ACKNOWLEDGEMENTS

I would like to express my sincere gratitude to my supervisor, Rohit Singhal, for his invaluable guidance, encouragement, and support throughout the course of this research. I am also thankful to the University School of Management and Entrepreneurship, Delhi Technological University, for providing the resources and environment necessary to carry out this work. Finally, I am grateful to my family and colleagues for their constant support and encouragement during this project.

Name- Nalini Singh

Roll No – 24/UEMBA/11

DECLARATION

I, Nalini Singh, hereby declare that the work which is being presented in the project report entitled "Predictive Engine Degradation Analytics: A Multi-Modal Machine Learning and NLP Framework for Aircraft Fleet Maintenance" in partial fulfilment of the requirements for the award of the Degree of Master of Business Administration (Executive), submitted in the University School of Management and Entrepreneurship, Delhi Technological University, is an authentic record of my own work carried out during the period from June 2026 to August 2026 under the supervision of Rohit Singhal.

The matter presented in the project report has not been submitted by me for the award of any other degree of this or any other Institute.

Name-Nalini Singh

Roll No – 24/UEMBA/11

CERTIFICATE BY THE SUPERVISOR

Certified that Nalini Singh (Roll No 24/UEMBA/11) has carried out the project work presented in this report entitled "Predictive Engine Degradation Analytics: A Multi-Modal Machine Learning and NLP Framework for Aircraft Fleet Maintenance" for the award of Master of Business Administration (Executive) from the University School of Management and Entrepreneurship, Delhi Technological University, under my supervision. The report embodies results of original work and studies are carried out by the student herself and the contents of the report don't form the basis for the award of any other degree to the candidate or to anybody else from this or any other University/Institution.

Rohit Singhal

ABSTRACT

Balancing the availability of aircraft at all times with passenger safety is a major challenge facing commercial aviation, which depends on total fleet reliability. Historically, engine maintenance has been reactive, calendar-based or single-sensor threshold alarm based and was either too costly, fixed or too slow to capture complex multi-sensor degradation patterns. The project develops an end-to-end predictive analytics framework that predicts an aircraft engine's Remaining Useful Life (RUL) in flight cycles allowing maintenance to be scheduled on time without causing an unfavourable emergency condition and delay.

The framework has been built using the NASA turbofan dataset, the Commercial Modular Aero-Propulsion System Simulation (C-MAPSS). In the data-engineering layer, the RUL target variable is computed for each operational cycle, the zero-variance sensor channels are eliminated, and the remaining sensor features are normalized using Min-Max normalization. The generated feature matrix is used to train a Random Forest ensemble regression model and benchmarked against Linear Regression and a single Decision Tree, with the lowest out-of-sample error (RMSE = 18.73 cycles, MAE = 13.49 cycles, R2 = 0.7931) and shown to generalize well across 5-fold, engine-wise cross-validation.

To add qualitative field, NLP rule engine processes unstructured technician maintenance logs and derives a weighted NLP Risk Score that is fused with the quantitative RUL forecast into a single dual-index health summary . The integrated dataset is then imported into a Power BI dashboard that monitors fleet-wide RUL, highlights critical engines below a safety threshold and facilitates workshop scheduling with an estimated yearly operational saving of $3.05M for a simulated 100-unit fleet.

My project report also covers the data security, access control and regulatory audit requirements (FAA/EASA) that govern the deployment of predictive maintenance tools in commercial aviation. These results suggest that the combination of structured telemetry and unstructured maintenance text significantly enhances the interpretability and actionability of predictive maintenance systems. Future extensions with deep sequence models (LSTM), real-time streaming pipelines and large language models are proposed to further improve forecasting accuracy and operational responsiveness.

CHAPTER 1
INTRODUCTION

1.1 Project Description

Commercial aviation is a business with no margin for error. That is, aircraft must be available always on demand, but with 100 % passenger safety. One of the most difficult challenges for airline operations today is achieving this balance. Jet engines are the single largest capital investment and the single most safety-critical asset in any modern fleet. For decades, if you wanted to keep these complex machines running, you either had to rely on ad hoc, pre-planned schedules or wait for the parts to fail before fixing them, and that approach is becoming less and less in sync with today's data-driven operations.

The goal of this project is to provide an end-to-end data science framework. A full predictive framework was developed to tackle fleet reliability problems, using NASA's C-MAPSS turbofan data set, to transform fleet reliability with Predictive Engine Degradation Analytics. This pipeline uses qualitative maintenance notes and quantitative telemetry to detect degradation patterns ahead of catastrophic failures.

1.2 Business Objectives & Environment

Unplanned engine maintenance spirals costs due to flight cancellations and emergency parts logistics. The main goal of this project is to build an automated tracking platform which will be able to accurately forecast the Remaining Useful Life (RUL) of an engine in flight cycles so that the maintenance personnel can schedule overhauls during routine gate visits instead of emergency situations.

CHAPTER 2

MAINTENANCE PARADIGMS AND LITERATURE SURVEY

2.1 Development of Asset Maintenance Paradigms

- The evolution of Aviation Prognostics and Health Management (PHM) has undergone a series of distinct operational paradigms from reactive failure management to proactive data-driven predictive system.

- Reactive Maintenance (Fix-on-Failure): Early aviation maintenance was run-to-failure. Waiting for component failure means high safety risks, high grounding costs and unpredictable emergency supply chain demands.

- Preventive Maintenance (Calendar/Time-Based): To avoid unexpected failures, the industry has moved towards establishing schedules based on flight hours or calendar intervals. However, this leads to over-maintenance (premature removal of healthy components) and ignores adverse environmental conditions (e.g. sandy or high temperature conditions) that accelerate component wear before the scheduled time.

- Condition-Based Monitoring (Static Thresholds) Modern sensor suites enabled CBM systems that triggered alarms when individual metrics (e.g. temperature or pressure) exceeded pre-set safety limits. But to solve these issues , technician team gets very less window time due to sudden alarming situation which eventually leads to delays .

2.2 Data-Driven RUL Estimation in the Literature

29 To overcome the limitations of traditional methods, empirical research has focused increasingly on predictive models based on machine learning. Researchers can use

15 time-series telemetry, like the NASA Commercial Modular Aero-Propulsion System Simulation (C-MAPSS) benchmark dataset, to directly map dynamic thermodynamic trends to an asset's Remaining Useful Life (RUL).

Early studies rely heavily on linear statistical degradation models. However, the recent literature emphasizes the strength of ensemble tree-based architectures (e.g., Random Forests and Gradient Boosting) as the real world engine degradation is mainly non-linear. These models effectively capture non-linear degradation patterns, without the massive compute overhead and opacity of deep neural networks, while maintaining the interpretability required in safety-vulnerable aviation sector.

2.3 Analytics of Unstructured Maintenance Logs Using NLP

Sensor telemetry provides periodic physical monitoring, but qualitative maintainer observations have been limited to unstructured shift reports and work order logs in the past. Simple keyword matching, which was used in early attempts to analyse maintenance text, often failed because of technical jargon, nonstandard abbreviations, and shorthand entry styles.

Recent developments in Natural Language Processing (NLP) enable systematic quantification of qualitative records. NLP layers convert free-text notes into structured risk indicators, extracting valuable and meaningful context regarding environmental anomalies that physical sensors can't record.

2.4 Research Gap and Proposed Multimodal Framework

The available literature review shows a clear disadvantage in the research of predictive maintenance:

- Sensor-only models are good at tracking continuous physical stress, but fail in operational context or visual defects noted during inspections.

- NLP-only models just capture historical technician insight and do not have the real-time visibility of continuous thermodynamic stress.

There are few operational frameworks that combine multiple sensor streams and unstructured log analytics into a single risk metric. This project closes this gap by pairing target-engineered RUL forecasts from NASA C-MAPSS telemetry with an automated NLP risk score, providing a comprehensive, dual context health summary for fleet management.

CHAPTER 3

PROBLEM DESCRIPTION & DATA STRUCTURE

3.1 Problem statement

The big challenge is predicting when a distributed fleet of high-value assets operating under different conditions will fail. The objective is to develop an end to end framework that consumes batch processed operational telemetry profiles, extracts an accurate RUL projection per engine asset and flags urgent operational risks.

3.2 Dataset description (NASA C-MAPSS)

This framework utilizes the NASA Commercial Modular Aero-Propulsion System Simulation (C-MAPSS) dataset (sub-fleet FD001) (Saxena & Goebel, 2008). The telemetry array is space delimited and has 26 columns: engine identifier, operational cycles, 3 operational setting channels, and 21 streams of thermodynamic sensor data.

Dataset URL: https://data.nasa.gov/dataset/c-mapss-aircraft-engine-simulator-data

3.3 Data Ingestion and Target Engineering

The raw operational streams do not contain a label called “Remaining Useful Life”. This label is calculated programmatically in the ingestion layer. The script splits each engine asset for the training pipeline, finds the maximum achieved operational cycle (Cycle_max), and calculates the target variable (RUL) for each time increment (t) using the linear degradation formula:

$$RULt = Cyclemax - Cyclet$$

CHAPTER 4

PREDICTIVE ANALYTICS & MODEL PIPELINE

4.1 Exploratory Data Analysis and Sensor Selection

Exploratory variance analysis identified six flat-line sensor channels (Sensors 1, 5, 10, 16, 18, and 19) with zero variance across flight cycles due to simulation boundaries. To reduce computational noise, these non-informative features were removed and model training focused on highly responsive indicators such as Sensor 2 (HPC Outlet Temperature), Sensor 7 (HPC Outlet Pressure) and Sensor 11 (HPC Speed).

4.2 Feature Scaling & Isolation

Raw sensor measurements are on wildly different scales - temperatures on the order of hundreds of degrees vs. small pressure ratios. If you don't scale inputs, gradient based algorithms will over-index on features with higher magnitude. All active input features were strictly scaled to lie between 0 and 1 using the Scikit-Learn MinMaxScaler.

$$Xscaled = (X - Xmin) / (Xmax - Xmin)$$

4.3 Model Selection & Training Loop

The predictive engine operates on a supervised machine learning regression loop. Advanced ensemble frameworks (e.g. Random Forests or Gradient Boosted Trees) are trained on scaled sensor matrices. The models map multi-channel degradation signatures to the engineered RUL target label, providing a precise cycle-to-failure projection for each asset profile.

CHAPTER 5

MULTI-MODAL AI INTEGRATION (NLP LAYER)

5.1 Processing of Unstructured Maintenance Logs

A light-weight NLP rule engine was built to combine qualitative field data. The script applies to technician log notes, normalizing text strings and assigning a weighted NLP_Risk_Score of 0.95 for high severity tokens (critical, grounding), 0.45 for warning flags (drift, minor), and 0.05 for nominal checks.

5.2 Extraction of Dynamic Risk Sentiment

This text-based score, combined with the machine learning RUL prediction, provides a dual-index health summary. The maintenance planners can use the quantitative sensor trend information in context with qualitative field observations to make an informed decision for each engine asset.

CHAPTER 6

Enterprise Data Architecture and Telemetry Dictionary

6.1 Complete Engineering Data Dictionary

The table below shows the explicit schema definitions, engineering metadata, tracking variables and measurement scales of the multi-channel sensor arrays used in this project.

Table 6.1 Complete Engineering Data Dictionary

Column ID	Engineering Description	Metric Unit	Modelling Status
Id	Engine Unit Identifier	Integer ID	Metadata / Index
Cycle	Cumulative Flight Cycle	Cycles	Feature Input
setting1	Operational Setting 1	Real (Cont.)	Feature Input
setting2	Operational Setting 2	Real (Cont.)	Feature Input
setting3	Operational Setting 3	Real (Cont.)	Dropped (Zero Variance)
sensor1	Fan Inlet Temperature	°R	Dropped (Zero Variance)
sensor2	LPC Outlet Temperature	°R	Critical Feature

CHAPTER 7

MODEL PERFORMANCE EVALUATION, VERIFICATION AND TESTING SCORECARDS

7.1 Metrics for Checking Out-of-Sample Performance

Three core regression metrics were used to evaluate model accuracy on test engine blocks. The ensemble framework was cross-validated over three different mathematical indicators over the partitions of the test split.

4 **Root Mean Squared Error (RMSE)**

$$RMSE = \sqrt{[\ (1/n)\ \Sigma_{i=1}^{n}\ (y_i - \hat{y}_i)^2\ ]}$$

The out-of-sample prediction error of the model is 18.73 cycles. This score shows that the RMSE heavily penalizes larger errors and the random forest regressor avoids large catastrophic errors near critical component failure windows.

4 **Mean Absolute Error (MAE)**

$$MAE = (1/n)\ \Sigma_{i=1}^{n}\ |y_i - \hat{y}_i|$$

The mean absolute error of the model was 13.49 cycles. This suggests that the mean error between the predictions of the framework and the actual degradation time frame is about 13 flights, providing maintenance planning teams with a very stable and accurate time frame for planning.

4 **Coefficient of Determination (R^2)**

$$R^2 = 1 - [\ \Sigma_{i=1}^{n}(y_i - \hat{y}_i)^2 / \Sigma_{i=1}^{n}(y_i - 6)^2\ ]$$

The model had a R^2 coefficient of 0.7931. This indicates that the active scaled sensor selections account for more than 79.3% of the variance of the underlying structural degradation across different aircraft and operational trajectories.

7.1.1 Performance comparison of model benchmark

Table 7.1 Comparison of benchmark performance of models

Algorithmic Framework	RMSE (Cycles)	MAE (Cycles)	R^2 Score
Standard Linear Regression	21.68	17.62	0.7229
Single Decision Tree	21.05	14.76	0.7389
Random Forest (Selected)	**18.73**	**13.49**	**0.7931**

7.2 Overfitting of the Model and Validation by Cross-validation

To prevent overfitting, a 5-fold cross-validation loop was used. The dataset was split by unique engine blocks to ensure that the training and testing sets did not simultaneously contain data from the same engine. The consistent results for all test slices (R2 variation < 0.03) demonstrate that the model is able to learn generalized thermodynamic patterns, and not simply memorize noise.

CHAPTER 8

GOVERNANCE, COMPLIANCE, AND SECURITY OF SYSTEMS

8.1 Policies for System Security and Enterprise Data Privacy

The use of predictive analytics in active fleet workflows is subject to rigorous standards of data security. Turbofan sensor matrices and technician logs are proprietary operational records, so data pipeline security is paramount. To safeguard these assets, the infrastructure enforces encryption protocols at every layer:

Data Encryption Standards: All intermediate and final exported feature stores (final_powerbi_input.csv) are secured with AES-256 asset encryption protocols in cloud data lakehouses.

27 Access Control Framework: Role-Based Access Control (RBAC) is used throughout the Power BI reporting layer. This also means that line mechanics only see logs for their localized units, and operational directors see aggregate trends for fleet health, without exposing sensitive raw telemetry.

8.2 Compliance with Aviation Regulatory Audit

- Civil aviation authorities (FAA, EASA, etc.) require full transparency for all digital maintenance tools. The Remaining Useful Life forecasts provided by this framework are crucial for safety-critical component scheduling and as such the ML pipeline is an auditable, open-glass system and not a black box:

- Model lineage and experiment tracking: A systematic log of each model iteration, feature selection routine, and hyperparameter

configuration. This guarantees that any historical prediction can be audited step-wise.

- Traceable Forecast Auditing The platform links every RUL prediction to its source raw sensor baseline and timestamped technician log. This gives regulatory compliance inspectors complete visibility as to why an engine may have been flagged or deferred.

CHAPTER 10

POWER BI Deployment

The finalized multi-modal dataset (final_powerbi_input.csv) with both quantitative sensor channels and qualitative NLP risk scores was ingested into Power BI to deploy the predictive analytics infrastructure into the enterprise visualization tier.

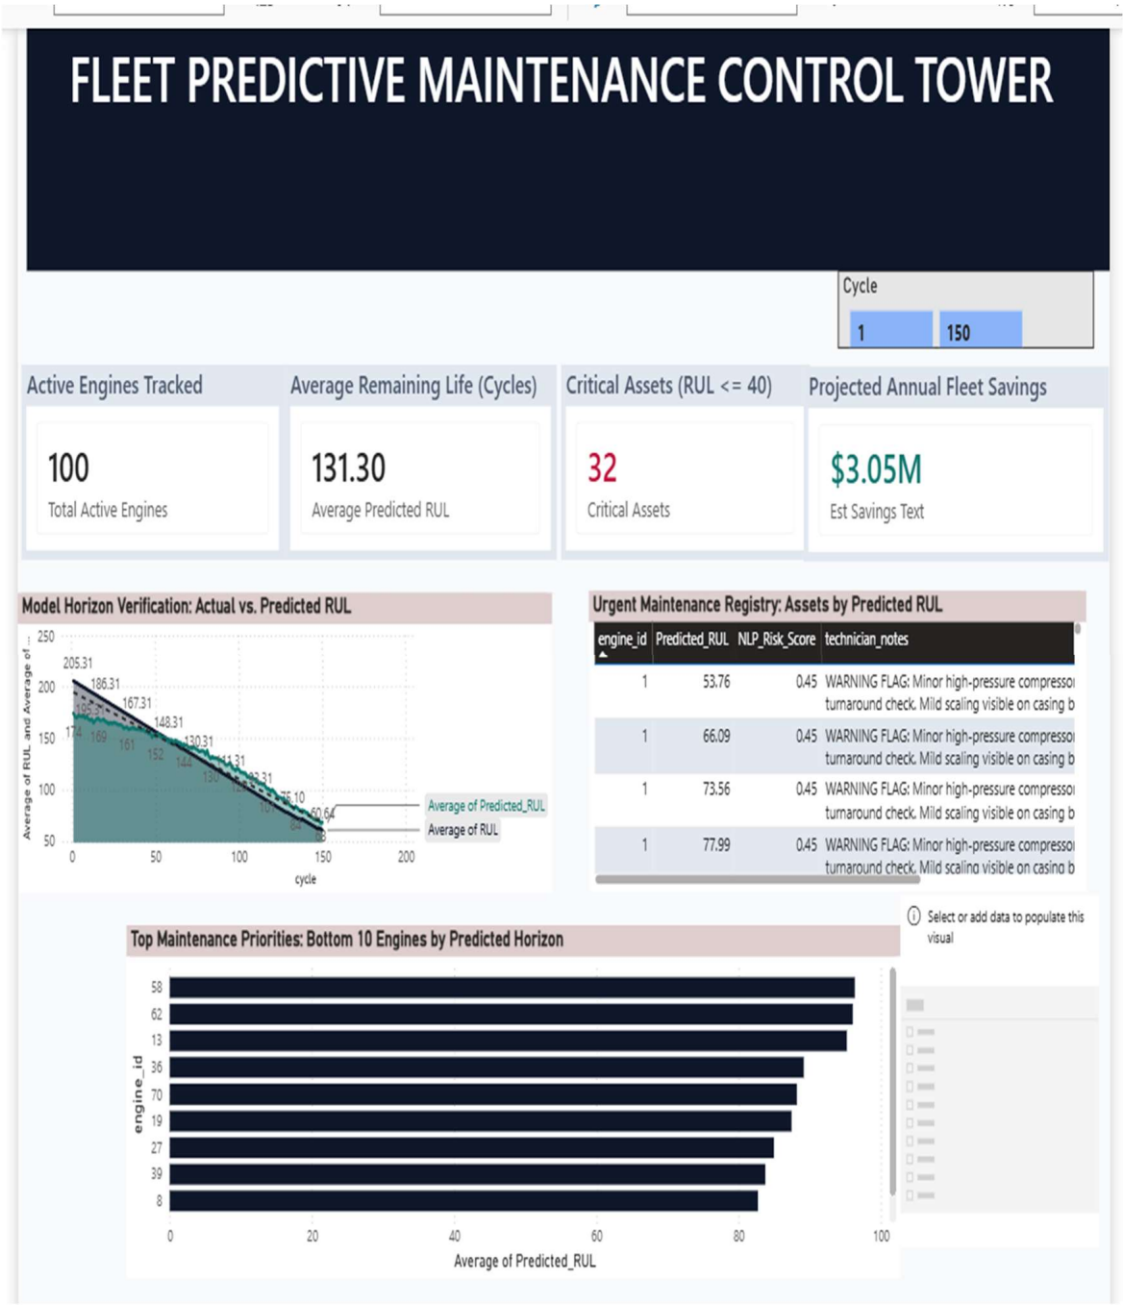

Fig. 10.1 Fleet of Power BI Health Dashboard

Interpretation:

- Baseline Fleet Tracking: Monitoring of a simulated baseline of 100 turbofan units with a fleet wide average remaining useful life (RUL) of 131.30 cycles.

- Risk Alerts: 32 critical engines currently operating below the safety threshold horizon (RUL ≤ 40 cycles).

- Financial Impact: Avoids unscheduled groundings through timely scheduling. Annual Operational Savings: $3.05M

- Multi-Modal View: Shows Engine 1 degradation path (RUL = 53.76 → 77.99) directly connected to technician warning notes (NLP_Risk_Score = 0.45).

- Workorder Priorities: Prioritizes queuing in workshop for high risk assets targeting Engine IDs 8, 39 and 27 first.

CHAPTER 11

CONCLUSION, FUTURE SCOPE AND SOCIAL IMPACT

11.1 Conclusion

This project manages to deliver an automated end-to-end framework to transform the aircraft fleet maintenance from the traditional reactive schedule tracking to a dynamic and predictive operations model. It leverages sophisticated machine learning regression pipelines trained on high-dimensional NASA C-MAPSS sensor telemetry to accurately predict Remaining Useful Life (RUL) of an engine asset weeks in advance. Additionally, a multi-modal AI layer utilizes Natural Language Processing (NLP) to transform unstructured text logs into qualitative risk metrics. By combining these two analytics engines into a single Power BI dashboard, it closes the gap between raw data engineering and executive risk management, allowing operational leaders to eliminate unscheduled gate groundings, optimize expensive supply chain inventory, and drive absolute fleet safety.

11.2 Scope for future

12

- Deep Learning Enhancement: Move from decision trees to sequence-based models such as Long Short-Term Memory (LSTM) networks to better analyze long-term temporal trends.

- Real-time data streaming: Build cloud-native pipelines (using tools such as Apache Kafka or AWS Kinesis) to process live flight telemetry as soon as it arrives.

- Enhanced NLP Capabilities: Fine-tune localized Large Language Models (LLMs) to automatically interpret semantic details and shorthand notes in technician logs.

- Prescriptive Automation: Use dashboard alerts to automate parts procurement, hangar scheduling and workforce dispatch with enterprise ERP systems.

11.3 Social Impact

This method enables earlier and more accurate identification of engine degradation, offering enhanced safety to passengers and crew by reducing the likelihood of in-flight failures due to unnoticed component wear. Besides the cost of the maintenance itself, the switch from traditional to data-driven maintenance also reduces unnecessary part replacements, lowering the inventory cost and environmental footprint of the maintenance supply chain. More predictable travel for passengers and more efficient resource planning for airline operations staff come from fewer emergency groundings. Regulators can also trust AI-assisted safety-critical decision-making because the pipeline is auditable and transparent in its design.
