjected to high temperatures or intense deterioration in particular places. Engine components and rocket nozzles are made of FG Al2O3/Al alloy, which has great resistance to heat and corrosion. This alloy was developed fairly recently. The manufactured FG polymer–ceramic composites in a different investigation to examine the impact of process variables on the mechanical and microstructure characteristics for use in aircraft [11].

3.2.2 Application in automobile engineering

Numerous vehicle parts require grading in heat, pressure, or stress, including flywheels, driveshafts, combustion chambers, race car brakes, and diesel engine pistons and cylinder liners. FGMs with gradient features are therefore ideal for these components. Furthermore, there is a chance to use FGMs with varying qualities in car body coatings. FGMs are quite expensive, therefore their usage in automotive applications is limited to crucial components of the vehicle [14].

To investigate the influence of graded structure on the microstructure behavior and physical as well as thermal parameters for automotive applications. According to the findings, the graded structure of FGMs improved the mechanical and thermal properties of vehicle brake rotors. A separate study investigated the influence of procedural parameters on the microstructure and mechanical properties of cylinder block liners in automobiles. The results indicated that the properties of FGM composites were superior to those of conventional composites in meeting the requirements of the intended application [15].

3.2.3 Application to fabricate machine parts

Functionally graded materials (FGMs) with graded structures are extensively utilized in manufacturing various engineering components, including cutting tools, forming molds, and machine engine blocks. These materials enhance the strength, thermal performance, and resistance to wear and corrosion of the components. Recently, FG WC/Co and TiCN–WC/Co have been employed in producing cutting tools such as turning tools, grinding and milling cutters, and twist drills. These materials improve surface wear resistance and hardness, thereby extending tool life, increasing feed rates, and reducing machining time [10, 11]. Additionally, FGMs are increasingly used in sports equipment like golf clubs, tennis rackets, and skis due to advancements in additive manufacturing processes. These developments enable the production of FGMs with graded properties, which reduce weight and friction, enhance durability, improve strength-to-weight ratios, and increase hardness and wear resistance.

3.2.4 Application in defense industries

In the defense sector, there is a growing trend to reduce vehicle weight and prevent crack propagation by utilizing functionally graded materials (FGMs). These graded structures are employed as penetration-resistant materials in the production of armor plates, bulletproof vests, and various defensive components such as guide rods, precision rollers, shafts, tubes, latches, axle housings, and firing pins. C. Huang and Y. Chen applied the FGM principle to create lightweight, high-impact-resistant, and cost-effective armor from Al2O3–ZrO2 composites using powder metallurgy. They conducted simulations to validate their experimental findings, demonstrating that FG Al2O3/ZrO2 composites with graded properties offer significant advantages over conventional composites, making them highly promising for defense applications [16].

4. Future scope and research gap

In previous sections, the methods of manufacturing and applications for FGMs were discussed, highlighting their advantages in creating smooth gradations and enhancing mechanical properties and wear resistance. This section addresses the research gaps and future directions for FGMs based on existing literature. FGMs offer significant advantages, making them crucial materials with a promising future. Researchers aim to refine production methods to expand their applications in line with the fourth industrial revolution. FGM processing methods can reduce thermal stresses, control deformation, corrosion, and wear, and enable the manufacture of complex structures with graded properties. However, challenges include mass production, quality control of the graded area, and cost, as well as enhancing production accuracy.

Future recommendations focus on five key areas: materials, processes, and mass production. These trends aim to optimize graded layers, incorporate new materials, refine manufacturing

methods, and expand applications. Particularly, mathematical modeling of FGMs is vital for understanding and predicting their properties. Future development will likely emphasize additive manufacturing to produce cost-effective, high-performance FGMs for automotive, aerospace, and biomedical applications. Despite current use, further research is needed to ensure reliability, especially in applications requiring continuous gradation. Dual gradient and hybrid FGMs via additive manufacturing are expected to be the next advancements.

5. Conclusions

FGMs exhibit graded properties from one point to another in a specific direction, making them an advanced form of conventional composites and it is concluded as:

- FGMs are evolving rapidly due to their superior mechanical and physical properties and that's why it has diverse applications across engineering, defence, petroleum, and transport sectors.
- This review paper explores the manufacturing methods, process parameters, and applications of FGMs. It identifies research gaps and future directions for FGM development.
- Despite recent advancements, certain aspects of FGMs still require further study. The paper outlines challenges and opportunities in the field, providing trends and suggestions for researchers.
- It serves as a comprehensive resource for researchers, academicians, and professionals to understand FGM concepts and complexities.
- The paper details key parameters and development sequences for achieving optimal graded properties. It offers study recommendations for new researchers and benefits all interested in FGM manufacturing, saving time and effort in the research process.

Exploring the dermal safety of green-synthesized Ag–TiO_2 nanocomposites for topical applications†

Archana Rana, *[ab] Shweta Parashar,[c] Diksha Singh,[c] Kavita Singh,[c] Debabrata Chanda,[bc] Anirban Pal,[bc] Ritu Srivastava [ab] and Shailesh Narain Sharma*[d]

We investigated Ag–TiO_2 nanocomposites (NCs) synthesized using leaf extracts of *Azadirachta indica* and *Mangifera indica* for topical applications. The Ag–TiO_2 NCs were first characterized by their spherical shapes, with sizes ranging from 20–26 nm to 5–6 nm, and a zeta potential value between −27 and −23 mV. DLS analysis revealed average particle sizes of 671 nm and 573 nm for Ag–TiO_2 NCs synthesized from *A. indica* and *M. indica*, respectively. The MICs of the nanocomposites were determined *via* dilution in both Gram-positive and Gram-negative bacteria to determine the optimal concentration for dermal applications. The cytotoxicity assay (MTT) of ATN and ATM compounds at MICs of 312.5 μg mL^{-1}, 625 μg mL^{-1}, and 1250 μg mL^{-1} showed that they were nontoxic to fibroblast cells. Further assessments of acute and subacute dermal safety were conducted on Charles Foster rats with NCs applied at 625 μg mL^{-1}, 3125 μg mL^{-1}, and 6250 μg mL^{-1} concentrations. Observations were made for any signs of dermal toxicity using behavioural and physical indices. In acute dermal toxicity, the NCs were applied once, and in subacute dermal toxicity, NCs were applied once daily for 28 days and observed for any sign of dermal toxicity using observation indices like behavioural changes, edema scores, and erythema scores. Post-experiment analyses of body weight, serum biochemistry, oxidative stress, and hematological profiles revealed that the nanocomposites exhibited significant antimicrobial activity. Notably, the safety evaluations indicated no adverse changes, suggesting these NCs are well-tolerated for dermal applications and show great promise for future topical applications.

1. Introduction

Nanomaterials are an emerging technology with various applications in science, particularly in the field of topical formulations. Cosmetic and skin-related products have become an essential part of many people's daily routines owing to growing awareness of the harmful biological effects caused by ultraviolet (UV) radiation, skin allergies and infections. Exposure to the sun can lead to serious issues, such as skin cancer, photoaging, DNA damage, erythema, and increased reactive oxygen species in the skin.[1] In today's world, sunscreens are expertly crafted with UV filters—both organic and inorganic—to provide essential protection against harmful UV radiations. Organic UV filters, such as octocrylene, oxybenzone, and avobenzone, have been on the market for decades. However, they can trigger severe skin allergies due to the accumulation of unwanted substances in the adipose tissue. Conversely, inorganic filters stand out for their remarkable benefits, including broad spectrum protection, exceptional photostability, and a unique whitening effect. These qualities not only enhance their effectiveness but also affirm their safety for all skin types. Available in an array of different forms—oils, lotions, gels, and convenient roll-on applications—these products not only safeguard the skin but also ensure a luxurious, enjoyable experience in the sun.[2] TiO_2 NPs have previously been recognized as an inert material used in the cosmetics industry, and they are considered safe for use on the skin, as authorized by the EU's Scientific Committee on Consumer Safety (SCCS), with a maximum concentration of 25%. This safety is likely owing to the high surface area of TiO_2 NPs, which enhances transparency in visible light while reflecting and scattering UV rays.[3] Thus, while NPs have gained popularity in sunscreen formulations, mounting concerns about their potential toxicity have emerged, sparking ongoing discussions about their safety on human skin.[4] Recent studies have highlighted the remarkable potential of titanium dioxide (TiO_2) and AgNPs, which are traditionally synthesized through a variety of physical and chemical methods involving reducing agents.[5] However, there is a growing interest towards more sustainable and cost-effective approaches—

known as green methods—that not only reduce energy waste but also eliminate the risks associated with toxic substances.

This innovative shift toward green synthesis not only enhances the safety of nanoparticle production, but also unveils the potential for these nanoparticles in medical treatments, owing to the abundance of rich phytochemicals that they harness.[6] This evolution in synthesis techniques promises a more sustainable future for nanotechnology, merging environmental stewardship with cutting-edge medical applications. Green-synthesized NPs have shown remarkable effectiveness in topical applications.

Kwek *et al.* studied the effect of extracted TiO_2 NPs from sunscreens tested *in vitro* and *ex vivo* on human epidermal skin cells, showing lower cytotoxic activity than in the pristine form.[7]

Similar studies have been conducted by Nilavuk Karasi *et al.* to synthesize TiO_2 NPs using *Capparis zeylanica* leaf extract and assess their effect on wound healing in Swiss albino mice. The results demonstrated that a higher dose of TiO_2 NPs concentration exhibited 99% wound healing on the 13th day. The histopathological studies have not shown any side effects, but produced more cells on the epithelium layer.[8] Similar studies have been conducted for heparin–polyvinylalcohol@TiO_2 nanocomposite bandages to treat burn injuries. The incorporation of the TiO_2 NPs porosity, degradation rate, and antimicrobial activity increases the cell viability to enhance the wound healing properties.[9] AgNPs are well known for their strong antimicrobial properties due to their ability to release silver ions, which can bind to and disrupt the cell walls and membranes of bacteria and other microorganisms. AgNPs have been employed as bactericidal agents in hygiene and medical purposes, and increasingly as nanomedicine for treating and cleaning burns and diabetic wounds, as well as for purification of equipment. Studies show AgNPs have antibacterial properties and absorb in the UV range. The current studies revealed that AgNPs protect skin from UVB rays in both mouse models and cell cultures.[10] Green synthesized AgNPs were added to pluronic F-127 hydrogels at different concentrations to study their effect on the wounds of mice. The closure of the wound was confirmed on the 10th day with 95% healing, and the treatment did not observe any skin irritation and can be used as a topical ointment.[11]

Kim *et al.* (2016) studied the dermal and eye toxicity of AgNPs in rats and rabbits and did not observe any sign of erythema, oedema, or irritation effects on the eyes.[12] Recently, some studies have been published by Elatter *et al.* on Ag@TiO_2, and Ag@SeO_2 core/shell NCs synthesized by *Beta vulgaris* L. extract for *R. solani* and *S. sclerotiorum* fungi. The reported values found for Ag@TiO_2 NCs were 314, 624 μg mL^{-1} and 930, 1390 μg mL^{-1}.[13] The studies reveal that Ag@TiO_2 NCs were (one and a half times) more efficacious than Ag@SeO_2 NCs. Citrus lemon leaf extract-mediated AgNPs have been applied as an ointment to treat the wounds of Sprague Dawley rats, and it could be used for the treatment of human wounds.[14] Ag–TiO_2 NCs are composite materials that combine different phases of silver nanoparticles (AgNPs) and titanium dioxide nanoparticles (TiO_2 NPs). These nanocomposites have attracted significant attention due to their unique properties, which are different from those of their components. The AgNPs that occupy the surface of TiO_2 decrease the band gap and increase the photocatalytic properties, and are proposed to be effective nanocomposites in sunscreen.[15] The combination of AgNPs and TiO_2 NPs can lead to synergistic effects, such as enhanced photocatalytic activity, antibacterial properties, and improved electrical conductivity. Ag–TiO_2 NCs have potential applications in various fields, such as water purification, food packaging, and medical devices. They can be used to disinfect surfaces, prevent the growth of bacteria and other microorganisms, and reduce the risk of infections.[16] Ag–TiO_2 NCs@PF-127 HNRs were studied against 4T1 cancer cells, and showed 90% inhibition against the cells at a concentration of 120 mg mL^{-1} under UV radiation.[17]

Despite numerous studies, TiO_2 NPs face several challenges, including high recombination rates of electron–hole pairs, a small band gap energy, and low absorption capacity. To address these issues, researchers have doped TiO_2 NPs with various metal nanoparticles, such as silver (Ag), gold (Au), and iron (Fe). This doping helps to reduce the band gap without compromising the crystallinity of the TiO_2 NPs, and facilitates the diffusion of charge carriers on the surface of the nanoparticles.[18]

The photocatalytic activity of Ag–TiO_2 NPs is enhanced at the interface between Ag and TiO_2 NPs when exposed to UV light. When UV light is present, photoinduced electrons are transferred from the silver nanoparticles (Ag NPs) to the titanium dioxide nanoparticles TiO_2 NPs, increasing their photocatalytic activity. The electrons that accumulate on the surface of the TiO_2 NPs react with oxygen or other molecules to produce superoxide radicals. Additionally, the holes generated during this process can oxidize hydroxyl groups (–OH) or water (H_2O) to create powerful oxidizing radicals, such as hydroxyl radicals ($^{\bullet}OH$). Moreover, TiO_2 NPs can be oxidized by these strong oxidizing radicals ($^{\bullet}OH$), resulting in the production of carbon dioxide CO_2 and several other oxidized intermediates.[19] The integration of AgNPs into TiO_2 NPs significantly diminishes the recombination of e^-/h^+ pairs, ultimately extending the lifespan of Ag–TiO_2 NCs. This remarkable enhancement owes its effectiveness to the captivating surface plasmon effect of AgNPs, which facilitates the transport of electrons from TiO_2 NPs to AgNPs.[20] Inorganic NPs (sunblock) were measured with SPF to reduce the erythema after evaluating the rate of absorption, toxicology, and skin reactions on human skin.[21] Recent studies on Ag/TiO_2 NPs (400 μg mL^{-1}) reveal that, when combined with blue light, there is a 42.79% reduction in cell viability in the A431 skin cancer cell line after 45 minutes, compared to using nanoparticles and light separately.[22] Ag-doped TiO_2 NPs studied on human cancer (liver) cell lines showed better results with the addition of AgNPs, as it only focused on destroying cancer cells.[23] Several studies show that TiO_2 NPs reduce the release of AgNPs, enhancing antimicrobial activity and decreasing health problems and pollution. It is highly used as a hydrogel for wound dressing, cosmetics, antimicrobial agents and semiconductors. These well-known studies promote for skin repairment and wound healing which indicate harmless process to human usage proved *via in vivo* and *in vitro*.[24]

In this study, we synthesized green Ag–TiO_2 NCs using extracts from medicinal plants, specifically *Azadirachta indica* (*A. indica*, also known as neem) and *Mangifera indica* (*M. indica*,

Open Access Article. Published on 27 March 2025. Downloaded on 4/8/2025 6:43:27 AM. This article is licensed under a Creative Commons Attribution-NonCommercial 3.0 Unported Licence.

as mango in India), which are commonly found in Asian countries. The synthesized Ag–TiO_2 NCs were assessed for their effects on the cytotoxicity assay (MTT) fibroblast cell line. They were determined to be nontoxic at concentrations up to twice the minimum inhibitory concentration (MIC). Additionally, the sub-acute toxicity of Ag–TiO_2 NCs—derived from *A. indica* (ATN = Ag–TiO_2 neem) and *M. indica* (ATM = Ag–TiO_2 mango) extracts—was safe at levels up to five times the MIC. This research paper presents novel findings on the dermal toxicity of Ag–TiO_2 NCs in CF rats, which have not been previously published.

2. Experimental methods and materials

2.1. Materials

A. indica and *M. indica* leaves were collected from the campus of NPL (National Physical Laboratory), New Delhi, India. The precursors used for synthesis include titanium isopropoxide [$Ti(OC_3H_7)_4$], silver nitrate ($AgNO_3$), iodo-nitrotetrazolium bromide and nutrient broth, which were purchased from Sigma-Aldrich chemicals. The microbial strains (*Staphylococcus aureus* MTCC 96, *Staphylococcus hominis* MTCC 657, *Escherichia coli* MTCC 8739, *Salmonella typhimurium* (MTCC 3232) and *Candida albicans* MTCC 183) were procured from Microbial Type Culture Collection (MTCC), Chandigarh, India.

2.2. Preparation of plant extract

The collected leaves of *A. indica* and *M. indica* were appropriately cleaned under tap water to eliminate dust residue. 30 g of each plant (*A. indica* and *M. indica*) leaves were used to prepare the leaf extract using 100 mL of deionized water, and the mixture was heated at 80 °C for 40 min. The reaction mixture was then filtered using Whatman no. 1 filter paper after cooling to room temperature, and stored at 4 °C.

2.3. Synthesis of Ag–TiO_2 NCs using *A. indica* and *M. indica* leaves extract

The green synthesis of Ag–TiO_2 NCs, followed by precursors (0.2 M) titanium(IV) isopropoxide (TTIP–Ti[$OCH(CH_3)_2]_4$) in 30 mL deionized water, was placed in a round-bottom flask stirred at 70 °C for 20 min. Thereafter, 3 mM silver nitrate ($AgNO_3$) solution with 30 mL of leaves extract of *A. indica* and *M. indica* was added slowly to the round-bottom flask with continuous stirring at 70 °C, following the protocol reported by Bhardwaj *et al.*[25] Slowly, the colour of the reaction mixture changed into a light grey color (could be due to the surface plasmon resonance), which indicates the formation of Ag–TiO_2 NCs. The reaction mixture of the NCs solution was centrifuged at 4000 rpm for 30 min to separate the suspended particles. Furthermore, the NCs particles were washed twice with deionized water to remove the extra product. The collected NCs were then dried overnight at 70 °C in the oven. The resulting Ag–TiO_2 NCs were annealed at 400 °C for 2 h to enhance their crystallinity. A schematic of the synthesis of Ag–TiO_2 NCs is shown in Fig. 1(a). Furthermore, the mechanism of Ag–TiO_2 NCs using plant extract is shown in Fig. 1(b). The TTIP reaction with D.I. water produces unstable $Ti(OH)_4$, which is further converted into TiO_2 through the condensation process. The hydroxyl group of phytochemicals (such as ascorbic acid, quercetin, nimbin, benzoic acid propyl ester) is attached to the surface of TiO_2 after the addition of the plant leaf extract. The addition of AgNPs on the surface of TiO_2 NCs is achieved through hydrogen bonding of the OH group of phytochemicals.

2.4. Structural and morphological characterization

Ag–TiO_2 NCs synthesized using plant leaf extract of *A. indica* and *M. indica* were characterized using Raman, SEM, XRD, FTIR, TEM, and UV-vis analysis. XRD (X-ray diffraction) patterns were recorded using a Bruker D-8 Advance X-ray Diffractometer instrument with Cu Kα with $\lambda = 1.54059$ Å, employing a scanning rate of 0.05° s^{-1} in the 2θ range from 10° to 80°. The

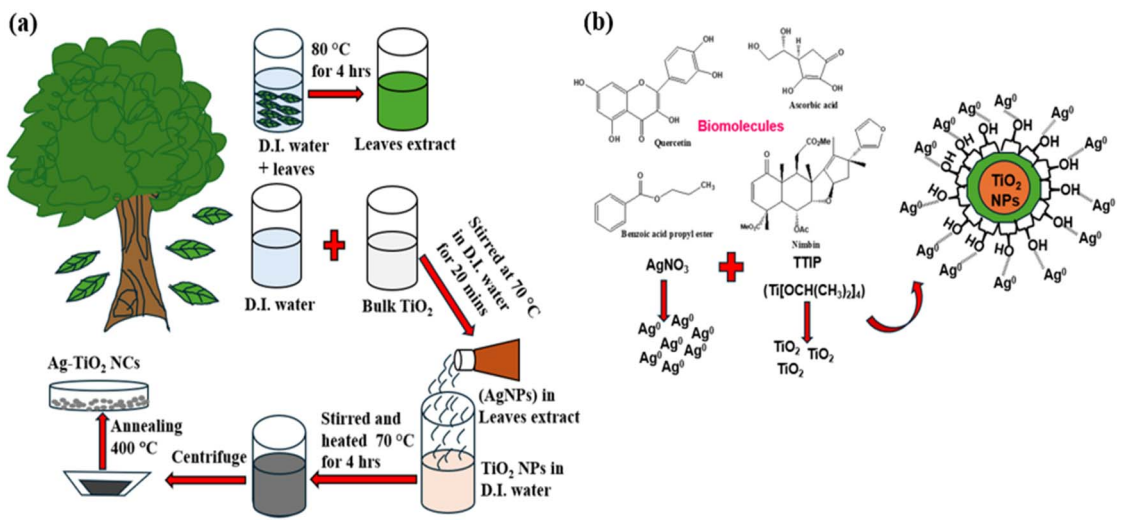

Fig. 1 Schematic of (a) the proposed green synthesis route of Ag–TiO_2 NCs using *A. indica* and *M. indica* leaf extracts and (b) mechanism of Ag–TiO_2 NCs.

absorbance of NCs between 200–800 nm was measured using a UV-vis spectrophotometer (Shimadzu UV-3101). The bandgap energy (E_g) of the NCs obtained may be determined using the following equation:

$$E_g = 1240/\lambda \text{ eV} \quad (1)$$

λ = wavelength (nm) and E_g = band gap (eV).

The powder sample was characterized using Fourier-transform infrared (FTIR) spectra (PerkinElmer FTIR spectrum BX-II analyzer) to investigate the functional groups, which were recorded in the 4000–400 cm^{-1} region.

Raman spectroscopy of NCs was performed using laser excitation at 514.5 nm with an argon ion laser power of approximately 80–100 mW.

The Malvern Panalytical equipment was used to test the stability and hydrodynamic diameter of spherical NCs using dynamic light scattering (DLS). The particle size was estimated using a Malvern (1062761) Zetasizer at 25 °C with a cuvette of 2 mm in an aqueous solution. The biochemical and oxidative stress values were calculated through SpectraMax Plus (384) instrument.

The size and shape of the NPs were assessed using a TEM (Transmission Electron Microscope) instrument from Jeol Ltd [Tokyo, Japan] with an acceleration voltage of 100 kV. The NCs for the TEM investigation were ultrasonicated for 15 minutes before mounting onto a copper grid with carbon coating to dry in the air. The shape of the NCs were studied using a SEM (scanning electron transmission) and EDAX instrument (ZEISS instrument).

2.5. Antimicrobial activities

The Ag and TiO_2 NPs have been studied separately using similar plants and methods for antimicrobial activities on plant pathogens using the disc diffusion method. AgNPs were synthesized using *A. indica* and *M. indica* leaf extract with plant pathogens showing a zone of inhibition of 21 mm (*A. rolfsii* fungi) and 17 mm (*X. oryzae* bacteria) *via* the zone of inhibition disc diffusion method.[26] Similarly, TiO_2 NPs were also synthesized using the same plants and studied against plant pathogens, such as *A. alternata*, *C. gloeosporioides*, *T. harzianum* and *A. rolfsii* fungi and *X. oryzae* as bacteria using the disc diffusion method. Studies on the non-linear optical properties (absorption and refractive index) were also calculated through the Z-scan method.[27] In the current study of Ag–TiO_2 (*A. indica* and *M. indica*), the broth dilution method MIC was performed. Quantitative estimation of microbial growth inhibition by samples was observed by the micro broth dilution assay using 96 well 'U' bottom microtitre plates, as mentioned by Srivastava *et al.*[28] The method employs a two-fold serial dilution technique to assess any given antimicrobial's MIC (Minimum Inhibitory Concentration) under testing. The MIC of the test sample is considered as the concentration at which no colour change is observed, starting from the highest to lowest dilution after incubation of the microtiter plates.

Nutrient broth (100 μL) medium was added to all wells. 100 μL of the sample was added to the first well at a concentration of 5000 mg mL^{-1} diluted with broth medium. The solution was mixed by continuous pipetting (up to 5–6 times) and then transferred 100 μL from the 1st well into the 2nd well. It was serially diluted (2-fold dilution) up to the 10th well for testing as an antimicrobial agent. The schematic of the antimicrobial activity is shown in Fig. 2.

The working inoculum was prepared by diluting 1 mL of the overnight grown culture with 19 mL of sterile broth to achieve a (CFU) of 1×10^6 cfu mL^{-1}. To each well was added 100 μL of this working inoculum, except for the negative control. Column 11 was used for the negative (sterility) control, and column 12 was used for plate sterility with only nutrient broth. After 18 h incubation at 37 °C, plates were evaluated by adding 50 μL of iodo-nitrotetrazolium bromide (stock-1 mg mL^{-1}) dye to achieve a final concentration of 0.02 mg mL^{-1}. The well exhibiting no growth in each row corresponded to that antimicrobial agent's MIC (μg mL^{-1}). The MIC values (μg mL^{-1}) recorded in this study are the mean of three experiments performed in replicates.

3. Cytotoxicity assay (MTT) of ATN and ATM in the fibroblast cell line

3.1. Principle

In 1983, Mosmann introduced the MTT assay, a standard method for assessing cell viability and cytotoxicity. This assay is based on the ability of living cells to reduce yellow tetrazolium salt (MTT) into purple formazan crystals, primarily through the activity of mitochondrial dehydrogenases. Enzymes located in other organelles, such as the endoplasmic reticulum, also play a role in this reduction.[29] Once MTT is taken up by live cells *via* endocytosis, it is metabolized and converted into insoluble formazan crystals, which are transported back to the cell surface, forming needle-like structures. These insoluble crystals are then dissolved using a solubilizing agent, such as DMSO, acidified ethanol, or SDS in diluted hydrochloric acid. The resulting solution is measured using a spectrophotometer at 570 nm to determine the level of cell viability.

3.2. Method

Fibroblast cell lines were cultured in a growth medium (DMEM with 10% heat-inactivated fetal bovine serum), and seeded at a density of 0.5×10^4 cells per well in a 96-well plate. These cells were allowed to adhere overnight at 37 °C in a 5% CO_2 incubator. Following attachment, the cells were treated with ATN and ATM at concentrations of (312.5 μg mL^{-1} (1/2× of MIC), 625 μg mL^{-1} (1× of MIC), and 1250 μg mL^{-1} (2× of MIC)), along with the vehicle control (DMSO), for 12 hours in a culture medium supplemented with 1% serum. After the treatment, 20 μL of MTT solution (prepared from a 5 mg mL^{-1} stock in PBS, 12 mM MTT) was added to each well and incubated for 4 hours. The MTT-containing medium was then carefully removed, and the formed formazan crystals were solubilized in 100 μL of DMSO for 10 minutes, resulting in a blue-coloured solution. Cell viability was assessed by measuring the absorbance of the formazan solution at 570 nm using a spectrophotometer. The

intensity of the color was directly proportional to the cell viability, and the viability was expressed as the percentage of survival. Each test was performed with ($n = 4$), and the data were presented as the mean ± SEM ($n = 4$).

4. Mixing of Ag–TiO_2 NCs (*A. indica* and *M. indica*) in sesame oil

Ag–TiO_2 NCs (*A. indica* and *M. indica*) having proven MIC were considered for evaluation of dermal toxicity and were accurately weighed. The MIC (μg mL^{-1}) was considered as × and in dermal toxicity, we have chosen 1×, 5×, and 10× concentrations for our study after suspending the NCs in sesame oil.

4.1. *In vivo* dermal toxicity

Animal studies were carried out according to protocols approved by the Institutional Animal Ethics Committee (IAEC) for Animal Facility, CSIR-CIMAP, Lucknow, UP, India (CIMAP/IAEC/2020-23/22), following the recommendations of the OECD test guidelines for dermal toxicity and FHSA regulations. Before commencing the study, the animals were familiarized with the experimental condition for one complete week (22 °C and a 12 hour dark/light cycle). The animals were given adequate rat feed and drinking water *ad libitum*. In acute dermal toxicity, 8 male and 8 female Charles Foster rats were taken. Following a week of acclimatisation, the animals were divided into 4 groups each with 2 male and 2 female rats (to obtain 8 spots of 1 square inch for the dermal application in each group). The lateral side of the abdominal region was clipped of hair and cleanly shaven with a marked area of a square inch on each side of the rats for applications of the NCs. Group 1 was considered as control, whereas groups 2 through 4 were considered the experimental groups, and were treated with the NCs at 1×, 5×, and 10× of MIC of the NCs. A similar grouping of animals and application procedure of NCs was followed for assessing the sub-acute dermal toxicity, wherein the test substance was applied once daily for 28 days.

4.2. Acute and subacute dermal toxicity

Ag–TiO_2 NCs were used at 1×, 5×, and 10× of MIC to evaluate the toxicity of the NPs. Ag–TiO_2 NCs were solubilized in sesame oil and applied on the marked area of the skin of the CF rats. We observed the animals for 24 hours, while archiving the images of the treated. We determined edema and erythema scores, and calculated the primary irritation index as reported previously.[30]

We performed the sub-acute dermal toxicity tests to determine the adverse effects of Ag–TiO_2 NCs upon repeated dermal exposure to rats. We gave 1×, 5×, and 10× of MIC to the animals for 28 days repeatedly in the marked area of the skin. We took a picture of the marked area before the application of the nanoparticle on day 0. After applying the NCs, the images of the marked area were collected once every 3 days. Animals were regularly monitored for any development of edema and erythema. The irritation index and primary irritation index were calculated for the experimental period of 28 days at 3 day intervals. We shaved the animal twice a week to remove the hairs for the application of the compound until the completion of the experiment. On the 28th day of the experiment, we recorded the body weight of the animals and collected blood from the retro-orbital plexus for biochemistry and hematology. The animals were then sacrificed under high-dose anesthesia (a combination of ketamine at 80 mg kg^{-1} and xylazine at 20 mg kg^{-1} given through the i.p. route), and vital organs like the lung, liver, heart, kidney, spleen, and brain were collected, inspected, and weights were recorded and expressed as absolute and relative organ weight.[31]

4.3. Statistical analysis

Hematological, biochemical, and oxidative stress data were analyzed using statistical calculation in Excel. For these parameters, the data are presented as mean ± standard deviation. The relevant significance level was determined at ($P \leq 0.05$) as applicable. Two-way ANOVA tests were used to examine the differences in the data collected from the groups and evaluate the measurements. We performed all of the experiments in triplicates, and expressed the data as mean ± SEM. Two-way ANOVA was used to calculate the *p*-value.

5. Results and discussion

5.1. Crystallographic structure

XRD was used to determine the crystal structures and phases present in the NCs. In the XRD pattern of Ag–TiO_2 NCs, the peaks observed in the pattern correspond to the diffraction of X-rays by the atoms in the crystal lattice of the NPs. The XRD pattern of silver–TiO_2 NCs shows peaks that correspond to both the silver and TiO_2 phases. In the XRD pattern of the silver–TiO_2 nanocomposites, the peak positions and intensities can provide information about the crystallite size, crystal structure, and composition of the NPs. The XRD pattern of Ag–TiO_2 NC (*A. indica* and *M. indica*) samples is shown in Fig. 3(a). The diffraction peaks at 2θ angles (with corresponding planes) at 25.3° (101), 48.05° (200), 53.9° (105), 55.06° (211), 62.4° (204), 68.76° (220), 70.3° (116), and 75.06° (215), respectively, are attributed to the anatase phase of TiO_2 NPs (JCPDS card no. 21-1272). The XRD pattern of Ag–TiO_2 NCs shows the characteristic peak of Ag at 2θ of 32.3° (111), and 37.9° (004) (JCPDS no. 04-0784).[32] In the sample containing both Ag and TiO_2, the diffraction band of the Ti (004) lattice plane appears at an angle of 37.9°, which is high enough to overlap with the (111) characteristics peak of Ag.[33,34] The XRD pattern in the present study indicates that the dual phases of Ag–TiO_2 NCs have been confirmed by the Ag NPs that were deposited on the surface of the TiO_2 particles. The crystallite size of Ag–TiO_2 NCs (*A. indica* and *M. indica*) was calculated using the Scherrer equation, where β = full width at half maximum, θ = diffraction angle at peak position, and λ = wavelength of X-ray radiation.

$$D = \frac{0.94\lambda}{\beta \cos \theta} \quad (2)$$

Open Access Article. Published on 27 March 2025. Downloaded on 4/8/2025 6:43:27 AM. This article is licensed under a Creative Commons Attribution-NonCommercial 3.0 Unported Licence.

The crystallite size for Ag–TiO_2 NCs was calculated as 7.23 nm and 7.9 nm at 400 °C annealing. Additionally, the XRD pattern exhibits the presence of AgNPs in NCs without coinciding with other peaks of TiO_2 NPs. The high crystalline nature of Ag–TiO_2 NCs is demonstrated by the presence of strong peaks in the data. The XRD pattern shows distinct diffraction peaks of Ag and TiO_2 phases for both samples, with the absence of any other peaks. The characterizations mentioned in the current paper have been studied only for Ag–TiO_2 NCs, whereas the characterization and results for Ag and TiO_2 NPs synthesized using the same plant extracts have been reported earlier for agricultural applications.[26,27]

5.2. Optical properties

The two main UV-vis absorption spectra of Ag–TiO_2 NCs (*A. indica* and *M. indica*) are shown in Fig. 3(b). The absorption bands are related to the electronic transitions in the NPs, which are affected by the size, morphology, and composition of the NPs. The first absorption band in the UV region is associated with the TiO_2 NPs' electronic transitions with a blue shift of 253 and 250 nm (*A. indica* and *M. indica*), which could be due to the AgNPs deposited on the surface of TiO_2 NPs.[35] The second absorption band in the visible region (redshift) is due to the SPR (Surface Plasmon Resonance) of the AgNPs observed at 460 and 468 nm (*A. indica* and *M. indica*).[36] The SPR band of AgNPs observed on the surface of TiO_2 significantly affected the absorption in the visible area of 450–550 nm, and the absorption edge also changes to the visible region for Ag–TiO_2 NCs.[37] The SPR band depends on the size, shape, and concentration of the AgNPs. Ag–TiO_2 NCs (*A. indica* and *M. indica*) was studied in the wavelength range of 200–600 nm. Furthermore, the significant shift in the dielectric property of the surrounding medium marked by the presence of AgNPs was also assigned to these improvements in the optical absorption of the Ag/TiO_2 NCs.[38]

5.3. Raman spectra

Raman spectroscopy is known as an incredibly effectual technique for detecting the vibrational modes of chemical bonds, and can precisely pinpoint the specific crystalline state of materials. In this study, we used this technique to study the Raman spectra of Ag–TiO_2 NCs in the frequency range of 150–800 cm^{-1}, shown in Fig. 3(c). The robust and intense peaks observed at 147 cm^{-1} (E_g (1)) and 199 cm^{-1} (E_g (2)) are optical modes of the anatase phase of TiO_2. The band located at 398 cm^{-1} (B_{1g}), 515 cm^{-1} (A_{1g}), and 641 cm^{-1} (A_{1g}/B_{1g}) assumed a low-frequency shift, corresponding to the LO-phonon in Ag–TiO_2 NCs. For Ag–TiO_2 NCs, all the Raman bands observed were for TiO_2, and the absence of an active band for Ag was due to the crystal symmetry of Ag.[39] However, the oscillations in the Raman spectra could be due to the oxygen atoms further changing the coordination environment of oxygen with the Ti^{4+} atom. Adding Ag atoms to the lattice of TiO_2 to maintain neutrality creates oxygen vacancies and forms Ag–O–Ti NCs.[40] The broadening of the peaks could be possibly attributed to the vibrational amplitudes and particle size.[41]

5.4. Evaluation of functional groups

The FTIR spectrum of Ag–TiO_2 NCs (*A. indica* and *M. indica*) shows the characteristic peaks of fundamental vibrations caused by N–H, O–H, and C–H stretching, measured in the 4000–2500 cm^{-1} range. The stretching vibrations for the absorbed –OH group of water molecules were observed at 3400 cm^{-1}. The C=C and C=O double bonds stretching vibrations are ascribed to the regions 2500–1500 cm^{-1}. The Ti–O–Ti bond stretching vibrations have been identified in the 700–500 cm^{-1} range. The peaks identified at 1287 and 1277 cm^{-1} represent the presence of Ag–O–Ti, which depicts the formation of NCs in Fig. 3(d).[42] The weak peaks observed for TiO_2 NPs were assigned to the lattice vibration range of 1380–1277 cm^{-1}. The Ti stretching vibrations were observed with a prominent peak at 1023 cm^{-1}.

5.5. DLS and zeta potential analysis

Dynamic light scattering is known for detecting the particle size distribution and zeta potential of aqueous nanocomposites of Ag–TiO_2 NCs (*A. indica* and *M. indica*) were determined using dynamic light scattering and a zeta sizer. Typically, the sample is dispersed in a suitable solvent and passed through a laser beam. The scattered light is then detected and analyzed to assess the size of the NPs in the sample. The size of Ag–TiO_2 NCs can vary depending on the synthesis method and the ratio of silver to titanium dioxide. It is important to note that DLS analysis can provide information about the hydrodynamic diameter of the NPs, which can be different from the actual size of the particles measured by TEM. It may be because the NPs are surrounded by a layer of solvent molecules, affecting their size and mobility. The average particle sizes of Ag–TiO_2 NCs (*A. indica* and *M. indica*) were 671 and 573 nm, respectively, as shown in Fig. 4(a) and (b). According to these findings, the presence of AgNPs on the surface of TiO_2 particles may prevent agglomeration.[43]

The zeta potential of these NCs refers to the electric charge that might be present on their surface, which affects their stability and dispersion in a liquid medium. The zeta potential of silver–TiO_2 NCs depends on various factors, such as the size and concentration of the NPs, the pH of the medium, and the presence of other ions. Typically, the zeta potential of these NCs is negative, indicating a repulsive force between them, preventing agglomeration or aggregation of the NPs. A high negative zeta potential is desirable for the stability of the nanocomposites in a liquid medium. The zeta potentials of Ag–TiO_2 NCs (*A. indica* and *M. indica*) were calculated as −27 mV and −23 mV, as shown in Fig. 4(c) and (d).

5.6. Morphological studies (TEM analysis)

The morphology and structure of Ag–TiO_2 NCs were analyzed using TEM, HRTEM and SAED, as shown in Fig. 5(a) and (b), to obtain more details of Ag–TiO_2 NCs (*A. indica* and *M. indica*). The TEM images demonstrate the mesoporous structure and explain the agglomeration of NCs. The TEM analysis of the TiO_2 NPs exhibited averaged particle sizes of 20–26 nm, which were made

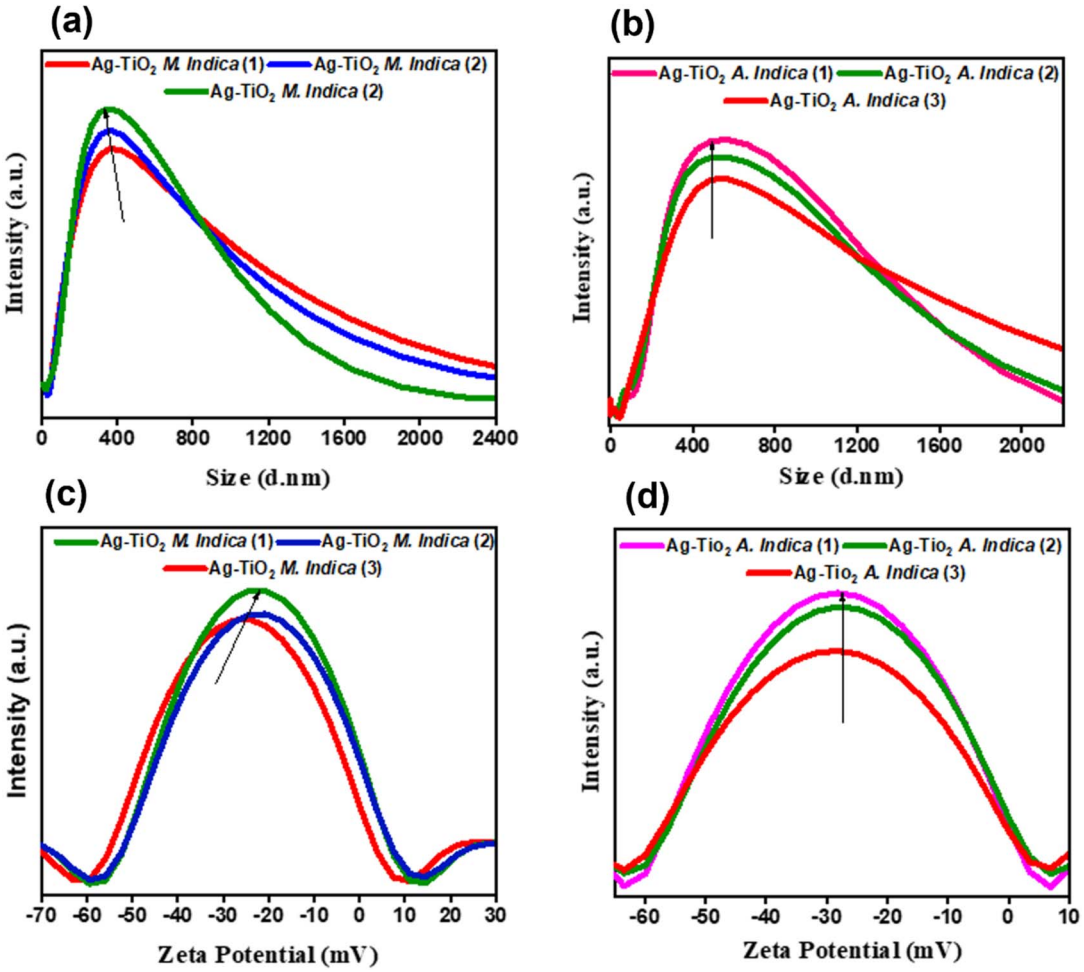

Fig. 4 (a and b) Dynamic light scattering and *Z*-average hydrodynamic diameter of Ag–TiO_2 NCs (*A. indica* and *M. indica*), (c and d) zeta potential measurements for Ag–TiO_2 NCs synthesized using *A. indica* and *M. indica* leaf extracts.

up of small-sized anatase crystallite-size NPs. Similar TiO_2 NPs have already been reported in our previous research paper.[28]

The small particles ranging from 5–8 nm for Ag NPs agree well with the XRD and UV results. The AgNPs were eventually distributed and arranged on the surface of the TiO_2 crystalline particles. The high-resolution TEM (HRTEM) images reveal that the lattice fringes of Ag have a plane spacing of 0.214 nm and 0.209 nm, which matches well with the (200) lattice distance, and the plane spacing of TiO_2 (anatase phase) is about 0.357 and 0.351 nm, which corresponds to the (101) plane, as shown in Fig. 5(c) and (d). These HRTEM parameters agreed with the X-ray diffraction (XRD) spectra. A SAED pattern of Ag–TiO_2 NCs (*A. indica* and *M. indica*) shows the polycrystalline nature of NCs. The observed rings in Fig. 5(e) and (f) are assigned to the (111), (004), (101), (200), and (211) planes of Ag and TiO_2 NPs.

5.7. SEM and EDAX analysis

The particle shape of green synthesized Ag–TiO_2 NCs were studied by SEM analysis which observed the spherical shape of both Ag and TiO_2 NCs. These images show agglomeration (minimum surface free energy) of the particles that exhibit a non-uniform particle distribution Fig. 6(a) and (b). These nanocomposites reported large surface areas, which makes them applicable for nano-medicine applications and also have more catalytic active sites. The elemental composition of Ag–TiO_2 NCs was determined by EDAX analysis and confirmed the presence of Ag (silver), Ti (titanium), and O (oxygen), as shown in Fig. 6(a) and (b).

5.8. Antimicrobial activity and determination of MIC of Ag–TiO_2 NCs

The minimum inhibitory concentration of Ag–TiO_2 NCs (*A. indica* and *M. indica*) against *Escherichia coli* and *Staphylococcus aureus* is tabulated below. Both Ag–TiO_2 NCs (*A. Indica* and *M. Indica*) with a MIC <2500 μg mL^{-1} were considered for testing against two Gram-positive bacteria (*S. aureus* & *S. hominins*), two Gram-negative bacteria (*E. coli* & *S. typhimurium*) and yeast (*C. albicans*). These NCs were active with the concentration (MIC <2500 μg mL^{-1}) against the mentioned microbes shown in Table 1. Based on the spectrum of the pathogens and the MIC, the activity is best in Ag–TiO_2 NCs (*A. indica*) compared to Ag–TiO_2 NCs (*A. indica*).

6. *In vitro* cytotoxicity of ATN and ATM in rat fibroblast cells

We evaluated the effect of ATN and ATM on the cytotoxicity and cell viability at three different concentrations (1/2×, 1×, and 2× of MIC) using the MTT assay in fibroblast cells. The results show that ATN and ATM did not affect the cell viability at any of the given concentrations, for up to 2× of MIC, as represented in Fig. 7(a) and (b). This suggests that ATN and ATM are non-toxic to fibroblast cells at the evaluated concentration of 2× of MIC.

7. Acute and sub-acute dermal toxicity

Based on the above performed antimicrobial tests, we chose 1×, 5× and 10× of MIC, *i.e.*, (625 μg mL^{-1}, 3125 μg mL^{-1} and 6250 μg mL^{-1}) for dermal toxicity. We observed that acute and sub-dermal toxicity testing of Ag–TiO_2 (*A. indica* and *M. indica*) NCs at up to 10× MIC in the CF rats did not cause any significant edema and erythema in the treated skin area in acute and sub-acute dermal toxicity (ESI: Fig. S1b.† Images of acute) (ESI: Fig. S1b.† Images of sub-acute). The erythema and edema in skin responses are each rated on a 0–4 scale individually. The irritation index was used to calculate the sum of the scores for erythema and edema. The primary irritation was calculated for each dose as the difference between the irritation index test site and control site, as reported by Kojic *et al.*[44] There was no sign of irritation and primary irritation index. These results show that Ag–TiO_2 is safe for short-term usage at up to 10× MIC. There was no significant skin damage or irritation, even with the compound used reputedly for 28 days. There was no significant behavioural change observed throughout the experiment.

7.1. Behavioural changes

The results from Ag–TiO_2 NCs (*A. indica* and *M. indica*) upon dermal application to CF rats are presented in Tables 2–5. The rats did not exhibit any significant behavioural abnormalities, skin effects, respiratory issues, difficulties in consuming food, or water, hair loss, or posture alignment.

7.2. Haematological, serum biochemical parameters and oxidative stress

The haematological profile was performed to understand whether the compound was causing any abnormalities. There were no significant changes observed in the total body weight, RBC, and WBC counts, as shown in Fig. S2(a) and (b).† Serum biochemistry also showed no substantial changes in the treated animals compared to the control. The cholesterol level, serum albumin, total serum protein, triglycerides, *etc.*, were comparable with the control group shown in S1, Tables 1 and 2.† No significant ($p > 0.05$) changes were observed in the biochemical parameters.

Nanomaterials are a developing technology with applications in science, and nanostructures are important tools within different areas of the field. However, there are various health hazards and environmental issues with chemically and physically synthesized NPs, and they are very expensive. A wide range of research has been carried out, and an alternative method has evolved, *i.e.*, green synthesis of the NCs. Medicinal plants are usually considered safe due to their natural occurrences. However, the toxicity and adverse effects of medicinal plant-based nanomaterials or composites need to be studied for regulatory clearances and their industrial application. Hence, we felt it was compulsory to perform *in vivo* dermal safety evaluation experiments for industrial uses to provide proven scientific evidence. Nowadays, dermal care products are gaining attention as individuals are showing greater interest in them. To present scientific evidence on environmental and health safety problems, this research incorporates both technical and societal difficulties.[45]

Nanomaterials have been studied *via* inhalation and oral and dermal routes based on biomedical needs.[46] Due to the unpredictability and ease of NCs exposure in typical applications, the dermal exposure route was selected amidst the possibilities.[47] AgNPs are being utilized in cosmetic consumer products, have the highest level of commercialization, and are employed in 30% of items that contain nanomaterials.[48]

The skin of rats was sensitized for 28 days, but no erythema or edema were observed (Tables 2 and 3). PII was also between 0–1, which means that the prepared $AgTiO_2$ NCs is safe to use in cosmetics for a short period (Tables 4 and 5). Acute and sub-acute toxicity help us to understand the toxic behaviour of compounds, and help to evaluate the morphological and physiological changes in the body.

For the acute toxicity test, Ag–TiO_2 NCs were left on rat's skin with different concentrations (625 mg mL^{-1} (1×), 3125 mg mL^{-1} (5×), and 6250 mg mL^{-1} (10×)) for 24 h, and there were

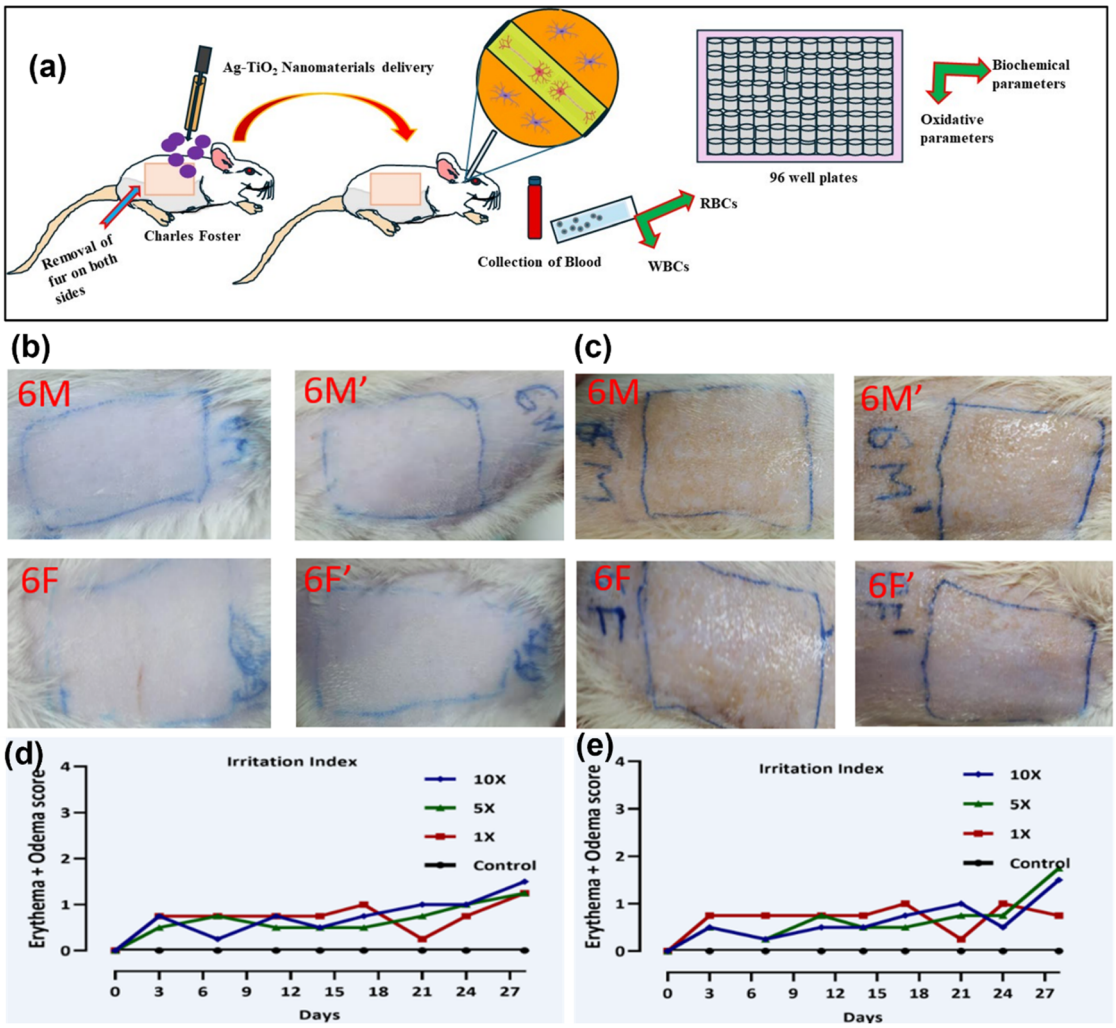

Fig. 8 (a) Illustration of the nanomaterial toxicity in Charles Foster species, (b and c) observation of high doses of Ag–TiO_2 NCs (derived from different plants), and (d and e) irritation index of both *A. indica* and *M. indica* Ag–TiO_2 NC samples.

no significant changes in the body weight and no skin irritation was observed in the rats. Furthermore, the sub-acute toxicity test after 28 days of Ag–TiO_2 NCs exposure on the skin with the above-mentioned concentration did not induce any skin irritation, as observed in Fig. S3(a) and (b).† The body weight, biochemical, and oxidative stress parameters, with repeated administration of Ag–TiO_2 NCs, were applied and compared with the control animals (applied only sesame oil) (S1 Tables 1 and 2†). The depiction of nanomaterials in Charles Foster rats has been studied using biochemicals, oxidative parameters, and irritation index, as illustrated in Fig. 8(a)–(e). The toxic traits of the current $AgTiO_2$ NCs are represented in Fig. 8(a), from removing fur of CF rats to testing for WBCs, RBCs, and other parameters. Fig. 8(b) and (c) shows the first and last day of $AgTiO_2$ NCs formulation on CF rats. Similarly, Fig. 8(d) and (e) depicts the irritation index behaviour of $AgTiO_2$ NCs after 28 days.

Based on the experimental observations, it is evident that the $AgTiO_2$ NCs can be used in cosmetics and topical formulations. However, further clinical studies are required to validate and ensure the safety and efficacy of $AgTiO_2$ NCs. NCs are essential to be used as a scientifically verified product. A thorough physicochemical characterization is crucial for establishing the link between NPs and toxicological reactions.[49] These statistics provide basic information about NPs that may be applied to risk evaluation in nanosafety. Modern techniques, including TEM, XRD, UV-vis, DLS, FTIR, and zeta-potential, were employed to evaluate the morphology, crystallinity, particle size, functional groups, and surface charge for Ag–TiO_2 NCs identification. They may have an impact on Ag–TiO_2 NCs toxicity.[50] Shaaban *et al.* mentioned that the AgNPs hydrogel formulation with a 2% addition showed wound healing of the skin without any side effects of erythema, edema, or irritation and hence can be well corroborated with the current observation.[51]

8. Conclusion

The results of this investigation demonstrate that Ag–TiO_2 NCs synthesized using *A. indica* and *M. indica* leaf extract have shown no harmful effects on animals during dermal

Open Access Article. Published on 27 March 2025. Downloaded on 4/8/2025 6:43:27 AM. This article is licensed under a Creative Commons Attribution-NonCommercial 3.0 Unported Licence.

application. We evaluated the effect of ATN and ATM on the cytotoxicity and cell viability at three different concentrations (1/2×, 1×, and 2× of MIC) using the MTT assay in fibroblast cells showing no toxic behaviour up to 2× of MIC. Rats treated with different doses of Ag–TiO_2 NCs (1×, 5×, and 10×) exhibited no side effects or abnormal symptoms over 4 weeks, as confirmed by the irritation index. Moreover, haematological, biochemical, and oxidative stress assessments revealed no differences between the control and treatment groups. Based on these findings, it can be concluded that green-synthesized Ag–TiO_2 NCs in concentrations up to 10× of MIC (6250 μg mL^{-1}) can be deemed safe for use in rat models for cosmetics and drug delivery. However, further investigation is necessary to evaluate the long-term exposure effects of green-synthesized Ag–TiO_2 NCs in cosmetics and medical treatments.

Data availability

Raw data were generated at the National Physical Laboratory, Pusa Road, Delhi and Central Institute of Medicinal and Aromatic Plants, Lucknow, Uttar Pradesh.

Abstract
The present study explores the psychometric properties of Synder et al.'s (1991) Adult Hope Scale in the Indian milieu and is based on three independent studies. Study 1 examines the factor structure of the scale using Exploratory Factor Analysis and Confirmatory Factor Analysis. Study 2 tests the internal consistency reliability using Cronbach's alpha and Composite Reliability. It aslo assesses convergent, discriminant, and criterion validities using the Average Variance Extracted, Fornell and Larcker testing system, and correlation coefficients between hope, gratitude, spiritual well-being, and distress scores. The final study examines the stability of the scale using test-retest reliability. The results of Study 1 suggested a two-factored (agency and pathways thinking) structure alike the original study. The second study asserted acceptable reliability and validity estimates and convergence with gratitude questionnaire- 6 (GQ- 6) and divergence with psychological distress scale (K10) scores. Furthermore, the scale successfully predicted the spiritual well-being of Indian students, thereby suggesting the scale's predictive validity in the Indian context. Finally, the test-retest reliability confirmed the stability of scale among Indian students. The study is one of the first to test the reliability and validity of the Adult Hope Scale and its associations with spiritual well-being, gratitude, and psychological distress, specifically in India.

Keywords Hope · India · Spiritual well-being · Gratitude · Psychological distress

Introduction

Hope is among the most revered concepts explored in various fields, including psychology, medical, organizational behavior, and theology (Bowers & Bowers, 2023). However, it has been defined differently by different researchers. Fromm (1968) suggested hope as a state of being. Lazarus (1999) expressed hope as an emotion. Waterworth (2004) labelled it as a cognitive process, and Pettit (2004) understood hope as a state of mind. Various researchers explain hope as a profound and all-prevailing human emotion, embodying optimism and a strong belief in the probability of the occurrence of positive events (Doe, 2020). It is one of the central facets of human nature that fuels resilience and encourages people to strive for a better future. It helps people realize a sense of purpose and gives them the courage to tackle challenges (Cheavens et al., 2019). Basically, it is an instilled longing for something better or a change from the present conditions and arises when people imagine a promising future that aligns with their ambitions (Doe, 2020).

Researchers like Garg (2023) compared hope with a torch that guides people through their dark and low times by reminding them that a new, bright, cherished, and improved future lies ahead. Researchers like Doe (2020) and Colla et al. (2022) highlighted that hope, accompanied by a sense of expectation, trust in positive future events, and faith in the ability and resources, encourages people to set and execute goals. At the same time, researchers also explain that hope recognizes the realism of the current situations and hindrances, thereby not restricting it to blind sanguinity and aspirant thinking (Garg, 2023). Instead, it acts as a dynamic and flexible mindset allowing people to reframe

disappointments and hindrances and motivate them to learn from their mistakes and change strategies accordingly (Doe, 2020). The nature of hope has attracted the world's attention, contributing to conceptualizing various theories and models involving hope.

Various researchers and social scientists have contributed to the literature and have presented seminal works on hope. Authors have conceptualized the psychodynamic perspective of hope as a fundamental basis for transformation. Further, the cognitive-behavioral perception of hope visualizes hope as "a desire to formulate goals or an individual's attempt to receive positive reinforcement by learning new behaviors" (Doe, 2020, p. 56). Synder et al.'s (1991) work on hope and the subsequent development of the *Adult Hope Scale* (AHS) has been regarded as one of the most pivotal contributions to the knowledge of hope. Snyder (2002) defined hope as "the perceived capability to derive pathways to desired goals and to motivate oneself via agency thinking to use those pathways" (p. 249). As per Synder et al.'s (1991) hope theory, hopeful thinking necessitates the effective amalgamation of agency and pathway thinking to account for future endeavours (Snyder, 2002). The development of pathways indicates an 'activity-oriented approach' when one has to achieve a major goal that has smaller objectives to achieve as well. These pathways fuel positive emotions in people that help them achieve the overarching goal (Yaghoobzadeh et al., 2018). In its dual facets, agency and pathways, hope is explained as one of the major positive sentiments that help individuals meet positive future events (Doe, 2020). The two factors of hope present goal-focused fortitude and a plan to meet those goals (Snyder et al., 1991).

Several studies have examined the antecedents and benefits of hope in different fields of study. Different scholars have asserted that hope leads to subjective well-being (Doe, 2020), greater purpose in life (Aghababaei et al., 2016), optimism (Hutz et al., 2014), gratitude (Witvliet et al., 2018), academic achievement, social change (Greenaway et al., 2016), resilience (Doe, 2020), and harmony in life and vitality (Doe, 2020). Other researchers reported a negative linkage of hope with depression and anxiety (Doe, 2020), posttraumatic disorder (Cheng et al., 2023), probability of developing a disease (Doe, 2020), and stress (Warber et al., 2011). Further, studies in the healthcare sector suggested that hope acts like an inner voice, the voice of others, or a motivator that helps patients maintain faith in a positive future and draws upon their spiritual well-being to respond to their current situation positively (Espedal, 2021).

The importance of hope further increased during the Covid- 19 period. During the period of covid 19, when the world halted its physical activities due to lockdown, people around the globe wished for faster control of the outbreak, and the 'hope' kept our expectations for a better future alive (Garg, 2023). The horrors of hospitals during the pandemic severely impacted medical personnel worldwide. Various studies on the mental health of medical practitioners suggested that hope and optimism positively moderated the mental health of medical practitioners (Doe, 2020). Studies on mental health further suggest that hope acts as an agent to reduce the negative impact of stress and anxiety and helps in faster recovery of mental health (Doe, 2020).

Motivation for the study

Positive psychology (1.0) asserts the role of positive emotions like hope and gratitude in ensuring well-being in normal times; however, positive psychology (2.0) looks beyond normal times. It tends to observe the efficacy of any positive emotion-based interventions in challenging times (Susarla et al., 2021). With the world facing tremendous challenges in the form of the Ukraine-Russia war, the rise of the Taliban in Afghanistan, impending global recession, the new virtual cold war, climate crisis, throat-cut competition, materialism, and greed, there is a need to reassess the implications of constructs like hope and gratitude amid these difficult times (Garg, 2023). Also, studies have shown strong linkages between gratitude and hope (Witvliet et al., 2018) during harsh times, suggesting a strong connection between the two positive emotions and the necessity to practice them in daily life to bounce back from such times (Susarla et al., 2021). Such studies have suggested that people should know to whom they are grateful, like their soldiers, doctors and others, and always hope to overcome difficult times (Susarla et al., 2021). Studies have also reported that people with higher levels of hope during difficult times, show a presence of spiritual well-being compared to those with lower levels or no hope of surviving such times (Cheng et al., 2023). Therefore, the present study tries to reignite the interest of scientists, academicians, and researchers in analysing hope, especially in a country like India, which is struggling with its own set of problems like population explosion, unemployment, price rise, communalism, casteism, poverty, wealth and digital divide, the disintegration of the robust joint family system, erosion of cultural values and health-related issues. The present study was conducted in the Indian context for the following plausible reasons.

First, like the rest of the world, India is also witnessing a sharp increase in cases related to mental health like psychological distress, anxiety, depression, loneliness, and suicidal tendencies. However, what makes the situation worse is the fact that mental health remains a taboo in Indian society. Talks and discussions over mental issues are still uncommon, especially among Indian teens and collegiates (Gaiha et al., 2020). Psychiatrists/psychologists tend to develop small interventions based on different positive constructs

like gratitude, hope, and optimism for both preventive and curative purposes. Thus, it is essential to understand the Indian notion of hope.
