Second, hope has special religious and philosophical connotations in India. The Indian philosophy (*darshan shastra)* highlights the need to understand the context and meaning of hope. *Swami Vivekananda* has highlighted the importance of hope in human life. He explains that in a world governed by sufferings and the cycle of birth and death, people hope they never get ill or die (Vivekananda, 2017). Further, *Advait Vedant*, one of the most prominent Indian schools of *darshan shastra*, suggests hope is the essence of life that enables and motivates an individual to quench the thirst for answers to questions such as self, the god, creation, or our objectives of wondering in this world (Namastu, 2018). This school explains that hope keeps the light of pursuit lit even in the lowest periods of one's life and connects them with God ("Hope for a Good Life," 2018). Shree Aurobindo explains that the *rajasic* actions (*karmas)* are performed under the influence of desire and hope to achieve the desired fruits (Namastu, 2018). Lord Krishna explains that every action has its karmic bondage, which awards the appropriate results of the actions done. Hence, for every righteous action, people hope for favorable rewards. The Lord further explains that liberated people are free from the karmic bondages, the cycle of birth and death, and the hope and sorrows of life (Namastu, 2018). India, a deeply religious country, is poised to accept any religiously ingrained intervention more easily and thoroughly than any other intervention. Therefore, it makes it more worthy of exploring hope in the Indian context.

Hope scales and adult hope scale

However, researchers have emphasized the crucial requirement of having a scale to precisely measure a phenomenon while conducting research (Garg, 2023). Regrettably, the existing Indian literature almost lacks studies that have either established a new scale or validated an existing one to assess hope in Indian collegiate. Previous researchers have developed and validated a number of hope scales like the AHS (Snyder et al., 1991), Herth Hope Index (HHI) (Herth, 1992), Integrative Hope Scale (IHS) (Schrank et al., 2011), Comprehensive Hope Scale (CHS) (Scioli et al., 2011), etcetera. Snyder et al.'s (1991) AHS is a twelve-item self-reported. It captures the trait hope in adults and college students. It is a two-factor scale: agency and pathways. Four items capture agency, the other four pathways, and the remaining four are filler items (Snyder et al., 1991). The items are rated on an eight-point Likert scale ranging from 1 (definitely false) to 8 (definitely true). The agency dimension denotes a sense of willpower to meet goals, whereas pathways are the ability to develop successful plans to realize these goals. Initially, Snyder et al. (1991) administered 45 items of the AHS to 384 students at the University of Kansas to explore the psychometric properties of the originally developed AHS. The reliability estimate-Cronbach's alpha of agency ranged between 0.71 and 0.76, and pathways ranged between 0.63 and 0.80. The authors also conducted temporal stability using test-retest reliability. The results of temporal stability reported significant coefficients between the different periods of tests. Finally, the convergent validity was tested on the data collected from 241 students. AHS positively correlated with the life orientation test (LOT), control perceptions, and esteem.

The present study selected AHS for psychometric evaluation for three reasons. First, the AHS scale measures trait hope, which is a stable and enduring characteristic than emotion and mood-based conceptualization of hope. Trait hope is one's general tendency to approach the goal with optimism and positivity. Second, AHS is based on the more comprehensive conceptualization of hope with two distinct components: agency thinking and pathways thinking. 'Agency' thinking represents one's capability to recognize, pursue, and achieve goals. 'Pathways' thinking reflects one's perceived ability to frame paths, strategies, and plans to achieve expressed goals. Thus, AHS offers a more comprehensive and holistic assessment of dispositional hope.

Third, AHS is one of the most widely used hope scales with psychometric properties examined in different settings. Redlich-Amirav et al. (2018) reported that thirty-one studies had explored the psychometric properties of AHS in different cultural contexts. And the scale has been adopted in these settings with/without modifications. Compared to AHS, the psychometric properties of the HHI, HIS and CHS have been evaluated only one to three times (Redlich-Amirav et al., 2018). It reflected the wide acceptability and adaptability of the AHS scale. This meant that AHS was already being used in India. However, upon conducting a detailed literature review, it was found that although AHS was used in the Indian context, a formal investigation of its psychometric properties was required, more specifically following the guidelines provided in STANDARDS (American Educational Research Association et al., 2014) and that too in the collegiates. Further, previous studies have not examined its second-order CFA and test-retest reliability. Also, earlier studies evaluated only Cronbach's Alpha to validate the scale's internal consistency reliability. Additionally, India is a diverse nation with varying cultural and linguistic backgrounds, so the psychometric properties of a psychometric instrument may vary accordingly. Therefore, based on the recommendation from authors like Deb et al. (2023), Garg (2023) and Kapur and Teotia (2018) to conduct a formal investigation of psychometric properties of AHS in

India, the current study not only examines the psychometric properties of AHS in India, it also bridges the gap in the literature by conducting a test-retest reliability study and uses more robust statistical techniques like McDonalds' Omega, average variance explained, Fornell and Larcker testing system among others to test the reliability and validity of AHS in India, that too among Indian university students.

Lastly, researchers like Garg (2023) have argued that when considering the adult population, researchers may tend to ignore university students or may have to ignore certain groups of university students based on the definition of adulthood specified in their respective national laws. Also, university life is considered a transition stage in which students face various challenges related to their academic performance, personal identity, and career planning issues, such as unemployment owing to the growing Indian population and relationship issues (Garg, 2023). The significance of such challenges has taken a toll on university students. Studies have shown that Indian university students suffer from various mental health issues like increased stress, depression, anxiety and identity issues due to challenges discussed earlier (Gaiha et al., 2020). Also, university students represent a new generation, which has moral and social values, beliefs, and attitudes developed based on various environmental factors affecting them. Hence, the challenges and generational differences that were previously discussed help create a unique perspective of hope among them. Also, these perspectives not only differ based on Western and Eastern cultural differences but also vary from state to state in a country like India, which calls for unity in its diversity. Therefore, it has become imperative to formally test the reliability and validity of the AHS in this context to ensure that the scale reflects how Indian university students experience hope.

Hence, the discussed motives mandate an examination of the psychometric properties of AHS in India, specifically, among Indian university students. The study's methodology is based on the guidelines provided by the American Educational Research Association et al. (2014). The first study validates the factor structure of AHS based on exploratory factor analysis (EFA) and confirmatory factor analysis (CFA). The next study examines the reliability and validity of the scale. Finally, the last study assesses the test-retest reliability of the scale.

Table 1 Demographic description

Study 1: factorial validity

Study 1 examined the factorial structure of the AHS in the Indian context with the help of exploratory factor analysis (EFA) and confirmatory factor analysis (CFA) conducted on two independent samples.

Data collection and participants

Data was collected from 741 students enrolled in Delhi Technological University, India, using an online survey. A Google form was randomly circulated among students' email addresses available on the university's website. It was taken care that no student was already suffering from major mental health issues like depression, and no student had more than five back papers as this pressure might cause the development of major mental health issues like depression. There were 325 (43.9%) female and 416 (56.1%) male participants. Students below 20 years were 314 (42.4%), 21–25 years were 244 (32.9%), 26–30 years were 112 (15.1%), and above 31 years were 71 (9.6%). Students from undergraduate (UG) courses numbered 393 (53.0%), postgraduate (PG) courses numbered 296 (39.9%), and doctor of philosophy (PhD) courses numbered 52 (7.0%). Among these 741 students, 285 (38.5%) belonged to science programs, 231 (31.2%) to management programs, and 225 (30.4%) to humanities programs. The sample size was deemed appropriate as Cochran (1977) has suggested a sample size of 384 at $p < 0.05$. Table 1 presents the demographic information of the participants.

Instrument

A structured survey form divided into three sections was used to collect data. The first section highlighted data privacy and ethical statements. Participants were promised anonymity and strict academic use of data. In addition, they were told that the data would not be shared with any third party. This section also collected informed consent from the participants. The second section collected demographic data like age, gender, education level, etcetera. The last section measured participants' hope using Snyder et al.'s (1991) AHS. The form was designed to end the survey at the end

of Sect. 1 if the participant clicks 'NO'/does not wish to participate. The survey form was designed in the English language. Also, the original scale was developed in the English language by Snyder et al. (1991). Further, English is promoted as one of the essential and official languages in India, especially by the Indian education system. It is taught from the initial academic years of the students and is emphasized as a language for educational and professional purposes. Hence Indian students develop a strong grasp of the language till they reach college to pursue their UG and PG degrees (Garg, 2023).

Scoring and interpretation of the scale

The scale is an eight-item two-dimensional scale, where one dimension is Pathway and the other is Agency. This is a positively rated scale, meaning the score for both dimensions and the overall scale are calculated based on an eight-point Likert scale ranging between 1 (definitely false) and 8 (definitely true). The scores are calculated by averaging the scores of items 2, 9, 10 and 12 for agency and 1, 4, 6 and 4 for pathways. The total score of the overall scale is calculated by averaging the scores of four statements from each dimension, i.e., by adding the scores of each of the four statements of agency and pathways. Further, lower average scores, i.e., less than 4, indicate lower levels of agency, pathways and overall AHS, and average scores above 5 indicate higher levels of hope in an individual (Snyder et al., 1991).

Analysis and results

The sample of 741 students was divided into two subsamples using the SPSS split sample function. Odd serial-numbered responses constituted subsample one (S1 with $n_1 = 371$) on which EFA was applied. Even serial-numbered responses formed subsample two (S2 with $n_2 = 370$) on which CFA was applied to validate the model fit of the factor structure resulting from EFA. The EFA was applied on the eight items forming agency and pathways subscales of the THS, and four filler items were neglected as directed by Snyder et al. (1991). Before EFA, Kaiser-Meyer-Olkin (KMO), and Bartlett's test of sphericity were carried out to examine the suitability of the collected data for factor analysis. The value of the KMO (0.837) was above the minimum required value of 0.70. Additionally, Bartlett's Test of sphericity proved to be significant at $p < 0.05$ level of significance. The results confirmed the appropriateness of data for conducting EFA. Consequently, EFA was applied using the principal axis factoring with *promax rotation* (oblique rotation, kappa =4) and Kaiser normalization. It resulted in the same two factors as the original AHS with nomenclature as pathways and agency. They could explain that 60.12% of the total variance resulted from EFA. Both factors comprised four items each. Table 2 reports factor loadings, commonalities (h^2), and total variance of eight items of the AHS in the Indian context.

CFA was conducted on subsample two of 370 college students to validate the two-factor solution derived from EFA. Bentler and Bonett (1980) suggest values of RMSEA < 0.08, SRMR ≤0.05, GFI ≥0.95, CFI ≥0.97, and TLI >0.90 as model fit indices. The two-factor THS reported satisfactory values of RMSEA =0.055, SRMR =0.029, GFI =0.963, CFI =0.982, and TLI =0.943. Additionally, the value of $\chi^2 = 53.906$, $df = 19$ at $p < 0.05$ ($p = 0.02$). Next, we conducted a second-order CFA. It, too, gave a satisfactory model fit based on the values of RMSEA (0.051), SRMR (0.027), GFI (0.965), CFI (0.986), TLI (0.947), $\chi^2 = 53.871$, $df = 18$ at $p < 0.05$ ($p = 0.01$). We compared both models based on χ^2 difference test. We found that the $\chi^2_{difference}$ was 0.035 for $df_{difference} = 1$, which was less than the recommended p-value at *significance level 0.05* and $df_{difference} = 1$, i.e. the obtained value was less than 1.84. Therefore, it was safe to assume that the model reported in the second-order CFA was better than the model reported in the first-order CFA

Table 2 Factor structure

No.	Statements	Loadings	h^2	Eigenvalues
Agency				
1	I energetically pursue my goals.	0.587*	0.345	1.701
2	My past experiences have prepared me well for my future.	0.642*	0.412	
3	I've been pretty successful in life.	0.712*	0.507	
4	I meet the goals that I set for myself.	0.661*	0.437	
Pathways				
1	I can think of many ways to get out of a jam.	0.897*	0.805	2.655
2	There are lots of ways around any problem.	0.716*	0.513	
3	I can think of many ways to get the things in life that are important to me.	0.781*	0.610	
4	Even when others get discouraged, I know I can find a way to solve the problem.	0.853*	0.728	
	Number of items	8		
	Eigenvalues	4.356		
	Explained Variance	60.12%

and that AHS is a multidimensional model. Thus, the results of CFA suggested satisfactory factorial validity of the two-factored eight-item AHS among Indian college students. These results follow the suggestions of the study conducted by Snyder et al. (1991). After factorial validity, the scale is subjected to further examination of the reliability and validity in Study 2. Figures 1 and 2 present the first-order CFA and second-order CFA models of AHS in the Indian context.

Study 2: reliability and validity testing

The study 2 examined the reliability of the two-factored AHS in the Indian context using Cronbach's Alpha (CA) and composite reliability (CR), whose acceptable values are 0.70 and above (Cronbach & Shavelson, 2004). It evaluated the convergent validated using average variance explained (AVE) values, which should be more than 0.50 to establish convergent validity. Discriminant validity was ensured with the help of Fornell and Larcker's (1981) criterion, which states that the square root of AVE values should be less than correlation values to establish the discriminant validity of a scale. Construct validity was adjudged through correlation analysis of AHS with gratitude and psychological distress. Finally, predictive validity was examined through correlation and regression analysis of AHS with spiritual well-being.

Data collection and participants

An online survey form was randomly circulated on email IDs of students of DTU; the only difference was that this time, we did not share the questionnaire with the students who were already approached during Study 1. Initially, the survey form was shared with 721 students, of whom 500 showed interest in the study and participated in the survey. Again, the exclusion criteria so formed in Study 1 were used, and the sample size was appropriate based on the sample size criteria suggested by Cochran (1977). There were 269 (53.8%) female participants and 231 (46.2%) male participants. Students from UG courses were 191 (38.2%), PG courses 246 (49.2%), and PhD courses 63 (12.6%). Of the surveyed participants, 175 (35.0%) were from science programs, 146 (29.2%) were from management programs, and 179 (35.8) were from humanities programs. There were 113 (42.2%) students below 20 years, 211 (42.2%) aged between 21 and 25 years, 91 (18.2%) aged between 26 and 30 years, and 85 (17.0%) were above 31 years. Table 1 presents the demographic information of the sample.

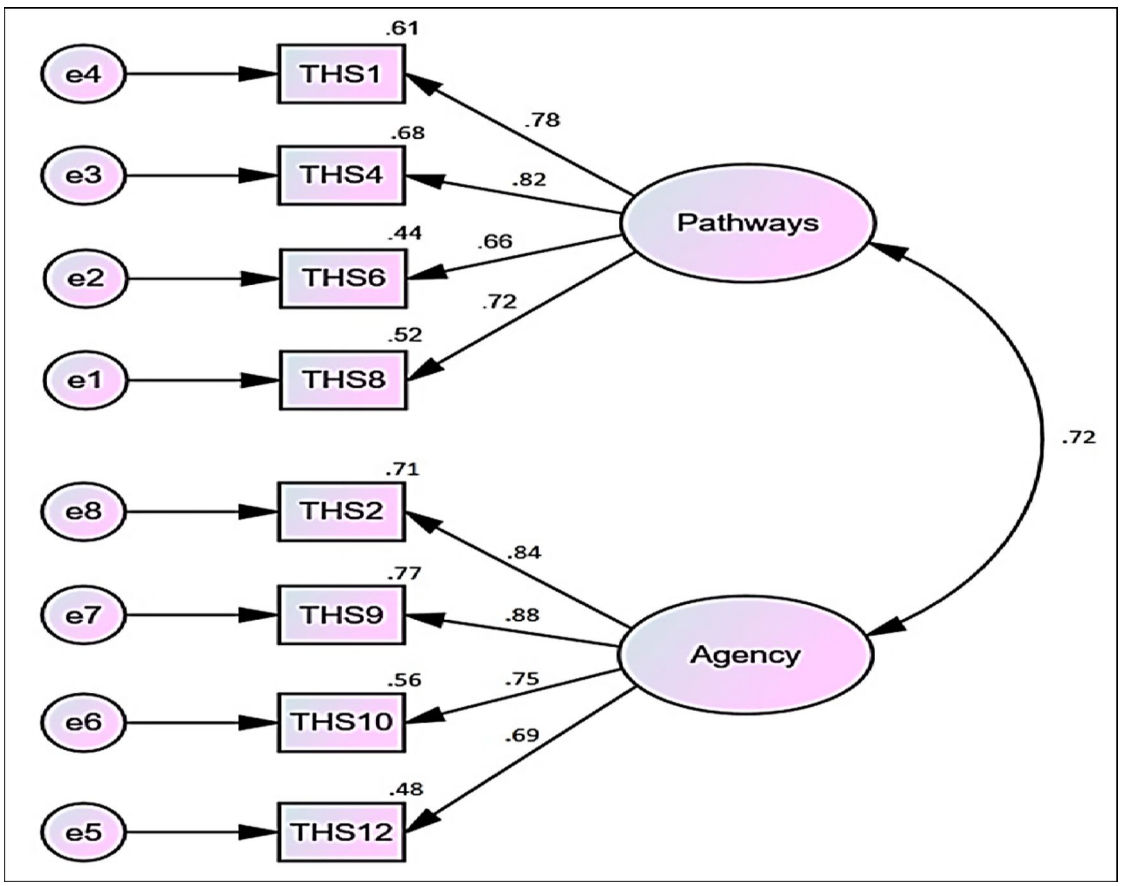

Fig. 1 Results of CFA model. Source: Primary Data

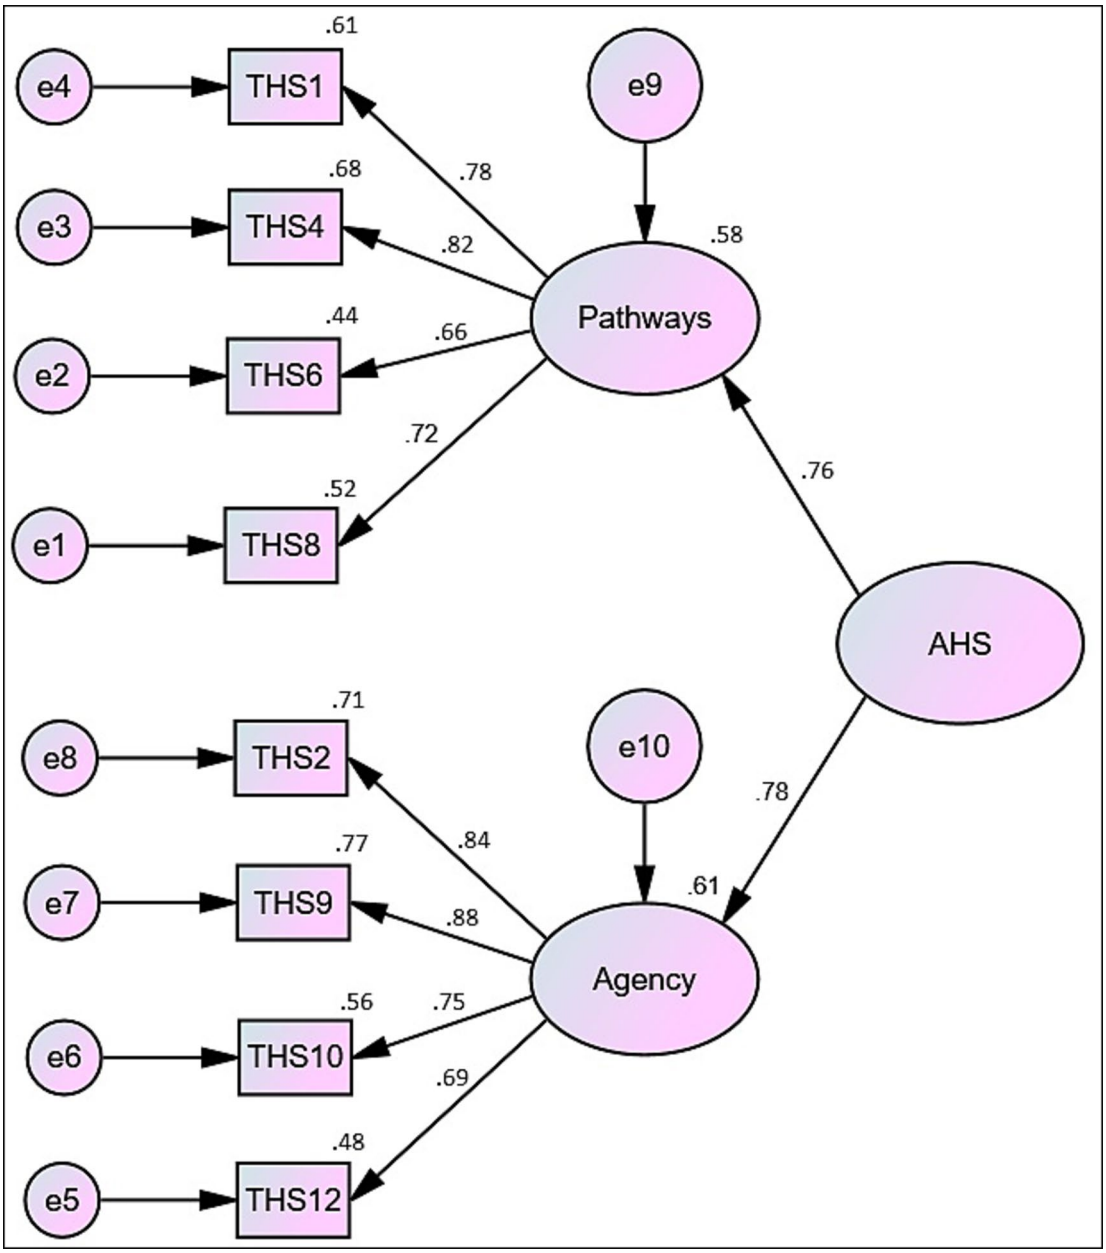

Fig. 2 Results of second order CFA model. Source: Primary Data

Instrument

An online structured questionnaire was used to collect the data. It was divided into six sections. The first section highlighted data privacy and ethical statements. Participants were promised anonymity and strict academic use of data. In addition, they were told that the data would not be shared with any third party. This section also collected informed consent from the participants. Section 2 gathered demographic information. Section 3 to Sect. 6 captured hope, spiritual well-being, gratitude, and distress, using respective instruments.

Hope

Since EFA and CFA did not suggest any deviation in the original AHS in the Indian context, the original AHS was used to measure college students' hope level on an eight-point rating scale ranging between 1 (definitely false) to 8 (definitely true).

Spiritual well-being

SWBS, established by Paloutzian and Ellison (1982), is a twenty-item six-point rating scale ranging between 1

(strongly disagree) to 6 (strongly agree). It examines an individual's relationship with the almighty and sense of life purpose and satisfaction. A higher score presents higher levels of relationship with God, a heightened sense of purpose, and satisfaction with life (Paloutzian & Ellison, 1982). A few items are "I do not find much satisfaction in private prayer with God" and "I feel that life is a positive experience."

Gratitude

GQ6, developed by McCullough et al. (2002), is a six-item seven-point rating scale ranging between 1 (strongly disagree) to 7 (strongly agree). It is used to examine an individual's experience of gratitude (Byrne, 2011). A few of its statements are "I have so much in life to be thankful for" and "I am grateful to a wide variety of people."

Psychological distress

Kessler Psychological Distress Scale (K10), developed by Kessler et al. (2003), is a ten-item five-point rating scale ranging between 1 (none of the time) to 5 (all of the time). It is used to measure one's psychological distress level. A few of its statements are "In the past four weeks, about how often did you feel hopeless?" and "In the past four weeks, about how often did you feel worthless?"

Analysis and results

Table 3 suggested that the CA values for overall AHS, pathways, and agency were 0.885, 0.879, and 0.862, respectively. Also, CR estimates for overall AHS, pathways, and agency were 0.880, 0.831, and 0.858, respectively. These values of CA and CR are greater than the threshold value of 0.7, thereby recommending AHS's reliability in the Indian context. The values of AVE for overall AHS, pathways, and agency were 0.57, 0.59, and 0.56, respectively, and were greater than the threshold value of 0.5. These results confirmed the convergent validity of AHS among Indian adults. Further, the table also reported that the square root AVE values were greater than the correlation between pathways and agency, confirming AHS's discriminant validity in the Indian sample.

The external convergent and discriminant validity were examined through the correlation coefficient between AHS, a similar (GQ- 6), and a dissimilar (K10) scale. Previous researchers have suggested that people with higher hope scores have higher levels of gratitude scores (Cheng et al., 2023). Also, people with higher hope scores have broadened their thought-action repertoire (Fredrickson, 2004) and, therefore, have lower psychological distress. Thus, it was hypothesized that AHS positively correlates with GQ6 and negatively correlates with K10. Table 3 recommended significant positive correlations between GQ6 and AHS ($r = 0.445$, $p < 0.05$), agency ($r = 0.419$, $p < 0.05$), and pathways ($r = 0.422$, $p < 0.05$). Also, the results suggested significant negative correlations between K10 and AHS ($r = -0.431$, $p < 0.05$), agency ($r = -0.462$, $p < 0.05$), and pathways ($r = -0.528$, $p < 0.05$). These results construct (convergent and divergent) validity of AHS in an Indian sample.

The broaden-and-build theory of positive emotions states that positive emotions like hope builds and broadens psychological and social resources for a person, which is instrumental to one's emotional and spiritual well-being (Fredrickson, 2004). Accordingly, it was hypothesized that hope significantly predicts the spiritual well-being of Indian adults. The acceptance of such a hypothesis would confirm the criteria validity of the scale. Table 3 reported significant

Table 3 Descriptive statistics, reliability, and validity measures and Correlation Matrix

positive correlations between SWBS and AHS ($r = 0.657$, $p < 0.05$), agency ($r = 0.601$, $p < 0.05$), and pathways ($r = 0.623$, $p < 0.05$). SWBS comprises two dimensions of spiritual well-being: religious and essential well-being. Table 3 also reported significant correlations between religious well-being and AHS ($r = 0.512$, $p < 0.05$), agency ($r = 0.481$, $p < 0.05$), and pathways ($r = 0.490$, $p < 0.05$). Also, there are positive associations between existential well-being and AHS ($r = 0.498$, $p < 0.05$), agency ($r = 0.438$, $p < 0.05$), and pathways ($r = 0.461$, $p < 0.05$). Table 4 reported that agency ($\beta = 0.498$, $p < 0.05$) and pathways ($\beta = 0.651$, $p < 0.05$) are significant predictors of spiritual well-being. These two variables of hop could explain 52.9% variations in adults' hope levels. Therefore, it recommended predictive validity of the scale in the Indian context.

Study 3: Test-retest reliability

In this study, the test-retest reliability of the AHS was explored by assessing the correlation coefficient between hope scores calculated by collecting the data twice.

Data collection and participants

An online survey form was shared with 400 randomly selected students from DTU, out of which 324 responded (at time T1). Again, we did not share the questionnaire with the students who were already approached during studies 1 and 2. After a gap of one month (at time T2), these respondents were again approached. The sequences of questions were changed to avoid familiarity bias. At time T2, 252 students answered the surveyed questions. There were 112 male (44.4%) and 140 (55.6%) participants. Participants aged below 20 were 65 (25.8%), between 21 and 25 years were 66 (26.2%), between 26 and 30 years were 72 (28.6%), and above 31 were 49 (19.4%). There were 125 (49.6%) undergraduate, 83 (32.9%) postgraduate, and 44 (17.5%) PhD students. Respondents from science courses were 84 (33.3%), management courses 118 (46.8%), and humanities courses 50 (19.8%). Again, the same participant selection criteria were followed, as the one followed in the study 1. The sample description is presented in Table 1.

Instrument

A structured questionnaire was shared with the students of DTU. It was divided into three sections. The first section provided data privacy, ethical, and informed consent statements as a standard practice. Next, the section captured the demographic information. Finally, the last section recorded the responses based on the AHS scale.

Analysis and results

Test-retest reliability was examined to assess AHS's stability and reliability over time. The correlations between scores of AHS and its two dimensions obtained in two different periods (time T1 and T2) were explored. Results recommended positive correlations in two scores of pathways ($r = 0.621$, $p < 0.05$), agency ($r = 0.695$, $p < 0.05$), and overall AHS ($r = 0.658$, $p < 0.05$), which confirmed the test-retest reliability of AHS in the Indian context.

Discussion

Hope is an essential trait that helps humans formulate goals and take action to achieve those goals (Snyder et al., 1991). It motivates people in their low times by letting them wish for a positive future (Doe, 2020). Hope is vital for physical, mental, emotional, and spiritual well-being (Doe, 2020). Researchers suggest hope provides comfort and decreases psychological distress (Doe, 2020). The presence of hope can diminish feelings of helplessness and give people a sense of control (Snyder, 2002). The Indian philosophy provides contexts and reasons, stating that hope connects people with the Almighty ("Hope for a Good Life," 2018).

Additionally, in the present world, when regional events have global impacts and life has become dull, positive emotions like hope and gratitude provide some relief to people and cushion the negative impact of unwishful incidences (Doe, 2020). Hence, the second wave of positive

psychology (PP 2.0) provides pieces of evidence to study and understand positive emotions. According to Fredrickson's (2004) broaden-and-built theory, positive emotions like hope and gratitude broaden a person's awareness and build psychological resources like spiritual quotient and resilience that cushion an individual against psychological distress and other negativities (Garg, 2023). Based on PP 2.0, Synder et al.'s (1991) work on dispositional hope has received worldwide acceptance. The authors provide a bi-dimensional model and scale for measuring dispositional hope. The first dimension is agency, which is the motivation to formulate goals, and the second is pathways which are an individual's motivation to take action to achieve planned goals. Also, Synder et al. (1991) have suggested validating the scale in cross-cultural contexts. Therefore, based on the recommendation of Snyder et al. (1991 and 2022), the current study's authors conducted a psychometric analysis of the AHS in the Indian milieu. The analysis is based on three independent studies.

Study 1 explored the factorial structure of AHS. EFA and CFA were used to analyze the factor model of AHS in India. The results of Study 1 confirmed the two-factor structure of AHS. For study 1, the sample was divided into two subsamples (SS1 and SS2). EFA was applied in SS1, and CFA was applied in SS2. Prior to applying EFA, the SS1 was subjected to the KMO test of sampling adequacy and Bartlett's test of sphericity. The value of the KMO test and significant Bartlett's test of sphericity confirmed the suitability of the sample to apply EFA. No statement was dropped during EFA, and it reported a two-factor model. This eight-item scale was further subjected to first-order and second-order CFAs to validate the factorial structure of the scale. The model fit indicators confirmed the factorial validity of the scale in both models. Further, the second-order CFA confirm that the AHS is a multidimensional scale. The model derived from this study is in line with the actual model presented by Snyder et al. (1991).

The second study assessed the reliability and validity of the AHS in India. The values of CA and CR suggested the internal consistency reliability of the AHS. Additionally, the AVE values of AHS and its two dimensions were greater than the threshold value (0.05), and the squared correlation of the factors was less than their AVE values, thus confirming the convergent validity of the scale. The criterion validity of the scale was explored by analyzing the correlation coefficients between AHS, GQ6, and K10. Significant positive correlations ($p < 0.05$) between AHS and GQ6 were reported, whereas a significant negative correlation was reported between AHS and K10, thus confirming the criterion validity of the scale. The two dimensions of the AHS, agency and pathway, contribute to the relationship, i.e., they indicate that both the ability to find routes to goals and the motivation to pursue them are associated with higher levels of gratitude. Hence, these results suggest that hope and gratitude are positively related, indicating that people with higher levels of hope also tend to experience higher levels of gratitude. Also, the Broaden-and-Built Theory suggest that positive emotions like hope broaden an individual's thought-action repository that leads to the development of psychological and social resources (Fredrickson, 2004). This broadening effect help people to manage and reduce psychological distress and provide a brighter outlook to life. On this ground, the results from our study suggest that pathways provide cognitive flexibility to the individuals, enabling them to navigate obstacles more effectively. Similarly, agency thinking empowers people to initiate and sustain actions towards their goals. Therefore, people with higher pathways and agency scores tend to reduce psychological distress. Further, to test the predictive validity of AHS, a regression analysis was conducted between AHS and SWBS, which confirmed the predictive validity of the scale. The results of regression analysis suggest that agency and pathways are strong predictors of spiritual well-being, suggesting that people with higher scores of agency and pathways can have higher sense of spiritual well-being. In other words, people with high agency believe in their abilities to achieve their goals, which gives them a higher sense of control which adds to their spiritual well-being as these types of people are likely to sense that they have a purpose and direction in their lives. Similarly, higher pathways scores suggest that people have the ability to generate multiple solutions to a problem, which can enhance their spiritual experience by fostering a proactive approach to life and its problems. Further, the results of this study align with those conducted by Cheng et al. (2023) and Witvliet et al. (2018). These authors have suggested that people with higher hope levels are more likely to develop gratuitous behavior and spiritual well-being than those with lower hope levels. Moreover, the results of our study align with other reliability and validity studies on the AHS, like those conducted by Kraft et al. (2021) in Pakistan, Vinueza-Solórzano et al. (2023) in Ecuador, and Nooripour et al. (2022) in Iran. These studies also reported a two-factor solution of the scale, the positive relationship of AHS with work engagement and AHS's negative relationships with burnout, mental distance, depression, stress, and anxiety (Nooripour et al., 2022; Vinueza-Solórzano et al., 2023).

The final study was conducted to explore the test-retest reliability of AHS. For this, the scale was administered to randomly select Indian college students. After one month, the scale was again administered to the students with a changed orientation/flow of the items. A significant correlation between the two scores confirmed the test-retest reliability of the scale. The results of the test-retest align with

the results of a similar study conducted in Pakistan by Kraft et al. (2021). Similar to the results of our study, Kraft et al. (2021) also reported a positive correlation between the results of test-retest reliability. From this standpoint, this study validates the AHS in the Indian context.

Implementations

The findings of the present study offer significant theoretical and practical implications. First, there is a dearth of a reliable and valid scale to measure dispositional hope in Indian college students. Validation of AHS in India can be considered a step toward addressing this gap. Secondly, the findings regarding dispositional hope are likely to motivate academicians, researchers, and practitioners to broaden their understanding of hope. While research on hope has primarily focused on its state and domain-specific nature, there is room in the literature to explore a more generalized nature of hope in psychological, philosophical, and other contexts ("Hope for a Good Life," 2018). Thirdly, researchers have suggested that there exists a gap in the use of hope in Indian psychology, and at the same time, philosophical thinkers around the globe also suggest that understanding hope merely limiting to a theoretical concept is not possible; instead, a generalized form of hope has to be talked about (Krafft & Choubisa, 2018). Hence, the results generated after utilizing the robustly validated AHS in India will contribute to the Indian psychology literature and help philosophical thinkers better explain their ideas on hope. Fourth, the analysis of the psychometric properties of AHS adds to the literature on positive psychology and the broad-and-built theory by Fredrickson (2004). Fourthly, validating the scale in the cross-cultural context allows researchers, academicians, and policymakers to comprehensively understand hope in different cultures. Also, the cross-cultural validation of the AHS will help the research community to certify that the scale is reliable and valid across the globe by providing evidence from India. Even the developers of AHS recommend a cross-cultural validation of the scale (Snyder et al., 1991). Lastly, researchers, academicians, and managers can use the scale to examine the interventions' efficacy to increase hope in people.

Limitations, the scope for future studies, and the conclusion

While the study presents insightful findings, it is essential to consider the study's limitations when understanding these findings. Firstly, the study is based on a sample of university students only, which might only present the perspective of hope from their side. In the future, researchers could gather data from a diverse sample of people of all ages. Secondly, apart from the test-retest reliability analysis (which makes the final study a longitudinal study), other studies are based on a cross-sectional survey, which presents its own inherent limitations. To overcome these limitations, Garg (2023) suggests that future researchers may use a mixed approach of qualitative and quantitative surveys like interviews and observations. Thirdly, the reliability testing was limited to internal consistency and test-retest reliability. Fourthly, the original scale was developed in English language by Snyder et al. (1991). Although we have discussed our reasons as to why we did not back translate the scale in Hindi language, future researchers are recommended to back translate the scale in Hindi, or any other language as deemed necessary. Future researchers may test inter-rater or alternate-form reliabilities for better understanding. Lastly, in accordance with the suggestions of previous psychometric property analysis studies, the scale needs to be validated in a cross-cultural setting.

To summarize, hope is one of the most powerful emotions and feelings in human life that can motivate people to formulate goals and act upon them. Therefore, to analyze the level of hope in people, a reliable and valid scale that measures hope is required. Hence, the present study tested the psychometric properties of AHS in India. The results from the factorial structure validity study confirmed the two factored solutions of the scale. The study on reliability and validity confirmed to scale to be reliable and valid in the Indian context.

Received: 19 December 2024; Revised: 11 February 2025; Accepted: 04 March 2025; Published: 08 April 2025

Abstract: The imbalanced surveillance video dataset consists of majority and minority classes as normal and anomalous instances in the nonlinear and non-Gaussian framework. The normal and anomalous instances cause majority and minority samples or particles associated with high and low probable regions when considering the standard particle filter. The minority particles tend to be at high risk of being suppressed by the majority particles, as the proposal probability density function (pdf) encourages the highly probable regions of the input data space to remain a biased distribution. The standard particle filter-based tracker afflicts with sample degeneration and sample impoverishment due to the biased proposal pdf ignoring the minority particles. The difficulty in designing the correct proposal pdf prevents particle filter-based tracking in the imbalanced video data. The existing methods do not discuss the imbalanced nature of particle filter-based tracking. To alleviate this problem and tracking challenges, this paper proposes a novel fractional whale particle filter (FWPF) that fuses the fractional calculus-based whale optimization algorithm (FWOA) and the standard particle filter under weighted sum rule fusion. Integrating the FWPF with an iterative Gaussian mixture model (GMM) with unbiased sample variance and sample mean allows the proposal pdf to be adaptive to the imbalanced video data. The adaptive proposal pdf leads the FWPF to a minimum variance unbiased estimator for effectively detecting and tracking multiple objects in the imbalanced video data. The fractional calculus up to the first four terms makes the FWOA a local and global search operator with inherent memory property. The fractional calculus in the FWOA oversamples minority particles to be diversified with multiple imputations to eliminate data distortion with low bias and low variance. The proposed FWPF presents a novel imbalance evaluation metric, tracking distance correlation for the imbalanced tracking over UCSD surveillance video data and shows greater efficacy in mitigating the effects of the imbalanced nature of video data compared to other existing methods. The proposed method also outshines the existing methods regarding precision and accuracy in tracking multiple objects. The consistent tracking distance correlation near zero values provides efficient imbalance reduction through bias-variance correction compared to the existing methods.

1. Introduction

Visual tracking is a critical task in vision-based applications in which the actions of humans are identified, and the human-computer interfaces are developed. Stochastic point tracking methods employ a state-space approach to model the linear or non-linear dynamics of the objects using the Kalman filter or particle filter. The Kalman filter fails when vision tracking problems are non-linear, non-Gaussian, and multi-modal. The PF solves such vision problems, which rely on the recursive construction of the state space's posterior probability density function (pdf). A set of random particles is produced to estimate the posterior pdf of the states of the tracked objects. In estimating the states of objects, these sets of particles are updated and propagated based on sequentially arriving observations. The particle filter better estimates hidden state variables than the other non-linear filters [1, 2]. However, due to the resampling procedure, the particle filter suffers from the problem of sample degeneration and impoverishment propagating in state space [3]. The resampling technique involves replacing the old set of particles with related weights with the new set of particles with related weights in more probable regions of state space when sample degeneration increases above a threshold. The resulting sample impoverishment pertains to the frequent selection of particles with high weights and the dying out of other particles with negligible weights when particles propagate after each time step [4, 5].

This work is open access and licensed under the Creative Commons CC BY 4.0 License.

The imbalanced surveillance video dataset consists of normal and anomalous instances. The normal and anomalous instances cause majority and minority samples associated with high and low probable regions. In the standard particle filter, the minority particles tend to be at high risk of being suppressed by the majority particles, as the biased proposal or importance pdf encourages only majority particles in the highly probable regions of the input data space. However, resampling tries to correct the bias to a small extent. The difficulty in designing the correct proposal or importance pdf prevents standard particle filter-based tracking in the imbalanced surveillance video data. Further, the problem of sample degeneration and sample impoverishment occurs due to the choice of a biased proposal or importance pdf ignoring the minority particles [6, 7].

Traditional tracking methods for imbalanced data suffer from the problem of occlusion and identity switching between objects. This problem worsens when the cost of tracking false negatives and false positives is the same. The resampling methods apply three actions for the imbalanced data: data, algorithmic, and hybrid-level. In this paper, multiple object tracking is based on hybrid-level actions on the majority and minority particles. This paper discusses converting the biased proposal or importance pdf into the unbiased proposal or importance pdf using hybrid-level action for the particle filter.

The authors [8] provided a theoretical justification for an evolutionary particle filter to prevent the problem of sample impoverishment without the application of visual tracking of the objects. The authors [9] proposed a whale optimization algorithm (WOA), which is a highly efficient swarm-based metaheuristic algorithm stimulated by the hunting behaviour of humpback whales (H-whales) and determine the best solution. The WOA avoids local optima and gets a global optimal solution. The WOA solves different constrained or unconstrained optimization problems for practical applications without reformulation in the algorithm. This algorithm is highly efficient compared to other metaheuristic algorithms and is found to help handle imbalanced data.

In keeping with the advantages of metaheuristic algorithms and fractional calculus in dealing with the problem of sample degeneration and impoverishment, this paper proposes a new fractional whale particle filter (FWPF) which fuses a novel fractional whale optimization algorithm (FWOA) [9] with the standard particle filter for multiple object tracking (MOT) in the imbalanced surveillance video data with tracking challenges. Multiple objects from the initial video frame are extracted through human intervention, and the particles and related weights are generated. Then, the particles are updated using the FWPF method. This operation is repeated until the best solution is determined. In this paper, contributions are as follows:

- Development of a complementary fractional whale particle filter (FWPF) that fuses the fractional calculus-based whale optimization algorithm and the standard particle filter under weighted sum rule fusion. Integrating the FWPF with an iterative Gaussian mixture model (GMM) with unbiased sample variance and sample mean allows the proposal or importance probability density function (pdf) to be adaptive to deal with the imbalanced nature of surveillance video data. The adaptive importance or proposal pdf leads the FWPF to a minimum variance unbiased estimator (MVUE) for effectively detecting and tracking multiple objects in the imbalanced surveillance video data. The novelty of the work is to convert the fixed biased proposal pdf into an unbiased adaptive proposal pdf to deal with imbalanced data.
- A novel imbalanced evaluation metric, tracking distance correlation (TDC), is employed to evaluate the bias and variance correction (imbalance reduction) caused by an unbiased proposal pdf in the imbalanced FWPF-based tracking over the biased proposal pdf in the standard particle filter-based tracking. Apart from TDC, other performance measures, such as multiple objects tracking precision and accuracy (MOTP and MOTA), the sample mean and variance are used for comparative evaluation with other existing methods in the presented work.

This paper is structured as follows: The second and third sections relate to the related works and the challenges, respectively. The fourth section recounts the mathematical formulations for the standard PF. The fifth section introduces the proposed FWPF for MOT in imbalanced surveillance video data. The sixth section details the results and discussion. Finally, the seventh section winds up the paper as the conclusion.

2. Related Works

In particle filter-based visual tracking, the object's states are unknown and can only be deduced from visual feature observations. Visual tracking has two main difficulties: the state hypothesis evaluation of the observed image and the search for the state space. Metaheuristic algorithm-based particle filter tries to solve such problems in visual tracking. The two main visual tracking procedures are bottom-up and top-down procedures. The former typically favors rebuilding the states of the objects by examining the objects in the video sequences. At the same time, the latter is used to build and examine a state hypothesis set based on object models[10]. The MOT has many tracking challenges, such as occlusion, confusion between objects, scale changes of objects tracked, tracking resumption, and variability in the number of objects. There are two steps in MOT: In the first step, the number and position of targets are inferred from the current frame at every iteration, and this step requires either a generative or discriminative model, whereas the second step refers to the

modelling of detection errors and the movement of the target [11]. The Markov-Chain-Monte-Carlo (MCMC) framework approximates the posterior pdf adaptively and estimates the best state of objects using the Markov chain. This method encounters the problems of sample degeneration and impoverishment while tracking multiple objects [12].

The authors [13] proposed an evolutionary particle filter using modified grey-wolf metaheuristics to resolve sample impoverishment. The method enhances exploitation and exploration properties in tracking. However, the technique had limited exploration of dynamic target object behaviors. In [14], authors proposed a chaotic local search model for irregular motion with fewer particles. A chaotic sampling procedure enhances particle distribution in high-likelihood areas. The method effectively handles occlusion and fast-motion challenges by introducing a histogram of dynamic information for motion representation. The method exhibits superior performance in comparison to leading-edge approaches in tracking accuracy. The method has limited exploration of chaotic optimization in higher dimensions. The authors [15] proposed the combination of quantum particle swarm and adaptive genetic metaheuristics to focus on interference factors affecting tracking efficiency and accuracy. The method effectively handles occlusion and fast motion. In [16], the authors proposed a Mean shift algorithm for particle prediction and modified particle swarm metaheuristics for detecting occlusions in dynamic environments. The anti-occlusion module in this method improves tracking performance during occlusions.

The authors [17] proposed the covariance matrix-based learning with biogeography-based metaheuristics for real-world object tracking utilizing suitability index variables and color histograms. In [18], the authors proposed mayfly position-weighting strategies and dynamic control for multi-target tracking. Additionally, chaotic optimization strategies enhanced velocity parameters in mayflies. This method required addressing new and faded targets. The authors [19] proposed an improved firefly algorithm for optimization for multitarget tracking addressing the particle filter's weight degradation issue. The method fell into premature convergence quickly. The authors [20] utilized convolutional features and superpixel segmentation to address challenges in target association during complex scenarios of intelligent transportation. The method lacks extensive evaluation of diverse datasets. In [21], the authors proposed an iterative particle filtering based on ant colony metaheuristics and locality-sensitive histogram models to address the target appearance under illumination variations. The method discussed an iterative unscented Kalman filter for proposal distribution. However, the technique does not explore real-time tracking applications.

3. Challenges

The most difficult problem in visual tracking is the occlusion of objects, in which the portions of occluded objects are only seen, and the tracking becomes very difficult after the occurrence of object occlusion. The entry and exit of multiple objects in video sequences also pose problems for tracking systems. Tracking 3D visual persons has also been a challenging task in computer vision. Multiple object confusion leads to mismatches in tracking. Another difficulty is handling variable-size objects and their inter-occlusion in video sequences, affecting the tracking process in video surveillance and monitoring systems. The other challenges include noisy video data, changes in scene illumination, multi-camera tracking, etc. The current literature does not address the imbalanced data issues of surveillance video data but suggests different techniques for multiple object tracking (MOT).

4. Particle Filter Fundamentals

The main aim of the PF method is the estimation of a posterior pdf $p\left(x_n \middle| y_{1:n}\right)$ from a time-varying state-space model consisting of motion model specified by a state transition pdf $p\left(x_n \middle| x_{n-1}\right)$ and observation model specified by the observation likelihood pdf $p\left(y_n \middle| x_n\right)$ where, x_n is the state vector of an object at discrete time-instant n, $y_{1:n}$ is the set of observations i.e. video frames from discrete time-instant 1 to the current discrete time-instant n, and y_n denotes the video frame at discrete time-instant n [1, 2, 3]. In the PF method, a posterior pdf or filtering pdf is computed according to prediction step and filtering or update step under the two-step recursion when a new video frame y_n is considered [4, 5]:

$$p\left(x_n \middle| y_{1:n-1}\right) = \int p\left(x_n \middle| x_{n-1}\right) p\left(x_{n-1} \middle| y_{1:n-1}\right) dx_{n-1} \tag{1}$$

$$p\left(x_n \middle| y_{1:n}\right) = \frac{p\left(y_n \middle| x_n\right) p\left(x_n \middle| y_{1:n-1}\right)}{\int p\left(y_n \middle| x_n\right) p\left(x_n \middle| y_{1:n-1}\right) dx_n} \tag{2}$$

But, the recursive computation of the above posterior pdf is not possible analytically. Instead, it is numerically approximated by a set of M random particles with related weights w at discrete time-instant n, $\left\{x_n^m, w_n^m\right\}_{m=1}^{M}$ and it is given as follows:

$$p\left(x_n \left| y_{1:n}\right.\right) \approx \sum_{m=1}^{M} w_n^m \delta\left(x_n - x_n^m\right) \tag{3}$$

Where $\delta(\cdot)$ denotes the Kronecker delta function. The particles are random samples of the state vector, and the weights have non-negative values that sum up to unity, i.e. $\sum_{m=1}^{M} w_n^m = 1$ and are interpreted as probabilities of the particles. In practice, we often cannot draw samples directly from a posterior pdf because it may not be a standard pdf. Instead, particles are easily drawn from an importance or proposal pdf $\pi\left(x_n \left| x_{n-1}^m, y_{1:n}\right.\right)$ which is a biased pdf approximating the important regions of input variables. In (3), RHS is characterised as follows:

$$x_n^m \sim \pi\left(x_n \left| x_{n-1}^m, y_n\right.\right) \tag{4}$$

$$w_n^j = \frac{\tilde{w}_n^m}{\sum_{m=1}^{M} \tilde{w}_n^m} \tag{5}$$

$$\tilde{w}_n^m = w_{n-1}^m \frac{p\left(y_n \left| x_n^m\right.\right) p\left(x_n^m \left| x_{n-1}^m\right.\right)}{\pi\left(x_n^m \left| x_{n-1}^m, y_n\right.\right)} \tag{6}$$

If the importance pdf is made equal to the state transition pdf, i.e. $\pi\left(x_n^m \left| x_{n-1}^m, y_n\right.\right) = p\left(x_n^m \left| x_{n-1}^m\right.\right)$ which, then, simplifies to the above equation as $\tilde{w}_n^m = w_{n-1}^m p\left(y_n \left| x_n^m\right.\right)$. The initialization of PF requires the generation of a set of random particles, $\left\{x_0^m, w_0^m\right\}_{m=1}^{M}$ from the prior pdf $p\left(x_0\right)$. Equations (4) to (6) show the recursive computing of the set of random particles with related weights for the representation of $p\left(x_n \left| y_{1:n}\right.\right)$ from the previous posterior pdf $p\left(x_{n-1} \left| y_{1:n-1}\right.\right)$ corresponding to a new observation y_n. The number of efficacious particles is expressed as

$$M_n^{eff} = \frac{1}{\sum_{m=1}^{M} \left(\tilde{w}_n^m\right)^2} \tag{7}$$

In the PF method, all the particles are assigned the exact weights, and at each discrete time-instant, the particles are propagated and assigned weights. As time evolves, degeneration of a set of particles occurs, and only a few particles are left with meaningful weights. A well-biased importance pdf and a resampling procedure can reduce the sample degeneration to a small extent. Still, it presents the supplementary challenges of sample impoverishment, resulting in a deficiency of sample diversity in the state space. Recursive update calculations of ineffective particles seriously degrade the performance of particle filters. The resampling procedure eliminates the small weighted random particles and replicates the large weighted random particles. This resampling procedure poses the problem of sample impoverishment due to the over-replication of large weighted random particles and the reduction in the number of meaningful particles. Finally, it becomes difficult for the new set of particles to keep track of the true states of targets. To overcome this problem, this paper proposes FWPF for MOT in surveillance video data.

5. Proposed FWPF for Multi-object Tracking

Fig. 1 represents the proposed FWPF-based hybrid model for MOT in surveillance videos. The first step is object extraction, in which the objects are extracted from the video through manual intervention by considering the features of the objects. The next step is particle generation, in which the particles are generated randomly for the extracted object in each video frame. Then, particle updation is performed to select the position of the multiple objects in the video frame. The particle updation uses a hybrid model of standard particle filter and FWOA methods. The standard particle filter updates the particles by calculating the weight of each particle in the extracted object and discarding the particles with small weights. In this way, the particles are resampled, and the optimal position of the object is determined. WOA is a swarm-based metaheuristic that assumes the present solution is the best prey [9]. Then, the search agents update their position to the high likelihood region of the best search agent to find the optimal solution.

5.1. Object Extraction from the Input Video

Let us assume that the proposed MOT method's input is a video consisting of n frames. The input video taken as input to the proposed method is represented as $V=\{V_i;1\le i\le n\}$ where V represents the video and n represents the number of frames in the video. The primary task in the visual tracking is to discover the moving objects from the initial frame by extracting the foreground objects. The extracted object is then given for the tracking process, which involves the identification of the object's trajectories. So, the MOT method requires an object extraction mechanism either from the initial frame of the video or when the object appears initially in the video. In this MOT method, the object is extracted manually from the video sequence at the initial frame. The detected objects from the video through manual intervention are denoted as $O=\{O_j;1\le j\le k\}$ where O represents the multiple objects set and k represents the number of objects presented in the input video V .

The preprocessing technique is based on weakly supervised object detection (WSOD). An adaptive background subtraction approach is employed to initialize the detection of moving objects over the frames. After moving objects are detected in the initial frames with little human intervention, they are weakly labelled as objects or non-objects by applying a distance-based classification method, and the same is continued in successive frames within the small spatiotemporal neighbourhood. With known positions and weak labelling for objects or non-objects, real-world video datasets are always unlabelled and imbalanced because they contain anomalies somewhere in the frames, and their exact locations are unknown. These weakly labelled objects are refined and localized by the weighted sum rule fusion of the complementary trackers for multiple objects over the frames. The WSOD-based complementary trackers (FWPF and standard PF) are suitable for unlabelled and imbalanced video datasets where limited data availability is a major concern.

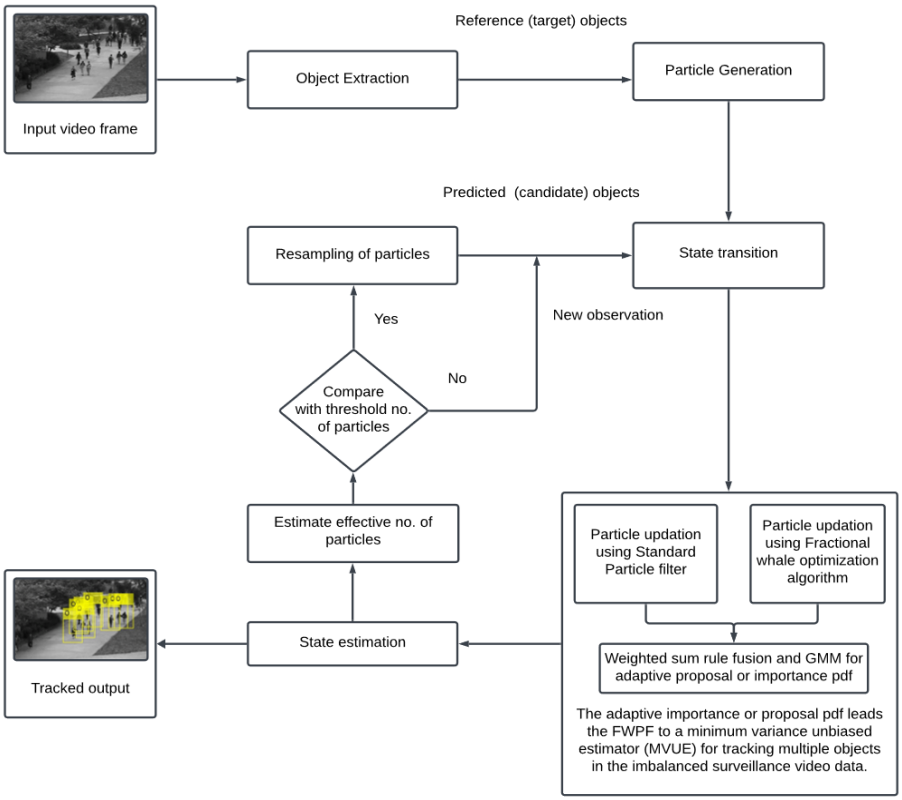

Fig.1. A proposed fractional whale particle filter method for MOT in the surveillance video

5.2. Multiple Object Tracking by Fractional Whale Particle Filter

This section describes the particle updating process in which the particles are updated using the standard particle filter and fractional calculus-based WOA method. Given the problem of sample degeneration and impoverishment in standard particle filters, the weighted sum rule fusion of FWOA and standard particle filter allows the biased proposal or importance pdf to be adaptive using the iterative Gaussian mixture model (GMM) with unbiased sample variance and sample mean.

A. Generation of Initial Particles

The particles are generated for every object after detecting the position of every object in the initial frame. Here, every object O_j contains v number of particles. The particles corresponding to every object are generated randomly to

evaluate the system's initial states. Here, the particles are used to describe the spatial and temporal attributes of moving objects in the video frames, and the particles are sampled based on the importance of the pdf.

B. Updating of Particles by Particle Filter for Visual Tracking

Once the particles are located in the initial frame, the movement (updating) of the particle is to be found to obtain the objects' location in the next frame. In a standard particle filter, the weight of each particle is determined based on the spatial and pixel correspondences. The spatial correspondence is computed based on the location of the objects using the Euclidean distance, and the pixel correspondence is computed based on the object's intensity using the Bhattacharyya distance. Once the weights of every particle are computed, they are multiplied by the previous position of the particle to find the location in the next frame. The new position of the object O_j at time T is determined as,

$$P_{O_j}^T(F) = \sum_{u=1}^{v} M_u^T C_u^T \tag{8}$$

Where v is the number of particles, is the centre of the particle u at time T and M_u^T is the weight of the particle u at time T. Here, the determination of the weight of each particle depends on the spatial pdf, $p\left(B_{O_j}^T \middle| C_u^T\right)$ and the colour pdf, $p\left(D_{O_j}^T \middle| C_u^T\right)$. The weight of the particle u at time T is determined as follows:

$$M_u^T = \frac{p\left(B_{O_j}^T \middle| C_u^T\right) p\left(D_{O_j}^T \middle| C_u^T\right)}{\sum_{e=1}^{v} p\left(B_{O_j}^T \middle| C_e^T\right) p\left(D_{O_j}^T \middle| C_e^T\right)} \tag{9}$$

The spatial pdf, $p\left(B_{O_j}^T \middle| C_u^T\right)$ is determined as follows:

$$p\left(B_{O_j}^T \middle| C_u^T\right) = \frac{1-k\left(y\left(C_u^T\right), y\left(P_{O_j}^{T-1}\right)\right)}{H} \tag{10}$$

Where, $y\left(C_u^T\right)$ is the centre of C_u^T and $y\left(P_{O_j}^{T-1}\right)$ is the centre of $P_{O_j}^{T-1}$. $k(\cdot)$ represents the Euclidean distance between $y\left(C_u^T\right)$ and $y\left(P_{O_j}^{T-1}\right)$. The denominator H in the above equation is computed based on the mean distance of the object region S located in the previous video frame with the height q and width p.

$$H = \frac{\sqrt{S_p\left(P_{O_j}^{T-1}\right)^2 + S_q\left(P_{O_j}^{T-1}\right)^2}}{2} \tag{11}$$

Then, the color pdf, $p\left(D_{O_j}^T \middle| C_u^T\right)$ is calculated as follows,

$$p\left(D_{O_j}^T \middle| C_u^T\right) = 1-W\left(g\left(P_{O_j}^{T-1}\right), g\left(C_u^T\right)\right) \tag{12}$$

Where, $W(\cdot)$ represents the Bhattacharyya distance obtained from (13). $g\left(P_{O_j}^{T-1}\right)$ and $g\left(C_u^T\right)$ denote the number of pixels in the bounding box surrounding the position of the object O_j at time $(T-1)$, i.e. $P_{O_j}^{T-1}$ and C_u^T, respectively.

Once the weights are computed, the particles which have lower weights are eliminated to improve the tracking accuracy. The remaining particles are the new set of particles for the next iteration. When a new set of particles is sampled, failure in the tracking gets repaired in the next few frames. In this way, the particles are resampled, and the object's new position is determined iteratively. The estimated result is applied to minimize the search area and the computation time during tracking.

C. Updating of Particles by Fractional-whale Optimization

The original whale optimization algorithm (WOA) copies the social behavior of the H-whales, which identifies the prey's location and encircles them. Since the placement of the optimal solution is unfamiliar at the beginning, the WOA

assumes the present solution as the target solution, beginning with a set of random solutions. Each iteration updates the search agent's position by either a randomly selected agent or the optimal solution. The process is repeated till it reaches the best solution. However, the WOA has a limited global search and a slow convergence rate [9].

The imbalanced surveillance video dataset introduces the drawbacks of overlapping objects during multiple object tracking, which causes problems with between-object imbalance and within-object imbalance with some missing or incomplete data. Such object imbalances occur when minority particles associated with low probable regions are not well separated from majority particles associated with high probable regions in specific areas of the input data space due to incomplete data. To counter this problem, the position of the particles is updated by the Fractional-whale optimization algorithm (FWOA), which aims to search the nearby position of the particles in the next frame to find the optimal position of the objects. This algorithm integrates the fractional calculus up to the first four terms, also known as adaptive multiple variable polynomials (AMFP), with the position update process of the whale optimization algorithm [22, 23].

The FWOA is a local and global search operator with inherent memory property. The FWOA adjusts the distribution of between-object and within-object generated particles using multiple imputation-based oversampling of minority particles in the targeted specific area of the input data space. The AMFP generates multiple different imputations for each missing data. If the missing or incomplete data are multivariate, they can be imputed from a joint multivariate normal or log-linear model. The AMFP imputes each majority particle only once for its missing data, whereas it oversamples each minority particle by replacing it with multiple imputations. Thus, all incomplete data are imputed with the oversampling of minority particles. One significant advantage of AMFP is that the oversampled minority particles are diversified with multiple imputations to eliminate data distortion, and all the observed data are kept unmodified. The FWOA approach results in low-bias and low-variance with greater efficacy for tracking precision and tracking distance in the imbalanced surveillance video dataset [24, 25].

i. Solution Encoding: Every solution is represented by a two-dimensional vector that indicates the position of the particles in the next frame.

ii. Fitness Calculation: The fitness is used to evaluate whether the generated solution is better. The fitness of every solution is calculated using the Bhattacharyya distance, which is given as follows:

$$Fitness = \sqrt{1-\frac{\sum_j \sqrt{l(j)m(j)}}{\sqrt{\sum_j l(j)\sum_j m(j)}}} \tag{13}$$

Where l and m represent the position of search agents in the present video frame and previous video frame, respectively.

iii. Algorithm: The algorithm for FWOA is explained below:

a. Initialization: The search agents are initially populated randomly and initiate their position randomly by surrounding the object's position. This process kicks up the search agents to move toward the likelihood region of the objects placed in the previous frame.

b. Fractional encircling prey: H-whales identify the prey's location and encircle them to find the position in the next iteration. In the shrinking encircling phase, the new position of the search agents is computed as follows:

$$\vec{G}(r+1) = \left(1-\vec{H}.\vec{F}\right)\vec{G^*}(r) - \vec{H}\cdot\left(\alpha\vec{G}(r) + \frac{1}{2}\alpha\vec{G}(r-1) + \frac{1}{6}\alpha(1-\alpha)\vec{G}(r-2) + \frac{1}{24}\alpha(1-\alpha)(2-\alpha)\vec{G}(r-3)\right) \tag{14}$$

Where $\vec{G^*}$ and $\vec{G}$ are the position vectors corresponding to the best solution and the search agent with r as the current iteration. $\vec{H}$ and $\vec{F}$ are both coefficient vectors. The encircling prey is modified with fractional calculus up to the four terms with fractional order of α to be in the range of $0 < \alpha < 1$. The fractional calculus is based on the generalized Grunwald-Letnikov Equation for the discrete fractional derivative with fractional order of α [24, 25].

Then, the updation of the coefficient vectors $\vec{H}$ and $\vec{F}$ are computed as follows:

$$\vec{H} = 2\vec{h}\cdot\vec{s} - \vec{h} \tag{15}$$

$$\vec{F} = 2\cdot\vec{s} \tag{16}$$

Where, $\vec{h}$ linearly decreases in the range $[2 \to 0]$ over the iterations, and $\vec{s}$ is a random vector in the range $[0,1]$.

c. Fractional exploitation phase: In the spiral updating position phase, the new position of the search agents is computed based on the following equation:

$$\vec{G}(r+1) = \left(1+e^{df}\cdot\cos(2\pi f)\right)\overrightarrow{G^*}(r) - e^{df}\cdot\cos(2\pi f)\cdot\left(\begin{array}{l}\alpha\vec{G}(r)+\frac{1}{2}\alpha\vec{G}(r-1)+\frac{1}{6}\alpha(1-\alpha)\vec{G}(r-2)+\\ \frac{1}{24}\alpha(1-\alpha)(2-\alpha)\vec{G}(r-3)\end{array}\right) \quad (17)$$

Where d is a constant denoting the state of the logarithmic helix in the range, f is a random number [-1,1] and '$\cdot$' is the element-wise multiplication. In the shrinking circling mechanism, the position of H-whales is updated as per (13) and (17) when the random probability of occurrence is less than or greater than $p = 0.5$.

d. Fractional exploration phase: The search agents search for prey (perfect solution) randomly, and the position of the search agent is updated based on the position of other search agents. This can be represented as:

$$\vec{G}(r+1) = (1-\vec{H}.\vec{F})\vec{G}_m - \vec{H}\cdot\left(\alpha\vec{G}(r)+\tfrac{1}{2}\alpha\vec{G}(r-1)+\tfrac{1}{6}\alpha(1-\alpha)\vec{G}(r-2)+\tfrac{1}{24}\alpha(1-\alpha)(2-\alpha)\vec{G}(r-3)\right) \quad (18)$$

Where, $\vec{G}_m$ is specified as a random position vector.

e. Termination: The FWOA is performed between either a circular or spiral movement, considering the value of p. Then, the process is repeated until it reaches the maximum number of iterations the user gives. After reaching the maximum iteration, the best prey location is assigned to $P_{O_j}^T(FW)$, which is the position of the particle in the next frame.

D. Weighted Sum Rule Fusion for Updating the New Position

The new position obtained through the PF and FWOA is combined with the weighted sum rule fusion to track multiple objects in the video sequence. The fusion provides the mean position of the PF and FWOA as the final tracking paths of the multi-objects. The following equation determines the new position of the object:

$$P_{O_j}^T = x_n = \frac{P_{O_j}^T(PF) + P_{O_j}^T(FW)}{2},$$

$$Z = \sum_{i=1}^{N=2}\alpha_i X_i \text{ such that } \sum_{i=1}^{N=2}\alpha_i = 1, \text{ and} \quad (19)$$

$$\sigma_Z^2 = \sum_{i=1}^{N=2}\alpha_i^2\sigma_{X_i}^2 = \alpha_1^2\sigma_{X_1}^2 + \alpha_2^2\sigma_{X_2}^2$$

Where $P_{O_j}^T(PF)$ is the new position of the object obtained by the PF method and $P_{O_j}^T(FW)$ is the new position of the object obtained by the FWOA. Since $P_{O_j}^T(PF)$ and $P_{O_j}^T(FW)$ are originated from the same video frame (data) distribution; they are not independent but are uncorrelated due to the FWOA-based tracker being complementary to the PF-based tracker. When treated as uncorrelated random variables, these complementary trackers produce a minimum variance, undergoing weighted sum rule fusion with equal weighting coefficients. If these complementary trackers achieve minimum variance for multiple objects, it will result in higher precision. The other score-level fusion techniques, like the maximum rule, minimum rule, product rule, median rule, etc., are not applied because these trackers are not independent [26, 27].

The weighted sum rule fusion is based on optimization by complementarity. One tracking model's incorrect detection and localization are complemented by another. If the trackers complement each other, they cancel out each other's random errors and help output correct or unbiased detection. These complementary trackers are uncorrelated but not independent because they originate from the same video frame (data) distributions. These trackers cause two complementary events which are mutually exclusive to each other. These trackers undergo the weighted sum rule fusion as per (19), where the terms X_i and α_i are uncorrelated random variables (two complementary trackers) and real weighting constants. The term Z is another random variable formed through weighted sum rule fusion. Further, we obtain the expression of the variance of Z in terms of the variances of X_1 and X_2 as given in (19). In statistics, precision is the reciprocal of the variance. In order to verify the approximated values of the precision, we assume $\sigma_{X_1}^2 = \sigma_{X_2}^2 = \sigma^2$ and consider different

values of α_1 and α_2. With $\alpha_1 = \alpha_2 = 0.5$, it is found that the averaging of two complementary trackers $\left(Z = \frac{X_1 + X_2}{2} \right)$ results in higher precision $\left(MOTP \propto \frac{1}{\sigma_Z^2} \right)$.

E. Adaptive Proposal pdf for the Imbalanced Data

The imbalanced surveillance video dataset consists of majority and minority classes as normal and anomalous instances. The normal and anomalous instances cause majority and minority samples associated with high and low probable regions. The minority particles tend to be at high risk of being suppressed by the majority particles, as the proposal or importance pdf encourages the highly probable regions of the input data space to remain a "biased distribution" in the standard particle filter. The proposal or importance sampling depends entirely on the choice of biased distribution, which results in a biased estimation of the discrete random measure. However, true and normalized importance weights are introduced to correct the bias to a small extent. The difficulty in designing the correct proposal or importance pdf prevents the use of particle filtering-based tracking in the imbalanced surveillance video dataset. Further, the standard particle filter tracker suffers from the problem of sample degeneration and sample impoverishment due to the biased proposal or importance pdf ignoring the minority particles [28, 29].

To alleviate this problem, The FWOA is fused with the standard particle filter under the weighted sum rule fusion to represent the proposal or importance pdf as a mixture of Gaussian distributions to deal with highly non-Gaussian true posterior pdf in the imbalanced data. Thus, FWOA adapts each component's weights and parameters in the GMM to result in the adaptive proposal or importance pdf for the FWPF, which balances exploring new areas of the state space with exploiting promising regions [30, 31].

i. Further to (19), a set of M random particles with associated weights u at discrete time-instant n, $\left\{ x_n^m, u_n^m \right\}_{m=1}^{M}$ is considered to denote x_n^1 and x_n^M as best (with a small selection pressure coefficient, α) and worst (with a large selection pressure coefficient, α) initial solution, whereas the associated weight u_n^m is defined to be Gaussian distributed with constraint as under:

$$u_n^m \propto \frac{1}{\sqrt{2\pi}\alpha M} \exp\left\{ -\frac{1}{2}\left(\frac{m-1}{\alpha M} \right)^2 \right\} \quad \text{such that} \quad \sum_{m=1}^{M} u_n^m = 1 \tag{20}$$

ii. The GMM, as the importance or proposal pdf, is generated for every p^{th} observations with Gaussian probability density function, characterized by the mean (μ) and variance (σ^2) as follows:

$$G_n^p\left\{ x_n^m(p) \right\} = \sum_{m=1}^{M} u_n^m \mathrm{N}\left(x_n^m(p); \mu_n^m(p), \left(\sigma_n^m(p) \right)^2 \right) \tag{21}$$

$$\mathrm{N}\left(x; \mu, \sigma^2 \right) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left\{ -\frac{1}{2}\left(\frac{x-\mu}{\sigma} \right)^2 \right\} \tag{22}$$

Where $x_n(p)$ denotes the pth element of the vector x_n. The unbiased sample mean and sample variance for the observations drawn from the Gaussian pdf are defined as follows:

$$\mu_n^m(p) = \bar{x}_n^m(p) = \frac{1}{M} \sum_{m=1}^{M} x_n^m(p) \tag{23}$$

$$\left\{ \sigma_n^m(p) \right\}^2 = \frac{1}{(M-1)} \sum_{m=1}^{M} \left\{ x_n^m(p) - \bar{x}_n^m(p) \right\}^2 \tag{24}$$

iii. Thus, the GMM generates N new samples that represent the progeny of the primary population. The most optimal function is assessed for all the newly generated samples. The M_n^{eff} fittest solution among the M current samples and N new samples are formed to find the best solution. The adaptive importance or proposal pdf, $G_n\left(x_n^m \right)$ now modifies (6) with (21) and (22) as follows:

$$G_n\left(x_n^m\right)=\prod_{p=1}^{Q}G_n^p\left(x_n^m\left(p\right)\right)=G_n^1\left(x_n^m\left(1\right)\right)\times G_n^2\left(x_n^m\left(2\right)\right)\times\cdots\times G_n^Q\left(x_n^m\left(Q\right)\right) \tag{25}$$

$$\tilde{w}_n^m=\frac{\frac{1}{M}\sum_{l=1}^{M}p\left(y_n\left|x_n^m\right.\right)p\left(x_n^m\left|x_{n-1}^l\right.\right)}{G_n\left(x_n^m\right)} \tag{26}$$

Once the weights are modified according to adaptive importance or proposal pdf, the particles $\left\{x_n^m,\tilde{w}_n^m\right\}_{m=1}^{M}$ are completely updated/resampled based on the modified posterior pdf from (3) till the completion of the epoch n as follows:

$$p\left(x_n\left|y_{1:n}\right.\right)\approx\sum_{m=1}^{M}\tilde{w}_n^m\delta\left(x_n-x_n^m\right) \tag{27}$$

6. Results and Discussion

The proposed approach is simulated using the "MATLAB2019b" software tool on a system with an "Intel" core processor and 2 GB RAM, as well as the "Windows-11" operating system. The imbalanced UCSD video data – 1 and 2 [32] are obtained using a stationary camera mounted on the building, observing the pedestrian walkways where the density varies from sparse to crowded. Some occlusions and scale changes cause anomalies like cyclists, carts, and skateboarders to move at nonlinear speed. Each video has 100 frames with an image resolution of 158×238 pixels. The reason behind considering this video data is that the camera's field of view leads to a heightened degree of perspective distortion and pronounced variations in the scale of moving objects. Furthermore, anomalous events encompass motion anomalies elicited by cyclists, carts, and skateboarders, as well as contextual anomalies. The simulation results are discussed in this section.

6.1. Evaluation Metrics

Multiple objects tracking accuracy (MOTA) can reveal how class imbalance affects the overall tracking performance. For instance, a disproportionately high false negative rate for a minority class could indicate that the tracker consistently struggles to detect or maintain tracks of these minority or anomalous objects. In statistics, precision is often defined as the inverse of variance. Intuitively, variance measures how spread out a set of values is from its mean, while precision indicates how close or concentrated those values are to the mean. As a minimum variance unbiased estimator, the proposed method considers the Multiple objects tracking precision (MOTP), which can assess how accurately the tracker localizes those objects, regardless of their frequency in the video. Tracking distance correlation (TDC) can assess object tracks' temporal consistency and reliability. This is particularly important when dealing with imbalanced video data, where the performance of minority or anomalous objects might be compromised.

A. Multiple Object Tracking Accuracy (MOTA)

This metric incorporates three types of errors: false negatives, false positives, and identity mismatches. For the most accurate tracking, a high MOTA value is desired. The total count of ground truth objects is GT_t at frame (time) t. The terms FN_t, FP_t, and $IDMM_t$ are the number of false negatives, false positives, and identity mismatches at frame (time) t, respectively [33, 34].

$$MOTA=1-\frac{\sum_t\left(FN_t+FP_t+IDMM_t\right)}{\sum_t GT_t} \tag{28}$$

B. Multiple Object Tracking Precision (MOTP)

The metric refers to the average difference between all true positives and their ground truth hypothesis. A high MOTP value is preferred for the most precise tracking. The average dissimilarity among all true positives and their corresponding ground-truth hypothesis is the Multiple Object Tracking Precision [33, 34].

$$MOTP=\frac{\sum_{t,i}d_{t,i}}{\sum_t c_t} \tag{29}$$

Where the terms $d_{t,i}$ and c_t are the bounding box overlap of the target i with its assigned ground truth object and the count of matches at frame (time) t, respectively. It is used to represent the ability of the tracker to evaluate the correct position of the object positions in a video frame. MOTP and MOTA values vary between 0 (no tracking) and 1 (fully tracked). Higher values of both MOTP and MOTA are desirable for accurate and precise tracking.

C. Tracking Distance Correlation (TDC)

This metric measures both linear and nonlinear association between the original tracking path (X) and algorithmic tracked path (Y) in the imbalanced particle filter-based tracking. TDC value varies between 0 (when two paths are the same) and 1 (when two paths are independent). This metric depends on distance covariance, and its minimum value shows the bias and variance correction from tracking based on a biased proposal pdf to tracking based on an unbiased proposal pdf as required for FWPF. The tracking distance correlation is represented as follows [35]:

$$TDC(X,Y) = 1 - \frac{TDCov(X,Y)}{\sqrt{TDVar(X)TDVar(Y)}} \tag{30}$$

Where $TDCov(\cdot)$ and $TDVar(\cdot)$ represent the paths's distance covariance and distance variance.

6.2. Experimental Results

The performance of the proposed method is evaluated using two videos obtained from the UCSD dataset [32], each containing 100 frames. The UCSD video datasets are considered limited, unlabelled, real-world imbalanced surveillance video datasets. Figs. 2 (a) and (c) represent the 7th, 21st, and 35th frames of video-1 (Bicycle) and video-2 (Cart). The experimentation is performed to track the different numbers of multiple objects (from one to eight) from video-1 and video-2, as shown in Figs. 2 (b) and (d).

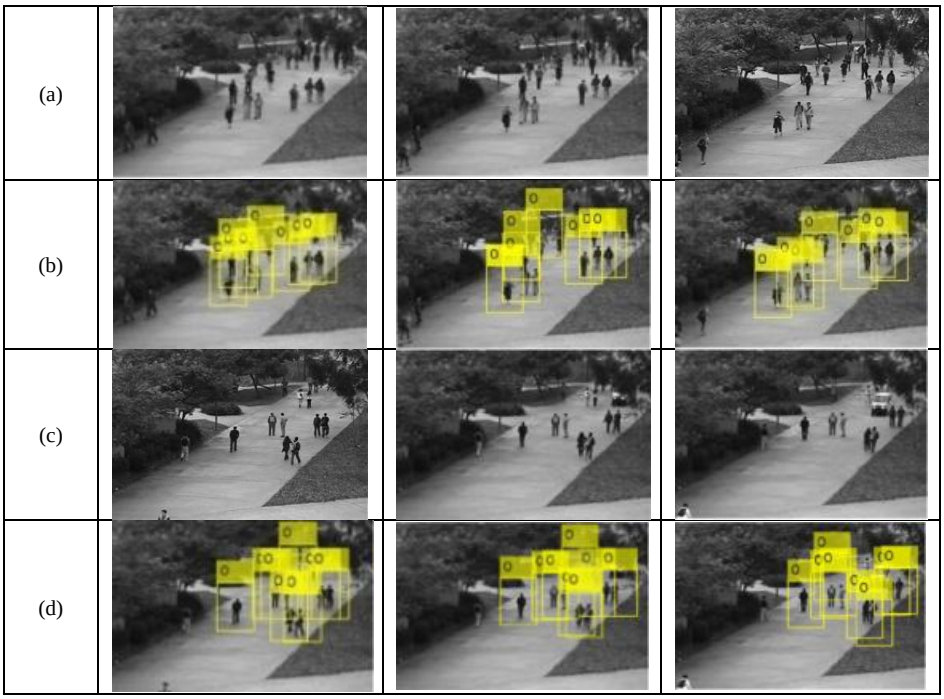

Fig.2. Proposed FWPF-based tracking over the original frames 7, 21, and 35 of the (a, b) UCSD video data – 1 [32] and (c, d) UCSD video data – 2 [32]

6.3. Performance Analysis

This section presents the comparative performance evaluation of the proposed FWPF with the existing methods like standard PF [1], Modified grey wolf particle filter (MGWPF) [13], Adaptive chaotic sampling particle filter (ACPF) [14], and Quantum particle swarm genetic particle filter (QPGPF) [15] when applying on the 100 frames extracted from UCSD video data – 1 and 2 [32].

A. Evaluation based on MOTP

Table 1 compares the average MOTP values of the proposed FWPF method with the existing methods [1, 13, 14, 15]

for the different numbers of individual tracked objects (from one to eight) in UCSD video data-1 and 2. Figs. 3 (a) and (c) depict the MOTP analysis curve for UCSD video data -1 and 2, respectively. The proposed method attains an average MOTP of 92.71% for UCSD video data -1, outperforming the MOTP values of 56.85%, 84.58%, 76.80%, and 70.63% achieved by PF, MGWPF, ACPF, and QPGPF, respectively. Similarly, the proposed method attains an average MOTP of 91.43% for UCSD video data -2, outperforming the MOTP values of 71.55%, 85.93%, 81.75%, and 78.82% achieved by PF, MGWPF, ACPF, and QPGPF, respectively.

B. Evaluation based on MOTA

Table 1 compares the average MOTA values of the proposed FWPF method with the existing methods [1, 13, 14, 15] for the different numbers of individual tracked objects (from one to eight) in UCSD video data-1 and 2. Figs. 3 (b) and (d) depict the MOTA analysis curve for UCSD video data -1 and 2, respectively. The proposed method attains an average MOTA of 90.73\% for UCSD video data -1, outperforming the MOTA values of 53.03%, 81.76%, 73.27%, and 67.31% achieved by PF, MGWPF, ACPF, and QPGPF, respectively. Similarly, the proposed method attains an average MOTA of 89.58% for UCSD video data -2, outperforming the MOTA values of 65.93%, 82.67%, 76.86%, and 75.46% achieved by PF, MGWPF, ACPF, and QPGPF, respectively.

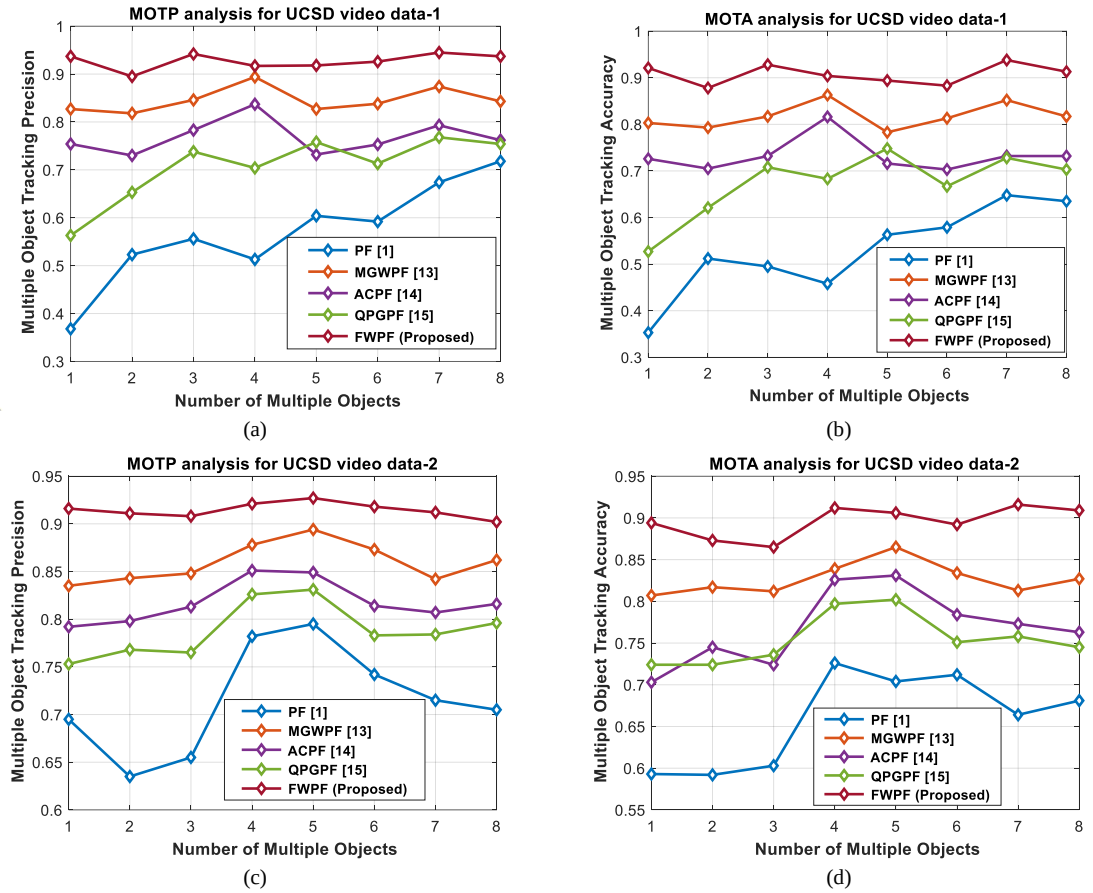

Fig.3. (a, b) MOTP and MOTA analysis curve and (c, d) MOTP and MOTA analysis curve for the UCSD video data - 1 and 2 [32]

C. Evaluation based on TDC

Table 2 compares the tracking distance correlation (TDC) values of the proposed FWPF method with the existing methods [1, 13, 14, 15] for the different numbers of individual tracked objects (from one to eight) in UCSD video data-1 and 2. Figs. 4 (a) and (b) depict the TDC analysis curve for imbalanced tracking over UCSD video data -1 and 2, respectively. The proposed method attains TDC value of 0.0038 (for tracking of eight multiple objects) for UCSD video data -1, outperforming the TDC values of 0.0388, 0.0166, 0.0214, and 0.0318 achieved by PF, MGWPF, ACPF, and QPGPF, respectively. Similarly, the proposed method attains TDC value of 0.0035 (for tracking of eight multiple objects) for UCSD video data -2, outperforming the TDC values of 0.0550, 0.0128, 0.0175, and 0.0319 achieved by PF, MGWPF, ACPF, and QPGPF, respectively.

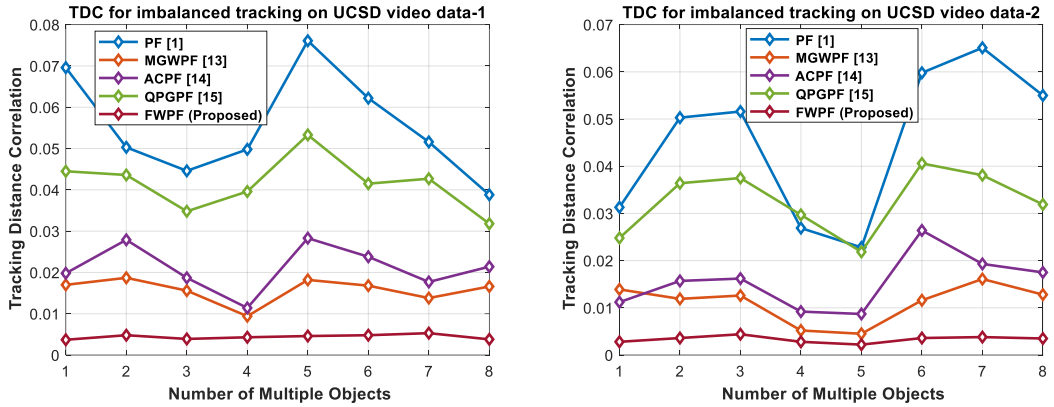

Fig.4. (a, b) Tracking distance correlation for imbalanced tracking on the UCSD video data – 1 and 2 [32]

Table 1. MOTP and MOTA comparison of methods in UCSD video data-1 and 2

Video	Methods	Average MOTP	Average MOTA
UCSD video data - 1 [32]	PF [1]	56.85	53.03
	MGWPF [13]	84.58	81.76
	ACPF [14]	76.8	73.27
	QPGPF [15]	70.63	67.31
	FWPF (Proposed)	92.71	90.73
UCSD Video data - 2 [32]	PF [1]	71.55	65.93
	MGWPF [13]	85.93	82.67
	ACPF [14]	81.75	76.86
	QPGPF [15]	78.82	75.46
	FWPF (Proposed)	91.43	89.58

Table 2. Tracking distance correlation for imbalanced tracking of (1 to 8) multiple objects over UCSD video data – 1 and 2

Video data	Methods	Tracking distance correlation for imbalanced tracking of (1 to 8) multiple objects over video data							
		1	2	3	4	5	6	7	8

D. Evaluation based on Sample Mean and Sample Variance

Tables 3 and 4 compare the sample mean and sample variance of the proposed FWPF method with the existing methods [1, 13, 14, 15] when applied over the imbalanced UCSD video data-1 and 2. The proposed method attains minimum sample mean and variance of 0.0044 (close to zero) and 3.25714 x 10^{-7} for UCSD video data - 1, as compared to sample mean (sample variance) values of 0.0554 (1.62203 x 10^{-4}), 0.0157 (8.8856 x 10^{-6}), 0.0211 (3.1324 x 10^{-5}), and 0.0415 (4.25221 x 10^{-5}) achieved by PF, MGWPF, ACPF, and QPGPF, respectively. Similarly, the proposed method attains minimum sample mean and variance of 0.0033 (close to zero) and 4.82679 x 10^{-7} for UCSD video data - 2, as compared to sample mean (sample variance) values of 0.0454 (2.57158 x 10^{-4}), 0.0110 (1.68079 x 10^{-5}), 0.0155 (3.45568 x 10^{-5}), and 0.0326 (4.56215 x 10^{-5}) achieved by PF, MGWPF, ACPF, and QPGPF, respectively.

Table 3. Sample mean and sample variance for imbalanced tracking of multiple objects (multiple observations) over UCSD video data -1

Methods	Sample mean	Sample variance
PF [1]	0.0554	1.62203×10^{-4}
MGWPF [13]	0.0157	8.88560×10^{-6}
ACPF [14]	0.0211	3.13240×10^{-5}
QPGPF [15]	0.0415	4.25221×10^{-5}
FWPF (Proposed)	0.0044	3.25714×10^{-7}

Table 4. Sample mean and sample variance for imbalanced tracking of multiple objects (multiple observations) over UCSD video data -2

Methods	Sample mean	Sample variance
PF [1]	0.0454	2.57158×10^{-4}
MGWPF [13]	0.0110	1.68079×10^{-5}
ACPF [14]	0.0155	3.45568×10^{-5}
QPGPF [15]	0.0326	4.56215×10^{-5}
FWPF (Proposed)	0.0033	4.82679×10^{-7}

E. Evaluation based on Bias-variance Correction for Imbalance Reduction

Tables 5 and 6 compare the bias-variance correction for imbalance reduction by the proposed FWPF method to the existing methods [1, 13, 14, 15] when applied over the imbalanced UCSD video data-1 and 2. The proposed method attains the correction of bias (variance) by -92.06% (-99.79%), -72.12% (-96.33%), -79.21 (-98.96%), and -89.40 (-99.23%) for imbalance reduction over UCSD video data - 1 when compared to PF, MGWPF, ACPF, and QPGPF, respectively. Similarly, the proposed method attains the correction of bias (variance) by -92.64% (-99.81%), -69.90% (-97.12%), -78.53 (-98.60%), and -89.77 (-98.94%) for imbalance reduction over UCSD video data - 2 when compared to PF, MGWPF, ACPF, and QPGPF, respectively.

Table 5. Bias-variance correction (imbalance reduction shown with negative sign) by the proposed method (FWPF as minimum variance unbiased estimator) in comparison with other methods for imbalanced tracking over UCSD video data -1

Methods	Bias correction (%)	Variance correction (%)
PF [1]	-92.06	-99.79
MGWPF [13]	-72.12	-96.33
ACPF [14]	-79.21	-98.96
QPGPF [15]	-89.40	-99.23

Table 6. Bias-variance correction (imbalance reduction shown with negative sign) by the proposed method (FWPF as minimum variance unbiased estimator) in comparison with other methods for imbalanced tracking over UCSD video data -2

Methods	Bias correction (%)	Variance correction (%)
PF [1]	-92.64	-99.81
MGWPF [13]	-69.90	-97.12
ACPF [14]	-78.53	-98.60
QPGPF [15]	-89.77	-98.94

F. Evaluation based on Computational Time and Limitations of Methods

Table 7 compare the computational time of the proposed FWPF method as compared to the existing methods [1, 13, 14, 15] when applied over the imbalanced UCSD video data-1 and 2. The proposed method processes the 100 frames each of UCSD video data-1 and 2 in 55.993 seconds and 25.775 seconds, respectively. The computational time is the lowest compared to the existing methods. The proposed method is suitable for limited (short-duration) video data obtained from fixed surveillance cameras under weakly supervised object detection settings. The limitations of other competing methods are as follows. In PF-based method, grid-based methods require a predefined state space, limiting uneven partitioning for high-probability density regions without prior knowledge. It highlights that the variance of importance weights increases over time, making degeneracy unavoidable. The computational cost of grid-based methods increases dramatically with state space dimensionality [1]. The MGWPF-based method may face challenges in motion blur and fast motion scenarios, leading to sample degeneracy. The convergence of the MGWO-PF algorithm can vary across different datasets, affecting performance consistency [13]. In the ACPF-based method, local representations fail to capture complex appearances effectively. Global representations are not robust to partial occlusions. Errors tend to accumulate during object model updates, leading to tracking failures under occlusions. The complexity and cost of global search pose an issue [14]. In the QPGPF-based method, the complexity of feature selection strategies is mentioned as a

burden on computational efficiency. The position updating equation has some limitations in optimizing the particle distributions with imbalanced video data. This method incurs higher computational costs despite improving target positioning accuracy [15].

Table 7. Computational time (in seconds per 100 frames of UCSD video data-1 and 2)

Methods	UCSD-1 [32]	UCSD-2 [32]
PF [1]	493.756	176.107
MGWPF [13]	119.621	54.758
ACPF [14]	145.072	67.198
QPGPF [15]	404.676	168.769
FWPF (Proposed)	55.993	25.775

6.4. Discussion

The proposed method is not meant for real-time tracking. Instead, it is used for limited, unlabelled real-world imbalanced video datasets. The limited video data from CCTV cameras for a particular time duration can be of important investigation by the law-enforcement authorities. Further, weakly labelled training data is generated using weakly supervised object detection. The weighted sum rule fusion of complementary trackers can further refine the localization of multiple objects. The proposed method tries to convert imbalanced tracking with a biased proposal pdf into balanced tracking with an unbiased proposal pdf in limited, unlabelled, real-world imbalanced video datasets. The conditions of extreme data imbalance with noisy input are generally found in the limited video data footage obtained from the video surveillance camera for a particular time duration. Weakly supervised object detection and refined localization by fusion of complementary trackers result in a better tracking model that deals with the imbalance in the limited video data footage [36]. As a minimum variance unbiased estimator, the proposed method exhibits bias-variance correction as an imbalance reduction factor, as shown in Tables 5 and 6.

The higher values of MOTP and MOTA are attained by the proposed FWPF method because it fuses the fractional calculus-based whale optimization algorithm and the standard particle filter under weighted sum rule fusion. Integrating the FWPF with an iterative Gaussian mixture model (GMM) with unbiased sample variance and sample mean allows the proposal or importance pdf to adapt to the imbalanced nature of surveillance video data. Thus, there are two trackers, one based on particle filter with a biased proposal or importance pdf and another based on FWOA with the adaptive proposal or importance pdf. Since these two trackers operate on the same video frame (data) distribution, they are not independent but are uncorrelated due to their complementary nature. These trackers deal with two complementary video data distributions that are mutually exclusive. These two trackers' weighted sum rule fusion leads the FWPF to a minimum variance unbiased estimation for effectively detecting and tracking multiple objects in the imbalanced surveillance video data. Since multiple objects are extracted with human intervention in the initial frame, making them weakly labelled (object or non-objects), the weighted sum rule fusion improves both MOTP and MOTA (with lowest TDC) over the frames due to the minimum variance achieved by these trackers being complementary. The FWPF, being an unbiased estimator, also results in the higher MOTP and MOTA overcoming the challenges of the imbalanced surveillance videos. The proposed method solves the problems of sample degeneration and impoverishment along with other tracking problems, such as scale change of objects tracked, occlusion, tracking resumption, etc [30, 31]. To justify the claim of the proposed method acting as a minimum variance unbiased estimator, the sample mean obtained from the multiple observations with different numbers of objects (from one to eight) is determined to be close to zero (unbiased) with minimum variance. The proposed method justifies the imbalance reduction through the bias-variance correction based on sample mean and sample variance obtained for multiple observations. The bias-variance correction (imbalance reduction) is attributed to an unbiased proposal pdf in the imbalanced FWPF-based tracking.

7. Conclusions

This paper fuses the fractional calculus-based whale optimization algorithm (FWOA) and the standard particle filter under weighted sum rule fusion. The fractional calculus up to the first four terms, known as adaptive multiple variable polynomials, makes the FWOA a local and global search operator with inherent memory property. Integrating the FWPF with an iterative Gaussian mixture model (GMM) with unbiased sample variance and mean allows the proposal or importance pdf to be adaptive to deal with the imbalanced surveillance video data, which is highly nonlinear and non-Gaussian. Thus, there are two trackers, one based on particle filter with a biased proposal or importance pdf and another based on FWOA with the adaptive proposal or importance pdf. In view of operating on the same video frame (data) distribution, these trackers are not independent but are uncorrelated due to their complementary nature. These two complementary trackers' weighted sum rule fusion leads the FWPF to a minimum variance unbiased estimation for effectively detecting and tracking multiple objects in the imbalanced surveillance video data. Since multiple objects are extracted with human intervention in the initial frame are weakly labelled (object or non-objects), the weighted sum rule fusion of these complementary trackers causes minimum variance, improving both MOTP and MOTA over the frames. The proposed method handles sample degeneration, impoverishment, and other tracking challenges, such as scale change

of objects tracked, occlusion, tracking resumption, etc. The resultant tracker, FWPF, achieves a higher MOTP of 92.71% (91.43%), MOTA of 90.73% (89.58%), TDC of 0.0038 (0.0035) for tracking of eight multiple objects in the imbalanced UCSD surveillance video data-1 (2) and outperforms the existing methods. The consistent tracking distance correlation near zero values infers the bias-variance correction for efficient imbalance reduction by the proposed method.

***Abstract*— A new approach based on autoencoder with GRU (gated recurrent unit) and discrete transforms for multi scale features of MRI images. Most of the systems fail to adequately handle sequentially dependencies or effectively leverage multi resolution scale. Therefore, in this paper we are analyzing a spatial and temporal features of brain tumor MRI images by imposing modified wavelet transforms for multi-scale analysis with a sequential modeling approach. Masoud Nickparver's Kaggle is used to train and test this model. In this study, 80% of the data are used for training and 20% of the data is used for testing. The implementation outputs give strong validation by achieving 98.88% classification accuracy for four classes. The F1 score and Precision of our novel framework are 98% and 98.30% respectively.**

Keywords*— Index Terms— MRI images, Spatial and Temporal features, Wavelet transform, GRU (gated recurrent unit), Autoencoder

I. INTRODUCTION

Brain tumors are masses created when abnormal growths in brain lesions occur inside of humans, directly affecting how well the brain functions to manage both voluntary and involuntary processes. It is a serious illness that contributes significantly to cancer mortality globally. The number of deaths from various cancers, including brain cancer, has increased, according to Cancer Statistics 2019 [1]. One effective non-invasive method for identifying brain anomalies is neuroimaging. The most widely used neuroimaging methods for diagnosing brain tumors are magnetic resonance imaging (MRI) and computed tomography (CT) scans. Using radio waves and powerful magnetic fields, MRI examines a body's physiology and anatomy [2] [3]. As a result, MRI is an effective method for identifying illnesses and physical abnormalities in the body. It can be used in many different medical imaging contexts. Nevertheless, it might be challenging to identify a tumor in a brain MRI; a specialist must review the pictures to ascertain whether a tumor is present. Additionally, determining the type of tumor and its location is crucial. CNN models are now a commonly utilized paradigm for MRI brain tumor identification, among other body part tumor detection. But these models give only spatial feature. In order to apply Computer Vision (CV) technology that can precisely detect and identify the existence of a tumor in an MRI, a strong solution is required [4][5][6]. Therefore, we are using the autoencoder and DWT to preserve the key characteristics of the time-series data while reducing the quantity of information. The autoencoder framework can handle complicated patterns in MRI images more effectively if DWT is incorporated. For local and global feature extraction, a probabilistic neural network (PNN) is designed where DCT, DWT, and PCA methods are used as decomposition and reduction [7]. The human hand is extremely agile and performs many different tasks. Therefore, author proposed recognition algorithms with the combination of wavelet neural network (WNN) and discrete wavelet transform (DWT) [8]. To convert the low resolution into high resolution, a combination of DWT for decomposition for enhancing the edges is designed to get the interpolation of high frequency sub bands The wavelet transform is used to break down the input data into its approximate and detailed components during the encoding process. This allows the autoencoder to concentrate on important characteristics while disregarding noise. In order to improve data structure preservation and minimize distortion, the signal can be rebuilt from its compressed representation during the decoding stage using the inverse DWT [9]. The detection and classification of MRI brain tumors are implemented using different wavelet transforms and support vector machines to differentiate between normal brain and tumor brain. But due to lack of scalability this method achieved low classification frequency [10]. Berkeley's wavelet transformation (BWT) and deep learning classifier have been used by the researchers to enhance performance and streamline the medical image segmentation procedure because of the large range of tumor tissues present in various individuals [11]. Utilizing the gray-level-co-occurrence matrix (GLCM) approach, significant features are retrieved from each segmented tissue and then optimized using a genetic algorithm. But this method was lack due to computational complexity and noise sensitivity [12]. A new technique for differentiating between benign and malignant brain tumours in MRI images uses contourlet transform and time adaptive self-organizing map, optimized by the whale optimization algorithm [13]. A single evaluation system that combines localisation, detection, and classification with other elements of image processing. Additionally, it makes use of the special powers of Ridgelet transformations to pinpoint the exact position of the cancer [14]. The Ridgelet-based approach used the Ridgelet transform in combination with the Grey Level Co-occurrence matrix for feature extraction and classification using Multi-Layer Preceptron (MLP) to classify MRI data into tumorous and non-tumorous, as well as meningioma and glioma.

This guarantees a comprehensive assessment of the localisation procedure even further.

II. Proposed Method

This section discusses a proposed autoencoder for brain tumor detection using maximal overlap discrete wavelet transforms, based on GRUs (Gated Recurrent Units) [15]. The diagram representing the proposed methodology is shown in Fig 1. Data collection, pre-processing, autoencoder-based feature extraction, and classification are some of its four stages. Each step's comprehensive description is given here.

A. Data Collection

Masoud Nickparver's Kaggle platform provided the original input brain tumor data for this model [16]. There are 7022 brain MRI pictures available for analysis of multiple brain tumors. Together with 1621 Meningioma, 1600 No-tumor, and 1757 Pituitary classes, the dataset also contains 1645 Glioma. This dataset combines the Fighshare [17], SARTAJ [18], and Br35H [19] datasets.

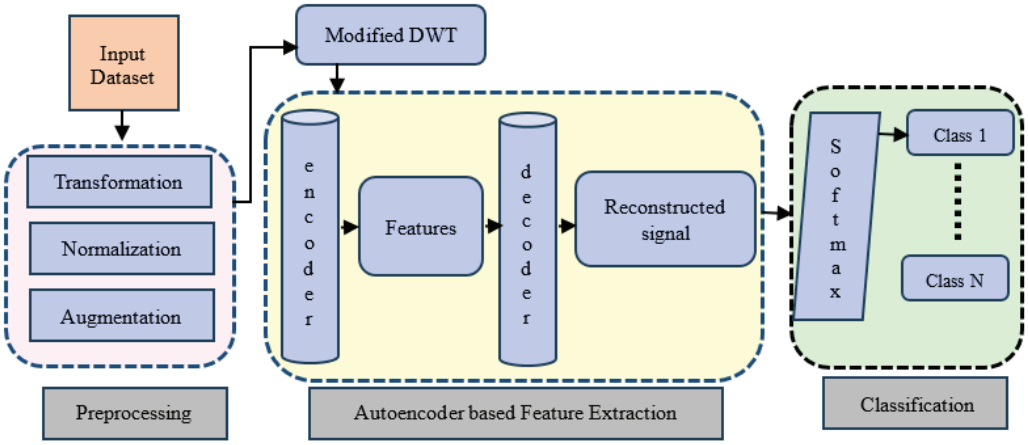

Fig. 1. Diagram representing proposed methodology

B. Data preprocessing

In this stage, the uniform resolution of all the images in the dataset is checked, and the pixel values are normalized to make processing them easier. An augmentation technique is used to further limit the problem of overfitting, as the size of the dataset in medical images is limited.

C. Autoencoder-Based Feature Extraction

After preprocessing the data, the images are first decomposed using maximum overlap DWT. To extract multi-scale features, this important step is completed. By doing this, images are transformed into wavelet coefficients, which are used to record frequency and spatial information. Here, using decomposed wavelet coefficients as features instead of raw pixel values improves the performance of the model. The decomposition of the image at various scales is provided as follows when maximum overlap DWT is applied to the input I_t:

$$I_t = \sum_{s=0}^{S} w_s(t) + C_S(t)$$

Where the wavelet coefficient is $w_s(t)$ and the scaling coefficient is $C_S(t)$.

Different resolutions of images are represented by set of coefficients given in the above transformation.

$$\{w_s(t)\}_{s=1}^{S}$$

These wavelet coefficients are features used by G RU-based encoders. GRU layers are now used to reduce the dimensions of wavelet transformed features.

In an encoder, GRU layers are stacked. Let the following be an input sequence:

$$I_t = \{w_s(t)\}_{s=1}^{S}$$

Where

$t = 1, \ldots\ldots, T$

Time steps are represented by T, whose vector of wave coefficient is given by I_t, because an MRI scan consists of multiple slices. Fig 2 illustrates the various hidden states z_t that each GRU layer possesses. GRU effectively captures sequential dependencies very efficiently at various levels. A reset gate and an update gate are the two gates. The update gate determines how much past state will be remembered, while the reset gate determines how much past state will be forgotten.

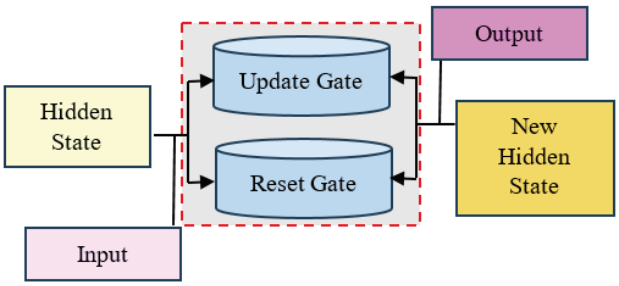

Fig. 2. GRU architecture

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on April 08,2025 at 06:13:55 UTC from IEEE Xplore. Restrictions apply.

The update gate, represented by the symbol ug_t, and the reset gate, represented by rg_t, are computed as follows:

$$ug_t = \sigma(w_{ug}.I_t + U_{ug}.z_{t-1} + b_{ug})$$
$$rg_t = \sigma(w_{rg}.I_t + U_{rg}.z_{t-1} + b_{rg})$$

The latent vector is given to the classifier for brain tumor classification once the autoencoder has been trained.

III. Experiment Results

A. Experiment Results

The original input brain tumor dataset, Masoud Nicaraven's Kaggle [16] used to train and assess the proposed model. Eighty percent of each dataset's data is used for training and twenty percent is used for testing in the deep learning approach. A batch size of 16 photos and a learning rate of 0.001 were used to run the trained model 100 times. This model is optimized using Adam. The testing data's validation criteria yield the best classification results after 100 iterations. The classifier output of our model is displayed in Figs. 3 and 4, where we can view the classification accuracy and loss outcomes for various parameters. This graph shows that overall classification accuracy in Fig. 3 achieves excellent performance for the validation of the proposed model. In training, it attains a classification accuracy of 98.88 while in testing, it reaches 98%.

The resulting confusion matrix displays the classification outcomes of a model with 98.88% accuracy in predicting pituitary, meningioma, glioma, and no tumor pictures. The correct predictions are represented as diagonal values. The 272 glioma images were correctly categorized as well. Misclassifications are shown by off-diagonal numbers for example, 26 glioma images were mistakenly identified as meningiomas.

B. Discussion

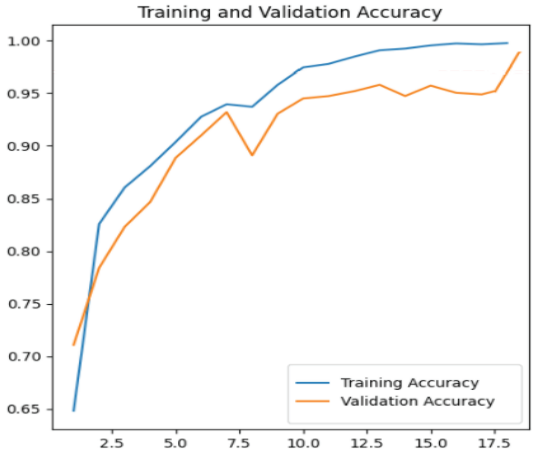

Fig. 3. Train and Test Accuracy

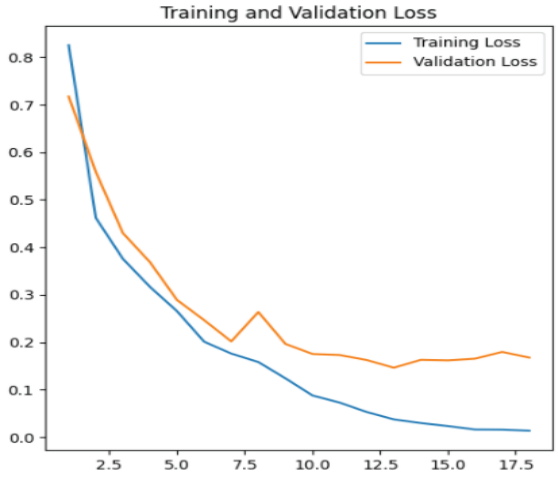

Fig. 4. Train and Test Loss

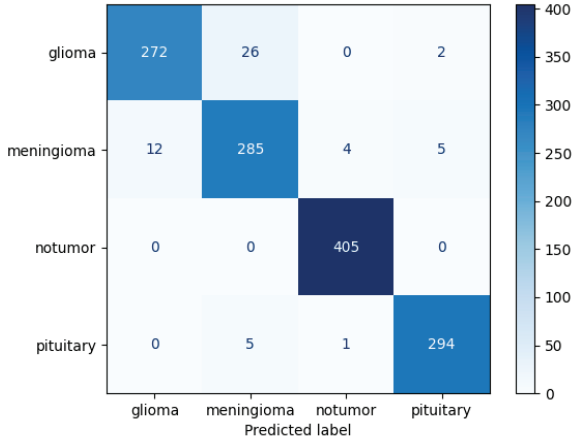

Fig. 5. Confusion Matrix

Table 1 contains a number of studies where academics have worked with various MRI picture difficulties to develop segmentation and feature extraction approaches. In order to identify tumour, it has been discovered with 86% classification accuracy using a support vector machine for classification and a discrete wavelet transform for decomposition. A model for MRI-based brain tumour identification by orthogonal wavelet transform and classification using deep learning achieved 98.5% classification accuracy and 98% precision. The contourlet transform based time adaptive self-organizing map is a unique approach to MRI brain tumour detection that obtained 98.5% classification accuracy, 97.9% F1 score and approximately 96.1% precision. Ridgelet transform, a revolutionary technique, was used to detect and localize brain tumours more accurately with classification accuracy of 98.65% of MRI images. Our proposed model, GRU with maximal overlap discrete wavelet has excellent results in comparison of existing models. The classification accuracy of our model is 98.88%, F1 score is 98% and precision is 98.3%.

IV. CONCLUSIONS

This paper provides a thorough examination of the issue of extracting tiny features from tumors in order to handle sequential dependencies or use multi-resolution scaling efficiently. The analysis of the spatial and temporal features of MRI images of brain tumors is being done using a new method based on autoencoder with GRU (gated recurrent unit) and discrete transforms for multi-scale analysis using a sequential modelling approach. This model is trained and tested using Masoud Nickparver's Kaggle platform. Eighty percent of the data in this study are utilized for training, while twenty percent are used for testing. Strong validation is provided by the implementation outputs, which achieve 98.88% classification accuracy across four classes. Our innovative framework has an F1 score of 98% and precision of 98.30%.

In future, this work can be extended to incorporate multi-modal data, such as integrating MRI with other medical imaging techniques. This can help to improve the robustness of brain tumor detection.

***Abstract*— Communications reliability and security of Matter-enabled IoT networks are now gaining even more prominence with their widespread acceptance and deployment. Nonetheless, such advancements indeed introduce further challenges, most notably in the detection of the diverse set of anomalies caused by device faults and DDoS attacks that may destabilize the network. This paper presents a hybrid anomaly detection system specifically designed for Matter-enabled IoT environments where rule-based filtering is incorporated with an ML-based detection approach leveraging Extreme Gradient Boosting (XGBoost). The rule-based module detects potential anomalies by applying predefined threshold conditions, and the XGBoost aims to curtail this detection into high detection capability and reduced false positives. The system is experimented with making the prediction on IoT telemetry data, achieving 97% precision, recall, and accuracy-greatly exceeding the lone detection strategies. The results prove how our approach can help mitigate the occurrence of false alarms, alongside imbalanced datasets being major obstacles in IoT networks' anomaly detection. Future research will further include the real-time detection application of sophisticated temporal models, scalable improvements, and security optimization within the confines of resource-constrained Matter-enabled IoT deployment.**

***Keywords*- Anomaly Detection, Matter-enabled IoT, Rule Based Filtering, XGBoost, Hybrid Detection System, Machine Learning**

I. INTRODUCTION

Matter-enabled IoT devices across diverse domains such as smart homes, industrial automation, and healthcare have created a new wave of connectivity and interoperability. These are the devices that provide cross-manufacturer interoperability, which means improved usability and performance in their operation. However, the greater the dependency on these systems, the consideration shifts to that of reliability of the network, security, and scale-out. Hardware failures, communication failures, and denial-of-service attacks have, therefore, to be found, as early as possible, in order to ensure the integrity of the system. The spread of IoT through adoption in smart homes, healthcare, and industrial automation serves to give an explosion of devices, hence terrific data throughput requiring advanced analysis [1]. Despite all these, IoT still faces many problems, such as many security measures are not implemented well in the devices in the resource-constrained environment, hence exposing the network to threats of DDoS attacks and data breaches [2]. These factors indicate the requirement of robust security and anomaly detection systems. IoT networks, especially those using protocols such as Thread, solve some of the challenges by enabling secure, low power IPv6 communication. The layers of Thread include 6LoWPAN and CoAP, which enhance scalability and efficiency. However, issues like standardization and power consumption remain a challenge for general adoption. Sensor reliability in dynamic IoT environments further requires advanced techniques, such as multi-agent distributed deep reinforcement learning, to guarantee correct anomaly detection and fault management [3].

This paper presents a hybrid anomaly detection system suitable for Matter-enabled IoT networks by combining rule-based filtering with XGBoost. Such a balance between simplicity and adaptability leads the system toward scalability and real-time anomaly detection, thus promising safe IoT ecosystems.

II. LITERATURE REVIEW

Mesh network for smart homes offers integrated advanced technology to provide more automation. This paper shows increased importance given by IoT to large grids to household devices. A four-layered sensor, gateway and network unit, man-servicing unit, and applications on the IoT laid increasing emphasis on mesh networks for reliability. Wireless Sensor Networks using low-cost devices, like the XBee module, showed improved communication robustness. The other solution is Message Queuing Telemetry Transport (MQTT), identified as a more suited solution for resource-constrained environments, low cost, and enriches smart home functionality.[4]

Most of the developments related to the theoretical foundations of Digital Twin technology in healthcare, implementation challenges, and combination of AI and IoT in creating Digital Twins of patients have been summarized. The barriers were first related to a lack of real-time data application and second a lack of empirical data to support the proposed models. The research reveals the revolutionary potential of Digital Twins in transforming patient monitoring and healthcare delivery, stressing the need for standardization in practice and stronger data protection

standards to ensure confidence in these emerging technologies.[5]

The IoT unification of physical objects with an Internet instrument opens boundaries for numerous applications, yet they become of great concern for cybersecurity attacks owing to the adjacent and dispersed devices in their cyberspace. The state-of-the-art survey on IDS and the Internet of Things highlights issues not only with interoperability but also with immature research and pseudo coverage of the various IoT attack vectors. Anomaly-based IDS, signature-based IDS, and specification-based IDS lack a consensus on the optimal placement of detection strategies and on how to establish them. This paper recommends giving further attention to extending any form of attack coverage, equipping the same with emerging technologies, and developing adaptable frameworks.[6]

The rapid proliferation of IoT devices creates a strong demand for effective, secure authentication protocols that can handle resource-constrained environments. Classic schemes involving time synchronization and nonce storage are highly impractical on low-power devices, leading to vulnerability against replay attacks. The innovative approaches introduced here - for example, a new challenge-response mechanism that achieves security with lower overhead compared to the use of time synchronization and nonce storage - strengthen authentication but minimize overhead, this represents a critical step in securing the Internet of Things (IoT) and its application-related interconnectivity.[7]

IoT has integrated itself into the daily life, but due to cost, size, and power constraints, the systems remain insecure against attacks. Distributed Denial of Service attacks are a severe threat to the IoT networks. This paper is a review of IDS and its ability to provide a boost with machine learning and deep learning. Gaps in literature of IDS datasets and anomaly detection methods are identified, and a resilient security framework is proposed against the evolving threats of IoT.[8]

This paper explores the deployment of honeypots on Raspberry Pi devices aims to increase IoT security in areas like health, where privacy and data must be safeguarded. Cowrie, Dionaea, and Glastopf are the honeypots used by the authors for attack pattern detection. Dionaea scans several protocols, which gives it the opportunity to detect a threat by looking into FTP login attempts and Denial of Service attacks, whereas Glastopf detects web attacks. Cowrie is a high-interaction honeypot, since it records interactions with the attacker. Observations regarding the low-cost honeypot configuration indicate that this honeypot is effective for detecting threats and gathering forensic data on IoT security in the face of evolving cyber threats. [9]

This paper examines a Sensor Fault Detection paper in Internet of Things (IoT) examines the issues occurring due to hostility and wrong reads. Although wireless sensor networks' research is mainstream, IoT would require specialized approaches because the context is different from WSN, and this discussion will give knowledge about outlier methods, advantages and disadvantages, of which the entire systematic literature study and industry review will be found. The study suggests a multi-agent distributed deep reinforcement learning approach to improve sensor reliability, addressing faults and anomalies in IoT environments.[10]

This paper covers the advantages and deployment techniques of wireless mesh networks in empowering IoT systems. As, wireless mesh networks are self-organizing topologies based on the ad hoc networking model and facilitate scale-up, robustness, and cost-effectiveness. They provide extended seamless coverage with minimal costs and eliminate single points of failure, thus increasing robustness. Transitioning from star networks to hybrid wireless mesh networks provides an enhanced performance of IoT systems. Challenges like possible network delays and infrastructural compatibility issues, still necessitating further research for large-scale deployment, exist.[11]

Data splitting is essential for unbiased model validation in statistics and machine learning. Holdout data, calibration, and validation increase accuracy. The R package Split is designed to optimize training/testing ratios that enhance inference reliability. On the other side, high-dimensional classifiers heavily rely upon resampling and optimal partitioning to generalize data. Random matrix theory provides advances in data splitting. Thereby assuring robust practices in data sciences and the development of trustworthy predictive models. [12]

III. DATA DESCRIPTION

The dataset adopted for this experiment sourced from telemetry information from an IoT communication system, targeted toward performance metrics for anomaly detection.

It was also developed to resemble real-world conditions within IoT and assist in classification models for detection of system behaviour. Some major points regarding the dataset are elaborated below.

*A. **Structure and Metrics***

The dataset includes key telemetry metrics necessary for network performance analysis. **Packet Drops** refer to dropped packets, which indicate both network instability and congestion. **Retry_Counts** refer to the number of retransmissions, which are useful in the analysis of interference and failures in delivery. **Message Delivery Time**, expressed in milliseconds, is the time required for delivery of a message when it is passed and successful in transmission, indicating system latency. The network states are classified using a Label (with 0 signifying a normal state and 1 indicating an anomaly) to enable proper anomaly detection and performance diagnosis.

*B. **Composition and Balance***

The dataset consists of normal and anomalous traffic and thus provides a balanced representation of communication system behaviours. Normal Traffic, or Class 0, reflects the standard patterns of communication when everything is

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 07:29:57 UTC from IEEE Xplore. Restrictions apply.

functioning normally and forms the bulk of the dataset. Class 1 or anomalous traffic, therefore captures instances of the behaviour of an anomalous system that fails to communicate or the inefficiency in network operation and represents a much smaller proportion of the dataset. Robustness and relevance were ensured through the dataset being curated from a pool of 1,000 records. Preprocessing was conducted to remove about 15% of noise and outliers. Thus, the final dataset has 850 high-quality instances, and normal and anomalous traffic is well balanced.

C. *Realism and Future Scope*

The dataset is synthetically generated but structured and designed to mimic the behaviour of a real-world IoT network in close detail. Nevertheless, there remains a major challenge in acquiring large, high-quality datasets from real IoT deployments.

IV. Proposed Methodology

A. *Architecture Overview*

This proposed hybrid anomaly detection system is for accurately and with very few false positives identifying anomalies on Matter-enabled IoT devices. There are four core modules in its architecture:

1) Data Collection Module:

- It collects the telemetry data coming from Matter enabled IoT devices.
- All of the monitored metrics, packet drops, retry counts, and delivery times of the message, will be logged continually.
- The gathered data is also put into structured formats and analysed.

2) Pre-Processing Module: The Pre-Processing Module is used for preparing raw telemetry data, which is noisy and inconsistent, to be fed into the anomaly detection module. The module begins by using Min-Max ormalization, which scales features so that all the data falls in the range

[0, 1], improving the performance of machine learning models. The data is divided into training and testing sets for supervised learning so that the model is trained on one portion while validated on another. For analysing temporal patterns, the data can also be divided into fixed-length windows, which enables more accurate insights when future extensions of the project necessitate handling sequential data. This pre-processing step ensures the data is clean, well-structured, and ready for anomaly detection algorithms.

3) Detection Module: It has its two fundamental modules namely, Rule-Based Filtering and XGBoost Classifier. Rule-Based filtering is meant for fast and quasi-real-time identification of suspect anomalies by applying operators established through previously set statistical thresholds called rules determined by analysts. For example, there could be an indication of anomalies once packet drops cross a threshold of mean + 2σ (packet_drops > mean + 2σ). Non-flagged data denotes those data points that do not cross above these thresholds and therefore are considered normal with no analytical measure. Based on choosing key metrics such as packet drops, retry counts, and message delivery time, those that exceeded a certain threshold were flagged as anomaly (1); the rest would be marked normal (0). This obviously helps in avoiding unnecessary processing and improving computational efficiency. The rule-based filtering is both computationally easy and efficient for such real-time detection but lacks adaptability to the changes in network behaviour over time. Since this limitation should not lead to the crumbling of the very foundation of anomaly detection work, some flagged data are resorted to by XGBoost Classification in the sense that it will be training the model using telemetry data for classifying anomalies (label 1) from false positives (label 0). Performance is assessed on XGBoost against classification metrics like precision, recall, F1-score, and overall accuracy. The dataset is split into 80% training and 20% testing, with the actual values, y_test, compared against predictions, y_pred. Precision indicates the total percentage correctly labelled as anomalies; recall estimates the model's capacity for finding all real anomalies; whereas the F1-score is that balanced view of both. Overall accuracy is how much data is correctly predicted: the proportion of total observed data this rate captures still makes sense.

4) Decision Engine: The Decision Engine aggregates the result of the Detection Module to finally produce the anomaly detection outputs.Non-flagged data is automatically categorized as normal (0) since it does not fit any abnormal activity. For data that is flagged, the XGBoost model processes it and gives it a classification either as true anomalies (1) or false positives (0). Other than classification, the engine also updates system logs to aid in post-incident analysis; each anomaly detected is logged for future checking. It also fires immediate alerts by showing the anomalies noticed at the end for the relevant stakeholders of the respective problems, ensuring response time.

B. *Anomaly Detection Pipeline Digram*

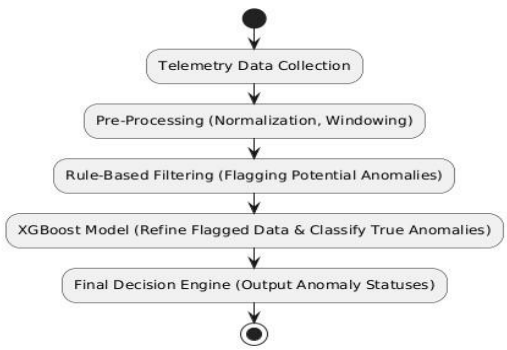

Figure 2: Detection Pipeline for Anomaly Detection

C. *Hybrid Anomaly Detection Algorithms*

1) Rule-Based Detection: The rule-based detection system identifies potential anomalies by applying predefined thresholds to telemetry data.

2) XGBoost Algorithm: The XGBoost-based anomaly detection algorithm refines the results of the rule-based system by leveraging supervised learning. It trains on

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 07:29:57 UTC from IEEE Xplore. Restrictions apply.

flagged data points to classify them as true anomalies or false positives. The use of gradient-boosted decision trees ensures high accuracy, recall, and precision, making it suitable for IoT telemetry data analysis.

3) Hybrid Detection System: The hybrid system integrates rule-based filtering and XGBoost refinement for robust anomaly detection. The pseudocode for the hybrid detection system is as follows.

Algorithm: Hybrid Anomaly Detection System

Procedure:hybrid_anomaly_detection(dataset): [A hybrid approach combines rule-based detection and machine learning for improved anomaly detection]

Step 1: Rule-Based Detection

1. Define thresholds for anomaly detection:

packet_drops_threshold := mean(packet_drops) + 2 std(packet_drops)

retry_counts_threshold := mean(retry_counts) + 2 std(retry_counts)

message_delivery_time_threshold := mean(message_delivery_time) + 2 std(message_delivery_time)

2. For each data point row in the dataset:

if

packet_drops > packet_drops_threshold **or**

retry_counts > retry_counts_threshold **or** message_delivery_time > message_delivery_time_threshold:

Flag the data point as anomalous (1).

else:

Flag the data point as normal (0).

3. Store the flags in the rule_based_flag column.

Step 2: Data Splitting

4. Separate data based on rule-based flags:

Approach	Precision (%)	Recall (%)	F1-Score (%)	Accuracy (%)
Rule-Based Filtering	92	87	89	90
XGBoost	100	99	99.5	99
Hybrid Model	97	97	96	97

flagged_data := data points where rule_based_flag = 1

non_flagged_data := data points where rule_based_flag = 0

5. Prepare flagged_data for machine learning:

Features: X := [packet_drops, retry_counts, message_delivery_time]

Labels: y := label.

6. **if** flagged_data has less than two unique classes:

Use rule-based predictions directly:

predictions:= rule_based_flag.

else: Proceed to Step 3.

Step 3: Train XGBoost on Flagged Data

7. Perform train-test split:

Divide X and y into X_train, X_test, y_train, and y_test using an 80-20 ratio.

8. Train an XGBoost model with the following parameters:

- n_estimators := 100
- max_depth := 3
- learning_rate := 0.1
- random_state := 42.

9. Fit the model on X_train and y_train.

10. Predict on X_test:

- y_pred := predictions on X_test.

11. Evaluate XGBoost performance using a classification report comparing y_test and y_pred.

12. Use the model to generate predictions for all flagged_data.

Step 4: Handle Non-Flagged Data

13. Assign predictions for non_flagged_data:

predictions := 0 (normal).

14. Combine flagged_data and non_flagged_data to create final_results.

Step 5: Evaluate Overall System

15. Compute the classification report comparing final_results[label] and final_results[predictions].

16. Return the overall system performance metrics.

V. EXPERIMENTAL RESULTS

A. Performance of the Anomaly Detection Model: The proposed hybrid anomaly detection system, tailored for Matter-enabled IoT devices. The rule-based detection method, although efficient in identifying anomalies based on simple thresholds, suffered from limited recall (87%) and high false positives due to its rigid nature. Conversely, the XGBoost model, trained on flagged anomalies, achieved perfect precision, recall, and F1-Score (100%), showcasing its ability to refine classifications effectively. The combined **hybrid system** improved overall performance by leveraging the strengths of both approaches. With precision at 97%, recall at 97%, and an F1-Score of 96%, the hybrid system achieved a balanced trade-off between sensitivity and specificity, making it suitable for real-time anomaly detection in IoT environments.

Table 1: Performance Metrics by the System

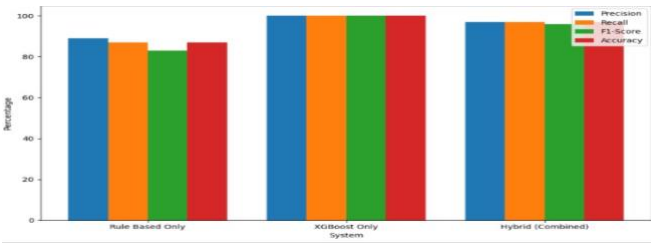

Figure 3: Performance Metrics by System

B. Parameter Tuning and Feature Analysis:

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 07:29:57 UTC from IEEE Xplore. Restrictions apply.

The parameter tuning process for the XGBoost model was key parameters of hyperparameter optimization, which were to maximize detection accuracy. The learning rate was set to 0.1 to maintain a balance between speed and accuracy in training; the maximum depth was adjusted to 5, which prevents overfitting, and more subtle interactions among features can be detected; and the number of estimators was set to 100 to retain efficiency without compromising performance. By applying these settings, the model showed good generalization to unseen data, with F1-score, as well as overall accuracy to be high. In addition, performing feature importance analysis demonstrated the importance of telemetry metrics in terms of anomaly identification. A packet drop was found to be 40% responsible for the aggregate importance, after retry counts account for 35%, and for message delivery times, 25%.

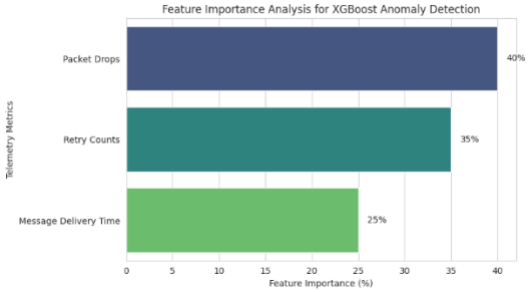

Figure 4: Feature Importance Analysis

VI. DISCUSSION

The hybrid approach successfully overcame the limitations of standalone methods since it effectively implemented real time anomaly detection for Matter-enabled IoT networks. Combining rule-based filtering for quick flagging of anomalies with XGBoost for more accurate classification helped achieve higher accuracy and minimized false positives. However, challenges such as data imbalance, where anomalies were significantly outnumbered by normal instances, required mitigation using oversampling techniques like SMOTE. The system still requires further optimization for real-time deployment on the resource-constrained IoT devices in order to run seamlessly. With these challenges aside, the system's performance puts it as one of the potential robust frameworks in anomaly detection on IoT environments with balance between precision and recall and still being adaptable to dynamic network behaviours.

VII. CONCLUSION

The main challenge addressed here is that in anomaly detection by Matter-enabled IoT networks, system reliability and security are important requirements. The number of current approaches, including the purely rule-based systems or standalone machine learning models, are deficient in their potential applications with serious limitations, like high false positives, lack of adaptability, and computational inefficiencies, under the harsh environment of resource constraints in IoT scenarios. This calls for a hybrid model that will bridge the gap of the accuracy and efficiency. The studied anomaly detection system is a hybrid system combining rule-based filtering and classification with XGBoost. It applies the rule-based system to the first level of anomaly detection by using predefined statistical thresholds and refines the flagged anomalies by using XGBoost to limit false positives and improve the accuracy of detection. The system was tested on telemetry data from IoT; it obtained 97% precision, 97% recall, and 96% F1-score, significantly outperforming the standalone rule-based approach.

Key Findings of the Study:

1. Rule-Based Detection is a computationally anomaly filtering mechanism, but its low recall (87%) causes many anomalies to be missed.
2. The XGBoost Model delivered 99 percent accuracy on flagging data that shows it worked well for perfecting the anomalous classification accuracy.
3. The Hybrid System has excellent balance between sensitivity and specificity.

This work contributes to a novel hybrid anomaly detection approach specifically suited to Matter-enabled IoT networks, pipelining rule-based filtering with machine learning, and through analysis of features, insight as to which is most critical of the anomaly indicators: it is message delivery time, scalable, and flexible toward static rule-based methods while also responsive toward computationally intensive ML models. Therefore, this work lays the foundation for increasing security in IoT networks. However, future work aims to adapt the threshold values, deep learning techniques like LSTM, and real-time deployment on edge devices, thereby increasing the anomaly detection capabilities.

State-of-the-art anomaly detection for the Matter-enabled Internet of Things networks suffers from limitations such as very high false positives, dependency on static thresholds, and difficulty dealing with imbalanced datasets. Classical rule-based techniques are simple, but they don't adapt much, and individual machine learning algorithms require large sets of labelled training data and aren't robust with real-world variability. Most of the present works do not experiment with hybrid methods that combine rule-based filtering with machine learning for achieving precision. Furthermore, the datasets used are also quite limited in terms of diversity. This work addresses these gaps by proposing a hybrid anomaly detection system that integrates rule-based filtering for fast anomaly flagging with XGBoost for finer classification, achieving a balance between the detection accuracy, computational efficiency, and real-world applicability in Matter-enabled IoT networks.

Future Work

The proposed concurrent anomaly detection system is efficient, but there is plenty of scope for scalability and adaptability improvements. Future work will include the investigation of more sophisticated deep learning techniques such as LSTMs to capture complex time-dependent patterns in telemetry data, allowing for better anomaly detection. The

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 07:29:57 UTC from IEEE Xplore. Restrictions apply.

system will also be optimized to work at scale for IoT deployments where IoT devices may vary in the order of tens of thousands, ensuring robustness. Real-time dashboards will be added for easier visualization of anomalies for actionable insights to the operators of the networks. Secure communication protocols will also eventually be integrated for the protection of telemetry data as it goes through the various points of transmission. Expanding support beyond Matter to multiple IoT protocols will give versatility and applicability. If these challenges are addressed well, we might be left with a very robust IoT network that's secure and resilient in changing environments.

Abstract—Digital signatures are essential for secure data interchange. However, most document signing solutions depend on cloud-based infrastructures, which may expose users to security vulnerabilities and significant computational requirements. This paper proposes designing and implementing a proximity mobile-based iHDoc digital document signing prototype to sign documents over a Near Field Communication (NFC) tap. It consists of Signer and Signee applications on two different mobile devices that tap to first mutually authenticate each other and then sign the document. iHDoc utilizes iDSign, a previously proposed secure and lightweight design framework based on Identity-based Cryptography (IBC). IBC eliminates the need for certificates by associating public keys directly with user identities, reducing computational and communication overhead and assisting in lightweight mutual authentication over HCE and resource-constrained mobile devices. NFC proximity reduces the risk of man-in-the-middle attacks and ensures the locality of reference. Performance comparison of iHDoc with IBC and RSA-based mutual authentication indicates that the iHDoc prototype performs better with iDSign due to reduced time and storage. It is, hence, suitable for the proximity-based, resource-constrained digital signature of documents.

Keywords—digital signatures, host card emulation (HCE), near field communication (NFC), identity-based cryptography (IBC), mobile devices, lightweight mutual authentication, session key establishment

I. INTRODUCTION

Digital document signing has become essential for secure data exchange in various fields, such as healthcare, legal contracts, and financial transactions [1]. The need for robust digital signature solutions has never been more critical. However, many existing solutions rely on cloud-based infrastructures, which expose users to potential vulnerabilities, high computational requirements and threats such as Man-in-the-Middle (MiTM) attacks. Cloud-based Public Key Infrastructure (PKI) systems, commonly used in popular signing platforms, often necessitate complex certificate management and online connectivity, creating security risks and limiting their usability in resource-constrained, offline, or mobile environments [2], [3]. The growing number of Android mobile devices presents the potential to digitize conventional paper-based processes that require in-person encounters, including government document approvals, legal contracts and delivery confirmations. These situations benefit from proximity-based solutions that guarantee secure, localized communication, facilitating in-person digital signature systems.

Near-field communication (NFC) offers a strong alternative for robust in-person, proximity-based digital communication.

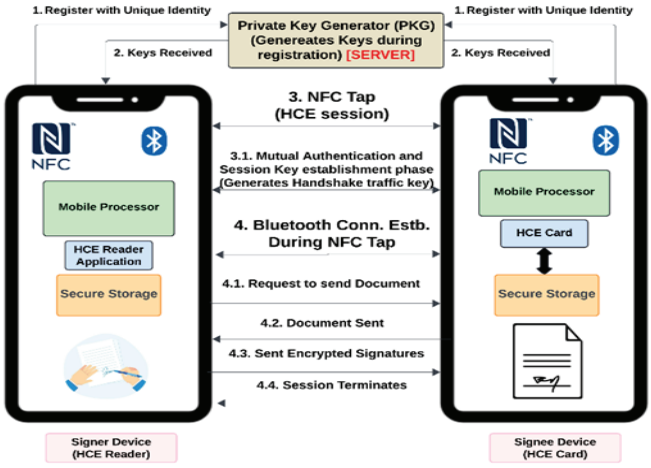

Fig. 1. Block Diagram of iHDoc.

It is a wireless communication technology that allows two devices to transfer data within short distance, typically within a few centimetres [4]. It operates in three modes: reader/writer mode for reading NFC tags, peer-to-peer mode for exchanging data between mobile devices, and Host Card Emulation mode (HCE), where the device function as a contactless smart card. The HCE mode enables secure two-way communication, allowing mobile devices to mimic contactless cards and reader applications. The versatility of HCE has made it a popular choice in applications such as smart health cards [5], payment solutions [6], and secure authentication systems. HCE employs Application Protocol Data Units (APDU) commands [7] based on ISO/IEC 14443 standards [8] for secure communication between the emulated card and reader application. NFC's locality ensures communication only within proximity, greatly reduces the possibility of proximity-based attacks, such as MiTM attacks.

Hence, this paper proposes the design and implementation of a novel iHDoc android mobile prototype application that makes use of NFC's HCE mode [4] and Bluetooth to address the shortcomings of existing solutions. It is a proximity-based digital document signing prototype designed for the in-person digital document signing on Android mobile devices. In iHDoc, the Signer and Signee tap mobile devices over NFC HCE mode to first mutually authenticate each other based on the lightweight iDSign framework [9]. After authentication, the applications establish an automated Bluetooth connection during the NFC tap to address the HCE mode's data transfer limitations and enable faster transfer of larger files. Finally, the document is securely transferred and digitally signed, as illustrated in the block diagram in Fig. 1.

TABLE I. COMPARISON OF EXISTING DIGITAL SIGNATURE SOLUTIONS

979-8-3315-2749-5/25/$31.00 ©2025 IEEE
Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 06:37:46 UTC from IEEE Xplore. Restrictions apply.

Existing Solution	Signature Type	Authentication Method	Internet Required	Encryption Model	Limitations
Adobe Sign [14]	PKI-based digital, Cloud Cert. or tokens	PKI certs, Hardware tokens, Cloud-based tokens	Required	RSA encrypt., High computational demand	High processing, Internet dependent
Visma Sign [15]	Strong ID signatures, cloud servers	External ID Verification (Banking, Mobile ID)	Mandatory for ID verification	Govt. ID verification	Cloud server dependent, Limited offline cap.
DocuSign [16]	E-sign, PKI-based digital	SMS, email, third-party integration	Required for auth. and cert. access	RSA encrypt, High comp. demand	Limited offline, Cloud dependency

A solid secure protocol is crucial for authenticating devices engaged in NFC HCE mode interactions to guarantee that only authorized entities participate in document signing. Conventional Rivest, Shamir, and Adleman (RSA) based authentication methods, such as those used in Transport Layer Security (TLS) and HTTPS protocols [10], necessitate large certificate exchanges which are computationally demanding and inappropriate for resource-constrained mobile devices. The low data transmission capability of HCE complicates the challenges associated with frequent, large-scale exchanges in certificate-based systems. To address these challenges, iHDoc prototype is based on the iDSign [9], a previously proposed framework that leverages Identity-based Cryptography (IBC) [11] along with a modified Lightweight Identity-based Transport Layer Security (iTLS) protocol [12] for lightweight mutual authentication and session key establishment. IBC uses a certificate-free methodology by associating public keys directly with user identities (e.g., email or phone), making it suitable for mobile and resource-constrained devices with reduced computational overhead. Additionally, the Hess Identity-based Signatures (IBS) scheme [13], built on the principles of IBC, is used for the digital signing of documents.

A. Main Contributions: The key contributions are as follows:

- Design and implementation of iDSign Framework [9] with NFC HCE mode [4] and Bluetooth: Demonstrates in-person signing on Android devices using the iDSign framework with low-energy NFC-based HCE for secure proximity authentication, mitigating risks like man-in-the-middle attacks, and Bluetooth for efficient post-authentication data transfer. This approach also has the potential for future remote signing capabilities.
- Comparative Analysis: Performance comparison of the proposed iHDoc prototype with IBC [9] and RSA-based mutual authentication [10] and digital signatures. Results indicate, IBC achieves faster execution, reduced storage, and improved suitability for mobile devices.
- Roadmap: The remaining paper's organization is as follows: Section II contains an overview of related work. Section III describes the system architecture and implementation details. Section IV presents a comparative performance evaluation. In the end, Section V concludes the paper with key findings and suggests future work to extend the system's capabilities to remote signing and improve cross-platform compatibility.

II. Related Work

In recent years, mobile digital signing solutions have become increasingly popular, with Adobe Sign [14], Visma Sign [15], and DocuSign [16] emerging as prominent choices [17]. These platforms largely depend on cloud-based architecture and PKI, which, although offering strong security, impose constraints that may impact usability and security, especially in mobile and offline environments. TABLE I presents the comparison of existing digital signature solutions.

Adobe Sign [14] employs PKI for authentication and document signing, which cloud-based certificates or hardware tokens can implement. Nevertheless, PKI systems frequently necessitate complex certificate management and incur considerable processing requirements, making them less suitable for resource-constrained devices. The dependence on a centralized authority for certificate validation makes Adobe Sign prone to network-based attacks and restricts offline capabilities.

Visma Sign [15] depends on strong ID verification techniques, such as banking or mobile ID, which require constant internet access for authentication. The dependence on external identity providers and centralized verification creates network weaknesses, making it inappropriate for environments with limited connectivity. Although Visma Sign provides secure, regulated authentication, it needs greater flexibility for offline or in-person signing.

DocuSign [16], a PKI-based service, supports many authentication techniques like SMS, email, and third-party connections. However, its dependence on cloud infrastructure limits its use in offline settings and introduces security risks related to remote authentication.

Although these technologies provide reliable document signing for remote and high-security scenarios, they often rely on constant internet access, making them inappropriate for offline usage. In contrast, the proposed iHDoc prototype overcomes these drawbacks by utilizing IBC with NFC HCE mode for tap-based in-person digital signing. Unlike PKI-based solutions, iHDoc's IBC prototype eliminates certificate administration, reducing computational load and simplifying key management for mobile devices. The NFC HCE mode tap requirement minimizes proximity attacks such as MiTM attacks. Moreover, iHDoc's offline signing capability makes it well-suited for environments with limited or no connectivity.

TABLE II. Symbols, Abbreviations, And Operators Description

Notations	Definitions
ID_S	Signer's Identity
ID_D	Signee's Identity
EK_S	Ephemeral Public Key of Signer
EK_D	Ephemeral Public Key of Signee
N_S	Large Random Nonce chosen by Signer
N_D	Large Random Nonce chosen by Signee

III. System Architecture And Implementation

The proposed iHDoc system is a functional prototype designed for in-person digitally signing documents on Android mobile devices. This prototype features an intuitive user interface (see Fig. 3.) designed to streamline the signing process, with distinct workflows for the Signer and Signee roles. The system utilizes the notations outlined in Table II to define the cryptographic operations and interactions between devices. A demonstration of the prototype in action is available in the Technical Report [18]. iHDoc builds on the theoretical foundation of the iDSign framework [9]. This section breaks down the architecture and implementation specifics, demonstrating how each component facilitates secure and efficient in-person digital signing.

A. System Components

The proposed iHDoc prototype comprises the following components:

- Private Key Generator (PKG): It is a server component that generates and distributes identity-based cryptographic keys.
- Signer Device: This device preserves the confidential signing credentials and commences the signing procedure. It functions as the NFC reader in Host Card Emulation mode.
- Signee Device: This device requests document signing and receives the signed document. It operates in NFC HCE mode to serve as a virtual card for data transmission.

B. Workflow Overview

The iHDoc workflow adopts a structured sequence from device registration to completing a digitally signed document. Fig. 2. details the prototype, which utilizes multiple libraries and technologies that work in unison to ensure secure, efficient document signing. The key steps are as follows:

1) Device Registration with PKG: Both the Signer and Signee devices register their unique identities (such as email or phone number) with the PKG. It uses these identities to generate corresponding public and private keys, leveraging IBC.

2) Keys Reception: The devices receive their respective keys (private and public) from the PKG.

3) Mutual Authentication and Session Key Establishment (NFC HCE Session) (For a detailed explanation, refer to iDSign Framework [9]):

a) During this tap-based interaction, both devices authenticate each other using iDSign's mutual authentication [9] and exchange ephemeral public keys (EKS, EKD), unique identifiers (IDS, IDD), nonces (NS, ND), and PKG details to establish trust.

b) Once registered, both devices initiate mutual authentication by tapping the devices, utilizing NFC HCE mode and IBC (as shown in Fig. 3 -B).

c) Both devices independently compute a shared secret using bilinear pairing curve operations. The shared secret is then processed through an HMAC-based key derivation function (HKDF) [19] to derive the session key HTK.

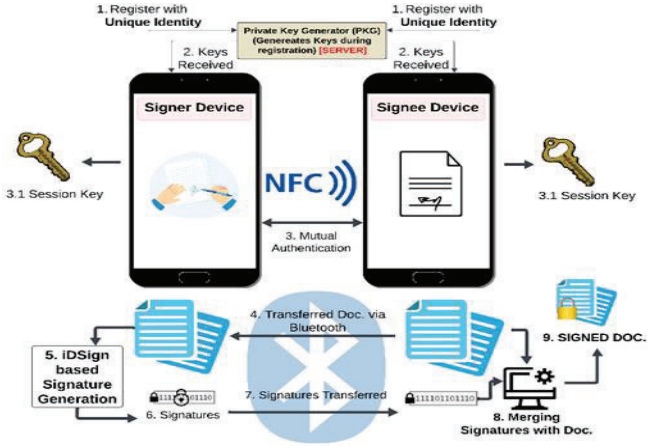

Fig. 2. iHDoc Prototype.

d) The Signee sends an encrypted message (EFMD) to the Signer, containing a random string (RS), a timestamp, and the incremented nonce (NS +1). The Signer decrypts EFMD using the session key, validates the parameters and responds with its encrypted message (EFMS) containing similar parameters. Successful validation completes mutual authentication, and the session key secures subsequent communication.

e) In addition to authentication, the Signer's Bluetooth name is shared with the Signee during the NFC tap, facilitating automatic Bluetooth pairing.

4) Document Transfer via Bluetooth: The Signee establish an automated Bluetooth connection and sends the document to the Signer (as shown in Fig. 3-C).

5) Digital Signature Generation: On receiving the document, the Signer uses the Hess IBS [13] scheme to generate the digital signature by utilizing the document's hash, the Signer's private key, and cryptographic parameters managed through the jPBC library [20], which facilitates pairing-based operations for IBC.

6) Signer then encrypts the signatures with the previously generated session key to guarantee secure transmission.

7) Signature Transmission: The Signer transmits the encrypted signature to the Signee device over the secure Bluetooth channel.

8) Signature Integration: The Signee decrypts signatures using the session key, incorporates it into the original document and completes the digital signing process. As shown in Fig. 3-C, the digital signature includes identifying information and a timestamp for authenticity within the document. The user can then choose to continue signing more documents or end the session (as shown in Fig. 3-C).

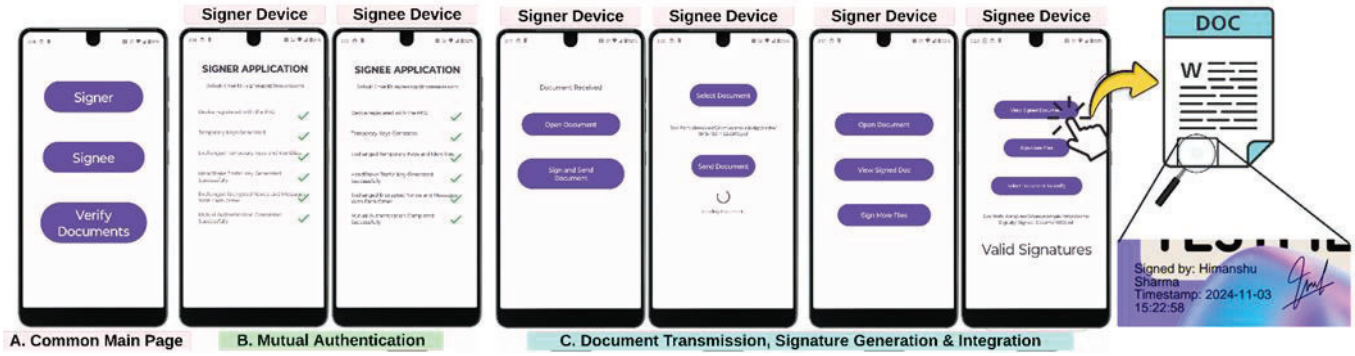

Fig. 3. Screenshots of iHDoc User Interface.

9) Signed Document Storage and Verification: The final signed document is stored locally and can be verified by any device using the Signer's public key.

C. Technologies and Libraries Used

This section breaks down the technologies and libraries incorporated into the iHDoc prototype, clarifying their functions in secure digital document signing on Android devices.

1) Android NFC with HCE: NFC technology in HCE mode [4] enables proximity, tap-based interactions between Android devices, simulating a physical smart card. This setup ensures robust session initiation by reducing vulnerability to man-in-the-middle attacks.

2) Bluetooth for Data Transfer: Bluetooth is used for effective data transfer following NFC-based authentication. This technique makes use of Bluetooth's stability and bandwidth for transferring larger files, such as PDF documents, post-authentication.

3) jPBC Library [20]: The Java Pairing-Based Cryptography (jPBC) library is an crucial element of the iHDoc system, facilitating all cryptographic functions based on IBC. The jPBC library enables bilinear pairing operations crucial for IBC, facilitating secure connections and digital signatures based on user identities instead of conventional public-key certificates. This pairing-based methodology, essential to iHDoc, facilitates the framework's lightweight yet safe cryptographic requirements, from mutual authentication to document signing. The library reduces the computational and storage demands commonly linked to certificate-based systems, enabling iHDoc to offer both security and efficiency, making it a perfect option for mobile applications.

4) Bouncy Castle Library [21]: Bouncy Castle provides essential cryptographic operations, including the HKDF (HMAC-based Key Derivation Function), which generates the symmetric session key (HTK) during the mutual authentication phase.

5) iText Library [22]: iText provides fast and seamless PDF file manipulation within the iHDoc system, offering tools for incorporating and verifying digital signatures.

6) Spring Framework for Local Server Setup [23]: A local server built with the Spring framework operates as the PKG, creating and distributing keys based on identity. When devices send identity information (e.g., email or phone number) to the server, it provides the corresponding identity-based cryptographic key pairs, facilitating iHDoc's IBC prototype.

IV. Performance Evaluation

This section evaluates the performance of the proposed iHDoc prototype, comparing its efficiency when using IBC versus RSA certificates. Using the same iHDoc prototype for both configurations enables an accurate assessment of the advantages of IBC in proximity-based mobile environments. Key metrics include timing and storage requirements, emphasizing the lightweight nature of IBC for mobile use. Testing and evaluation are conducted on devices including the Samsung Galaxy Tab Active 2, Motorola G84, OnePlus Nord 2T, and Poco X6 Pro, covering diverse hardware combinations.

A. Timing Comparison of Core Components

TABLE III compares the approximate time taken for different components in iHDoc with IBC [9] and RSA [24] when processing a document of 1MB size. The components analyzed include Mutual Authentication, Bluetooth File Transfer, Signature Generation, and Signature Integration.

- Mutual Authentication: iHDoc with IBC achieves a faster mutual authentication time (0.479 sec) than RSA (0.702 sec) due to the absence of certificate verification in IBC, thus reducing computational overhead.
- Bluetooth File Transfer: The time for Bluetooth transfer remains similar in both configurations, as Bluetooth communication is independent of the cryptographic method.
- Signature Generation: iHDoc with IBC also performs faster signature generation (0.207 sec) compared to RSA configuration (0.232 sec), reflecting the

TABLE III. Approximate Timing Comparison of Diff. Components for Document of Size 10 MB

Scheme	Mutual Authentication (sec)	Bluetooth File Trans. (sec)	Signature Generation (sec)	Signature Integration (sec)	Total (sec)
IBC [9]	0.479	68.32	0.273	0.521	69.59
RSA [24]	0.778	68.37	0.298	0.530	69.97

TABLE IV. APPROXIMATE CREDENTIALS STORAGE REQUIREMENTS

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 06:37:46 UTC from IEEE Xplore. Restrictions apply.

Scheme	Public Key Size (bytes)	Private Key Size (bytes)	Certificate Size (bytes)	Symmetric Session Key Size (bytes)	P_{Pub} (bytes)	P (bytes)	Total (bytes)
IBC [9]	**128**	**20**	**-**	**128**	**128**	**128**	532
RSA [24]	**256**	**256**	**1024**	**128**	**-**	**-**	1664

efficiency of the Hess IBS scheme used in iHDoc with IBC configuration.

- Signature Integration: The time required for signature integration is slightly lower in iHDoc with IBC (0.421 sec) compared to RSA (0.428 sec), benefiting from the streamlined IBC approach.

The results in TABLE III demonstrate that IBC offers reduced processing times in the mutual authentication and signature generation phases, emphasizing the advantages of lightweight cryptography for digitally signing documents on mobile devices.

B. Storage Requirements

TABLE IV compares storage requirements for credentials and cryptographic keys in iHDoc leveraging IBC and RSA certificate-based keys. The RSA configuration requires more storage due to including public/private key pairs and certificates, whereas the IBC configuration significantly reduces storage requirements by eliminating certificates.

- RSA Key and Certificate Storage: In RSA configuration, each device requires storage for RSA keys and certificates and requires approximately 1664 bytes for storage.
- IBC Key Storage: IBC configuration eliminates certificates, reducing storage needs to only 532 bytes for storing public and private keys, the master public key (PPub), and the generator (P). Hence, IBC is more suitable for mobile devices with limited storage capacity.

As shown in Table IV, the total storage requirement for iHDoc with IBC [9] is 532 bytes, which is significantly lower than the 1664 bytes required for the RSA [24]. This reduction in storage requirements is critical for mobile devices, where storage space is often limited.

C. Document Size vs. Signing Time

Fig. 4. illustrates the relationship between document size and total signing time in iHDoc with IBC. As document size increases, the time taken for signing also increases, largely due to Bluetooth transfer time. For smaller documents (e.g., 0.1 MB), the signing time is relatively low (around 14 seconds), but for larger documents (e.g., 60 MB), the signing time increases substantially (up to 404 seconds). This graph highlights iHDoc's scalability and the impact of document size on overall performance.

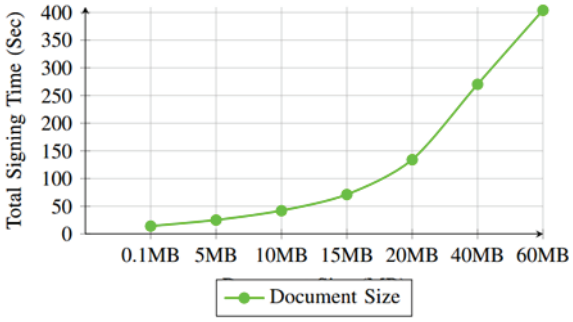

Fig. 4. Relationship between Total Signing Time and Doc. Size in iHDoc with IBC [9].

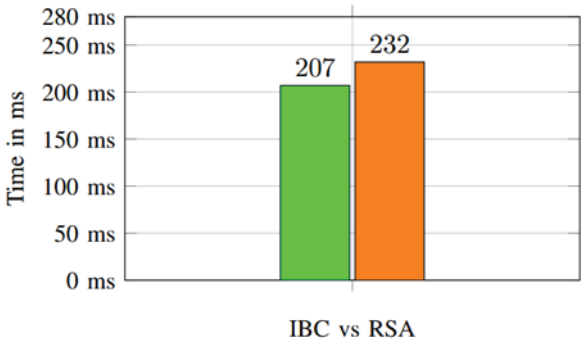

Fig. 5. Comparison of Sign. Generation Time for iHDoc with IBC [9] and RSA [24]

D. Signature Generation Time Comparison

Fig. 5. shows the comparison of signature generation time between iHDoc with IBC and RSA. The signature generation time in IBC is approximately 207 ms, while RSA requires 232 ms. This performance difference highlights the efficiency of the iDSign's IBC-based signature scheme [13] in iHDoc, making it well-suited for mobile environments with limited computational resources.

The performance evaluation shows that iHDoc with IBC outperforms RSA configuration in terms of time and storage efficiency. Mutual authentication and signature generation phases are faster with IBC due to the lightweight cryptographic approach, while storage requirements are lower since it does not use large certificates and keys. Additionally, the impact of document size on signing time demonstrates the scalability of iHDoc. In contrast, the overall reduced signature generation time illustrates the effectiveness of the Hess IBS scheme in mobile applications.

V. Conclusion And Future Work

This paper presents iHDoc, a secure and lightweight prototype based on the iDSign framework [9] for in-person digital document signing on Android smartphones. Utilizing NFC HCE mode [4] for proximity, tap-based authentication, iHDoc mitigates proximity-based threats, such as man-in-the-middle attacks, enhancing security in mobile settings. IBC enables iHDoc to function without digital certificates, reducing computing requirements and making it suitable for resource-limited devices. In contrast to conventional PKI-based systems, iHDoc facilitates offline signing, enhancing its applicability in regions with restricted connectivity. Performance evaluations demonstrate iHDoc's efficiency, with faster execution times and reduced storage requirements compared to RSA-based configuration, highlighting its capability in secure, lightweight mobile applications.

Future work will extend iHDoc for remote signing while maintaining its security advantages, improving platform compatibility, and exploring hybrid signing modes. Furthermore, incorporating a Secure Element [5] will improve credential security and optimize cryptographic functions. iHDoc offers a versatile and resilient solution for safe mobile

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 06:37:46 UTC from IEEE Xplore. Restrictions apply.

document signing by integrating proximity security with strong offline capabilities.

Abstract: The study aims to evaluate effects of storage duration and storage temperature on changes in vitamin profile of formulated aquafeeds.Two aquafeeds are formulated one as extrusion processed fishmeal replacement diet comprising aquatic macrophyte greater duckweed(Spirodela polyrhiza) as D1, other as non-substituted fishmeal diet from pelettization D2. Diets are stored for sixmonths (180days) under four storage temperature conditions; -20o, 4o,ambient and 45oC namely T1,T2,T3 and T4, respectively. Changes in water-soluble and fat-solublevitaminprofile is assessed bimonthly up to sixmonth storage (at 0,60,120,180 days) for both the diets. Both diets at all storage temperatures,show substantial loss in water- miscible andfat-miscible vitamins namely A, E, K, B2, B12, C, 60-day further.Noteworthily in D2, intense diminutions in vitaminDcontent was observable during four month storage at T4 condition, while temperature, duration and interaction effects on vitamin D were significant ($P \leq 0.05$)for D1.Thiamin retentions in D2 are influenced by interference from antinutrients; whileco-elutants affect B6 determinations in D2. Evidently, incurred loss of most vitamins were highest at end of storage underT4 conditions.The paper highlights effect of temperature, duration on dietary storage profile of vitamins as essential nutrients,affecting quality and shelf-life of stored processed feeds suggesting at best utilizationregimes during storage.

Keywords: aquafeed, storage, temperature, vitamins, antinutrients, bioavailability.

1. Introduction

Fish is a valued source of quality dietary protein with reasonably significant extent of most indispensable amino acids, omega-n3 essential fatty acids - eicosapentaenoic, docosahexaenoic (EPA and DHA), minerals and vitamins. Digestibility and bioavailability of proteins, minerals and vitamins obtained from fish foods is higher compared to any plant-based food product. Fish is growingly becoming global staple; in fulfilling food requirement of world population rural as well as urban. Feed is the foremost important input for fish welfare and health in sustainable intensive aquaculture productions[1]. Demanding pursuit for alternative sources of protein and oil; wholly or partly substituting fish meal (FM) and fish oil (FO) in aquafeeds [2] accord to FAO recommendations on lessening their consumption from extract fishing, as well to meet sustainable UN goals for fisheries and aquaculture. In this direction much focus has shifted in finding and use of non-conventional alternative feed source towards aquaculture growth and developments [3,4]. To this effect potential of aquatic origin macrophytes such as duckweeds (belonging to family Lemnaceae) have been explored as alternative feed constituent. Spirodela polyrhiza and duckweeds at large offer abundant nutritional profiles significantly comparable to animal feed [5,6] with

their partial inclusion in fish diets known to appreciably augment growth responses as well as nutritional attributes of fish [7].

Fish require vitamins in trace quantities as vital organic substances for important physiological functions. Vitamins are classified as water and lipid-miscible forms due to their miscibility in aqueous environment. Water-soluble vitamins comprise vit. B-group including in them B1, 2, 3, 5, 6, 7, 9,12 (namely thiamin, riboflavin, niacin, pantothenic acid, pyridoxine, biotin, folate, cobalamin) and ascorbate (vit. C). Vitamins (vit.) function mainly as coenzymes contributing to metabolic processes (B1, B2); in red blood cell formation, fatty acid- and amino-acid metabolism (B6, B12), amino acid interconversions (B6); bone formation, collagen synthesis and immunoregulatory functions (vit. C) [8]. Due to their hydrophilic property these vitamins are miscible in aqueous solutions. Vit. C is the most labile water-soluble vitamin, known for its antioxidant attributes. Vit.C is a co-substrate for enzymes involved in the biosynthesis carnitine, and neurotransmission. Fish like humans lack capability of vit. C biosynthesis and can fulfill it through dietary supplementation. Dietary inclusions of vit. C is found to improve growth, hematological parameters, carcass nutrients and feed conversion ratio in Labeo rohita[9]. Fat-miscible vit. A, D (calciferols), E (tocopherol), K are bound to lipophilic fraction in feeds and are transported, as well absorbed, in similar fashion as fats [10]. These vitamins have antioxidant properties (vit.A,E), hematological (vit. K) and immunostimulatory functions (A,D) hence contribute to fish and consumer health.Vit. A has essential function in vision, embryonic development, growth, reproduction, and differentiation [11]. Vit. E can prevent fragility of erythrocytes and due to its anti-oxidant mechanism prevent free radical oxidation of dietary (PUFA) and membrane lipids [12]. Loss of vitamins from diet is evident during processing, storage and due to leaching in aquatic conditions.Vit A, E and C due to their free radical sequestration potential have strong antioxidant properties. Thus, are prone to similar oxidative effects during storage. Storage loss of vit. A is reported due to oxidative influences [13]. Cessation of vitamins during prolonged storage (>180 days) is related to lipidic rancidity ensuing peroxidation[14]. Storage loss of vitamins require over compensations as supplementations to balance available levels from diet.

Storage feeds are prone to oxidative loss of lipids, proteins and vitamins as essential dietary nutrients. Autooxidation of lipids, proteins in feed can also decrease abundance of vitamins as natural antioxidants in feed ingredients [15]. Largely, diminution of feed vitamins is accentuated due to high temperature, humidity, extreme pH, light exposure, presence of elements and lipidic free radicals. Water soluble forms of vitamin are prone to storage effects showing losses due thermal, processing, storage and feed matrix properties. Extrusion processing of feed can affect nutritional quality of diet at various degrees.Diet composition along with extruder parameters including temperature, shear, screw type, pressure, and size of die have great influence on physical and nutritional quality of extruded feed [16]. Depending on extrusion conditions heat susceptible vitamins can be lost, with protein-sugar reactions at high extrusion temperatures deteriorating feed nutrient profiles [17,18] evaluated vitamin stability due to extrusion, and pelleting procedures at three months storage, reporting extrusion loss of thiamine (88%) compared to pelleting loss (60- 96%). Even coated forms of ascorbate are largely lost at high rates to extrusion. Most susceptible vitamins to extrusion were thiamine (due to high shear rates of extrusion), vit. A, C and folate. [19] evaluated impact of extrusion temperatures and encapsulation procedure on vitamin stability to conclude high stability of micro-encapsulated vitamin compared to un-encapsulated forms in feed. Since many parameters need to be optimized for extrusion processing of feeds, the technique requires precise controlled operating conditions to restore maximal nutrient benefits from feedsonsubsequentutilisation.

Nutrient quality and safety are two most important attributes of healthy diet [4].There is a larger scope towards increase in fish production as well as their nutrient value for human consumption by judicious improvement in feed formulations and management of processed feed during storage, handlings; in farming environment. Storage help administer timely requirement of feed in aquaculture; nevertheless, improper storage or storage handlings can intensify feed spoilage [20]. Proper storage of feed is imperative for safeguard of feed quality, ensuring overall fish health and consumer beneficence. Knowledge of storage sequels help assess losses during prolonged feed utilizations, suggesting harmonization of stored processed feeds to maximise nutritional benefit for the fish and incidentally the consumers.The present study explores feed storage changes in composition of water- soluble, fat-soluble vitamins essential to fish nutrition in influencing overall feed quality during storage,at longduration variable temperature conditions. This work provides comparison of plant and fishmeal based formulated feeds to ascertain their response to the storage variables.

2. Materials and Methods

2.1Formulation of feed

Aquafeeds were formulated using Interactive Fish Feed Designer (IFFD) software version 2 [21] as per composition given in table 1. Extrusion based compounded diet (D1), was formulated comprising fishmeal as major protein source with substitution of S. polyrhiza and wheat flour as minor protein sources, plant-oil sunflower oil was substituted for fish oil. Dry ingredients were well mixed with subsequent addition of oil and sifted through fine mesh, subjecting to extrusion pelleting with addition of extra pure milli-Q water (Synergy ultrapure, Millipore, Germany). Two-kilogram sinking pellet extruded feed was prepared based on twin-screw extrusion technique (BTPL lab model twin-screw food extruder, Kolkata, India) using 2.5 mm die as per set conditions with extruder rpm 214, cutter rpm 545, feeder rpm 10, extruder torque 13.9, heater1 (65°C) and 2 (70°C), temperature of final mass 101°C. Extruded feed was dried in feed drier (Hicon, India) for 4h at 35oC, then kept at room conditions(1h) and packaged for storage in sealable bags. For D2 (non-extruded diet)hot water (60oC) was added to well kneaded feed ingredients,subjecting to pelletization (Kent, India) through 2mm die. Prepared diet pellets were driedand packed for storage as D1.

2.2 Feed storage

Three replicates (n=3) per temperature condition were kept for storage. Diet samples atT1,T2 and T3 conditions were stored in resealabletransparent plastic bags whereasT4 sampleswere kept in capped transparent glass bottles (Borosil, India) duringstorage. Daily temperature record was maintained towards T3 storage using thermo-hygrometer(ThermoPro TP53, US),table 2.Mean (± standard error, SE)temperature records for D1 ranged between 18.5oC (±3.25)to 29.5oC(±4.15) and D2 between 17.7oC (±1.90)to28.45oC (±2.55). Replicates (n=3) for four temperature conditions under study were drawn bimonthly (at 0, 60th, 120th, 180th day) during each assessment.

2.3 Preparation of feed sample

As per standard method 950.02, samples were milledto fine particles and sieved (1mm) to obtain fine powder [22]. Powdered diet was thoroughly mixed beforeanalysis of vitamin profile. Each assay was performed in replicatesfor calculation of mean for the evaluation of results.

2.4 Vitamin analysis

2.4.1Chemicals and Reagents

Vitamin standards, retinyl acetate (vit. A) (No.46958, Sigma-Aldrich Chemicals private limited, India), thiamine hydrochloride (B1), riboflavin (B2), pyridoxine hydrochloride (B6), cyanocobalamin (vit. B12) and L-Ascorbic acid (vit. C) (No. 47858, 47861, 47862, 47863, 47869 respectively), cholecalciferol (vit.D3), ergocalciferol (vit. D2), vit. K1 (No. 95271 Bio-xtra sum of isomers, HPLC grade) at high purity >98% were purchased from Sigma-Aldrich, USA. E-acetate was obtained from Himedia laboratories private limited, India at purity >97%. Taka-diastase, source Aspergillus oryzae (No. 86247) was obtained from Sigma-Aldrich (USA). n-butanol, chloroform (SRL, Sisco Research Laboratories, India), acetone, sodium acetate (extrapure AR SRL, Sisco Research Laboratories, India), sulphuric acid (Merck, India), methanol, acetonitrile (HPLC grade, Merck, India), metaphosphoric acid (No.239275, Sigma-Aldrich Chemie GmbH, Steinheim, Germany) were also procured. Standard solutions were prepared using extrapure Milli-Q water at pH7.

2.4.2 Sample preparation for vitamins

Water-soluble vit. B1, B2, B6, B12 and C, were assayed according to the method of [23]. Extraction was performed in triplicates. For vit. B1, B2, B6 and B12 estimation diet sample(2g) was added with 25mL H_2SO_4 (0.1N) solution in a conical flask. Sample solution was incubated for 30min at 121oC in oven. Contents were cooled at room temperature and using 2.5M sodium acetate, pH was adjusted to 4.5. Then, 50mg Taka-diastase enzyme powder was added to the sample. After gentle vortex for 1min, preparation was stored in oven at 35oC for 18h. The digested mixture was filtered through Whatman filter (No.4). Filtrate was diluted with 50mL Milli-Q ultrapure water. Extract was re-filtered through 0.45μm micropore syringe filter, into HPLC vial. For the estimation of vit. C,10g diet samplewas blended and homogenized with 25mL extracting solution comprising 0.3M metaphosphoric acid and 1.4M acetic acid. After 15min centrifugation at 10,640g (fixed-angle rotor 12181 Sigma 2-16K, Germany)mixture was filtered using Whatman filter (No. 4). Fat-soluble vitamins (A, D, E and K) were estimated following the method of [24]. Briefly,in a falcon tube 0.5g sample was mixed with 8mL chloroform and acetone mixture in the ratio 70:30. Nitrogen (N_2) gas was flushed through the sample and tube was tightly capped. Contents were vortexed for 1min and tube was left to stand for 5min then

vortexed again for 30s. Mixture was centrifuged at 1702g (fixed-angle rotor 12181 Sigma 2-16K, Germany), 25oC for 5min. After centrifugation, 1mL supernatant was transferred for drying in aN2 evaporator. Completely dried extract was dissolved in 1mL n-butanol. Reconstituted extract was filtered using 0.4□m syringe filter and kept in HPLC vial for further analysis.

2.4.3 Determination and quantification

Stock solutions of vitamin standards 1.0mgmL-1 were prepared. Standard calibration was performed to obtain linearity at concentrations 0.25, 0.5 and 1.0mgmL-1. Chromatographic analysis of vitamins was conducted by ultra-high pressure liquid chromatography (UHPLC Thermo Fisher, model Dionex Ultimate 3000) with stationary phase C18 column (3µm,150x4.6mm). 20□L of sample extract was injected into the HPLC system. Simultaneous separation for vit. B1, B2, B6, B12 was achieved at a flow rate of 0.5mLmin-1, wavelength 270nm using MeOH : 0.023M H3PO4 (33:67 ratio, pH 3.54) as mobile phase. For estimation of vit. C, flow rate of 1mLmin, wavelength 254 nm and acetonitrile (ACN, 100%) as mobile phase solvent was deployed. Fat-soluble vit. A,D,E,K were determined at flow rate 1.8mLmin-1, UV absorbance 290nm, 100% MeOH as mobile phase.

2.5Statistical analysis

For both fat and water-soluble vitamins, data is represented as mean□SE. Analysis of variance (two-way ANOVA) consideringmajor effects of temperature, storage duration and interaction on vitamin contentof formulated feedsis performed using SPSS statistics (IBM, version 25)[25]. Statistical differencesare reported by honestly significant difference (HSD). Level of significance $P \leq 0.05$based on Tukey's post-hoc analysis is considered[26].

3. Results and Discussion

3.1Water-soluble vitamin storage changes

3.1.1 Vitamin C

Among all storage temperatures, vit. C retention at end of 180 day storage duration is highest at T1 condition, (Fig.1a,1b), in order T1 (89% D1, 86.13% D2) > T2 (85.3% D1, 81.02% D2) >T3 (51.38% D1, 79.56% D2) >T4 (39.45% D1, 51.82% D2) retentions. Significant difference ($P \leq 0.05$) due to temperature, duration and interaction effects was found for vit. C values in D1. For D2, storage effects of duration were highly significant. Neither temperature nor interaction had significant effect on changes in vit. C for D2. Although D1 and D2 depict gradual loss of vit. C over low temperature storages (T1,T2 and T3); losses are evidently higher at T4 due to intense temperature effects. This is in agreement with works of [27, 28], reporting decreased vit. C levels in formulated feeds due to extrusion, pelletization processing based moisture and heat addition, causing rapid losses at extreme conditions. Vit. C in aquafeeds is susceptible to processing, storage losses [29]. Additionally, oxidative, non-oxidative and leaching losses of vit. C in fish feeds are reported. In fishes, dietary deficiency of vit. C can impair collagen synthesis leading to scurvy, lordosis, scoliosis, impaired wound healing, lethargy and anemia symptoms [29, 30]. [31], recommends 67.17 mgkg-1 of ascorbate in grass carp feed for optimum growth parameters of juveniles. Reducing potential of vit. C can be utilized by its supplementation to diets containing high levels of polyunsaturated fats thereby, preventing oxidation of feed lipids [32]. Vit. C potentiates antioxidant effects of vit. E in protecting lipids against peroxidative distress [33].

VITAMIN C

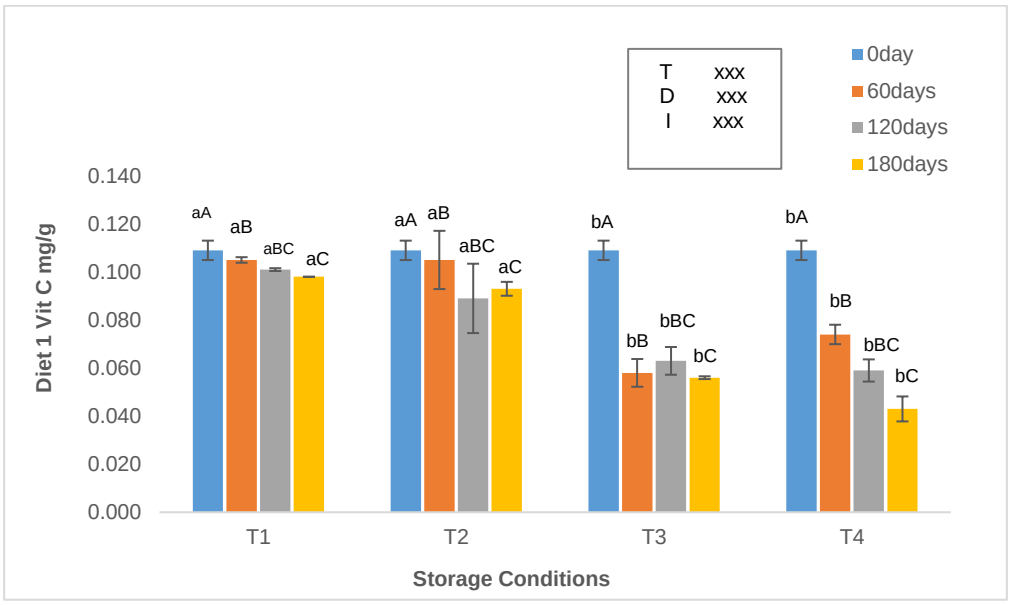

Fig.1a

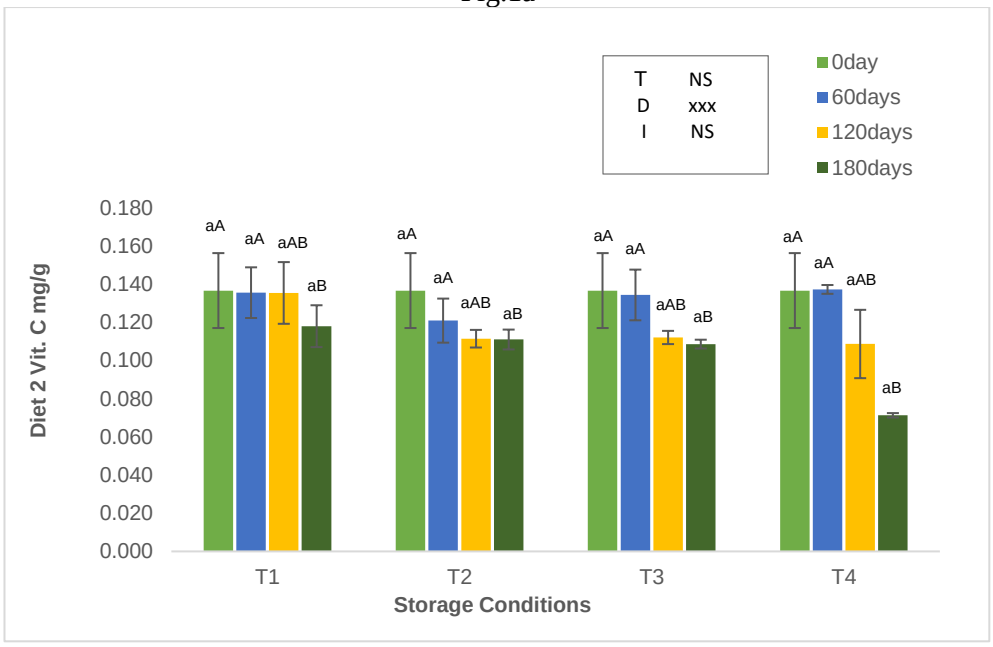

Fig.1b

3.1.2 Vitamin B1 (thiamin)

Gradual decrease in vit. B1 is evident bi-monthly at all storage temperatures for D1, (fig.1c). Incurred losses being higher at high temperatures T4 (55.81% vit. B1 present) >T3 (61.88% present) compared to higher retentions at low temperatures T1 (66.06%), T2 (66.17%) at end of storage duration. Thiamine is thermolabile and susceptible to losses at high temperature processing (extrusion) as well as low moisture conditions. Extrusion loss of thiamin up to 50% is reported by [18]. As per [8] thiamin retentions ranged between 60-80% in extruded feeds stored for 3months at ambient temperatures. Although, non-extruded D2, show initial increase in thiamin concentration up to 120 days, with decreases at later duration between fourth to sixth month across storage temperatures, (fig.1d). These findings are in good agreement to study based on frozen foods [34], reporting initial increase in thiamin content during storage, processing; followed by storage decrease of thiamin, yet no proposed mechanism could be explained. We believe that this effect may be due to interaction effects of thiamin with dietary antinutrients mainly phytochemicals such as tannins, which would have overestimated vit. B1 peaks in chromatographic run. Additional work by [35] provide support to this hypothesis on thiamin-tannin interaction indicating formation of adducts (weak bonds) between thiamin and oxidized tannin to be co-

eluted at same retention values during thin-layer chromatographic analysis. Compared to extruded diets, non-extruded diets are prone to interaction influence of polyphenols. Extrusion processing can reduce tannins and their interference on bioavailability of dietary nutrients (proteins, lipids, vitamins and minerals). Duration effects on storage thiamin are significant for both diets while temperature and interaction significantly (P≤0.05) impact thiamin concentration only in D2.

VITAMINB1

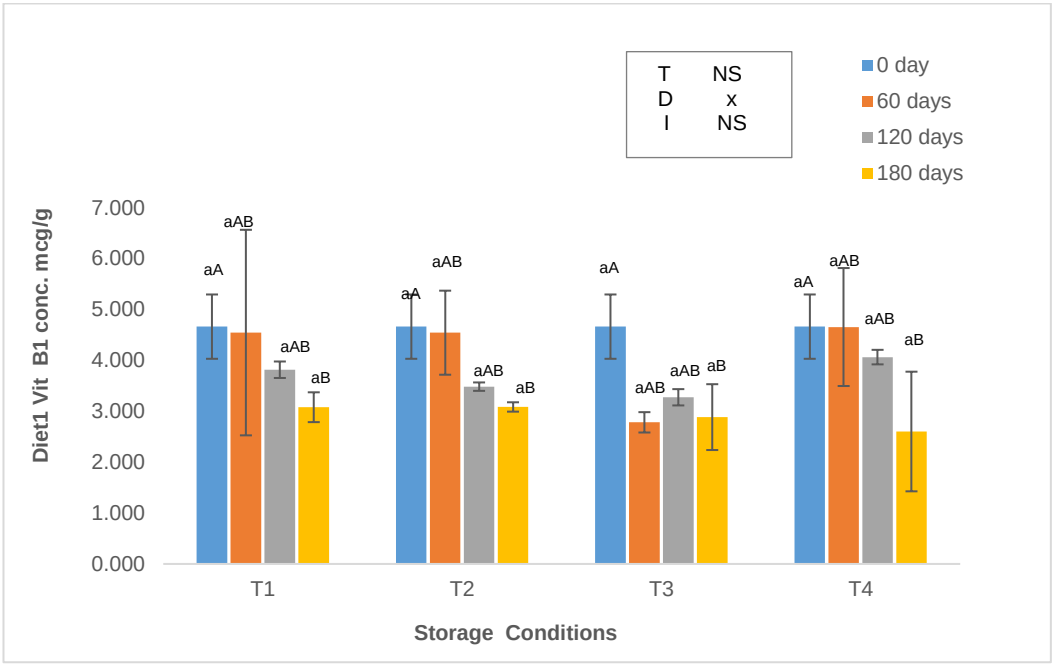

Fig.1c

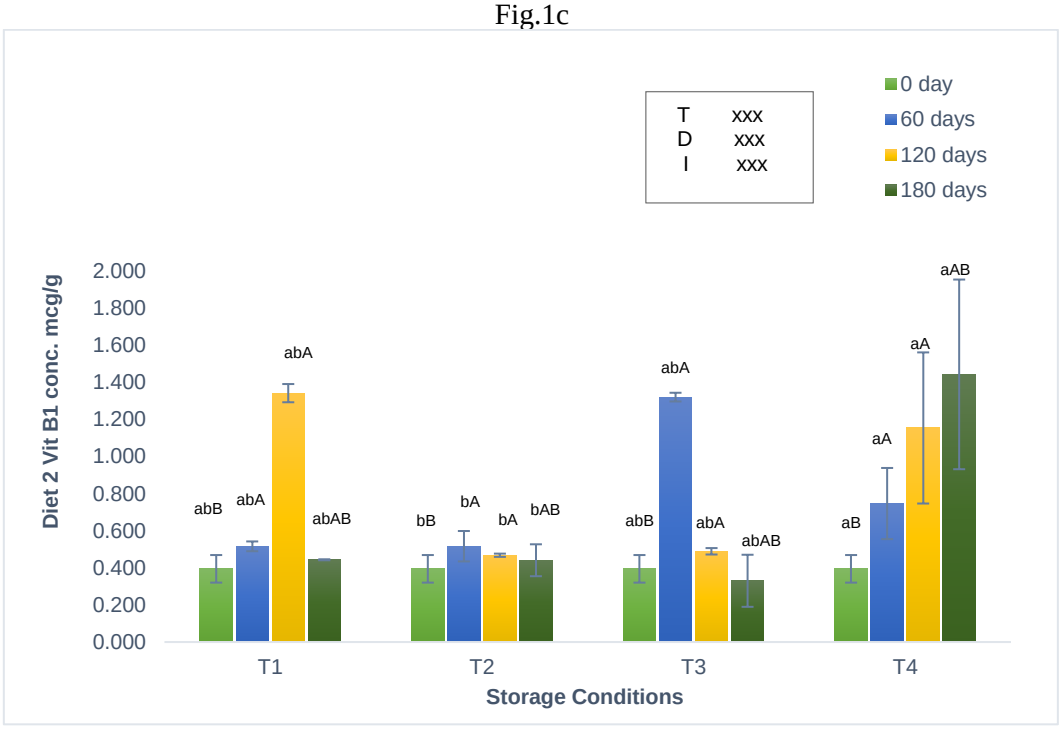

Fig.1d

3.1.3 Vitamin B2 (Riboflavin)

Vit. B2 in D1 show significant (P≤0.05) duration effects with decrease from initial to two-month storage at all temperatures. Effects of temperature and interaction on B2 changes are insignificant for D1; whereas temperature, duration, and not interaction impacts vit. B2 concentrations in D2 significantly (P≤0.05).[36] described higher heat loss of riboflavin compared to thiamin. Increasing temperatures relate to decreases in riboflavin retention [37, 38]. It is noteworthy that vit. B2 decline intensely over storage durations in D1 compared to D2, (fig.1e,1f). In D1 at 60th day, vit. B2 value at T1 decreased

from initial concentration of 0.352 to 0.003 mcgg-1 (with loss of 99.15% that is merely 0.85% retention) and remained undetected beyond two months. At T2, 60-day conc. depicts 15.34% retention (0.054 mcgg-1), at T3 6.57% is retained (0.023 mcgg-1), T4 (7.95% retention at 0.028 mcgg-1). Vit. B2 could not be determined in D1, at any storage temperature during fourth month and at T1, T4 during sixth month. Extrusion loss of riboflavin is large up to 50%. These losses due to extrusion are dependent on increasing shear rates due to increase in screw speed, moisture [19]. Extrusion does not have direct thermal effect on B2 recoveries, rather it increases B2 loss by reducing residence time achieved by increasing screw speed and moisture decrease [18,39]. For non-extruded D2, vit. B2 show significant loss at each storage interval compared to initial concentration. Retention values of vit. B2 at second, fourth and sixth months were determined respectively at T1 as 96.49%, 84.21%, 57.89%; T2 as 96.49%, 78.95%, 71.93%; T3 as 66.67%, 38.60%, 42.11%; and, T4 as 29.82%, 0%, N.D (not defined at end of storage). This is in agreement to [19,39]; elaborating higher retention rates of riboflavin under optimal conditions of processing. Being thermostable, B2 is less prone to temperature effects compared to thiamin; unless affected by processing parameters, composition of food matrix, oxidation, pH, moisture and presence of oxygen. Riboflavin is a light sensitive vitamin. Its stability is affected by oxygen, moisture and water activity [40]. Presence of oxygen during storage can severely accelerate B2 deterioration rate [41]. Photosensitization (visible or UV light exposure) of riboflavin, under oxygenated conditions can form reactive singlet oxygen further capable of oxidative degradation of other vitamins-A,C,D and E along with dietary proteins and lipids[40]. Packaging material plays an important role in B2 photostability. Intense losses of B2 can occur due to improper exposure to light from package material even when other conditions of storage (pH, temperature, moisture) are optimum [42]. Rapid loss of riboflavin from milk packaged in transparent bottle, sachet has been reported, compared to light protected milk packaging in carton or dark bottle [43]. Since transparent packaging was used for storage packaging, following may be the reason for vit. B2 deterioration in our storage diets.

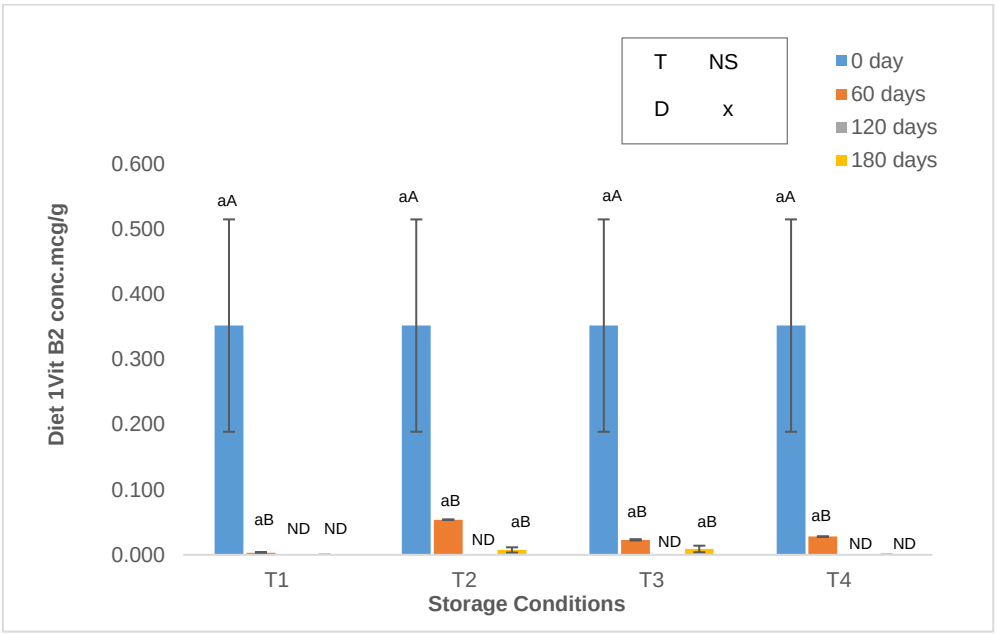

Fig.1e

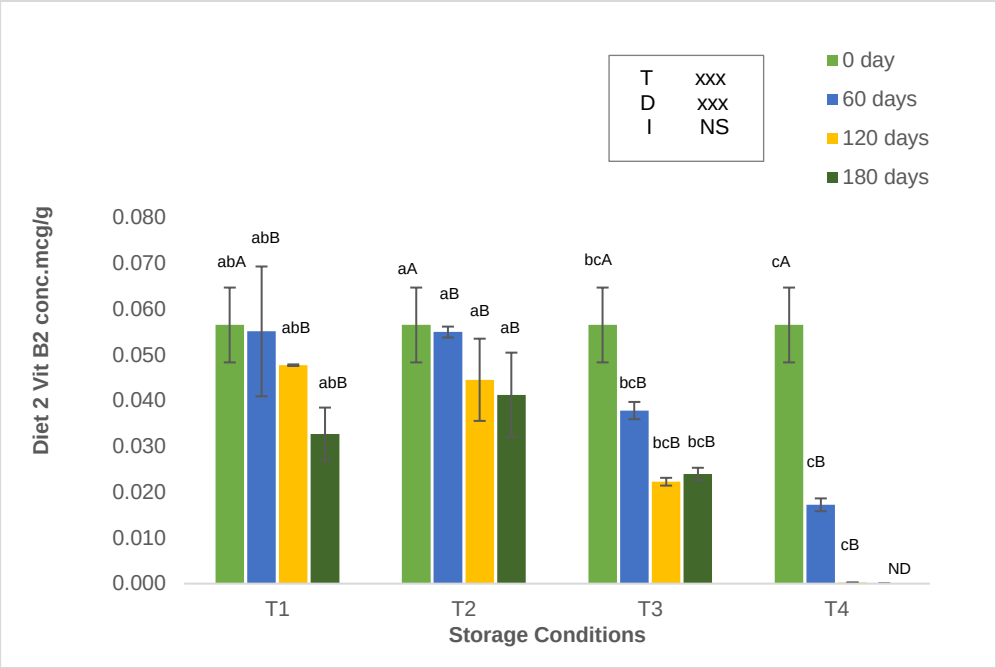

Fig.1f

3.1.4 Vitamin B6 (pyridoxine)

In D1, vit. B6 retention at end of 60,120,180 day followed 69.48%, 61.49%, 56.76% respectively at T1; 88.63%, 72.52%, 83.44% at T2; 98.53%, 75.90%, 74.54% at T3; 90.20%, 73.19%, 46.51% at T4, (fig.1g). D1 results show significant effects ($P \leq 0.05$) of temperature, duration and interaction. D2 depicts significant decrease in retention of B6 at end of storage at all temperatures, with T1,T2,T3 values at 80.37%, 80.74%, 71.48%, except with slight chromatographic overestimation at T4. Overestimations compared to initial storage content are also noteworthy for D2 at 60th day at T2, T3,T4 storage and 120th day T1, T3,T4 conditions (fig.1h). This trend may be due to artifacts of enzymatic activities (here taka-diastase) on release of bound forms vit. B1, B6 and B12 [44] as well as chromatographic overestimation due to co-elutions; a problem in simultaneous estimation of vitamins during single chromatographic run [45]. Vit. B6 exists as six distinct forms of which three vitamers- pyridoxal, pyridoxine and pyridoxamine (PL, PN, PM respectively) are relevant in chromatographic determinations. Presence of several bioactive forms of the vitamins, along with their physicochemical heterogeneity make simultaneous analysis difficult task. Variable forms and properties of B6 vitamers complicate analysis of pyridoxine [46]. Thus, applications reporting food estimations determine B6 concentration as sum of vitamers PL+PM+PN [47], PL and PM being interconvertible forms [48]. In plant-based foods PN dominates; while PM, PL are found in animal origin foods. All these forms (PL, PM, PN) exist in compounded diets consisting of plant and animal-based ingredients. According to [44], enzyme protocol in vit. B6 estimation increased their content due to the release of bound forms from food matrix; this release being under effect of enzyme concentration, purity and differential ability of enzyme combinations used to release specific forms of B6 vitamers.

VITAMINB6

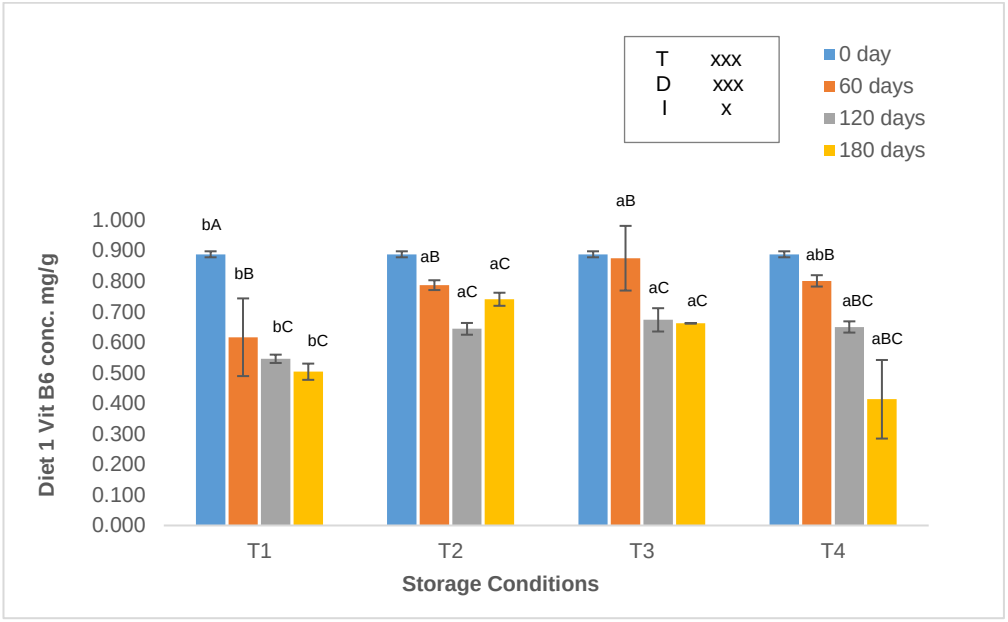

Fig.1g

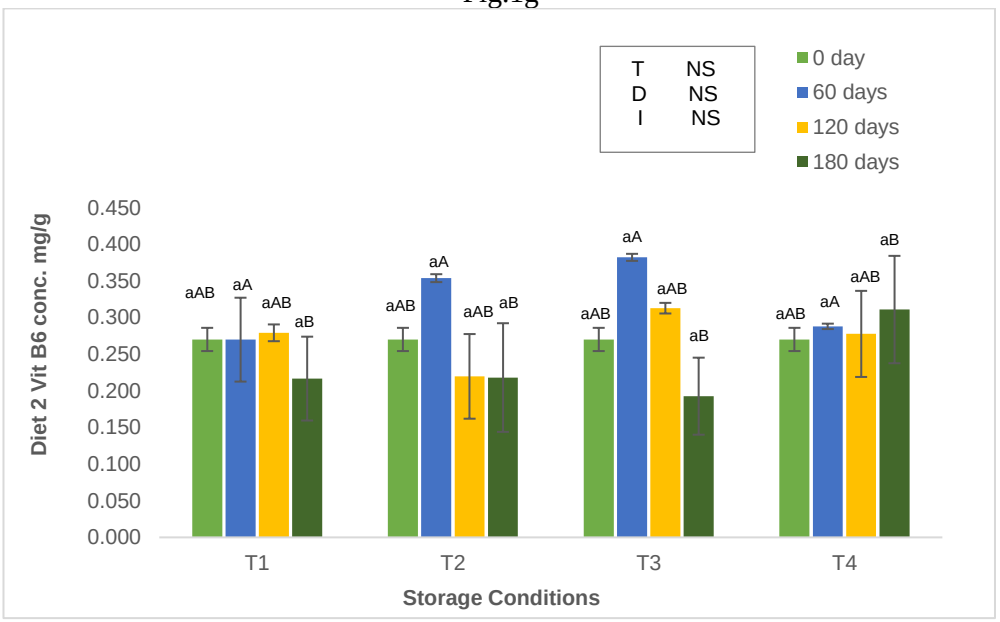

Fig.1h

3.1.5 Vitamin B12 (cobalamin)

In both diets, at each temperature condition variations in vit. B12 content exhibited duration based significant effects ($P \leq 0.05$), between initial and final storage. Temperature and interaction effects are not visible in vit. B12 changes in D1(fig.1i). For D2, duration and interaction effects are highly significant for changes in vit. B12 value, but no noteworthy effect of temperature lies for both diets during storage (fig.1j). T1 retention of cobalamin estimated at 45.27% for D1, 74.07% (D2); T2 (32.92% D1), (55.56% D2); T3 (28.81% D1), (49.38% D2); T4 (65.84% D1), (77.78% D2) clearly with higher vit. B12 retentions in D2 during storage. Although T1, T2 retentions for vit. B12 are higher compared to T3, in both diets at the end of storage; T4 values at 180-day in both diets are highest although this increase at T4 is unexplainable. As per [39] few studies are available on cobalamin; and possibly fewer about its storage behavior in fish feeds limiting our knowledge on the possible effects of variables on cobalamin changes. Present work may fulfill this gap in literature.

VITAMINB12

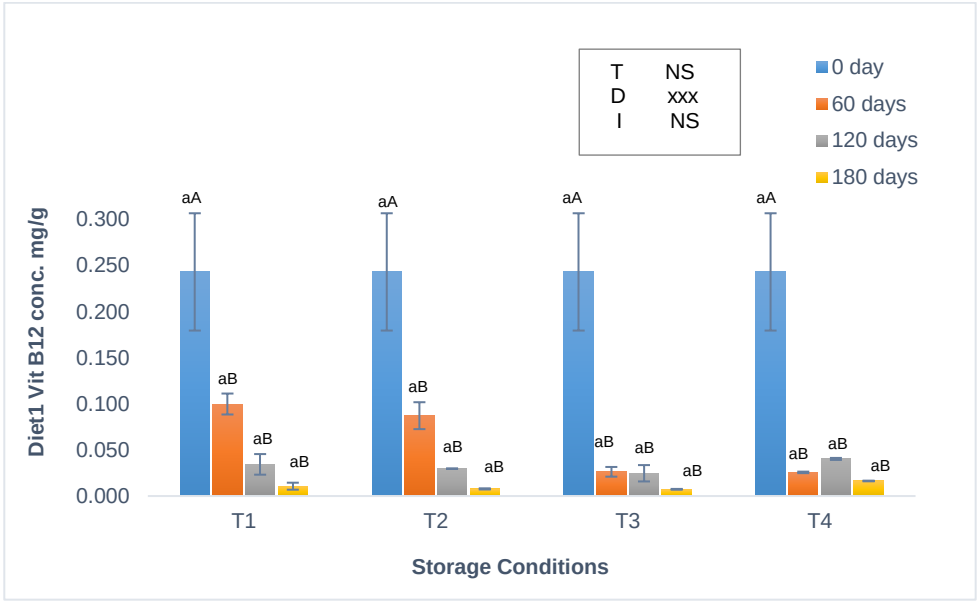

Fig.1i

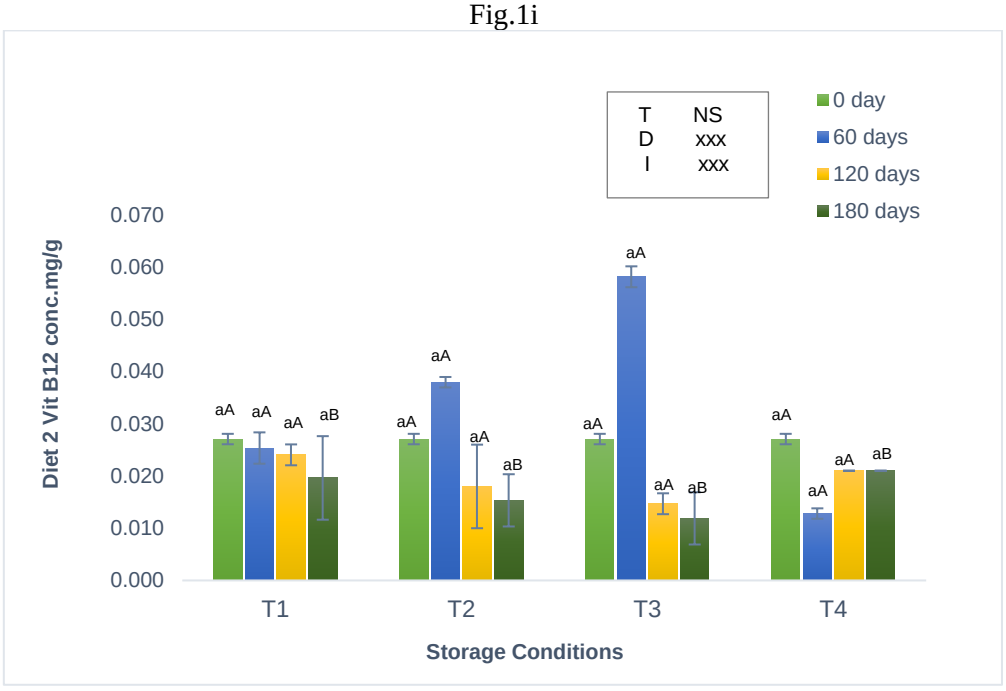

Fig.1j

3.2 Fat-soluble vitamin storage changes

Fat-soluble vitamins are also prone to effects of storage and feed processing variables. Moreover, lipid oxidation in stored diets yield hydroperoxides that reduce availability of fat-soluble vitamins in storage feeds [20].

3.2.1 Vitamin A (retinyl acetate)

At each bimonthly assessment vit. A decreased at all storages temperature in both diets. In D1 end of duration vit. A retentions follow T1(72.52%), >T2 (38.65%), >T3 (20.96%), >T4 (3.26%) showing decline across increments in storage temperatures (fig.2a). Similar trends are observable towards vit. A retention rates in D2, at 71.37% (T1), 68.46% (T2), 24.48% (T3), 4.98% (T4), fig.2b. Under feed storage regime higher vit. A retentions in D2 than D1 explains less severe effects of pelleting compared to extrusion. Temperature affects vit. A values in D2significantly ($P \leq 0.05$), between low temperature (T1,T2) and other temperature conditions (T3,T4), between T3 and T4. Between subject effects of temperature and duration on vit. A storage depletion are highly significant (P=0.000) for both diets, with significant interaction effects only towards D2. High temperatures above 100oC, moisture, extrusion conditions (such as screw speed) have extreme impact on vit. A depletion [13,18,49].Vit. A has essential

function in vision, embryonic development, growth, reproduction, and differentiation [11]. Vit. A is extremely labile to oxidative loss arising from lipid, protein oxidations following free radical attacks.

VITAMIN A

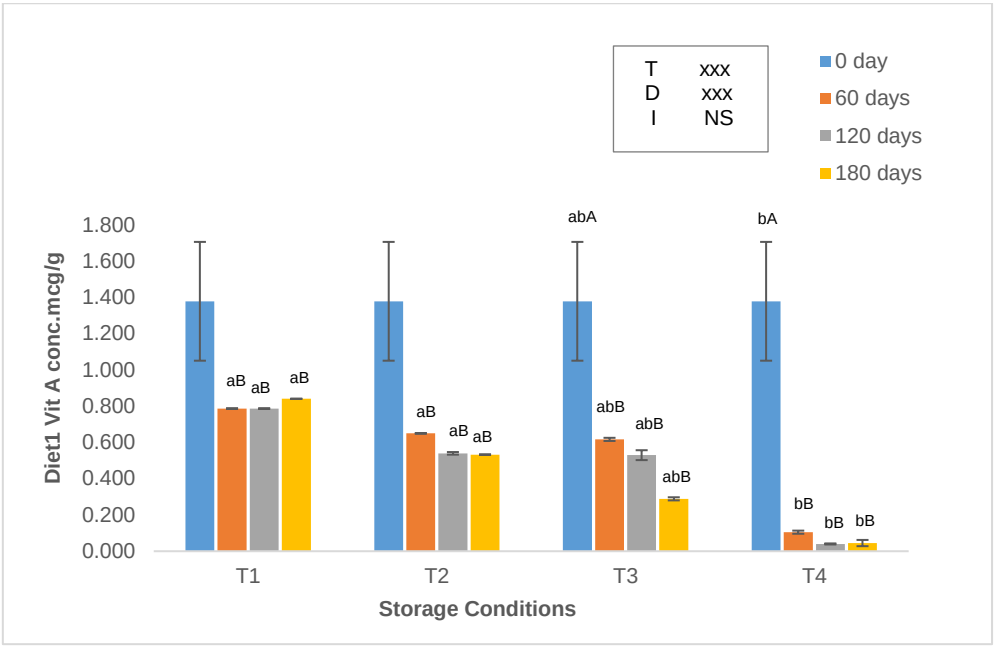

Fig.2a

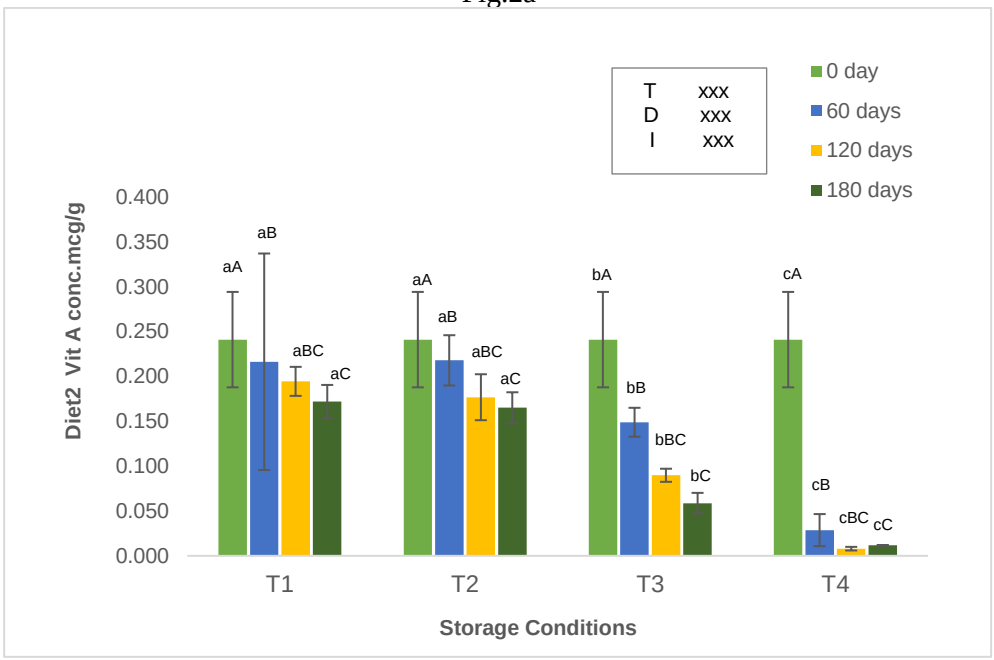

Fig.2b

3.2.2 Vitamin D (vit. D2 ergocalciferol, vit. D3 cholecalciferol)

Detectable vit. D in D1 is plant-based form ergocalciferol (vit. D2). For D2 animal-based form cholecalciferol (vit. D3) was quantifiable. Estimated retention of vit. D2 (in diet D1) at end of storage accounted 99.40% (T1), 50.57% (T2), 30.21% (T3), 39.54% (T4), fig.2c. Severe losses of vit. D3 were encountered in pelleted stored diet with incurred losses accounting 100%, fourth storage month onwards at T4 storage. Even at T1,T2 and T3 accountable vit. D3 retentions were low as 38.46%, 26.92%, 7.69% respectively (fig.2d). These results are in alignment to [36],depicting high pelleting losses of vit. D3 nearing 80-90% with stable extrusion changes. Only duration effects (P=0.000) are noteworthy for vit. D3 changes over storage, with no significant effect due to temperature (P=0.084) or interaction (P=0.442). Alterations in vit. D2 was significantly ($P \leq 0.05$) under impact of temperature, duration and their interactions as well.

VITAMIN D

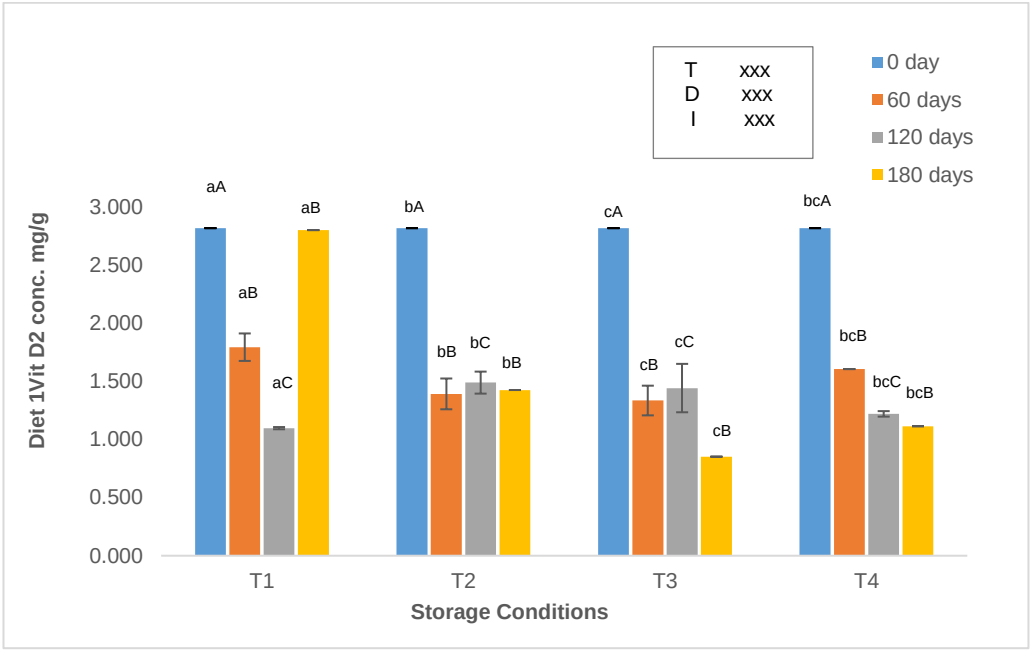

Fig.2c

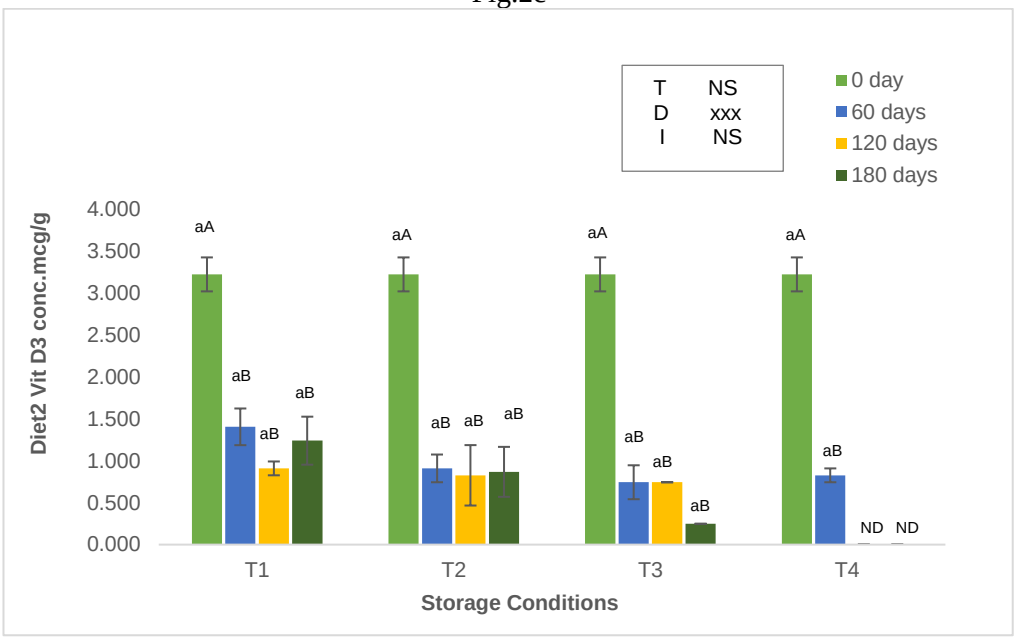

Fig.2d

3.2.3 Vitamin E (tocopherol)

Vit. E loss ranging from 39.41% to 51.36% are estimated for extruded diet D1, at end of storage, (fig.2e).At storage culmination,pelleted D2 loss accounted between 59.78%-80.43% (fig.2f).Variabilities in dietary loss of tocopherols may be with effect to thermal oxidation, degree of lipid rancidity, presence of light, or metal chelators typically zinc, iron, and copper [50]. Vit. E can prevent fragility of erythrocytes and due to its anti-oxidant mechanism prevent free radical oxidation of dietary (PUFA) and membrane lipids [12]. Dietary vit. E requirements for rohu fryis determined to be 131.91 mgkg-1 dry weight of feed by [12] and diet conc. 120 mgkg-1for Atlantic salmon [51]. Vit. E along with vit. A, C have strong antioxidant properties owing to their free radical sequestration potential. Thus, are prone alike to oxidative effects during storage.

VITAMIN E

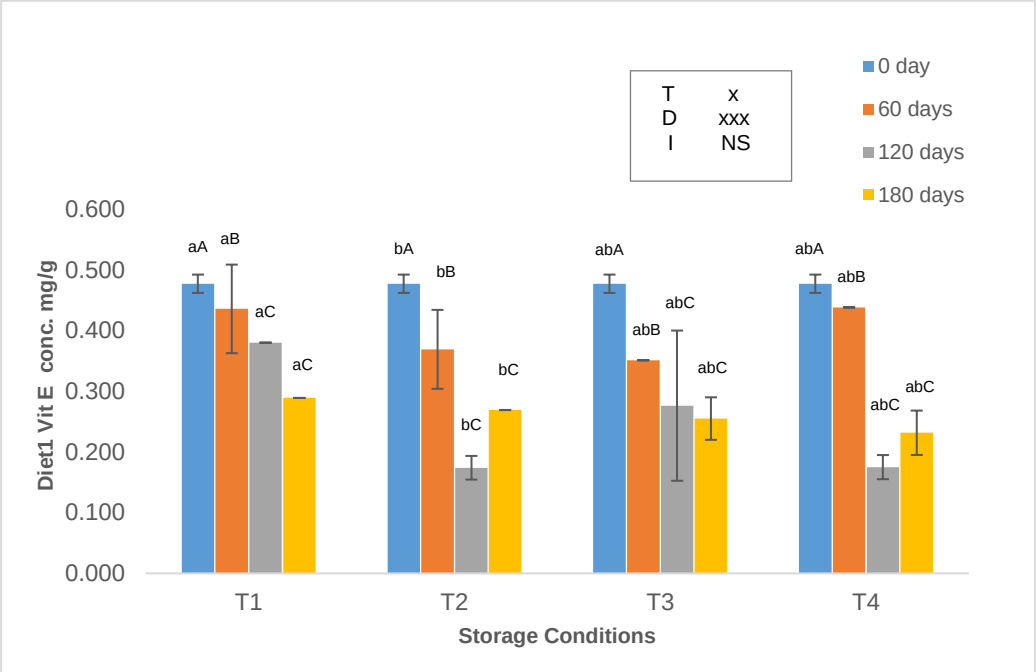

Fig.2e

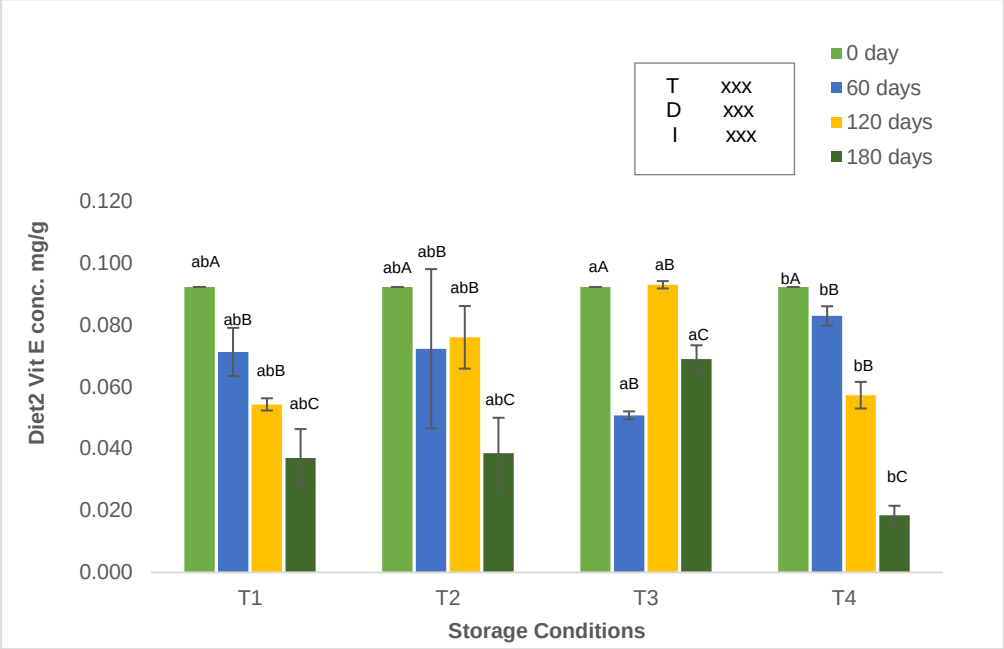

Fig.2f

3.2.4 Vitamin K1 (Phylloquinone)

Vit. K1 in feeds was identified as trans- and cis-isomers (fig.2g-2i) at chromatographic retention times (RTs) 1.09-1.15 for cis-, 1.77-1.807 for trans- isomer. Of these, only trans-form of vitamin K1 is biologically relevant [52]. K1-trans, during storage, in both diets (fig.2g,2h) show significant between-subject-effect for duration; but not for storage temperature and interaction. Incurred losses are higher for extruded diet (between 41.28%to64.41%), than pelleted D2 (4.81%-49.89%).

VITAMIN K

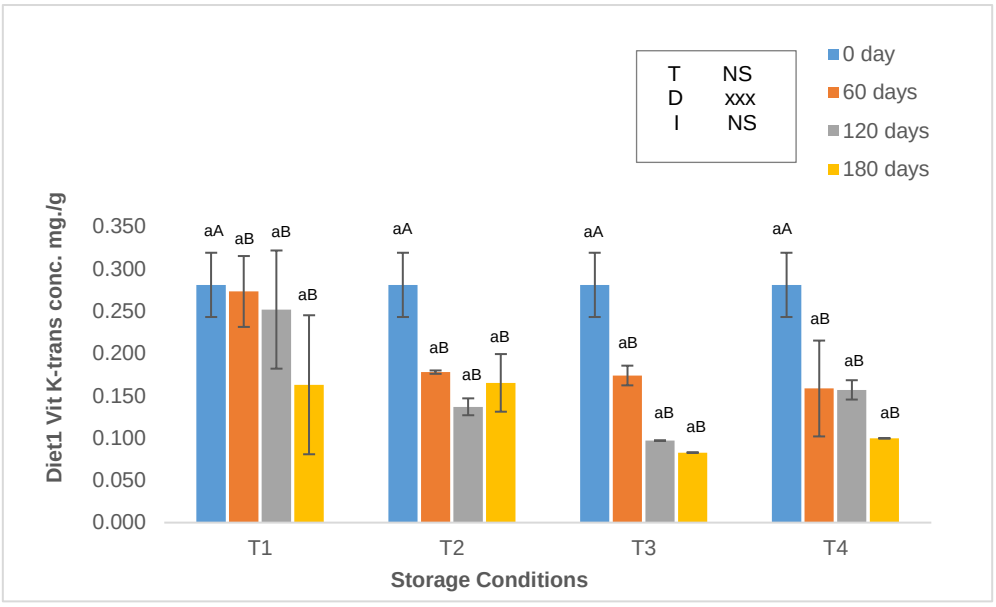

Fig.2g

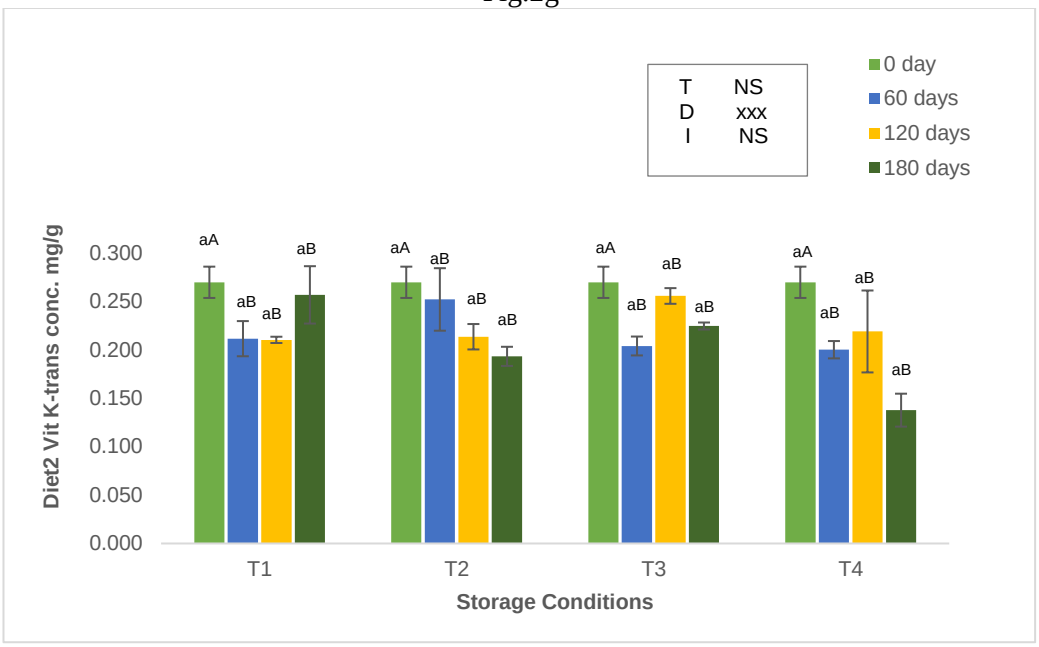

Fig.2h

4. Conclusions

The study evaluates effect of storage duration, temperature and their interaction, on vitamin profile in fish feeds prepared from extrusion and non-extrusion pelletization procedures. For both diets, substantial storage loss in water- miscible (B2, B12 and C), and fat-miscible (A, E, K) vitamins is evidentfrom 60-day onwards, at all storage temperatures. Intense diminutions in vit. D content was observable during four month storage at T4 condition for D2; while storage temperature, duration and interaction effects on dietary vit. D were significant ($P \leq 0.05$) for D1. D2 retentions for thiamin are influenced by interference from antinutrient factors in feed; while co-elutants affect determination of vit. B6 in D2. Through the study, it is evident that depletion in essential micronutrients with regard to feed vitamins incurs severe loss to feed quality. Incurred loss of most vitamins were highest at end of storage under high temperature T4 conditions.These diminutions are caused by oxidativeas well asnon-oxidative changes in vitamins along with interactive consequences of other dietary nutrients (proteins, lipids, elements/metals)on vitamin profileduring storage. It is noteworthy thatvitamin analysis and estimation is strongly influenced by processing technique, co-elutionand antinutrient interferences during chromatographic run.Furthermore, the studyhelps cogniseimpact of temperature and duration on feed

quality at storage inventories, and in farmingenvironments. Storage depletion of vitamins signify need to develop feed formulae taking into consideration the percentage loss of each nutrient from the foodstuffs, specifying at strategic formulation of feedkeeping in account storage impacts.Additionally, these findings offer helpful information for fish farmers in managing storage of formulated feeds, with an aim to prolong their shelf-life safeguarding significant amount of the total production costs of fed-aquaculture and incidental consumer health.

Abstract
Monitoring vital signs using a photoplethysmogram (PPG) signal has gained considerable attention, allowing users to monitor anyone, anywhere, and anytime with an objective. In recent years, advances in wearable technology and signal processing techniques have paved the way for accurate and reliable vital sign monitoring using PPG signals. Early detection of cardiovascular diseases can help the physician treat the disease promptly; thus, realtime monitoring of vital signs has emerged. Any deviation in the threshold value of vital signs can indicate potential threats to the cardiovascular system. The need to monitor vital signs in realtime using wearable devices has attracted the interest of the healthcare industry in developing simple and efficient vital sign estimation algorithms. This research introduces a framework to estimate the following important vital signs: heart rate (HR), respiratory rate (RR), blood pressure (BP), and blood oxygen saturation (SpO2), concurrently by overcoming the limitations posed by state-of-the-art techniques that primarily focus on individual or two vital sign estimations. Our proposed approach leverages signal processing techniques to determine the above-mentioned vital signs seamlessly and accurately. This innovation enhances the efficiency of vital sign monitoring and presents a unified solution for comprehensive health assessment. The widespread use of wearable devices for monitoring realtime health status in everyday life manifests in using PPG sensor-enabled wearable devices to perform more complex computational tasks. To date, the algorithms proposed to process an input PPG signal often use multiple processing steps to estimate any vital signs. This can increase the computational complexity of these algorithms, making it challenging to deploy devices with limited computational resources. The proposed work introduces a computationally efficient framework to estimate all four vital signs using the signal framework. The experimental results obtained with the proposed framework demonstrate that the proposed work outperforms the state-of-the-art estimation accuracy and computational complexity.

Keywords Blood pressure (BP) monitoring · Heart rate (HR) · Medical devices · Oxygen saturation level (SpO2) · Photoplethysmography (PPG) · Respiratory rate (RR) · Wearable device

Introduction

Vital signs are measurements of the primary functions of the human body. They are called "vital" because they reflect the essential functions needed to sustain life. The clinical value in measuring vital signs such as heart rate (HR), blood pressure (BP), respiratory rate (RR), and blood oxygen saturation (SpO2) using wearable devices provides a valuable opportunity in the field of digital health [1]. Wearable devices can continuously compute vital signs, thus obtaining measurements made without the conscious knowledge of the individual. The growing interest in using wearable health monitoring devices has naturally expedited PPG sensor-enabled wearable device development. Several algorithms to design wearable devices enabling electrocardiography (ECG) and photoplethysmography (PPG) sensors are discussed in the state of the artwork. Although the state-of-the-art shows significant results, wearable techniques still face research challenges concerning the computational complexity, accuracy, and reliability of data processed by these algorithms [2]. While ECG remains the gold standard for analyzing health status, its complexity, cost, and portability present hurdles to adopting its use in personnel homecare settings. The healthcare industry is trying to find a feasible approach to

monitoring and tracking multiple vital signs from a simple, easy-to-use wearable device to tackle the limitations of ECG. Potable wearable sensors are desirable, especially in emerging healthcare [3]. As a result, the healthcare industry's interest in leveraging PPG signals for vital sign estimation is growing due to their affordability, usability, and potential to monitor vital signs continuously. This feature makes PPG techniques more accessible for remote health monitoring and personalized home care.

PPG is an optical method to detect volumetric blood changes during a cardiac cycle. The PPG technique is technically simple to integrate with wearable devices for monitoring realtime vital signs [4].

Over the past few years, PPG sensor-based healthcare devices have been widely used to capture vital signs in clinical settings. PPG signals are produced by detecting blood content and volumetric changes in the microvascular bed of tissue. Pioneering work in wearable healthcare devices has demonstrated the potential of analyzing PPG signals for extracting vital signs in realtime [5]. However, addressing key challenges such as sensor quality, data transfer, and battery life is crucial for improving the effectiveness and practicality of wearable devices for vital sign monitoring. For instance, PPG data acquisition requires an optimal sampling frequency to balance data quality and system constraints. While higher sampling frequencies improve accuracy by capturing more detailed information, they also lead to increased data transfer requirements, higher memory utilization, and high computation requirements, leading to increased power consumption, which impacts the battery life of wearable devices. On the other hand, lower sampling frequency may compromise the accuracy of vital sign estimation, especially in real-time applications where precision is critical. Thus, careful attention must be paid to selecting a suitable sampling frequency to balance these trade-offs while designing a wearable device. The primary cardiac component of the PPG signal typically falls within the 0.5–5 Hz range, while motion artifacts and noise span higher frequencies up to 20 Hz [6]. To accurately capture the vital signs (such as HR, BP, RR, and SpO2) without aliasing, the sampling frequency is well above the minimum required to capture the cardiac behavior accurately. A higher sampling rate ensures accurate signal representation but increases data transfer size, processing power, and battery consumption, which needs to be balanced in wearable devices. Therefore, selecting an optimal sampling frequency is crucial for capturing accurate PPG signals while considering system constraints like power consumption and data transfer.

Further, accurately extracting vital signs using wearable devices poses a significant challenge due to motion artifacts in the acquired PPG signal. Therefore, to achieve reliable and precise vital sign estimation, it is essential to separate the motion artifact component from the vital sign components [7].

To this end, a novel algorithm based on group sparse mode decomposition (GSMD) techniques to separate motion artifacts components and the clean PPG signal components from monitoring all vital signs from a single PPG sensor signal. The proposed framework indicates that the clean PPG signal frequency spectrum consists of a dominant frequency component within the desired frequency range of vital signs [8]. The computation of the dominant frequency component guarded by a low-frequency component indicates the vital sign. In this study, the framework is designed to provide a novel solution to vital sign estimation that can be measured continuously using a wearable PPG sensor. Next, to refine the value of vital signs in real-time, a vital sign tracking algorithm is proposed that enables accurate estimation of vital signs in real-time.

Methodology

Data acquisition and segmentation

This work proposes a GSMD algorithm-based vital sign estimation framework, as shown in Fig. 1. The proposed framework considers HR, SpO2, RR, and BP. No common publicly available dataset provides the PPG signal recording for all vital signs. Thus, a publicly available benchmark dataset for each vital sign is used to analyze the proposed work's performance.

Dataset description

Four publicly available datasets (IEEE SPC [9], BIDMC [10], Capnobase [11], and MIMIC-3 [12]) are employed to check the potential of the proposed vital sign estimation framework. The datasets are recorded using a sampling frequency of 125 Hz, except for the Capnobase dataset, which has a sampling frequency of 300 Hz. Table 1 depicts the details of the dataset used to compute the vital signs.

Window segmentation

Segmentation of PPG signals is a common approach for continuously estimating vital signs. PPG signal segmentation in consecutive windows provides a mechanism for analyzing the PPG signal incrementally in realtime. A PPG signal acquired in realtime may contain physiological information and noise information. Segmentation of the PPG signal in a consecutive window allows the framework for adaptive and continuous analysis [13]. It can track vital signs without waiting to process the complete signal. In realtime processing, segmentation of the signal using a sliding windows

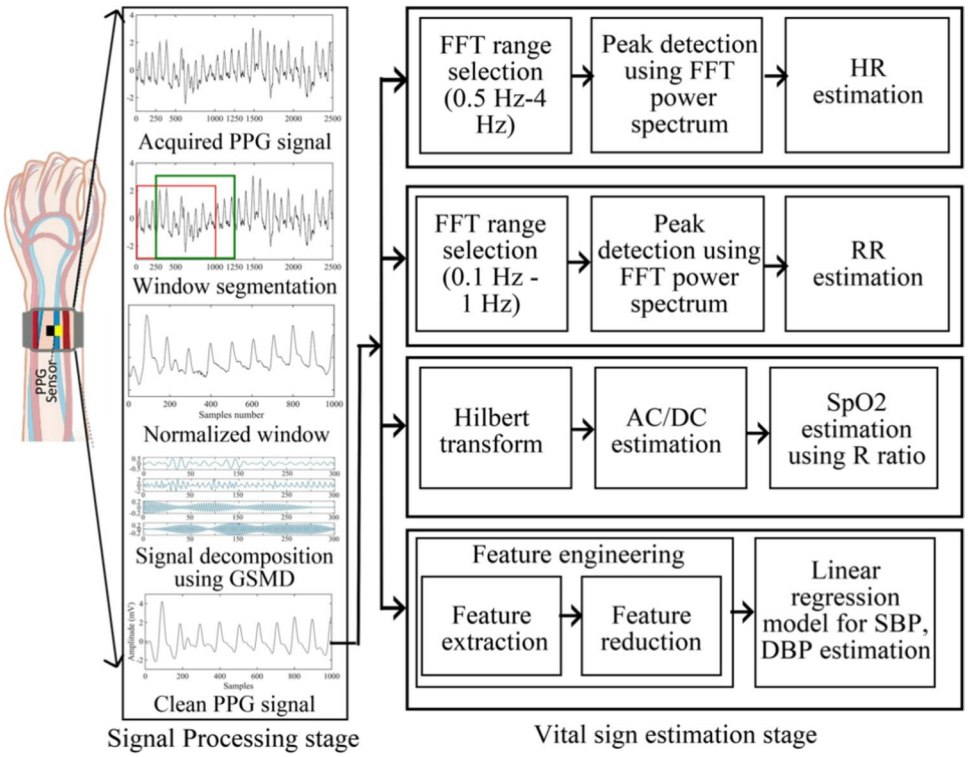

Fig. 1 Functional overview of the proposed vital sign estimation framework

scheme, in which windows advance in time as a new signal arrives, increases accuracy and reliability.

In Table 1, the window size represents the sample duration used to compute the true value of vital signs. In the proposed work, to generalize the model and consider each vital sign with the same scale, the proposed work is evaluated with the same window segmentation protocol used to estimate the true value of the vital sign. These true values of vital signs are used to check the efficacy of the proposed framework. Table 1 shows the total number of windows framed with each dataset employed to compute the true value of vital signs.

Signal decomposition

This work uses the GSMD algorithm to separate the frequency components of the PPG signal and the motion artifacts/noise component. GSMD decomposes the acquired PPG signal, which is non-stationary, into a distinct set of intrinsic mode functions (IMFs). Each IMF has limited bandwidth, and the frequency band of each IMF has no common spectra. The GSMD algorithm uses an ideal filtering technique designed in the frequency domain to extract each individual IMF from the PPG signal [14]. These filters isolate the desired frequency components from the signal. The filter bank f_a is modeled as an on–off group-sparse vector, reflecting that specific frequency components are present in distinct groups.

The coefficients of the ideal filter bank are estimated using a penalized least-squares approach. The penalty term utilized in the estimation process involves a weighted $\ell 0$-norm, and the weighting parameters are determined using techniques that involve energy detection over short windows.

Table 1 Vital sign dataset description and window formation

Dataset	Vital sign estimate	Duration of record (in second)	Window size (in second)	Step size (in second)	Number of windows framed
IEEE SPC [9]	HR	300	8	2	3204
BIDMC [10]	SpO2	480	8	1	4440
Capnobase [11]	RR	480	32	3	5102
MIMIC-III [12]	SBP, DBP	600	8	2	3610

The penalty term encourages both on–off and group-sparsity properties in an ideal filter bank, which promotes the presence of certain groups of frequencies and keeps other frequencies zero. A regularization parameter λ is also used, and its optimal value depends on factors like noise variance and window size. The decomposed levels are adaptive. The GSMD algorithm adjusts the window size based on the bandwidth of different IMFs and estimates the noise variance from the measured data, thus providing adaptivity. After convergence, the estimated filter bank f_a is decomposed into nonoverlapping filters f_{ai}. Each filter f_{ai} contains a block of adjacent nonzero entries in f_a. These filters are then used to extract individual IMFs. Thus, GSMD reduces user intervention by adaptively decomposing an input PPG signal into several IMFs. The utilization of the weighted l0-norm and the group sparsity algorithm converges the complete framework in a relatively short time compared to similar algorithms.

The key highlights of the proposed GSMD-based vital sign estimation framework are as follows.

- This work introduces a computationally efficient framework to estimate all four vital signs using the signal framework that solely requires a PPG signal, unlike existing frameworks that concentrate on single or paired vital sign estimations.
- Our approach proposes a comprehensive solution capable of simultaneously assessing all vital signs using a single wearable device, offering a holistic picture of an individual's health status in realtime.
- The proposed GSMD-based algorithm utilizes the concept of group sparsity to identify specific frequency components that are grouped.
- GSMD converges relatively quickly and is suitable for decomposing long signals. This efficiency is advantageous when dealing with extended data sequences.

Additionally, the GSMD algorithm automatically extracts the IMFs related to the clean PPG signal, and the sum of these IMFs provides a clean PPG signal. Algorithm 1 depicts the stepwise process of the proposed GSMD-based vital sign estimation framework.

Algorithm 1: Proposed GSMD-based estimation of vital signsusing corrupted PPG signal

Input: Acquired PPG signal. (Vital sign estimation dataset)
Result: HR, SpO_2, RR, SBP, DBP
1: Segregate S into a consecutive window containing N samples.

$$S^b = (S((b-1)\times w)+1 \ldots . S((b-1)\times w)+N)$$

Where w is the step size equal to two seconds, b is the window number
2: for b = 1 to Z do; Z is the total number of eight-second window.
3: Obtain normalized S^b using the relation:

$$S^b = \frac{S^b - \mu\left(S^b\right)}{\sigma\left(S^b\right)}$$

Here, μ and σ represent the mean and standard deviation, respectively.
4: Decompose S^b into J basic functions called intrinsic mode functions (IMFs)

$$S^b = \sum_{j=1}^{J} h_j^b$$

5: h_j is optimally calculated by using a relation

$$h_j = \mathrm{T}^{-1}(IF_j \quad C_S), j = 1,\ldots..,J,$$

C_S and IF_J are the discrete cosine transform (DCT) coefficient vectors of the input signal and an ideal filter. T^{-1} is the inverse DCT
6: Construct the matrix of the obtained IMF
$M \in R^{J\times N}$: $M = [h_1; h_2; \cdots h_j]$
7: Obtain the denoised signal $X^b = \sum_{j=1}^{J} h_j^b$
8: Detect the peak of the dominant frequency component corresponding to the vital sign
9: Estimate the vital the using the detected dominant peak frequency F_d
10: end for
12: return estimated vital sign

Figure 2 depicts the corrupted PPG signal acquired during physical exercise, and Fig. 3 indicates the clean PPG signal obtained using the GSMD algorithm.

Vital sign estimation

HR estimation

Estimating HR using a PPG signal is a standard non-invasive method for realtime monitoring of an individual's HR. The number of heartbeats per minute (BPM) is termed HR. HR is an essential vital sign that reflects the rate at which the heart pumps blood throughout the body. Generally, the average HR for adults lies between 60 and 100 BPM, although the HR range varies based on individual factors such as age, fitness level, and medical conditions [15]. Daily physical activity, stress, emotions, temperature, and health can

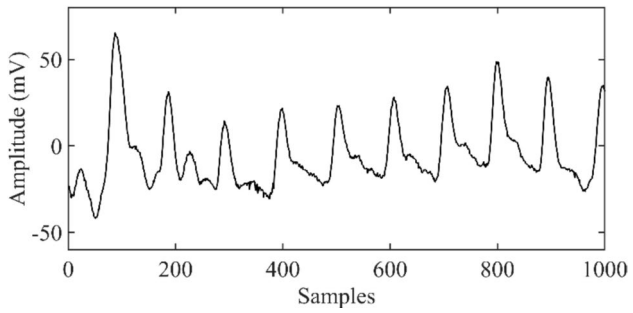

Fig. 2 Motion artifact corrupted PPG signal of subject 15 taken from IEEE SPC dataset

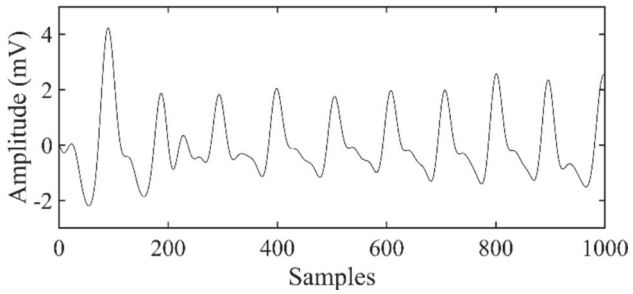

Fig. 3 The representation of a clean PPG signal was obtained using the GSMD algorithm

influence HR. Continuous monitoring of HR plays a pivotal role in healthcare, sports, and fitness as it provides valuable information about the cardiovascular system and indicates an individual's health status. HR can be monitored by manually counting pulse beats at a certain arterial point. Recently, electronic devices embedded with PPG sensors have been commonly used for realtime continuous monitoring of HR. Tracking changes in HR in realtime can help assess cardiac health, track fitness progress, and identify abnormalities in cardiac function. The clean PPG signal obtained from the GSMD algorithm is used to estimate the HR. Estimating HR from a clean PPG signal using the Fast Fourier Transform (FFT) to identify the dominant peak frequency is a common and effective method [16]. FFT transforms the time-domain signal into its frequency-domain representation. The output is a complex spectrum that contains information about the signal's frequency content. Signal transformation helps identify the signal's different frequency components, including the HR frequency. Further, to identify peaks, the magnitude spectrum of the complex spectrum is computed, which provides the distribution of signal energy across different frequencies. The obtained magnitude spectrum is examined to locate the potential peaks. Examine the magnitude spectrum to locate local maxima. These represent potential peaks in the signal. One common approach is to iterate through

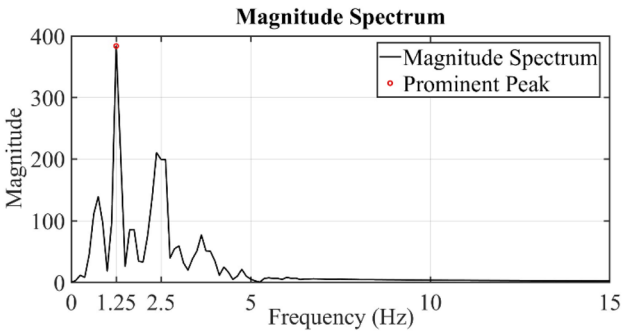

Fig. 4 Magnitude spectrum representation of clean PPG signal to extract dominant peak frequency

the magnitude spectrum and compare each point with its neighboring points. If the magnitude of the point is greater than its neighbors, it can be considered a local maximum. Figure 4 shows the magnitude spectrum of the clean PPG signal with a.

red marker indicating the frequency of the prominent peak corresponding to HR. After identifying potential peaks, the frequency bin of the peak with the highest magnitude in the FFT spectrum is determined. The frequency of the prominent peak is used to compute HR in BPM using the relation. Since FFT output is in Hz, thus converting the peak frequency from Hz to HR in BPM, Eq. (1) is used.

$$HR\,(BPM) = prominent\,peak\,frequency \times 60 \tag{1}$$

RR estimation

RR indicates the number of breaths a person completes in one minute. RR is commonly used in clinical assessments to assess the individual's respiratory health status. For adults with good health status, the value of RR typically lies between 12 and 20 breaths per minute (BPM). However, factors like age, physical condition, and health conditions cause RR to deviate from its normal value. Table 2 depicts the variation in RR with age.

Realtime monitoring of RR is vital in healthcare settings, as it provides valuable information about individuals' lung and cardiovascular functions [17]. RR deviation from its standard threshold value, or abnormal RR, can indicate forthcoming illness. Monitoring changes in blood volume during inhalation and exhalation can provide valuable information about RR. During inhalation, the pressure within the thoracic cavity decreases, increasing intrathoracic volume [18]. This results in an influx of blood into the thoracic cavity, increasing the venous blood return to the heart.

Conversely, during exhalation, the pressure within the thoracic cavity increases, leading to a decrease in intrathoracic volume. The increase in thoracic pressure impedes the return

Table 2 Variation in RR with change in age

Age	Rate (BPM)
Birth to 6 months	30–60
6 months to 1 year	30–50
1–3 years	24–40
3–5 years	22–34
5–12 years	16–30
12–70 years	12–20
> 70 years	15–20

of venous blood to the heart. This concept is often used to estimate RR using a PPG signal. Respiratory rate estimation using a PPG signal is common in healthcare and wearable devices. The PPG waveform reflects these variations as blood volume changes due to inhalation and exhalation [19].

PPG signal captures the volumetric change in the blood due to respiration; thus, the acquired PPG signal consists of periodic variations associated with RR. Thus, to identify the dominant peak frequency corresponding to the RR, the proposed work used FFT-based dominant peak detection techniques to estimate RR using the PPG signal. Figure 5 shows the magnitude spectrum of the clean PPG signal with a red marker indicating the frequency of the prominent peak corresponding to RR.

After identifying potential peaks, the frequency bin of the peak with the highest magnitude in the FFT spectrum within the RR frequency range is determined. The frequency of the prominent peak is used to compute the RR in breath per minute (BPM) using the relation. Since FFT output is in Hz, Eq. (2) converts the peak frequency from Hz to RR in BPM.

$$RR\,(BPM) = prominent\,peak\,frequency \times 60 \tag{2}$$

BP estimation

The force of blood exerted on the artery wall during the systolic and diastolic phases of the heart is termed BP. BP is typically expressed in pressure values, namely systolic BP (SBP) and diastolic BP (DBP). The pressure in the arteries when the heart beats and pumps blood into the circulation is noted as SBP, which is usually the first and highest number in a BP measurement. Conversely, the pressure in the arteries when the heart is at rest between beats is termed DBP. DBP reflects the constant pressure in the circulatory system. BP is measured in millimeters of mercury (mmHg) and is an essential indicator of cardiovascular health. Any deviation in the threshold BP levels can indicate abnormal conditions of individual health. The potential of realtime monitoring of BP using PPG signals has attracted significant interest in the healthcare industry [20].

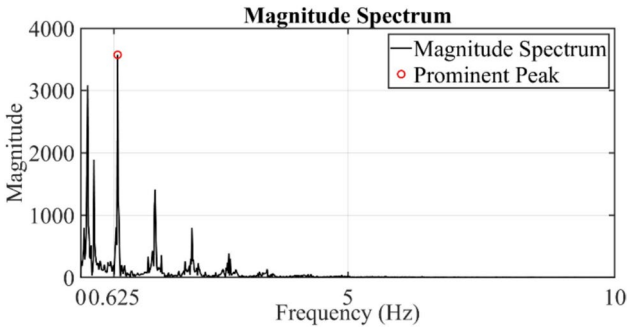

Fig. 5 Magnitude spectrum of clean PPG signal for extracting dominant peak frequency

This interest is driven by the need for continuous monitoring of BP in realtime, which is essential in diagnosing and managing cardiovascular diseases. The gold standard for monitoring BP is the arterial BP (ABP) technique. ABP is considered typical for its accuracy and reliability. However, the invasive nature limits the ABP use in the hospital. Traditionally, cuff-based mercury sphygmomanometers have been the standard for BP measurement; however, they are not suitable for continuous monitoring due to discomfort and the time it takes to obtain a reading [21].

In contrast, a cuffless, non-invasive monitoring system has emerged to resolve the above issue, allowing individuals to monitor their BP continuously. PPG and ECG are promising techniques when used with artificial intelligence (AI) for monitoring and diagnosing cardiovascular diseases (CVD). PPG is particularly favored due to its affordability, ease of use, portability, and suitability for wearables. As a result, there is growing interest in leveraging PPG signals and AI algorithms to develop innovative solutions for continuous BP monitoring and early detection of cardiovascular issues, ultimately improving the management of cardiovascular health.

Recent research has been focused on developing single-sensor-based continuous BP monitoring solutions to overcome the limitations of multiple sensors. This approach aims to provide convenience and comfort to users while maintaining accuracy. There is no direct measure to monitor SBP and DBP solely from a PPG signal. PPG signals offer valuable information about blood volume changes and pulse waveforms, but they require careful calibration and predictive models to estimate BP accurately [22].

The proposed work combines the potential of the GSMD algorithm with a linear regression-based machine learning model to create a realtime BP monitoring device. Linear regression is a relatively lightweight machine-learning algorithm that can provide reasonable results while being computationally efficient. The clean PPG signal obtained from the GSMD algorithm is processed to extract features for model training. The extraction and selection of highly

correlated features is crucial for extracting SBP and DBP information from the PPG signal. Initially, a subset of features, namely absolute deviation (MAD), entropy, power spectral density (PSD), dominant peak frequency (Freq), the index of the maximum value (*midx*), mean and standard deviation (std) within each window is extracted from the clean PPG signal obtained using the GSMD algorithm.

The clean PPG signal makes extracting reliable features accurately representing SBP and DBP monitoring easier. These features help train a model to learn the relationships between extracted features and ground-truth BP labels, leading to better model performance. Moreover, machine learning models trained on features extracted with a clean PPG signal improve their generalized capability. However, a model trained on a corrupted PPG signal may learn to adapt to noise rather than the underlying physiological patterns related to BP.

Further, the filter method selects the best feature with a high correlation with the target SBP and DBP values. Filter methods are feature selection methods that choose features based on some criteria before building the model. The filter method is computationally efficient and does not require multiple-model training. Also, the filter method is less prone to overfitting in the feature selection phase. The proposed work uses a correlation coefficient and the chi-square-based feature filtering approach. The correlation coefficient filter method filters out irrelevant features from the features set by evaluating the correlation between the input feature and the target BP value. This step retains the highly relevant feature strongly correlated with the target value. Based on the analysis with different features, a threshold value of 0.6 is fixed in the proposed work—the feature whose correlation value is above 0.6 is considered relevant. Additionally, the chi-square method is performed to filter the feature set. A contingency table is designed between the individual feature and the target BP value to obtain the *p*-value using the chi-square test for feature filtering. This Table reflects the frequency of each combination of features and the target BP value. The chi-square test is implemented on the contingency table to obtain the *chi*-square statistic and the *p*-value. The *p*-value represents the significance between the feature set and the target BP value. The feature that obtains a *p*-value less than or equal to 0.05 indicates that the feature is likely to be informative in predicting the BP value. Based on the filtering method, *midx* is identified as the best feature, which correlates highly with the target BP value (Fig. 6). This feature obtains the optimized linear regression equation for predicting SBP and DBP.

Initially, a grid search optimization algorithm is used to find the optimized value of the linear regression model's hyperparameters a and b, where *a* is the intercept and *b* is the slope of the PPG feature. The optimization algorithm likely controls the coefficients of the linear equation used to predict

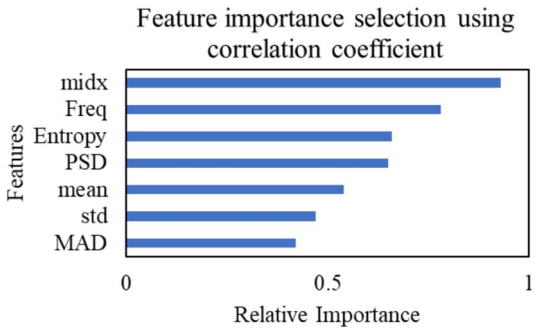

Fig. 6 Feature and its importance in estimating BP

SBP and DBP from PPG features. Further, to improve the generalized capability of the model, a fivefold cross-validation approach is used to split the input data into five subsets.

To evaluate the model efficiency with different values of hyperparameters *a* and *b*, mean absolute error (MAE) is used as a performance metric. During each fold, the model iterates through different combinations of hyperparameters *a* and *b* within the defined search range. For each combination of hypermeters, the proposed framework trains the linear regression model using the training data. After training, the trained model predicts the SBP and DBP values for the testing data. The MAE parameter is computed based on the predicted and actual values of SBP and DBP. The value of *a* and *b* at which the model obtains the minimum MAE value is filtered as an optimized hypermeter for that combination of hyperparameters and fold. The obtained value of MAE for each combination of fold and the optimized hyperparameters is kept in a matrix for comparison. After completing fivefold cross-validation, the framework finds the best combination of hyperparameters that provides the lowest MAE across all folds. This combination of a and b is considered an optimized hyperparameter setting for the model. Once the framework obtains the optimized hyperparameters, the framework trains the final linear regression model using the entire dataset. The obtained final linear regression is based on an optimized hyperparameter using a fivefold cross-validation approach intended to be the best-performing model. After training with the optimized hyperparameters, the linear regression model provides a linear equation. This equation represents the correlation between PPG features and the predicted SBP and the DBP value.

This study uses linear and nonlinear regression as data-driven models to predict the PPG signal's SBP and DBP values. The linear regression model is a lightweight machine learning model form of regression used to predict the SBP and DBP values. Linear regression is a supervised machine learning algorithm that predicts SBP and DBP values based on the extracted features. Linear regression assumes a linear relationship between the input features and the true SBP

and DBP values. The coefficient of linear regression is optimized, and the best-fit line equation that minimizes the sum of squared differences between the estimated and true values is computed. Conversely, nonlinear regression can capture a more complex relationship between the estimated and the true value. The complexity of the nonlinear regression model is higher than the linear model, as nonlinear regression requires more parameter tuning.

SpO2 estimation

Blood oxygen saturation (SpO2) is an important physiological parameter that measures the percentage of oxygen-bound hemoglobin in the blood. SpO2 is an important parameter that checks an individual's respiratory and circulatory status; thus, it is commonly used in healthcare for patient monitoring. SpO2 measurement helps assess how well oxygen is transported to the body tissues. Change in SpO2 value about its threshold can be an early indicator of abnormality in the respiratory, cardiovascular, and circulation systems [23]. A pulse oximeter is a device that captures the interaction between light and the volume of blood. It is commonly used in households and clinics to measure SpO2. The pulse oximeter consists of two light-emitting diodes (LED) of different wavelengths. Red and infrared LEDs are commonly used in pulse oximeters to measure the light absorbed by oxygenated (HbO2) and deoxyhemoglobin (Hb) hemoglobin (*Hb*). A pulse oximeter computes the SpO2 using the relation shown in Eq. (3) by analyzing the concentration of light absorbed by oxygenated and deoxygenated hemoglobin.

$$SpO2(\%) = \frac{C(HbO_2)}{C(HbO_2) + C(Hb)} \times 100 \tag{3}$$

In a healthy body, the typical value of SpO2 typically lies in the 95% to 100% range. A SpO2 value lower than 95% indicates the body has a low oxygen level in the blood, termed hypoxemia. Untreated hypoxemia can result in respiratory diseases and heart problems. Moreover, if not treated promptly, a deficient value of SpO2 can endanger life. Thus, continuous monitoring of SpO2 in realtime can help the physician to diagnose patients with chronic respiratory conditions. The proposed work possesses a single PPG sensor to monitor SpO2. A Hilbert transform is applied to the clean PPG signal to compute its envelope. The envelope represents the variation in the PPG signal amplitude due to a change in blood flow. Further, the envelope's alternating (AC) and direct (DC) components are obtained to compute the *R*-ratio. The AC component indicates the variation in amplitude due to pulsatile blood flow and is calculated as the difference between the envelope's maximum and minimum values. The mean value of the envelope depicts the DC component, representing the baseline or non-pulsatile part of the signal. The *R*-ratio depicts the ratio of AC components to DC components.

The state-of-the-art techniques indicate that the R-value-based computation of SpO2 does not always provide reliable outputs. Thus, classical signal processing approaches fail to provide accurate and reliable solutions. The advancement in the machine learning model shows the potential to overcome the drawbacks of traditional signal processing methods to estimate SpO2 [24]This work estimates the SpO2 value using three simple machine learning-based regression models: linear, nonlinear, and polynomial. Equation (4) represents the optimized calibration curve formula obtained using polynomial regression to estimate the SpO2 value. Equation (4) relates the SpO2 value with the *R*-ratio.

$$SpO_2 = (-45.060 \times R^2 + 30.354 \times R + 94.845) \tag{4}$$

The derived formula is validated on a separate dataset to assess its accuracy and generalizability.

Post-processing stage

A post-processing stage is introduced in this work to enhance the accuracy and reliability of the algorithm. This stage leverages the inherent temporal variation of vital signs. Specifically, when subjects engage in intense physical exercise or when the frequency of motion artifact components is closely aligned with that of the true vital sign component, the post-processing stage aids in tracking the vital sign within the current window. This improvement enhances the overall performance of the proposed algorithm, making it more robust in challenging situations where motion artifacts or vital sign variations might otherwise pose difficulties. The clean PPG signal extracted from the based algorithm extracts the vital signs despite directly considering the obtained vital sign values computed using a clean PPG signal provided

by the GSMD algorithm. A vital sign tracking algorithm is used to refine the value of the vital sign. This step involves the proposed framework to improve the reliability of the proposed algorithm in realtime. A signal quality index (SQI) parameter qualifies the PPG signal windows as clean/corrupted to classify the correct/incorrect vital sign prediction. The proposed work initially uses the GSMD to denoise the PPG signal. The denoise PPG signal is passed to the vital sign estimation algorithm to estimate the vital sign. Four SQIs, namely, entropy, signal-to-noise ratio (SNR), skewness, and zero-crossing parameters, are analyzed to check the reliability of the estimated vital signs.

A unified SQI parameter consolidates individual SQI parameters into a singular value to enhance signal quality analysis. Before consolidation, all SQI parameters undergo normalization to unify them onto a common scale. The resultant combined SQI index offers a comprehensive perspective of the PPG signal derived from the collective evaluation of various SQI indexes within the signal. Different weights are assigned to each normalized SQI parameter. A higher weight is assigned to that SQI parameter, which provides significant information regarding motion artifacts in a PPG signal. After weight assignment, all the SQI parameters are combined to give a single composite SQI metric. For the algorithm to flag the signal quality as acceptable or not acceptable, an optimum threshold value for the composite SQI metric is assigned. The selection of the threshold value is fixed based on the performance of the proposed algorithm on different threshold values. Suppose a PPG signal window SQI index parameter is less than the specified threshold value. In that case, it indicates that the PPG signal window is affected by strong motion artifacts, and the vital sign value obtained with such a window is erroneous. A vital sign smoothing algorithm is used to refine the vital sign value of such corrupted windows. The PPG signal window flag is not acceptable. The vital sign value of that window is replaced using a not-valid value (*NaN*). The *NaN* value is considered an outlier in the vital sign, which is replaced by the smoothing algorithm for accurate vital sign estimation. A linear interpolation protocol is used to replace the *NaN* value. The steps involved in the smoothing algorithm are depicted in Algorithm 2.

Algorithm 2: Proposed SQI index-based Smoothing Algorithmusing History Tracking of estimated vital sign

Input: GSMD-based motion artifact-free PPG signal window of length N samples.

$$X^b = \left[X^1, X^2, X^3, \ldots\ldots X^Z\right]$$

Result: Refine estimated vital sign value using the smoothing algorithm.

1: Compute the composite SQI index parameter

$$SQI_{comp} = f(x)$$

Where, $f(x)$ is a function that computes the SQI of the PPG signal

2: Define the optimum threshold value (τ)

3: If composite SQI ≥ τ, $vitalsign_{estimated} \leftarrow vitalsign_{refined}$ Flag estimated vital signs acceptable and jump step 8; otherwise, follow steps 3 to 7.

4: Flag the obtained vital sign value as not valid value (*NaN*)

If $SQI_{comp} \leq \tau$, the estimated vital sign is flagged as not valid: $vitalsign_{estimated} \leftarrow NaN$

Use the interpolation to replace the *NaN* value

5: Retrieve the non-NaN value from the original vital sign data.

$vitalsign_{valid} = \{\text{vitalsign}_i \in vitalsign_{estimated} | vitalsign_i \neq NaN\}$

6: Omit *NaN* values by applying the *NaN* handling function:

$$vitalsign_{valid} = omitNaN(vitalsign_{estimated})$$

7: Specify the window size to implement the moving average function to smooth the signal.

$$vitalsign_{refined} = \frac{1}{q}\sum_{i=k}^{k+q-1} vitalsign_{estimated}, \quad \text{for } k = 1, 2, \ldots. N\text{-}q+1$$

Where *NaN* values are omitted

8. Process the signal as a refined estimated vital sign.

9: end for

10: return vital signs estimated

In those windows where *NaN* represents the corrupted estimated vital sign value, the *NaN* value is replaced by the mean of the estimated vital sign value of the previous three windows. Each window is checked for its SQI value. If the SQI value of a particular window is below a specified threshold value, then the estimated value is discarded, and vital sign tracking is used.

This work analyzes the PPG signal using the GSMD approach using four SQI indices to determine accurate vital sign prediction based on the SQI index. If a window SQI index is reported lower than the specified threshold, then that window is passed to the tracking algorithm to refine the vital sign value.

Results analysis

This section is divided into five subsections. No work has been reported to estimate all vital signs using a single framework. Thus, to analyze the proposed framework's performance, subsequent sections are designed to compare the results of an individual vital sign with state-of-the-art work.

Performance analysis of vital sign estimation

The performance analysis of the proposed vital sign estimation framework is visualized and analyzed using a violin plot. In a violin plot, the width of the plot at a location indicates the density of data points. The violin plot contains both mean and median lines. The difference in the position of mean and median values between the two groups (vital sign estimated and vital sign true) provides insights into the average performance of the proposed framework. Figure 7 shows the violin plot comparing the estimated and true value of various vital signs. The shape, mean, and median values of true and estimated vital signs are almost identical, thus indicating the potential of the proposed framework that estimates multiple vital signs using a single algorithm. The proposed framework is a computationally efficient algorithm that can be embedded in a wearable device for realtime monitoring of vital signs.

The proposed work is the first framework in the literature to estimate four vital sign values simultaneously. The proposed framework allows individuals to select the vital sign parameter. The primary concern in designing a wearable health monitoring device is the accuracy of results in realtime. Monitoring vital signs in realtime faces the hurdle of motion artifacts, which affect the accuracy of the vital signs; thus, analysis becomes erroneous. In the proposed work, the motion artifact components are separated by using a computationally efficient GSMD algorithm. GSMD provides a clean PPG signal component. To critically analyze the performance of the proposed framework, besides the violin plot, the Pearson correlation coefficient (r) and the mean absolute error (MAE) are computed for each vital sign, represented by Eqs. (5) and (6), respectively.

$$r = \frac{n\left(\sum xy\right) - \left(\sum x\right)\left(\sum y\right)}{\sqrt{\left[n\sum x^2 - \left(\sum x\right)^2\right]\left[n\sum y^2 - \left(\sum y\right)^2\right]}} \tag{5}$$

$x \rightarrow vitalsign_{true}\ y \rightarrow vitalsign_{estimated}$

$$MAE = \frac{1}{W}\sum_{b=1}^{W} \left|vitalsign_{true}(b) - vitalsign_{estimated}(b)\right| \tag{6}$$

Result analysis of HR estimation

Continuous HR monitoring via PPG-equipped wearables presents challenges regarding precision in HR estimation.

The proposed algorithm reliably attains superior accuracy when the subject indulges in various physical activities. The proposed algorithm is trained and tested using the IEEE SPC dataset recorded during the subject undergoes physical activity closer to realtime daily routine activities. The algorithm's performance is assessed by measuring the MAE (BPM), violin plot, and the Pearson correlation plot. The proposed framework has shown an MAE of 1.28 BPM for IEEE SPC datasets. Table 3 compares the results of the proposed method with those of recently published algorithms. Notably, the MAE value outperforms those of other state-of-the-art methods.

The violin plot in Fig. 8 shows the difference between $HR_{estimated}$ and HR_{true} values. As observed from Fig. 8, the maximum density of error point (estimated—true) lies within the range of − 2.5 BPM to 2.5 BPM.

Additionally, Fig. 8 shows that most data points are within the small error range, indicating that the difference in errors within the HR range is minimal and remains within an acceptable threshold. The experimental outcomes demonstrate that the proposed algorithm effectively performs when tested with datasets collected while subjects are engaged in vigorous physical activities, such as weight lifting and boxing.

Result analysis of BP estimation

The mean error (ME) and the standard deviation (SD) of the error are computed for both SBP and DBP values to check the performance of the BP estimation algorithm. The obtained values of ME and the SD are checked to find if the values of ME and SD suit the criterion provided by the Association for the Advancement of Medical Instrumentation (AAMI) and the British Hypertension Society (BHS). The AAMI standard assesses compliance based on whether the ME in the performance of both SBP and DBP is below five mmHg, along with the requirement that the SD of the error remains under eight mmHg. The BHS standard criterion to check the performance of the framework is summarized in Table 4. A BP estimation device must achieve B-grade for SBP and DBP per BHS standards. The performance of the proposed framework is validated using data from 1557 subjects with 3610 windows. The results are compared against the BHS standard. The optimized linear model equation for which the model shows the lowest MAE is considered. The equation of the linear regression model performed in MATLAB® software and the structure of the SBP and DBP model is as follows:

Linear regression equation:

$$\mathrm{SBP} = 113.0048 + 3.5783 \times \mathrm{PPG_feature}$$

$$\mathrm{DBP} = 74.1955 \pm 0.13513 \times \mathrm{PPG_feature}$$

Using the proposed algorithm, 81.29% of windows pose an MAE below 5 mmHg for SBP, while 86.81% pose an MAE below 5 mmHg for DBP. Comparing the above values with the BHS standards from Table 5 confirms that the requirements for Grade A in the BHS standard are met. Further, the framework resulted in MAE values of 2.56 and 3.25 mmHg for SBP and DBP, respectively, thus meeting the requirements of the AAMI standard. These MAE values for both SBP and DBP are within the range of AAMI standards. These findings highlight the effectiveness and reliability of the proposed model for BP estimation. The performance of the proposed framework to estimate BP is evaluated using different performance assessment measures such as MAE, Bland–Altman plot, and violin plot. The MAE values of 2.46 and 2.56 on training and testing databases, respectively, are obtained. Further, for DBP, MAE values of 3.19 and 3.25 on training and testing databases, respectively achieved using the linear regression model, demonstrate the superiority of the proposed model over the other data-driven models. The results show that using GSMD, the performance of the model training is improved using features extracted from the clean PPG signal for BP estimation.

Table 6 compares the performance of the proposed work with related state-of-the-art work. For a fair comparison, Table 6 consists of the same performance metrics and database. The proposed study, which used the combination of GSMD and linear regression to predict SBP and DBP, achieved better performance than the related state-of-the-art studies found in the literature.

the literature. Additionally, the performance of the GSMD-based RR estimation method from the PPG signal is assessed using the Bland–Altman plot and Pearson correlation coefficient. Table 7 reveals that MAE values obtained with the proposed approach are lower than in previous works. The correlation between RR_{true} and $RR_{estimated}$ obtained with the proposed framework is visualized in the violin plot, as shown in Fig. 8.

The LOA for the signals from the Capnobase dataset ranges from − 2.1 to 2.3 BPM. As evident from Fig. 8, the error differences are minimal and within acceptable limits, suggesting that the proposed RR estimation method exhibits good agreement with the true data and can be used for real-time RR monitoring.

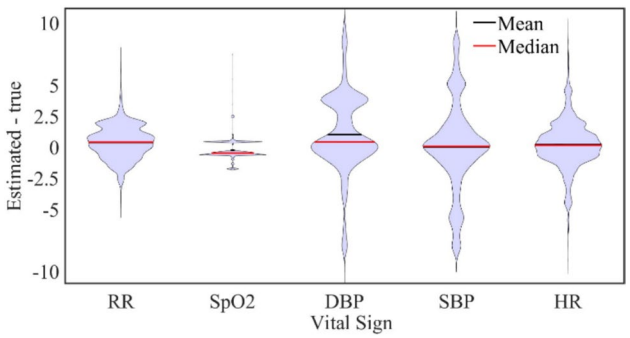

Fig. 8 Violin plot representation for vital sign estimation

Result analysis of SpO2 estimation

Reflectance PPG data collected using the SpO2 data acquisition platform used as the true value is synchronized with the acquired PPG signal. Three regression machine learning models, namely, linear, nonlinear, and polynomial regression models, are exclusively tested on the test data. Nonlinear and polynomial regression can capture nonlinear relationships between the feature and the true BP value. However, nonlinear regression models are not restricted to polynomial functions and can employ a wider range of nonlinear forms to describe the relation.

Polynomial regression, an extension of linear regression, specifically uses polynomial functions to model the relationship between the PPG feature and the true value of BP. The proposed work's polynomial regression demonstrated commendable performance over the remaining two. Table 8 indicates that the proposed work outperforms similar state-of-the-art work. From Fig. 8, it can be observed that most correctly predicted observations have a lower error rate in estimating the SpO2 value.

Discussion

Monitoring continuous vital signs using PPG-enabled wearable devices presents ongoing challenges regarding accuracy. The proposed novel framework consistently delivers

high accuracy for vital sign tracking, even during intense physical activity. The framework performance is evaluated through the dataset available publicly for individual vital signs. Its effectiveness is assessed by calculating the MAE and analyzing the violin plot. Tables 3, 6, 7, and 8 compare the results of the proposed work with the state-of-the-art work for individual vital signs such as HR, BP, RR, and SpO2, respectively. The last row of Tables 3, 6, 7, and 8 highlights the results of the proposed algorithm. Among the previously reported algorithms, the proposed algorithm for estimating vital signs outperforms most of the previously reported methods. Based on the results obtained, the proposed framework is a promising solution for predicting vital signs. In Table 3, the last column represents the MAE values achieved with the proposed approach. Table 3 reveals that the MAE value obtained with the proposed approach is small compared to previous works. However, it's important to note that the works in references [25, 26] necessitate an additional 3-axis accelerometer sensor to provide a reference motion artifact signal. This requirement increases the overall system complexity and energy consumption. The performance of the approach presented in reference [29] relies on the simultaneous use of an ECG signal alongside the PPG signal. The inclusion of an additional ECG sensor increases the system's complexity. In contrast, the proposed PPG signal denoising technique, GSMD, stands out as it doesn't require an additional reference signal. Thus, the GSMD-based algorithm reduces the overall system complexity and energy consumption, making it a more practical and efficient choice for real-time HR estimation. In Table 6, the work proposed in [20, 35, 37, 39, 41, 42] extracted features from ECG and PPG signals. These methods show notable MAE for SBP and DBP estimation, but the need for additional

ECG sensors increases the computation complexity of the device. The work proposed in [36] shows an acceptable performance through the AAMI and BHS standards. However, further improvements in MAE and the model's reliability can be improved by including more data. The work proposed in [38] does not satisfy the BP estimation standard. The work proposed in [40] uses three PPG signal variants to extract features for model training. Maintaining a correlation between the PPG signal and its first and second derivatives is challenging in realtime. Violin plots of SBP and DBP are shown in Fig. 8, indicating that the difference in errors within the BP estimation is minimal and remains within an acceptable threshold. The work proposed in [53] segregates the complete range of SpO2 values into twenty classes. Instead of making predictions, the proposed model does the classification task. The MAE is calculated based on the prediction of the classifier. The work proposed in [54] shows an acceptable performance. However, statistical research has indicated that further improvements can be made to the model by increasing the data and enhancing the selectivity of the variables. The work proposed in [55] uses red, IR, and green LEDs. SpO2 is determined by processing the red and IR PPG signals captured from the wrist, and the green PPG signal is used as a reference to determine the window size for the moving average filter. The green color aids in eliminating noises present in the signal. In [24], 107 features are extracted to train the different machine learning regression models, thus having a large computational complexity. The performance of the work proposed in [54] relies on the additional reference signal, increasing the model's computational complexity. HRV estimation using PPG signals is critical for assessing autonomic nervous system health but is often impeded by inaccuracies in interbeat interval detection and motion artifacts. The proposed framework enhances HRV analysis through GSMD. GSMD-based denoising refines the PPG signal, allowing accurate detection of IBIs even in real-time environments. Unlike traditional methods, which require additional reference signals, the proposed framework uses only PPG signals, reducing device complexity while achieving competitive accuracy. RR estimation from PPG signals poses challenges due to the weak respiratory components often masked by noise and motion artifacts. The proposed framework addresses these challenges by leveraging the GSMD algorithm to decompose the PPG signal and isolate low-frequency respiratory components. The GSMD's adaptive decomposition capability automatically tunes the bandwidth, ensuring optimal isolation of respiratory signals and eliminating the need for manual parameter adjustments.

The GSMD-based vital sign estimation results obtained from corrupted PPG signals show that estimated vital signs are highly correlated with the true value of vital signs in the presence of noises and motion artifacts. A post-processing stage is employed to enhance the accuracy and reliability of the proposed framework. Based on the natural variation property of the vital sign concerning the time, the post-processing stage is used to refine the value of the vital sign.

The proposed framework's evaluation is primarily based on publicly available datasets, which may not encompass all possible variations in user demographics (e.g., age, skin tone, and physiological conditions). These datasets are recorded under specific demographic conditions. The proposed framework primarily evaluates performance during moderate physical activities. Its applicability to scenarios involving vigorous exercises or outdoor environments, where motion artifacts and environmental noise are more significant, remains to be explored. Further, the proposed framework validation on diverse and larger datasets is needed to generalize the framework's applicability. Further, collaborations with medical institutions will also be pursued to validate the framework clinically on patients with cardiovascular diseases, establishing its reliability as a comprehensive tool for healthcare monitoring in diverse and challenging real-world conditions. To address the limitations of the study and further advance the study, future work will focus on evaluating the framework performance using diverse and larger realtime acquired datasets encompassing a wide range of user demographics, including variations in age, skin tone, and physiological conditions. Additionally, experiments should be conducted in realtime scenarios involving vigorous physical activities and outdoor environments to assess the framework's robustness against motion artifacts and environmental noise. Collaboration with clinical experts to validate the framework on clinical-grade data and exploring its integration with wearable devices for realtime monitoring would significantly expand its applicability and practical use.

Conclusion

This work introduces a health monitoring framework design that estimates HR, BP (SBP, DBP), RR, and SpO2. The framework presents the GSMD algorithm to clean the motion artifacts corrupted PPG signal in this work. This framework leverages a single PPG signal and a computationally efficient signal processing algorithm for continuous vital health monitoring. In the proposed work, a few highly correlated features are extracted from the PPG signals, and computationally efficient, simple linear regression-based machine learning models are employed to map these features to SBP, DBP, and SpO2 values. The results successfully demonstrated that the proposed framework can accurately estimate vital sign values compared to true measurements.

This work introduces signal pre-processing, feature extraction, and feature filtering steps to ensure that meaningful features are provided in the model. A total of 7 features were initially extracted, and then feature selection algorithms were applied to reduce the computational complexity for BP estimation. For SpO2, a single R-value is used as a feature for model training. Three models are trained for BP and SpO2 estimation, with linear and polynomial regression delivering the best performance, respectively. A post-processing stage is introduced in the proposed framework to improve the accuracy of the vital signs in realtime. When subjects engage in intense physical exercise or when the frequency of motion artifact components is closely aligned with that of the true vital sign component, the post-processing stage aids in tracking the vital sign within the current window. This improvement serves to enhance the overall performance of the proposed framework. The MAE value obtained for all the vital signs shows a better performance of the proposed framework. It surpasses the performance of those reported in existing literature, establishing them as state-of-the-art models. The proposed framework used a computationally efficient GSMD algorithm and signal processing block, which holds significant potential for developing wearable, non-invasive, realtime devices for vital sign estimation and offers a valuable contribution to healthcare technology. Thus, in the future, the proposed framework will be deployed in the computationally efficient STM 32 processing device for realtime estimation of vital signs.

***Abstract*—Memristors are a combination of the words Memory and Resistor, it never forgets. It is a passive element which remembers the amount of current that flowed through it and is small in size. All these qualities of a memristor make it highly advantageous and useful in the upcoming times for chip manufacturing and designing. Latches are sequential circuits using them in master-slave configuration a flip flop can be generated which is highly useful in applications such as counters, registers, etc. In this paper we implement a Modified version of D-latch and flip flop using memristors and Transmission gates to improve the switching speed and to obtain full voltage swing. Further we show a comparative analysis of proposed modified D-latch and flip-flop with an earlier method along with a timer counter as an application of the D-flip flop circuit. Paper also explains the challenges of using MRL gates in complex circuits. TEAM model of memristor and 180nm technology node files are used in simulation of all the circuits using Cadence Virtuoso.**

***Index Terms*—TEAM, Pass Transistor, Transmission Gate, MRL, Latch, Flip-Flop, Timer Counter.**

I. Introduction

Until 1971, the resistor, capacitor, and inductor—the three fundamental circuit elements—dominated circuit theory. The resistor establishes a relationship between voltage and current, the capacitor connects voltage to charge, and the inductor links current to magnetic flux. The link between the Flux and Charge was missing until Prof. Leon Chua [1] postulated the missing link on a basis of logical symmetry. He named this as a Memristor which is a combination of two words: Resistor and Memory.

Memristor relates charge and magnetic flux by:

$$d\phi = M(q)dq \tag{1}$$

The M value is known as the memristance of the memristor or the ability to charge the resistance based on the amount of charge that has passed through the memristor in the past. Memristors were only theoretical devices until the year 2008 when Stanley Williams implemented the first practical memristor at HP labs. It was a Pt/TiO2 based bipolar device. It was termed ReRAM (resistive switching random access memory) and was called a subset of Memristor. It is a two-terminal nonlinear resistor, a passive element which it does not stores any energy, it remembers the last amount of current passed through it or the last value of voltage applied to it.

Memristor-based logic circuits provide us with lots of benefits such as nonvolatility, faster switching rates, etc. There are many memristor-based logic designs, some of them are IMPLY, Memristor Aided Logic (MAGIC), Memristor Ratioed Logic (MRL), Modified Gate Diffusion Input (M-GDI), etc. This paper mainly focuses on the MRL Logic Circuits and briefly discusses the reasons why it is not used for implementation of D-latch and D-flip flop. Flip-flops and latches are fundamental sequential logic elements used for data storage. A D-latch (data latch) allows data to pass through only when the enable signal is active, storing it otherwise. The D flip-flop, triggered by clock edges, ensures synchronized data storage and transfer, making it vital for timing-critical applications.

II. Literature Review

There are various memristor models that are available for use. One of the most used and accurate is ThrEshold Adaptive Memristor Model (TEAM) of memristor presented in [2]. Earlier models such as linear ion drift model and non linear ion drift models had some limitations under threshold dependent applications. TEAM model takes these models forward by taking the threshold voltage applications in account. These threshold dynamics are highly useful in precise circuits and critical applications where control over the activation and transition of states is required. The paper [2] reviews the situations where the earlier models failed or did not provide acceptable results and compares TEAM model with others with an aim to demonstrate the improvements, accuracy and efficiency.

Many researchers have explored the use of memristor models in creation of logic gates and using those logic circuits for creation of latches and flip-flops, one such method of creation of D-flip flop is shown in [17], the paper presents the limitaions of using the CMOS D flip flops such as power consumption, and overall circuit size which is big due to presence of large number of transistors. Since the memristors use low power and have higher switching speed as compared to traditional

CMOS gates. The paper used another memristor model named Knowm memristor model and TSMC 180nm technology node files to implement the NOR gate and using that gate a D latch using cross coupled orientation was created and further using master slave configuration D flip flop is created. Similar methods of creation of logic gates and other circuits using those circuits have been presented in papers [3] - [12] . Other significant memristor model has been presented in [13].

A. Contributions and organization

In this paper, we implement a modified D-latch circuit, explain its functionality, and compare its performance with a previous D flip-flop design [3] using a single NMOS pass transistor. The proposed design replaces the pass transistor with a transmission gate, improving speed, power consumption, and robustness.

In Section III, we discuss the MRL-based design of basic logic circuits. In Section IV, we introduce the modified D-latch circuit. Section V presents circuit outputs, observations, and comparisons. In Section VI, we highlight a Timer Counter application using cascaded flip-flops based on the modified design. Finally, concluding remarks are provided in Section VII.

III. Circuit Designing using Memristors

Logic Gates are the most fundamental components of all the digital systems and circuits. They are used to execute many logical operations that might be required by a circuit, logic gate output is dependent on the input combinations and the logical operation that it is designed to perform. The logic gates are made by a combination of transistors, resistors, capacitors etc. Logic gates designed using transistors are CMOS logic gates. This paper presents a study of memristor based logic gates mainly MRL (Memristor Ratioed Logic) and MAGIC.

MAGIC orientation focuses on using only the memristors to create the logic gates, whereas the MRL used both memristors and CMOS Inverters and hence it is also known as the Hybrid CMOS Memristor Logic Design.

A. Design and Functioning of Basic Gates

In order to create a flip flop or a latch we need the basic logic gates mainly AND and OR gates which can be later converted to NAND and NOR using the MRL logic according to which the output of two gates is passed through a CMOS inverter to achieve the desired outputs of NAND and NOR.

In AND gate "Fig. 1", two memristors are connected in anti-serial manner and its functioning can be easily understood as follows:

Case 1: When both the the inputs A and B are equal to zero. The memristor resistance from N-P is "high" and P-N resistance is "low", so no current flows through the memristors and the output received is zero.

Case2: When both the inputs A and B are equal to one. The memristor resistance from N-P is "low" and P-N resistance is "high", so the current through both the memristors flows towards the output and a logic 1 output is received.

Case 3: When the inputs are A=0 (gnd) and B=1(Vdd), or A=1(Vdd) and B=0(gnd), the memristor with input 0 has high resistance from N-P and low resistance from P-N, and the memristor with input 1 has low resistance from N-P and high resistance from P-N. Due to this the current flows from the higher value towards the lower value and no current flows towards the output resulting a logic 0 as output.

In a similar way the functioning of OR gate can be explained and the truth tables of both the gates can be verified.

Simply adding a CMOS inverter at the output of the AND and OR gate circuits gives us the required NAND and NOR gates this method of using CMOS inverter at output is MRL logic.

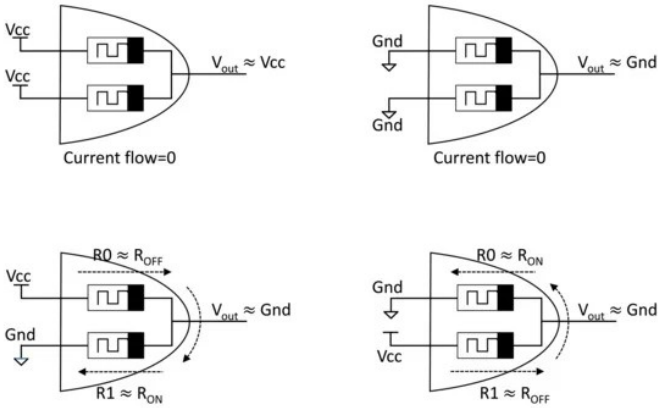

Fig. 1. MRL AND Gate Logical Operation [4]

A comparative analysis of the memristor based and conventional CMOS NAND and NOR gates on basis of power consumption and number of transistors is shown in the Table I. The power consumption is calculated using the simulation software which uses the average power consumption formula:

$$P_{av} = \frac{V_{DD}}{T} \int_0^T i_{DD}(t)\, dt \tag{2}$$

where P_{av} is the average power,
V_{DD} is the supply voltage,
$i_{DD}(t)$ is the supply current as a function of time,
T is the time period.

TABLE I
Comparison of CMOS and Memristor Based Gates

Component	Power Consumption	Transistor Count
CMOS NAND Gate	2.267 μW	4
Memristor Based NAND Gate	1.514 μW	2
CMOS NOR Gate	1.5181 μW	4
Memristor Based NOR Gate	0.846 μW	2

B. ThrEshold Adaptive Memristor (TEAM) Model

The TEAM model is a general memristor model [2]. The TEAM model is simple to use and very flexible. Its simplicity improves the efficiency of the simulation and thus the model

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 07:33:48 UTC from IEEE Xplore. Restrictions apply.

has acceptable accuracy. The model is suitable for memristive circuit designs and has been implemented in VerilogA for use in simulations [2].

In this project TEAM model of memristor is used with two additional parameters added to the model VSET and VRESET to tackle the 01 and 10 states of logic gates.

- VSET: Sets the memristor to value 1 when the output of memristor is above a certain threshold value.
- VRESET: Resets the memristor to value 0 when the output of memristor is below a certain threshold value.

C. Flip Flop and Latch using the Basic Gates

The creation of basic logic gates makes the creation of flip flops and latches easier theoretically but using the NAND and NOR gates created using MRL creates a problem. As explained in the previous section at states 01 and 10 the current flows from higher potential node to lower potential node, this creates a problem for circuits with feedback from output to input, example JK flip flop.

In such a circuit when the input logic gate is in a state where both inputs are different there will be a reverse flow of current due to which the overall output of the circuit may get disturbed, this causes a lot of reliability issues in using the basic logic gates created using memristors. Cascading several of these gates may lead to a floating output (between logic ”0” and logic ”1”) due to voltage degradation. Since memristors are passive devices, they cannot amplify signals.

This can be solved at the cost of overall power consumption and transistor count by adding buffers to the circuit. Other methods to make D-latch and D-flip flop is shown in [3]. The method presented in [3] includes the use of memristors, buffers and NMOS pass transistor to make the D-latch and flip flop. This paper takes that circuit and presents a comparative analysis of this circuit with the one which replaces the single pass transistor with the transmission gate.

D. Real Time Applications of Memristor Based Gates

Memristor although postulated in 1971 and later implemented by HP Labs in 2008 is still not used in real time applications due to issues and claims about its reliability and practical functionality. Multiple memristor models are present to theoretically explain the working of the memristors but using these models device modeling is still a big challenge. Using these models and different memristor orientations various applications are implemented using software based simulations, one such application is Half and Full Adder.

IV. Proposed Methodology

This section will show a Modified D-Latch and D-Flip Flop Circuit. In the paper [3] the authors have proposed a design of a positive level D-Latch, which consists of a single nmos pass transistor, memristors and a few inverters ”Fig. 2”. The pass transistor acts as a switch, when the clock signal is given at the gate of the transistor, controlling the switching function.

When the clock signal is high the pass transistor acts as a closed switch which allows the D signal to pass through it,

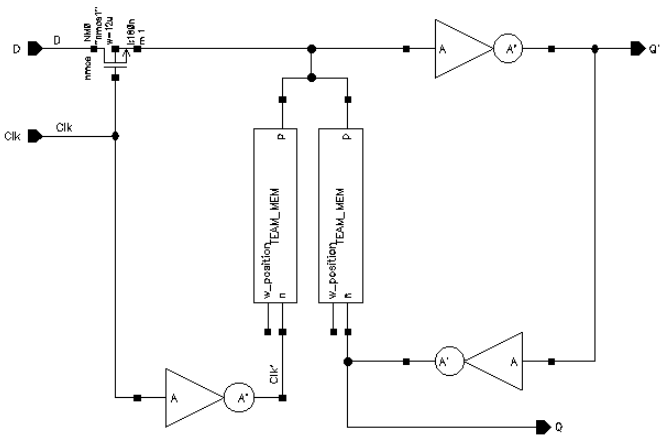

Fig. 2. D-Latch Circuit using NMOS Pass Transistor [3]

and the pass transistor acts as a open switch or it is in high impedance state when clock signal low is passed through it.

When the clock signal is high, the input D flows through the transistor to the output. When the clock signal becomes low, the current value of D is stored at the output, thus preventing changes until the clock signal goes high again. The latching mechanism is implemented using two memristors: one receives the inverted clock signal, and the other operates in a feedback loop. When the clock is high, feedback is disabled, but when it is low, the feedback activates, enabling the input to be latched securely.

This circuit does not get stuck even though it has a feedback loop as when the feedback is active both the memristors which are essentially in the AND gate configuration have same values at input because of presence of two inverters or a buffer in the feedback loop.

A. Modified Circuit Using Transmission Gate

A transmission gate is a simple yet effective switch in digital circuits, consisting of a PMOS and an NMOS transistor connected in parallel. It uses a control signal to determine its state:

When the control is active, the gate conducts, allowing signals to flow freely in either direction. When the control signal is inactive, it blocks the signal. This design minimizes voltage drops and ensures efficient signal transfer, making it ideal for applications like multiplexers, latches, and flip-flops where precise and low-resistance switching is crucial.

Disadvantage of using a single NMOS pass transistor is that it passes a ’Strong 0’ and ’Weak 1’. Whereas in transmission gates ”Fig. 3” since both nmos and pmos are present in parallel so the issue of passing a weak signals is solved.

When the input signal A is low, both nmos and pmos are cut off and circuit acts as an open switch. When A is high the transistors are biased to conduct and circuit acts as a closed switch, so we can say transmission gates are voltage controlled switches which passes either a strong 0 or a strong 1 based on the control signal value. Because of this the circuit

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 07:33:48 UTC from IEEE Xplore. Restrictions apply.

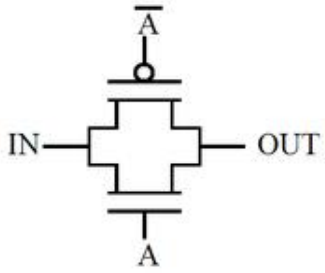

Fig. 3. Transmission Gate

is able to achieve full voltage swing, the node capacitance is reduced, lower switching energy required to charge up the node, switching rate is also improved. The modified D-latch circuit can be seen in "Fig. 4",

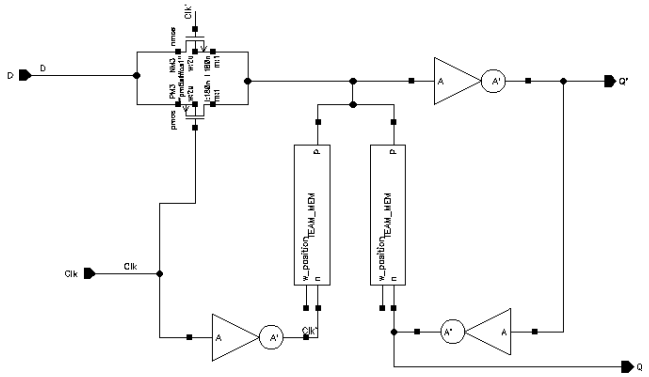

Fig. 4. Modified D-latch using Transmission Gate

a D-flip flop created using the master slave configuration connecting two D-latches is also shown in "Fig. 5" The outputs of both the circuits is shown in "Fig. 6" and "Fig. 7" respectively.

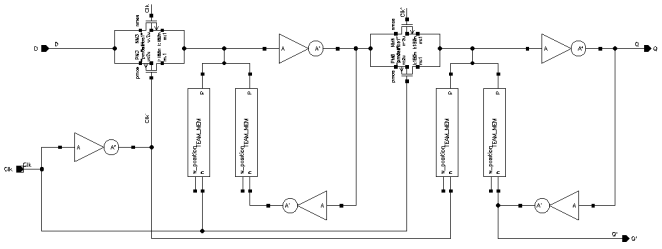

Fig. 5. Modified D-Flip Flop using Transmission Gate

V. Results and Analysis

A comparison on the basis of number of transistors, memristors, power consumption, and circuit delay is presented in Table II. The outputs of circuits "Fig. 4", "Fig. 5" are shown in "Fig. 6" and "Fig. 7" respectively. Both the outputs of latch and flip flop can be verified, it can be observed that the outputs have good switching and full voltage swing.

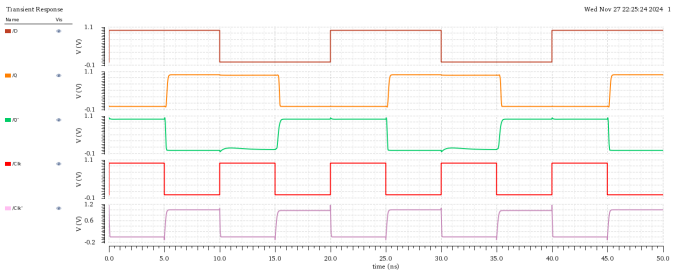

Fig. 6. Modified D-latch Output

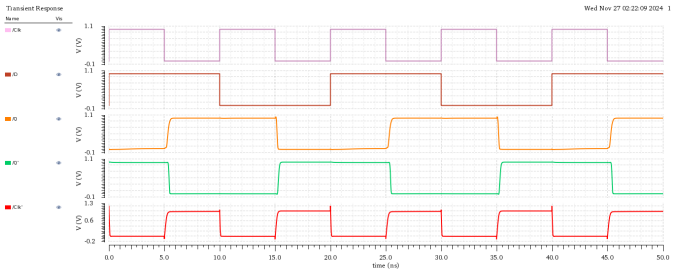

Fig. 7. Modified D-Flip Flop Output

TABLE II
Comparison of Implemented Circuits

Comparison Parameters	**Circuits**			
	D-Latch using Pass Transistor	***D-Latch Using Trans-mission Gates***	***D-Flip Flop using Pass Transistor***	***D-Flip Flop using Trans-mission Gates***
No. of Transistors	7	8	14	16
No. of Memristors	2	2	4	4
Avg. Power (Watt)	5.04μ	5.42μ	7.54μ	8.05μ
D to Q Delay (Seconds)	10.185μ	5.324μ	5.287μ	5.16μ

Delay and Power consumption was calculated using the virtuoso software calculator tool. The comparison table shows the slight increase in power consumption of the circuit which is mainly due to increased transistor, and significantly low delay in D-Latch due to use of transmission gates.

VI. Application

A timer counter "Fig. 8" using the modified D-flip flop circuit presented in "Fig. 5" is made using the symbol of flip flop, the output of the circuit "Fig. 9" is ideal and verifies that the latch and flip flop circuit works correctly.

The output shows slight degradation of the outputs which is due to cascading of 4 memristor based D-flip flops and as discussed earlier memristors are non- amplifying circuits cascading them leads to output degradation.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 07:33:48 UTC from IEEE Xplore. Restrictions apply.

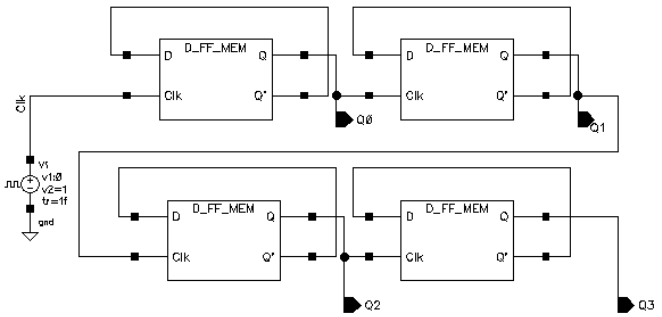

Fig. 8. Timer Counter using Modified D-flip flop symbol

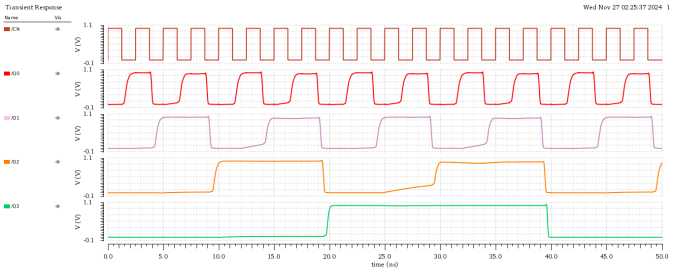

Fig. 9. Timer Counter Output

VII. Conclusion

Based on the comparison it is observed that the circuit using the transmission gate has slightly higher power consumption due to increased transistor count. The delay is lesser due to better switching capability of transmission gate. A trade-off between power and performance is observed. The power usage is slightly increased while other important parameters take benefit of the transmission gates. Using the Modified D-Flip Flop a timer counter as an application is also shown which verifies the functioning of the modified circuit with good results.

Abstract:

$CaBi_2Nb_2O_9$ (CBNO) phosphors doped with Ho^{3+} and Yb^{3+} ions were synthesized through a conventional solid-state reaction technique. The microstructure of the prepared samples was characterized using scanning electron microscopy (SEM). The energy bandgap was determined using diffuse reflectance spectroscopy (DRS). Down- and Up- converted photoluminescence analyses were conducted to examine the excitation and emission behaviours of the as prepared phosphors, along with the decay lifetimes measurement under 980 nm excitation. Up-conversion (UC) emission spectra revealed emission bands at 545 nm, and 658 nm, which correspond to the $^5F_4/^5S_2$ to $^5I_8$, and $^5F_5$ to $^5I_8$, transitions of Ho^{3+} ions, respectively. Analysis of UC emission intensity variation with pump power of 980 nm laser source confirmed the involvement of a two-photon absorption mechanism. The chromaticity coordinates derived from the emission spectra positioned the light emission in the green region. Studies of temperature-dependent photoluminescence (TD-PL) highlighted the phosphor's high thermal stability, supported by its notable thermal activation energy. This study shows encouraging results thereby demonstrating the potential of CBNO phosphors for applications in solid-state

Introduction:

Due to their special optical characteristics generated from 4f–4f electronic transitions, oxide materials doped with rare earth (RE) ions have garnered interest for their use in photonic devices [1–3]. These materials are vital to many industries, such as commercial products, everyday applications, and cutting-edge technologies. White light-emitting diodes (w-LEDs), lasers, display technology and solar cells are some of the key areas where RE doped materials find immense uses.. InGaN blue LEDs with yellow phosphor (YAG: Ce^{3+}) are a popular choice for producing white light because of their high efficiency, small size, light weight, improved durability, and long operating lives [3–6]. However, because of inadequate red light output, this method has problems including a low colour rendering index (CRI) and a high correlated colour temperature (CCT). Utilising trichromatic phosphors in conjunction with ultraviolet (UV) chips is an alternate method of enhancing CRI. Researchers are encouraged to further optimise phosphor characteristics due to the growing demand for sophisticated illuminating materials. Low light efficiency and unstable correlated colour temperature (CCT), two intrinsic problems of the commonly used commercial red phosphor (Y_2O_2S: Eu^{3+}) , are caused by colour reabsorption and degradation [7–9]. Oxide materials have become extremely flexible for a variety of applications due to their strong chemical stability and moderate synthesis capabilities. Single-phase white light-emitting phosphors, which are effectively activated by near-UV LED chips, have emerged as the go-to remedy for overcoming these difficulties [10,11]. Over the past few decades, scholars have given this technique a lot of attention. Due to its remarkable precision, high sensitivity, and quick response, optical thermometry has been increasingly popular recently.

Accepted Manuscript

Various host materials, such as phosphates, silicates, zincates, vanadates, niobates, and tungstates, can be doped with rare earth (RE) ions. Among these, niobates stand out as dependable host materials due to their outstanding chemical and thermal stability and their eco-friendly characteristics [12–14]. Niobium oxides, specifically, possess a low phonon frequency, which effectively reduces non-radiative transitions and enhances the fluorescence intensity of phosphors. Aurivillius-type bismuth-layered structure ferroelectrics (BLSFs) have attracted interest due to their general formula $(Bi_2O_2)^{2+}$ $(A_{m-1}B_mO_{3m+1})^{2-}$,, and their relatively high Curie temperature (T_c), which contributes to their superior thermal stability [12,15]. CBNO, a member of this family with m=2, incorporates Ca^{2+} at the A site and Nb^{5+} at the B site within its pseudo-perovskite $(CaNb_2O_7)^{2-}$ blocks. Its structure alternates between $(Bi_2O_2)^{2+}$ layers and $(CaNb_2O_7)^{2-}$ units, which contain double NbO_6 octahedral layers [16] . CBNO exhibits low phonon energy, which helps minimize non-radiative relaxation processes. This feature significantly boosts photoluminescence efficiency by reducing multi-phonon relaxation. CBNO also exhibits relatively thermal stability, due to its high Curie temperature and chemically robust layered structure. Unlike sulfide-based phosphors, which tend to deteriorate under high temperatures and humid conditions, CBNO maintains its luminescent performance even in demanding environments. CBNO provides a stable environment for controlled doping and enhanced energy transfer between sensitizer (Yb^{3+}) and activator (Ho^{3+}) ions. This improvement in up-conversion emission efficiency makes CBNO a promising candidate for applications in anti-counterfeiting, security printing, and biomedical imaging. Although the perovskite blocks can accommodate various cations, modifying the bismuth oxide layers remains challenging. To date, there has been no research on CBNO doped with Ho^{3+}/Yb^{3+} ions for fabricating white LEDs.

Doping is a fundamental technique in materials science, involving the incorporation of specific atoms into a host material to develop hybrid materials with customized properties. RE ions are highly regarded for their ability to emit a wide range of colors from the UV to IR regions. Their remarkable green emission, long-lived excited states, and numerous ladder-like energy levels give them this ability, making them ideal for use in lighting and display technologies [17,18]. Despite these advantages, up-conversion (UC) phosphors doped solely with Ho^{3+} have low excitation efficiency and weak emission under near-infrared (NIR) stimulation, primarily due to limited absorption. Yb^{3+} ions, with their strong absorption cross-section near 980 nm, are effective at transferring excitation energy to Ho^{3+} ions, making them excellent sensitizers [19–22]. By co-doping Ho^{3+} with Yb^{3+} the emission efficiency of Ho^{3+} can be significantly

Accepted Manuscript

improved. The distance between donor ions (Yb^{3+}) and acceptor ions (Ho^{3+}) often changes with different doping concentrations, affecting energy transfer efficiency [23]. Therefore, optimizing the Ho^{3+}/Yb^{3+} doping ratio is essential to enhance energy transfer and overall performance.

In this study, we synthesized a series of new CBNO: xHo^{3+}/yYb^{3+} phosphors using a solid-state reaction method at high temperatures. Systematic analysis is done to check the influence of test temperatures, Ho^{3+}/Yb^{3+} concentrations, and laser pump powers on UC luminescence. We have given a thorough demonstration of the transfer of energy mechanism of the Ho^{3+}/Yb^{3+} co-doped system. The suitability of the synthesised phosphor for uses in solid-state lighting and optical thermometry was finally evaluated.

2. Synthesis and instrumentations:

In this work, a high-temperature solid-state reaction method was utilized to synthesize a series of CBNO: xHo^{3+} (x = 1.0, 2.0, 3.0, 4.0, and 5.0 mol%) and CBNO: xHo^{3+}/yYb^{3+} (x = 3.0 mol%, y = 1.0, 2.0, 3.0, 4.0, and 5.0 mol%) doped phosphors. The raw materials used, $CaCO_3$ (Thermo Fisher 98%), Bi_2CO_3 (Loba Chemie 99%), Nb_2O_5 (Loba Chemie 99.9%), Ho_2O_3 (Central Drug House 99.9%), and Yb_2O_3 (Loba Chemie 99%), were weighed according to the stoichiometric ratios. The materials were transferred in an agate mortar, ground for 1 hour to achieve a uniform powder, and then transferred into an alumina crucible. The mixture was heated to 1250°C using a programmable furnace and allowed to cool to ambient temperature. After cooling, the samples were again ground to get the final powder form required for experimental characterisations. The complete synthesis process is shown in Fig. 1.

XRD data was recorded using a Bruker D8 setup using Cu (K_α=1.54 Å) wavelength. Morphological, elemental, and energy dispersive X-ray (EDX) analyses were conducted using a JEOL 7610F Plus microscope. A Jasco V-770 UV-Vis spectrophotometer was used to acquire the materials' diffuse reflectance spectra at room temperature. Jasco FP-8300 Spectrofluorometer, fitted with a Xenon lamp, was used to record the excitation and emission spectra. The up-conversion (UC) emission spectra were recorded using a 980 nm continuous-wave (CW) diode laser coupled with a fast CCD spectrometer (ULS2048x64, Avantes, USA). For temperature-dependent UC emission studies, the spectra were captured with a CCD spectrometer. The UC decay times were determined using the Horiba PTI Fluorescence Master System in conjunction with FelixGX software.

Accepted Manuscript

3. Result and discussion

3.1 XRD and FE-SEM:

The phase formation of the as-prepared phosphor was initially examined utilizing XRD analysis. The XRD patterns of the undoped CBNO phosphor align with the standard reference data for CBNO (card no. 49-0608) reported in our previous published work [24]. The XRD patterns of the undoped, singly Ho, and codoped Ho/Yb CBNO phosphors are shown in Fig.2. The absence of additional phases confirms that the samples are of single-phase. CBNO is characterized by an orthorhombic crystal structure belonging to the A21am space group, with lattice parameters a = 5.4827 Å, b = 5.4415 Å, c = 24.8974 Å, and $\alpha = \beta = \gamma = 90°$.

The morphology and particle size of the synthesized phosphors were examined using FE-SEM technique. Fig. 3(a, c) presents SEM images of undoped, single Ho, and Ho^{3+}/Yb^{3+} doped CBNO phosphors revealing their irregular shape. Agglomeration of particles is observed, likely due to the high-temperature synthesis and grinding processes. The particle size of the prepared samples falls within the range of 3-8 μm, aligning with the typical size of 2–10 μm for commercial phosphors, making them suitable for pc w-LED applications. Fig.3(d-f) represents the EDX images of undoped, single Ho, and Ho^{3+}/Yb^{3+} doped CBNO phosphors. The EDX images shows the presence of all the precursors used in the host lattice.

3.2 DRS and band gap calculations:

The DRS spectra of Ho^{3+} and Ho^{3+}/Yb^{3+} ion-doped CBNO phosphors, illustrated in Fig. 4, span the wavelength range of 200–1000 nm. Two distinct bands are seen in the visible region at 543 nm and 649 nm, corresponding to electronic transitions from the $^5I_8$ ground state of Ho^{3+} ions to the $F_4/^5S_2$ and $^5F_5$ excited states, respectively [25]. The absorption band was observed in NIR region owing to Yb^{3+} ions at wavelength 978 nm corresponding to transition $^2F_{5/2} \rightarrow {}^2F_{7/2}$. Given the strong absorption cross-section of Yb^{3+} in the NIR region, a 980 nm laser was employed to record the up-conversion photoluminescence (PL) spectra and associated lifetime curves. The optical band gap for both phosphor series was calculated using the Kubelka-Munk method [26,27].

$$F(R)h\nu = C(h\nu - E_g)^n \qquad (1)$$

Here Planck's constant (h), the incident light frequency (v), a proportionality constant (C), and the optical band gap (E_g) are key parameters in this analysis. The value of n, which determines the nature of the electronic transition, depends on whether it is direct or indirect, as well as

Accepted Manuscript

allowed or forbidden. In this study, the direct band gap was calculated using n=1/2. Fig. 5 depicts the $(\alpha h\nu)^2$ versus hν plots for both singly Ho^{3+} doped and Ho^{3+}/Yb^{3+} doped phosphors. The calculated optical band gap was 4.71 eV for the Ho^{3+}-doped sample and 4.79 for the Ho^{3+}/Yb^{3+} doped, based on the extrapolated slope of the Tauc plot. These values are consistent with previously reported findings. A smaller band gap increases the number of ions reaching the excited state, thereby boosting photoluminescence (PL) intensity.

3.3 PL characteristics:

Fig. 6(a) depicts the photoluminescence (PL) excitation spectra for CBNO: xHo^{3+} phosphors (x= 1.0, 2.0, 3.0, 4.0 & 5.0 mol%) measured at the green emission wavelength of 545 nm. The spectra reveal several bands corresponding to transitions from the, ground state to various excited states, including , $^3H_5$ (362 nm), $^5G_4$ (388 nm), $^5G_5$ (419 nm), $^5G_6$ (456 nm), $^3K_8$ (477 nm), and $^5F_2$ (487 nm) [28,29]. These transitions are consistent with data previously reported by Carnall et al. Among them, the $^5I_8 \rightarrow {}^5G_6$ transition at 456 nm exhibits the highest intensity, making it the preferred wavelength for analyzing the visible photoluminescence spectra of Ho^{3+}-doped CBNO phosphors at varying concentrations.

Fig. 6(b) depicts the PL emission spectra of these phosphors under 456 nm excitation. A prominent emission band is observed at 545 nm, ascribed to the $^5F_4/{}^5S_2 \rightarrow {}^5I_8$ transition of Ho^{3+} ions [30–32]. Additionally, a weaker band is present at 658 nm, attributed to the $^5F_5 \rightarrow {}^5I_8$ transition. The 545 nm emission band is significantly more intense compared to the 658 nm band in the presented spectra.

The emission spectra of CBNO : xHo^{3+}/yYb^{3+} phosphors (x=3.0 mol%, & y = 1.0, 2.0, 3.0, 4.0 & 5.0 mol%) recorded at 456 nm excitation, are depicted in Fig. 7. When exposed to blue light, the co-doped CBNO phosphors exhibit visible emissions. Three prominent peaks are observed at wavelengths of 485 nm, 545 nm, and 658 nm, which correspond to the transitions $^5F_3 \rightarrow {}^5I_8$, $^5F_4/{}^5S_2 \rightarrow {}^5I_8$, and $^5F_5 \rightarrow {}^5I_8$ respectively [33,34]. As shown in Fig. 7, the emission intensity increases with higher concentrations of Yb^{3+}, which is attributed to energy transfer from Yb^{3+} to Ho^{3+} ions and cross-relaxation between them [25]. Additionally, up-conversion (UC) properties of Ho^{3+}/Yb^{3+} co-doped CBNO phosphors were investigated, given that Ho^{3+} ions alone show minimal emission under 980 nm excitation.

Accepted Manuscript

Fig. 8 represents the up-conversion (UC) spectra of the synthesized CBNO: Ho^{3+}/Yb^{3+} phosphors under 980 nm laser excitation, spanning the 475–750 nm range. The spectra show two distinct emission bands in the green, and red regions at 545 nm, and 658 nm, respectively. These bands correspond to transitions of Ho^{3+}ions from the $^5F_4/^5S_2$, and $^5F_5$ excited states to the $^5I_8$ ground state [34,35]. The intensity of the UC emission increases with rising Yb^{3+} ion concentration. Since Ho^{3+} ions have a low absorption cross-section at 980 nm, Yb^{3+} ions act as sensitizers, transferring energy to Ho^{3+} ions, which then act as activators. The spectra indicate a steady increase in UC emission as the Yb^{3+} concentration rises to 5.0 mol%, attributed to the effective energy transfer from Yb^{3+} to Ho^{3+} ions, enhancing luminescent efficiency and leading to stronger red and green emissions. Power-dependent photoluminescence studies were also carried out to further confirm the up-conversion process.

3.4 Pump power dependence analysis:

A CBNO sample co-doped with 3.0 mol% Ho^{3+} and 5.0 mol% Yb^{3+} was subjected to a 980 nm laser with adjustable power to explore energy transfer mechanisms between Ho^{3+} and Yb^{3+} ions. Figure 9(a) illustrates the variations in green and red emission intensities as a function of pump power. The up-conversion (UC) spectra reveal that the green emission is more prominent than the red emission. At lower pump powers, the UC intensity increases significantly but begins to level off at higher powers, likely due to heat generation within the material. The relationship between emission intensity and pump power generally follows a power-law trend [36,37]:

$$I_{up} = (P_{in})^n \qquad (2)$$

The parameters I_{up}, P_{in}, and n correspond to the intensity of up-conversion (UC) luminescence, the power of the pump laser, and the number of photons involved in the process, respectively. Figure 9(b) illustrates a log relationship between pump power and emission intensity for the sample. The slopes (n) determined for the 545 nm and 658 nm emissions were 1.53 and 1.97, respectively. These values are consistent with the expected value of approximately 2, characteristic of two-photon processes. This indicates that the green and red emissions in the phosphor result from two-photon excitation mechanisms.

3.5 Energy transfer mechanism:

Accepted Manuscript

The energy transfer mechanism is depicted in the energy level diagram for Ho^{3+} and Yb^{3+} ions in Fig. 10. Yb^{3+} ions transition from the $^2F_{7/2}$ ground state to the $^2F_{5/2}$ excited state when excited by a 980 nm laser. In this process, Yb^{3+} ions act as sensitizers, transferring energy to Ho^{3+} ions via phonon-assisted mechanisms, which excite the Ho^{3+} ions to the $^5I_6$ state. Once in the $^5I_6$ state, some Ho^{3+} ions are further excited to higher energy states, such as $^5F_4$ and $^5F_5$, through either excited-state absorption (ESA) or energy transfer (ET) from Yb^{3+} ions [19,38]. These ions in higher states relax non-radiatively to lower energy levels. From there, radiative transitions occur from the $^5S_2/^5F_4$, and $^5F_5$ states to the $^5I_8$ state, leading to green, and red emissions, respectively [20]. These emissions can involve two -photon processes. The two photon emission arises from the accumulation of energy in the $^5S_2/^5F_4$, and $^5F_5$ levels through sequential ESA, and ET, processes, as shown in Fig. 10.

3.6 Colorimetric coordinates:

Figure 11(a) and (b) display the colorimetric properties of the as-prepared phosphors, derived from DC and UC photoluminescence emission data respectively. The CIE coordinates for both Ho^{3+}-doped and Ho^{3+}/Yb^{3+} co-doped samples under 456 nm and 980 nm excitations are summarized in Table 1. As depicted in the figures, all the CIE coordinates fall within the green region. The correlated color temperature (CCT) values were calculated using McCamy's formula [39]

$$CCT = -449n^3 + 3525\,n^2 - 6823.2\,n + 5520.3 \quad (3)$$

The parameter n is calculated using the formula n = (y−0.1858)/(x−0.3320), where x and y represent the calculated CIE coordinates. The corresponding CCT values are provided in Table 1. These findings indicate that the CIE coordinates and CCT values confirm the potential of the synthesized phosphors for solid-state lighting applications.

Color purity is a critical parameter for w-LED applications. For the synthesized phosphor samples, the color purity was estimated from the equation given below [24,40]:

$$\text{Color purity} = \frac{\sqrt{(x-x_{ee})^2+(y-y_{ee})^2}}{\sqrt{(x_d-x_{ee})^2+(y_d-y_{ee})^2}} \quad (4)$$

Accepted Manuscript

In this formula, (x,y) denotes the CIE chromaticity coordinates of the samples, the CIE coordinates for traditional white light are represented by (x_{ee},y_{ee}), while the CIE coordinates of the dominant wavelength are shown by (x_d,y_d). For the calculations, (x_{ee},y_{ee}) was set to (0.33, 0.33). The calculated color purity values for the optimized sample CBNO: xHo^{3+}/yYb^{3+} (x =3.0 mol%, y = 5.0 mol%) phosphor is 97.2%. Such high levels of color purity highlight the strong potential of these sample for use in w-LEDs. Therefore, CBNO: Ho^{3+}/Yb^{3+} stands out as a viable candidate for applications in lighting and multicolor display systems.

3.7 PL Decay curves:

The up-conversion (UC) decay experiments were performed to study the UC mechanism and the energy transfer mechanisms between Ho^{3+} & Yb^{3+}. Fig. 12 displays the corresponding decay curves that were captured at 545 nm under pulsed 980 nm laser stimulation. The double-exponential function was used to fit the curves [2,41]:

$$I = I_0 + A_1 * \exp\left(-\frac{t}{\tau_1}\right) + A_2 * \exp(-\frac{t}{\tau_2}) \qquad (5)$$

Here, t stands for time, τ_1 & τ_2 are the corresponding decay durations, and A_1 and A_2 are constants. The up-conversion emission intensities at time t and the beginning time (t = 0) are denoted by I and I_0, respectively. The following formula was used to determine the average decay lifetimes for each sample [42,43]:

$$\tau_{exp} = \frac{A_1\tau_1^2 + A_2\tau_2^2}{A_1\tau_1 + A_2\tau_2} \qquad (6)$$

The Table 1 shows the average decay durations at 545 nm emission for the CBNO: 3.0 mol% Ho^{3+}/yYb^{3+} phosphors generated by a 980 nm laser with y = 1.0, 2.0, 3.0, 4.0, and 5.0 mol%). Higher Yb^{3+} concentrations result in lower decay lifetimes for 545 nm emission wavelength, suggesting that energy transfer from Yb^{3+} to Ho^{3+} becomes more effective with increasing Yb^{3+} concentrations. The up-conversion process may contain additional energy transfer mechanisms or migration paths, which could account for the single-exponential function's incomplete fit to the decay curves. Fig. 12 shows the trend of decay lifespan values with different Yb^{3+} concentrations.

3.8 Temperature Dependent PL(TD-PL):

The thermal stability of phosphors is a critical aspect of their performance. Fig. 13(a) presents the temperature-dependent photoluminescence (TD-PL) spectra of CBNO: xHo^{3+}/yYb^{3+} (x

Accepted Manuscript

=3.0 mol%, y = 5.0 mol%) phosphor, recorded under 980 nm laser source over the temperature range of 300 to 410 K. The spectra demonstrate a gradual decrease in PL intensity as the temperature increases, without any observable shift in the emission peaks. This reduction in PL intensity is attributed to non-radiative transitions caused by thermal quenching. As the temperature increases, the lattice undergoes slight expansion and structural disorder, which alters the local crystal field surrounding the luminescent centers, thereby diminishing emission intensity [44,45]. The activation energy (ΔE) is determined using the Arrhenius equation, expressed as follows [46,47]:

$$I_T = \frac{I_0}{1 + C\exp\left(-\frac{\Delta E}{K_B T}\right)} \quad (7)$$

Here, I_0 and I_T represent the emission intensities at 300 K and temperature T (in Kelvin), respectively, C is a constant, and k_B denotes the Boltzmann constant (8.629×10^{-5}eV/K).The plot of $\ln(I_T/I_0-1)$ against $1/k_BT$ is shown in Fig. 13(b). The activation energy, calculated from the slope of this graph, is determined to be 0.293 eV. This value is higher than those reported in the literature, indicating superior thermal stability of the phosphor [25,48,49]. These results, derived from the TD-PL spectra of CBNO: x Ho^{3+}/y Yb^{3+} (x =3.0 mol%, y = 5.0 mol%) doped phosphor, confirm its excellent thermal stability.

4. Conclusion:

A series of CBNO phosphors doped with Ho^{3+} ions and co-doped with Ho^{3+}/Yb^{3+} ions were synthesized using a solid-state reaction technique. Morphological studies indicated that the phosphor particles are in the micrometer size range, and elemental mapping confirmed the even distribution of all the constituent elements across the phosphor surface. Both up-conversion (UC) and down-conversion (DC) photoluminescence (PL) studies demonstrated intense green light emission at 545 nm, with UC emission excited by a 980 nm laser and DC emission excited by a 456 nm xenon lamp. The relationship between pump power and UC intensity provided details about the photon interaction mechanisms in the UC process. Decay measurements under 980 nm excitation revealed a steady decrease in lifetime at 545 nm. Chromaticity coordinates analysis placed the phosphor emissions in the green region. These results highlight the material's potential for various applications, including green light-emitting diodes (LEDs), display systems, security printing, phototherapy, and solid-state lighting technologies.

Abstract- The rise of portable devices in our everyday lives has made power optimization a critical focus in contemporary VLSI technology. In recent years, static random-access memory (SRAM) has gained popularity due to its superior performance in VLSI design processes that operate at the submicron or nanoscale. Numerous SRAM cells have been developed to work effectively at lower voltages and with minimized latency. This paper introduces a newly proposed 8T SRAM cell design that offers enhanced read stability when compared to 6T SRAM cells. To tackle the issue of power leakage, two PMOS transistors are incorporated into both the read and write circuits. The proposed 8T SRAM cell demonstrates a marked reduction in leakage current relative to 6T SRAM cells. SRAM serves as the primary memory for small cache-less embedded processors, leading to the development of memories that utilize an SRAM cell optimized for various process parameters, such as energy, stability, and power limitations.

Keywords: low-power SRAM, stability, energy efficiency, power consumption, and static random-access memory (SRAM).

I. INTRODUCTION

The radix-2 system is prevalent in digital logic systems, employing binary representation that utilizes two symbols to denote logic levels. Systems are categorized as multi-valued logic systems when the radix exceeds 2, [1], [2], [3], [4], [5]. For instance, ternary logic employs three symbols, or logic states: zero, one, and two. In the context of the ternary system, $log_3^{(2n)}$ bits are necessary to represent a binary integer comprising n bits. In VLSI circuits, addressing pin-out challenges becomes particularly difficult when managing multi-valued logic. The static random-access memory (SRAM) cell operates as a latch, using back-to-back connected inverters for data storage. It includes a bit line (BL) and a select line, where the BL of the SRAM cell retains either read or write data when the select line is activated [6]. Introducing ternary inverters in place of the inverters within a binary SRAM cell allows for the design of a ternary static random-access memory (TSRAM) cell [7], [8], [9], [10], [11]. The SRAM cell designed for ternary logic aims to facilitate the creation of larger memory arrays by utilizing ternary logic circuits [12]. A traditional ternary inverter is used in a conventional ternary SRAM cell. The under-consideration design is poor in the storage of value and gives a considerable voltage drop that negatively influences the read/write processes within SRAM cells. To overcome this issue, it is crucial to create a ternary inverter cell capable of consistently providing the correct output voltage for each of the three states found in ternary logic [13], [14]. In modern scenarios, the emergence of Carbon Nanotube Field-Effect Transistors (CNTFETs) has introduced complications concerning complexity and stability in SRAM design. To overcome these problems, a new technology named Enhanced Gate Diffusion Input-based Ballistic Wrap Gate CNTFET (EGDI-BWGCNTFET) has been proposed. This method is utilized alongside ternary static random-access memory (T-SRAM) to improve stability, lower standby power usage, decrease voltage drop and effectively store read/write values within SRAM cells [15].

II. LITERATURE SURVEY

The literature survey has one of the main focuses on the literature review. It also provides details about current area techniques. The survey is divided into the following sections.

A. Definition of the Research Questions

In this step, we formulate the research questions (RQs) that will guide our work. We have formulated four Research Questions.

RQ1: What are various designs for stability analysis of low-power SRAM cells?
RQ2: What are the different low-power SRAM architectures?
RQ3: What are various designs for energy- and power-efficient SRAM cells?
RQ4: What are the various parameters for SRAM cell analysis?

B. Conduct Search

The objective of searching is to find the journal or conference paper that investigated the low-power SRAM cells. The search is normally based on some keywords. By choosing the suitable keywords, we can select a keyword. The keywords used to search for research articles are listed below: SRAM, stability analysis, static noise margin (SNM), low power low swing, leakage power, Energy efficiency, and Power consumption.

C. Screening of Papers

To ensure that all the papers considered for review were directly relevant to the research questions, Specific inclusion

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 06:43:07 UTC from IEEE Xplore. Restrictions apply.

and exclusion criteria were set. Table 1 describes the inclusion and exclusion criteria used in this study.

TABLE. I. INCLUSION AND EXCLUSION CRITERIA

Criteria for Inclusion	Criteria for Exclusion
Studies that focus on improved stability of SRAM cells	Studies not in English
Studies focusing on various approaches for energy-efficient, leakage power, and stability analysis	Studies not related to any of the research questions.
Studies that conduct high-performance SRAM cell analysis of their research	Studies whose findings are unclear and ambiguous

D. Summary of Research Review

Based on the literature review, a summary of all research articles is given below in Table 2. It includes the name of the technique, technology, summary, and observation.

TABLE. II. SUMMARY OF RESEARCH REVIEW

Title and Authors	Publisher and Years	Technology	Summary and observation
8T-SRAM Cell with Improved Read and Write Margins in 65 nm CMOS Technology F. Moradi et al. [16].	IFIP International Federation for Information Processing, 2015	65 nm CMOS TSMC technology	The study suggests that an 8T-SRAM cell improves gate leakage power consumption and write margin compared to a 6T-SRAM cell, but increases subthreshold leakage, highlighting the need for further research.
A Review of Circuit-Level Leakage Minimization Techniques in CMOS VLSI Circuits R. Lorenzo & S. Chaudhury [17].	IETE Technical Review, 2016	NA	This study focuses on leakage power dissipation, a significant issue in high-performance chips and VLSI circuits. It categorizes various techniques and evaluates their reliability under process, voltage, and temperature changes. The analysis and experimental findings guide selecting the most effective method for reducing leakage power. Limitations include potential increased circuit delay, data retention issues, and the need for additional transistors.
Cell Stability Analysis of Conventional 6T Dynamic 8T SRAM Cells in 45NM Technology K. Dhanumjaya et al. [18].	International Journal of VLSI Design & Communication Systems (VLSICS), April 2012	45 nm Technology	This study compares a dynamic column-based power supply 8T SRAM cell to a regular 6T SRAM. N-curve measurements were utilized to determine read stability and write capabilities. According to simulation results, the suggested 8T SRAM cell provides greater read stability, higher read current, and lower leakage current in 45 nm technology than the typical 6T SRAM.
Pre-Charged Local Bit-Line Sharing SRAM Architecture for Near-Threshold Operation T. W. Oh, H. Jeong, J. Park, and S. Jung [19].	IEEE Transactions on Circuits and Systems, October 2017, 2017	22-nm FinFET technology	This paper describes a static random-access memory (SRAM) with pre-charged local bit-line sharing (PCLBS) that functions near the threshold. Prior SRAMs, such as average-8T and full-swing local bit-line (FSLB), used a low-capacitance local bit-line pair to improve read stability. However, the average-8T SRAM has considerable delays because of incomplete local bit-line development.
A low-power SRAM with charge cycling-based read and write assist scheme H. Zhang et al. [20].	2020, IEEE	14nm FinFET	This work describes a bit-line charge cycling-based read-and-write assist circuit for static random-access memory that leverages energy that would otherwise be wasted on bit lines to precharge them in the following cycle. The NBL Circuit is used as a writing help to reduce latency and increase writing skills.
Low power self-controllable voltage level and low swing logic-based 11T SRAM cell for high-speed CMOS circuits K. Gavaskar, U. S. Ragupathy [21].	Analog Integrated Circuits and Signal Processing (2019)	30 nm CMOS technology.	The article discusses the development of a low-power 11T SRAM cell using two voltage sources connected to the bit line and bit bar line. This method effectively removes swing voltage at output nodes, reducing dynamic power loss in SRAM cells. The self-controllable voltage level technique uses a PMOS transistor as a switch and NMOS transistors as series resistors, reducing leakage current and static power dissipation. However, the use of additional transistors may increase the overall area.
A Novel Low Power and Swing Restoration SRAM Logic Circuit Technique, R. M. Rawat [22].	International Journal of Engineering Research & Technology (IJERT), 2018	180 nm Technology	The study aims to enhance read and write operations for 8T SRAM cells, which outperform 6T cells using Swing Restoration Dual Node Voltage, reducing read and write time and improving stability, while utilizing PMOS transistors with narrower widths.

E. Research Gaps

1. During the Read and Write operation in the 6T SRAM cell, poor read stability and write ability are provided due to voltage drops occurring at the node voltages [19], [20], [21], [22].

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 06:43:07 UTC from IEEE Xplore. Restrictions apply.

2. The standard 6T SRAM cell has poor write performance owing to disturbances in the node voltage at the downscaled cell supply voltage [17].
3. The severe (read disturb) problems that SRAM memory has been facing are high leakage power consumption and instability due to continuous downscaling of the process technology [17].
4. The memory array is responsible for the consumption of a major amount of power of the total power consumed by the chip [20].

F. Research Objectives

The following are the expected objectives:

1. To design SRAM cells for low power and high speed.
2. To develop an improved stability of low-power SRAM cells.
3. To develop a low-leakage SRAM cell.

III. PROPOSED METHODOLOGY

Designing an 8T (8-transistor) static random-access memory (SRAM) cell involves creating a stable memory element using transistors. The 8T SRAM cell is a common design choice for on-chip memory due to its low leakage and good read and write characteristics.

A. Problem statement

In the existing work, the power consumption of the 6T SRAM and 5T CNTFET SRAM cells for all write and read operations is very high [23], [24], [25], [26], [27], 28].

B. Rationale for Undertaking This Research Work

To overcome these challenges, it is essential to present solutions that can successfully overcome the issues at hand.

The current SRAM architecture based on the 5T design exhibits significant drawbacks, including elevated leakage power, inefficient power utilization, and a lack of precise stability [23], [24], [25], [26], [27], 28]. These shortcomings serve as the driving force behind our research endeavors.

C. Our Research Contribution

The primary contributions of this research endeavor are the following: In this research work, an 8T SRAM design utilizing electrostatic doped-gate all-around CNTFETs is proposed for enhancing read/write assist performances with stability. The 8T SRAM Cell design uses an Electrostatic Doped-Gate All Around CNTFET (EDGA-CNTFET) to properly retain data in read/write signals.

In the pull-down network, two electrostatic doped-gate all-around CNTFETs (N5 and N6) are interconnected in a Darlington configuration. The memory cell that has been proposed is made up of EDGA CNTFETs (N1, N2, P1, P2, N5, and N6). Additionally, access transistors N3 and N4, which are also EDGA CNTFETs, are controlled by word lines. This arrangement establishes the storage nodes Q and QB. Routes for writing and reading are provided by the bit lines BL and BLB. The incorporation of Darlington electrostatically doped gate-all-around CNTFET in the SRAM cell's pull-down network enhances the memory cell's power consumption performance during both write and read operations [29]. Subsequently, the proposed 8T SRAM cell design, utilizing electrostatically doped gate-all-around CNTFET (EDGA-CNTFET), is simulated with the HSPICE simulation tool. The performance of the EDGA-CNTFET based on the 8T SRAM cell design is assessed in terms of read SNM, write SNM, read delay, write delay, average write power consumption, and average read. Evaluations are conducted on the power consumption, as well as write and read access times. Then the proposed electrostatic doped-gate all-around CNTFETs (EDGA-CNTFET)-based 8T SRAM cell design is compared with existing method-like designs of differential TG-based 8T SRAM cells for ultralow-power applications [23], reliable 8T SRAM for high-speed searching, and logic-in-memory operations [24], respectively.

D. 6T SRAM Cell

During a read operation of a 6T SRAM cell, the bit line access transistor directly accesses the data storage node, as illustrated in Figure 1. As illustrated in Figure 1, during the reading process, the voltage at the storage node changes due to the interaction of the cross-coupled inverter pair and the bit line. BL and BLB represent bit lines, while WL represents word lines. WL controls the access transistor and facilitates both read and write operations. Bitline acts as a node for both input and output. Data from the SRAM cell is transferred to the sense amplifier during the read operation through the bit line. In this specific technology, the minimum transistor length is 130 nm [30].

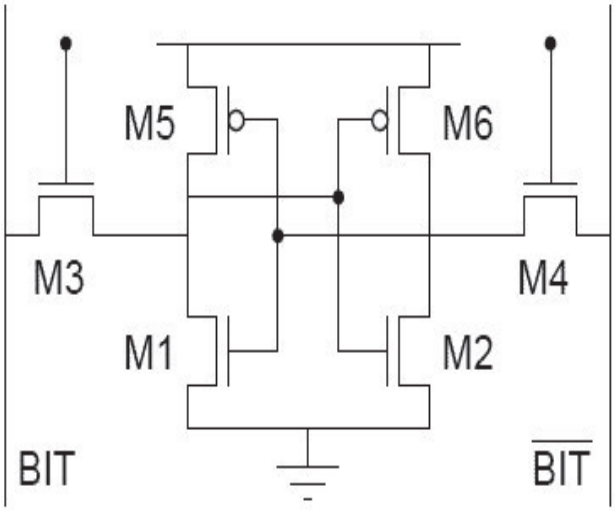

Fig. 1. 6T SRAM Cell [30].

E. Proposed 8T SRAM Cell

The proposed SRAM cell employs dual voltage and swing restoration Inverter (SRI) in order to enhance the node voltage performance during retention, read, and write operations. Delay and stability are also shown in Figure 2. Low-power 6T SRAM and proposed 8T SRAM cell design comparison is made, and it shows that 8T SRAM cell has a better read, write, and retention performance than that of the 6T SRAM cell. These reasons result in an increase in Static Noise Margins (SNM), which improves the read and write capability of the bit cell. The result of this is an increased SNM, which ensures a strong read and write ability of the bit cell.

IV. DISCUSSIONS

This section discusses the proposed 8T SRAM cell's write ability, read stability, and hold static noise margin.

A. Hold Stability

The most commonly used metric to determine retention stability is the static signal-to-noise ratio of an SRAM cell. Retention stability is usually evaluated when the cell is in the retention state. In this state, the word line is disabled such that the cell is disconnected from the bit line. SNM is defined here as the maximum noise passed to the storage node such that the cell contents don't collapse.

B. Read Stability

The RSNM measures the read stability in the SRAM cell. Comparing the conventional 6T SRAM cell, the isolation of storage nodes in the proposed 8T SRAM cell improves the RSNM.

C. Write Stability

Write stability is examined through the WSNM. The isolation of the nodes that store in the proposed 8T SRAM cell leads to a larger WSNM than does the existing 6T SRAM cell. The write trip point assesses the write capabilities of the SRAM cell, indicating how difficult it is to alter storage nodes. It is determined by gradually increasing the bit-line voltage from 0 to Vdd and recording the instant that the cell flips, causing the Q and Q bar to alter their recorded values. The value of the bit-line voltage at the intersection of internal storage nodes Q and QB bar represents the write trip point.

V. CONCLUSIONS

This article focuses on the existing design approaches for creating SRAM cells. The integrated circuits, find their application in high-speed and low-power SRAM cells. This paper presents a novel design for a proposed 8T SRAM cell, incorporating both differential bit lines and word lines. This innovative configuration effectively reduces leakage current in comparison to other designs, making it especially well-suited for applications where minimizing power consumption due to leakage is a critical consideration. Moreover, the proposed 8T SRAM cell outperforms the 6T SRAM cell. Furthermore, the proposed 8T cell has better read and write stability than the 6T SRAM cell. Overall, the 8T SRAM cell, highlights its suitability for high-performance, power-efficient, and reliable circuit applications. The various approaches utilized in different SRAM cells were investigated, with a focus on low-power SRAM cell design.

Abstract
Twitter (now known as "X") is a popular medium for Covid-19 related discussions. This paper presents a novel case study on sentiment analysis and topic modeling of Covid-19 vaccine-related tweets of users geo-located in India in the duration of 12 December 2020 to 11 November 2021 in the course of which more than half of the country's 1.3 billion population got vaccinated. The sentiment analysis was performed, on day-wise basis, using unsupervised lexicon-driven sentiment analysis tools AFINN and Valence Aware Dictionary and sEntiment Reasoner, as well as BERTweet and Covid-Twitter-BERT transformer models pre-trained on Covid-19 tweets. The models were comparatively evaluated on a smaller annotated dataset of Covid-19 vaccine-related tweets prior to the longitudinal analysis. AFINN was ultimately chosen due to its better performance and ease of use for large unannotated data. AFINN analysis revealed that 51.38% of the 44,130 tweets were neutral, while 38.84% were positive, and 9.78% negative. Latent Dirichlet Allocation was used for topic modeling at the peak points corresponding to large sentiment fluctuations in the positive and negative longitudinal graphs derived using AFINN. The positive and negative vocabularies at peak points were scrutinized to derive insights on national/international events that triggered a change in public opinion. These findings could guide policy makers in gathering intelligence on misinformation and associated sentiments, and planning counter-measures to combat anti-vaccine campaigns. This study informs future strategies to counter vaccine hesitancy through targeted communication aimed at vulnerable groups that experience high anxiety and psychosocial burden during the pandemic.

Keywords Twitter · Covid-19 vaccine · Sentiment analysis · Topic modeling · Longitudinal studies

1 Introduction

Twitter (now known as "X") is an easily accessible social media platform where people constantly express their opinions about national and international events. The Covid-19 pandemic and the ensuing lockdown imposed in several countries caused a significant rise in the number of people turning to social media platforms like Twitter to express their feelings, doubts and apprehensions. The vaccination program underway in several countries is considered universally as one of the most effective ways to counter the spread of the virus (Chakraborty et al. 2023). Several vaccines got worldwide recognition, such as AstraZeneca, Moderna, Pfizer, and Sputnik, while domestic vaccines developed by low- and middle-income countries got approval after a long procedural delay. Naturally, this sparked a widespread discussion on the shortage and efficacy of imported and domestic vaccine brands among the Twitter users in developing countries like India. Twitter, now popularly known as "X", became the most popular social media platform in India for obtaining real-time updates during the Covid-19 pandemic due to its outreach among students, middle-class working group, high-class income group, corporate world, political leaders and celebrities, though constrained by ethnic and demographic biases, and use of English as the primary medium of communication (Jain et al. 2021). The online discussions ranged from hope and willingness to participate in the vaccination program to despair as the deadly Delta variant caused much fatalities globally. Vaccine sentiment analysis and topic modeling from geo-tagged social media posts is now considered significant research (Hussain et al. 2021; Dubey 2021) since it helps to identify the (1)

dynamically evolving public opinion regarding vaccines (2) the specific counties or countries having a more skeptical attitude towards certain vaccines (3) local and international news or events that triggered a change in the public sentiment towards vaccination and the vaccine brands. It is crucial for the government and policy makers to understand the public mood from social media platforms so that timely interventional steps can be introduced for vaccine procurement, vaccine approval, promoting vaccination and reducing vaccine hesitancy through educational campaigns.

Sentiment analysis techniques are broadly classified into unsupervised and supervised approaches. Some popular unsupervised tools are Valence Aware Dictionary and sEntiment Reasoner (VADER) (Hutto and Gilbert 2014), TextBlob (Loria et al. 2014) and AFINN (Nielsen 2011) that assign a sentiment score to each tweet (the polarity of the score indicates the sentiment−positive or negative). Supervised methods perform text classification using bag-of-words feature representations (Susan and Keshari 2019) and sequential word embeddings (Nguyen et al. 2020; Müller et al. 2023), that are learned using machine learning classifiers and transformers, respectively. A common issue with the Twitter data related to the Covid-19 pandemic is the lack of sentiment annotations by human analysts, and the smaller size of datasets with skewed or imbalanced class profiles, that makes supervised learning a challenging task. The use of domain-specific pre-trained transformer models such as BERTweet (Nguyen et al. 2020) and Covid-Twitter-BERT (CT-BERT) (Müller et al. 2023) that are pre-trained on Covid-19 tweets, mitigates the issue to some extent.

1.1 Motivation for the study

Vaccinations started in India, the most populous country in the world, on 16 January 2021. India with its population of 1.3 billion was the second country most affected by the pandemic (Mirza et al. 2024). It also became, on 21st October 2021, the second country to cross the 1 billion mark of the number of doses of vaccines administered. 50% of the country's population had got vaccinated by November 2021. The second Covid-19 wave, that was attributed to the Delta (B.1.617.2) variant, wreaked havoc in India in the months of May–June 2021 with an increase in the numbers of hospitalizations and fatalities while the vaccination program was still underway in the country. The second wave of Covid-19 had peaked on 7 May 2021 with 4.14 lakh daily cases, as observed from the graph in Fig. 1.

It would be therefore a constructive case study to monitor the public receptiveness towards the vaccination program by analyzing the trending topics in social media on the days when sentiments (positive or negative) of the Twitter users peaked. The stakeholders of such a sentiment-cum-topic analysis study are government officials, policy makers and vaccine manufacturers who could devise timely measures to counter vaccine hesitancy based on shifting opinions on social media.

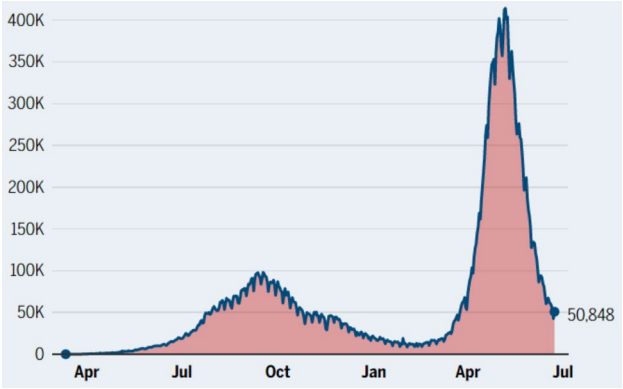

Fig. 1 The peak (right-side) in the number of daily confirmed cases during the second Covid-19 wave in India in the months of April to July 2021 [data provided by Ministry of health and family welfare, Government of India]

2 Research questions

Specifically, this study attempts to answer the following research questions:

RQ1: How to effectively use unsupervised sentiment analysis tools for predicting day-wise sentiments of Covid-19 vaccine-related tweets of users geo-located in India?

RQ2: How to effectively extract the topics of discussion on the days when positive and negative sentiments peaked on Twitter?

RQ3: How to correlate the extracted topics and sentiments with events of national and international importance that may have been the cause and effect of the outburst of opinions on social media platforms?

To answer the research questions, this study presents a novel approach for longitudinal sentiment analysis and dynamic topic modeling of geo-tagged tweets of users from India in the duration from 12 December 2020 to 11 November 2021 while the vaccination program was rolled out and the deadly second Covid-19 wave progressed through the country. While AFINN was used for sentiment analysis, Latent Dirichlet Allocation (LDA) was used for dynamic topic modeling at positive and negative sentiment peaks in the longitudinal graphs. To the best of our knowledge, there is no other work that has dynamically analyzed the sentiments of Twitter users in India before and after vaccinations started in India on 16 January 2021, for an almost one-year duration encompassing the rise and abatement of

the devastating second wave, along with topic analysis of the peak points in the longitudinal sentiment graph.

2.1 Main contributions

The main contributions of the paper are summarized as follows:

1. We performed longitudinal sentiment analysis (over time) using AFINN to identify positive and negative sentiment fluctuations in the duration of 12 December 2020 to 11 November 2021 for Twitter users in India. The time window was selected to coincide with the rollout of the vaccination program in India, and the complete duration of the second wave of the Coronavirus in India, until the point when the country had recovered from its aftereffectsby November 2021.

2. The number of positive, negative and neutral tweets were summed up separately for each day, creating three longitudinal graphs, one for each sentiment. The major peaks in the positive and negative sentiments in the longitudinal graphs indicate a significant fluctuation in public sentiment.

3. We used LDA for discovering the trending topics under discussion on the specific dates corresponding to peaks in the sentiment graphs. The top-20 salient terms were identified based on their frequencies of occurrences in the top-20 topics detected through LDA at the peak points in the positive and negative sentiment graphs. The positive and negative vocabularies at the sentiment peaks were objectively analyzed to understand the hopes, fears and doubts of the public regarding vaccine efficacy and availability.

4. We manually collated news articles at sentiment peaks in the longitudinal graphs in order to identify the national/international events that may have caused the sentiment fluctuations and outburst of opinions. The impact of the public discussions on social media on society and governing authorities were qualitatively analyzed.

The rest of the paper has the following organization structure. Related research is presented in Sect. 3, the proposed methodology is detailed in Sect. 4, the experimental setup and the results are discussed and analyzed in Sect. 5, and the final conclusions are summarized in Sect. 6.

3 Related work

Sentiment analysis is a reliable means for understanding the dynamically evolving sentiments of the public who take to social media for exulting over sports events (Vashishtha and Susan 2019), discussing positive or negative reviews of some place, object or event (Ghosh et al. 2021), or expressing apprehensions about natural calamities (Mendon et al. 2021). Mining public sentiments from social media is an essential part of disaster management as argued by the authors in Ragini et al. (2018). The authors extracted textual features such as bag-of-words and part-of-speech tagging, and compared different classifier models for determining the public opinion to philanthropic aids received in response to a disaster. A disaster-specific word embedding trained on the Nepal and Italy earthquakes was adopted by the authors in Behl et al. (2021) to determine public sentiments from Covid-19 related tweets. Some recent works have focused on the Covid-19 vaccination drive in different countries and its impact on social media. Most of these case studies focus on finding the overall sentiment (positive, negative, neutral) in a particular time frame. Dubey (Dubey 2021) analyzed the public sentiments and emotions towards Covishield and Covaxin, the two vaccines popularly administered in India, and proved that there was more positivity associated with the Covishield vaccine. The author used the National Research Council (NRC) Emoticon lexicon to detect eight emotions and sentiments (positive or negative) in tweets posted over five days, specifically, in between 14th January 2021 to 18th January 2021, coinciding with the launch of the vaccination program in India. In a related work (Batra et al. 2021), Batra et al. linked emotions such as joy, surprise, etc. expressed in tweets related to Covid-19 with ongoing events in six countries. Long-short term memory (LSTM) and its variants were used for the prediction. In a related work (Hu et al. 2021), US-based tweets were evaluated using VADER for detecting spatio-temporal patterns in sentiments, and the emotions of tweets were analyzed using National Research Council Canada Lexicon (NRCLex). The authors in Jayasurya et al. (2021) analyzed temporal graphs of sentiments predicted using 14 machine learning models. They used a dataset which had been annotated using VADER and TextBlob, two of the most popular unsupervised sentiment analysis systems. The outcome was a set of dates on which highest numbers of positive, negative and neutral tweets were recorded. Umair et al. (Umair et al. 2023) performed sentiment analysis using bidirectional encoder representations of text along with Naïve Bayes and Support Vector Machine (SVM) classifiers to detect sentiments of tweets posted by users on Twitter. The authors highlighted the utility of Geographic Information System (GIS) to gain the sentiments of people in a specific region.

Previous works in literature (Bansal et al. 2023, 2022) have explored the use of pre-trained transformer models for classifying tweets related to Covid-19 vaccines. However, such applications have limited scope due to insufficient amount of annotated data available for training. Supervised learning models, on the whole, require lots of training data, with annotated sentiment labels, which is found lacking in the case of Covid-19 vaccine-related posts on social media. Text oversampling (Choudhry et al. 2022) does not improve the results of supervised learning for imbalanced datasets, as proved in Bansal et al. (2023). Unsupervised lexicon-based

sentiment analysis tools such as VADER, AFINN and TextBlob are popularly used in the absence of sufficient ground truth annotations. Their popularity is due to (i) the lack of annotated Twitter datasets pertaining to Covid-19 related discussions (ii) the dynamic and evolving nature of the sentiments derived from sequential tweets (Vashishtha and Susan 2019) that renders supervised machine learning a challenging task (Behl et al. 2021). Public optimism in the US and UK towards the vaccination program was evaluated from 300,000 Facebook and Twitter posts in Nguyen et al. (2020) using a weighted ensemble of VADER, TextBlob and BERT. It was noted that while VADER and TextBlob predicted well for the positive sentiments, BERT performed better for the negative sentiments. 10% of the tweets were labeled manually by the team for facilitating supervised learning and computation of precision scores. Niu et al. (Niu et al. 2022) classified the sentiments of tweets pertaining to Japanese users before and after the vaccination started in Japan. The sentiments were classified using Amazon Web Services (AWS) and were found to be more negative in nature due to apprehensions and confusion regarding the vaccination process.

Topic modeling of Covid-19 related tweets would help to understand the hotspots of discussion in a particular time frame or on a specific date. LDA is the most popular unsupervised tool used for topic modeling of Covid-19 tweets, primarily due to its ease of use and effective performance (Lin 2023; Lyu et al. 2021; Ahammad 2024). Phase-wise application of LDA aids in understanding the dynamic changing content of topics under discussion. Dynamic topic modeling was performed on worldwide tweets using LDA in Sharma et al. (2022). This project was implemented over five temporal phases in the duration of 20 December 2020 to 16 October 2021. The top-10 significant terms or unigrams were plotted for each temporal phase in the form of bar charts. The topmost discussion that surfaced from the topic analysis was the appraisal and criticism of different vaccine brands.

Sentiment analysis of Covid-19 tweets may be complemented by topic analysis for providing a more interpretable quantitative and qualitative analysis of social media posts. Examples of such an agglomeration include XLNet transformer model and Word Clouds (Bansal et al. 2022), pre-trained BERTweet transformer model and Word Clouds (Bansal et al. 2025), and VADER and Word Clouds (Verma et al. 2022). Word clouds are a simple and effective means for extracting significant terms in a document. The font size in the word cloud represents the count of the word in the document. Kwok et al. collected 31,000 tweets of Australian users in the timespan of January to October 2020, and performed sentiment analysis and topic modeling using LDA (Kwok et al. 2021). A pre-defined library in R was used to classify the tweets into either positive or negative sentiment, and one of the eight emotions: fear, anger, anticipation, trust, joy, surprise, disgust, and sadness. As per their findings, two-thirds of the tweets were positive and only one-third were negative or skeptical of the vaccines. Melton et al. performed sentiment analysis and topic modeling on Reddit posts on a month-by-month basis (Melton et al. 2021). Their findings reiterated previous research on the sentiments being primarily positive towards the vaccination process. The topic modeling results revealed that users were mostly concerned with the side-effect of vaccines than any other topic. An interesting related research area is stance analysis (Martínez et al. 2023; Küçük and Arıcı 2022; Yanto et al. 2021) wherein the respondents are classified based on their stance on certain issues pertaining to the Covid-19 vaccination program. This would require annotation of tweets with pre-defined stance labels (Melton et al. 2021) (Martínez et al. 2023) or a stance analysis from general public by asking them to reply to pre-defined questions with labeled stances (Küçük and Arıcı 2022). This problem is different from the sentiment and topic analysis problem tackled in this paper wherein the emotional polarity of social media posts is the focus of investigation. Table 1 summarizes a few case studies following distinctive approaches for sentiment analysis and/or topic modeling of Covid-19 vaccine-related discussions on social media.

Previous case studies on Covid-19 vaccine-related social media posts have several limitations. Firstly, most works have conducted isolated studies on sentiment analysis and topic modeling, and ignore the strong correlation between sentiment labels and the topic of discussion. Secondly, dynamic topic modeling is not the usual norm, and clusters of topics are usually detected for the entire database corresponding to a predefined time window. Thirdly, very few studies have attempted to correlate the detected topics with national/international events that may have triggered a discussion on social media.

In the current case study, we seek to advance over existing methods by introducing dynamic topic modeling of vaccine-related discussions at sentiment fluctuations in the longitudinal sentiment graphs, in order to identify the events of national/international importance that led to a surge in public opinion. Moreover, we chose a timeline encompassing the vaccination rollout in India and coinciding with the spread of the second Covid-19 wave.

4 Proposed methodology

This section presents the proposed strategy for longitudinal sentiment analysis and topic modeling at sentiment fluctuations in the longitudinal graphs. Figure 2 visualizes the

Table 1 Summary of some distinctive studies on sentiment analysis and topic modeling of Covid-19 vaccine-related discussions on social media

Author & Year	Dataset used	Sentiment analysis method	Topic modeling method	Key findings
Lyu et al. (2021)	1,499,421 tweets collected between 11 March 2020 to 31 January 2021	Weekly mean sentiment scores computed using National Research Council of Canada Emotion Lexicon	LDA	16 topics were detected that were grouped into 5 themes. In a separate study, it was found that the sentiments were majorly positive as the vaccinations progressed
Marcec and Likic (2022)	701,891 tweets on AstraZeneca, Pfizer and Moderna vaccines from 1 December 2020 to 31 March 2021	Longitudinal sentiment analysis (day-wise) using AFINN	N/A	It was observed that while the sentiments for Pfizer and Moderna appeared to be positive and stable, the AstraZeneca vaccine garnered more negative sentiments over time
Qorib et al. (2023)	42,796 tweets from 26 September 2021 to 7 November 2021	Five machine learning classifiers and three vectorization techniques for daily sentiment analysis of tweets annotated using Azure machine learning, VADER and TextBlob	N/A	The authors observed a daily increase in the positive sentiments computed by VADER indicating a growing warmer response of the public towards the vaccination program
Bansal et al. (2023)	6,000 annotated tweets available from online dataset	Domain-specific transformer models:—CT-BERT and BERTweet that are pre-trained on Covid-19 tweets	N/A	Domain-specific transformers outperform generic transformers for the sentiment analysis task. Also, text oversampling is not beneficial for learning from skewed class distributions
Lin (2023)	226,373 tweets from 1 December 2020, to 15 November 2021	N/A	LDA with agglomerative clustering for detecting top-20 topics in a phase-wise manner	The dendogram of topic clusters revealed that discussions centered on vaccine brands, booster doses and vaccine effectiveness
Lindelöf et al. (2023)	5,163 negative tweets from 1 March 2020 to 31 July 2021	Negative tweets were segregated using support vector machine	BERTopic model was used for topic modeling of negative tweets	The topics detected were primarily about conspiracy theories, vaccine safety and vaccine side-effects
Boucher et al. (2023)	596,987 tweets on HPV vaccine during the Covid-19 pandemic from January 2019 to May 2021	BERT transformer model fine-tuned on random samples annotated by analysts	Thematic analysis of tweets was performed using hierarchical agglomerative clustering of topic themes and TF-IDF computation	The method heavily relied on the analysis of vaccine-hesitant group (negative tone detected) and vaccine-confident group (neutral tone detected) in social networks
Catelli et al. (2023)	1,602,940 tweets from January 2021 to February 2022	Count of features based on co-occurrences of noun phrases and sentiment words for eg. (AstraZeneca, hospitalized)	MultiWordNet lexical database for the qualitative analysis of tweets	It was concluded that while positive tweets were more about scientific breakthroughs, negative tweets were more about delayed vaccine development and vaccine safety
Ahammad (2024)	10,728 news headlines and posts	VADER	LDA	Negative sentiment analysis revealed 20 topics on vaccine effectiveness, while positive sentiment analysis revealed 18 topics on complacency in vaccination procedure

Table 1 (continued)

Author & Year	Dataset used	Sentiment analysis method	Topic modeling method	Key findings
Bansal et al. (2025)	65,164 and 11,190 tweets associated with Covaxin and Covishield vaccines, respectively, from January 2021 to May 2021 (phase 1) and June 2021 to November 2021 (phase 2)	VADER	Word-cloud analysis of positive and negative tweets	Analysis revealed that the number of negative tweets were more than positive tweets due to discussion on "low availability of vaccines" as indicated from the pre-dominant n-grams in word clouds

workflow of the proposed approach. Each step is detailed in the following sub-sections. We start with a description of data collection and text pre-processing steps, before detailing the sentiment analysis and topic modeling procedures.

4.1 Data collection

We gathered geographically-filtered tweets originating from India from the "Covid-19 all vaccines tweet" dataset provided by Gabriel Preda on Kaggle (https://www.kaggle.com, gpreda, all-covid19-vaccines-tweets[Accessed last on 31st Dec 2021]. 2021). This dataset contains world-wide geotagged tweets related to seven Covid-19 vaccines (Pfizer, Sinopharm, Sinovac, Moderna, Oxford/AstraZeneca, Covaxin, Sputnik-V) collected using Twitter API from public tweet streaming data. The dataset has 16 feature columns (id, user_name, user_location, user_description, user_created, user_followers, user_friends, user_favourites, user_verified, date, text, hashtags, source, retweets, favorites, is_retweet). A visualization of the dataset, illustrating the 16 features and the values they assume, is shown in Fig. 3.

4.2 Text pre-processing

The user_location attribute of the dataset is used to determine the country from which the tweet originated, and the tweets originating from India were filtered out by regular expression-based pattern matching of the keyword "india". We dropped the tweets having ambiguous user locations which amounted to 29% of the 141,645 worldwide tweets available in the dataset. We collected a total of 44,130 vaccine-related tweets originating from India in the duration of 12 December 2020 to 11 November 2021. A natural language toolkit was used to pre-process the data. The tweets were first pre-processed and cleaned using regular expressions prior to the sentiment analysis stage. Since the supervised models and lexicons used in the study are trained on the English language, therefore, we removed all non-English words from the tweets. All characters were converted to lower case and punctuations were removed. All URLs, hashtags, emails and non-printable characters were removed. Further, in addition to removing the English stopwords, the following commonly-occurring keywords were identified and removed from the tweets: '#covid', '#coronavirus', '#coronavirusoutbreak', '#coronavirusPandemic', '#covid19', '#covid_19', '#epitwitter', '#ihavecorona''. The deletion of these irrelevant details was performed to further enhance the results of sentiment analysis.

4.3 Sentiment analysis of geo-tagged tweets

AFINN is a rule- and lexicon-based unsupervised sentiment analysis tool created by Finn Årup Nielsen (Nielsen 2011)

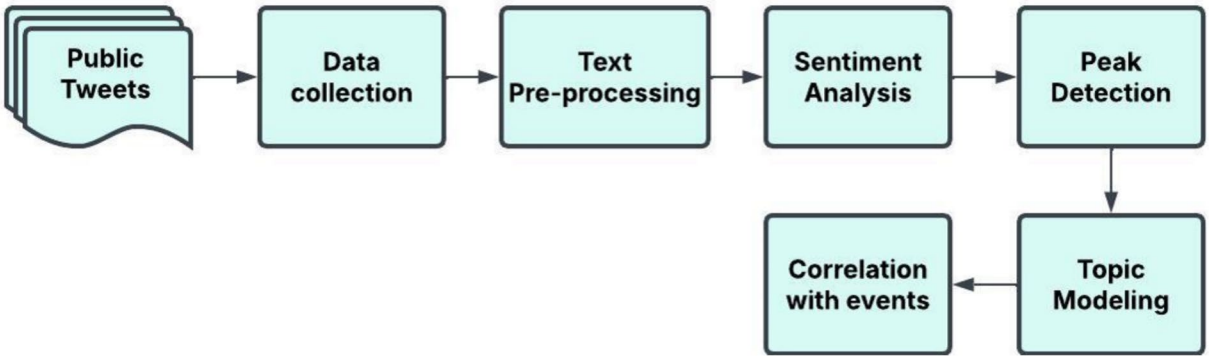

Fig. 2 Workflow of the proposed approach

that is popularly used for the sentiment analysis of social media posts. It computes a compound score for each sentence ranging from -5 (most negative) to + 5 (most positive). If the score is positive, it indicates a positive sentiment. If the score is negative, it indicates a negative sentiment. We consider the AFINN lexicon for the sentiment analysis of geo-tagged tweets since apart from being efficient, it is unsupervised and does not require training; it is difficult to acquire annotated tweet datasets associated with vaccine-related discussions. In the majority of cases, tweets that contained words like "good", "effective", "protects", "approve", "proud" etc. were correctly labeled as positive. For instance, the tweet "*Pfizer's Coronavirus Vaccine Protects Against New Variants Found in UK, South Africa: Study*" was correctly classified as positive with a score of + 1. Likewise, negative tweets were characterized by words like "dead", "adverse", "suffered", "infection". For instance, the tweet "*Two dead in #Norway, received #Pfizer's coronavirus vaccine recently*" was correctly classified as negative with a score of -3. Another instance is the tweet "*No mention of efficacy …which is 50%… lowest amongst all Vaccine #COVID19Vaccines #Moderna #PfizerBioNTech #CovidVaccine #Covishield*", that is correctly predicted as negative (score of -2). On the other hand, non-committal posts like "*Would you vaccinate or not?*", or those tweets stating facts, such as "*Pfizer-BioNTech to produce 2 billion doses of COVID-19 vaccine in 2021* | via *@IndiaTVNews*", were correctly classified as neutral (score of 0).

4.4 Topic modeling at sentiment peaks and correlation with events

The following steps were undertaken for analyzing the sentiment outputs. Longitudinal graphs (Valdez et al. 2020) of positive, negative and neutral sentiments versus time were plotted on a day-wise basis between 12 December 2020 to 11 November 2021. The number of positive, negative and neutral tweets were summed up separately for each day, creating three longitudinal graphs, one for each sentiment. The peaks in the sum of positive and negative sentiments in each of the longitudinal graphs indicate a fluctuation in public opinion. The five highest peaks corresponding to the positive sentiment and the five highest peaks corresponding to the negative sentiment are derived from the positive and negative longitudinal graphs, respectively. The rank is determined from the decreasing order of the day-wise tweet count in the respective longitudinal graph (positive or negative). For determining the sentiment peaks corresponding to significant sentiment fluctuations in the graphs, we follow previous research (Nguyen et al. 2013) that extracts the highest peak points for positive and negative sentiments, respectively. We then performed dynamic topic modeling over sentiment peaks (both positive and negative) in the longitudinal graphs in order to understand the events that influence public receptiveness to government policies related to the vaccination program. Positive and negative vocabularies of the trending topics were extracted at each sentiment peak for identifying the topics that may have led to a fluctuation in public sentiments. Salient terms having high term frequencies were extracted from the top-20 topics detected using LDA. The top-20 salient terms at the peak points were also visualized using bar charts indicating the overall term frequency which is a popular indicator of the significant keywords in a document (Susan and Keshari 2019; Sicilia-Garcia et al. 2002; Garner et al. 2019; Sharma et al. 2023). Dynamic topic modeling over moving time windows helps to identify various events of national/international importance that may have influenced discussions and sentiment fluctuations on social media. To set the LDA hyperparameters, we followed the guidelines in literature (Panichella 2021). The number of topics was set to 20, alpha which influences topic distribution in each document was set to 0.05 (= 1/[number of topics]), beta which influences term

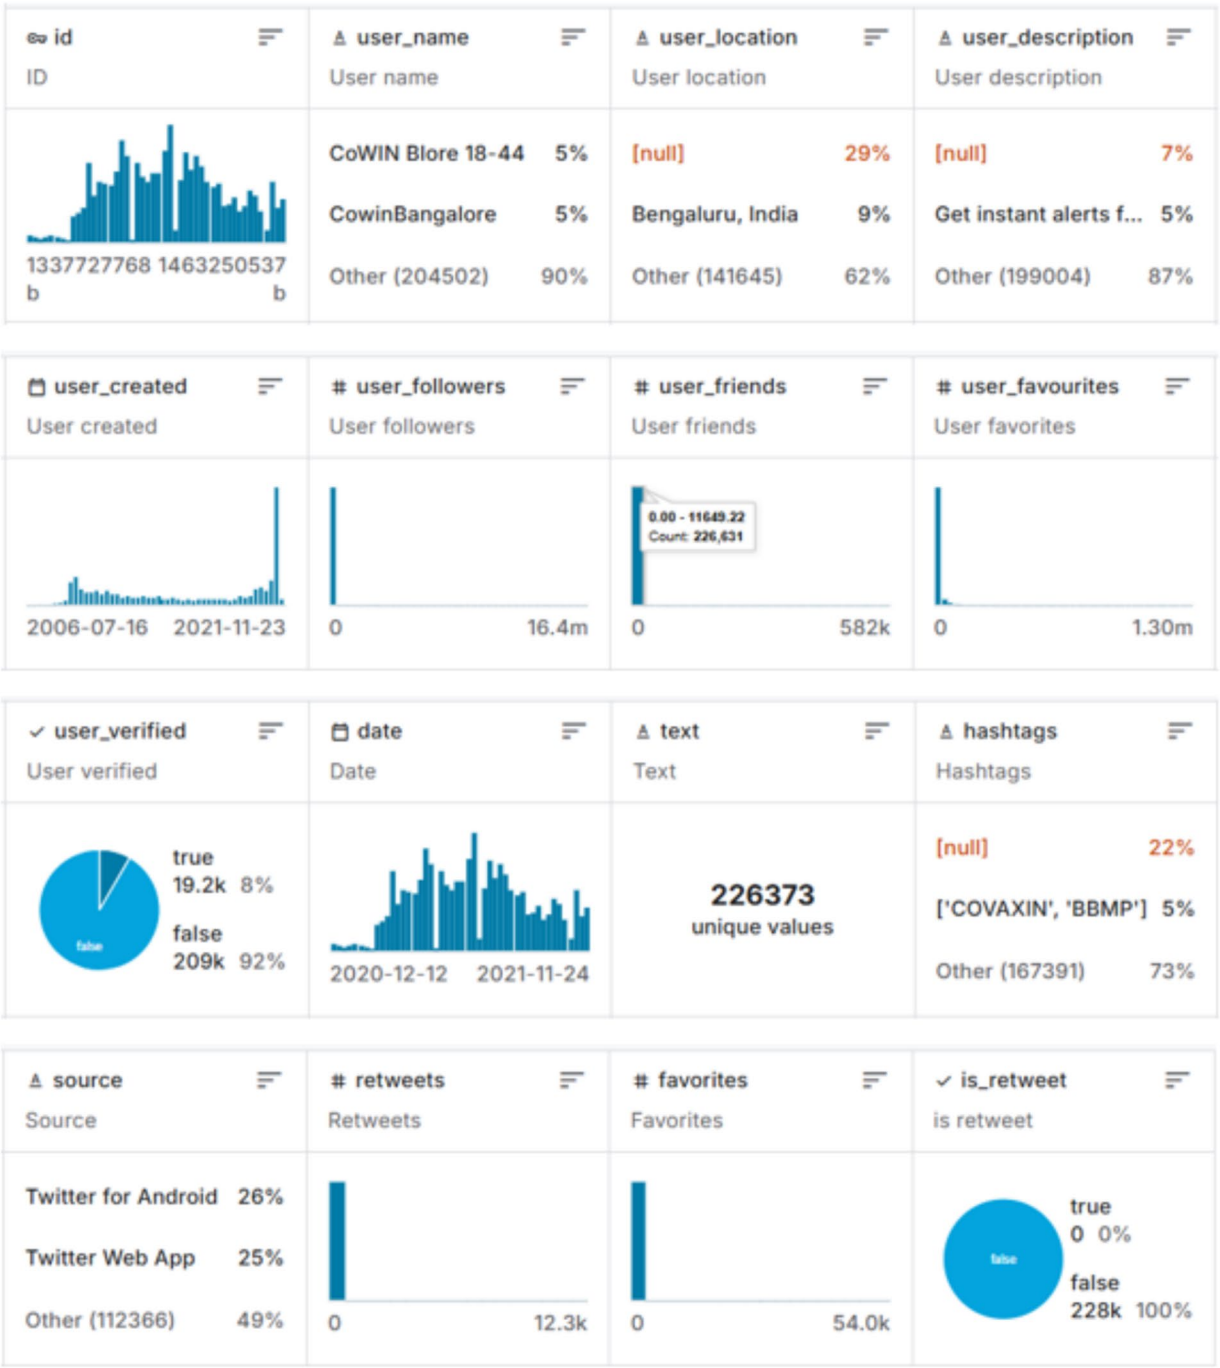

Fig. 3 Visualization of the dataset illustrating the 16 features and the values they assume

distribution in each topic was set to 0.05 (= 1/[number of topics]), and number of iterations was set to 200. We found that the list of salient terms did not change significantly when the number of topics was varied between 10 to 30. For correlating the detected topics with national/international events, a manual curation of leading news articles published in online portals of leading newspapers, magazines, World Health Organization (WHO) website (for constant updates on vaccine brands), and Reuters international news agency, is performed, pertaining to the specific dates on which sentiment peaks are detected

in the longitudinal graphs. A manual approach is taken due to the complexity of real-world events and to ensure correctness in linking contexts.

5 Results and discussions

This section presents the results and analysis of the experimentation. All experiments were conducted in Python (version 3.8) on a 2.8 GHz Intel core PC. The code used in our experiments and the associated data are made available online[1] to facilitate future research.

5.1 Performance comparison of popular sentiment analysis systems on a smaller annotated tweets dataset

We first present a comparative analysis of some popular supervised (XLNet, CT-BERT and BERTweet transformer models) and unsupervised (VADER, AFINN, TextBlob) sentiment analysis systems trained on a smaller annotated subset of the dataset which was also released by Gabriel Preda (https://www.kaggle.com, gpreda, all-covid19-vaccines-tweets[Accessed last on 31st Dec 2021]. 2021). This comparison serves as a precursor to the ultimate sentiment analysis performed on the complete set of 44,130 unannotated tweets using AFINN. There are a total of 6,000 tweets in the smaller annotated dataset out of which the majority (3,680 tweets) are neutral tweets, 1,900 are positive tweets while the negative tweets are in a minority (420 tweets). A five-fold cross-validation was performed for the supervised models using different 80:20 train-test splits of the dataset. Training using supervised models is expected to be biased towards the neutral sentiment due to class-imbalance, while the negative sentiments are likely to be mis-classified due to inadequate representation. It was proved in previous research (Bansal et al. 2023) that over-sampling using Language Model based Oversampling Technique (LMOTE) and Synthetic Minority Oversampling Technique (SMOTE) does not improve the performance of supervised models when the minority samples are few, as in this case. The reason is that data augmentation based on limited training data (few minority samples), generally produces noise, which may degrade the overall performance. In case of the unsupervised models—VADER, AFINN and TextBlob, no hyperparameters are involved since they are lexicon-based and do not require training. These models generate a compound sentiment score whose value determines the sentiment polarity of the input text. For instance, for a given sentence, VADER generates a compound score for each sentence in the range + 1 (most positive) to − 1 (most negative). The AFINN tool computes a compound score in the range + 5 (most positive) to − 5 (most negative), while TextBlob computes a compound score in the range + 1 (most positive) to − 1 (most negative). CT-BERT and BERTweet are pre-trained transformer models trained on English tweets on the Covid-19 pandemic. For the supervised models, Adam optimizer was used with a learning rate of 2e−5. The loss function is the cross-entropy loss function. While CT-BERT is trained on 160 million Covid-19 related English tweets, BERTweet is trained on 850 million English tweets with 5 million tweets belong to the Covid-19 pandemic. We additionally fine-tuned the BERTweet and CT-BERT models on the smaller annotated dataset, for enhanced performance while predicting the sentiments of the larger unannotated dataset comprising 44,130 tweets. From a comparison of the accuracy, F1-score and Mathew's correlation coefficient (MCC) scores of all six models, shown in Fig. 4, we observe that BERTweet and CT-BERT among the supervised models, and VADER and AFINN among the unsupervised models, showcase the best performance on the basis of F1-score and MCC which are the best indicators of model performance under class imbalance. Therefore, we plot the longitudinal sentiment graphs for the 44,130 unannotated tweets using all four models AFINN, VADER, BERTweet, and CT-BERT, in the next phase of our experiments.

5.2 Sentiment analysis of geo-tagged tweets

A temporal analysis of the positive and negative tweets over the duration of one year reveals the dynamically evolving emotional mindset of the people towards the ongoing vaccination program as the country progressed through the devastating second wave caused by the Delta variant of SARS-Cov-2 coronavirus in the months of April-July 2021. The neutral tweets are not considered for the analysis since they do not reflect the emotional mindset of the users. Figures 5 and 6 illustrate the longitudinal sentiment graphs corresponding to day-wise aggregated counts of positive, negative and neutral tweets, computed using VADER and AFINN, respectively, in the duration of 12 December 2020 to 11 November 2021. Likewise, Figs. 7 and 8 illustrate the longitudinal sentiment graphs corresponding to the pre-trained models BERTweet and CT-BERT.

In the initial months from December 2020 to February 2021, the number of vaccine-related tweets were relatively low in all the four graphs since vaccinations were a new concept. The vaccination program was launched in India on 16 January 2021. All three sentiments are shown in the longitudinal graphs to comprehend the relative scales of the three sentiments. The neutral tweets that mostly state facts about Covid-19 vaccines form a significant chunk of the total

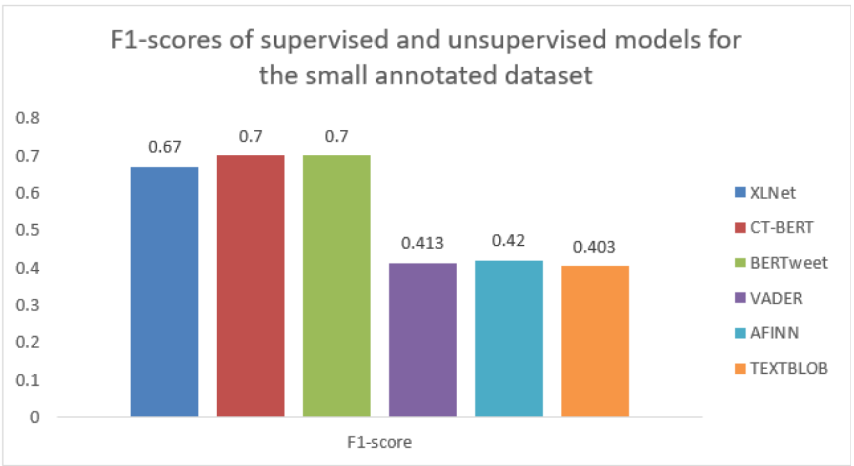
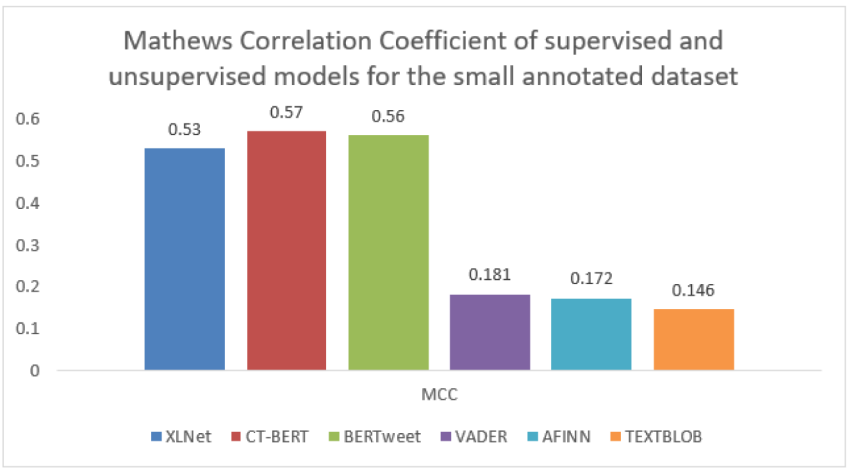
(a)



(b)



(c)

Fig. 4 Accuracy, F1-score and MCC scores of supervised (XLNet, CT-BERT, BERTweet) and unsupervised (VADER, AFINN, TextBlob) sentiment analysis systems for the smaller annotated dataset

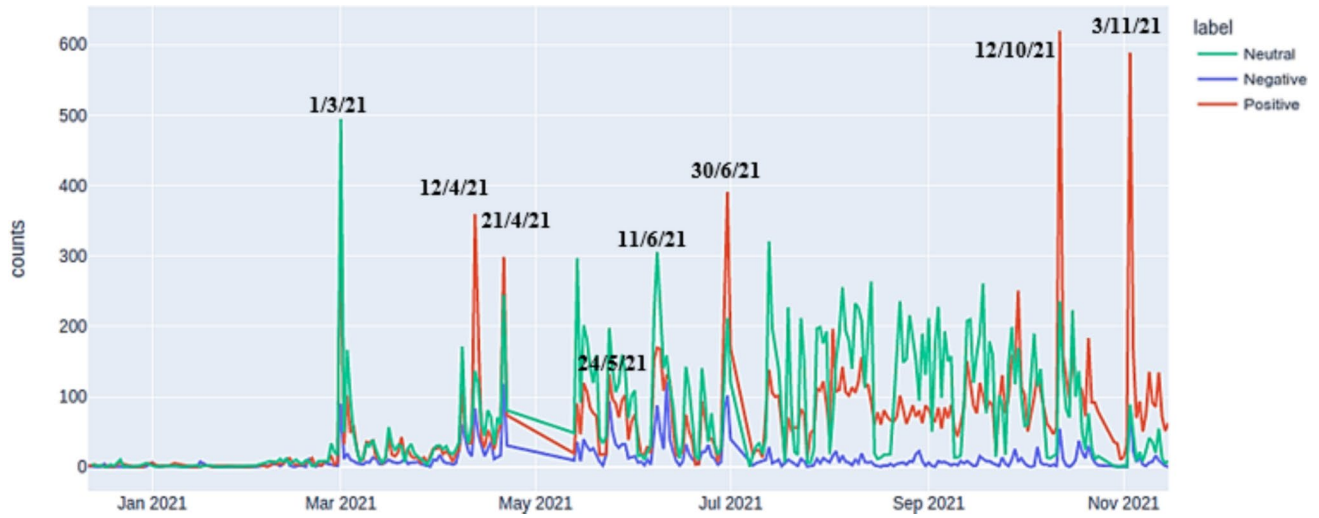


Fig. 5 Sentiment analysis graph using VADER showing the day-wise aggregated count of positive, negative and neutral tweets in the duration of 12 December 2020 to 11 November 2021. The highlighted dates indicate the peaks in the longitudinal sentiment graphs

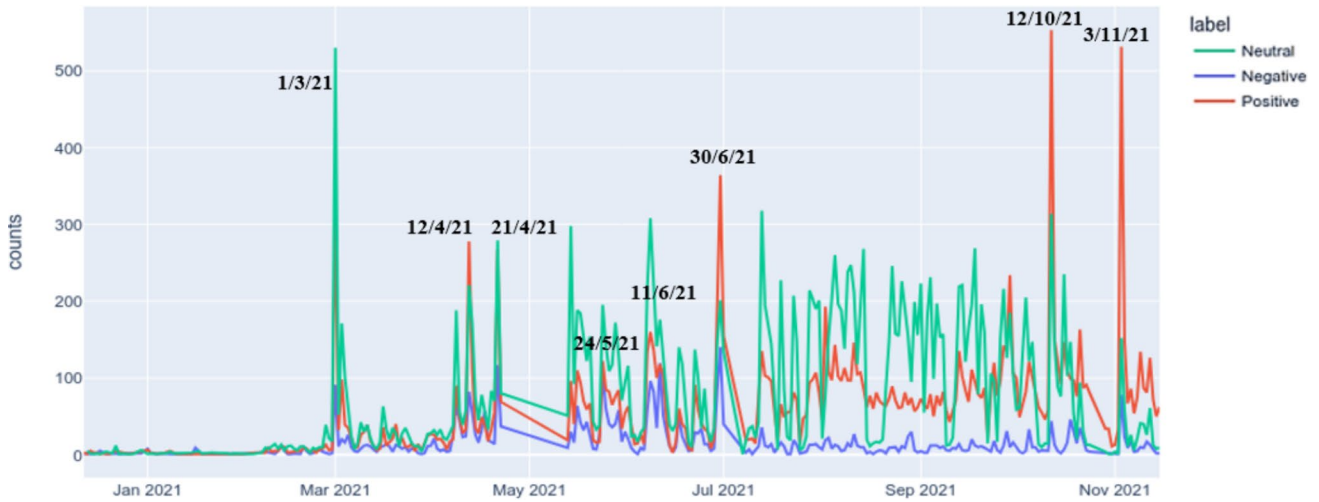

Fig. 6 Sentiment analysis graph using AFINN showing the day-wise count of positive, negative and neutral tweets in the duration of 12 December 2020 to 11 November 2021. The highlighted dates indicate the peaks in the longitudinal sentiment graphs

number of tweets. The number of positive tweets is, at most times, higher as compared to the number of negative tweets, which indicates that the majority of users hold a positive attitude towards vaccination. The negative tweets have a higher concentration in the duration of April 2021 to July 2021 during the progression of the second wave in India.

VADER and AFINN detect the negative tweets efficiently, especially during the second wave in April-July 2021, as observed from Figs. 5 and 6, respectively. The results of AFINN were comparatively superior to VADER in the experiments conducted on the smaller annotated dataset (Fig. 4). A comparison of the graphs in Figs. 5 and 6 proves that the negative sentiments are more well-defined in the AFINN graph with a reduced gap between the positive and negative graphs during the second wave (April-July 2021), as compared to the VADER graph where a significant gap exists between the positive and negative sentiments even at the peak of the second wave (April–July 2021). Therefore, we consider the AFINN results for topic modeling in the next phase of experiments.

An examination of the BERTweet and CT-BERT longitudinal graphs in Figs. 7 and 8 reveal that most of the tweets were predicted as neutral, and a small minority as positive, while a miniscule population of tweets were labeled as negative. The supervised models, therefore, are prone to biases and inaccuracies, and do not classify positive and negative

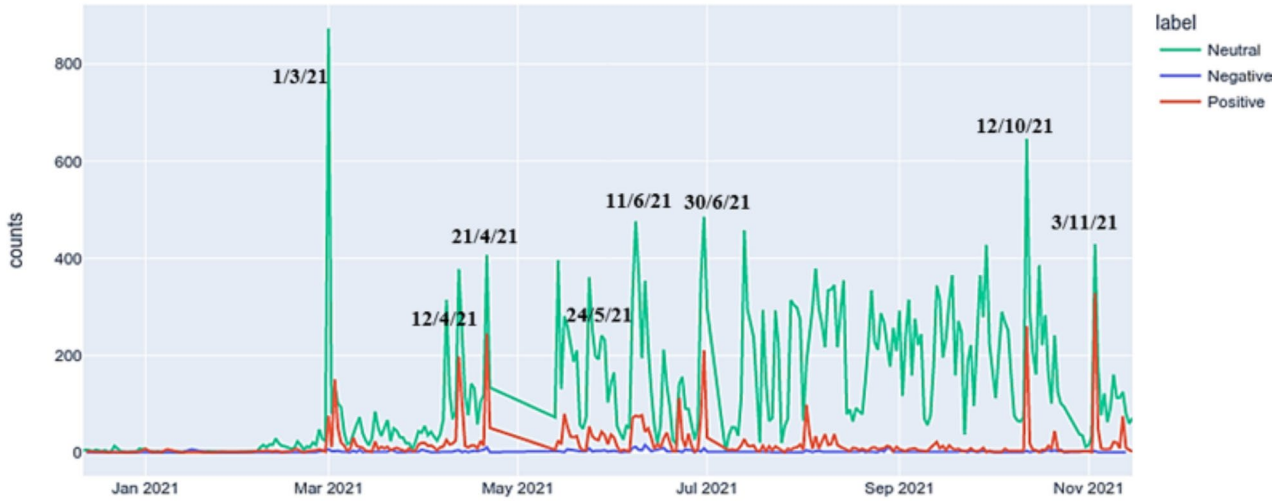

Fig. 7 Sentiment analysis graph using BERTweet showing the day-wise count of positive, negative and neutral tweets in the duration of 12 December 2020 to 11 November 2021. The highlighted dates indicate the peaks in the longitudinal sentiment graphs

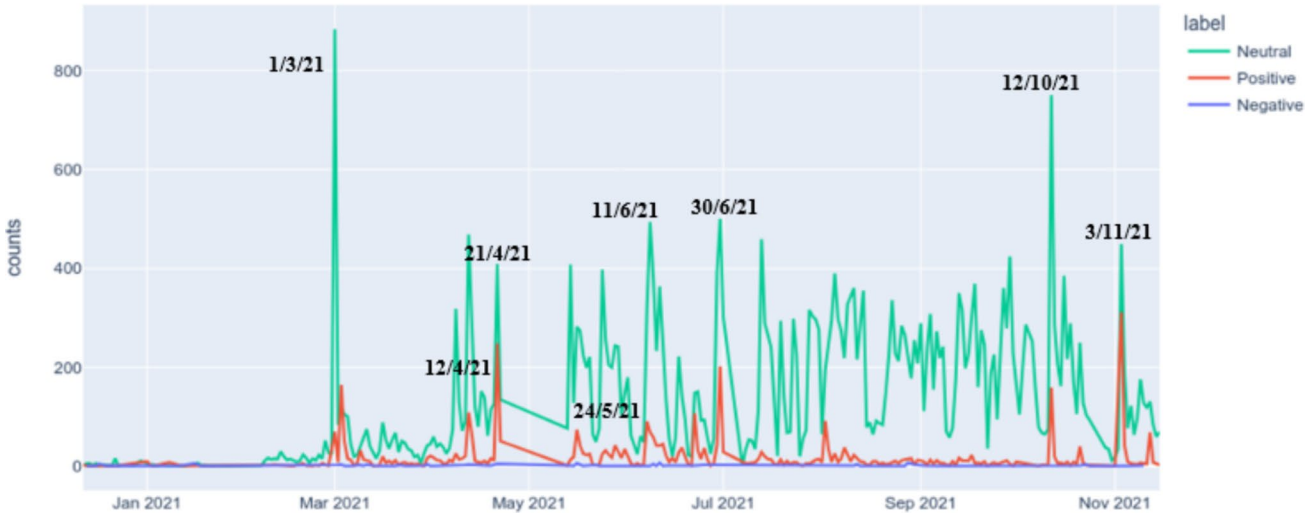

Fig. 8 Sentiment analysis graph using CT-BERT showing the day-wise count of positive, negative and neutral tweets in the duration of 12 December 2020 to 11 November 2021. The highlighted dates indicate the peaks in the longitudinal sentiment graphs

sentiments as well as the unsupervised models in this particular test scenario. This disparity becomes more evident in the months of October–November 2021, towards the end of the time window, when the majority of the tweets were predicted as neutral by the supervised models and positive by the unsupervised models. This result was on expected lines since the performance of the supervised models was bound to be affected by the imbalanced class profile of the small annotated dataset on which it was fine-tuned on (Sect. 5.1). The positive sentiment peaks in the graphs in Figs. 5, 6, 7, 8 were found to mostly coincide, though the actual counts significantly differed.

A statistical significance test (Cohen's Kappa) revealed that AFINN and VADER results showed near perfect agreement (Kappa = 0.8204), whereas there was a notable disagreement of predictions between AFINN and CT-BERT (Kappa = 0.09728), and between AFINN and BERTweet (Kappa = 0.1251). There was moderate agreement of predictions between the two supervised models CT-BERT and BERTweet (Kappa = 0.669) illustrating the unstable and outcome of supervised learning for a limited dataset with skewed class distribution.

AFINN is ultimately chosen as the sentiment analysis system for determining the sentiment peaks for topic modeling due to its better performance and ease of use for large

unannotated data. Out of the 44,130 tweets, 22,672 tweets (51.38%) were detected as neutral, 17,141 tweets (38.84%) were detected as positive, and 4317 tweets (9.78%) were detected as negative, by AFINN. The number of positive sentiments significantly increased after the second wave subsided in July 2021, as observed from the higher peaks in October–November 2021 (Fig. 5), indicating a higher optimism and willingness to participate in the vaccination program.

5.3 Topic modeling at sentiment peaks

We analyzed the positive and negative sentiment graphs over time, and identified the topics of discussion at sentiment fluctuations in the graphs using LDA which is an unsupervised machine learning model for topic modeling. The five highest peaks corresponding to the positive sentiment (Pos) and the five highest peaks corresponding to the negative sentiment (Neg) are shown in Table 2. The rank is determined from the decreasing order of the day-wise tweet count in the respective longitudinal graph (positive or negative). For determining the sentiment peaks corresponding to significant sentiment fluctuations in the graphs, we followed previous research (Nguyen et al. 2013) that analyzes the top-ranked peak points for positive and negative sentiments, respectively. As per Table 2, the sentiment peaks (positive and negative), determined by the above procedure, were observed on the specific dates−1 March 2021, 12 April 2021, 21 April 2021, 24 May 2021, 11 June 2021, 30 June 2021, 12 October 2021 and 3 November 2021. These dates are also shown highlighted in the longitudinal graphs in Figs. 5, 6, 7, 8. We perform topic modeling on the tweets associated with the days corresponding to the sentiment peaks listed in Table 2. Table 3 shows the results of topic analysis on the specific dates that correspond to peak points in the positive and negative sentiment graphs. The top-20 frequently occurring terms, also known as salient terms, in the top-20 topics detected through LDA are used for the analysis. The frequencies of the salient terms in the topics detected at sentiment fluctuations are visualized in the form of bar charts in Figs. 9, 10, 11, 12, 13, 14, 15, 16 for the dates entered in Table 3 and highlighted in Figs. 5, 6, 7, 8. The green bars in Figs. 9, 10, 11, 14, 15, 16 indicate positive sentiments while the red bars in Figs. 12, 13 represent negative sentiments. These bar charts help to infer the most discussed topics on Twitter, on specific dates, which may have caused the spikes in the sentiment graph.

For correlating the detected topics with national/international events, a manual curation of leading news articles published in online portals of leading Indian newspapers (The Hindu, New Indian Express), Indian magazines (India Today), WHO website (www.who.int), and Reuters news

Table 2 Sentiment peaks in day-wise longitudinal graphs of positive and negative sentiments

	1st positive peak	2nd positive peak	3rd positive peak	4th positive peak	5th positive peak	1st negative peak	2nd negative peak	3rd negative peak	4th negative peak t	5th negative peak
Date	12/10/21	3/11/21	30/6/21	1/3/21	12/4/21	30/6/21	11/6/21	21/4/21	24/5/21	1/3/21
Tweet count	553	531	364	335	278	140	119	117	107	91

The five highest peaks corresponding to the positive sentiment and the five highest peaks corresponding to the negative sentiment are shown date-wise, the rank being determined from the respective positive and negative tweet counts

Table 3 Topic modeling using LDA at sentiment peaks (specific dates mentioned in Table 2) in the longitudinal graphs in the duration of 12 December 2020 to 11 November 2021 (positive and negative sentiment labeling using AFINN)

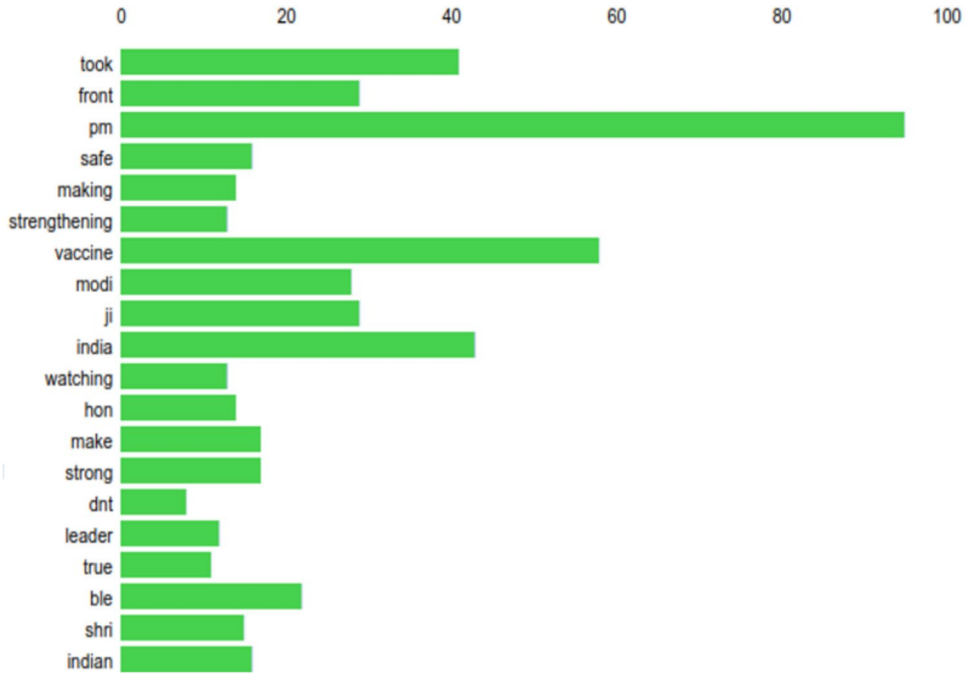

Fig. 9 Salient term frequencies in the top-20 topics detected from the positive sentiment tweets using LDA on 1 March 2021

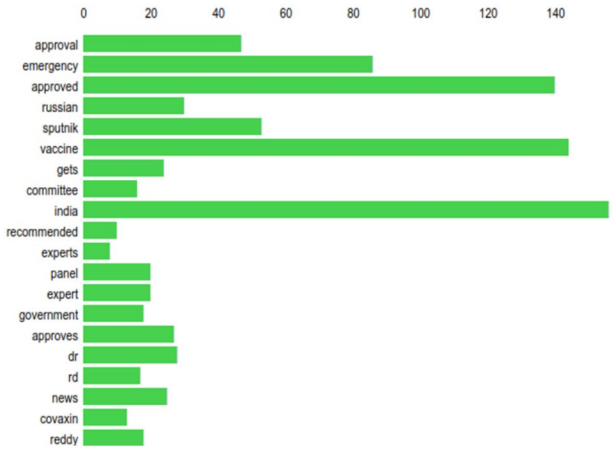

Fig. 10 Salient term frequencies in the top-20 topics detected from the positive sentiment tweets using LDA on 12 April 2021

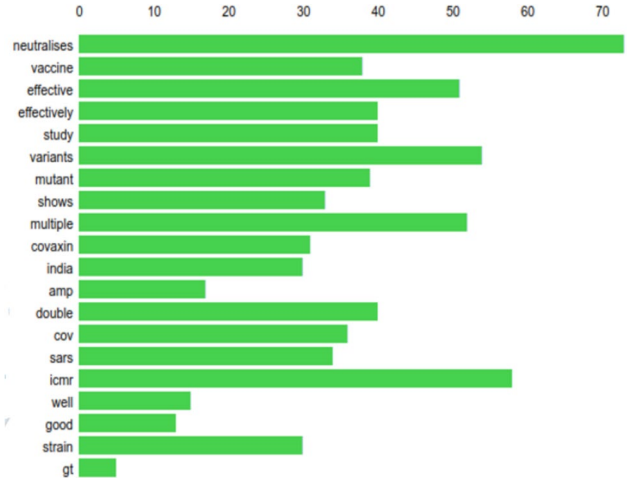

Fig. 11 Salient term frequencies in the top-20 topics detected from the positive sentiment tweets using LDA on 21 April 2021

agency (www.reuters.com), is performed, pertaining to the specific dates on which sentiment peaks are detected in the longitudinal graphs. Table 3 enlists the significant national/international events (with citations to news articles) that occurred on these dates that may have influenced a shift in public opinion. The impact of each event and its discussion on boosting public confidence and framing government policies is summarized in the last column of Table 3.

As noted from Fig. 9, the trending topic on 1 March 2021 was− Indian Prime Minister/PM took the first dose of vaccine (identified by the highest term frequency topics: 'india', 'pm', 'took', 'vaccine'); the most frequent salient term being 'pm'. An overall positive outlook towards vaccination was experienced due to the much-publicized event.

The most-occurring salient terms on 12 April 2021 was observed to be 'approval', 'emergency', 'sputnik', 'vaccine', 'India'. The trending topic can be surmised to be the approval of the Russian vaccine Sputnik-V for emergency use in India, at a time when the country was in the initial stage of the second wave and the number of Covid-19 confirmed cases was rapidly increasing. The news came as a relief to many citizens and resulted in a positive sentiment spike on 12 April 2021.

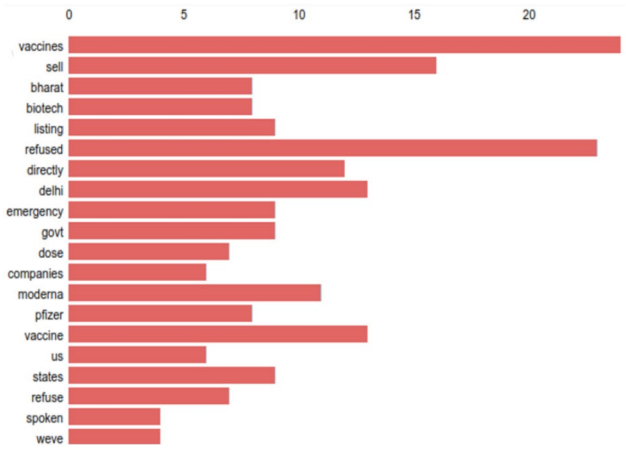

Fig. 12 Salient term frequencies in the top-20 topics detected from the negative sentiment tweets using LDA on 24 May 2021

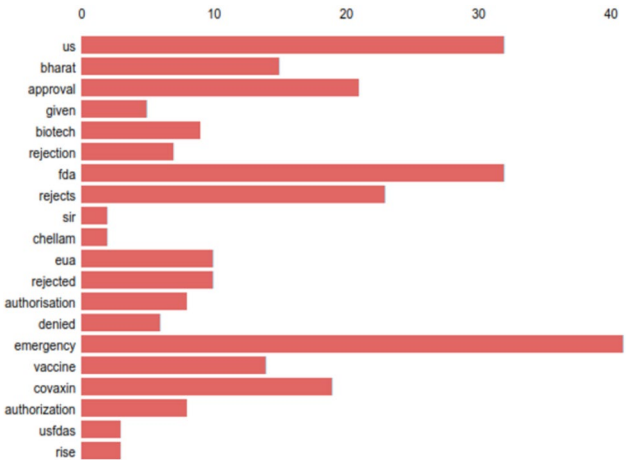

Fig. 13 Salient term frequencies in the top-20 topics detected from the negative sentiment tweets using LDA on 11 June 2021

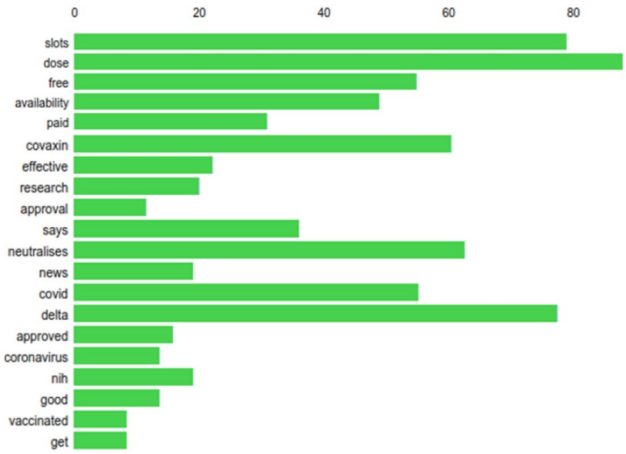

Fig. 14 Salient term frequencies in the top-20 topics detected from the positive sentiment tweets using LDA on 30 June 2021

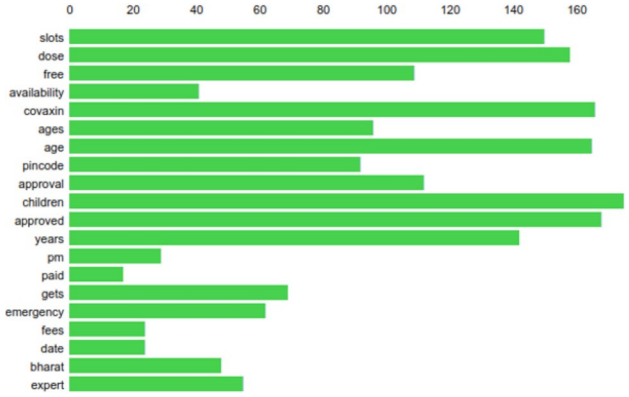

Fig. 15 Salient term frequencies in the top-20 topics detected from the positive sentiment tweets using LDA on 12 October 2021

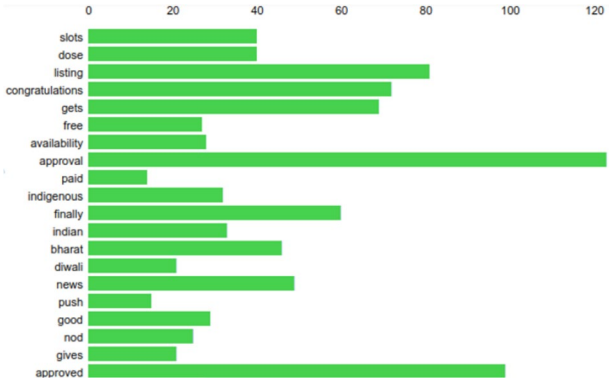

Fig. 16 Salient term frequencies in the top-20 topics detected from the positive sentiment tweets using LDA on 3 November 2021

As per Fig. 11, the top-salient terms on 21 April 2021 were 'covaxin', 'effective', 'neutralises', 'multiple', 'variants', 'icmr'. The trending theme was the positive news of the domestic vaccine Covaxin neutralizing multiple Covid-19 variants as per news released by the Indian Council of Medical Research (ICMR). The public received this news with optimism, as the news served to mitigate fears and apprehensions about the efficacy of the domestic brand.

Fig. 12 reveals the trending topics of 'vaccines', 'sell', 'refused', 'directly', 'delhi', 'moderna', 'vaccine', which corroborates with the news of Pfizer refusing to sell vaccines to the Delhi government on 24 May 2021. At this point the second wave had advanced throughout the country, and the overall outlook was negative and the positivity was low as indicated by the vocabulary at negative sentiment peaks, shown in Fig. 12.

The number of negative tweets spiked on 11 June 2021 (lowest positivity of -1) when an US-based organization (FDA) did not allow the approval of the domestic vaccine Covaxin for emergency use (topics: 'us', 'approval', 'fda',

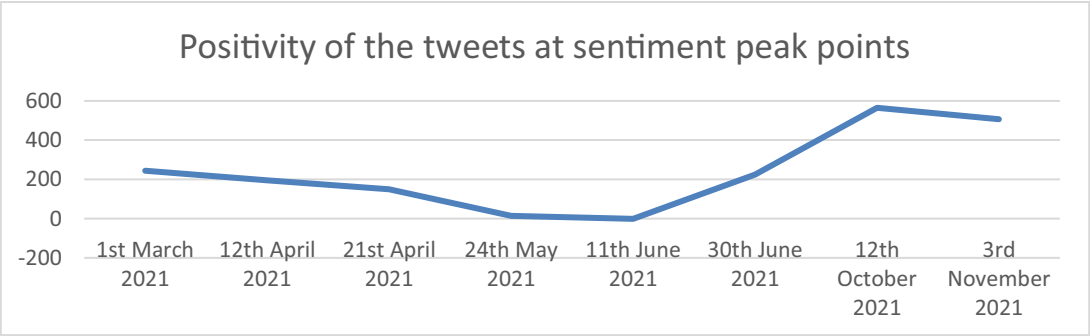

Fig. 17 Positivity graph showing the number of positive tweets in surplus of the number of negative tweets on the specific dates corresponding to sentiment peaks (shown in Table 3)

'rejects', 'emergency', 'covaxin') at a time when the second Covid-19 wave was at its peak (Fig. 13). The public morale and confidence were at their lowest at this point.

The salient terms detected on 30 June 2021 were−'covaxin', 'neutralises', 'delta', 'slots', 'dose', 'free', 'availability'. At a time when the number of Covid-19 cases was slowly declining, news of the efficacy of the domestic vaccine Covaxin neutralizing the Delta variant that caused the second wave, and its free availability for the public, boosted the public confidence once again, as evident from the positive vocabulary in Fig. 14.

The highest number of positive tweets (highest positivity score of 565) were recorded on 12 October 2021 (Fig. 15) when the domestic vaccine Covaxin got approval for administration to children aged between 2 to 18 years (topics: 'slots', 'dose', 'covaxin', 'age', 'children', 'approved', 'years'), indicating that is an example of policy-making in the right direction.

Once the second wave had significantly abated, the positivity towards vaccines increased and rose to an all-time high in the months of October-November 2021 as the public became more enthusiastic towards the vaccination program and expressed willingness to get vaccinated. The most frequently occurring salient terms on the date 3 November 2021 were−'listing', 'congratulations', 'gets', 'approval', 'finally', 'approved'. This points to the event of Covaxin getting global approval by World Health Organization (WHO). A positive spike in sentiments is observed on this occasion at the backdrop of an undercurrent of optimism and positivity at having overcome the worst of the deadly second wave.

The column of trending topics in Table 3 summarizes the primary themes (detected using LDA) that sparked an emotional discussion on Twitter. A scrutiny of the themes or trending topics in Table 3, over time, reveal a low confidence in the vaccination program and vaccine efficacy at the beginning. The positivity measure in Table 3 is computed as the difference between the daily count of positive and negative tweets, and is shown plotted as a function of time in Fig. 17.

As noted from Table 3 and the positivity curve in Fig. 17, a positive spike in sentiments was observed with news of the Prime Minister getting vaccinated dominating the discussions on 1 March 2021 (topics: 'india', 'pm', 'took', 'vaccine'). However, the positivity reduced significantly during the second Covid-19 wave which affected India in the months of April–July 2021. This was followed by days of apprehensions of imported vaccine availability as observed from the low positivity surrounding the news of Pfizer and Moderna deal cancellation (24/5/2021). Concerns about vaccine approval and vaccine efficacy of the domestic vaccine Covaxin predominated the discussions in the interim period. Public confidence got to an all-time high in October–November 2021 with news of vaccine availability for kids (12/10/2021) and WHO approval of the domestic brand Covaxin (3/11/2021). Additionally, the trending topics at sentiment peaks would help the government to frame policies to combat vaccine hesitancy and boost public confidence in the vaccination program. This includes alternative and faster strategies for vaccine availability, imported vaccine procurement, and obtaining global approval for domestic vaccine brands by speeding up the trials for vaccine approval, as observed from the major national/international events listed in Table 3 corresponding to high positivity values (12/10/2021, 3/11/2021).

5.4 Discussions

To summarize, in order to address the research questions raised in Sect. 2, we propose a novel approach for longitudinal sentiment analysis with dynamic topic modeling at positive and negative sentiment peaks. The answers to specific research questions are provided as follows. *RQ1: How to effectively use unsupervised sentiment analysis tools for predicting day-wise sentiments of Covid-19 vaccine-related tweets of users geo-located in India?* We performed

sentiment analysis of tweets originating from India, using AFINN, on a day-wise basis, in the duration of 12 December 2020 to 11 November 2021 when both the vaccination program and the second Covid-19 wave were simultaneously experienced in the country. *RQ2: How to effectively extract the topics of discussion on the days when positive and negative sentiments peaked on Twitter?* LDA was used for dynamic topic modeling at sentiment peaks corresponding to significant fluctuations in the positive and negative longitudinal sentiment graphs. *RQ3: How to correlate the extracted topics and sentiments with events of national and international importance that may have been the cause and effect of the outburst of opinions on social media platforms?* The topics detected using LDA are correlated with manually collated news articles on the days when positive and negative sentiments peaked to identify the national/international events that may have led to an outburst of opinions on social media. The main topics of discussion detected at the sentiment fluctuations using LDA are summarized as: (1) the Prime Minister takes a dose of the vaccine (2) approval for emergency use of Sputnik-V vaccine (4) concerns about the availability of vaccines and delay in getting approval for Covaxin, the domestic vaccine, from US-based FDA (5) euphoria about WHO approval of Covaxin and its approval for kids.

In general, the public sentiments expressed on Twitter, mostly positive, had an impact on boosting the public receptiveness towards the vaccination program. The government policy makers can derive useful insights from the positive and negative vocabularies of trending topics at the sentiment fluctuations, to take timely steps such as vaccine procurement, vaccine approval, and improve vaccine trials for efficacy evaluation, and above all, communicate all progress achieved to an anxious public who always tend to keep their hopes high even in the face of adversity as evident from the numbers of positive tweets as compared to the numbers of negative tweets.

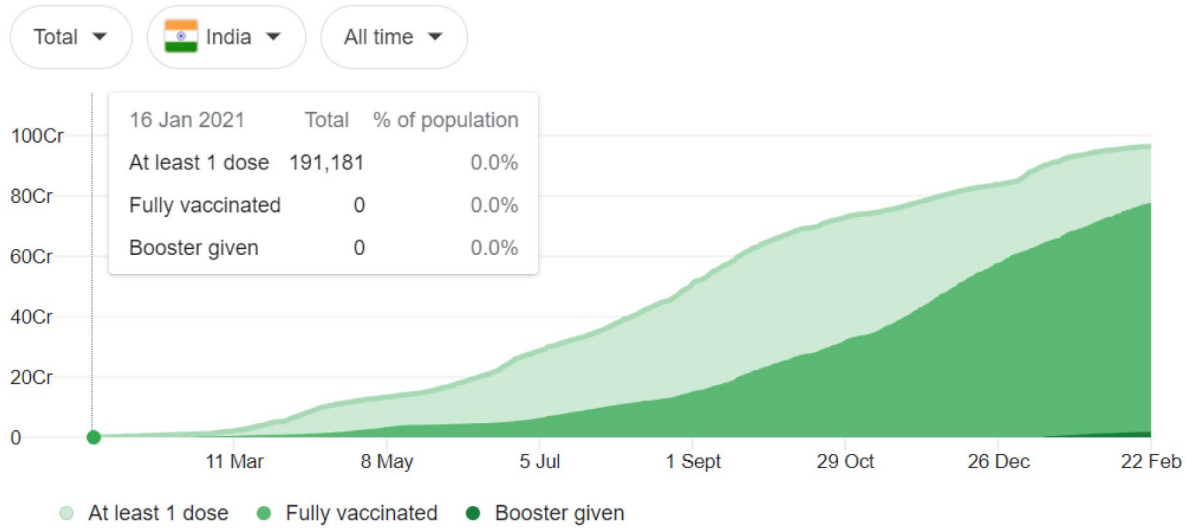
5.5 Correlating sentiments on social media with actual vaccination trends in India

The vaccination trends in India are shown in Fig. 18. This graph agrees with our previous observations. After a slow start in January 2021, the pace of vaccinations started picking up in March, and declined a bit during the second wave, and finally picked up pace in October and November, with the peak of vaccinations occurring around 21 October 2021, when the mark of 1 billion vaccinations (first or second dose) was crossed. The overall public sentiments towards vaccinations can thus be deemed to be positive. Notably, on 11 November 2021, 54.1% of the Indian population had got at least the first dose of vaccine. Recent studies on the public perception towards vaccination has established that there is increasing positivity and trust in regard of Covid-19 vaccinations (Saleh et al. 2023). However, some aspects that inculcate fear and doubts still remain, primarily regarding vaccine safety and the spread of disinformation. It is suggested that social media platforms may be used effectively by governments to disseminate fake information about vaccines. For instance, if negative sentiments spike, authorities can launch targeted social media campaigns or expedite vaccine shipments.

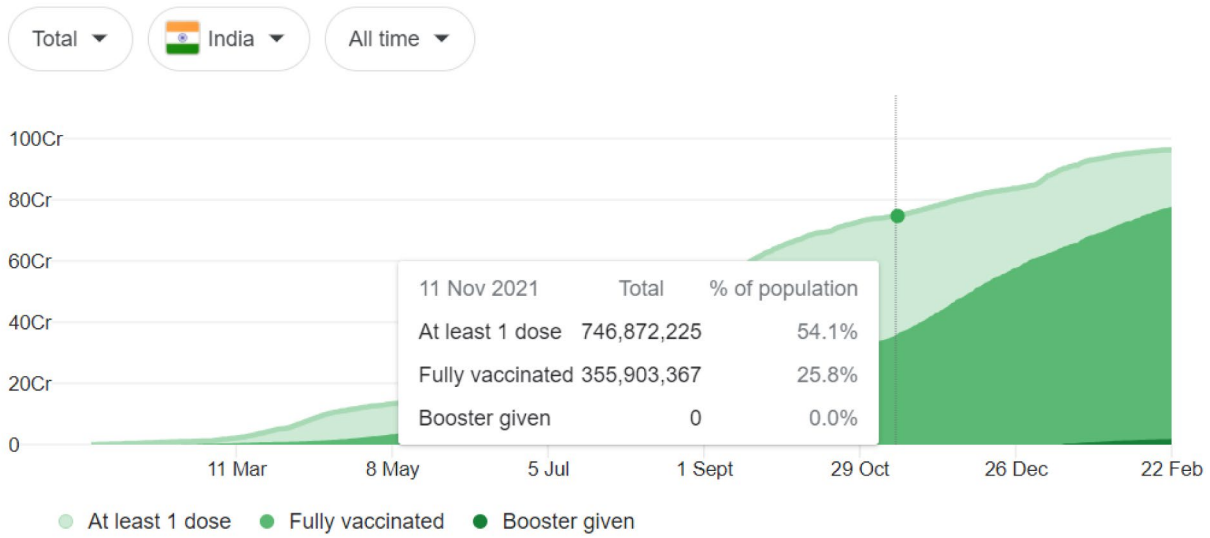
5.6 Challenges and limitations

Our work is not without its limitations. The English tweets that are analyzed for sentiments are not representative of the sentiments of the entire population of a country like India that has many languages and dialects. In the current experiments, the authors segregated and analyzed English tweets due to the ease of application of sentiment analysis tools. Unsupervised sentiment analysis tools like AFINN perform sentiment analysis of English texts only. Even pretrained transformer models like BERTweet and CT-BERT are trained on English tweets. Most languages lack a lexicon connecting words with sentiments or emotions. Though supervised models with neural networks at the core have been proposed for sentiment analysis of Hindi tweets (Gupta et al. 2021), such approaches require a large dataset annotated with sentiment labels for training the models. For handling multi-lingual texts, Google Translate API (https://translate.google.com) is often integrated with sentiment analysis tools attuned to English texts which may not lead to a desirable outcome due to translation-induced errors (Rashid et al. 2024; Mohammad et al. 2016). The machine translation service provided by Google can achieve both forward and backward translation. However, the translated text is prone to lingual errors as proved by researchers in Mondal et al. (2019) who worked on the translation of English to Bengali and vice versa. Future research in the development of multilingual sentiment analysis systems based on multilingual transformer models such as mBERT, XLM, and XLM-R (Bhattacharjee et al. 2024; Doddapaneni et al. 2021), or use of efficient translation APIs such as Yandex translation API (Miller 2023) would aid in effective translation of social media posts to Indic languages like Hindi. Additionally, the use of word embeddings based on FastText encoding of the n-gram components of a word makes it possible for pretrained models like ALBERT to handle the morphological variations in the multi-lingual text in Indian tweets in a more effective manner (Kakwani et al. 2020).

Another limitation is the algorithm-induced biases that contribute to the misinterpretation of sentiments in vaccine-related discussions. Unsupervised models like AFINN and VADER do not require training, are not affected by class imbalances, and are relatively fast and easy to execute



(a)



(b)

Fig. 18 Vaccination trends [data provided by Ministry of health and family welfare, Government of India]. Details provided for **a** vaccination data on 16 Jan 2021, **b** vaccination data on 11 Nov 2021

algorithms. However, they do have some limitations. A manual scrutiny of the sentiments predicted by AFINN revealed that the use of certain words that were semantically ambiguous, sometimes, contributed to a wrong prediction. For instance, it was found that the word "positive" that was used to indicate a corona-positive lab result resulted in the tweet being labeled as positive by AFINN, while it actually indicated to a negative sentiment. As an example, the tweet "*New #COVID19 strain: 20 #UK returnees to #India test positive for the new variant.*" was incorrectly labeled as positive (score of + 2) by AFINN. The misinterpretation of "positive" and "negative" was responsible for most of the mis-classifications. Similarly, some tweets that contained the word "emergency" in the context of the emergency use authorization of a vaccine was mis-interpreted by AFINN as a negative sentiment. One instance is the tweet "*#WHO*

Grants Pfizer-BioNTech #Coronavirusvaccine For Emergency Use #PfizerBioNTech" which was wrongly predicted as negative (score of -1) by AFINN. An interesting conflict of predictions was observed when on the positive occasion of WHO granting approval for emergency use of vaccines, one associated tweet "*WHO Grants 'Emergency Validation' For Pfizer-BioNTech Covid Vaccine, Paving Way For Global Access*" was classified as negative by VADER and positive by AFINN. Another tweet referring to the same event "*The @WHO World Health Organization has approved the #PfizerBioNTech #vaccine for emergency use, paving the way for lower and middle-income countries to begin immunizing their populations against #Covid*" was classified as positive by VADER, though it was classified as neutral by AFINN due to the occurrence of both positive (approved) and negative words (emergency) in the same tweet. This establishes that AFINN can derive the emotional tone of the text in a more effective manner than VADER, agreeing with the numerical quantification of results on the annotated subset of tweets in Fig. 4.

A small rule-based post-processing step may be added to correct such semantic errors. Examples of rules that may be integrated with lexicon-based methods are:

(i) The co-occurrence of words "test" and "positive" in the tweet would result in the label being modified as "negative".
(ii) The co-occurrence of words "test" and "negative" in the tweet would result in the label being modified as "positive".
(iii) The co-occurrence of words"approve", "emergency" and "use" in the tweet would result in the label being modified as "positive".

The performance of BERTweet and CT-BERT depend, to a large extent, on the size of the annotated training set and whether its class distribution is balanced or not. BERTweet and CT-BERT are supervised models pre-trained on COVID-19 text, and hence they are able to distinguish phrases specific to Covid-19 that are present in the limited training set. However, these models are sensitive to the insufficiency of training data and an imbalanced class distribution which are common issues with pandemic-related tweets.

Additionally, there is a lack of annotated tweets for Covid-19 vaccination based discussions on Twitter that makes supervised sentiment analysis a difficult task. A small annotated version of the dataset containing 6,000 tweets is available for supervised classification (https://www.kaggle.com, gpreda, all-covid19-vaccines-tweets [Accessed last on 31st Dec 2021]. 2021). However, since we have concentrated on a larger duration for the analysis, covering a larger number of tweets (44,130), therefore we decided to go for unsupervised sentiment analysis to detect the sentiment peaks. We chose AFINN since it achieved higher performance than VADER or TextBlob. AFINN has been used by several researchers in the past to gain useful insights into the public opinion (Nielsen 2011; Marcec and Likic 2022), and we took the cue from these previous work for our experiments as well.

6 Conclusion

The vaccination drive for Covid-19 pandemic is underway worldwide, with 67% of the world's population having received both primary doses of the vaccine as on 31st December 2023.[2] Initial public skepticism has given way, over time, to a more positive outlook towards vaccination which is considered as the one of the most effective means for achieving immunity. However, vaccinating the complete population in under-developed and developing countries is a dream yet to be realized. In the loom of the uncertainty over the vaccination process, government policies, availability of vaccines, side-effects of vaccines, and the emergence of new mutants of the Coronavirus, people tend to vent their frustration, fears, hopes, and opinion on social media platforms. This paper evaluates the vaccine-related tweets posted on Twitter from users in India in the critical period of 12 December 2020 to 11 November 2021 as India battled and recovered from the deadly second wave of the Coronavirus, while the vast population of 1.3 billion Indian citizens were in the process of getting convinced on getting vaccinated. We trace the public sentiments in this duration through longitudinal sentiment graphs plotted on a day-wise basis using AFINN which is an unsupervised sentiment analysis tool (and cross-verified using VADER, and pre-trained transformer models BERTweet and CT-BERT), and find the positive and negative vocabularies topics of discussion on the dates which led to the sentiment fluctuations using LDA and salient term frequency analysis. Our findings indicate that, overall, the outlook of the users is positive towards the vaccination program, as indicated by the positivity curve plotted over time. Eight time points along the longitudinal sentiment graphs indicate sentiment fluctuations corresponding to peaks in the positive and negative sentiments plotted on a day-wise basis. The main topics of discussion detected at the sentiment fluctuations using LDA are summarized as: (1) the Prime Minister takes a dose of the vaccine (2) approval for emergency use of Sputnik-V vaccine (4) concerns about the availability of vaccines and delay in getting approval for Covaxin, the domestic vaccine, from US-based FDA (5) euphoria about WHO approval of Covaxin and its approval for kids. The public response got warmer and more

[2] https://data.who.int/dashboards/covid19/vaccines

and more positive in October–November 2021 by when a majority of the country's population had received the first dose of the vaccine as the country progressively recovered from the second Covid-19 wave. The case study conducted in this research is unique in the following aspects: (1) nearly a year-long data, (2) major national events linked with sentiment fluctuations, and (3) combination of sentiment modeling and LDA for topic analysis. AFINN analysis revealed that 51.38% of the 44,130 tweets were neutral, while 38.84% were positive, and 9.78% negative.

These findings could guide policy makers in gathering intelligence on misinformation and associated sentiments, and planning counter-measures to combat anti-vaccine campaigns. Real-time monitoring of negative peaks can prompt immediate governmental responses, communication strategies, or logistic adjustments. Our work suggests a strategy which would enable early detection of the loss of confidence in vaccines, so that suitable measures such as imported vaccine procurement, domestic vaccine approval, and imported and domestic vaccine efficacy trials be conducted at a faster pace in order to restore public optimism. This study informs future strategies to counter vaccine hesitancy through targeted communication aimed at vulnerable groups that experience high anxiety and psychosocial burden during the pandemic. The limitations of this study include exclusion of non-English tweets, lack of annotated data which constrains the use of supervised models, and skewed or imbalanced data in which negative tweets are significantly less than positive or neutral tweets. As the future scope of this work, we suggest subjectivity analysis of tweets (Yaqub et al. 2020) as an auxiliary step to sentiment analysis, since it would reflect the beliefs, emotions and speculations of the users, in addition to the polarity detection achieved by sentiment analysis tools. This would aid in accessing the emotional states of users, and the public in general, facilitating improved decision-making based on opinions expressed on the Web. The results could also be enhanced by using a Covid-19 based text summarization model (Karotia and Susan 2023) in conjunction with sentiment analysis for effective opinion summarization and topic analysis from social media posts. Other possible future extensions include using domain-adaptive pretraining on larger vaccine-labeled corpora, cross-lingual sentiment detection, advanced stance detection, or real-time monitoring dashboards.

Author contributions S.S wrote the main manuscript and supervised the research. A.B conducted the primary investigation. All authors were involved in the conceptualization, methodology, data curation, and software validation.

***Abstract*—This study introduces a newly developed Modified Sigma-Pi Neural Network (MSPNN) architecture designed to identify the dynamics of the plant. The proposed structure is an extension of the classical sigma-pi neural network (SPNN) and includes a self-feedback loop at the output node of the output layer. Since sigma-pi artificial neural networks contain additive and multiplicative units in their structure. We apply the back-propagation optimization algorithm to train the proposed MSPNN model. The results of the proposed neural network are compared with preexisting models, such as the Jordan neural network, the feedforward neural network, and the sigma-pi neural network. An analysis of the simulation data indicates that the proposed architecture of MSPNN is more effective than the other models.**

***Index Terms*—Identification, Sigma-Pi neural network, dynamical systems**

I. Introduction

The application of dynamical systems has grown significantly in engineering [1]. Nonlinear systems are challenging to solve, so system identification is required to understand mathematical modeling [2], [3]. The system identification process uses various techniques, including ANN, genetic algorithms, fuzzy systems, etc. ANNs are widely used in many aspects of our lives [4], [5]. They are an essential component of modern technology. Their data processing and analysis application is one of the most exciting areas for neural networks [6]. We refer to a class of ANNs as higher-order neural networks (HONNs). The SPNN model belongs to HONNs and has a rapidly expanding field [7]. The recurrent layer of sigma-pi units has product units. We handle these units using a procedure that involves addition and multiplication. In contrast, the output layer has summing units [8]. The weights of the input to the hidden layer remain fixed at unity. The weights recurrent to the output layer are adjustable [9]. An optimization algorithm obtains these tunable weights during the training process [10]. It is possible to optimize the parameters of the ANN model in different ways. The backpropagation algorithm is the most essential optimization method in machine learning [11]. Using the biological concept of recurrent neural networks, sigma-pi neural networks represent an emerging area of study in machine learning [12]. They are an effective tool for handling numerous data, such as signals, pictures, and time series data [13]. Sigma-Pi neural networks are known for their ability to represent complicated relationships, contextual information, and time series dependencies over long periods [14]. A more significant approximation with a faster convergence property, better storage capacity, and stronger fault tolerance capabilities are just a few of the distinctive qualities of higher-order neural networks (HONNs) compared to ordinary neural networks [15]. HONN is a neural network that offers a stronger classification capacity than linear neurons by providing nonlinear decision limits [16]. HONNs simultaneously combine additive and multiplicative units. As an example of HONN, Shin and Gosh put out the Sigma-pi model in 1991, which has a significantly different design from other ANN models [17], [18]. Since they use additive and multiplicative structures compared to many artificial neuron networks [19]. This article introduces a modified sigma-pi neural network (MSPNN) model, which aims to identify the dynamics of the given dynamical plant. During training, a backpropagation optimization approach is applied to reduce identification errors. Different neural networks, such as the sigma-pi neural network, the Jordan network, and the feedforward network, are used to compare the proposed strategy. I have organized this paper as follows. The MSPNN model is described in section 2 in terms of its architecture and mathematical formulation. In section 3, a learning approach for training parameters is described. The results of the simulation are presented in section 4. The conclusion is presented in section 5, and references are given at the end.

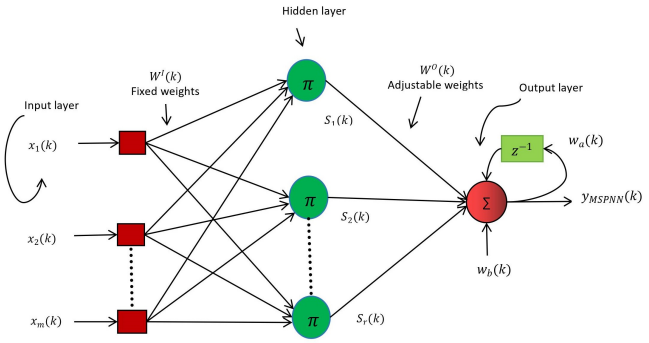

Fig. 2: Modified sigma-pi neural network model

II. Overview of MSPNN and SPNN model

The article introduces the architecture of the SPNN model, comprising three layers: input, hidden, and output, as illustrated in Figure 1. As shown in Figure 2, the proposed MSPNN model is an extension of the standard Sigma-Pi Neural Network model. MSPNN also includes 3 layers: input, hidden, and output. The proposed MSPNN model has a self-feedback loop that sends values later to the output node of the output layer. This is what makes it different from the SPNN model. Here, $X_j(k) = \{x_1(k), x_2(k)...x_m(k)\}$ represents the external input vector m-dimensional. The weights that connect the input layer to the recurrent layer remain fixed to unity. This $w_{qu}^O(k)$ represents the adjustable weights of the uth recurrent layer to the qth output layer. In the architecture of the MSPNN model, an additional self-feedback loop is present with a tunable weight $w_a(k)$ at the output neuron and $w_b(k)$ an adjustable bias weight at the output neuron. When a hidden layer initiates a field, it performs the following calculation:

$$V_{ir}(k) = \prod_{j=1}^{m} x_j(k) \tag{1}$$

The response of hidden neurons is:

$$S_{ir}(k) = V_{ir}(k) \tag{2}$$

The nonlinear activation function (tangent hyperbolic activation function) is applied to each hidden neuron, and then it produces the following output:

$$P\{V_{ir}(k)\} = tanh\{V_{ir}(k)\} \tag{3}$$

output layer performs the result of the output node.

$$V_o(k) = \left\{ \sum_{q=1} P\{V_{ir}(k)\} w_{qu}^O(k) \right\} \tag{4}$$

The $3rd$ layer has a linear activation function, purelin $f(.)$. The proposed model with a linear activation function yields the following output:

$$y_{MSPNN}(k) = f\{V_o(k)\} \tag{5}$$

III. Learning algorithm

A learning approach obtains the parameter update equations. To derive the equations for the weight modifications, we employed the dynamic backpropagation algorithm [20]. It is a method of minimizing an objective function based on gradient descent. We use the chain rule to find the partial derivatives of the error function in relation to the network weights. This method gives us the parameter update equations. During training, the parameters are adjusted to reduce the identification error $e_i(k)$. The objective function of the study is the MSE, or instantaneous mean squared error.

$$E(k) = \frac{1}{2} {e_i}^2(k) \tag{6}$$

$$E(k) = \frac{1}{2} [y(k) - y_{MSPNN}(k)]^2 \tag{7}$$

where $E(k)$ is the mean squared error (MSE), $y(k)$ is the desired output, and $y_{MSPNN}(k)$ is the proposed model's output. For every weight parameter, the updated equations are developed by subtracting the significant component of the objective function from the weight value in the derivative $2nd$ of the objective function. The equation below describes the process of updating the model parameter.

$$W_{new}(k+1) = W(k) - \eta \frac{\partial E(k)}{\partial W(k)} \tag{8}$$

The learning rate, denoted as η, ranges from 0 to 1. The chain rule is used to find the equations for updating the output parameters.

$$\frac{\partial E(k)}{\partial w_{qu}^O(k)} = \frac{\partial E(k)}{\partial y_{MSPNN}(k)} \times \frac{\partial y_{MSPNN}(k)}{\partial V_o(k)} \times \frac{\partial V_o(k)}{\partial w_{qu}^O(k)} \tag{9}$$

$$where \quad \frac{\partial E(k)}{\partial y_{MSPNN}(k)} = -e_i(k), \frac{\partial y_{MSPNN}(k)}{\partial V_o(k)} = 1, \frac{\partial V_o(k)}{\partial w_{qu}^O(k)} = S_{ir}(k) \tag{10}$$

$$\frac{\partial E(k)}{\partial w_{qu}^O(k)} = -e_i(k)\{S_{ir}(k)\} \tag{11}$$

$$\frac{\partial E(k)}{\partial w_b(k)} = -e_i(k)(-1) \tag{18}$$

IV. Simulation Outcomes

One non-linear system is used in the simulation study to compare how well the MSPNN, SPNN, JRNN, and FFNN models work. The initial values of the parameters are selected at random, and the starting learning rate is 0.00006. Based on

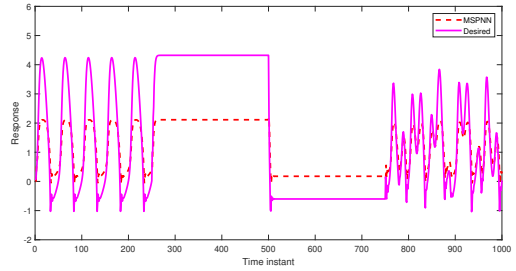

Fig. 5: Validation response obtained from MSPNN

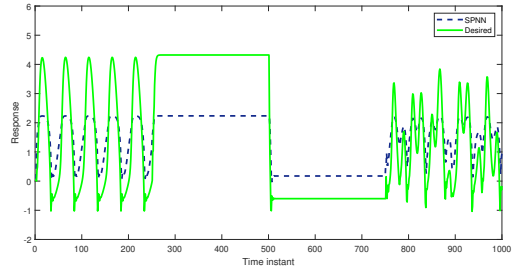

Fig. 6: Validation response obtained from SPNN

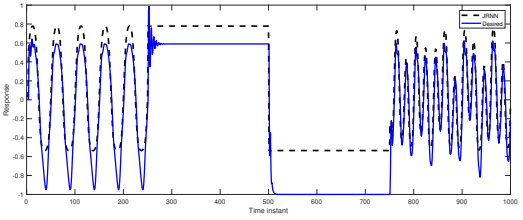

Fig. 7: Validation response obtained from JRNN

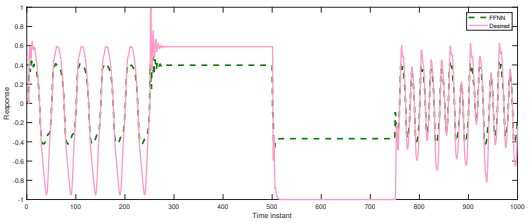

Fig. 8: Validation response obtained from FFNN

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 07:25:20 UTC from IEEE Xplore. Restrictions apply.

[17], the dynamics of the plant is represented by the non-linear difference equations.

$$y_p(k) = F[y_p(k-1), y_p(k-2)] + r_e(k) \tag{19}$$

where

$$F = \frac{(y_p(k-1)y_p(k-2)(y_p(k-1)+2.5)}{1+y_P^2(k-1)+y_P^2(k-2)} \tag{20}$$

F is considered unknown but differentiable and $r_e(k)$ is the externally applied input. A total of 600 iterations and 1000 samples are utilized to train the system's parameters at an initial learning rate of 0.00006. The external input used is $r_e(k) = 0.3\cos(\pi k/45)$ for $0 < k < 650$ and $r_e(k) = 0.3\sin(\pi k/50) + 0.1\cos(\pi k/45)$ for $650 < k < 1000$. We can see the mean squared error (MSE) and mean average error (MAE) graphs after the training process in Fig. 3 and Fig. 4. Table 1 presents the performance of the statistical error after training. Compared to the other models, the suggested MSPNN model has lower MSE, MAE, and root mean squared error (RMSE) values. Once training is complete, we apply an additional external input to assess the model's capacity for generalization. Here is the updated external input:

$$r_e(k) = \begin{cases} \sin\left(\frac{\pi k}{25}\right) & \text{if } k \leq 250 \\ 1 & \text{if } 250 < k \leq 500 \\ -1 & \text{if } 500 < k \leq 750 \\ 0.3\sin\left(\frac{\pi k}{25}\right) + 0.1\sin\left(\frac{\pi k}{32}\right) & \\ +0.6\sin\left(\frac{\pi k}{10}\right) & \text{if } 750 < k \leq 1000 \end{cases} \tag{21}$$

Figures 5-8 show the validation responses derived from the MSPNN, SPNN, JRNN, and FFNN models. The visual comparison of each model's ability to reveal the dynamics of the intended system throughout the validation stage is shown in these graphics. The MSPNN's validation response demonstrates a closer alignment with the actual system outputs, indicating its superior accuracy and ability to handle complex nonlinear behaviors.

V. Conclusion

This article proposes the MSPNN model, a modified sigma-pi neural network. Dynamical systems with non-linear dynamics can be identified with it. The suggested neural network is a modified version of the current SPNN model. It has a self-feedback loop whose weight can be changed. The plant's previous value and the external input's current value have been the only two inputs used to execute the suggested model. We apply the backpropagation optimization algorithm to train the adjustable weight parameters. This article compares the proposed MSPNN model with several other models (such as SPNN, JRNN, and FFNN) after training. The simulation analysis results are shown in Table 1. They show that the proposed network works more efficiently and has lower error rates (MSE and MAE) than the others. The enhanced functionality of the proposed model is attributed to its architectural design, which includes a self-feedback loop in the output layer, which improves the network's ability to handle temporal dependencies and nonlinear dynamics while reducing approximation errors.

Abstract
The paper presents the analysis and discussions on a Surface Plasmon resonance (SPR) based Photonic Crystal Fiber (PCF) Refractive index (RI) Biosensor, designed specifically to detect two of the most widespread diseases—HIV-caused AIDS and Sickle cell anaemia. The detection is purely dependent on the RI of the affected cells (1.42 for HIV and 1.38 for Sickle cell anaemia), compared to 1.35 for normal cells. The proposed RI biosensor has concave-shaped microchannels on either side of the PCF acting as a channel, where the plasmonic material interacts with the bio-analytes of HIV-infected and sickle cells. Additionally, a layer of MXene, an emerging 2D plasmonic enhancer is coated on the microchannels, to enhance the sensor performance in terms of sensitivity and confinement loss. Moreover, the optimized structure achieved wavelength sensitivities of 10,571.43 nm/RIU and 3500 nm/RIU for the Gold PCF sensor, and 14,142.86 nm/RIU and 4000 nm/RIU for MXene-Gold PCF sensor for HIV-infected cell and Sickle cell anaemia, respectively. Hence, the proposed SPR biosensor using MXene has the potential for the early detection of HIV and Sickle cell anaemia.

Keywords MXene-coated · Sickle Cell Anaemia · HIV · Concave-Shaped Microchannel · Surface Plasmon Resonance · Confinement Loss

1 Introduction

Surface plasmon resonance (SPR) is an extensively preferred optical technique employed in photonic crystal fibers (PCF) which is an evolved form of optical fiber consisting of periodic arrangement of micro structured air holes for enhanced light confinement (Elabdein et al. 2024). SPR technique entails the collective excitation of surface plasmons which

Published online: 20 April 2025

are electromagnetic waves that propagates parallel to the metal–dielectric interface. The surface plasmons resonate with the light striking on the metal and leads to a dip in the reflected light intensity thereby changing the reflection conditions, making it very quick to respond to any small refractive index (RI) variations in vicinity. Even small traces of bio-analyte could be detected by exploiting this special feature of the SPR technique (Capelli et al. 2023; Divya et al. 2023).

Of late, this technique has been explored widely by integrating it with PCFs and has opened various new gates in the field of biosensing, as it provides a real time and label-free monitoring. PCFs are fibers having perforated air holes along the length and same are worked as cladding and widely used for applications like supercontinuum generation (Khamaru and Kumar 2024a, b; Garg et al. 2024), terahertz communication and sensing (Singh et al. 2024a, b) etc.

SPR based PCF RI biosensors offer a promising diagnostic tool in the field of medicine (Opoku et al. 2023). It has enabled the detection of various diseases like cancer, malaria, tuberculosis and coronavirus (Singh and Prajapati 2023; Meshginqalam 2022; Divya et al. 2024; Gupta et al. 2023). These diseases are examined based on the RI differences in the bio-analytes between the normal blood cell and the infected blood cell, as these biosensors are highly sensitive to RI variations.

The utilization of plasmonic materials like Gold, Silver or Copper facilitates and provide a platform for the occurrence of SPR (Chaudhary et al. 2022; Zhang et al. 2024; Luo et al. 2022). Gold is the often-favoured plasmonic material due to its excellent chemical stability and biocompatibility. Silver and Copper also exhibit certain qualities like high conductivity which make it good plasmonic materials but in view of real-time fabrication, silver and copper suffers from environmental oxidation. The sensitivity can be further enhanced by using certain 2-D materials like Titanium dioxide (TiO_2) (Zhang et al. 2021), Germanium-antimony-telluride ($Ge_2Sb_2Te_5$) (Zhang et al. 2022), Molybdenum Disulphide (MoS_2) (Kumar et al. 2024), black phosphorous (Gupta et al. 2025) which are known as plasmonic enhancers. These materials, when coupled with the plasmonic material such as gold or silver, yield enhanced sensitivity (Zhang et al. 2021). Nonetheless, these 2D materials put forward certain constraints like reduced conductivity, low adsorption stability, poor biocompatibility and high hydrophobicity. However, there is a class of 2D materials called MXene, which has excellent conductivity, flexibility in functionalization, large surface area and hydrophilic in nature, allowing for uniform dispersion of plasmonic material (Mumtaz et al. 2022).

MXenes are a group of 2D materials discovered by Naguib et al. in 2011 (Jeon et al. 2020) consisting of a transition metal carbide or nitride or carbonitride in a honey-comb like structure. MXenes are synthesized from its precursor MAX phase by selective etching using Hydrofluoric acid etchants and delamination. Further, MXene's properties can be altered based on our objective by changing the surface functional groups (Bhargava Reddy et al. 2022). This paper presents a MXene-Gold coated concave shaped microchannel SPR PCF multipurposed biosensor.

In recent years, many works have been published in the PCF-SPR sensing domain. In 2024, a D-shaped dual core SPR PCF sensor was reported for the precise measurement of a broad analyte RI range of 1.22 to 1.36, with a maximum sensitivity of 22,100 nm/RIU (Fei et al. 2024). Another work on an SPR PCF Gold coated sensor was reported in the same year. It has achieved a sensitivity of 14,100 nm/RIU (Melwin and Senthilnathan 2024). Yimin Mao et al. presented a highly sensitive MXene coated SPR PCF RI sensor for cancer detection which demonstrated the sensitivity enhancing potential of MXene. It reported a maximum wavelength sensitivity of 9286 nm/RIU for breast cancer cell (Mao et al.

2024). Various MXene coated SPR PCF sensors were also proposed by researchers like the one reported in 2023 for bio-analyte detection. Farhan Mumtaz et al. presented a novel D-shaped highly sensitive SPR PCF RI sensor exhibiting a very high wavelength sensitivity of 47,260 nm/RIU at an analyte RI of 1.42 (Mumtaz et al. 2022). Although, SPR PCF MXene coated Biosensors for the detection of various diseases have already been reported in available literatures, none has been reported yet for the detection of both HIV and Sickle cell anaemia using SPR PCF Biosensor. Elizabeth Caroline Britto et al. exhibited a paper on photonic crystal-based nanoscale multipurpose biosensor for detection of HIV, anaemia and brain tumor. It achieved a sensitivity of 1034 nm/RIU for HIV and 1071 nm/RIU for anaemia (Britto et al. 2024). So, the proposed design is focused mainly on the detection bio-analytes of Human Immunodeficiency Virus (HIV) causing AIDS and Sickle Cell Anaemia using SPR PCF RI Biosensor.

HIV is an infection that invades our body's immune system. The extreme stage of infection leads to an extremely dangerous condition called Acquired Immuno-Deficiency Syndrome (AIDS). Globally, around 40 million people are currently affected with this infectious disease among which 1.4 million are children. The death toll ranges up to 50 million in the past 40 years (Parums 2024). The high mortality rate is the consequence of the fact that it has no definite cure. However, there exists many treatment approaches like antiretroviral therapy (ART) that has potentially expanded the life span of the infected individuals by reducing the viral load content in the body (Gandhi et al. 2023). But this is only effective in the early stages of infection, which necessitates the early diagnosis of the HIV infection. There are several diagnostic tools for detecting HIV, such as Enzyme-Linked Immunosorbent Assay (ELISA) and rapid antibody tests (Tavakoli et al. 2017). But these techniques pose certain constraints like limited sensitivity (during acute infection stage), need for labelled antibodies and failure to detect HIV subtypes. The proposed SPR PCF RI biosensor appears to be a superior detection technique in comparison with most conventional techniques, as it provides a label-free detection with a potential of achieving lower detection limits giving higher sensitivity. Another benefit of using SPR PCF RI Biosensor includes its broad specificity, which allows for the detection of multiple HIV subtypes (HIV1 and HIV2). HIV1 and HIV2 are the subtypes of HIV. This paper focusses on HIV1 because it is more common and more easily transmitted compared to HIV2, which is rarer. The RI of normal blood cell bears a value of 1.35, while that of HIV1 is 1.42. This increment in the RI of blood cell after infection occurs as a result of viral load accumulation in the cell, leading to the alteration of the cellular composition (altered protein and lipid concentration) (Kumar et al. 2022; El-assar et al. 2023).

Another suitable application for the proposed sensor is the detection of Sickle Cell Anaemia. It is an inherited disorder resulting in abnormal haemoglobin which in turn alters the appearance of the red blood cells to C or sickle shaped cell. The sickle cell leads to constricted blood flow causing further complications like anaemia and infection. The treatment involves only oral medications to reduce pain and further damage of the cell. It doesn't have a definite cure (Tisdale et al. 2020). However, there are several diagnostic techniques like genetic testing, haemoglobin electrophoresis, Complete blood count (CBC) etc. However, SPR PCF RI Biosensor offers much more promising results as it is a label-free technique providing higher sensitivity. The normal cell RI is, again, 1.35. But the RI of sickle cell anaemia is found to be 1.38 (Kumar et al. 2022). The change RI occurs due to the sickling of cells as it causes Haemoglobin S (HbS) polymerization (Kumar et al. 2022).

The paper proposes the design and structural analysis of a MXene coated concave-shaped microchannel SPR PCF sensor for the detection of HIV infected cell and Sickle cell anemia. The proposed sensor offers a high sensitivity of the discussed biological cells.

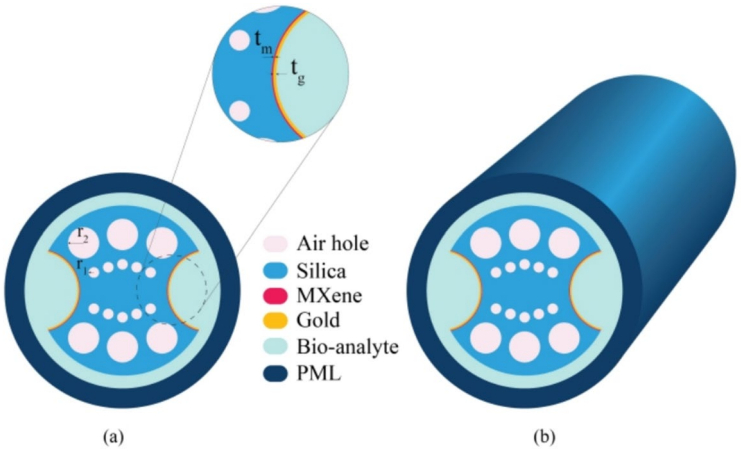

Fig. 1 **a** 2D view of the Microchannel MXene coated sensor, **b** 3D view

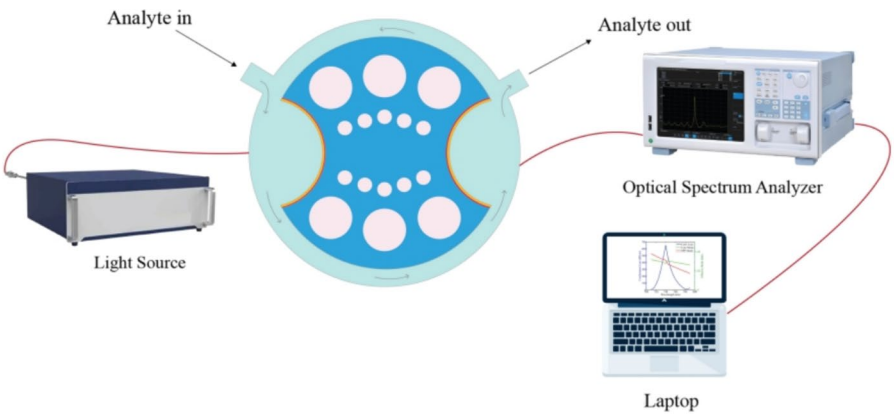

Fig. 2 Proposed experimental arrangement for the presented bio-sensor

Apart from high sensitivity, the designed PCF- SPR sensor is proposed for the for the detection of sickle cell and HIV.

2 Structural design of the proposed concave-shaped microchannel spr pcf sensor

2.1 Structural design

The illustration of the proposed sensor design and the experimental setup is depicted in Fig. 1 and 2. The structural design contains dual sets of airholes arranged in a concentric semi-circular pattern on both the halves of the circular PCF sensor of radius 4200 nm. The radii of the small and big airholes are defined as r_1 and r_2 respectively.

To ensure enhanced interaction of the core mode with plasmonic material, few airholes from both the semicircular concentric sets are eliminated for the incorporation of the concave shaped microchannels on either side of the PCF (Majeed and Ahmad 2024). The arrangement of these airholes is done against a fused silica material background, which forms the core of the PCF. The plasmonic material, gold (t_g) is coated on the concave shaped microchannel on either side of the PCF, which lies in contact with the analyte layer. Additionally, a 14 nm (t_m) layer of MXene (plasmonic enhancer) is sandwiched between silica and gold film of the concave shaped microchannel. This hybrid layer of gold and MXene promotes a more effective coupling and also enhances the field interaction with the analyte. Consequently, this results in an elevated sensitivity with lower detection limits (Mu et al. 2023). The analyte layer has a thickness of 0.5 µm and it contains the bio-analytes of HIV infected cell and Sickle cell anaemia affected blood cells, with a RI of 1.42 and 1.38 respectively. Lastly, a Perfect Matching Layer (PML) of 0.7 µm thickness is added to minimize the electromagnetic wave reflections and for the absorption of radiation energy (Tasnim et al. 2021).

The main core-forming backdrop material is silica, whose RI is given by the wavelength dependent Sellmeier equation,

$$nsi = \sqrt{\left(1 + \frac{\left(B_1 \times \lambda^2\right)}{\lambda^2 - C_1} + \frac{\left(B_2 \times \lambda^2\right)}{\lambda^2 - C_2} + \frac{\left(B_3 \times \lambda^2\right)}{\lambda^2 - C_3}\right)} \tag{1}$$

where $B_1, B_2, B_3, C_1, C_2 and C_3$ are Sellmeier coefficients bearing values of 0.69616300, 0.407942600, 0.897479400, $4.67914826 \times 10^{-3}\mu m^2$, $1.35120631 \times 10^{-2}\mu m^2$, $97.934002\mu m^2$ respectively (Li et al. 2023).

Drude-Lorentz model is used to determine the electrical permittivity of the plasmonic material gold, followed by calculating its square root, resulting in the RI of gold.

$$\varepsilon_{Au} = \varepsilon_{\infty} + \frac{\omega_D^2}{\omega\left(\omega + i\gamma_D\right)} - \frac{\Delta\varepsilon\Omega_L^2}{\left(\omega^2 - \Omega_L^2\right) + i\Gamma_L\omega} \tag{2}$$

where ε_{∞} is given by 5.9673 and ω_D, γ_D and $\Delta\varepsilon$ are the plasma frequency, decaying frequency and weighting factor respectively (Khamaru and Kumar 2024b)

$$n_{Au} = \sqrt{\varepsilon_{Au}} \tag{3}$$

The RI of the 2-D plasmonic enhancer MXene can be determined by fitting the curve using the experimental data of the real and imaginary part of permittivity as a function of wavelength (Dillon et al. 2016). The data specifically represents the permittivity of Ti_3C_2Tx, where T is the surface termination element. Fluorine is taken for this proposed case. We obtain two sets of sixth-order polynomial equations representing the real and imaginary parts of permittivity, ε_1, and ε_2, respectively.

$$\varepsilon_1 = p_1 \times (\lambda^6) + p_2 \times (\lambda^5) + p_3 \times (\lambda^4) + p_4 \times (\lambda^3) + p_5 \times (\lambda^2) + p_6 \times (\lambda) + p_7 \tag{4}$$

$$\varepsilon_2 = q_1 \times (\lambda^6) + q_2 \times (\lambda^5) + q_3 \times (\lambda^4) + q_4 \times (\lambda^3) + q_5 \times (\lambda^2) + q_6 \times (\lambda) + q_7 \tag{5}$$

The real and imaginary part of MXene's RI can be obtained from the following equation (Kumar et al. 2023)

$$n^2 = \frac{\sqrt{\varepsilon_1^2 + \varepsilon_2^2} + \varepsilon_1}{2}, k^2 = \frac{\sqrt{\varepsilon_1^2 - \varepsilon_2^2} - \varepsilon_1}{2} \tag{6}$$

where n and k are the real and imaginary part of the RI. The validity for these equations extends up to around 1770 nm wavelength and is applicable exclusively for 14 nm thickness of MXene.

2.2 Fabrication feasibility

For the practical execution of the suggested sensor various approaches are adopted, first one being the Stack-and-Draw technique for the precise creation of the intended PCF. It is an economical approach involving several steps like preform preparation, consolidation by applying the required temperature and pressure, followed by Drawing process and cooling. This process enables the incorporation of the nanometre ranged airholes into the PCF with ease.

For the homogenous integration of the plasmonic metal layer of gold with the PCF, there exists many methods like Atomic layer deposition (ALD), Sol–Gel method, Physical vapour deposition (PVD), Thermal evaporation and Chemical vapour deposition (CVD). However, CVD is the most commonly used technique for the nano-scale range deposition of gold (Chaudhary et al. 2022).

The plasmonic enhancer MXene is prepared from its precursor MAX phase and it is coupled with gold nanoparticle layer by employing ultrasonication for obtaining uniform integration (Li et al. 2018). This hybrid layer is then attached to the PCF using physical vapour deposition. Since both the plasmonic materials, gold and MXene are biocompatible, the bio-analyte can be passed in through the PCF with ease, facilitating easy analysis. Therefore, the fabrication of the suggested sensor is in accordance with the existing advanced innovations.

3 Simulation results and analysis

3.1 Analysis of the core and SPP mode

The simulation software COMSOL Multiphysics was used for analyzing the sensor performance of the proposed biosensor. Modelling and simulation are done using a numerical approach called Finite Element Method (FEM) using a finer mesh design as shown in Fig. 3.

As demonstrated in the Fig. 4, the phase matching condition is observed when the effective mode indices of both SPP mode (red line) and the core-guided mode (green line) intersects with each other. Here, we observe the dispersion relation corresponding to an analyte RI of 1.38, whose resonant wavelength is observed at 740 nm. Consequently, a sharp confinement loss peak occurs at this resonant point, which corresponds to maximum energy transmission between the core-guided mode and SPP mode in the biosensor. The core mode, SPP mode and SPR mode for gold only probe and MXene-gold probe are displayed in Fig. 5 (a-f). The gold only probe provides maximum loss of 1381.2 dB/cm for analyte of RI 1.38 whereas on incorporating MXene with gold, the maximum loss decreased to

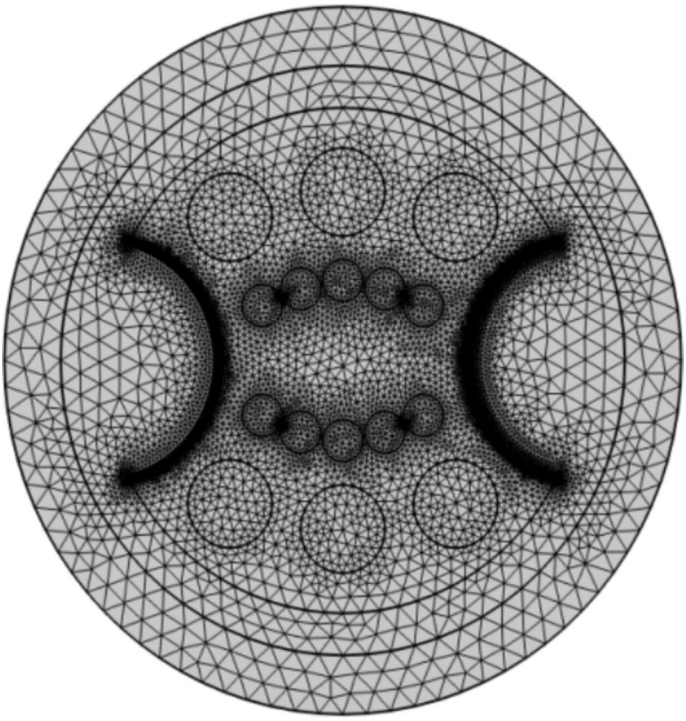

Fig. 3 Meshed view of the proposed design

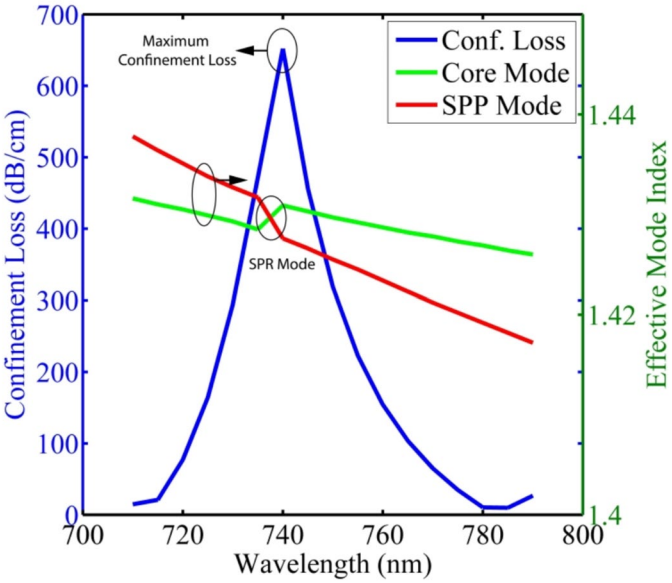

Fig. 4 Dispersion relation of analyte of 1.38 and loss spectrum

652.06 dB/cm. Therefore, the MXene-gold probe can be a better substitute for decreasing the loss for lower RI analytes.

3.2 Optimization of the geometrical parameters

The suggested sensor is found to offer promising results in the detection of HIV cell and Sickle cell anaemia. The sensor performance is further amplified by optimization of the structural parameters. Those parameters are optimized which plays an essential role in deciding the sensor's sensitivity and loss spectrum. In this work, three of the parameters are chosen and are subjected to variations. Firstly, the gold layer thickness parameter (t_g) is varied, keeping others constant. An optimized magnitude t_g is obtained and fixed for the further optimization of the radius of small and big air holes. The sensor performance, is quantified by obtaining the value of wavelength sensitivity and also by considering a moderate loss spectrum. Wavelength sensitivity is demonstrated by the equation (Meng et al. 2022),

$$S_\lambda\left(\frac{nm}{RIU}\right) = \frac{\Delta\lambda_{peak}}{\Delta n_a} \tag{7}$$

Confinement loss can be defined as (Hossain et al. 2020)

$$C_L = 8.686 \times \frac{2\pi}{\lambda} \times I_m\left(n_{eff}\right) \times 10^4 \frac{dB}{cm} \tag{8}$$

3.2.1 Influence of the plasmonic enhancer MXene

A 14 nm layer of the 2D plasmonic enhancer MXene is coated along the concave-shaped microchannels on either side of the gold based SPR PCF Biosensor. As we can see in

Fig. 6, initial analysis conducted on the gold (40 nm) only biosensor resulted in a sensitivity of 9714.29 nm/RIU and 3000 nm/RIU whose coupling wavelength occurs at 1295 nm and 705 nm for the RI of 1.42 and 1.38, corresponding to HIV infected cell and Sickle cell anaemia. Further analysis with the MXene-gold hybrid layered PCF SPR sensor revealed a significant surge in the wavelength sensitivity to 13,071.43 nm/RIU and 3500 nm/RIU where coupling occurs at 1550 nm and 740 nm for HIV cell and Sickle cell anaemia. The enhanced sensitivity results from the various properties of MXene such as elevated surface area (promoting higher analyte interaction), metallic conductivity causing effective coupling and biocompatibility. Thus, MXene coated sensor has the potential for the detection of HIV and sickle cell anaemia.

3.2.2 Influence of the thickness of gold layer

The gold layer thickness is carefully optimized to elevate the sensor performance. In view of initial study, a 40 nm thickness of gold layer and 14 nm MXene layer, a maximum sensitivity of 13,071.42 nm/RIU and 3500 nm/RIU and a loss of 4246.6 dB/cm and 652.06 dB / cm is obtained for HIV infected cell and sickle cell anaemia respectively. A slight elevation in wavelength sensitivity to 13,571.42 nm/RIU and 3666.66 nm/RIU for HIV and Sickle cell anaemia respectively is noticed when a 35 nm thick gold layer is used. However, the thinner gold layer leads to a higher loss spectrum due to the reduced excitation of the surface plasmon polaritons (SPPs). On employing a thicker gold layer (45 nm), a significant reduction in the wavelength sensitivity to 12,714.28 nm/RIU and 3500 nm/RIU is detected.

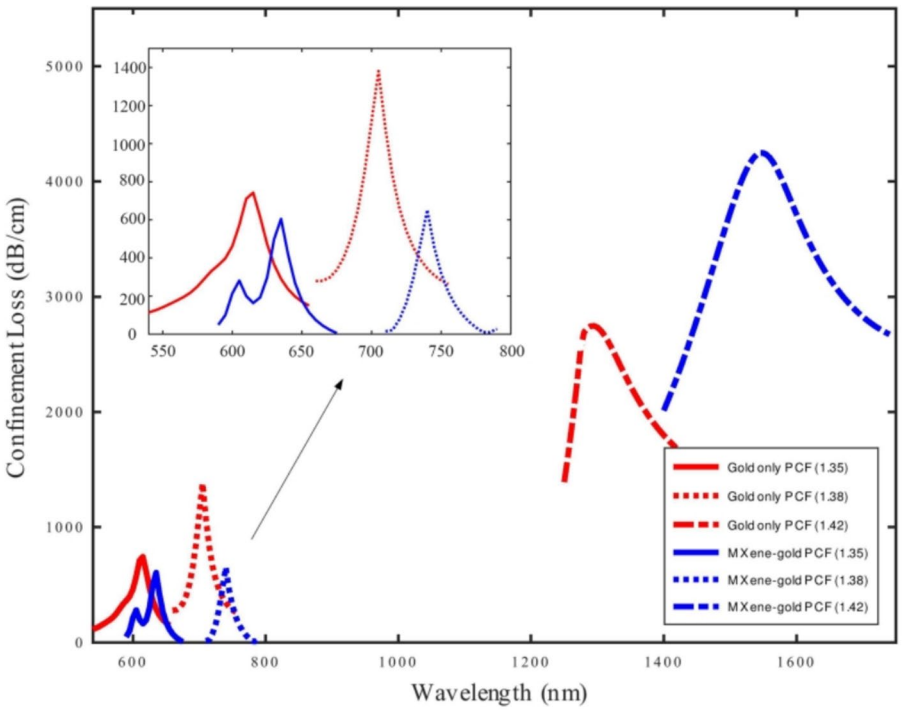

Fig. 6 Comparison of gold only PCF and MXene-Gold PCF

As the thickness of gold layer rises, the evanescent field produced by the SPPs penetrates lesser into the surrounding analyte. This reduced interaction with the bio-analyte makes it less responsive to the RI variations, resulting in lower sensitivity. In view of the moderate loss spectrum and an elevated wavelength sensitivity, optimized sensor performance is obtained at a thickness of 40 nm gold layer. The graphical summary of the gold layer thickness optimization is demonstrated in the Fig. 7.

3.2.3 Influence of the radius of smaller air holes

The air holes in vicinity to the core plays a pivotal role in ensuring efficient coupling between the core mode and SPP mode. The radius is varied and assigned three different values (200 nm, 250 nm and 300 nm) as shown in the Fig. 8. The wavelength sensitivity of HIV infected cell and sickle cell anaemia increased from 13,071.43 nm/RIU and 3500 nm/RIU to 13,357.14 nm/RIU and 3833.33 nm/RIU when the radial parameter was varied from 200 to 250 nm with the increment of 50 nm. The sensitivity of HIV cell could be further increased to 15,825.71 nm/RIU for a radius of 300 nm. However, its loss spectrum reaches a very high and undesirable value of 5144.80 dB/cm. This is due to the fact that bigger air holes near the core causes leakage of optical energy to the cladding and plasmonic metal layers leading to radiative losses. Moreover, it curtails the RI contrast between the core and cladding. This degradation in the sensor performance cannot be encouraged and hence, the airhole of radius 250 nm is opted as the optimized parameter.

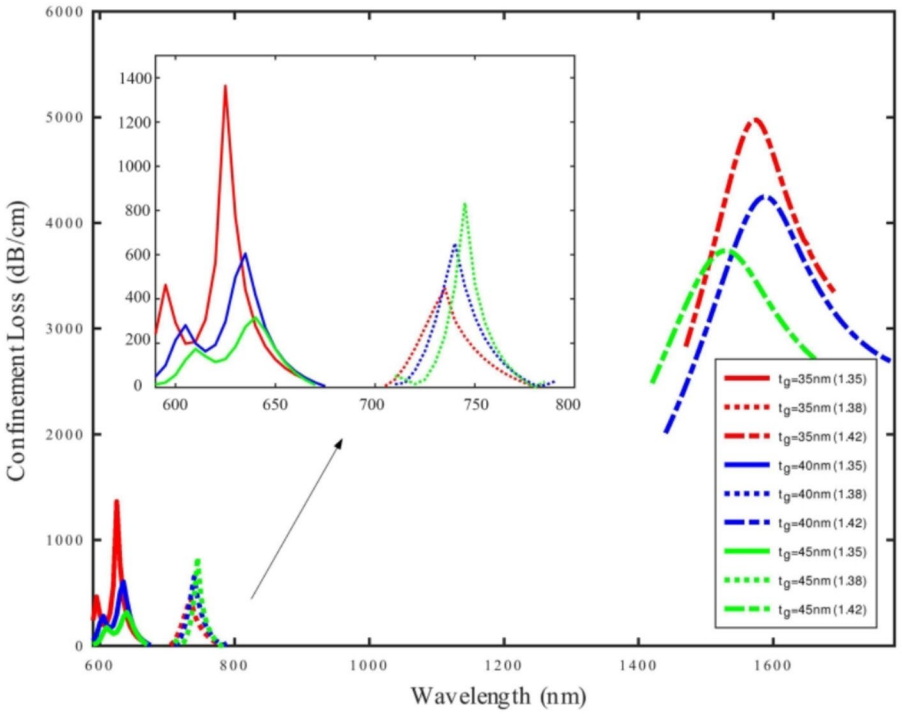

Fig. 7 Gold thickness optimization of the MXene-gold PCF

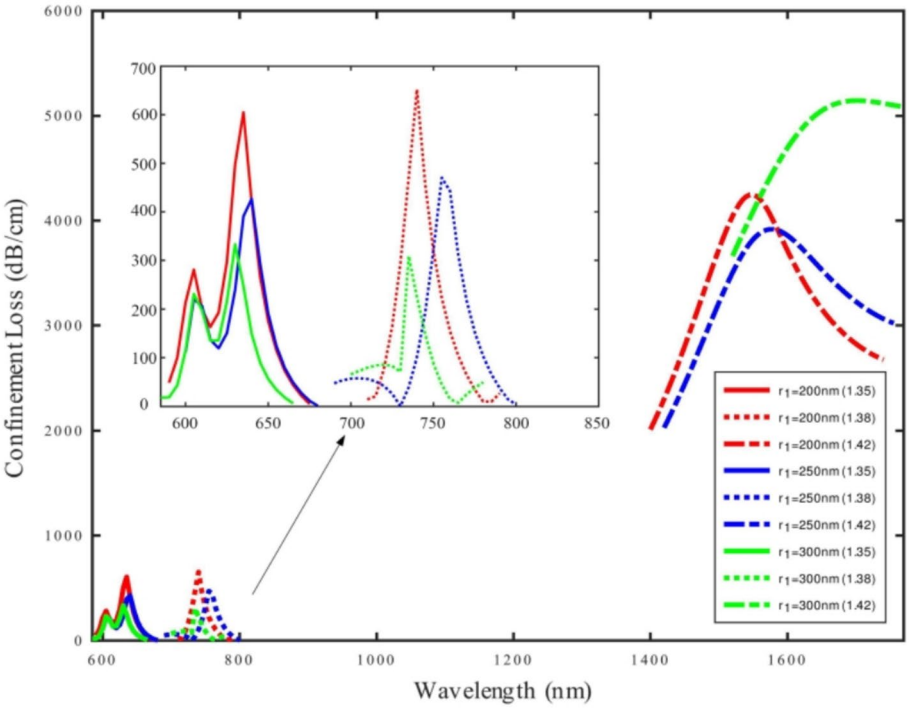

Fig. 8 Small airhole radius optimization of the MXene-gold PCF

3.2.4 Influence of the radius of bigger air holes

The size of the outer set of bigger airholes can largely influence sensor performance by altering the sensitivity and confinement loss. A boost in wavelength sensitivity to 14,142.86 nm/RIU and 4000 nm/RIU for HIV cell and sickle cell anaemia respectively, is observed at a radius of 525 nm, in comparison to both 475 nm and 575 nm. On inspecting the loss peaks given in the Fig. 9, we can conclude that moderate loss is also obtained at 525 nm radius, bearing a value of 4655.3 dB/cm and 475.37 dB/cm for HIV and sickle cell respectively. We can also observe that the smaller airhole (475 nm) gave a much higher confinement loss as they diminish the effective mode index contrast between the core and cladding. Moreover, inefficient coupling caused by smaller airholes results in inadequate energy transmission, resulting in higher loss. Therefore, optimized sensor performance is obtained at a radius of 525 nm.

The analysis using the initial parameters revealed how the utilization of MXene along with gold reflected in an increase in wavelength sensitivity of the PCF sensor. The optimized parameters are tabulated at Table 1. After optimization of thickness of gold and radii of both big and small air holes, we can observe a significant hike in both Gold only and MXene-Gold PCF. The wavelength sensitivity of gold only PCF for HIV cell and Sickle cell anaemia extracted as 13,071.42 nm/RIU and 3500 nm/RIU, on using the optimized structural parameters as shown in Fig. 10. A surge is observed in MXene-gold PCF also, wherein the sensitivity increased to 14,142.85 nm/RIU and 4000 nm/RIU for HIV and

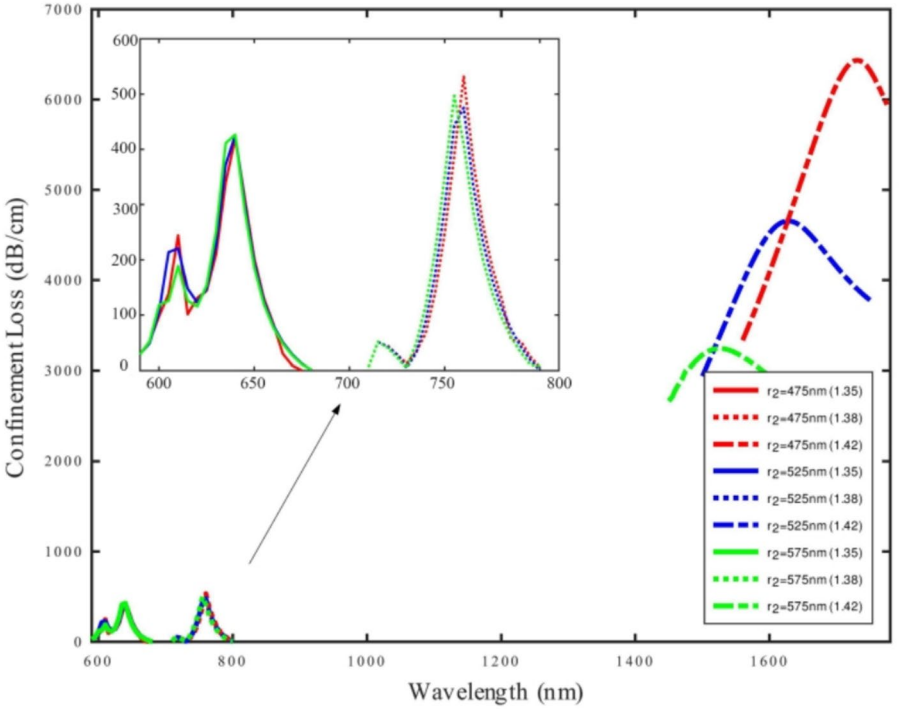

Fig. 9 Big airhole radius optimization for MXene-gold PCF

Table 1 Optimized parameters

Parameter	t_m	t_g	r_1	r_2
Value	14 nm	40 nm	250 nm	525 nm

sickle cell anaemia respectively and the analysis is displayed in Fig. 11. The comparative study is also tabulated in Table 2. The HIV and sickle cell anaemia are first detected through photonic crystal probe by britto et al. (Britto et al. 2024). In comparison to previous sensor, the proposed sensor offers an advanced sensitivity and the same is displayed in Table 3.

3.3 Tolerance study of the structural parameters

To study the tolerance of the structural parameters, the dimensions are adjusted at a range of ± 5% to analyze the significant variations in the optimized results. The first tolerance study covers the variation of gold thickness by ± 5%, shows no variation in the sensitivity with a change in confinement loss by ~ ± 10% from the optimized results. After discussing the thickness of gold, the small air holes are varied by ± 5%, observing negligible variation with the optimized sensitivity. The respective loss at 1.38 RI (Sickle cell) have suffered alterations of ~ ± 8%. At final step of tolerance study, big air holes are altered by ± 5%, again showing minor changes in the sensitivity magnitude with loss variations of ± 6%. The

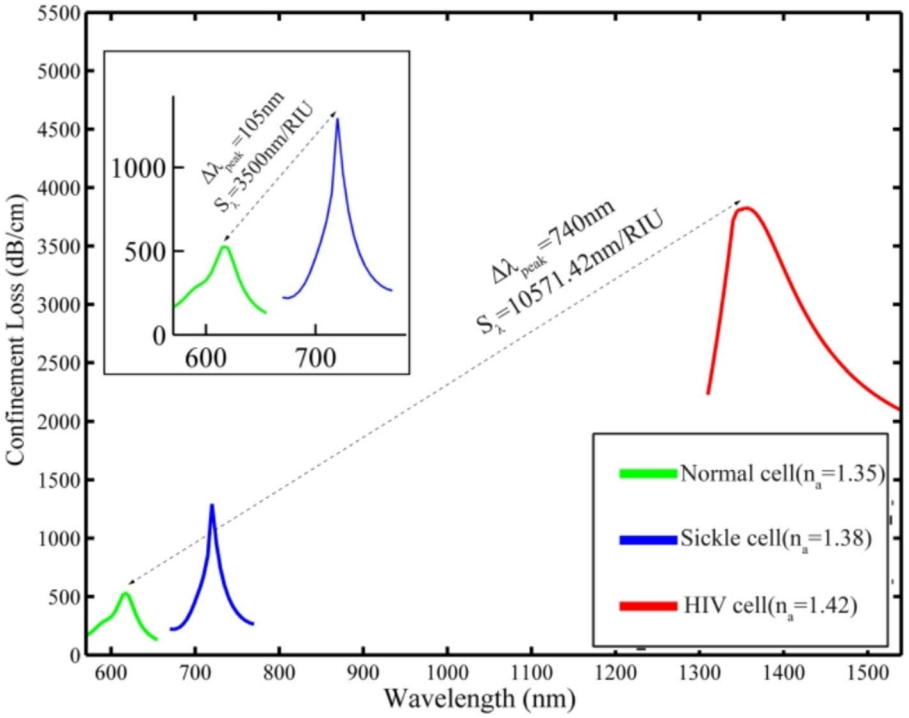

Fig. 10 Loss spectra and sensitivity of only gold PCF with optimized parameters

whole tolerance study concludes that the sensitivity is not affected by ± 5% variations of the parameters, which creates our proposed sensor highly feasible to experimental fabrication, and can tolerate minor dimensional instabilities. The performance analysis of only gold sensor and MXene-gold SPR sensor is shown through bar graph in Fig. 12.

4 Conclusion

HIV caused AIDS and Sickle cell anaemia are two of the most threatening diseases in the present scenario. Although there exist many treatment approaches, none is useful in the case of delayed detection. The aim of this work is to fabricate a biosensor reliant on the RI of the bio-analytes of HIV infected cell and Sickle cell anaemia, facilitating a much earlier detection. The proposed design put forth a PCF sensor based on SPR for the concurrent detection of HIV infected cell and Sickle cell anaemia. The two sets of semi-concentric arrangement of air holes offers an eye-shaped core, with a MXene-Gold hybrid layered coating on the microchannels on either side. The concave shaped microchannels produce a much-pronounced wavelength sensitivity as it provides optimized light guidance and

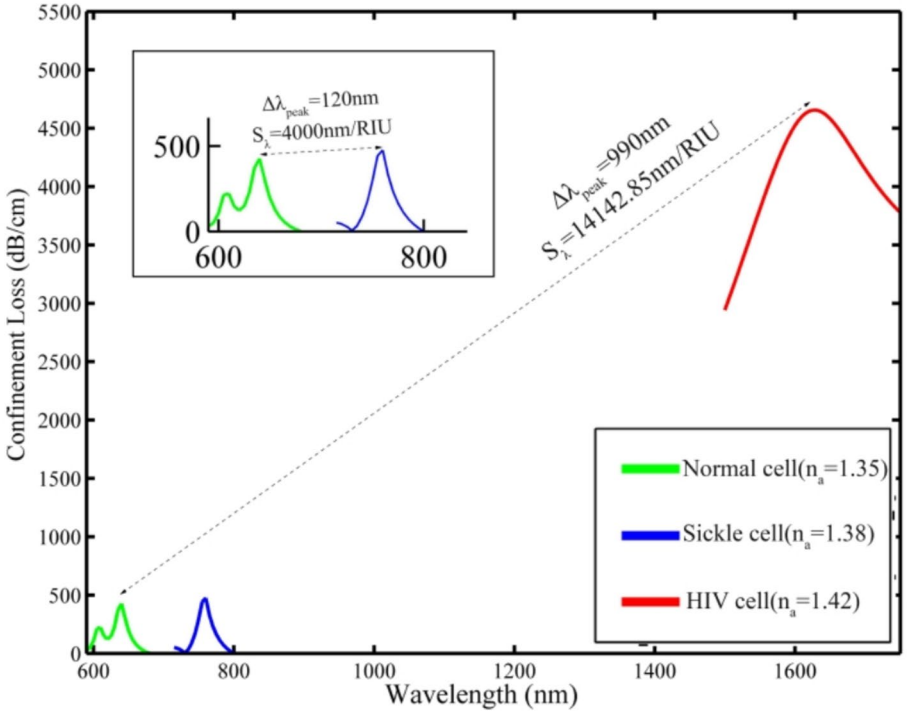

Fig. 11 Loss spectrum and sensitivity for MXene-gold PCF with Optimized parameter

Table 2 Comparative study between only gold PCF and MXene-gold PCF using optimized parameters

Biosensing application	Only Gold sensor		MXene-Gold sensor	
	Wavelength sensitivity (nm/RIU)	Confinement loss (dB/cm)	Wavelength sensitivity (nm/RIU)	Confinement loss (dB/cm)
HIV cell detection	10,571.42	3825.1	14,142.85	4655.3
Sickle cell anaemia detection	3500	1293.2	4000	475.37

enhanced surface area, resulting in increased coupling of evanescent field. The highlight of the design is the appropriate use of the bio-compatible, 2D plasmonic enhancer MXene along with a layer of gold for maximizing the wavelength sensitivity. A noticeable rise of sensitivity from 10,571.42 nm/RIU and 3500 nm/RIU (Gold only PCF) to 14,142.85 nm/RIU (+34%) and 4000 nm/RIU (+15%) (MXene-Gold PCF) can be achieved on optimization of the structural parameters. Therefore, in view of the desired sensor performance based on wavelength sensitivity and confinement loss spectra for the suggested sensor, it is appropriate for the detection of HIV infected cell and Sickle cell anaemia.

Keywords: ANN, RSM, HHO, Biodiesel, Biogas, Nanoparticles

Abstract. This study explores the use of biogas and nanoparticle-doped biodiesel as sustainable options for compression-ignition (CI) engines, driven by worries about the depletion of fossil fuels and their environmental effect. This study provides a complete overview of the interconnected impacts of engine load, nickel oxide nanoparticle doping rate, Neem biodiesel mix ratio, and biogas flow rate on the performance and emissions of a CI engine. Response Surface Methodology (RSM) provides a means to comprehend and conduct organized experiments, while Artificial Neural Network (ANN) is capable of capturing intricate non-linear interactions. Both models undergo thorough statistical analysis utilizing several assessment metrics to reveal the impact of each input parameter on important outcomes. This study also extensively explores the important field of optimization, focusing on the progress achieved in RSM and ANN models. RSM's desirability function optimized the output parameters at 67.45% engine load, 96.06 ppm NDR, 10.7 % BBR and 0.85 kg/h BFR, while ANN with Harris Hawks Optimization (HHO) optimized the output parameters at 67.01% engine load, 98.39 ppm NDR, 8.41% BBR and 0.846 kg/h BFR. This integrated approach offers a robust framework for enhancing the sustainability and efficiency of CI engines, presenting practical solutions for transitioning toward cleaner energy systems.

Introduction

Despite its reliance on fossil fuels, the internal combustion engine continues to be a prominent factor in transportation. The limited availability and environmental impacts of these resources, such as the release of greenhouse gases and air pollution, need a fundamental change in our approach towards sustainable alternatives. Biogas, an abundant and sustainable fuel produced by the anaerobic decomposition of organic material, presents a very promising option. Biogas is mostly composed of methane (CH_4) in addition to carbon dioxide (CO_2) and other minor gases. Biogas, although having a carbon-neutral combustion cycle, might result in higher levels of NO_X emissions because of its naturally high combustion temperature [1].

Biodiesel, a fuel made from vegetable oil, offers an additional sustainable alternative. Nevertheless, the elevated viscosity and lower cetane number of this substance in comparison to diesel might result in diminished engine performance and heightened emissions [2]. Nanoparticle doping is a potential approach to enhance the properties of biodiesel. Nanoparticles such as ceria (CeO_2) and ceria-zirconia ($CeZrO_2$) have shown promise in augmenting combustion, decreasing emissions, and boosting stability [3].

To achieve optimal engine performance and reduce emissions while using sustainable fuels, it is necessary to have a thorough grasp of how different elements interact with each other. The

combustion characteristics and emissions are greatly influenced by engine load. Elevated loads result in higher temperatures inside the combustion chamber, which in turn leads to an increase in the generation of nitrogen oxides (NO_X) [4].

Similarly, the pace at which nanoparticles are doped may have an impact on combustion efficiency, stability, and emissions. An ideal doping rate may optimize combustion by increasing the availability of oxygen and enhancing ignition characteristics. Nevertheless, an excessive amount of doping may result in the aggregation of particles and an increase in viscosity, which can have a detrimental effect on the performance of the engine [5].

The biodiesel mix ratio in conjunction with conventional diesel is crucial in establishing the equilibrium between sustainability and engine performance. Increasing the mix ratios may enhance lubricity and decrease smoke emissions [6]. Nevertheless, the use of biodiesel might result in reduced brake thermal efficiency (BTE) and higher brake specific fuel consumption (BSFC) owing to the lower calorific value of biodiesel in comparison to diesel [7].

To achieve optimal engine performance and reduce emissions while using sustainable fuels, it is necessary to have a thorough grasp of how different elements interact with each other. The combustion characteristics and emissions are greatly influenced by the engine load. Elevated loads result in higher temperatures inside the cylinder, which in turn leads to an increase in the generation of nitrogen oxides (NO_X) [8,9]. Similarly, the pace at which nanoparticles are doped may have an impact on combustion efficiency, stability, and emissions. An optimum doping rate may optimize combustion by increasing the availability of oxygen and enhancing ignition characteristics. Nevertheless, an excessive amount of doping may result in the aggregation of particles and an increase in viscosity, which can have a detrimental effect on the performance of the engine [10].

The biodiesel mix ratio in conjunction with conventional diesel is a critical factor in establishing the equilibrium between sustainability and engine performance. Increasing the mix ratios may enhance lubricity and decrease smoke emissions [11,12]. Nevertheless, the use of biodiesel might result in reduced brake thermal efficiency (BTE) and higher brake specific fuel consumption (BSFC) owing to the lower calorific value of biodiesel in comparison to diesel [13,14]. It is important to carefully examine the flow rate of biogas, since too much flow might result in power loss and incomplete combustion. This may lead to a rise in hydrocarbon (HC) emissions as a consequence of unburned fuel particles escaping from the combustion chamber [15,16]. Identifying the most efficient biogas flow rate is crucial in order to strike a balance between power generation and emissions.

It is necessary to go beyond developing models to achieve optimal engine performance and reduce emissions while using sustainable fuels. The Desirability Function Approach (DFA) in Response Surface Methodology (RSM) provides a robust method for addressing the trade-offs between competing goals in optimization [17-19]. Within the framework of CI engines, this might include the simultaneous reduction of NOx emissions and the maximization of BTE (Brake Thermal Efficiency). The DFA methodology enables the consolidation of distinct desire functions for each answer into a unified overall desirability function. This overall function guides the optimization process towards a solution that fulfills all objectives [20,21].

The objective of this study is to explore the combined effects of nanoparticle-doped biodiesel, biogas, and engine parameters on the performance and emissions of compression ignition (CI) engines. It aims to identify optimal conditions that enhance engine efficiency and minimize harmful emissions. The novelty lies in the use of advanced modeling techniques, such as RSM and ANN, along with Harris Hawks Optimization (HHO) to capture complex interactions between variables. This integrated approach provides valuable insights for optimizing sustainable fuel usage in CI engines.

Materials Research Proceedings 49 (2025) 571-580 https://doi.org/10.21741/9781644903438-57

Material and Methods

This section provides a comprehensive description of the experimental setup, which encompasses the specifications of the CI engine, the kinds of biogas and nanoparticle dopants used, and the procedure for preparing the nanoparticle-doped biodiesel.

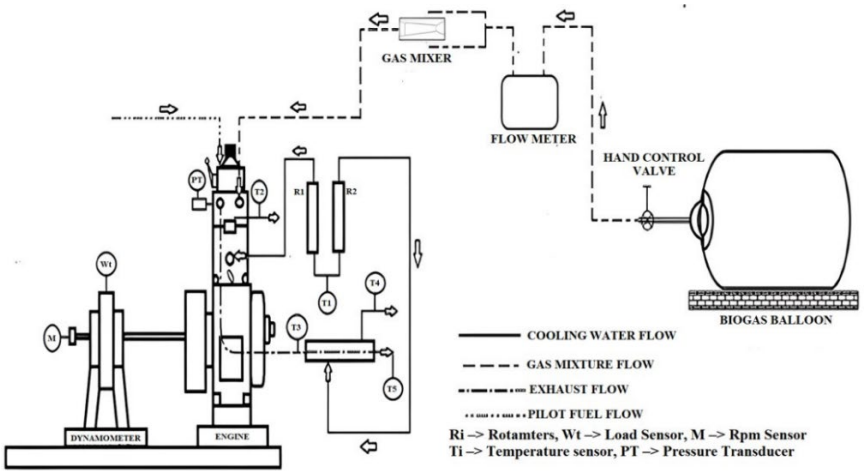

Fig. 1. *Schematic representation of test setup after modification*

The experiment was conducted using a single-cylinder, four-stroke, constant-speed compression ignition (CI) engine with a rated power of 3.5 kW. An eddy current dynamometer was used to apply engine load, which ranged from 2.4 kg (20%) to 12 kg (100%). To monitor the engine's performance, rotameters measured the flow of water for cooling, while airflow and fuel flow were tracked using a manometer and fuel flow meter, respectively. Temperature sensors (PT100) were strategically placed at various points in the engine cylinder to continuously record data. These sensors were connected to a National Instruments (NI) unit, which relayed the data to a computer via Engine Soft software. To facilitate dual-fuel operation, a gas-air mixing device was incorporated into the setup, designed according to engine specifications. A schematic of the test setup and gas mixer, based on our previous research, is shown in Fig. 1 [21].

Experimental Design

As given in Table 1, the nickel oxide Nanoparticle Doping Rate (NDR) was varied between 0 and 100 ppm, as nanoparticles are known to enhance combustion by facilitating better oxidation and improving fuel efficiency. The neem biodiesel blend ratio (BBR) ranged from 0% to 20% by volume, encompassing the transition from pure diesel to biodiesel, with the blend ratio being a critical factor in improving engine lubricity and reducing particulate emissions. Higher biodiesel content generally improves the engine's sustainability but can reduce the calorific value of the fuel, which impacts fuel efficiency. The Biogas Flow Rate (BFR) was varied from 0 to 1 kg/h, as biogas, primarily composed of methane, serves as a supplemental fuel in dual-fuel engines.

Table 1 *Input Parameters and Levels*

Input Parameters	Units	Symbol	Levels		
			-1	0	1
Engine load	%	Load	20	60	100
Nanoparticles doped rate	ppm	NDR	0	50	100
Biodiesel blend rate	%	BBR	0	10	20
Biogas Flow rate	kg/h	BFR	0.5	0.75	1

Fuel Properties

The physiochemical properties of diesel (D 100), raw neem oil (LO), and pure biodiesel (BBR100) were evaluated using various ASTM testing procedures, and the results are presented in Table 2.

Table 2 *Fuel properties*

Properties	Unit	Testing methods	D 100	NR	BBR 10	BBR 20	BBR 100
Kinematic Viscosity (40 °C)	cSt	D-445	2.98	30.6	3.15	3.36	4.21
Density (40 °C)	kg/m^3	D-1298	841	920	828.3	834.2	881
Calorific Values	MJ/kg	D-240	43.9	38.4	43.5	43.03	40.5

Cetane Number	-	D-4737	51	38	50	49	42

Modeling and Optimization

RSM Modelling

The modeling and optimization of engine performance and emissions were carried out using Response Surface Methodology (RSM), which is well-suited for analyzing and optimizing complex systems with multiple variables. RSM relies on polynomial regression models that approximate the relationship between the input variables (such as NDR, BBR, BFR, and load) and output responses. These models were derived by fitting second-order polynomial equations (Equation 1) to the experimental data, which included both linear and quadratic terms to account for the direct and non-linear relationships between input parameters and responses. Interaction terms between parameters were also included in the models to explore how combinations of variables could have a synergistic or antagonistic effect on engine performance and emissions. For example, the interaction between NDR and BBR may have a combined impact on BTE or NOx emissions, which could not be captured by examining the effects of each variable in isolation.

$$Y= b_0 + \sum_{i=1}^{4} b_i x_i + \sum_{i=1}^{4} b_{ii} x_i^2 + \sum_{i\leq 1\leq j}^{4} b_{ij}\, x_i x_j \quad (1)$$

x_i is an independent input factor, whereas Y is the dependent output. This polynomial equation has an intercept coefficient denoted by b_0. The quadratic coefficients are denoted by b_{ij}, the interactive coefficients by b_{ii}, and the linear coefficients for Load, NDR, BBR, and BFR by bi. Design Expert software was used to achieve the model fitting. To validate the accuracy of the regression models, Analysis of Variance (ANOVA) was employed. This method decomposes the variation in the response variable to assess the statistical significance of the input factors and their interactions. Goodness-of-fit metrics such as R^2 were used to quantify how well the model represented the data, with high values indicating a good fit.

ANN Modelling

The fundamental design of an Artificial Neural Network (ANN) consisting of three layers. The arrows in the image depict the flow of data through the network. Data enters the input layer, propagates through the hidden layer, and reaches the output layer, where the final prediction is made [13].

A multilayer perceptron (MLP) architecture with an input layer, two hidden layers, and an output layer makes up the Artificial Neural Network (ANN) utilized in this study. Input data is represented by the input layer, and buried layers use activation functions to process it. The last forecast is produced by the output layer, where the amount of neurons is proportional to the output categories. Each output is assigned to its own network in order to train the DOE findings. Neuron

combinations ranging from 1 to 10 are used to train the network's hidden layers. After that, we follow the procedure in Table 3 to choose the neuron pairings with the lowest RMSE. For each output, a new network is constructed using the best neuron combination that was achieved. The backpropagation technique was used to train the network, with the Mean Square Error (MSE) serving as the performance metric and the Levenberg-Marquardt method (trainlm) as the training function. By experimenting with several combinations for each output, we were able to find the optimal neuron configuration for the hidden layers. The configuration with the lowest Root Mean Square Error (RMSE) was then chosen. Training accounted for 70% of the DOE's 30 runs, while testing and validation each accounted for 15%.

Table 3 architecture for engine outputs

BTE	BSEC	NO_X	HC	CO	SO
4-6-5-6	4-9-3-6	4-9-3-6	4-10-8-6	4-6-6-6	4-4-2-6

Optimization of RSM and ANN model

In RSM optimization, the desirability function is used to handle multiple response variables. It assigns a desirability score between 0 and 1 to each response, based on its optimal value and permissible range. The individual desirability scores are then combined, typically using the geometric mean, to form an overall desirability score. The goal is to find the combination of input variables that maximizes this overall desirability, optimizing conflicting response variables simultaneously. This approach allows for balancing competing objectives to identify the best solution.

Results and Discussion

RSM Model Analysis

The empirical models for analyzing key engine responses—Brake Thermal Efficiency (BTE), Brake-Specific Energy Consumption (BSEC), Nitrogen Oxides (NOx), Hydrocarbons (HC), Carbon Monoxide (CO), and Smoke Opacity (SO)—were derived using the experimental data from varying the input parameters: engine load, nanoparticle doping rate (NDR), biodiesel blend ratio (BBR), and biogas flow rate (BFR). Each model includes coefficients that determine how each parameter affects the response variable, either positively or negatively. Positive coefficients indicate a direct relationship, where an increase in that parameter will proportionally increase the response (e.g., engine load and NDR positively affect BTE). Negative coefficients suggest an inverse relationship, where an increase in the parameter results in a decrease in the response (e.g., BBR and BFR negatively affect BTE).

$$BTE = 15.9776 + 4.33371 * A + 0.79072 * B + -1.12249 * C + -1.5205 * D + 0.244867 * AB + -0.458222 * AC + -0.566295 * AD + -0.0629676 * BC + -0.0850689 * BD + 0.12252 * CD + -1.95413 * A^2 + -0.132335 * B^2 + 0.0170302 * C^2 + -0.173233 * D^2 \quad (4)$$

As given in equation 4, For BTE, engine load showed the largest positive influence, with increasing load resulting in a proportional rise in BTE due to enhanced combustion efficiency. NDR also positively impacted BTE, though its effects diminished beyond a certain threshold. In contrast, BBR and BFR reduced BTE, as higher BBR decreases the calorific value of the fuel, and excess biogas flow reduces combustion temperature, causing incomplete combustion and lower thermal efficiency. The interaction between load and NDR had a synergistic effect on BTE, meaning that increasing both load and NDR simultaneously resulted in a higher BTE. However, load with BBR or BFR exhibited antagonistic effects, meaning their combined increase led to a reduction in BTE.

$$BSEC = 21.9175 + -7.89433 * A + -1.40957 * B + 2.37464 * C + 1.70115 * D + 0.391571 * AB + -0.853927 * AC + -0.4978 * AD + -0.100708 * BC + -0.0652905 * BD + 0.126599 * CD + 5.06601 * A^2 + 0.0570941 * B^2 + 0.0420941 * C^2 + 0.440009 * D^2 \quad (5)$$

As given in equation 5, The Brake-Specific Energy Consumption (BSEC) model showed that BFR and BBR had a directly proportional relationship with BSEC, meaning that as BFR or BBR increased, so did the energy consumed per unit of work. This suggests that higher biodiesel blends and biogas flows require more energy to achieve the same power output, likely due to the lower energy density of the fuels. On the other hand, engine load and NDR had a negative impact on BSEC, with higher load and NDR leading to better fuel utilization and reduced energy consumption per unit of output. The interaction between load and NDR was synergistic, meaning that increasing both resulted in significant reductions in BSEC. Load with BBR or BFR exhibited antagonistic effects, as the increased energy demands of these factors offset the efficiency gains from higher loads.

$$NO_X = 246.545 + 136.083 * A + -17.9106 * B + 15.7414 * C + -37.9381 * D + -10.0984 * AB + 10.0213 * AC + -22.6869 * AD + -0.976769 * BC + 2.64935 * BD + -2.33765 * CD + 6.23173 * A^2 + 2.68564 * B^2 + -6.19198 * C^2 + -9.78391 * D^2 \quad (6)$$

As given in equation 6, For NOx emissions, the model showed a direct relationship with engine load and BBR, meaning that higher engine loads and increased biodiesel blending resulted in higher NOx emissions due to the higher combustion temperatures associated with these factors. Conversely, BFR and NDR exhibited a negative relationship with NO_X, meaning that increasing these variables led to a reduction in NO_X emissions. This was likely due to the oxygenation effect of biogas and nanoparticles, which improves combustion efficiency and reduces the formation of NO_X. The interaction between load and BBR, as well as between NDR and BBR, had a synergistic effect on NO_X emissions, while other combinations showed antagonistic effects. For example, compared to the BBR20-NDR100 blend, NO_X emissions decreased by 14% with BBR20-NDR0 and decreased by 27.15% for BFR1-NDR100 compared to BFR0.5-NDR100.

$$HC = 44.9637 + -6.77761 * A + -4.45204 * B + -2.79144 * C + 2.98671 * D + 0.618654 * AB + 0.382929 * AC + -0.231771 * AD + 0.249148 * BC + -0.268035 * BD + -0.16326 * CD + 0.731055 * A^2 + 0.267014 * B^2 + 1.24267 * C^2 + 1.17926 * D^2 \quad (7)$$

As given in equation 7, For HC emissions, the positive coefficients for BFR indicated that higher biogas flow leads to increased HC emissions, likely due to incomplete combustion at higher biogas flow rates. On the other hand, load, NDR, and BBR negatively affected HC emissions, meaning that higher loads, NDR, or BBR values helped reduce HC emissions. The interactions between load and NDR, load and BBR, and NDR and BBR exhibited synergistic effects on HC, indicating that optimizing these combinations could help reduce unburned hydrocarbons. At the same central load and BFR level, the BBR20-NDR100 blend showed a 17% decrease in HC emissions compared to BBR20-NDR0. In contrast, when comparing BFR1-NDR100 to BFR0.5-NDR100, there was an observed increase of 13.02% in HC emissions.

$$CO = 0.0929081 + -0.0212321 * A + -0.00945834 * B + -0.00649946 * C + 0.00726853 * D + 0.001596 * AB + 0.0004185 * AC + -0.00136361 * AD + 0.000490613 * BC + -0.00054915 * BD + -0.00037665 * CD + 0.0317948 * A^2 + 0.00100293 * B^2 + 2.9251e-06 * C^2 + 0.000302925 * D^2 \quad (8)$$

As given in equation 8, For CO emissions, the positive coefficient of BFR indicated that higher biogas flow leads to increased CO emissions, likely due to incomplete combustion at high biogas concentrations. The negative coefficients for engine load, BBR, and NDR suggest that higher load, biodiesel blend ratios, and NDR reduce CO emissions by improving combustion efficiency. The most sensitive interactions for CO emissions were observed between load and NDR, as well as load and BBR. Compared to the BBR20-NDR100 blend, CO emissions decreased by 14% with BBR20-NDR0, but increased by 11.9% when comparing BFR1-NDR100 to BFR0.5-NDR100.

Materials Research Proceedings 49 (2025) 571-580 https://doi.org/10.21741/9781644903438-57

$$SO = 28.8435 + 13.2206 * A + -2.02695 * B + -1.2147 * C + -4.41904 * D + -0.924537 * AB + -0.553756 * AC + -2.00184 * AD + 0.0855113 * BC + 0.306983 * BD + 0.184264 * CD + -0.127199 * A^2 + -0.458502 * B^2 + -0.300336 * C^2 + 1.33338 * D^2 \quad (9)$$

As given in equation 9, Finally, for Smoke Opacity (SO), the presence of positive coefficients for engine load and negative coefficients for BFR, BBR, and NDR indicated that SO increased with higher load but decreased with higher biogas flow, biodiesel blend ratio, and nanoparticle doping rate. The combination of load with BFR showed the most significant effect on SO, as increasing both parameters led to increased smoke opacity. Compared to the BBR20-NDR100 blend, SO decreased by 13% for the BBR20-NDR0 blend, but increased by 26.15% when comparing BFR1-NDR100 to BFR0.5-NDR100.

From the ANOVA analysis, high F-values (Table 4) confirm that the model effectively explains the variation in experimental data. Engine load had the highest F-value, followed by BFR, BBR, and NDR, indicating that engine load has the most significant influence on the output responses. The high R^2 values for all responses suggest the model closely matches the experimental data. ANOVA analysis also showed that the lack of fit is insignificant with P-values greater than 0.05.

Table 4 *Analysis of variance (F-value) and R^2 for performance and emission measurements*

Source	BTE	BSEC	NO_X	HC	CO	SO
	F-value	F-value	F-value	F-value	F-value	F-value

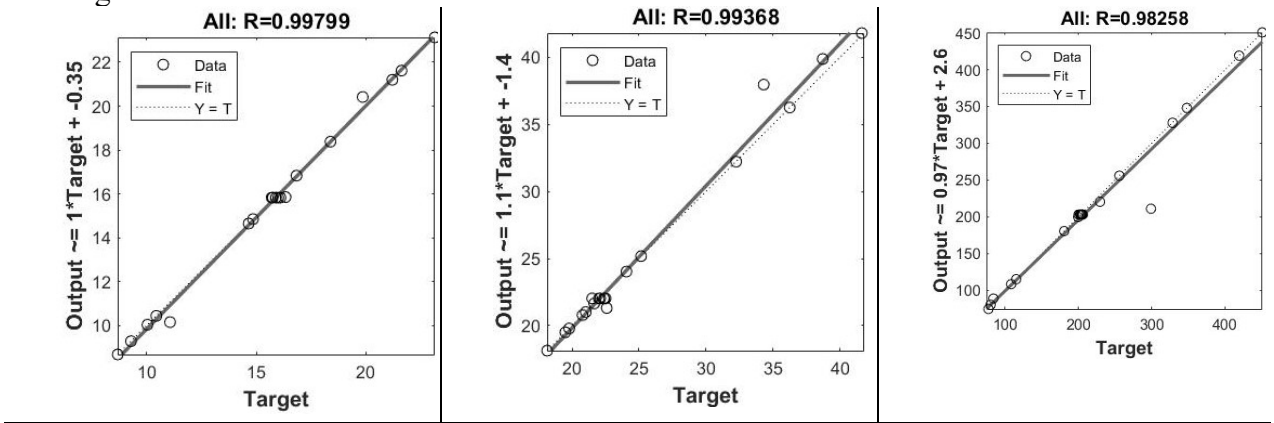
ANN Model Analysis

The network's output parameter-corresponding correlation coefficient (R) was computed for each phase of training, testing, and validation. You can see the total correlation coefficients for all the dependent responses in Figures 3 and 4. The high R values observed across all networks indicate that the data was effectively trained using the DOE, reinforcing the reliability and robustness of the regression model.



(a) BTE (b) BSEC (c) NO_X

Fig. 4 *R as a function of (d) HC, (e) CO, and (f) SO as inputs to the trained network*

Optimization of RSM and ANN Model

The RSM model exhibiting the highest desirability of 0.71 (Fig. 5) identified an optimal solution that predicts the following values: BTE at 16.58%, BSEC at 20.28 MJ/kWh, NO_X at 239.704 ppm, HC at 41.06 ppm, CO at 0.085%, SO at 27.2%. These predictions correspond to an engine load of 67.45%, NDR of 96.06 ppm, BBR of 10.7%, and BFR of 0.85 kg/h.

The ANN-HHO optimization process concluded after 102 generations, yielding optimal values for BTE, BSEC, NO_X, HC, CO, and SO of 16.87%, 19.76 MJ/kWh, 234.85 ppm, 41.47 ppm, 0.0857%, and 27.26%, respectively, at an engine load of 67.01%, NDR of 98.39 ppm, BBR of 8.41%, and BFR of 0.846 kg/h.

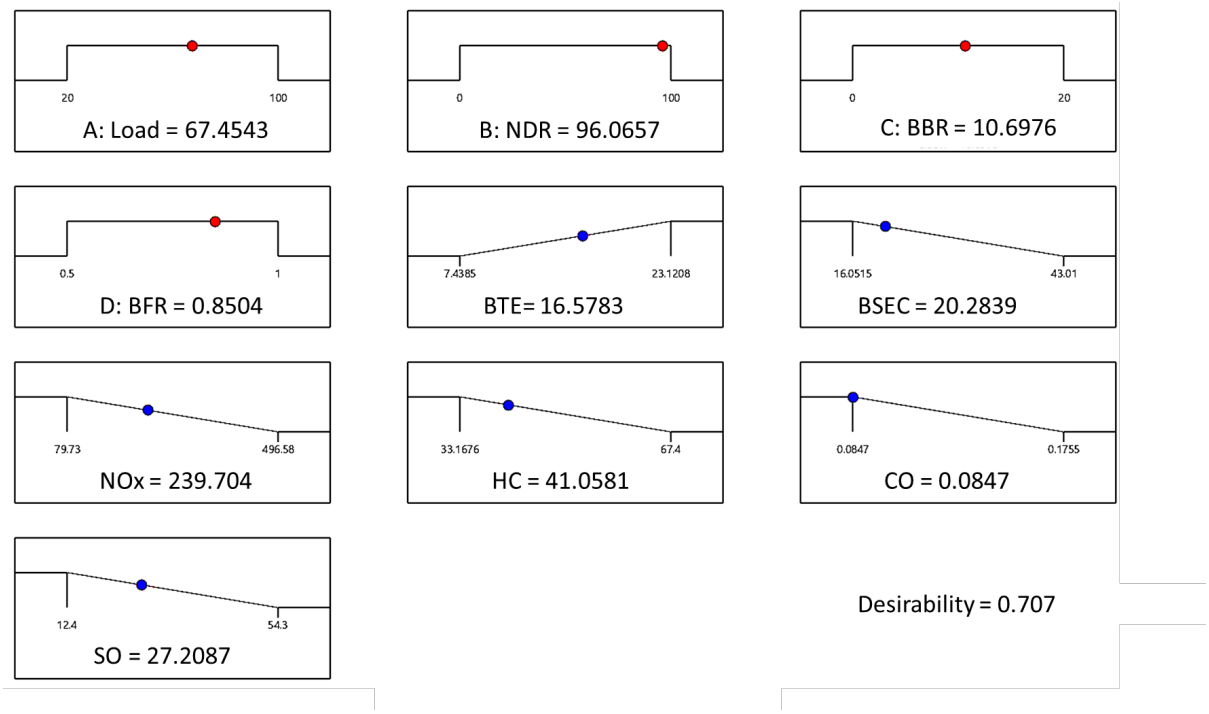

Fig. 5 *Desirability Plot*

Conclusions

This study yields the following conclusions:

1. The F-value of engine outputs derived from the RSM model indicates that, among the input variables, engine load exerts the most significant influence on the output responses, followed by BFR, NDR, and BBR in that order.

2. The evaluation metrics indicate low prediction error and high model performance for both regression analysis RSM and ANN, with a higher R2 suggesting that RSM is more accurate and reliable.
3. RSM optimization indicated an optimal engine output response at 67.45% engine load, 96.06 ppm NDR, 10.7% BBR, and 0.85 kg/h BFR. The optimization of the ANN-GA model revealed an optimal engine output response at 67.01% engine load, 98.39 ppm NDR, 8.41% BBR, and 0.846 kg/h BFR. Based on the optimized results from both the RSM and ANN models, it can be concluded that the combination of nanoparticles is effective.

The integration of biogas and biodiesel demonstrates promise in achieving reduced greenhouse gas emissions while maintaining engine performance. The application of optimization tools such as the HHO algorithm enhances the decision-making process for engine parameter tuning. This approach paves the way for adopting sustainable fuel technologies in CI engines, contributing to global efforts in reducing reliance on fossil fuels.

If you follow the “checklist” your paper will conform to the requirements of the publisher and facilitate a problem-free publication process. Thank you for your help in this matter.

NoCiPUF: NoC-Based Intrinsic PUF for MPSoC Authentication

Deepank Grover, *Graduate Student Member, IEEE*, Tarun Sharma, *Graduate Student Member, IEEE*, Sneha Agarwal, *Graduate Student Member, IEEE*, Sidhartha Sankar Rout, Anushka, Madhur Kumar, and Sujay Deb, *Senior Member, IEEE*

***Abstract*— Modern Multi-Processor-Systems-on-Chips (MPSoCs) use Network-on-Chips (NoCs) as a scalable and efficient communication fabric. The applications running on these devices rely on frequent communication with central database servers, which are vulnerable to impersonation attacks by adversarial clones. We propose NoCiPUF, a novel NoC-based intrinsic Physically-Unclonable-Function (PUF) framework for MPSoCs authentication. We re-use the circuit switched nature of NoC with path-pairs as challenges to obtain secret responses, collectively called challenge-response-pairs (CRPs). Due to the random nature of manufacturing variations, equal hop paths exhibit unequal delays. We leverage the delay differences of flits traversing in equal-hop paths to generate unique responses. NoCiPUF is fully-synthesizable and readily scalable as it requires changes only at the behavioral level. To counter Machine-Learning (ML)-based modeling attacks on PUFs, we provide a comprehensive technique and reduce the prediction accuracy to ∼52%. NoCiPUF framework incurs low area (0.76%) and power (1.14%) overheads and has no impact on NoC performance in normal mode due to independent authentication mode. Obtained responses have near-ideal PUF metrics and are verified against the NIST randomness test suite. This scheme offers high number of CRPs in larger NoC networks (> 0.74 million CRPs in 5 × 5 mesh), proving its scalability.**

***Index Terms*— MPSoC authentication, physically-unclonable-function (PUF), network-on-chip (NoC), challenge-response-pairs (CRPs), on-chip variations, ML-resilience.**

I. Introduction

CONVENTIONAL Systems-on-Chip (SoCs) have evolved into multi-processor SoCs (MPSoCs), incorporating a multitude of processing elements to serve a diverse set of applications on a single chip. NoC serves as an efficient and scalable intra-core shared communication fabric in state-of-the-art MPSoCs, supporting up to hundreds of peripherals. The scalability, high bandwidth and design flexibilities offered by NoC has made it the popular industrial choice over bus-based interconnects [1], [2].

The NoC supported modern MPSoCs are being deployed in various domains ranging from smartphones to automotive grade applications, often dealing with sensitive data.

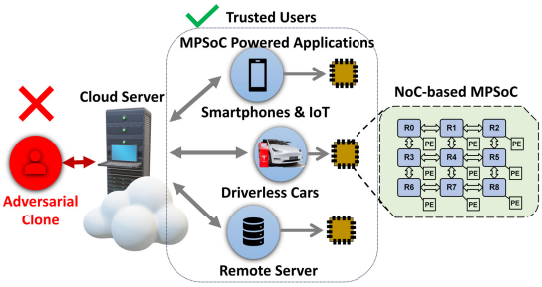

Fig. 1. Need for authentication of MPSoCs.

They primarily run applications that require heavy computations and frequent communication with central data servers to exchange and store user-critical information. Moreover, this type of communication among distributed remote servers, catering to a larger, central database is bound to rise in near future. However, these central databases are vulnerable to unauthorized access via adversarial clones impersonating the original MPSoC device, to access confidential information or flood the server with malicious data [3].

As shown in Fig. 1, in the absence of some authentication primitive, any adversarial (or malevolent) device similar to trusted devices can easily gain access to the central server. This can lead to loss of confidential user data and severely impacts the server performance. The report [4] lists multiple data breaches due to authentication vulnerabilities in systems of tech giants like Change Healthcare causing $870 million loss in first quarter of 2024 and affecting more than 100 million customers. A recent example of an attack is [5], in which an "unauthorized party" obtained access to "basic personal information" stored in NXP's online server(s). The described threat model makes the argument for the need to verify if a non-trusted or cloned MPSoC is trying to access or exchange data with the server. Even though several schemes deploy hash and ciphers to generate public/private keys, their complex nature coupled with low speed and area intensive nature makes them a costly choice. The existing MPSoCs are already complex enough. This necessitates the need for a scheme that is easily integrable in MPSoCs and has low area, power and performance overheads. One such scheme is Physically-Unclonable-Functions (PUFs).

The PUFs are popularly used by parent servers to authenticate in-field devices against adversarial clones. PUFs rely on randomly infused manufacturing (process) variations in CMOS

circuits to harness secret keys (responses) corresponding to certain inputs (challenges) [6]. The absence of additional on-device on-chip storage for secret keys and security key management makes PUF more attractive compared to their conventional cryptography-based counterparts [7], [8], [9]. Extrinsic PUFs require dedicated on-chip placement, making them more susceptible to side-channel and layout recognition attacks [10], [11]. However, intrinsic PUFs re-use the existing on-chip circuitry to extract the responses. For example, the SRAM PUFs use power-on states to extract the PUF responses, requiring limited changes to existing circuit [12]. They incur lower area and power overheads as only few changes are required in original design [13]. Therefore, we focus on intrinsic PUFs in this work.

In the domain of NoCs, existing router-crossbars can be utilized to realise intrinsic PUFs [14]. But such schemes often assume and work on specific gate-level implementation of various router blocks and require transistor and layout level changes, rendering them non-generic. Such modifications are not directly synthesizable as they can not be specified at behavioral level and require intervention in standard cell flow, leading to increased design effort, flow-complexity, and turn-around-time. Synthesized gate-level netlists can also be used to filter approximately equal gate-delay paths to realise intrinsic PUFs [15]. But this approximation not only adds a default delay-based bias in PUF responses but filtering only quality CRPs makes it computationally heavy and reduces set of usable CRPs. Moreover, scaling and technology-portability challenges will persist as the netlists size grow further for modern NoC-MPSoCs. Also, these schemes are silent over ML-based modeling attacks which are quite common in the domain of PUFs [16]. A detailed qualitative comparison with these schemes has been provided in Section V. Hence, these shortcomings necessitate the need for a more generic scheme for realising intrinsic PUFs with minimal impact on the power, performance and area of NoC-MPSoCs. Such scheme should be readily compatible with conventional standard-cell flow and scalable with increasing NoC size. In current work, we solve aforementioned challenges by exploiting the fundamentally symmetric multi-hop paths in NoC to our benefit, to extract the secret responses.

We propose NoCiPUF, a novel, fully-synthesizable *NoC-based intrinsic-PUF* framework for MPSoC authentication. Our scheme requires only behavioral-RTL level architectural changes in baseline NoC-routers, which eliminates requirement of manual intervention in existing standard-cell flow for NoCs. By limiting our scheme to RTL level modifications, technology portability becomes extremely easy and the framework can be scaled to any N×N NoC size using these minor changes in the router. NoCiPUF makes use of equal nominal delays corresponding to equal hop paths in a given NoC. The comparison of flit arrival times (delays) of such equal-hop paths at a common destination in an asynchronous setting yields unpredictable outputs encoded as PUF responses, unique to a given chip. The random distribution of manufacturing process variations across NoC among router components and interlinks [17] are responsible for the variations in otherwise nominally equal delays. Asynchronous flit-transfer during circuit switching [18], [19] preserves inherent delays of selected paths. These path-pairs constitute the challenges.

However, merely suggesting the re-use of the existing circuit does not provide the comprehensive view of how the modified system will work with the added functionality of intrinsic PUF [14]. In other words, given the complex nature of NoC-MPSoCs, questions like where do the PUF-enabled authentication operation fit in with the existing system operations, how do the challenges using the existing circuit blocks get applied or what exactly constitutes the challenges have to be answered whenever an intrinsic PUF is suggested. In this paper, we answer these questions by, 1) introducing an independent authentication mode in NoCiPUF besides its normal functioning mode, 2) providing elaborate algorithms to determine CRP space for given NoC size at design time, and 3) providing a systematic strategy to define and apply challenges for generating unique responses. Therefore, to the best of our knowledge, NoCiPUF is the first one to offer this degree of completeness which provides an intrinsic PUF framework for NoC based MPSoC authentication.

Intrinsic nature of the proposed PUF in NoC offers an inbuilt protection against discovery using side-channel attacks, reverse engineering, layout-recognition or modeling attacks [10], [11], [20]. However, the existing PUF implementations have been proved to be vulnerable to ML-based modeling attacks [16], with CRP prediction accuracy up to $\sim$ 99%. Therefore, we investigate the ML-resilient nature of NoCiPUF's CRPs. We find that the proposed framework inherently offers an error in the prediction accuracy of about $8\% - 18\%$. To further reduce the prediction accuracy, we suggest an ML resilient technique for state-of-the-art ML models used in PUF domain, i.e., LR (Logistic regression), SVM (Support-vector-machine), CMA-ES (Covariance matrix adaptation evolution strategy), and DNN (Deep neural network). We reduce prediction accuracy to $\sim$ 52%, which is close to ideally accepted value of 50%. This technique results in area and power overheads of 0.76% and 1.14%, respectively. These overheads are very low, justifying that the suggested ML-resilience technique is lightweight.

The framework is applicable for any NoC-based device deployed in-field every time the parent server needs to authenticate it prior to granting access to the server database. The NoCiPUF offers a wide range of challenge path-pair combinations, which is indicated by the CRP space computed for different NoC sizes. This ensures that the framework can function even if a particular node is faulty, as many other alternative challenge paths can be utilised in such cases.

Fig. 2 highlights the general authentication flow, with steps numbered (in circles) in the figure. Upon receiving a request from an in-field NoC-based MPSoC, the server first throws a challenge (CN_M) to the MPSoC (SoC_M; step 1.) and then the flit-pairs are sent over two equal-hop circuit-switched paths (step 2.). Upon reaching the comparator, a response (RN_M) is generated (step 3.) based on the path-delay comparison, and is sent to the server (step 4.). This response is then compared against the corresponding CRP entry in the parent-server's LUT. Our work is aimed at providing the on-chip NoC framework as required to support intrinsic-PUF operation.

The key contributions of this work are summarized as follows:

- We propose NoCiPUF, a fully-synthesizable and scalable NoC-based intrinsic PUF framework for MPSoC authentication which exploits unpredictability of flit-arrival

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 06:49:13 UTC from IEEE Xplore. Restrictions apply.

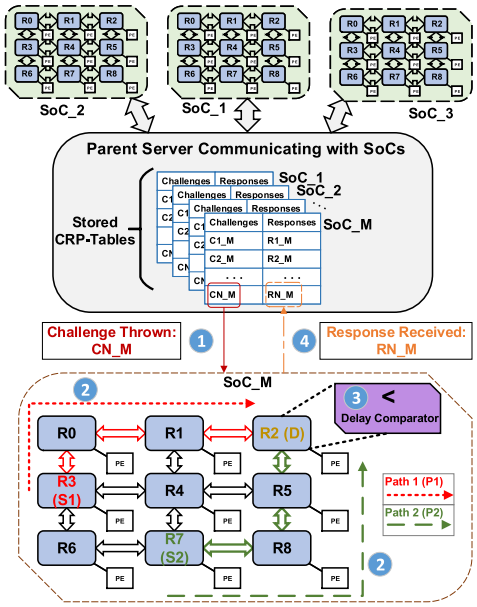

Fig. 2. A parent server authenticating the SoCs connected to it. Challenge (CN_M) is being sent to SoC_M. NoCiPUF framework is being used to generate response RN_M using P1 and P2.

delays owing to symmetric nature of multi-hop paths in NoC to encode PUF responses.

- NoCiPUF framework provides independent operation modes for authentication and normal working of NoC using circuit and packet switching strategies.
- Our framework involves all changes at behavioral level, making it directly compatible with standard ASIC design flow.
- We also investigate the ML-resilient nature of suggested framework and reduce the accuracy of response prediction to acceptable levels ($\sim$ 52%) using an on-chip lightweight post-processing technique.
- The intrinsic nature of proposed framework results in low area (0.76%) and power (1.14%) overheads.
- Monte-Carlo analysis has been performed to measure the PUF metrics, yielding 51.24% (31.26-bits) uniqueness and 53.3% uniformity. The framework achieved 96.95% and 97.34% reliabilities against temperature and voltage respectively. Responses are further validated with NIST randomness test suite.

The rest of the paper is organized as follows: Section II provides the background to PUFs, basics of NoC and switching strategies, and some authentication aspects of MPSoCs. Section III elaborates the hardware changes of proposed framework, algorithm used to find challenge path-pairs, and applied technique for ML-resilience. Section IV provides implementation details of the proposed methodology, discusses simulation results of intrinsic PUF parameters achieved using NoC, and reports the associated hardware overheads, followed by Section V which provides a detailed qualitative comparison of our work with related works. The last Section VI concludes this work.

II. Background

Before describing the proposed framework, it is important to understand various elements contributing to this work.

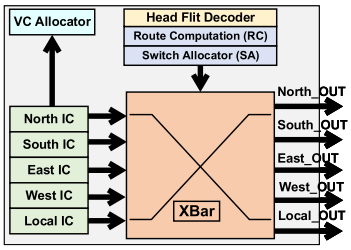

Fig. 3. Baseline NoC router architecture.

In this section, we briefly elaborate on the concept of PUFs and their intrinsic nature, followed by an overview of a baseline NoC, and packet and circuit switching strategies. We also investigate and highlight the state-of-the-art works in the domain of SoC authentication.

A. Intrinsic PUFs and Quality Metrics

PUFs use manufacturing process variations to generate a set of unique fingerprints (responses) corresponding to a set of inputs (challenges) from integrated circuits, in the form of CRPs. Intrinsic PUFs use existing circuitry available in the design to generate CRPs. The state-of-the-art intrinsic SRAM PUFs [12] have offered better reliability and energy efficiency as compared to their conventional counterparts. The intrinsic nature as a part of a larger circuit makes them harder to locate and be detected on the chip, making them a popular choice [15]. The effect of manufacturing process variations is reflected across NoC-routers (among various circuit blocks in them) and wires (interlinks), inherently affecting the multi-hop path delays.

For a given PUF, its CRPs should satisfy some measurable quality metrics at *inter*-chip and *intra*-chip level, to qualify for its practical feasibility. The *uniformity* (an intra-chip metric) indicates how varied the response bits are for different challenges. 50% uniformity indicates that the response bits are not biased towards either bit, 0 or 1. Its value is calculated by averaging the binary bits $r_{i,j}$ of the over m, n-bit responses obtained from the given chip, using the following relation:

$$Uniformity = \frac{1}{m}\sum_{i=1}^{m}\left(\frac{1}{n}\sum_{j=1}^{n} r_{i,j}\right) \times 100\% \qquad (1)$$

where $r_{i,j}$ represents j^{th} response bit corresponding to the ith challenge.

The *uniqueness* (an inter-chip metric) is used to measure the amount of variation in the response bits across different chips for the same challenge. It helps to distinguish a chip uniquely from other chips having same type of PUF implemented. The ideal value is 50% and it implies lower probability of repetition of responses among multiple chips. It is found by averaging the hamming distance (HD) of n-bit responses (R_i,R_j) among k chips using by the following relation:

$$Uniqueness = \frac{2}{k(k-1)}\sum_{i=1}^{k-1}\sum_{j=i+1}^{k}\frac{HD(R_i, R_j)}{n} \times 100\% \qquad (2)$$

The *reliability* (an intra-chip quantity) is an indicator of the bit-error-rate (BER), i.e., the variation in response bits

obtained against identical challenge given to the same chip under different environmental conditions. Intra-chip HDs for responses at different environmental conditions *env* (voltage or temperature variations) are averaged using following relation to find the corresponding BER:

$$HD_{INTRA} = \frac{1}{m}\sum_{env=1}^{m}\frac{HD(R_i, R_{i,env})}{n} \times 100\% \quad (3)$$

where R_i represents the response obtained at nominal voltage and temperature, $R_{i,env}$ represents the n-bit response at a temperature or voltage value of env, for i^{th} chip, and m is the total number of samples recorded (at different voltages and temperatures). Reliability is defined to be $(100\% - HD_{INTRA})$. Ideal reliability should be 100% when the response bits to a corresponding challenge do not change across varied environmental conditions. We realize the PUF functionality and measure the above metrics to establish feasibility of proposed framework. Choice of number of hops, path pairs and size of network determine the size of CRP space (summarized in Section III.)

B. NoC: Basic Working and Switching Strategies

Baseline NoC consists of various units: switch allocator (SA), route computation (RC), cross bar (XB), virtual-channel (VC) allocator, flit decoder (as per requirement), input controller (IC) (inclusive of input buffers), as shown in Fig. 3. These components are generally modified as per the design requirement. The RC stage computes the next node or identifies if the current node is the final destination. The SA stage then configures the XB to divert the incoming flit to correct directional output port. Then the flit passes through XB stage and is received by the input buffer (inside the IC) of the next node with allocated virtual channel (decided using VC allocator). If the current router is destination of corresponding flit, the XB is configured to divert it to local output (Local_OUT in Fig. 3).

We consider commonly adopted packet-switching (PS) with XY routing for the baseline router. In the PS, the RC stage calculates the next node for the current packet based on the

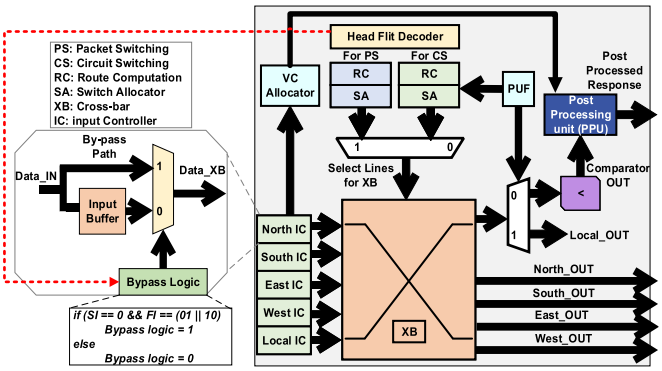

Fig. 5. Proposed router architecture.

source and destination node ID present in head-flit (HF) using XY routing scheme. HF, followed by body-flit (BF) and tail-flit (TF) of this packet propagate in a wormhole manner after XB is configured. Another switching scheme called circuit-switching (CS) is also prevalent in the domain of NoC [25]. Unlike PS, CS first reserves the path from source to destination using the HF and then the BF and TF traverse through this set-up path in one go. Some earlier works have leveraged the power and performance benefits of CS and proposed hybrid switching based NoC solutions [18], [19], [26].

C. Authentication Aspects of MPSoCs

Authentication in MPSoCs has been addressed in multiple aspects. These works target two different abstraction levels: at intra-NoC level (secure communication among the routers) and at MPSoC as a whole-system level (against third party or off-chip adversary). Some of these schemes are applicable when the SoC is being used in field (post-deployment) and some deal with authenticating the SoC still at foundry or testing facility (pre-deployment). We have classified these works accordingly in Table I.

For the context of this paper, we discuss some works which address SoC-authentication against external entities. The work [15] offers a boolean-satisfiability solver (SAT) based solution to use DFT-sensitizable combinational paths as PUFs in conventional benchmark circuits. They offer multi filter and post processing approach to select PUF-feasible paths from multitude of available gates. The work [27] uses watermarked paths inside NoC to verify if the IP with buyer has been sold by correct seller. If the buyer suspects any malicious activity in the system using this IP or there is a need to track illegal distribution, watermark identification is carried out. The works [23], [24] target chip authentication against suspicious activities at third-party level, like foundry or compromised testing facility. They rely on assumption that, the design house is able to establish a communication with the chip prior to deployment while still at foundry or testing facility to authenticate it. The work [14] attempts to construct PUFs out of individual router cross-bars in NoC. They modify NoC cross-bar and provide simulation results to validate the quality metrics.

Our work provides the authentication framework applicable to an NoC-based MPSoC deployed in-field by generating secret keys using NoC paths' inherent delays. We elaborate the corresponding routing and switching schemes, modes of

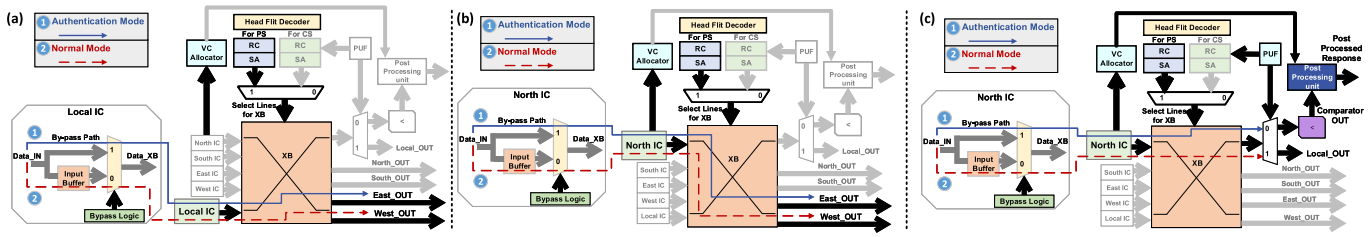

Fig. 6. Flow of BF and TF inside router during normal and authentication modes when router is either, (a) source, (b) intermediate or, (c) destination node.

operation (authentication and normal), along with minor modifications in existing routers, making the framework feasible for any given NoC and can be easily scaled up. Additionally, as both circuit-switching and packet switching are enabled, the SoC can use either type of switching as per requirement.

III. The NoCiPUF Framework

In a NoC, data packets can be sent from a source router (S) to a destination router (D) via different paths. Packets are typically split into flits as head-flit (HF), body-flit (BF) and tail-flit (TF). HF is mainly responsible for routing and other flags, BF carries the payload for the application and TF marks the end of packet. A path is a sequence of routers a flit would need to traverse starting at S and ending at D. Considering two different paths P1 (between source S1 and D) and P2 (between source S2 and D), if P1 and P2 have equal hop count (H), then ideally, flits launched from S1 and S2 should reach D after an identical delay. However, because of manufacturing variations, the delays along both paths differ. In the proposed scheme, a multi-bit delay-comparator is used at D to enable parallelism to determine which flit arrives first. This choice of a path pair PP (P1, P2) in the network forms the NoCiPUF's challenge space. We describe the behavioral changes required in the NoC router to support the PUF based authentication operation. The modified router is the fundamental unit of the NoC in our experimental setup. The multi-bit interconnects between routers are of equal-length and require no modifications. This approach ensures a physically symmetric NoC structure by the virtue of identical routers and interconnects throughout the NoC. The following subsection III-A discusses the working of NoCiPUF framework while elaborating corresponding modifications required in the router hardware for authentication. The subsection III-B elaborates the algorithms used to find NoC-paths suitable for PUF operation and reports the CRP space with respect to number of hops and NoC mesh size.

A. Authentication Scheme and the Modified Router

To support the authentication operation in addition to regular data-flow, we classify data transfer in the proposed framework among three modes of operation: 1) CS for authentication mode (CSA), 2) PS for normal mode (PSN), and 3) CS for normal mode (CSN). PS and CS refer to packet and circuit switching respectively. In order to differentiate among these modes, we define three types of header-flits as shown in Fig. 4. All the three types of HF have 3-MSBs dedicated to identify the type of switching (1st bit: switching identifier, SI) between CS (SI=0) or PS (SI=1) and type of flit (2nd and 3rd bits: flit-identifier, FI). Table II shows the significance of various possible combinations of the 3-bits.

TABLE II
Switch and Flit Indicator Bits in the Head Flit

SI bit (1)	FI bits (2)	Mode	Flit Type
0	00	CSN Mode	HF
0	01	CSN or CSA mode	BF
0	10	CSN or CSA mode	TF
0	11	CSA mode	HF
1	00	PSN mode	HF
1	01	PSN mode	BF
1	10	PSN mode	TF
1	11	NA	NA

The baseline router is modified to support these modes and flits. The modified router architecture required to support the proposed framework is shown in Fig. 5. This router architecture contains separate route-computation (RC) and switch-allocation (SA) units to support hybrid switching (PS and CS), a PUF unit to identify common destination corresponding to challenge (explained later), modified input-controller-IC with bypass path, and a multi-bit comparator unit to generate response bits parallely. The head-flit decoder is used to switch between the NoC's authentication (CSA) and normal (PSN or CSN) modes of operations and to differentiate among the flits corresponding to the three modes. The SI and FI bits in the HF (Fig. 4) govern this decision. The bypass logic inside the IC as shown in Fig. 5 receives the SI and FI bits as inputs from the head-flit decoder to switch the MUX above it. Bypass logic selects by-pass path for BF and TF during CSA and CSN whereas the buffered path is selected for the HF in all modes (CSA, PSA, CSN), for BF and TF in normal mode (PSN). The bypass logic is summarized using if-else statement in the Fig. 5 to indicate how the input controller switches between different modes of NoC operation.

The Fig. 6 illustrates the datapath taken by the BF and TF during normal (here, PSN) and authentication modes (CSA) of operations. We choose PSN as normal mode for this illustration because it uses conventional packet-switching in a typical baseline NoC. It is assumed in this illustration that the HF has already switched the XBar (XB) for the upcoming flits. For simplicity, a convention of East and West output ports for CSA and PSN modes respectively, is taken. Fig. 6a shows the flit starts from the local port if it is in source router node and crosses the XB and reaches the east output port. If it is PSN mode, then, buffered path inside the IC is chosen whereas it is bypassed during CSA mode. Flits flow similarly in any intermediate router, except they enter router through a directional node (North in Fig. 6b) unlike the source router. For destination router (Fig. 6c), the de-multiplexer transfers the flits to comparator in CSA mode and to local output node (connected to processing element) in PSN mode. The Fig. 7 further illustrates flow of the pair of flits during CSA mode

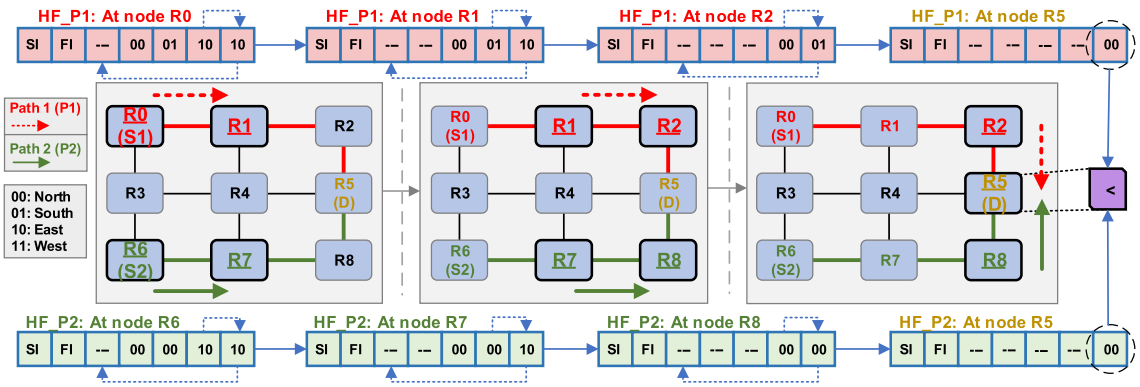

Fig. 7. Path set-up phase using simultaneous travel of two HFs along two equal hop (=3) paths. Updates in the HFs due to right shift has been shown. At destination node, both HFs point towards "00" (north) and hence XB switches to comparator output.

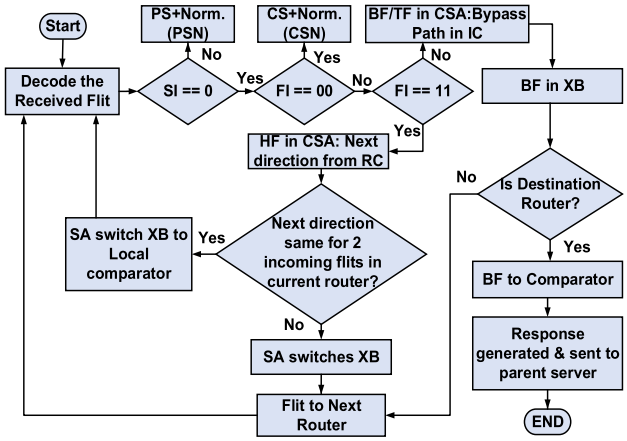

Fig. 8. NoCiPUF-router flow during authentication mode.

exclusively. The above discussion shows that the flits traveling in normal (PSN) mode of operation are not affected by the changes done for authentication (CSA) mode, implying no performance overheads during normal mode of operation.

As shown in Fig. 4 for CSA, rest of the HF contains bit-pairs (Next_1, Next_2, etc.) indicating the next directional node to be reserved to set-up the pre-encoded path. The two bits per pair, correspond to one of the four available directions. An example of directional mapping and flit-traversal in a 3-hop path-pair during authentication mode (CSA) can be observed in Fig. 7 and can be referred to visualize the framework at NoC level. To ensure design simplicity during the authentication mode, we use right-shift (while preserving SI and FI bits) to bring bit-pair for next router at LSB position in HF. The route-compute (RC) unit decodes the 2-LSBs to identify the direction of next router, and SA switches XB accordingly. This routing strategy is inspired from vector-based routing [28]. As seen in Fig. 7, the updates in HFs: HF_P1 (path, P1) and HF_P2 (path, P2) are indicated at the top and bottom of the figure, respectively.

Whenever the two HFs, launched from sources S1 and S2, arrive at a common node (D), the next bit-pairs (which were already pre-set to point to the same direction) flag this node as the destination. The dotted circles in HF_P1 and HF_P2 at node R5 in the Fig. 7 show '00' bits indicating both want north output port. PUF-unit sets select-line of DeMUX as '0' to divert upcoming flits to the comparator during CSA, and to '1' in other two modes. This is followed by BF and then TF un-reserves the path. The remaining two flits, BF and TF in path-pairs flow in the same manner, except there is no right shift involved as the IC bypasses other router components (except XB) to preserve the effect of process variations along the path.

Fig. 8 shows the proposed router's behavior during the CSA mode. After receiving the flit, the head-flit decoder identifies the flit-type and the mode. For SI = 0 and FI = 11, HF is identified and CSA mode is selected (Table II) and RC computes the next router node. The SA then configures the XB by generating select lines. The HF decoder also sets the MUX above XB to select input from CS based RC and SA stages. The last-bit-pair in the challenge HFs, is designed to ensure that both the HFs from S1 and S2 point to the same direction (in our case, north) as soon as they reach the common destination (D) node. After the destination node is identified, SA configures the XB to divert rest of the incoming flits to comparator using bypass paths in IC (right side of Fig. 8). This is followed by the BFs to flow asynchronously and concurrently in the reserved paths (Fig. 7). On arriving at the destination node, XB diverts both the BFs to the comparator to generate the final response bits. We exploit the complete BFs from the two paths as input to multi-bit comparator (of the same length as the flit) to generate the multi-bit response. This response is then sent to parent server to compare against the stored CRP entry present in it.

During the CSA mode, bypass paths in router IC are activated for the BFs and TFs. These bypass paths skip sequential elements inside the routers and provide asynchronous transfer, thereby preserving the much-needed unpredictability in delays due to manufacturing process variations (PVs). This avoids clocked latching and locking, preserving the expected PUF behavior. The comparator is implemented using parallel DFFs (D-flip-flops) equal to the required number of bits in each response. These DFFs receive the two body flits (from P1 and P2) as their clock and data inputs. Now, even though the nominal delays of equal hop paths should make BFs arrive exactly at the same time instant, PVs cause them to be delayed unpredictably. This eliminates the need to measure individual flit delays as whichever BF arrives earlier, dictates the output of the DFFs and hence the complete response. NoCiPUF framework ensures that all bits in BFs from S1 and S2 cause same transition i.e. 0 to 1 at the comparator inputs. The CSN mode only requires the destination ID to decide the next

router for path-setup, based on availability during regular data flow. For PSN, HF stores information regarding source and destination node IDs. HF goes to input buffer, followed by RC and then SA generates select line for other flits flowing in wormhole fashion. We have considered XY routing for PS mode but there is no restriction on any routing strategy with respect to our scheme.

We now describe the algorithms used for determining CRP space for the given NoC, where the challenges are defined in terms of path pairs.

B. The Challenge-Response-Pair Space

We aim to find all possible path pairs (P1, P2) for all possible triplets (S1, S2, D), in the given N×N mesh network, to calculate the available CRP space. The challenges are pre-calculated at the design-house itself, based on the size of NoC required, avoiding the need to generate them on the fly. This can be done first by finding all possible multi-hop paths using a depth-first search approach as presented in Algorithm 1, and then pairing equal hop non-overlapping paths with common destination using Algorithm 2. After all such path-pairs have been found, they are stored as challenges at the parent server, which are mapped to the PUF responses for different chips after the enrollment procedure at the chip-manufacturer's end.

In Algorithm 1, in the function *obtain_paths*, we define three data structures, $path_dict$, $visited_nodes$ and $direction_list$. The $path_dict$ stores paths sorted according to the number of hops, $visited_nodes$ stores the visited routers in the path and $direction_list$ contains the allowable directions for a router. For instance, in a mesh based network, only two directions are possible for corner nodes. When the destination router is reached (line 4), the taken path arranged by number of hops is returned (line 5 and 6). When path is being determined (lines 7-21), we consider if the node has been visited earlier (line 8-10). This is done to avoid overlapping in the path. We then consider all the possible directions a packet can take while leaving the present router. If the next router on the path has been visited already (line 13-15), we consider the router present in another direction. If the router has not been visited, it is appended to the $visited_nodes$ array and the above process is repeated till it reaches the destination router.

In Algorithm 2, we look at the flow to extract non overlapping path pairs from the set of all possible path-pairs. We aim to obtain all possible path pairs for the authentication flow as discussed in Section III-A. We consider two source routers and one destination router, such that all three are different (line 3). We calculate all possible paths between the source and destination router (line 4 and 5) using function *obtain_paths* as discussed in Algorithm 1 and traverse through them. Then, for a given source pair and destination nodes, if the number of hops are equal and no node is common amongst the two paths, (line 9), the resultant paths are marked to be used for PUF mode. Now these common destination, equal-hop path-pairs are ready to be stored at the parent server in CRP table.

The maximum number of hops (H_{max}) allowed is determined by the mesh size (N×N). Table III shows the possible number of path-pairs supported by the proposed router micro-architecture, corresponding to hops for different NoC-mesh sizes. This table is compiled using Algorithms 1 and 2. The

four possible directions for the flit traversal at every node in the chosen path are represented by two bits. If there are "H" hops in the path, it corresponds to "H×2" bit-space in the HF. In our experiment, each HF is 64-bits long. Leaving the three MSB SI and FI bits, the remaining 61 bits can support up to 30-hop paths (applicable for NoC size 6×6 and above). As seen in Table III, network 5×5, which can support up to 12 hops, has over 7.42×10^5 (> 0.74 million) possible path-pairs. This observation implies that when the proposed NoCiPUF framework is scaled up, the maximum possible hops increases and when supported with a longer HF, it leads to an even larger CRP-space. Modern-day NoCs are typically deployed in multi-node systems to seamlessly integrate hundreds of cores [29], [30]. Such systems require NoCs with mesh sizes 8×8 and above. Given the NoCiPUF's trend of exponential growth of the number of path-pairs (challenges) with increasing network size, one can easily conclude the possibility of a multi-million CRP space for NoC sizes 8×8 and above. Therefore, our intrinsic authentication enabled solution is perfectly suited for exa-scale MPSoC systems. Section IV shows various PUF-metric plots, which are classified according to the number of hops for a 4×4 NoC.

We have applied the challenges generated using algorithms 1 and 2 during simulation of the network with the proposed router architecture to obtain the results reported in next section.

C. Resilience Towards Modeling Attacks

Delay based extrinsic PUFs are inherently vulnerable to ML-based modeling attacks. For conventional Arbiter PUFs,

such trained models are able to impersonate the trusted device by predicting the responses correctly with over 95% accuracy [16]. This observation prompts us to investigate the ML-resilience of NoCiPUF against the ML based modeling attacks and further suggest countermeasures to reduce the prediction accuracy to acceptable levels.

1) ML Attack Mechanism: For launching a ML based attack, the adversary first queries the trusted PUF device to collect a subset of CRPs as training data for models like LR, SVM, CMA-ES or DNN. To query the device means to throw a challenge and receive a response. Then the adversary trains a ML model based upon the received responses from the queries. Once the model is trained, the adversary uses this trained model to impersonate the trusted device (having PUF) by predicting new responses as and when queried by the parent server. Other attack strategies which involve tailoring ML-models to exploit the specific obfuscation mechanisms of

TABLE IV
ML-ACCURACY OF RESPONSE PREDICTION

ML Model	Without ML-Res.	After ML-Resilience
LR	78.82%	48.21%
SVM	82.99%	48.19%
CMA-ES	79.51%	56.62%
DNN	86.14%	54.81%

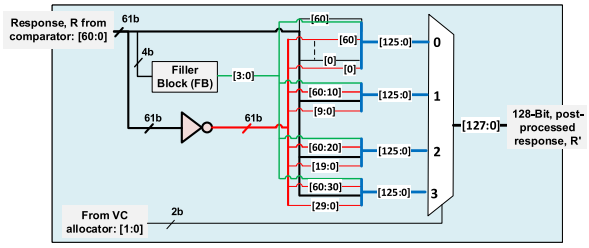

Fig. 9. Post-processing unit (PPU) inside router to counter ML attacks.

PUFs also exist [31]. Unlike the extrinsic PUFs using MUX chains or ring-oscillators, we re-use existing NoC structure to implement the PUF operation. The existing switches (routers) and interlinks are used to harness the unique responses. The already complex nature of NoC, combined with multitude of possibilities of path-pairs (hence, challenge-space) spread across the network makes it an extremely difficult task for an attacker to model the equivalent PUF hardware at their end. This provides a primitive layer of protection against the modeling attacks, by the virtue of the way NoCiPUF defines the PUF operation and provides a huge and scalable CRP space. This results in a nearly $8\% - 18\%$ decrease in the default prediction accuracy of NoCiPUF CRPs when no ML attack protection strategy is used, as shown in first column of Table IV

2) ML-Resilient Technique: To address the ML-based modeling attacks, existing works introduce more non-linearity in PUF stages using entropy sources based on advanced-encryption-standard (AES) [32] or XOR network [33], or complex of pseudo-LFSR networks [34]. Such schemes can only be applied for standalone extrinsic PUFs and incur very high area and power overheads. Also, due to their highly complex nature, these schemes are difficult to integrate with existing MPSoCs.

On the other hand, some schemes offer runtime-reconfigurability of CRPs or post-processing of challenges in PUFs to counter ML-modeling attacks [35], [36]. These schemes effectively conceal randomized post-processing steps from the attacker, and cause the adversarial model train on incorrect challenge-response mapping. Taking motivation from these reconfigurable approaches, for NoCiPUF, we deploy a post-processing hardware unit (thereafter called PPU) inside the router to modify the generated responses, as shown in Fig. 9. We assume that this post-processing hardware and its functionality are not known to the attacker. The PPU receives two sets of inputs, one is the default 61-bit response, R which is the output of comparator as explained in Section III-A and the second is the 2-bit signal received from the VC allocator of the router as shown in top and bottom left of Fig. 9, respectively. The PPU extends the 61-bit response (R) to a 128-bit post-processed response (R') using any one out of four predefined post processing rules. These rules can be defined

as: rule-1): add filler bits between every two bits; rule-2) to shift the response bits by x_1-bits, rule-3) by x_2-bits and rule-4) by x_3-bits. Rest of the bit-positions are occupied by filler bits.

In our implementation, we selected $x_1 = 10$, $x_2 = 20$, and $x_3 = 30$ and utilized the complement of response bits as filler bits. As shown in the Fig. 9, the incoming 61-bit response is inverted to generate 61 filler bits, making a total of 122-bits. The rest of the 4 filler bits are also obtained from the original response as indicated in the filler-block (FB) in the figure and the final 2 MSBs are the bits received from the VC allocator, making the rest of the 6 bits. The four rules are implemented by rearranging the response and filler bits as shown in the right side of the figure. The 4×1 MUX receives the re-arranged inputs for all four cases, and the 2 bits from the VC allocator to decide which input to select as the final, post-processed response. Therefore, the bit-extension rules implemented using the rewiring the real response and filler bits gets easily integrated with existing hardware. For example, for rule 2), where shifting by 10-bits is required, the LSB bits [9:0] are followed by next real response [60:0] bits, followed by inverted filler bits [60:0] and finally the last MSB positions are occupied by 4-bits from FB unit. The 2-MSBs from VC allocator are further appended by the 4×1 MUX in all the four cases. These 2-MSBs represent the ID of recently used VC just before CSA run, which results in completely unpredictable selection among the four rules. So, effectively, for the same challenge, the PPU can result in 4-possible responses, based on the randomly selected rule. The 2-MSBs of 128-bit processed response indicate the applied rule number and are used by the parent server to select real 61 response bits. The information about all possible rules is supplied beforehand to the server by the design-house. Now, for an adversary querying the NoCiPUF, its ML model will be trained to map every 64-bit challenge to a single 128-bit response. This response can be mapped to any of the four possible cases, unknown to the attacker and hence the trained model. So whenever the server receives a response generated by the trained adversarial model, it will use the 2-MSBs to choose the decoding scheme. Now, it is highly unlikely that the decoded-response bits picked by server match with stored, golden response. This is because the predicted response was based on training with the post-processed responses received earlier, which are subject to change with time even if the challenge remains the same. This results in dramatic reduction of model's prediction accuracy in correctly modeling the underlying NoCiPUF.

We tested this scheme and trained the model with 80% of CRPs $(5,411)$ and measured accuracy on remaining 20% CRPs $(1,352)$. We used default parameters for LR and SVM, where $C = 1.0$ with $lbfgs\ solver$ and $kernel = rbf$. For CMA-ES, all initial parameters were set to 0 with an initial sigma of 0.5. We ran 250 iterations to find the best model and have reported the results for the same. For the DNN model, we constructed a 3-layer neural network with real and sigmoid activation for the first two and the last layer, respectively. We used $Adam$ optimizer and ran 50 epochs with a batch size of 32. As shown in Table IV, suggested post-processing scheme brings down prediction accuracy of various ML models from more than $\sim 81\%$ to around 50% (average = 51.96%), which is close to ideally expected value for ML-resilience in PUFs because this means probability of guessing the correct response by trained model is almost that of coin-flip, rendering the trained model unreliable. We make sure that the PUF's randomness and the metrics of uniformity, uniqueness and reliability remain unaffected by the ML resilient post-processing operation as the originally generated response bits (61-bits) are still preserved. The associated hardware overheads are provided in the next section.

IV. Experimental Setup & Results

We have considered a 4×4 NoC with mesh topology for experiments in this paper. The proposed NoCiPUF router is shown in Fig. 5. As explained earlier, the proposed router architecture supports hybrid switching (PS and CS). The baseline router considered for comparison is shown in Fig. 3. This baseline router is assumed to have PS and XY routing implemented. The extracted intrinsic PUF's validity and correctness has been quantified in terms of uniformity, uniqueness and reliability (explained in Section II-A). For the experiments, we have assumed 64-bit wide flits supported by 64-bit wide inter-node links. The 3 MSBs of the 64-bit flit indicate the SI and FI. This leaves the remaining 61-bits which are used as challenge in head-flit (HF), and as the required trigger in body-flit (BF) to generate the 61-bit response at a given destination router. We use a 61-bit comparator at every router to obtain the 61-bit response concurrently. This approach makes sure that every challenge fetches the complete multi-bit response in one go, thus avoiding the requirement of applying multiple challenges for longer response. As can be observed from Table III, hops (H) up to 7 are supported by 4×4 mesh which occupy 14 bits of challenge HFs. The BF is configured to have all 1s so that the transition of 0 to 1 (in both the chosen paths P1 and P2) can be observed at the comparator's inputs. The responses are obtained using Monte-Carlo SPICE simulations that have been carried out on Eldo using the ST-Microelectronics SVT 65nm Technology library. Each Monte-Carlo simulation represents a separate instance (fabricated chip). We consider all possible CRPs for 4×4 NoC mesh as shown in Table III for validating the randomness of NoCiPUF's responses, using NIST suite [37]. We have synthesized the NoC using Cadence Genus to report area and power overheads for comparative analysis.

In the following sub-sections, we report the measured PUF metrics, NIST randomness results, and area and power comparisons with baseline NoC and state-of-the-art router based intrinsic PUF.

A. Uniformity, Uniqueness and Reliability

The data used to calculate the three standard PUF metrics corresponds to original responses (61-bit) obtained just after the comparator stage, independent of their post-processing for ML-resilience. This is because only these 61 bits will be selected automatically by the parent server from among the 128-bit extended response and then compared with golden LUT entry.

Uniformity is an indicator of the average bias of the resultant PUF's responses towards bit 0 or bit 1. Ideal value is 50%. Using equation (1), and taking values of $n = 61$ (response bits corresponding to comparator output) and $m = 200$ (number of responses obtained), our Monte-Carlo SPICE simulation results yield uniformity of 53.3% across all the responses

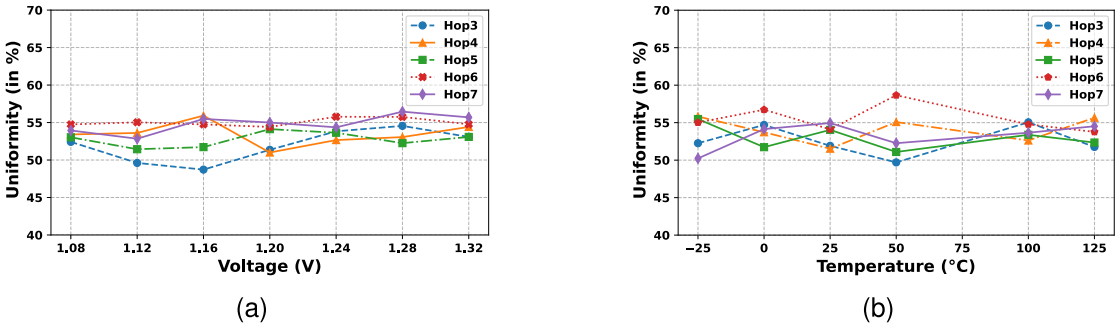

Fig. 10. Uniformity trends at different conditions: (a) as voltage is varied with steps of 40mV, (b) as temperatures are varied from −25° C to 125° C.

which is very close to the ideally expected value. This value is collected at temperature of 25° C and voltage of 1.2V. Plots in Figs. 10a, 10b show the trend of uniformity across various voltages and temperatures respectively. Uniformity varies from 49.23% (30.03-bits, HOP=3, 1.16V) to 56.27% (34.32-bits, HOP=4, 1.16V) across voltages and from 49.7% (30.32-bits, HOP=3, 50° C) to 58.66% (35.78-bits, HOP=6, 50° C), across temperatures for all the hops.

As shown in Fig. 2, fabricated chips should have different response (RN_M) to same challenge (CN_M) thrown to them during the PUF operation. Inter-chip variation, also called uniqueness, indicates how varied are the responses among the given set of chips for same challenge thrown to them. It is measured using equation (2), taking $k = 200$. In Fig. 11a, we can observe that for 200 Monte-Carlo simulations (i.e., analogically 200 chips) at hops ranging from H=3 to H=7 the average HD converges to ∼50% for all hops. Exact values vary from 50.94% (31.07-bits, HOP=7) to 51.58% (31.46-bits, HOP=3) per 61-bit response at nominal conditions of 1.2V, 25° C. The overall average uniqueness is 51.24% (31.26-bits) which is almost the ideal inter-chip variation expected. Plots in Figs. 11b and 11c show trends for uniqueness as temperatures and voltages are varied respectively. Minimum and maximum uniqueness values across all temperatures are 49.66% (30.29-bits, HOP=6, 50° C) and 51.71% (31.54-bits, HOP=3, 50° C) respectively. Minimum and maximum uniqueness values across all voltages are 50.53% (30.82-bits, HOP=4, 1.16V) and 51.70% (31.53-bits, HOP=3, 1.12V) respectively. This trend shows that the NoCiPUF-CRPs are resilient against varying temperatures and voltages in terms of inter-chip variations as the corresponding uniqueness values remain nearly ideal.

The intra-chip variation indicates the reliability of PUF responses against varying environmental conditions. Same challenge is thrown to the same chip (here, same Monte-Carlo instance) under different environmental conditions in terms of voltage and temperature variations. As per the equation (3), the average of intra-chip HDs (HD_{INTRA}) represent BER of the PUF. The plots in Figs. 12a, 12b show the distribution of intra-chip HDs with varying temperatures and voltages respectively. We vary temperatures ranging from −25° C to 125° C and record the responses, to obtain plots shown in Fig. 12a. It can be observed from the plot that, for different number of hops, the frequencies of large HD values converge to zero, indicating a very low BER. The average BER against temperature changes is found to be 1.9-bits per 61-bit response, meaning 96.95% reliability. The Fig. 12b shows the distribution of intra-chip HDs among responses for various hops as the voltage supply is varied from −10% to +10% around 1.2V. The reliability against voltage variations is found to be 97.34%. This implies an average BER of 1.7-bits. The plots in Figs. 12c, 12d show the percentage of reliably generated bits (reliability values) at different temperatures (with respect to 25 ° C) and at different voltages (with respect to 1.2V) respectively. These reliably generated bits vary from 95.23% (58.1-bits, HOP=7, −25° C) to 98% (59.8-bits, HOP=7, 0° C), per 61-bit response for different temperatures. Voltage changes result in reliably generated bits varying from 95.26% (58.11-bits, HOP=4, 1.16V) to 98.75% (60.23-bits, HOP=7, 1.24V). We have further calculated the BER for extreme conditions of high temperature (125° C) and low voltage (1.08 V) to be 5.9 bits per 61-bit response. It can be clearly observed from the plots in the Fig. 12 that the suggested intrinsic PUF framework shows good (close to ideal) resilience against environmental variations of temperature and voltage. The same observation can be extended to the two metrics of uniformity and uniqueness as NoCiPUF shows nearly ideal values to these metrics at different voltages and temperatures also. The state-of-the-art works [12] have reported the BER of as low as zero ($\sim 3.76e-08$), however our work additionally offers resilience to a variety of ML models and its NoC centric intrinsic nature makes it scalable for large MPSoCs. Furthermore, the corresponding values for uniqueness, uniformity and, reliability against voltage and temperature values for the work [14], which proposed implementation of Arbiter PUF in NoC router, are: 49.3%, 56.46% and 94.71% and 94.82% respectively.

B. NIST Randomness Analysis

The NIST [37] provides a test-suite to quantify randomness of random and pesudo-random number generators. We use this suite to evaluate the quality of randomness of responses produced from the proposed authentication mechanism implemented as intrinsic PUFs in the mesh NoC.

NIST randomness suite requires multiple (thousands or more) bit-sequences pertaining to a single TRNG instance, NoCiPUF in our case. We chose one random Monte-Carlo instance and apply challenges to generate the corresponding responses. We obtained 6, 764 61-bit responses amounting to 412, 604 bits using this method. To run the tests, we split these into 64-bit, 6, 446 bit-streams (rounded off). It can be observed from the Table V that almost all the tests fetch near ideal results (above 90%). The Table V also shows the corresponding P-values for every test. P-value greater

Delay	1.3ns	1.4ns	5.2ns

than 0.01 is the criteria used by the NIST suite to imply if that the given bit-sequence passed the test.

C. Overheads Analysis

The differences between the baseline and proposed NoC router can be observed by comparing Figs. 3 and 5, respectively. To support hybrid switching, additional RC and SA units have been augmented in existing routers. PUF control unit has been added (Fig. 5) for CSA mode to decide how the HF will be decoded in CS mode and where should the upcoming flits travel in case of destination router. Further, bypass paths are enabled in IC. Extra multiplexers are required in IC (to bypass) after RC-SA stage (to select between CS or PS), and a demultiplexer is needed to decide where the flit should go at the destination node (to the comparator for CSA and local output for CSN/PSN). We target a performance of 1 GHz to calculate all the overheads resulting due to hardware changes.

TABLE VII
QUALITATIVE COMPARISONS

	Ref. [14]	Ref. [15]	NoCiPUF
Intrinsic PUF implementation style	Comparison of delays associated with cross-bar in a single router	Comparison of delays associated with gates in a synthesized netlist	Comparison of delays associated with equal hop path-pairs in NoC
Level of abstraction (Ease of implementation)	Circuit level (moderate)	Gate level (difficult)	Behavioral level (easy)
ML Resilience in Intrinsic PUF	Not provided	Not provided	Provided, up-to ∼52% unpredictability of responses
Inherent bias in nominal delays	No	Yes	No
Detailed visibility of authentication and normal operation modes	No	No	Yes
PUF specific special layout requirement	Yes	No	No
CRP space Computational Complexity	Low	High	Moderate

These hardware changes for NoCiPUF are reflected as 0.52% area overhead and 0.77% power overhead as compared to baseline router. We have reported the delays to generate the responses once the challenge is applied. For the proposed NoCiPUF, longest possible 7-hop path for the 4×4 NoC incurs a delay of 1.3ns. Second column in Table VI summarizes these area and power overheads as compared to the baseline NoC.

Further, we also added hardware for on-chip post-processing of responses for ML-resilience (PPU) at every router. This incurs some additional power, area and delay overheads, apart from overheads from just PUF-specific changes. Cumulative overhead of NoCiPUF after addition of ML-resilient hardware becomes 0.76% in terms of area, and 1.14% in terms of power. The maximum delay to generate a single 128-bit post-processed response is measured to be 1.4ns. This delay has increased only slightly compared to previous observation. These results are summarized in the third column of Table VI. We can observe that even with additional hardware required to counter ML-attacks by adversary, the overheads are still under manageable limits, making the suggested framework seamlessly scalable. Additionally, introducing more number of post-processing rules will not only provide protection against more advanced ML models but based on the current number, will incur overheads well under practical limits.

We further compare the proposed NoCiPUF framework with an existing work [14] which used individual routers to implement Arbiter PUFs and summarize the overhead comparison in the fourth column of Table VI. It should be noted that this work does not provide any guarantee against ML resilience and hence there is no equivalent hardware used in their implementation. We can observe that as compared to baseline, their area overhead is 1.26% which is more as compared to our work, even after including ML resilience in NoCiPUF. The power overhead is 0.22% which is lower than our work, but is less significant, given the fact that our framework offers ML resilience also. However, the delay to generate response from the single router after the challenge is applied is measured to be 5.2ns. This delay is ∼4x that of the NoCiPUF response generation delay. There are several benefits of NoCiPUF over the work [14] in terms of completeness of operation, functionality and implementation worthiness, which are elaborated in the next Section V.

The following section highlights the qualitative comparisons with works in the existing literature relevant to the proposed authentication framework.

V. DISCUSSION AND QUALITATIVE COMPARISONS

As mentioned in Section II-C, several works target SoC authentication in various aspects. In this section, we provide qualitative comparisons with some works relevant to the context of this paper. These comparisons have been summarized in Table VII. The work [14] proposes to realize intrinsic PUFs using the multiplexers in the crossbar (XB) of a NoC router, limiting their scope to individual routers. This makes router-to-router communication and interaction among intra-router components ambiguous during PUF operation. In contrast, we have defined separate modes to integrate the intrinsic PUF operation in a given NoC. These modes are supported by corresponding HFs, to ensure proper communication among routers and provide intra-router strategy during authentication operation in NoCiPUF. Their scheme assumes a specific implementation of XB and modifies it along with the use of pass-transistors (PTL) between multiplexer stages. However, as we have suggested all changes at the behavioral level, they require no specific implementation of XB or of any other router components, and hence do not need any special consideration regarding the PTL or standard cell technology library. This makes NoCiPUF directly adaptable to existing standard cell flow for NoCs. Moreover, we highlight the creative use of head-flit in vector-routing-based CS in conjunction with RC, SA and XB to generate select lines for path reservation. The work [14] does not, however, address how a router should be provided with challenge information to produce select lines for their XB.

In the work [15], the authors suggest a method to obtain intrinsic PUFs in combinational netlists using path-pairs. The scheme is applicable only to gate-level netlist and requires multiple computations to select paths. Their scheme requires SAT-based PHAETON engine to find path-pairs and separate algorithms for tap-point-optimization, and these computations depend on the number and the type of gates present in synthesized netlists. However, they have tested their scheme for benchmarks circuits having few tens of thousand gates only, while modern MPSoCs can have up to millions of gates. Therefore, such multi-layered computations are bound to be heavy when applied to larger and more complex MPSoCs, making their scalability questionable. However, we have developed much simpler algorithms to find NoC path-pairs corresponding to CRP space. These can be easily reproduced and adopted for any given NoC size and topology, strengthening the generosity of our framework for NoC-based MPSoCs. Moreover, the work can only select approximately equal paths, which are subject to unequal nominal delays, thereby causing an inherent bias in delays. This biasness causes metrics such as uniformity to degrade. This phenomena necessitates an additional layer to further filter out the paths with near-ideal metrics, further reducing the set of usable CRPs. In contrast, we use all the available non-overlapping

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 06:49:13 UTC from IEEE Xplore. Restrictions apply.

This article has been accepted for inclusion in a future issue of this journal. Content is final as presented, with the exception of pagination.

equal-hop path-pairs amounting to equal nominal delays, ensuring maximum unpredictability due to no approximation, when flits arrive at destination node. Additionally, in our framework there is no need to take individual gate delays into account while computing the CRP space. Remarkably, none of the aforementioned intrinsic PUF schemes have talked about resilience to ML based modeling attacks, whereas, we address the ML resilience using a lightweight technique. The other works which offer ML resilience are extrinsic in nature [38]. The ML resilience offered by NoCiPUF (∼52%) is extremely close to the ideally expected value of 50%.

Other works related to authentication, such as digital IP watermarking in NoC, provide only a singular watermark per IP to verify if it is sold by a trusted seller [27]. However, using NoCiPUF facilitates multiple CRPs for the same MPSoC. So, in the event that a secret key is eavesdropped by an adversary, the next authentication phase will have a choice from the huge CRP space provided by NoCiPUF. Some schemes target chip authentication at foundry and/or testing facility [23], [24], which is different from the focus of our work.

VI. Conclusion

In this work, we propose NoCiPUF, a robust, feasible and effective authentication methodology to reuse the interconnect fabric of NoC-based MPSoCs. Our scheme is based on intrinsic PUF derived from equal-hop path-pairs in NoC. We also provide a comprehensive technique to counter most common ML-based modeling attacks on strong PUFs and successfully reduce the prediction accuracy from over 86−% to around 52%. The results promise near-ideal intrinsic-strong-PUF behavior with a uniqueness of 51.24% (31.26-bits), reliability against temperature and voltage to be 96.95% and 97.34% respectively, and uniformity of 53.3%. We also showcase robustness of PUF responses against NIST randomness test suite where tests yield more than 90% pass rate among the input response bit-streams. We make efficient use of hybrid switching, which not only re-uses circuit-switched paths for authentication but enables choice between packet and circuit switched paths for regular data flow. The resultant area and power overheads are 0.76% and 1.14% respectively with respect to equivalent baseline NoC. The algorithmically calculated usable paths-pairs clearly indicate that the CRP-space rises exponentially, up to > 0.74 million with network size of just 5×5 NoC, which is remarkably suitable for securing advanced and complex MPSoCs which require larger NoCs.

Received: 8 November 2024; accepted: 31 March 2025

The work aims to investigate and evaluate the biodetection capability of a nanowire MOSFEB detector for label-free biomedical applications. The study adopts a numerical computational-cum-simulation methodology to modulate, control and optimize sensitivity through dielectric modulation. Doping, a controllable factor prior to the fabrication process, plays a crucial role in enhancing the sensitivity of similar biosensors, thus making this work valuable. It is evident in the study that lower doping levels in the source and drain result in a greater percentage change in sensing metrics, whereas higher doping levels lead to a more significant relative change in sensing metrics. Additionally, the study comprehensively investigates the effect of drain voltage, material engineering, cavity dimensions/location, temperature, and device parameters on sensitivity. Sensitivity improvements of 18.573%, 13.979%, and 13.459% are achieved through gate, oxide, and channel engineering, respectively in the proposed biosensor. The study also addresses effect of trap charges on device reliability, alongside the calculation of the limit of detection. The results indicate that the silicon source exhibits better reliability and fewer short channel effects compared to other materials. Practical limiting factors have been taken into consideration in terms of non-unity fill-in factor and different filling profiles. The detector has also been compared with its junctionless variant, demonstrating a sensitivity enhancement of 95.716 mV for K_{bio}=5. The nanowire detector has been benchmarked against reported works in literature in terms of sensitivity.

1 Introduction

Field effect transistors (FETs) have made substantial impact in the realm of electronics, offering a variety of specialized types that cater to a wide array of applications[1,2]. The versatility in FET is extensively utilized in the biomedical field, where it is used for different clinical tasks. One of the extensively researched applications is biosensing[3]. An exemplary biosensor should be highly sensitive to all the biomolecules, indicated by the difference in the value of different sensing metrics, demonstrating a high sensitiveness (response). The insertion of biomolecules into cavities primarily alters the profile of the channel's electric field and potential. Researchers have investigated different FET architectures for biomedical applications, such as extended-gate FETs, ion-sensitive FETs (ISFETs), and nanowire FETs, each offering specific benefits regarding sensitivity, selectivity, and fabrication simplicity[3-6]. The selection of semiconductor materials is also significant; silicon is widely used due to its simplified (common) processing methods, while new materials like graphene and molybdenum disulfide are promising for improved analog performance.

A biosensor is an analytical device used for the rapid detection of bio-chemical species (biomolecules). Biosensors are either label-based, using unique labels to identify targets, or label-free, suitable for untagged

*Corresponding author: (E-mail: anjana.0889@gmail.com)

analytes. The choice between these approaches is contingent upon the specific analytical requirements and the biochemical properties of the target analytes[7]. Label-free detectors offer particular utility in scenarios where molecular tagging is challenging or undesirable, and for the direct detection of unmodified target entities (biochemical species). Conversely, label-based detectors leverage the unique properties of molecular tags to achieve highly specific target identification (improving specificity). Label-less detection is preferred for its simplicity, affordability, and suitability for real-time analysis. Due to their exceptional sensitivity, MOSFET based label-free biosensors (MOSFEB)[4] have garnered significant popularity in the field of bioelectronics[8]. Harnessing the remarkable properties of semiconductors, MOSFEB stands at the forefront of biotechnology, along with its integration with nanotechnology innovation. By capitalizing on the subtle modulation of electrical properties upon biomolecular interactions, these biosensors enable label-free, rapid, and ultrasensitive detection, underscoring their role in revolutionizing fields such as personalized medicine and bioprocess monitoring[9]. These biosensors use the molecular properties (dielectric constant and charge density) of different biochemical species for label-free detection, which means that the device can directly detect the test biomolecule without any tagged entity[4]. The primary principle behind the detection ability of every MOSFEB is dielectric modulation of the sensing parameter. Figure 1 (a-b) demonstrate the fundamental device principle and basic detection principle in nanowire MOSFEB. These detectors leverage selective biorecognition elements to detect and quantify target analytes such as biomolecules, pathogens, or chemicals. The threshold voltage is the commonly used sensing parameter, but apart from this, various characteristics like subthreshold slope, off-current, I_{ON}/I_{OFF} ratio, and transconductance can be used to analyze the sensitivity. The detector derives its name from the fact that it uses a transistor whose charge carrier transportation mechanism is modulated by electric field (FET), and it incorporates dielectric engineering (MOS) for label-free detection of biochemical species. Hence, the name Nanowire MOSFEB Detector (Nanowire MOSFET + Biomolecules Detector: MOSFET for biomolecules detection), abbreviated as NWM-BD. The term "nanowire" in nanowire MOSFEB refers to its surrounding gate (SG) architecture, which enhances electrostatic control over the channel and improves charge carrier transport. The versatility of MOSFEB extends beyond their basic operational principle, encompassing a wide array of design variations and sensing mechanisms.

Several researchers have explored the concept of biomolecule sensing in transistors through gate oxide modulation. But not much-related work (doping dependent sensitivity analysis) has been done in the past, a very few authors have partially shown the effect of doping on sensitivity[10,11]. The effect of channel doping on the sensitivity of a junctionless biosensor was recently discussed[8]. Recently, a few authors have reported nanotube FET-based biosensors for detecting the biomolecule species using different sensing metrics[4,12]. Authors, such as Yadav *et al.*[13], Sharma *et al.*[9], Kumari *et al.*[14], Goel *et al.*[15] and many more, have recently reported different types of FET-

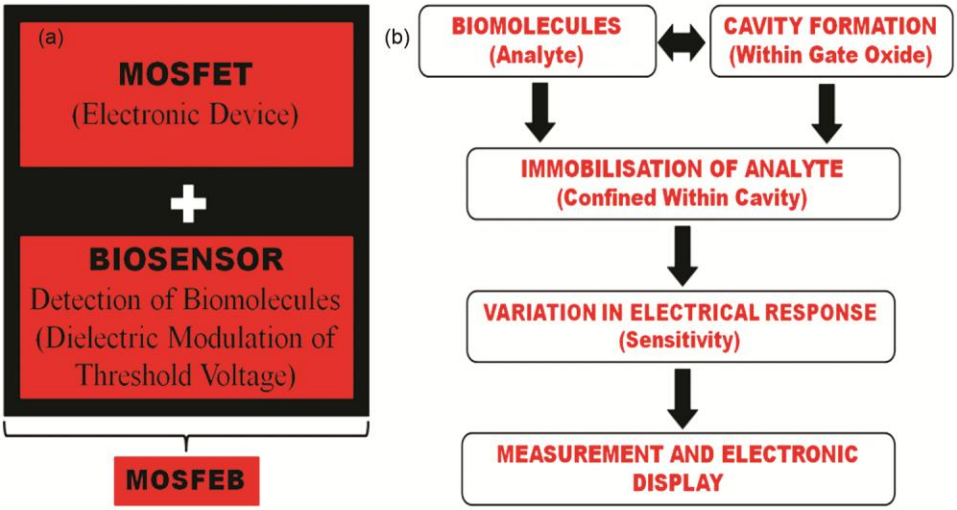

Fig. 1 — (a) Device principle, and (b) flowchart of the generalized biosensing phenomenon in NWM-BD[8,9]

based biosensors based on dielectric engineering. Upon reviewing various literature sources, it becomes apparent that researchers have investigated various potential variants for BioFETs. However, detailed exploration of doping-dependent sensitivity modulation remains largely unexplored in the existing research. Hence, the novelty of this paper as well as main goal of this work is to examine the sensitivity modulation in the nanowire MOSFEB because of doping. Doping becomes critically important in controlling and modulating sensitivity, as it is a parameter that can be adjusted before fabrication[16], highlighting the significance of this research. The second objective is to explore the other side of the nanowire MOSFEB detector, which includes studying the effect of temperature, structural parameters, trap charges, drain bias, source/channel/drain engineering techniques as well as steric hindrance on the sensitivity.

2 Device Structure and Computational Framework

2.1 MOSFEB Specifications

3D and 2D view of the nanowire MOSFEB detector is shown in Fig. 2 (a-b), respectively. The proposed detector, employing dielectric engineering by immobilizing biomolecules within the embedded cavity, is specifically designed for detecting various charged and neutral biochemical species. The measurable response of the detector is defined by changes in threshold voltage or subthreshold slope, although several other metrics have also been taken into consideration. A poly-silicon gate (work function: 4.96 eV) has been used, which has the advantage regarding fabrication simplicity and increased operating temperature range over the metallic gate. A symmetric and two-sided cavity of dimensions 14*2 nm^2 is embedded inside SiO_2 layer[8,12]. Figure 2(c) shows the detailed fabrication steps[17-19]of the proposed biosensor in the form of a flowchart. A precise cavity with the specified dimensions can be created using multiple rounds of dry etching, without compromising the quality of the gate oxide[20]. The biosensor features a dual cavity of 14×2 nm², enabling immobilization of biomolecules smaller than 14 nm, with the maximum detectable size depending on orientation (up to 14 nm horizontally and 2 nm vertically). This study primarily focuses on the upper detection limit, assuming full cavity occupancy while accounting for steric hindrance effects.

2.2 Simulator Setup and Specifications

The proposed biosensor's behavior is examined using parameters specified in Table 1 through the SILVACO TCAD simulator[21]. Various models are integrated into the simulation: the SRH model manages carrier generation and recombination, the CONMOB model correlates impurity profiles with low-field mobility at room temperature, and the AUGER model accommodates recombination effects at high doping densities. Additionally, the CVT model encompasses dependencies of mobility on doping, temperature, and field, while the FLDMOB model addresses field-dependent mobility. The BGN model handles bandgap narrowing attributed to degenerate as wellas high doping levels, and NEWTON

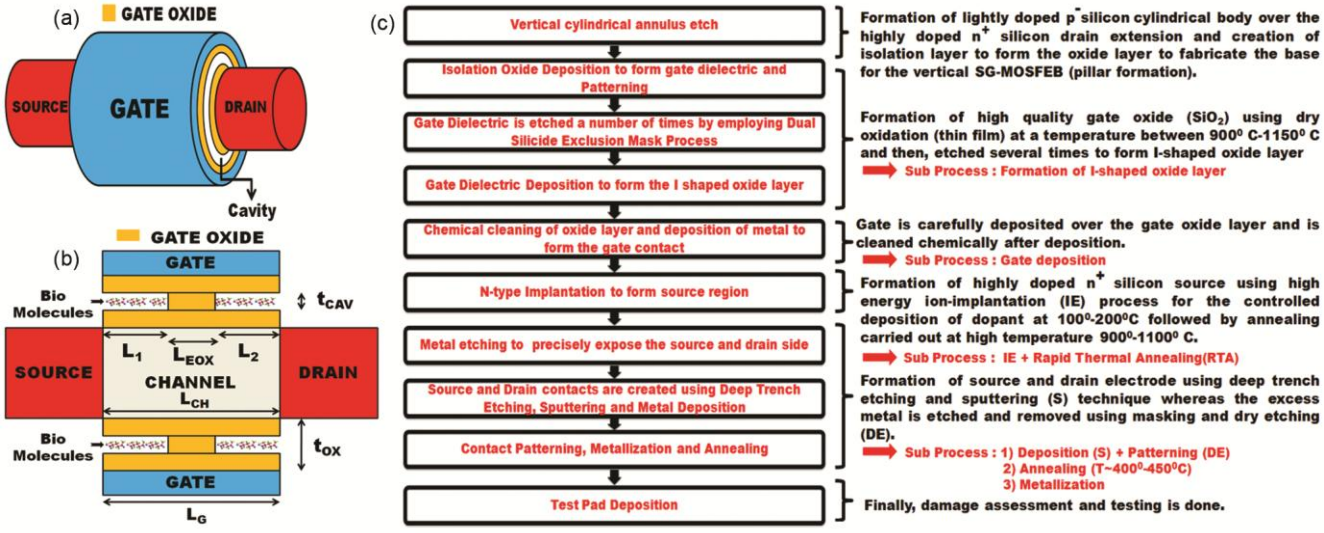

Fig. 2 — (a) 3D view, (b) 2D view, and (c) fabrication process flow-chart illustrating the basic fabrication steps of NWM-BD[20]

GUMMEL method is implemented to resolve the intricate, nonlinear coupled equations.

2.3 Methodology

Charge density (ρ) as well as dielectric constant (K_{bio}) is used to characterize various biomolecules. Biomolecules are either neutral (ρ=0) or charged (ρ≠0) with some finite dielectric constant. The different test biomolecules used in this study are mentioned in Table 1. Here, ρ of the biomolecule is kept constant, while keeping constant K_{bio}=5 to cover a large number of biomolecules (positively/neutral/negatively charged biomolecules). It is assumed that the cavity is occupied by air (dielectric constant of air is taken as K_{air}=1) in the absence of biomolecules[9,12]. When the test biomolecule (K_{bio}≠1) gets immobilized inside the cavity, threshold voltage (along with other device characteristics) gets changed because lateral field and gate oxide capacitance undergo changes when biomolecules are localized inside the cavity. Thus, the potential distribution gets modified across the channel[8, 24]. The relative difference in the sensing parameter's value is used as the qualitative indicator in the biosensing investigation of a nanowire MOSFEB detector. The numerical computational methodology used for the sensitivity analysis is shown in Fig. 3 as a flowchart. The relative change in the sensing metric (first formula) is preferred over fractional or percentage change for evaluating the biosensing performance. It provides a more accurate measure of sensitivity by directly comparing baseline and sensing values, whereas fractional or percentage change is tied to relative values, which may misrepresent true sensitivity.

Table 1 — Structural parameters of NWM-BD

Parameters		Value
Cavity thickness (t_{cav})		2-8 nm
Gate length (L_G)		30 nm
Source doping (N_S)		$1*10^{13}$ to $5*10^{20}$/cm^3
Channel length (L_{CH})		30 nm
Material	Source	n-type
	Channel	p-type Silicon
	Drain	n-type
Channel doping (N_C)		10^{10}/cm^3
Drain doping (N_D)		$1*10^{13}$ to $5*10^{20}$/cm^3
Drain/Source length		10 nm
Total oxide layer thickness (t_{ox})		4-10 nm
Biasing		V_{DS}=(0-1) V V_{GS}=(0-1) V
Drain/Channel/Source radius		10 nm
Cavity length		L_1= 14nm L_2= 14nm
Gate oxide		SiO_2
Gate work-function		4.96 eV
Oxide length (L_{OX})		L_{OX}= 30nm
BIOMOLECULES		
Hydroprotein(K_{bio}=5)[15]		
DNA (K_{bio}=5 & ρ= -1*10^{11}/cm^2)[22]		
Amino acids (K_{bio}=5 & ρ= +1*10^{11}/cm^2)[23]

3 Results and Discussion

3.1 Energy Band Diagram and Potential

Figure 4 illustrates the shift across energy bands within the nanowire MOSFEB detector across various operational conditions. In Fig. 4 (a), changes in drain/source doping levels lead to shifts in energy band positions; higher doping levels in the source increase electron density, pulling the bands downwards (Fermi level tends to moves inside the conduction band in n-type drain/source). Meanwhile, Fig. 4 (b) demonstrates how different biomolecules inside the cavity affect the positions of energy bands, influencing both the lateral electric field and gate capacitance in the channel. This interaction results in slight adjustments to the energies of both valence band as well as conduction band[8]. Contour plots in Fig. 5(a-c) depicts electron concentration profiles for negatively, neutral, and positively charged bio-chemical species.

Figure 6 presents the electron concentration contour plot across the channel in the nanowire MOSFEB detector, depicting different doping conditions. In Fig. 6(a), the contour plot shows the density of electrons at $N_C=10^{10}/cm^3$ and $N_D=N_S=10^{14}/cm^3$. In contrast, Fig. 6(b) shows the electron concentration contour plot at $N_S=N_D=10^{19}/cm^3$ and $N_C=10^{10}/cm^3$. It is evident that the peak electron concentration is localized near the channel surface. The localization of peak electron concentration near the channel surface underscores

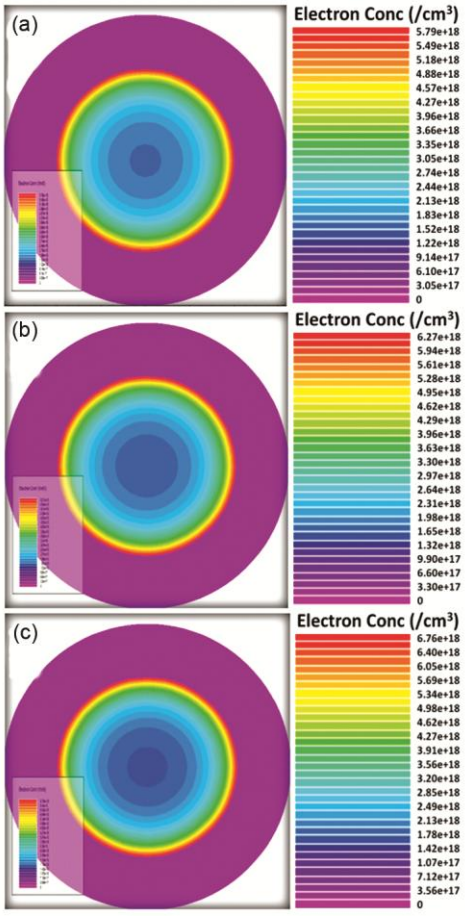

Fig. 5 — Contour plot of density of electrons (K_{bio}=5, $N_C=10^{10}/cm^3$,$N_D=N_S=10^{19}/cm^3$& $V_{DS}=V_{GS}$=1V) at different charge density (a) ρ=-1*10^11/cm^2, (b) ρ=0, and (c) ρ=+1*10^11/cm^2 of biomolecules in NWM-BD

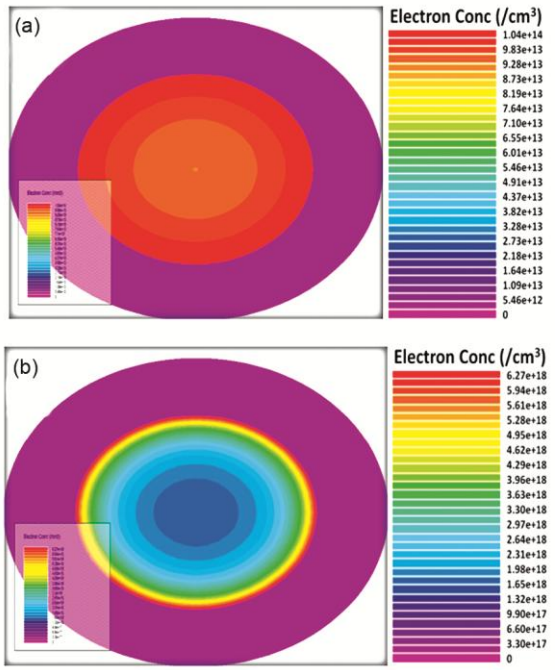

Fig. 6 — Contour plot of density of electrons (K_{bio}=5 & V_{GS}=V_{DS}=1V) at (a) N_C=10^{10}/cm^3, N_S=N_D=10^{14}/cm^3, and (b) N_C=10^{10}/cm^3, N_D=N_S=10^{19}/cm^3 in NWM-BD

the importance of surface phenomena in MOSFEB. Increasing the source doping enhances the electron concentration, thereby influencing the drain current[25]. The presence of bio-chemical species changes the electron concentration near the Si-SiO_2 interface by increasing the gate capacitance. The influence of biochemical species on the gate capacitance, as evidenced by the electron concentration changes, underscores the device's capability for label-free detection[8,26,27].

Figure 7 of the nanowire MOSFEB detector, the potential profile across the channel is illustrated. The main plot illustrates variations in the potential profile due to different doping levels of the source and drain. Meanwhile, the inset focuses on the potential profile in the presence of different biomolecules. Modifying the doping levels of the drain and source adjusts the potential barriers at the drain-channel and source-channel junctions, influencing the overall potential distribution across the channel[25,28]. The presence of biomolecules changes the gate capacitance and field profile, which in turn modifies the channel potential. Increasing the doping levels of the drain and source results in a notable rise in the channel's potential.

3.2 Effect of Equal Drain and Source Doping

Increasing the doping levels of both the source and drain results in two primary effects[16,29]. As the doping

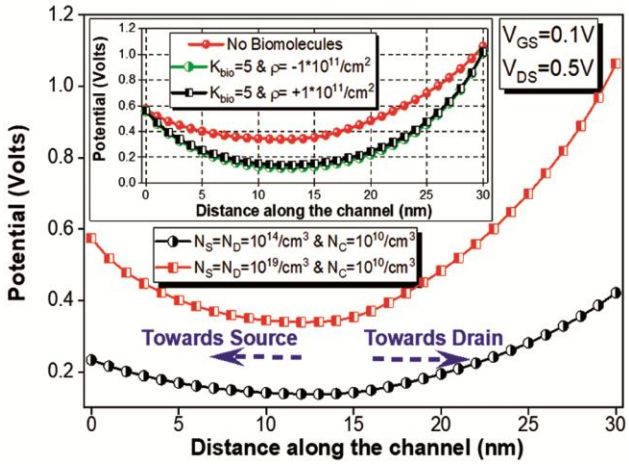

Fig. 7 — Potential profile across the channel at different source/drain doping in NWM-BD(*[INSET] Shows the potential profile across the channel in the presence of different biomolecules*)

levels of the drain and source are raised uniformly from low to high values, 'Effect 1' is observed, where a significant portion of the depletion region extends into the channel. 'Effect 2', on the other hand, involves a gradual reduction in the overall width of the depletion layer with increasing doping. Thus, both 'Effect 1' and 'Effect 2' become evident as the doping level of the drain and source increases. 'Effect 2' predominates at lower doping levels, reducing the depletion layer width and effectively increasing the channel length. Conversely, at higher doping levels, 'Effect 1' becomes more prominent, causing the depletion region to penetrate deeper into the channel and thereby decreasing the effective channel length. Figure 8 visually illustrates both 'Effect 2' and 'Effect 1'. The notation a_b_c denotes the doping levels of the source ($1*10^a$ cm^{-3}), channel ($1*10^b$ cm^{-3}), and drain ($1*10^c$ cm^{-3}), respectively, while S_C_D refers to source_channel_drain.

Table 2 presents data on the threshold voltage and its corresponding sensitivity across various doping levels (with same drain and source doping), considering different biomolecules filling the cavity. Initially, as doping increases, 'Effect 2' predominates by narrowing the depletion width. This reduces the depletion region coverage at the channel ends, thereby increasing the effective channel length. Consequently, a higher gate voltage is required to activate the device, resulting in an increase in the threshold voltage. As doping levels further increase, 'Effect 1' becomes more dominant. With higher source and drain doping compared to the channel, the depletion region extends significantly into the channel at both

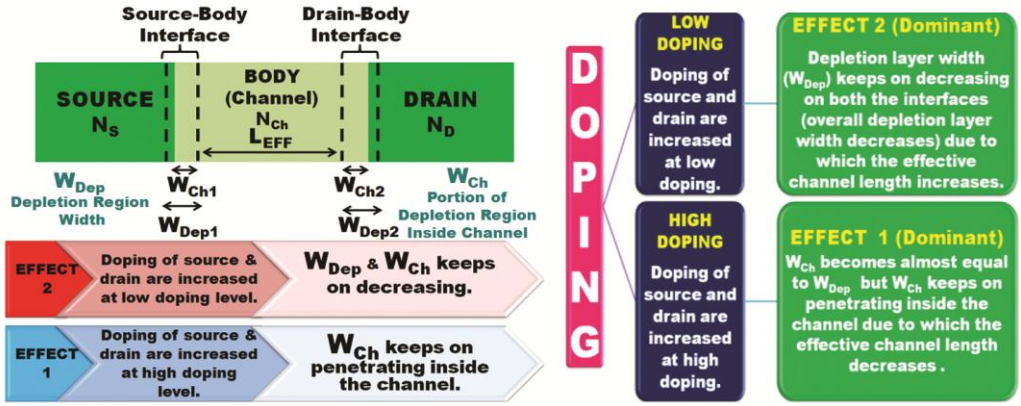

Fig. 8 — Visualization of the effect of doping on effective channel length in MOSFEB

Table 2 — Threshold voltage and threshold voltage sensitivity at different doping

	Doping (cm^{-3}) Source_Channel_Drain	Threshold Voltage (V_t : Volt)			Threshold Voltage Sensitivity (S_{Vt} : Percentage)		
		k_{bio} = 5					
		ρ $-1*10^{11}$ cm^{-2}	ρ 0	P $+1*10^{11}$ cm^{-2}	ρ $-1*10^{11}$ cm^{-2}	ρ 0	P $+1*10^{11}$ cm^{-2}
D_a	10^{13}_10^{10}_10^{13}	0.0459207	0.045366	0.0429468	453.0462	446.3645	417.2300

D_d	10^{16}_10^{10}_10^{16}	0.244491	0.241664	0.236106	49.4078	47.6803	44.2838
D_e	10^{17}_10^{10}_10^{17}	0.330133	0.315766	0.286625	44.9446	38.6368	25.8424
D_f	10^{18}_10^{10}_10^{18}	0.388328	0.371414	0.349767	40.7057	34.5771	26.7336
D_g	10^{19}_10^{10}_10^{19}	0.430309	0.416805	0.402911	74.1571	68.6916	63.0684
D_h	10^{20}_10^{10}_10^{20}	0.411948	0.399756	0.387387	133.8607	126.9394	119.9176

junctions. This shortens the effective channel length, requiring less gate voltage to activate the device and causing a reduction in the threshold voltage[16].Hence, the threshold voltage initially rises with doping, reaching a maximum value, but beyond a certain doping level, it begins to decrease, as depicted in Fig. 9(a). As seen in Fig. 9(b), although the sensitivity obtained is quite high at low doping, the conductivity of the device is quite low at such low doping, which limits the selection of low doping for MOSFET. The doping values D_a-D_h are specified in Table 2. In the current study, the threshold voltage sensitivity modulus is considered and given in Eq. 1. Since sensitivity is measured in terms of magnitude (i.e., the change in the sensing metric) rather than the sign of this change, taking the modulus ensures a consistent and comparative assessment of biosensor performance across different operational conditions.

$$S_{V_t} = \left| \left(\frac{V_{t(air)} - V_{t(bio)}}{V_{t(air)}} \right) * 100 \right| \quad \ldots (1)$$

At lower doping levels, 'Effect 2' tends to be predominant[30]. Increasing the doping of both the source and drain reduces the depletion width at the junctions of the drain-channel and source-channel, resulting in an increase in the depletion capacitance (C_{dep}). The subthreshold swing, inversely related to the subthreshold slope and directly proportional to C_{dep}, consequently increases as the depletion width decreases. This leads to a decrease in the subthreshold slope at lower doping levels[29,31]. At higher doping levels, 'Effect 1' becomes dominant, causing an increase in the subthreshold slope. A local minimum in the subthreshold slope can be seen in Fig. 10.

Table 3 illustrates the subthreshold slope observed at various symmetric doping levels for the source and drain. This metric is influenced by the doping levels of the drain, channel, and source, as well as by the presence of biomolecules within the cavity. Initially, the subthreshold slope sensitivity (S_{SS}) decreases until it reaches a minimum value, reflecting the relative difference $|SS_{(air)} - SS_{(bio)}|$ (where $SS_{(air)}$ and $SS_{(bio)}$

indicate the subthreshold slope with the cavity filled with air and biomolecules, respectively). Further equal increase in the doping rate leads to an enhancement in the S_{SS}. This trend is depicted in Fig. 11(a), 11(b), and 11(c), which shows the S_{SS} with negatively charged, neutral, and positively charged biomolecules in the cavity, respectively. The presence of charged biomolecules alters the flat-band voltage, thereby modifying the channel's field and potential profile[8, 15]. Table 3 also provides details on the

subthreshold slope sensitivity at different doping levels when the cavity immobilizes various biomolecules. Equation (2) outlines the formula for subthreshold slope sensitivity, emphasizing the absolute value to underscore the biosensor's sensitivity to relative changes rather than absolute metrics.

$$S_{SS} = \left| \left(\frac{SS_{(air)} - SS_{(bio)}}{SS_{(air)}} \right) * 100 \right| \quad \ldots(2)$$

3.3 Effect of Unequal Source and Drain Doping

To explore the effects of differing doping levels, the source and drain doping are independently adjusted (varied). A reference doping level (RD) is set with the channel doping equals to $1*10^{10}/cm^3$ and drain/source doping equals to $1*10^{19}/cm^3$. When the drain doping is increased beyond the reference level, channel as well as source doping remains unchanged. Conversely, while increasing the source doping above the reference level, channel as well as drain doping are held constant. Table 4 outlines the specific doping levels for D_{D1}-D_{D3}, D_{RD}, and D_{S1}-D_{S3}.

Increasing N_D above the reference level reduces the effective channel length, requiring less gate voltage to activate the device and resulting in a lower threshold voltage. Figure 12 displays how the threshold voltage varies without and with biomolecules. Biomolecules increase the threshold voltage due to the formation of a strong lateral electric field across the channel. Consequently, the fractional change $|V_{t(air)} - V_{t(bio)}|/V_{t(air)}$ increases as drain doping levels rise. This relationship is visually represented in Fig. 13, which illustrates the sensitivity of threshold voltage variation with respect to N_D.

As N_D increases beyond the reference level, the depletion region extends further into the channel at the drain junction[29,31]. This extension results in a reduction of the depletion capacitance (C_{dep}), leading to a decrease in the subthreshold swing while increasing the subthreshold slope. Figure 14(a) illustrates this trend. Additionally, Fig. 14 (b) shows that the fractional change $|SS_{(air)} - SS_{(bio)}|/SS_{(air)}$ increases as the drain doping level exceeds the reference doping.

As previously mentioned, when N_S is increased, Fig. 12 illustrates a decrease in the threshold voltage. The fractional change $|V_{t(air)} - V_{t(bio)}|/V_{t(air)}$ increases with higher source doping levels, as shown in Fig. 13. Furthermore, high N_S lead to a deeper penetration of the depletion region at the source-channel junction into the channel. This diminishes the C_{dep}, causing an increase in the subthreshold slope, as depicted in Fig. 14(a). Additionally, Fig. 14(b) illustrates that the subthreshold slope sensitivity also rises with

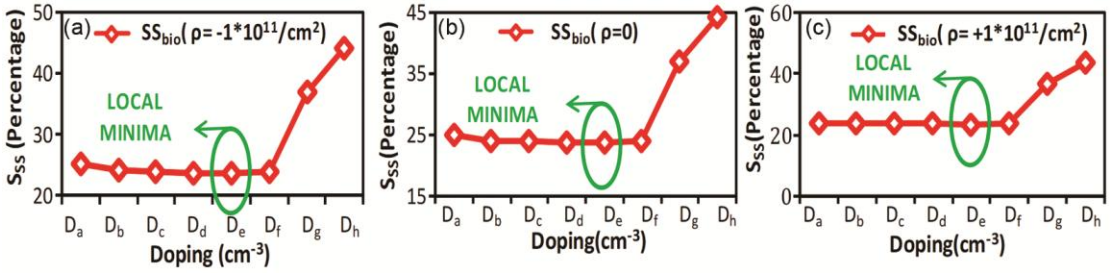

Fig. 11 — S_{SS} variation in the NWM-BD for (a) negatively charged (ρ=-1*10^{11}/cm^2), (b) neutral (ρ=0), and (c) positively charged (ρ=+1*10^{11}/cm^2) biomolecules at different doping (V_{DS}=0.5V, N_C=10^{10}/cm^3& K_{bio}=5)

Table 4 — Threshold voltage sensitivity & subthreshold slope sensitivity at different doping

increasing N_S compared to the reference doping. In MOSFEBs, high doping in the source and low doping in the channel enhance charge carrier transport due to a reduced energy band gap. This doping configuration also increases the tunneling probability, altering the potential barrier at the source-channel junction, which is dependent on the electric field and gate/drain voltage. As a result, there is a larger current variation for the same range of applied voltage. The sensitivity of nanowire MOSFEB detector to biomolecules is attributed to the dependence of drain current, threshold voltage, and subthreshold swing on the source-to-channel potential barrier.

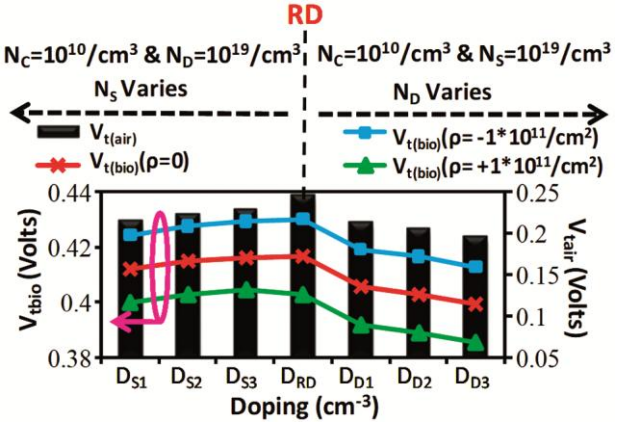

Fig. 12 — V_t variation in the NWM-BD when the cavity is filled with air and biomolecules (k_{bio}=5, N_C=10^{10}/cm^3& V_{DS}=0.5V)

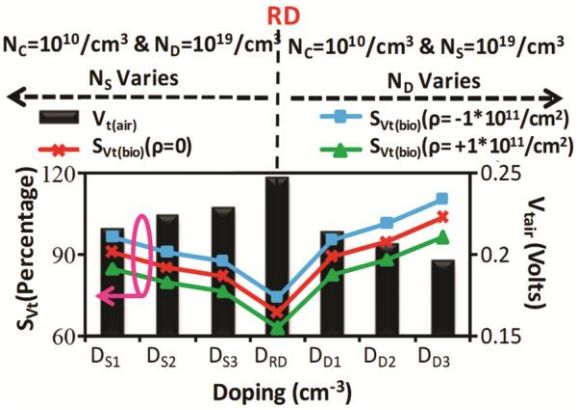

Fig. 13 — S_{Vt} in the NWM-BD for asymmetric doping variation (k_{bio}=5, N_C=10^{10}/cm^3& V_{DS}=0.5V)

Table 4 details the sensitivity of subthreshold slope and threshold voltage to different bio-chemical species under different drain/source doping conditions. Figure 15 illustrates the relative changes in subthreshold slope (ΔSS) as well as threshold voltage (ΔV_t) calculated at various doping levels. The findings highlight that negatively charged biomolecules exhibit pronounced ΔSS as well as ΔV_t absolute values, particularly at higher doping levels. As a sensitivity measure, threshold voltage yields a greater percentage sensitivity and relative change compared to subthreshold slope, rendering it more suitable for biosensing applications. Figure 16 depicts the variation in drain current (I_{DS}) at different doping, indicating enhanced current generation with increased doping due to the additional charge carriers generation.

Figure 17 illustrates the impact of V_{DS} on S_{SS} and S_{Vt} under symmetric and asymmetric doping conditions. For symmetric doping (SD), low source/drain doping (N_D=N_S=10^{19}/cm^3, N_C=10^{10}/cm^3) and high source/drain doping (N_D=N_S=10^{14}/cm^3, N_C=10^{10}/cm^3) are analyzed to observe the effects of drain biasing on sensitivity. Symmetric case (SD) features high doping (N_D=N_S=10^{19}/cm^3) and low doping (N_D=N_S=10^{14}/cm^3) levels, while asymmetric case (ASD) involves differing levels for the source and drain (N_D=10^{19}/cm^3, N_S=10^{20}/cm^3). Increasing the drain voltage correlates with increased S_{SS} and S_{Vt}. The observed increase in S_{SS} and S_{Vt} with rising V_{DS} can be attributed to the enhanced lateral electric field, which amplifies the impact of biomolecule-induced surface charge modulation on the channel

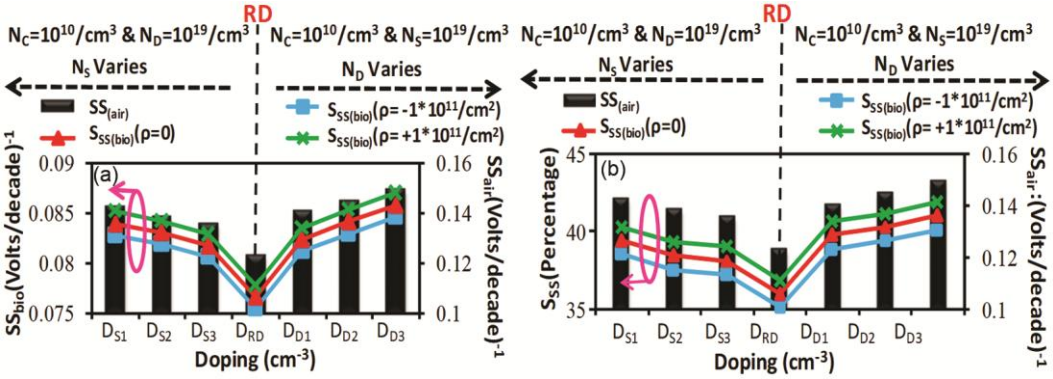

Fig. 14 — (a) SS, and (b) S_{SS} in the NWM-BD when the cavity is filled with biomolecules (k_{bio}=5, N_C=10^{10}/cm^3& V_{DS}=0.5V)

characteristics[24,32]. However, it is crucial to avoid exceeding a specific drain voltage limit to prevent device damage and ensure operational integrity. While higher V_{DS} generally improves sensitivity, it's important to note that this comes at the cost of increased power consumption and potential thermal effects, necessitating a careful balance in practical biosensing applications.

Table 5 shows the shift in the values of SS and V_t, which shows a higher relative change at high doping. It is quite evident from the above discussion that higher percentage change is obtained at low doping, whereas higher relative change is obtained at high doping. But, it should be kept in mind that conductivity is quite less at low doping and tunneling effect becomes prevalent at very high doping. Hence, an optimized doping should be considered for MOSFEB before fabrication. It is also interesting to note that the relative change or shift in the value of metric is a more reliable parameter in assessing the sensitivity of a MOSFEB detector. Relative change indicates the true value whereas percentage change indicates the relative fraction (modulated value) of the sensitivity.

3.4 Effect of Steric Hindrance and Cavity Dimensions

Steric hindrance is an important limiting factor in practical biosensors, resulting in a non-unity fill-in factor. The fill-in factor refers to the fraction of the total volume inside the cavity that is filled by the

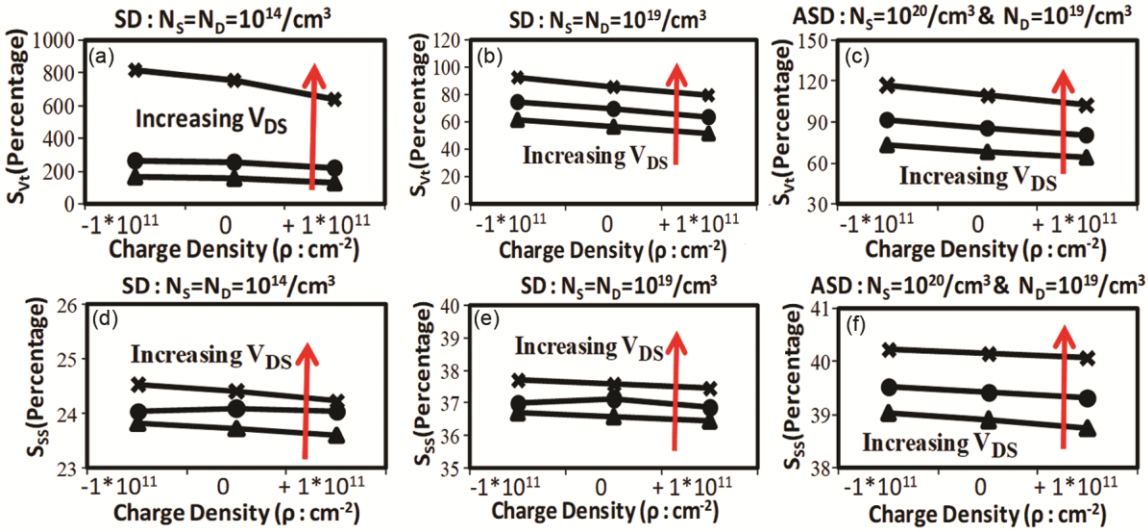

Fig. 17 — Impact of V_{DS} on (a-c) S_{Vt}, and (d-f) S_{SS} at different doping (k_{bio}=5, N_C=10^{10}/cm^3& V_{DS}=0.5V) in NWM-BD

biomolecules. The effect of steric hindrance is usually studied by considering different fill-in factors (such as horizontal or lateral filling) or fill-in profiles. Steric hindrance is a practical problem that arises from the partial hybridization of biomolecules. As a result, biomolecules only occupy a fraction of the cavity, impeding further filling of the remaining portion of the cavity. Hence, its effect must be thoroughly studied. Table 6 illustrates the impact of biomolecule location at different fill-in factors (horizontal filling) by dividing the cavity on both sides of the source and drain into four parts. Although a high fill-in factor generally results in high sensitivity[4] due to the immobilization of a large number of biomolecules, the location of the biomolecules significantly influences sensitivity, especially in partially filled cavities. For instance, although the fill-in factor of case 5 is more significant (higher) than that of case 4, the sensitivity in case 4 is higher, and the same observation can be made for other cases, such as case 10 and case 11. The influence of fill-in factor and profile on sensitivity underscores the importance of considering nano-scale phenomena in macroscopic device performance.

The fill-in factor of case 1 and case 4 are the same, but the location of the biomolecules is different in both cases. In case 1, the biomolecules are located near the source, resulting in higher sensitivity. This is because the threshold voltage is mainly affected by the potential hill appearing at the source-channel junction[28], and the biomolecules near the source affect this potential hill more than when they are near the drain. Similar observations can be made for other cases, such as case 5 and case 10, case 11 and case 14. The observed variations in sensitivity across different fill-in profiles offer valuable insights for developing computational models to predict and enhance biosensor responses. In the era of machine learning, these insights are crucial, as artificial intelligence can be harnessed to accurately predict and improve the sensitivity of biodetectors.

Figure 18 shows the effect of the fill-in factor (lateral filling), and Fig. 19 depicts how different fill-in profiles affect the threshold voltage sensitivity. These findings underscore the need for precise control over biomolecule immobilization techniques to achieve desired fill-in patterns and optimize sensor performance. A higher fill-in factor directly correlates with the increased sensitivity. The fill-in profile refers to the pattern filled by biomolecules within the cavity, with a symmetrical fill-in profile considered on both sides of the cavity. The concave fill-in profile has demonstrated the highest sensitivity compared to

Table 6 — Effect of fill-in factor and location of biomolecules on sensitivity

other fill-in profiles. This sensitivity is due to the accumulation of biomolecules near the source-channel junction, which enhances the coupling between the gate and channel. As a result, the biomolecules near the source exerts stronger control over the flow of charge carriers, thereby increasing sensitivity. Further investigation into the kinetics of biomolecule immobilization and their spatial distribution within the cavity could lead to innovative strategies for improving sensor sensitivity and specificity.

Table 7 displays the impact of cavity thickness/length on sensitivity. The relationship between cavity dimensions and sensitivity underscores the importance of optimizing the sensing area in MOSFET-based biosensors. An increase in

Table 8 — Impact of parameters on sensitivity

Parameters		Threshold voltage shift (ΔV_t : mV) A	B	C
Radius of Channel (a: nm)	10	183.228	169.724	155.838

B : K_{bio}=5 & ρ= 0

cavity size results in elevated sensitivity levels for both threshold voltage and subthreshold slope. This is due to the greater number of charge carriers immobilized within the cavity, which enhances the device's sensitivity to biomolecules. Further investigation could explore whether there's an optimal cavity size beyond which sensitivity gain diminishes, balancing performance with practical fabrication constraints.

Table 8 presents the influence of channel radius and temperature on the sensitivity. It is observed that as the channel radius increases, the sensitivity decreases. This reduction in sensitivity is attributed to the diminished control of the gate over the channel, primarily caused by the decrease in capacitive coupling. This trade-off between channel size and

sensitivity suggests that optimizing device geometry is crucial for balancing performance with manufacturability. However, it is important to note that the number of intrinsic charge carriers also increases with the increasing temperature, which leads to an increase in sensitivity. Therefore, while increasing the channel radius may have a negative impact on sensitivity due to reduced gate control, the increase in intrinsic charge carriers (due to an increase in temperature) counters this effect and contributes to an overall increase in sensitivity. The temperature dependent sensitivity increases underscores the need for precise temperature control in biosensing applications to ensure consistent and reliable measurements

3.5 Effect of Material Engineering

Material engineering also enhances the sensitivity of nanowire MOSFEB detectors[4]. Basically, material engineering refers to the i) use of different source/drain materials, ii) use of multi-gate architecture, iii) use of graded channel engineering, and iv) use of gate oxide stacking.

3.5.1 Source/Drain Engineering

Table 9 presents the threshold voltage sensitivity (threshold voltage shift) resulting from the use of different drain/source materials. This analysis examines how the conventional material, silicon, compares to alternative materials. The selection of drain/source materials also influences the device's resistance to biofouling and chemical degradation, factors that are essential for long-term stability in biological environments. This factor is crucial, as altering the drain and source materials affects the potential barrier at both the drain and source junctions. These junctions are pivotal since the charge carriers contributing to the total current are significantly influenced by these barriers at the channel-drain and channel-source interfaces. Among all the materials tested, silicon shows the highest sensitivity. Generally, materials with lower bandgaps are more sensitive to biomolecular interactions, whereas those with larger bandgaps exhibit more significant relative changes in sensing metrics[4,6,33,34]. However, each has its disadvantages: lower bandgap materials tend to increase leakage current (leading to false turn-on of the detector) and have lower breakdown voltages, while higher bandgap materials pose fabrication challenges due to high defect density and low carrier mobility, limiting their use in high-speed applications[4,34]. The interface between the chosen drain/source material and channel plays a significant role in determining the overall device performance, highlighting the need for careful material selection and interface engineering.

Table 9 — Impact of different materials on sensitivity in NWM-BD

Material			Biomolecules		
Source	Drain	Bandgap (300 K)	A	B	C
Si	Si	1.1 eV	183.228	169.724	155.838
Ge	Ge	0.7 eV	138.007	112.942	93.721
GaAs	GaAs	1.42 eV	114.408	94.589	77.298
InP	InP	1.351 eV	119.287	103.669	81.870
InSb	InSb	0.18 eV	72.115	57.346	40.379
GaSb	GaSb	0.726 eV	172.390	145.498	126.571
InAs	InAs	0.36 eV	160.284	139.330	115.690

A : K_{bio}=5 & ρ= -1*10^{11}/cm^2 C : K_{bio}=5 & ρ= +1*10^{11}/cm^2

B : K_{bio}=5 & ρ= 0

It is noteworthy that sensitivity is not solely dependent on the bandgap of the semiconductor material. Other factors, such as electron mobility, electron affinity, charge carrier density and doping profiles, also play crucial roles. Therefore, all these factors must be carefully analyzed before selecting the material for the source and drain. In general, materials with lower bandgaps have lower energy bandgaps but higher electron and hole mobility, whereas materials with higher bandgaps have higher energy bandgaps but lower mobility of electrons and holes. Consequently, silicon's sensitivity remains the highest. In the following next sections, the focus shifts primarily to three materials, specifically those with lower energy bandgaps: silicon, germanium, and indium arsenide (InAs). Germanium is considered one of the best alternatives to silicon, despite its disadvantages[35], while InAs is another promising compound semiconductor material with high potential for use in biosensor detectors[36,37].

3.5.2*Oxide Engineering*

Figure 20 demonstrates the influence of gate oxide stacking on threshold voltage sensitivity at t_1=1nm and t_2=3nm. It can be observed that sensitivity is increased when SiO_2 and high-K dielectric are stacked. The observed increase in sensitivity with gate oxide stacking can be attributed to the improved capacitive coupling between the gate and the channel, allowing for more effective modulation of the channel conductivity by biomolecular interactions[38]. The choice of high-K material and its thickness ratio with

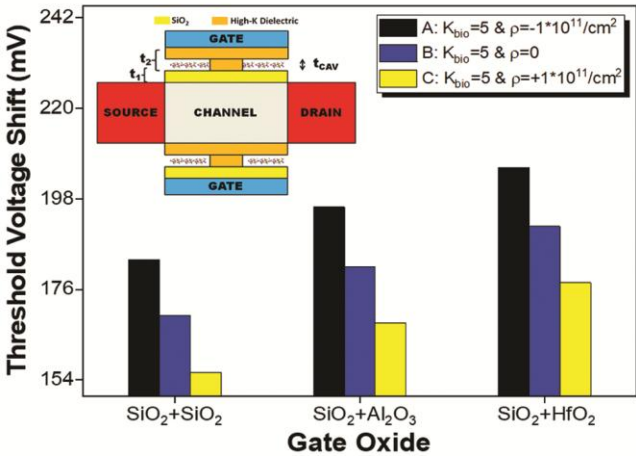

Fig. 20 — Effect of gate-oxide stacking on sensitivity in NWM-BD

SiO_2 can be further optimized to balance sensitivity gains with overall device performance and reliability. However, it is essential to remember that this approach also increases fabrication complexity, as high-k dielectric deposition is subject to certain limitations[8]. The increased fabrication complexity associated with high-K deposition might be mitigated by emerging deposition techniques or alternative high-K materials that are more compatible with standard CMOS processes.

3.5.3 *Gate and Channel Engineering*

Apart from doping and gate oxide stacking, sensitivity also increases due to dual gate architecture[39] and graded channel due to the enhanced electric field[40].To study the impact of gate engineering on sensitivity, dual gate architecture has been considered in nanowire MOSFEB with equal gate length for both gates (rest, all the parameters have been considered the same). The work function of gate-1 and gate-2 are ϕ_{G1} and ϕ_{G2} respectively. The work function of gate-1 (near to source) is greater than that of gate-2 (near to drain) so as to obtain high sensitivity[28]. The work function difference between the gates creates a built-in electric field along the channel, which can be optimized to enhance the device's response to biomolecular interactions. Reversing the value of the work function decreases the sensitivity of the biosensor since a high work-function gate effectively modulates the flow of charge carriers by controlling the source-channel potential barrier. As discussed in the previous section, the source-channel barrier highly affects the sensitivity as compared to the drain-channel potential barrier. The dual gate architecture not only improves sensitivity but also offers better control over the channel, potentially reducing short-channel effects in nanoscale devices. While dual gate architecture offers improved sensitivity, it's important to consider the trade-offs in terms of fabrication complexity and potential increase in parasitic capacitances[14,41,43].

For considering the effect of channel engineering, a dual-step graded doping profile has been considered for the channel. The channel has been divided into two equal parts with doping of N_{CH1} (part of the channel near to source) and N_{CH2} (part of the channel near to source). Lateral step-graded doping in the channel enhances the sensitivity by creating a doping gradient that improves charge carrier mobility. This gradient facilitates faster charge transport and increases the effective carrier concentration, resulting in enhanced current and voltage modulation[40]. Consequently, sensitivity increases due to the step-graded doping profile. Keeping $N_{CH2}>N_{CH1}$, the potential barrier at the source junction is lower (compared to the drain junction), which facilitates smooth transportation of charge carriers, and hence, high sensitivity is obtained when compared to the case where $N_{CH1}>N_{CH2}$[40]. The dual-step graded doping profile not only improves sensitivity but also helps in mitigating short-channel effects, which is crucial for scaling down device dimensions. While step-graded doping improves sensitivity, it's important to consider the challenges in precisely controlling doping profiles at nanoscale dimensions and their potential impact on device-to-device variability[44]. Table 10 shows the percentage improvement in sensitivity due to gate and channel engineering. Future research could explore more complex graded doping profiles, such as continuous gradients or multi-step profiles, to further enhance sensitivity and device performance.

3.6 Impact of Trap Charges, Cavity Location, and LOD

The device reliability is affected mainly by various factors, including trap charges (can adversely impact device performance by altering the electrical characteristics leading to inaccurate biosensor readings), off-current, and hot carrier injection.Trap charges in the gate oxide can lead to shifts in the threshold voltage and degradation in device performance over time. Trap charges may occur in the device as a result of defects during the manufacturing process. These interface trap charges decrease the device's reliability and accelerate the aging mechanism. Different source materials may exhibit varying susceptibilities to trap charges formation,

Table 10 — Impact of gate and channel engineering on sensitivity

Bio Molecules	ΔV_t (mV) With GE	ΔV_t (mV) Without GE	% Improvement
GE: Gate-Engineering ($L_G=L_{G1}+L_{G2}$ & $L_{G1}=L_{G2}$) ϕ_{G1}=5.1 eV[45] and ϕ_{G2}=4.1 eV[46]			
A	212.291	183.228	15.861
B	198.811	169.724	17.137
C	184.782	155.838	18.573
GE: Gate-Engineering ($L_G=L_{G1}+L_{G2}$ & $L_{G1}=L_{G2}$) ϕ_{G1}=4.1 eV[46] and ϕ_{G2}=5.1 eV[45]			
A	191.910	183.228	4.738
B	178.204	169.724	4.996
C	162.995	155.838	5.234

Bio Molecules	ΔV_t (mV) With CE	ΔV_t (mV) Without CE	% Improvement
CE: Channel-Engineering ($L_{CH}=L_{CH1}+L_{CH2}$ & $L_{CH1}=L_{CH2}$) $N_{CH1}=10^{10}/cm^3$ and $N_{CH2}=10^{15}/cm^3$			
A	204.577	183.228	11.651
B	190.004	169.724	11.948
C	176.813	155.838	13.459
CE: Channel-Engineering ($L_{CH}=L_{CH1}+L_{CH2}$ & $L_{CH1}=L_{CH2}$) $N_{CH1}=10^{15}/cm^3$ and $N_{CH2}=10^{10}/cm^3$			
A	189.001	183.228	3.150
B	175.618	169.724	3.472
C	161.279	155.838	3.812

A : K_{bio}=5 & ρ= -1*10^{11}/cm^2 C : K_{bio}=5 & ρ= +1*10^{11}/cm^2

B : K_{bio}=5 & ρ= 0

influencing the choice of materials for specific biosensing application. The impact of different interface trap charges (assumed across the length L_{EOX} across the oxide channel interface at doping $N_D=N_S=10^{19}/cm^3$ and $N_C=10^{10}/cm^3$) has been examined across various source materials for K_{bio}=5 in Table 11.

Mitigation strategies, such as optimized annealing processes or the use of high-quality interfacial layers, can help reduce the impact of trap charges on device reliability. Both positive and negative interface trap charges ($\pm$ 1*10^{12}/cm^2) have been considered on the channel-oxide interface[47]. Notably, the silicon source material has demonstrated superior reliability (lowest change in threshold voltage due to trap charges). The gate-all-around architecture also proven effective in mitigating several short-channel effects compared to the planar architecture. Hot carrier injection (causes oxide breakdown) is an undesired effect that affects long-term reliability. This is mainly due to the high electric field near the drain end. Table 12 displays the

Table 11 — Impact of trap charges on sensitivity

Source Material	Trap Charges	ΔV_t (mV)	Change in ΔV_t (mV)
Si	WPITC	166.992	2.732
	WITC	169.724	-
	WNITC	171.289	1.565
Ge	WPITC	168.529	5.447
	WITC	173.976	-
	WNITC	178.825	4.849

	WITC	176.882	-
	WNITC	182.239	5.357

WPITC: With Positive Interface Trap Charges
WITC: Without Interface Trap Charges
WNITC: With Negative Interface Trap Charges

Table 12 — Peak electric field and off-current variation for different source materials

Source Material	Peak-Field (V/m)	I_{OFF} (pA)
Si	1.411*10^6	75.552
Ge	1.936*10^6	131.029
InAs	2.891*10^6	152.998

peak electric field near the drain end and off-current at V_{GS}=0V and V_{DS}=1V for K_{bio}=5. Excessive off-current contributes to power wastage and reduced overall device reliability.It can be seen that silicon has a lower off-current (due to its high band gap) and low electric field compared to other materials. Hence, the silicon is more reliable than other materials.

The limit of detection (LOD) refers to the minimum concentration of a biochemical species that a biosensor can detect. The analytical assessment of LOD involves the application of curve fitting and regression analysis techniques[48,49]. LOD is determined by analyzing the drain current sensitivity response for K_{bio}=5. In Fig. 21, the plot demonstrates the relationship between the fractional change in drain current ($\Delta I_{DS}/I_{DS}$) and the varying concentration range of the biomolecule within the cavity, spanning from 0.0001 to 1000 mg/ml. The inset compares the LOD of nanowire MOSFEB detector using different source materials. It is observed that the LOD obtained for the silicon source is approximately 11.61 / 27.24% higher than the LOD obtained for Ge/InAs source. Moreover, the stability and repeatability of the sensor's performance over multiple uses and different environmental conditions are critical aspects that ensure consistent and dependable detection capabilities. Continuous advancements in material science and nanotechnology contribute to the development of more efficient and precise biosensors,

further pushing the boundaries of LOD and enhancing their practical applications in various fields.

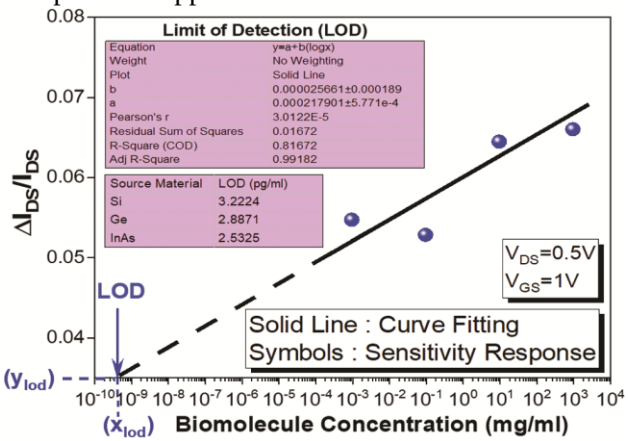

Fig. 21 — Current sensitivity response curve in NWM-BD

Table 13 — Impact of cavity location on sensitivity

Threshold voltage shift (ΔV_t : mV)					
Cavity Length			Biomolecules		
L_1 (nm)	L_{EOX} (nm)	L_2 (nm)	A	B	C
0	2	28	130.008	118.291	102.226
14	2	14	183.228	169.724	155.838
28	2	0	225.667	209.791	196.009

A : K_{bio}=5 & ρ= -1*10^{11}/cm^2 C : K_{bio}=5 & ρ= +1*10^{11}/cm^2
B : K_{bio}=5 & ρ= 0

Cavity location also plays a crucial role in affecting the sensitivity of nanowire MOSFEB detector. Table 13 shows the effect of cavity location on sensitivity (the aspect ratio is kept the same by keeping the total length L_1+L_{EOX}+L_2 constant). The biosensor is highly sensitive to biomolecules when the cavity is embedded near the source. As discussed in the previous section, biomolecules inside the cavity (near the source junction) effectively controls the flow of charge carriers via capacitive coupling[25, 50-51]. Hence, the biosensor becomes more sensitive to biomolecules. Advanced simulation and modeling techniques can aid in precisely determining the optimal cavity location and configuration to achieve the highest sensitivity and selectivity. These considerations are vital for the development of next-generation biosensors with superior performance metrics.

3.7 Comparison with Junctionless Variant

Junctionless variants have fabrication advantage over the inversion type variants[52]. Here, in Fig. 22, the sensitivity of the nanowire MOSFEB has been compared with its junctionless variant. The proposed MOSFEB shows over ~95mV improvement over the

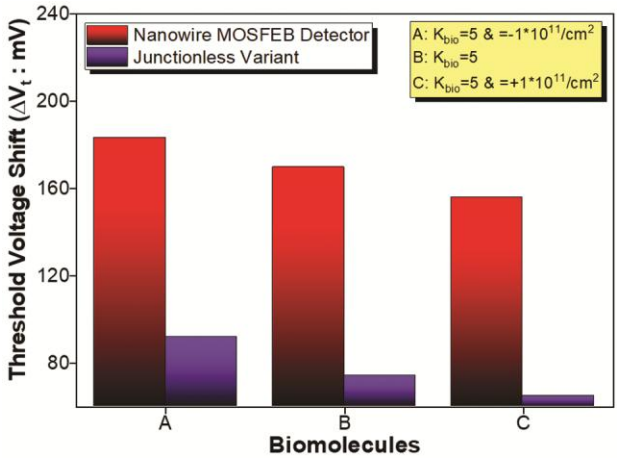

Fig. 22 — Comparison of NWM-BD with its junctionless variant

junctionless variant for K_{bio}=5. And the same trend can be seen for the charged biomolecules also. For junctionless variant, the doping and type of the semiconductor material used in this analysis is same for source/channel/drain (doping considered here is 10^{19}/cm^3).

Junctionless FET based-biosensors typically exhibit lower sensitivity in terms of threshold voltage changes compared to conventional inversion-mode FETs due to their distinct operating principles[53,54]. While inversion-mode MOSFETs rely on surface conduction in a thin inversion layer, junctionless MOSFETs operate through bulk conduction in a heavily doped channel. This bulk conduction mode makes junctionless devices less sensitive to surface charge changes induced by biomolecule interactions or localization inside the cavity. Additionally, the weaker gate control and reduced electrostatic coupling in junctionless devices result in a smaller impact on the threshold voltage when biomolecules interact with the detector[15]. Consequently, the threshold voltage in junctionless devices is less responsive to the presence of bio-chemical species, leading to lower sensitivity compared to their inversion-mode counterparts. Despite their lower threshold voltage sensitivity, junctionless MOSFET biosensor offers potential advantages in terms of simpler fabrication processes, reduced short-channel effects, and potentially lower noise levels, which can be beneficial in certain biosensing applications where these factors are prioritized over absolute sensitivity[1].

3.8 Sensitivity Analysis for Different Biomolecules

Different biomolecules have significance in the biomedical field. Biomolecules such as Uricase (K_{bio}=1.54), Streptavidin (K_{bio}=2.1), Biotin

Table 14 — Threshold voltage shift for different neutral biomolecules

Biomolecules	Reference	Sensitivity ΔV_t (mV)	Sensitivity S_{Vt} (Percentage)
Uricase	12	65.54873	26.529
Streptavidin	12	97.0815	39.291
Biotin	40	118.595	47.998
APTES	12	140.6225	56.913
Hydroprotein	15	169.724	68.691
Keratin	9	207.2831	83.892
Gelatin	24	254.7775	103.114

Table 15 — Benchmarking the performance of NWM-BD detector with similar biosensors

Structure	K_{bio}	S_{Vt} (V)	Reference
NWM-BD (Our Work)	12	0.2547	-
GaN-GME-DE-SNW-FET	8	0.1050	9
TGRC-MOSFET	8	0.0072	55
QG-MC-MOSFET	12	0.1610	56
TGAA-NWFET	2.1	0.0172	57

(K_{bio}=2.63), ChOx (K_{bio}=3.3), APTES (K_{bio}=3.57), Keratin (K_{bio}=8) and Gelatin (K_{bio}=12) are some of the commonly used neutral biomolecules.The sensitivity of the biosensor increases with the increasing dielectric constant (K_{bio}). High K_{bio} increases the coupling between the charge carriers and gate via capacitive coupling. Hence, the sensitivity increases with increasing K_{bio}. Table 14 presents the sensitivity comparison for these biomolecules. Table 15 is a benchmark for comparing the performance of nanowire MOSFEB detector to that of similar biosensors.

Label-free biosensors, including NWM-BD, inherently face challenges in achieving high selectivity. While our biosensor exhibits high sensitivity to the target analyte, selectivity can be enhanced by incorporating selective recognition elements, such as a bioreceptor layer, though this may increase fabrication complexity and reduce sensitivity. As selectivity remains a fundamental challenge in label-free biosensors, sensitivity is often the primary benchmark. The nanosensor (NWM-BD) functions by immobilizing biomolecules within a nanogap cavity, requiring advanced fabrication techniques for precise nanoscale dimensions, adding complexity to the process. However, the proposed nanosensor offers high sensitivity and cost-effectiveness compared to conventional biosensors, making it promising for label-free biosensing. Despite its high sensitivity, its selectivity is relatively low but can be improved with an additional bioreceptor layer at the cost of increased fabrication complexity. Additionally, repeated usage may cause wear and tear, potentially reducing the sensor's operational lifetime and reusability.

4 Conclusion

This paper presents a comprehensive sensitivity analysis of a nanowire-based MOSFEB detector, focusing on the impact of doping on sensitivity. The uniqueness of this study lies in its methodology, which investigates sensitivity enhancement through doping modulation and the effect of partially filled cavities (steric hindrance) at different fill-in factors and profiles. Both relative and percentage sensitivity are considered in the sensitivity exploration. The findings indicate that sensitivity exhibits a greater percentage change at lower doping levels, while the relative change peaks at higher doping levels. Various parameters, including cavity dimensions, material engineering, drain voltage, operating temperature, oxide stacking, source material, and channel radius, significantly influence sensitivity. The analysis of steric hindrance reveals that the location of biomolecules impacts sensitivity more than their fill-in factor. The detector shows a sensitivity enhancement of approximately 95.716 mV over its junctionless variant (for K_{bio}=5), with oxide and gate engineering techniques contributing more significantly to sensitivity enhancement than other engineering methods. The proposed biosensor achieves a limit of detection of 3.2224 pg/ml. Doping, bias, and biomolecule location are also the critical factors in determining sensitivity revealed through various simulated results. This work provides a valuable framework for studying and enhancing the sensitivity of similar biosensors, offering a thorough investigation into biosensing performance.

Abstract Industry 4.0 is revolutionizing the construction industry by integrating advanced technologies to enhance efficiency and productivity. This article offers insights into implementing Industry 4.0 in the construction industry of developing nations like India. However, its implementation faces significant challenges due to diverse barriers. Hence, this research explores and prioritizes these barriers for the effective implementation of Industry 4.0 within the construction industry. This study delved into 20 barriers across five primary criteria, utilizing an extensive literature review and expert input. A Fuzzy Analytical Hierarchy Process is applied to prioritize the barriers. The utilized Fuzzy framework significantly deals with unreliability and ambiguity. A case study of the Indian Construction Company illustrates the suggested model. A sensitivity study was conducted to verify the model's resilience. The findings reveal that high initial investment, lack of funding, data management, and security are notable barriers to the implementation of Industry 4.0 within the construction industry of developing nations. The insights of this study serve as valuable resources for managers and policymakers in strategizing effective implementation of Industry 4.0.

Keywords Barriers · Industry 4.0 · Fuzzy analytical hierarchy process (FAHP) · Construction industry

1 Introduction

The construction industry is undergoing a profound transformation with the advent of Industry 4.0, integrating digital technologies into physical processes and reshaping traditional practices. Newman et al. (2021) argued that I4.0 technologies such as "Building Information Modeling (BIM), Internet of Things (IoT), and robotics," etc., are modernizing construction projects, increasing productivity, and improving safety standards. BIM, specifically, has emerged as a cornerstone of digital transformation in construction, facilitating collaborations among stakeholders for effective decision-making (Liu et al. 2021). According to Omrany et al. (2023), the application of IoT sensors and devices on construction sites allows for live tracking of equipment, environmental conditions, and materials, leading to proactive maintenance and optimal resource utilization. Moreover, robots and automated technologies have simplified construction operations by automating repetitive jobs and boosting precision (Javaid et al. 2021).

Despite the potential benefits, implementation of I4.0 in the construction industry faces distinct barriers such as implementation cost, poor standards, legal issues, cyber security, and workforce skills gaps "(Singh et al. 2023; Yap et al. 2022; Oesterreich and Teuteberg 2016)." Analysis of these barriers is crucial for effectively implementing I4.0 in the construction industry.

This study examined 20 specific barriers categorized into five major groups, incorporating insights from literature reviews and expert opinions. "The aim was to offer a comprehensive understanding of these barriers, primarily focusing on the Indian construction industry." "Fuzzy Analytical Hierarchy Process (FAHP) is utilized to assign weights to the identified barriers and prioritize them. Moreover, the proposed model is examined for sensitivity

Published online: 10 April 2025

analysis to establish its consistency. The relative ranking can assist decision-makers, engineers, stakeholders, and the Government in strategizing the implementation of I4.0 in the Indian construction industry."

This study is classified into further sections, such as a review of I4.0 barriers, a focus on problem definition, outlining the two-phase model and applying the proposed model, presenting results and discussions, followed by drawing conclusions, discussing managerial implications, and addressing study limitations.

2 Examining existing literature

Barriers to Implementing I4.0 in Developing Countries.

In recent years, academicians and researchers have focused on integrating I4.0 practices in the construction industry (Ribeiro et al. 2024; Mansour et al. 2023; Sajjad et al. 2023; Newman et al. 2021; You and Feng 2020). However, implementing I4.0 remains in its infancy within developing nations, owing to numerous barriers (Demirkesen and Tezel 2022). The literature seeks to address various barriers that hinder the adoption of I4.0 in the construction industry of developing countries (Tayal et al. 2023; Sajjad et al. 2023; Singh and Misra 2021; Maskuriy et al. 2019; Osunsanmi et al. 2018). "This article categorizes barriers into five primary classifications, each with its own sub-criteria. This classification is drawn through a literature review and multiple rounds of discussions with experts. Table 1 illustrates the final investigated barriers of I4.0 in the construction Industry."

2.1 Financial barriers

Most of the literature outlines that in developing nations, high initial investments for purchasing and installing machinery, software, etc., act as a prime barrier in implementing I4.0 (Demirkesen and Tezel 2022; Singh et al. 2023). Organizations encounter financial challenges due to a lack of funding from financial institutions and reluctance from investors to contribute to risky projects (Olsson et al. 2021; Newman et al. 2021). According to Watts et al. (2023), the construction industry faces uncertainty in investment returns due to project complexity, market volatility, and technological obsolescence. Moreover, cost–benefit analysis for I4.0 investments can be challenging due to project complexity and long-term benefits (Kumar et al. 2021a, b; Hong et al. 2018). Therefore, factors such as intangible benefits, unpredictable project outcomes, and dynamic technical landscapes complicate evaluating potential returns, making decision-making difficult.

2.2 Technological barriers

Past research (Demirkesen and Tezel 2022; Aripin et al. 2019) "illustrates that the complexity of technologies like

Building Information Modeling (BIM) is a significant barrier to I4.0 implementation in the construction industry." Okonkwo et al. (2023) also emphasize the challenges of poor standardization and protocols in I4.0 technologies, leading to compatibility issues and escalated construction budgets. Without standardized interoperability frameworks, businesses may incur significant costs when customizing and connecting disparate systems. Lau et al. (2021) argued that complexities in storing and securing vast data with data integrity, confidentiality, and privacy compliances are further critical barriers. According to Siriwardhana and Moehler (2023), inadequate skill gaps and training needs among construction workplaces hinders the integration of I4.0 in the construction industry. A lack of digital literacy and technical competencies might limit the proper installation and use of innovative technology.

2.3 Regulatory barriers

"Strict privacy regulations, such as General Data Protection Regulation (GDPR), mandate data handling and permission rules, which may complicate data collecting and sharing in construction projects"(Almatari et al. 2023; Yap et al. 2022). Advanced automation systems and robotics raise new safety concerns and potential liabilities, needing strict adherence to industry norms and regulations to mitigate risks successfully (Spaan and Abraham 2023). Technological developments may result in changes in job roles and skill needs, creating concerns about labor displacement and fair access to opportunities, which can create ethical and social implications as substantial barriers to adoption (Umeokafor and Teizer 2023). According to Hanuar et al. (2023), limited or poor tax rebates and incentives for investing in I4.0 technologies in construction can serve as a technological barrier. Construction firms may be hesitant to invest in technological upgrades without adequate financial incentives or tax rebates, affecting the industry's pace of adoption and innovation.

2.4 Organizational barriers

Literature reveals that a lack of visionary leadership within construction organizations can impede the implementation of I4.0 technology (Olsson et al. 2021; Zulu et al. 2023). Without strong leadership and a clear vision for digital transformation, organizations may struggle to set strategic goals, manage resources effectively, and rally support for technical projects. Organizational resistance such as cultural norms, fear of job displacement, or reluctance to deviate from traditional practices are significant barriers to implementing I4.0 technology in construction (Govindan and Arampatzis (2023). Studies (Demirkesen and Tezel 2022; Orzes et al. 2018) illustrate that Short-term focus and risk aversion can hinder the implementation of I4.0 in construction. Singh et al. (2023) argued that the lack of relevant performance measures designed for I4.0 initiatives affects organizational efforts to monitor the effectiveness and impact of technological investments. Organizations may struggle to justify investments, manage resources appropriately, and track progress toward digital transformation objectives without defined metrics for evaluating outcomes and demonstrating ROI.

2.5 Market barriers

Nagy et al. (2021) "indicate that the construction industry is fragmented, with various small and medium-sized firms (SMEs) functioning independently. This fragmentation affects the adoption of I4.0 technologies since businesses may lack the scale and resources to invest in and implement advanced solutions successfully." Market constraints stem from a lack of customer awareness and comprehension of the potential benefits of I4.0 technologies in construction, resulting in poor adoption rates of I4.0 in the construction industry (Demirkesen and Tezel 2022). According to Balkhy et al. (2021), Vendor lock-in, where construction firms become dependent on specific technology providers or platforms, can limit flexibility, raise prices, and reduce interoperability with alternative solutions, stifling market competition and innovation. The construction industry is susceptible to market volatility due to factors such as economic fluctuations, regulatory changes, and geopolitical uncertainties that interrupt investment cycles, cause project delays, and undermine confidence in long-term technology investments, posing barriers to the widespread adoption of I4.0 technologies (Martinez and Pfister 2023).

3 Research objectives and methodology

"Despite the global push towards digital transformation, the construction industry in developing economies lags behind due to several challenges, including financial constraints, technological complexity, regulatory issues, organizational barriers, and market-related factors. Based on the literature review, the following research gaps are identified:"

i. *Lack of Focus on Developing Countries* Much of the existing research on Industry 4.0 (I4.0) adoption is centered on developed nations, where technological readiness, infrastructure, and regulatory frameworks are more robust (Ribeiro et al. 2024; Newman et al. 2021). However, the specific challenges faced by developing countries, such as limited funding, skills shortages, and inadequate regulatory support, have not been extensively explored. Developing countries

face additional financial barriers, such as high initial investment and lack of access to capital (Demirkesen and Tezel 2022; Kumar et al. 2021a, b). This research addresses the gap by focusing on the Indian construction industry and exploring the barriers to I4.0 implementation within a developing economy context.

ii. *Comprehensive Analysis of Barriers* Previous studies have identified various barriers to I4.0, such as technological complexity, workforce skill gaps, and regulatory challenges (Osunsanmi et al. 2018; Singh et al. 2023). However, most studies focus on individual barriers without providing a comprehensive, multi-dimensional analysis. The existing literature often needs a holistic perspective on the interconnectedness of these barriers. By categorizing barriers into financial, technological, regulatory, organizational, and market-related groups and using Fuzzy Analytical Hierarchy Process (FAHP), this study offers a more detailed, prioritized analysis of these barriers in the construction industry of developing nations (Mansour et al. 2023; Bajpai and Misra 2022).

iii. *Lack of Prioritization Framework* Despite the identification of barriers to I4.0, there needs to be a universally accepted framework for their prioritization, which limits practical decision-making for industry stakeholders (Liu et al. 2021). The lack of structured methods to evaluate the significance of different barriers leaves decision-makers without clear guidance on allocating resources efficiently. This study fills that gap by using Multi-Criteria Decision-Making (MCDM) techniques, precisely the fuzzy logic approach, to create a data-driven model for ranking barriers to I4.0 implementation (Pathak et al. 2022). This structured prioritization provides actionable insights for stakeholders in the construction industry.

iv. *Scarcity of Case Studies in the Construction industry* Although there is a growing body of literature on I4.0 adoption in sectors such as manufacturing and logistics, construction still needs to be explored (Shafei et al. 2024). The unique challenges the construction industry faces, such as project-specific customization, complex supply chains, and the need for real-time data integration, are not adequately addressed in the current research (Maskuriy et al. 2019). "By applying its analysis to a real-world case study of an Indian construction company, this research fills a significant gap in the literature. It validates the effectiveness of the proposed methodology within the construction industry."

By addressing these gaps, "this study contributes to a deeper understanding of how the construction industry in developing nations can overcome barriers to the adoption of I4.0 technologies, offering practical recommendations for industry leaders, policymakers, and researchers."

"The goal of this study is to examine the barriers experienced by the Indian construction industry in the integration of I4.0 technologies. This study has two primary goals: first, to identify the barriers to I4.0 adoption in the Indian construction industry, and second, to prioritize these barriers using the "FAHP" technique."

This study uses a two-phase hybrid strategy to explore and prioritize barriers. "Initially, barriers to I4.0 implementation in the Indian construction industry are identified via a literature analysis and expert consultation. The barriers and sub-barriers are then analyzed and prioritized using the FAHP technique." Fig. 1 illustrates the proposed/planned research design.

3.1 Fuzzy AHP (FAHP)

"The Analytic Hierarchy Process (FAHP) is a popular numerical method in the field of Multi Criteria Decision Making (MCDM)," developed by Saaty (1991). AHP is a powerful decision-making method that handles uncertainty and ambiguity in decision-making processes. "Its importance in I4.0, notably in the construction industry, stems from the complex and diverse nature of construction projects. Table 2 depicts contemporary uses of Fuzzy AHP".

Chang (1996), created an extent analysis method that applies to each criterion g_i.

$$M_{gi}^{1}, M_{gi}^{2}, \ldots\ldots\ldots.., M_{gi}^{m}, i = 1,2,3,4, \ldots\ldots.., n$$

"The $M_{gi}^{j}(j = 1,2,3,4, \ldots\ldots\ldots.., m)$ are Triangular Fuzzy Numbers (TFN), as depicted in Table 3. Triangular Fuzzy Numbers (TFN) are used to represent uncertainty in decision-making processes. A TFN is expressed as a triplet (l,m,u)(l, m, u)(l,m,u), where: l(lower bound) represents the smallest possible value, m(middle value) represents the most likely value, and u(upper bound) represents the largest possible value."

This fuzzy number is called "triangular" because its membership function is shaped like a triangle. TFNs are widely used in the Fuzzy Analytical Hierarchy Process (FAHP) to handle imprecision in expert judgments, allowing for a flexible and more realistic representation of data in scenarios where exact numbers are hard to determine. In this study, TFNs facilitate the comparison of barriers to Industry 4.0 by quantifying subjective opinions with these ranges.

Chang's analysis outlines the following steps:

Step 1 "The value of fuzzy synthetic (S_i) for the ith criterion is given as:"

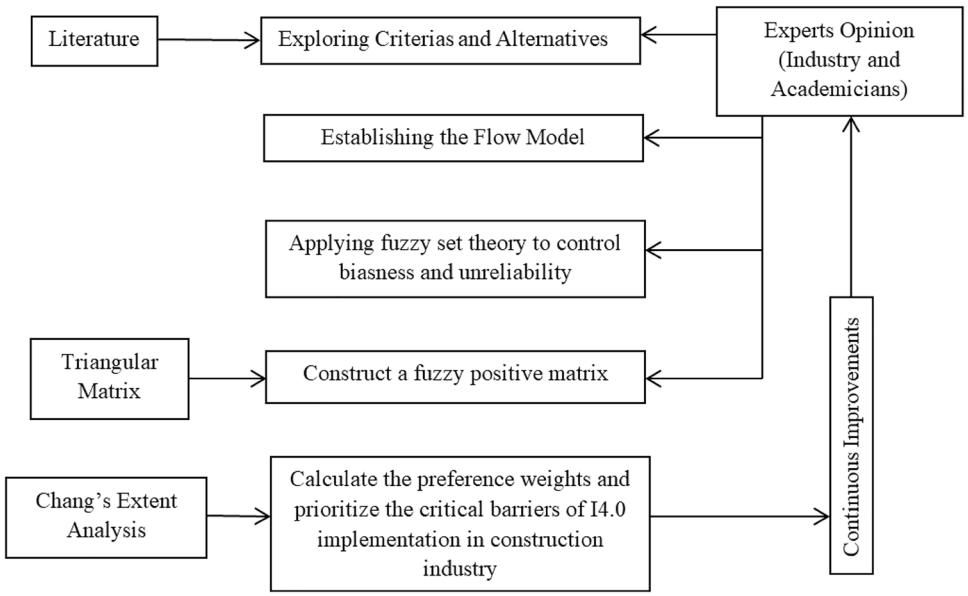

Fig. 1 Proposed research design

Table 3 Triangular fuzzy number (TFN) scale. *Source* Prakash and Barua (2015)

Lingual variables	Fuzzy triangular numbers
Equal	(1, 1, 1)
Very low	(1, 2, 3)
Low	(2, 3, 4)
Moderate	(3, 4, 5)
High	(4, 5, 6)
Very strong	(5, 6, 7)
Extreme	(7, 8, 9)

$$S_i = \sum_{j=1}^{m} M_{gi}^{j} \times \left[\sum_{i=1}^{n}\sum_{j=1}^{m} M_{gi}^{j}\right]^{-1} \tag{1}$$

$$\sum_{j=1}^{m} M_{gi}^{j} = \left(\sum_{j=1}^{m} l_{ij}, \sum_{j=1}^{m} m_{ij}, \sum_{j=1}^{m} u_{ij}\right)$$

$$\left[\sum_{i=1}^{n}\sum_{j=1}^{m} M_{gi}^{j}\right]^{-1} = \left(\frac{1}{\sum_{i=1}^{n}\sum_{j=1}^{m} u_{ij}}, \frac{1}{\sum_{i=1}^{n}\sum_{j=1}^{m} m_{ij}}, \frac{1}{\sum_{i=1}^{n}\sum_{j=1}^{m} l_{ij}}\right)$$

where 'm' signifies the most favorable value, 'u' denotes the maximum value and 'l' represents the minimum value.

Step 2 The level of probability of $S_2 = (l_2, m_2, u_2) \geq S_1 = (l_1, m_1, u_1)$ is defined as

$$V(S_2 \geq S_1) = {}_{x \geq y}{}^{sup}\left[\min(\mu_{s_1}(x), \mu_{s_1}(y))\right]$$

$$V(S_2 \geq S_1) = \begin{cases} 1, & if\ m_2 \geq m_1 \\ V(S_2 \geq S_1) = 0, & if\ l_1 \geq \mu_2 \\ \frac{l_1 - u_2}{(m_2 - u_2) - (m_1 - l_1)} = \mu_d \end{cases} \quad (2)$$

where μ_d is the maximum convergence of fuzzy numbers $\mu_{s_1} and \mu_{s_2}$. (Fig. 2).

Step 3: "The probability of a convex fuzzy number being bigger than k convex fuzzy numbers $S_i (i = 1,2, \ldots .., k)$ can be defined as:"

$$\begin{aligned} &V(S \geq S_1, S_2, \ldots \ldots \ldots .., S_k) \\ &V[(S \geq S_1), (S \geq S_2), \ldots \ldots \ldots \ldots ., (S \geq S_k)] \\ &= minV[(S \geq S_i), \\ &i = 1,2, \ldots, kassumingthatd\prime(A_i) = minV(S_i \geq S_k) \end{aligned} \quad (3)$$

$Fork = 1,2, \ldots .., n, (k \neq i)$, the weight vectors are illustrated by

$$W\prime = (d\prime(A_1), d\prime(A_2), \ldots \ldots .., d\prime(A_k))^T \quad (4)$$

Step 4: Following normalisation, the normalised weight vectors are depicted by:

$$W\prime = (W_1\prime, W_2\prime, \ldots \ldots \ldots, W_n\prime)^T \quad (5)$$

3.2 Computational complexity of the proposed methodology

The manuscript proposes the use of a Fuzzy Analytical Hierarchy Process (FAHP) for prioritizing barriers to Industry 4.0 (I4.0) implementation in the Indian construction industry. The computational complexity of FAHP arises from several factors, mainly the number of criteria and pairwise comparisons required, as well as the fuzzification and defuzzification processes inherent in the fuzzy logic framework. Specifically, FAHP involves multiple steps:

i. *Pairwise Comparisons* FAHP requires pairwise comparisons of all criteria and sub-criteria. If there are n criteria, the number of comparisons needed is $\frac{n(n-1)}{2}$. This creates a quadratic relationship in terms of computational complexity.
ii. *Fuzzification and Defuzzification* Each comparison is represented by triangular fuzzy numbers, which need to be synthesized and converted into crisp values. These operations are computationally expensive, typically requiring operations such as fuzzy multiplication, addition, and defuzzification using centroid methods. The complexity of these operations depends on the number of fuzzy numbers and their degree of precision, which adds further computational overhead.
iii. *Normalization and Weight Calculation* After defuzzification, the weights are normalized, and a final priority vector is computed. While the normalization itself is linear, synthesizing the fuzzy matrices and computing the synthetic extent values adds to the overall complexity.

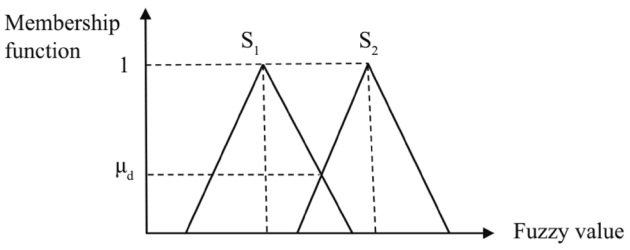

Fig. 2 Convergence of fuzzy numbers

Thus, the overall computational complexity of the FAHP method can be approximated as **O(n^2)** for pairwise comparisons, with additional overhead for fuzzification and defuzzification steps, potentially reaching **O(n^3)** depending on the precision of the fuzzy numbers used.

3.3 Comparison to existing methodologies

i. *Traditional AHP* Traditional Analytical Hierarchy Process (AHP) is widely used in multi-criteria decision-making (MCDM). The complexity of AHP primarily arises from the pairwise comparison matrix, where each criterion is compared with others, leading to a quadratic complexity **O(n^2)** (Saaty 1991). However, AHP lacks the ability to handle uncertainty and imprecision in judgments, making it less suitable for scenarios involving high ambiguity, like Industry 4.0 implementation in construction. FAHP overcomes this limitation by integrating fuzzy logic, allowing decision-makers to express preferences more flexibly using linguistic variables.
ii. "*Fuzzy TOPSIS* Fuzzy Technique for Order Preference by Similarity to Ideal Solution (Fuzzy TOPSIS) is another common method in MCDM problems." Its computational complexity is similar to FAHP, with the complexity for ranking alternatives being quadratic. However, Fuzzy TOPSIS does not inherently incorporate hierarchical structuring of criteria, which FAHP offers. Fuzzy TOPSIS is often preferred when the decision problem focuses on ranking a set of alternatives rather than dealing with hierarchical structures (Prakash and Barua 2015).

iii. "*DEMATEL and Fuzzy DEMATEL* Decision Making Trial and Evaluation Laboratory (DEMATEL) and its fuzzy variant are also used for barrier analysis in complex systems." DEMATEL captures the cause-effect relationships among criteria, adding another layer of computational complexity compared to AHP or FAHP. DEMATEL's matrix operations and handling of causal relationships typically make it more computationally intensive, often reaching **O(n^3)** for larger matrices (Wu et al. 2021). However, FAHP's structured hierarchy and direct pairwise comparison make it simpler and more intuitive for prioritization tasks.

iv. *Hybrid Methods* Other hybrid methods like **PCA-Fuzzy AHP** (Kumar et al. 2021a, b) and **SWARA-COPRAS** integrate multiple techniques to overcome limitations of single MCDM methods. While these methods can achieve more accurate results, they often come at the cost of increased computational complexity. Hybrid methods involving fuzzy logic typically show **O(n^3)** complexity, making them more computationally demanding than pure FAHP approaches.

The FAHP method proposed in the manuscript has a computational complexity of **O(n^2)** to **O(n^3)**, primarily depending on the number of criteria and the fuzzification process. Compared to traditional AHP, FAHP better handles uncertainty but incurs higher computational costs. Fuzzy TOPSIS and DEMATEL also offer alternatives, with DEMATEL being more computationally intensive due to its causal relationship analysis. The choice between these methodologies depends on the decision context, but FAHP provides a good balance between computational efficiency and the ability to model uncertainty, particularly for the barrier prioritization problem discussed in the manuscript.

4 Implementation of the proposed model

The proposed model is implemented in a Construction Company (identity withheld for confidentiality reasons) situated in northern India. The company is considered for the case study because it is a prominent player in the Indian construction industry. The company is renowned for its extensive expertise in significant construction projects using modern technologies.

4.1 Data collection

A survey was developed with insights from the literature study and disseminated to experts and decision-makers. Their expertise was used to explore common barriers in the construction industry to the acceptance of I4.0 technologies. The study considers decision-makers from both industry and academia to mitigate potential biases toward their respective organizations. "Eight professionals with over 15 years of experience in the construction industry were chosen to refine identified barriers and construct a pairwise decision matrix." "Twenty barriers were eventually classified into five major categories based on both literature research findings and expert opinions, as detailed in Table 1. A visual illustration of the Fuzzy AHP framework is shown in Fig. 3, which showcases the use of the Fuzzy AHP method to prioritize barriers to Industry 4.0 implementation." The process involves several key steps:

i. *Problem Definition* Barriers to Industry 4.0 are identified through literature reviews and expert input, categorized into financial, technological, organizational, market, and regulatory barriers.

ii. *Hierarchy Structuring* The identified barriers are arranged into a hierarchical structure, with the main objective at the top and sub-barriers underneath.

iii. *Pairwise Comparisons* Experts perform pairwise comparisons between barriers using Triangular Fuzzy Numbers (TFNs) to express uncertainty. The fuzzy scale captures the relative importance of each barrier.

iv. *Fuzzy Synthesis* Fuzzy synthetic values are computed to aggregate expert judgments, reflecting the overall importance of each barrier.

v. *Defuzzification* The fuzzy values are converted into crisp values to simplify the comparison of barriers.

vi. *Ranking and Sensitivity Analysis* Barriers are ranked based on their defuzzified scores, and sensitivity analysis ensures that the results are stable.

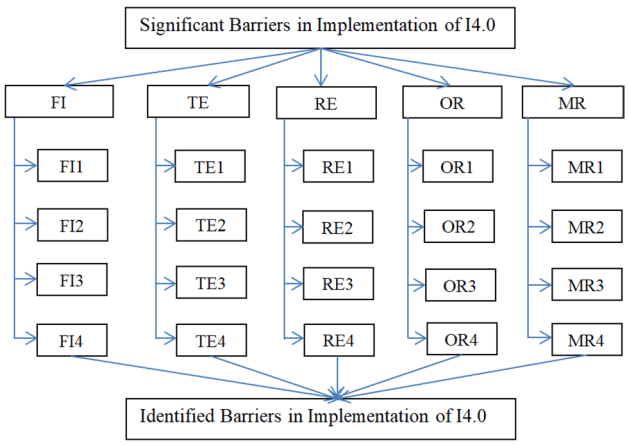

Fig. 3 Fuzzy analytic hierarchy framework for identifying barriers to I4.0 implementation

Fuzzy logic handles uncertainty and ambiguity in expert judgments, making the decision-making process more flexible and realistic. It enables the quantification of subjective opinions, which is crucial in complex scenarios like Industry 4.0 implementation, where precise data may not always be available. This approach enhances accuracy and helps decision-makers prioritize actions based on reliable, nuanced evaluations.

4.2 Computation of "fuzzy synthetic weight"

"Decision-makers conducted pairwise analysis of major criteria using a TFN scale (Table 3)." Table 4 displays the pairwise assessments of major barriers based on lingual statements and expressions.

"Equation (1), calculates fuzzy synthetic weights for five major barriers, as shown below:"

S(FI) = (7.00,11.00,15.00) x [0.020,0.031,0.039] = (0.140,0.341,0.585).

S(OR) = (4.91,6.33,8.50) x [0.020,0.031,0.039] = (0.098,0.196,0.331).

S(TE) = (6.00,8.50,11.33) x [0.020,0.031,0.039] = (0.120,0.263,0.441).

S(MR) = (2.11,2.58,3.83) x [0.020,0.031,0.039] = (0.042,0.079,0.149).

S(RE) = (4.50,6.66,9.00) x [0.020,0.031,0.039] = (0.090,0.206,0.351).

Equations (2) and (3) are used to compute the minimum possible degree:

m(FI) = min $V(S_1 \geq S_k)$ = min(1,1,1,1), whereas values for further criterias are m(OR) = 0.568, m(TE) = 0.794, m(MR) = 0.033, m(RE) = 0.609.

"The final weight vector is determined by": $W_v = (1.000, 0.568, 0.794, 0.033, 0.609)^T$

"The final weight values are calculated after normalization as:"

W = (0.655, 0.372, 0.520, 0.021, 0.399).

"Table 5 illustrates the final relative weights and ranking of the major barriers or criteria. The ranking of the main barriers is FI > TE > RE > OR > MR." Financial barriers are ranked as the most critical category in the manuscript, surpassing technological, regulatory, organizational, and market-related barriers. These barriers include high initial investment costs, lack of funding, and uncertainty in cost–benefit analysis, which are critical challenges for implementing Industry 4.0 in the construction industry.

Table 5 Relative weight and ranks of major barriers

Criteria	Relative weights	Rank
FI	0.655	1
OR	0.372	4
TE	0.520	2
MR	0.021	5
RE	0.399	3

The dominance of financial barriers implies that decision-makers prioritize addressing funding and investment issues before tackling technological upgrades or regulatory compliance. This ranking suggests that without resolving financial constraints, advancements in other areas, such as technology adoption and workforce development, are likely to be stalled, impacting the overall progress of Industry 4.0 integration in the construction industry.

"Likewise, the pairwise assessment of sub-barriers was conducted as illustrated in Tables 6, 7, 8, 9, and 10." These tables evaluate how each sub-barrier contributes to the overall category by assigning relative importance using a Triangular Fuzzy Number (TFN) scale. Each sub-barrier is compared with others based on expert opinions, assessing which barrier poses a more significant challenge to Industry 4.0 adoption.

"Ultimately, the global weights of individual sub-barriers were computed by multiplying the relative weights of the major barriers by those of the sub-barriers." Table 11 shows the final ranking of I4.0 barriers based on the global weights assigned to each barrier.

5 Results and discussions

The fuzzy AHP approach provides a rational answer for comparing two barriers, assisting decision-makers in prioritizing them. This article uses AHP approach to investigate the barriers to the application of I4.0 in the Indian construction industry. "It encourages organizations to understand the barriers of implementing the I4.0 in their construction processes. It illustrates the ranking of barriers

Table 10 Pairwise assessment of regulatory sub-barrier (RE)

	RE1	RE2	RE3	RE4
RE1	(1.00,1.00,1.00)	(0.20,0.25,0.33)	(3.00,4.00,5.00)	(0.25,0.33,0.50)
RE2	(3.00,4.00,5.00)	(1.00,1.00,1.00)	(0.33,0.50,1.00)	(0.20,0.25,0.33)
RE3	(0.20,0.25,0.33)	(1.00,2.00,3.00)	(1.00,1.00,1.00)	(2.00,3.00,4.00)
RE4	(2.00,3.00,4.00)	(3.00,4.00,5.00)	(0.25,0.33,0.50)	(1.00,1.00,1.00)

based on their prioritized weightage values, with financial, technological, regulatory, organizational, and market-related barriers grouped in descending order, as shown in Table 5." Financial barriers are the most significant barriers to the implementation of I4.0 in the construction industry, and sub-barriers are prioritized as FI1 > FI3 > FI4 > FI2. Initial Costs incurred in purchasing modern machinery, improving infrastructure, and obtaining digital tools required for automation and digitization act as significant determinants (Demirkesen and Tezel (2022). Limited budget allocations and lack of funding such as loans, venture capital, or investment are major constraints. This limited access to external funding sources exacerbates the issue of obtaining the resources required for I4.0 implementation (Watts et al. 2023). Moreover, the complexity of conducting comprehensive cost–benefit analyses due to data availability and quality poses additional barriers to I4.0 implementation (Newman et al. 2021; Taher 2021). Decision-makers confront difficulties in effectively forecasting the return financial benefits (ROI) of technology investments due to factors such as changing market dynamics, fast-expanding technology trends, and project-specific variables (Singh et al. 2023). Construction projects comprise of sensitive information such as project blueprints, financial data, and stakeholders' personal information. Implementing I4.0 in construction processes exposes them to cyber security

Table 11 Final ranks and global weights of sub- barriers

Criteria	Relative weights	Barriers	Relative weights	Global Weights	Rank
FI	0.655	FI1	0.746	0.489	1
		FI2	0.276	0.181	11
		FI3	0.471	0.309	2
		FI4	0.379	0.248	8
OR	0.372	OR1	0.720	0.268	5
		OR2	0.334	0.124	16
		OR3	0.464	0.173	12
		OR4	0.391	0.145	15
TE	0.520	TE1	0.516	0.268	4
		TE2	0.486	0.253	7
		TE3	0.532	0.277	3
		TE4	0.461	0.240	9
MR	0.021	MR1	0.444	0.009	19
		MR2	0.607	0.013	17
		MR3	0.595	0.012	18
		MR4	0.281	0.006	20
RE	0.399	RE1	0.395	0.158	14
		RE2	0.425	0.170	13
		RE3	0.488	0.195	10
		RE4	0.651	0.260	6

dangers such as data breaches, ransomware attacks, and malicious hacking (Humayun et al. 2021). Construction projects are frequently unique and highly customized, necessitating expertise solutions to fulfill specific needs. "Building Information Modeling (BIM), Internet of Things (IoT), augmented reality (AR), robotics, and sophisticated analytics are all examples of I4.0 technologies. Aripin et al. (2019) argued that integrating and managing these complex technologies within the ecology of construction projects necessitates extensive knowledge and resources."

Moreover, due to poor standards and protocols, companies are hesitant to invest in I4.0 technologies due to concerns about compatibility and implementation obstacles (Singh et al. 2023). The construction industry employs a varied workforce with varying degrees of literacy and abilities, but a lack of digital skills may cause a struggle to operate and troubleshoot I4.0 technologies, leading to productivity losses and frustration. This necessitates specific training programs that cater demands of the construction industry (Siriwardhana and Moehler 2023; Ebekozien et al. 2023). Therefore, ranking of technological sub-criteria is TE3 > TE1 > TE2 > TE4. "The relative significance of the sub-criteria within the category of regulatory barriers is RE4 > RE3 > RE2 > RE1, which illustrates that Companies may be hesitant to incur the financial risk, especially if tax rebates are not available to mitigate potential losses (Mustaffa et al. 2022)." While automation can improve productivity and safety, it also raises ethical concerns regarding labor displacement and its effect on lives in the construction industry. Resistance from labor unions and advocacy groups concerned about job loss may hinder the implementation of I4.0 technologies (Boya et al. 2022). Addressing these ethical and social challenges necessitates consultation with local communities and stakeholders to ensure that technological adoption is consistent with their values and goals. Moreover, without clarity on liability issues, companies may be hesitant to employ I4.0 technologies for fear of legal ramifications in case of an incident (Yap et al. 2022). Companies may perceive these risks as barriers due to the absence of robust risk management strategies and regulatory guidance. Incorporating privacy regulations may need robust encryption, access controls, and data anonymization mechanisms, which might add complexity and cost to the implementation of I4.0 technology (Almatari et al. 2023). The ranking of organizational barrier stands as OR1 > OR3 > OR4 > OR2, implying that without strong leadership and vision at the organizational level, there may be resistance to change from employees who are comfortable with traditional methods (Olsson et al. 2021; Govindan and Arampatzis 2023). Risk-averse leaders may be hesitant to invest in I4.0 efforts unless there is demonstrable proof of success or established case studies in the industry (Orzes et al. 2018). Moreover, the lack of performance measures poses challenges for decision-makers to justify the ROI of I4.0 investments to stakeholders such as investors, clients, and regulatory agencies, thus limiting future funding and support for technology adoption efforts (Singh et al. 2023; Demirkesen and Tezel 2022). Finally, the market-related

barriers ranking is MR2 > MR3 > MR1 > MR4, which outlines that limited awareness of I4.0 potential benefits (Demirkesen and Tezel 2022) and fear of single vendor lock-in (Balkhy et al. 2021) are the most significant barriers in the implementation of I4.0 in the construction industry.

6 Analysis of sensitivity

According to the findings of Chang et al. (2007), even little changes in relative weights can result in a different ranking of obstacles in the final assessment. "The sensitivity analysis is carried out to confirm the stability of the ranking of barriers by observing how it changes with variations in the relative weights of criteria for implementing I4.0" (Singh et al. 2023; Kumar et al. 2021a, b; Singh and Misra 2021). The sensitivity analysis confirms the dominant impact of financial barriers on the prioritization of other factors. The value of the financial barrier is incrementally raised from 0.1 to 0.9, with increments of 0.1, and the resulting alterations in the ranking of other criteria are observed, illustrated in Table 12. Technological barriers show the most significant variations in their weight values. "The ranking of specific sub-barriers fluctuates with the main barriers." The variation in global weight of financial barriers to 0.1 results in data management and security (TE3) at the top position and market volatility (MR4) at the lowest position. While approaching closer to the normalized value of 0.665, high initial investment (FI1) emerges as the most significant barrier. The sensitivity analysis results are illustrated in Table 13, and Fig. 4 depicts variances in the criteria ranking.

Table 12 Impact of incremental increase (0.1 to 0.9) in FI barrier values on other criterias

Criteria	Normalized weight	Run 1	Run 2	Run 3	Run 4	Run 5	Run 6	Run 7	Run 8	Run 9
FI	0.655	0.100	0.200	0.300	0.400	0.500	0.600	0.700	0.800	0.900
OR	0.372	0.618	0.577	0.536	0.495	0.454	0.413	0.330	0.288	0.246

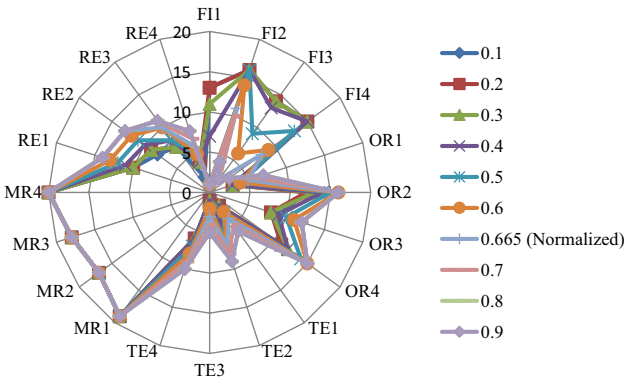

Fig. 4 Ranking variations after sensitivity analysis

7 Conclusion

Due to increasing concerns about resource scarcity and mounting pressure to transition to sustainable business models, organizations have commenced integrating I4.0 practices into their construction projects. "Nevertheless, in developing countries like India, various barriers hinder the efficient implementation of I4.0 in the construction industry." In the case of practical implementation, decision-makers face difficulty in making sound judgments, making it complex to overcome them all at once. "This study explores and prioritizes the barriers using a robust MCDM method for implementing I4.0 in the Indian construction industry. It encompasses 24 barriers categorized into five major groups, identified through a literature review and expert consultation. The fuzzy AHP methodology was utilized to determine the influence ranking of each barrier." An empirical case from an Indian construction company validates the proposed approach. "The findings of this study demonstrate that high initial investment, lack of funding, data security, poor tax rebates, and lack of leadership are the most notable barriers to I4.0 implementation in the construction industry. The outcomes of this study would aid decision-makers and governmental bodies in strategizing tangible regulations that incentivize organizations to adopt I4.0. Finally, sensitivity analysis measures volatility in barriers rank when altering the criteria weights."

8 Managerial implications

The empirical investigation conducted in the Indian construction industry presents a thorough compilation of barriers hindering I4.0 adoption. This investigation of barriers provides valuable insights for construction industry managers to develop strategic plans and integrate processes for implementing I4.0 technologies. This ensures that resources such as budget, time, and personnel are directed toward addressing the most critical barriers first, thereby maximizing the chances of successful implementation. Prioritization enables decision-makers to anticipate resistance to change and develop change management strategies to mitigate potential challenges, such as employee training and cultural shifts. "Findings of this article illustrate the importance of government initiatives in providing economic incentives and tax benefits to encourage organizations to invest in technology and innovation." Managers can use these insights to ensure regulatory compliance and allocate resources efficiently. "Overall, identifying and assessing barriers to I4.0 in the construction industry enables managers to make informed decisions, allocate resources effectively, and traverse the complexities of technology implementation to create innovation and competitive advantage." The study's conclusions not only assist the case company in overcoming considerable barriers but also support its progress towards sustainable development, thereby contributing to the national economy.

9 Practical implications

"The research conducted in this study on Industry 4.0 (I4.0) implementation within the construction industry, particularly in developing nations like India, provides critical insights for industry professionals, policymakers, and decision-makers. Below are the detailed practical implications based on the findings:"

i. *Financial Planning* High initial investments and funding challenges are major barriers to adopting Industry 4.0 in the construction industry. Companies should focus on long-term financial strategies, exploring public–private partnerships or government subsidies to overcome these financial constraints.
ii. *Workforce Development* A significant barrier is a lack of skilled labor for handling advanced technologies like BIM, IoT, and robotics. Implementing targeted training programs and upskilling initiatives is crucial for companies to harness the full potential of Industry 4.0 technologies.
iii. *Data Security and Management* Integrating digital technologies raises concerns about data management and cyber security. Construction companies must invest in secure data handling processes and adhere to regulatory compliance frameworks, such as GDPR, to mitigate risks associated with data breaches.
iv. *Standardization and Protocols* The paper emphasizes standardizing protocols for better system interoperability. Construction firms should collaborate with industry bodies to adopt global standards that

ensure smoother integration of digital tools and processes.

v. *Government and Regulatory Support* Regulatory barriers, including poor tax incentives, hinder Industry 4.0 implementation. Policymakers should provide tax benefits, rebates, and more transparent legal frameworks to encourage firms to adopt advanced technologies without facing financial or legal uncertainties.

These insights can help construction firms and policymakers strategize effectively for a smoother transition to Industry 4.0, enhancing productivity, efficiency, and competitiveness.

10 Validity and future scope

The study emphasized using the Fuzzy Analytical Hierarchy Process (FAHP), a well-established Multi-Criteria Decision-Making (MCDM) technique, which ensures the rigorous prioritization of barriers to Industry 4.0 implementation in the construction industry. The barriers and their prioritization were validated through expert input, ensuring that the study reflects practical and expert-backed insights. We have reiterated that the sensitivity analysis conducted verifies the stability and robustness of the results, confirming the validity of the prioritization framework.

Future research can apply the proposed model to other developing countries or sectors beyond construction to examine if similar barriers exist and if the methodology remains effective across different contexts. We will suggest studying how barriers to Industry 4.0 implementation evolve over time, especially with the rapid advancement of technologies and changing market dynamics. Incorporating other decision-making frameworks, such as Fuzzy DEMATEL, or hybrid approaches combining FAHP with other methods like TOPSIS, could provide more nuanced results. Future research could focus on barriers associated with specific technologies under Industry 4.0 (e.g., BIM, IoT, Robotics) to provide more tailored insights. Further longitudinal studies could track the effectiveness of overcoming these barriers in real-world projects, providing feedback loops for refining the model.

11 Limitations

"This study has limited scope of exploring and prioritizing barriers to I4.0 implementation in India's construction industry. The construction industry is inherently complex, with numerous interrelated factors influencing the implementation of I4.0 technologies. AHP may struggle to capture the full complexity of these relationships, which can be further analyzed through the Fuzzy DEMATEL approach." "Moreover, the suggested theoretical model can be validated by Confirmatory Factor Analysis (CFA) or Structural Equation Modeling (SEM)." The findings of this study can also undergo comparison using various MCDM techniques, such as SWARA and COPRAS, within a fuzzy environment.

Appendix A List of abbreviations

S. No.	Abbreviation	Full form	Definition
1	AHP	Analytical Hierarchy Process	A multi-criteria decision-making method that uses pairwise comparisons to rank alternatives or criteria
2	FAHP	Fuzzy Analytical Hierarchy Process	An extension of AHP that integrates fuzzy logic to handle uncertainty and ambiguity in decision-making
3	I4.0	Industry 4.0	The fourth industrial revolution, focused on digital technologies like IoT, robotics, and AI in manufacturing

S. No.	Abbreviation	Full form	Definition
4	MCDM	Multi-Criteria Decision Making	A set of methods for evaluating and prioritizing alternatives based on multiple criteria
5	TFN	Triangular Fuzzy Number	A fuzzy number represented by three values (lower, middle, and upper), used to model uncertainty in data
6	BIM	Building Information Modeling	A digital representation of the physical and functional characteristics of a construction project
7	IoT	Internet of Things	A network of interconnected devices that communicate and exchange data to optimize operations in real-time
8	CFA	Confirmatory Factor Analysis	A statistical technique used to test whether a set of variables aligns with an expected factor structure
9	SEM	Structural Equation Modeling	A multivariate statistical analysis technique used to analyze structural relationships between measured variables
10	SWARA	Step-wise Weight Assessment Ratio Analysis	A decision-making method used for ranking alternatives by assigning weights step-by-step
11	COPRAS	Complex Proportional Assessment	A decision-making method that ranks alternatives by comparing their performance in relation to criteria
12	GDPR	General Data Protection Regulation	A European regulation designed to protect the privacy and data of individuals within the European Union

Parametric Analysis of Organic LED and Photo-Diode Based Sensor for Heart Rate Detection

Sugandha Yadav, Poornima Mittal, and Shubham Negi*

Conventional Light emitting diode and photo-diode integration is the best suitable combination for point-of-care diagnostic in the field of sensor applications. However, these approaches based on inorganic devices are not scalable to incorporate multiple bio-marker. As a solution, this work proposes the methodology for bio-medical application using organic LED (OLED) and photo-diode to make a highly efficient, ultra-flexible, and low-cost sensor. In this paper, a green charge generation based OLED and organic photo diode (OPD) are utilized for heart rate measurements. The methodology is basically based on the fluorescence emission where green light having wavelength of 497 nm falls on the blood cells. Furthermore, a different intensity wavelength is sensed by the photodiode. The proposed OLED exhibits current and luminescence parameters of 0.92 A and 8 363.6 cd m^{-2}, correspondingly. Moreover, the presented OPD demonstrates dark currents and photocurrent of 10.2 and 174.5 nA, subsequently. This proposed technique can be also investigated in terms of other biomedical applications such as oxygen sensor, cancer detection, corona detection etc.

1. Introduction

Ultra-thin and flexible sensors are highly promising for health-care applications.[1–7] To produce flexible wearable sensors, two devices are vital: 1) organic LED (OLED) and 2) organic photo diode (OPD). OLED is generally used for light emission which falls on the sample and OPD receives the light which is emitted by the sample. Various researchers have utilized these two devices for so many health-care based sensor applications to make flexible devices. Titov et al.[8] utilized a combination of OLED and OPD which is suitable for low-cost compact optical detection for the sensing applications. Furthermore, Katchman et al.[9] demonstrated quantitative detection of IpG antibodies using human serum with the help of light emitting diode and photo diode.

Lim et al.[10] presented an oxygen sensor device using the same OLED-OPD combination. Herein, simultaneous monitoring of $tcpO_2$ is incorporated for the detection in any part of the human body. Addition to this, Lochner et al.[11] reported a low-cost flexible pulse oximeter using organic devices, LED and photo diode. The proposed device is able to measure oxygenation and pulse rate with the errors of 2% and 1%, correspondingly. Furthermore, Khan et al.[12] demonstrated a reflectance oximeter sensor device using a light emitter, a detector and an optical barrier between emitter and detector. Using this method, the researchers designed three sensor geometries which are rectangular geometry, bracket geometry, and circular geometry. Additionally, Lee et al.[13] proposed a compact flexible OLED-OPD sensing device for covid-19 detection. The device successfully detects SARS-CoV-2 RNA within 20 min using fluorescence detection.

Our work investigates few biomedical applications based on the light detection methodology using OLED-OPD integration. The in-depth discussion about the methodology is provided in the below sections. The complete paper is categorized in seven different sections. As discussed already above, Section I is about the introduction which includes various sensing applications using OLED and OPD. Afterward, Section II showcases the light detection methodology using these devices. Moreover, Section III illustrates the novel OLED structure for heart rate detection. Thereafter, in Section IV, OPD is investigated in order to measure the heart rate in human. Additionally, Section V depicts the methodology for the heart rate detection. Next, Section VI incorporates the comparison of few researchers' work for heart rate detection. Eventually, Section VII incorporates the necessary conclusions.

2. Light Detection Methodology Using OLED-OPD Integration

The block diagram in **Figure 1** depicts methodology for light-based detection technique using OLED and photo-diode. Here, OLED is used as light emitting device whereas, organic photo-diode is utilized as light detector as per their basic characteristics. The light from LED falls on sample which further excites the sample based on the nano particles present inside the sample and fluorescence emission occurs.

Eventually, photodiode provides current values at the specific wavelengths as per the detection technique. This idea of excitation and absorption in terms of wavelength is very promising for

	Pentacene	10
EML	Polymer green SPG-01T	40
ETL	BPhen	30
Cathode	LiF	1
Cathode 1	Al	150

proposed OLED device. The device contains eight different layers starting from cathode, thereafter electron transport layer (ETL), emissive layer [EML], charge generation layer, hole transport [HTL], and anode. **Table 1** depicts the materials and thickness for all the mentioned layer. The results are obtained using Silvaco Atlas simulation tool wherein, a model, i.e., Langevin's recombination rate is applied in the 2-D device simulator for the study of recombination rate. Moreover, to understand the carrier's transportation in a device structure, Poole-Frenkel mobility model is utilized which provides the results under specified boundary conditions. Figure 2a illustrates the simulated structure of the proposed device.

It is evident that every light has its own specific wavelength. Herein, the calculation of wavelength for the utilized green OLED is performed. As shown in Table 1, the material for EML SPG-01T contains the energy band gap of 2.5 eV.[22]

We know that energy gap (E_g) = $h\nu$where, $\nu = \frac{c}{\lambda}$ hence, Eg = $\frac{hc}{\lambda}$ (in Joule), and

$$\lambda = \frac{hc}{\mathrm{Eg}} \ (in\ meters) \tag{1}$$

In Equation (1), the parameters h, λ, and c represent Planck's constant, wavelength, and speed of light, subsequently.

After incorporating all the values in Equation (1),

$$\lambda = \frac{6.626 \times 10^{-34} \times 3 \times 10^{8}}{2.5 \times 1.6 \times 10^{-19}} \tag{2}$$

$$\lambda = 497\mathrm{nm} \tag{3}$$

It is clear from the final value of λ that the proposed OLED exhibits green color wavelength as the green light ranges from 495 to 570 nm.

To refine the improvement of the reference device on the basis of luminescence and current density, a charge generation layer is incorporated. With the help of CGL, the lost part of light during the recombination can be restored which eventually enhances the device performance in terms of efficiency and EL emission.[23] These layers are made of two different materials (n type & p type) and act same as electrodes. The charge carriers are generated based on the external applied biasing and inserted to the EML where the recombination happens and light is produced.[24] The reason behind opting a suitable CGL layer is completely based on the work function parameter. The work function of charge generation layer should be closely matched with the work functions of the nearby layer. In this research, The CGL is placed in between Bphen and NPB, which contains the HOMO as 6.0 and 5.4 eV, correspondingly. These work functions are closely matched with CGL layer which contains Pentacene (5 eV) and C70 (6.1 eV) materials as hole injector and electron injector, respectively. Thereby, easy facilitation of charge carriers occurs.

The 20 nm CGL is placed inside the EML (see Figure 2b) in the proposed device. It is the combination of two materials which are Pentacene (10 nm) and C70 (10 nm). Inclusion of CGL in OLED contributed significant improvement in charge injection. Thereby, the device exhibits higher current density and refined luminous properties.[25–28] The reason behind the significant enhancement is that in D_1 top layer (Pentacene) of CGL performs as hole injector element and bottom layer (C70) conducts like electron injector. As a result, holes in Pentacene layer will start moving toward cathode and will arrive to EML. In the same manner, electrons in C70 layer will be attracted to anode side and reach to EML. Herein, CGL in D_1 is enclosed inside the EML. Thereby, generated excess electrons and holes are directly moving to the EML. This automatically provides the direct increment in the recombination rate of D_1.

A circuit is designed (see Figure 2d) for driving the above-mentioned OLED using a voltage-controlled device, i.e., vertical OTFT.[29] In vertical TFTs, the channel length is very much reduced (in nano-meters) because of vertical channel formation.[30–32] Moreover, organic TFTs are preferable over inorganic transistor as the organic devices contain excellent mechanical flexibility, low-cost large area fabrication.[33–35] Also, these devices offer the possibility to adapt to low temperature processes for fabrication such as solution printing, dip coating, etc.[36] Hence, V-OTFT is a good choice for utilization to drive any circuit.

The driver V-OTFT is connected in series with the OLED device which balances the amount of current inside the OLED. Thereby the operation can be controlled. It is clear from the Figure 2d that the current is same from V_{DD} to anode terminal because of the series connection of both the devices. Hence, the current across anode is now completely dependent on V_{DD} and gate voltage which eventually control the luminescence of OLED.

The V-OTFT provides the current when it is conducted in the linear or saturation region for which the equations are given below,

$$V_{DS} < V_{GS} - V_{th}; \quad Linear\ Region \tag{4}$$

$$V_{DS} \geq V_{GS} - V_{th}; \quad Saturation\ Region \tag{5}$$

where, "V_{th}" is the threshold voltage, "V_{GS}" and "V_{DS}" stand for gate to source voltage and drain to source voltages, subsequently. Now to drive the OLED, 5 V voltage is required at node 3 (see Figure 2d) to attain maximum current density and luminescence. The circuit is operated in linear region to achieve the control on the OLED performance parameters by varying the V_{DS}. Here, the gate voltage is constant at 5 V and the drain voltage VDD is vary-

Table 2. Materials and thickness for each layer of D_2.

Layer	Material and dimensions for Proposed Device (D_2)	
	Material	Thickness [nm]
Anode	ITO	20
HTL1	PEDOT:PSS	90
CGL	C70	10
	Pentacene	10
Acceptor	C60	40
Donor	CuPc	20
ETL	BPhen	12
Cathode	Al	150
Cathode 1	LiF	1

ing from 0 to 5 V. Figure 2c illustrates the results of the proposed driver circuit.

The Figure 2e illustrates a variation in anode voltage at node 3. It is proven here that the proposed circuitry is capable of generating a potential difference of 5 V at anode for the proper operation of OLED. The current and luminescence curves are obtained as 0.92 A and 8 363.6 cd m^{-2}, respectively, at 5 V. It can be concluded that anode voltage of the OLED is controlled by varying the V_{DD} as illustrated in Figure 2d which further regulates the luminescence parameter of the light emitting diode.

4. Novel OPD Using CGL for Bio-Medical Applications

First, a multilayered OPD is validated in our previous work[37] with the simulation tool Silvaco Atlas to set the boundary conditions for the proposed work in terms of materials, thickness, and other important parameters. Thereafter, in this work, a novel structure of photo-diode (D_2) is proposed which contains CGL layer inside the active layer. This CGL layer is incorporated to design a highly efficient OPD which consists of Pentacene and C70 as hole injectors and electron injectors, correspondingly. Addition to this, the electrodes terminals anode and cathode consist of indium Tin Oxide (ITO) and Aluminum (Al), respectively. Furthermore, ETL and hole transport layer (HTL) consist of the materials BPhen and PEDOT:PSS (poly(3,4-ethylenedioxy thiophene):polystyrene sulfonate), correspondingly. Moreover, the active layer which is the combination of acceptor and donor is composed of C60 and CuPc, respectively. **Table 2** demonstrates all the incorporated materials along with their thickness for each layer. **Figure 3**a depicts the simulated structure of the novel photo diode.

The in-depth explanation of the working of the CGL based proposed device D_2 is provided now. The CGL is the mixture of two different layers; one is C70 and the other is Pentacene which are opted to generate free electrons and holes, correspondingly. As illustrated in Figure 3b, CGL layers are placed inside the active layer. The thickness of the incorporated C70 and Pentacene is 50 and 20 nm, respectively. After providing external voltage to D_2 in such a pattern where anode is attached to the negative terminal and cathode is attached to the positive terminal of the battery, a barrier potential is generated. Hence, a depletion region is developed. The charge carriers inside the depletion region are bounded with this barrier potential and are not able to move further. Thereby, no current flow is attainable. At the moment, when light encounters the acceptor-donor layer, the immobile electrons-holes pairs will procure some energy and become mobile. Furthermore, large number of electrons from C70 layer will be attracted toward anode. In the same way, Pentacene generates large number of free holes which further reach to the cathode. These mobile charge carriers will be added up with the active layer's charge carriers. As a result, significant large number of dark currents and photocurrent are obtained as 10.2 and 174.5 nA, respectively as shown in Figure 3c. Hence, it is made clear that charge generation layer played vital role for refining the performance of the proposed D_2 structure. Figure 3d depicts the current values at different wavelengths.

5. Heart Rate Detection

Photoplethysmography (PPG) is very popular medical technology to measure heart rate and blood oxygen in real time.[38,39] This device was most widely used device during the 2019 pandemic to measure the health conditions. The working principle follows the mentioned (In Section II) light detection methodology which contains a LED and a photo-diode. A target light beam falls from the LED on the blood tissue, and photo-diode senses it and converts it into an electrical signal. Various researchers have devoted their efforts in designing a highly efficient, motion tolerant, and low noise PPG sensor. Kim et al.[40] proposed an "All in one sensor" by integrating OLED an OPD which can detect heart rate, blood pressure, and heart rate variability. Moreover, Lochner et al.[11] presented all organic optoelectronic sensor to measure the human pulse rate using green and red OLEDs and single flexible OPD. The device exhibits only 1% error in the pulse rate measurement.

Pandey et al.[41] also designed an OLED-OPD flexible sensor in which heart rate is measured with 96% accuracy. Addition to this, the ideas for flexible and wearable devices for pulse oximetry sensor are discussed by Dcosta et al.[42] In this research, the geometry, design, processing technique, encapsulation, etc. are also provided. Furthermore, Jhuma et al.[43] presented a review which is focused on the growth of PPG sensors in terms of their flexibility. Moreover, Simone et al.[44] proposed an organic reflectance PPG array using 16 × 16 OPD pixel. The pixel device exhibits the sensitivity up to 950 nm and low dark current as 10^{-6} mA cm^{-2}. Additionally, Bilgaiyan et al.[45] investigate OPD performance for refining the sensing ability of PPG sensor.

In our work, we have presented a methodology for the detection of heart rate using flexible novel green OLED (D_1) and OPD (D_2) as outlined in **Figure 4**. The utilization of green OLEDs in PPGs is quite prevalent. This light contains high skin absorption coefficient. So, it provides better contrast signal.[47] **Table 3** outlines the few researchers' work for the comparison with the proposed work in terms of OLED color and its wavelength. It can be clearly seen that all the excitation wavelengths are from range of green OLED. The detection methodology is basically based on the emission of wavelength from OLED and detection of wavelengths at OPD. A target light beam of 497 nm emitted from OLED falls on human blood tissues. Some of this light is absorbed by the blood and remaining light is detected by the photo-diode, cor-

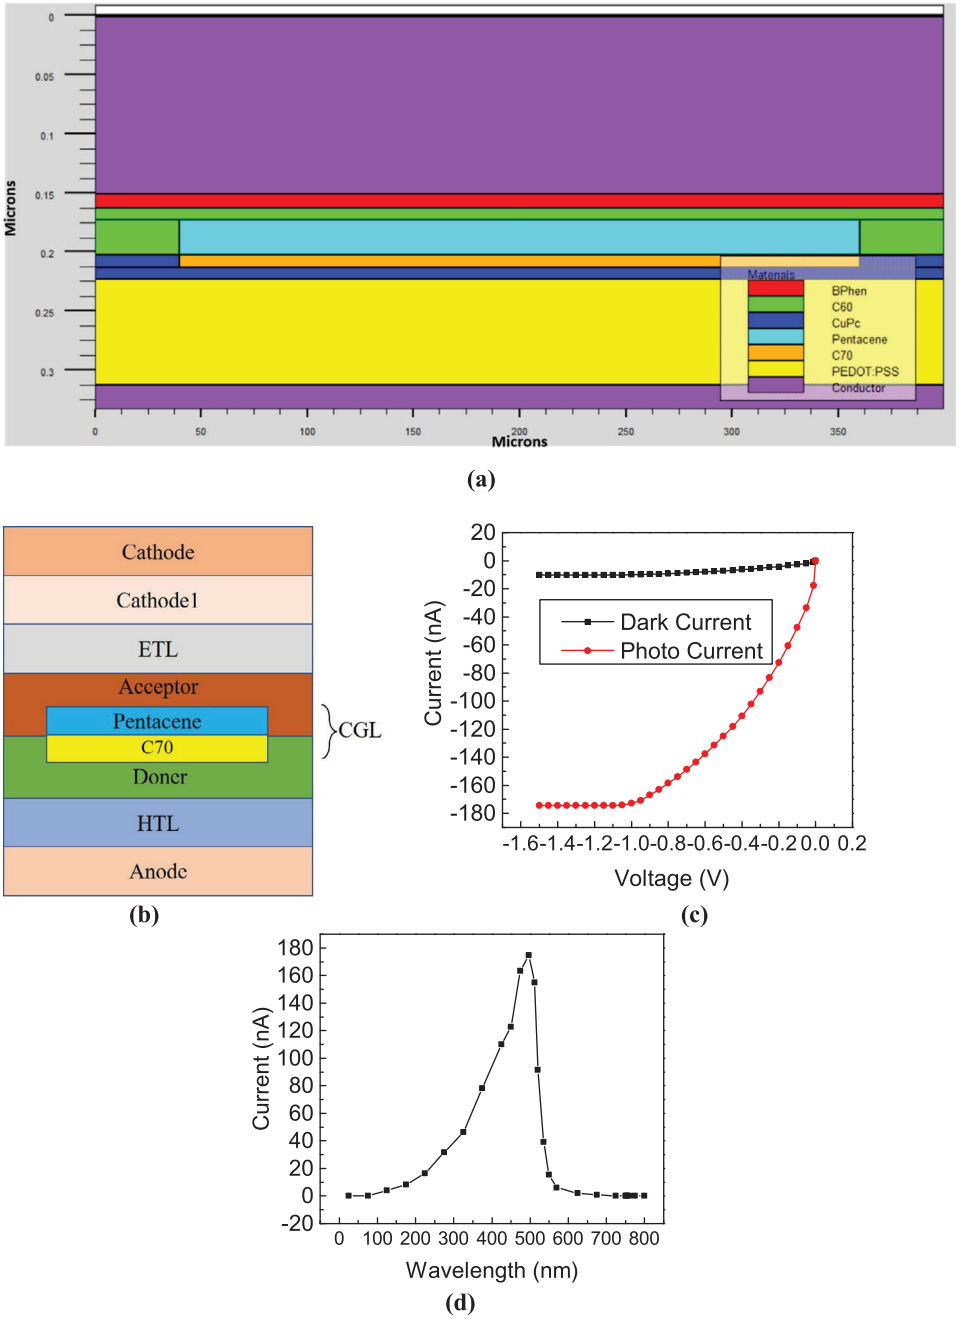

Figure 3. a) Simulated OPD, b) Proposed Design of OPD, c) Dark and Photo Currents and d) Current Values at various Wavelengths.

respondingly a photo current is produced. If the volume of the arterial blood is higher in case of systole (during the heart's contraction phase), it will absorb large amount of light. Hence, low intensity wavelength will be reflected toward the photo-diode. Thereby, less current will be obtained by the photo-diode. On the contrary, in case of diastole (during the heart's relaxation phase) when blood volume is less, blood tissues will absorb less amount of light. So higher intensity wavelength will be detected by the photo-diode which will eventually produce higher output current. Herein, this methodology concludes that less photocurrent results in higher heart-rate and vice-versa as outlined in **Table 4**.

The above discussed methodology calculates the current outputs at different light intensities having the same wavelength of 497 nm. The variation of light intensities is because of the change in blood volume. Herein, it is investigated that the proposed photo diode is capable of producing the different current values at different light intensities by varying the input voltage from 0–5 V using V-OTFT.

Here, ten luminescence values (L_1–L_{10}) at different voltages are taken from the output of the proposed D_1 device as outlined in **Table 5**. As drawn in **Figure 5a**, when the light beams (B_1–B_{10}) having different luminous values (L_1–L_{10}) with the same target

wavelength of 497 nm are sensed by the photo diode, it will produce different values of currents as indicated in **Table 6**. Because, all the light beams contain different intensity and luminescence. Figure 5b shows the light intensities at various light beams. This proposed method can be compared with the real time situations where volume of blood in the blood vessels is varied all the time. Accordingly, OPD produces output currents and the device concludes the heart rate.

6. Other Bio-Medical Applications Based on OLED-OPD Sensor

This section draws some other applications based on the sensing devices using OLED-OPD integration as highlighted in **Table 7**. Various researchers have utilized these flexible combinations using different emission and detection wavelengths for bio-medical diseases. Lochner et al.[11] presented a pulse oximeter sensor by using OLED and photo diode. Herein, the input wavelength is considered as 532 nm which represents the green color light, and detection wavelength is opted as 640 nm which is responsible for the red color light. Moreover, Katchman et al.[9] proposed point-of-care detection of circulating cancer biomarkers. In this research, emission wavelength is chosen as 520 nm (green color), and detection wavelength is chosen as 604 nm (orange color).

Negi et al.[48] worked on an ovarian cancer detection using 330 nm emission wavelength and 440 nm detection wavelength. Furthermore, Lim et al.[16] discussed the methodology for wearable oxygen sensor using OLED-OPD integration. The emission and detection wavelength are opted here as 380 and 497 nm. Additionally, Khan et al.[12] proposed an organic multi-channel optoelectronic sensor. This work is suitable for various health monitoring applications. Herein, red color light is utilized for the emission with the wavelength of 720 nm, and violet color wavelength is used for the detection with 420 nm wavelength.

7. Conclusion

This work introduces a technique for heart rate detection using CGL based ultra-flexible OLED and OPD. A green OLED is opted as a light source which contains the wavelength of 497 nm. To drive the novel OLED, a vertical thin film transistor is utilized which is also flexible and includes less channel length for smooth and efficient performance. Afterward, this paper proposed an organic photo-diode which produces a peak photocurrent and dark current of 10.2 and 174.5 nA, respectively. Herein, the current density and luminescence by the OLED are obtained as 0.92 A and 8 363.6 cd m^{-2}, correspondingly. The additional layer, i.e., CGL used in the both devices makes them highly efficient. The methodology depicts that during the diastole, higher current will be produced by the OPD as blood cell absorbs less green light. On the contrary, the OPD provides lesser current in the case of systole due to less absorption of the green light by presented blood cells in the blood vessels. The discussed method may be further explored in the other sensing bio-medical applications such as cancer detection, PPG sensor, oxygen sensor, hemoglobin sensor etc.

Keywords: Electric Vehicle (EV) Retrofit, Internal Combustion Engine (ICE), Brushless DC Motor, Lithium-ion Battery, GT Suite Simulation, Electric Two-Wheeler (e-TW)

Abstract. This paper presents the performance study of a retrofitted Bajaj DTS Si motorcycle, converted into an electric two-wheeler (e-TW). Initially, this two-wheeler had internal combustion engine (ICE). This paper presents two distinctive simulation models of retrofitted e-TWs, using GT Suite platform. The first model explores the feasibility of upgrading from the ICE vehicle to an e-TW, with a 1.5 kW Hub motor and 48V/28Ah battery. This model projects speed of 52 km/h and a distance over 29km. The second model explores the feasibility of upgrading from the first model to a new e-TW, with a 5 kW BLDC motor and 72V/78Ah battery. This model projects speed of 80.44 km/h and a range over 130.25 km on a single charge of the battery. This paper confers the details of designing Simulink models using the GT Suite platform. It includes theoretical calculations, simulation methodology and analysis of results, highlighting the software's utility in electric vehicle design and optimization.

Introduction

In major Indian cities, 66% of pollution is contributed by internal combustion engine (ICE) driven two-wheelers. One hundred forty-eight million two-wheelers were sold in India during the year 2011-2020. These two-wheelers include motorcycles, scooters, and mopeds. Twenty-one million two-wheelers were sold during 2019 itself. However, the radical increase in air pollution obliges the transition from ICE based vehicles to electric two-wheelers (e-TWs) [1].

In response to the pressing need to combat air pollution and reduce carbon emissions, there is a growing imperative to transition away from internal combustion engine (ICE) vehicles towards electric alternatives. However, the high cost of new EVs often presents a significant barrier to widespread adoption. Retrofitting existing ICE vehicles with electric drivetrains offers a pragmatic and cost-effective solution to accelerate the transition towards clean transportation.

Furthermore, discarding vehicles running on ICE results in misuse of resources and faster environmental degradation. Retrofitting, therefore, is the best option for replacement of already existing ICE vehicles.

Through meticulous research and engineering innovation, this paper aims to redefine the electric motorbike landscape. This offers consumers an electric alternative that not only meets but surpasses their expectations, but also paves the way for a future where EVs set the standard for performance and environmental responsibility.

The Indian driving cycle (IDC) was developed and formulated in 1985 after thorough road testing and research conducted by the Automotive Research Association of India (ARAI) [2].

This paper explores the feasibility and benefits of retrofitting the body of an ICE two-wheeler with an electric motor bike, by comparing the ICE model with the retrofitted 1.5 kW hub motor

and the retrofitted 5 kW BLDC motor [3]. This paper utilized the IDC to replicate the typical operation of the retrofitted bike on Indian terrain.

Description of research methodology

This work focuses on enhancement of speed and range of a conventional ICE vehicle by its retro-fitment to an e-TW. Considering the basic retrofitted BAJAJ DTS SI motorcycle, having speed of 52 km/h and distance range of 29 km, the research aims to surpass the capabilities of ICE vehicles. This paper strives to match and eventually exceed the performance standards of traditional vehicles while prioritizing efficiency and sustainability [4].

Equipment of Retrofitted EV.

The basic block diagram representing a retrofitted EV is shown in Figure 1. The retrofitted EV consists of following main equipment: (1) Throttle, (2) Battery Controller, (3) Motor Controller, (4) Motor, (5) Wheels.

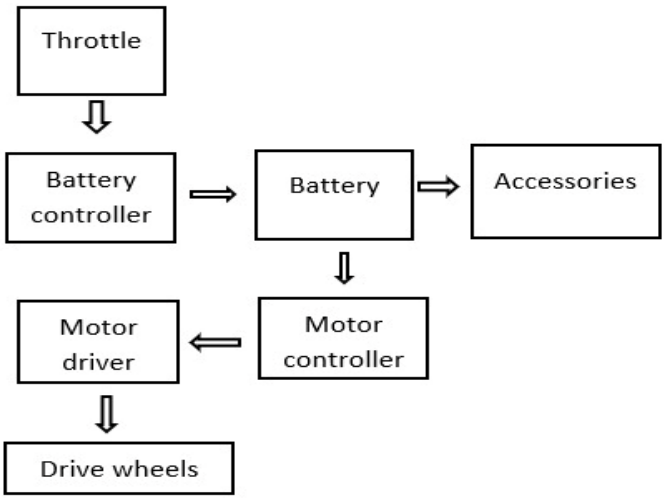

Figure 1. Schematic diagram of a two-wheeler

In Figure 1, the rider's twist of the throttle translates into a control signal. This signal is sent to the battery controller, which manages the flow of electricity from the battery. Based on the throttle input, the battery controller regulates voltage and current output to the motor controller.

The motor controller then translates this signal into precise power delivery for the motor driver. Finally, the motor driver controls the high-power current that spins the motor, propelling the motorbike forward through the wheels.

Contribution of the Work.

This research work contributes following significant aspects to the EV field:

1. Usage of vehicle dynamics is incorporated in order to perform the computation of motor power and battery capacity.
2. Mathematical modelling of battery pack is presented in accordance with the motor capacity and range of the vehicle.
3. The GT Suite v2023 is utilized for designing the simulation models in order to verify feasibility of analytical models.
4. For validating the obtained results from analytical models and simulation models, the assimilation of IDC is performed for highlighting the significance of the work in real time scenario with respect to Indian road conditions.

Analytical Modelling.

In order to compute motor power and battery capacity using vehicle dynamics, four forces acting on the vehicle are needed to be considered. These forces are: (1) Rolling resistance force (F_{rr}), (2) Aerodynamic drag force (F_{ad}), (3) Gradient force (F_g) and (4) Acceleration force (F_a) [5]. Various specifications of the vehicle used in the analytical modelling is presented in Table 1.

Table 1. Vehicle Specifications for analytical modelling

Parameter	**Value**
Total Mass, m	$220\ kg$
Gear Ratio, G_r	6
Transmission efficiency, η	0.97
Rolling coefficient, F_r	0.013
Drag coefficient, C_d	0.9
Vehicle Frontal area, A_f	$0.75\ m^2$
Mass density of air, ρ	$1.225\ kg/m^3$
Wheel radius, r	$0.216\ m$
Velocity, v	$78\ km/h$
Distance Covered, s	$100\ km$
Gradient Angle, θ	0°

The rolling resistance force is computed using Equation (1). The velocity, V, in SI units, is $21.67\ m/s$. The aerodynamic drag force is given by Equation (2). By considering zero initial velocity (u) and computing acceleration, a, force due to acceleration, F_a, is calculated using Equation (3)-(4). The Gradient force is also calculated by using Equation (5).

$$F_{rr} = m \times g \times F_r \times \cos\theta \quad (1)$$

$$F_{ad} = 0.5 \times \rho \times A_f \times C_d \times V \quad (2)$$

$$a = \frac{V^2 - u^2}{2 \times s} \quad (3)$$

$$F_a = m \times a \quad (4)$$

$$F_g = m \times g \times \sin\theta \quad (5)$$

The calculation of total traction force is performed using Equation (6). The wheel torque, T_w, is calculated using Equation (7). Equation (8) gives the wheel speed, N_w. Thus, motor torque (T_m), motor speed (N_m) and motor power (P_m) are computed using Equation (9), (10), (11) respectively.

$$F = F_{rr} + F_{ad} + F_a + F_g \quad (6)$$

$$T_w = F \times r \quad (7)$$

$$N_w = \frac{V}{2 \times \pi \times \frac{r}{60}} \quad (8)$$

$$T_m = \frac{T_w}{G_r \times \eta} \quad (9)$$

$$N_m = G_r \times N_w \times \eta \quad (10)$$

$$P_m = \frac{2 \times \pi \times N_m \times T_m}{60} \quad (11)$$

For battery pack design calculations, assuming the controller efficiency of 0.95, total energy of battery, E_{b_t}, is computed using Equation (12)-(13).

$$t = s/v \quad (12)$$

$$E_{b_t} = \frac{P_m \times t}{controller\ efficiency} \quad (13)$$

The available energy from battery is thus calculated using Equation (14). {The Depth of Discharge (DOD) value is assumed to be 0.9}. In this work, the battery pack of voltage rating 72 V is used, with nominal voltage of each cell being 3.65 V. So, the number of cells in series are found to be 20. Hence, battery capacity, C_b, is calculated using Equation (15). Assuming cell capacity of 13 Ah, the number of cells in parallel are found to be 6. Thus, all the computation results are presented in Table 2.

$$E_b = E_{b_t} \times DOD \quad (14)$$

$$C_b = \frac{E_b}{72} \quad (15)$$

Table 2. Analytical modelling computation results

Parameter	Value
F_{rr}	28.06 N
F_{ad}	194.15N
a	0.00235 m/s^2
F_a	0.5165 N
F_g	0 N
F	222.72 N
T_w	48.11 Nm
N_w	958.02 rpm
T_m	8.27 Nm
N_m	5575.70 rpm
P_m	4.83kW
t	1.28 h
E_{b_t}	6.18 kWh
E_b	5.56kWh
C_b	77.26 Ah

Design of proposed simulation models

The proposed simulation model of retrofitted e-TW is designed in GT Suite and the model is represented in Figure 2. This simulation model consists of all major components interconnected together to form an EV bike model. A brief discussion of all the necessary components of the designed model is presented in this section.

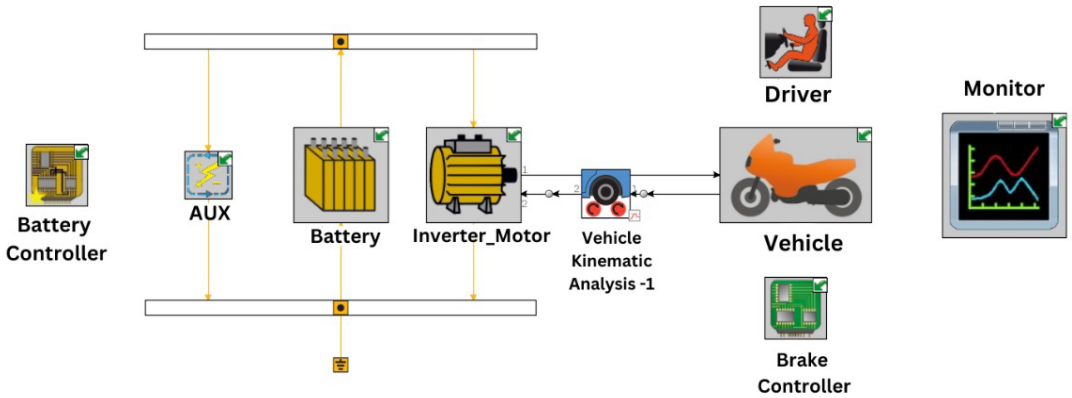

Figure 2: Designed Simulation model using GT-Suite

Battery and Battery Controller.

This model has used a $72V/78Ah$ Nickel Manganese Cobalt (NMC) Lithium-ion battery. They offer a good balance of energy density, power density, and thermal stability, making them popular choices for EV applications [6-7].

The control system in an EV bike manages various aspects of battery operation, including charging, discharging, thermal management, and state-of-charge (SoC) estimation. It also includes Battery Management System (BMS) components responsible for monitoring individual cell voltages, temperatures, and currents to ensure safe and efficient battery operation [8-9]. The BMS composes of specification like minimum discharge voltage limit of 27.5V, maximum charging voltage limit of 40.15V, and maximum C rate during discharge of 3.

Motor and Motor Controller.

The electric motor is the primary propulsion system of an EV bike, responsible for converting electrical energy from the battery into mechanical energy to drive the wheels. A 5 kW Brushless DC (BLDC) motor is used in this project due to its high efficiency, compact size, and low maintenance requirements [10-11].

The motor inverter, also known as the motor controller or power electronic unit, serves as the interface between the battery pack and the electric motor. It controls the speed, torque, and direction of the motor by regulating the frequency, amplitude, and phase of the electrical signals supplied to the motor windings.

Vehicle and Driver.

The GT-Suite modelling offers aerodynamic simulation capabilities to simulate airflow around the vehicle body. Thus, by optimizing aerodynamic shapes and reducing drag improves the energy efficiency of the vehicle. To achieve this, it allows to specify mass of the vehicle and driver, frontal area of the bike, gear ratio, tire radius, and drag coefficient values. The specifications mentioned in Table 1 are utilized in simulation modelling using GT Suite.

The modelling of driver is carried out using driver block. This block has inputs such as throttle, braking, steering, and manoeuvring through predefined control algorithms or user-defined functions. The designed model is tested using IDC in order to represent different driving conditions throughout the test duration.

Results and discussion

This section presents various tests performed to assess the performance of the designed model and their corresponding results are discussed. The GT-Suite platform has the facility of dashboard monitors, as shown in Figure 3.

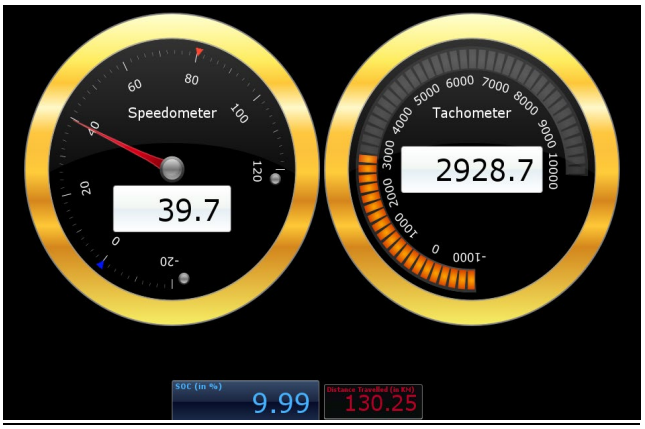

Figure 3. GT Suite dashboard monitor

The dashboard is pivotal in providing essential information to the driver and enriching the overall driving experience. In the designed simulation model, a user-friendly and informative dashboard interface is crafted. It showcases the state of charge (SoC) level, tachometer and speedometer readings, drive cycle, and distance travelled by the e-TW. The different conditions under which the designed model is tested are presented in four different case studies.

Case 1: Drive Cycle Test

The drive cycle test in GT-Suite serves as a valuable tool for engineers and researchers to analyse, optimize, and validate vehicle performance in a wide range of driving conditions. Thus, ultimately leading to the development of more efficient, cleaner, and safer vehicles.

The Standard Indian Drive Cycle is represented in Figure 4. This graph represents the standard driving pattern of an e-TW on Indian terrain.

The vehicle speed plot for drive cycle test is presented in Figure 5. The simulation results revealed valuable insights into the performance of the bike under the IDC conditions. It is observed that the electric bike demonstrated efficient energy utilization and satisfactory range coverage under the stop-and-go traffic conditions characteristic of the IDC. Additionally, the analysis of motor efficiency and battery SoC variations provided useful information for optimizing the electric bike's powertrain configuration and energy management strategies. In this test, it has been observed that the maximum speed attained is 42 km/h just as the standard IDC condition and the simulation repeats every 110 s. Comparison of Figure 4 and Figure 5 shows that the retrofitted bike followed the standard IDC during this test.

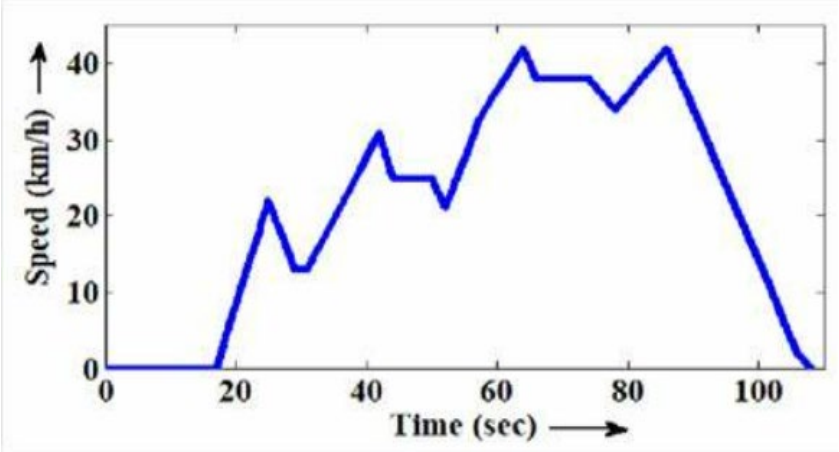

Figure 4. Standard Indian Drive Cycle

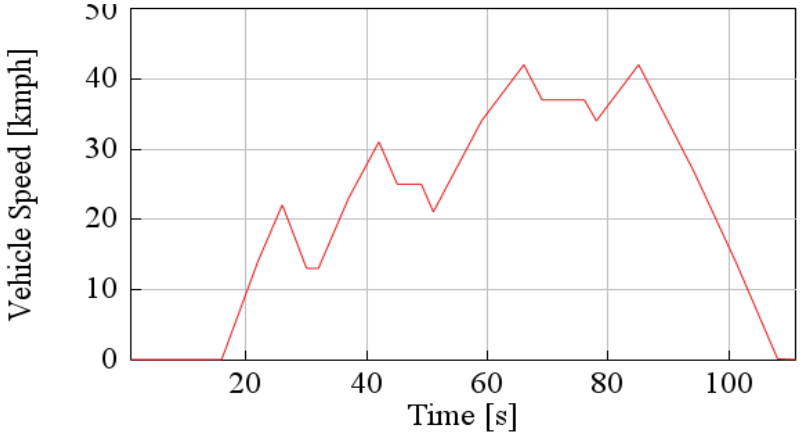

Figure 5. India drives cycle (IDC) actual response representation

Case 2: Maximum Speed Test

This test is conducted to assess the vehicle's performance capabilities and limitations under high-speed operating conditions. It also allows for the determination of the vehicle's maximum speed. The vehicle speed plot for maximum speed test is presented in Figure 6. The simulation results from the maximum speed test revealed the maximum achievable speed of the bike is $80.44\ kmph$. Additionally, the analysis of battery current ($88.17\ A$) and power consumption ($5.72\ kW$) provided insights into the thermal constraints and potential overheating risks associated with prolonged high-speed operation.

The motor speed plot, obtained using Tachometer, is presented in Figure 7. Further, the simulation results from the motor maximum speed case revealed valuable insights into the brake torque ($6586\ Nm$), efficiency (97%), and motor losses ($0.42\ kW$). The upper limit of the motor is found to be $5927\ rpm$. In addition, a plot depicting the maximum motor torque was acquired. The maximum wheel torque plot, presented in Figure 8, illustrates the results of the maximum wheel torque test, revealing a peak torque of 55.79 Nm achievable by the wheel. Obtaining the wheel torque facilitates the calculation of motor torque using the gear ratio and motor efficiency.

Torque reaches its maximum when speed is zero, as the vehicle is stationary and requires significant torque to overcome rolling resistance. Initially, tractive effort demands substantial torque. However, as speed increases, torque decreases to 45 Nm, as most power is directed towards reaching maximum speed, thereby diminishing torque.

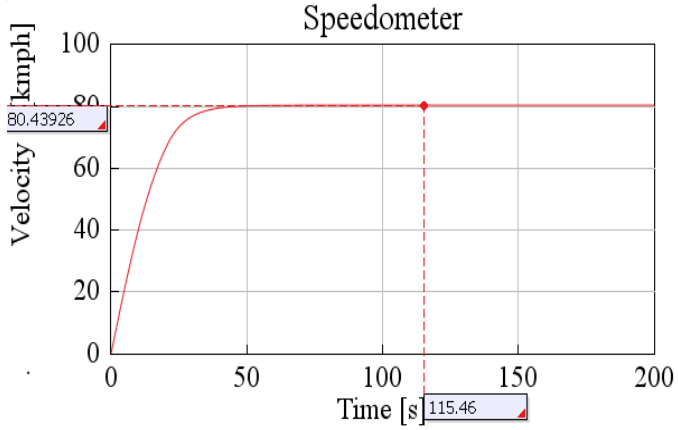

Figure 6. Speedometer result indicating peak speed attained by vehicle

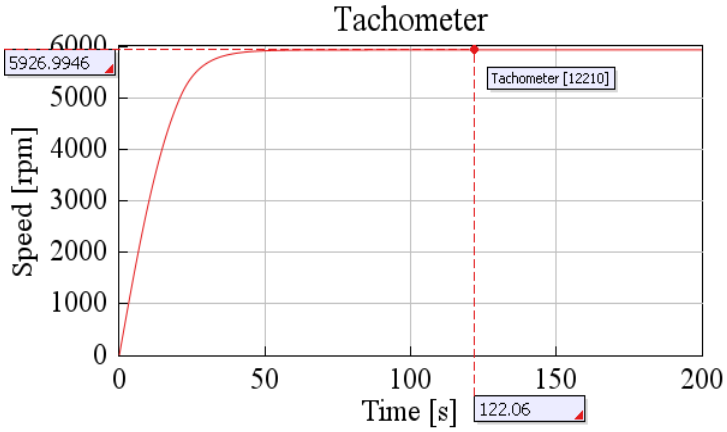

Figure 7. Tachometer result indicating peak speed attained by motor

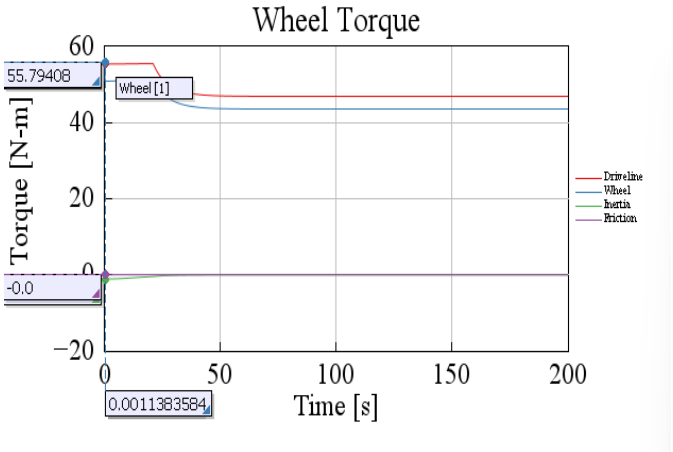

Figure 8. Analysis results indicating torque attained by the wheel

Case 3: Acceleration Test

The acceleration test serves to optimize powertrain performance, evaluate vehicle acceleration, and validate simulation models for the development of EV.

The acceleration plot is presented in Figure 9. The simulation results from the acceleration test revealed the acceleration behaviour of the bike ($8.56\ m/s^2$). The vehicle's acceleration profile, time to reach specific speed ($10\ s\ at\ 40.4\ km/h$), and wheel torque output characteristics ($54.1\ Nm$) during acceleration manoeuvres are observed. Additionally, the analysis of energy consumption provided insights into the powertrain efficiency (97 %) and energy utilization ($3.36\ kW$) during acceleration.

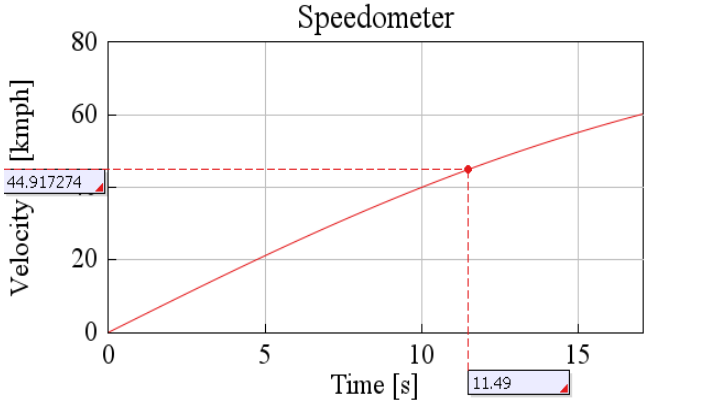

Figure 9. Speedometer result indicating the vehicle acceleration

Case 4: Vehicle's Range Test

The vehicle range test conducted plays a crucial role in evaluating, optimizing, and validating the range of EVs highlighting its overall performance. It also allows to acquire the knowledge of the total distance covered on a single charge of battery.

The displacement plot with respect to time is presented in Figure 10. The simulation results from the vehicle's range test provided valuable insights into the range capabilities and energy consumption patterns of the bike. The vehicle's range is found to be $130.25\ km$, with observed maximum current consumed ($32.5A$), battery terminal power ($2.05\ kW$), battery SOC ($100\% - 10\%$), and maximum driving speed ($42.1\ kmph$).

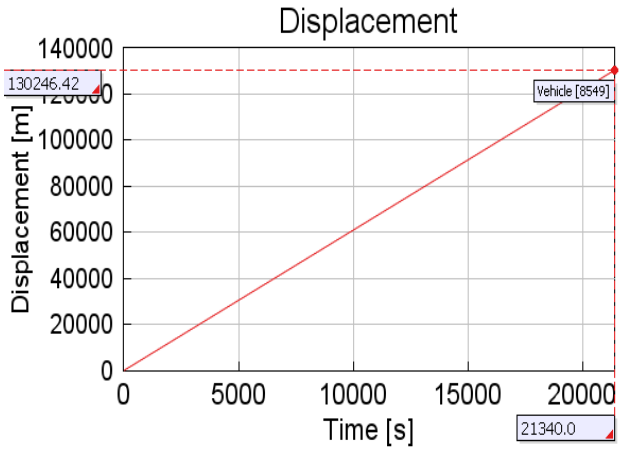

Figure 10. Analysis results depicting vehicle's range

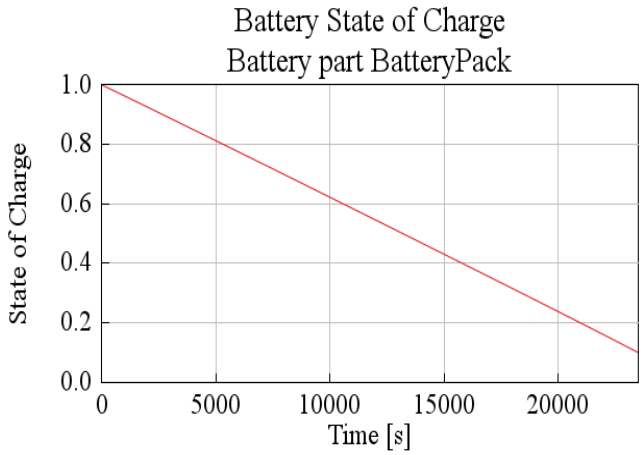

Figure 11. Battery State of Charge (SoC) during vehicle's range test

The battery's SoC behaviour is shown in Figure 11 during the IDC Vehicle Range test. During this test, battery discharges from 100 % to 10 %, indicating a depth of discharge of 90 %. A decline in battery SoC is observed during different driving phases, such as acceleration, cruising, and idling.

Comparative analysis of vehicle performance

This section is dedicated to the discussion regarding the comparative analysis results, obtained from analytical modelling and designed simulation modelling. The compilation of results is presented in Table 3.

Table 3: Comparative analysis results ($\boldsymbol{p.u.}$ means per unit)

Characteristic of e-TW	Analytical modelling	Simulation modelling	Error
Wheel Torque	48.11Nm	55.79 Nm	$-0.14\ p.u.$
Motor Torque	8.27Nm	9.59 Nm	$-0.16\ p.u.$
Maximum Speed	78km/h	80.44 km/h	$-0.03\ p.u.$
Maximum Range	100 km	130.25 km	$-0.30\ p.u.$
Wheel Speed	958.02 rpm	982.78 rpm	$-0.02\ p.u.$
Motor Speed	5575.7 rpm	5927.00 rpm	$-0.06\ p.u.$

It has been observed that the simulation model yields slightly higher values compared to the analytical model. Considering the small error (< -0.3) across all comparative analysis results, it can be demonstrated that the GT Suite platform is highly accurate.

Materials Research Proceedings 49 (2025) 186-196 https://doi.org/10.21741/9781644903438-19

Further, comparison of performance of ICE two-wheeler is performed with two types of retrofitted vehicles. The comparative results are presented in Table 4. It depicts the various specifications of the ICE vehicle, specifications of retrofitted model with 1.5 kW hub motor, and specifications of retrofitted model with 5 kW BLDC motor (both designed by GT suite).

Table 4. Comparison of ICE vehicle with two retrofitted e-TW

Attribute	**ICE vehicle**	**Retrofitted model (1. 5 kW Hub motor)**	**Retrofitted model (5 kW BLDC motor)**
Battery Capacity	$12V, 5Ah$	$48V, 28Ah$	$72V, 76Ah$
Maximum Velocity	85 km/h	52 km/h	$80.44km/h$
Range	60 km/l	29 km	130.25 km
Maximum Torque	7.85 Nm	22.5 Nm	9.59 Nm
Maximum Speed	5000 rpm	636.6 rpm	5927.00 rpm
Running Cost	High	Low	Low
Emissions	High	None	None
Rank	**3**	**2**	**1**

In Table 4, the ranks are awarded to the vehicles in accordance to their performances. It is observed that retrofitted model with 5 kW BLDC motor, has the maximum vehicle range with one charge of the battery and it is also capable to attain the maximum speed of 80.44 $kmph$, which is in agreement with the ICE vehicle. Also, this retrofitted model has increased torque capabilities. Hence, rank 1 is awarded to this retrofitted model. Similarly, the comparison shows that the retrofitted model with low power rating of 1.5 kW Hub motor secures Rank 2, since it also saves emissions and provide 22.5 Nm of maximum torque. However, it does not attain commendable displacement range and maximum speed. Therefore, it lacks in the vehicle's overall performance, as compared to retrofitted model with 5 kW BLDC motor. Further, ICE vehicle secures rank 3 because it offers high emissions, which are less environmentally friendly. Thus, retrofitting of ICE vehicles to EVs with suitable components are proved to be the better solution for sustainable, more favourable and less cost-intensive transport systems.

Conclusion

This study effectively evaluates motor power, battery capacity, and vehicle performance metrics using analytical method as well as simulation modelling. The analysis and simulation methodology highlight the potential of GT Suite in EV design and optimization. The analysis results showcase a significant improvement in speed and range with the upgraded motor and battery configuration. Ultimately, this study contributes following valuable insights into the practicality and benefits of transitioning from ICE vehicles to electric alternatives, offering a promising pathway for sustainable transportation solutions:

- The analytical modelling is successfully carried out using practical values of vehicle dynamics. This helps in recognizing the understanding of motor power and battery capacity computation for knowledge enhancement in real time scenario of the road condition.
- Battery pack calculation is successfully carried out for understanding of the series or parallel combination of cells by implementation of mathematical modelling. These values of combination of battery cells (series and/or parallel) are utilized in simulation models.
- The simulation model of retrofitted e-TW is designed having 5 kW BLDC motor using highly accurate GT Suite platform. This platform helped in analysing four significant case studies, namely, drive cycle test (using IDC), maximum speed test, vehicle range test and acceleration test.

- Using comparative analysis results, it is found that the simulated model shows negligible errors in motor speed, wheel speed, maximum speed and maximum range. However, there are removable errors in wheel torque and motor torque, if few parameters are altered during analytical modelling.

ABSTRACT

This study investigates a coprecipitation method for the production of zinc oxide nanoparticles (ZnO NPs) using anthocyanin (ATH) extract derived from red cabbage (RC) that acts as a reducing, capping and stabilising agent. The efficacy of these NPs in the photocatalytic degradation of crystal violet (CV) dye is assessed thoroughly considering all the relevant influencing parameters such as pH levels, catalytic dosage, and dye concentration, among others. The structural, morphological, surface charge and presence of different functional groups of the synthesized NPs were then analysed using XRD, SEM-EDX, BET, and FTIR. The average particle size of the synthesized ZnO NPs and ZnATH-(O) NPs was 31.12 nm and 27.91 nm, respectively. The BET analysis determined that the surface area of ZnO NPs was 15.685 m^2/ g, and that of ZnATH-(O) NPs was 25.187 m^2/ g. In contrast to ZnO NPs, ZnATH-(O) NPs exhibit efficient photocatalytic degradation of CV dye. This is due to their improved stability, reduced size, increased surface area and optimized structure. The influence of various parameters like initial dye concentration, catalyst dosage, pH and ionic strength was also assessed under 90 min visible light irradiation. It was observed that ZnATH-(O) NPs show maximum photocatalytic degradation of CV dye in 90 min of visible light irradiation with a degradation efficiency of 96.12 %. This green synthesis method mitigates the environmental consequences associated with conventional chemical synthesis and utilizes the plentiful and renewable resources present in RC, thereby offering a sustainable alternative to a deteriorating environment.

1. Introduction

The rapid industrialization and urbanization of recent decades have led to a significant increase in the release of synthetic dyes into aquatic environments [1–3]. Among these, crystal violet (CV) dye, which is frequently used in printing, textiles, and other sectors, presents a significant risk because of its high toxicity, persistence, and possible carcinogenicity [4–6]. Conventional techniques used to treat water contaminated with dye, such as coagulation [7], flocculation and adsorption frequently lack effectiveness, cost-efficiency, and environmental sustainability [8]. Therefore, the quest for inventive and environmentally friendly methods to reduce the detrimental impacts of these contaminants has become a crucial area of attention in environmental research.

Photocatalysis, capable of harnessing light to activate semiconductor materials that can degrade organic pollutants, emerges as a promising solution [9,10]. Zinc oxide nanoparticles (ZnO NPs) have gathered considerable interest in this field because of their distinctive optical and electrical characteristics, such as a broad energy gap (3.37 eV), a high exciton binding energy (60 meV), and a robust photocatalytic activity [5,11]. These properties enable ZnO NPs to generate reactive oxygen species (ROS) such as hydroxyl radicals ($OH^{\cdot}$) and superoxide (O_2^{-}) anions under UV irradiation, which can effectively degrade complex organic pollutants, including dye molecules, into less degraded entities like CO_3^{2-}, NO_3^{2-} and H_2O [12]. Moreover, ZnO NPs are biocompatible, easy to synthesise, and non-toxic, making them an ecologically benign choice for water treatment and other applications [13,14].

Conventional methods adopted to synthesize ZnO NPs frequently employ toxic compounds like sodium hydroxide, zinc nitrate, and other organic solvents. Additionally, these approaches need energy-intensive procedures such as sol–gel, hydrothermal, and chemical vapour deposition (CVD) techniques [15]. These technologies not only give rise to environmental and safety concerns but also provide obstacles in achieving constant NPs size and morphology, which are crucial for achieving optimal photocatalytic performance. As an outcome of these challenges, the field of green synthesis has gained prominence,

emphasising the use of natural, renewable resources and environmentally benign processes [16]. Among various natural sources, plant extracts rich in bioactive compounds, such as anthocyanins (ATH), have demonstrated substantial potential in the biosynthesis of NPs [5]. ATH found abundantly in red cabbage, perform dual functions as reducing and capping agents, enhancing the NPs' stability and functionality through their antioxidant properties [17]. The mechanism involves the reduction of zinc ions (Zn^{2+}) to zinc oxide (ZnO) facilitated by the phytochemicals present in the extract, leading to the formation of NPs with controlled size and shape.

Red cabbage (*Brassica oleracea* var. *capitata f. rubra*) (RC) is highly beneficial for this purpose because it contains a significant amount of ATH, is inexpensive and is easily accessible [18]. ATH extract is derived from RC, which is rich in micronutrients and some phytochemicals, such as Vitamin C and K, β-carotene, minerals, fibres, total polyphenols and glucosinolates. ATHs are the glycosylated forms of anthocyanidins (aglycones) [19]. The key functional groups present in ATH extract include hydroxyl (–OH) and methoxy ($–OCH_3$) groups attached to the phenolic rings, which significantly contribute to their antioxidant properties. Additionally, ATH contains glycosidic bonds where sugars like glucose or galactose are linked to the aglycones, enhancing their solubility and stability in aqueous environments. The presence of carbonyl (C=O) groups in the core structure further contributes to the electron structure [20]. ATH extracted from RC possesses potent reducing characteristics and the capacity to chelate metal ions, rendering them exceptionally efficient in the development of NPs. In addition, the utilization of RC extract aligns well with the principles of green chemistry, as it eliminates the requirement for dangerous chemicals and diminishes the total ecological impact of the synthesis process. ATH extracted from RC is highly versatile and effective, providing them with the possible potential for synthesizing ZnO NPs with improved photocatalytic characteristics.

This research presents a groundbreaking approach to synthesize ZnO NPs using ATH extract derived from RC for photocatalytic degradation of CV dye. While previous studies predominantly utilized thermal routes for synthesising ZnO NPs from ATH, this study introduces a novel method: coprecipitation using NaOH as the co-precipitating agent. Furthermore, the study aims to compare the performance of these bio-derived ZnO NPs (ZnATH-(O) NPs) with those synthesized via traditional methods [21]. The methodology involves optimizing the synthesis parameters such as pH, catalytic dosage, and concentration of the dye solution to achieve desirable catalytic properties for maximum degradation. The photocatalytic activity was assessed by monitoring the degradation of CV dye under visible light irradiation, measuring the change in absorbance over reaction time to determine the degradation rate constants. The significance of this work lies is two-fold: it advances the fundamental understanding of green nanotechnology and proposes practical solutions for environmental remediation. Through comparative analysis, it highlights the advantages of these ZnATH-(O) NPs, paving the way for future innovations in the fields of photocatalysis and environmental science.

2. Materials and methods

2.1. Materials

Red cabbage (*Brassica oleracea* var. *capitata*) (RC) was procured from the local market in Delhi, India, for ATH extraction. Hydrochloric acid (HCl), Anhydrous Ethanol (EtOH) and sodium hydroxide (NaOH) were acquired from Thermofischer chemicals. Zinc acetate dihydrate [$Zn(CH_3COO)_2{\cdot}2H_2O$] was obtained from S.D Fine Chemical Limited. All the experiments were conducted using distilled water.

2.2. Synthesis

2.2.1. Extraction of anthocyanin (ATH) from RC

ATH was extracted from RC (*Brassica oleracea* var. *capitata*) by employing a similar methodology as reported in the literature [22–24], using pure EtOH as a solvent with modifications as shown in Fig. 1. The procedure involved cutting and washing of fresh RC using distilled water. Then, excess moisture was removed using a muslin cloth. 100 g of RC were pulverised and mixed with 150 ml of pure EtOH solvent in an Erlenmeyer flask for 36 h at 4 °C to extract phytochemicals. Subsequently, the mixture was filtered, and the resulting filtrate was centrifugated at 4000 rpm for 10 min for further purification. Afterwards, the pH of the mixture was first maintained at 2, using HCl. Then, the mixture was kept in the dark at 4 °C for 36 h. Afterwards, the pH of the solution was adjusted to 7 by adding NaOH, and it was further kept at a temperature of 4 °C for future use.

2.2.2. Synthesis of zinc oxide nanoparticles (ZnO NPs) without ATH extract

A cost-effective co-precipitation method was employed to synthesize ZnO NPs from the precursor $Zn(CH_3COO)_2{\cdot}2H_2O$ and NaOH, as shown in Fig. 2. 1 g of $Zn(CH_3COO)_2{\cdot}2H_2O$ was added to a beaker containing 50 ml of distilled water during the synthesis process, and it was constantly agitated for 15 min at room temperature. Additionally, the pH of the mixture was kept at 10 by gradually adding 1 M NaOH solution, and the resulting mixture was then stirred at 450 rpm for 4 h in an ambient condition. Finally, the white-coloured precipitate formed was filtered and rinsed with 1:1 EtOH solvent and distilled water. Then, the product was dried at 60 °C in an oven for 24 h. Afterwards, the dried product was crushed into a fine powder using a mortar and pestle and then calcined for two hours at 450 °C in a muffle furnace.

2.2.3. Phyto-fabrication of ZnO NPs with ATH extract (ZnATH-(O) NPs)

The phyto-fabrication of ZnO NPs was carried out using ATH extract, depicted in Fig. 3. Firstly, 1 g of $Zn(CH_3COO)_2{\cdot}2H_2O$ was dissolved in 50 ml distilled water and stirred for 15 min at room temperature. Afterwards, 5 ml of extracted ATH solution was added and stirred for the next 30 min. At this point, the colour of the solution turned orange. Additionally, a 1 M NaOH solution was added to the solution in a dropwise manner to maintain its pH at 10, and the resulting solution was then agitated further for 4 h. The resulting white precipitate was then filtered and rinsed with distilled water and EtOH solvent in a 1:1 ratio. The isolated product underwent a 24 h drying process at 60 °C, followed by a 2 h calcination in a muffle furnace at 450 °C. The probable mechanism for the synthesis of ZnO NPs using ATH extract is shown in Fig. 4.

2.3. Characterization techniques

A powder X-ray diffractometer (XRD) using CuKα radiation (Rigaku Ultima IV model) was employed for the crystallographic analysis of the synthesized NPs. The XRD patterns were recorded within a 2θ range of 10 °C–80 °C, with a step size of 0.02° and a scanning rate of 1.0 s/step, at 298 K. A Perkin Elmer BX-II Fourier-transform infrared spectrometer equipped with a KBr disk was utilized to investigate the functional groups present in the prepared NPs within the range of 500–4000 cm^{-1}. The produced NPs were further analyzed using SEM-EDX analysis with Zeiss EVO-18 instrument. The nitrogen adsorption–desorption approach was employed to achieve the average dispersion of pore sizes and specific surface area (S_{BET}) of NPs at 77 K, which was examined by the Quanta chromium Nova-1000 equipment. The Zeta potential of the synthesized NPs was determined by the Malvern Zeta-Sizer Nano series meter (Version 7.13). The photocatalytic degradation of CV dye was assessed using a WinCary 300 UV–vis spectrophotometer at the wavelength of maximum absorption (λ_{max}) of 580 nm.

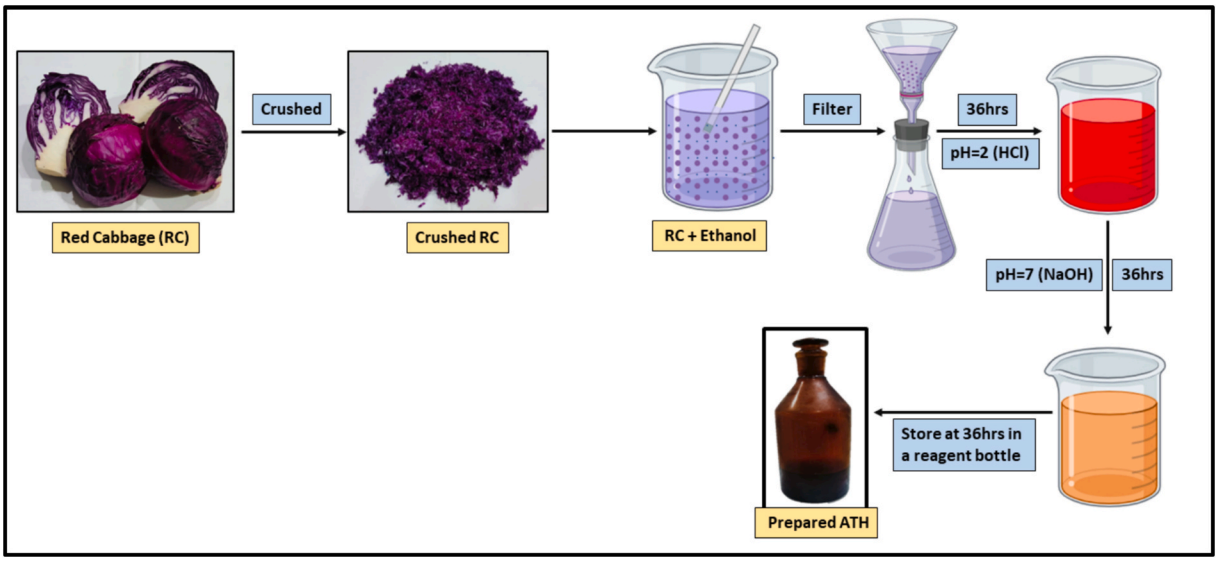

Fig. 1. Extraction of ATH from RC (*Brassica oleracea var. capitata*).

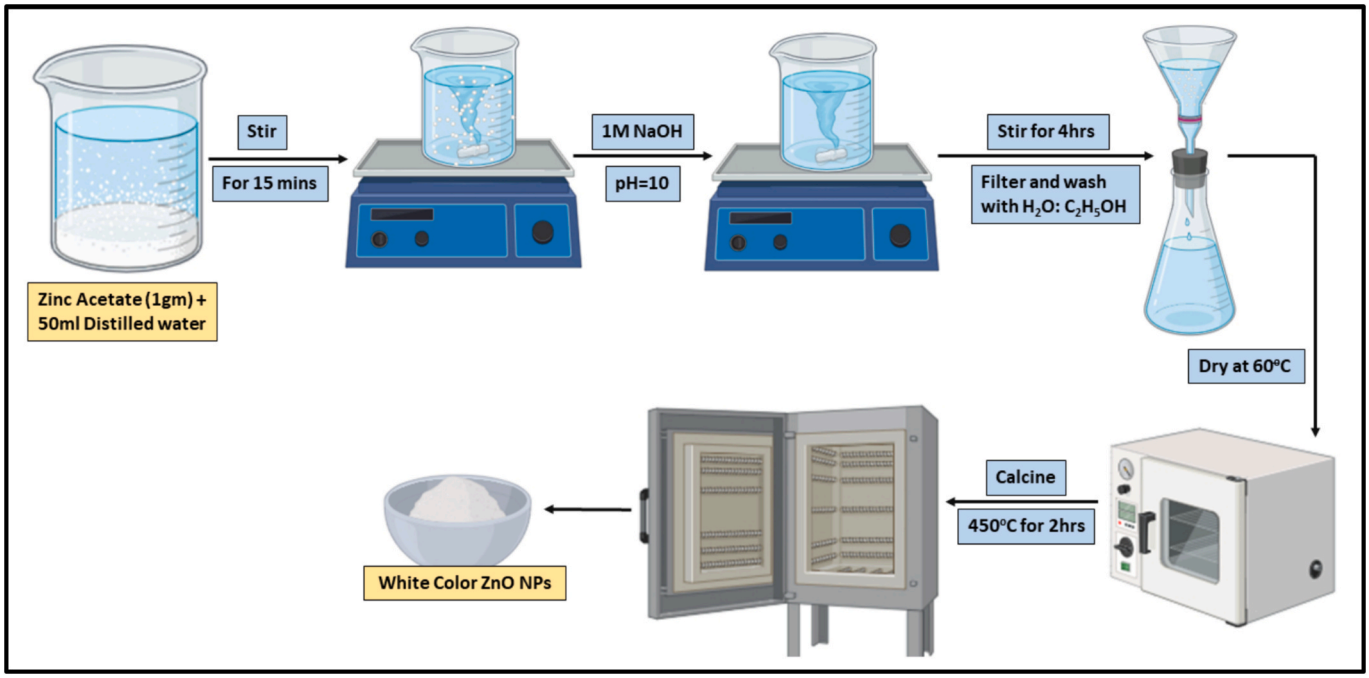

Fig. 2. Schematic representation of the synthesis of ZnO NPs.

2.4. Evaluation of photocatalytic activity

The degrading capacity of NPs towards azo dyes was evaluated for CV dye. Firstly, a predetermined quantity of CV dye was used to generate a stock solution with a 100 mg/L concentration. Standard solutions of varying concentrations (10–50 mg/L) were prepared by diluting 100 mg/L stock solution of CV dye. A cylindrical batch reactor with an annular shape was employed to carry out the photocatalysis of CV dye. The reactor was illuminated with a 125 W high-pressure xenon bulb. The synthesized NPs were used to photodegrade CV dye solution in the presence of a visible light source to assess its photocatalytic activity. Before irradiation, a 30 min adsorption of CV dye was performed using NPs synthesized via both methodologies (ZnO NPs and ZnATH-(O) NPs), was performed to establish adsorption–desorption equilibrium between the pollutant (CV dye) and photocatalyst. Subsequently, the CV dye solution was subjected to a light source exposure in the presence of ZnATH-(O) NPs while being continuously stirred for 90 min at 450 rpm. At a fixed time interval of 10 min, 3 mL samples were taken and then centrifuged for 5 min at 4000 rpm. The degradation percentage was determined by applying Eq. (1).

$$\boldsymbol{Percentagedegradation}(\%) = \left(\frac{\boldsymbol{C_i} - \boldsymbol{C}}{\boldsymbol{C_i}}\right) \times 100 \quad (1)$$

The variable $\boldsymbol{C}$ represents the CV dye solution concentration in the reaction mixture containing photocatalyst after time t. On the other hand, $\boldsymbol{C_i}$ represents the initial concentration of CV without any catalyst. After analysis, the photocatalytic degradation of CV dye was found to follow pseudo-first-order kinetics, as shown in Eq. (2).

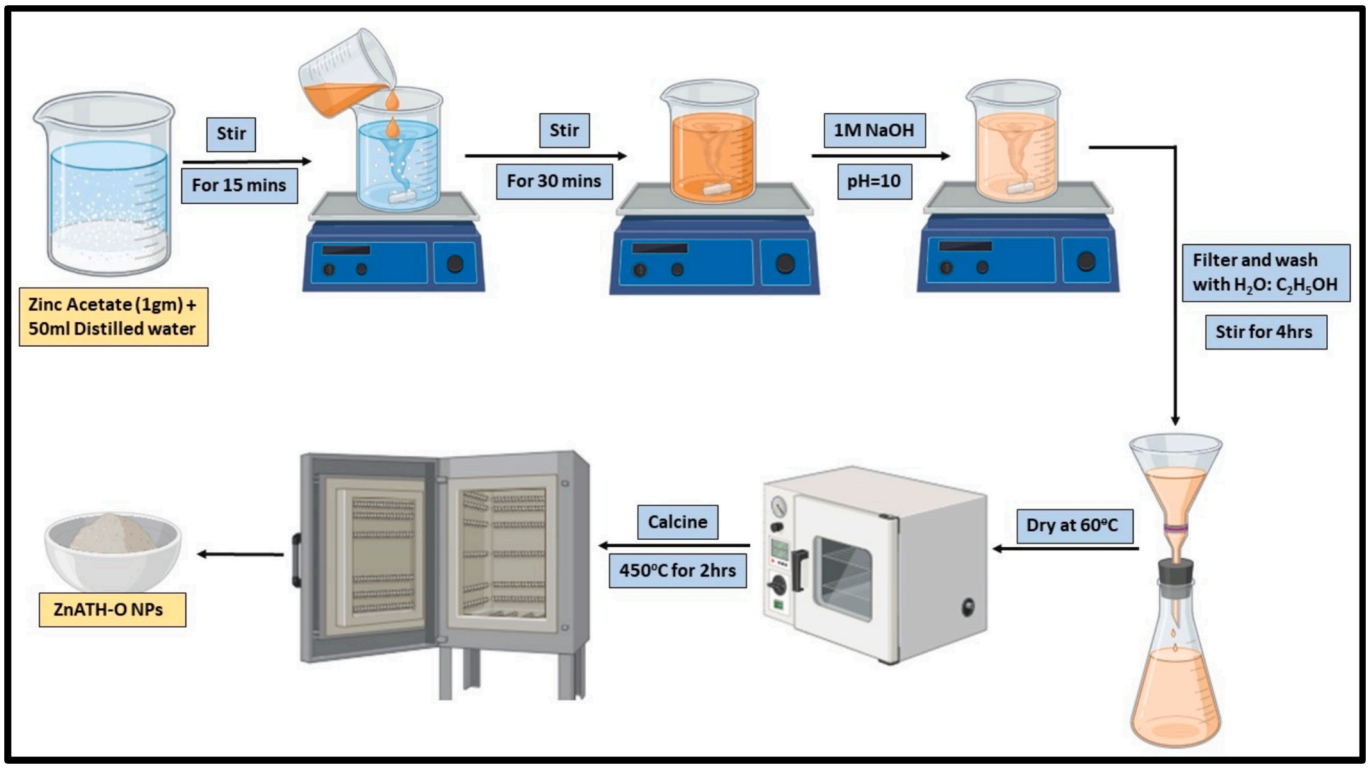

Fig. 3. Systematic methodology for the preparation of ZnATH-(O) NPs.

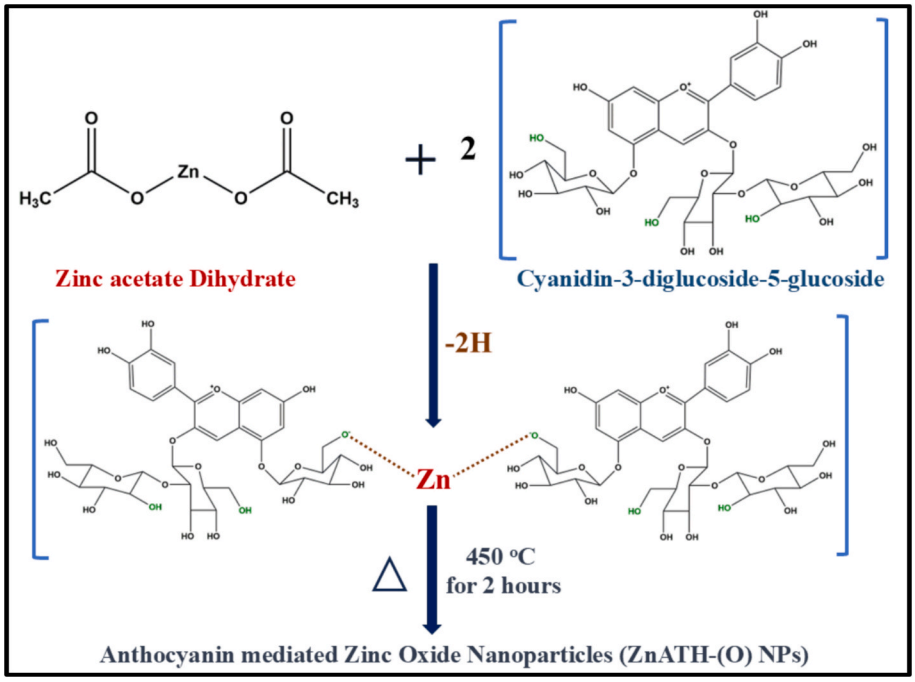

Fig. 4. Probable mechanism of green synthesis of ZnO NPs using ATH leaf extract. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

$$ln\left(\frac{C}{C_i}\right) = Kt \quad (2)$$

Here, C represents the final concentration of CV dye at time t, C_i denotes the initial dye concentration at t = 0, and K represents the rate constant.

The Beer-Lambert law (Eq. (3)) was employed to create a calibration plot that correlates absorbance with concentration to ascertain the unidentified concentration of the dye.

$$A = \varepsilon Cl \quad (3)$$

The reaction kinetics of the process were quantified in terms of photocatalytic degradation as mentioned in Eq. (4).

$$\ln\left(\frac{C}{C_i}\right) = ln\left(\frac{A_2}{A_1}\right) = kt \quad (4)$$

where A_1 and A_2 denotes the initial and final absorbance of CV dye. The impact of various influencing variables such as reaction time, dye concentration, dose of catalyst, and pH of dye solution on catalytic degradation of CV dye using ZnATH-(O) NPs were also measured. In addition, the influence of the ionic strength of NaCl on the degradation efficiency, degradation of CV dye in real water samples and the recyclability of ZnATH-(O) NPs as photocatalyst were also examined.

3. Result and discussion

3.1. Characterization of ZnO NPs and ZnATH-(O) NPs

The comparative XRD patterns of ZnO NPs and ZnATH-(O) NPs are shown in Fig. 5 a. The ZnATH-(O) NPs were found to imitate the hexagonal wurtzite ZnO structure described in the literature [25,26]. The ZnO NPs exhibit distinct and strong diffraction peaks at 2θ = 31.72°, 34.36°, and 36.2°, which correspond to the (1 0 0), (0 0 2), and (1 0 1) crystallographic planes. The d-spacing values for these planes are 2.81 Å, 2.60 Å, and 2.47 Å, respectively. As, these values are consistent with those reported in the literature and match the standard JCPDS file (JCPDS No. 01-080-0074) for ZnO.

The average size of the crystallites was determined using Debye Scherrer's equation:

$$D = \frac{k^*\lambda}{\beta^* cos\theta} \quad (5)$$

where D represents the diameter of the crystallite, k is the Scherrer constant, λ represents the wavelength of the incident X-ray (0.15418 nm), β refers to the full width at half maximum (FWHM) of peaks, and θ represents the diffraction angle. The mean crystallite size of ZnO NPs was determined to be 31.12 nm, using Debye Scherrer's equation.

The XRD pattern of ZnATH-(O) NPs has an identical structure with that of ZnO NPs and shows a minor shift in peak positions, which can be attributed to the incorporation of ATH extract into the Zn-(O) matrix, confirming the dual function of ATH extract as reducing and capping agent. The mean crystallite size of ZnATH-(O) NPs was determined to be 27.91 nm, which corroborates the successful reduction in size of NPs synthesized using ATH extract as compared to that of ZnO NPs synthesized via the conventional co-precipitation method without ATH extract [27]. However, despite this incorporation, the overall crystal planes (1 0 0), (0 0 2), and (1 0 1) remain dominant, indicating that the hexagonal wurtzite structure of ZnO is still retained, as these values were compared with the JCPDS file (JCPDS No. 01–076-0704).

The synthesized NPs were further analysed using FTIR spectroscopy, which was recorded in the range of 500–4000 cm^{-1}, as shown in Fig. 5 b. The ZnO NPs display a wide and strong IR band at 3488 cm^{-1}, corresponding to the stretching vibrations of O–H bonds caused by adsorbed water molecules on the surface [5]. In addition, the FTIR spectra of ZnO NPs display a distinctive peak at 648 cm^{-1}, which signifies the stretching vibration of metal–oxygen bonds (M−O) in ZnO NPs.

However, in the case of ZnATH-(O) NPs, additional peaks were observed at 1445 cm^{-1}, 1144 cm^{-1}, and 1053 cm^{-1}. These peaks are attributed to the stretching of C=O bonds, the presence of –COO groups, and the bending vibrations of C–H bonds in the organic moieties found in ATH extract, respectively. The characteristic peaks at 2987 cm^{-1} and 2899 cm^{-1} are due to C–H and CH_2 stretching vibration. Additionally, a broad and strong band appeared at 3467 cm^{-1}, corresponding to the stretching vibration of O–H bonds [28]. Furthermore, the decrease in the wavenumber of the M−O linkage band from 648 cm^{-1} to 604 cm^{-1} is due to the addition of ATH extract, which acts as a reducing, capping and stabilising agent, as reported in the literature [29,30]. The incorporation of ATH extract onto the ZnO matrix causes the shift in M−O vibration bands to lower wavelength, thereby decreasing the bond strength and further leading to the formation of new bonds of ZnO with the phytochemicals present in ATH extract.

The SEM analysis was carried out to examine the surface morphology and to calculate the average particle size of ZnO NPs and ZnATH-(O) NPs using Image J software, as shown in Fig. 6 a and c. The SEM image of ZnO NPs reveals a morphology resembling plates, and the particles' average size was approximately 29.54 nm [5]. Meanwhile, ZnATH-(O) NPs display a less agglomerated uneven shape, with an average particle size of approximately 21.43 nm [31]. The shift from a plate-like morphology to an irregular shape could be attributed to the introduction of ATH extract, which functions as a capping and reducing agent. This inference is supported by the observed decrease in the size of NPs, as mentioned in the XRD analysis (Table 1). EDX analysis was conducted to analyse the elemental composition of ZnO NPs and ZnATH-(O) NPs, as depicted in Figs. 6b and d. The EDX analysis confirmed that all the elements in the lattice are uniformly distributed.

The BET approach was utilised to estimate the specific surface area (S_{BET}), pore volume, and average pore size of the produced NPs (Table 2). Fig. 7 a shows the nitrogen adsorption–desorption isotherm of the produced ZnATH-(O) NPs. The S_{BET} values for ZnO NPs and ZnATH-(O) NPs were determined to be 15.685 m^2/g and 25.187 m^2/g, respectively. The pore volume of the synthesized ZnO NPs and ZnATH-(O) NPs was determined using the BJH (Barret-Joyner-Halenda) method. The pore volume was found to be 0.159 cc/g for ZnO NPs and 0.224 cc/g for

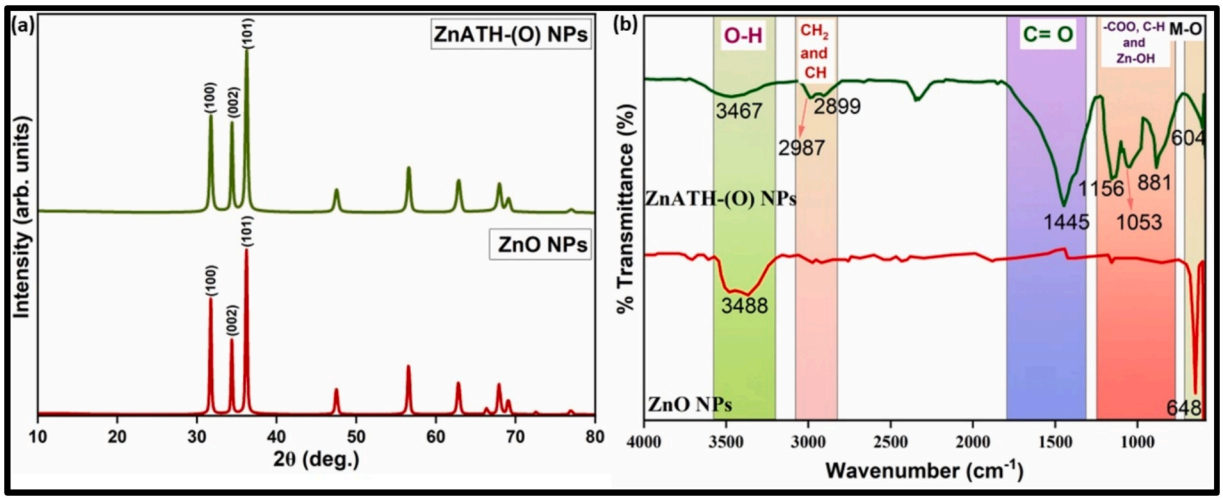

Fig. 5. Comparative (a) XRD pattern and (b) FTIR spectrum of ZnO NPs and ZnATH-(O) NPs.

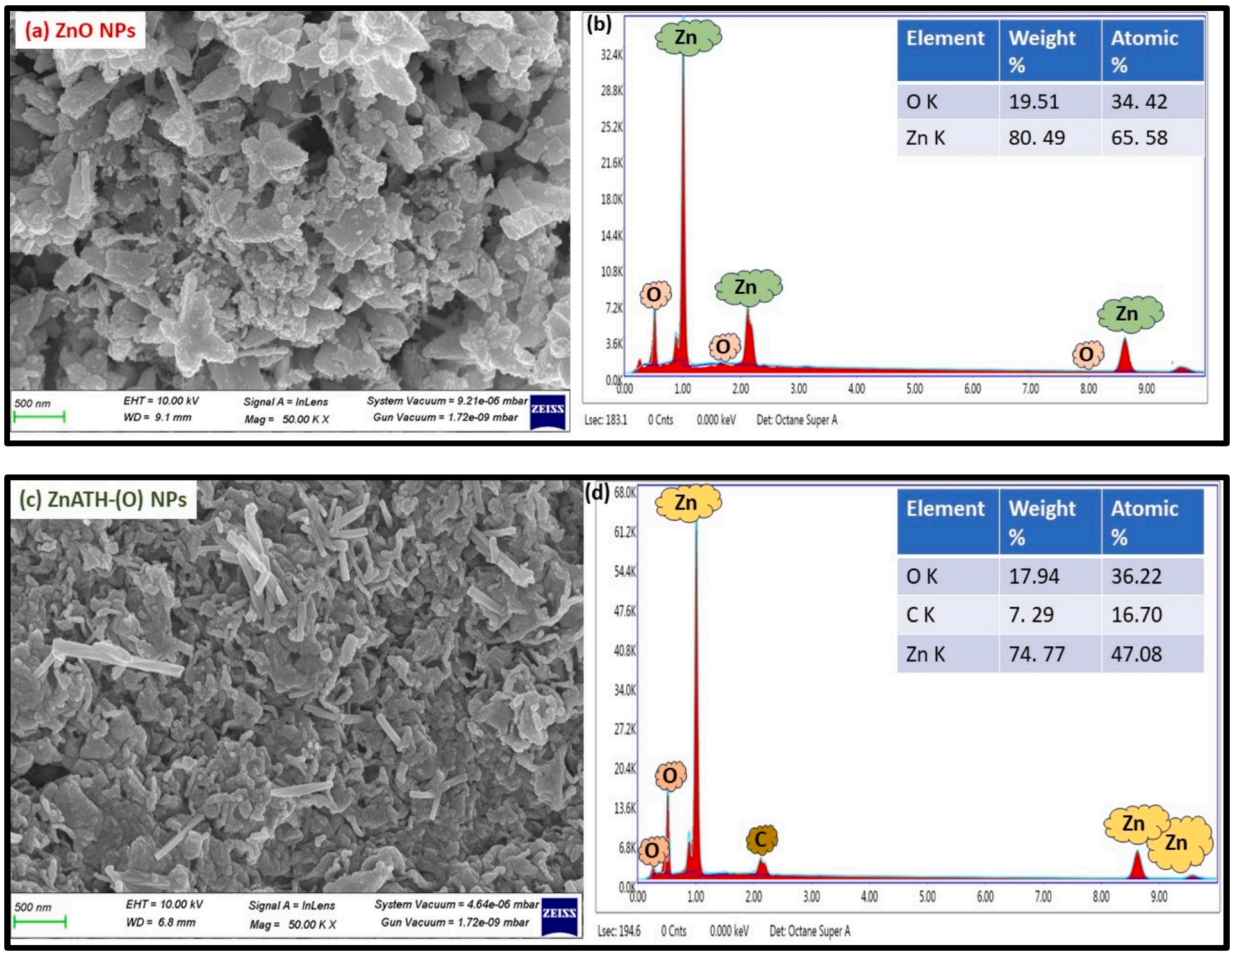

Fig. 6. SEM-EDX of (a),(b) ZnO NPs and (c),(d) ZnATH-(O) NPs.

Table 1
The average crystallite and particle size of the synthesized ZnO and ZnATH-(O) NPs calculated from XRD, SEM and BET analysis.

Nanoparticles (NPs)	XRD	SEM	BET
ZnO NPs	31.12 nm	29.54 nm	29.82 nm
ZnATH-(O) NPs	27.91 nm	21.43 nm	20.15 nm

Table 2
The Specific surface area (S_{BET}), Pore Volume, and Pore Diameter of the synthesized ZnO and ZnATH-(O) NPs calculated from BET analysis.

Nanoparticles (NPs)	Specific Surface Area (S_{BET})	Pore volume	Pore Diameter
ZnO NPs	15.685 m^2/g	0.159 cc/g	2.982 nm/g
ZnATH-(O) NPs	25.187 m^2/g	0.224 cc/g	2.015 nm/g

ZnATH-(O) NPs, as shown in Fig. 7 b. The mean pore diameter was determined to be 2.982 nm/g for ZnO NPs and 2.015 nm/g for ZnATH-(O) NPs. The data above validates that the ZnATH-(O) NPs exhibit a greater surface area and pore volume than the ZnO NPs. The IUPAC classification suggests that Type IV isotherm with an H3 hysteresis loop is followed by ZnATH- (O) NPs. The pores have a diameter of more than 2 nm, indicating that the produced NPs are non-rigid aggregates of plate-like to irregular morphology and are macroporous in nature [32,33]. The results obtained from BET analysis are consistent with SEM data, which demonstrates plate-like to irregular morphology and reduced pore size after successful incorporation of ATH extract over the ZnO matrix. Consequently, the presence of macro-porosity and the expansion of the surface area contribute to the favourable photocatalytic degradation properties of ZnATH-(O) NPs.

Zeta potential analysis was used to measure the surface charge of the produced NPs. In the present work, the surface charge was found to be −40.9 mV, suggesting that the surface of ZnATH-(O) NPs has a higher negative charge than that of ZnO NPs, having −69.07 mV. The higher negative zeta potential indicates the presence of negatively charged ions or functional groups on the surface of ZnATH-(O) NPs. These charged entities generate an electrical repulsion between the NPs, which hinders their tendency to agglomerate together or form larger groups. A higher negative zeta potential value corresponds to increased repulsion and enhanced stability of the ZnATH-(O) NPs in the solution, confirming the role of ATH as a stabilising agent.

3.2. Photocatalytic degradation of CV dye

The photocatalytic experiments were conducted to assess the efficacy of synthesized ZnO NPs and ZnATH-(O) NPs as catalysts in degrading CV dye molecules from wastewater. The photocatalytic degradation investigations were conducted using 100 mL aqueous solutions of CV, with a concentration of 20 mg/ L and 0.1 g of synthesised ZnO NPs and ZnATH-(O) NPs under visible light irradiation for 90 min. Hence, it was found that ZnO NPs as a catalyst show 81 % photodegradation of CV dye, while on the other hand, ZnATH-(O) NPs show 96 % photocatalytic degradation of CV dye, as shown in Fig. 8 a and 8b. Therefore, further analysis of other catalytic degradation parameters was carried out using ZnATH-(O) NPs as a highly efficient photocatalyst. The comparative plot of degradation efficiency of ZnO NPs and ZnATH-(O) NPs is shown in

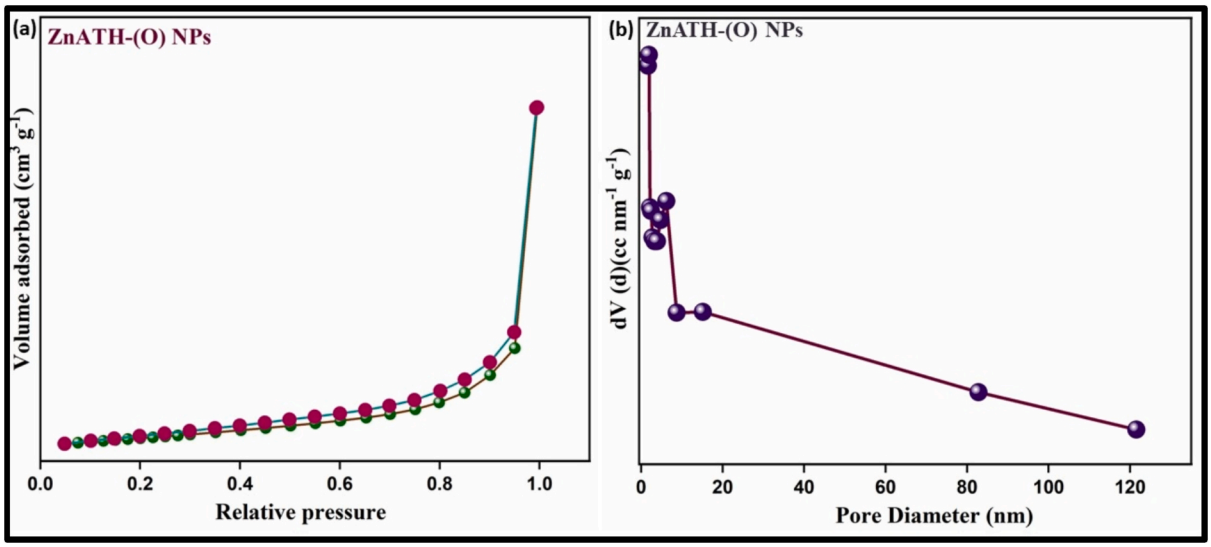

Fig. 7. (a) N_2 adsorption–desorption isotherm and (b) pore size distribution plot of ZnATH-(O) NPs.

Fig. 8 c.

3.2.1. Influence of reaction time

The study investigated the relationship between reaction time and the percentage of CV degraded over a period of 90 min using a 100 mL aqueous solution of CV with a concentration of 20 mg/L and a catalyst (ZnATH-(O) NPs) amount of 0.1 g. Fig. 8 c shows the plot of degradation efficiency versus reaction time, confirming that the degradation efficiency of CV dye increases with an increase in reaction time. The degradation efficacy increased by 62.84 % and 96.12 % in the first 30 and 90 min, respectively. The ZnATH-(O) NPs reach equilibrium after 90 min, as no substantial increase is observed after 96.12 %. The increase in degradation efficacy is attributed to the electrostatic attraction and intermolecular hydrogen bonding between CV molecules and the available active sites on the ZnATH-(O) NPs surface [5]. However, as time increases further, the quantity of available sites reduces, resulting in a slight decrease in the degradation efficiency of ZnATH-(O) NPs after 60 min. It was found that the photocatalytic degradation of CV dye molecules follows pseudo-first-order kinetics. The R^2 value was calculated to be 0.991, which signifies that the experimental results suited well with pseudo-first- order kinetic model. The rate constant was calculated to be $-0.03778\ min^{-1}$. The plot of $ln\left(\frac{C}{C_i}\right) vst$ is shown in Fig. 8 d.

3.2.2. Influence of dye concentration

The initial concentration of CV dye was varied from 10 to 50 mg/L with an increment of 10 mg/L (Fig. 9 a). The efficiency of photocatalytic degradation of CV declined progressively from 97.59 %, 97.31 %, 94.17 %, 91.48 %, and 88.58 % at concentrations of 10–50 mg/L, respectively. Hence, the efficacy of ZnATH-(O) NPs in photocatalytic degradation of CV dye was higher at lower dye concentrations and remained satisfactory up to 20 mg/L. At lower concentrations, there is more degradation of CV molecules on the surface of the ZnATH- (O) NPs than at higher concentrations. However, the amount of OH and O_2^- radicals may not be enough to degrade larger concentrations of CV dye [34]. Additional intermediates may be produced, leading to competition with the OH generated by photo-induced holes. Therefore, based on the above parameters, the highest amount of CV dye that can be degraded through a photodegradation mechanism using 0.1 g of ZnATH-(O) NPs in 90 min is determined to be 20 mg/L.

3.2.3. Influence of catalyst dosage

The study further focused on evaluating the effectiveness of photodegradation of CV dye using varying amounts of catalyst. The studies were performed using 100 ml of 20 mg/L standard solutions of CV dye with stirring at 450 rpm and irradiation using a 125 W xenon lamp. The catalyst doses were varied from 0.05 g to 0.15 g. Fig. 9 b clearly demonstrates a significant improvement in the photodegradation efficiency of CV dye from 76.74 % to 98.13 % using ZnATH-(O) NPs as photocatalyst. As the amount of catalyst increases, the active sites on the catalyst surface also increase, leading to an increase in holes and hydroxyl radical generation [35].

3.2.4. Influence of initial pH

pH is an important influencing factor in photocatalytic studies since it significantly degrades different dyes and organic contaminants. Moreover, it substantially impacts the implementation of effective wastewater treatment methods. It was observed that a photodegradation efficiency of <90 % was achieved when the pH value was 3, as indicated by data in Fig. 10 a. However, when the pH value of the dye solution was increased from 3 to 7, the photodegradation efficiency increased from 90.52 % to 98.80 %, respectively. This is due to the electrostatic interaction between the negatively charged NPs and the positively charged CV (pKa = 5.31) molecules. The results indicate that there is an increase in the concentration of hydroxyl (OH) radicals under neutral pH conditions, which leads to an increase in the photodegradation of CV dye by ZnATH-(O) NPs. However, the degradation efficiency drops from 98.80 % to 86.56 % as the pH further rises from 7 to 9. This can be attributed to the deprotonation of surface hydroxyl groups resulting in weaker electrostatic interaction between the catalyst surface and CV molecules, decreasing the effectiveness of the negative charge on the NPs' surface [36].

3.2.4.1. Point of zero charge (pH_{pzc}). The point of zero charge (pH_{pzc}) was investigated to determine the surface charge of the ZnATH-(O) NPs using the salt addition process. In the current study, 20 mL of 0.1 M NaCl solutions with initial pH (pH_i) values adjusted to 3, 5, 7, and 9 were mixed with 0.02 g of catalyst. The solutions were then allowed to settle at room temperature for 24 h. After agitating the suspensions, the final pH (pH_f) value was recorded, and ΔpH was calculated using the Eq. (6).

$$\Delta pH = pH_f - pH_i \tag{6}$$

The plot of ΔpH *vs* pH_i is displayed in Fig. 10 b. ZnATH-(O) NPs were found to have a pH_{pzc} value of 7.40, implying that at pH < 7.40, their

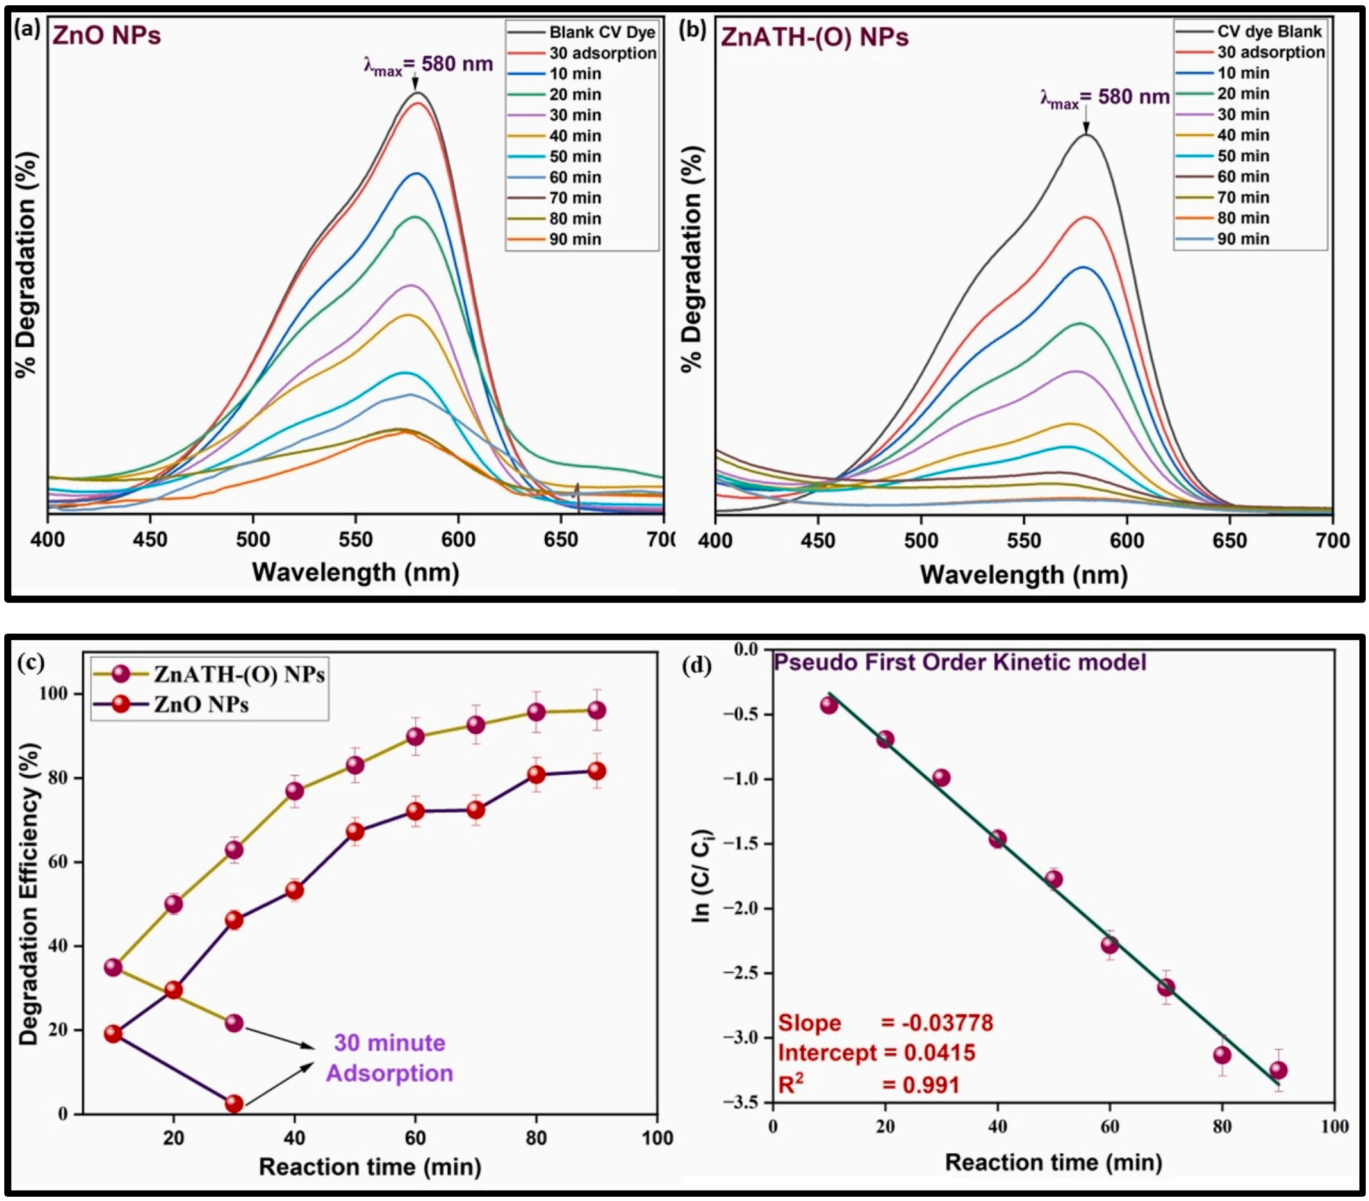

Fig. 8. (a) Degradation efficiency of ZnO NPs, (b) ZnATH-(O) NPs, (c) comparative plot of reaction time on the degradation efficiency of ZnO NPs and ZnATH-(O) NPs, and (d) Pseudo-first-order kinetic model.

surface is negatively charged. Consequently, this promotes electrostatic interaction between the cationic CV molecules and eases their degradation onto the ZnATH-(O) NPs surface. On the other hand, at pH values higher than 7.40, the positively charged catalyst surface electrostatically repels the CV cations, thereby decreasing the degradation efficiency [37]. This result is consistent with the data obtained by studying the effect of pH on the photocatalytic degradation of CV dye. It was observed that the degradation efficiency decreases on increasing the pH of the solution from 7 to 9.

3.2.5. *Influence of ionic strength*

Photocatalytic degradation of CV dye has shown that the nature and concentration of the electrolyte ionic species (such as NaCl and KCl) significantly impact the quantity of dye degradation. Inorganic salts and ionic species are commonly employed as levelling and dye-promoting agents in printing and dyeing procedures. So, it is important to examine the impact of ionic strength on the photodegradation of CV dye molecules, as shown in Fig. 11 a. It was found that the increase in ionic strength promoted the degradation of CV dye due to a combination of Na^+ with photoelectrons generated from the surface during irradiation [38].

This leads to the enhanced accessibility of H^+ for further reaction, as mentioned in Eq. (7). As the concentration of Na^+ increases from 0.00 to 0.005 M, the formation of $OH^{\cdot}$ radicals will be faster, resulting in enhanced efficacy of ZnATH-(O) NPs in degrading CV from 97.6 % to 99.8 %.

$$ZnATH-(O)NPs + h\nu \rightarrow ZnATH-(O)(h^+ + e^-) \quad (7)$$

$$Na^+ + e^- \rightarrow Na \quad (8)$$

$$h^+ + H_2O \rightarrow OH^{\bullet} + H^+ \quad (9)$$

$$h^+ + OH^- \rightarrow OH^{\bullet} \quad (10)$$

3.2.6. *Photocatalytic degradation of CV dye in real water samples*

To assess the applicability of the synthesized phytofabricated ZnO NPs, we have examined their ability to degrade CV dye from tap water,

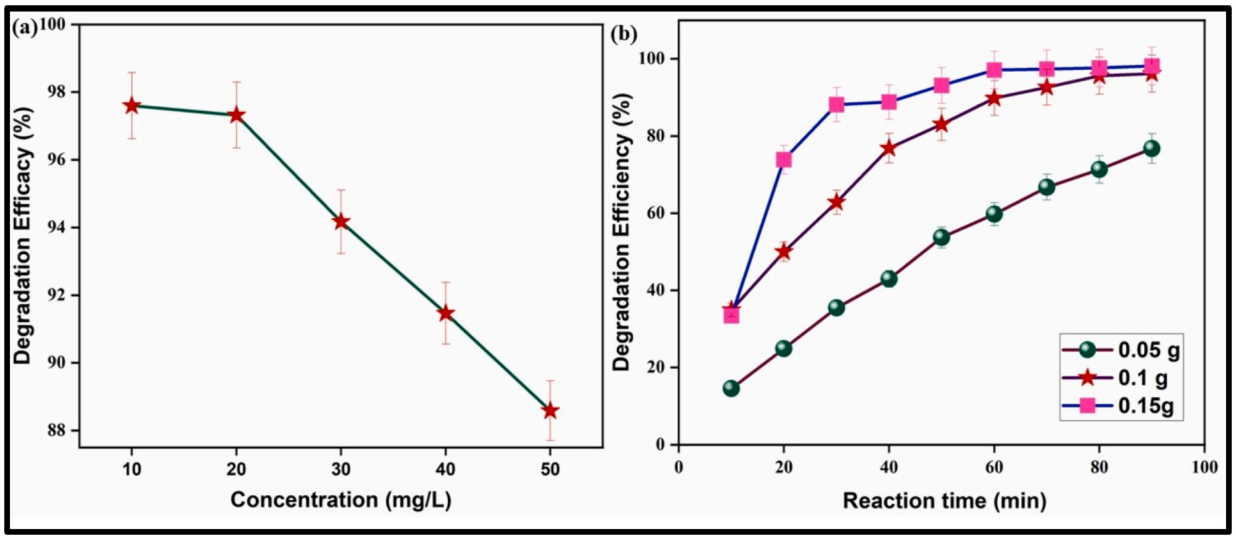

Fig. 9. (a) Impact of initial dye concentration on the degradation efficiency, and (b) impact of catalyst dosage on the degradation efficiency.

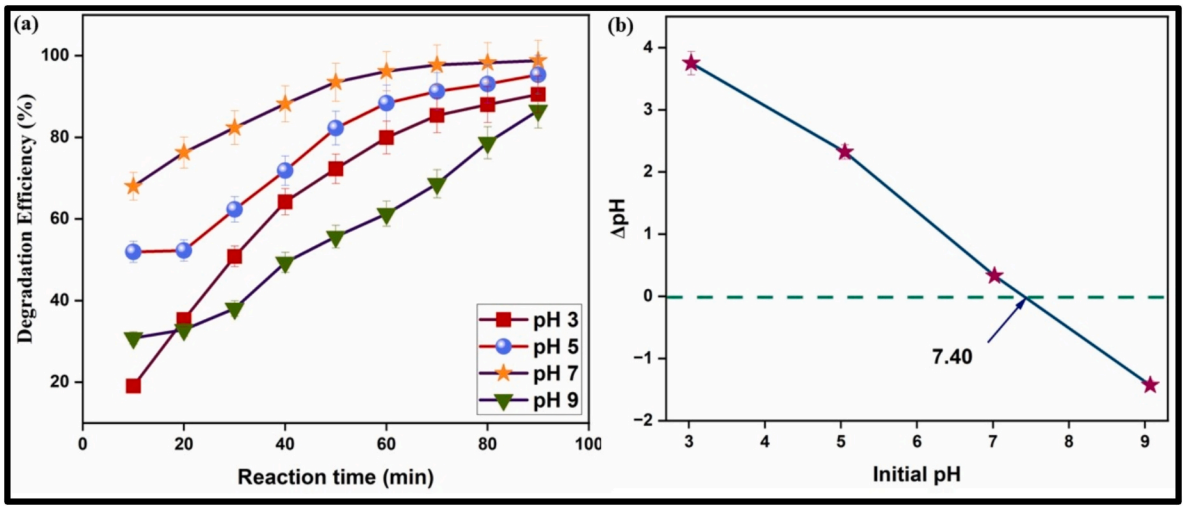

Fig. 10. (a) Influence of pH on the degradation efficiency with an increase in reaction time, and (b) pH_{pzc} plot for ZnATH-(O) NPs as a catalyst.

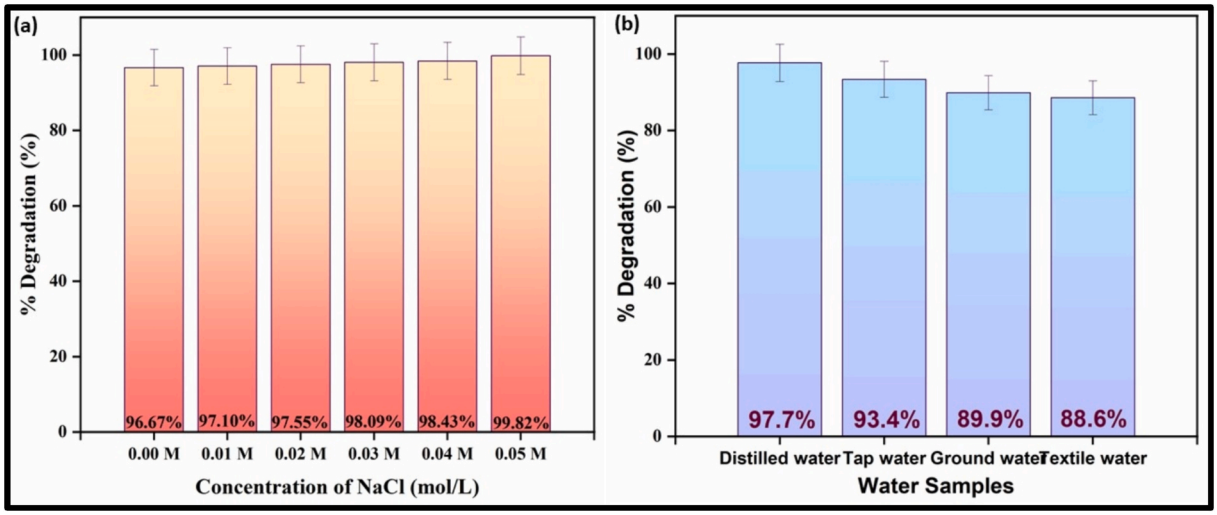

Fig. 11. (a) Influence of Ionic strength of NaCl on the degradation efficiency of ZnATH-(O) NPs, and (b) Degradation percentage of CV dye in different water samples.

groundwater, and textile water. The results obtained from analysing real water samples were subsequently compared to those of distilled water (Fig. 11b). The textile wastewater collected from the Bawana Industrial Area in New Delhi, India, was initially filtered to eliminate solid aggregates before being analysed. Due to the presence of minimal amounts of CV dye in the original samples, they were supplemented with a specific concentration of the catalyst. The percentage degradation of CV dye follows the following order: distilled water (97.7 %), tap water (93.4 %), groundwater (89.9 %), and textile water (88.6 %). Therefore, the synthesized ZnATH-(O) NPs can be used for environmental remediation in actual wastewater. These findings provide strong evidence for the current study than those previously published in the literature.

3.2.7. *Different photocatalysts for photocatalytic degradation of CV dyes*

The study also examined the most suitable parameters and degradation efficiency of recently discovered catalysts for eliminating CV, comparing them with ZnATH-(O) NPs (Table 3). The results demonstrated that the catalyst utilized in the current investigation exhibited exceptional efficacy in degrading CV dye within a 90 min of visible light irradiation, surpassing the performance of other catalysts. Furthermore, compared to other catalysts, its larger surface area is accompanied by a negatively charged metal oxide surface. The NPs surface greatly enhances its ability to adsorb cationic CV dye.

3.2.8. *Recyclability of catalyst*

A study was conducted to assess the recyclability of the catalyst, ensuring its suitability for real-time applications. After the photocatalytic degradation process, the catalyst was collected and rinsed with a water–ethanol mixture to regenerate it. Subsequently, it was dried in an oven to assess its ability to be reused. The CV dye exhibited a degradation efficiency of over 94.12 % in the initial three cycles but declined to 89.79 % after the fourth cycle (Fig. 12). Therefore, the ZnATH-(O) NPs exhibited efficient catalytic capabilities and could be utilized repeatedly. These ZnATH-(O) NPs have the potential to degrade the CV dye more efficiently as compared to those reported in the literature because of their enhanced surface area, reduced size and optimised stable structure as mentioned in Table 3.

4. Plausible mechanism of photocatalytic degradation of CV dye

The possible mechanism for the photocatalytic degradation of CV dye molecules involves three main steps: (i) demethylation leading to photogeneration of electron-hole pairs (e^-- h^+) between the valence bands (VB) and the conduction bands (CB) due to excitation of ZnATH-(O) NPs, (ii) fragmentation of the central aromatic ring of CV dye molecules followed by the aromatic side rings, and (iii) conversion of the resulting fragments into intermediate molecules, such as R-NH_3^+, phenol, and aniline.

The process involves the formation of aldehydic/carboxylate species, followed by the conversion of these intermediates into end products, including CO_2, H_2O, NO_3^{2-}, and NH_4^+. The majority of the reaction intermediates are generated from the fragmentation of the aromatic ring of the CV dye. The dye fragments undergo degradation, resulting in the formation of further chemical intermediates such as aldehydes, carboxylic acids, phenols, and amines [31]. These intermediates are

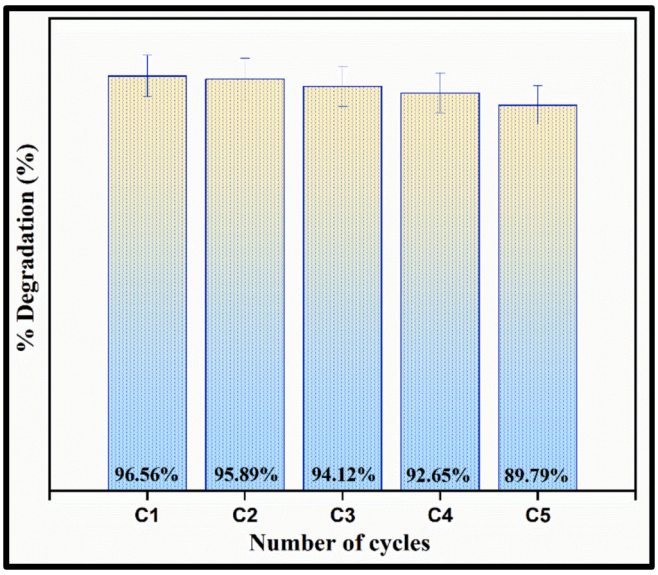

Fig. 12. Reusability of ZnATH-(O) NPs as catalyst for upto five cycles.

eventually transformed into CO_2, H_2O, NO_3^{2-}, NH_4^+ and CO_3^{2-} ions. The first stage entails the creation of an e^- and h^+ pair in the conduction and valence bands of ZnATH-(O) NPs when exposed to xenon light, as explained in Eq. (11).

$$\boldsymbol{ZnATH-(O)NPs + h\nu \rightarrow e^-_{CB} + h^+_{VB}} \quad (11)$$

The generated e^- and h^+ are transported to the surface of the photocatalyst. The rate of recombination of charge carriers slows down, leading to the separation of the generated e^--h^+ pairs to the surface. Secondly, the surface electrons (e^-) reduce oxygen (O_2) molecules to produce superoxide radicals ($\bullet O_2^-$), which further recombine with surface electrons to form peroxide molecules [4,6]. In addition, the surface holes/ proton (h^+) either oxidize water (H_2O) molecules to produce hydroxyl radicals (•OH) or directly oxidize the CV dye. These reactions are mentioned in Eqs. (12)–(15).

$$\boldsymbol{O_2 + e^- \rightarrow O_2^{\bullet} + H^+} \quad (12)$$

$$\boldsymbol{H^+ \rightarrow HOO^{\bullet}} \quad (13)$$

$$\boldsymbol{HOO^{\bullet} + e^- + H^+ \rightarrow H_2O_2} \quad (14)$$

$$\boldsymbol{H_2O + h^+ \rightarrow OH^{\bullet} + H^+} \quad (15)$$

The reactive species and intermediates ($\bullet O_2^-$, •OH, and h^+) are highly unstable, so they readily activate the redox processes and break down the CV dye into CO_2, H_2O, or inorganic ions, respectively, as presented in Eq. (16).

$$\boldsymbol{CV\ dye\ molecule + (O_2^{\bullet -}, OH^{\cdot}, and\ h^+) \rightarrow CO_2 + H_2O + inorganic\ ions} \quad (16)$$

Therefore, the aromatic rings decompose, resulting in the

degradation of colour of CV dye solution. The reaction steps are presented in Fig. 13. The photodegradation mechanism of CV dye can be comprehended by referring to Fig. 14, which illustrates the degradation of CV dye utilizing ZnATH-(O) NPs as a photocatalyst.

5. Conclusions

The present work explores the innovative synthesis and application of phytofabricated ZnO NPs using ATH extract from RC for the photocatalytic degradation of CV dye. The phytofabricated ZnO NPs show remarkable properties like a reduced particle size of 27.51 nm, irregular morphology, enhanced surface area, and improved surface charge. These characteristics starkly contrasted with those of ZnO NPs synthesized via the chemical co-precipitation method, which exhibited a larger size of 31.9 nm and a plate-like morphology with low surface area as compared to ZnATH-(O) NPs. The synthesized ZnATH-(O) NPs can be effectively utilised as catalysts in the photocatalytic degradation of CV dye using 100 ml CV dye solution of 20 mg/L dye concentration at neutral pH, under visible light irradiation for 90 min. The results revealed a superior degradation efficiency of the CV dye by the phytofabricated ZnO NPs, attributed to their smaller size and increased surface area, which facilitated more effective interaction with the dye molecules. In addition, ZnATH-(O) NPs show satisfactory reusability and a reasonable degradation efficiency of 89.79 % after five consecutive regeneration cycles.

This study improves the basic comprehension of green nanotechnology by minimizing chemical pollution and emphasizing its practical applications in environmental rehabilitation and environmental sustainability. By harnessing natural plant extracts like ATH from RC for NPs synthesis, reducing reliance on hazardous chemicals and minimising the environmental impact associated with conventional synthesis methods. The successful application of phytofabricated ZnO NPs for the degradation of harmful dyes not only highlights their potential in wastewater treatment but also emphasizes the broader implications of adopting sustainable and eco-friendly approaches in various industrial and environmental contexts. In conclusion, the integration of phytofabrication techniques with advanced nanotechnology presents a promising pathway for addressing environmental challenges. This study highlights the potential of using green-synthesized ZnO NPs to achieve efficient photocatalytic degradation of pollutants, offering a glimpse into a future where sustainable solutions are at the forefront of technological advancements for a cleaner and healthier planet.

Abstract
Radio-frequency/Wireless Optical Communication (RF/WOC) systems are used for long-distance transmission where the optical signals are severely impacted by atmospheric turbulence. This article provides the performance analysis of a dual-hop RF/WOC system where RF and wireless optical channels undergo Nakagami-m and Fisher-Snedecor ($\mathcal{F}$) distributions with approximate Beckmann distribution respectively. This system can operate with either coherent heterodyne detection (HD) or non-coherent intensity modulation with direct detection (IM/DD) scheme. The mathematical formulation of the cumulative distribution function (CDF) is derived for instantaneous overall received signal-to-noise ratio (SNR) using the fixed gain amplify and forward (AF) relaying technique. Its CDF is being utilized to create new analytical formulas for outage probability (OP), average bit error rate (ABER), and ergodic capacity (EC). Moreover, asymptotic analysis for the performance metrics is performed to get more insights. Additionally, a single WOC system that was previously studied and modeled by $\mathcal{F}$ fading distribution with pointing errors is compared with the proposed system. The analytical findings demonstrate that the performance of the system is exacerbated by essential factors, including atmospheric turbulence and pointing errors and the HD scheme is preferable to a IM/DD scheme. Moreover, ABER with CBPSK modulation is found better than other binary modulation schemes. Additionally, results reveal that the considered system has remarkable performance improvement over a single WOC system.

Keywords Nakagami-m distribution · Fisher-Snedecor distribution · Beckmann distribution · Cumulative distribution function

1 Introduction

Wireless optical communication (WOC) has served as an effective technology for huge demands of 5G and beyond communication to support high data rates for coverage areas ranging from a few nanometres to more than a 1000 km. Due to the shortage of licensed radio spectrum, WOC accommodates the rapidly rising bandwidth demands, higher data rate, immunity to electromagnetic interference, better security, and unrestricted access to the spectrum [1]. Terrestrial Free space optical (FSO) technology is beneficial for last-mile problems in future-generation networks, optical fiber backup, inter-city backhauls, emergency recovery, offshore communication, and military applications. It also served as an alternative solution to optical fiber communication systems as it offers rapid deployment and fast setup time, more flexibility, and low maintenance costs [2]. Due to the benefits indicated above, FSO has gained enormous attention in which a laser beam is used to transmit the data wirelessly. The performance of the FSO system is hindered by atmospheric turbulence and pointing errors and also limits the communication range to a few hundred meters [3, 4]. These constraints can be reduced by a dual-hop radio frequency/ wireless optical communication (RF/WOC), considered as RF/ FSO systems with different relaying techniques, where

the relay is positioned as an intermediary node between the source and the destination to enhance the long-range transmission. This approach combines the robustness of RF with the high-speed, high-capacity benefits of optical communication, making it suitable for diverse applications like long-distance communication, disaster recovery, and secure data transmission. In such systems, data is transferred from source to relay through the RF channel during the first hop. Afterward, the relay sends it in a subsequent hop across the FSO channel to the destination. Different relaying techniques are used at the relay such as decode and forward (DF) [5, 6] and amplify and forward (AF) [7]. The relay in the DF relaying technique decodes the input signal, reduces the noise, and forwards it to the destination whereas, in the AF-based relaying technique, the relay boosts the incoming signal using either variable gain or constant gain and then transmits it to the destination [8]. AF relay-based system has advantages over the DF due to its less complexity and simpler implementation [9]. Recently many researchers have examined the performance metrics for DF and AF-based dual-hop RF/FSO systems with pointing error using different detection schemes as enumerated in Table 1.

Various fading models have been used such as Rician, Rayleigh, Nakagami-m, $\eta-\mu$, and $k-\mu$ shadowed distributions have been used for RF links. Some distributions like $\eta-\mu$ and $k-\mu$ shadowed distributions have more mathematical complexity due to their complex confluent hypergeometric function in contrast to simple distributions like Rayleigh, Nakagami-m, and Rician [10]. Additionally, the Nakagami-m is generalized distribution, and other RF channels such as the single-sided Gaussian channel, Rayleigh channel, Rician channel, and AWGN channel are obtained as its special case.

For the FSO link, several fading models such as Gamma–Gamma ($\Gamma\Gamma$) distribution [11], Malaga ($\mathcal{M}$) distribution [12], Exponentiated Weibull (EW)[13], Double Generalized Gamma (DGG) distribution [14], and Fisher-Snedecor ($\mathcal{F}$) distribution [15] have been employed to describe the environment turbulence regimes. Although the $\Gamma\Gamma$ distribution is widely used only for strong turbulence conditions whereas $\mathcal{M}$ distribution, EW distribution, DGG distribution, and $\mathcal{F}$ distribution are acceptable for all turbulence conditions. But $\mathcal{M}$ distribution, EW distribution, and DGG distribution are mathematically more intractable than $\mathcal{F}$ distribution [15].

In addition to the atmospheric turbulence, pointing errors are another risk factor for FSO links which are caused by the transmitter and receiver being out of alignment [16]. To characterize this misalignment, many statistical models including Rayleigh [17], Hoyt [18], lognormal-Rician [19], Beckmann, and approximation Beckmann distribution [20] have been presented. Beckmann distribution is the generalized pointing error model. Since several models are included as a special case. Due to the intricacy of its mathematics, Beckmann distribution does not have a closed-form solution. Then, a modified Rayleigh distribution is used to approximate the Beckmann distribution to create the approximation Beckmann distribution [20].

However, different digital binary modulation schemes, aperture averaging, and different detection schemes are just a few methods utilized to improve performance. Various digital binary modulation methods are used to assess the effectiveness of dual-hop RF/FSO systems in literature [33, 34]. Additionally, the aperture averaging technique has been

employed by some authors to minimize the effects of fading by averaging out intensity fluctuations to enhance the system performance [35]. Moreover, different optical detection techniques have been used at the receiver in the literature such as coherent heterodyne detection (HD) scheme, and non-coherent intensity modulation/ direct detection (IM/DD) scheme [36]. For scenarios requiring high spectral efficiency and long-distance communication, HD is advantageous despite its complexity. In contrast, for short-range, cost-sensitive applications, IM/DD is typically preferred due to its simplicity and lower cost. The choice between these schemes depends on factors such as distance, required data rates, security needs, and budget constraints [37].

Inspired by the literature mentioned above, we have considered the fixed gain AF-based dual-hop RF/FSO system where the RF link is followed by the Nakagami-m distribution and the FSO link is experienced by $\mathcal{F}$ distribution with a pointing error that follows the approximation Beckmann distribution in this paper. According to the author's knowledge, no prior work was explored for this kind of investigation. Moreover, Nakagami-m is a generalized distribution, and its special case for varying RF fading parameters yields different RF channel models including the Rayleigh, Rician, and single-sided Gaussian channels. It also reveals the statistical modeling of multipath fading channels (caused by reflections, refraction, diffraction, and scattering by surrounding objects, buildings, and others) and its mathematical form is more analytically tractable as compared to other distributions. Additionally, $\mathcal{F}$ distribution is more popular and applicable to all atmospheric turbulence conditions. Therefore, this work can serve as the benchmark for research findings.

The key aspects of this study are as follows:

- A dual-hop RF/FSO system employing a fixed-gain AF relaying technique is used to generate a closed-form formulation of CDF for instantaneous end-to-end (E2E) received signal-to-noise ratio under coherent HD and non-coherent IM/DD detection schemes.
- Based on its CDF, exact novel unified analytical expressions such as outage probability (OP), average bit error rate (ABER) for different digital binary modulation schemes, and ergodic capacity (EC) are evaluated where OP and ABER are presented in Meijer's G function, and EC is gained in bivariate Meijer's G function.
- Additionally, the resultant expressions are formulated asymptotically to acquire a deeper understanding.
- Exact and asymptotic expressions are simulated on MATLAB, and their performance is examined while accounting for the effects of fading caused by atmospheric turbulence and misalignment.
- Lastly, the performance of the considered system is contrasted to a single WOC system that was the subject of earlier research and is regarded as an FSO system represented by $\mathcal{F}$ distribution.

This paper is divided into different sections. The system model under consideration is covered in Sect. 2. Section 3 provides the CDF for instantaneous received SNR under both detection schemes. The exact and asymptotic mathematical frameworks for performance metrics are presented in Sect. 4. The simulated results are shown and then compared to an existing single FSO system in Sect. 5. The paper's conclusions are presented at the last.

2 System model of the proposed system

Figure 1 shows a proposed system that comprises a source, (S), a relay, (R), and a destination, (D). The data is passed from S to R via the RF link. The received signal at R is written as:

$$y_{SR} = h_{RF}x + n_{RF} \tag{1}$$

where x denotes the information sent by the S, h_{RF} is the channel coefficients represented by Nakagami-m distribution, and $n_{RF} \sim \mathcal{N}(0, \sigma_{RF}^2)$ is an additive white gaussian noise (AWGN) containing zero mean and variance, σ_{RF}^2.

Afterward, the RF signal is converted into an optical signal at R, which is then amplified with gain G and transmitted to D via the FSO link. The signal received at D is expressed as:

$$y_{RD} = \eta_{FSO}h_{FSO}Gy_{SR} + n_{FSO} \tag{2}$$

Substituting Eq. (1) into Eq. (2), it becomes:

$$y_{RD} = \eta_{FSO}h_{FSO}G\left(h_{RF}x + n_{RF}\right) + n_{FSO} \tag{3}$$

where η_{FSO} is the conversion coefficient,$n_{FSO} \sim \mathcal{N}(0, \sigma_{FSO}^2)$, h_{FSO} is the channel gain of the FSO link which is represented as $h_{FSO} = h_a h_p$, where h_a is the atmospheric turbulence modelled by $\mathcal{F}$ distribution and h_p is the pointing loss characterized by approximation Beckmann distribution. The instantaneous received SNR,$\gamma_{RF} = \frac{|h_{RF}|^2}{\sigma_{RF}^2}$, and average received SNR, $\overline{\gamma}_{RF} = \frac{\mathbb{E}^2|h_{RF}|}{\sigma_{RF}^2}$ are represented for the RF link.

The probability density function (PDF) and CDF of the RF link that experiences the Nakagami-m distribution are given by Siddharth et al. [38]

$$f\left(\gamma_{RF}\right) = \frac{m^m {\gamma_{RF}}^{m-1}}{\Gamma(m)\overline{\gamma}_{RF}{}^m} \exp\left(\frac{-m\gamma_{RF}}{\overline{\gamma}_{RF}}\right) \tag{4}$$

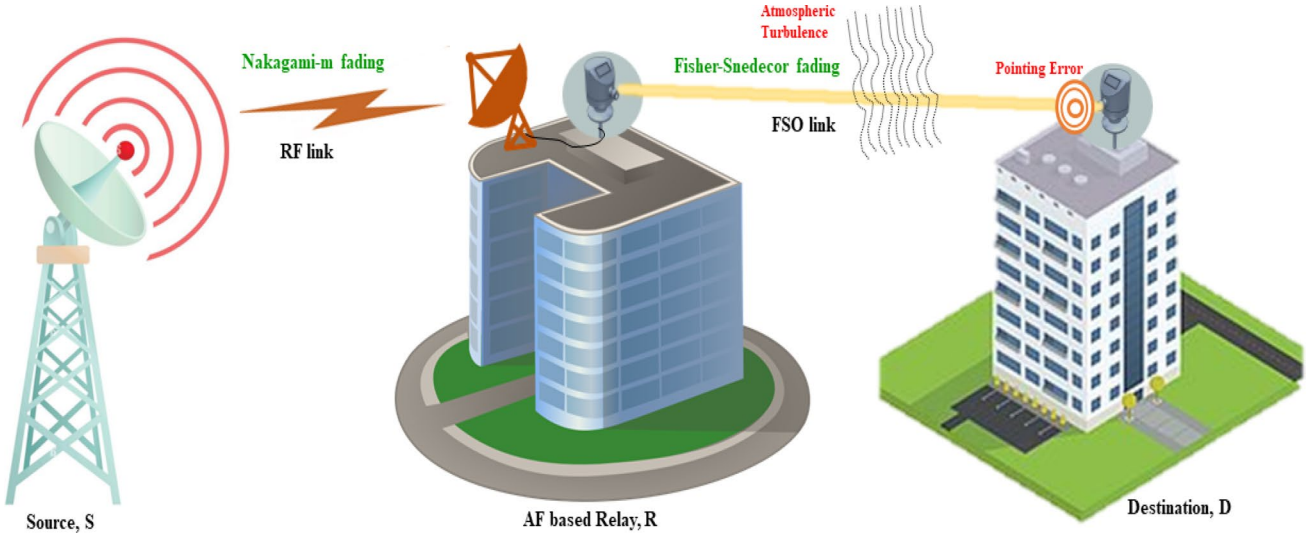

Fig. 1 System model of the dual-hop RF/FSO communication system under the influence of pointing error

$$F(\gamma_{RF}) = \frac{\gamma\left(m, \frac{m}{\overline{\gamma}_{RF}}\gamma_{RF}\right)}{\Gamma m} \tag{5}$$

where, $\gamma(-,-)$ denotes the lower incomplete Gamma function, and $\Gamma(.)$ represents the Gamma function respectively, and RF fading parameter, $m \geq 0.5$.

The instantaneous received electrical SNR, γ_{FSO} and average received electrical SNR, $\overline{\gamma}_{FSO}$ for the coherent HD and non-coherent IM/DD detection schemes are written as $\gamma_{FSO} = \frac{|\eta h_{FSO}|^t}{\sigma_{FSO}^2}$ and $\overline{\gamma}_{FSO} = \frac{\eta^t \mathbb{E}^t |h_{FSO}|}{\sigma_{FSO}^2}$, where t = 1, and 2 are represented for coherent HD and non-coherent IM/DD detection schemes respectively.

The nth moment of h_{FSO} is given by Ding et al. [32]

$$\mathbb{E}|h_{FSO}|^n = \left(\frac{A_{mode}(b-1)}{a}\right)^n \left(\frac{{\xi_{mode}}^2 \Gamma(b-n)\Gamma(a+n)}{({\xi_{mode}}^2 + n)\Gamma(b)\Gamma(a)}\right) \tag{6}$$

The PDF and CDF of γ_{FSO} that follow the $\mathcal{F}$ distribution are given by Badarneh et al. [34]

where, $G_{p,q}^{m,n}[.]$ is the Meijer's G function and values of a and b are determined as follows:

$$a = \frac{1}{\exp(\sigma_{lnS}^2) - 1}; b = \frac{1}{\exp(\sigma_{lnL}^2) - 1} + 2 \tag{9}$$

where σ_{lnS}^2 and σ_{lnL}^2 represent the small-scale and large-scale log-irradiance variances respectively, $\xi_{mode} = \frac{w_{eq}}{2\sigma_{mode}}$, $w_{eq} = \sqrt{\frac{\sqrt{\pi} {w_b}^2 \mathrm{erf}(v)}{2v\exp(-v^2)}}$, $\sigma_{mode} = \left(\frac{3\mu_x^2\sigma_x^4 + 3\mu_y^2\sigma_y^4 + \sigma_x^6 + \sigma_y^6}{2}\right)^{\frac{1}{6}}$, $v = \sqrt{\frac{\pi}{2}}\left(\frac{g}{w_b}\right)$, $A_{mode} = A_0\Omega$, $A_0 = (\mathrm{erf}(v))^2$, $\Omega = e^{\left(\frac{1}{{\xi_{mode}}^2} - \frac{1}{2{\xi_x}^2} - \frac{1}{2{\xi_y}^2} - \frac{\mu_x^2}{2{\xi_x}^2\sigma_x^2} - \frac{\mu_y^2}{2{\xi_y}^2\sigma_y^2}\right)}$, $\xi_x = \frac{w_{eq}}{2\sigma_x}$ and $\xi_y = \frac{w_{eq}}{2\sigma_y}$, where ξ_{mode} refers to the displacement deviation of pointing error, w_{eq} indicates the receiver's equivalent beam width, σ_{mode} implies the receiver's pointing error displacement standard deviation, w_b means gaussian beamwidth, g signifies the receiver's aperture radius, non-zero boresight errors μ_x, μ_y

$$f(\gamma_{FSO}) = \frac{{\xi_{mode}}^2 {\gamma_{FSO}}^{-1}}{t\Gamma(a)\Gamma(b)} G_{2,2}^{2,1}\left[\frac{a{\xi_{mode}}^2 {\gamma_{FSO}}^{\frac{1}{t}}}{(b-1)\left(1+{\xi_{mode}}^2\right)\overline{\gamma}_{FSO}^{\frac{1}{t}}}\middle| \begin{matrix} 1-b, 1+{\xi_{mode}}^2 \\ a, {\xi_{mode}}^2 \end{matrix}\right] \tag{7}$$

$$F(\gamma_{FSO}) = \frac{{\xi_{mode}}^2}{\Gamma(a)\Gamma(b)} G_{3,3}^{2,2}\left[\frac{a{\xi_{mode}}^2 {\gamma_{FSO}}^{\frac{1}{t}}}{(b-1)\left(1+{\xi_{mode}}^2\right)\overline{\gamma}_{FSO}^{\frac{1}{t}}}\middle| \begin{matrix} 1-b, 1, 1+{\xi_{mode}}^2 \\ a, {\xi_{mode}}^2, 0 \end{matrix}\right] \tag{8}$$

and different jittersσ_x,σ_y represent horizontal and elevation displacements respectively.

3 CDF of the proposed system

When fixed-gain AF relaying strategy is employed, instantaneous E2E received SNR, denoted as $\gamma_{E2E,AF}$ is given by Sharma et al. [23]:

$$\gamma_{E2E,AF} = \frac{\gamma_{FSO}\gamma_{RF}}{\gamma_{FSO} + C} \tag{10}$$

where, $C = \frac{1}{\sigma_{RF}^2 G^2}$

$$F_{\gamma_{E2E,AF}} = \int_0^{\infty} \frac{\gamma\left(m, \frac{m\gamma}{\overline{\gamma}_{RF}}\left(\frac{\gamma_{FSO}+C}{\gamma_{FSO}}\right)\right)}{t\Gamma(a)\Gamma(b)\Gamma(m)} \cdot {\xi_{mode}}^2 {\gamma_{FSO}}^{-1} G_{2,2}^{2,1}\left[\frac{a{\xi_{mode}}^2 \gamma_{FSO}^{\frac{1}{t}}}{(b-1)\left(1+{\xi_{mode}}^2\right)\overline{\gamma}_{FSO}^{\frac{1}{t}}}\middle| \begin{matrix} 1-b, 1+{\xi_{mode}}^2 \\ a, {\xi_{mode}}^2 \end{matrix}\right] d\gamma_{FSO} \tag{13}$$

Afterward, expand $\gamma(n,x)$ in the form of series as given by Gradshteyn and Ryzhik [39]

$$\gamma(n,x) = (n-1)!\left[1 - exp(-x)\sum_{m=0}^{n-1}\frac{x^m}{m!}\right] \tag{14}$$

On the substitution of Eq. (14) into Eq. (13) and after simplification, the CDF is reduced to

$$F_{\gamma_{E2E,AF}} = \underbrace{\frac{\xi_{mode}^2}{t\lceil(a)\lceil(b)}\int_0^{\infty}\gamma_{FSO}^{-1}G_{2,2}^{2,1}\left[\frac{a\xi_{mode}^2\gamma_{FSO}^{\frac{1}{t}}}{(b-1)\left(1+\xi_{mode}^2\right)\overline{\gamma}_{FSO}^{\frac{1}{t}}}\middle|\begin{matrix}1-b,1+\xi_{mode}^2\\ a,\xi_{mode}^2\end{matrix}\right]d\gamma_{FSO}}_{I_1} - \underbrace{\frac{\xi_{mode}^2}{t\lceil(a)\lceil(b)}e^{-B}\sum_{n=0}^{m-1}\frac{(B)^n}{n!}\int_0^{\infty}\left(\frac{\gamma_{FSO}+C}{\gamma_{FSO}}\right)^n exp\left(-\frac{BC}{\gamma_{FSO}}\right)\gamma_{FSO}^{-1}G_{2,2}^{2,1}\left[\frac{a\xi_{mode}^2\gamma_{FSO}^{\frac{1}{t}}}{(b-1)\left(1+\xi_{mode}^2\right)\overline{\gamma}_{FSO}^{\frac{1}{t}}}\middle|\begin{matrix}1-b,1+\xi_{mode}^2\\ a,\xi_{mode}^2\end{matrix}\right]d\gamma_{FSO}}_{I_2} \tag{15}$$

Afterward, CDF for instantaneous E2E received SNR, denoted as $F_{\gamma_{E2E,AF}}$ of the considered system becomes:

$$F_{\gamma_{E2E,AF}} = P_r\left[\frac{\gamma_{FSO}\gamma_{RF}}{\gamma_{FSO}+C} \le \gamma|\gamma_{FSO}\right] \tag{11}$$

where, $P_r[.]$ represents the probability that the instantaneous E2E received SNR, $\gamma_{E2E,AF}$ is less than or equal to γ.

After performing some algebraic manipulations, Eq. (11) is written as:

$$F_{\gamma_{E2E,AF}} = \int_0^{\infty} P_r\left[\gamma_{RF} \le \frac{\gamma\left(\gamma_{FSO}+C\right)}{\gamma_{FSO}}\right] f\left(\gamma_{FSO}\right) d\gamma_{FSO} \tag{12}$$

Substituting Eqs. (5) and (7) into Eq. (12), the CDF for $\gamma_{E2E,AF}$ is written as:

assuming, $B = \frac{m\gamma}{\overline{\gamma}_{RF}}$

After applying Eq. (07.34.21.0009.01) given in [40], the term I_1 becomes:

$$I_1 = 1 \tag{16}$$

Utilizing expression Eq. (1.111) provided by [39] and using the formula $e^x = G_{01}^{10}\left(-x\middle|\begin{matrix}-\\0\end{matrix}\right) = G_{10}^{01}\left(-\frac{1}{x}\middle|\begin{matrix}1\\-\end{matrix}\right)$, the term I_2 is reduced to:

$$I_2 = \frac{\xi_{mode}^2}{t\lceil(a)\lceil(b)}e^{-B}\sum_{n=0}^{m-1}\frac{B^n}{n!}\sum_{k=0}^{n}\binom{n}{k}C^k\int_0^{\infty}\gamma_{FSO}^{-1-k}G_{1,0}^{0,1}\left(\frac{\gamma_{FSO}}{BC}\middle|\begin{matrix}1\\-\end{matrix}\right) G_{2,2}^{2,1}\left[\frac{a\xi_{mode}^2\gamma_{FSO}^{\frac{1}{t}}}{(b-1)\left(1+\xi_{mode}^2\right)\overline{\gamma}_{FSO}^{\frac{1}{t}}}\middle|\begin{matrix}1-b,1+\xi_{mode}^2\\ a,\xi_{mode}^2\end{matrix}\right]d\gamma_{FSO} \tag{17}$$

With the aid of Eq. (07.34.21.0013.01) given in [40], Eq. (17) is obtained in a closed-form as:

$$I_2 = \frac{\xi_{mode}^2}{t\Gamma(a)\,\Gamma(b)} e^{-B} \sum_{n=0}^{m-1} \frac{B^n}{n!} \sum_{k=0}^{n} \binom{n}{k} C^k \frac{t^{a+b-1}}{(2\pi)^{t-1}} \left(\frac{1}{BC}\right)^k G_{2t,2t+1}^{2t+1,t}\left(BC\left(\frac{a\xi_{mode}^2}{(b-1)\left(1+\xi_{mode}^2\right)\frac{1}{\overline{\gamma}_{FSO}}} \right)^t \middle| \begin{matrix} \left(\frac{1-b}{t}\right), \left(\frac{-b+t}{t}\right), \left(\frac{1+\xi_{mode}^2}{t}\right), \left(\frac{\xi_{mode}^2+t}{t}\right) \\ \frac{a}{t}, \left(\frac{a+t-1}{t}\right), \left(\frac{\xi_{mode}^2}{t}\right), \left(\frac{\xi_{mode}^2+t-1}{t}\right), k \end{matrix} \right) \tag{18}$$

Substituting Eqs. (16) and (18) into Eq. (15), the unified expression of CDF for instantaneous E2E received SNR is obtained as:

4 Performance parameters

Novel analytical formulations for the outage probability, average bit error rate, and ergodic capacity of the considered system are evaluated in this section.

$$F_{\gamma_{E2E,AF}}(\gamma) = 1 - \frac{\xi_{mode}^2}{t\Gamma(a)\,\Gamma(b)} \frac{t^{a+b-2} e^{-\frac{m\gamma}{\overline{\gamma}_{RF}}}}{(2\pi)^{t-1}} \sum_{n=0}^{m-1} \frac{\left(\frac{m\gamma}{\overline{\gamma}_{RF}}\right)^n}{n!} \sum_{k=0}^{n} \binom{n}{k} \left(\frac{m\gamma}{\overline{\gamma}_{RF}}\right)^{-k} G_{2t,2t+1}^{2t+1,t}\left(\frac{C m\gamma}{\overline{\gamma}_{RF}\overline{\gamma}_{FSO}} \left(\frac{a\xi_{mode}^2}{(b-1)\left(1+\xi_{mode}^2\right)} \right)^t \middle| \begin{matrix} \mathfrak{B}_1 \\ \mathfrak{B}_2 \end{matrix} \right) \tag{19}$$

where

$$\mathfrak{B}_1 = \left[\mathfrak{B}_{11}, \mathfrak{B}_{12}, \mathfrak{B}_{13}, \mathfrak{B}_{14}\right] = \left[\left(\frac{1-b}{t}\right), \left(\frac{-b+t}{t}\right), \left(\frac{1+\xi_{mode}^2}{t}\right), \left(\frac{\xi_{mode}^2+t}{t}\right) \right]$$

$$\mathfrak{B}_2 = \left[\mathfrak{B}_{21}, \mathfrak{B}_{22}, \mathfrak{B}_{23}, \mathfrak{B}_{24}, \mathfrak{B}_{25}\right] = \left[\frac{a}{t}, \left(\frac{a+t-1}{t}\right), \left(\frac{\xi_{mode}^2}{t}\right), \left(\frac{\xi_{mode}^2+t-1}{t}\right), k \right]$$

Further, by employing DF at the relay, the instantaneous E2E received SNR, $\gamma_{E2E,DF}$ is given as

$$\gamma_{E2E,DF} = \min(\gamma_{RF}, \gamma_{FSO}) \tag{20}$$

Afterward, CDF for instantaneous E2E received SNR, $\gamma_{E2E,DF}$ of the considered system is

$$F_{\gamma_{E2E,DF}}(\gamma) = F\left(\gamma_{RF}\right) + F\left(\gamma_{FSO}\right) - F\left(\gamma_{RF}\right)F\left(\gamma_{FSO}\right) \tag{21}$$

By substituting Eqs. (5) and (8) into Eq. (21), we obtained the CDF of $\gamma_{E2E,DF}$ for DF relaying system.

4.1 Outage probability, $F_{\gamma_{E2E,AF}}(\gamma_{th})$

It plays a vital role in determining how reliable a considered system is. When the instantaneous E2E received SNR is less than the tolerable threshold SNR, it is deemed to be in outage i.e. $F_{\gamma_{E2E,AF}}(\gamma_{th}) = P\left(\gamma_{E2E,AF} \le \gamma_{th}\right)$. The outage probability, $F_{\gamma_{E2E,AF}}(\gamma_{th})$ is obtained by replacing γ with γ_{th}in Eq. (19), and it is found as:

$$F_{\gamma_{E2E,AF}}(\gamma_{th}) = 1 - \frac{\xi_{mode}^2}{\Gamma(a)\,\Gamma(b)} \frac{t^{a+b-2} e^{-\frac{m\gamma_{th}}{\overline{\gamma}_{RF}}}}{(2\pi)^{t-1}} \sum_{n=0}^{m-1} \frac{\left(\frac{m\gamma_{th}}{\overline{\gamma}_{RF}}\right)^n}{n!} \sum_{k=0}^{n} \binom{n}{k} \left(\frac{m\gamma_{th}}{\overline{\gamma}_{RF}}\right)^{-k} G_{2t,2t+1}^{2t+1,t}\left(\frac{C m\gamma_{th}}{\overline{\gamma}_{RF}\overline{\gamma}_{FSO}} \left(\frac{a\xi_{mode}^2}{(b-1)\left(1+\xi_{mode}^2\right)} \right)^t \middle| \begin{matrix} \mathfrak{B}_1 \\ \mathfrak{B}_2 \end{matrix} \right) \tag{22}$$

To get more useful performance insights for the high value of SNR, i.e. $\overline{\gamma}_{RF} \to \infty$ and $\overline{\gamma}_{FSO} \to \infty$, we assume $\lim_{\overline{\gamma}_{RF}\to\infty} e^{-\frac{m\gamma_{th}}{\overline{\gamma}_{RF}}} = 1$ and expand the Meijer-G function in Eq. (22) using Eq. (07.34.06.0040.01) given as [40], By doing so, an asymptotic expression of outage probability is obtained as:

$$F^{\infty}_{\gamma_{E2E,AF}}(\gamma_{th}) = 1 - \frac{\xi^2_{mode}}{\Gamma(a)\,\Gamma(b)} \frac{t^{a+b-2}}{(2\pi)^{t-1}} \sum_{n=0}^{m-1} \frac{1}{n!} \sum_{k=0}^{n} \binom{n}{k} \left(\frac{m\gamma_{th}}{\overline{\gamma}_{RF}}\right)^{n-k} \sum_{j=1}^{2t+1} \left\{ \frac{\prod_{\substack{i=1 \\ i\neq j}}^{2t+1} \Gamma(\mathfrak{B}_{2i} - \mathfrak{B}_{2j}) \prod_{i=1}^{t} \Gamma(1 - \mathfrak{B}_{1i} - \mathfrak{B}_{2j})}{\prod_{i=t+1}^{2t} \Gamma(\mathfrak{B}_{1i} - \mathfrak{B}_{2j})} \left(\frac{Cm\gamma_{th}}{\overline{\gamma}_{RF}\overline{\gamma}_{FSO}} \left(\frac{a\xi^2_{mode}}{(b-1)(1+\xi^2_{mode})} \right)^{t} \right)^{\mathfrak{B}_{2j}} \right\} \tag{23}$$

The asymptotic $F^{\infty}_{\gamma_{E2E,AF}}(\gamma_{th})$ expression can be rewritten in terms of the diversity order, G_d i.e., $F^{\infty}_{\gamma_{E2E,AF}} \propto (\overline{\gamma})^{-G_d}$ where $\overline{\gamma}_{RF} = \overline{\gamma}_{FSO} = \overline{\gamma}$ and $G_d = \min\left(\frac{a}{t}, \left(\frac{a+t-1}{t}\right), \left(\frac{\xi_{mode}{}^2}{t}\right), \left(\frac{\xi_{mode}{}^2+t-1}{t}\right), k\right)$ which determines the slope of the outage probability.

$$p^e = \underbrace{\frac{q^p}{2\lceil p} \int_0^{\infty} e^{-q\gamma}\gamma^{p-1} d\gamma}_{I_3} - \underbrace{\frac{q^p}{2\lceil p} \frac{\xi^2_{mode}}{\Gamma(a)\,\Gamma(b)} \frac{t^{a+b-2}}{(2\pi)^{t-1}} \sum_{n=0}^{m-1} \frac{1}{n!} \sum_{k=0}^{n} \binom{n}{k} \left(\frac{m}{\overline{\gamma}_{RF}}\right)^{-k+n} \int_0^{\infty} \gamma^{n-k+p-1} e^{-\left(q+\frac{m}{\overline{\gamma}_{RF}}\right)\gamma} G^{2t+1,\,t}_{2t,\,2t+1}\left(\frac{Cm\gamma}{\overline{\gamma}_{RF}\overline{\gamma}_{FSO}} \left(\frac{a\xi^2_{mode}}{(b-1)(1+\xi^2_{mode})} \right)^{t} \middle| \begin{matrix} \mathfrak{B}_1 \\ \mathfrak{B}_2 \end{matrix} \right)}_{I_4} \tag{25}$$

4.2 Average bit error rate, p^e

The another crucial parameter is ABER which is expressed for several digital binary modulation schemes as given by Han et al. [31]

$$p^e = \frac{q^p}{2\lceil p} \int_0^{\infty} exp(-q\gamma)\gamma^{p-1} F_{\gamma_{E2E,AF}}(\gamma) d\gamma \tag{24}$$

where, different binary modulation schemes are represented by p and q and achieved by setting the values of both.

Substituting Eq. (19) into Eq. (24), it becomes:

Utilizing the integral Eq. (3.381.4) of [39] and after simplification, the term I_3 becomes

$$I_3 = 0.5 \tag{26}$$

By employing the expression Eq. (07.34.21.0088.01) as given in [40], the term I_4 is obtained as:

$$I_4 = \frac{q^p}{2\lceil p} \frac{\xi^2_{mode} t^{a+b-2}}{\lceil a \lceil b (2\pi)^{t-1}} \sum_{n=0}^{m-1} \frac{1}{n!} \sum_{k=0}^{n} \binom{n}{k} \left(\frac{m}{\overline{\gamma}_{RF}}\right)^{-k+n} \left(q + \frac{m}{\overline{\gamma}_{RF}}\right)^{-n+k-p} G^{2t+1,t+1}_{2t+1,2t+1}\left(\frac{Cm}{\overline{\gamma}_{RF}\overline{\gamma}_{FSO}} \left(\frac{a\xi^2_{mode}}{(b-1)(1+\xi^2_{mode})} \right)^{t} \Big/ \left(q + \frac{m}{\overline{\gamma}_{RF}}\right) \middle| \begin{matrix} (1-n+k-p), \left(\frac{1-b}{t}\right), \left(\frac{-b+t}{t}\right), \left(\frac{1+\xi^2_{mode}}{t}\right), \left(\frac{\xi^2_{mode}+t}{t}\right) \\ \frac{a}{t}, \left(\frac{a+t-1}{t}\right), \left(\frac{\xi^2_{mode}}{t}\right), \left(\frac{\xi^2_{mode}+t-1}{t}\right), k \end{matrix} \right) \tag{27}$$

On the substitution of Eqs. (26) and (27) into Eq. (24) and after some mathematical manipulations, the closed-form expression of ABER for digital binary modulation schemes is obtained as follows:

$$p^{e} = 0.5 - \frac{q^{p}}{2\lceil p}\frac{\xi_{mode}^{2} t^{a+b-2}}{\lceil a \lceil b (2\pi)^{t-1}} \sum_{n=0}^{m-1} \frac{\left(\frac{m}{\bar{\gamma}_{RF}}\right)^{n}}{n!} \sum_{k=0}^{n} \binom{n}{k} \left(\frac{m}{\bar{\gamma}_{RF}}\right)^{-k} \left(q + \frac{m}{\bar{\gamma}_{RF}}\right)^{-n+k-p} G_{2t+1,2t+1}^{2t+1,t+1}\left(\frac{\frac{Cm}{\bar{\gamma}_{RF}\bar{\gamma}_{FSO}} \left(\frac{a\xi_{mode}^{2}}{(b-1)\left(1+\xi_{mode}^{2}\right)}\right)^{t}}{\left(q + \frac{m}{\bar{\gamma}_{RF}}\right)} \middle| \begin{matrix} \mathfrak{B}_3 \\ \mathfrak{B}_2 \end{matrix} \right) \tag{28}$$

where

$$\mathfrak{B}_3 = \left[\mathfrak{B}_{31}, \mathfrak{B}_{32}, \mathfrak{B}_{33}, \mathfrak{B}_{34}, \mathfrak{B}_{35}\right] = \left[(1-n+k-p), \left(\frac{1-b}{t}\right), \left(\frac{-b+t}{t}\right), \left(\frac{1+{\xi_{mode}}^{2}}{t}\right), \left(\frac{{\xi_{mode}}^{2}+t}{t}\right)\right]$$

Similar to the asymptotic OP expression, an asymptotic expression for the ABER is obtained by using Eq. (07.34.06.0040.01) provided by Wolfram [40] in Eq. (28) as follows:

$$p^{e\infty} = 0.5 - \frac{q^{p}}{2\lceil p}\frac{\xi_{mode}^{2} t^{a+b-2}}{\lceil a \lceil b\ (2\pi)^{t-1}} \sum_{n=0}^{m-1} \frac{1}{n!} \sum_{k=0}^{n} \binom{n}{k} \left(\frac{m}{\bar{\gamma}_{RF}}\right)^{n-k} \left(q + \frac{m}{\bar{\gamma}_{RF}}\right)^{k-n-p} \sum_{j=1}^{2t+1} \left\{ \frac{\prod_{\substack{i=1 \\ i\neq j}}^{2t+1} \Gamma\left(\mathfrak{B}_{2i} - \mathfrak{B}_{2j}\right) \prod_{i=1}^{t+1} \Gamma\left(1 - \mathfrak{B}_{3i} - \mathfrak{B}_{2j}\right)}{\prod_{i=t+2}^{2t+1} \Gamma\left(\mathfrak{B}_{3i} - \mathfrak{B}_{2j}\right)} \left(\frac{\frac{Cm}{\bar{\gamma}_{RF}\bar{\gamma}_{FSO}} \left(\frac{a\xi_{mode}^{2}}{(b-1)\left(1+\xi_{mode}^{2}\right)}\right)^{t}}{\left(q + \frac{m}{\bar{\gamma}_{RF}}\right)} \right)^{\mathfrak{B}_{2j}} \right\} \tag{29}$$

where, $G_d = \min\left(\frac{a}{t}, \left(\frac{a+t-1}{t}\right), \left(\frac{{\xi_{mode}}^{2}}{t}\right), \left(\frac{{\xi_{mode}}^{2}+t-1}{t}\right), k\right)$ is obtained.

4.3 Ergodic capacity, $\overline{C}_t$

The upper bound on the EC of the considered system related to complementary CDF is given as [21]

$$\overline{C}_t = \frac{\alpha_t}{\ln(2)} \int_0^{\infty} \left(1 + \alpha_t \gamma\right)^{-1} F^{c}{}_{\gamma_{E2E,AF}}(\gamma) d\gamma \tag{30}$$

where $\alpha_t = 1$ and $\frac{e}{2\pi}$ signifies the coherent HD and non-coherent IM/DD detection schemes. $F^{c}(\gamma)$ is the complementary CDF represented as

$$F^{c}{}_{\gamma_{E2E,AF}}(\gamma) = 1 - F_{\gamma_{E2E,AF}}(\gamma) \tag{31}$$

On the substitution of Eq. (19) into Eq. (31), the complementary CDF is obtained as follows:

$$F^{c}_{\gamma_{end-to-end}}(\gamma) = \frac{\xi_{mode}^{2}}{\lceil(a)\lceil(b)} \frac{t^{a+b-2} e^{-\frac{m\gamma}{\bar{\gamma}_{RF}}}}{(2\pi)^{t-1}} \sum_{n=0}^{m-1} \frac{\left(\frac{m\gamma}{\bar{\gamma}_{RF}}\right)^{n}}{n!} \sum_{k=0}^{n} \binom{n}{k} \left(\frac{m\gamma}{\bar{\gamma}_{RF}}\right)^{-k} G_{2t,2t+1}^{2t+1,t}\left(\frac{Cm\gamma_{th}}{\bar{\gamma}_{RF}\bar{\gamma}_{FSO}} \left(\frac{a\xi_{mode}^{2}}{(b-1)\left(1+\xi_{mode}^{2}\right)}\right)^{t} \middle| \begin{matrix} \mathfrak{B}_1 \\ \mathfrak{B}_2 \end{matrix} \right) \tag{32}$$

Further, substituting Eq. (32) into Eq. (30), it can be expressed as:

$$\overline{C}_t = \frac{\alpha_t}{\ln(2)} \frac{\xi_{mode}^{2}}{(a)(b)} \frac{t^{a+b-2}}{(2\pi)^{t-1}} \sum_{n=0}^{m-1} \frac{\left(\frac{m}{\bar{\gamma}_{RF}}\right)^{n}}{n!} \sum_{k=0}^{n} \binom{n}{k} \left(\frac{m}{\bar{\gamma}_{RF}}\right)^{-k} \int_0^{\infty} \left(1 + \alpha_t \gamma\right)^{-1} e^{-\frac{m\gamma}{\bar{\gamma}_{RF}}} \gamma^{n-k} G_{2t,2t+1}^{2t+1,t} \left(\frac{Cm\gamma_{th}}{\bar{\gamma}_{RF}\bar{\gamma}_{FSO}} \left(\frac{a\xi_{mode}^{2}}{(b-1)\left(1+\xi_{mode}^{2}\right)}\right)^{t} \middle| \begin{matrix} \mathfrak{B}_1 \\ \mathfrak{B}_2 \end{matrix} \right) d\gamma \tag{33}$$

Exploiting the two expressions of Eqs. (8.4.3.1) and (8.4.2.5) given as [41] in Eq. (33), it is written as:

$$\overline{C}_t = \frac{\alpha_t}{\ln(2)} \frac{\xi^2_{mode}}{\Gamma(a)\Gamma(b)} \frac{t^{a+b-2}}{(2\pi)^{t-1}} \sum_{n=0}^{m-1} \frac{\left(\frac{m}{\overline{\gamma}_{RF}}\right)^n}{n!} \sum_{k=0}^{n} \binom{n}{k} \left(\frac{m}{\overline{\gamma}_{RF}}\right)^{-k} \gamma^{n-k} G^{1,0}_{0,1}\left(\frac{m\gamma}{\overline{\gamma}_{RF}} \middle| \begin{matrix} - \\ 0 \end{matrix}\right) G^{1,1}_{1,1}\left(\alpha_t\gamma \middle| \begin{matrix} 0 \\ 0 \end{matrix}\right) \int_0^{\infty} G^{2t+1,t}_{2t,2t+1}\left(\frac{C m\gamma}{\overline{\gamma}_{RF}\overline{\gamma}_{FSO}} \left(\frac{a\xi^2_{mode}}{(1+\xi^2_{mode})(b-1)}\right)^t \middle| \begin{matrix} \left(\frac{1-b}{t}\right), \left(\frac{t-b}{t}\right), \left(\frac{1+\xi^2_{mode}}{t}\right), \left(\frac{\xi^2_{mode}+t}{t}\right) \\ \frac{a}{t}, \left(\frac{a+t-1}{t}\right), \left(\frac{\xi^2_{mode}}{t}\right), \left(\frac{\xi^2_{mode}+t-1}{t}\right), k \end{matrix}\right) d\gamma \tag{34}$$

With the aid of Eq. (07.34.21.0081.01) of [40] in Eq. (34) which results the ergodic capacity in the closed-form expression as follows:

$$\overline{C}_t = \frac{\alpha_t}{\ln(2)} \frac{\xi^2_{mode}}{\Gamma(a)\Gamma(b)} \frac{t^{a+b-2}}{(2\pi)^{t-1}} \sum_{n=0}^{m-1} \frac{1}{n!} \sum_{k=0}^{n} \binom{n}{k} \left(\frac{m}{\overline{\gamma}_{RF}}\right)^{-1} G^{0,1:1,1:2t+1,t}_{1,0:1,1:2t,2t+1}\left(\begin{matrix} -n+k \\ - \end{matrix} \middle| \begin{matrix} 0 \\ 0 \end{matrix} \middle| \begin{matrix} \left(\frac{1-b}{t}\right), \left(\frac{t-b}{t}\right), \left(\frac{1+\xi^2_{mode}}{t}\right), \left(\frac{\xi^2_{mode}+t}{t}\right) \\ \frac{a}{t}, \left(\frac{a+t-1}{t}\right), \left(\frac{\xi^2_{mode}}{t}\right), \left(\frac{\xi^2_{mode}+t-1}{t}\right), k \end{matrix} \middle| \frac{\alpha_t\overline{\gamma}_{RF}}{m}, C\left(\frac{a\xi^2_{mode}}{(1+\xi^2_{mode})(b-1)\overline{\gamma}^{1/t}_{FSO}}\right)^t \right) \tag{35}$$

5 Numerical results and discussion

In this section, the performance of the considered system is analyzed for both detection schemes under the influence of atmospheric turbulence and pointing errors. For this purpose, the following parameters are considered in accordance [32, 34]. For the RF channel, $m = 2$ has been taken. The transmission range, $L = 3.5$ km, and optical wavelength, $\lambda = 1550$ nm are chosen for the FSO link. The refraction index structure parameter,$C_n^2 = 5 \times 10^{-15}$ $m^{-\frac{2}{3}}$, 2×10^{-14} $m^{-\frac{2}{3}}$ and 8×10^{-14} $m^{-\frac{2}{3}}$ are considered for weak, moderate, and strong turbulent environments respectively. The Rytov variance,$\sigma_1^2 = 0.4023$, 1.6092, and 6.4369 are obtained using $\sigma_1^2 = 0.5C_n^2 k^{7/6} L^{11/6}$, where$k = \frac{2\pi}{\lambda}$. The corresponding values of $(a, b) = (4.5916, 7.0941)$, (a, b) = (1.8276, 3.9363), and (a, b) = (1.4262, 3.5297) are calculated from Eq. (9) for weak, moderate, and strong turbulent environments respectively, taking into account the inner scale of turbulence, $l_0 = 5.98$ mm, outer scale of turbulence,$L_0 = 0.8$ m, and receiver aperture diameter$D = 2g = 10$ mm . The average SNR for the different hop, i.e. $\overline{\gamma}_{RF} = \overline{\gamma}_{FSO} = \overline{\gamma}$ and fixed gain, C = 1 are considered. Moreover, the agreement between asymptotic and exact analytic expressions offers valuable insights into the system's performance. The results of the considered system are compared with those available in the literature [34].

The exact and asymptotic expressions for OP given by Eqs. (22) and (23) are demonstrated in Figs. 2, 3, and 4 and are plotted against average SNR, $\overline{\gamma}$ for both detection schemes at $\gamma_{th} = 0$dB.

Figure 2 shows how turbulence conditions change the OP performance while keeping other parameters fixed at $w_b/g = 10$, $(\sigma_x/g, \sigma_y/g) = (8, 1)$, $(\mu_x/g, \mu_y/g) = (3, 1)$ and $\xi_{mode} = 0.6650$. The findings demonstrate that atmospheric turbulence severity put a negative impact on the system performance for both detection schemes. Additionally, it finds that OP with $t = 1$ outperforms with $t = 2$ indicating that HD detection scheme performs better than IM/DD detection scheme. Further, it can also be seen that AF relaying scheme is better as compared to DF relaying scheme.

How the behaviour of jitters affect the OP performance, Fig. 3 shows the impacts of $(\sigma_x/g, \sigma_y/g)$ with fixed values of $w_b/g = 10$, and $(\mu_x/g, \mu_y/g) = (3, 1)$ under strong

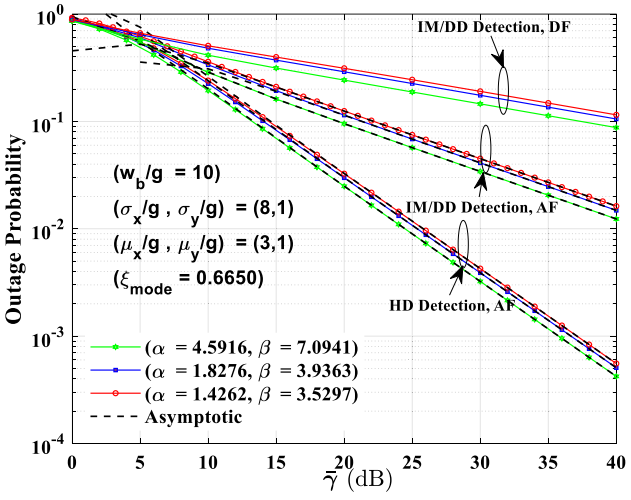

Fig. 2 OP for different atmospheric turbulence regimes considering both detection schemes using AF and DF relaying techniques

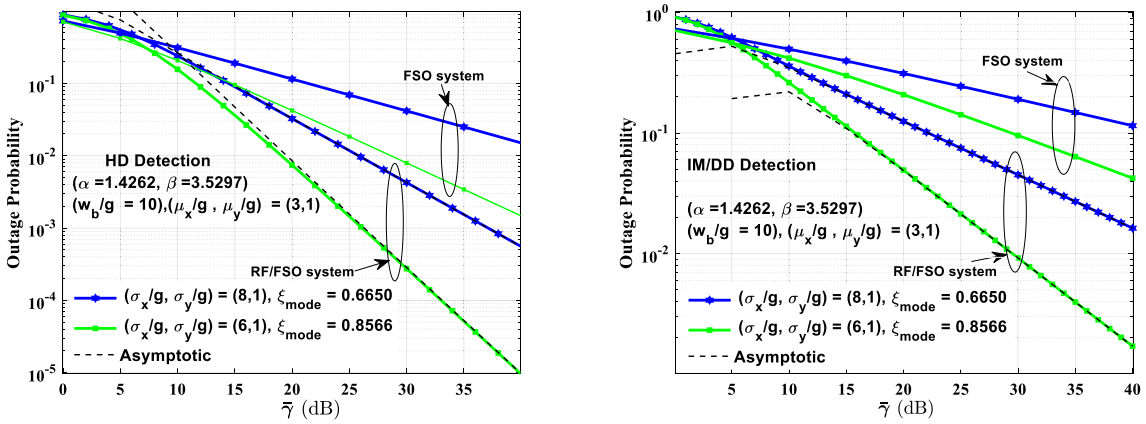

(a) HD detection scheme (b) IM/DD detection scheme

Fig. 3 OP for different values of $(\sigma_x/g, \sigma_y/g)$ under strong turbulence conditions

turbulence for both detection schemes. The results indicate that higher the value of jitters corresponding value of ξ_{mode} decreases which deteriorates the OP performance as shown in Table 2. It also shows that the impact of jitters is less on the OP of dual hop RF/FSO system than that of a single FSO system given in literature [34].

The effect of beamwidth, w_b on the OP at settings of $(\sigma_x/g, \sigma_y/g) = (8,1)$, and $(\mu_x/g, \mu_y/g) = (3,1)$ presents in Fig. 4 under strong turbulence for both detection schemes. The results indicate that a smaller value of w_b/g, corresponding value of ξ_{mode} decreases which depreciates the OP performance as presented in Table 3.

Exact and asymptotic expressions for ABER given in Eqs. (28) and (29) are plotted against average SNR, $\overline{\gamma}$ for both detection schemes as presented in Figs. 5, 6, 7, and 8. The ABER is demonstrated in Fig. 5 for the setting of $w_b/g = 10$, $(\sigma_x/g, \sigma_y/g) = (8,1)$, $(\mu_x/g, \mu_y/g) = (3,1)$ and $\xi_{mode} = 0.6650$ under different atmospheric turbulence conditions using the CBPSK modulation scheme. It exhibits that the system bit error rate performance becomes poor as the turbulence condition turns stronger for both detection schemes. It is also seen that HD improves ABER performance in comparison to IM/DD.

Figure 6 portrays the ABER for $w_b/g = 10$, $(\sigma_x/g, \sigma_y/g) = (8,1)$, $(\mu_x/g, \mu_y/g) = (3,1)$ and $\xi_{mode} = 0.6650$ using CBPSK, CBFSK, DBPSK, RZ-OOK, NBFSK, and NRZ-OOK modulations scheme under strong atmospheric turbulence conditions in both detection schemes. It is also reported that ABER with CBPSK modulation outperforms other modulations for both detection schemes. For instance, at $\overline{\gamma} = 30$ dB, ABER is 6.960×10^{-4} ,9.490×10^{-4}, 1.056×10^{-3}, 1.301×10^{-3}, $1.443 \times 10^{-3}$and 1.808×10^{-3} for CBPSK, CBFSK, DPSK, RZ-OOK, NBFSK, and NRZ-OOK respectively for HD and

$w_b/g = 7, \xi_{mode} = 0.4681$	4.210×10^{-2}	1.772×10^{-1}	1.833×10^{-1}	3.775×10^{-1}
$w_b/g = 13, \xi_{mode} = 0.8627$	6.943×10^{-5}	7.521×10^{-3}	8.731×10^{-3}	9.351×10^{-2}

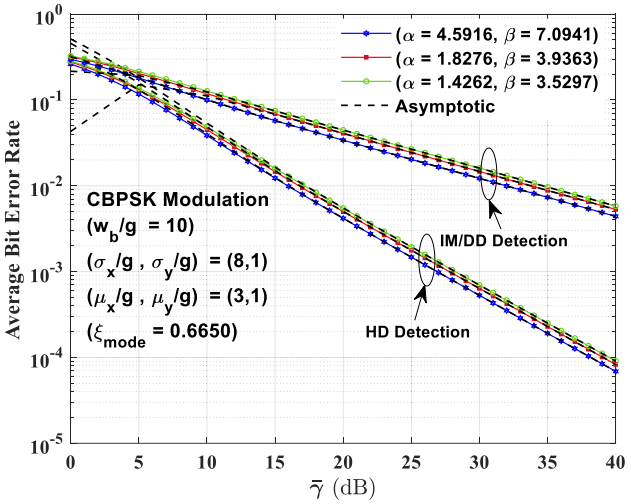

Fig. 5 ABER for different atmospheric turbulence conditions using HD and IM/DD detection schemes with CBPSK modulation

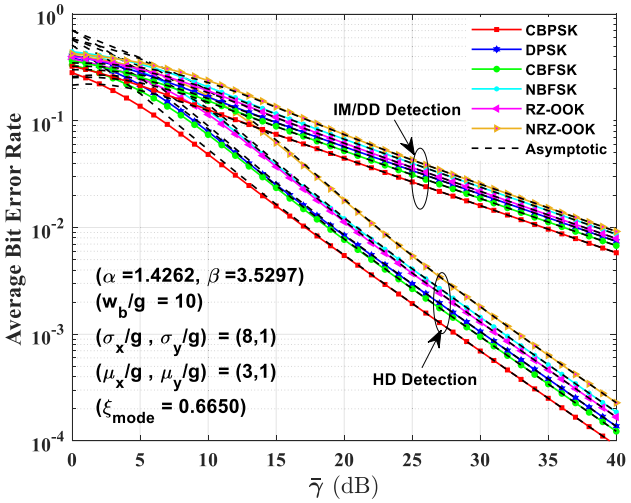

Fig. 6 ABER for various CBPSK, DPSK, CBFSK, NBFSK, RZ-OOK, and NRZ- OOK modulations under strong turbulence conditions with both detection schemes

$1.606 \times 10^{-2}, 1.873 \times 10^{-2}, 2.054 \times 10^{-2}, 2.186 \times 10^{-2}$, $2.396 \times 10^{-2}$and 2.554×10^{-2} for CBPSK, CBFSK, DPSK, RZ-OOK, NBFSK, and NRZ-OOK respectively for IM/DD detection scheme.

Figure 7 presents the influence of $(\sigma_x/g, \sigma_y/g)$ on the ABER at $w_b/g = 10$, and $(\mu_x/g, \mu_y/g) = (3,1)$ under strong turbulence for both detection schemes with CBPSK modulation. It indicates that the value of jitters corresponds smaller value of ξ_{mode} result in the degradation of ABER performance. However, as highlighted in Table 4, the impact of pointing error for a single FSO link is larger than the considered system.

Figure 8 depicts the impact of w_b on the ABER for fixed values of $(\sigma_x/g, \sigma_y/g) = (8,1)$ and $(\mu_x/g, \mu_y/g) = (3,1)$ with CBPSK modulation. The result implies that the ABER performance goes worse with the small value of w_b/g corresponding ξ_{mode} decreases. ABER performance for the single FSO system with a pointing error is less than the concerned system as provided in Table 5.

EC of the considered system given in Eq. (35) is plotted against average electrical SNR, $\overline{\gamma}$ for both detection schemes as displayed in Figs. 9, 10, and 11. The EC of the concerned system is shown in Fig. 9 at fixed

$(\sigma_x/g, \sigma_y/g) = (6,1), \xi_{mode} = 0.8566$	2.023×10^{-5}	2.039×10^{-3}	2.848×10^{-3}	2.982×10^{-2}

$w_b/g = 10$, $(\sigma_x/g, \sigma_y/g) = (8,1)$, $(\mu_x/g, \mu_y/g) = (3,1)$ and $\xi_{mode} = 0.6650$ by varying atmospheric turbulence conditions. It tells that as the turbulence level increases, EC performance decreases. Furthermore, the concerned system for the HD detection scheme performs much better than IM/DD detection scheme.

Figure 10 depicts the influence of $\left(\sigma_x/g, \sigma_y/g\right)$ on the ergodic capacity for $w_b/g = 10$ and $(\mu_x/g, \mu_y/g) = (3,1)$

$w_b/g = 13, \xi_{mode} = 0.8627$	1.803×10^{-5}	1.922×10^{-3}	2.693×10^{-3}	2.908×10^{-2}

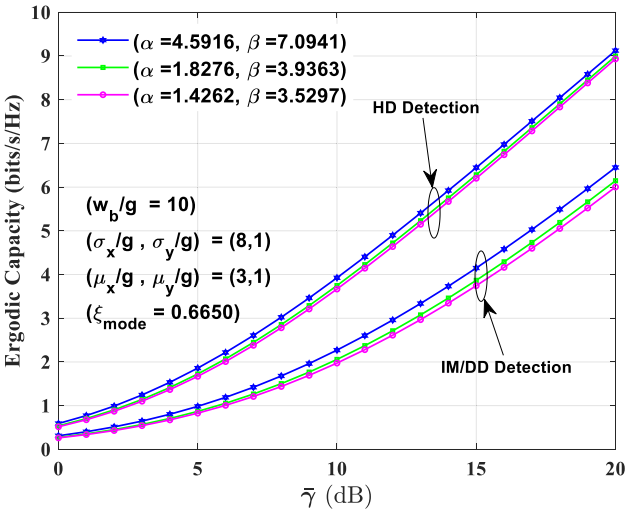

Fig. 9 EC under different atmospheric turbulence conditions for both detection schemes

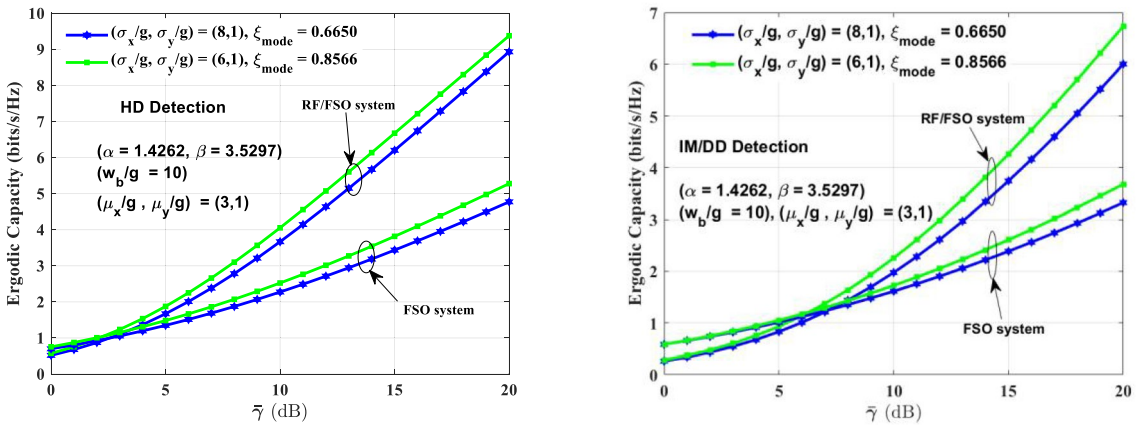
under strong turbulence for both detection schemes. Similar to the OP and ABER performance, EC is significantly impacted by jitters. Furthermore, as reported in Table 6, It indicates that a single FSO system is more influenced than the concerned system.

Figure 11 demonstrates the impact of w_b on the system's EC for the fixed values of $(\sigma_x/g, \sigma_y/g) = (8,1)$ and $(\mu_x/g, \mu_y/g) = (3,1)$ under strong turbulence for both detection schemes. It suggests that the EC performance goes better with the increase of w_b/g and ξ_{mode} in both detection schemes. Also, EC for a single FSO system with pointing error is inferior to the concerned system as outlined in Table 7.

6 Conclusion

In this paper, analysis was done on the effectiveness of an AF-based relay dual-hop RF/WOC system for different detection schemes where RF and FSO links are distinguished by the Nakagami-m and $\mathcal{F}$ distributions with pointing errors respectively. An exact closed-form mathematical representation of the CDF for overall instantaneous received SNR was formulated. Subsequently, novel exact and asymptotic expressions for performance metrics were obtained. The numerical results indicated that the turbulent severity in the environment



(a) HD detection scheme (b) IM/DD detection scheme

Fig. 11 EC for different values of w_b/g under strong turbulence conditions

Table 6 EC for various values of jitters $(\sigma_x/g, \sigma_y/g)$.

Parameter values	System			
	EC (bits/s/Hz) for HD detection scheme, Fig. 10a		EC (bits/s/Hz) for IM/DD detection scheme, Fig. 10b	
$(\mu_x/g, \mu_y/g) = (3, 1)$, $w_b/g = 10, \overline{\gamma} = 15$ dB, Strong Turbulence	Dual-hop system	Single FSO system	Dual-hop system	Single FSO system
$(\sigma_x/g, \sigma_y/g) = (8,1)$, $\xi_{mode} = 0.6650$	6.202	3.436	3.744	2.387
$(\sigma_x/g, \sigma_y/g) = (6,1)$, $\xi_{mode} = 0.8566$	6.676	3.817	4.263	2.608

Table 7 EC for various values of w_b/g.

Parameter values	Systems			
	EC (bits/s/Hz) for HD detection scheme, Fig. 11a		EC (bits/s/Hz) for IM/DD detection scheme, Fig. 11b	
$(\sigma_x/g, \sigma_y/g) = (8,1)$, $(\mu_x/g, \mu_y/g) = (3, 1)$, $\overline{\gamma} = 15$ dB, Strong Turbulence	Dual-hop system	Single FSO system	Dual-hop system	Single FSO system
$w_b/g = 7, \xi_{mode} = 0.4681$	5.055	2.731	2.849	1.995
$w_b/g = 13, \xi_{mode} = 0.8627$	6.685	3.826	4.275	2.613

and the pointing error degraded the performance. Moreover, ABER with CBPSK modulation was found better than other binary modulation schemes. Furthermore, it was also seen that a coherent HD detection scheme-based system exhibits better system performance than a non-coherent IM/DD detection scheme. Additionally, this work was contrasted with a single FSO system using the same parameters. In comparison to a single FSO system, it was found that the proposed system tends to ameliorate the consequences of atmospheric turbulence and pointing error.

Author contributions Rekha Rani, M. Lakshmanan, Anup Mandpura, N. Jayanthi have analyzed the system performance by using Matlab and Mathematica and prepared the manuscript.

Funding The authors declare that no funds, grants, or other support were received during the preparation of this manuscript.

Data availability No datasets were generated or analysed during the current study.

Rekha Rani is currently pursuing the Ph.D. degree in Electronics and Communication Engineering from Delhi Technological University, Delhi. She has 8 years of experience in academics and industrial research. She has number of research publications and book chapters. Her research interests include the Wireless Communication, Channel Modeling, Optimal Power Allocation, Channel Estimation and Free Space Optical Wireless Communication.

Dr. M. Lakshmanan is a highly accomplished academician and researcher with over 22 years of teaching experience and 15 years of research expertise. He holds a B.E. in Electronics and Communication Engineering from Madras University, an M.E. in Communication Systems from Anna University, and a Ph.D. from VIT University. Currently, he serves as Professor and Dean IQAC at Sri Eshwar College of Engineering, Coimbatore, Tamilnadu, India. Dr. Lakshmanan is a recognized expert in NBA, NAAC & ABET Accreditation, and NIRF & QS Ranking. He has mentored numerous professional institutions and universities across the nation to achieve the highest grades and ranks in accreditation and rankings respectively. With a Senior Member status in IEEE and UACEE, and fellow in IETE and IEI, he also holds Life Memberships in ISTE, ACM, IACSIT, and IAENG. Dr. Lakshmanan is an Executive Committee Member of IETE Noida Section since July 2022. His extensive research contributions include over 100 papers published in reputed SCI/SCIE/ESCI and Scopus indexed journals, along with 4 patents published in India and 2 patents granted in Australia. He is a sought-after speaker, having delivered keynote talks and invited lectures in various FDPs, workshops, and seminars. Actively involved as a reviewer for SCI/SCIE and Scopus indexed journals, he has reviewed more than 200 papers. Dr. Lakshmanan has received multiple prestigious awards, including the Best Administrator Award and Best Researcher Award for 2024 awarded by The Innovative and Advanced Multidisciplinary Research Foundation (IAMRF) in collaboration with the Prerna Education Research Society, Award of Excellence in Research for 2022-23 in National Faculty Award, Researcher of the Year Award (Engineering, Male) for 2021 in 3rd International Business & Academic Excellence Awards, Best Researcher Award for 2021 in International Excellence Award, and the Award of Emerging Leader for 2018 in Higher Education Leadership Meet – 2018 (HELA 2018). Additionally, he has been honored with the Active Researcher award five times from VIT University. His current research interests span Wireless Communication and Networks, Security Algorithms, Device to Device Communications, Digital Communication, Information Theory and Coding, Signal and Image Processing, Artificial Intelligence, Deep Learning, and Machine Learning.

Anup Kumar Mandpura (Member IEEE) received the B.Tech degree in Electronics Engineering from Banaras Hindu University, Varanasi, India in 2006,M. Tech degree in Digital Signal Processing from the Indian Institute of Technology, Guwahati, India in 2009 and the Ph.D. degree in wireless communication, from the Indian Institute of Technology, Delhi, India in 2018. He is currently working with the Department of Electrical Engineering, Delhi Technological University, Delhi, India as an Assistant Professor. His research interests include performance analysis of 5G and beyond wireless communication systems, energy harvesting communication systems, microwave/millimeter-wave systems and signal processing and machine learning with application to Control Systems, PV systems and Seismic data.

Dr. N. Jayanthi is an Assistant Professor in the department of Electronics and Communication Engineering at Delhi Technological University, since 2007. She has done B.E. in Electronics and Communication Engineering from Bharathidasan University, Trichy, Tamil Nadu and M. Tech. in Communication Systems from National Institute of Technology, Trichy. She has completed her Ph.D. thesis titled "Analysis of Digitized Historical Inscriptions and Manuscripts at Delhi Technological University. Her area of research interest includes image processing, Pattern recognition, machine learning and Communication systems. She has published a number of technical papers in International Conferences and reputed Journals. She has completed two DST sponsored projects titled "Development of OGC standards-based sensor network for intelligent traffic management" and "Development of frame work for imaging, restoring and archiving inscription and manuscript" in the capacity of co-principal investigator. Currently she is working on the Project titled "Digitizing manuscripts at the Indira Gandhi National Centre for the arts and facilitating online access to digitized documents ", in collaboration with iHub Drishti Foundation, IIT Jodhpur. She is member in professional societies such as IEEE and Intelligent Transport system (ITS) and also life member in Pattern Recognition and Artificial Intelligence (IUPARI). She is secretary of IEEE intelligent transportation systems society for Delhi chapter. Also, she is Co-Chair of technical council DTU.

Abstract

Bankruptcy in future would lead to heavy losses, and attempts should be made to reduce it and prevent such a loss in advance. Potential misclassification of potential and futurist bankruptcy can be referred to as an audit failure. Predicting bankruptcy for different users, including investors, auditors, creditors and regulators, is essential. Various prediction models have been considered in other studies, and this research study includes multiple techniques like random forest, ANN, and logistic regression. The main reason behind the prediction of financial distress is that it will help ensure an increase in compatibility with the decision-making process. In this study, 1111 companies were considered liquidated and restructured by NCLT since its inception, i.e., 2016. Of these, 342 companies had their resolution plan approved from 2017 to 18 till December 2023, while 769 companies were liquidated. The selected companies' financial information has been considered for the last five years, and machine learning (Random forest, Artificial neural network) and traditional models (Logistic regression) have been used to predict the outcome of the firm (in terms of bankruptcy or restructuring) with their respective level of accuracy. The study, firstly, reveals that machine learning models have better predictive accuracy than statistical models. Secondly, the model's predictive accuracy is highest near the year/event of distress; as we move further from the year of liquidation/restructuring, the accuracy declines. Thirdly, financial variables and firm-specific characteristics have better precision and accuracy than only assessing the firms based on economic parameters.

1 Introduction

Bankruptcy exerts a detrimental impact on any corporation. Various methodologies can predict bankruptcy, which is crucial for diverse users, including investors, auditors, creditors, and regulators. Future bankruptcy could result in substantial losses, necessitating proactive measures to mitigate and preempt such losses. Misclassification of potential and future bankruptcy could lead to allocating scarce financial resources to inefficient firms, further leading to the erosion of public finance. Consequently, there is a need to enhance the accuracy of bankruptcy prediction. Techniques need to be developed to ensure stakeholders derive certain benefits.

Business failure is not an abrupt outcome or event; it is a process where firms undergo various stages of financial distress before liquidation or being declared bankrupt. This underscores the importance of early detection signs, enabling management to take corrective actions and avert failure. Intuitive credit risk management benefits all stakeholders: lenders, management, shareholders, investors, and regulators. Basel III norms re-emphasise the importance of credit risk management by developing credit risk models, which would, in turn, lead to decreased delinquencies in bank loans and Non-performing assets (NPA). Early warning models are widely used to evaluate a company's financial health; however, this analysis should be contextualized within value creation, which is the primary objective of firms operating in capital markets. Conservative corporate strategies are often viewed as safer, lowering both risk and returns, whereas aggressive strategies are associated with higher levels of risk and returns, as indicated by models like the Altman Z-Score (Bolek & Gniadkowska-Szymańska, 2023).

While there is existing literature on predicting financial distress, there remains a need to reevaluate the models used for such predictions. Credit risk models, which have been used interchangeably for insolvency and bankruptcy prediction and financial distress prediction (Gepp et al., 2010), initially employed Logistic regression (LR) for distress prediction. However, with Artificial Intelligence techniques such as Artificial neural networks and Support vector machines, predictive modelling has become a crucial tool for decision-making (Abu-Mostafa, 2001).

This research contributes to developing financial distress prediction models by utilising parsimonious information, including financial ratios derived from the economic data provided by firms. The quantitative variables considered include leverage, liquidity, and corporate profitability. Various prediction models have been explored in different studies; this research incorporates techniques like Decision trees, Random forests, and Artificial neural networks (ANN) and conducts a comparative analysis with the traditional method of Logistic Regression. The study has been performed on 1111 firms that were under financial distress and were liquidated or underwent restructuring through NCLT from 2017 to 2023.

The trade-off theory posits that firms must balance the costs and benefits associated with debt usage. Key advantages of debt financing include the interest tax shield, reduced financing costs, and preservation of ownership structure, while the associated costs encompass bankruptcy expenses and the likelihood of

financial distress. This necessitates robust credit risk management by lenders and financial institutions (Suresh et al., 2023). Credit risk management is of utmost concern in India, also due to the alarming rate at which the NPAs have risen over the last several years. This led the Central bank, i.e. The Reserve Bank of India, to develop various schemes to reduce the exposure of commercial banks to ever-escalating issues of NPAs. Corporate debt defaults were governed by different laws and regulations before 2016, like the Sick Industrial Companies Act (SICA), 1985, Debt Recovery Act, 1993, Corporate Debt Restructuring (CDR), Strategic Debt Restructuring (SDR), Securitization and Reconstruction of Financial Assets and Enforcement of Security Interest Act (SARFAESI), 2002 and Company Law, 2013 (amendments to Companies Act). These laws and regulations failed to solve the banks' twin balance-sheet problem, which led to the conversion of standard assets (loans) of the banks to sub-standard assets and finally into NPAs. The continuing increase in the number of NPAs has advocated the implementation of a uniform code to recover and resolve stressed assets. Insolvency and Bankruptcy Code (IBC) was implemented in India in 2016. As per IBC 2016, companies undergoing financial distress can approach the National Company Law Tribunal (NCLT), the legal body that would appoint insolvency professionals (IP) to manage the process. The result would be either restructuring the stressed assets or liquidating the company under trial. (Gupta, 2022).

This study evaluates the predictive ability of Logistic Regression and two machine learning models (Random Forest and Artificial neural network). The purpose is to find a suitable model for predicting whether a company can be restructured or needs to be liquidated so that the misclassification can be eliminated. The main reason behind this is that stakeholders need to decide while classifying firms that are financially distressed and are potential candidates that could face bankruptcy in future. This would ensure an increase in compatibility towards the decision-making process.

The analysis indicates that predictive accuracy is enhanced when firm-specific characteristics, such as age, industry, and size, are incorporated alongside financial variables. Among the models evaluated, Random Forest demonstrated the highest efficacy in predicting financial distress, followed by neural networks and logistic regression, suggesting that machine learning models generally surpass traditional statistical models for this application. Additionally, company size was identified as a significant determinant of distress outcomes, with smaller firms being more susceptible to liquidation, a finding consistent with prior studies by Almaskati et al., (2021) and Sehgal et al., (2021). Furthermore, the predictive accuracy of all models declined as the forecasting horizon increased, a trend similarly reported by Charalambakis and Garrett (2019) and Sehgal et al., (2021). Key financial variables contributing to distress prediction include Profit After Tax as a percentage of total income, Return on Assets, and Interest Coverage.

The rest of the paper proceeds as follows: Sect. 2 reviews the literature, Sect. 3 describes the study's objective, Sect. 4 highlights the data and methodology, and Sect. 5 provides the results and discussion. Finally, Sect. 6 concludes and provides the scope for future research.

2 Review of Literature

2.1 Studies Employing Statistical Model for Predicting Distress

Since the 1960s, many types of research have focused on companies that have become bankrupt. "Insolvency" refers to a company's financial situation when it finds it difficult to generate successful performance to satisfy the liabilities. The companies conduct financial analyses to ensure long-term viability. The study warns about potential risk and solvency issues by analysing a company's financial performance through its liquidity, financial stability and creditability. Many studies have been conducted in different fields to adapt the insolvency prediction model for businesses in other sectors. Research has been conducted to predict the solvency of various firms. The previous researchers incorporate both financial and non-financial aspects in computation. Studies mainly focus on financial ratios derived from financial reports instead of non-financial elements like a firm's age or management expertise.

In many published studies, financial ratios have been used to forecast solvency. Beaver (1966) analysed thirty ratios split into six groups. The ratio was chosen from different groups, which specified various solvency problems like current ratio, total debt/ cash flow, etc. Altman (1968) used the Z-score model to predict financial bankruptcy. The study used different variables estimated using a balance sheet and income statement. Z-score models indicated the probability of avoiding failure. The variables considered for evaluating the firms' financial conditions were coverage, activity, leverage, profitability and liquidity (Altman et al., 2010). Zmijewski (1984) developed a weighted probit model for predicting bankruptcy. Hopwood et al. (1994) noted that financial distress is related to a probability of going bankrupt. Rather than using a multiplicity of various financial ratios used in previous research, this study is based on specific models, including logistic regression, ANN, etc. Some earlier studies (DeFond and Jiambalvo, 1994) have considered a model incorporating various ratios that helped measure liquidity, solvency, and profitability. The author selected the model based on a quantitative measure named the Zmijewski score.

Various research studies have indicated the use of qualitative measures of financial distress. As per evidence provided in research studies by Gajpal et al., (1994), Gilson et al. (1990), Giroux and Wiggins (1984) and Turetsky (1997), there is use of negative operating cash flow, omitting or reducing dividend payment, debt default includes default in loan payments or technical default. Troubled debt restructuring has also been used to indicate financial distress before a firm goes bankrupt. The study has used qualitative variables as dummy variables.

John and John (1993) suggested that financial distress could progressively result in negative operating cash flows. Giroux and Wiggins (1984) consider negative cash flows signalling a decline in corporate financial status. In the study, Foster et al., (1998) mentions that any firm's cash flow provides vital information to the investors and helps evaluate the chances of economic distress. As per the author's opinion, negative operating cash flow implies a tendency towards

insufficient working capital and future cash position. This could lead to the survival of the firm in the long term.

Dielman and Oppenheimer (1984) noted that a firm's dividend decisions could be vital in identifying financially distressed firms. The authors mentioned in the study that firms generally follow a stable dividend policy when the firm is financially healthy. DeAngelo et al., (1994) contended that any firm facing financial problems could think of omitting or cutting dividends. Hence, dividend changes, mainly reductions in the amount of dividends, might predict financial distress. Dividend omissions or reductions were measured as dummy variables.

Chen & Church (1996) have mentioned that when a firm is about to fail, its financial ratios deteriorate. However, a clear indication of potential problems could lead to bankruptcy, and it becomes challenging to encounter debt obligations. It is not easy to comply with lending agreements and make scheduled payments. Additionally, when certain firms violate the debt covenants, the creditors might accelerate debt maturity and impose higher re-contracting costs on the lenders (Anandarajan et al., 2001). Further, any technical defaults would constrain the freedom of action while operating in the firm (Smith & Warner, 1979). When the firm defaults on the debt agreements and cannot provide a remedy through re-negotiation or doesn't get a waiver from the creditors, there is a higher chance of becoming bankrupt when the company defaults (Varadraj & Abhay, 2014).

Previous studies have regarded Troubled debt restructurings (TDR) as a distinct stage in the financial distress continuum (as mentioned by Giroux & Wiggins, 1983 and Turetsky, 1997). TDR results from various private debt renegotiations to resolve or remedy debt defaults (Anandarajan et al., 2001). As a result of TDR, current and future cash flows related to debt service might improve. TDR firms that are unsuccessful might end their bankruptcy. TDR could be considered a clear signal about financial distress, which could indicate bankruptcy.

As per Ooghe and Prijcker, (2008), lower financial independence, weaker profitability, increased expenses and lower cash flows were considered the critical solvency predictors. The study observed increased expenditure at constant turnover, which might help predict financial problems and inadequate professional competence for implementing decisions arising from various non–financial predictors. Bhimani et al. (2010) applied eleven financial ratios: financial coverage, capital/ total asset, investment ratio, days in payables and receivables, interest cost, financial coverage, solidity, gross income and return on equity. They have highlighted days and payables in receivables that determine the payment behaviour of creditors and debtors. In a study of Taiwan electronics market by Su and Huang (2010), firm failure prediction for Taiwan's electronics companies is conducted using the Logit regression model, the KMV option-based asset valuation model, and the ZPP GARCH autoregressive time series simulation model. It was concluded that the predicted failure probabilities are much larger using the Logit model than the other models.

Al-Kassar and Soileau (2014) selected specific ratios based on assets and liabilities, and there was no credit interval for failure in prediction. The study indicated that the higher the profitability and other ratios, the lower the solvency risk. When this ratio is lower, the risk of solvency is high. Mironiuc et al., (2015) indicated that the current ratio, average collection, financial leverage, liquidity, financial expenses,

and other ratios indicated that factors were significant statistically in predicting the firm's solvency position. Liang et al., (2016) have used ratios like cash flow, growth, turnover, profitability, solvency, and capital structure to assess bankruptcy. The study observed profitable and solvency ratios as the most significant ratios to predict solvency.

2.2 Studies Employing Machine Learning to Predict Distress

In the current times, machine learning (ML) is considered to be a cross between Computer Science and Statistics. Artificial INTELLIGENCE (AI) has been constantly improved, and big data is easily accessible in different sectors. The computation cost has been reduced, and people can use AI in the best way possible. AI's evolution directly impacts the technology market, mainly the firms related to AI (Lu et al., 2018).

Network structures with more robust mapping capacity could manage the interaction between non-linear associations and variables. Artificial neural networks (ANNs) are a solution for different Machine learning (ML) models. They are used in the financial sector to predict exchange rates, financial distress, credit scoring, and portfolio management.

Among the early studies, Henley and Hand (1996) used the k-nearest neighbour (k-NN) algorithm to assess the customer's ability to pay loans. Galindo and Tamayo (2000) performed a comparative examination of machine learning and statistics to determine mortgage loan defaults. They concluded that the best estimates were provided by CART Decision trees, followed by neural networks and k-NN.

Anandarajan et al., (2001) used an artificial neural network to predict the bankruptcy of financially distressed firms. They used the Zmijewski distress score, which incorporates ratios measuring profitability, liquidity, and solvency.

Yeh and Lien (2009) examined the forecasting accuracy of a few data mining techniques and observed that artificial neural networks (ANN) estimated the default more accurately than the other models.

Decision trees were used by Gepp et al., (2010) to predict business failure, and they observed that decision trees were far superior to traditional discriminant analysis. Similarly, Bhandari and Iyer (2013) used ratios on 50 failed and 50 non-failed US firms. They concluded that discriminant analysis was a better predictor than the cross-validation approach adopted under the data mining technique. Li et al. (2014) evaluated distress and the effectiveness of financial ratios using data envelopment analysis and logistic regression on a dataset of Chinese enterprises. Their results confirmed the theory that using efficiency information improves prediction ability.

Morum and Roy (2013) employed seven financial ratios to predict corporate sickness in the Indian Steel industry. They developed the model using stepwise logistic regression and cluster analysis on 40 companies classified as sick and non-sick. The authors believed that stepwise logistic regression has a better predictive ability than the other methods.

In the study, Bapat & Nagale (2014) compared the predictive powers of three distinct distress models for Indian listed companies: discriminant, logistic, and neural

network. They opined that neural networks were the most accurate regarding precise classification.

Behr and Weinblat (2017) conducted another study using machine learning tools, logit regression, decision trees, and random forests. The study included German, French, Italian, British, Spanish, and Portuguese firms. They observed that distressed firms had a spiralling debt ratio, liquidity ratio, return on sales and return on assets, which were significant bankruptcy predictors.

Khemakhem and Boujelbene (2018) integrated financial and non-financial data to create a credit score model. Their research revealed that profitability ratios, repayment capability, and solvency are essential default indicators.

Addo et al., (2018) worked on binary classifiers using machine learning models to forecast loan default probabilities. They concluded that decision trees are more accurate than neural networks for predicting distress.

Shrivastava et al. (2018) predicted a corporate crisis for enterprises in India that did not have bankruptcy specifics. Based on their data, they argued that the Bayesian technique performed better in accuracy and predictive ability than the standard logistic model. In another study in the same year by Nair and Sachdeva (2016) on 574 Indian manufacturing companies classified as distressed and non-distressed, it was established that profitability and efficiency ratios were of utmost importance while predicting distress. Tang et al., (2019) used the random forest model to ascertain the credit card default risk for the firms involved in China's energy business. Their results indicated that the overdraft ratio and the amount of credit card costs significantly affect credit risk. De Paula et al., (2020) analysed data from a Brazilian credit union's loan transactions for credit risk. They established the superiority of the random forest technique in estimating credit scoring compared to logit regression. Shrivastava et al., (2020) employed logistic regression, random forest, and Ada Boost to predict bank failure. Ada Boost provided the highest level of accuracy when compared to the other approaches.

Golbayani et al. (2020) used four machine learning techniques deemed helpful in previous studies (bagged decision trees, random forest, support vector machine, and multilayer perceptron) on a dataset, and the results show that decision tree-based models perform better on the chosen datasets.

Recently, a study of 12,000 small and Medium enterprises concluded that the Random Forest algorithm had the highest prediction accuracy compared to Logistic regression and Artificial Neural networks (Malakauskas & Lakštutienė, 2021).

Gupta (2022) evaluated four machine learning models on the companies under IBC and revealed that random forest outperforms the other three techniques: Support Vector Machine, Decision tree and Logit model.

A study was performed to predict financial distress amongst Fintech companies by employing an artificial neural network model. The study pinpointed Return on capital, current ratio, quick ratio and debt-to-equity ratio as significant predictors of financial distress. (Halteh et al., 2024).

Alvi and Arif, (2024) undertook a thorough longitudinal analysis of non-financial firms in Pakistan and an extensive assessment of machine learning algorithms for predicting default risk. The lack of early warning indicators within the non-financial

sector contributes to insolvency and financial distress, which in turn adversely affects the economy and drives higher unemployment rates.

Most studies employing data mining techniques opine that machine learning models outperform statistical models in terms of discriminatory power and precision. It was also discovered that machine learning algorithms for credit distribution led to allocation to safer and larger borrowers, reducing lenders' losses.

The current study intends to bridge the gap in the existing literature by comparing the predictive accuracy of statistical models and machine learning models on companies under IBC to predict bankruptcy or reorganisation. It is imperative to develop specific models based on assessing the likelihood of defaulting on a counterparty. The financial institutions deal with counterparty default now and then, a tragic issue they face. The lenders, financial market players, and government should reduce counterparty defaults to protect the creditor's interest and restore a firm's sustainability. Financial Distress Prediction intends to solve problems by classification through financial ratios, which could describe a firm's current situation for a particular period. Also, there is a need to identify the economic and firm-specific factors that can serve as an early indicator of default.

3 Objectives of the Study

The current study caters to the following objectives-

- To predict whether the firm will become bankrupt or be restructured by NCLT based on the analysis of financial information in the form of financial ratios using Machine Learning Techniques and Statistical Techniques.
- To understand the key ratios that define the impending default
- To identify the impact of non-financial variables like age, size of the firm and industry group on the predicting default.
- To assess the predictive ability of model(s) years before the restructuring/liquidation.

4 Data and Research Methodology

This study is analytical in nature. It focused on analysing five years of data from 1111 companies.

Most published studies have used healthy firms as the control group. In this study, 769 companies were considered liquidated by NCLT since its inception, i.e., 2016, and 342 companies had their resolution plan approved from 2017 to 18 till December 2023. Table 1 shows the details of the companies included in the study's sample. The selected companies' financial information has been considered for five years before being liquidated or restructured. We used financially stressed firms admitted to NCLT as the sample of study to ensure increased compatibility to a realistic decision-making process as adopted by Anandarajan et al., 2001. This is because

Table 1 Year-wise data of restructured and liquidated companies (source-IBBI)

Year	No. of cases admitted in IBBI for restructuring	No. of restructured cases available in CMIE prowess	No. of cases admitted in IBBI for liquidation	No. of liquidated cases available in CMIE prowess	Total Number of distressed firms for which the data is available	Financial and Non-Financial data collected for the years
2016–17	Nil	**Nil**	23	**16**	16	2011–12 to 2015–16
2017–18	19	**7**	376	**158**	165	2012–13 to 2016–17

2021–22	144	**46**	231	**58**	104	2016–17 to 2020–21
2022–23	189	**72**	155	**20**	92	2017–18 to 2021–22
2023–24 (Till December 2023)	208	**98**	354	**65**	163	2018–19 to 2022–23

The bold text signifies the best out of all the values signifying the superiority of a model over the others based on that specific parameter

the Resolution Professionals have to decide to classify a financially distressed firm (rather than a financially healthy firm) as a potential candidate for bankruptcy.

The observations regarding 1111 companies for the past five years gave us 5555 firm observations, which were used to identify the key financial ratios that predict the outcome of economic distress.

Table 2 gives a snapshot of sample characteristics from various industries.

The industry classification is based on the National Industrial Classification (NIC) 2008, adopted by the Government of India to disseminate industry-wise economic data.

Table 3 Based on an extensive literature review, the financial ratios and the independent variables employed in the study.

The literature review shows that machine learning has been used to predict bankruptcy and credit risk management since the 1990s. Statistical tools, which relied more on assumptions of normality and linearity of data, gave way to machine learning techniques, which were data-driven, robust, and distribution-free (Gupta, 2022).

Statistical Techniques were predominant from the 1960s until the 1990s, with Multivariate discriminant analysis (MDA), proposed by Altman (1968), and Logit analysis (LA) being the prominent ones (Bellovary et al., 2007). Altman used six financial ratios from the companies' financial statements to measure risk, and since then, numerous studies have used the Altman MDA model. (Martin, 1977) Developed an early warning model predicting bank failure using Logit Analysis and compared it with Linear Discriminant Analysis.

In addition to these, Ohlson (1980), Jones and Hensher (2004), and Canbas et al., (2005) used more improved and innovative modelling techniques. Statistical

Table 2 Various industries to which the sample companies belong

S. no	Industry	No. of companies restructured	No. of companies liquidated	Total
1	Mining and Quarrying	01	Nil	01

Industry	Industry Group of the firm

techniques required fulfilling the assumptions about the data concerning normality and linearity. The researchers were required to define the structure of the model a priori and then estimate its parameters to fit in the data (Gupta, 2022).

Machine learning techniques appeared in the late 1980s as an alternative and an improvement over the statistical models (Bellovary et al., 2007). Machine Learning techniques are data-driven and tend to be more computationally based. Numerous papers have been published using various machine-learning techniques for distress prediction. They are non-parametric, and despite requiring more computational power, they have become the primary bankruptcy prediction method, outperforming statistical models (Clement, 2020). Machine learning models are good at classifying almost any variable selection method and are more robust to multicollinearity (Liang et al., 2015).

Since both statistical and Machine learning techniques have their own merits and limitations, the study employs one statistical technique and two machine learning techniques to identify the accuracy and performance of each method.

The study applies random forest, artificial neural network, and logistic regression models, which are used to predict the firm's outcome (in terms of bankruptcy or reorganisation)[1] With a certain level of accuracy.

The following techniques were used for data analysis:

- Random Forest (Machine Learning model)—This model is a supervised algorithm that creates a random forest. Many decision trees are combined to make a random forest. It is used in regression and classification problems. This structure is easier to understand, and its interpretation is straightforward. It has certain advantages: the tree structure is visualised, and there is no need for extensive data preparation for analysis (Aker & Karavardar, 2023). Also, the diversity is created by incorporating the benefit of double randomisation, where each tree is estimated based on a synthetic sample drawn randomly from an estimation sample (Klaus-Peter Hellwig, 2021)
- Artificial Neural network (Machine Learning model)—This model adopts the human brain system and can generalise knowledge for predicting future events. This model is used widely for optimisation support and prediction with a back-propagation algorithm (Alamsyah et al., 2021).
- Logistic Regression (Statistical technique)–This model emerged as the most suitable for handling situations wherein the dependent variable is classified or categorical. It helps in determining cause-effect relationships with certain explanatory variables. The prediction in this model is made using equations. This model is focused on finding an equation that would minimise the difference between the dependent variable's actual value and the independent variable's predicted value (Özdamar, 2002). Cross-validation and stratified sampling techniques were adapted to conduct the modelling as specified by Japkowicz and Shah (2011).

4.1 Data Pre-processing

Machine learning models follow the Garbage in, Garbage out (GIGO) principle (Arora & Saurabh, 2022). Therefore, the data must be preprocessed before the modelling stage for accurate results. Preprocessing required dealing with an imbalanced dataset, as the liquidated firms were dominant in number, and spreading the sample to enable random selection of instances. SMOTE, spread subsample, and randomise filter were used to deal with this.

Ten sets were randomly created using 10-fold cross-validation, with 100 iterations performed to get the best results. Cross-validation is a technique for evaluating model performance on unseen data.

[1] Bankruptcy and Liquidation have been used interchangeably.
Restructuring and reorganisation have been used interchangeably as reorganisation is financial restructuring.

4.2 Optimisation Parameters for Model

The study is based on machine learning models that must be tuned for optimum results. Optimizing the hyperparameters to achieve the best possible model architecture is often necessary to implement machine learning algorithms successfully (Beniwal et al., 2023). The hyperparameter optimisation for the machine learning models is as follows-

1. Random Forest—The default batch size was 100, the number of iterations remained the same, and the seed's initial value remained 1.
2. Neural Network—The neural network's learning rate was 0.3, and the batch size was 100. The hidden layers were set to half the sum of attributes and class.

4.3 Performance Evaluation Metrics

The study applied the performance evaluation metrics to evaluate the model's predictive and classification ability: the Confusion Matrix and its indicators, ROC (Receiver Operating Characteristics), and the Gini coefficient.

4.3.1 Prediction Performance (Confusion Matrix) and its Indicators

A confusion matrix gives valuable information about the classifier's performance by comparing actual and predicted classes (Balasubramanian et al., 2019).

A sample confusion matrix is provided in Table 4.

4.3.1.1 Sample Confusion Matrix The reorganised cases have been referred to as positive, and bankrupt cases have been referred to as unfavourable.

Classification accuracy rates calculated from the confusion Matrix as follows-

1. *Accuracy ratio (AR)*: It is the proportion of cases that have been correctly classified (positive or negative).

$$\text{Accuracy Ratio} = (\text{Npp} + \text{Nnn})/\text{Total Sample}$$

   where, Npp(Nnn) is the number of positive(negative) cases classified as positive(negative)
2. *Sensitivity*: It is the proportion of negative cases correctly classified as harmful.

Table 4 Sample Confusion Matrix

Predicted			
Actual		Positive	Negative
	Positive	TP	FN
	Negative	FP	TN

$$\text{Sensitivity} = \text{Nnn}/(\text{Nnn} + \text{Nnp})$$

where Nnn (Nnp) is the number of negative (negative) cases classified as negative(positive)

3. *Specificity*: It is the proportion of positive cases correctly classified as positive and is measured as follows-

$$\text{Specificity} = \text{Npp}/(\text{Npp} + \text{Npn})$$

where, Npp(Npn) is the number of positive(positive) cases classified as positive(negative)

4. *Precision*: is the proportion of correctly classified negative cases out of all those classified as harmful. It is measured as.

$$\text{Precision} = \text{Nnn}/(\text{Nnn} + \text{Npn})$$

where, Nnn(Npn) id number of negative(positive) cases classified as negative(negative)

5. *Type I and Type II errors*: Type I error is the proportion of negative cases classified as positive. In contrast, type II error is the proportion of Positive cases classified as unfavourable.

$$\text{Type I error} = 1 - \text{Sensitivity}$$
$$\text{Type II error} = 1 - \text{Specificity}$$

6. *Gini Coefficient*: The Gini coefficient is an essential tool for assessing the consistency in the results of a machine learning model. It is also the widely used index for validating credit scoring models. (Gupta, 2022).
   It is calculated as G=2(AUROC)–1

Classification rates calculated from the confusion Matrix provide information about assessing a classification model's accuracy and appropriateness. Out of all the parameters discussed above, the most important one from a decision-maker's perspective is the type I error. The reason is that the cost of classifying a negative case as positive far exceeds that of a positive case as unfavourable. For example, the losses to a bank from lending to a bankrupt firm (Type I error) are expected to be much higher than the losses from refusing to lend to a typical going concern, which are the foregone interest payments (Type II error) (Almaskati et al., 2021). It is worth mentioning, however, that the costs to society and the economy from Type II errors might be significant when suitable opportunities are systematically declined due to this error (Almaskati et al., 2021). Thus, error cost should be an essential criterion for model evaluation (Adnan Aziz & Dar, 2006).

4.3.2 Classification Power (Receiver Operating Characteristic (ROC) Curve) and Gini Coefficient

Apart from the confusion matrix and its accuracy rates for prediction ability, the ROC curve or Area under the curve (AUC) and the Gini coefficient are used as classification ability indicators.

The analysis uses the sensitivity (the percentage of default positive outcomes that have been correctly classified) v/s 1- specificity (the percentage of default adverse outcomes that have been correctly classified) to make the curve. The false positive rate is plotted on the horizontal axis, with the actual positive rate on the vertical axis. With this, we get the area under the ROC curve (AUROC) based on a particular model. The area ranges from 0.5 (for a worthless model) to 1 (for a perfect classifier). The larger the area under the curve, the better the model's classification ability.

The Gini Coefficient highlights the difference between a base classifier (taken as the default 0.5 for each class) and the classifier model in question.

5 Results and Discussion

The results indicate the output of a Machine Learning or statistical technique in the form of Accuracy Rate, Precision, Type I error and AUC. The output was generated by first including only financial variables and later incorporating firm-specific characteristics with the economic variables.

The analysis was spread over five years before the date of Liquidation/restructuring. Also, the study was carried out each year by including financial variables only and later on by including financial variables and firm-specific characteristics. It was observed that the accuracy rate was higher when firm-specific characteristics were included along with the economic variables to predict the financial distress outcome of the firm. Also, the accuracy declines as we move further away from the date of liquidation/restructuring. However, accuracy cannot be considered as the criteria for measuring the prediction accuracy of a model. According to (Hsieh, 1993). The cost linked with Type I error is higher for the stakeholders than the cost related to Type II error, so the best model is the one with the lowest Type I error.

The results of the various models one year before bankruptcy/reorganisation are given in Table 3. As we compare Panels A and B, we observe that the accuracy rate, precision, area under the curve (AUC), and Gini coefficient provide a better classification and prediction measure when the firm-specific characteristics are included with the financial variables. Out of the three models employed in the study, the Random Forest is the best bet in the distress prediction models as it has the lowest Type-I error. As per Anandarajan et al., (2001), "The objective of learning classifications from sample data is to classify and predict successfully on new data. A classifier's error rate is the most commonly used measure of success or failure. The error rate is statistically defined as the error rate of the classifier on an asymptotically large number of new cases that converge in the limit to the actual population distribution." For the analysis results, one year before the actual event of bankruptcy/restructuring, as shown in Table 5. It can be seen that type-I error is

Table 5 One year before Bankruptcy/reorganisation

Model	Accuracy rate	Precision	Type I error (1-sensitivity)	AUC	Gini coefficient
Panel A: Only financial variables					
Random Forest	**0.613**	0.586	**0.087**	**0.631**	**0.262**
Neural network	0.557	0.559	0.233	0.565	0.13
Logistic	0.543	0.543	0.146	0.518	0.036
Panel B: Financial variables and firm-specific characteristics					
Random Forest	**0.735**	0.711	**0.160**	**0.784**	**0.568**
Neural network	0.727	0.736	0.244	0.740	0.48
Logistic	0.718	0.708	0.204	0.764	0.528

The bold text signifies the best out of all the values signifying the superiority of a model over the others based on that specific parameter

lower in the analysis done when considering only financial variables. One reason for that could be that as the firm approaches bankruptcy or restructuring, the financial position of the firm, as exhibited in the financial statements, has already deteriorated to a great extent. An analysis of attributes using the attribute selector indicates that size, Return on Total Assets, and Interest cover are the significant attributes impacting the firm's failure. Thus, as the firm nears failure, the ability to pay the financial creditors becomes a major deciding factor in terms of the fate of the firm.

As we move further away from the date of liquidation and restructuring, we see (Table 6) that the accuracy rate of the model declines. Also, the probability of type-I error increases. This highlights that distress prediction is more accurate one year before liquidation/restructuring. Also, the attributes impacting the final decision concerning the firm's fate are size, and Gross fixed asset utilisation ratio. The size of the firm plays a significant role, and this follows the results as defined by Malakauskas and Lakštutienė, (2021) and Arora and Saurabh, (2022).

Table 6 Two years before Bankruptcy/Reorganisation

Model	Accuracy rate	Precision	Type I error (1-sensitivity)	AUC	Gini coefficient
Panel A: Only financial variables					
Random Forest	**0.577**	0.568	**0.164**	**0.617**	**0.234**
Neural network	0.557	0.581	0.414	0.604	0.208
Logistic	0.522	0.531	0.166	0.546	0.092
Panel B: Financial variables and firm-specific characteristics					
Random Forest	**0.736**	0.715	**0.166**	**0.789**	**0.578**
Neural network	0.723	0.729	0.241	0.745	0.490
Logistic	0.723	0.711	0.196	0.754	0.508

The bold text signifies the best out of all the values signifying the superiority of a model over the others based on that specific parameter

(1994) opine that a firm is in financial trouble if its Earnings before interest, tax, depreciation, and amortisation (EBITDA) are less than its expenses. Therefore, the current study examines three years before the firm is adjudicated to be liquidated or restructured and calculates the accuracy rate and other prediction and classification indicators.

As we look at the results of Table 7, we see better prediction accuracy and a lower type-I error. This signifies that the prediction based on financial variables and firm-specific characteristics was more accurate three years before the firm was declared bankrupt or eligible for restructuring.

Thus, it can be analysed that to predict a firm's financial distress, it is imperative to look into its performance as soon as it starts showing warning signals regarding low income and inability to pay operational creditors. Three years before the judgement of the distressed firms as bankrupt or restructured, the significant attributes/variables that are important are size and Profit after tax as a percentage of total income.

Early detection of a firm's movement towards failure in the early stages benefits business stakeholders. (Ashraf et al., 2019) In all the years of analysis, random forest emerged as a clear winner in predicting early distress and had the lowest Type I error, indicating its superiority over the traditional Logit model. This can be due to the fundamental difference between traditional statistical and Machine Learning models in handling data and making predictions. Statistical models, such as linear and logistic regression, are based on predefined assumptions about data distribution and variable relationships. These models are typically parametric, assuming a specific functional form (e.g., linearity) to define the relationship between input variables and the outcome. Statistical models are often effective with smaller datasets and perform well when the relationships among variables are well-understood. However, their predictive accuracy can be limited if data distribution assumptions are unmet. Here, the dataset comprises 1111 firms, which is a large dataset in terms of statistical models. On the other hand, Machine-learning models focus on flexible learning from complex, high-dimensional data, resulting in enhanced predictive capabilities. ANN

Table 7 Three years before Bankruptcy/Reorganisation

Model	Accuracy rate	Precision	Type I error (1-sensitivity)	AUC	Gini coefficient
Panel A: Only financial variables					
Random Forest	**0.607**	0.590	**0.153**	**0.665**	0.33
Neural network	0.591	**0.627**	0.437	0.653	**0.306**
Logistic	0.546	0.554	0.270	0.567	0.134
Panel B: Financial variables and firm-specific characteristics					
Random Forest	**0.729**	**0.709**	**0.174**	**0.782**	**0.564**
Neural network	0.701	0.707	0.259	0.739	0.478
Logistic	0.707	0.698	0.215	0.745	0.490

The bold text signifies the best out of all the values signifying the superiority of a model over the others based on that specific parameter

follows Random Forest, indicating the superiority of machine learning models over conventional prediction models. The study's results are similar to those reported by Gupta, (2022), Balasubramanian et al., (2019), and Sehgal et al., (2021).

6 Summary of Findings

The analysis indicates that predicting a firm's financial distress necessitates early detection through evaluating performance indicators, particularly when warning signs such as declining income and an inability to meet obligations to operational creditors become apparent. This would enable the firm to move towards sustainable measures in terms of innovation and creativity so as to deal with the ever-growing and dynamic business environment (Jain & Gupta, 2018; Sinha et al., 2009). The predictive accuracy of distress models improves considerably when firm-specific characteristics, including age, industry, and size, are incorporated alongside financial variables. Among the models assessed, Random Forest demonstrated the highest predictive efficacy, followed by neural networks and logistic regression, underscoring the superior performance of machine learning algorithms compared to traditional statistical models in forecasting financial distress. Firm size emerged as a particularly influential determinant, with smaller firms exhibiting a greater vulnerability to liquidation, consistent with prior findings by Almaskati et al., (2021) and Sehgal et al., (2021). Furthermore, the analysis revealed a decline in predictive accuracy as the forecasting horizon extended, aligning with observations by Charalambakis and Garrett (2019) and Sehgal et al., (2021). Key financial variables influencing distress prediction were profit after tax as a percentage of total income, return on assets and interest coverage. Notably, the cost associated with Type I errors exceeded that of Type II errors, emphasising the importance of models with minimised Type I errors. Finally, while statistical models offer interpretability through predefined relationships, machine learning models leverage flexibility in learning from complex, high-dimensional data, enhancing predictive capabilities.

7 Conclusion

Financial distress leads to significant economic losses for all stakeholders, making it imperative to identify early distress signals. It encompasses several adverse consequences, including reduced market share and reputational standing, increased capital costs, a withdrawal of favourable trade credit terms from suppliers, and losses associated with asset sales conducted under distressed conditions (Li, 2024). Additionally, financial distress often leads to the departure of valuable human capital and heightened exposure to aggressive strategies from competitors. This paper aimed to determine the predictive and classification ability of the traditional logit model with the machine learning models. It also aimed at determining the relative importance of the various attributes in predicting distress. Classic financial ratios proposed by Turetsky and McEwen, (2007), Altman et al., (2017) and Almaskati et al., (2021) were used, along

with the firm's specific characteristics, such as its age, size, and industry. A comparative analysis was done to identify the impact of including non-financial variables in the model.

The traditional logit model was compared to two machine learning models: Random forest and Artificial Neural network. The predictive ability of the three models was compared using the AUC under the ROC curve and the type-I error. The Random Forest model emerged as the clear winner, followed by ANN and the logit model, thereby highlighting the supremacy of machine learning models over traditional models. The analysis also identified the highest predictive ability years before the firm failed. It was found that three years before the liquidation/restructuring of the firm, the Random Forest model had the highest predictive accuracy and lowest error rate. It is also observed that all the models had a predictive accuracy greater than 75%, thus confirming their robustness.

The study involved the firms that were referred to NCLT, and to the best of our knowledge, it is the first paper using the database of only distressed firms as compared to an equivalent number of solvent firms in line with the study undertaken by Balasubramanian et al., (2019).

To predict financial distress, it is imperative to look into the firm's size and significant financial variables like Profit after tax as a % of total income, Return on assets and Interest coverage. This can aid the managers in assessing the economic health of their firms and serve as a significant indicator for the investors who are willing to invest in such firms. It can significantly contribute to the banking sector, helping them identify the default firms and save their balance sheets from the Non-Performing Asset (NPA) problem.

Further, the analysis can be extended by incorporating macroeconomic factors such as inflation, GDP growth, etc. Machine learning algorithms like Naïve Bayes can be used to perform sentiment analysis of other components of Annual reports like Management discussion and analysis (MD&A). A Naïve Bayes classifier assigns a probability to the word or text, whether positive or negative (Arora & Saurabh, 2022). A detailed industry-based study can also be undertaken to predict specific patterns of financial distress in the Indian economy. This study included all companies restructured or liquidated by the NCLT, regardless of their industry. An industry-specific analysis, however, could provide more comprehensive insights and yield more robust results. The study is based on the financial ratios derived from CMIE Prowess. Also, the missing ratios, which are irrelevant and can't be computed for a particular industry, were imputed by the machine-learning software WEKA based on the median values. Such adversities can be handled when the study concerns a particular industry.

Abstract
Penicillium oxalicum PBG30 produced an extracellular phytase in solid-state fermentation and maximum production was obtained (200 ± 6.01 U/g DMR) at 30 °C after 5 days. The optimal temperature and pH for enzyme were 70 °C and 3.0, respectively. The phytase is thermostable with $T_{1/2}$ of 1 h at 70 °C and showed broad-substrate specificity with K_m and V_{max} values of 4.42 mM and 909.1 U/ml, respectively with calcium phytate. Phytase activity was enhanced in the existence of metal ions and surfactants and retarded by SDS, EDTA, sodium molybdate, DTT, and ß-ME. Phytase exhibited resistance against trypsin and pepsin with better storage stability at 4 °C and −20 °C. Insoluble phytates (metal and protein) were efficiently hydrolyzed by fungal phytase showing liberation of inorganic phosphate in a time-dependent manner. Also, the phytic acid reduction was observed in phytase-treated fish feed with the lowest phytic acid occurring in a diet supplemented with 1500 FTU/kg dose of phytase. Furthermore, phytase was converted into vanadium-dependent peroxidase. Fungal phytase, due to its thermostability, protease resistance, broad substrate specificity, and ability to hydrolyze phytate forms, has the potential to serve as an additive for improving nutrient digestibility in the food and feed industry.

Keywords Phytase · *Penicillium oxalicum* · Thermostable · Protease-resistant · Insoluble phytates · Fish feed · Haloperoxidase

Introduction

Phytase is a well-known feed enzyme in today's world that hydrolyses the phytic acid into lower esters of myo-inositol and inorganic phosphate. It also releases other phytate-associated nutrients necessary for the organisms [1]. Phytic acid or phytate is a precursor of organic phosphorus and is predominantly present in the plant's seeds. Phytate, the complex form of phytic acid binds metal ions, amino acids, proteins, digestive enzymes, and other biomolecules. Due to the chelation property, phytate acts as an anti-nutritive factor [2]. Phytic acid can be reduced by physical and chemical methods which decreases the nutritive value, hence enzymatic action (phytase) is required for the degradation of phytic acid [3]. In ruminant animals, phytase is found in the microbes of the gut region while it is absent in monogastric animals [4]. Since monogastric animals lack phytase in the digestive tract, phytate molecules accumulate inside the body and are excreted out in the soil via fecal matter [1]. In the soil, various phytase-containing microbes are present that break phytate molecules and liberate phosphorus which goes to water bodies by run-off or leaching [5]. The released phosphorus forms algal blooms that lead to eutrophication and phosphorus pollution in water. Therefore, supplementation of phytase in monogastric animals as a feed additive is

requisite for their growth and development. Phytase ameliorates the nutritive value of feed and also reduces the level of phosphorus in the environment thus minimizing water pollution. It also limits the need for inorganic phosphorus and therefore restricts the load on non-renewable rock phosphate [4]. Although phytase enzymes have been reported from many microorganisms (bacteria, fungi, yeasts) they are still lacking in fulfilling the properties of an ideal phytase [6]. Thermostable, protease-resistant, broad pH range, substrate-specificity, long shelf life, and cost-effectiveness are the properties of an ideal phytase. The commercially available phytases either lack one or more features of an ideal phytase [4]. Therefore, the necessity of an ideal phytase in the industries is continuously increasing.

Solid-state fermentation (SSF) is the most widely adopted cost-effective method that uses agricultural waste as a substrate and reduces its accumulation. SSF is a simple process to operate and maintain for fungal enzyme production. It requires less water, minimal oxygen supply and less energy, while producing higher yields compared to other fermentation methods. The parameters used in the SSF significantly influence microbial growth and enzyme production, making the selection of appropriate physio-chemical factors a critical aspect [7]. Purification and characterization are important aspects that demonstrate the properties of phytase enzyme and thus need to be studied. Purification includes precipitation and dialysis followed by chromatography techniques [8]. Purification and biochemical characterization of phytase from various fungal species have been reported in the literature [9–15].

Phytic acid or phytate complexes are commonly present in plant-based food and feed ingredients which are insoluble in the GIT pH of monogastric animals. Consequently, monogastric animals are unable to utilize certain nutrients, resulting in nutrient deficiencies that can lead to malnutrition and severe health complications. The addition of phytase to the diet releases bounded nutrients and ameliorate the nutritional quality of the food and feedstuffs [16]. The application of phytase in lowering phytic acid amount has been studied in poultry feed ingredients [15], and wheat flour [12, 15, 17]. Also, the liberation of inorganic phosphate, reducing sugar and protein content was observed along with the reduction of phytic acid [16–18].

Phytase can act as haloperoxidase when vanadate is incorporated with phytase. Vanadium is an analog of phosphate molecules and an inhibitor of acid phosphatase. It binds to the active site of histidine acid phosphatase (HAP)-phytase and converts it into peroxidase. Vanadium haloperoxidase is similar in structure to phytase except for the presence of vanadate instead of phosphate. This semi-synthetic haloperoxidase is involved in various catalytic oxidative reactions [19, 20].

The present study deals with the production of extracellular phytase obtained from *Penicillium oxalicum* PBG30 using agricultural waste during the SSF method followed by the biochemical characterization to determine the properties of phytase. The involvement of phytase in hydrolysing insoluble metal- and protein-phytate complexes commonly found in food and feed ingredients as well as its role in degrading phytic acid in the fish feed, was studied to assess its potential as an additive in the food and feed industry. Additionally, the conversion of phytase enzyme to semi-synthetic haloperoxidase using vanadium was examined.

Materials and Methods

Culture Conditions

Penicillium oxalicum PBG30 was cultured on the potato dextrose agar (PDA) media at 30 °C and maintained at 4 °C on PDA slants, and also at − 20 °C in glycerol stock. The fungal spores were scrapped from 72 h old culture via a sterile loop by adding 25 ml normal saline solution containing 0.1% Tween 80 and the spore count was estimated by a hemocytometer and 1 ml of spore suspension (7.7×10^7 CFU/ml) was used as inoculum for the production of phytase [18, 21].

Phytase Production in SSF

Ten gram of wheat bran was used with 20 ml production medium of pH 7.0 consisting 0.5% Urea, 0.1% $MgSO_4.7H_2O$, 0.1% KCl and 0.1% $FeSO_4.7H_2O$ [22]. The medium was autoclaved for 20 min at 121 °C and then allowed to cool at room temperature. One ml of spore suspension was added and incubated for 5 days at 30 °C. The culture filtrate was extracted and centrifuged at 10,000 rpm for 10 min at 4 °C. The phytase activity was calculated from the supernatant using phytase assay [18, 21].

Phytase Assay

Phytase activity was calculated by estimating the liberation of inorganic phosphate from the calcium phytate substrate at 70 °C with 0.1 M sodium acetate buffer (pH 3.0) through the Fiske and Subbarow [23] method [18]. Each 1.0 ml reaction mixture contained 0.5 ml substrate dissolved in buffer and 0.5 ml enzyme diluted with buffer. Blank and control (substrate and enzyme) were also prepared during the experiment and performed in triplicate. The substrate control consisted of 0.5 mL substrate with 0.5 mL buffer, while the enzyme control consisted of 0.5 mL enzyme with 0.5 mL buffer. The tubes were incubated for 5 min at 70 °C in a water bath. Following this, 1.0 mL of TCA, 1.0 mL of distilled water, and 0.5 mL of 9 N H_2SO_4 were added, and the tubes

were incubated for additional 10 min at room temperature. After incubation, 0.5 ml of ammonium molybdate (6%) was added and the tubes were kept for 15 min in the dark. Then, 0.5 mL of freshly prepared $FeSO_4$ was added and the tubes were kept for 30 min in the dark. The absorbance was measured at 660 nm [23]. Phytase activity was calculated using the regression equation derived from the standard curve of KH_2PO_4 [25]. One unit indicates the amount of phytase used to liberate 1 nmol of inorganic phosphorus per sec under assay conditions [24]. The phytase activity is expressed as a unit per gram of dry mouldy residue (U/g DMR).

Biochemical Characterization of Phytase

For characterization, the enzyme was concentrated using ammonium sulphate precipitation method. The crude enzyme solution was placed in a beaker and stirred using a magnetic stirrer. Ammonium salt was added slowly to the extract until it reached 80% saturation. The entire procedure was conducted at 4 °C, followed by overnight incubation to allow the precipitated enzyme to settle. The sample was centrifuged at 10,000 rpm for 10 min at 4 °C and the pellet was re-suspended in 0.1 M sodium acetate buffer (pH 3.0). Dialysis was then carried out at 4 °C. A suitable length of dialysis membrane was cut and pre-treated to activate it. After cooling, the membrane was filled with the precipitated enzyme and tied at both ends. The dialysis bag was submerged in 20 mM sodium acetate buffer (pH 3.0) and kept on a magnetic stirrer at 4 °C. The buffer was changed at least three times. After dialysis, the sample was centrifuged at 10,000 rpm for 10 min at 4 °C. The supernatant was collected and the pellet discarded. The clear supernatant was used for characterization studies [9].

Effect of Temperature on the Activity and Stability of Phytase

To determine the optimum value of temperature, a phytase assay was carried out from 30 °C to 80 °C in 0.1 M sodium acetate buffer (pH 3.0) with 1 mM calcium phytate. To investigate the thermostability of phytase, the enzyme was incubated at 70° and 80 °C in a buffer of pH 3.0 for 2 h. Samples were collected at regular intervals and the assay was performed at 70 °C (pH 3.0) [9, 18].

Impact of pH on the Activity and Stability of Phytase

To evaluate the optimum value of pH, phytase enzyme activity was studied at 70 °C with a buffer of different pH range 2.5—8.0 (0.1 M glycine–HCl buffer pH 2.5, 0.1 M sodium acetate buffer pH 3.0—6.0, 0.1 M tris–HCl buffer pH 7.0—8.0). For assessing the pH stability of phytase, the enzyme was dissolved in pH (3.0, 5.0) and incubated at 70 °C. Samples were collected at 0, 5, 10, 30, 60, and 120 min interval and the assay was performed at 70 °C (pH 3.0) [9, 18].

Determination of Substrate Specificity and Kinetic Constants

The specificity of phytase towards different substrates, viz, sodium phytate, calcium phytate, glucose-6-phosphate, p-nitrophenyl phosphate, adenosine triphosphate (ATP), adenosine diphosphate (ADP), and adenosine monophosphate (AMP) was examined. The phytase assay was performed at 70 °C with a pH 3.0 and 1 mM substrate concentration, using calcium phytate as the substrate, with its activity considered as 100%. The kinetic parameters (K_m and V_{max}) were evaluated from the Lineweaver–Burk plot by using different concentrations of calcium phytate (0.1—2 mM) and the assay was conducted at 70 °C (pH 3.0) [9, 18].

Effect of Organic Solvents, Detergents, Metal ions, and Inhibitors on Phytase Activity

The experiments were performed to determine the influence of organic solvents (ethanol, methanol, butanol, propan-2-ol, acetone, DMSO) and detergents (SDS, Tween-20, Tween-60, Tween-80, Triton-X) on phytase activity. In the reaction mixture, different concentrations of organic solvents (2 and 5%) and detergents (0.1 and 0.5%) were added [9].

Similarly, the effect of metal ions and inhibitors on phytase activity was analyzed by providing different metal ions (Ca^{2+}, Co^{2+}, Cu^{2+}, Mg^{2+}, Mn^{2+}, Fe^{3+}, Fe^{2+}, Na^{+}) and inhibitors (sodium azide, EDTA, sodium molybdate, ß-ME, DTT) with 1 mM and 5 mM concentrations in the reaction mixture.

The enzymatic assay was performed along with the control. The control value is taken as 100% having no additional chemical [9, 26].

Effect of Proteolytic Enzymes and Storage Conditions on Phytase Activity

The phytase enzyme was treated with 1% (w/v) trypsin and pepsin for 2 h at 37 °C. The samples were taken at the desired interval (0, 30, 60, 120 min) and a phytase assay was performed [18, 25]

Phytase was kept for 6 months in different conditions (room temperature, 4 °C, −20 °C), and activity was determined at the desired interval. Activity on the 0 th day is considered 100% [9].

Hydrolysis of Insoluble Phytates

Metal phytates (Ca^{2+}, Co^{2+}, Mg^{2+}, Mn^{2+}, Fe^{2+}, Cu^{2+}, Zn^{2+}) were formed by mixing each metal ion along with sodium phytate. 100 mM stock solution of metal ions ($CaCl_2{\cdot}2H_2O$, $CoCl_2{\cdot}2H_2O$, $FeSO_4{\cdot}7H_2O$, $MgCl_2{\cdot}6H_2O$, $MnCl_2{\cdot}4H_2O$, $ZnCl_2{\cdot}7H_2O$) and 10 mM of sodium phytate were prepared in distilled water separately. Both were mixed in equal volume and kept at 4 °C for overnight incubation. The precipitated salts were centrifuged at 10,000 g for 5 min at 4 °C. The supernatant was discarded and the pellet was washed three times with distilled water, and finally suspended in 5 ml of 0.1 M Na-acetate buffer (pH 3.0). Each phytate salt was treated with 20 U of phytase and incubated at 37 and 50 °C. Samples were taken at different intervals (3, 6, 12, 24 h) and salts were pelleted by centrifuge. The supernatant was used to determine the amount of released inorganic phosphate at 600 nm [25]. The protein-phytate complex was made by adding an equal amount of lysozyme (2.5 mM) in distilled water and sodium phytate (3 mM) in distilled water and kept overnight at 4ºC. Centrifuge the solution at 10,000 g for 5 min at 4ºC and discard the supernatant. Washed the pellet three times with distilled water, dissolved in buffer and 20 U of phytase was added into it. The reaction was incubated at 30ºC and samples were collected at defined intervals (0, 5, 10, 30, 60, 120, 360 min). Centrifuge the sample and inorganic phosphate was estimated in the supernatant at 600 nm [25].

Phytic Acid Reduction in Fish Feed Using Fungal Phytase

The formulation of the feed sample is mentioned in Table 1 containing 35% protein in the diet. Different doses of phytase were added to the feed ingredients (500 FTU/kg, 1000 FTU/kg, 1500 FTU/kg). The pellet of different diets was formed with the help of pelletizer. The determination of phytic acid in the phytase-treated and untreated feed pellet was performed by Gao et al. [27] method. Firstly, the sample was treated with 10 ml of 2.4% HCl and kept on a shaker for 16 h at 220 rpm. Centrifuge the sample for 20 min with 10,000 rpm at 10 °C and the obtained supernatant was shifted to falcon consisting of 1 g NaCl. Again, the mixture was shaken at 350 rpm for 20 min so that salts dissolved completely and settled by keeping it at 4 °C for 60 min or −20ºC for 20 min. After that, centrifugation was done at 10,000 rpm for 20 min. The supernatant was used to estimate the phytic acid content by adding 500 µl Wade's reagent (containing 0.03% ferric chloride and 0.3% sulfosalicylic acid) and kept for 20 min incubation. The absorbance was taken at 500 nm [20, 28]. The quantity of phytic acid in the diet was calculated through the regression equation of the standard curve of sodium phytate.

Transformation of Phytase into Haloperoxidase

Phytase was mixed with ammonium metavanadate (5 and 10 µM) and incubated at 30 °C for 4 h with 100 rpm. H_2O_2 and guaiacol were added to the solution and absorbance was recorded at 470 nm for each minute up to 10 min [20]. The relative activity of phytase was also calculated during the experiment.

Statistical Analysis

All the experiments were carried out in triplicate. The values were reported as the mean and standard error (mean ± S.E). The significance level was determined using a t-test and is expressed as a p-value. IBM SPSS Statistics software is used for the statistical analysis. Sigma plot (version 10.0) is used for creating the graphs.

Results and Discussion

Phytase Production in SSF

SSF is the commonly used approach nowadays for the production of enzymes. In this process, microbes are grown on a solid substrate in either the absence or a low amount of water [2]. The agricultural waste or residues are commonly utilized as a solid substrate that makes the production cost-effective and also resolves the issues that occur due to their accumulation [29]. SSF has been utilized by various fungi for the production of phytase [10, 16, 24, 30, 31]. The highest amount of phytase production was achieved (200.41 ± 6.01 U/g DMR) with 10 g wheat bran moistened with

Table 1 Composition of the control and experimental diets

Feed ingredients (g)	Diet I (control)	Diet II	Diet III	Diet IV
Soybean flour	181.57	181.57	181.57	181.57
Wheat flour	118.40	118.40	118.40	118.40
Fish oil	3.00	3.00	3.00	3.00
Vitamins and minerals	1.20	1.20	1.20	1.20
Phytase	-	500 FTU/kg	1000 FTU/kg	1500 FTU/kg

media (0.5% Urea, 0.1% $MgSO_4.7H_2O$, 0.1% KCl and 0.1% $FeSO_4.7H_2O$) in 1:2 ratio of pH 7.0, incubated at 30 °C for 5 days. The other fungal strains that produced phytase were *A. oryzae* (506.12 U/g DMR) [20], *A. awamori* NRC- F18 (437.195 ± 7.16 IU/g) [35], *A. niger* NT-7 (208.30 ± 0.22 U/g DMR) [16], *P. adiposa* (24.48 0.3 U/gds) [30]. These variations in phytase levels occurred due to the utilization of different fungi, substrates, production media, and fermentation conditions. Among the various substrates used for the SSF method, wheat bran is commonly used because it is rich in carbon, nitrogen, amino acids, and a high amount of phytic acid [32]. Due to the presence of phytate, it acts as an inducer for the production of phytase [33]. It is easily available, has a low cost, and provides support to the growth of fungi [16, 34]. The involvement of wheat bran in the production of phytase has been mentioned in various studies [16, 31, 35].

Biochemical Characterization of Phytase

Partial purification of *P. oxalicum* phytase was done by ammonium sulphate precipitation followed by the dialysis method. The crude sample expressed the lowest specific activity (0.31 U/mg) with a total enzyme activity of 381.57 U. After 80% ammonium sulphate precipitation, the sample showed 357.48 U activity with 1.23 U/mg specific activity. Further, the dialyzed sample exhibited 1.52 U/mg specific activity with total enzyme activity (211.04 U). The dialyzed enzyme was purified to homogeneity with 4.9-fold and a yield of 55.31%. Further, purification by column chromatography was omitted to make the process cost-effective. The phytase isolated from *A. niger* CFR 335 reported yields of 66.8% with a 4.1-fold and 71.9% with a 2.7 purification fold following the precipitation and dialysis methods, respectively [36]. Similarly, Saxena et al. [12] found 1.42-fold purification after the dialysis of *A aculeatus* APF1 phytase with a 25.54% yield. The phytase obtained from *T. purpureogenus* NSA20 was concentrated by precipitation and dialysis methods exhibiting yields of 39.8% and 11.9% with 2.6 and 5.9 purification folds, respectively [14]. Table 2 demonstrate the comparison of biochemical properties of phytases isolated from different fungi.

Effect of Temperature

During food and feed processing, enzymes have to face extreme temperatures, therefore they must be resistant to high temperature. The *P. oxalicum* phytase exhibited more than 80% activity at the temperature ranging between 55 to 80 °C (Fig. 1a), however, the optimal activity was recorded at 70 °C, showing its survival at high temperature. In other studies, the optimal activity of fungal phytases was observed between 30 and 65 °C [9, 12, 24, 28, 36, 41–45]. Ajith et al. (2019) found maximum activity of *A. foetidus* MTCC 11682 phytase at 37ºC [37]. However, the phytases obtained from *A. niger* BIONCL8 [15], *P. oxalicum* [38], and *A. fumigatus* exhibited optimal activity at 40ºC [11] while the phytases isolated from *R. oligosporus* MTCC 556 exhibited optimal activity at 50ºC [39], *A. fumigatus* at 55ºC [17], *A. niger* 7 A-1 at 56ºC [10] and *A. niger* NT7 at 60ºC [16].

The thermostability of phytase is studied at 70° and 80 °C. The *P. oxalicum* phytase is found thermostable at 70 °C with half-life of 60 min, while at 80 °C the phytase lost 70% activity within 60 min (Fig. 1b). However, the studies carried out on the *A. niger* BIONCL8 showed that it lost 70% phytase activity [15], and *A. fumigatus* lost 86% phytase activity [11] within 1 h at 80 °C. In the case of *A. niger* 7 A-1, only 9.3% activity is left after 5 min of incubation at 80 ºC [10] and *A. oryzae* retains only 4.2% phytase activity after 1 h [40]. A reduction in the phytase activity of *A. fumigatus* was observed after 1 h at 70 ºC [11]. In another study, phytase obtained from *A. fumigatus* showed 90% activity after 20 min while exhibiting more than 50% at 2 h [17]. The thermostable half-life of *A. oryzae* phytase was found at 300 min at 50 °C [9], while at 70 ºC phytase lost its activity within 100 min [24]. In the case of *P. oxalicum,* > 70% of activity was lost within 10 min [38].

Effect of pH

pH is a critical parameter that influences enzyme activity by changing the ionic composition in its microenvironment. The phytase is active in the acidic range (2.5–5.0) and found optimum at pH 3.0 (sodium acetate buffer) during the assay. The stomachs of humans and animals are acidic because their pH range between 1.5–3.5, therefore, the phytases active at this acidic pH are considered useful in the food and feed industry. Likewise, *A. aculeatus* APF1 [12], and *A. niger* [41] exhibited the optimum pH at 3.0. In contrast, neutral pH is mentioned in *P. oxalicum* EUFR-3 [38]. As shown in Fig. 2a, phytase activity declined in alkaline conditions due to changes in the ionic state of amino acids. The reduction of phytase activity in alkaline pH was observed in case of *R. oligosporus* MTCC 556 [39], *A. niger* NT7 [16], *A. niger* BIONCL8 [15], *A. niger* 7 A-1 [10] and *A. oryzae* [9, 24].

The stability of pH was checked with both pH 3.0 and 5.0. In pH 3.0, 50% phytase activity was retained for up to 60 min, while in pH 5.0, 50% activity was found within 40 min (Fig. 2b). In the case of *A. oryzae*, 80% phytase activity was reported with pH 3.0 and 5.0 for 45 min and 100 min respectively [9]. *A. niger* BIONCL8 phytase exhibited pH stability at 2.0 and 8.0. At pH 2.0, phytase showed 80% activity with incubation of 24 h, while at pH 8.0, it retained more than 50% activity [15].

Table 2 Comparison of properties of phytases isolated from various fungi

Fungal source	Optimum temperature (°C)	Optimum pH	Thermostability	Protease resistance after 120 min	Substrate specificity	References
Penicillium oxalicum PBG30	70	3.0	$t_{1/2}$ 60 min at 70 °C and 30% activity left after 1 h at 80 ºC	88% and 80% activity with pepsin and trypsin	sodium phytate, calcium phytate, p-nitrophenyl phosphate, ATP, ADP, Glucose-6-phosphate and AMP	Current study
P. oxalicum EUFR-3	40	7.0	5.35% activity left after 20 min at 80 °C	–	–	[38]
Aspergillus niger BIONCL8	40	2.1	30% activity left after 1 h of incubation at 80 °C	–	Sodium phytate	[15]
A. fumigatus	55	5.5	Retain > 50% activity after 2 h at 70 °C	–	Calcium phytate	[17]
A. niger NT7	60	2.6, 4.8	$t_{1/2} \leq$ 60 min at 70 °C	70.12% and 52.35% activity with pepsin and trypsin	Sodium phytate	[16]
A. tubingensis TEM 37	45	2.0, 5.5	Possess 100% activity after 3 h at 80 °C	Retain 88% and 98% activity with pepsin and trypsin	D-Glucose-6-phosphate, D-Fructose-6-phosphate, ATP, ADP, AMP, Sodium phytate	[13]
A. aculeatus APF1	50	3.0	Only 6–7% activity left after 5 min at 80 °C	Retain 74% and 73% activity with pepsin and trypsin	Calcium phytate	[12]
A. foetidus MTCC 11682	37	3.5, 5.5	56% activity after 30 min at 80 °C	–	–	[37]

A. niger 7 A-1	56	5.3	9.3% activity left after 5 min at 80 ºC	–	Sodium phytate, Phenyl phosphate, Naphthyl phosphate, p-Nitrophenyl phosphate, Glycerol-2-phosphate, Glucose-1-phosphate, ADP and AMP	[10]
A. oryzae SBS50	50	5.0	$t_{1/2}$ 10 min at 80 °C	Retain 97% and 62% activity with pepsin and trypsin	sodium phytate, calcium phytate, potassium phytate, ADP, ATP, glucose-6-phosphate and p-nitrophenyl phosphate, β-glycerophosphate	[9]

Table 2 (continued)

Fungal source	Optimum temperature (°C)	Optimum pH	Thermostability	Protease resistance after 120 min	Substrate specificity	References
Rhizopus oligosporus MTCC 1116	50	5.5	55% and 30% activity left after 5 min at 70 °C and 80 °C	–	Sodium phytate, glucose-6-phosphate, glucose-1-phosphate, disodium pyrophosphate, ATP and GTP	[39]

Substrate Spectrum of Fungal Phytase

The phytase exhibited broad substrate specificity, a characteristic feature of an enzyme to be used for the animal feed. The highest specificity is observed with sodium phytate and considered as best substrate for *P. oxalicum* phytase. Other studies also demonstrated the maximum specificity of sodium phytate with phytases obtained from *P. oxalicum* KCTC6440 [41], *A. flavus* [28], *R. oligosporus* MTCC 556 [39], *A. niger* 7 A-1 [10]. The order of specificity is sodium phytate > calcium phytate > p-nitrophenyl phosphate > ATP > ADP > Glucose-6-phosphate > AMP (Fig. 3a).

The K_m and V_{max} were measured from the Lineweaver–Burk plot (Fig. 3b) and found to be 4.42 mM and 909.1 U/ml respectively. The K_m represents the enzyme affinity towards the substrate while V_{max} is the value at which all the active sites of enzymes were occupied by the substrate. The K_m and V_{max} values for *A. oryzae* phytase were 1.14 mM and 58.82 U/ml [9], and *A. aculeatus* APF1 phytase were 3.21 mM and 3.78 U/mg [12] with calcium phytate as a substrate. In other studies, the K_m and V_{max} values of phytase with sodium phytate were 0.545 mM and 600 U/mg for *P. oxalicum* PJ3 [43], 0.48 mM and 672 U/mg for *P. oxalicum* KCTC6440 [42], 0.815 mM and 1092 U/mg for *R. mucilaginosa* [44], 3.35 mM and 1.27 U/mg for *A. niger* BIONCL8 [15].

Effect of Organic Solvents, Detergents, Metal Ions and Inhibitors

Organic solvents have a positive impact on phytase activity. It increases in the presence of ethanol, methanol, butanol, propan-2-ol (isopropyl alcohol), acetone, and DMSO (Fig. 4a). Ethanol showed the maximum stimulatory effect on both 2 and 5% concentrations. The response of hydrophobic residues to the activity of phytase is negligible. In the existence of ethanol, methanol, butanol, and acetone, phytase activity was enhanced in *A. oryzae* [9]. The inhibitory effect of ethanol, butanol, isopropanol and acetone was observed in *A. niger* BIONCL8 [15]. In *A. aculeatus* APF1 phytase, butanol reduced the activity, acetone and isopropanol slightly affected while ethanol did not influence activity [12]. The functional group and molecular structure of organic solvents are accountable for designing the artificial environment around the enzyme which affects the enzyme structure and its catalytic properties. Depending upon the type of conformational modifications, phytase activity is affected. It can either stimulate or inhibit the enzyme activity [9]. Limited studies are available on the effect of organic solvents on phytase. Due to the presence of organic solvents solubility of hydrophobic residues is enhanced, it avoids reactions with water molecules, makes enzymes more stable

and reusable, and protects them from microbial contamination [13].

In our result, Tween 20, Tween-60 and Tween-80, Triton-X-100 increased the phytase activity, while SDS decreased the activity (Fig. 4b). SDS has been mentioned as an inhibitor for phytases obtained from *P. oxalicum* [38], *A. oryzae* [9], and *A. fumigatus* [11]. Contrasting to the result, Tween 20 showed the inhibitory action on *A. foetidus* MTCC 11682 phytase [37]. Detergents can also increase or decrease the enzyme activity depending upon the type of interacting molecule whether it is anionic, cationic, or non-ionic. It binds with protein molecules and changes the tertiary structure of protein [9]. SDS is an anionic detergent that is not specific and can attach anywhere to the protein and unfold the protein. It made conformational changes in the active site and thus inactivated the enzyme. Non-ionic detergents (Tweens and Triton X-100) do not bind on the surface of the protein and thus either stimulate or do not influence the activity of phytase by making conformational changes in the enzyme structure.

The involvement of metal ions in the regulation of enzyme catalysis is crucial. The influence of different metal ions was observed on phytase activity (Fig. 5a). Inhibition of phytase activity is possibly due to the association of metal and substrate complex which restricts the binding of substrate with enzyme or the modification of enzyme active site due to binding of ions [12], while enhancement in activity might be due to the requirement of metal ions in the activation of enzymes [44]. In the presence of Ca^{2+}, Co^{2+}, and Cu^{2+}, a significant enhancement is shown in the phytase activity which might be due to an increase in interaction between substrate and enzyme. Similarly, the involvement of Ca^{2+} in stimulating the phytase activity of *A. niger* NT7 [16], *A. fumigatus* [11], *A. oryzae* [9] has been mentioned

in the literature. Co^{2+} was also found to increase the phytase activity in *A. niger* NT7 [16], and *A. oryzae* [9] but in contrast, Cu^{2+} inhibited the phytase activity in *A. niger* NT7 [16], *A. oryzae* [9], and *A. niger* BIONCL8 [15]. Mg^{2+} represented a non-significant positive impact on the activity at both concentrations. A similar stimulatory effect of Mg^{2+} is shown in *A. oryzae* [9], and *A. niger* BIONCL8 [15]. At 1 mM concentration of Mn^{2+}, phytase activity was stimulated moderately but inhibited at high concentrations. Mn^{2+} decrease the activity of phytase obtained from *A. flavus* [28], and *A. niger* BIONCL8 [15]. With both concentrations of Na^{+} ions, activity was low as compared to the control during the study. The inhibitory effect of NaCl was observed with *P. oxalicum* [38] and *A. niger* BIONCL8 [15]. Dissimilar to this, Na^{+} enhances the activity in *R. mucilaginosa* [44]. There is no such effect of metal ions on the activity of *A. tubingensis* TEM 37 phytase [13].

The effect of inhibitors on phytase activity was also analyzed. Except for sodium azide, rest inhibitors (EDTA, ß-ME, DTT, sodium molybdate) were involved in suppressing the phytase activity as shown in Fig. 5b. Maximum inhibition was shown with sodium molybdate. In the literature, EDTA was involved in inhibiting the activity of phytase isolated from *P. oxalicum* [38], and *A. tubingensis* TEM 37 [13] indicating the requirement of metal ions for the activity. Dissimilar to this, EDTA increases the phytase activity in *A. niger* BIONCL8 [15] and has no impact on the phytase activity of *A. oryzae* [9], and *A. aculeatus* APF1 [12]. ß-ME and DTT were also reported to decrease the phytase activity of *A. niger* UFV-1 [45], and *P. oxalicum* [38], depicting the importance of sulfhydryl groups in the catalysis of phytase [45]. Sodium molybdate and sodium azide were involved in lowering the phytase activity of *A. oryzae* [9], and *A. tubingensis* TEM 37 [13] respectively.

Effect of Proteases

Pepsin and trypsin are two important digestive enzymes present in animals and human beings. For the utilization in animal feed, phytase must have the ability to resist the action of both enzymes. As shown in Table 3, there is no significant reduction in phytase activity against trypsin and pepsin treatment indicating the enzyme is protease resistant. Pepsin showed 8 and 12% reductions in phytase activity after incubation of 1 and 2 h respectively while trypsin exhibited 10–20% reduction in phytase activity within 1–2 h. The phytase isolated from *A. niger* UFV-1 exhibited more than 90% activity in the presence of pepsin and trypsin treatment for 1 h [45]. Similarly, the phytase obtained from *A. aculeatus* APF1 and *A. tubingensis* TEM 37 exhibited 74% and 73% and 88 and 98% activity after 120 min of treatment with pepsin and trypsin respectively [12, 13].

Table 3 Effect of proteases on phytase activity

Sample	Phytase activity (%)			
	0 min	30 min	60 min	120 min
Control	100	95 ± 0.98	92 ± 0.99	89 ± 0.32
Pepsin treated	100	99 ± 0.77	92 ± 0.09	88 ± 0.18
Trypsin treated	100	90 ± 1.24	90 ± 1.40	80 ± 1.31

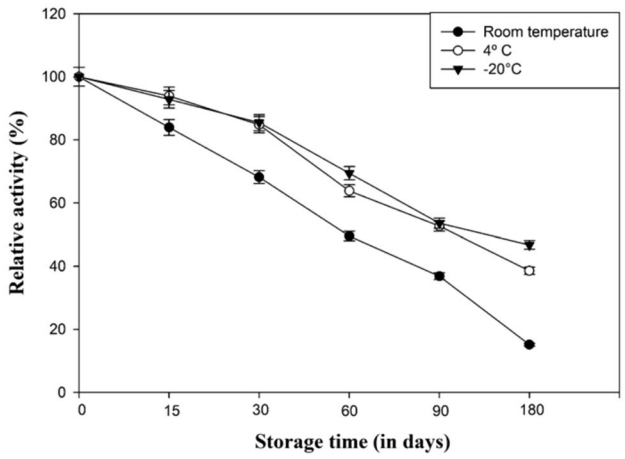

Fig. 6 Effect of storage conditions (RT, 4 °C and −20 °C) on phytase activity

Storage Life

The stability of the enzyme depends upon the molecule and storage conditions [9]. As shown in Fig. 6, 43% of the phytase activity is exhibited at −20 °C and 38% at 4 ℃ after 6 months, while 15% of the activity is left with phytase stored at room temperature. When the enzyme is stored in liquid, frozen, or powder form at different temperatures, it faces stress due to changing microenvironmental conditions and thus conformational modification occurs in the enzyme [9]. A similar study was observed in the shelf life of *A. oryzae* phytase and 4 ℃ was found as the most suitable storage condition retaining 63% phytase activity after 6 months, while 56% activity was exhibited with the sample kept at −20 °C [9]. *A. niger* CFR 335 showed more than 80% phytase activity at room temperature after the incubation of 3 months [36]. *P. adiposa* phytase expressed a reduction in its activity after incubation of 24 days at room temperature, 32 days at −20 °C, and 42 days at 4 °C [30].

Hydrolysis of the Insoluble Phytates

Phytic acid is associated with various metal ions and is available in the complex form of insoluble metal phytate. These insoluble complexes are unable to be digested by monogastric animals and restrict the assimilation of P and other essential metal ions. In the case of plants, phytic acid is adsorbed on clays or found in the form of insoluble salts of Fe and Al (acidic soils) or salts of Ca (alkaline soils). These insoluble salt forms are unable to be utilized hence must be hydrolyse by phytase before their absorption [25]. In the case of humans and animals, these insoluble metal phytate complex leads to malnutrition conditions [46]. As shown in Fig. 7, *P. oxalicum* PBG30 is capable of hydrolyzing insoluble metal phytate complex at both 37 and 50 °C. It releases inorganic phosphorus from the metal ions complex which increases with time. All the metal complexes of Ca^{2+}, Co^{2+}, Mn^{2+}, Cu^{2+}, and Zn^{2+} showed efficient hydrolysis and release of inorganic phosphate except Mg^{2+}, and Fe^{2+}. Similarly, the hydrolysis of insoluble salt phytates by *A. oryzae* was reported [25]. They showed that hydrolysis action occurred at 50 °C was better than 25 °C and liberation of inorganic phosphate was enhanced with time. *A. niger* NT-7 phytase was also capable of releasing metal ions from the insoluble metal phytate complex and showed more liberation of $Zn^{2+} > Ca^{2+} > Co^{2+} > Fe^{2+} > Fe^{3+}$ at 50 °C than 37 °C [46]. Phytate complexes of Ca, Mn, Mg, Zn, and Cd were hydrolysed more efficiently by *A. niger* phytase than the complexes of Al and Fe-phytates [47].

Phytic acid also makes complexes with proteins, amino acids, and enzymes and restricts their utilization. Plant-based proteins are usually found as insoluble

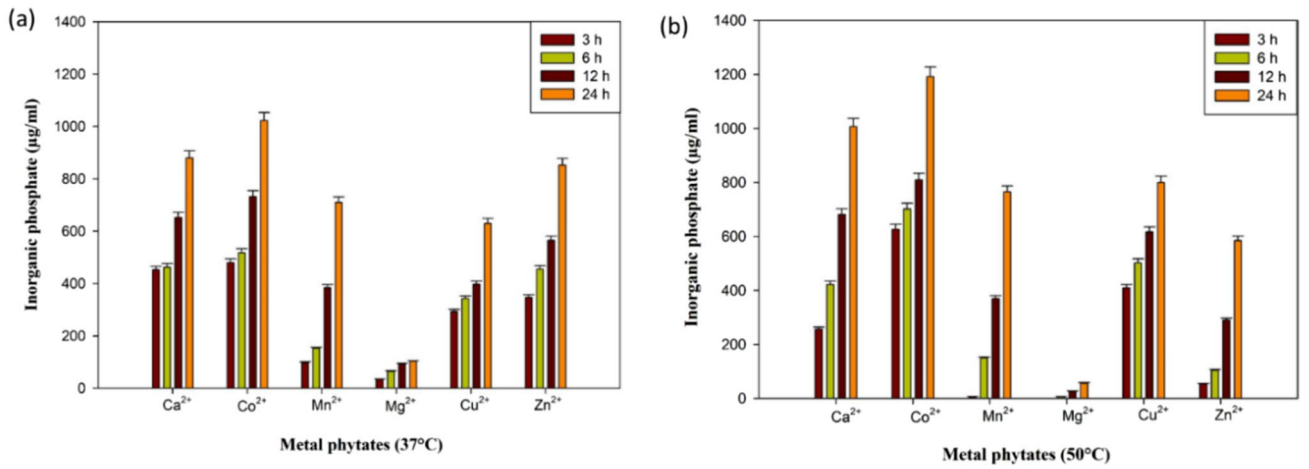

Fig. 7 Hydrolysis of insoluble metal phytates by *P. oxalicum* PBG30 phytase **a** at 37 °C **b** 50 °C

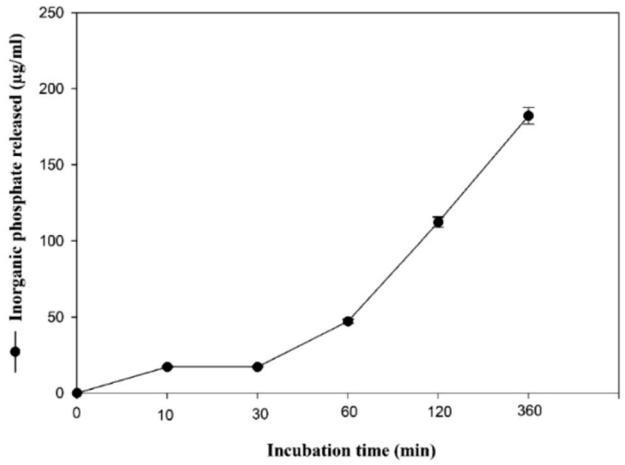

Fig. 8 Hydrolysis of lysozyme-phytate complex by *P. oxalicum* PBG30 phytase at 30 °C

protein-phytate complex forms and are thus beyond the approach of monogastric animals. Due to the phytate-protein complex, turbidity occurred in the solution [46]. In the present study, a turbid solution was observed when sodium phytate was mixed with lysozyme. The release of inorganic phosphate was increased with time as shown in Fig. 8. Similar work was performed on the hydrolysis of phytate association with BSA and lysozyme by using the phytase of *A. oryzae*. Further, they described the time-dependent relation between inorganic phosphorus and the absorbance of the solution. Inorganic phosphorus was increased while absorbance was decreased with time [25]. Kumari and Bansal [46] also studied the relation of the absorbance of turbid solution with the release of inorganic phosphate from the phytate-lysozyme complex in the presence of *A. niger* NT-7.

Phytic Acid Reduction in Fish Feed

In the plant-based feed, phytic acid is present in major amounts. Phytase hydrolyzes the phytic acid and liberates inorganic phosphate along with associated minerals from the feed. The application of phytase in the formulation of fish feed is analyzed to determine the reduction of phytic acid in feed. The phytase-treated sample showed less amount of phytic acid as compared to the untreated sample. As shown in Table 4, the control diet (without the addition of phytase) showed 50.43 mg/g phytic acid which decreases as the dosage of phytase increases in the diet. The sample with 1500 FTU/kg exhibited minimum phytic acid. Similar to this, *S. cerevisiae* MTCC 5421 phytase is mixed with refined wheat flour and pearl millet flour before forming naan and rabadi, and the amount of phytic acid was measured in control food (without phytase) and phytase-treated food. Naan and rabadi prepared with phytase enzyme showed 95% and 100% reduction of phytic acid respectively [48]. In other reports, there was a reduction of phytic acid amount in bread (70%), tandoori (75%), and naan (62.5%) prepared from dough of wheat flour supplemented with recombinant phytase of *Sporotrichum thermophile* [49]. Also, tandoori and naan made from recombinant phytase of *Pichia anomala* showed a 67.5% and 23.2% decrease in phytic acid respectively [50].

Haloperoxidase Activity

Phytase acts like a haloperoxidase when reacted with ammonium metavanadate and enhances the peroxidase activity while decreasing its activity (Fig. 9). The mechanism behind that is vanadium ion gets incorporated in the active site of phytase and makes a semi-synthetic peroxidase. This peroxidase tends to catalyze the sulfoxidation of thioanisole. Structurally, vanadium chloroperoxidase resembles acid phosphatases and acts as a substitute for phosphate and binds to phosphoryl transfer enzyme, thus reaching the intermediate state of reaction and decreasing the phytase activity. Vanadate acts as an anion and binds with positively charged amino acids present in the active site of phytase. By interfering with the phosphoesterase activity, it changes the enzyme functionality and develops a vanadate-dependent haloperoxidase. Only HAP phytase behaves as haloperoxidase due to the similarity in their active site [50, 51]. Likewise, the semi-synthetic peroxidase behaviour of phytase was studied in *S. thermophile* [51], *P. anomala* [50], and *A. oryzae* [20]. The application of vanadate synthesizes peroxidase found in the formation of radiolabelled monoclonal antibodies, quantification of chloride amount in samples, diagnostic purposes, antimicrobial work, and immunological studies [50, 51].

Table 4 Estimation and reduction of phytic acid in the diet after the addition of phytase

Sample	Phytic content (mg/g feed)	Reduction in phytic acid level (%)
Diet I (Control)	50.43 ± 1.15	0
Diet II (Control + 500 FTU/kg phytase)	33.00 ± 0.13	34.6
Diet III (Control + 1000 FTU/kg phytase)	30.37 ± 0.45	39.8
Diet IV (Control + 1500 FTU/kg phytase)	26.91 ± 0.83	46.6

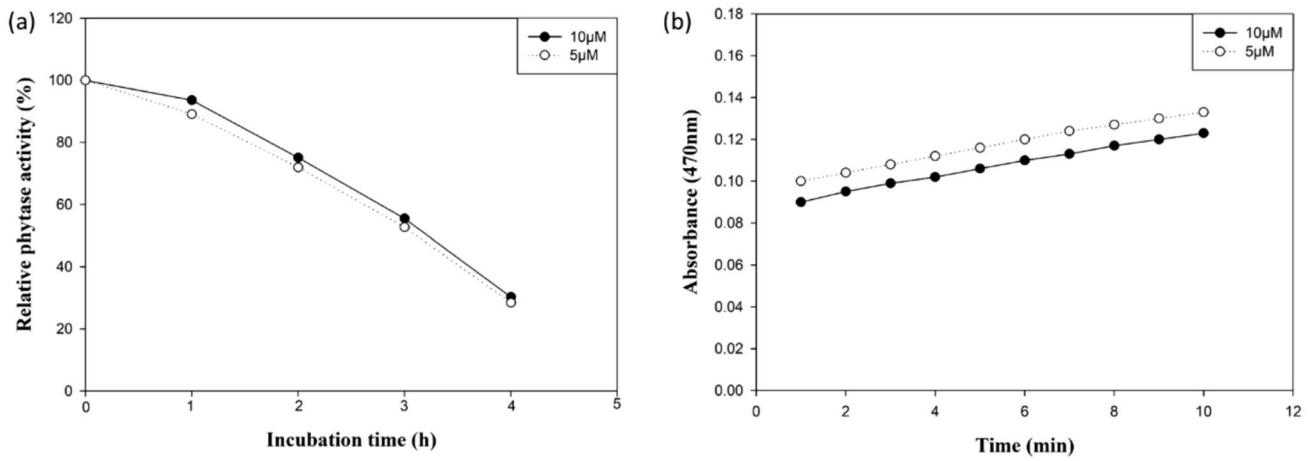

Fig. 9 Reduction of phytase activity **a** and increase in peroxidase activity **b** with time

Conclusion

Wheat bran is used for the production of *Penicillium oxalicum* phytase through the SSF method. After optimizing the conditions using the OVAT approach, phytase production was enhanced by 2.4-fold. The *P. oxalicum* PBG30 phytase exhibits thermostability, acidity tolerance, broad substrate specificity, and protease resistance. Its high thermostability protects the enzyme during the pelleting process in feed production. The acidic nature of phytase helps it to survive and function effectively in the gastrointestinal tract. Its resistance to proteases help in withstanding the action of digestive enzymes such as trypsin and pepsin, allowing it to efficiently degrade phytic acid. Due to these distinctive features, phytase can serve as an ideal additive in the food and feed industry. *P. oxalicum* PBG30 phytase showed the hydrolysis of metal-phytate and protein-phytate complexes and leading to the liberation of inorganic phosphate in a time-dependent manner. This indicates that *P. oxalicum* PBG30 phytase is effective in improving the nutritional content of food and feedstuffs. Additionally, the phytase plays a role in reducing phytate levels in fish feed, which helps decrease P levels in water bodies, thereby mitigating environmental pollution. The presence of haloperoxidase activity in vanadium-modified phytase suggests potential for clinical, immunological, and various biotechnological applications. However, further research is imperative to validate these possibilities.

Acknowledgements The author acknowledges the Department of Biotechnology, Delhi Technological University, Delhi, Department of Microbiology, Maharshi Dayanand University, Rohtak and Aqua Research Lab, Department of Zoology, University of Delhi, Delhi for supporting this research work.

Author's Contributions The original draft was prepared and edited by P and all the experiments were performed by her. Data were analyzed by P, BS, BG and JGS. The draft was critically revised and improved under the supervision of BS, BG, RKG and JGS. All authors read and approved the final manuscript.

Funding The author (Ms. Priya) gratefully acknowledges the financial assistance as Junior/Senior research fellowship from the University Grants Commission (UGC), New Delhi, India.

Abstract

This study establishes a novel cooling-power cogeneration system which utilizes Parabolic Trough Solar Collectors (PTSC) employing Air, Carbon dioxide (CO_2), and Helium (He) as heat carrying fluids. This heat is utilized by Organic Flash Cycle (OFC) connected to two-phase ejector which simultaneously generates electricity, and cooling for refrigeration and air conditioning. The system proposed provides a promising solution that can help in reducing greenhouse gas emissions and increasing overall efficiency and energy savings. Modelling & simulation through Engineering Equation Solver (EES) is performed to investigate the effect of solar flux, and type of solar heat transfer fluid (SHTF) on exit temperature of SHTF. Promotion of solar flux increases the temperature of SHTF which is found highest for He and lowest for CO_2. A parametric analysis is done to find out the outcome of design parameters. Cogeneration cycle connected to He operated PTSC performs good relative to Air and CO_2 as SHTF. Exergy destruction is found to be 53.87 %, 22.09 %, and 6.15 % in PTSC, OFC, and in two-phase ejector respectively while production of power, exergetic refrigeration, & exergetic air-conditioning as 4.02 %, 10.65 %, 3.22 % respectively.

Keywords: Parabolic trough solar collectors (PTSC), Organic flash cycle (OFC), two-phase ejector, cogeneration, exergy

1. Introduction

Increased level of living standard of people and the rapid industrial development led to an exponential increase in demand of energy in the last few decades. Most of this increased energy demand is met by fossil fuel combustion in a single energy generation unit that leads to problematic issues like the fast depletion of fossil fuel reserves, increased level of pollutant emissions, and global warming. To combat these issues, it is required to find out the clean and renewable energy source and development of potential and sustainable combined energy system [1, 2]. Among the renewable sources of energy, solar energy is a universal energy source and has the potential to vanquish all the environmental threats, and has the capability to produce electric power and heat for diverse requirements of domestic and industrial sectors' energy in a sustainable fashion. Kalogirou [3] discussed the different styles of solar panels & collectors and its various applications. Al Mughanam and Khaliq [4] introduced a novel cycle to generate the electricity and cooling, simultaneously, and run by concentrating collectors. They have presented a parametric study of the cycle in view of its exergetic and energetic perspectives.

Concentrating solar collectors (dish collectors, Heliostat field, and PTSCs) are very popular devices worldwide due to their conversion of solar radiations to heat. PTSCs considered as the most promising systems as it supplies energy with enhanced stability and reliability in cost-effective manner in regions & sites receiving high direct normal irradiations (DNI) [5, 6]. However, stand-alone solar operated electricity generation systems are presently not very popular in comparison with traditional fossil fuel driven plants due to its more initial investment, lesser efficiency, discontinuous power supply, etc. So, efficient use of solar energy at peak summer for cooling and power generation is close coincidence of requirement of extreme cooling load when rich solar radiations are available [7, 8]. Much work has been done on the integrated solar heat

driven Organic Rankine Cycle (ORC) and Absorption Refrigeration Cycle (ARC) because ORC presents the benefits of operation flexibility and desirable efficiency [9]. Exergy analysis is performed for the solar operated combined system of ARC with the ORC. Result points the components having significant exergy destruction which effecting the cycle function [10]. The investigation of combined ORC (for power), LiBr-H_2O based ARC (for refrigeration), and process heater (for heating), respectively is done and results shows the advantage of using the ARC on the outcome of cycle [11]. The simulation of evacuated tube collector based NH_3-H_2O absorption refrigeration system is done using hourly solar radiation data. The outcome shows the importance of variation of air temperature on the output of system [12]. The exergy analysis of solar tower operated Steam Rankine Cycle (SRC) combined with ARC for electric and refrigeration output. A great improvement in system outcome is noticed with the increase in the DNI [13]. LiBr-H_2O & NH_3-H_2O are very popular working fluid pairs used in ARC for different range of cooling temperatures. When the evaporator temperature requirement is less than 0^oC, LiBr-H_2O based ARC will not work. NH_3- H_2O based ARC is widely used for refrigerating the thermal load of below 0^oC [14]. However, in NH_3-H_2O based ARC, a rectifier (energy consuming device) is required, which degrade the outcome of the system.

In view of the constraints imposed by ARC, a further new alternative heat operated sustainable cooling cycle is required. Ejector Refrigeration Cycle (ERC) now a days seems to be very fascinating cooling choice owing to high energy efficiency, low cost, silent operation, and flexibility in refrigerants use [15, 16]. Therefore, to address the purpose of utilizing the low-grade solar energy source more effectively, ERC & ORC are adopted to utilize waste heat. The exergetic evaluation of a cooling-power system is done wherein an ERC was adopted to augment the thermodynamic performance of ORC [17]. The approach of efficient employment of solar heat by means of ejector in ORC for refrigeration & power is continued by Khaliq [18]. Zhang and Mohamed [19] inspect the response of properties of hydrocarbons refrigerants in solar operated

ORC integrated to ERC in view of thermodynamic outcome. Elakhdar et al. [20] hybridized the PTSC, to meet the building energy demand, with a thermal system consists of ORC & ERC which uses Thermal oil (as heat transfer fluid) and the results showed hourly response of the model. Mahdavi et al. [21] investigated a new type of power, cooling, and heating cogeneration system using Therminol VP1 operated PTSC as the primary energy source to drive the dual-pressure ORC combined with ERC. The proposed configuration was analyzed and the system efficiencies found to be 20.26% (energy efficiency) and 15.81% (exergy efficiency), respectively. Yadav et al. [22] showed the exergy analysis of a new configuration combining the ORC with a secondary ejector & an internal heat exchanger and PTSC using Therminol oil as solar fluid. They determined the second law efficiency of the proposed configuration as 18% using isobutane as the working fluid which claimed to be higher than those of the systems employing an ejector between the ORC turbine and condenser.

In the Combined Cooling and Power (CCP) cycles described above, majority of the solar heat was aimed to be utilized for power generation, but most of the works focus on traditional ORC and an ERC to exploit the solar heat to produce electricity and cooling. Power generation with ORC has a disadvantage of temperature mismatching between the thermal energy source stream and the working fluid stream of ORC, resulting in the increase of heat transfer irreversibilities leads to performance reduction. Employment of ERC with the use of single-phase pure leads to lower thermodynamic performance and provide cooling at one level of temperature either for refrigeration or air conditioning. To overcome with such limitations, Organic Flash Cycle (OFC) is considered which uses a separator tank and a flasher and is gaining wide acceptance owing to provide significant reduction in exergy destruction and increased turbine output [23, 24]. Few studies conducted the analysis of OFC from the viewpoints of thermodynamics to utilize the solar heat for power generation. The outcome of OFC & ORC is compared with due focus on thermodynamic behavior of working fluids and heat source temperature is done by Lee et al. [25].

They favored OFC because it shows better performance for harnessing the low temperature heat sources. Varma et al. [26] proposed and conducted the thermodynamic investigations of an OFC considering the partial flashing of preheated water and mixing of separated vapor with turbine streams for power enhancement. Their investigation was limited to comparison of the performance of OFC with ORC and did not perform the parametric analysis of the cycle from energy and exergy perspectives which is desired to diagnose the real potential of OFC.

Referring to CCP cycles, very few literatures focus on the integration of OFC with ERC driven by low temperature heat sources. Moreover, employing single-phase ejector driven by exhaust heat of ORC turbine leads to a reduction in turbine power owing to maintain sufficient heat to vaporize the ERC working fluid, further, the cycle has the limitation of providing cooling in single mode either for refrigeration or air conditioning. In this regard, application of two-phase ejector refrigeration cycle which provide cooling in two different temperatures range and can fulfil the requirement of refrigeration and air conditioning, simultaneously, which makes full use of excess power generated by solar energy driven OFC can be considered as an enthralling method in view of improving its energy outcome and conserving the turbine power output. Various investigations are conducted to analyze the outcome of two-phase ejector cooling cycles. A vapor compression refrigeration system is analyzed using different working fluids with two-phase ejector by Kornhauser [27]. Chaiwongsa and Wongwises [28] analyzed the consequences of varying the exit diameter of nozzle & throat for the ERC consist of single evaporator and a refrigerant separator. Pottker et al. [29] analyzed the experimental model for the application of R410A refrigeration in ejector cooling system without considering the ejector dimensions and found a considerable increase in the Coefficient of Performance (COP) of refrigeration system. Lawrence [30] conducted a theoretical & experimental examination of a two-phase ejector refrigeration cycle using the refrigerants working on low pressures. Lawrence and Elbel [31] analyzed the outcome of using the R143a & R1234yf as refrigerants in ERC and an increase of 5% and 6% of COP was

observed. For different component efficiencies, the outcome of two-phase ejector was examined by Wang and Yu [32]. They suggest a new method of analysis of ejector by combining its model with reported data.

Above reported investigations clearly indicates that majority of the solar collectors employs to drive the cooling-power cogeneration systems uses water, thermal oils, and molten salts as solar heat transfer fluid. Utilization of these fluids as SHTF brings some challenges such as water is appropriate only for performing the temperature limit up to 100 ℃, and for higher temperature limits, water is pressurized. Thermal oils are being used in many industrial applications up to 400 ℃ and molten salts can be used up to 600 ℃ (solidification at lower temperature occurs) [33 -35]. To mitigate the risks and limitations associated with the use of water, oil, and molten salt, employment of gases as the solar heat transfer medium in the PTSC is being used to operate the systems at high temperature level. Few illustrations can be noticed in the published work where PTSCs using gases as solar heat transfer medium have been successfully utilized for refrigeration, and power-cooling cogeneration [36, 37].

It is observed from the literature review that the investigation of OFC operated cooling-power cycle run by PTSC is very limited and further investigation on this area is required. In this regard, this study introduces an innovative integrated system for combined generation of electricity, and cooling at two different levels of temperature to satisfy the needs of refrigeration and air conditioning. This configuration relies on a unique integration that harnesses high intensity solar radiation of a region and recovers waste heat from the turbine which effectively producing electricity and cooling in this novel setup. A detailed energetic-exergetic evaluation is conducted to diagnose the real potential of proposed cogeneration system. Another contribution of this research is the assessment of the impact of climatic conditions on the rate of cleaner production of cooling and electric power and on the exergetic efficiency of the cogeneration. This detailed

analysis and exploration of climatic condition effects on the system's functionality and outcome have not been extensively investigated in past studies. Therefore, this investigation fills a crucial gap of the reported literature by revealing new insights and findings in these areas, thus advancing the knowledge, and understanding of integrated systems.

The main novelties of the present work are as follows:

- To develop a new type of cogeneration system utilizing gaseous working fluids in concentrating solar collectors to operate in high temperature levels for the co-production of electricity and cooling at two different level of temperatures.
- Conduct a comprehensive steady-state energy and exergy analysis of the developed cogeneration system using EES (Engineering Equation Solver) [38].
- Depict the exergy distribution of incident radiations into the various exergetic outcomes.

2. System description

Fig. 1 is the proposed system that shows an innovative combination of OFC using R124 as the working fluid to generate power, along with a bottoming cycle that incorporates a two-phase ejector to simultaneously provide cooling for air-conditioning and refrigeration. PTSCs are chosen as the best solar devices for capturing and utilizing solar radiation. Air, CO_2 and He are used as heat transfer fluids in the PTSC field to transfer heat. The high-temperature heat transfer fluid (state 18) enters the heat recovery vapor generator (HRVG) of the OFC, and the OFC absorbs the thermal energy from the SHTF. High temperature SHTF passes through HRVG causes the increase of fluid temperature of OFC & consequently forms superheated vapor (22). The SHTF exits the HRVG (state point 16) and enters (state point 17) the PTSC field through a solar pump1. One part of pressurized hot liquid (30) from HRVG is given to high pressure flasher (HPF) unit (33) via expansion valve1 (EV1). In this cycle HRVG consists of three zones namely, economizer (ECO), evaporator (EVA) and superheater (SH). In High Pressure Flasher (HPF), this liquid is flashed to

saturated vapor (35) which is supplied to the turbine and into liquid (34) connected to Low Pressure Flasher (LPF) via EV2 wherein it flashed and separated into liquid (36) and saturated vapor (37). This arrangement caused two extra streams of fluid into the turbine is, one from HPF and the other from the LPF and hence generate a greater amount of power which is enough to drive the compressor and pumps, and to meet the electricity requirement of a building. The vapors (23) coming from the turbine rejects the heat at regenerator (23−24) and then condensed (25). The condensate is pumped (via pump2) and then passes through regenerator (27) and mixed with liquid (36) is then pumped (via pump3) to HRVG (29) to repeat the cycle. To achieve the desired cooling, the two-phase ejector cycle employs R600a as working fluid. The vapor from the Separator (10) via heat exchanger enters the Compressor (C) (11) and then the condenser2 (Cond2) (1) to reject the heat into ambient. The saturated liquid leaving the Cond2 (2) goes to the air- conditioner (AC) via heat exchanger (HX) and Expansion Valve3 (EV3). This heat exchanger (HX) exchanges the heat between the liquid leaving the Cond2 and the saturated vapor approaching the Compressor. The stream from the air-conditioner (AC) (5) and enters to the Ejector (Eje) as primary fluid of motive nozzle. The high-velocity vapor creates the low-pressure region at the mixing chamber inlet and sucks the vapor from Refrigerator (ref) (9). A normal shock wave occurs as mixed fluid enters the in constant area part and causes a pressure increase and the decelerates in the diffuser as shock takes place and then enters the Separator (Sep) (6). The separator (Sep) separates the fluid into two parts namely, liquid (7) goes to the Refrigerator (ref) that produces refrigeration effect (8) and the saturated vapor (10) is routed to Compressor (C) (11) via heat exchanger (HX). Table 1 depicts some relevant properties of SHTF.

3. Computational Method

Examination of the cogeneration model is conducted in four stages:

- PTSC is working with gaseous SHTF that drives the proposed cogeneration model.

- OFC using R124 as the working fluid to generate power
- A two-phase ejector cycle is used to simultaneously provide cooling for air-conditioning and refrigeration
- Energy and exergy examination of the model is conducted.

The modelling is done on EES using three gaseous fluids is made. The properties of the working fluids R124 (working fluid for OFC), and R600a (working fluid for the two-phase ejector) basic were computed by employing the REFPROP 6.01 [39]. Thermal analyses of the proposed model is executed using the EES.

Global Warming Potential, or GWP, is a measure of how destructive a climate pollutant is. Refrigerants today are often thousands of times more polluting than carbon dioxide (CO_2). The GWP of a gas refers to the total contribution to global warming resulting from the emission of one unit of that gas relative to one unit of the reference gas, CO_2, which is assigned a value of 1. GWPs can also be used to define the impact greenhouse gases will have on global warming over different time periods or time horizons. These are usually 20 years, 100 years, and 500 years. The refrigerants considered here in this investigation are R124 and R600a (Hydrocarbon) and their employment in thermodynamic cycles for power generation and cooling offers very less GWP compared to commonly used refrigerants. Therefore, their use provides a global push towards low Global Warming potential alternatives.

Assumptions are made regarding the proposed cogeneration cycle [20, 25, 31, 36]:

- Flow is assumed to be steady, frictionless & 1-dimensional in components of proposed cogeneration model.
- Heat loss from the components, kinetic and potential energy change of stream of proposed cogeneration model assumed negligible.
- Expansion valves follow isenthalpic process.

- Pressure drops in components assumed negligible.
- Pumps and expander have fixed Isentropic efficiency.
- Only physical exergy is considered for calculation purpose.
- The ambient Pressure P_0 is 101.325 kPa and Temperature T_0 is 25 ℃.

3.1. Energy and exergy analyses

For the proposed cogeneration model, an exergetic investigation is done, which reports the amount of exergy destruction in the components of the model.

Conservation of mass principle expresses the steady state operation as:

$$\Sigma \dot{m}_i - \Sigma \dot{m}_o = 0 \quad (1)$$

Conservation of energy principle expresses the steady state operation as:

$$\sum \dot{Q} - \dot{W} = \dot{m}\left(h_0 + \frac{C^2}{2} + gz_0\right) - \dot{m}\left(h_i + \frac{C^2}{2} + gz_i\right) \quad (2)$$

where h, c and z are the specific enthalpy, bulk velocity and elevation of flowing stream.

Table 2 shows the Energy balance for the components of the of the model are obtained using Eqs. (1) and (2).

The specific exergy of flowing stream while neglecting the kinetic and potential exergies is formulated as:

$$e_x = (h - h^*) - T_0(s - s^*) \quad (3)$$

where * represents the property at datum state.

For a control volume working on steady state, Exergy destruction equation is given as:

$$\Sigma\left(1 - \frac{T_0}{T}\right)\dot{Q}_j - \Sigma\dot{W} + \Sigma\dot{m}_i e_{x_i} - \Sigma\dot{m}_o e_{x_o} - \dot{E}_{x,D} = 0 \quad (4)$$

Table 3 shows the Exergy destruction expression for the components of the of the model.

3.2. Proposed cogeneration model's overall performance indicators

The PTSC system comprises absorber tube which is fixed along the focal length of parabolic concentrator and a reflective cover is employed to decrease the heat loss of absorber tube [20]. The gaseous fluid absorb heat in the collector and it passed via central tube of PTSC. Part of this heat is transferred via HRVG to OFC to generate electricity for the grid and to drive the compressor of ejector cooling cycle. Incident rate of solar energy that PTSC receives ($\dot{Q}_{solar}$) is given by [36]:

$$\dot{Q}_{Solar} = G_b A_p \tag{5}$$

$$\dot{Q}_u = \dot{m}_{SHTF}(h_{18} - h_{17}) = \eta_{en,PTSC}\ G_b A_p \tag{6}$$

Exergy destruction rate of process of solar heat absorption from sun to receiver (s-r) is determined as:

$$\dot{E}_{x,D,s-r} = \eta_{opt}\ \dot{E}_{x,Solar} - \dot{Q}_{abs}\left(1 - \frac{T_0}{T_r}\right) \tag{7}$$

where $\dot{E}_{x,Solar}$ and $\dot{Q}_{abs}$ are defined by the equations below:

$$\dot{E}_{x,Solar} = G_b A_p \left\{1 - \frac{4}{3}\frac{T_0}{T_{solar}} + \frac{1}{3}\left(\frac{T_0}{T_{solar}}\right)^4\right\} \tag{8}$$

$$\dot{Q}_{abs} = \eta_{opt}\ \dot{Q}_{Solar} \tag{9}$$

Exergy destruction rate of the transfer of heat from receiver to fluid (r-f) is expressed as:

$$\dot{E}_{x,D,r-f} = \dot{Q}_u\left(1 - \frac{T_0}{T_r}\right) - \dot{E}_{x,u} \tag{10}$$

$$\dot{E}_{x,u} = \dot{Q}_u - \dot{m}\ c_p.T_0\ \ln\left[\frac{T_{out}}{T_{in}}\right] - T_0\dot{m}\frac{\Delta P}{\rho_{fm}T_{fm}} \tag{11}$$

The term $\dot{Q}_{Solar}$ and $\dot{Q}_u$ are defined above by equations (1) and (2), respectively.

Rate of exergy destroyed in the solar collector is given by:

$$\dot{E}_{x,D,col} = \dot{E}_{x,D,s-r} + \dot{E}_{x,D,r-f} \tag{12}$$

Outcome of the proposed model is assessed via thermal and exergy efficiencies, which are determined through the first and second laws of thermodynamics. The thermal efficiency of the proposed model can be expressed as [33]:

$$\eta_{th} = \frac{\dot{W}_{net}+\dot{Q}_{ref}+\dot{Q}_{AC}}{\dot{Q}_{solar}} \quad (13)$$

where, $\dot{W}_{net}$ represents the net power output, $\dot{Q}_{ref}$ denotes the refrigeration capacity and $\dot{Q}_{AC}$ denotes the air-conditioning capacity, $\dot{Q}_{solar}$ is the total solar energy input to the system.

The exergy efficiency of the proposed system can be expressed as follows [17]:

$$\eta_{ex} = \frac{\dot{W}_{net}+\dot{E}_{ref}+\dot{E}_{AC}}{\dot{E}_{solar}} \quad (14)$$

where, $\dot{E}_{ref}$ and $\dot{E}_{AC}$ are exergy accompanied $\dot{Q}_{ref}$ and $\dot{Q}_{AC}$ respectively, and are given by:

$$\dot{E}_{ref} = \dot{Q}_{ref}\left(\frac{T_0}{T_{ref}} - 1\right) \quad (15)$$

$$\dot{E}_{AC} = \dot{Q}_{AC}\left(\frac{T_0}{T_{AC}} - 1\right) \quad (16)$$

where, T_0, T_{ref}, T_{AC} are the ambient temperature, refrigeration temperature, and air-conditioning temperature, respectively.

Mathematical equations formulated for PTSC considering heat transfer details to analyses the SHTF outlet temperature of is provided in the Ref. [34].

Proposed system takes into account the exergy of solar incident collected and divided into exergy output, exergy destructed, and exergy lost. The application of global exergy balance shows:

$$\dot{E}_{x,F,k} = \dot{E}_{x,P,k} + \dot{E}_{x,D,k} + \dot{E}_{x,L,k} \quad (17)$$

where, $\dot{E}_{x,F,k}$ = fuel or input exergy; $\dot{E}_{x,P,k}$ = product or output exergy; $\dot{E}_{x,L,k}$ = exergy loss; $\dot{E}_{x,D,k}$= exergy destruction.

For the proposed model, fuel (F) is the incident solar radiation. The distribution of incident exergy into exergy output, exergy destruction, and exergy lost has been presented for better understanding of the proposed model [36].

The input parameters taken for calculation purpose of the model are shown in Table 4.

The value of solar direct beam irradiation, temperature of Sun, and the ambient temperature are taken as 800 W/m^2, 5770 K, and 293K, respectively, because these are the most acceptable values of solar irradiance, Sun temperature, and ambient temperature in the Middle East region. The concentration ratio 26.37, the aperture area 69.6 m^2, the parabola width 5.8 m, and an optical efficiency 80% were taken because these have been considered as the satisfying values for the commercial parabolic trough collector, Eutrotrough ET150. This collector is a representative example of PTSCs as it has been used in many applications worldwide.

4. Results and discussion

4.1 Model validation

In order to ensure the accuracy of the calculations, the model presented in this paper was first verified. Due to the lack of a system of the same form for comparison, the OFC and the ejector sub-systems were verified separately. Table 5 shows a comparison between the present model and the literature results for the OFC [26]. The model for the OFC performance is validated by Verma and Srinivas [26]. The OFC turbine output and its exergy efficiency are determined as 1292 kW and 26.84%, respectively compared to OFC turbine output 1248 kW and exergy efficiency 26.21% obtained in [26]. The performance of the two-phase ejector is verified through the results obtained by Lawrence and Elbel [31]. The cooling outputs (refrigeration and air conditioning capacities) of

the present system are determined as 165 kW and 515 kW, respectively, compared to 1558 kW and 504 kW of the results obtained by [31]. The cooling output of the presently developed system is marginally higher than that of the [31] as PTSC using gaseous heat transfer fluids entails a major input to the system. A small deviation is found between the present findings and the results from the literature [26, 31] and in sum, the data obtained from present investigation make a solid accept to conduct future research in the area for the exploitation of solar thermal potential of the hot region to enhance the sustainable production of cooling and electric power. The relative errors of energy efficiency are within 3%, while those of exergy efficiency are within 1%.

Since, proposed system performance depends on the climatic conditions, therefore, the influence of variation of average solar intensity (solar flux), the ambient temperature, the temperature of the evaporators of refrigeration, and air conditioning sub-systems is examined. Influence of solar flux is investigated on the power produced by turbine of OFC and on the cooling outputs.

4.2 Effect of climatic conditions on cogenerations system performance

The performance of the cogeneration system depends on the climatic conditions; the solar flux and the ambient temperature.

Fig. 2 shows the effect of variation of solar flux on the temperature (T_{18}) of SHTF leaving the PTSC where the values of outlet temperature of the collector are different from gas to gas. Promotion of solar flux (G_b) raises the incident rate of solar energy received by PTSC which leads to increase in the useful heat gained by the SHTF as it is indicated from eq. (6). For the fixed mass flow rate of SHTF, increase in useful heat gained by the SHTF results in the rise of outlet temperature of SHTF (T_{18}) leaving the PTSC. This trend is observed for all three SHTFs (Air, CO_2, and He). So, solar flux (G_b) has the positive effect on the temperature of SHTF (T_{18}) leaving the PTSC. The outlet temperature of SHTF (T_{18}) is achieved highest for He and lowest for CO_2 owing to higher thermal conductivity of He and lower for CO_2. For He, it increases from 312.5 ℃

to 434.7 ℃, for Air from 300 ℃ to 413.6 ℃, and for CO_2 from 283.9℃ to 387.1℃, when solar flux is increased from 600-1000 W/m^2. The highest outlet temperature in case of He is achieved because of its higher heat transfer coefficient and lowest pressure drop. Higher heat transfer coefficient assists in increasing the heat transfer from the absorber to fluid which reduces the absorber temperature and resulted in lower thermal losses. Based on these findings, Helium can be considered as the most suitable solar heat transfer fluid for the PTSC employed to drive the cooling-power cycles applied in large number of applications up today.

Fig. 3 illustrates the variation in mass flow rate of the working fluid (R124) of OFC by changing solar flux (600-1000 W/m^2) for three different SHTFs namely Air, CO_2, and He. This is explained as the value of solar flux increases, useful heat gain by SHTF increases and consequently, more heat is supplied to the OFC working fluid at Evaporator (EVA) which resulted in high flow rate of OFC working fluid because of the rise of temperature of SHTF which in turn raise the degree of superheat at the superheater (SH) as shown by equations of EVA and SH respectively in Table 2. The mass flow rate of the working fluid of OFC cycle is highest when the SHTF is He followed by CO_2 and Air because the specific heat of He is highest followed by CO_2 and Air. The mass flow rate of OFC cycle for He increases from 37.19 kg/s to 60.9 kg/s, for CO_2 from 36.48 kg/s to 60.16 kg/s, and for Air from 35.76 kg/s to 59.38 kg/s with the change in solar flux from 600-1000 W/m^2.

It is clear from the Fig. 1 that the Turbine power ($\dot{W}_T$) is produced by three streams of OFC: first stream (22) is coming from SH, second stream (35) is coming from High Pressure Flasher (HPF) and third stream (37) is coming from Low Pressure Flasher (LPF). As explained in Fig. 3, with the increase in solar flux, useful heat gain by SHTF increases which results in the increased mass flow rate and increased superheating of OFC working fluid. So, power produced by first stream (22), increases with the increase in solar flux. As the pressure of HPF is fixed, the temperature of flash

Accepted Manuscript Not Copyedited

Downloaded from http://asmedigitalcollection.asme.org/thermalscienceapplication/article-pdf/doi/10.1115/1.4068339/7456566/tsea-24-1619.pdf by Delhi Technological University user on 08 April 2025

Journal of Thermal Science and Engineering Applications. Received December 15, 2024;
Accepted manuscript posted April 1, 2025. doi:10.1115/1.4068339
Copyright © 2025 by ASME

stream (35) is fixed. So, increase in solar flux, results in the increased mass flow rate of flash vapor (35) of OFC working fluid. So, power produced by second stream (35) increases with the increase in solar flux. Similarly, pressure of LPF is fixed, the temperature of flash stream (37) is fixed. So, increase in solar flux, results in the increased mass flow rate of flash vapor (37) of OFC working fluid. So, power produced by third stream (37) increases with the increase in solar flux. So, total power produced by turbine ($\dot{W}_T$) will be the summation of the power produced by all three streams. The variation of solar flux on the power produced ($\dot{W}_T$) by the turbine of OFC cycle is shown in Fig. 4. It is evident that the turbine output ($\dot{W}_T$) of the OFC cycle increases for all SHTFs (Air, CO_2, and He) with the increase in the solar flux. The increased turbine power will not only increase the electricity but also produce more cooling because of the greater amount of power supplied to compressor of two-phase ejector. This unique system is designed such a way that the excess amount of electricity will be supplied to off grid areas at the time of off-peak cooling load requirements. It is also noticed that the turbine output is highest for He and followed by the CO_2 and Air which is due to the highest mass flow rate of working fluid (R124) of OFC cycle for He followed by the CO_2 and Air. Turbine output ranges from 981.4 kW to 1600 kW for He, 960.2 kW to 1579 kW for CO_2, and 939.7 kW to 1557 kW for Air, with the change in the solar flux from 600-1000 W/m^2.

The turbine output of the OFC cycle is utilized for two purposes. Half of the power produced by turbine is employed for electricity generation and remaining power output is utilized to drive the compressor of ejector cycle producing the refrigeration and air-conditioning outputs. It is explained in Fig.4, increase in solar flux leads to increase in turbine power output ($\dot{W}_T$) of the OFC cycle. This is because increase of solar flux raises the evaporator temperature which correspondingly increase the turbine entry pressure leading to higher pressure ratio of turbine. As half of the turbine power is utilized to run the compressor of ejector cycle, the compressor input

power also increases with the increase in solar flux. Increase in compressor power leads to increase the refrigeration output as well air-conditioning output of the two-phase ejector cycle. Fig. 5 depicts the variation of the refrigeration output and air-conditioning output of ejector cycle with solar flux. It is shown that both the outputs of two-phase ejector cycle increase for all SHTFs (Air, CO_2, and He) with the increase in the solar flux. For the He, the refrigeration output ranges from 1245 kW to 2063 kW and air-conditioning output from 376.7 kW to 624.1 kW is highest, followed by CO_2 [refrigeration output from 1261 kW to 2081 kW and air-conditioning output from 381.9 kW to 630 kW] and for Air it is lowest [refrigeration output from 1276 kW to 2097 kW and air-conditioning output from 387 kW to 635.4 kW] with the increase of solar flux from 600-1000 W/m^2.

Fig. 6 depicts the effect of increase of solar flux on cooling exergy outputs of two-phase ejector cycle. According to the figure, both the exergetic outputs of two-phase ejector are improved for all SHTFs (Air, CO_2, and He) with the rise in the solar flux. For the He, the exergy of refrigeration output ranges from 241.5 kW to 394 kW and exergy of air-conditioning output from 10.008 kW to 15.94 kW is highest, followed by CO_2 [exergy of refrigeration output from 236.5 kW to 388.8 kW and exergy of air-conditioning output from 9.506 kW to 15.33 kW] and for Air it is lowest [exergy of refrigeration output from 231.3 kW to 383.3 kW and exergy of air-conditioning output from 9 kW to 14.91 kW] with the increase of solar flux from 600-1000 W/m^2. The reason of increase in both the exergy outputs being the increase in turbine output of OFC cycle due to the increase in mass flow rate of the working fluid of OFC cycle which is utilized to run the compressor of this cycle as mentioned in Fig. 4. The exergetic output of air conditioning sub-system is found to be significantly lower than the exergetic output of refrigeration sub-system. This is because the evaporator temperature of refrigeration system is far away from the ambient temperature and hence provide larger exergy compared to air conditioning which is close to ambient. This clearly shows

analysis of exergy is an important tool for the development of strategies to use energy resource for the production of cooling at different levels of temperature.

Thermal efficiency of the system is defined as overall useful energy output (net electrical output, refrigeration output and air-conditioning output) to the total energy input ($\dot{Q}_{solar}$) as defined in eq. (5). Similarly, the exergy efficiency of the system is defined as overall exergy output (net electrical output, exergy of refrigeration output and exergy of air-conditioning output) to the total exergy input ($\dot{E}_{solar}$) as defined in eq. (8). The variation of thermal and exergy efficiencies of the system for different SHTFs (Air, CO_2, and He) with the change in solar flux as shown in Fig. 7. The thermal and exergy efficiency is found to decrease for all the SHTFs with the increase in the solar flux. With the increase in solar flux, the increase in the energy output (i.e., net electric output of turbine, refrigeration output, and air-conditioning output) is less in comparison to increment in the solar energy input which lead to the decrease the thermal efficiency of the system for all SHTFs. For He, the thermal efficiency decreases from 16.72% to 16.62%, for CO_2, it decreases from 16.71% to 16.61%, and for Air 16.70% to 16.60% with the increase in solar flux from 600- 1000 W/m^2. It is also important to note that with the increase in solar flux, the increase in the exergy outputs (summation of all exergetic outputs) is less in comparison to increment in the exergy of solar energy input which lead to decrease the exergy efficiency of the system for all SHTFs. Furthermore, the exergy efficiency for He decreases from 6.096 % to 6.067%, for CO_2 from 6.094% to 6.063%, and for Air from 6.091% to 6.054% with the increase in solar flux from 600-1000 W/m^2. This is because the increase in the solar flux leads to high temperature of the SHTF which increases the thermal losses (high losses of energy and exergy at high temperature) from the PTSC.

The variation of thermal and exergy efficiencies of the system for different SHTFs (Air, CO_2, and He) with the change in ambient temperature as shown in Fig. 8. The thermal and exergy efficiency

Accepted Manuscript Not Copyedited

Copyright © 2025 by ASME

is found to decrease marginally for all the SHTFs with the increase in the ambient temperature. For He, the thermal efficiency decreases from 16.72% to 16.68%, for CO_2, it decreases from 16.70% to 16.66%, and 16.68% to 16.64% for Air. Since an increase in ambient temperature decreases the thermal losses between the system and environment which provide an increment in the energy input to the cycle and this leads to decrease the thermal efficiency of the system for all SHTFs. Since exergy accompanied by thermal losses is much less than the thermal losses, therefore, an increment in the exergy supplied to cycle is greater than its energy counterpart and hence, the exergy efficiency of the system is less than its thermal efficiency for all three fluids. Further, the rate of decline in exergy efficiency is greater than the thermal efficiency owing to larger decrease in the exergy accompanied by cooling outputs produced by refrigeration and air conditioning sub-systems. The exergy efficiency for He decreases from 6.099 % to 6.064 %, for CO_2 from 6.097% to 6.062%, and for Air from 6.087% to 6.056% with the increase in ambient temperature from 17^0C to 37^0C. This is because the increment in the exergy output is less than the increment in the exergy input.

4.3 Effect of varying the OFC turbine inlet pressure on cogeneration performance

Fig. 9 depicts the impact of variation of turbine inlet pressure on the thermal and exergy efficiency of the system. As the turbine inlet pressure increases, enthalpy of vaporization of the working fluid (R124) of OFC decreases and consequently mass flow rate of working fluid (R124) of OFC increase. So, for same amount of heat input in PTCS, the work output of turbine increases which results in increase in the energy output (i.e., net electric output of turbine, refrigeration output, and air-conditioning output) and consequently thermal efficiency increases. In similar fashion, for same amount of exergy input in PTCS, the work output of turbine increases which results in increase in the exergy output (i.e., net electric output of turbine, exergy of refrigeration output, and exergy of air-conditioning output) and consequently exergy efficiency increases. So, thermal and

Copyright © 2025 by ASME

exergy efficiency of the system increases for all SHTFs with the increase in turbine inlet pressure of the OFC which is due to the increase in mass flow rate of working fluid (R124) of OFC. For He, the thermal efficiency is highest which increases from 14.83% to 19.38%, followed by CO_2 and increases from 14.62% to 19.17%, and lowest for Air, from 14.41% to 18.95% with the increase the turbine inlet pressure from 1800 kPa to 2200 kPa. Furthermore, the exergy efficiency for He is highest which increases from 5.463 % to 7.123%, followed by CO_2 and increases from 5.361% to 7.021%, and lowest for Air, from 5.256% to 6.914% with the increase in turbine inlet pressure from 1800 kPa to 2200 kPa.

4.4 Effect of varying the refrigeration and air conditioning evaporator temperatures on cogeneration system efficiencies

Fig. 10 illustrates the effect of change of refrigeration evaporator temperature (T_{ref}) on the thermal and exergy efficiencies of the overall system. An increase in refrigeration evaporator temperature (from -25^0C to -15^0C), the refrigeration output ($\dot{Q}_{ref}$) and air-conditioning output ($\dot{Q}_{AC}$) of two-phase ejector cycle increases due to which the energetic output of the proposed system increases. This is due to increase in mass flow rate of the refrigerant (R600a) of two-phase ejector cycle and hence its thermal efficiency increases. For He, the thermal efficiency is highest which increases from 15.72% to 18.19%, followed by CO_2 and increases from 15.62% to 18.08%, and lowest for Air, from 15.50% to 17.97%, with the increase the refrigeration evaporator temperature from -25^0C to -15^0C. On the other hand, exergy efficiency of the overall system decreases with the increase of the refrigeration evaporator temperature. The decrement in the exergy efficiency of the cycle is because the exergy of refrigeration output reduces with the rise of refrigeration evaporator temperature. The exergy efficiency for He is highest which decreases from 6.138 % to 6.018%, followed by CO_2 and decrease from 6.133% to 6.015%, and lowest for Air, from 6.128% to 6.009% with the increase in refrigeration evaporator temperature from -25^0C to -15^0C.

Fig. 11 shows the effect of change of air-conditioning (AC) evaporator temperature (T_{AC}) on the thermal and exergy efficiencies of the overall system. An increase in AC evaporator temperature (from 15^0C to 25^0C), the refrigeration output ($\dot{Q}_{ref}$) and air-conditioning output ($\dot{Q}_{AC}$) of two-phase ejector cycle increases due to which the energetic output of the proposed system increases. This is due to increase in mass flow rate of the refrigerant (R600a) of two-phase ejector cycle and hence its thermal efficiency increases. For He, the thermal efficiency is highest which increases from 16.34% to 17.06%, followed by CO_2 and increases from 16.32% to 17.03%, and lowest for Air, from 16.29% to 17.00%, with the increase the AC evaporator temperature from 15^0C to 25^0C. Similarly, the exergy efficiency of the overall system increases marginally with the increase in AC evaporator temperature. The reason being exergy of refrigeration output increases and exergy of air-conditioning output decreases resulting in marginal increase in the exergy efficiency with the rise of AC evaporator temperature. The exergy efficiency for He is highest which increases from 6.076 % to 6.087%, followed by CO_2 and increases from 6.074% to 6.085%, and lowest for Air, from 6.068% to 6.079% with the increase in AC evaporator temperature from 15^0C to 25^0C.

4.5 Breaking down of solar exergy input into the exergy produced, exergy destroyed, and the exergy loss

Fig. 12 show the breaking down of solar exergy and its destruction due to generation of entropy in various components of the system when it is operated at baseline conditions. The exergy accompanied by solar rays falling on the PTSC is considered as 100% exergy source driving the proposed cogeneration. The highest exergy destruction rate is observed at PTSC (53.87%) followed by OFC (22.09%), two phase ejector cycle (6.15%), and remaining 17.89% is the exergy output of cogeneration system. This percentage of exergy reveals critical insights into the performance of individual sub-systems, highlighting areas for performance improvement of real-world cogeneration systems driven by solar energy. Computation of exergy destruction in sub-systems assist in diagnosing the real potential of this newly developed cogeneration system.

Comparing with the exergy destroyed in the PTSC employing thermal oil as solar heat transfer fluid (58.47%) [21], the exergy destructed in presently used PTSC (53.87%) is considerably lesser. Results shows PTSC has by far the highest exergy destructive sub-system, followed by the OFC. Therefore, it seems that system modifications, of which the aim is to reduce exergy destruction in the PTSC and OFC, have a major potential to increase the power output of OFC for enhancing the electric power output. The exergy destruction in the OFC can be mitigated by employing the zeotropic mixtures instead of pure organic fluids as the working medium. The third highest exergy destructive sub-system is the two-phase ejector where majority of the exergy is destroyed in its condenser and evaporators. The exergy in these components can be significantly mitigated by increasing the evaporator temperature and decreasing the condenser temperature which in turn decrease the exergy destroyed in the two-phase ejector. This will contribute towards an enhancement in the cooling output desired to refrigerate the thermal loads of air conditioning and refrigeration. Classification of the output exergy gives turbine output (4.02%), refrigeration output (10.65%) and air-conditioning output (3.22%). The exergy destruction in PTSC is dominant in the whole system because high quality solar insolation is absorbed by the receiver at higher temperature which leads to greater thermodynamic losses in the collector. The second highest destruction of solar exergy is found in the OFC mainly due to throttling of cycle working fluid from economizer pressure to evaporator pressure which is the saturation pressure corresponding to temperature of high-pressure flasher. Expansion of the mixture of two-streams in the turbine with the significant difference exergy of two streams further contribute to larger destruction of solar exergy by the OFC. The two-phase ejector is determined as the third largest destruction of solar exergy which is majorly due to friction losses associated with the fluid stream passes through the ejector and due to the entropy generated via non-isentropic expansion of flowing stream in the nozzle. Separation of refrigerant R600a stream into two streams; saturated vapor (state 10) and

saturated liquid (state 7) and the throttling of saturated liquid in the expansion valve (7- 8) further contributes to destruction of exergy in the cooling cycle.

5. Conclusions

In conclusion, this investigation undertook an in-depth evaluation of an innovative solar-driven cooling-power cogeneration system, seamlessly integrating diverse technologies such as parabolic trough collectors, organic flash cycle, and two-phase ejector cooling cycle. Through rigorous energy and exergy analyses, the quantified system performance yielded key quantitative outcomes affirming its efficacy. Important features of this proposal are that system does not rely on electricity from grid. Part of electricity generated by OFC is supplied to grid, and remaining is expended in driving the compressor of two-phase ejector which is aimed to produce refrigeration and air conditioning. The influence of using gases as solar fluid and change of weather conditions have been examined on the energetic and exergetic performances of the devised cogeneration and major findings of the study can be shown as below:

- Helium (He) is determined to be the gaseous SHTF which absorbed highest solar energy by showing a 28.11% increase in its temperature while passing through the collector and in case of the use of CO_2 it is increased by 26.65% when solar flux is promoted from 600 to 1000 W/m^2.

- By increase of solar flux from 600 to 1000 W/m^2, mass flow rate of the working medium of OFC is significantly enhanced but it is marginally varied with the change in type of SHTF employed in PTC.

- OFC turbine output, and the refrigeration and air conditioning outputs of two-phase ejector shows upward trends when the solar flux increases from 600 to 1000 W/m^2.

- Cooling exergy produced by two-phase ejector is found considerably increasing with the rise of solar flux. Rate of increase in exergy of refrigeration is greater than the rate of exergy accompanied by air conditioning.

- The impact of varying the OFC turbine inlet pressure on system efficiencies is considerably large but change of solar flux shows a little impact on them.

- Results obtained for the distribution of solar exergy in the system components reveal that 53.87% of solar exergy is destroyed by PTSC followed by 22.09% in OFC, and 6.15% in two-phase ejector cycle, and remaining solar exergy is converted into power exergy (4.02%), refrigeration exergy (10.65%) and exergy accompanied by air-conditioning (3.22%). The findings clearly reveal PTSC as the maximum exergy destructive component (53.87%) of the system and it needs improvement on priority. The exergy destruction in the PTSC can be obtained by employing use of multiple concentration ratios in the collector, use of internal fins in absorber of PTSC, and by applying coating over absorber tubes which decrease the loss of heat from collector to environment and therefore, by decreasing the transfer of heat between ambient and system boundary the entropy transfer via heat reduces which in turn decrease dissipation of exergy.

This investigation's unique integration of multiple technologies paves a sustainable pathway to address the ever-increasing demands of a growing global population and rising living standards. As results through this research provides essential groundwork, subsequent efforts must translate the immense promise into practical implementations.

The proposed system of cooling and power come with numerous scopes and novelty. The developed model mainly investigates on a few operational parameters, whereas there are many more aspects of employment in real-world scenario such as environmental impact

and economic expenses along with the consideration of the variation of heat losses, pressure drop, and component efficiency. All investigations are conducted with the steady-state condition which limits the ability to predict the variation of cooling loads of refrigeration and air conditioning across various times of the day. To facilitate the scopes of improvements of this investigation, an advanced exergy analysis, exergo-economic evaluation, multi-objective optimization can be carried out. Investigation into the scalability and adaptability of the proposed cooling and power system for different geographical locations and CSP technologies will be essential for its broader implementation, ensuring a comprehensive and robust approach.

ABSTRACT

With advancements in technology, the number of people using various social networks to share information daily has increased exponentially. To spread information to maximum users, there is a need to effectively identify highly influential nodes in social networks. Still, existing centrality measures and methods have drawbacks relating to computational complexity and accuracy. The proposed method considers the Game of Thieves algorithm to rank influential nodes in social networks effectively with lower computational time that outperforms existing closeness centrality, eigenvector, Game Theory, and VoteRank^{++} algorithms. To evaluate the performance of the proposed work, experiments were conducted on synthetic and real-world network datasets. The results were evaluated with the help of the Susceptible-Infected-Recovered (SIR) model and Node Removal Procedure (NRP) evaluation metrics. These results showed that GOT outperforms the existing measures by 12% on average while giving more accurate results than the standard algorithms for large-scale networks.

1 | Introduction

In recent decades, social networking has become a crucial medium for connecting with people and disseminating information with the help of technology. It plays an important role in modern society, allowing people to share information. In recent years, Social Networking platforms like X, LinkedIn, Facebook, Instagram, and so on have grown exponentially. Currently, there are 4.95 billion users[1] globally on over 130 social media platforms, which are expected to reach 5.85 billion by 2027. A social network can be described as a group of nodes (people, groups, organizations, etc.) that is connected by links/edges showing relations between them. It is widely applicable in areas such as organizational studies, psychology, economics, information science, and criminology [1] leading to additional challenges for the application of social network analysis (SNA) methods.

SNA focuses on the exchange of resources between individuals, groups, or organizations. Many complex systems, like social networks, utilize SNA to identify key or influential individuals. These individuals can be thought of as "hubs" within the network, and their actions can significantly influence the behavior of the entire network. Thus, it is possible to track the spread of information by determining the key players in the dissemination of messages. This can be useful in understanding how rumors spread, allowing for the potential to intervene and control the spread of misinformation [2].

The existing approaches used to find these influential nodes include centrality measures, like degree, closeness, and betweenness centrality measures [3]. These measures assess the importance of a node based on its connections to other nodes in the network. Degree centrality measures the number of neighbors of

© 2025 John Wiley & Sons Ltd.

a node but fails to accurately measure the centrality of a node. A node having a higher number of connections but lying in the periphery of the network would have a higher degree as compared to a more central node with a lesser number of connections [4]. Closeness centrality is based on the distance between each pair of nodes in the network, while betweenness centrality is based on the frequency with which a node acts as a bridge between other nodes. Betweenness and closeness centralities give better results than degree centrality, but high computational complexity limits their application in large-scale social networks [3].

K-shell algorithms [5] strip away the outer layers of a network, with the core nodes considered more influential. However, in a significant drawback, they may assign the same influence value to many nodes in some special networks.

The above-discussed methods assume that a node's influence is contingent only on its own importance. Information entropy [6] considers the impact of neighbors' importance on a node's influence. Popular random walk models like PageRank [5] and LeaderRank [7] give better results for finding influential nodes in directed networks but fail to do so for undirected networks. Recent approaches using game theory [8] model social interactions as cooperative games to detect dominant influencers in the networks.

While there have been many efforts to identify influential nodes in social networks, the scope for improvement exists in terms of accuracy and efficiency. Further research is needed to address the limitations of existing methods and to develop new approaches to better determine the influence of nodes in real-world networks. This study will explore the use of the Game of Thieves (GOT) algorithm for identifying influential nodes in a network and evaluate its performance through experiments on real-world and synthetic datasets.

The GOT algorithm is a new approach for analyzing complex networks, including identifying the influential nodes in networks. This algorithm relies on the notion of a "diffusion process," in which a certain behavior or characteristic spreads through the network from one individual to another. The GOT algorithm simulates this diffusion process and uses it to determine which individuals are most likely to start or stop the spread of the behavior. It considers the strategic behavior of the nodes during the influence spread, and it can identify influential nodes more realistically [3].

The main challenge with earlier proposed methods was the greater amount of computation cost associated with these methods. GOT can compute the importance of both vertices and edges in a network in polylogarithmic time as opposed to the quadratic time taken by classical methods. The worst-case implementation of GOT is limited by $O(\log^3 |V|)$ where V is the number of nodes in a network. The lower computational complexity of GOT makes it much faster and more scalable (both in the number of nodes and edges/connections) than already existing methods [3].

The evaluation results suggest that GOT outperforms other centrality algorithms based on computational complexity by an average of 12% and provides more accurate results for large-scale networks.

The key contributions of this research work are as follows:

1. This paper introduces a comprehensive evaluation of the GOT algorithm for finding influential nodes in social networks.
2. The algorithm identifies influential nodes that have a significant impact on the network structure and properties when removed from the network. These nodes can represent individuals who have many connections within the network or bridge different subgroups within the network. Once influential nodes have been identified, they can be targeted for interventions to leverage their influence within the network.
3. In terms of computational complexity, it outperforms earlier proposed methods to find nodes that drive the dissipation of information, opinions, or behaviors within the network.
4. This study makes several significant contributions to the field of network analysis and provides an effective algorithm for identifying the influential nodes in a network.

The remainder of this paper is organized as follows. Section 2 presents various studies conducted in the field of finding influential nodes in a complex network. Section 3 describes the preliminary concepts that need to be understood for a better understanding of the proposed work. Section 4 details the proposed methodology and datasets used. The algorithmic explanation and flowchart along with its illustration for a network are described in Section 4. In Section 5, the experimental setup used is explained to compute the results. The results of the analysis are discussed in Section 6. Finally, concluding remarks and the scope of future work are discussed in Section 7.

2 | Related Work

The identification of influential nodes in complex networks is a critical area of research in SNA. A wide range of centrality measures has been proposed to quantify node importance, reflecting their position and connections within the network. These measures aim to determine the nodes that have the most significant influence, either directly or indirectly, on the network's structure and dynamics.

Traditional centrality measures: Common centrality measures, such as degree centrality, betweenness centrality, closeness centrality, and eigenvector centrality [2], are widely used to identify influential nodes. Degree centrality quantifies the importance of nodes based on the number of direct connections, while betweenness centrality highlights nodes that serve as bridges in the network. Closeness centrality, on the other hand, focuses on nodes that can quickly access other nodes, and eigenvector centrality considers the importance of neighbors when evaluating a node's influence. These traditional centrality measures are foundational but have limitations, particularly in dynamic networks where the influence of nodes may change over time.

Cluster-based and heuristic approaches: The clustered local degree centrality measure improves on traditional centrality measures by considering local clustering around a node and the

15320634, 2025, 9-11, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.70044 by Delhi Technological University, Wiley Online Library on [30/04/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

degrees of its neighbors [9]. This approach identifies influential nodes based on the local network structure rather than global network properties. Meanwhile, heuristic clustering methods group nodes into clusters based on similarity, with the most influential node in each cluster selected as a potential seed node. Although these methods are computationally efficient, they often exhibit low accuracy, as they are prone to getting trapped in locally optimal solutions [10].

Limitations of traditional methods and diffusion models: Traditional centrality measures often fail to capture the complexity of diffusion processes within networks. To address this, more sophisticated methods, such as the PageRank algorithm, are used for influence maximization problems. The PageRank algorithm assesses the importance of nodes by considering both the quantity and quality of their connections, reflecting the spreading of influence through the network. However, these methods still fall short in many scenarios, prompting the development of alternative approaches.

Optimization and simulation-based approaches: One notable advancement is the use of optimization techniques, such as the gray wolf optimization algorithm, proposed by Zareie [11]. This method formulates the influence maximization problem as an optimization challenge, taking into account the influence of nodes and the distances between them. Compared to earlier heuristic approaches, the gray wolf optimization algorithm showed improved performance and reduced computational time.

Simulation-based methods also provide valuable insights into node influence. The Linear Threshold Model (LTM) [12], for instance, simulates the spread of information across a network to identify influential nodes by analyzing their potential to initiate or stop the spread. While these models are effective, they are sensitive to parameter choices and may not always accurately represent real-world dynamics.

VoteRank^{++} and game theory approaches: Recent advancements in influence maximization have introduced algorithms like VoteRank^{++} [12], which iteratively select influential nodes based on varying voting abilities. In this method, nodes with different degrees have different voting powers, allowing for more accurate identification of important nodes in the network.

Game theory has also been increasingly applied to influence maximization problems. The explosion-trust (ET) Game Model [13] incorporates two critical factors—the degree of rumor explosion and the degree of trust in the source node—to develop a model for rumor spreading. This approach, along with the EDGly algorithm and SV-based games for community-based networks [14], has shown promise in finding influential nodes within specific communities.

Hybrid and deep learning approaches: While individual centrality measures are effective in specific contexts, they often lack the capacity for comprehensive evaluation. Therefore, combining multiple centrality measures has become a popular approach. Random walk algorithms [7] integrate these measures through preference analysis, ranking influential nodes more robustly.

Furthermore, hybrid approaches that combine classical methods with modern machine learning techniques have gained attention. For example, deep learning methods that utilize network embedding and deep reinforcement learning have been proposed to address the influence maximization problem, offering more efficient and accurate results. Graph embedding techniques help overcome the limitations of traditional algorithms by providing a more nuanced representation of nodes and their relationships.

Several modified approaches have also been proposed, such as the modified spider monkey optimization-based method, which incorporates graph embedding and the k-means algorithm to improve the detection of influential nodes in graph networks [15].

Community-aware and multicomponent centrality approaches: Recent work has increasingly focused on community-aware centrality approaches and multicomponent centrality metrics [16–26]. These methods recognize that nodes within communities may have different roles and influences depending on their membership in specific subgroups. By integrating community structure into the centrality measures, these approaches offer a more granular and context-aware assessment of node influence in complex networks.

Within the research community, one can see that considerable work has already been done to find the influential nodes in complex networks. Despite the advances, there are still some drawbacks to the current study. For example, centrality measures can be unreliable in capturing the true influence of a node in a network because they depend on limited information and can be influenced by the network structure. In addition, game-theoretic models can be computationally complex and may not accurately reflect the dynamics of real-world networks.

The GOT algorithm is a recent addition to the literature that addresses these limitations. This research builds upon the existing literature by applying the GOT algorithm to identify influential nodes in a network and comparing its performance to traditional centrality measures and simulation-based methods using real-world and synthetic datasets. This paper presents the fundamental ideas and principles of the GOT approach and how it identifies the influential node in an optimal manner for a social network.

3 | Preliminaries

This section includes background knowledge of the concepts required for the better understanding of the proposed work.

3.1 | GOT

The algorithm analyzes the interaction between a set of "virtual diamonds" (vdiamonds) and a group of wandering "thieves" (moving across the network in search for vdiamonds) in a graphical network.

At the start, each node is endowed with wandering thieves and vdiamonds. A thief has two states: "loaded" (it carries one vdiamond) and "empty" (it does not carry any vdiamond). A thief

15320634, 2025, 9-11, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.70044 by Delhi Technological University, Wiley Online Library on [30/04/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

moves from one node to a randomly chosen neighboring node to look for vdiamonds; when he finds a vdiamond, the thief brings it back to his home node by retracing the previous path and goes in search of another vdiamond. This vdiamond becomes immediately available for the other wandering thieves to steal.

Initially, all node hosts have the same given number of thieves and vdiamonds [3]. The algorithm moves in epochs. At each epoch, all thieves move from their current node to the next one and change state when they steal a new vdiamond from other nodes.

Consider an undirected graph, $G = (V, E)$, where (V) is the set of vertices/nodes, and (E) is the set of edges between nodes.

At the first epoch; initial state:

$$\upsilon_{0n} : \text{number of vdiamonds at node } n, n \in V$$

As the game proceeds, at epoch T, the state of the graph can be described as:

υ_{Tn}: number of vdiamonds at node $n, n \in V$.

α_{Tn} : number of loaded thieves crossing link, $e \in E$.

So, the average number of vdiamonds, υ_n, present at node n, $n \in V$ and average number of loaded thieves, α_e, traversing link e, $e \in E$ after the game runs for T epochs can be calculated as:

$$\upsilon_n = \frac{1}{T}\sum_{i=0}^{T}\upsilon_{in} \tag{1}$$

$$\alpha_e = \frac{1}{T}\sum_{i=0}^{T}\alpha_{ie} \tag{2}$$

At the end of all the game runs, the node with lower value of υ_n is considered more influential than a node with higher value of υ_n.

3.2 | Information Diffusion Models

The information diffusion models are mathematical frameworks widely used for evaluating how information and behaviors spread among individuals in SNA. With the help of these models, the dynamics of information flow and the factors that influence the rate and extent of diffusion in social networks can be studied. To validate the efficacy of the suggested method, the node removal procedure (NRP) and the susceptible infected recovered (SIR) models have been used to assess the rationality of the node ranking results.

3.2.1 | SIR

The SIR model is the most popular diffusion model used in SNA to study the propagation of infectious diseases, rumors, and information in a network. It has been applied to various real-world scenarios, including the spread of HIV, COVID-19, and SARS [27].

This model takes the entire disease-spread population to estimate the number of individuals infected in a period and predicts the growth of the disease.

The model divides the individuals/nodes in a network into one of three discrete states: susceptible (S), infected (I), and recovered (R).

The state variables of each state can be defined as:

$S(t)$ = number of individuals who are not infected yet at time t

$I(t)$ = number of infected individuals who transit disease at time t

$R(t) = n$umber of individuals recovered at time t

The set of differential equations that describe the dynamics of disease transmission and recovery in a network can be expressed as follows:

$$\frac{dSt}{dt} = -\beta StIt \tag{3}$$

$$\frac{dIt}{dt} = \beta StIt - \gamma It \tag{4}$$

$$\frac{dRt}{dt} = \gamma It \tag{5}$$

In the model, at time $t = 0$, few nodes are in I state and act as disease spreaders in the network. The rest nodes are in state, S. The rate at which nodes get infected can be defined as transmission coefficient, β, and γ denotes the recovery rate of infected nodes to become immune to the disease. There has also been an assumption for recovered nodes that they will never be reinfected again. The variations in the susceptible (S), infected (I), and recovered (R) population can be studied over the course of the infection. Diffusion dynamics play a significant role in determining the spread of influence in networks, and the SIR model provides a relevant framework for studying this phenomenon.

3.2.2 | NRP

NRP is a widely accepted technique for determining the accuracy of identified influential nodes in a network. It is a non-compartmental diffusion model [28] used in SNA to simulate the spread of information and opinions in a network. The model includes a node removal process, which removes nodes from the network based on certain criteria, such as their centrality.

This plays a pivotal role in the experimental process. Based on the scores assigned by the metric, each node in the graph is arranged in sorted order. The sorting process begins with the most critical/influential node and proceeds down to the least significant node. Nodes are gradually removed from the graph, one by one, following the order established during the sorting step [29]. As

15320634, 2025, 9-11, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.70044 by Delhi Technological University, Wiley Online Library on [30/04/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

each component is removed, two crucial aspects of the remaining graph are carefully measured: the size of the Giant Component (GC) and the number of connected components (CC).

The primary objective in NRP is to identify a metric that demonstrates desirable characteristics. A metric is considered superior if it produces a greater number of connected components while simultaneously minimizing the size of the giant component. By maintaining this delicate balance, the metric remains effective throughout the NRP process.

4 | Proposed Methodology

4.1 | Brief Description of GOT

As discussed in Section 3.1, GOT identifies influential nodes in a complex network by employing the idea of a diffusion process. The drivers of this algorithm are "thieves," with one thief present at each node. Each node of the network is considered to have a predetermined quantity of virtual diamonds or "vdiamonds" present initially.

The strategic behavior of the thieves to collect the vdiamonds is used to find the influential nodes in the network. Each thief has an associated state which can be "empty," if the thief is not carrying a vdiamond or "loaded," if the thief is carrying a vdiamond. A thief in "empty" state picks a vdiamond from a node and deposits it at its home node. The influence of each node is measured by the average of the number of vdiamonds at that node. The nodes with lower averages are considered more influential in comparison to nodes with higher average numbers of vdiamonds. A lower average signifies that a greater number of thieves have frequented a particular node, and therefore, this node can exert its influence on the home nodes of those thieves.

The GOT algorithm can also be used for finding the influence of edges by keeping a track of the average number of thieves in a loaded state passing through the edge. The edge with a higher average is considered more influential than the edge with a lower average. For the purpose of this study, the influence of edges is not considered in the network. During initialization, random initialization is chosen to simulate a variety of starting conditions or to ensure that results are not biased by a fixed starting configuration.

4.2 | Example Network

UlFigure 1 illustrates the functioning of GOT on an example network of eight nodes, labeled A–H. The label for each figure in the illustration represents the influence of the nodes at the mentioned epoch. The illustration shows the behavior of thieves in the network at certain intervals between epochs 1 and 1000. The first epoch represents the initial state of the network. Each node has two thieves and five vdiamonds at epoch 1 in the illustration above.

At each epoch, the network follows the GOT algorithm once, and the number of vdiamonds gets updated. The mean of the diamonds for each node after each epoch is calculated. The lowest mean value represents the most influential node. In order to determine the rank, the nodes are arranged in ascending order using the mean value of the vdiamonds. The labels alongside the nodes represent the ranks after that number of epochs; that is, the

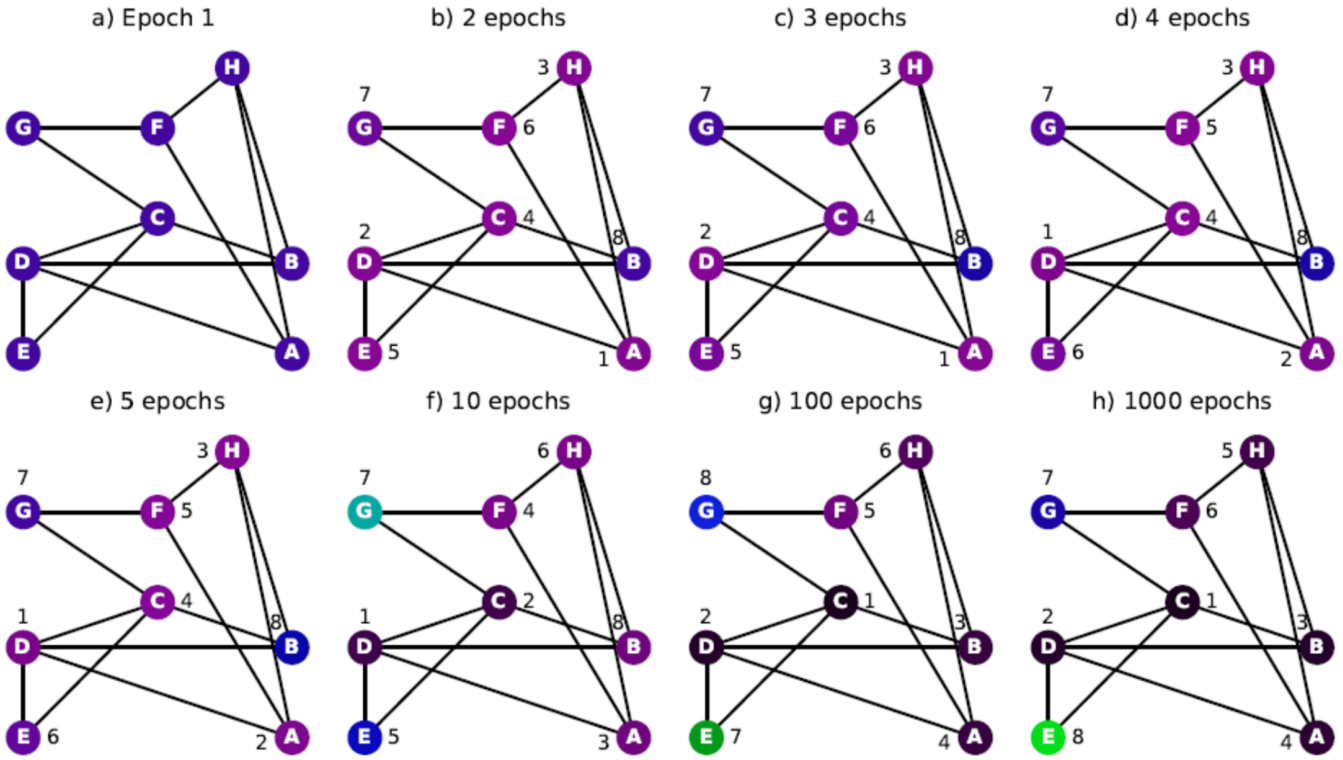

FIGURE 1 | Running GOT on a sample network.

rank 1 node is the most influential node in the network, and the rank 8 node is the least influential.

4.3 | Algorithm Description

Based on the technical framework defined in Section 4.1 and the example covered in Section 4.2, this section formulates the algorithm for the proposed approach. For a proper understanding of the method, some notations are defined as follows:

- n_u^t is the number of vdiamonds at vertex $u \in N(G)$ at epoch t
- h_x is the home node of thief x
- c_x is the current location of thief x
- s_x is the current state of thief x representing either "empty" or "loaded" state
- $\prod_u$ is the set of all nodes directly connected to node u by an edge
- Δ_x is the path followed by thief x to reach the current node from its home node
- ϕ_u is the average number of vdiamonds at each node u
- Ω_u is the total number of vdiamonds at each node u
- T_f is the number of epochs for which the algorithm is run on the network G (Algorithm 1).

ALGORITHM 1

Input: Target Network, $G(N, E)$
Output: Average number of vdiamonds, ϕ_u, at each node $u \in N(G)$

```
1 for i in range (1, T_f):
2   for each thief j in G:
3     if s_j is empty then:
4       set c_j = random(u) where u ∈ j
5       if c_j ∈ j then:
6         update Δ_j to include path till first occurrence of c_j
7       else
8         append c_j to Δ_j
9       if n^i_{c_j} >  0 then:
10        set s_j = loaded and update n^i_{c_j} := n^i_{c_j} − 1
11    else
12      if c_j= h_j then:
13        set s_j= empty and update n^i_{c_j} := n^i_{c_j} + 1
14      else
15        set c_j to the last but one location in Δ_j and remove
          the last node from Δ_j
16  end for
17 for each node v in G:
18   Ω_v := Ω_u + n^i_v
19 end for
20 end for
21 for each node v in G
22   set φ_v = Ω_v/T_f
23 end for
24 Return u for each node u ∈ N(G)
```

A brief description of the algorithm is provided below:

Step 1: This step covers the lines 1–2 of the algorithm. In this step, all the thieves in the graph are iterated over for a total of T_f epochs.

Step 2: This step describes the lines 3–8 of the algorithm. In this step, the next location is decided for a thief j if the current state of the thief, s_j is "empty." A node, $u \in \prod_u$, is chosen as the next location for thief j based on the weighted probability of the edges given by:

$$p\left(e_v^u\right) = \frac{n_u^t}{\sum_{u \in \prod_u} w_v^x} \tag{6}$$

where e_v^u is an edge between nodes v and u, w_v^x is the weight of edge between nodes v and u and $p\left(e_v^u\right)$ is the probability of selecting e_v^u.

The dynamic list Δ_j contains the nodes previously visited by the thief. If the thief has already visited the next location c_j previously then, Δ_j is modified such that it contains the nodes up to the first occurrence of cj. If the thief has not visited c_j previously then, c_j is appended to Δ_j.

Step 3: In this step, the new location of the thief in "empty" state is checked for vdiamonds. If c_j has vdiamonds, the thief takes one vdiamond and its state changes to 'loaded' and the number of vdiamonds at this node is updated. This step concludes the actions taken by a thief in an initially "empty" state for an epoch. This step covers lines 9 and 10 of the algorithm.

Step 4: This step covers lines 11–13 of the algorithm. In this step, c_j of a thief j in the "loaded" state initially is considered. If the thief is at its home node, it drops its held vdiamond at this node and its state is set to "empty" with the number of vdiamonds at the home node of the thief increasing by 1.

Step 5: This step covers lines 14–16 of the algorithm. If the thief carrying vdiamond is not at its home node, its next location is the last but one node in Δ_j. Then c_j is updated and the last node is deleted from Δ_j. This step concludes the series of actions taken by a thief in initially "loaded" state for an epoch.

Step 6: This step illustrates lines 17–19 of the algorithm. All the nodes in the network are iterated over to calculate the number of the vdiamonds at each node. For each node, n_v^i is added to Ω_v.

Step 7: This step covers lines 21–23 of the algorithm. In this step, ϕ_v is calculated by dividing Ω_v by the number of epochs T_f.

4.4 | Flowchart

The flowchart in Figure 2 provides a step-by-step overview of the approach followed. The target network G is taken as the input for the algorithm. In the pre-processing phase, the network is

15320634, 2025, 9-11, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.70044 by Delhi Technological University, Wiley Online Library on [30/04/2025]. FIGURE 2 | Overview of the proposed work.

prepared for the algorithm by allocating an equal number of vdiamonds to each node initially. The GOT algorithm is applied on the network, and the output obtained is then sorted according to decreasing influence, that is, in increasing order of the average number of vdiamonds at nodes.

The next phase involves comparing the output of GOT with other approaches of finding influential nodes (such as centrality measures, etc.) and evaluating the performances using the different diffusion models as discussed in previous section (Section 3.2.1), respectively. The most influential k nodes are selected for evaluation, where k is a pre-decided number. For this research, k is taken as the number of nodes in the entire network. The results obtained from the diffusion models are represented as graphs and tables, which are further discussed in the results section.

5 | Experimental Setup

This section presents the experimental setup for the proposed work. GOT and the other measures, including Centrality, were

15320634, 2025, 9-11, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.70044 by Delhi Technological University, Wiley Online Library on [30/04/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

used to find the order of influence of nodes in a social network. The social networks used consisted of both synthetic and real-world datasets, as mentioned in Section 5.1. The datasets are further classified into weighted and non-weighted networks. Section 5.2 gives the details about the evaluation metrics used to compare the algorithms. The evaluation metrics considered in the study are: computational time analysis (Section 5.2.1), SIR (Section 5.2.2), and NRP (Section 5.2.3).

The implementation was done in Python and mainly using the NetworkX library for simulating the social networks. GOT was implemented by taking inspiration and ideas from other centrality-based algorithms that were used directly from the inbuilt implementations. VoteRank^{++} and game theory were taken from their respective sources [14] and re-implemented based on the requirements.

For the implementation, computation, and evaluation of results, a typical desktop PC was used (Intel i5 9600k with six cores and six threads with 16GB RAM on Windows 10 Operating System). The code was implemented on PyCharm IDE and run on Python 3.

5.1 | Datasets

This section describes the various online real-world social network datasets as well as synthetic datasets of varying contexts, sizes, and complexities used for the study.

The description of the real-world networks' datasets used is as follows:

1. Email-eu [30]: This dataset has information about all incoming and outgoing emails between members of the research institution. There is an edge (a, b) in the network if person a has sent person b at least one email.
2. Newman [31]: This dataset has a two-mode network due to two types of "nodes"—authors and papers—with connections existing between different node types.
3. Facebook Combined [32]: Facebook data has been made anonymous by adding a new value to each user's Facebook internal ID.
4. Congress-Bills [33]: In this dataset, US Congresspeople are the nodes, and the network represents the sponsors and co-sponsors of legislative bills.
5. US Power-Grid [34]: Transformers, substations, and generators serve as the nodes of this network of a high-voltage power grid, and high-voltage transmission lines serve as the ties.
6. Facebook Like [35]: The Facebook-like online social network represents an interesting two-mode network where weight can be assigned based on the number of messages that a user posts to a topic.
7. Wiki-Votes [36]: Administrators make up a very small portion of Wikipedia contributors. Users cast votes to advance a current user to the administrator position.
8. p2p Nutella network [37]: A series of images showing the topology of the Gnutella peer-to-peer file-sharing network, with nodes standing in for hosts and edges standing for connections between the hosts.
9. CA-Hep [37]: Citation-Author (CA) high energy physics (HEP) collaboration network is from the e-print that covers scientific collaborations between authors' papers submitted to this category.
10. Epinions [38]: This online social network is a who-trust-whom part of the general consumer review website Epinions.com. The statistical details of real-world networks used are shown in Table 1.

The results were calculated for both non-weighted and weighted synthetic networks. The weights of the edges in weighted networks were randomly assigned, ranging from 1 to 10.

The statistical details of the synthetic networks used are shown in Table 2 and the description of the three synthetic networks used for the experiments is as follows:

1. Erdos Renyi [39]: A random graph $G_{n,p}$, generated by randomly connecting nodes (n) with edges (M), where each edge is included with a fixed probability (p), independent of other edges. The other parameter *seed* is set as a seed for random number generation. The number of edges can be calculated: $E = p \times {}^{n}_{2}C$.

   The graph can be represented as:

   $$G_{n,p} = erdos_renyi_graph(N = n, p = 0.15, seed = 7)$$

2. Barabasi Albert [40]: This models a random synthetic network $G_{n,m}$, where new nodes are added incrementally and connected to the nodes having a higher degree. The new node is connected to the node (i) with probability (p_i):

   $$p_i = \frac{k_i}{\sum_j k_j}, \text{ where } k_i \text{ is the degree of node } i.$$

   The total edges E can be found as follows:

   $$E = n \times m; \text{where } m = int(0.01 \times n) \text{ denotes the number of nodes in the initial graph.}$$

   The graph can be represented as:

   $$G_{n,m} = barabasi_albert_graph(N = n, m, seed = 7)$$

3. Watts Strogatz [41]: This model, $G_{n,k,p}$, interpolates between these two extremes by randomly rewiring some edges, k of a regular lattice. The number of edges in Watts–Strogatz network is given by:

   $$E = n \times k/2, \text{ where } k \text{ is mean degree.}$$

   The graph can be represented as:

   $$G_{n,k,p} = watts_strogatz_graph(N = n, k = int(0.01 * N), p = 0.4, seed = 7)$$

TABLE 3 | Computational complexity.

Algorithm	Computational complexity
Degree centrality [3]	$O(V)$
Page Rank [5]	$O(k * V)$
Betweenness centrality [3]	$O(V \|\| E)$
Closeness centrality [3]	$O(V^3)$
Game theory [11]	$O(k * V^2)$
VoteRank^{++} [12]	$O(k * V^2 * \log \|V)$
Eigen Vector [42]	$O(V^3)$
Game of Thieves (*GOT*) [1]	$O(log^2 \|V\|) < O(GOT) < O(log^3 \|V\|)$

5.2 | Evaluation Metrics

5.2.1 | Computational Time (C_t)

In comparing influence estimation algorithms, C_t is an important factor, as most applications require faster and more efficient algorithms. Computationally efficient algorithms can have practical applications in real-world problems involving large-scale, complex networks. Hence, a comparison was done based on the time required for different algorithms to identify influential nodes in each dataset. The algorithms considered for this purpose are degree centrality [3], Page Rank [5], betweenness centrality [3], closeness centrality [3], game theory [11], Eigen Vector [42] VoteRank^{++} [12], and GOT [1].

Table 3 shows the time complexity of the above-mentioned algorithms in terms of vertices, V, and edges, E. GOT's computational complexity is limited by $O(\log^2|V|) < O(\text{GOT}) < O(\log^3|V|)$. This is primarily because GOT has a fully distributed [5] design for the coverage of nodes, which means each node in the network can run parallelly without interfering with other node's computations. This distributed architecture allows it to analyze networks more quickly when traditional methods are inefficient.

5.2.2 | SIR

SIR model was used to simulate how well were the top $K\%$ influential nodes, identified by each algorithm, able to spread influence in the network. Initially, top 1% nodes were infected with the rest of the nodes considered as susceptible. The infection factor, β, was set to 0.15 and the recovery factor, γ, was set to 0.1. An average of 100 runs was considered to determine the results of the model. The model works [3] on the idea that at every stage, an infected node can further infect its neighbors with a probability β and an infected node can recover with the probability γ. The term $R_0 = \frac{\beta}{\gamma}$ is known as the reproduction rate [12] and is extremely important for explaining the spreading potential. If $R_0 > 1$, then rumor is likely to spread widely. Otherwise, it dies out.

5.2.3 | NRP

In social networks, node removal can help to predict how the removal of individuals affects the information spreading nature [29] in a network. This can be useful for identifying the most influential nodes. For example, in the case of social media platforms, it can help us to determine who the top influencers or nodes in the network are. This essentially determines the

15320634, 2025, 9-11, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.70044 by Delhi Technological University, Wiley Online Library on [30/04/2025]. FIGURE 5 | Results for SIR for datasets: (a) Facebook combined; (b) US Power Grid; (c) Facebook Like; (d) p2p Nutella; (e) Newman; (f) Email-eu; and (g) CA-Hep.

influence spreading capacity and helps to evaluate the various algorithms.

Each algorithm is run to assign influence scores to the nodes, and they are sorted based on these scores. The order is from the most influential node to the least influential node. Further, the nodes from the sorted list are removed one by one from the network, and the size of the Giant Component and the number of connected components are computed after the removal. A node influence estimation metric is better if the number of connected components is as big as possible. In addition, the size of the giant component should be as small as possible [27].

6 | Results Discussions

This section lists the results of the experiments conducted as part of the study: computational time analysis (Section 6.1), SIR results (Section 6.2), and NRP results (Section 6.3). The experiments were conducted under the setup detailed in Section 5.

6.1 | Runtime Comparison of Proposed GOT With Existing Popular Algorithms

Tables 4 and 5 show the time (in seconds) each algorithm takes on the various real-world benchmark datasets and synthetic datasets, respectively. This data is also represented in Figures 3 and 4 for real-world and synthetic datasets, respectively.

GOT outperforms closeness and betweenness centrality measures substantially in Wiki Votes, US Power Grid, p2p Nutella, Newman, and CA-hep datasets, but underperforms in Facebook Combined, Facebook Like, Email-eu, and Congress Bills datasets. A clear distinction is observed in the relative performances of GOT and the two centrality measures based on the dataset size. Betweenness and closeness centralities perform better on datasets with a lesser number of nodes. Meanwhile, GOT performs better on datasets with a larger number of nodes. This difference can be attributed to the computational cost of overheads associated with GOT for smaller networks.

Degree centrality, eigenvector centrality, and Page Rank are almost instantly computed. A possible explanation for this result can be based on their inbuilt implementations and possible precomputations at the time of the network building phase.

For large datasets (having more than 50,000 nodes) like Twitter and Epinions, GOT was able to compute the influential nodes in under 2 h with the proposed experimental setup. Other algorithms could not complete the computation even after a reasonable period (over 36 h). Their runtime could not be ascertained due to system constraints. This is explained by the cubic and quadratic worst-case time complexities for these methods in comparison to the polylogarithmic time complexity for GOT, as explained in Section 5.1.

6.2 | SIR

Figure 5 shows the results obtained with SIR simulations on the real-world datasets. The graphs shown are plotted with the x-axis representing time and the y-axis representing the sum of infected and recovered nodes. The plotted graphs show the spread of information in the network over time. A steeper rise in the graphs denotes a faster information spread, indicating a more accurate identification of influential nodes.

As shown in Figure 5, GOT slightly outperforms all algorithms for every dataset. It dissipates the information at a faster rate than the other algorithms, indicated by its steep rise. It reaches the peak faster than the rest of the algorithms in the Facebook Combined and US power grid datasets and are on par with other algorithms for the rest of the datasets. This shows improved accuracy by GOT in identifying the most influential nodes in the network.

6.3 | NRP

The graphs in Figure 6 show the results obtained after performing the NRP on the datasets, as discussed in Section 5.2.3. The area under the curve (AUC) for the size of the giant component

15320634, 2025, 9-11, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.70044 by Delhi Technological University, Wiley Online Library on [30/04/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

and the number of connected components is plotted to perform an overall comparison between the algorithms. The greater value of the number of connected components and the lower value of the size of giant components are the preferred characteristics. Table 6 shows the AUC for the size of giant components versus the number of removed nodes in the NRP, and Table 7 shows the calculated number of connected components in NRP for each algorithm.

GOT outperforms all algorithms in high energy physics (Figure 6a,b), Facebook combined (Figure 6d,e) and Erdos-Renyi (Figure 6g,h) datasets using both AUC—size of giant component and AUC—number of connected components. It has the highest area under the graph for the number of components and the lowest for the size of giant components among all the algorithms in each of these datasets. This result highlights the superior ability of GOT in identifying the influential nodes in a network.

Figure 6c,d show the Congress Bills Dataset in which GOT lags behind the other algorithms. Though it can also be observed that in this dataset Closeness and Betweenness perform the best in the number of connected components, while betweenness outperforms all the algorithms substantially in terms of the size of giant component.

This highlights the limitation of GOT, particularly in smaller networks like Congress Bills, which are not complex enough for the algorithm to understand the influence spreading behavior.

As was observed for runtime results in Section 6.1, GOT underperforms relative to other algorithms in smaller and less complex datasets.

7 | Conclusion

SNA has become increasingly important in the era of online social networks having billions of daily active users. This has led to a massive increase in the sizes of social networks along with their complexity. In this work, the evaluation of the GOT algorithm to rank influential nodes in social networks effectively with lower computational time is done. GOT was evaluated against multiple influential node identification algorithms in real-world and synthetic datasets using run time comparison, SIR, and NRP evaluation metrics. The results illustrate that GOT gives a faster and more accurate results in comparison to the other algorithms, particularly for large-scale networks. The limitations of GOT are highlighted in small networks. It is observed that GOT performs worse than most of the other algorithms, even the established centrality metrics, in small-sized networks. The algorithm takes more time to run due to the overheads and implementation inefficiencies in the smaller datasets. Additionally, the use of randomness in the algorithm causes poor performance in smaller networks due to less network complexity and reduced epochs. The random placement of thieves can sometimes lead to suboptimal starting positions, affecting the efficiency and convergence of the algorithm. While this randomness promotes exploration, it can also limit the algorithm's ability to consistently find the optimal solution, especially in complex or noisy networks. In the future, more potential strategies, such as enhanced initialization techniques or hybridizing GOT with other optimization approaches, may be applied to mitigate these limitations. Further study in the field of influential nodes is required to find a single algorithm that offers good results in all kinds of networks with reasonable computational time.

Endnotes

[1] Globally, there were 5.3 billion internet users as of October 2023. In total, 4.95 billion people use social media platforms, representing 61.4% of the world's population.

Abstract
The increasing demand for energy and concerns about environmental degradation have accelerated the transition to renewable energy systems. This research paper explores the engineering solutions that enable sustainable energy production, including solar, wind, hydro, biomass, and geothermal energy. Advances in energy storage, grid integration, and efficiency enhancement technologies are discussed to highlight the role of engineering in achieving a sustainable energy future. Additionally, the paper examines the challenges in implementing renewable energy on a large scale and proposes innovative solutions for overcoming these barriers.

Keywords: Renewable Energy, Sustainable Engineering, Solar Power, Wind Energy, Energy Storage, Grid Integration, Smart Grids, Energy Efficiency

Introduction
The global energy crisis and climate change concerns necessitate a shift from fossil fuels to renewable energy sources. Engineering innovations play a crucial role in harnessing renewable energy efficiently and integrating it into existing infrastructure. This paper examines various renewable energy systems, their technological advancements, and engineering solutions for improving sustainability.

Solar Energy Systems
1. Photovoltaic (PV) Technology
Solar photovoltaic systems convert sunlight into electricity through semiconductor materials. Advances in PV technology, including perovskite solar cells and bifacial panels, have improved efficiency and reduced costs. Research is also focused on tandem solar cells and multi-junction solar cells, which can achieve higher conversion efficiencies.

2. Solar Thermal Systems
Concentrated solar power (CSP) plants use mirrors to focus sunlight and generate heat, which drives turbines for electricity production. Engineering solutions such as thermal energy storage, hybrid CSP-PV systems, and advanced heat transfer fluids enhance efficiency. The integration of AI-driven tracking systems further optimizes solar panel orientation for maximum energy capture.

3. Building-Integrated Photovoltaics (BIPV)
BIPV systems integrate solar panels into buildings, replacing traditional construction materials while generating electricity. Advances in transparent solar cells and flexible thin-film solar panels are expanding their applications.

Wind Energy Solutions

1. Aerodynamic Blade Design

Innovations in wind turbine blade materials and designs, such as carbon fiber composites and smart rotor technology, enhance energy capture and durability. The development of vertical-axis wind turbines (VAWT) has provided solutions for urban energy generation, where traditional horizontal-axis wind turbines (HAWT) are not feasible.

2. Offshore Wind Farms

Offshore wind farms provide higher energy yields due to stronger and more consistent wind patterns. Floating turbine technology, improved anchoring systems, and predictive maintenance using IoT sensors enhance their feasibility and resilience. Hybrid offshore platforms combining wind, solar, and wave energy are being explored.

Hydropower and Biomass Energy

1. Small-Scale Hydropower

Micro and pico-hydropower systems provide decentralized energy solutions, especially in remote areas. Advances in turbine efficiency, modular designs, and fish-friendly hydropower solutions reduce environmental impact while improving energy generation.

2. Biomass Energy Conversion

Engineering innovations in biomass gasification, anaerobic digestion, and biofuel production optimize energy output while minimizing environmental impact. Waste-to-energy technologies, including municipal solid waste gasification and algae-based biofuels, contribute to circular economy models and carbon neutrality.

Geothermal Energy and Storage Technologies

1. Enhanced Geothermal Systems (EGS)

Engineering advancements in deep drilling techniques, artificial reservoir stimulation, and high-temperature-resistant materials enhance the viability of geothermal energy in various locations. The development of closed-loop geothermal systems has reduced the environmental concerns associated with traditional geothermal extraction.

2. Energy Storage Solutions

Efficient storage systems, including lithium-ion batteries, flow batteries, hydrogen-based storage, and supercapacitors, address intermittency challenges in renewable energy sources. Innovations in solid-state batteries and gravity-based storage systems provide promising alternatives for long-duration energy storage.

Grid Integration and Smart Energy Systems

1. Smart Grids and Demand Response

Smart grids optimize electricity distribution through real-time monitoring, automated control, and demand-side management. AI-driven predictive analytics enhance grid stability by forecasting energy demand and supply fluctuations. Vehicle-to-grid (V2G) technology allows electric vehicles to act as distributed energy storage units, stabilizing the grid during peak demand periods.

2. Hybrid Renewable Energy Systems

Integrating multiple renewable sources with storage and smart grid technologies improves energy reliability and sustainability. Hybrid microgrids incorporating solar, wind, and battery storage provide resilient power solutions for remote communities and disaster-prone areas.

3. Power-to-X Technologies

Power-to-X (P2X) solutions convert excess renewable energy into synthetic fuels, hydrogen, and chemicals for use in industrial applications. Green hydrogen production through electrolysis is gaining traction as a clean energy carrier for sectors that are difficult to electrify, such as heavy industry and transportation.

Challenges and Future Prospects

Despite rapid advancements, challenges such as high initial costs, resource intermittency, energy storage limitations, and policy barriers remain. Future research aims to develop cost-effective, scalable, and efficient renewable energy systems through engineering innovations. International collaboration on standardization, subsidies for clean energy technologies, and investment in next-generation energy infrastructure will accelerate the transition to a fully renewable energy-powered world.

Conclusion

Renewable energy systems are essential for a sustainable future, and engineering solutions play a critical role in their optimization. Advancements in solar, wind, hydro, biomass, geothermal energy, and storage technologies will drive the transition toward a cleaner, more resilient energy landscape. Smart grids, AI-driven energy management, and hybrid renewable energy systems will further enhance efficiency and integration. Through continued innovation and policy support, the global energy sector can achieve carbon neutrality and sustainable development.

Keywords: attribute-based encryption | blockchain | scyther tool | security

ABSTRACT

Innovations in technology are revolutionizing healthcare, driving a shift toward patient-centric smart healthcare systems. Mobile health (mHealth) leverages innovations in wearable sensors, telecommunications, and IoT to establish a novel healthcare model that prioritizes the patient, enabling real-time monitoring, personalized interventions, and improved access to care, ultimately fostering a proactive approach to health management and enhancing overall patient outcomes. However, safeguarding patient data transparency, security, and privacy within mHealth systems presents significant challenges, particularly concerning personal health records (PHR). Ciphertext-Policy Attribute-Based Encryption (CP-ABE) offers a competent answer to facilitating one-to-many data sharing in healthcare environments. Nevertheless, several issues must be addressed before CP-ABE can be widely deployed. These include the need for timely and effective attribute revocation when user attributes change, resistance to collusion attacks, and ensuring data integrity. This paper proposes a revocable and secure fine-grained access scheme using blockchain and CP-ABE. We compare four prominent state-of-the-art schemes through comprehensive experimentation with our proposed approach. Our results demonstrate the relative performance of our scheme, showing a significant reduction in computational costs. Specifically, the key generation cost is reduced by ≈35% to 67%, and the encryption cost is reduced by ≈26% to 39%. A detailed analysis of communication, computational, and storage overhead reveals that our suggested solution offers a distinct advantage in terms of efficiency. The Scyther tool is employed to verify the security measures and assess the accuracy of proposed methodologies, subsequently conducting experiments to showcase its efficacy.

1 | Introduction

The world of healthcare has witnessed a noteworthy evolution with the emergence of mHealth, which builds upon the established foundation of electronic health (eHealth). As a subdomain of eHealth, mHealth capitalizes on the ubiquitous nature of mobile devices to deliver three core functionalities. Firstly, it facilitates the acquisition of health-related data directly from patients. Secondly, the acquired data is securely stored on servers managed by healthcare providers, ensuring its integrity and accessibility. Finally, mHealth empowers disseminating healthcare information to authorized users [1]. By implementing secure, attribute-based, fine-grained access controls, this data distribution can be tailored to specific user roles, such as medical practitioners, researchers, and patients [2]. The healthcare sector generates substantial critical data, presenting valuable research opportunities. However, a primary challenge within the mHealth ecosystem lies in safeguarding the inherent sensitivity of this health information. The potential threat of unauthorized access or attacks necessitates robust security measures to mitigate the risk of data breaches caused by internal and external actors [3]. Furthermore, the online dissemination of sensitive patient

© 2025 John Wiley & Sons Ltd.

information to facilitate research activities presents considerable privacy and security challenges for researchers [4]. Integrating mHealth devices with Electronic Health Records (EHRs) presents opportunities and challenges for patient privacy. EHRs, a comprehensive digital record of an individual's medical history, contain highly sensitive information such as diagnoses, allergies, medications, and immunization dates. This data is directly linked to a patient's real identity, making it crucial to ensure appropriate access controls. However, patients may only sometimes desire to share their mHealth data history with every healthcare provider. Historical health data may be sensitive or irrelevant to the current medical condition. Therefore, a key concern within the mHealth ecosystem is the ability of patients to exert granular control over their healthz information [5].

To mitigate this challenge, a pioneering approach termed ABE [6] has garnered significant attention. ABE furnishes a scalable framework for enforcing detailed access control on encrypted data. ABE offers a granular approach to access control for encrypted data [7]. Employing the attributes and access policies built into secret keys and ciphertexts is possible. In CP-ABE, users' secret keys are correlated with a specific set of attributes. Meanwhile, a sender generates ciphertexts accompanied by access policies dictating the required attributes for decryption [8] as illustrated in Figure 1.

1.1 | Our Contributions

Over recent years, the widespread adoption of modern medical sharing systems has facilitated convenient access to healthcare services. Due to its inherent benefits, ABE has emerged as an effective strategy for securing these systems. However, the practical deployment of ABE-based medical sharing raises significant concerns regarding user privacy, data confidentiality, and overall system security. Data users (visitors) seek anonymity regarding their access patterns, even from issuing authorities.

This paper presents a data access control scheme that is both expressive and secure. We propose a new Blockchain-based CPABE (BloCPABE) scheme to achieve revocation and privacy-preserving capabilities. The proposed BloCPABE scheme introduces anonymous key generation, enhancing user anonymity and mitigating the potential for collusion attacks. We design a fine-grained data access control methodology that leverages CP-ABE in conjunction with blockchain technology. The key contributions of this research work are demonstrated below:

- A secure CP-ABE scheme, named BloCPABE, is proposed to address security challenges in mHealth systems. The scheme enables efficient attribute revocation by updating the associated secret key and ciphertext, requiring minimal computational overhead.
- The proposed scheme establishes user privacy, backward and forward security, and is resistant to collusion attacks.
- Blockchain technology is leveraged to store outsourced data, ensuring immutability and tamper-proof integrity.
- The scheme incorporates the Linear Secret Sharing Scheme to formulate access structures, ensuring the confidentiality of the message and preventing private information leakage.
- Security measures and the proposed methodologies are rigorously evaluated and validated using the Scyther tool.

1.2 | Road Map

The systematic outline of this research paper is presented in this way: Section 2 gives preliminary studies on bilinear maps, the LSSS, and blockchain technology. The Section 3 surveys the pertinent literature. The Section 4 delineates the foundational construction of BloCPABE. The Section 5 details a concrete construction of BloCPABE. Section 6 offers a formal verification and security analysis of the scheme. Section 7 provides a

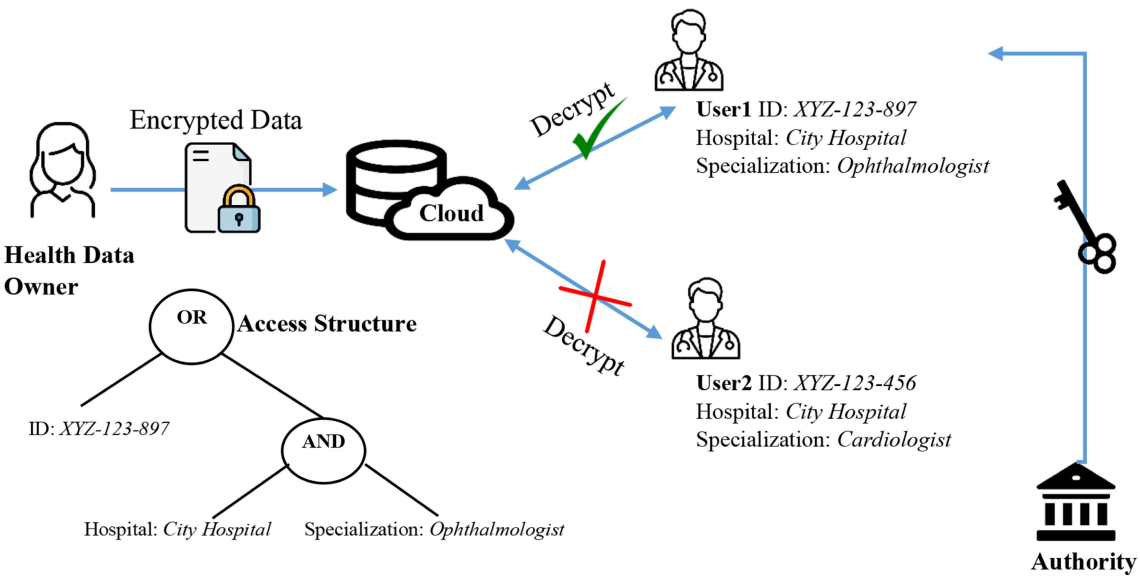

FIGURE 1 | A cloud-based health data storage system employing CP-ABE scheme.

performance analysis, including experimental and simulation results. Lastly, Section 8 concludes the study and suggests paths for future research.

2 | Preliminaries

Here, we outline several basic and additional concepts that are employed in our scheme.

2.1 | Attribute-Based Encryption

ABE is a framework that utilizes user attributes for data encryption rather than relying solely on user identities. This approach enables any individual who meets a specified set of attributes to decrypt the data, eliminating the necessity for a unique key for each user. In ciphertext policy ABE, the access policy is incorporated within the ciphertext, and the attribute set is associated with the user's private key. This arrangement grants the data owner complete authority over who is permitted to decrypt their data. Also, Table 1 provides a list of the key notations used in this paper, along with their respective descriptions. CP-ABE comprises four key algorithms:

- **Setup**$(\lambda) \rightarrow (PP, MSK)$: Here, Setup takes the security parameters as input and produces the PP and the MSK.
- **Encrypt**$(PP, \mathbb{A}, data) \rightarrow CT$: This algorithm uses PP, the access structure $\mathbb{A}$, and the data file as inputs to produce the encrypted ciphertext (CT).
- **KeyGen**$(PP, MSK, S) \rightarrow SK$: This algorithm takes the PP, the MSK, and the attribute set (S) to produce private key (SK) of the user.
- **Decrypt**$(PP, CT, SK) \rightarrow data$: This algorithm uses the PP, the CT, and the SK to decrypt the ciphertext and recover the original data.

2.2 | Bilinear Pairing

Consider two multiplicative cyclic groups $\mathbb{G}_0$ and $\mathbb{G}_T$, both having the same prime order p and g which depicts the generator of $\mathbb{G}_0$. We say $e : \mathbb{G}_0 \times \mathbb{G}_0 \rightarrow \mathbb{G}_T$ is a bilinear pairing if the following properties hold:

- *Bilinearity*: $\forall a, b \in \mathbb{Z}_\rho$ *and* $g_1, g_2 \in \mathbb{G}_0$, $e(g_1^a, g_2^b) = e(g_1, g_2)ab$.
- *Non-degeneracy: There exists* $g_1 \in \mathbb{G}_0$, $e(g_1, g_1) \neq 1$
- *Computability*: $e(g_1, g_2)$ *is efficiently computable for all* $g_1, g_2 \in \mathbb{G}_0$ *in polynomial time.*

2.3 | Decisional Q-Parallel Bilinear Diffie-Hellman Exponent Assumption

The definition of the Decisional q-parallel BDHE problem is as described by Waters, B [9]. *Given a bilinear map* $(p, \mathbb{G}_1, \mathbb{G}_2, e, g)$, *choose random* $a, s, b_1, \ldots, b_q \in \mathbb{Z}_p$. *If the adversary* $\mathfrak{A}$ *is given*

TABLE 1 | Notations and their description.

Notation	Descriptions
CA	Certificate authority or Central authority
AA	Attribute authority (Hospital)
DO	Data owner (patient or health data owner)
DU	Data user (physician, researcher, etc.)
$\mathfrak{A}$	Adversary
$\mathfrak{C}$	Challenger
λ	Security Parameter
G_1, G_T	Multiplicative cyclic group of prime order p
g	Generator of G_1
e	Mapping function $e(G_1, G_1) \rightarrow G_T$
$\mathcal{H}$	Collusion resistant hash function
PP	Public Parameter
GPP	Global Public Parameter
MK	Master Key generated by the CA
uid_k	Unique identifier for user k
$Certificate(uid_k)$	User's certificate
$UPK_{uid_k}, UPK'_{uid_k}$	User Public Key
$USK_{uid_k}, USK'_{uid_k}$	User Secret Key
MSK	Master Secret Key generated by AA
PK	Public Key generated by AA
$\mathcal{U}$	Universe of attributes controlled by AA
VK_x	Version key of the attribute
AK_x	Public attribute key of the attribute
S	Attribute sets of user
SK	Decryption key for DU generated by AA
$\mathbb{A}$	Access structure
CT	Ciphertext
$\hat{x}$	Revoked attribute from user
$AUK_{\hat{x}}$	Attribute update key
$KUK_{\hat{x},k}$	user key update key
$CUK_{\hat{x}}$	Ciphertext key update

$$\vec{y} = g, g^s, g^a, \ldots g^{a^q}, g^{a^{q+2}}, \ldots, g^{a^{2q}}$$

$$\forall 1 \leq j \leq q, g^{s.b_j}, g^{a/b_j}, \ldots, g^{a^q/b_j}, g^{a^{q+2}/b_j}, \ldots, g^{a^{2q}/b_j}$$

$\forall 1 \leq j, k \leq q, \quad k \neq j, g^{a.s.b_k/b_j}, \ldots, g^{a^q.s.b_k/b_j}$ *it must be difficult to distinguish between* $e(g,g)^{a^{q+1}s} \in \mathbb{G}_2$ *and a random element* $R \in \mathbb{G}_2$. *An algorithm* $\mathfrak{C}$ *guesses* $z \in \{0, 1\}$ *with advantage* ε *in solving the Decisional q-parallel BDHE problem in* $\mathbb{G}_2$ *if*

$$\left| Pr[\mathfrak{C}(\vec{y}, T = e(g,g)^{a^{q+1}s}) = 0] - Pr[\mathfrak{C}(\vec{y}, T = R) = 1] \right| \geq \varepsilon$$

As in [9], *we can say that the Decisional q-parallel BDHE assumption holds if there is no polynomial time algorithm to solve the Decisional q-parallel BDHE problem with a non-negligible advantage.*

2.4 | Linear Secret-Sharing Schemes (LSSS)

A secret-sharing scheme P over a set of parties P is called linear over $\mathbb{Z}_\rho$ if the following conditions hold:

- *The shares for each party form a vector over* $\mathbb{Z}_\rho$.
- *There exists a share-generating matrix* $M \in \mathbb{Z}_\rho^{l\times n}$ *with* l *rows and* n *columns which can make shares for* $\prod$. *For all* $i \in \{1, \ldots, l\}$ *the* i^{th} *row of* M *is labeled via a function* ρ, *that associates* M_i *to the party* $\rho(i)$. *Considering the vector* $\overrightarrow{v} = (s, r_2, \ldots, r_n) \in \mathbb{Z}_\rho^n$, *where* $s \in \mathbb{Z}_\rho$ *is the secret to be shared, and* $r_2, \ldots, r_n$ *are randomly chosen from* $\mathbb{Z}_\rho$, *then* $M_{\overrightarrow{v}}$ *is the vector of* l *shares of the secret* s *according to* $\prod$. *The share* $M_{\overrightarrow{v}}$ *belongs to party* $\rho(i)$.

Waters, B. shows [9] that every linear secret-sharing scheme according to the above definition also enjoys the linear reconstruction property, defined as follows: Suppose that $\prod$ is an LSSS for the access structure $\mathbb{A}$. Let $S \in \mathbb{A}$ be any authorized set, and let $I \subseteq \{1, \ldots, l\}$ be defined as $I = \{i : \rho(i) \in S$. There exist constants $w_i \in \mathbb{Z}_\rho$ with $i \in I$ that satisfy that if λ_i are valid shares of any secret s according to $\prod$, then $\Sigma_{i\in I} w_i\lambda_i = s$ holds. According to the access control requirements of the paid data-sharing scenario, our system utilizes LSSS to support any monotonic access structure.

2.5 | Blockchain Technology

Blockchain is a decentralized digital ledger composed of interconnected blocks. Each block stores data, including transaction details, with a cryptographic hash connected it to the previous block as illustrated in Figure 2, ensuring immutability and data integrity. This structure provides transparency and security as all network participants maintain a copy of the ledger, collectively validating and recording data. Blockchain can be public, allowing anyone to participate, or private, restricted to authorized members. The core characteristics of this technology are decentralization, transparency, security, and immutability, enabling applications across various domains. Blockchain technology can be categorized into hybrid, private, and public blockchains.

A public blockchain is characterized by its open nature, where any node can generate transaction data and access all information contained within the blocks. In contrast, a private blockchain is managed by a single entity, with only a limited array of authorized nodes accessing the stored records. A hybrid blockchain integrates elements from both public and private blockchains, enabling organizations to balance control with the transparency and security inherent in public blockchains. This approach provides a way to harness the benefits of both models while maintaining a degree of governance. In this work, we have employed Ethereum, an open-source platform designed to facilitate smart contracts and decentralized applications. Ethereum offers a robust framework for developing distributed applications. It leverages the Ethereum Virtual Machine to execute smart contracts. A defining characteristic of Ethereum is its ability to support smart contracts, allowing developers to design, deploy, and execute intricate applications on the platform. These contracts are self-executing, following predefined conditions,

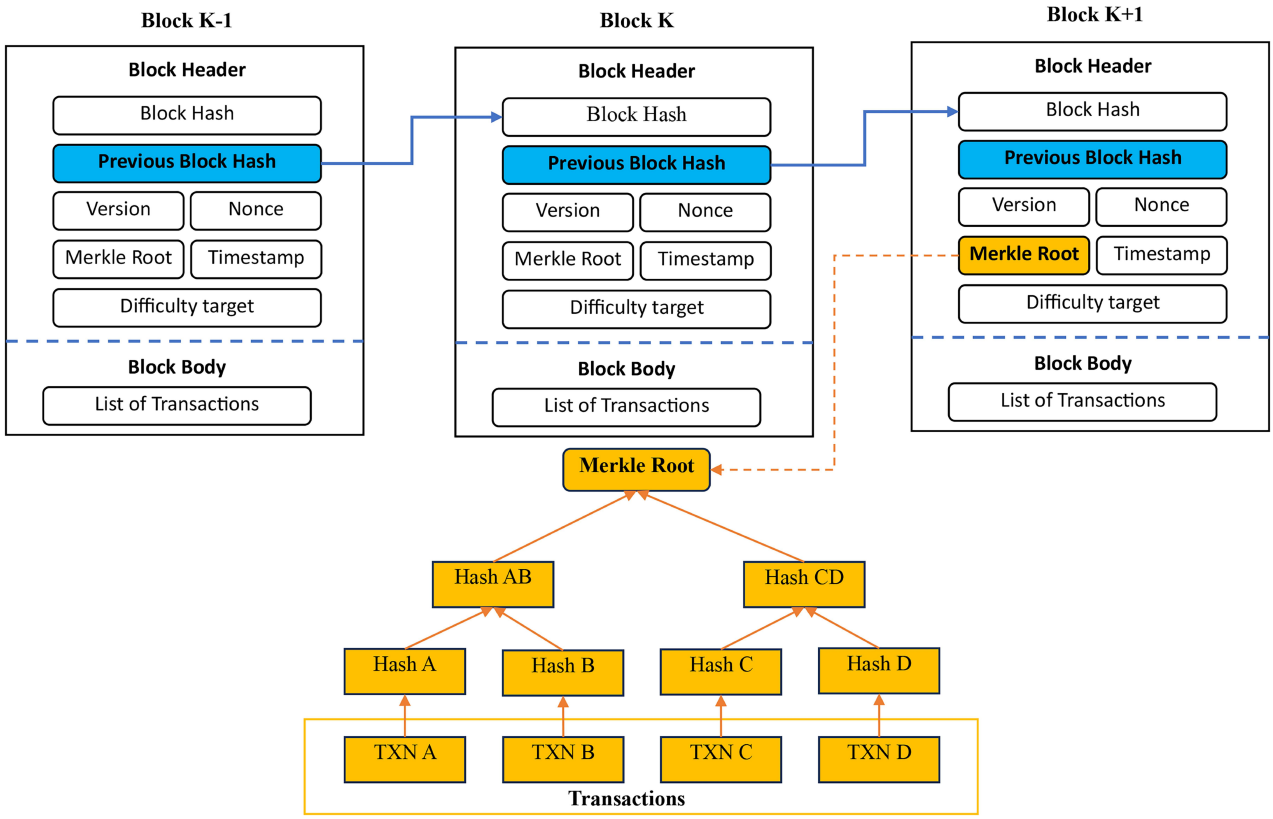

FIGURE 2 | Illustration of the block structure.

which removes the reliance on intermediary entities, as detailed in Section 7.

3 | Related Works

In this section, we review the studies closely related to and relevant to our study. ABE, which Sahai et al. [10] introduced, has emerged as the dominant paradigm in the cryptographic access control for encrypted data. Bethencourt et al. [6] made a significant contribution to the field of CP-ABE by proposing a scheme that supports a tree-based access structure. This scheme is more adaptable and practical than KP-ABE. While ABE proposed by Bethencourt et al. [6], Waters, B. [9], Sahai et al. [10], and similar systems offer the advantages of one-to-many encryption, but inherent security concerns remain. Specifically, the single authority entrusted with key issuance to all eligible users can decrypt any ciphertext utilizing the distributed secret keys. Riepel et al. [11] implement FABEO, CP-ABE scheme, which has more concise ciphertexts, reduced pairings, and enhanced efficiency in both optimal and adaptive security scenarios.

A CP-ABE scheme that can support Non-Equivalence Logic (NEL) is developed by Yamada et al. [12] using a method for converting monotonic access structures into non-monotonic ones, which is originally proposed by Ostrovsky et al. [13]. Additionally, this CP-ABE scheme is capable of handling sets and access policies with unlimited sizes. This scheme exhibits greater complexity compared to conventional CP-ABE, resulting in increased overhead.

In the work of Chase, M. [14], a multi-authority CP-ABE (MCP-ABE) scheme is presented that leverages a central authority (CA). This CA possesses the capability to decrypt all ciphertexts within the system. This inherent decryption ability used by the CA introduces a vulnerability in the security position of decryption key storage.

Later, Chase et al. [15] introduced an MA-ABE scheme that operates without a centralized trusted authority. However, under this scheme, data consumers are required to obtain at least one attribute from each AA, thus limiting its practicality. In contrast, Lewko et al. [16] developed a CP-ABE scheme featuring fully decentralized multi-authorities, eliminating the necessity for attribute authorities to collaborate. Consequently, data consumers can acquire any desired number of attributes from any AA within this framework.

Yang et al. [17] address the critical challenge of data access control in cloud storage systems, particularly in the context of untrusted servers and the limitations of existing CP-ABE schemes. They propose a novel revocable multi-authority CP-ABE scheme that enhances expressiveness, efficiency, and security, allowing multiple authorities to independently issue attributes while ensuring effective attribute revocation with backward and forward security. However, the approach may face challenges related to the complexity of managing multiple authorities and the potential for increased overhead in communication and coordination. Additionally, while the proposed method improves efficiency by reducing the need for extensive ciphertext updates, it may still encounter scalability issues as the number of users and authorities grows.

To address the risks associated with semi-honest cloud servers, Miao et al. [18] propose a method that involves splitting secret keys associated with certain attribute sets. This approach allows healthcare providers and patients to securely exchange sensitive health information while only ensuring access is restricted to authorized individuals. The implementation challenges concerning scalability and the mechanism for attribute revocation related to the study require discussion.

Data consumers can leverage third-party servers for decryption computations to mitigate the computational burden associated with the decryption phase. Tu et al. [19] introduced a multi-authority CP-ABE scheme supporting decryption outsourcing. In this system, data consumers do not have to do any complicated bilinear pairing operations during the decryption phase. The security of ciphertext entrusted to a third-party custodian presents potential vulnerabilities to tampering, as documented by Guo et al. [20]. Blockchain technology mitigates this risk by demonstrably guaranteeing both data integrity and non-repudiation. These inherent cryptographic properties underpin the increasing adoption of blockchain across diverse application domains.

Jiang et al. [21] propose a data traceability generation method and a data access control scheme for edge clouds, ensuring EHRs integrity and confidentiality. The scheme uses ABE with a blockchain to provide secure data storage, fine-grained access control, and attribute revocation. However, the proof of correctness in the scheme is insufficient and may not satisfy the equations.

$$= \frac{e(C', K)}{e(\prod_{i\in I} C_i^{w_i}, L) \times \prod_{i\in I} e(D_i^{w_i}, K_{\rho(i)})}$$

$$= \frac{e(g^s, g^{\frac{a}{z}} g^t)}{e(\prod_{i\in I} (g^{a\lambda_i}(g^{V_{x_i}})^{-r_i})^{w_i}, g^t) \times \prod_{i\in I} e((g^{r_i})^{w_i}, (g^{V_{x_i}})^t)}$$

After simplifying the equation further, we get:

$$= \frac{e(g,g)^{\frac{s\alpha}{z}} e(g,g)^{st}}{e(g,g)^{ast}} \neq e(g,g)^{s\alpha/z} \quad where \sum_{i\in I} w_i\lambda_i = s$$

Leveraging advancements in cryptography, Guo et al. [22] sought to bolster user privacy and security through a novel encrypted data access control solution. Their architecture hinges on smart contracts orchestrating interactions between data owners (DOs), users, and attribute authorities. However, a key limitation of their approach lies in employing symmetric encryption by DOs for data encryption, resulting in a cumbersome key management overhead.

To alleviate this burden, Qin et al. [23] proposed an MA-ABE scheme that utilizes a consortium blockchain to establish trust bridges between attribute authorities. While their proposed solution effectively addresses the key management overhead, it also introduces certificate authorities as a potential point of vulnerability, raising concerns about single points of failure within the system's architecture.

15320634, 2025, 9-11, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.70064 by Delhi Technological University, Wiley Online Library on [30/04/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

To enhance system security and address application requirements in resource-constrained environments, Wei et al. [24] proposed a revocable hierarchical scheme, RS-HABE. This scheme extends the original ABE by incorporating user revocation, secret key delegation, and ciphertext updating mechanisms. ABE has been widely applied in cloud services due to its rich expressiveness of ABE policies. However, traditional ABE schemes suffer from high computational overhead and lack verifiability, making them less efficient and less secure for cloud-based applications. To address this, Hou et al. [25] proposes a blockchain-based solution that improves decryption efficiency and allows users to verify the accuracy of decryption performed by external parties. This approach offers a more secure and efficient way to control access to data saved in the cloud.

The increasing reliance on cloud computing for managing PHRs has necessitated robust encryption methods to ensure data confidentiality. Zhang et al. [8] introduced ABE with keyword search, which addresses several issues related to key management and access control by enabling fine-grained access control. Enhancing usability in dynamic healthcare settings, the authors [2] introduce an innovative access control scheme known as PAFR-ABE, designed to safeguard users' identities during the secret key generation process, thereby thwarting unauthorized access to sensitive health data. The proposed framework incorporates a dynamic revocation system that enhances the effective administration of secret keys, thereby removing the necessity for updates for non-revoked users.

The authors [26] present a verifiable encryption scheme that incorporates blockchain technology to enhance security and accountability in data management. This scheme's multi-authorization mechanism enables various authorities to regulate user attributes, thereby improving flexibility and scalability in access control. The performance analysis indicates the scheme's effectiveness; however, empirical evidence is required to validate its efficiency and overall impact.

From the above literature, the research gaps are found:

- Some traditional ABE schemes rely on a central authority for key issuance, which can pose significant risk.
- Existing schemes often struggle with effective attribute revocation, particularly in dynamic environments where users frequently change roles or permissions.
- Conventional storage systems frequently depend on centralized designs that are susceptible to manipulation, lack immutability, and fail to offer comprehensive audit trails.

Based on the preceding discussion, this research paper introduces a secure access control mechanism utilizing blockchain and ABE. The proposed approach leverages the InterPlanetary File System (IPFS) for storing encrypted data, thereby mitigating blockchain resource limitations and centralized storage systems' reliability concerns. This method not only enhances security and adaptability but also facilitates attribute policy concealment and attribute revocation.

4 | Blocpabe'S Basic Construction

This section presents a concise overview of our proposed framework. The system model depicted in Figure 3 describes a secure

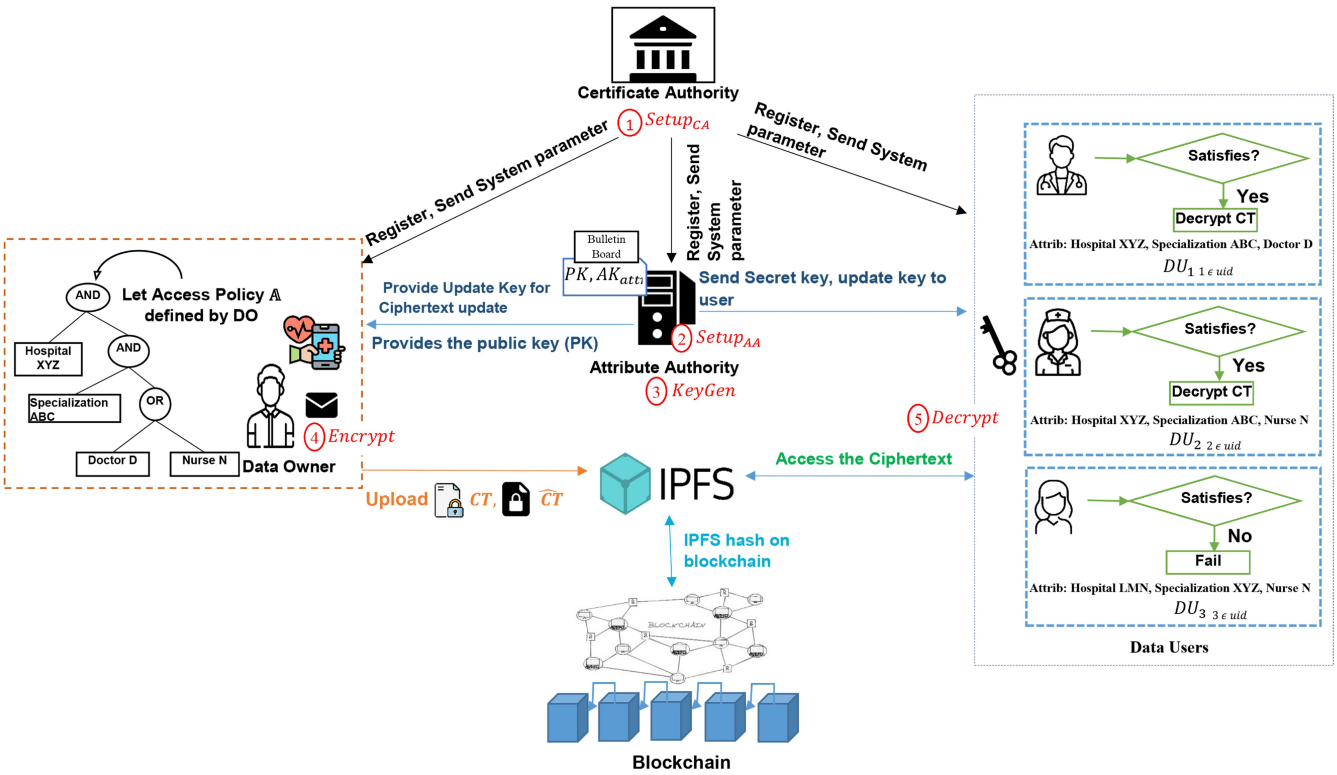

FIGURE 3 | Overview of system model.

15320634, 2025, 9-11, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.70064 by Delhi Technological University, Wiley Online Library on [30/04/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

and decentralized data-sharing framework that integrates ABE with IPFS and blockchain technology to enforce fine-grained access control over encrypted data. At the core, the Certificate Authority initializes the system by generating system parameters and registering participants, such as the Attribute Authority (AA) and Data Users. The AA is responsible for managing attributes and keys, including generating public keys and issuing secret keys to users based on their assigned attributes. A Data Owner (DO) defines an access policy that determines who can access the data. The DO encrypts the data using ABE under the policy and uploads the ciphertext to the IPFS for decentralized storage. To ensure data integrity and tamper-proof access, the IPFS hash of the ciphertext is stored on the blockchain. The proposed system model outlines the operational framework of the scheme, providing a detailed evaluation of its components as follows.

4.1 | System Model

Here, we have described all the participating entities and their contribution to the system model below:

- **Certificate Authority (CA):** CA operates as a globally recognized root of trust. Its primary function is to establish and manage identities within a system. It assigns unique identifiers to the users and authority. Additionally, the CA assumes responsibility for system initialization, including user and attribute authority registration and disseminating global public parameters and a master secret key. While possessing a privileged role, the CA is functionally constrained, acting as an "honest-but-curious" entity with no direct involvement in attribute management or generating attribute-associated secret keys.
- **Attribute Authority (AA):** AA exercises exclusive control over the management of attributes. It encompasses the issuance, updating, and revocation of attributes. AA is responsible for constructing the secret key for the users.
- **IPFS**: IPFS is a decentralized file storage network that uses content addressing to identify and retrieve files. Instead of traditional location-based addressing, where files are accessed by their storage location, IPFS retrieves files based on a unique hash derived from their content. The encryption process generates ciphertext and associated metadata, including a policy string that governs access control.
  The encrypted data is then serialized into JSON format before being uploaded to IPFS. IPFS, a decentralized peer-to-peer file system, assigns a unique content identifier (CID) to the serialized data. This CID is a reference for retrieving the data from the IPFS network, ensuring its availability across a distributed network of nodes.
- **Blockchain:** Blockchain is a decentralized and immutable ledger designed for recording transactions and tracking assets. The IPFS CID is recorded on the blockchain through a smart contract. This contract stores metadata related to the encrypted data, such as its IPFS hash, ensuring the data integrity and existence are verifiable. By recording this metadata on the blockchain, we leverage the blockchain's immutability to guarantee that the reference to the data remains accurate and tamper-proof.
- **Data Owner (DO):** In the system, DO is responsible for storing data on the decentralized storage and sharing with data consumers or users. The owner defines an access policy, encrypts the data according to this policy, and then sends the encrypted data to the centralized storage for secure storage and controlled access.
- **The Data User (DU):** DU is the data consumer who wants to get the data. CA assigns the UID to the user. If the attributes of the DU align with the stipulated access policy, the message can be successfully retrieved.

4.2 | Algorithm Description

Our BloCPABE framework is structured into distinct phases, each incorporating specific methods as briefly illustrated below:

Phase 1: Setup

- $Setup(1^{\lambda})$: 1^{λ} here is a security parameter which $Setup$ algorithm takes as input and generates global public parameter GPP and master key MK as output. Meanwhile, authority and users are registered by the CA, and AA also performs the setup to generate public (PK) and secret keys (MSK).

Phase 2: Secret Key Generation

- $KeyGen(GPP, MSK, S_k)$: The algorithm takes the GPP, MSK, and attribute assigned to the user and generates the corresponding secret key (SK_{uid_k}).

Phase 3: Encryption of message

- $Encrypt(GPP, PK, \mathbb{A}, msg)$: The algorithm requires the GPP, public key, an LSSS access structure $\mathbb{A}$ and message msg as input and generates ciphertext CT.

Phase 4: Decryption Process

- $Decrypt(CT, USK'_{uid_k}, SK_{uid_k})$: The algorithm takes CT, the global secret key of user, and SK_{uid_k} as input and returns the message.

Phase 5: Attribute Revocation

- $Revoke(\hat{x}, uid_k)$: This algorithm includes the update keygen algorithm ($UKeyGen$), secret key update ($Update_{SK}$), and ciphertext update algorithm ($Update_{CT}$). The attribute $\hat{x}$ of user uid_k is revoked, and a new secret key and ciphertext are generated for the non-revoked users.

4.3 | Threat Model and Security Goals

CA and AA are assumed to be fully trusted. In the case of a malicious DU, unauthorized DUs might collude to gain access to the encrypted data.

- **Fine-grained access control:** To control access for retrieving health data, the data owner creates a detailed access structure based on specific attributes. This framework guarantees that only authorized DUs have access to the encrypted

15320634, 2025, 9-11, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.70064 by Delhi Technological University, Wiley Online Library on [30/04/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

information. Unauthorized DUs, regardless of how they combine their attributes and keys, cannot extract confidential details from the encrypted data.

- **Confidentiality:** In this system, data access is restricted to devices that meet specific criteria, and only these authorized devices can receive a unique decryption key.
- **Non-repudiation:** It states that the origin of data cannot be denied. It provides irrefutable proof that a specific person or entity sent or created particular information. It is crucial in digital transactions and communications as it prevents parties from disavowing their actions or commitments.
- **Collusion resistance:** Malicious users could pool their decryption keys to access protected data that none can open independently. The system should be robust enough to prevent such collaborative attacks.
- **Data integrity:** The system must rigorously safeguard the integrity, consistency, and accuracy of data stored on the blockchain from its creation to its final state. Once data is recorded on a blockchain, cannot be altered or deleted without the network's consensus. It creates an unbreakable chain of records, making it virtually impossible to tamper with data.
- **Policy Privacy:** The access structure embedded within encrypted data should remain hidden from blockchain and unauthorized users to ensure data privacy.

4.4 | Security Model

Here, we provide a security model structured as an interactive game between the two entities here known as challenger $\mathfrak{C}$ and adversary $\mathfrak{A}$, following the framework from Waters, B. [9]. The security process unfolds as follows:

Setup: The *Setup* algorithm is run to produce the parameters of the system. The $\mathfrak{C}$ uses the $Setup_{AA}$ algorithm to formulate the PK and the MSK. The challenger keeps the MSK and shares the public key PK with the $\mathfrak{A}$.

*Phase*1: The $\mathfrak{A}$ can make adaptive queries to the $\mathfrak{C}$ to obtain secret keys. Following these queries, $\mathfrak{C}$ executes the *KeyGen* algorithm and provides the corresponding secret key to $\mathfrak{A}$.

Challenge: The adversary $\mathfrak{A}$ presents two messages, msg_0 and msg_1, of equal length, along with a challenge access structure $\mathbb{A}^*$ that cannot be satisfied by any of the attributes inquired in *Phase*1. $\mathfrak{C}$ flips a coin $\zeta \in 0, 1$ and generates a ciphertext $CT^* \leftarrow Encrypt(GPP, PK, msg_\zeta, \mathbb{A}^*)$, which is then given to $\mathfrak{A}$.

*Phase*2: The $\mathfrak{A}$ continues to request secret keys from $\mathfrak{C}$ under the same conditions as in *Phase*1.

Guess: The $\mathfrak{A}$ guesses the value of ζ as ζ'. The adversary's advantage is calculated as $|Pr[\zeta = \zeta'] - \frac{1}{2}|$.

Definition 1. Blo*C*ABE is secure if all polynomial-time adversaries have at most a negligible advantage in the above game.

5 | Concrete Construction

Section 5 provides a thorough construction of the BloCPABE scheme. BloCPABE is constructed by taking inspiration and combining the idea of Waters, B. [9] and Yang et al. [17]. The scheme consists of algorithms such as system initialization ($Setup_{CA}, RegisterUser, Setup_{AA}$), $KeyGen$, $Encrypt$, $Decrypt$, $UKeyGen$, $Update_{SK}$, and $Update_{CT}$ (illustrated in Figure 4).

5.1 | Proposed Blocpabe Scheme

Phase 1: System Initialization (Setup): In this phase, algorithms such as $Setup_{CA}$, $RegisterUser$, and $Setup_{AA}$ are executed.

- **Global Initialization** ($Setup_{CA}$): In this sub-algorithm, the CA utilizes a security parameter, denoted as λ, which dictates the length of the input group. The CA selects two multiplicative cyclic groups, $\mathbb{G}_1$ and $\mathbb{G}_T$, each of prime order p. Here, g serves as the generator of $\mathbb{G}_1$, and $e : \mathbb{G}_1 \times \mathbb{G}_1 \rightarrow \mathbb{G}_T$ represents a bilinear map. CA selects a collusion-resistant hash function $\mathcal{H}$, which matches the binary string $\{0,1\}^*$ to the random element in $\mathbb{G}_1$, expressed as $\mathcal{H} : \{0,1\}^* \rightarrow \mathbb{G}_1$. CA randomly selects two numbers $a, b \in_R \mathbb{Z}_p$, constructs the $MK = (a, b)$, and publishes GPP to all the system's members.
  $GPP = (g, g^a, g^b, \mathcal{H})$.
  Furthermore, both AA and users are required to undergo registration with CA to acquire globally unique identifiers uid_k (for users) and aid (for AA) that validate their legal identities.
- ***RegisterUser***: Here in our system, DU and DO are referred to as users (with different roles) (Subsection 4.2). It is assumed that CA runs the $RegisterUser$ algorithm within a secure environment, ensuring the confidentiality of all transmitted data. Upon system initialization, each user submits a registration request to the CA. The CA verifies the user's identity and subsequently assigns a uid_k and also creates $Certificate(uid_k)$ for uid_k. The identifier uid_k is a randomly generated value within the prime field $\mathbb{Z}_p$, that is, $uid_k \in \mathbb{Z}_p$. After this, it randomly chooses the two numbers $\gamma_k, \gamma'_k \in_R \mathbb{Z}_p$ to generate the public/private key pair as $UPK_{uid_k} = g^{\gamma_k}, UPK'_{uid_k} = g^{\gamma'_k}$ and $USK_{uid_k} = \gamma_k, USK'_{uid_k} = \gamma'_k$.
- **Attribute Authority Setup** ($Setup_{AA}$): This sub-algorithm is managed by an AA to generate the MSK and PK. The AA within the system manages a universe of attributes $\mathcal{U}_{aid}$ and for each attribute $x_i \in_R \mathcal{U}_{aid}$, AA generates the public attribute key AK_{x_i} along with the version key VK_{x_i}. AA chooses two random exponents $\alpha, y \in \mathbb{Z}_p$ and compute the PK and a secret key MSK as:

  $$PK = e(g, g)^\alpha, MSK = (\alpha, y).$$

  For each attribute $x_i : (x_i \in \mathcal{U}_{aid})$, AA chooses version key as $VK_{x_i} = \upsilon_{x_i}$ and get the corresponding attribute key $AK_{x_i} = (g^{\upsilon_{x_i}} \mathcal{H}(x_i))^y$. Attributes are kept confidential and known only to AA, whereas PK and AK_{x_i} are published publicly with system entities.

Phase 2: Key generation (PHR user authorization): When the user seeks access to the data, it requests the secret key SK_{uid_k}

15320634, 2025, 9-11, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.70064 by Delhi Technological University, Wiley Online Library on [30/04/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

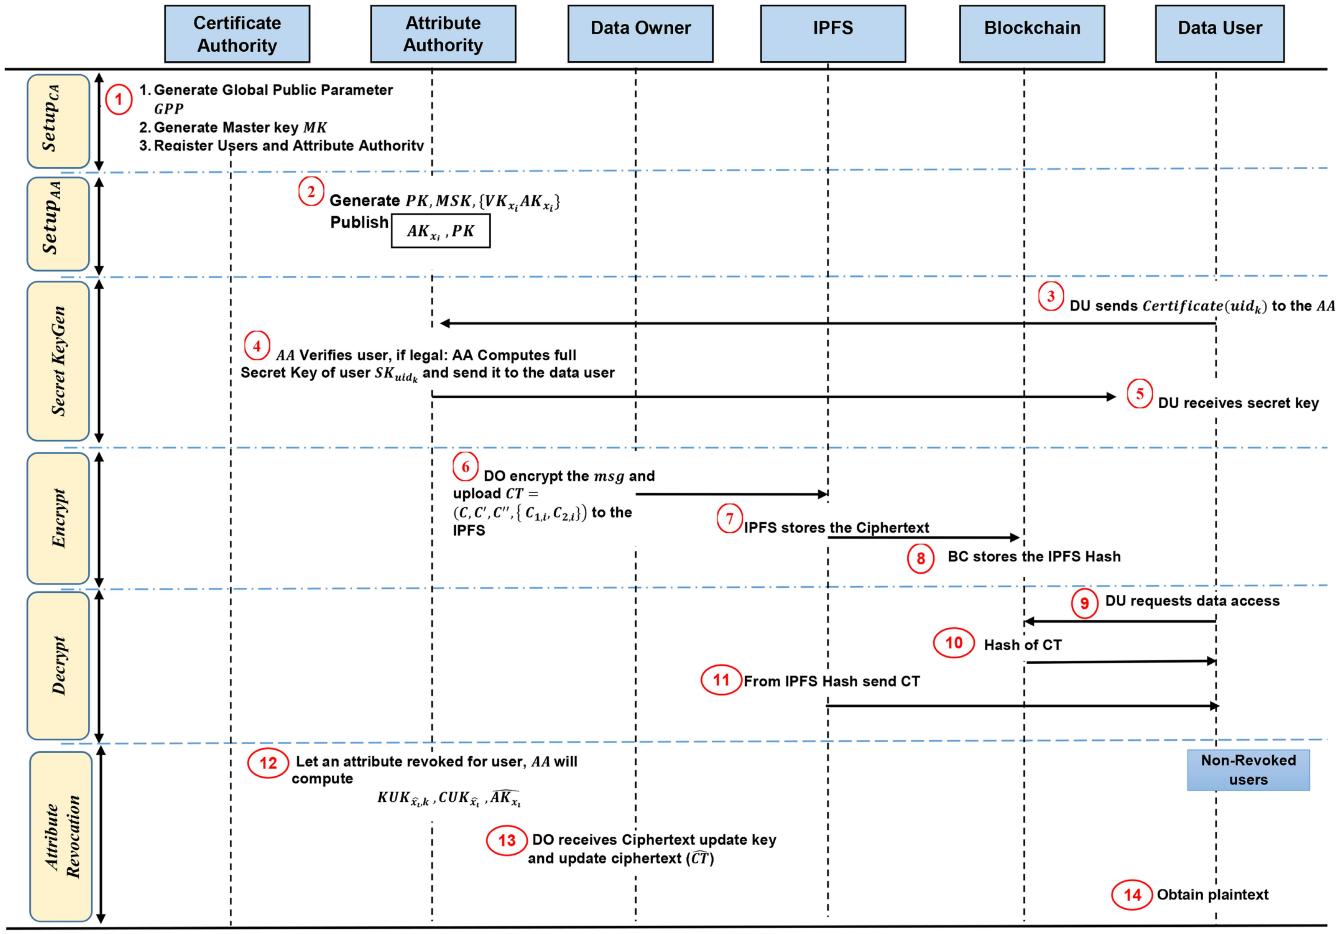

FIGURE 4 | Illustration of the proposed scheme.

from the AA. AA assigns a set of attributes $S_k \in \mathcal{U}_{aid}$ to the legal user according to its identity and role in the system. Subsequently, uid_k gives $Certificate(uid_k)$ to the AA, and upon verifying the user's identity, the authority executes the $KeyGen$ algorithm. It selects $t_k \in_R \mathbb{Z}_p$ and for each user uid_k it generates

$$K_k = g^{\alpha} g^{a\gamma_k} g^{bt_k},$$

$$K'_k = g^{t_k}, K'' = g^{\gamma t_k},$$

$$\forall x_i \in S_k \ : \ K_{x_i,k} = g^{\gamma' {}_k \gamma t_k} . (g^{\upsilon_{x_i}} \mathcal{H}(x_i))^{\gamma \gamma_k}$$

$$SK_{uid_k} = \left\{ K_k, K'_k, K''_k, \{K_{x_i,k}\}_{x_i \in S_k} \right\}$$

Phase 3: Encryption Process (Outsourcing PHR on decentralized storage): Access to a data owner PHR is granted to authorized healthcare professionals, including physicians and nurses, upon satisfaction of specific conditions. Before outsourcing data to the decentralized storage, the PHR owner encrypts the data using an encryption algorithm. As discussed in Subsection 4.2, it takes the public parameter, message, public keys of relevant authorities, and LSSS access structure. (M, ρ) is an access structure where M is a matrix with $l \times n$ elements, and ρ maps the rows of M into the attributes set. The DO subsequently selects a random column vector $\vec{\upsilon} = (s, \upsilon_2, \upsilon_3, \ldots, \upsilon_n)$, where $\upsilon_2, \upsilon_3, \ldots, \upsilon_n$ are applied to share s. DO computes $\lambda_i = M_i . \vec{\upsilon}$ for $\forall i \in [1, l]$, where M_i is a vector corresponding to the ith row of matrix M. DO randomly choose $\tau_1, \tau_2, \ldots, \tau_l \in \mathbb{Z}_p$ and compute the CT as

$$C = msg.e(g, g)^{\alpha s}$$

$$C' = g^s, C'' = g^{bs},$$

$$\forall i \in [1, l] \ :$$

$$C_{1,i} = g^{a\lambda_i} . ((g^{\upsilon_{\rho(i)}} \mathcal{H}(\rho(i)))^y)^{-\tau_i}, C_{2,i} = g^{\tau_i}, \rho(i) \in \mathcal{U}_{aid}$$

$$CT = \{C, C', C'', \{C_{1,i}, C_{2,i}\}\}$$

Phase 4: Decryption Process (Accessing the PHR): To access the encrypted data, a DU submits a request to the decentralized storage. Those DUs that meet the access policy defined in the CT can decrypt the information. The DU runs the local decryption algorithm as briefly illustrated in Subsection 4.2.

Case 1: If user attributes necessary of decryption $\notin \mathbb{A}$ then $\perp$.

Case 2: If user attributes necessary of decryption $\in \mathbb{A}$ then algorithm recovers the msg as: $I = \{i : p(i) \in \mathcal{U}_{aid}\} \subseteq [1, \ldots, l]$ and compute the coefficient $\{w_i \in \mathbb{Z}_p\}_{i \in I}$ so that $\Sigma_{i \in I} w_i \lambda_i = s$. The decryption algorithm computes

15320634, 2025, 9-11, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.70064 by Delhi Technological University, Wiley Online Library on [30/04/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

$$\frac{e(C', K_k)e(C'', K'_k)^{-1}}{\prod_{i\in I}\left(e(C_{1,i}, UPK_{uid_k})e(C_{2,i}, K_{\rho(i),k})e(C_{2,i}, K''^{USK'_{uid_k}}_k)^{-1}\right)^{w_i N_A}}$$

to obtain the original message (msg), the user computes

$$msg = \frac{C}{e(g,g)^{\alpha s}}$$

Phase 5: Attribute Revocation: When an attribute $\hat{x}_i$ is revoked for user uid'_k by AA, the system should implement a mechanism to invalidate the user's ability to decrypt ciphertexts containing that attribute. It prevents the revoked user from accessing PHRs protected by policies that require the revoked attribute. For users whose attributes remain valid, AA should update their secret key to maintain system security and integrity. The attribute revocation of our work is somewhat similar to the Yang et al. [17].

1. *Update Key by AAs*: When $\hat{x}_i$ is revoked from the user, the AA runs the $UKeyGen$ algorithm as illustrated in Subsection 4.2. It firstly chooses a random versions key $v'_{\hat{x}_i}$ and generate the attribute update key $AUK_{\hat{x}_i} = y\left(v'_{\hat{x}_i} - v_{\hat{x}_i}\right)$, then AA compute the $KUK_{\hat{x}_i,k}$ and $CUK_{\hat{x}_i}$.
$KUK_{\hat{x}_i,k} = g^{\gamma_k.y(v'_{\hat{x}_i} - v_{\hat{x}_i})}$
$CUK_{\hat{x}_i} = -\left(y\left(v'_{\hat{x}_i} - v_{\hat{x}_i}\right)\right)$
The AA update the attribute key of revoked attribute $\hat{x}_i$ by computing
$\widehat{AK}_{\hat{x}_i} = AK_{\hat{x}_i}.g^{AUK_{\hat{x}_i}}$
and send the message about $\hat{x}_i$ updates to the data owner under the safe channel.

2. *Secret Key Update by Non-revoked Users*: Upon receiving the $KUK_{\hat{x}_i,k}$ from the AA, user will run the $Update_{SK}$ algorithm to update the secret key as
$\widehat{SK}_{uid_k} = (\widehat{K}_k = K_k, \widehat{K'_k} = K'_k, \widehat{K''_k} = K''_k,$
$\widehat{K}_{\hat{x}_i,k} = K_{\hat{x}_i,k}.KUK_{\hat{x}_i,k},$
$\forall x_i \in S_k, x_i \neq \hat{x}_i : \widehat{K}_{x_i,k} = K_{x_i,k})$
The $KUK_{\hat{x},k}$ is associated with revoked uid_k so that revoked users can easily be identified and differentiated. Consequently, revoked users cannot obtain the updated key.

3. *Ciphertext Update by the Data Owner*: Upon receipt of the key $CUK_{\hat{x}}$ from the AA, the owner will execute the $Update_{CT}$ algorithm to refresh the ciphertext. Initially, the data owner gathers the ciphertext components $(C_{1,i}, C_{2,i})$ that includes the attribute $\hat{x}$ from the blockchain. The updated ciphertext is then calculated as follows:
$\widehat{CT} = (C = msg.e(g,g)^{\alpha s}, C' = g^s, C'' = g^{bs},$
$\forall i \in [1,l]:$
if $\rho(i) = \hat{x}_i : \widehat{C}_{1,i} = C_{1,i}.(C_{2,i})^{CUK_{\hat{x}_i}},$
if $\rho(i) \neq \hat{x}_i : \widehat{C}_{1,i} = C_{1,i}, \widehat{C}_{2,i} = C_{2,i}).$

5.2 | Correctness Proof

Definition 2. Our scheme is correct because the following equations are satisfied.

Proof.

$$\frac{e(C', K_k)e(C'', K'_k)^{-1}}{\prod_{i\in I}\left(e(C_{1,i}, UPK_{uid_k})e(C_{2,i}, K_{\rho(i),k})e(C_{2,i}, K''^{USK'_{uid_k}}_k)^{-1}\right)^{w_i N_A}}$$
$$= e\left(C', K_k\right) e\left(C'', K'_k\right)^{-1}$$
$$= e\left(g^s, g^{\alpha} g^{a\gamma_k} g^{bt_k}\right).e\left(g^{bs}, g^{t_k}\right)^{-1}$$
$$= e(g,g)^{s\alpha}.e(g,g)^{sa\gamma_k}.e(g,g)^{sbt_k}.e(g,g)^{-bst_k}$$

canceling

$$e(g,g)^{sbt_k}.e(g,g)^{-bst_k}$$

we get,

$$= e(g,g)^{sa\gamma_k}.e(g,g)^{s\alpha}$$

for each $i \in I$, assume $p(i) \in \mathcal{U}_{aid}$:

$$= \prod_{i\in I}\left(e\left(C_{1,i}, UPK_{uid_k}\right) e\left(C_{2,i}, K_{p(i),k}\right) e\left(C_{2,i}, K''^{USK'_{uid_k}}_k\right)^{-1}\right)^{w_i N_A}$$

simplifying the equation:

$$= e(g^{a\lambda_i}.((g^{v_{p(i)}}\mathcal{H}(p(i))^y)^{-\tau_i}, g^{\gamma_k}).e(g^{\tau_i}, g^{\gamma'_k yt_k}.$$
$$(g^{v_{p(i)}}\mathcal{H}(p(i)))^{y\gamma_k}).e\left(g^{\tau_i}, g^{yt_k\gamma'_k}\right)^{-1}$$
$$= e\left(g,g\right)^{a\lambda_i\gamma_k}.e\left(g, g^{v_{p(i)}}\mathcal{H}(p(i))\right)^{-\gamma_k y\tau_i}.e\left(g,g\right)^{\tau_i\gamma'_k yt_k}.$$
$$e\left(g, g^{v_{p(i)}}\mathcal{H}(p(i))\right)^{\tau_i y\gamma_k}.e\left(g,g\right)^{-\tau_i yt_k\gamma'_k}$$
$$= e(g,g)^{a\lambda_i\gamma_k}$$

after we get,

$$\prod_{i\in I}\left(e(g,g)^{a\lambda_i\gamma_k}\right)^{w_i N_A} = e(g,g)^{sa\gamma_k}, \quad \Sigma_{i\in I} w_i\lambda_i = s,$$

then it computes,

$$\frac{e(g,g)^{sa\gamma_k}.e(g,g)^{\alpha s}}{e(g,g)^{sa\gamma_k}} = e(g,g)^{\alpha s}$$

to obtain the message

$$= \frac{C}{e(g,g)^{\alpha s}}$$
$$= \frac{msg.e(g,g)^{\alpha s}}{e(g,g)^{\alpha s}}$$
$$= msg$$

□

6 | Security Analysis

Here in this Section 6, a detailed security analysis of BloCPABE is discussed:

Theorem 1. *The proposed system model is protected against repudiation attack.*

15320634, 2025, 9-11, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.70064 by Delhi Technological University, Wiley Online Library on [30/04/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Proof. By permanently recording data in a tamper-proof manner and verifying the identity of transaction participants through digital signatures, blockchain ensures that actions cannot be denied. □

Theorem 2. *BloCPABE ensures the integrity and resistance to tampering.*

Proof. BloCPABE ensures the integrity and resistance to tampering with encrypted data by utilizing the inherent properties of blockchain technology. Since the hash of encrypted data is stored on a blockchain, any attempts to tamper with or alter the data would require a consensus among the majority of nodes on the network, making it virtually impossible to manipulate the data without being detected. By its very design, blockchain is a decentralized and immutable ledger that records transactions across a network of computers. Once data is entered into the blockchain, it is cryptographically linked to the previous blocks, forming a chain resistant to modification. Any attempt to alter a previous block would require recalculating and altering all subsequent blocks, which is computationally infeasible in a well-distributed network. □

Theorem 3. *Our scheme protects and maintains the confidentiality of data, ensuring access is limited to authorized users only.*

Proof. BloCPABE facilitates robust, fine-grained access control, ensuring that sensitive data is securely delivered to authorized users while protecting it from unauthorized access. It guarantees that only users who satisfy the predefined access policy can access the encrypted data. Furthermore, the data owner encrypts the data and stores it in decentralized storage while sharing the corresponding secret key with authorized users through a secure channel, preventing potential adversaries from accessing the plaintext. □

Theorem 4. *The proposed framework is resistant to the collusion attack.*

Proof. In scenarios where multiple users collaborate, they might potentially decrypt the ciphertext by combining the attributes. When malicious users collude, they may attempt to combine their attributes to decrypt the ciphertext. However, since the secret key is linked to each user's unique identifier uid, collusion between two users with different identifiers uid and uid' will not enable them to recover the factor $e(g,g)^s$. Consequently, such collusion will not allow these users to gain unauthorized privileges. □

Theorem 5. *The scheme provides both backward and forward security.*

Proof. Forward security guarantees that once a user's decryption key (secret key) is revoked, they can no longer access newly encrypted data. Backward security, on the other hand, ensures that a newly generated decryption key cannot be used to access ciphertext that was encrypted prior to the key's creation. It prevents a user from accessing sensitive information that was encrypted before they were granted access, thereby maintaining the confidentiality of historical data. The proposed scheme incorporates attribute revocation to guarantee both backward and forward security. Upon attribute revocation, only users possessing valid attributes can update their secret keys to the latest version. Additionally, ciphertexts are updated using a ciphertext update key, preventing newly added users from accessing previously encrypted data. □

Theorem 6. *BloCPABE scheme is IND-CPA secure if the Decisional q-PBDHE assumption maintains, that is, No polynomial-time adversary $\mathfrak{A}$ attempting to selectively break BloCPABE system with a challenge matrix of size $l^* \times n^*$ will succeed if the Decisional q-PBDHE assumption holds.*

Proof. The details of the proof are referred to Waters, B. [9]. □

6.1 | Formal Verification

To perform the formal verification of our protocol, we have employed the Scyther Tool [27] as shown in Figure 5. Other than Scyther, there are numerous tools such as AVISPA [28], Proverif [29], and TAMARIN [30] that are used for the formal security analysis [31]. The Scyther tool analyzes a protocol described in Security Protocol Description Language (SPDL) and formulates security claims for each role specified in the protocol. It then verifies that these assertions are accurate; in other words, it checks the correctness of these claims. Scyther tool is designed to function with an unlimited number of sessions, though this capability does not ensure indefinite correctness. In situations where this limitation applies, Scyther will indicate, "No attacks within bounds." If the tool identifies no specific attacks or attack patterns, it will report "No attacks."

The implementation code of the entire BloCPABE protocol is very large, but to provide a brief understanding of the protocol, a code snippet illustrating the system initialization of BloCPABE is given in Figure 5a. The code snippet showcases the exchange of messages between the CA, AA, and users (where "users" refers to both DO and DU). Each entity exchanges data using the *send* and *recv* actions. The *send* action describes a participant in the protocol sending a message to another participant, while the *recv* action implies that a participant is prepared to accept an incoming message.

The implementation of the BloCPABE protocol in Scyther contains five participants: CA, AA, DU, DO, and BC. Here, the Scyther tool also assesses claims such as $Weakagree$, which verifies that all parties involved are actively executing the protocol. $Nisynch$ ensures that data is handled consistently throughout the execution of the protocol. $Niagree$ guarantees that the sender believes the intended receiver actively participates in the one-way authentication protocol. $Alive$ confirms the receiver's active status after the protocol's execution and verifies that they have initiated the expected response. Finally, $Commit$ confirms that the protocol has successfully established a valid claim.

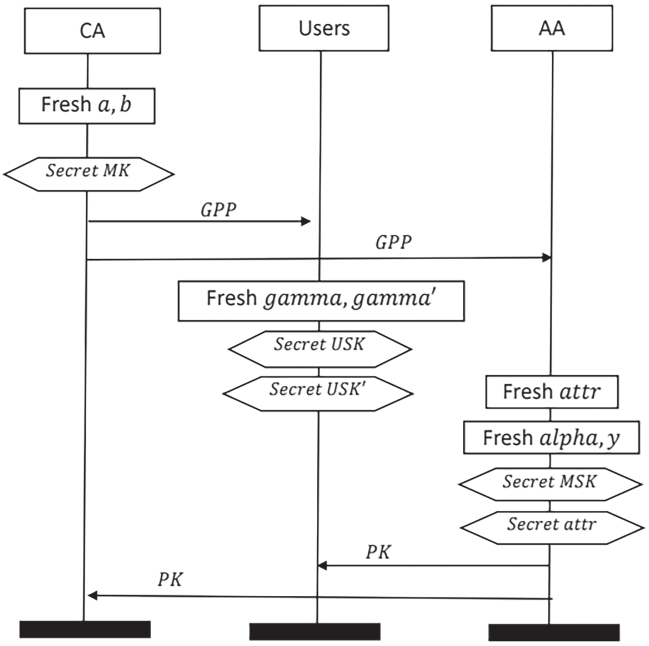
The security is evaluated over five runs with adversarial parameters to determine the most suitable attack, with a maximum of 10 patterns per claim, as shown in Table 2.

15320634, 2025, 9-11, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.70064 by Delhi Technological University, Wiley Online Library on [30/04/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

```
protocol BloCPABE(CA,Users,AA){
role CA{
claim(CA,Secret,MK);
send_1(CA,Users,GPP);
send_2(CA,AA,GPP);
recv_4(AA,CA,PK);
}

role Users{
claim(Users,Secret, USK);
claim(Users,Secret, USK');
recv_1(CA,Users,GPP);
recv_3(AA,Users,PK);
}
role AA{
claim(AA,Secret,MSK);
claim(AA,Secret,attr);
recv_2(CA,AA,GPP);
send_3(AA,Users,PK);
send_4(AA,CA,PK);
}
}
```

(a)



(b)

FIGURE 5 | Formal verification of the system initialization phase: (a) a code snippet of the setup phase and (b) a sequence diagram.

TABLE 2 | Parameter setting in Scyther.

Parameters	Values
Maximum number of runs	5
Matching type	Typed matching
Search Pruning	Find best attack
Maximum number of patterns per claim	10
Attack graph font size	14

In the setup phase (system initialization phase), we investigate the attacks between the transmission from the CA to users, from the CA to the AA, and from the AA to the users. The *Secret* claim ensures the protocol parameters remain confidential and protected from unauthorized observers or intruders. Scyther evaluates the following protocol claims: $Claim(CA, Secret, MK)$ for the CA, $claim(Users, Secret, USK)$ and $claim(Users, Secret, USK')$ for the users, and $claim(AA, Secret, MSK)$ and $claim(AA, Secret, attr)$ for the AA. MK is the master key, and is defined in blocpabe.spdl as $macro\ MK = keys(a, b)$, where $keys$ is a function. Similarly, USK and USK' defined as $macro\ USK = gamma$ and $macro\ USK' = gamma'$. MSK is defined here as $macro\ MSK = keys(alpha, y)$. The sequence diagram Figure 5b illustrates that role CA performs a *send* action to send message/data to Users using $send_1(CA, Users, GPP)$ and to AA using $send_2(CA, AA, GPP)$. The Users claim the secrecy of USK, USK'. The role AA sends the message to the CA and the Users with $send_3(AA, Users, PK)$ and $send_4(AA, CA, PK)$ respectively, where PK is defined as $macro\ PK = map(g, g)power(alpha)$. The SPDL language is used to implement our suggested scheme, and the verification protocol results (Table 3) have confirmed its correctness.

7 | Performance Analysis

This section presents a theoretical analysis that includes a comparison of features or functionalities, along with an evaluation of computation (Subsubsection 7.1.2), communication (Subsubsection 7.1.3), and storage (Subsubsection 7.1.4) overhead of relevant existing schemes. Additionally, it offers an experimental analysis of encryption and decryption times across varying numbers of attributes.

7.1 | Theoretical Analysis

7.1.1 | Features Comparison

To evaluate the scalability of our scheme, we conducted a comparative analysis with several established CP-ABE schemes. We have assessed the functionality of BloCPABE in comparison with the schemes described in [6], [17], [24], [1], [23], [19], [5], [11], [12] and [25], as detailed in Table 4.

As outlined in Table 4, we conduct an analysis based on several key aspects, including type, group type, and the access structure utilized. It also encompasses the level of renovation, whether at the attribute or user level, as well as support for key updates and ciphertext updates. Furthermore, the analysis considers who is responsible for updating the ciphertext, the provision of non-repudiation, and protection against collusion attacks. We also assess whether the scheme ensures both forward and backward security, integrates blockchain technology for immutability and data integrity, and provides formal verification to confirm the absence of potential attack vectors. A "✓" indicates support for the technology, a "✗" indicates a lack of support, and "×" denotes that it is not explicitly mentioned.

15320634, 2025, 9-11, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.70064 by Delhi Technological University, Wiley Online Library on [30/04/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

TABLE 3 | Scyther verification results.

Claim				Status	Comment
BloCPABE	CA	BloCPABE, CA1	Secret keys(a,b)	Ok Verified	No attacks
	Users	BloCPABE, Users1	Secret gamma	Ok Verified	No attacks
		BloCPABE, Users2	Secret gamma	Ok Verified	No attacks
	AA	BloCPABE, AA1	Secret keys(alpha,y)	Ok Verified	No attacks
		BloCPABE, AA2	Secret attr	Ok Verified	No attacks
Done					

This comparison focuses on various functional aspects critical for the practical deployment of these schemes in sensitive data-sharing environments. All the considered schemes are of the CP-ABE type and utilize the LSSS access structure, enhancing each scheme's expressiveness. Bethencourt et al. [6] scheme utilizes the tree access structure, and Riepel et al. [11] scheme uses the boolean formulae and MSP access structure. The scheme in [6], [17], [12], [24], [23], [19], [11], [5], [25] and our take prime order group, while [1] adopts composite order group.

In terms of revocation mechanisms, the schemes proposed by Yang et al. [17], Tu et al. [19], and our system support attribute-based revocation, while Wei et al. [24] scheme implements user-based revocation. Other schemes do not incorporate any form of revocation. Regarding key and ciphertext updates, the scheme [17], [24], [19], and our facilitate both the key update and ciphertext update. The server handles the ciphertext update in [17], [24], and [19], while the owner is responsible for ciphertext updates in our scheme. When evaluating security characteristics, such as user collusion, forward/backward security, and non-repudiation, the schemes by [5], [25], and our scheme support non-repudiation and leverage blockchain technology for the secure storage of encrypted data, ensuring data integrity. The schemes [17], [24], [19] and our support the forward and backward security as well. Additionally, [17], [23], [19], and our scheme provides protection against user collusion. Furthermore, our scheme is formally verified using the Scyther tool.

7.1.2 | Computation Overhead

Before assessing the computational overhead, we have examined of the execution time for each operation as shown in Table 5. The duration for each operation has been estimated utilizing the Charm framework [32] on a supersingular curve SS512. The analysis presented in Table 5 indicates that hash operations, exponentiation in $\mathbb{G}_1$ and $\mathbb{G}_T$, and pairing operations are significant contributors to the computational cost associated with ABE schemes. Further, Table 6 illustrates the computational overhead across different schemes, highlighting the costs associated with key generation, encryption, and decryption processes. We include the following schemes in our evaluation: Yang et al. [17], BSW07 [6], FABEO [11] and Yamada et al. [12]. Let T_E denote the time required for exponentiation operations in $\mathbb{G}_1$ and $\mathbb{G}_T$. Specifically, T_E is measured as 0.82201ms in $\mathbb{G}_1$ and 0.07321ms in $\mathbb{G}_T$. The $|S|$ represents the number of attributes possessed by user uid_k, which are utilized in constructing uid_k's secret key. Additionally, let T_P signify the time for pairing operations and H' the time for hash operations. The m denotes the number of attributes in the ciphertext. In schemes employing LSSS access structure, m corresponds to the number of rows in the Linear Secret-Sharing Schemes (Subsection 2.4) matrix $M_{l\times n}$. The term I_e represents the minimum number of interior nodes required to satisfy an access structure, and $|I|$ indicates the number of attributes involved in the decryption of ciphertext.

This paper utilizes these time measurements (Table 5) in Table 6 to construct the computational times for key generation, encryption, and decryption with a varying number of attributes. The computation cost for the 100 number of attributes in BSW07 can be calculated as $(2|S|+2)T_E + |S|H'$, that is, $(2\times 100+2).0.82201 + 100\times 1.8171 \approx 348.12$ ms, let for Yamada et al. scheme keygen time is $(6\times 100+2)\times 0.82201 = 494.85 \approx 498.26$ ms. Our scheme's computation cost for keygen 100 attributes is $(2\times 100+2)\times 0.8171 \approx 162.88$ ms. Similar to the keygen, the computation cost for encryption for schemes such as Yang et al., for 100 number of attributes can be calculated as $(5\times 100+3)\times 0.82201 + 0.537239 = 414 \approx 424.21$ ms including an additional overhead Δ associated with the encryption process. The results depicted in Figure 8a,b illustrate that the proposed scheme, along with the schemes BSW07, Yamada et al., Yang et al., and Fabeo, demonstrates superior efficiency in secret key generation and encryption compared to other approaches. The computation cost associated with the decryption (shown in Figure 8c) of our scheme is comparatively higher than FABEO, BSW07, and Yamada et al. and lower than Yang et al.(discussed in detail in Subsection 7.2). Addressing the reduction of decryption costs while maintaining the security of the scheme is an area we plan to explore in future work.

7.1.3 | Communication Overhead

The Subsubsection 7.1.3 provides an overview of the communication overhead analysis, including both the count of communicated messages and the overall communication cost incurred. Specifically, Subsubsection 7.1.3 indicates that the number of public parameters for the schemes proposed by BSW07, Yamada et al., Yang et al., FABEO, and our own are 5, 7, 4, 3, and 4, respectively.

Table 7 outlines the communication overhead of various CP-ABE schemes and presents the public parameter, secret key, and ciphertext used in the schemes by BSW07, Yamada et al., Yang et al., and FABEO. These schemes utilize public parameters, as follows: BSW07 includes $\{\mathbb{G}_0, g, h, f, e(g,g)^{\alpha}\}$, Yamada et al.

TABLE 5 | Average execution time for each operation.

Operation	Time
Multiplication time in $\mathbb{Z}_p$	0.001129 ms
Exponentiation time in $\mathbb{G}_1$	0.82201 ms
Exponentiation time in $\mathbb{G}_T$	0.07321 ms
Multiplication time in $\mathbb{G}_1$	0.00479 ms
Multiplication time in $\mathbb{G}_T$	0.001039 ms
Inverse Operation time in $\mathbb{G}_1$	0.000509 ms
Inverse Operation time in $\mathbb{G}_T$	0.00323 ms
Time for hash operation	1.8171 ms
Time for pairing operation	0.537239 ms

employ $\{g, H, U, V, V', W, e(g,g)^{\alpha}\}$, Yang et al. use $\{g, g^a, g^b, \mathcal{H}\}$, and FABEO incorporates $\{\mathcal{G}, \mathcal{H}, e(g_1, g_2)^{\alpha}\}$.

The number of messages in the secret key for each scheme is 3, 6, 3, and 3, respectively. These are as follows: BSW07 includes D, D_j, D'_j, Yamada et al. incorporates $\{D_1, D_2, \{K_{i,1}, K_{i,2}, K'_{i,1}, K'_{i,2}\}\}$, Yang et al. uses $\{K_{uid,aid}, K'_{uid,aid}, \{K_{x_{aid},uid}\}\}$, and FABEO employs $\{sk_1, \{sk_2\}, sk_3\}$. Similarly, in the ciphertext, the communicated messages are as follows: BSW07 includes $\{\widetilde{C}, C, \{C_y, C'_y\}\}$, Yamada et al. use $\{C_0, C_1, \{C_{i,1}, C_{i,2}, C_{i,3}\}\}$, Yang et al. employ $\{C, C', C'', \{C_i, C'_i, D_i, D'_i\}\}$, and FABEO includes $\{ct_1, \{ct_{2,j}\}, \{ct_{3,i}\}\}$.

As elaborated in Section 5, our scheme utilizes public parameters (PP) $g, g^a, g^b, \mathcal{H}$. Furthermore, the secret key (SK) in our scheme comprises the set $\{K, K', K'', \{K_{x_i}\}\}$, as detailed in Figure 6. The total number of communicated messages in ciphertexts is 5, represented as $CT = \{C, C', C'', \{C_{1,i}, C_{2,i}\}\}$. When compared to the schemes by Yamada et al. and Yang et al., the communication overhead of our scheme remains relatively affordable, as illustrated in Figure 6.

7.1.4 | Storage Overhead

Figure 7 presents a comparison of storage overhead across the BSW07, Yamada et al., Yang et al., FABEO, and our proposed scheme. In this analysis, we evaluate the secret key size and ciphertext size for different CP-ABE schemes as shown in Table 8. Let $|L_{\mathbb{G}_1}|$ represent the bit size of an element in the source group $\mathbb{G}_1$, and $|L_{\mathbb{G}_T}|$ represent the bit size of an element in the target group $\mathbb{G}_T$. These schemes are based on the symmetric pairing SS512, where in the elliptic curve SS512, the sizes of the fields corresponding to $|\mathbb{Z}_p|$, and $|L_{\mathbb{G}_1}|$ are 20 bytes, and 64 bytes respectively. These field sizes are applied to calculate the size of ciphertext and secret key in Figure 7, and the results are depicted in Subsection 7.1.4.

It can be seen from Figure 7a that our scheme results in significantly lower storage overhead compared to the Yamada et al. $(4|S|+2)|L_{\mathbb{G}_1}|$ and BSW07 schemes $(2|S|+1)|L_{\mathbb{G}_1}|$. Additionally, the difference in storage overhead between the FABEO $(|S|+1)|L_{\mathbb{G}_1}|$, Yang et al. $(|S|+2)|L_{\mathbb{G}_1}|$ and our proposed

Schemes	Public parameter	Secret key	Ciphertext	Total overhead
BSW07	5	3	4	12
Yamada et al.	7	6	5	18
Yang et al.	4	3	7	14
FABEO	3	3	3	9
Proposed	4	4	5	13

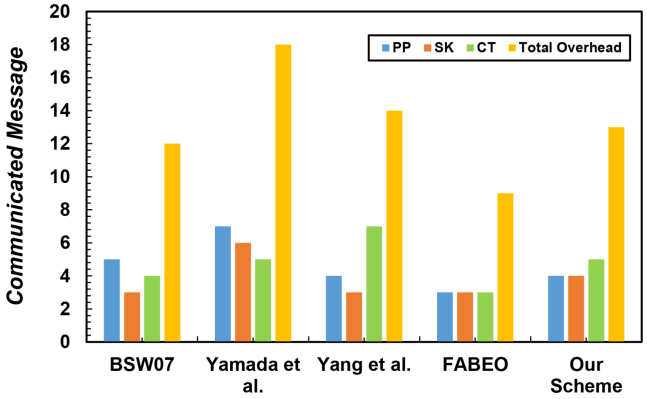

FIGURE 6 | Communication overhead of various schemes.

scheme $(|S|+3)$ $|L_{\mathbb{G}_1}|$ is minimal. Regarding ciphertext storage, FABEO has the smallest cost, expressed as $(m+1)|L_{\mathbb{G}_1}| + 1|L_{\mathbb{G}_T}|$. The BSW07 scheme also has a relatively low overhead at $(2m+1)|L_{\mathbb{G}_1}| + 1|L_{\mathbb{G}_T}|$, which is close to the size of our ciphertext $(2m+3)|L_{\mathbb{G}_1}| + 1|L_{\mathbb{G}_T}|$. In comparison to the schemes by Yang et al. and Yamada et al., our scheme demonstrates lower storage overhead (Figure 7b).

7.2 | Experimental Analysis

This section outlines a simulation-based experimental study aimed at comparing the proposed scheme with state-of-the-art algorithms in the field. The experiment is conducted across three common aspects: Key generation, data encryption, and data decryption. All the experiments are carried out on a personal computer equipped with an AMD Ryzen 5 5500U processor featuring Radeon Graphics, RAM 16 GB, and an SSD 512 GB [33], running Ubuntu 22.04 LTS as the operating system. Our algorithms are implemented in Python 3.10.0 utilizing the "Charm-Crypto" [32] framework on a 512-bit supersingular elliptic curve (SS512) with 160-bit order.

Figure 8 demonstrates the time efficiency of the CP-ABE schemes concerning key generation, encryption, and data decryption. Note that some of the schemes do not address attribute revocation; therefore, only the common aspects are compared in this analysis. In the key generation stage, we evaluated the time consumption of the key generation algorithm by varying the number of attributes, as illustrated in Figure 8a. As the number of attributes increases, we observe a corresponding rise in key generation time for all five schemes. While Yang et al.'s scheme is designed for multi-authority ABE, we evaluated it in a single-authority for computational time comparison. Our proposed scheme demonstrates a notable advantage in key generation time compared to BSW07, Yamada et al., Yang et al., and FABEO. When evaluating with 10 attributes, the key generation times for BSW07, Yamada et al., Yang et al., FABEO, and our scheme are 36.22, 51.95, 28.21, 30.78, and 16.24 ms, respectively. Similarity evaluating with 100 attributes, the time is 348.12, 498.26, 248.78, 268.84, and 162.88 ms, respectively.

To guarantee consistency in the encryption and decryption process, each ciphertext is produced based on "AND" access policies, such as $ATTR_1$ AND $ATTR_2$ AND $ATTR_3$ AND ... AND $ATTR_N$, where N ranges from 2 to 100. Also, to ensure the reliability of execution time data, each experiment is conducted 20 times. The average of these trials is used to calculate the final execution time. As depicted in Figure 8b, the encryption algorithm's execution times for access policies with 10, 50, and 100 attributes are measured across five schemes: BSW07, Yamada et al., Yang et al., FABEO, and our proposed scheme. The results indicate that encryption under these policies consumed 36.69, 35.25, 44.98, 40.03, and 36.46 ms, respectively, for 10 attributes; 177.36, 170.84, 216.48, 181.84, and 169.80 ms for 50 attributes; and 352.86, 340.32, 424.21, 363.48, and 337.70 ms for 100 attributes. Our proposed encryption scheme demonstrates a notable improvement in computational efficiency compared to existing approaches. While there is a marginal performance gap between our scheme and Yamada et al.'s, our solution exhibits better encryption performance.

As depicted in Figure 8c, the execution time of the decryption algorithm for access policies with 10, 50, and 100 attributes are measured across five schemes: BSW07, Yamada et al., Yang et al., FABEO, and our proposed scheme. The results indicate that decryption under these policies consumed 11.64, 18.35, 33.93, 2.37, and 27.79 ms, respectively, for 10 attributes; 54.24, 86.23, 160.34, 3.04, and 130.20 ms for 50 attributes; and 107.16, 171.23, 315.20, 3.50, and 130.20 ms for 100 attributes. The decryption time results presented in Figure 8c indicate that our scheme takes more time compared to BSW07, Yamada et al., and FABEO.

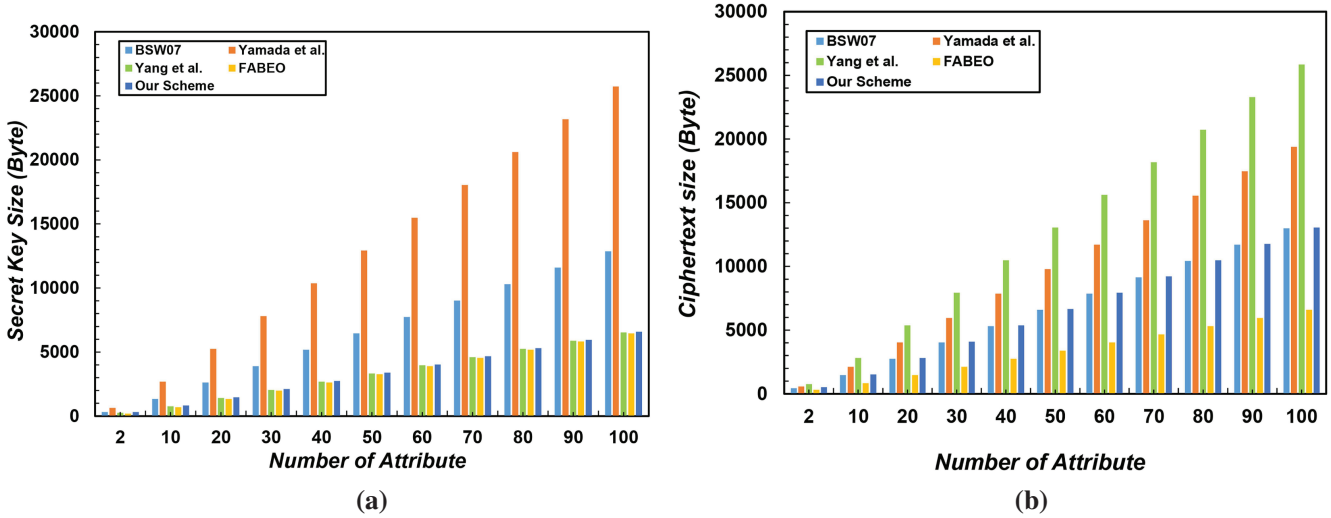

FIGURE 7 | The storage overhead computed for various ABE schemes: (a) key size and (b) ciphertext size.

TABLE 8 | Storage overhead comparison of proposed work with the existing schemes.

Schemes	Secret key size	Ciphertext size
BSW07	$(2\|S\|+1)\|L_{\mathbb{G}_1}\|$	$(2m+1)\|L_{\mathbb{G}_1}\|+1\|L_{\mathbb{G}_T}\|$
Yamada et al.	$(4\|S\|+2)\|L_{\mathbb{G}_1}\|$	$(3m+1)L_{\mathbb{G}_1}+1\|L_{\mathbb{G}_T}\|$
Yang et al.	$(\|S\|+2)\|L_{\mathbb{G}_1}\|$	$(4m+2)\|L_{\mathbb{G}_1}\|+1\|L_{\mathbb{G}_T}\|$
FABEO	$(\|S\|+1)\|L_{\mathbb{G}_1}\|$	$(m+1)\|L_{\mathbb{G}_1}\|+1\|L_{\mathbb{G}_T}\|$
Proposed	$(\|S\|+3)\|L_{\mathbb{G}_1}\|$	$(2m+3)\|L_{\mathbb{G}_1}\|+1\|L_{\mathbb{G}_T}\|$

This additional computational overhead arises from pairing operations and secret key processing tasks associated with each attribute that the user possesses, which increases with the number of attributes stated in the access policy. Through rigorous theoretical and empirical analysis, our proposed scheme demonstrates notable advantages in functionality and computational efficiency compared to existing approaches. The detailed simulation of our proposed CP-ABE scheme with blockchain is analyzed in Subsection 7.3.

7.3 | Blockchain Simulation

To evaluate the effectiveness of the proposed model, a prototype illustrated in Figures 3 and 4 is tested on a system specification given in Subsection 7.2. We developed the smart contract using Solidity and tested it on RemixIDE. For blockchain simulation, we utilized Ethereum on Ganache-Truffle Suite [34], leveraging Web3.js as the communication interface. In this simulation, we assessed our CP-ABE scheme when integrated with IPFS 0.20.0 (InterPlanetary File System) and the Ethereum blockchain. The primary objective is to evaluate the efficiency of the ABE scheme by leveraging IPFS for decentralized storage and Ethereum for recording metadata.

Initially, a smart contract is deployed on a local Ethereum blockchain (Ganache), designed to store IPFS hashes associated with encrypted data. Encrypted content is serialized and uploaded to IPFS, ensuring a decentralized and immutable storage solution. Figure 9 details the overhead associated with the entire process, including the encryption time, the outsourcing of encrypted data to IPFS, and the recording of the hash on the blockchain. The time taken increases with the number of attributes. With 2 attributes, the observed overhead is 0.256 s; with 50 attributes, it rises to 3.882s; and with 100 attributes, it grows to 8.447 s. This increase in processing time highlights the challenges that arise as the array of attributes increases; the complexity and time required for encryption, data outsourcing to IPFS, and blockchain interactions become significant.

8 | Conclusion and Future Scope

The security, privacy, and access control challenges in mHealth systems are addressed in this paper by the proposal of the BloC-PABE scheme. Additionally, the system facilitates the efficient revocation of attributes with minimal computational latency, guaranteeing that user access rights are promptly updated in response to attribute modifications. The results demonstrate that the BloCPABE is computationally more efficient than existing ABE methods. In particular, we observed a reduction in key generation costs by 35% to 67% and encryption costs by 26% to 39%, which underscores the efficiency enhancements of the approach. The BloCPABE scheme is designed to resolve critical concerns in healthcare data sharing by ensuring user privacy, forward/backward security, and resistance to collusion attacks. The solution further enhances security by guaranteeing the immutability and tamper-proof integrity of outsourced data through the integration of blockchain technology. These findings reveal that the BloCPABE scheme is highly secure and privacy-preserving, rendering it appropriate for real-time, fine-grained access control in mHealth systems. This work has substantial implications, as it offers a solution for enhancing the security and privacy of patient health records and enabling the efficient exchange of sensitive health data. Through theoretical complexity analysis and experimental experiments, we verified the efficiency and feasibility of our designs. The algorithm's scalability and versatility will be enhanced by refining it to

Keywords: Biogas, Rice Straw, Anaerobic Digestion, Feed Ratio

Abstract. The use of agricultural wastes for the production of renewable energy is becoming more popular as communities look for long-term solutions to problems related to waste management and energy. An abundant residue of rice farming, rice straw offers a promising fuel to produce biogas by anaerobic digestion. The aim of this research paper is to analyze the method of converting rice straw into biogas. A culture of bacteria breaks down complex organic compounds present in rice during the anaerobic digestion process to produce methane-rich biogas. To improve the yield and quality of biogas, optimization strategies like adjusting process parameters are investigated. To reduce global warming and advance sustainable development, the results highlight rice straw's potential as a renewable energy source and call for its usage.

Introduction

Recently, the international community has become more determined to find sustainable sources of power; this is because they are worried about the environment and need to prevent global warming [1]. Among all kinds of renewable energy, biogas is considered as a good choice due to its flexibility, efficiency and being eco-friendly. In fact, making use of rice straws for biogas production can completely change how people generate electricity and deal with waste. The benefits, drawbacks, prospects, and risks associated were examined with using various portions of wheat and rice straw as a feedstock for the bio-based economy [2,3].

Rice is consumed by almost half of the world's population so it is no surprise that it is grown in many countries [4]. Two studies of the trials wherein straw was consumed, using field probing straw consolidation and ignition chamber analysis to examine the impact of rice straw consumption on methane and nitrous oxide discharges were conducted. By a factor of 2.1, the Emission Factor of methane obtained from dry rice straw (>10% moisture content) exceeded the default IPCC level. Methane was the primary driver of all outflows and GWP, despite the fact that the nitrous oxide Emission Factor was nearly identical to the IPCC estimate. This commitment will even be problematic in light of the regular increase in methane Emission Factors as a dampness substance component, as described in several analyses [5]. However, large quantities of agricultural waste known as rice straw are produced during rice farming activities such as burning them off or letting them rot where they lie which causes pollution through release into the atmosphere as smog or greenhouse gasses like methane. Various estimates of the air pollutants released by burning crop wastes in India's fields, broken down by state [1]. This not only harms our surroundings but also means we ignore important fuel resources available to us. The conversion of rice straw to biogas offers an attractive avenue towards addressing the two issues.

The research provided a thorough understanding of the detrimental effects of crop residue mismanagement in India, specifically with regard to stubble burning. It also discusses other, more promising methods of managing crop residues, such as the use of bioenergy if widely used, will not only lessen the effect of crop residue management on the environment but also create additional value for the agricultural industry worldwide [6]. The different options for transforming a "waste"

object into a valuable one were also examined [7]. It could be accomplished by producing electricity from biomass, serving as a hotspot for domesticated animal feed, assisting in the management of disintegration, or even producing necessary end products like medicines, health products, and composts. This essay aims to investigate optional environmentally friendly disposal methods that India could implement.

The rice straw recycling, with particular attention to the energy circumstances in China and around the world, managing biogas digestate [8]. In contrast, *Mothe and Polisetty* examined how using rice straw in combination with other co-substrates and the right pretreatment could be a sustainable way to reduce risks to the health and environment while increasing the production of biomethane [9]. In contrast, rice straw was pretreated chemically and biologically (with NaOH, HCl, $CO(NH_2)_2$, and cellulase) at room temperature (approximately 20℃) to enhance its biodegradability and boost the production of anaerobic biogas.

Biogas, made up of CH_4 and CO_2, is produced by anaerobic digestion through fermentation of organic materials by microorganisms. Rice straw is made up of cellulose and hemicellulose, which makes it an excellent fuel for biogas production due to its renewability and availability. The effectiveness of three pretreatments to increase the production of biogas from rice straw: microwave, ammoniation, and microwave-assisted ammoniation (MAA) were examined [10]. In order to reduce environmental pollution, an overview of the most promising options for managing paddy straw and converting biogas to bio-CNG is provided in this article [11]. The performance of fresh and dry rice straw was evaluated in this study at 35°C during batch anaerobic digestion. The findings revealed that the biogas produced from fresh rice straw was 400.5 mL/g of volatile solids, which was more than 40.9% produced from the substrate made of dry rice straw [12,13]. In contrast, a 1 m^3 floating drum anaerobic digester was used to determine the ideal parameters for the production of biogas from the anaerobic digestion of rice straw using Response Surface Methodology (RSM) [14].

This research paper seeks to explain and analyze the conversion process of rice straw and other agricultural wastes into useful biofuel like biogas which can be used as a source of energy. Complete process of anaerobic digestion used for the conversion was studied. This paper also analyzed various process parameters that affect the production of biogas through anaerobic digestion. The effect of various changes of process parameters were examined and the consequence of each parameter on production of biogas was compared to find the best possible solution for getting maximum production of biogas.

Biogas from Rice Straw Good for Sustainable Energy

Making biogas from rice straw using anaerobic digestion is a good way to make sustainable energy. It helps to reduce carbon in the energy industry and fight climate change by releasing less greenhouse gases. Moreover, it answers the growing need for clean and renewable power supply[15]. In addition to this, the process gives opportunities for employment creation in rural areas. Another thing that can be done towards sustainability is refraining from burning rice straw on fields. It has been estimated that about 300 million tons of waste rice straw are burned in fields across Asia every year thereby adding to greenhouse gasses emitted into the atmosphere [16]. Furthermore, respiratory diseases as well as premature deaths are caused by burning rice straws. Nonetheless, biogas production from rice straw has been proved successful but much still remains untapped on this technology. With Biogas energy made out of rice husk it can be used for green power generation or cook with heat produced from it can also serve heating and electricity purposes while being supplied through power systems or other means like fuel cells etcetera. Converting it into biogas contributes to sustainable energy production through utilization of residues left after harvesting rice crops too [17]. Mechanical pretreatment may help overcome some challenges encountered during biogas production from this type of feedstock i.e., straw. The THDI Equation may be utilized in assessing how far these processes would go towards ensuring

sustainable development goals get achieved within our societies more especially those living near such facilities should take note so that they do not complain later on when things fail them again [18].

MATERIALS AND METHOD

Rice straw

Rice straw is a residual material from rice harvesting. As the primary staple food, rice provides half of the world's population with both protein and energy. As a staple crop, rice is widely consumed across India. In the financial year 2023 India produced 135 million metric tons of rice. This indicates steady rise in rice production since 2017. Whereas more than any other nation, China produced approximately 146 million metric tonnes of rice in the 2022–2023 crop year as observed from Fig. 1. With more than 135 million metric tonnes of rice produced in that crop year, India ranks second.

In the past, rice straw was harvested manually using traditional methods. After that, it served as a raw ingredient for pulp and paper, fertilizer, and animal feed industries. In spite of this, technology development leads to rise in rice straw collection expenses and time-consuming parameters. As a consequence, a very low percentage of the rice straw, up to 20%, is further used, while farmers burn the rest amounting to 50% for the preparation of the fields for the subsequent crop. Burning techniques release a variety of harmful pollutants, such as carbon monoxide (CO), sulfur dioxide (SO_2), and nitric oxide (NO_X), as well as greenhouse gasses (GHGs) including carbon dioxide (CO_2), methane (CH_4) resulting in respiratory diseases.

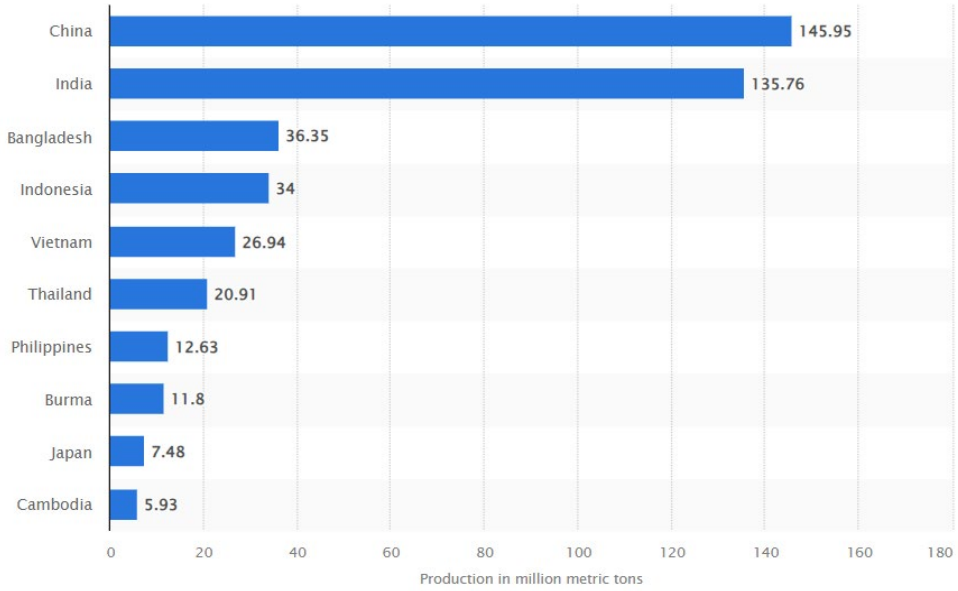

Figure 1. Rice production by top 10 nations (Source: US Department of Agriculture 2024)

Properties and Composition of Rice Straw

The properties of rice straw can be divided into three main areas, to determine its utility: (i) physical characteristics; (ii) thermal qualities; and (iii) chemical composition.

Physical characteristics include bulk density, heat capacity, and thermal conductivity. The most important consideration for managing and storing rice straw is density. Thermal properties and heating value are crucial in the process of turning biomass into energy. Lignin, cellulose, hemicellulose/carbohydrates, and nutritional contents are among the components of chemical composition that have an impact on application-specific aspects including soil fertility and livestock feed.

Materials Research Proceedings 49 (2025) 549-558 https://doi.org/10.21741/9781644903438-55

Physical properties

The dry matter density of loose rice straw can range from 14-18 kg/m³. Chopped straw with lengths ranging from 1-10 mm can have densities in range from 50 to 120 kg/m³, depending on the apparatus used. Depending on the machinery used, the straw's size, mass density, and compression ratio will vary. A circular rice straw bale of 65 cm in length and 55 cm in diameter has a mass density between 65 and 85 kg/m³. The density of rice straw briquettes, with a diameter of 85 mm and a thickness ranging from 8-16 mm, is 360–440 kg/m³. Pellets of rice straw, measuring 9 mm in diameter and varying in height from 40 -60mm have density ranging from 600-700 kg/m³. The moisture content of the straw affects its heating value, which is important if the waste is intended to be used as bioenergy.

Thermal properties

The calorific value of rice straw is 14.2 MJ/kg is comparable to that of rice husks. As the first components to be driven off during combustion, the volatile carbon, combined with water, nitrogen, sulfur and hydrogen are referred to as volatiles in the proximate analysis. The range of 60.55 to 69.70% for the volatile matter (VOM) concentration of rice straw is proportional to the biomass of sugarcane bagasse, corn straw, and wheat straw. The final examination reveals the elemental oxygen, hydrogen, carbon, nitrogen and sulfur content of rice straw. In comparison to fossil fuels, rice straw biomass contains more oxygen and hydrogen but less carbon content. The ratio of H:C in rice straw is 0.94:1.06 and O:C is 1.1:1.36.

Table 1. Composition of Rice straw

S. No	Component Found in Rice Straw	Quantity (wt. %)
1.	Cellulose	43
2.	Hemicellulose	25
3.	Lignin	12
4.	Ash and Silica	34 - 44
5.	Glucose	19 - 22
6.	Arabinose	2 - 4
7.	Mannose	1.8 - 2
8.	Galactose	0.4
9.	Non-Structural Components	16 - 20

Chemical properties

The three main components of lignocellulose biomass are hemicellulose, cellulose and lignin. Glycoside linkages bind the subunits of monomeric D-glucose together to form cellulose, an essential component. Depending on how the structure is organized, cellulose is further divided into two forms: crystalline, which is more organized, and amorphous, which is less organized and is typically more relevant for fermentation. The cellulose and lignin molecules are held together by hemicellulose, giving the structure its tensile strength as depicted in Table 1. The mosaic structure made up of alcohols—is protected by lignin.

Anaerobic Digester

Anaerobic digesters are basically enclosed areas where anaerobic process breaks down organic waste from compost. The anaerobic bacteria converts the organic waste into fuel-grade biogas.

Components of Anaerobic Digesters-

i. Tank or Vessel: An anaerobic digester's primary component is a tank or vessel that contains the organic substrate and creates a controlled environment for the process of anaerobic digestion.
ii. Mixing System: To guarantee substrate and microbial population uniformity throughout the digestion, many anaerobic digesters use a mixing system.
iii. Gas Collection System: During anaerobic digestion, biogas is created and builds up in the digester vessel's headspace. The biogas is collected and captured for further processing or usage using a gas collecting system, which typically consists of pipelines, valves, and a gas storage tank.
iv. Effluent Removal System: Liquid effluent is regularly or continuously released from the digester during the anaerobic digestion process. The digestate is removed from the digester vessel using devices like pumps or gravity drainage systems.

ANAEROBIC DIGESTION

Anaerobic digestion is the process by which anaerobic bacteria decomposes organic materials in the absence of oxygen, such as animal dung, plant waste, and food wastes [19,20]. A sealed vessel known as a digester or reactor—which is built in various sizes and shapes depending on the site and feedstock conditions—is where the process of anaerobic digestion for the production of biogas takes place [21,22]. Complex microbial populations found in these digesters break down the waste material to produce digestate, or the solid and liquid byproducts of the anaerobic digestion process, and biogas that is discharged from the digester [23]. The reactions involved in the anaerobic digestion process are depicted in Table 2. The various stages involved in the anaerobic digestion are depicted in Fig. 2.

Hydrolysis

The goal of the hydrolysis process is to convert organic macromolecules into smaller pieces so that acidogenic bacteria can use them. While hydrolysis in anaerobic digestion can occur as an electrochemical process, it primarily occurs as a biological one. Hydrolytic bacteria release extracellular enzymes during the hydrolysis process, which can change lipids, proteins and carbohydrates into long-chain fatty acids and amino acids. Acidogenic bacteria cell membranes allow the hydrolysis products to permeate through after enzymatic cleavage. To improve the breakdown of these sugars, enzymes are frequently added.

Acidogenesis

Acidogenic bacteria produce volatile fatty acids (VFAs) and other compounds by absorbing the products formed during hydrolysis through their cell membranes. Larger organic acids like acetates and other organic acids make up VFAs. VFA concentrations can vary greatly for digesters operating at varied pH and temperature levels. The precise concentrations of intermediates produced in the acidogenesis stage depends on the digester's circumstances. It is commonly accepted that acidogenesis proceeds more quickly than any other stage of anaerobic digestion, with acidogenic bacteria regenerating in less than 36 hours. It is commonly known that digester failure is caused by VFA acidification.

Acetogenesis

A fraction of the initial substrate becomes eligible for acetoclastic methanogenesis when acetate is produced during acidogenesis. The process that turns highly volatile fatty acids (VFAs) and other intermediates into acetate is called acetogenesis. Lipids go through two distinct processes of acetogenesis at the same time: acidogenesis produces acetate from glycerol and β-oxidation produces acetate from LCFAs.

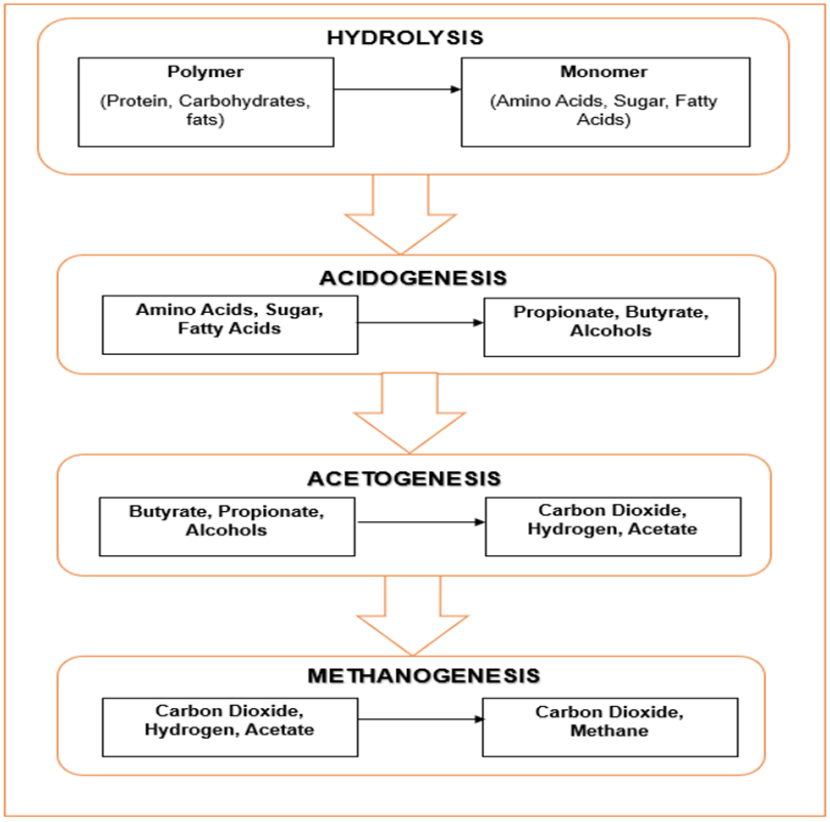

Figure 2. Stages involved in anaerobic digestion process

Methanogenesis

The last phase of anaerobic digestion is methanogenesis, in which methanogenic bacteria consumes available intermediates to generate methane. A class of oxygen-sensitive obligatory anaerobic archaea are known as methanogenic microorganisms. Methanogenic microbes need a higher pH and a lower redox potential in order to carry out methanogenesis. Methanogenesis ends when the production of biogas ceases, which can happen after 40 days or so. The volatile solids concentration and capacity of a sludge can be used to assess the degree of digestion.

Table 2. Reactions involved in anaerobic digestion process

Reactants	Products	Organisms Involved
$4H_2 + HCO_3^- + H^+$	$CH_4 + 3H_2O$	Most Methanogens
$4HCO_2 + H^+ + H_2O$	$CH_4 + 3HCO_3^-$	Many Hydrogenotrophic Methanogens
$2CH_3COOH + HCO_3^-$	$2CH_3COO^- + H^+ + CH_4 + H_2O$	Methanosarcina and Methanothrix
$4CH_3OH$	$3CH_4 + HCO_3^- + H_2O + H^+$	Methanosarcina and other Methylotrophic Methanogens

RESULTS AND DISCUSSION

Feed Ratio Adjustment

Rice straw is cut into smaller pieces, which reduces the particle size of rice straw breaking down the cell walls, increasing the organic substrate's availability for microbial breakdown. Size

reduction of rice straw increases surface area and disrupts its polymer structure, which boosts the yield and rate of hydrolysis during digestion.

After cutting the rice straw into smaller pieces making it more suitable for the anaerobic digestion process in the digester, rice straw is mixed with water making a mixture of water and rice straw (v/v) to feed into the digester. Feed is taken in different ratios of water and rice straw to check production of biogas (methane) from different feed ratios in digester from anaerobic digestion, to check at what ratio maximum biogas production occurs.

Three different feed ratios are taken for this experiment:

- 1:4 (1 unit rice straw and 4 units water)
- 1:5 (1 unit rice straw and 5 units water)
- 1:6 (1 unit rice straw and 6 units water)

Test results were conducted on a daily basis to check the biogas production on daily basis at different percentages of feed added to the anaerobic digester (see Table 3).

Table 3. Methane Production at different hydraulic retention time

Days	Digester 1 (1:4)	Digester 2 (1:5)	Digester 3 (1:6)
Day 1	34.6%	43.3%	45.9%
Day 3	35.2%	44.1%	46.3%
Day 5	36.9%	45.3%	48.1%
Day 7	37.7%	45.4%	56.6%
Day 9	40.1%	48.2%	57.1%

In Fig. 3, the methane production at different feeding days was depicted. It showed that higher days of feeding has more potential of methane production.

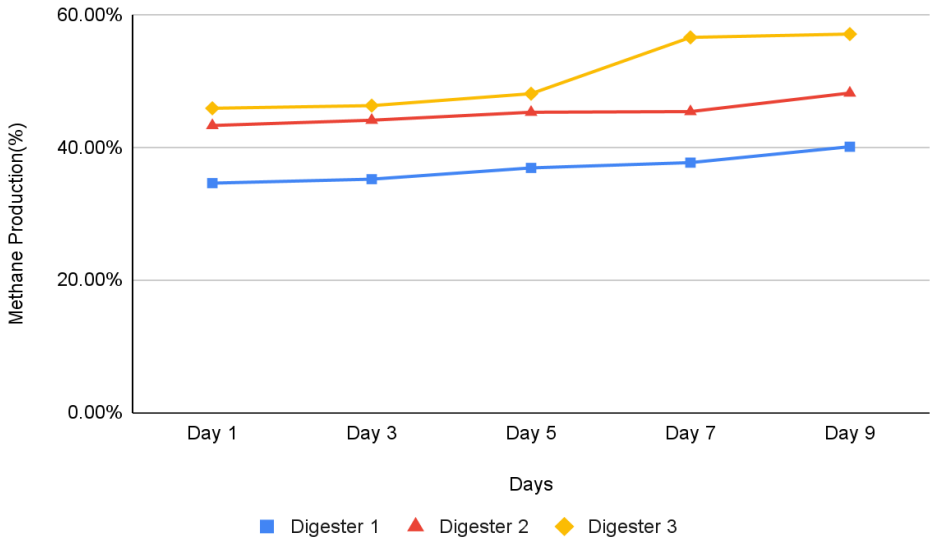

Figure 3. Methane production versus feeding days

From the experiment, it is concluded that maximum production of biogas (methane) from rice straw through anaerobic digestion occurs at 1:6 feed ratio producing 57.1% methane. The results for methane production at different feed ratios are represented in Table 4.

Table 4. Methane production at different feed ratios

FEED RATIO in kg (Rice Straw: Water)	1:4	1:5	1:6
METHANE PRODUCTION	40.1%	48.2%	57.1%

Temperature Variation of feed

Rice Straw feed is taken at different temperature ranges, Psychrophilic (35-40℃), Mesophilic (45-50℃) and Thermophilic (55-60℃) for different feed ratios (1:4, 1:5, 1:6) in biogas digesters to check variations in production of biogas from anaerobic digestion at different temperature and find what is the effect of temperature on overall production and working of bio-enzymes (Table 5).

Temperature has a big impact on methane-forming bacteria's activity. In general, the generation of biogas rises with temperature. Digesters are heated in colder climates because of this reason the ideal temperature range is between 30℃ and 40℃. Methanogen activities are weakened by low temperatures, sudden systemic changes, or both. An essential factor in the effective anaerobic digestion of rice straw is temperature. It is necessary for both economic input and maximized methane production. From the experiment it can be concluded that maximum production of biogas (methane) from rice straw through anaerobic digestion occurs at 45℃ producing 58.5% methane.

Table 5. Methane production at different temperatures

Temperature	Digester 1 (1:4)	Digester 2 (1:5)	Digester 3 (1:6)
35℃	38.40%	46.50%	52.00%
45℃	52.30%	56.80%	58.50%
55℃	45.60%	49.80%	54.70%

CONCLUSIONS

From the experiments conducted it can be determined that maximum production of biogas (methane) occurs when the feed ratio of rice straw and water is 1:6. Production of biogas increases by approx. 9% when ratio is changed from 1:5 to 1:6 and by 17% when it is changed from 1:4 to 1:6. This concludes that changing feed ratio has a big impact on biogas production by anaerobic digestion.

Similarly, analysis of the experiments also shows that maximum production of biogas (methane) occurs when temperature of the sludge is kept between 40-50℃. Raising the temperature has a number of benefits, including making organic compounds more soluble, which makes them easier to accessible to microorganisms, accelerating biological and chemical reactions, enhancing chemical-physical characteristics like the diffusivity of dissolved substrates, boosting the rate at which liquids transfer to gasses, quickening the pace at which pathogenic bacteria die, and generating a more vigorous oxidation reaction at high temperatures. But a significant increase in temperature is also harmful as it tends to kill the bacteria responsible for biogas production. Experiment shows that production of biogas increases by 10-15% when temperature is increased from 35℃ to 45℃. There is also a decrease in production when temperature is further increased to 55℃, production decreases by 7-8% at high temperatures.

Keywords: CDR data | fraudulent call detection | knowledge-enhanced optimal graph neural network | sheepdog hunt optimization

ABSTRACT

Rapid advancements in mobile communication technologies have led to the progression of telecom scams that not only deplete individual fortunes but also affect social income. Hence, fraudulent call detection gains significance, which not only aims to proactively recognize the frauds, but also alleviate the fraudulent activities to manage external losses. Though the traditional methods, such as rule-based systems and supervised machine learning techniques, actively engage in detecting such fraudulent activities, they fail to adapt to the evolving fraud patterns. Therefore, this research introduces a sheepdog hunt optimization-enabled knowledge-enhanced optimal graph neural network classifier (SDHO-KGNN) approach for detecting fraudulent calls accurately. The effectiveness of the proposed SDHO-KGNN approach is achieved through the combination of the power of graph representation learning with expert insights, which allows the proposed SDHO-KGNN approach to capture complex relationships and patterns within telecom data. Additionally, the integration of the SDHO algorithm enhances model performance by optimizing the discrimination between legitimate and fraudulent calls. Moreover, the SDHO-KGNN classifier captures the intricate call patterns and relationships within dynamic call networks, thereby attaining a better accuracy, precision, and recall of 93.8%, 95.91%, and 95.53% for 90% of the training.

1 | Introduction

Over the past few years, the swift expansion of mobile communication technology has ushered in numerous benefits, revolutionizing the way to connect and communicate. Wireless communication networks have undergone significant development during the past few decades, progressing from 1G in the 1980s to 5G in 2019. Every generation sought to overcome the shortcomings of its predecessor, primarily about latency and mobility, density, security and privacy, and data rates and capacity. Consequently, the future 5G/6G networks intend to provide great flexibility to the network operators concerning the allocation of coverage, speed, and the capacity of diverse use cases. Although the 5G deployment phase has already started [1], its full potential has not yet been reached in mobile communication. Meanwhile, 6G intends to transform communication by integrating the digital, biological, and physical realms to give people new experiences via immersive virtual worlds and augmented intelligence [2]. Specifically, artificial intelligence (AI) and machine learning (ML) techniques are expected to drive 5G by continuing the network softwarization and cloudification initiatives toward the development of intelligent telecommunication networks that led to 6G [3]. To fully realize the potential and benefits of 6G, cyber resilience, privacy, and trust are essential prerequisites. Further, these prerequisites will propel 6G development and are essential to attaining even faster and more dependable

connectivity than 5G [4]. Telecommunication fraud [1], often shortened to telecom fraud, involves the fraudulent acquisition of significant public and private assets through deceitful means, such as fabricated narratives conveyed through messages, calls, and various communication channels [5]. As science and technology have progressed, the methods of telecommunications network fraud have evolved as well, becoming increasingly precise and efficient and spreading more extensively [2, 6]. Contemporary fraudsters often adopt behaviors that closely resemble those of typical users, operating in well-coordinated groups. This shift in their approach presents a formidable challenge when it comes to identifying telecom frauds within the vast volume of regular call records [7]. Fraudsters may have various motives, one of which could be to evade service charges or minimize them, ensuring they do not bear the full expense of the actual service. In addition, their intentions may extend beyond cost reduction, with the fraudster's ultimate goal being to exploit the provider's network for profit. These fraudulent activities result in substantial financial losses for the telecom industry [8]. Fraudsters are continuously adopting more advanced fraud tactics to evade detection. They employ various fraud tools and concepts, including Benford's theory, Z scores, computer assisted auditing tools (CAATs), and ratio analysis, to detect financial fraud. In contrast, social network analysis (SNA) serves as a nonfinancial fraud detection method that assists organizations in identifying unusual connections among individuals and entities [9, 10].

Presently, telecom operators have implemented diverse fraud detection systems aimed at mitigating losses stemming from fraudulent activities. Those systems analyze customer data within telecom networks using a range of mathematical techniques to identify potential fraudulent customers; also, those detection methods examine the information formed by the users to discover the suspected user and notify managers, in that way, the loss caused by the frauds is reduced by the telecom operators [11]. Various ML and deep learning approaches are utilized in the field of fraudulent call detection [12]. ML algorithms are employed to analyze call data and recognize patterns indicative of fraudulent activity. This can include supervised learning for classification or anomaly detection techniques. Creating user profiles and monitoring their calling behavior to detect deviations from normal usage, such as sudden changes in call volume or international call activity, is also used to identify fraud. In recent years, research efforts have primarily focused on crafting intricate features for phone call data using expert knowledge and subsequently applying ML algorithms for classification. These encompass conventional ML approaches such as support vector machine (SVM) [13, 14], random forest (RF) [15], as well as deep learning methods like convolutional neural networks (CNN) [16], long short-term memory (LSTM) [12], and recurrent neural networks (RNN) [17]. More recently, graph neural networks (GNN) have come into play for extracting interactive insights among users and making predictions [18].

Most existing fraud detection approaches [19–21] have conducted their experiments using either synthetic data or undisclosed real-world data, making it difficult for other researchers to reproduce their results. Additionally, as CDR typically consists of unstructured data, employing a grid-based data processing method for their analysis can result in the loss of significant structural information, potentially leading to a substantial reduction in detection accuracy [22]. In the GNN [23] model, if the issue of class imbalance is not taken into account during the design of the model, the majority class could disproportionately influence the loss function [24]. This could cause the trained GNN to excessively classify instances from these majority classes, leading to inaccuracies in predicting samples from the minority class, which is our primary concern. When applying these models to graphs with imbalanced class distributions, existing GNN approaches tend to excessively prioritize the majority class, resulting in less effective embedding results for the minority class [25]. Additionally, the Neural Factorization Autoencoder (NFA) based method [26] is employed to detect fraudulent call activity, in which the execution time for the detection system is high. The traditional methods for outlier detection primarily depend upon clustering-based [27] and distance-based [28] perceptions. Nevertheless, these methods of telecom fraud detection depend deeply on the applicability of features to the task of categorization. When the feature space is huge, the occurrence of unrelated, unwanted, unacceptable, or noising features in the data may automatically affect the model's performance [29]. Moreover, the recent approaches have data complication, which typically comprises multilevel, multi-granularity, multidimensional data that make the processing and application of data intricate and miscellaneous [25]. Next, ambiguity, changeability, and repetition of the data make difficulties in telecom fraud detection. Also, mixed data, which frequently encompass non-single heterogeneous data such as categorical and arithmetical data, make the detection process challenging to process the data efficiently [30].

This research introduces an effective framework to identify fraudulent calls using SDHO-knowledge-enhanced optimal GNN in the 5G/6G networks. Initially, the data collected from the CDR graph dataset are verified with the data present in the blacklist table, which provides information about the data as normal or abnormal. When data are deemed to normal, the data are transmitted to its intended destination via the data transmission module. This module verifies the information using knowledge-enhanced optimal GNN, which enriches the graph representation by adding semantic information about nodes, edges, and relationships. The SDHO algorithm is employed to enhance the model's performance and efficiently fine-tune the classifier by incorporating the characteristics of sheepdog and coati optimization. When the information is cross-verified, the classifier determines whether the call is normal or abnormal. If it is determined that the call is abnormal, the data are forwarded to the prevention module, where the process is stopped by the prevention module, and the blacklist table is updated. The primary contribution of this research is further detailed in the ensuing discussion.

1.1 | Sheepdog Hunt Optimization Algorithm (SDHO)

The SDHO algorithm is formulated by combining the hunting traits observed in coatis [31], together with the herding attributes of collies [32]. These characteristics combination eradicates issues like overall instability and computational complexity, and they offer advantages by accelerating convergence speed and elevating classification accuracy.

1.2 | Sheepdog Hunt Optimization Algorithm-Enabled Knowledge-Enhanced Optimal Graph Neural Network(SDHO-KGNN)

The integration of the SDHO algorithm with the KGNN enables the model to accurately detect fraudulent calls. The model can adapt to evolving fraud tactics by continuously updating its knowledge base, ensuring it remains effective in detecting emerging threats. KGNN significantly enhances fraud call detection by leveraging external knowledge to improve accuracy, reduce false positives, adapt to evolving threats, provide interpretability, and handle large-scale call networks.

The manuscript is further divided into the following sections. Section 2 explains the advantages and challenges of existing research, Section 3 includes the proposed methodology and block diagram, Section 4 describes the experimental results and comparative discussion of this research, and Section 5 expands the conclusion of the research.

2 | Literature Review

Existing methods in the research of fraudulent call detection, with advantages as well as drawbacks, are elaborated in this section.

Xuxu Zheng et al. [33] initiated a technique for detecting fraud, employing similarity and multi-view GNN. In this approach, a weight parameter is employed to increase the importance of fraud samples that have been flagged or labeled. However, there is a risk of overfitting the training data, especially if not enough labeled fraud examples are available. Xinxin Hu et al. [25] deployed a GAT-COBO model for fraud detection which can adapt to evolving fraud tactics and patterns in real-time, making them suitable for dynamic environments. However, GNNs can be challenging to interpret, making it difficult to grasp the logic behind the model's decisions. Yan Jiang et al. [7] designed a HESM approach for fraud detection, which enhances the superiority of the model. However, the model can be challenging to interpret, making it difficult to comprehend the reasoning behind the model's choices.

Zhen Z. and Gao J. [22] suggested a CNN method for fraud detection using CDR data. In the suggested method, an end-to-end model was offered to recognize new distinctive features without automatically designed features. Also, the suggested model achieved satisfying outcomes on the challenges in the detection part of telecommunication. The developed method extracted behavior data from raw CDR effectively, nevertheless, combining it with communicating data was still an unresolved issue. John C. Daka and Mayumbo Nyirenda [34] used a SIM Box model for fraud detection in telecommunication. The system can operate in real-time, allowing for immediate identification and response to fraudulent activities as they occur. However, ANNs can be challenging to interpret. Jianbing Yan [35] presented a C-BiLSTM algorithm for fraud detection. The utilization of intelligent algorithms allows for the automated and efficient identification of fraudulent call information, potentially reducing the workload for human operators. The output of intelligent algorithms may be challenging to interpret, making it difficult to understand the reasoning behind specific decisions. Gao P. et al. [36] suggested a reinforced cost-sensitive graph network (RCGN) to detect the head of fraud in telecom fraud. The deep deterministic policy gradient (DDPG) technique was utilized to optimize the coefficients of mass dynamically, and a graph was constructed using CDR, and three base classifiers were united to predict the results and final results of classification. The integration of three base classifiers in the RCGN made the detection of fraud effective, however, the usage of a small-size dataset in the RCGN method was the limitation, which lacked the experiments of comparison.

2.1 | Challenges

- In the automated fraudulent call detection approach [12], the LSTM model attained limited performance due to the formation of data, which is not a series at all times to acquire the arrangement relationship between each dimension. Moreover, the DNN model has a major risk of overfitting, which was exposed using the drift evaluation concept.
- Training and using ANN-based models may require substantial computational resources, which could be a limitation for some organizations. The system's efficiency relies significantly on the quality and comprehensiveness of the call traffic data. Inaccurate or partial data can result in false alarms or overlooked instances of fraud [34, 37].
- Mobile social network fraud detection datasets often suffer from class imbalance, where genuine user activities significantly outnumber fraudulent ones. Handling this imbalance effectively is crucial [22].
- GAT-COBO heavily relies on the quality and availability of data. Noisy or incomplete data can affect its performance. GNNs can be challenging to interpret, making it difficult to comprehend the reasoning behind the model's choices [25].
- Detecting temporal patterns in telecom fraud, and enabling real-time detection and adaptation also face challenges related to data quality, complexity, interpretability, and resource requirements, which need to be carefully considered when applying the approach in practice [38].

3 | Sheepdog Hunt Optimization Algorithm-Enabled Knowledge-Enhanced Optimal Graph Neural Network Classifier

Detecting and mitigating fraudulent actions like telecom fraud, phishing calls, and robocalls that can result in financial setbacks for both service providers and customers is essential to enhance cyber resilience, privacy, and trust in the evolving 5G/6G networks [33]. The major goal of this research is to detect fraudulent calls utilizing the SDHO-knowledge-enhanced optimal GNN in the evolving 5G and 6G networks that often give network operators a significant deal of flexibility in allocating speed, coverage, and capacity for enhancing telecommunication. Initially, data will be gathered from the CDR graph dataset, preprocessed, and subsequently cross-referenced with the information contained in the Blacklist table. In the realm of telephone calls, a blacklist table serves as a repository of specific phone numbers or entities regarded as undesirable or potentially harmful. Telecommunication systems use this table as a point of reference to

21613915, 2025, 4, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ett.70101 by Delhi Technological University, Wiley Online Library on [01/05/2025]. FIGURE 1 | Schematic representation of the fraudulent call detection utilizing SDHO-enabled knowledge-enhanced optimal GNN model.

block or restrict calls originating from or directed to the numbers listed within it. The blacklist table categorizes the data as either normal or abnormal. When data are deemed normal, this is transmitted to its intended destination via the data transmission module. This module validates the information using the knowledge-enhanced optimal GNN [38], which represents an innovative approach that merges the capabilities of GNN with external knowledge sources to augment the model's learning and inference abilities. The integration of external knowledge into GNNs via the knowledge-enhanced GNN framework offers several advantages by enriching the graph's representation with semantic information about nodes, edges, and relationships. This deepens the model's comprehension of the data it processes, leading to improved feature extraction and representation learning. Furthermore, an SDHO algorithm is developed by combining the traits of the sheepdog and the coati. This algorithm facilitates effective tuning of the classifier. The classifier cross-validates the information, and if data are identified as normal, the call is recorded and forwarded to the intended destination. In contrast, if the data are classified as abnormal, it is directed to the prevention module, where the process is terminated, and the blacklist table is updated accordingly. Figure 1 demonstrates the schematic illustration of the fraudulent call detection mechanism utilizing the SDHO-enabled knowledge-enhanced optimal GNN model.

3.1 | Input Telecom Records

Here the data are collected from the CDR graph dataset [39] typically includes structured data representing various aspects of telecommunications activities in 5G/6G networks. These call records serve as the foundational data for analysis. These call records are typically organized as nodes within a graph dataset, with connections (edges) representing relationships or interactions between them.

3.2 | Preprocessing of Call Records

Preprocessing is required to enhance the quality of the data since the raw data typically contain instances that are weakly regulated and may have out-of-range and missing values. Here, the missing values from the CDR graph dataset are handled by removing the rows with non-values, ensuring a cleaner dataset.

3.3 | Blacklist Table

A blacklist table is a database or list containing specific items, such as phone numbers, email addresses, IP addresses, or entities that are considered undesirable, potentially harmful, or suspicious. The primary purpose of a blacklist is to restrict or block access to or communication with the items within it. In telecommunications, blacklists are used to prevent fraudulent activities and are often used to protect individuals' privacy and security. Unwanted behavior serves as the basis for blacklist inclusion, and its dynamic nature keeps it up to date against new threats. The adoption of blacklists is primarily motivated by security and privacy concerns, offering people and organizations a strong defense against known and unknown threats. A proactive strategy, connection with larger security systems, and frequent updates all enhance a blacklist table's ability against possible threats.

3.4 | Training Phase

The knowledge graph neural network (KGNN) is trained on a CDR graph dataset that involves particular procedures designed for telecom data. Here the preprocessed data are ready for the KGNN by encoding call kinds, stamps, and phone numbers into numerical representations. Embedding layers for nodes, capturing distinct representations for every phone number, and

21613915, 2025, 4, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ett.70101 by Delhi Technological University, Wiley Online Library on [01/05/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

attention techniques to identify intricate links in call patterns are common features of the model architecture. In training, the KGNN compares and predicts associations inside the CDR graph to minimize a loss function.

3.5 | Knowledge-Enhanced Optimal Graph Neural Network Classifier

Graph-based fraud detection has gained popularity and considerable attention due to the prevalence of fraud incidents that manifest as graph structures. One category of research in this domain centers on identifying unusual nodes [40, 41] and specific abnormal subgraph configurations [42, 43] within static networks. A knowledge-enhanced graph neural network (KGNN) for fraud call detection typically extends a standard GNN architecture with the integration of domain-specific knowledge graphs, which can capture valuable domain-specific information from knowledge graphs which can lead to better performance in fraud call detection. By incorporating external knowledge, KGNNs can generalize better to unseen or rare patterns. KGNNs can transfer knowledge from one domain to another through shared knowledge graphs. This transfer learning capability is valuable in situations where data from one domain can inform predictions in another.

Constructing a graph where nodes represent subscribers in the mobile network, the node features represent the behavior of these subscribers, and the edges represent communication interactions between subscribers enables us to build a network representation. Fraudulent subscribers within the network are potentially identified using GNNs [44].

A user behavior graph is denoted as $U = (B, \chi, A_d, E, N)$ established within a mobile network context. Here, B represents the set of users in the mobile network as nodes, where $B = \{w_1, w_2, w_3, \ldots\ldots\ldots\ldots\ldots w_n\}$. The edges in the graph represent as $E = \{\alpha_1, \alpha_2, \alpha_3 \ldots\ldots\ldots\ldots\ldots \alpha_m\}$. $\alpha_j = (w_{cj}, w_{zj}) \in E$ is an edge between w_{cj} and w_{zj}, where $w_{cj}, w_{zj} \in B$. Additionally, $\chi = \{s_1, s_2, s_3, \ldots\ldots\ldots\ldots\ldots\ldots s_n\}$ denotes the collection of original behavioral features of subscribers, with each $\chi_i \in \Re^d$ representing the behavioral feature vector of the user w_i. These feature vectors are aggregated into the feature matrix $\chi \in \Re^{N\times D}$ for the graph U. The adjacency matrix $A_d \in \Re^{N\times N}$ encodes the relationships within the graph, which $a_{i,j} = 1$ indicates the presence of an edge between nodes i and j, while $a_{i,j} = 0$ signifies a connection. Lastly, $N = \{r_1, r_2, r_3, \ldots\ldots\ldots r_n\}$ constitutes the labels associated with nodes in the set B. In the context of a given subscriber behavior graph, the utilization of GNNs facilitates the learning of node embedding representation. The general formulation of GNNs is given as

$$h^l_{\text{out}} = \text{update}\Big(\text{Agg}\Big(\{h^{l-1}_v \forall v \in N(v)\}W^l_{\text{agg}}\Big), h^l_{\text{in}}, W^l_{\text{update}}\Big) \quad (1)$$

where h^l_{in} and h^l_{out} represents the input and updated node embeddings at the lth layer, correspondingly. h^{l-1}_v refers to the embeddings of neighboring nodes from the previous layer. W^l_{agg} and W^l_{update} denote trainable matrices for the aggregation function and update function at the lth layer, correspondingly. These notations are commonly used to describe the elements and operations in GNN architecture for node embedding and updating processes.

$$h^l_w = \sigma\big([C_l \cdot \text{agg}(\{h^{(l-1)}_v \forall v \in N(v)\}), D_l h^{l-1}_w]\big) \quad (2)$$

where the notations and process described can be summarized as follows: h^l_w represents the node w at the current layer l and h^{l-1}_w represents the previous layer $(l-1)$, $h^{(l-1)}_v$ denotes the node embeddings of neighboring nodes from the previous layer, C_l and D_l are trainable weight matrices, σ represent a nonlinear activation function, agg stand for the aggregator.

The generation of h^l_w follows these steps:

Initially, each node aggregates features from its nearby neighbors using the AGG aggregator, resulting in a unified vector $h^l_{N(w)}$. Then graph SAGE then appends the node's prior representation to its neighborhood feature vector. The concatenated vector is subsequently processed through an MLP with a softmax activation function. The output produced by the MLP becomes the updated representation for the node, which is utilized as input in the subsequent layers. The domain-specific knowledge graph is integrated into the model. The attention mechanism is employed to determine the impact of knowledge nodes on the message-passing procedure, which is denoted as

$$\begin{aligned} h^{(l+1)}_w = {} & \text{propagate}\left(h^{(l)}_w, \{h^{(l)}_v \forall w \in N(v)\}\right) \\ & + Q\left(h^{(l)}_w, \{k_j \forall j \in \text{knowledge graph}\}\right) \end{aligned} \quad (3)$$

where k_j represents the knowledge nodes in the knowledge graph.

The attention mechanism for knowledge graph integration is as follows:

$$\begin{aligned} & Q\left(h^{l-1}_w, \{k_j \forall j \in \text{knowledge graph}\}\right) \\ & \quad = \text{soft max}\left(\{\alpha_j * f\left(h^{(l)}_v, k_j\right) \forall j \in k\text{nowledge graph}\}\right) \end{aligned} \quad (4)$$

The softmax is utilized for binary fraud/non-fraud predictions. Figure 2 shows the architecture of knowledge-enabled optimal GNN.

3.6 | Sheepdog Hunt Optimization

The proposed SDHO algorithm draws inspiration from combining the hunting traits of coati [31] and herding traits of the Border Collie [32] to find the optimal solution that promotes detection accuracy. By incorporating these characteristics, the SDHO algorithm can prioritize making smart decisions based on evolving patterns in the call data.

3.6.1 | Motivation

The SDHO algorithm is utilized to deal with complex high-dimensional problems, which potentially reduce computational bottlenecks in large-scale fraud detection systems. This can lead to faster and more scalable fraud detection. The SDHO algorithm efficiently generated the optimal solution by preventing the algorithm from getting trapped in the local

21613915, 2025, 4, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ett.70101 by Delhi Technological University, Wiley Online Library on [01/05/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

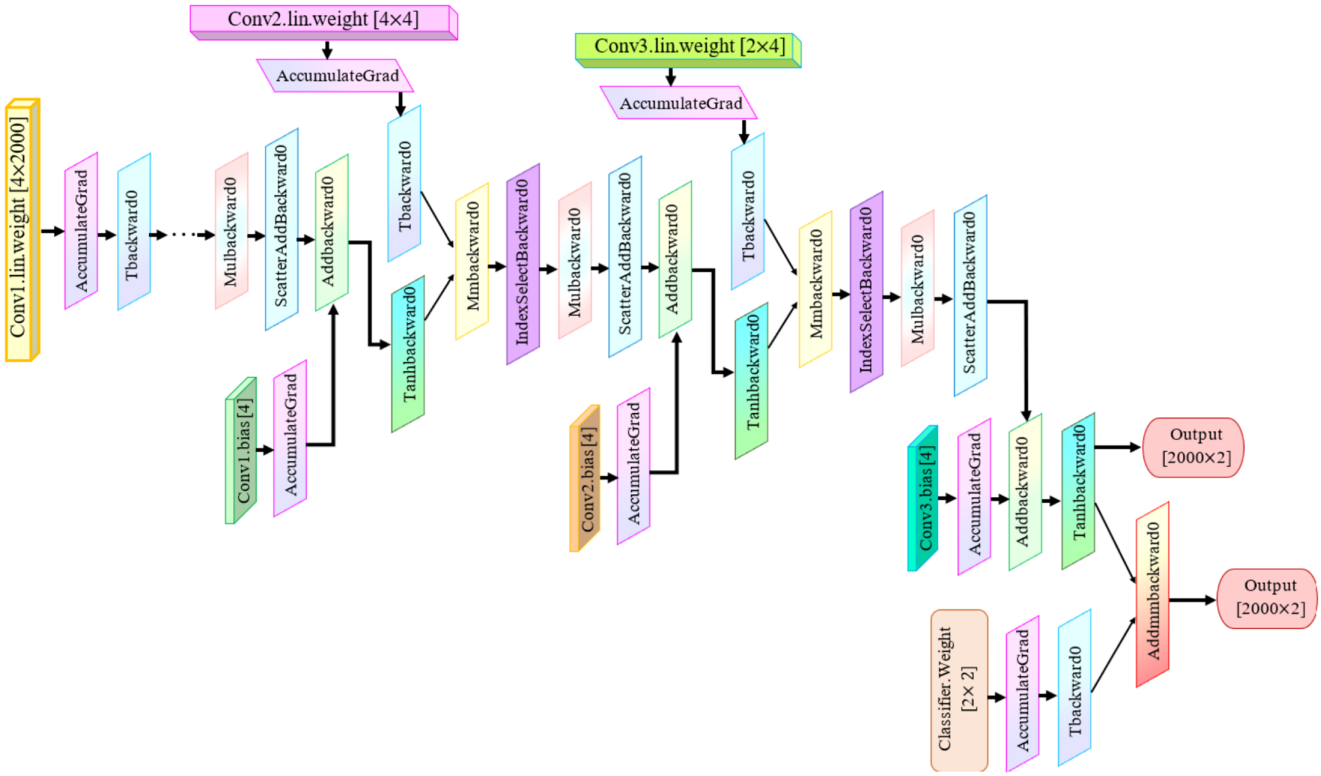

FIGURE 2 | Architecture of knowledge-enabled optimal GNN.

optima. The SDHO algorithm shows its great ability in balancing the search process, this can be particularly useful when dealing with complex call data among various fraud detection mechanisms. Additionally, the SDHO algorithm allows high-speed convergence to offer appropriate values for decision variables in detection tasks.

3.6.2 | Inspiration

Coatis, referred to as coatimundis, belong to the Procyonidae family and are categorized under the *Nasua* and *Nasuella* genera [45]. They are mammals with an omnivorous diet, which includes the consumption of both invertebrate and small vertebrate prey. The diet of these arboreal animals often includes iguanas, which are typically located in trees. Their hunting strategy is characterized by coordinated group efforts, wherein some individuals ascend trees to induce the iguana to descend while others engage in rapid pursuit and capture [46]. Notwithstanding their proficient tactics, they are susceptible to predators and avian predators of substantial size. This behavior can inspire an optimization algorithm that involves multiple agents collaborating to solve complex problems, such as detecting fraudulent calls, where different pieces of information must be gathered and analyzed collectively. *Canis lupus familiaris*, commonly known as sheepdog [32], is an extraordinary dog breed that is renowned for its exceptional herding capabilities and strong work ethic and exhibits a remarkable aptitude for situational assessment and adaptive decision-making [47]. This inspired the development of a metaheuristic algorithm that emulates their behavioral traits. In the context of herding, these canines employ a unique strategy, opting for lateral and frontal approaches rather than traditional rearward herding methods. In the herding context, canines employ a gathering technique where they exert control from the flanks and the front to collect and guide livestock toward a designated location, commonly referred to as gathering. In the process of controlling livestock, canines exhibit a behavior akin to that of wolves. This includes crouching, bowing their heads, raising their hindquarters, and angling their tails downward, a conduct referred to as stalking. Canines emulate the victim selection behavior observed in wolves, referred to as giving an eye or eyeing. In instances where individuals within the group exhibit deviant behavior, these highly intelligent canines employ an intense gaze directed at the individuals in question, applying psychological pressure to guide the collective movement in the desired direction. The algorithm could draw inspiration from their speed and efficiency to develop optimization techniques that operate swiftly and effectively in processing and analyzing large volumes of call data.

3.6.3 | Initialize the Population

Population initialization is the process of creating an initial set of potential solutions that the algorithm will evolve and improve upon during the optimization process. The key goals of population initialization are diversity and coverage of the search space to increase the chances of finding a global optimum.

$$X^{tH} = X^t + r_1\left(I_g - I \cdot X^t\right) + r_2(u - l) \tag{5}$$

where r_2 represents a random number, u and l is denoted as upper and lower bound.

$$r_2 = \frac{r_{\max} - r_{\min}}{r_{\max}} \in [0, 1] \tag{6}$$

21613915, 2025, 4, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ett.70101 by Delhi Technological University, Wiley Online Library on [01/05/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

$$r_1 = e^{\left(\frac{X_{\text{worst}} - X^t}{\sum X_{\text{best}}}\right)} \tag{7}$$

3.6.4 | Fitness Evaluation

The fitness function assesses the solution's quality for every individual within the population; apply the fitness function to calculate its fitness score. This step involves solving or simulating the problem using the individual's parameter values or configuration and measuring its performance based on the fitness function. Higher fitness scores indicate better solutions.

$$\text{Fit} = \max\left(\text{acc}\left(X^t\right)\right) \tag{8}$$

3.6.5 | Claim the Population Gaps

Split the population equally based on fitness. Solutions with higher fitness are regarded as Group 1 (guard), while solutions with fitness below $\text{fit}\left(X^{\text{best}}\right)$ are grouped under Group 2 (herd).

3.6.6 | Herd Population Update

The herd population represents a set of potential solutions or individuals that are being evolved or optimized toward finding an optimal solution for a given problem. These are herd candidates, which obey or follow the best solutions for sooner convergence.

$$X^{tH} = V^{tH} \cdot D^{tH} + \frac{1}{2} A^{tH} \times D^{tH} + r_3\left(X^t_{\text{per}} + X^t\right) \tag{9}$$

where V^{tH} denotes velocity, D^{tH} is the duration of travel, A^{tH} is represented as acceleration.

$$V^{tH} = \left(\sqrt{V^t \cdot \left(\tan\theta_1\right)^2 + 2 \cdot A^t \times X^t}\right) + \delta\left(X_{\text{global}} - X^t\right) \tag{10}$$

where $\delta = 0.5$ when the herd is away from the guard, $\delta = 1$ when the herd is near to guard.

3.6.7 | Guard Population Update

The purpose of the guard population is to dynamically adapt the search behavior of the algorithm, ensuring a proper balance between exploration and exploitation. It helps in achieving an optimal convergence rate while maintaining the diversity of the solutions. The update process of the guard population is typically performed periodically to ensure that the algorithm continuously adapts to the evolving search landscape. By updating the guard population in each iteration, the algorithm can adjust its exploration and exploitation based on the current state of the search.

$$X^{tH} = X^t + \frac{1}{2}\alpha X^{t-1} + \frac{1}{2}\alpha(1-\alpha)X^{t-2} + V^{tH} \times D^t + \frac{1}{2} A^t \cdot \left(T_r\right)^2 + V^{tH} * L \tag{11}$$

Here is the loudness factor to assemble the herd and represents traversal time. A guard should be aware of enemies to protect the herd.

$$V^{tH} = V^t + r_4 c_1 \cdot \left(X_{\text{pee}} - X^t\right) +_5 c_2 \cdot \left(X_{\text{global}} - X^t\right) + D^t c_3 - X^t * \partial^t \tag{12}$$

Distance direction, alertness factor c_2, and awareness coefficient c_1 help guard to protect the herd from enemies.

3.6.8 | Enemy Modulation

The enemies follow a tricky process of the fox, and they try to betray the herd. The vision radius is defined through the observation angle and the scaling parameter, which is represented as,

$$g = \begin{cases} a\frac{\sin(\phi_0)}{\phi_0} & \text{if } \phi_0 \neq 0 \\ \theta & \text{if } \phi_0 = 0 \end{cases} \tag{13}$$

where g represents the vision radius, $\phi_0 \in (0, 2\pi)$ is the observation angle, which is selected for every individual, θ indicates the arbitrary value among 0 and 1, which is set at the beginning of the algorithm, $a \in (0, 0.2)$ represents the parameter of scaling which is set after the iteration of every individual in the inhabitants to model arbitrarily varying the distance from the solution during the enemy approaching. The position of enemies is modulated as

$$\begin{cases} X_0^{\text{new}} = \text{ag} \cdot \cos(\phi_1) + X_0^{\text{actual}} \\ X_1^{\text{new}} = \text{ag} \cdot \sin(\phi_1) + \text{ag} \cdot \cos(\phi_2) + X_1^{\text{actual}} \\ X_2^{\text{new}} = \text{ag} \cdot \sin(\phi_1) + \text{ag} \cdot \sin(\phi_2) + \text{ag} \cdot \cos(\phi_3) + X_2^{\text{actual}} \\ \ldots. \\ X_{n-2}^{new} = ag. \sum_{k=1}^{n-2} \sin(\varphi_k) + ag. \cos(\phi_{n-1}) + X_{n-2}^{actual} \\ X_{n-2}^{new} = ag. \sin(\phi_1) + ag. \sin(\phi_2) + \ldots.. + ag. \sin(\phi_{n-1}) + X_{n-1}^{actual} \end{cases} \tag{14}$$

The location is updated based on the position of the enemy to attain the optimal solution. This model signifies the characteristics of an enemy after it spots a prey and attempts to approach as near as possible to strike, and if it fails when exposed to attempts to access the alternate one likewise.

3.6.9 | Termination

If $t < t_{\max}$, the loop ends, else the process continues to fitness evaluation population split and so on. Figure 3 shows the overall flowchart for the SDHO optimization algorithm and Algorithm 1 demonstrates the pseudocode of the proposed SDHO-KGNN model.

4 | Result and Discussion

This section presents the research findings of the SDHO-enabled knowledge-enhanced optimal GNN classifier for fraudulent call detection clearly and objectively.

4.1 | Experimental Setup

The experimental setup employed the PYTHON software on a Windows 10 operating system equipped with 8GB of RAM. These selections of software and the operating system were deliberately chosen to align with the needs of the implementation. The system's 8GB of RAM provided the necessary computational resources for the successful execution of the experiments.

4.2 | Dataset Description

CDR graph dataset [39]: A CDR (Call Details Record) graph dataset is a collection of structured data that represents telecommunications activities, particularly call and message

interactions between users. This dataset provides valuable insights into the communication patterns and behaviors of individuals or entities in a network. The dataset comprises information on 101,174 customers, encompassing 17 attributes, including an indicator of whether a customer has churned. Among the customers, there are a total of 8830 churners. Some of the variables in the dataset include state, account length, phone number, international plan, mail plan, number of voice mail messages, total day minutes, and so on. They comprise various data fields, including called number, caller number, time, and date of the call. The attributes of the dataset are Gmail message, day charge, eve mins, night charge, CustServ Calls, eve calls, Intl charge, Intl Mins, night calls, day mins, eve charge, night mins, and Intl calls.

4.3 | Performance Metrics

The metrics utilized to assess the effectiveness of fraud call detection are accuracy, precision, and recall, which are formulated as follows:

$$\text{Accuracy} = \frac{C_{\text{TP}} + C_{\text{TN}}}{C_{\text{TP}} + C_{\text{TN}} + C_{\text{FP}} + C_{\text{FN}}} \tag{15}$$

$$\text{Precision} = \frac{C_{\text{TP}}}{C_{\text{TP}} + C_{\text{FP}}} \tag{16}$$

$$\text{Recall} = \frac{C_{\text{TP}}}{C_{\text{TP}} + C_{\text{FN}}} \tag{17}$$

where C_{TP} denotes the true positive, C_{TN} indicates the true negative, C_{FP} is false positive, and C_{FN} is the false negative.

4.4 | Experimental Results

In this section, Figure 4 displays the input for KGNN, this shows the initial formation of the model process, potentially identifying the key factors influencing its predictions. Figure 4 comprehends the nature of input data in a more complex manner, improves transparency, and makes it easier to grasp the KGNN's following outputs.

Figure 5 demonstrates the image results obtained from the experiment. Green points represent the sending nodes, while blue points represent the receiving nodes. Initially, calls from the sender are analyzed using the blacklist table. If a call is identified as fraud, it is routed to the protection module and terminated; otherwise, it proceeds to reach its destination. This identification of fraud calls indicates the model's ability to effectively detect fraudulent calls. This visual representation makes it easier to quickly and thoroughly comprehend the effectiveness of the fraud call detection mechanism. The system's ability to successfully route valid calls to their intended recipients while blocking or ending the fraudulent ones using the blacklist table can be seen in Figure 5.

4.5 | Performance Analysis for Sheepdog Hunt Optimization Algorithm-Enabled Knowledge-Enhanced Optimal Graph Neural Network

The efficacy of SDHO-enabled KGNN is assessed using a CDR dataset, employing the TP metric, and employing various *k*-fold cross-validation schemes with folds labeled 6, 8, and 10. Furthermore, TP values ranging from 50 to 90 are taken into account, along with different epoch sizes of 100–500.

4.5.1 | Performance Analysis for Sheepdog Hunt Optimization Algorithm-Enabled Knowledge-Enhanced Optimal Graph Neural Network With Training Percentage

The performance outcomes of SDHO-enabled KGNN in fraud call detection, considering various epoch values, are visualized in Figure 6. In Figure 6a, the accuracy is measured in terms of TP 90 for epochs 100, 200, 300, 400, and 500, yielding values of 66.83%, 73%, 74.47%, 78.91%, and 93.8%. Similarly, Figure 6b shows precision for TP 90, where the SDHO-enabled KGNN achieves values of 71.17%, 77.61%, 78.98%, 84.88%, and 95.91% for respective epochs. Moreover, in Figure 6c, the SDHO-enabled KGNN shows specificity values of 68.28%, 72.17%, 76.82%, 78.02%, and 95.53% for TP 90, corresponding to the different epoch values.

4.5.2 | Performance Analysis for Sheepdog Hunt Optimization Algorithm-Enabled Knowledge-Enhanced Optimal Graph Neural Network With *k*-Fold

The results depict the SDHO-enabled KGNN's performance in detecting fraud calls based on various epoch values as shown in Figure 7. Figure 7a presents the evaluation of SDHO-KGNN with epoch values 100, 200, 300, 400, and 500 attains an accuracy of 68.27%, 68.67%, 70%, 71.65%, and 94.25%, respectively for *k*-fold 10. Figure 7b presents the evaluation of SDHO-enabled KGNN with epoch values of 100, 200, 300, 400, and 500, focusing on precision within the context of a 10 *k*-fold cross-validation. The corresponding sensitivity values achieved are 65.61%, 65.99%, 67.79%, 68.46%, and 96.4%. Moreover, Figure 7c demonstrates the SDHO-enabled KGNN's performance, the attained recall values are 60.15%, 69.12%, 73.43%, 74.31%, and 83.15% in terms of *k*-fold 10 for respective epochs.

4.6 | Comparative Methods

The following techniques are used in the comparison: neural network (NN) [48], RNN [17], BiLSTM [35], deep CNN (DCNN) [49], GNN [50], graph neural network with BCO

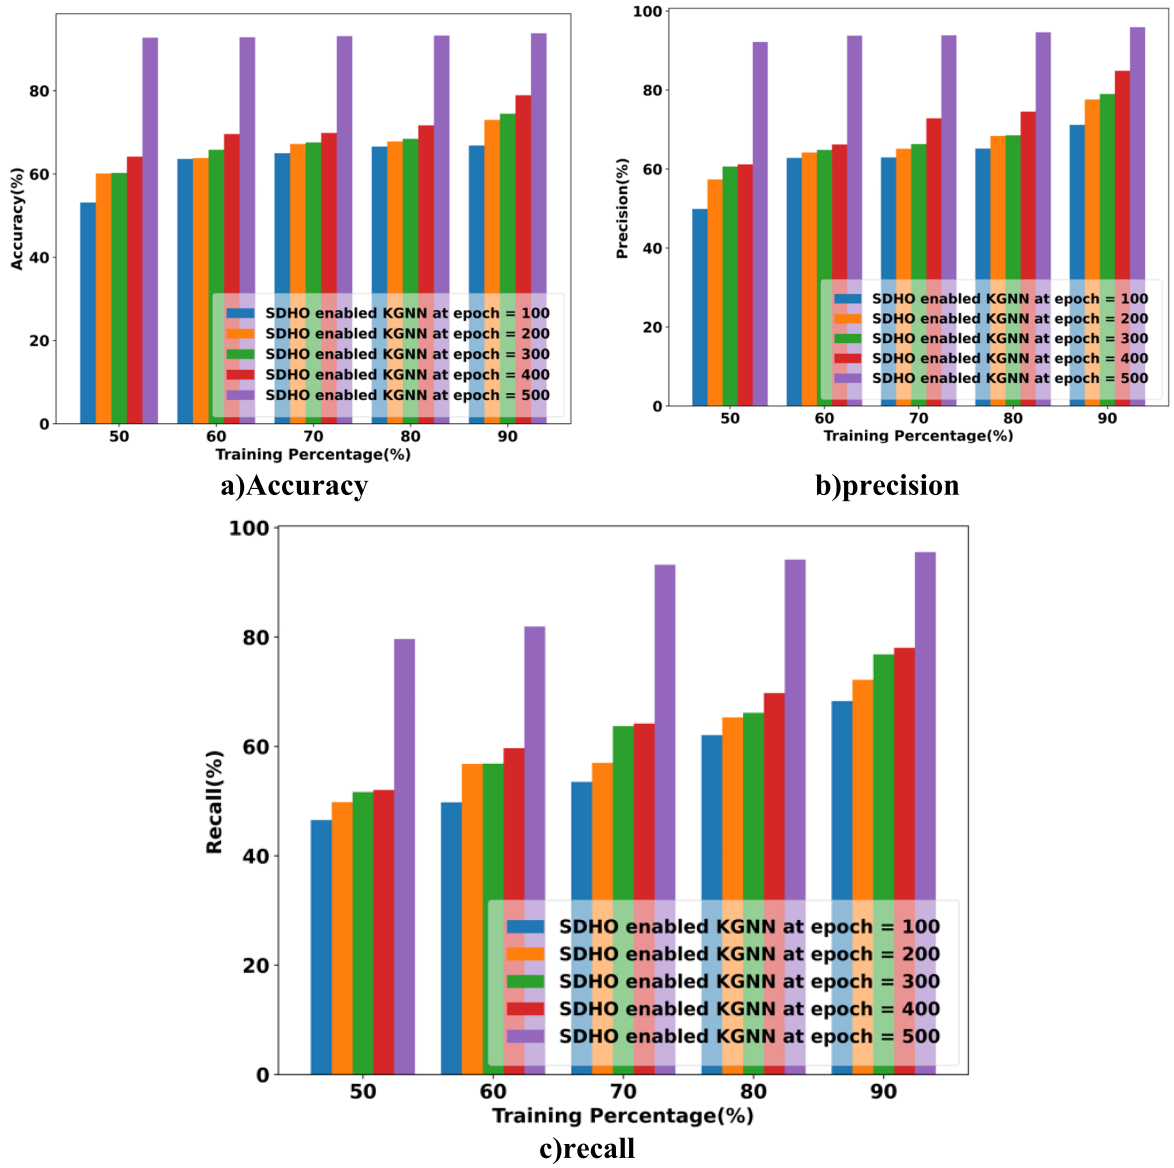

FIGURE 6 | Performance analysis with TP.

(GNN-BCO) [51], graph neural network with COA (GNN-COA) [44], SDHO-enabled KGNN.

4.6.1 | Comparative Evaluation With Training Percentage Analysis

Figure 8 visually illustrates a comparison of the SDHO-enabled KGNN accuracy, precision, and recall strategies with those of other methods. As shown in Figure 8a, the accuracy of SDHO-enabled KGNN at TP 90 is 93.8%, an improvement of 43.41% over the current NN, 27.61% over RNN, 27.49% over BILSTM, 23.77% over DCNN, 22.86% over GNN, 16.81% over GNN-BCO, and 12.53% over GNN-COA. This improvement is due to the use of SDHO, which enables the KGNN to make accurate predictions by tuning its parameters. A similar increase of 47.61% compared to NN, 27.62% compared to RNN, 26.49% compared to BILSTM, 23.78% compared to DCNN, 22.57% compared to GNN, 15.97% compared to GNN-BCO, and 4.87% compared to GNN-COA can be seen in Figure 8b, where the precision of the suggested technique at TP 90 is assessed at 95.91%. This shows that the model reduces the false positives and enhances the model's ability to precisely identify the relevant instances. Additionally, in Figure 8c, it is evident that the recall achieved by the SDHO-enabled KGNN reaches 95.53% at TP 90, showing that the model excels in identifying positive cases. This demonstrates a significant enhancement compared to NN by 33.18%, RNN by 31.56%, BILSTM by 37.9%, DCNN by 19.86%, GNN by 19.86%, GNN-BCO by 19.57%, and A7 by 14.39%. The enhancement in these outcomes indicates that the suggested approach surpasses the other conventional techniques, proving its effectiveness in identifying fraudulent calls.

4.6.2 | Comparative Analysis With *k*-Fold

The SDHO-enabled KGNN underwent a comparative analysis, and the results were measured using accuracy, precision, and recall, as illustrated in Figure 9. With a *k*-fold value of 10, the accuracy achieved by SDHO-enabled KGNN reached 94.25%,

21613915, 2025, 4, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ett.70101 by Delhi Technological University, Wiley Online Library on [01/05/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

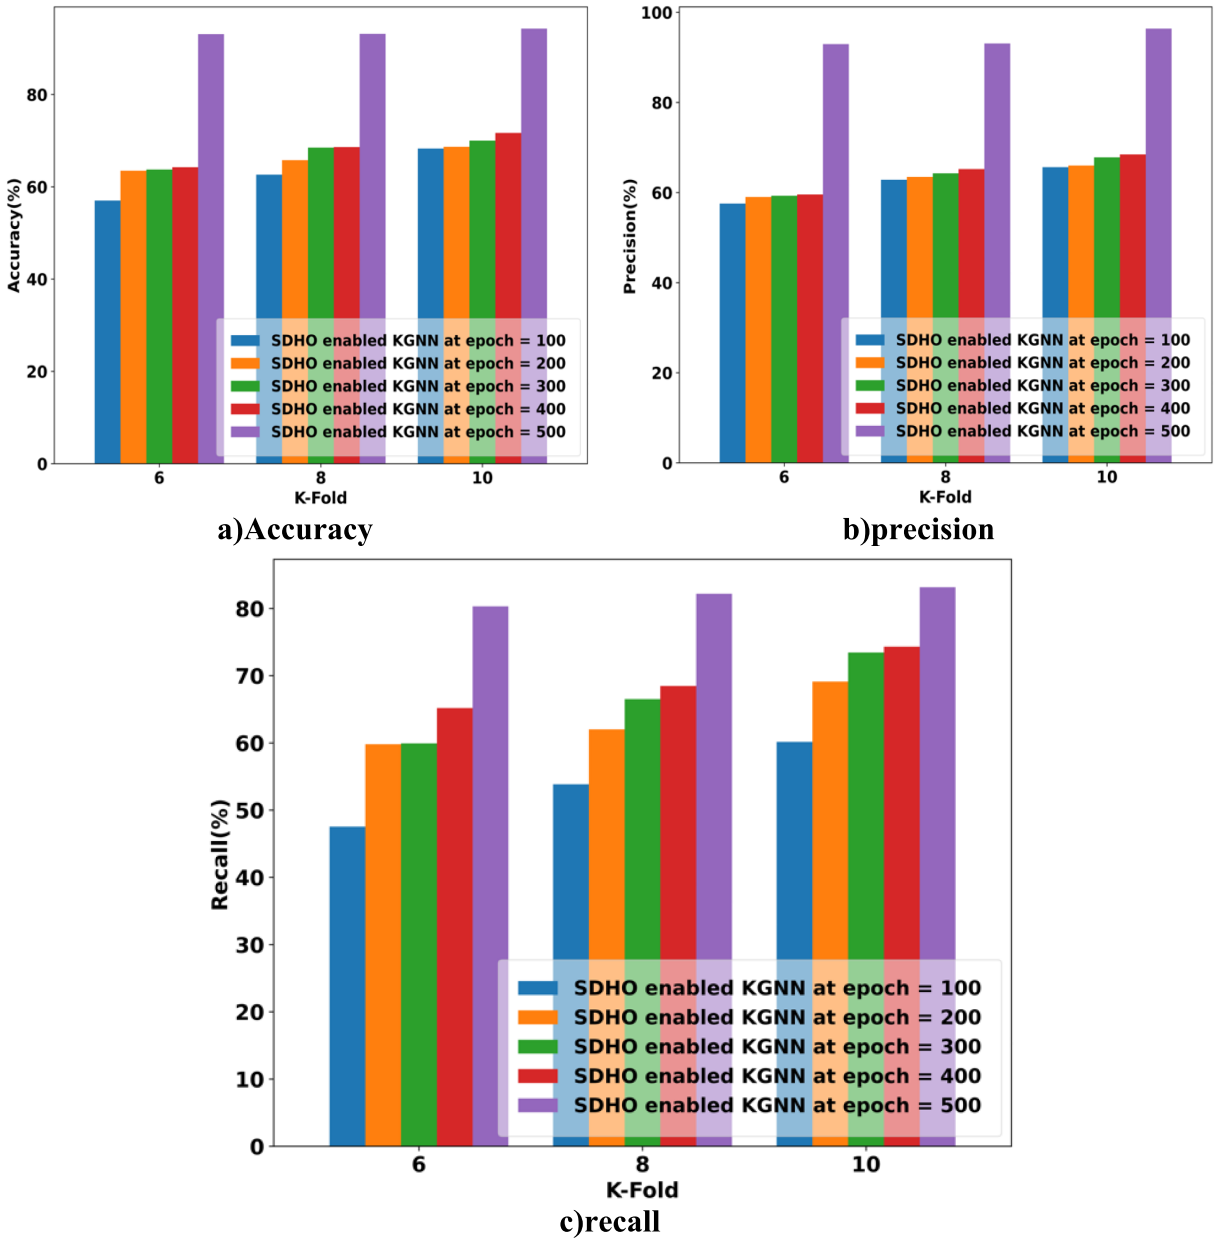

FIGURE 7 | Performance analysis with *k*-fold.

showing effective improvement of 41.19% over the existing NN, 37.26% over RNN, 32.51% over BILSTM, 30.51% over DCNN, 29.03% over GNN, 25.03% over GNN-BCO, and 22.32% over GNN-COA, as shown in Figure 9a. SDHO ensures that the model adapts well to diverse subsets of data during cross-validation. This adaptability allows the KNN to make accurate predictions across diverse folds. Similarly, the precision attained by SDHO-enabled KGNN reached 96.4% for *k*-fold 10, showing improvement of 44.96% over the existing NN, 37.02% over RNN, 33.57% over BILSTM, 33.50% over DCNN, 31.94% over GNN, 29.67% over GNN-BCO, and 27.91% over GNN-COA, as shown in Figure 9b. These improvements show that the model can effectively minimize false positives than other conventional methods. Additionally, for *k*-fold 10, the recall attained by SDHO-enabled KGNN reached 83.15%, showing improvements of 25.59%, 25.46%, 17.14%, 16.87%, 3.64%, 1.6%, and 0.86% over the existing methods NN, RNN, BILSTM, DCNN, GNN, GNN-BCO, and GNN-COA, respectively, as shown in Figure 9c. The improvement in these results shows that the developed method outperforms the other conventional methods, demonstrating its efficiency in detecting fraudulent calls.

4.7 | ROC Analysis

The ROC analysis of the proposed SDHO-enabled KGNN model with existing methods is shown in Figure 10. When the false positive rate is 0.6%, the true positive rates of the existing NN, RNN, BiLSTM, DCNN, GNN, GNN-BCO, GNN-COA methods, and the proposed SDHO-enabled KGNN model are 0.7046%, 0.8427%, 0.8759%, 0.9052%, 0.9501%, 0.9514%, and 0.9518%, respectively. Thus, it is clear that the proposed SDHO-enabled KGNN model achieved higher accuracy in fraudulent call detection when

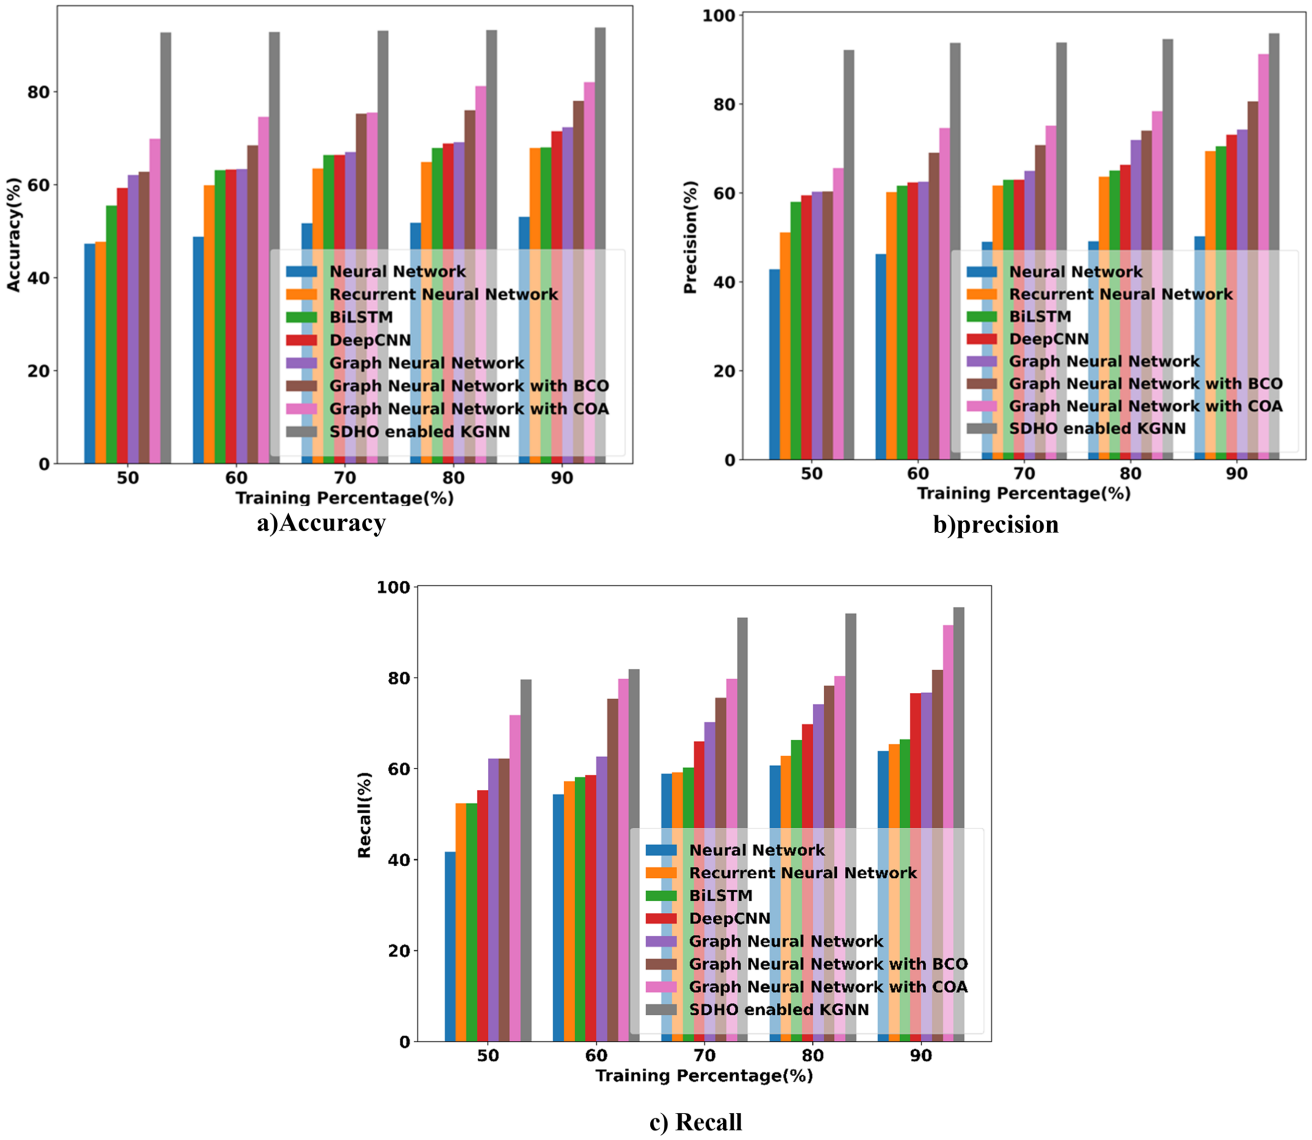

FIGURE 8 | Comparative analysis with TP.

compared to the existing NN, RNN, BiLSTM, DCNN, GNN, GNN-BCO, GNN-COA methods.

4.8 | AUC Analysis

AUC is utilized to evaluate the performance of the classifier, and it is typically calculated using the methods of numerical integration, like the trapezoidal rule, which is applied to the results of ROC analysis. The value of AUC always ranges from 0 to 1, and the variation is clearly shown in Figure 11.

4.9 | Model Loss and Accuracy Graph Analysis

Figure 12 shows the accuracy analysis of the proposed SDHO-enabled KGNN model with the epoch ranges from 0 to 100. At epoch 0, the accuracy of the proposed method is 0.0964, then it rises to 0.324 for epoch 20. At epoch 40, the accuracy gradually increases to 0.545. Further, at epoch 60, it reaches 0.691, 0.802 for epoch 80, and lastly, the accuracy attained for epoch 100 is 0.903.

Figure 13 shows the loss analysis of the proposed SDHO-enabled KGNN model with epoch ranges from 0 to 100. The loss attained by the proposed SDHO-enabled KGNN model are 0.903, 0.417, 0.268, 0.183, 0.129, and 0.096 for epochs 0, 20, 40, 60, 80, and 100, respectively.

4.10 | Comparative Discussion

In this section, the feasibility of fraudulent call detection through automatic feature learning techniques is analyzed to improve the security of telecommunications. Considering the security issues associated with the 5G and future 6G networks, this section will concentrate on the specific techniques related to fraudulent call detection in the context of 5G/6G networks. From the experimental validation, there are still some challenges that limit the applicability of the competent techniques, and the results are depicted

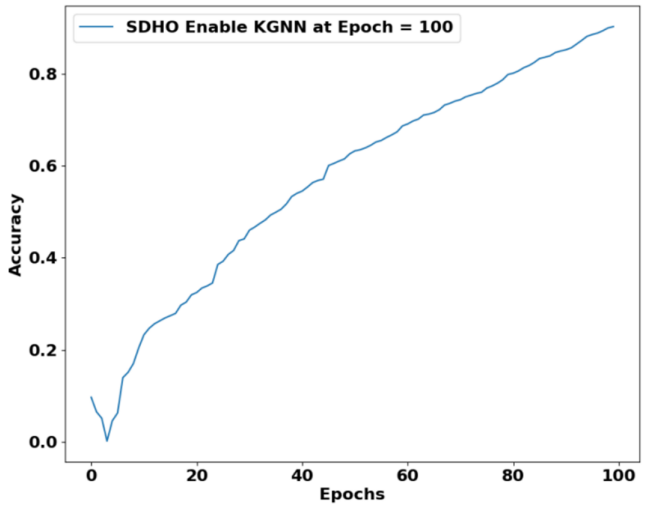

FIGURE 12 | Analysis of accuracy with respective epoch.

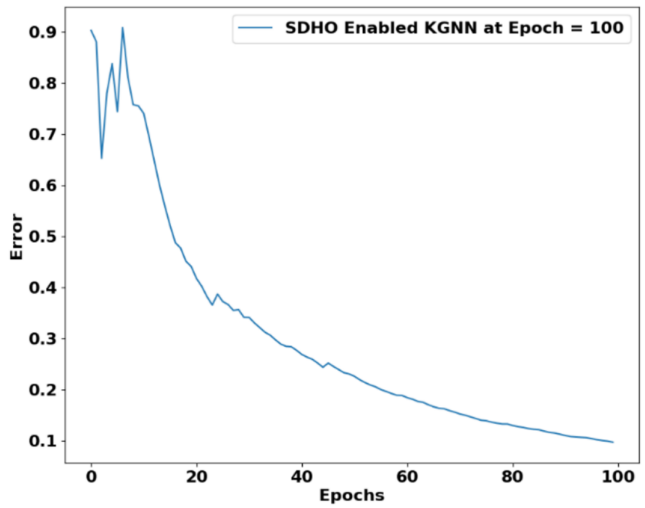

FIGURE 13 | Analysis of loss with respective epoch.

in this section. NN, RNN, BiLSTM, DCNN, GNN, GNN-BCO, and GNN-COA are the conventional approaches utilized for fraud call detection. These approaches contain various drawbacks; training deep learning models, such as DCNN and GNN, can be computationally intensive and may require access to powerful hardware or cloud resources. RNN, BiLSTM, and GNN can be complex and less interpretable. The performance of these models can be notably affected by the quality and accuracy of the data employed for training. Data that are noisy or incomplete can result in less than optimal outcomes. The SDHO-enabled KGNN model is developed to overcome these limitations. KGNNs offer significant advantages for fraud call detection by leveraging external knowledge to improve accuracy, reduce false positives, adapt to changing fraud patterns, and provide interpretability while handling large-scale and dynamic call networks. Remarkably, the proposed SDHO-enabled KGNN model outperforms the other existing techniques, showing its effectiveness in fraud call detection. The incorporation of KGNN helps to learn intricate patterns and relationships, which enhances its ability to detect fraud calls, and the use of SDHO increases the model's performance by tuning the classifier and reduces the computational complexity of the model. High accuracy across diverse training percentages and various *k*-fold ensures that the model performs well consistently demonstrating its ability to adapt and learn diverse amounts of labeled data. The result indicates that the developed method attains a high accuracy of 93.8% in detecting fraudulent calls by adapting to changing fraud patterns. Unlike other conventional methods, the proposed method balances between precision and recall ensuring that the model not only excels in high accuracy but also in identifying fraud calls and minimizes the false positives as well as false negatives. Consequently, the proposed approach learns implicit features that are more resilient to a fraudulent phone number's constantly changing dynamic and call behavior over time and improves the security of 5G/6G networks. Table 1 depicts the comparative analysis between the SDHO-enabled KGNN and other conventional methods with TP 90 and *k*-fold 10.

5 | Conclusion

In this research, a novel fraudulent call detection approach for 5G/6G networks is proposed with advanced strategies to improve the security and privacy of the user. In the realm of fraudulent call detection, the integration of KGNN as a classifier represents a cutting-edge and highly effective approach. KGNNs combine the power of graph-based modeling with external knowledge sources, yielding a range of compelling advantages. By incorporating domain-specific knowledge such as historical fraud patterns and network relationships, KGNNs significantly enhance accuracy and robustness that excel in distinguishing fraudulent calls from legitimate ones, thus minimizing false positives and reducing operational overhead. Moreover, KGNNs adapt to evolving fraud tactics by continuously updating their knowledge base, ensuring a proactive stance against emerging threats. Furthermore, the integration of SDHO-enabled KGNNs to excel in few-shot learning and anomaly detection, enabling the identification of new, previously unseen fraudulent patterns. Customizable to specific organizational needs, these models foster industry collaboration, creating a collective defense against fraud. Specifically, the proposed approach facilitates effective fraudulent call detection and is crucial in the 5G/6G era, as it enhances user privacy and security by terminating the requirement to transfer sensitive information and enhances network performance in terms of security. The experimental results demonstrate that the SDHO-enabled KGNN approach outperforms traditional methods and commonly employed techniques in fraud call detection. Specifically, it achieves an impressive overall accuracy, precision, and recall of 93.8%, 95.91%, and 95.53% with a TP rate of 90%, respectively. Future work could involve refining knowledge integration techniques, enhancing real-time processing capabilities, exploring federated learning for collaborative fraud detection across organizations, and addressing privacy concerns. Additionally, developing methods to handle adversarial attacks on the knowledge-enhanced GNN model is a crucial area for improvement. The proposed model will be extended with a hybrid deep learning mechanism by focusing on a different number of attributes in the data to improve performance that serves as the future direction of research.

2025 10th International Conference on Signal Processing and Communication (ICSC) | 979-8-3315-1189-0/25/$31.00 ©2025 IEEE | DOI: 10.1109/ICSC64553.2025.10968002

***Abstract*— This study investigates the Dielectric Modulated Dual Metal Gate Gallium Nitride Junctionless Accumulation Mode Nanowire FET (DM-DG-GaN-JAM-NWFET) as a potential biosensor for applications in the biomedical field. To assess its sensing capabilities, neutral and charged biomolecules are analyzed, focusing on the effects of different dielectric constants and charge densities on the device's electrostatic properties. Key parameters, including threshold voltage (V_{TH}) and on-current (I_{on}) are examined to evaluate the sensitivity of device. Additionally, the performance of the Dual Metal Gate Gallium Nitride Junctionless Accumulation Mode (DG-GaN-JAM) Nanowire FET is compared with that of the Single Metal Gate Gallium Nitride Junctionless Accumulation Mode (SG-GaN-JAM) Nanowire FET. The results highlight that the DM-DG-GaN-JAM-NWFET biosensor is highly effective for biosensing applications.**

Keywords*— *biomolecules, dual metal, gallium nitride, junctionless accumulation mode, nanowire

I. INTRODUCTION

With advancements in technology, the size of MOSFETs has significantly decreased. This scaling was primarily aimed at improving device response times and enhancing gate controllability. However, it has also led to pronounced Short Channel Effects (SCEs), which become critical at the nanoscale. These effects include reduced velocity saturation, gate control over the channel, Drain Induced Barrier Lowering (DIBL), and the hot electron effect [1]-[3]. To mitigate these effects, numerous innovative designs have been developed, such as FinFETs, Gate-All-Around (GAA) MOSFETs, and multi-gate FET architectures [4]-[5]. Excessive series resistance and thermal issues in GAA structures often arise from abrupt p-n interfaces at the source-channel and channel-drain. To address these challenges, J.E. Lilienfeld proposed the Junctionless (JL) Transistor in the 1920s [6], later successfully fabricated by Colinge et al. [7]. This design eliminates p-n junctions and doping concentration gradients, simplifying fabrication. However, its highly doped channel can lead to mobility degradation [8]. To resolve this, the Junctionless Accumulation Mode (JAM) FET was proposed [9], which incorporates a lightly doped channel and heavily doped drain and source to enhance mobility, improve conductivity, and minimize parasitic resistance compared to JL FET. FET biosensors have made remarkable progress in electrochemical biosensing. Biomolecules influence the electrical behavior of sensors by modifying the gate terminals. Recently, there has been growing interest in dielectric modulated FET, which utilize the dielectric constant of biomolecules. This structure detects both uncharged and charged biomolecules [5,10]. High current sensitivity is needed to detect biomolecules at low concentrations. Various multigate FET have been explored for detecting both neutral and charged biomolecules, incorporating different types of nanocavities. Dual metal gate (DG) and GAA FETs offer improved frequency performance and lower power consumption. A key challenge in CMOS downscaling is the thinning of the SiO_2 gate dielectric, which has now approached its limit. This thin dielectric causes direct electron tunneling, leading to leakage currents that degrade performance of circuit. High-k dielectrics are employed to address this issue, but they can exacerbate SCEs. These effects can be mitigated by optimizing gate stack structures and controlling the Equivalent Oxide Thickness (EOT).

Advancements in technology drive the adoption of new materials to address the limitations of existing ones. Gallium Nitride (GaN) has gained attention as a potential material for MOS devices because of its advantages: a wide bandgap enabling higher breakdown voltage, strong piezoelectric effects for enhanced carrier concentration, high electron drift velocity for faster applications, and low intrinsic carrier density for high-temperature stability. These properties position GaN as a superior channel material compared to silicon [11,13]. Additionally, GaN-based biosensors are rapidly advancing due to their exceptional sensitivity, fast response, compact size, and potential for multi-array integration [13-14].

This research introduces the combination of Gallium Nitride (GaN) with Junctionless Accumulation Mode Nanowire Field Effect Transistor (JAM-NWFET) technology to enhance the biosensors sensitivity, enabling the detection of different biomolecules such as proteins, enzymes, DNA etc. To meet the growing demand for ultrasensitive biosensing applications, the Dielectric Modulated Dual Metal Gate Gallium Nitride Junctionless Accumulation Mode Nanowire FET (DM-DG-GaN-JAM-NWFET) is introduced. To further improve device performance, gate stack and Gate Material Engineering, such as dual metal gate, are employed. Additionally, a comparison of dual metal gate (DG) in GaN-JAM-NWFET

with single metal gate (SG) GaN-JAM-NWFET shows that the dual metal gate improves carrier velocity, gate transport efficiency, and diminishes the hot carrier effect. Therefore, the results demonstrate that the DM-DG-GaN-JAM-NWFET biosensor is more apt for ultrasensitive biosensing applications compared to its single metal gate counterpart.

II. DEVICE STRUCTURE

Fig. 1 describes the 2D structure of the Dielectric Modulated Dual Metal Gate Gallium Nitride Junctionless Accumulation Mode Nanowire FET (DM-DG-GaN-JAM-NWFET), designed for use as a biosensor. The parameters of the proposed structure are summarized in Table 1. The source (N_D^+), channel (N_D), and drain (N_D^+) regions are fabricated using Gallium Nitride (GaN). N-type GaN is utilized for the channel due to its superior electron mobility, which enables a high drain current [13]. A 2 nm layer of Aluminium Oxide (Al_2O_3) is formed over the channel, while a Hafnium Oxide (HfO_2) is placed at the center of the nanogap. Al_2O_3 is a highly effective dielectric material employed with GaN to enhance performance. During the fabrication process, the sacrificial material between the lower gate metal and the upper gate oxide layer is etched, forming a nanocavity. This biosensor can be realized as dielectric-modulated (DM) FET. When there are no biomolecules, the surrounding air (K=1) fills the nanogap. The nanogap thickness is 2 nm, the same as the insulating layer. Biomolecules like Biotin (K=2.63), APTES (K=3.57), and DNA (K=8), is placed into the nanogap [5]. Dual Metal Gate (DG), achieved through Gate Material Engineering (GME), divide the gate into two halves: Gate1 (L_{G1}) and Gate2 (L_{G2}), each with different work functions (ϕ_{m1} and ϕ_{m2}). The higher work function, ϕ_{m1}, is positioned near the source, while the lower work function, ϕ_{m2}, is located near the drain. Device simulations were performed using Silvaco Atlas TCAD, which includes models for Shockley-Read-Hall (SRH) recombination, field-dependent mobility (FLDMOB), concentration-dependent mobility (CONMOB), band-to-band tunneling (BBT.STD), Boltzmann statistics, and the Newton-Gummel numerical method.

TABLE I. DEVICE PARAMETERS

Various Parameters	Symbols	DM-DG-GaN-JAM-NWFET	DM-SG-GaN-JAM-NWFET
Length of Channel	L_{ch}	22 nm	22 nm
Source/Drain Length	$L_{S/D}$	10 nm	10 nm
Length of Gate1 and Gate2	$L_{G1} = L_{G2}$	11 nm	11 nm
Nano-gap Cavity Length	L_1=L_2	8 nm	8 nm
Length of Region II and Region III	L_3=L_4	3 nm	3 nm
Channel Doping	N_D	10^{18} cm^{-3}	10^{18} cm^{-3}
Source/Drain Doping	N_D^+	10^{19} cm^{-3}	10^{19} cm^{-3}
Gate Work Function	φ_{m1}, φ_{m2}	5.14 eV, 4.36 eV	5.1 eV
Oxide Thickness	t_{Al2O3}	2 nm	2 nm
Hafnium Oxide Thickness	t_{ox}	2 nm	2 nm
Nano-gap Cavity Thickness	t_{ox}	2 nm	2 nm
Channel Radius	R	5 nm	5 nm

III. SIMULATIONS AND RESULTS

This section explores the detection of biomolecules like Biotin, APTES, and DNA, having different dielectric constants, using DM-DG-GaN-JAM and DM-SG-GaN-JAM NWFETs. Figure 2 illustrates the energy band diagrams of the DM-DG-GaN-JAM NWFET and DM-SG-GaN-JAM NWFET for air (K=1) and DNA (K=8) biomolecules. Variation in biomolecules dielectric constant within the cavity have a significant effect on energy band at the channel-drain junction, leading to noticeable changes in device conduction. The presence of DNA molecules increases the Conduction Band Energy (CBE) and Valence Band Energy (VBE) compared to air (K=1). Additionally, the DM-DG-GaN-JAM NWFET exhibits higher CBE and VBE values compared to the SG-GaN-JAM NWFET for both biomolecules. This is attributed to the reduced influence of high-speed electron movement, which mitigates hot carrier effects [12, 14].

Fig. 3 illustrates the drain current variation for various biomolecule dielectric constants in both NWFETs. The threshold voltage of both devices experiences a significant shift when biomolecules are absent in the cavity, as indicated in the figure.

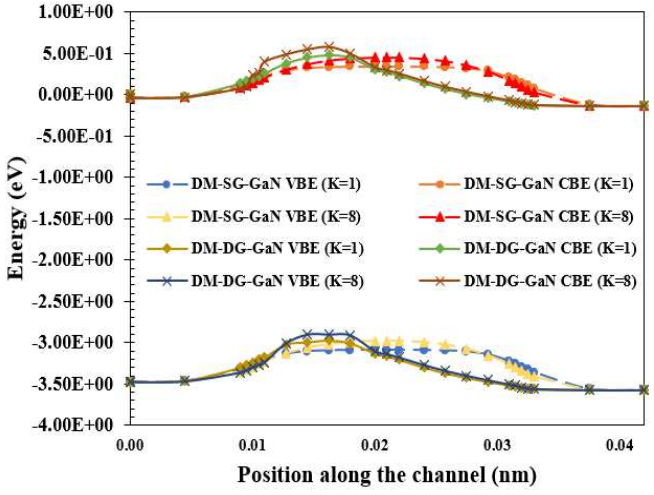

Fig. 2. Energy band diagrams of both devices for air(K=1) and DNA (K=8) biomolecules

As biomolecules with different dielectric constants fill the nanogaps, the threshold voltage shifts back toward the initial value observed in the absence of biomolecules [5,14]. It is evident from Fig. 3 that the DM-DG-GaN-JAM NWFET exhibits a greater change compared to the DM-SG-GaN-JAM NWFET for sensing Biotin, APTES, and DNA. Due to dual-metal gate (DG) structure in the GaN-JAM NWFET, the impact of high-speed electrons is reduced, thereby decreasing hot carrier effects, unlike in single-metal gate (SG) structure [5,14]. As a result, the DM-DG-GaN-JAM NWFET shows a more significant change in drain current, enhancing biomolecule detection.

Fig. 4 illustrates logarithmic drain current versus gate voltage, indicating subthreshold (leakage) current. In subthreshold region, leakage current reduces from Biotin to DNA. The greater dielectric constant of DNA, in comparison to Biotin, improves gate control, causing the threshold voltage to shift upward. This makes it more difficult to turn-on the channel, thus reducing the subthreshold leakage current [5,14]. Additionally, the DM-DG-GaN-JAM NWFET shows lower subthreshold leakage current compared to the DM-SG-GaN-JAM NWFET. The dual metal gate (DG) in the GaN-JAM NWFET mitigates the effects of high-speed electrons, minimizing short-channel effects and making it more suitable for biomolecule detection than the single-gate (SG) FETs.

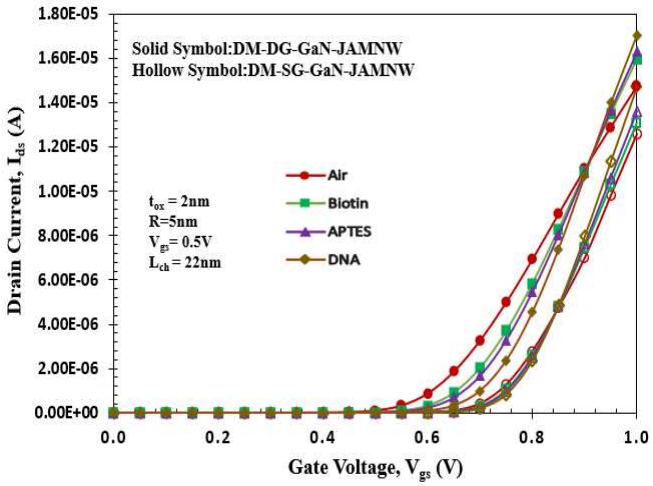

Fig. 3. Drain current (I_{ds}) for various biomolecule dielectric constant in both NWFETs.

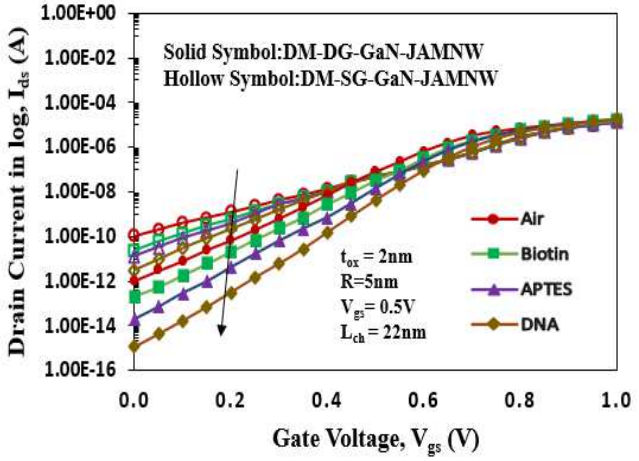

Fig. 4. Drain current (I_{ds}) in log scale for various biomolecule dielectric constant in both NWFETs.

Fig. 5 illustrates the transconductance (G_m) variation for different biomolecule dielectric constant. Transconductance is a key factor in assessing the performance of GaN-based biosensors. A higher transconductance indicates lower power consumption, which is crucial for portable biosensors [5]. As depicted in the figure, the DM-DG-GaN-JAM NWFET has higher transconductance with larger drain current compared to the DM-SG-GaN-JAM NWFET, owing to its improved channel control and reduced SCEs [5].

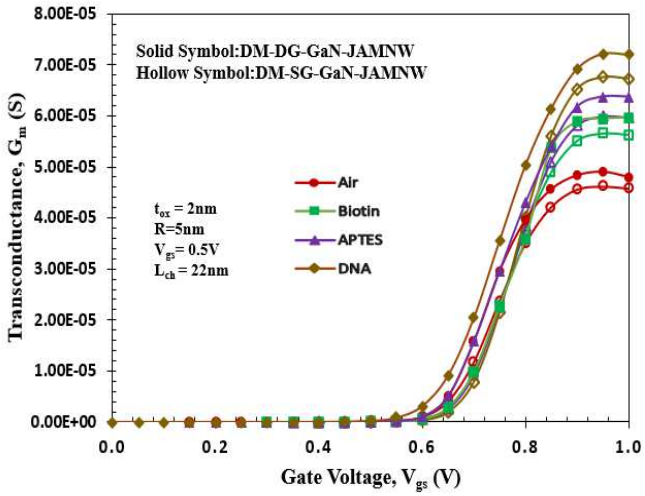

Fig. 5. Transconductance variation for different biomolecule of both devices

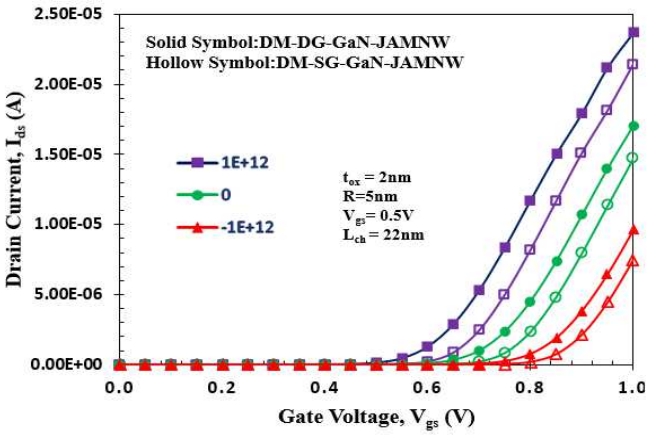

Fig. 6. Drain current (I_{ds}) variation for different DNA biomolecule concentrations in both devices

Fig. 6 demonstrates the simulation of I_{ds} versus V_{gs} for both DM-DG-GaN-JAM NWFET and DM-SG-GaN-JAM NWFET biosensors, with biomolecules of DNA (K = 8) carrying both positive and negative charge densities (Q_f) in the nanogaps. As the positive charge concentration in the nanogap increases, the curves shift toward larger drain currents, resulting in increased channel conductance and a lower threshold voltage (V_{TH}). Conversely, an increase in negative charge density results in a shift toward lower drain currents, with a corresponding increase in V_{TH} [5]. It is evident that the DM-DG-GaN-JAM NWFET outperforms the DM-SG-GaN-JAM NWFET because of its more gate control of the channel, with a higher drain current.

Sensitivity is a critical aspect of sensor design. For FET biosensors, it is typically evaluated by examining the relative change in an electrical characteristic that shows the

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 07:25:37 UTC from IEEE Xplore. Restrictions apply.

presence of biomolecules. This characteristic may include factors like ON-state current (I_{on}), Subthreshold Swing (SS), I_{on}/I_{off}, and threshold voltage (V_{TH}). Mathematically, sensitivity (S) is expressed as [5]:

$$S_{V_{TH}} = \frac{V_{TH,bio} - V_{TH,air}}{V_{TH,air}} \quad (1)$$

$$S_{I_{on}} = \frac{I_{on,bio} - I_{on,air}}{I_{on,air}} \quad (2)$$

$$S_{SS} = \frac{SS_{bio} - SS_{air}}{SS_{air}} \quad (3)$$

$$S_{I_{on}/I_{off}} = \frac{I_{on}/I_{offbio} - I_{on}/I_{offair}}{I_{on}/I_{offair}} \quad (4)$$

The biomolecule sensitivity is assessed by modifying the dielectric constant and observing the corresponding change in threshold voltage. A larger shift in threshold voltage leads to higher sensitivity (S_{VTH}). Fig. 7 clearly demonstrates that DM-DG-GaN-JAM NWFET is more sensitive than DM-SG-GaN-JAM NWFET in sensing Biotin, APTES, and DNA biomolecules. This enhanced sensitivity is attributed to the proposed dual metal gate configuration, which enhances the V_{TH} sensitivity of the biosensor [5]. As the dielectric constant rises, the sensitivity improves, showing a linear relationship between sensitivity and threshold voltage as indicated in Fig. 7 graph.

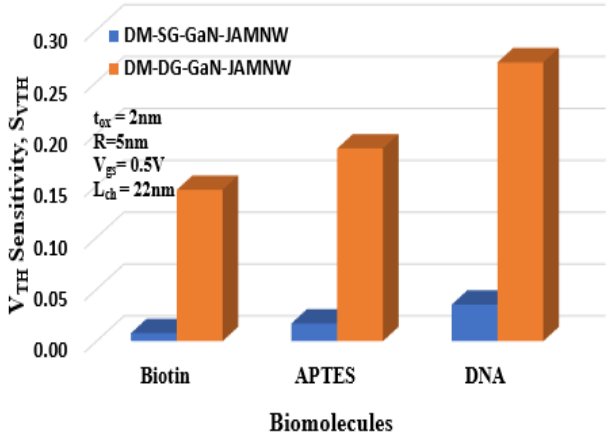

Fig. 7. V_{TH} sensitivity for various biomolecules

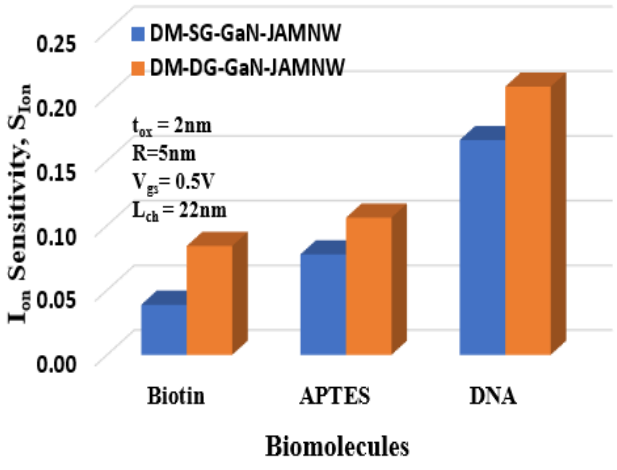

Fig. 8. I_{on} sensitivity for various biomolecules

Fig. 8 illustrates ON current sensitivity for both structures, with the DM-DG-GaN-JAM NWFET showing significantly higher sensitivity than the DM-SG-GaN-JAM NWFET. A higher dielectric constant enhances the interaction between the biomolecule and the gate region, thereby increasing the ON current to its peak value [5].

Fig. 9 and Fig. 10 present the sensitivity of I_{on}/I_{off} ($S_{Ion/Ioff}$) and Subthreshold Swing (S_{ss}) for the two structures under comparison. The DM-DG-GaN-JAM NWFET demonstrates notably superior sensitivity in both metrics compared to the DM-SG-GaN-JAM NWFET. This improvement is due to the higher dielectric constant, which enhances the interaction between the biomolecule and the channel, leading in greater ON current. Additionally, the reduction in the OFF current is facilitated by the dual-gate, which mitigates short-channel effects (SCEs) [5,10].

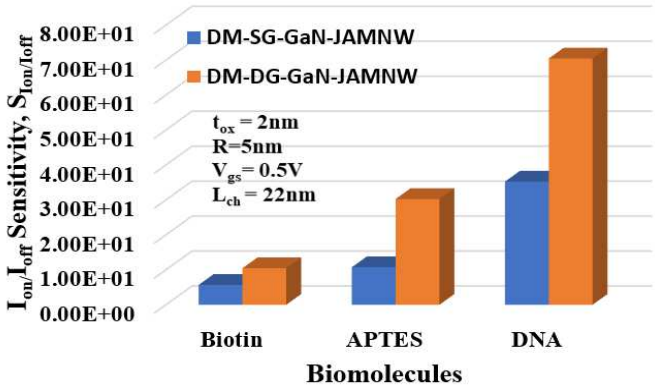

Fig. 9. I_{on}/I_{off} sensitivity for various biomolecules dielectric constant

TABLE III. S_{VTH} SENSIVITY COMPARISON OF THE PROPOSED DM-DG-GAN-JAM NWFET FOR APTES BIOMOLECULES

Device specifications	Ref. (S. Sharma et al. 2020) [13]	Ref. (S. Yadav et al. 2024) [10]	DM-SG-GaN-JAM-NWFET	Proposed DM-DG-GaN-JAM-NWFET
Cavity thickness	4 nm	2 nm	2 nm	2 nm
Cavity length (nm)	30 nm	50 nm	16 nm	16 nm
Channel length	50 nm	100 nm	22 nm	22 nm
Dielectric constant of biomolecules	APTES (K=3.57)	APTES (K=3.57)	APTES (K=3.57)	APTES (K=3.57)
S_{VTH} Sensivity	0.05879	0.0427	0.02	0.19

Fig. 11 illustrates the variation in V_{TH} sensitivity with charge density for DNA biomolecules. The DM-DG-GaN-JAM NWFET exhibits superior sensitivity compared to other devices in detecting various concentrations of charged biomolecules. This enhanced sensitivity can be attributed to the dual-metal gate structure, which mitigates the influence of high-speed electron movement, thereby enhancing biomolecule detection efficiency [5,14].

A detailed comparison of various parameters is enlisted in Table II. Table III presents a comparison of the proposed DM-DG-GaN-JAM NWFET with recently published devices that detect the same biomolecule, APTES (K=3.57), ensuring a fair comparison for detection. The comparative analysis highlights that the DM-DG-GaN-JAM NWFET excels in S_{VTH} sensitivity, outperforming over existing structures.

IV. CONCLUSION

Dielectric Modulated Dual Metal Gate Gallium Nitride Junctionless Accumulation Mode Nanowire FET (DM-DG-GaN-JAM-NWFET) has been introduced as a biosensor due to its enhanced detecting capabilities. Sensitivity and drain current variation have been used as key biosensing factors for detecting biomolecules in the nanogap. This research also includes a comparison between the DM-DG-GaN-JAM and DM-SG-GaN-JAM NWFETs based biosensors. The DM-DG-GaN-JAM-NWFET exhibits a larger variation in drain current compared to the DM-SG-GaN-JAM-NWFET. Additionally, the threshold voltage sensitivity for DNA detection is higher in the DM-DG-GaN-JAM-NWFET based sensor. Also, the ON-current sensitivity is enhanced in the DM-DG-GaN-JAM-NWFET. Hence, the analysis demonstrates that the DM-DG-GaN-JAM-NWFET biosensor is more effective for ultrasensitive biosensing applications.

Abstract

This paper focuses on the design and implementation of silicon slab waveguides (SSWs) based all-optical XOR and XNOR logic gates. Utilizing silicon's high refractive index at optical communication wavelengths (1.55 μm), these gates exhibit strong optical confinement and efficient propagation in SSWs. The proposed design is optimized for both transverse electric and transverse magnetic modes. By strategically introducing air holes at key intersections of the waveguide, phase variations are induced to achieve the desired output logic for XOR and XNOR logic operations. These gates demonstrate femtosecond-scale propagation delays, significantly outperforming traditional logic gate designs, with low propagation losses and compact design.

Keywords: logic gates, silicon slab waveguide, XOR gate, XNOR gates, propagation losses

1. Introduction

Traditional electronic logic gates are approaching their physical and performance limits. Optical logic gates have emerged as a promising solution, offering higher speeds and lower power consumption. Recent advancements in optical logic gate implementation [1] have explored a diverse range of approaches, including semiconductor optical amplifiers (SOAs), four-wave mixing, microring resonators, two-photon absorption (TPA), spatial filtering, and photonic crystal structures [2–7]. Various optical gate designs have been explored, utilizing technologies such as SOAs, nonlinear fibers, and photonic crystals. Among these, silicon photonics has garnered significant attention for its potential to revolutionize data processing and signal transmission [8]. Silicon's high refractive index and compatibility with CMOS fabrication processes make it an ideal platform for integrating optical components into scalable and low-cost photonic circuits.

Silicon slab waveguides (SSWs), enhanced with photonic crystal structures, promise to transform data transmission, signal processing, and computing capabilities. Recent studies on SSW-based logic operations [1, 9–11] have primarily aimed at improving waveguide performance by minimizing propagation losses and optimizing dispersion characteristics, thereby facilitating functionalities such as wavelength conversion and optical amplification. Recent progress in silicon waveguide technology has substantially impacted optical communication and information processing, driven largely by developments in silicon photonics [12]. Among these, SSW-based logic gates have gained prominence due to their unique advantages [1, 13]. Silicon's high refractive index contrast enables strong light confinement and compact designs, making it ideal for miniaturized photonic circuits. This compact design is compatible with standard CMOS fabrication processes [14, 15], making silicon waveguides an appealing solution for scalable and These waveguides can also integrate nonlinear optical effects, enabling functionalities of all optical logic gates with high-speed operation and low energy requirements [16, 17].

The proposed XOR and XNOR gates serve as essential building blocks for universal logic circuits, with their implementation in an all-optical framework enabling interference between electromagnetic fields from two input waveguides at the waveguide junction. A significant advantage of this switching architecture is the high signal contrast between the on and off states at the output port, while also eliminating back-reflections into the input ports. Due to the instantaneous nature of the interference, the switching process within the

waveguide junctions is inherently ultrafast, making it well-suited for the development of low-power, high-speed optical computing systems.

The realization of all-optical SSW-based universal logic gate operations leverages linear interference effects in dielectric crossed waveguide structures, where photons serve as information carriers, significantly enhancing data bandwidth. This linear approach minimizes excessive heating within the structures, as only low electromagnetic intensities are required to drive the switching and logic elements [18]. The switching mechanism relies on the interference of a signal (Gaussian source) originating from two input ports and one control port at the waveguide junction. When the incoming signal and the control signal are in phase, constructive interference occurs, yielding a logic output of 1. Conversely, when these signals are out of phase, destructive interference takes place, resulting in a logic output of 0. Due to the low field intensities and the potential for a high degree of integration, linear interference effects present a promising approach, which will be explored further in this study [19, 20].

Further all the earlier reported works on logic gates operate on the non-linear phenomena such as four-wave mixing and TPA. Complex designs of logic gates based on resonant modes in microring cavities have been reported. Also, logic gates have also been designed on the photonic crystal platform operating on the principle of photonic band gap guidance. However, this paper focuses on the design and implementation of all-optical XOR and XNOR logic gates designed on SSW operating on linear interference effect in a simple dielectric crossed waveguide structure, which can be easily fabricated with the existing technology [21]. The novelty of the present work lies in its simple design relying on the linear interference phenomena with low power requirement. We leverage silicon's intrinsic properties for high-speed optical computing. This configuration enables tighter mode confinement, allowing the structure to support both transverse electric (TE) and transverse magnetic (TM) modes [22] with minimal propagation loss and high efficiency [23]. The finite-difference time-domain software, MIT electromagnetic equation propagation, is utilized for the simulation, optimization, and implementation of NAND and NOR logic gates for both polarizations. The simulation parameters include a spatial resolution with a step size of 20, a perfectly matched layer as the boundary condition, and an iteration unit of 200 [24].

2. Design of XOR and XNOR all optical logic gates

The design of (16 * 16) μm^2 2D device using *Y* shaped SSW on based XOR and XNOR optical logic gates is proposed leveraging the distinct propagation characteristics of TE and TM modes to achieve all-optical logic operations. At the core of the structure there is a *Y* shaped SSW [25, 26] SSW with two input ports (A and B) with an angle of 120° and one output port of dimension 7 μm long and width of 0.241 μm for TE mode and 0.345 μm for TM mode. A reference waveguide has been created which is indicated as reference R, used to create phase difference between input signals resulting into interfere either constructively or destructively for both polarizations, depending on the phase angle of the light beam launched into the waveguide. The phase angle of the input light beam can be varied, as demonstrated by Birr *et al* [27]. However, phase angle has to introduce manually in the reference waveguide. This waveguide functions as the primary medium for light propagation to realize XOR and XNOR logic operations [28].

To enhance the performance and mode control for TE and TM mode respectively, air holes are strategically placed within the structure as shown in figures 1(a) and (b). Figures 2(a) and (b) show the variation of transmission intensity vs. radius of the air hole for TE and TM mode respectively. For TE mode maximum transmission intensity is obtained at the radius of radius of 0.15 μm at center of waveguide. For TM mode the optimized radius of air hole is obtained as 0.05 μm placed at 0.5 μm below center of waveguide.

The waveguides are engineered for single-mode operation, with width d optimized at 0.241 μm for TE mode and 0.345 μm for TM mode, ensuring efficient mode confinement and minimal propagation loss. The single-mode condition is governed by equation (1),

$$v_c = \frac{c}{2d\sqrt{n_1^2 - n_2^2}} \tag{1}$$

d is the width of the SSW, n_{Si} is the refractive index of silicon ($n_{\mathrm{Si}=3.47}$), n_{air} is the refractive index of air, and c is the speed of light in a vacuum.

The performance of SSW based XOR and XNOR logic gates is evaluated by realization of the truth table and calculation of power loss. Power loss, key to efficiency is calculated as

$$\mathrm{loss} = 10\log_{10}\left(\frac{P_{\mathrm{out}}}{P_{\mathrm{in}}}\right), \tag{2}$$

where P_{in} and P_{out} are input and output powers, respectively [29]. Higher output power indicates greater gate efficiency. The contrast ratio (CR) [30] is defined as,

$$\mathrm{CR\,(dB)} = 10\ln\left(\frac{P_{\mathrm{out}}|ON_{\mathrm{min}}}{P_{\mathrm{out}}|OFF_{\mathrm{max}}}\right) \tag{3}$$

where $P_{\mathrm{out}} \mid ON_{\mathrm{min}}$ and $P_{\mathrm{out}} \mid OFF_{\mathrm{max}}$ represent the minimum and maximum output powers for logic levels '1' and '0.' Modulation depth (MD) [31] is calculated using equation (4),

$$\mathrm{MD} = \left(\frac{T|ON_{\mathrm{max}} - T|OFF_{\mathrm{min}}}{T|ON_{\mathrm{max}}}\right) \times 100\% \tag{4}$$

where $T \mid ON_{\mathrm{max}}$ and $T \mid OFF_{\mathrm{min}}$ are the maximum and minimum transmission values for logic levels '1' and '0.'

Data rate as determined using the Nyquist equation is given by [32],

$$\mathrm{Data\ rate} = 2\mathrm{B}\log_2(M) \tag{5}$$

where $M = 4$ which indicates the total number of signal levels (00, 01, 10, and 11), while B (optical bandwidth) is given by equation (6),

$$B = \left(\frac{c}{\lambda^2}\right)\Delta\lambda. \tag{6}$$

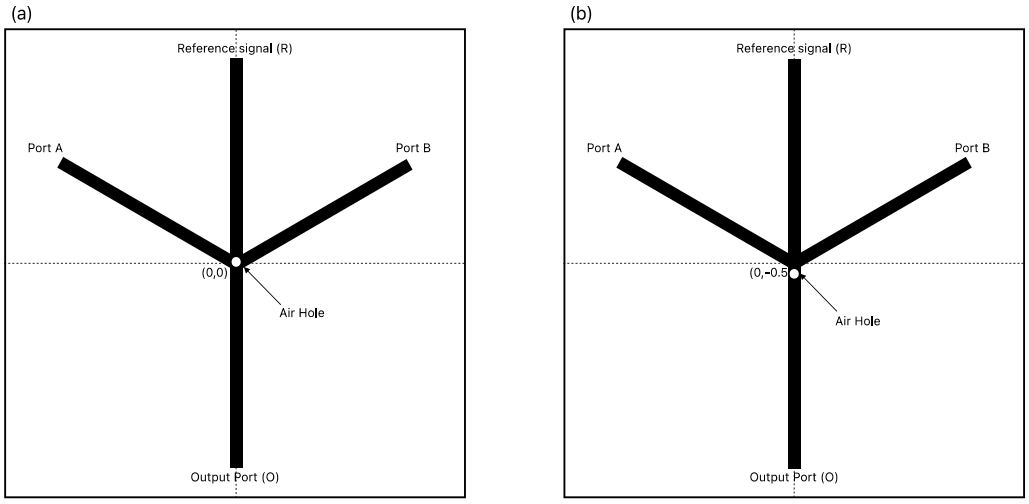

Figure 1. The schematic structure of the XOR and XNOR logic gates created using silicon slab waveguides (SSWs) (a) for TE mode, (b) for TM mode of propagation.

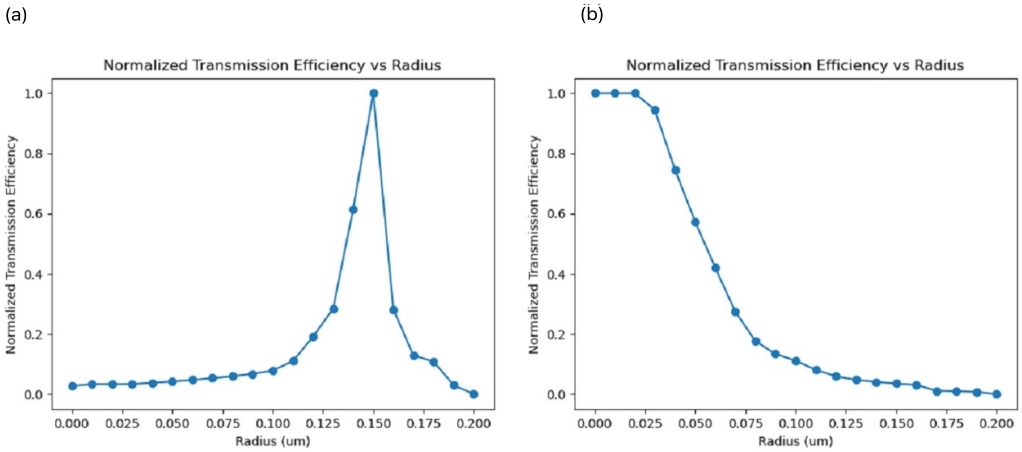

Figure 2. Variation of transmission intensity with radius of air hole (a) for TE mode, (b) TM mode.

with $\lambda = 1.55$ μm and $\Delta\lambda = 10$ μm, $B = 1.25$ THz yielding a data rate of 5 Tb s^{-1}.

The output-to-input power ratio determines the logic states: values above 0.5 indicate logic '1' and below 0.5 indicate logic '0'. This precise differentiation between logic states ensures accurate signal detection.

3. Realization of all optical XOR and XNOR logic gate

3.1. XOR logic gate

The intensity distribution for different input combinations is depicted in figure 3 for TE mode and TM modes. This figures provide a visual representation of how the optical power is distributed within the waveguide for each input state. For both TE mode and TM mode, the intensity is concentrated within the central waveguide when the output is '1', indicating efficient transmission. For the input combination (1, 1), the intensity drops significantly, showing that the XOR gate is successfully suppressing the output signal.

Table 1 shows the truth table of the realized all optical XOR logic gate, where output reflects the expected logic behavior. Table 1 also shows the calculated losses for both TE and TM modes. These losses are indicative of how efficiently the gate operates in both modes, which are crucial for determining its application in photonic circuits.

3.2. XNOR logic gate

The intensity distribution for the XNOR gate under various input conditions is shown in figure 4 for TE mode and TM mode respectively. For both TE mode and TM mode the intensity is concentrated within the central waveguide for the (0, 0) input, indicating strong signal transmission for the logic '1' output. For input configurations that yield a '0' output (e.g., 0, 1 or 1, 0), the intensity reduces significantly.

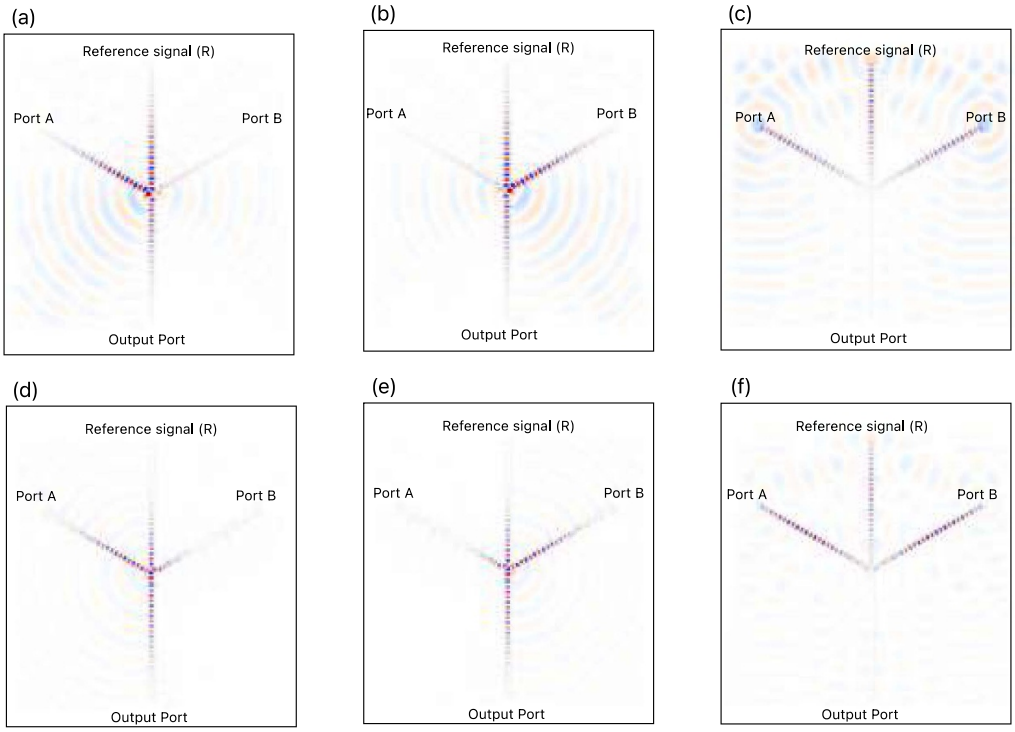

Figure 3. The intensity distributions of the XOR logic gate for TE mode of propagation (a) $A = 1$, $B = 0$, $R = 1$ ($\phi = 0°$), $O = 1$, (b) $A = 0$, $B = 1$, $R = 1$ ($\phi = 0°$), $O = 1$, (c) $A = 1$, $B = 1$, $R = 1$ ($\phi = 180°$), $O = 0$ and for TM mode of propagation (d) $A = 1$, $B = 0$, $R = 1$ ($\phi = 0°$), $O = 1$, (e) $A = 0$, $B = 1$, $R = 1$ ($\phi = 0°$), $O = 1$, (f) $A = 1$, $B = 1$, $R = 1$ ($\phi = 180°$), $O = 0$.

1	1	0	1 ($\phi = 180°$)	0.2609 P_{in}	5.8346	0.1843 P_{in}	7.3432

Table 2 summarizes the truth table along with losses for the realize XNOR gate for both polarizations

4. Analysis of XOR and XNOR optical logic gate

Various parameters such as maximum transmission, CR and MD for the designed XOR and XNOR gates have been calculated and summarized in table 3.

Figure 5(a), illustrates the time evolution curve of the proposed structure for TE mode, showing that the time taken for the output power to increase from 0%–90% of the average steady-state output power, P_{av}, is $ct = 0.21$ μm or $t_1 = 0.419$ fs. The response time consists of two components: the transmission delay ($t_{11} = 0.33$ fs) and the time required for the output power to increase from 0% to 90% ($t_{12} = 0.24$ fs). Given that the system operates on linear materials, the fall time from P_{av} to 10% of P_{av} can approximately be taken as $t_{12} = 0.24$ fs. Consequently, the logic gate can produce a narrow pulse with a width of $2t_{12} = 0.48$ fs, then the response time is 0.81 fs. Similarly, figure 5(b) depicts the time evolution curve of the proposed structure for TM mode where $t_1 = 0.70$ fs, $t_{11} = 0.37$ fs, $t_{12} = 0.33$ fs, $2t_{12} = 0.66$ fs leading to the response time of 1.03 fs.

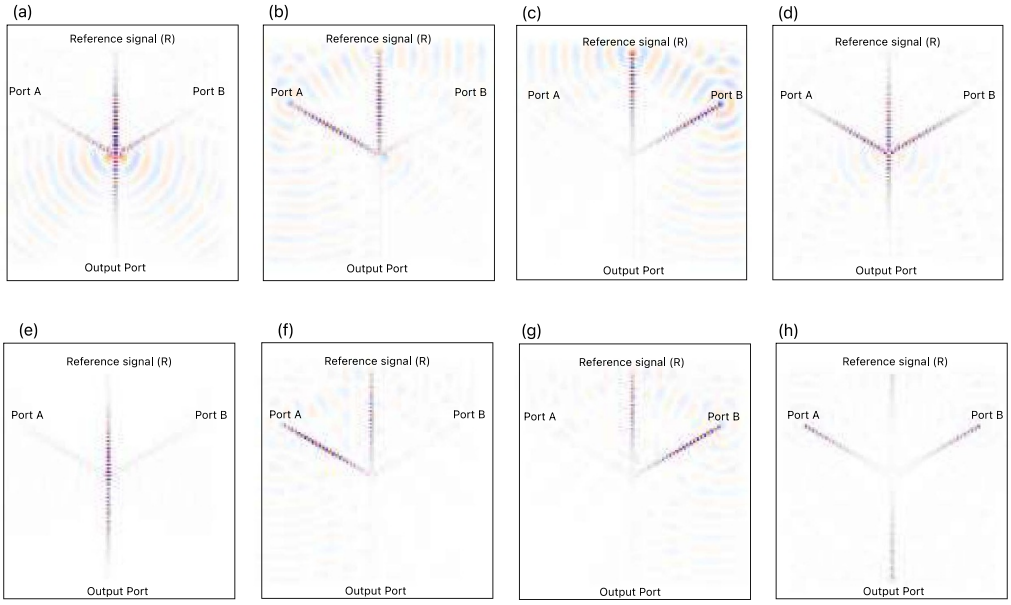

Figure 4. The intensity distributions of the XNOR logic gate for the TE mode of propagation (a) $A = 0$, $B = 0$, $R = 1$ ($\phi = 0^\circ$), $O = 1$, (b) $A = 1$, $B = 0$, $R = 1$ ($\phi = 180^\circ$), $O = 0$, (c) $A = 0$, $B = 1$, $R = 1$ ($\phi = 180^\circ$), $O = 0$, (d) $A = 1$, $B = 1$, $R = 1$ ($\phi = 0^\circ$), $O = 1$and for TM mode of propagation (e) $A = 0$, $B = 0$, $R = 1$($\phi = 0^\circ$), $O = 1$, (f) $A = 1$, $B = 0$, $R = 1$ ($\phi = 180^\circ$), $O = 0$, (g) $A = 0$, $B = 1$, $R = 1$ ($\phi = 180^\circ$), $O = 0$, (h) $A = 1$, $B = 1$, $R = 1$ ($\phi = 0^\circ$), $O = 1$.

The proposed all-optical logic gate design operates at very low power levels, making it a promising candidate for the development of all-optical integrated circuits [33]. A tolerance study, crucial from a fabrication perspective, was conducted by varying the air hole radius by $\pm 5\%$. The results indicate that this variation leads to an approximately 3% change in transmitted intensity for the TE mode and $\sim$0.8% for the TM mode.

The proposed all-optical SSW-based universal logic gates are evaluated against previous works based on key performance criteria, including the number of logic functions achieved, operating wavelength, CR, and response time, as summarized in table 4. The data in this table demonstrates that the proposed gates successfully perform the required logic operations while achieving a significantly higher CR and operating at the commercially viable wavelength of 1550 nm.

5. Conclusion

This paper demonstrated the design of all-optical XOR and XNOR logic gates utilizing SSWs for high-speed, low-power optical computing. These gates are optimized for fundamental logic operations, with a fan-in of 2 and fan-out of 1, showcasing their ability to perform essential computing functions. The gates maintain minimal propagation losses while ensuring precise logic operations, making them highly suitable for integration into larger photonic computing systems. The ability to control and leverage both TE and TM modes provides additional flexibility for optimizing performance across a range of computing applications.

***Abstract*—Digital image forgery is the process of manipulating an image to deceive or mislead observers with real or manipulated content. Median filtering is widely used to smooth images and obscure traces of tampering, making its detection critical for image forensics. However, identifying median filtering becomes more complex when additional operations, such as compression, resampling, or noise addition, are applied. To address this issue, we propose a lightweight convolutional neural network (CNN) model named SobelMNet, specifically designed for detecting median filtering in compressed images. The proposed model utilises a Sobel filter-based preprocessing step to enhance the residual differences between the original and manipulated images. These residuals, which capture subtle features indicative of median filtering, are analysed by CNN for classification. Further, the proposed model is evaluated on grayscale low-resolution images generated from the Dresden dataset for both binary and multiclass classification tasks. The model achieved a remarkable detection accuracy of 99.43% in median filter detection and outperformed state-of-the-art methods in various scenarios, including combinations of median filtering with Gaussian blur, resampling, and additive white Gaussian noise (AWGN) with an average accuracy of 98.32%. Finally, its lightweight architecture ensures computational efficiency, making it practical for real-world forensic applications.**

***Index Terms*—Median Filter, CNN, Sobel Filter, Operation Chain**

I. Introduction

Digital images play a vital role in modern communication, entertainment, and archiving, spanning areas such as social media, academic visuals, and medical imaging [1]. However, with the rise of advanced editing tools, image manipulation has become widespread and increasingly complex [2]. This has significant implications, such as spreading misinformation and forging legal documents, highlighting the need for reliable forensic methods to verify image authenticity and detect alterations [3].

Image manipulation ranges from simple contrast adjustments to complex filtering techniques. Among these, the median filter is widely used due to its ability to reduce noise while preserving edges [4]. This nonlinear filter replaces each pixel's value with the median of surrounding pixels, making it effective for noise removal [5]. While helpful for preprocessing, the median filter can also obscure evidence of tampering, making its detection critical in image forensics.

Detecting median filtering is essential for tracing an image's processing history and identifying potential alterations [6]. Researchers have explored various methods, from statistical feature extraction to advanced deep learning models [7], to uncover artefacts specific to median filtering. [8].

Deep learning has advanced image forensics, enabling the detection of subtle changes that are often invisible to the human eye. Models such as support vector machine (SVM), CNNs and generative adversarial networks (GANs) have been adapted to identify processing artefacts, including those from median filtering. These models are highly effective due to their ability to extract detailed features and complex analysis in forensic classification models. However, challenges remain, particularly when dealing with low-resolution or heavily compressed images [9]–[11].

II. Realted Work

Earlier statistical methods were utilised for image manipulation detection. Zhang et al. [12] introduce a statistical method for detecting median filtering manipulations in digital images using a second-order Local Ternary Pattern (LTP). The LTP captures texture changes caused by median filtering by encoding local derivative direction variations. Kernel Principal Component Analysis is applied to reduce feature dimensionality. Some commonly used statistical methods for detecting median filtering involve histogram residuals, which effectively capture distinctive patterns in images. These patterns, resulting from the median filter operation, allow for the identification of filtered images by analysing variations in the histogram's distribution [13], [14]. Gao and Gao [15] find differences in the pixel values of the image in four directions using pixel-pair histograms and autoregressive moving average coefficients, which outperform compressed JPEG images and low-resolution images. Similarly, Gao et al. [16] compute the first-order and second-order difference images using joint conditional probability density functions. Additionally, principal component analysis is employed for dimensionality reduction, making the model efficient for filter detection in JPEG-compressed and low-resolution images. Kang et al. [17], [18] give an autoregressive model that uses the statistical property of median filter for detection and localisation median filter in an image. The above models outperform work for image forensics but compromise if there is a chain of operations.

The introduction of machine learning and deep learning models has significantly enhanced the ability to detect com-

plex operations applied to images. Jin et al. [19] present a median filtering detection method for RGB images using dark channel residual extraction, multi-scale fusion, and GANs. The dark channel residuals reduce content interference, while multi-scale fusion captures traces from different filter sizes. GANs improve robustness and replace SVM classification. The method outperforms existing techniques, especially with small blocks and JPEG compression, and aims to extend to grayscale images. A CNN-based method introduces MFNet [20] for detecting median filtering in small or compressed images. It uses nearest neighbour interpolation to up-sample images, enhancing the difference between original and filtered versions. MFNet incorporates two mlpconv layers to improve nonlinear classification, followed by three convolutional layers for feature extraction. The method shows significant improvements, especially for images as small as 16×16, and offers potential for broader application in digital image forensics. Ahmed and Islam [21] discuss an approach that leverages the streaking effect caused by median filtering, using SVMs with 10-fold cross-validation to distinguish between median-filtered and unfiltered images. This method also performs well on compressed and low-resolution images. Another study [22] combines texture features extracted via GLCM with streak area analysis, employing an 18-dimensional feature set processed through neural networks to identify median filtering under various manipulations like JPEG compression and Gaussian blur. An advanced CNN-based framework introduces the MFFNet [23], integrating high-pass filters and Squeeze-and-Excitation modules, excelling in detecting manipulations in compressed, low-resolution images. Despite advancements, limitations include challenges in handling operator chains, which are multiple operations on images, including median filtering, and scaling methods to large datasets. These methods demonstrate a shift from traditional SVMs to robust deep learning architectures for feature learning and classification. A deep learning-based approach is introduced for detecting median filtering in the DCT domain. The method employs an Adaptive Filtering Layer to focus on relevant frequency ranges and a multi-scale convolutional block with a maxout function for effective feature extraction. The approach shows superior performance over existing methods, particularly for low-resolution and compressed images [24].

A limitation in existing methods is the decrease in accuracy when detecting median filtering, especially when it is followed by operations such as Gaussian blur, downsampling, or noise addition. Additionally, some techniques are highly dependent on high-resolution images, making them less effective for low-resolution or resized images.

III. Proposed Work: CNN-Based Model

Proposed SobelMNet, a two-dimensional residual-based 2D CNN, specifically designed for detecting traces of median filter in digital images. The key features of the proposed approach are as follows:

1) The Sobel filter-based residual is introduced as the preprocessing layer in the model. This filter kernel modifies the image pixels and generates residuals that amplify the classifier's ability to distinguish between different classes.
2) After the Sobel residual processing, we extract features that emphasise the statistical and structural differences in the image. These features are designed to make it easier for the neural network to identify whether an image has been median-filtered.
3) A lightweight neural network architecture is used for analyzing the extracted features and classifying the images. The network is efficient and can handle both binary tasks and multiclass classification.
4) The model is evaluated on images with low resolution and compression artifacts to ensure it works effectively even under challenging conditions.
5) To further validate the model's robustness, we tested it on images processed with median filtering followed by other operations like Gaussian blur, downsampling, additive white Gaussian noise (AWGN), and compression. This shows that the model can handle more complex real-world scenarios.

The architecture consists of three primary blocks designed to handle image feature extraction and classification efficiently: Preprocessing block, feature extraction block, and classification block as discussed in subsections.

A. Preprocessing Layer

This block applies a Sobel filter to enhance the edges in the image. The Sobel filter helps detect subtle changes introduced by median filtering, which tends to blur edges. By emphasizing these changes, it makes the subsequent feature extraction phase more effective. The input is a grayscale image, typically of size 64×64 pixels.

The Sobel filter [25] is a well-known edge-detection operator commonly used in image processing. It is especially effective for highlighting changes in intensity or gradients within an image. The filter works by using two convolution kernels: one to measure the gradient in the horizontal direction (Sobel-X) and another for the vertical direction (Sobel-Y). The gradient magnitude is then computed to identify edges, which represent significant transitions in pixel intensity. Let the input image be denoted as I, with dimensions $H \times W$.

Step 1: Sobel Filter Kernels The Sobel filters for the x- and y-directions are defined as:

$$K_x = \begin{bmatrix} -1 & 0 & 1 \\ -2 & 0 & 2 \\ -1 & 0 & 1 \end{bmatrix}, \quad K_y = \begin{bmatrix} -1 & -2 & -1 \\ 0 & 0 & 0 \\ 1 & 2 & 1 \end{bmatrix}.$$

Step 2: Convolution Operation Convolve the input image I with K_x and K_y to compute the gradients in the horizontal and vertical directions, respectively:

$$G_x = I * K_x, \quad G_y = I * K_y,$$

where $*$ denotes the convolution operation, and G_x, G_y are of size $H \times W$.

Copyright 2025. Global IT Research Institute (GIRI). All right reserved.
Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on April 08,2025 at 05:52:39 UTC from IEEE Xplore. Restrictions apply.

Step 3: Sobel Residual Calculation Combine the gradients using the Euclidean norm to compute the residual:

$$R_{\text{Sobel}}(i,j) = \sqrt{G_x(i,j)^2 + G_y(i,j)^2},$$

where i, j denote the pixel coordinates. The output R_{Sobel} is an edge-enhanced image of the same dimensions as the input ($H \times W$).

The Sobel filter can reveal subtle changes caused by enhanced edges and highlight residuals that are left behind by median filtering, such as the streaking effect left by median filtering. When applied to noisy images, it makes these residuals easier to observe. This enhanced information is used in machine learning models or neural networks to help them more accurately identify manipulated images, especially when distinguishing between original and filtered versions.

B. Feature Extraction Layer

The architecture model, shown in Figure 1, consists of four convolutional layers designed to progressively extract hierarchical features. Each block includes a convolutional layer followed by batch normalization and a ReLU activation function. A kernel of size 3×3 is applied in each convolutional layer. In the figure, FM represents feature maps, with the dimensions provided at each stage. Max-pooling layers are incorporated between convolutional layers to reduce spatial dimensions while preserving essential features, and dropout layers are included to minimise the risk of overfitting.

C. Classification Block

The features obtained from the previous block are converted into a one-dimensional vector and then passed through fully connected layers for advanced decision-making. The model is designed to classify multiple types of operations applied to an image, including a single median filter or a median filter followed by operations such as Gaussian blur, resampling, and AWGN for compressed and low resolution image datasets. The model classifies images by extracting hierarchical features through convolutional layers and fully connected layers, The final layer generates output class probabilities, enabling binary or multi-class classification depending on the number of classes in a training dataset. During training, the Adam optimiser adjusts the model's parameters, while CrossEntropyLoss is used to compute the loss.

IV. Experiment and Result

A. Dataset Description

To evaluate the performance of the proposed model in detecting image manipulations, we created a custom image dataset based on the high-quality Dresden dataset [24]. A total of 10,000 images were cropped to 64x64 pixels and converted to grayscale to standardize the input data. Pre-compression and post-compression were applied with a quality factor (QF) of 80, before and after performing single or multiple operations. This process simulates the degradation typically caused by compression algorithms. After the initial compression, median filtering with 3x3 and 5x5 kernel sizes was applied to simulate manipulation. The dataset for median filtering includes an equal distribution of 50% images processed with a 3x3 kernel and 50% with a 5x5 kernel. As shown in Table I, the images were compressed again to replicate multiple stages of image processing. The final dataset includes 30,000 training images, 6,000 validation images, and 10,000 test images for each class. This diverse set of images allows for robust model training and evaluation. The approach ensures that the model can detect manipulations effectively across various image quality levels and processing stages.

For binary classification, the following two classes were defined: The sequence of operations for an image (I) undergoing compression with QF 80, followed by median filtering (MF) with kernel sizes of 3x3 or 5x5, and then compression again with QF 80 can be represented as:

$$\text{I} \xrightarrow{\text{Compression}} \xrightarrow{\text{Median Filter}} \xrightarrow{\text{Compression}} \text{MF(I)}$$

In multi-class classification, the sequence of operations the image I undergoes is pre-compression with QF 80, then an initial median filtering, followed by another operation O as given in table I, and finally, post-compression with QF 80. This can be expressed as:

$$I \xrightarrow{\text{Compression}} \xrightarrow{\text{Median Filter}} \xrightarrow{O} \xrightarrow{\text{Compression}} O(\text{MF}(I))$$

TABLE I: Image manipulation operations and parameters applied to the dataset

Operation	Parameters
Median Filtering (MF)	Window sizes: size=3, size=5
Gaussian Blurring (GB)	Kernel sizes: (3, 3), (5, 5)
Resampling (RS)	Scaling factors: 1.2, 1.5
Additive Gaussian Noise (AWGN)	Noise variance: var=0.5^2, var=2^2
JPEG Compression	Quality factors: QF=80%

B. Performance Evaluation of Median Filter Detection Model

In this subsection, we discuss the results obtained from the model's training and evaluation. The training and validation performances are presented, followed by a detailed discussion of the confusion matrix and the model's ability to classify manipulated and original images.

1) Single Manipulation Detection: For binary classification, the model is trained, and the best model is saved, with the overall training accuracy of 96.83% and validation accuracy of 98.89%. The validation accuracy of the class median filter is 99.43% and the original accuracy is 97.75%. These high accuracies suggest that the model can effectively distinguish between manipulated and original images in the dataset.

We compare True positive rate (TPR) of SobelMNet with other existing methods designed for median filtering detection under similar parameters. Table II presents the result of the proposed method in comparison with MedFCN [22] and Streak analysis [21]. The accuracy of the median filter detection approach has been demonstrated to be competitive with state-of-the-art techniques, but further improvements in distinguishing original images are still required.

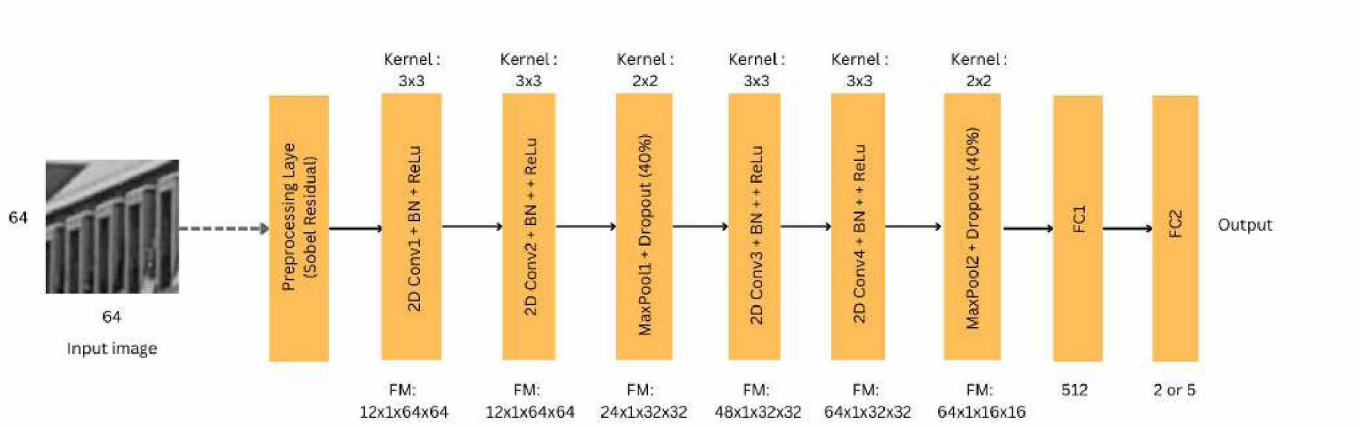

Figure 1: SobelMNet architecture

TABLE II: Comparison of SobelMNet with Different Methods

Method	True Positive Rate (TPR)
Proposed Method	99.43%
MedFCN [22]	98.50%
Streak [21]	97.80%

2) Multiple Manipulation Detection: This section presents the evaluation of the proposed model's performance on the median filter chain dataset. The results include the validation accuracy, class-specific performance, and the confusion matrix. Additionally, the trends in training and validation accuracy and loss are shown in Figure 3.

The model achieved a best validation accuracy of 98.32%, showcasing its effectiveness in identifying manipulated and original images. Table III presents the confusion matrix in percentage, providing a comparative representation of the model's classification performance across five classes. Class-specific accuracies demonstrate the robustness of the model across different image manipulations.

TABLE III: Confusion Matrix for Median Filter Chain Classification with True and Predicted Class labels.

True Class	Predicted Class				
	MF	**MF+AWGN**	**MF+GB**	**MF+RS**	**ORG**
MF	88.33	0.00	5.18	0.06	0.55
MF+AWGN	0.00	100.00	0.00	0.00	0.00
MF+GB	0.25	0.00	93.97	0.06	0.04
MF+RS	0.03	0.00	0.63	93.72	0.00
ORG	1.24	0.00	0.42	0.01	99.41

Figure 3 illustrated the trends in training and validation accuracy and loss. The training accuracy and validation accuracy consistently improved over epochs, demonstrating effective learning and generalization. The training loss decreased steadily, while the validation loss remained low, confirming that the model was not overfitting to the training data. The proposed model's performance on the median filter chain dataset demonstrates its high accuracy and robustness in distinguishing various manipulated and original images. The results underscore the model's potential for real-world applications in image forensics.

C. Result and Analysis

The proposed model SobelMNet achieves 99.43% accuracy in detecting median filtering on low-resolution, compressed images. It outperforms state-of-the-art methods like MedFCN and streak analysis in True Positive Rate (TPR) given in table II. Additionally, it accurately identifies complex operations such as median filtering combined with Gaussian blur, resampling, or AWGN, achieving an average accuracy of 98.32% and the highest accuracy of 100% when the image contains a median filter and AWGN, as shown in Table III.

V. Conclusion and Future Work

The paper presented SobelMNet, a lightweight model that utilized a Sobel filter residual to detect differences between an original image and an image processed with a median filter. Designed with fewer parameters, the model was highly efficient and effectively tested whether an image had been manipulated with a median filter or other median filter chain operations. The results demonstrated that SobelMNet outperformed existing models, achieving an impressive accuracy of 99.43% on compressed and low-resolution images.Moreover, the model offered computational efficiency while maintaining high performance, making it suitable for real-world scenarios involving low-resolution images, such as those found in social media, legal evidence, and archival data. SobelMNet also demonstrated robust performance across diverse images using the Dresden dataset. In future work, this model could be extended and applied to detect other types of image manipulations. SobelMNET's future research can focus enhancing SobelMNet's generalization to detect image manipulations, deepfake generation, copy move forgery, and inpainting can

Space Physics of the Universe and the Evolution of π Space Quantum

Nishant Sahdev, Chinmoy Bhattacharya

Abstract: ***The mathematical constant π, defined as the ratio of a circle's circumference to its diameter, has remained an important base of mathematics and science, yet its origins and connections to fundamental universal properties remain elusive. Traditionally viewed through a mathematical lens, this study proposes a novel perspective, linking π to the space-time of the universe. Building on Lord Kelvin's mathematical formulation involving the square root of π, we explore its physical significance as a measure of the interplay between surface and bulk properties of matter in the cosmos. We demonstrate that π governs critical relationships in spatial pressure dynamics, linking "direct space," "inverse space," and "hybridised space" in equilibrium. Furthermore, π is shown to underlie the transition between bulk and surface phenomena, influencing fundamental processes such as harmonic motion. These findings suggest that π is not merely a mathematical abstraction but a universal parameter deeply embedded in the structure and dynamics of space-time. This perspective opens new avenues for understanding π in relation to the physical universe, offering insights into its non-converging nature and its role as a driving force in cosmic processes.***

I. INTRODUCTION

The space of the universe is composed of space points or the point spaces [10]. The physical variables of the space (in the form of quantum) [12], example - entropy, force, energy, EM - wave, time, mass, etc., and others are formed from the translation, rotation, and vibration of the said space points.

There does exist an equilibrium between 'Direct linear space' and 'Reciprocal or inverse linear space'. In the following Figure 1, the said three spaces have been shown diagrammatically. The concept of the 'direct space - inverse or reciprocal space' is:

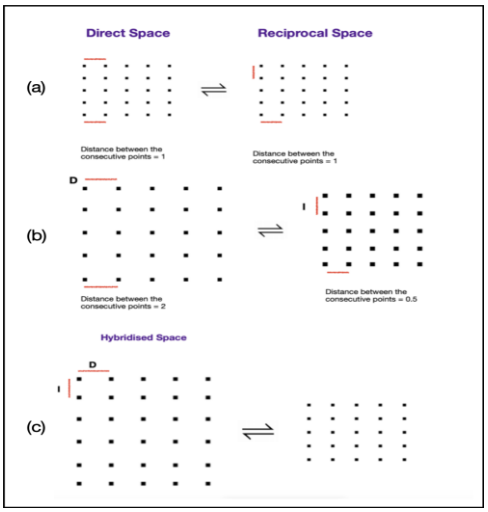
I. The product of the distance between two consecutive points in the direct space (D) and the corresponding distance between two points in the inverse space (I) is always unity
II. Whenever there is any event taking place in either of the two said spaces, the inverse event will take place in the other space. For example following figure 1 (b), the distance between the two consecutive points of direct space is doubled, the distance of the two consecutive points in the inverse space will be halved such that the product of the two new distances retained to be unity.
III. The hybridised space of the universe is formed from the 'direct space' and the 'reciprocal space' in the manner shown in Figure 1(c) below.

So each side (H) of a 'unit cell' of the hybridised space is a geometric mean of D and I: $H = (D \times I)^{1/2.}$



[Fig.1: (a, b & c) Geometry of Direct Space, Inverse Space & Hybridised Space] [10]

This is to understand the fact that the space of the universe must exist in the form of 'hybridised' space, as explained above. Otherwise, the space would have either expanded infinitely or contracted to such an extent that everything would have completely collapsed.

We learn a great deal from the literature about various aspects of the universe, including phenomena such as 'space ripples,' 'gravitational waves,' and 'distorted spacetime,' among others [14]. Notably, the parameter π is intricately related to these phenomena, as seen in the Einstein Field Equations (EFE) of the general theory of relativity. However, there is limited scope in the current literature for students and the scientific community to gain a clear understanding of the physical significance of the parameter π [15]. Until the parameter π is thoroughly understood, the cloud of ambiguity surrounding the

© Copyright: All rights reserved.

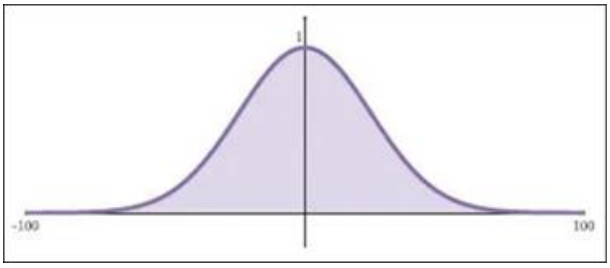
theories of relativity, cosmology, and space physics will continue to loom overhead.

If the space points in the 'direct space' and the 'reciprocal space,' or the 'direct space' and the 'reciprocal space' themselves, continued to remain in equilibrium with each other forever, no energy [4], no mass, no matter would have formed at all, and no evolution would have taken place—neither of plants, trees, rivers, oceans, mountains, the animal kingdom, nor the human race of the universe..

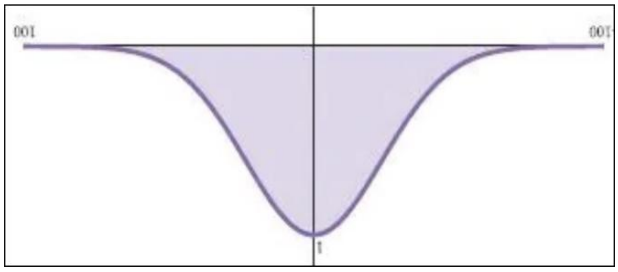
For matter to form, the space points must come closer to each other and interact. In the linear 'direct space' and the associated 'reciprocal space,' the mathematical probability of the space points coming closer to each other is very low because the said points are static. For matter (mass and energy) to form, the space points must move from the bulk interior of the space to the surface, interact with each other, and then flow back to the bulk of the space. A dynamic equilibrium must exist in the space as follows.

Rate at which the space points move from the bulk to the surface = Rate at which the space points move from the surface to the bulk of the space

So, to enable the above equilibrium to occur, space possesses its own impulses, which are short-lived 'push forward forces (PFF)' and 'pull back forces (PBF)'. As shown in Figures 2 and 3, these forces are represented as exponential functions. They exhibit peak maxima or minima, are of a non-converging type, and extend infinitely in both directions.



[Fig.2: The Short-Lived Force Impulse of the Direct Space of the Universe in the form of Square Root of Pi] [12]



[Fig.3: The Short-Lived Inverse Force Impulse of the Reciprocal or Indirect Space of the Universe in the form of Inverse of Square Root of Pi] [12]

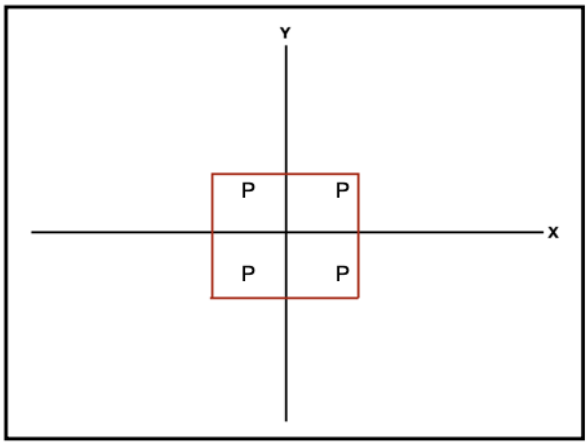
The area under the curves of the Figure 2 and 3 is being represented by Lord Kelvin equations as given below [12]:

$$\int_{-\infty}^{\infty} e - x2\, dx = \sqrt{\pi}. \quad \ldots \quad (1)$$

The area under the curve of Figure 3 is obtained by inverting the LHS and RHS of the above equation (1), which gives us the expression $(1/\pi)^{1/2}$. The value of the above integral, or the area under the curve, is 1.772... (which is the sum of all the smallest possible unit squares under the curve in Figure 2, and the said unit squares are made up of the points in direct space) [13]. Though the above equation of Lord Kelvin is very important and significant for the proper understanding of the quantum nature of the universe, it must be noted that this equation has been highly neglected since its inception in the 19th century. Neither mathematicians nor physicists have fully realized the profound underlying philosophy of the said equation, and as a result, it has not earned the recognition it deserves. In this article, it will be straightforwardly proven that the principles of classical physics, quantum physics, quantum mechanics, the theories of relativity, the recently discovered Theory of Space Quantization (TSQ) [2], and modern quantum computing are all based on π, and this π is grounded in this single equation of Lord Kelvin. The π parameter is an integral part of all the aforementioned theories, as well as an essential element of our very breath of life. The origin of this π can only be traced back to the space and the equation of Kelvin.

As has been mentioned earlier in this article [9], any event occurring in the direct space enforces an inverse event in the reciprocal space [10]. So this 'PFF short lived impulse $(\pi)^{1/2}$' of the direct space is reciprocated as a 'PBF short lived impulse $(1/\pi)^{1/2}$' of the reciprocal space [3]. Now, in direct space, the superposition (overlapping or hybridisation) of the four numbers of 'PFFs' occurs, and a π quantum is evolved from it. Similarly, the overlapping of the four numbers of 'PBFs' in reciprocal space produces an 'anti-π or inverse π space quantum.

- Note that to obtain the square of any variable, say P, representing a straight line segment, the usual practice is to place the variable P in both longitudinal and lateral positions first, and then place them at equal distances in the diametrically opposite direction. The enclosed area is computed as shown in Figure 4 below, and the same principle has been followed to find the topology of π and (1/π), respectively.



[Fig.4: Process of Finding out the Square of a Variable P] [3].

Figures 5 and 6 below show the mechanism of formation of the π quantum and anti π quantum respectively.

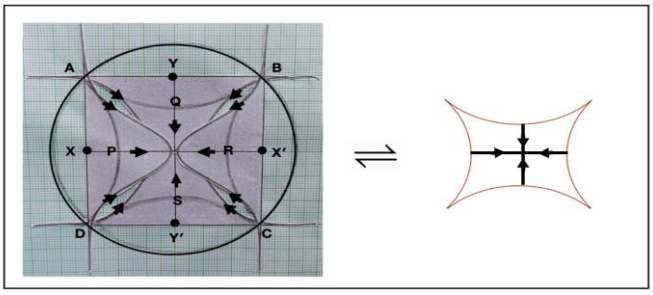
[Fig.5: Evolution of π Quantum From √π From the Space Time in the from of the Smallest Circle of the Universe] [1]



[Fig.6: Evolution of Anti π Quantum (2-D Saddle)] [5]

In Figure 5, the Following Points are to be Noted:

1. At the junction points A, B, C & D of the four numbers of √π areas, the two perpendicular forces are acting in each of the points (for point A, AK & AE, for point B, BL & BH, for point C, CG and CM, for point D, DF, DN and the resultants of the said forces are AP, DS, RC & DS respectively. So due to this resultant forces acting on points A, B, C & D, the points A, B, C & D are driven outwards and the new positioning of the said 4 points become P, Q, R & S respectively.
2. The sixteen numbers of points starting from X, H, Q, L, Y, K, P, E, X′, F, S, N, Y′, M, R, G, in fact form the circumference of a circle and whose area would be π.
3. This said π, or the circle formed, is the smallest possible circle in the universe, with an area of π and a radius of unity (OP = OQ = OR = OS = 1.0). It should be noted that this unit length represents the smallest possible length in the universe.
4. Now, in Figure 5, O is the midpoint of YY′. As the length of YY′ increases, the distances between points P & Q and R & S will also increase, causing the circumference of the circle to increase. Therefore, the circumference of the circle is directly proportional to the diameter YY′, and the constant of proportionality is indeed π. The ratio of the circumference to the diameter of a circle is constant, but the reason behind this constancy, or the mechanism responsible for it, has yet to be discovered. In this article, the long-standing mystery is revealed.
5. In Figure 6, it is shown that four (1/√π) areas come into close proximity with each other to form a (1/π) area or a 2D saddle APDSCRB. In fact, partial overlaps of the (1/√π) curves occur, and as shown in Figure 6, a significant pullback situation develops, causing the points X, X′, Y, and Y′ to be pulled inward and shifted to the points P, Q, R, and S, respectively, thus forming the saddle APDSCRB. The area of the 2D saddle [8] thus formed is (1/π).
6. Einstein postulated that somewhere in the universe, there does exist a point of singularity [14]. However, it was a qualitative statement, which originated from the high level of his intuitiveness [12]. Here, it is shown in the 'inverse space' that point O is the point of singularity, as all the forces are directed towards point O only (as shown by the arrows in Figure 6) [5]. In the recently discovered Theory of Space Quantization (TSQ) it has been shown that from the said point of singularity [11], the entire cosmological phenomena of the universe [7] have evolved.

A. Different Interpretations of π and (1/π)

- *Interpretation 1:* Regarding Figure 5, it should be noted that the space points along the diameter XX′ of the circle are in a state of certainty, but as soon as they move to the circumference of the circle, the positional uncertainty increases. Now, XX′ can be considered the bulk, and the circumference is the surface. Therefore, π can be interpreted as an index of:

'Push of the space points from bulk certainty to surface uncertainty' or 'the forward push forces of the universe' in the form of the quantum of the smallest possible volume of direct space.'

For the same reasoning as above but in the inverse sense, (1/π) is an index of:

'Pull of the space points from surface uncertainty to bulk certainty' or 'the backward pull forces of the universe' in the form of the quantum of the smallest possible volume of inverse space.'

- *Interpretation 2:* The forward push force, by which the space points from the bulk of direct space are driven to the surface of direct space (in the form of π or multiples of π), multiplied by the pull-back force, by which the space points from the surface of inverse space are driven toward the bulk of inverse space (in the form of the reciprocal of π or its multiples), is unity.

- *Interpretation 3:* The 'pressure,' P, of the hybridised space of the universe in a state of equilibrium is unity, since. P = [(push forward force, π) x (pull back force, 1/π) = 1. The pressure is a dimensionless parameter indeed. In the 'time-space' of the universe the above said equilibrium does persist but sometimes in a day the π –(1/π) equilibrium shifts to the right hand side or to the left hand side and as a result the pressure fluctuates (either P>1 or P< 1) and such fluctuations in pressure leads to the 'tides' in the rivers and oceans and as a result the water rises to high level when P>1 and the level falls when P<1.

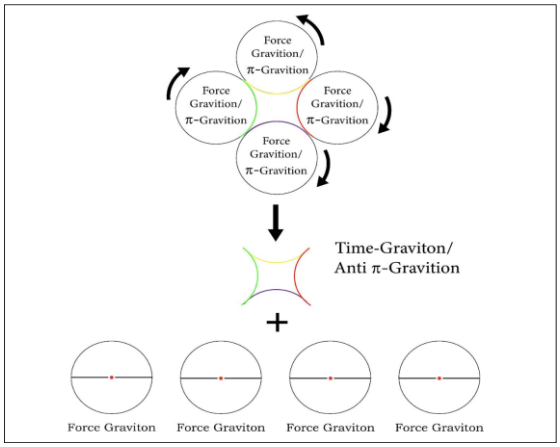
- *Interpretation 4:* π is an expanding factor of linear space that is transformed into non-linear space or space with curvature. As shown in Figure 5, the points of the linear space (A, B, C, and D) are mapped to points on the curvature of the circle. For example, if we consider that throughout the length XX′ in Figure 5, there are n points in space and the radius is r, then the average distance between the space points is (r/n) [1]. When these points are shifted and placed on the circumference of the circle [14],

the average distance between the points becomes (πr/n), which is greater than (r/n)

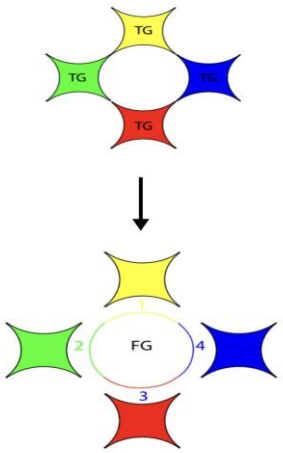
© Copyright: All rights reserved.

[16]. Therefore, another definition of π in relation to the space points would be: π = (Average inter space points distance in the curved direct space)/ (Average inter space points distance in the linear direct space) (1/π) = (Average inter space points distance in the curved direct space)/ (Average inter space points distance in the curved indirect space) So π is the factor of the enlargement or expansion of direct linear space and (1/π) is the factor of the squeezing of the linear direct space [17].

- *Interpretation 5:* π and 1/π, being the universal space quanta of the universe, are interconvertible with each other. In Figure 7 below, from the topological orientations of four π quanta in space, one anti-π quantum is formed [6]. The corollary is also true: from the topological orientations of four anti-π quanta in space, one π quantum is formed [7].



[Figure 7 (a) Formation of π Quantum from Anti π Quantum] [7]



[Fig.7(b): Formation of π Quantum from Anti π Quantum in the Space] [7]

B. From the Very Ancient Days People Have Been Educated Mainly the Following Properties of π

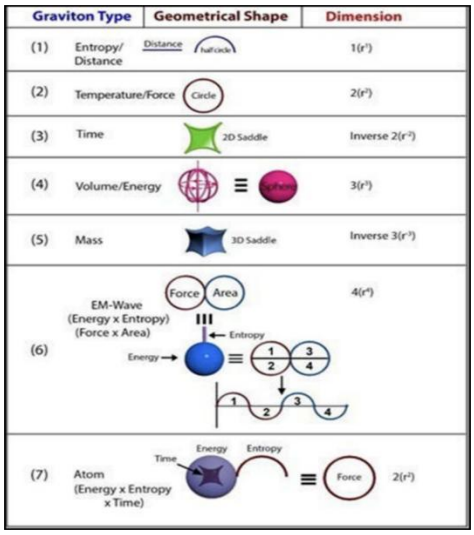
1. The parameter π is a universal constant in the fields of science, principally in mathematics, physics, and geometry.
2. The parameter π is irrational, and its value is 3.14159265359…; it is also a non-terminating, non-repeating decimal.
3. It is the ratio of the perimeter to the diameter of a circle, which always yields a non-converging value of 3.14159265359…
4. The half-circumference of a circle subtends an angle of π radians at the center of the circle (such that π radians = 180 degrees).

Regarding the π parameter, numerous discussions have been held in the past, many research papers published, and countless seminars organised. Various equations for π have been proposed over time, in all corners of the globe, to understand its origin and its mysterious non-converging character. This is, in fact, an endless exercise, and discussions are still ongoing to this day, but the mystery remains elusive.

The parameter π is a closely related, real-life constant of the universe, omnipresent and reminiscent of the eternal proverb, 'God is omnipresent.' The global scientific community has been fascinated by this god-like parameter, π, and honors it by observing a particular day each year as International π Day—March 14th.

The current research article reveals all the mysteries of π. The non-converging nature of π is deeply rooted in the geometry of the square root of π, as shown in Figure 2. The area under the curve in Figure 2 asymptotically extends to infinity, imparting the form of an irrational number. Since the square of any irrational number is always irrational, π, being the square of the square root of π, is also irrational. Similarly, the reciprocal of π (1/π) is also irrational, since the reciprocal of the square root of π is irrational as well (the reciprocal of any irrational number is always irrational). The circle shown in Figure 5 represents the smallest possible circle in the universe, with its radius considered to be unity. Similarly, the 2D saddle shown in Figure 6 represents the smallest 2D saddle in the universe, with its radius also considered to be unity.

[The π is the most fundamental quantum or packet (π quantum) of the following push forward quantum of the direct space of the universe (as shown in Figure 8)] [9].



[Fig.8: Geometrical Profile of the Space Quantum of the Universe] [9]

C. π Circles and Energy Continuum

The space π circles formed from π cannot have radiuses (r) of any value of desire. The values of r have to be full integers like 1, 2, 3, 4, 5, 6 etc..since the lengths of the space (of all the direct space, inverse space and the hybridised space) are

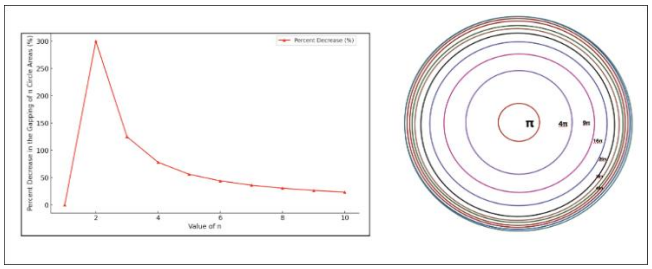
© Copyright: All rights reserved.

quantized and the lengths cannot be a fraction. Niels Bohr proposed that the electrons cannot rotate around the nucleus in any orbit of their own choice but only in the selected orbits they can rotate and those are the quantized orbits. As a matter of fact what he had talked about is 'space quantization' but how and why space is quantized in the integral form of π (as described in the previous paragraph) could not be demonstrated by him. The mystery of space quantization is revealed and described in this article only for the first time in science through π 'space quantum'.

The following table shows how the energy levels increase from the smallest possible circle with an area of π ($\pi(1)^2$, where r is the radius of the smallest circle) to $\pi(2)^2$, $\pi(3)^2$, $\pi(4)^2$, $\pi(5)^2$, or 4π, 9π, 16π, 25π, and so on, up to $n^2\pi$, where n is an integer with values 1, 2, 3, 4, 5, etc.

Table-I: Percent Change of Gaping of the π Circles with Increase of n

Value of n	Value of n2(π)	Gap of the area of the circle over the previous value of n	Percent increase of grapping
1	*	-	
2	4π	3π	300%
3	9π	5π	125%
4	16π	7π	78%
5	25π	9π	56%
6	36π	11π	44%
7	49π	13π	36%
8	64π	15π	30.6%
9	81π	17π	26.5%
10	100π	19π	0.234



[Fig.9: Graphical Presentation of the Percentage Change of Gapping of the Area of the π Circle with Increase of n] [14]

From the data presented in Table1 and from the Figure 9 (Percentage decrease of gaping of the areas of the circles against the value of n) it is being clearly revealed that the gaping of the circles The energy decreases exponentially, and ultimately, the gap disappears. In the language of quantum physics, the energy levels of the electrons around the nucleus transition from quantized to a continuous state, or the energy levels become continuous from a state of 'discontinuous,' 'discrete,' or 'quantized.' The physical significance of the phenomenon is that higher energy levels cannot remain confined within a certain area or volume, as this would have led to the death of living organisms due to the high energy density. The spread of the higher energy levels must be greater so that their intensity is reduced at any point in space. This is why the 'energy density of space remains constant' [1]. This is also referred to as the safeguard of nature against the 'UV catastrophe' [14].

D. Simple Harmonic Motion and π

In Figure 5, the length OP is considered to be unity, representing the radius of the smallest circle. The space point O is at the bulk, and the point P is on the surface/circumference. Due to the angular force developed from point A, as shown in the figure, the space point O moves to position P, and point P reaches position S. Since the circumference of the circle is 2π (which is divided into 4 equal segments: PS, SR, RQ, and RP), the length of each segment is (π/2). Thus, the unit length of OP (the distance from the surface space point P to the bulk space point O) is transposed to a length PS [where length = (π/2), representing the distance between the two surface points P and S], and it becomes (π/2) times its original length. This effect is referred to as 'the surface-to-bulk certainty being transposed to surface-to-surface uncertainty of the space points.'

For the 2D saddle, as shown in Figure 6, by the same reasoning, this can be described as 'surface-to-bulk uncertainty being transposed to bulk-to-bulk certainty' [for the segments AQ and QO or DS and SO]. The effect of π is to increasingly randomise the space points, while the effect of (1/π) is to take the space points to an ordered arrangement, ultimately approaching 'singularity.'

In simple harmonic motion (the case of a horizontal pendulum), a π space quantum is responsible for the smallest possible oscillation of the pendulum. The first swing of the pendulum from its mean position is driven by the first angular force (say AP, as shown in Figure 5), which moves the pendulum bob from point P (the mean position) to position S (say extreme left). The next angular impulse of force, DS, brings the pendulum bob back to the mean position, where point S moves to point R. In the subsequent angular impulse, force CR moves the pendulum bob to the extreme right position, and point R reaches point Q. The final angular impulse brings the bob back to the mean position, and point Q returns to point P. This completes one full 'time period of oscillation' of the pendulum.

II. CONCLUSION

The following conclusions are being drawn:

1. There exist short-lived force impulses in direct space, in the form of the square root of π, which are Gaussian in nature. From the topological combinations of the four numbers of such impulses, the universal π parameter is formed in the shape of a circle.
2. The mechanism for the formation of circular quantum forces in the universe is revealed in the exercise conducted in this article, which was previously elusive.
3. There do exist short-lived inverse force impulses in the indirect or inverse space in the form of the square root of (1/π), which are also Gaussian in nature. From the topological combinations of the four numbers of such impulses, the universal (1/π) parameter is formed in the shape of a circle.
4. The mechanism of the formation of inverse circular quantum forces in the universe is revealed in the exercise conducted in this article, which was also elusive earlier.
5. The simple harmonic motion of a horizontal pendulum makes use of the four numbers of short-lived force impulses in direct space (in the form of the

© Copyright: All rights reserved.

square root of π) to complete one full cycle of evolution (T), which gives rise to the formation of the π space quantum. In other words, one π space quantum (which already exists in space) disintegrates and generates a full cycle of the pendulum's revolution. At the same time, due to this full oscillation, a π space quantum is evolved and subsequently put back into space. The principle of energy conservation is maintained in this manner. The moral of this phenomenon is that whatever quantum is borrowed from space to perform work (such as entropy quantum, force quantum, energy quantum, etc.) must be repaid to space. Similarly, if space borrows a quantum from a system, it repays it.

6. The physics of simple harmonic motion (such as the swinging of pendulums), as taught to students at the school and higher levels, must be updated immediately, as the current material being taught is largely abstract.

- The following concepts of conventional physics regarding the horizontal pendulum are contradictory:
- The velocity of the pendulum bob is maximum at the mean position.
- The accelerations of the pendulum bob (towards the mean position) are maximum at the extreme left and extreme right positions, respectively.

The contradictory nature of the above two statements lies in the fact that for each swing of the pendulum (a. mean position to extreme left, b. extreme left to mean position, c. mean position to extreme right, and d. from extreme right back to the mean position), the angular forces of exactly the same magnitude are acting. Hence, in each swing, the pendulum sweeps out the same volume of space and moves with the same velocity throughout its movement. This suggests that the simple harmonic motion of a pendulum is quantized, not continuous. Therefore, applying Newton's laws of motion (which are valid for continuous motion) and using equations such as Force = mass x acceleration to derive the kinetic equations of motion of a pendulum are not justified. This new approach needs to be discussed.

7. The non-converging character of π originates from the topology or geometry of the infinitely spread, short-lived force pulses of the universe in the form of the square root of π, and this non-converging character is retained in the value of π as well.

DECLARATION STATEMENT

After aggregating input from all authors, I must verify the accuracy of the following information as the article's author.

- **Conflicts of Interest/ Competing Interests:** Based on my understanding, this article has no conflicts of interest.
- **Funding Support:** This article has not been funded by any organizations or agencies. This independence ensures that the research is conducted with objectivity and without any external influence.
- **Ethical Approval and Consent to Participate:** The content of this article does not necessitate ethical approval or consent to participate with supporting documentation.
- **Data Access Statement and Material Availability:** The adequate resources of this article are publicly accessible.
- **Authors Contributions:** Each author has individually contributed to the article. Great Idea given by Dr. Chinmoy Bhattacharya and synopsis, conceptualization, methodology, writing and critical thinking done by Nishant Sahdev.

AUTHOR'S PROFILE

Chinmoy Bhattacharya earned his PhD in Polymer Physics in 1988 and completed post-doctoral research on liquid crystal polymers at Laval University, Canada. Returning to India in 1991, he joined ICI India Ltd. and later founded his own paint company. He is a former chairman of the Indian Paint Association and a leading figure in India's paint industry. Bhattacharya's research spans quantum gravity, cosmology, and dark matter, culminating in a unified quantum gravity theory and a novel space quantization model. He has numerous publications in prestigious journals, including his work on a new initiator for free radical polymerization, published in *Polymer Chemistry* (Royal Society of Chemistry, DOI: 10.1039/COPY00180E). As a guest faculty member at the University of Calcutta, he teaches Colour Physics, Polymer Physics, and Rheology of Coatings to postgraduate students, continuing to inspire the scientific community.

Nishant Sahdev is a distinguished researcher in Theoretical Physics and currently serves as a Research Affiliate at the University of North Carolina at Chapel Hill, United States. With extensive national and international experience at prestigious institutions, Nishant's academic journey spans Delhi Technological University, New Delhi, India, and the University of Debrecen, Hungary. His work is based on quantum gravity, cosmology, and dark matter, contributing to the development of a unified quantum gravity theory and an innovative space quantization model. Nishant has published extensively in leading scientific journals and has further honed his expertise in advanced mathematics during research training at King's College London, England. Dedicated to expanding the frontiers of scientific knowledge, Nishant's current work focuses on pioneering theories and equations that challenge conventional understanding. Beyond his academic pursuits, he is also a passionate romance writer and a columnist for national newspapers, seamlessly blending science with creative expression.

SS-EMERGE - self-supervised enhancement for multidimension emotion recognition using GNNs for EEG

Chirag Ahuja[1,2]✉ & Divyashikha Sethia[2]

Self-supervised learning (SSL) is a potent method for leveraging unlabelled data. Nonetheless, EEG signals, characterised by their low signal-to-noise ratio and high-frequency attributes, often do not surpass fully-supervised techniques in cross-subject tasks such as Emotion Recognition. Therefore, this study introduces a hybrid SSL framework: Self-Supervised Enhancement for Multidimension Emotion Recognition using Graph Neural Networks (SS-EMERGE). This model enhances cross-subject EEG-based emotion recognition by incorporating Causal Convolutions for temporal feature extraction, Graph Attention Transformers (GAT) for spatial modelling, and Spectral Embedding for spectral domain analysis. The approach utilises meiosis-based contrastive learning for pretraining, followed by fine-tuning with minimal labelled data, thereby enriching dataset diversity and specificity. Evaluations on the widely-used Emotion recognition datasets, SEED and SEED-IV, reveal that SS-EMERGE achieves impressive Leave-One-Subject-Out (LOSO) accuracies of 92.35% and 81.51%, respectively. It also proposes a foundation model pre-trained on combined SEED and SEED-IV datasets, demonstrating performance comparable to individual models. These results emphasise the potential of SS-EMERGE in advancing EEG-based emotion recognition with high accuracy and minimal labelled data.

Keywords EEG, Self-Supervised Learning, GNN, Constrastive Learning, Cross-Subject Emotion Recognition

The rapid advancement in data acquisition technologies and the exponential growth in data volume have made it increasingly inadequate to rely solely on supervised datasets to gain insights into environmental phenomena or understand the human brain's complexities. Supervised learning paradigms require vast amounts of labelled data, often expensive,time-consuming, and limited scope. In fields such as Computer Vision (CV)[1,2], Natural Language Processing (NLP)[3,4], and Audio Processing[5,6], recent progress has underscored the significance of leveraging extensive data available on the internet to develop foundation models. These models capture fundamental principles governing these modalities or their intermodal relationships, enabling robust performance even with limited labelled data.

Understanding brain dynamics through Electroencephalogram (EEG) signals provides crucial insights into neurological activities. These non-invasive signals are crucial in applications like emotion recognition, stress estimation, and sleep staging[7–9]. In the context of EEG-based emotion recognition, evaluations can be conducted in several ways to validate the robustness and generalizability of models:

1. **Subject-Independent Evaluation (a.k.a. Cross-Subject or LOSO):** This method tests the model's ability to generalise across individuals. It involves training the model on data from a subset of subjects and testing it on data from entirely new subjects not included in the training set. This evaluation is crucial for applications where the model must perform well on new users without retraining.
2. **Subject-Dependent Evaluation:** This approach tests the model on the same subjects but on different sessions or instances than those used for training. It assesses how well the model performs when it has already been exposed to data from the test subjects during training. This type of evaluation might be less challenging than subject-independent tests since the model is already tuned to the characteristics of the specific subjects.

3. **Subject-Mixed Evaluation (a.k.a. Trial-Level Random Split):** In this evaluation, all EEG trials across subjects are pooled together and randomly split into training and testing sets (e.g., 80-20), without ensuring subject separation. As a result, trials from the same individual may appear in both training and test sets. While this setup facilitates rapid benchmarking of model architectures, it does not accurately reflect cross-subject generalization and may lead to inflated performance due to subject-specific feature leakage.

These evaluation strategies are essential for developing EEG-based systems that are both effective and adaptable to various real-world scenarios. However, unlike more straightforward data types encountered in Computer Vision (CV) or Natural Language Processing (NLP), EEG data collection is fraught with unique challenges. These challenges include variability in sensor types, data collection errors, and individual differences in demographics and health, all of which contribute to high noise levels and low signal. These issues are particularly pronounced in emotion recognition, where the relevant signals can be subtle and frequently masked by artifacts or unrelated physiological events. Representation learning isolates and enhances the informative components of EEG signals crucial for distinguishing between emotional states. It mitigates the need for extensive labelled datasets for each emotional state by leveraging the intrinsic properties of the data.

Self-supervised learning (SSL), a prominent method within representation learning, excels in extracting rich representations from unlabeled EEG data[10–13]. By learning from the inherent variability among individuals, SSL facilitates the development of models that are accurate and capable of generalising across diverse subjects[14,15]. Once trained, these models can be fine-tuned for specific downstream tasks, such as emotion classification, with only minimal labelled data. It represents a significant paradigm shift in machine learning, especially for applications with scarce or expensive labelled data. The SSL techniques can be broadly categorised into two main types:

- *Generative Models:* These models aim to reconstruct their input data, thereby learning rich and detailed data representations. The process involves predicting missing parts of data or generating new data instances based on the observed data, which helps the model capture the underlying structure of the input distribution.
- *Contrastive Models:* These models learn by comparing and contrasting different data instances. They typically work by distinguishing between similar (positive) and dissimilar (negative) pairs of data instances, which sharpens their ability to discern critical features that define the data.

Both approaches have proven effective across various domains, including image processing, natural language understanding, and audio recognition, by leveraging large amounts of unlabeled data to learn valuable representations without explicit annotations. Specifically, in the context of EEG signals, a survey by Rafiei et al.[16] indicates that generative modelling-based SSL techniques excel with smaller datasets. In comparison, contrastive learning techniques benefit from larger datasets.

Recent advancements in Self-Supervised Learning (SSL) have significantly impacted emotion recognition using EEG signals[17–20]. Based on state-of-the-art research, the following summary illustrates diverse SSL techniques and their applications to EEG data analysis, as detailed in Table 1.

Background and related work

The Multi-view Spectral-Spatial-Temporal Masked Autoencoder (MV-SSTMA)[17]employs a generative SSL approach to reconstruct signals across spectral, spatial, and temporal domains using the Masked AutoEncoder (MAE) technique, achieving high accuracy on the SEED dataset[21]. However, it shows a significant decrease in performance in self-supervised settings compared to fully-supervised ones. Additionally, MV-SSTMA's[17] reliance on multi-head attention for spatial modelling assumes all channels are interconnected, potentially leading to overfitting, as it does not consider the actual electrode placements.

Graph-based Multi-Space Self-Supervised (GMSS)[19]utilises a spatial contrastive approach via Simple Contrastive Learning (SimCLR)[11]within a Graph Neural Network (GNN). It models spatial and spectral domains, showing decent cross-subject performance on SEED[21], but lacks robustness on the more challenging SEED-IV[22] dataset, indicating limitations in model adaptability across datasets.

Work	SSL Tech.	Model	Domains	SEED[21]		SEED-IV[22]		Limitations
				Fully SL	SSL	Fully SL	SSL	
MV-SSTMA[17]	Generative	Multi-Domain reconstruction (MAE)	Spectral, Spatial and Temporal	95.32	83.49	92.82	82.55	Doesn't explore the Contrastive Learning
GMSS[19]	Spatial Contrastive (SimCLR)	GNN	Spatial and Spectral	86.52	76.04	86.67	65.31	Cross-subject is decent across SEED[21]but poor on SEED-IV[22] shows it lacks across different datasets.
DS-AGC[20]	Contrastive (SimCLR)	GNN	Spatial and Spectral	85.00	82.18	65.79	61.32	SEED[21]numbers are good for cross-subject whereas SEED-IV[22] fully-supervised numbers show that the model is not robust.
SGMC[18]	Meiosis-based Contrastive Learning	ResNet(CNN)	Temporal	94.04	89.83	NA	NA	Only models in the temporal domain, without fully exploiting the potential of spatial interactions between channels. Also, it does not evaluate cross-subject evaluation.

Table 1. State of the art Emotion Recognition work done using SSL. SL: Supervised Learning, SSL: Self Supervised Learning, Tech.: Technique.

Differential Entropy-based Self-Attentive Graph Convolution (DS-AGC)[20], which incorporates spatial contrastive learning with Simple Contrastive Learning (SimCLR)[11]and a Graph Neural Network (GNN) architecture, demonstrates good cross-subject performance on the SEED dataset[21]. However, it struggles with robustness on the SEED-IV dataset[22] in both fully-supervised and self-supervised settings. It indicates that the model architecture may not be sufficiently adaptable or resilient, as it fails to perform effectively even in fully-supervised scenarios.

Self-Supervised Group Meiosis Contrastive Learning (SGMC)[18]implements a contrastive model using SimCLR[11], over a group of subjects coming from the same stimuli while performing meiosis augmentation and contrastive loss for self-supervised learning with a Convolutional Neural Network (CNN) architecture, focusing on the temporal domain. It shows outstanding results on SEED[21]but does not evaluate its performance on SEED-IV[22], nor fully utilises spatial interactions between EEG channels. Furthermore, it lacks evaluation across cross-subject variations. Enhancing contrastive learning with meiosis-based techniques improves model performance by creating more diverse negative samples.

The works summarised in Table 1 collectively highlight a recurrent theme: while SSL techniques have significantly advanced emotion recognition from EEG data, they still face challenges in maintaining robustness across diverse subjects and datasets. These limitations often stem from model architectures that focus predominantly on individual domains such as temporal, spatial, or spectralâ€"without effectively integrating them.

Causal Convolutions, as employed in Temporal Convolutional Networks (TCNs), address temporal dependencies by ensuring that each time step is influenced only by the current and past inputs, preserving the causality intrinsic to EEG signals[23–25]. This feature is particularly beneficial for emotion recognition, where the sequence of brain activity reflects emotional transitions. Furthermore, dilated convolutions allow TCNs to capture long-range temporal dependencies without excessive computational overhead, providing an efficient alternative to recurrent networks.

*Graph Attention Networks (GATs)*dynamically enhance spatial domain modelling by assigning varying importance to interactions between EEG channels. Unlike static graph methods, GATs utilise an attention mechanism that identifies the most relevant electrode relationships for a given emotional or cognitive state, making them highly adaptable to the variability present in EEG data[26,27]. This capability is crucial for capturing spatial dependencies, as interactions between brain regions vary across subjects and tasks. GATs prioritise key spatial patterns, improving robustness in subject-dependent scenarios.

*Spectral Embeddings*leverage frequency-domain features to encode EEG signals into a compact and meaningful vector space. Differential Entropy (DE), in particular, has been widely recognised as one of the most practical features for emotion recognition, as it captures variability across critical frequency bands (e.g., delta, theta, alpha, beta, and gamma)[7,17]. By deriving DE-based embeddings before modelling spatial and temporal aspects, SS-EMERGE ensures that frequency-domain information is preserved and seamlessly integrated into the overall representation.

The combination of these techniquesâ€"temporal modelling with Causal Convolutions, spatial relationship modelling with GATs, and frequency-domain encoding with Spectral Embeddingsâ€"offers a unified and holistic framework in SS-EMERGE. Each component contributes uniquely to addressing the inherent challenges of EEG-based emotion recognition. Temporal modelling captures the dynamic evolution of emotional states, spatial modelling identifies critical inter-channel relationships, and spectral embeddings provide robust frequency-domain features. Together, these techniques enable SS-EMERGE to achieve superior generalizability and performance across diverse datasets and subject variations, overcoming the limitations of methods that prioritise single-domain representations.

This work proposes a comprehensive approach to enhance EEG-based emotion recognition by integrating self-supervised learning with multidimension graph neural networks. The key innovations and contributions of this work are as follows:

1. Proposal of SS-EMERGE model for SSL training for Emotion Recognition with main contributions as follows:
   (a) *Temporal, Spatial, and Spectral Integration*: Combines causal convolutions for encoding temporal interactions, and using Graph Attention Transformer (GAT)[28]inspired by famous multivariate time series anomaly detection model, MTAD-GAT[27]for learning spatial channel interactions, and borrowing integration of spectral domain by using spectral embeddings from MV-SSTMA[17]. The multidimension integration ensures a holistic representation of EEG signals, capturing the intricate dynamics in different domains.
   (b) *Meiosis Augmentations Based Contrastive Learning*: Integration of the meiosis-based contrastive learning technique proposed by SGMC[18]for EEG. It performs contrastive learning on groups of stimuli, such as video samples in SEED[21]and SEED-IV[22], instead of individual subject samples. The augmentation technique cross-exchanges EEG segments within a video group, creating new augmented samples that facilitate contrastive learning and enhance the model's ability to generalise across different subjects and emotional states.
   (c) *Foundation Model for SEED and SEED-IV*: Proposes a foundation model for both SEED[21]and SEED-IV-[22]datasets that can be further fine-tuned on data collected through the same EEG sensor used by SEED-[21]and SEED-IV[22] to be used for the downstream task of Emotion Classification.
2. Evaluates Subject Dependent performance on SEED[21]and SEED-IV[22] datasets:

(a) Subject dependent SSL performance with respect to fully-supervised learning for SGMC[18] and SS-EMERGE.
(b) The effect of foundational pretraining while combining SEED[21]and SEED-IV[22] on cross-subject classification performance.

This work introduces a novel SS-EMERGE model that integrates SSL and GNN for advanced emotion recognition from EEG data. It addresses key challenges, including the need for extensive labelled datasets and handling high noise and variability in EEG signals. The SS-EMERGE model achieves 95.05% accuracy on SEED[21]and 83.67% on SEED-IV[22] with minimal labelled data for emotion recognition.

The structure of this paper is organised as follows: First, Section 2 defines the problem statement and details the proposed solution. Next, Section 4 showcases the experimental results obtained by applying the methodology described in Section 2. It is followed by a Section on Experimental Setup. Finally, Section 5 summarises the findings and discusses potential future research directions.

Methodology

This section details SS-EMERGE for emotion recognition using a comprehensive framework that integrates multiple domains of EEG data processing. The methodology includes a pretraining phase with Meiosis-based contrastive learning followed by a fine-tuning phase with labelled data. The system processes EEG data in spectral, spatial, and temporal domains, utilising specialised network components for each aspect.

Figure 1 describes the overall flow of SS-EMERGE that integrates a dual-phase approach to enhance the effectiveness of an EEG-based emotion recognition model. Phase-1 (pretraining) and Phase-2 (fine-tuning) followed by evaluation for the held-out subject, are briefly explained as follows:

1. **Phase-1 (pretraining without labels)**: This phase learns the generalised features from a diverse EEG dataset using self-supervised contrastive learning. This phase employs components such as meiosis-based constrative learning without using the emotion labels of the sample. By leveraging data from all subjects except one (N-1 subjects), this phase captures broad patterns and features inherent in the entire dataset, promoting generalisation across different contexts and conditions[29].
2. **Phase-2 (Fine-tuning with labels)**: The fine-tuning phase aims to adapt the pre-trained model to the downstream emotion classification task. This phase involves fine-tuning the pre-trained model with a classifier head using Cross-Entropy Loss on the same N-1 subjects. It ensures that the model is specifically tailored to recognise the emotional states from the EEG data of the given subjects.
3. **Prediction on the hold-out subject**: Finally, the prediction happens on all the sessions of the hold-out subject (the Nth subject) for evaluation.

Model architecture

The SS-EMERGE model architecture leverages a combination of advanced techniques to process EEG signals for emotion recognition effectively. This section explains each component in the model architecture, from input and initial processing, spectral, temporal, and spatial modelling to latent representation modelling. Figure 2

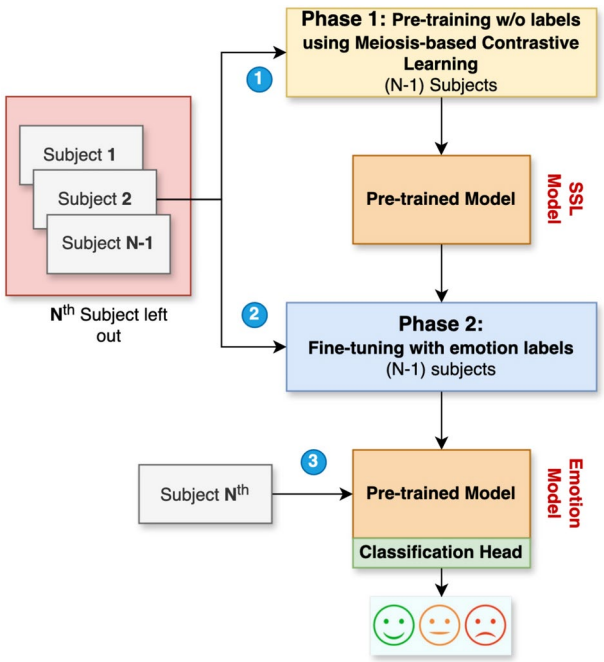

Fig. 1. SS-EMERGE Flow Diagram.

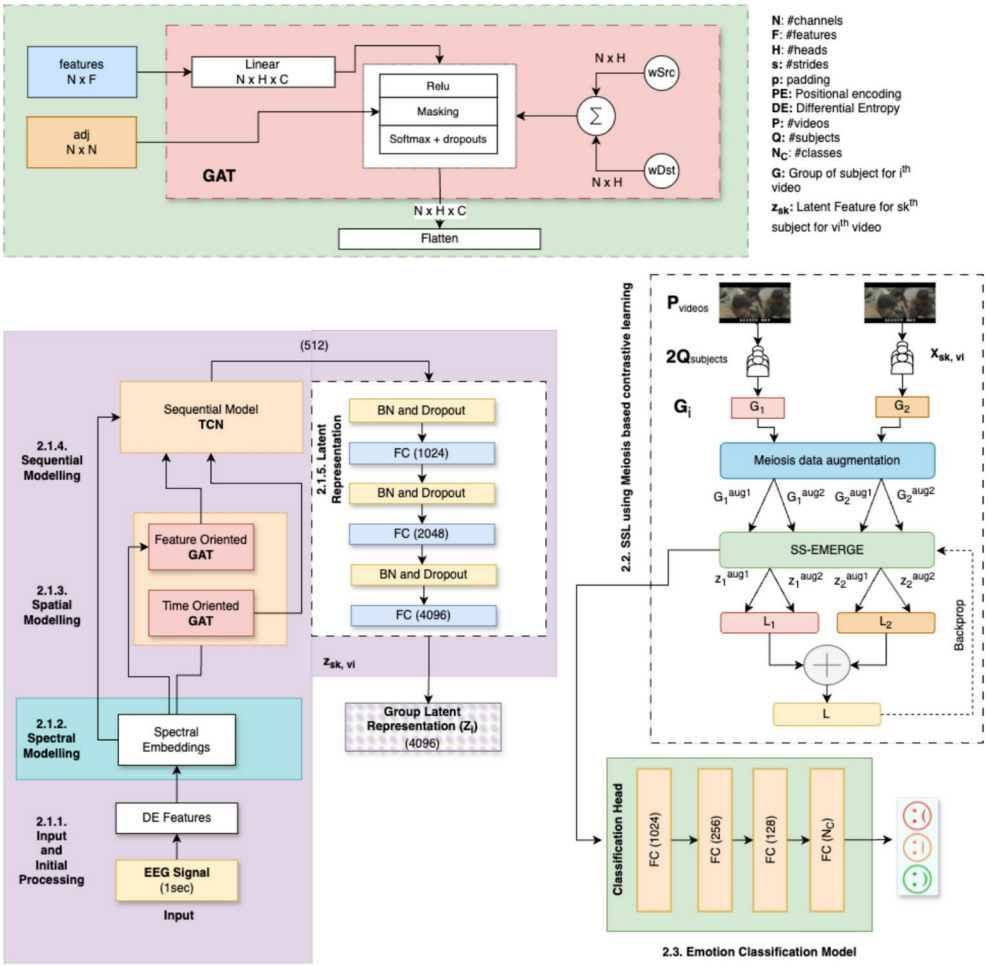

Fig. 2. SS-EMERGE backbone architecture for representation learning using SSL and fine-tuning for emotion classification label and associate with the text not clear.

illustrates the SS-EMERGE backbone architecture that learns the latent representations in Phase-1 (pretraining), followed by Phase-2 (fine-tuning), which fine-tunes the pre-trained network adding the classification for downstream emotion recognition task.

Input and initial processing
The input to the model consists of raw EEG signals segmented into 1-second intervals. These short segments help capture the immediate brain responses associated with different emotional states. From these EEG signals, Differential Entropy (DE)[9,30] features are extracted. DE features are robust in representing the spectral properties of EEG signals, making them particularly suitable for emotion recognition tasks.

Spectral domain modelling
SS-EMERGE leverages the Differential Entropy (DE) feature, which has demonstrated effectiveness in EEG-based emotion recognition tasks[31]. The model extracts DE features $X = (x_1, x_2, \ldots, x_N) \in \mathbb{R}^{N\times C\times F}$ from EEG signals in the spectral domain and transforms them into samples $\tilde{X} = (\tilde{x}_1, \tilde{x}_2, \ldots, \tilde{x}_N) \in \mathbb{R}^{N\times C\times T\times F}$ using an overlapping window of T seconds, where F represents frequency bands ($\delta : 1-4$ Hz, $\theta : 4-8$ Hz , $\alpha : 8-14$ Hz, $\beta : 14-31$ Hz, and $\gamma : 31-50$ Hz) converted by a Short-Time Fourier transform (STFT) for each channel C. In the spectral embedding layer, SS-EMERGE projects the i-th sample, $\tilde{x}_i$, which resides in $\mathbb{R}^{C\times T\times F}$, into a D-dimensional space using a linear layer. This process embeds the spectral information of the EEG signals into $\tilde{x}_i^{(s)} = \tilde{x}_i w^{(s)} + b^{(s)}$, where $w^{(s)}$ is the weight vector in $\mathbb{R}^{F\times D}$ and $b^{(s)}$ is the bias in $\mathbb{R}^{D}$. It finally reshapes $\tilde{x}_i$ to $C \times T \times D$dimensional embedding shape. Later, Positional Encoding (PE)[32] layer retains the temporal position of all channels C by adding sine-cosine encoding on each ith time step of signal with length T of every channel to facilitate later encoding.

Spatial domain modelling
Inspired by the Multivariate Time-series Anomaly Detection via Graph Attention Network (MTAD-GAT)[27], which first passes the time series through 1D Conv followed by two GAT networks. SS-EMERGE integrates two

types of Graph Attention Transformers (GAT)[26] to effectively capture spatial using Feature-Oriented GAT and temporal dependencies via Time Oriented GAT in the EEG signals.

1. **Feature Oriented GAT**: This layer constructs a graph where nodes represent different features simultaneously, and edges depict the relationships or interactions between these features. It effectively models the spatial relationships among various EEG features, enhancing the model's ability to understand how different features interact at a given moment in time.
2. **Time Oriented GAT**: This layer constructs a graph where nodes represent the same feature across different time points, and edges represent the temporal dependencies between these nodes. It captures the temporal progression of individual EEG features over time, allowing the model to track changes and developments in feature values across the duration of the signal[33].

Temporal domain modelling

In SS-EMERGE, **sequential modelling** is handled using a **Temporal Convolutional Network (TCN)** to capture temporal dependencies in EEG signals. Unlike recurrent architectures, TCN employs **causal convolutions**[34], ensuring that each output at a given time step is influenced only by current and past inputs while preserving the chronological order of EEG sequences.

The **TCN module** processes **spectrally and spatially enriched embeddings** using stacked **1D convolutional layers** with dilation, allowing the network to model **long-range dependencies** without the vanishing gradient problem of recurrent models. This makes it highly efficient for EEG-based emotion recognition.

As illustrated in Figure 2, sequential modelling in SS-EMERGE follows a structured pipeline:

1. **Input Features:** Spectral embeddings from the **Spectral modelling** module.
2. **Feature-Oriented and Time-Oriented GAT:** Extracts spatial relationships in EEG signals.
3. **Temporal Convolutional Network (TCN):** Models sequential dependencies over time.
4. **Batch Normalisation and Dropout Layers:** Prevent overfitting and stabilise learning.

Latent representation

Graph Attention Transformers (GATs) first process outputs through a series of Batch Normalization (BN) and Dropout Layers with a dropout rate of 0.2 before passing them to the Fully Connected (FC) layers. It starts with batch normalisation to stabilise the learning process and incorporates a dropout of 0.2 to prevent overfitting. Subsequent layers increase in neuron count from 1024 to 2048 and then 4096, each refining the features into a high-dimensional latent representation that encapsulates comprehensive EEG signal information.

Phase-1: SSL using Meiosis-based contrastive learning

Phase 1 (pretraining) learns the latent representation using Meiosis-based constrastive learning to the discriminative capabilities of a model by leveraging the augmented pairs created through Meiosis Data Augmentation. In the context of EEG data, constrastive learning learns distinct differences in brain responses that can signify various cognitive or emotional states in response to identical stimuli. Meiosis augmentation enhances EEG-based emotion recognition by cross-exchanging signal segments from different subjects within the same group. It creates augmented pairs, where positive samples come from subjects who watched the exact video (same stimuli), and negative samples come from different video groups (different stimuli). Meiosis-based Contrastive Learning helps the model to distinguish between similar and dissimilar stimuli, improving its ability to recognise emotions.

Meiosis data augmentation

Meiosis data augmentation aims to enhance EEG-based emotion recognition by augmenting one group sample to generate two groups that preserve the same stimuli-related features. It involves aligning stimuli in the EEG group to construct positive pairs, thereby increasing the meaningful difficulty of the model decoding EEG samples.

1. **Group Creation:**

   (a) *Sampling EEG Data:* Select $2Q$ subjects EEG recordings $(X_{s_1}, X_{s_2}, \ldots X_{s_{2Q}},)$ based on their exposure to specific video clips P videos $(v_1, v_2, \ldots, v_P)$, where each clip serves as a unique stimulus.

   (b) *Group Formation:* For each selected video clip v_i, form groups G_i consisting of EEG samples from the $2Q$ subjects. Thus, a group G_i for video clip v_i is defined as:

$$G_i = \{X_{s_1}^{v_i}, X_{s_2}^{v_i}, \ldots, X_{s_{2Q}}^{v_i}\}$$

Each group G_i shares similar stimuli-related features among its samples.

2. **Meiosis Data Augmentation:**

   (a) *Individual Pairing:* For an original group of EEG signals $G_i = \{X_{s_k}^{v_i} \mid k = 1, 2, \ldots, 2Q\}$ (corresponding to a video clip v_i), pair the signals randomly to form Q pairs: $\{X_{s_1}^{v_i}, X_{s_{1+Q}}^{v_i}\}, \{X_{s_2}^{v_i}, X_{s_{2+Q}}^{v_i}\}, \ldots, \{X_{s_Q}^{v_i}, X_{s_{2Q}}^{v_i}\}$.

(b) *Crossover:* Meiosis receives a randomly given split position c (where $1 < c < T - 1$) to perform the crossover transformation for each pair, exchanging data of the first c sampling points between the two signals. It results in augmented pairs $\{\{\tilde{X}^{v_i}_{s_k}, \tilde{X}^{v_i}_{s_{k+Q}}\} \mid k = 1, 2, \ldots, Q\}$.
(c) *Separation:* The transformed signals are then randomly divided into two groups. Paired transformed signals are placed in different groups X and Y, which results in two homologous groups of EEG $\tilde{G}^i_X = \{\tilde{X}^{v_i}_{s_k} \mid k = 1, 2, \ldots, Q\}$ and $\tilde{G}^i_Y = \{\tilde{X}^{v_i}_{s_{k+Q}} \mid k = Q+1, Q+2, \ldots, 2Q\}$ that share similar group-level stimuli-related features.

3. **Constructing the Minibatch:**

(a) Equation 1 shows that for one minibatch of P group samples G, $2P$ group samples $\tilde{G}$ are obtained through the Meiosis augmentation process.

$$\tilde{G} = \{\tilde{G}^i_t \mid i = 1, 2, \ldots, P; t \in \{1, 2\}\} = \text{Meiosis}(G) \tag{1}$$

(b) $\tilde{G}^i_X$ forms a positive pair with $\tilde{G}^i_Y$ and forms negative pairs with any other $2(P-1)$ group samples.

Contrastive learning setup
Contrastive learning uses meiosis-augmented pairs to train a model that learns to distinguish between pairs that share the same stimuli label (positive pairs) and pairs that come from different stimuli labels (negative pairs). Figure 2shows that the pretraining phase maximises the similarity between positive pairs and minimises the similarity between the negative pairs in the latent space[5]. The complete contrastive learning happens along with the Meiosis Augmentation as follows:

1. *Augmentation:* Meiosis augmentation generates pairs of EEG signals $\tilde{G}^i_X$ and $\tilde{G}^i_Y$ by cross-exchanging segments from different subjects within the same group. For instance, $\tilde{G}^i_X$ might contain segments from subject i and $\tilde{G}^i_Y$ from subject j, both corresponding to the same stimuli.
2. *Feature Extraction:* SS-EMERGE extracts latent features z_X for the augmented pairs $\tilde{G}^i_X$ and $\tilde{G}^i_Y$, generated by meosis augmentation[35].
3. *Similarity Measurement:* Equation 2 calculates the similarity between the latent representations z_X and z_Y using cosine similarity. It quantifies how close the representations of the augmented pairs are in the latent space[36].

$$s(z_X, z_Y) = \frac{z_X \cdot z_Y}{\|z_X\| \|z_Y\|} \tag{2}$$

4. *Contrastive Loss:*Finally, Phase-1 employs constrative loss to train the model using SimCLR[11] loss function. The loss function penalises large deviations between the similarity scores and their expected values based on the temperature-scaled cross-entropy in Equation 3:

$$\ell^X_i = -\log \frac{\exp(s(z^X_i, z^Y_j)/\tau)}{\sum_{j=1, j\neq i}^{P} \exp(s(z^X_i, z^X_j)/\tau) + \sum_{j=1}^{P} \exp(s(z^X_i, z^Y_j)/\tau)} \tag{3}$$

Here, P denotes the number of groups, τ is the temperature parameter, and $[j \neq i]$ is an indicator function that equals 1 if j is not equal to i[37].
Equation 4 then calculates the combined loss across all the groups in a batch of Stochastic Gradient Descent.

$$L = \frac{1}{2P} \sum_{i=1}^{P} (\ell^X_i + \ell^Y_i) \tag{4}$$

Algorithm 1 outlines the end-to-end Phase-1 pretraining using contrastive learning with meiosis augmentation. It starts by extracting group-level features and projecting them to latent space. It helps obtain group representations. The algorithm then minimises the distance between positive pairs and maximises amongst the negative pairs[38].

Phase-2: fine-tune emotion classification model

In Phase-2 (fine-tuning), the pre-trained SS-EMERGE model generates the latent representation but further fine-tunes using the classification head seen in Figure 2 for emotion classification modelling. It only learns the parameters of the classification head without changing other model parameters.

Model Architecture and Training Procedures:

1. **Classifier Head**: The classifier consists of additional fully connected layers that further process the latent representation of dimension D. These layers are followed by a softmax layer to produce the final emotion class probabilities (N_C).

(a) *Fully Connected Layers*: The layers with 1024, 256, and 128 neurons progressively transform and reduce the dimensionality of the latent representation.

Initialization:
Set the number of epochs E_1
Initialize the model parameters
for each epoch $t = 1, 2, \ldots, E_1$ **do**
    Video Clip Sampling:
    Sample P video clips per iteration until all video clips are enumerated
    EEG Sample Extraction:
    Extract $2P \times Q$ EEG samples $D = \{X_{sk}^{vi} | i = 1, 2, \ldots, P; k = 1, 2, \ldots, 2Q\}$
    Pack these samples into groups $G = \{G_i | i = 1, 2, \ldots, P\}$
    Meiosis Data Augmentation:
    Randomly generate a fixed split position c (where $1 < c < M - 1$)
    Apply Meiosis crossover to each group to generate augmented samples $\tilde{G} = \{\tilde{G}_i^t | i = 1, 2, \ldots, P; t \in \{X, Y\}\}$
    Feature Extraction and Projection:
    Extract group-level features
    Project features to latent space to obtain group representations
    Loss Calculation:
    Calculate the loss L using Equation 3
    Model Update: state Perform backpropagation to calculate gradients state Update the parameters of the model using the optimiser
end for

Algorithm 1. Pretraining with Meiosis-Based Contrastive Learning

(b) *Class Logits (FC (N_C))*: This layer outputs N_C neurons, where N_C corresponds to the number of emotion classes.
(c) *Softmax Layer*: Converts the logits into class probabilities using Softmax.

2. **Training Procedure**:

(a) Finally, Phase 2 fine-tunes the classifier head over the pre-trained model using labelled EEG data.
(b) The training process involves minimising a cross-entropy loss, which learns to discriminate different predicted class probabilities and the true emotion labels.
(c) It optimises the network using Stochastic Gradient Descent (SGD), with appropriate learning rate scheduling to ensure convergence shown in Table 2.
(d) It regularises the model training using a dropout of 0.5 and batch normalisation to prevent overfitting.

Phase	Parameter	Value
SSL Phase	Learning Rate	1×10^{-3}

Experimental setup

Dataset

This work conducts experiments on the SEED[21]and SEED-IV[22] datasets, known for their robust emotional state annotations and varying class distributions. These datasets provide a comprehensive and balanced foundation for evaluating the performance of emotion recognition models.

1. **SEED-IV Dataset** [21]: Consists of EEG recordings from 15 subjects (7 males and 8 females) as they watched film clips designed to evoke specific emotions. Each subject contributed 45 samples, evenly distributed among three emotion labels: happy, sad, and neutral, resulting in a total of 675 samples[21]. The signals were recorded using a 62-channel ESI NeuroScan System, with a sampling rate of 1,000 Hz. To facilitate analysis, the signals were downsampled to 200 Hz and bandpass filtered between 0–75 Hz to remove unrelated artifacts.
2. **SEED-IV Dataset** [22]: Includes data from the same 15 subjects, with each providing 72 samples distributed across four emotion labels: happy, sad, fear, and neutral, leading to a total of 1,080 samples[22]. The experimental setup and data processing methods were similar to those used in the SEED[21] dataset. However, the bandpass frequency filter was set to 1–75 Hz for SEED-IV, and the DE features were normalised to ensure consistency across samples.

The balanced distribution of samples across subjects and emotion classes in both datasets ensures an unbiased training and evaluation process.

Data preparation

For both SEED[21]and SEED-IV[22] datasets, each trial of EEG signal in each channel undergoes L2 normalisation to ensure that the data from different trials are on a similar scale. The movie videos are divided into 1-second windows. Given the varying lengths of the trial videos, adjacent windows are segmented from front to back according to the time axis until the coverage of windows exceeds the video range.

Evaluation strategy

To rigorously assess the generalisation capabilities and performance stability of the SS-EMERGE model, this work employs a robust evaluation strategy involving subject-mixed and subject-independent testing frameworks. The Leave-One-Subject-Out (LOSO) cross-validation scheme is utilised to ensure comprehensive evaluation:

1. **Subject-Independent / Cross-Subject Evaluation (LOSO)**:
   - **Fully-supervised Learning**: For each cycle of LOSO, the model is trained on EEG data from $N-1$ subjects using all available labels. The model is then tested on the left-out subject, assessing its adaptability to new individual data unseen during the training phase.
   - **Self-Supervised Learning**: Begins with pretraining a base model on all subjects without labels to capture generalisable features. The model is then fine-tuned on minimal labelled data from the left-out subject, optimising the blend of learned representations with subject-specific adjustments.
2. **Subject-Mixed / Trial-Random Evaluation**:
   - Conducted using a random train-test split (80-20%) to evaluate the model's architecture and ability to generalise across a random data selection, focusing not specifically on individual subject differences.

Training parameters for SSL and classification model

Phase-1 (pretraining) and Phase-2 (fine-tuning) select the hyperparameters used by SGMC[18] along with the default settings of the optimiser. These settings yield good subject-independent and subject-dependent performance without the rigorous need for hyperparameter tuning. Table 2 lists all the hyperparameters with their corresponding default values during pretraining and fine-tuning of the Emotion Classification model.

Results and discussion

The results presented in this section evaluate the performance of SS-EMERGE in different experimental settings in the SEED[21]and SEED-IV[22] datasets. The evaluation focuses on three key aspects as follows:

- Experiment 1: Subject-Mixed and Cross-Subject Evaluation of Base-Model Architecture Using fully-supervised Learning
- Experiment 2: Comparative Analysis of Self-Supervised vs Full-Supervised Learning for Cross-Subject Adaptation
- Experiment 3: Foundational pretraining by combining SEED and SEED-IV.

Experiment 1: choosing a base model architecture

EEG-based emotion recognition is inherently challenging due to subject-specific variations. A cross-subject generalisation is particularly difficult, as models must adapt to significant intersubject variability. This experiment compares the ResNet used by SGMC[18] with the proposed SS-EMERGE, a fully-supervised model trained for EEG emotion classification. The objective is to determine the most effective fully-supervised backbone model for emotion recognition for cross-subject.

Model	Setup	Positive (%)	Neutral (%)	Negative (%)	Average (%)
ResNet	Subject-Mixed	89.7	90.0	89.8	89.83
	Cross-Subject	68.5	69.8	65.2	67.83
SS-EMERGE	Subject-Mixed	96.2	92.5	94.1	94.27
	Cross-Subject	87.4	83.1	81.9	84.13

Table 3. Performance of models on SEED[21] dataset under subject-independent and cross-subject setups.

#Samples	SGMC	SS-EMERGE
SEED Dataset[21]		
10% (fine-tuned)	73.29%	75.50%
50% (fine-tuned)	82.91%	86.13%
100% (fine-tuned)	90.75%	92.35%
SEED-IV Dataset[22]		
10% (fine-tuned)	52.30%	58.10%
50% (fine-tuned)	68.05%	76.75%
100% (fine-tuned)	75.20%	81.51%

Table 4. Self-Supervised Learning Comparison of SGMC[18]and SS-EMERGE on SEED[21]and SEED-IV[22] datasets.

Unlike previous studies that rely primarily on subject-independent evaluations, this work evaluates cross-subject, ensuring that the model is trained on $N-1$ samples of a partial sample of subjects and tested on rest. This approach rigorously assesses cross-subject generalisation.

From Table 3, ResNet achieves 67.83% accuracy under the cross-subject evaluation, demonstrating its limited ability to generalise across subjects. In contrast, SS-EMERGE outperforms ResNet, achieving 84.13%, highlighting its effectiveness as a fully-supervised backbone model for EEG-based emotion recognition. Both models exhibit stronger performance in the random-split setting due to similarities in intra-subject training and testing data.

Experiment 2: cross-subject evaluation under self-supervised and fully-supervised learning

Having established SS-EMERGE as the superior fully-supervised backbone in Experiment 1, this experiment evaluates SS-EMERGE, a self-supervised learning (SSL) approach that combines contrastive learning with classification. SS-EMERGE is compared against SGMC, which also employs SSL, and SS-EMERGE, the strongest fully-supervised model from Experiment 1.

The SEED[21]and SEED-IV[22] datasets are used to analyse how SSL compares with fully-supervised learning under cross-subject conditions. The model is fine-tuned using varying percentages of labelled data (10%, 50%, and 100%) to evaluate performance under different data availability scenarios.

From Table 4, SS-EMERGE consistently outperforms both SGMC and SS-EMERGE across all labelled data settings. Notably, when fine-tuned with only 10% labelled data, SS-EMERGE achieves 75.5% accuracy on SEED, compared to 74.12% for SS-EMERGE and 73.29% for SGMC. Also, when compared with fully-supervised counterpart, SEED[21] achieves 84.13% cross-subject performance as compared to 92.35% of SSL.

Experiment 3: foundational pretraining using SEED and SEED-IV datasets

This experiment evaluates the impact of foundational pretraining using the combined datasets of SEED[21]and SEED-IV[22]. Given that both datasets share identical channel configurations, data integration during pretraining is streamlined. The distinct video stimuli in each dataset require a specialized approach for stimulus identification. To address this, a composite identifier that merges the dataset and video ID is used, ensuring accurate alignment with subject-specific emotional responses.

Baseline models

The baseline models for this study include:

- **Vanilla SGMC**: This model operates solely in the temporal domain using a ResNet architecture, focusing on capturing dynamic temporal features.
- **SS-EMERGE**: An advanced model that integrates features across temporal (T), spectral (F), and spatial (S) domains using a Graph Attention Transformer (GAT)[28].

Ablation studies

Ablation studies are performed to assess the impact of each domain:

1. **SS-EMERGE.FT**: Focuses on the spectral and temporal domains, evaluating the models ability to utilize these features for emotion recognition.

#Samples	SGMC T	SS-EMERGE.FT FT(Proposed)	SS-EMERGE.TS TS(Proposed)	SS-EMERGE FTS(Proposed)
SEED Dataset[21]				
10%	73.29%	73.82%	73.51%	**74.11%**
50%	83.71%	84.02%	83.84%	**84.42%**
100%	83.04%	85.56%	85.12%	**88.87%**
SEED-IV Dataset[22]				
10%	58.33%	56.81%	55.53%	**57.92%**
50%	66.44%	62.32%	61.02%	**63.54%**
100%	77.64%	76.31%	75.08%	**82.75%**

Table 5. SSL Performance with foundational pretraining for SEED[21]and SEED-IV[22].

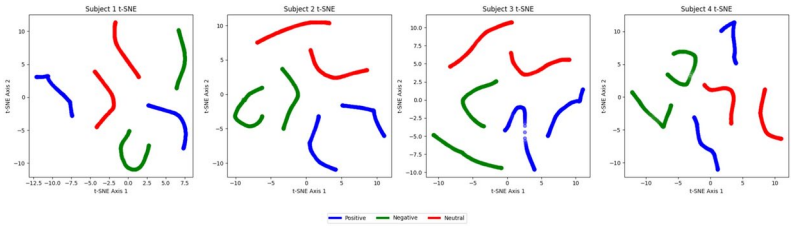

Fig. 3. TSNE visualization of SEED[21] embeddings.

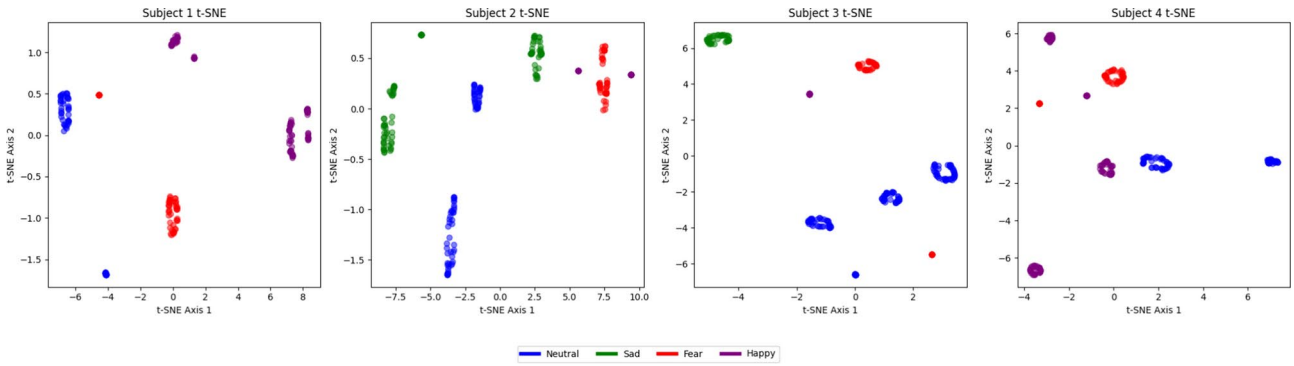

Fig. 4. TSNE visualization of SEED-IV[21] embeddings.

2. **SS-EMERGE.TS**: Analyzes the integration of temporal and spatial domains, omitting spectral features to determine the importance of spatial information.

These models are evaluated on a subject-independent basis due to computational constraints, which also guide the domain-specific ablation studies.

The SEED[21]and SEED-IV[22] datasets are processed under identical protocols to ensure uniformity, as detailed in subsection 3.2. Stimuli are uniquely tagged with dataset-specific prefixes, facilitating clear differentiation and integration into the SGMC model without modifications. Foundational pretraining employs contrastive loss to enhance feature discrimination across emotional stimuli without using labels.

In the fine-tuning phase, labels are reintroduced, tailoring the model to the distinct emotional patterns of each dataset. Performance is evaluated directly on the subjects from the training data, avoiding cross-subject validation.

As shown in Table 5, pretraining on the combined datasets significantly improves model accuracy 88.80% on SEED and 81.50% on SEED-IV[21,22], demonstrating the efficacy of cross-domain pretraining. This approach represents the first attempt to merge and assess these datasets for cross-subject performance.

Experiment 4: visualisation of underlying embedding

The t-Distributed Stochastic Neighbor Embedding (t-SNE) visualisations in Figures 3 and 4illustrate the feature representations from the SS-EMERGE on the SEED[21]and SEED-IV[22] dataset. The t-SNE projections reduce the 4096-dimensional feature space to a 2-dimensional space for visualisation. The clustering of SS-EMERGE learnt

features shows distinct and well-separated clusters. The more precise separation of clusters of the SS-EMERGE indicates that it enhances the model's ability to capture the discriminative features due to its rich representation learning.

Conclusion and future work

This study presents the SS-EMERGE model, a novel self-supervised learning approach using multidimension graph neural networks to enhance EEG-based emotion recognition. Evaluated on the SEED and SEED-IV datasets, SS-EMERGE consistently outperforms the SGMC baseline and fully-supervised models, particularly when labelled data is limited. The model shows substantial performance gains with just 10% and 50% labelled data and achieves its highest accuracy with full data utilisation, highlighting its potential for applications with scarce labelled resources.

Furthermore, SS-EMERGE demonstrates its capability as a foundational model for emotion recognition by efficiently leveraging combined datasets during pretraining. Future research could explore integrating additional diverse EEG datasets to improve model robustness further and investigate the efficacy of meiosis-based contrastive learning for enhanced group-level feature representation. This direction is promising for advancing emotion recognition technologies in real-world scenarios.

Data availability and access

The data used in this study is available on SEED[21] and SEED-IV[22]. Access to the datasets can be requested through the following link: https://bcmi.sjtu.edu.cn/home/seed/.

***Abstract*—This paper presents an optimal LQR-Integral based controller (LQR-I) for balancing control of the Double Link Rotary Inverted Pendulum (DL-RIP) system. It is one of the challenging topics in control and robotics due to its nonlinearity and instability, also complex system due to 3 degree of freedom rotary system. This system uses a motor to control and balance two rigid links serially connected pendulums in a vertically upward direction. Pole-zero mapping is used to determine the stability of the system. In this paper, a performance analysis of the system is done with an LQR-I controller using three reference paths (Square, Sawtooth, and Sinusoidal wave), two of which are discontinuous and one continuous path. The system shows less overshoot and deflection to stabilize the pendulum vertically upwardly with a continuous sinusoidal reference path compared to a square and sawtooth wave.**

Keywords—LQR-I, DL-RIP, eigenvalues.

I. Introduction

An underactuated system is a type that has fewer actuators than the degree of freedom and has attracted many researchers in the control engineering field. Challenges occur in controlling these systems due to their complexity, path-tracking instability, and nonlinearity [1]. Some examples of these systems are robotics systems (flying robots, rotary pendulums, etc), marine vessels (ships like oil tankers, autonomous underwater vehicles), and aerospace vehicles. One of the well-known underactuated systems is the inverted pendulum, which has fewer actuators than the control variable and benchmark system used in research for broad performance analysis of different controllers. Different types of inverted pendulum systems are seen in the literature view, which can be grouped into two parts: dynamic cart-type and rotary-type [2]. Controlling the pendulum's position on a cart in linear motion has been done using a conventional proportional integral derivative (PID) controller. The issues in conventional control, such as high overshoot time taken to settle, are resolved using optimal and intelligent controllers. An LQR controller [3] was applied to control the arm and pendulum angle of the rotary inverted pendulum and to enhance the performance of the system's ode hybrid intelligent controller. A double-link serially connected rotary system has been designed and developed to enhance the system's complexity by checking the controllers' robustness and broad exploration [4]. In a double-link pendulum, the movement of one link also affects the second link's movement for stabilization at a vertically zero position. Section II contains mathematical modeling, the Controller is explained in section III, and the Result and Discussion are in section IV.

II. Mathematical Modeling of Double link Rotary Inverted Pendulum (DL-RIP)

The system configuration mainly depends on two factors: the method of actuators, which are two ways viewed in literature, linear and angular, and how many degrees of freedom the system has. Linear inverted pendulum links are directly coupled to the motor shaft, which means at least two degrees of freedom system, one for base position and another for angle pendulum, respectively [5]. For a higher degree of freedom, links in the system are increased, or a single link can move in various directions. As it increases, the complexity in the modeling of the system and its controlling is increased, and if the system is rotary, it becomes more difficult [6].

A. Model Convention

The rotary arm pivot is attached to the servo system and actuated. The servo turns in an anti-clockwise direction when motor voltage is greater than zero (Vm >0); thus, the arm also increases positively, with length Lr, movement of inertia Jr, and its angle theta when rotated in an anti-clockwise direction because both movements are interdependent [7]. The whole assembly of the double pendulum is connected to the rotary arm. The first short-sized, bottom pendulum has a length of L_1, mass m_1, and center of mass l_{m1} with a moment of inertia about its center J_1 connected to the base of the rotary arm. The second upper side pendulum has a length of L_2, mass m_2, and center of mass l_{m2} with a moment of inertia about its center J_2 connected to the end of the first pendulum with the hinge of mass m_h. The angle of the bottom pendulum is alpha ($\alpha>0$), and the top one is phi ($\varphi>0$), which is zero when the pendulum is perfectly balanced in a vertical upright position.

For highly complicated systems like robotic manipulators with multiple joints, a systematic method named the Lagrange method is used to determine the equation of motion of systems.

Particularly, the equation that explains the motion of the rotary arm and pendulum angle with respect to motor voltage is obtained through the Euler-Lagrange equation, as mentioned in equation (1).

$$\frac{\partial^2 L}{\partial t \partial \dot{q}_i} - \frac{\delta L}{\delta q_i} = Q_i \tag{1}$$

Generalized coordinates $q_{i,}$ also called Lagrange coordinates, are three for this system, as present in equation (2), and their first derivates are corresponding velocities. With the generalized equation (1), the Euler-Lagrange dynamics for this system are mentioned in equation (3)

$$q^T = [\theta(t), \alpha(t), \phi(t)] \tag{2}$$

$$\left.\begin{aligned} \frac{\partial^2 L}{\partial t \partial \dot{\theta}} - \frac{\delta L}{\delta \theta} &= Q_1 \\ \frac{\partial^2 L}{\partial t \partial \dot{\alpha}} - \frac{\delta L}{\delta \alpha} &= Q_2 \\ \frac{\partial^2 L}{\partial t \partial \dot{\phi}} - \frac{\delta L}{\delta \phi} &= Q_3 \end{aligned}\right\} \tag{3}$$

Now, the generalized force Q_i is used to describe the non-conservative force like viscous damping force (B), the torque generated by a motor (ζ_m) applied to a system with respect to generalized coordinates [8]. The generalized force acting on:

(a) Rotary arm

$$\left. Q_1 = \zeta_m - B_r\left(\frac{d}{dt}\theta(t)\right)\right\} \tag{4}$$

(b) Bottom and top pendulum

$$\left.\begin{aligned} Q_2 &= -B_1\left(\frac{d}{dt}\alpha(t)\right) \\ Q_3 &= -B_2\left(\frac{d}{dt}\phi(t)\right) \end{aligned}\right\} \tag{5}$$

To determine the Lagrange equation of the system, first needs to find out its total kinetic and potential energy, and their difference is defined as Lagrange dynamics [9]. The total potential energy of the system (PT) is the summation of the total potential energy of the elastic of the system, link 1, link 2, and hinge. The total kinetic energy of the system (KT) is the summation of kinetic energy due to the rotation of the arm due to the rotational and translation motion of the pendulum's first and second hinge, as shown in equation (6).

$$\left.\begin{aligned} P_T &= P_{elastic} + P_1 + P_2 + P_{hinge} \\ K_T &- K_{arm} + K_{rot1} + K_{rot2} + K_{trans1} + K_{trans2} \\ L &= P_T - K_T \end{aligned}\right\} \tag{6}$$

After computing the Lagrange equation and generalized force coordinate, these values are put in equation (3) to determine the non-linear equation of motion for the system by computing all derivative parameters. To linearize, the non-linear equation uses a linearized function, as mentioned in equation (7).

$$\left.\begin{aligned} f_{line.} = f(z_o) &+ \left(\frac{\partial^2 f(z)}{\partial z_1}\right)_{z=z_o} (z_1 - a) \\ &+ \lim_{x\to\infty}\left(\frac{\partial^2 f(z)}{\partial z_2}\right)_{z=z_o} (z_2 - b) \end{aligned}\right\} \tag{7}$$

Linear State-space equations are mentioned in equation (9), where x is the state, and u is the control input [10]. The state space variable chosen should at least contain generalized coordinates, and their first derivative, as given in equation (8), y, is the system's output.

$$\begin{aligned} x^T &= \begin{bmatrix} \theta(t) & \alpha(t) & \phi(t) & \dot{\theta}(t) & \dot{\alpha}(t) & \dot{\phi}(t) \end{bmatrix} \\ y^T &= \begin{bmatrix} \theta(t) & \alpha(t) & \phi(t) \end{bmatrix} \end{aligned} \tag{8}$$

$$\sum := \begin{cases} \dfrac{dx}{dt} = Ax(t) + Bu(t) \\ y(t) = Cx(t) + Du(t) \end{cases} \Leftrightarrow \begin{pmatrix} A & B \\ C & D \end{pmatrix} \tag{9}$$

After linearizing the nonlinear equation and solving acceleration terms, the state space matrix of the rotary double inverted pendulum was obtained, as presented below.

$$A = {}^{1}\!/_{F_t} \begin{bmatrix} 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & a_{42} & a_{43} & 0 & 0 & 0 \\ 0 & a_{52} & a_{53} & 0 & 0 & 0 \\ 0 & a_{62} & a_{63} & 0 & 0 & 0 \end{bmatrix} \tag{10}$$

where, $$a_{42} = L_r g(m_1^2 l_1^2 + 2m_1^2 m_h^4 L_1^5 m_2^2 l_1^3) \tag{11}$$

$$a_{43} = -m_1 l_1 L_r m_2 g(-l_1 + L_1) \tag{12}$$

$$\left.\begin{aligned} a_{52} = g\{&L_r^2 L_1 m_2 (m_1 + m_h) + L_1 L_r^2 (m_h^2 + m_1^2) \\ &+ J_r L_1 (m_1 + m_h) + 2L_1 L_r^2 m_h m_1\} \end{aligned}\right\} \tag{13}$$

$$a_{53} = -m_2 g\{L_1 L_r^2 (m_2 - m_1) + J_r L_1\} \tag{14}$$

$$a_{62} = -{}^{g}\!/_{L_2} \begin{Bmatrix} L_1^2 L_r^2 (m_1^2 - m_1 m_2) + L_r^2 L_1 L_2 m_2 (m_1 + m_2) \\ + J_r L_1 L_2 (2m_1 + m_h) + 2L_r^2 L_1 L_2 m_h m_1 \\ + L_r^2 L_1 L_2 (m_1^2 + m_h^2) + L_r^2 L_1 (m_1 m_2 - m_1^2) \end{Bmatrix} \tag{15}$$

$$\begin{aligned} a_{63} = {}^{g}\!/_{L_2} \{&J_r m_2 L_1 (L_2 + L_1) - 2L_1^2 L_r^2 m_1 (m_2 + m_h) \\ &+ L_1^2 J_r (m_1 + m_h)\} \end{aligned} \tag{16}$$

$$C = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \end{bmatrix} \tag{17}$$

III. CONTROLLER

The system's stability is checked using the state space characteristic equation, calculated as the determinant of (s*I-A), where I is the identity matrix and plots the system's pole-zero and Nyquist plot, as mentioned in Fig. 1 and 2. The open loop eigenvalues are [0 -29.52 12.27 7.23 -10.19 -2.14]. The eigenvalues show that two poles lie on the right-hand side, and the system's step response diverges from the Nyquist plot. It is also clear that the system is not stable. Hence, the system is highly unstable.

To stabilize the system, firstly shift all the poles on the right-hand side using the pole placement technique, and after that, use the optimal optimization algorithm to find the gain of the system and apply a feedback loop by implementing the integral term to control or stabilize the pendulum in a vertically upward direction with minimum deflection, which means using a LQR feedback controller with a small integral mode shows in Fig. 3.

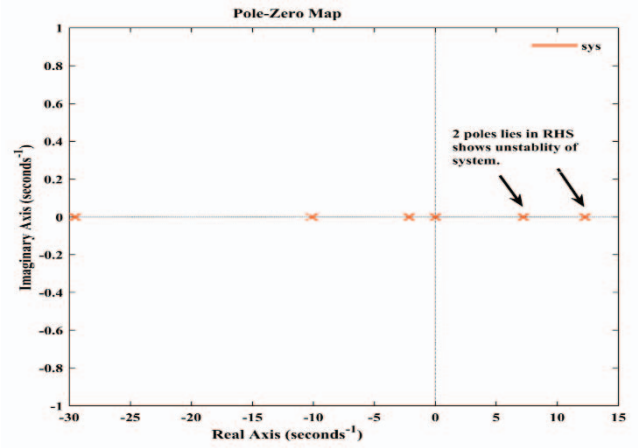

Fig. 1. Pole- Zero Map

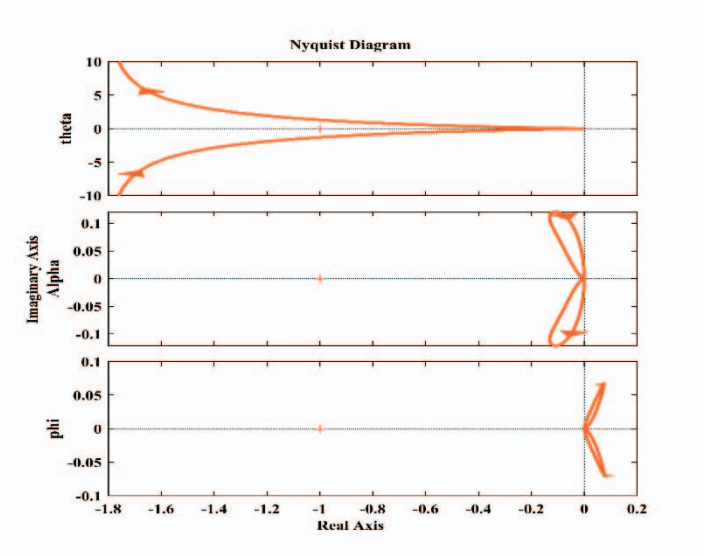

Fig. 2. Nyquist plot of the system

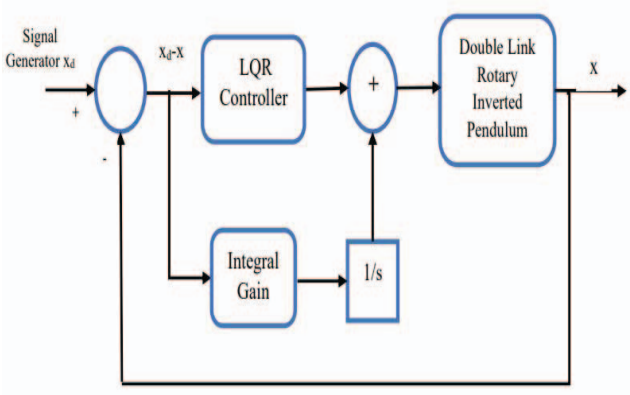

Fig. 3. Block Diagram of Controller Implementation

In the LQR controller, mathematical algorithm-controlled feedback gain is used to design optimal control, enabling the closed-loop system to be stable and high-performance. It uses a weighting parameter instead of eigenvalue placement. It minimizes the cost function that maps the variable to a real number, as mentioned in equation (19), which uses all state variables. Q and R denote positive definite weighting matrix. Equation (20) represents the matrix algebraic Riccatti equation

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on May 01,2025 at 07:24:17 UTC from IEEE Xplore. Restrictions apply.

whose solution 'V' is required to determine the optimal feedback gain 'k'.

$$E = \int_0^{\infty} x(t)^T Q * x(t) + u(t)^T R * u(t) d(t) \tag{19}$$

$$A^T V + VA + BR^{-1}B^T V + Q = 0 \tag{20}$$

$$u = -\sum k_j (x_d - x_j);\ k = R^{-1}B^T A^T V \tag{21}$$

The feedback loop stabilizes the servo to the desired position (θ_d) while minimizing the pendulum deflection. The reference state is defined as:

$$x_d = \theta_d \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad \text{and} \, u = k(x_d - x) \tag{22}$$

After introducing the integral term, the overall system state-variable and reference state are mentioned in equation (23).

$$\rho^T = \left[\theta(t) \quad \alpha(t) \quad \phi(t) \quad \dot{\theta}(t) \quad \dot{\alpha}(t) \quad \dot{\phi}(t) \int \theta(t)\right]$$
$$\rho_d = \left[\theta_d(t) \quad 0 \quad 0 \quad 0 \quad 0\,0 \quad \int \theta(t)\right] \tag{23}$$

IV. Result and Discussion

This section analyzes the response of the DL-RIP system using an introduced optimal integral controller by taking different signals as reference paths like square, sinusoidal, and saw-tooth. After tunning the weighting matrix of the LQR controller, taking R= 20 and Q is equal to diag[5 1 1 5 12 0 0.9], set Q(7,7) = 0.9 to introduce a small integral gain to track servo error, with the help of MATLAB code obtains the gain value k of the controller shows in equation (24) and closed-loop eigenvalue of the system is given below in equation (25).

$$k = \begin{bmatrix} 0.12 & -16.47 & -37.68 & 0.437 & -12.54 & -4.43 & 0.127 \end{bmatrix} \tag{24}$$

$$E = [-0.4221+0.38i,\ -0.4221-0.38i,\ -3.348,\ -6.3040,\ -10+3.055i,\ -10-3.055i,\ -50] \tag{25}$$

Taking the amplitude of gain block 30 to generate a step with an amplitude of 30 degrees. The pendulum maintains its balance about the vertical position (zero angle) while tracking the 30-degree servo angle, as shown in response to the rotary arm system with setpoint square, sin, and sawtooth wave.

In the case of a square setpoint, the arm maintains its balance at 47. 48 degrees in 11 sec with an overshoot of 13 percent, but with a sawtooth wave, it maintained balance at 37.67 degrees in 12 sec with an 11 percent overshoot, less than a square case. In both cases, the discontinuity occurs in the path, and at the discontinuity point, it is disturbed with their track and again achieved as required, shown in Fig. 4 and 5. When tested with sinusoidal setpoint, it maintained balance at 32.57 degrees in 13 sec with 1.89 % overshoot only; hence, when no discontinuity occurs in the desired path, less overshot occurs during the stabilization of the system, and also, less error occurs, as in this case 2.57 shows in Fig. 6. Also compare this LQR-I controller response with existing LQR, the response with LQR-I controller is better than existing one as shown in Fig.6. The overshoot and settling time less.

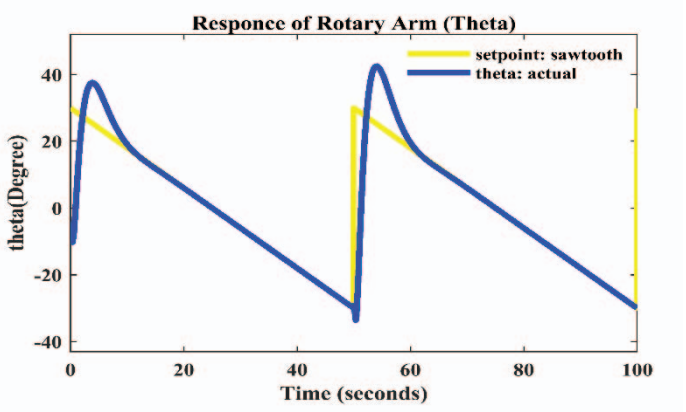

Fig. 4. Rotary Arm Response with Sawtooth Setpoint

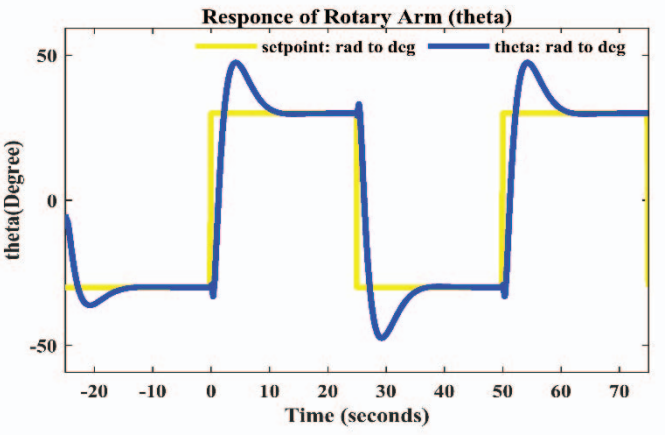

Fig. 5. Rotary Arm Response with Square Setpoint

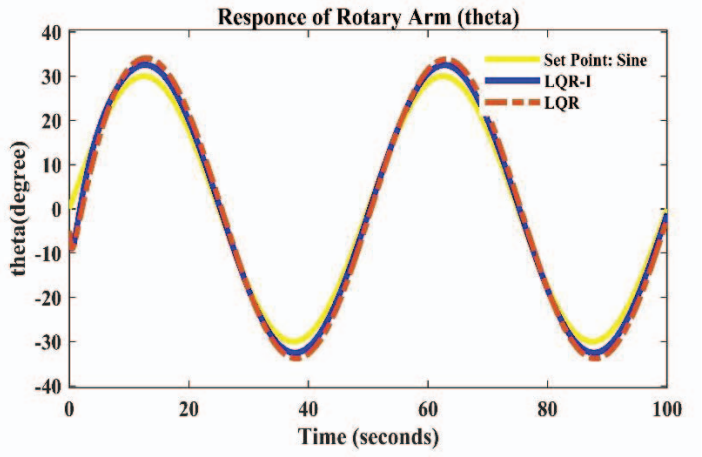

Fig. 6. Rotary Arm Response with Sinusoidal Setpoint

In all three cases, the first and second pendulum stabilization behavior in the vertical upward direction is presented in Fig. 7 and 8. In the sinusoidal reference case, the pendulum stabilizes with less overshoot and less error but takes more time than the other two cases. Also, the system tracks the desired path in all three cases, but with sinusoidal, small deflection occurs with the desired path, and less disturbance occurs.

Sawtooth	1	0.0428	1.93	1.96

V. CONCLUSION

The proposed DL-RIP system demonstrates stable vertical upward movement when utilizing the LQR-I controller. The analysis of three distinct input cases—sinusoidal, square, and sawtooth waveforms—shows that the system achieves superior tracking and performance with sinusoidal inputs, delivering a smoother and more accurate response. Furthermore, the LQR-I controller outperforms the standard LQR controller, as evidenced by its reduced overshoot of 1.89% and a faster rise time of 0.38 seconds. These results highlight the effectiveness of the LQR-I controller in improving stability and dynamic response for the DL-RIP system, making it a robust solution for applications requiring precise control and minimal oscillations.

***Abstract*— Stuttering is a common speech disorder which results in involuntary repetitions, prolongations, blocks or interjections while speaking. Detection and evaluation using traditional methods is time-consuming. Therefore, we conduct a study on 2 classification based deep learning models for stuttering detection: 1) a model which comprises of a Convolutional Neural Network (CNN) followed by Long-Short Term Memory (LSTM) and Attention layers 2) a model which comprises of a CNN followed by LSTM layer only. We used the SEP-28K dataset for training and evaluating our models. These models take mel spectrogram as input and perform binary classification for each disfluency label of the SEP-28K dataset. The CNN + LSTM + Attention model achieved a higher accuracy of 70.47% in detecting prolongation, 60.80% in block and 56.90% in word repetition compared to the CNN + LSTM model, which achieved 69.43%, 60.34% and 55.23% for the same labels, respectively. However, the CNN + LSTM model outdid the attention-based model in classifying fluent/no-stutter instances with 66.52% accuracy against 61.50% and sound repetition with 65.22% accuracy against 64.25%. For interjection, both the models had similar performance in terms of accuracy. For F1 scores, the CNN + LSTM + Attention model showed improvement in block, prolongation, sound and word repetition classifications, while the CNN + LSTM model observed better results for fluent/no-stutter and interjection detection.**

Keywords—Stuttering, CNN, LSTM, Attention, mel spectrogram, SEP-28K

I. Introduction

Stuttering causes speech disfluency which affects the day-to-day lives of people suffering from it. People who stutter are prone to anxiety, low self-esteem and several other mental health issues because they often feel shame when they are not able to speak fluently **[1]**. The most common symptoms that indicate stuttering include: Prolongation, Repetition, Block and Interjection. Prolongation is a type of stuttering in which a person holds out a sound for too long. Repetition involves repeating a sound or word multiple times during speech. Blocks are gaps or breaks in speech. Interjections are usually the filler-words used by the people who stutter to hide stuttering like 'umm', 'uh' and 'well'. There can be multiple causes of stuttering. Developmental stuttering usually begins in early childhood, starting with episodic stuttering which may progress to blocks and prolongations **[2]**. Acquired stuttering consists of sound repetition without typical anxiety or secondary behaviour. Stuttering can also be triggered by traumatic events **[3]** and Neurogenic stuttering is usually caused by brain injuries and diseases **[4]**.

Thus, the diagnosis of stuttering is important as it can help in detecting underlying diseases as well. Speech-language pathologists (SLP) are the healthcare professionals who diagnose and treat patients that suffer from stuttering. However, stuttering detection is a time-consuming and laborious task because SLPs need to interact with patients in different situations to evaluate their speech and behaviour. Therefore, we conduct a study on LSTM and LSTM-Attention based CNN models for stuttering detection. Our models were trained on the SEP-28K **[5]** dataset.

Table 1: Types of Disfluencies

Disfluency Type	*Example*
Prolongation	*I eat cheeeeeerry.*
Blocks	*I…… eat cherry…*
Interjections	*I eat umm cherry.*
Sound Repetition	*I e-e-e-eat cherry.*
Word Repetition	*I eat eat eat cherry.*

Our key contributions are as follows: 1) Implementing CNN + LSTM and CNN + LSTM + Attention based models for stuttering detection, to classify whether a person is stuttering or not in an audio clip. 2) We used the SEP-28K dataset for conducting our experiments- trained and evaluated our models for different stuttering types and made comparisons between both models.

The rest of the paper is organized as follows: In Section-2, we have discussed about the work that has been done on Stuttering Detection. In Section-3, we describe the SEP-28K dataset and in Section-4, we explain the architecture of the LSTM-attention model. In Section-5, we present the experimental results and Section-6, concludes the work.

II. Related Work

Different deep learning methods have been proposed in the literature for stuttering detection **[6]**.

Kourkounakis et al. **[7]** proposed a model FluentNet that consists of a Squeeze-and-Excitation Residual convolutional neural network which facilitates the learning of strong spectral frame-level representations, followed by a set of bidirectional long short-term memory layers that aid in learning effective temporal relationships. An attention layer has been used in the model to identify the important portions of the speech to

979-8-3315-1189-0/25/$31.00 ©2025 IEEE

enhance performance. It was implemented on the UCLASS**[8]** dataset as well as LibriStutter: a disfluency dataset based on the public LibriSpeech dataset with synthesized stutters.

Lea et al. **[5]** prepared a large stuttering dataset named SEP−28k and used the ConvLSTM (Convolutional LSTM) model to detect various types of stuttering. On SEP-28K, the model performed poorly for blocks and word repetitions as compared to other disfluency labels.

Al-Banna et al. **[9]** also proposed a model for stuttering detection to evaluate stuttering severity. The model accepted log mel spectrogram and used a 2D atrous convolutional network to learn speech spectral and temporal features. They evaluated the performance of the model on UCLASS and FluencyBank **[10]** datasets. According to their experimental results the model performed better than pre-existing methods for prolongation in terms of F1 score on the FluencyBank and UCLASS datasets.

Hamdi et al**. [13]** proposed an augmentation pipeline which was applied on the pre-filtered data and used pitch-shifting technique to augment the raw signal as well as spectral data augmentation technique to augment the computed mel-spectrograms.

III. DATA

In this paper we reference the dataset SEP-28K which is a publicly available stuttering events in podcasts dataset prepared by Lea et al**. [5]** from a set of 385 podcasts. From each podcast, 3 seconds long segments are chosen which gives us an aggregate of 28,177 segments.

SEP-28K consists of stuttering clips labelled according to the following categories: disfluent and non-disfluent. In this paper we concern ourselves only with the disfluent labels of this dataset. These labels are prolongations, repetitions, blocks, interjections, fluent. Each label has values 0, 1, 2 or 3 for the number of listeners (out of 3) who agreed with the respective label.

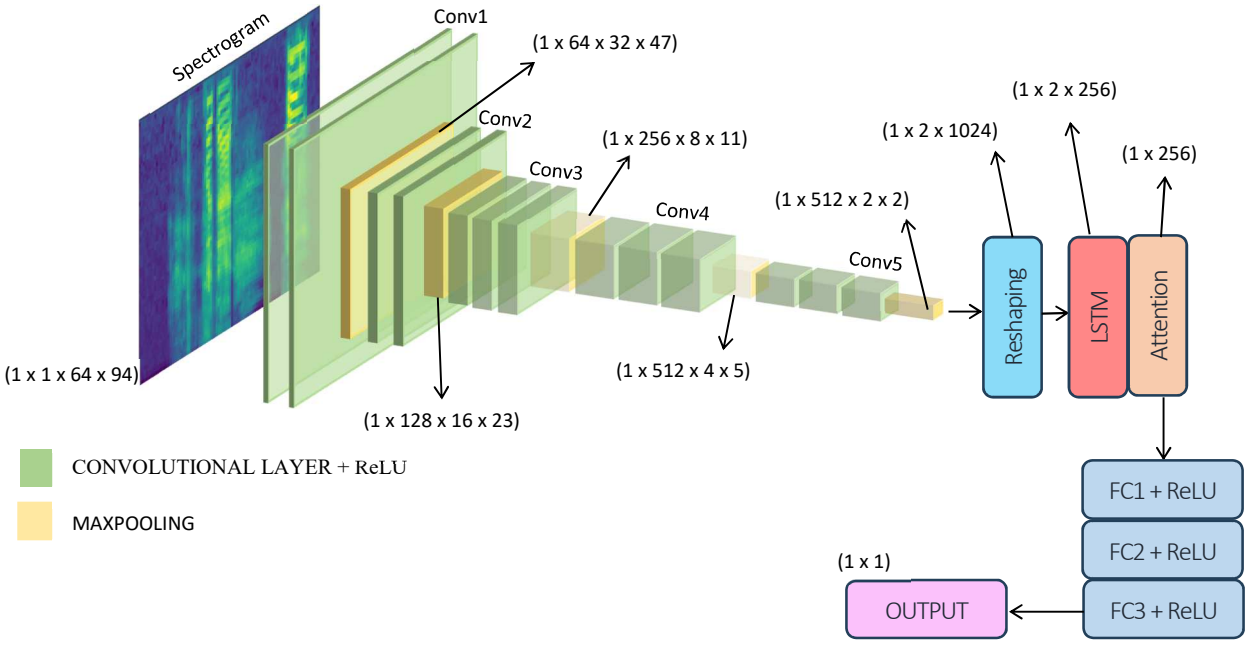

Fig 1: Model architecture- CNN+ LSTM+ Attention

Sheikh et al**. [11]** addressed the class imbalance problem in stuttering detection via a multi-branching scheme and by weighting the contribution of classes in the overall loss function, and conducted their experiments on the SEP-28K dataset over the baseline (StutterNet **[12]**). They used data augmentation to deal with data scarcity. Training the model with augmented data gave better results than the multi-branching StutterNet in terms of macro F1-score. They also proposed a new model, a multi-contextual (MC) StutterNet. It captured multiple contexts of the speech clips. This model had a better performance than the single context based multi-branching model for the dataset.

An LSTM-Attention based model similar to the one we use for our experiments, has been used for Covid-19 detection.

We have chosen samples from shows 'HeStutters', 'IStutterSowhat', 'MyStutteringLife', 'StutterTalk' and 'WomenWhoStutter'. This reduces the total samples in our experiment to 21,120. We randomly select 80% of these samples to train the model whilst the remaining 20% are reserved for testing the model. We have also converted the label values into binary i.e. 0 and 1 by setting values equal to and greater than 1 as 1, and the values less than 1 as 0. This allows us ease of classification into true and false categories.

IV. Model Architecture.

The LSTM-Attention model is a hybrid architecture designed to integrate CNN for feature extraction, the LSTM component for capturing the temporal features and the Attention layer to improve performance by identifying the most important features. The CNN component is based on the VGG-16 **[14]** architecture, consisting of 5 blocks of convolutional layers. Each mel spectrogram of the dimensions 64 x 94 is passed through the CNN layers and then the output is reshaped into a tensor of dimensions 2 x 1024. The reshaped output obtained from the CNN layers is then passed through 2 LSTM layers each consisting of 256 units. An attention mechanism **[13]** is then applied to the LSTM output. The attention layer includes a linear layer with 256 units, a Tanh activation, and a Softmax function. The attention output is element-wise multiplied with the LSTM output and summed. The output of the attention layer is then passed through 3 fully-connected layers with 4096 units, 4096 units and 1unit respectively. Similarly, we have the LSTM-only model, but the attention layer is removed.

Table 2: Experimental Results – Accuracy(%)

Model	Disfluency / Stuttering Label of SEP-28K					
	Block	Prolongation	Sound Repetition	Word Repetition	Interjection	Fluent/ No stutter
VGG-16+LSTM+Attention	**60.80**	**70.47**	64.25	**56.90**	72.11	61.50
VGG-16+LSTM	60.34	69.43	**65.22**	55.23	72.11	**66.52**

Table 3: Experimental Results - F1 Score(%)

Model	Disfluency / Stuttering Label of SEP-28K					
	Block	Prolongation	Sound Repetition	Word Repetition	Interjection	Fluent/ No stutter
VGG-16+LSTM+Attention	**57.87**	**61.07**	**41.69**	**33.67**	61.55	70.77
VGG-16+LSTM	56.53	58.01	41.40	31.11	**61.82**	**77.49**

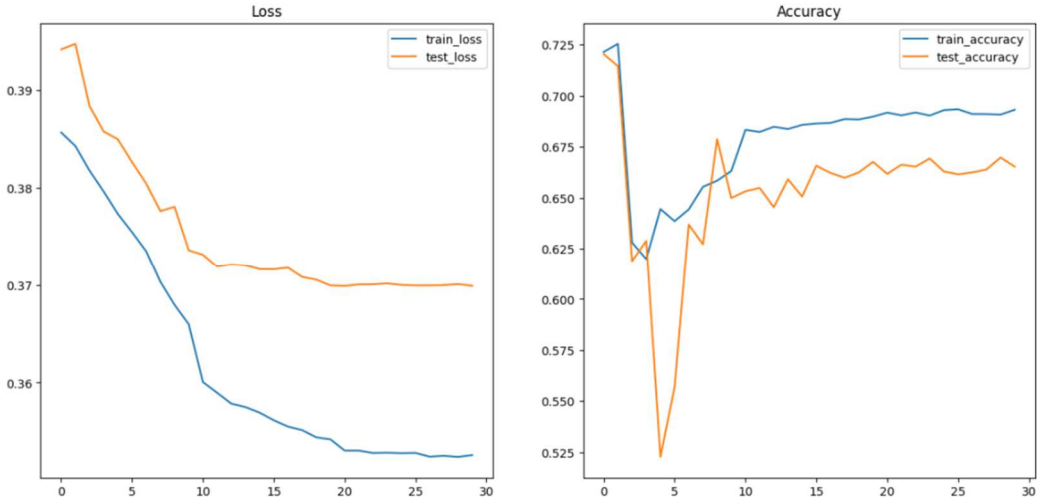

Fig 3: Training and validation loss/accuracy for CNN - LSTM on fluent-label data

V. Experimental Results

A. Setup

We used PyTorch for processing and converting the audio clips into mel spectrograms, as well as building the models. The dataset was highly imbalanced, so we used a weighted loss function. The weight for the positive class was calculated by dividing the number of negative samples by positive samples. We used the Adam optimizer set at a learning rate of 0.00001 and weighted binary cross-entropy loss to train the models for 30 epochs with each batch of size 32 samples.

B. Evaluation and Results

To evaluate the models' performance, we used two metrics: accuracy and F1-score. We used 80% of the data for training and the remaining 20% for testing the models.

We trained and evaluated our models using the SEP-28K dataset. We carried out two experiments: the first with a CNN + LSTM model, and the second with a CNN + LSTM + Attention model. This was done for each disfluency (prolongations, sound repetitions, word repetition, blocks, interjections, and fluent) separately. For each disfluency, the models performed binary classification. **Tables 2, 3** show the results of the experiments. **Figures 2, 3** show the training and validation losses and accuracies for our 2 models for the fluent/no-stutter label.

The CNN + LSTM + Attention model performed better in terms of accuracy for word repetition, prolongation, and block compared to the CNN+LSTM model. While the CNN+LSTM model performed better for sound repetition and no stutter labels. For the interjection label both models have similar accuracy.

VI. Conclusions

This paper presents a study on stuttering detection using an LSTM-Attention based hybrid CNN model and an LSTM based hybrid CNN model. Our models perform binary classification by taking a mel spectrogram as an input to identify whether a person has one of the disfluencies (Prolongation, Block, Interjection and Repetition). The CNN component of our models extracts the relevant features, the LSTM component captures the temporal features and the Attention layer improves the performance by identifying the most important features.

We compared the results of two experimental results, one with the CNN - LSTM model and the other with the CNN-LSTM-Attention model. We used the SEP-28K dataset for all our experiments. In order to deal with the imbalanced dataset, we used a weighted loss function. The CNN - LSTM - Attention model had better performance in terms of accuracy for Word repetition, Prolongation, and Block detection as compared to the CNN - LSTM model. While the CNN - LSTM model performed better for sound repetition and no stutter labels.

In our future work we will be exploring different model architectures similar to **[15][16][17]** and evaluate their performance against our baseline models.

Dielectric properties

ABSTRACT

Herein, we investigate the impact on electroactive phase and dielectric properties of polyvinylidene fluoride (PVDF) on addition of hydrothermally synthesized SnO_2/MXene (SNMX) nanocomposite with different concentration (0.25 wt%, 0.50 wt%, 0.75 wt%) as nanofillers. The pure and SNMX/PVDF composite films were fabricated using solution casting method. Morphological and structural analyses revealed a modified spherulitic structure, indicating a transformation from the non-polar phase (52 %) to the polar ($\beta + \gamma$) phase (86 %). The dielectric measurements were conducted over a frequency range of 20 Hz to 1 MHz at different operating temperature to examine the various relaxations occurring in the polymer. At 25 °C and an applied field frequency of 20 Hz, the relative dielectric permittivity of the SNMX/PVDF composite film (0.75 wt%) elevates approximately 25-fold relative to the pristine PVDF film, with a concomitant reduction in loss tangent. Further, the relative dielectric permittivity of all films intensifies with rising operating temperature. At 100 °C, the relative dielectric permittivity amplifies from 165 to 250 compared to room temperature for the 0.75 wt% nanofiller concentration. The increment in dielectric properties with addition of SNMX are attributed to a) the enhancement of the electroactive phase, which favours molecular reorientation, b) the presence of SnO_2 semiconductive layer on the surface of MXene flakes that prevent formation of conductive pathways, thus improves the interfacial polarization through the Maxwell–Wagner–Sillars (MWS) effect in addition to dipolar polarization. A piezoelectric flexible nanogenerator (PENG) fabricated from the 0.75 wt% SNMX/PVDF nanocomposite film generated a maximum peak to peak voltage is 105 V.

1. Introduction

In recent years, flexible dielectric materials have garnered significant interest due to their potential applications in the rapidly developing field of flexible nanoelectronics. In this context, dielectric polymers have attracted considerable attention because of their desirable physical and chemical properties [1–3]. However, polymers generally exhibit lower dielectric constants compared to inorganic materials. For instance, polyvinylidene fluoride (PVDF), a prototypical dielectric polymer, has a dielectric constant of approximately 6.8 and a loss of about 0.0184 at 1 kHz, owing to its fluorinated structure [4]. In contrast, inorganic materials such as ZnO, TiO_2 and $BaTiO_3$ demonstrate much higher dielectric constants at room temperature [5–7]. Despite excellent dielectric properties, inorganic ceramics possess limitations, including brittleness, limited tunability, susceptibility to dielectric breakdown, and low toughness. As a result, their use in flexible nanoelectronics is constrained [8].

In contrast, PVDF offers strong flexibility, and excellent mechanical strength which make it suitable for flexible nanodevices. However, due its low dielectric constant than the inorganic materials hinder its application to nanoelectronics devices. Thus, researchers are trying to improve the dielectric constant and electroactive phase of PVDF. It exists in three phases: α, β, and γ with the β and γ phases being electroactive [9]. In recent times, polymer nanocomposites, incorporating inorganic nanofillers into the polymer matrix, enhancing PVDF's dielectric properties while retaining the advantages of both materials [1]. However, increasing the filler content raises the dielectric constant, but it also leads to higher dielectric loss, reduced flexibility and crystallinity [3, 10].

The choice of nanofiller also influences phase transitions within the

polymer. SnO_2, nanostructures have been established as an efficient inorganic nanofiller [11,12]. For example, Zhe et al. reported a high dielectric constant of approximately 300 at 10 kHz for SnO_2/PVDF nanocomposites with a high nanofiller concentration of 0.16 vol% [11]. Adding nanostructure of inorganic materials significantly elevates specific surface interactions, which improves PVDF's electroactivity thus the dielectric properties [12].

Similarly, $Ti_3C_2T_x$ MXene has gained attention as an effective conductive filler due to its exceptional electrical conductivity of approximately 6500 S/cm and an elastic modulus of around 0.33 TPa [13,14]. MXene-based polymer nanocomposites are capable of achieving high dielectric constants with low percolation thresholds. However, as the filler loading approaches the percolation threshold, there is a significant boost in dielectric constant, dielectric loss, and electrical conductivity. This underscores the necessity for surface modifications, such as the incorporation of insulating or semiconductive layers, to optimize the material's performance [13–15].

Recently, incorporation of inorganic nanomaterials/MXene nanocomposites as nanofillers have attracted considerable interest among researchers due to their notable advantages. Specifically, the dispersion of semiconductive layer of inorganic nanomaterials on MXene nanosheets obstruct the establishment of conductive pathways. Thereby suppressing the electrical conductivity and enhances the charges at surfaces, thus improves the dielectric properties [15–17]. Like as Feng et al. synthesized $BaTiO_3$/MXene/PVDF composites, incorporating 8 wt % $BaTiO_3$ and 2 wt% MXene, which exhibited a dielectric constant of 77 and a loss of 0.15 at 100 Hz [16]. Similarly, at 1 kHz, the MXene/-TiO_2/MoS_2/P(VDF-HFP) nanosheet-loaded nanocomposite films, with an optimal loading of 8.0 wt%, demonstrated a high dielectric constant of 944 while maintaining a low dielectric loss of 0.19 [15]. Similarly, the incorporation of filler into the PVDF matrix has proven to be highly effective in enhancing the piezoelectric performance of PVDF. For instance, Kumari P. et al. Reported the improved output power 0.14 mW/cm^2 of PVDF films upon the addition of $BaTiO_3$ nanofillers [18].

Interestingly, to the best of our knowledge, the impact of SNMX nanocomposite fillers on dielectric behaviour of PVDF films has not been previously reported. Additionally, the most studies focus on higher filler concentrations, typically exceeding 5 wt%, which can reduce crystallinity, alter electroactive properties, and form networks within the polymer matrix [2]. These changes can affect electrical conductivity and augments dielectric loss. To overcome these challenges, this study employs a very low filler concentration of SNMX nanofillers, demonstrating high dielectric constant and low loss at lower filler loading [10]. The reduced filler content did not compromise the transparency, flexibility, or crystallinity of the nanocomposite films.

In this study, we have synthesized a nanocomposite of SnO_2 nanoparticles with 20 wt% of $Ti_3C_2T_x$ MXene nanosheets using hydrothermal method. The synthesized SNMX nanocomposite was used as nanofiller for the fabrication of PVDF composite films with three different weight concentrations (0.25 wt%, 0.50 wt%, and 0.75 wt%). Notably, the SNMX nanocomposite has been shown to preferentially induce the electroactive β and γ phases in PVDF. Additionally, significant improvements in the dielectric properties have been observed, with relative dielectric permittivity (ε_r) of 150 and 165 and loss tangent (tanδ) of 0.8 and 2.1 at 20 Hz for the 0.50 wt% and 0.75 wt% SNMX/PVDF composite films, respectively. Temperature-dependent studies indicate that at 100 °C, the relative dielectric permittivity of the 0.75 wt% SNMX/PVDF composite film reaches 250. The enhanced electroactive behaviour and dielectric properties, coupled with the exceptional durability of the SNMX/PVDF films, suggest their potential application as flexible power sources in portable electronic devices employing piezoelectric technology. Notably, the piezoelectric flexible nanogenerator (PENG) made from the 0.75 wt% SNMX/PVDF nanocomposite film produces a peak-to-peak voltage of 105 V.

2. Experimental section

2.1. Materials

All reagents used in the experiment were of analytical grade and were employed without any modifications, as received. MAX phase Ti_3AlC_2 (≥90 %, particle size of ≤100 μm), hydrofluoric acid (HF, 40 wt %), stannic chloride pentahydrate ($SnCl_4.5H_2O$), sodium hydroxide (NaOH), N-dimethylformamide (RG, 99.8 %) (DMF), Urea (CH_4N_2O) and hydrochloric acid (HCl) were purchased from Sigma-Aldrich Chemical Co. Ltd. The used polyvinylidene fluoride (PVDF) powder was purchased from Alfa Aesar.

2.2. Synthesis of tin oxide nanostructure (SnO_2)

A low-cost hydrothermal method was used to synthesize SnO_2 nanoparticles as shown in Fig. 1 (a). 4 g of $SnCl_4.5H_2O$ was dissolved in 30 mL ethanol and magnetically stirred to obtain a clear solution. Subsequently 1.095 g of citric acid was added into the solution and further stirred for 2 h. The resultant white solution was transferred to an autoclave filled with 70 % capacity and treat it hydrothermally for 8 h at 160 °C. After the reaction time, the precipitates were centrifuged and washed multiple times with DI water and ethanol. The collected precipitate was dried at 60 °C for 12 h.

2.3. Synthesis of MXene

$Ti_3C_2T_x$ sheets were produced by selectively etching the Al layer from the MAX phase Ti_3AlC_2 and then delaminating it using an intense layer delamination method [14]. First, 1 g of MAX phase powder was mixed with 48 % concentrated hydrogen fluoride (HF) for 24 h at room temperature using a magnetic stirrer. The mixture was filtered and the obtained precipitates washed multiple times with deionized water and centrifuged until the pH reached 7. Finally, the filtered black slurry was dried for 6 h at 80 °C and grinded into a fine powder to obtain $Ti_3C_2T_x$ MXene sheets. The used synthesis process is depicated in Fig. 1 (b).

2.4. Synthesis of SnO_2/MXene (SNMX) nanocomposite

The SnO_2/MXene nanocomposite was synthesized using the hydrothermal method. This process involved sonicating SnO_2 and $Ti_3C_2T_X$ (20 wt%) in 100 mL of distilled water, followed by the addition of 0.32 g of urea and dropwise addition of 40 μL of HCl. The resulting solution was then sealed in an autoclave and heated at 120 °C for 8 h. The resulting powder was extracted, centrifuged, and then sequentially cleaned with ethanol and deionized water. It was then allowed to dry overnight at 60 °C in an oven. The produced SnO_2/MXene nanocomposite are referred to as SNMX nanocomposite.

2.5. Synthesis of PVDF film

PVDF powder was dissolved in a 10 wt% solution of N-dimethylformamide (DMF) to produce the flexible, free-standing PVDF films. The mixture was stirred at ambient temperature for a duration of 4 h. The resulting solution was then applied to cleaned glass slides and annealed at 80 °C in a microwave oven for 2 h. Subsequently, the films were detached to yield flexible, free-standing films.

2.6. Synthesis of SNMX/PVDF composite films

Polyvinylidene fluoride (PVDF), SNMX powder, and DMF were used in the preparation of flexible composite films. PVDF powder was first dissolved in DMF for 1 h at room temperature using a magnetic stirrer, resulting in a homogeneous and clear solution. On the other hand, SNMX powder was added to DMF in varying concentrations (0.25 wt%, 0.50 wt %, and 0.75 wt%) and ultrasonically agitated for 1 h at room

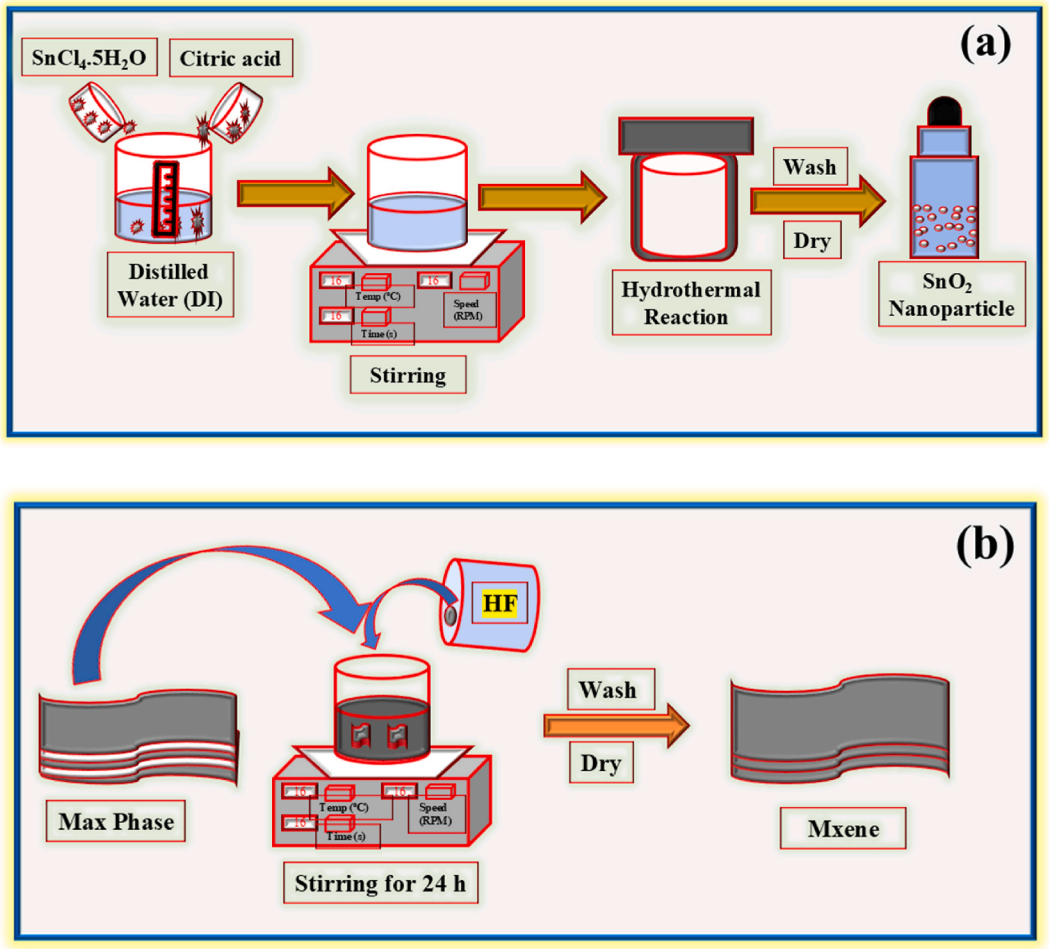

Fig. 1. A stepwise depiction of the synthesis processes for (a) SnO_2 nanoparticles and (b) Mxene flakes.

temperature. The PVDF solution was then combined with the synthesized different wt% SNMX solutions and stirred for 40 h at room temperature to get a slurry type solution of SNMX/PVDF composite. The resulting solution was then applied to cleaned glass slides and annealed at 80 °C in a microwave oven for 2 h. Subsequently, the films were detached to obtained flexible, free-standing films. Further, the thickness of the synthesized films was measured using digital vernier calliper and the measured thickness values of the synthesized composite films are tabulated in Table 1.

2.7. Fabrication of the piezoelectric flexible generator

The flexible composite films were sectioned into small pieces, each measuring 2.5 cm × 2.5 cm, and aluminium tape was applied to both surfaces to function as the top and bottom electrodes for the piezoelectric flexible nanogenerator (PENG). Copper wires were then attached to the aluminium tape using copper tape to measure the output signals when pressure was applied and the device was connected to an external circuit. Fig. 2 (a & b) illustrates both the schematic diagram of the fabricated PENG device and a digital photograph of the prepared

PENG devices.

2.8. Characterizations

The crystal phases of the synthesized samples were determined using a Rigaku Ultima IV X-ray diffractometer (XRD) equipped with a Cu Kα (λ = 1.5418 Å) radiation source. The scans were performed at a rate of 2° per minute across a 2θ range of 5°–70°. An energy-dispersive X-ray spectroscopy (EDX) system (SwiftED3000, Oxford) was used for elemental mapping and compositional analysis, and an FEI Quanta 200 field emission scanning electron microscope (FESEM) was used to analyse the surface morphology of the samples. Fourier transform infrared (FTIR) spectroscopy (NICOLET 5700) was used to analyse the electroactive phases of the PVDF and composite films. The dielectric characteristics were measured using an impedance analyzer (E4990A), with a frequency range of 20 Hz to 10 MHz.

3. Results and discussion

3.1. X-ray diffraction

Structural characterization of the MAX phase Ti_3AlC_2 (before HF etching) and synthesized MXene $Ti_3C_2T_x$ (after HF etching) were performed using X-ray diffraction (XRD), as shown in Fig. 3(a). XRD pattern of the MAX phase is in good agreement with the data presented in JCPDS card no. 00-052-0875.A characteristic sharp peak corresponding to the Al layer is observed in the MAX phase at 2θ = 38.92° along the preferred (104) direction, which needs to be fully etched out during the synthesis process. The other prominent peaks at 2θ = 9.4°, 38.04°, 41.74°, 60.2°, and 74.2° correspond to the (002), (101), (105), (110), and (118) planes, respectively. After HF treatment, the characteristic diffraction peak at 2θ = 38.92° (104) corresponding to Al disappears in the XRD pattern of MXene $Ti_3C_2T_x$, confirming the complete removal of Al from the MAX phase. Most notably, the diffraction peak for the (002) plane shifts backward after HF etching, from 2θ = 9.4° in the MAX phase to 2θ = 9.02° in the MXene. This peak shift is attributed to the intensify in the c-lattice parameter of the MXene and indicates the formation of an interlayer gap in the layered structure. The XRD peaks match well with JCPDS card no. 00-032-1383, confirming the successful synthesis of MXene $Ti_3C_2T_x$ sheets from the MAX phase by HF etching [13–19].

Fig. 3(b) displays the XRD pattern of nanocrystalline SnO_2 nanoparticles (NPs). The strong diffraction peaks indicate excellent crystallinity and tetragonal rutile phase of the SnO_2. The diffraction peaks at 2θ = 26.58°, 33.94°, 38.02°, 51.80°, 54.75°, 58.09°, and 65.87° are well indexed to (110), (101), (200), (211), (220), (002), and (310) planes, respectively, according to JCPDS Card No. 41–1445 [2,11]. The SNMX composite exhibited almost all of the distinct peaks of both MXene and SnO_2, suggesting successful synthesis of SNMX nanocomposite [20]. The modest broadening of the peaks, is attributed to an increase in d-spacing and a rise in the orderliness of the crystal planes.

Fig. 4(a) presents the X-ray diffraction (XRD) patterns for all the films under investigation, spanning a 2θ range from 10° to 50°.The α, β, and γ phases constitute the majority of the PVDF and SNMX/PVDF composite films at varying concentrations. The diffraction peaks at 18.4°, 20.0° and 26.6° which can be indexed to the (020), (110), and (021) planes, respectively, correspond to the α phase of PVDF. The XRD pattern displays two moderate peaks at approximately 18.5° and 39.0°, and a strong peak at 20.3°, which can be affiliated to the γ phase. These diffraction peaks correspond to the (110/101), (020), and (211) planes, respectively. In contrast, a weak peak at 38.8°, corresponding to the (002) plane, and at 20.6°, corresponding to the (110/200) plane, are predominantly associated with the β phase. Fig. 4(b) is the magnified version of the XRD within the range of 15°–25°. The pattern reveals a noticeable decrease in the intensity of peaks associated with the α phase, while the intensities of peaks corresponding to the β and γ phases elevate significantly with the rising concentration of SNMX. The intensifies in

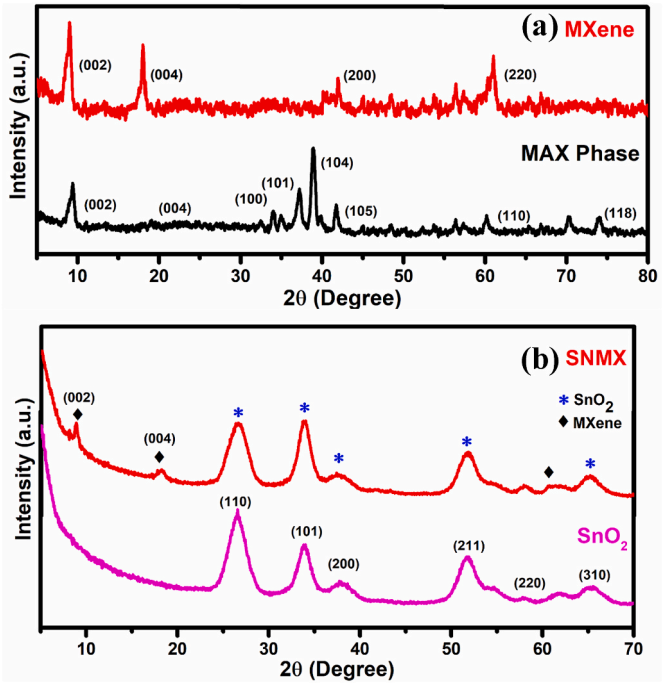

Fig. 3. XRD patterns of (a) MAX powder (Ti_3AlC_2) compared to MXene, and (b) comparison between SnO_2 nanoparticles and SNMX nanocomposite.

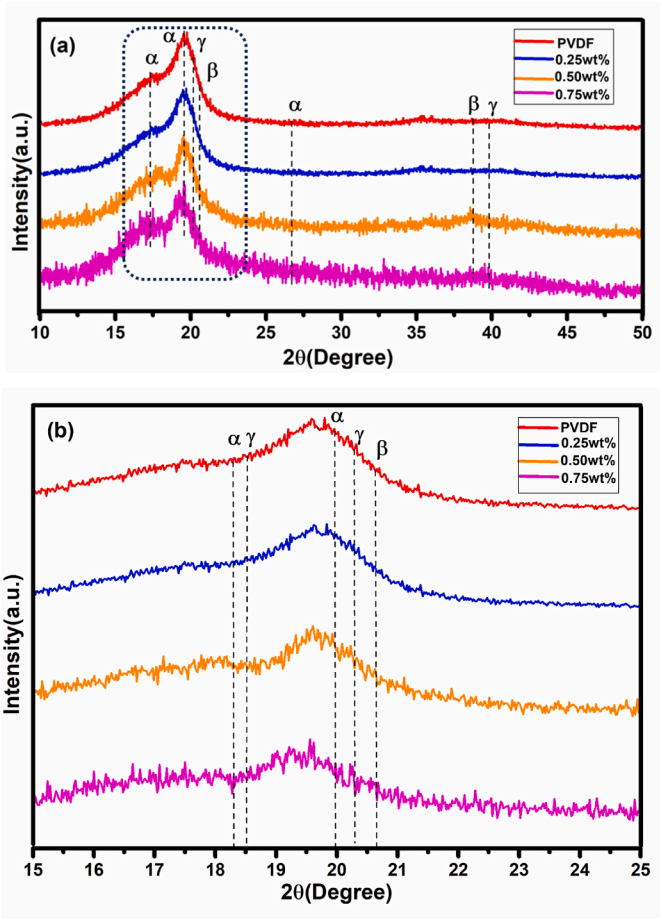

Fig. 4. XRD pattern of (a) representative samples and (b) magnified view highlighting the phases.

intensity of the (β + γ) phase suggesting the phase transition in the composite films due to the presence of nanofiller [9,10,21]. Further, the intensity ratio of the EA (β + γ) phase to the α phase has been estimated, and it was found that the electroactive (EA) phase of the highest 0.75 wt % SNMX/PVDF films is 1.3 times greater than that of the pure PVDF film. The obtained EA phase ratio corresponding to PVDF, 0.25 wt% SNMX/PVDF, 0.50 wt% SNMX/PVDF and 0.75 wt% SNMX/PVDF are 0.58, 0.62, 0.73, and 0.80 respectively. It is also important to highlight that the crystallinity of the PVDF films progressively decreases as the concentration of the nanofiller increases. This decrement in the crystallinity may be due to formation of new nucleation sites. However, as the concentration of nanofiller is very low so decrement in the crystallinity is very low as compared to reported data [15]. Thus, the obtained XRD results confirms that EA phase of the films increases without significant loss the crystallinity of the polymer.

3.2. Fourier transform infrared spectroscopy (FTIR)

Fig. 5 (a) displays a plot of the FTIR spectrum of pure PVDF and SNMX/PVDF films in the range of 400–1500 cm^{-1}. The spectra show peaks that correspond to the different phases (α, β and γ) of the PVDF. The exclusive peaks for the α phase are at approximately 488,534,616,764, 976 and 1207 cm^{-1}; for the β phase, they are at 473 and 1275 cm^{-1}; and for the γ phase, they are at 482, 811 and 1234 cm^{-1}. The absorbance for the β+γ phases is notably stronger than that of the α phase, as indicated by the peaks at 837 and 511 cm^{-1}. Consequently, the electroactive β and γ phases can be characterized by the presence of these two peaks. Several studies suggest that the peaks at 1431 and 1429 cm^{-1} can be used as characteristic bands for the β and γ phases, respectively [9,10,21]. To clearly observe how the loading of SNMX affects the intensity of the unique peaks, magnified spectra in the ranges of 740 cm^{-1} to 860 cm^{-1} and 1140 cm^{-1} to 1320 cm^{-1} have been plotted and are shown in Fig. 5 (b & c). It can be seen that the intensity of the α phase peaks at 764 cm^{-1} and 976 cm^{-1} decreases, while the intensity of the β+γ phase (837 cm^{-1}) and γ phase (1235 cm^{-1}) increases with the increment in the percentage of SNMX in the PVDF matrix, suggesting transformation of α phase into β andγphases. The absorption peak at 764 cm^{-1} cans be attributed to the bending of the CF_2 skeleton, whereas that at 837 cm^{-1} originates from the rocking of the CH_2, the stretching of the C-C skeleton and CF_2, these two peaks correspond to the non-polar α- and polar β-phases [5]. In fact, for the 0.75 wt% film, the α phase peaks nearly disappear due to the incorporation of SNMX in PVDF matrix. The relative fraction (F_{EA}) of the EA phases (β andγ) in terms of crystalline components has been calculated using equation (1) for all the films [22].

$$F_{EA} = \frac{I_{837}}{\left(\frac{K_{837}}{K_{764}}\right) I_{764} + I_{837}} \times 100\% \quad (1)$$

In this context, F_{EA} represents the fraction of the electroactive phase, while I_{837} and I_{764} denote the peak intensities at wavenumbers 837 cm^{-1} and 764 cm^{-1}, respectively. The values of K_{837} (7.7 × 10^4 cm^2/mol) and K_{764} (6.1 × 10^4 cm^2/mol) correspond to the molecular absorption coefficients at these respective wavenumbers.

The fraction formula indicates that when SNMX nanofiller incorporated into the PVDF matrix, the F_{EA} intensifies. The calculated F_{EA} values for various samples have been plotted in Fig. 5(d). The F_{EA} of the 0.75 wt % film (86 %) is 1.5 times higher compared to that of the pure film (52 %). These results align with the XRD results, which showed a decrease in the α content of the composite films and an increase in their EA phase. The rise in the electroactive phase suggests that the molecules have reoriented [10]. In this case, the polarization induced by the SNMX nanofillers promotes this reorientation. The material's elevates dielectric constant, which will be discussed subsequently, further illustrates this reorientation and the associated enhancement of the electroactive

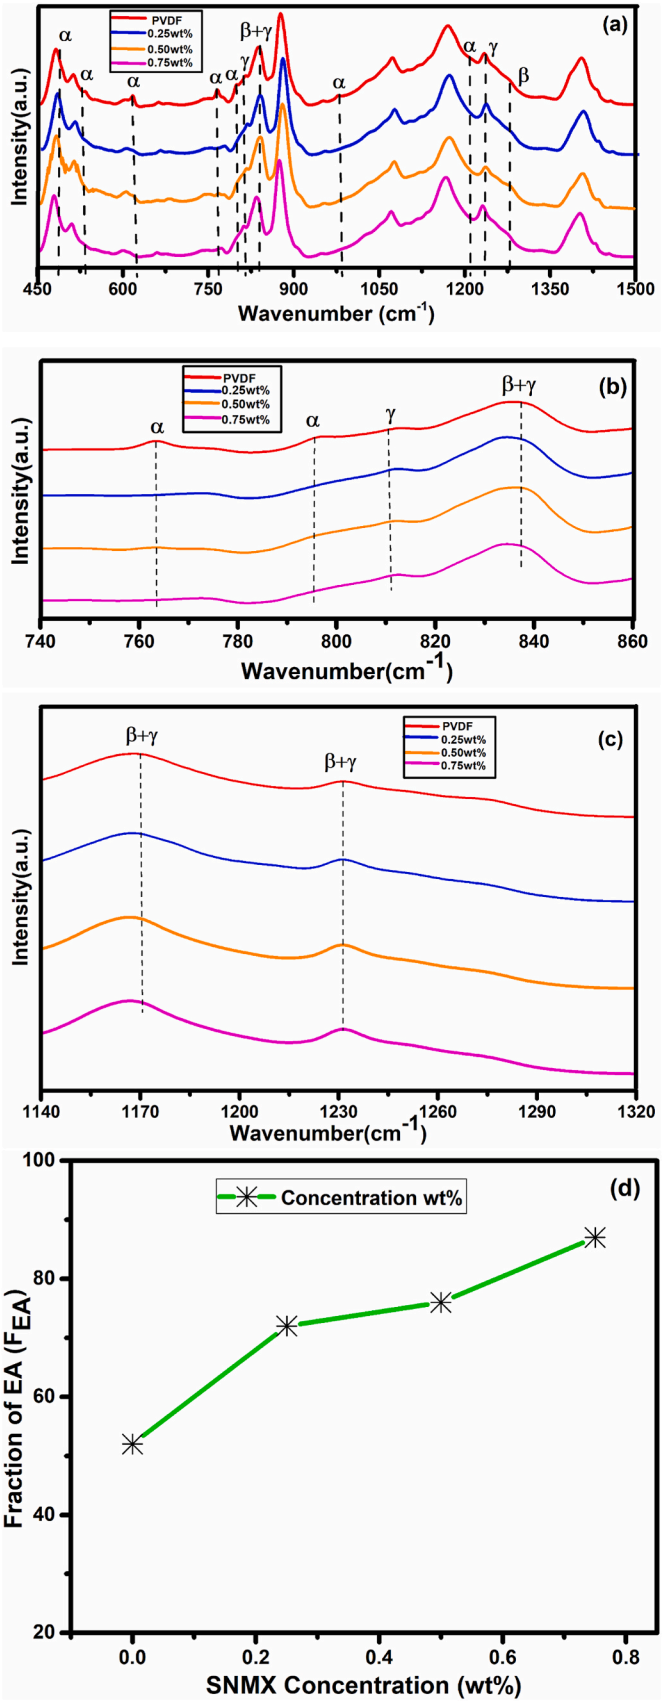

Fig. 5. FTIR spectra of all samples across different ranges: (a) 400–1500 cm^{-1}, (b) 740–860 cm^{-1}, (c) 1140–1320 cm^{-1}, and (d) plot of the fraction of EA versus SNMX concentration (wt%).

(EA) content.

3.3. Morphological and compositional analysis

FESEM analysis was employed to investigate the morphology and structure of exfoliated MXene, SnO_2 nanoparticles (NPs) and the SNMX nanocomposite. Fig. 6(a–f) shows the obtained images at low and high magnification. After the HF treatment of the MAX phase (which exhibited an uneven surface and tightly packed structure), transformed into an accordion-like morphology of MXene, as depicted in Fig. 6 (a & b). Additionally, the parallel arrangement of MXene layers resulted from the specific etching direction of "Al" [19]. The nanocrystalline morphology of SnO_2 nanoparticles (NPs) is shown in Fig. 6 (c & d). Further, the FESEM analysis confirmed the composite synthesis by the high dispersion of NPs among the MXene flakes. It can be clearly observed that the SnO_2 NPs are integrated in between the MXene layers preventing their restacking. However, some aggregated SnO_2 NPs are dispersed on top of the MXene sheets. EDX was employed to verify the elemental composition of the SNMX composite. The peaks for Sn, Ti, C, and O are observed in the EDS spectra within the 1–10 keV region as shown in Fig. 7(a). The atomic percentages of the SNMX nanocomposite are listed in the Table in the spectra [20]. The distribution of SnO_2 nanoparticles across the MXene is confirmed by the elemental mapping of the SNMX nanocomposite, which shows the presence of mixed elements of SnO_2 and MXene in the characterized area and represented in Fig. 7(b–g).

FESEM images of pure PVDF and the SNMX/PVDF composite films are presented in Fig. 8(a–d). The porous and spherulitic microstructure observed in both pure and SNMX/PVDF composite films. The morphologies of all the composite films are nearly identical. It can be observed as the SNMX filler concentration increases the surface of the films become more porous thereby suggesting uniform dispersion of SNMX nanocomposite within the PVDF matrix. Which facilitates the migration of charges within the composite film and aids in aligning the dipoles in a specific direction [22,23]. Additionally, the increment in the number of pores further indicates that incorporation of SNMX nanocomposite enhances the surface roughness of the composite films.

3.4. Impedance spectroscopic: dielectric parameters

Dielectric spectroscopy has been employed to investigate the dielectric behaviour of the prepared films. The dielectric properties of bulk or nanoscale solid materials are influenced by the spatial distribution and alignment of the local electric field within the system. Consequently, the temperature dependence and frequency-dependent relative dielectric permittivity and loss tangent offer valuable insights into the defect behaviour, structural changes and transport mechanisms within the solid [24–26].

The dielectric constant exhibits a complex nature and can be expressed as Equation (2):

$$\varepsilon^* = \varepsilon_r - j\varepsilon_r'' \tag{2}$$

The real part of the complex dielectric constant (ε^*), also known as the relative dielectric permittivity (ε_r), measures the electrical energy stored in the material when a necessary alternating electric field is applied. In contrast, the imaginary part (ε"), the dielectric loss, describes the energy dissipated in the material, as the molecules undergoing polarization are unable to match the rate of oscillation of the external electric field [27].

The relative dielectric permittivity (ε_r) and loss tangent for the materials were determined using Equations (3) and (4), respectively.

$$\varepsilon_r = \frac{Cd}{A\varepsilon_0} \tag{3}$$

$$tan\,\delta = \frac{\varepsilon_r''}{\varepsilon_r} \tag{4}$$

where A is the electrode area, ε_0 is the permittivity of free space (8.85×10^{-12} F/m), d is the sample thickness, C is the capacitance [23–26].

Fig. 9(a–d) shows the variation of the relative dielectric permittivity with frequency (20 Hz - 10 MHz) of the applied electric field at different operating temperatures for all the films. It is evident that the relative dielectric permittivity (ε_r) intensifies with temperature across the entire frequency range, while it diminishes with higher frequency. Furthermore, the incorporation of the SNMX nanocomposite into the PVDF matrix significantly enhances the relative dielectric permittivity of the films. At room temperature and 20 Hz, the relative dielectric permittivity elevates from 7 for pristine PVDF to 35 with 0.25 wt%, 147 with 0.50 wt%, and 165 with 0.75 wt% SNMX/PVDF composite films. Increase in relative dielectric permittivity with the addition of SNMX may be attributed to enhanced Maxwell–Wagner–Sillars (MWS) interfacial polarization and easy charge migration at lower applied frequency [24–26]. As the nanofiller concentration increases, polarization driven by the alignment of interfacial charges between the polymer and the

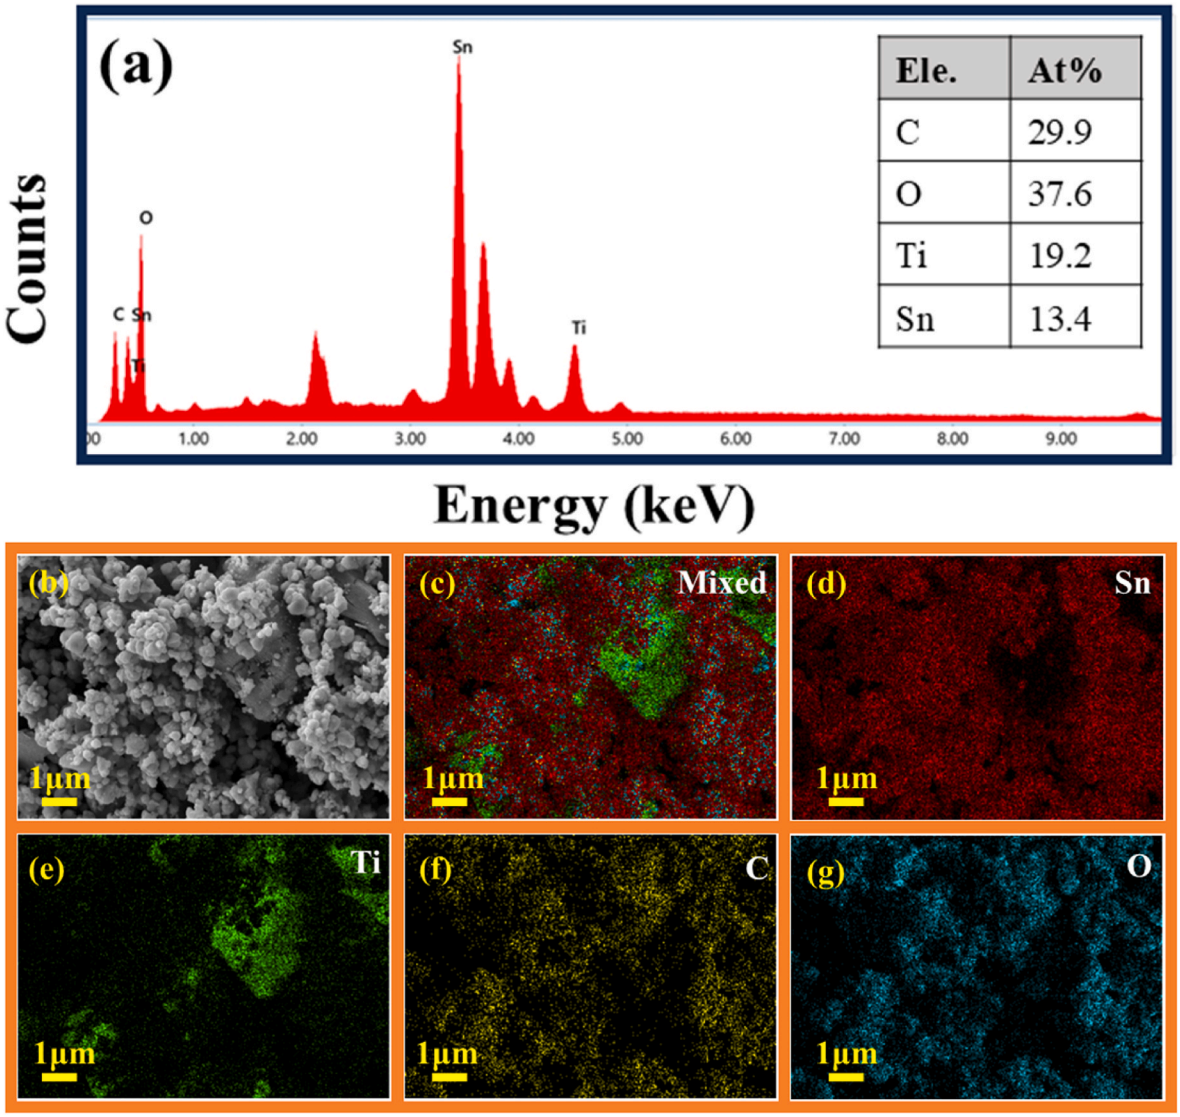

Fig. 7. (a) EDX analysis, and (b to g) elemental mapping of the SNMX nanocomposite.

SNMX nanofiller intensifies. Furthermore, as β and γ phases of PVDF are known to exhibit the highest spontaneous polarization. Thereby, the enhancement in EA phase means increment in the polar phase with loading of SNMX nanofillers favouring the reorientation of the molecules in applied external electric field. Thus, the film with high EA content demonstrates the maximum dielectric constant [10,23].

At higher operating temperatures, ε_r continues to proliferate, reaching approximately 250 at 100 °C and 20 Hz, while the relative dielectric permittivity of pure PVDF increases to 60 under the same conditions. At room temperature, the dielectric constant boosts by about 25 times, whereas at 100 °C, it increases approximately 4 times compared to pure PVDF films. These results indicate that even a small amount of SNMX nanocomposite as nanofillers significantly improves the relative dielectric permittivity of PVDF at room temperature. The observed escalation in the relative dielectric permittivity with rising operating temperature can be ascribed to the enhanced segmental motion of the molecular chains in PVDF [23,28].

While additional nanofiller would likely increase the relative dielectric permittivity, it would also result in higher dielectric loss. The variation of the loss tangent (tanδ) with applied frequency (20 Hz - 10 MHz) is plotted for all the films at different working temperature and displayed in Fig. 10(a–d). It has been observed that the loss tangent amplifies as the nanofiller SNMX concentration grows in the PVDF. At 20 Hz and room temperature, the loss tangent of the nanocomposite films with 0.25 wt%, 0.50 wt% and 0.75 wt% SNMX is approximately 0.5, 0.75 and 2.3, respectively, while that of pure PVDF is around 0.2 under the same conditions. The frequency-dependent changes in loss tangent may attributed to different relaxation mechanisms within the materials. One is the α-relaxation in the crystalline region, accounts for the loss tangent at low frequencies. The increase in dielectric loss at higher frequencies suggests a second relaxation peak corresponding to α-relaxation in the amorphous region, occurring in the 1 MHz–10 MHz range [23]. It is interesting to note that the obtained losses are significantly lower with enhanced relative dielectric permittivity as compare to the previous reported data [10,11]. The lower losses are attributed to significant enhancement in the EA phase with low concentration of the SNMX fillers without reducing the crystallinity of the PVDF. For lower filler loadings, up to the percolation threshold, the filler is encapsulated within the PVDF matrix, acting as small, individual capacitors that collectively enhance both ε_r and tanδ [15]. The reduced relative dielectric permittivity and loss tangent of SNMX/PVDF nanocomposites, as compared to PVDF, can be attributed to mobility constraints. The presence of nanoparticles hinders the movement of polymer chains, resulting in an increase in relaxation time and a shift of the relaxation process to lower frequencies. As a result, nanocomposites with a SNMX content exhibit a decrease in dielectric loss [23].

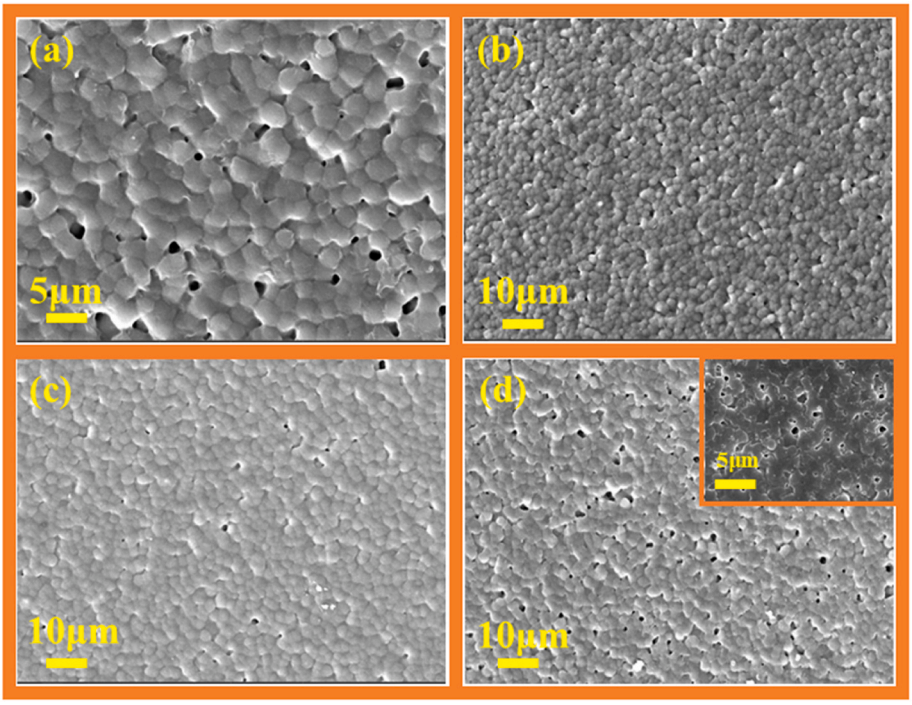

Fig. 8. FESEM images of (a) pure PVDF, (b) 0.25 wt% SNMX/PVDF, (c) 0.50 wt% SNMX/PVDF, and (d) 0.75 wt% SNMX/PVDF.

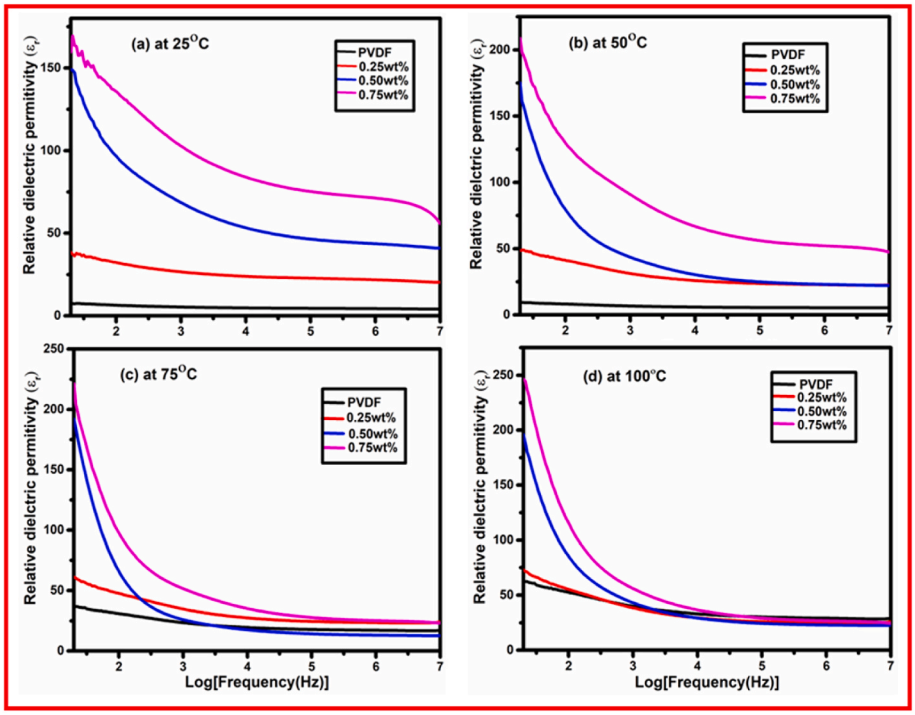

Fig. 9. Relative dielectric permittivity ε_r spectra of PVDF and SNMX/PVDF composites films at (a) 25 °C, (b) 50 °C, (c) 75 °C, and (d) 100 °C.

Further, the temperature-dependent loss tangent behaviour suggests that the losses increase with elevated operating temperatures for all films, except for the 0.75 wt% SNMX nanocomposite film. The 0.75 wt% film demonstrate highest loss tangent (~2.3) at room temperature and lowest loss tangent (~1.1) at 50 °C. However, on further increment in the operating temperature (75 and 100 °C) the loss increases to ~ 1.5 and remains same. Also, the losses of 0.25 wt% and 0.50 wt% films at 100 °C becomes twice that of the at room temperature. The obtained relative dielectric permittivity and loss tangent values at different operating temperature at a frequency of 20 Hz is demonstrated in Fig. 11 (a and b).

A comparison of recent studies on the enhancement of the relative dielectric permittivity of PVDF using different nanofillers is provided in Table 2. Although, some reports demonstrate high relative dielectric permittivity with higher loss tangent at substantial wt% of nanofillers. That leads to degradation in crystallinity and flexibility of the PVDF

11	SnO_2@MXene/PVDF	0.75 wt%	165	2.1	20 Hz	This work

films.

Thus, the obtained dielectric results and findings enhance our understanding the influence of SNMX nanofillers in PVDF matrix. The results suggest that the synthesized films have the potential to act as flexible dielectric material in various industries, including electronics, energy storage, and telecommunications.

4. Piezoelectric flexible nanogenerator (PENG) studies

An oscilloscope was used to measure the generated voltage output after constructing the piezoelectric flexible nanogenerator (PENG) device using the synthesized SNMX/PVDF flexible composite films. The graphs in Fig. 12(a–d) display the open-circuit voltage produced by the devices with different concentrations of SNMX nanocomposites in the PVDF matrix when force was applied using a manual taper. The plots demonstrate that the open-circuit voltage intensifies as the SNMX content in the PVDF matrix rises. The observed peak-to-peak voltage (PPV) outputs for the composite films are 65 ± 1.5 V, 97 ± 1.5 V and 105 ± 1.5 V, corresponding to 0.25 wt%, 0.50 wt% and 0.75 wt% SNMX nanofillers in the PVDF matrix, respectively. While the virgin PVDF film PPV output is 32 ± 1.5 V. The voltage output from the PENG device follows an alternating voltage waveform [2,10,18].

The range of load resistances influences the resulting power density. Therefore, power density of 0.75 wt% SNMX/PVDF composite films were investigated across the load resistances from 500 kΩ to 10 MΩ. The obtained variations in power density as a function of load resistance is presented in Fig. 13. The formula used to calculate the output power density of the PENG device is given in Equation (5). Where V is the voltage across the load resistance R and A is the effective area of electrodes.

$$P = \frac{V^2}{R \times A} \tag{5}$$

The power density increases up to 3 MΩ, reaching a maximum of 0.44 μW/cm^2, after which it decreases as the load resistance continues to increase. According to the maximum power transfer theorem, maximum power is achieved when the internal impedance of the source matches the external load resistance [22].

The PPV output of 0.75 wt% SNMX/PVDF composite film is enhanced by more than three times than that of the pristine PVDF film. It has been reported that boosting the dielectric constant, reducing the film thickness, and improving the surface roughness of the active material are highly effective in improving the performance of the PENG [24,28,32]. Further, the nanofillers are commonly incorporated into polymer matrices to enhance the dielectric constant and the surface roughness of polymers. Thus, this enhancement in PPV output may be attributed to increased relative dielectric permittivity and improved surface roughness of the 0.75 wt% SNMX/PVDF film as suggested by the FESEM. The energy harvested by the PENG can be used to power small circuits, functioning as a nanogenerator.

5. Conclusion

SNMX/PVDF composite films, made of PVDF and SNMX nanocomposites, have been studied for their electroactive phase formation and significant enhancement of dielectric characteristics over a wide frequency range (20 Hz–1 MHz). When 0.75 wt% SNMX is added to the PVDF matrix, the SNMX/PVDF composite film exhibits the maximum electroactive phase yield (F_{EA} = 86 %). FTIR and XRD analyses confirm that the electroactive phases in the SNMX/PVDF films have nucleated. In particular, the SNMX/PVDF films loaded with 0.50 wt% and 0.75 wt% SNMX nanocomposite at 20Hz and room temperature exhibit the high relative dielectric permittivity, 150 and 165, respectively, with notably low loss tangent. The temperature-dependent dielectric characteristics of the manufactured films shows that the relative dielectric permittivity of composite films increase rapidly as compare to pure PVDF. The largest peak-to-peak voltage produced by a piezoelectric flexible nanogenerator (PENG) made from 0.75 wt% SNMX/PVDF nanocomposite film is 105V. Therefore, the SNMX/PVDF composite films with increased electroactive phase, superior dielectric properties and enhanced PPV as PENG suggest that they may/can meet the needs of next-generation electronic components, such as power conditioning, flexible film capacitors, and pulsed power generators.

ABSTRACT

This paper presents a systematic analysis of temperature-dependent coupling characteristics in a photonic crystal waveguide (PCW) coupler. Unlike previous works that primarily rely on either numerical simulations or experimental studies, our approach integrates an analytical framework based on Coupled Mode Theory (CMT) with computational validation using COMSOL Multiphysics. The proposed PCW coupler, composed of silicon rods in air, exhibits a significant reduction in coupling length, enhancing its suitability for photonic integrated circuits (PICs). Through a combination of Plane Wave Expansion (PWE) simulations and wavelength-domain modelling, we demonstrate that the coupling length decreases with increasing temperature, indicating enhanced efficiency for thermally sensitive applications. The study not only provides theoretical insights into thermo-optic coupling in PCWs but also offers a practical design strategy for compact photonic devices operating at variable temperatures.

1. Introduction

The increasing interest in developing photonic crystal (PC) based devices and their applications is predominantly due to the versatility in the control and manipulation of light in customized microstructures. Moreover, continual advancements in PC fabrication technology play a crucial role in the actualization of various key PC applications such as sensing physical quantities such as temperature [1], pressure [2,3], and refractive indices of bio-analytes [4]. Other notable applications include waveguide devices and add/drop multiplexing devices [5], PC nanocavity lasers [6], optical switching [7], etc. Control over the propagation of light on a subwavelength scale using the photonic bandgap (PBG) effect has enabled the integration of these applications in photonic integrated circuits (PICs) [8,9]. The intricate light confinement in photonic crystal waveguides (PCWs) facilitates the realization of complicated PICs [10].

Coupled mode theory (CMT) offers a framework to describe the behaviour of light as it propagates, focusing on the interactions between various modes in optical systems. This theory is particularly useful for modelling how modes in waveguides and resonators interact, facilitating the calculation of coupling coefficients and an understanding of interference phenomena [11]. CMT is applicable to optical cavities linked with waveguides, where the interaction between cavity modes and waveguide modes is explained through the field equivalence principle, providing a precise depiction of light behaviour in these systems [12]. The temporal coupled-mode theory (TCMT) has been developed to account for optical phenomena in structures like metasurfaces, addressing asymmetry by integrating the propagation phase into the coupling terms, thereby offering insights into the interaction between light and matter [13]. Additionally, CMT has been adapted to explore acousto-optic interactions in optomechanical crystals, enabling the directional control of elastic waves over optical waves and the study of infinite optical modes resulting from nonlinear interactions [14].

While previous studies have extensively explored the behavior of PCWS under various external factors, most investigations either focus on purely numerical simulations or experimental validations without an analytical framework. The absence of an integrated approach limits the generalizability of results and their applicability to photonic integrated circuits (PICs). Furthermore, conventional studies often overlook the explicit temperature-dependent derivation of coupling length, which is critical in real-world applications where thermal variations influence device performance. Our work addresses these gaps by developing a

hybrid analytical-numerical approach, leveraging the well-established Coupled Mode Theory (CMT) alongside computational simulations in COMSOL. This study has been used to deduce a temperature-dependent expression for coupling length for the proposed PCW coupler design. This methodology allows for a more systematic and scalable analysis, ensuring that theoretical predictions align with simulated outcomes, thereby enhancing the design flexibility of temperature-sensitive photonic devices.

The study proposed in this paper introduces a novel methodology to theoretically analyze how temperature influences the coupling characteristics of waveguide directional couplers within two-dimensional PCs. The design features two parallel photonic crystal waveguides constructed from silicon (Si) rods in a hexagonal lattice arrangement with air as the background medium, both sharing identical geometries and separated by a row of rods with a reduced radius. By leveraging the thermo-optic effect inherent in Si, this research investigates the variations in the coupling parameters such as the coupling length resulting from changes in temperature. The coupling length is computed for the optical wavelength of 1.33 μm, across various temperatures within the range 300 K–400 K, by utilizing the wavelength domain simulations in the commercially available software COMSOL Multiphysics. This study offers important perspectives on enhancing PCWs for temperature-sensitive applications in PICs.

2. Theoretical design

The proposed design consists of a hexagonal lattice of dielectric silicon (Si) rods in air with a lattice constant 'a' and radius of the rods 'r', taken as 0.2a. Two rows of Si rods are removed, with a row of smaller-sized rods placed in between them to form a defect layer. Hence, a pair of parallel PCWs is formed, with one waveguide each on either side of the defect layer, constituting a PCW directional coupler. The schematic diagram of the proposed PCWs is shown in Fig. 1.

2.1. Design optimization

The design parameters were systematically optimized to ensure strong field confinement and minimal coupling losses. Using parametric simulations in COMSOL and Plane Wave Expansion (PWE) methods, the following optimizations were made.

- The lattice constant 'a' has been varied in the range 400–500 nm. The value a = 450 nm is found to align the midgap corresponding to the photonic bandgap with the optical wavelength ~1.33 μm. This value yields the best trade-off between compactness and efficient mode propagation.
- The radius of the silicon rods 'r' is chosen to be r = 0.2a to obtain a wide bandgap for TM mode operation.
- The defect rod radius r_d has been varied from 0.1a to 0.2a. An optimal value of r_d = 0.15a results in maximal field overlap and enhanced coupling efficiency.
- The spacing between the waveguides, which corresponds to one row of reduced-radius rods, has been selected to balance between strong coupling and minimal crosstalk.

The optimized parameters for the proposed design have been summarized in Table 1.

Table 1
Optimized Structural parameters for the proposed PCW coupler.

Parameter	Symbol	Optimized Value	Effect on Coupling Behavior
Lattice constant	a	450 nm	Ensures mode matching with λ = 1.33 μm
Rod radius	r	0.2a	Maintains wide photonic bandgap
Defect radius	r_d	0.15a	Maximizes coupling efficiency
Operating wavelength	λ	1.33 μm	Matches the midgap frequency

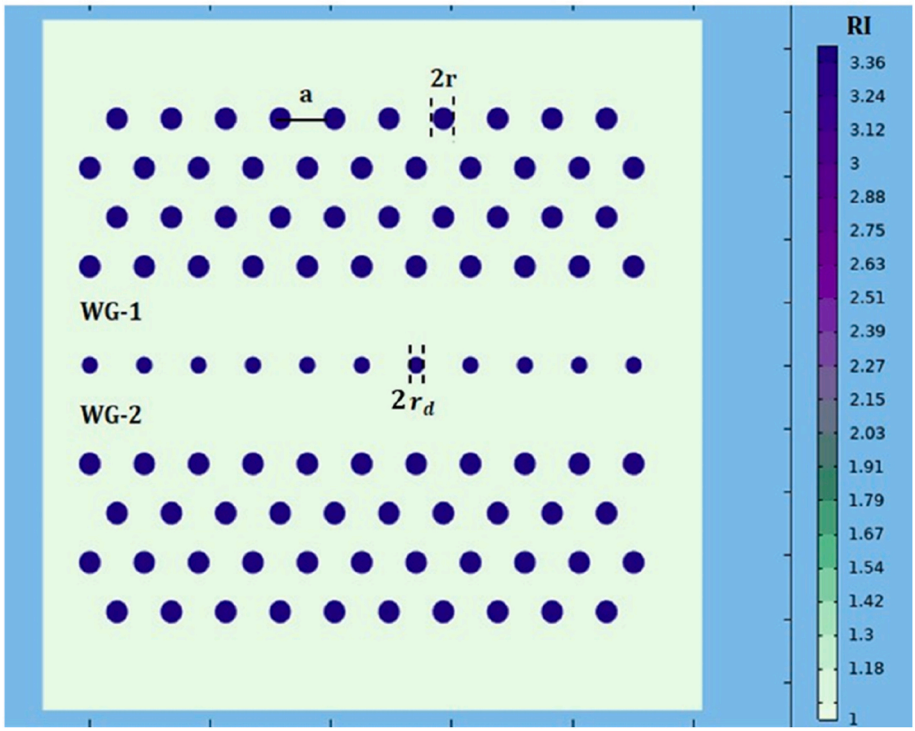

Fig. 1. Schematic design and refractive index profile of the proposed structure at 300 K.

2.2. Analytical modelling

The analytical modelling is based on the Coupled Mode Theory (CMT), which provides a mathematical framework to describe light propagation and power transfer between two coupled waveguides. In the case of two identical PCWs placed in proximity, the even and odd supermodes exhibit different propagation constants β_{even} and β_{odd}.The power transfer between the waveguides is governed by the phase difference between these supermodes, and the complete coupling of power occurs at specific interaction lengths, known as the coupling length L_c, given by:

$$L_c = \frac{\pi}{\Delta\beta} = \frac{\pi}{\beta_{odd} - \beta_{even}}$$

Here, $\Delta\beta$ is directly influenced by the thermo-optic induced change in the refractive index of silicon rods. The increase in temperature modifies the index contrast, leading to a larger $\Delta\beta$, and hence a reduced coupling length.

The difference in propagation constants $\Delta\beta$ due to increase in temperature can also be expressed as:

$$\Delta\beta\,(T) = \beta_{odd}(T) - \beta_{even}(T)$$

As temperature increases, the refractive index of Si increases linearly. The following relation is a widely accepted linear approximation for the refractive index of silicon as a function of temperature, particularly valid in the near-infrared region (~1.3–1.55 μm) and within moderate temperature ranges (300–400 K) [15]:

$$n(T) = n_0 + \gamma(\mathrm{T} - T_0)$$

where $\gamma = 1.86 \times 10^{-4}\ K^{-1}$ is the thermo-optic coefficient for silicon. This change in $n(T)$ alters β values, due to shift in modal dispersion and thus, causes $\Delta\beta$ to increase. Consequently, the coupling length L_c decreases, as deduced by Equation (7) derived in Section 4.2. This dependency is verified with numerical simulations the results of which are represented in Fig. 6 in Section 4.3.

3. Temperature dependence & thermo-optic effect in silicon

In this study, Equation (1) below is utilised to determine the refractive index (RI) and the corresponding dielectric constants of the dielectric rods across temperatures ranging from 300 K to 400 K. The refractive index of silicon in the infrared (IR) region [1] can be expressed as:

$$n = 3.38\left(1 + 3.9 \times 10^{-5} \times T\right)\ 77\mathrm{K} < \mathrm{T} < 400\ \mathrm{K} \qquad (1)$$

where T represents the temperature of the silicon rods. This linear dependence of RI on temperature is depicted in Fig. 2. The values of refractive index and dielectric constant derived from this equation are then applied in the PWE (Plane Wave Expansion) simulations to obtain the photonic bandgap (PBG) of the proposed structure. Further, wavelength domain simulations in COMSOL Multiphysics have been performed at different temperatures in the specified range to study the

effect of temperature variation on the coupling between the PCWs.

4. Results and discussion

The photonic bandgap of the PCW structure has been calculated using PWE simulations. The structure shows a wide bandgap for the transverse magnetic (TM) mode ranging from 0.27 to 0.45 in the normalized frequency units (a/λ), where λ is the wavelength in vacuum. The dispersion diagram in Fig. 3 shows the bandgap of the PCW structure at room temperature (~300 K), corresponding to a midgap wavelength of ~1.33 μm for the optimized 'a' and 'r' values. It is inferred that two guided TM modes emerge inside the PBG, originating from the splitting of an isolated single waveguide mode. These are the supermodes of the composite PCW structure, named as the odd and even modes as per the plane of symmetry between the waveguides. The central row of rods has been modified to tune the dispersion properties of the supermodes, and thus the coupling characteristics.

When two identical waveguides (WGs) are positioned close enough for their fields to interact, light can be transferred from one waveguide to the other through a process known as evanescent field coupling [16]. Efficient optical power transfer between the waveguides occurs when their mode profiles are similar, as explained by the coupled mode theory (CMT) [17–20]. For parallel waveguide directional couplers, the maximum power transfer $\boldsymbol{T}$ from the initial waveguide is described by the following relationship [21]:

$$\boldsymbol{T} = \left(1 - \frac{\boldsymbol{k}^2}{\boldsymbol{k}^2 + \Delta\boldsymbol{\beta}^2/4}\right) \tag{2}$$

where $\boldsymbol{k}$ represents the coupling coefficient, a key parameter proportional to the field overlap between the two adjacent waveguides (refer to Equation ($\boldsymbol{A13}$) derived in the Appendix). $\Delta\boldsymbol{\beta}$ is the difference in their respective propagation constants, also known as the *phase mismatch term* [22], and is expressed as:

$$\Delta\boldsymbol{\beta} = \frac{\boldsymbol{2\pi}}{\boldsymbol{\lambda}}\,\Delta\boldsymbol{n} \tag{3}$$

where, λ represents the operating wavelength.

4.1. Switching in coupler

A 2 × 2 directional coupler comprising of two closely positioned waveguides is characterized by the odd and even eigenmodes or supermodes. CMT stipulates that on placing two parallel and identical PCWs close to each other, the defect mode splits into an even and odd mode. The odd and even modes have different propagation constants (refer to Equation ($\boldsymbol{A6}$) in Appendix), namely $\boldsymbol{\beta_o}$ and $\boldsymbol{\beta_e}$ respectively, for every frequency. Switching happens when the relative path length of light is altered by half a wavelength, corresponding to a phase difference of $\boldsymbol{\pi}$ [23]. For a device length L, the change in refractive index required to switch from one state to another is given by $\Delta n.\boldsymbol{L} = \boldsymbol{\lambda/2}$.

The device proposed here uses a directional coupler in closely spaced PCWs to switch light. The propagation of a light in one of the WGs can be described using the superposition of the fundamental even and odd modes. It utilizes the fact that one of the two supermodes of the PCW coupler has a lower group velocity. The **coupling length** or the **switching length** ($\boldsymbol{L_{SW}}$) is defined as the length of the adjacent waveguides where the phase difference between these two modes equals an odd multiple of π. Thus, for a directional coupler based switching operation, the following condition must be satisfied [24]:

$$|\boldsymbol{\beta_e} - \boldsymbol{\beta_o}|\,\boldsymbol{L_{SW}} = (\boldsymbol{2n+1})\boldsymbol{\pi}, \mathrm{n} = 0, 1, 2\ldots\ldots$$

where, n is an integer number. Likewise, if the two modes have a phase difference which is an even multiple of π (i.e. 2mπ, with m being an integer) then the light is coupled back to the initial waveguide again.

The coupling length is a function of the splitting of the two modes. In the case of the proposed PCW coupler, the coupling length ($\boldsymbol{L_c}$) i.e., the distance required for complete power transfer between the waveguides (refer to Appendix), is given by Refs. [25–28]:

$$\boldsymbol{L_c} = \frac{\boldsymbol{\pi}}{\boldsymbol{2k}} = \frac{\boldsymbol{\pi}}{|\boldsymbol{\beta_2} - \boldsymbol{\beta_1}|} = \frac{\boldsymbol{\pi}}{\Delta\boldsymbol{\beta}} \tag{4}$$

Here, the propagation constants of the fundamental modes of the individual PC waveguides are taken as $\boldsymbol{\beta_1}$ and $\boldsymbol{\beta_2}$. Also, the coupling coefficient $\boldsymbol{k}$ is defined as, $\boldsymbol{k} = \frac{|\boldsymbol{\beta_2}-\boldsymbol{\beta_1}|}{\boldsymbol{2}}$.

4.2. Effect of temperature

The bandgap wavelength, corresponding to the band diagram in Fig. 3, is modulated using the thermo-optic change of refractive index in silicon. The change in refractive index leads to a change in the photonic band structure. Due to the considerable thermo-optic coefficient of Si, the refractive index of Si can be increased by 0.013 with a temperature change of 100 K based on Equation (1). As the temperature increases above the room temperature, the transmission spectrum of the PCW structure shifts to larger wavelengths. The band-edges corresponding to the PBG, along with the midgap wavelength, show a shift with an increase in temperature as reported in our earlier studies [1,4]. This temperature-induced shift in the bandgap also leads to changes in the coupling characteristics and parameters including the coupling length of the proposed PCW directional coupler.

On introducing a temperature variation ($\Delta\boldsymbol{T}$) (increasing $\boldsymbol{T}$ beyond the room temperature), Equation (1) can be used to determine the change in the refractive index ($\Delta\boldsymbol{n}$) of the Si rods as follows:

$$\Delta\boldsymbol{n} = \boldsymbol{13.182} \times \boldsymbol{10^{-5}} \times \Delta\boldsymbol{T} \tag{5}$$

Further, substituting the RI change from Equation (5) into the phase mismatch term in Equation (3), it is obtained that:

$$\Delta\boldsymbol{\beta} = \frac{\boldsymbol{2\pi}}{\boldsymbol{\lambda}}\left(\boldsymbol{13.182} \times \boldsymbol{10^{-5}} \times \Delta\boldsymbol{T}\right) \tag{6}$$

The difference in the propagation constants ($\Delta\boldsymbol{\beta}$) from Equation (6) is introduced in Equation (4) for theoretically computing the coupling length ($\boldsymbol{L_c}$) with variation in temperature.

$$\boldsymbol{L_c} = \frac{\boldsymbol{\lambda}}{\boldsymbol{2}\,(\Delta\boldsymbol{n})} = \frac{\boldsymbol{\lambda}}{\boldsymbol{2} \times \left(\boldsymbol{13.182} \times \boldsymbol{10^{-5}} \times \Delta\boldsymbol{T}\right)} \tag{7}$$

Here, the operating wavelength λ is taken as the midgap wavelength of the PC structure for simulations. This wavelength (~1.33 μm) is launched into the first waveguide (above the defect layer named WG-1 in Fig. 1). For the purpose of this study, Equation (7) represents the

condition required to switch light from one state to another as discussed in section 4.1. This condition is clearly temperature dependent. As indicated by CMT, the phase shifts between the odd and even modes at different frequencies are different since one of the modes exhibits a lower group velocity. Likewise, the phase shifts between the two modes will be different for different temperatures. This is because the odd and even modes, having different propagation constants and different group velocities, will experience the temperature induced change in refractive index differently. Hence, the effects of superposition of the even and odd modes are expected to be different at different temperatures, making the distance of optical power transfer different for different temperatures. This has been corroborated by computational results in the following section.

4.3. Coupling simulations and power transfer

For the wavelength domain simulations in COMSOL, to excite light propagation in WG-1, a point dipole source with only a z-component of electric field $\mathbf{E_Z}$ with an amplitude of 1 V/m is launched into WG-1 at a wavelength of 1.33 μm which is the midgap wavelength of the PC structure. This wavelength is chosen to minimize the dispersion and coupling losses in the proposed PCW structure.

Due to the second waveguide (below the defect layer named WG 2 in Fig. 1) being in close proximity to the first one, the launched field couples from WG-1 to WG-2. This is because there is an evanescent field extending outside each waveguide (WG). Since the two parallel guides are placed close enough, these parts of the evanescent fields must overlap spatially. The overlap of modes through the evanescent field induces a redistribution of energy between the WGs.

If the two WGs run parallel for a sufficient distance (which is the case here), the exchange of power can be highly significant. The field then starts coupling back to WG-1 and it keeps coupling back and forth over the interaction length of the two PCWs as shown in Fig. 4. It shows the electric field (ewfd) surface plot obtained using the wavelength domain computations run in COMSOL.

Thus, as per the coupled mode theory (CMT), there is a periodic exchange of power between the two PCWs (refer to Equations (***A19***) and (***A20***) in the Appendix). This power transfer is periodic with distance or the interaction length (along the direction of propagation). This periodic variation of field with the interaction length along the propagation direction (z) is depicted in Fig. 5. The electric field ($\mathbf{E_Z}$) values along the interaction length of the PCWs are obtained from the wavelength domain simulations and imported in a tabulated format for plotting. This graph, as shown in Fig. 5 for a sample value of temperature T = 310 K, is also plotted for different values of T above the room temperature (T > 310 K). The blue dotted line represents $\mathbf{E_Z}$ as a function of the interaction length in WG-1 in which the field is launched, hence the blue dotted line starts at the launch value $\mathbf{E_Z} = 1$ V/m. At this point the field value in WG-2, represented by the red dotted line, is negligible.

As power transfer takes place periodically between the two PCWs, the field values vary periodically with distance. The distance at which complete power transfer takes place from WG-1 to WG-2, i.e. the distance between the peak values of $\mathbf{E_Z}$ in the two PCWs, is taken as the value of the coupling length for that temperature.

From Fig. 5, which depicts the variation of the normalized $\mathbf{E_Z}$ value along the interaction length of the PCW/, the average value of $\boldsymbol{L_c}$ at 310 K is approximately 1689.545 nm. Similarly, the coupling length is calculated at different values of T, where T > 300 K.

The values of $\boldsymbol{L_c}$ have been obtained at different temperatures above the room temperature (~300 K) as described above. The variation of coupling length with temperature is depicted in Fig. 6. The coupling length shows a decreasing trend with increase in temperature as seen from Fig. 6. These simulation results are corroborated by Equation (7) and its interpretation discussed in section 4.2. As the mismatch between the propagation constants of the odd and even modes increase with temperature ($\boldsymbol{\Delta\beta}$ given in Equation (6)), the coupling length, $\boldsymbol{L_c} = \frac{\pi}{\Delta\beta}$, decreases, and a higher coupling coefficient is achieved. It can be inferred that the coupling efficiency increases above the room temperature with even a slight change in the refractive index of the Si rods. This study provides crucial perspectives on the effect of increase in temperature above the room temperature, which may occur due to the heating in such Si-based PCW devices and PICs. Additionally, it also offers important insights on enhancing Si-based PCWs for temperature-sensitive applications in PICs.

4.4. Comparative analysis

The proposed PCW directional coupler has been compared with previously published works, as presented in Table 2. Table 2 clearly shows that the proposed coupler shows a much shorter coupling length than the existing PhC-based structures, employing coupling mechanisms, without compromising on the functionality. A shorter coupling length minimizes lattice spacing and propagation losses, playing a crucial role in the development of compact and efficient devices optimized for integration. In designing PhC-based compact integrated modules, downscaling device dimensions can be of great use. Hence, the proposed design emerges as an efficient one in realizing couplers which are more compact than the existing ones. The design is flexible and can be optimized to have different operating wavelengths. It exhibits efficient light switching for a low refractive index change, which may result out of device heating above room temperatures, thus making it suitable for testing device performance above the room temperature.

5. Conclusion

The impact of temperature variation on the coupling parameters of a photonic crystal waveguide (PCW) coupler has been studied theoretically. The directional coupler has been implemented on a 2-D hexagonal lattice photonic crystal (PC) composed of Si rods in air. The thermo-optic

effect in Si is leveraged to obtain variation in its refractive index with an increase in temperature above the room temperature (~300 K). As per the calculations using the Plane Wave Expansion (PWE) method, the proposed PC structure shows a photonic bandgap (PBG) for the TM mode and this PBG is found to shift with changes in temperature. The coupling length is computed at different temperatures by means of wavelength domain simulations done in COMSOL Multiphysics software. The coupling length shows a decreasing trend with an increase in temperature which is corroborated theoretically by the well-known coupled mode analysis of identical waveguides placed in close proximity to each other. The proposed coupler exhibits a much smaller coupling length, providing a compact yet efficient design which works for even a small change in refractive change over a considerable range of temperature. This investigation provides valuable insights into optimizing PCWs for temperature-sensitive applications in PICs**.**

APPENDIX

The well-known coupled mode equations, used in the analysis of two optically interacting waveguides placed in the vicinity of each other, are given by Refs. [28,39]:

$$\frac{\partial a}{\partial z} = -i\beta_1 a - ik_{12} b \tag{A1}$$

$$\frac{\partial b}{\partial z} = -i\beta_2 b - ik_{21} a \tag{A2}$$

Where, β_1 and β_2 denote the propagation constants of the modes propagating along the z direction in the individual waveguides (WGs); k_{12} and k_{21} denote the coupling coefficients. The field amplitudes in the individual WGs, a and

b, are given by:

$$a = a_0 e^{-i\beta_1 z}$$

$$b = b_0 e^{-i\beta_2 z}$$

For a pair of identical WGs, $k_{12} = k_{21}$

For analysing the system of coupled waveguides, we consider the postulate that there exists a wave in the composite structure travelling with a phase constant β. The wave in the composite system is the superposition of the modes of the individual WGs. The field amplitudes in WG-1 and WG-2 are then given by:

$$a = a_0 e^{-i\beta z} \tag{A3}$$

$$b = b_0 e^{-i\beta z} \tag{A4}$$

Substituting $(A3)$ & $(A4)$ in the coupled mode equations $(A1)$ & $(A2)$, we get

$$-i\beta a_0 = -i\beta_1 a_0 - ik_{12} b_0$$

$$-i\beta b_0 = -i\beta_2 b_0 - ik_{21} a_0$$

Rearranging the above equations gives,

$$(\beta - \beta_1) a_0 - k_{12} b_0 = 0$$

$$(\beta - \beta_2) b_0 - k_{21} a_0 = 0$$

The above equations yield the following matrix,

$$\begin{bmatrix} \beta - \beta_1 & -k_{12} \\ -k_{21} & \beta - \beta_2 \end{bmatrix} \begin{bmatrix} a_0 \\ b_0 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

For a non-trivial solution, we have

$$\begin{vmatrix} \beta-\beta_1 & -k_{12} \\ -k_{21} & \beta-\beta_2 \end{vmatrix} = 0$$

$$\Rightarrow \beta^2 - (\beta_1+\beta_2)\beta + \beta_1\beta_2 - k^2 = 0 \tag{A5}$$

where, $k^2 = k_{21}k_{12}$

Now, (A5) is a quadratic equation in β and its two solutions are:

$$\beta = \frac{(\beta_1+\beta_2) \pm \sqrt{(\beta_1+\beta_2)^2 - 4(\beta_1\beta_2 - k^2)}}{2}$$

Simplifying the above equation leads to

$$\beta = \frac{1}{2}(\beta_1+\beta_2) \pm \sqrt{\frac{(\beta_1^2+\beta_2^2-2\beta_1\beta_2)+4k^2}{4}}$$

$$\Rightarrow \beta_{s,a} = \frac{1}{2}(\beta_1+\beta_2) \pm \sqrt{1/4(\beta_1-\beta_2)^2 + k^2} \tag{A6}$$

Thus, the composite system of waveguides has a set of two independent modes, one with the propagation constant β_s known as the *symmetric mode* (or the even mode), and the other with the propagation constant β_a known as the *anti-symmetric mode* (or the odd mode).

Hence, the general solutions to the coupled mode equations, given by (A3) and (A4), are modified to:

$$a(z) = a_s e^{-i\beta_s z} + a_a e^{-i\beta_a z} \tag{A7}$$

$$b(z) = \frac{\beta_s-\beta_1}{k_{12}} a_s e^{-i\beta_s z} + \frac{\beta_a-\beta_1}{k_{12}} a_a e^{-i\beta_a z} \tag{A8}$$

Assuming that at $z = 0$ unit power is launched into WG-1 and there is no power in WG-2.

So, the initial conditions at $z = 0$ yield:

$$a_s + a_a = 1 \tag{A9}$$

$$\frac{\beta_s-\beta_1}{k_{12}} a_s + \frac{\beta_a-\beta_1}{K_{12}} a_a = 0 \tag{A10}$$

Solving equations (A9) and (A10) gives,

$$a_a = \frac{-(\beta_1-\beta_s)}{\beta_s-\beta_a} \tag{A11}$$

$$a_s = \frac{\beta_1-\beta_a}{\beta_s-\beta_a} \tag{A12}$$

Substituting (A11) and (A12) into equations (A7) and (A8) gives the z dependent amplitudes in the two WGs:

$$a(z) = \frac{\beta_1-\beta_a}{\beta_s-\beta_a} e^{-i\beta_s z} + \left(\frac{\beta_s-\beta_1}{\beta_s-\beta_a}\right) e^{-i\beta_a z}$$

$$b(z) = \left(\frac{\beta_s-\beta_1}{k_{12}}\right)\left(\frac{\beta_1-\beta_a}{\beta_s-\beta_a}\right) e^{-i\beta_s z} + \left(\frac{\beta_a-\beta_1}{K_{12}}\right)\left(\frac{\beta_s-\beta_1}{\beta_s-\beta_a}\right) e^{-i\beta_a z}$$

Power in WG-1 will be given by:

$$|a(z)|^2 = 1 - \frac{k^2}{\frac{1}{4}\Delta\beta^2 + k^2} \sin^2\left\{\left(\sqrt{\frac{1}{4}\Delta\beta^2 + k^2}\right) z\right\} \tag{A13}$$

And power in WG-2 will be given by:

$$|b(z)|^2 = \frac{k^2}{\frac{1}{4}\Delta\beta^2 + k^2} sin^2\left\{\left(\sqrt{\frac{1}{4}\Delta\beta^2 + k^2}\right) z\right\} \tag{A14}$$

Equations (A13) and (A14) represent the power transfer equations in a directional coupler for the case of non-identical waveguides.

For the case of identical waveguides, we have $k_{12} = k_{21} = k$ and

$$\beta_1 = \beta_2 = \beta_0 \tag{A15}$$

Using equation (A6) the propagation constant for the symmetric mode becomes:

$$\beta_s = \beta_0 + k \tag{A16}$$

And for the anti-symmetric mode:

$$\beta_a = \beta_0 - k \tag{A17}$$

Substituting equations $(A15), (A16), (A17)$ in equations $(A11)$ and $(A12)$, we get

$$a_s = a_a = 1/2 \tag{A18}$$

Substituting these in $(A7)$, we get

$$a(z) = \frac{1}{2}e^{-i(\beta_0+k)z} + \frac{1}{2}e^{-i(\beta_0-k)z}$$

$$= \frac{1}{2}e^{-i\beta_0 z}\left\{e^{-ikz} + e^{ikz}\right\}$$

$$a(z) = e^{-i\beta_0 z}\, cos(kz)$$

Therefore, power in WG-1 is given as

$$|a(z)|^2 = cos^2(kz) \tag{A19}$$

Substituting $(A15), (A16)$ *and* $(A17)$ in $(A8)$, we obtain

$$b(z) = \frac{1}{2}e^{-i(\beta_0+k)z} - \frac{1}{2}e^{-i(\beta_0-k)z}$$

$$= -\frac{1}{2}e^{-i\beta_0 z}\left(e^{ikz} - e^{-ikz}\right)$$

$$= (-i)\, e^{-i\beta_0 z}\, sin(kz)$$

$$= e^{-i\pi/2}e^{-i\beta_0 z}\, sin(kz)$$

$$b(z) = e^{-i\left(\beta_0 z + \frac{\pi}{2}\right)}\, sin(kz)$$

Hence, the power in WG-2 is given by

$$|b(z)|^2 = sin^2(kz) \tag{A20}$$

Equations $(A19)$ and $(A20)$ represent the power transfer equations for the system of identical waveguides. From these equations, it is evident that complete power transfer from WG-1 to WG-2 takes place at $z = \frac{\pi}{2k}$. This distance is defined as the *coupling length* for the case of identical waveguides.

Towards Creating an Ecosystem of Paperless Society: Unveiling Issues and Challenges in Adoption of DigiLocker

Rajan Yadav*

ABSTRACT

DigiLocker, a free document storage and sharing cloud-based platform, is an e-governance project of the Indian government under its Digital India initiative. Though the government has been working to make this initiative successful, a considerable portion of the population is unaware of the service. The few aware of this initiative have yet to opt for a DigiLocker. The present study attempts to identify the issues and challenges that affect the adoption and use of these services designed to create a paperless society. The proposed framework of the study is based on the theoretical underpinning of the Technology Adoption Model (TAM), the Unified Theory of Acceptance and Use of Technology (UTAUT) and the Unified Model of Electronic Government Adoption (UMEGA). The study analysed the data using PLS-SEM, including the moderation impact of select variables. The study identifies various factors that act as motivators and deterrents in adopting and using DigiLocker and provides strong empirical support to frame suitable strategic interventions to sensitize people to improve further usage and adoption.

Keywords: *DigiLocker, technology adoption, e-governance, PLS-SEM*

INTRODUCTION

The Digital India Programme of the Government of India envisions making India a digitally empowered society and knowledge economy with an emphasis on digital empowerment of citizens by improving e-governance, services-on-demand, and digital infrastructure. Sustained efforts are being made to create collaborative linkages on various citizen-centric projects to transform the traditional service delivery process into a seamlessly integrated process that is available on a real-time basis to all citizens in a transparent, convenient, and secure manner. Over the years, various State and Central Government initiatives have been undertaken to navigate into an era of e-governance. Persistent efforts have been made at government and grassroots levels to improve public service delivery and simplify access to it.

The revolution of information technology has penetrated almost all domains. The increasing use of cloud platforms has provided individuals with ease of access. DigiLocker is one such scheme launched by the government of India, which provides free 1 GB cloud storage to store documents in digital form for the citizens of India. This initiative is a part of the government's Digital India initiative. Documents such as PAN cards, Passports, driving licenses, etc, can be stored in DigiLocker and carried easily by individuals. Therefore, such an initiative by the government of India has provided ease to storing all such documents in the digital locker, which is a cloud-based space for keeping documents in digital form. This initiative is widespread through newspapers and electronic media. The Central Board of Secondary Education has opened 80 lakh digital

* *Professor, Delhi Technological University, Delhi, rajanyadav@dtu.ac.in*

lockers for the students of 10th and 12th class. However, only 2,06,57,736 registered users and 116 issuer organizations of DigiLocker exist to date. Maharashtra has the highest number of registered users of DigiLocker, whereas Delhi ranks 11th, with only 2,73,658 registered users. States like Sikkim, Mizoram and Chhattisgarh have the lowest registrations to date. Therefore, there is a need to study the reasons for not adopting a free service which ensures the safe storage of documents. The present study is therefore aimed to understand the level of awareness of individuals for DigiLocker and to explore the various factors which affect the technology adoption process.

2. Objectives of the study

- To identify the motivators and inhibitors of low adoption and usage of DigiLocker.
- To analyse the impact of social, demographic, economic and geographic variation in the adoption of DigiLocker.
- To propose an empirical, evidence-based strategic framework to improve the adoption and usage of DigiLocker.
- To suggest a few measures to policymakers for widespread awareness of DigiLocker.

3. Literature Review

User Acceptance of Information Technology (UAIT) is a prerequisite for effectively implementing any information technology-based project (AlAwadhi et al., A., 2008). UAIT is the "initial decision made by the individual to interact with the technology" (Venkatesh et al., 2004).

UAIT is followed by adoption, defined as the "direct experience with the technology after an individual has decided to accept it" (Venkatesh et al., 2004).

Most of the research in the information technology acceptance field spans around the path-breaking work of Davis (1989). He proposed the TAM, the most popular model for explaining the intention and behaviour of individuals for technology acceptance. TAM theorizes that two precursors form behavioural intention: perceived usefulness and ease of use (Venkatesh & Davis, 2000). Perceived usefulness is defined as the extent to which a user perceives that technology adoption will enhance his/her performance. On the other hand, perceived ease of use revolves around minimizing efforts for using a technology. It was also proposed that perceived ease of use affects perceived usefulness since the easier a technology is, the more useful it can be (Venkatesh, 2000). The model was parsimonious and has been applied in several studies over the last three decades. It has been used to study faculty members' intention to use learning management systems (LMS) (Fathema et al., 2015), consumer acceptance of e-commerce "" and acceptance of E-learning in developing countries (Tarhini et al., 2017).

Another model that is significant in understanding technology adoption was given by Venkatesh, Morris, Davis, and Davis (2003), named the UTAUT model. It consists of four variables: effort expectancy, performance expectancy, social influence and facilitating conditions. It also captures the moderating influence of gender, age, experience, and voluntariness of use (Im et al., 2011). The UTAUT model rationalises that effort expectancy is significant in users' adoption of information technology. The model explains the 70 per cent variance, which is much higher than TAM. This model is said to be more synthesized and complete since it has merged eight different models discussed in information system literature. These models (TRA, TAM, TPB, the Motivational Model (MM) (Davis et al., 1992), the combined TAM and TPB (C-TAM-TPB) (Taylor et al., 1995), the Model of PC Utilization (MPCU) (Thompson et al., 1991) DOI and Social Cognitive Theory (SCT)) had their origins in sociology and psychology. UTAUT explains how acceptance of information technology differs across various individuals. The moderators used in the model also emphasize the differences in intention to use technology in terms of different age groups and gender.

Though digital services are provided in various countries, there are challenges in usage and adoption. Developing countries, particularly, face a lack of infrastructure, awareness and technical skills required to

adopt ICT (Sivathanu, 2018). The DigiLocker initiative results from cloud computing technology (Khandekar & Devadiga, 2016); it enables the virtual storage of various pictures and documents. This initiative is under the Digital India government scheme. It has helped to provide a digital space wherein citizens of India can store documents issued by the government and other public authorities. A top priority project of the Hon. Narendra Modi Administration, the completed Digital India initiative has specific plans aimed at restructuring the National Informatics Centre. (Petare et al., 2015).

3.1. Conceptual Model

Figure 1 below provides the proposed relationships among the dependent and independent variables. It also shows the moderating variables which have been tested for their contingent effect on the relationships among the constructs. Each relationship (arrow) in the conceptual model represents a hypothesis tested using PLS-SEM.

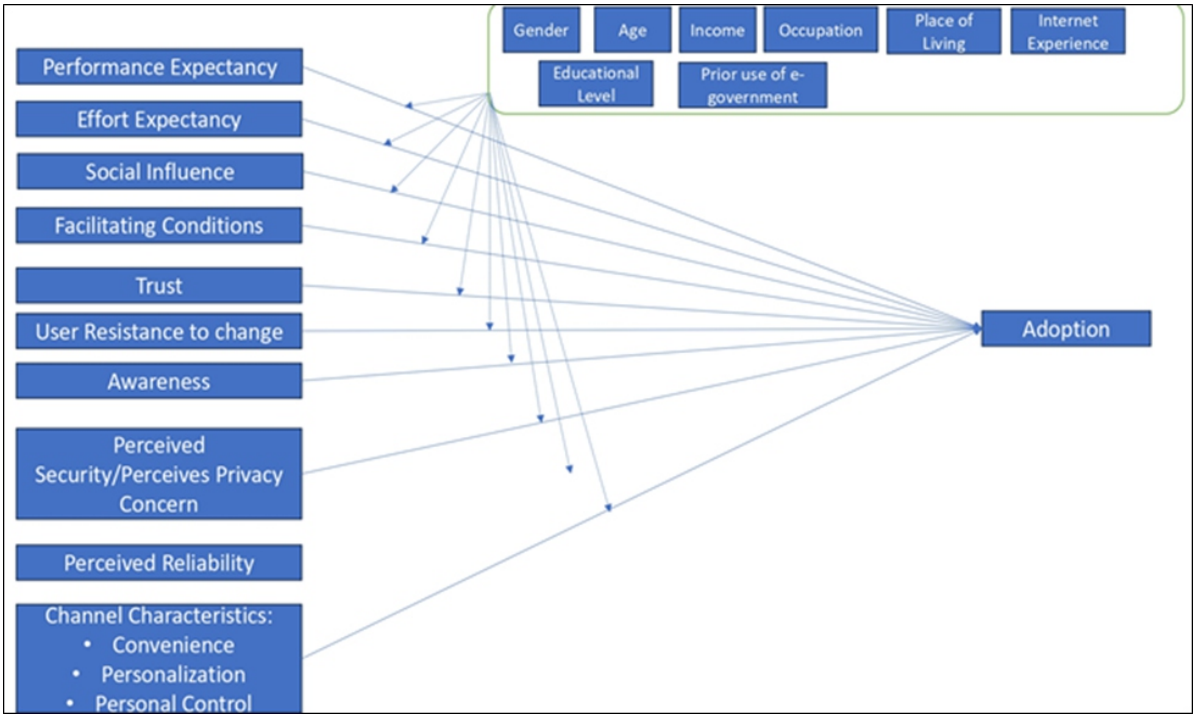

Figure 1 : Conceptual Model

4. Research Methodology

The target population for our study included Indian citizens residing within the country, aged 15 and above, who regularly used essential IT-enabled services. A Google survey form was administered across various social media platforms to collect data to ensure broad distribution and reach within the target audience. The study employs a cross-sectional descriptive research design. We have captured data at a specific time, providing a snapshot of the population's perceptions and behaviours.

This study utilised a non-probability convenience sampling technique to reach respondents easily accessible to the researchers, resulting in a final sample size of 145 participants. We analysed data using Partial Least Squares-Structural Equation Modelling (PLS-SEM), a method suitable for complex analyses with relatively smaller minor samples. Smart-PLS 4 software was employed for analysis, enabling the research team to interpret relationships and draw meaningful insights from the collected data.

5. Data Analysis

5.1. Measurement Instrument

Items were taken from extant research to maintain the validity of the content of the model. These items were modified to adopt the context of the adoption of DigiLocker. The table below displays the constructed items as well as their sources.

Table 1: Construct Items

5.2. Model assessment in Smart PLS 4

Each item's construct reliability and validity were assessed to test the measurement model. Cronbach's α, Composite Reliability (CR) and Average Variance Extracted (AVE) were computed to assess the reliability and convergent validity **(Table 2)**. We calculated the Variance Inflation Factor (VIF) to check the multicollinearity between variables. The threshold limit of Cronbach's α is 0 to 1, and values above 0.7 suggest an acceptable level of reliability. In our study, Cronbach's α varies from 0.879 to 0.962, under the threshold limit. The threshold limit of composite reliability is that the value should be greater than 0.7.

In our study, Composite Reliability varies from 0.919 to 0.969, which is under the threshold limit. We computed the AVE test to assess the convergent validity. The threshold limit for AVE is that the value should be greater than 0.5. In our study, AVE ranges from 0.714 to 0.887, under the threshold limit.

The study assessed the multi-collinearity among the constructs in the model using VIF. Many research frameworks based on OLS Regression observe multi-collinearity among two or more constructs demonstrating a linear relationship. In such cases, the values of different path coefficients may be consistent. However, the results may not be robust and reliable due to high VIF values, which indicate high muti-collinearity. A VIF value above 4 is acceptable and an indicator of low multi-collinearity. The study found the VIF values in all the relationships as per the thumb rule i,e. < 4 permitting to proceed further with the analysis.

Our study's VIF values range from 1 to 8.919, indicating varying degrees of multicollinearity between variables. In our study, some values are greater than 5 because the sample size we chose is small, and the variables are homogeneous. Several variables demonstrate high levels of multicollinearity, with PE2 showing the highest VIF at 8.919, followed closely by T5 at 7.987, PE1 at 7.7, T6 at 7.148, FC1 at 7.021, and EE4 at 7.548. A moderate level of correlation is present in several variables, including CC1, CC2, and CC3 (all around 6), A2 (5.381), PE3 (6.855), SI5 (6.034), FC2 (6.211), and T4 (5.411). All interaction terms of construct factors with daily internet usage and education level show VIF values 1, indicating no multicollinearity issues in these relationships and no correlation.

We computed the Heterotrait-Monotrait (HTMT) ratio to assess the discriminant validity. The threshold limit for the HTMT ratio is that values should be below 0.90. In our study, the HTMT values vary from 0.007 to 0.938 **(Table 3)**. To evaluate the model's fit and determine how well the model explains the observed data, we computed the R2 value. If R2 value is greater than 0.50, it indicates strong explanatory power. In our study, the R2 value is 0.801 **(Table 4)**.

Table 2: Composite Reliability

	Cronbach's α	CR (rho_c)	AVE
A	0.936	0.959	0.887

αTable 4: R-Squared Values

	R-square
A	0.801

1.1. Hypothesis testing

To check the significant relationship between variables, we run bootstrapping with 5000 samples. We look at the path coefficient (i.e. P- value) to check for a significant relation between variables. To have a significant relation between values, the p-value should be less than 0.005.

This is illustrated in **Table 5** and **Figure 2**; findings suggest that significant factors help in the Adoption of DigiLocker. We opt for education level and daily internet usage as a key moderator influencing the adoption of DigiLocker.

From the findings, we discovered that effort expectancy, facilitating conditions and performance expectancy significantly impact the adoption of DigiLocker. EE -> A (p value 0.019), **FC -> A** (p value 0) and **PE -> A** (p value 0.003). Furthermore, we also discovered that education level and daily internet usage have not moderately influenced the adoption of DigiLocker.

6. Managerial Implications

The study is highly relevant for policymakers since the initiative for DigiLocker is based on having more paperless transactions. However, the response to DigiLocker so far is lukewarm. Therefore, all stakeholders in this project must understand the problems individual citizens face while adopting this application, their threats and challenges. The study's findings provide input to policymakers for designing awareness campaigns to spread this initiative to various parts of the country. They also put forward the factors that affect the technology adoption process in a developing country like India. A study of such magnitude is highly relevant for society because it will serve as a barometer to understand the underlying reasons for non-acceptance of a technology-based platform despite being offered free of cost. The present study has also proposed a practical framework to harness the utility of DigiLocker. Hence, in the long run, such findings will help to create better policies for the masses in terms of improvement in IT infrastructure and other vital areas.

Abstract

Understanding and analyzing video actions are essential for producing insightful and contextualized descriptions, especially for video-based applications like intelligent monitoring and autonomous systems. The proposed work introduces a novel framework for generating natural language descriptions from video datasets by combining textual and visual modalities. The suggested architecture makes use of ResNet50 to extract visual features from video frames that are taken from the Microsoft Research Video Description Corpus (MSVD), and Berkeley DeepDrive eXplanation (BDD-X) datasets. The extracted visual characteristics are converted into patch embeddings and then run through an encoder-decoder model based on Generative Pre-trained Transformer-2 (GPT-2). In order to align textual and visual representations and guarantee high-quality description production, the system uses multi-head self-attention and cross-attention techniques. The model's efficacy is demonstrated by performance evaluation using BLEU (1-4), CIDEr, METEOR, and ROUGE-L. The suggested framework outperforms traditional methods with BLEU-4 scores of 0.755 (BDD-X) and 0.778 (MSVD), CIDEr scores of 1.235 (BDD-X) and 1.315 (MSVD), METEOR scores of 0.312 (BDD-X) and 0.329 (MSVD), and ROUGE-L scores of 0.782 (BDD-X) and 0.795 (MSVD). By producing human-like, contextually relevant descriptions, strengthening interpretability, and improving real-world applications, this research advances explainable AI.

Keywords: Video-based Description Generation, Transformer Models, Explainable AI, Autonomous Systems, Natural Language Processing

1 Introduction

In computer vision and natural language processing, creating informative textual descriptions of events that occur in video sequences is a fundamental problem known as "video description generation" [1]. In contrast to static image captioning, video-based description generation involves an awareness of object interactions, temporal dependencies, and contextual linkages in order to provide narratives that are both contextually rich and coherent. Applications like intelligent surveillance, multimedia retrieval, autonomous driving, and human-computer interaction greatly benefit from these capabilities. Capturing dynamic scene

changes, identifying pertinent objects, and producing descriptions that appropriately reflect the changing context are the challenges [2] [3]. Conventional methods for comprehending videos, such as object detection and action recognition, mostly concentrate on figuring out "what" is happening in a scene. Explaining "why" things happen is more difficult, though, particularly in complex, multi-agent systems where behaviour is influenced by environmental suggestions [4]. Known as video captioning or video-based description generation, the process combines textual and visual modalities to generate interpretable and informative natural language descriptions [5] [6]. The ability to produce context-aware and semantically relevant video descriptions has greatly improved with recent developments in deep learning, especially transformer-based systems.

This work presents a novel transformer-based architecture for generating video descriptions by effectively combining text and image modalities. Using a GPT-2 encoder-decoder with multi-head attention and ResNet50 for visual feature extraction, the model is trained on diverse datasets, including MSVD and BDD-X. Training is optimized with gradient accumulation and mixed precision to boost efficiency. Evaluated using BLEU (1–4), CIDEr, METEOR, and ROUGE-L, the model produces fluent, contextually relevant descriptions aligned with human annotations, contributing to advancements in video explainability and AI-driven understanding.

The major contributions of the proposed work are summarized below:

- To provide natural language descriptions of video sequences, the following work proposes a transformer-based architecture that integrates a GPT-2-based language model with the visual features retrieved by ResNet50.
- The method combines video datasets from various sources (MSVD, and BDD-X), allowing the model to generalise across domains. High-quality training samples are guaranteed via sophisticated preprocessing.
- Gradient accumulation and mixed precision training are used to optimise the model, increasing computing efficiency without sacrificing output quality.
- Fluency, contextual relevance, and coherence are ensured by thoroughly evaluating the generated descriptions using BLEU (1–4), CIDEr, METEOR, and ROUGE-L standards.
- Although this method is extremely beneficial for intelligent transportation and autonomous driving, it can also be used in other fields, including robotics, assistive technology, and surveillance.

The remaining sections of the paper are organized as follows: Section 2 examines relevant studies in multimodal learning and video description generation. The suggested methodology, including feature extraction, model architecture, and dataset preprocessing, is described in Section 3. Experimental results and assessment results are presented in Section 4. Lastly, conclusions and possible future study directions are covered in Section 5.

2 Related Work

In computer vision and natural language processing, video-based description creation is an essential task that allows systems to produce textual summaries of visual content. The creation of video descriptions must consider temporal relationships, object interactions, and dynamic scene changes across frames, in contrast to static image captioning. Early video description generation approaches included recurrent neural networks (RNNs) or long short-term memory (LSTM) networks for text synthesis and convolutional neural networks (CNNs) for feature extraction.

A Sequence-to-Sequence (Seq2Seq) model trained on MSVD [7] was presented by Venugopalan et al. [8] to produce video descriptions. However, because of the limits of LSTMs, these models have trouble handling contextual inconsistencies and long-range dependencies. Later, to make generated descriptions more relevant, attention techniques were added [9]. Transformer-based models have led to a considerable improvement in video captioning systems. End-to-end dense Video Captioning was proposed by Zhou et al. [10], who used spatiotemporal attention mechanisms to grasp multiple frames. Compared to conventional RNN-based models, MART (Memory-Augmented Recurrent Transformer), which was introduced by Lei et al. [11], performs more

effectively at capturing long-term video dependencies. More recently, multimodal pretraining for video-language understanding has been investigated by VideoBERT [12] and ClipBERT [13]. These methods achieve state-of-the-art outcomes on datasets such as MSVD [7] and MSR-VTT [14] by aligning textual and visual representations. Datasets such as Berkeley DeepDrive eXplanation (BDD-X) [15] have been useful for producing explainable AI-driven annotations for vehicle-based video description generation. Studies like Shoman et al. [4] integrated explainability processes into vision-language models and concentrated on justification-based video descriptions for autonomous driving. An attention-guided transformer was developed by Cui et al. [16] to improve contextual reasoning in captioning models based on BDD-X.

Recent advancements in multimodal learning combine text, audio, and visual data. Hori et al.[17] introduced an audio-visual attention model using speech and scene context, while Yu et al.[18] enhanced captioning on datasets like Flickr8k and MSVD using spatiotemporal object graphs. These methods improve contextual awareness, particularly in dynamic scenarios like vehicle interactions. Despite progress, generating accurate, human-like video descriptions remains challenging. The proposed approach addresses this by combining a GPT-2 encoder-decoder with ResNet50-based feature extraction, outperforming prior methods on BLEU (1–4), CIDEr, METEOR, and ROUGE-L. It refines multimodal embeddings for context-aware captions and boosts efficiency with gradient accumulation and mixed precision training. By bridging explainable vehicular (BDD-X) and general (MSVD) video captioning, the model delivers interpretable, context-rich descriptions suitable for real-world use.

3 Overview of the Proposed Work

The proposed study introduces a transformer-based, context-aware reasoning framework for generating logical and relevant video descriptions. Leveraging the BDD-X and MSVD datasets, the system learns from both action-justified driving videos and diverse scene representations. It employs an optimized GPT-2 encoder-decoder model with multi-head attention and ResNet50-based visual feature extraction to enhance contextual understanding. Training is guided by action-justification pairs from BDD-X and captioned sequences from MSVD, promoting coherent, human-like output. Gradient accumulation and mixed precision training boost computational efficiency without compromising accuracy. Evaluations using BLEU (1–4), CIDEr, METEOR, and ROUGE-L show superior performance over traditional methods. The basic architecture of the proposed framework is shown in Figure 1, which further demonstrates the pipeline for data pre-processing, model training, and description generation.

3.1 Data Pre-processing

The input data includes video frames from the BDD-X and MSVD datasets. Video frames are extracted, pertinent images are filtered, and then the frames are transformed into structured input for the model as part of the pre-processing pipeline. ResNet50, which converts spatial information from images into high-dimensional feature vectors, is used for feature extraction. After that, a linear projection and position encoding method are used to patch and embed these feature vectors. The GPT-2 encoder-decoder module then receives the processed embeddings and aligns the word/-token embeddings with the appropriate visual features. To further improve model resilience, tokenization, data augmentation, and train-test splits are used.

3.2 Model Architecture

The proposed method combines a GPT-2 encoder-decoder model to generate context-aware descriptions of vehicle actions with ResNet50 to extract image features. The model is fine-tuned on the BDD-X and MSVD datasets to become optimal in dynamic scenarios for generating meaningful descriptions. The training process employs gradient accumulation and mixed precision training to achieve optimal computing efficiency.

ResNet50 acts as a feature extractor by passing each input frame $x \in \mathbb{R}^{3\times H\times W}$ through a series of convolutional, batch normalization, ReLU, and residual layers. The output feature vector f is

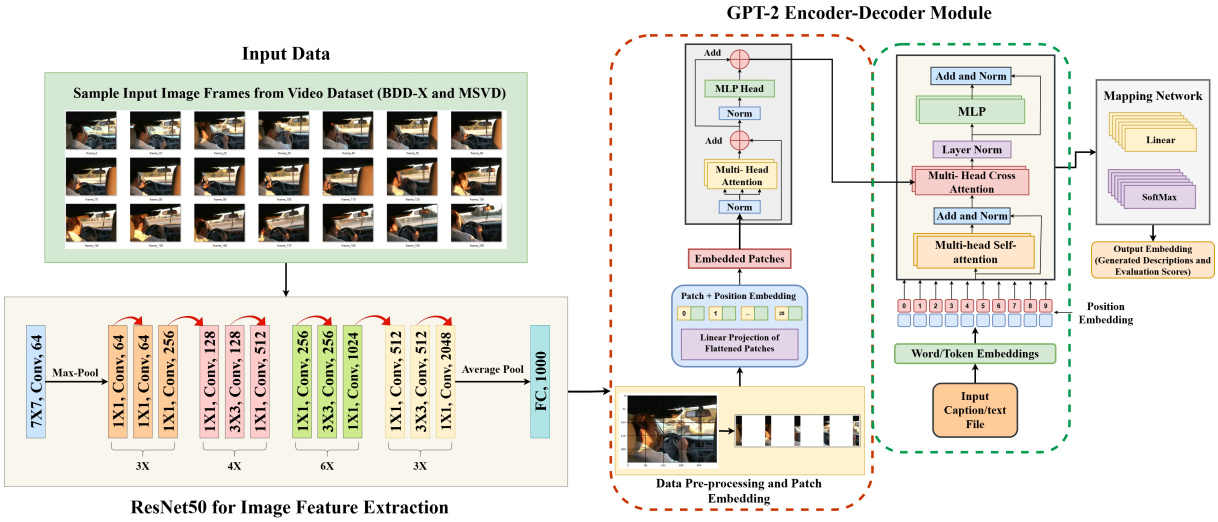

Fig. 1: Framework for the Proposed Model (ResNet50-GPT2): The system incorporates ResNet50 for image feature extraction and a GPT-2 encoder-decoder model to generate context-aware video-based image descriptions.

computed as:

$$f = \text{ResNet50}(x) = \text{AvgPool}(F_{\text{res}}(x)) \quad (1)$$

where, F_{res} denotes the output of the final convolutional block, and AvgPool is the global average pooling operation applied to extract the final feature representation $f \in \mathbb{R}^{2048}$.

Using position embeddings $P \in \mathbb{R}^{N \times d}$ and a learnable linear projection $W_p \in \mathbb{R}^{2048 \times d}$, the visual characteristics retrieved by ResNet50 are transformed into embedded visual tokens:

$$E_v = fW_p + P \quad (2)$$

The GPT-2 model uses these embedded patches as input tokens to produce descriptions that are logical and sensitive to context. The model utilizes self-attention mechanisms to enhance contextual understanding, formulated as:

$$\text{Self-Attention}(Q, K, V) = \text{Softmax}\left(\frac{QK^T}{\sqrt{d_k}}\right)V \quad (3)$$

where d_k is the key vector dimension, and Q, K, V represent the query, key, and value matrices.

To maintain the semantic relevance of the generated descriptions to video-based activities, the multi-head cross-attention method aligns image embeddings with textual descriptions. The decoder uses attention-weighted contextual embeddings to improve the textual output:

$$\text{Decoder-Attention}(Q, K, V) = \text{Softmax}\left(\frac{QK^T}{\sqrt{d_k}}\right)V \quad (4)$$

The final word prediction probability is computed as:

$$y_t = \text{Softmax}(W_o h_t + b_o) \quad (5)$$

where W_o and b_o are the output weight matrix and bias, respectively, and h_t represents the hidden state at time step t.

To enhance generalization, the model employs a combined loss function incorporating cross-entropy loss and L2 regularization:

$$\mathcal{L} = -\sum_{t=1}^{T} \log P(y_t \mid y_{<t}) + \lambda \|\theta\|^2 \quad (6)$$

where λ is the regularization parameter and $P(y_t \mid y_{<t})$ denotes the probability of predicting y_t given prior words.

In BLEU-4, CIDEr, METEOR, and ROUGE-L metrics, the proposed framework outperforms traditional methods, ensuring that the generated descriptions are sensible, logical, and context-aware. These metrics are utilized to analyze the

contextual validity and linguistic quality of the descriptions generated by the GPT-2 model for unseen videos upon training. The method achieves performance improvement over traditional methods by contrasting the generated descriptions with ground-truth annotations. Ultimately, the framework generates natural language narratives that effectively describe dynamic visual scenes, promoting explainability in a range of applications.

The following summarizes Algorithm 1 for the proposed model and its evaluation:

Algorithm 1 Context-Aware Description Generation

4 Experimental Analysis

The proposed model was implemented in PyTorch and evaluated on Google Colab Pro+ using 52 GB RAM, an NVIDIA A100 GPU (40 GB VRAM), and a virtual Intel Xeon CPU. It generates context-aware descriptions using a GPT-2 encoder-decoder (approximately 66.7M parameters) and ResNet50 for visual feature extraction. Input frames were resized to `(batch_size, 224, 224, 3)`. Training was conducted over 75 epochs with the AdamW optimizer (learning rate 1×10^{-5}, weight decay 0.01), using a batch size of 32 and gradient accumulation. Mixed precision training and gradient clipping were applied to improve computational efficiency and training stability. The model was trained using the MSVD dataset[1], which contains short descriptive captions for diverse video clips, and the BDD-X dataset[2], which includes over 26K annotated actions across 8.4M frames and 6,970 videos. During preprocessing, linguistic descriptions were tokenized and structured into action-justification pairs, while image frames were embedded via ResNet50 and projected linearly into patch embeddings. These embeddings were then fed into the multi-head self-attention module of the GPT-2 encoder-decoder to align image and text contexts effectively. Performance was evaluated on a 20% test split using BLEU-4, CIDEr, METEOR, and ROUGE-L. The model consistently outperformed conventional captioning techniques, demonstrating its ability to generate logical, contextually accurate descriptions across diverse visual inputs. The architecture's use of self- and cross-attention mechanisms ensured semantic accuracy and narrative coherence, reinforcing its applicability in real-world visual captioning tasks. The following Table 1 depicts the overall architectural structure of the proposed framework.

4.1 Ablation Study:

Utilising the BDD-X and the MSVD datasets, an ablation research was carried out to evaluate the contribution of various components in the suggested model. The research methodically eliminated or altered important architectural components, such as multi-head attention, gradient accumulation and mixed precision training optimisations, and visual feature extraction (ResNet-50), in order to assess each component's effect

	GPT-2 + Single-Head Attention	0.731	0.705	0.673	0.634	1.032	0.257	0.672
	GPT-2 + Without Gradient Accumulation	0.785	0.758	0.723	0.681	1.142	0.278	0.710
	ResNet50-GPT2 (Proposed)	**0.860**	**0.835**	**0.800**	**0.755**	**1.235**	**0.312**	**0.782**
MSVD	Baseline GPT-2 Model	0.710	0.685	0.654	0.612	0.980	0.242	0.651
	GPT-2 + Single-Head Attention	0.742	0.715	0.683	0.641	1.105	0.265	0.685
	GPT-2 + Without Gradient Accumulation	0.798	0.772	0.740	0.698	1.231	0.293	0.724
	ResNet50-GPT2 (Proposed)	**0.880**	**0.855**	**0.823**	**0.778**	**1.315**	**0.329**	**0.795**

on model performance. Model modifications were compared using the BLEU-1 to BLEU-4, CIDEr, METEOR, and ROUGE-L metrics, which provided a thorough assessment of the effects of each component on the quality of description production. As can be seen from Table 2, the results demonstrate the importance of each element in producing textual descriptions for video frames that are both logical and contextually rich. The model's performance on the MSVD and BDD-X datasets highlights the importance of each architectural component. The most significant impact came from removing ResNet-50, leading to major performance drops—BLEU-4 and CIDEr declined by 15.4% and 25.4% on BDD-X, and 21.3% and 25.5% on MSVD—emphasizing the need for strong visual features. Replacing multi-head attention with a single-head variant caused moderate losses, notably a 16.0% drop in CIDEr on MSVD, showing its role in capturing fine-grained text-visual interactions. Omitting gradient accumulation reduced training efficiency and led to average BLEU-4 and CIDEr decreases of 9.8% and 7.5%, confirming its value for stable optimization. Figure 2 illustrates these results. The proposed framework obtained the best scores on all evaluation measures, outperforming the ablated versions on all the datasets consistently. The improvements are especially clear in MSVD and BDD-X, where temporal dependency modeling and interpreting intricate visual scenes are critical. This better performance is a result of the synergy among multiple important elements: ResNet50 for feature extraction of high-level spatial features from images, GPT-2 as a strong language model with the ability to produce fluent and coherent text sequences, multi-head attention for modeling fine-grained alignments between visual and linguistic modalities, and gradient accumulation with mixed-precision training for efficient and stable optimization. The use of GPT-2, specifically, adds to the model's capacity to generate contextually accurate and linguistically advanced descriptions. Collectively, these features make the proposed framework capable of generating high-quality, context-aware descriptions, with each module contributing significantly to the overall performance improvement.

4.2 Results and Analysis:

To assess the efficacy of the suggested architecture, we carried out a comprehensive performance analysis on two benchmark datasets: MSVD and

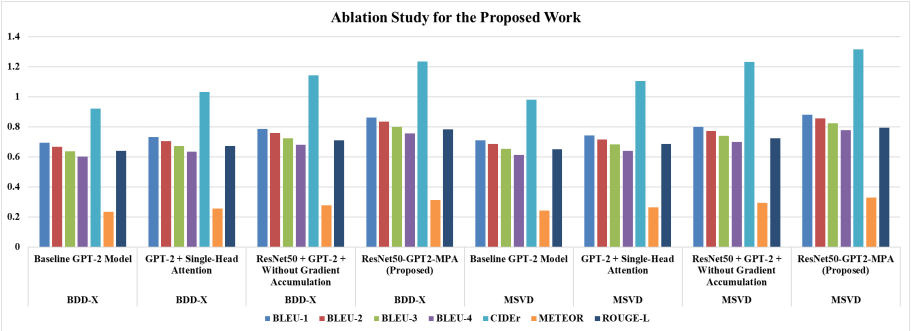

Fig. 2: Demonstration of Ablation Study for the Proposed Work

Table 3: Results and Analysis of the Proposed Framework

Dataset	BLEU-1	BLEU-2	BLEU-3	BLEU-4	CIDEr	METEOR	ROUGE-L
BDD-X	0.860	0.835	0.800	0.755	1.235	0.312	0.782
MSVD	0.880	0.855	0.823	0.778	1.315	0.329	0.795

BDD-X. The suggested framework was tested against many model ablations, such as excluding gradient accumulation, using single-head attention, and removing ResNet-50. The evaluation's findings are compiled in Table 3. The outcomes shown in the table demonstrate how well our suggested methodology performs across datasets, consistently achieving top scores in all evaluation metrics. While high BLEU scores reflect fluency and grammatical accuracy, the superior performance in CIDEr and METEOR highlights strong semantic alignment and high-quality descriptions. With a BLEU-4 score of 0.778 and a CIDEr score of 1.315, the MSVD dataset showcases the model's strength in producing diverse and precise captions for short video content. Similarly, the BDD-X dataset results—0.755 BLEU-4 and 1.235 CIDEr—illustrate the model's robustness in capturing intricate driving scenes and generating contextually appropriate, descriptive narratives. Consistently high ROUGE-L scores (0.795 for MSVD and 0.782 for BDD-X) further validate the framework's ability to generate outputs that closely align with human references. Notably, elevated CIDEr values emphasize the model's effectiveness in capturing contextual and domain-specific nuances, while higher METEOR scores reflect improved alignment and paraphrasing capabilities. Figure 3 demonstrates the graphical representation of the results obtained for the proposed framework. In general, the findings demonstrate that the suggested approach greatly improves the ability of video-based descriptions, resulting in syntactically fluid, semantically rich, and contextually relevant descriptions.

4.3 Comparison With State-of-the-Art Methods:

We compare the performance of the suggested model with current state-of-the-art (SOTA) captioning methods on two benchmark datasets—BDD-X and MSVD—in order to assess its efficacy. A thorough evaluation employing several evaluation metrics, such as BLEU-1 to BLEU-4, CIDEr, METEOR, and ROUGE-L, is given by the results in Table 4. On both datasets, the proposed framework significantly outperforms earlier approaches, proving its capacity to produce more semantically precise and contextually rich descriptions for behaviours involving vehicles. Specifically, the suggested model leads in terms of BLEU-4 and CIDEr scores, demonstrating enhanced description coherence and relevance. The table's comparative analysis demonstrates how the BDD-X and MSVD datasets have advanced regarding vehicle action comprehension and general video-based description generation. Previous models like OSCAR [21], ViT-GPT2 [20], X-LAN [19], and AoANet [22] showed consistent improvements in descriptive quality on the BDD-X dataset, with AoANet receiving the highest

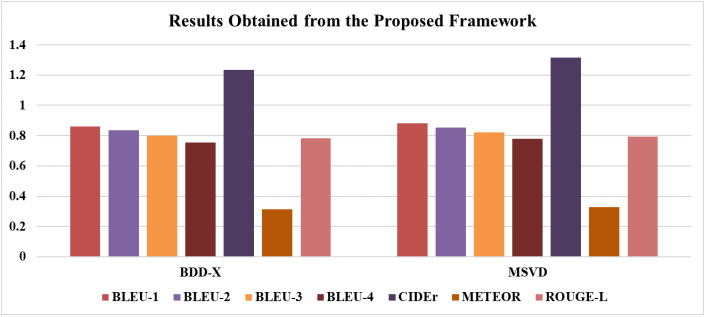

Fig. 3: Graphical Representation of the Results Obtained

Table 4: Comparison of State-of-the-Art Models for Vehicle Action Understanding

Dataset	Model	BLEU-1	BLEU-2	BLEU-3	BLEU-4	CIDEr	METEOR	ROUGE-L
BDD-X	GPT-2 (Baseline)	0.312	0.285	0.210	0.152	0.653	0.185	0.356
	X-LAN [19]	0.451	0.412	0.356	0.293	0.998	0.265	0.541
	ViT-GPT2 [20]	0.482	0.445	0.398	0.324	1.086	0.258	0.523
	OSCAR [21]	0.510	0.472	0.423	0.358	1.124	0.276	0.548
	AoANet [22]	0.532	0.495	0.442	0.372	1.189	0.289	0.573
	ResNet50-GPT2 (Proposed)	**0.860**	**0.835**	**0.800**	**0.755**	**1.235**	**0.312**	**0.782**
MSVD	GPT-2 (Baseline)	0.334	0.305	0.243	0.178	0.705	0.192	0.372
	Show, Attend and Tell [23]	0.480	0.443	0.395	0.304	0.943	0.252	0.520
	M^2 Transformer [24]	0.520	0.486	0.438	0.391	1.270	0.292	0.586
	Dense Video Captioning [25]	0.498	0.463	0.412	0.357	1.135	0.268	0.552
	GRU-EVE [26]	0.535	0.502	0.456	0.370	1.246	0.285	0.594
	ResNet50-GPT2 (Proposed)	**0.880**	**0.855**	**0.823**	**0.778**	**1.315**	**0.329**	**0.795**

scores. However, with a BLEU-4 score of 0.755 and a CIDEr score of 1.235, the proposed model outperforms all of these approaches, significantly advancing over prior research. Similarly, on the MSVD dataset, transformer-based models such as M^2 Transformer [24] and GRU-EVE [26] performed well, with GRU-EVE achieving a BLEU-4 score of 0.370 and CIDEr of 1.246. The proposed model demonstrates clear improvements, especially in BLEU-4 (0.778) and CIDEr (1.315), showcasing its ability to generate contextually rich and semantically aligned descriptions. Figure 4 depicts a graphical representation of SOTA methods. Overall, the suggested approach continuously outperforms comparison on all datasets, setting new benchmarks and proving its ability to capture fine-grained contextual information for interpreting video-based actions.

5 Conclusion and Future Direction

The proposed approach successfully combines ResNet50 for feature extraction with an improved GPT-2 model, allowing for the production of contextually aware, high-quality descriptions of video footage from the BDD-X and MSVD datasets. Through the use of transformer-based language modelling, the method guarantees descriptions that are consistent with ground-truth annotations and logical. In comparison to traditional approaches, the combination of ResNet50 for visual feature extraction and GPT-2 for text generation, as well as dataset augmentation, gradient accumulation, and mixed precision training, improves training efficiency and performance. Although transformer-based architectures are effective when used for large datasets, the study emphasizes that domain-specific fine-tuning is necessary to produce accurate and comprehensible descriptions. Future steps will involve implementing cross-modal attention mechanisms, sophisticated vision-based encoders, and optimized preprocessing methods to further improve model adaptability. The generalization and compatibility across other domains would be enhanced by expanding datasets to encompass a wider

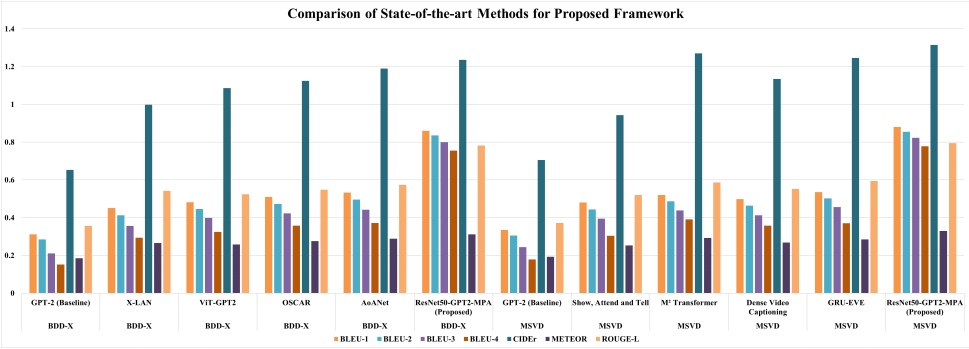

Fig. 4: Graphical Representation of the SOTA Methods

range of real-world circumstances. By enhancing interpretability, transparency, and decision-making clarity, this research advances explainable AI and increases the adaptability and dependability of automated video comprehension for a range of applications.

***Abstract*—Image description generation is essential for accessibility and AI understanding of visual content. Recent advancements in deep learning have significantly improved natural language processing and computer vision. In this work, we propose Tri-FusionNet, a novel image description generation model that integrates transformer modules: a Vision Transformer (ViT) encoder module with dual-attention mechanism, a Robustly Optimized BERT Approach (RoBERTa) decoder module, and a Contrastive Language-Image Pre-Training (CLIP) integrating module. The ViT encoder, enhanced with dual attention, focuses on relevant spatial regions and linguistic context, improving image feature extraction. The RoBERTa decoder is employed to generate precise textual descriptions. CLIP's integrating module aligns visual and textual data through contrastive learning, ensuring effective combination of both modalities. This fusion of ViT, RoBERTa, and CLIP, along with dual attention, enables the model to produce more accurate, contextually rich, and flexible descriptions. The proposed framework demonstrated competitive performance on the Flickr30k and Flickr8k datasets, with BLEU scores ranging from 0.767 to 0.456 and 0.784 to 0.479, CIDEr scores of 1.679 and 1.483, METEOR scores of 0.478 and 0.358, and ROUGE-L scores of 0.567 and 0.789, respectively. On MS-COCO, the framework obtained BLEU scores of 0.893 (B-1), 0.821 (B-2), 0.794 (B-3), and 0.725 (B-4). The results demonstrate the effectiveness of Tri-FusionNet in generating high-quality image descriptions.**

***Index Terms*—Image Description Generation, Natural Language Processing, Computer Vision, Transformers, Dual Attention Mechanism, Artificial Intelligence.**

I. Introduction

In order to improve accessibility and comprehension, image description generation, which is essential to computer vision and artificial intelligence— involves producing textual descriptions of images. These descriptions, which make use of transformer architectures and deep learning, seek to accurately capture the context and content of images [1]. By combining computer vision and natural language processing, this multimodal method allows machines to understand and communicate with visual content in a way that is similar to that of humans. The goal of the research is to find image-processing algorithms that efficiently link textual and visual elements while preserving linguistic fluency. Applications include social media image annotation, real-time navigation systems, visual question answering, helping the blind, and self-driving automobiles. After breakthroughs in image classification models, adversarial examples are being developed for more complex tasks like image description generation [2].

Corresponding author: Dr. Bindu Verma (email: bindu.cvision@gmail.com).

Transformer models excel in generating image descriptions using self-attention but struggle with complex relationships. Single transformers may fail to capture both global and local details, while dual models often struggle to integrate visual and textual information effectively. This can hinder fine-grained visual understanding and complicate non-autoregressive techniques [3]. To address these issues, we propose a model combining Vision Transformer (ViT) with dual attention, RoBERTa, and a CLIP integration module. ViT transforms images into embedding sequences, capturing global and local features through transformer layers and pre-training on large datasets for image classification. RoBERTa, based on BERT, enhances textual context understanding by leveraging extensive text pre-training [4]. CLIP, developed by OpenAI, enables vision-language learning by aligning image and text representations for multimodal tasks [5].

With dual attention, the suggested Tri-FusionNet architecture combines three transformers to improve image descriptions by making them more contextually relevant and advanced. This fusion includes a CLIP integrating model for textual representation generation, a RoBERTa decoder for category derivation and a Vision Transformer (ViT) for feature capture. By combining ViT, RoBERTa and CLIP with dual attention, one may enhance the quality of descriptions and build a robust and flexible system for producing visual descriptions.

The major contribution of the proposed framework is highlighted below:

- This work presents a novel image description-generating model called Tri-FusionNet, which represents a major breakthrough in multi-modal approaches to generating precise and contextually rich descriptions. This method improves the model's fine-tuning capabilities by combining several components, which increases the efficacy of creating image descriptions.
- The combination of ViT encoder with dual-attention, RoBERTa decoder, and CLIP integration module is employed to create an efficient model that maximizes the interaction between different modalities, resulting in more accurate and contextually appropriate image descriptions.
- The proposed framework addresses the challenges posed by different benchmark datasets by developing a model

that can adapt to the characteristics of each dataset as well as potentially setting new state-of-the-art results on these datasets.

Organization of the paper is as follows: Section II explores prior research and previous works. Section III provides a comprehensive presentation of the suggested framework. Section IV presents and analyses the experimental design, benchmark dataset information, results and ablation study. Section V provides a conclusion as well as a discussion of the ability of the study and its future directions.

II. Related Work

Deep learning frameworks have been investigated for autonomous image description systems. These frameworks are extensively used in the fields of computer vision and human-computer interaction. The transformer exhibits potential for multi-modal tasks such as visual description creation, as it is skilled at collecting long-range dependencies and modeling sequential data. Li et al. [6] developed the EnTangled Attention (ETA) Transformer, exhibiting state-of-the-art performance on the MSCOCO dataset, whereas Cornia et al. [7] presented M2, a Meshed Transformer with Memory, for image description generation. Furthermore, a Multi-modal Transformer (MT) model was introduced by Yu et al. [8], that stores intra-modal and inter-modal interactions in a single attention block, enabling precise description development and sophisticated multi-modal reasoning.

Radford et al. [9] demonstrated that pre-training a model to predict image-caption pairs from a dataset of 400 million (image, text) pairs enables zero-shot transfer to various downstream tasks, achieving competitive performance without task-specific training. MiniGPT-v2 is a unified model designed to handle diverse vision-language tasks like image description, visual question answering, and visual grounding, using unique task identifiers to improve learning efficiency and performance on various benchmarks [10]. In order to improve image captioning performance on the MS COCO and Flickr8k datasets, Yang et al. [11] suggested SAMT-Generator, a multi-stage transformer feature enhancement network with second attention and Maxout decoding. A novel approach of the S^2 transformer was developed that integrated Spatial-aware Pseudo-supervised and Scale-wise Reinforcement modules, achieving state-of-the-art results on the MSCOCO benchmark [12]. Yang et al. [13] presented a fully Transformer-based image captioning model called CA-Captioner, which applies HAPE positional encoding, LSM, RNorm function, and LFE, thereby achieving improved performance on the MS COCO, Flickr8k, and Flickr30k datasets, especially in terms of BLEU4 and CIDEr metrics.

On the Flickr30k and MSCOCO datasets, Parvin et al. [14] proposed a double-attention framework that outperformed state-of-the-art models. By utilising previous activations to improve semantic attention and performance, PMA-Net [15] integrates prototypical memory vectors into Transformer-based image captioning, attaining a 3.7 CIDEr boost on the COCO dataset. By treating heterogeneous encodings (such as visual and textual) as augmented views and using a shared encoder with contrastive loss to improve representation quality and a hierarchical decoder to adaptively weigh views, HAAV [16] presents a novel method for image captioning. It achieves notable CIDEr improvements on MS-COCO (+5.6%) and Flickr30k (+16.8% with SSL) datasets. DualVision Transformer (Dual-ViT) was introduced by Yao et al. [17], providing higher accuracy with effective token vector compression. Spatial Pyramid Transformer (SPT) was mainly used for adaptive semantic interaction across grid resolutions, preserving spatial and fine-grained information, achieving state-of-the-art performance on MS-COCO [18] for image description generation.

The challenges of creating image descriptions remain, despite the progress made in medical imaging and NLP with models such as ETA Transformer, Multi-modal Transformer (MT) and Dual-Level Collaborative Transformer (DLCT). These challenges include the semantic gap between language and vision, as well as the absence of global information that is critical for scene comprehension. The suggested Tri-FusionNet combines dual attention, RoBERTa and CLIP transformers with Vision Transformer (ViT) to address these issues. By using ViT for image embedding, RoBERTa for textual interpretation, and CLIP for visual-textual fusion, it is possible to improve understanding of visual content.

III. Proposed Framework

Recently, image description creation has gained a lot of attention as a challenging topic combining computer vision and natural language processing (NLP). Although the current models have come a long way, there is still an opportunity for development in producing precise and contextually appropriate descriptions. This work presents Tri-FusionNet, which combines a dual attention mechanism with Vision Transformer (ViT), CLIP, and RoBERTa decoder to improve spatial and channel-wise information extraction from images. Better descriptive words are generated over a range of images, advancing image description generation. The model is optimized with Adam optimizer and Cross-Entropy loss over epochs. Its performance is assessed using metrics including BLEU, CIDEr, ROUGE-L, and METEOR scores on benchmark datasets. Figure 1 represents the framework of the proposed approach.

A. Overview of the Proposed Architecture:

1) Data Pre-processing: The data preprocessing step in the proposed Tri-FusionNet framework involves normalizing the input images' pixel values to enhance the model's performance. The mean and standard deviation of the pixel values throughout the dataset are computed to accomplish this. The distribution of the pixel values is then altered to have a standard deviation (or variance) of one and a mean of zero. This normalization process reduces the effect of varied lighting or contrasts between images by standardizing the range of pixel values. The model can learn more from the data by focusing the values around zero and scaling them to have unit variance, guaranteeing that each feature contributes equally to the training process. Figure 1(a) demonstrates the Data Pre-Processing step. Next, to prepare the data for the Vision Transformer (ViT) encoder module in image description generation,

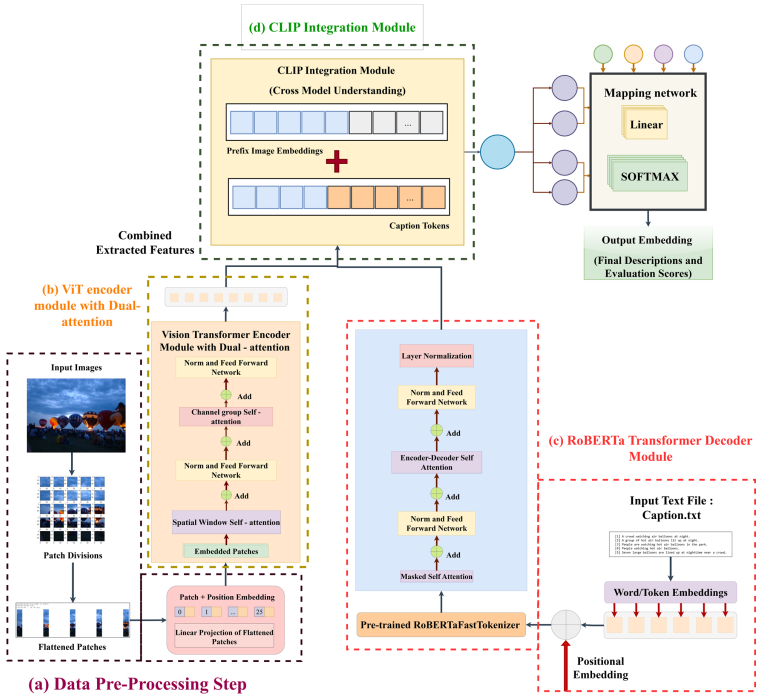

Fig. 1. Structural representation of Tri-FusionNet framework: The architecture consists of three phases: firstly, high-level visual features are first extracted from pre-processed images using a Vision transformer encoder with dual-attention mechanism; next, words from the input caption file are tokenized by a RoBERTa decoder; and last, the combined data is fed into a CLIP-integrating module to create image descriptions using dense network layers.

input images are divided into fixed-size patches. To construct embeddings, each patch is flattened and projected linearly. The process of patch extraction and positional encoding is thoroughly explained in the `supplementary.tex` file. The ViT encoder receives sequences of tokenized patches that have been enhanced with positional data. Through this procedure, the model is able to efficiently collect the image's spatial and visual properties, which sets the stage for the next tasks, like labeling the image.

2) Vision Transformer Encoder Module with Dual Attention Mechanism: The input image is divided into fixed-size patches using the Vision Transformer's encoder-based architecture, which is then processed through transformer layers and linearly embedded. Its ability to retrieve relevant data from both spatial and channel-wise dimensions is enhanced by the dual-attention process, which makes accurate descriptions possible. In the vision transformer encoder with a dual attention mechanism, we adopt a hierarchical layout. The encoder combines spatial window attention with channel-group attention and is structured into four phases: (a) insertion of the patch embedding layer, (b) application of spatial window attention, (c) utilization of channel-group attention, and (d) incorporation of the jointly extracted features. Figure 1(b) demonstrates the Vision encoder module with dual-attention mechanism. In the initialization phase, the input is in the form of patches along with positional embedding obtained from the data pre-processing stage. Assuming a visual feature R with dimensions $R^{(P\times C)}$, where P represents the total number of patches and C is the total number of channels, the standard global self-attention is represented by Equation (1):

$$S_A(Q,K,V) = \text{Concat}(\text{head}1,\ldots,\text{head}N_h), \quad (1)$$

where,

$$\text{head}_i = \text{Attention}(Q_i,K_i,V_i) = \text{Softmax}\left(\frac{Q_iK_i^T}{\sqrt{C_h}}\right)V_i \quad (2)$$

here, $\text{Q}_i = X_i \times (W_i)^Q$, $\text{K}_i = X_i \times (W_i)^K$ and $\text{V}_i = X_i \times (W_i)^V$. Consider $R^{P\times C_h}$ dimensional visual features with N_h heads, where X_i represents the ith head of the input feature and W_i denotes the projection weights for the ith head in the context of Q, K, V, with $C = C_h \times N_h$.

The model concurrently arranges spatial window attention and channel group attention in the vision transformer with a dual attention mechanism to obtain both local and global data but with a linear complication to the spatial dimension. The spatial window attention algorithm calculates self-attention within local windows, which are positioned to equally and non-overlapping segments in the field of vision. Assuming the presence of N_w distinct windows, each comprised of P_w patches, the total number of patches, denoted as P, can be expressed as $P = P_w \times N_w$. The representation of spatial window attention is given by Equation (3):

$$\text{Attention}w(Q,K,V) = (\text{Attention}(Q_i,K_i,V_i))^{N_w}\ i = 0 \quad (3)$$

where each $Q_i, K_i, V_i \in \mathbb{R}^{P_w\times C_h}$ are local window queries, keys, and values, respectively, and P is the spatial size presenting the linear complexity.

An alternative viewpoint on self-attention is provided by channel-wise attention, which ensures thorough spatial domain coverage by concentrating on tokens at the patch level as

opposed to pixels. Each transposed token, with the number of heads set to 1, engages with global data in a linear spatial complexity along the channel dimension. $C = N_g \times C_g$ is the outcome of letting C_g represent the number of channels in each group and N_g the number of groups. As a result, Equation (4) defines global channel group attention, which allows tokens at the image level to interact across channels.

$$\text{Attention}c(Q, K, V) = \left((\text{Attentiongroup}(Q_i, K_i, V_i))^T \right)_{i=0}^{N_g} \tag{4}$$

where, every $Q_i, K_i, V_i \in \mathbb{R}^{P \times C_g}$ represents grouped channel-wise image-level queries, keys and values.

The final encoder output of the Vision Transformer using the dual attention mechanism can be represented by Equation (5):

$$E_{\text{output}} = \text{Concat}(\text{Attention}_w(Q, K, V), \text{Attention}_c(Q, K, V)) \tag{5}$$

$\text{Attention}_w(Q, K, V)$ represents the spatial window attention and $\text{Attention}_c(Q, K, V)$ represents the channel group attention, as defined in Equations (3) and (4), respectively. In order to achieve linear complexity in both dimensions for computational efficiency, the final encoder output combines channel group attention and spatial window attention. In contrast to spatial-wise global attention, channel attention functions globally, aggregating information rather than locally. It is a complement to spatial window attention. By distributing weights according to how relevant they are to the task, the model uses its attention mechanism to prioritize particular image patches. By using these weights, heat maps are produced that show the areas of the image where the model focuses. On the heat map, places that are important for accurate and contextually rich descriptions are indicated by intense areas.

3) RoBERTa Decoder: The study presents a novel approach to image description generation that combines natural language processing (NLP) and computer vision. A Vision Transformer (ViT) with dual attention is employed to extract visual information. Simultaneously, textual data from a "caption.txt" file is used during training to build word embeddings and guide the model in learning semantic relationships between images and their descriptions. This process helps optimize the model and align visual and textual features effectively. During inference, the model does not require an input description or text file. Instead, it generates a new description based solely on the visual features extracted from the input image. This distinction ensures the model's flexibility and generalization, enabling it to produce unique and contextually rich descriptions for each image. These embeddings are seamlessly integrated into a decoder model based on RoBERTa, an enhanced version of BERT, along with ViT-extracted image features. Figure 1(c) demonstrates the step involved in the RoBERTa decoder module.

The decoder uses RoBERTa's pre-trained language understanding abilities to contextualize the data from the text and image embedding, allowing it to produce descriptions that generate better explanations and are relevant to the context. To decode and generate image descriptions, the RoBERTa decoder module is obtained from the following Equation (6).

$$D_{\text{Output}} = \text{RoBERTaDecoder}\left(W_{\text{emb}}, C\right), \tag{6}$$

where, W_{emb} represents the word embeddings generated from the caption data, C is the additional contextual information derived from the original caption file, and D_{Output} is the output generated by the RoBERTa decoder, which consists of the final description of the image. Through multiple layers of feed-forward neural networks and self-attention, multiple word embeddings are processed by the RoBERTa decoder, which enables it to efficiently contextualize the textual information.

4) CLIP Integration Module: The final step of the proposed approach involves generating image embeddings using a Vision Transformer (ViT) with a dual attention mechanism and text embeddings using the RoBERTa decoder. This integration aims to combine the ViT encoder, RoBERTa decoder, and CLIP for effective image description generation. During the embedding generation process, the ViT encoder is used to obtain image embeddings from the image dataset, while the RoBERTa decoder generates text embeddings from the caption data. The joint representation of the image and its corresponding text is then obtained by aligning these embeddings in the subsequent phase. Specifically, CLIP's encoder is used to align the visual and textual embeddings through contrastive learning, ensuring that the visual and textual features are mapped into a shared space for accurate description generation. The embeddings obtained from both the ViT encoder and the RoBERTa decoder are concatenated to form a unified representation, as shown in Equation (7):

$$CLIP_{\text{integration}} = \text{Concatenate}(E_{\text{output}}, D_{\text{output}}), \tag{7}$$

where E_{output} is the image embedding from the ViT encoder, D_{output} is the text embedding from the RoBERTa decoder, and $CLIP_{\text{integration}}$ represents the combined embedding used by the CLIP model. This integrated representation helps generate coherent and accurate image descriptions by aligning the visual and textual information effectively. The model uses a contrastive loss function in the embedding space to distinguish between positive and negative pairs, ensuring the alignment between visual and textual features. The final integration module, after encoding and decoding the image-description pair, generates the output descriptions. The architectural explanation of the CLIP integration module is explained in the `supplementary.txt` file.

The reference file for descriptions is crucial in assessing how well the Tri-FusionNet model generates descriptions. Visual features extracted from images are projected into a higher-dimensional space using a linear layer, allowing the model to capture intricate relationships among input features. These features are then normalized into a probability distribution across the lexicon of possible words or tokens using a Softmax layer. During training and evaluation, the model generates predicted descriptions, which are compared to reference descriptions using evaluation metrics such as CIDEr, ROUGE-L, BLEU 1-4, and METEOR to assess the model's ability to capture and translate context and image semantics into accurate descriptions.

The Tri-FusionNet model operates through a synergistic pipeline. The Vision Transformer (ViT) encoder with dual attention, RoBERTa decoder, and CLIP integration module

collaborate to generate accurate and contextually rich image captions.

- To handle input images, the Vision Transformer (ViT) encoder flattens, divides them into patches, and embeds positional encodings. Its dual attention method combines Spatial Window Self-Attention, which concentrates on local spatial relationships to maintain contextual importance, with Channel Group Self-Attention, which catches fine-grained features inside image channels. As a result, both local details and global context are successfully represented in the rich visual feature embeddings.
- To process the input text file with ground truth descriptions, the RoBERTa decoder tokenises the text, embeds the tokens, then decodes them into contextual embeddings. It uses its pre-trained language understanding to ensure fluency and coherence and Masked Self-Attention to concentrate on sequentially relevant tokens. This produces textual embeddings that effectively express the descriptions' semantic meaning and linguistic structure.
- Using a contrastive learning technique, the CLIP integration module maps both modalities into a common latent space by aligning textual embeddings from the RoBERTa decoder and visual features from the ViT encoder. By facilitating cross-modal fusion and preserving semantic coherence, this alignment makes it possible to produce linguistically correct and visually justified descriptions.

The model optimizes for metrics such as BLEU, CIDEr, METEOR, and ROUGE-L and provides accurate and contextually rich descriptions through parallel processing, dual attention, and contrastive learning. By utilizing each module's unique capabilities to convert raw image and text inputs, the approach guarantees high-quality description generation. The detailed algorithm of the proposed model is given in the `supplementary.tex` file.

IV. Experimental Analysis

The proposed model was evaluated using Google Colab Pro+ with 52 GB RAM, an NVIDIA A100 GPU (40 GB VRAM), and a virtual Intel Xeon CPU. Implemented in Keras and TensorFlow 2.12, Tri-FusionNet integrates three transformer modules, increasing computational demands. Optimization techniques like parallelization, mixed precision training, and resource management reduce memory usage and ensure efficiency. Despite its complexity, model parallelism enables viability on limited hardware. Scalability tests on larger datasets showed a linear increase in training time, demonstrating efficient scaling. Optimized attention mechanisms and parameter sharing enhance computational efficiency compared to state-of-the-art models, balancing performance with resource constraints. The model was tested on MSCOCO[1], Flickr8k[2], and Flickr30k[3], with efficiency, cost, and scalability compared in Table I.

Because of its transformer and CLIP components, the proposed Tri-FusionNet model has a moderate processing cost but excels at handling huge datasets. On the other hand, BLIP Transformer [20] provides a fair trade-off between cost and performance, whereas models such as NIC [19] and M2 Transformer [7] are more resource-efficient but less scalable.

TABLE I
Comparison of Tri-FusionNet with state-of-the-art models on scalability and computational cost.

Model	Architecture	Scalability	Computational Cost	Efficiency
NIC [19]	CNN with Attention Mechanism	Limited scalability	Low cost and less resource-intensive	Good for smaller tasks but lacks richness
BLIP Transformer [20]	Vision-Language Pretraining	Scales well with efficient pretraining	Moderate cost and compact architecture	Balanced performance and cost
M2 Transformer [7]	Memory-Augmented Transformer	Effective for mid-sized datasets	Moderate cost and memory-efficient	Competitive with moderate resources
Tri-FusionNet	**ViT, RoBERTa, CLIP**	**Handles large datasets**	**Moderate cost and memory efficient**	**Superior image-text alignment**

The implementation details of the proposed framework is demonstrated thoroughly in `supplementary.tex` file.

A. Ablation Study:

An ablation study was carried out in order to fully comprehend the contributions of each element in the suggested image description generation model. The objective of this study is to assess the impact of the proposed Tri-FusionNet model, which integrates the CLIP model, RoBERTa and Vision Transformer (ViT) with dual attention, on the overall performance. Through heat map analysis, the model can learn more about how it interprets visual cues and focuses on various areas of the image. This comprehension can enhance the model's architecture, boost its functionality, and make the model's decision-making process more interpretable, as shown in Figure 2.

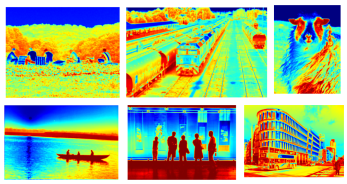

Fig. 2. Example of obtained heat maps based on dual-attention mechanism.

A thorough study of the outcomes within the framework of the work proposed for MSCOCO dataset is shown in Table II. It presents various results of evaluation metrics for different models applied to the input image dataset.

The Tri-FusionNet model sets a new benchmark by significantly outperforming baseline models among those evaluated on the MSCOCO dataset for image description generation, including the CNN-RNN Model, CNN-LSTM Model, ViT with Attention, ViT with Dual Attention, Vanilla ViT, ViT only, RoBERTa Transformer, CLIP Transformer, and ViT with RoBERTa Model. It achieves a 1.88 CIDEr score increase and notable BLEU values (0.893, 0.821, 0.794, and 0.725). Tri-FusionNet also demonstrates better precision, recall, and alignment with reference phrases, along with enhanced n-gram

RoBERTa Transformer	0.73	0.68	0.51	0.43	1.54	0.62	0.50
CLIP Transformer	0.66	0.54	0.43	0.32	1.09	0.51	0.38
ViT and RoBERTa	0.74	0.63	0.55	0.46	1.80	0.68	0.56
ViT+ RoBERTa + CLIP	0.78	0.69	0.65	0.58	1.83	0.73	0.62
Tri-FusionNet (Proposed)	**0.893**	**0.821**	**0.794**	**0.725**	**1.88**	**0.78**	**0.689**

overlap, as shown by its ROUGE-L score of 0.689 and METEOR score of 0.78. When compared to the ViT + RoBERTa + CLIP model, which achieves scores of 0.78 for METEOR, 0.69 for ROUGE-L, 0.65 for BLEU-4, 0.58 for BLEU-3, 1.83 for CIDEr, 0.73 for BLEU-2, and 0.62 for BLEU-1, Tri-FusionNet's performance highlights the effectiveness of its integrated attention mechanisms. The dual-attention mechanism proves especially useful, while the Vanilla ViT model demonstrates the strength of vision transformers. The CLIP Transformer outperforms the RoBERTa Transformer, despite the latter's slight under-performance.

Table III displays a comprehensive analysis of the results obtained from the Flickr8k dataset in the context of the proposed work. It presents various evaluation metrics for different models applied to the input image. The Flickr30k

TABLE III
PERFORMANCE METRICS OF IMAGE DESCRIPTION GENERATION MODELS IN THE FLICKR30K DATASET

Model	B-1	B-2	B-3	B-4	C	M	R-L
CNN-RNN Model	0.45	0.35	0.30	0.20	0.900	0.231	0.197

Tri-FusionNet (Proposed)	**0.767**	**0.654**	**0.647**	**0.456**	**1.679**	**0.478**	**0.567**

dataset is used to evaluate several image description generation models, including ViT with RoBERTa, CNN-LSTM, Vanilla ViT, ViT with Attention, ViT with Dual Attention, ViT only, and RoBERTa Transformer. Despite its simplicity, the CNN-RNN Model provides competitive metrics and BLEU scores (0.20 to 0.45) as a baseline. The CNN-LSTM Model shows minor improvements, particularly in METEOR and ROUGE-L ratings. As demonstrated by higher METEOR, ROUGE-L, and BLEU-1 to BLEU-3 scores, the ViT with Attention and ViT with Dual Attention models benefit from attention mechanisms that improve language detail capture. While the RoBERTa Transformer performs exceptionally well in BLEU-2 and BLEU-3, the Vanilla ViT variant also performs robustly. The ViT + RoBERTa + CLIP model achieves scores of 0.741 for METEOR, 0.621 for ROUGE-L, 0.573 for BLEU-4, 0.428 for BLEU-3, 1.092 for CIDEr, 0.389 for BLEU-2, and 0.432 for BLEU-1. The Tri-FusionNet model produces accurate and varied visual descriptions, outperforming other models across BLEU-1 to BLEU-4 and achieving a BLEU-4 score of 0.456.

Table IV displays a comprehensive analysis of the results obtained from the Flickr8k dataset in the context of the proposed work. It presents various evaluation metrics for different models applied to the input image. Using CNN-LSTM and

TABLE IV
PERFORMANCE METRICS OF IMAGE DESCRIPTION GENERATION MODELS IN THE FLICKR8K DATASET

Model	B-1	B-2	B-3	B-4	C	M	R-L
CNN-RNN Model	0.467	0.435	0.370	0.323	0.670	0.131	0.137
CNN-LSTM Model	0.433	0.232	0.225	0.118	0.301	0.128	0.235
ViT with Attention	0.547	0.343	0.323	0.217	0.607	0.234	0.131
ViT with Dual Attention	0.543	0.436	0.344	0.246	1.002	0.253	0.121
Vanilla ViT	0.632	0.511	0.320	0.242	0.255	0.316	0.153
ViT Only	0.542	0.466	0.342	0.266	0.675	0.344	0.343
RoBERTa Transformer	0.553	0.459	0.413	0.337	0.983	0.312	0.156
CLIP Transformer	0.525	0.324	0.244	0.132	1.065	0.234	0.289
ViT and RoBERTa	0.745	0.513	0.456	0.312	1.189	0.298	0.457
ViT+ RoBERTa + CLIP	0.756	0.652	0.518	0.460	1.231	0.321	0.528
Tri-FusionNet (Proposed)	**0.784**	**0.678**	**0.538**	**0.479**	**1.381**	**0.389**	**0.654**

CNN-RNN as baseline models, the Flickr8k dataset compares several image description models. While Vanilla ViT performs well in BLEU-1 to BLEU-2, attention mechanisms in ViT with Attention and ViT with Dual Attention models enhance visual descriptions. In BLEU-3 and CIDEr, ViT only, the RoBERTa Transformer outperforms the CLIP Transformer, which lags slightly behind. The ViT + RoBERTa + CLIP model achieves scores of 0.756 for METEOR, 0.652 for ROUGE-L, 0.518 for BLEU-4, 0.460 for BLEU-3, 1.231 for CIDEr, 0.321 for BLEU-2, and 0.528 for BLEU-1. ViT and RoBERTa work together to create a balanced model. Nonetheless, the suggested Tri-FusionNet surpasses all other models, attaining the highest ratings in CIDEr, ROUGE-L, and BLEU-1 to BLEU-4 measures, demonstrating its efficiency in producing precise and diverse image descriptions.

By combining language and vision transformer components, the Tri-FusionNet consistently outperforms other models in the MSCOCO, Flickr30k and Flickr8k datasets, demonstrating its superior architecture for image description generation and producing better image descriptions. It also yields higher scores in BLEU-1 to BLEU-4 metrics and CIDEr, ROUGE-L and other metrics.

B. Results and Analysis:

The approach was evaluated on three benchmark dataset: MSCOCO, Flickr30k and Flickr8k for the proposed architecture. The following Table V represents the results obtained for the MSCOCO dataset.

Using four sets of test images from the MSCOCO dataset, the table presents a thorough comparison of ground-truth descriptions and predicted descriptions generated by a model. This is an effective way of assessing and determining how well the model can provide meaningful and accurate descriptions of images.

TABLE V
QUANTITATIVE RESULTS OBTAINED ON MSCOCO DATASET

Test Image	Ground Truth	Predicted Description
	Two men playing frisbee on grass surrounded by trees.	Two men playing frisbee on grass.
	Trains on railway tracks, with trees and blue sky.	Trains on tracks with trees.
	Vegetables including carrot, radish and turnip on a table.	Green and red vegetables on a table.
	A red bus in front of a white building with blue sky.	A white building with blue sky.

TABLE VI
QUANTITATIVE RESULTS OBTAINED ON FLICKR30K DATASET

Test Image		
Ground Truth Descriptions	1. A white woman standing in a grocery store not-so-candidly posing for the camera while examining the items on a shelf 2. The lady with the shopping cart is surrounded by toys galore and various children's bicycles. 3. A woman in a green winter coat stands with a cart in the middle of a department store isle 4. a woman in a green jacket is in the toy aisle with a shopping cart and her purse 5. The woman in the green coat is pushing a cart through the toy aisle	1. Six men are sitting or laying on a patch of earth in a wooded area. 2. A group of workers sitting in a field take a break from work. 3. A group of men are sitting in the farm fields taking a break. 4. Six men sit in a field of crops containing wooden crates. 5. Pickers working out on a farm
Predicted Description	A woman in a green coat shops in the toy aisle with a cart.	Six men take a break in a field.
Test Image		
Ground Truth Descriptions	1. A gray bird stands majestically on a beach while waves roll in. 2. A white crane stands tall as it looks out upon the ocean. 3. A tall bird is standing on the sand beside the ocean. 4. A large bird stands in the water on the beach. 5. A water bird standing at the ocean 's edge.	1. A group of people stares at a wall that is filled with drawings in a building. 2. There are 5 people here looking at some pictures on the wall. 3. Five people are taking in an exhibit of Japanese art. 4. People watching at the arts in exhibition. 5. Five people looking at artwork.
Predicted Description	A bird stands tall on the beach.	Five people looking art in a building.

Table VI aims to showcase how well the model aligns for Flickr30k dataset. Four sets of test images are listed in the table, together with the accompanying ground truth descriptions and the model's predicted descriptions for each. This table is as an assessment tool, demonstrating the model's capacity to produce accurate and relevant descriptions for a range of images found in the Flickr30k dataset.

Table VII is designed to demonstrate the alignment of the model with the actual content of the images, as indicated by the provided ground truth descriptions for the Flickr8k dataset. Four sets of test images are included in the table, each with the corresponding ground truth descriptions and the predicted descriptions from the model. This table serves as a means of assessment, showcasing the model's capacity to provide accurate and perceptive descriptions for a range of images from the Flickr8k dataset.

TABLE VII
QUANTITATIVE RESULTS OBTAINED ON FLICKR8K DATASET

Test Image		
Ground Truth Descriptions	1. A winter landscape with four people walking in the snow. 2. Beautiful snowy landscape with people treading through the snow. 3. Cross-country skiers are traveling towards the mountains at sunset. 4. Four people walking across thick snow during a sunset. 5. The sun is almost behind the snowy mountains.	1. A beautiful sunset with three people in a boat on the lake. 2. As the sunsets 3 people are on a small boat enjoying the view. 3. Three people are in a canoe on a calm lake with the sun reflecting yellow. 4. Three people are on a boat in the middle of the water while the sun is in the back. 5. Three people in a boat float on the water at sunset.
Predicted Description	Four people walk through a snowy mountain.	Three people enjoying a beautiful sunset from a boat.
Test Image		
Ground Truth Descriptions	1. "a crowd wearing red , cheers on the red football team." 2. Football players in red congratulate each other as crowds in red cheer behind. 3. The Oklahoma Sooners football team discuss their game while fans cheer. 4. Two football players talk during a game. 5. Two Oklahoma Sooner football players talk on the sideline.	1. The two small dogs run through the grass. 2. Two fluffy white dogs running in green grass. 3. Two small dogs run through the grass. 4. Two small dogs that look almost identical are playing in the grass. 5. Two yellow dogs run together in green grass.
Predicted Description	A crowd in red cheers on the football team.	Two small dogs run through the green grass.

When compared to reference descriptions, the model produces predicted descriptions during the training and evaluation phases. The model's efficacy in capturing visual semantics and context is evaluated by comparing the predicted and real descriptions using metrics such as BLEU 1-4, CIDEr, METEOR and ROUGE-L. Table VIII provides an overview of a framework that has been suggested for the development of image descriptions from the three datasets.

TABLE VIII
OVERALL RESULTS OBTAINED FROM THE PROPOSED MODEL

Dataset	B-1	B-2	B-3	B-4	C	M	R-L
MSCOCO	0.893	0.821	0.794	0.725	1.88	0.78	0.689
Flickr30k	0.767	0.654	0.647	0.456	1.679	0.478	0.567
Flickr8k	0.784	0.678	0.538	0.479	1.381	0.389	0.654

The performance metrics of the proposed model are shown in the table for the MSCOCO, Flickr30k and Flickr8k datasets. These metrics include BLEU-1 to BLEU-4, CIDEr, METEOR and ROUGE-L scores. The suggested framework obtained BLEU scores for MSCOCO of 0.893 (B-1), 0.821 (B-2), 0.794 (B-3) and 0.725 (B-4) and for CIDEr, METEOR and ROUGE-L, 1.483, 0.358 and 0.789, respectively. With BLEU scores ranging from 0.767 (B-1) to 0.456 (B-4), bolstered by a CIDEr score of 1.679 and METEOR (0.478) and ROUGE-L (0.567) ratings suggesting sufficient matching and overlap, competitive performance was observed on the Flickr30k dataset. A CIDEr score of 1.381, favorable matches, and overlap was shown by BLEU scores on the Flickr8k dataset, which varied from 0.784 (B-1) to 0.479 (B-4). METEOR (0.389) and ROUGE-L (0.654)

scores also showed favorable matches and overlap. Across a range of benchmark datasets, the proposed approach performs well overall in producing image descriptions. The graphical depiction of the outcomes is shown in Figure 3. These scores

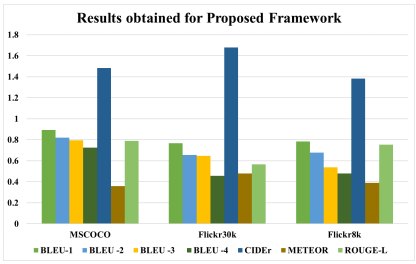

Fig. 3. Graphical representation of the results obtained from the datasets for the proposed Tri-FusionNet framework.

serve as evaluations of the model's performance in generating descriptions that align well with the reference descriptions. Higher scores indicate a higher degree of similarity and quality in the generated descriptions.

Table IX presents a qualitative comparison between the ground truth descriptions and the descriptions generated by the proposed model, highlighting successful and unsuccessful predictions and error analysis.

TABLE IX
QUALITATIVE ANALYSIS OF GENERATED IMAGE DESCRIPTIONS

Test Image	Ground Truth Description	Generated Description	Remarks/Error Analysis
	A white dog is holding a purple frisbee in its mouth on the green grass.	White dog holding purple frisbee on grass.	**Success:** Correct identification of objects and actions.
	A gold and black motorcycle parked on a paved surface road.	A car parked on road.	**Failure:** Incorrect object recognition.
	Three ducks stand by a calm pond with a wooden fence in front of them.	Three ducks stand by pond.	**Success:** Correct identification of objects and actions.
	A red and white vintage plane on display in a museum.	Spaceship preparing to launch.	**Failure:** Incorrect object recognition.

The following table compares the generated descriptions of four sample images with ground truth annotations to evaluate the performance of an image captioning model. Successful examples include correctly identifying "three ducks on a peaceful pond" and "a white dog clutching a purple frisbee on grass." These cases demonstrate the model's ability to recognize objects and actions in straightforward scenarios. However, the model exhibits notable failures, such as mistaking a gold and black motorcycle for "a car parked on a road" and, in row 4, misidentifying a red and white vintage plane as "a spaceship preparing to launch." These errors highlight the model's difficulty in accurately identifying complex objects or understanding the context of the scene. This analysis provides valuable insights into the model's strengths in simple situations and its limitations when faced with more intricate or ambiguous visuals, offering guidance for improving the model's training and recognition capabilities.

C. Comparison with Other State-of-the-art Methods:

A comprehensive generalisation analysis highlights the performance of the proposed model outside of the training set by assessing its capacity to produce image descriptions over a wide range of visual domains and datasets. A comparison study of image description generation models using the MSCOCO dataset is presented in Table X, which evaluates model performance using metrics such as BLEU, METEOR, CIDEr and Rouge-L.

TABLE X
COMPARATIVE ANALYSIS OF IMAGE DESCRIPTION GENERATION MODELS ON MSCOCO DATASET

Model	BLEU	METEOR	CIDEr	Rouge-L
Topic-based multi-channel attention (TMA) model [21]	0.658	-	0.800	0.534
Transformer based local graph semantic attention (TLGSA) [22]	0.724	-	1.003	0.534
Dynamic-balanced double-attention [23]	0.741	0.254	1.107	0.537
Meshed Transformer [7]	0.816	0.294	1.293	0.592
Global Enhanced Transformer [24]	0.816	0.284	1.301	0.591
Multimodal Transformer [8]	0.817	0.294	1.30	0.596
S^2 Transformer [12]	0.811	0.296	1.335	0.591
PMA-Net [15]	0.847	0.305	1.414	0.613
HAAV [16]	0.810	0.302	1.415	-
SPT Transformer [18]	0.812	0.296	1.344	0.592
Geometry attention transformer [25]	0.811	0.384	1.27	0.591
Vision-enhanced and Consensus-aware Transformer [26]	0.822	0.296	1.345	0.596
X-transformer + Faster RCNN [27]	0.821	0.296	1.334	0.598
Local-global guidance for transformer [28]	0.861	0.392	1.329	0.651
SAMT [11]	0.774	0.284	1.205	0.572
Tri-FusionNet (Proposed)	**0.893**	**0.780**	**1.880**	**0.689**

The performance of different models on the MSCOCO dataset indicates strong progress in image description generation. Models like Meshed Transformer [7], Global Enhanced Transformer [24], and Multimodal Transformer [8] show strong overall performance in terms of high scores obtained in BLEU, METEOR, CIDEr, and Rouge-L metrics. In contrast, models like Topic-based multi-channel attention (TMA) [21], Transformer-based local graph semantic attention (TLGSA) [22], and Dynamic-balanced double-attention [23] have relatively weaker performance, especially in terms of BLEU and CIDEr scores. Geometry Attention Transformer [25] and S^2 Transformer [12] obtain the best CIDEr scores, while Local-global guidance for transformer [28] reaches the best Rouge-L score of 0.651. Among the best-performing models, PMA-Net [15] and HAAV [16] obtain CIDEr scores higher than 1.4. In addition, PMA-Net obtains the best BLEU score of 0.847 among all the models. However, Tri-FusionNet breaks all other records as the new baseline, obtaining state-of-the-art performance scores for both BLEU 0.893, METEOR 0.780, CIDEr 1.880, and also Rouge-L with a 0.689 score in all the tested metrics, which highlights its capacity in producing better descriptions with semantic accuracy of an image for all the existing models.

To further validate the performance of the proposed Tri-FusionNet model, we evaluated it on the online MSCOCO test server, which is widely used as a benchmark for image description generation. The comparative results are presented in Table XI, highlighting the superior performance of Tri-

FusionNet in all the metrics, demonstrating its efficiency in generating contextually rich and accurate image descriptions.

TABLE XI
COMPARATIVE ANALYSIS OF IMAGE DESCRIPTION GENERATION MODELS ON ONLINE MSCOCO TEST SERVER

Model	BLEU	METEOR	Rouge-L	CIDEr
NIC [19]	0.714	0.302	0.521	0.945
m-RNN [29]	0.753	0.301	0.593	0.926
ReviewNet [30]	0.810	0.301	0.609	0.967
SCN [31]	0.828	0.309	0.619	1.013
Adaptive [32]	0.834	0.311	0.628	1.051
Att2all [33]	0.859	0.312	0.635	1.157
GateCap [34]	0.863	0.319	0.644	1.190
LSTM-A [35]	0.862	0.312	0.635	1.170
Up-Down [36]	0.877	0.322	0.648	1.192
RFNet [37]	0.877	0.327	0.657	1.240
GCN-LSTM [38]	-	0.330	0.660	1.259
SGAE [39]	0.882	0.327	0.661	1.252
AoANet [40]	0.880	0.338	0.667	1.282
Tri-FusionNet (Proposed)	**0.885**	**0.750**	**0.678**	**1.580**

Table XII compares various image description generation models using the Flickr30k dataset. The analysis includes metrics for evaluating the models' performance, such as BLEU, METEOR, CIDEr, and Rouge-L.

TABLE XII
COMPARATIVE ANALYSIS OF IMAGE DESCRIPTION GENERATION MODELS ON FLICKR30K DATASETS

Model	BLEU	METEOR	CIDEr	Rouge-L
Topic-based multi-channel attention (TMA) model [21]	0.650	-	0.334	0.436
Transformer based local graph semantic attention (TLGSA) [22]	0.643	-	0.450	0.489
Dynamic-balanced double-attention [23]	0.678	0.209	0.517	0.500
HAAV [16]	0.743	0.251	0.856	-
Multimodal Transformer [8]	0.744	0.236	-	-
Local-global guidance for transformer [28]	0.758	0.263	0.708	0.560
X-transformer + Faster RCNN [27]	0.753	0.253	0.707	0.543
Tri-FusionNet (Proposed)	**0.767**	**0.478**	**1.679**	**0.567**

Models like Transformer-based local graph semantic attention (TLGSA) [22], Topic-based multi-channel attention (TMA) [21], and Dynamic-balanced double-attention [23] show lower performance, particularly in BLEU and CIDEr, indicating limitations in generating high-quality descriptions. While the Multimodal Transformer [8] performs well in BLEU and METEOR, it lacks comprehensive metric coverage. Local-global guidance for Transformer [28] and X-transformer + Faster RCNN [27] demonstrate strong BLEU and CIDEr scores but fall slightly behind in Rouge-L. HAAV [16] achieves notable performance, especially with a CIDEr score of 0.856. However, the proposed Tri-FusionNet outperforms all models, achieving the highest scores across all metrics: 0.767 for BLEU, 0.478 for METEOR, 1.679 for CIDEr, and 0.567 for Rouge-L, establishing it as the most effective model for generating accurate and contextually rich descriptions on the Flickr30k dataset.

Table XIII presents a comparative analysis of various image description generation models on the Flickr8k dataset. It offers evaluation metrics for evaluating how well various models perform, including BLEU, METEOR, CIDEr and Rouge-L.

Models like TLGSA based on transformer [22], Vision encoder-decoder [41], Topic-based multi-channel attention [21], and Optimal transformers with beam search [42] have performance relatively lower and are bad at BLEU and CIDEr score, due to the lesser ability for producing high quality and relevant descriptions. Specifically, even though SAMT [11] has scores of BLEU and METEOR comparatively better values, it also lacks other competitive values of CIDEr and Rouge-L. On the other hand, proposed Tri-FusionNet obtains excellent results with setting new state-of-the-art for all metrics: BLEU-0.784, METEOR-0.389, CIDEr-1.381, and Rouge-L - 0.654. Such results emphasize that the proposed Tri-FusionNet model is more likely to produce exceptional, meaningful, and expressive image descriptions compared to existing models for Flickr8k.

TABLE XIII
COMPARATIVE ANALYSIS OF IMAGE DESCRIPTION GENERATION MODELS ON FLICKR8K DATASET

Model	BLEU	METEOR	CIDEr	Rouge-L
Topic-based multi-channel attention (TMA) model [21]	0.630	-	0.472	0.465
Transformer based local graph semantic attention (TLGSA) [22]	0.659	-	0.471	0.565
Vision encoder decoder [41]	0.395	0.177	0.380	0.297
Optimal transformers with Beam Search [42]	0.634	0.1987	0.520	-
SAMT [11]	0.682	0.212	-	0.448
Tri-FusionNet (Proposed)	**0.784**	**0.389**	**1.381**	**0.654**

V. CONCLUSION AND FUTURE DIRECTION

In this paper, a new model, Tri-FusionNet, for generating image descriptions that combine the CLIP transformer, RoBERTa, and the Vision Transformer with dual-attention processes, was presented. The proposed model outperforms state-of-the-art models as a result of extensive trials on the MSCOCO, Flickr30k, and Flickr8k datasets. It achieved notable gains across important evaluation criteria, such as BLEU, METEOR, CIDEr, and ROUGE. The model is successful because it can capture both local and global image data, use the CLIP transformer to effectively align textual and visual modalities, and employ RoBERTa for improved language understanding. The suggested model has useful applications in real-time image captioning systems, including autonomous car systems for scene detection, assistive technologies for the blind, and content management systems for automatic image tagging. Deploying the model still presents difficulties, though, such as managing edge devices' demanding processing requirements, ensuring the system is resilient to threats and noisy inputs, and resolving ethical challenges like bias in generated captions. Furthermore, the model's performance may be impacted by the unpredictability introduced by real-world settings, such as occlusions, dim lighting, computational cost, and other social circumstances. To enable more extensive real-world applications, future research will concentrate on improving fine-tuning procedures, tackling deployment issues, and extending the model's capabilities through sophisticated multimodal fusion techniques.

Supplementary Material The supplementary material contains additional experimental details, architectures and algorithm of the proposed work. The file `supplementary.txt` is available alongside this manuscript in the submission system.

KEYWORDS

urban greening, climate adaptation, UN SDGs, green infrastructure, strategic urban planning

Highlights

- Urban greening can improve air quality, health, biodiversity, and climate resilience.
- Collaboration among communities and stakeholders is key to urban greening success.
- Community engagement ensures acceptance and long-term success of green infrastructure.
- Barriers like funding, regulations, and resistance impede green infrastructure projects.
- Accurate data and planning are essential for maximizing green infrastructure benefits.

Urban greening plays a crucial role in enhancing climate resilience, environmental quality, public health, and societal wellbeing. Policy makers at all levels are increasingly embracing greening and other nature-based solutions; however, successful implementation of these approaches requires a multidisciplinary strategy involving collaboration, community engagement, and adaptive interventions. This paper synthesizes key insights from an expert panel, comprising representatives of government agencies, research institutions, private sector, and local authorities, forming an international panel of experts, convened by the RECLAIM Network Plus (https://www.reclaim-network.org). Funded by the United Kingdom Research and Innovation (UKRI), this network project brings together over 650 members from 40 plus countries. It provides national leadership in urban greening, serving as a "one-stop-shop" for towns and cities to access green and blue infrastructure support, resources, and peer connections. The paper highlights grand challenges, priorities, successful case studies and opportunities in urban greening initiatives. The importance of strategic planning is also addressed, together with technological advancements and access to suitable data for maximizing the impact of green infrastructure as well as innovative funding models, such as corporate social responsibility and green finance. This work highlights the importance of an integrated, inclusive, and forward-thinking approach to urban greening for more resilient, sustainable, and equitable cities. Further, it emphasizes the need for cross-sector collaboration among local authorities, researchers, and businesses, as well as community involvement in successful planning for both short- and long-term outcomes. Ultimately, urban greening strategies must be informed by future climate scenarios while prioritizing equity and social justice to ensure adaptation options benefitting all communities.

1 The role of urban greening in climate resilience and liveability

Urban greening, encompassing nature-based solutions (NbS) and green-blue-gray infrastructure (GBGI), has emerged as a vital strategy for building climate-resilient and livable cities, addressing biodiversity loss, and supporting Sustainable Development Goals (SDGs) (Wang et al., 2023; Kumar, 2021; Jones et al., 2022a). As urban populations continue to grow and climate change intensifies, urban communities worldwide are facing environmental challenges, including extreme heat, increased flooding, deteriorating air quality, noise pollution and biodiversity loss. Effective integration of urban greening—incorporating street trees, parks, urban forests, wetlands, green roofs and green walls, and permeable surfaces (Kumar et al., 2024a,b)—contributes to enhancing environmental sustainability and public wellbeing (Astell-Burt and Feng, 2019). One of the most critical roles of urban greening is its contribution to climate resilience. Cities experience the urban heat island (UHI) effect, where built-up areas absorb and retain heat, leading to higher temperatures compared to surrounding rural areas (Oke, 1982; Yang et al., 2024). Urban greening helps mitigate this phenomenon by providing shade, cooling through evapotranspiration, and reducing heat absorption. Green spaces, such as parks, tree-lined streets, and gardens, can significantly lower local temperatures, making cities more comfortable spaces, while also reducing energy demand and mitigating heat emissions from cooling systems (Yang et al., 2024; Kumar et al., 2024b). Unlike gray infrastructure, NbS do not further exacerbate the root causes of climate change through reliance on emissions-intensive products such as concrete. The cooling effect of vegetation becomes even more crucial during heatwaves, which are becoming more frequent due to climate change. By incorporating greening, cities can help mitigate heat-related illnesses, reduce strain on healthcare systems, and help prevent heat-induced impacts on worker productivity (Jones et al., 2024). Beyond temperature regulation, integrating blue (water bodies) and green (vegetation) elements with gray infrastructure enables cities to develop more holistic and sustainable flood management strategies compared to the traditional drainage systems. While impervious surfaces in cities prevent rainwater from naturally soaking into the ground, leading to increased runoff and urban flooding (Redfern et al., 2016), GBGI and Sustainable Drainage Systems (SuDS) offer effective solutions (Vesuviano et al., 2025). By mimicking natural water cycles, GBGI and SuDS not only reduce flood risk but also improve water quality, replenish groundwater reserves, and prevent polluted stormwater overflow that can contaminate natural waterways and compromise vital ecosystems (Monachese et al., 2025). GBGI and SuDS also serve functional purposes besides significantly enhancing the aesthetic quality of urban environments. The presence of green spaces and water features has been demonstrated to contribute to recreational opportunities, aesthetic enjoyment, and the overall wellbeing of urban residents (Johnson and Geisendorf, 2022). Furthermore, these systems can serve as educational opportunities concerning water management and environmental stewardship (Well and Ludwig, 2022). Finally, integrating NbS, such as reforestation for slope stabilization, into urban planning enhances climate resilience by mitigating landslide risks. Integrating NbS into conventional risk reduction infrastructure can significantly enhance public wellbeing and promote long-term sustainability (Alcántara-Ayala, 2025; Devanand et al., 2023).

Urban greening offers significant advantages in improving air quality (Abhijith et al., 2017; Islam A. et al., 2024; Kaur et al., 2025). Trees and vegetation function as natural air purifiers, efficiently capturing airborne pollutants such as particulate matter (Kumar et al., 2024a). In heavily polluted urban areas, a well-designed urban greening strategy can lead to significant health benefits, including reduced respiratory illnesses, improved public health and lower healthcare costs (Mueller et al., 2022; Jones et al., 2019; Nemitz et al., 2020). Beyond improving local air quality, urban greening

reduces atmospheric concentrations of carbon dioxide through carbon sequestration (Page et al., 2021). However, some challenges remain in balancing NbS implementation to avoid hindering the vertical dispersion of air pollution emitted at ground level, such as the case of avenue planted trees in deep street canyons (Buccolieri et al., 2009; Abhijith et al., 2017; Kumar et al., 2019a).

Urban greening initiatives contribute to biodiversity conservation while concurrently enhancing environmental stewardship among urban populations (Roslund et al., 2021; Prescott et al., 2016). The integration of fragmented urban green spaces like urban forests, wetlands, and community gardens provides crucial habitats for diverse wildlife, promotes ecological balance, and ensures essential services such as pollination and pest control (Bowler et al., 2025; Dainese et al., 2019). While the Intergovernmental Panel on Climate Change recommends 30%–50% natural reserves globally to facilitate the natural recovery of terrestrial and marine ecosystems (IPCC, 2023), urban greening could partially contribute to this aim by connecting fragmented spaces in urban areas, thus supporting broader conservation efforts.

Beyond its environmental benefits, urban greening plays a vital role in improving social wellbeing (Kumar et al., 2019b). Green spaces provide residents with accessible opportunities for recreation, relaxation, and exercise in nature, leading to improved physical and mental health. Access to these areas has been shown to reduce stress, anxiety, and depression (Cohen-Cline et al., 2015), while encouraging physical activity and social interaction (Pretty and Barton, 2020; Pretty et al., 2003). Urban parks, community gardens, and tree-lined streets foster social cohesion by providing gathering spaces for diverse communities. Specifically, in high-density urban areas, small interventions such as green walls, green gates or pocket parks can substantially improve residents' quality of life (Abhijith et al., 2025; Kumar et al., 2024a). Despite the many beneficial aspects of NbS, several challenges remain in their implementation, as discussed in Sections 2–4.

2 Evolution of urban greening: past, present, and future

2.1 The past: an evolution of urban greening

Urban development has undergone significant transformations over the centuries, driven by industrialization, technological advancements, and changing social and economic conditions, among other factors. In Europe, the Roman concept of "*rus in urbe*," or countryside created within a building or city, was an early integration of natural landscapes into urban environments. In South Asia, the ancient towns in the Indus Valley in the Indian subcontinent exemplify early urban planning incorporating nature (Gregory, 2008). This includes traditional water harvesting structures and sustainable water management (Sharma, 2006). Mesopotamian and Persian civilizations notably exemplified by Persian gardens from sixth century BC Achaemenid dynasty, integrated green spaces into their landscapes for aesthetic, climatic and spiritual purposes, often representing paradise (UNESCO World Heritage Centre, 2025). Early advancements in urban sanitation infrastructure were excavated at Mohenjo-daro (2600–1800 BC) in present-day Pakistan (Jansen, 1985). Pre-industrial green spaces in Europe were often tied to aristocratic estates, religious institutions, or communal lands, such as Paris' Luxembourg Gardens established in the early seventeenth century and London's 142-hectare Hyde Park, established in the sixteenth century, which was initially developed for private hunting purposes (Self, 2014) before it was opened to the public in the following century (Porter, 1995). The gardens of Schönbrunn Palace is another example of an early urban green space, dating back to the fourteenth century, originally planned as a hunting ground, and later opened for public usage in the eighteenth century (Schönbrunn, 2025).

Rapid urbanization during the Industrial Revolution led to the widespread replacement of natural landscapes with gray infrastructure: roads, buildings, and engineered drainage systems. While this contributed to economic development, it also resulted in significant environmental challenges, including air and water pollution, UHI, and the loss of green spaces. Some cities developed public parks as an attempt to address overcrowding and poor living conditions, including New York's Central Park and Sefton Park in Liverpool. There are also many historic examples of the recognition of the benefits of green pockets for the health and wellbeing of the local community, in smaller cities and towns. One such example is the 4 acres of St Thomas Leisure Ground in Exeter, opened on 30th March 1891 for Queen Victoria's Jubilee, at the instigation of the Local Board of Health (Devon Gardens Trust, 2025).

In the early twentieth century, the Garden City movement advocated for the integration of green elements within planned urban developments, such as green belts and parks (Howard, 1902). At the same time, many Western cities underwent a transition toward a car-centric urban development model as automobile ownership rates increased. In the United States, car registrations tripled from 8 million to 26 million between 1920 and 1930 (Gavanas, 2024). This resulted in urban sprawl, with many cities expanding their road networks significantly by the 1950s (Barrington-Leigh and Millard-Ball, 2015). Initiatives to rebalance rapid urbanization with ecological stewardship followed (Mumford, 1938). The 1960s and 1970s brought a renewed focus on urban greening, driven by environmental concerns, the degradation of urban environments and legislative pressure, including the establishment in the USA of the U.S. Environmental Protection Agency in 1970 and the passage of the Clean Air Act and Clean Water Act. A significant shift in urban planning philosophy manifested advocating for the integration of natural systems and a closer collaboration between urban designers and scientists (McHarg, 1969). The eco-urbanism movement of the 1980s put a renewed focus on nature as greening, and the 1990s to early 2000s brought growing concern over human and urban pressures on ecosystems, with the emerging concepts of green infrastructure and ecosystem services (Di Marino et al., 2023).

Today, over three-quarters of global cities have adopted urban greening policies, integrating sustainability with urban growth (Khamdamov and Usmanov, 2024). As cities worldwide grapple with the challenges of climate change, pollution, and declining biodiversity, urban greening has emerged as a key strategy for building urban resilience and enhancing liveability. Studies show

that greater green space availability is associated with better health outcomes such as lower mortality rates and improved mental health and sleep quality (Galitskaya et al., 2024). A green coverage between 10% and 20% has shown measurable health advantages (Nieuwenhuijsen et al., 2017). Neighborhoods maintaining at least 30% tree canopy coverage demonstrate significant improvements in mental, physical, and social health, as emphasized by the "3–30–300 rule" (Konijnendijk, 2023). The 3–30–300 rule offers clear urban greening guidelines, setting three minimum standards: (i) every citizen should be able to see at least three trees from their home, (ii) their neighborhood should have 30% tree canopy cover; and (iii) they should not live more than 300 m away from the nearest public park or green space.

2.2 The present: a new understanding of urban greening

In recent decades, urban greening has gained significant recognition for its importance for people's wellbeing, improving quality of life, and building sustainable cities (Di Marino et al., 2023). As topics such as climate resilience, environmental justice, and community engagement have become more prominent within built environment discourse, urban greening has emerged as a core element of sustainable and resilient urban planning. Urban planners and policymakers have embraced this concept, incorporating GBGI and NbS into their strategies, with GBGI exemplifying a multifunctional approach by integrating vegetation, water bodies, and built environment elements to create sustainable urban spaces.

Today, over 130 countries have incorporated NbS actions in their nationally determined SDG contributions, complementing technology-based solutions, including in urban contexts (IUCN, 2016). In relation to this, the International Union for Conservation of Nature and Natural Resources's Global Standard for NbS consolidates ecosystem-based approaches aligning urban greening strategies with SDGs (IUCN, 2020).

Various urban greening initiatives worldwide are aiming to address climate risks, SDGs, improving public health, and enhancing ecological sustainability. Examples are presented in chronological order of references:

- **Copenhagen's Cloudburst Management Plan**: A city-wide strategy designed to manage extreme rainfall events through the use of green roofs, permeable surfaces, and green corridors, which also enhances urban aesthetics and air quality (The City of Copenhagen, 2012).
- **UK's 25-Year Environment Plan, A Green Future**: This plan promotes biodiversity net gain (BNG) and SuDS to integrate water-sensitive urban design into city landscapes [Department for Environment, Food and Rural Affairs (DEFRA), 2018].
- **Indian Government's Sustainable Development Goals and Urban Local Bodies**: This guidance proposes key indices to promote and monitor sustainable urban stormwater management practices, aiming to enhance flood resilience and ensure effective drainage solutions in new developments (Government of India, 2018).
- **Welsh Government's National Standards for SuDS (2018)**: These standards require new developments of more than one dwelling or where an area covered by construction work equals or exceeds 100 m^2 to include SuDS features that comply with national standards (Welsh Government, 2018).
- **Natural England's Green Infrastructure Framework (2023)**: This tool highlights the institutional push for increasing green cover in urban residential areas, with an ambitious target of achieving 40% green cover in cities (Natural England, 2023).
- **South Australia's Long-Term Vision**: The State Government has created a vision for "a resilient and liveable Adelaide for all: cooler, leafier, and more biodiverse," setting priority actions for greener infill development and improving greening equity (Government of South Australia, 2024).
- **Singapore's City in Nature Plan**: This initiative aims to increase urban greening while promoting biodiversity conservation (Government of Singapore, 2025).
- **UKRI's Tomorrow's Engineering Research Challenges**: This strategic initiative by the umbrella UK science funding body prioritizes green materials and environmentally conscious engineering practices, aiming for engineering advancements that positively contribute to the planet (EPSRC, 2025).

Collectively, such initiatives highlight a fundamental shift in urban planning, where green spaces are not seen as mere decorative elements but as crucial infrastructure for resilience and wellbeing. Cities worldwide are adopting innovative solutions to address urban challenges, including the integration of green roofs and vertical gardens, in the context of urban resilience and adaptation planning (Saqib et al., 2024).

2.3 Future directions: technology-driven and inclusive urban greening

Urban greening is expected to become increasingly data-driven, leveraging technologies such as Geographic Information Systems (GIS), artificial intelligence (AI), and remote sensing to optimize the design and management of green infrastructure (Stessens et al., 2021; Rahmati, 2024). These tools will enable built environment professionals (e.g., landscape architects, developers, city planners) to more effectively assess environmental needs, target adaptation options, model the impact of greening interventions, and monitor the effectiveness of urban green spaces in a holistic way. Future urban greening will integrate Internet of Things (IoT), AI, and real-time analytics for smart water management, optimizing flow, and drainage efficiency (Langenheim et al., 2022). Digital twin technology and AI-driven planning will enable real-time simulations and optimized GBGI and SuDS (Dembski et al., 2020; Xu et al., 2024). Advanced permeable pavements and bioengineered materials will enhance infiltration and pollutant filtration, leveraging nanotechnology for contaminant absorption (Verma et al., 2024). In addition to technologically driven future approaches, there is also an increasing emphasis on citizen/community engagement in urban planning processes, however addressing structural barriers and ensuring meaningful participation remain ongoing challenges (Sondou et al., 2025).

Green finance, corporate sustainability and decision-making processes that are informed by a comprehensive economic valuation of the net benefits of urban greening (including its environmental, social, and health benefits), are also expected to play an important role in shaping the next phase of urban greening (Williams et al., 2025; Tefera et al., 2023). Policies promoting investment in green bonds, environmental, social, and governance (ESG) frameworks, and public–private partnerships are expected to accelerate large-scale greening projects. Additionally, smaller-scale community-led urban greening initiatives will be vital to ensuring that cities remain inclusive, mitigating the risk of "green gentrification," where the introduction of urban green spaces inadvertently displaces low-income residents due to rising property values.

Finally, as climate change intensifies, urban greening strategies will need to be resilient and adaptive. Cities will need to focus on climate-resilient landscaping considering their micro-climatic conditions, for example, selecting appropriate drought-resistant plant species, water-sensitive urban designs, and ecological corridors that promote biodiversity. Urban agriculture, vertical gardens or farms, and rooftop farms are also expected to gain prominence, addressing both food security and environmental sustainability in growing urban populations (Drottberger et al., 2023).

3 Best practice in urban greening

Urban areas worldwide have implemented innovative greening projects that serve as effective models for sustainable development. Inspiring case studies showcasing tangible benefits and strategies have emerged from urban greening initiatives, with platforms like the Urban Nature Atlas compiling best practices globally, as does the NbS Initiative's approach for rural areas (Urban Nature Atlas, 2025; Nature-based Solutions Initiative, 2025; Debele et al., 2023). Analyzing these case studies is crucial for understanding effective strategies, benefits, and lessons learned in urban greening, informing future urban planning and sustainability efforts.

3.1 Selected case studies

The following curated selection of 10 case studies, presented in alphabetical order of the name of city, has been drawn from authors' recommendations and discussions at the RECLAIM Network Plus Conference (http://www.reclaim-network.org):

1. Adelaide, South Australia has unveiled a street tree planting plan to increase canopy cover from 33% to 40% by 2035, complemented by green infrastructure initiatives like water-sensitive urban design (City of Adelaide., 2024). Similarly, Melbourne, Victoria, has implemented the Urban Forest Strategy 2021–2032, aiming for a "resilient, healthy, and diverse" urban environment. This strategy targets increasing tree canopy cover from 22% to 40% by 2040, while also focusing on urban forest diversity, vegetation health, soil moisture, water quality, and biodiversity enhancement (City of Melbourne., 2021).
2. Brazil's Ministry of the Environment initiated the Cidades+Verdes Program (França and Ramos de Almeida, 2021) to enhance urban green areas, aiming to improve quality of life for 85% of Brazilians living in cities. The Urban Environmental Registry (CAU) was created to map and share information about these areas, allowing municipalities to register urban green spaces and citizens to access and evaluate them. Urban greening initiatives in Brazil largely focus on rain gardens to address frequent storms and flooding (ICLEI, 2025). Examples include: (1) Belo Horizonte, Minas Gerais, implemented three rain gardens to improve urban drainage; (2) Niterói, Rio de Janeiro: The Parque Orla Piratininga Alfredo Sirkis project, a 680,000 m^2 linear park along the P iratininga Lagoon, featuring 35,290 m^2 of filtering gardens to protect and restore local ecosystems; (3) São Paulo, São Paulo, installed rain gardens across the city to mitigate flooding during the rainy summer season; and (4) Curitiba, Paraná, launched the city's first Urban Farm in 2020, dedicating 4,000 m^2 to organic food production, with plans for an additional 11,000 m^2 unit. Other regions have also implemented green infrastructure, primarily for flood prevention. These efforts highlight Brazil's commitment to nature-based solutions, enhancing resilience and urban quality of life.
3. Cardiff, Wales, United Kingdom has launched an ambitious "*One Planet Strategy*" (Cardiff Council, 2020). This 10-year afforestation programme aims to support Cardiff to be a carbon neutral city by 2030, increasing green cover and promoting community engagement in sustainable development. Since its inception, the programme has planted over 82,000 trees across the city, emphasizing local community participation and encouraging residents to take ownership of green spaces. Cardiff Council, with Welsh Government funding, is developing flood risk reduction plans for Whitchurch Brook, a historically heavily modified local watercourse. This project combines green infrastructure with SuDS techniques to control surface water flow while improving public space areas. The project integrates green infrastructure and SuDS to manage surface water and enhance public spaces. Design and planning are being led by a sustainable development consultancy, with community input shaping the solutions (Cardiff News Room, 2023). This participatory approach has not only strengthened environmental stewardship but also fostered social cohesion, demonstrating that urban greening can be both an ecological and a social asset.
4. Copenhagen, Denmark has implemented green roof policies to improve building insulation, manage stormwater, and enhance urban biodiversity (City of Copenhagen., 2010; Ansel and Appl, 2025). While green roofs reduce buildings' energy consumption, ground-level greening offers greater social and environmental benefits in dense urban areas. The city now emphasizes street-level greenery like pocket parks, green walls, and community gardens. Copenhagen's Østerbro "Climate Quarter" exemplifies this approach, featuring urban greening projects that mitigate flood risks and improve public spaces, such as Sankt Kjeld's Square and Taasinge Plads (Larsen, 2018).
5. In Exeter, England, United Kingdom, the campus of the UK Met Office headquarters has earned a Biodiversity

Benchmark certificate (The Wildlife Trusts, 2025), highlighting its commitment to maintaining a rich ecological zone amid a developed area (Met Office, 2021, 2025a). The project includes pollinator-friendly meadows, water-efficient landscaping, and protected habitats for local wildlife. This initiative exemplifies how large organizations can incorporate biodiversity conservation into their urban footprint, serving as a model for businesses looking to integrate sustainability into their operations.

6. The Zero Carbon Initiative in Guildford, England, United Kingdom combines urban tree planting with SuDS to mitigate urban heat stress and manage stormwater (Zero Carbon Guildford, 2025) as well as installation of green screens and school living gate (Abhijith et al., 2025). The combination of these strategies exemplifies a holistic approach to urban greening, where multiple ecological and infrastructural benefits can be achieved simultaneously.
7. Nanjing, Jiangsu Province, China is home to the Vertical Forest project, an innovative urban afforestation initiative integrating nature-based solutions into architecture. This project features two towers in the Pukou District, standing at 200 and 108 m, with facades adorned by alternating balconies and greenery. Housing over 800 trees and 2,500 shrubs across 4,500 m^2, the design incorporates 27 native species. This approach enhances biodiversity, improves air quality, reduces surface temperatures, and regulates humidity, ultimately enhancing urban livability (Boeri Architetti, 2025).
8. New York City's MillionTreesNYC program, a landmark public–private partnership, aimed to plant one million trees across the city, focusing on underserved neighborhoods lacking green spaces (Fisher et al., 2014). Exceeding its goal ahead of schedule, the project demonstrated effective collaboration among government agencies, non-profits, and local communities. The success of MillionTreesNYC highlights the importance of long-term maintenance and community engagement in urban greening projects.
9. Singapore, a global leader in urban greening, has pioneered nature integration into its cityscape through the "City in Nature" plan. This initiative builds on decades of green infrastructure development, expanding tree-lined streets, rooftop gardens, and vertical greenery on high-rises (Government of Singapore, 2025). The city's green corridors connect parks and natural reserves, fostering wildlife and providing accessible green spaces for residents. Driven by strong government policies, technological innovation, and public–private collaboration, Singapore's approach exemplifies how urban greening can be seamlessly incorporated into high-density environments, balancing economic growth with ecological sustainability.
10. The Trees for Homes (TfH) programme in South Africa is an urban greening initiative promoting biodiversity enhancement and climate adaptation through household tree planting. The initiative was established around 1992 as a flagship urban greening initiative by the organization Food and Trees for Africa. In the Zandspruit neighborhood, the TfH project incorporated key sustainable livelihood principles, including being people-centered, responsive and participatory, multi-level, conducted in partnership, sustainable and dynamic. However, it was also noted that a key barrier to success in vulnerable communities was instability of tenure (Sachikonye et al., 2016). The TfH initiative has recently partnered with Johannesburg Inner City Partnership to train local environmental champions to act as Community Educators, who receive specialist training in climate change, tree care, environmental ethics, and community engagement.

3.2 Learning from successful urban greening projects

The 10 case studies of successful projects offer valuable lessons for enhancing urban living through NbS, highlighting the importance of active community involvement, integrated urban design, and long-term sustainability in creating climate-resilient urban spaces. Innovative approaches, including transforming existing buildings into green spaces, further demonstrate the potential for integrating nature into densely built environments. These successful strategies provide insights for cities worldwide to develop context-specific, innovative solutions for more climate-resilient urban spaces.

The longevity of well-designed green spaces is exemplified by the UK's urban parks, such as St. Thomas People's Park in Exeter, established in 1891 (Exeter Memories, 2009). Originally created as a safe space for children and vulnerable people, the park continues to serve the local community over a century later, underscoring the importance of sustainable design in GBGI projects.

Maximizing the public health benefits of GBGI projects requires effective cross-sector collaboration. In Surrey, efforts to integrate public health expertise into environmental initiatives have shown promise, with general practitioners engaging in discussions about air pollution and climate change (Zero Carbon Guildford, 2025). However, these efforts often remain isolated highlighting the need for greater coordination to address overarching priorities such as health inequalities and community empowerment.

To enhance GBGI project effectiveness, public health practitioners should be involved in co-creation and planning stages, while challenges persist, including limited financial and human resources. Research from Cardiff Council and Vale University Health Board area has revealed that air pollution disproportionately affects poorer areas (Cardiff Council, 2025), emphasizing the need to align GBGI projects with public health priorities. Overcoming these barriers requires a coordinated approach that integrates public health as a primary driver of greening initiatives, rather than a secondary co-benefit, ensuring that urban planning prioritizes both environmental and health outcomes.

4 Key challenges and strategic solutions for implementing urban greening

Urban greening initiatives, despite their well-documented benefits, face numerous challenges including financial and

regulatory constraints, space limitations, impacts on the vertical dispersion of air pollution, maintenance issues, year-round effectiveness limitations due to climate variations and plant species types, lack of interdisciplinary collaboration, and resistance to innovation within established structures and processes (Grunewald et al., 2021; Haaland and van den Bosch, 2015). Overcoming these obstacles require supportive policies, innovative financing, technological advancements, and inclusive community engagement. Some of the key challenges and strategic solutions (Figure 1) are presented in subsequent sub-sections.

4.1 Financial constraints, sustainable funding, and economic value

Urban greening strategies, such as GBGI and NbS offer long-term economic benefits such as reduced healthcare costs, energy savings, and improved property values. However, high upfront costs for land acquisition, infrastructure development, maintenance and misconceptions deter both public and private investment (Riedman et al., 2022; Rowley et al., 2022). Municipal budgets are often stretched, and many greening initiatives rely on single-source or short-term funding, limiting their long-term viability (C40 Cities Climate Leadership Group, 2022).

Government budgets and grants typically cover only capital costs for urban greening projects, excluding or providing limited-term funding for ongoing maintenance and operational expenses only. Consequently, many projects face neglect due to insufficient resources for routine upkeep, resulting in degraded green spaces that fail to achieve their intended outcomes (Albro, 2020).

Establishing sustainable funding mechanisms, such as public-private partnerships, green bonds, and community-led stewardship programmes, can help address the challenge of maintaining urban greening over time (Nash et al., 2021). Importantly, green and surface-based climate adaptations are likely cheaper to implement than large traditional gray infrastructure projects like sewer expansions (Xu et al., 2021). To encourage continuing public investment, it is crucial to demonstrate the financial rewards of NbS, particularly in terms of climate change resilience for issues like flooding.

The health benefits associated with NbS provide another compelling argument for urban greening initiatives, especially when addressing air quality and heat stress. While general wellbeing improvements may be subjective, quantifying health costs related to these issues and assessing potential cost reductions through environmental improvements can justify financial investments in urban greening. Techniques to quantify the economic value of ecosystem services provided by urban green infrastructure (Mell et al., 2016; Jones et al., 2019; Fletcher et al., 2021) can position these solutions as cost-effective approaches to building climate resilience, while offering a dual benefit of improved public health and enhanced urban sustainability (Elmqvist et al., 2015).

Innovative financing mechanisms can provide solutions to these challenges. For example, green bonds, corporate ESG funding, crowdfunding, and public–private partnerships (PPPs) offer possible solutions to ensure long-term investment. Green bonds provide a structured financial tool for municipalities and businesses to raise capital for environmental projects, while corporate ESG funding encourages businesses to invest in urban greening as part of their sustainability commitments. In particular, PPPs can help to distribute financial risk while leveraging private sector efficiency and public sector oversight (Naumann et al., 2011). Crowdfunding platforms raise small contributions for urban greening projects like tree planting and parks. Social impact funds and blended finance combine public, private, and philanthropic investments for social and environmental returns, as seen in the World Bank's Urban Resilience Fund (World Bank, 2015). Green Real Estate Investment Trusts (REITs) finance eco-friendly real estate with integrated green spaces (Hin Ho et al., 2013). Utility-backed financing reinvests savings from reduced water, energy, or stormwater costs into green infrastructure. Additionally, cities can introduce incentives such as tax breaks or subsidies for developers who incorporate greening elements into their projects. Establishing dedicated municipal budgets for urban greening and integrating it into broader urban resilience plans ensures that green infrastructure is not treated as an afterthought but as a critical component of sustainable city planning. Finally, training programs for local communities in green space management and ecological restoration can create job opportunities while fostering a culture of environmental stewardship.

Economic valuation is crucial for effective urban greening and management, requiring comprehensive decision-support tools that accurately assess both benefits and costs. Such tools can guide policymakers in determining optimal quantities, locations, and species of plants, while balancing urban greening with infrastructure development. Current frameworks fall short in capturing the full spectrum of benefits, including improved air quality, carbon storage, water management, energy efficiency, and public health (Tefera et al., 2023). Consequently, sustainable greening costs often seem to outweigh benefits, stemming from inadequate long-term benefit accounting, limited predictive modeling capabilities, and insufficient reliable data. Addressing these challenges is essential for making informed urban greening decisions that create more sustainable and liveable cities.

4.2 Regulatory and governance challenges

Fragmented governance structures, unclear policies, and bureaucratic delays hinder the planning and execution of urban greening projects. Multiple agencies, including local governments, urban planners, environmental departments, and private developers, often operate independently, leading to siloed decision-making and slow project approvals. For example, policies such as the UK's Greening Policy, which aims for 40% green cover in urban residential areas (Natural England, 2023), may struggle with enforcement due to the limited capacity of local authorities. Similarly, at the local scale, initiatives like the Guildford Borough Council's goal to double Biodiversity Net Gain (BNG) from the standard 10% to 20% encounter implementation challenges, as biodiversity policies are established at the county level but enforced by district and borough councils. Similar issues arise with other planning commitments, such as affordable housing and green infrastructure, which are often approved but not

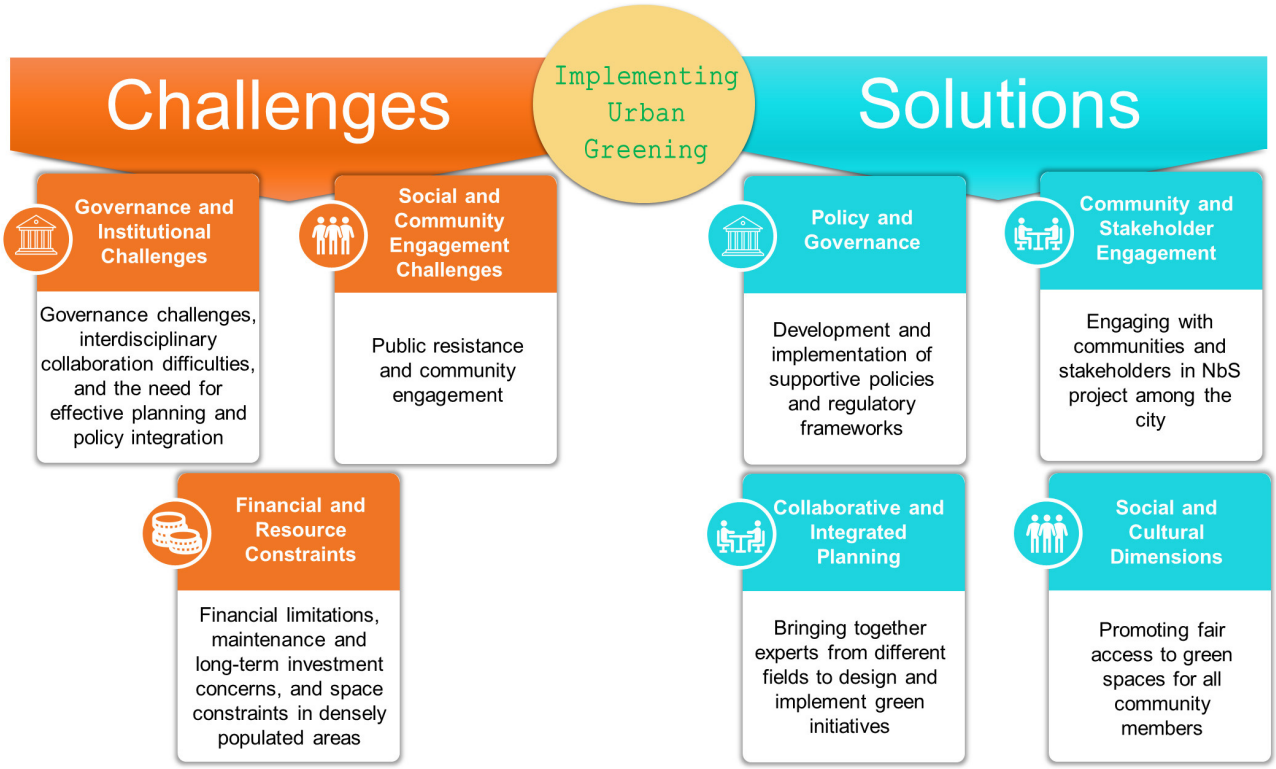

FIGURE 1
Challenges and solutions for implementing urban greening in cities. A summary of key barriers to urban greening, including limited land availability, high costs, regulatory constraints, and fragmented governance, alongside potential solutions such as multifunctional land use, streamlined policies, stakeholder collaboration, and innovative green infrastructure integration.

delivered due to cost and regulatory constraints. Addressing these challenges requires strategic planning, supportive policy frameworks, strengthening coordination among stakeholders, streamlining approval processes, and enhancing policy frameworks that actively promote urban greening.

Large city-scale urban greening should adopt agile management approaches that allow for flexibility and continuous improvement based on environmental and social feedback. Thus, urban greening should be embedded within broader climate adaptation plans to enhance resilience against environmental challenges such as heat waves, floods, and pollution. By aligning greening efforts with broader urban resilience strategies, cities can maximize the impact of adaptation options and ensure long-term sustainability. Governments should enforce green infrastructure requirements, such as BNG, green roofs, urban forests, and permeable surfaces in new developments. Strengthening urban greening legislation at national and local levels ensures that towns and cities can prioritize sustainable development over short-term economic gains.

Reducing bureaucratic delays and improving coordination between local governments, environmental agencies, and developers can accelerate project implementation. However, challenges in enforcing green infrastructure commitments can arise due to under-resourced planning departments. For instance, Surrey County Council, responsible for the local nature recovery strategy including a goal of planting 1.2 million trees, faced such difficulties in executing their green initiatives effectively (SCC, 2021).

4.3 Space constraints: balancing development and sustainability

Urban morphology plays a crucial role in determining the spatial extent and types of greening strategies that can be effectively implemented in cities (Owen et al., 2024; Kumar et al., 2024a,b). As urban areas expand, limited land availability forces green infrastructure to compete with development, making it crucial to plan ahead rather than retrofitting later. Existing urban structures, high costs, and regulatory barriers often constrain the implementation of green spaces, particularly when retrofitting developed areas. These challenges are compounded by the fact that stakeholders, such as shop owners and local communities, may have minimal influence over decisions regarding GBGI projects, especially in town centers.

To overcome these space constraints, urban planners must adopt innovative approaches and technologies. Integrating vertical gardens, rooftop gardens, green corridors, and pocket parks can maximize the use of limited space in developed areas. However, these solutions require strategic design to ensure they maximize ecological and social benefits without compromising urban functionality. Furthermore, urban planning strategies need to shift toward prioritizing multifunctional land use that balances development with environmental sustainability.

Effective implementation of GBGI solutions requires a holistic approach. This includes the ability to quantify the cost–benefit of green infrastructure compared to traditional gray solutions,

considering both immediate and long-term impacts. Moreover, it is essential to incorporate the "voice" and needs of local communities in GBGI interventions, whether in existing urban areas or new developments. By involving stakeholders in the decision-making process and adopting innovative planning strategies, cities can more effectively address space constraints and create sustainable, liveable urban environments that benefit both residents and the ecosystem.

Regarding green space distribution, community engagement is crucial (Riedman et al., 2022). It ensures that the focus extends beyond merely achieving percentage targets of green area coverage in a given region. Instead, it emphasizes placing appropriate solutions in strategic locations. The physical impacts of green spaces are spatially linked, diminishing with distance. Solely examining citywide percentages of green spaces may obscure the fact that benefits are not uniformly experienced across the entire urban landscape. Therefore, a targeted and communicative approach helps distribute benefits more effectively, particularly to disadvantaged communities.

4.4 Community engagement and public awareness campaigns

Community-driven initiatives, where residents are involved in the planning, maintenance, and stewardship of green spaces, can significantly enhance public support and project sustainability (Aslanoglu et al., 2025). Without proper engagement, communities may feel excluded from decision-making processes, leading to distrust and reluctance to support greening efforts. Additionally, in some cases residents and businesses may oppose greening projects due to misconceptions or factual concerns about land-use changes, maintenance responsibilities, and perceived inconveniences. These could be related with concerns about green gentrification, including increased property taxes, possibilities of fallen tree limbs, changes in neighborhood aesthetics and in traffic management; all these can potentially lead to opposition from local communities (Nobles and Moore, 2024; Meenar et al., 2022).

Effective community engagement involves transparent communication, co-creating projects with local residents, and addressing concerns about land use changes. Participatory decision-making processes, including town hall meetings, co-creation workshops, and citizen-led greening programs, empower communities to take ownership of green spaces. Public participation in tree planting, park maintenance, and urban gardening has been shown to foster a sense of ownership and encourages community stewardship of green spaces (e.g., Jennings et al., 2016; Bressane et al., 2024). This not only enhances public support for urban greening but also strengthens social cohesion and long-term stewardship of these spaces. The public can also actively participate in maintaining the green space, contributing to its design, and engaging in green space science outreach initiatives. Involving diverse stakeholders, such as local governments, non-profit organizations, and private developers, ensures that greening projects receive the necessary financial and logistical support while being aligned with broader urban development goals. The collaboration with communities in co-creating solutions is essential for reflecting the needs and preferences of local residents.

Educating citizens on the environmental and health benefits provided by urban greening features such as the green spaces further reinforce the importance of urban greening (Nguyen and Chidthaisong, 2024). Schools, workplaces, and community organizations can actively promote greening initiatives, emphasizing the role individuals can play in supporting these efforts (Zhang et al., 2024). Integration of urban greening into public health initiatives can also increase awareness of their benefits and encourage behavioral changes that support greener lifestyles and green social prescribing (Kruize et al., 2019). Governments and NGOs can leverage digital platforms, citizen science initiatives, social media, and interactive workshops to engage diverse audiences and inspire collective action through established behavior change levers that include identity-based social contagion, and the use of trusted messengers, normative appeals and "shared destiny narratives."

4.5 Equity and inclusivity in urban greening

Urban greening initiatives must prioritize equity and inclusivity to ensure fair distribution of benefits across all communities. Socially disadvantaged groups often face disproportionate environmental challenges, making equitable access to green infrastructure crucial (Hsu et al., 2022; Richards et al., 2023; Williams et al., 2025). To address this, there is a need for: (1) Ensuring that all communities, especially low-income and marginalized groups, benefit equally from improved air quality, cooling effects, and recreational opportunities; (2) Addressing disparities by recognizing that disadvantaged communities often suffer worse environmental consequences compared with more affluent areas, and tailor interventions accordingly; (3) Mitigating gentrification by implementing policies to prevent displacement and maintain affordable housing alongside greening projects; (4) Guiding urban greening efforts with social justice considerations to create healthier, more inclusive urban environments for all residents (Anguelovski and Corbera, 2023). By incorporating these principles, cities can develop urban greening strategies that not only improve environmental quality but also promote social equity and community wellbeing.

One of the major challenges of urban greening is the risk of green gentrification, where improved environmental quality leads to increased property values, ultimately displacing low-income residents (Jelks et al., 2021). While new parks, tree-lined streets, and urban forests enhance the overall liveability of a city, they can also attract wealthier residents and investors, making housing unaffordable for marginalized communities. To counter this, policymakers must integrate greening initiatives with affordable housing policies. Rent control measures, community land trusts, and mixed-income housing developments can help ensure that existing residents are not forced out due to rising costs. Additionally, designing green spaces that cater to diverse socio-economic groups, such as multipurpose parks, community gardens, and culturally relevant recreational areas, can promote inclusivity and prevent the exclusive transformation of neighborhoods. Implementing greening guidelines such as the 3–30–300 rule can help reduce inequity of access to greenspace, and thereby avoid

green gentrification, although there are substantial challenges to retrospectively achieving these targets in densely built up cities (Owen et al., 2024). Nevertheless, it remains a valuable aspiration for cities wanting to increase their greenspace, especially in residential areas.

Ensuring urban greening aligns with social and environmental justice requires prioritizing communities that historically lack access to green spaces. Low-income neighborhoods, often characterized by limited tree cover and fewer parks, experience higher temperatures, greater vulnerability to disasters, increased air pollution, and lower overall wellbeing. Greening efforts should be directed toward these areas to reduce health disparities and improve climate resilience (Rigolon et al., 2021). Public health benefits, such as reduced heat-related illnesses, improved air quality, and enhanced mental wellbeing, should be central to urban greening policies. Moreover, incorporating climate justice principles, where the needs of vulnerable populations are at the forefront of urban planning, ensures that greening efforts do not disproportionately benefit affluent areas while neglecting marginalized communities.

Equitable urban greening also requires addressing intersectional issues, such as accessibility, safety, and cultural inclusivity (Endalew Terefe and Hou, 2024). Green spaces must be designed to accommodate people of all ages, abilities, and backgrounds. Features such as wheelchair-accessible paths, shaded rest areas, and appropriately-lit public parks improve accessibility and usability for all residents. Safety concerns, particularly in marginalized neighborhoods, should be addressed through community-led monitoring programs and strategic placement of greenery to avoid creating isolated areas. Furthermore, integrating cultural elements into green spaces, such as indigenous planting practices, spaces for traditional celebrations, and art installations reflecting local heritage, enhances community identity and encourages greater use of urban greening. Where minority communities feel a sense of belonging in a local greenspace, their experiences of greenspace are often very positive (Palmer et al., 2025).

4.6 Interdisciplinary collaboration for effective implementation

Effective GBGI design and implementation requires expertise from various fields, including urban planning, environmental science, engineering, architecture, public health, economics and social sciences (Butt and Dimitrijević, 2022). However, a lack of interdisciplinary coordination often results in disjointed efforts that fail to maximize the full potential of urban greening. For example, planners may focus on aesthetics, or succumb to pressures for more housing, without considering ecological benefits or giving ecological benefits less priority, while engineers may prioritize stormwater management, the landscape architect will value biodiversity conservation, and so on.

The diverse knowledge base required to deliver a comprehensive plan, points to the need of a project manager or other champion that is able to coordinate all the various parts into one harmonious whole (Figure 2). While ambitious targets for tree cover and green space exist, there is criticism that public health practitioners are not leading environmental and greening initiatives to the standards imposed e.g., by air pollution reduction goals. Local authorities acknowledge efforts to engage with health professionals but work often happens in silos due to resource constraints and lack of effective communications. Despite good research and monitoring, effective collaboration remains limited.

Public health should not just be a co-benefit but a driving force in greening strategies, especially as pollution and health inequalities are often concentrated in disadvantaged areas. Encouraging cross-sector collaboration, knowledge-sharing, and integrated planning approaches can lead to more holistic and effective urban greening solutions. By proactively addressing these challenges, cities can harness the full potential of green infrastructure to enhance climate resilience, biodiversity, and overall liveability for future generations.

Urban greening calls for stronger collaboration between networks to achieve ambitious targets such as 40% green cover in urban areas (Natural England, 2023). Bringing together experts from urban planning, climate science, ecology, public health, and civil engineering can help foster new and holistic solutions that address multiple urban challenges simultaneously. Considering the needs of people in greenspace planning also involves understanding how their needs change as they go about their lives in the city, locally where they live, but also where they work and travel in between. Concepts such as "people-sheds" help formalize these requirements (Jones et al., 2022b). Cities should create cross-sector partnerships among local governments, businesses, academic institutions, and non-governmental organizations (NGOs) to pool resources, knowledge, and expertise. Such collaborations can accelerate project implementation, enhance innovation, and ensure urban greening aligns with broader sustainability and resilience goals.

4.7 Leveraging technological advancements

Data-driven planning plays an important role in optimizing urban greening initiatives. Technologies such as Geographic Information System, Machine learning, artificial intelligence, and availability of suitable, spatially coherent data (remote sensing, aerial imagery or satellite photography), enable spatial risk assessments at unprecedented resolution, thus enabling identification of areas most in need of green infrastructure (Fletcher et al., 2021). By harnessing these new tools, urban planners can maximize the ecological and social benefits of green spaces while ensuring efficient resource allocation. AI techniques have been applied to optimize green-blue infrastructure for climate resilience, analyzing complex environmental data to improve the design and management of green and blue spaces (Shaamala et al., 2024). Other works showed that AI-driven models coupled with publicly available satellite data can improve urban planning, resource allocation, and green blue space conservation (Hasan et al., In press). AI and multimodal datasets have the potential to help create holistic and adaptable systems that integrate green and blue infrastructure to address interconnected climate-related challenges

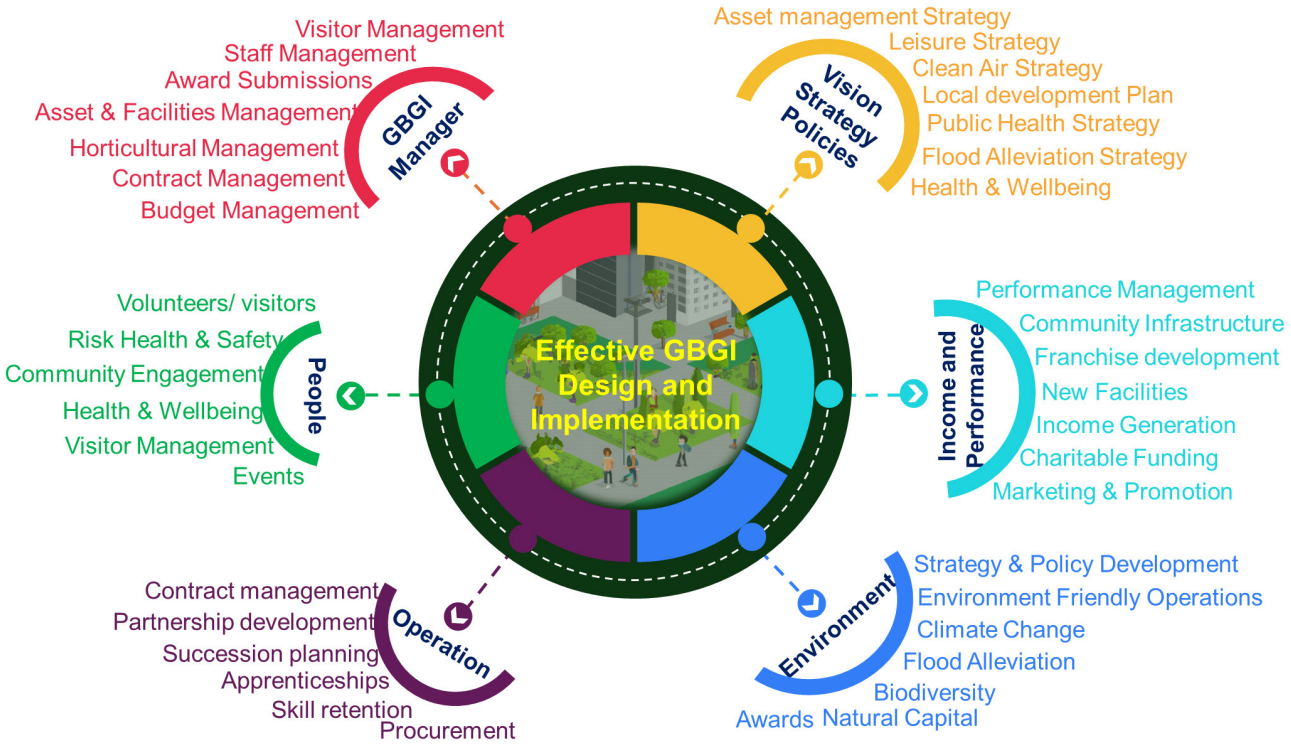

FIGURE 2
Dimensions for effective GBGI design and implementation. This diagram illustrates the interconnected dimensions for a successful GBGI project, including GBGI manager, people, operation, environment, income and performances and vision, strategy and policies. Adapted from APSE (2019).

such as flood control, biodiversity enhancement, and urban cooling (Islam M. R. et al., 2024).

The UK Met Office, for example, is committed to improving climate projections and ensuring their practical use for organizations and individuals (Met Office, 2025b). Additionally, organizations like UKRI are funding projects that generate large-scale environmental data, such as mapping the heat registry of every house in the UK to identify areas needing intervention. Ensuring that all funded research is open-source allows stakeholders, authorities and researchers to access valuable data and target interventions or research gaps. However, a major challenge lies in managing the volume of data and making it easily accessible. Addressing this requires investment in large-scale data infrastructure and smart interface solutions.

4.8 Long-term management strategies

Adaptive management strategies are essential for sustaining urban greening efforts in the long run, along with monitoring and evaluation. Regular environmental assessments using remote sensing technologies, satellite imagery, and GIS mapping can help monitor the health and effectiveness of green spaces and ecosystems. These tools enable urban planners to identify areas in need of intervention, track biodiversity trends, and assess the cooling impact of different greening solutions. Integrating urban greening with climate adaptation policies, such as flood mitigation through green infrastructure, drought-resistant landscaping, and urban heat island reduction strategies, enhances the resilience of cities against climate risks. Moreover, maintaining green spaces requires sustainable funding and governance structures. Many urban greening initiatives face long-term financial challenges, particularly when initial investments are not accompanied by maintenance plans (Pearsall et al., 2024). Innovative financing mechanisms, such as green bonds, corporate social responsibility (CSR) contributions, and public–private partnerships, can help secure ongoing funding.

5 Conclusion and future outlook

Urban areas have undergone a transformation from walkable, compact spaces to car-dominated sprawl. In recent years, there has been an increased focus on the development of sustainable and environmentally-friendly urban areas. This transition highlights the complex interplay of technological, social, and environmental factors that influence such developments. As urbanization accelerates, the demand for sustainable urban development has increased significantly. This urgency is further emphasized by global initiatives, such as the Sustainable Development Goals (SDGs), especially SDG11, which focuses on Sustainable Cities and Communities. Additionally, other SDGs, such as SDG 3, 7, 8, 9, 12, and 13 underline the importance of creating resilient and sustainable urban environments.

Urban greening is not just an aesthetic enhancement but a fundamental component of sustainable urban development.

Integrating GBGI into new and existing urban areas can help tackle environmental challenges while creating healthier, more livable spaces. With strategic planning, investment, and community engagement, urban greening can transform cities into climate-resilient, vibrant, and inclusive places for present and future generations, addressing the issues of extreme heat, air pollution, and loss of biodiversity. However, effective implementation of GBGI requires a multidisciplinary approach that aligns policy support, financial mechanisms, community engagement, and technological advancements. By addressing key challenges and leveraging collaborative governance, innovative funding, and data-driven decision-making, cities can successfully scale up GBGI, shifting from gray infrastructure dominance to climate-resilient inclusive urban landscapes.

Looking forward, urban greening will increasingly be shaped by technological advancements, innovative financing mechanisms, and a stronger emphasis on community participation and social equity. By embracing cutting-edge strategies and fostering multi-sectoral collaboration, future urban areas can strike a balance between development and sustainability, ensuring a greener, healthier, and more resilient world for future generations. Effective urban greening requires a comprehensive strategy that includes policy support, innovative financing, technological advancements, interdisciplinary collaboration, and community participation. Additionally, by addressing financial barriers, streamlining governance, utilizing data-driven decision-making, and fostering public engagement, cities can successfully implement urban greening initiatives. To ensure inclusive climate-resilient urban greening, urban areas must prevent green gentrification, prioritizing underprivileged communities, adopting adaptive management strategies, and securing long-term funding. As urban populations continue to grow and climate change intensifies, inclusive urban greening with careful and strategic planning is not just an option but a necessity for building just and sustainable cities.

Funding

The author(s) declare that financial support was received for the research and/or publication of this article. This work is conducted as part of the United Kingdom Research & Innovation (UKRI)-funded RECLAIM Network Plus (EP/W034034/1; EP/W033984/1). The network is jointly funded by three UKRI research councils: the Engineering and Physical Sciences Research Council (EPSRC), the Natural Environment Research Council (NERC), and the Arts and Humanities Research Council (AHRC). PK and co-leads acknowledge the support received through the UKRI funded GP4Streets (APP44894), DEFRAG (NE/W002892/1), GREENIN (APP55977), NERC-FAPESP funded GreenCities (NE/X002799/1; NE/X002772/1; FAPESP Grant No. 2022/02365-5), and the University Global Partnership Network (UGPN)-funded UGPN-NBS projects.

Acknowledgments

The authors gratefully acknowledge the contributions of all RECLAIM Conference panel members, attendees, co-leads, coordinating staff, event organizers, speakers, and collaborating partners. We also extend our appreciation to the University of Surrey's Global Centre for Clean Air Research (GCARE) team for their invaluable support in running both the conference and network operations. The names of co-authors are listed in alphabetical order following the core writing team.

Conflict of interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

The author(s) declared that they were an editorial board member of Frontiers, at the time of submission. This had no impact on the peer review process and the final decision.

Artificial neural network-genetic algorithm

ABSTRACT

Hydrogen energy is the cleanest energy. It has many applications in different sectors, such as power generation, industrial, and transportation. The conventional H_2 production methods are energy-consuming and generate a huge amount of pollution. Hence, a non-polluting method for H_2 production is necessary to utilize the benefit of cleaner fuel. The current work used a vortex flow plasma reforming process to generate H_2 from the methanol-water mixture. The process involved plasmolysis of methanol-water mixture to produce H_2. Additionally, the process parameters like feed flow rate (0.5–4.5 LPM), methanol concentration (5–35 %) and voltage (4–8 V) were optimized using RSM and ANN-GA models, and the influencing parameters were determined using the ANOVA test. The results showed an optimal hydrogen production rate of 229.2 mol/day (for 0.3 MHz), 265.0 mol/day (for 1.7 MHz) and 285.8 mol/day (for 2.4 MHz) for RSM at 4.5 LPM and 35 % methanol concentration while 267.0 mol/day for ANN-GA at 4.5 LPM, 33.8 % methanol concentration and 7.4 kV input voltage. The optimized parameters were used in the experimental setup, and an error of 4–7 % was observed for the RSM model and 2.5 % for the ANN-GA model. Therefore, the ANN-GA model showed better reliability than the RSM model. Further, the results may be used for commercial-scale H_2 production for various applications.

1. Introduction

Hydrogen is a clean fuel with many applications in different sectors, such as power generation, industrial, and transportation. However, hydrogen production requires enormous energy from conventional plants that pollute the environment [1]. Currently, many processes/methods are available for hydrogen production; however, the maximum hydrogen generation is through steam reforming (about 95 %), followed by electrolysis (about 4 %). The steam reforming is an energy-consuming and pollution-generating process [2,3]. And the raw materials are mainly natural gas and coal gas, which further degrades the environment [4,5]. Another hydrogen-producing method is plasma reforming, which can be a game changer in low energy consumption, eco-friendliness, and less polluting raw materials for hydrogen production [6–8]. The plasma generation requires electricity, which may be generated from renewable energy sources, further reducing dependence on conventional fuels during production [9] (see Table 10).

Plasma reforming is a process where a high-voltage plasma arc creates a very high-temperature zone (also called plasma arc zone), say about 20000 °C, with enough energy to break down hydrogen bonds from its compounds to produce hydrogen ions [10]. These hydrogen ions recombine to form hydrogen molecules (or gas) that can be separated and used for various applications [11,12]. *Pang* et al. [13] evaluated the functioning of the allo-thermal steam gasification and the non-thermal steam gasification of the wood particles on the hydrogen generation rate using the electrically heated drop tube reactor. Syngas composition produced using plasma-assisted gasification contained H_2 (38.5 %), CO (38.4 %), CO_2 (12.7 %), and CH_4 (10.3 %) at 760 °C, respectively. A 20 % increase was noticed in syngas production by non-thermal plasma systems compared to allo-thermal gasification. *Bulychev* et al. [14] analyzed the acoustic plasma method in liquid decomposition at low temperatures. The H_2 production rate attained was 2 L/min with a 100 mL capacity reaction chamber, and the feed rate of about 60–70 % of the energy efficiency factor was achieved depending upon the feed mixture composition.

Methanol and water are prominent sources of hydrogen production using different production methods. The hydrogen content in methanol and water is more than 10 %, while the low energy requirement for

hydrogen extraction gives them an advantage over other sources. Typically, the methanol has about 12.5 % of hydrogen content. The benefits of producing hydrogen from methanol are its less toxic nature, the fact that it is liquid at room temperature, and hydrogen generation at a comparatively lower temperature. These advantages developed an interest in methanol as a greener hydrogen production source. *Budhraja* et al. [15] simulated the hydrogen production process from methanol via a reforming process. The result showed a 0.57 hydrogen mole fraction with a more than 90 % methanol conversion percentage.

Plasma reforming has different operating parameters that influence the hydrogen production in a system [16,17]. Hence, understanding parameter performance in hydrogen production is crucial to enhance hydrogen production [18]. The influence of discharge frequency, input power, and liquid feed rate on the plasma-steam reforming of methanol and synergistic plasma-catalyst systems described a rise in the frequency accelerating the methanol conversion initially and then reduced. In contrast, 17.89 % and 21.86 % more methanol conversion and H_2 yield were obtained with activated catalyst than without catalyst [19]. *Huang* et al. [20] modified the plasma reforming system by adding a heater and varying the amplification ratio for hydrogen generation from the methanol-water mixture. Effects of increasing operating voltage and temperature showed approximately 50 % upsurge in hydrogen generation. In contrast, the influence of discharge power, type of carrier gas, and the moisture content of the raw material in the non-thermal arc plasma reactor showed that the gas yield enhanced with the rise in discharge power and higher moisture content; however, air as carrier gas showed the best gas yield and H_2/CO ratio against N_2 and Ar.

Once the influencing parameters were determined, a statistical relationship was developed between different parameters and response values. This relationship generates predicted values for each parameter input interaction [21–23]. Hence, the optimal output (or hydrogen production) was computed through the developed model. The researchers used different statistical model tools like response surface methodology (RSM) and artificial neural network (ANN) for optimization. *Shiraishi* et al. [24] studied the performance of the Ni electrode and Ni plate on the in-liquid plasma breakdown of methanol for hydrogen generation. The in-liquid plasma method achieved a hydrogen yield of 67 % for methanol conversion, and the hydrogen generation rate increased by 2.3–3.5 times with the Ni porous plate placed above the electrode. *Lian* et al. [25] examined the performance of O_2 to C ratios, steam/carbon (S/C) ratios, and specific energy input (SEI) on the oxidative methanol-reforming for onboard hydrogen generation using a gliding arc plasma reactor. Methanol conversion was accelerated with the rise of the O_2 to C ratio, although the lesser energy efficiency was recorded with the upsurge in either the S/C ratio or SEI. In contrast, the methanol conversion of 88 % and energy efficiency of 74 % was achieved by an O_2/C ratio of 0.30, an S/C ratio of 0.5, and an SEI of 24 kJ/mol, respectively.

The current work developed a vortex flow plasma reformer for hydrogen production from the water-methanol mixture. No study was observed for vortex flow plasma reforming in open literature. The plasma vortex created more spots for plasma and feed interaction, resulting in higher hydrogen production. The various input parameters were computed, and their influence on H_2 production was calculated. An RSM model was generated using parameters like feed flow rate, methanol concentration, and input voltage at different levels. The inputs were analyzed for optimal values, and their influences were recorded using Analysis of Variance (ANOVA). An ANN-GA model was also developed using the same parameters, and the data was analyzed for a better optimal solution. The results from RSM, ANN-GA, and experimental data were compared, and it was observed that ANN-GA has a better correlation between parameters and response than the RSM model. This way, the input parameters were optimized for better hydrogen production parameters and enhanced yield. Therefore, the output data may be used to develop a commercial-scale hydrogen production plant.

2. Material and method

The raw materials and the production process of hydrogen were proposed in this section. The mathematical modeling and parameter optimization were performed using response surface methodology (RSM) and artificial neural network-genetic algorithm (ANN-GA) models.

2.1. Raw materials

The commercial grade methanol (ONGC/LPG/09/2015), which was 99.9 % pure and distilled water (de-ionized/de-mineralized), was procured to prepare a water-methanol mixture at different methanol concentrations (5 %, 20 % and 35 %) to be fed into the reactor. All the high-grade chemicals did not require further processing to prepare samples for plasma reformer feed. The samples contained a water-methanol mixture in different compositions (i.e., Sample 1: 5 % methanol + 95 % water; Sample 2: 20 % methanol + 80 % water; and Sample 3: 35 % methanol + 65 % water, respectively).

2.2. Feed atomization

The water-methanol mixture cannot be fed directly to the plasma reformer/reactor; therefore, the feed atomization was carried out. Three different ultrasonic transducers (or atomizers) with frequencies of 0.3 MHz, 1.7 MHz, and 2.4 MHz were installed for feed atomization. The ultrasonic transducers and their circuit are shown in Fig. 1[26]. The working principle of the ultrasonic transducer depends on the sound frequency at the ultrasonic level generated by the metal diaphragm connected with the piezo-ceramic element. The ultrasonic sound waves vibrate the metal diaphragm to convert liquid feed into minute droplets with a diameter within a few nanometres (nm) range. The atomized feed was then fed into the plasma reformer for further processing. The specifications of the atomizers are depicted in Table 1.

2.3. Plasma reforming process

Water-methanol reforming was carried out in the plasma reformer designed and developed in the laboratory (Fig. 2). The plasma reformer consists of two electrodes (one cylindrical copper-based alloy and another neodymium-based ring-type magnet) placed in a cylindrical tube with an inner diameter of 20 mm [26]. A high-voltage generator was designed with a flyback transformer that generated a potential difference between 1.0 kV and 10 kV at the output terminals. The atomized feed was fed into the reformer and passed through the two electrodes. The plasma arc jumps from the Cu electrode to the magnet electrode when the distance between the two electrodes ranges from 7 mm to 13 mm. The plasma arc created a high-temperature zone that breaks down the hydrogen bond of the feed. Hence, water and methanol

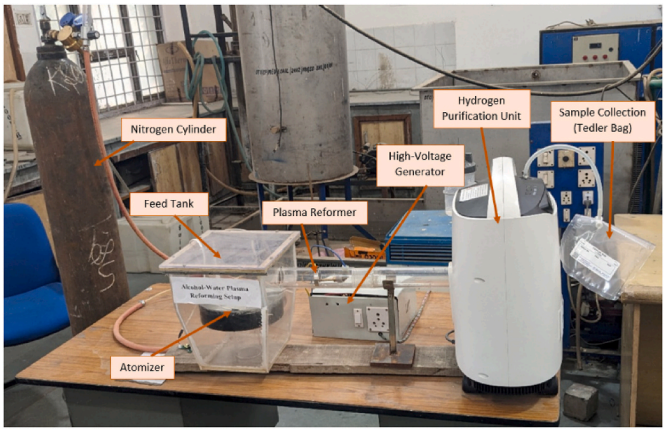

Fig. 2. Experimental setup for plasma reforming.

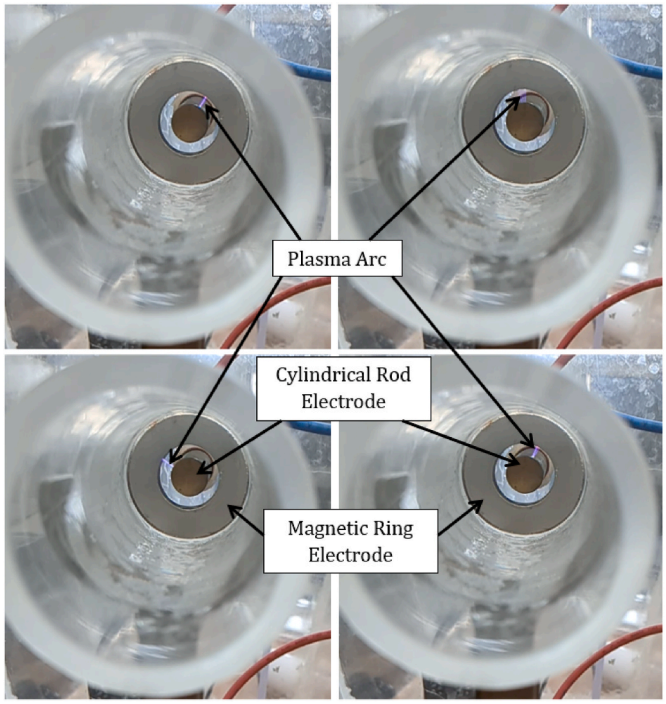

Fig. 3. Plasma arc vortex formation inside plasma reformer.

molecules split into species like H, CO, and O ions. These ions recombine to form compounds like H_2, CO_2, and CO.

The methanol-reforming process involves reactions (1), (2), and (3) as stated below [15]:

$$CH_3OH \rightarrow HCHO + H_2 \quad (1)$$

$$HCHO + H_2O \rightarrow HCOOH + H_2 \quad (2)$$

$$HCOOH \rightarrow CO_2 + H_2 \quad (3)$$

Whereas the other reactions involved in the methanol reforming process include reaction (4), (5), (6) where reaction (6) is water gas shift reaction [27].

$$CH_3OH + H_2O \leftrightarrow CO_2 + 3H_2 \quad (4)$$

$$CH_3OH \leftrightarrow CO + 2H_2 \quad (5)$$

$$CO + H_2O \leftrightarrow CO_2 + H_2 \quad (6)$$

The H_2 molecules were separated and stored in hydrogen storage bags, and tedlar bags of 1 L were used to collect samples to test the product's purity. The plasma arc vortex was formed within the plasma reformer is presented in Fig. 3[26].

2.4. Hydrogen purification

Hydrogen purification becomes very necessary to obtain pure hydrogen for applications such as fuel for fuel cells and other industrial applications. The gaseous mixture coming out of the plasma reformer consists of H_2, N_2, CO, CO_2, etc. The hydrogen purification was performed by passing a pressurized gaseous mixture through a zeolite sieve. The void diameter of the zeolite sieve was slightly more than the kinematic diameter of hydrogen molecules; thus, the hydrogen molecules passed through the sieve, whereas other gaseous molecules, being larger than the void diameter, got stuck. Once the first sieve got choked from larger gaseous molecules, the other sieve began working. After purification, a small amount of hydrogen gas passes through the first sieve in the reverse direction. The choked voids get unblocked and become ready for operation after the second sieve gets choked. Therefore, the zeolite sieve's automatic ON/OFF switching performs a continuous hydrogen purification. The specifications of the hydrogen purification unit used are mentioned in Table 2.

The purified hydrogen was taken for sample testing in tedlar bags for qualitative gas chromatography analysis. The specifications of the gas chromatography used are depicted in Table 3.

2.5. Hydrogen production rate

The amount of hydrogen gas produced during the plasma reforming process was measured in hydrogen production rate, R_{H_2} (mol/day) using Eq. (7),

$$R_{H_2} = \frac{W_{H_2}}{T \times 24} \quad (7)$$

Where W_{H_2} represents the amount of hydrogen produced in mol, and T represents the total time in hours.

2.6. Response surface methodology

Response Surface Methodology (RSM) provides a systematic method for conducting experiments and analyzing data. It allows for the creation of empirical models that establish the relationship between input parameters (such as feed flow rate, methanol concentration, and voltage) and the output response (hydrogen production rate). Response surface

methodology (RSM) offers valuable insights into the impacts of individual factors and their interactions on the intended outcomes. Therefore, the experimental variables in the hydrogen production process were optimized using the RSM. As depicted in Table 5, the central composite design (CCD) generated a 20-run design of experiments (DoE) with three input variables at three levels. The RSM model generated empirical relationships between input and output variables to investigate the impacts of the various parameters at different levels. The various input variables involved in generating DoE for CCD were feed flow rate (FFR), methanol concentration (MeOH), and input voltage (Voltage).

A CCD design consisting of 6-central, 6-axial, and 8-factorial points was used to generate a quadratic Equation (8) that represented Y as the response variable (Hydrogen production rate); P, Q, and R as input variables (depicted in Table 2); β as intercept; β_1, β_2 and β_3 as first-order coefficients; β_4, β_5 and β_6 as interactive coefficients; β_7, β_8 and β_9 as a second-order coefficient and β_{10} as associated error, respectively.

$$Y = \beta_0 + \beta_1(P) + \beta_2(Q) + \beta_3(R) + \beta_4(PQ) + \beta_5(QR) + \beta_6(RQ) + \beta_7(P^2) + \beta_8(Q^2) + \beta_9(R^2) + \beta_{10} \quad (8)$$

In the earlier study, *Budhraja* et al. [27] used RSM-CCD to optimize hydrogen production from a water-methanol mixture via a reforming process. The optimized hydrogen selectivity of 84.81 % was achieved against the maximum simulated hydrogen selectivity of 82.76 %. Similarly, in another study, *Budhraja* et al. [28,29] optimized biohydrogen production using an anaerobic digester. The optimized hydrogen yield of 25.27 % was found against the maximum yield of 24.6 %. In another study, *Budhraja* et al. [30] optimized the biodiesel yield using the RSM model and observed a 92 % optimized yield against 89 % of the maximum experimental biodiesel yield.

2.7. Artificial neural network-genetic algorithm

Another tool used to optimize process parameters was the artificial neural network-genetic algorithm (ANN-GA) model. An ANN-GA model is a computational model that performs data interpretation and predictions based on the human brain and natural evolution. The correlation coefficient (R) for the hydrogen production rate was computed.

3. Results and discussion

This section describes the results obtained during experimentation and analyses the results through discussions. The effects of various process parameters, namely input voltage, methanol concentration, and feed flow rate, were studied. The three ultrasonic transducers with ultrasonic frequencies of 0.3 MHz, 1.7 MHz, and 2.4 MHz were used to atomize the water-methanol mixture, and the effects with different parameters were observed. The results obtained were discussed separately for each parameter, taking the other two parameters constant. The regression analysis and the interactive effects of the various parameters were also studied. The optimized results were obtained and compared with the experimental results obtained.

Table 4
Operating parameters for the RSM model.

Parameter	Unit	Levels		
		−1	0	1
P-Feed Flow Rate	LPM	0.5	2.5	4.5
Q-Methanol concentration	%	5	20	35
R-Voltage	kV	4	6	8

3.1. Empirical design & regression analysis

The three process parameters involved in the optimization process are feed flow rate (FFR), methanol concentration (MeOH), and input voltage (Voltage). Table 2 shows that a DoE was generated in CCD for three factors at three levels. A 20-run hydrogen production rate (HPR) design matrix was developed using three different ultrasonic frequency transducers (0.3 MHz, 1.7 MHz, and 2.4 MHz). The residual (or percentage error) was computed using actual and predicted values received through analysis and depicted in Table 3.

Experimental randomizations reduced the response variations. The predicted values were produced through a response model for each ultrasonic frequency transducer {Equation (9), Equation (10), and Equation (11)} with a 95 % confidence level. Here, the terms FFR, MeOH, and Voltage were linear; $(FFR)^2$, $(MeOH)^2$, and $(Voltage)^2$ were quadratic terms; and (FFR x MeOH), (MeOH x Voltage) and (Voltage x FFR) were interactive terms for hydrogen production rate at relative frequencies.

$$HPR\ (0.3\ MHz) = -10.661 + 61.049\ FFR - 0.006\ MeOH - 1.950\ Voltage + 0.595\ FFR{*}MeOH + 0.753\ FFR{*}Voltage + 0.070\ MeOH{*}Voltage - 7.549\ FFR^2 - 0.007\ MeOH^2 + 0.051\ Voltage2 \quad (9)$$

$$HPR\ (1.7\ MHz) = -11.837 + 68.784\ FFR - 0.937\ MeOH + 2.013\ Voltage + 0.492\ FFR{*}MeOH + 0.697\ FFR{*}Voltage + 0.032\ MeOH{*}Voltage - 6.694\ FFR^2 + 0.021\ MeOH^2 - 0.269\ Voltage2 \quad (10)$$

$$HPR\ (2.4\ MHz) = -21.500 + 81.859\ FFR - 0.658\ MeOH + 4.952\ Voltage + 0.345\ FFR{*}MeOH + 0.781\ FFR{*}Voltage + 0.011\ MeOH{*}Voltage - 7.711\ FFR^2 + 0.021\ MeOH^2 - 0.499\ Voltage2 \quad (11)$$

The F-values and p-values of the parameters were calculated from analysis of variance (ANOVA) tests. The proportion between the mean square errors was defined as the F-value. A higher F-value determined the significance of a parameter. Similarly, the variation between the group means described the p-value. The relevance of a parameter was described by the p-value <0.001, respectively. Here, the ANOVA tables were developed for each ultrasonic frequency (Table 4, Tables 5, and Table 6), and each parameter's significance was determined for the hydrogen production rate. Table 4, Tables 5, and Table 6 concluded that the feed flow rate and the methanol concentration were the most significant parameters through F-values and p-values calculations for each ultrasonic frequency transducer.

The coefficient of regression (R^2) values of each ultrasonic frequency transducer were also calculated for the hydrogen production rate. It determined the model's adequacy and showed the competence of the outcomes with the statistically predicted values. The values closer to unity showed better predictions for the model. Through Table 7, it was concluded that the R^2 values of the outputs from each ultrasonic frequency transducer were closer to 1 (unity). It showed a good correlation developed among the experimental and predicted values for hydrogen production rate.

3.2. Interactive effects of parameter

The analysis of the interactive effects of the parameters generated a relationship between two parameters taken together to the response value. The relationship was developed using model equations for each response value. A 3D surface contour graph was developed with two parameters, and a response value described the interactive effects of the parameters considered during the analysis.

The interactive effects of different parameters with a 0.3 MHz ultrasonic frequency transducer for HPR are shown in Fig. 4. In Fig. 4 (a), the FFR and MeOH were taken together. In contrast, in Fig. 4 (b), the MeOH and Voltage and in Fig. 4 (c), the Voltage and FFR were taken

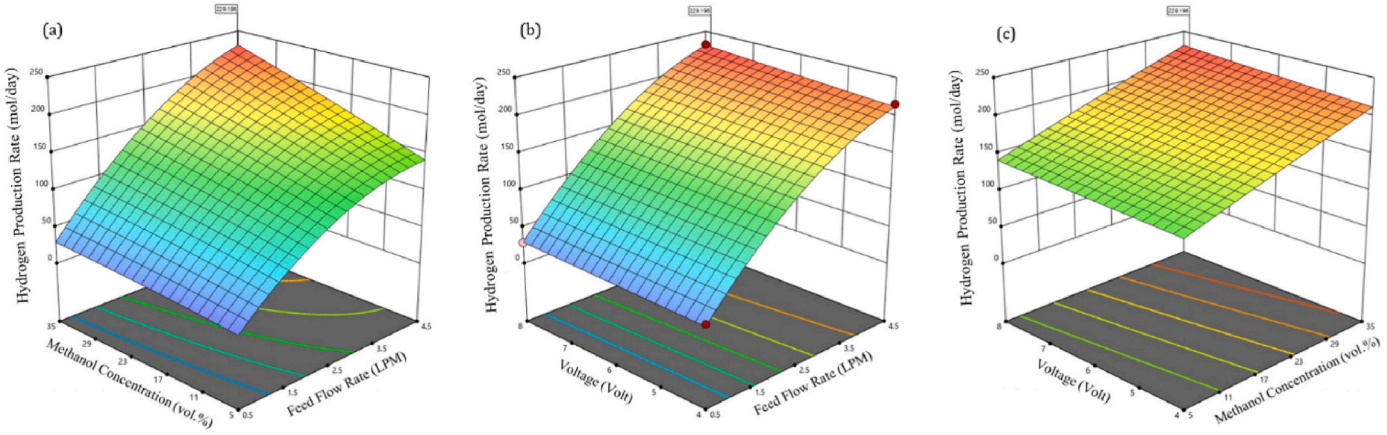

Fig. 4. 3D Surface contour curve of hydrogen production rate for 0.3 MHz transducer frequency (a) MeOH vs. FFR; (b) Voltage vs FFR; and (c) Voltage vs MeOH.

together. The results showed that the FFR of 4.5 LPM and MeOH of 35 % vol. generated the highest HPR. Fig. 4 (b) showed the highest HPR at 4.5 LPM and all input voltages. Similarly, Fig. 4 (c) showed peak HPR at higher MeOH at all voltage ranges. Here, the peak HPR was 229.2 mol/day achieved with optimized parameters.

The interactive effects of different parameters on HPR using a 1.7 MHz ultrasonic frequency transducer are shown in Fig. 5. Fig. 5 (a) generated interaction between FFR and MeOH; Fig. 5 (b) generated interaction between MeOH and Voltage; and Fig. 5 (c) generated interaction between Voltage and FFR. The improvement in the HPR from the 0.3 MHz ultrasonic frequency transducer was seen, and the peak was attained at 265.0 mol/day. Here, Fig. 5 (a) showed a peak value of HPR at FFR of 4.5 LPM and MeOH of 35 % vol., whereas Fig. 5 (b) showed the highest value at 4.5 LPM and all voltage ranges. Similarly, the peak value in Fig. 5 (c) was at higher methanol concentrations and all voltage ranges.

The interactive effects of different parameters with a 2.4 MHz ultrasonic frequency transducer for HPR are presented in Fig. 6. In Fig. 6 (a), the FFR and MeOH were taken together, while in Fig. 6 (b), the MeOH and Voltage were brought together, whereas in Fig. 6 (c), the Voltage and FFR were taken together. The interactions of parameters showed a maximum HPR of 285.8 mol/day. Fig. 6 (a) showed a peak value at 4.5 LPM and 35 % vol. methanol concentration. Fig. 6 (b) showed maximum HPR at 4.5 LPM and all voltage ranges. Similarly, Fig. 6 (c) showed the peak value of HPR for all voltage ranges and at 35 % vol. methanol concentration. The discussion showed that the higher ultrasonic frequency contributed to a higher hydrogen production rate. Also, the higher methanol concentrations and feed flow rates contributed to enhanced hydrogen production rate, which showed that hydrogen generation was mainly due to methanol conversion.

Table 8 shows the percentage error for hydrogen production rate at optimal parameters of different transducer frequencies against experimental results. It was observed that a maximum error of 6.7 % and a minimum error of 4.1 % were computed when optimal parameter values from the RSM model were used in the experimentation setup. Therefore, an error of the 4–7 % order is within the tolerable limits (see Table 9).

3.3. Artificial neural network (ANN)

The correlation coefficient (R) value for the hydrogen production rate reached unity, showing a reliable regression model (see Fig. 7). The high R values observed across all networks indicate that the data was effectively trained using the DOE, reinforcing the reliability and robustness of the regression model. Here, the ultrasonic transducer frequencies (0.3 MHz, 1.7 MHz and 2.4 MHz) were also considered as the optimizing parameter along with feed flow rate (0.5–4.5 LPM), methanol concentration (5–35 %) and voltage (4–8 V), respectively. It will help find the optimized ultrasonic frequency for atomization that will enhance the hydrogen production rate. The optimized value of HPR achieved was 267.0 mol/day at 4.5 LPM feed flow rate, 33.8 % vol. methanol concentration, and 7.4 kV input voltage for 1.7 MHz transducer frequency. Therefore, the 1.7 MHz ultrasonic transducer frequency would be selected for optimized hydrogen production rate. In contrast, the experimental results showed 260.4 mol/day HPR at the above parameters. Hence, an error of about 2.5 % was observed for the ANN-GA model against experimental results.

3.4. Optimal values (comparative results)

This section discussed the comparative results obtained from RSM, ANN-GA, and experimental data. The optimal values of the parameters obtained from the RSM and ANN-GA model were used to perform experiments, and the results from the experimental data were computed for percentage error. The percentage errors for RSM values were between 4 % (for 1.7 MHz ultrasonic transducer frequency) and 7 % (for 0.3 MHz ultrasonic transducer frequency), whereas the percentage error for the ANN-GA model was about 2.5 % (for 1.7 MHz ultrasonic transducer frequency). Here, the ultrasonic transducer frequencies (0.3 MHz, 1.7 MHz and 2.4 MHz) were also considered as the optimizing parameter along with other process parameters; therefore, no separate results were obtained for different ultrasonic transducer frequencies. The comparative result showed that the ANN-GA model is superior in optimization to the RSM model, with a lower error percentage during analysis.

Table 10
Error percentage for the optimal parameters from the RSM model.

Transducer Frequency (MHz)	Parameters			Hydrogen Production rate (mol/day)		%age error
	Feed Flow Rate (LPM)	Methanol concentration (%)	Voltage (kV)	Predicted	Experimental

2.4	4.5	35	7.54	285.8	270.5	5.4

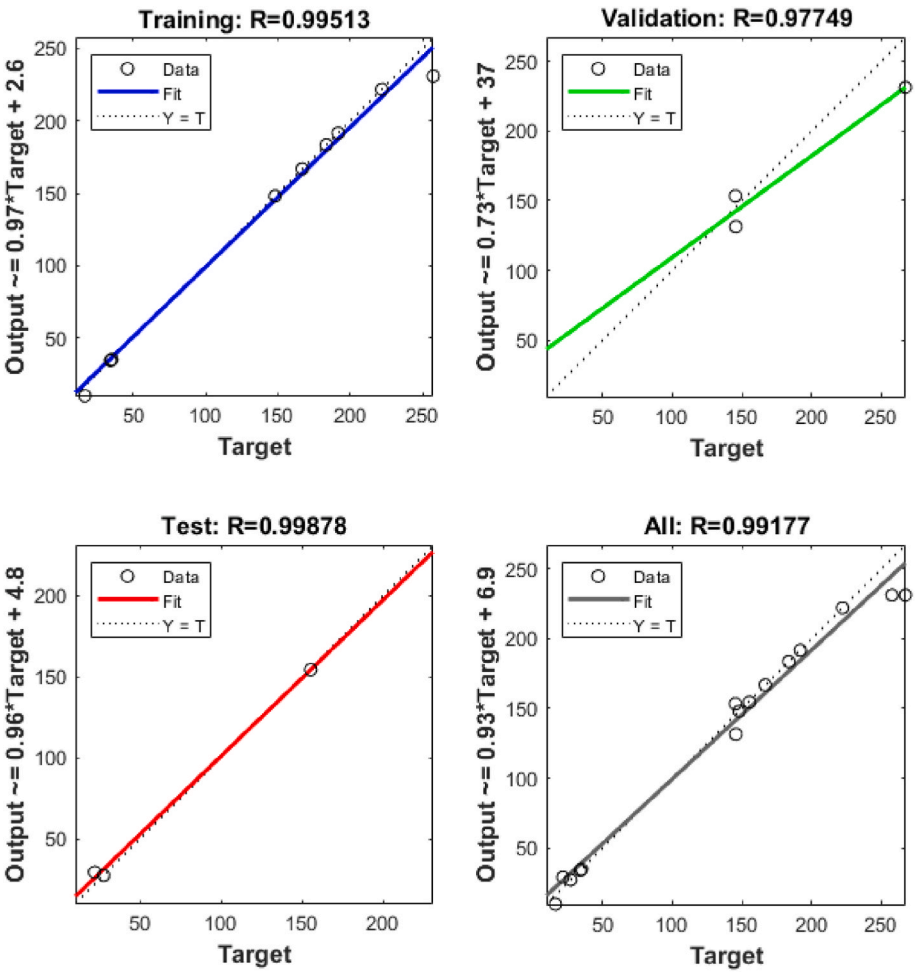

Fig. 7. Coefficient of correlation (R) for hydrogen production rate.

3.5. Hydrogen purity analysis

The purity of a compound is an essential criterion; hence, the gaseous mixture was collected in a 1 L tedlar bag and tested for the gas composition using Agilent make gas chromatography (GC) having thermal conductivity detector (TCD). The composition of a gaseous mixture was found to have the following gases: hydrogen, carbon dioxide, nitrogen, and oxygen, as observed in Fig. 8 (a). It was observed that about 32.2 % of hydrogen content was present in the gaseous mixture.

The gas mixture was then purified using an oxygen concentrator-type hydrogen purification unit, and the samples were collected after the gas purification. The same procedure was followed to determine the purified gas composition. It was observed that the hydrogen content in the sample rose to about 99 %, and a small fraction of about 1 % of oxygen was present after the purification, which could be the oxygen released during methanol-reforming.

4. Conclusions

The experimental analysis of hydrogen production using plasma reforming of water-methanol mixture was performed. The study was conducted on the influence of three operating parameters: input voltage, methanol concentration, and feed flow rate at different ultrasonic transducer frequencies, i.e., 0.3 MHz, 1.7 MHz, and 2.4 MHz, respectively. The operating parameters varied to understand their interactive influence on the hydrogen production rate. The data was optimized using response surface methodology and an artificial neural network-genetic algorithm. The following outcomes were observed.

- Higher ultrasonic frequency has positive impacts on hydrogen production rate.
- The F-values and p-values of the methanol concentration and feed flow rate showed they were significant parameters in the plasma reforming process.
- The R^2 value from RSM showed good competence of the outcome with the statistically predicted values.
- The optimal hydrogen production rate of 229.2 mol/day (for 0.3 MHz), 265.0 mol/day (for 1.7 MHz), and 285.8 mol/day (for 2.4 MHz) for RSM were observed at 4.5 LPM and 35 % methanol concentration while 267.0 mol/day for ANN-GA at 4.5 LPM, 33.8 % methanol concentration, and 7.4 kV input voltage.
- The higher methanol concentration enhanced the hydrogen production rate.
- The ANN-GA model also showed correlation coefficient values close to unity; thus, the model was reliable.
- The experimental tests on the optimized values of RSM and ANN-GA models showed 4–7 % and about 2.5 % percentage errors, demonstrating the ANN-GA model's superiority over RSM.

Therefore, the experimental analysis of plasma reforming of a water-methanol mixture showed the potential of generating a gaseous mixture rich in hydrogen gas. The hydrogen production was successfully optimized for an enhanced production rate. The results obtained were

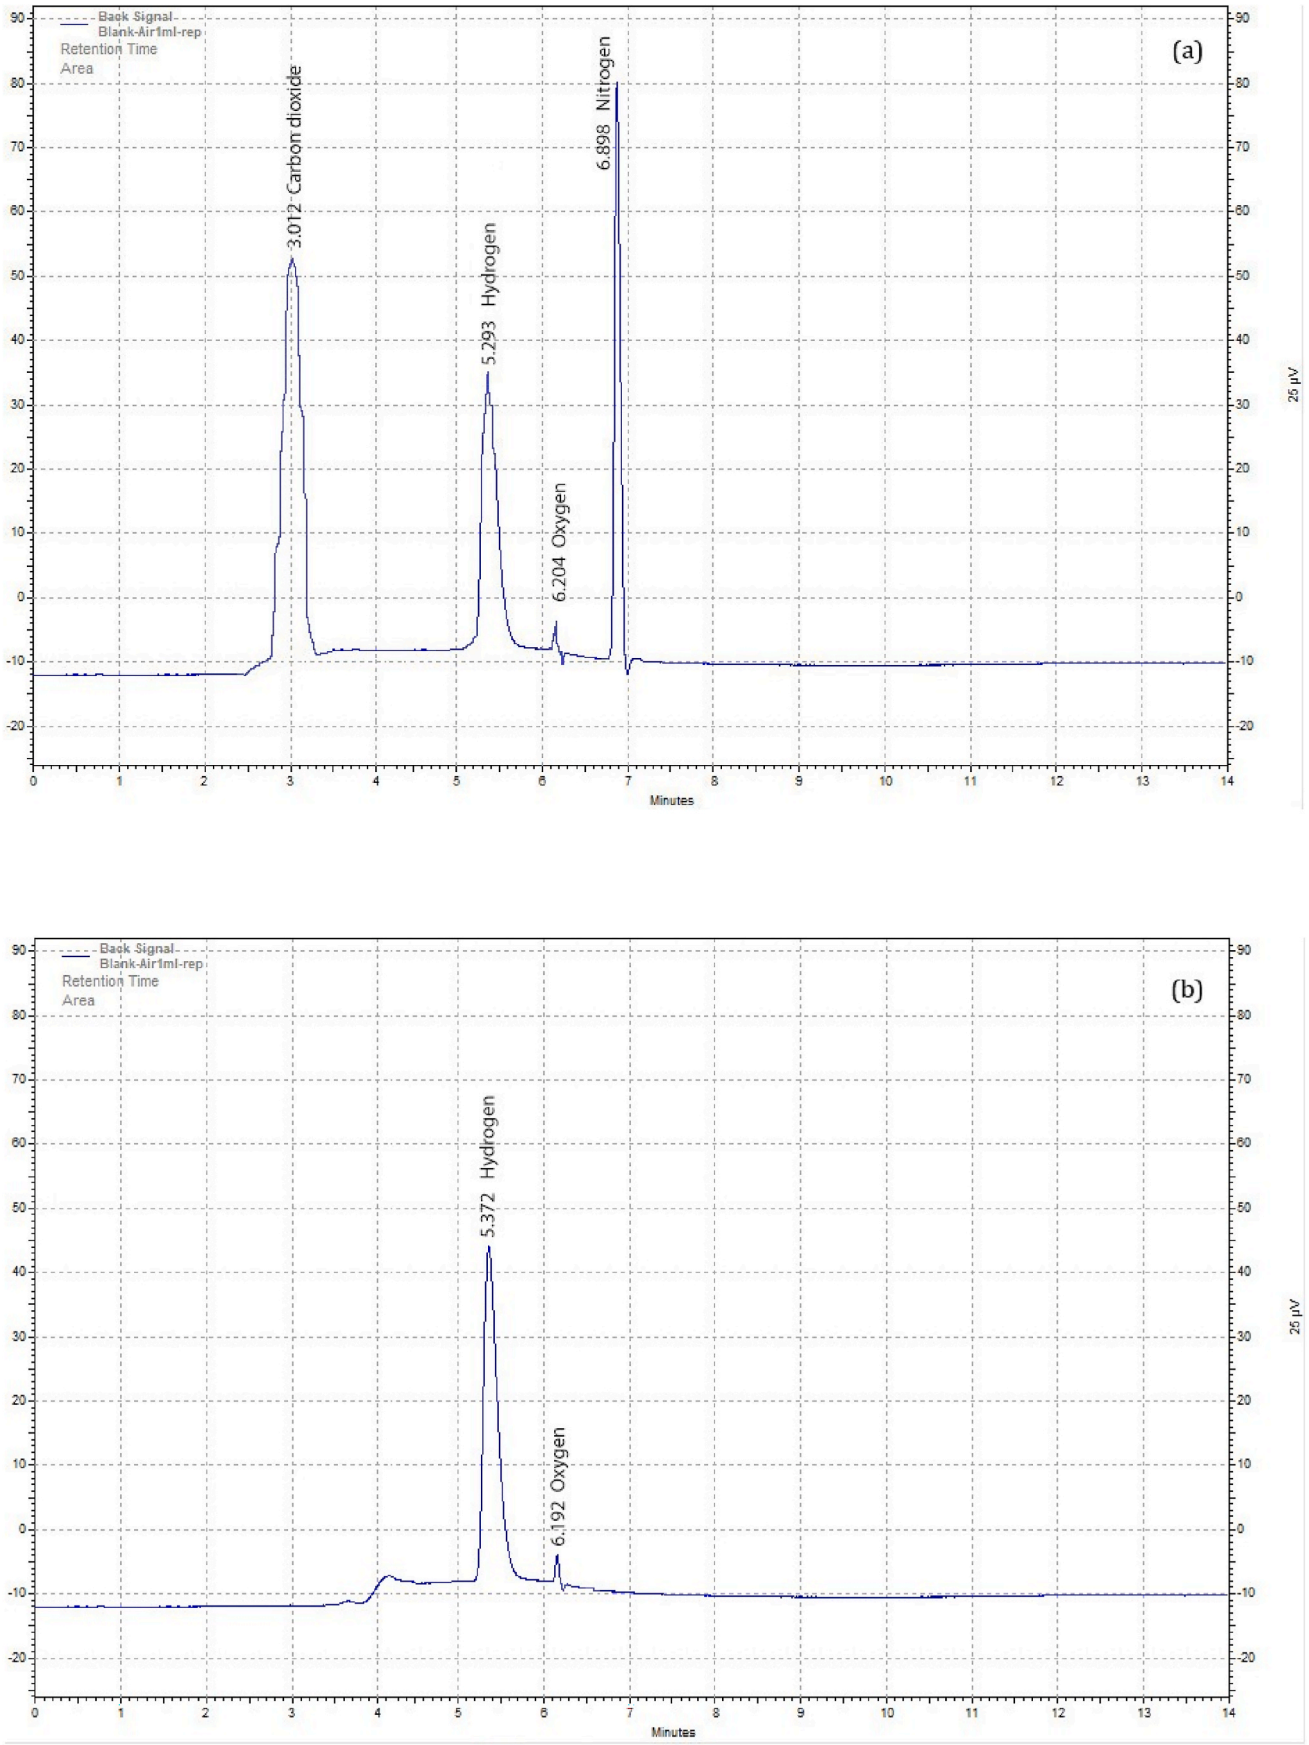

Fig. 8. Chromatogram for (a) gaseous mixture and (b) purified gas.

reliable. Further work may be performed to up-scale the plasma reactor for commercialization, and other process parameters may also be considered for optimization.

Zn/Cu Layered Double Hydroxide as a Catalyst for the Synthesis of Highly Functionalized Pyrazole Derivatives

Charu Gupta,[a] Bhamini Pandey,[a] Poonam Singh,[a] and Ram Singh*[a]

A 2D layered double hydroxides (LDHs) of Zn/Cu that belongs to a diverse category of anion-exchangeable layered structures was prepared. The synthetic inorganic LDHs material was characterized by employing various techniques such as Fourier transform infrared (FTIR), Scanning electron microscope (SEM), Powder X-ray diffraction (XRD), and thermogravimetric analysis (TGA). The prepared heterogeneous catalyst mediated the synthesis of highly functionalized pyrazole derivatives via a one-pot reaction between arylaldehyde, malononitrile, and phenylhydrazine in ethanol at room temperature with excellent yields of 76%–94%. Notably, the catalyst can be simply retrieved from the reaction mixture using filtration, and it can be reused multiple times without experiencing a substantial decrease in its activity.

1. Introduction

The study of two-dimensional materials has gained significant attention in recent years, particularly in the context of developing adsorbents, heterogeneous solid catalysts, catalyst supports, metal-sulfur batteries, electrodes, and so on[1–3] Layered double hydroxides (LDHs) are 2D materials characterized by their general formula $[M^{2+}_{(1-x)}M_x^{3+}(OH)_2](A^{n-})_{x/n}.zH_2O]$ belong to a diverse category of anion-exchangeable layered structures. The commonly used metal cations in divalent and trivalent forms include Mg^{2+}, Zn^{2+}, Mn^{2+}, Co^{2+}, Ca^{2+}, Fe^{2+}, and Co^{3+}, Fe^{3+}, Mn^{3+}, Al^{3+}, and Cr^{3+}, respectively and the anions are usually carbonate, chloride, nitrate, or acetate.[4–6] The versatile behavior of LDHs is derived from their facile synthesis and ability to modify their positively charged layers and negatively charged interlamellar region.[7] This versatility results in diverse applications of LDHs in various fields. Kamali et al. showed the removal of As(III) ion from aqueous solutions by using a new nanospherical graphene that was modified with LDHs[8] and also contributed to various organic syntheses.[9–11] Furthermore, recent years have witnessed a surge in research focusing on utilizing LDHs-based catalysts in multicomponent reactions (MCRs). These reactions involve the simultaneous participation of multiple reactants where LDHs play a pivotal role in enhancing the selectivity and efficiency of the reaction.[12–15]

LDHs act as heterogenous catalysts and offer distinct advantages including easy and efficient separation, contributing to cost-effective catalyst recovery.[16,17] MCRs comprise an important class of chemical transformations that have been applied to almost all fields of organic and medicinal chemistry.[18] These convergent procedures incorporate three or more reactants into a final product in one-pot, thus combining high levels of complexity and diversity generation with low synthetic cost and high atom economy.[19] Most of the reactions performed are multicomponent one-pot reactions. MCR has been a successful method for the synthesis of heterocyclic compounds including pyrazoles.[20,21] Pyrazole scaffold leads to diversified applications in different areas such as technology, medicine, and agriculture.[22] They are also described as inhibitors of protein glycation, antibacterial, antifungal, anticancer, antidepressant, anti-inflammatory, antituberculosis, antioxidant as well as antiviral agents.[23–28]

Generally, the synthesis of 5-amino-pyrazole-4-carbonitrile derivatives is a three-component reaction of aromatic aldehyde, malononitrile, and phenylhydrazine. For the synthesis of pyrazoles and their derivatives many catalysts and reagents have been studied such as Fe_3O_4@Alg,[29] sulfonic acid-functionalized polyvinyl alcohol (SPVA),[30] Fe_3O_4@SiO_2@Tannic acid,[31] NaCl,[28] 2-amino-6-oxo-3-(piperidinylamidino)-4-(4methoxyphenyl)-6,7-dihydro-pyrano[2,3-d]-5,7-thiazol derivative (MATYPd Complex),[32] graphene oxide–TiO_2,[33] oxone,[34] taurine,[35] and molecular iodine.[32] LDHs materials have found many applications in the heterogeneous catalysis field including photocatalysts, electrocatalysts, and thermocatalysts.[37] The composition, particle size, morphology, and surface defect structure, as well as the electronic properties of LDHs can be modulated by various synthetic strategies and their porous nature and larger surface area made them a suitable catalyst for various reactions including Michael addition affording the coordinatively unsaturated active sites (e.g., low-coordinated steps, edges, and/or corner atoms) which facilitate heterogeneous catalysis.[38] In this manuscript, we utilized LDHs materials as a catalyst for a multicomponent one-pot approach for the synthesis of substituted 5-amino-pyrazole-4-carbonitrile framework.

Table 1. The effect of temperature with catalyst (40 mg) on the yield of the product **4a**.

Entry	Temp. (°C)	Time (min)	Yield (%)
1	80	60	70
2	70	60	70
3	60	60	75
4	50	60	77
5	40	60	80
6	RT (~30 °C)	60	83
7	RT (~30 °C)	30	90
8	RT (~30 °C)	12	90

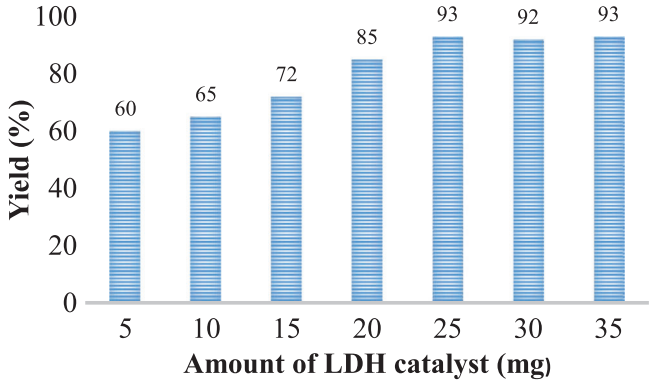

Figure 2. Catalyst optimization with yield for the synthesis of pyrazole **4a**.

2. Experimental Section

2.1. General Procedure for Synthesis of Catalyst Zn/Cu LDHs

Zn/Cu LDHs was prepared in accordance with the method specified in[39] which is briefly described as follows: Salts of zinc acetate dihydrate (4.49 mmol) and copper acetate monohydrate (0.49 mmol) were dissolved in 20 mL of deionized (DI) water. Then, 35 mL of H_2O_2 solution (5 mL H_2O_2 + 30 mL DI water) was added to the metal salts solution with continuous stirring, followed by ultrasonication for 30 min. Afterward, the resulting solution was stirred for 24 h and later dried at 60 °C. The obtained blue color powder was characterized with FTIR spectra, Powder X-ray diffraction (PXRD),

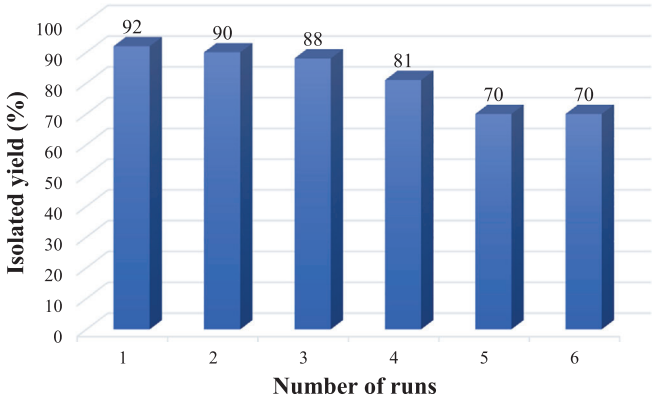

Figure 4. Reusability of the catalyst for the product **4a**.

thermogravimetric analysis (TGA), and Scanning electron microscope (SEM). This was used for the reaction.

2.2. General Procedure for the Preparation of Pyrazole Derivatives (4)

The synthesized catalyst (25 mg) was introduced into a reaction mixture containing benzaldehyde (1.0 mmol) and malononitrile (1.0 mmol) in ethanol solvent (3 mL). The mixture was stirred at room temperature until the formation of a white precipitate was observed. Subsequently, phenylhydrazine (1.0 mmol) was added to the resulting reaction mixture at room temperature under stirring for a duration of 5–10 min. The progress of the reaction was monitored using a thin-layer chromatography (TLC) plate in hexane and ethyl acetate (4:1 v/v). After completion of the reaction, water (30 mL) was added to the reaction mixture and filtered. The catalyst was separated, dried, and reused for the reaction. The filtrate was mixed with ethyl acetate and separated. The organic layer was subjected to a rotary evaporator to obtain the crude product that was further re-crystallized from ethanol (The spectra given in Supporting Information).

5-Amino-3-(2-nitrophenyl)-1-phenyl-1H-pyrazole-4-carbonitrile **(4a)**: IR (KBr, cm^{-1}) 3421, 3295, 3057, 2218, 1601, 1533, 1491, 1333, 1253, 1162, 1070, 990; ^1H NMR ($CDCl_3$): δ 8.31 (s, 2H, NH_2), 8.27 (d, 1H, J = 8.0 Hz, ArH), 7.99 (d, 1H, J = 8.6 Hz, ArH), 7.60 (t, 1H, ArH), 7.40 – 7.36 (m, 2H, ArH), 7.32 – 7.25 (m, 2H, ArH), 7.13 (d, 1H, J = 8.8 Hz, ArH), 6.94 (t, 1H, ArH); HRMS (ESI-MS) (m/z): calcd for $C_{16}H_{11}N_5O_2$, 305.29; found, 306.09

5-Amino-1,3-diphenyl-1H-pyrazole-4-carbonitrile **(4b)**: IR (KBr, cm^{-1}) 3312, 3027, 2204, 1617, 1597, 1442, 1358, 1257, 1132, 1065, 928; ^1H NMR ($CDCl_3$): δ 7.65 – 7.62 (m, 3H, ArH, NH_2), 7.38 – 7.23 (m, 6H, ArH), 7.10 (d, 2H, J = 7.6 Hz, ArH), 6.8 (t, 1H, ArH); HRMS (ESI-MS) (m/z): calcd for $C_{16}H_{12}N_4$, 260.30; found, 262.12

5-Amino-3-(4-methylphenyl)-1-phenyl-1H-pyrazole-4-carbonitrile **(4c)** IR (KBr, cm^{-1}): 3306, 3026, 2914, 2117, 1595, 1483, 1252, 812; ^1H NMR ($CDCl_3$): δ 7.67 (s, 2H, NH_2), 7.55 (d, 2H, J = 8.4 Hz, ArH), 7.36 – 7.23 (m, 4H, ArH), 7.17 (d, 1H, J = 8.0 Hz, ArH), 7.10 (d, 1H, J = 8 Hz, ArH), 6.86 (t, 1H, ArH), 2.36 (s, 3H, ArH); HRMS (ESI-MS) (m/z): calcd for $C_{17}H_{14}N_4$, 274.33; found, 275.28.

3. Results and Discussion

3.1. Preparation and Characterization of Zn/Cu LDHs Catalyst

The preparation of the catalyst Zn/Cu LDHs was done according to the literature method.[39] Salts of zinc acetate dihydrate and copper acetate monohydrate were dissolved in DI water. To this solution, aqueous H_2O_2 solution was added with continuous stirring, followed by ultrasonication and stirring. This was filtered and the solid was dried at 60 °C. The obtained blue color powder

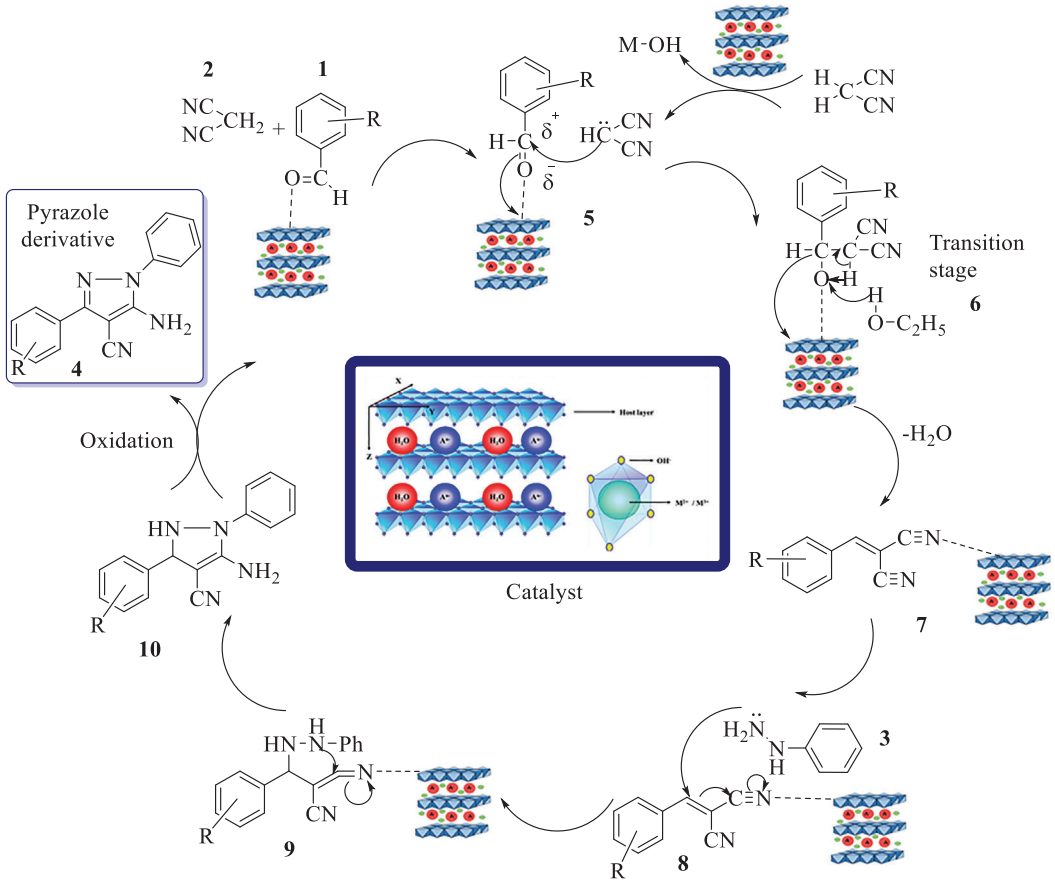

Figure 6. A proposed reaction mechanism for the synthesis of pyrazole derivatives.

was characterized with FTIR spectra, PXRD, TGA, SEM, and used for the reaction.

FTIR spectroscopy was used to analyze the presence of characteristic bands of hydrotalcite-like materials in the infrared spectrum of LDHs. In Figure 1a, the signal within the range of 3000–3500 cm^{-1} corresponds to the stretching vibrations associated with the hydrogen bonds formed by the —OH groups and water molecules present in the internal gallery region. The interlayer acetate anions are characterized by the presence of antisymmetric and symmetric stretching vibrations at 1570 and

1428 cm^{-1} respectively.[40] The bands at 1023, 693, and 615 cm^{-1} correspond to C—H rocking vibration of the CH_3 group, O—C—O bending, and CO_2^- rocking vibrations, respectively. These observations confirm the existence of interlayered water molecules and acetate anions. Additionally, a small band can also be seen around 521 cm^{-1} which can be attributed to the vibrational mode of M—O bonds.[41]

The PXRD pattern of the catalyst synthesized using the acid hydrolysis route is presented in Figure (1b). The obtained d-spacing values are also given in the PXRD pattern. The pattern shows a sharp and intense peak at 12.13° which is followed by the weak intensity peaks at 19.54, 24.22, 33.01, 35.53, and 37.86° corresponding to (002), (003), (004), (101), (006), and (103) hkl planes, respectively, confirming the formation of the lamellar structure of LDHs.[42] Furthermore, thermal analysis technique was employed to study the stability of catalyst (Figure 1c). As the temperature rises, three-level mass reduction became apparent with a total weight loss of 56%. The initial decline in mass, occurring at temperatures below 210 °C, can be attributed to the release of water from the sample, primarily situated on the surface and within the layers. The second and third degradation steps observed below 380 °C, might be associated with the dihydroxylation of brucite layers and decomposition of acetate anions, respectively.[43]

The morphology of synthesized catalyst was examined using SEM/EDX analysis technique (Figure 1d). The SEM micrograph showed that LDHs particles are present in plate-like arrangement. The elements present in the synthesized catalyst were confirmed by EDX analysis which also indicated that there exists a uniform distribution of zinc, copper, carbon, and oxygen elements in the lattice. The porosity and surface area of synthesized Zn/Cu LDHs was found to be 3.656 nm and 61.842 m^2g^{-1}, respectively as determined using adsorption-desorption isotherm (BET method). The result was in accordance with the literature value.[39] These results demonstrated that the catalyst exhibited a moderately high surface area offering ample number of active sites for the reaction to take place.

3.2. Synthesis of Pyrazole Derivatives Using LDHs Zn/Cu Catalyst

We have started the reaction with electron-withdrawing aryl aldehyde, 2-nitrobenzaldehyde (**1a**) with the view that if a reaction proceeds with this substrate, the process will be useful to another substrate also. Knoevenagel condensation is performed at room temperature using **1a** and malononitrile (**2**) reactants to yield 2-arylidenemalononitrile (**7**), which goes through a transition stage in the solvent ethanol. Further, Michael addition takes place between Knoevenagel product and phenylhydrazine (**3**) which undergoes rearrangements to give the final product, 5-amino-3-(2-nitrophenyl)-1-phenyl-1H-pyrazole-4-carbonitrile (**4a**) on oxidation.

To optimize the amount of catalyst and reaction temperature, a series of reactions were performed using reagents (**1a**), (**2**), and (**3**) over a varied range of temperature and catalyst amounts. First, we optimized the temperature by performing the reaction of **1a** with **2** and **3** using a random 40 mg of the catalyst (Table 1). We observed an increase in isolated yield in lowering the temperature from 80 °C to RT (~30 °C). Under optimized conditions, **4a** was obtained in 90% yield at RT in 12 min (Table 1, entry 8). Also, refluxing/heating to longer periods gave less yields with multiple unidentified spots on TLC. After fixing the temperature to RT, we optimized the amount of catalyst for the same reaction as 25 mg where **4a** was obtained in 92% yield (Figure 2).

The effect of solvent on the product yield was also studied which suggested that with nonpolar solvents such as toluene and benzene the product was obtained with negligible yield (Figure 3). However, polar solvents like ethanol and methanol resulted in significant yields within a short period of time as polar solvents released proton that was abstracted by oxygen of arylaldehyde (**6**) in the transition stage which undergoes rearrangement to form benzylidene malononitrile (**7**) by removing water molecule. The synthesized solid heterogeneous catalyst was recovered at the end of pyrazole synthesis, washed with ethanol, dried in the oven for 6–7 h, and reused for the conse-

quent run under vacuum at 70 °C. The dried catalyst was further reused for the next cycle of the same reaction and it showed decreasing in catalytic activity from cycle 4 (Figure 4).

The stability of the recycled catalyst was studied using FTIR and FESEM (Figure 5). The FTIR spectrum of recycled catalyst confirmed the presence of characteristic peaks of LDHs with a slight shift and weakening of the intensity of the absorption bands suggesting minor structural changes. The appearance of additional peaks can be attributed to the possible interaction between the reaction intermediates and the catalyst. Additionally, in the FESEM micrograph there appear small aggregated particles on the surface of the catalyst which may be due to the deposition of reaction residues due to chemical or thermal stress. The plate-like morphology of the LDHs is still visible, however some layers appear fragmented with rough edges.

A mechanism is proposed for the formation of highly functionalized pyrazoles using LDHs catalyst (Figure 6). In the catalyst, the metal centers (Zn/Cu) impart acidic sites and the acetate ions/ hydroxyl ions act as a weak base. The Knoevenagel condensation takes place between the arylaldehyde derivatives (**1**) and malononitrile (**2**) and the reaction is initiated by the attack of the polarized carbonyl oxygen from the arylaldehyde derivative on the metal center of the catalyst (**5**). The hydroxyl group present in the catalyst detached the acidic proton from malononitrile to produce the carbonium anion which reacts with the carbonyl group of benzaldehyde to give an intermediate or transition stage (**6**) which undergoes rearrangement to give the benzylidene malononitrile (**7**). The Michael addition takes place between benzylidene malononitrile (**7**) and phenylhydrazine (**3**) to give the Michael addition product (**10**). After that, the Michael addition product undergoes intermolecular cyclization which further undergoes rearrangement to give final product **4** on oxidation.

To observe the prosperity of the reaction, a wide variety of structurally different aromatic aldehydes, including electron releasing and electron-withdrawing substituents, were used, and gave the corresponding products in excellent yields without the formation of any major byproducts (Table 2).

4. Conclusion

We have successfully prepared the heterogenous solid catalyst, liquid double hydroxides (LDHs) of Zn/Cu, and characterized it using FTIR spectra, PXRD, TGA, and SEM. Furthermore, the prepared catalyst served as an efficient heterogenous catalyst in the preparation of pyrazole derivatives. The one-pot multicomponent cycloaddition of arylaldehyde, malononitrile, and phenylhydrazine in the presence of prepared LDHs afforded the pyrazole derivatives in 76%–94% yield. The developed procedure showed easy work up with catalyst reusability of four cycles with almost consistent catalytic efficiency.
