PREFACE

This is the **Ninety first** Issue of Current Awareness Bulletin started by Delhi Technological University, Central Library. The aim of the bulletin is to compile, preserve and disseminate information published by the faculty, students and alumni for mutual benefits. The bulletin also aims to propagate the intellectual contribution of Delhi Technological University (DTU) as a whole to the academia.

The bulletin contains information resources available in the internet in the form of articles, reports, presentations published in international journals, websites, etc. by the faculty and students of DTU. The publications of faculty and student which are not covered in this bulletin may be because of the reason that the full text either was not accessible or could not be searched by the search engine used by the library for this purpose.

The learned faculty and students are requested to provide their uncovered publications to the library either through email or in CD, etc. to make the bulletin more comprehensive.

This issue contains the information published during **July, 2020**. The arrangement of the contents is alphabetical. The full text of the article which is either subscribed by the university or available in the web is provided in this bulletin.

Central Library

CONTENTS

1. A Comparative Study of Image Dehazing Algorithms, ***3.Anil Singh Parihar***, ***8.Yash Kumar Gupta***, ***8.Yash Singodia***, ***8.Vibhu Singh*** and ***6.Kavinder Singh***, Computer, DTU

2. A Detailed Study on Generative Adversarial Networks, ***3.Shailender Kumar*** and ***7.Sumit Dhawan***, Computer, DTU

3. Adaptive Droop based Control for Active Power Sharing in Autonomous Microgrid for Improved Transient Performance, Surya Prakash, ***8.1.Vaibhav Nougain***, and Sukumar Mishra, Electrical, DTU

4. An Embedding-based Deep Learning Approach for Movie Recommendation, ***3.Ram Murti Rawat***, ***8.Vikrant Tomar*** and ***8.Vinay Kumar***, Computer, DTU

5. Analysis of demand risks for the Indian automotive sector in globally competitive environment, ***3.Girish Kumar***, Rajesh Kr. Singh, ***8.1.Rishabh Jain***, ***8.Raman Kain*** and ***8.Naveen***, Mechanical, DTU

6. Analysis of Total Quality Management (TQM) Barriers on its Performance using TOC, ***6.Rakesh Kumar*** and ***3.R.S. Mishra***, Mechanical, DTU

7. Anomalous Object Tracking in Distributed Camera Network, ***8.MD Shahbaz Khan*** and ***3.Indu Sreedevi***, DTU

8. Arduino GSM based Power Theft Detection and Energy Metering System, ***8.Vivek Kumar Jaiswal***, ***6.Hritik Kumar Singh*** and ***3.Kuldeep Singh***, Electrical, DTU

9. Best criteria selection based PROMETHEE II method, ***6.Anjali Singh***, ***3.Anjana Gupta*** and Aparna Mehra, Mathematics, DTU

10. Breast cancer burden in Africa: evidence from GLOBOCAN 2018, ***3.Rajesh Sharma***, USME, DTU

11. Capsmf: a novel product recommender system using deep learning based text analysis model, ***3.Rahul Katarya[1]*** and ***7.1.Yamini Arora[2]***, Computer[1] and IT[2], DTU

12. Citation-Based Scientific Paper Summarization Using Game Theory, ***3.Anil Singh Parihar***, ***6.Anjali Jain*** and ***8.1.Archit Gupta***, Computer, DTU

13. Comparative Analysis of PWM Techniques and SVPWM operated V/f control of Induction Motor having different power ratings, ***8.Divyam***, ***8.1.Ayushi Saxena***, ***6.Bharat Singh*** and ***3.J. N. Rai***, Electrical, DTU

14. Comparative Analysis of Route Planning Algorithms on Road Networks, ***3.R. K. Yadav***, ***8.Giriraj Kishor***, ***8.Himanshu*** and ***8.Kishan Kashyap***, Computer, DTU

15. Comparative Study of Static VAR Compensation Techniques – Thyristor Switched Reactor and Thyristor Switched Capacitor, ***8.Divyam***, ***8.1.Ayushi Saxena***, ***6.Bharat Singh*** and ***3.J. N. Rai***, Electrical, DTU

16. Comparative study on air quality status in Indian and Chinese cities before and during the COVID-19 lockdown period, ***8.Aviral Agarwal***, Aman Kaushik, ***8.Sankalp Kumar*** and ***3.Rajeev Kumar Mishra***, Environmental, DTU

17. Control and Design of Seven-Level Cascaded Multilevel Converter for Transformerless Large-Scale Photovoltaic Integration, ***6.Jyoti Kulkarni***, ***3.Narendra Kumar*** and Bhim Singh, Electrical, DTU

18. COVID 19 Global Pandemic: Impact on Management of Supply Chain, ***6.Rakesh Kumar*** and ***3.R.S. Mishra***, Mechanical, DTU

19. Deep Learning Approach for Arbitrary Image Style Fusion and Transformation using SANET model, ***7.Pratibha Rathi***, ***7.Pranav Adarsh*** & ***3.Dr. Manoj Kumar***, Computer, DTU

20. Dementia Detection Using Machine Learning by Stacking Models, ***3.Ram Murti Rawat***, ***8.Mohammad Akram***, ***8.Mithil*** and ***8.Setti Suneel Pradeep***, Computer, DTU

21. Descriptive epidemiology of incidence and mortality of primary liver cancer in 185 countries: evidence from GLOBOCAN 2018, ***3.Rajesh Sharma***, USME, DTU

22. Design and analysis of a dual-polarization multiband oval ring patch antenna with L-stubs and folded meander line for C-band/X-band/ Kuband/ K-band communications, ***6.Karteek Viswanadha*** and ***3.N.S.Raghava***, Electronics, DTU

23. Detecting Intrusions and Attacks in the Network Traffic using Anomaly based Techniques, ***3.Vinod Kumar***, ***8.Vinay Choudhary***, ***8.Vivek Sahrawat*** and ***8.Vinay Kumar***, Computer, DTU

24. Developing a framework for evaluating sustainability index for logistics service providers: graph theory matrix approach, ***6.Anchal Gupta*** and Rajesh Kumar Singh, DTU

25. Disease Detection in Coffee Plants Using Convolutional Neural Network, ***3.Manoj Kumar***, ***8.Pranav Gupta***, ***8.Puneet Madhav*** and ***8.Sachin***, Computer, DTU

26. Dual-Modal Emotion Recognition Using Discriminant Correlation Analysis, ***3.Dr. Rajiv Kapoor***, ***8.Suhail Saifi***, ***8.Tarun Kapoor***, ***8.Utkarsh Bisaria*** and ***8.Nikhil Singh***, Electronics, DTU

27. Effect of Distributed Damping on the Dynamic Behavior of Flexible Chassis of Heavy Road Vehicle Under Standardized Random Road Responses, Ashish Gupta and ***3.Vikas Rastogi***, Mechanical, DTU

28. Effect of friction stir processing on mechanical properties and heat transfer of TIG welded joint of AA6061 and AA7075, ***6.Husain Mehdi*** and ***3.R.S. Mishra***, Mech, DTU

29. Effect of Mesh Size on Soil-Structure Interaction in Finite Element Analysis, ***7.Nasasira Derrick*** and ***3.Amit Kumar Srivastava***, Civil, DTU

30. Efficient strip to slot waveguide mode converter using fast quasi-adiabatic approach, Nikhil Dhingra, Geetika Jain Saxena, ***3.Kamal Kishor*** and Enakshi Khular Sharma, Physics, DTU

31. Energy Efficient Transmission Trends Towards Future Green Cognitive Radio Networks (5G): Progress, Taxonomy and Open Challenges, ***6.Akanksha Srivastava***, Mani Shekhar Gupta and Gurjit Kaur, Electronics, DTU

32. Ensemble learning-based approach for crack detection using CNN, ***8.Vibhu Kailkhura***, ***8.S. Aravindh***, ***8.Shashank Shekhar Jha*** and ***3.N. Jayanthi***, Electronics, DTU

33. Environment Monitoring System for Agricultural Application using IoT and Predicting Crop Yield using Various Data Mining Techniques, ***8.Gautam Gupta***, ***8.Rashi Setia***, ***8.Archana Meena*** and ***3.Bhavnesh Jaint***, Electrical, DTU

34. Estimation of COVID-19 Prevalence under Closed Population using Capture-Recapture approach, ***6.Rakesh Kumar*** and ***3.R.S.Mishra***, Mechanical, DTU

35. Experimental studies of vapour compression refrigeration system with eco-Friendly primary refrigerant and brine mixed with nano particles as secondary refrigerant, Uma Shankar Prasad, ***3.R.S. Mishra*** and R.K. Das, Mechanical, DTU

36. Experimental Validation of Fully Informed Particle Swarm Optimization Tuned Multi-Loop L-PID Controllers for Stabilization of Gantry Crane System, ***3.Sudarshan K Valluru***, ***8.Daksh Dobhal***, ***8.Kumar Kartikeya***, ***8.Manpreet Kaur***, ***3.Madhusudan Singh*** and ***8.Arnav Goel***, DTU

37. Filter Based Scalable Blockchain for Domestic Internet of Things, ***8.Aditya Shyam Bazari***, ***8.Aditya Singh***, ***8.Abdul Ahad Khan*** and ***3.Rajni Jindal***, Computer, DTU

38. FLEXIBLE SOLAR POWER TREE - A CONCEPT, Mukesh Kumar, ***3.J P Kesari*** and Lokesh Rana, Mechanical, DTU

39. Forecasting the Probability of Cost Overrun Risk of Indian Construction Projects using Fuzzy Model, Savita Sharma, ***3.Pradeep K. Goyal*** and R.C. Chhipa, Civil, DTU

40. Fuzzy Logic based Automatic Generation Control, ***8.MD Shadan Salik***, ***8.Shaurya Priyal***, ***8.1.Neha Khokher*** and ***3.DR. Narendra Kumar***, Electrical, DTU

41. Generating Visible Spectrum Images from Thermal Infrared using Conditional Generative Adversarial Networks, ***8.Neeraj Bhat***, ***8.Navneet Saggu***, ***8.Pragati*** and ***3.Sanjay Kumar***, Computer, DTU

42. GloVeInit at SemEval-2020 Task 1: Using GloVe Vector Initialization for Unsupervised Lexical Semantic Change Detection, ***8.Vaibhav Jain***, Computer and Mathematics, DTU

43. Gratitude, social intelligence, and leadership among university teachers: mediation and moderation analysis, ***3.Naval Garg***, Anuradha Jain and B.K. Punia, USME, DTU

44. Implementation Strategy for Resource Optimization of FPGA-Based Adaptive Finite Control Set-MPC using XSG for a VSI System, Vijay Kumar Singh, ***7.1.Ravi Nath Tripathi***, and Tsuyoshi Hanamoto, Electrical, DTU

45. Modelling and optimisation of magnetic abrasive finishing process based on a non-orthogonal array with ANN-GA approach, ***6.S. Ahmad*** , ***3.R. M. Singari*** and ***3.R.S. Mishra***, Mechanical, DTU

46. Modelling Logistic Growth Model for COVID-19 Pandemic in India, ***3.Minni Jain***, ***8.Prajwal Kumar Bhati***, ***8.Pranav Kataria*** and ***8.Rohit Kumar***, CSE, DTU

47. Morphological and Swelling Potential Evaluation of Moringa oleifera Gum/Poly(vinyl alcohol) Hydrogels as a Superabsorbent, Suhail Ahmad, Kaiser Manzoor, ***3.Roli Purwar*** and Saiqa Ikram, Chemistry, DTU

48. Multi-dimensional aggregation: a viable solution for interval data, ***3.Shailender Kumar***, Computer, DTU

49. Node Classification in Complex Networks using Network Embedding Techniques, ***3.Sanjay Kumar***, ***8.Sanidhya Chaudhary***, ***8.Saksham Kumar*** and ***8.Raj Kumar Yadav***, Computer, DTU

50. Nonlinear dynamics of a time-delayed epidemic model with two explicit aware classes, saturated incidences, and treatment, ***6.Kanica Goel***, Abhishek Kumar and ***3.Nilam***, Mathematics, DTU

51. Numerical heat transfer analysis & predicting thermal performance of fins for a novel heat exchanger using machine learning, ***7.Gaurav Krishnayatra***, ***7.Sulekh Tokas*** and ***3.Rajesh Kumar***, Mechanical, DTU

52. On Black–Scholes option pricing model with stochastic volatility: an information theoretic approach, ***6.Luckshay Batra*** and ***3.H. C. Taneja***, Mathematics, DTU

53. ON CERTAIN GENERALIZATIONS OF S, ***3.S. SIVAPRASAD KUMAR*** AND ***6.KAMALJEET GANGANIA***, Mathematics, DTU

54. On the Outage Probability and BER of a DF-Based Multi-Hop System Over and □ □ -Extreme Fading Channels, Tau Raphael Rasethuntsa, ***8.Manpreet Kaur*** and Sandeep Kumar, Computer, DTU

55. Performance analysis of beamforming aided uncorrelated mm-Wave MIMO system for IEEE 802.15.3c standard, Anand Agrawal, Vimal Kumar Mishra, Ashish Gupta and ***6.1.Bajrang Bansal***, Electronics, DTU

56. Performance of Masonry Infill Framed Structures During Earthquake: A State-Of-The-Art Review, Priyanka, ***3.Alok Verma*** and Shobha Ram, Civil, DTU

57. PMS-Sharing : Framework for Automatically Authenticating users in a Group to Allow Sharing Storage, Nitesh Suthar and ***3.Rajesh Kr. Yadav***, Computer, DTU

58. Predicting Link Sign in Online Social Networks based on Social Psychology Theory and PageRank, ***3.Sanjay Kumar***, ***8.Sudhanshu Shekhar Singh*** and ***8.Vipul Gupta***, Computer, DTU

59. Real Time Experimental control and Design of FOP□□ and L-PID Controllers tuned by Invasiveweed optimization for Trajectory Control of TRAS, ***7.1.Hem Prabha*** and ***8.Rajul Kumar***, Electrical, DTU

60. Realization of Regula-Falsi Iteration based Double Precision Floating Point Division, ***8.Riya Jain*** and ***3.Neeta Pandey***, Electronics, DTU

61. Real-Time Implementation of the Optimal Predictor and Optimal Filter: Accuracy Versus Latency, SYED ASEEM UL ISLAM, ***8.1.ANKIT GOEL*** and DENNIS S. BERNSTEIN, Mechanical, DTU

62. Selection of sustainable transport system: a case study, ***8.Abhishek Singh***, Amulya Gurtu and Rajesh Kumar Singh, Civil and Environment, DTU

63. SIX SIGMA APPLICATION IN KETCHUP INDUSTRY FOR DAMAGED GLASS BOTTLES: A CASE STUDY, ***8.1.YATHARTH SHARMA***, ***8.SARMAD HASSAN*** and ***8.RAJAT KUMAR***, Mechanical, DTU

64. Sodium hydroxide effect on the mechanical properties of flyash-slag based geopolymer concrete, ***6.Manvendra Verma*** and ***3.Nirendra Dev***, Civil, DTU

65. Spatial Landslide Risk Assessment at Phuentsholing, Bhutan, Abhirup Dikshit, ***3.Raju Sarkar***, Biswajeet Pradhan, Saroj Acharya and Abdullah M. Alamri, Civil, DTU

66. SUBORDINATION AND RADIUS PROBLEMS FOR CERTAIN STARLIKE FUNCTIONS, ***3.S. SIVAPRASAD KUMAR*** AND ***6.KAMALJEET GANGANIA***, Mathematics, DTU

67. Suppression of Lower Order Harmonics for the full modulation range for a 2-level inverter fed IM drive with a switched capacitive filter technique forming a 42-sided Voltage Space Vector Structure, ***7.1.Rahul Dewani***, Rakesh R, K. Gopakumar, Umanand Loganathan Dariusz Zielinski and Leopoldo G. Franquelo, Electronics, DTU

68. The prospective application of a graphene/MoS2 heterostructure in Si-HIT solar cells for higher efficiency, Chandra Kamal Borah, ***3.Pawan K. Tyagi*** and Sanjeev Kumar, Physics, DTU

69. Theoretical analysis for transmission of Gaussian and sine time irradiance of electromagnetic beam in collisional dusty plasmas, ***6.Ruchi Sharma*** and ***3.Suresh C. Sharma***, Applied Physics, DTU

70. Theoretical Framework of Collaboration between MSME and Private Engineering Colleges to Co-exist during COVID-19, ***3.Seema Singh***, Humanities, DTU

71. Towards Social & Engaging Peer Learning: Predicting Backchanneling and Disengagement in Children, ***8.Mononito Goswami***, ***8.Minkush Manuja*** and ***8.Maitree Leekha***, Computer, DTU

72. Tribological characterisation of thermal sprayed CrC alloyed coating – A review, ***6.Navendu Gupta***, Shailesh Kumar Singh and Shailesh Mani Pandey, Mechanical, DTU

73. Ubiquitin biology in neurodegenerative disorders: From impairment to therapeutic strategies, ***6.Dhiraj Kumar***, ***6.Rashmi K. Ambasta*** and ***3.Pravir Kumar***, Biotechnological, DTU

74. Women Empowerment in India: A Critical Analysis, ***3.Seema Singh*** and ***6.Antra Singh***, Economics, DTU

1. *Chancellor*

2. *Pro Vice Chancellor*	***2.1.*** *Ex Pro Vice Chancellor*
3. *Faculty*	***3.1.*** *Ex Faculty*
4. *Teaching-cum-Research Fellow*	***4.1.****Asst. Librarian*
5. *Alumni*	
6. *Research Scholar*	***6.1.*** *Ex Research Scholar*
7. *PG Scholar*	***7.1.*** *Ex PG Scholar*
8. *Undergraduate Student*	***8.1.*** *Ex Undergraduate Student*

PREFACE

This is the **Ninety first** Issue of Current Awareness Bulletin started by Delhi Technological University, Central Library. The aim of the bulletin is to compile, preserve and disseminate information published by the faculty, students and alumni for mutual benefits. The bulletin also aims to propagate the intellectual contribution of Delhi Technological University (DTU) as a whole to the academia.

The bulletin contains information resources available in the internet in the form of articles, reports, presentations published in international journals, websites, etc. by the faculty and students of DTU. The publications of faculty and student which are not covered in this bulletin may be because of the reason that the full text either was not accessible or could not be searched by the search engine used by the library for this purpose.

The learned faculty and students are requested to provide their uncovered publications to the library either through email or in CD, etc. to make the bulletin more comprehensive.

This issue contains the information published during **July, 2020**. The arrangement of the contents is alphabetical. The full text of the article which is either subscribed by the university or available in the web is provided in this bulletin.

Central Library

CONTENTS

1. A Comparative Study of Image Dehazing Algorithms, ***3.Anil Singh Parihar***, ***8.Yash Kumar Gupta***, ***8.Yash Singodia***, ***8.Vibhu Singh*** and ***6.Kavinder Singh***, Computer, DTU

2. A Detailed Study on Generative Adversarial Networks, ***3.Shailender Kumar*** and ***7.Sumit Dhawan***, Computer, DTU

3. Adaptive Droop based Control for Active Power Sharing in Autonomous Microgrid for Improved Transient Performance, Surya Prakash, ***8.1.Vaibhav Nougain***, and Sukumar Mishra, Electrical, DTU

4. An Embedding-based Deep Learning Approach for Movie Recommendation, ***3.Ram Murti Rawat***, ***8.Vikrant Tomar*** and ***8.Vinay Kumar***, Computer, DTU

5. Analysis of demand risks for the Indian automotive sector in globally competitive environment, ***3.Girish Kumar***, Rajesh Kr. Singh, ***8.1.Rishabh Jain***, ***8.Raman Kain*** and ***8.Naveen***, Mechanical, DTU

6. Analysis of Total Quality Management (TQM) Barriers on its Performance using TOC, ***6.Rakesh Kumar*** and ***3.R.S. Mishra***, Mechanical, DTU

7. Anomalous Object Tracking in Distributed Camera Network, ***8.MD Shahbaz Khan*** and ***3.Indu Sreedevi***, DTU

8. Arduino GSM based Power Theft Detection and Energy Metering System, ***8.Vivek Kumar Jaiswal***, ***6.Hritik Kumar Singh*** and ***3.Kuldeep Singh***, Electrical, DTU

9. Best criteria selection based PROMETHEE II method, ***6.Anjali Singh***, ***3.Anjana Gupta*** and Aparna Mehra, Mathematics, DTU

10. Breast cancer burden in Africa: evidence from GLOBOCAN 2018, ***3.Rajesh Sharma***, USME, DTU

11. Capsmf: a novel product recommender system using deep learning based text analysis model, ***3.Rahul Katarya[1]*** and ***7.1.Yamini Arora[2]***, Computer[1] and IT[2], DTU

12. Citation-Based Scientific Paper Summarization Using Game Theory, ***3.Anil Singh Parihar***, ***6.Anjali Jain*** and ***8.1.Archit Gupta***, Computer, DTU

13. Comparative Analysis of PWM Techniques and SVPWM operated V/f control of Induction Motor having different power ratings, ***8.Divyam***, ***8.1.Ayushi Saxena***, ***6.Bharat Singh*** and ***3.J. N. Rai***, Electrical, DTU

14. Comparative Analysis of Route Planning Algorithms on Road Networks, ***3.R. K. Yadav***, ***8.Giriraj Kishor***, ***8.Himanshu*** and ***8.Kishan Kashyap***, Computer, DTU

15. Comparative Study of Static VAR Compensation Techniques – Thyristor Switched Reactor and Thyristor Switched Capacitor, ***8.Divyam***, ***8.1.Ayushi Saxena***, ***6.Bharat Singh*** and ***3.J. N. Rai***, Electrical, DTU

16. Comparative study on air quality status in Indian and Chinese cities before and during the COVID-19 lockdown period, ***8.Aviral Agarwal***, Aman Kaushik, ***8.Sankalp Kumar*** and ***3.Rajeev Kumar Mishra***, Environmental, DTU

17. Control and Design of Seven-Level Cascaded Multilevel Converter for Transformerless Large-Scale Photovoltaic Integration, ***6.Jyoti Kulkarni***, ***3.Narendra Kumar*** and Bhim Singh, Electrical, DTU

18. COVID 19 Global Pandemic: Impact on Management of Supply Chain, ***6.Rakesh Kumar*** and ***3.R.S. Mishra***, Mechanical, DTU

19. Deep Learning Approach for Arbitrary Image Style Fusion and Transformation using SANET model, ***7.Pratibha Rathi***, ***7.Pranav Adarsh*** & ***3.Dr. Manoj Kumar***, Computer, DTU

20. Dementia Detection Using Machine Learning by Stacking Models, ***3.Ram Murti Rawat***, ***8.Mohammad Akram***, ***8.Mithil*** and ***8.Setti Suneel Pradeep***, Computer, DTU

21. Descriptive epidemiology of incidence and mortality of primary liver cancer in 185 countries: evidence from GLOBOCAN 2018, ***3.Rajesh Sharma***, USME, DTU

22. Design and analysis of a dual-polarization multiband oval ring patch antenna with L-stubs and folded meander line for C-band/X-band/ Kuband/ K-band communications, ***6.Karteek Viswanadha*** and ***3.N.S.Raghava***, Electronics, DTU

23. Detecting Intrusions and Attacks in the Network Traffic using Anomaly based Techniques, ***3.Vinod Kumar***, ***8.Vinay Choudhary***, ***8.Vivek Sahrawat*** and ***8.Vinay Kumar***, Computer, DTU

24. Developing a framework for evaluating sustainability index for logistics service providers: graph theory matrix approach, ***6.Anchal Gupta*** and Rajesh Kumar Singh, DTU

25. Disease Detection in Coffee Plants Using Convolutional Neural Network, ***3.Manoj Kumar***, ***8.Pranav Gupta***, ***8.Puneet Madhav*** and ***8.Sachin***, Computer, DTU

26. Dual-Modal Emotion Recognition Using Discriminant Correlation Analysis, ***3.Dr. Rajiv Kapoor***, ***8.Suhail Saifi***, ***8.Tarun Kapoor***, ***8.Utkarsh Bisaria*** and ***8.Nikhil Singh***, Electronics, DTU

27. Effect of Distributed Damping on the Dynamic Behavior of Flexible Chassis of Heavy Road Vehicle Under Standardized Random Road Responses, Ashish Gupta and ***3.Vikas Rastogi***, Mechanical, DTU

28. Effect of friction stir processing on mechanical properties and heat transfer of TIG welded joint of AA6061 and AA7075, ***6.Husain Mehdi*** and ***3.R.S. Mishra***, Mech, DTU

29. Effect of Mesh Size on Soil-Structure Interaction in Finite Element Analysis, ***7.Nasasira Derrick*** and ***3.Amit Kumar Srivastava***, Civil, DTU

30. Efficient strip to slot waveguide mode converter using fast quasi-adiabatic approach, Nikhil Dhingra, Geetika Jain Saxena, ***3.Kamal Kishor*** and Enakshi Khular Sharma, Physics, DTU

31. Energy Efficient Transmission Trends Towards Future Green Cognitive Radio Networks (5G): Progress, Taxonomy and Open Challenges, ***6.Akanksha Srivastava***, Mani Shekhar Gupta and Gurjit Kaur, Electronics, DTU

32. Ensemble learning-based approach for crack detection using CNN, ***8.Vibhu Kailkhura***, ***8.S. Aravindh***, ***8.Shashank Shekhar Jha*** and ***3.N. Jayanthi***, Electronics, DTU

33. Environment Monitoring System for Agricultural Application using IoT and Predicting Crop Yield using Various Data Mining Techniques, ***8.Gautam Gupta***, ***8.Rashi Setia***, ***8.Archana Meena*** and ***3.Bhavnesh Jaint***, Electrical, DTU

34. Estimation of COVID-19 Prevalence under Closed Population using Capture-Recapture approach, ***6.Rakesh Kumar*** and ***3.R.S.Mishra***, Mechanical, DTU

35. Experimental studies of vapour compression refrigeration system with eco-Friendly primary refrigerant and brine mixed with nano particles as secondary refrigerant, Uma Shankar Prasad, ***3.R.S. Mishra*** and R.K. Das, Mechanical, DTU

36. Experimental Validation of Fully Informed Particle Swarm Optimization Tuned Multi-Loop L-PID Controllers for Stabilization of Gantry Crane System, ***3.Sudarshan K Valluru***, ***8.Daksh Dobhal***, ***8.Kumar Kartikeya***, ***8.Manpreet Kaur***, ***3.Madhusudan Singh*** and ***8.Arnav Goel***, DTU

37. Filter Based Scalable Blockchain for Domestic Internet of Things, ***8.Aditya Shyam Bazari***, ***8.Aditya Singh***, ***8.Abdul Ahad Khan*** and ***3.Rajni Jindal***, Computer, DTU

38. FLEXIBLE SOLAR POWER TREE - A CONCEPT, Mukesh Kumar, ***3.J P Kesari*** and Lokesh Rana, Mechanical, DTU

39. Forecasting the Probability of Cost Overrun Risk of Indian Construction Projects using Fuzzy Model, Savita Sharma, ***3.Pradeep K. Goyal*** and R.C. Chhipa, Civil, DTU

40. Fuzzy Logic based Automatic Generation Control, ***8.MD Shadan Salik***, ***8.Shaurya Priyal***, ***8.1.Neha Khokher*** and ***3.DR. Narendra Kumar***, Electrical, DTU

41. Generating Visible Spectrum Images from Thermal Infrared using Conditional Generative Adversarial Networks, ***8.Neeraj Bhat***, ***8.Navneet Saggu***, ***8.Pragati*** and ***3.Sanjay Kumar***, Computer, DTU

42. GloVeInit at SemEval-2020 Task 1: Using GloVe Vector Initialization for Unsupervised Lexical Semantic Change Detection, ***8.Vaibhav Jain***, Computer and Mathematics, DTU

43. Gratitude, social intelligence, and leadership among university teachers: mediation and moderation analysis, ***3.Naval Garg***, Anuradha Jain and B.K. Punia, USME, DTU

44. Implementation Strategy for Resource Optimization of FPGA-Based Adaptive Finite Control Set-MPC using XSG for a VSI System, Vijay Kumar Singh, ***7.1.Ravi Nath Tripathi***, and Tsuyoshi Hanamoto, Electrical, DTU

45. Modelling and optimisation of magnetic abrasive finishing process based on a non-orthogonal array with ANN-GA approach, ***6.S. Ahmad*** , ***3.R. M. Singari*** and ***3.R.S. Mishra***, Mechanical, DTU

46. Modelling Logistic Growth Model for COVID-19 Pandemic in India, ***3.Minni Jain***, ***8.Prajwal Kumar Bhati***, ***8.Pranav Kataria*** and ***8.Rohit Kumar***, CSE, DTU

47. Morphological and Swelling Potential Evaluation of Moringa oleifera Gum/Poly(vinyl alcohol) Hydrogels as a Superabsorbent, Suhail Ahmad, Kaiser Manzoor, ***3.Roli Purwar*** and Saiqa Ikram, Chemistry, DTU

48. Multi-dimensional aggregation: a viable solution for interval data, ***3.Shailender Kumar***, Computer, DTU

49. Node Classification in Complex Networks using Network Embedding Techniques, ***3.Sanjay Kumar***, ***8.Sanidhya Chaudhary***, ***8.Saksham Kumar*** and ***8.Raj Kumar Yadav***, Computer, DTU

50. Nonlinear dynamics of a time-delayed epidemic model with two explicit aware classes, saturated incidences, and treatment, ***6.Kanica Goel***, Abhishek Kumar and ***3.Nilam***, Mathematics, DTU

51. Numerical heat transfer analysis & predicting thermal performance of fins for a novel heat exchanger using machine learning, ***7.Gaurav Krishnayatra***, ***7.Sulekh Tokas*** and ***3.Rajesh Kumar***, Mechanical, DTU

52. On Black–Scholes option pricing model with stochastic volatility: an information theoretic approach, ***6.Luckshay Batra*** and ***3.H. C. Taneja***, Mathematics, DTU

53. ON CERTAIN GENERALIZATIONS OF S, ***3.S. SIVAPRASAD KUMAR*** AND ***6.KAMALJEET GANGANIA***, Mathematics, DTU

54. On the Outage Probability and BER of a DF-Based Multi-Hop System Over and □ □ -Extreme Fading Channels, Tau Raphael Rasethuntsa, ***8.Manpreet Kaur*** and Sandeep Kumar, Computer, DTU

55. Performance analysis of beamforming aided uncorrelated mm-Wave MIMO system for IEEE 802.15.3c standard, Anand Agrawal, Vimal Kumar Mishra, Ashish Gupta and ***6.1.Bajrang Bansal***, Electronics, DTU

56. Performance of Masonry Infill Framed Structures During Earthquake: A State-Of-The-Art Review, Priyanka, ***3.Alok Verma*** and Shobha Ram, Civil, DTU

57. PMS-Sharing : Framework for Automatically Authenticating users in a Group to Allow Sharing Storage, Nitesh Suthar and ***3.Rajesh Kr. Yadav***, Computer, DTU

58. Predicting Link Sign in Online Social Networks based on Social Psychology Theory and PageRank, ***3.Sanjay Kumar***, ***8.Sudhanshu Shekhar Singh*** and ***8.Vipul Gupta***, Computer, DTU

59. Real Time Experimental control and Design of FOP□□ and L-PID Controllers tuned by Invasiveweed optimization for Trajectory Control of TRAS, ***7.1.Hem Prabha*** and ***8.Rajul Kumar***, Electrical, DTU

60. Realization of Regula-Falsi Iteration based Double Precision Floating Point Division, ***8.Riya Jain*** and ***3.Neeta Pandey***, Electronics, DTU

61. Real-Time Implementation of the Optimal Predictor and Optimal Filter: Accuracy Versus Latency, SYED ASEEM UL ISLAM, ***8.1.ANKIT GOEL*** and DENNIS S. BERNSTEIN, Mechanical, DTU

62. Selection of sustainable transport system: a case study, ***8.Abhishek Singh***, Amulya Gurtu and Rajesh Kumar Singh, Civil and Environment, DTU

63. SIX SIGMA APPLICATION IN KETCHUP INDUSTRY FOR DAMAGED GLASS BOTTLES: A CASE STUDY, ***8.1.YATHARTH SHARMA***, ***8.SARMAD HASSAN*** and ***8.RAJAT KUMAR***, Mechanical, DTU

64. Sodium hydroxide effect on the mechanical properties of flyash-slag based geopolymer concrete, ***6.Manvendra Verma*** and ***3.Nirendra Dev***, Civil, DTU

65. Spatial Landslide Risk Assessment at Phuentsholing, Bhutan, Abhirup Dikshit, ***3.Raju Sarkar***, Biswajeet Pradhan, Saroj Acharya and Abdullah M. Alamri, Civil, DTU

66. SUBORDINATION AND RADIUS PROBLEMS FOR CERTAIN STARLIKE FUNCTIONS, ***3.S. SIVAPRASAD KUMAR*** AND ***6.KAMALJEET GANGANIA***, Mathematics, DTU

67. ***Abstract*—Haze poses a great challenge in modern-day applications. Removing haze is a challenging task because haze varies with the depth of the scenes in the image. Many automated systems like surveillance systems, object tracking, etc. use the dehazing methods internally to improve their overall performance in a hazy environment. Hence, recovering the original image from the hazy image is a crucial task. This paper provides a detailed survey of many algorithms that have been proposed for haze removal, which refines the image, either by using statistical observation of the scene or by network-based learning method. These algorithms have been assessed quantitatively and visually to compare based on their dehazing potential. The paper presents a comparative study of the various image dehazing methods having a different way of estimation of transmission and atmospheric light. This paper reviews different prior-based technique and learning-based technique image dehazing algorithms.**

***Index Terms*—Image dehazing, learning-based, CNN, Enhancement, Atmospheric scattering model**

I. Introduction

Image enhancement endeavours to improve the visual quality of an image. Image can degrade due to lighting, atmosphere, device issues and many other reasons. Researchers presented different approaches to deal with different issues and achieve image enhancement. Contrast enhancement [1]–[5], Haze removal [6]–[14], and Low-light enhancement [15]–[17] are a part of Image Enhancement.

The visibility of outdoor regions is deteriorated in adverse weather conditions with the presence of haze, fog, water droplets and various different particles in the atmosphere. The presence of haze is a dominant issue that decreases the contrast level and brings the noise to the image. Consequently, haze removal and improving the colour of the image becomes a difficult task. The volume of the haze or fog depends on the floating particles in the environment. These bits of particle absorb and scatter light, which reflects back from scene objects. The degree to which light scatters, rely on the separation gap between the object and the observer. Object tracking [18], Object detection [19], Action recognition [20], surveillance systems ,environment monitoring and other automated systems require clear and haze-free images to work properly. Moreover, It is difficult to perform any other vision-based task effectively in a hazy image. Thus, Haze removal becomes a necessity. Many researchers [21], [22] performed haze removal with the help of multiple images. These methods attempt to take more than one scene-image with an intent to learn the different features of the image. Separate images contain different features and thus, can help in capturing haze relevant feature effectively. However, it is sometimes not possible to have multiple images for feature extraction. It is a challenging task to distil out pertinent haze features from a single input image because of very less information provided by a single image. Various researchers [7], [8], [23]–[25] endeavoured to single image haze removal. The dehazed outputs produced by many single image dehazing algorithms appeared pleasing to the eye and the overall complexity also got reduced. Hence, addressing this problem is important in computer vision to recover images from the haze regions for useful information. The paper presents a contrasting examination of several image dehazing algorithms.

Section-II presents Atmospheric scattering model. Section-III contains Brief discussion of various single image dehazing methods. Section-IV propounds a detailed comparative analysis. Section-V is used for the conclusion.

II. Atmospheric Scattering Model

The Atmospheric scattering model [6] is extensively exploited to deal with hazy images. The model is stated as:

$$\mathbf{I}^c = \mathbf{R}^c\mathbf{T} + L^c(1 - \mathbf{T}) \tag{1}$$

here **I** depicts input-image, **R** denotes the scene radiance of the image, c denotes colour channels, and Transmission **T** depicts quantity of light that falls straight to lens of the

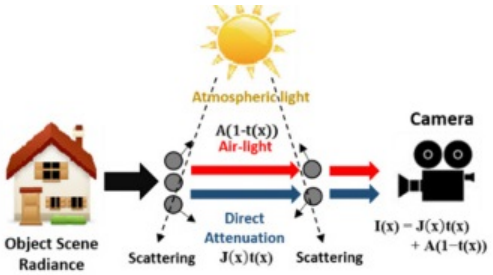

Fig. 1. Atmospheric Scattering Model [26]

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 06:00:15 UTC from IEEE Xplore. Restrictions apply.

camera without getting dispersed and L tells the atmospheric light. Also, the transmission is proportionate to the exponential distance between object and lens, therefore

$$\mathbf{T} = e^{-\beta \mathbf{D}} \tag{2}$$

here β is the atmosphere coefficient of scattering and **D** denotes the distance between the camera and the object. The model is widely employed in image dehazing to produce enhanced results **R** from input **I** by evaluating **T** and L.

III. LITERARY SURVEY

The main objective of image dehazing methods is to produce outputs that contains appropriate visible object in the image with almost no noise. This paper presents a brief deliberation of various image dehazing methods that are commonly used. Image dehazing can be used in variety of applications. Various methods are proposed by researchers to remove haze from an image and generate images with better image quality. The analysis contains prior-based and learning-based approaches. In the following section, various algorithms will be discussed.

A. DARK CHANNEL PRIOR

The dark channel prior (DCP) [7] forms on the statistical knowledge of outside scene without fog. It is built on the inspection that the local patchs Ω, which are not a part of sky region, have some pixels, with less intensity values in no less than one of the colour channel. These low intensities are accounted by the presence of shadows, colourful objects and dark surfaces. DCP is built on atmospheric model of image formation (1). The approach estimates Atmospheric light using dark-channel which is given as:

$$\mathbf{R}^{dark} = \min_{c \varepsilon (R,G,B)} (\min_{y \varepsilon \Omega} \mathbf{R}^c) \tag{3}$$

where $\mathbf{R}^{dark}$ denotes dark-channel, and Ω denotes a patch size. After estimation of dark-channel, it estimates Transmission map as:

$$\widehat{\mathbf{T}} = 1 - \omega \min_{c} (\min_{y \varepsilon \Omega} (\mathbf{I}^c / L^c)) \tag{4}$$

where $\widehat{\mathbf{T}}$ denotes Transmission map, and L^c denotes the channel-wise atmospheric light. DCP, assumes that the R^{dark} of a haze free image is nearly 0, and L^c is always non-negative.

$$\mathbf{R}^{dark} \rightarrow \min_{c \varepsilon R,G,B} (\min_{y \varepsilon \Omega} \mathbf{R}^c(y)) \tag{5}$$

Since, the Complete elimination of haze may appear displeasing to the eye. Thus, DCP preserves few traces of haze in the image to take care of the aerial perspective for distant objects. It is done by introducing a new parameter ω, which is set to 0.9.

$$\widehat{\mathbf{T}} = 1 - \omega \min_{c} (\min_{y \varepsilon \Omega} (\mathbf{I}^c(y) / L^c)) \tag{6}$$

The scene radiance can be recovered by using estimated Transmission, and Atmospheric light. Hence, It computes the final dehazed image as:

$$\mathbf{R} = \frac{\mathbf{I} - L}{max(\mathbf{T}, t_0)} \tag{7}$$

where t_0 denots the lower bound for Transmission, which keeps transmission at particular lower limit.

DCP work appropriately when images do not contain any white or brighter object. DCP generates artifacts while dealing with images having white object. In DCP, transmission is dependent on atmospheric light and prior. Thus, a improved prior can provide better enhancement.

B. COLOR ATTENUATION PRIOR

Colour attenuation prior (CAP) [8] is built on the scrutiny that, the difference in the intensity of brightness and that of an image saturation varies hazy regions of an image than haze-free regions greatly. For hazy parts, this difference is vast, whereas, the difference is low for the haze-free regions. Hence, It could be inferred that $\mathbf{D} \propto \rho \propto \mathbf{B}$ - **S**, where **D** symbolize the depth of scene, ρ is the haze concentration in the image, **S** is the intensity of saturation whereas **B** is the intensity brightness of the scene. CAP estimates depth map using the following learning model:

$$D(p) = \delta_0 + \delta_1 B(p) + \delta_2 S(p) + \varepsilon(p) \tag{8}$$

p is the position, in the image, $\delta_0, \delta_1, \delta_2$ are unknown parameter and θ_0 is equal to 1.0, θ_1 is equal to -1.0 and ϵ is a input image. The depth map can be estimated using equation (8). CAP estimates of atmospheric light by choosing the brightest 0.1% pixel in the depth and selecting the pixels intensity corresponding to them in the input image. Transmission map can be estimates by using Eq (3). Hence, The scene radiance can be estimated as:

$$\mathbf{R} = \frac{\mathbf{I} - L}{min(max(e^{-\beta \mathbf{D}}, 0.9), 0.1)} + L \tag{9}$$

It limits transmission map between a lower bound and upper bound to achieve natural enhancement. CAP performs better than DCP as it uses depth for transmission estimation. However, it sometimes provides limited enhancement. Since, it uses hard thresholding to limit the scene radiance.

C. RANKING CNN

Ranking Convolutional Neural Networks [11] attempts to cover the drawbacks of the results attained from [9] and [10].Any image has two features that play a major role in the formation of transmission map. They are called the structural and the statistical features. Some of the finest CNN may attain success in evaluating the structural features but most of them

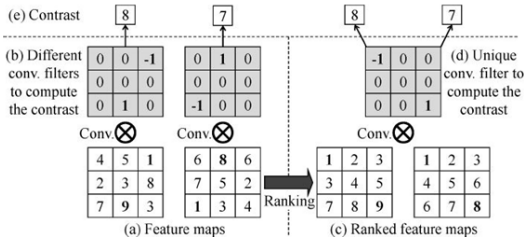

Fig. 2. Calculation of statistical feature (contrast) [11]

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 06:00:15 UTC from IEEE Xplore. Restrictions apply.

fall short while estimating statistical details. The Ranking layer was proposed keeping both these features in mind as it can estimate both the above said features. Ranking Layer takes feature maps as input and then return an output of ranked maps with the same shapes and sizes. The role of this layer is just to change the ordering of the input map. This aids the overall dehazing process by increasing its efficiency in calculation of features.

It can be observed from the 2 that for the calculation of the statistical feature other CNN may need many convolution filters but the ranking layer needs only one filter.This Ranking Layer is then inserted into the classical CNN to get an estimation over the pixel-wise transmission. The remaining part is a regression network followed by a Random Forest generator to increase performance. The obtained result is then passed for smoothing and rectified result is then coalesced with L, which is evaluated by calculating the 0.1% pixels having the highest intensities in the Dark Channel, to produce final results.

Ranking CNN attempts to learn haze characteristics using ranking layer. The other techniques are unable to distinguish statistical and structural details in the image. Ranking CNN evaluates statistical details with structural details from an image. While the other methods were taking many traversals of the filters to calculate the statistical details, the ordering of elements in the layer aids in the calculation of statistical details like contrast easily and does not require many traversals. This approach does not assumes that the transmission is constant locally instead it aims to find transmission at every pixel of the image, thereby increasing the overall image enhancement ability.

D. DEHAZE NET

DehazeNet [10] was proposed which being a [CNN] could be trained for memorizing haze characteristics and the effects they have in transmission. DehazeNet attempts to learn associations between hazy areas and their transmission. The attributes such as Dark Channel, Maximum Contrast, Colour Attenuation and Hue Disparity, if removed from an image makes the image haze-free. To improve the chances of convergence this method also brings with it a novel non-linear activation function known as Bilateral-Rectified Linear Unit (BReLU).

The structure of DehazeNet is a combination of many convolutional, pooling layers stacked back to back along with the presence of activation functions as shown in Fig. 3 The main feature of DehazeNet includes haze relevant characteristic extraction from the whole image using a non linear regression based on BReLU. Network learns the training parameters through Stochastic Gradient Descent (SGD) and Mean-Squared Error (MSE) is its loss function. The end result of this network is the efficient calculation of transmission map.

During the estimation of transmission near the sky region, some of the values of the outliers in CAP [8] fluctuates. However, DehazeNet is able to calculate the transmission with greater precision. Also, CAP performance degrades badly when the concentration of haze increase which is not observed in DehazeNet. Further, BReLU is an efficient activation function that helps in image restoration and conversion.

E. MULTISCALE CNN

To evaluate the transmission MSCNN [9] presented a two step approach. First, a rough outline depicting the transmission is obtained utilizing a Coarse-Scaled Network. The produced rough result containing the overall details of the image is then passed along to the second phase. Convolution, pooling, upsampling are some of the operations performed during the first phase. Second, the Fine-Scaled Network enhances the overall structure of the intermediate passed onto it. The coarse transmission is provided here as an add-on feature map. The transmission here gets refined due to the features learned by the fine-scaled model through forward and backward iterations. MSCNN model is as shown in Fig. 4.

Some methods depends on prior based knowledge and fails as compared to MSCNN because MSCNN tries to learn the haze relevant features with the help of an end to end CNN. MSCNN method includes the effects of priors and other details acquired by the forward and backward iterations of the network. Hence, it provides a better haze representation as compared to other dehazing techniques.

F. AOD NET

All-In-One Dehazing Network (AOD-Net) [12] evaluates haze-free results directly from the foggy image without separate evaluation of transmission and airlight. AOD Net changes the atmospheric model into a K-module based model. The

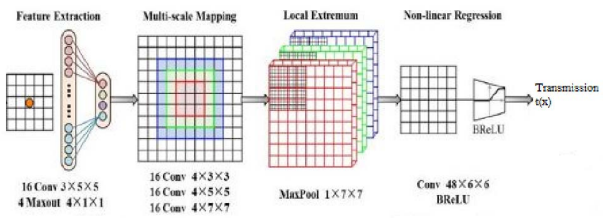

Fig. 3. Architecture of DehazeNet [10]

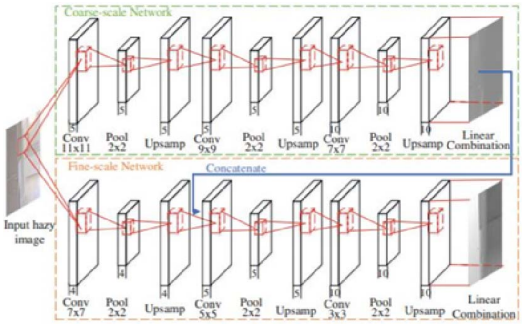

Fig. 4. MSCNN model [9]

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 06:00:15 UTC from IEEE Xplore. Restrictions apply.

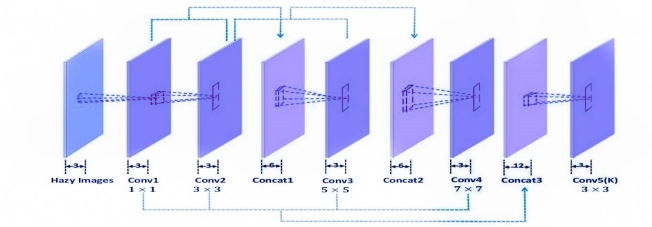

Fig. 5. Architecture of AODNet [12]

K-module based model incorporates the effect of the transmission, and airlight, Using Eq. (1).

$$\mathbf{R} = \frac{1}{\mathbf{T}}\mathbf{I} - L\frac{1}{\mathbf{T}} + L \tag{10}$$

The purpose here is to entangle L and $\frac{1}{T}$ into K.

$$\mathbf{R} = \mathbf{KI} - \mathbf{K} + b \tag{11}$$

where b has default value 1 and is a bias.Here,

$$\mathbf{K} = \frac{\frac{1}{\mathbf{T}}(\mathbf{I} - L) + (L - b)}{\mathbf{I} - 1} \tag{12}$$

After the model is converted as per the K module equation, the next step is the clean image conversion module that incorporates many pixel wise additions and multiplication layers. The results then obtained as the dehazed outputs. Because of the fact that the dehazed output is produced by a single network run, AOD Net has its application that it can be inserted with other learning based models for faster overall results. Fig. 5 shows AOD Net framework.

AOD Net is robust in cases when there are objects with colour alike atmospheric light. In those cases DehazeNet [10], MSCNN [9] show very less details. Also, the artifact problems are present in DCP [7], CAP [8], DEHAZENet [10], MSCNN [9], however AOD Net is artifact free method.

G. DCPDN (Densly Connected Pyramid Dehazing Network)

Zhang, and Patel [13] deveoped an end-to-end model for removal of haze using Generative Adversarial Network(GAN). The model learns structural relation from the images. The model consists of encoder-decoder structure which can learn transmission, airlight and can dehaze the image simultaneously. Transmission is better calculated with the help of multi-pool mapping. Also, atmospheric model has been included for better optimization for overall learning process. DCPDN has less ability for being temporally coherent. Fig. 6 represents the architecture of the model which contains 4 modules : 1. Pyramid Structure Transmission Estimation Map. 2. Atmospheric light estimation module. 3. Overall Dehazing. 4. GAN Joint Discriminator .

It optimizes GAN using the edge-preserving loss function. In practice they concatenated images free from fog with the transmission and then leveraged use of joint-discriminator loss function as:

$$\begin{aligned}\min_{G_t,G_d}\max_{D_j \text{ oint}} \mathbb{E}_{I\sim p_{\text{data }(I)}}\left[\log\left(1 - D_j \text{ oint }(G_t(I))\right)\right] + \\ \mathbb{E}_{I\sim p_{\text{data }(I)}}\left[\log\left(1 - D_j \text{ oint }(G_d(I))\right)\right] + \\ \mathbb{E}_{t,J\sim p_{\text{data }(t,J)}}\left[\log D_{\text{joint}}\left(t, J\right)\right]\end{aligned} \tag{13}$$

Several CNN-based methods like Ranking-CNN [11], MSCNN [9], restricts their ability by only taking into account of transmission map for their CNN framework whereas AOD-Net [12] solves this issue with their light-weight CNN.

H. FFA-NET

Qin *et al.* [14] presented a fusion end-to-end attention model for image dehazing. It uses Channel Attention and Pixel Attention modules which considers features based on different channels. The use of residual learning is stated to bring less vital features like thin haze. Feature Fusion Module is used to learn different features on different channels. It provides more weight to important features like thick haze regions with fusion of weights from different channels.

Fig. 7 shows Feature Attention module in FFA-Net. It consists of with basic residual learning which consists N group architectures which learns the less important features like low frequency and hazy region to avoid through multiple skip connections. The feature attention module improves the performance of the algorithm which consists of channel and pixel attention modules. Channel attention relies on the fact that the channels of image consists of different features and spatial-information is obtained by using global average pooling, with

WPSNR [28]	20.8030625	17.9290625	16.6680625	18.91295	17.8942375	15.81585	15.12675
MSE	0.117425	0.2021125	0.2319625	0.1611125	0.175525	0.250725	0.3226125

convolution layers and element wise multiply with the weights of channels as:

$$g_{\mathrm{c}} = H_{\mathrm{p}}(F_{\mathrm{c}}) = \frac{1}{Height * Width} \sum_{i=1}^{Height} \sum_{j=1}^{Width} I_{\mathrm{c}}(i,j) \quad (14)$$

$$CA_{\mathrm{c}} = \sigma(Conv(\delta(Conv(g_{\mathrm{c}})))) \quad (15)$$

$$F^{*}{}_{\mathrm{c}} = CA_{\mathrm{c}} \otimes F_{\mathrm{c}} \quad (16)$$

,where I_c denotes $\mathrm{c_{th}}$ channel of Image with pixel position at (i,j), H_p indicates the global average pooling layer, σ is a sigmoid function, δ denotes the ReLu function, CA_c denotes the channel weights which is multiplied with input F_c.

Pixel Attention module is further used by the network to learn more information about thick hazy regions. It consists of convolution lanes and element-wise multiplication and outputs the Feature Attention module.

$$PA = \sigma(Conv(\delta(Conv(F^{*})))) \quad (17)$$

$$\tilde{F} = F^{*} \otimes PA \quad (18)$$

,where PA_c denotes output of Pixel Attention, which is further element-wise multiplied to obtain Feature Attention .

Previous CNN-based models like Ranking-CNN [11], DehazeNet [10], MSCNN [9], AOD-Net [12] handle the attention modules for channel and pixel-wise as uniform, but, as thin haze and thick haze should have different weighting factors and with the heterogeneous nature of haze distribution along different channels are also taken in consideration.

IV. QUALITATIVE AND QUANTITATIVE ANALYSIS

This section presents the analysis of above-discussed methods. For computing differences and evaluate efficiencies among different dehazing methods, both quantitative and qualitative analysis are necessary. Fig. 8 depicts the outputs that are produced by distinct dehazing techniques. Fig. 8(a) shows the input image with haze. Fig. 8(b-h) represents output of He [7], Zhu [8], Li [12], Ren [9], Cai [10], Qin [14], Zhang [13] respectively. It can be noted that Fig. 8(b) is removing haze efficiently but at times suffer from halo-artifacts near the boundaries of the subject such as tree or building. Fig. 8(c) does not suffer from excess saturation and brings out the real colours. The outputs of Fig. 8(d) have sharper details and maintains the colour accuracy of the image.In the presence of objects having colour close to white light, this method shows robustness and performs efficiently. Fig. 8(f) eradicates haze nicely and the colour distribution is also uniform thereby producing good results. But as the number of hazy images increases, the visual evaluation becomes harder and biased. Therefore it is required to present the quantitative evaluation of the above-mentioned methods. Learning-based techniques require a lot of data for learning complex features so after research, the datasets that are used in these methods for learning haze relevant features are: RESIDE [29], NYU Depth v2 [30], Middlebury Stereo [31], NTIRE [32], FRIDA [33], I-HAZE [34], and O-HAZE [35]. The codes and weights given by authors are used for fair comparison. Further, the image quality is tested using metrics such as Structure Similarity In-

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 06:00:15 UTC from IEEE Xplore. Restrictions apply.

dex(SSIM) [27], Peek Signal-to-Noise Ratio(PSNR), Weighted Peek-Signal-to-Noise Ratio(WPSNR) [28] , and Mean Squared Error. Since these are widely used metrices for analyzing image dehazing methods. The synthetic image data is used from the project sites of [36], [37] to gather the result with application of those metrics. Quantitative results are compared in Table 1. The value of these metrics are averaged out for the images of data set.

V. CONCLUSION

After analyzing Image dehazing approaches, it can be observed that each approach contains their own limitations. This paper depicts an extensive inspection of various state of art image dehazing approaches. It is observed that the statistical methods fail in regions where the object's colour was identical to the atmospheric light. Statistical methods performs better in quantitative analysis. However, in Qualitative analysis these methods shows various artifacts. The algorithms either produced a halo effect or erased the object. The learning based methods performed efficiently on most of the images. The contrast of learning based methods is similar to the statistical methods. The learning based approach performs appreciably in qualitative analysis. The performance of statistical methods can be improved using improved prior knowledge and parameters. Learning-based methods can overfit on a dataset thus, it must consider the overfitting conditions appropriately.

***Abstract*—From past decades, along with increase in computing power, different generative models have also been developed in the area of machine learning. Among all such generative models, one very popular generative model, called as Generative Adversarial Networks, has been introduced and researched upon, in past few years only. It is based on the concept of two adversaries constantly trying to outperform each other. Objective of this review is to extensively study the GAN related literature and provide a summarized form of the studied literature available on GAN, including the concept behind it, its objective function, proposed modifications in base model, and recent trends in this field. This paper will help in giving a thorough understating of GAN. This paper will give an overview of GAN and discuss the popular variants of this model, its common applications, different evaluation metrics proposed for it, and finally its drawbacks, conclusion of the paper and future course of action.**

Keywords—deep learning; generative adversarial networks; neural network; generative model; image processing

I. INTRODUCTION

There has been many advancements in the field of machine learning, especially deep learning as more and more computing or processing power is becoming available. Deep Learning helps us in extracting high level, useful and abstract features from the input data and using those features in classification and generation tasks. This approach is commonly known as representation learning and is based on how the human mind learns anything. Concept of generative models (based on deep learning) forms the basis of Generative Adversarial Networks (or GANs). Traditional generative models like Restricted Boltzmann machine [15] and Variational Auto Encoder [14] were based on concepts like Markov chains and maximum likelihood estimation. Based on the distribution of input data, they estimate the distribution of generated data, but as a result of not being good in generalization, their performance and outcome is affected. A new concept in the field of generative models, called as Generative Adversarial Networks (GANs) was introduced in the year of 2014 by Goodfellow et al. [1]. It consists of one generator and one discriminator, which are adversaries of each other and thus, constantly trying to outperform each other and thus, improving themselves in the process of doing so. GANs are based on learning the joint probability distribution.

Image Synthesis is a problem which has been researched a lot upon. It means generating an image based on the hidden and visible features of an already existing image. GANs are being used largely in the area of image synthesis (or image processing, in general) as they have been proven to work really well with the images. GANs consist of two models which are trained simultaneously against each other. Generator is tasked with generating new data points based on how the data points are distributed in input samples and thus, deceiving the Discriminator with the generated/fake data points as real data points. Discriminator is tasked with catching the bluff of Generator by classifying the received data points as generated or a real (taken directly from the input sample space). It is similar to a zero-sum game between two opponents. Models are trained using back-propagation [17] and dropouts (to prevent over-fitting).

GANs can be classified based on their architecture and loss function used to train the generator [16]. It has been shown that GANs can produce pretty good and high quality images which seem convincing enough to be considered as real images. GANs have grown exponentially since they were first proposed in 2014. As of now, there are many variants of generative adversarial networks, each created specifically for a specific problem in multiple research areas like image synthesis, style transfer, image enhancement, image to text conversion, text to image conversion, detecting an object, etc., making GANs a hot topic for research purpose as well as in real world applications. Despite all the growth and research going on, GANs suffer from some problems and have shortcomings [9] like vanishing gradient, mode collapse, non-convergence, absence of universal performance evaluation metrics. Also, various solutions have been proposed for above mentioned drawbacks.

This survey analyses and presents theory, applications, shortcomings, state of the art variants of GANs and recent trends in this field. This survey is organized in parts as follows. Section II defines the background, structure and loss function of GANs. A comparison of variants of GANs is presented in Section III. Section IV discusses different evaluation metrics. The applications of GANs are given in Section V. Section VI

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:56:00 UTC from IEEE Xplore. Restrictions apply.

discusses the shortcomings of GANs. Finally, Section VII gives the conclusions and future scope.

II. THEORY AND STRUCTURE OF GAN

A. Basic Theory

Behind the motivation for GANs, is Nash equilibrium of Game Theory [1], which is a solution for a non-cooperative game between two adversaries, in which each player already knows all the strategies of other player, therefore no player gains anything by modifying their own strategy.

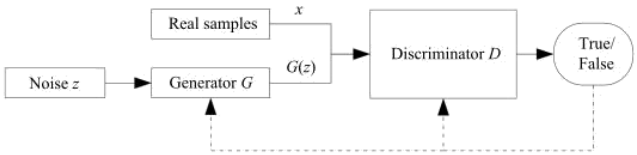

Fig. 1. Structure of Generative Adversarial Networks

The main aim of GAN is to arrive to this Nash equilibrium. Fig. 1 depicts the basic structural model of a standard GAN. Any function which can be differentiated can be used as the function for equations of generator as well as discriminator. Here, G and D are two differentiable functions that represent the generator and the discriminator respectively. Inputs given to D is x (real data), and z (random data or simply, noise). Output of G is fake data produced as per the probability distribution of actual data (or pdata), which is termed as G(z). If actual data is given as input to Discriminator, it should classify the input data as real data, labeling it 1. If fake or generated data is given as input to Discriminator, it should classify the input data as fake data labeling it 0. Discriminator strives to classify the input data correctly as per the source of data, On the other hand, Generator strives to deceive the Discriminator by making generated data G(z) similar and in line with the real data x. This game like adversarial process helps in improving the performance of both Discriminator and Generator slowly and gradually throughout the process. Therefore, slowly, Generator is able to generate better images that look more real, because it has to fool the improved and more efficient Discriminator (when compared to the previous iteration of training).

B. Loss Function

In this part of the section, loss function and learning methodology of GANs will be discussed. Following is the mathematical representation of loss function (or objective function) of GANs, as discussed in [1].

$$min_G max_D V(D, G) = E_{x\sim p(x)}[log\, D(x)] + E_{x\sim p(z)}[log(1-D(G(z)))] \quad (1)$$

where,
x - Obtained by sampling the distribution of real data or p(x).
z - Obtained by sampling the distribution of prior data or p(z) (which can be Gaussian or Uniform distribution).
E[x] - Expected value of any random variable x.
D(x) - The probability that x is sampled from actual data and not from the generated data.

Main aim of Discriminator is to maximize the objective function by minimizing D(G(z)) along with maximizing D(x), which signifies Discriminator is classifying real data as real and fake data as fake. Main aim of Generator is to minimize the objective function by maximizing D(G(z)) which signifies that Discriminator is classifying generated data (which is fake) as real. The training data consists of real data as well as generated data. Discriminator is initially trained on real as well as fake data. After that, its weights are made non trainable. Then the generator is trained. This process is repeated until required level of performance is achieved. In initial phase of learning, due to poor performance of Generator, Discriminator can catch the lie and reject generated samples easily as they are easily distinguishable from the real samples. Therefore, saturation of log(1 − D(G(z))) happens and derivative tends to 0, preventing gradient descent from occurring. So, to correct this, Generator is now trained to maximize the value of log(D(G(z))) instead of minimizing the value of (1 − D(G(z))). This modified objective function results in the derivative to be high and provides much better gradients in the initial phases of learning

III. GAN MODELS

Since the idea of GAN was proposed, many variations have been done in the original model, resulting in different models of GANs. These variations include the improvement of structure for efficiency, changes done for any specific application or problem statement like, style transfer from one image into another [18], image enhancement [13], completing an incomplete image [20-21], and generating an image from text [19].

A. Fully Connected or Vanilla GAN

It was first introduced as a baseline model for GANs in 2014 by Goodfellow et al. [1]. As the overlap of probability distributions of actual data and fake data is very little, the measure of similarity between two distributions, also known as the Jensen-Shannon divergence, may become constant, which results in the problem of vanishing gradient. It doesn't perform that well in the case of more complex images.

B. Deep Convolutional GAN (DCGAN)

Another variant of GANs was proposed by Radford et al. (2015) [4], known as Deep Convolutional Generative Adversarial Networks (DCGANs), which is based on Convolutional Neural Networks with following changes:

- Removing fully connected hidden layers.
- In the generator, a fractional-strided convolutions are used instead of pooling layers. In the discriminator, strided convolutions are used instead of pooling layers.
- Using the concept of batch normalization in generator as well as discriminator.
- Applying ReLU activation function in all but the last layer of generative model. LeakyReLU activation function is applied in each and every layer of the discriminator.

C. Wasserstein GAN (WGAN)

Wasserstein GAN (WGAN) was proposed by Arjovsky et al. [5] to resolve the issue of vanishing gradient. Instead of the Jensen-Shannon divergence, it uses the Earth-Mover distance, for calculating the similarity between probability distribution of real or actual data and fake or generated data. Discriminator is represented using f, which is a critic function, and is built on Lipschitz constraint. WGAN, though useful in a comparatively stable training of GANs, still produces data samples which are low in quality and even sometimes fail in the process of converging.

D. Wasserstein GAN with Gradient Penalty (WGAN-GP)

This model can be considered as an improvement to the basic WGAN, proposed by Gulrajani et al. [12]. They found that the weight clipping in GAN, which is done in order to apply a Lipschitz constraint on the critic, leads to failure in training. This causes abnormal behavior. So an alternative was proposed to apply the Lipschitz constraint on critic, that is, it works by penalizing the value of norm of the gradient of the f (or critic function) with respect to the input, instead of clipping of weights. This method tends to converge quickly and generates samples of relatively high quality when compared to WGAN version with weight clipping.

E. Least Square GAN (LS-GAN)

In conventional GANs, during the process of back-propagation, sigmoid cross entropy loss function is used. However, sometimes, during the learning process, the issue of vanishing gradient occurs due to this particular loss function. As a solution, Mao et al. [22] came up with LS-GAN. It uses the least square loss function. LS-GANs generate higher quality images and also are more stable during the whole learning process compared to normal GANs.

F. Semi-GAN (SGAN)

In basic GAN, during training, only one class label is required which is used to specify data source (real or fake). Odena [10] proposed Semi GAN (SGAN) by further adding class labels (say, N) of actual data while discriminator D is trained. After training, D will classify the input to one of the N+1 classes, where the extra class is used to specify the data source as per G. It is shown that this method can create a better classifier which generates samples of high quality when compared to standard GAN, as it is trained to learn the features and associates them with correct class labels.

G. Conditional GAN (C-GAN)

In conventional GAN, only latent space is provided to generator. The conditional GAN, as proposed by Mirza [11] changes that by providing an additional parameter (label y) along with latent space, to the generator and train it to produce corresponding images. Discriminator is provided with real images and label as its input, to distinguish real images better. It is shown that this model can produce digits similar to those of MNIST dataset, conditioned on class labels (0, 1, 2, 3…9). Hence, the name is Conditional GAN.

H. Bidirectional GAN (BiGAN)

In normal GANs, the generator learns by mapping latent feature vector to real data probability distribution. But it lacks an efficient mechanism which maps the real data to data in latent space. Bidirectional GANs (BiGANs) was proposed by Donahue et al. [23]. It maps the actual data probability distribution on to latent space, hence helping to learn to how to extract relevant features.

IV. EVALUATION METRICS

Apart from the manual inspection and evaluation, of samples produced by Generator module of GANs, there are some quantitative measures like Average Log Likelihood [24], Inception Score (IS) [9], Wasserstein metric [5], Frechet Inception Distance (FID) [25], etc. IS should be high and FID should be low for high quality generated images. Based on these evaluation metrics, GAN model's performance can be better judged and thus can be improved by introducing the required modifications in model.

Log-likelihood (also called as Kullback-Leibler divergence or KL divergence) is one of the widely used standard metrics for evaluating and measuring the performance of generative models [24]. It helps in measuring the likelihood of generated distribution being consistent with actual data distribution. Maximum likelihood or 0 KL divergence will produce perfect samples which will seem real.

Inception Score is probably one of the most used evaluation metric for GAN evaluation, and it was proposed by Salimans [9]. A pre-trained neural network (for example, Inception v3 model) is used to capture the relevant and important properties of generated samples, i.e., image quality and image diversity. High image quality is represented by narrow distribution of label and high image diversity is represented by uniform distribution of labels of all samples combined. As both distributions are very much dissimilar (one is narrow, another is uniform), KL divergence should be high, further giving good Inception score.

$$KL\ divergence = KL(C||M) = p(y|x) * (log(p(y|x)) - log(p(y))) \quad (2)$$

where,
C is conditional probability distribution, p(y|x) and,
M is marginal probability distribution, p(y)

Inception score doesn't measure the variations in fake images if contrasted with actual images, therefore Heusel et al. [25] introduced Frechet Inception Distance. It works on the features and transforms generated data and maps it to feature space. This feature space is obtained by the last pooling layer, just before output classification. It is summarized by calculating the covariance as well as mean for fake and actual data. By calculating this Frechet Inception Distance (also known as Wasserstein-2 distance) between these Gaussian distributions, quality and variation of produced data is measured.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:56:00 UTC from IEEE Xplore. Restrictions apply.

As of yet, there is no unanimous decision regarding which one is a better evaluation measure. Different scores focus on different aspects of the image generation process. But some metrics seem more plausible than others, like FID has the advantage of being more robust to noise. And as claimed in [25], FID can tell us how similar are real and fake images, and this measure is considered more efficient than IS.

V. APPLICATIONS OF GANS

GANs are being used widely in fields like Image processing and Natural Language Processing. Following are few of the main applications of GANs apart from classical application of generating data similar to the input data.

1) Inter-domain conversion of content of one image to another using CGAN was proposed by Isola et al. [18]. It is named pix2pix which is effective at generating photos from label maps and colorizing images.
2) Zhu et al. [18] propose CycleGAN, which can also be used for translating image from one domain to another, in the absence of a training example of paired images. It can perform style transfer, photo enhancement, object transfiguration, attribute transfer, etc.
3) Solution to the problem of Image super-resolution was provided in [13], where Ledig et al. present SRGAN. VGG network [26] is used as the discriminator. It is shown in [13] that it is possible to generate photorealistic image with high resolution. But the texture information which SRGAN generates, doesn't seem that much real, and is noisy. Therefore, Wang et al. [29] propose an Enhanced Super-Resolution Generative Adversarial Networks (ESRGAN) which aims to improve the network's architecture.
4) Zhang et al. [28] propose that GAN can generate such sentences which seem too real by utilizing the concept of long short term memory (LSTM). Li et al. [30] use GANs to perform speech to text conversion by capturing the relevance of the dialogue. SeqGAN [31] uses reinforcement learning to not only generates speech but even poems and music.
5) Antipov et al. [27] introduced a model on the concept of GAN that can be used for automatic face aging. It produces synthetic images. Facial attributes are modified in similar kinds of work but in this, emphasis is given on preserving basic facial attributes and original person's identity in aged version of the face.

Fig. 2. Few examples of applications of GANs [8]

VI. DRAWBACKS

The main shortcoming in the training process of GANs is that there is always a risk of mode collapse. It occurs when data produced by GANs is mostly focused on very less modes or sometimes even on one single mode, which results in comparatively less diverse samples. A solution to the above problem is batch regularization or mode regularization. In this, decent size of batches of data samples or various data points are included so that the diversity is improved. Another solution is proposed in [33], in which the samples generated by different models are combined together. Moreover, optimizing the objective function (like done in WGAN [5]) can resolve the problem as well.

The lack of stability in the process of training is a big issue in itself. The GAN model's parameters oscillate, destabilize and never converges to the Nash equilibrium, that is each opponent always countermeasures other opponent actions, making the models harder to converge. In contrast to the other generative models, GANs evaluation problem is much more challenging as there is no consensus on what evaluation metrics should be used for GANs [34]. Another shortcoming of GANs is the problem of diminished gradient. It occurs if the discriminator gets very powerful while training, causing the gradient of generator's function to reduce and slowly vanish, and in turn, the generator learns nothing. This imbalance between models of generator and discriminator, results in overfitting. Also, GANs are very much sensitive to the selection of hyper parameters.

VII. CONCLUSION AND FUTURE SCOPE

This paper analyses and summarizes the background of GANs, its basic theory, structure, variants, evaluation metrics, applications, shortcomings and future scope. It gives an overall and broad understanding of the literature present on GAN. A wide variety of applications of GANs is shown in this paper. New as well as better solutions to new and existing challenges in GANs are yet to be explored with an aim to increase the efficiency of GANs. The field of GAN is a promising research area, but even with all the development in its research area, it has its own problems like unstable training, non-convergence, lack of consensus on an evaluation metric, requirement of more computing power and the model's complexity. In conclusion, GAN is an interesting and useful research field with many applications but also, a lot of work needs to be done to overcome existing challenges, as it is still comparatively a new field.

New work is being continuously done to overcome the limitations of GANs. For example, WGAN can resolve the mode collapse problem as well as the training instability problem, but only partially. Therefore, preventing the problem of mode collapse in GANs remains an open research problem. Also, other research areas include the presence of Nash equilibrium and the theory of the convergence of a GAN model. GANs are being widely utilized in the area of Computer Vision but comparatively not that much in other fields like Natural Language Processing. This limitation is

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:56:00 UTC from IEEE Xplore. Restrictions apply.

because of the different properties related to image and non-image data. GANs can be used for interesting applications in various fields, therefore research is going on for that and also on how to increase the efficiency and improve the performance of GAN.

Adaptive Droop based Control for Active Power Sharing in Autonomous Microgrid for Improved Transient Performance

Surya Prakash, Student Member IEEE, Vaibhav Nougain, and Sukumar Mishra, *Senior Member, IEEE*

***Abstract*—This paper presents a decentralised adaptive droop based control for active power sharing between parallel inverters in autonomous microgrids. The work is focused on improving the transient performance of the system proposing a robust controller. The analysis does not require load current measurement where the Lyapunov analysis based control takes load current as a disturbance to the system. The mathematical analysis takes a more practical form of *LC* filter configuration where the dynamics due to resistances across the *LC* is also taken into consideration. Controller gain conditions are taken into consideration employing a detailed Lyapunov analysis. A comparative study of the conventional droop control with the proposed adaptive droop control is included in the work. MATLAB has been employed as the simulink platform for the comparative study. In addition, for experimental verification, FPGA based hardware setup has been developed and the related results are presented to verify the real-time operation of proposed adaptive control.**

***Index Terms*—Point of Common Coupling (PCC), Low Voltage (LV), Medium Voltage (MV), Backstepping Control, Voltage Source Converter (VSC), Phase Locked Loop (PLL), Constant Power Load (CPL), Adaptive Droop**

NOMENCLATURE

p	Instantaneous active power
q	Instantaneous reactive power
P	Filtered active power
Q	Filtered reactive power
V_{odq}	PCC point voltage in *dq* frame of reference
V^*_{odq}	Virtual PCC point voltage in *dq* frame of reference
V_{idq}	Inverter output voltage in *dq* frame of reference
I_{idq}	Inverter current in *dq* frame of reference
I^*_{idq}	Virtual Inverter current in *dq* frame of reference
I_{odq}	Load current in *dq* frame of reference
L_f	Filter Inductance
R_f	Resistance associated with the filter inductance
C_f	Filter Capacitance
R_d	Equivalent leakage Resistance associated with the filter capacitance
ω^*	Nominal system frequency
ω_o	Reference system frequency
m	Static droop for Real Power sharing
α	Adaptive droop for Real Power sharing
e_1, e_2	Current Tracking Errors
e_3, e_4	Voltage Tracking Errors

I. INTRODUCTION

THE penetration of power electronic interfaces in the power system has changed the course of how electricity is perceived. Power electronic interfaces have made it possible for the renewable sources (solar, wind, fuel cell etc.) to be either interface with the conventional utility grid or to be able to get locally consumed upon generation forming an autonomous microgrid [1]. The sources of such microgrid, i.e., distributed generators (DGs) are interfaced with Voltage source converters (VSCs). The VSCs, running in parallel, is responsible for controlling the frequency and voltage profile of the system due to the absence of grid [2]. The multi-DG configuration, in parallel shares the total power of the microgrid. The discussed control objective could be met by employing centralised [3], distributed [4] or decentralised methods [5].

The primary challenge for the autonomous microgrid is maintaining voltage and frequency of operation for proper operation of the loads. Once the primary challenge is dealt, the secondary challenge surfaces which are meeting the load demand in a microgrid. Once the secondary problem is addressed, the tertiary and final challenge is, maintaining the power-sharing between different sources proportionately to ensure the sources not hitting their current limit for their operational longevity. The droop control based power-sharing is widely accepted due to its decentralised nature [6]-[7]. However, droop based approach has the inherent problem of a trade-off between the voltage regulation and power-sharing accuracy [8]. To elaborate, a larger value of droop gives better power-sharing. However, the oscillations increase for such cases [9]. Transient operations in power-sharing in such microgrid setups cause overstressing, which affects the life of DG units. Mitigation of such transients is necessary to ensure the longevity of VSCs [10]-[11]. The transient and steady-state performance of the system is dependent on the control architecture employed. The conventional Proportional-Integral (PI) control has **I** (Integral) which is responsible for the robust steady-state performance. However, it is also responsible for the sluggish transient performance of the controller. The hierarchical droop based control [12]-[14] has been discussed employing radial basis

function neural network (RBFNN). However, such schemes are sluggish due to multiple control layers. The idea of single control layer modern non-linear controllers have surfaced in the power domain for improved transients performance of such microgrid setups. Sliding mode control (SMC) [15]-[16] has been proposed to improve the transient response of the system. However, SMC inherently suffers from the problem of chattering along the sliding surface. The authors in [17] employ Adaptive Neural Network (ANN) control to conclude improved transient performance. However, the gain re-tuning for different configurations is a problem of control in [17]. The authors in [18] introduce a robust Takagi-Sugeno (T-S) fuzzy control for a parallel islanded AC microgrid. However, the complexity of such control makes its implementation difficult [19].

The idea of the proposed work is improvement of transient performance for active power sharing employing an Adaptive control. Virtual inputs [20] are introduced to frame a non-linear systematic recursive control design. The transient performance of such virtual input based control has been validated in [21]. The proposed adaptive control is a simple, robust approach without the problem of chattering as in SMC. A detailed Lyapunov analysis is used to design the gain conditions for the proposed control. The performance of the proposed adaptive control is tested under dynamic AC (RLC) transients, CPL transients and fault transients.

The rest of the paper is organised as follows. Section II presents the system architecture of the autonomous microgrid. Section III gives the modelling of parallel VSCs, including system dynamics, control problem formulation, control synthesis, generation of firing signal and tuning of control gains. Section IV gives the simulation results. Section V presents the hardware results for the proposed adaptive control.

II. System Architecture

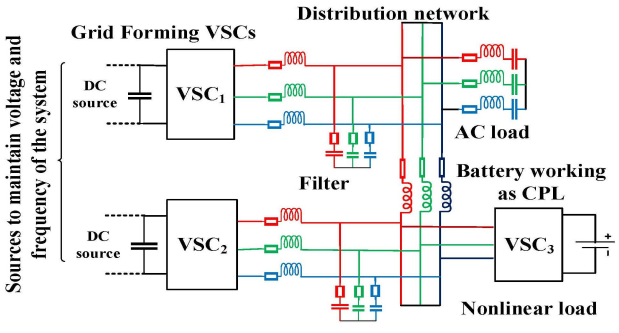

Fig. 1: Autonomous Microgrid setup

The system under consideration is an autonomous microgrid with its abstract presentation depicted in Fig. 1. Since the network is a distribution type in nature, the operating voltage of the system is 400V (phase to phase). The coupling between active and reactive power is not taken into consideration since the filter inductance value is considerable in such cases [22]. A Constant Power Load (CPL) has been taken into account due to its nature of negative incremental resistance which tends to destabilise the distribution network [23]. The different loads are distributed in nature, and hence, if the load current is a requirement for controlling the autonomous microgrid, a large number of current sensors are required. The proposed analysis does not require load current measurement, saving the cost of multiple load current sensors. The DG units and the loads are interfaced employing filter and distribution network, as shown in Fig. 1. The filter configuration employed is *LC* type where the resistances R_f (across L_f) is also included in the dynamics of the proposed analysis. The control architecture is built around the degree of freedom of the filter parameters (L_f, R_f and C_f). The power electronic interfaces, i.e., VSCs, are modulated using a control strategy obtained from Lyapunov based Adaptive technique which has been discussed in the following section.

III. Modelling of Parallel VSCs in Autonomous Microgrid

The control objective of the VSCs operating in parallel is to maintain the voltage and frequency of the autonomous microgrid, sharing the total load power in the microgrid. The instantaneous active power, p shared by each VSC is the microgrid can be calculated as

$$p = V_{od} I_{id} + V_{oq} I_{iq} \tag{1}$$

where the parameters employed can be seen in Fig. 3. The fundamental component of power, P is obtained using a low pass filter and is expressed as

$$P = \frac{\omega_c}{s + \omega_c} p \tag{2}$$

where ω_c is the cut-off frequency of the low pass filter.

The approach applied widely for such control objective is Proportional-Integral (PI) based static droop control [24]-[25]. The proposed adaptive method employs an adaptive droop control governed by,

$$\omega_0 = \omega^* - (m + \alpha) P \tag{3}$$

where ω_0 is the reference frequency of the autonomous microgrid, ω^* is the nominal frequency which is taken to be 314 *rad/s*, m is the static droop and α is the adaptive droop. Intuitively, the adaptive droop term is responsible for the improved transient response of the power-sharing in the autonomous setup. The idea behind introducing α is, increasing static droop, m improves the power-sharing; however, a low-frequency is introduced in the system if the value of static droop is very high [24]. Hence, a low value of m with adaptive α improves the power-sharing and helps to eliminate the problem of low-frequency oscillations in the system.

A. Control Design Using Lyapunov analysis based Adaptive Technique

The control design is derived using Lyapunov energy function of the autonomous system. The analysis employs adaptive technique to introduce parameter estimate ($\hat{\alpha}$) for adaptive term (α) and virtual control inputs (i^*_{1dq}, V^*_{odq}) in

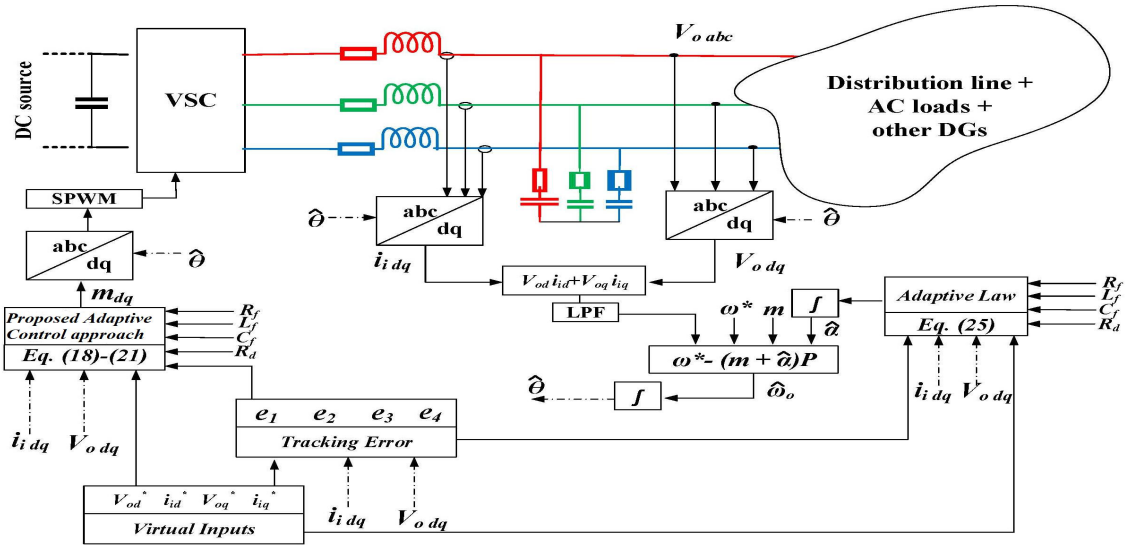

Fig. 2: Proposed Adaptive Control

the system dynamics [20]-[21], [26] (the terms are elaborated subsequently). The control technique takes load current (i^*_{odq}) as disturbance focusing on the notion of boundedness of the tracking error (e_1, e_2, e_3, e_4) dynamics. The results ensure exponential convergence of the tracking errors to a bound. Control gains introduced (γ, k_1, k_2, k_3, k_4) in the analysis are employed to vary the bound for the errors.

B. Mathematical analysis

The dynamics of the 3ϕ autonomous inverter setup is given using Kirchoff's law where the system is transformed into the direct-quadrature (*d-q*) form from the 3ϕ form. R_f are considered in the dynamics to present a more practical filter configuration. The system after the *d-q* transformation can be represented with the following differential equations where the notations are as indicated in Fig. 3.

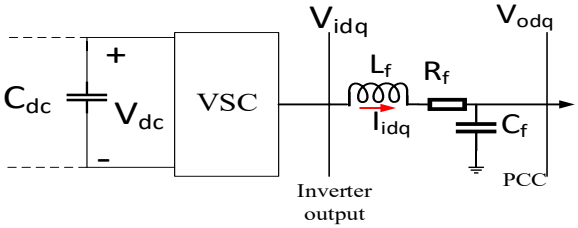

Fig. 3: The direct-quadrature equivalent of the 3ϕ (abc) single VSC configuration

1) System Dynamics:

$$\dot{i}_{1d} = -R_f i_{1d}/L_f - V_{od}/L_f + V_{id}/L_f + \omega_0 i_{1q} \quad (4)$$

$$\dot{i}_{1q} = -R_f i_{1q}/L_f - V_{oq}/L_f + V_{iq}/L_f - \omega_0 i_{1d} \quad (5)$$

$$\dot{V}_{od} = i_{1d}/C_f - i_{od}/C_f + \omega_0 V_{oq} \quad (6)$$

$$\dot{V}_{oq} = i_{1q}/C_f - i_{oq}/C_f - \omega_0 V_{od} \quad (7)$$

The discussed technique does not require load current measurement and hence i_{od} and i_{oq} are considered to be disturbances with an upper bound.

$$|i_{od}| < \bar{d}_1 \qquad |i_{oq}| < \bar{d}_2 \quad (8)$$

2) Control Problem Formulation: The closed loop system is considered for the control problem formulation. The tracking error dynamics for the system is defined as,

$$\begin{bmatrix} e_1 \\ e_2 \\ e_3 \\ e_4 \end{bmatrix} = \begin{bmatrix} i_{id} - i_{id}* \\ i_{iq} - i_{iq}* \\ V_{od} - V_{od}* \\ V_{oq} - V_{oq}* \end{bmatrix}$$

where $i_{1d}*$ and $i_{iq}*$ are the virtual input current references to the *d-axis* and *q-axis*; $V_{od}*$ and $V_{oq}*$ are the static virtual *d-axis* and *q-axis* voltage references. Inclusion of the tracking error dynamics modify eq. (4)-(7) to represent the closed loop error dynamics for the system (eq. (9)-(12)).

$$\dot{e}_1 = -R_f e_1/L_f - R_f i^*_{1d}/L_f - V_{od}/L_f + V_{id}/L_f + \omega_0 i_{1q} - \dot{i}^*_{1d} \quad (9)$$

$$\dot{e}_2 = -R_f e_2/L_f - R_f i^*_{1q}/L_f - V_{oq}/L_f + V_{iq}/L_f + \omega_0 i_{1d} - \dot{i}^*_{1q} \quad (10)$$

$$\dot{e}_3 = e_1/C_f + i^*_{1d}/C_f + \omega_0 e_4 + \omega_0 V^*_{oq} - i_{od}/C_f \quad (11)$$

$$\dot{e}_4 = e_2/C_f + i^*_{1q}/C_f - \omega_0 e_3 - \omega_0 V^*_{od} - i_{oq}/C_f \quad (12)$$

3) Adaptive Control Synthesis: The Lyapunov Energy Function for the state dynamics of the autonomous inverter is defined as;

$$V_1(e_1, e_2, e_3, e_4) = \frac{1}{2}L_f e_1^2 + \frac{1}{2}L_f e_2^2 + \frac{1}{2}C_f e_3^2 + \frac{1}{2}C_f e_4^2 \quad (13)$$

2168-6777 (c) 2020 IEEE. Personal use is permitted, but republication/redistribution requires IEEE permission. See http://www.ieee.org/publications_standards/publications/rights/index.html for more information.
Authorized licensed use limited to: University of Exeter. Downloaded on May 05,2020 at 15:09:36 UTC from IEEE Xplore. Restrictions apply.

This article has been accepted for publication in a future issue of this journal, but has not been fully edited. Content may change prior to final publication. Citation information: DOI 10.1109/JESTPE.2020.2988712, IEEE Journal of Emerging and Selected Topics in Power Electronics

where the energy function is positive definite and radially unbounded. The derivative of the energy function is further realized as;

$$\dot{V}_1(e_1,e_2,e_3,e_4) = L_f e_1\dot{e}_1 + L_f e_2\dot{e}_2 + C_f e_3\dot{e}_3 + C_f e_4\dot{e}_4 \quad (14)$$

Parameter estimation error for the adaptive term is defined as,

$$\tilde{\alpha} = \alpha - \hat{\alpha} \quad (15)$$

where $\hat{\alpha}$ is the known estimate of adaptive droop, α.

$$\eta = m + \hat{\alpha} \quad (16)$$

where η is a parameter used for simplification. The estimated reference system frequency is defined as,

$$\hat{\omega_o} = \omega^* - \eta P \quad (17)$$

The direct-quadrature derivative of virtual current inputs (i^*_{1d} and i^*_{1q}) and the direct-quadrature modulated inverter output voltages (V_{id} and V_{iq}) of the autonomous inverter are defined as,

$$V_{id} = R_f i^*_{1d} + V^*_{od} + L_f \dot{i}^*_{1d} - \hat{\omega_o} L_f i^*_{1q} - k_1 e_1 \quad (18)$$

$$V_{iq} = R_f i^*_{1q} + V^*_{oq} - L_f \dot{i}^*_{1q} - \hat{\omega_o} L_f i^*_{1d} - k_2 e_2 \quad (19)$$

$$i^*_{1d} = -C_f \hat{\omega_o} V^*_{oq} - k_3 e_3 \quad (20)$$

$$i^*_{1q} = -C_f \hat{\omega_o} V^*_{od} - k_4 e_4 \quad (21)$$

Hence, incorporating the derivative of virtual current inputs and the modulating inverter output voltages (eq. (18)-(21)), the derivative of the energy function is given as;

$$\begin{aligned}\dot{V}_1(e_1,e_2,e_3,e_4) = &-(R_f+k_1)e_1^2 - (R_f+k_2)e_2^2 - k_3 e_3^2 \\ &-k_4 e_4^2 - e_3 i_{od} - e_4 i_{oq} + L_f e_1 i^*_{1q}\tilde{\alpha}P - L_f e_2 i^*_{1d}\tilde{\alpha}P \\ &+C_f e_3 V^*_{oq}\tilde{\alpha}P - C_f e_4 V^*_{oq}\tilde{\alpha}P\end{aligned} \quad (22)$$

Now, the idea is to introduce another energy function to take the terms with $\tilde{\alpha}$ into consideration.

$$V_2(e_1,e_2,e_3,e_4,\tilde{\alpha}) = V_1 + 0.5\tilde{\alpha}^2 \quad (23)$$

Taking the derivative of new energy function,

$$\dot{V}_2(e_1,e_2,e_3,e_4,\tilde{\alpha}) = \dot{V}_1 - \tilde{\alpha}\dot{\hat{\alpha}} \quad (24)$$

The derivative of the estimate of adaptive term is defined as,

$$\dot{\hat{\alpha}} = -P(L_f e_1 i^*_{1q} + L_f e_2 i^*_{1d} - C_f e_3 V^*_{oq} + C_f e_4 V^*_{od}) \quad (25)$$

The idea of designing $\dot{\hat{\alpha}}$ is to shape the energy function, V_2 eliminating the terms which are impeding the decay of energy function derivative. Accounting eq. (25), the derivative of the energy function is modified to the form,

$$\dot{V}_2(e_1,e_2,e_3,e_4,\tilde{\alpha}) = -(R_f+k_1)e_1^2 - (R_f+k_2)e_2^2 - k_3 e_3^2 - k_4 e_4^2 - e_3 i_{od} - e_4 i_{oq} \quad (26)$$

The idea is to upper bound the derivative of the energy function considering the direct-quadrature profile of load current and their derivative as disturbances in the system.

$$\dot{V}_2(e_1,e_2,e_3,e_4,\tilde{\alpha}) \le -(R_f+k_1)e_1^2 - (R_f+k_2)e_2^2 - k_3 e_3^2 - k_4 e_4^2 + |e_3|\bar{d}_1 + |e_4|\bar{d}_2 \quad (27)$$

The evaluation of control gains (k_1–k_4) is based on the philosophy of exponential convergence of tracking errors (e_1–e_4) towards a bounded region around equilibrium point. The exponential convergence of tracking errors is guaranteed if the derivative of the energy function can be expressed in the form, $\dot{V}_2 \le -\gamma V_2 + c$ ensuring uniform ultimate boundedness of the energy function and the tracking errors.

$$\dot{V}_2 \le -(R_f+k_1)e_1^2 - (R_f+k_2)e_2^2 - \gamma C_f e_3^2 - \gamma C_f e_4^2 - |e_3|\left[(k_3-\gamma C_f)|e_3| - \bar{d}_1\right] - |e_4|\left[(k_4-\gamma C_f)|e_4| - \bar{d}_2\right] \quad (28)$$

The control gains (k_1–k_4) are defined as,

$$k_1 = k_2 = \gamma L_f - R_f \quad (29)$$

$$k_3 \ge \gamma C_f + \bar{d}_1/|e_3| \quad (30)$$

$$k_4 \ge \gamma C_f + \bar{d}_2/|e_4| \quad (31)$$

4) Generation of the Firing Signal for the inverter: The autonomous inverter is fired using the proposed control philosophy. The SPWM technique employed for firing includes generation of m_{dq}, inverse Park's Transformation (m_{dq} to m_{abc}), comparing with carrier sinusoid to generate the firing signal. The generation of m_{dq} is defined employing eq. (18)-(19) as,

$$\begin{bmatrix} m_d & m_q \end{bmatrix} = \frac{2}{V_{dc}} \begin{bmatrix} V_{id} & V_{iq} \end{bmatrix}$$

5) Eigen Value Synthesis: The control objective of exponential convergence of tracking error towards a bound requires tuned value of introduced control gains (k_1–k_4). Eq(29)-(31) give the range of control gains. The dynamics is then employed to do the eigenvalue synthesis studying variation of control gains on the system performance. The synthesis gives the idea of small-signal stability of the system with the variation of control gain parameters. The state-space representation is expressed as,

$$\dot{x}(t) = \boldsymbol{A}x(t) + \boldsymbol{B}u(t) + \boldsymbol{D}d(t) \quad (33)$$

where $\boldsymbol{A}$ is the state matrix, $\boldsymbol{B}$ is the input matrix and $\boldsymbol{D}$ is the disturbance matrix [see eq. (32)]. $x = [e_1\ e_2\ e_3\ e_4]^T$ gives the state variables, $u = [V^*_{od}\ V^*_{oq}]^T$ gives the inputs, $d = [d_1\ d_2\ d_3\ d_4]^T$ gives the disturbances in VSC state-space representation. The eigenvalues are plotted for varying control gains. Fig. 4 shows the eigenvalue loci for varying k_1,k_2,k_3,k_4. Table I & II shows the eigenvalues for different k_1,k_2,k_3,k_4. It can be seen from table I that $k_{1min} > 0$. Similar studies are presented subsequently to verify the values of k_{2min}, k_{3min}, k_{4min} for system stability.

IV. Simulation Results and Discussion

MATLAB/Simulink platform is employed for the simulation-based validation. The system considered is shown in Fig. 1. The simulation events considered for the comparison between the proposed control and the conventional PI control are elaborated in Table III. The events are kept similar to ensure proper comparison of control actions.

A. Simulation Events

1) AC load transients: Initially, both VSCs operating in parallel are contributing *320W* each (*m=22.86e-4*, α*=0*) when the AC load is consuming *640W* as can be seen in Fig. 6(a). A load transient of *640W* occurs at *t=1.3s* making the total load *1280W* as explained in Table III. The value of the adaptive droop increases to *10.27e-4* from *0* for both VSCs

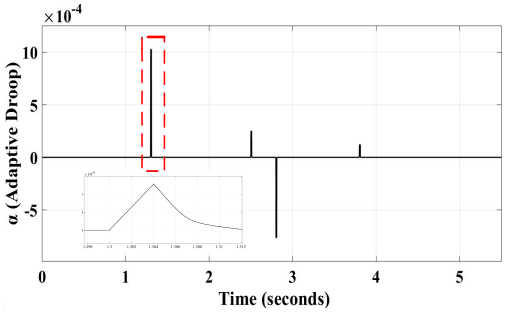

Fig. 5: Variation of adaptive droop, α with time with Event transients indicated in Table III

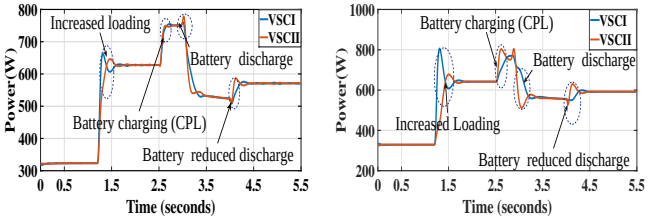
TABLE III: Event transients captured for comparison in Fig. 5



Parameter	Time of operation	Value
$P_1 + P_2$ (W)	0.0 s to 1.3 s	640 W (320 W each)
$P_1 + P_2$ (W)	1.3 s to 2.5 s	1280 W (640 W net change)
$P_1 + P_2$ (W)	2.5 s to 2.8 s	1480 W (200 W net change)
$P_1 + P_2$ (W)	2.8 s to 3.8 s	1020 W (460 W net change)
$P_1 + P_2$ (W)	3.8 s to 5.5 s	1120 W (100 W net change)

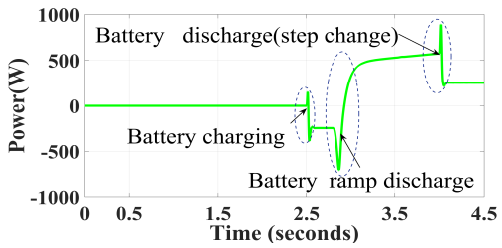
This article has been accepted for publication in a future issue of this journal, but has not been fully edited. Content may change prior to final publication. Citation information: DOI 10.1109/JESTPE.2020.2988712, IEEE Journal of Emerging and Selected Topics in Power Electronics

and again reduces to *0*. The idea is to obtain better power sharing and also to eliminate the low-frequency oscillations with the adaptive term. The variation of α can be seen in Fig. 5. The proposed adaptive control also mitigates the transients better than PI control as can be seen, comparing Fig. 6(a) and Fig. 6(b). The peak overshoot for the proposed control is lesser than that for PI control. Fig. 6(c) shows the frequency profile for the proposed control and Fig. 6(d) for PI control. Similar to the power response, the proposed control mitigate the transients in frequency in a better manner.



2) CPL transients: A *42V* lead-acid battery connected on the DC side of VSC_3 acts as CPL for the autonomous microgrid. At *t=2.5s*, CPL switching of *200W* (battery charging) occurs in the system. Another CPL switching of *460W* (battery discharging) occurs at *t=2.8s*. Fig. 7 validates the performance of proposed controller mitigating the CPL transients. The performance is validated to be better than the conventional PI control.

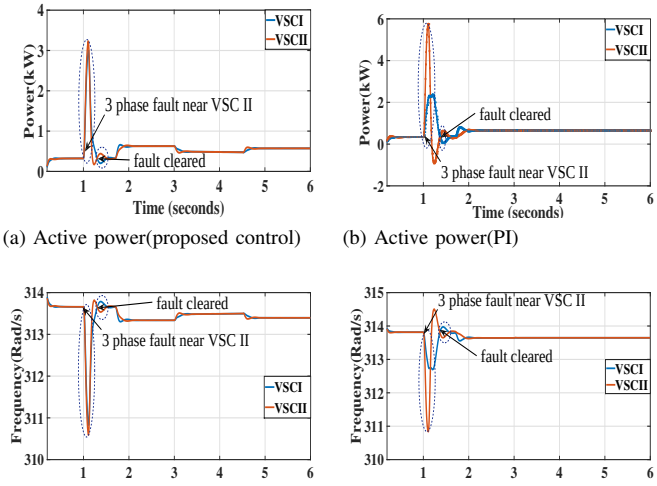
(c) Frequency(proposed control) (d) Frequency(PI)

Fig. 6: MATLAB/simulink responses for transient events explained in Table III



(a) CPL response

Fig. 7: MATLAB/Simulink responses of CPL operation explained in Table III

3) Fault transients: The case of transient mitigation during an AC faults contingency is discussed here. A 3ϕ fault occurs near VSC_2 for *100ms* at *t=1s* and is cleared at *t=1.1s* [see Fig. 8]. The contribution to the fault is dependent on the control employed. It can be seen that power-sharing has a better profile for the proposed control than for PI control. Fig. 8(a) shows both VSCs contributing *P=3.2 kW* whereas Fig. 8(b) shows VSC_2 contributing *P=5.8 kW* alone while VSC_1 contributing around *P=2 kW*. The frequency output of both VSCs are shown in Fig. 8(c) & (d). The proposed controller has better performance in terms of maintaining the same frequency to the distribution system. As it can be seen that during the transient, both VSC maintain the almost identical frequency when the proposed controller is applied. However, with the conventional PI controller VSC, I & VSC II have different frequency response during the transient as the drop in VSC II frequency output is higher than the VSC I frequency output. The settling time for the proposed control is also lesser than that for PI control. It means that for power restoration after a fault isolation, the proposed approach restores the system at *t=1.45s* whereas the conventional PI restores the system at *t=1.92s*.

However, the steady-state error is zero for the case of PI control, whereas the steady-state error is in a bound for the proposed approach. The proposed analysis gives uniform ultimate boundedness of the tracking errors. Hence, the error converges exponentially to a bound around the equilibrium point (zero).

V. Experimental Results

A. Experimental setup

The hardware validation of the proposed adaptive backstepping is carried out using an FPGA based NI- PXIe system. The scaled-down assembly for hardware validation is shown in Fig. 9 where the system shown in Fig. 1 has been implemented in a lab scale setup at *110V*. The two VSCs responsible for maintaining the voltage and frequency of the system and also for sharing the load proportionately are shown in the figure as VSC1 and VSC2. For constant power load (CPL), series combination of *12V* lead-acid batteries are connected on the DC side of a VSC through a bi-directional converter. The voltages and currents measurements are taken employing voltage sensors (LV25-P) and current sensors (LA55-P), shown in Fig. 9. Also, the RLC type loads connected to the system is shown as load banks in the figure. FPGA board (NI sbRIO 9606 and

9683) is used for data acquisition and processing of signals. NI LabView is employed to design the control algorithms shown as SCADA1, SCADA2 and SCADA3 in Fig. 9.

(a) Steady state voltages and currents

(b) Steady state active and reactive power

(c) THD in voltages

(d) THD in currents

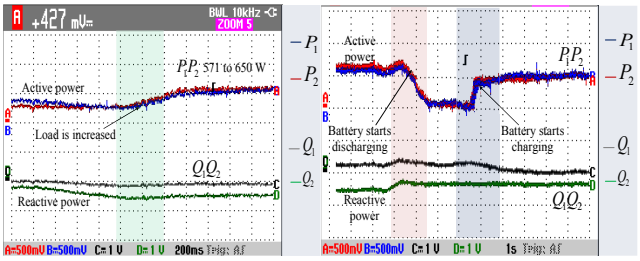

Fig. 10: Experimental Results (steady state)

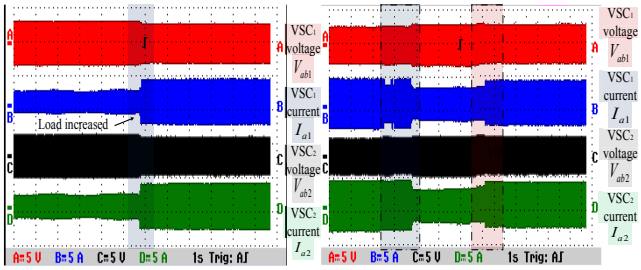
B. Steady state response (VSC_1 & VSC_2)

Fig. 10(a) shows the voltage and current profile of VSCs running in parallel. Fig. 10(a) includes the VSC_1 and VSC_2 voltages and currents while the system is operating in steady-state. The output voltage of VSCs is at 110 V while both are supplying 3 A current to the loads connected to the system. The active and reactive powers of both VSC combined is shown in Fig. 10(b). The net active power transferred by VSC1 and VSC2 is of 571 W and reactive power transferred is of 20 Var. The VSCs share *571W* as seen in Fig. 10(b). Total Harmonic Distortion (THD) in AC phase voltage for the proposed backstepping control is 1.7% (see Fig. 10(c)) while THD in the current plot is 1.04%. (see Fig. 10(d)).



C. Dynamic state response (VSC_1 & VSC_2)

The performance of power-sharing during a load transient (*571W* to *650W*) is studied next. Fig. 11(a) shows the pro-

Fig. 12: Experimental Results (load changes)

portional power-sharing profile of both VSCs for the load transient. Fig. 11(c) shows the voltage and current profile of VSCs for such an operation. It can be seen that the current by each VSC increases from *3A* to *4.1A*. The loads are increased to make the loading dynamic, and it can be seen that the active power is increased from 571 W to 650 W and similarly the reactive power demand is also increased from 20 Var to 32 Var. However, this increased in active power demand is proportionally shared by both VSCs, which support the claim of the proposed control philosophy.

D. Dynamic state response with CPL (VSC_1, VSC_2 & VSC_3)

CPL operations in the form of battery charging and discharging are studied next. Three lead-acid batteries (*12V, 42Ah* each) in series are interfaced with a bi-directional converter operating in current control mode. The output of the bi-directional converter is connected to the DC link of VSC_3. The DC link of VSC is maintained at *48V*. Initially, battery discharges which reduce the power requirement (*571W* to *450W*) from the VSC set. The battery is made to charge next,

increasing power requirement from *450W* to *560W*. Fig. 11(b) shows the contribution of each VSC in the CPL operation. The current contribution drops from *3A* to *1.9A* when the battery starts to discharge. The current contribution starts to increase again from *1.9A* to *2.9A* when the battery starts charging. The sequence of events and the following current contributions are elaborated in Table IV. CPL dynamics has been presented in Fig. 12(a), 12(b). In steady-state, the battery is discharging at *1.8A*. A step-down transformer (*5:1*) is connected between distribution lines and VSC_3. The AC side voltage of VSC_3 is at *22V*.

TABLE IV: Events during real time CPL operation

Parameter	Time of operation	Value
$P_1 + P_2$ (W)	0.0 s to 1.5 s	571 W (285.5W each)(Fig. 9(b))
$P_1 + P_2$ (W)	1.5 s to 4.5 s	450 W (79W net change)(Fig. 9(b))
$P_1 + P_2$ (W)	4.5 s to 6 s	560 W (110W net change)(Fig. 9(b))
$i_{a1}\&i_{a2}$ (W)	0 s to 2.5 s	3A each (Fig. 9(b))
$i_{a1}\&i_{a2}$ (W)	2.5 s to 4.5 s	1.9A each (Fig. 9(b))
$i_{a1}\&i_{a2}$ (W)	4.5 s to 6 s	2.9A each (Fig. 9(b))

E. Comparision between PI based control and proposed control reponse (VSC_1 & VSC_2)

(a) Active power sharing (PI control) (b) Active power sharing (proposed control)

Fig. 13: Experimental Results (comparision between PI and proposed control)

Similar to the simulation results, a comparison between the PI-based control and the proposed control is carried out in real-time. The performance of power-sharing during a load transient (*571W* to *650W*) is studied next. Fig. 13(a) shows the proportional power-sharing profile of both VSCs for the load transient when PI control is applied for both VSCs. The loads are increased to make the loading dynamic, and it can be seen that the active power is increased from 571 W to 650 W. The same steps are carried out for the proposed adaptive droop based control to maintain the uniformity. The active power-sharing dynamics for the proposed control is shown in Fig. 13(b) The proposed adaptive backstepping control mitigates the transients better than PI control as can be seen in Fig. 13, as the peak overshoot for the proposed control, in case of VSC_2 is lesser than that for PI control.

VI. Conclusion

The work proposes an adaptive droop based control for active power-sharing between VSCs in an autonomous microgrid. The adaptive term introduced in the droop control acts as a feed-forward term and is responsible for the transient performance of the system. A Lyapunov based technique has been proposed, which ensures uniform ultimate boundedness (UUB) of the tracking errors. The focus of the work is on transient mitigation for different transients in the system. A thorough comparison of the proposed control with the conventional PI control is presented employing MATLAB/Simulink as the platform. AC load variations, Constant Power Load (CPL) switching, AC faults restoration transients are considered for the comparison. FPGA based hardware setup is employed to study the real-time performance of the proposed adaptive control.

An Embedding-based Deep Learning Approach for Movie Recommendation

Ram Murti Rawat
Assistant Professor, Department of COE, Delhi Technological University, Delhi, India.

Vikrant Tomar, Vinay Kumar
Undergraduate Student, Department of COE, Delhi Technological University, Delhi, India.

Abstract - **Recommender systems are employed either as tools or algorithms, whose key task is to efficiently predict the ratings for items and recommend items, using the data generated by users. It assists users in finding items that they will like. Hence, recommendation systems are becoming an essential part of some applications, e-commerce websites, and online streaming services, etc. This paper emphasizes on recommendation system for movies whose main objective is to propose a movie recommendation system through a deep learning technique. The size and complication of websites have increased due to the rapid growth of the internet. On these websites, it has become time-consuming and extremely difficult for the users to find the information that they are searching for. Therefore, a collaborative filtering-based movie recommendation system using deep learning and embedding is proposed. The proposed system is evaluated by calculating the RMSE and MAE values. The proposed method is compared with other machine learning algorithms and some state-of-the-art methods. Our model gave an MAE score of 0.7305 and an RMSE score of 0.9311. It performs better than some previous approaches to collaborative-filtering based movie recommendation.**

Keywords – Recommendation system, artificial neural network, collaborative filtering, embedding, machine learning

I. INTRODUCTION

A recommendation system is now a central part of all e-commerce applications and online entertainment services. The recommendation system gains data about the user's preferences for a particular item (e.g. songs, movies, games, music, etc.) in two different ways. An implicit way of obtaining user data involves observing the user's past behavior such as order history, watched movies, and search queries. Another way of obtaining data is done by gathering the user's previous ratings and likes. The size and complication of websites have increased due to the exponential growth of the internet. On these websites, it has become time-consuming and extremely difficult for the users to find the information that they are searching for. Recommendation systems assist users in finding the information that is within their interests by some interaction with the user. A Recommendation system predicts the rating for items that the user has not rated yet based on his previous ratings and ratings by similar users. Recommendation systems have been a field of research for decades now, but the curiosity remains high because of the plenty of practical applications and the problem abundant domain. Recommender systems deliver tailored information by the familiarity of the user's interests by interaction or experience with that user. As online streaming services are becoming a part of our lives, the recommendation systems have gained importance. With this in mind, our objective is to work on a collaborative filtering-based deep learning strategy for the movie recommendation system. Collaborative filtering is an approach for recommendation systems that depends on the ratings given by a particular user along with the ratings for items given by other similar users. New items of interest can be recommended to the users if the ratings are precisely predicted for an item that the user has not yet rated. In this way, movies are recommended that are different than the user's previously watched movies. Whereas, a Content-Based Recommender only recommends movies based on the similarity between items. The basic idea behind content-based filtering is that if someone likes an item, then he or they will also like a "similar" item. It usually works well when it's easy to determine the properties of each item. Collaborative filtering helps users find diverse items if there are users with similar preferences. Different ways of performing collaborative filtering are present and have been implemented. One way is to create a user profile based on user's ratings and watch history and then find similar users using the k-nearest neighbor algorithm. Similarity can be defined in various ways between the users. The user profile can be defined as a vector of continuous values and then use some comparison measures like cosine similarity. Matrix factorization is one other known method for performing collaborative filtering. In this algorithm, a user-item matrix is composed, then it is factorized into two different matrices such that the inner dimension of the matrices denotes some latent factors. The representation of these factors in the above factorization helps recommend new unique items to the users. Now, deep learning is proving to be quite accurate in recommendation tasks. The popularity increase of deep learning in recommendation systems is due to its state-of-the-art performance and highly accurate predictions. Deep learning better represents the user's interest, features of the item, and past interactions between them as compared to other previous approaches to recommendation systems. A movie recommendation system using the deep learning technique and embedding layers are used.

II. Related Work

Recommender systems are classified into three different techniques that are content-based [5], [6], collaborative filtering [7], [9]-[10], [20], hybrid [13], [14]. Also, clustering algorithms are used for recommendation purposes as it helps cluster similar users into groups. In a movie recommendation model, the system learns the previous user ratings then these ratings help the system to recommend news movies to users using different approaches. Collaborative filtering [7], [9]-[10], [20] is becoming extremely important as this technique is used by many of the recommender systems. Hybrid approaches use the combination of both the content and collaborative-based filtering techniques. Memory-based and model-based are the two main types of collaborative filtering techniques. Memory-based collaborative filtering [4], [16] discoveries similar users in the user space corresponding to a specific user and then recommend movies to that user dynamically. There are two problems related to this approach that are high computational complexity and sparsity of data. An item-based method for collaborative filtering was proposed by different authors to resolve these issues. They calculated the similarity amongst the nearby region items about a fixed entity. This usually uses the k-nearest neighbor algorithm to find groups of similar items. This technique reduced the time complexity to some extent and made accurate predictions. Model-based collaborative filtering [3], [8] approach prepares a model in advance based on the previous item ratings by the user and then the model delivers item recommendation. The model is prepared using different machine learning algorithms. This approach is scalable and solves data sparsity, but time complexity is higher than other techniques. The most general method of achieving collaborative filtering is to use a k-nearest-neighbor approach between users [7]. Clustering also helps in finding similar groups in userspace. K-Means clustering is the most common clustering algorithm. An effective collaborative movie recommendation system was proposed which uses a hybrid K-Means clustering with a Cuckoo search algorithm for optimization [1]. There is another popularly known technique matrix factorization for performing collaborative filtering [19]. Deep learning has reformed various fields of computer engineering, and now it is being extensively used in recommendation systems [2], [15], [20]. Wang et al. [20] built a collaborative model for recommendation using deep learning which works both on content data and rating matrix. A recommendation system is proposed by Elkahky et al. [15] using deep learning which uses search queries and web browsing history provided by users. But there is a limitation of this method, as it needs history and search queries which are not accessible all the time. Wei et al. [21] proposed a movie recommendation model using deep neural networks for prediction of movie ratings by mining the characteristics of items and is particularly used to cold start items. A deep learning technique for collaborative filtering based on autoencoders precisely predicts the movie ratings [2]. There is another extraordinary approach to applying collaborative filtering known as matrix completion (MC). In this technique, the rating matrix is approximated to a low-rank rating matrix. This is a mathematically complex approach. In 2014, Kalofolias et al [23] introduced a regularization of the MC model known as the geometric matrix completion (GMC) model by adding additional information in the form of user and item graphs. In [11], a more efficient graph-regularized method for matrix completion was proposed using alternating least squares optimization method (GRALS). More understandable and simpler approach with Embedding layers and deep neural networks is proposed.

III. Proposed Work

A. Dataset Description

MovieLens 100K data set is used in the proposed model. The MovieLens data sets were collected by the GroupLens Research Project at the University of Minnesota [22]. This data set contains 100,000 ratings in the range of 1 to 5 for 1682 movies from a user base of 943. The data set has been preprocessed and includes only those users who have rated more than 20 different movies. It also contains simple demographic information of users (age, gender, occupation, zip) and information of movie genres. 80% of the dataset will be used for training and rest 20% will be used for testing. The data of users who did not have complete information were removed. **u.data** file is the main file used in building the model. It contains the rating data from a user for a particular movie. It has 4 columns UserID, MovieID, Rating, Timestamp.

The distribution of ratings in range 1 to 5 is shown in Fig 1.

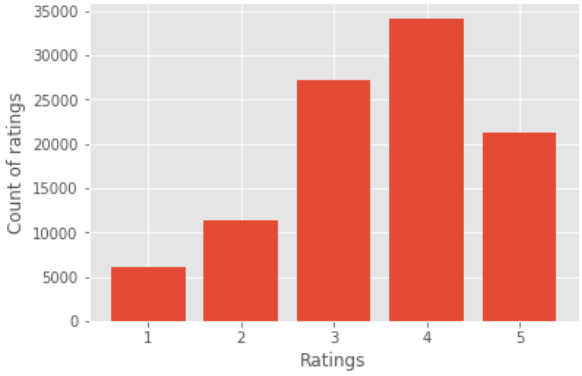

Fig. 1. Distribution of ratings

B. The architecture of the Model

After observing and pre-processing the dataset, 943 unique users and 1,682 unique movies is detected in the MovieLens dataset. However, the users and movie IDs are passed directly into our deep learning network because the model will try to find the relation between IDs that are not present. Our algorithm uses the embeddings to convert these IDs to a continuous vector of fixed size as machine learning algorithms

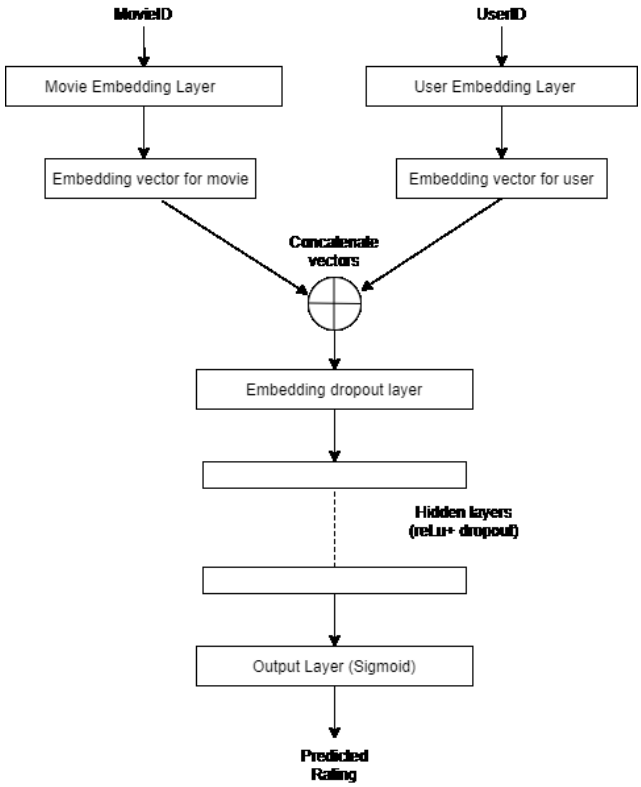

Fig. 2. Structure of network

expects numerical values as input. An embedding vector will be produced for a userID and one embedding vector for a movieID from the embedding space of 943 and 1682 respectively. Then, the vectors are concatenated into one and then passed to the dropout layer. The dropout layer is used to avoid the over fitting of a model. In each training epoch, dropout randomly sets outgoing edges of the layer to 0 with some predefined probability. Next, several fully-connected hidden layers are added with a dropout probability and reLU activation function. Each hidden layer can have a different value of output features and dropout probability. The input features are decided based on the output features of the previous layer. Finally, the predicted rating should be sent as an output for the input user and model IDs. For this, an output layer with a sigmoid activation function is employed and later rescale in the range of 1 to 5. The weights of the neurons in each layer are updated in each training epoch with a back propagation algorithm. The structure of our proposed network used as our model for predicting ratings is as shown in Fig.2.

C. Multi-Layer Perceptron (MLP)

Multi-Layer Perceptron (MLP) is a category of artificial neural networks (ANN). ANN a technique encouraged by the biological neuron network that makes up the human brain. This network learns to accomplish tasks by examining examples, without being explicitly programmed. The MLP is made up of several layers (an input layer, an output layer, and one or more hidden layers) that contains nodes with different activation functions. MLPs are fully connected, which means each node in a layer is connected to every node of the immediate next layer. The input layer receives the input data. No information processing is done on this layer. The received input is conveyed to the following layer, the hidden layer. The data directed from the input layer is processed in the hidden layers and passed to the next layer i.e. output layer. In MLP, many artificial neurons and hidden layers can be obtained. MLP can solve more complex tasks by adding a large number of neurons and layers for processing. However, it will increase the computation time. The output layer is the final layer, every node of the last hidden layer is connected to the final output layer, and hence, the result of the processed data from the hidden layer is produced at this layer. Fig. 3 shows a simple multi-layer perceptron. The advantages of MLP are:

1) It can solve highly complex and complicated problems.
2) It can handle missing data.
3) It learns the weights on its own using the backpropagation algorithm. Thus, it solves a wider range of problems than the algorithms.

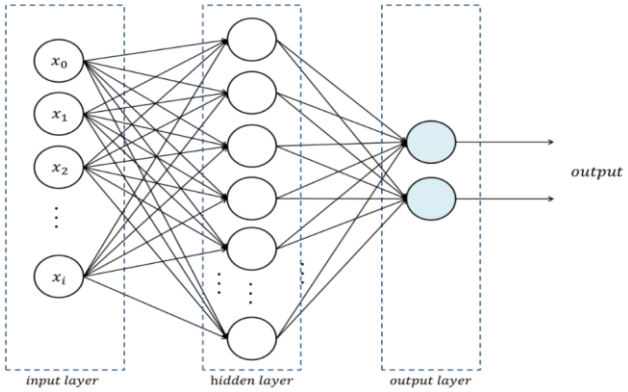

Fig. 3. Simple Multi-Layer Perceptron Model

D. Embeddings

An embedding is a conversion of discrete or categorical variables into a vector of continuous numerical values. In the view of deep learning, embeddings are multi-dimensional vector with learned continuous values that represent discrete or categorical variables. The embeddings are used in reducing the dimension of categorical variables and conveniently represent categories in a transformed space that can be used as input to neural networks and other machine learning algorithms. Embeddings have 3 basic purposes:

1. Finding nearest neighbors in the embedding space. It can be used in making recommendations based on item properties and user interests.
2. It can be used as input to various machine learning algorithms for a supervised learning problem.
3. Used in visualizing of relations between categorical variables and their characteristics.

Neural network embeddings overcome the problems of another simple method for transforming categorical variables, that is, one-hot encoding.

E. Root Mena Square Error

Root Mean Square Error (RMSE) is a common evaluation metric used in calculating the accuracy of a system. RMSE is calculated by taking the square root of the mean squared errors. The mean value is calculated by dividing the sum of the squared difference between actual and predicted output by the number of samples. Equation (1) represents the RMSE value.

$$\text{RMSE} = \sqrt{\frac{\sum_{i=0}^{N}(predicted_i - actual_i)^2}{N}} \quad (1)$$

N is the total number of instances. The smaller RMSE value means better performance for the system. Thus, a system which produces smaller RMSE value will provide better recommendations.

F. MAE

Mean Absolute error (MAE) is a similar evaluation metrics as RMSE. It is calculated by the mean of absolute error values. Absolute error is the positive value of the difference between the predicted output and the actual output. The equation for MAE is mentioned in (2).

$$\text{MAE} = \frac{\sum_{i=0}^{N}|predicted_i - actual_i|}{N} \quad (2)$$

IV. Experimental Result & Analysis

First, some pre-processing of the data is done on the dataset for the desired input for machine learning algorithms. The dataset is divided into two parts in which 80% is for training data and the rest 20% is test data for verification of the result. Our network has 4 basic parameters. To check the performance of our recommender system model, the RMSE and MAE is calculated corresponding to various values of these parameters.

Table 1. RMSE and MAE value for different parameter values.

k	hidden	emb_dropout	Dropouts	MAE	RMSE
100	[300, 200, 100]	0.02	[0.25, 0.25, 0.25]	0.7375	0.9371
100	[200, 100]	0.01	[0.15, 0.15]	0.7324	0.9321
75	[100, 200]	0.02	[0.25, 0.25]	0.7349	0.9353
50	[200, 300, 400]	0.02	[0.20, 0.20, 0.20]	0.7374	0.9355
50	[400, 300]	0.02	[0,25, 0.25, 0.25]	0.7319	0.9315
125	[100, 200]	0.02	[0.20, 0.25]	0.7337	0.9340
125	**[500, 400, 300]**	**0.01**	**[0.15, 0.15, 0.15]**	**0.7305**	**0.9311**
200	[300, 200, 300]	0.02	[0.25, 0.25, 0.20]	0.7353	0.9356
150	[200, 300, 200]	0.02	[0.25, 0.25, 0.25]	0.7402	0.9345

The size of embedding vectors for each unique user and movie is denoted by k. The hidden parameter is a list of values each corresponds to the number of output features of the hidden layers. The emp_dropout represents the dropout probability of the embedding dropout layer. The dropout parameter is a list of dropout probabilities for each hidden layer. Table 1 shows the RMSE and MAE for different parameter values.

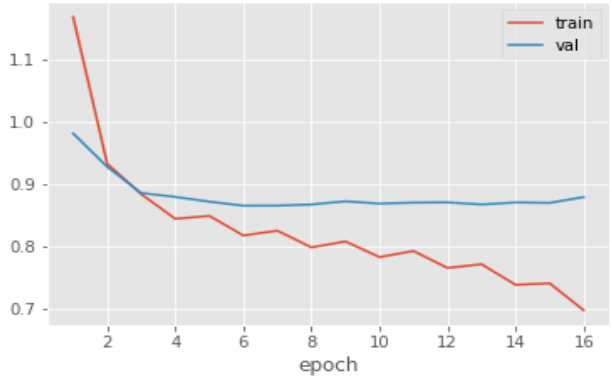

Fig 4. Training and Validation Error vs the number of Epoch

Fig. 4 shows how the training and validation errors are changing with increasing training epochs of the model. The training error is decreasing continuously but the validation error first decreases till epoch 6 but almost stays the same after that. Table 2 shows the corresponding RMSE and MAE values for a single parameter configuration but only changing k value, i.e. the size of output embedding from the embedding layer. The parameter configuration for the comparison is two hidden layers have [400, 300] output features, emp_dropout value is 0.02, dropout values are [0.25, 0.25].

Table 2. Evaluation metric values for different k.

k	*MAE*	*RMSE*
50	0.7359	0.9315
75	0.7330	0.9313
100	0.7370	0.9339
125	0.7315	0.9308
150	0.7338	0.9313
175	0.7328	0.9324
200	0.7331	0.9306

The proposed algorithm is compared with different algorithms for collaborative filtering. KNN is the K-nearest neighbor algorithm, which is a supervised machine learning algorithm for classification. PCA (Principal Component Analysis) is a technique for dimensionality reduction. A genetic algorithm (GA) is a nature-inspired algorithm. SOM refers to Self-organizing Map which maps a higher dimension input into a lower dimension. Clustering is an unsupervised learning algorithm that groups together similar items. GMC (geometric matrix completion) and GRALS (Graph regularized matrix completion method) are both state-of-the-art methods used for

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:56:24 UTC from IEEE Xplore. Restrictions apply.

collaborative filtering. KMEANS CUCKOO is a combination of K-Means clustering and Cuckoo search optimization technique. EMBEDDING+ANN is our proposed approach which uses Artificial Neural networks and Embedding. Table 3 shows the MAE and RMSE values for different algorithms. Our algorithm performs better than all of the algorithms in terms of RMSE value and has a larger value of MAE than just the KMEANS CUCKOO algorithm. Fig. 5 and 6 show the plot for different algorithms vs RMSE and MAE respectively.

Table 3. RMSE and MAE values for different algorithms

ALGORITHM	MAE	RMSE
KNN	-	1.124
PCA-GAKM	0.94	-
PCA-SOM	0.98	-
SOM-CLUSTER	0.75	-
GAKM-CLUSTER	0.76	-
KMEANS CUCKOO	0.68	1.2363
GMC	-	0.996
GRALS	-	0.945
EMBEDDING + ANN	**0.7305**	**0.9311**

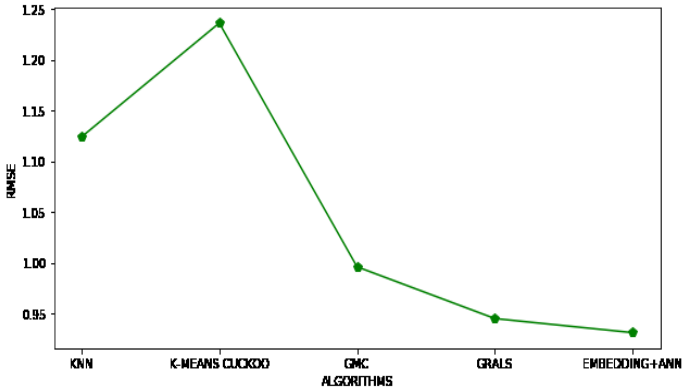

Fig 5. RMSE vs Different Algorithms

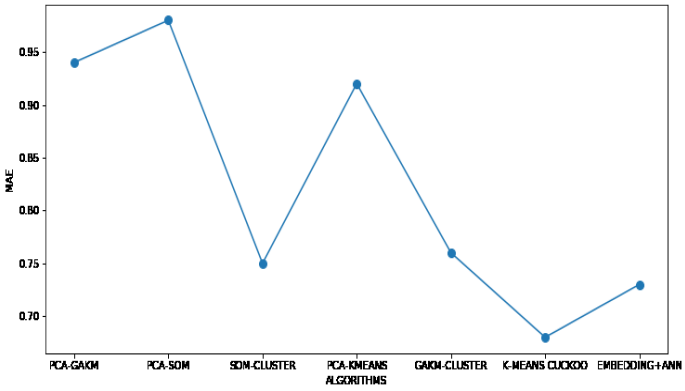

Fig 6. MAE vs Different Algorithms

V. CONCLUSION

In this paper, a collaborative recommender system using an embedding-based deep learning approach is implemented. MovieIDs and UserIDs are compared at the embedding layer to a vector of continuous values of a specific size. Then we add various layers with certain weights for processing of our input data. The hidden layers have a reLu activation function and have a dropout probability for better results. Finally, an output layer with sigmoid activation is added for the prediction of ratings. The movie ratings are predicted for the users in test data and calculated the evaluation metrics based on those predictions. Based on the evaluation metrics, our model gives better results than other machine learning algorithms in terms of MAE and RMSE values. Also, the proposed technique is compared with some state-of-the-art methods and provided more accurate results. While recommending new movies to a user, the rating based on the model is predicted and recommend the movie with higher ratings to the user. The deep learning technique with embedding layers has an additional advantage of scalability. In the future, a hybrid model will be built to give better recommendations. A combination of various machine learning algorithms can help make the recommendation system more efficient and accurate. Ensemble learning is also one of the techniques that will exploit in movie recommendation systems.

Abstract

Purpose – The purpose of this study is to understand the different types of risks affecting the demand for the automotive sector in India. The study is further trying to illustrate an approach for analyzing the relative intensities of these risks in the present uncertain business environment.

Design/methodology/approach – Risk on the overall demand is assessed by a combined Bayesian – multi-criteria decision-making approach. Data related to the different factors, affecting their product demand is collected from major automobile firms. Then, weights for these factors are evaluated by applying the analytic hierarchy process approach. Further, these weights are used in the Bayesian analysis network to evaluate the risk intensity for different subgroups, namely, political, economic, social, technological and environmental.

Findings – From the literature and experts' opinion, total 16 risk factors have been finalized and these are further grouped into 5 categories i.e. political, economic, social, technological and environmental. It is observed that the demand for organizations functioning in the automotive sector is more vulnerable to economic risk as compared to other risks considered in the study.

Practical implications – Managers and decision makers of associated organizations can use the proposed framework to assess the demand risks so as to pre-evaluate their demand corresponding to future changes. Factors can be added or removed and importance could be assigned to different risk factors according to the prevailing business environment for an organization or sector. This will also help the organizations to conduct a more effective risk management in an uncertain business environment.

Originality/value – The study will help in better understanding of the various demand risks prevalent in the Indian auto sector. The methodology used, provides a novel approach for assessing the macroeconomic demand risks and can be used by the firms working in the automotive sector. The proposed methodology could be used for assessing supply chain risk or any other business initiative risk. The suggested approach will help managers in devising flexible management techniques so as to mitigate the risk.

1. Introduction

The automobile industry plays a significant role in the economic growth of any country (Ramey and Vine, 2004). According to data released by the Press Information Bureau (2019a, 2019b), Government of India, the automotive sector contributes around 7.1% to India's total gross domestic product (GDP) and is expected to grow to 12% by the year 2026. It also constitutes 49% of the manufacturing GDP and 27% of the industrial GDP. This industry is one of the largest employers and provides about 37 million direct and indirect jobs (Press Information Bureau, 2019a, 2019b). Thus, it could be inferred that the auto-component sector is one of the core contributors to the development of the Indian economy (Singh *et al.*, 2007). However, manufacturers in this industry are subjected to huge variations in the demand of their products, as, the demand is highly cyclical. Inaccurate presumption in the demands can lead to huge losses both directly and indirectly. Thus, manufacturers and dealers must properly assess and create a balance between the demand and supply and carry the optimal mix of products for each period in the business cycle. Therefore, it is very important to conduct a prior risk-based decision-making process so as to evaluate the forces that have an impact on the demand. Decision-making is a process involving interdependence in complex situations, which possess multiple (and generally opposing) objectives and uncertainty concerning the outcomes (Azis, 2005). According to Wu *et al.* (2015), risk-based decision-making has been always important for being competitive in global markets.

In India, the automotive demand began to experience a downfall from the last quarter of the calendar year 2018 and intensified with the passage of every month in 2019. According to the Society of Indian Automobile Manufacturers (SIAM), in 2018–2019, the overall vehicle sales fell by 8%, with total retail sales accounting for 16,82,656 units as compared to 18,21,538 units sold in March 2018. Two-wheeler sales fell by a sharp 17% in 2018-2019 from the previous year (SIAM). All categories saw a "de-growth" since March 2018, which was one of the biggest months for retail sales. This has also affected the automotive dealerships negatively, leading to the closure of about 300 of them across the country. Hundreds of thousands of jobs have also been cut citing slumping sales of cars and motorcycles, with many companies forced to shut down factories for days and axe shifts (ACMA, Automotive Components Manufacturers Association of India, 2020; SIAM, Society of Indian Automobile Manufacturers, 2020). The country's GDP too witnessed a slow-down, one of the main reasons for which is believed to be the decline in the automobile demand (Press Information Bureau, 2019a, 2019b). Through this study, we would like to analyze the factors that affect the auto demand globally and, thus, assess the risk proposed by each of those factors.

In the past, various studies have been done to relate the sales of automobiles to customer choices and vehicle attributes (Chand and Avikal, 2015; Aghdaie and Yousefi, 2011; Donatos and Kioulafas, 1990). Sales forecast of vehicles have also been studied using conventional models (Berkovec, 1985; Geurts and Kelly, 1986; Shahabuddin, 2009; Wang *et al.*, 2011). Some work has also been dedicated to automobile sales assessment using macroeconomic factors (Wetzel and Hoffer, 1982; Muhammad *et al.*, 2012; Zhang *et al.*, 2017). Gupta *et al.* (2019), Chirra and Kumar (2018), Zahraee *et al.* (2018), Mangla *et al.* (2015), are amongst a few researchers, who have carried out work on the supply chain in the auto sector. Their studies were limited to the management of production and the working efficiency of an organization by choosing the best supply chain network. However, they were unable to address the risks, which control the demand for its products, which are external to the direct control of an organization and sometimes even unknown to it. Nauhria *et al.* (2011), have identified the competitive priorities based on the manufacturing system and their relative importance for the Indian automobile industry. Chuang and Zhao (2019), have studied the effect of sales demand on the level of inventories for better dealership. Marx *et al.* (2020) have shown that

how governmental decision and policies have led to booming of the Brazilian automobile manufacturing industry. Study has also been done to improve the productivity of Indian automobile firms using knowledge management (Patil and Warkhedkar, 2016).

It has been observed from the above discussion and the literature review in Section 2, that enough research has not been carried out in the past to relate auto demand with the factors that lie outside the control of an organization (Chand and Avikal, 2015; Nauhria *et al.*, 2011, Patil and Warkhedkar, 2016). Auto sales are either attributed to vehicle features or to a few major macroeconomic factors or to any other practice followed by the organization explicitly, such as the supply chain network (Gupta *et al.*, 2019; Chirra and Kumar, 2018; Mangla *et al.*, 2015). Sales forecasting has been done using previously available data by applying conventional models (Wang *et al.*, 2011; Shahabuddin, 2009; Geurts and Kelly, 1986). In this study, it has been tried to understand and analyze all the factors and the risk emerging from these factors that may either explicitly or implicitly impact the demand for the entire auto-industry rather than just an organization.

This study is trying to answer the following research questions:

RQ1. What are the factors that affect the demand in automotive sector?

RQ2. How to determine the relative weights of these factors?

RQ3. How to assess the impact of overall risk in net demand?

The structure of this paper is as follows: Section 2 i.e. literature review deals with the detailed description of different risk factors affecting the demand in the auto sector and also examines the model to be used in the study. In Section 3, the research methodology is discussed. Section 4 deals with the results and numerical illustration. Section 5 discusses the obtained results, managerial implications and theoretical implications of the study. Finally, Section 6 deals with the limitations of the study and scope of future work.

2. Literature review

In this section, review analysis has been done to extract the risk factors affecting the demand and to identify the most appropriate tool for analyzing these risks. Risk factors have been finalized through literature review and experts' opinion. In the Section 2.1, each of these factors have been described briefly along with appropriate references and examples as applicable. Section 2.2 examines the model used for factor ranking. The significance of using multi-criteria decision-making (MCDM) is also discussed. Moreover, past studies on the use of the analytic hierarchy process (AHP) for ranking of criteria have been also reviewed. Section 2.3 describes the various terms regarding risk assessment and risk management. Consequently, the model to be used for risk assessment in the present study is derived.

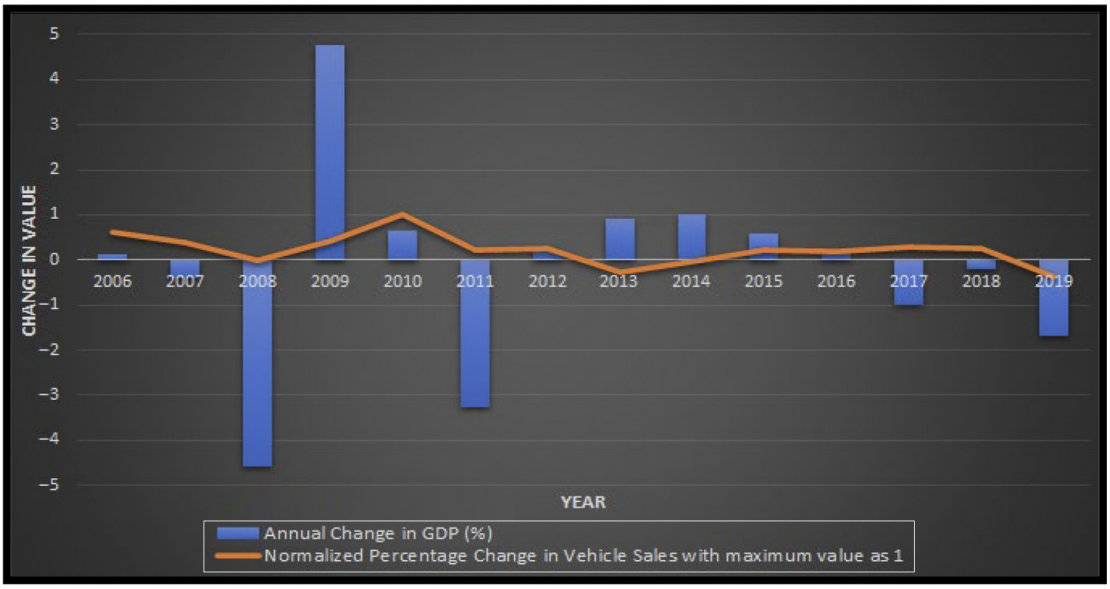
2.1 Risk factors for automotive demand

The automotive demand is dependent on various factors. In this section, we have described these factors along with a brief discussion on the same. From the literature on automobile demand factors, and by experts' opinion, 16 risk factors have been finalized. These 16 factors have been grouped into 5 categories, namely, political, economic, social, technological and environmental. These risk factors are summarized in Table A1 given in the Appendix.

2.1.1 Political risk.

2.1.1.1 Tax policies. These policies refer to the tax rates and incentives that governments provide so as to take the control of variation in demands and consumption rates. Taxes generally include the corporate taxes and the indirect taxes that consumers have to pay

while purchasing (e.g. Goods and Services Tax). Tax policies may also include rebates and other forms of incentives that government might provide so as to increase or decrease the consumption rates. It is generally seen that demand rises as soon as the consumer starts to benefit from the policy and vice versa. Study by Pritchard and DeBoer (1995), Alberini and Bareit (2016) and Ott and Andrus (2000), show the change in consumer behaviour for car purchase with tax variation. Customers are always attracted towards the vehicles and ownership schemes that levy lower taxation rates.



2.1.1.2 Environmental laws. These are the laws, which are implemented by the governments so as to address the problem of rapidly increasing environmental pollution. These may be different in different countries but generally, exist everywhere. These may include rules pertaining to use of vehicles that run on electricity or energy sources other than oil or shifting to modified grades of fuel. Various vehicle emission standards are also set up by the nations. According to the expert reviews demand of vehicles, generally has a negative correlation with the frequency of changes in the environmental laws as, the consumers are confused whether it is the right time to purchase or not. For example, in India one of the major reasons for stagnation in the demand of ic-engine vehicles is attributed to the government's policy to shift to Bharat Stage (BS)-VI (cleaner grade of fuel) from BS-IV by April, 2020 and to completely switch to electric vehicles by 2030 so as to reduce the air pollution.

2.1.1.3 Vehicle regulations. These are the rules and regulations set up by the governments for the manufacture and sale of new vehicles and to ply on the roads. These include some pre-requisites that the vehicle must satisfy such as the axle norms, safety standard norms and emission norms, and those which need to be followed while in use such as, the motor vehicle act. By expert reviews, it is known that sales drop with frequent changes in these rules. According to SIAM, the sales of commercial vehicles dropped by nearly 10% in May 2019, at 68,847 units as compared to 76,517 units in May 2018, which is mainly attributed to the new axle norms. Effect of government policies on the performance of automobile manufacturers was studies by Yadav and Sagar (2015).

2.1.2 Economic risk.

2.1.2.1 Economic growth and development. This imply to the rate at which the increase of per capita income takes place. It also includes, the inflation rate and the tax rates, which indirectly determine the net disposable income. New cars have a high-income elasticity of demand i.e. their demand is highly sensitive to a change in the real income of consumers, keeping all other things constant. When real incomes rise, the demand for new vehicles is expected to expand. Muhammad *et al.* (2012), Shahabuddin (2009) and Dargay (2001), had shown the impact of income rates on the sales of cars. Tambade *et al.* (2019), found that in case of Indian automobile industry business environment plays a very crucial role amongst the other factors. The graph shown in Figure 1 is plotted to simultaneously analyze the percentage change in vehicle sales with respect to the annual change in the GDP of India (Ministry of Road Transport and Highways, Government of India; Press Information Bureau, 2019a, 2019b; The World Bank). It could be clearly noticed that in most cases there exists a strong direct correlation between the two i.e. vehicle sales show a positive sign with an increase in GDP and vice versa.

2.1.2.2 Acquisition and running costs. These include the cost of the vehicle and the costs incurred while running it such as the fuel costs, insurance and maintenance. Hike in these costs lead to a decrease in the number of buyers. High fuel price, though, does not always bring a decline in demand, as a new vehicle would be technologically more advanced and fuel efficient than the older one, thus offering the buyer a chance to save money. Research by Hamilton (1983), Mork (1989), Lee and Ni (2002), Barber *et al.* (1999) and Duncan (1980), show that how significant increase in fuel price could impact car sales.

Source: Ministry of Road Transport and Highways, Government of India; PIB 2019; The World Bank

Figure 1.
Percentage change in vehicle sales w.r.t. annual change in the GDP

2.1.2.3 Inflation rate. Many economists, businessmen and other experts maintain that moderate inflation levels i.e. between 2%-3% are needed to drive the consumption, assuming that higher levels of spending are crucial for economic growth. Inflation, less than this might lead to under development and higher inflation rate may lead to significant rise in price of commodities. As auto industry makes up a good portion of a country's GDP it is necessary to maintain a low inflation rate (Chifurira *et al.*, 2014).

2.1.2.4 Availability of credit or finance. Some of the new customers may purchase a vehicle in one single payment but many mainly depend on securing a finance agreement. Even though interest rates may decrease according to government monetary policy, it still remains hard to get a new loan for a car and also, the rate of interest on unsecured credit keeps on rising. Thus, the high real rate of interest on car loans does not allow new buyers to purchase. Ludvigson (1998), had found that an increase in the rate of interest on loans poses a significant negative impact on car sales. A similar observation was also made by Muhammad *et al.* (2012), in their research on the analyzing the impact of economic variables on automobile sales.

2.1.2.5 Employment rate. Muhammad *et al.* (2012) and Shahabuddin (2009) have studied the effect of rate of employment on the sales of new vehicles. Better rate of employment means, more money in the hands of consumers leading to better consumption rates, and thus, increased demand. This process is cyclical in itself, i.e. decline in employment rate leads to lower demands and lower demand leads to again decline in the employment. Thus, the reason becomes the consequence of the problem. This is valid for the auto sector as well.

2.1.3 Social risk.

2.1.3.1 Mass transit systems. According to a few experts, less availability of good public transport system leads to increased demand of personal vehicles. Similarly, a good transport facility leads to less demand of automobiles. Improvement of public transport and reduction in distance to the nearest railway station leads to less dependence on private vehicles (Rith *et al.*, 2019). A well-planned metro network leads to decrease in private vehicle ownership by 2% ∼ 3% (Mulalic *et al.*, 2016).

2.1.3.2 Cab ridership services. Similar to the mass transit system, better cab facility leads to decreased demand of private vehicles. Consumers, generally prefer riding a cab, rather than driving themselves. Cab services are growing better and better by providing comfortable rides at competitive prices. This has led to a risk for the automobile industry. Rawal and Sisodia (2017), have shown that how the acceptance of cab services have increased in India.

2.1.3.3 Vicinity of roads and availability of parking. Ample of driving and parking space leads to comfort and helps in saving a lot of time. Thus, it encourages consumers to purchase new vehicles. On the other hand, congestion and lack of parking, forces users to avail mass transit and cab services. With rapidly increasing population and speedy urbanization, a well-developed transport system is required as individual vehicles cannot be copped up in such a large volume (Barbero and Galeota, 2019).

2.1.4 Technological risk.

2.1.4.1 Introduction of new vehicles. With introduction of vehicles with new designs and features, it is generally expected that the sales would also rise. Consumers who are pioneer innovators and early adopters are attracted towards new and modular looks. If the vehicles have an upper edge above the past running models, it would generate good reviews and demands would shoot up. Automobile industry is fast changing dynamic market, the growth of which depends upon the competitive technology (Nag and De, 2020; Yadav and Sagar, 2015).

2.1.4.2 Automation. Other than the looks and design, consumers also look for sophisticated and user-friendly functions and automatic features. According to Andrea and Smith (1994) and Aghdaie and Yousefi (2011), customers look for specifications, performance and automation while selecting amongst vehicles.

2.1.4.3 Engine efficiencies. It has been seen in the past that with the use of research and development, new technologies to enhance the fuel efficiency (such as modified fuel supply systems, integrated starter generator, start-stop technology and modified gear ratios) have evolved. Such features act as a huge mode of attraction for the consumers. Customers are easily encouraged to purchase new vehicles if they have better efficiencies than their older ones. Andrea and Smith (1994) and Aghdaie and Yousefi (2011), also showed that customers have higher demands for vehicles with higher fuel efficiencies.

2.1.5 Environmental risk.

2.1.5.1 Pollution levels. With the rapidly changing climate patterns all over the world whose root cause is pollution, it becomes a big risk factor for the automotive business. An automobile, from the start of its manufacturing, throughout its use and till the end of its scrapping, leaves a giant footprint of metals, carbon and other chemically toxic wastes. It leads to rise in all forms of pollution. Manufacturers need to think of ways to mitigate this risk by pre-planning the alternative risk barriers. More movement of people and goods lead to more pollution and emission of greenhouse gases (Barbero and Galeota, 2019).

2.1.5.2 Season and climate. During a certain period of the year the demand may remain very low (such as the rainy season) while during some other time the demand suddenly shoots up (like during the festive season). Vehicle manufactures should be ready to bear such fluctuations in the demand by prior mitigation strategies. Busse *et al.* (2015), found that the purchase of an automobile is highly dependent on the weather, which is controlled by psychological effects, rather than by classical utility theory. Bloesch and Gourio (2015), too suggest that though weather has a temporary, but a significant impact on the economic activities.

2.2 Ranking of the risk factors

Demand pattern of automobiles, as observed from discussion in the previous sub-section, depends upon many different factors. Sorting of these factors according to their relative importance requires the consideration of various evaluation notions. Therefore, it is known as MCDM

problem i.e. decision-making in the presence of multiple and generally conflicting criteria (Rao, 2007). MCDM techniques have been widely used in the studies of risk analysis and management (Chand *et al.*, 2015a, 2015b, 2017). The AHP can be used for the assessment of relative weights for the given factors in a complex problem involving many criteria (Singh, 2013; Chauhan, 2016). The essence of the AHP is that human judgements, and not just the underlying information, can be used in performing the evaluations. The AHP converts these evaluations to numerical values that can be processed and compared over the entire range of the problem. A numerical weight or priority is derived for each element of the hierarchy, allowing diverse and often incommensurable elements to be compared to one another in a rational and consistent way. This capability distinguishes the AHP from other decision-making techniques (Saaty, 1980). Chhabra *et al.* (2017) have used it for analyzing green logistics alternatives in context to an automotive organization. Apak *et al.* (2012) have used AHP to research preferences of a customer for features of luxury cars. Chand and Avikal (2015), have also used AHP in their research to select medium range cars on the basis of different criteria such as cost, performance and fuel consumption Kumar and Singh (2012) have used fuzzy AHP for evaluation of third-party logistic provider. AHP has been used to analyze productivity and wastage reduction for an Indian manufacturing firm (Chauhan, 2016). Very recently, AHP has been used for factor weight calculation of internet of things and big data in customer relationship management (Abu Ghazaleh and Zabadi, 2020). Al Hammadi and Hussain (2019), have used AHP to help decision makers in public health care sector to sort out the factors that affect sustainable organizational performance. It has also been used to prioritize the indicators of managerial success (Ghosh, 2013).

In the classical AHP, a decision maker is asked to supply exact pairwise comparison ratios for each attribute in each level of the hierarchy (Saaty, 1980). However, these decisions might be imprecise due to uncertainty in human opinions in statistical context (Saaty and Vargas, 1987; Moreno-Jimenez and Vargas, 1993; Basak and Saaty, 1993; MacKay *et al.*, 1996). Outcomes of real-life problems are usually not bivalent i.e. there is no clear-cut solution such as "yes" or "no" (Tong and Bonissone, 1980). Zadeh (1965), had introduced the concept of fuzzy set theory (FST) in decision-making, to show the linguistic variables on a numbered scale. The extended form of AHP method was proposed by Chang (1996). It combines the use of FST with the AHP method, i.e. the data used for AHP is a fuzzy number. Thus, when uncertainty exists, FST could be used (Leung and Cao, 2000; Taylan, 2014). Accuracy in assigning weights to some given alternatives could be increased by using fuzzy-MCDM methodology (Bellman and Zadeh, 1970). As the preferences in AHP are usually judgements of human beings based their perception, Leung and Cao (2000) believe that the fuzzy approach allows a more accurate description of the decision-making process. Torfi *et al.* (2010), in their research based on calculating weight using fuzzy AHP have found that AHP is one of the most outstanding MCDM approaches, used to obtain the relative weights. Fuzzy AHP, has also been used in studies regarding supply chain problems (Gupta *et al.*, 2019; Kumar and Rahman, 2017; Yadav and Sharma, 2016; Mangla *et al.*, 2015; Singh and Sharma, 2014). Recently, it has also been used to rank the criteria that determine the stress amongst hospitality and tourism employees (Vatankhah *et al.*, 2020). Thus, in comparison with other MCDM methods, the AHP method has widely been used in similar scenarios and the fuzzy AHP technique, could provide with more accurate results in many practical decision-making problems.

2.3 Risk assessment

Risk implies any form of consequence or the probability of a major loss (Tipu, 2017). Risk analysis is the "systematic use of available information to identify hazards and to estimate the risk to individuals, property and the environment" (IEC 60300-3-9, 1995). Risk evaluation is the:

> [. . .] process in which judgments are made on the tolerability of the risk on the basis of a risk analysis and taking into account, the factors such as, socioeconomic and environmental aspects (IEC 60300-3-9, 1995).

Risk assessment is the "overall process of risk analysis and risk evaluation" (IEC 60300-3-9, 1995). Risk management is a continuous management process with the objective to identify, analyze and assess the potential uncertainty related to an activity and to identify and introduce risk control measures to reduce or completely eliminate the potential harms to the system, as well as the environment (Rausand, 2013; Chand *et al.*, 2014). Framework for risk analysis, evaluation and assessment, given by Rausand (2013), is shown in Figure 2.

Risk analysis has three main parts, namely, to identify the possible undesired events, the likelihood of these events and the consequences of these events (Kaplan and Garrick, 1981). Singh *et al.* (2008) have observed that organizations should develop competencies to evaluate their risks for being competitive in global market. Quantitative risk assessment requires two quantities, namely, the probability of the occurrence of a loss and the magnitude of the potential loss (Ayyub, 2014). According to Rausand (2013), there are three main approaches to probability:

(1) The classical approach;

(2) The frequentist approach; and

(3) The Bayesian or subjective approach.

The first two approaches i.e. the classical and the frequentist approach are used when there is either a fixed sample space of outcomes or when the experiment can be repeated again and again. The Bayesian or the subjective approach is used when these conditions do not exist. In this, the probability is considered to be subjective i.e. there is a numerical value in the interval [0, 1] representing an individuals' degree of belief about the probability of an event to occur.

Thus, the Bayesian network analysis is a good risk assessment methodology that may be used for analyzing qualitatively, quantitatively or both, depending on the scope of the analysis. One of the earliest researches for risks assessment by using Bayesian analysis was done by Pai *et al.* (2003). Bayesian analysis has also been used for optimization of the cost (Narayanan *et al.*, 2005), to conduct diagnostics (Kao *et al.*, 2005; Kauffmann *et al.*, 2002) and to analyze the flexibility in supply chains (Milner and Kouvelis, 2005; Wu, 2005). Nielsen and Jensen (2009) and Alexander (2003), have used the Bayesian network analysis in the business field, for multi-variate and integrated analysis of the risks, for monitoring and evaluating intervention strategies. Bayesian network analysis has also been used to

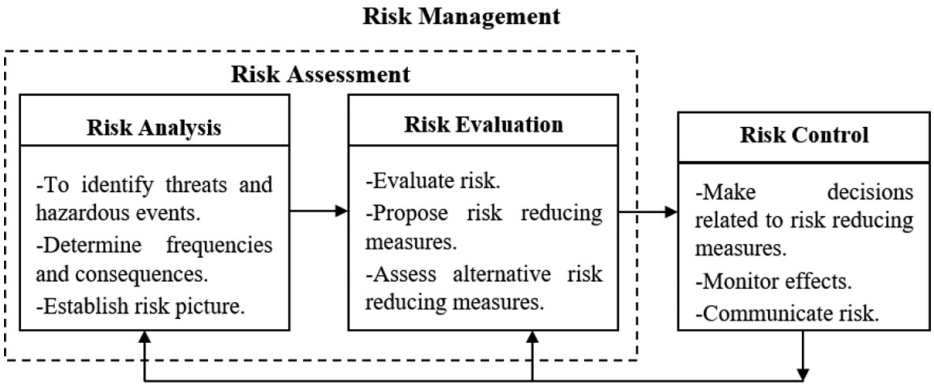


Figure 2.
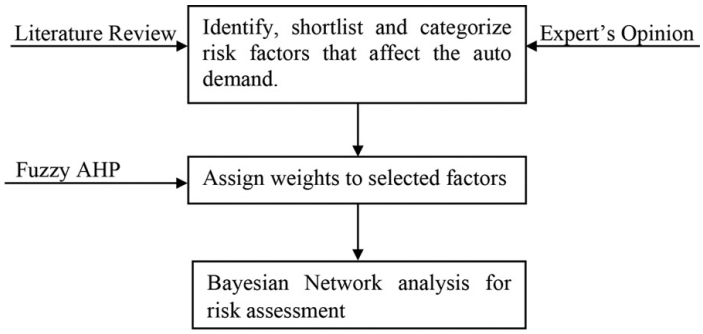
Risk analysis, evaluation, assessment and management

Source: Rausand (2013)

examine the fluctuations in exchange rates caused by monetary fundamentals (Charfi *et al.*, 2019). Dalla Valle and Giudici (2008), used the Bayesian methods to integrate the scarce and inaccurate quantitative data with prior information provided by the experts to estimate operational loss distributions. In a different research, to assess the enterprise risk, Bonafede and Giudici (2007), had shown that the Bayesian networks are a useful tool to integrate different information and to study risk distribution by using the data collected from the experts. Salehi *et al.* (2020), have used the Bayesian approach to analyze the predictability of the firm level data for determining macroeconomic factors, and suggest that it is a good method, which provides results similar to the classical theory.



Through the above literature analysis, three important aspects regarding the significance of the present study have been drawn. Firstly, various studies have been presented to illustrate the different factors on which demand of the automotive sector depends. Different authors have worked upon different risk factors as presented in Table A2. Secondly, the application of fuzzy AHP technique has been also reviewed. Finally, to assess the probability of the risk factors under such a scenario, the Bayesian network analysis application has been studied. In an industry working under practical situations, the risk for demand may not always depend only on a few factors in a selected field, rather it is often diversified and interconnected over a vast network of factors (Kumar *et al.*, 2019). In this study, the risk through all the factors has been assessed by a combined Bayesian- MCDM model. Factors have been collected through Section 2.1, factor weights have assigned by using the fuzzy AHP technique and risk probability has been assessed using the Bayesian network analysis.

3. Research methodology

The factors affecting the sales of automotive have been identified and discussed in the final section. The methodology includes, application of fuzzy AHP and Bayesian analysis. For applying AHP, level of importance for each of the demand factor is required. This was achieved by expert survey of the decision makers of four different firms. Profile of experts is given in Table A3 in the Appendix. Thus, the obtained level is based on personal opinions and thoughts supported with some historical data, which makes the use of FST necessary. Relative weights for each of the factor is obtained by the importance level in fuzzy AHP, further the weights obtained by fuzzy AHP are used to assess the relative risk for each factor and its subgroup through the Bayesian analysis. Figure 3 shows the flowchart of the applied research methodology in this study.

3.1 Fuzzy set theory

Definition 1. A fuzzy number ($\tilde{\tilde{n}}$), which is triangular in nature, is denoted by triplet Tr (j,k,l), where [j-lower, k-middle and l-upper]. In terms of the membership function ($\mu_{\tilde{\tilde{n}}}$), the graphical representation is shown in Figure 4.

Source: Self-created

Figure 3.
Flowchart of the applied methodology

$$\mu_{\tilde{\text{n}}} = \begin{cases} \dfrac{x-j}{k-j} & ;\text{for } \text{j} \le \text{x} \le \text{k} \\ \dfrac{x-l}{l-k} & ;\text{for } \text{k} \le \text{x} \le \text{l} \\ 0 & ;\text{otherwise} \end{cases} \tag{1}$$

Definition 2. Let two fuzzy-triangular numbers be, $\tilde{\tilde{\text{x}}}_1 = (\text{j}_1, \text{k}_1, \text{l}_1)$ and $\tilde{\tilde{\text{x}}}_2 = (\text{j}_2, \text{k}_2, \text{l}_2)$, then the mathematical operations associated with these fuzzy numbers are given as following:

- "adding" two Fuzzy Tr. Numbers:

$$\begin{aligned} \tilde{\tilde{\text{x}}}_1 \oplus \tilde{\tilde{\text{x}}}_2 &= (\text{j}_1, \text{k}_1, \text{l}_1) \oplus (\text{j}_2, \text{k}_2, \text{l}_2) \\ &= \left[(\text{j}_1 + \text{j}_2), (\text{k}_1 + \text{k}_2), (\text{l}_1 + \text{l}_2)\right. \end{aligned} \tag{2}$$

- "subtracting" two Fuzzy Tr. Numbers:

$$\begin{aligned} \tilde{\tilde{\text{x}}}_1 \ominus \tilde{\tilde{\text{x}}}_2 &= (\text{j}_1, \text{k}_1, \text{l}_1) \ominus (\text{j}_2, \text{k}_2, \text{l}_2) \\ &= \left[(\text{j}_1 - \text{j}_2), (\text{k}_1 - \text{k}_2), (\text{l}_1 - \text{l}_2)\right. \end{aligned} \tag{3}$$

- "multiplication" of two Fuzzy Tr. Numbers:

$$\begin{aligned} \tilde{\tilde{\text{x}}}_1 \otimes \tilde{\tilde{\text{x}}}_2 &= (\text{j}_1, \text{k}_1, \text{l}_1) \otimes (\text{j}_2, \text{k}_2, \text{l}_2) \\ &= \left[(\text{j}_1 \times \text{j}_2), (\text{k}_1 \times \text{k}_2), (\text{l}_1 \times \text{l}_2)\right. \end{aligned} \tag{4}$$

- "dividing" two Fuzzy Tr. Numbers:

$$\begin{aligned} \tilde{\tilde{\text{x}}}_1 / \tilde{\tilde{\text{x}}}_2 &= (\text{j}_1, \text{k}_1, \text{l}_1) / (\text{j}_2, \text{k}_2, \text{l}_2) \\ &= \left[(\text{j}_1 / \text{j}_2), (\text{k}_1 / \text{k}_2), (\text{l}_1 / \text{l}_2)\right. \end{aligned} \tag{5}$$

Definition 3. Distance between two fuzzy numbers:

Chen (2000), gave the vertex method for finding the distance between to fuzzy Tr. Numbers.

$$\text{d}\left(\tilde{\tilde{\text{x}}}_1, \tilde{\tilde{\text{x}}}_2\right) = \left\{\frac{1}{3}\left[(\text{j}_1 - \text{j}_2)^2 + (\text{k}_1 - \text{k}_2)^2 + (\text{l}_1 - \text{l}_2)^2\right]\right\}^{1/2} \tag{6}$$

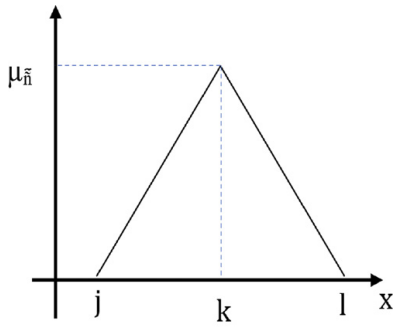


Figure 4.
Depiction of Fuzzy-Triangular number $\tilde{\tilde{x}} = (\text{j}, \text{k}, \text{l})$

Source: Rao (2007)

Definition 4. De-fuzzifying the fuzzified values:

Let $\tilde{\tilde{x}} = (j, k, l)$ represent a fuzzy number. The fuzzy number can defuzzied by the centre of gravity method given in equation (6) Jager *et al.* (1992).

$$\text{De fuzzify}\left(\tilde{\tilde{y}}_i\right) = \frac{1}{3}[j + k + l] \tag{7}$$

3.2 Fuzzy analytic hierarchy process method

As discussed in the literature review, in this study, the AHP technique is applied in its extended form, to determine the weights of the concerned factors. Thus, the geometric mean method of fuzzy AHP is used and the detailed procedure for the same is given in this section. The conventional basic AHP method is not capable to handle the imprecision of human judgments. While, fuzzy AHP, an improved form of AHP is able to handle this issue. The scale used for this analysis is given in Table 1.

In the AHP method, factor importance is first obtained in linguistic terms from decision makers from different firms or organizations based on their level of importance. Then, an aggregated pairwise comparison matrix is constructed amongst the considered factors for their weight calculation. The level of importance obtained from the expert review are converted into triangular fuzzy numbers (TFNs) as per the Table 1.

The complete process of fuzzy AHP, used in this study is explained in five steps:

Let the TFN is represented by:

$$\tilde{\tilde{x}}_i^r = (j_r, k_r, l_r), \text{ where, } r = (1, 2, 3, \ldots., m)$$

Step 1: Calculate the fuzzy geometric mean value, $\tilde{\tilde{r}}$,

$$\tilde{\tilde{r}}_i = \left((j_{i1} \times j_{i2} \times \ldots. \times j_{im})^{1/m}, (k_{i1} \times k_{i2} \times \ldots. \times k_{im})^{1/m}, (l_{i1} \times l_{i2} \times \ldots. \times l_{im})^{1/m}\right. \tag{8}$$

Step 2: Calculate the sum of all the fuzzy geometric mean values,

$$\sum_{i=1}^{m} \tilde{\tilde{r}}_I = [r_1 \oplus r_2 \oplus r_b \oplus \ldots\ldots. \oplus r_m] \tag{9}$$

Step 3: Calculate the fuzzy weights, $\tilde{\tilde{w}}_I$, for all the fuzzy geometric mean values,

$$\tilde{\tilde{w}}_i = r_i \otimes [r_1 \oplus r_2 \oplus r_b \oplus \ldots\ldots. \oplus r_m]^{-1} \tag{10}$$

Step 4: Defuzzify the fuzzy weights to obtain weights, w_i,

$$w_i = \frac{1}{3}[j_{w1} + k_{w2} + l_{w3}] \tag{11}$$

Level of importance	Triangular fuzzy number
1	(1, 1, 1)
2	(1, 2, 3)
3	(2, 3, 4)
4	(3, 4, 5)
5	(4, 5, 6)

Source: Kannan *et al.* (2013)

Table 1. Triangular fuzzy number of a given level of importance

Step 5: Obtain the normalized weights, (w_{ni}) by following,

$$w_{ni} = w_i / \sum w \tag{12}$$

3.3 Bayesian analysis

A Bayesian network graphically represents the probability distribution for a large set of variables (Pai *et al.*, 2003). In a Bayesian network, nodes depict random variables. Nodes that are not connected imply that those variables are independent of each other (Heckerman, 1996). Each node, associated with a probability function takes a particular set of values as input and gives the probability of the variable represented by the node as output (Heckerman, 1996; Nielsen and Jensen, 2009).

The Bayes' Theorem was given by Thomas Bayes in the late 1700*s* who worked on the concept of conditional probability. It states that:

$$P(H|E,r) = \frac{P(H\ |r) \times P(E|H,r)}{P(E|r)} \tag{13}$$

The equation, i.e. P(H|E,*r*) represents the probability of any hypothesis H after considering the occurrence of event E on any past event r. The term P (H|*r*) is the probability of occurrence of H given that only *r* occurs. The likelihood is represented by the term P (E|H,*r*), which gives the probability of the E assuming H and *r* are true. The term, P(E|*r*) is independent of H and is regarded as a normalizing or scaling factor (Niedermayer, 2008). Thus, we see that the Bayesian network analysis could be used for combining subjective a hypothesis with the available evidence. A combined diagram for the AHP and Bayesian Network Analysis is presented in Figure 5.

4. Results and analysis

Results are analyzed in two parts. First, we obtain the relative weights for each of the factors by applying the fuzzy AHP MCDM technique on the data received from industry experts.

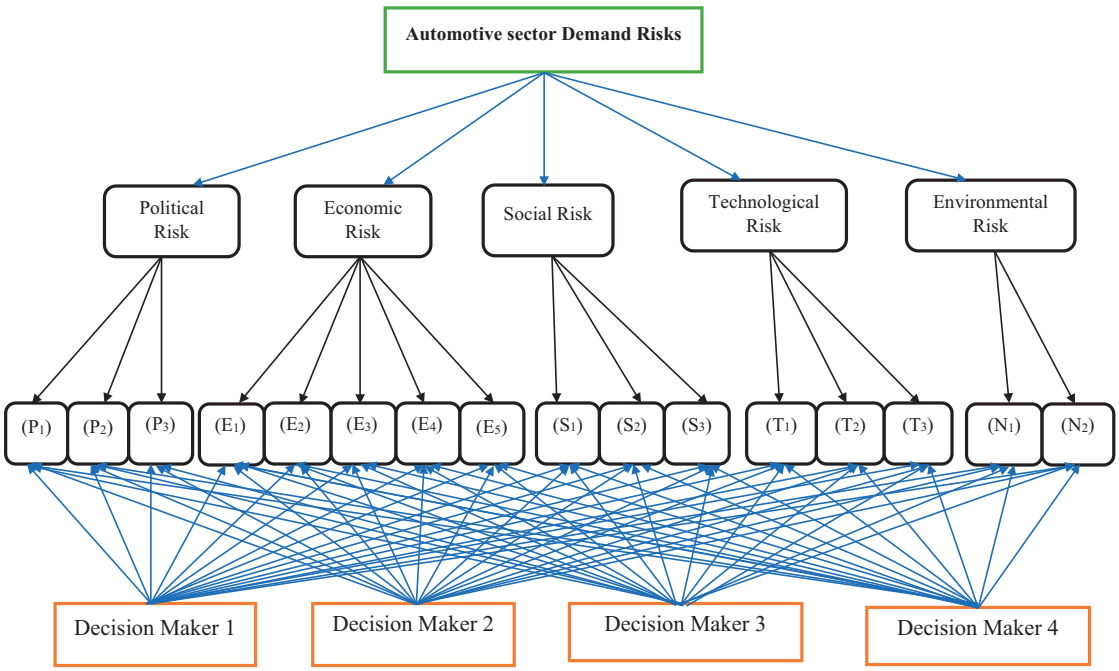

Figure 5.
Integrated AHP and Bayesian Network for automotive risk assessment

Secondly, these weights are used in the Bayesian network to assess the risk for each of the node, and then on each category of risk. The numerical illustration for the same is shown in the following section.

4.1 Numerical illustration

First, the weights for all the risk factors based on their relative importance were collected from four decision makers. Importance of different factors as obtained from the decision makers is given in Table A4 in the Appendix.

4.1.1 Analysis based on fuzzy analytic hierarchy process. Steps to obtain the final ranking of factors affecting the demand of automotive have been illustrated:

Step 1: Following the procedure explained in the research methodology, an integrated pairwise comparison matrix for all the factors (based on expert reviews) is obtained and is presented in Table A5 in the Appendix.

Step 2: By using equation (8), the Fuzzy Geometric Mean ($\tilde{r}$) for each fuzzy number with respect to each of the factors are obtained. For example:

$$\tilde{r}_i = (1 \times 1 \times \ldots \times 1)^{1/16}, (1 \times 1 \times \ldots \times 2)^{1/16}, (1 \times 1 \times \ldots \times 3)^{1/16}$$
$$\Rightarrow \tilde{r}_i = (1.000, 1.500, 2.059)$$

Step 3: Using equation (10), the fuzzy weights, ($\tilde{\tilde{w}}_i$), for all the fuzzy geometric mean values are calculated. For example:

$$\tilde{\tilde{w}}_1 = (1.000, 1.500, 2.059) \otimes [(1.000, 1.500, 2.059) \otimes (1.000, 1.500, 2.059) \otimes \ldots\ldots \ldots \otimes (0.642, 0.760, 1.000)]^{-1}$$
$$\Rightarrow \tilde{\tilde{w}}_1 = (0.04317, 0.08823, 0.16268)$$

Step 4: Using equation (11), each of the fuzzy weights ($\tilde{\tilde{w}}_i$), are defuzzified, to obtain the crisp weights (w_i). For example,

$$w_1 = \frac{1}{3}[0.04317 + 0.08823 + 0.16268]$$
$$\Rightarrow w_1 = 0.0980266$$

Step 5: Final value of normalized weights, (w_{ni}) are obtained using equation (12),

$$w_{n1} = 0.0980266/(0.0980266 + 0.0980266 + \ldots\ldots + 0.0504733)$$
$$\Rightarrow w_{n1} = 0.0870986$$

Calculated values of normalized weights are given in Table A6 in the Appendix.

4.1.2 Analysis based on bayesian network. Normalized weights obtained by fuzzy AHP are given in Table A6 in Appendix. These are used to calculate their respective probability of impact on the demand by solving them through Bayesian network analysis.

Using the formula given in equation (13), the risk for each of the category is calculated,

$$P(\text{Political Risk}) = \frac{\Sigma(\textit{Probability of political risk factors}) \times (\textit{Probability of event occurence})}{\Sigma(\textit{Probability of event occurence})}$$

$$\Rightarrow \mathrm{P(Political\,Risk)} = (P_1 + P_2 + P_3)/(1 + 1 + 1)$$
$$= (0.0732081 + 0.0448465 + 0.0732081)/3$$
$$= 0.06375423$$

Similarly, the risk for all the categories is calculated. The results have been tabulated in Table A7 in the Appendix.

Using the results obtained after applying the Bayesian analysis, different categories of risk are arranged in decreasing order of their magnitude in Table 2. It is observed that economic risk is the most important risk category followed by political, social, technological and environmental risks, respectively.

5. Discussion of findings

This study identifies the different types of risk factors impacting the demand in the automotive industry and presents an approach for modelling and evaluating risk factors for the demand in this sector. By the help of literature review and experts' opinion, total 16 risk factors are identified and these are further grouped into 5 categories i.e. political, economic, social, technological and environmental. Risk profile on the overall demand was assessed by a combined technique of fuzzy AHP and Bayesian network analysis approach. Relative weights for these factors are evaluated by applying the fuzzy AHP approach on the basis of the inputs received from expert interviews. Further, these weights are used in the Bayesian analysis to evaluate the risk for the different subgroups and its impact on the final demand is assessed. After the application of Bayesian analysis, it is observed that organizations are more vulnerable to economic risk. It means, organizations should try to control major dimensions of economic risks such as acquisition and running cost, inflation rate and availability of credit or finance carefully. Thus, from this study, it can be inferred that the changes in demand are more driven by economic factors.

Economic risks include- the economic growth and development, acquisition and running costs, inflation rate, availability of credit or finance and the employment rate. Figure 1 validates the finding that vehicle sales largely depend on the GDP. Study by Muhammad *et al.* (2012) also shows that in the Association of Southeast Asian Nations countries, these economic factors have a noteworthy deep-rooted correlation with the automobile sales. Further, Dargay and Gately (1999), have found that in India, being a developing country, the percentage change in vehicle sales was even more than twice the percentage change in GDP, in between 1966 and 1992. Results by Patra and Rao (2017), in their study regarding economic factors using co-integration and vector models suggest that GDP has a direct relation with the automobile demand, while, the prices and lending rates have an inverse relationship.

Economic risk is followed by political risk, which contain the tax policies, environmental laws and vehicle regulations. This type of risk is again outside the direct control of the firms and possess a huge amount of risk for the demand. Studies suggest that these factors too

Table 2. Risk categories in descending order of risk

Rank	Risk category
1	Economic risk
2	Political risk
3	Social risk
4	Technological risk
5	Environmental risk

contribute greatly to the demand of the automotive (Fridstrøm and Østli, 2017; Clibborn *et al.*, 2016; Alberini and Bareit, 2016; Ott and Andrus, 2000; Pritchard and DeBoer, 1995). Further, from the studies itself, it could be seen that though social and technological factors also impact the overall demand, the intent of these risks is not that high and often lies between 2%-3% (Mulalic *et al.*, 2016; Rith *et al.*, 2019; Barbero and Galeota, 2019; Rawal and Sisodia, 2017; Aghdaie and Yousefi, 2011; Andrea and Smith, 1994). Amongst these factors, the technological ones could be directly or indirectly controlled by an organization itself. Chatterjee *et al.* (2020), suggest that competency in these factors is important for an organization to expand its customer base. At last, the seasonal factors, may have a control on the demand only for a short range of time. These could easily be anticipated by the organizations and its effects could simply be mitigated. Team of experts considered for this study were again consulted with final results of the study. All the experts agreed with final findings and its significance for the industry.

5.1 Managerial implications

The analysis of different types of risks and assessment of the overall risk to the demand in automotive sector will help the industries in this sector in devising their strategies for better gains. The model used in this study would help the associated practitioners to easily assess the risk through each factor at any moment by using appropriate support data. This will, in turn, assist them in a better preparation for facing the future circumstances (for e.g. a sharp surge or decline in the demand) and to deal with the risk situation with accurate mitigation plans by the anticipation of the future demand. For a better efficiency and increased profits, the factors and their categories having higher risk should be given priority to be reduced earlier. The organizations need to devise and implement their policies accordingly. This study reveals that economic risk has the highest magnitude, therefore organizations need to modify their plans more often so as to move hand in hand with the economic changes. These changes majorly include- the economic growth, costs, inflation rate, liquidity and employment. As discussed earlier, the demand increases with economic growth and decreases with an increase in costs, inflation and unemployment. Thus, the rate of production should go hand in hand with the data regarding these aspects. Deviation from the appropriate rate of production may eventually lead to huge losses for the organization. This is valid for all other categories of risk as well. Hence, prioritizing risk factors becomes an essentially important step for risk assessment and its management.

5.2 Theoretical implications

This study has a threefold theoretical contribution to the literature regarding automobile demand and risk assessment. The research contributes:

- to understand the risk factors affecting demand of automotive;
- to study a model that prioritizes these factors by assigning relative weights to them; and
- to assess the risk from each of these factors and correspondingly the overall risk on automotive demand.

Till present there is no single study available where all the external factors affecting the automotive demand have been discussed. In the current study, these factors have been collected through thorough literature and expert reviews. Relative weights have been assigned by applying the fuzzy AHP MCDM technique by using human judgements supported with historical data, and eventually risk probability of each factor has been assessed using the Bayesian network analysis. Thus, it lays the foundation for development

of a new Bayesian MCDM hybrid model for calculation of probability of occurrence of different phenomenon in other areas of study as well. In any sector or industry, it is often required to analyze different factors affecting the outcome of a phenomena, to prioritize the factors and to manipulate their depth of occurrence on the event. The applied methodology provides immense help to the user in assessing and prioritizing factors that lie outside the limits of his direct control. This model would also be extremely useful when an experiment cannot be conducted again and again or when a large sample space of data cannot be gathered. It would also be helpful, when the list of factors varies for organizations or when an organization wants to vary its own importance for the different factors. A successful combination of the fuzzy AHP and Bayesian network is, hence, found to be a very good tool for risk or probability evaluation. Other researchers can use this integrated approach in context to other sectors for analyzing the risks.

6. Limitations and future scope

While the study is very helpful in analyzing the demand risk for the automobile industry, it has a few limitations too. One of the limitations of this study is that the risk factors taken into consideration for assessing are based on literature review and experts' opinions. Therefore, these factors or their extent, could change in the future depending upon the sector and business environment. If a new factor, identical to a non-optimal factor, is introduced, then the ranking of the existing factor may change. Belton and Gear (1983), suggest that the reason for this inconsistency in ranking is that the relative performance measures of all alternatives in terms of each attribute is summed to one. Instead of having the relative performance values sum up to one, dividing each relative performance value by the maximum value in the corresponding vector of relative values was proposed. This avoids the rank reversals when a new non-optimal factor is added. Sometimes it has also been observed that the AHP is not able to include the effects resulting from inter-reliant factors (Gurumurthy *et al.*, 2013). So, there is a necessity to present the interdependencies amongst the factors. In this study, a large sample space of data is not available, as only a limited number of experts could be contacted to gather the data. Though, it has been tried to be resolved by using FST, but there may still be some scope of error, which could be easily removed if it is applied to an industry practically. Other limitation is that it does not provide the mitigation plans for the assessed risks. In the future these mitigation plans can also be devised so as to negate the risk from each of the factors. The suggested approach may also help managers in devising risk mitigation plans. Continuing with this, processes for lean and agile systems can also be implemented to overcome these risks. Future studies may be carried out for finding new risks and possible mitigation strategies in emerging business environment of circular economy and Industry 4.0. Findings may be further validated through case and empirical studies.

The applied methodology can be used to evaluate the factors that affect the demand and the overall risk imposed by them on the auto industry. Organizations need to maintain balance between the production and change in forces of factors affecting demand. Managers and decision makers of associated organizations can use the proposed framework to pre-evaluate their demands corresponding to the future changes. Anticipated demands will help significantly in cost-saving and also in maximizing the profits and to increase the efficiency. This study provides a novel approach for assessing the demand risks. Similar approach can be also applied for other manufacturing sectors. This study can also be extended to assess the physical factors that affect the production rate in an industry. Subjectivity caused due to limited number of experts can be solved by empirical or case-based studies.

Appendix

Political risk	Economic risk	Social risk	Technological risk	Environmental risk
Tax policies (P_1) Environmental laws(P_2) Vehicle regulations (P_3)	Economic growth and development (E_1) Acquisition and running cost (E_2) Inflation rate (E_3) Availability of credit or finance (E_4) Employment rate (E_5)	Mass transit system (S_1) Cab ridership services (S_2) Vicinity of Roads and availability of parking (S_3)	Introduction of new vehicles (T_1) Automation in vehicles (T_2) Engine efficiencies (T_3)	Pollution levels (N_1) Season and climate (N_2)

Table A1. Classification of factors affecting the risk of automotive

Risk	Risk category	References
Economic growth and development	Economic	Muhammad *et al.* (2012), Shahabuddin (2009), Dargay (2001), Tambade *et al.* (2019)
Introduction of new vehicles	Technological	Nag and De (2020), Yadav and Sagar (2015)
Acquisition and running costs	Economic	Hamilton (1983), Mork (1989), Lee and Ni (2002), Barber *et al.* (1999), Duncan (1980), Chand and Avikal (2015)
Inflation rate	Economic	Chifurira *et al.* (2014)
Availability of credit or finance	Economic	Ludvigson (1998), Muhammad *et al.* (2012)
Tax policies	Political	Pritchard and DeBoer (1995), Alberini and Bareit (2016), Ott and Andrus (2000), Clibborn *et al.* (2016)
Employment rate	Economic	Muhammad *et al.* (2012), Shahabuddin (2009)
Mass transit systems	Social	Rith *et al.* (2019), Mulalic *et al.* (2016)
Cab ridership services	Social	Rawal and Sisodia (2017), Akbari *et al.* (2018)
Vicinity of roads and availability of parking	Social	Barbero and Galeota (2019)
Automation	Technological	Andrea and Smith (1994), Aghdaie and Yousefi (2011)
Engine efficiencies	Technological	Andrea and Smith (1994), Aghdaie and Yousefi (2011), Chand and Avikal (2015)
Pollution levels	Environmental	Barbero and Galeota (2019)
Season and climate	Environmental	Busse *et al.* (2015), Bloesch and Gourio (2015)

Table A2. Risk factors affecting product demand

Experts	Designation	Education qualification	Company where employed
Expert 1	Senior manager	MBA	Omax Auto
Expert 2	Manager	MBA	Maruti Suzuki
Expert 3	Assistant manager	MBA	Honda
Expert 4	Technical expert	PGDBA, M.Tech.	Mercedes

Table A3. Experts profile

Table A4. Level of factor importance according to decision makers

S. no.	Factors	Level of importance DM1	DM2	DM3	DM4
1.	Economic growth and Dev. (e.g. disposable income, etc), E_1	4	4	4	2
2.	Introduction of new vehicles with newer technology, T_1	5	4	4	3
3.	Acquisition and running costs, E_2	2	4	4	4
4.	Inflation rate, E_3	2	2	5	5
5.	Availability of credit/ finance, E_4	1	3	3	5
6.	Tax policies (taxes on purchase, incentives, etc), P_1	4	2	3	4
7.	Environmental laws (EVs, cleaner fuels, etc), P_2	1	2	2	4
8.	Vehicle regulations (Axle, safety, emission, etc), P_3	3	1	3	3
9.	Employment rate, E_5	2	1	1	4
10.	Public transport, S_1	2	1	3	2
11.	Cab services, S_2	3	4	4	3
12.	Vicinity of roads/ availability of parking spots, S_3	2	2	2	3
13.	Automation in vehicles, T_2	2	4	1	2
14.	Engine efficiencies, T_3	4	1	2	1
15.	Pollution levels, N_1	1	3	3	2
16.	Season and climate, N_2	1	2	3	1

About the authors

Dr Girish Kumar is Associate Professor in Mechanical Engineering Department at Delhi Technological University, Delhi, India. He has more than 22 years of experience in industry, teaching and research. His teaching and research areas include Reliability Engineering, Maintenance Management, Quality engineering, Stochastic Modeling, etc. He holds a PhD degree in Reliability Engineering from Indian Institute of Technology Delhi, India. Dr Kumar has published 25 papers in International Journals and conference proceedings.

Dr Rajesh Kr. Singh is a Professor at the Management Development Institute, Gurgaon, India. His areas of interest include supply chain management, Industry 4.0, quality management and circular economy. He has about 170 research papers published in reputed international/national journals and

conferences. He has published papers in journals such as *Resources, Conservation and Recycling, Journal of Cleaner Production, Industrial Management and Data Systems, Production planning and Control, Singapore Management Review, International Journal of Productivity and Performance Management, Benchmarking: An International Journal, Journal of Modelling in Management, Competitiveness Review: An International Business Journal, Global Journal of Flexible Systems and Management, International Journal of Productivity and Quality Management, International Journal of Services and Operations Management, International Journal of Automotive Industry and Management, International Journal of Logistic Systems Management, IIMB Management Review and Productivity Promotion.* Rajesh Kr. Singh is the corresponding author and can be contacted at: rksdce@yahoo.com

Mr Rishabh Jain is an undergraduate student at Delhi Technological University, (formerly known as Delhi College of Engineering), New Delhi, India. He is pursuing his Bachelor in Technology with Mechanical Engineering as major. His areas of interest include- decision-making, risk-modelling and other concepts of industrial engineering management.

Mr Raman Kain is a final year student at Delhi Technological University, New Delhi, India. He is pursuing his B.Tech with Mechanical Engineering as major. His areas of interest include- creative problem solving, risk analysis and concepts of quality management.

Mr Naveen is a final year student at Delhi Technological University, New Delhi, India. He is pursuing his Bachelor in Technology with Mechanical Engineering as major. His specialization is automotive engineering.

Analysis of Total Quality Management (TQM) Barriers on its Performance using TOC

Rakesh Kumar[1], Prof. R.S. Mishra[2]
[1]*Ph.D Scholar,* [2]*Professor, Department of Mechanical Engineering, Delhi Technological University, Delhi, India-110042*

Abstract: ***This study examines and analyzes the TQM factors which act as barrier and affects its performance. TQM view the organization as a collection of processes that must be continuously improved through utilization of the knowledge and experience of associates in all functions and at all levels. The industries must be more focused on understanding their own structure in terms of production/ service processes. Theory of Constraints (TOC) focuses on the weakest ring(s) in the chain to improve the performance of process systems. In this situation, TOC becomes an important problem structuring and solving methodology which changes the way of thinking of decision makers. This paper includes the extensive literature review on Theory of Constraints and suggested that how the same approach to analyze the performance of the Total Quality Management system.***

Keywords: Performance measurement, Theory of constraints (TOC), TQM.

I. INTRODUCTION

In today scenario of the industrial increasing competitiveness and cutthroat competition to capture wide market has led to the introduction of unconventional manufacturing management strategies such as just-in-time (JIT), material resources planning (MRP), Six-sigma quality control (SSQC), Lean Manufacturing and the theory of constraints (TOC). The basic concept of Theory of Constraints, shortly known as TOC assumes that the performance of the organization or say organizational system is adversely affected by constraints present in the system. Within the organizational system process, various functions are performed that are part of aiding the increase within production. The TOC then develops an explicit approach to manage these constraints to maximize throughput with continuous improvement. That's why it was also called that TOC is a multi-faceted systems methodology that has been progressively developed to assist people and organizations to think about problems, develop breakthrough solutions and implement those solutions successfully. The TOC defines a constraint as, *"Anything that prevents the organisation from achieving higher performance versus its goal"*. So, in the case of a profit-making organisation this centers on what limits. The TOC claim is that there are few constraints to any system preventing it from achieving its goal. Although TOC originally focused on physical resource constraints the underlying constraints are commonly policy, or deeper paradigm constraints. TOC uses cognitive mapping to verify this assumption where necessary, but there are many other authors who acknowledge the importance of underlying core problems that constrain system improvement. The main objective of this study is to identify the critical factors which behaves like bottleneck is required for TQM implementation in the organization, and these factors act as the critical chain. TOC is a complex methodology requiring skill and cooperation to implement. The past literature about the link between TQM practices and organization performance gives contradictory results. So the purpose of this study is to develop a conceptual framework and a research model showing the relationship between TQM implementation and performance measures of organization. Most of the previous works show that TQM has significant relationship with firm's performance. However, the examining of moderators is less given in previous work, which mediators are known generally as general tools and techniques without specific focus on types of improvement. And also to determine the effects of moderators TPM, SPC, Lean such as which improve the relationship between TQM practices and firm's performance.

II. LITERATURE REVIEW

In past TOC has developed rapidly in terms of both methodology and area of applications. Dettmer (1995) in his literature compared the system approach taken by TQM and TOC. He argued that TQM views the system in terms of discrete processes and then optimizes the quality in each process, whereas TOC improves performance by concentrating on the weakest link in the total system. It is apparent, however, that without subsequent identification of the weakest links, and application of the philosophy to these groups or processes within the organization, major improvements cannot be achieved. Dettmer further described the CRT technique of TOC is as functional rather than organizational and as such is blind to internal and external system boundaries.

©IJRASET: All Rights are Reserved

The TOC is providing a method of focusing improvement on the critical areas, and thus has the potential for much faster improvement towards a more global goal. The TOC can also contribute by emphasizing methods of dealing with change. The main obstacle for broader implementation of TQM in many industrial organizations, the need to win over those who do not believe in the method and who find it difficult to wait for TQM payoffs when they are battling daily problems.

The TOC provides some answers to these problems by contributing the Socratic thinking process for dealing with change, and potentially creating ownership and commitment throughout the organization. The focus on the weakest links helps also in hastening the improvement and generating more apparent results at a quicker pace. To address the policy constraints and effectively implement the process of on-going improvement, Goldratt (1990, 1994) develop a generic approach called the "thinking process" (TP).

Literature concerning TOC in different manufacturing system, like, JIT and TOC buffering philosophies are compared and suggested that improved system performance stems from the strategic placement of buffers in DBR(Drum-Buffer-Rope), which maximizes protection of the constraint from variation rather than attempting to protect each individual station is given by Watson, K.J.et.al (2008). Spencer, M.S. et.al (1995) also supported through his paper that DBR technique of TOC can be used to improve current production operations.

Gupta, S., (1997), Perez, J.L. (1997) and Watson, K.J. et.al (2003) advocated for the same technique of TOC for managing the supply chains systems. Boyd and Gupta (2004) established TOC as a theory by identifying the underlying construct "throughput orientation" along with its three dimensions: Mindset, Measures and Methodology. The thinking process tools of TOC provide techniques for identifying and solving root problems – which is a stated aim of TQM practices. Cox et al. (2003) provided some real-life examples of the applications of the TOC thinking process tools to quality problems.

A. TOC Method to Address TQM

A number of authors and quality experts consider that TQM principles and practices are universally applicable to any organization (Deming, 1982) regardless of the organisational contextual factors (e.g. size, technology, culture or external environment) (Zhao et al., 2004). Despite the claimed benefits of TQM, the relevant literature points to many research studies that indicate a high rate of failures in the process of implementing TQM practices, due to barriers that hinder its implementation (Sila, 2007; Soltani and Wilkinson, 2010).

TQM, Six-sigma, Lean Manufacturing, TOC all these strategic tools aiming similar manner, but with distinct flavor. These quality improvement tools first create its own virtual system in the existing system where it has to be implemented with active participation of the employee. In our further analysis of the relationship between TQM and TOC we will use the following definition of TQM (Dahlgaard et al., (1998): TQM is a company culture characterized by increased customer satisfaction through continuous improvements, in which all employees actively participate.

Researchers exploited these strategic tools far away from its actual usages. Like Six-sigma was initially developed by Motorola in later 80's for the product centric defect reduction and quality improvement tool, later it was experimented and successfully implemented in various areas.

Schonberger (2008) points out that the objective of Six Sigma programs is to create a higher perceived value of the company's products and services in the eyes of the customer. Six Sigma is a well-established approach that seeks to identify and eliminate defects, mistakes or failures in business processes or systems by focusing on those process performance characteristics that are of critical importance to customers (Snee, 2004).

Ehie and Sheu (2005) were able to integrate the theory of constraints with the DMAIC concept for achieving continuous quality improvement. Similarly, Lean manufacturing is designed for the process improvement as well as reduction/elimination of the existing waste, and further it also applied in the field which were substantial.

TQM is a wide concept since it embraces the whole organization and its processes instead of focusing on the product. It is also considered by many to be a holistic approach, which seeks to convert the culture and structure of the organization into a total commitment to quality (Barad, 1996). TQM is generally considered to be based on a number of core values such as customer focus, decisions based on facts, process orientation, continuous improvement, everybody's commitment and leadership; see Hellsten and Klefsjo (2000).

Table I: Linkage of Barriers to TQM

Factors	Barriers
Support Quality	• Lack of Leadership commitment • High turnover of management level • Company work culture is not synergetic with company goal and objectives • Difficult to change employee mindset about quality • Lack of information about quality
Support Internal Communication	Lack of coordination amongst departments
Provide quality resources	Lack of sufficient funds to mobilize TQM driven activities
Use competent personal	• Poor education levels of workers • Low morale (absenteeism, industrial action etc.) • Lack of skill of workers • High worker turnover • Indiscipline (non-conformances with procedures)
Support Competence	• Insufficient Training about quality • Management related training is not achieving organizational training targets
Provide quality Infrastructure	• Poor condition of machine • Ineffective maintenance programs • Poor condition of equipment spare part procurement
Control Purchasing Process	• Raw material does not confirm with the specification • Spontaneous delivery of raw materials • Difficulty in procurement of raw material

The core idea of TOC is that every system has at least one constraint that prevents from achieving the goal to a larger degree. Constraints can be physical resources or policies. TOC develops a set of procedures and methodologies to identify and optimize such constraints. In this paper TQM is considered as a system under the organizational system and the barriers are considered as the constraints, which hinders the quality goal. And the well-known fact is that the success of the system depends on everybody's participation (one of the core principles of TQM).

The Theory of Constraints is based on five steps.

1) Identify the system's constraints(s)
2) Decide how to exploit the system's constraint(s)
3) Subordinate everything else to the above decision
4) Elevate the system's constraint(s)
5) If, in the previous steps, a constraint has been broken, go back to step 1, and do not allow inertia to cause a system's constraint.

The system's constraint is that part of the system that constrains the objective or goal of the system. The issues with TOC is that the constraints must be kept operating at its full capacity, if not then entire process slows further. The organization where TQM is implemented, and the barriers/hurdles/constraints even if identified must be kept operating to maintain the pace of the production. Upstream operations must provide only what the constraint can handle and downstream operations will only receive what the constraint can put out. Total Quality Management System is system of any organizational systems. It is known that System of systems is a collection of task-oriented or dedicated systems that pool their resources and capabilities together to create a new, more complex system which offers more functionality and performance than simply the sum of the constituent systems.

The failures in implementing TQM are typically attributed to organisational contingent, situational or contextual factors such as unsupportive organisational culture, resistance to change, lack of resources, or uncommitted leadership (Zhao et al., 2004; Sadikoqlu and Zehir, 2008). It is also said about TQM that it is system that starts with consumers and ends with them. So successful implementation of TQM improves organizational performance and leads to high degree of satisfaction to customers and employees.

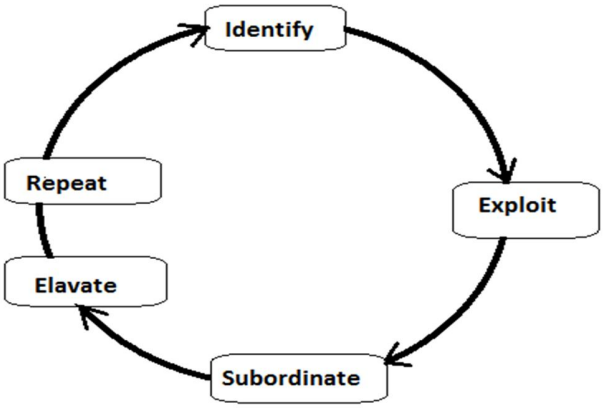

Figure1. Five aiming steps of the TOC

TQM systems include the procedures for quality planning strategy and operations, for setting capital and operating budgets, for measuring and rewarding performance, and for reporting progress and conducting meetings. many companies introduced total quality management as a new management system. But while TQM enabled firms to focus more effectively on process improvements, the ability to implement strategy across organizational units remained elusive. Companies' management systems were still tactical and operational, not strategic. In terms of the TQM system's constraint is the existing barriers. The whole performance of TQM system depends on successful run of the TQM drivers and enablers and the TQM driver depends on the TQM capability. Consequently, it is essential to keeping in view the quality goals. In Step 1 this needs to be identified. By identifying these barriers, company management can increase their understanding of implementation failure and the subsequent removal of these barriers can lead to the possibility of successful implementation. Thus, any company that was rated as high performing was evaluated as moving toward successful implementation of TQM practices. Activities to remove barriers for consensus encompasses a wide range of activities including leadership, decision-making tools, and other tools or tactics to restructure culture and/or to re-motivate employees to the TQM paradigm. As it is a system, then the maximum possible utilization needs to be achieved. This may mean to eliminate those factors which were identified as obstacle for the accomplish the quality improvement procedure as soon as possible or reducing the number of barriers. It will mean ensuring that there is always analysis of the system to do. Thus the system's constraint is exploited (Step 2). If this is the constraint, then there is no point running the enablers: so every other TQM tools needs to be subordinated to remove the bottleneck if still present (Step 3). To achieve the goal/ objective, the system's constraint may need to be `eliminated' or minimized. The enablers, the capacity of the system, has been increased, or `elevated' (Step 4). The application of Step 4 may have changed the system's constraint. With its increased drivers, the original bottleneck may no longer be constraining the system, so the new bottleneck needs to be identified, and the process repeated (Step 5). Thus, this is a process of continual improvement.

B. TOC Strategies

The core premise of TOC is that any organization or system's performance is limited most by a "constraint" — the thing that most blocks throughput. Identifying the nature and location of the system's constraint is the key to continuous system improvement, stated by Srikanth et al. (1997). TOC is a data-driven approach like other continuous improvement processes uses Identify the system's constraints, decide how to exploit the constraint(s), Subordinate everything else to the above decisions, Elevate the constraint(s) and Don't let inertia become the new constraint - go back to step 1, but do not allow previous decisions made in steps 2 to 4 to become constraints because TOC views constraints as positive, not negative. Because constraints determine the performance of a system, a gradual elevation of the system's constraints will improve its performance. According to Dettmer (1995), he compared the system approach taken by TQM and TOC. He argued that TQM views the system in terms of discrete processes and then optimizes the quality in each process, whereas TOC improves performance by concentrating on the weakest link in the total system. Whether organization manages stand-alone or multiple projects, whether those projects are small or large, whether customers are internal or external, or whether the nature of the work performed is product development, construction, design, IT, or service; most projects are difficult to manage because of two things:

©IJRASET: All Rights are Reserved

1) They involve uncertainty, and
2) They involve three different and opposing commitments: Due date, budget, and content

The main strategies of TOC along with tasks and its descriptions summarized in Table II.

Table II

TASK	Description
Identifying "What to Change?"	Organization must effectively address the underlying root causes that lead to the problems.
Identifying "To What to Change To?"	To address these root causes and coping mechanisms, a comprehensive solution must be provided. The solution includes: 1) a robust planning process, 2) a more effective scheduling process, 3) a methodology for introducing work that actually leads to increased capacity, 4) execution processes that provide excellent project control, visibility and decision support, and 5) work behaviors that are more conducive to good project performance.
Identifying "How to cause the change?"	The right people must be brought into the picture at the right time, in just the right way. The process must move slowly enough to permit identification of essential changes, yet fast enough that it does not lose the momentum that is necessary to sustain continued progress.

III. CONCLUSION AND FUTURE RESEARCH

The performance of the Total Quality Management (TQM) System is the responsibility of every person involved in all activities related to the company. As in this work TQM considered as a management system for a customer-focused organization that involves all employees in continual improvement. This paper combines the powerful and practical management theories – theory of constraints over TQM. When applied this concept enable managers to analyse and control the most important factors in their firm – the constraints – in new ways.

TOC may be also applied for the lean manufacturing, six-sigma, Business process reengineering (BPR), supply chain management (SCM) and logistic system by considering them as a system inside the system. Cellular manufacturing system and group technology is also one of the untouched field where TOC strategic management tool may be implemented in the similar fashion for the better result. All the above mentioned the defined process or system functions as intended and produces intended results under normal operating conditions. So, as a future work, the barriers may be ranked and weighted to get the precise result is recommended. Choosing the right TOC tool for the desired solution is also the one of the most challenging job always.

Anomalous Object Tracking in Distributed Camera Network

MD Shahbaz Khan, Dr Indu Sreedevi
Delhi Technological University
New Delhi, India
mdshahbaz_bt2k16@dtu.ac.in, s.indu@dtu.ac.in

***Abstract*—The paper introduces a novel framework for real-time tracking of an object with higher precision in a Pan-Tilt-Zoom (PTZ) camera network. In the above-mentioned framework, the object which behaves anomalously is picked for tracking. An SVM classifier has been used to pick anomaly behaving object among all the objects present in a frame. It is a self-initializing algorithm as it does not require user intervention for object detection. Target detection is followed by its autonomous tracking in the distributed camera network. Hence it does not make the system bulky and takes less time to execute. The paper implements multiple object tracking using Discriminative Correlation Filtering with Channel and Spatial Reliability(CSR-DCF) tracking algorithm. Existing works are based on Particle filtering or Kalman filtering algorithms which are computationally complex and not self-initializing.**

I. INTRODUCTION

An efficient and fast algorithm is required for tracking a specified object from a frame having many objects using distributed PTZ camera based network. For each frame, some objects are at a higher priority for tracking than the rest. Although it is possible that none of the objects needs to be tracked in a particular sequence of frames. In such cases, tracking is not initialized till an anomaly behaving object is detected. Act of running, bending or picking was considered as anomalous behaviour. For detecting an anomaly behaving object, SVM based classifying model is trained. The distance of centroid of an object from its contour was used as a feature for developing the SVM model. This leads to the enhancement of the computational efficiency of the proposed algorithm. Sink frame of a particular camera in the network serves as the source frame for the other. For the mentioned decision-making task, the paper proposes a real-time, computationally efficient algorithm in which the camera having sink frame generates a histogram and is transmitted to all the adjacent cameras. Other cameras generate a histogram for their respective source frame and compare it with the received one. Camera having the same histogram starts tracking the object. Use of histogram formation and their comparison results in a smooth tracking at the time of object handover from one field of view (FOV) to another. Real-time and computationally fast algorithms are required for surveillance of densely populated public places using distributed PTZ cameras. The proposed approach assumes overlapping FOV between adjacent cameras in the network with the same resolution of the sink and the source frame of the neighbouring cameras.

II. LITERATURE LAYOUT

Several algorithms have come up to make object tracking autonomous with higher precision and real-time. However, on increasing the number of cameras in the network, their computational efficiency decreases manifold. Algorithms like [1],[2] do not consider the formation of the shadow of objects while few other algorithms like [3] are not suited for public places where the number of objects is more than an ordinary scenario. Current works in this field [3] attempts to track the object using particle filtering algorithm along with user intervention. As far as places with larger crowds are concerned, particle filtering algorithms are not efficient and do not yield real-time processing of data. CSR-DCF based tracking is a multi-object tracking algorithm and hence it can handle a large number of objects in crowd places. Paper [2] deals in Kalman filtering based object tracking, which is not efficient for real-time object tracking. In the case of Kalman filtering, noise is measured by modelling it as additive white Gaussian noise (AWGN). This makes the noise measurement in each frame as a joint Gaussian distribution. This, in turn, makes the object tracking vague when there is a bifurcation in the path of the object. This paper implements CSR-DCF tracking algorithm which is one of the best available real-time object tracking algorithm as discussed in table II. In papers like [1], object tracking is initialized by detecting the object in the very first frame by using the user interface. This, in turn, binds the algorithm from being fully autonomous. To eliminate this bottleneck, our approach proposes the concept of self-initialization of the object. Self initialization can be defined as the detection of an object of interest by the system itself. This paper implements self-initialization by choosing the object of interest as per its anomalous behaviours among all the objects present in that frame. The anomaly behaving object is picked using the SVM model. The model has been trained by using the distance of centroid of the object from its contour. No sooner did the object is detected, then its tracking gets started in all the cameras present in that distributed camera network. This algorithm proves to be efficient for the crowded region as it can track the movement of a suspicious object by itself. Each camera in the network tracks the object and communicates with adjacent cameras when the object of interest leaves its FOV. This novel method of object handover eliminates the chance of object missing during tracking in a

multi-camera system and hence yields a higher accurate tracking.

III. Problem Statement

The paper aims to find the solution for the detection of anomaly behaving object followed by its tracking in a distributed camera network. The intent is to improve the tracking accuracy and precision in comparison with probability and Gaussian distribution-based tracking algorithms[3] and [2] like particle filtering and Kalman filtering. The proposed methodology also eliminates random id generation technique[3] used to track objects in multiple cameras. Moreover, the proposed algorithm of object handover reduces the probability of object missing during its tracking in a multi-camera network system.

IV. Anomalous Behaviour Detection

The prerequisite for this algorithm is the minimum number of objects to be present in the camera frame which is achieved by classifying objects as normal and abnormal behaving groups. Activities like running, bending, or the act of picking are classified as anomalous behaviour in this paper as shown in figure 5 & 8. The paper proposes Principal Component Analysis (PCA) based feature extraction followed by its classification as anomalous behaviour using Support Vector Machine (SVM) classifier as discussed in [4] and the result has been collected in the table I. To prepare an SVM model, the maximum distance of any point on the contour from the centroid of the object was calculated and was used as features for SVM classier.

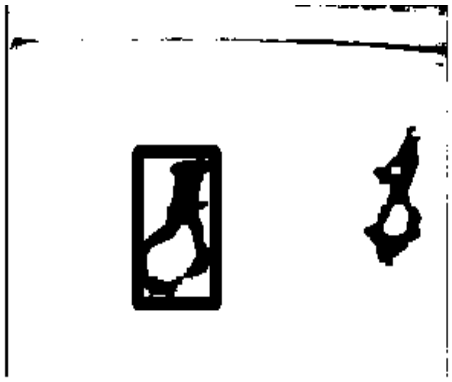

Fig. 1. A person running classified as anomalous behaviour

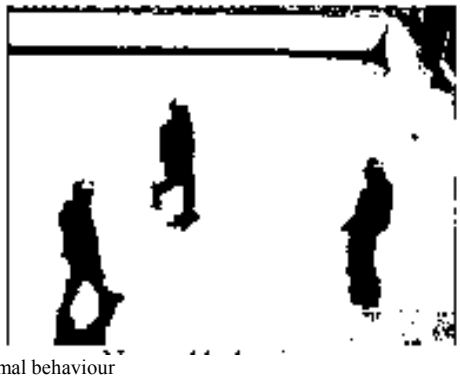

Fig. 2. Normal behaviour

Fig. 3. A person bending in the pathway – classified as anomalous behaviour.

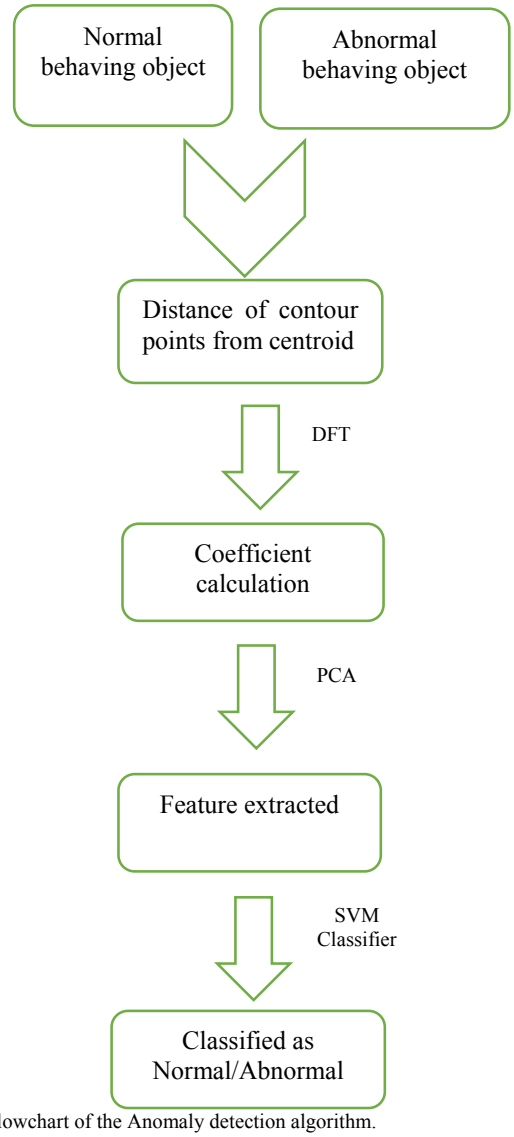

Fig. 4. Flowchart of the Anomaly detection algorithm.

First of all, the contour of every object was formed. Then using the below-mentioned formula, the centroid of that object was obtained.

$$x_c = \frac{1}{N}\sum_1^N x_i \quad (1)$$

$$y_c = \frac{1}{N}\sum_1^N y_i \quad (2)$$

where x_c, y_c are the coordinates of the centroid of contour.

For each point on contour, Euclidean distance was calculated and was transformed to coefficients by using DFT (Discrete Fourier Transform), which was later used for feature extraction using PCA (Principal Component Analysis).

A. PCA Based Feature Extraction

To extract features from each frame of camera input, PCA algorithm was implemented. The training dataset was divided into two groups namely G1, G2 each having 'n' training samples. Eigenvector of features was generated as follows: -

1) For each group of the dataset, a matrix '*X*' was formed having 'n' rows of samples and 'c' columns of features.

2) From the feature matrix '*X*', covariance matrix 'C' was computed as

$$C = (X - X')^T (X - X') \quad (3)$$

3) For the computed covariance matrix, eigenvector and eigenvalues were determined using the following relation

$$CV = V\Lambda \quad (4)$$

Where V is eigenvector and Λ is an eigenvalue.
Out of 'c' columns of Λ, we picked 'k' number of columns thus reducing the feature vector size to n x k.

B. SVM Classifier

As per the statistical learning theory [5],[6] & [7], SVM is one of the most precise classifying algorithms. The paper implements SVM for classifying the extracted features into normal and abnormal behaviour by using separating hyperplane. The constructed hyperplane was localized by maximizing the separating margins and consequently, it led to the formation of nonlinear decision boundary in the training dataset.
By implementing SVM algorithm, an optimal hyperplane was found such that it divides the dataset into two groups completely. In the course of building the SVM model, a hyperplane is adjusted by maximizing the margin between data values and hyperplane. Margin maximizes by minimizing the cost function.
Where cost function $J(x, y, f(x))$ is defined as,

$$J(x, y, f(x)) = \begin{cases} 0, \text{if } y * f(x) \geq 1 \\ 1 - y * f(x), \text{else} \end{cases} \quad (5)$$

On building the SVM model for training data, it was tested on the testing dataset whose labels was known. The hyperplane was further adjusted to get the maximum accuracy of classification. At the end of testing, the SVM model was used for unknown data.

Anomaly Behaviour Detection Algorithm

Prerequisites: Continuous video dataset, the dataset must contain anomaly behaviour, the dataset should contain video of the different timing of day having varying brightness.

Behaviour Detection:
1. Dividing the dataset into training and testing data group in a ratio of 1:4.
2. Extracting features from training dataset.
3. Optimizing number of features required to detect behaviour using PCA.
4. Adjusting the location of hyperplane by minimizing the cost function using SVM.
5. Applying the trained model to the testing dataset and evaluating the precision percentage.
6. If the precision is not more than 85% (as depicted in table I), then the number of data example in training dataset was increased and step 6 was repeated.
7. Else proceed to apply the trained model to an unknown dataset.

V. CSR-DCF ALGORITHM

In this paper, we have applied background subtraction to our input data before detecting anomaly behaviour. For the abovementioned task, background segmentation algorithm (based on Gaussian Mixture) was used, as it flexible for diurnal changes and for shadow detection as well. This algorithm is based on two research papers [8],[9] given in the year 2004 and 2006 respectively. On detecting an abnormal behaving object in a frame, the tracking algorithm starts executing. A rectangle bounding box is formed around that region of interest with a different colour for different objects in each frame. CSR-DCF algorithm was implemented for tracking objects which is a real-time processing algorithm with higher precision.
As discussed in [10], CSR-DCF is a tracking algorithm which provides learning with higher efficiency and better integration of filter updates and tracking. In this algorithm, spatial reliability map is used which helps to adjust filter support to enhance the accuracy of tracking. Similarly, reliability scores are calculated to check the quality of filters and thus helps in evaluating coefficients in localization.
This paper proposes a novel framework of object tracking based on discriminative correlation filtering followed by channel and spatial reliability scores[11]. It is a proximity-based algorithm which learns a set of filters to represent the object and uses them to find the highest correlated point in the adjacency of tracking an object from the previous frame.

A. Spatially Correlation Filters

With the help of the following approach, we comprehend the importance of learning correlation filters. For a given set of 'n' channels with features f = $\{f_k\}_{k=1:n}$ and target templates h = $\{h_k\}_{k=1:n}$, and the position of the object is determined by locating the highest frequency of ĝ(h),

$$\hat{g}(h) = \sum_{k=1}^{n} f_k \star h_k \quad (6)$$

where $\star$ is circular convolution operator & $\hat{g}(h)$ is correlation response.

Similarly, to find optimum correlation filter h, we have to minimize

$$\mathcal{E}(h) = \|\hat{g}(h) - g\|^2 + \lambda\|h\|^2 \quad (7)$$

where g is the expected output.

To find the efficiency of tracking, we transformed it into Frequency Domain as

$$\mathcal{E}(h) = \| \sum_{k=1}^{n} diag(\hat{f}_k)\hat{h}'_k - \hat{g}' \|^2 + \lambda\|h\|^2 \quad (8)$$

And on minimizing the above equation we get,

$$\hat{h}_k = (diag(\hat{f}_k)\hat{g}') \odot^{-1} (\sum_{k=1}^{n} diag(\hat{f}_k)\hat{f}'_k + \lambda) \quad (9)$$

where $\odot^{-1}$ is element-wise division operator and the above result can be used to design correlation filter trackers.

On considering each channel to be independent, we get the cost function as

$$\mathcal{E}(h) = \sum_{k=1}^{n} \|f_k \star h_k - g\|^2 + \lambda\|h\|^2 \quad (10)$$

To scale, we introduce a factor depending upon the discriminative power of feature channels which is termed as channel weights $w = \{\hat{w}_k\}_{k=1:n}$ and whose correlation response is given by,

$$\hat{g}(h) = \sum_{k=1}^{n} f_k \star h_k \cdot \hat{w}_k \quad (11)$$

B. Correlation Filter Learning

As mentioned above, it has been assumed that the correlation filter is independent of channels, hence it allows to consider the case of one filter only. The constraints are formalized as following

$$h_c \; m \odot h \equiv 0 \quad (12)$$

where h_c is defined as the dual variable with the above constraints.

On using Lagrangian augmentation [9], we find the following outcome

$$s\mathcal{L}(\hat{h}_c, h, \hat{I}|m) = \|diag(\hat{f}_k)\hat{h}'_k - \hat{g}\|^2 + \lambda\|h_m\|^2 + [\hat{I}^H(\hat{h}_c - \hat{h}_m) + \hat{I}^H(\hat{h}_c - \hat{h}_m)'] + \mu\|\hat{h}_c - \hat{h}_m\|^2 \quad (13)$$

Here in the above equation, we have introduced a new term μ which is the constraint penalty value and its value is updated by the following equation.

$$\mu^{i+1} = \beta\mu^I \quad (14)$$

C. Spatial Reliability Map

On locating the target, the region of interest is extracted from the frame and is used for updating the filter. The constrained filter uses spatial reliability map m_p, which is the collection of pixels of training model matching with that of the testing mode. To determine m_p, we have designed the following algorithm.

While the algorithm is getting executed for tracking, f oregr ound, and background of the object is stored in colour histogram c. Let $v_i = [y_i^c, y_i^x]$ is the observation i.e., it denotes the colour of y_i^c along with the y_i^x position for each pixel and m_p = random variable indicating the unknown foreground/background. For y_i to be observed on output, its joint probability was found as follows

$$\begin{aligned} p(y_i) &= \sum_{j=0}^{1} p(y_i | m_i = j)p(m_i = j) \\ &= \sum_{j=0}^{1} p(y_i^c | m_i = j)p(y_i^x | m_i = j)p(m_i = j) \end{aligned} \quad (15)$$

Algorithm 1 CSR-DCF

Prerequisites: Image I_i, the position of an object in previous frame pos_{i-1}, scale k_{i-1}, filter h_{i-1}, image histograms c_{i-1}, channel reliability w_{i-1}.

Determination and approximation of scale:-

1. Locating target at pos_i : finding the highest frequency in a correlation between filter (h_{i-1}) and extracted features (f) at pos_{i-1} position and adjusted by reliability scores (w).
2. Calculation of $\hat{w}$(det) (detection validation) with the help of per-channel responses.
3. Scale k_i was calculated, with the help of pos_i.
4. Colour histograms for foreground as well as the background were calculated and updated using $\hat{w}$(det) (detection validation).
5. Reliability map m_p was calculated using the above-mentioned relation.
6. Filter $\hat{h}$ was calculated and updated using m_p.
7. Using h, learning channel reliability was determined.
8. Calculate channel reliability from learning channel reliability & detection reliability.
9. Each filter hi was updated using the relation $h_i = (1-\eta)h_{i-1} + \eta\hat{h}$.
10. Channel reliability w_i was updated using the expression $w_i = (1-\eta)w_{i-1} + \eta\hat{w}$.

VI. Object Handover

In a distributed camera network, each camera is capable of processing the data and extracting information out of it. Cameras in a network can communicate with each other wirelessly in a range of 100m. The exchange of data between two cameras was done using OFDM modulation (Orthogonal

Frequency-Division Multiplexing). The advantage of using OFDM modulation is that it provides versatility in the presence of multiple channels.

The problem arises in handing over the object from one camera to the other. To eliminate the object handover problem, this paper implements the following algorithm:-

OBJECT HANDOVER ALGORITHM

Case 1: If the system has not yet detected any anomaly behaviour.
- i. In this case, each camera will keep on processing the input frames for anomaly detection.
- ii. If any anomaly behaviour is detected, then that camera will switch to case 2 else will continue to execute case1.

Case 2: if any anomaly behaviour is detected.
- i. Object tracking algorithm will be applied to the camera input in which anomaly action has been detected.
- ii. Camera tracking the anomaly behaving object will stop executing the anomaly detection algorithm for new objects.
- iii. As soon as the object becomes the sink for a camera, the camera generates its histogram from the last frame (say h1).

Case 3: when the object moves out of FOV of one camera
- i. In this case, the anomaly detection algorithm is paused and for each camera histogram of the new entering object is calculated (say h2).
- ii. Then both colour histograms (h1 and h2) are compared and the camera (say C2) whose histogram matches with h1, is now used for tracking.
- iii. The object tracking algorithm is applied to the camera (C2) input frame and case 2 is followed.

*Figures 6,7 and 9,10 illustrate the above-mentioned algorithm.

VII. EXPERIMENTAL RESULTS

The above experiment was performed on a dataset collected from Computer Vision Laboratory CVLAB ('https://cvlab.epfl.ch/data/data-pom-index-php/'). The mentioned dataset consists of inputs of 4 cameras located at different worldly points but with the same intrinsic parameters. On implementing the above-proposed algorithm, real-time object detection was done using anomaly behaviour detection technique with the following results

TABLE I. RESULT OF SVM CLASSIFIER

RESULT OF SVM CLASSIFIER		
Behaviour	***Success rate***	***No. of testing samples***
Normal	97%	297
Anaomaly	86%	328

The above-proposed algorithm was tested on the dataset at VOT2016 [12] benchmark which is comprised of 14 videos (7 training and 7 testing). On rigorous testing and comparison with various tracking algorithms, we got the following result (Table II).

TABLE II. COMPARISONS OF TRACKING ALGORITHMS

Tracking Algorithm	EAO	Aav	Fav	Total
Proposed method	0.34	0.510	0.851	-0.001
CCO Tracking	0.33	0.520	0.856	-0.006
TCN Net.	0.33	0.521	0.961	-0.110
SSA Tracking	0.32	0.531	1.044	-0.193
MLD Filter Based	0.31	0.482	0.833	-0.041
Staple	0.30	0.512	1.351	-0.539
DOC	0.29	0.513	1.233	-0.430
EB Tracking	0.29	0.441	0.902	-0.171
SRB Tracking	0.29	0.504	1.251	-0.547
STAPLEp	0.29	0.533	1.321	-0.498

*EAO – Expected Average Overlap
*A_{av} – Average Accuracy
*F_{av} – Average Failure
*Total = EAO + A_{av} - F_{av}

The above-mentioned comparison of various tracking algorithms was carried on the ground of expected average overlap, average accuracy and average failure. For an ideal tracking algorithm expected average overlap and average accuracy should be higher while lower average failure is preferred. In the case of real tracking algorithms, we need to compromise between these three parameters. To bring uniformity in comparison, a total usefulness function formed whose formula has been mentioned above. The higher total usefulness value for a tracking algorithm is, better that algorithm is to use. From the above table, we conclude that our tracking algorithm is better among the rest as its total usefulness value is higher than rest tracking algorithms.

Fig. 6. C1 detected object being tracked by the camera C2.

Fig. 7. Tracking object moving out of C2 camera being tracked by the camera C3

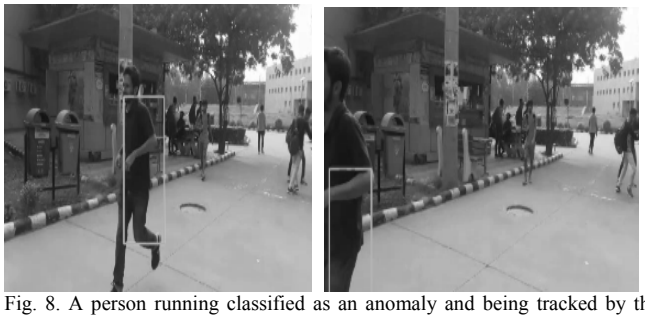

Fig. 8. A person running classified as an anomaly and being tracked by the camera C1.

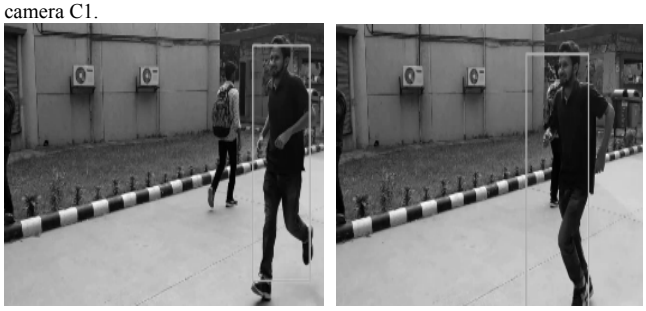

Fig. 9. C1 detected object being tracked by the camera C2

Fig. 10. Tracking object being moved out of C2 and tracked by camera C3

*Fig. 6-10 depicts the results of packing anomaly behaviour (running, bending and picking) using 3 cameras C1,C2 and C3.

VIII. Conclusion and future scope

This novel framework proposes an accurate and precise method for object tracking in distributed cameras. It is a real-time based approach with higher computational efficiency for tracking in a camera network. One of the important feature of this algorithm is self-initialization, which do not require user interventions. The proposed algorithm deals with the tracking of anomaly behaving objects using CSR-DCF based algorithm. Running, bending or picking has been classified as anomaly behaviour and based on this classification, objects are picked for tracking. For tracking the object, CSR-DCF algorithm has been implemented which is faster and more precise. Histogram comparison-based algorithm has been implemented to handover the object from one camera to the other in the network system.

Acknowledgement

I express my deepest gratitude to all those who helped me make this research complete and meaningful in all sense. First of all, I would like to thank our faculty in-charge, Prof. S. Indu & Dr Ayesha Chowdhary, whose contribution to this research work is incredible. They helped me to get through this research work by providing their valuable suggestions and sparing their precious time. Furthermore, I acknowledge the contribution of other staffs of the ECE department (DTU), who helped me by providing their valuable suggestions related to my topic. Last but not least, I am highly thankful to my parent and friends, who provided me moral support in times of distress and failure and played a vital role to make this work complete in all sense.

Abstract: Electrical energy has been considered as an essential form of energy. Whether it is Industrial need or household need, electricity is a must. Nowadays, with the increasing need for electricity, power theft is also increasing. This power theft is a severe problem like load scheduling will just become a hoax because of this Theft. Also, in developing countries like India, this power theft is 30%- 40% of total generated power and the electricity board has to provide this from their funds this results in major losses to electricity boards. This paper presents a way to detect power theft, alert the consumer, and cut off the supply accordingly. When unauthorized actions are detected, and a separate message is sent back to the microcontroller to remove the illegal supply, an SMS is sent automatically to the user via the GSM module. The GSM is interspersed with a unique system energy meter with a relay to handle the non-technical losses, problems with billing, and variations in voltage fluctuations

Keyword **– GSM, Atmega328, LM2596, Arduino GSM**

Introduction

Over the last few decades, communications technology has improved through connectivity and boundaries. The use of the "Embedded Program in Communication" provides various interesting applications. Electricity is now more than necessary. The demand for electricity is increasing continuously. With increasing electricity demand, power theft is also on the rise. Power theft is a concerning issue even in the most efficient power systems like in USA and a moderately efficient system like in Malaysia [1]. It has become important to improve the system performance and to avoid Theft. The purpose of this project is to design a system to monitor any power consumed before the power meter, and that is power pilferage. If some power theft is detected, that results in penalty or disconnection of energy supply to the respective consumer, and simultaneously an SMS is sent to the control unit. In the past, numerous non-technical and scientific methods for detecting electricity pilfering have been suggested. Non-technical procedures may involve customer inspection with a suspect load profile. Although regular inspections can help reduce theft, such action calls for the massive labour force and enormous effort. In most situations, this attempt always fails due to employee dishonesty. “The use of the main observer meter at the secondary distribution terminals are some of the technological ways to detect pilferage [3], harmonic generator [6], genetic support vector machines [7], extreme learning machine, power line impedance technique [8] [3].

However, these technical approaches can be effectively implemented only if proper communication is ensured between the central control station and the appropriate test points. Recently, energy meters based on GSM network have been proposed. These meters provide the energy metering and remote load control system facility [3]. In this paper, an energy metering scheme based on GSM is introduced to deal with various aspects of electricity theft. The proposed system avoids meter abuse and bypassing irregularities.

Existing Technology

The meter is manipulated to display low readability, bypass meter, and billing irregularities. Advanced distribution automation and dynamic price models relying on automated metering (AMR) and advanced measuring infrastructure (AMI) can overcome the billing irregularities and requirements for more employees [3]. However, this system has failed to benefit the atmosphere for energy theft and requires frequent inspection by NTL. Electrical cables, coaxial cables, optical fiber, infrared, Bluetooth are also used for current communication technologies but do not have reliability, communication speed, high installation costs, and maintenance are expensive and risky.

Methodology

For successful completion of this project, the following steps were carried out in a sequential manner

- Literature Reviewing: This includes exploring various documents and books regarding this topic.
- Problem identification: identifying the problem and its consequences.
- System modelling: Combining different elements to describe the system.
- System analysis and simulation: This indicates how the system behaves using proteus.
- Proposing Solution: designing of power theft control system to use power wisely.

Proposed System

In this paper, the energy stealing system is proposed to send the SMS using a GSM Network. The most common methods of electricity theft are to bypass the phase line, cut off the neutral line, bypass the entire meter, and distort the energy meter. The current transformer is blinded to zero current, bypassing the phase line. The voltage transformer shows zero potential by disconnecting the neutral line and giving the local ground. The entire meter is bypassed, and the energy meter is measured at zero. Faulty readings are triggered by tampering the energy meter with unauthorized modification. The main contributions of this paper as follows

- The proposed system uses only a very small number of components and a simple electricity theft algorithm.
- The customer is warned initially after several warnings, the connection of the customer is being cut, and data is simultaneously sent to the control center
- Compared to other techniques discussed, total system costs are relatively low.
- It can be integrated with existing meters and new meters of production processes.

Many named and unnamed manners for theft of electricity are also available. The use of a single household meter cannot detect and control these types of theft. An observation meter is used in the proposed system to identify such unrecounted theft. Figure 1 shows the observer meter. Measure the overall household energy consumption at agreed time intervals. For example, outside an apartment building, this type of meter can be installed. In this case, all the apartments in this apartment building measure the energy consumed. The household meters communicate their measured units via SMS to the central meter. The central meter detects the theft of electricity when both values are significantly different. Since the observer meter can be read individually, households in which theft occurred can be calculated based on zero or low power consumption. The central meter informs the server of potential theft locations via SMS. The authority may send technical personnel to check the households reported and detect the dishonest consumer [3].

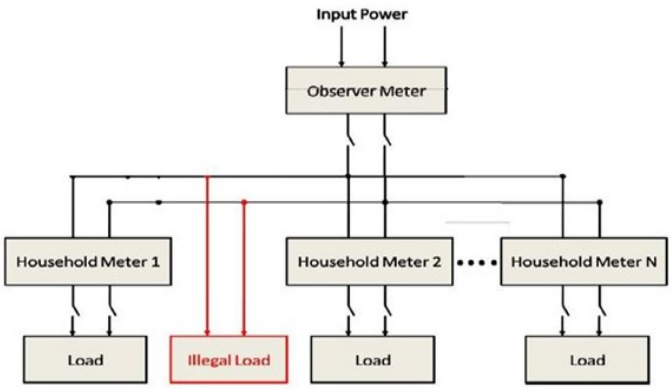

Figure 1: Block Diagram

Block Diagram

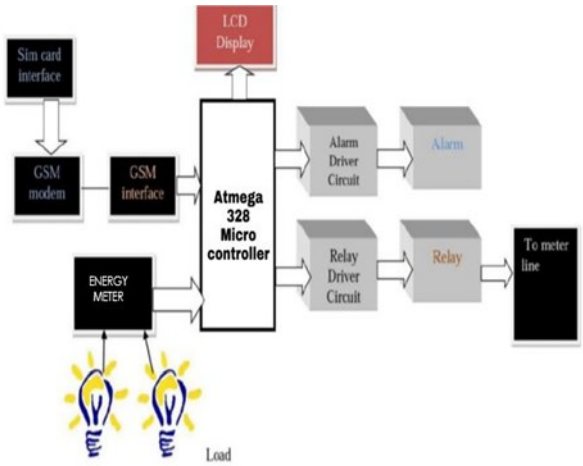

Figure 2: Proposed Architecture

The aims of the proposed program are mainly to monitor electricity theft through enhanced GSM communication features. Figure 2 shows the block diagram of the prototype. The most important components included power meter, GSM module [10], LM2596 voltage regulator, Arduino UNO [9], PC817 optocoupler, and LCD. The prototype model is a device that uses energy to link a variable load. The PC817 optocoupler and the CAL (calibration) energy meter LED is attached for the detection of consumed units. At 3200 imp/kWh the pulse rate of the power meter is. The LED blink rate is, therefore, directly proportionate to the load. To record consumed units, the output of the optocoupler is forwarded to the microcontroller.

Proposed Circuit

In the circuit first, a power supply block i.e. IC LM2596, which is made by TEXAS INSTRUMENT is introduced. This is used to get a constant 5v DC output, that is used to power 16*2 LCD, Microcontroller, Relay Module.

Data pins of the LCD display are connected to digital pins of the microcontroller (pin-6,7,8 & 9) which is used as output pins. GSM module is also interfaced with the microcontroller through digital pins 2 and 3(in the software part this is defined as transmitter and receiver pins). A buzzer is also connected to pin 11 of the microcontroller which functions in case of theft. Also, a relay is used to trip the load in case of theft, this is connected to pin 10 of the microcontroller.

Two energy meters are used one is named as master energy meter and other as a house energy meter. These meters are connected to pins A0 and A1(Analog input pins) of microcontroller through PC817(optocoupler). Optocoupler's input terminals are connected to calibration LED of Energy meter and output is connected to pins A0 & A1

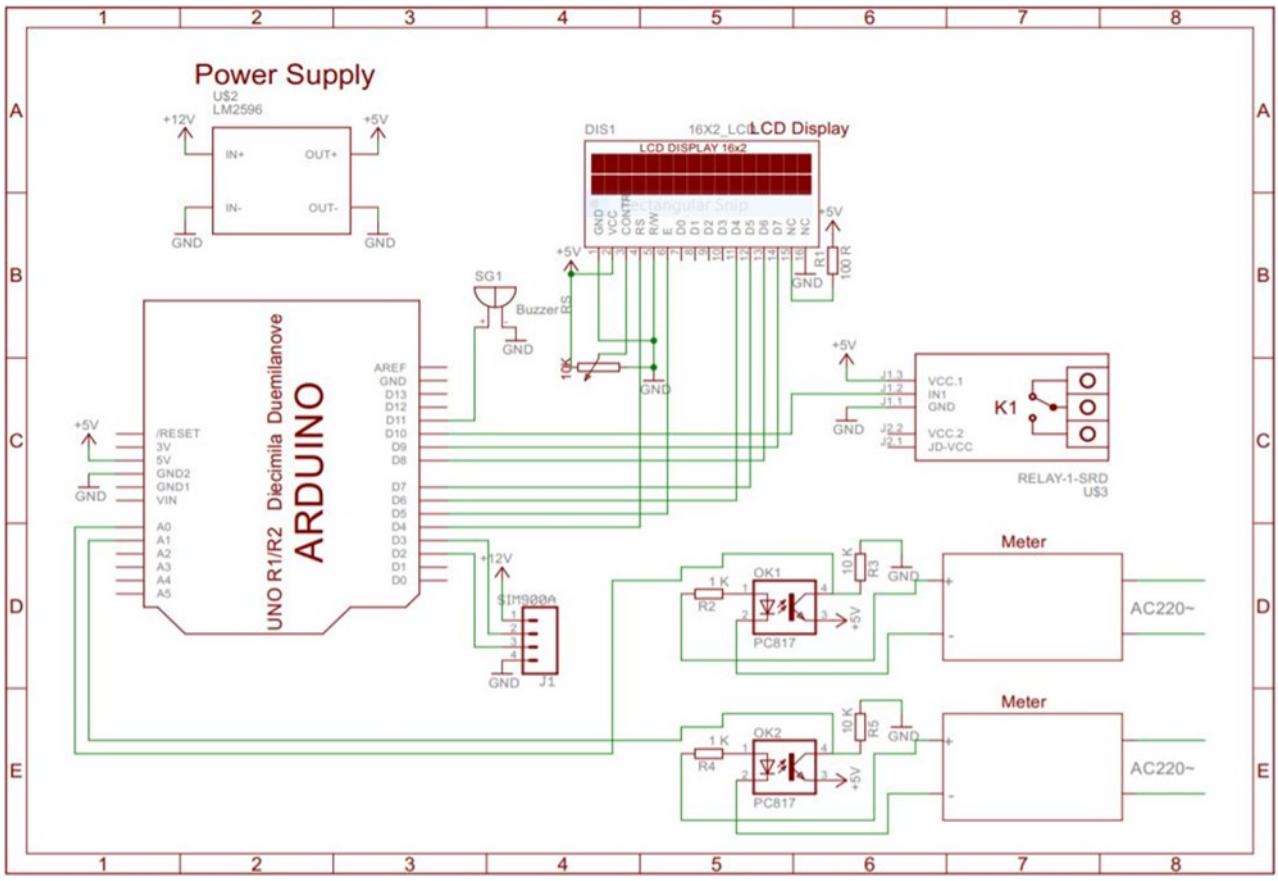

Figure 3: Circuit diagram

Hardware Design

The 230V AC power supply is given to energy meter and then connected to the load through the relay. The input of 5V for Arduino is given by a voltage regulator LM2596 from the 12V supply. The output pin of optocoupler PC817 is given to Arduino through A0 and A1. The interfacing of GSM and Arduino is made. The input 12V GSM is given through a 220 to 12V AC to DC adaptor. The corresponding message is sent through GSM.

Working

The power supply from the distributor is given to the system. This supply consists of 230 volts. The transmission lines are used to provide power supply to the consumer using electric poles at a particular distance. The system has an Arduino Atmega328, energy meter, and GSM module attached to it. Here the power supply is step down from the 230-volt power supply into 5 volts by the power supply circuit because our system uses a 5-volt power supply. The 230-volt power supply is stepped down 12 volts via a 12-volt step-down transformer so now the power supply will be 12 volts. It uses an LM2596 voltage regulator to get a 5-volt power supply which is given to our system. This 5-volt power supply given to an Atmega328 and GSM module. The system has Arduino, Energy meter, and GSM module. The master energy meter tracks the quantity of the energy units supply through it then it sends the unit consumed to Atmega328. Now Atmega328 stores this data in memory. As the supply reaches to slave energy meter it will count the number of energy units consumed. The data at the slave energy meter will be transfer to Atmega328. The Atmega328 will analyze the two data present. If the number of energy units reached varies. The Atmega328 will trigger the GSM module. The GSM module sends the SMS to the consumer about the amount of difference occurred in the transmission cable. The distributor will track the amount of loss happen and puts a penalty to the consumer. The distributer is informed about the energy loss happen to them by the system's action.

Programming

The code for the program is done in Arduino IDE and then it is burned into the Arduino. For the simulation part, Keil software is used to convert the program into .hex file. The programming logic followed is depicted in the flow chart.

Conclusion

The proposed method of power theft minimizes the heavy power and revenue loss that results from the theft of power by customers. With the completion of the project, it is concluded that power theft can be effectively reduced by detecting when does the power theft occurs and simultaneously informing the authorities to disconnect the power to the house or customer trying to steal the power supply by an integrated automatic breaker that is attached to the unit. The system is used to send or communicate data to the consumer domain as well through a GSM wireless network. The proposed system will reduce energy waste and save more for future use.

Abstract

In recent years, PROMETHEE II has emerged as one of the most efficient and successfully applied outranking method in multi-criteria decision making (MCDM) problems. Conventional PROMETHEE II method presumes that the weights of the criteria are known beforehand, and this is rather a stringent assumption. Moreover, the number of preference indices to be evaluated in the method grows enormously with an increase in the number of alternatives to be ranked. In this work, we look at these concerns and propose a methodology inspired by PROMETHEE II that identifies the best criteria first and then, the preference indices are computed with respect to these criteria only. The algorithm is customized in such a way that it curtails the computational time complexity of PROMETHEE II to a great extent. Here, a large number of alternatives-criteria evaluation matrices are simulated with random numeric data to illustrate the proposed method and evaluate its performance. Statistical analysis on the stability of the rankings and the conformity measure proves that the proposed approach may be preferred over PROMETHEE II and TOPSIS methods. Rank correlation coefficients are evaluated, and they indicate the efficacy of the proposed method.

1 Introduction

MCDM problems involve analysing the subjective assessments of a finite number of alternatives under a certain predetermined, finite number of criteria by an expert/decision-maker (DM) or a group of experts/decision-makers (DMs). In the latter case, it is called a multi-criteria group decision making (MCGDM) problem, see[1]. Over the last few decades, numerous MCDM methods have been proposed under different set-ups for selecting the best alternative among the available ones. For ready reference, see[2–5]. The advancement in MCDM methods is stimulated not only by different applications to real-life problems but also by researchers' inclination towards introducing extended decision-making methodologies as discussed in[6].

1.1 Research issues and need for the present work

Conventional PROMETHEE (Preference Ranking Organization Method for Enrichment Evaluations) method is one of the most successfully practiced MCDM method. The technique was designed by Brans[7] and extended by Vincke and Brans[8]. The PROMETHEE II version is a protracted method that requires a priori knowledge of the criteria weights. It presumes that the decision-maker is a well-versed expert in the domain of the problem to decide upon these weights, reflecting the importance of criteria in ranking the alternatives. This imparts a subjective character to criteria weights varying which alter the ranking of the alternatives. Another concern is that the computational efforts in PROMETHEE II method increase with the number of alternatives and criteria. For a given decision-making problem with 'm' alternatives and 'n' criteria, one needs to evaluate '$mn(m-1)$' preference indices. This paper combines these two interrelated issues. One it noticed that these many computations are necessarily not required and another that the prior knowledge of the criteria weights can be dropped from the PROMETHEE II method.

1.2 Key differences between closely related studies and the work presented in this paper

The significant differences between the proposed work and closely related studies available in the literature are as follows:

1. In literature[9–11], the conventional PROMETHEE II method and its extensions are framed to evaluate '$mn(m-1)$' preference indices for a given decision making problem with 'm' alternatives and 'n' criteria. In this study, we have customised the existing procedure in such a manner that the reckoning process of preference indices lowers to a great extent.
2. The classical PROMETHEE II method presumes the weights of the criteria beforehand. In the available literature, various techniques like AHP, Entropy[12, 13], etc. are also used to evaluate the weight vector of the criteria. Although,

many researchers have designed various tools like weight stability intervals, walking weights, PROMETHEE VI[14, 15], etc. to study the repercussion of these values, but it brings subjectivity in the decision making process that can change the ranking of the alternatives. So, in this paper, we have first recognized the best criterion(a)/feature(s) for each alternative and then assign the uniform weight to the best criteria and no importance i.e., zero weight to the vestigial criteria. Such procedure of weight assignment to criteria is anomalous as it involves both the alternatives and criteria and vary with each alternative in an MCDM problem. Even after the withdrawal of prerequisite of the prior knowledge of weight vector, the statistical discussion given in Sect. 5 reveals that the suggested scheme performs efficiently. The ranking obtained by the proposed methodology is highly correlated as well as more stable than the classical PROMETHEE II ranking. Also, this practice dissolves the element of subjectivity from the criteria importance in an MCDM problem.

3. The computational complexity of an algorithm is also an indicator of its efficiency. The traditional PROMETHEE II has computational time complexity of $O(m^2n)$. Recently, Calders and Assche[16] suggested the method that curtails the time complexity of PROMETHEE with linear preference function to $O(mn\log(m))$. In our study, the computational time complexity of the proposed approach is of $O(mn)$ that makes the performance of the algorithm remarkable.
4. The statistical analysis is an essential and significant element of any methodology to prove its efficiency. In view of statistical studies discussed in Sect. 5, the ranking of alternatives obtained by the proposed algorithm is not merely highly correlated with the classical PROMETHEE II and TOPSIS methods' ranking but also more stable for 10 distinct pairs of numbers of alternatives and criteria. The conformity values also assert the analogous efficacy of proposed algorithm and PROMETHEE II. The conformity of designed method may be agreeing the traditional PROMETHEE II but the reduced complexity of the suggested scheme is the highlight of the work.

1.3 Focus of the present study

In this paper, we propose a methodology inspired by PROMETHEE II, which deliberates on first identifying the best criteria for each alternative and then evaluates the preference indices for these criteria only. The procedure is customised in such a way that the number of preference indices to be estimated reduces to a greater extent. Moreover, the method proposes to assign uniform weights to the best criteria and zero weight to the remaining criteria with each alternative. In this way, no single weight vector is attached to the criteria; instead, the weight vectors depend both on the alternatives and the criteria and vary with alternatives in an MCDM problem. The algorithm is contrived in such a manner that it also curtails the computational time complexity of the classical PROMETHEE II to a noteworthy extent.

The suggested method is validated by randomly generating a large number of alternatives-criteria evaluation matrices which are also used to compute stability degree and conformity measure of the method. To demonstrate the efficiency of the

designed algorithm, the study includes PROMETHEE II and TOPSIS methods in the statistical analysis which exhibits that the proposed method is comparable with the existing methods and can be opted by the practitioners for real-life decision-making problems.

1.4 Organization of the paper

The organization of remainder of this paper unfolds as follows. Section 2 briefs the literature of the two MCDM methods - PROMETHEE II and TOPSIS. Section 3 describes the proposed method. Section 4 presents an example by simulating alternatives-criteria evaluation matrix to illustrate the proposed method. Section 5 discusses the analysis and efficiency of the method via stability degree, conformity measure and rank correlation coefficient. Section 6 concludes the paper.

2 Literature survey

The outranking methods aim to build a preference relation, called an outranking relation, through a series of pairwise comparisons of alternatives to be evaluated on criteria. The study of the outranking method PROMETHEE commenced with the pioneer works of Brans and his collaborative in the early eighties. The PROMETHEE-I method for partial ranking and PROMETHEE II method for the complete ranking of the alternatives were proposed in the work of Brans[7]. The success of these two methods led to the development of more versions of PROMETHEE method, namely, PROMETHEE III, IV, and V. Human brain representation was incorporated in PROMETHEE VI method, proposed by Brans and Mareschal[15] followed by PROMETHEE GDSS for group decision-making, introduced by Macharis et al. [17] and the visual interactive module GAIA (Geometrical Analysis for Interactive Aid) for graphical representation, given by Mareschal and Brans[18, 19]. Moreover, Figueira et al.[20] introduced two extended approaches: PROMETHEE-TRI for handling sorting problem and PROMETHEE CLUSTER for nominal classification. All these versions and extensions of PROMETHEE have been applied in many fields, including environment management[9, 11], business and financial management[10, 21], chemistry[22, 23], energy management[24, 25], social management[26, 27], and many more. For a comprehensive survey of PROMETHEE methods see[28]. Among all the methods of this family, PROMETHEE II is the most acclaimed and frequently used one.

Among numerous other MCDM methods, TOPSIS (Technique for Order Preference by Similarity to Ideal Solution) is a compensatory method that determines the solution which is at the shortest distance from the positive ideal solution and the farthest distance from the negative ideal solution of the MCDM problem. It has been often used across different application areas since its inception by Hwang and Yoon[29]. TOPSIS has been successfully applied in supply chain management and logistics[30, 31], health, safety and environment management[32, 33], human resources management[34, 35], energy management[36, 37], and many more. One can refer to[29, 38] for a detailed

description and working of the method and to the work of Behzadian[39] for a comprehensive survey on the use of TOPSIS method in MCDM. We have briefly mentioned this method here for it has been used in the latter part of this paper for performance analysis and comparison. Both methods require a priori knowledge of criteria weights for aggregating the information in data for penultimate ranking of alternatives. This assumption makes the methods sensitive to the choice of criteria weights.

3 Proposed methodology

An MCDM problem involves m alternatives A_i, $i = 1, \ldots, m$, to be evaluated on n criteria C_j, $j = 1, \ldots, n$. Let $I = \{1, \ldots, m\}$ and $J = \{1, \ldots, n\}$ be the indices sets of alternatives and criteria respectively. Let an alternative-criteria evaluation matrix be $R = [r_{ij}]_{m\times n}$, where r_{ij} represents the evaluation of ith alternative on jth criteria. The proposed method involves the following steps:

Step 1: The classical PROMETHEE II method characterizes six types of preference functions to compare the alternatives under various cost and beneficial criteria. The provision of distinct preference functions makes the normalization process a choice in classical PROMETHEE II. In this paper, the pairwise difference is adopted as the preference function that requires the uniformity of all criteria. Hence, the normalization process becomes a fundamental requirement for the method.

Normalize the matrix R using linear normalization given as $R_{norm} = [\widetilde{r}_{ij}]_{m\times n}$, where

$$\widetilde{r}_{ij} = \begin{cases} \dfrac{r_{ij} - \min\limits_{i\in I}\{r_{ij}\}}{\max\limits_{i\in I}\{r_{ij}\} - \min\limits_{i\in I}\{r_{ij}\}} & \text{if } j\text{th criterion is a beneficial criterion;} \\ \dfrac{\max\limits_{i\in I}\{r_{ij}\} - r_{ij}}{\max\limits_{i\in I}\{r_{ij}\} - \min\limits_{i\in I}\{r_{ij}\}} & \text{if } j\text{th criterion is a cost criterion.} \end{cases}$$

The max-min normalization is preferred as the above process converts all criteria into the beneficial criteria that makes nature of all criteria uniform and it is also an essential requirement for the upcoming step.

Step 2: For a given alternative A_i, find the maximum value over all criteria

$$M_i = \max_{j\in J}\{\widetilde{r}_{ij}\}.$$

Let M_i be achieved on k_i number of criteria ($k_i \leq n$), say, $C_{\gamma_i(1)}, \ldots, C_{\gamma_i(k_i)} \in \{C_1, \ldots, C_n\}$; set $J_i = \{\gamma_i(1), \ldots, \gamma_i(k_i)\}$.

Step 3: For $j \in J_i$, evaluate the preference index $P_j(A_i, A_{i'})$, $i, i' \in I$, $i \neq i'$, as follows:

$$P_j(A_i, A_{i'}) = \begin{cases} 0 & \text{if } \widetilde{r}_{ij} \leq \widetilde{r}_{i'j} \\ \widetilde{r}_{ij} - \widetilde{r}_{i'j} & \text{otherwise.} \end{cases}$$

Here $P_j(A_i, A_{i'})$ is the preference index (value) of the alternative A_i over alternative $A_{i'}$ under criterion C_j. So, for the ith alternative, the preference indices $P_j(A_i, A_i')$, $j \in J_i$, are computed only under those criteria which correspond to the maximum evaluation of the alternative A_i.

The conventional PROMETHEE II method requires $mn(m-1)$ preference indices to participate in the procedure to rank m alternatives on n criteria whereas the designed method reduces it to evaluate only $((m-1)\sum_{i=1}^{m} k_i)$ number of preference indices.

Step 4: Compute the cumulative preference index $\pi(A_i, A_i')$, for $i, i' \in I$, $i \neq i'$, as follows:

$$\pi(A_i, A_i') = \frac{1}{k_i} \sum_{j \in J_i} P_j(A_i, A_{i'}).$$

The conventional PROMETHEE II method assumes the criteria weight vector beforehand. In the proposed method, since the criterion(a) having maximum value represents the best feature(s) of an alternative, hence, for each $i \in I$, we propose to attach the uniform weight $1/k_i$ with criteria in J_i, and weight zero with all remaining criteria in $J \setminus J_i$.

The concern of the prior knowledge of weight vector may be dropped as the statistical results given in Sect. 5 validate the efficiency and competency of the proposed algorithm. The ranking obtained by proposed algorithm is highly correlated as well as more stable than the classical PROMETHEE II ranking. It also makes the approach independent of the decision-makers' perspective on the criteria importance/weights.

Step 5: Determine the outgoing and the incoming flows described respectively as follows:

$$\phi^+(A_i) = \frac{1}{m-1} \sum_{\substack{i'=1 \\ i \neq i'}}^{m} \pi(A_i, A_{i'}), \quad i \in I,$$

$$\phi^-(A_i) = \frac{1}{m-1} \sum_{\substack{i'=1 \\ i \neq i'}}^{m} \pi(A_{i'}, A_i), \quad i \in I,$$

and, compute the net flow

Table 1 Computational time complexity of PROMETHEE II and designed methodology

Principle activity	PROMETHEE II	Proposed method
1. Normalization	$O(mn)$	$O(mn)$
2. Preference indices and cumulative preference indices	$O(mn(m-1))$	$O(m(m-1)+mn)$
3. Net flows	$O(m(m-1))$	$O(m(m-1))$
4. Sorting the net flows values to rank	$O(m\log m)$	$O(m\log m)$
Computational time complexity	$O(m^2n)$	$O(mn)$

$$\phi(A_i) = \phi^+(A_i) - \phi^-(A_i), \qquad i \in I.$$

Step 6: The alternatives are ranked with the largest value of $\phi(A_i)$ considered as the best alternative.

Remark 3.1 For a given $m \times n$ alternatives-criteria evaluation matrix, the computational time complexity of suggested scheme is $O(mn)$ which is indeed less than the complexity $O(m^2n)$ of the conventional PROMETHEE-II method. Table 1 depicts the same.

The time complexity of proposed method has also decreased to a noteworthy extent. Hence, the designed methodology abridges the complexity of PROMETHEE II method.

The flowchart given in Fig. 1 summarizes the proposed method.

4 Illustrative example

Consider an MCDM problem with 7 alternatives and 9 criteria, out of which, criteria C_1, C_2, C_3, C_6, C_8, C_9 are the beneficial criteria and criteria C_4, C_5, C_7 are the cost criteria. The 7×9 alternative-criteria evaluation matrix is populated with a random data from $U(0, 1)$ distribution to illustrate the proposed method. Let this matrix be R.

$$\begin{bmatrix} 0.2956 & 0.9715 & 0.5639 & 0.2711 & 0.1345 & 0.3183 & 0.3315 & 0.5127 & 0.6675 \\ 0.5696 & 0.6743 & 0.3813 & 0.104 & 0.0997 & 0.2724 & 0.4562 & 0.2391 & 0.4185 \\ 0.5231 & 0.1166 & 0.0101 & 0.5562 & 0.4602 & 0.0472 & 0.7755 & 0.876 & 0.9642 \\ 0.6077 & 0.9339 & 0.9153 & 0.3164 & 0.717 & 0.2123 & 0.8049 & 0.8063 & 0.238 \\ 0.4758 & 0.5839 & 0.8552 & 0.9422 & 0.1279 & 0.3202 & 0.346 & 0.2821 & 0.6372 \\ 0.2278 & 0.4051 & 0.1107 & 0.924 & 0.7876 & 0.2157 & 0.0529 & 0.2402 & 0.1467 \\ 0.4636 & 0.2086 & 0.5459 & 0.6851 & 0.4435 & 0.6745 & 0.4678 & 0.6737 & 0.898 \end{bmatrix}.$$

The normalized matrix is evaluated using the normalization process defined for cost and beneficial criteria in step 1 of Sect. 3 and is given as R_{norm}.

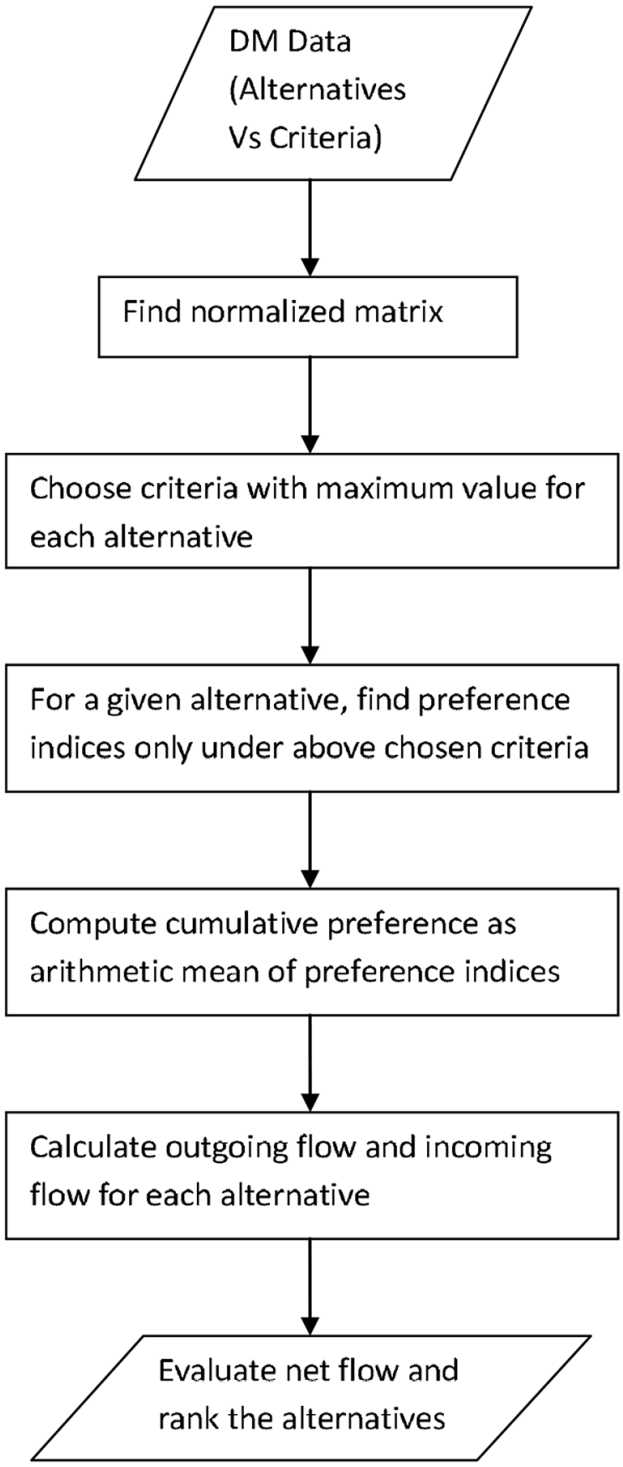

Fig. 1 Flow chart for the proposed methodology

$$R_{norm} = \begin{bmatrix} 0.1785 & 1.0000 & 0.6118 & 0.8006 & 0.9494 & 0.4322 & 0.6295 & 0.4296 & 0.6371 \\ 0.8997 & 0.6524 & 0.4101 & 1.0000 & 1.0000 & 0.3590 & 0.4637 & 0.0000 & 0.3325 \\ 0.7773 & 0.0000 & 0.0000 & 0.4605 & 0.4759 & 0.0000 & 0.0391 & 1.0000 & 1.0000 \\ 1.0000 & 0.9560 & 1.0000 & 0.7466 & 0.1026 & 0.2632 & 0.0000 & 0.8906 & 0.1117 \\ 0.6528 & 0.5466 & 0.9336 & 0.0000 & 0.9590 & 0.4352 & 0.6102 & 0.0675 & 0.6000 \\ 0.0000 & 0.3375 & 0.1111 & 0.0217 & 0.0000 & 0.2686 & 1.0000 & 0.0017 & 0.0000 \\ 0.6207 & 0.1076 & 0.5919 & 0.3067 & 0.5002 & 1.0000 & 0.4483 & 0.6824 & 0.9190 \end{bmatrix}$$

Table 2 Maximum value and the index set of criteria at which the maximum value is achieved

Alternative	Maximum value (M_i)	Index set of criteria J_i
A_1	1	{2}
A_2	1	{4, 5}
A_3	1	{8, 9}
A_4	1	{1, 3}
A_5	0.9590	{5}
A_6	1	{7}
A_7	1	{6}

The maximum value M_i and the index set J_i of each alternative are given in Table 2.

The preference indices are evaluated under the criteria that attain the maximum value for given alternative as mentioned in Table 3.

Note the number of preference indices to be evaluated is 60, whereas the conventional PROMETHEE II method would have taken 378 evaluations.

The cumulative preference indices are given in Table 4.

For each alternative, the outgoing flow, the incoming flow, and the net flow are depicted in Table 5.

By net flow values, A_1 is the best alternative, followed by A_7 and A_2.

To validate the proposed method, the ranking of alternatives are also obtained by conventional PROMETHEE II and the TOPSIS method. The weights of the criteria in the former approach are taken to be uniform for the nine criteria. The two variants of TOPSIS method described in the literature, please see[40], differ only in the normalization process. Here, we use TOPSIS with linear normalization (same as in Step 1 of the designed methodology) to make a conducive comparison with the ranking of the suggested method. In this work, the solution procedures for PROMETHEE II and TOPSIS methods are not provided, but one can see[9, 38] for the reference. The rankings of seven alternatives by the three methods are tabulated in Table 6.

The ranking achieved by the designed method is same as ranking from the two conventional methods, making the proposed method promising.

5 Empirical analysis and discussion

Although in certain situations, the proposed methodology, PROMETHEE II method, and TOPSIS (with linear normalisation) can result in similar rankings (as in above example), but eventually they can lead to different rankings. Therefore, compatibility and stability of rankings obtained by various decision-making methods must be analysed for the validity and efficiency of the new method.

1.	Proposed method	$A_1 > A_7 > A_2 > A_5 > A_4 > A_3 > A_6$
2.	PROMETHEE II	$A_1 > A_7 > A_2 > A_4 > A_5 > A_3 > A_6$
3.	TOPSIS with linear normalization	$A_1 > A_7 > A_2 > A_4 > A_5 > A_3 > A_6$

Wu et al.[41] discussed the quantitative method for measuring the stability of rankings in group decision-making. The stability degree of an MCDM method is a quantitative measure, with values in [0, 1], and the highest degree gives the most stable ranking.

Conformity measure evaluates the performance of an MCDM method vis a vis other MCDM methods, and it is to be minimised to improve the performance of an MCDM method, see[42].

The rank correlation coefficient is used to analyse the similarity between the rankings given by each method. Commonly used rank correlation coefficients are

Spearman's rank-order correlation coefficient, Kendall's tau-b and Pearson's correlation coefficient. The Kendall's tau-b is a non-parametric rank correlation coefficient which computes the degree of similarity between two sets of ranks for the same set of objects. The Kendall's tau-b coefficient also takes into account ties in rankings, a feature desirable in the context of our present study.

For m (number of alternatives), n (number of criteria), and q (number of randomly generated MCDM matrices), the procedure of computing the aforementioned measures is discussed below.

Step 1: For $t = 1$ to q,
generate a random alternative-criteria evaluation matrix R_t of size $m \times n$.
Step 2: Pass each R_t, $t = 1, \ldots, q$, into three methods {Proposed Method, PROMETHEE II, TOPSIS} to obtain rankings for the m alternatives. The total number of such rankings is q for each of the three methods.
Step 3: Computing the stability degree:

3(a)(i) Determine the score matrices $(SM)_{Algo} = [N_{is}]_{m \times m}$, where N_{is} is the number of times an alternative A_i appears at the sth position in q ranks obtained in Step 2, and $Algo \in \{$ Proposed Method, PROMETHEE II, TOPSIS $\}$. For example, in matrix $(SM)_{ProposedMethod}$, the N_{21} depicts the number of times the alternative A_2 appears at 1st position while ranking the alternatives using the proposed methodology.

3(a)(ii) For each method, evaluate the weighted score vector as $S_{Algo} = (SM)_{Algo} W$, where the weight vector is taken as $W = (m-1, m-2, \ldots, 1, 0)^T$ from the voting rule of Borda count method, as discussed in[41], and $Algo \in \{$ Proposed Method, PROMETHEE II, TOPSIS $\}$. The alternatives are ranked with the first one having the highest score in S_{Algo} vector[1].
The combined (overall) ranking of alternatives and the score vector S_{Algo}, where $Algo \in \{$ Proposed Method,PROMETHEE II, TOPSIS $\}$, are used to calculate the stability degree of the rankings.

3(b)(i) Let $I^{(1)}_{Algo}$ and $I^{(2)}_{Algo}$ be the sets of indices in I corresponding to the alternatives having rank respectively, 1 and 2 in the combined ranking obtained by the $Algo$. Note that the sets $I^{(\ell)}_{Algo}$, $\ell = 1, 2$, can have more than one single index. Calculate the vector $U_{Algo} = (u^1_{Algo}, \ldots, u^m_{Algo})$, as follows:

[1] The vector S_{Algo} is formed by combining q alternative-criteria matrices to rank the alternatives; this scheme can easily be extended to the Group Decision MCDM problems.

$$u^k_{Algo} = \begin{cases} S^k_{Algo} & \text{if } \; k \notin I^{(1)}_{Algo} \cup I^{(2)}_{Algo} \\ \frac{S^k_{Algo}+S^b_{Algo}}{2} & k \in I^{(1)}_{Algo}, \\ & \text{and for any index } \; b \in I^{(2)}_{Algo} \\ \frac{S^k_{Algo}+S^b_{Algo}}{2} & k \in I^{(2)}_{Algo}, \\ & \text{and for any index } \; b \in I^{(1)}_{Algo}. \end{cases}$$

Here, S^k_{Algo}, S^b_{Algo} are the k-th and b-th components of the vector S_{Algo} respectively.

3(b)(ii) Find the stability degree ρ_{Algo} of $Algo \in$ { Proposed Method, PROMET-HEE II, TOPSIS }, by computing sine of the angle between the vectors S_{Algo} and U_{Algo} as follows:

$$\rho_{Algo} = \frac{||S_{Algo} \times U_{Algo}||}{||S_{Algo}||\,||U_{Algo}||}, \quad \times \text{ stands for the cross product .}$$

Step 4: Computing the conformity values:

4(i) For $t = 1$ to q, compute the conformity values

$$C^t_{Algo} = \sum_{i=1}^{m} \left(\text{ Net Flow}^t_{Algo,(i)} - \text{ Mean Flow}^t_{(i)} \right)^2,$$

$Algo \in$ { Proposed Method, PROMETHEE II, TOPSIS }. For TOPSIS, the net flow value of each alternative is replaced by its relative closeness value. And the mean flow for each alternative is evaluated by taking the arithmetic mean of the net flow values (or relative closeness values for TOPSIS) of m alternatives, for each of the three methods.

4(ii) Determine the mean and the variance of these conformity values.

$$\overline{C}_{Algo} = \frac{1}{q} \sum_{t=1}^{q} C^t_{Algo}$$

$$\sigma^2_{C_{Algo}} = \frac{1}{q} \sum_{t=1}^{q} (C^t_{Algo} - \overline{C}_{Algo})^2.$$

4(iii) Apply the hypothesis testing to test the significance of the difference between the three vectors $C_{Algo} = \{C^1_{Algo}, C^2_{Algo}, \ldots, C^q_{Algo}\}$, $Algo \in$ { Proposed Method, PROMETHEE II, TOPSIS }.

Step 5: Computing the rank correlation coefficient:

5(i) Go to step 3 and obtain the combined rank for each of the three methods using 3(a)(i) and 3(a)(ii).

5(ii) Evaluate Kendall's tau-b correlation coefficient to analyse the similarity between the rankings given by each method.

Table 7 Stability degrees from three methods

S. No.	No. of alternatives	No. of criteria	Proposed method	PROMETHEE	TOPSIS

2	5	6	0.00106	9.3287×10^{-5}	0.00019
3	7	9	0.00033	5.3452×10^{-6}	1.4254×10^{-5}
4	10	10	0.00056	0.00015	4.9690×10^{-5}
5	10	15	0.00023	3.2299×10^{-5}	0.00013
6	12	15	0.00014	0.00011	3.9711×10^{-5}
7	15	20	0.00014	2.9994×10^{-5}	3.8341×10^{-5}
8	20	25	8.7711×10^{-5}	6.1415×10^{-5}	5.4092×10^{-5}
9	25	40	0.00016	4.0659×10^{-5}	6.6232×10^{-5}
10	30	50	0.00011	0.0001	0.0001

In the empirical analysis, we took different pairs (m, n) for alternatives-criteria and for each such pair we randomly simulated 1,00,000 independent and identically distributed matrices of size $m \times n$. The global stability degrees of the combined rankings of these 1,00,000 matrices with different numbers of alternatives and criteria are reported in Table 7.

It is evident from Table 7 that, for each pair of alternatives and criteria, the rankings delivered by the designed method are more stable than those given by the other two methods. This approves the advantage of the proposed method in solving MCDM problems.

Next, we compute the conformity vectors C_{TOPSIS}, $C_{\text{PROMETHEE}}$ and $C_{\text{Proposed Method}}$ for 1,00,000 matrices of size $m \times n$, as generated in stability analysis. To check if there is a significant difference between these three vectors, we set the two null hypotheses $H_0^{(1)}$ and $H_0^{(2)}$ and their corresponding alternate hypotheses $H_1^{(1)}$ and $H_1^{(2)}$ as follows:

$$
\begin{aligned}
H_0^{(1)} &: \overline{C}_{\text{TOPSIS}} - \overline{C}_{\text{Proposed Method}} = 0,\\
H_1^{(1)} &: \overline{C}_{\text{TOPSIS}} > \overline{C}_{\text{Proposed Method}},\\
H_0^{(2)} &: \overline{C}_{\text{Proposed Method}} - \overline{C}_{\text{PROMETHEE}} = 0, \quad \text{and}\\
H_1^{(2)} &: \overline{C}_{\text{Proposed Method}} > \overline{C}_{\text{PROMETHEE}}.
\end{aligned}
$$

The one-tailed Z-test is conducted at 99% level of significance. The results are reported in Table 8.

From Table 8, the proposed method performs better than the TOPSIS method. And the Z-statistics confirms the rejection of the null hypothesis $H_0^{(1)}$ at 99% significance level which concludes that the mean conformity of the proposed algorithm is less than that of the TOPSIS method to a noteworthy extent. It is also worth noticing that although the mean conformity of the PROMETHEE II

10	30	50	3.3546	0.1081	0.9082	0.0341	0.8517	0.0272	21.5876	1.2969

is lower than the designed method yet the null hypothesis $H_0^{(2)}$ is accepted given the Z-statistics at 99% confidence. It signifies that there is essentially no significant difference between $\overline{C}_{\text{PROMETHEE II}}$ and $\overline{C}_{\text{Proposed Method}}$. Hence, the efficiency of the proposed method and the PROMETHEE II method are analogous.

To analyse the performance of the suggested scheme, for a small sample size data, the above procedure is followed for sample size 10 and 20. The conformity vectors C_{TOPSIS}, $C_{\text{PROMETHEE}}$ and $C_{\text{Proposed Method}}$ are evaluated and hypothesis testing is carried out to check if there is a significant difference between these three vectors. The two null hypotheses $H_0^{(1)}$ and $H_0^{(2)}$ are same as before.

The one-tailed t-test is conducted at 99% level of significance. The results are reported in Table 9 for sample size 10 and in Table 10 for sample size 20. The p-value is mentioned in the bracket.

From Tables 9 and 10, we can conclude that the proposed algorithm performs better than the TOPSIS method with the same reason as for the large sample size. And also, the efficiency of the suggested method and PROMETHEE II are comparable. The analysis indicates the efficiency and adeptness of the designed method.

For the next analysis, various pairs (m, n) for alternatives-criteria are taken and for each such pair, 10 independent and identically distributed matrices of size $m \times n$ are randomly simulated. The combined rankings for each of the three methods are obtained, and Kendall's tau-b correlation coefficients are evaluated using IBM SPSS Statistics 21 software as given in Table 11.

It is evident from Table 11, that the ranking obtained by the proposed method is highly correlated with the rankings acquired by PROMETHEE II and TOPSIS with statistically significant p-values.

In summary, the proposed algorithm is an efficient and conducive approach. The method obtains the most stable ranking of the alternatives that is highly correlated with the rankings acquired by the existing methods. Also, the conformity values assert the better performance of the suggested scheme in comparison to TOPSIS while the efficacy of the suggested approach and PROMETHEE II are analogous.

Note: The experts and researchers working in this field may arise a concern that the weights of the criteria reflect the preferences of the DM and hence, the omission of pre-defined criteria weight vector is not justifiable. In reference to this issue, the authors agree with the fact that the individual's preference of the criteria is of significant importance, but it is not always possible for DM to quantify his preference for all available criteria. It may also be claimed that various well-known techniques to evaluate the exact criteria weights exist in the literature. The adoption of such techniques is the DM's choice, but these methodologies add to the complexity of the decision situation and emanate the decision-making as a time-consuming process. In such a scenario, the suggested method calculates the criteria weights itself to overcome the subjectivity of human thinking in the decision-making. The statistical results given in Sect. 5 confirm the legitimacy of the proposed method and hence, validate the efficacy and competency of the scheme.

6 Conclusions

PROMETHEE II is a highly researched and most applied outranking method. In this paper, inspired by the PROMETHEE II method, we proposed a scheme which overcomes two concerns with the PROMETHEE II method. One is the prior knowledge of the criteria weight vector, and second is the number of computations going in the performance indices, especially when the number of alternatives is large. The computational time complexity of the classical PROMETHEE II has also reduced from $O(m^2n)$ to $O(mn)$ that makes the algorithm efficient. The stability analysis confirms the suitability and usage of the proposed method by experts/decision-makers. The conformity analysis proves that the designed method is equally as good as the classical PROMETHEE II method. The correlation coefficient approves the ranking given by the proposed method makes the method more desirable.

We envision that the proposed method can be extended to the scenarios when information is expressed through linguistic variables, interval-valued linguistic variables, or fuzzy numbers.

Acknowledgements The authors wish to express their gratitude to the esteemed referees for their valuable observations and comments in improving the quality of this research work.

Authors' Contributions Anjali Singh performed the computations and drafted the manuscript. Anjana Gupta and Aparna Mehra conceived of the presented theory and verified the analytical methods. All authors provided critical feedback and helped shape the research, analysis and manuscript. All authors read and approved the final manuscript.

ABSTRACT

Background Breast cancer is the leading malignancy in African females. This study aims to examine the breast cancer burden in Africa using recently released GLOBOCAN 2018 estimates.

Methods The incidence and mortality estimates of age- and country-wise burden of breast cancer in 54 African countries were obtained from GLOBOCAN 2018.

Results In Africa, breast cancer caused 74 072 deaths, and 168 690 cases were estimated to have occurred in 2018. The age-standardized incidence rate stood at 37.9/100 000 in Africa, varying from 6.9/100 000 in the Gambia to 69.6/100 000 in Mauritius. The age-standardized mortality rate stood at 17.2/100 000 in 2018, ranging from 4/100 000 in the Gambia to 29.1/100 000 in Somalia in 2018. Nigeria was the leading country in terms of absolute burden with 26 310 cases and 11 564 deaths, followed by Egypt with 23 081 new cases and 9254 deaths. The mortality-to-incidence ratio for Africa stood at 0.44, varying from 0.24 in Libya to 0.68 in the Central African Republic.

Conclusion To tackle breast cancer burden in Africa, the main challenges are late-stage disease presentation, lack of screening and therapeutic infrastructure, lack of awareness and limited resources.

Keywords Africa, breast cancer, GLOBOCAN, incidence, mortality

Introduction

Breast cancer is the leading cancer group in African females and its burden has been rising steadily in the last three decades owing to factors such as longevity, westernization of lifestyle characterized by delayed marriages, a shorter period of breast-feeding and lower age at menarche.[1–5] The mortality rates are higher and survival rates are lower in Africa than developed countries due to poor oncologic care, ranging from prevention to palliation.[6] The different disease outcomes and survivorship in Africa were ascribed to genetic variation[7] and tumor stage at diagnosis.[8] Much of breast cancer (80–90%) arises sporadically due to a multitude of risk factors, whereas a small percentage is associated with inherited gene mutations (e.g. BRCA 1 or BRCA 2).[9, 10]

This study examines the burden of breast cancer in Africa using recently released GLOBOCAN 2018 estimates.[11] We examined the estimates of age- and country-wise, and age-standardized rates of incidence and mortality of breast cancer in 54 African countries in 2018 in the light of country-level human development index (HDI).[12] The HDI is a summary indicator of three indicators of development: health (life expectancy), education (mean years of schooling and expected years of schooling) and income (gross national income (GNI) per capita). It is a better indicator of human development than its components as it not only reflects healthcare resources (through income per capita) in a country but also encompasses general conditions of population health (through life expectancy) and general awareness levels (through years of schooling). Country-level survival rates of breast cancer were approximated using mortality-to-incidence ratio (MIR), which is a useful proxy of survival rates of different neoplasia.[2, 13, 14] The examination of leading malignancy in African females is expected to help realign public health priorities toward emerging public health concerns such as breast cancer and shape the public health policy toward cancer control and management to achieve

better disease outcomes and improve the quality of life of breast cancer patients.

Methods

Breast cancer estimates for 54 African countries were obtained from GLOBOCAN 2018.[11, 15, 16] The estimates were produced only for invasive carcinoma classified as C50 by the International Classification of Diseases, tenth version (ICD-10). GLOBOCAN 2018 estimates were produced for 18 nonoverlapping age-groups: under 5, 5 to 9, 10 to 14, 15 to 19, 20 to 24, 25 to 29, 30 to 34, 35 to 39, 40 to 44, 45 to 49, 50 to 54, 55 to 59, 60 to 64, 65 to 69, 70 to 74, 75 to 79, 80 to 84 and 85 plus. All-age and age-specific incidence and death counts were reported along with 95% uncertainty intervals (UIs), which reflects the uncertainties associated with cancer registry coverage and death registration, data quality and timeliness of data reporting.[11, 15]

All the GLOBOCAN 2018 estimates are available at global cancer observatory (gco.iarc.fr), and a brief account of Globocan methodology is presented in Appendix 1. The 5-year survival rate of breast cancer was approximated using the country-level MIR, which was calculated by dividing all-age death count with all-age incidence count.

Human development index

We also examined the association of breast cancer burden and country-level HDI.[12, 17] HDI is an indicator of country-level development, which is a composite index of three indices: income index, education index and health index. Each of these indices had values varying between 0 (lowest) and 1 (highest), and the final HDI was calculated by taking the geometric mean of three indicators.[12]

Odd os breast cancer incidence

We also examined the cumulative risk of developing and dying from breast cancer in African countries during their lifetime (below the age of 75 years) using the following formula.

$$\text{Cumulative Risk} = 1 - \exp^{-\text{CR}}$$

In the above equation, CR denotes cumulative rate and was calculated by $\text{CR} = \sum_i \text{Rate}_i * T_i$ and Rate_i is the rate of incidence or mortality in ith age-group and T_i is the number of years in the ith age-group. The odds of developing or dying from breast cancer were calculated as per the following.

$$\text{ODDS} = \frac{1}{\text{Cumulative Risk}}$$

Results

Geographical distribution of breast cancer

In Africa, breast cancer caused an estimated 74 072 deaths [95% UI, 67 345–81 472] with 168 690 [152 332–186 804] cases were estimated to have occurred in 2018. The age-standardized incidence rate (ASIR) stood at 37.9/100 000 in Africa, whereas the age-standardized mortality rate (ASMR) stood at 17.2/100 000 in 2018. Nigeria was the leading country in terms of absolute burden with 26 310 [23 610–29319] cases and 11 564 [10 302–12 981] deaths followed by Egypt with 23 081 [21 734–24 512] new cases and (9254 [8707–9836]) deaths in 2018 (Fig. 1a and b; Supplementary Table S1). Geographically, high all-age incidence counts were also reflected in high all-age death numbers, the age-standardized rates, however, were quite asymmetric between incidence and mortality in Africa (Fig. 1a–d).

The ASIR was highest in Mauritius (69.6/100 000) and lowest in the Gambia (6.9/100 000) in 2018 (Fig. 1c; Supplementary Table S1). Besides Mauritius in eastern Africa, there were pockets of high incidence rates in north Africa (e.g. Algeria: 55.6/100 000; Egypt: 52.4/100 000), central Africa (e.g. Republic of Congo: 37.8/100 000) and southern Africa (e.g. South Africa: 49/100 0000; Zimbabwe: 38.4/100 000) (Fig. 1c). The ASMR was the highest in Somalia (29.1/100 000), with the Gambia recording the lowest ASMR of 4/100 000 in 2018. The high ASMRs were mostly concentrated near central and northeast Africa toward the great horn of Africa (e.g. Central African Republic: 23.9/100 000; Somalia: 29.1/100 000; Eritrea: 24.8/100 000; Sierra Leone 25.4/100 000). Low ASMRs were largely concentrated toward the southeastern region of Africa (e.g. Botswana: 7.1/100 000; Madagascar: 7.5/100 000).

The MIR for Africa stood at 0.44 in 2018 with widespread variation across the region ranging from 0.24 in Libya to 0.68 in Central African Republic (Fig. 1e; Supplementary Table S1). High MIRs were mostly concentrated in central sub-Saharan Africa (SSA) (e.g. Central African Republic: 0.68; Equatorial Guinea: 0.64), eastern SSA (e.g. Somalia: 0.675; Eritrea: 0.58) and western SSA (e.g. Niger: 0.64; Chad:0.59). The MIRs were the lowest in north Africa (e.g. Algeria: 0.28; Libya: 0.24).

Age-wise, breast cancer incidence and deaths increased up to the 45–49 age-group and declined after that (Fig. 2). This pattern was preserved in nearly all African countries, with the incidence being the highest in middle age-groups (30–49) (Supplementary Figure S1a and b).

Association between breast cancer burden and HDI

Figure 3a–c displays the relationship between various metrics of breast cancer burden and country-level HDI. Both

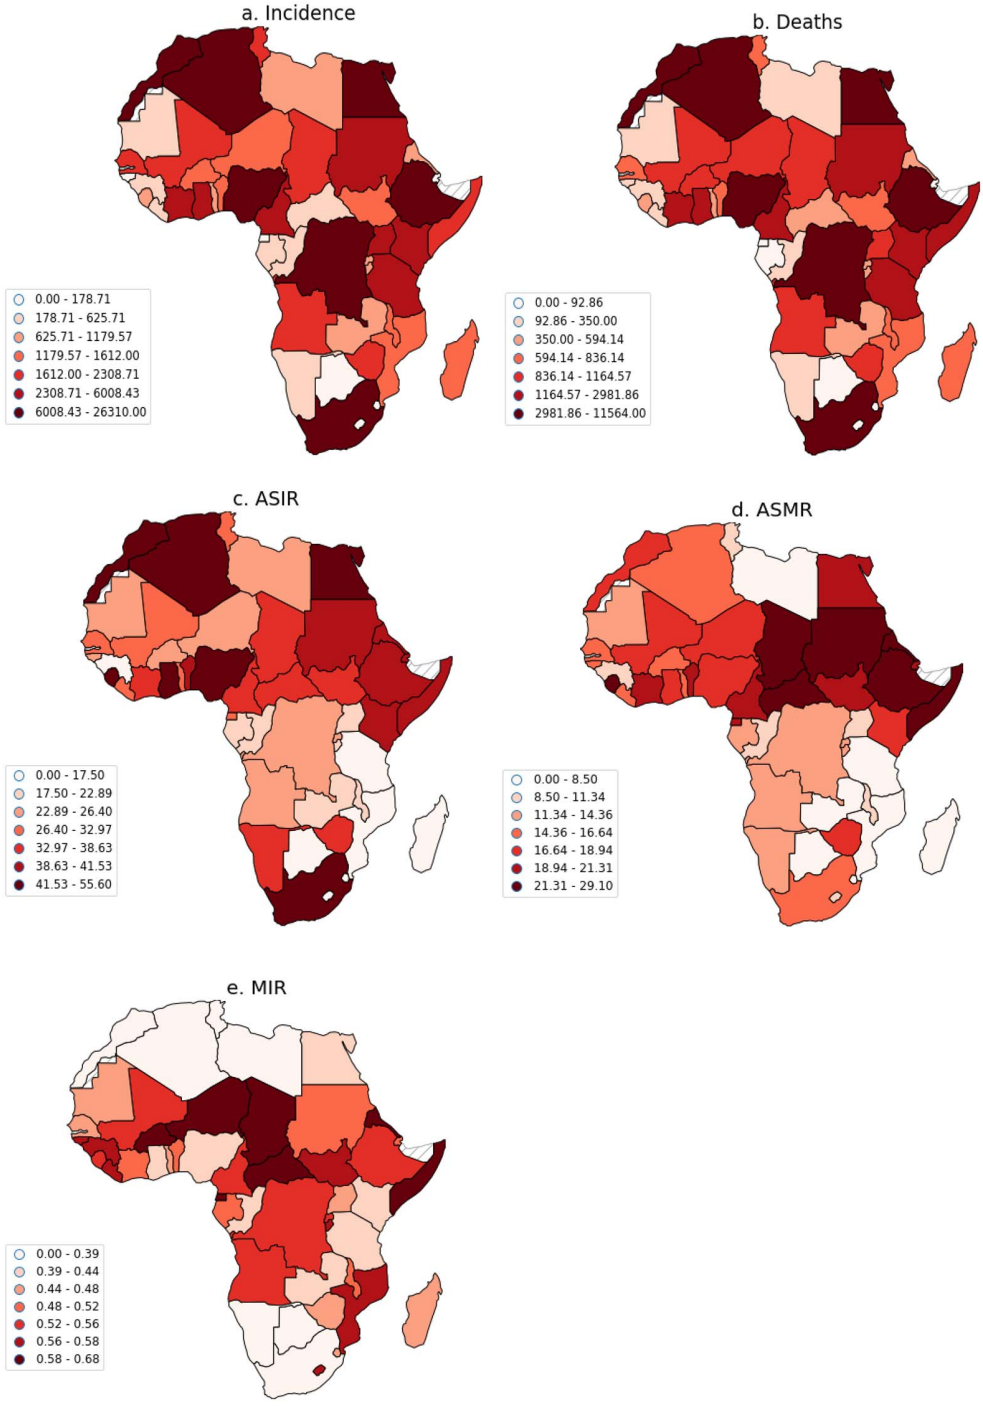

Fig. 1 Geographical distribution of breast cancer burden in Africa (a) Incidence (b) Deaths (c) ASIR (d) ASMR (e) MIR. Incidence: All-age new cases; Deaths: All-age death counts; ASIR: Age-standardized incidence rate; ASMR: Age-standardized mortality rate; MIR: Mortality-to-incidence ratio. Data Source: GLOBOCAN 2018 (IARC). Figure couldn't show the heatmap for the countries Cape Verde, Comoros, Mauritius and Sao Tome and Principe whose country-specific values can be obtained from Supplementary Table S1.

all-age incidence count and ASIRs were positively linked with HDI, albeit with few exceptions, with comparatively developed countries having high counts as well as incidence rates (Fig. 3a). The relationship between all-age incidence and HDI, although statistically insignificant (at 5% level of significance), was positive; the relationship between ASIR and HDI, however, was positive and statistically significant (Supplementary Table S2). Mortality, however,

Downloaded from https://academic.oup.com/jpubhealth/article-abstract/doi/10.1093/pubmed/fdaa099/5869901 by Delhi Technological University user on 20 July 2020

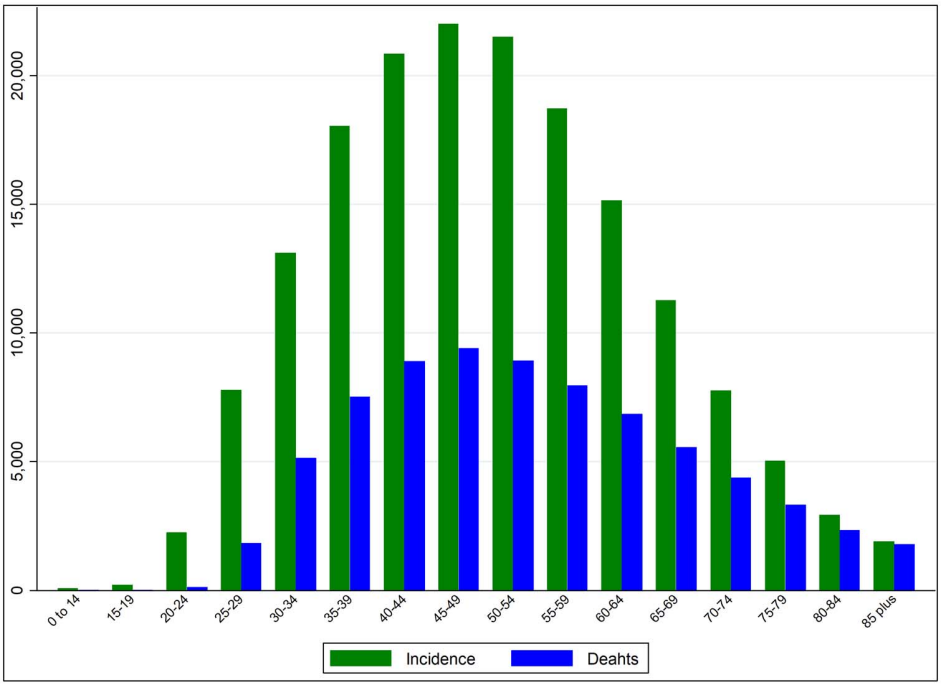

Fig. 2 Age-group wise distribution of breast cancer incidence and death counts in 2018. Incidence: Age-wise new cases; Deaths: Age-wise death counts. Data Source: GLOBOCAN 2018 (IARC).

showed a slightly different relationship with HDI; all-age death counts were positively linked (although statistically insignificant) with HDI, the ASMRs, however, were negatively associated (although statistically insignificant) with HDI (Fig. 3b; Supplementary Table S2). MIR, a proxy for 5-year survival rate had strong negative and statistically significant association (at 1% level of significance) with HDI (R-squared: 0.6384), with high HDI countries of Africa (e.g. Algeria, HDI:0.75 and MIR:0.28; Mauritius, HDI: 0.79 and MIR: 0.33) registering comparatively higher survival rates (i.e. low MIR; Fig. 3c and Supplementary Table S2).

Odds of breast cancer

In Africa, the odds of developing breast cancer were 1 in 25 females (probability: 3.94%) during their lifetime (before the age 75 years), whereas 1 in 57 females (probability: 1.77%) were expected to die of breast cancer during their lifetime (Fig. 4; Supplementary Table S3). The risk of developing breast cancer varied 10-fold in Africa; it was the highest in Mauritius (7.27%, odds: 1 in 14) and the lowest in the Gambia (0.71%, odds: 1 in 141). The probability of dying from breast cancer varied 7-fold in Africa, from 0.42% (odds: 1 in 240) in the Gambia to Somalia (2.97%, odds: 1 in 34). We noted that the odds of developing cancer were higher in comparatively developed countries of Africa, whereas the risk of breast cancer death displayed a negative association with HDI (Supplementary Figure S2a and b).

Discussion

Main finding of this study

Across Africa, the breast cancer burden rose from 92 600 cases and 50 000 deaths in 2008 (as per GLOBOCAN 2008[18]) to 168 690 cases and 74 072 deaths in 2018 (as per GLOBOCAN 2018). The age-standardized rates also displayed increases, with ASIR rising from 28/100 000 in 2008[18] to 37.9/100 000 in 2018, whereas the ASMR rose marginally from 16/100 000 in 2008[18] to 17.2/100 000 in 2018. While the incidence rates increased in developed countries, too, the rise in mortality rates is specific to Africa in line with previous research.[2] As per GLOBOCAN 2018, the ASIR was 84.8/100 000 in North America and 86.7/100 000 in Oceania, whereas the same stood at 37.2/100 000 in Africa in 2018. ASMR, in contrast, was lower in North America (12.6/100 000) and Oceania (14.9/100 000) in comparison with Africa (17.2/100 000). As per GLOBOCAN 2018, in terms of ASIR, no African country featured in top 10, whereas three African countries featured in top 10 in terms of ASMR (In fact, no African country featured in top 25 in terms of ASIR, but 12/25 countries belonged to Africa in terms of ASMR.). High incidence rates, along with low mortality rates in developed regions of the world, reflect diagnosis of breast cancer at an early stage and the fact that better treatment is available in these countries.[19]

What is already known on this topic

International Agency for Research on Cancer (IARC) previously published GLOBOCAN estimates for the year 2008 and 2012.[20, 21] In the latest iteration, the cancer estimates were provided for the most recent year 2018. While few studies examined the global burden of breast cancer in multicountry context,[2, 5] no study has examined the most recent estimates of breast cancer burden in Africa.

What this study adds

This study examined the burden of breast cancer in 54 African countries measured in terms of age-wise and age-standardized rates of incidence and mortality. The MIR ratio was employed to approximate the 5-year survival rates and the country-wise metrics of breast cancer burden were comprehensively examined in light of the development status of a country measured by its HDI. With few exceptions, greater socioeconomic status measured by HDI was linked with high ASIRs and low ASMRs (Fig. 3a and b). High ASIRs in developing countries of Africa relates to the similar risk factors as in developed countries as well as better screening of breast cancer in a few of these countries. MIR, a proxy for survival rate, had a strong negative and statistically significant association with HDI. The poor survival rates in SSA countries have been documented before[6, 22] and are due to low awareness levels, lack of screening availability and cancer care infrastructure, among other factors.[23]

We found that 50% of patients were below the age 50 (74% below the age of 60) with higher HDI countries had more breast cancer patients in older age-groups as high HDI characterizes greater development and longer life spans (Supplementary Fig S3). Previous studies have highlighted the issue of younger age-profiles of breast cancer patients in Africa.[24] Although lower life expectancy in African countries compared to developed countries is considered to be the biggest reason, younger age of breast cancer patients among African−American women[25] also suggests there must be few factors other than life expectancy such as genetic factors or environmental factors that predispose females of African origin to breast cancer at earlier age.[24] These patterns are particularly concerning given that breast cancer among young women tends to be clinically and pathologically more aggressive with higher mortality rate than that in older women.[26]

Late-disease presentation is a hallmark of breast cancer burden in Africa.[27] A meta-analysis on breast cancer presentation in Africa by Jedy-Agba *et al*.[27] found late-stage presentation varying from 30% in South Africa to 98% in Nigeria with disease presentation also differing among black and nonblack women. As per Abdulrahman and Rahman,[28] 50–75% of African women present with advanced disease, whereas only 11% of breast cancer patients presented with advanced disease (stage III or IV) in the USA.[29] In a country-specific study, Islami *et al*.[30] reported 74% of breast cancer patients in Cote d'Ivoire and 81% in the Democratic Republic of Congo presented with advanced disease.

The advanced disease presentation in Africa results in poor disease outcomes and hence, lower survival rates.[6] The survival rates were found to be 12 and 46% in Gambia and Uganda, respectively.[22] In Africa, lack of awareness, fear of mastectomy and societal fears were a few of the patient-specific reasons responsible for the late-disease presentation and higher mortality rates.[2–4, 23] Moreover, many African women also show up to a traditional healer on first noticing symptoms, who promises treatment without any painful surgery or medicine, which further delays proper diagnosis and poor prognosis ensues.[31–33] In addition to the above patient-specific factors, late-disease presentation also reflects poor oncologic infrastructure, week referral systems and lack of screening services in Africa[23].

While many developed countries can reduce case fatality rates for breast cancer by promoting early detection using mammography screening, many African countries lack either access to screening equipment and services or the means to promote them due to misconception and lack of population awareness. As far as screening is concerned, the developed countries' approach of screening through mammograms cannot be emulated in African countries due to a lack of resources and awareness.[34] As per breast health global initiative, there must be phased approaches toward breast cancer detection as per country's resource availability; in limited-resource settings, the focus must be on raising awareness and capacity building and in highest-resource settings, the focus must be on screening of asymptomatic women.[35]

As mammographic screening is not cost effective in low-resource settings in Africa, clinical breast examination (CBE) may prevent the delay in diagnosis and can facilitate earlier disease presentation. Preliminary results from randomized control trials (RCTs) on the efficacy of CBE in low- and medium-income countries have revealed success in downstaging and early detection of breast cancer.[36–38] Although CBE has not been recommended as primary screening device due to nonconclusive evidence of its mortality-reduction effects, its cost-effectiveness and relative success in downstaging of cancer in RCTs makes it suitable to be recommended for those women who do not receive regular mammograms either because it is not recommended (women aged < 40 and > 69) or because breast mammograms are costly. It can also present an opportunity for healthcare providers to educate women on breast cancer, risk factors, role of early detection in progression and lastly, self-breast examination.[39, 40]

Downloaded from https://academic.oup.com/jpubhealth/article-abstract/doi/10.1093/pubmed/fdaa099/5869901 by Delhi Technological University user on 20 July 2020

Breast cancer risk factors pertain to the duration of breast-feeding, age at menarche and menopause, hormone status, life expectancy, dietary risk factors, exposure to ionizing radiation and genetic predisposition.[41, 42] Few of these risk factors were not prevalent in Africa earlier; in recent times, however, life expectancy is increasing, infant mortality is falling along with declining fertility rates, marital behaviors, and reproductive patterns are changing in Africa.[43, 44] Cumulatively, these behavioral changes have been termed westernization of lifestyle, which has resulted in higher breast cancer risk in African women.[3]

Cancer care infrastructure ranging from preventive medicine to palliative care is often scarce in low- and medium-income countries, including Africa.[24, 45] For instance, even though surgery is the primary treatment option of breast cancer and sometimes the only treatment option, a small percent of breast cancer patients in low- and medium-income countries such as in Africa have access to safe, affordable and timely surgery.[46] Only 25 of the 43 responding African countries had CBE available at public primary healthcare level, whereas 15 of 43 African countries had mammograms available at the public primary health level (Supplementary Table S4) (Only 16 of 43 African countries had national level cancer control plan or strategy by 2014.).

Limitations of the Study

The quality and reliability of estimates depend crucially upon the degree of representativeness and the quality of source information[11, 15]. As per Bray *et al*.[47], across SSA, there were only four population-based registries (Kampala, Uganda; Harare, Zimbabwe; Blantyre, Malawi and PROMEC, South Africa). Moreover, as population-based cancer registries are not available in many of the African countries and estimates were obtained using data from neighboring countries, which may be underreported in few of these countries. Therefore, the breast cancer estimates reported and examined in this paper are expected to be biased. Moreover, the modeling effort may result in too wide UIs, which may render policy deductions lesser useful in few countries.

Conclusion

With ~ 170 000 cases and ~ 75 000 deaths, breast cancer has become one of the most significant public health threats in Africa with incidence rates fast approaching that of developed countries and mortality rates higher than that of developed countries. Breast cancer is a cause of concern in Africa owing to increasing incidence, high mortality, low survival rates, late-stage disease presentation and lack of cancer infrastructure. Increasing life expectancy and westernizing lifestyles will result in greater breast cancer burden in Africa in the near future, and the public health systems in Africa have to gear up to tackle this enormous public health threat. In addition to boosting oncologic infrastructure, there must be effective educational campaigns to educate women about the importance of early detection of malignancy and access to care[48]; for this purpose, low-cost interventions such as CBE can be employed to educate women on all issues relating to breast cancer. Lastly, there must be an increased focus on establishing cancer registries and expanding the coverage of already existing ones in Africa.

Abstract

Researchers and data scientists have developed different Recommender System Algorithms such as Content-Based and Collaborative-Based in order to filter a large amount of information available on the internet and hence, recommend only the relevant and essential content based on the personalized interests of users. Information acquired explicitly by collecting users' ratings for an item lead to the problem of data sparsity. Many researchers have been currently working towards the improvement of rating prediction accuracy by integrating the auxiliary information along with the ratings provided by the users. This paper proposes a novel product recommender system called as "CapsMF", it applies the advanced neural network architecture Capsule Networks (Caps) for document representation, and MF represents Matrix factorization. In the proposed approach, we have enhanced a deep neural network text analysis model by adding a newly discovered neural network architecture; Capsule Networks stacked on bi-directional Recurrent Neural Network (Bi-RNN) for the robust representation of textual descriptions of items and users. The Deep Neural Network text analysis model is integrated with the Probabilistic Matrix Factorization to generate improved recommendations. The experiment has been performed on two real amazon datasets resulting in the enhancement of rating prediction accuracy, the recall, and the precision of top-n recommendations, in comparison to the basic and hybrid Recommendation System Algorithms. Also, text analysis model involving Capsule Networks stacked with Recurrent Neural Networks (RNNs) have outperformed the baseline models that have single Convolutional Neural Networks (CNN) or CNN combined with Bi-RNN in text analysis.

1 Introduction

In this digital era, people use e-commerce websites for shopping and social media sites for news and related information. The problem arises when there are varieties of options available while searching for a thing. It is tough for the end users to find the critical content they are looking for according to their interest. The solution for this new digital era issue is Recommender Systems (RS). These are being deployed on e-commerce websites and on the social media platforms that extract the personal information related to the users and recommend them the relevant content and information that they want depending on their interest, activity, and behavior. For example, movies, books, clothes, tweets are being recommended to the people visiting different web sites. Recommender System [22] is an application of Web Mining. This process discovers interests and behavior from large amounts of data without human interference and hence, ranks the most relevant content or items using the rating prediction of the users visiting a website. The researchers and data scientists that filter the information according to the personalized interests of the users have developed different types of Recommendation System Algorithms and techniques. A recommender system can extract information related to a user in two different ways: explicitly or implicitly.

One can get the information related to the users explicitly by collecting the ratings for an item given by a user, and it can be acquired implicitly by monitoring the behavior of users on the different websites related to the product [2]. Their behavior includes songs heard, applications downloaded, websites visited, movies watched, books read. Social information can be compiled by scraping the users' accounts on different social websites, for example, what kind of posts they like, their followers, followees and different activities on social media can tell a lot about the preference of the users, and hence, personalized recommendations can be more accurate and precise [15, 18].

Based on the information about different items and users, two categories of recommendation algorithms developed are Content-Based, Collaborative-based. Out of these, Matrix Factorization technique based on Collaborative Filtering (CF) gives the best recommendations [21]. The limitation observed in the current system is that information acquired explicitly by collecting users' ratings for an item lead to the problem of data sparsity because not every user rate every other movie. The accuracy of rating prediction for an item reduces, thereby not satisfying the needs of the customer. Many researchers inclined towards the improvement of rating prediction accuracy by integrating the auxiliary information along with the ratings provided by the users. It has been observed in related works that integrating the textual data along with rating data has brought an improvement in the rating prediction accuracy. However, document modeling approaches are different in different research papers.

Various topic modeling approaches and deep neural network models [36] are being used to represent the textual description of items and users for improving the rating prediction accuracy and recall and precision of top-n recommendations. The recent models integrate matrix factorization with textual data generate a textual representation of documents using deep neural network architectures; they are more effective as they extract semantic information from the text.

Capsule Networks bring an improvement in the old neural network architecture, and it works better than the Convolutional Neural Networks (CNN). There are certain disadvantages of using the convolutional neural networks, few areas where CNN lacks, Capsule Networks have overcome those limitations, and now it is a better neural network architecture for

developing models to solve the problems in different domains. Capsule Networks are primarily used for Classification of Images in different categories [8].

CN can also be applied in the areas of NLP and RS to utilize textual information more efficiently. Neural Networks can be trained to learn numeric representations of various words and phrases using models such as Word2Vec and Glove and can be applied to classify the data in different categories.

This research paper has successfully executed the following points:

We have addressed the limitations of CNN based document modeling approach as well as CNN and RNN based text representation approach.

We have proposed a novel and powerful Deep Neural Network text analysis model combining Capsule Networks and Bi-directional RNN to accomplish the textual representation of items' and users' reviews to improve recommendation performance.

Experiments results prove that exploiting ratings, items' and users' reviews have improved rating prediction accuracy, precision, and recall of top-n recommendations.

The rating Prediction accuracy on proposed model "CapsMF" has shown improvement over PMF, DRMF-Item, DRMF-User, and DRMF by 26%, 4.7%, 3.5%, and 1.7% in terms of MAE.

Different hybrid Recommendation Models using items' and users' reviews as auxiliary information have been described in the Related Work. The theory related to Capsule Networks and Bi-RNN and Recommendation algorithm, Probabilistic Matrix Factorization is explained in the Methodologies section. The proposed deep neural network text analysis model and the integration of PMF with a novel text analysis model are explained in the Proposed Approach section of the Paper. The last section of the paper deals with Experiment and Results along with Conclusion and Future Work associated with this approach.

2 Related work

Here, we have discussed different models that combine textual data with Recommendation System algorithms providing recommendations to the users. In [11], a brief about text classification using Capsule Networks(CN) has been explained. The different hybrid recommendation systems that have been proposed by the researchers that combine textual data and recommendation algorithms are explained further.

CTR, Collaborative Topic Regression [30], incorporates the advantages of collaborative-based, MF algorithm and probabilistic topic modeling approach for recommending research based articles to the scientists online. Content analysis is done using the Topic modeling approach (LDA) combined with latent factor models using MF for recommending the unseen articles [28]. Their approach worked well as it recommended completely unrated articles to the users that were useful and hence, predictions were made in the right manner. Various efficient algorithms have been proposed in further years that have worked upon these models and have improved them. In HFT [19] model, the authors have developed a statistical model that combines hidden dimensions in the rating matrix with the topics extracted from the text of the review given by users. This methodology helped in predicting users' rating on unseen movies and further recommends them. The models developed by them helped in the discovery of genre and identified the most informative reviews. Their model "HFT", Hidden Factor Topics has addressed the most occurred problem in recommendation tasks, Cold-Start. Their model performed better than the latent factor-based recommender system improving accuracy

by 5–10% [32]. The model RMR [17], proposed by the authors, have combined the content-based and collaborative based filtering techniques to develop a novel integrated recommender system. Their model "RMR", Rating meets reviews combined the rating model with a topic model to generate recommendations and thereby solving the "cold-start" problem, that is recommending the new products to the users that have not been rating using the description of the item. Their model also works on the side of the item. For modeling the ratings, they have used a mixture of Gaussian, unlike above researchers that have used MF method. They have compared their model with the above described, HFT and CTR and has shown that their model has performed better in terms of rating prediction accuracy. CDL [32], Collaborative Deep Learning brought a change in the topic modeling approach by learning the numeric representation of textual data by applying deep learning techniques on the item description document. In this paper, they have proposed the hierarchal Bayesian Model, which applies deep learning on the textual data and Collaborative filtering approach on rating data in a joint manner. They have used SDAE, Stacked Denoising Autoencoders, neural network approach combined with the Collaborative Filtering method in order to integrate the rating and content information, thereby advancing the quality of recommender systems. Convolutional Matrix Factorization (ConvMF) [14], this model addresses the rating data sparsity by learning the text document using single CNN. The CNN considers the surroundings of the word order that has improved the representation of latent features in the description of the items' documents. Their model integrates PMF and CNN to upgrade the rating prediction task and hence, refine the quality of recommendation of items or movies to the end-users. LZhang et al. [35] proposed combining CF algorithm with an artificial neural network (ANN) to enhance the scalability and remove the sparsity of recommendation systems. Quadric Polynomial Regression model extracts the latent features, and these features then becomes the input to the deep neural network for predicting the rating scores. The model used to extract the hidden features improves the traditional matrix factorization method [35]. Dual-Regularized Matrix Factorization (DRMF) [34], this is the recent research work in the field of integrating textual data description with PMF. They have exploited the textual description of items and users both and then predicted the rating score. They have also adopted a unique multi-layered neural network model that combines CNN and bi-directional GRU that has given a better latent representation of the text. The content representation regularized the latent models for the items and users in MF.

Different expert recommendation systems have also been designed to recommend the experts in different domains for solving problems using the information retrieval process. It helps in the detection of knowledgeable people expert in his or her area. The combination of search engines and NLP can be used to retrieve the experts in this kind of recommendation systems [12]. Different tags and their syntactic patterns associated with Web 2.0 such as audio, video, movies can be exploited for recommendation to solve the cold start problem [1, 23].

This research paper is being inspired by the above-related work explained. Our proposed approach brings an improvement in the text analysis model so that the textual representation gets better, thereby improving the quality of recommendations.

3 Why capsule networks over CNN?

Capsule Networks were newly discovered Neural Network Architecture by Geoffrey Hinton in 2017. They have been applied in various domains such as Image Classification, Natural Language Processing (NLP), text classification, etc. [31]. This is a breakthrough in the domain

of Deep Learning. It has overcome the various drawbacks in the CNN and shown effective results in the classification problems. The max pooling function used in CNN to extract the highest features is not efficient and results in reduced computational complexity. It has been replaced by Dynamic Routing Algorithm that is very efficient in recognizing the spatial relationships and hence improving the classification accuracy. "Routing-by-agreement" proposed by Geoffrey Hinton, helps in retaining the relevant information and features of the content and sends the features from lower-level to higher level only if the content is being matched [6].

CNN does not consider the spatial information, whereas CN does, and that increases its power. Replacing the CNN by CN in the deep neural network text analysis model has increased the rating prediction accuracy and hence reducing the root mean squared error (RMSE). The experiment and results are presented in the further sections.

4 Why deep neural networks for text analysis?

In recent times, the research in deep learning has enhanced. It is being used in different domains such as computer vision, image classification, NLP, Recommender Systems, etc. They have improved the accuracy in different classification and regression problems. They are more complex to understand and take more time in training, but the results generated are more effective and precise. They perform better in extracting semantics from documents and hence, generating an effective text representation of documents [9]. As we saw Capsule Networks perform better than CNN, as they have a dynamic routing algorithm that simultaneously takes feedback from simple entities.

Similarly, Bi-directional GRU is good at temporal modelling, that is, it stores information related to past and present. These neural networks are good in feature extraction and dimensionality reduction. Hence, we have proposed a DNN model for text analysis and generating the representation of items' reviews and users' reviews.

5 Methodologies

This section discusses the different methodologies adopted in order to implement a product recommender system.

6 Probabilistic matrix factorization

PMF [25] is collaborative filtering, model-based technique. The task of the algorithm is to infer the preferences of the users based on the ratings given by users. And what other similar users have liked? In this algorithm, the rating matrix of items and users are given, but it is a sparse matrix because not every user rate every other movie. The main aim is to fill the missing entries to predict the rating that a user would give to an unseen movie and then recommend those to the user based on predicted rating score.

PMF factorizes the rating matrix into a product of two smaller (low-rank) matrices. Given a rating matrix of M products and N users, and integer rating 1 to 5, the matrix is factorized into two latent feature matrices of users and items.

The two users and items latent feature-based matrices is learned from the observed rating matrix. PMF models ratings as drawn from a normal distribution. User and item features are determined using mean values. It assumes that ratings are normally distributed.

$$\widehat{r}_{ui} \sim N\left(p_u q_i^T, \sigma^2\right) \tag{1}$$

Where r_{ui} represents predicted rating score, N represents normal distribution, p_u represents user-feature vector and q_i represents item-feature vector.

σ^2 represents variance used to model noise of rating matrix.

User Feature Vector can be represented as:

$$p_{uf} \sim N\left(0, \sigma_p^2\right) \tag{2}$$

Here, p_{uf} represents user feature vector, N represents the normal distribution, σ_p^2 represents variance used to model noise of user latent feature vector matrix.

Item Feature Vector can be represented as:

$$q_{if} \sim N\left(0, \sigma_p^2\right) \tag{3}$$

Here, q_{if} represents item feature vector, N represents the normal distribution, σ_p^2 represents variance used to model noise of item latent feature vector matrix.

In this research, we have compared our model with the basic Probabilistic Matrix Factorization approach. In this proposed integrated model, parameters can be learned using the MAP approach.

7 Deep neural network for text representation

The Deep Neural Network (DNN) Text Analysis Model is being used for generating the text representation of both items and users. A unique and powerful DNN model has been implemented to learn the hidden features of textual reviews. The DNN Text Analysis Model first goes through three Capsule Network (CN) Layers and learns the text representation with these CNs. After learning the semantics and orientation of the text by concatenating three CN Layers, the text is encoded into numbers using Bi-directional Gated Recurrent Unit (Bi-GRU), a variation of RNN. The Framework of DNN Text Analysis Model consists of the Embedding Layer first, and then three CN Layers stacked on a Bi-directional GRU Layer, and finally the Output Layer that projects the hidden features of the reviews.

8 Embedding layer

The input data needs to be encoded in integer; the algorithm does not take strings as input and work on it. Here, the Embedding Layer in Keras is essential. It helps in providing a dense representation of words and learns the relationship between the words. In this research, we have used a pre-trained embedding (Glove) [20] to get the dense representation of the reviews

of items and users and learn the relationship between the words in the reviews. It helps in extracting the semantic relationship between the words. It encodes the meaning of words into vectors.

9 Capsule networks

Capsule Networks [24] are newly developed Deep Neural Network architecture introduced by Geoffrey Hinton in 2017. These networks brought an improvement in the Convolutional Neural Networks (CNN). Capsule Networks have overcome the limitations observed in CNN's. The main advantages of CNs that makes it different from CNN and more efficient are dynamic routing and equi-variance. Dynamic routing Algorithm [7] is the central concept behind capsule networks. Analogous to backpropagation in Artificial Neural Network, Dynamic Routing between capsules help the capsules in communicating with each other and creating the text representations [27].

10 Routing by agreement

A capsule network is built up by combining several layers. The Capsules present in the lower level of capsule network architecture correspond to simple entities that further combine to form an image. For example, in the image of a house (complex entity), the two smaller entities are rectangle and triangle. According to the concept of Routing by Agreement as specified by Geoffrey Hinton, the capsules at lower level bet on the presence of a complex entity at a higher level. Moreover, these bets are combined to get the output of capsules at a higher level [30]. For example, the presence of two simple entities, rectangle, and triangle, works with each other to bet on the presence of a complex entity at a higher level, i.e. house. A coupling effect is observed in this concept. Here, capsules at lower level try to predict the output of the capsule at the higher level and if the predictions made by capsules at lower level conform to the actual output of capsule at a higher level, the coupling coefficient between the two capsules increases.

11 Mathematics behind capsule networks

Consider two layers t and t + 1 having m and n capsules respectively. The main aim is to compute the activations of the capsules at layer t + 1 given the activations at lower layer t. Let u denotes the activations of capsules at layer t. The task is to calculate v, activations of capsules at layer t + 1 [7].

For a capsule j at layer t + 1,

12 Calculation of prediction vectors

The first step involves the calculation of the prediction vectors of the upper layer using the capsules at lower layer. The prediction vector is calculated by a capsule i (of layer t) for the capsule j (of layer t + 1):

$$\overline{U_{j\backslash i}} = W_{ij}U_i \tag{4}$$

Where Wij is the weight matrix

13 Calculation of the output vector

The output vector s_j is calculated using the weighted sum of all the prediction vectors given by the capsules of layer t for the capsule j [19].

$$s_j = \sum_{i=1}^{m} c_{ij}\overline{u_{j\backslash i}} \tag{5}$$

The scalar cij is the coupling coefficient between capsule i (of layer t) and j (of layer t + 1). The iterative dynamic routing algorithm determines the coupling coefficient.

14 Apply the squashing function

After calculating the output vector, the squashing function is applied to the output vector v_j of the capsule j:

$$\mathrm{v_j} = \mathrm{squash}\left(\mathrm{s_j}\right) \tag{6}$$

Squash Function performs the non-linear transformation and works as an activation function for capsule networks like ReLU function used in convolution networks.

15 Bi-directional gated recurrent unit

We have used Bi-Directional Gated Recurrent Unit stacked on Capsule Networks to enhance the text representation. Gated Recurrent Unit (GRU) solves the different problems observed in RNNs [29] such as long-term dependency and vanishing/ exploding gradient problem. These are the most effective neural networks when the context of the input is required. GRU uses two gates, update gate and reset gate in order to maintain the information passed long ago.

Mathematically, Update gate is represented using z_t for the time step t using the following equation,

$$z_t = \sigma\left(W^{(z)}x_t + U^{(z)}h_{t-1}\right) \tag{7}$$

Where x_t represents input unit, W (z) represents the weight, h_t-1 represents the information from previous input units and U (z) is the weight associated with the previous input units. They are both added, and the output is obtained between zero and one due to the sigmoid function applied.

The update gate reduces the vanishing gradient problem as it helps in determining the amount of past information required to be forwarded in the time ahead [5].

The Reset gate also plays an important role to forget the not so required past information. The equation for the reset gate is:

$$r_t = \sigma\left(W^{(r)}x_t + U^{(r)}h_{t-1}\right) \tag{8}$$

Where x_t represents input unit, W(r) represents weights associated with the input unit, h_t-1 represents information from previous input units and U(r) represents weights associated with the previous input units. The sigmoid function is applied after summing the results of the input unit and previous input units.

Now, the following formula shows the final output that would be generated using the reset gate that restores the past information and removes the irrelevant information from the past [25]. The new memory content generated using the Reset gate is given as:

$$h_t^{'} = \tanh(W_{x_t} + r_t \odot U h_{t-1}) \tag{9}$$

The h_t' represents the ongoing memory content. The present memory content is generated by multiplying the corresponding weights to the input x_t and multiplying the corresponding weight of previous input units. After that, the element-wise product is calculated between reset gates and weighted previous input units. Then, the non-linear activation function tanh is applied to generate the results. The closing Memory at the present time step t is calculated using the following equation:

$$h_t = z_t \odot h_{t-1} + (1 - z_t) \odot h_t^{'} \tag{10}$$

In this equation, h_t represents the closing memory content vector generated, z_t represents the update gate and h'_t represents present memory content.

16 Output layer

After going through the embedding layer, Capsule Network Layer and bi-GRU Layers, the features extracted by the last layer are outlined on a k-latent dimensional space by using hyperbolic tanh activation function.

$$\alpha = \tanh\left(G^{*}h + b\right) \tag{11}$$

Here, G represents the projection matrix obtained in the output Layer, h represents the output obtained from the bi-directional GRU layer, and b is the bias. Dropout [26] is also used in the model to prevent the over-fitting in the projection matrix. The main aim behind Dropout is dropping hidden or visible neurons in a neural network model to prevent the over-fitting. Dropout is a regularization technique that helps in reducing the interdependence between the nodes in the neural network.

The above-mentioned text analysis neural network layers described converting a raw document into a densely distributed representation, as shown in Fig. 1. Given X, the document of items' reviews and Y, the documents of users' reviews, the DNN text analysis model transforms X to beta and Y to alpha. Alpha and beta are the densely distributed representation of the raw documents of users and items, respectively.

Keras functional API [4] is being used to define the neural network model for text analysis and getting the projection matrix for the further process. The model parameters are learnt by applying the back-propagation algorithm. The input sequence, output, and the corresponding loss function are defined for the model. In the Proposed Work section, the algorithm is being explained used for implementing the DNN text analysis model based on Keras.

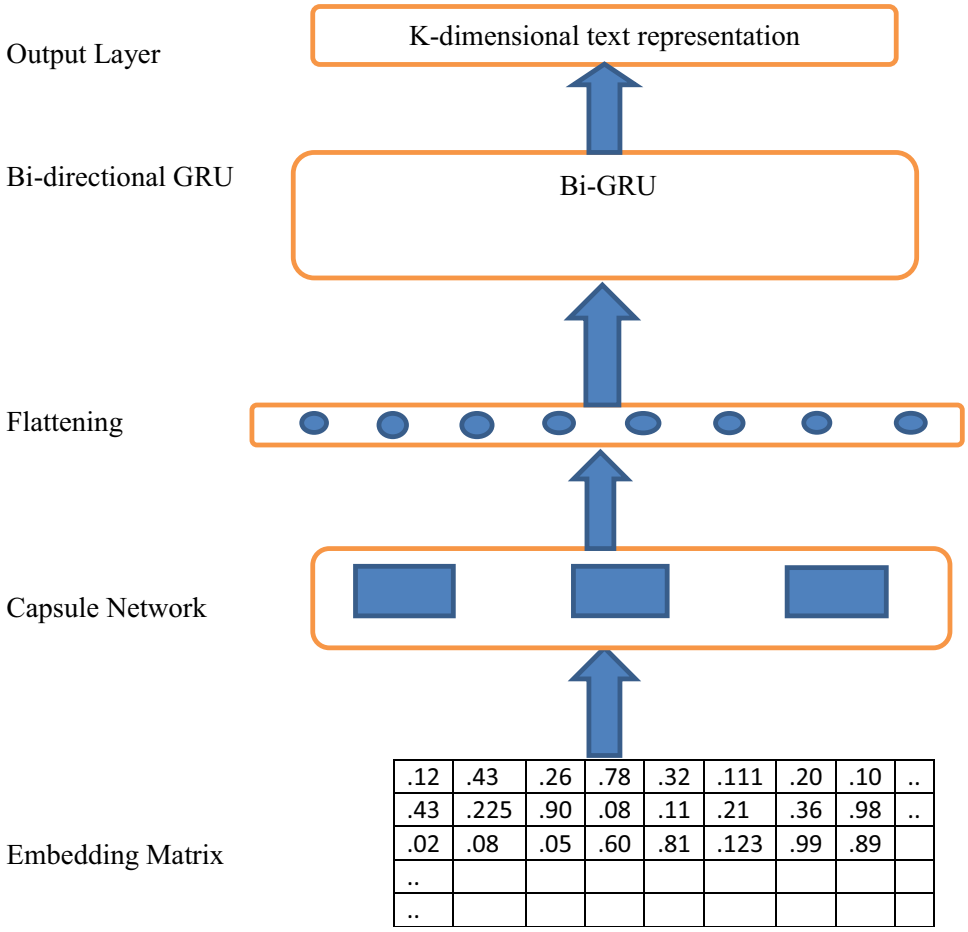

Fig. 1 Deep Neural Network text analysis model generating the representation of users' and items' reviews

17 Proposed work

In this segment, we have described the algorithm implemented for text analysis of reviews of items and users of different products. The matrix obtained from the text analysis is then integrated with the collaborative filtering based PMF method to generate more accurate and precise recommendations.

18 The model

The Algorithm gives the details about the implementation of Text Analysis Neural Network Model that involves different layers starting from Embedding Layer, Capsule Network Layers and Bi-directional GRU layers that extract features from the description documents and project them into k-dimensional space. It outputs a latent document k-dimension matrix that helps in improving the product recommendations.

The earlier similar models have used convolutional neural networks (CNN) [37] for latent document matrix that had certain limitations. These limitations have been overcome using capsule network layers.

The Algorithm is documented below, showing all the different layers that have been applied and implemented to get the k-dimensional matrix of the user and item reviews document. The document is first converted into a numerical matrix using the embedding layer representing the

text as a sequence of word embedding. Then, the document representation is learned through capsule networks, and the semantics of the reviews are encoded by going through the bi-directional GRU layers.

Algorithm: Deep neural network (dnn) text analysis model

```
Input: vocabulary size, e, d, s, gru_dim, k, init_W, n_capsule, n_routings, caps_dim;
Output: DNN text analysis Model
{Embedding Layers}
input_sequence = Input (shape= (d * s,))
seq_emb = Embedding (vocabulary size, e, weights= [init_W / 20], trainable=False) (input_sequence)
{Capsule Layers}
caps_1 = Capsule (num_capsule=n_capsule, dim_capsule = caps_dim,
routings = n_routings, share_weights=True) (seq_emb)
x = Flatten () (caps_1)
caps_2 = Capsule (num_capsule=n_capsule, dim_capsule=caps_dim,
    routings = n_routings, share_weights=True) (x_3)
x = Flatten () (caps_2)
caps_3 = Capsule (num_capsule=n_capsule, dim_capsule=caps_dim,
    routings=n_routings, share_weights=True) (caps_3)
x = Flatten () (caps_3)
x = concatenate ([caps_1, caps_2, caps_3])
{Bi-directional GRU Layers}
x_gru = Bidirectional (GRU (gru_dim, return_sequences=True)) (x)
x = Flatten () (x_gru)
{Output Layer}
seq_dropout = Dropout (dropout_rate) (x)
out_seq = Dense (output_dimesion, activation='tanh') (seq_dropout)
dnn_text_analysis = Model (input_sequence, out_seq)
dnn_text_analysis (optimizer='rmsprop', loss='mse')
return dnn_text_analysis;
```

19 CapsMF: integration of deep neural network text analysis model and PMF

Here, we describe the integration of PMF with the text analysis model and the equations involved in generating user latent feature vector and item latent feature vector. The main aim of the MF technique is to generate user and item hidden feature vectors [16] that particularly describe the choices of the users, and they are obtained from both the ratings and the reviews of items and users.

20 User latent vector

User i as a latent vector represented as:

$$p_i = €_i + \alpha_i \tag{12}$$

Where p_i represents user latent vector, $€ \sim N(0, \sigma_p^2 I)$, α_i represents user document latent vector.

Integrating the above we obtain the user latent model as:

$p_i \sim N(\alpha_i, \sigma_p^2)$, here I represent the identity matrix.

21 Item latent vector

Item j as a latent vector represented as:

$$q_j = €_j + \beta_j \tag{13}$$

Where q_j represents item latent vector, $€ \sim N(0, \sigma_q^2 I)$, β_j represents item document latent vector.

Integrating the above, we obtain item latent model as:

$q_j \sim N(\beta_j, \sigma_p^2 I)$, here I is the identity matrix.

22 Prediction

Suppose, M represents the number of users, and N represents the number of items, R represents the given rating matrix. The missing rating in the rating matrix is predicted using the formula "P^TQ", where P represents the user latent matrix of dimension k X M and Q represents the item latent matrix of dimension k X N.

$$\overline{R} = N\left(P_i^T Q_j, \sigma^2\right) \tag{14}$$

Next is the Flow Chart representing the Learning of different parameters in this model.

Figure 2 above describes the learning of different parameters used in the model "CapsMF" using Maximum a Posteriori (MAP) approach. First, rating matrix, item document, and user document are given as input to the model. Then, Item Content and User Content are pre-processed by removing the stop words and applying lemmatization and convert into embedding input using a pre-trained embedding (Glove) [20] to get the dense representation of the

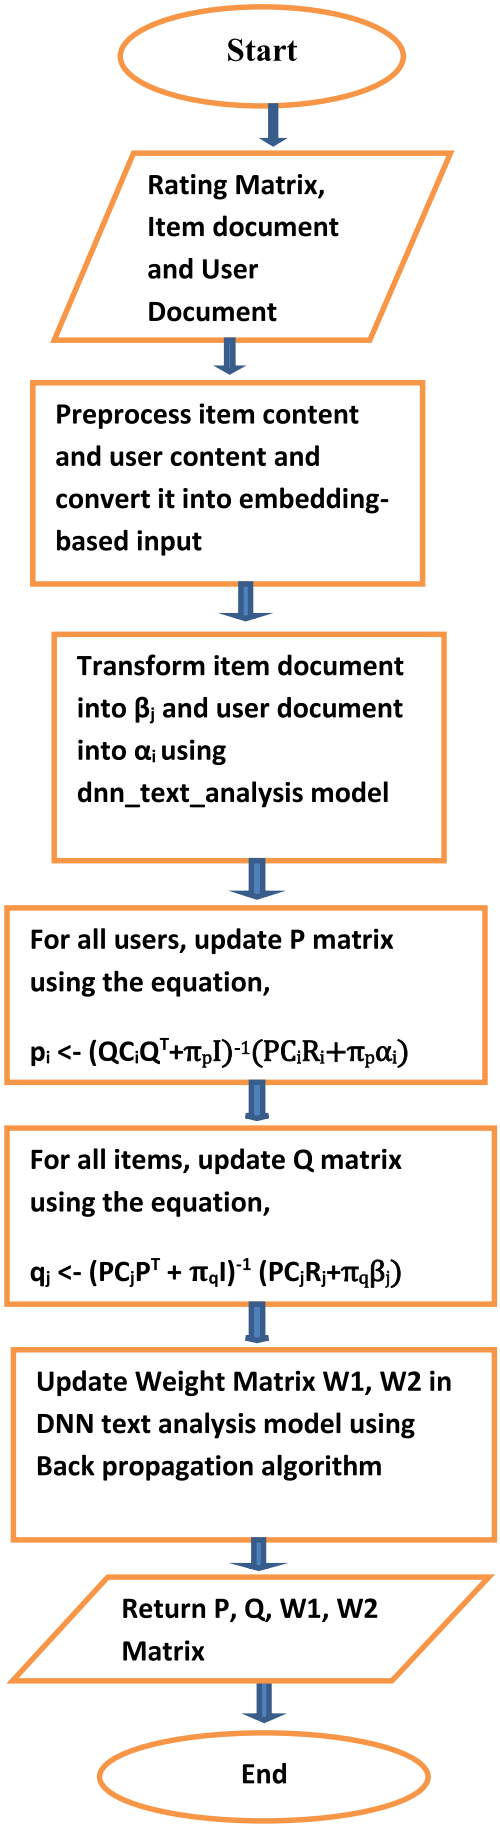

Fig. 2 Learning parameters in the proposed model CapsMF

Table 1 Description of the datasets

Datasets	Number of Users	Number of Items	Total Reviews/Ratings	Rating Scale
AIV (Amazon Instant Video)	5130	1685	37,126	1–5
AA (Apps for Android)	87,721	13,209	752,937	1–5

reviews of items and users. The document matrices generated for users and items and the text representation is learned through DNN text analysis model. Item document is transformed into β_j, and user document is transformed into α_i using the algorithm described in Section 6.1. After transforming the item reviews document and user reviews document, the user latent matrix and item latent matrix is updated using the equations given in the flow chart. The Weight Matrices W1 and W2 applied in DNN text analysis model are updated using Back Propagation Algorithm. When the number of iterations is over, return the User Latent Matrix, Item Latent Matrix, and Weight Matrices.

23 Experiment and results

We have conducted the experiments on the two amazon datasets, one is "Amazon Instant Video (AIV)", and the other is "Apps for Android (AA)". Both the datasets are taken from Amazon Product Reviews site (http://jmcauley.ucsd.edu/data/amazon/). This site contains reviews of different kind of products as well as metadata regarding the product. We have considered only the reviews and ratings of the products. We have taken 5-core datasets, in these 5-core datasets, the users and items have five reviews each. Table 1 describes the datasets that have been used for implementation. The Rating is given from one to five to an item by a user.

We have conducted the experiments on Google Colaboratory Notebook using GPU since the dataset is too large and deep learning models take time in training. We have used different evaluation metrics to compare the proposed model with the recommendation models already published. Root Mean Squared Error (RMSE) and Mean Absolute Error (MAE) have been extensively used for comparing the performance of rating predictions.

Table 2 Parameter settings of π_p and π_q for rating prediction

	Amazon Instant Video		Apps for Android	
Models	Π_p	Π_q	Π_p	Π_q
PMF	0.1	0.01	0.1	0.01
DRMF-Item	1	10	1	100
DRMF-User	10	0.1	100	0.1
DRMF	100	10	10	100
CapsMF	100	10	10	100

Where $\Pi p = \sigma^2 / \sigma_p^2$ and $\Pi q = \sigma^2 / \sigma_q^2$.

σ^2 represents variance used to model noise of rating matrix, σ_P^2 represents variance used to model noise of user latent feature vector matrix and, σ_P^2 represents variance used to model noise of user latent feature vector matrix.

Also, parameters related to Capsule Layer are set accordingly for "CapsMF":

$n_c = 50$; $n_r = 5$; $n_d = 100$

Here, n_c = number of capsules, n_r = number of routings and n_d = Capsule Dimension.

Table 3 Parameter settings of Π_p and Π_q for top-N recommendation

	Amazon Instant Video		Apps for Android	
Models	Π_p	Π_q	Π_p	Π_q
PMF	1	5	5	10
DRMF-Item	0.5	5	10	1
DRMF-User	5	0.5	10	1
DRMF	5	0.5	10	1
CapsMF	5	0.5	10	1

Where $\Pi p = \sigma^2 / \sigma_p^2$ and $\Pi q = \sigma^2 / \sigma_q^2$.

σ^2 represents variance used to model noise of rating matrix, σ_P^2 represents variance used to model noise of user latent feature vector matrix and, σ_P^2 represents variance used to model noise of user latent feature vector matrix.

Also, parameters related to Capsule Layer are set accordingly for "CapsMF":

$n_c = 50$; $n_r = 5$; $n_d = 100$

Here, n_c = number of capsules, n_r = number of routings and n_d = Capsule Dimension.

$N = 300$ for top-N recommendations.

We have also calculated the precision and recall for assessing the accuracy of top- n recommendations.

24 Different evaluation metrics

The formulas used for different evaluation metrics is described here:

$$\mathrm{MAE} = \sum_{i,j} \left| r_{ij} - \overline{r_{ij}} \right| / N \tag{15}$$

Where r_{ij} represents the actual rating, r'_{ij} represents the predicted rating and N represents the count of samples.

$$\mathrm{RMSE} = \text{square root} \left(\sum_{i,j} \left(r_{ij} - r'_{ij} \right)^2 \right) / N \Big) \tag{16}$$

Precision and Recall are calculated to assess the accuracy of top-N recommendations, we have calculated these metrics for top-300 recommendations given to the users.

$$\text{Precision@N} = (\#\text{of recommended items@N that are relevant}\} / (\#\text{of recommended items@N}) \tag{17}$$

Table 4 Rating prediction performance of different models on AIV dataset

Models	MAE	RMSE
PMF	0.9627	1.2088
DRMF-Item	0.7419	1.0101
DRMF-User	0.7325	0.9866
DRMF	0.7190	0.9661
CapsMF	0.7064	0.9593

Table 5 Rating prediction performance of different models on AA dataset

Models	MAE	RMSE
PMF	1.1829	1.4773
DRMF-Item	1.0664	1.3763
DRMF-User	0.9638	1.2617
DRMF	0.9071	1.1930
CapsMF	**0.8878**	**1.157**

The best values are shown in bold.

According to the accuracy comparisons shown in the tables above, it can be concluded that CapsMF, the model described has shown improvement in terms of MAE and RMSE on the two datasets: AIV and AA.

$$\text{Recall@N} = (\#\text{of recommended items@N that are relevant})/(\text{total}\#\text{of relevant items}) \quad (18)$$

25 Parameter settings

Different values that have been set for π_p and π_q are given in Tables 2 and 3.

26 Results

The different values of evaluation metrics obtained on implementing the different models are shown in this section. The baseline models are PMF, DRMF-Item, DRMF-User, and DRMF, as explained earlier in the related work. For the right results, we have averaged the results of five-folds in order to estimate the prediction and recommendation performance accurately.

Below Table 4 shows the results of rating prediction performance of different models on AIV dataset in term of MAE and RMSE.

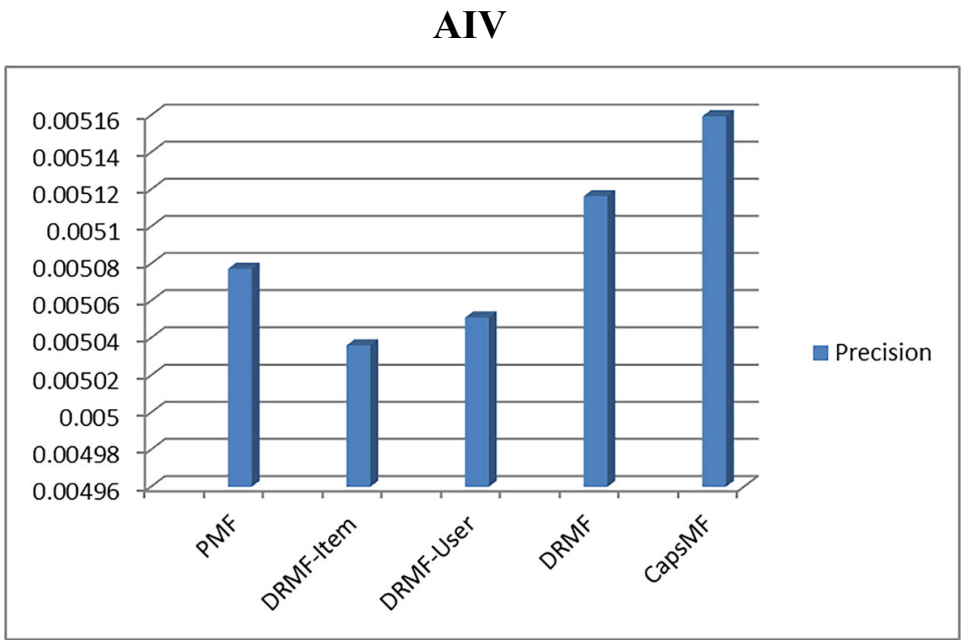

Fig. 3 Top-300 ranking performance in terms of precision

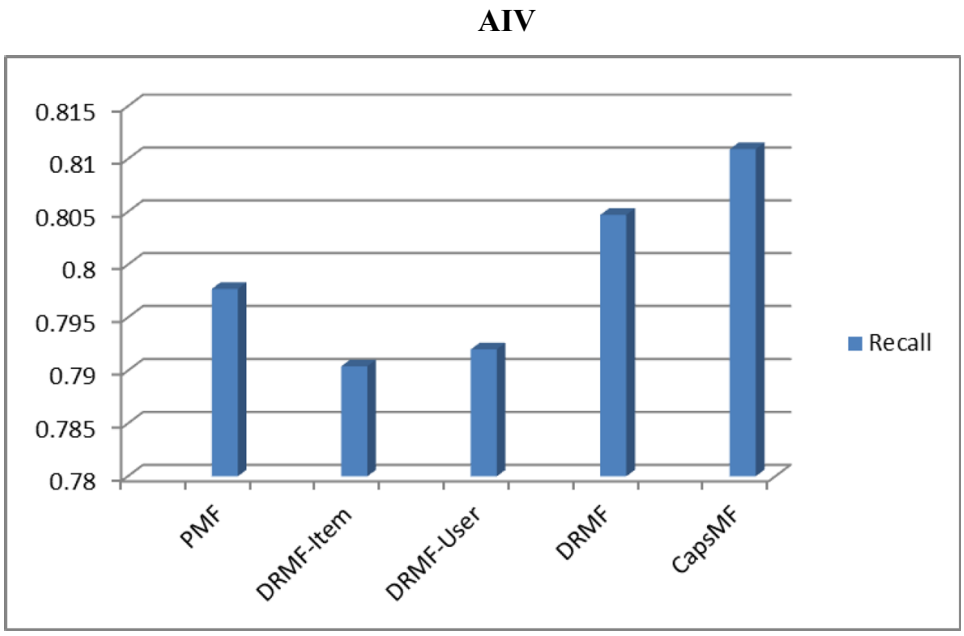

Fig. 4 Top-300 ranking performance in terms of recall

Table 5 shows the results obtained when rating prediction is implemented using different Models on AA dataset. Rating Prediction performance of different models is shown based on MAE and RMSE, respectively.

27 Graphical analysis of results

Here, we have shown the ranking performance of different Models on the two datasets AIV and AA graphically in term of Precision and Recall.

Below Figs. 3 and 4 graphically represent the top-300 recommendation performance of different Models on AIV dataset in term of precision and recall respectively.

Figures 5 and 6 show the results obtained while implementing the task of Top-N recommendations on AIV dataset in term of precision and recall, respectively. Here, the value of N varies from 50 and ends at 300. It is noteworthy that there is not much gain in top-n recommendation performance.

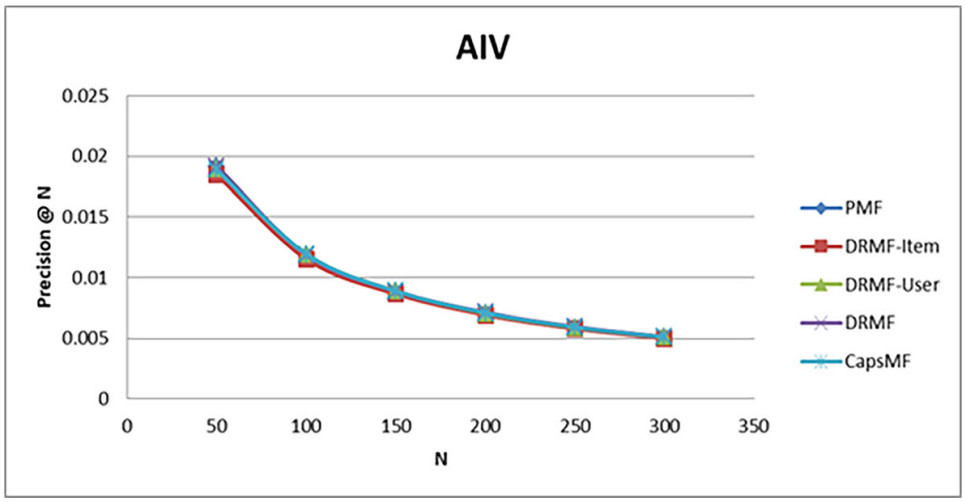

Fig. 5 Top – N recommendation in term of precision

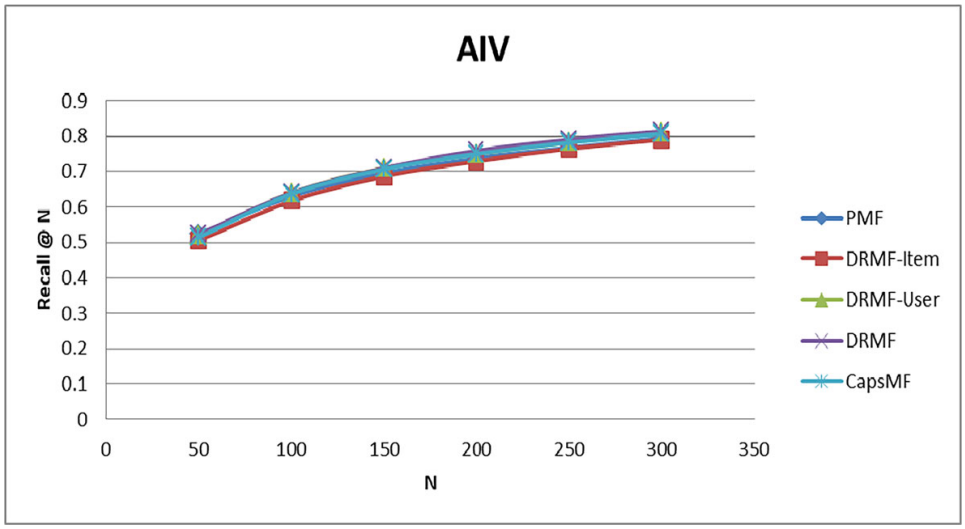

Fig. 6 Top-N ranking performance in term of recall

We can observe in the charts above that the proposed approach "CapsMF" has shown better recommendation performance on AIV dataset. Both RMSE and MAE have smaller values than the baseline Models implemented. All the models have been implemented on Google Colaboratory Notebook in Python using GPU for getting the results faster. Higher values of Precision and Recall prove that recommendation performance has improved over the baseline Models described in the related work.

Following are the graphical representations of the results obtained on "Apps for Android (AA)" dataset. Figure 7 shows the ranking performance of top-300 recommendations in term of Precision graphically on the AA dataset.

Figures 8 and 9 graphically represents the ranking performance of items in term of Precision and Recall on AA dataset. The value of N in Top-N recommendation performance varies from 50 to 300.

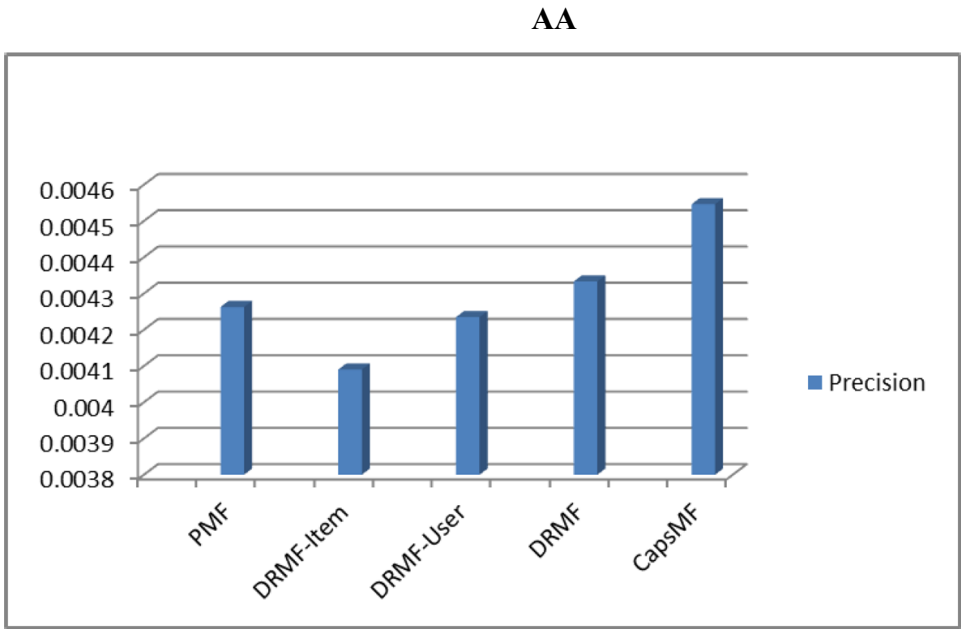

Fig. 7 Top-300 recommendation performance in terms of precision

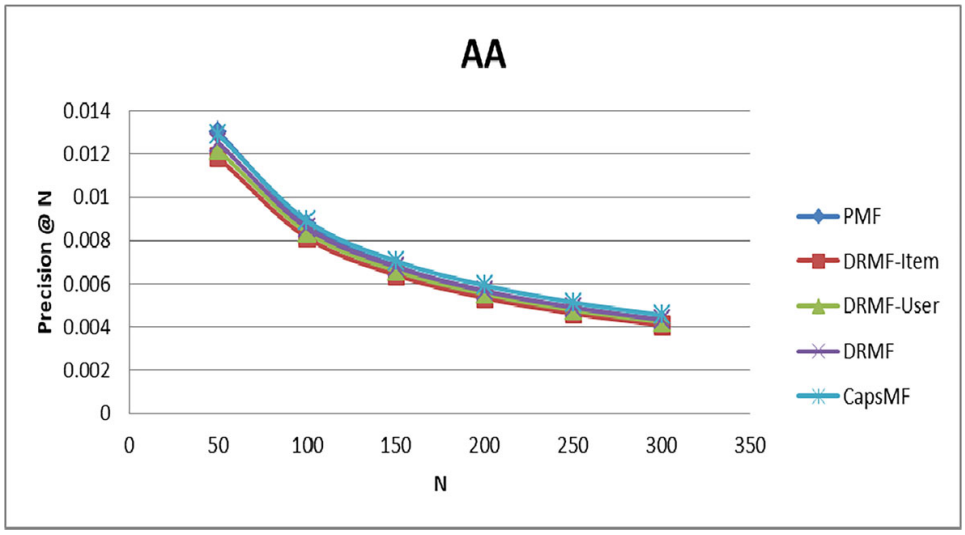

Fig. 8 Top-N recommendation performance in term of precision

28 Performance comparisons

Above we have shown the results in the tables and analysis of the different models on rating prediction and top-n recommendations using column charts. As we can observe that CapsMF, the proposed deep neural network model for text analysis has shown better performance when integrated with Matrix factorization (MF) Technique. For the task of rating prediction on AIV dataset, CapsMF has shown improvement over PMF, DRMF-Item, DRMF-Use, and DRMF by 26%, 4.7%, 3.5%, and 1.7% respectively in term of MAE. In term of RMSE, CapsMF has improved over PMF, DRMF-Item, DRMF-User, and DRMF by 20.6%, 5.02%, 2.76%, and 0.7% respectively.

For the task of top-n recommendation on AIV dataset, CapsMF has shown significant improvement when compared with the other models of similar type in terms of both precision and recall. We have chosen $n = 300$. It has improved by 1.6% when compared with PMF and 2.3%, 2%, and 0.8% improvement w.r.t DRMF-Item, DRMF-User and DRMF in term of Precision. Similar significant improvements have been observed in terms of Recall @ 300 on AIV Dataset.

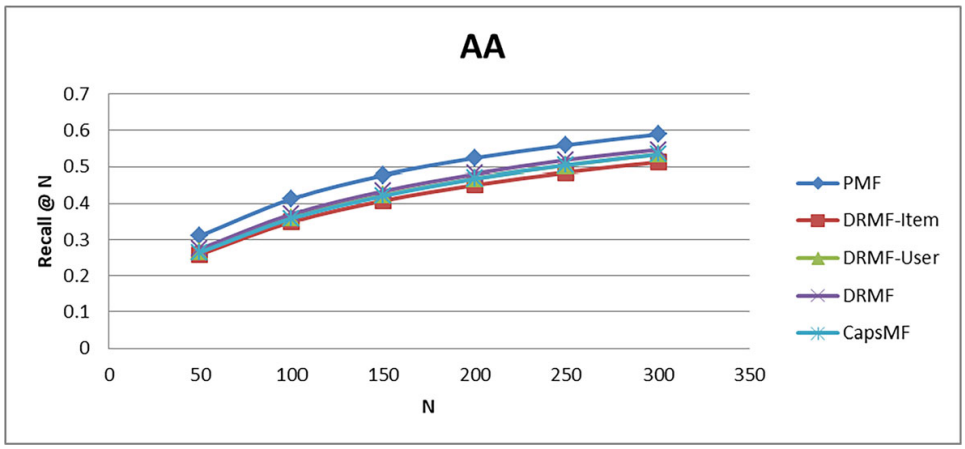

Fig. 9 Top-N ranking in term of recall similarly, when the proposed approach "CapsMF" is implemented on Apps for Android (AA) dataset has shown improvement over the baseline models on two different tasks, one of rating prediction and another, the ranking performance of items that are being recommended to the users

When the task of rating prediction and top-n recommendation are implemented on "Apps for Android (AA)" dataset, significant improvements have been recorded. CapsMF has shown better rating prediction accuracy over the baseline models. It has outperformed the baseline models PMF, DRMF-Item, DRMF-User, and DRMF by 25%, 16.7%, 7.8%, and 2.12% respectively in term of MAE. Similarly, RMSE values have also been reduced when calculated on the models by 21.6% when compared with PMF, 15.9%, 8.29%, 3.01% when compared with DRMF-Item, DRMF-Use, and DRMF respectively.

We can observe that the proposed model CapsMF has shown better results on a larger dataset, "Apps for Android (AA)".

29 Conclusion and future work

In this research paper, we have addressed the limitations of CNN based document modeling approach as well as CNN and RNN based text representation approach. We have proposed a novel and powerful DNN text analysis model stacking Capsule Networks and Bi-directional RNN to generate the textual representation of users' and items' reviews integrated with PMF to improve recommendation performance. Experiments results have proved that exploiting ratings, items' and users' reviews have improved rating prediction accuracy and precision and recall of top-n recommendations. It can also be concluded that the proposed model, "CapsMF", performs better on more massive datasets as compared to smaller datasets. Both the users and items reviews have been considered to build the separate deep neural network for text analysis. Hence, it has resulted in better recommendations to the users and also solves the cold-start problem in recommender systems.

There are still certain limitations that come with Capsule Networks; one that has been observed while performing the experiments is that capsule networks take times in training. The advantage is that it takes fewer data points in training as compared to CNN.

In future works, we would refine the deep neural network for text analysis with new deep learning technologies getting discovered for analysis of text for getting a better representation of the text. We would apply the proposed model in different recommendation datasets and scenarios such as social recommendations [3], joint-recommendation, group recommendation [33], etc. Other contextual information related to users and items such as images, tweets [10, 13], metadata about products can be integrated with collaborative based filtering technique to enhance the personalized recommendations.

***Abstract*—Given the vast amount of research-oriented literature, any new research work asks for a comprehensive literature review. This process is typically very time-consuming. Citation information of a paper is a reflection of its contributions to the researcher's group. We use the citations of the paper to generate a comprehensible and informative summary, which will reduce the time taken to review the paper. In this paper, we propose a novel evolutionary game-theoretic approach to summarize scientific papers. A set of two-player games is played to choose the most relevant sentences in the paper that should be a part of the summary. Our method doesn't require an annotated dataset with gold summaries, thus levitating the need for a large, manually created dataset, which would be a primary requirement for any supervised approach. We have evaluated our results against human-expert generated summaries and state-of-the-art methods.**

Keywords—Extraction based text summarization, game theory

I. INTRODUCTION

Scientific articles are being published at a rate faster than ever. Whenever someone tries to enter a new field of research, they have to go through a large amount of literature to become familiar with the current progress achieved in that area. Reducing the complexity of this task is the main motive behind developing automatic summarizers for scientific papers. Scientific paper summarization is divergent from summarization of general articles [1] as these are divided into different sections, involve complex technical terms, and are much longer as compared to general articles. As of now, Scientific paper summarization follows two strategies. One of them uses the paper's abstract. Now, while the authors' perspective of the contents of a paper is concisely reflected in its abstract, it is also essential to include the views of the scientific community and the impact the paper has had on it. As a remedy to this problem, the second strategy, i.e., citation-based summaries, was proposed [2]. The citation summaries are formed by using a set of citations of an article.

We propose an approach that combines both these strategies. Also, instead of using citation sentences directly (as they may not contain enough relevant information or are even inaccurate sometimes), we follow the methodology of [3] , by making use of cited text spans, i.e., A collection of sentences in the cited paper that is referred to, by the citing sentences from other papers, for generating summaries. Our model takes a reference paper to be summarised and constructs its summary by aggregating and integrating contents from the abstract, and the cited text spans using game theoretical techniques. Hence it includes both the author's vision and the scientific communities' perspective.

We use the SciSummNet corpus as described in [4] as our dataset. It provides over 1,000 papers in the ACL anthology network with their citation networks (e.g., citation sentences, citation counts) and their comprehensive, manual summaries. For evaluation, we use the benchmark gold summaries provided in the CL-SciSumm shared task [5] . The evaluations show that our method outperforms the existing state-of-the-art methods and provides summaries which inculcate the outlook of the author and the research community.

II. RELATED WORK

Early works in scientific article summarization [6, 7] , produced the summaries of target papers based only on their contents. [1] formulated these summaries by identifying suitable content from the papers using a naïve Bayes classifier. But, the discourse of the paper didn't provide any information about the impact of the paper on the scientific community and their views on it. As a solution to this problem, citation-based summarization was proposed. A summary of an article created by using a set of sentences in other articles that cite that article is called its citation summary. According to [8] , citation summaries, while overlapping with the abstract of an article, also focus on other aspects and provide additional information that is not contained in the abstract of an article.

Further research deemed the direct use of citation sentences for summarization as inaccurate as they may not provide enough information and sometimes may even be imprecise. So, [3, 9] proposed identifying the relevant context (usually a set of sentences) in the reference paper (original paper) for each citation and using that for summarization. Such a set of sentences is usually called a 'text

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 06:00:35 UTC from IEEE Xplore. Restrictions apply.

span,' and in this case, it is known as cited-text span. The summaries formed using these cited-text spans would include the insights of the research community while being composed of discourse from a stable source (only a single paper) and, thus, be more comprehensible and coherent. [10] performed experiments that show that summaries formed by using cited text spans outperformed those formed by using the citation sentences directly. CL-SciSumm shared task [5] also uses the cited text-spans based approach.

III. PRELIMINARIES

Skip thoughts, [11] is a model consisting of an encoder based on a recurrent neural network that is used to encode input sentences to a given size output feature vector. This output is used as an input to two decoders. One of the two generates the previous sentence from the context of this vector, and the other one generates the next sentence of the document given the context of the input vector. Outputs from the two decoders are used to train the encoder. Skip thoughts network is trained on the dataset of reference papers whose summaries need to be generated to convert a given sentence of the paper into a fixed-size feature vector.

In classic game theory, we define a set of players, player ={1,2…..n}and every player has a corresponding set of strategies, $strategy_i$ = {1,2…..m}. The payoff is the reward a player earns by playing a strategy in a particular game setting. Utility function relates strategies chosen by all players to the payoff, mathematically defined as, $U=strategy_i \times \ldots \times strategy_j$. To play the game, each player selects a strategy, and the utility function depends on the combination of strategies played simultaneously by all the players involved rather than one player. A crucial assumption being that all the players are rational, and their essential goal is to boost the estimation of U. In non-cooperative games, players first consider what the other people can play, and then choose an ideal strategy.

Nash equilibria can be defined as the stable state of a system where changing the strategy of only one player while keeping the strategies of other players the same gives incentives to other players. In other words, it is the state of a system when each player gets the highest payoff at the given strategy spaces of the complete game. Furthermore, most games involve mixed strategies for players, which are probability distributions over pure strategies. Consider a set of pure strategies, $strategy_i$ = {1,2….m}. In a mixed strategy setting, each pure strategy is assigned a probability, $X = \{x_1, x_2 \ldots .. x_m\}$ where each component x_i is the probability of a player selecting its ith strategy.

In a game between two players, the payoff of the first player from a strategy i whose probability in mixed strategy setting is p concerning the strategy j of the other player whose probability in mixed strategy setting is q will be $u_{ij} = p.A_1.q$ where A_1 is the payoff matrix of the first player.

Evolutionary game hypothesis veers off from the old-style idea as in a player can play the game with all the co-players winning a halfway result after each game and afterward acquires the complete total of every single fractional result as the last result. In this hypothesis, the players over and over take part in games and update their methodology space at every emphasis, considering the adjustments granted during past games. The payoff of a pure strategy h for player i in this setting is given as,

$$u_i\left(e_i^h\right)=\Sigma_{j=1}^{n}\left(A_{ij}x_j\right)_h \quad (1)$$

where x_k denotes the mixed strategy space of player k and A_{ij} is the payoff matrix between player i and j. The average payoff for this player is evaluated as,

$$u_i(x)=\Sigma_{j=1}^{n} x_i^T A_{ij} x_j \quad (2)$$

The probabilities in the mixed strategy space of each player are refreshed by the replicator dynamic condition [12] to accomplish Nash equilibria.

$$\dot{x}=\left[u\left(e^h,x\right)-u(x,x)\right].x^h \ \forall h \in x \quad (3)$$

We have utilized the discrete rendition of this condition, in our work [13] in our work. At each time step, the strategy space is updated following this equation until the system attains Nash equilibrium.

$$x^h(t+1)=x^h\frac{u\left(e^h,x\right)}{u(x,x)} \quad (4)$$

IV. PROPOSED WORK

We took the concept of evolutionary game theory and applied it to the task of text summarization. We take abstract sentences and the citation sentences of the reference paper as the players of the game. Each player plays a game against all the other players, similar to an evolutionary game setting. Weightage of a game in updating the strategy space of a player depends on the similarity between the two players (or sentences). We build a weight matrix W as,

$$w_{ij}=0.7*\text{similarity}\left(\text{player}_i, \text{player}_j\right)+0.3*\text{auth_score}_{(i,j)} \quad (5)$$

where $player_i$ & $player_j$ denote players i & j respectively and $auth_score_{(i,j)}$ is relative authority score of the paper which contains $player_i$ to the authority score of the paper which contains $player_j$ and similarity is cosine similarity between vectors of the respective players. The relative weightage of these two scores for which this method works best has been calculated through experimentation. This set of weights gives the best results. We then convolve the W matrix with a Gaussian filter to smooth it. The set of strategies of each player is a set of sentences similar to the player sentence in the reference paper. The size of the strategy space of each player is kept the same. We initialize the probabilities equal in the mixed strategy setting. We define the payoff matrix A_{ij}

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 06:00:35 UTC from IEEE Xplore. Restrictions apply.

between players i and j where similarity is the cosine distance between the vectors of $strategy_{ik}$ and $strategy_{jl}$ as,

$$a_{ij}^{kl} = similarity\left(strategy_{ik}, strategy_{jl}\right) \quad (5)$$

We follow the aforementioned discrete dynamic equation (4) for updating probability to attain Nash equilibria in the above system where the payoff of the h^{th} pure strategy of $player_i$ is defined as,

$$u_i\left(e_i^h\right) = \Sigma_{j=1}^{n}\left(w_{ij} A_{ij} x_j\right)_h \quad (6)$$

and the average payoff of $player_i$ is defined as,

$$u_i(x) = \Sigma_{j=1}^{n} x_i^T (w_{ij} A_{ij} x_j) \quad (7)$$

We can terminate updating the probabilities once Nash equilibrium is attained that is the state of the game becomes stable or after a fixed number of iterations.

Our method finds the most suitable representation of abstract and citation sentences in the paper and scores them in order of their relevance in a summary.

For each player, the best strategy that is the one having maximum probability in the player's mixed strategy is chosen as the best representative of that player. Then all these representative strategies are compared together and sorted in the decreasing order of the average payoff of their respective player. The sentences are chosen to be a part of the summary in the priority of their sorted order and taking care that similar sentences are not being added to the summary. The sentences chosen for the summary by the above method are then arranged in the order in which they appear in the reference paper, and then the summary can be reduced to 200 words by omitting last sentences as later parts of a paper are very specific for a summary compared to sentences at the beginning of the paper.

The intuition behind this being that for a player, the strategy which is coherent with all other strategies of all other players, will have a better pure strategy payoff than the rest of the other strategies of that player, which will lead to a gain in its probability, increasing its probability from the same initial value in the mixed strategy of that player. Thus, the strategy with maximum probability can be taken as the representative of that player. It is the most suitable sentence in the reference paper, which is similar to the player and also coherent with the other sentences of the summary. The importance of the representative strategy, in summary, will be indicated by the average payoff of the respective player as more will be the average payoff of a player more relevant will be its strategy to the summary.

V. Experimentation and Results

We have used human-annotated, Scisumm dataset [2], ScisummNet which constitutes of 1000 papers in the domain of ACL anthology network along with their human expert generated summaries to test our model.

We trained the skip thoughts network with the reference papers of the dataset and used the cosine distance between skip thought vectors as a similarity measure to create strategy space for each player. For building the weight matrix and payoff matrix, we used a weighted score of cosine distance between skip thoughts vectors and tf-idf vectors of the sentences as an altered cosine similarity measure. We used a weight of 0.8 for skip thought vectors similarity and 0.2 for tf-idf vectors similarity, the values of these weights were determined experimentally. We then convolved the weight matrix with a Gaussian filter to smooth it. We followed the system dynamics for the above-mentioned evolutionary game theory model to generate summaries.

An overall framework of our model is shown in Fig. 1. Abstract and citation sentences of the reference paper are players of the game. Tf-idf and skip-thoughts vector encodings are used to create the strategy space of each player and for building payoff and weight matrices. Evolutionary game dynamics are followed to get a suitable representative of every player and to rank those representatives in order of their importance in the summary. Dissimilar sentences are chosen in the order they have been ranked in. This set of sentences is arranged in the order in which they appear in paper to generate the summary.

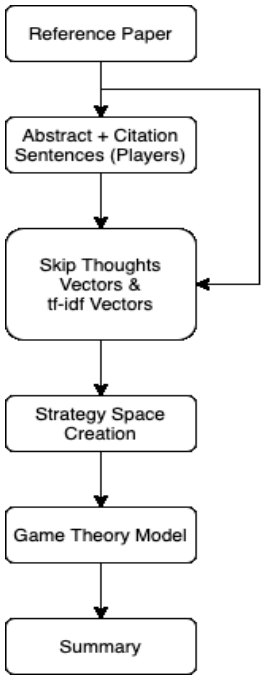

Fig. 1. Proposed Framework.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 06:00:35 UTC from IEEE Xplore. Restrictions apply.

In Fig. 2, we present an abstract of a reference paper from the above dataset on the topic "Unsupervised Semantic parsing". The summary generated by our method is shown in Fig. 4.

We took two players from the same reference paper whose abstract is cited in Fig. 3, one being a relevant sentence("We evaluate our approach by using it to extract a knowledge base from biomedical abstracts and answer questions.") to the summary and the other being a sentence("The sentence can be rephrased as "Utah is next to Idaho," "Utah shares a border with Idaho," etc.") that is too specific for a summary and doesn't add much information to it and show the contrast in the curve of average payoff between a coherent, informative player that is integral to a summary and a player that is not important concerning a summary. The obtained graph (Fig. 3) is in concurrence with our intuition.

"We present the first unsupervised approach to the problem of learning a semantic parser, using Markov logic. Our USP system transforms dependency trees into quasi-logical forms, recursively induces lambda forms from these, and clusters them to abstract away syntactic variations of the same meaning. The MAP semantic parse of a sentence is obtained by recursively assigning its parts to lambda-form clusters and composing them. We evaluate our approach by using it to extract a knowledge base from biomedical abstracts and answer questions. USP substantially outperforms Text Runner, DIRT and an informed baseline on both precision and recall on this task."

Fig. 2. Abstract of reference paper on the topic "Unsupervised Semantic parsing".

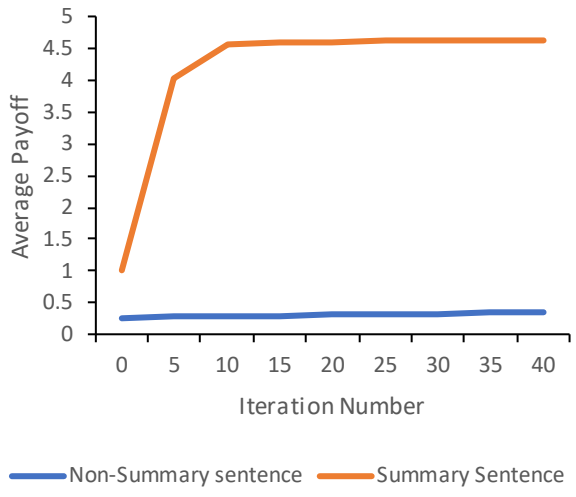

Fig. 3. Average payoff vs. iteration number graph between a summary and a non-summary sentence.

"Our USP system transforms dependency trees into quasi-logical forms, recursively induces lambda forms from these, and clusters them to abstract away syntactic variations of the same meaning. We evaluate our approach by using it to extract a knowledge base from biomedical abstracts and answer questions. In this paper we develop the first unsupervised approach to semantic parsing, using Markov logic. The semantic parse of a sentence is derived by starting with logical forms in the lexical entries and recursively composing the meaning of larger fragments from their parts. Markov logic makes it possible to compactly specify probability distributions over complex relational domains, and has been successfully applied to unsupervised coreference resolution and other tasks.To address this problem, we impose local normalization constraints on specific groups of formulas that are mutually exclusive and exhaustive, i.e., in each group, we require that Eki=1 ewi = 1, where wi are the weights of formulas in the group.6Regularizations, e.g., Gaussian priors on weights, alleviate this problem by penalizing large weights, but it remains true that weights within a short range are roughly equivalent. and update agenda and candidate operations until agenda is empty return the MLN with learned weights and the semantic parses Another major challenge in USP learning is the summation in the likelihood, which is over all possible semantic parses for a given dependency tree."

Fig. 4. Summary generated by our method.

We have evaluated the results, both qualitatively and quantitatively.

A. Quantitative Measure

We have used ROGUE metrics (Recall-Oriented Understudy for Gisting Evaluation) [14] for quantitative evaluation. ROGUE-2 estimates recall and F1 Measure for the bigram overlap between gold and generated summary. We gather from Table 1 that our approach performs as good as the GCN model of the ScisummNet [2] generated summaries, which is the benchmark for this dataset.

TABLE I. ROGUE-2 SCORES

Summarizer	Recall	F1 Measure
Abstract	28.52	29.40
Our Approach	34.61	32.73

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 06:00:35 UTC from IEEE Xplore. Restrictions apply.

Baseline	33.88	31.54

B. *Qualitative Measure*

We gathered a group of 50 people and asked them to score summaries generated by our method on a scale of 0-10 on the parameters of coherence and covering the paper's citation information. Our summaries got an average score of 8.2, which symbolizes that the method generates a comprehensible summary that represents citation information adequately.

VI. CONCLUSION

Citation information of a paper is an outlook of its influence on the researcher's community; thus, appending citation information to a paper's summary is crucial to a faster and comprehensive reviewing of the paper and deciding its relevance in one's work. Our method proposes an unsupervised game-theoretic approach to the task of citation-based text summarization, which levitates the need of a large human-annotated dataset. Our experiments show that our method generates better and comprehensive summaries than the abstract of the paper and the previous citation-based text summarization work. Additional features can be added to bias the weight and payoff matrices. Generic sentence embedding approaches with the semantic representation of the input will lead to better results. We hope that our game-theoretic approach to this task contributes to more novel work in this domain.

***Abstract*— The paper makes a comparative study among the different Pulse Width Modulation (PWM) techniques including – Space Vector Pulse Width Modulation (SVPWM), Sinusoidal PWM (SPWM) and Multiple PWM (MPWM). These techniques are defined, examined and compared to generate gate pulses for a three phase Voltage Source Inverter (VSI). The modulation index is varied for achieving the comparative analysis of these techniques. Pulse Width Modulation techniques are preferred because of low harmonic content obtained in the output voltage and current, fixed switching frequency and higher utilization of the DC bus. Also, SVPWM is then used for achieving V/f control of squirrel cage Induction Motor having different power ratings.**

Keywords—pulse width modulation, space vector pulse width modulation, sinusoidal pulse width modulation, multiple pulse width modulation, induction machine, V/f control

I. INTRODUCTION

An inverter is a power electronic converter used for obtaining ac power from dc power at the required output voltage and given frequency. They can be mainly categorized as Current Source Inverters (CSI) and Voltage Source Inverters (VSI). Voltage Source Inverters have a stiff dc voltage source at the input whereas Current Source Inverters have a stiff current source at the input. The output voltage waveform of the inverter can be sinusoidal, quasi-square wave or square wave with some distortions and can be controlled with the help of switches. The harmonic distortions in the output voltage and current can be considerably reduced by using proper switching schemes. Pulse Width Modulation is one such technique which can be implemented to achieve an efficient switching scheme.

Pulse Width Modulation is a method which uses a pulse wave whose pulse width is modulated to achieve a variation of the mean value of the output waveform. It is a way to control the switching sequence and time period for the power electronic switches used in an inverter. If the switch is ON for longer durations in a cycle, it will result in higher average output of the inverter. [1] The proportion of the ON duration of the switch to the total time period is known as the duty cycle. Also, the switching power loss is very low as negligible current flows in the OFF state of the device and the voltage drop is also negligible. Fig. 1 represents the block diagram for the PWM technique.

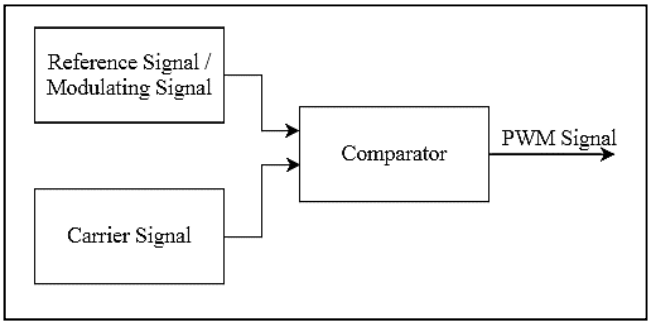

Fig. 1. Block Diagram depicting PWM Technique

The distortion in the output waveform is due to the presence of harmonics. Harmonics are the frequency component of the voltage present at integral multiples of the frequency of the main signal. This can be measured by the Total Harmonic Distortion (THD):

$$THD = \frac{\sqrt{(\sum_{n=2}^{\infty} V_{n_rms}^2)}}{V_{fund_freq}} \quad (1)$$

The THD is affected by the Modulation Index (M_A), which can be defined as the ratio of the peak value of the reference signal to the maximum value of the carrier signal.

IM are the most commonly used machines, especially as motors, because of excellent running conditions and low maintenance. Induction motors aggregate to 70-75% of total electrical load. Though the speed control techniques of IM are not much effective, V/f control is considered as the most popular method. In this paper, V/f control of Induction Motor having different power ratings is achieved by using SVPWM.

II. TYPES OF PWM TECHNIQUES

A. Multiple PWM

In this method, multiple pulses are given to the switches in each half cycle. The reference signal is measured against a carrier wave in order to obtain the gate pulses of equal width for the switches of the VSI. It is also known as Uniform Pulse Width Modulation.

B. Sinusoidal PWM

In this method, the sinusoidal reference or modulating wave is measured against a large frequency carrier wave in order to generate gate pulses to be fed to the VSI.

C. Space Vector PWM

This is a technique which uses an algorithm for modifying the pulse width as per the given reference vector. In this method, vectors are used to represent all possible switching in a space having two dimensional voltage. This is obtained by the transformation to three phase independent vectors from the three phase dependent vectors. The assumption includes a constant reference vector for the corresponding sampling time. The sampling frequency is dependent on the ON and OFF times of the device used, which should be ideally infinite. Thus, for minimum total harmonic distortion and minimum switching losses, the maximum possible sampling frequency is selected. [3]

The line side frequency and magnitude of the fundamental component are regulated using the magnitude and frequency of the reference voltage vector. [1] In SVPWM, there is a unique correspondence between a three-phase system and a space vector in complex plane, which is represented in a mathematical manner.

III. METHODOLOGY

A. Implementation of SVPWM

SVPWM Technique involves transformation of three phase sinusoidal signal into revolving voltage vector in complex plane (abc to dq axis transformation) with constant magnitude revolving with constant angular frequency.

The six switches in a three phase inverter correspond to 8 switching states (all combinations of ON and OFF of the six switches) which are called voltage vectors in the three phase VSI structure. The switching sequences of the six switches should abide by these two restrictions - out of the six switches, three must always be in the ON state and the remaining switches must be in the OFF state. Also, both the switches of the same leg of the inverter should always be driven by two complementary pulse signals.

Fig. 2 shows the vectors in complex plane in different sectors. There is a 60° angle amidst any two neighboring non-zero vectors. In the meantime, zero voltage to the load is applied by V0 and V7 (two zero vectors) at the origin as there is no transfer of power in these switching states due to short circuit. The eight vectors- V0 to V7 are called basic space vectors. The required voltage reference vector V_{ref} can be obtained by applying the same transformation to desired output voltage in the dq plane. [5]

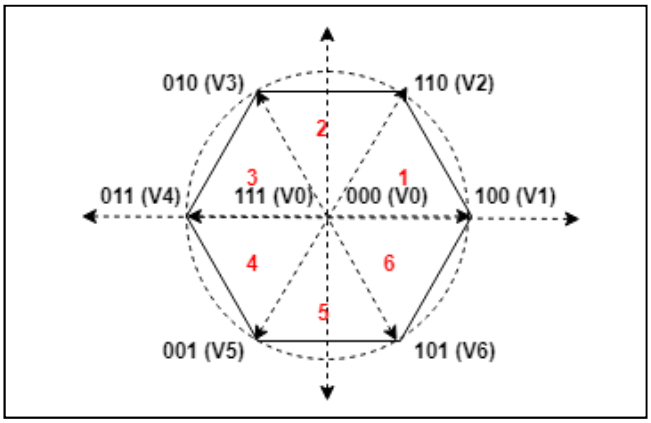

Fig. 2. Possible switching sequence for the VSI

Main function of SVPWM is to estimate voltage reference (V_{ref}) vector with the help of inverters eight switching pattern and this approximation is done by generating output voltage of inverter in small sampling period which is equivalent to V_{ref} in the same period. This V_{ref} voltage vector has discrete rotation in complex plane between sectors portioned at 60° hence forms hexagon trajectory. Decomposition of this vector on real and imaginary axis indicates that it coincides with the generating switching vector. Switching time at any sector by using V_{ref} as a combination of adjacent vectors can be determined by using Fig. 4 as:

$$T_1 = \frac{\sqrt{3}*T*|\overrightarrow{V_{ref}}|}{V_{dc}} sin(\frac{n\pi}{3} - \alpha), \quad (2)$$

$$T_2 = \frac{\sqrt{3}*T*|\overrightarrow{V_{ref}}|}{V_{dc}} sin(\alpha - \frac{(n-1)\pi}{3}), \quad (3)$$

$$T_0 = T - T_1 - T_2. \quad (4)$$

where T is the time period and n denotes number of sector ranging from 1 to 6. Also, α should lie between 0° and 60°. [5]

The switching time for the different sectors using (2), (3) and (4) for the VSI can be summarized as in Table I.

TABLE I. SWITCHING TIMES FOR VSI

Sector	Upper Switches (S_1, S_3, S_5)	Lower Switches (S_4, S_6, S_2)
1	$S_1=T_1+T_2+T_0/2$ $S_3=T_2+T_0/2$ $S_5=T_0/2$	$S_4= T_0/2$ $S_6= T_1+T_0/2$ $S_2= T_1+T_2+T_0/2$
2	$S_1=T_1+T_0/2$ $S_3= T_1+T_2+T_0/2$ $S_5= T_0/2$	$S_4= T_2+T_0/2$ $S_6= T_0/2$ $S_2= T_1+T_2+T_0/2$
3	$S_1= T_0/2$ $S_3= T_1+T_2+T_0/2$ $S_5= T_2+T_0/2$	$S_4= T_1+T_2+T_0/2$ $S_6= T_0/2$ $S_2= T_1+T_0/2$
4	$S_1= T_0/2$ $S_3= T_1+T_0/2$ $S_5= T_1+T_2+T_0/2$	$S_4= T_1+T_2+T_0/2$ $S_6= T_2+T_0/2$ $S_2= T_0/2$
5	$S_1= T_2+T_0/2$ $S_3= T_0/2$ $S_5= T_1+T_2+T_0/2$	$S_4= T_1+T_0/2$ $S_6= T_1+T_2+T_0/2$ $S_2= T_0/2$
6	$S_1= T_1+T_2+T_0/2$ $S_3= T_0/2$ $S_5= T_1+T_0/2$	$S_4= T_0/2$ $S_6= T_1+T_2+T_0/2$ $S_2= T_2+T_0/2$

The switching times as per Table I have been used in the MATLAB Simulink simulation for the Space Vector Pulse Width Modulation for VSI. Fig. 3, Fig. 4, Fig. 5 and Fig. 6 represent the implementation of this technique using MATLAB Simulink.

B. *Implementation of Sinusoidal PWM*

In SPWM inverter the pole-voltage pulse widths for a time period varies in a sinusoidal manner. The sinusoidal pulse width modulation technique revolves around comparison of a triangular carrier signal having high frequency with a sinusoidal modulating signal which gives the fundamental frequency component of the output current and voltage waveform. The maximum value of the modulating signal should not be more than the maximum value of the carrier signal for linear operation. The lower and upper switches of the VSI are controlled using this comparator output. Fig. 7, Fig. 8, Fig. 9 and Fig. 10 represent the implementation of this technique using MATLAB Simulink.

C. *Implementation of Multiple PWM*

In MPWM inverter the pole-voltage pulse widths for a time period varies in a square wave manner. The multiple pulse width modulation technique revolves around comparison of a triangular carrier signal having high frequency with a square modulating signal which gives the fundamental frequency component of the output current and voltage waveform. The maximum value of the modulating signal should not be more than the maximum value of the carrier signal for linear operation. The lower and upper switches of the VSI are controlled using this comparator output. Fig. 11, Fig. 12, Fig. 13 and Fig. 14 represent the implementation of this technique using MATLAB Simulink.

D. *Implementation of V/f control of IM using SVPWM*

For the speed control of IM, though there is no best or effective way to control the speeds, the V/f control is still the most popular method. Since,

$$V = \sqrt{2}\pi f \emptyset_m N \quad (5)$$

$$B_m \propto V/f \quad (6)$$

We operate at the knee-point of the B-H curve, we do not want to vary the maximum magnetic field density (B_m). Hence, voltage and frequency are varied in such a manner that the V/f ratio is always constant. Since the maximum torque (τ_m)

$$\tau_m \propto (V/f)^2 \quad (7)$$

Hence, in V/f control, τ_m remains same and thus the power increases linearly with the rotor speed. Here, the V/f ratio is taken to be 8. This has been plotted for various induction motor drives having different power ratings using SVPWM and unity modulation factor. [9] Fig. 15 represents the implementation of this technique using MATLAB Simulink.

IV. SIMULATION RESULTS

The paper discusses about the software implementation of various PWM techniques namely SVPWM, SPWM and MPWM through MATLAB Simulink. The ultimate objective of either of these techniques is to obtain alternating output voltage with minimum harmonics and maximum fundamental component. By analyzing and comparing their THD Analysis with varying Modulation Indices, the observations can be summarized as follows:

A. *SVPWM*

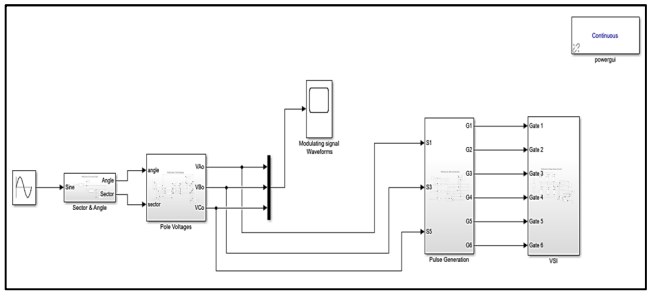

Fig. 3. MATLAB Simulink model for SVPWM with parallel RL load of 50Ω and 5 mH

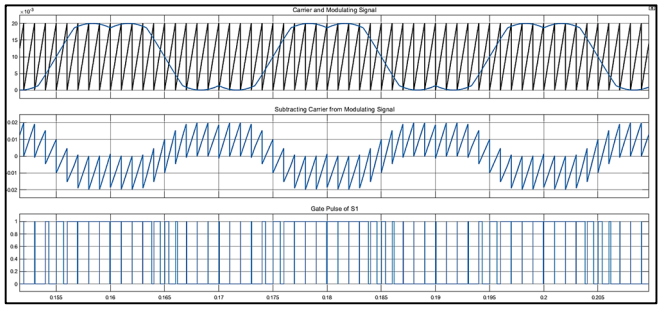

Fig. 4. Waveforms for carrier signal, modulating signal, comparator output and gate pulse for switch S1 at $M_A = 1$

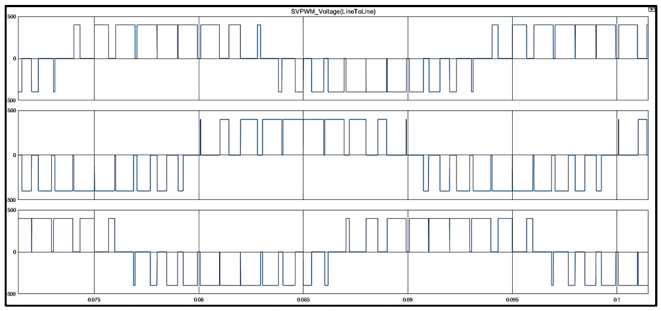

Fig. 5. Waveforms for output line voltages for SVPWM

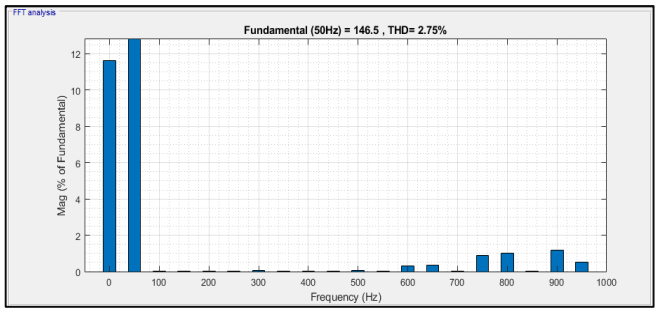

Fig. 6. THD for output current of VSI for SVPWM

B. *SPWM*

V. OBSERVATIONS

The three PWM techniques namely- MPWM, SPWM and SVPWM were compared for different modulation indices (M_A) ranging from 0 to 6 and the ratio of corresponding value of peak fundamental output line voltage (V_{01}) to constant dc supply voltage (V_{dc}=400V) was noted for all the three techniques. The observations have been summarized in Table II.

TABLE II. COMPARISON OF MPWM, SPWM AND SVPWM

MA	V_{01}/V_{dc}		
	MPWM	SPWM	SVPWM
0	0	0	0
0.4	0.44	0.3475	0.4005
0.6	0.6565	0.50725	0.598
0.8	0.8645	0.67025	0.79575
1.0	1.09575	0.848	1.0005
1.1	1.10625	0.9245	1.048
1.2	1.10625	0.95475	1.05775

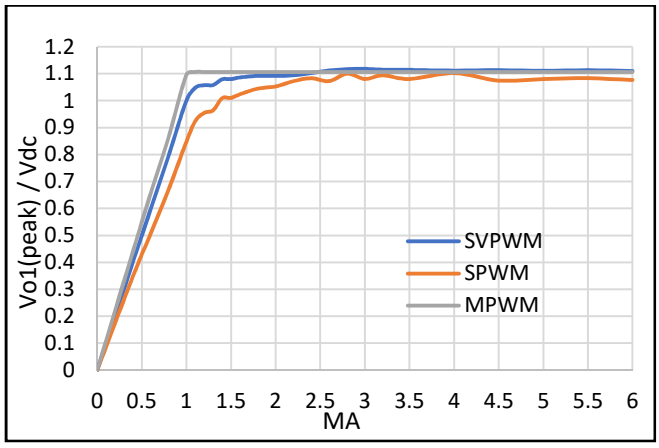

Fig. 16. Plot for V_{01}/V_{dc} Vs M_A for MPWM, SPWM and SVPWM

From Fig. 16 it is observed that the fundamental output voltage for SVPWM is 17.98% higher than that for SPWM at unity modulation index. Also, for a range of modulation index from 0.4 to 1.6, the mean fundamental output voltage for SVPWM is 12.37% higher than that for SPWM.

It is also observed from Fig. 6, Fig. 10 and Fig. 14 that the THD in output current is least for SVPWM (THD=2.75%), followed by that for SPWM (THD=3.51%) and the highest for MPWM (THD=4.76%).

Also, the peak line to line output VSI voltage is highest for MPWM as the pulse widths are almost same but the current produced by MPWM has highest distortion and thus is not preferred for practical use.

SVPWM technique, at unity modulation index and constant load torque of 10 Nm, was then used for achieving the V/f control of IM of different power ratings, the simulation results of which have been summarized in Table III.

TABLE III. COMPARISON OF V/F CONTROL OF DIFFERENT POWER RATING OF IM USING SVPWM

IM WITH POWER RATING OF 4 KW		
SPEED (RPM)	TORQUE (NM)	POWER (W)
1452	10.2	1561
1263	10.6	1409
1075	10.11	1139
886.8	9.95	923.1
698.9	9.94	727.3
513.2	9.83	527.9
337	10.8	387.2
77.55	10.19	82.74
IM WITH POWER RATING OF 7.5 KW		
SPEED (RPM)	**TORQUE (NM)**	**POWER (W)**
1477	9.69	1500
1289	10.08	1361
1101	9.71	1119
913	9.69	927
724.1	9.63	729.7
505.1	11.89	628.7
419.3	19.07	837.4
125.2	4.58	60.1

IM WITH POWER RATING OF 15 KW		
SPEED (RPM)	TORQUE (NM)	POWER (W)
1494	9.95	1557
1305	11.17	1527
1118	9.97	1167
929.6	10.21	994
740.6	12.31	954.7
530	53	3300

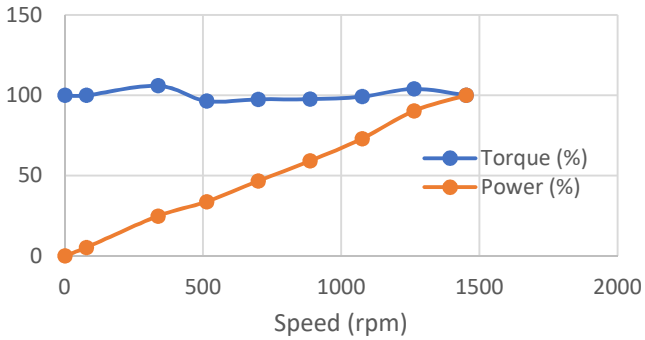

Fig. 17. 4 kW IM characteristics for V/f control

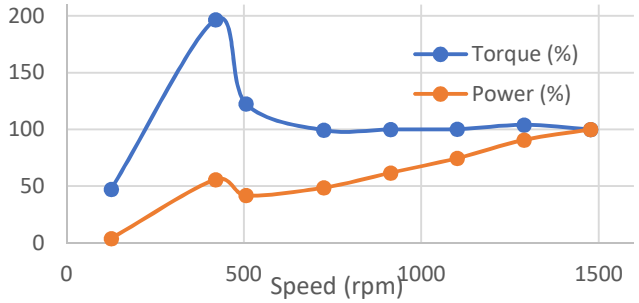

Fig. 18. 7.5 kW IM characteristics for V/f control

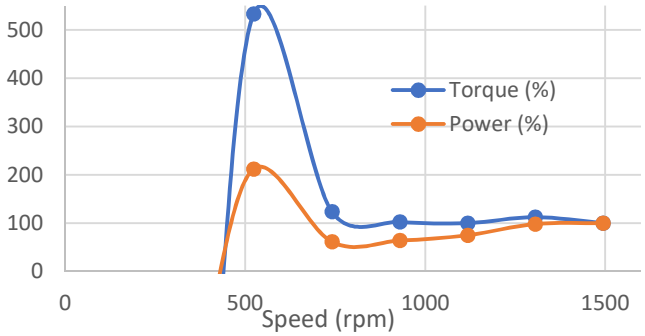

Fig. 19. 15 kW IM characteristics for V/f control

From Fig. 16, we observe that the torque remains almost constant throughout the V/f operation and the power varied linearly with the rotor speed.

From Fig. 17, Fig. 18 and Fig. 19, we observe that in the low frequency region, since the inductance becomes very low, the circuit becomes resistive in nature and hence the impedance does not vary with frequency, so with decreasing voltage and frequency, the current in the machine decreases and hence torque decreases.[12] Therefore, in low frequency region (< 37.5% of the rated frequency), the performance of IM deteriorates. Also, as the machine power rating increases, there is a decrease in the impedance of the machine and hence it becomes constant with respect to frequency even in the relatively higher frequency range (in the low frequency region) and accordingly we observe a greater dip in the torque with the increase in the power rating of the IM.

VI. CONCLUSION

Here, SVPWM Technique was used to reduce harmonics in output current of the VSI. Also, it was compared with other PWM techniques, namely – SPWM and MPWM, it can be concluded that SVPWM provides the least THD in the output line current when compared to SPWM and MPWM and MPWM provides the highest THD. Also, the maximum line output VSI voltage is higher for SVPWM as compared to SPWM. Although the maximum line output VSI voltage is high for MPWM, it is not preferred due to presence of high harmonic distortions in current. For MPWM, V_{01} saturates for M_A greater than unity, i.e. over modulation region. However, in case of SPWM and SVPWM, V_{01} can be increased even in the over modulation region, though non-linearly, and does not saturate as in MPWM. Thus, based on above conclusions, SVPWM is a more sophisticated and effective technique for inverter operation and hence is used for the V/f control.

We also conclude that V/f control should not be preferred in the lower frequency range and the performance of IM deteriorates in this region.

Further, in future, the concept of Random PWM (RPWM) implementing random switching frequency method can be employed along with the above implementation of the pulse width modulation techniques for achieving a harmonic content spread over the entire harmonic spectrum and not particularly on one harmonic frequency.

ACKNOWLEDGMENT

We would like to thank Prof J.N. Rai, for his constant motivation and guidance during the project. Without his timely help and support, the completion of this paper wouldn't have been possible. We would also like to thank the publisher of the research papers from where we have taken reference.

***Abstract* — It is merely impossible to know the history of Route Planning Algorithms. It can be imagined that from the very primitive era, animals have dedicated their time to find the shortest path to reach their food. This kind of algorithms is one of the most practised ones and forms the basis for solving many real-world problems. But like most of the graph algorithms, they were proposed in the mid-twentieth century. The applications of these algorithms are many, the most important one is its usage in Routing and Navigation based applications like Google Maps, Ola and, Uber. Here, the road network is resolved as a large graph with nodes as coordinates holding some meaning and edges as ways/paths connecting adjacent coordinates, then route planning algorithms are applied for finding the shortest path between two nodes in the graph created. A noteworthy application is in Routing data packets on the internet; the Open Shortest Path First (OSPF) routing protocol is based on the Dijkstra algorithm and is used in autonomous systems like Local Area Network (LAN). It is also being used in routing especially long-distance calls. Another interesting usage can be seen in the Currency Arbitrage strategy where currencies are bought and sold instantaneously from one market to another to make a profit from the exchange rate divergences. Due to applications in so many important fields, these algorithms are studied rigorously yet to come up with a more optimized version targeting certain scenarios or in general. It is in this understanding that this paper delves into the study and implementation of various route planning algorithms and portrays their performances based on efficiency, in comparison with each other when running on a graph obtained from real road network data. This paper will also deduce a set of parameters that affects the traffic flow and the evaluation metrics that should be considered when applying those algorithms.**

Keywords — Graph Theory, Route Planning Algorithms, Shortest Path, Dijkstra, A* search, Landmark Heuristic, Contraction Hierarchy, Transit Node Routing, Fitness Function, Genetic Algorithm.

I. INTRODUCTION

One of the first papers on the shortest path algorithms was given by Dantzig in the year 1958 to sort the list of edges based on the distance from the source node and to ignore the arcs of the list involving nodes which have been reached earlier. The complexity of the proposed algorithm was $O(n^2 logn)$, where n is the number of nodes in the graph. In the following year, Dijkstra proposed an improved method where a list of size n was maintained and for each vertex, the best path found so far was stored. The complexity was $O(n^2)$ and later it was realized that an efficient data structure like heaps can even reduce the running time to $O(m + nlogn)$. In 1964, Neel Nilson invented a heuristic-based approach to speed up the Dijkstra algorithm and named it A1; then in 1968 with the help of Bertram Raphael, Peter E. Hart gave the concept of consistent heuristic and named versions of the algorithms using it as A* [1]. In the case of road-networks, the size of the graph is huge and the Dijkstra algorithm is not time-efficient for the shortest path search queries due to enlarged search space [10]. Therefore, many improvements to the shortest path algorithm were proposed in 2007-2010 by the professors of KIT, Germany including D. Schultes, P. Sanders, and others. These algorithms include ALT, Contraction Hierarchies, and Transit Node Routing to speed up Dijkstra and are exhaustively being used by many routing based applications. The research is still going on in this field.

Estimating the optimal path to reach from one location to another on roadway networks is one of the most concerning tasks in the conveyance, distribution, and logistics applications. The routing algorithms should be highly scalable to accommodate various distributions amongst road networks that highly depend on the geography and demography of a given place.

This research paper aims to address the widely known algorithms for route planning that is being used on the motorway systems. Based on the implementation results of the route planning algorithms, a comparison based on the efficiency of these algorithms applied on a graph obtained from a real instance of a road network.

Afterwards, various parameters are inferred that create an impact over deciding the cost of a path. Various Evaluation metrics that should be taken into consideration for estimating the efficacy of a routing algorithm are also mentioned.

II. LITERATURE OVERVIEW

Route planning algorithms

There are several route planning algorithms applied in road networks, these are:

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:58:23 UTC from IEEE Xplore. Restrictions apply.

1) Dijkstra algorithm: This algorithm calculates the shortest paths from a given node (the start node) to all the other nodes in the graph [6]. One of the popular implementations of this algorithm is by maintaining a priority queue where priority is the degree of closeness with the start node. Hence, it comes under the famous Single Source Shortest Pathfinding algorithms. The nodes are visited in a sequence based on proximity with the start node and the algorithm terminates when either the target node is popped from the queue (i.e. settled) or all the nodes are settled depending upon the terminating condition being used. The correctness of the algorithm fails for negative edge weights and negative edge cycles. Bellman-Ford algorithm is a dynamic programming-based approach that works for such graphs and overcomes the limitation of the Dijkstra algorithm [3].

2) A* algorithm: A* is a successor of the Dijkstra algorithm and uses a heuristic function that approximates the distance to the target node which helps in leaning towards the target with an idea of the direction to expand the nodes rather than expanding them based on the closeness with source node. To perform an efficiently heuristic function is expected to be consistent or monotone and hence admissible [4]. A heuristic function is *consistent* if, for every node *n* and its neighbor *s*, its value for *n* is never greater than the sum of step cost of getting to *s* and the heuristic value for *s*. Hence:

$$h(n) \leq h(s) + dist(n, s) \quad (1)$$

3) A*, Landmarks, and Triangle Inequality algorithm: ALT (A* Landmark Technique) is a preprocessing-based, goal-directed and more efficient technique than the Dijkstra algorithm. The heuristic used by this algorithm uses one basic principle called reverse triangle inequality which states that the length of a side of any triangle is always greater than the difference in the length of the other two sides. Using this theorem, a set of landmarks are chosen and then the heuristic value for a particular node is taken as the maximum difference in the pre-computed shortest path-length of any landmark from that particular node and the target node [4]. The pre-computation for this heuristic to become a good lower bound is massive and depends upon the number of landmarks chosen as for each landmark the 'to' and 'from' distance for every other node in the graph needs to be stored or at least one of the two if the graph is undirected. It further depends on how isolated these landmarks are from each other; creating a set of the landmarks situated at the maximum distances from each other is an N-P Hard problem [7] as finding the maximum length path in a directed cyclic graph is an N-P Hard problem too.

4) Contraction Hierarchy: Here a contraction graph is created from the original graph where every node has a level assigned based on the sequence of contraction and this sequence is based on ordering the nodes by some measure of importance [8]. Contraction of a node deals with adding shortcuts if the shortest path between its neighbors goes via it; this step makes it the most efficient route planning technique but increases the pre-computation time. During the query, an upward graph is formed starting from the source with edges directed from the lower level to a higher level, and a backward graph from the target is also formed in the same manner. Dijkstra algorithm from the source and the target is applied to the upward and downward graph respectively.

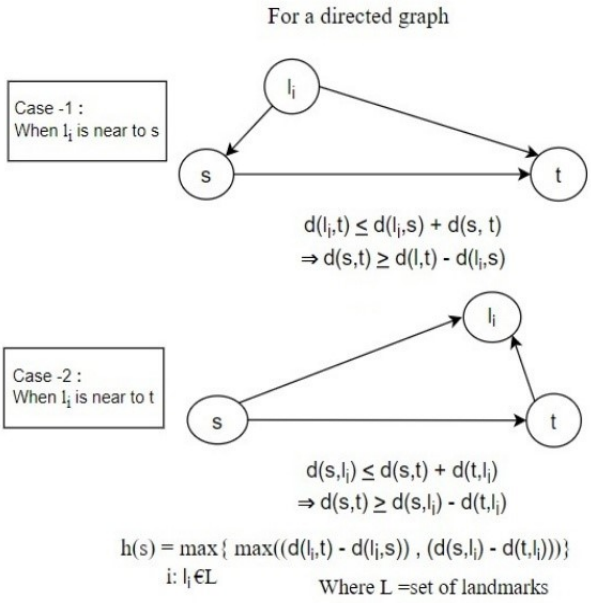

Fig. 1: Calculating the Heuristic Value for Node's' using ALT

From the set of common nodes settled in both the graphs '*S*':

$$dist(s, t) = min\{dist(s, v)+dist(v, t): v \in S; s, t \in V\} \quad (2)$$

The basis of this algorithm is the optimal node ordering (achieved using simple heuristics) [8], based on that forward and backward graphs are formed. Unidirectional Dijkstra turns out to be useless for the hierarchical approach.

The above methodology of applying search algorithms from both the source and target nodes comes under Bidirectional Search and is seen to be much efficient when compared to unidirectional search as the number of nodes expanded is significantly lesser.

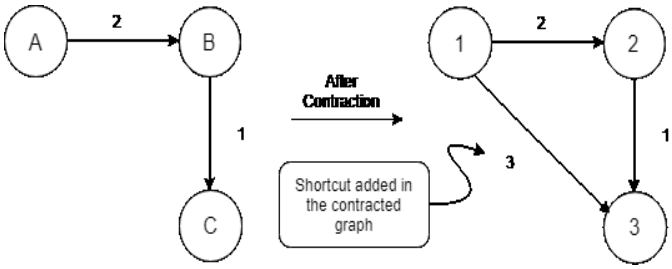

Fig. 2: Creating Contraction Graph (Here, Node Ordering is based on the Sequence of Node Contraction.)

5) Transit Node Routing: Transit Node Routing (TNR) is a technique and not a whole, independent algorithm in itself; for example one of the famous TNR variants uses Contraction Hierarchy pre-computations in its implementation. Its major drawback is the time it spends in

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:58:23 UTC from IEEE Xplore. Restrictions apply.

preprocessing which is significantly larger than even Contraction Hierarchy but this makes it the most efficient algorithm of its type. The underlying observation in TNR is: For multiple long distant routes with common start point and varying destination points, the initial portion of the shortest path route will always be one of the 'few' standard routes [9]. The nodes present at the periphery of this initial portion are called access nodes and a separate list of these nodes is maintained for both the source (say *X*) and the destination (say *Y*) also storing the distance from them respectively. Say $x \in X$ and $y \in Y$ then during query processing, the minimum of *dist(x, source) + dist(x, y) + dist(y, destination)* from every combination of *x* and *y* (total: $|X| + |Y|$) is taken as the shortest path from source to destination.

The most widely known variant of TNR uses Contraction Hierarchy for pre-computation [9]. CH orders the node in such a way that a node occurring in many shortest paths is assigned a higher level in the hierarchy. Hence a set of nodes above a certain threshold level is chosen for selecting the access nodes (called transit nodes). From the source node, a forward search in the upward graph is run and all the transit nodes settled during the run become access nodes. During this Dijkstra run, edges leaving access nodes remain unrelaxed. Similarly, a backward search in the downward graph from the destination node is run to collect its access nodes.

6) Multi-label Algorithms: The above routing algorithms only apply for a scalar number as the edge-weight that is the travel-time but there are also other important criteria that should be taken into consideration while calculating the most optimal path. These factors are discussed in the later section. All the above-mentioned algorithms can be transformed to consider these kinds of criteria but due to the dynamic nature of the road-network, the graphs are also dynamic and the weight also changes with time hence a mean value of these criteria is taken making these algorithms still static in nature.

7) Genetic Algorithm: Genetic algorithm (GA) falls in the range of meta-heuristic inspired by the process of natural selection. It belongs to the larger class of Biologically-inspired algorithms. In this paper, GA Algorithm is primarily used to generate high-quality solutions, enhance and explore the solution to route optimization problems [13].

Working: GA initiates its procedure with a population of candidates (also referred to as a chromosome). Each individual represents that it can be a feasible solution to the problem. Then, each individual is associated with some fitness value according to the fitness function. The fitness function is designed following the solution's quality [15]. The reproduction process generates the next generation of individuals by two distinct processes named 'repair/crossover and 'mutation'.

Need for GA: In maximum real-existence eventualities, the shortest path might not be a great course for the user. In fact, distinct customers may additionally opt for exclusive routes depending on the traffic congestion level, road incidents, and different time various quantities. Therefore, want to explore a multi-objective optimization algorithm that can deal with many distinctive targets simultaneously.

Crossover: It is a process that starts with two fittest individuals (viz. Parents). Also, crossover requires that they should have at least one different gene in both parents and afterward, the traditional method of one point crossover operation is simulated, and finally, any variant of the mutation function is applied on generated offsprings to remove feasible loops and add randomness in the solution [15].

Parent Selection: One of these three specific choice schemes for parent selection:

- Roulette wheel choice
- Rank-primarily based choice
- Match selection (with a tournament size of 2).

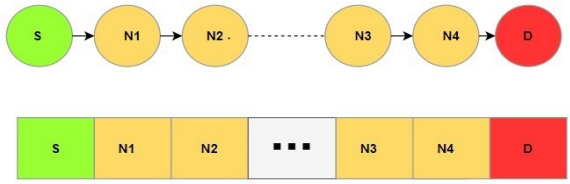

Fig. 3: Representation of a Chromosome

III. Enhancement Techniques for the Route Planning Algorithms

Through this part, the techniques that can be used to enhance the proficiency of the prevailing route planning algorithms is introduced for real and large network of roads based on the information obtained so far. Firstly, discussed the most crucial parameters that must always be considered while designing the algorithms for route planning and then mentioned some other parameters that can be implemented in their designing process to improve their performance on real road networks. After discussing these parameters, found and present some performance evaluation metrics to be used for evaluating the performance of various algorithms used in route planning for real and large road networks.

Now the input parameters are discussed, criteria for determination of the best route and evaluation metrics for route planning algorithms one by one in the next sections.

A. Crucial Parameters for route planning algorithms

Here, the most crucial parameters are discussed that must be always considered as parameters for designing the route planning algorithms. The parameters to be considered are as follows:

- Knowledge about the starting location: The beginning point for travel or the point on the map from where the journey commences.
- Knowledge about the destination location: The point on the map where the journey terminates or the end point for travel. Information regarding the objective for travelling is also useful.
- Features of road network: This information contains the details such as the number of lanes on that particular road, the present traffic scenario of the road, weather

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:58:23 UTC from IEEE Xplore. Restrictions apply.

conditions of the area, information about incidents such as accidents and road blockages etc.

- Vehicle characteristics and other insights: This information contains the details such as vehicle-related conditions including the size and speed of vehicle, the fuel remaining in the fuel tank, any specific condition related to traveller or the path to be chosen, the operating hours of vehicle etc.

Along with the aforementioned parameters, there are some other parameters that can be utilized in the process of designing the route planning algorithms such as the features of vehicle, i.e., its condition and physical specifications and also the information regarding the present traffic and future predictions of traffic on the road network [11]. These mentioned parameters assists in the process of choosing the best route.

For the implementation of routing algorithms on real and large road networks, there is a need to provide the current traffic conditions, the graph of road networks, the traffic prediction data, and the characteristics of vehicle as input parameters. These input parameters are processed in the routing algorithm and continuously updated with respect to the changing traffic conditions and occurrence of specific incidents.

The goal of routing algorithm is to determine the most optimal route to reach the target location (destination) from vehicle's current location (origin). This route is suitably changed in order to prevent such updates from affecting the selected travel path as well as making the route unavailable for variable duration and have to note that the features of vehicle is a very crucial input for route planning as vehicle's weight, its height and its vehicle class (e.g. bus, car, train) are crucial parameters to determine the best route in accordance to the physical capacities of the road networks (like lanes, flyovers, underpasses, type of highway etc.) and the driving regulations of our country.

B. Criteria for determination of the best route for these algorithms

In case needed to determine the best route from the start location to the destination location as per the request of driver, then first deduce the metric or the set of metrics which must be utilized in order to compare the different routes from a set of routes for that specific vehicle [11]. In order to measure and identify an optimal route by the objective function, the objective function to be composed of a single metric or a composed of a set of metrics applicable to any of the aforementioned algorithms is needed. In some studies, researchers have applied a wide variety of parameters in their routing algorithms. Now in the further section, presented the most valuable metrics that the route planning algorithms may utilize to find out the requested route as per our need.

- Time taken for travel: According to this metric, tend to look for the quickest route for journey instead of the smallest one (in terms of distance) among all the available routes. The quickest route implies a solution path that converges to the destination within the shortest time. Due to the dynamic nature of road and its associated parameters, the quickest route might not be the same as the smallest route. Furthermore, needed to update the quickest path continuously as the vehicle moves towards its destination and that too in accordance with the traffic conditions on road networks which change rapidly.

- Travel distance: In a road network, the values of the length of all roads have a specific value. When talk about finding the shortest path, it means interested in a path for a given vehicle through which it travels with the least distance from the start point to the destination point on its journey.

- Cost of travel: The cost of travel refers to all the expenses that have been incurred during the journey. It includes the cost of fuel used in addition to the total amount of toll taxes paid by the vehicle's driver on the route. This cost is affected by several factors such as the length of path to cover, the number of halting points on the route, the vehicle-type and the dimension and condition of road chosen for travel. So, to get a cost efficient route, routing algorithms can use this criterion, and provide a low cost route for reaching the destination location to the driver.

- Traffic conditions: The traffic conditions of the road network refer to the traffic congestion levels. If the traffic congestion on one route is less as compared to the other route, the vehicle must take the path having less traffic congestion, if the travel time for this path is also less, so as to reach the destination location in minimal time.

- Ease of driving: In a road network, the driver tends to choose a route which is smooth, safe and comfortable. This metric can be thought of a metric solely based on the driver's preference and several other parameters such as the dimensions of road, the number of traffic signals on road, the number of lanes and turns on road etc.

- Integration of two or more metrics: As per this criterion, two or more of the aforementioned criteria can be integrated with one another to act as a single metric to handle the preferences of a specific driver.

C. Evaluation metrics for route planning algorithms

Evaluation metrics are the certain parameters that are used for evaluating the performance of a particular algorithm. These metrics assist in differentiating between the different routing algorithms based on their performance measure. The four significant evaluation metrics that can be used for evaluating route planning algorithms are computational complexity, execution time, quality of the solution, and scalability.

- Computational complexity: Computational complexity refers to the computational performance of a particular route planning algorithms and the resources it requires for its execution. For instance, an algorithm may not be the best routing algorithm if it finds the most optimal route with a very high complexity, even if has comparatively low journey time, especially when the route needs to be continuously updated during the vehicle's journey.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:58:23 UTC from IEEE Xplore. Restrictions apply.

- Execution time: The execution time of these algorithms also serves as an evaluation criteria. The algorithms having overall less execution time for a variety of route is considered to be better than the others.
- Quality of the solution: In case to find multiple best routes, need to use a metric to find the best out of all the available routes. For this purpose, use this particular metric to compare the different solutions obtained by using different algorithms based on various parameters mentioned earlier, and then determining which of these algorithms provides the most optimal route by giving a value closest to the solution.
- Scalability: Scalability for a routing algorithm refers to the change in the performance and efficiency of a routing algorithm when the real network of roads is scaled up or down in terms of size. Hence, an algorithm which is efficient for a particular area might be inefficient or inapplicable when the area under consideration is increased in size.

IV. Experimental Results And Analysis

To fulfil the aim i.e. to present a comparison of various route planning algorithms, the above-stated algorithms namely-: Dijkstra, ALT, Contraction-Hierarchy, and Transit Node Routing algorithms (plus bidirectional variants) were implemented in Java on Eclipse IDE. On a simple weighted directed (cyclic) graph with no self-loop having a total of 422047 nodes and 1011274 edges obtained from parsing the OSM road-network data for the union territory of India 'Delhi', following line graphs (Execution Time (in ms) vs. Query number) were obtained when aforementioned algorithms were run for 420 shortest path queries between randomly chosen source and target nodes:

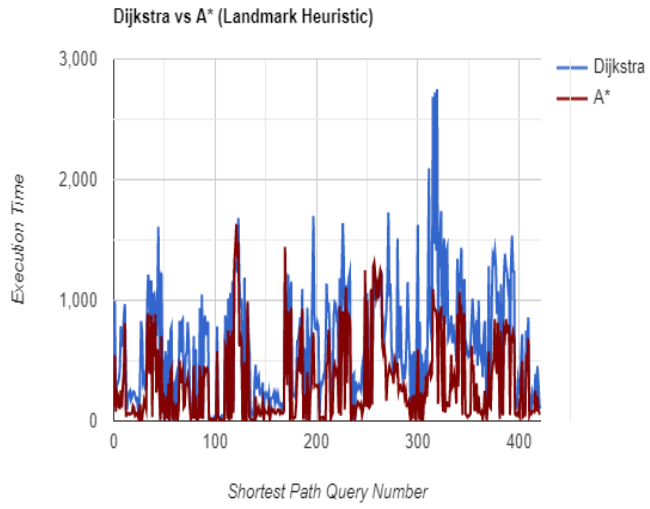

Fig. 4: A Comparison between Dijkstra and ALT based on Execution Time.

- Apparently, for most of the queries, ALT algorithm proved to be more efficient than the Dijkstra algorithm.
- On testing against various values of landmark-set size, the threshold for the given graph is 8 as beyond this value, no significant improvement in efficiency of the ALT algorithm was observed.

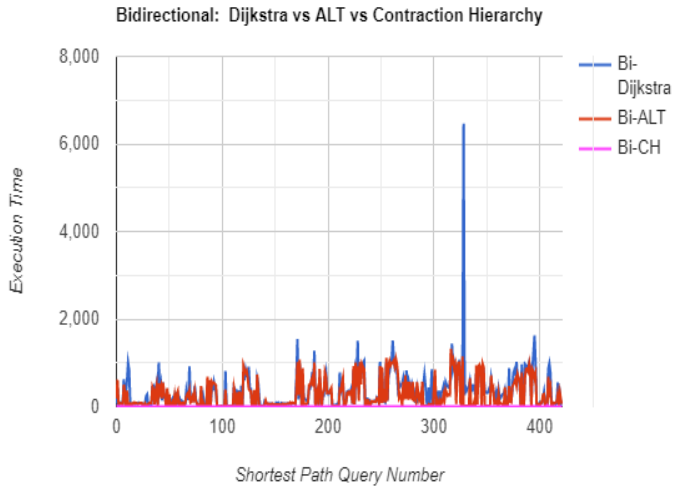

Fig. 5: A Comparison between Bidirectional Dijkstra, Bidirectional ALT and Bidirectional Contraction Hierarchy.

- Here, the blue peaks in the graph depict that the Bidirectional Dijkstra algorithm is least efficient amongst the three.
- As expected, Contraction Hierarchy took negligible time to calculate the optimal path for any of the queries.
- The difference between the execution time of Bidirectional Dijkstra and ALT was thin in many queries due to smaller path-length.

Fig. 5 shows the bidirectional variant of the three algorithms namely Dijkstra, ALT, and CH. When Bidirectional Dijkstra and ALT were run on the same 420 queries, results were difficult to interpret. Sometimes ALT performed better and other times Bidirectional Dijkstra had upper hand. But in the below graph (Fig. 6), the efficiency of Bidirectional Dijkstra emerged clearly for relatively longer path lengths where ALT took much longer times to process those queries.

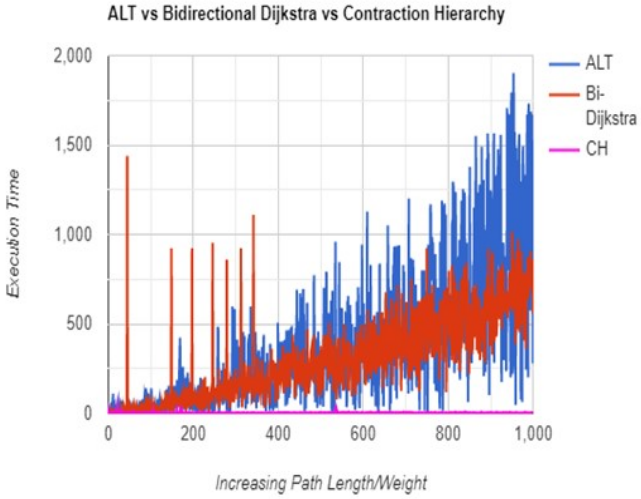

Fig. 6: A Comparison between Bidirectional Dijkstra, ALT and CH based on Increasing Path Length.

- The longest path length was estimated to be around 1300 km (by running on 10 different queries).

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:58:23 UTC from IEEE Xplore. Restrictions apply.

- Bidirectional Dijkstra proved to be better than ALT when the path length was relatively larger with respect to the longest path length found in the graph [2] while CH outperforms all of them.

The below Figs. (Fig. 7 and 8) were obtained after running Transit Node Routing and Contraction Hierarchy on the simple directed weighted graph obtained from Andorra.osm file. Due to heavy preprocessing required by both the algorithms Andorra.osm was chosen to create a smaller graph. Andorra is a European Country with an area of only 468 km^2. From the bar graphs, it can be clearly seen that the preprocessing and query time are completely opposite of each other for TNR and CH. The time spent during preprocessing is compensated with the improvement seen during the shortest path query processing in the case of Transit Node Routing.

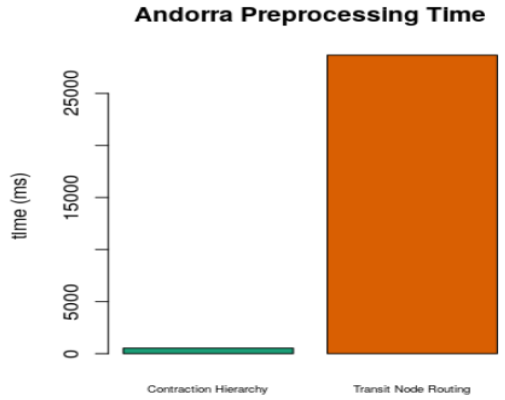

Fig. 7: Bar graph for comparing pre-computation time between CH (in green) and TNR (in orange)

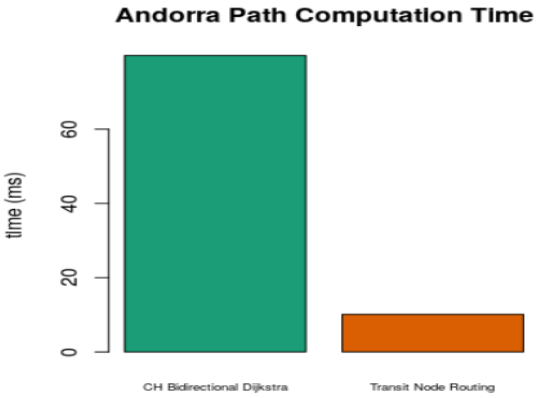

Fig. 8: Bar graph for comparing query execution time between CH (in green) and TNR (in orange)

V. Conclusion

It can be concluded that in order to create a more efficient route planning algorithm a compromise has to be made by doing more pre-processing. Transit Node Routing is the fastest route planning technique with approximately constant query processing time but with the highest pre-computation time. Contraction Hierarchy is one of the simplest ways to calculate the shortest path distance between two nodes in a graph and A* algorithms can also be fast with a good admissible heuristics while finding the shortest path is not always effective in real-time scenarios of the motorway systems as there are several parameters, the most important being the traffic that also contribute majorly in determining the optimal path.

***Abstract*— The paper makes a comparative study of the two Static VAR Compensation (SVC) techniques - Thyristor Switched Capacitor (TSC) and Thyristor Switched Reactor (TSR). These techniques are defined, examined and compared. The major constituent of the power flow should be active power and a sufficient and minimal amount of reactive power should be allowed to flow in the transmission line. For power system stability and reliability, there arises a need to compensate the reactive power flow. This Reactive Power Compensation has been done on a medium transmission line, which was modelled by scaling down to practically achievable parameters in a laboratory setup, for different load values. Thus, the paper also enables appropriate and relevant selection of the FACTS Controller based on the type and rating of load and also provides scope for implementation in the laboratory.**

Keywords—flexible AC transmission system, static VAR compensation, modelling of transmission line, thyristor switched reactor, thyristor switched capacitor

I. INTRODUCTION

FACTS is a system made up of power electronic components and power system components to improve the stability and controllability of the power transmission line system and improve its power transferring capability. The introduction of the power electronic devices such as the thyristor created new avenues for the invention of devices such as FACTS controllers. In short, the FACT system is utilised to improve the controlling capability of the power system transmission network by using power electronic devices and by introducing capacitive or inductive power in the power system.

In conventional AC power transmission networks, the capability of transferring AC power is restricted due to the effect of several factors such as voltage limit, short circuit current limit, transient stability limit, thermal limits etc. These factors provide the maximum limit for the electrical power that can be effectively transferred via the transmission lines without making any harm to the transmission lines and the electrical equipment involved. This is done typically by bringing about modifications in the power transmission system structure. Although, this is not an easy task in the modern power system. Thus, alternative method of getting highest power transmission capacity without any modifications in the power system structure is preferred. With the use of inconstant impedance electrical components such as inductors and capacitors, the entire energy or power is not able to reach the load from the source. Instead, a part of this is stored in such devices in the form of reactive power and reaches back to the source. This enables us to meet the reactive power demand of the load locally at the receiving end itself, and thus, the substantial quantity of power transmitted to the load or the active power is always lower than the apparent power. This also helps in maintaining the receiving end voltages at desirable values and increases the reliability of the power system. For optimal power transmission, the real power should always be equal to the total power or the power factor should be unity. This is where the role of reactive power compensation comes in achieving FACTS. [3]

II. STATIC VAR COMPENSATION

SVC is considered as the one of the earliest generations of FACTS controllers. The compensator is made up of a rapid thyristor regulating a shunt capacitive bank and an inductor to impart compensation in shunt. They are made up of shunt associated inconstant impedance components such as capacitor or inductor whose output can be modified via thyristor switches, to incorporate these inductive or capacitive reactance into the power line. They may also be located in the centre of the transmission line to enhance the maximal power transmission capacity and at the terminal of the transmission line to make up for the fluctuations arising out of different loading. The two types of SVCs are-

A. TSR

It is basically made up of a inductor which is shunt connected and the impedance of which is controlled using a Thyristor switch in a stepwise manner. TSR comprises of a reactor in series with bidirectional thyristor switches. This method is used to adjust the received reactive power by the load in a system with varying conditions. The difference in the sending and receiving reactive power leads to the difference in sending and receiving end voltages, TSR helps to reduce the difference between these two voltages and improves the voltage regulation of a power system. The inductor absorbs

the excess lagging VARs present in a capacitive system and maintains a balance of the reactive power, thus equalizing voltages at both the ends of the transmission line. [4]

B. TSC

It is basically made up of a capacitor which is shunt connected and the impedance of which is controlled using a Thyristor switch in a stepwise manner. TSC comprises of a capacitor in series with bidirectional thyristor switches. This method is used to adjust the received reactive power by the load in a system with varying conditions. The difference in the sending and receiving reactive power leads to the difference in sending and receiving end voltages, TSC helps to reduce the difference between these two voltages and improves the voltage regulation of a power system. The capacitor present in TSC provides the excess lagging VARs present in an inductive system and maintains a balance of the reactive power, thus equalizing voltages at both the ends of the transmission line. [5]

III. METHODOLOGY

A. Modelling of Transmission Line [1]

A Π-model of transposed medium transmission line with length 200 km, voltage level of 220 kV and the rating of 500 MVA is chosen for the analysis in order to inculcate the effect of both TSC and TSR and to help in their comparison. The transmission line model used is shown in Fig. 1 and Fig. 2. [8]

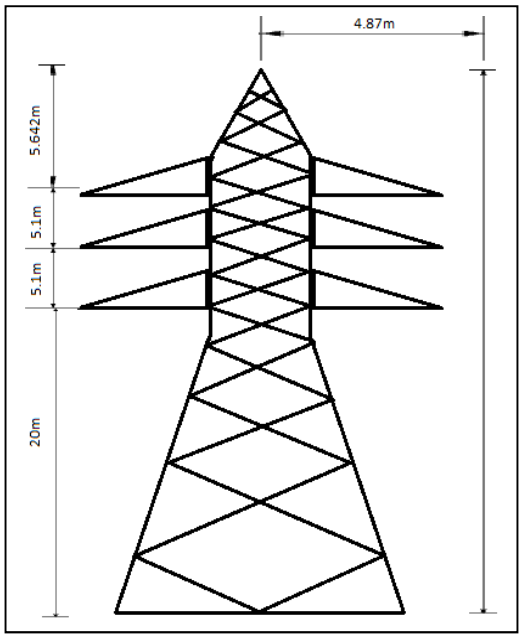

Fig. 1. Transmission Line Tower Design

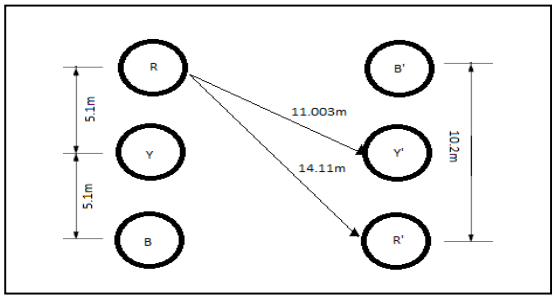

Fig. 2. Transposed Model for Transmission Line

Calculating Geometric Mean Distance (GMD), [7]

$D_{m1} = D_{m3} = [(5.1)(10.2)(9.75)](11.003)]^{1/4}$ m

$D_{m2} = [(11.003)(11.003)(5.1)(5.1)]^{1/4}$ m

Thus, $GMD = [D_{m1}D_{m2}D_{m3}]^{1/3} = 8.24$ m (1)

where D_{m1}, D_{m2} and D_{m3} are the mutual geometric mean distances for the three phases.

Calculating Geometric Mean Radius (GMR), [7]

$D_{s1} = D_{s3} = [(14.11)(0.7788 \times 7.5 \times 10^{-3})]^{1/2}$ m

$D_{s2} = [(9.75)(0.7788 \times 7.5 \times 10^{-3})]^{1/2}$ m

Thus, $GMR = [D_{s1}D_{s2}D_{s3}]^{1/3} = 0.27$ m (2)

where D_{s1}, D_{s2} and D_{s3} are the self-geometric mean distances for the three phases.

Inductance per phase of transmission line from (1) and (2),

$L_{ph} = \frac{\mu}{2\pi}\ln(\frac{GMD}{GMR})$ H/m = 0.683mH/km [7]

Capacitance per phase of transmission line from (1) and (2),

$C_{ph} = \frac{2\pi\varepsilon}{\ln(\frac{GMD}{GMR})}$ F/m = 16.26 nF/km [7]

B. Transmission Line Ratings

Length, L = 200 km
Voltage, V = 220 kV
Frequency, f = 50 Hz
Power, S = 500 MVA
L_{ph} = 0.683 mH/km
C_{ph} = 16.26 nF/km

C. Per Unit Calculations for Transmission Line Parameters

Current in line, $I = \frac{S}{V} = 2.2727$ kA

Base impedance, $Z = \frac{V}{I} = 96.8\ \Omega$

Total inductance for 200 km,

L = (0.683 x 200) mH = 136.6 mH

Total capacitance for 200 km,

C = (16.26 x 200) nF = 3.252 µF

$X_L = \omega L = 2\pi fL = 42.91415\ \Omega$

$X_C = \frac{1}{\omega C} = 978.81268\ \Omega$

X_L (p.u.) $= \frac{XL}{Z} = 0.44332$ p.u.

X_C (p.u.) $= \frac{Xc}{Z} = 10.1117$ p.u.

Y_C (p.u.) = 0.098895 p.u.

D. Scaling down Transmission Line Parameters for 5kVA, 220V model

Current in line, $I' = \frac{S\prime}{V\prime} = 2.2727$ kA

Base impedance, $Z' = \frac{V\prime}{I\prime} = 9.68\ \Omega$

X_L (actual) = X_L (p.u.) x Z' = 4.2913 Ω

L (actual) $= \frac{XL}{\omega} = 13.66$ mH

X_C (actual) = X_C (p.u.) x Z' = 97.88125 Ω

C (actual) = ω X_C = 32.52 µF

E. ABCD Parameters of Transmission Line [7]

$$\begin{bmatrix} A & B \\ C & D \end{bmatrix} = \begin{bmatrix} \frac{YZ}{2}+1 & Z \\ Y\left(\frac{YZ}{4}+1\right) & \frac{YZ}{2}+1 \end{bmatrix}$$

$$= \begin{bmatrix} 1.02192 & j0.44332 \\ j0.099978 & 1.02192 \end{bmatrix}; \text{A} = 0^0, \text{B} = 90^0$$

F. Load Values

In order to achieve a complete and effective comparative analysis, both the leading and lagging loads are considered having a fixed power rating, i.e. 200 W, which is practically feasible to implement, for various power factor values.

TABLE I. LOAD VALUES FOR LAGGING LOADS

S.No.	Load Values	R (in Ω)	L (in H)
1.	0.1 pf lag, 200 W	2.42	0.0766
2.	0.2 pf lag, 200 W	9.68	0.1509
3.	0.3 pf lag, 200 W	21.78	0.2204
4.	0.4 pf lag, 200 W	38.72	0.2824
5.	0.5 pf lag, 200 W	60.5	0.3355
6.	0.6 pf lag, 200 W	87.11	0.3697

TABLE II. LOAD VALUES FOR LEADING LOADS

S.No.	Load Values	R (in Ω)	C (in µF)
1.	0.1 pf lead, 200 W	2.42	132.195
2.	0.2 pf lead, 200 W	9.68	67.123
3.	0.3 pf lead, 200 W	21.78	45.9613
.	0.4 pf lead, 200 W	38.72	35.8785
5.	0.5 pf lead, 200W	60.5	30.376
6.	0.6 pf lead, 200 W	87.11	27.4028

G. Equations Involved [7]

The real and reactive power at receiving end of the transmission line can be given as:

$$\text{P}_\text{R} = \left|\frac{VsVr}{B}\right| \cos(\beta - \delta) - \left|\frac{AVr^2}{B}\right| \cos(\beta - \alpha) \quad (1)$$

$$\text{Q}_\text{R} = \left|\frac{VsVr}{B}\right| \sin(\beta - \delta) - \left|\frac{AVr^2}{B}\right| \sin(\beta - \alpha) \quad (2)$$

For the transmission line under analysis, $\beta = 90^0$, $\alpha = 0^0$, $V_R = 1$ and $V_S = 1$, and P_R can be calculated from the load values used. Thus, δ can be calculated from (1). This value can be substituted in (2) to find Q_R.

Also, lagging VARs requirement of the transmission line with load is $|Q_R|$ and

$$Q_{cll} = - Q_R$$

Reactive power of load,

$$|Q_{load}| = P_R \tan \varphi$$

where cos φ is the power factor of the load.

For lagging loads, there is reactive power requirement and thus, a shunt capacitor is required for providing this reactive power and thus to compensate the reactive power.

Lagging VARs (in p.u.) provided by the shunt capacitor,

$$Q_c = |Q_{load}| - |Q_{cll}|$$

Thus, value of required capacitor,

$$\text{C}_\text{reqd} = \frac{|Qc| \times 5000}{\omega V^2} \text{ F} \quad (3)$$

For leading loads, there is a reactive power supply and thus these surplus lag VARs have to be absorbed by the shunt reactor and thus to compensate the reactive power.

Lagging VARs (in p.u.) provided by the shunt reactor,

$$Q_L = |Q_{load}| + |Q_{cll}|$$

Thus, value of required reactor,

$$\text{L}_\text{reqd} = \frac{\omega |Q_L| \times 5000}{V^2} \text{ H} \quad (4)$$

IV. SIMULATIONS

The model was simulated for all lagging, leading and no load values as in Table I and Table II. In the simulations, a triac has been used instead of back to back thyristor, which gives similar effect as two back to back thyristor with common gate to provide the bidirectional flow of power. Fig. 4, Fig. 5 and Fig. 6 show the snapshot of the simulation diagram for lagging load, no lead and leading load respectively.

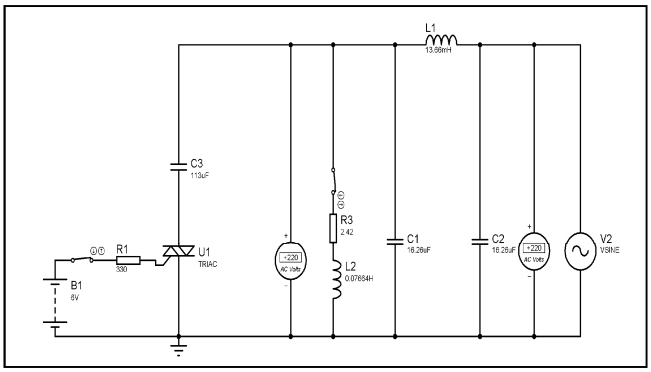

Fig. 4. Simulation snapshot for 0.1 pf lag, 200 W load using TSC

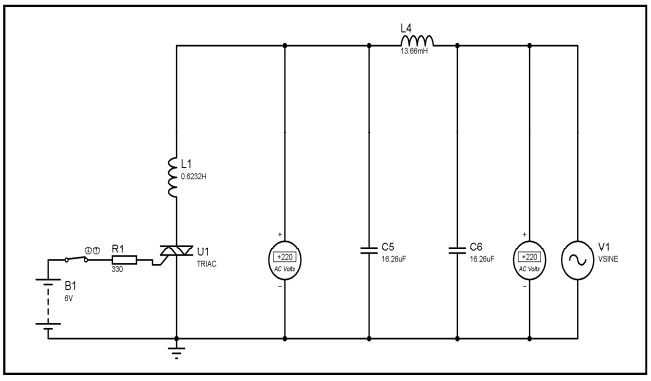

Fig. 5. Simulation snapshot for no load using TSR

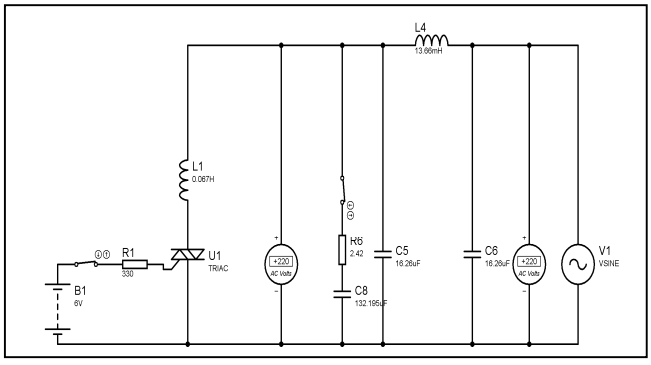

Fig. 6. Simulation snapshot for 0.1 pf lead, 200 W load using TSR

V. CALCULATIONS

The required $|Q_c|$ and $|Q_L|$ has been calculated for the load values and corresponding C_{reqd} and L_{reqd} has been calculated using (3) and (4) for each of the load values. After obtaining the required values of capacitor and inductor for compensating each of the loads, the voltage before and after compensation is noted through simulation.

TABLE III. CALCULATIONS FOR C_{REQD} FOR LAGGING LOADS

Load	Load Values		$\|Q_C\|$ (p.u.)	C_{reqd} (µF)	Compensation	
					Before	After
	R (Ω)	L (H)			V_R	V_R
0.1 pf lag, 200 W	2.42	0.0766	0.3481	113.0	191	220
0.2 pf lag, 200 W	9.68	0.1509	0.1461	48.062	207	220
0.3 pf lag, 200 W	21.78	0.2204	0.0773	25.449	213	220

VI. OBSERVATIONS

A. Lagging Loads

TABLE VI. OBSERVATIONS FOR LAGGING LOADS

pf	Q_{load} (VARs)	Q_C (VARs)
0.1 lag	1989.97	1740.975
0.2 lag	979.79	730.800
0.3 lag	635.96	386.965
0.4 lag	458.25	209.265
0.5 lag	346.41	97.415
0.6 lag	266.67	17.67

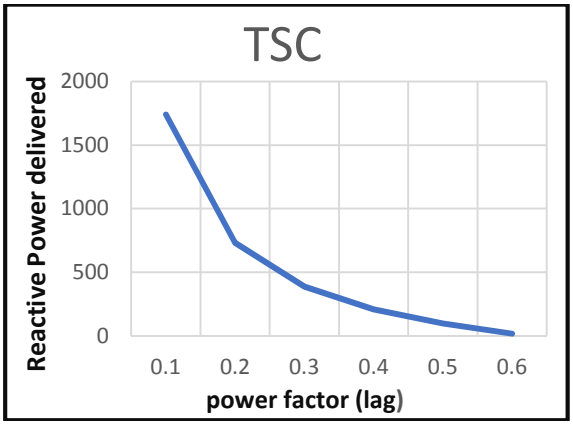

Fig. 7. Reactive Power Delivered Vs Power Factor for lagging loads

From Table VI and Fig. 7, as shown above, it is observed that for a given real power demand (200W), as the power factor of the load is increased from 0.1 to 0.2, the reactive power demand of the load decreases by 1010.17 VARs. Further, as the power factor increases from 0.5 to 0.6, the reactive power demand decreases by 79.74 VARs. Therefore, the requirement of the compensating reactive VARs to be supplied by the TSC decreases as the power factor increases.

As the power factor improved to 0.6 pf lag then the reactive power demand of the lagging load became almost equal to the lagging power supplied by the capacitive transmission line and hence the requirement of the compensation is almost negligible (17.67 VARs), and is depicted by the graph in Fig. 7, tending to zero.

B. No Load

Under no load conditions, it is observed from Table IV, that for proper compensation, an inductor is required. This proves that a medium transmission line, having a length of 200km has a dominating capacitive nature, and due to this capacitance effect, surplus reactive power is injected in the transmission line and is responsible for the increase in the voltage level of receiving end. This is phenomenon of increase in the receiving end voltage due to capacitance effect of the transmission line is known as Ferranti Effect.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:54:43 UTC from IEEE Xplore. Restrictions apply.

C. Leading Loads

TABLE VII. OBSERVATIONS FOR LEADING LOADS

pf	Q_{load} (VARs)	Q_L (VARs)
0.1 lead	1989.97	2238.97
0.2 lead	979.79	1228.75
0.3 lead	635.96	884.995
0.4 lead	458.25	707.252
0.5 lead	346.41	595.405
0.6 lead	266.67	515.66

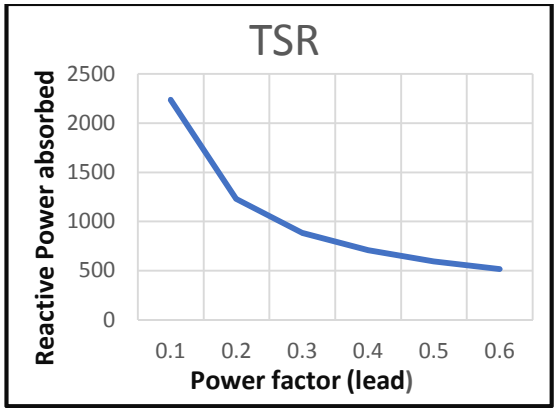

Fig. 8. Reactive Power Absorbed Vs Power Factor for leading loads

From Table VII and Fig. 8 as shown above, it is observed that for a given real power demand (200W), as the power factor of the load is increased from 0.1 to 0.2, the reactive power absorbed decreases by 1010.2 VARs. Further, as the power factor increases from 0.5 to 0.6, the reactive power absorbed decreases by 79.74 VARs. Therefore the requirement of compensating reactive VARs to be absorbed by the TSR decreases as the power factor increases.

VII. CONCLUSION

The paper presented the comparison of FACTS Static VAR Controllers, i.e. TSC and TSR on a medium transmission line for varying loads (No Load, Lagging and Leading loads) and with the help of modelling and mathematical calculations, in order to compensate the reactive power, thereby attaining equal sending end and receiving end voltage levels. We can also conclude that the above chosen transmission line depicted Ferranti Effect and hence TSR is required to compensate this effect. The method employed to achieve the improvements outlined are, introduction of a TSR to absorb the reactive power and TSC to deliver the reactive power demand. This improves the capacity of an already built transmission line and is used to meet the increasing load demands, by locally meeting the reactive power demands at the receiving end itself, and hence achieving the goal of flexible transmission and voltage regulation.

The above comparative study can be experimentally implemented and verified in a laboratory setup. The accuracy of the experimental results in the laboratory setup may vary on the availability of the exact capacitor and inductor rating. Though the above study has been implemented for a medium transmission line, in future, the study can be extended for short and long transmission lines as well.

ACKNOWLEDGMENT

We would like to thank Prof J.N. Rai, for his constant motivation and guidance during the project. Without his timely help and support, the completion of this paper wouldn't have been possible. We would also like to thank the publisher of the research papers from where we have taken reference.

Abstract

Amidst COVID-19 pandemic, extreme steps have been taken by countries globally. Lockdown enforcement has emerged as one of the mitigating measures to reduce the community spread of the virus. With a reduction in major anthropogenic activities, a visible improvement in air quality has been recorded in urban centres. Hazardous air quality in countries like India and China leads to high mortality rates from cardiovascular diseases. The present article deals with 6 megacities in India and 6 cities in Hubei province, China, where strict lockdown measures were imposed. The real-time concentration of $PM_{2.5}$ and NO_2 were recorded at different monitoring stations in the cities for 3 months, i.e. January, February, and March for China and February, March, and April for India. The concentration data is converted into AQI according to US EPA parameters and the monthly and weekly averages are calculated for all the cities. Cities in China and India after 1 week of lockdown recorded an average drop in $AQI_{PM2.5}$ and AQI_{NO2} of 11.32% and 48.61% and 20.21% and 59.26%, respectively. The results indicate that the drop in AQI_{NO2} was instantaneous as compared with the gradual drop in $AQI_{PM2.5}$. The lockdown in China and India led to a final drop in $AQI_{PM2.5}$ of 45.25% and 64.65% and in AQI_{NO2} of 37.42% and 65.80%, respectively. This study will assist the policymakers in devising a pathway to curb down air pollutant concentration in various urban cities by utilising the benchmark levels of air pollution.

Keywords Air quality index · China · COVID 19 · India · NO_2 · $PM_{2.5}$

Introduction

In the present time, with the emergence of rapid globalisation and urbanisation, megacities in developing nations are facing severe health issues due to ambient air pollution. According to WHO (World Health Organization), seven million people die each year because of exposure to polluted air (UN Environment Programme 2018). Numerous epidemiological studies in the past two decades have highlighted outdoor air pollution as a cause of various respiratory diseases such as asthma, premature deaths and cardiovascular diseases. These have been identified as primary causes of mortality. In such cases, the population living in the vicinity of major roadways in metropolitan cities suffers the most (Park et al. 2020). In urban areas, 80% of people live in concentrations exceeding the WHO limits (Błaszczyk et al. 2017). Motor-vehicle emitted compounds in urban areas which include carbon monoxide (CO); nitrogen oxides (NO_x); coarse (PM_{10}), fine ($PM_{2.5}$), and ultrafine ($PM_{0.1}$) particle mass, black carbon, polycyclic aromatic hydrocarbons and benzene which are found in elevated concentrations as reported by Venkatram and Schulte (2018). Moreover, studies suggest that particulate matter and NO_2 levels are higher in cities with greater transportation activity and urban backgrounds (Rodríguez et al. 2016). PM_{10} and $PM_{2.5}$ are the two primary particulate matters monitored all over the world. However, $PM_{2.5}$ possesses a higher health risk as compared with PM_{10} because of its high retention time and ability to penetrate deep into the lungs and enter the bloodstream (US EPA 2018). The WHO ambient air quality guidelines suggest an annual mean $PM_{2.5}$ concentration limit of 10 μg/m^3 and 25 μg/m^3 for the 24-hourly mean. The NO_2

limit is 40 μg/m^3, and 200 μg/m^3 for the annual and 1-h mean, respectively (World Health Organization 2005).

At the dawn of twenty-first century, developing economies like India and China are undergoing rapid industrialisation and modernisation, which are leading to hazardous levels of air pollution similar to the Industrial Revolution in Europe. It is well-understood that megacities in both countries like Beijing, Shenyang, Taiyuan, New Delhi, Mumbai, and Chennai are the world's most polluted cities (Zhu 2005). The primary sources of air pollution in India have been identified as vehicular emissions, industrial emissions, coal combustion, biomass burning, road dust, and refuse burning (Pant and Harrison 2012). Likewise, the poor air quality in China is a matter of global concern. The air pollution caused by transportation and industries is a serious environmental issue in urban settlements, and 50% of the PM in the urban air comes from traffic emissions (Li et al. 2017). Kumar and Joseph (2006) analysed ambient and kerb site air pollution correlation of PM_{10}, $PM_{2.5}$, and NO_2 in Mumbai, India. The results indicated a strong correlation between $PM_{2.5}$ and NO_2 at the ambient site due to vehicular emission as a result of high traffic density. A 2016 report estimated that only 3% of the Chinese population and less than 1% of the Indian population have exposure to $PM_{2.5}$ concentrations complying with WHO guidelines (IEA OECD 2016), although, an overall monotonic decrease in air pollutants was recorded in China from 2015 to 2018 (Fan et al. 2020). The existing levels of ambient $PM_{2.5}$ and NO_2 are above the safe limit. A 2017 report on global air pollution stated that China and India contribute to 52% of global $PM_{2.5}$—attributable deaths (1.525 million deaths) (Health Effects Institute 2019). In the past decades, both countries have been pro-active towards the efforts reducing air pollution. However, no long-term solution has been identified yet. Numerous academic studies have been conducted in both nations regarding the growing air pollution and its health effects. Kumar and Mishra (2018) conducted an assessment of major air pollutants at 36 transport corridors in Delhi, India, and the results of the study concluded that 31 corridors had "severe" and "very poor" AQI, and high traffic volume in most corridors is characterised by traffic-induced human health risks. It has been found that high levels of ambient $PM_{2.5}$ and NO_2 increase the risk of cardiovascular diseases and lung cancer in humans (Liu et al. 2018; Siddique et al. 2010).

In late December 2019, there was an outbreak of a highly contagious disease caused by the novel coronavirus, SARS-CoV-2. The first case emerged from Wuhan City, Hubei Province, China. The disease has been identified as Coronavirus disease (COVID-19). It's an outbreak, recognised as a "Pandemic" by WHO, has been extensively worldwide and exponential with more than 200 countries and territories reporting 3,267,936 cases and 234,703 deaths (7.18%) as of April 30, 2020 (WHO 2020). Individuals with underlying health problems, weak immunity, and the elderly are most likely to become extreme cases (Chen et al. 2020a). The critical sources of infection are patients infected with the novel coronavirus and those with asymptomatic infection (Wang et al. 2020a). Studies indicate correlation between the long-term exposure to air pollutant and COVID 19 death rate. Cities with hazardous air quality face a serious threat from the pandemic (Wu et al. 2020b; Conticini et al. 2020). Therefore, in the absence of a vaccine or treatment available for COVID-19, there has been a coordinated global response of imposing "lockdown" measures on citizens. As of now, more than a third of the worldwide population is under restriction. India recorded 34,867 COVID-19 cases (as of 30-04-2020) and a nationwide lockdown was imposed in India on March 25, 2020 for 21 days (MoHFW 2020). The lockdown constrained people from stepping out of their homes. Transport services, road, air, and rail, were suspended along with institutions and industrial establishments except for essential goods and services (Jain and Sharma 2020) and has been extended up to May 3, 2020. In parallel, 82,862 cases (as of 30–04-20) were recorded in China and 82% of these cases were recorded in Hubei Province (National Health Commission of the People's Republic of China 2020).

In Hubei province, Wuhan was regarded as the epicentre (Zhang et al. 2020) of the virus. On January 23, 2020, Hubei province, China, was kept under community quarantine with the shutdown of public transport, educational institutes, business centres, parks, and other social contacts to slow down the spread of COVID-19 (Wilder-Smith and Freedman 2020).

Further restrictions in Hubei province were lifted on March 23, 2020.With the implementation of lockdown and other federal restrictions in various countries around the globe, a visible reduction in air pollution is found in megacities. This study is aimed at quantifying and analysing the reduction in air pollution due to the lockdown imposed in two overpopulated and highly polluted countries of the world, viz. China and India, to determine the effect of lockdown on the air quality in an urban environment. The results of this study will help in gauging the ability of a full lockdown on reducing air pollution. Further, it will help in devising a response plan for unforeseen episodes of the high level of air pollution in urban environments.

Methodology of the study

Site selection

For the present study, 6 cities have been selected, each from India and Hubei Province, China. These locations are selected based on the availability of historical air pollution data, population density, monitoring station network, and the number of positive COVID-19 cases per million people. Selected cites

with their population, the number of monitoring stations taken into account, COVID-19 cases per million people, their geographical coordinates, and start and end date of lockdown are given in Table 1.

Parameters for analysis

For the analysis of the effect of the lockdown imposed by the governing authorities on the air quality, $PM_{2.5}$ and NO_2 are selected as parameters of the study. Both of these pollutants have a direct relationship with various anthropogenic activities that were restricted due to the lockdown (US EPA 2018; Ministry for the Environment New Zealand 2020). Hence, analysing these parameters assist in espying the effect of lockdown on the air quality of the selected locations.

Data collection and interpretation

During the data collection, 24-h average concentration (μg/m^3) data is taken for $PM_{2.5}$, and hourly average concentration data is taken for NO_2 (ppb) from respective EPAs of the locations selected. The data is collected in China for 13 weeks starting from January 1, 2020 except for Wuhan for which data was collected for 15 weeks since the lockdown was imposed till April 8, 2020. In India, data is collected for 13 weeks starting from February 1, 2020 to April 30, 2020. For the years 2016–2019, the data for Hubei Province, China has been collected from January 1 to March 31, and similarly, for India, the data has been collected from February 1 to April 30.

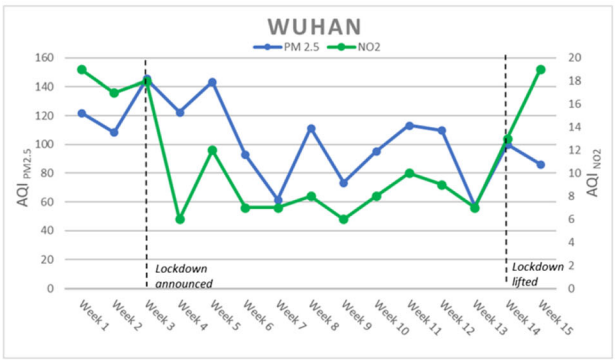
Weekly average data of $PM_{2.5}$ and NO_2 for the mentioned months has been calculated for the selected monitoring stations. The average value of the $PM_{2.5}$ and NO_2 concentration in a city is calculated by taking an average of all the monitoring stations selected, located at various distant locations throughout the city. The average value of the concentration of $PM_{2.5}$ and NO_2 is converted to individual AQI ($AQI_{PM\ 2.5}$ and AQI_{NO2}) by using the protocol suggested by US EPA for reporting the air quality data using the Air Quality Index (AQI) (Mintz 2012).

To analyse the changes in the $AQI_{PM2.5}$ and AQI_{NO2} levels, for each city, various drop percentages are calculated. The immediate drop percentage is calculated by the difference in average $AQI_{PM2.5}$ and AQI_{NO2} of the weeks before and after the lockdown was enforced. The final $AQI_{PM2.5}$ and AQI_{NO2} drop percentages are calculated by the difference in average $AQI_{PM2.5}$ and AQI_{NO2} of the week before lockdown and the last week when lockdown restrictions were lifted. Five-year and 1-year $AQI_{PM2.5}$ drop percentages in the year 2020 are calculated for January, February, and March in China and February, March, and April in India. It has been calculated by the difference in average $AQI_{PM2.5}$ of months of years 2016 and 2019 to the same months of 2020 for 5-year and 1-year drop percentages, respectively.

Results and discussion

With the parameters of immediate and final $AQI_{PM2.5}$ and AQI_{NO2} drop percentages, and 5 year and I year drop percentages of $AQI_{PM2.5}$, analysis for the cities in China and India has been done followed by a comparative assessment between the two countries.

Air quality analysis for the selected cities of China



Due to a large number of reported cases, Wuhan and its neighbouring cities (Huanggang and Ezhou) implemented a lockdown on January 23, 2020 followed by several cities on

Table 1 General Information of the Selected Cities (Office of the Registrar General and Census Commissioner 2011; National Bureau of Statistics of China 2010; Central Intelligence Agency 2018; MoHFW 2020; National Health Commission of the People's Republic of China 2020)

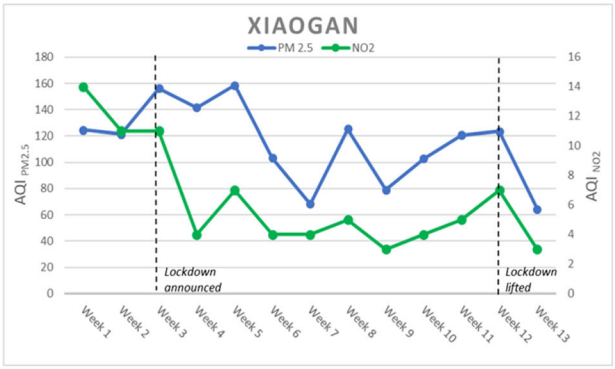
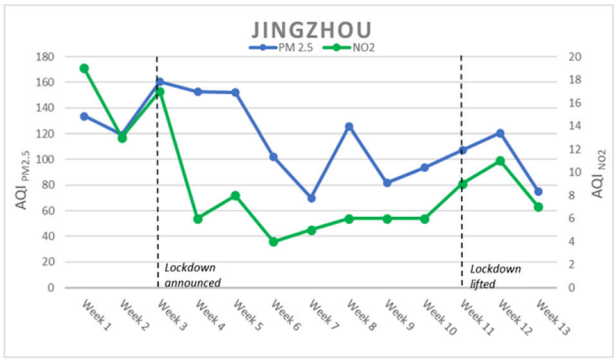
	Jaipur	6.42	4	234.51	27° 03′ 33″ N 75° 18′ 19″ E

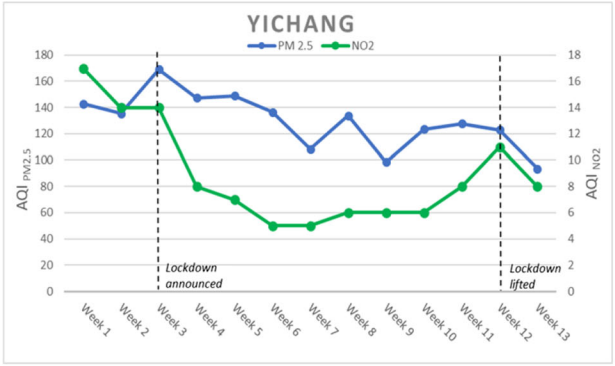
January 24, 2020 (Wu et al. 2020a). Wuhan, having the highest number of cases than any other city in China enforced lockdown with strict federal orders restraining anthropogenic activity to minimal level (Lu 2020), which entailed the highest immediate AQI_{NO2} (69.35%) and $AQI_{PM2.5}$ drop (15.95%) among the selected cities. In contrast, Xiangyang recorded the lowest immediate and final AQI_{NO2} drop of − 3.22% and − 16.40%, respectively. This trend is observed since Xiangyang is one of the most industrialised cities in central China, and due to the high demand for PPE kits and testing equipment, industries were working at double shifts to meet the demand (Hubei Provincial People's Government 2020).



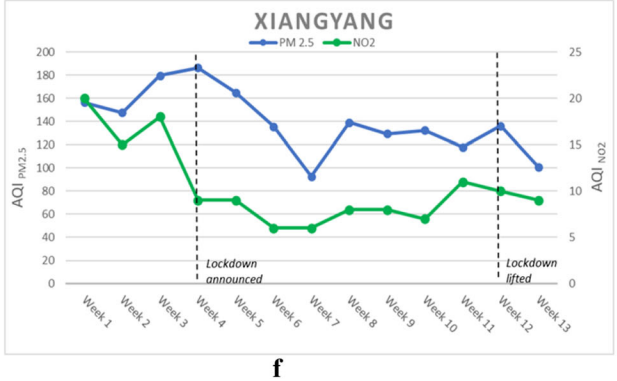
The average immediate and final AQI_{NO2} drop recorded is 48.61% and 26.64%, respectively. It can be concluded that the final AQI_{NO2} drop percentage is lower than the immediate AQI_{NO2} drop percentage; as the lockdown progressed, citizens had to get out of their homes for necessary essential commodities. Every city experienced a drop in $AQI_{PM2.5}$ (Fig. 1a, b, c, d, e, and f); on an average, the immediate $AQI_{PM2.5}$ drop is 11.28%; subsequently, the average final $AQI_{PM2.5}$ drop is 26.37%. Before lockdown was implemented, every city had $AQI_{PM2.5}$ within unhealthy for sensitive groups (101–150) and unhealthy (151–200) range according to US EPA standards. Nevertheless, the $AQI_{PM2.5}$ level



a



b



c

d

e

f

Fig. 1 Weekly averages of $AQI_{PM2.5}$ and AQI_{NO2} for cities of China

reduced and reached the moderate category during the lockdown period. Furthermore, for January, February, and March 2020, the cities recorded the lowest $AQI_{PM2.5}$ levels in 5 years (Fig. 2a, b, c, d, e, and f). As the virus started to spread in Hubei province in January, the citizens avoided leaving their homes as a self-precautionary measure. As the lockdown was implemented from January 23, 2020 in various cities, a drastic drop has been recorded in $AQI_{PM2.5}$ levels

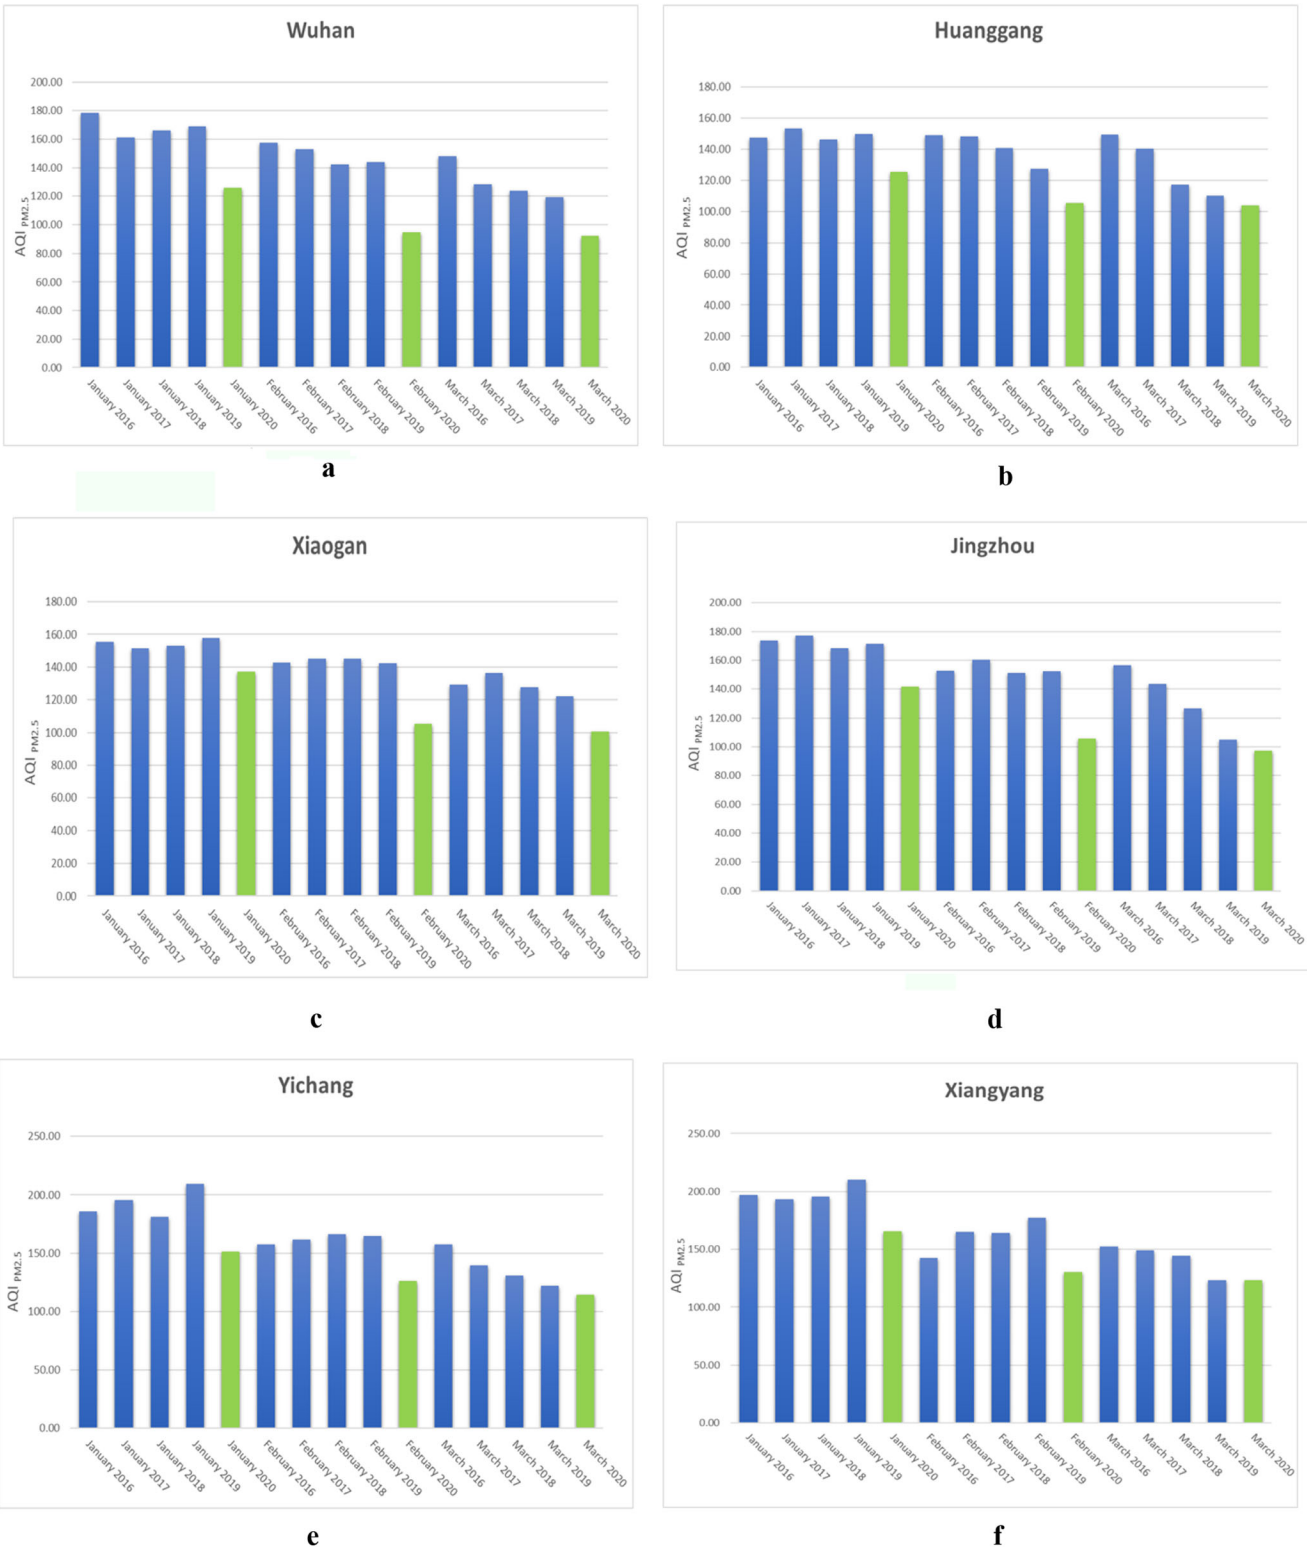


Fig. 2 Past 5 years' averages of $AQI_{PM2.5}$ for cities of China

from week 3 to week 4 (Fig. 1a, b, c, d, e, and f). The $AQI_{PM2.5}$ level remained constant through 2016–2019, to a certain degree for January and February. The highest 5-year and 1-year $AQI_{PM2.5}$ drop were recorded in Wuhan: 39.96% and 34.21%, respectively, while the lowest was found in Xiangyang: 8.53% and 26.55%, respectively. The average 5-year $AQI_{PM2.5}$ drop for January, February, and March, are 18.14%, 25.74%, and 29.18%, respectively. Subsequently, the average 1-year $AQI_{PM2.5}$ drop for January, February, and March are 20.17%, 26.31%, and 9.97%, respectively. It can be recorded that the 5-year and 1-year $AQI_{PM2.5}$ drop percentages are comparable in all months except March.

Additionally, meteorological conditions have an essential influence on the variations of $PM_{2.5}$ and NO_2 concentrations in the ambient environment (Agarwal et al. 2006). The cities Wuhan, Huanggang, and Xiaogan recorded a spike of $AQI_{PM2.5}$ and AQI_{NO2} levels (Fig. 1a, b, and c) in week 5 which led to a gradual decline in the forthcoming weeks of $AQI_{PM2.5}$ and AQI_{NO2}. The increase in the AQI levels was due to low precipitation recorded in week 5 in the three cities; total average precipitation for the three cities for week 4 and 5 were 42.6 mm and 0.34mm, respectively. In the subsequent weeks, rainfall intensity increased, which led to the drop in $AQI_{PM2.5}$ and AQI_{NO2} levels; the total average rainfall in weeks 6 and 7 for the three cities were 19.94 mm and 22.07 mm. In week 8, it has been observed from the Fig. 1a, b, c, d, e, and f that there is an increase in $AQI_{PM2.5}$ and AQI_{NO2} levels. Wuhan experienced 4.2mm precipitation in Week 8, as compared with 28.6mm and 39.4mm precipitation in Week 7 and Week 9, respectively. Hence, the abrupt increase in $PM_{2.5}$ and NO_2 in the cities is due to the low precipitation received in central China in Week 8 (19th–25th, February 2020). In the 13th week, a sharp decrease in $AQI_{PM2.5}$ and AQI_{NO2} levels is recorded. The mean rainfall in six cities in the 12th week is 14.23 mm. In contrast, the 13th week recorded heavy precipitation in all cities with mean average rainfall as 66.36 mm.

Air quality analysis for the selected cities of India

India enforced a nationwide lockdown from March 24, 2020, to May 3, 2020, after successive extensions as a preventive measure against COVID-19 pandemic. As the lockdown was implemented from March 24, 2020, a drastic drop has been recorded in $AQI_{PM2.5}$ levels of all selected cities from week 7 to week 8 (Fig. 3a, b, c, d, e, and f). Maharashtra, western peninsular state of India, has recorded the most cases of COVID-19 and deaths, 12,296 and 521, respectively (MoHFW 2020), and among the six megacities of India. Its capital, Mumbai, has shown the highest immediate drop of both AQI_{NO2} and $AQI_{PM2.5}$, i.e. 76.28% and 34.02%, respectively. Kolkata recorded the highest final $AQI_{PM2.5}$ drop (76.67%), and Lucknow recorded the least immediate drop in $AQI_{PM2.5}$ (6.47%) partly due to negligible precipitation in week 8. Chennai experienced the least immediate and final drops of AQI_{NO2}, which are 32.14% and 20.95%, respectively. It can be understood because of Chennai having an already low value of AQI_{NO2} (Fig. 3a) in week 7 and the weeks before the lockdown (Table 2).

The 6 cities experienced an average immediate $AQI_{PM2.5}$ drop of 20.21%, and an average final $AQI_{PM2.5}$ drop of 37.42%. Each one of the six Indian cities in the study recorded an immediate and final AQI_{NO2} drop with the average immediate AQI_{NO2} drop of 59.26% and an average final AQI_{NO2} drop of 65.80%. It has shown an overall drop in both $AQI_{PM2.5}$ and AQI_{NO2}. The average 5-year $AQI_{PM2.5}$ drop for the months of February, March, and April is recorded as 16.05%, 26.68%, and 37.51%, respectively; subsequently, average 1-year $AQI_{PM2.5}$ drop for the months of February, March, and April is 3.48%, 17.98%, and 27.06%, respectively. Chennai recorded the highest 5-year drop and 1-year drop in $AQI_{PM2.5}$ in April 2020 as 59.79% and 42.90%, respectively. All cities, except Mumbai in April 2020 and Chennai in March 2020, recorded the lowest $AQI_{PM2.5}$ levels in March and April 2020 as compared with the past 5 years. Mumbai is the only Indian city in the study to have shown a 1-year rise (1.09%) in an average $AQI_{PM2.5}$ in April 2020 (Fig. 4a, b, c, d, e, and f). A spike in $AQI_{PM2.5}$ was recorded (Table 3) between weeks 9 and 10 in New Delhi. It is as a result of reported fireworks incidents recorded on April 5, 2020, the day-wise $AQI_{PM2.5}$ levels of week 9 and 10 are given in Fig. 3b (The Indian Express 2020).

Furthermore, meteorological factors have an essential factor in the reduction and increase of $PM_{2.5}$ and NO_2 concentrations in the ambient environment. It can be recorded from Fig. 3c, in Kolkata, that $AQI_{PM2.5}$ and AQI_{NO2} have decreased augmented by heavy precipitation in the weeks 11, 12, and 13 with 29.20 mm, 80.90 mm, and 60.20 mm, respectively. However, in the preceding weeks 9 and 10, there was no precipitation. On the other hand, New Delhi, Lucknow, and Jaipur recorded an increase in $AQI_{PM2.5}$ in week 11 due to high surface winds in northern India due to dust storms from western India according to the Ministry of Environment and System of Air Quality and Weather Forecasting and Research (SAFAR) (Fig. 3b, e, and f) (ANI News 2020).

Comparative analysis and discussion between China vs India

An entire month lockdown was implemented in February 2020 in Hubei province, China; likewise in India, the month of lockdown was April 2020. The 1-year drop for February in China comes out to be 26.31%, whereas, for April in India, it is 26.06%. Hence, it can be deduced from the results that an entire month lockdown in urban centres results in a drop of around 26% in $AQI_{PM2.5}$ if compared with previous year

Fig. 3 Weekly averages of $AQI_{PM2.5}$ and AQI_{NO2} for cities of India

Table 2 Chennai weekly AQI_{NO2} averages (CPCB-CCR 2020; Mintz 2012)

	Week 1	Week 2	Week 3	Week 4	Week 5	Week 6	Week 7	Week 8	Week 9	Week 10	Week 11	Week 12	Week 13

value. Several academic studies have been conducted to study the relationship between the local meteorological factors and concentration of various pollutants (viz. $PM_{2.5}$ and NO_2) (Guo et al. 2017). The prime factors which influence the concentration of $PM_{2.5}$ and NO_2 have been identified as precipitation, ambient temperature, wind speed, and relative humidity.

Table 3 Delhi daily AQI_{NO2} and $AQI_{PM2.5}$ averages (CPCB-CCR 2020; Mintz 2012)

	April 1, 2020	April 2, 2020	April 3, 2020	April 4, 2020	April 5, 2020	April 6, 2020	April 7, 2020	April 8, 2020	April 9, 2020	April 10, 2020	April 11, 2020	April 12, 2020	April 13, 2020
AQI_{NO2}	7	9	10.75	12.33	11	8	9.5	11	13	11.67	8.33	12	12.33
$AQI_{PM2.5}$	92.75	77.2	88.2	97.75	116	137	94.67	90.67	93.5	124.25	122.25	113	128.75

However, the 12 selected cities tend to show a tremendous reduction in the concentration of $PM_{2.5}$ and NO_2 due to lockdown enforcement. It reflects that cutting down on anthropogenic sources of various pollutants can be useful in reducing the AQI.

Huanggang, China, has a population of 6.62 million, and the $AQI_{PM2.5}$ and AQI_{NO2} of Huanggang before the lockdown were 147.1 and 12, respectively. After the first week of implementation of lockdown, there was found a decrease of 13.40% and 58.54% in $AQI_{PM2.5}$ and AQI_{NO2}. Likewise, Jaipur, India, has a population of 6.42 million and the $AQI_{PM2.5}$ and AQI_{NO2} of Jaipur before the lockdown was implemented were 115.7 and 15, respectively. After the first week of the implementation of lockdown, a decrease of 27.50% and 60.37% in $AQI_{PM2.5}$ and AQI_{NO2} was recorded. Both cities have a comparable population and immediate AQI_{NO2} drop, but the immediate $AQI_{PM2.5}$ drop differs by 14.1%. The lowest week average $AQI_{PM2.5}$ recorded in Huanggang and Jaipur was recorded 68.7 and 73.4, respectively. Both the cities' $AQI_{PM2.5}$ has dropped down from unhealthy for sensitive groups to moderate air quality. Within 4 weeks of implementation of lockdown, Huanggang experienced a drop of 53.30% and 65.85% in week average $AQI_{PM2.5}$ and AQI_{NO2}. Furthermore, Jaipur saw a drop of 36.56% and 67.49% in week average $AQI_{PM2.5}$ and AQI_{NO2} in just 2 weeks.

For a holistic view, the cities selected in India recorded an average immediate $AQI_{PM2.5}$ and AQI_{NO2} drop of 20.21% and 59.26%, respectively. In contrast, on the other hand, the cities in China recorded an average drop of 11.32% and 48.61%, respectively. After 6 weeks of implementing the lockdown, cities in India recorded an average drop in $AQI_{PM2.5}$ and AQI_{NO2} of 37.42% and 65.80%, respectively, while cities in China recorded a drop of 42.54% and 56.67% respectively. From these results, it can be inferred that the drop in $PM_{2.5}$ is rather gradual as compared with the sudden drop in NO_2 concentrations throughout the cities.

As shown in Fig. 5, the drop in $AQI_{PM2.5}$ of coastal cities (viz. Chennai, Mumbai, and Kolkata) is relatively more significant than inland cities. The exceptional drop in $AQI_{PM2.5}$ in the coastal cities is vastly due to the coastal winds which are very prominent in these cities. Previous studies conducted in these coastal cities show that coastal regions show a significant drop in $PM_{2.5}$ in the morning as compared with inland regions (Chen et al. 2020b; Gupta et al. 2004). The three coastal cities incorporated in the present study record an average immediate $AQI_{PM2.5}$ drop of 24.96%, and the final average $AQI_{PM2.5}$ drop was found as 54.90%. On the other hand,

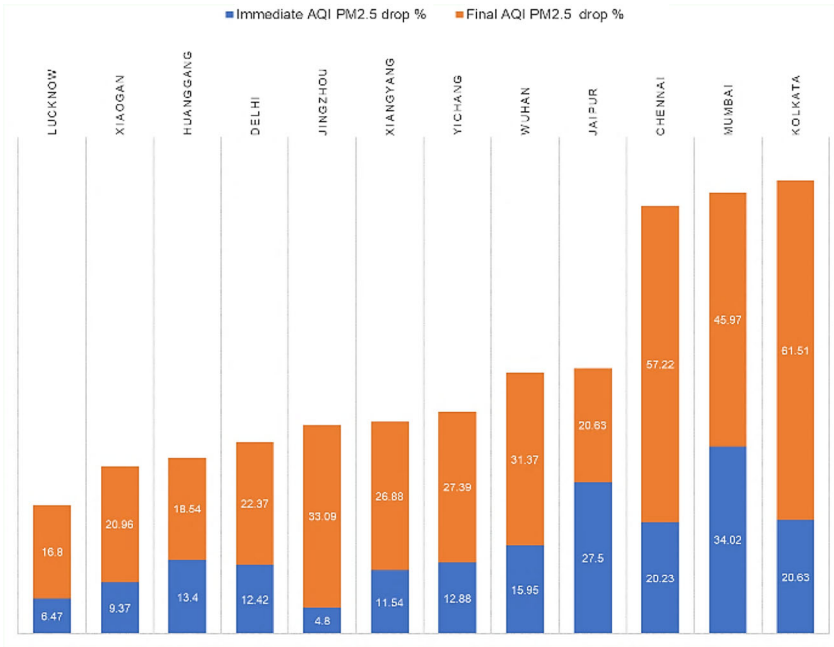

Fig. 5 Immediate and final Drop percentages of $AQI_{PM2.5}$ for all cities

the inland region cities recorded an average immediate $AQI_{PM2.5}$ drop of 12.70% and the final average $AQI_{PM2.5}$ drop of 24.23%. The drop in average immediate and final $AQI_{PM2.5}$ of cities in inland regions is moderate as compared with the drop in coastal regions.

Drop-in AQI_{NO2} also shows similar trends as $AQI_{PM2.5}$ (Fig. 6). The coastal cities recorded a much higher percentage of drop in AQI_{NO2} as compared with cities in inland regions. The coastal cities, except for Chennai, show an exceptionally high drop in AQI_{NO2}. Mumbai and Kolkata recorded an immediate AQI_{NO2} drop of 76.28% and 55.70%, respectively, whereas the final AQI_{NO2} drop is 92.58% and 76.67%, respectively. However, Chennai is a coastal city that recorded a much lower percentage drop in AQI_{NO2} as compared with the other two coastal cities, AQI_{NO2} of Chennai was already at a record low values between 3 to 5 before even lockdown was implemented. Xiangyang recorded an increase in AQI_{NO2} levels after the implementation of lockdown. Xiangyang, being a heavily industrialised city, had industries that were operating during the lockdown to produce essential medical equipment.

Conclusion

Both the nations followed different protocols for implementing lockdown in each country, although the lockdown in both of the nations was found effective in declining the rate of spread of COVID-19 cases (Wang et al. 2020b; Barkur et al. 2020), and it played a significant role in reducing the air pollution to record low values. The significant findings of the study are as follows:

- In China, the week before the lockdown was enforced, 4 out of 6 cities had an $AQI_{PM2.5}$ in the unhealthy category. Wuhan and Huanggang were found in unhealthy for sensitive group category. In the last week of lockdown, 5 out of 6 cities were found to be in unhealthy for sensitive group category except for Wuhan, which was found in the moderate category.
- In India, the week before the lockdown was enforced, 5 out of 6 cities had an $AQI_{PM2.5}$ that is unhealthy for sensitive group category except Chennai that was found under the moderate category. In the sixth week of lockdown, all cities were found in the good and moderate category except Delhi and Lucknow, which were found to be in unhealthy for sensitive group category.
- Meteorological factors are an essential factor in order to address pollutant concentration in ambient environment. Henceforth, meteorological should be taken into account before the execution of a response plan to mitigate pollution in urban cities around the world.
- For all 12 cities, a gradual decline has been recorded in $AQI_{PM2.5}$ levels in subsequent lockdown weeks. The mean immediate and final $AQI_{PM2.5}$ drops are 15.76% and 31.89%, respectively. However, in the case, AQI_{NO2} levels, a sharp decline has been recorded in the first week of lockdown. The mean immediate and final AQI_{NO2} drops are 53.93% and 46.22%, respectively.
- The coastal cities (viz. Chennai, Mumbai, and Kolkata) recorded a more significant decline in $AQI_{PM2.5}$ and AQI_{NO2} as compared with the other inland region cities.

The lockdown implemented in various regions around the world provided us with a unique opportunity to identify the

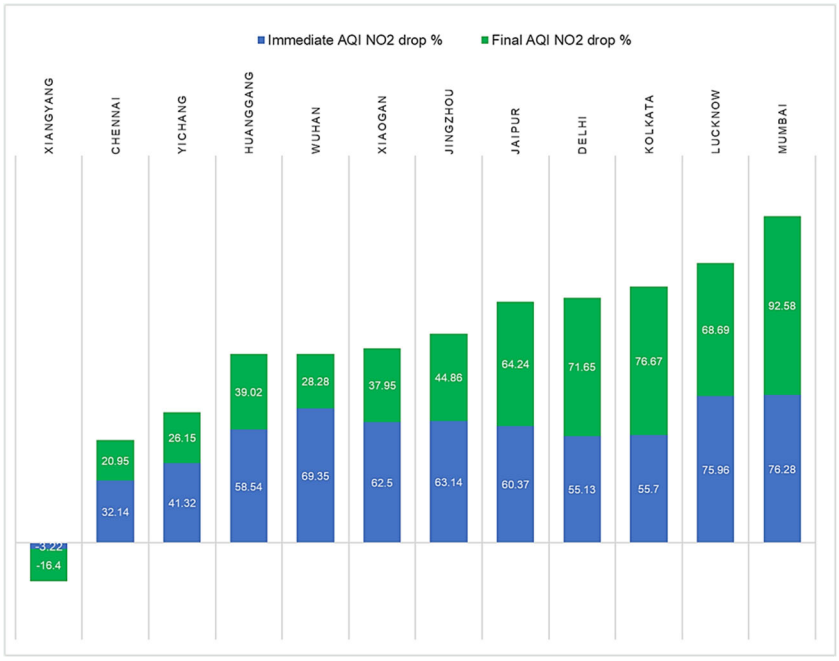

Fig. 6 Immediate and final Drop percentages of AQI_{NO2} for all cities

benchmark levels of pollutants in various urban cities around the world. The findings of the study will assist the governing authorities and policymakers to calibrate a proper response plan to bring down the ever-increasing pollution levels in various developing urban regions across the globe, especially China and India.

Abstract In this work, the design and control of seven-level H-bridge multilevel converter are carried out for the grid integration of large photovoltaic (PV) system without bulky line frequency transformer, as the multilevel converter provides a direct integration to the medium voltage grid. This system is a single-stage system to reduce cost and control complexity. Its control uses a decoupled current control with synchronous reference frame (SRF) and phase locked loop (PLL) with low switching frequency phase-shifted pulse width modulation (PWM) technique. It reduces the switching losses and hence improves the efficiency. The outer loop of control comprises of a separate maximum power point technique (MPPT) controller for each PV array to overcome the unpredictable irradiance level variations, ambient temperature, shading effect and other relevant factors. The improved perturb and observe (P&O) MPPT algorithm is used to track the maximum power from the PV array to give the accurate results. A significant reduction in total harmonic distortion (THD) in the grid current because of the increased number of steps in output AC voltage waveform of multilevel converter and consequently reduction in size of the filter component are achieved. Simulative experiments are carried out in MATLAB/Simulink, and the performance is validated in accordance with the IEEE-519 standard.

Keywords MPPT · PV generation · SRF-PLL · Phase-shifted PWM · VSC · THD

Introduction

The fuels used in conventional power plant are depleting and polluting in the nature. Hence, to get clean, ever available, reliable and environment-friendly electricity generation, the usage of renewable energy sources, like solar and wind, is increasing since last two decades. Lots of research are being done on power converters to interface these renewable sources to the grid, and multilevel converter has been perceived as gen-next technique to connect renewable energy sources with the grid. Multilevel converters are advantageous over the traditional two-level converter due to increased scalability, lower harmonics content, reduced filter components, low switching frequency, less voltage stress across switching device and an increased efficiency. Many multilevel topologies like diode clamped, flying capacitor and cascaded H-bridge are reported in the literature. Out of which, cascaded H-bridge (CHB) multilevel converter is the best suitable configuration for photovoltaic (PV) generation as multistring PV plant naturally provides the isolated DC source for each bridge of the CHB converter [1–5].

For grid interfacing of PV system, single-stage (requires only DC–AC converter) as well as double-stage PV systems (require both DC–DC converter and DC–AC converter) is reported in the literature [6–18]. This system is a single-stage H-bridge multilevel converter to eliminate DC–DC stage, for reducing the cost and also control complexity in the system.

As multilevel converter provides the direct connection to the medium voltage grid, hence eliminating the need

Published online: 27 July 2020

of large size and heavyweight transformer for grid interfacing, only a low frequency transformer is sufficient for providing galvanic isolation to limit leakage current [13].

Extracting maximal power from the solar PV array is also a challenge. Researchers have tried to track the maximum power using various approaches known as "MPPT techniques." Different techniques for implementing the concept of MPPT have been developed and reported in the literature [19]. In this system, separate improved P&O algorithm is conceived due to good accuracy and deployed for tracking the maximum power from each PV panel [20, 21] and each controlled by separate controller to overcome the unpredictable irradiance level variations, ambient temperature, shading effect and other relevant factors [18].

Its control comprises the decoupled current controller with SRF-PLL and PWM control for the modulation. A number of multicarrier PWM techniques are discussed in [22]. The low switching frequency phase-shifted PWM technique is employed in this work, which reduces the switching losses and hence improves the efficiency. With an increase in the number of steps (corresponding to the number of levels achieved) in the AC voltage output waveform in the multilevel converter, the THD in output grid current waveform is reduced, which also contributes to reduced size filter component. Moreover, a low switching frequency used in given work produces low acoustic noise, which eliminates the need of high value of an inductive filter; hence, only a low-value inductive filter is sufficient for the filtrating. The reduction in size of filter further results in reduction in the cost of system [18, 22, 23].

Many methods for synchronized connection, i.e., "integration" of large solar PV plant to the grid, are reported in the literature [9–11]. In [11], multipulse converters are used in large solar PV grid-connected system to minimize harmonics in the voltage waveform resulting in good power quality, lower switching losses and good reliability in comparison with the two-level topologies, but the good designing of transformer and interfacing magnetic is required for proper operation of multipulse-based system. The authors in [10] have reported "a novel scheme suitable for high-voltage and large-capacity photovoltaic power stations."

Some topologies for grid integration of single-phase converter are discussed in [12–15]. Here, a 3-Φ, 1.48 MW, 3.3 kV and 50 Hz power–frequency grid-integrated solar photovoltaic plant interfaced through H-bridge cascaded seven-level multilevel converter with phase-shifted PWM operated at 500 Hz switching frequency is proposed. The performance of the system is analyzed on MATLAB/Simulink.

System Description

The system as shown in Fig. 1, is a 1.48 MW, 3.3 kV, 50 Hz, 3-Φ seven-level cascaded H-bridge (CHB) converter with low switching frequency of 500 Hz.

In cascaded multilevel converter, the number of levels is equal to (2 * number of H-bridge per phase + 1) [23], and hence, seven-level converter consists of nine H-bridges, three H-bridges in each phase and is fed by the separate PV array. A distinct MPPT algorithm is needed for each PV array.

Design of System

The system is designed for 1.48 MW power, 50 Hz frequency, 3.3 kV voltage, and it includes the design of PV array, the DC-link capacitor and DC-link voltage, other specifications of the system, which are given in Table 1.

Selection of V_{dc} Voltage

In case of L number of level converter, for each individual H-bridge connected to the PV array, the DC-link voltage (V_{dc}) is calculated as in [23],

$$V_{rms} = 0.612 * (L-1) * V_{dc} \qquad V_{dc} = 898.692\,\text{V}. \tag{1}$$

V_{dc} is taken as 905 V.

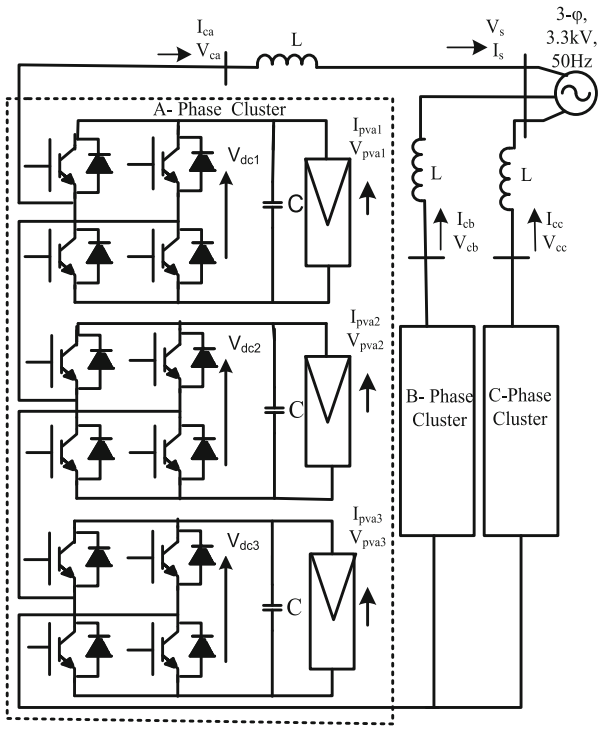

Fig. 1 Seven-level grid-interfaced converter PV system

Table 1 Component specifications

Component	Value
Power	1.48 MW
Voltage (V_{rms})	3.3 kV
Frequency	50 Hz
Switching frequency	500 Hz
Inductor (L)	5.4 mH
No of parallel paths in SPV array (N_p)	23
No of series paths in SPV array (N_s)	30
Voltage of PV array at maximum power (V_{mmp})	30.2 V
Current of PV array at maximum power (I_{mmp})	7.95 A
Open-circuit voltage of PV array (V_{oc})	37.5 V
Short-circuit current of PV array (I_{sc})	8.61 A
DC-link voltage (V_{dc})	905 V
DC-link capacitor (C_{dc})	14,500 μF

Design Calculations for Selection of PV Array

The required power rating of each PV array for a seven-level CHB converter consisting of nine PV array for 1.48 MW power grid is calculated as,

$$P_{mmp} = \frac{(\text{power rating of system})}{(\text{number of total PV array})} = 1.48\,\text{MW}/9 = 164.44\ \text{kW} \quad (2)$$

To obtain the PV array of 164.44 kW power (P_{mmp}) and V_{dc} of 905 V, a Sharp ND H230Q2 model is selected from PV array library, and numbers of PV modules in parallel and series are selected as,

$$N_s = V_{dc}/V_{mmp} = 30 \quad (3)$$

$$N_p = P_{mmp}/\left(N_s * I_{mmp} * V_{mmp}\right) = 23 \quad (4)$$

Selection of Capacitor for DC-Link

The DC-link voltage (V_{dc}) for each H-bridge connected to the PV array is obtained in accordance with the principle of conservation of energy for V_{dc} recovery in 5 ms and 1.2 overloading factor a, as [24],

$$\begin{aligned} {}^1\!/_2 * C_{dc}\left(V_{dc}^2 - V_{dc1}^2\right) &= K_1 * 3 * V * a * I * t \\ C_{dc} &= (0.1 * 164444 * 0.005)/ \\ &\quad (0.5 * (905 * 905 - 898.7 * 898.7)) \\ C_{dc} &= 14471.5\,\mu\text{F} \end{aligned} \quad (5)$$

It is selected as, $C_{dc}(C)$ = 14,500 μF.

Control Algorithm

The used algorithm for the control of the PV system connected to the three-phase AC grid is shown in Fig. 2. The maximum power developed by the PV array is tracked using an improved P&O algorithm. The decoupled current controller having a feedforward term, separate controller for each DC-link capacitor, SRF and PLL is used for controlling the voltage source converter (VSC) [25].

MPPT Algorithm

As shown in Fig. 3, by using an improved P&O MPPT algorithm, the maximum power is extracted from PV array and a suitable V_{dc_ref} is generated in this work. In this improved P&O MPPT algorithm, the detail of variation in current (ΔI_{pv}) is also considered along with the variation in voltage (ΔV_{pv}) and power (ΔP_{pv}) as in the P&O algorithm. In case of insolation change, normal P&O technique fails to differentiate between variation in the power on account of insolation variation and due to the perturbation, which is taken care of by improved P&O algorithm [20, 21].

Control of VSC

The voltage measured from each DC link is compared with the individual V_{dc_ref} given by each MPPT algorithm, as shown in Fig. 4. The error voltage (difference between the two) is processed by a proportional–integral (PI) controller to provide the active current loss component I^*_d, through the DC link, which is given as,

$$I_d^*(k) = I_d^*(k-1) + K_p\{V_e(k) - V_e(k-1)\} + K_i * V_e(k) \quad (6)$$

where V_e(k) and $V_e(k-1)$ are the error voltages at given sampling instants k & $(k-1)$ and K_p & K_i are proportional and integral gain constants. The sum of all reference DC-link currents along with the feedforward term is compared with the direct current component obtained by Park transform from the grid current as,

$$\begin{bmatrix} I_d \\ I_q \\ I_0 \end{bmatrix} = \frac{2}{3}\begin{bmatrix} \sin(\theta) & \sin\left(\theta - \frac{2\pi}{3}\right) & \sin\left(\theta + \frac{2\pi}{3}\right) \\ \cos & \cos\left(\theta - \frac{2\pi}{3}\right) & \cos\left(\theta + \frac{2\pi}{3}\right) \\ \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \end{bmatrix}\begin{bmatrix} I_a \\ I_b \\ I_c \end{bmatrix} \quad (7)$$

The grid detection angle (θ) for Park transformation is obtained from three-phase PLL. I^*_q, the reference quadrature current (set to zero for feeding grid current at unity power factor) is compared with the quadrature current component obtained from Park transformation.

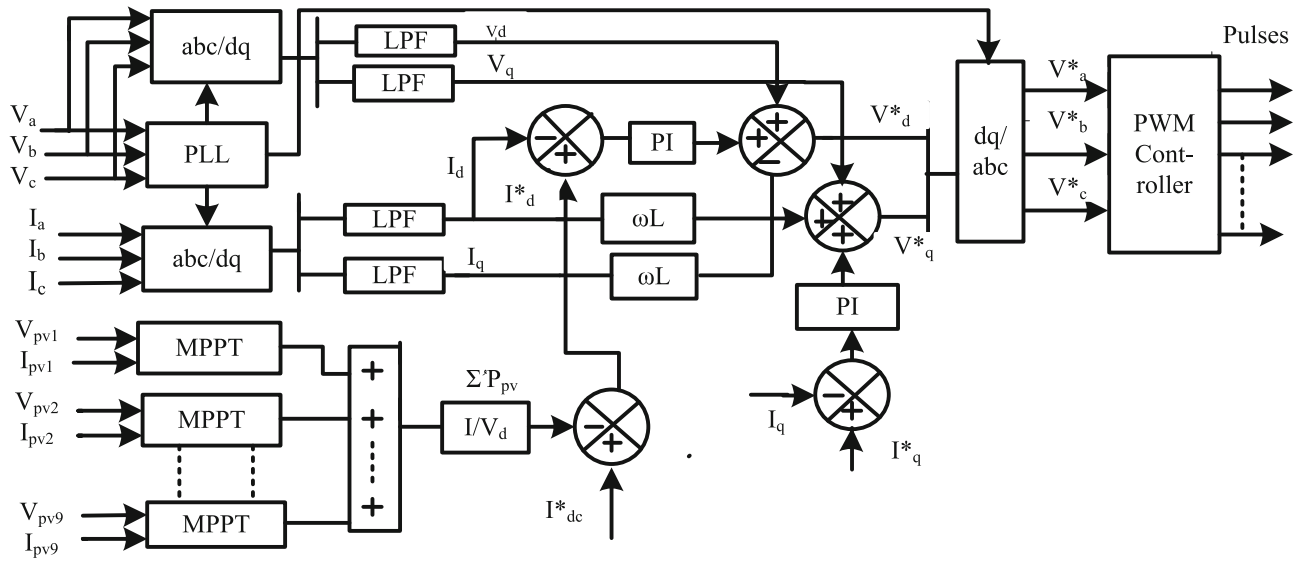

Fig. 2 Control algorithm

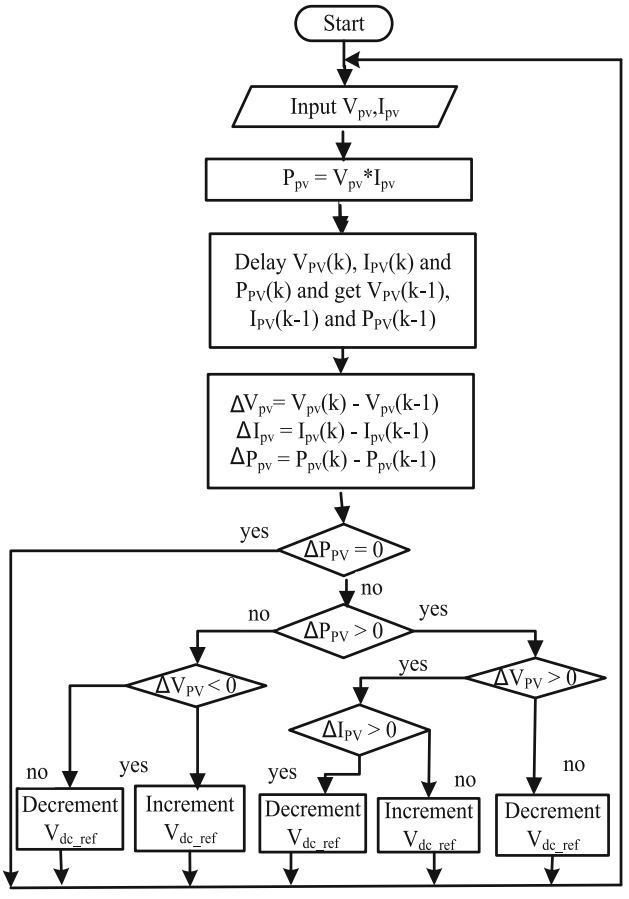

Fig. 3 Flowchart for improved P&O MPPT algorithm

Similarly, using Park transformation, direct and quadrature components of grid voltages (V_d & V_q) are calculated as follows.

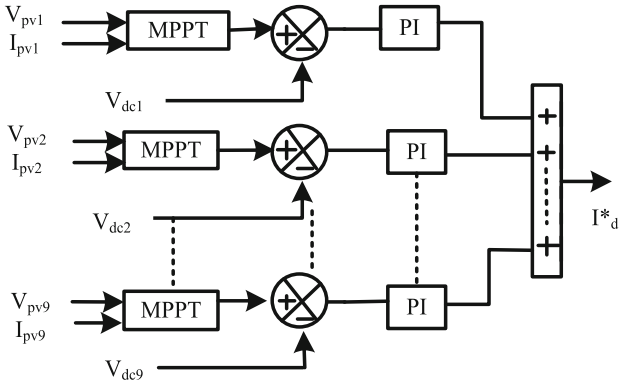

Fig. 4 Control algorithm for generating I^*_{dc}

$$\begin{bmatrix} V_d \\ V_q \\ V_0 \end{bmatrix} = \frac{2}{3} \begin{bmatrix} \sin(\theta) & \sin\left(\theta - \frac{2\pi}{3}\right) & \sin\left(\theta + \frac{2\pi}{3}\right) \\ \cos(\theta) & \cos\left(\theta - \frac{2\pi}{3}\right) & \cos\left(\theta + \frac{2\pi}{3}\right) \\ \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \end{bmatrix} \begin{bmatrix} V_a \\ V_b \\ V_c \end{bmatrix} \tag{8}$$

The reference direct-axis voltage and quadrature-axis voltages are calculated as follows,

$$V_d^*(k) = V_d^*(k-1) + K_{p2}\{I_{de}(k) - I_{de}(k-1)\} + K_{i2} * I_{de}(k) + V_d - I_q^* \omega L \tag{9}$$

$$V_q^*(k) = V_q^*(k-1) + K_{p3}\{I_{qe}(k) - I_{qe}(k-1)\} + K_{i3} * I_{qe}(k) + V_q + I_d^* \omega L \tag{10}$$

where $I_{de} = (I^*_d - I_d)$, $I_{qe} = (I^*_q - I_q)$ and ωL is the coupling reactance. K_{p2}, K_{i2}, denote the proportional and

integral gains of direct-axis current controller and K_{p3} and K_{i3} are the proportional and integral gains of quadrature-axis current controller. The reference voltages (modulating signal) for the PWM controller are obtained using inverse Park transform.

In PWM controller, phase-shifted modulation technique is used, in which, for seven-level (L) converter, six (i.e., $(L-1)$), triangular carrier signals are generated [23]. The phase shift (φ_{cr}) between two adjacent carrier waves is given by

$$\begin{aligned}\varphi_{cr} &= 360^\circ/(L-1)\\ &= 360^\circ/6 = 60^\circ\end{aligned} \tag{11}$$

Each carrier (V_{cr1}–V_{cr6}) is compared with V_{ref} signal for generating pulses as shown in Fig. 5.

Results and Discussion

The system, shown in Fig. 1, is designed and simulated in MATLAB/Simulink, and the results are discussed as follows.

Response of System

The solar power incident on the PV array set equal to 1000 W/m^2 and temperature 25 °C for steady-state performance of the system and dynamic performance of the system is studied when insolation level is changed from 1000 to 400 W/m^2 at 0.6 s. The system performance is validated by the simulative results consisting of the grid voltages (V_{sabc}), grid current (I_{sabc}), AC phase voltage of VSC (V_{cbc}), PV voltage (V_{pv}), SPV current (I_{pv}), the power (P), PV voltage & current for array 1 of A-phase (V_{a1pv} & I_{a1pv}), PV voltage & current for array 1 of B-phase (V_{b1pv} & I_{b1pv}), PV voltage & current for array 1 of C-phase (V_{c1pv} & I_{c1pv}) as depicted in Figs. 6a and b and 7a–c. The maximum active power transfer is evident at a power factor of unity.

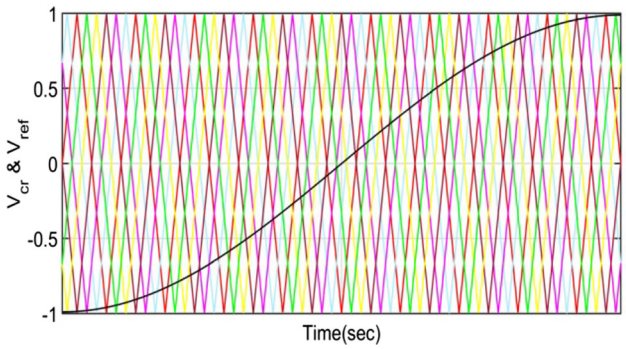

Fig. 5 Phase-shifted PWM scheme

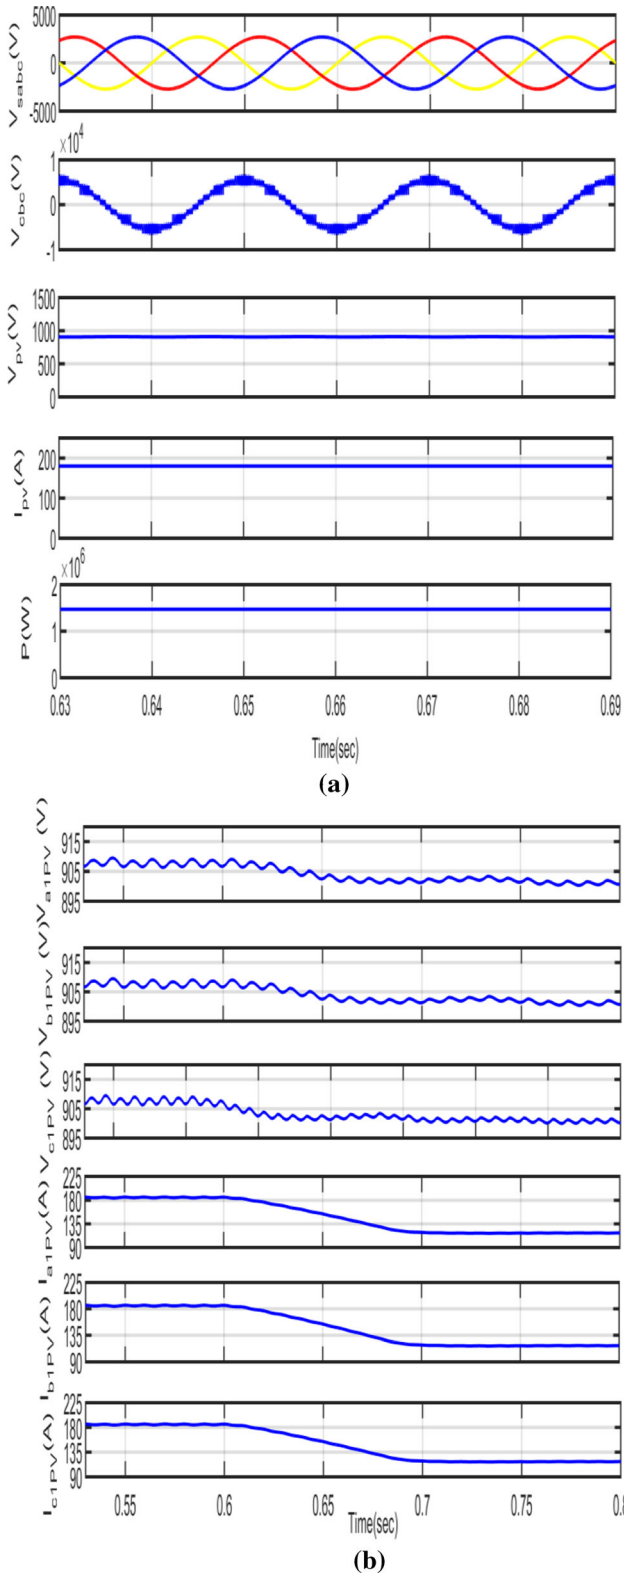

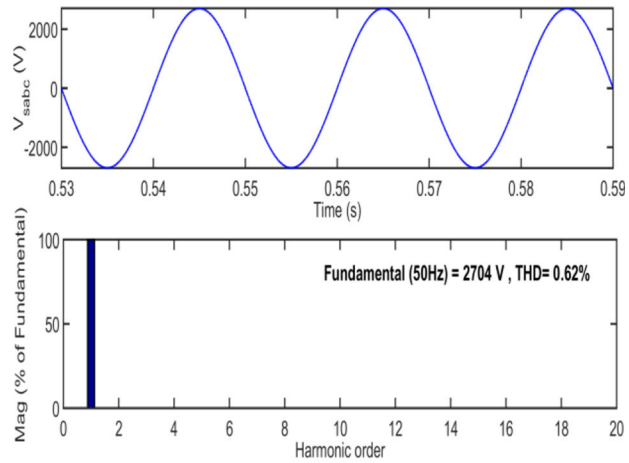

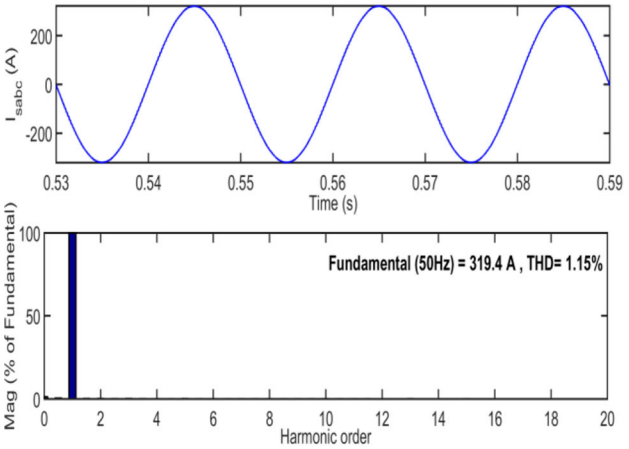

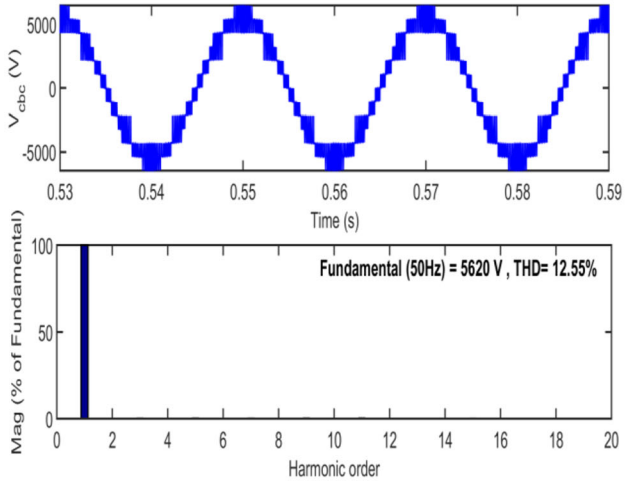

Fig. 6 **a** Steady-state performance at insolation level 1000 W/m^2, **b** dynamic performance when insolation level is changed from 1000 to 400 W/m^2 at 0.6 s for seven-level CHB grid-interfaced system

(b)

(c)

Fig. 7 Waveform and harmonic spectra of **a** line voltage, **b** line current and **c** converter line voltage at 1000 W/m^2

Improvement in Power Quality

Figure 7 shows the waveforms for the line voltage, line current (I_a) and converter line voltage (V_{cbc}) and harmonic spectra along with THD levels at 1000 W/m^2 levels. The THD values of 0.62%, 1.15% and 12.55% at insolation of 1000 W/m^2 and temperature of 25°, respectively, are observed for line voltage, line current and converter line voltage. The THD of the supply current is observed to be within the limits set by the IEEE-519 standard [26]. A minor variance is seen, though the power factor is also close to unity.

Conclusion

The design and control of single-stage transformerless seven-level H-bridge cascaded multilevel converters have been carried out with the decoupled current controller based on SRF-PLL and phase-shifted PWM at lower (500 Hz) switching frequency for large-scale photovoltaic grid-integrated plant. The low switching frequency reduces the switching losses, and hence, an improvement in the efficiency is achieved. An enhanced power quality is observed because of increased steps in output multilevel converter voltage waveform as compared to a two-level converter. It is attributed to the reduction in the supply current THD and reduction in size of filter components. Only an inductive filter is used for filtrating, which further results in reduction in the cost. The performance of the system is observed satisfactory at 1000 W/m^2 insolation level and 25° temperature and has been validated in accordance with the IEEE-519 standard [26].

COVID-19 Global Pandemic: Impact on Management of Supply Chain

Rakesh Kumar[1], R.S. Mishra[2]
[1,2]*Department of Mechanical Engineering, Delhi Technological University, Delhi, India-110042*

***Abstract*— To understand more about the global impact of (corona virus disease, detected in December, 2019, hereafter named) COVID-19 on supply chain management, a set of questionnaire is designed which addressed four pertinent themes focusing on product classification including export product, import product, elective product and emergency product. The questionnaire consisted of ten multiple choice questions including three open-ended questions (appendix A). The questionnaire was targeted at those organizations which were practicing supply chain management function as a core or a department of organization and was distributed online in interest groups using various social media platforms. The questionnaire was open from 26th March 2020 to 20th April 2020 and did not collect any identifiable data. Valid responses were represented as categorical data and presented in percentages.**

***Keywords*— COVID-19; supply chain management, product classification**

I. INTRODUCTION

The global downturn's speed and harshness due to COVID- 19 have significant implications for the supply chains of global manufacturers. That kind of volatility wreaks havoc on traditional supply chain planning: the process for determining production levels, raw-material purchases, transport capacity, and other vital factors, largely by examining historical patterns of demand. Indeed, the forecasting challenge is particularly acute because in many upstream industrial settings, as supply partners along the chain anticipate that demand will fall, the supply chain appears to be decoupling from downstream consumption—the focus of most forecasting models. In fact, risk managers and other executives fail to anticipate the effects, both negative and positive, of events that occurred. At first glance, for instance, a thunderstorm in a distant place wouldn't seem like cause for alarm. It was initially reported to the World Health Organization (WHO) on December 31, 2019 about Coronavirus disease 2019 (COVID-19) identified amid an outbreak of respiratory illness cases in Wuhan City, Hubei Province, China. On January 30, 2020, the WHO declared the COVID-19 outbreak a global health emergency. On March 11, 2020, the WHO declared COVID-19 a global pandemic.

The appeal of Janata Curfew on March 22,2020 by Hon'ble Prime Minister of India that the nation is set to observe an unprecedented shutdown and on March 24,2020 India imposed a 21-day lockdown, which was announced, comes after a call from the UN health agency, WHO, for the country to take "aggressive action".

What can companies do to prepare themselves for this sort of situation? True, there's no easy formula for anticipating the way risk cascades through a company or an economy. But we've found that executives who systematically examine the way risks propagate across the whole value chain—including competitors, suppliers, distribution channels, and customers—can foresee and prepare for second-order effects more successfully. Especially China, Korea, Japan, Germany and the US are also at of global value chains, so their woes will produce 'supply-chain contagion' in virtually all nations, Richard Baldwin and Beatrice Weder di Mauro apprehended this fact in their e-book on Economics in the Time of COVID-19. These nations are central to the global supply chains in many manufactured goods. The near term impacts—missed shipments, border-crossing delays, and communications problems—are easily understood. Less clear is the longer-term effect of increased uncertainty on lead times and demand and what that means for supply chain strategy. "Risk is something you can predict. If you flip a coin, over time you know that half will be heads and half will be tails. The nature of choice between heads and tails involves a risk because you can bet with these probabilities. So, in conditions of risk, you can distribute your investment into certain proportions against different outcomes that you may expect," Kim said (Minyoung Kim, associate professor of strategy and international business at the University of Kansas)."But uncertainty means there's nothing you can do about it beforehand. You know neither the outcomes nor the probability. I would call that the 'unknown unknown.' This could be a natural disaster or Brexit. If you knew, you might prepare against it. But you don't know that you don't know." The new uncertainty COVID-19 will require companies to rethink their supply chain strategy. For many, that effort begins with a reassessment of their demand-based strategy, which in recent years has been touted as the preferred approach to supply chain management.

International Journal of Emerging Technology and Advanced Engineering
Website: www.ijetae.com (ISSN 2250-2459, ISO 9001:2008 Certified Journal, Volume 10, Issue 04, April 2020)

Observing the scenario of Indian market S. Srinivasamurthy, Research Director, Enterprise Solutions and ICT Practices, IDC India says, "While the actual impact of COVID-19 on India market will be evident by middle of 2020, we expect a slowdown in terms of discretionary IT spending, contract renewals and new deals getting signed as enterprises recalibrate by cost structure in coming months. Existing project executions have also taken a hit due to travel restrictions in place. Corporates across the country implementing alternative ways of working, i.e. work from home, it is generating a parallel corporate line that demands to be connected from where they want, when they want and to who they want. But the different sets of challenges that the IT teams within the organization are grappling with - how to secure data and assets from cyber threats. Companies can meet most challenges noted above with a sound supply chain strategy, with IT as the key enabler. Though the complexities of India's supply chain may appear overwhelming, understanding and mastering them is a critical success determinant for an organization attempting to serve customers in India. An efficient review of supply chain design will help better position companies in what is becoming an increasingly competitive marketplace.

Supply chain in Indian Economy

Supply chain costs in India represent as much as 13 percent of the Gross Domestic Product (GDP). This is almost twice the percentage in developed countries: in the U.S., supply chain costs amount to 8.5 percent of the GDP. ARC Advisory Group categorizes supply chain challenges in India into two groups: demand side challenges and supply side challenges. Demand side supply chain challenges in India relate to price and variety. With 28 States and 7 Union Territories, differing considerably in dress, food tastes, customs, traditions and purchasing habits, it's almost impossible for a single manufacturer to address the wide variety of consumer requirements. Thus, it is important for manufacturers to partner with local distributors and retailers who can help develop products that will appeal to local consumers, at appropriate price points. When it comes to COVID-19's immediate aggregate demand shock (i.e purchases drop) is observed, for which, two aspects are to distinguish: real-world and emotional. Real-world since some consumers are or will be prevented from getting to stores, so their demand disappears from the market. Similarly, some home delivery services are suspended, so goods and consumers are approaching together less frequently.

Emotional since – as happened in the wake of the Global Crisis – consumers and firms tend to embrace a 'wait-and-see' attitude when faced with massive Knightian uncertainty (the unknown-unknowns) of the type that COVID-19 is now presenting to the world. This, quite naturally, makes trade flows susceptible to demand shocks (purchases drop) and supply shocks (production drop). The supply shock aspects of COVID-19 – factory closures, travel bans, border closings and the like – will reduce exports across the border. Many vendors have been successful in selling "no-frills," standardized products to rural segments in India only. Big Bazaar, Hindustan Unilever, Maruti, Tata Motors and Hero have offerings relevant to this price-sensitive segment of the population. Other successful examples of localized low-price products include Siemens' pacemakers, Godrej's Chotukool refrigerator, and General Electric's ECG. Supply side supply chain challenges in India mainly relate to poor infrastructure, complex tax infrastructure, weak distribution system, fragmented market, and lack of technology adoption. Richard Baldwin and Beatrice Weder di Mauro as responsible editor mentioned in their recent e-book on Economics in the Time of COVID-19, the disruptions that companies, individuals and governments are experiencing imply that globalisation and integration may be at risk from such health shocks i.e. COVID 19. Firms will probably take into account the lesson they are learning that global supply chains can be abruptly broken by this health shock.

II. Literature Review

Businesses dependent on global sourcing are facing hard choices in crisis management amid the supply chain disruptions due to COVID-19. The impact of the coronavirus pandemic on global supply chains is a major disruption, along the lines of having an earthquake or a tsunami. This is an unprecedented type of disruption. The uncertainties ahead swing between extremes. The main target of managing the supply chain is to realize and neutralize the uncertainties in the supply chain. Uncertainties in the supply, process and demand are recognized to have a major impact on the manufacturing function. As this paper focuses on the impact of COVID-19 on the supply chain management, the literatures were reviewed nearby similar context of reputed journals related to the flexibility, agility and pro-activeness of the supply chain.

Angkiriwang, R. et al. (2014) in his study obtain insights into the typology of uncertainty and relevant strategies adopted by manufacturing companies to achieve better supply chain flexibility.

International Journal of Emerging Technology and Advanced Engineering
Website: www.ijetae.com (ISSN 2250-2459, ISO 9001:2008 Certified Journal, Volume 10, Issue 04, April 2020)

Strategies are classified into reactive (buffering) and proactive (redesigning). A framework is developed that links supply chain uncertainty, as result the two types of strategies for achieving supply chain flexibility and the relevant objectives to be achieved. The research is endorsed by four case studies and are compared in terms of uncertainty typology and strategies being adopted to improve supply chain flexibility. supply chain flexibility (SCF) entails the implicit requirement of flexibility within and between all partners in the chain (Duclos *et al.*, 2003). Vickery, S.(1999) to establish the linkage, examined dimensions of supply chain flexibility and their relationships with environmental uncertainty, business performance, and functional interfaces. Prater et al. (2001) used five case studies to show the techniques of better trade-off between vulnerability (uncertainty) and supply chain agility by creating a link between the two called supply chain exposures. They considered and found two main problems of European industries, that is, in accurate forecasting and in developing an efficient and effective supply chain (SC) structure. The work described exposure as the degree to which an agile supply chain must be overextended (i.e. vulnerable) and, therefore, should be restructured or adjusted to address the issues in international SCs. To obtain high service levels at a low cost for emergency supply options in terms of lateral transshipments and direct deliveries, Alfredsson, P. et al. (1999) consider a two-echelon inventory system. An analytical model is used to calculate relevant performance measures. Comparison of the results of the model with the results of other models indicates that the combined use of lateral transshipments and direct deliveries can lead to significant cost savings. Agrawal, S. et al. (2019) emphasized about the segregation of products into different classified categories is essential for reverse supply chain also.

Like COVID-19, the earthquake and tsunami that struck Japan in March 2011 directly impacted over 27000 businesses whose production, warehousing, and retail facilities were destroyed or disabled by the natural disaster. Supply chain disruption is defined MacKenzie, C. A (2014) as a disruptive event that causes production difficulties for multiple suppliers and in which at least two of these suppliers deliver non-identical goods or services to at least two competing firms. The severity of a supply chain disruption can be measured by the number of entities that encounter difficulties in receiving or delivering materials or goods due to an unplanned event (Craighead et al., 2007).

A number of authors have tried to develop a framework for relationship between the typology of uncertainty and the type of strategies chosen for better supply chain. The study proposed in this article follows real time approach of the disruption COVID-19. The survey based work analyzes what supply chain firms should do during a severe supply chain disruption under uncertain conditions.

III. Motivation For The Research

The current COVID-19 global effect greatly motivated for this work. As India goes into a 21-day lockdown, there is some confusion arises about the e-commerce delivery of essential goods. According to lockdown rules, delivery of essential goods and groceries from e-commerce sites is allowed. Services like Grofers, BigBasket and Milkbasket allege their delivery people have been beaten up on the road. Facing difficulties, Flipkart has temporarily shut down service. Others too vary(www.indiatoday.in). The three East Asian manufacturing giants – China, South Korea, and Japan – account for over 25% of US imports, and over 50% of US imports of computer and electronics products. Apparel and footwear companies are particularly vulnerable to East Asian supply disruptions. The Economist magazine pointed to the vulnerability of the electronics industry with its practice of keeping very lean inventory levels and the lack of alternative sources for many electronic components. The optics sector is likewise highly exposed. The heart of the outbreak, Hubei province, is known as China's 'optics valley' since so many firms manufacturing fiber optic components are located there (these are essential inputs for telecoms networks). The automobile sector, especially in East Asia, is already significantly disrupted by ruptures in international supply chains. For example, a shortage of parts coming from China has forced Korean carmaker Hyundai to shut all its car plants in Korea. The Japanese firm Nissan closed a factory in Japan temporarily. The shock has even reached Europe. Fiat-Chrysler has recently warned that it could soon halt production at one of its European factories. Jaguar Land Rover, a UK-based auto company, announced it might to run out of parts from the end of February,2020. To stave this off, it had flown in emergency supplies from China in suitcases [7].

IV. Problem Description

The basis used by marketers to classify the products are: (i) On the basis of durability and tangibility of the product (ii) On the basis of Consumer Shopping Habits and (iii) On the basis of use in industry.

International Journal of Emerging Technology and Advanced Engineering
Website: www.ijetae.com (ISSN 2250-2459, ISO 9001:2008 Certified Journal, Volume 10, Issue 04, April 2020)

Traditionally products have various classifications, consumer products and industrial/business products is based on use is classified. Consumer product is further classified as: convenience products, shopping products, specialty products and unsought products and industrial product is classified as: material and parts (these goods enter the product directly), installation, accessory equipment, operating supplies. In general, the consumer goods directed to ultimate end-users, but the buyers seek product and marketing is important for it, but the industrial products used to produce other products and services, and usually vendors seek buyers. Based on durability it's classified as durable and non-durable and few classified products on the basis of tangibility, tangible and non-tangible also. But It is vital to design a product classification method in order to support global supply planning and improve the supply chain performance.

A. Product classifications

With respect to the present study and to measure the impact of COVID-19 on SCMs, the products are classified on basis of exigency as export products, import products, elective products and emergency products. Categorization of the product is important one for those organizations which were dealing with supply chain, the basis they can maintain it in their data base and exploit it at the time of need. This categorization helps to do planning accordingly by evaluating its gravity to the present situation of the demand.

Export products: those products which is manufactured by manufacturer for the specifically export purposes.

Import products: The product which will arrive from other country.

Elective products: Also called optional product which have substitute for the customer.

Emergency products: In this category those products will lie which are critically necessary for providing care for people. Viz. medical devices, medical products, productive equipment, masks, screeners, disinfectants and so on.

Companies use to handle complicated supply chain operation but lacks in product classification system. It is vital to design a product classification method in order to support global supply planning and improve the supply chain performance. That part of this research for future work. Also, Product Classification System is supposed to be applied in supply planning prioritization, inventory management and workforce balancing, etc.

The things which are considered as mechanism for the propagation of economic shocks, or economic contagion are: Products (tangible), people, services, know-how(skill), financial capital, foreign direct investment (FDI), international banking, and exchange rates. The flow of global economies dependencies is connected by cross-border by these mechanisms, and product is considered at top priority among all the above. Companies are learning the lesson that global supply chains can be abruptly broken by a health shock and will adjust accordingly. Financial intermediaries and regulators are likely to incorporate pandemic shocks into their future risk assessments and stress tests.

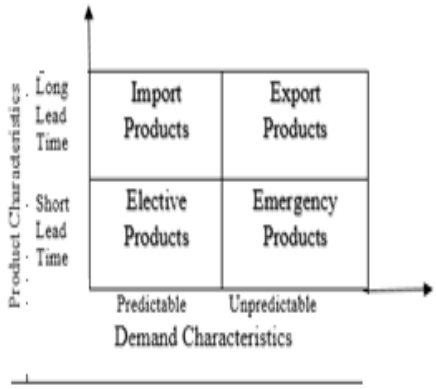

Figure 2. Characteristics of Export, Import, Elective and Emergency Product

V. Data Collection And Analysis

A. Questionnaire development

A questionnaire was developed based on the practical practice of supply chain in various organizations proposed for the study and aimed at gathering information related to dealing with the basis of classification of the product and its impact in context to Indian supply chain industry. With the help of available literature and telephonically talk with the experts the questionnaire is developed and suggestions were incorporated and questionnaire was improved before distribution for data collection. Survey form was developed with the help of google forms. The survey questionnaire is available in Appendix A. The survey was sent to the top management person who was handling these organizations via mail as well as in person asking people to participate in the survey. The given deadline for data collection for the responses was of 26th March to 20th April 2020.

International Journal of Emerging Technology and Advanced Engineering
Website: www.ijetae.com (ISSN 2250-2459, ISO 9001:2008 Certified Journal, Volume 10, Issue 04, April 2020)

B. Questionnaire administration

The questionnaire was self-administered, and the survey for the study with target population of supply chain industries were conducted through google form, online. The survey link was sent on email addresses of the respondents with a cover letter. Nowadays, web-based survey is being widely used by researchers because of less time required, ease of availability, real time data compilation, and lower cost than other surveys. With the help of google search engine, the dedicated organization were searched with their e-mail address to consult for the survey. Justdial.com helps more to lean the time of searching to those companies. To cover the entire India, the companies of Delhi, Kolkata, Mumbai, Chennai, Bangalore, Hyderabad and Ahmedabad were selected, besides these cities Pune, Goa, Nagpur, Coimbatore, Indore, Nashik, Vadodara, Jaipur, Mysore, Vizag, Chandigarh and Surat, many companies are there which associated with supply chain operations. The questionnaires were sent to the respondents in single phases. 300 forms were sent to different organizations through google forms and responses were analyzed. Total 130 responses were received 35 were incomplete so discarded. An effective response rate of 43.3% was achieved which is found adequate for the present study.

C. Respondent's profile and non-response bias

Due to time constraint, in single phases, total 300 e-mails were sent to the selected supply chain dedicated organizations for the survey. Overall, 130 responses were found suitable for the study. Participating organizations in the survey belong to (Original Equipment Manufacturer) OEM, Fast Moving Consumer Goods (FMCGs) and SCM consultant. Respondents who have participated in the survey represent different levels of management including top position to middle level and executive level employees and mostly belong to logistics department, marketing & sales, corporate strategy, and supply chain departments. Non-response bias with web-based survey was accessed by splitting the sample into two groups based on receiving date of the responses. Early response group consisted of 67 responses and late response group consisted of 63 responses. The t-test was performed on the difference in early response group and late response group. It yielded no statistically significant difference between the mean of two groups ($p > 0.05$). In addition, statistical tests show that there is no significant difference among samples.

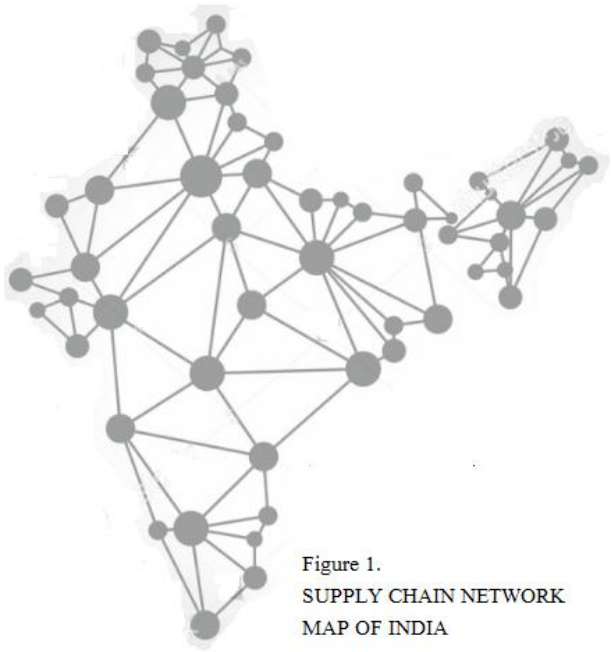

Figure 1.
SUPPLY CHAIN NETWORK MAP OF INDIA

VI. Result And Discussion

To understand more about the global impact of COVID-19 on supply chain management, we designed a questionnaire that addressed four pertinent themes including export product, import product, elective product and emergency product. The questionnaire consisted of 7 multiple choice questions and three open-ended questions (appendix A). The questionnaire was targeted at supply chain organizations and was distributed online in interest groups using various social media platforms. The questionnaire was open from 26th March to 20th April 2020 and did not collect any identifiable data. Valid responses were represented as categorical data and presented in percentages.

Impact studies with individual SCM organization data

This section describes a new wave of research that is based on samples of organization collected precisely to study strength of chain of supply with the help of product classification. The sampling was designed to examine organizations in different product category zones and to select organizations within country across a wide range of product. The survey instrument was designed to measure accessibility of products in places without barriers and hindering when situation is unfavorable.

International Journal of Emerging Technology and Advanced Engineering

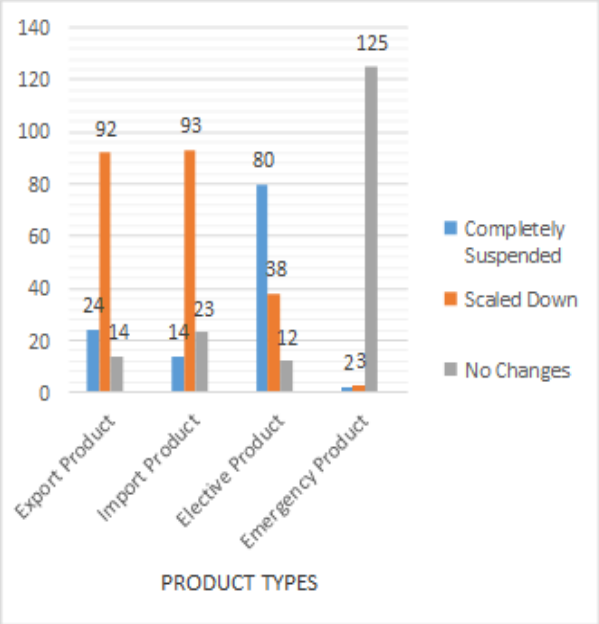
The instrument collected information about the choices that organizations made: which product to ship, which product to hold and which inputs to purchase. Precise Products classification give solutions and support decision-making for Global Supply Planning. For example, higher priority of products requires shorter lead time of supplying. The crisis never took place for time with the organization, but the plan was put in place and organization feel secure knowing that should it happen, they would be safe. For all the effort, resources, and consideration put into designing the most efficient manufacturing facilities and systems, it should be a natural next step to protect them by developing crisis response plans. Fisher is an acknowledged pioneer in the classification of supply chain strategies, claiming that there are basically two types of supply chain strategies, physically efficient and market responsive (Harris, 2007).



A total of 130 individual responses were obtained from the supply chain firms. Of these, 32(24.6%) were from the Delhi, 21 (16.1%) were from Kolkata, 10 (07.6%) were from Mumbai, 17 (13.0%) were from the Chennai, 17 (13.0%) were from Bangalore,19 (14.6%) were from Hyderabad and 14 (10.7%) were from Ahmedabad. Of the 130 respondents, 85(65.3%) were working Supply Chain as a part of OEM. When asked about export product, 102 (78.4%) replied that export product orders were either suspended or scaled down. When asked about import product, 118 (90.7%) replied that import product were either suspended or scaled down. With regards to elective products, 120 (92.3%) replied that at least some, if not all elective products orders were cancelled. The majority of orders cancelled were due to its availability of substitute product or not felt essential and emergency by the customer. On the contrary, 125 out of 130 respondents (96.2%) are still delivering all emergency products (Figure 1). For a large majority of respondents (113 out of 130, 87.0%), face-to-face multidisciplinary or team meetings have been reduced or cancelled entirely, and have been replaced by online messaging platforms, video conferencing, teleconferencing or email discussions. The rate of response also reflects the effect of lockdown.

As only 13% response from Mumbai and also we got news that Maharashtra counts highest death due to COVID-19. The impact of COVID-19 on supply chain services has been far-reaching. The majority of respondents have reported a reduction or cessation of export products orders and elective product orders, whilst continuing with emergency products.

Numbers from group purchasing organization Premier and data software companies show the supply chain gaps in getting needed personal protective equipment (PPE) to those on the front lines. Data on increasing orders of PPE in the hospital setting and the arc of COVID-19 calls compared to a typical flu season show the pandemic in a new light. Healthcare systems, distributors and purchasing organizations, along with state and federal governments, rely on real-time data to manage supplies and model their equipment and staffing needs. so manufacturers and their complex webs of suppliers, who in many cases lack that same experience or large-scale backup plans. The result: a chaotic scramble resulting in production delays, product shortages, and higher prices.

E-commerce giant Amazon has announced that it will only deliver high-priority products. In view of the challenges faced by the delivery executives, the Karnataka government on Monday issued a notice stating that e-commerce and home delivery fall under essential services and hence should be exempted from the restrictions imposed on citizens to curb the spread of the coronavirus. Following the suit, Maharashtra too issued an order stating that the e-commerce services such as food, medicine, etc should not be included in the restrictions that are imposed to contain the virus. Grofers founder had tweeted his apology to the customers for not being able to deliver their products on time. He stated “We @grofers are having a lot of trouble getting essentials to people who need them as our warehouses are asked to shut, and trucks and delivery partners are being stopped by the police. We apologize to our customers and are working hard to find a solution.” Flipkart also suspended its services temporarily.

***Abstract*—For real-time applications of arbitrary style transformation, there is a trade-off between the quality of results and the running time of existing algorithms. Hence, it is required to maintain the equilibrium of the quality of generated artwork with the speed of execution. It's complicated for the present arbitrary style-transformation procedures to preserve the structure of content-image while blending with the design and pattern of style-image. This paper presents the implementation of a network using SANET models for generating impressive artworks. It is flexible in the fusion of new style characteristics while sustaining the semantic-structure of the content-image. The identity-loss function helps to minimize the overall loss and conserves the spatial-arrangement of content. The results demonstrate that this method is practically efficient, and therefore it can be employed for real-time fusion and transformation using arbitrary styles.**

Keywords—image processing; deep learning; neural style transfer; computer vision; arbitrary image stylization; SANET; ASPM; convolutional neural networks.

I. INTRODUCTION

In the recent few years, various research works contributed to improve and accelerate the development of deep learning methods for continuous reformations of style transformation procedures. Arbitrary style transformation is the process of fusing new artistic styles with the content of the given image to create impressive artworks. NST was first introduced and explained by Leon A. gatys in 2015. Based on this idea presented by Gatys, many NST applications like a deep dream, prisma, and ostagram, etc. have been released to generate amazing artworks. The method proposed by Gatys [1] [2] follows an iterative procedure for the optimization of the generated image, which makes it computationally expensive and slow. However, the quality of the generated output is quite impressive. After that, numerous models have been proposed based on the optimization of the employed model. Johnson et al. [3] and Ulyanov et al. [4] [5] proposed fast offline approaches for generating output in a single feed-forward-pass, but their model is limited in the number of styles, and the quality of the result is also reduced. For fusing arbitrary styles using a single model, some ASPM approaches have been introduced. The swap model [6] was stated that employs the patch match procedure to substitute the features of content by the nearest match of characteristics of the style. Li et al. [7] specified multilevel stylization by recursively employing whitening-color-transformation to enhance the quality of output and to protect the content-structure. AdaIN [8] model changes the mean-variance of the content-image to match with style-image for transforming features. Avatar-net [9] model contains a style-decoder model based on patch-match and an hourglass network for adapting styles on multiscale. To solve the trade-off between content and style losses, this paper presents a new loss function identity-loss and a network consist of an integration of two SANET models for preserving both content-structures and style-characteristics. The arrangement of the paper is as follows. Below in section 2, background information of style transformation methods is given, which covers the explanation of some IBAR methods along with their drawbacks. Section 3 provides information about the existing neural methods of style transformation and their categorization into online and offline divisions. Section 4 illustrates the analysis of optimization approaches and expansion areas of NST by providing some detailed information about them. Section 5 demonstrates the implementation results and its comparison with other existing models. Finally, section 6 summarizes the conclusion.

II. BACKGROUND

In this section, the background information of the approaches used in style transformation before the evolution of deep learning is explained. The techniques in the taxonomy of image-based artistic rendering (IBAR) were employed for the stylization of two-dimensional images. First, the procedure of

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 24,2020 at 09:25:38 UTC from IEEE Xplore. Restrictions apply.

some IBAR [10] methods are described and then their drawbacks are reviewed.

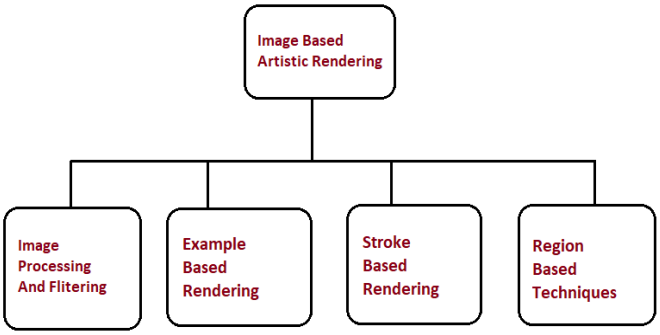

Fig.1: Categorization of IBAR techniques

A. *Stroke-based rendering*

It is the process of integrating portraits, paintings, and artworks by providing the strokes or marks on a digital canvas using brushes, lines, and tiles [11]. For converting a photograph into a particular style, virtually some brush strokes are superimposed at some positions on a digital canvas. It can create conventional arts based on the brush, for instance, an oil painting. This procedure generally starts from a source picture by sequentially adding strokes to modify that picture and ultimately composing a nonphotorealistic image that looks like the original photograph carrying an exquisite style. The limitation of SBR methods is that all SBR approaches are intended to create a single distinct style and therefore is not proficient for composing arbitrary styles. It illustrates the non-flexibility of this approach.

B. *Region-based techniques*

RBT is used to accommodate the effects based on the content in regions. Previous RBT algorithms [12] deteriorate the shape of structures in managing the arrangement of strokes. The latter method introduces an IBAR procedure [13] based on regions to alter the semantic geometry of photographs for generating creative effects. This algorithm replaces parts of the picture by many canonical patterns for constructing uncomplicated shape rendering results. In this approach, a source image and target photograph are distributed into many areas using the method based on graphs. The semantic conformity is estimated between them based on colors, patterns, and texture. Ultimately, the colors and textures are transferred for each area by employing a patch match method. Drawbacks of RBT methods are similar to SBR, all RBT approaches are intended to create a single distinct style and therefore is not proficient for composing arbitrary styles. It represents the non-flexibility of this approach.

C. *Image-processing and filtering*

Usually, the IPF approach for rendering is simple to implement and effective in application. IPF techniques [14] apply to real-time rendering and accommodate multicore CPU and GPU. Bilateral and Gaussian filters are employed to compose the effects of cartoons. Kuwahara filter is an exciting range of filters for preserving edges. It works relatively well on pictures of high contrast. These filters eliminate features in sharp regions and preserve shape outlines in areas of low contrast. Some other filters are morphological, diffusion, and shock filter. Gradient-domain techniques are also utilized in which the result is interpreted by creating a gradient field. The drawback of IPF is that style variety, and diversity is inadequate.

D. *Example based techniques*

EBR [15] understands the mapping within the prototype pairs containing the source photograph and the corresponding styled artwork. The learned mapping is employed to style arbitrary pictures. EBR can work in two categories by performing texture transformation and color transformation. The proposed framework named image analogy is a supervised method containing two stages, namely the design stage and application stage. In the design stage, it intends to study the analogous mapping between the pairs of source pictures and target outputs. The data used for training in image-analogy contains combinations of input-pictures along with the corresponding stylized output-pictures. In the application phase, learned mapping is applied to new target photographs to produce relevant analogous results. The main drawback of this method is the unavailability of training data. This method fails to capture the structure of images accurately and uses only low-level features of the picture.

III. NEURAL STYLE TRANSFER

NST is a machine learning technique that takes two images in input, one of which is the content-input image and another one is called a style-input image, for example, the artwork in a famous painting and blend them to transform the input images into an output image that looks like the picture called content-image but it will be painted similarly to the picture called style-image. Neural style transfer uses deep learning and its convolution neural networks to perform this amazing task. It is much propitious for artists and widely used by them to impose their artwork on digital photographs. It was first introduced and explained by Leon A. Gatys in 2015. After the Gayts, several endeavors are in progress related to the style transfer and its algorithms to perform training and learning faster as much as possible and to extend the procedure of style transfer techniques from static images to videos, audios, and other mediums. Neural methods of style transfer are broadly divided into two categories. One of which is the online method and the other one is the offline method.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 24,2020 at 09:25:38 UTC from IEEE Xplore. Restrictions apply.

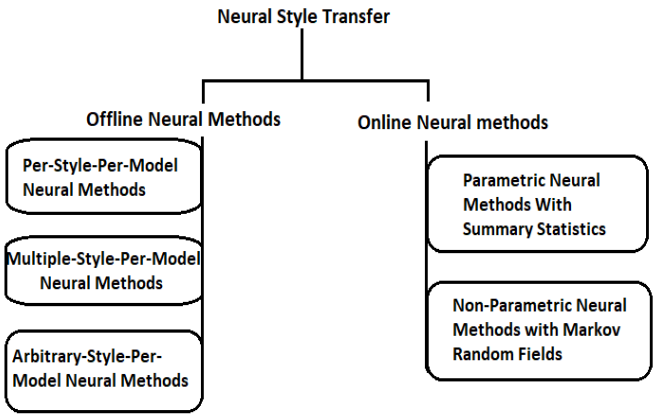

Fig.2: Categorization of NST techniques

A. *Online neural methods*

One of the famous applications in the field of style transfer is Deep-dream, which is based on the online approach of NST. The online method focuses on the optimization of the generated output image but not on the improvement of the applied model. This approach employed several iterations for enhancing the quality of the output image. Due to the multiple iterations, this procedure is much time consuming and computationally expansive. Therefore it is also known as the slow neural method for a style transformation. The process is to extract the content information and style representation from input images and then apply this extracted information to the CNN model for recombining both components to generate the artistic output. Gradient descent algorithm is used for the optimization of the result by minimizing the value of loss function. These online methods differ in the approach of applying the content and style representation to the CNN model so categorized into two classes.

1) Parametric online neural methods: These methods employed spatial representation summary and statistics to generate artworks. Gatys et al. [1] [2] in 2015 proposed an algorithm that applies deep CNN model VGG 19 for extracting structure, shape, and texture, etc. related information of content and style features from preprocessed input pictures. This information is spatially modeled in different layers of VGG 19 and used for the reconstruction of target artwork. VGG nineteen network is composed of sixteen layers of convolution and five layers for pooling, where higher layers are handled to represent the content characteristics. Style-image input is passed through the VGG network, and the gram matrix is employed to store style characteristics. The overall loss is a linear combination of both content and style losses balanced by parameters calculated through the one thousand iterations of gradient descent. Content loss is computed in terms of mean squared difference. The α and β hyperparameters provide the appropriate weights to both components of loss for balancing the equation of total loss function.

$$L_{total} = \alpha L_{content} + \beta L_{style} \quad (1)$$

$$L_{content}(C, G, L) = 0.5 \sum_{ij} \left(a[L](C)_{ij} - a[L](G)_{ij}\right)^2 \quad (2)$$

$$L_{GM}(S, G, l) = \frac{1}{4N_l^2 M_l^2} \sum_{ij} \left(GM[l](S)_{ij} - GM[l](G)_{ij}\right)^2 \quad (3)$$

$$L_{style}(S, G) = \sum_{l=0}^{L} w_l \times L_{GM}(S, G, l) \quad (4)$$

Here S, C, G, and GM are used to represent style-image, content-image, output generated-image, and gram-matrix, respectively. Activation of layer L is used for the calculation of content-loss. N_l is the number of channels in the feature map, and M_l is the product of the height and width of the feature map. After that demystifying approach [16] of NST was introduced that employs a different method for the statistical representation of style features. In this procedure, the gram matrix was replaced by MMD. It states that the minimization of maximum-mean-dispersion is comparable to the matching of gram-matrices. Several different methods for the representation of style were used, which include Gaussian, linear, polynomial and batch-normalization, etc. In 2017, Lapstyle NST was presented [17], which added a laplacian-loss function to calculate the overall loss. This laplacian-loss preserves the low-level fine details of the content characteristics and is aimed to reduce the distortion of edges, shapes, structure, contour, and colors of original input when converted to artistic output.

2) Non-parametric online neural methods: In 2016, Li and wand [18] proposed a method of style transformation that employed a combination of Markov-random-field models and deep CNN for synthesizing two-dimensional artworks. This approach works well with both photo-realistic and non-photo-realistic transformation of style. For minimizing loss, it uses limited memory BFGS algorithm. This algorithm matches style on the level of neural-patches. Hence, it is suitable for preserving the fine details of the structure. They formed a new function for calculating the style-loss and content-loss by calculating Euclidean distance between patches using the energy function of MRF-neural-patch-matching. The characteristic of this algorithm is that it produces considerably well-resulting artwork for photo-realistic styles, especially if the shape, structure, and panorama of both content-image and style-image are alike. Though, it usually doesn't work well if there is a great difference in view and arrangement of structures of content-image and style-image because the patches in both pictures could not be paired accurately.

B. *Offline neural methods*

Earlier explained the online method uses the iterative approach of gradient descent for improving the quality of generated output. Therefore it consumes a large amount of computation time when image size is considerably large. To overcome this limitation of speed, offline neural methods were introduced. This approach is much speedy compared to the previous procedure because it generates the output artwork in a single feed-forward-pass by optimizing the adopted model. As it mainly focuses on the optimization of the applied model, hence it is also known as the model-optimization-based offline method of NST. This offline approach is further divided into three categories based on the number of styles generated by the model in its output artwork.

1) The offline neural model generating single style-PSPM: For adopting an individual style, this approach optimizes the employed model. Johnson et al. [3] proposed a parametric method of training a feed-forward-network for the task of style transformation. This method replaces the per pixel losses by perceptual losses computed using high-level features of

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 24,2020 at 09:25:38 UTC from IEEE Xplore. Restrictions apply.

images. The system contains two components of the network, which are image-style transformation network and loss-network. Image-style transformation network is a deep residual CNN that can convert input images to an artistic output by understanding the mapping. It is trained using stochastic-gradient-descent for minimizing the weighted combination of loss-functions, which is computed by employing loss-network. Perceptual losses measure the similarities and dissimilarities of images more precisely compared to per pixel losses. Another similar approach proposed by Ulyanov et al. [4] uses multi-scale architectures that can be trained faster and result in a smaller loss in content and texture characteristics and better visual quality while working with comparatively few parameters. These are very lightweight models that are capable of generating artworks comparable to the quality of output produced by Gatys et al., and their speed is almost 100 times faster. However, these are also limited in considering the small details and depth information. After that, a new advance concept was introduced, which is known as instance-normalization [5]. It means normalization is applied to every single image in place of the batch of images. It converges faster, learns quickly, and significantly improves the visual quality of generated stylized artwork. This model can be trained rapidly, reduces the overall loss, and enhances the diversity of network output.

The non-parametric approach of single-style per model offline neural methods uses MGAN [19]. It is a markovian model applied to generative adversarial networks for learning the mapping between different representations of the same content-image. MGAN utilized the imagenet dataset for adversarial-training. It successfully preserved the coherent texture of compact content-images, and the speed of synthesis is remarkably fast. MGAN network consists of two subnetworks, namely discriminator and generator, for improving the model in iterations. This method lacks in transferring non-texture style, such as facial-features of two different face-pictures. Facial-features cannot be interpreted as texture because these require the understanding of expression, poses, and gender, etc. semantic characteristics.

2) The offline neural model generating multiple styles-MSPM: Above mentioned PSPM procedures can generate artistic output hundred times speedier than previous offline neural methods based on image-optimization. But it needs to train several network models individually to generate output for every distinct style-image. It exhibits inflexibility and excessive time consumption in training for each style. For reducing the irrelevant time consumption during the separate training of various models in PSPM, a new approach was introduced for consolidating multiple-styles into a single model, which is known as MSPM. In 2017, Dumoulin et al. [20] proposed that it is possible to model different styles at the same time by using the same parameters in the convolutional network. For incorporating different styles, shifting and scaling of parameters is required in the layers of instance normalization, which is called conditional-instance-normalization. CIN is an alteration of style-transformation networks that is uncomplicated, scalable, flexible, and efficient for incorporating diversity in output artwork. By consolidating affine parameters of different styles, it can be applied to incorporate multiple-styles in one output artwork.

After this style-bank method [21] was introduced, that is an aggregate of various convolution filter-banks. One style is expressed by every filter-bank explicitly in that combination. For converting a picture to a specific style, the corresponding filter-bank is turned over the intermediate feature-embedding generated by a single autoencoder. While keeping a fixed autoencoder, it is possible to carry out incremental-learning for appending a new style by training a new filter-bank. This style-bank fusion approach works in two ways, linear and region-based. In linear fusion, the style-bank layer is fed with a linear combination of multiple styles. While in region-based fusion, content-image is disintegrated into some disjoint regions using automatic k-means clustering, and then combined style transformation can be conducted using more than one style simultaneously. But the size of the model expands as the number of styles learned by it increases, which is a drawback. To eliminate this limitation, Zhang and Dana [22] explored the capabilities of a single CNN model VGG 16 for consolidating both content and style in one network. The Multiple-style-generative network was introduced, which can control the size of brush strokes in the real-time transfer of style. In MSG-Net, the comatch layer was used to represent styles in two-dimensional ways. For the comatch layer, it is possible to differentiate and train end to end, but tough to conserve the fine details of structures.

3) The offline neural model generating arbitrary styles-ASPM: The third type of offline neural method is ASPM that intends to build one model for all styles. It states that a single model can be trained to transfer any arbitrary style. ASPM is also divided into two types. Parametric-ASPM employed spatial representation summary and statistics to generate artworks while nonparametric-ASPM applies MRF for texture-modeling.

Style-Swap: Chen and Schmidt [6] proposed the first algorithm for nonparametric-ASPM in which they introduced the concept of style-swap for training an inverse network to generate the stylized output for any arbitrary style. At first, a set of patches having sufficient overlap for both content and style activations are extracted for computing in a previously trained VGG network. Each content patch is matched with style patches to find the closest and similar match for swapping. Then content activation is reconstructed by averaging areas of overlapping. This approach of one-model-for-any-style is more flexible than the previous methods but generates less appealing results in which the content is preserved thoroughly, whereas the style is not reflected adequately.

AdaIN: In parametric-ASPM, Huang, and Belongie [8] modified conditional-instance-normalization (CIN) to adaptive-instance-normalization (AdaIN) instead of training a network for parameter prediction. The above-mentioned style swap method takes a considerable amount of time and occupies much memory, but AdaIN is a simplistic approach with the low cost of computation. For the given input pictures, AdaIN modifies the mean value and variance value of both content-image and style-image for matching. AdaIN layer efficiently

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 24,2020 at 09:25:38 UTC from IEEE Xplore. Restrictions apply.

transfers the feature-characteristic statistics for performing style transformation. After that, a decoder is used for inverting the output of the AdaIN layer, and the VGG encoder is utilized for measuring loss. It is a good parametric-ASPM approach for performing stylization in real-time, but it is insufficient in the generalization of new styles. Therefore, it is challenging to synthesize intricate style patterns consist of fine details and complex structures.

WCT: Li et al. [7] changed the AdaIN-layer of the above-described model by a combination of the whitening-color-transformation network. The objective is to protect the arrangement and composition of content. Whitening-transformation receives content-activations from the encoder and then produces a filtered representation of content-image. After that, coloring-transformation is applied for consolidating the style-patterns into the filtered content design, and the decoder provides stylized output artwork. This method is good in generalizing distinct styles as learning is not required of every style, but not useful in delivering sharp-features and small strokes-details.

Avatar-net: It blends the images based on the semantic-arrangement of content and employs multi-scale stylization in a single feed-forward pass [9]. It is better than WCT that requires several recursive feed-forward passes. Avatar-net uses a style-decorator and an hourglass-network. Patch-based style decorator module is used to decorate the content features with style patterns while retaining the semantic properties of content. The hourglass network is employed for a multi-scale adaptation of style. But its output depends on the patch size, and therefore usually, it is unable to express the local and global styles simultaneously.

SANET Model: It stands for the style attentional network that can blend style-patterns in the content-image efficiently and flexibly [23]. It uses a kernel that can learn similarities rather than fixed kernels. This neural-network model modifies the self-attention mechanism to understand the mapping between content and style features. For synthesizing artworks, this model takes two images in input, which are content-image I_c and style-image I_s. By applying the encoder module, which is a previously trained VGG nineteen network, both the input-images are encoded into an intermediate representation. After encoding both input-images, both the obtained feature-maps F_c and F_s, are applied to two distinct style attentional networks to produce the combined feature-map F_{cs}.

$$F_c = E(I_c) \tag{5}$$

$$F_s = E(I_s) \tag{6}$$

$$F_{cs}^{r41} = SANET_{r41}(F_c, F_s) \tag{7}$$

$$F_{cs}^{r51} = SANET_{r51}(F_c, F_s) \tag{8}$$

$$F_{csc}^{r41} = F_c + W_{cs} F_{cs}^{r41} \tag{9}$$

$$F_{csc}^{r51} = F_c' + W_{cs}' F_{cs}^{r51} \tag{10}$$

$$F_{csc} = conv_{3\times3}\left(F_{csc}^{r41} + upsamle\left(F_{csc}^{r51}\right)\right) \tag{11}$$

$$I_o = D(F_{csc}) \tag{12}$$

Here F_{csc}^{r41} and F_{csc}^{r51} are the synthesized feature-map values generated by applying 1xl conv-net to the output feature-maps of SANETs. F_{csc} is the integrated output feature-map achieved by applying 3x3 conv-net to the resulting feature-maps obtained by relu_4_1 SANET and upsampled relu_5_1 SANET. The combined output of these SANETs is concatenated by passing through a symmetric-decoder, which produces the final output-image I_o. This method is both effective and practically efficient. It flexibly performs style transformation using the loss function that unites traditional style-reconstruction-losses and the newly introduced identity-loss.

$$L = w_c L_c + w_s L_s + L_{id} \tag{13}$$

$$L_c = \left\| \overline{E(I_o)^{r41}} - \overline{F_c^{r41}} \right\|^2 + \left\| \overline{E(I_o)^{r51}} - \overline{F_c^{r51}} \right\|^2 \tag{14}$$

$$L_s = \sum_{i=1}^{L} \left\| \mu(\varphi_i(I_o)) - \mu(\varphi_i(I_s)) \right\|^2 + \left\| \sigma(\varphi_i(I_o)) - \sigma(\varphi_i(I_s)) \right\|^2 \tag{15}$$

$$L_{id} = w_{id1}(\|I_{cc} - I_c\|^2 + \|I_{ss} - I_s\|^2) + w_{id2} \sum_{i=1}^{L} \begin{pmatrix} \|\varphi_i(I_{cc}) - \varphi_i(I_c)\|^2 \\ + \|\varphi_i(I_{ss}) - \varphi_i(I_s)\|^2 \end{pmatrix} \tag{16}$$

Here L_c is content-loss, L_s is style-loss and w_c, w_s are the weights assigned respectively. $\overline{F_c^{r41}}$ and $\overline{F_c^{r51}}$ are channel-wise-normalized mean, variance feature-map values of content-image. $\overline{E(I_o)^{r41}}$ and $\overline{E(I_o)^{r51}}$ are channel-wise-normalized mean, variance feature-map values of output-image after passing through the encoder. φ is the feature-map value of the layer of encoder denoted by i. L_{id} is identity-loss and w_{id1}, w_{id2} are the weights assigned to identity-loss. This loss function helps to preserve the structure of content-image while simultaneously maintains the style-patterns.

IV. OPTIMIZATION AND EXPANSION OF NST

Optimization algorithms are applied to optimize the output of NST by minimizing the value of loss-function. They work during training and learning of the model to update the weights and finding the relevant values for parameters to get an optimal solution. In Table 1, some popular optimization methods [24] are discussed with their merits and drawbacks.

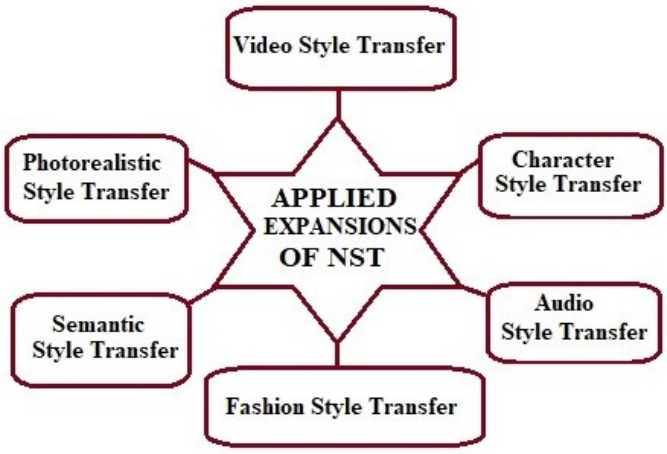

Fig.4: Expansion of NST in various applications

approach [26] was suggested that applies a flow-subnetwork to compose feature-flow and to consolidate the knowledge of optical-flow. This model is based on a network that contains a previously trained combination of encoder and decoder. The semantic transformation [27] of style is an expansion of NST, which is applied to a pair of input images holding analogous content. The method is to obtain a semantic correlation between content-image and style-image. Hence, the style of every region of style-image is applied to the corresponding semantically analogous part of the content-image. Style transformation is also operated on characters [28] for producing unique fonts and unusual text-effects. By collectively training the conditional-generative model and an ornamentation-network model, the style transformation of characters can be accomplished. Another expansion is to generate distinct sound effects by allotting the desired style from the target-audios [29]. It uses two approaches based on iterative optimization of audio and optimization of the employed model. Photorealistic transformation [30] refers to

Table 1: Analysis and comparison of optimization algorithms

Type	Description	Merits	Drawbacks
Gradient Descent-optimizer	It is a traditional algorithm for the optimization of neural network models. It updates weights and tunes the parameters of the model iteratively to minimize the value of loss function.	Updates weights in neural network models iteratively.	It is very slow and takes ample computation time for huge datasets. It is difficult to regulate the learning rate as the algorithm sometimes stuck in local minima.
AdaGrad-optimizer	It applies a separate learning-rate for each parameter. It modifies the learning rate of the parameter at each step based on the computation of the previous gradients of that parameter.	Very helpful for handling scattered data and it is not required to set the learning rate manually.	Its main limitation is the decrease and decay in its learning rate value.
AdaDelta-optimizer	It is an improvement of AdaGrad-optimizer. It entirely replaces the learning-rate parameter by the exponential moving-average of squared-deltas.	No need for the learning-rate parameter.	There is a necessity of two-state variables for saving the second-moments of gradients and the variation in parameters.
Adam-optimizer	It is an adaptive-method for defining separate learning-rates for every parameter using momentum and therefore termed as adaptive-moment-estimation.	It separately defines the learning-rate for every parameter.	Its gives better result in the starting of training, but performance diminishes as the time increases. Therefore, for some tasks, it does not converge to an optimum value.
L-BFGS-optimizer	It is a limited-memory-BFGS algorithm in the family of QUASI-Newton-methods because it takes a small amount of memory. It uses a line-search approach, which makes it much steady in training and more accessible to examine for convergence.	It is the most efficient, speedy, and popular approach of optimization compared to previous methods.	It does not scale well while updating and calculating gradients. Hence, there is a necessity of mini-batch-training that needs to estimate gradients on small subsets of data.

Several approaches of NST are expanded to style transformation of audio, video, and characters, etc. For altering the style of videos, the requirement is to achieve a smooth variation among contiguous frames of video. A method [25] based on iterative optimization of images uses temporal-consistency loss obtained by calculating optical-flow. It produces stylized videos by excluding temporal-artifacts but requires significant time for computing results. Another

the transfer of style of arrangements of colors. Its primary intent is to conserve the fundamental structure of the content-image by utilizing a two-stage optimization method, namely stylization, and smoothing. Hence, for decreasing the deformation of content-image, it employs photorealism-regularization. Another expansion of NST approaches is in the field of fashion [31] to create clothes containing the desired styles of fashion. In the synthesized output, the applied GAN-

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 24,2020 at 09:25:38 UTC from IEEE Xplore. Restrictions apply.

model should protect the basic design of cloth while blending with the given target style.

V. IMPLEMENTATION RESULTS AND ANALYSIS

The characteristics of various distinct procedures for neural style fusion and transformation are thoroughly analyzed [32]. The charts given below in Fig.5 and Fig.6 represent the comparison of running time performance on input-images of distinct dimensions. It has been observed that the algorithm based on optimization of image proposed by Gatys et al. [1] takes a considerable value of computation time when compared with offline methods based on optimization of employed models [3] [4] [5]. However, the quality of generated results is better when compared to others. For real-time applications of arbitrary style transformation, there is a trade-off between the quality of results and the running time of existing algorithms. Therefore, a balance should be maintained between quality and speed.

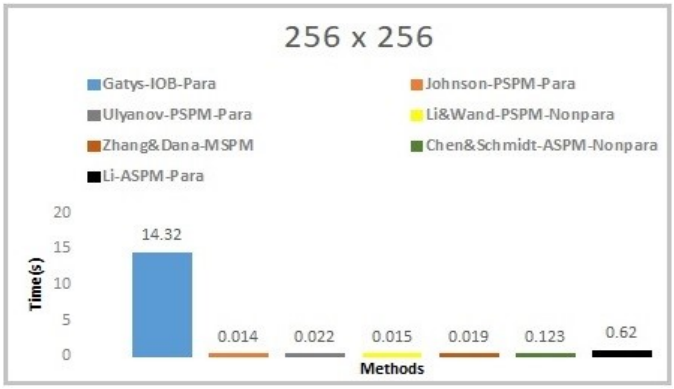

Fig.5: Comparison of the run-time of some NST approaches on 256×256 dimensional images

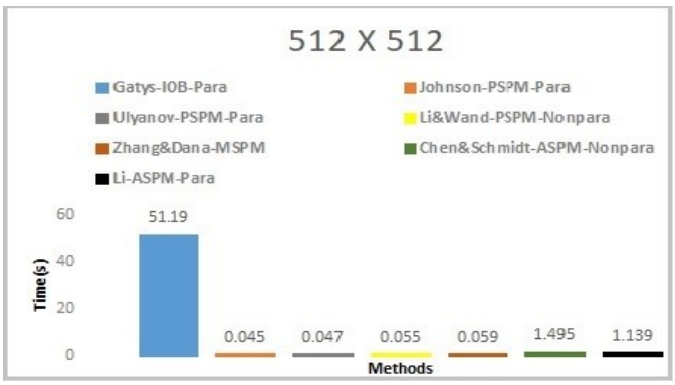

Fig.6: Comparison of the run-time of some NST approaches on 512×512 dimensional images

A network of the SANET model is deployed using Anaconda, PyTorch 0.4.1, CUDA 9.2, and open CV 3.4.2 python. During the training of the model for content-images VOC 2012 dataset is used, and for the style-images WikiArt dataset is used. A PC comprising Windows 10, Intel Core i5 eighth-generation quad-core CPU, NVIDIA Geforce GTX 1050 GPU, and a RAM of size 8 gigabytes is used. It also demands an internet of extremely high-speed. Programming Language used is python. The input is taken as two pre-processed images and resized them to 512×512. During training, the size of each batch is six, and 180000 default iterations are applied. The initial values assigned to weights while computing the loss are as follows, w_c=1.0, w_s=4.0, w_{id1}=50, and w_{id2}=1. It has been perceived that, if the weight w_c is increased in the absence of identity-loss function, then spatial-distribution and structure of content-image can be protected but with a lack of style-features. However, if the weights for identity-loss function are increased, then it's possible to preserve the semantic-arrangement of content along with sustaining the style-features. Consequently, the total loss is estimated by incorporating identity-loss along with content and style losses. Adam optimizer is applied to minimize the value of loss function. The encoder uses a previously trained VGG nineteen network. Two SANET models are jointly trained and integrated by taking the VGG feature-maps as inputs and encodes output feature-maps using distinct layers Relu_4_1 and Relu_5_1. Outputs of these SANETs are combined by using the symmetric decoder. After that, the trained network of SANET models is applied to the pictures taken by us on our college campus to examine the execution time and quality of the obtained results.

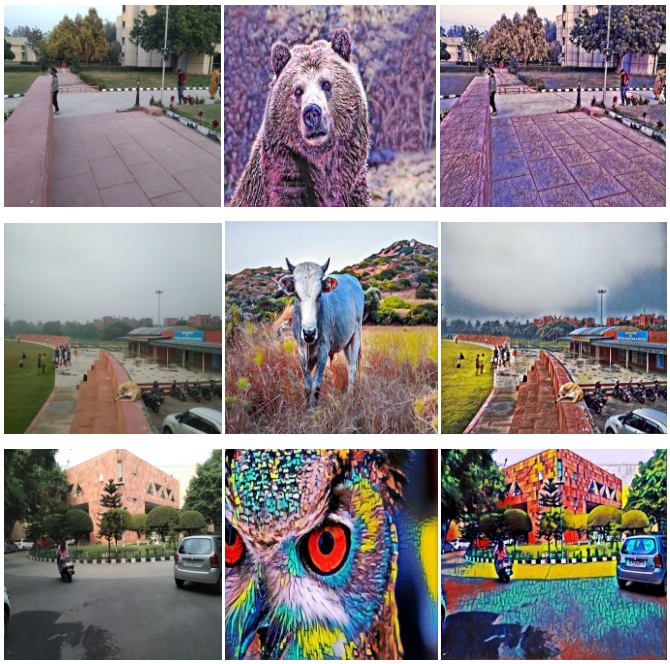

Fig.7: Experimental results of style transformation using SANET model

For determining the quality of the SANET network, its comparison is analyzed with four types of models for fusing and transforming arbitrary-styles. It is observed that AdaIN [8] is the fastest ASPM approach, but it renders a suboptimal result as it copies the channel wise mean-variance value, and the trained decoder usually attach frequently seen similar patterns and style-textures to all stylized outputs. Hence, its resulting output is less appealing and sometimes fails to retain the distribution of colors. Despite matching the second-order-statistics optimally in WCT [7], sometimes, it creates unseen and collapsed-patterns. Avatar-Net [9] blends the images based on the semantic-arrangement of content and employs multi-scale stylization. Still, because of its dependence on the patch size, it fails to realize the local and global style-patterns

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 24,2020 at 09:25:38 UTC from IEEE Xplore. Restrictions apply.

simultaneously. Seldom Avatar-Net and WCT render the blurred hair-texture and distorted vision of content due to the collapsed brush strokes. In contradiction, the network containing two integrated SANET models can generate various exquisite styles efficiently.

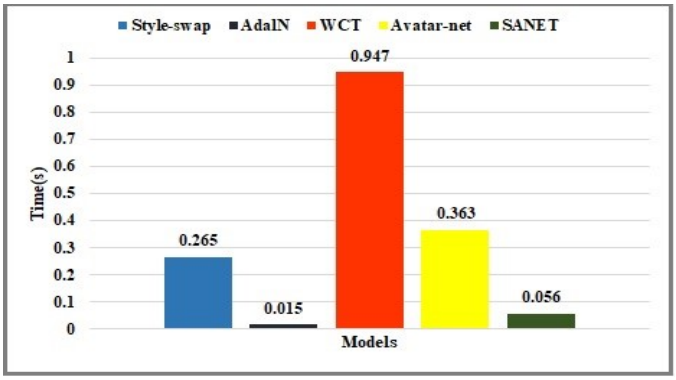

Fig.8: Comparison of execution time of SANET with other ASPM models

The graph in Fig.8 displays a comparison of the running time of SANET with other existing methods of arbitrary style transformation for images of 512×512 dimensions. SANET is much faster than style-swap, Avatar-net, and WCT models but a bit slower in comparison to AdaIN. However, the quality of the result surpasses AdaIN and others. Therefore, this method is both effective and practically efficient.

VI. CONCLUSION

This paper presents an advanced network containing a combination of two SANET Models for style fusion and transformation. This network ensures the semantic-arrangement and spatial-distribution of content-image while fusing with the characteristics of new arbitrary style-patterns by computing a new identity-loss component. The execution time of different NST algorithms are compared on input-images of distinct dimensions. It is observed that online neural models are slow but deliver better results in comparison to fast offline neural models. In all existing approaches, there is a trade-off between the quality of results and the running time of existing algorithms. Our results demonstrate that this model is much faster than other ASPM models and produces results with better quality and flexibility, which makes it much effective and practically efficient. They are planning to expand this model for the style transformation of videos in the future.

***Abstract*— Dementia is a syndrome which weakens the memory, thinking, behavior, and the ability to perform normal day-to-day activities. Although dementia mainly affects older people, it is not a part of aging. Machine Learning (ML) is considered as one of the contemporary approaches in predicting, identifying, and making decisions without having human involvement. ML is quickly evolving in the medical industry ranging from diagnosis to visualization of diseases and the study of disease transmission. The present study aims to explore the usage of the stacking of two models, namely gradient boosting machine and artificial neural network is used in the prediction of dementia and validate its performance through statistical analysis.**

Keywords*— *Machine learning, OASIS, Artificial Neural Network, Gradient Boosting Machine, Stacking, Ensemble Learning

I. INTRODUCTION

Machine learning (ML) is considered as an integral part of Artificial Intelligence (AI), also a data analysis technique that computerizes the explanatory model structure. In most scenarios, based on the learning method, two types of ML algorithms (supervised & unsupervised) were used [1]. At present, these algorithms are engaging in all the major industries like healthcare, banking, transport, social media, etc. [1] [2]. Above all, the medical industry is advancing quickly with high volumes of information and increasing difficulties in inventory and patient outcomes. Economically developed nations such as the USA, Japan, and European countries are even facing problems with the enormous collection of medical data [3]. However, by using conventional techniques, it is not possible to analyze this significant volume of information because of time consumption and efforts. Therefore, ML techniques are coming up with various algorithms and programs to avoid these issues. Besides that, the selection of a proper algorithm is not an easy task since it depends on multiple factors such as data volume, information type, and outcomes related to industry requirements [1][4].

Nowadays, Machine Learning algorithms are progressively utilized in neuro-imaging studies like a prediction of Alzheimer's disease (AD) from auxiliary MRI. Also, many studies attempted different ML strategies in predicting AD and their causes [3] [5]. In the study of AD prediction and retrieval, a multistage classifier utilizing ML, including Naive Bayes classifier, support vector machine (SVM), and K-nearest neighbor (KNN) is used to group Alzheimer's illness in the more acceptable and effective way [6]. Similarly, a study from Ref. [7], concluding that the utilization of locally linear embedding (LLE) kind of unsupervised learning is utilized to categorize AD based on fundamental MRI data. Besides, some preliminary studies with ML techniques concluded that these methods are valid and accomplish with high precision (up to 98%) in diagnosing clinical events with analysis of patient medical records [8][4].

Despite it, AD is one of the standard types of dementia and associated mostly with older people [9]. In this paper, a brief explanation is given on the prediction of dementia and calculate performance by using a Stack of two models, namely Gradient Boosting Machine and Artificial Neural Network, i.e., Ensemble Learning. Ensemble learning is a ground-breaking ML method that has shown significant advantages in numerous applications. An ensemble with regards to ML can be extensively characterized as an ML framework that is built with a lot of individual base learners as ensemble members working in parallel and whose predicted results are joined to deliver a single output for a given issue. This single output should have better performance on average than any other ensemble member with uncorrelated error on the target datasets [10].

II. LITERATURE REVIEW

The use of AI in the domain of healthcare has seen vast popularity in recent years, albeit it has a long history. In the 1970s, an expert system was designed for aiding progress in healthcare. Continuous research and development are features of this domain. Many researchers have attempted to address

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:52:38 UTC from IEEE Xplore. Restrictions apply.

this topic and a brief overview of which is presented in the forthcoming section [11].

A short survey of the related work is included in this section. Tohka et al. [12] used Alzheimer's disease Neuroimaging Initiative dataset for comparison of various feature selection techniques by using machine learning for dementia for anatomical brain MRI. SVM and Logistic Regression are used as classifiers, and then it is applied post feature selection techniques. It shows that removing age feature improves the average accuracy with all the classifiers, although the author isn't clear about the discoveries of this investigation for other brain diseases [13].

Zhang Y et al. [14] have proposed a computer-aided diagnosis (CAD) system for MRI images of brain-based on Eigenbrains. This approach generates eigenbrain images based on EEG using key slices from the 3D volumetric data from the MRI. Subsequently, Kernel SVM is included and trained by particle swarm optimization algorithm. The proposed approach was effective in AD subject prediction and discriminant brain-region detection in MRI scanning; still, some advantages and disadvantages of eigenbrain also exist, such as it achieves very high classification accuracy, which can be improved further by combining other features. However, it is essentially two-dimensional, which does not reduce the redundancy along the slice direction; also, it needs preprocessing of spatial registration, which costs a large amount of computation power.

Moradi E et al. [15] has proposed a technique for identifying mild cognitive impairment (MCI) as a transitional stage between age-related cognitive decline and AD. A novel MRI – based biomarker that was developed using machine learning strategies. Noteworthy techniques used in this model included using semi-supervised learning on data available from AD patients and performing feature selection using regularized logistic regression, removing aging effects from MRI data before classifier training to prevent possible confounding between changes due to AD and those due to standard aging, and construction of an aggregate biomarker by learning separate MRI biomarker and subsequently combining age and cognitive measures about MCI subjects by applying random forest classifier. Their aggregate biomarker achieved a very high predictive performance. However, it needs preprocessing of each MRI image, which requires 8 min per image on a high-performance system, thus costs a large amount of computation power.

III. EXPLORATORY DATA ANALYSIS

Analysis of the relationship between the various features of OASIS data explicitly through the graph is a crucial step to understand the nature of the data and eventually to develop a machine learning model. The following figures are implemented to achieve the same.

The graph illustrated in Fig.1 suggests that gender and dementia are correlated and that men are more likely to be affected by dementia than women. It also indicates that women having dementia are diagnosed late, meaning that they show symptoms a little late as compared to men.

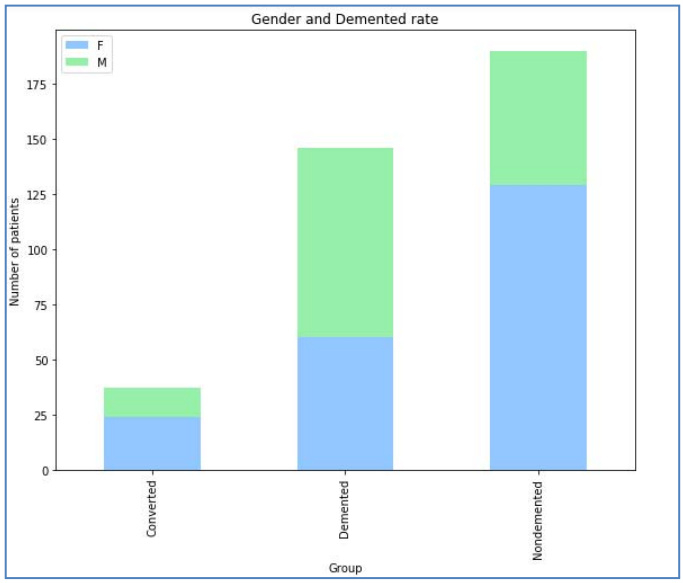

Fig. 1. Gender-wise distribution of dementia

The graph illustrated in Fig. 2 suggests that the Mini-Mental State Examination (MMSE) score of people who have dementia is lowest. In contrast, the people nondemented have high MMSE scores, and the people classified as converted have MMSE scores between those two classes.

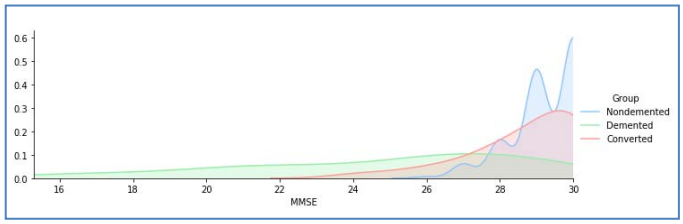

Fig. 2. Distribution of MMSE for nondemented, demented and converted Group

The graph illustrated in Fig. 3 suggests that Atlas Scaling Factor (ASF) value is higher for the converted Group than the demented Group and nondemented Group. This results in the addition of ASF in the feature set.

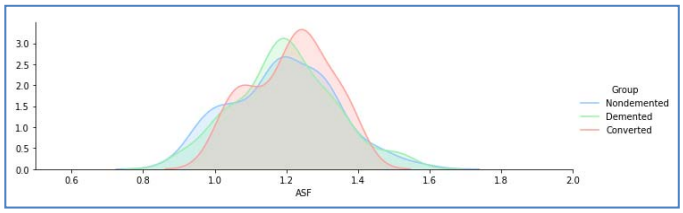

Fig. 3. Distribution of ASF for nondemented, demented and converted Group

The graph in Fig.4 proposes that the estimated Total Intracranial Volume (e-TIV) value is higher for the converted Group than the demented Group and nondemented Group. This results in the presence of e-TIV in the feature set.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:52:38 UTC from IEEE Xplore. Restrictions apply.

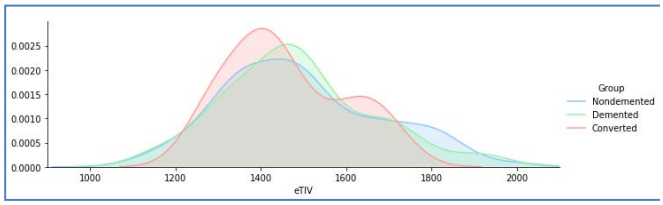

Fig. 4. Distribution of e-TIV for nondemented, demented and converted Group

The graph illustrated in Fig.5 suggests that the nondemented Group has a higher brain volume ratio than the demented and converted Group. This is assumed to be because of the dementia disease that affects the brain resulting in shrinking its tissue.

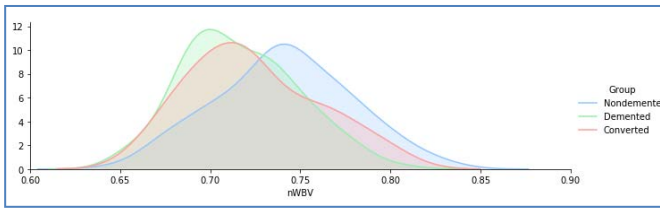

Fig. 5. Distribution of n-WBV for nondemented, demented and converted Group

The following table shows the min, max, mean, and median of the OASIS Dataset features.

TABLE I. OASIS Dataset min, max, mean, median

Feature	Min	Max	Mean	Median
MR Delay	0.0	2639.0	595.11	552.0
EDUC	6.0	23.0	14.6	15.0
SES	1.0	5.0	2.41	2.0
MMSE	4.0	30.0	27.34	29.0
CDR	0.0	2.0	0.29	0.0
eTIV	1106.0	2004.0	1488.13	1470.0
nWBV	0.64	0.84	0.73	0.73
ASF	0.88	1.587	1.19	1.19

IV. DATA COLLECTION AND PROPOSED METHODOLOGY

A. Dataset

A longitudinal collection of OASIS - MRI data set, comprising of demented and nondemented subjects with right-hand (R) type aging from 60 to 96 is considered. A sample size of 150 subjects, including men and women, have attended scanning sessions more than two visits; sessions were separated by at least one year with 373MR Sessions [16]. The sample training data included with demographic values of Subject ID, MRI ID, Group, Visit, MR delay, Sex, Age, Social Economic Status (SES), Education level (EDUC), Mini- Mental State Examination (MMSE), Clinical Dementia Ratio (CDR), estimated Total Intracranial Volume (e-TIV), normalized Whole Brain Volume (n-WBV), and Atlas Scaling Factor (ASF). In particular, some subjects treated as demented at initial visit later transformed into the nondemented managed by converted type. If CDR value is equal to zero, the subjects were considered as mostly nondemented, simultaneously if CDR ≥ 1, the subjects will face the tendency to have dementia [9].

1. *Data collection*

The trained data set collected from the Open Access Series of Imaging Studies (OASIS) included longitudinal MRI data of 150 subjects.

2. *Data Preprocessing*

Real-world data is available more likely incomplete with missing entries. Therefore, data preprocessing is one of the data mining techniques to address this issue. Missing entries were filled-up by the median of particular attribute values.

3. *Attribute Selection*

Select a specific characteristics to predict the outcome to do mapping with input correspondence values. Group column is chosen as an output variable that corresponds to the dementia status based on other input variables.

4. *Input variable matching*

The performance of any ML model largely depends on the number of input attributes taken into consideration. To maintain better performance, the selection of the corresponding attributes, instead of selecting multiple ones is important. Features such as SUBJECT_ID, MRI_ID, Visit, and Hand were removed as they were not affecting the groups in any way. Hand Feature was removed because the dataset consists of MRI of Right-handed people only.

5. *Classifier*

Three groups of dementia are considered they are, demented, nondemented, and converted.

B. Methodology

In this paper, stacking is used, which is an ensemble learning technique that involves combining multiple machine learning models to improve the machine learning results [10]. Similarly, here two machine learning models are used for the classification of Demented, Nondemented, and Converted groups, and the result of one model is added as an additional feature to the existing dataset. This new dataset is fed to the other model to train.

The two models that are used here are Gradient Boosting Machine and Artificial Neural Network. The reason for selecting Gradient Boosting Machine is because of its fast processing and iterative nature to improve from a weak classifier to a robust classifier. It is an ensemble meta-algorithm that primarily reduces bias and also variance, which is an essential criterion to analyze our models and prevent them from over-fitting [13].

Artificial neural networks are found to be effective as general nonlinear models with applications to medical diagnosis, prognosis, and survival analysis. Dementia syndrome is very complicated. The relationship between various risk factors is not dependent; thus, most of the

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:52:38 UTC from IEEE Xplore. Restrictions apply.

traditional statistical models are inapplicable. The second model ANN is chosen because of its nonlinear adaptive processing system made of a large number of artificial neurons in the right way to connect each other. The ANN can solve the problems of unambiguous and uncertain medical information more effectively and since it can monitor complex relations; therefore, ANN is selected as a second model here [4].

Our problem is a multi-class classification problem as it contains three classes Demented, Nondemented and Converted thus there are two heuristic methods for multi-class classification, they are:

1. *One-vs-Rest*
2. *One-vs-One*

Here the One-vs-Rest heuristic method is used on Gradient Boosting Machine.

Fig. 6 illustrates the idea of using three different Gradient Boosting Machine for each separate Group – nondemented, demented, and converted.

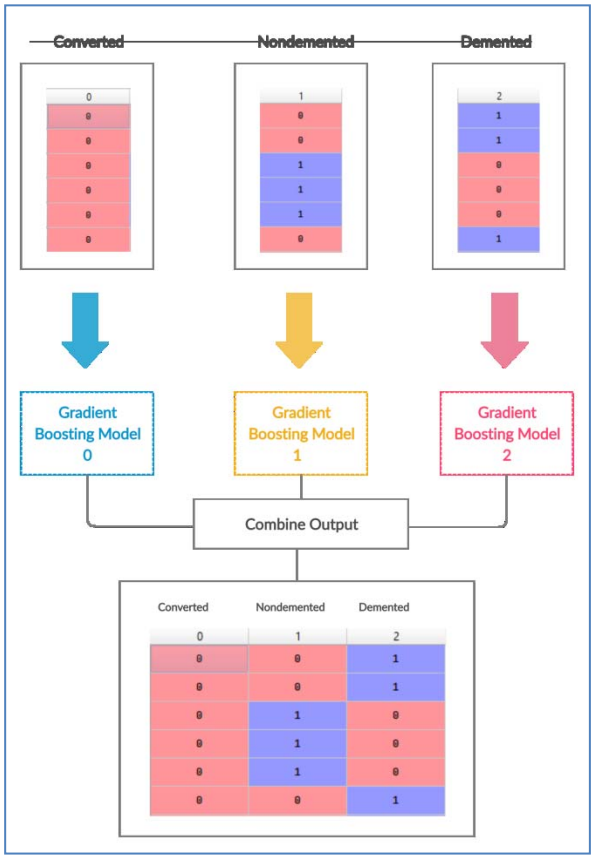

Fig. 6. Training 3 Gradient Boosting Machine

After training on the test data, these three Gradient Boosting Models predict the output for the whole dataset, and their predicted output is combined and added to the original dataset as another feature, which is later fed to the ANN Model for training and testing as illustrated in Fig.7.

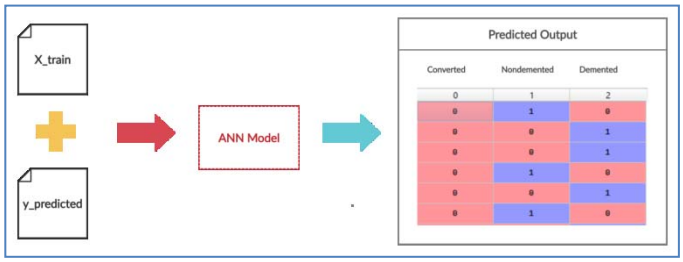

Fig. 7. Predicted Output + Original Dataset fed to ANN Model

V. RESULT

The same data is tested on the Gradient Boosting Model and ANN Model separately, and then the combined version of these two models. The following results are observed:

Fig. 10. Classification Report of Stack Model – [0, 1, 2] stands for [Converted, Demented, Nondemented]

From the above results, it is clearly observed that the ANN produced excellent results as it detects the highest number of demented and nondemented groups correctly. Still, the problem with that is its precision and recall for detecting converted Group is zero, as seen in the Classification Report of ANN Model in Fig. 9 and in the confusion matrix in TABLE III; hence this model is not appropriate to choose alone for dementia analysis. The solo Gradient Boosting Model also provides excellent results giving weighted average accuracy of 87% as seen in the Classification Report in Fig. 8 and confusion matrix in TABLE II, but it is observed that the stack model provides the highest weighted average accuracy of 89%, the best precision and recall for all the groups, as seen in its Classification Report in Fig. 10, and the confusion matrix in TABLE IV.

VI. CONCLUSION

This paper introduces a method of detecting dementia from auxiliary MRI reports and a few other features. Gradient Boosting Machine and ANN are exploited as well as their stacking with each other to achieve these tasks. The Neural Network is trained with the new dataset, including the predicted output of the Gradient Boosting Machine, produced the best results as compared to the results produced by both the models' individually.

Dementia is one of the significant health issues that has challenged health experts worldwide. Also, it mostly happened in older people with age > 60. For more than two decades, healthcare professionals are working continuously to find a method to forecast it in the earlier stages and to find a medicine that can cure. Unfortunately, yet there are no proper medicines to cure this disease completely. Many computer scientists are working along with medicinal institutions performing research activities on this disease. Still, there is an extreme need for the identification of relevant characteristics that can forecast the detection of dementia.

It tis then approached with the stacking of models for classification and prediction of dementia and achieved optimized results with efficient performance values. The future work involves the identification of a new set of attributes that can help in detecting early cognitive impairment and dementia.

Abstract

Purpose: This study aims to examine the burden of primary liver cancer in 185 countries in 2018.
Methods: The estimates of incidence, mortality and prevalence of primary liver cancer were procured from GLOBOCAN 2018. The development status of a country was measured using the human development index—a composite indicator of income per capita, education and life expectancy.
Results: Globally, primary liver cancer resulted in an estimated 781 631 deaths at age-standardized mortality rate of 8.5/100 000, and 841 080 cases were estimated to be diagnosed in 2018. Males accounted for 596 574 cases and 548 375 deaths, which is more than twice the burden of primary liver cancer in females (cases: 244 506; deaths: 233 456). The global age-standardized incidence rate was 9.3/100 000 in 2018, varying from Morocco (1.1/100 000) to Mongolia (93.7/100 000). There were remarkable variations in terms of age-standardized mortality rate, too, which ranged from 1/100 000 in Nepal to 75.4/100 000 in Mongolia. East Asia was the top region contributing 55.6% of global cases and 54.7% of global deaths.
Conclusions: Since majority of the primary liver cancer burden pertains to hepatocellular carcinoma and screening approaches are yet to be fully proven, the policy focus must be on prevention approaches through the hepatitis-B vaccine, early detection of hepatitis-C infection, reduced alcohol consumption, obesity control, reduced aflatoxin exposure and containment of other modifiable risk factors.

Key words: liver cancer, incidence, mortality, mortality-to-incidence ratio, GLOBOCAN

Introduction

Primary liver cancer (PLC) is the fourth leading cause of cancer death among all cancer groups worldwide [1], and its incidence and mortality have increased in the last three decades [2]. PLC has one of the worst 5-year survival rates among 18 cancer groups examined in Concord-3 [3]. Histologically, hepatocellular carcinoma (HCC) constitutes 70–85% of PLC, while 10–25% is intrahepatic cholangiocarcinoma (ICC) [4,5]. Hepatitis-B virus (HBV) and hepatitis-C virus (HCV) contributes around 80% of HCC across the globe [6]. Aflatoxin exposure is another significant risk factor of HCC in Africa and East Asia [7]. The main source of Aflatoxin exposure is fungi, such as Aspergillus Flavas and Aspergillus Parasiticus [8]. Apart from HBV and HCV infections, other risk factors of HCC are alcohol consumption, obesity and non-alcoholic fatty liver disease (NAFLD) [9].

Liver cancer not only exerts substantial burden in adults, it also exerts significant burden in children and adolescents; around 67–80% of pediatric PLC is hepatoblastoma and the rest 20–33% is HCC [10]. The incidence of HCC is greater than hepatoblastoma in East Asia, while the converse is true in the Western countries [11,12]. In hyperendemic countries such as China, HCC in younger children

is mostly acquired through perinatal exposures [13–15]; in contrast, in low-endemic areas, the common causes of HCC are tyrosinemia and other metabolic disorders [10].

For cancer control policy formulation and implementation at the global, regional and national levels, it is pertinent to understand the epidemiology of PLC. This study envisages to systematically examine the epidemiology of PLC in 185 countries drawing upon estimates from GLOBOCAN 2018 [1,16,17]. This study provides a comprehensive and comparable assessment of PLC burden measured in terms of all-age and age-standardized incidence, mortality and prevalence at the global, regional and national levels. Following previous literature [18–21], the mortality-to-incidence ratio (MIR) is employed as a proxy for 5-year survival rates. I also studied the PLC epidemiology, both age- and sex-wise, in the light of the socio-economic status of countries measured using the human development index (HDI, [22]). While previous studies on PLC epidemiology either focussed on select countries or regions, this is the first study providing a comprehensive assessment of PLC burden in 185 countries for one of the most recent year (2018).

Materials and methods

GLOBOCAN 2018 estimates

The estimates of incidence and mortality of PLC for 185 countries were drawn from GLOBOCAN 2018 [1,16,17]. The estimates of PLC pertained to code C22 (liver and intrahepatic bile ducts cancer) of the international classification of disease (ICD) tenth revision (ICD-10). The GLOBOCAN estimates were available in terms of age-wise and sex-wise incidence, mortality and prevalence (1-year, 3-year and 5-year) for the year 2018. All-age and age-specific incidence and death counts are reported along with 95% uncertainty intervals (UIs) inside square brackets; these UIs reflect uncertainties associated with availability and quality of data from the cancer registry, death registration and timeliness of data reporting [1,16,17].

The age-wise estimates were examined for the 16 age groups: below-15, 15 to 19, 20 to 24, 25 to 29, 30 to 34, 35 to 39, 40 to 44, 45 to 49, 50 to 54, 55 to 59, 60 to 64, 65 to 69, 70 to 74, 75 to 79, 80 to 84 and 85-plus. The PLC estimates were provided by GLOBOCAN for 185 countries in 21 world regions as defined by the United Nations Population Division (UNPD). In addition to incidence, mortality and 5-year prevalence, I also examined the global, regional and national MIR, which is employed as a proxy for 5-year survival rates. The MIRs were calculated as the ratio of all-age death counts and all-age incidence counts of the mean estimates.

Human development index

The comparative performance of countries in terms of various indicators of PLC burden was evaluated vis-à-vis a country's socio-economic status measured by its HDI [22,23]. HDI, an indicator of socio-economic status, is proposed and developed by the United Nations Development Program (UNDP). HDI has been used as an indicator of socio-economic status of countries in previous epidemiological studies too [20,21]; the advantage with this indicator is that it is a composite indicator of three indicators of development, namely, gross national income (GNI) per capita, education (composite construct of mean years of schooling and expected years of schooling) and longevity (life expectancy at birth). The UNDP rescales each of these indicators on a 0 (lowest) to 1 (highest) scale, and the geometric mean of three indicators provides the final value of the HDI as per the following formula [22].

$$\mathrm{HDI} = \sqrt[3]{\mathrm{INCOME} * \mathrm{EDUCATION} * \mathrm{LE}}$$

INCOME denotes income index; EDUCATION denotes education index; LE denotes life expectancy index. HDI values were drawn only for the year 2018, which is consistent with GLOBOCAN estimates. Based on HDI values, countries were categorized by UNDP into four groupings: low HDI (HDI < 0.550), medium HDI (0.550–0.669), high HDI (0.700–0.799) and very high HDI (>0.800).

Results

Global and regional burden

Globally, 841 080 [95% UI, 817 635–865 198] cases of PLC were estimated to be diagnosed at an age-standardized rate of 9.3/100 000 in 2018 (Table 1). The PLC resulted in an estimated 781 631 [737 605–828 285] deaths at an age-standardized rate of 8.5/100 000. Globally, the 5-year prevalence of PLC was 675 210 in 2018. East Asia was the leading region in terms of both incidence and death counts, with 467 327 [459 452–475 337] cases and 427 932 [421 450–434 514] deaths, respectively, in 2018 (Table 1). South-east Asia was the second leading region with 89 010 [83 523–94 858] cases and 88 429 [82 662–94 599] deaths in 2018. The 5-year prevalence was again the highest in East Asia (383 221), followed by South-east Asia (69 441) and South-central Asia (35 246). East Asia also had the highest age-standardized incidence rate (ASIR) of 17.7/100 000, with the lowest ASIR estimated in South-central Asia (2.5/100 000). The age-standardized mortality rate (ASMR) was again the highest in East Asia at 16/100 000, and the lowest ASMR was recorded by South-central Asia at 2.3/100 000 (Table 1).

Country-wise burden

Country-wise, China, USA and Japan were the three leading countries in terms of new cases with 392 868 [386 346–399 500], 37 948 [37 032–38 887] and 35 535 [34 731–36 358] cases, respectively, in 2018 (Supplementary Table S1). In terms of death counts too, China was the leading country with 273 014 [268 132–277 985] deaths, followed by the USA with an estimated 20 564 [19 973–21 172] deaths in 2018. Vietnam was ranked third in terms of death counts with 19 708 [17 974–21 609] deaths, which is higher than Japan (18 539 [17 987–19 108]) even though Vietnam had lesser number of new cases (25 335 [23 628–27 166]) than Japan (35 535 [34 731–36 358]). In terms of 5-year prevalence, China (296 780), Japan (43 875), USA (31 023) and South Korea (25 015) were the leading countries (Supplementary Table S1).

The top three countries in terms of ASIR were Mongolia (93.7), Egypt (32.2) and the Gambia (23.9) with Algeria (1.4), Morocco (1.1) and Nepal (1.1) recording the lowest ASIR (Fig. 1a). The ASMR mostly followed the patterns of ASIR with Mongolia (75.4), Egypt (31.8) and the Gambia (26.2) as the three leading countries and Nepal (1/100 000) had the least ASMR (Fig. 1b). At the global level, the MIR was 0.93, varying from 0.44 in Samoa to 1.6 in Iceland (Fig. 1c).

Among the countries with >100 estimates cases, I also plotted the ASIRs, ASMRs and MIRs as per HDI categories (Fig. 2a–c); this figure illustrates that where ASIR and ASMRs displayed mixed patterns as per HDI levels, in terms of MIR, however, high HDI and very high HDI countries had comparatively lower MIR than low

Incidence: all-age new cases; deaths: all-age death counts; ASIR: age-standardized incidence rate (cases per 100 000); ASMR: age-standardized mortality rate (counts per 100 000); prevalence: 5-year prevalence; MIR: mortality-to-incidence ratio. The MIR was calculated by dividing all-age death counts with all-age incidence. Data source: GLOBOCAN 2018 (IARC).

and medium HDI countries (Fig. 2c).[1] For instance, Belarus (0.67), New Zealand (0.73) and South Korea (0.73), the very high HDI countries, recorded one of the lowest MIRs. Uganda (0.86) in the low HDI category, Zambia (0.89) in medium HDI category and Libya (0.77) and Mongolia (0.79) in the high HDI category recorded the lowest MIR in their respective categories.

Sex-wise burden

Globally, males accounted for 596 574 [576 976–616 838] cases and females accounted for 244 506 [231 861–257840] cases in 2018. Male ASIR (15.5/100 000) was again higher than the female ASIR (6.5/100 000). In terms of death counts too, males accounted for nearly two-third of fatalities with 548 375 [511 583–587 813] deaths

[1] I also plotted ASIR, ASMR and MIR as per world bank country classification in low, lower-middle, upper-middle and high income countries (Supplementary Figure S1). The results were almost similar as to that of HDI (Fig. 2) classifications with few exceptions. Country classification was based on GNI per capita available at https://datahelpdesk.worldbank.org/knowledgebase/articles/906519 (accessed on 13 May, 2020).

Downloaded from https://academic.oup.com/jjco/article-abstract/doi/10.1093/jjco/hyaa130/5876941 by Delhi Technological University user on 03 August 2020

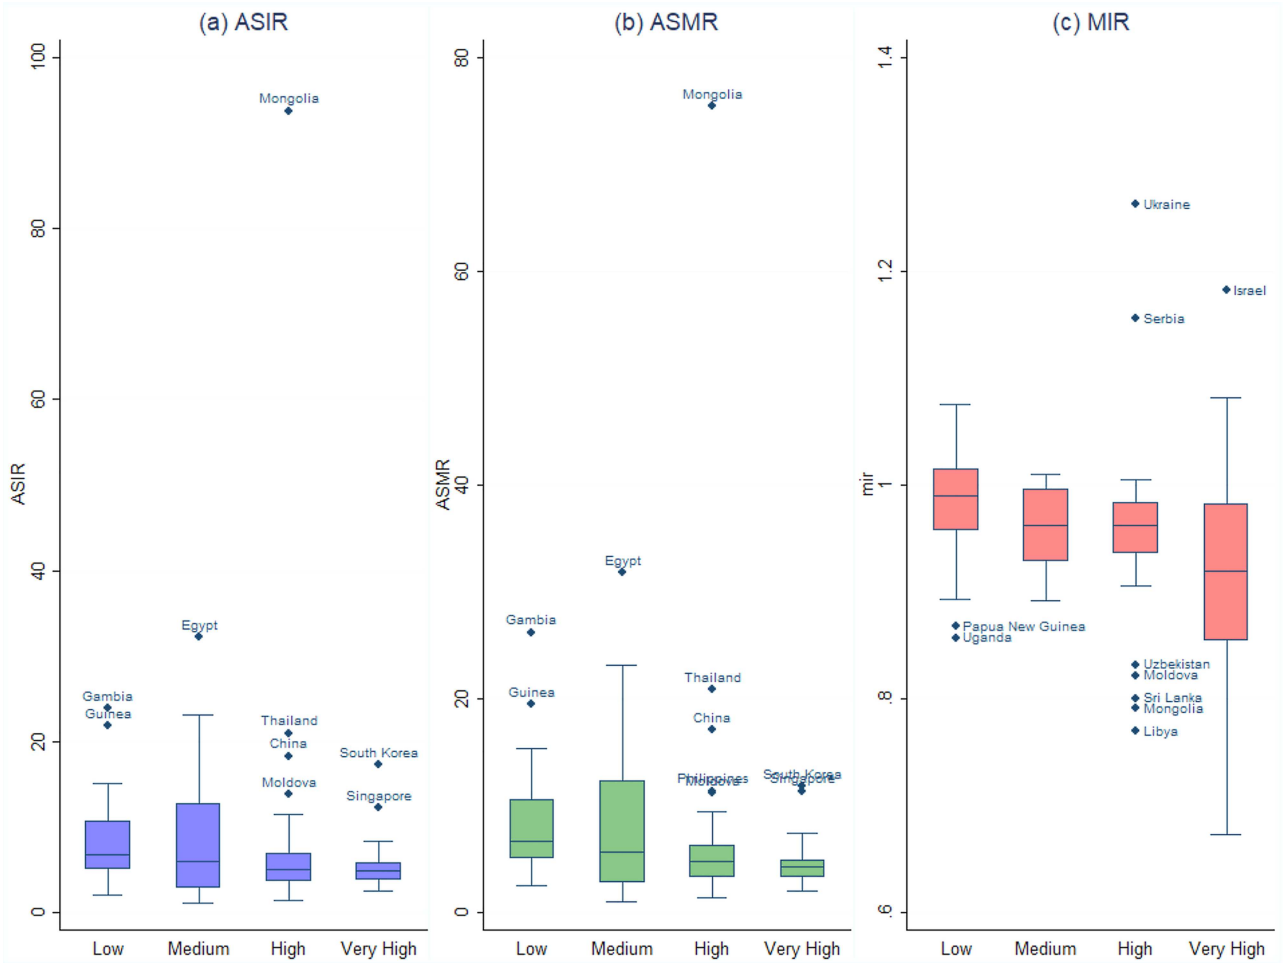

Figure 2. Boxplot of HDI category wise primary liver cancer statistics. (a) ASIR (b) ASMR (c) MIR. The MIR was calculated by dividing all-age death counts with all-age incidence. The MIR was calculated by dividing all-age death counts with all-age incidence. The countries were categorized by United Nations Development Program (UNDP) as low (HDI < 0.550), medium (0.550–0.669), high (0.700–0.799) and very high (>0.800). The estimates of liver cancer burden were drawn from GLOBOCAN 2018.

and the rest of 233 256 [209 922–259 184] deaths due to PLC occurred in females. Male ASMR (14.2/100 000) was also more than double than that of female ASMR (6.2/100 000). The male–female difference in incident cases and death counts was also preserved in regions (Fig. 3a–d). Few regions such as East Asia and South-east Asia had greater disparities in males and females, registering 3-fold difference or more between males and females (Fig. 3a–d). Similar differences were observed across regions in terms of ASIR and ASMR. Few regions in America (e.g. Central America and South America) had lesser male–female disparities in terms of counts as well as age-standardized rates (Fig. 3a–d).

Age-wise distribution

Globally, PLC incidence and deaths peaked in the 64–69 age group with a worsening ratio of death counts and cases in older age groups (Fig. 4). The age-wise distribution of incidence and mortality differed remarkably between different HDI groupings with higher incidence and mortality in older age groups for countries higher in the development spectrum (Supplementary Figure S2). For instance, in low and medium HDI categories, cases and deaths plateaued in 54–59 age groups and declined thereafter, whereas very high HDI category had maximum estimated deaths in the older-most age group (85-plus). Moreover, the low HDI group of countries had a non-negligible portion of cases and deaths in child and adolescent age groups (below the age 20); in contrast, the proportion of PLC cases and deaths in other HDI groupings was much lower in those aged below 20 (Supplementary Figure S2).[2]

Discussion

The PLC cases and deaths increased from 748 000 and 695 000, respectively, in 2008 (GLOBOCAN 2008, [24]) to 841 080 and 781 631, respectively, in 2018. The age-standardized rates underwent a reduction with ASIR falling from 10.8/100 000 in 2008 [24] to 9.8/100 000 in 2018 and the ASMR falling from 10.0/100 000 in

2 Similar results were observed when countries were categorised geographically in 21 world regions. Supplementary Figure S3 illustrates percentage of cases and deaths in four non-overlapping age groups (below-20, 20–29, 50–69 and 70-plus) in 21 world regions. It shows that nearly 30–40% of PLC cases and deaths occurred in the below-50 age groups in all regions of Africa (except North Africa); in contrast, in nearly all European regions, >90% cases and deaths occurred in above-50 age groups (Supplementary Figure S3).

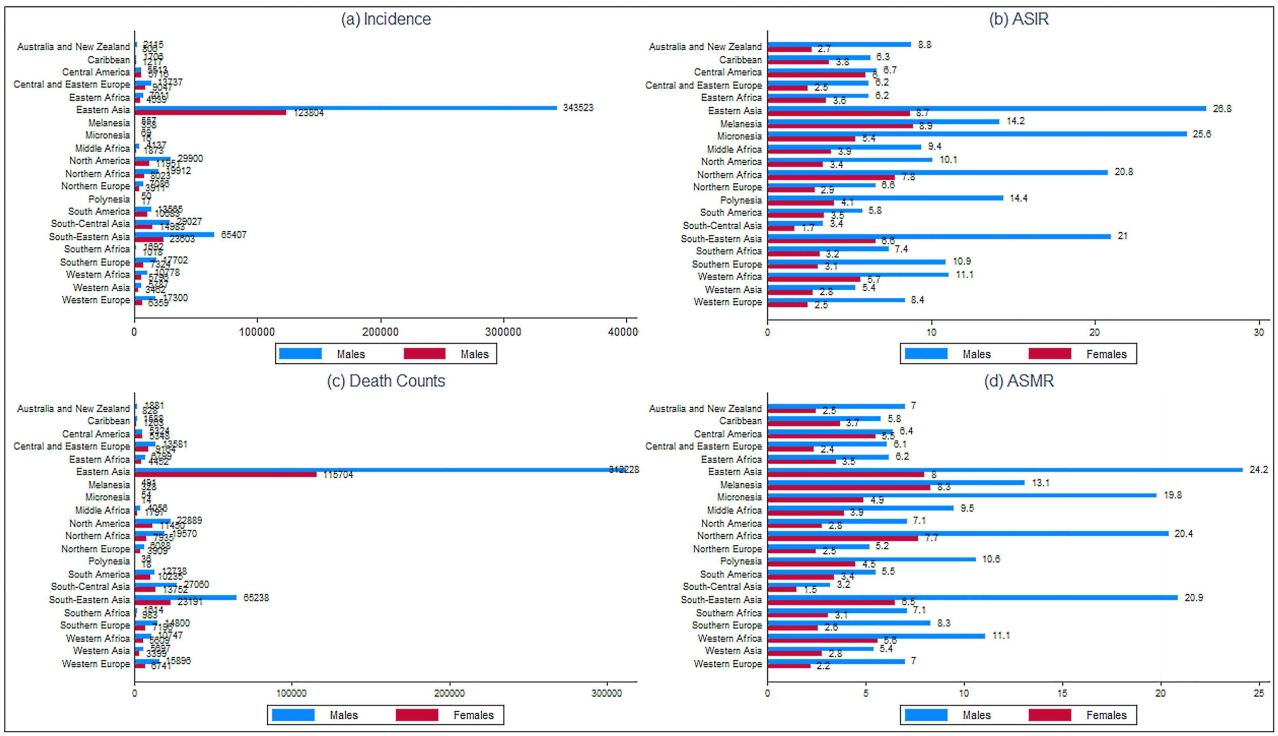

Figure 3. Sex-wise burden of primary liver cancer in 21 regions. Incidence: all-age new cases of liver cancer; deaths: all-age deaths due to liver cancer. The estimates of liver cancer burden were drawn from GLOBOCAN 2018.

2008 to 8.5/100 000 in 2018. PLC has one of the worst survival rates [3], which is also evident from very high MIR of PLC in comparison with other cancer groups. The MIR of PLC was 0.93 in 2018 as per GLOBOCAN 2018 estimates [1], which is only better than that of pancreatic cancer (0.94). In comparison, the MIR of PLC was worse than that of other frequent cancer sites: breast cancer (0.30), prostate cancer (0.28), colorectum cancer (0.48), stomach cancer (0.76) and lung cancer (0.84).[3] East Asia was the top region contributing 55.6% of global cases and 54.7% of global deaths. The age-standardized rates were again the highest in East Asian countries led by Mongolia with ASIR of 93.7/100 000 and ASMR of 75.4/100 000 in 2018.

Concord-3 [3] demonstrated that 5-year survival rates of liver cancer ranged 5–30% across countries, and the highest survival rates ranging between 20 and 29% were observed in South Korea, Singapore and Taiwan. Following previous studies [18–21], MIR was employed as the proxy for 5-year survival rates, and there were marked differences in MIR at the country level. I found that low HDI countries generally recorded high MIRs (i.e. lower 5-year survival rates) and lower MIRs (or higher 5-year survival rates) were recorded by developed countries such as South Korea, Singapore and Japan, which corroborates previous findings of higher 5-year survival rates in developed countries than the developing ones [3].

Males accounted for nearly two-third PLC cases and deaths in 2018, with several regions recording male age-standardized rates triple or more than females (Fig. 3). Such gender-wise disparities were observed in previous epidemiological studies [2] as well as in rodent HCC models, too [25,26]. The male–female differences in PLC incidence are commonly associated with anticarcinogenic effects of female sex hormones [27,28] and lower prevalence of alcohol consumption in females than males [29].

A vast majority of PLC incidence pertains to HCC arising from HBV or HCV infections with HBV infection as the dominant risk factor of HCC in South-east Asia and Africa and HCV infection identified as the leading risk factor of HCC in developed countries such as Japan [30]. HCV infection, for instance, contributes to 70% of HCC cases in Japan [31], which has decreased to 60% recently [32]. World Health Assembly held in May 2016 endorsed Global Health sector strategy 2016–21, which calls for the elimination of viral hepatitis, 96% of which comprises of HBV and HCV, as public health target by 2030 through reduction of new infections by 90% and associated mortality by 65% [33]. Due to increased HBV vaccination coverage, HBV prevalence has decreased across the world in percentage terms over 1990–2005, yet the number of HBsAg positive persons has increased from 223 million to 240 million with high endemicity in Sub-Saharan Africa [34].

Regarding the HCC burden due to HCV infection, the development of direct-acting antiviral drugs (DAAs) has significantly boosted the treatment paradigm of HCV infections [35]. The DAAs, taken orally, target specific proteins, and improves sustained virologic response rate (SVR) to >90% and ~100% in a few instances [35,36]. These DAAs hold enormous potential in developing countries such as India, where HCV treatment rates are low [37]. Moreover, the low-cost generic versions of DAAs make these cost-effective in developing countries such as India [38].

Diabetes mellitus [39,40] and obesity [41] are other identified risk factors of PLC. Obesity and diabetes are not only associated with HCC but are associated with increased risk of ICC, too [42]. The

[3] The MIR for different cancer groups is calculated by the author using GLOBOCAN 2018 estimates [1,16,17].

Downloaded from https://academic.oup.com/jjco/article-abstract/doi/10.1093/jjco/hyaa130/5876941 by Delhi Technological University user on 03 August 2020

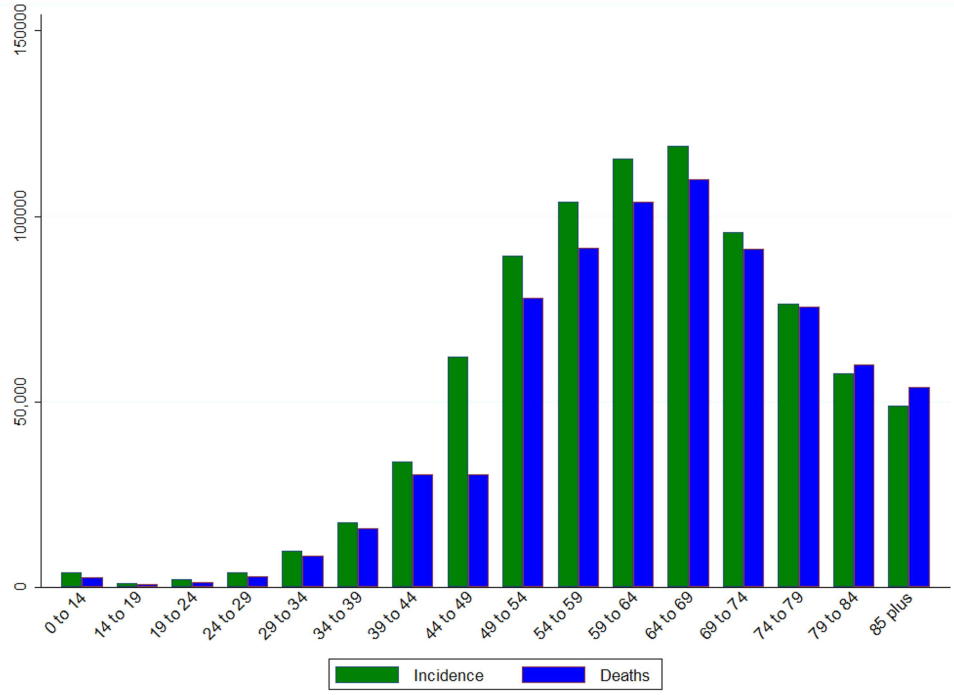

Figure 4. Age-group wise distribution of incidence and mortality of primary liver cancer in 2018. Incidence: new cases; deaths: deaths due to liver cancer. The estimates of liver cancer were drawn from GLOBOCAN 2018.

unabated incidence and prevalence of diabetes mellitus is expected to further result in an increasing burden of chronic liver diseases, including PLC worldwide [43]. In addition to HBV and HCV, the incidence of NAFLD related to HCC has been increasing worldwide, with prevalence varying from 6 to 35% in different countries [44,45].

Moreover, NAFLD has been identified as the fastest-growing cause of cancer-related deaths [46]. The prevalence of NAFLD has increased in parts of East Asia, USA, Europe and Australia [47]. Although the focus on HBV infection and vaccination is expected to result in the downward trend of HCC in Asia, the increasing trend of other risk factors such as obesity, diabetes mellitus and NAFLD is expected to negate the gains from HBV vaccination [31].

China is the leading country in terms of both incidence and death counts. Although China has employed tremendous efforts to shed its leadership position in liver diseases through disease prevention, diagnosis, management and therapeutics [48], still, China was ranked first as per GLOBOCAN 2018 estimates contributing 46.7% cases and 34.9% deaths in 2018. HBV vaccination is fully embedded into the neonatal immunization program in China since 2002 [49]. Despite expanded access to HBV vaccine in China, 20% of children aged below 5 years, and 40% of those aged 5–19 remain unprotected from HBV infection [50]. As described earlier, China may have worked tremendously for expanded access to HBV vaccination; the growth of other risk factors such as obesity may contribute to a greater burden in the future. For instance, China experienced a 414% increase in overweight and obesity between 1982 and 2002 [51].

In several low and medium HDI countries, PLC exerted a significant burden in child and adolescent age groups (Supplementary Figure S2). Pediatric HCC is different from adult HCC in a few key aspects [52,53]. For instance, in adults, HCC arises along with prolonged chronic hepatitis and cirrhosis [54]; in children and adolescents, however, HBV infection is acquired perinatally or due to inherited metabolic disorders [55,56]. Moreover, HCC in children and adolescents is more advanced than in adults [57]. Thus, screening of children whose mothers are HBV carriers is essential in the early detection of pediatric HCC [58].

As far as early screening and detection of liver cancer in adults is concerned, few approaches using ultrasonography, α-fetoprotein (AFP) levels in serum, and surveillance of cirrhosis patients have been considered. The American Association for liver diseases (AASLD) in 2005 issued level 1 recommendation for screening of liver cancer using ultrasonography at six-month intervals for high-risk patients [59]. The AASLD's recommendation, however, was based on a randomized control trial (RCT) conducted in China that demonstrated mortality-reduction benefits of liver cancer screening in the treatment group [60]. The reported benefits of screening, however, were put into question [61]. Currently, major US agencies, which provide recommendations on cancer screening, do not endorse standard or routine screening for liver cancer, as is the case with mammographic screening for breast cancer and colonoscopy for colorectal cancer.[4]

Although, screening for liver cancer hasn't been recommended, United States Preventive Services Task Force (USPSTF) recommends screening for HCV infection in adults aged 20–79 years [64]. It was done due to two reasons. First, there is a sharp spurt in HCV infection in young adults aged 20–39 years in the USA, which coincides with

[4] United States Preventive Services Task Force (USPSTF) has not recommended for liver cancer screening; the American cancer society found no convincing evidence for screening recommendation of PLC [62]; the national cancer institute (NCI) found no convincing beneficial effects of PLC screening [63].

Downloaded from https://academic.oup.com/jjco/article-abstract/doi/10.1093/jjco/hyaa130/5876941 by Delhi Technological University user on 03 August 2020

nation-wide surge in the rate of injection drug use [65]; second, nearly half of HCV patients are unaware of the disease; thereby leading to late diagnosis, which results in life-threatening complications such as cirrhosis and HCC [66].

In summary, apart from worse survival rates, the PLC epidemiology is profoundly different from other frequent cancer groups in a few key aspects. First, geographically other cancer groups such as breast cancer [21], colorectal cancer [67] and stomach cancer [68] are quite dispersed across the world; the PLC, however, is highly concentrated in Asia. Second, while screening modalities are available for breast cancer, colorectal cancer and prostate cancer [20,21,67], there are less-than-ideal or proven screening modalities available for early screening and detection of PLC. Third, a non-negligible number of cases and deaths occurred due to liver cancer in children and adolescents, which is quite different from other frequent cancer groups such as prostate cancer [20], breast cancer [21] and colorectal cancer [67], which predominantly affect comparatively older age groups.

Limitations

There are two limitations of the study. First, the reliability of GLOBOCAN estimates crucially depends upon data availability from population-based cancer registries (PBCRs). In several low- and medium-income countries, however, either PBCRs are not available or lack sufficient coverage. In the absence of reliable and high-quality data from PBCRs, the GLOBOCAN estimates draw strength from data available either from regional registries or from neighbouring countries; the estimates reported and examined in this paper, therefore, are expected to be biased. Second, I employed HDI as an indicator of socio-economic status of a country, which is one of the widely employed indicators of socio-economic status of a country. For a set of countries, with data unavailability, the incidence to mortality ratios (method 3a of incidence) and MIRs (method 3 of mortality) were scaled as per HDI of countries and HDI of respective regions [16].[5] The general patterns of results, however, were similar if GNI per capita was considered as the indicator of development.

Conclusions

In the absence of proven screening devices for PLC, primary prevention through containment of risk factors seems to be the apt choice as a large percentage of PLC cases can be prevented through HBV vaccination, containment of alcohol consumption and obesity control. A large portion of PLC is HCC, and there exists proven vaccination against HBV; it is time to identify high-risk areas and scale up the vaccination in high-risk adults who would have missed the compulsory doses of the HBV vaccine. Moreover, as effective treatment of HCV infection is available through DAAs, early detection of HCV infection must be ensured to prevent HCV-induced sequelae such as cirrhosis and HCC. Lastly, policy makers must keep a strict vigil on the increasing prevalence of risk factors such as NAFLD, obesity and diabetes, which can reverse the gains achieved through HBV vaccination and DAA treatment regimens.

[5] As per Ferlay et al [16], the formula of estimation of such countries is modified as below.Method 3b: $I_{\text{National}} = M_{\text{National}} * \left(\frac{I_{\text{Regional}}}{M_{\text{Regional}}}\right) * \left(\frac{\text{HDI}_{\text{National}}}{\text{HDI}_{\text{Regional}}}\right)$
Method 3: $M_{\text{National}} = I_{\text{National}} * \left(\frac{M_{\text{Regional}}}{I_{\text{Regional}}}\right) * \left(\frac{\text{HDI}_{\text{Regional}}}{\text{HDI}_{\text{National}}}\right)$

***Abstract*— Technology has become the backbone of today's Information and Communication Technology. Today a large number of transactions are carried out online and thus possess a risk of information stealing and misuse. Intrusion Detection techniques are thus developed and applied to the networks and individual host computers to detect such intrusive actions and alarm the administrators. A secure machine-controlled anomaly detection system is a more practical procedure to help in network analysis. An anomaly detection system (ADS) examine the network flow and focuses on detecting uncommon network behaviour, and classify them into attacks. The propsoed research work present a comparison of some of these intrusion detection techniques using different machine learning algorithms and ensemble learning. A subset of attributes (significant) is chosen from the primitive set of attributes using a random forest regressor technique, and then, the chosen set of significant features is used to train different classifiers. Moreover, the proposed work has been analyzed by experimenting on one of the publically available dataset CICIDS2017, available from the Canadian University of Cybersecurity.**

***Keywords*— Classification, anomaly detection system (ADS), CICIDS2017, machine learning.**

I. INTRODUCTION

Established institutions and ample folks communicate with one another over the internet every day. Within the past twenty years, where the number of individuals using the net services has been hyperbolic. Today this range has exceeded four billion and is increasing exponentially. Moreover, any business, government enterprise, or industry relies heavily on technology to conduct their day to day activities, transactions, or communicate. The data today is not restricted to have a physical presence, the e-money, photos, texts, id passwords, videos, and many more forms of virtual or online data also exists. And there is a need to preserve and safeguard this online data. There is an improvement in infrastructures and the protocols of the wireless devices and IoT applications. Online services and networks are often used for communicating and exchanging sensitive information. Attackers often peep into these networks and get access to sensitive and confidential information which suggests the requirement for some mechanism to detect such actions and then alert the authorities about the same.

The recent COVID-19 outbreak further forced the world to adopt the concept of work from home to keep their services and businesses running, and this remote working mechanism comes with a whole new and wider dimension of internet and network security, with making their networks more vulnerable to cyber-attacks. With the remote working concept, a greater amount of sensitive and confidential information has to be shared via the network, which brings dozens of opportunities for the hackers and the intruders to steal this sensitive information and data. Mobile office and work from home concept allow the employees, who are authorized to access the corporate network and have to share sensitive information over the mobile or computer networks.

Every aspect of cybersecurity reviles around the CIA triad. The C here stands for confidentiality, which means keeping the data hidden from unwanted access. I stand for integrity means keeping the data unaltered throughout the transmission process. The sent and received data over the net should be the same. Finally, the A stands for availability, meaning the data should be available to the intended use when required. And security aspects enforces us to be ready with backups whenever the data is lost or is delayed. There are some major network attacks:

- DNS cache poisoning attack, it tricks the DNS

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:59:53 UTC from IEEE Xplore. Restrictions apply.

servers and makes it accept a fake DNS address of the corresponding IP address of the requested legitimate websites. This attack is primarily used for malicious banking credential stealing.

- Another major network attack is the man-in-the-middle attack. An intruder places itself between two hosts, who think that they are directly communicating with each other but the communication is happening between the middle attacker with each of the two hosts simultaneously. This attack has the potential to access and modify the information passing to and fro the network and hence compromising the CIA triad principles.
- Denial of service attack challenges the availability principle of security goals. The hosts or the severs are overwhelmed by bombarding them with huge unnecessary requests, which results in the crashing of the systems and making legitimate users starve for accessing the required resources. This may delay the entire service of an enterprise and severely affect the time-bound services, which can cause slow network performance. The DoS attack may also be made in a distributed fashion and is known as distributed denial of service attack, where a combined network of physically separate machines are used to overwhelm the server with the request.

It is a challenge for the researchers to develop efficient algorithms to detect such types of network attacks before harm is caused to the victim organization. For this purpose, some benchmarking datasets are required to evaluate the developed algorithms and techniques.

In this paper, some tasks are implemented for detecting an anomaly in networks by making use of effective machine learning techniques. Also, for evaluating the most useful features or attributes and consider them for further study, a random forest regressor algorithm is used during pre-processing.

The rest of the research paper is structured into various sections. The related work that has been done in the field of anomaly detection is highlighted in section 2. Section 3 presents the background details regarding the dataset and algorithms used for our study. Section 4 consists of the details of the pre-processing stage and the experimental setup. Section 5 then compares the results of various algorithms and analyses them. Section 6 concludes our work and Section 7 presents the scope for future work.

II. RELATED WORK

For anomaly detection in networks by machine learning techniques, a large quantity of harmful and harmless network traffic data is required for training and testing steps, However, real-time network traffic can't be used in public due to security problems [1] and thus to develop efficient intrusion detection systems, several datasets have been simulated in almost real environments. DARPA 98, KDD 99, CAIDA (Centre of Applied Internet Data Analysis), NSL-KDD, ISXC 2012 and, CICIDS 2017 are various datasets for network anomaly detection. The initially available datasets were DARPA dataset [2], which was made publically available in 1998, and several improvements were made to it after that."Contests were organized in the initial years for introducing effective new techniques for intrusion detection. With all the advancements and new emerging attacks, there was a need for more comprehensive, balanced, up to date and perfect datasets" [3]–[4]. Recently, the Canadian University of Cybersecurity launched a new dataset, containing novel attacks. This dataset is named as CICIDS-2017. Moreover, this dataset also incorporates all the 11 criteria of a good dataset, as suggested by the authors of [8].

For anomaly detection, these datasets are used as a benchmark in performance evaluation. There is no single "Fit-For-All" algorithm for detecting various attacks differing enormously based on their source, target, and mode of application. The anomaly detection systems are often classified based on the type of environment in which they are deployed as "Host Anomaly Detection Systems" and "Network Anomaly Detection Systems" [6]. The proposed work aim to detect attacks by finding anomalies in the "Network Anomaly Detection Systems" in this paper. Another classification of ADS can be based on techniques employed in implementing them. There are mainly two categories: "Signature-based ADS" and "Anomaly-based ADS". Signature-based ADS were prevalent in real-world applications since the last decade. But due to their inability to detect zero-day attacks, they are replaced by anomaly-based ADS. Signature-based ADS were based on concepts like string matching, regular expressions, and finite state machines [7].

III. BACKGROUND

A. Network Intrusion Detection System

The network of computers was first secured by Network Hardening Principle. Network hardening refers to the process of securing networks by making configuration changes to reduce vulnerabilities. But these changes are often a burden on the administration and hence other mechanisms were evaluated. One such mechanism evolved was of firewall, where one can disable and filter the unnecessary services and restrict access to them. This was achieved but creating manual rules for traffic, similar to the white-listing process. This came with its challenge of adding or deleting new rules, every time some new service was desired to work or restrict and thus causing inconvenience for the administrators.

All these challenges were resolved with the advancement in the field of artificial intelligence. Machine learning concepts

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:59:53 UTC from IEEE Xplore. Restrictions apply.

provided an important and efficient way to monitor and analyze the traffic flowing across the networks. These techniques let us make a baseline of what our normal network traffic looks like and then any deviation from this baseline can be treated as an anomaly and users can be alarmed regarding the suspicious network traffic presence. The requirements for these anomaly detection systems are :

- an architecture to collect and extract the traffic data,
- a good dataset schema to store the data along with its attributes, and
- efficient algorithms to analyze this stored data to deduce outliers and intrusions from it.

Today most of the systems employ more efficient and effective anomaly-based systems using the machine learning algorithms which can generalize the type of attacks from real-time network traffic. Machine learning algorithms generally consists of two phases – the "learning phase" and the "inference phase" [8]. The learning phase enables us to build the network traffic profile, which generalizes the benign and normal traffic passing through the network. During the inference phase, any abnormal behaviour is treated as an anomaly and indicates the presence of attack, and the system administrators are alerted about the same.

For anomaly detection in networks by machine learning techniques, a large quantity of harmful and harmless network traffic data is required for training and testing steps. The anomaly detection-based approach focuses on detecting uncommon network behaviour by examining network flow. This anomaly detection technique has been booming in detecting attacks that's not encountered yet, thus it is effective against zero-day attacks.
There are various difficulties in the implementation of NIDS:

- First, the detection rate (DR) is needed to be enhanced and False Prediction Rate should be reduced.
- Second, extracting, recording, and selecting the important features is a very crucial process as the classifier's performance is completely dependent on the choice of input features. Hence, a dataset with good quality and quantity of features is desired.
- Third, unbalanced and skewed datasets can become a significant hurdle in the wholesome analysis of the performance of proposed algorithms, and results may be skewed. Therefore, the dataset must be well balanced and contain records for all attacks and labels in the right prevalence ratio.

B. Description of CICIDS 2017 Dataset

At the University of New Brunswick, the Canadian Institute for Cybersecurity created CICIDS2017 [9]. This dataset consists of a 5-day (3rd July- 7th July 2017) data stream on a network created by computers having up-to-date operating systems like Windows7 / 8.1 / 10, Ubuntu 12/16, Kali and Mac. DoS (Denial of Service) HULK, DDoS (Distributed DoS), FTP-Patator, DoS Slowloris, SSH-Patator, DoS SlowHTTPTest, DoS Goldeneye, Botnet, PortScan, Web Attack, Infiltration, Heartbleed are various types of attacks present in the datasets available. The 2017 CICIDS dataset has the subsequent benefits over other datasets:

- The obtained information is the real-world data; obtained from a testbed consisting of real computers.
- Data streams are collected from computer systems with the up-to-date operating system. There's operating system diversity (Windows, Linux, and Mac) between each victim computer.
- Datasets are labeled. To apply the machine learning techniques, feature extraction, which is an important step, was applied and 85 features (see Appendix A for the feature list) were obtained.
- Both raw information (pcap files - captured network packets files) and processed data (CSV files- comma-separated data files) are out there to work on.
- In the course of deciding which attack to take place, the 2016 McAfee security report was used, therefore there's a large and up-to-date assortment of attacks.
- It is more abundant than other datasets regarding protocols used. It conjointly includes the HTTPS (Hypertext Transfer Protocol Secure) protocol additionally to FTP, HTTP, SSH, and e-mail protocols.

On the other hand, CICIDS2017 dataset has subsequent disadvantages:

- Raw data files and processed data files are giant (97.9 GB and 1147.3 MB respectively).
- Unlike the KDD99 and NSL-KDD datasets, CICIDS2017 doesn't have separate files dedicated to training and testing. These sections ought to be created by users. The way to do that is handled within the creation of the training and testing section.
- The formation of DARPA98, KDD99 then NSL-KDD is analogous to an evolutionary process. At every step, faults and deficiencies within the previous dataset have been discovered, and measures were taken to forestall them. On the other hand, CICIDS 2017 is incredibly new and has not been studied much yet, therefore it's possible to contain some minor mistakes. What these mistakes are and the way to repair them is processed within the Data Pre-processing section.

Dataset is divided into a training dataset and a testing dataset. 80% of original dataset instances are selected randomly and referred to as a training dataset and the remaining instances are referred to as testing datasets.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:59:53 UTC from IEEE Xplore. Restrictions apply.

C. Random Forest As Feature Selection Technique

Random forest works on the concept of the fair election as result is based on the prediction of several independent decision trees and a group of decision trees having the same prediction will outperform individual decision trees. It uses a random subset of a given dataset and a random subset of features for creating an individual decision tree so that individual decision tree has little amount of correlation with each other.

To ensure that individual decision tree has little amount of correlation with each other random forest uses the following two methods:

- Bagging (Bootstrap Aggregation) – Decision trees are very sensitive to changes in the dataset. The random forest takes advantage of this property of decision trees and allows every individual decision tree to select a subset of the dataset from the available dataset in a random way. This results in independent and different decision trees. This process of allowing random selection of data is known as bagging.
- Randomness in feature – When a node is splitted in a decision tree, every possible feature is used to select the path to be taken in the process of making predictions. In contrast, random forest allows every individual decision tree to select a subset of features from the available feature list in a random way. This results in even more variations among the different decision trees and lower correlation across trees and tress become more independent from each other.

For feature selection, random forest technique assigns weight to different features according to how much a particular feature reduces the accuracy in the classification of the individual decision tree. Dependent variables have a low weight assigned as the Random forest technique ensures that there is a little amount of correlation between individual decision trees.

D. Ensemble Learning

The ensemble method's goal is to mix the prediction results of multiple learning algorithms. Many base classifiers/regressors designed and trained a different learning algorithm for better predictions than individual learning models. Ensemble Methods are divided into two groups

- Sequential ensemble methods – Here base learners are geerated sequentially. The dependence of base learners on each other is exploited here. AdaBoost is a suitable example.
- Parallel ensemble methods – Here base learners are generated parallely. The independence of the base learners is used here. Random Forest is an example.

The concept behind the ensemble classifier is to mix different machine learning algorithms and based on majority vote also called hard voting or the average prediction chances also called soft voting to make predictions. Such a classifier is often useful for a group of equally well-performing classifier/regressor to balance out their weaknesses. In the majority vote, the output for a selected sample is that category label that represents the bulk of the category labels classified by each regressor/classifier. e.g. Different predictions for a given sample (To classify whether the given image is of a hot dog or not).

- model 1 -> yes
- model 2 -> yes
- model 3 -> no

then using the ensemble learning model will predict "yes" based on the majority class prediction. Soft vote predicts the category label as an average of the sum of predicted probabilities. Specific weights are often assigned to each classifier/regressor through the weight parameter. Once weights are assigned, the expected class label probabilities for each classifier/regressor are collected, multiplied by the allotted classifier's weight, and averaged. The final class label is then predicted from the individual category label with the best average likelihood.

IV. EXPERIMENTS

A. Data pre-processing

Various techniques for data pre-processing are performed on the dataset downloaded from the official CICIDS2017 website [10]. Dataset is pre-processed to get rid of the mistakes and defects present. It's necessary to pre-process the dataset before training and testing. For this, some defects within the CICIDS2017 dataset are processed and corrected. One major is the class imbalance problem [12], which is corrected by following the pre-processing stage.

The dataset contains 3119345 records, collected, and analyzed using CICFlowMeter [11]. Once the records are examined, it is seen that around 2.5 lacks records are incomplete or incorrect. The primary step is to delete the surplus records. The next error within the dataset is within the columns that form up the features. The dataset contains 86 columns that define the properties e.g. Flow ID, Source IP, Source Port, etc. The Fwd Header Length feature (which tells about the forward direction data flow for total bytes used) was repeated two times one in the 41st column and second time in the 62nd column. This error is removed by deleting the repeating columns. Table 1 contains the description of the dataset.

Another editing that needs to be done in the dataset is to convert the value of the features including string and categorical values (Flow ID, Source IP, Timestamp, External IP, Destination IP) into numerical data to be easily understandable by different machine learning algorithms. This

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:59:53 UTC from IEEE Xplore. Restrictions apply.

is often be done using LabelEncoder() function provided by the Sklearn package. In this way, all string values that don't seem to be understandable by machine learning operations can get integer values and become more efficient for further processing. The "Label" tagged column is also modified, if there is an attack then it's value will be 1 and if there is no attack then it's value will be 0. Finally, some structural changes are done to the dataset, including:

- In the Label feature, the character "–" (Unicode Decimal Code &#8211) used to identify the web attack subtypes (Brute Force and SQL Injection) should get replaced with the character "-" (Unicode Decimal Code &#45), as utf-8, the default Pandas library, won't recognize it. Otherwise, the Pandas library won't recognize this character and can fail.
- "Flow Bytes/s", "Flow Packets/s" features have valued to like "Infinity" and "NaN" with numerical values, that are changed to -1 and 0 respectively to make them efficient for various machine learning algorithms.

Table 1. Description of CICIDS2017 Dataset

Recording Day	pcap file size (GB)	Recording Hours	CSV file size (MB)	Attack
Mon	10.0	Full Day	257	-
Tues	10.0	Full Day	166	SSH-Patator, FTP-Patator
Wed	12.0	Full Day	272	DoS Hulk, GoldenEye, Slowloris, Slowhttptest, Heartbleed
Thurs	7.7	Morning	88	Web Attacks
		Afternoon	103	Infiltration
Fri	8.2	Morning	72	Bot
		Afternoon	190	PortScan, DDos

B. Experimental Setup

The technical specifications of the computer used in the implementation:

- CPU: "Intel(R) Core (TM) i5-7200U CPU @ 2.70GHz"
- RAM: 8 GB
- OS: "Windows 10 Pro 64-bit"
- GPU: "Nvidia 940 mx 8gb ddr4"

Jupyter-Notebook 5.7.8 on Anaconda 2019.03 with Python 3.7.3 is used for implementing data pre-processing steps and various machine learning algorithms. Various python libraries are used: pandas, matplotlib, and sklearn. The preprocessed training data set having optimal features yielded by the pre-processing stage are used for the comparison of various machine learning classifiers, with the ensemble learning approach. Machine learning classifiers and ensemble learning classifiers are trained for 1000 epochs.

C. Performance Measures

The results of the algorithms are evaluated and compared according to four measures i.e. accuracy, recall, precision, and F1-Score. These measures have a value between 0 and 1. If the value is close to 1, then the performance of the algorithm used increases, and if the value is close to 0, then it decreases.

- Accuracy – The ratio of correctly predicted instances to a total number of instances in the dataset.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (1)$$

- Recall (Sensitivity) – The ratio of instances predicted as an attack to all the instances corresponding to attacks.

$$Recall(Sensitivity) = \frac{TP}{TP + FN} \quad (2)$$

- Precision – The ratio of correctly predicted data instances as an attack to all data instances predicted as an attack.

$$Precision = \frac{TP}{TP + FP} \quad (3)$$

- F-measure (F-score/F1-score) – The harmonic-mean of recall/sensitivity and precision. This measure is the most important. Hence, more focus is given on F-measure.

$$F1 - Score = \frac{2 * (Sensitivity) * (Recall)}{Sensitivity + Recall} \quad (4)$$

Where,
TP: Actual attack data predicted as an attack.
FP: Actual no-attack data predicted as an attack.
FN: Actual attack data predicted as no-attack.
TN: Actual no-attack data predicted as no-attack.

V. RESULTS AND DISCUSSION

In this section, the results of the study carried out are presented. The performance evaluation criterion is based on the values of the F1-measure. Histograms are created to visualize the comparison between different features and different machine learning algorithms. A random forest regressor [13] is used for necessary feature selection. First, a simple principal component analysis (PCA) is used for feature selection, but PCA is not efficient when there is an enormous amount of feature in the dataset. The below figure shows the importance of various features.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:59:53 UTC from IEEE Xplore. Restrictions apply.

Table 2. Important features with importance weights computed using random forest [9]

FEATURES	IMPORTANCE WEIGHT ($*10^{(-5)}$)
Standard Backward Packet Length	24656
Flow Byte/s	17876
Forward Packets Total Length	11721
Standard Forward Packet Length	6389
Standard IAT	1017
Minimum IAT	658
Total IAT	499
Flow Duration	413
Maximum Flow IAT	354
Maximum Backward Packet Length	339
Mean IAT	329
Backward Packets Total Length	135
Minimum Forward Packet Length	63
Flow Packet/s	58
Mean Backward Packet Length	53
Mean Forward Packet Length	51
Total Backward Packet/s	23
Total Forward Packet/s	13
Maximum Forward Packet Length	12
Minimum Backward Packet Length	8

Table 2 exhibits the importance weight of the top 20 important features computed using random forest after data pre-processing.

Four machine learning algorithms, ID3 (Decision Tree), MLP, ensemble learning, and Naïve Bayes, are used and compare them on the premise of various performance evaluation criterion i.e. precision, recall, accuracy, and F1-Score. Table 3 exhibits the value of precision, recall, accuracy, and F1-Score of various algorithms. The resulted performance based on F1-measure is as follows (F1-measure takes a value between 0 and 1): Ensemble Learning (NB, ID3 and, MLP): 0.89, ID3: 0.95, MLP: 0.84 and Naive Bayes: 0.82.

Table 3. Performance evaluation data for different algorithms

"ML Algorithm"	Precision	Recall	Accuracy	F1-Score
Naïve Bayes	0.82	0.82	0.8165	0.82
ID3	**0.95**	**0.95**	**0.9515**	**0.95**
Ensemble Learning	0.89	0.89	0.891	0.89
MLP	0.84	0.84	0.8387	0.84

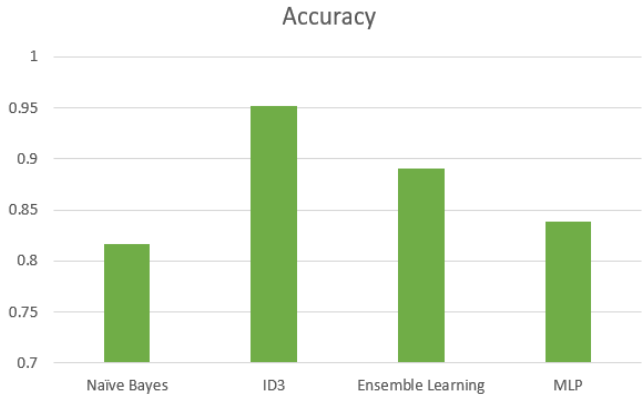

Fig. 1. Comparing Accuracy Parameter of Algorithms

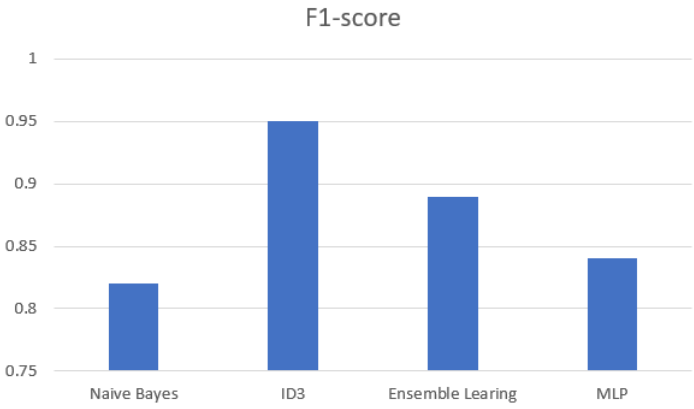

Fig. 2. Comparing F1 score of Algorithms

Fig. 1 and fig. 2 exhibit the accuracy comparison and F1-Score comparison respectively that are obtained after applying various machine learning algorithms. It is evident from fig. 1 and fig. 2 that ID3 and Ensemble Learning perform best out of the various algorithms applied after data pre-processing and feature selection.

Why ID3 come out with the best results?

- ID3 (Iterative Dichotomiser 3) is very intelligible, versatile, and easy to debug. It'll work with classification and regression problems. If you are attempting to predict a categorical value or to predict a continuous value ID3 will handle both problems, but it can handle categorical data efficiently than Naïve Bayes and MLP.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:59:53 UTC from IEEE Xplore. Restrictions apply.

- All Decision Trees is that they solely want a part of data, and they can build a classifier directly from that data. Whereas in other algorithms, choosing features is up to you. There's no way to just toss a part of data, and it picks the most important features that it'll use to classify.
- ID3 is quick regarding computation than other algorithms. ID3 does not produce classifiers using all datasets. It's an iterative method in which a rule is computed and every data record that satisfies the rule is going to be removed and additional rules are generated until all data records aren't covered.

VI. CONCLUSION

The study aims to implement the task for detecting an anomaly in networks by making use of effective machine learning techniques and compare their efficiencies. CICIDS2017 dataset has been used because of its wide attack diversity and up-to-datedness. A network flow is described by the features (over eighty) contained within the dataset. A subset of attributes is chosen from the primitive set of attributes using the Random Forest Regressor technique to make our mind up that which feature is used in machine learning algorithms. Finally, four machine learning algorithms i.e. Naive Bayes, ID3, MLP, and ensemble learning, is practiced on the dataset. The resulted performance based on F1-measure is as follows (F1-measure takes a value between 0 and 1): Ensemble Learning (NB, ID3 and, MLP): 0.89, ID3: 0.95, MLP: 0.84 and Naive Bayes: 0.82. The lower accuracy and huge false alarm rates were also tackled to a great extent. Also, the class imbalance problem was rectified to get better results.

VII. FUTURE SCOPE

In this paper, the primary aim is to implement numerous machine learning algorithms independently of one another for anomaly detection in networks. However, this technique has weak practical applicability in real life. To overcome this drawback, a multi-layered /hierarchical machine learning structure is often designed. Moreover, because of such a structure, it's attainable to save time, CPU power, and memory. There is no "fit-for-all" solution for intrusion detection task [14]. For example, in a two-tiered structure, the primary layer is often created from quick and computationally low-cost algorithms such as Naïve Bayes, therefore network traffic can be observed continuously and at a minimal cost. The primary step, when detecting an anomaly, is to transmit it to an upper layer composed of algorithms with higher performance such as ID3, ensemble learning, etc. The ultimate layer that creates up the determination mechanism takes the preventive decision to protect the network against various attacks. Also, the dataset used, consist of CSV (comma-separated values) files, was obtained from a network of computers created by the Canadian Institute for Cybersecurity. This work is open to future enhancements. Unluckily, in real-time systems, this technique isn't much viable. However, this drawback can be resolved by adding a module that catches real network data and makes it practicable with various machine learning algorithms.

Accepted 17 June 2020

Abstract

Purpose – The purpose of this study is to identify sustainability practices and to propose a framework for evaluating the sustainability index of logistics service providers (LSPs).

Design/methodology/approach – Sustainable practices followed by LSPs are identified through literature review and analysis of a case study. Thirteen such sustainable practices are identified. Thereafter, with expert inputs, nine sustainable practices are shortlisted and considered for the evaluation of the sustainability index in the proposed framework. Graph Theory Matrix Approach has been applied to evaluate the sustainability index of an LSP.

Findings – Major practices identified for evaluating sustainability index include the use of recyclable packaging, use of renewable energy sources, green procurement, reduction in carbon emissions, use of CNG/electric vehicles, rainwater harvesting and so on. The sustainability index of an LSP is evaluated by using the proposed framework.

Practical implications – LSPs can benchmark their sustainability index with respect to the best in the industry. Based on it, LSPs can also identify potential areas for improvement.

Originality/value – Novelty of the study lies in the proposed framework for evaluation of sustainability index which can be used to develop strategies for green logistics. LSPs can also improve their performance in terms of sustainability measures by adopting green logistics.

Keywords Logistics service providers, Sustainable practices, Sustainability index, Graph theory matrix approach, case study

Paper type Research paper

1. Introduction

"Sustainability" – a term first coined by the World Commission on Environment and Development (WCED) in the year 1987 (WCED, 1987) – was adopted gradually by most of the organizations around the world. In the year 2015, the United Nations has set up 17 sustainable development goals (SDGs) for improving sustainable development in business organizations as well as world economies, with a target to achieve these goals by 2030 (Szabo *et al.*, 2016; Salvia *et al.*, 2019; Modgil *et al.*, 2020). Due to this, organizations worldwide are seeking to implement sustainable solutions. With the increasing scarcity of resources as well as increasing needs of society and organizations, there is an urgent need to ensure sufficient availability for current use and conserve for meeting the needs of future generations. Moreover, the environment is continuously deteriorating (Seidel *et al.*, 2013). Therefore, many organizations including logistics service providers (LSPs) are adopting and implementing sustainable practices for optimum use of scarce resources and taking steps for a better global future.

Compared to other industry segments, LSPs contribute more toward environmental degradation in terms of noise and air pollution, carbon emissions, fuel consumption, global warming, resource depletion, and so on (Jazairy and Haartman, 2018). The logistics sector is

International Journal of Productivity and Performance Management
© Emerald Publishing Limited
1741-0401
DOI 10.1108/IJPPM-12-2019-0593

expected to grow exponentially, which will lead to even worse environmental conditions (Wang *et al.*, 2016). Therefore, LSPs are required to initiate sustainable logistics solutions for handling current and upcoming environmental challenges. Previous studies have explored the benefits of the adoption of green practices by various organizations (Perotti *et al.*, 2012; Dubey *et al.*, 2017; Majumdar and Sinha, 2018). Many authors have also discussed the impact of the implementation of sustainable practices on firms' performance (Perotti *et al.*, 2012; Green *et al.*, 2019). Ansari and Kant (2017) explored the positive impact of the sustainable practices of logistics service providers on their efficiency, productivity, and profitability. Many authors have also highlighted the importance of the triple bottom line approach in logistics for improving sustainability (Agrawal *et al.*, 2016; Agrawal and Singh, 2019; Halldorsson, 2019; Kumar and Goswami, 2019).

The existing literature focuses more on green logistics practices in developed countries compared to developing countries (Gandhi *et al.*, 2015; Mangla *et al.*, 2015; Agrawal and Singh, 2019). Gupta and Singh (2020) indicate the need for greater emphasis on developing countries to create a balance between environmental sustainability and the operational excellence of LSPs. Presently, due to environmental consciousness, even consumers in developing nations have started expecting green products. LSPs in developing economies have initiated sustainable practices but only on a small scale. In India, LSPs have started transforming their processes into green processes by changing their conventional fleet into CNG (Compressed Natural Gas) or hybrid fleets for reducing carbon emissions. LSPs have also initiated various activities such as planting trees in the surroundings of their facilities, storing rainwater for washing vehicles and installing solar panels for saving electricity (Gupta *et al.*, 2018). LSPs are also working toward a reduction in waste, which is created in different forms such as underutilized resources, replication of tasks, and inadequate planning of resource allocation (Qian *et al.*, 2019). Moreover, LSPs are exploring alternative ways of reducing carbon emissions, fuel consumption, and noise levels for long-term sustainability. Despite the measures being adopted by LSPs, the actual adoption rate is very low due to lack of continuous evaluation measures. Owing to the lack of appropriate frameworks in the literature, most LSPs struggle in evaluating their sustainability index (Chhabra and Singh, 2016). There is, therefore, a need to perform an in-depth analysis of sustainable practices followed by LSPs and to evaluate the sustainability index of such providers in a developing country. This study analyzes and evaluates the sustainability performance of LSPs in the Indian context. The main objectives of this study are as follows:

(1) To identify the sustainable practices followed by LSPs

(2) To analyze the sustainable practices specifically for LSPs in the Indian context

(3) To evaluate the sustainability index using a Graph Theory Matrix Approach (GTMA)

(4) To propose a framework for evaluating the sustainability index of LSPs

This study is further elaborated under the following sections. Section 2 comprises the literature review on green initiatives and sustainable practices followed by LSPs. In Section 3, the case study method is used to identify and analyze sustainable practices in developing economies. In Section 4, the sustainability index has been evaluated by using GTMA. The implications of the study along with future scope are discussed in Section 5. The conclusions of the study are concluded in Section 6.

2. Literature review

There is a significant body of literature available on evolution, adoption, and implementation of sustainable practices in both the manufacturing and service sectors (Perotti *et al.*, 2012;

Anwer *et al.*, 2018; Majumdar and Sinha, 2018; Mensah and Casadevall, 2019). Sustainability means the conservation of natural resources and judicious use of resources for long term business continuity. Due to continuous environmental degradation and scarcity of resources, resource sustainability has become an important concern for all organizations including LSPs (Coaffee, 2008; Zhang *et al.*, 2017). LSPs have started redefining their conventional processes into green processes as a contribution towards society and the environment (Ferreira *et al.*, 2015). Previous studies discussed the adoption and importance of sustainability in the field of logistics (Gandhi *et al.*, 2015; Mangla *et al.*, 2017). Centobelli *et al.* (2017) conducted a systematic literature review on green and sustainable practices followed by LSPs by exploring more than 415 articles from 1960 to 2014. Evangelista *et al.* (2018) conducted a comprehensive literature review on the environmental sustainability of LSPs for the period of 2000–2016.

Researchers have not only conducted comprehensive literature reviews on environmental sustainability but also discussed the benefits that organizations can obtain by implementing sustainable practices. Various authors captured different aspects of logistics and linked them with sustainability measures. For example, Wilding *et al.* (2012) highlighted the importance of supplier assessment and collaboration in improving sustainability. Martinez-Jurado *et al.* (2014) explored the relationship between lean management, supply chain management, and sustainability. Marques (2019) conducted a detailed and systematic literature review on sustainable supply network management from a knowledge perspective. Many practitioners have already proved the strong relationship among the implementation of sustainable practices, an increase in profitability, and improvement in organizational performance (Perotti *et al.*, 2012; Singh *et al.*, 2016; Ansari and Kant, 2017). Several researchers have established the relationship among implementation of green sustainable practices and organizational culture, service quality, and operational performance (Zhu *et al.*, 2008; Bask *et al.*, 2018; Garcia-Dastugue; Eroglu, 2019; Green, 2019; San-Ong *et al.*, 2019).

Despite the extensive literature on logistics and sustainability, LSPs, specifically those in developing countries, are yet to implement green practices in all their processes (Agrawal and Singh, 2019). As a result, it is imperative for LSPs in emerging economies to practice resource conservation and ensure long-term business continuity (Singh and Agrawal, 2018). Moreover, organizations, including LSPs, are expected to follow strict guidelines for environmental protection, issued by the government and the United Nations (UN). The UN has set sustainable development goals (SDGs-7, 12 and 13) for the implementation of sustainable practices in the organizations (The Sustainable Development Goals Report, 2019). The UN has also emphasized the development of metrics and indicators for measuring sustainable development at the environmental, social, and economic levels. On the other end, consumers are also becoming proactive and demanding eco-friendly products (Green *et al.*, 2015). These requirements by the government, the UN, and customers are building pressure on LSPs.

Many authors have discussed the hurdles in the adoption of sustainable practices and highlighted methods for measuring the performance of sustainable supply chains (Taticchi *et al.*, 2013; Baird, 2017; Thanki; Thakkar, 2018). Pazirandeh and Jafari (2013) critically evaluated the impact of sustainability strategies on logistics efficiency using structural equation modeling (SEM). Tajbakhsh and Hassini (2015) proposed a performance measurement framework for measuring the sustainability of various industries based on seven sustainability dimensions (economic, environmental, social, reputable, valuable, equitable, and sustainable). Trianni *et al.* (2019) analyzed 26 small and medium manufacturing organizations of Germany and Italy and observed that the organizations accorded more importance to economic indicators over environmental and social indicators. They developed a novel framework for measuring sustainability indicators. Gardas *et al.* (2019) analyzed sustainable supply chain determinants for measuring the business performance of the oil and gas supply chain. Chowdhury and Paul (2020) reviewed the

applications of multi-criteria decision-making methods (MCDM) for measuring performance, including enablers of, and barriers to, corporate sustainability.

Most LSPs struggle in evaluating their sustainability index due to the lack of appropriate frameworks (Chhabra and Singh, 2016). It is crucial to measure the performance of LSPs in terms of their sustainability. This study proposes a framework for measuring the sustainability index of LSPs. This will help other LSPs understand their current position and take corrective measures if required. This provides a significant opportunity to conduct an in-depth analysis of the sustainable practices followed by LSPs in developing countries and to evaluate their sustainability index to understand the current situation of LSPs in the Indian market. Therefore, the following research questions have been developed:

RQ1. What are the sustainable practices followed by LSPs in developing countries to fulfill the UN's sustainable development goals?

RQ2. How can the sustainability of Indian LSPs be measured?

RQ3. What suggestions can be made to other LSPs for better achievement of SDG goals?

The sustainable practices followed by LSPs are identified through a literature review as discussed in the next section and a case study is also conducted on Indian LSP to understand their sustainable practices closely as discussed in Section 3.

2.1 Identification of sustainable practices from literature review

Previous studies have explored sustainable practices adopted by LSPs specifically in context to developing countries. It has been observed that LSPs have emphasized on the reduction of carbon emissions and fuel consumption as an initiative towards the environmental protection (Yao *et al.*, 2015; Aldakhil *et al.*, 2018; Liu *et al.*, 2018). Agrawal *et al.* (2016) have explored the importance of reverse logistics to assist return management and to make optimum use of resources. Renewable resources like solar and hydro products are more preferred nowadays over expensive single time use products for long term sustainability of products (Dubey *et al.*, 2017; Sureeyatanapas *et al.*, 2018). Reuse and recycling of packaging material and pallets are also done through plastic totes and heavy containers in order to save resources (Boubeta *et al.*, 2018). The adoption of green practices in the logistics sector has also become evident by converting manual processes (paper-work) into e-processes (paper-less) through digitalization (Kayikci, 2018). The following sustainable practices are identified through the literature review:

(1) *Use of reusable or recyclable packaging:* To promote green practices, several LSPs have started using plastic totes and heavy-duty containers which are cost-efficient and can be used for multiple trips (Centobelli *et al.*, 2018; Regattieri *et al.*, 2019). Paper, cardboard, corn starch, and bubble wrap, etc. are biodegradable and preferred for packaging (Gupta *et al.*, 2020). In India, Transport Corporation of India (TCI) and Agarwal Packers and Movers Ltd. are actively reusing and recycling packaging materials for making cost-effective and sustainable logistics system (Bhushan and Malviya, 2018)

(2) *Use of renewable energy sources:* The best way to conserve limited resources is to maximize the use of renewable energy sources. LSPs have initiated the use of solar energy and hydropower for many logistical activities instead of single-time use electric ones. Installation of solar panels for producing electricity (Fontes, and Freires, 2018; Gupta *et al.*, 2018), transparent roofs for natural light to enter during daytime (Tascioglu and Keser, 2019) and storage of rainwater for gardening and cleaning vehicles (Piecyk and Björklund, 2015; Gupta *et al.*, 2018) indicate the prominent use of natural resources by LSPs. All Cargo Logistics sets a wonderful example by providing renewable energy transportation from end to end logistics (Choudhary, 2019).

(3) *Green procurement:* Green procurement is the foremost step towards green logistics (Teixeira *et al.*, 2018). LSPs prefer to purchase products or services, which will cause a minimum adverse effect on the environment. The use of alternative fuel, proper planning for unutilized material, waste reduction, and use of recyclable and reusable products can support green procurement initiatives (Meehan and Bryde, 2011; Centobelli *et al.*, 2018). DHL has adopted green logistics to make our planet more sustainable by reducing emissions and moving towards the circular economy.

(4) *Reduction in carbon emissions:* LSPs have taken initiatives for low carbon supply chain integrations. This initiative has a positive impact on LSPs' environmental and financial performance (Qian *et al.*, 2019). LSPs are required to take appropriate solutions for carbon emission reduction and to develop strategies for a sustainable environment (Guiffrida *et al.*, 2011; Tang *et al.*, 2015; Aldakhil *et al.*, 2018; Liu *et al.*, 2018). Damco, DHL and TNT are offering green services and reducing carbon footprints through various services (Das and Kulkarni, 2018).

(5) *Use of CNG/Electric fleet:* Many LSPs are making use of CNG vehicles to reduce cost, pollution, and fuel consumption (Gupta *et al.*, 2018). The use of CNG/electric vehicles (fuel-free) helps in reducing the noise level and making the air clean. LSPs are also looking forward to adopting e-vehicles in the coming years (McKinnon, 2010; Liu *et al.*, 2018). Almost all Indian LSPs including Safe Express, CTC freight carriers Ltd. and Sal Logistics Pvt. Ltd., etc. are using more of the CNG vehicles to save cost and fuel.

(6) *Resource optimization:* Due to the scarcity of resources, LSPs are looking forward to the alternative options to use limited resources in an optimum way (Centobelli *et al.*, 2017). Conservation of resources will help in the smooth functioning of logistics operations in the future. LSPs are optimizing resources by making maximum use of natural resources over man-made products (Choudhury *et al.*, 2018; He *et al.*, 2018; Winkler and Zinsmeister, 2019). Om Logistics Ltd. conserves its natural resources by making maximum use of solar light and rainwater harvesting in their warehouses.

(7) *Reduction in fuel consumption:* Less fuel consumption by LSPs is considered as economic, social and environmental initiative (Blanco and Sheffi, 2017). Automobile companies are adding fuel-saving features in new vehicles by using new engine technologies. Moreover, the transition from fuel to electric vehicles is a great initiative for reducing fuel consumption and environmental pollution (Tang *et al.*, 2015; Yao *et al.*, 2015). Although, in India, there are many infrastructural bottlenecks to implement e-vehicles entirely, but the government is working in this direction. Jayem Logistics has significantly contributed towards eco-friendly transportation, reduction in fuel consumption, and pollution.

3. Study of sustainable practices in context to an Indian LSP

Most of the identified sustainable practices from the literature review are in context to both developing and developed countries. There is, therefore, a need to understand and identify the sustainable practices of Indian LSPs more closely to make this study more relevant in the Indian context. A real case illustration on Indian LSP has been discussed to have a thorough understanding of sustainable practices followed by them. The information is collected based on multiple visits and discussions with middle and senior management of the case organization.

3.1 Profile of case organization (ABC ltd.)

ABC Ltd. (given name) started its business as a multi-modal transportation organization in the mid-1980s in India. Its objective is to provide logistics support to the manufacturing organizations in the nation as well as across boundaries. With an annual turnover of around INR 1,500 crores (the US$ 225.47 million), it serves all the significant businesses sectors such as automobile, hardware, telecom, retail and pharmaceuticals.

The organization has a wide distribution network of more than 3,500 client base of domestic, transnational, and international presence majorly in the corporate B2B sphere. It provides service to most of the automobile manufacturers and more than 2000 auto segment part producers in India. Their customer base includes all significant brand names like Mahindra and Mahindra, Maruti Suzuki India Ltd., SUZUKI Motors, India Yamaha Motors Pvt. Ltd., Toyota, Daimler, Honda Motors India, Heromoto Corp, Tata Motors, Samsung Electronics India Limited, VIVO Mobiles India, Bharati Airtel, Cadila Pharmaceuticals, Arvind Fashions, etc. ABC Ltd. is conferred with many awards, recognitions, and excellence awards for its outstanding contribution to the logistics sector both in domestic and international services.

3.2 Organizational assets

ABC Ltd. ensures timely delivery and assured services to the clients through its technologically advanced assets. The organization offers modernized multi-client and dedicated warehousing spaces over more than 100 locations with its captive warehousing strength of more than 20 lac square meters in PAN India. It manages hub and spoke distribution through more than 40 Cross-Dock centers and 700 branches for Part Truck Load (PTL) distribution. This Indian LSP delivers more than 14,000 pin codes pan India and is serving over 85 countries through its own offices, joint ventures, exclusive partners, etc.

The case organization offers door to door customized deliveries through more than 4,500 modern technologically advanced, all-weather containerized vehicles of varied capacities ranging from 0.5 metric tons to 40 metric tons. It has more than 5,000 trained workforce, who work sincerely 24 by 7 for committed services, and customer query resolution. ABC Ltd. is equipped with advanced in-house created applications and SAP software along with ORACLE based databases for providing timely and accurate information to all stakeholders. It also uses modern advanced information technology tools and real-time applications to track and trace consignments through owned servers.

3.3 Organizational processes

The organization's order processing is made effective with invoice creation on behalf of their customers, while also creating and managing receipts for storage and dispatch of shipments, and sales tax or excise duties. It also incorporates key parameters like time and motion studies for optimization of resources, designing of warehouse layout, 5S support, and adaptable stock piling arrangements by using the latest and coordinated IT tools for the smooth functioning of warehouses. For managing inventory, the organization prefers to arrange their stocks by using concepts of LIFO (Last in First Out), FIFO (First in First Out), etc. This LSP also encourages the usage of mathematical models along with IT tools for analyzing the inventory costs, transportation costs, and stock management.

An ideal mix of roadways, railways, and the airways are offered by the organization to handle customer consignments and to serve them as per commitments. It offers flexibility to the customers in terms of selection of cargo, selection of location, the type of product and the size of shipments. This LSP also provides value-added services which include services like labeling and kitting of goods, packaging with bubble wrap or directly in carton boxes, and

sorting of goods. Document maintenance, packaging redesigning, consultancy on supply chain optimization, and return logistics are also provided.

3.4 Sustainability measures

In order to conserve natural resources, ABC Ltd. is carrying out numerous activities to manage resources at the ecological, societal and economic levels. The organization is also certified with ISO 14001:2015 certifications for maintaining green practices for sustainability.

Some of the sustainable practices that it follows are as under:

(1) *Reduction in carbon emissions:* All the trucks are outfitted with GPS technology which helps in tracking the exact location, while also enabling reduction in carbon emissions. The organization takes exceptional consideration for vehicles which have valid pollution check and carbon emission certificates.

(2) *Green practices:* ABC Ltd. plants more than 5,000 trees annually to enhance green cover around their warehouses. There is a culture of planting tree saplings on various occasions as a step towards environmental conservation. Air sanitizing plants are also grown around warehouses or distribution centers to purify the air and make surroundings clean.

(3) *Digitalization of processes:* The case organization is adopting process automation, in order to change its manual transactions to digital processes. This initiative not just reduces the use of paper and makes document handling easier but also brings transparency to the system.

(4) *Use of solar energy:* To optimize resources, ABC Ltd. has adopted proper conservation of natural resources. Additionally, the organization has installed solar panels on the roofs of most of the warehouses to generate power and to give back to society by saving electricity.

(5) *Use of natural/Renewable resources:* With preference to use natural light, the organization has built transparent roofs at their facilities. This reduces carbon emission and helps in saving electricity.

(6) *Rainwater harvesting:* Committed to green practices, ABC Ltd. utilizes rainwater stored in its underground tanks for further use in washing vehicles, cleaning the floors, or gardening purposes.

(7) *Education initiatives:* In line with PMKVY (Prime Minister Kaushal Vikas Yojna, Government of India scheme), the organization is running its non-profit education and training institute to increase employability of individuals in the logistics industry. Under this initiative, it offers various short term courses related to logistics and supply chain along with practical training sessions. The meritorious candidates are offered to work with the organization according to their abilities and domain knowledge.

(8) *Healthy working environment:* Offering employee friendly policies and environment, this LSP provides its employees with flexible working hours. In order to provide a comfortable and sound environment, residential and mess services are provided to the employees.

3.5 Selection of sustainable practices

After identifying thirteen sustainable practices from the literature review and case analysis, a dedicated team of three experts with over ten years of experience and working with leading

Indian LSPs, helped in finalizing the sustainable practices in Indian context. In order to achieve this, a list of all identified sustainable practices was shared with experts and their inputs were solicited on application of these practices in their respective organizations and ensuing impact on performance. The level of application of these sustainable practices in their organizations helped in understanding the importance of sustainability in Indian context. After expert inputs, nine sustainable practices were finalized. Out of these nine, five were identified from literature, one was from the case study and three were found to be common in both case study and literature review. The final list of sustainable practices after discussing with Indian experts is given in Table 1. As the objective of this study is to evaluate the sustainability index, therefore, the GTMA is applied for evaluating the sustainability index. The detailed research methodology will be discussed in the next section.

4. Evaluation of sustainability index- Graph Theory Matrix Approach (GTMA)

After identifying sustainability practices, a framework for the evaluation of the sustainability index of an LSP is proposed in this study. The Graph Theory Matrix Approach has been applied for the evaluation of the sustainability index, which considers any number of quantitative and qualitative sustainable practices simultaneously. The conventional methods like cause and effect diagram, process flow charts and block diagrams are not

suitable for further mathematical analysis whereas this method establishes the directional relationship among variables and also take care of their interdependencies by mathematical analysis (Raj *et al.*, 2010; Jain and Raj, 2016; Hudnurkar; Ambekar, 2019).

It is a more preferred approach over conventional methods for representation and quantification. Digraph assists in the graphical representation of variables, which supports better visual analysis and provides valuable inputs for mathematical modeling. Many researchers have applied the GTMA in different fields. Franceschini *et al.* (2006) have used this approach for finding the quality index. Darvish *et al.* (2009) applied GTMA for the ranking of contractors. Attri *et al.* (2014) used this method to compute the intensity of TPM (Total Productive Maintenance) barriers. Apart from manufacturing, many authors have applied this approach in diversified areas such as to model the various mechanisms required for supply chain coordination (Kaur *et al.*, 2006), to evaluate the technology-based self-service banking service quality (Sindhwani and Goel, 2015), to analyze disposition decisions in reverse logistics (Agrawal *et al.*, 2016), to find the agility index of supply chains (Singh *et al.*, 2017), for quantifying the barriers in the implementation of technologies (Bhandari *et al.*, 2019) and to measure the flexibility index for supply chains (Singh and Kumar, 2019), etc.

It is found to be a very important decision-making tool that helps in creating associations among variables and evaluating by forming an index. Based on the literature review and case study, nine sustainable practices have been identified in this study as shown in Table 1. This approach includes various steps of developing a digraph between variables depending upon their mutual correlations. The research methodology framework is shown in Figure 1. Further, a permanent function is computed by developing a permanent matrix by using Equation (1).

4.1 Variables digraph

The sustainable practices adopted by LSPs are represented in the form of nodes and edges by developing a variable digraph as shown in Figure 2. The nodes represent the sustainable practices and the edges represent their linkages. S_i shows the inheritance of practices and s_{ij} shows the degree of dependence of jth practice on ith practice. It also indicates the directed edge from node i to node j. The linkages among all sustainable practices taken in this study are shown in Figure 2. The digraph for detailed analysis has been discussed in Figure 3.

The permanent function of sustainable practices (Perm S) shown in Figure 3 is written as:

$$\text{Perm } S = \begin{vmatrix} S1 & s_{12} & s_{13} & s_{14} & s_{15} & s_{16} & s_{17} & s_{18} & s_{19} \\ s_{21} & S2 & s_{23} & s_{24} & s_{25} & s_{26} & s_{27} & s_{28} & s_{29} \\ s_{31} & s_{32} & S3 & s_{34} & s_{35} & s_{36} & s_{37} & s_{38} & s_{39} \\ s_{41} & s_{42} & s_{43} & S4 & s_{45} & s_{46} & s_{47} & s_{48} & s_{49} \\ s_{51} & s_{52} & s_{53} & s_{54} & S5 & s_{56} & s_{57} & s_{58} & s_{59} \\ s_{61} & s_{62} & s_{63} & s_{64} & s_{65} & S6 & s_{67} & s_{68} & s_{69} \\ s_{71} & s_{72} & s_{73} & s_{74} & s_{75} & s_{76} & S7 & s_{78} & s_{79} \\ s_{81} & s_{82} & s_{83} & s_{84} & s_{85} & s_{86} & s_{87} & S8 & s_{89} \\ s_{91} & s_{92} & s_{93} & s_{94} & s_{95} & s_{96} & s_{97} & s_{98} & S9 \end{vmatrix}$$

4.2 Quantification of S_is and s_{ij}s

To find out the value of the permanent function (Perm S), there is a need to quantify S_is and s_{ij}s. The qualitative measure of inheritance of practices (S_i) is rated on a scale of 1–5 by experts by considering 1 to be the lowest and 5 to be the highest. The qualitative measures of interdependencies among sustainable practices (s_{ij}) have been quantitatively measured by finding the relative dependence on each other based on the value assigned by experts and

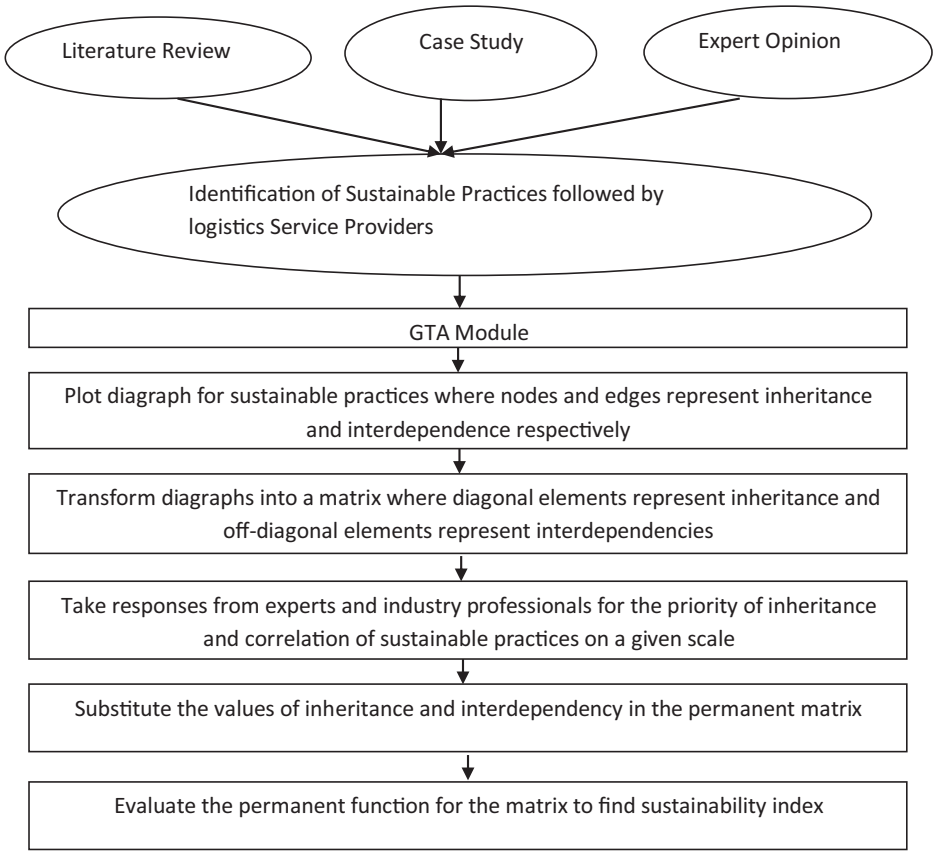

Figure 1.
Research methodology framework

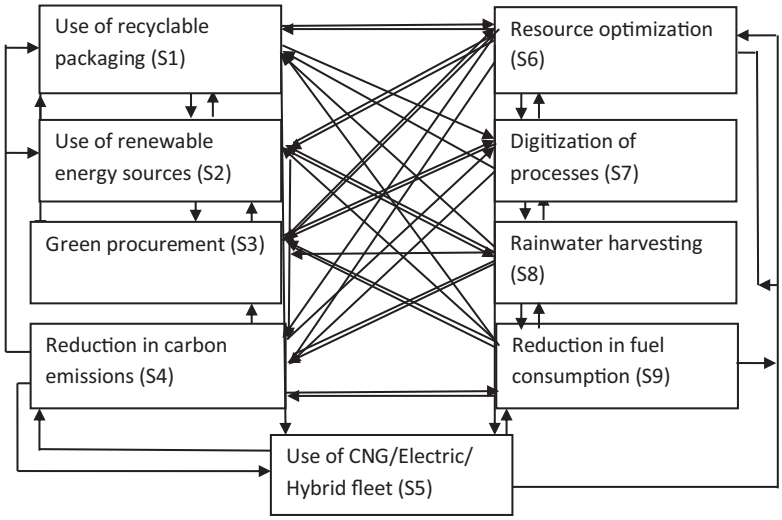

Figure 2.
Interaction among sustainable practices followed by LSPs

discussed in Table 2. A structured questionnaire was designed and sent to all concerned. The experts have been asked to respond on the importance given to sustainable practices (*S*1 to *S*9) and also to rate the relative dependence of one sustainable practice on another according to criteria given in Table 2. For instance, s_{12}- dependence of sustainable practice 2 on sustainable practice 1 which means the degree of dependence of use of energy renewable resources (*S*2) on use of recyclable packaging (*S*1) and similarly, the relative dependence will find for all other possible combinations.

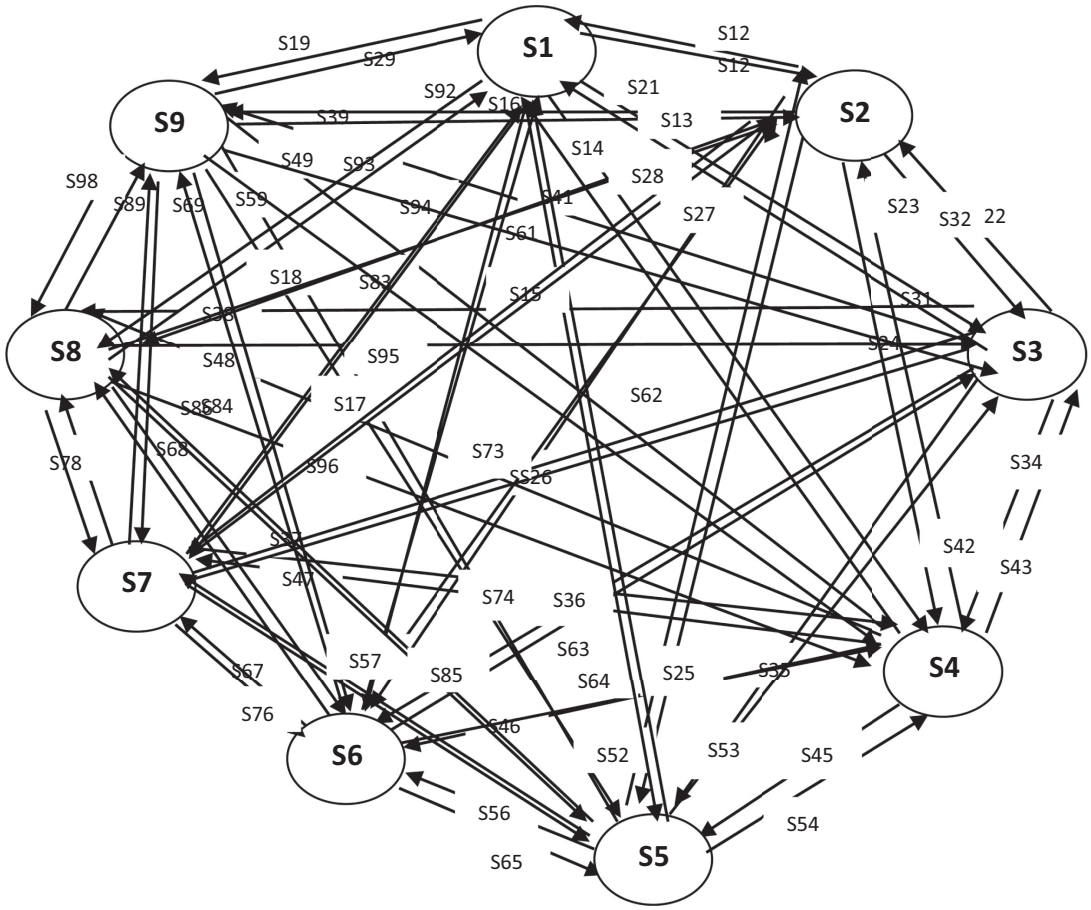

Figure 3.

4.3 Variables' permanent matrix

The permanent function is a mathematical expression which helps to determine the sustainability index of LSPs. The calculation for the permanent function is almost the same as finding the determinant of the matrix but considers only positive terms. The value of the permanent function of sustainable practices (Perm *S*) is computed by using Equation (1) which is given as follows.

$$
\begin{aligned}
perm S = {} & \prod_{i=1}^{9} Si + \sum_{i=1}^{8}\sum_{j=i+1}^{9}\sum_{k=j+1}^{3}\sum_{l=k+1}^{4}\sum_{m=l+1}^{5}\sum_{n=m+1}^{6}\sum_{o=n+1}^{7}\sum_{p=o+1}^{8}\sum_{q=p+1}^{9}(s_{ij}s_{ji})S_kS_lS_mS_nS_nS_pS_q \\
& + \sum_{i=1}^{7}\sum_{j=1+1}^{8}\sum_{k=j+1}^{9}\sum_{l=k+1}^{4}\sum_{m=l+1}^{5}\sum_{n=m+1}^{6}\sum_{o=n+1}^{7}\sum_{p=o+1}^{8}\sum_{q=p+1}^{9}(s_{ij}s_{jk}s_{ki} + s_{ik}s_{kj}s_{ji})S_lS_mS_nS_oS_pS_q + \\
& \left[\begin{array}{l}
\sum_{i=1}^{6}\sum_{j=1+1}^{9}\sum_{k=j+1}^{8}\sum_{l=i+2}^{9}\sum_{m=1}^{8}\sum_{n=m+1}^{9}\sum_{o=n+1}^{9}\sum_{p=o+1}^{9}\sum_{q=p+1}^{9}(s_{ij}s_{jk})(s_{kl}s_{lk})S_mS_nS_oS_pS_q \\
+\sum_{i=1}^{6}\sum_{j=i+1}^{8}\sum_{k=j+1}^{9}\sum_{l=j+1}^{9}\sum_{m=1}^{8}\sum_{n=m+1}^{9}\sum_{n=m+1}^{9}\sum_{o=n+1}^{9}\sum_{p=o+1}^{9}\sum_{q=p+1}^{9}(s_{ij}s_{jk}s_{kj}s_{li} + s_{il}s_{lk}s_{kj}s_{ij})S_mS_nS_oS_pS_q
\end{array}\right] \\
& + \left[\begin{array}{l}
\sum_{i=1}^{7}\sum_{j=1+1}^{8}\sum_{k=j+1}^{9}\sum_{l=1}^{8}\sum_{m=l+1}^{9}\sum_{n=m+1}^{9}\sum_{o=n+1}^{9}\sum_{p=o+1}^{9}\sum_{q=p+1}^{9}(s_{ij}s_{jk}s_{ki} + s_{ik}s_{kj}s_{ji})(s_{lm}s_{ml})S_nS_oS_pS_q \\
+\sum_{i=1}^{5}\sum_{j=1+1}^{8}\sum_{k=i+1}^{9}\sum_{l=j+1}^{9}\sum_{m=1}^{8}\sum_{n=m+1}^{9}\sum_{o=n+1}^{9}\sum_{p=o+1}^{9}\sum_{q=p+1}^{9}(s_{ij}s_{jk}s_{kl}s_{lm}s_{mi} + s_{im}s_{ml}s_{lk}s_{kj}s_{ij})S_nS_oS_pS_q
\end{array}\right] \\
& + \left[\begin{array}{l}
\sum_{i=1}^{6}\sum_{j=1}^{8}\sum_{k=i+1}^{9}\sum_{l=j+1}^{9}\sum_{m=1}^{8}\sum_{n=m+1}^{9}\sum_{o=n+1}^{9}\sum_{p=o+1}^{9}\sum_{q=p+1}^{9}(s_{ij}s_{jk}s_{kl}s_{li} + s_{ik}s_{lk}s_{lk}s_{kj}s_{ji})(s_{mn}s_{nm})S_oS_pS_q \\
+\sum_{i=1}^{4}\sum_{j=i+1}^{8}\sum_{k=i+1}^{9}\sum_{l=j+1}^{9}\sum_{m=1}^{8}\sum_{n=m+1}^{9}\sum_{o=n+1}^{9}\sum_{p=o+1}^{9}\sum_{q=p+1}^{9}(s_{ij}s_{jk}s_{ki} + s_{ik}s_{kj}s_{ji})(s_{lm}s_{mn}s_{nl} + s_{ln}s_{nm}s_{ml})S_oS_pS_q \\
+\sum_{i=1}^{4}\sum_{j=i+1}^{9}\sum_{k=j+1}^{6}\sum_{l=i+1}^{9}\sum_{m=k+1}^{8}\sum_{n=k+2}^{9}\sum_{o=n+1}^{9}\sum_{p=n+2}^{9}\sum_{q=p+1}^{9}(s_{ij}s_{ji})(s_{kl}s_{lk})(s_{mn}s_{nm})S_oS_pS_q \\
+\sum_{i=1}^{4}\sum_{j=i+1}^{8}\sum_{k=j+1}^{9}\sum_{l=i+1}^{9}\sum_{m=i+1}^{9}\sum_{n=j+1}^{9}\sum_{o=j+1}^{9}\sum_{p=j+1}^{9}\sum_{q=j+1}^{9}(s_{ij}s_{ji})(s_{ij}s_{jk}s_{kl}s_{lm}s_{mn}s_{ni} + s_{in}s_{nm}s_{lk}s_{kj}s_{ji})(s_{mn}s_{nm})S_oS_pS_q + \ldots
\end{array}\right]
\end{aligned}
\tag{1}
$$

Substituting the values of the variables in the permanent matrix and compute the value of the permanent matrix (Perm S) by putting values in Equation (1):

$$
\text{Perm } S = \begin{vmatrix}
S1 & s_{12} & s_{13} & s_{14} & s_{15} & s_{16} & s_{17} & s_{18} & s_{19} \\
s_{21} & S2 & s_{23} & s_{24} & s_{25} & s_{26} & s_{27} & s_{28} & s_{29} \\
s_{31} & s_{32} & S3 & s_{34} & s_{35} & s_{36} & s_{37} & s_{38} & s_{39} \\
s_{41} & s_{42} & s_{43} & S4 & s_{45} & s_{46} & s_{47} & s_{48} & s_{49} \\
s_{51} & s_{52} & s_{53} & s_{54} & S5 & s_{56} & s_{57} & s_{58} & s_{59} \\
s_{61} & s_{62} & s_{63} & s_{64} & s_{65} & S6 & s_{67} & s_{68} & s_{69} \\
s_{71} & s_{72} & s_{73} & s_{74} & s_{75} & s_{76} & S7 & s_{78} & s_{79} \\
s_{81} & s_{82} & s_{83} & s_{84} & s_{85} & s_{86} & s_{87} & S8 & s_{89} \\
s_{91} & s_{92} & s_{93} & s_{94} & s_{95} & s_{96} & s_{97} & s_{98} & S9
\end{vmatrix}
$$

$$
= \begin{vmatrix}
4 & 5 & 9 & 8 & 5 & 9 & 5 & 5 & 9 \\
5 & 3 & 7 & 9 & 6 & 9 & 5 & 8 & 7 \\
1 & 3 & 2 & 9 & 9 & 7 & 9 & 6 & 8 \\
2 & 1 & 1 & 2 & 9 & 8 & 8 & 7 & 9 \\
5 & 4 & 1 & 1 & 4 & 7 & 5 & 5 & 9 \\
1 & 1 & 3 & 2 & 3 & 4 & 9 & 9 & 9 \\
5 & 5 & 1 & 2 & 5 & 1 & 2 & 5 & 5 \\
5 & 2 & 4 & 3 & 5 & 1 & 5 & 2 & 6 \\
1 & 3 & 2 & 1 & 1 & 1 & 5 & 4 & 3
\end{vmatrix}
$$

Perm $S^* = 2,30,595,214,680$

The best possible value of the index can be computed by taking the highest possible value of all variables. The value of inheritance of all sustainable practices is kept maximum, that is, 5 and the diagonal cells of the permanent matrix are kept 5 as maximum. This maximum index can be used as a reference for benchmarking of sustainability performance. Substituting all values in Equation (1) and the maximum theoretical index can be:

$$\text{Perm } S = \begin{vmatrix} 5 & 5 & 9 & 8 & 5 & 9 & 5 & 5 & 9 \\ 5 & 5 & 7 & 9 & 6 & 9 & 5 & 8 & 7 \\ 1 & 3 & 5 & 9 & 9 & 7 & 9 & 6 & 8 \\ 2 & 1 & 1 & 5 & 9 & 8 & 8 & 7 & 9 \\ 5 & 4 & 1 & 1 & 4 & 7 & 5 & 5 & 9 \\ 1 & 1 & 3 & 2 & 3 & 5 & 9 & 9 & 9 \\ 5 & 5 & 1 & 2 & 5 & 1 & 5 & 5 & 5 \\ 5 & 2 & 4 & 3 & 5 & 1 & 5 & 5 & 6 \\ 1 & 3 & 2 & 1 & 1 & 1 & 5 & 4 & 5 \end{vmatrix}$$

Perm $S^* = S^*_{\max} = 3,63,706,047,040$

S^* represents the sustainability index of LSPs. This value of sustainability index can be also used for comparison with other LSPs. It can help them in positioning themselves in terms of the adoption and implementation of sustainable practices. LSPs can analyze the importance and relationships among sustainable practices and can be implemented in their respective organizations for improving sustainability. The maximum value $S^*_{\max}$ represents the maximum index of sustainability that LSPs can achieve by adopting and implementing maximum sustainable measures.

5. Discussion

In this study, the GTMA is used to compute the sustainability index of LSPs. When the resources are limited and the environment is degrading at a very fast pace in the current market situation, the evaluation of sustainability index can help LSPs in finding suitable solutions to adopt and implement sustainable practices in their inbound and outbound processes. It can help LSPs to devise some strategies for improving the adoption and implementation of sustainable practices, in turn, positively impacting the performance of LSPs. The implementation of sustainable practices by LSPs will also help in reducing wastage of resources which further encourages the circular economy.

From the above case illustration, it has been observed that the sustainability index (S) of the given LSP is comparatively lesser than the best possible value of the sustainability index (S^*). This reflects that there is a scope of improvement for an LSP by implementing more sustainable practices in their logistical operations. LSPs can develop strategies for revision in their processes and can plan for improvement in terms of sustainability. On similar lines, Mangla *et al.* (2019) explored the agro-food supply chain by analyzing four Indian dairy-based organizations and developed strategies for improving the supply chain and logistics performance in emerging economies using the GTMA approach.

The sustainability index can also assist LSPs in positioning themselves and comparing them with their peer service providers. LSPs can develop their strategies for improving their performance through increased use of green practices. Several articles on the implementation of sustainable practices have discussed their importance in developing countries. For the successful implementation of sustainable practices, LSPs should come forward to identify the issues related to sustainability implementation and should formulate a proper strategy for handling them effectively. Similarly, Agrawal *et al.* (2016) evaluated the outsourcing index, which is very useful for managers and practitioners in formulating strategies for outsourcing reverse logistics decisions. In Bangladesh, Moktadir *et al.* (2018) applied graph theory for

identifying barriers for implementing sustainable manufacturing practices in the leather industry. They have also suggested that the managers should formulate strategies for optimum utilization of limited resources to reduce wastage. It also validates our findings in context to Indian LSP.

5.1 Managerial implications

The major implication of this study is that LSPs should select factors for evaluating the sustainability index depending upon the prevailing business environment. These factors may vary as per region and sector. Based on the sustainability index, LSPs may choose to find potential areas for improvement and a green logistics strategy can be developed accordingly. Organizations with low sustainability index can identify their weak areas and can work upon them to increase their sustainability index. Organizations with high sustainability index can compare their values with maximum possible value and can further work in the direction to achieve that level. This framework will be helpful for LSPs in benchmarking their performance with global standards in the era of the circular economy.

5.2 Limitations and future scope

In this study, a case analysis has been done for understanding the sustainable practices of LSPs. Findings from a case may vary with change in sector and location. Therefore, for the generalization of these findings, this study can be further validated by taking more case studies on LSPs in different contexts. This work can be extended for small LSPs as the future scope of the existing work. Apart from considered criteria, other sustainability criteria in context to an emerging circular economy can be also considered for further modification of framework. Further, the results can be compared after evaluating the sustainability index by different methods to check the robustness of the framework. The study may be further extended to comparing the sustainability index of logistics companies from developing and developed countries. It will help in the identification and adoption of advanced sustainability practices by LSPs of developing countries for continuous improvement. The study will not only encourage the organizations but also the society to conserve resources and make proper utilization of available resources.

6. Conclusion

In today's business environment of the circular economy, almost every organization is taking initiatives for reducing environmental degradation and increasing the sustainable use of resources. LSPs are continuously exploring innovative and sustainable ways to contribute to society and the environment. Sustainable practices adopted and implemented by various LSPs have been identified from previous studies. The case study method is also adopted to make the current study more relevant and realistic for LSPs. A real case study on an Indian LSP has been presented to clarify their processes and adoption of sustainable practices in their logistical activities. The information is based on observations and discussions with middle and senior management during multiple visits to the case organization.

This study makes two major contributions. The first is the identification of major sustainable practices in the logistics sector. The second is a framework for the evaluation of the sustainability index. The use of recyclable packaging, renewable energy sources, green procurement, carbon emissions reduction, use of CNG fleets, resource optimization, digitalization of processes, rainwater harvesting and reduction in fuel consumption are the major sustainable practices. Although previous studies have explored many performance measurement frameworks, these frameworks are not so relevant in the era of the circular economy. This study included prominent sustainability practices while evaluating the

sustainability index. We have used GTMA approach for evaluation of the sustainability index of LSPs. The application of this framework is illustrated using the real case of Indian LSP. The sustainability index can also help LSPs in formulating strategies to achieve the UN's sustainability goals. It will motivate LSPs to implement green logistics practices in their operations. This framework will also be helpful for LSPs in comparing their performance against global standards.

Abstract— Every year, the crop output of India is significantly affected due to delayed detection of diseases in crops. This research is a contribution to the farmers in their battle against coffee plants diseases. It will help in timely detection of diseases, resulting in increased coffee production output of India. Many coffee plant diseases like Leaf Rust, Cercospora Spots have clear visual symptoms and thus can be extracted and their classification can be done. Convolutional Neural Networks (CNNs) has proved its efficiency and accuracy in the field of image classification and pattern recognition. Hence it can act as a powerful tool in the diagnosis of coffee leaves diseases since these symptoms have clearly distinguishable patterns. Thus, a Convolution Neural Network model is proposed which utilizes the technique of Transfer Learning, reducing the training time taken by the model significantly. Further, to achieve a higher success rate, Data Augmentation technique is applied to enlarge the dataset used to train the network. The proposed model has achieved a high accuracy of 97.61%.

Keywords— Convolutional Neural Network, Coffee Plant Disease, Data Augmentation, Transfer Learning.

I. INTRODUCTION

Coffee is one of the most popular beverages and an important commercial product which is cultivated in more than 50 countries across the globe. Every day an estimated 2.25 billion coffee cups are consumed throughout the world.[1] India is among the top producers of coffee globally and has the finest quality of coffee grown in the shade rather than direct sunlight, anywhere in the world[2]. With an estimated 319,500 metric ton of coffee produced in the year 2018-19[3], of which almost 80% is exported throughout the globe. The amount of revenue generated from the coffee industry is projected to be at USD 987m in the year 2020 and its market is projected to increase annually at 7.4%. [4]

Coffee plants are highly vulnerable to various pests and diseases. Crop loss due to such diseases in coffee plants is estimated at 20-30% of the country's total production[5]. Chemical control's success on any disease depends on the disease pathogenesis stage at which the fungicide is applied [1]. Inexperienced and careless usage of pesticide may result in increased resistance of the pathogens in the long run, severely affecting the capability of plants to fight. Thus, the detection of plant diseases in an accurate and timely manner is an essential aspect of precision agriculture [2].

Soft computing can play a crucial role in the accurate and timely detection of such biotic stresses that attack the leaf of a coffee plant. Various techniques such as genetic algorithms [3], machine learning, use of computer vision and image processing [4], expert systems have been an area of active research to detect such diseases [5]. These methods have not been widely adopted due to low efficiency and success rate. In [6], the authors have used both image processing and artificial neural network to achieve a success rate of 90%. Some plant diseases do not have any conspicuous visual symptoms, however most common diseases found in coffee leaves have clear visual symptoms as shown in the Fig. 1. For example, the symptoms of coffee leaf rust (CLR) disease are oily spots on the upper surface of coffee leaf which are minute and yellowish in color, and expands further into a large circular spot that with time, turn to bright orange to red and at last, to brown with a yellow border[6].

Deep Learning have completely dominated the field of image classification for the last few years, thus the proposed Convolution Neural Network is used to detect coffee leaf diseases and categorize them into 5 classes – Healthy, Diseased Leaves with Cercospora spots, Phoma, Coffee Leaf Rust(CLR), and Leaf Miner with a high success rate.

The subsequent sections in the paper are organized in the following order: Section II describes the dataset used for training the model in detail. Section III explains the architectural components like Inception V3 model, Data augmentation technique and working of the proposed model. Section IV describes the various tests and experiments performed. In section V, the result is presented. Section VI contains a conclusion along with the future work.

II. DATASET

The pre-processed dataset [7] contains a wide variety of images of coffee leaves for disease detection. The pre-processing of data has been done to eliminate unwanted details and enhance the symptomatic features.

The images contain both disease-free and diseased leaves, affected by different types of biotic stresses. Dataset is divided in two parts – leaf dataset consisting of original images of the leaves and other one containing cropped images of symptoms. Fig. 1 shows the division of the dataset- disease categories with the corresponding number of leaf images.

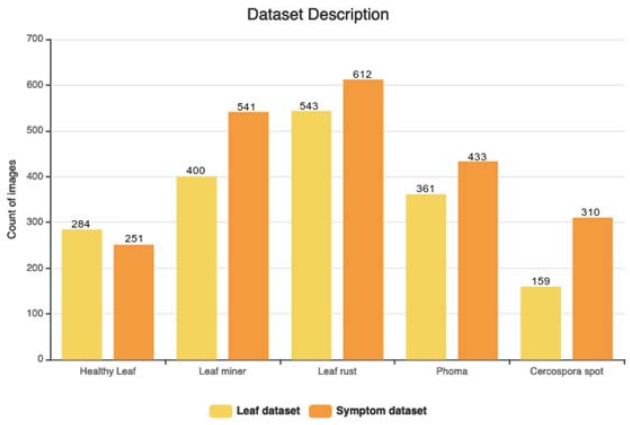

Fig. 1. Dataset Description

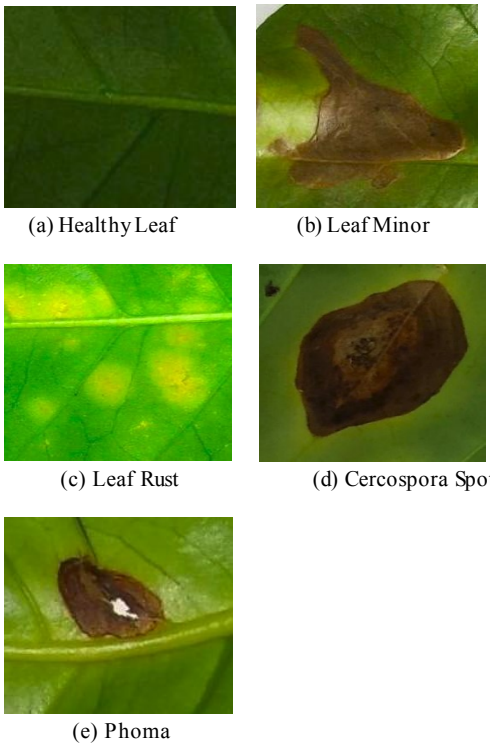
Details of each dataset is described below:



Leaf dataset: It contains images of coffee leaves and a CSV file with labels as different biotic stresses. All original images have the dimensions of 2048x1024 pixels.

Fig. 2. Sample of coffee leaves in Leaf Dataset

It consists of a total of 1747 images divided into 5 different classes - Healthy leaves, Infected leaves with Phoma, Leaf Miner, Coffee Leaf Rust and Cercospora Spots. Fig. 2 shows a sample of images found in this dataset.

Symptom dataset: A total of 2147 cropped images of the symptomatic parts of leaves are present. It is divided as per the named labelled classes - healthy leaves, leaf miner, leaf rust, phoma and cercospora. These are the 5 categories into which have classified our coffee leaves. Fig. 3 shows a sample of images available in this dataset. It is further divided into training, validation and test folders.

(a) Healthy Leaf (b) Leaf Minor

(c) Leaf Rust (d) Cercospora Spot

(e) Phoma

Fig. 3. Sample of cropped images showing only symptomatic leaf parts from Symptom Dataset

III. NETWORK ARCHITECTURE AND WORKING

The proposed network uses a Sequential model for classification. This Sequential model has been implemented using the Keras library in python language. The model has approximately 21 million parameters. Mini-Batch Gradient Descent (MBGD) is the optimization algorithm used to update the parameters. It performs much faster compared to conventional gradient descent algorithms. Fig. 4 represents the proposed neural network architecture. The images provided for training are input into the model in batches. The batch size value is kept as 32 with epoch value as 20. 1488 images belonging to 5 different classes is used for training the model and the image size has dimensions of 299x299 pixels.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:48:41 UTC from IEEE Xplore. Restrictions apply.

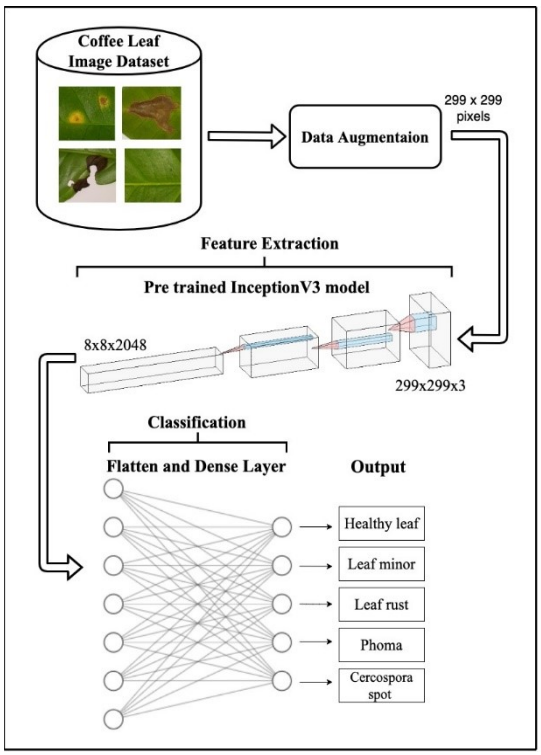


Fig. 4. Network Architecture

In the following sub-sections, explained the techniques of data augmentation and transfer learning and how it has enabled the proposed model to provide highly accurate testing results.

A. Data Augmentation

Data Augmentation is used to enhance the generalizability of the model. It applies augmentation techniques to produce a set of new images that are modified versions of our input data by application of image transformations, contrast changes, blurring images without changing their labels. It creates a varied and enlarged dataset and so the model is able to learn more features in a robust manner [8] and also prevents the problem of overfitting.

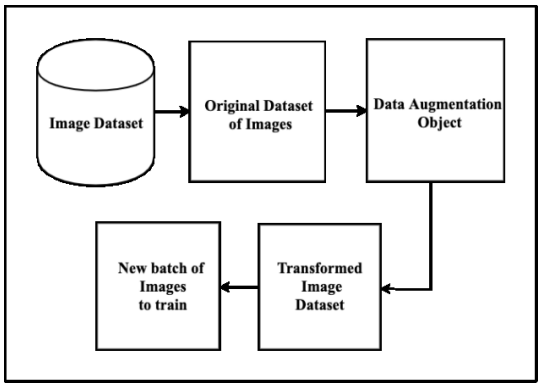

Fig. 5. Data Augmentation on the batch of images

Even though the technique enlarges the dataset but still cannot replicate the practical diversity found in nature. This is why only the image of symptomatic parts of leaves are used rather than considering the entire leaf [9]. In the proposed model and have used the in-place data augmentation technique using the Keras library in python. Implementation is called in-place because the transformation is applied on runtime i.e. it ensures that at each and every epoch new transformed image is input to the network which ultimately ensures high accuracy.

B. Transfer Learning

Transfer learning is a methodology that uses a pre-trained neural network. It makes use of knowledge gained while training on one dataset to be used on other datasets. It uses parametric values like weights and biases obtained while working on a large dataset and uses this knowledge to train on the new dataset. Image classification involves two processes, feature extraction and classification. With the help of transfer learning, one can reuse the part of the model involved in the feature extraction process and train the model for the classification part on a new dataset.

The model that used here for transfer learning is Inception v3 model. It is a 48-layer deep neural network. This model has been trained over a million images from ImageNet Database belonging to around 1000 different classes and have used TensorFlow hub library to perform transfer learning in our model and further added a flatten and a dense layer to our network. It changes the dimensionality of data and prevents the problem of overfitting of data. It has been used in the classification part.

C. Optimization Algorithm

Optimization algorithms help in the minimization (or maximization) of a given mathematical function F(x) which depends on the values of model's parameters and is used in carrying out computations for the output values. One such algorithm is Gradient Descent which falls under the umbrella of first-order optimization algorithms.

$$\theta = \theta - \alpha \nabla_\theta C(\theta; x_i, y_i) \qquad (1)$$

where θ is optimization parameter, C (θ; xi, yi) is the cost, (xi, yi) represents the data-point from the training set.

Mini-Batch Gradient Descent algorithm is used and the dataset is divided into batches of 32 images each. It combines the advantages of both Stochastic Gradient Descent and Batch Gradient Descent algorithms. The disadvantage of BGD is that it runs over the whole dataset to take a single step in the direction of minima. In contrast, SGD computes gradient for each randomly chosen datapoint which is faster but loses the advantages of vectorization and is error-prone also.

D. Categorical Cross-Entropy

Loss functions are used to evaluate the performance in the model. If our model predicts data that is highly deviated from the actual results, then loss function scales up to a large value.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:48:41 UTC from IEEE Xplore. Restrictions apply.

Thus, better predictions mean minimum value of loss function. There are many loss functions like Mean squared Error, Cosine Similarity, Binary Cross-entropy etc. One such loss function is Categorical Cross-Entropy. It is used for multi-class classification. It compares the distribution of our predictions with the actual labels. The probability of the true class is kept as 1 and for all other classes, the probability is kept 0. The equation is given as:

$$L(y, \hat{y}) = -\sum_{j=0}^{m} \sum_{i=0}^{n} (y_{ij} * log(\hat{y}_{ij})) \qquad (2)$$

where $\hat{y}$ is the predicted value and y representing the actual value, m and n represent the total number of data points and the total number of classes respectively.

IV. EXPERIMENTS

To implement this model, divided the dataset for training, validation and testing. 70% of images are used for training the model, 15% each for validation and testing. To create a varied dataset, data augmentation is implemented. The new output images are of dimensions 299x299 pixels. To decrease the training time and increase the performance, used InceptionV3 structure which is a pre-trained network. The convolutional layers that are present in it have pre-trained weights and biases. After each epoch, a new set of images are produced that are passed to the inception model. It forms the feature extraction part of the network.

Along with it, a dense and flatten layer are added to our sequential model. These layers serve in the classification part of the model. The flattening layer is used to convert a multidimensional output from a convolution layer to a linear output such that it can be directly fed into the neural network layer or to regular dense layer. Then, the dense layer performs the calculations and applies Softmax activation function.

Categorical cross-entropy is the loss function used and also tested the model for different values of learning rate as presented in Table I.

TABLE I. ACCURACY AND LOSS VALUE VARIATION WITH DIFFERENT LEARNING RATES

Learning Rate	Accuracy (%)	Loss Value
0.0001	95.82	0.48
0.001	95.22	0.42
0.005	97.61	0.35
0.01	97.31	0.36
0.1	74.03	1.73
1	32.01	10.1

Accuracy of the model increased with increase in learning rate at first, reaching a maximum at 0.005 with an accuracy of 97.61%, and started to decrease further. Hence, final value of the learning rate in the model is 0.005. Mini-batch gradient descent is used as the optimizer algorithm. Small batch size results in reduced accuracy [10]. Thus, batch size of 32 is used for maximum accuracy as shown in Table II.

TABLE II. BATCH SIZE VS ACCURACY

Batch Size	Accuracy (%)	Loss Value
4	94.03	0.49
8	95.22	0.49
16	97.31	0.36
32	97.61	0.35
64	97.01	0.37

V. RESULT

Using data-augmentation, transfer learning and MBGD as an optimizer, the proposed convolution neural network, has achieved an overall testing accuracy of 97.61% with a loss value of 0.35.

Table III represents how accuracy and loss improve with successive iterations. With every epoch, the accuracy increases and loss decrease significantly. After iteration 10, there is no significant improvement in the accuracy of our model although loss value continues to decrease slightly.

TABLE III. VARIATION IN ACCURACY AND LOSS VALUE WITH EPOCH

Epoch Number	Accuracy (%)	Loss Value
1	61.52	1.5752
2	73.43	0.7284
5	94.93	0.3632
8	97.01	0.3560
10	97.61	0.3535
12	97.61	0.3532

Further, Fig. 6 also clearly show that the value of loss and accuracy with varying epochs becomes nearly constant as more iterations are made.

The coffee leaf images dataset are not used directly but rather used Data Augmentation technique to enhance the variety of training data, resulting into a much more reliable and accurate model and also avoids the problem of overfitting. The Transfer Learning method is applied which makes the training process faster and efficient. Moreover, flatten and dense layers are added to the network which helps in the classification process. Fig. 8 shows the confusion matrix based on the predicted results.

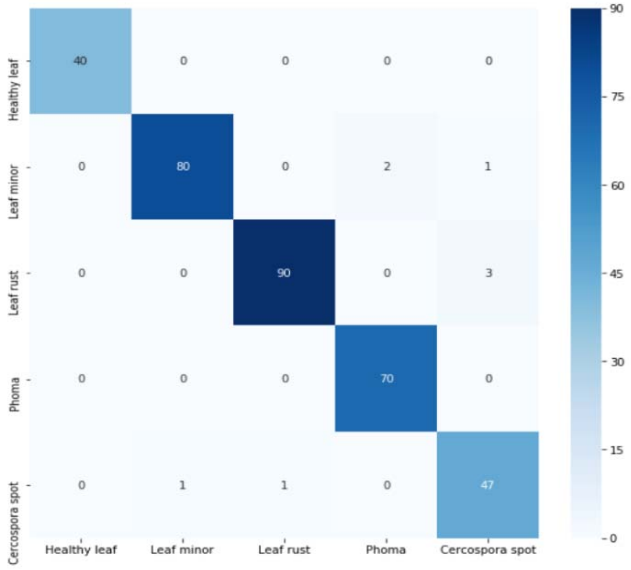

Fig. 8. Confusion matrix for proposed model

The average sensitivity and specificity computed for the proposed model is 0.974 and 0.992 respectively.

Table IV shows a comparison between various other techniques.

TABLE IV. COMPARISON OF DIFFERENT TECHNIQUES

S. No.	Technique Used	Accuracy (%)	Loss Value
1	Fuzzy Logic Based Expert System (using Decision Tree) [5]	85%	Not Available
2	Radial Basis Function Neural Network [11]	95%	Not Available
3	CNN with Data augmentation [12]	95%	0.10
4	CNN with data augmentation and transfer learning (using Inception V3 architecture) *	97.61%	0.35

*proposed model

The values of different hyper-parameters used in the proposed neural network are in Table V.

TABLE V. VALUES OF VARIOUS HYPER-PARAMETERS

Hyper-parameter	Value
Activation function	Softmax
Loss function	Categorical cross-entropy
Momentum	0.9
Batch size	32
Learning rate	0.005
Optimization function	Mini-batch gradient descent

VI. CONCLUSION AND FUTURE WORK

This research paper presents the use of deep convolutional neural networks in the detection and classification of healthy and unhealthy coffee plants. The unhealthy plant leaves are classified into 4 classes – Coffee Leaf Rust, Cercospora Spots, Leaf Miner, Phoma which are commonly occurring biotic stresses in coffee plants. One of the main contributions in our work is to propose a neural network for coffee plant disease detection with a very high level of accuracy.

In summary -

1. Identification and classification of coffee plant diseases by using the proposed neural network achieve a record-breaking accuracy of 97.61%.
2. With the help of this methodology, coffee plants farmer could be helped in timely identification of the diseases which will help in increasing the coffee production output of India.

As future work, aim to explore the requirements and necessary changes to our neural network to be able to accommodate various other new diseases in coffee plants and also account for variable environmental factors.

To make an even better prediction and achieve higher accuracy for a wide variety of diseases in coffee plants, additional variables such as temperature, air moisture, time of plantation and location weather are required.

***Abstract*— A dual-modal framework is presented for human emotion recognition based on Discriminant Correlation Analysis. For visual features, key-frames are selected from the video sequences and features are extracted using a Residual Neural Network. The Tuning Network (T-Net) is used for fine-tuning of these visual features. From the audio channel, Intensity, MFCC, pitch, F0 envelope, Line Spectral Frequency (LSF), and Zero Crossing Rate (ZCR) is evaluated along with their delta regression coefficients. Discriminant Correlation Analysis based feature fusion is used to fuse audio and visual modalities.**

Keywords*— Dual-Modal Framework, Discriminant Correlation Analysis, T-Net, Residual Neural Network, Feature Fusion

I. INTRODUCTION

One of the key tasks for Human-Computer interaction is detecting and recognizing human emotions. Humans express emotions using different modalities, such as facial expressions, hand movements, speech, body posture, etc. Out of all these modalities, facial expression and speech are studied the most for human emotion recognition. For recognizing facial expression a lot of different challenges are faced due to head pose variations, illumination changes, 2D and 3D rotations, etc. For speech emotion recognition, major challenges include the extraction of significant features and finding appropriate classifiers. To improve the emotion recognition process, both audio and visual information extracted from the video clips are used . For detecting and recognizing facial expressions first, the face is detected in each frame using a Multi-Task CNN [7]. 2-D rotation is eliminated by aligning the face using facial landmarks. After face detection and alignment, key-frames are extracted from the frame sequence. The key-frames remove the redundant information inside video frames and make the process computationally less expensive by reducing the number of frames for processing.

For visual feature extraction, Xiaobai Li [1] used LBP histograms on three planes (LBP-TOP). To solve the problem of the variable number of key-frames, temporal interpolation was used, but it is computationally more expensive as compared to our approach. Junkai Chen [2] used Histograms of Oriented Gradients over three orthogonal planes (HOG-TOP) and concluded that compared with LBP-TOP, HOG-TOP is more robust and efficient. LBP-TOP and HOG-TOP, although maintains the temporal information, does not provide the extent of quality seen in features extracted using deep neural networks. In our framework, visual features are extracted from the key-frames using a Deep Residual Neural Network. The extracted features are fine-tuned using another Neural Network to reduce dimensionality and improve accuracy.

S. Sahoo [3] also proposed an audio-visual based emotion recognition system in which they used MFCC as audio and LBP as a visual feature and applied decision level fusion. The classification was done using HMM (Hidden Markov Model) and SVM classifier for audio and visual features respectively. For the audio part, the following features is extracted along with their delta regression coefficients: Intensity, MFCC, pitch, F0 envelope, Line Spectral Frequency (LSF), and Zero Crossing Rate (ZCR). Some statistical functions are applied to these features to extract a large and relevant amount of features from audio modality.

Junkai Chen [2] compared the accuracy of feature and decision level fusion and obtained better results with the former technique. In our framework, after extracting features from both modalities, Discriminant Correlation Analysis (DCA) [26] based feature level fusion is performed, which gives us highly information-rich fused data capable of representing both modalities together.

The final prediction is made on the feature vector obtained after the fusion of audio-visual modalities. The method was tested on SAVEE [4], CREMA-D [5], and eNTERFACE'05 [6] dataset and results were compared for audio, visual and fused audio-visual features.

II. FRAMEWORK

A. Visual Feature Extraction

1) Face Tracking and Face Alignment

One very important part of the emotion detection and recognition process is face detection and alignment. Significant challenges are faced due to 2D-3D rotation, different pose, lighting conditions, and different camera angles. Recently CNN's have proved to be very useful in solving a lot of computer vision tasks. A three-stage multi-task deep cascaded convolution network [7] is used for face detection and face alignment. In stage one, for the generation of candidate windows, fast Proposal Network is used. A refinement network (R-Net) is used in the second stage and the last stage The Output Network (O-Net) is used to produce the facial-key landmark position.

This 3-stage cascaded network has proved to be more accurate and less computationally expensive over the state-of-the-art techniques. The facial-key landmarks produced by the Output Network are used for face detection and alignment.

2) Key Frame Extraction

Rapid facial movements [8] between frames is analysed by studying the difference observed in LBP features.

a) Feature Difference analysis (FDA)

FDA is used to compare the difference in LBP features in sequential video frames within an interval.

The currently observed frame is referred to as the Target Frame (TF) when an interval of H frames is analysed. Start Frame (SF) and End Frame (EF) are the κth frames before and after TF respectively. Where κ is 1/2 × (*H*-1). The average of SF and EF is referred to as the Mean Feature Frame (MFF).

LBP histograms from each TF are compared to its MFF using the Chi-Squared distance. Any rapid facial movement results in high dissimilarity.

b) Threshold and peak estimation

The face is divided into 36 blocks and FDA is done for every block. Average of α largest FD values are used to describe each frame.

$$L = \frac{1}{\alpha}\sum_{j=1}^{\alpha}(value_j) \tag{1}$$

Contrasting is required to avoid errors due to local peak variations and noise:

$$L_{new\,i} = L_i - \frac{1}{2}(L_{i+k} + L_{i-k}) \tag{2}$$

Negative values are set to 0 as they represent that there are no sudden movements. Finally, the threshold is computed as:

$$th = L_{new\,mean} + \tau \times (L_{new\,max} - L_{new\,mean}) \tag{3}$$

Where τ is a percentage parameter and lies between 0 and 1. Subsequent peaks are separated by a distance of κ/2.

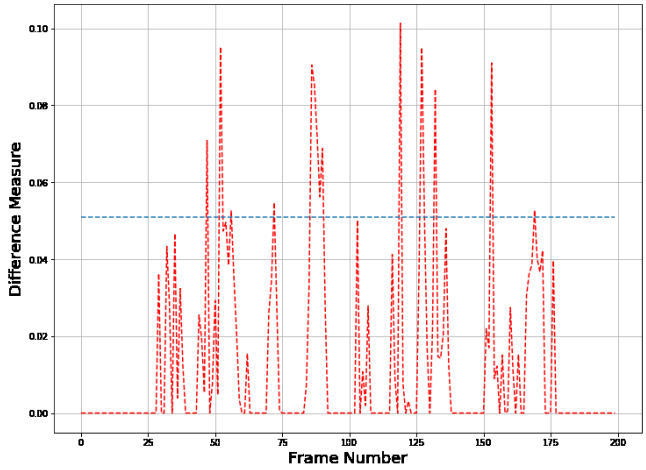

Fig.1. Plot showing FD vector vs. frame number

To obtain a constant number of key-frames from different videos, a new vector F is calculated as:

$$F_i = L_{new\,i} - th \tag{4}$$

λ frames with the highest corresponding values in F are selected as key-frames.

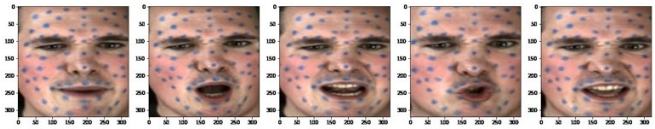

Fig.2. Key-frames extracted from a video of person JK in SAVEE expressing Anger

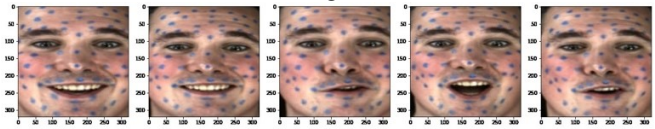

Fig.3. Key-frames extracted from a video of person JK in SAVEE expressing Happiness

3) ResNet-50

ResNet-50 is used [9], which is a 50 layer Residual Neural Network on each key-frame for feature extraction. The network can be trained on the emotion recognition datasets but better results are obtained using transfer learning on ImageNet [10] weight and bias.

Frames are fed to the Residual Network and feature vectors with 2048 dimensions are obtained. This method is repeated for each key-frame in a video sequence. For example, if there are λ key-frames, then the final feature vector with shape (λ×2048) is obtained for each video sequence.

4) Fine Tuning Video Features, T-Net

ResNet-50 operates on individual frames extracted from a video sequence, to represent each video with a single feature

vector, different approaches can be taken. The simplest way is to take mean overall the key-frames to obtain the average-feature set. This method is the least expensive in terms of computational power but the temporal information is not retained because the order of occurrence of frames inside the video sequence is not taken into consideration.

Temporal-information can be preserved using a feature descriptor that works in both the spatial and temporal domains. For example, Xiaobai Li [1] used LBP over three orthogonal planes (LBP-TOP) proposed by Zhao and Pietkäinen [11] as a feature descriptor, but according to previous studies, traditional LBP-TOP feature which uses all three histogram XY, XT, YT does not always yield the best performance. Xiaobai Li has used five different combinations of LBP histograms on three planes to increase performance. These methods, although maintains the temporal information does not provide the extent of quality seen in features extracted using deep neural networks like ResNet-50.

Taking mean overall key-frames not only results in loss of temporal information but also reduces the training data by a factor of λ, where λ is the number of key-frames per video. To solve this problem a method is proposed where instead of taking the mean overall key-frames, each key-frame is treated as an individual sample for training by assigning it the label of the video it is extracted from. This feature vector is referred to as the extended feature vector. The average and extended feature vector have same dimensions and only differ in the number of samples, in extended feature vector one video are split into λ samples and in the average feature vector, one video is represented by only one sample by taking mean overall the key-frames. A neural network is trained using the extended feature vector. This network is referred to as the tuning-network (T-NET). The output of the last dense layer of T-Net on the average feature set is used as the final visual feature vector.

B. Audio Feature Extraction

Audio have been used as our second modality for analysis. Human beings make use of both their facial expressions as well as their speech to express their emotions. Hence audio analysis is also very important which can give us some really important features to judge the emotion of a human being. For audio analysis, multiple features have been extracted that are quite relevant to express human emotions.

The feature set extracted consists of Intensity, MFCC, pitch, F0 envelope, Line Spectral Frequency (LSF), and Zero Crossing Rate (ZCR). It has been seen that by using time derivatives of these parameters, which are also called delta regression coefficients, the overall performance of the system can be improved hence delta regression coefficients have also been added for each of the above-mentioned parameters in our features set.

But there is a problem of variable feature-length of each audio sample depending on the duration of the audio clip (total number of frames will be different per audio clip). Thus, the coefficients of these features cannot be considered as it is, so to tackle this, some statistical functions have been applied on each of the parameters such that a fixed-length feature vector per audio clip can be obtained. The following statistical functions are applied: arithmetic mean, max/min value, range, linear regression coefficients, standard deviation, linear and quadratic error, kurtosis, skewness, and inter-quartile ranges.

Let us see what are the above-mentioned features mathematically are and how they are relevant features for detecting human emotions:

1) Pitch

It is the perceptual feature for a human listening to a particular sound. So in the emotion detection task, it is one of the important features to be determined. There are various time domain and frequency domain algorithms to determine pitch, also known as algorithms to find fundamental frequency(F0). Mathematically, the pitch for speech signal s is given as:

$$P(s) = D\{log|D(s.{w_n}^H\|s\|)|\} \quad (5)$$

Where D stands for DFT function, $\|s\|$ for the length of the signal and ${w_n}^H$ for hamming Window.

2) Intensity

Physically, the Intensity of a sound is defined as the amount of energy carried by an audio signal per unit time through a unit area. Mathematically, Intensity for a given sound signal s can be calculated as:

$$I_i(s) = \frac{\sum_{n=1}^{N}(s_{i+n}).{w_n}^H}{\sum_{n=1}^{N}{w_n}^H} \quad (6)$$

3) MFCC (Mel-frequency Cepstral Coefficient)

Mel-frequency Cepstral Coefficient (MFCC) is one of the most popular feature extractors in the field of audio analysis. It is the state-of-the-art audio feature extractor till now. The basic ideology behind this method is just to mimic the behaviour of human ears.

MFCC is calculated by a series of steps which have been explained in [12] very clearly. Finally, MFC coefficients are calculated by taking Discrete Cosine Transform (DCT) to decorrelate the filter bank coefficients, which is given by:

$$M_i = \sum_{k=1}^{N}\cos[i(k-1)\frac{\pi}{N}], \qquad i = 1,2,3 \dots P \quad (7)$$

Where P represents the number of cepstral coefficients $X_k, k = 1,2, \dots N$ is the log energy output of the k^{th} filter and N represent the number of triangular filter bank filters.

4) ZCR (Zero Crossing Rate)

The Zero-Crossing Rate (ZCR) of an audio frame is determined as the rate of change of sign of the signal in one frame duration.

Mathematically, ZCR for a frame $(Z(i))$ of length l can be calculated as:

$$Z(i) = \frac{1}{2l}\sum_{n=1}^{l}|sgn[s_i(n)] - sgn[s_i(n-1)]| \quad (8)$$

Where,

$$sgn[x_i(n)] = \begin{cases} 1, s_i(n) \geq 0 \\ -1, \ s_i(n) < 0. \end{cases}$$

C. Feature Fusion Technique

After extracting audio and visual features, the Discriminant Correlation Analysis (DCA) have been applied based feature fusion.

DCA is one of the robust fusion techniques. This technique is applied at the feature level, where a rich amount of information is available. In this fusion technique both of the feature, vectors are scaled in such a manner that inter-class correlation can be minimized within feature vectors and further scaled so that pair-wise correlation between two feature vectors can also be maximized. For more understanding, consider the following example:

Assume that η number of data samples have been collected that correspond to m different class labels. Now, let us divide this η columns matrix into m sections. In this matrix $u_{ij} \in U$ is j^{th} sample vector in the i^{th} class, $\overline{u_i}$ represents mean of the u_{ij} vectors belong to i^{th} class and $\bar{u}$ represents mean of the whole feature set i.e., $\overline{u_i} = \frac{1}{\eta_i}\sum_{j=1}^{\eta_i} u_{ij}$ and $\bar{u} = \frac{1}{\eta}\sum_{j=1}^{m} \eta_i \overline{u_i}$. Therefore, the inter-class scatter matrix can be described as :

$$S_{bu_{(p\times p)}} = \sum_{i=1}^{m} \eta_i (\overline{u_i} - \bar{u})(\overline{u_i} - \bar{u})^T = \boldsymbol{\varphi}_{bu}\boldsymbol{\varphi}_{bu}{}^T \quad (9)$$

Where p denotes the total number of features,

$$\boldsymbol{\phi}_{bu_{(p\times m)}} = \left[\sqrt{\eta_1}\,(\overline{u_1} - \bar{u}), \sqrt{\eta_2}\,(\overline{u_2} - \bar{u}), \ldots, \sqrt{\eta_m}\,(\overline{u_m} - \bar{u})\right]$$

So, if $p>>m$, which will be the case most of the time in real-world situations it will always be simple to compute $(\boldsymbol{\varphi}_{bu}{}^T\boldsymbol{\varphi}_{bu})_{(m\times m)}$ as covariance matrix instead of evaluating $(\boldsymbol{\varphi}_{bu}\boldsymbol{\varphi}_{bu}{}^T)_{(p\times p)}$. In [13] it has been shown that the most important eigenvectors of $\boldsymbol{\varphi}_{bu}\boldsymbol{\varphi}_{bu}{}^T$ can be acquired by simply mapping the eigenvectors of $\boldsymbol{\varphi}_{bu}{}^T\boldsymbol{\varphi}_{bu}$. Hence, just need to obtain eigenvectors of the matrix $(\boldsymbol{\varphi}_{bu}{}^T\boldsymbol{\varphi}_{bu})_{(m\times m)}$.

Now, to get well-separated classes, $\boldsymbol{\varphi}_{bu}{}^T\boldsymbol{\varphi}_{bu}$ should be a diagonal matrix. To diagonalize it, transformation can be used , given as:

$$A^T(\boldsymbol{\varphi}_{bu}{}^T\boldsymbol{\varphi}_{bu})A = \hat{\Delta} \quad (10)$$

Where A represents a matrix of orthogonal eigenvectors and $\hat{\Delta}$ represents a diagonal matrix where eigenvalues are sorted in descending order.

Now, consider $B_{(m\times c)}$ a matrix which consists of c eigenvectors obtained from A matrix by selecting c largest non-zero eigenvalues, such that:

$$B^T(\boldsymbol{\varphi}_{bu}{}^T\boldsymbol{\varphi}_{bu})B = \Delta_{(c\times c)} \quad (11)$$

Hence, the corresponding c most important eigenvectors for scatter-matrix in Eq. 7 can be acquired by simply mapping: $B \rightarrow \boldsymbol{\varphi}_{bu}B$:

$$(\boldsymbol{\varphi}_{bu}B)^T S_{bu}(\boldsymbol{\varphi}_{bu}B) = \Delta_{(c\times c)} \quad (12)$$

Therefore, $\theta_{bu} = \boldsymbol{\varphi}_{bu}B\Delta^{-1/2}$, is the weight which diagonalizes S_{bu} and lowers the dimensions of our matrix U from p to c, i.e.,

$$\theta_{bu}{}^T S_{bu}\theta_{bu} = I, \quad (13)$$

$$U'_{(c\times\eta)} = \theta_{bu_{(c\times p)}}{}^T U_{(p\times\eta)} \quad (14)$$

Where, U' is the transformed version of U in which classes are well-separated and inter-class correlation is minimized.

Similarly, another feature setcan be solved for, V and find transforming weight θ_{bv}, which minimize inter-class correlation in V feature vector and lowers the dimensions from q to c.

$$\theta_{bv}{}^T S_{bv}\theta_{bv} = I, \quad (15)$$

$$V'_{(c\times\eta)} = W_{bv_{(c\times q)}}{}^T V_{(q\times\eta)}\,. \quad (16)$$

Till now transformed U to U' and V to V', such that between class correlation has been minimized but now need to further transform U' and V' such that features of U' will have non-zero correlation only with corresponding features in another set, in V'. To accomplish this need to diagonalize another matrix, which is called the between-set covariance matrix, $S'_{uv} = U'V'^T$. For this task, singular value decomposition (SVD) can be used :

$$S'_{uv_{(c\times c)}} = X\,\Sigma Y^T \Rightarrow X^T S'_{xy} Y = \Sigma \quad (17)$$

Where, U' and V' have the rank of order c and $S'_{uv\ (c\times c)}$ is non-degenerate. Thus, Σ is a diagonal matrix in which only diagonal elements are non-zero. So, have $\theta_{du} = X\Sigma^{-1/2}$ and $\theta_{dv} = Y\Sigma^{-1/2}$ such that:

$$\left(X\Sigma^{-\frac{1}{2}}\right)^T S'_{uv}\left(Y\Sigma^{-\frac{1}{2}}\right) = I, \quad (18)$$

Where, S'_{uv} gets unitized. Therefore, transformed finally our feature vectors as:

$$U^* = \theta_{du}{}^T U' = \underbrace{\theta_{du}{}^T\theta_{bu}{}^T}U = \theta_u U \quad (19)$$

$$V^* = \theta_{dv}{}^T V' = \underbrace{\theta_{dv}{}^T\theta_{bv}{}^T}V = \theta_v V \quad (20)$$

Where $\theta_u = \theta_{du}{}^T\theta_{bu}{}^T$ and $\theta_v = \theta_{dv}{}^T\theta_{bv}{}^T$ are the final transformation weights for U and V, respectively.

Hence after transforming our audio feature vector, say U to U' and visual feature vector, say V to V', feature level

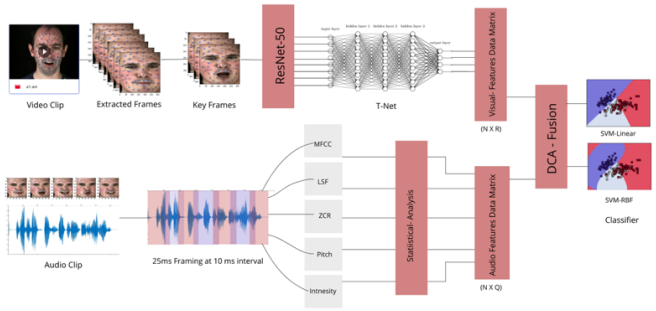

Fig.4. Proposed framework

fusion can be performed by simply concatenating or taking the summation of the transformed feature vectors as shown:

$$Z_1 = \begin{pmatrix} U^* \\ V^* \end{pmatrix} = \begin{pmatrix} W_u{}^T U \\ W_v{}^T V \end{pmatrix} = \begin{pmatrix} W_v & 0 \\ 0 & W_u \end{pmatrix}^T \begin{pmatrix} U \\ V \end{pmatrix} \quad (21)$$

Or

$$Z_2 = U^* + V^* = W_u{}^T U + W_v{}^T V = \begin{pmatrix} W_u \\ W_v \end{pmatrix} \begin{pmatrix} U \\ V \end{pmatrix} \quad (22)$$

However, the concatenation method have been used to fuse audio (U) and visual (V) feature vectors i.e., Z_1.

III. Experiment and Results

In this section, qualitative and quantitative analysis is done in the terms of accuracy with other existing techniques on three datasets i.e. SAVEE, CREMA-D, and eNTERFACE'05 and results are compared for audio, visual and fused audio-visual features.

A. SAVEE

The SAVEE database contains recordings from 4 different actors expressing 7 different emotions. The database has a total of 480 audio-visual clips recorded at 60fps. We merged classes 'Sadness' and 'Disgust' due to their high co-relation and to maintain a constant 6-class classification on each dataset.

For key-frame extraction, the value of H is set to H = 19 (to maintain 0.3 sec). The default value of 0.5 is used for τ. For LBP, radius r is set to r = 3 and neighboring points to $8 \times r = 24$. λ is set to 20. The output of the third dense layer of T-Net on the average feature vector is used as the final visual-feature set for fusion. For audio features, a frame size of 25ms at the rate of 10ms is used. 12 MFCC coefficients, 8 line spectral frequencies along with other features with their respective delta regression coefficients are extracted from each frame. Hence in total $24 \times 2 = 48$ different types of features are calculated and 17 statistical functions are applied on each of these features, therefore in total $48 \times 17 = 816$ types of audio features are calculated per audio clip.

After getting feature data matrices from both the modalities i.e., $X_{(480\times816)}$ from audio and $Y_{(480\times512)}$ from visual, DCA fusion is applied which gives us the fused feature vector of dimension (48×10) for classification. SVM [14] with linear and RBF kernel is used for classification at each stage.

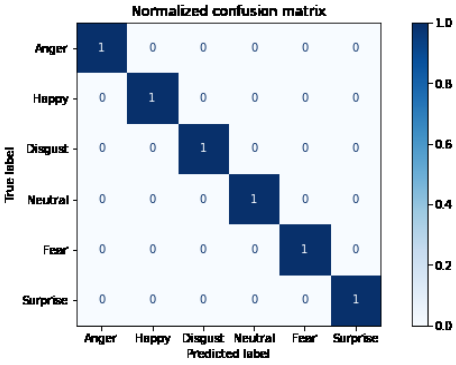

Fig. 5. Confusion matrix for 6 classes evaluated using audio-visual features with SVM classifier on the SAVEE dataset.

TABLE 1
Accuracy on SAVEE dataset

Feature type	Classifier	Accuracy
Visual	SVM (RBF)	99.00%
Audio	SVM (RBF)	90.70%
Audio-Visual	SVM (linear)	100%

This table represents the accuracy of our classification model when only the audio feature vector is used i.e. $X_{(480\times816)}$ which is 90.70%, when only visual feature vector is used i.e. $Y_{(480\times512)}$ which is 99.00% and when a DCA based fused vector is used which is 100%.

B. CREMA-D

CREMA-D contains 7,442 clips from 91 actors. The sentences are presented using 6 different emotions at four different levels. For our application, all levels of emotions are considered as one.

For key-frame extraction, the value of H is set to H = 11 (to maintain 0.3 sec). The default value of 0.5 is used for τ. For LBP, radius r is set to r = 3 and neighboring points to $8 \times r = 24$. λ is set to 20. The output of the third dense layer of T-Net on the average feature vector is used as the final visual-feature set for fusion. For audio features, a frame size

of 25ms at the rate of 10ms is used. 14 MFCC coefficients, 10 line spectral frequencies along with other features with their respective delta regression coefficients are extracted from each frame. Hence in total $28 \times 2 = 56$ different types of features are calculated and 17 statistical functions are applied on each of these features, therefore in total $56 \times 17 = 952$ types of audio features are calculated per audio clip.

After getting feature data matrices from both the modalities i.e., $X_{(7442\times952)}$ from audio and $Y_{(7442\times512)}$ from visual, DCA fusion is applied which gives us the fused feature vector of dimension (7442×10) for classification. SVM with linear and RBF kernel is used for classification at each stage.

C. eNTERFACE'05

The eNTERFACE'05 contains audio-visual clips from 46 subjects reacting to six different situations and expressing 6 different emotions. The videos are recorded at a 25fps frame rate.

For key-frame extraction, the value of H is set to $H = 7$ (to maintain 0.3 sec). The default value of 0.5 is used for τ. For LBP, radius r is set to $r = 2$ and neighboring points to $8 \times r = 16$. λ is set to 20. The output of the third dense layer of T-Net network on the average feature vector is used as the final visual-feature set for fusion. For audio features, a frame size of 25ms at the rate of 10ms is used. 12 MFCC coefficients, 10 line spectral frequencies along with other features with their respective delta regression coefficients are extracted from each frame. Hence in total $26 \times 2 = 52$ different types of features are calculated and 17 statistical functions are applied on each of these features, therefore in total $52 \times 17 = 884$ types of audio features are calculated per audio clip.

After getting feature data matrices from both the modalities i.e., $X_{(1166\times884)}$ from audio and $Y_{(1166\times512)}$ from visual, DCA fusion is applied which gives us the fused feature vector of dimension (1166×10) for classification. SVM with linear and RBF kernel is used for classification at each stage.

IV. CONCLUSION

Our proposed framework based on Discriminant Correlation Analysis on three different standard datasets have been successfully applied: SAVEE, CRAMA-D, and eNTERFACE'05. Our results on CREMA-D outperform other previously proposed frameworks in [20, 21, 22] and achieve state-of-the-art results with a recognition rate of 95.90%. On SAVEE and eNTERFACE'05, our results are equivalent to state-of-the-art results which are 100% and 98.5% respectively as compared to the results in [16]. In future, neural networks will be used for audio feature extraction.

RESEARCH PAPER

Effect of Distributed Damping on the Dynamic Behavior of Flexible Chassis of Heavy Road Vehicle Under Standardized Random Road Responses

Ashish Gupta[1] · **Vikas Rastogi**[2]

Received: 22 April 2019 / Accepted: 23 May 2020

Abstract
This paper evaluates the dynamics of a heavy road truck on different random road conditions, whereas the issue of beam flexibility is also being accompanied. Heavy vehicles like trucks and buses having a large structure to carry their load ride in all kinds of terrains, for thousands of miles without failing structure. Structure (chassis or frame) of the truck should be able to sustain all types of vibration (i.e., longitudinal, transverse and flexural). This study starts with developing an analytical model with consideration of the Rayleigh beam approach, where the rotary inertia of the beam has also been admitted. This work also considered internal damping of the chassis, which has been neglected in past studies specifically for flexural vibration. Further bond graph model of the flexible structure of a heavy road vehicle is developed, where this model is derived through modal expansion approach. The dynamic response of the structure is analyzed under various random road conditions at different vehicle speeds. These random models of the road are developed according to ISO 8608 standard, whereas four (H1–H4) kinds of road categories are considered. Results show the dynamic response of the chassis under a real road response so that parameters of the various parts of the structure can be evaluated, which further raises the ride comfort and road holding capability of the structure. Further, this work also examines the effect of structural damping or internal damping on the dynamics of the system.

Keywords Lagrangian approach · Bond graph · Frame flexibility of the chassis · Structural damping · Random road conditions

1 Introduction

Ride vibration is a principal concern for vehicle dynamics, where frame flexibility plays a very significant role. Numerous studies have been conducted on problems of ride vibration. However, very few studies have been carried out to study the effect of vibration, which includes a flexible frame. It has been generally noticed that the flexural vibration can be neglected for smaller vehicles, relatively for stiffer automobiles. However, trucks and the long heavy vehicle experience significant beaming mode vibration (Margolis and Edeal 1989). Ibrahim (1996) has created a model of truck frame through FEM where he calculated the modal properties of the frame. The results were presented in terms of PSD and RMS of the vehicle vertical response. Most of the analyses on the effects of chassis flexibility in vehicle dynamics were based on the use of particular model developed, whereas the FEM (finite element method) and the modal superposition theory have been extensively used to calculate the modal properties of the frame structure. Generally, the problem occurs due to the beam flexibility of the vehicle, which is termed as 'beaming response of the vehicle' (Rideout 2012). Rideout and Khan (2010) presented the model of the frame flexibility issue for truck model. They created a pitch plane model which involved longitudinal dynamics and transverse frame vibrations. Huang and Zeng (2010) studied about flexural vibration problems for high-speed passenger rail vehicle, where car body was modeled through Euler beam approach. This research underlined

the effect of internal damping in ride comfort of rail vehicle. Kumar et al. (2017) analyzed the whole-body vibration for railway system. They have considered biodynamic model of human for the assessment of ride comfort, where whole-body model was integrated with flexible bogie model system. The flexible bogie system was modeled through Euler–Bernoulli beam approach. Similarly in other studies, Euler–Bernoulli approach was attempted to introduce beam flexibility in heavy truck chassis modeling (Zhou et al. 2009; Kim and Yim 1994). Heavy long vehicles have a ladder-type chassis structure across the whole length of the vehicle. These structures are stiffer in bending, which can respond to bending frequencies more than 20 Hz. When the engine and other elements are mounted on the structure, these bending frequencies are reduced up to 8 Hz, for highly stiffer frames (Cai-hong and Zeng 2010; Tomioka et al. 2017). Tomioko and Takigami (2015) have conducted the experimental study on flexural beam to evaluate the effect of frame flexibility on passenger comfort. Some other studies apparently show that the beaming frequency is higher than the rigid frequency of the vehicle (Tomioka et al. 2006; Agostinacchio et al. 2014). However, in large vehicles, beaming frequency is influenced by road inputs.

A lot of research has been conducted considering the issue of frame flexibility in the analysis of railway vehicle. But, limited studies were reported on dynamic analysis of heavy road vehicles considering random road disturbances. A country like India, where multifarious road conditions are present, which creates an infirm condition before all leading automobile industries to maintain comfort level as per standard on every road conditions. Some studies have mentioned that structural damping can participate in ride quality improvement. So, in the present work frame flexibility has been incorporated by considering frame as Raleigh beam, which also includes the effect of the rotary inertia. Lagrangian approach has been applied to obtain the energy equations for the vehicle system, which resulted from the well-known rigid body modes and the modal parameters of the frame flexibility. The work involves the importance of structural or internal damping of beam-type chassis structure on flexural vibration and ride quality of the heavy vehicle with random road disturbance prescribed by ISO 8608 (Meirovitch 1980) as input. The bond graph approach has been utilized to model the vehicle with flexible frame. Besides the beam response, the effect of different road conditions as per ISO 8608 and vehicle speeds on the dynamics of vehicle has also been presented. The work begins with deriving Lagrange equation of frame considered as Rayleigh beam for truck flexural response. Then, this formulation is being extended for bond graph modeling with or without consideration of structural damping effect. Simulations were carried out to visualize the beaming mode response with respect to random road conditions as prescribed by ISO 8608.

2 Analytical Framework for Heavy Vehicle System Through Classical Mechanics

2.1 Generalized Lagrange's Equation for a Continuous System

It is a well-known fact that the Lagrange formulation provides one of the most convenient ways of writing down the equation of motion for a wide range of mechanical systems. The principal advantage of Lagrange's equation is that it is easier to apply to dynamical systems other than the simplest. This formulation is created from scalar quantities of kinetic energy, potential energy and work expressed in terms of generalized coordinates and developed for universal handling of dynamical systems (Mukherjee and Karmakar 2000). The equation is formulated equations of motion from the principle of least action. This density function is a function comprised of time, transverse displacements and transverse velocities, and up to second derivatives of displacements to space coordinates x, which may be expressed as

$$\widehat{L}\big(w(t,x),\dot{w}(t,x),w'(t,x),w''(t,x),\dot{w}'(t,x)\big)=\hat{T}(t,x)-\hat{V}(t,x) \tag{1}$$

where $\widehat{L}(\cdot)$ is the Lagrangian density function and $\hat{T}(\cdot)$ is the kinetic energy density, which may be expressed as,

$$\widehat{T}(x,t)=\widehat{T}(\dot{w}(x,t),\dot{w}'(x,t)) \tag{2}$$

Moreover, $\hat{V}(t,x)$ is the potential energy density, which has the following functional dependence,

$$\widehat{V}(x,t)=\widehat{V}(w'(x,t),w''(x,t)) \tag{3}$$

The next step is used for finding the equation of motion and the boundary conditions for the beam through the variational principle (see Appendix 2). This formulation yields

$$\delta\int_{t1}^{t2}\widehat{L}\big(w(t,x),\dot{w}(t,x),w'(t,x),w''(t,x),\dot{w}'(t,x)\big)\mathrm{d}t=0 \tag{4}$$

where $\delta(\cdot)$ is infinitesimal variation operator and it is very similar to the total derivative operator; the only difference is that $\delta(\cdot)$ does not vary with time. Another significant property of infinitesimal operator is that it commutes with the differential operator. Using the extremization condition, one may obtain

$$\int_0^L\int_{t1}^{t2}\delta\widehat{L}\big(w(t,x),\dot{w}(t,x),w'(t,x),w''(t,x),\dot{w}'(t,x)\big)\,\mathrm{d}x\mathrm{d}t=0 \tag{5}$$

or

$$\int_0^L \int_{t1}^{t2} \left[\frac{\partial \widehat{L}}{\partial w}\delta w + \frac{\partial \widehat{L}}{\partial \dot{w}}\delta \dot{w} + \frac{\partial \widehat{L}}{\partial w'}\delta w' + \frac{\partial \widehat{L}}{\partial \dot{w}'}\delta \dot{w}' + \frac{\partial \widehat{L}}{\partial w''}\delta w'' \right] \mathrm{d}x\,\mathrm{d}t = 0 \tag{6}$$

The detailed derivation of the variational formulation is presented in "Appendix 1."

2.2 Analytical Formulation for Flexural Behavior of the Truck Chassis Structure

An analytical formulation for flexural behavior of the truck structure is being attempted in this section. The vehicle base is modeled as a rigid body with a local coordinate reference frame (w, x) attached to the center of mass (M) and aligned with the inertia principal axes as shown in Fig. 1. It has density (ρ) and $p$itch inertia (J) with respect to the body $W_1(t) - W_2(t)$ displacement axis, EI flexural rigidity and $\theta(t)$ pitch velocity of the base. It is connected with the suspension system to different elements of the vehicles. The spring stiffness characterizes the spring and damper in the suspension system k_s and damping coefficient R_s, respectively. The various displacements of the vehicle are described $w(x, t)$ with respect to the equilibrium positions. As the vehicle is assumed to be rigid, its motion can be described by the vertical displacement (bounce) as $w(x, t)$ and the rotation about the transverse horizontal axis (pitch) as $\dot{\theta}(t)$.

The model of the vehicle is being created with the following assumptions:

- The components of the vehicle body act as a rigid body.
- The springs and dampers of the suspension system have linear characteristics.
- The spring damper system is assumed to be massless.
- The tire is assumed to provide stiffness and thus modeled as a spring element.
- The positions of the two ends of the spring connecting two rigid bodies or connecting one rigid body and one contact point are required as input data.
- The spring damper system connects each rigid body.
- The traveling road is assumed to be straight.
- The road inputs are assumed to be random.

The analytical framework of truck chassis can be assumed as a free–free beam structure, where Rayleigh beam approach is being adopted. Let us consider a transverse deflection of the beam $w(x,t)$, where x varies from 0 to beam length L. The formalism of beam flexibility is easily obtained through the well-known Lagrangian equation. Lagrangian density variation may be obtained from the following expression as

$$L = \left[\frac{1}{2}\int_0^L \left(\rho A \dot{w}(x,t)^2 + \rho I \dot{w}'(x,t)^2\right)\mathrm{d}x - \frac{1}{2}\int_0^L \left(EIw''(x,t)^2\right)\mathrm{d}x \right] \tag{7}$$

where ρ is the mass density, A is the area of cross section, EI is the rigidity and I is the second moment of area of the cross section of the beam about the neutral axis. In Eq. (7), the first term represents kinetic energy of the beam, the second term presents as inertial energy and the final term is strain energy. The variational formulation presents a refined and classical method of deriving the equation of motion of a dynamical system, where all the boundary conditions of a system can be revealed. However, fundamentals of variational formulation for the continuous system are detailed in "Appendix 2."

The equation of motion is obtained after applying a variational formulation and boundary conditions in free vibration condition, which may be expressed as

$$\rho A \ddot{w}(x,t) - \left(\rho I \dot{w}''(x,t)\right)' + \left(EIw''(x,t)\right)'' = 0 \tag{8}$$

This equation of motion is based on Rayleigh beam model. The term $\left(EIw''(x,t)\right)''$ is usually referred to as the

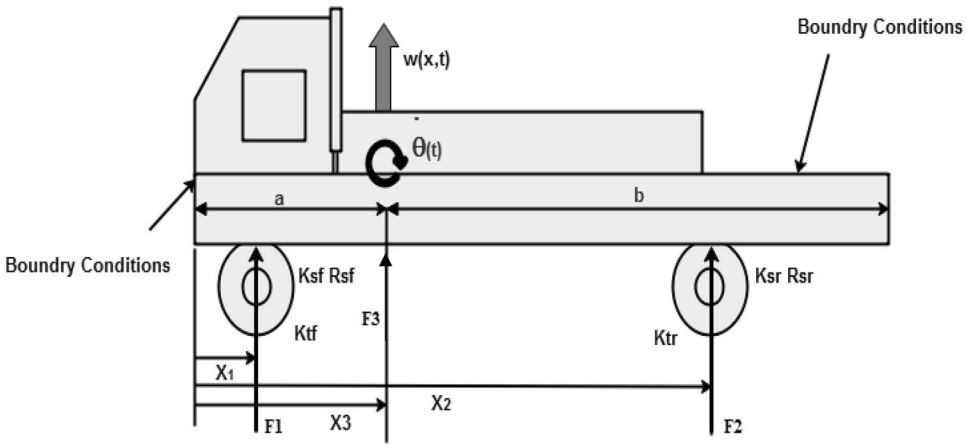

Fig. 1 Schematic diagram of a continuous frame of vehicle

flexural term, where EI is called the flexural stiffness and $\left(\rho I\dot{w}''(x,t)\right)'$ is known as the rotary inertia term. If this term is zero, then Eq. (8) will become a Euler beam model. Thus, the term $\left(\rho I\dot{w}''(x,t)\right)'$ can also be named as a Rayleigh beam term.

Assume a modal solution for Eq. (8) in the form of

$$w(x,t) = W(x)e^{i\omega t} \tag{9}$$

where ω is the eigenfrequency and $W(x)$ is the eigenfunction. The actual solution of the equation may be obtained by taking the real part of the solution. Substituting the modal solution in the field Eq. (8) yields after rearrangement as

$$-\omega^2\left[\rho AW - \left(\rho IW'\right)'\right] + \left(EIW''\right)'' = 0 \tag{10}$$

which along with the corresponding boundary condition represents the eigenvalue problem for a Rayleigh beam.

2.3 Modal Analysis for Uniform Rayleigh Beam

Considering Eq. (10) as a uniform beam and substituting in Eq. (9) a solution of the form

$$W(x) = Ce^{\lambda x} \tag{11}$$

where C and λ are constants, Eq. (10) can be rewritten as

$$EI\lambda^4 - \omega^2\rho I\lambda^2 - \omega^2\rho A = 0 \tag{12}$$

yielding

$$\lambda^2 = \frac{1}{2EI}\left[\omega^2\rho I \pm \sqrt{\omega^4\rho^2I^2 + 4\omega^2EI\rho A}\right]$$

Thus, the spatial equation (real form) of Eq. (12) has the general solution, which may be expressed as

$$W(x) = A\cosh\lambda x + B\sinh\lambda x + C\cos\lambda x + D\sin\lambda x \tag{13}$$

Here, one may consider a uniform Rayleigh beam for which the free–free boundary conditions are given by

$$W(0) = 0, \quad W'(0) = 0, \quad W''(l) = 0, \quad W'''(l) = 0, \tag{14}$$

Using, Eq. (14) in Eq. (13) yields the frequency equation as

$$\cosh\lambda_n l\cos\lambda_n l - 1 = 0 \tag{15}$$

The solution of Eq. (15) yields

$$\lambda_n = \left(\frac{2n+1}{2}\pi\right)\frac{1}{l}$$

Moreover, the mode shape function may be expressed as

$$\begin{aligned} W_n(x) = {} & (\cos\lambda_n l - \cosh\lambda_n l)(\sin\lambda_n x + \sinh\lambda_n x) \\ & - (\sin\lambda_n l - \sinh\lambda_n l)(\cos\lambda_n x + \cosh\lambda_n x) \end{aligned} \tag{16}$$

Thus, one may obtain the natural frequency of Eq. (6), which may be written as

$$\omega_n = \lambda_n^2\frac{1}{\left[1+\lambda_n^2\frac{I}{A}\right]^{1/2}}\sqrt{\frac{EI}{\rho A}} \tag{17}$$

It is recognized that conditions are force-free at this point, which permits $\omega_n = 0$ to be a mode frequency. Thus, Eq. (10) will be written as

$$\frac{\mathrm{d}^4W}{\mathrm{d}x^4} = 0 \tag{18}$$

or

$$W = c_1x^3 + c_2x^2 + c_1x + c_4 \tag{19}$$

There are two possible solutions for Eq. (13), which satisfied all boundary conditions. They are $W = \text{const}$ and $W = ax + b$. These are called rigid body modes, and it is convenient to assume them as rigid body rotation of the beam about the centrally located center of mass. Thus,

$$W_{00}(x) = 1 \tag{20}$$

and

$$W_0(x) = x - \frac{L}{2} \tag{21}$$

Let us consider an analysis for truck chassis, which is presented in Fig. 1. In this figure, the half model of the road truck is supported by front and rear suspension, which exerted an external force on the beam over the various road responses. From equation of motion, Eq. (8) will be rewritten as

$$\begin{aligned} & \rho A\ddot{w}(x,t) - \left(\rho I\dot{w}''(x,t)\right)' + \left(EIw''(x,t)\right)'' \\ & = F_1\delta(x-x_1) + F_2\delta(x-x_2) + F_3\delta(x-x_3) \end{aligned} \tag{22}$$

where F_1 and F_2 are the force exerted by front and rear suspension systems, respectively, and F_3 is dead weight on the beam, $\delta(\cdot)$ is the Dirac delta function, x_1 and x_2 are the respective distance from left end to the front and rear suspension of the vehicle, respectively, and x_3 is the distance of dead weight from the left end. One may assume that the solution of Eq. (22) is separable in space and time, and the forced solution has the following form,

$$w(x,t) = \sum_{n=0}^{\infty} W_n(x)U_n(t) \tag{23}$$

where $W_n(x)$ depends on the spatial position and $U_n(t)$ depends on time. Introducing Eq. (23) into Eq. (22), and multiplying each term by $W_m(x)$ and integrating with respect

to $x=0$, $x=l$, one may then use the orthogonal property to the modes and obtain

$$\int_0^l \rho A W_n^2 \mathrm{d}x\ddot{U}(t) + \omega_n^2(\rho I\lambda_n^2 - \rho A)\int_0^l W_n^2 \mathrm{d}xU(t) = F_1 W_n(x_1) + F_2 W_n(x_2) + F_3 W_n(x_3) \tag{24}$$

$$\rho A\left(1 - \frac{I}{A}\lambda_n^2\right)\int_0^l W_n^2 \mathrm{d}x\ddot{U}(t) + \rho A\left(1 - \frac{I}{A}\lambda_n^2\right)\omega_n^2\int_0^l W_n^2 \mathrm{d}xU(t) = F_1 W_n(x_1) + F_2 W_n(x_2) + F_3 W_n(x_3) \tag{25}$$

Equation (25) can be represented in general form as

$$m\ddot{U}(t) + kU(t) = F_1 W_n(x_1) + F_2 W_n(x_2) + F_3 W_n(x_3) \tag{26}$$

where

$$m = \rho A\left(1 - \frac{I}{A}\lambda_n^2\right)\int_0^l W_n^2 \mathrm{d}x$$

$$k = m\omega_n^2\int_0^l W_n^2 \mathrm{d}x$$

Now one may write the first frequency modes (Karnopp et al. 2012)

$$\left[\rho A\int_0^l (1)_n^2 \mathrm{d}x\right]\ddot{U}_{00} = F_1 + F_2 + F_3 \quad \text{or} \quad m\ddot{U}_{00} = F_1 + F_2 + F_3 \tag{27}$$

which states that the external force accelerates the center of mass of the beam. The other zero frequency mode yields

$$\left[\rho A\int_0^l \left(x - \frac{l}{2}\right)^2 \mathrm{d}x\right]\ddot{U}_{00} = F_1 + F_2 + F_3 \tag{28}$$

or

$$J\ddot{U}_0 = F_1 + F_2 + F_3$$

This equation states that the moment of the external forces about the center of mass produces angular acceleration $\ddot{U}_{00}$, where J is the centroid moment of inertia of beam. The next subsection will present the formulation, which includes structural damping.

2.4 Incorporation of Structural Damping

Now one may consider internal damping (the detailed derivation of internal damping is presented in "Appendix 2" for ready reference) of the beam and Eq. (22) may be rewritten as

$$\rho A\ddot{w}(x,t) - \left(\rho I\dot{w}''(x,t)\right)' + \left(EIw''(x,t)\right)'' - \mu_I I\left(\dot{w}'''\right)' = F_1\delta(x - x_1) + F_2\delta(x - x_2) + F_3\delta(x - x_3) \tag{29}$$

$$\rho A\ddot{w}(x,t) - \left(\rho I\dot{w}''(x,t)\right)' + \omega^2(\rho I\lambda^2 - \rho A) - \mu_I I\left(\dot{w}'''\right)' = F_1\delta(x - x_1) + F_2\delta(x - x_2) + F_3\delta(x - x_3) \tag{30}$$

where μ_I is the structural damping coefficient, δ is the Dirac delta function, x_1 and x_2 are the respective distance from left corner to the front and rear suspension of the vehicle and x_3 is the distance of dead weight from the extreme left corner of the vehicle. F_1 and F_2 are the suspension forces of the front and rear suspension system, respectively, and F_3 is the dead weight. The front and rear suspension forces of the vehicle may be expressed as

$$F_1 = C_{\mathrm{s}}^{\mathrm{f}}(V_{\mathrm{f}} - \dot{w}_1) + K_{\mathrm{s}}^{\mathrm{f}}\left(\int_0^t V_{\mathrm{f}}\mathrm{d}t - w_1\right) \tag{31}$$

$$F_2 = C_{\mathrm{s}}^{\mathrm{r}}(V_{\mathrm{r}} - \dot{w}_2) + K_{\mathrm{s}}^{\mathrm{r}}\left(\int_0^t V_{\mathrm{r}}\mathrm{d}t - w_2\right) \tag{32}$$

where $C_{\mathrm{s}}^{\mathrm{f}}$ and $C_{\mathrm{s}}^{\mathrm{r}}$ are, respectively, damping coefficient of the front and rear damper; V_{f} and V_{r} are the road velocity input at front and rear wheel, respectively; $K_{\mathrm{s}}^{\mathrm{f}}$ and $K_{\mathrm{s}}^{\mathrm{r}}$ are the suspension stiffness of front and rear suspension system, respectively; $\dot{w}_1$ and w_1 are the velocity and displacement of front sprung mass; and $\dot{w}_2$ and w_2 are the velocity and displacement of rear sprung mass.

One may assume solution similar to Eq. (24); applying Eqs. (23)–(30), one may obtain a solution as

$$\int_0^l \rho A W_n^2 \mathrm{d}x\ddot{U}(t) + \omega_n^2(\rho I\lambda_n^2 - \rho A)\int_0^l W_n^2 \mathrm{d}xU(t) - \rho I\lambda_n^2\int_0^l W_n^2 \mathrm{d}x\ddot{U}(t) - \mu_I I\lambda_n^4\int_0^l W_n^2 \mathrm{d}x\dot{U}(t) = F_1 W_n(x_1) + F_2 W_n(x_2) + F_3 W_n(x_3) \tag{33}$$

Rearranging Eq. (33), one may obtain

$$\rho A\left(1 - \frac{I}{A}\lambda_n^2\right)\int_0^l W_n^2 \mathrm{d}x\ddot{U}(t) + \rho A\left(1 - \frac{I}{A}\lambda_n^2\right)\omega_n^2\int_0^l W_n^2 \mathrm{d}xU(t) - \mu_I I\lambda_n^4\int_0^l W_n^2 \mathrm{d}x\dot{U}(t) = F_1 W_n(x_1) + F_2 W_n(x_2) + F_3 W_n(x_3) \tag{34}$$

Finally, Eq. (34) may be represented as

$$m_n\ddot{U}(t) + R_n\dot{U}(t) + k_nU(t) = F_1W_n(x_1) + F_2W_n(x_2) + F_3W_n(x_3) \tag{35}$$

where

$$m_n = \rho A\left(1 - \frac{I}{A}\lambda_n^2\right)\int_0^l W_n^2\mathrm{d}x, \tag{36}$$

$$k_n = m\omega_n^2\int_0^l W_n^2\mathrm{d}x, \tag{37}$$

$$R_n = \mu_I I\lambda_n^4\int_0^l W_n^2\mathrm{d}x \tag{38}$$

Equations (36–38) show that the rotary inertia affects the dynamics of the beam, which is not being taken in case of Euler beam. However, in this case, the value of $I/A \cdot \lambda_n^2$ is always less than 1. Generally, distributed elements that one may obtain to involve in almost all the system models are lightly damped. The location of structure damping cannot be precisely identified from where it arises. The mechanism of energy dissipation is very typical and complicated; some dissipation takes place because of the plastic deformation and some of the energy radiation from material surfaces. It is not assured in the modeling that individual conventional damper will attach to model for representing the damping of distributed elements. It can happen if the damping includes functionally by incorporating it into individual modes. This is accompanied by merely appending R-elements to the mode oscillators of the modal bond graph. R-element is represented in Eq. (30), where μ_I is varied from 0.01 to 0.1. The next subsection will present the bond graph modeling to visualize the simulation for different parameters.

3 Bond Graph Modeling of the Truck Chassis Structure

The physical system of a truck chassis (pitch plane model) with front and rear suspension system driven over the random road is presented in Fig. 1. The boundary condition of the structure is taken as free–free. The dynamic disturbance in vertical direction of the vehicle due to random road conditions is the main attraction of this modeling. The longitudinal and lateral dynamics are not considered in the modeling. The bond graph technique is being used as a modeling tool, and the bond graph of the system is created through formulation, which was developed in the previous section. Figure 2 presents the bond graph model of a flexible infinitesimal beam, whereas Fig. 3 shows the bond graph model of a flexible beam with internal damping along with suspension system. The rigid body modes appear simply as inertia elements with associated modal stiffness and damping. The first inertia parameter is the beam mass (M), and second is the beam moment of inertia (Jg). The transformer (-TF-) elements are connected to the rigid body modes, which correctly apply the forces and moments to these elements. The modal masses are taken from Eq. (36), whereas modal stiffness and modal damping can be taken from Eqs. (37) and (38), respectively.

The system is entirely flexible in transverse and bending, but torsionally rigid. Each 0-junction is attached to each 1-junction with modal components through transformer (TF) elements with moduli equal to appropriate mode function. The transformer function is moduli with shape function (W_n), and the values of this function can be determined from Eq. (16). The attached systems are then appropriately appended to the external 0-junction bonds to form a complete, low-order, very accurate model. Figure 3 shows a general finite mode representation with two input (front and rear) location, where Eq. (26) represents a governing contribution of *i*th mode.

In the real world, distributed elements have some damping properties, which resist vibration level up to a certain level. No mechanism can quickly identify the value of damping on specific. However, only the quantity of dissipative energy can be determined. It is customary not to attempt to perform detailed modeling of the damping mechanism, but instead to include damping functionally by incorporating its individual modes. This is accomplished by simply appending R-elements to the mode oscillator of the bond graph. The bond graph model of the distributed system including damping modes is presented in Fig. 3. The governing equation of this configuration is mentioned in Eq. (23).

4 Numerical Simulation

Computer simulation can compress the performance of a system over the years into a few minutes of the computer running time. The parameters used for simulation for truck chassis system are presented in Table 1. Simulation models are relatively flexible and can be modified to accommodate the changing environment to the real situation. At present, most of the simulation models are made using differential equations. In this research, a half car flexible model with suspension systems is investigated at

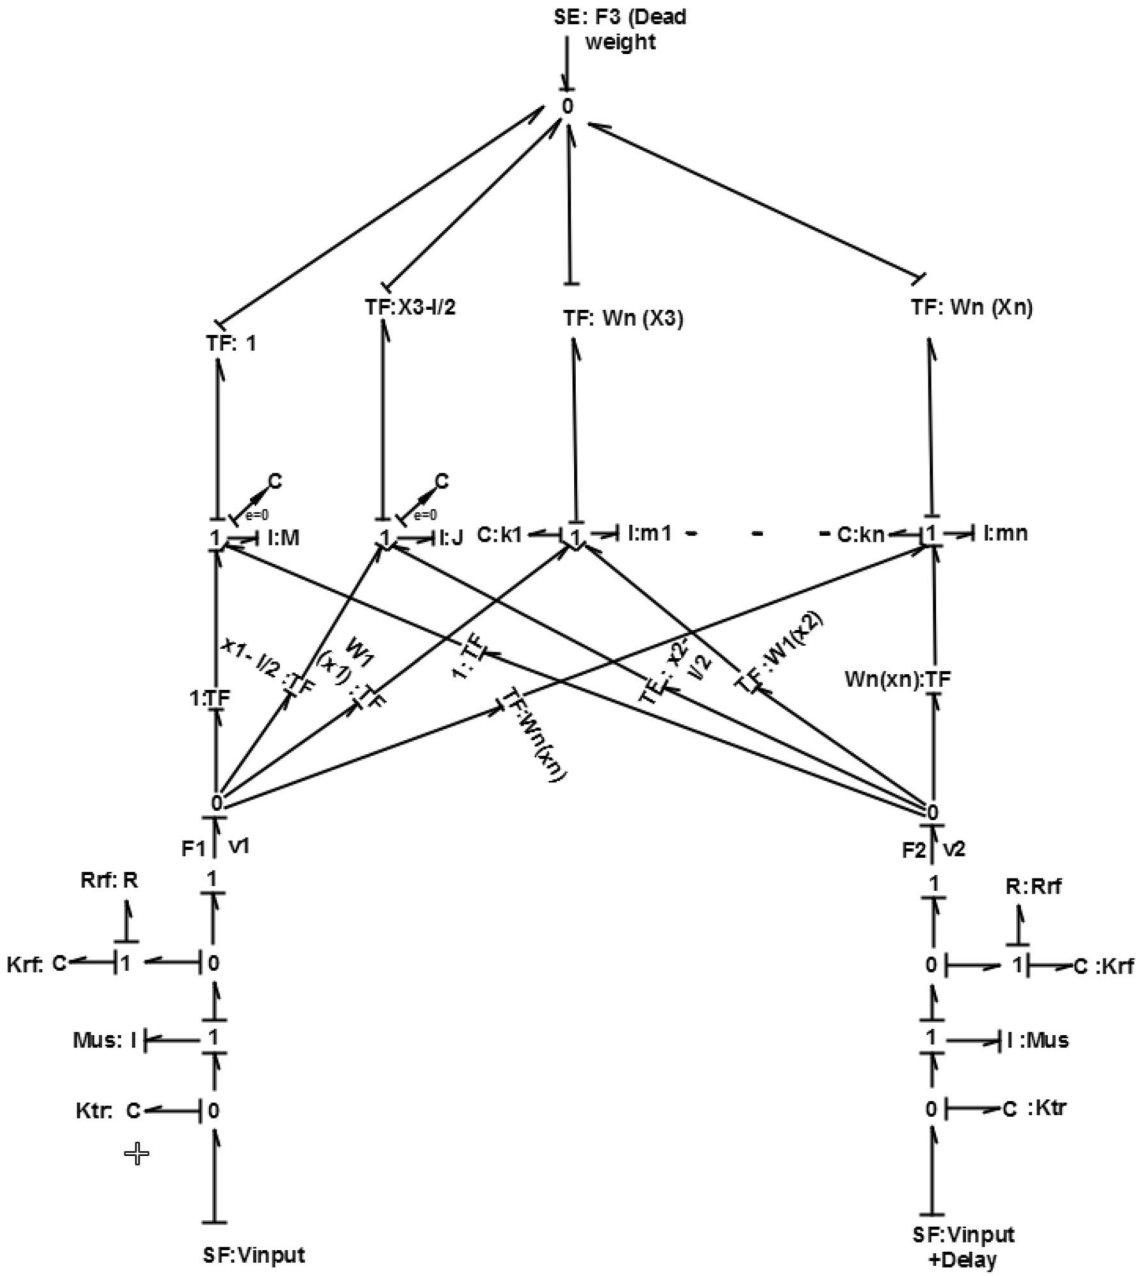

Fig. 2 Bond graph model of truck chassis considering internal damping

different operating speeds on different road profile inputs using bond graph technique and simulators of SYMBOLS Sonata® and MATLAB/Simulink® software are used (Gupta and Rastogi 2016; Hassani 2013; Mukherjee and Samantaray 2006). The bond graph model of the vehicle is simulated for 10 s to obtain different output responses. In total, 1024 records are used in the simulation and error is kept in the order of 5.0×10^{-4}. Fifth-order Runge–Kutta Gill method is used in this present work to solve the various differential equations generated through bond graph model.

4.1 Road Inputs

Two types of road profile inputs of the simulation of this system are used, viz. steady-state input and random road input.

4.1.1 Sine Wave Input

The steady-state input has been taken in a sinusoidal form, and the following expression is used for simulation (Hagedorn and DasGupta 2007):

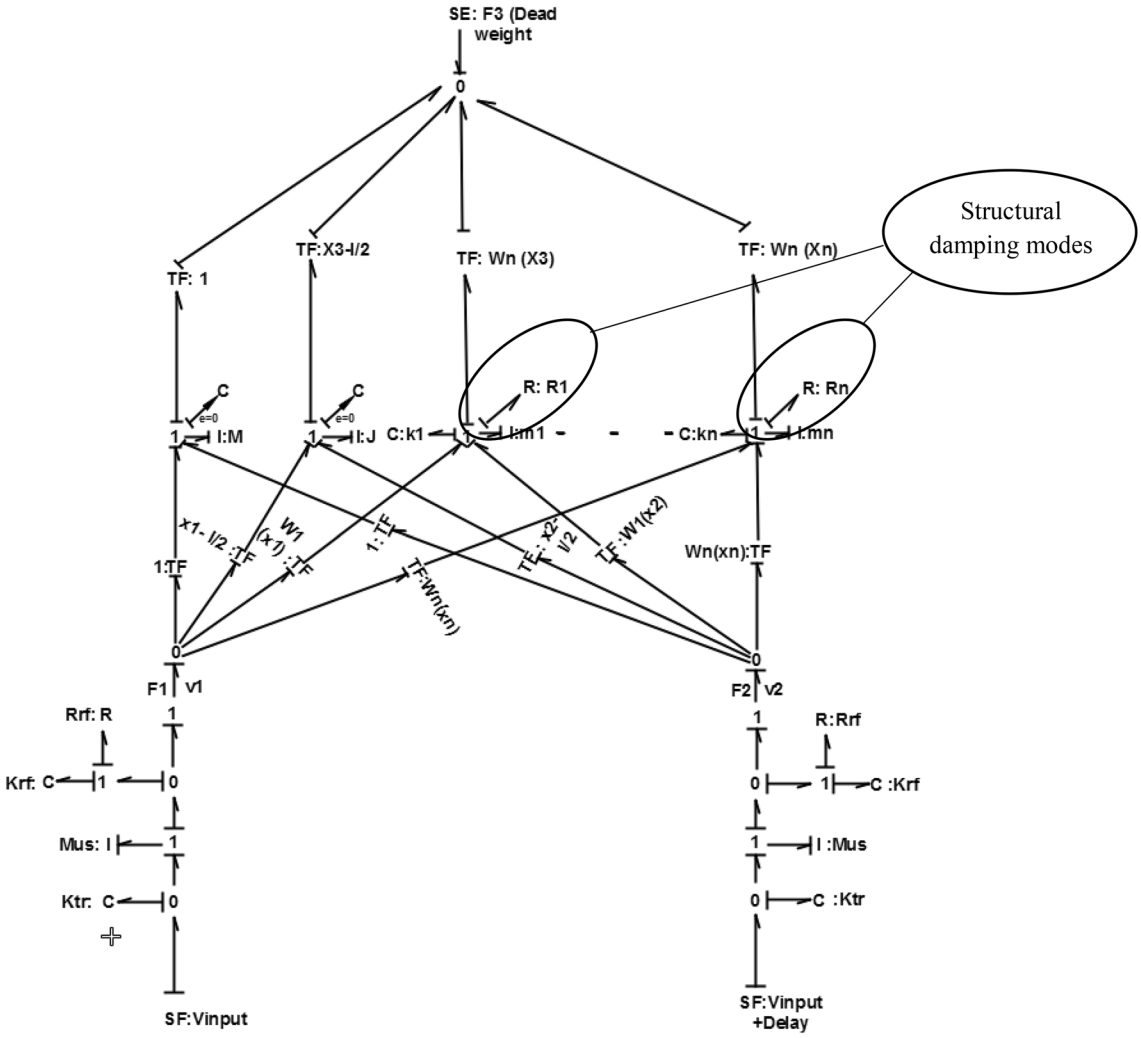

Fig. 3 Bond graph model of truck chassis considering internal damping

Table 1 Simulation parameters for flexible chassis system (Rideout and Khan 2010)

Parameter	Value	Unit
Vehicle length	10	m
Frame mass (Mg)	4350	kg/m
Frame inertia (J)	24,000	kg/m^2
Suspension stiffness (K_{sf}, K_{sr})	375, 870	kN/m
Suspension damping (R_{sf}, R_{sr})	31,895, 33,384	Ns/m
Flexural rigidity (EI)	1.05e+08	N m^2
Unsprung mass (Mus)	50	kg
x_1, x_2, x_3, x_4	2.95, 5.75, 7, 3	m

$$V_{\text{input}} = A_{\text{jump}} * \omega * \sin(\omega * t), \quad \text{for front wheel} \tag{39}$$

$$V_{\text{input}} = A_{\text{jump}} * \omega * \sin(\omega * (t + d/v)), \quad \text{for rear wheel} \tag{40}$$

where A_{jump} is the amplitude of vibration and ω is the excitation frequency.

4.1.2 Random Road Condition

A random road profile is generated according to the International Organization for Standardization (ISO 8608). It gives a depiction of the road profile through estimation of the PSD of the vertical displacements G_d, as a function of spatial frequency $n(n = \Omega/2\pi(\text{cycles})/\text{m})$ and also of angular spatial frequency Ω. ISO 8608 introduces a classification, which is evaluated in accordance with conventional values of spatial frequency $n_0 = 0.1$ cycles/m and angular spatial frequency $\Omega_0 = 1$ cycles/m. There are eight classes of roads mainly

identified from classes H1 to H8 according to the values of $G_d(n)$ and $G_d(\Omega)$ established in ISO 8608, which are shown in Table 2 (Meirovitch 1980).

In the simulation, ISO 8608 provides the roughness of the road surface profile, which may be stated using the following equations:

$$G_d(n) = G_d(n_0)\left(\frac{n}{n_0}\right)^{-w} \tag{41}$$

$$G_d(\Omega) = G_d(\Omega_0)\left(\frac{n}{n_0}\right)^{-w} \tag{42}$$

where w denotes the waviness and its value is taken to be 2 in this case. In this research, random road inputs have been developed by taking into consideration the PSD of vertical displacement G_d as a function of spatial frequency n.

Beginning with a distributed road profile to specify the value of spatial frequency n, looped within a frequency band Δn, the PSD function value is represented through the following expression as

$$G_d(n) = \lim_{\Delta n \to 0}\left(\frac{\psi_x^2}{\Delta n}\right) \tag{43}$$

where the mean square value is denoted by ψ_x^2 which signifies the component of the signal for spatial frequency n contained by the frequency band Δn. Accordingly, the signal of road profile is discretized, and thus, it is characterized by a series of elevation points along with evenly spaced ones. Here, road profile length is denoted by L, whereas the sampling interval is denoted by B. Further, the maximum value of sampling spatial frequency c is $1/B$, the maximum effective sampling spatial frequency (n_{eff}) is $n_{\max}/2$ and the discretized spatial frequency values n_i are equally spaced under the frequency domain, with an interval of (Δn) as $1/L$.

So herein, generic spatial frequency value n_i can be regarded as $i{\cdot}\Delta n$ and Eq. (43) may be written in the discrete form as

$$G_d(n) = \frac{\psi_x^2(n_i, \Delta n)}{\Delta n} = \frac{\psi_x^2(i \cdot \Delta n, \Delta n)}{\Delta n} \tag{44}$$

where i varying from 0 to N as $\frac{n\max}{\Delta n}$, one may obtain the road profile by a simple harmonic function

$$h(x) = A_i \cos(2\pi \cdot n_i \cdot x + \phi) = A_i \cos(2\pi \cdot i \cdot x \cdot \Delta n + \phi) \tag{45}$$

where the amplitude is denoted by A_i, spatial frequency is denoted by n_i and phase angle is φ. One may generate a harmonic signal through mean square value

$$\psi_x^2 = \frac{A_i^2}{2} \tag{46}$$

Therefore,

$$G_d(n_i) = \frac{\psi_x^2(n_i)}{\Delta n} = \frac{A_i^2}{2 \cdot \Delta n} \tag{47}$$

It has been shown in several works that the development of an artificial road profile using Eq. (45) is only possible if the PSD function of vertical displacements is well known, presuming a random phase angle φ_i following a uniform probabilistic distribution within range 0 to 2π. The artificial profile can be given as

$$\begin{aligned} h(x) &= \sum_{i=0}^{N} A_i \cos(2\pi \cdot n_i \cdot x + \phi_i) \\ &= \sum_{i=0}^{N} \sqrt{2 \cdot \Delta n \cdot G_d(i \cdot \Delta n)} \cdot A_i \cos(2\pi \cdot i \cdot x \cdot \Delta n + \phi) \end{aligned} \tag{48}$$

Using Eq. (47) in Eq. (45), a random road profile can be generated according to ISO classification by the following equation,

Table 2 ISO 8608 values of $G_d(n_0)$ and $G_d(\Omega_0)$

Road class	$G_d(n_0)$ (10^{-6} m^3)		$G_d(\Omega_0)$ (10^{-6} m^3)		Category
	Lower limit	Upper limit	Lower limit	Upper limit	
H1	–	32	–	2	New roadways with asphalt layers
H2	32	128	2	8	New roadways with concrete layers
H3	128	512	8	32	Old roadways layers which are not maintained
H4	512	2048	32	128	Roadways layer consisting if cobble stone layers or similar materials
H5	2048	8192	128	512	Very poor road condition
H6	8192	32,768	512	2048	Off-road condition
H7	32,768	131,072	2048	8192	–
H8	131,072	–	8192	–	–
	$n_0 = 0.1$ cycles/m		$\Omega_0 = 1$ cycles/m		

$$h(x) = \sum_{i=0}^{N} \sqrt{\Delta n.} \cdot 2^{k} \cdot 10^{-3} \cdot \left(\frac{n_0}{i \cdot \Delta n}\right) \cos(2\pi \cdot i \cdot x \cdot \Delta n + \phi) \tag{49}$$

where x is the abscissa variable from 0 to L; Δn is $1/L$; $n_{\max}$ is taken as $1/B$; N is $\frac{^{n}\max}{\Delta n}$ or L/B; where $L = 250$, $N = 100$; and constant is denoted as k, depending on ISO road profile classification. It has also assumed integers augmenting from 3 to 9, which corresponds to the profiles from classes H1 to H8 (as shown in Table 3); here, k is assumed to take the value 3 corresponding to the class H1 road profile and $G_d(n_0)$ is taken to be 32, where n_0 is 0.1 cycles/m and φ_i is the random phase angle following an uniform probabilistic distribution within range 0 to 2π. In this work, four road conditions (H1-H4) are considered, which is shown in Figs. 4, 5, 6 and 7.

The simulation of different road categories is obtained by MATLAB/Simulink of the previously discussed ISO 8608 random input. This road profiles are simulated for five different speeds, viz. 40 kmph, 60 kmph, 80 kmph, 90 kmph and 100 kmph. Figure 4 shows H1 road condition, where unevenness of the random-type road with maximum magnitude is 0.03 m in an upward direction at 40 km/h and − .035 m in a downward direction at 100 km/h. Similarly, H2, H3 and H4 road categories have a maximum magnitude 0.06 m, 0.12 m and 0.24 m, respectively, in an upward direction at 40 km/h and − 0.65 m, − 0.12 m and − 0.24 m, in a downward direction at 100 km/h.

Table 3 k values for ISO road roughness classification

Road class		k

H3	H4	5
H4	H5	6
H5	H6	7
H6	H7	8
H7	H8	9

5 Results and Discussion

The model is exhibited first on sine wave input from start to end and runs for 20 s with zero initial conditions. The amplitude of sine wave is 0.01 m, and the input frequency is taken 50 Hz. In Fig. 8, the magnitude of the vertical acceleration is 0.8 m/s^2 in un-damped condition, whereas acceleration amplitude has been reduced to 0.7 m/s^2 in damped condition. Thus, the magnitude of vibration has been reduced from 12 to 15% due to the impact of structural damping of the vehicle chassis. Similarly, in Fig. 9, the amplitude of pitching acceleration has been reduced up to 20% due to the influence of structural damping. However, frequencies in both conditions have almost similar values. The dead load on the center of chassis has been taken around 500 N, which lies in the downward direction.

The RMS acceleration responses of truck chassis at the first three modes at sine wave condition are shown in Fig. 10a–c. In these figures, the un-damped condition of the beam is superimposed over damped condition. The frequencies of the first three modes are 34.4 Hz, 86.89 Hz and 174.8 Hz, respectively. Figure 10a–c shows that the acceleration magnitude is continuously reduced, whereas maximum acceleration is found at the first mode, and minimum

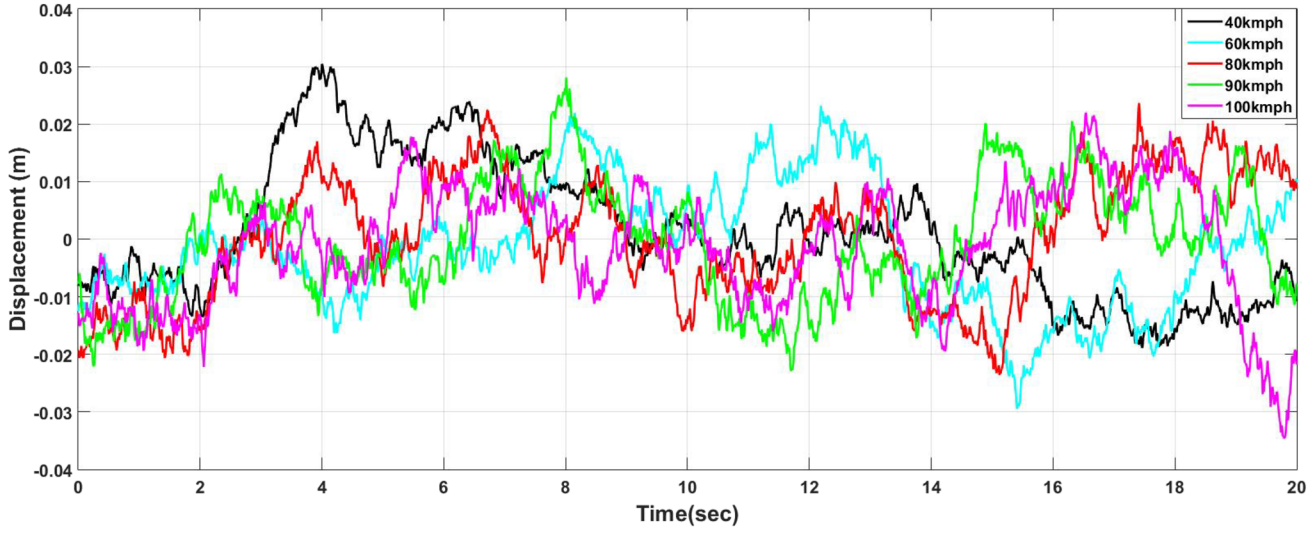

Fig. 4 Random road profile of H1 road category at 40 kmph, 60 kmph, 80 kmph, 90 kmph and 100 kmph

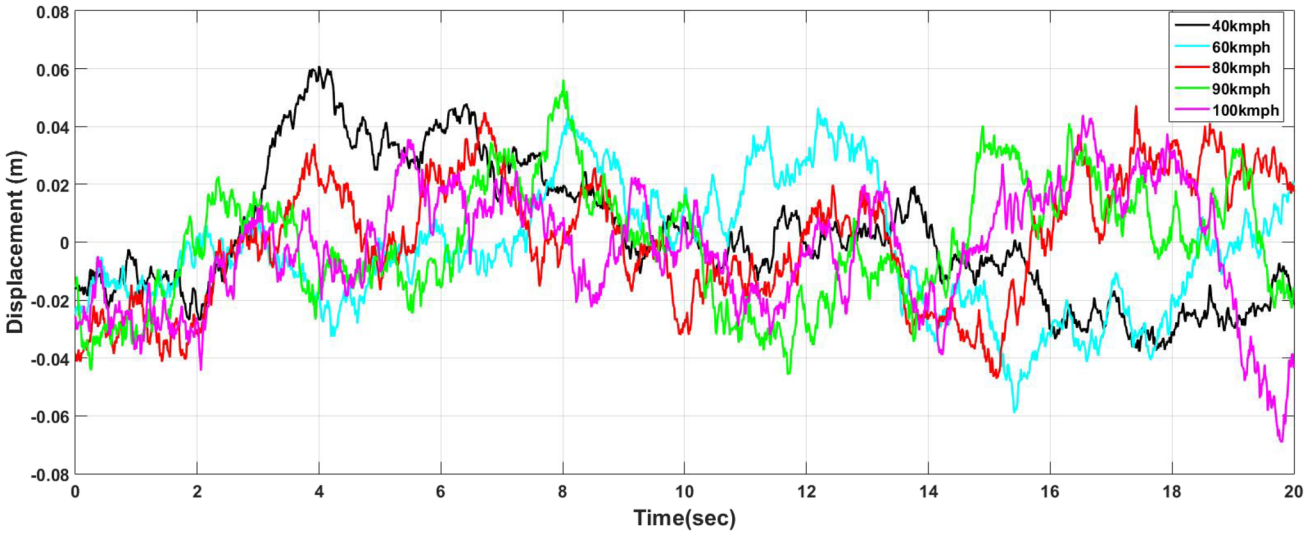

Fig. 5 Random road profile of H2 road category at 40 kmph, 60 kmph, 80 kmph, 90 kmph and 100 kmph

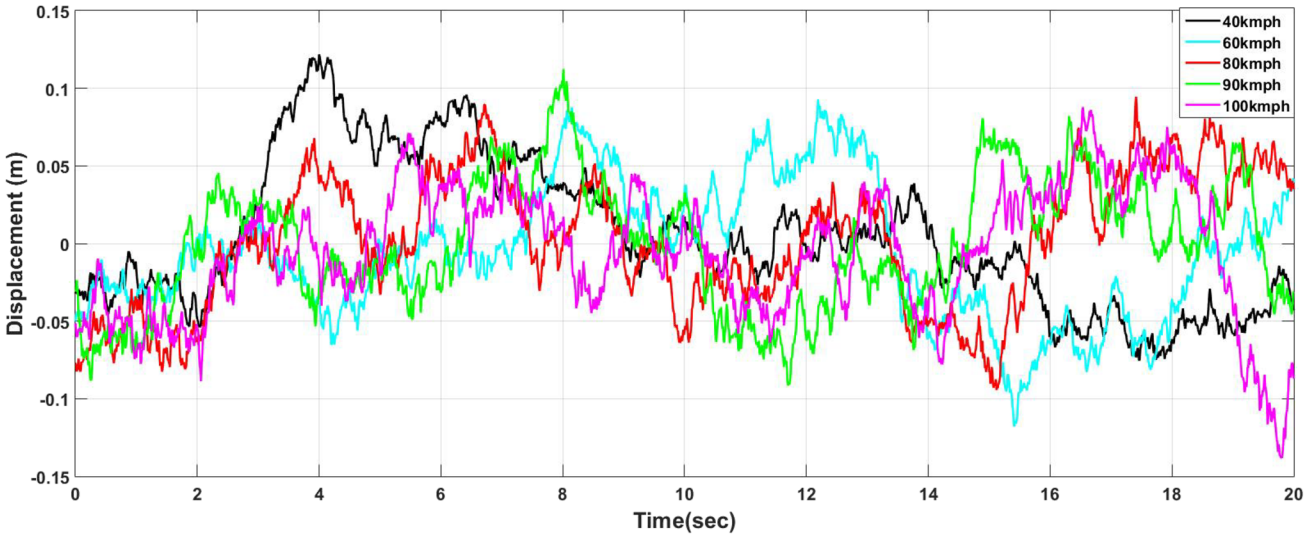

Fig. 6 Random road profile of H3 road category at 40 kmph, 60 kmph, 80 kmph, 90 kmph and 100 kmph

acceleration is in the third mode. The influence of internal damping is presented in terms of RMS acceleration response, whereas the amplitude has reduced due to the effect of internal damping at the same frequency.

The ride comfort analysis may be evaluated through RMS acceleration of the vehicle chassis. Figures 11, 12, 13 and 14 present the RMS acceleration response of the truck CG for four different classes of roads (H1–H4) as prescribed by ISO 8608. The H1 is the best class, and H4 represents the worst road class in these four classes. The model is simulated for each road class at different speeds ranging from 40 to 100 kmph with and without consideration of the internal damping of the chassis. Figures 11, 12, 13 and 14 show that the magnitude of vertical acceleration increases with vehicle speed and with road class. Figure 11a demonstrates the truck response neglecting the chassis damping, where maximum RMS acceleration magnitude is observed as 0.65 m/s^2 at 100 km/h and 0.25 m/s^2 at 40 km/h on H1 class road. This peak acceleration magnitude gets reduced up to 0.58 m/s^2 at 100 km/h and 0.22 m/s^2 at 40 km/h with due consideration to chassis structural damping, as shown in Fig. 11b. A similar kind of result has been noticed in other plots shown in Figs. 12, 13 and 14. Thus, it is evident from the above results that internal structural damping of the base structure of heavy vehicle plays an important role

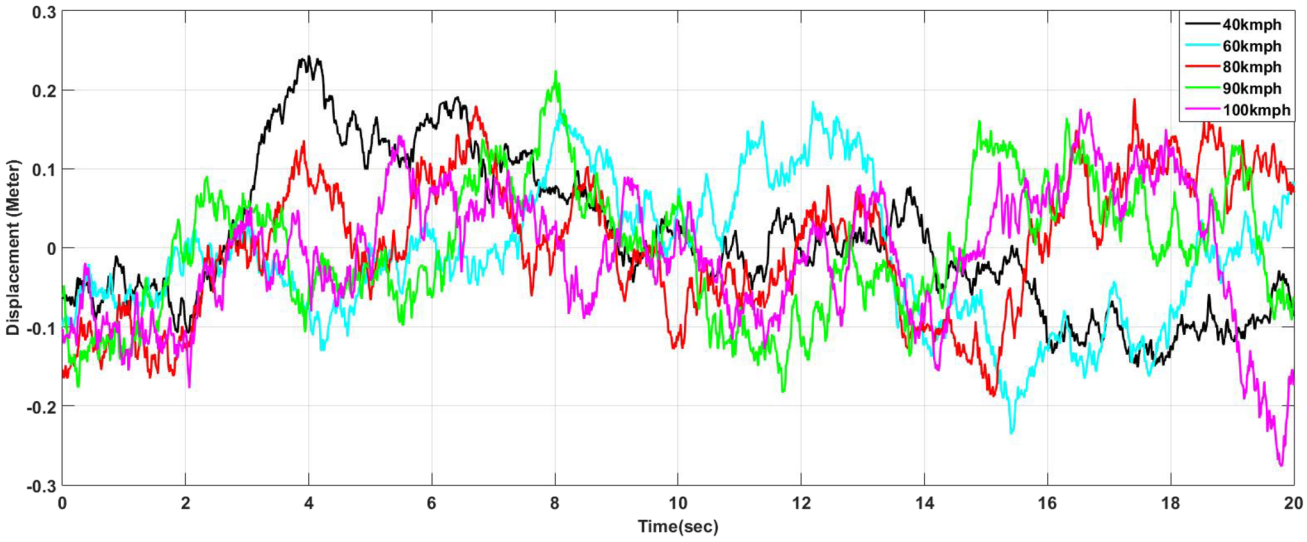

Fig. 7 Random road profile of H4 road category at 40 kmph, 60 kmph, 80 kmph, 90 kmph and 100 kmph

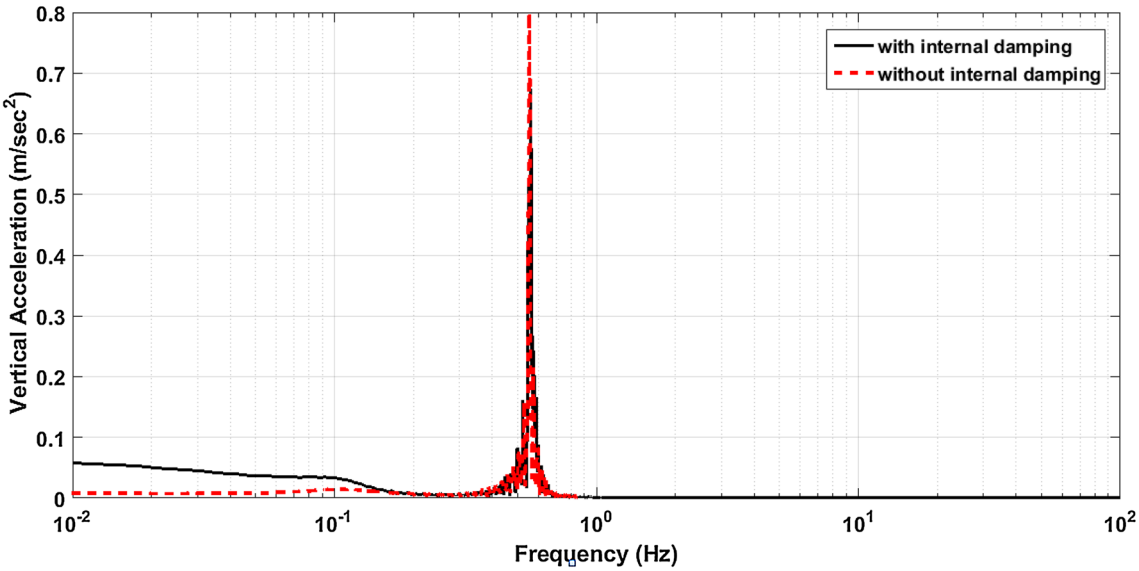

Fig. 8 Vertical response of vertical acceleration of chassis at steady-state input

and it needs to be included in the dynamical model of the vehicle to get the true dynamic behavior of the vehicle.

It has been observed that from the RMS curves that the H1 road condition is perfect for driving the vehicle for long duration, whereas it is not advisable to drive vehicles for long duration on H4 road condition. Indian roads lie between H2 and H3 conditions. So, a driver can comfortably drive the given vehicle at 60–80 km/h in single stretch without a break.

6 Conclusions

Numerous models have been constructed for the heavy vehicle system, but most of the models are developed with the lumping process. In this work, an analytical framework for truck chassis has been developed through classical mechanics and through extended Lagrangian approach. The following conclusion has been drawn from present research work:

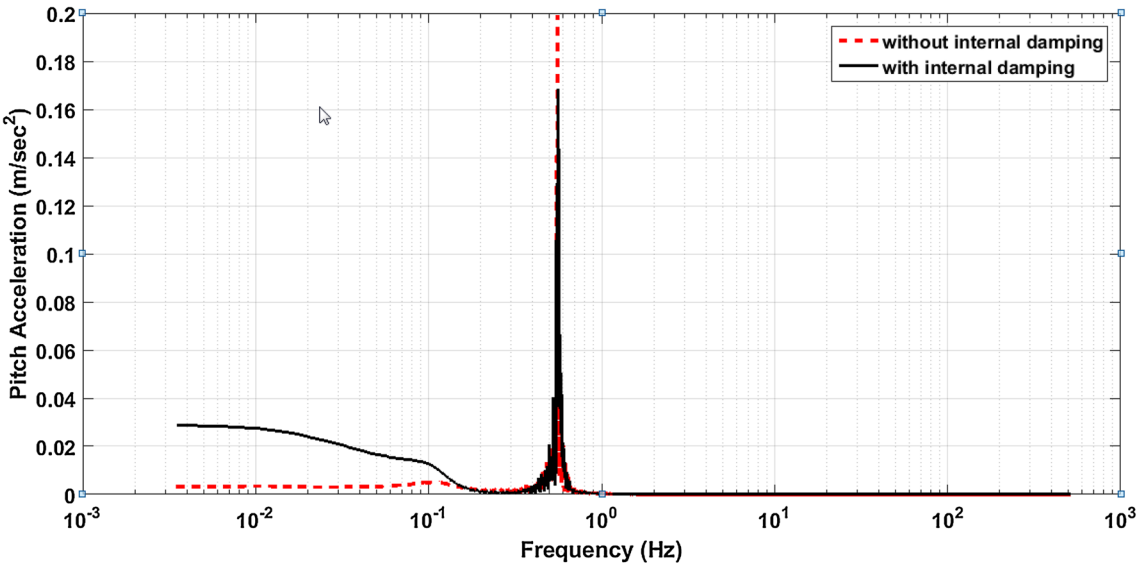

Fig. 9 Response of pitch acceleration of chassis at steady-state input

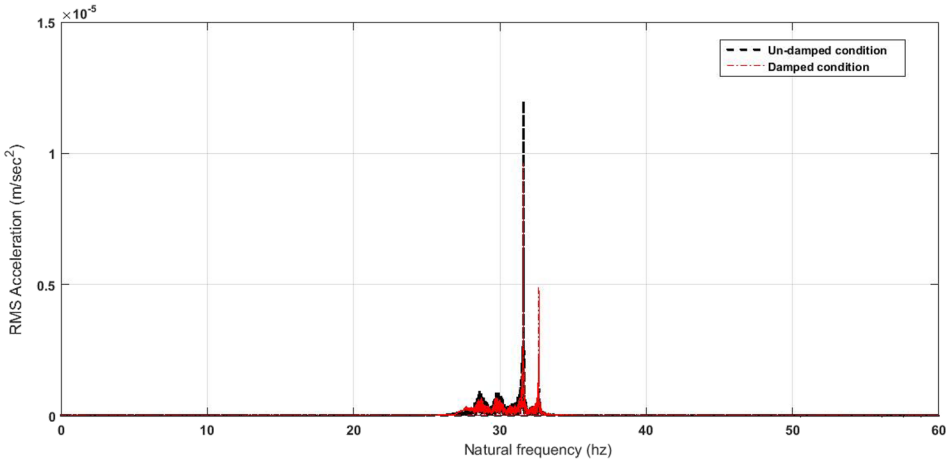
- In the classical mechanics approach, the idea of lumped–distributed modeling has been explored within the framework of bond graphs.
- The Lagrange variation of truck chassis, including flexural behavior has been constructed, where it was integrated with lumped suspension system. However, the structural damping effects were also involved in terms of fifth-order partial differential term in generalized equation of motion. The detailed derivation for fifth-order differential term is presented in "Appendix 1."
- The integrated bond graph model of flexural beam was the extended form of the analytical model. Results have been presented under the two types of road conditions, i.e., sine wave input and random road input. In sine wave road conditions, the vertical response of flexural beam is reduced up to 12–15% and pitch response of beam is reduced up to 20% due to the structural damping effect. In random road conditions, four types of road category (H1, H2, H3, H4) have been used at four different speeds (40 kmph, 60 kmph, 80 kmph and 100 kmph).
- It is depicted from the result that maximum acceleration at maximum speed (100 kmph) of chassis has been increased up to 0.5 m/s^2 in H1–H2 conditions, 1 m/s^2 in H2–H3 conditions and 2.25 m/s^2 in H3–H4 conditions. Similarly, the solution has been extended for structural or internal damping, whereas maximum acceleration at maximum speed has been reduced up to 10%, 5%, 7% and 5% (approx.) in H1, H2, H3 and H4 road conditions, respectively.

Appendix 1

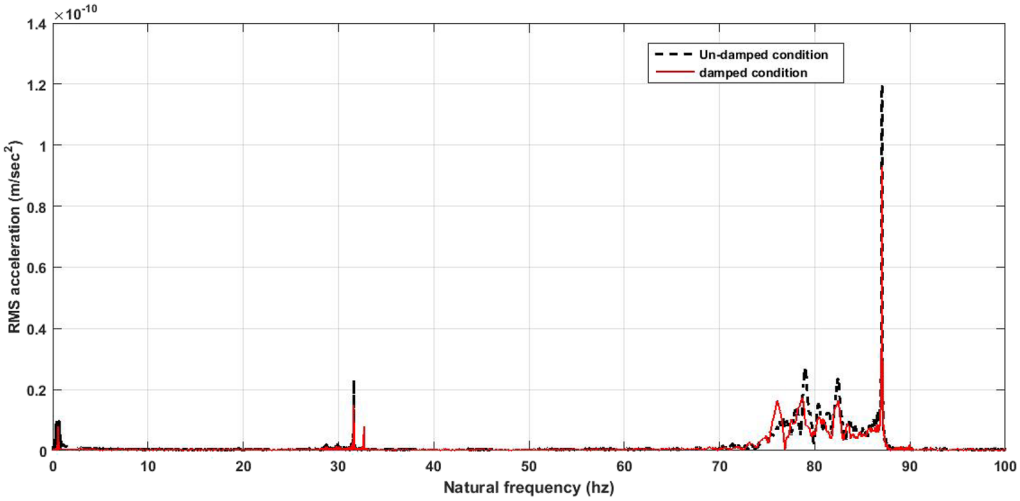
This appendix gives a brief introduction to the variational formulation of dynamics of continuous systems. Consider for simplicity a one-dimensional continuous system with the field variable $w(x, t)$ which uniquely represents the configuration of the system at any time t. In the course of temporal evolution of the system, let the configurations at two time instants $t = t_1$ and $t = t_2$ be recorded as, respectively, $w(x, t_1)$ and $w(x, t_2)$. The actual path is that any infinitesimal variation over that path should leave the value of I unchanged (Hagedorn and DasGupta 2007). Now the action integral may be expressed as

$$I = \int_{t_0}^{t_1} \int_{x_0}^{x_1} \delta L(\ldots)\, \mathrm{d}t\mathrm{d}x \tag{50}$$



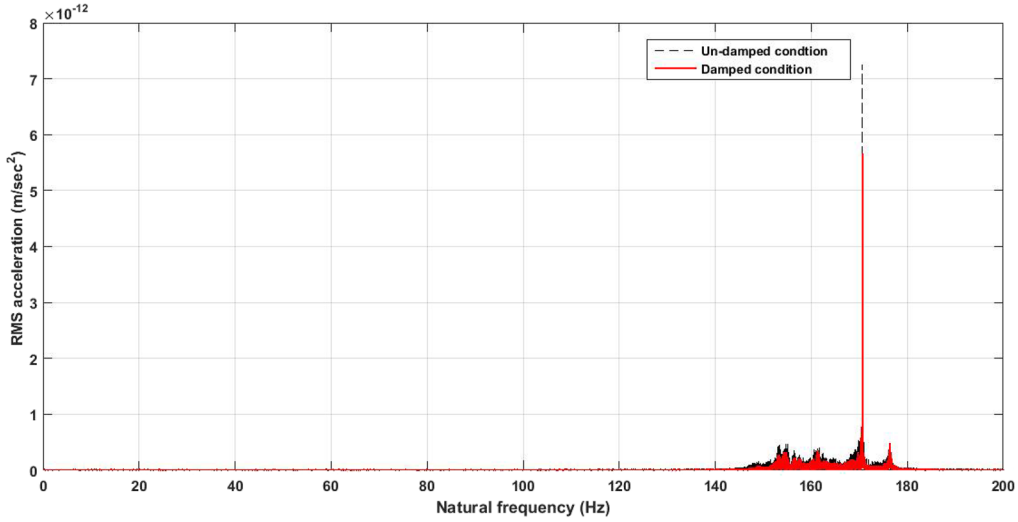
Using the extremization condition of Eq. (50), one may obtain

$$\int_{t_0}^{t_1} \int_{x_0}^{x_1} \delta \hat{L}\left(w, w', \dot{w}, w'', t\right) \mathrm{d}t\mathrm{d}x = 0 \tag{51}$$



One may write Lagrangian density variation,

$$\delta \hat{L} = \frac{\partial \hat{L}}{\partial w}\delta w + \frac{\partial \hat{L}}{\partial \dot{w}}\delta \dot{w} + \frac{\partial \hat{L}}{\partial w'}\delta w' + \frac{\partial \hat{L}}{\partial w''}\delta w'' \tag{52}$$



Introducing Eqs. (51) and (52), one may have

×10^-5
Un-damped condition
Damped condition
RMS Acceleration (m/sec^2)
Natural frequency (hz)

(a)

×10^-10
Un-damped condition
damped condition
RMS acceleration (m/sec^2)
Natural frequency (hz)

(b)

×10^-12
Un-damped condtion
Damped condition
RMS acceleration (m/sec^2)
Natural frequency (Hz)

(c)

◂**Fig. 10** RMS acceleration response of different modes of chassis under sine wave condition: **a** first mode = 34.4 Hz; **b** second mode = 86.89 Hz; **c** third mode frequency = 174.8 Hz

$$\int_{t_0}^{t_1}\int_{x_0}^{x_1}\left[\frac{\partial\hat{L}}{\partial w}\delta w+\frac{\partial\hat{L}}{\partial\dot{w}}\delta\dot{w}+\frac{\partial\hat{L}}{\partial w'}\delta w'+\frac{\partial\hat{L}}{\partial w''}\delta w''\right]\mathrm{d}t\mathrm{d}x=0 \tag{53}$$

The next step is to transform the integrand in Eq. (52) into one containing only δw, i.e., one that is free of $\delta\dot{w},\delta w',\delta w'',\delta\dot{w}'$. This can be accomplished by integration by parts, with respect to both space and time.

$$\begin{aligned}&\int_0^l\frac{\partial\hat{L}}{\partial w}\delta w\Big|_{t_1}^{t_2}\mathrm{d}x+\int_{t_0}^{t_1}\left[\frac{\partial\hat{L}}{\partial w''}\delta w''+\left\{\frac{\partial\hat{L}}{\partial w'}-\frac{\partial}{\partial x}\left(\frac{\partial\hat{L}}{\partial w''}\right)\right\}\delta w\right]\Bigg|_0^l\mathrm{d}t\\&+\int_{t_0}^{t_1}\int_{x_0}^{x_1}\left[\frac{\partial\hat{L}}{\partial w}-\frac{\partial}{\partial t}\left(\frac{\partial\hat{L}}{\partial\dot{w}}\right)-\frac{\partial}{\partial x}\left(\frac{\partial\hat{L}}{\partial w'}\right)+\frac{\partial^2}{\partial x^2}\left(\frac{\partial\hat{L}}{\partial w''}\right)+\frac{\partial^2}{\partial x\partial t}\left(\frac{\partial\hat{L}}{\partial\dot{w}'}\right)\right]\delta w\,\mathrm{d}t\mathrm{d}x=0\end{aligned} \tag{54}$$

But the vertical displacement δw is arbitrary by definition, which implies that it can be assigned values at will provide these values are compatible with the system constraint, such as geometric conditions at the end points. Let $\delta w=\delta w'=0$ at $x=0$ and $x=l$. One may conclude that Eq. (54) can be satisfied for all values of δw in the open domain $0<x<l$.

Thus,

$$\frac{\partial\hat{L}}{\partial w}-\frac{\partial}{\partial t}\left(\frac{\partial\hat{L}}{\partial\dot{w}}\right)-\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{\partial\hat{L}}{\partial w'}\right)+\frac{\partial^2}{\partial x^2}\left(\frac{\partial\hat{L}}{\partial w''}\right)+\frac{\partial^2}{\partial x\partial t}\left(\frac{\partial\hat{L}}{\partial\dot{w}'}\right)=0 \tag{55}$$

Equation (55) represents the *Lagrange differential equation of motion* for this continuous system and must be satisfied at every point of open domain $0<x<l$.

$$\frac{\partial\hat{L}}{\partial w''}\equiv 0\quad\text{or}\quad\delta w|_{x=0}\equiv 0 \tag{56a}$$

$$\left.\frac{\partial\hat{L}}{\partial w''}\right|_{x=l}\equiv 0\quad\text{or}\quad\delta w|_{x=l}\equiv 0 \tag{56b}$$

$$\left.\frac{\partial\hat{L}}{\partial w'}-\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{\partial\hat{L}}{\partial w''}\right)\right|_{x=0}=0\quad\text{or}\quad\delta w|_{x=0}\equiv 0 \tag{57a}$$

$$\left.\frac{\partial\hat{L}}{\partial w'}-\frac{d}{dx}\left(\frac{\partial\hat{L}}{\partial w''}\right)\right|_{x=l}=0\quad\text{or}\quad\delta w|_{x=l}\equiv 0 \tag{57b}$$

Equations (56–57) are known as the boundary conditions and only two boundary conditions must be satisfied at either end, one from condition Eq. (56) and other from Eq. (57), which shows that clearly the selection is not arbitrary, but it must reflect physical conditions at two ends.

Appendix 2

In this formulation, the vertical translation of a uniform free–free beam is considered. If the internal damping of the material is involved in the system, then the strain displacement relationship or Hook's law equation can be written as Karnopp et al. (2012) and Hagedorn and DasGupta (2007).

$$\sigma(x,t)=E\varepsilon(x,t)+\mu_I\varepsilon(x,t) \tag{58}$$

The strain displacement relation at any height from the plane of the neutral fibers can be written as

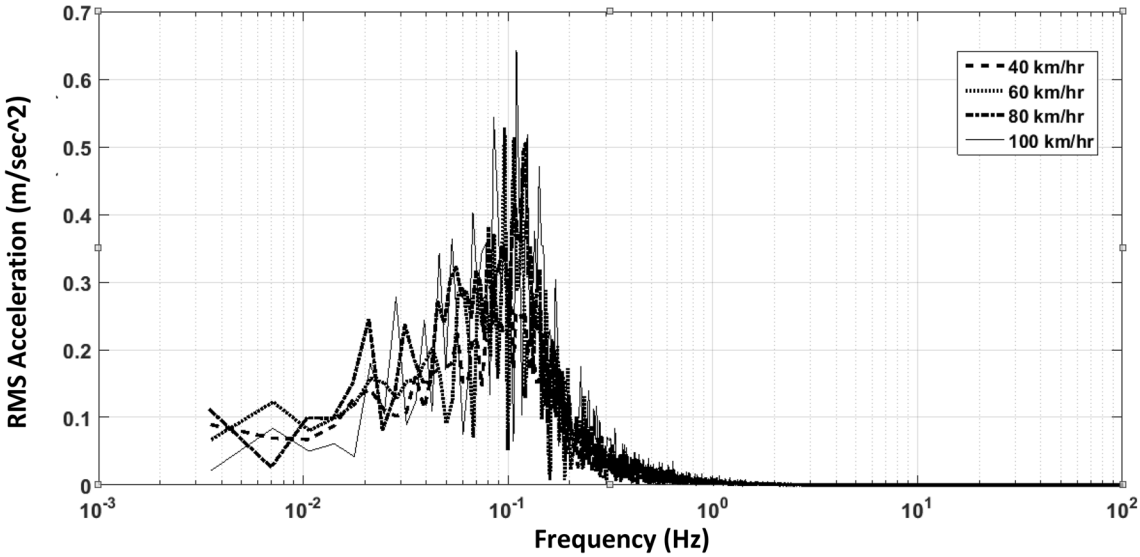
$$\varepsilon(x,t)=\frac{zw''(x,t)}{\left[1+w'^2(x,t)\right]^{\frac{3}{2}}}\approx -zw''(x,t)\quad(\text{Assuming } w'<<1) \tag{59}$$

The bending moment at any section (from Fig. 15) can be written as

$$M(x,t)=-\int_{h/2}^{-h/2}z\sigma(x,t)\mathrm{d}A=-\left(E\varepsilon(x,t)+\mu_I\varepsilon(x,t)\right)\int_{h/2}^{-h/2}z^2\mathrm{d}A \tag{60}$$

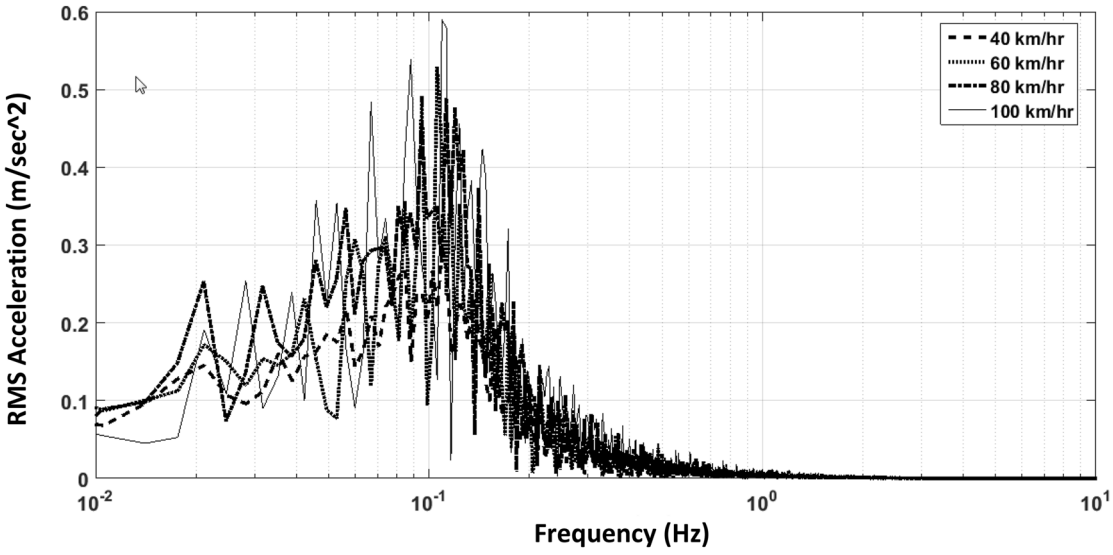
$$\Rightarrow\quad -\left(EIw''(x,t)+\mu_I I\dot{w}''(x,t)\right) \tag{61}$$

where I is the moment of inertia cross section of beam about the neutral axis. The equation of the vertical force of an infinitesimal beam is



$$(\rho A\mathrm{d}x)\ddot{w}(x,t)=p(x,t)\mathrm{d}x+(V+\mathrm{d}V)\cos(\psi+\mathrm{d}\psi)-V\cos\psi$$

or



$$pA\ddot{w}(x,t)=p(x,t)+V' \tag{62}$$

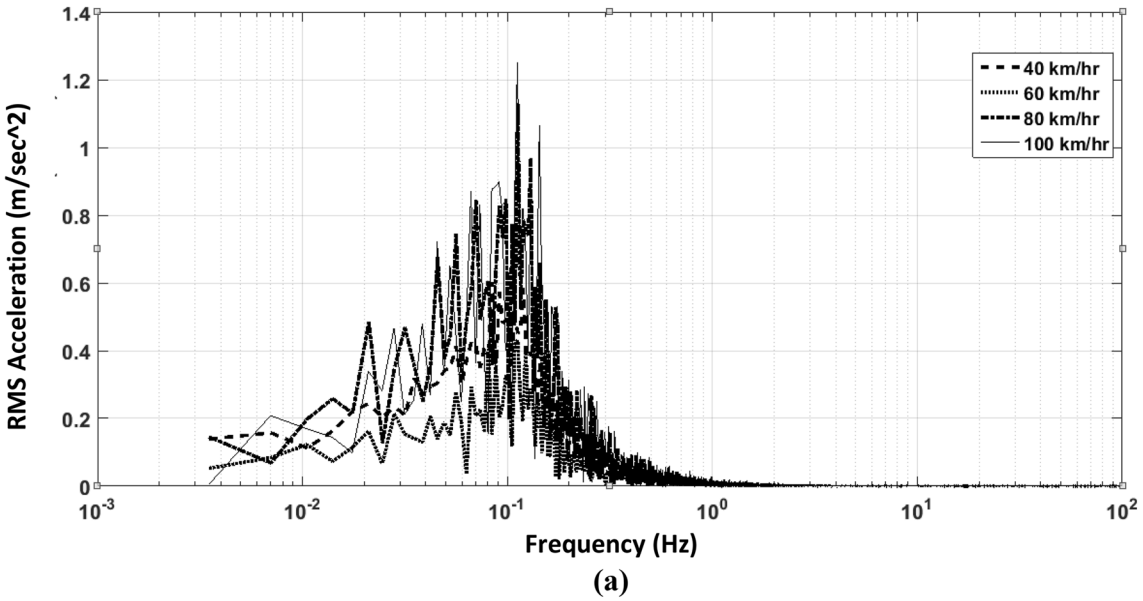
The rotational dynamics of infinitesimal beam may be written as

$$(\rho I\mathrm{d}x)\ddot{\psi}=(M+\mathrm{d}M)-M(V+\mathrm{d}V)\frac{\mathrm{d}x}{2}+V\frac{\mathrm{d}x}{2}$$

(a)

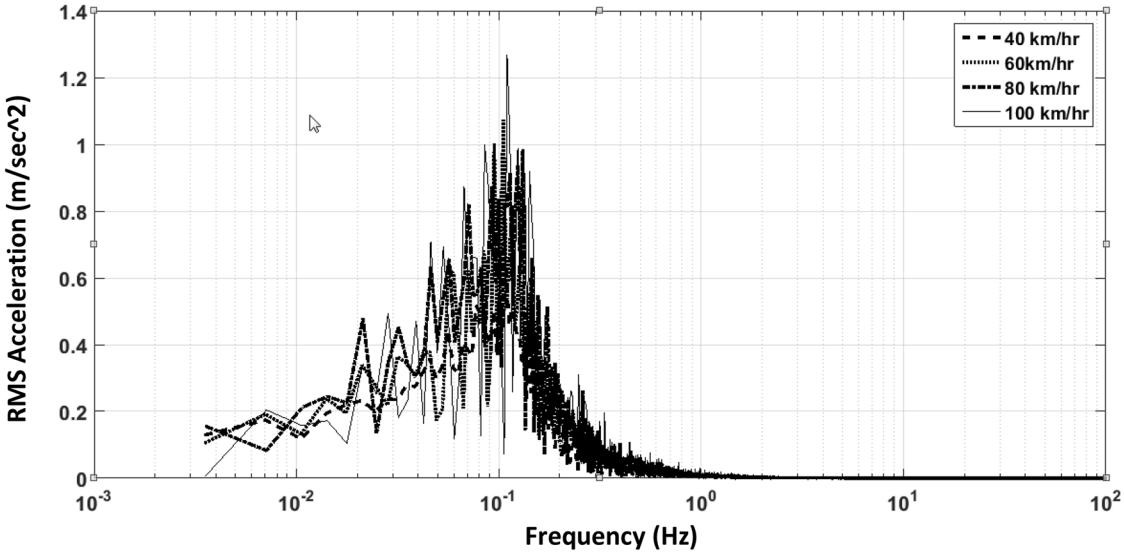
(b)

Fig. 11 **a** Response of chassis acceleration at various random road inputs in H1 road as per ISO 8608. **b** Response of chassis acceleration consideration of internal damping at different random inputs in H1 road condition as per ISO 8608



or

$$\rho I\ddot{\psi} = M' + V \tag{63}$$



One may write $\psi = \frac{w'(x,t)}{1+w'^2(x,t)} \approx w'(x,t)$Thus, from Eqs. (62) and (63), one may have

$$\rho A\ddot{w}(x,t) - \rho I\ddot{w}''(x,t) + \mu_I I\dot{w}''''(x,t) + EIw''''(x,t) - p(x,t) = 0 \tag{64}$$

The third term of Eq. (64) represents the structural damping or internal damping of the beam.

ABSTRACT

Tungsten inert gas (TIG) welding is the most commonly used joining process for aluminum alloy for AA6061 and AA7075 which are highly demanded in the aerospace engineering and the automobile sector, but there are some defects occur during TIG welding like micro-crack, coarse grain structure, and porosity. To improve these defects, the TIG welded joint is processed using friction stir processing (FSP).

This paper presents the effect of friction stir processing on TIG welding with filler ER4043 and ER 5356 for dissimilar aluminum alloy AA6061 and AA7075. The mechanical characterization, finite element formulation and mathematical equations of heat transfer of TIG + FSP welded joints are investigated using ANSYS Fluent software by adjusting process parameters of FSP. The results show that the maximum compressive residual stress 73 MPa was obtained at the fusion zone (FZ) of the TIG weldment with filler ER4043, whereas minimum compressive residual stress 37 MPa was obtained at stir zone (SZ) of the TIG + FSP with filler 5356. The maximum heat flux 5.33 × 106 W/m2 and temperature 515 °C have observed at tool rotation 1600 rpm with a feed rate of 63 mm/min. These results give a satisfactory measure of confidence in the fidelity of the simulation

1. Introduction

Friction stir welding (FSW) is a solid-state joining process that uses a non-consumable tool to join similar or dissimilar materials. The FSW does not involve the melting of parent material, which have many advantages on conventional fusion welding processes [1]. The FSW process involves the heat generation, which produced by pressure and friction between the tool and the workpiece. As a result of the generated heat, the weldment surfaces in contact soften become plasticized [2]. The modern development in the automobile sector and defense sector have been transformed from conventional materials to light material such as aluminum alloy. Due to excellent physical and mechanical properties of Al-alloy such as high corrosion resistance, low density, high strength to weight ratio and high thermal conductivity, it is mostly used for making various components such as military aircraft, rocket, and rocket launcher, axle shafts, rims, bumpers, and car bodies. FSW is used in the fabrication of automotive and shipbuilding components, aircraft structural components and reducing structural weight [3–7]. To study material flow and temperature distribution in friction stir welding of similar or dissimilar aluminum alloys many authors developed the CFD model to analyze the plastic flow, heat transfer and heat generation in the welding process [8–10], and the effect of tool profile on the material flow [11–13]. Due to low heat generation in the friction stir welding, the residual stresses are also low in the weldment. The transverse force of friction stir welding tools plays an important role in stress measurement [14–16]. The residual stresses in the weldment have a big impact on the performance of the welded structure. So far, information on the residual stress distribution of FSW has been limited [17]. The effects of tool feed rate on residual stresses of FSW of Al-alloy joints were studied with synchrotron X-ray measurement and analyze the residual stresses in longitudinal and transverse directions [16]. Many researchers have used finite element methods for the residual stress distribution in FSW. The computational fluid dynamic supports the heat transfer model and heat source of friction stir welding. The residual stress depends on the empathetic of heat transfer during FSW, although the correct prediction of temperature distribution depends on the heat source [18–20]. FSW can affect the performance of the residual stresses in

Nomenclature

u	Plastic flow velocity	τ	Max. Shear stress
μ	Non-Newtonian viscosity	η	Mechanical efficiency
p	Pressure	ω	Angular velocity
ρ	Density	P_N	Normal pressure
U_1	Welding velocity	q_1	Total heat generation rate
z	Zener Hollomon parameter	T_a	Ambient temperature
a and n	Material constant	σ	5.67×10^{-16} J/(K^4 m^2 s)
Q	Temperature activation energy	ε	Convection heat transfer coefficient
Z	Temperature effective strain rate	h_b	Heat transfer coefficient
K	Thermal conductivity	σ_2	Friction stress
C_p	Specific heat	σ_1	Tensile stress
S_i	Heat generation rate	d	Main grain diameter
h_t	Emissivity at top surface	k	Constant
r	Radial distance from tool axis	R_S	Shoulder radius
A_r	Small area on tool pin	R_P	Tool pin radius
V	Control volume under A_r	h_{b0}	Heat transfer parameter of bottom.surface
θ	Angle of negative x-axis	μ_f	Spatially variable fraction slip.between the work piece and tool
		S_b	Heat generation rate due to plastic.deformation

the weldment and the processing parameters such as rotating tool may affect the development of residual stresses [21,22]. The mechanical properties, grain size are dependent on tool geometry, processing parameters and chemical composition of alloying elements. A new grain structure could be formed in friction stir welding by controlling the process parameter and heat input [23–27]. Comparison of residual stresses of TIG and FSW has been done for AA6061 and AA7075, and found that the longitudinal residual stress is larger than the traverse residual stress in the welded joint [28]. There are no successful investigations have been done to find out residual stress and heat transfer in TIG welded joint with friction stir processing. The small plate having the dimension of 150 mm × 25 mm × 0.8 mm, have been investigated, as a result, the properties at the beginning and end of the welded joints can be significantly different. The tensile strength first increases and then decreases with the growth of rotational speed. Three layers i.e. top, middle, and bottom, have considered measuring the microhardness of the welded joint. The top layer of the weld has a higher recrystallization degree and dynamic recovery and the bottom layer is strongly stirred under mechanical action of the tool pin such that each layer of welded joint shows the different mechanical properties [29]. A new welding approach of TIG+FSP was successfully applied to the AA2024 to enhance the mechanical properties of the TIG welded joints. They conclude that the defects and porosities in the TIG welded joints are completely reduced by the FSP process and modified the microstructure and mechanical properties of the TIG+FSP welded joint [30]. The application of FSP on the TIG welded joint improved the ductility and tensile strength of the FSW and TIG welded joint of AA5083-H111 and results revealed best-reduced dimple size [31].

In this work, the effect of FSP on TIG welding for dissimilar Al-alloy AA6061 and AA7075 with filler wire ER4043 and ER5356 was carried out and analyze the mechanical properties, residual stress distribution and heat transfer in (TIG+FSP) welded joint. The present study was focus on the improvement of mechanical properties and the residual stress distribution of the TIG-welded joint with different filler wire (ER4043 and ER5356) by using a friction stir processing approach. This topic is carefully selected after noticing that there is little literature review available on the TIG+FSP welding approach. The outcomes of this paper will give the new approach for enhancing the mechanical properties and heat transfer of TIG+FSP welded joints which play a huge role in welded structures.

2. Materials and methods

Two AA6061 and AA7075 aluminum alloy plates having dimensions (150 mm × 40 mm × 6.2 mm) were welded together using the TIG+FSP welding approach. V butt joints of 45° were prepared for TIG welding with the help of milling cutter and power hacksaw. There are two types of samples were prepared for TIG welded joint. In the first sample, ER4043 filler wire was used and for the second sample, ER 5356 filler wire was used. The chemical composition of filler rod and base materials are shown in Table 1. The processing parameters and filler wire are strappingly affected by the mechanical properties of the welded joint. In this work, the filler wire of ER4043 and ER5356 of diameter 2.4 mm were used to join a single V groove plate at voltage 22 V and current 50 amp for all welding processes. Argon (25 L/min) is used as a shielding gas and travel speed 3.6 mm/s to fabricate the joint.

After TIG welding, the FSP technique was used on TIG weldment to improve the welding quality and mechanical properties. The non-consumable H13 steel tool with pin diameter, shoulder diameter and a pin length of 3 mm, 19.5 mm, and 5.5 mm respectively was used. 0° tilt angle was used during friction stir processing on the AA6061 and AA7075 plate at a rotational speed of 800 rpm−1600 rpm and a traverse speed of 63 mm/min is shown in Fig. 1(a). The tool nomenclature is shown in Fig. 1(b). The processing parameters of TIG welding and friction stir processing are shown in Table 2 and Table 3.

Fig. 2 demonstrate the dimension of the tensile sub test specimen as per ASTM E8. The tensile test specimens were sliced and machined from the welded joint using a milling cutter and shaper machine. Single-pass FSP is used to fabricate TIG+FSP welded joint. Three sub tensile specimens were tested on a UTM machine at

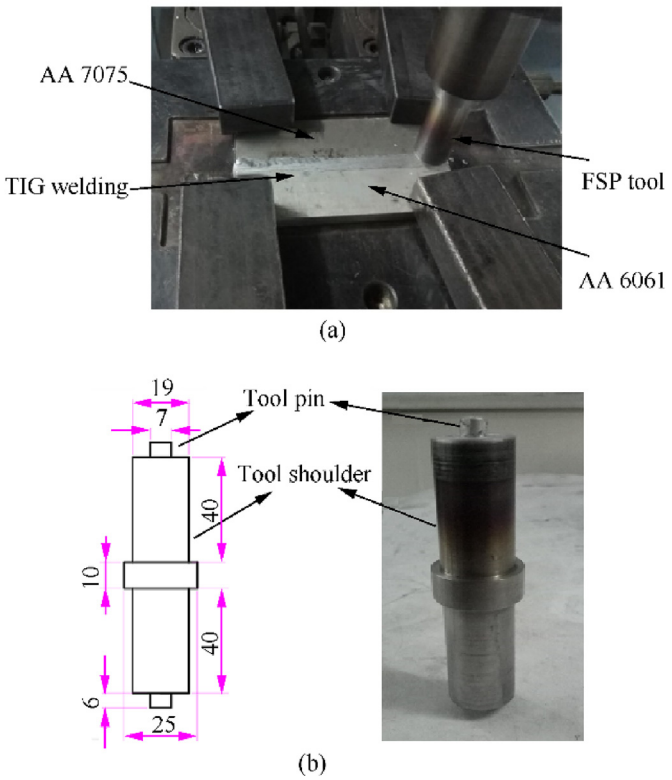

Fig. 1. (a) FSP process after TIG welding, (b) Friction stir processing tool of H13 tool steel.

room temperature and the average of these three results is taken. Vicker microhardness machine was used for measuring the hardness across the welded joints with a load of 100 g and dwell time 30 s. Microstructure observations were carried out using a scanning electron microscope (SEM) for TIG and TIG+FSP welded joints.

3. Numerical modeling [10]

For incompressible flow, the continuity equation in the direction of x, y and z is given by

$$\frac{\partial u_i}{\partial x_i} = 0 \tag{1}$$

The momentum conservation equation of the heat source is given as

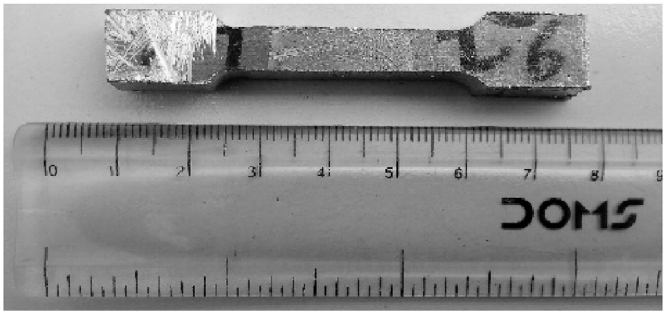

Fig. 2. Dimension of tensile test specimen as per ASTM E8.

$$\rho \frac{\partial u_I\, u_j}{\partial x_i} = -\frac{\partial P}{\partial x_j} + \frac{\partial}{\partial x_I}\left(\mu \frac{\partial U_j}{\partial x_i} + \mu \frac{\partial U_i}{\partial x_j}\right) - \rho\, U_1 \left(\frac{\partial U_j}{\partial x_I}\right) \tag{2}$$

The flow stress can be calculated as

$$\sigma_e = \frac{1}{\alpha} \sinh^{-1}\left[\left(\frac{z}{A}\right)^{1/n}\right] \tag{3}$$

$$A = 1.80 \times 106 + 1.74 \times 10^8 (\%C) - 6.5 \times 10^7 (\%C)^2 \tag{4}$$

$$\alpha = 1.07 + 1.70 \times 10^{-4} T - 2.8 \times 10^{-7} T^2 \tag{5}$$

$$n = 0.2 + 3.96 \times 10^{-4} T \tag{6}$$

$$z = \varepsilon \exp\left(\frac{Q}{RT}\right) \tag{7}$$

The effective strain may be written as

$$\varepsilon = \left(\frac{2}{3}\, \varepsilon_{ij} \varepsilon_{ij}\right)^{1/2} \tag{8}$$

Where ε_{ij} is given by

$$\varepsilon_{ij} = \frac{1}{2}\left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i}\right) \tag{9}$$

So, the viscosity can be calculated as

$$\mu = \frac{\sigma_e}{3\varepsilon} \tag{10}$$

The thermal energy conservation equation at steady state is given by

Table 2
Processing parameters of TIG welded joint [32].

Working Parameters	Shielding Gas/(L·min^{-1})	Current/A	Electrode Diameter/mm	Voltage/V	Welding Speed/(mm·s^{-1})
Description	25 (Argon)	50	3.2	22	3.6

Table 3
Processing parameters of friction stir processing [33].

Sample No	Current	Welding Speed/(mm·min^{-1})	Tool rotational speed/rpm	Frequency	Tilt angle/(°)
1	6.9	63	800	28.52	0
2			1000	33.36	
3			1250	40.00	
4			1600	52.61	

Please cite this article as: Mehdi H, Mishra RS, Effect of friction stir processing on mechanical properties and heat transfer of TIG welded joint of AA6061 and AA7075, Defence Technology, https://doi.org/10.1016/j.dt.2020.04.014

$$\rho C_P \frac{\partial (u_i T)}{\partial x_i} = -\rho C_P U_1 \frac{\partial T}{\partial x_i} + \frac{\partial}{\partial x_i}\left(k \frac{\partial T}{\partial x_i}\right) + S_i + S_b \tag{11}$$

Then S_i may be written as

$$S_i = \left[(1-\delta)\eta\tau + \delta\mu_f P_N\right]\ (\omega_r - U_1 \sin\theta)\ \frac{A_r}{V} \tag{12}$$

During friction stir welding, mixing is not atomic, only grains structure is deformed not mixing of atoms.

$$\phi = 2\left[\left(\frac{\partial u_1}{\partial x_1}\right)^2 + \left(\frac{\partial u_2}{\partial x_2}\right)^2 + \left(\frac{\partial u_3}{\partial x_3}\right)^2\right] + \left(\frac{\partial u_1}{\partial x_2} + \frac{\partial u_2}{\partial x_1}\right)^2 + \left(\frac{\partial u_1}{\partial x_3} + \frac{\partial u_3}{\partial x_1}\right)^2 + \left(\frac{\partial u_3}{\partial x_2} + \frac{\partial u_2}{\partial x_3}\right)^2 \tag{13}$$

3.1. Boundary conditions

When the work-piece top surface away from the tool shoulder edge, the boundary condition for heat exchange involves both convection and radiation heat transfer. However, at the sides and the bottom surface of the work-piece, the boundary condition for heat exchange involves only convection heat transfer. The heat generation rate at the interface between tool and the work-piece can be given be given by

$$f = \frac{J_w}{J_T} = \frac{\sqrt{(k_\rho C_P)_W}}{\sqrt{(k_\rho C_P)_T}} \tag{14}$$

Where T and W denote the tool and work piece respectively. The heat flux continuity on the shoulder interface yields

$$k \left.\frac{\partial T}{\partial z}\right|_{top} = \frac{J_w}{J_w + J_T}\ q1 \quad R_P \le r \le R_s \tag{15}$$

Where J_w and J_T are the heat conducted to the work-piece and tool respectively

$$J = \sqrt{k\rho\ C_p} \tag{16}$$

Where C_p is heat capacity, ρ and K are density and thermal conductivity respectively.

The total heat generation rate may be written as

$$q_1 = [\eta(1-\delta)\tau + \delta\mu f.P_H]\ (\omega r - U_1 \sin\theta) \tag{17}$$

The heat transfer coefficient may be calculated as.

$$k \left.\frac{\partial T}{\partial z}\right|_{bottom} = h_b (T - T_a) \tag{18}$$

Value of h_b can be calculated as

$$h_b = h_{b0}(T - T_a)^{0.25} \tag{19}$$

The heat transfer due to radiation and convection is written as

$$k \left.\frac{\partial T}{\partial z}\right|_{top} = h_t (T - T_a) + \sigma\varepsilon^1 \left(T^4 - T_a^4\right) \tag{20}$$

In this model, the computational region is considered as a single-phase visco-plastic non-Newtonian fluid and the FSW tool is considered as rotating in a fixed position as shown in Fig. 3. The material flows into the computational domain from the inlet velocity and out from outlet velocity at the welding speed (traverse speed). Top, bottom and side surfaces of the work-pieces are considered equivalent to the wall surface, having the same velocity as welding speed but opposite in direction.

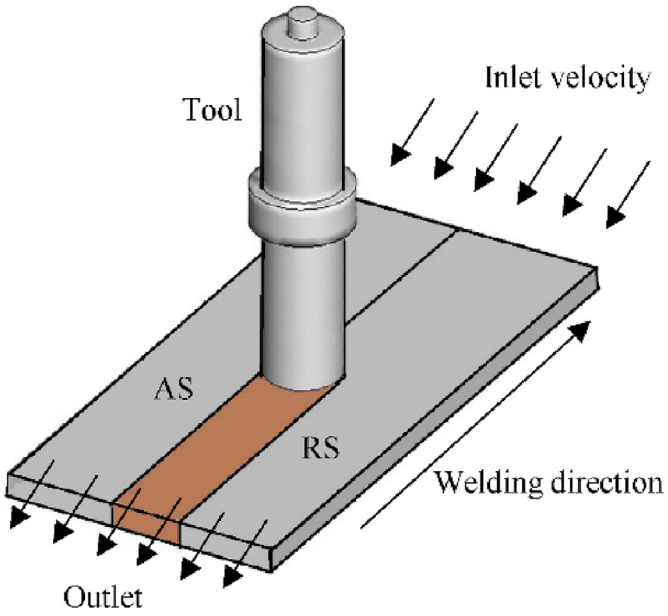

Fig. 3. Boundary condition.

Velocity at the tool pin periphery have been defined in terms of tool translation velocity and the tool pin angular velocity

$$\left.\begin{aligned} u &= (1-\delta)(\omega R_P \sin\theta - U_1) \\ v &= (1-\delta)\omega R_P \cos\theta \\ w &= k\ \frac{\omega}{2\pi} R_P \end{aligned}\right\},\ R_P \le r \le R_S \tag{21}$$

Similarly, at the shoulder contact, the velocity boundary condition may be written as

$$\left.\begin{aligned} u &= (1-\delta)(\omega r \sin\theta - U_1) \\ v &= (1-\delta)\omega r \cos\theta \end{aligned}\right\},\ R_P \le r \le R_S \tag{22}$$

3.2. Material properties

The density of AA7075 and AA6061 is taken as constant, equals to 2810 kg/m^3 and 2700 kg/m^3 respectively, while the specific heat and thermal conductivity are considered as temperature dependent properties [34] as given below

$$k = 25.2 + 3.98 \times 10^{-1} T + 7.36 \times 10 - 6T^2 - 2.25 \times 10^{-7} T^3$$
$$C_P = 929 - 6.27 \times 10^{-1} T + 1.48 \times 10 - 3T^2 - 4.33 \times 10^{-8} T^3$$

3.3. Residual stress measurement by cosα method

A mini portable X-ray diffraction apparatus (pulstec μ-X360) used for analyzing the residual stresses in welded joint of AA6061 and AA7075 samples. The X-ray incident angle was set 35° and ±5° oscillation was applied. The X-ray incident time was 4–5 min throughout this process for each sample. Under these conditions, a diffracted beam from the workpiece surface has captured the

Please cite this article as: Mehdi H, Mishra RS, Effect of friction stir processing on mechanical properties and heat transfer of TIG welded joint of AA6061 and AA7075, Defence Technology, https://doi.org/10.1016/j.dt.2020.04.014

images of the welded plates at 50 μm resolution, the size of the beam spot is approximately 2.5 mm for 1.2 mm pinhole collimator.

For residual stress determination, the cosα method was described [35]. The translation from the diffractometer space to the sample inherently more complex due to the 2D planar geometry of the measurement and can be expressed as

$$q_s = \begin{bmatrix} \cos\eta \sin\psi_0 + \sin\eta \cos\psi_0 \cos\alpha \\ \cos\eta \sin\psi_0 \sin\varphi_0 + \sin\eta \cos\psi_0 \sin\varphi_0 cos\alpha + \sin\eta \cos\varphi_0 \sin\alpha \\ \cos\eta \cos\psi_0 + \sin\eta \sin\psi_0 cos\alpha \end{bmatrix} \tag{23}$$

The strain projection along (η, α) coordinates can be written as in terms of scattering vector and strain component as

$$\begin{aligned} \varepsilon_\alpha &= q_i \cdot q_j \cdot \varepsilon_{ij} \\ \varepsilon_{ij} &= \frac{1+\nu}{E}\sigma_{ij} - \delta_{ij}\frac{\nu}{E}\sigma_{kk} \end{aligned} \tag{24}$$

So, the strain projection may be written as

$$\varepsilon_\alpha = \frac{1+\nu}{E} q_i q_j \sigma_{ij} - \frac{\nu}{E}\sigma_{kk} \tag{25}$$

Now, defining two parameters a_1 and a_2 for linear determination of σ_{11} and σ_{22}

$$a_1 = \frac{1}{2}[(\varepsilon_\alpha - \varepsilon_{\pi+\alpha}) + (\varepsilon_{-\alpha} - \varepsilon_{\pi-\alpha})] \tag{26}$$

$$a_2 = \frac{1}{2}[(\varepsilon_\alpha - \varepsilon_{\pi+\alpha}) - (\varepsilon_{-\alpha} - \varepsilon_{\pi-\alpha})] \tag{27}$$

After re-expressing of Eq. (26) and Eq. (27) to lead the final relationship for this method.

$$\begin{aligned} a_1 = \frac{1+\nu}{E}\sin\psi_0 \sin 2\eta \cos\alpha [\sigma_{11}(1+\cos 2\varphi_0) \\ + \sigma_{22}(1-\cos 2\varphi_0) + 2\sigma_{12}(\sin 2\varphi_0)] \end{aligned} \tag{28}$$

$$\begin{aligned} a_2 = \frac{1+\nu}{E}\sin\psi_0 \sin 2\eta \sin\alpha [\sigma_{22} \sin 2\varphi_0 - \sigma_{11} \sin 2\varphi_0 \\ + 2\sigma_{12} \cos 2\varphi_0] \end{aligned} \tag{29}$$

at $\varphi_0 = 0$, the above equations will be

$$a_1 = \sigma_{11}\frac{1+\nu}{E}\sin 2\psi_0 \sin 2\eta \cos\alpha \tag{30}$$

$$a_2 = 2\sigma_{12}\frac{1+\nu}{E}\sin\psi_0 \sin 2\eta \sin\alpha \tag{31}$$

Thus the term cosα in Eq. (30) is the origin of the name for this method.

The value of stresses after re-expression maybe written as

$$\sigma_{11} = -\frac{E}{(1+\nu)} \frac{1}{\sin 2\psi_0 \sin 2\eta} \tag{32}$$

$$\sigma_{12} = -\frac{E}{2(1+\nu)} \frac{1}{\sin 2\psi_0 \sin^2\eta} \tag{33}$$

4. Results and discussion

4.1. Tensile strength

In order to analyze the effect of friction stir processing on the TIG-welded joint, the tensile load applied on TIG and TIG+FSP welded joint by universal testing machine (UTM) at room temperature and fractured surfaces obtained from the tensile test were compared with one another. Three test specimens were tested at each condition and the average of these three results are presented in Tables 4–10. The tensile strength of the weldment made by TIG and TIG+FSP techniques are compared. Due to the absence of porosity, small grain size and presence of extra material in the welded region with filler wire, the tensile strength of TIG+FSP obtained higher value than the conventional TIG joining process. Filler ER5356 present in the welded joint makes more compact pressure leading to increase bond strength instead of filler ER4043. The grain size in the fusion zone for ER5356 is smaller than the ER4043. The tensile strength with filler ER5356 was obtained higher than ER4043 [36]. According to Hall Petch equation $\sigma_1 = \sigma_i + kd^{(-1/2)}$, the tensile strength is inversely proportional to the grain size [37]. The tensile strength of the TIG-welded joint using filler 4043 and 5356 was calculated 158.6 MPa and 172.2 MPa respectively which is less than the TIG+FSP as shown in Table 4. The tensile strength of the TIG+FSP welded joint increased with increasing tool rotational speed. The highest tensile strength (233.17 MPa) was observed in TIG+FSP with filler ER5356 at tool rotational 1600 rpm with feed rate 63 mm/min. Three statistical parameters are investigated i.e., standard deviation (SD), standard error (SE) and 95% confidence interval for TIG+FSP welded joint with filler ER4043 and ER5356 as shown in Tables 5–10. The standard deviation (SD) provides the deviance of the experimental

values from the mean it may be calculated as $SD = [\Sigma(X_i - M)^2/(N-1)]^{1/2}$ and the standard error is a quantity used to measure how to close the prediction values to the experimental values. *SE* is calculated as $SE = SD/N^{1/2}$, where N= No of observation and M = mean.

The confidence interval has shown that tensile strength and hardness increased with increasing tool rotation, whereas residual stress decreased with increasing tool rotation.

4.2. Micro-hardness

The micro-hardness distribution of the TIG-welded joint of AA6061 and AA7075 with different filler wire and TIG+FSP weldments with different processing parameters were analyzed by Vickers hardness testing results are shown in Fig. 4. Vicker microhardness machine was used for measuring the hardness across the welded joints with a load of 100 g and dwell time 30 s. The hardness distributions are asymmetrical in the weld center due to the microstructure of the advancing side and retreating side introduced by unsteady plastic flow from the base metal to the weld center [38–40]. The hardness slopes downward from the base metal to the welded region. The hardness fluctuates largely on the advancing side while the hardness holds steady in the retreating side [41].

The alloying elements such as Si and Mg existing in the weld center make precipitation reaction and form a strong precipitate of Mg_2Si to give a higher strength as shown in Fig. 5(a). Fig. 4 shows the micro-hardness profile at the heat-affected zone of aluminum alloy 6061 and 7075. It showed a significant difference, where the

Please cite this article as: Mehdi H, Mishra RS, Effect of friction stir processing on mechanical properties and heat transfer of TIG welded joint of AA6061 and AA7075, Defence Technology, https://doi.org/10.1016/j.dt.2020.04.014

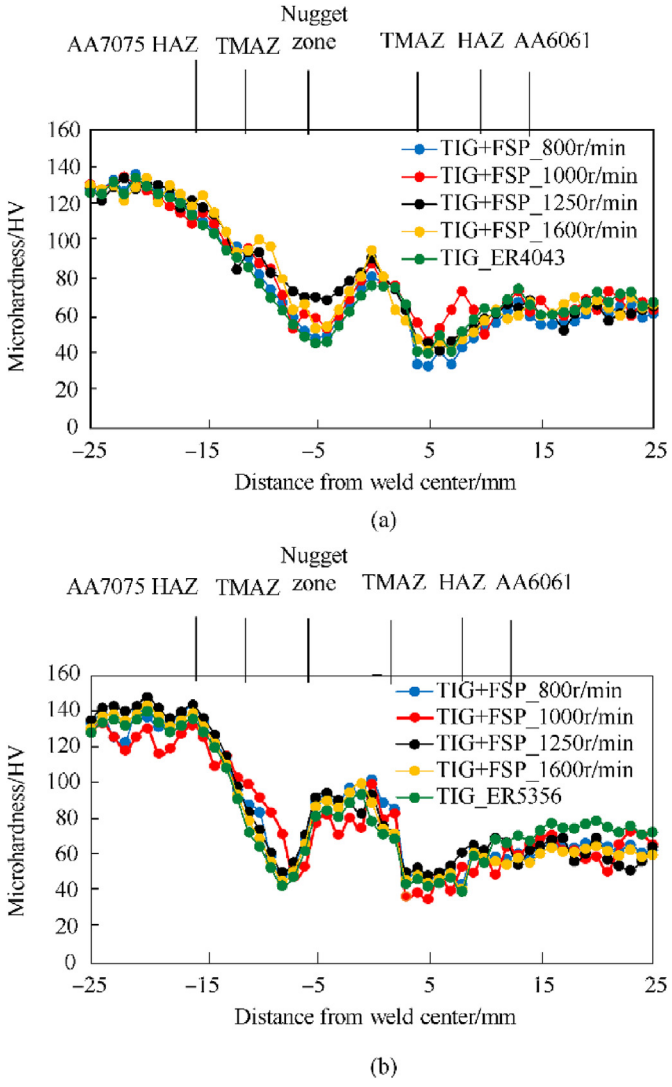

Fig. 4. Comparison of micro-hardness of TIG and TIG+FSP, (a) filler wire ER4043, (b) filler wire ER5356.

welded joint using filler ER4043 showed a lower average hardness value compared to filler ER5356. The hardness value at the center of weldment for filler ER4043 and ER5356 are 96 HV and 102 HV respectively, during welding, the filler wire ER4043 shows the columnar grains while fine equiaxed grains are found in ER5356. It may be analyzed that the fine equiaxed grains improve mechanical properties than the columnar grains [42].

4.3. XRD and EDX analysis

X-ray diffraction (XRD) analysis has been taken on transverse cross-sections of dissimilar TIG and TIG+FSP welded joint of AA6061 and AA7075 with filler ER4043 and ER5356. The corresponding pattern for the welded joints are shown in Fig. 5 and found four major phases i.e. Al, Al_2CuMg, $MgZn_2$, and Mg_2Si. Magnesium (Mg) and Silicon (Si) elements were found in the weldment besides the aluminum (Al), it is found that Mg and Si created the phase after the precipitation reaction in the weldment. The very high intensity was found from aluminum, because of the fragmentation of precipitates the intensity of $MgZn_2$ was decreases after friction stir processing on TIG welded joint with filler ER5356. The alloying elements such as Si and Mg existing in the weld center make precipitation reaction and form a strong precipitate of Mg_2Si to give a higher strength. The same phase of Al_2CuMg was detected in both the cases (filler ER4043 and ER 5356).

The hardness of the FSP joints is based on boundary energy, brittle intermetallic formation, strain hardening and precipitates formation in the joint. Fine recrystallized grains and increase of grain boundaries in the (SZ) of AA6061 and AA7075 joints predict higher hardness. Because of fine precipitates and fine grains structure, the stir zone is associated with plastic deformation and high temperature, due to precipitates formation at high temperature along the grain boundaries the hardness value of TIG+FSP at 1600 rpm with filler ER5356 recorded higher values than the TIG welded joints. The energy-dispersive X-ray spectroscopy (EDX/EDS) of the TIG-welded joint with filler ER4043 and ER 5356 welded joint has been analyzed. It was found that the atomic percentage of Si and Mg in the welded joint is higher than the other elements. Fig. 5(b) and (c) illustrates the EDX image and percentage of element concentration at fusion zone (FZ) in the TIG welded joint with filler ER4043 and ER5356. Zinc (Zn), Magnesium (Mg) and Silicon (Si) elements were found in the weldment besides the aluminum (Al), it is found that Mg, Zn, and Si created the phases after the precipitation reaction in the weldment.

4.4. Residual stresses measurement

A mini portable X-ray diffraction apparatus (Pulstec μ-X360) at Delhi technological university, Delhi, India was used to determine the residual stresses in weldment of AA6061 and AA7075 by the cosα method. The cosα method was introduced in japan for residual stress analysis in 1978 [43]. This method is allowed the stress analysis by capturing the results by a single incident X-ray beam via a 2D detector. It shows the peak center is very stable throughout the welding. Debye ring and distortion ring is obtained by using cosα method. An investigation has been done to analyze the residual stress. The 3D Debye ring and distortion ring of welded samples are shown in Fig. 7. The X-ray incident angle was set 35° and ±5° oscillation was applied. The variation of residual stresses in the transverse direction of weldment with filler ER4043 and ER5356 are shown in Fig. 6(a) and (b). Residual stresses (compressive or tensile) will influence the mechanical behavior of the welded joint. It can reduce brittle fracture strength, buckling strength and cracking in the weldment. Residual stress is also influenced by the prediction of brittle failure and affect the lifetime prediction of the component [44–47]. Residual stress contributes both negative and positive effects to the weldment, generally, the tensile residual stress leads to a negative effect on the weldment [48]. When the fixtures are unconstrained and the welded plate temperature is reduced to room temperature, the material in the nugget zone (NZ) tends to recover, but the material in the heat-affected zone (HAZ) has smaller deformation and will prevent the recovery process in NZ, so the maximum residual stress occurs in the boundaries of the HAZ with a minimum in the NZ. The deformation on the advancing side and retreating side differ, causing the recovery processes to differ too. So the residual stress cannot be symmetry to the welding line [49]. The base material AA7075 on LHS of the weldment shows a minimum compressive residual stress, however, the residual stress gradually increases from the base material to towards the weldment and then decreases till second base material AA6061. The maximum residual stress occurs in the location where the equivalent of the plastic strain is decreased suddenly. The maximum compressive residual stress 71 MPa were located at the fusion zone (FZ) of the TIG weldment with filler ER4043, whereas minimum compressive residual stress 37 MPa was obtained at stir zone (SZ) of the TIG+FSP with filler 5356, the residual stresses profile of TIG+FSP were not symmetrical about the centerline of the

Please cite this article as: Mehdi H, Mishra RS, Effect of friction stir processing on mechanical properties and heat transfer of TIG welded joint of AA6061 and AA7075, Defence Technology, https://doi.org/10.1016/j.dt.2020.04.014

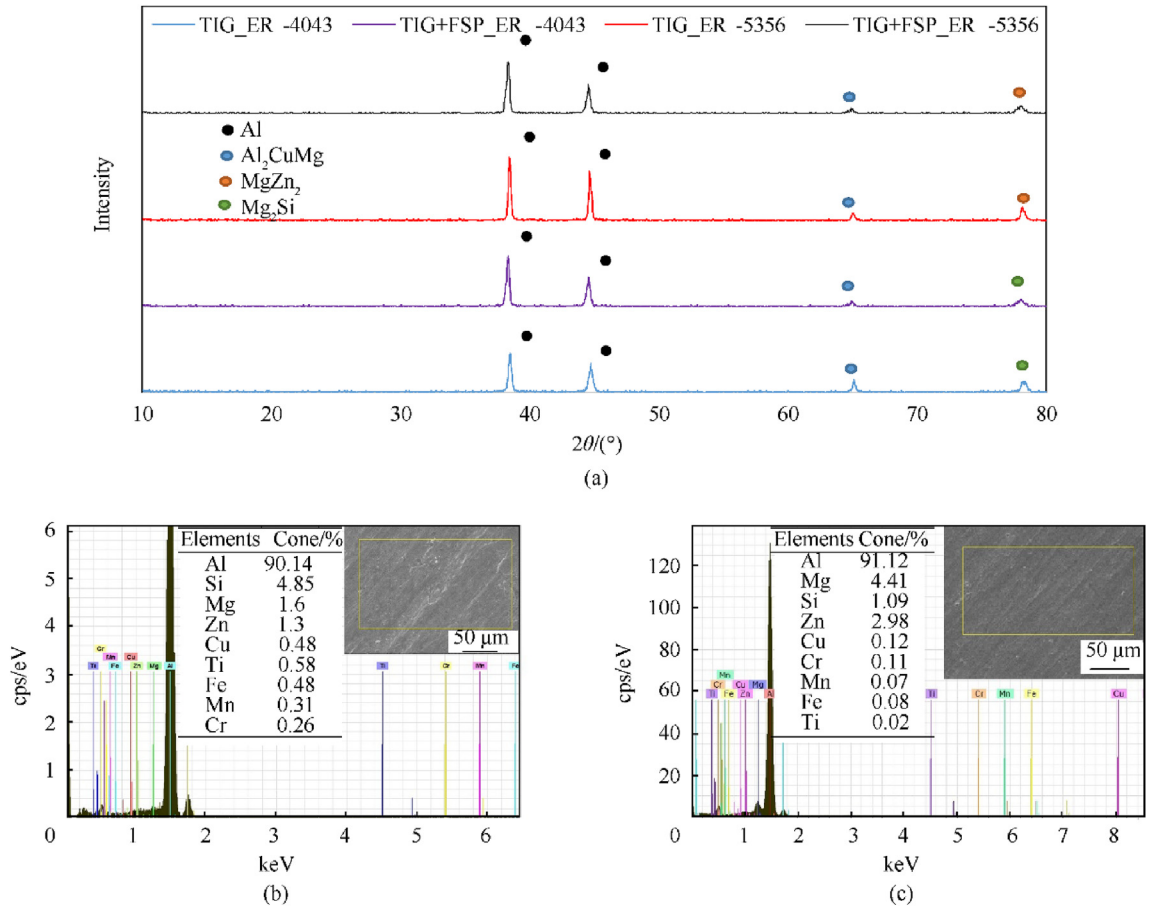

Fig. 5. (a) XRD peaks of TIG and TIG+FSP welded joint, (b&c) EDX analysis of TIG welded joint in fusion zone with filler ER4043 and filler ER 5356.

weldment for both the cases. The left side peak value of the weldment was greater than the right side because the forming processes are different for the retreating side (RS) and advancing side (AS).

4.5. Model validation

To confidently use CFD results for investigating the TIG+FSP process, the CFD model has to be correctly defined and a thorough validation has to be achieved. The model was first applied to simulate the experimental work on friction stir welded joint of Al-alloy 6061 carried out by Hwang el al [50]. The experimental temperatures were measured by thermocouple units placed equally at a distance of 5 mm, along the traverse direction of the rotating tool. The tool rotational speed and traverse speed, was 920 rpm and 20 mm/min respectively. The present simulation result was validated by this experimental results which gives the satisfactory amount of assurance in the fidelity of the simulation of welded joints as shown in Table 11.

4.6. Temperature variation in TIG+FSP process

The experimental temperature results of TIG+FSP measured by thermocouples. The advancing side temperatures in the transverse direction are A_1, A_2, A_3, and A_4 and the retreating side has R_1, R_2, R_3, and R_4. The peak temperature of advancing side is marginally higher than the retreating side [51,52]. The temperature of FSP tool is symmetric about the tool axis. The high temperature in the vicinity of the welding tool is attributed to the localized heat generation. During the TIG+FSP process, the temperature of the base plate around the welding tool is around the 765 K. It is still lower than the melting point of AA6061 and AA7075. When the position weld bead is far away from the FSP tool, the temperature drops quickly as shown in Fig. 9(a) and (b). Fig. 8 shows the temperature distribution plot for TIG+FSP welding at 160 s. During this simulation, eight points were observed to obtain the temperature-time curves which can be compared with the experimental results. The area around the FSP tool reached the maximum temperature. The maximum temperature was observed 760 K at the advancing side whereas minimum temperature was observed 307 K at the retreating side. Higher heat is generated in the SZ at high tool rotation, the prevailing thermal conditions are controlled by the distribution and availability of precipitates in the matrix. Fig. 10 shows the temperature variation profile on the mid-section of the top surface of (TIG+FSP) welded joint with different processing parameters. The region where its peak temperature is higher almost 450 °C in (TIG+FSP) of AA6061 and AA7075 aluminum alloy at tool rotational speed of 1600 rpm. The heat is transmitted to the aluminum alloy which is preheated during tool rotation. The initial heating was predicted as the monitoring thermal contour of the rotating tool. When the rotating tool moves on the monitoring location, the temperature contour leads to slow cooling. Due to the relation between tool pin rotation and material flow, the higher shearing rate was observed at (A.S). Thus the temperature of (RS) is slightly lower than the (AS), while almost the symmetric temperature was observed at the bottom of the welded joint.

The estimated maximum temperature about 515 °C was calculated in the stir zone of the TIG+FSP welded joint at tool rotation of

Please cite this article as: Mehdi H, Mishra RS, Effect of friction stir processing on mechanical properties and heat transfer of TIG welded joint of AA6061 and AA7075, Defence Technology, https://doi.org/10.1016/j.dt.2020.04.014

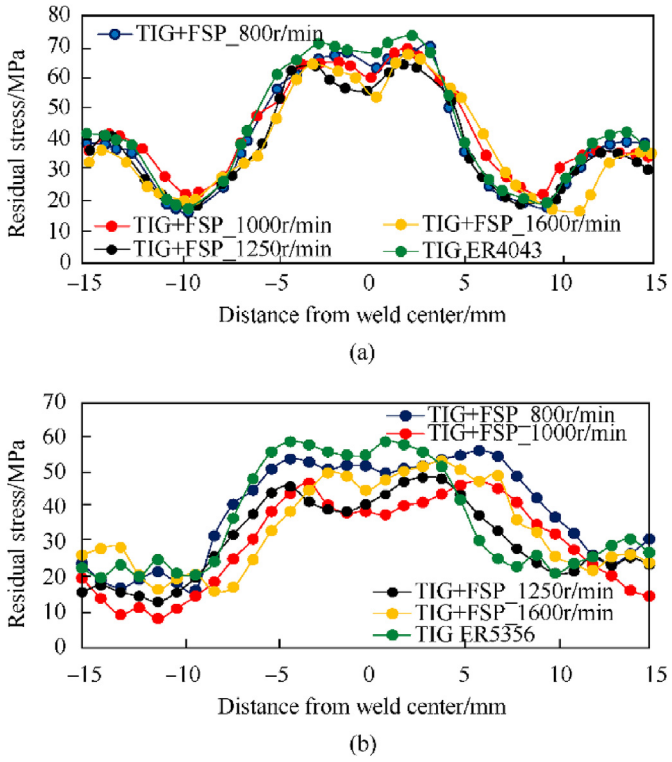

Fig. 6. Variation of transverse compressive residual stress at the welded joint, (a) filler ER4043, (b) filler ER5356.

1600 rpm whereas 408 °C was calculated in the stir zone at 800 rpm. The temperature and heat flux distribution with different processing parameters are shown in Figs. 10 and 11. In general, the temperature values at the (A.S) about 10–25 °C greater than the

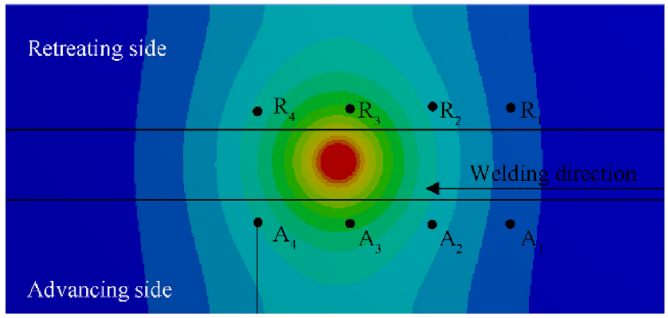

Fig. 8. Temperature contour of TIG+FSP at 160 s.

(R.S), When the tool approaches the target location then there is a rapid change in the temperature, while the slower cooling rate was observed when the tool moves away from the target location [53]. The variation of heat flux at the tool workpiece interface is shown in Fig. 11. It was observed that the heat flux is directly proportional to the tool rotational speed. The maximum heat flux about 5.33×10^6 w/m^{2}was obtained in the SZ at 1600 rpm, whereas minimum heat flux was obtained at 1000 rpm. The non-uniformity was observed in the heat flux pattern at different processing parameters of the tool, because the rapid recirculation of plasticized material, the heat flux rate does not lead to the variation of local temperature.

4.7. Microstructure analysis of TIG and TIG+FSP welded joint

For metallography observation, samples were first ground and mechanically polished and then etched in keller reagent (HNO_3, HF and HCL) and observed by the microscopic machine. The microstructure of TIG welded joint of Al-6061 and 7075 with filler ER4043 and ER 5356 were observed at fusion zone as shown in

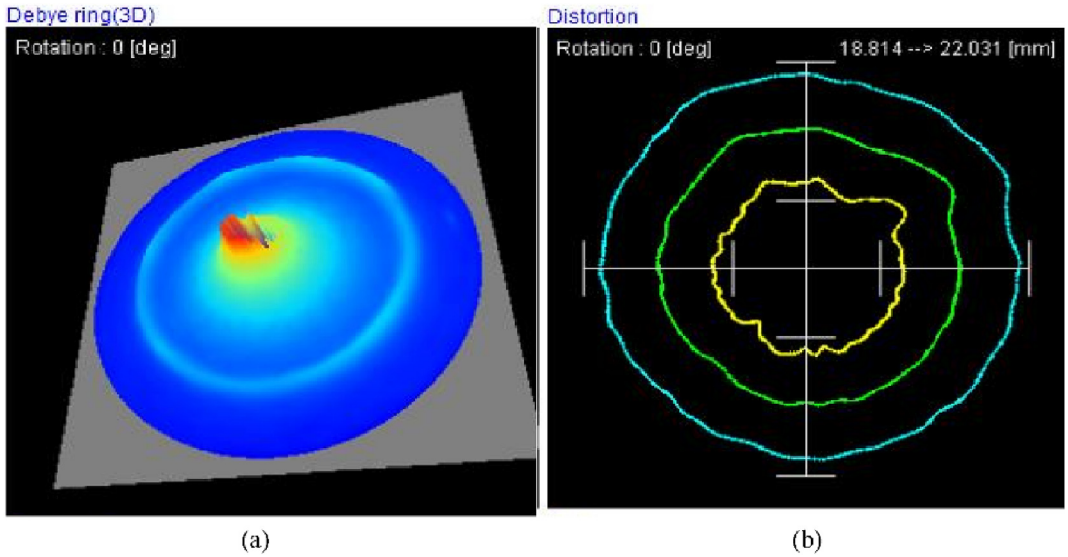

Fig. 7. (a) 3D Debye ring at the center of the TIG+FSP welded joint, (b) 2D Distortion ring at the center of the TIG+FSP welded joint.

Table 11
Validation of temperature distribution of friction stir welded joint of AA6061 [50].

Author	Rotation speed/rpm	Traverse speed/(mm·min^{-1})	Maximum temperature/°C
Present result	920	20	398

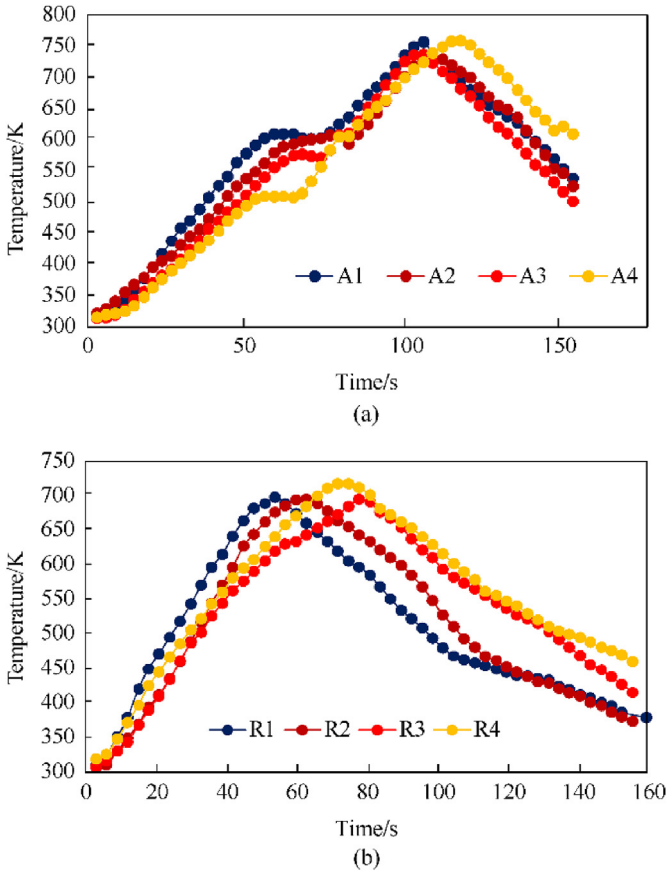

Fig. 9. Variation of temperature during TIG+FSP welding: (a) Advancing side, (b) Retreating side.

Fig. 12. The dispersed precipitates of Al_2CuMg intermetallic compound were observed in welded region and coarse equiaxed grains were also observed in fusion zone with filler ER4043. The equiaxed grains is absent due to the material close to the fusion line provides plenty of sources for the crystal nucleation of the liquid metal during the TIG welding [54]. Fine grains with small precipitates was reported in TIG welded joint with filler ER5356 as compare to ER4043.

Three different zones have been recognized in TIG+FSP weldment at low magnification due to mechanical and thermal stresses caused by the processing parameters. These zones are nugget zone (NZ), thermo-mechanically affected zone (TMAZ), and heat affected zone (HAZ). The formation of nugget zone shape in TIG+FSP welded joint is recognized to the maximum deformation and plasticization in the material which shows the fine recrystallized equiaxed grains. The formation of nugget shapes depends on thermal gradient, processing parameters and tools geometry in the work-piece [55]. Therefore, coarse grain structure of TIG welded joint is transformed into the uniform and fine grains structures in the weld nugget zone due to adequate softening of material revealed the maximum tensile strength and microhardness of the TIG+FSP welded joint as shown in Fig. 13. At high welding speed, the weld nugget zone is more homogenous than those produce low welding speed because high heat input gives the effective recrystallization and more homogenous temperature distribution in weld nugget zone. The grains size in stir zone change crucially which is depend on the heat input and processing parameters [56,57].

The grain size of TIG weldment were analyzed by the image J software and observed grain size in fusion zone with filler ER4043 and ER5356 are 20.4 μm, and 18.2 μm. Fig. 14 shows the effect of tool rotational speed on grain size of TIG+FSP welded joint at nugget zone. It can be conclude that the rotational speed has a significant effect of grain size of the welded joint. When the rotational speed increases, grain size decreases, this observation give the satisfactory amount of assurance with Yupeng Li [58]. The average minimum grain size i.e. 3.4 μm was observed in TIG+FSP with filler ER5356 at tool rotational speed 1600 rpm.

Fig. 15 shows the fractured surface after the tensile test. In this analysis two mode of failure were observed. The fractured occurs in retreating side at low rotational speed (800 rpm), on the other hand failure was observed in advancing side at high tool rotational speed (1600 rpm). This observation gives the satisfactory amount of assurance with Mishra [5]. SEM fractograph has been taken from the fractured tensile test. fracture morphology between the TIG and TIG+FSP shows that TIG welded portion shows the large voids whereas TIG+FSP welded portion shows fine dimples, this is the evidence of crack nucleation and growth 4 mm away from the weld line. The ductile fracture of welded joint occurs, an improvement in

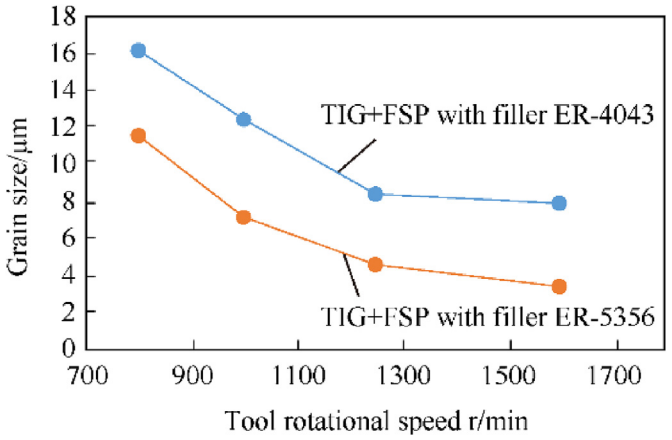

Fig. 14. Effect of tool rotational speed on grain size of TIG+FSP welded joint.

ductility may be achieved when the cavity nucleation could be suppressed [59]. The maximum inter-facial normal stress is depends upon the grain particle size and the volume fraction of the grain particles [60]. The fractured surface at room temperature were shown in Fig. 15.

The large dimples and quasi cleavage with sharp edge and various depth were found on the fractured tensile specimen surface of TIG welded joint with filler ER4043 and ER5356as shown in Fig. 15(a) and (b). Many large and equiaxed dimples were observed in TIG welded joint with filler ER4043 whereas the main fractured mode was quasi cleavage with lot of tiny dimples gathered around the large and quasi cleavage dimples found in filler ER5356 which shows the ductile fracture. The FSW processing parameters effect the temperature distribution and material flow across the TIG welded joint. Fig. 15(c) shows the SEM micrograph of factored surface of TIG+FSP welded joint, finer dimples are observed in TIG+FSP weldment as compare to TIG welded joint, which shows the better mechanical properties.

5. Conclusion

A new welding approach has been investigated to see the effect of FSP on TIG welding for dissimilar alloy AA6061 and AA7075 followed by the different filler wire ER4043 and ER5356. The mechanical characterization, finite element formulation and mathematical equations of heat transfer of TIG+FSP welded joints are investigated using ANSYS Fluent software by adjusting process parameters of FSP. The confidence interval has shown that tensile strength and hardness increased with increasing tool rotation, whereas residual stress decreased with increasing tool rotation. The maximum compressive residual stress 71 MPa were located at the fusion zone (FZ) of the TIG weldment with filler ER4043, whereas minimum compressive residual stress 37 MPa was obtained at stir zone (SZ) of the TIG+FSP with filler 5356. The large dimples and quasi cleavage with sharp edge and various depth were found on the fractured tensile specimen surface of TIG welded joint with filler ER4043 and ER5356 whereas fine dimples are observed in TIG+FSP weldment, which shows the better mechanical properties. TIG+FSP resulted in generated fine grains of 3.2−4 μm. The grain size decreases by increasing the tool rotational speed. The minimum grain size was obtained in TIG+FSP welded joint with filler ER5356 at 1600 rpm.

The asymmetry of the temperature distribution during TIG+FSP welding of AA7075 and AA6061 determined by numerical simulation corresponded with the experimental results. The peak temperatures on AS were higher than the RS of 20 K. The heat transfer is

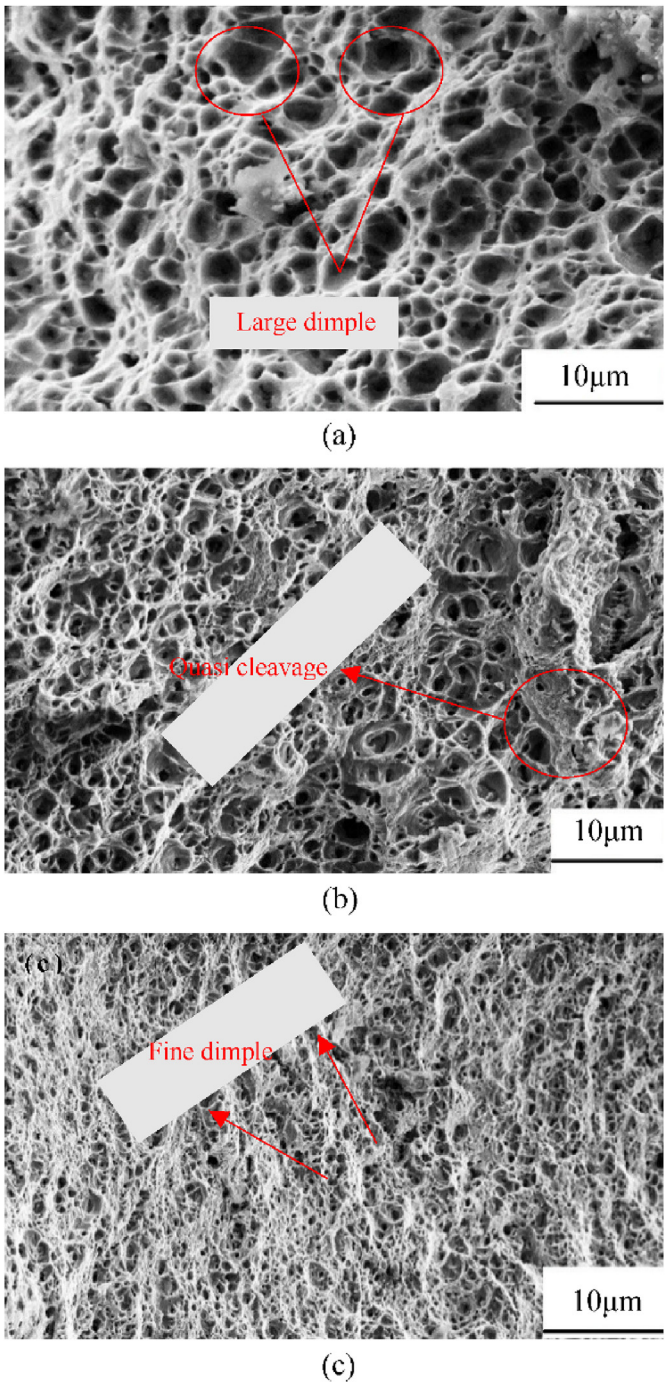

Fig. 15. SEM images of fractured tensile specimen, (a) TIG welded joint with filler ER4043, (b) TIG welded joint with filler ER4043, (c) TIG+FSP welded joint.

analyzed by the effect of different processing parameters of FSP tool. The temperature at advancing side is higher than the retreating side. The predicted peak values of temperature at the weld region was calculated by the ANSYS software and found the maximum temperature about 515 °C at tool rotation of 1600 rpm, whereas the maximum heat flux rate about 5.33×10^6 was observed at 1600 rpm.

***Abstract*- Numerous consitutive models have been developed over the past years for modelling the stress-strain behaviour of soils, using finite element and/or finite difference calculations of soil structures and soil/structure interaction problems under axisymetric, plane strain, and/or general three dimensional conditions. Selection of the appropriate parameters and soil model can have a significant impact on the results of numerical analysis. In this study, the interaction of soil and reinforced cement concrete raft foundation in a sandy soil at a depth of 9m below the existing ground level is analysed by using with both analytical and finite element analysis (FEM). Analytical calculations were done using method available in literature and a finite element analysis was carried out using the hardening soil model available in PLAXIS 2D (2020, connect version). The results obtained from analytical calculations were compared with those obtained from the Hardening Soil (HS) Model. In the model sizes of mesh were changed and there effect on interaction behaviour is observed by studying the strength and deformation results obtained from FEM analysis. It was observed that very fine mesh size gave more accurate results compared to the other sizes.**

Keywords- Plaxis, sand, settlement, Raft

I. INTRODUCTION

Evaluation of correct strength and deformation behaviour of raft resting on the soil is important for safe and economical design. Strength and deformation behaviour of raft foundation can be analysed by different numerical methods. With the development of numerical methods such as finite element anaylsis and finite difference method, it has become feasible to analyse and predict the behaviour of complex soil structures and soil/structure interaction problems. Such anaylses depend on the representation of the relations between stresses and strains in a given material and are represented by a consitutive model, consisiting of mathematical expressions that model the behaviour of soil in a single element. Therefore the purpose of a consitutive model is to simulate the soil behaviour with sufficient accuracy under all conditions with sufficient accuracy under all loading conditions in the numerical computations.

II. LITERATURE REVIEW

The Hardening Soil model was established in 1999 [1]. In the framework of the theory of elasticity. The model involves friction hardening to model the plastic shear strain in deviatoric loading, and cap hardening to model the plastic volumetric strain in primary compression.because of these two types of hardening, the model is accurate for problems (like excavations) involving a reduction of mean effective stress and at the same time mobilization of shear strength. The verification and formulation of this model was discussed [1]. It is an advanced and latest model for the simulation and modelling of soil behaviour. The Hardening soil model requires the input of 10 parameters, i.e. three reference stifness parameters (E_{50}^{ref} for triaxial compression, E_{ur}^{ref} for triaxial unloading and E_{oed}^{ref} for oedometer loading) at a reference stress level P^{ref}, a power, *m*, for the stress dependent stifness formulation, poisson's ratio for unloading and reloading, μ_{ur}, the mohr coulomb strength parameters, Ø, and c, the dilatancy angle, ψ, the K_o value in primary one-dimensional compression (K_o^{nc}), a parameter called the failure ratio, R_f which determines the strain level at failure [2]. Fig. 1 shows the failure criterion of the harening soil model in principal stress space. The yield surface of the hardening soil model is not fixed in principal stress space, but it can expand due to plastic straining. The Plaxis hardening model can be used to accurately predict displacement and failure for general types of soils in various geotechnical applications [3]. The model does not include anisotropic strength or stiffness, nor time-dependent behaviour (creep). The hardening soil model is also known for stress-dependency of stiffness moduli [4]. This explains that all stiffnesses increases with the pressure.

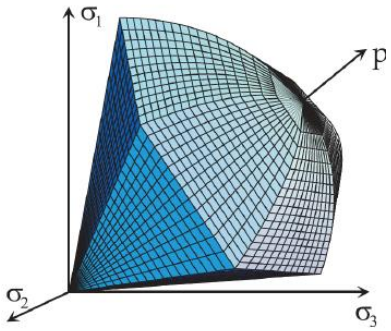

Figure 1: Failure criterion of the Hardening soil model in principal stress space [1].

The Hardening Soil model, also called as HS-Standard was explained by [1]. In order to modify the important phenomena which is exhibited by soils such as:

1. Densification, defines as decrease of the voids volume in soil due to plastic deformations, which also decreases the void ratio,

(This work is licensed under a Creative Commons Attribution 4.0 International License.)

International Journal of Engineering Research & Technology (IJERT)
ISSN: 2278-0181
Vol. 9 Issue 06, June-2020

2. Stress dependent stiffness, is basically an observed technique of increasing the stiffness modules with the increasing of confining stress,
3. Soil stress history, explains the accounting for preconsolidation process and its effects,
4. Plastic yielding, is very important which accounts for the development of irreversible strains with reaching a yield criteria,
5. Dilatancy, explains as the uses for an occurrence of negative volumetric strains during shearing.

This model is known to be one of the simplest and important in the class of latest models designed to handle the small strain stiffness as explained by [5]. It has two plastic mechanisms, shear and volumetric. Different to the other material models such as the Cap model or the Modified Cam Clay model, the magnitude of soil deformations, stresses, forces, etc. can be modelled more accurately by using three different input stiffness parameters which is related to triaxial loading stiffness (E_{50}), triaxial unloading-reloading stiffness (E_{ur}), and oedometer loading modulus (E_{oed}).
There are five parameters in the hardening soil model differ than the MC model is:

1. (E_{50ref}) secant modulus 50% strength[kN/m^2]
2. (E_{oedref}) Oedometric modulus [kN/m^2]
3. (E_{urref}) Unloading-reloading modulu[kN/m^2]
4. (ν_{ur}) Unloading-reloading Poisson's ratio [-]
5. (m) Exponent of the stress-stiffness function

Parameters previously used in MC model:

1. (Ø) Friction angle [°]
2. (c) Cohesion [kN/m^2]
3. (ψ) Dilatancy angle [°]

The hardening model can be used to predict displacement and failure for different types of soils in various geotechnical applications. This model does not include anisotrpic strength or stifness, nor time-dependent behaviour (creep). It's capabilities for dynamic applications are limited, but this model is, in principle, without any doubt the most accurate general soil model.

A. *Correlation between Angle of Friction and Standard Penetration Number*

The peak friction angle Ø', of granular soil has also been correlated with N_{60} by several investigators. A correlation between N_{60} and Ø' was given by [6] in a graphical form, which can be approximated as,

$$Ø'(deg) = 27.1 + 0.3N_{60} - 0.00054[N_{60}]^2 \quad (1)$$

B. *Correlation between Modulus of Elasticity and Standard Penetration Number*

The modulus of elasticity of granular soils (E_s) is an important parameter in estimating the
elastic settlement of foundations. A first order estimation for E_s was given by [7] as

$$\frac{E_S}{p_a} = \propto N_{60} \quad (2)$$

Where
α = 5 for sands with fines
10 for clean normally consolidated sands
15 for clean overconsolidated sands
p_a= atmospheric pressure in the same units as E_s
N_{60}= Field standard penetration number

III. PROBLEM STATEMENT

Bearing capacity requirement is a basic criteria to be satisfied in the analysis and design of shallow foundations. The criterion on bearing capacity ensures that the foundation does not undergo shear failure under loading. The use of standard penetration test in the analysis of bearing capacity has received numerous attentions [8]. Details of the field application of Standard Penetration Test are specified in IS 2131 [9]. This paper attempts to report interaction behavior of raft foundations resting on sand using Finite element software package provided by Plaxis 2D (connect editon). Steps for modeling is presented in fig. 2 from the model definition to the output results

IV. SELECTION OF PARAMETERS

Parameters used in this study were obtained through laboratory investigation of the undisturbed samples collected from site located at Noida in India, as most of the strata is having poorly graded sand, collection of undisturbed sample was difficult. Hence, the result of standard penetration test conducted as per IS 2131 [9] is used for analysis . Table 1 summarizes the selection of model paramters for analysis of the hardening soil model used in this study.

SOIL PROFILE AND BOREHOLE DETAILS

The samples were collected from two bore holes drilled at GH-01A/01, SECTOR-16, GREATER NOIDA WEST, U.P (India) and tested as per the relevant protocol of bureau of Indian Standard. The results of SPT are presented in Table2.

ANALYTICAL METHOD

The analytical calculations were done in accordance with Indian standards IS 6403 [10] and permissible settlement is restricted as per IS 1904 [11].

Based on the shear criterion IS code 6403 [10], net ultimate bearing capacity for local shear failure for a cohesionless sand

$$q_{nu} = q(N_q - 1)s_q d_q i_q + \frac{1}{2} B\gamma N_\gamma s_\gamma d_\gamma i_\gamma w' \quad (3)$$

Where s_q, s_γ= shape factors

d_q, d_γ= depth factors

i_q, i_γ= Inclination factors

N_q, N_γ= Bearing capacity factors

w', w''= Correction factor for location of water table.

Assuming there will be rise in water table during mansoon and water will reach to a level of bottom of raft.

$$\emptyset' = tan^{-1}(0.67 tan\emptyset) = 22.78^o$$

Nq=8.76, Nγ=8.44

$$from\ equation\ (3), q_{nu} = \gamma D_f (N_q - 1)s_q d_q i_q w' + \frac{1}{2} B\gamma N_\gamma s_\gamma d_\gamma i_\gamma w'' = 2209.88 KN/m^2$$

Assuming a factor of safety of 2.5, net safe bearing capacity(q_{ns}) $= 883.95 KN/m^2$

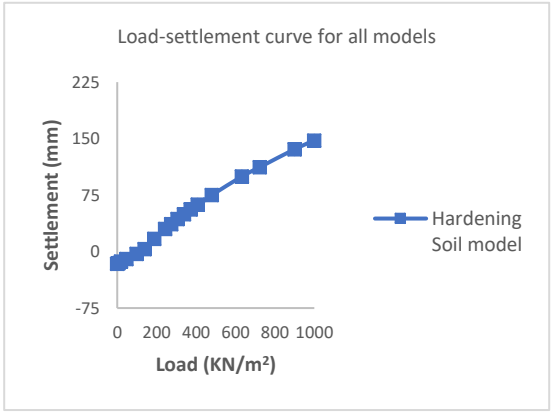

Figure 4: Load-settlement relationship for the Hardening soil model

75mm allowable settlement, from equation 4, q_n= 456.7KN/m^2.Therefore, considering the lower of the two values obtained, Allowable bearing capacity of the foundation was obtained as 456.7KN/m^2.

V. NUMERICAL ANALYSIS

Plaxis 2D was used to evaluate the performance of the Hardening Soil model model to estimate the bearing capacity of a raft foundation situated at a depth of 9m below the surface and to investigate the relationship between the results obtained. Fig 3 shows a sketch of the prototype dimensions showing the location of the water table. Simulations for different excavation stages were done. The distance between the boundary of the floor of the model and the lower boundary of the footing plays an important role in the pattern of bearing capacity value obtained.

Vol. 9 Issue 06, June-2020

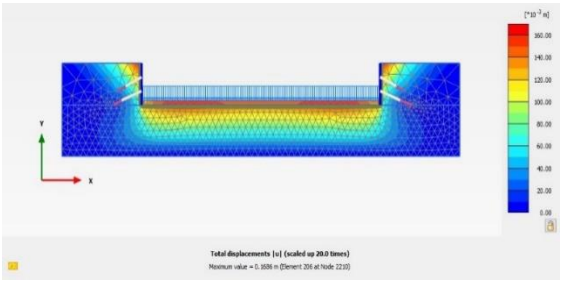

Figure 5: Output image showing total vertical displacement of foundation

To eliminate the effect of this factor, the bottom line intended at a distance greater than 2d.

It can be seen from fig 4, that Plaxis 2D software provides a linear load-settlement relationship for the hardening soil model, which is variant from the theoretical load-settlement curve for a foundation on sandy soil. The curve also indicates an initial negative settlement indicating a swelling in the soil before the footing is placed and load is applied. The reason for initial negative settlement is due to release of in situ soil pressure due to excavation.

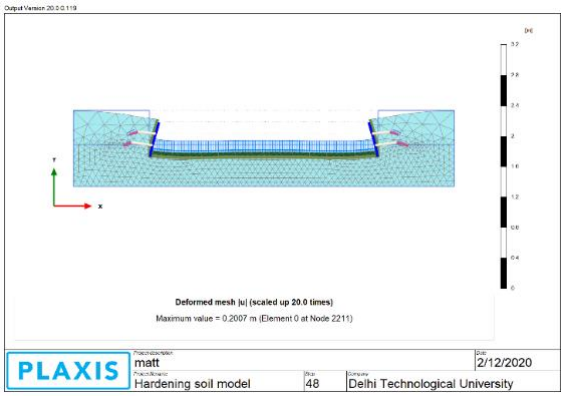

Figure 6: Deformed mesh of foundation.

It can be seen from the graph that settlement increases directly proportional to increase in stress applied on foundation. A value of 481KN/m^2 is obtained at 57mm settlement. It can be seen that the hardening soil model provides a result close to the value obtained from the IS code calculation (456.7KN/m^2) therefore making it more accurate to use in the field for design of foundations. Fig 5 shows the deformation of the raft footing after applying the design load. The contours are drawn for different displacements value below the raft.

Fig 6 shows the typical deformed mesh of the foundation. Three excavation stages were input into Plaxis software since the foundation is laid at a 9m depth. To support the dry excavation, anchors were used. The anchors were prestressed with 500KN force.

VI. EFFECT OF CHANGES OF MESH SIZE ON THE BEARING CAPACITY OF FOUNDATION

Here, the effect of mesh size changes on the model output results was analysed. Different mesh sizes were used in Plaxis 2D which are; very coarse, coarse, medium, fine and very fine. It should be noted that the mesh size of 15 nodal element, is a better distribution of nodes and more accurate results than to element with six nodes. Therefore, the analysis of 15 nodal element is used. Table 3 shows the effect of changes of mesh size on settlement pressure of foundation for 75mm settlement. Figure 7 shows the effect of change in mesh size on deformation of a raft foundation.

TABLE 3: EFFECT OF CHANGE IN MESH SIZE ON ALLOWABLE BEARING CAPACITY OF FOUNDATION

Allowable bearing capacity of foundation at 75mm settlement (KN/m^2)	Change in type of mesh size
494	Very coarse
488	Coarse
480	Medium
465	Fine
460	Very fine

From Fig 7, it can be seen that there is slightly or no difference in the pressure for 75mm of settlement. But at settlement more than 75 mm the effect of mesh size is to decrease the settlement for a given pressure if mesh size is increased from very fine to very coarse.

VII. CONCLUSION

Based on the findings, the following conclusions can be drawn;

1. The bearing pressure for a given settlement obtained by the hardening soil model was closer to the IS analytical method. However an initial settlement of 20mm should be deducted to cater for the swelling provided by plaxis FEM, because of removal of insitu stress because of excavation.
2. Mesh size with 15 nodal elements produces more accurate results as compared with element with six nodes.
3. The mesh sizes influences the bearing pressure for a given settlement. The influences are negligible at a settlement value of 75mm, but influences increase with increase in settlement.
4. Bearing capacity value increases with increase in refinement of mesh size in Finite element analysis. When a finer mesh is used, the value of bearing capacity obtained at a particular settlement is higher than that obtained when a coarse mesh is used. This therefore means researchers should ensure that a fine mesh is used when carrying out finite element analysis to obtain more accurate results.

Abstract

We present an ultra-compact strip to slot waveguide mode converter to facilitate excellent fundamental mode coupling between the strip and slot waveguide over a broad wavelength range. The design utilizes tapered waveguide geometries for adiabatic mode conversion. The taper profiles are optimized using a fast quasi-adiabatic approach to achieve the adiabatic mode conversion within the smallest possible length. We numerically demonstrate a conversion efficiency of 99.4% at a wavelength 1.55 μm with a variation of <1.5% over a bandwidth of 100 nm and <5% over a bandwidth of 200 nm. In addition, the design is ultra-compact with a footprint of only 1.23×3.7 μm^2 and offers a high tolerance to the possible fabrication inaccuracies.

Keywords: adiabatic tapers, quasi-adiabatic dynamics, strip to slot converter, silicon photonics

1. Introduction

The slot waveguide can confine light within a nanoscale low index gap between two high index strips and hence facilitates strong light matter interaction. This property of slot waveguide has been utilized in a number of applications including optical modulation [1], all-optical signal processing [2,3], biosensing [4-6] and absorption-based sensing [7]. The use of polymer filled slot waveguide for modulation and all-optical signal processing allows efficient use of the non-linearity in polymers [1-3]. In biosensing applications, a strong interaction between the waveguide mode and the functionalized waveguide surface of the slot waveguide results in a better sensitivity with smaller device footprint [8,9]. However, scattering losses associated with slot waveguides are, in general, higher than that of the strip waveguides. Hence, the use of slot waveguides is better suited to the abovementioned applications while for most of the other photonic integrated circuits (PICs), the strip waveguide is a better choice due to its low loss and tight confinement. Also, the efficient designs of grating couplers and edge couplers, to allow coupling of light between the photonic chip and an optical fiber, are available for the strip waveguides [10]. To benefit from the advantages of both the waveguide geometries, there is a need for efficient coupling between the fundamental mode of the strip waveguide and the slot waveguide. Direct butt coupling results in a high loss due to a large mismatch between the fundamental mode of the strip and the slot waveguides and hence a mode converter is needed for efficient coupling of light between these waveguides. Few of the reported designs of the

Accepted Manuscript

strip to slot waveguide mode converters are solely based on adiabatic mode evolution [11-13]. For adiabatic mode evolution based V-shaped mode converter [11] and ultra-low loss converter [12], the coupling efficiency strongly depends upon the sharpness of the taper tip and hence poses challenges in terms of fabrication. The other design [13] based on adiabatic mode evolution is improved in terms of fabrication tolerance; however, the device footprint can be significantly improved by the appropriate choice of the taper profiles. The other category of strip to slot converter is based on split and combine technique. This technique requires the use of an addition splitter section prior to an adiabatic mode evolution based combiner section [14-17]. The technique utilizes either a y-splitter [14] or a MMI [15-17] to split the light into two strip waveguides followed by a tapered section for adiabatic evolution of the fundamental mode of these evanescently coupled strip waveguides into the fundamental mode of the slot waveguide. The performance of these designs is limited by the 3 dB response of the y-splitter or MMI. Also, the design with y-splitter has a very large device footprint and requires integrated heaters to compensate the phase error due to the differential length between the two arms [14].

We propose a compact and broadband strip to slot waveguide mode converter based on adiabatic mode evolution. In order to achieve adiabatic mode conversion within the smallest possible length, we optimize the taper profiles using a fast quasi-adiabatic (FAQUAD) [18,19] approach. Using the optimized tapers, a very high mode conversion efficiency is obtained over a broad wavelength range with a footprint of only 1.23×3.7 μm^2. The design also offers a very high tolerance to the possible fabrication inaccuracies.

2. Design criteria and optimization

The proposed strip to slot waveguide mode converter is designed for silicon-on-insulator platform with dimensions of the slot waveguide optimized specifically for biosensing applications [9]. Cytop is chosen as the cladding material as its refractive index ($n_c = 1.3335$ at $\lambda = 1.55$ μm [20]) matches well with the aqueous solutions used for biosensing and hence makes it an appropriate choice for cladding or microfluidic channel in integrated photonic biosensors [21-23]. Optimizing the mode converter with Cytop cladding also allows the freedom to use the mode converter within the sensing region with no significant change in the conversion efficiency. The cross-sectional view of the strip and slot waveguides, with corresponding dimensions and the field profile (E_x) of the fundamental quasi-TE mode, are shown in Fig. 1. The effective indices of the TE_0 mode of the strip waveguide and slot waveguide are obtained as 2.4277 and 1.6810, respectively.

It is clearly visible from the modal profile of the slot waveguide [Fig. 1], that the electric field is confined to the low index slot between the two silicon strips which is also evident from its low effective index. For direct butt coupling between strip waveguide and slot waveguide, with dimensions given in Fig. 1, a maximum coupling efficiency of only 70% is possible.

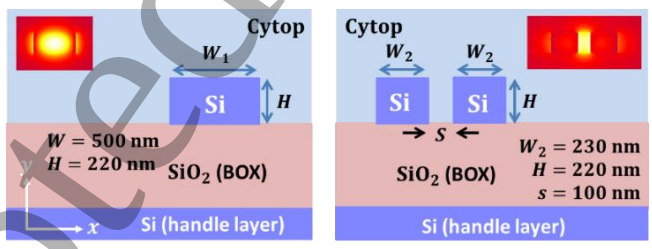

Fig. 1. Cross-sectional view of the cytop-clad silicon strip and slot waveguides with corresponding fundamental TE mode profile (E_x)

In waveguide based biosensing, the primary aim is to maximize the interaction between the waveguide mode and the functionalized waveguide surface. To find the optimum dimensions (W_2 and S) of the slot waveguide, we assume a biorecognition layer with refractive index 1.5 and thickness t directly above the waveguide surface (see inset of Fig. 2). As the sensitivity of a bio-sensor depends on the interaction between the propagating mode and the bio-recognition layer, the fill factor (FF), which represents the fraction of mode power confined in a given region, is calculated in the bio-recognition layer. For three values of S, equal to 80 nm, 100 nm, and 120 nm, the variation in the FF is shown as a function of W_2 in Fig. 2(a) and Fig. 2(b) for t = 5 nm and t = 10 nm, respectively. For each value of S, there exists an optimum value of W_2, for which the FF of the mode is maximum within the biorecognition layer. The FF increases with a decrease in S, however, the minimum value of S, which can be used is limited by the fabrication constraints. A spacing equal to or greater than 100 nm can be easily fabricated using

Accepted Manuscript

the 193 nm immersion photolithography and hence, we fix S = 100 nm. For S = 100 nm, the FF does not change much for values of W_2 between 210 nm and 230 nm. Hence, we choose W_2 = 230 nm for the ease of fabrication. From Fig. 2(a) and Fig. 2(b), it can be observed that the optimized dimensions of the slot waveguide do not change significantly with t.

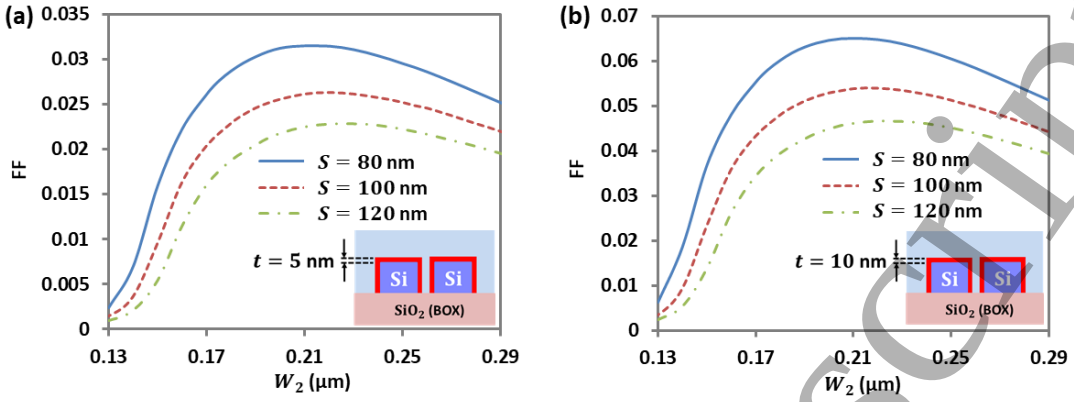

Fig. 2 Fill factor for the fundamental quasi-TE mode in the biorecognition layer of thickness (a) 5 nm and (b) 10 nm

The top view of the proposed strip to slot waveguide mode converter, consisting of two tapered sections (I and II), is shown in Fig. 3. In section I, a 230 nm strip is gradually coupled to the input strip waveguide by reducing the spacing from 500 nm to 100 nm. This ensures adiabatic coupling between the fundamental mode of the strip waveguide and the fundamental supermode of the evanescently coupled waveguides with a spacing of 100 nm at interface II. In section II, the width of the input strip waveguide is adiabatically reduced from 500 nm to 230 nm to form a slot waveguide.

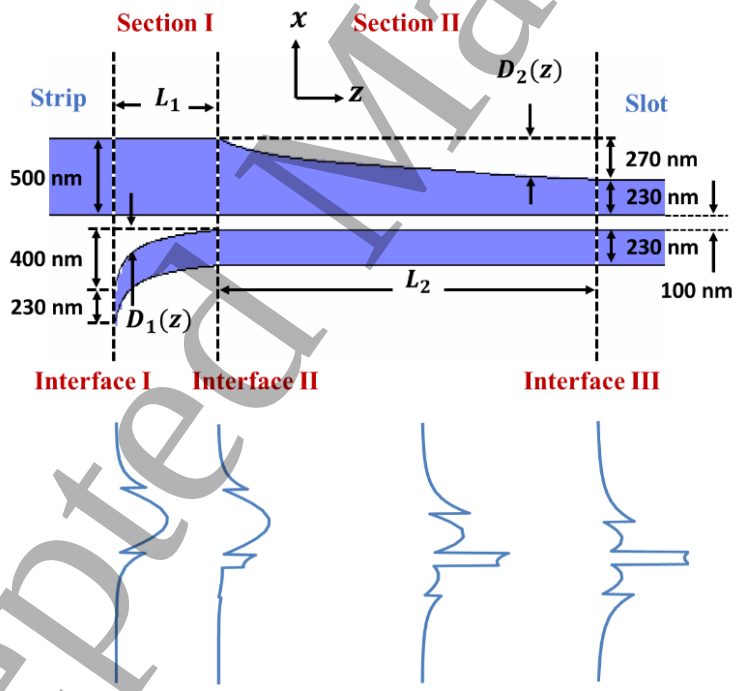

Fig. 3. Top view of the proposed design of mode converter with two tapered sections (I and II) along with the modal profiles of the fundamental quasi-TE mode at different positions along the length of the converter

The field profile (E_x), shown at different positions along the converter, shows the evolution of the fundamental mode as it propagates through the device. It is also possible to directly connect the 500 nm strip at interface II without the need for section I; however, this will result in the power loss at the interface II due to a small difference in the modal profiles of the fundamental mode of the strip waveguide and the fundamental supermode on the right hand side of interface II. Also, without the section I, the fabrication imperfections at the front edge of the 230 nm waveguide may affect the performance. Hence, we choose to design the mode converter with both tapered sections

Accepted Manuscript

I and II.

The tapering in both the sections should be slow enough to support adiabatic mode evolution, i.e., if the fundamental mode is excited at the input interface I, the power should remain in the fundamental mode as the geometry changes from a strip waveguide to a slot waveguide. A linear taper, in general, requires large length to ensure such an adiabaticity and hence results in a large device footprint. Different taper shapes [24,25] and techniques [26,27] to obtain taper profiles to support adiabatic mode evolution with shorter length of tapered sections have been suggested. However, none of these techniques provide a simple recipe to obtain the optimum taper profile for a specific application. In quantum mechanics, where the Hamiltonian changes with time, the adiabatic theorem defines an adiabaticity condition [28] in which a particle in the n^{th} eigenstate of the initial Hamiltonian remains in the n^{th} eigenstate of the changing Hamiltonian. An approach called fast quasi-adiabatic (FAQUAD) [29] can be used to optimize a single control parameter in the changing Hamiltonian of a quantum system to perform the process as fast as possible and still keeping it as adiabatic as possible. The optimization of the control parameter is done by maintaining the adiabaticity parameter to a small constant value over the entire process duration. The FAQUAD approach has been successfully translated to waveguide geometries, which vary along the propagation direction. It has been used in designing a variety of integrated photonic devices, based on z-varying optical waveguide structures, including a mode-sorting asymmetric Y-junction [30], a polarization splitter-rotator [31] and a 3-dB coupler [32]. For optical waveguides, the adiabaticity parameter (c_{nm}) for controlling the power transfer from m^{th} mode to n^{th} mode along a z-dependent waveguide geometry is given by [18,19]

$$c_{nm}(z) = \left| \frac{\iint \left[\frac{\mathrm{d}\boldsymbol{E_m}}{\mathrm{d}z} \times \boldsymbol{H_n} \right] \cdot \hat{z}\, \mathrm{d}x\mathrm{d}y}{(\beta_m - \beta_n)} \right| \tag{1}$$

where, $\mathrm{d}\boldsymbol{E_m}/\mathrm{d}z$ represents the derivative of the electric field of the m^{th} mode at a position z along the propagation length, $\boldsymbol{H_n}$ represents the magnetic field of the n^{th} mode with β_m and β_n the propagation constants of m^{th} mode and n^{th} mode, respectively. To ensure the adiabatic mode evolution, the adiabaticity parameter $c_{nm}(z)$ should be less than a desired small value ε throughout the length. For the proposed design, the FAQUAD protocol is used to distribute the adiabaticity uniformly over the entire taper length by controlling a single taper parameter. In our design, this taper parameter $D(z)$ is equals to $D_1(z)$ in section I and $D_2(z)$ in section II, as shown in Fig. 3. The Eq. (1) can also be represented in terms of $D(z)$ as

$$c_{nm}(z) = \left| \frac{\iint \left[\frac{\mathrm{d}\boldsymbol{E_m}}{\mathrm{d}D} \times \boldsymbol{H_n} \right] \cdot \frac{\mathrm{d}D}{\mathrm{d}z} \hat{z}\, \mathrm{d}x\mathrm{d}y}{(\beta_m - \beta_n)} \right| = F_{nm}(D) \frac{\mathrm{d}D}{\mathrm{d}z} \tag{2}$$

where, $F_{nm}(D)$ is given by

$$F_{nm}(z) = \left| \frac{\iint \left[\frac{\mathrm{d}\boldsymbol{E_m}}{\mathrm{d}D} \times \boldsymbol{H_n} \right] \cdot \hat{z}\, \mathrm{d}x\mathrm{d}y}{(\beta_m - \beta_n)} \right| \tag{3}$$

For ideal strip to slot mode conversion, the fundamental mode excited at interface I should propagate adiabatically throughout the length of the tapers to transform into the fundamental mode of the slot waveguide. In principle, a waveguide supports a few guided modes and infinite number of radiation modes. However, the radiation modes can be discretized to a finite number of modes using appropriate computational boundaries. The mode solvers in Photon Design [33] use reflecting boundaries to obtain the complete basis set in terms of finite number of guided and radiation modes. Hence, to ensure the adiabatic mode evolution of the fundamental mode, the sum of the adiabaticity parameters over all the N higher order modes, i.e., $c(z) = \sum_{n=2}^{N} c_{n1} = (dD/dz)F(D)$, where the parameter $F(D)$ is given by $F(D) = \sum_{n=2}^{N} F_{n1}(D)$, should be below a desired small value ε. The finite element method (FEM) and eigenmode expansion (EME) method [34], in Photon Design, are used for the calculation of $F(D)$. The variation in the parameter $F(D)$, represented by $F(D_1)$ for section I and $F(D_2)$ for sections

Accepted Manuscript

II, is shown as a function of D_1 and D_2 in Fig. 4(a) and Fig. 4(b), respectively. For a higher value of $F(D)$, a lower value of dD/dz is required to maintain constant value of $c(z)$ throughout the length of taper. Hence, the taper profile can be chosen in such a way that the slope of the taper is high where $F(D)$ is small and vice versa.

To find the optimum taper profiles $D(z)$, the adiabaticity parameter should be equal to a constant value ε throughout the length of the taper, i.e.,

$$\varepsilon = F(D)\frac{dD}{dz} \tag{4}$$

Integrating from 0 to z along the length of the taper results in

$$\varepsilon\int_0^z dz = \int_0^D F(D)\,dD \tag{5}$$

At $z = L$, where L is the length of the taper, $D = D_f$ and ε can be calculated as

$$\varepsilon = \frac{1}{L}\int_0^{D_f} F(D)\,dD \tag{6}$$

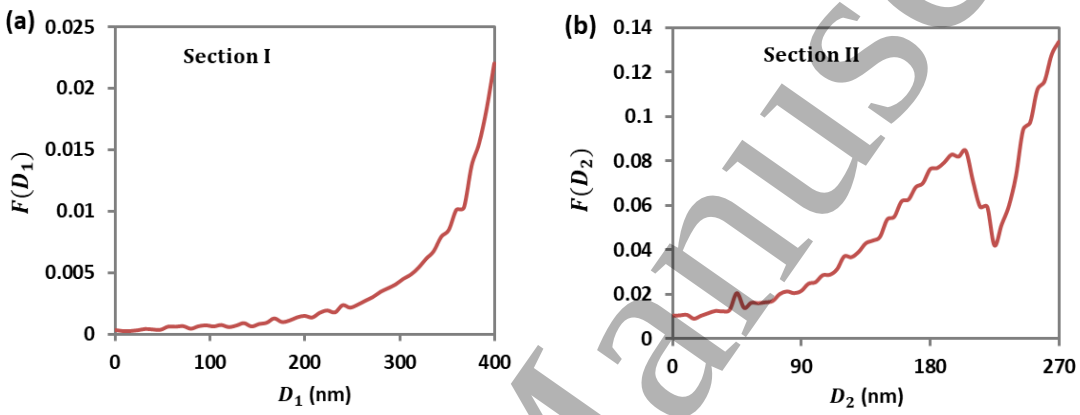

Fig. 4. (a) $F(D_1)$ as a function of D_1 [section I] and (b) $F(D_2)$ as a function of D_2 [section II]

Hence, by substituting the expression for ε from Eq. (6) into Eq. (5), the taper profile $z(D)$, which ensures a constant value of $c(z)$, can be obtained as

$$z(D) = L\frac{\int_0^D F(D)\,dD}{\int_0^{D_f} F(D)\,dD} \tag{7}$$

The optimized taper profiles for tapered sections I and II, obtained using Eq. (7), are shown in Fig. 5(a) and Fig. 5(b), respectively, along with the corresponding linear profiles for comparison. The parameter $F(D_1)$ and $F(D_2)$ and hence the taper profiles $D_1(z)$ and $D_2(z)$ are calculated at wavelength 1.55 μm. The use of these optimized taper profiles with constant $c(z)$ are expected to give rise to a significant reduction in the required length of the taper while maintain a low sensitivity towards wavelength and high tolerance towards the fabrication inaccuracies. The results shown in the section 4 validate these points.

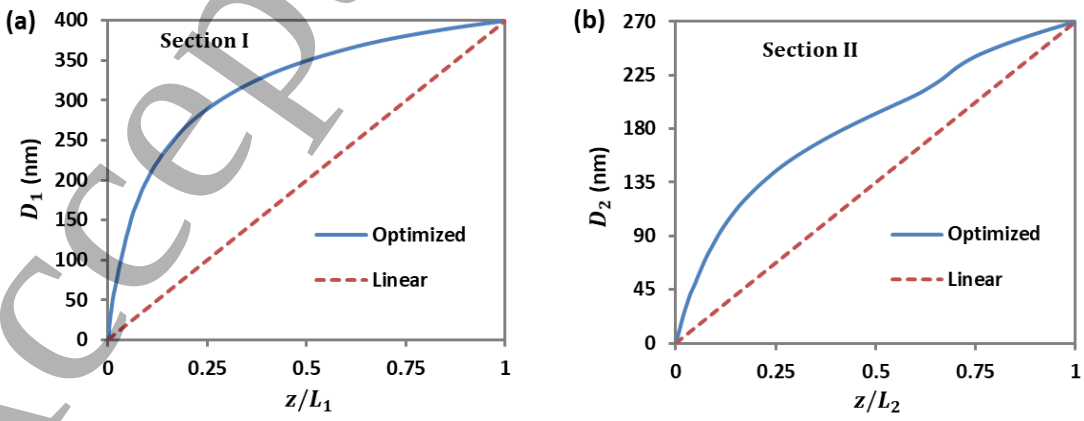

Fig. 5. Optimized taper profiles and corresponding linear profiles as a function of normalized position along the

Accepted Manuscript

length of the taper for (a) section I and (b) section II

3. Propagation through the optimized design

In order to estimate appropriate values of the length of the optimized tapers, we study the fractional power retained in the fundamental mode in propagating from interface I to interface II in section I and from interface II to interface III in section II as a function of lengths L_1 and L_2, respectively. For comparison, the corresponding study for the linear tapers is also carried out. The results shown in Fig. 6(a) and Fig. 6(b) for both linear and optimized tapers clearly show that optimized tapers perform better than the linear tapers at smaller lengths. At higher values of taper length, the conversion efficiency for both linear and optimized taper starts to converge to a maximum value. As the requirement is to obtain an efficient design with footprint as small as possible, the optimization of the taper profiles is important. For section I, although the first maximum in the Fig. 6(a) is observed at a taper length of 1.9 μm, we choose $L_1 = 0.79\,\mu\text{m}$, which provide sufficiently high value of fractional power (99.9%) in the fundamental mode at the output of section I. For section II, the length of the taper is chosen as $L_2 = 2.91\,\mu\text{m}$, corresponding to the first maximum (99.6%) in Fig. 6(b).

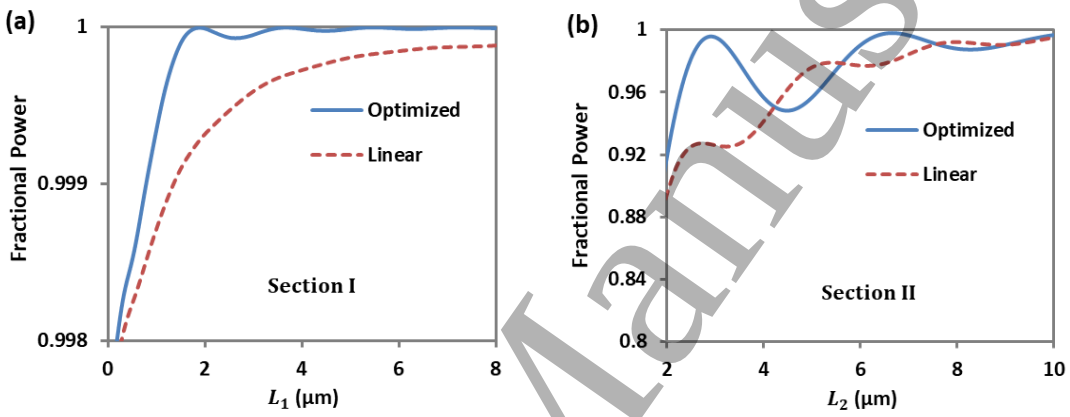

Fig. 6. Fractional output power for both optimized and linear tapers as a function of length of tapered section for individual (a) section I and (b) section II

Further, we look at the distribution of the adiabaticity parameter $c(z)$ along the length of the optimized tapers and compare it with the corresponding distribution for linear tapers of same length. The variation is shown in Fig. 7(a) and Fig. 7(b) with corresponding lengths $L_1 = 0.79\,\mu\text{m}$ and $L_2 = 2.91\,\mu\text{m}$. It can be clearly seen that the adiabaticity parameter $c(z)$ has a small value ε and is uniformly distributed over the entire length of the optimized tapers, as expected from the earlier discussion. A small noise in the $c(z)$ is due to the limited accuracy of the FEM solver. To maintain the value of $c(z)$ for the linear taper below the value obtained for the optimized taper, the slope (dD/dz) of the linear taper has to be reduced by an increase in the length of the linear taper by at least five times for section I and three times for section II.

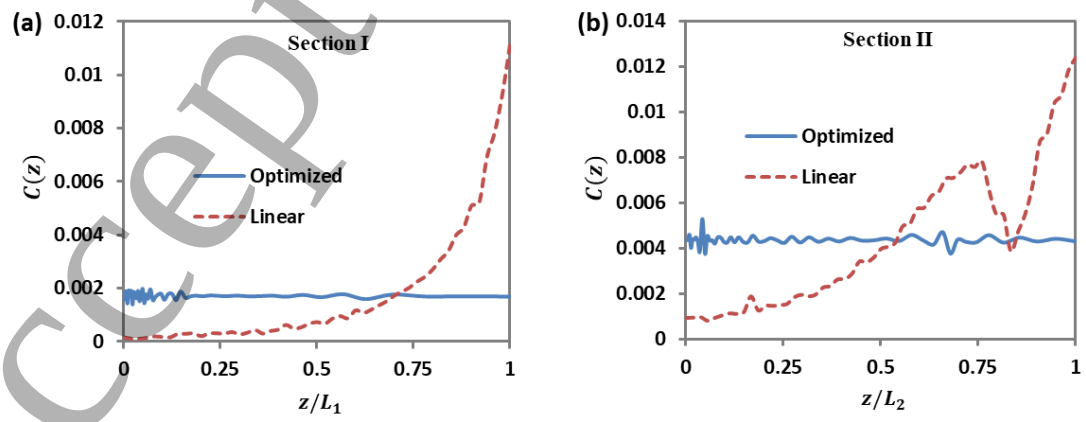

Fig. 7. (a) Distribution of parameter $c(z)$ throughout the length of taper for linear and optimized designs for (a) section I and (b) section II

Accepted Manuscript

The propagating field (E_x) through the proposed design, with $L_1 = 0.79\,\mu m$ and $L_2 = 2.91\,\mu m$, is shown in Fig. 8 for the input excitation by the fundamental strip mode at $\lambda = 1.55$ µm. It can be seen that the fundamental mode of the strip waveguide, excited at the input end, evolves adiabatically into the fundamental mode of the slot waveguide at the end of the converter. The conversion efficiency of the complete design is obtained as 99.4% at the design wavelength of 1.55 µm with a device footprint of only 1.23×3.7 µm^2.

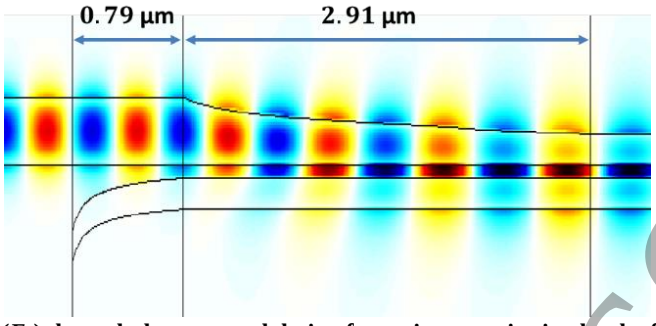

Fig. 8. Propagating field (E_x) through the proposed design for an input excitation by the fundamental mode of the strip waveguide

4. Wavelength response and fabrication tolerance

As the design utilizes the adiabatic mode evolution instead of conventional evanescent coupling, the design can be expected to be less sensitive to wavelength and fabrication variations. The mode conversion efficiency is plotted as a function of wavelength in Fig. 9. A variation of <1.5% in the conversion efficiency for a bandwidth of 100 nm and <5% for a bandwidth of 200 nm is observed which shows the broadband nature of the proposed design.

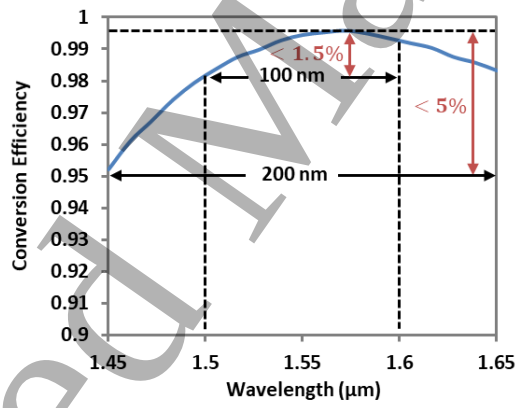

Fig. 9. Strip-to-slot waveguide fundamental mode conversion efficiency as a function of wavelength

The fabrication of the proposed design involves a single lithography and etching step which can be easily realized using the 193-nm immersion lithography followed by reactive ion etching [35]. The variation in the thickness of the device layer is entirely dependent on the SOI wafer. On the other hand, the width variation primarily depends on the lithography and etching process. Using 193-nm deep ultraviolet (DUV) lithography process, a linewidth accuracy of ±20 nm, and uniformity in the device layer thickness within ±10 nm can be easily achieved. The statistical results for a large-scale manufacturing shows the standard deviation in both the linewidth and thickness under 5 nm [36].

To study the fabrication tolerance of the proposed design, we consider a ±20 nm variation in the width and the thickness of the silicon device layer. These limits are more than sufficient to find the design tolerance of the proposed design to fabrication inaccuracies. First, we look at the conversion efficiency as a function of variation (ΔW) in width with $\Delta H = 0$ and then as a function of variation (ΔH) in height with $\Delta W = 0$ as shown in Fig. 10(a). Next, to calculate the worst-case conversion efficiency, we first vary the height and width by same magnitude simultaneously, as shown in Fig. 10(b), and then with different signs, as shown in Fig. 10(c). For the worst case, the conversion efficiency is found to be >96.5%. The results show the highly tolerant nature of the proposed strip

Accepted Manuscript

to slot waveguide mode converter to the possible fabrication inaccuracies.

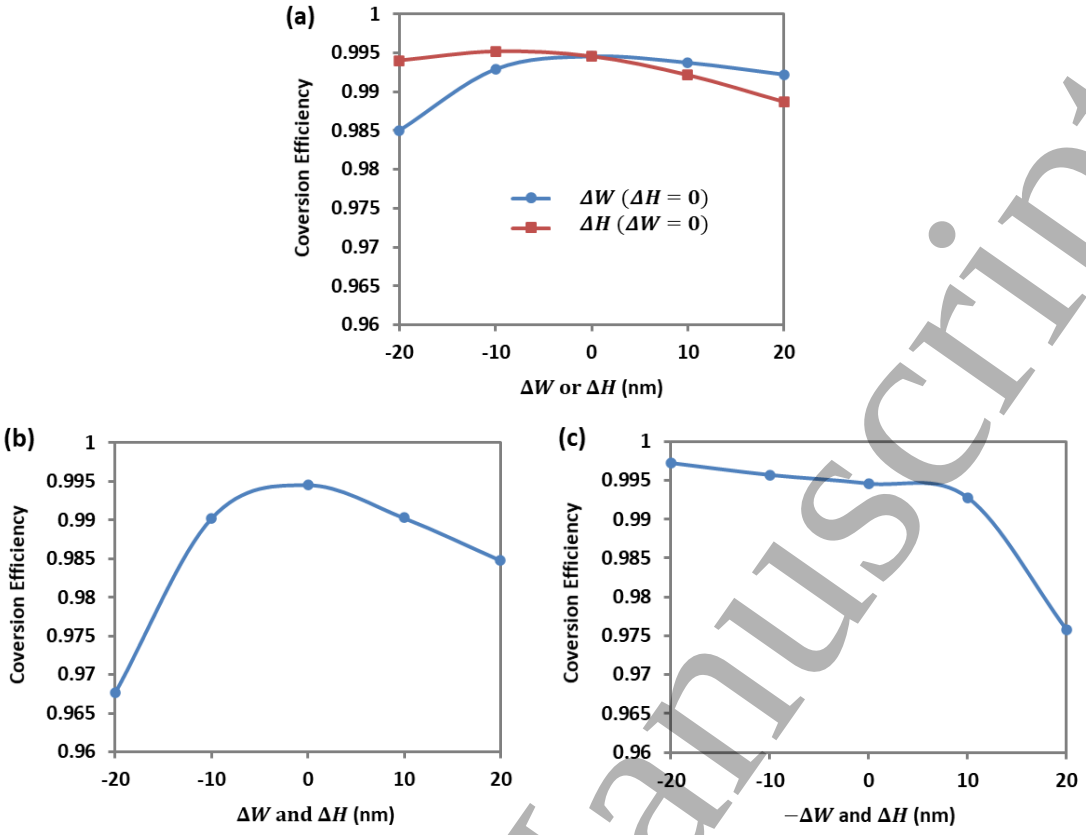

Fig. 10. Variation in the conversion efficiency as a function of deviation from the optimized parameters (a) deviation in width with optimized value of height and deviation in height with optimized value of width (b) deviation in width and height by same magnitude (c) deviation in width and height by same magnitude but with opposite signs

For the characterization of the proposed design, the grating couplers [37] need to be fabricated to allow in/out coupling from/to a single mode fibre (SMF). As the efficient designs of the grating couplers are not available for slot waveguide, an additional slot to strip converter needs to be fabricated as shown in Fig. 11(a) in order to allow coupling to the output SMF. As the loss associated with the proposed mode converter is very low, the inaccuracies in the measurement can arise due to a slight variation in the coupling efficiency of the grating couplers. Hence, to reduce the influence of such errors in the measurement, it is better to use a number of these sections in sequence [Fig. 11(b)] and to calculate the average response. To subtract the response of the grating couplers with respect to the fabricated design, a calibration structure consisting of two grating couplers connected through a strip waveguide is also need to be fabricated.

Accepted Manuscript

A tunable laser source, with operating wavelength range 1450 nm to 1650 nm, can be used as an input source. A polarization controller is required to control the polarization of the input light to allow efficient coupling from input SMF to the fundamental quasi-TE mode of the strip waveguide. To measure the wavelength response, the power can be coupled through the output grating coupler to an output SMF to observe the wavelength response using an optical spectrum analyzer.

The proposed design allows coupling between a standard strip waveguide and a symmetric slot waveguide, which confines the light within the narrow slot between the two silicon strips. However, there also exist other slot waveguide geometries including asymmetric slot waveguide [38], strip-loaded slot waveguide [1-3,39], plasmonic slot waveguide [40], and a slotted photonic crystal waveguide [41]. The mode converter for the asymmetric slot waveguide can be designed using two tapered sections by following a procedure similar to the one used for the symmetric slot waveguide. To facilitate the coupling between the strip waveguide and the other geometries of slot waveguides, the designs based on adiabatic mode evolution has been reported in the literature [39-41]. Each of these designs require certain number of tapers to facilitate the required mode coupling. The taper profiles in these designs can be optimized using the FAQUAD approach to allow efficient mode conversion with smaller device footprint.

5. Conclusion and discussion

Strip to slot waveguide mode converters are pivotal components in slot waveguide based integrated photonic devices [1-8,42]. The overall performance of these devices also depends on the performance metrics of the mode converters used to facilitate efficient fundamental mode coupling between the strip and slot waveguides. Hence, a design based on adiabatic mode evolution is proposed to obtain efficient fundamental mode coupling from a strip waveguide to a slot waveguide. A fast quasi-adiabatic approach is utilized to obtain optimized taper profiles which maintain a low constant value of adiabaticity parameter throughout the taper length. Using the optimized taper profiles, a very high (99.4%) conversion efficiency is obtained with small lengths of tapers, resulting in an ultra-compact footprint of only $1.23\times3.7\ \mu m^2$. In addition, the design is ultra-broadband with a variation of <1.5% in the conversion efficiency over a bandwidth of 100 nm and <5% over a bandwidth of 200 nm. The design also offers a very high tolerance to the fabrication inaccuracies.

Energy Efficient Transmission Trends Towards Future Green Cognitive Radio Networks (5G): Progress, Taxonomy and Open Challenges

Akanksha Srivastava, Mani Shekhar Gupta and Gurjit Kaur

***Abstract*—With the growing cognizance about environmental concern and global warming-related to communication technologies, the researchers have been seeking some solutions to diminish the consumption of energy in the telecommunication industry. There is a remarkable advancement in mobile communication from simple voice-based devices to ubiquitous data-hungry smartphones. Nearly, 8 billion mobile subscribers are expected to be added by 2030 and also required an extra spectrum to serve. The existing static spectrum allocation-based technologies are not in a position to fulfill this extra spectrum requirement and handle this future traffic load. This volatile evolution of global traffic data urges research attention globally and can be handled by future cognitive radio networks. There is also a demand for providing fast speed and seamless services for which operators need to deploy more base stations continuously and increase the transmitting antenna power. As a result, a drastic hike in emissions of carbon dioxide into the environment, and exposure to harmful radiations in large amounts which is also authentically harmful to humans, animals, and birds. This increased energy consumption and scarcity of resources have made the energy as a geopolitical issue for 21 century. In this direction, this work contributes by introducing cognitive-based green communication technology to ensure the environmental and health concerns caused due to hike in the CO_2 level. In the second phase, an enlightening survey on futuristic approaches for making the future wireless networks green is covered with pros and cons. In the third phase, this paper provides a framework of research challenges with ongoing project activities on green communication which further requires attention from the research community.**

***Index Terms*—Green communication, Carbon dioxide emissions, Carrier aggregation, Massive MIMO, D2D communications, Green IoT, Cognitive radio network.**

I. Introduction

In the last few years, the mobile telecommunication industry has increased exponentially. The call for wireless applications is growing because of the astronomical boom of mobile subscribers, multimedia applications, and data applications. In this work, the word green cognitive radio (CR) communication is used to express an efficient method of the congregation of energy-efficient technologies at different levels to reduce the unfavorable effects of technology on the environment. Globally, by the year 2022, the internet user population will be increased from 45.3% to 59.7% [1]. In addition to this, Fig. 1 depicts the growth rate of different parameters from 2018 to 2025 [2]. The nuts and bolts of a telecommunication network are a mobile node, access network and a backbone core network. Base Stations (BSs) are the key component of the radio access network that connects mobile phone devices to a core network. So, with a growth rate in the number of mobile subscribers per day, the growth rate of BSs is also increasing. According to [3] it is expected that during period $2017-2021$, the BS market of Long Term Evaluation (LTE) system will increase by more than 17 percent compound annual growth rate (CAGR). Available literature work centering on improving both quality of service (QoS) and quality of experience (QoE), while ignoring the increased demand for energy for the mobile communication system. This increasing energy demand has motivated us to work on the subject of cognitive-based green communication with the objective of energy-efficient wireless communication. Based on our studies, we found two major goals of the green communications network. The first is to reduce the CO_2 emission from the system and second is to save energy by reducing transmitting power which will lead to reducing the operational expenditures (OPEX). The off-grid sites (to serve in remote areas) are the main cause of CO_2 emission. Mostly diesel-power generators are required for working on such sites. Presently, as the number of mobile subscribers is increasing, nearly 43% of the total CO_2 emission is contributed by the mobile communication system and this value will increase by 51% of the total in 2020 [4]. Due to the different segments of the mobile communication system, the CO_2 level is continuously increasing in the atmosphere. Fig. 2 represents the level of CO_2 emissions by a different segment of the communication system during 2010, 2015 and in 2020. The measure of data traffic related to a mobile node is expected to touch nearly 621.90 million Tbytes/year by 2025 while in the year 2012, it was 45 million Tbytes/year [5]. The electrical energy consumption by the ICT will be increased from 611 to $1,752$ Tera-watt hours by 2030 [6]. This rapid energy consumption rate by wireless communication networks will cause a serious problem in the future if no steps are taken to change the existing trend.

A. Motivation for Green Communication

The telecommunication industry expressions a serious energy consumption challenge. This industry is growing rapidly to serve the smartphone user anywhere, anytime and anyone. The simple reason is that every human is using dual a SIM card enabled phone. At the end of 2019, in the Asia Pacific there were 2.9 billion (nearly the world's half population) mobile subscribers [7]. India and China are the most populous

Journal Pre-proof

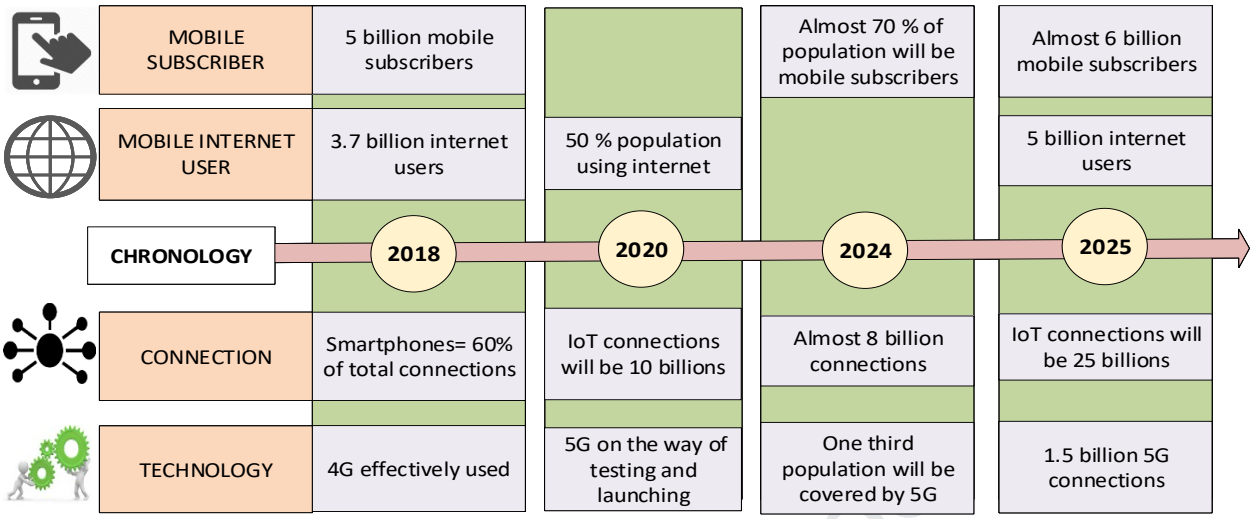

Fig. 1: Breakthrough in the field of telecommunication industry

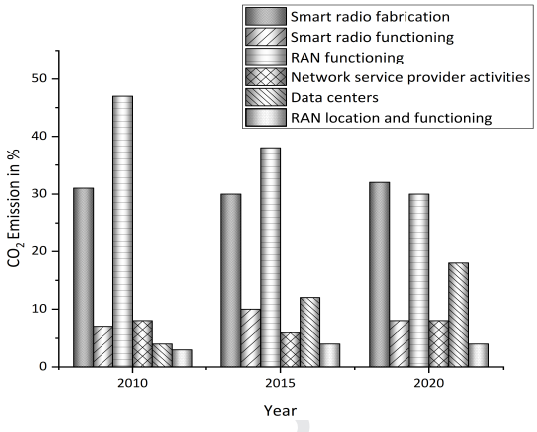

Fig. 2: Variation in carbon footprint produced by various parts of mobile communication system

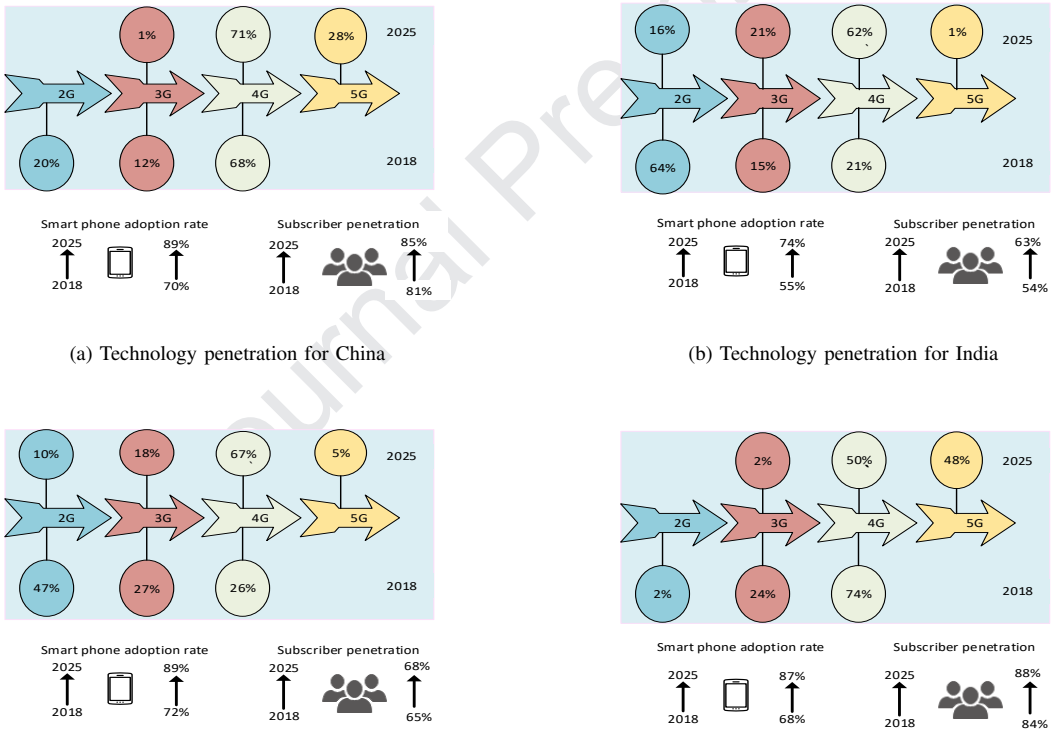

countries, which jointly covers nearly two-thirds of total mobile users. Nearly, 71.9 million mobile users are expected to be added in China by 2025, which is nearly 1.2 billion (85%) of the total population [8]. On the other hand, in India, it is expected to be nearly 207.9 million (22% of total Asia Pacific) by 2025. So, this makes a remarkable improvement in digital literacy and advanced mobile phones. In 2018, Indonesia was developed as a third-largest mobile phone market in the world (behind India and China) [9]. The smartphone adoption rate is to be expected very high (nearly 90% of total connections) for Indonesia by the end of 2025. Fig. 3 depicts the technology penetration of the four fastest-growing countries. Fig shows the percentage of the population which was using the different wireless generation (2G, 3G, 4G and 5G) in 2018 and how much this percentage value will be changed when we will reach 2025. In China and Japan, the 2G population will completely remove till 2025, on the other hand, some populations will present in India and Indonesia. In addition to this, Fig. 4 represents the addition of new mobile users globally till June 2019 in million [10] and Fig. 5 shows the mobile broadband adoption rate for different countries from 2015 to 2020.

The wireless communication networks have experienced a prodigious evolution from 1G to 5G networks. Nowadays 4G is effectively in use and 5G on the way of testing and launching. Recently, during the testing of the 5G network, 100s of birds dropped from the sky at Hague in the Netherlands [11]. The 5G antenna was situated at the Dutch railway station, to examine how large the 5G range was. At once, birds fell dead from the sky and the ducks that were swimming in nearby ponds seemed to respond very strangely. To escape from radiation, they were instantaneously inserting their heads inside water whereas some flew away. If they all had a healthy body, healthy blood, no effect of any virus and bacterial infection then the reasonable explanation behind this incident is using of microwaves in 5G having a serious impact on birds' hearts. It highly resonates with erratic pulsed microwaves (millions per second) which harm body organs [12]. Table II represents the upgradation of the various generation of wireless networks. This table reflects different characteristics, to discuss a tangible contrast among the generations of wireless networks. In 5G a drastic growth in the CO_2 emissions is presented.

To overcome this problem a pathway is designed in Fig. 6 which represents greenhouse gas (GHG) deductions across different sectors to reach 2030. Fig. shows that the amount of CO_2 was present almost 440 MMT in 2015 and the target is to reduce this value to 261 MMT till 2030. To curb such enormous emissions, various technologies have been discussed in this paper. This paper focuses on the mobile sector and provides comprehensive data on changing trends of information and communication technology (ICT) on the

B. Key contribution of survey

This work coveres, an up-to-date survey and technical aspects of advances which is providing future research directions to the foremost study on energy-efficient green communication in cognitive radio networks (CRNs). The key contributions of this work can be outlined as follows:

- A complete survey on green wireless communication networks have been covered in a single paper, with consideration of energy-efficient transmission.
- The futuristic technologies like cognitive radio, carrier aggregation, Terahertz communication, Internet of Things (IoT), massive MIMO (multiple-input multiple-output) and mm wavelength are briefly reviewed to prepare for advancing recent research contributions. These future

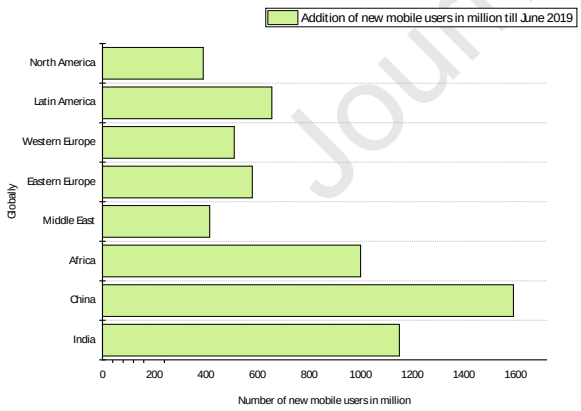

Fig. 4: Addition of new mobile users globally in million till June 2019

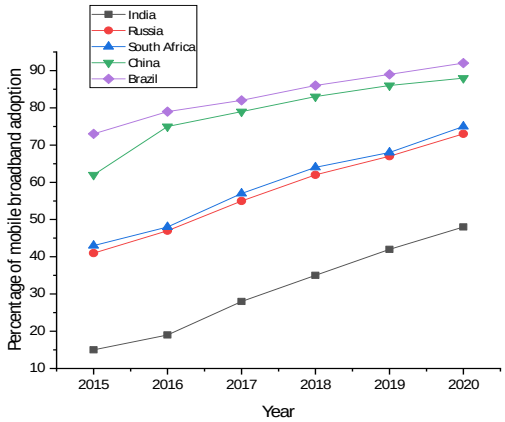

Fig. 5: Mobile broadband acquisition rate

technologies for 5G are proficient for improving the energy efficiency of the next generation wireless networks with high QoS and low GHG emissions.

- Starting with the impact of the increasing number of mobile users globally, their demands for different services and their adverse effects on the environment are discussed in detail.
- Several energy efficiency metrics used for the calculation of different parameters at different levels of communication system have been illustrated.
- Various future research directions and challenges in the pathway of green network are also covered to handle the implementation challenges.

C. Paper Organization

The progression of the work is maintained as in Fig. 7. In Section II, the recent facts and figures are briefly discussed

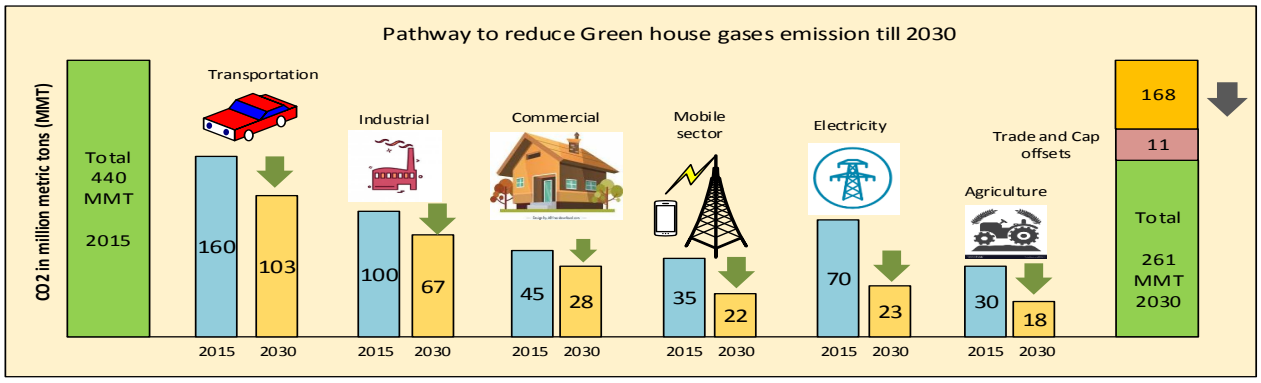

Fig. 6: Aim to reduce GHG across various sectors to reach 2030

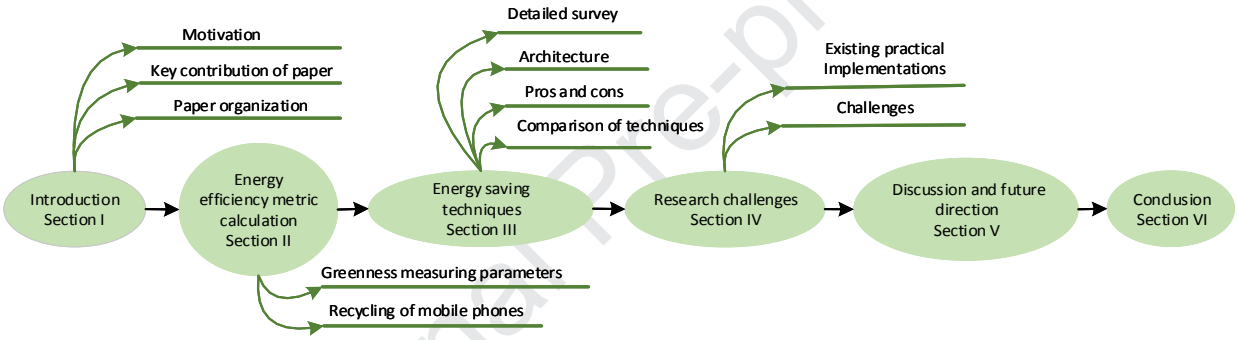

Fig. 7: Paper organization

with energy efficiency metrics for greenness calculation. The main purpose of this section is to familiarize with the vital facts and the expressive concern of an energy aware green CRN research which is the subject of attention. In Section III, various energy aware techniques have been discussed with their concept, detailed survey, merits and demerits and also discussed how they are capable of supporting green networking for next generation (5G) networks. A comparison is performed to highlight the role of each techniques to make communication energy-efficient. Various research challenges associated with green communication have been discussed in Section IV. Future research directions have been explored in Section V. Finally, conclusion is presented in Section VI.

II. Energy Efficiency Metrics for Greenness Calculation

A. Energy Efficiency Measurement (EEM)

As we know, the cellular system is the largest component of ICT sector. So, EEM statistics have encouraged both academia and industry researchers to evolve methods to cut down the energy expenditure of cellular system and make the wireless network system greener. The primary goals of energy-aware green CRNs are:

- Improving EE.
- Improvement in the tradeoff between energy-saving and seamless connectivity.
- Reducing unnecessary GHG emission.
- Proper utilization of resources.

Fig. 8 represents that in a wireless communication network BS consumes the maximum amount of energy as compared to the other component of the network [13]. The number of BSs are continuously increasing to provide better QoE expected by mobile users. Thus, energy consumption will also increase proportionally. Nowadays this is a very crucial subject for research to find out some effective methods to minimize energy consumption by fixed and dynamic components of BS while maintaining the QoS. The internal components like digital signal processors, power amplifier (PA), feeder cables and cooling system of BS are considered under the fixed components while network planning, deployment and management based on proper load balancing are under the dynamic components. For the conversion of a base station into a green base station, several schemes have been suggested in

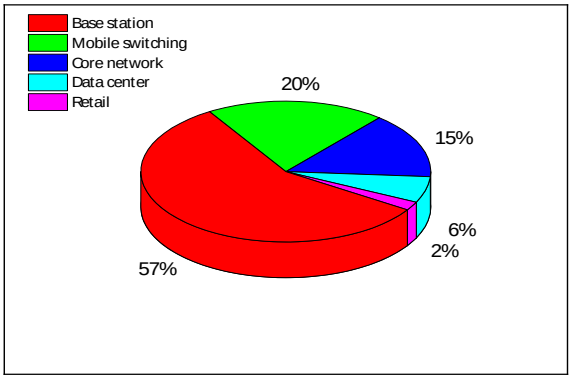

Fig. 8: Energy consumption w.r.t. different components of communication system

[14]. A game theory-based scheme considers heterogeneous networks for the reduction of power consumption at the base station level is discussed in [15]. A novel network architecture having energy-efficient techniques based on the physical layer and cross-layer of cellular networks is represented in [16]. Different research activities and projects based on energy-efficient communication has been considered in [17].

The various components in wireless networks consume different amounts of energy. So, for calculating and comparing the amount of energy which is consumed by the various components and a communication system as a whole, EE metrics are used. Researchers have been proposed different levels (facility, component, and system) for measuring EE metrics [18]. The high-level systems such as data centers are considered under the facility level [19]. Presently, with the upsurge in research activities on green energy efficient wireless networks, some standard organizations like European Technical Standards Institute (ETSI) and Alliance for Telecommunications Industry Solutions (ATIS) are making efforts to describe diverse EE metrics for wireless networks. The EE metrics consist of three major metrics as follows:

1) Energy Efficiency: EE is a very essential metric to measure in green wireless CRN [20]. This can be obtained by dividing network output energy to network input energy consumption [21] and expressed as

$$\eta = \frac{\text{Network output energy}}{\text{Network input energy consumption}} \tag{1}$$

here η represent EE. The best EE can be achieved by minimizing total power consumption and maximizing the data rate.

2) Secrecy Energy Efficiency: This is another important metric consider under the system level. The high value of this metric provides better security in the CRN [22] [23]. This is given by

$$S_{EE} = \frac{Secrecy\ rate}{Power\ consumption\ at\ \text{network}} \tag{2}$$

here secrecy rate (SR) is defined as the difference of data transmission rate of the transmitter-receiver link to the transmitter-eavesdropper link and S_{EE} represents secrecy energy efficiency.

3) Area Energy Efficiency: The A_{EE} metric is considering for a dense deployment [15]. This can be obtained by dividing overall energy efficiency to the macro cell area and given by

$$A_{EE} = \frac{Energy\ efficiency}{Total\ area\ of\ macrocell} \tag{3}$$

here A_{EE} is area energy efficiency.

The readers can discover different taxonomy of green communication metrics which are summarized in Table III.

B. Recycling of Mobile Phones

Usage of recyclable stuff for manufacturing of next generation devices can help to make the environment eco-friendly. For example cell phones are manufactured by some scanty natural resources likes plastic, copper, etc and also contain some non-biodegradable materials. This can surge the GHG effect if it did not correctly dispense when the cell phones are in a dead state. In Australia, almost 24 million cell phones are existing in cupboards and drawers which are not currently used [35]. Presently, the whole world is fighting against vast energy consumption and GHG effect. So, the trends for recycling cell phones are ever-increasing because 90% material of cell phones is recyclable. Fig. 9 represents the cell phone recycling process with a percentage of CO_2 emitted at each stage.

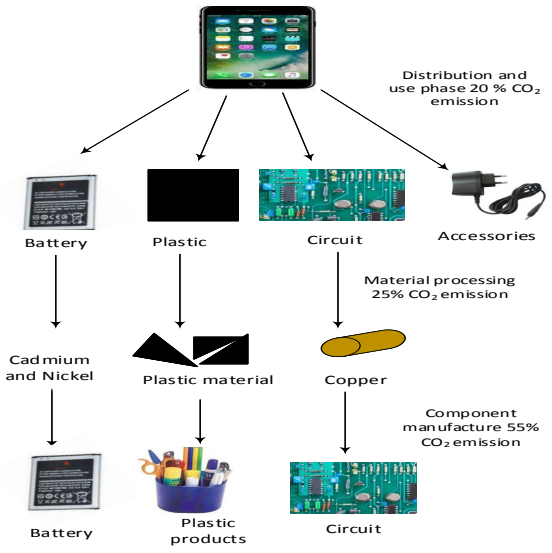

Fig. 9: Cell phone recycling process with CO_2 emission

III. Energy Efficient Techniques

In this section, several traditional and recent advanced energy efficient communication approaches for future CRNs (5G) are considered with their detailed overview in an informational manner. Various energy-efficient communication approaches are highlighted in a classification tree as shown in Fig. 10. These different approaches are introduced by researches to handle various inspiring topics allied with green CRNs.

TABLE III: Summary for several EE metrics evaluation in green communication networks

Level	Metric	Remark	Unit	Reference
Facility level	Power usage efficiency	It gives the ratio of total power consumption at facility level to the total power consumption at equipment level.	PUE ≥1	[24], [25]
Facility level	Data center efficiency	Reciprocal of PUE	DCE in percentage	[24]
Element level	Telecommunications energy efficiency ratio (TEER)	Ratio of maximum throughput to total power consumption.	$Gbps/Watt$	[26]
Element level	Telecommunication equipment energy efficiency rating (TEEER)	Calculated by summing the amount of energy consumed by the equipment for various traffic conditions.	$-\log(\frac{G_{bps}}{Watt})$	[27]
Element level	Energy consumption rating (ECR)	Ratio of energy consumed to the adequate system capacity.	$Watt/Gbps$	[18]
Element level	ECR-weighted (ECRW)	Evaluated in the similar manner as ECR but energy consumption is in ECRW is calculated as $0.25E_i$+$0.4E_h$+$0.35E_f$ here E_i, E_h and E_f represents Energy consumption in idle mode, half load and full load.	$Watt/Gbps$	[18]
Access point level	Energy consumption rate	Energy used to transmit a piece of information.	J/bit	[28] [15]
Access point level	Spectral efficiency	For a communication system, the transmitted information rate to a given frequency	$b/s/Hz$	[29] [30]
Access point level	Power efficiency	Ratio of output power to input power	-	[18]
Access point level	Energy consumption index	Ratio of (BS/AP) input power to the key performance indicator. ECI evaluate the power utilization efficiency of a BS. ECI inversely proportional to EE.	-	[31] [32]
System level	Power per bit per area	The average power used in terms of the average transmission rate and the coverage area.	$W/bps/m^2$	[33] [32]
System level	Energy per bit per unit area	The energy consumed for transferring the bits for a particular coverage area.	$J/bit/m^2$	[25]
System level	The power consumed per unit area	Ratio of power consumed to unit area	W/km^2	[34]
System level	Performance Indicator in urban areas (PI urban)	Ratio of total number of mobile users to the total power consumed by the base station/ access point.	$Users/Watt$	[34] [18]
System level	Performance Indicator in rural areas (PI rural)	Ratio of coverage area to the total power consumption by the base station/ access point.	$km^2/Watt$	[34]
System level	Energy reduction gain	Defined as the derivative of energy consumption gain metric.	ERG in percentage	[26]

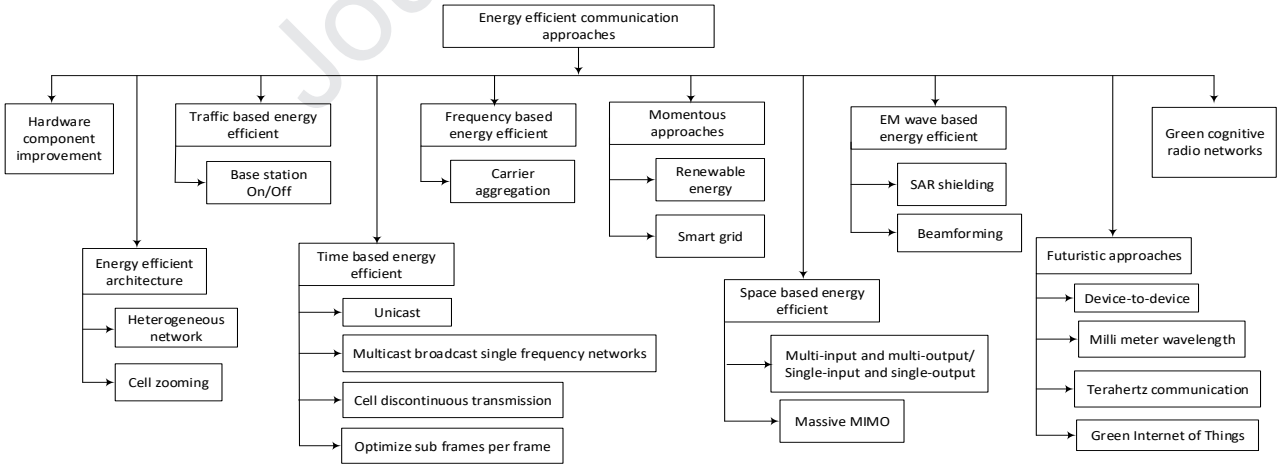

Fig. 10: A classification tree of different energy efficient communication approaches

A. *Hardware Component Improvement*

In the telecommunication system, the PA consumes maximum amount of energy (nearly 60%) in the BS. Therefore, for OPEX cost reduction a highly proficient PA is necessary for green CRNs. In [41], various techniques for improving EE related to PAs and cables used in the feeder and cooling components are discussed. An operating point of the most efficient PA is adjacent to the saturation region. In [42], the author has

TABLE IV: Approaches to enhance the EE of power amplifiers

Approaches	Description	Energy saved	References
Doherty designs	Unique design method which is able to offer significant enhancements in EE.	30 to 35%	[18], [36]
Switched mode power amplifier (SMPA)	SMPA works on the principle that the active device works in saturation, therefore it works as a switch, so either current or voltage waveforms are alternatively reduced to decrease overlapping. This leads to minimizing power dissipation. If a transistor is considered as an ideal switch, 100% of efficiency can be attained by appropriate designing of the network.	80-90%	[19]
Enhancement in digital pre-distorted Doherty architecture and gallium nitride (GaN) amplifiers	GaN is a special material that is characterized by large breakdown voltage, high current density, and high frequency. Excellent power dissipation and thermal conductivity are used in the construction of power amplifier transistors, which enhance the efficiency of the system.	50%	[37]
Inverse Class F	Considered for WiMAX network having carrier frequency approximately 2.45 GHz.	74%	[38]
Envelope tracking designs	To track the input signal magnitude envelop this technique uses amplifier's drain bias.	Up to 60%	[37]
Class-AB with digital pre-distortion	Class AB with digital pre-distortion amplifiers, display gain roll-off at small input power and at saturation this property helps reduce energy.	50%	[39]
Light Radio Cubes	Alcatel-Lucent has been designed as an innovative BSs in 2012 which reduces a large amount of energy consumption as compared to the existing radio access network devices.	50%	[40]
Class J Amplifier	Due to the presence of nonlinear capacitance, the Class-J amplifier represents high efficiency. This nonlinear capacitance generates a harmonic voltage which reduces the phase difference between current components and fundamental voltage.	70 to 90%	[19]

discussed that PA operates in the linear region due to non-constant envelope signals of orthogonal frequency-division multiplexing (OFDM) modulation and nonlinear effects ranged from 6 to 12 dB below saturation region. For designing of PA, the following factors are having major importance:

- Wider bandwidth for communication.
- Follow linearity property, to provide higher-order modulation technique.
- Improved BS energy efficiency to achieve OPEX.
- Higher average output power levels.

The higher value of DC power supply is required for the operation of PAs. During a day, the traffic load is not constant like in-office hours traffic load is high and in the night it is low. So, a large amount of power is wasted at night because the working of PAs does not depend on traffic load. To overcome this challenge two techniques can be used. In first, the PAs can be deactivated in some time slots with no data transmission. In second, an operating point of PA can adjusted to reduce devouring of power and also optimize the power efficiency for different traffic load scenarios (low, medium and high). The major advantage of this technique is that it saves the maximum amount of energy but high replacement cost is its limitation. Table IV summarizes a survey of various approaches that have been used to improve the hardware component of the communication system and also represents how much amount of energy can be saved by these approaches.

Instead of several endeavors, an improvement in hardware approach for saving energy at BS is not in a position to achieve the desired result. Ineffective utilization of resources also results in a large amount of energy wasted. So, for designing energy-efficient green CRNs, exploitation of both network-level and equipment level approaches are required. In the succeeding subsection of the paper different approaches are discussed to improve EE.

B. Energy-Efficient Architecture

Energy-efficient architecture considers an efficient approach for both energy efficiency improvement and energy saving. This approach is based on the cooperation among BSs to offer the best QoS to mobile subscribers and save energy at low traffic. In this subsection, two techniques such as heterogeneous networks (HetNets) and cell zooming are discussed.

1) Heterogeneous Networks (HetNets): HetNets represents a layered architecture that has different networks for providing the service to the same mobile subscriber. Considering the small size cell (like femto, pico, and microcells) to reduce consumption of energy and enhance the throughput of the network. These cells differ in data rate, size, capacity, output power, coverage and also emit a different amount of CO_2 as indicated in Fig. 11 (the size of the cloud). As the diagram represents that macrocells are having the largest coverage area and least CO_2 emission while femtocell is having less area but emits the maximum amount CO_2. The principle of the HetNet approach is the deployment of macrocells for providing complete network coverage, while small cells will come in an operational state when the traffic demand increases in that area. In [48], [49] author considers both scenarios heterogeneous and homogeneous (microcells and macrocells) networks having a different number of microsites, based on data traffic situations for calculating EE. The results indicated that better EE can achieve in HetNets deployment. Fig. 12 represent architecture in which different networks are deployed to form HetNets. The deployment of more microsites in network increases the throughput of the network. In fig., various links like (macro-macro, macro-micro, macro-pico, macro-femto etc.) are present.

Table V summarizes the various schemes and algorithms used in the available literature to improve EE in HetNets. The table also showing the description and percentage of

TABLE V: Algorithms/Schemes for improving energy efficiency using Hetnet

References	Objective	Description	Energy saved	Scheme/Algorithm
[43]	Multi-layer nature of HetNets is analyzed which shows energy consumption depends on the traffic requirement and BS hardware components.	Consider the classical 0-1 Knapsack issue. The scheme is analyzed to reduce consumption of energy by adapting the BS on/off situation.	35%	On/off scheme
[44]	Micro BSs have been Deployed in the area where macro BSs were situated and calculated saved power at the various radius of micro BSs.	Analyze the placement of various BSs based on a new power-saving metric.	Maximum energy is saved in Greedy BSs deployment algorithm as compared to others	Region-based, Grid-based and Greedy BSs deployment algorithm
[45]	Deployment of the heterogeneous network which is having different size cells (micro, pico, and femto) for achieving green efficient system.	An energy-saving method is proposed that permits femtocell BS to completely switch off its communication and processing when not involved in an active call.	37.5%	Voice traffic model
[46]	To calculate the EE gains	Implementation of femtocells within a microcell, while maintaining QoS. The results show that the usage of femto cells minimize the power consumption of the integrated network.	70%	Fast fading and path loss model
[37]	To analyze the impact of energy efficiency.	Deployment of different picocell in a macrocell.	60%	-
[47]	Investigate the area power consumption in terms of network performance metric	Discuss the effects of many deployment policies on the power consumption of mobile system.	55%	Power consumption models

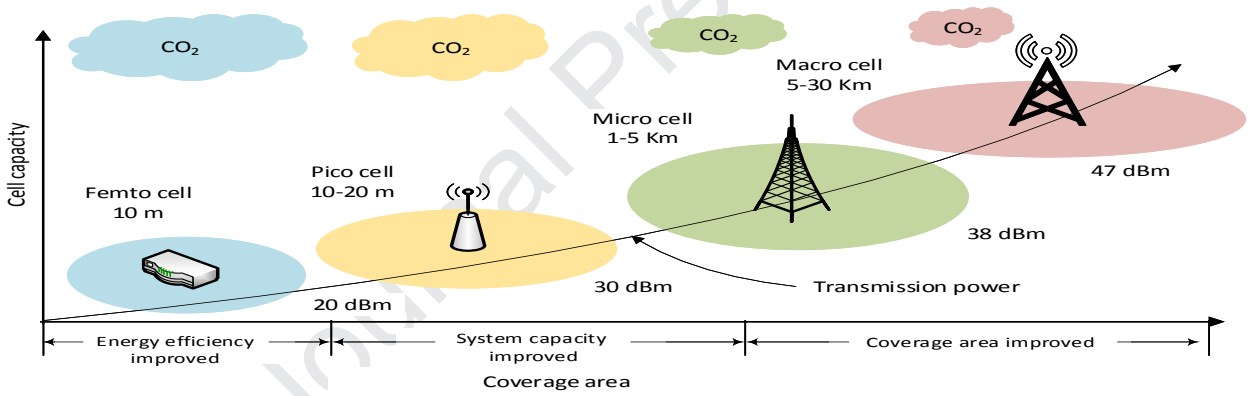

Fig. 11: Power consumption by different cell size for HetNet

energy saved by these schemes. A combination of different networks and smaller size cells provides an improvement in EE, coverage, and capacity because of the short transmitter-receiver distances. There are also some challenges in this technique, including the organization of the HetNets interfaces and the dead zone problem.

2) Cell Zooming: Cell zooming technique not only saves energy but also improve network performance. In this technique, the size of the cell varies with variation in traffic load, state of channel and requirement of mobile subscribers. In the condition of high traffic load, the congested cell will be in the zoom-in mode and low traffic cells will be in zoom out mode to provide the service to the mobile subscribers of the congested cell. In cell zooming algorithm the time is represented by $'T'$ (called cell zooming period). There are three stages in each period such as coordination, transition and serving phase as shown in Fig. 13. A cell zooming server (also known as the brain of the system) will sense the traffic situation and then decides the occurrence of cell zooming operation. A specific control message is released after the sensing process. After coordination with neighbor cells, the required cell will zoom in/zoom out by cell zooming server under the serving phase. The working of the cell zooming approach is represented in Fig. 14 having a seven cells cluster cellular network. Six nearby cells are covering one central cell as shown in Fig. 14a. The position of BSs is at the center of each cell. In a cell, mobile nodes are located arbitrarily. The central cell will perform a zoom-in operation when the cell is congested by the movement of mobile nodes into this cell. Thus, the size of the cell is minimized as shown in Fig. 14b. On the other hand, The central cell will perform the zoom-out operation, in the case when the movement of the mobile node will out from the central cell. As from Fig. 14c. congestion can be avoided by the zoom-in operation of neighboring cells.

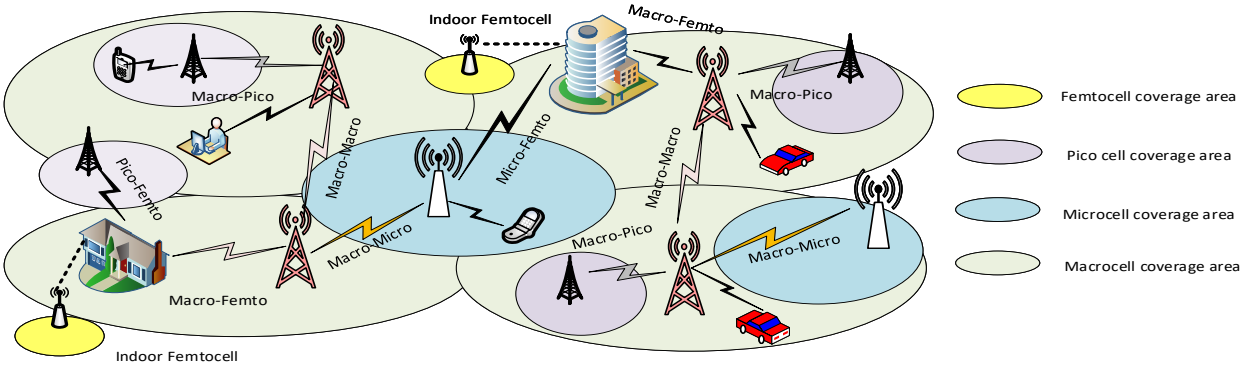

Fig. 12: Architecture for energy efficient HetNets

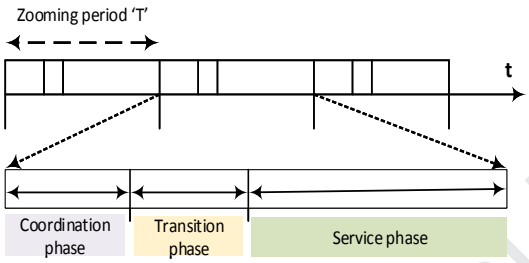

Fig. 13: The framework of cell zooming process

The mobile users will get service by nearby cells when the central cell is less congested and goes in sleep mode as shown in Fig. 14d. Table VI represents the literature based on many algorithms which are used for cell zooming technique. Almost 50% of energy can be saved by cell zooming technique.

There are various benefits of the cell zooming technique. It provides proper load balancing and reduces the blocking probability. This technique also enhances the battery life of the handset and throughput but intercell interference is the main disadvantage of this technique when some active nearby cells perform zooms out operation simultaneously. In cell zooming operation, coverage holes (no network coverage at some places) may occur. The newly arrived mobile user can be served by performing zoom in operation by nearby cells to cover these unreachable areas.

C. Traffic based Energy Efficient Approaches

The traffic based energy-efficient approache is discussed in the following subsections.

1) Base Station ON/OFF Technique: In wireless networks, energy can be saved while maintaining QoS by turning off idle wireless resources and BSs. The traffic load condition varies with space and time in the coverage region. So, underutilized BSs can be dynamically turned off. The user can be served by remaining BSs which are in an active mode of operation [54].

To ensure global coverage, the telecom operators are expanding to almost remote areas. Fig. 15a shows the data of off-grid and poor-grid BS from 2014 to 2020. Due to the absence of electrical grids, the off-grid BSs are expensive. In 2009, a telecom company named China Mobile has minimized the expenditure of energy (nearly 36 million kWh/year) by applying BS sleep control. In [55], an optimization approach related to reducing the consumption of energy is suggested with QoS constraints. The model is a combination of signal propagation models and a set of actual sized universal mobile telecommunications system (UMTS). The outcome consists of very useful constraints like guaranteed service rates, full coverage, minimum delay and accomplishes a significant reduction in network energy almost 35 and 57%. The amount of consumed energy depends on the BS type and application scenario. From Fig. 15b, 15c, and 15d, it is cleared that how much energy percentage is consumed by the separate parts of different BSs.

In a few cases, the power utilized by the BS is considered as zero in sleep mode but in actual it consumes very less power as compared to the active state of BS. However, the BS never goes in completely off state, it may still utilize some power like detection power [56]. This type of power consumption can not be ignored, especially in BSs that do not have on-site cooling systems and installed in a small location. Sleep mode is further divided into many sleep levels. In [57], an opportunistic sleep concept is discussed with an idea of BS sleep only for a certain period to improve the system capacity. The range of energy saving depends on various traffic load conditions and lies from 13% to 41%. In [58], an author describes four status of the BS and their respective power consumption ratio as represented in Table VII.

The BS with sleep/wake-up strategy is discussed in [59]. According to the traffic density, BS switches among active, sleep and off mode. Presently, a new module named as sleep/wake-up is augmented in each BS. Nearly 72.9% of energy can be saved by using this module. In [60], the distance between BS and the mobile node are considered as criteria

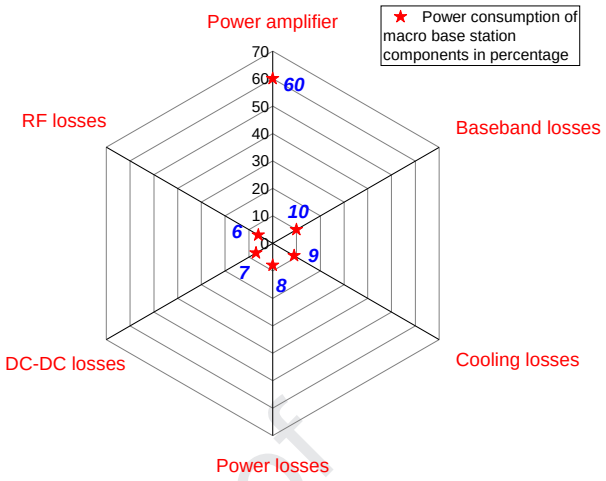
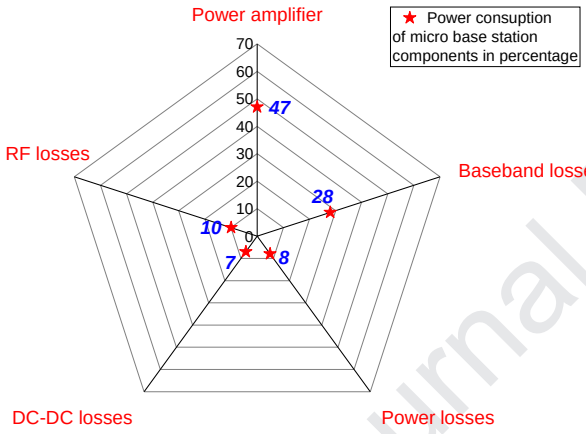
S.no.	Base station status	Power consumption ratios
1	On	100
2	Standby	50
3	Sleep	15
4	Off	0

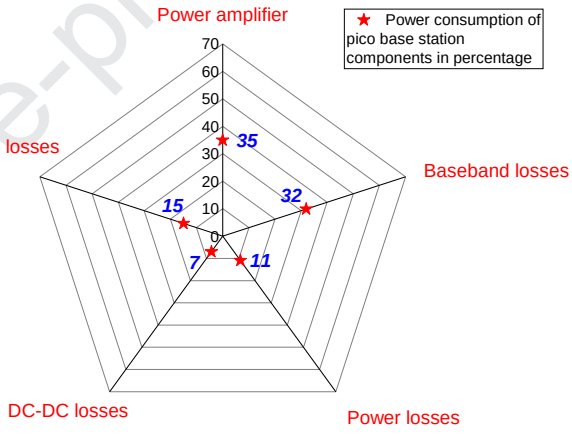


for decision making about making BS in on/off state. This technique reduces the energy consumption of nearly 29%. The switching period of the BS (switching from on to off and off to on state) is associated with QoS and plays an important role [61]. In [62] the author investigates that the processing time, required for handoff is ranged from 50 ms and 100 ms. The cooperation among BSs is necessary to serve the mobile users belonging from switched-off cites. A flowchart is proposed, related to BS on/off operation to attain an energy-efficient solution as represented in Fig. 16. The BS on/off technique achieves a remarkable trade-off between QoS and energy saving. To make the energ-efficient system, the uncovered region related to inactive BSs is covered by increase the transmission power of active BSs. Since the BS power is limited so an issue related to network coverage occurs. The battery life of the mobile users is also affected by this approach because of the requirement of high power at the receiver end to maintain connectivity with nearby BS.

D. Time based Energy Efficient Approach



In the time domain approach, the PA of LTE base station is temporally turned off during low network traffic in the downlink and idle channel state. This power-saving solution is tightly associated with the LTE system frame structure. The concept of the frame structure, reference signals (RS) and control signals have investigated in [63]. LTE downlink uses orthogonal frequency division multiple access (OFDMA)



(a) Increment of base station from year 2014-2020

(b) Energy consumed by the different part of Macro base station

(c) Energy absorbed by various parts of Micro base station

(d) Energy absorbed by various part of Pico base station

Fig. 15: Energy consumed by different parts of different BS

approach. In this, an RS signal performs two main tasks in the network such as channel estimation for the mobile node and search neighbor cell for handover [64]. There are mainly three techniques to minimize the number of RSs.

1- Normal unicast:- The LTE frame consists of 7 symbols per slot. The RSs, applies in 0, 4, 7 and $11th$ OFDM symbols at every subframe. This pattern of RSs keeps on slot $1-4$ and $6-9$ of subframe and does not apply on slot 0 and 5 of the subframe. Slots 0 and 5 are used to transmit control signals [65].

2- Multicast Broadcast Single-frequency Networks (MBSFN):- The services like mobile TV and DTH use the MBSFN technique in the LTE system. In this, the pattern of RSs keeps only in slot 1. So, the number of RSs is reduced.

3- Cell Discontinuous Transmission (DTX)/Microsleep:- In DTX approach, the RSs signals are not transmitted in slot $1-4$ and $6-9$ of subframe if no mobile node is found in the active state [63].

Fig. 17 represents that each frame of the LTE system includes 10 subframes (from 0 to 9) and there are 7 OFDM symbols in one slot. In a single slot, four RSs are used for communication purposes. Some amount of energy is required for the transmission of RSs. In cell discontinuous transmission technique no RS is sent for idle and low traffic load condition so the maximum amount of energy can be saved in this technique as compared to the normal unicast and MBSFN technique in which RSs are sent at low traffic conditions.

In [66], a dynamic subframe allocation technique is introduced for multimedia broadcast multicast services with MBSFN. In [67], an upcoming network traffic load is predicted by MBSFN. The BS turning off periods are calculated with the help of MBSFN based energy-saving technique [68]. In this technique, the needful resources are pre-calculated based on traffic load. Thus, more energy is saved by keeping off underutilized resources. This technique also has features

Journal Pre-proof

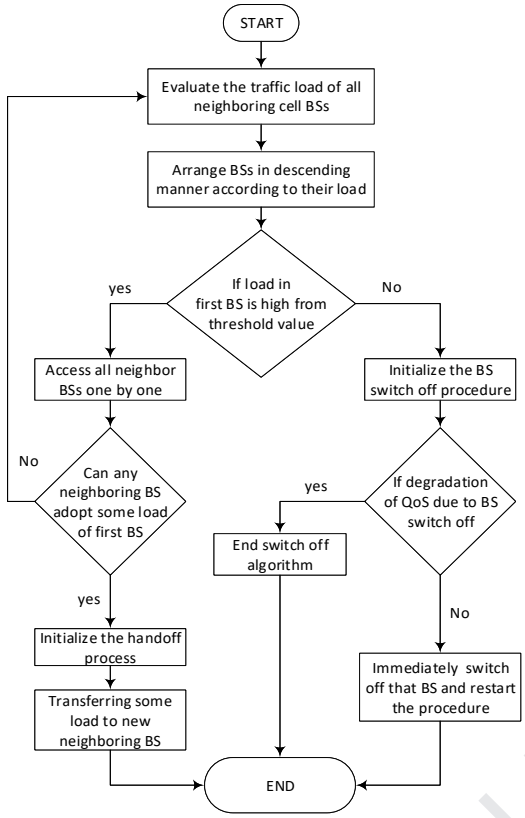


Fig. 16: Flow diagram of proposed BS sleeping operation

like backward compatibility, delay and process time [69]. In addition to this, Fig. 18 shows the trade-off between on period of PA in a frame to the energy-savings for various time-domain approach. The maximum amount of energy can be saved by the extended cell DTX technique. This technique gives the best results for rural areas where traffic is low and idle case scenario. This technique also saves energy at components levels like cooling systems, DSP units and ADC/DAC devices in turn-off time duration. Some mobile node faces troubles due to the large number of RSs during synchronization operation with BS. Thus, the mobile node may fail to admit in DTX mode. This reduces the battery life of the mobile node and causes a negative effect. There is also difficulty arises during control signal decoding.

E. Frequency based Energy Efficient Approaches

Energy-efficient approache based on frequency is discussed in the following subsection.

1) Carrier Aggregation: The LTE-A (Long Term Evolution Advanced) system uses the bandwidth of up to 100MHz in different frequency bands [70]. Such frequency bands are 450–470 MHz, 698 – 960 MHz, 1710 – 2025 MHz, 2110 – 2200 MHz, 2300 – 2400 MHz, 2500 – 2690 MHz and 3400 – 3600 MHz define by the International Telecommunication Union (ITU) [71]. The carrier aggregation (CA) technique used by the LTE-A, exploits and supports various frequency bands. The concept of the CA technique is to amalgamate two or more component carriers (carrier frequency) into one frequency to amplify the channel capacity and data rate. The frequencies belonging to the same or different frequency bands can be combined in this technique [72]. The concept is represented in Fig. 19. In [73] author considers multi-cell and single cell scenario to analyze the impact of CA on overall power, send by eNodeB. A relation among assigned bandwidth, cell radius, and the total send power by the eNodeB is expressed as:

$$eNB_{TP} = \frac{2R^{\alpha}(2^{\frac{D\times\sigma}{BW}-1})\mu \times BW \times N_0}{(\alpha+2)kd_0(-\ln[1-P_{r(out)}]^{\frac{1}{M}})} \quad (4)$$

Where eNB_{TP} represents the total send power of eNodeB and R is the cell radius. α gives the value of channel path loss exponent, D is the minimum data rate for better QoS. The total number of active users is represented by σ. The term BW, μ, T and K represent transmission bandwidth, modulation coefficient, noise temperature and Boltzman constant respectively. Here $K = 1.38X10^{-23}m^2kgs^{-2}K^{-1}$. The transmission power in both scenarios decreases by nearly 65% by applying the CA technique and EE of the network improves. According to [74], the carriers are combined into groups in CA technique and separate PAs serve every group individually. The limitation of this approach is that the BS with total carriers must have individual PA connected to every group of carriers.

CA supports aggregation of licensed carrier and unlicensed frequency spectrum. Hence unlicensed bands are also utilized. Scaling of the carrier also facilitates the expanded coverage. This technique also helps in enhancing network efficiency and optimizes user experience. Multiplexers are required at transmitter end to combine the carrier components and RF filters are required at the receiver end to isolate carrier components. PAs and switches are specially designed to fulfill the need of CA-based RF system. These additional components raise the cost of the apparatus and device manufacturers and also increases system complexity.

F. Momentous Approach

1) Renewable Energy Resources: Usage of renewable energy resources (RER) in the mobile communication system for making the system greener is a very remarkable approach. With growing wireless communication, infrastructure needs a high amount of electricity. These RER is used for powering cellular system and having many advantages. The major advantage and popular justification behind using RER are to make the environment eco friendly and reduce the emission of GHG. Currently, India has more than 320000 mobile phone towers, which consume almost 3 billion liters of diesel per year. This switching from diesel to solar and other alternative energy sources will result in deduction of nearly 6 million tons of CO_2 emissions and save nearly 1.5 billion in operating expenses for wireless communication tower companies. Switch to RER can produce millions of carbon credits that could balance the OPEX on telecommunication towers. Areas like islands and deserts where the installation of a smart power grid is difficult, the RER can be considered as a problem

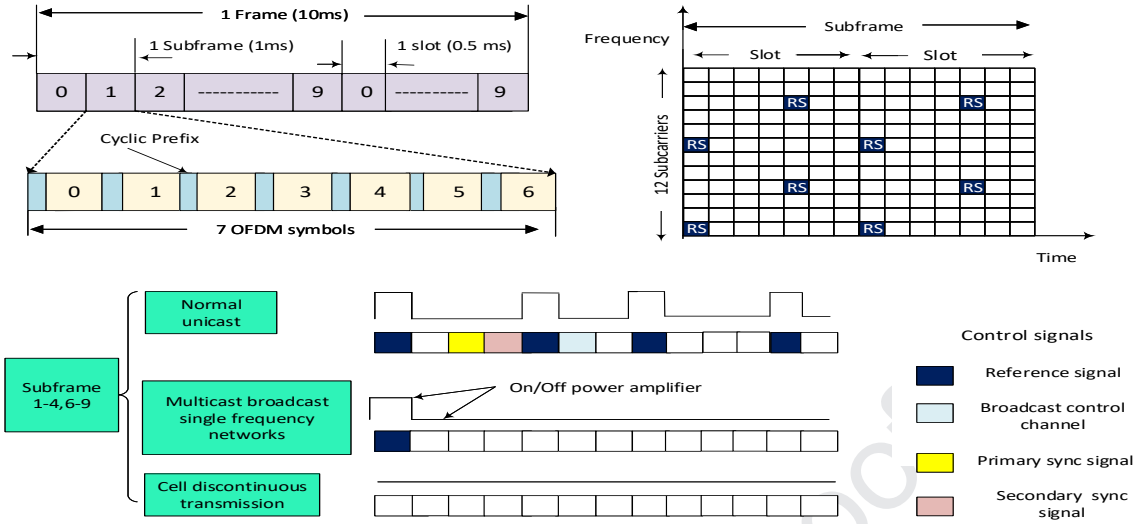

Fig. 17: Reduction of RSs in LTE frame for idle and low traffic load condition

TABLE VIII: The value of power consumption for various cellular BSs

Base Station Type	NTRX (number of transceiver chains)	PA (W) power consumed at power amplifier system	BB (W) power consumed at baseband system	Cooling (%)	Mains Power(%)	DC-DC (%)	RF (W)	Total per TRx (W)	Total Power for NTRX (W)
Macro	6	128.2	29.6	10	9.0	7.6	12.8	225.0	1350
Micro	2	6.2	2.6	0.0	9.0	39.0	54	72.3	745.8

Femto	2	1.1	2.5	0.0	11.0	9.0	0.6	5.3	10.5

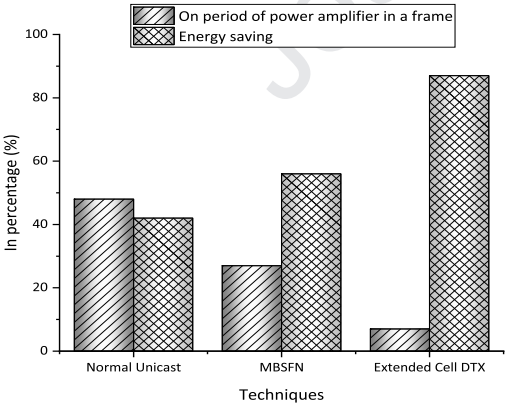

Fig. 18: Tradeoff between active time of power amplifier and energy saving

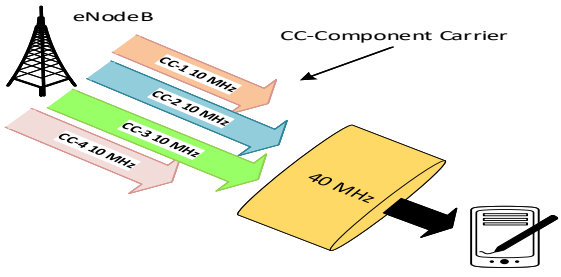

Fig. 19: Concept of carrier aggregation

solving solution [75]. Until now, in such types of areas, mobile operators depend on diesel generators for working of BS which is one of the most pollutant origins of energy and also very expensive because of its price and transportation [76]. The several RER likes sunlight, wind, biomass energy are not only sustainable but also clean in nature and can be used in future networks. The GSM Association has been initiated a program named as "Green Power for Mobile" to support industries related to telecommunications and also to establish several RER for proper operation of 640000 new and prevailing off-grid BSs [77]. With this initiative, nearly 0.347% of the global diesel consumption saved.

In [78] the author describes how RER can reduce the practical realization and working costs of upcoming future

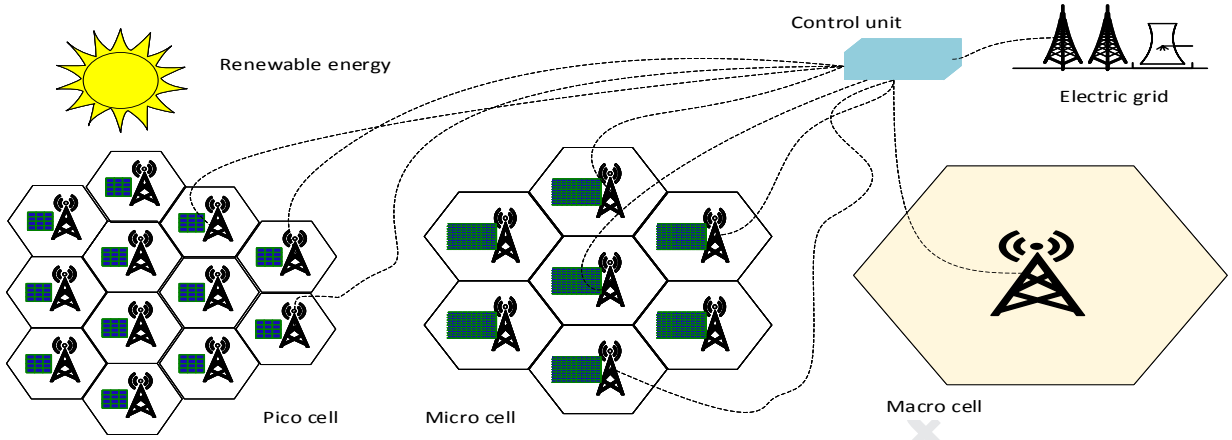

Fig. 20: Addition of renewable energy resource with cellular system

wireless communication systems. Sunlight is an excellent RER used for electricity generation. Another RER used for powering the BSs are wind power, fuel cell, hydro-power and hybrid (solar and wind) system, etc. Fig. 20 depicts the utilization of RER with the wireless communication system. Here solar panels are connected with BSs of the macrocell and microcell to convert solar energy into electrical energy [76]. The major components responsible for power consumption in BS are PA, baseband unit, RF module, cooling system, DC power supplies and losses incurred in feeder [79]. The power consumption in BS can be determined as

$$P_{consumed\ at\ BS} = N_{TRX}\frac{P_{BB}+P_{PA}+P_{RF}}{(1-\xi_{DC})(1-\xi_{MS})(1-\xi_{cool})} \quad (5)$$

here N_{TRX} is the number of transceiver chains. The P_{BB}, P_{PA} and P_{RF} denote power consumed by baseband system, PA and RF system, respectively. The ξ_{cool}, ξ_{MS} and ξ_{DC} represent losses associated with the cooling system, main power supply and DC power supply, respectively. The P_{PA} can be given by the ratio of antenna feeder power output to the addition of PA efficiency (η_{PA}) and feeder loss (ξ_{feeder}) and expressed as

$$P_{PA} = \frac{P_{output}}{\eta_{PA}(1-\xi_{feeder})} \quad (6)$$

Table VIII represents the consumption of power (as a percentage of the overall consumption of power) associated with various parts of BS. The consumption of BS power is divided into two types named as static and dynamic. In first, the power consumption remains constant. In the second, power consumption depends on the number of transceivers deployed and traffic-load. In BS the PA consumes maximum power about 50 to 60% of the total power, and linearly depends on traffic-load. This can be expressed as

$$P_{Consumed} = N_{TRX}(P_{static} + \tau_p P_{Dynamic}) \quad (7)$$

where $0 < P_{Dynamic} \leq P_{\max}$

Here τ_p is the slope of traffic load dependent power consumption. The term $P_{Dynamic}$ and P_{static} represents static and dynamic power respectively.

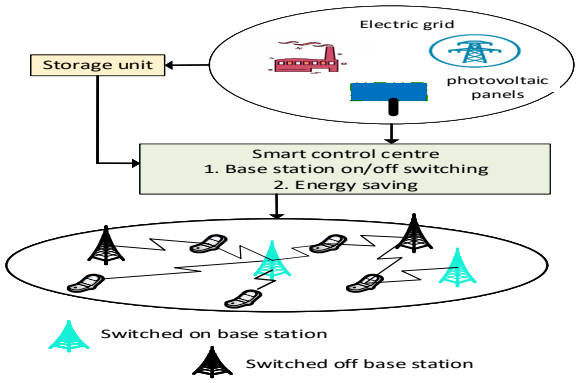

Fig. 21: Future wireless network powered by smart grid

2) Smart Grid: This is an integrated communication system which has various major subsystems such as wired/wireless communication channels, the smart control center (also work as a transmitter/receiver) and software-based management systems. Fig. 21 represents the architecture of future green wireless communication networks concurrently powered with the help of a smart grid and locally deployed RER. The key component of the architecture is the smart control center which sets up the connection between operator and smart grid to optimize wireless network operations like resources management, taking decisions about turning on/off the BSs periodically and storage of auto-generated energy amount etc. For a power supply, the BSs cluster is linked with the electric grid and also connected to the locally generated RE, which generates energy by the array of photovoltaic panels. Due to the irregular production of the RE, the system is connected

TABLE IX: Comparison among various techniques in terms of energy saving

	SISO	SIMO	MISO	MIMO
Merits	Simple circuitry	Known as receiver diversity	Transmitter diversity	Improvements channel throughput
	At short distance SISO system is more energy efficient than others	Under low traffic SIMO system is more energy efficient than others	Less battery consumption	Improve EE for long distance communication
	No additional processing required	Overcome the effects of ionospheric fading and interference	Multiple antennas are combined to decrease errors and increase data speed	Reduce co-channel interference
	Diversity not required	Easy to implement	Reduce the problems of intermittent reception	Improve channel capacity and channel robustness
	$C_{SISO} = B\log_2(1+\frac{S}{N})$	$C_{SIMO} = A_r B\log_2(1+\frac{S}{N})$	$C_{MISO} = A_t B\log_2(1+\frac{S}{N})$	$C_{MIMO} = A_t A_r B\log_2(1+\frac{S}{N})$
	here C, B and S/N are respectively capacity, bandwidth and signal to noise ratio	here C, B, S/N and A_r are respectively capacity, bandwidth, signal to noise ratio and no of receiving antenna	here C, B, S/N and A_t are respectively capacity, bandwidth, signal to noise ratio and no of transmitting antenna	here C, B, S/N, A_t and A_r are capacity, bandwidth, signal to noise ratio, no. of transmitting and receiving antennas respectively
Demerits	Limited performance	Additional processing required at receiver	Additional processing required at transmitter	Requires high processing
	Channel bandwidth is limited	Problem of battery drain	Channel capacity is not Improve	Complex circuitry
	Low throughput	High cost than SISO	High cost than SISO	High cost

with a storage unit, which stores the extra amount of produced RE that can use when RE is not generated, so that the uneven production of RE can be compensated. There is an additional connection between the smart grid and the storage unit shown in the figure. Hence, this storage unit may be used to harvest energy produced from the grid. The arrows represent the possible direction of energy flow.

There are several benefits of using a smart grid in next-generation wireless networks. For mobile operators, the smart grid can be work as a tool for the optimization of energy acquirement, bound their CO_2 emission and reduce their energy bills. The main functions performed by the smart grid are i) To integrate control and information technologies for increasing the generation. ii) Efficient allocation and utilization of energy. iii) To serve consumer's mobile with safe and secure functionality of the smart grid. iv) To design demand-based management that provides controlling choices and secure information to consumer's mobile. In [80], the cost of power consumption with maintaining consumers is minimized by the integration of the smart grid and RER. In [81] a novel combined architecture of RER and electrical grid for wireless networks is designed to utilize the advantages of network operators and smart grid.

In [82], a real-time energy management system based on the smart grid is suggested with the beamforming technique to limit the cost of energy consumption by using locally generated RER. In cooperation with a smart grid, the network state depends on several factors like mobile subscriber density, day of the week (weekend, holiday, working), day time (noon, office, busy hour, midnight) and user's behavior profile, etc.

Smart grid often encourages cost-effective energy saving and high penetration of local renewable energy generation to support future green communication network and also, minimizes the overall emission of total harmful CO_2 with improved QoS. The smart grid system is complex and has number of problems that required to be handled in order to set up a consistent and efficient communication system.

G. Space based Energy Efficient Approach

The various space based energy efficient approaches are discussed as:

1) Multiple-input and Multiple-output (MIMO): This is the most promising approach considers for designing of future networks. Without increasing the transmission bandwidth and power, this technique has overcome the problem of fading and improves the data rate, capacity, and throughput as compared to other antenna systems.The fading effect at the receiver end can be minimized using diversity coding concepts in the MIMO system. Available literature indicates that EE of MIMO system is highest than the other antenna transmission like SISO (Single-input/Single-output), MISO (Multiple-input/Single-output) and SIMO (Single-input/Multiple-output) due to the existence of a larger number of antennas. Table IX shows a comparison among these techniques in energy-efficient communication perceptive.

In [83], three important parameters such as capacity, path loss and delay are considered to make energy-efficient green BS. A trade-off between diversity gain (transmitting similar signals through multiple paths) and multiplexing gain (sending independent signals) is discussed in [84]. In [85] author stated that energy can save at BS by employing steerable directional antennas work on frequency 28 GHz and 38 GHz. In [86], a resource allocation scheme is introduced to decrease the amount of data transmission energy. According to [87], [88]

energy saving MIMO technology depends on traffic demand in that area, so by proper traffic load adaptation, the performance of the MIMO system can improve. In [89], the number of reference signals in MIMO system is decreased in frequency and time domain to make transmission energy-efficient. In [90], a switch-off RF and PA units based novel approach is introduced to reduce energy consumption. It means, at low traffic system, switching from M-antennas to 1 antenna reduces the consumption of energy by the factor 1 by M.

2) Massive MIMO (M-MIMO): M-MIMO is one of the advanced technology of MIMO having several antennas at BS. This technique requires shorter wavelengths (higher frequencies) because the system needs to physically pack more antennas into a small area than the other mobile network [91]. This approach is not only energy efficient but also spectrum efficient. The main advantage is that a BS can serve multiple subscribers simultaneously within the same spectrum. This results in better multiplexing and array gain at the same time. Now the question is for green massive MIMO system, how many antennas are required? In [92] author suggested that in the M-MIMO system, a BS can have X antennas and subscribers have Y single-antenna. A subscriber can scale down uplink power to X and $\sqrt{X}$. In [93], a power consumption model is investigated for obtaining an energy-efficient optimal solution by installing $150 - 250$ antennas to serve a large number of mobile subscribers. Fig. 22 depicts the concept of M-MIMO where an array of antennas is situated in BS and serves multi users simultaneously. Table X summarized a literature survey on M-MIMO techniques and table XI provides a comparison between MIMO and massive MIMO considering energy saving prospect.

H. Electromagnetic Radiation based Energy Efficient Approach

Now a day's mobile communication networks have become an important part of human life. Enormous efforts are dedicated to developing mobile communication services without thinking about the adverse effects of its on human. It is always a topic of discussions among people about the installation of BSs near the residential areas. The Electromagnetic Radiation (EMR) from these BSs causes long-term effects on animals, birds, and humans. The literature stated that BS's EMR causes low risk if antennas are not directly in contact. But the long-term effects of this radiation are still concerning. Paradoxically, BS is considered as the main source of EMR exposure, even though there is a greater health risk from the emissions by mobile phones because those antennas are directly in contact with the human body usually head and ear when it operates. This EMR can interpose the working of our body organs particularly that of our brain and also the reason for some serious health problems such as depression, insomnia and a shortened attention span [102]. A report of the World Health Organization (WHO) shows the classification of RF emissions as a carcinogen of the group 2B category, which is a category shared by lead and pesticides. This study suggests that excess usage of cellphone leads to the development of malignant tumors, especially of the brain. Some research also indicates that exposure to non-ionizing radiation can lead to skin problems, fatigue, headaches, allergies, Parkinson's disease, Alzheimer's disease and more [103]. To overcome this problem, Specific Absorption Rate (SAR) are explored to minimize EMR. Thus, these techniques provide the direction for the designing of next generation low-EM exposure to wireless networks.

EMR Metrics– For finding the direction of EMR of any antenna, two factors named as directivity of an antenna and transmit power are used. The antenna which radiates uniformly in all direction is known as an omnidirectional antenna on the other hand directional antennas radiates in a particular direction. The high value of antenna gain causes stronger the signal in a particular direction. According to the electric and magnetic field theory, depending upon the distance from the transmitting antenna two regions exist such as Far-field and Near-field regions. The two main metrics are used in this field for calculating the EMR, first, is SAR considered for near-field and the second is power density for the far-field. Fig. 23 shows EMR fields. Characterizing the EMR fields in the reactive area is a little bit complicated. The human body easily absorbs the energy transmitted within the reactive near-field region. In the reactive near-field region, the field strength changes inversely with the cube of separation from transmitting antenna i.e., $1/(distance^3)$.

SAR– SAR is evaluated when the body is influenced by EMR. Since the phone is generally near to the body, so EMR from communicating node is typically in the near-field. The value of EMR exposure in the near-field region is calculated for a given period t -

EMR exposure $(J/kg) = SAR.t$

$$SAR = \frac{\delta}{\delta t}\left(\frac{\delta E_A}{\delta M}\right) = \frac{\delta}{\delta x}\left(\frac{\delta E_A}{\Psi \delta V}\right) \tag{8}$$

Where E_A gives the value of energy absorbed by the body, V, M and Ψ represents volume, mass and density of the body, receptively [104]. Different body parts have different SAR value because of different absorption rate as represented in Table XII. *EM Radiation Reduction Techniques–*The target of the 5th generation network is to increase the spectral efficiency, throughput and data rate as well as it also focuses on criteria like improving latency, energy efficiency and reducing EMR exposure from the wireless networks. In this paper some approaches are discussed that are using to decrease the transmit power and EMR exposure levels and SAR of wireless networks because these parameters are directly related to each other. These EMR reduction techniques are:

1) SAR Shielding: Environment and human health [111] have been unpleasantly affected by the increased EMR in the surrounding. The absorption of this EMR by the human body is defined as SAR. For human health higher SAR is very injurious. Different manufacturers have a different value of SAR and this value is governed by several environmental bodies around the world. SAR shielding is used to overcome this problem. In this technique, a metamaterial/ferrite is sandwiched between the human head and mobile, to minimize SAR [112]. The conductivity of ferrite materials is very small therefore there is a small current-induced [113]. The

TABLE X: A summary on Massive MIMO techniques

Proposal	Methodology	Scheme/Algorithm	Route	Remark	Reference
To design cell-free MIMO downlink, which provides the service of various single antenna users in the same frequency-time resource.	Work on spectral efficiency with the consideration of the consequence of channel approximation errors, power control, non-orthogonality of pilot channels and backhaul power consumption.	Conjugate beamforming scheme with consideration of local channel state information.	Downlink channel	Design optimal power control algorithm which increase EE as well as access point power constraint and user spectral efficiency.	[94]
Energy utilization in massive MIMO system is optimized.	For a massive MIMO network consider single-cell and multi-cell scenarios.	Bisection searching algorithm	Uplink channel	Optimizing pilot sequences length and find optimal parameters for energy efficient massive MIMO system.	[95]
Work on joint power allocation in source, channels and relay to maximize the EE.	Massive MIMO relaying technique has been used to enhance wireless PHY security, even with no instantaneous legitimate channel state information.	Energy-efficient power allocation scheme	Downlink channel	Energy-efficient joint source and relay power allocation schemes maximize the EE.	[96]
This paper presents the performance of MIMO cellular systems with pilot contamination.	Consider uniformly distributed user location scheme, find out the area EE in a cell.	Power consumption model	Uplink channel	Investigate closed-form estimation of the area spectral efficiency for multi cell multiuser massive MIMO systems.	[97]
Investigate the zero-forcing beamforming, maximum ratio transmission and scaling laws of EE.	Circuit power, transmit power, pilot contamination, and channel estimation errors are considered for improving the EE.	Realistic channel models' scheme	Downlink channel	-	[98]
Design cell free architecture with the consideration of user centric approach to improve coverage.	An interaction between alternating and sequential optimization is considered.	Hybrid analog/ digital beamformers	Uplink/ Downlink channel	To maximize global EE downlink power control algorithms are used.	[99]
Multi-user, multi-cell, state is considered in which every user work to improve their EE.	Integration of antenna arrays are considered	Distributed power control algorithm	Uplink/ Downlink channel	Evolutionary game theory (EGT) is analyzed to maximize the fairness between users in the network.	[100]
Enhancement in system EE, spectral efficiency and reduce energy consumption for massive MIMO system.	Use full duplex method to improve spectral efficiency and EE.	Self-backhauling and energy harvesting jointly used	Uplink/ Downlink channel.	System EE improved by reducing multi-tier interference	[101]

magnetic field region of an incident EM wave is revoked by this metamaterial/ferrite. This metamaterial has negative permittivity. When metamaterial/ferrite is layered between the human head and mobile model, the value of SAR reduces to 47.68% over 1 gram of tissue on the other hand 27% and 52% over 1 gram of tissue at frequency 900 and 1800 MHz.

TABLE XI: Comparison between MIMO and Massive MIMO

Parameters	MIMO	Massive MIMO
Energy Efficiency	Improved EE	100 times improved than MIMO because of the focus of radiated energy on UE.
Capacity	Improved Capacity	Five times improved than MIMO and coverage of lower frequency bands.
System Hardware	Less complex using up to 10 antennas	More complex using upto 100 antennas
Channel modeling	Easy channel modeling	Complex channel modeling
Battery lifetime	Reduces battery lifetime of MIMO based system because of faster processing of complex and computationally intensive signal processing algorithms.	More reduce battery lifetime as compared to conventional MIMO.
Battery spectrum efficiency	Improved SE	Improved SE because of large multiplexing gain as well as antenna array gain
MIMO based system	WiMAX (IEEE 802.16), WLAN (IEEE 802.11), 4G systems, LTE	Advanced WLAN (802.11ac, 802.11ad), LTE Advanced, 5G system.
Operation Mode	Operate in frequency division duplex (FDD) and time division duplex (TDD) both.	Massive MIMO was originally invented for the TDD operation, but can potentially be applied also in FDD operation.
Throughput	Having high downlink and uplink throughput because of multiple antennas and spatial multiplexing technique.	Large improvement in throughput

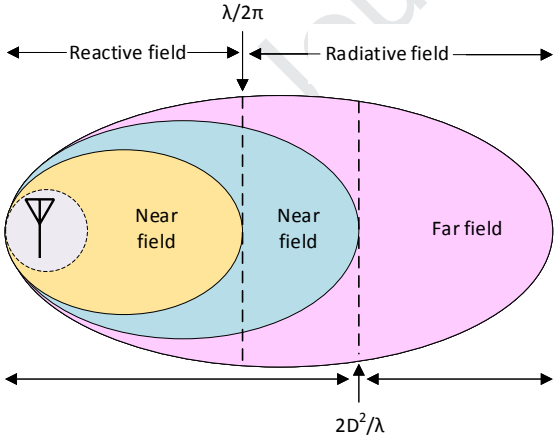

Fig. 23: Effect of EM radiation fields

Recently, the German Federal Office has published a list of top 16 smartphones emitting the most radiation with a SAR. The Xiaomi Mi A1 releases the most radiation with a SAR of 1.74 watts per kilogram while the ZTE Axon Elite and Samsung Galaxy Note 8 have emerged as the lowest radiation-emitting

TABLE XII: Different SAR calculation for different body parts

Metric	Description	Calculative Formula
Whole Body Averaged SAR (WBA-SAR)	Defined as the total power take in by the body to the mass of the body.	$WBA_{SAR} = \frac{1}{M_B}\int_{R_B} SAR(\delta m)$ Where M_B, R_B shows the mass and region of the body
Specific Organ Averaged SAR (SOA-SAR)	This depicts the absorption of EM fields by the tissue or specific organ of the body.	$OSA_{SAR} = \frac{1}{Mo}\int_{Organ} SAR(\delta m)$ Here $Mo, Organ$ shows the organ mass and organ under consideration.
Spatial Peak Averaged SAR (SPA-SAR)	Discussed as maximum local SAR averaged over organ specific mass.	-

phones with a SAR of 0.17 watts per kilogram.

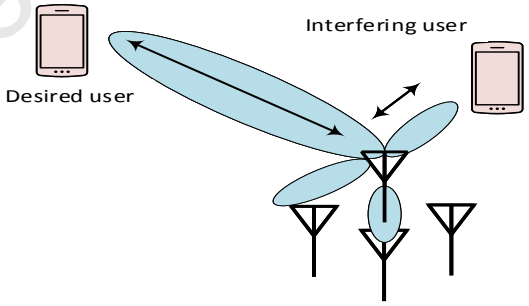

Fig. 24: Principle of Beamforming.

2) Beamforming: A direct approach to reduce power consumption from the mobile communication system is beamforming. An array of antennas is used in this technique to focus EMR towards every desired mobile phone user direction. In the beamforming approach, each transmitting signal of the mobile subscriber is multiplied by complex weights. These weights are adjustable and have a signal's phase and magnitude in a specific direction. By using the DSP algorithms, the exact location of the user can be tracked in the beamforming technique. So, the signal strength in a specific direction maximizes while interference, EMR exposure and transmit power reduces [114]. Fig. 24 shows the principle of beamforming. In figure, the beam formation is in the direction of the desired user. Table XIII represents a detailed survey of the beamforming techniques in terms of energy saving.

I. Futuristic Approach

In this subsection, various important futuristic approaches like Device-to-device (D2D) communications, Mm wave and Green IoT is discussed in an informational fashion.

TABLE XIII: Survey of Beamforming technique

Proposal	Remark	Reference
Authors investigate the effect of beamforming for SAR improvement.	Reducing the absorption of EM radiation by placing nulls in the head direction. Results indicate that a SAR reduction can be achieved at least 10 dB in this method.	[105]
To overcome the problem of EM radiation exposure radiated from mobile equipment, a less complex, SAR-aware optimum beamformer is investigated.	The SAR-aware beamformer for multi-antenna terminals is used to improve transmission power constraints and SNR. Results indicate that the SAR-aware beamformer performs better than the traditional method and provide SNR gain up to 5 dB.	[106]
Propose hybrid beamformers to fulfill the objective of reducing power while maintaining users' QoS requirements.	The author presents a phase array switching framework to comprehend the eigenmode selection beamforming. Results show that the investigated eigenmode selection method can attain a significant amount of power savings.	[107]
An energy-efficient multi-cell multi-cluster coordinated joint beamforming scheme is investigated.	The author works on antenna specific higher power constraints to overcome the problem of non-linear distortion in power amplifiers. It represents the relation between beamformers and binary antenna selection variables and numerical results illustrate the gains achieved in the form of EE.	[108]
In this paper user scheduling problem and joint multicast beamforming was discussed and another goal is to minimize the total transmitting power of multiple channels.	An algorithm based on Convex relaxation is proposed. Extensive mathematical researches illustrate the benefits of the suggested co-design model over random scheduling and fixed scheduling in terms of power ingesting.	[109]
At the transmitter end, a digital-beamforming method depends on DSP was investigate	The solution presented high throughput and improved data rate for a cost-effective 5G wireless access network which operates at frequency 28 GHz and also represents an improvement in EE.	[110]

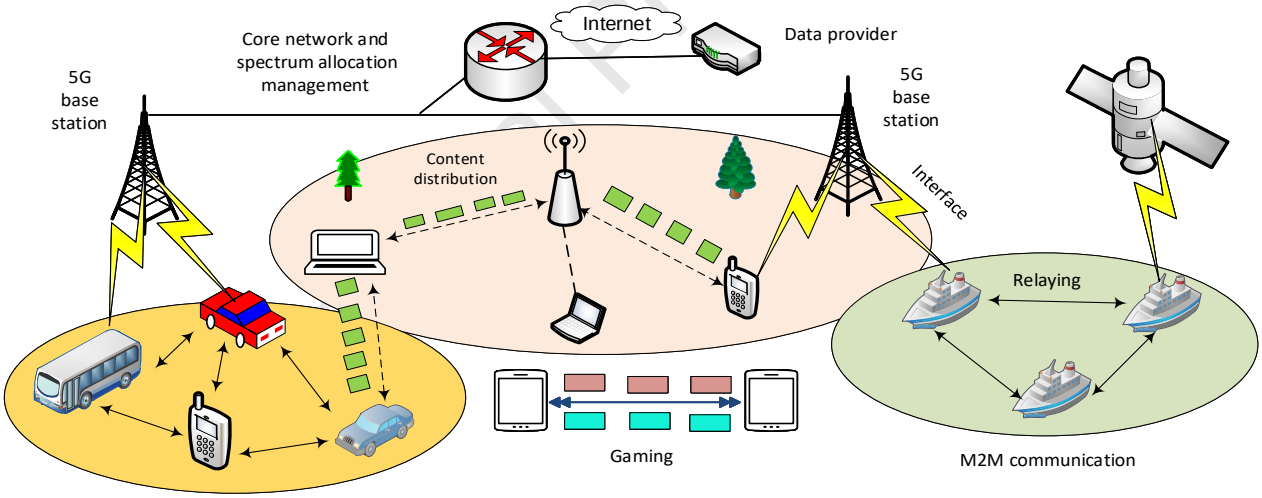

Fig. 25: Energy efficient D2D communications model

1) D2D Communications: D2D transmission is one of the effective technical approaches to reduce the consumption of power and improve the data transmission rate. In this technique two physically separated nearby located nodes can directly communicate with each other with low transmit power [115]. Thus, a remarkable amount of energy can be saved at BSs. In the case of wireless network unavailability and network congestion, D2D communications offer alternative communication. The D2D approach is recognized as a public safety network for future wireless communication by FCC (Federal Communications Commission) because of low cost and high data rates.

An energy-efficient high-level D2D communications model is represented in Fig. 25. Here different users are linked with BS via a cellular interface. These users are also communicating directly via D2D links between nodes. Several Radio Access Technologies (RATs) including 3GPP evolution like Bluetooth and Wi-Fi standards are used to establish direct links between communicating nodes such as mobile phones and laptops. In Vehicular to Infrastructure (V2X) communication, a dedicated 802.11p standard operates in the frequency band of 5.9 GHz is used by cars in an intelligent transport system (ITS).

TABLE XIV: Comparison of existing surveys of D2D in terms of energy efficiency

Proposal	Methodology	Technology	Route	Evaluation	Achieved Performance	Reference
Enhance power efficiency	Exhaustive search	LTE-A	Downlink	Simulation on system level	20% energy can be saved	[116]
Improve power efficiency	Heuristic algorithm	LTE	Uplink	Simulation on system level	30% power efficiency improved	[117]
Increase power efficiency	Linear programming	OFDMA	Uplink/Downlink	Simulation on system level	40% to 80% energy saved	[118]
Enhance EE	Linear programming	OFDMA, LTE-A	Uplink/Downlink	Simulation on system level	50% energy saved	[119]
Improve EE	-	LTE	Uplink	Simulation on numerical based	Improved EE from 0.9 bps/Hz/mW to 22 bps/Hz/mW	[120]
EE management	Inducement mechanism based on open market and sealed market model for D2D (auction algorithm)	OFDM	Downlink	Framework for cooperative and D2D communications	37% energy saved	[121]
Analysis of EE	-	LTE	Uplink	-	Energy saved bps/Joule	[122]
Analysis of EE	Distributed resource allocation algorithm	LTE	Uplink	Tradeoff between EE and SE	Energy saved in bits/Hz/J	[123]

Depends on the spectrum usage, this approach is divided into two categories named inband D2D and outband D2D. In first, the identical licensed band is exploited by both D2D and cellular networks. The major drawback of inband D2D communications is interference prompt by D2D to the cellular link. The unlicensed spectrum is utilized by D2D links in outband D2D communications. The reason behind the usage of the unlicensed spectrum is to limit the interference between cellular links and D2D network. But, more interface requires to connect different wireless technologies like ZigBee, Bluetooth and, Wi-Fi [124].

In [125], joint optimization of adaptive power allocation and uplink subcarrier assignment-based approach is investigated for cellular and D2D network to achieve improved EE. Various power controlling algorithms used for D2D communications have been explained in [126] [17]. Power and resource block allocation using game theory has been discussed in [127]. The author represents a cross-layer optimization scheme in conjunction with nash equilibrium under the accurate availability of channel state information (CSI) [128]. In [129], the author suggests a joint scheme of power control and resource allocation. The adoption of a two-layer method is involved, to achieve an optimal solution for energy efficient architecture. Table XIV provides a complete survey of D2D in terms of energy efficiency.

2) Mm Wave: For next-generation networks, Millimeter waves are the most promising approach. For delivering fast multimedia services, high-quality audio-video, and real-time services, a large amount of bandwidth is required. Due to a large number of consumers, the traffic congestion problem in the network will be arisen by 2030. To solve this problem the fifth generation network uses millimeter wavelength. The signals are operating between 30 and 300 GHz and being shifted to a higher spectrum. On the other hand, this technology has a large penetration loss, high signal attenuation and extremely susceptible to blockage effects which lead to the limited coverage area. Spatial multiplexing technique is used

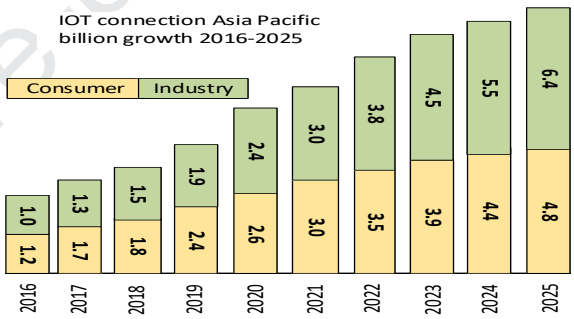

Fig. 26: Growth rate of IoT in Asia Pacific

for transmission and reception because the wavelength is very small. To obtain the high capacity, fast data rate and reduction in energy consumption, an array with directional transmission between MS and BS is used in this technique [130] . Table XV provides a complete survey of mm wave technique in terms of energy efficiency.

3) Terahertz communication band: In the upcoming decade, it is expected that the data rates will be increased up to 12 Gbps or more. This requirement of a high data rate cannot be fulfilled by a licensed band spectrum [137]. In addition to this mmWave technology alone cannot realize the need for a high data rate since there is only 9 GHz bandwidth for data communication. Free Space Optical (FSO) communication systems may be one of the solutions with minimum operating power for this demand but it requires direct line of sight (LOS) communication between the transmitter and receiver, which makes it impractical for mobile communication. So the most promising solution to achieve the demand of high data rate is Terahertz (THz) communication band which is least considered frequency region, where the data can be transmitted over non-line-of-sight (NLOS) links. Terahertz Band com-

munication will improve the spectrum scarcity and capacity of wireless communication networks. In the upcoming future THz bands are predicted for the development of various applications in both nanoscale communication and classical networking field [138]. The frequency region above and below the THz band is the infrared and microwaves. The THz frequency band (between 0.1 THz and 10 THz) will provide ultra-high-speed data transmission within the areas up to 10 m (PAN). The necessity to deal with this rapid progression of wireless services and related applications has required a large research activity that explores the optimal options for designing of user-oriented context-aware next generation (5G) wireless communication network. The 5G network is not only expected to improve the performance of information and communication devices but also capable to solve many pervasive issues of this field. The several applications related to 5G green communications in THz band are represented in Fig. 28.

4) Green IoT: The goal of the Internet of Things (IoT) is to link millions of users with each other using sensors like RF identification, and is the most evolving technology for making the foundation of the green CRNs. Large energy is required for exchanging information among millions of users. Fig. 26 represents the growth rate of IoT in the Asia Pacific in terms of consumers as well as industry. The goal of Green IoT is to enhance an EE of IoT devices and making the environment healthy. In [139] author projects that the usage of RFID will grow exponentially in the upcoming years. So, if this forecast is even nearby the reality, then a large amount of energy consumption will arise due to the more battery power will be demanded by all active RFIDs. So, to solve this problem, this work focuses on making the IoT technology green by applying numerous approaches. The IoT framework management involves identification, sensing,

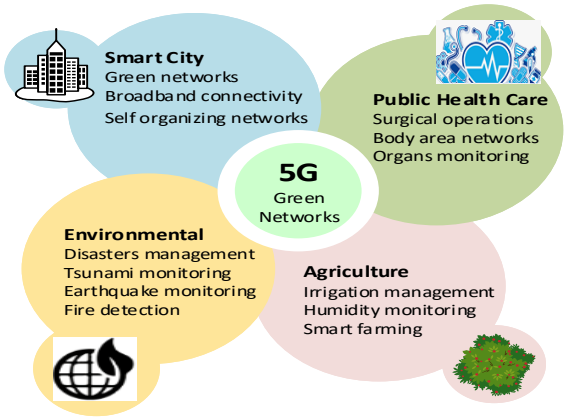

Fig. 28: Future applications related to 5G green networks

analyzing, communication, computation facilities and semantics. Identification is the initial process which guarantees that needed information sends to the accurate destination. Sensing works on collecting information and data, then sends to data centers. Considering different parameters and conditions, this collected data is then scrutinized for different services and operation purposes. The different parameters sensed by sensors are real time traffic, humidity, pressure, rate of pollution, temperature, etc. Combining different networks and objects for performing any task will comes under communication. Technology likes Bluetooth, Wi-Fi, etc are used to complete communication. The microprocessors, microcontrollers, embedded systems, FPGA, CPLD, ASIC, and various software applications perform the computation. Green IoT concept visualizes in Fig. 27. The figure shows that for the design of a smart city every element of a smart city like smart homes, smart agriculture, smart building, etc are connected by the IoT. People will use the internet for different purposes like traffic control, traffic monitoring, medical purpose, etc [140].

The main motive of green IoT is to make the environment green from its designing level to its implementation level. There are two ways to achieve this objective. The first is that the IoT will aid in eradicating the greenhouse effect produced by present applications and second is to optimize itself to reduce the greenhouse effect. Different scientific approaches for designing of green IoT are discussed in [141]. A framework is proposed for constructing the green IoT in [142]. Moreover, green cloud computing [143], green sensor networks [144], green RFIDs and green data-centers plays an important role in designing green IoT.

The IoT is developing technology for future green networks that have capability to change the way we observe IT industry. The green IoT approach is going to have an enormous influence on how we handle with convinced glitches in our everyday life and it is surely going to make our survives easier and better. There are five principles of achieving green IoT. Considering a small network size will save a large amount of energy and improved EE. Select only desired information by proper sensing and eliminate extra data also helpful for energy saving. The integration of different networks and implementation with proper policy making will lead towards green IoT and reduce carbon footprints. There should be a proper tradeoff between parameter is also very necessary. Fig. 29 describe the classification of green IoT techniques and Table XVI represents a detailed comparative survey of these techniques.

J. Green Cognitive Radio Networks Approach

According to the report of CISCO on data uses, in 2017−22, the telecommunication traffic originated by mobile subscribers is predictable to have nearly tenfold [155]. For new mobile subscribers and upcoming data-hungry devices, the availability of unused frequency bands is very low. Because, a report published by the FCC says that, nearly complete accessible bandwidth for wireless network communications has been almost allocated [156], [157]. Also, a study utters that nearly 75% of the assigned bandwidth is not properly used due to the static spectrum allocation scheme [158]. This generates an abundant gap between the existing requirement of additional bandwidth and presents an allocation scheme. The CRNs are the most promising, emerged and key enabling technology of future networks. This technology provides the freedom to utilize underutilized frequency bands by allowing Secondary Users (SUs) to access licensed frequency bands which are not used by Primary Users (PUs) opportunistically [159]. When the primary user comes back to the channel, the SU has to switch to another unoccupied channel belonging from the different network for consistent communication. The performance of SU has affected by the appearance of high prioritized PUs. Fig. 30 represents an idea behind green cognitive radio networks (GCRNs). The Fig.30a shows existing static spectrum allocation policy which fails in heavy traffic load situation and frequency bands are highly utilized. In Fig. 30a, the number of mobile subscribers are more in-network 'A' and cause heavy traffic load, whereas the other networks B, C, D and E have less traffic load with underutilized frequency bands. Fig. 30b, represents the difference between CR and non-CR technology. Fig. 30c represents an optimal utilization of available frequency bands (called white space) by using dynamic spectrum allocation policy. The mobile node can switch from one network to another network after making the decision using the cognitive property. A dynamic spectrum allocation policy requires key functions like dynamic spectrum environment, spectrum sensing, sharing and management respectively, in GCRN as shown in Fig. 30d.

It is very challenging to design a green CRN because it involves the optimization of dynamic spectrum allocation as well as optimal exploitation of green energy. The various functionalities are performed in the energy-efficient CR.

- Spectrum Sensing and Analysis- For designing the energy-efficient spectrum sensing approach the main task is to analyze the performance indicators to find out the presence of the primary user. Various types of spectrum sensing with energy efficiency related issues are represented in Fig. 31.

Journal Pre-proof

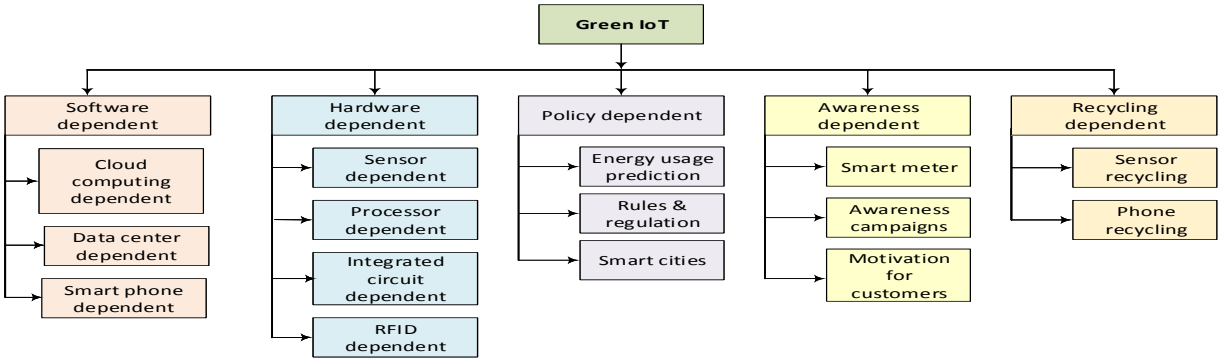

Fig. 29: Classification of Green IoT techniques

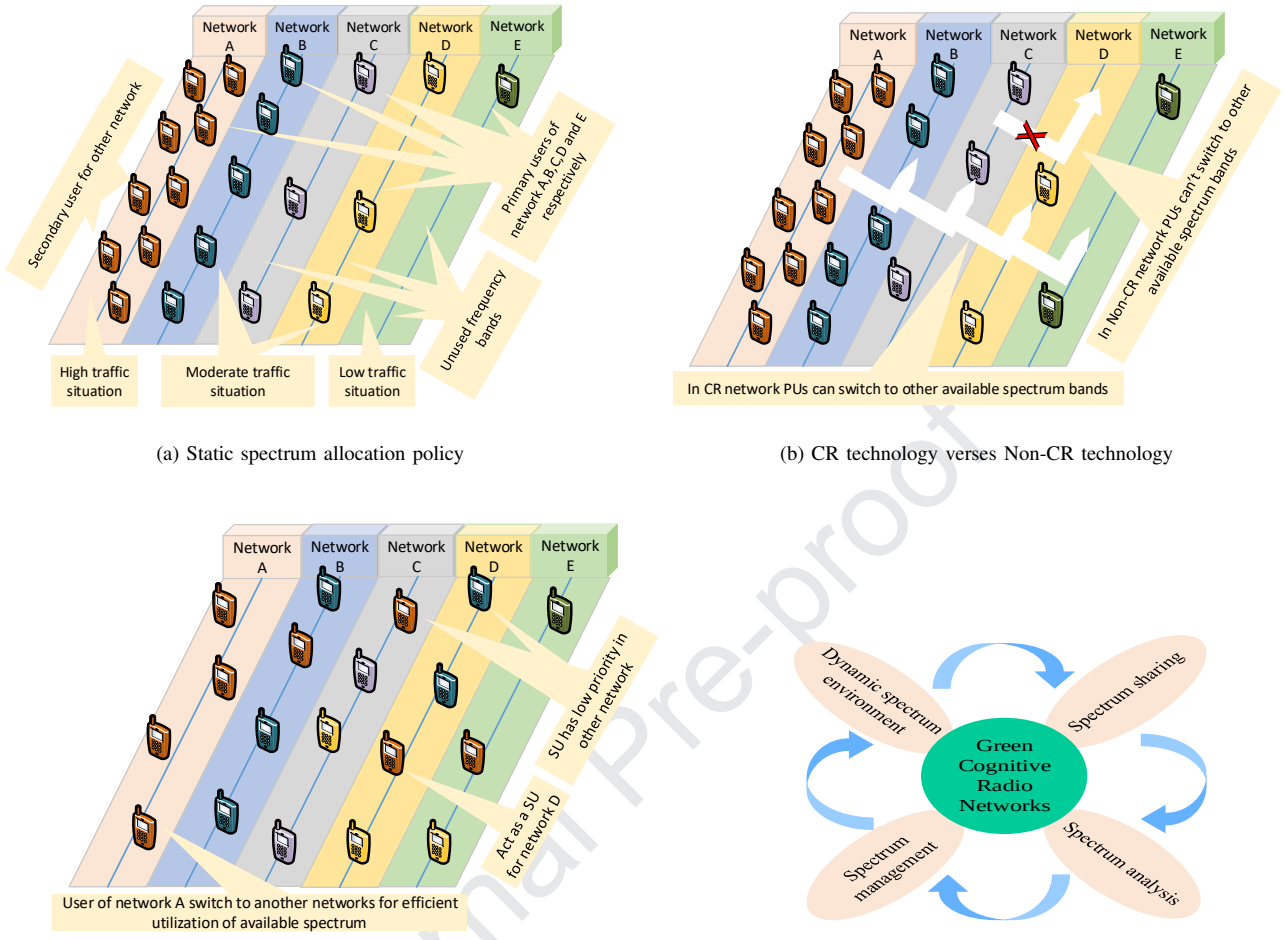

TABLE XVI: Comparative survey of green IoT techniques

Approach	Consider Technology	Energy saving process	Tradeoff	Real time implementation	Metric	Reference
Hardware dependent	Relay	Load balancing among different nodes	Communication delay	Possible	End to end delay	[145]
Software dependent	Sensors	Selective sensing	Privacy, energy overheads	Highly possible	Energy efficiency	[146]
Policy dependent	Information management	Information collected from various section of building to develop energy efficient guidelines.	Data security	Highly possible	Data efficiency	[147]
Software dependent	Cloud computing	To decrease data traffic dynamic packets are downloaded from access points.	QoS may be compromised	Possible	Packet transmission rate	[148]
Software dependent	Smart phones	Calculation of energy consumed by smart phone applications	Security and data privacy	Possible	Energy efficiency	[149]
Software dependent	Data centre	Workload sharing among physically separated data centers	Highly complex	Not possible	Data center efficiency	[150]
Hardware dependent	Integrated circuits	Inbuilt sensors on-chip are used to decrease network traffic load	High cost	Possible	Radio efficiency	[151]
Awareness dependent	Smart metering	Track various types of devices and evaluate the energy consumption rate.	Security and data privacy	Possible	Power efficiency, transmitted power	[152]
Policy dependent	Smart buildings	Guidelines and approaches to reduce energy consumption.	User dependency	Not possible	Energy per bit per area	[153]
Hardware dependent	RFID	Passive sensors are used for evaluation	Communication delays	Possible	Spectral efficiency	[154]

- Green Relaying in Cognitive Radio- In CRNs, authentic end-to-end data transmission among secondary users need a large amount of power, which leads to harmful interference to primary users. Relay technology is capable to boost the overall performance by saving energy. Because of the shorter transmission distance, the path loss is very low in this technology.
- Cooperative Cognitive Radio Networks- Cooperative communication is considered as the most promising solution to tackle the issue of multipath fading. This provides energy-efficient communication and also reduces the detection time due to the usage of spatial diversity. Cooperative communication protocols are working in two modes named as Decode-and-Forward and Amplify-and-Forward. The cooperative communications in CRNs, can be classified into two classes such as cooperation among secondary users and cooperation between the primary user and secondary users respectively.

Now the question is how do CRNs reduce power consumption and provide green communication? So, the answer is for wireless communication system bandwidth efficiency is always a pivotal concern and there exists a rich state of the art on this topic, focusing on improving bandwidth efficiency. The solution lies under Shannon's capacity formula which describes the trade-off between power and bandwidth. The capacity various logarithmically with power, but linearly with bandwidth. It reflects that to decrease power, larger bandwidth will be required or in other words, handle the spectrum dynamically and optimally. This is the principle of CR. Table XVII having a detailed survey of cognitive Radio technique in terms of energy saving.

IV. Challenges and Existing Practical Implementations of Green Communication

The framework to enhance the EE of telecommunication the system has a holistic view which considers possibly all facts and figures of an ecosystem for green communication. The several challenges related to green communication are listed as:-

- For estimating any energy efficient solution, the required energy for the manufacturing of a communication system (called embodied energy) has a very significant role.
- The surge of EE at a single stage of the communication system might be the reason for the decline at another stage of the system. For instance, the usage of a cognitive radio system may decrease the transmission energy by using proper bandwidth but drain additional power in the process of sensing the spectrum hole of the second network.
- There should be a respectable trade-off between EE and QoS. Like the aforementioned usage of BS sleep modes technique, more energy can be saved during off mode of some cells. But, it is compulsory to stipulate the cell waking time in advance as well otherwise, the QoS may degrade.
- There should be also a proper trade-off between flexibility and EE which depicts in Fig. 32.

The energy-efficient solution depends on certain guidelines, concepts, parameters, energy consumption models and considerations. The energy consumption of the telecommunication system is load-dependent and implementation-dependent. These are the challenges for modeling the energy- efficient system. The EE metric for a green telecommunication system is generally expressed in the form of performance per unit of energy. The performance usually measured in terms of efficiency and throughput for the energy-efficient communication system. Other key challenges for designing the green energy-efficient system are cross-layer adaptation, system reconfiguration, load balancing, and multi-domain scheduling. It is necessary to gauge EE from a new perspective for

TABLE XVII: Comparative survey of CR technique

Objective	Description	Energy saved	Scheme/Algorithm	Reference
Cultivating the EE of cellular networks	The author investigates the cooperation between BSs and television stations in sending UE relying on an opportunistic usage of the TV spectrum. The unoccupied TV spectral frequency band is utilized in an opportunistic manner.	41%	Explores the joint employment of cooperation techniques and cognition	[160]
For CRNs examine the EE with the relation of area spectral efficiency	A constant base station power consumption model is considered for both perfect and imperfect detection in the case of cognitive as well as primary users.	35%	Stochastic geometry approach	[161]
The author has described the method to attained maximum EE in a spectrum sharing atmosphere.	With consideration of EE, the trade-off between throughput and transmit power in a centralized CRNs is explored.	28%	Spectrum-sharing model	[162]
The effect of interference power, interference gain on energy consumption and optimal sensing time of the channel is described.	For multiband CRNs power allocation and optimal sensing time algorithm are proposed.	30%	Multiband sensing-based scheme	[163]
Research work is dedicated to energy-efficient optimum power allocation tactics for green CR in fading channels.	For both delay-insensitive and delay sensitive CR, EE improvement schemes are investigated with the consideration that the channels are suffered from fading and primary user coexists with a secondary users.	25%	Convex optimization methods and Dinkelbach's method	[164]

designing and developing novel energy-efficient architecture. The pathway represented in Fig. 6 to implement in the real world for making communication green is also having several challenges that need to be paid consideration too in this research area.

Several challenges, related to green communication for next generation networks are represented in Fig. 33.

There are some international projects with the aim of exploring possible ways to reduce CO_2 emission, transmitted power of telecommunication system, health effects, and EMR exposure are discussed in Table XX

Journal Pre-proof

TABLE XVIII: Assessment of the Energy-Efficient strategies

Approaches for Green communication	Techniques	Metrics for Green performance evaluation	Saved Energy/Reduced power	Parameter Consideration	Applied Domain	Merits	Demerits
Hardware Component Improvement	Doherty architecture and GaN based amplifier	EE, PA Efficiency	Up to 51%	Peak-to-average power ratio	At infrastructure level	Energy can be saved in a large amount	Less flexible
	Switch mode power amplifier	Energy Consumption Rate	70%	Linearity	At infrastructure level	A large amount of energy can be saved	For hardware replacement large cost required, some upper limits for hardware implementation
Energy Efficient Architecture	Hetnet	CapEx and OpEx		Interference, handoff	Always macro cells remain in active mode, while small cells will come in active mode when traffic increases.		Required high radio interference management
	1. Microcell-Macrocell	CapEx and OpEx	45%	Interference	At infrastructure level	Low implementation cost	Handoff management
	2. Picocell-Macrocell	CapEx and OpEx	62%	Handoff	At infrastructure level	Prolonged handset lifetime	Handoff management
	3. Femtocell-Macrocell	CapEx and OpEx	80%	Interference	At infrastructure level	Higer SNIR	Interference management
	4. Femtocells (urban area)-Marocell (Suburban area)-Portable femtocell (rural area)	CapEx and OpEx	Reduced by 83% to 87%	Handoff	At infrastructure level	Improvement in EE and low transmission power	Handoff management
	5. Femtocell (Highly populated urban area)-Picocell (Less populated urban area)-Microcell (suburban areas)-portable femtocells (rural areas)	CapEx and OpEx	79-80.2%	Interference	At infrastructure level	Low path loss	Interference management
	6. Macrocells (Fully coverage area)-femtocells, picocells, and microcells (border regions)	CapEx and OpEx	10%	Handoff	At infrastructure level	Improve coverage	Handoff management
	Cell Zooming	CapEx and OpEx		Problem of dead zone, coverage holes	BS coverage area continually changes with variation on the real time traffic		Maintain tradeoff between energy saving and performance
	1. Zoom out Active cell in Commercial area	CapEx and OpEx	30%		At infrastructure level	Inexpensive implementation and testing	Handoff management
	2. Zoom out Active cell in Residential area	CapEx and OpEx	38-40%		At infrastructure level	Improve throughput	Interference management
	3. Zoom out Active cell in uniformly distributed area	CapEx and OpEx	25-40%		At infrastructure level	Proper traffic load balancing	Handoff management
	4. Zoom out Active cell in Office area	CapEx and OpEx	45%		At infrastructure level	Improvement in EE	Interference management
Traffic based energy efficient	Base station ON/OFF	Sleep mode energy saving, Energy consumption index, performance indicator, Energy consumption gain		Battery life of UE, coverage	Mobile users transfer connection from off BS to on BS	Energy savings depend on the time period over which each of the BSs is switched off	Maintain trade-off between energy saving and QoS, less accurate in modelling
	1.Distance based evaluation		29%				
	2.Real time Traffic based evaluation.		30-35%				
Time based energy efficient	1. Unicast	Electricity cost, state of battery	38.5-45%	Proper synchronization	LTE BS	High energy reliability, deactivate unused subframe	Degrade battery life of UE

Journal Pre-proof

TABLE XIX: Assessment of the Energy-Efficient strategies

	2.MBSFN		56%				
	3.DTX		80%				
	4.Optimize subframes in each frame		90%				
Frequency based energy efficient	Carrie Aggregation	Latency, gain and axial ratio	Power reduces up to 65%	Compatibility, Complexity	4G LTE	Power reduce by double factor band	Because of early hand-off, radio link failure increases, Difficult for two networks to work together
Momentous Approach	Renewable energy	Cost efficiency	10%, energy savings depend on BSs installation and location, speed of wind	BSs location, other natural energy resources	At infrastructure level	Less expensive, long-term solution for off grid	High replacement cost, for on grid BS limited gain
	Smart Grid	Cost of electricity, on-grid energy consumption	Up to 30%	Resource management, QoS	At infrastructure level	Energy savings through reducing consumption, Improved environment	Required proper infrastructure
Space based energy efficient	MIMO	Spectral efficiency, Energy efficiency	55%	Effect on the UE	At infrastructure level	Improved capacity and spectral efficiency	High circuit power, reduces battery lifetime
	Massive MIMO	Transmission Power, Energy consumption	Depends on number of switched off antenna	Spatial multiplexing, space time block coding	At infrastructure level	Large throughput	Complex channel modeling, more loop interference and training symbols
EM Radiation based energy efficient	SAR Shielding	Power density, Whole body averages SAR	A large amount of energy can be saved	Signals coming from the sensor array	At UE level	Save body organs and tissues from harmful waves	Enhancement depends on a special material and design
	Beamforming	SAR exposure	A large amount of energy saved	Signals coming from the sensor array	At antenna level	Improve system coverage and capacity, improved SINR in the desired direction	High hardware complexity. Advanced processing DSP chip is required. High Battery drain due to large power requirement
Green Cognitive Radio Network		Throughput, network energy cost	Upto 50% by proper spectrum management	Spectrum hole, unutilized bandwidth	Performance depends on real time load distribution information of whole network	User oriented, low cost, various application	Performance depends on spectrum unavailability, Delay is involved due to sensing operation
Futuristic Approach	D2D method	Average sum rate, BS power consumption	15-40% Depends on the number of intermediate devices	Switch off the devices for a deterministic traffic	Device on off depends upon the distance between the transmitter and receiver	Low transmitter and circuit power	Packet encoding and decoding is required, Interference management, D2D mobility management, Synchronization among devices
	Mm wave	Data rate, outage probability, coverage probability	Up to 20%	Privacy, security	At antenna level	Cost-effective	High circuit power and signaling overhead required atmospheric loss, pathloss and shadowing
	IoT	Energy efficiency, end to end delay, weighted throughput	Up to 30%	Compatibility, complexity	At infrastructure level	Reduce human effort, improve security	Complex network, device recognition and difficult to locating in IoT

V. Discussion and Forward Way Research Direction

Various energy-efficient approaches examined in previous sections are valuable to design energy-efficient green communication system and network. Integrating all these approaches into a combined approach can lead the revolt in the field of green communication. The next-generation networks are anticipated to realize the necessities of the mobile subscribers as well as deliver a solution for energy-efficient green communication.

Green communication networks have been broadly subjugated in bestowing a plentiful range of real-time multimedia applications. The Fig.34 demonstrates the extensive summary of upcoming future networking technologies likes Software Defined Networks, Supermassive MIMO, Terahertz Communication, Ultra-Dense Networks, IoT Communication, Quantum Communication, Beamforming and NOMA. However, the future research direction and issues related to green communication networks are also summarized in Fig.34. On the basis of studied literature the future research directions can be summarized as:

- In supermassive MIMO, usage of multiple antennas requires very high power consumption and a great amount of overhead. This problem can be overcome using the spatial diversity concept.
- The EE of terahertz communication in multiple cell scenario requires to be explored to eradicate interference-effect.
- The consumption of high power in communication system circuits is a critical issue in the usage of renewable energy for designing a green communication system.
- The cost factor involved in the practical realization of IoT technology is another significant research subject for the future.
- The power control strategy in hardware and efficient algorithms in the software of the IoT system can be used to achieve optimum SNR and reduce interference.

To realize the green communication network environment, an intelligent advanced energy-efficient technique requires to be developed. Different energy-efficient techniques have been immensely deliberated in this survey. However, there are still new research areas for more effort to be achieved in this field. This part of the section delivers future research directions that entail the consideration of the research community. These new directions are discussed as:

1) Cooperative Heterogeneous Network (HetNet) Architecture: The upcoming generation of networks is likely to provision incorporation of various networks having diverse services and protocols. So, vertical handover, management of interference, enhancement in network capacity with the attention of energy efficient communication system is an important research topic. The tradeoff between spectral and energy efficiency and a tradeoff between network coverage and QoS in HetNet network also requires more investigation.

2) Green Networks: Energy-efficient approaches are the main prerequisite for the designing of GCRN. Thus, a new research area to minimize the EMR effect by the green networks is desired to be investigated. Two key research issues associated with GCRN are (1) decrease in consumption of power and energy overhead instigated by communication among mobile nodes and (2) optimization of dynamic spectrum allocation techniques to improve EE without distressing QoE of mobile subscribers.

3) Experimental Testbeds for Green Networks: For analyzing an impact of suggested energy-efficient approach for green networks, it is vital to test these approaches on realistic testbeds. In this way, the hardware realization issues can be identified and would be able to check the viability of these proposed approaches. The absence of mature green networks modules in prevailing simulators offer new research direction to enterprise an experimental testbed to provision green networks.

4) Security: Auspicious of protected communication in green networks is a significant design objective for consistent advance next-generation wireless networks. It is a challenge to design an energy efficient approach for green communication to handle the EMR and GHG effect jointly with the utilization of RER for saving energy. In the available literature, energy-efficient approaches are focusing on the security of either network or mobile nodes. Secured green communication for both networks and mobile nodes, along with energy-efficient encrypted technique is required in future wireless communication systems.

5) Green networks Model for LTE/Wi-Fi coexistence: LTE network supports the modern wireless networks like carrier aggregation, massive MIMO, HetNet, D2D network with multiple cells of small size. The adaptive energy-efficient approach designed for green networks would be a promising technology in such advanced wireless networks. For example, HetNet comprises multiple cells of different sizes (termed as femto, pico, and microcells). So, the management of interference causes more complexity in networks. The coexistence of two different networks with combining their capabilities and energy- saving proposals would help in the formation of green networks, which is still an energetic research direction and will receive further attention.

Fig. 35 represents the advanced technologies i.e. next step towards futuristic wireless networking. These technologies are blockchain, machine learning, artificial intelligence, big data, advanced beamforming.

VI. Conclusion

This paper scrutinized the trends of the telecommunication system in the last decade which visualize a move towards following energy- efficient green communication for the purpose of designing next-generation networks. For each energy efficient technique, an outline of the existing state of the art research, merits, demerits, open issues, challenges, and possible forward way research direction has been investigated.

Lessons Learned by the survey

- *Lesson 1*: Select an appropriate EE metric for performance measurement at facility, component, access point and network level. Green mobile communication is an important chunk of corporate social obligation which

endeavors to minimize greenhouse gases and carbon footprint in green ICT services for customers. The government should propose protocols, rules, and regulations to certify the service provider as a green service provider. So, mobile operators have to combat global warming by decreasing their CO_2 emissions.

- *Lesson 2*: The joint application of the BS sleep method with hybrid beamforming provides better cost reduction and flexibility. The increased demand for mobile data and the internet needs a paradigm shift towards broader bandwidth accessibility in GCRN and mm-Wave frequency band. Massive MIMO contains a larger number of antennas which minimize transmitted power. The main attention lies on the utilization of relay for the future green networks as well as small size cells and their role in the formation of energy-efficient communication systems.

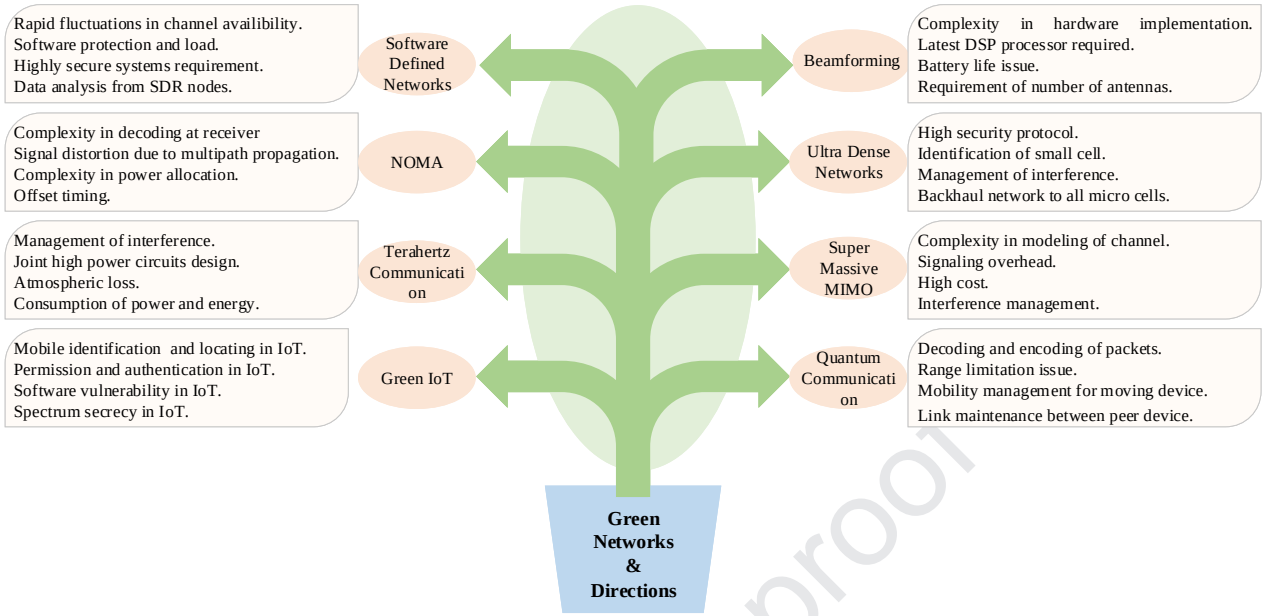

Fig. 34: Green communication future networks and related research directions

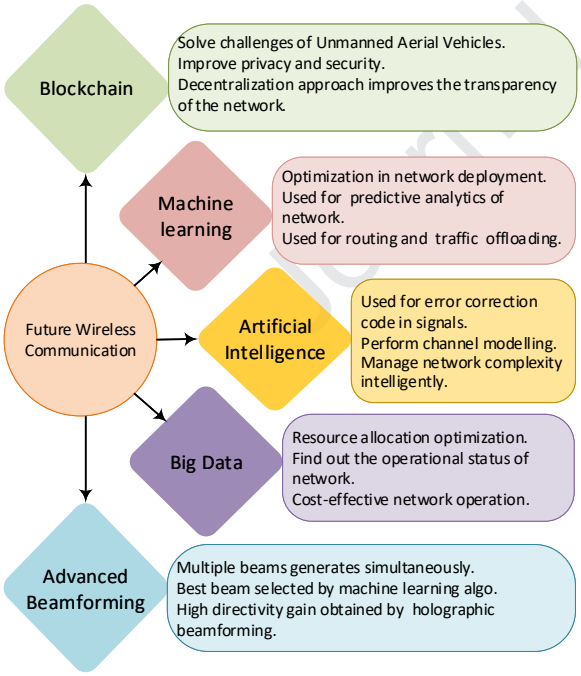

Fig. 35: Advance communication technologies i.e. Next step towards future wireless networks

The green cognitive radio networks have a great potential to handle inevitable demands of extra spectrum in next generation wireless networks. But have some limitation in applying methods in existing communication systems. The most prominent limitations of the current methods are such as practical hardware realization, interference and handoff management, proper traffic load balancing among different candidate networks, non-zero latency in real-time services and applications, appropriate densification limit of a network (how much density of the network is adequate?), lack of self-optimizing and self-configuring network devices, complex circuitry, requirements of system reconfiguration, cost factor and privacy and security management.

- *Lesson 3*: ICT attempts to achieve the target to reduce 13% of the global GHG emissions by 2035 with the help of– i) Development of miscellaneous IoT applications to support efficient energy management ii) Advancement of multimedia applications and mobile broadband and iii) Designing and development of system software by introducing functionality of the network, to analyze the behavior of the network's traffic and improving spectral efficiency gains. To pursue energy-efficient green communication, the impact of the mobile life cycle on the carbon footprint is discussed.

Authors' detail:

Akanksha Srivastava has received her B. Tech. degree in Electronics and Communication Engineering from Uttar Pradesh Technical University (now Dr. A.P.J. Abdul Kalam Technical University), Lucknow, India in 2010, and her M. Tech. degree in Electronics and Communication Engineering from Dr. A.P.J. Abdul Kalam Technical University, Lucknow, India in 2014. She is pursuing her Ph.D. degree in Electronics and Communication Engineering from Delhi Technological University, Delhi, India. She is also working as a Principal Investigator in a project under Women Scientists Scheme-A (WOS-A) funded by Department of Science and Technology, Government of India (vide File No. SR/WOS-A/ET-154/2017) at the department of electronics and communication engineering, Delhi Technological University, Delhi. From 2014 to 2018, she was an Assistant Professor in the Department of Electronics and Communication Engineering at Pranveer Singh Institute of Technology, Kanpur, India. She has various publications in conferences, journals and book chapters, etc. Her current research includes Green Communication, Energy Efficient Wireless Networks, Cognitive Radio Networks, Wireless Communication, and Heterogeneous Networking.

Mani Shekhar Gupta has received his B. Tech. degree in Electronics and Communication Engineering from Uttar Pradesh Technical University (now Dr. A.P.J. Abdul Kalam Technical University), Lucknow, India in 2009 and his M. Tech. degree in Electronics and Communication Engineering from National Institute of Technology, Hamirpur, India in 2011. He is currently pursuing his Ph.D. degree in Electronics and Communication Engineering from National Institute of Technology, Hamirpur, India. He worked as an Assistant Professor in Department of Electronics and Communication Engineering at Pranveer Singh Institute of Technology, Kanpur, India, from 2011- 2017. He has qualified national level Graduate Aptitude Test in Engineering (GATE) and was a recipient of the GATE Financial Scholarship from 2009 to 2011. Currently, he is a recipient of research fellowship from Ministry of Human Resource Development (MHRD), Government of India. He has various publications in conferences,

journals and book chapters etc. His current research includes Cognitive Radio Networks, Vehicular networks, Spectrum and mobility management, Wireless communication, Next Generation Networks, Resource allocation and Heterogeneous networking.

Gurjit Kaur is an Associate Professor in the Department of Electronics & Communication Engineering at the Delhi Technological University (DTU), Delhi, India and having 16 years of research and teaching experience in well-reputed institutes. She was awarded a 'Gold Medal' by former President of India Dr. A P J Abdul Kalam for being the overall topper of the Punjab Technical University, Jalandhar in B.Tech program. She has completed her M. Tech degree in 2003 and Ph.D. in 2010 from PEC University of Technology, Chandigarh. She has also authored many books at the international and national level. She contributed various book chapters in well-renowned publishers' books i.e., IGI, Springer, CRC, etc. For her outstanding research work she received Prof. Indira Parikh 50 Women in Education Leader Award in World Education Congress, Mumbai, India in 2017. Due to her pioneer research, her name is also listed in Who's Who in Science and Engineering Directory, USA and her biography was also published by International Biographic Centre, Great Britain as 2000 Outstanding Scientists. She is also a reviewer of various reputed journals. Her research interests mainly include Optical CDMA, Wireless Communication system, high-speed interconnect and IoT.

***Abstract*— Crack detection is of pivotal importance in civil engineering and other related applications. Traditional methods of human inspection are tedious and severely limited. Automated crack detection by conventional image processing techniques is challenging due to their inability to discriminate crack features from background noise. Inhomogeneous lighting, shadows, and surface finish hinder the performance of digital image processing methods. The use of convolutional neural networks has helped achieve remarkably better results in the field of computer vision. Ensemble learning is an approach to aggregate the results of a number of individual models for classification or regression. Ensemble learning for crack detection has been implemented using deep convolutional neural networks (DCNN) in this paper. The models are evaluated on a number of performance metrics, namely–(i) accuracy, (ii) precision, (iii) recall (iv) Matthews correlation coefficient (MCC), (v) AUROC, and (vi) F1 score. Experimental results show the robustness of the ensembling method and offer promising scope in crack detection. They outperform the current best performance on open source concrete crack dataset. The ensemble models achieved much better performance than their individual counterparts with the best ensemble achieving a validation accuracy of 99.67%.**

Keywords—crack detection, convolutional neural network (CNN), transfer learning, ensemble learning

I. INTRODUCTION

Concrete structures suffer from decay over time by various means. Cracks develop on the surface, which need to be properly detected. A need for Structural Health Monitoring(SHM) arises as the properties of concrete depends on many factors and are often hard to predict in practice. SHM is a process aimed at providing real-time and accurate information about structural conditions and performance on a proactive basis. SHM is very economical and provides good returns. The cost of installing and implementing an SHM system is only 0.5% to 3% of total construction and repair costs, respectively [1]. Having an SHM system in place can save a lot of money and human lives. Manual detection of cracks cannot set a uniform standard and is subject to an individual's expertise. Automated crack detection overcomes this problem by precise inspection without human error. The application of traditional algorithms of image processing for crack detection led to satisfactory results.

Yamaguchi et al., 2010 [2] used a percolation based image processing method for fast crack detection. A terminate and skip procedure was used where only the crack pixels were checked instead of the background. Circularity of percolated region was then found to set the threshold for classifying pixels. Salman et al., 2013 [3] proposed to use a Gabor filter of a given orientation, which was convolved with the input pre-processed image. After the completion of convolution, the real component of the response out of the kernel was threshold to generate a binary output image. Finally, the binary images resulting from the differently oriented filters were combined by logical OR operation to produce an output image that contained detected crack segments. Yiyang et al., 2014 [4] proposed a glass crack detection algorithm using image processing techniques. The crack information was obtained by making use of image pre-processing, segmentation, and feature extraction of the glass crack image. The pre-processing task involved image smoothing filtering and image sharpening. A twice threshold segmentation was used in [5], and road marking was removed by the Otsu threshold algorithm. Segmentation was done by the improved adaptive iterative threshold segmentation algorithm. Shan et al., 2016 [6] proposed a Canny-Zernike combination algorithm for image processing. SIFT (Scale Invariant Feature Transform) was used for feature extraction. The nearest neighbor algorithm was applied to match the feature points extracted by the SIFT algorithm. Inhomogeneous illumination of the surface and discriminative crack features being confused with background noise are a challenging task for image processing methods.

The image processing algorithms have now been largely outperformed by artificial neural network-based methods. Of the various neural networks in use, the most significant for computer vision is the convolutional neural network (CNN). It offers the advantage of lesser computation in terms of a lesser number of weights to train for a single kernel that can be applied repeatedly to all the portions of the image. It is also able to learn features automatically. The first use of CNNs for crack detection was implemented by Zhang et al., 2016 [7]. They applied CNN on images downsized from a road image of 3264 x 2248 and achieved substantial accuracy. Li et al. [8] used a modified version of GoogLeNet for concrete crack detection. A deep learning-based CNN architecture was proposed to detect cracks in concrete surfaces in [9]. A comparative study was conducted to show the performance difference between CNN and traditional image processing techniques for the purpose of crack detection [10]. The vision-based method using deep CNN performed quite better than the traditional Canny and Sobel edge detection technique. Li et al., 2019 [11] used AlexNet as the CNN architecture for crack detection, and the model was trained for optimum learning parameters.

Ensemble learning is the approach to use multiple models for accurate prediction. The results of the individual models are combined by various methods to achieve better accuracy. The technique of ensembling has been applied in various domains. Shahin at al. [12] discuss the improved accuracy of their approach using ensemble learning for the problem of skin lesion classification. Ensemble models yield promising results when the individual models have significant diversity among them [13].

In this paper, ensemble learning is applied with the motive of crack detection. The paper is structured in smaller sections for better understanding. Section II discusses the concept of Convolutional Neural Networks. Section III is based on ensemble learning. Section IV elaborates the methodology adopted in this paper for crack detection. Section V includes the specifications of the dataset used. Section VI lists the results. Analysis of results is done in section VII. Section VIII presents the conclusion.

II. CONVOLUTIONAL NEURAL NETWORKS

A Convolutional Neural Network (CNN) is a deep learning algorithm that takes an image as an input, learns the various features of that image, and then classifies them into their respective classes. The CNN architecture is similar to the pattern of the neurons in a human brain. It enables machines to perceive the world as humans do by applying relevant filters to capture the spatial and temporal dependencies of an image successfully. The convolution layer and pooling layer are used in feature learning. The Fully Connected layers and the softmax layer are used for the classification task. All the mentioned components are explained in detail as follows:

A. Convolution Layer

It is the core building block of a Convolutional Network and does most of the computational tasks. The input image is essentially an array of pixel values. The kernel or a filter is also an array of numbers (called weights or parameters). The depth of this filter is the same as that of the input. The filter starts convolving around the input by multiplying the pixel values element-wise. These multiplications are then summed up to a single number. This process is then repeated for every unique location. After sliding the filter over all locations, an activation or feature map is obtained. The objective of this operation is to extract high-level features such as edges from the input image.

B. Pooling Layer

The pooling layer reduces the images into a form that is easier to process, without losing critical features. It is responsible for reducing the spatial size of the feature map. Through dimensionality reduction, the computation cost to process the data is reduced. This layer also controls overfitting to some extent. There are two types of pooling available - max pooling and average pooling. Studies have shown that max pooling performs a lot better than average pooling. The convolution layers and pooling layers together form structural units which can be increased to suit the complexity of the image but at the cost of increased computational power.

C. Fully Connected Layer

The Fully Connected layer represents the typical layer of a neural network wherein the activation of a neuron in next layer is determined by its connections with all neurons in the present layer. The FC layers are attached to the end of the network. They take the output of the preceding layers as input and the last FC layer gives an N-dimensional vector output, where N is the number of classes. Each number in this vector represents the confidence of model for a particular class.

D. Softmax Layer

The softmax function limits the output between 0 to 1 and allows it to be directly interpreted as a probability. Since they are interpreted as a probability, they must sum to unity. A softmax layer is typically the final layer in a CNN.

III. ENSEMBLE LEARNING

Stochastic optimization is employed by deep convolutional neural networks (DCNNs) to learn. However, due to their sensitivity to small fluctuations in the training dataset, their performance gets limited as the variance in predictions becomes high. Random noise from training data also gets modeled into the learning process leading to overfitting of data. The objective is to reduce model variance and improve robustness and generalization. Training multiple, diverse models and pooling in their predictions is a practical approach to reduce variance. This is the basis of the ensemble learning process, which yields results that are superior to any individual model [14]. Ensemble learning is known to improve the performance of a model or reduce the probability of an unfortunate selection of a poor one [15]. However, merely using ensemble learning does not guarantee better results. Only smartly chosen ensemble models would provide a substantial improvement in the results.

Most of the ensemble learning algorithms work on different data distribution schemes to individual models and the different combination methods of constituent classifier results. In the proposed work, the individual models are trained by using the whole of the training data.

IV. METHODOLOGY

For the purpose of crack detection, the concept of ensemble learning is applied as it provides improved results. A flow diagram illustrating the steps involved is shown in Fig.1.

Various pre-trained CNNs are used as the base models which vary in architecture and performance. A fastai library [16] is used for deep learning, which is an open-source library built on top of Pytorch [17] and provides powerful learning techniques. The pre-trained CNN models with ImageNet [18] are used. These models are fine-tuned for the specific task of crack detection. The fastai library provides good default values for the hyperparameters involved and the option to train different layers of the network at different learning rates. Hence, the initial layers which recognize basic image features are trained at lowest learning rate and the final layers at the highest learning rate. All the models are trained on the training data and their performance is analyzed on the common validation set.

For building ensemble models, a combination that is expected to show improved results should be selected. The selection criteria has been used to choose the base model combination is based on the following two characteristics-

- The diversity in architecture of the individual base models
- Analyzing the confusion matrix of each model on the crack dataset. The critical parameters of false negatives and false positives were taken into account while deciding the combinations of ensemble models which could lead to improvement.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 28,2020 at 05:00:11 UTC from IEEE Xplore. Restrictions apply.

The selected model combinations are then used to build ensemble models. The model combinations are indexed in table III. The ensembling methods used in this paper include the most popular techniques of averaging, voting and weighted voting [15]. Using these methods on all the model combinations, various ensemble models are built. The ensemble models are then validated on the same validation dataset used for individual base models and the performance is analyzed.

Let there be *M* number of models for classifying the sample into *C* classes. Then the various ensembling methods may be formulated as below.

1) Averaging

This method is based on taking the simple algebraic average of the predictions of the base models and then treating the average as the final prediction of the ensemble model. If the prediction of the i^{th} model for the j^{th} class to an image input *X* be given as $y_{i,j}(X)$ then the ensemble prediction for the j^{th} class will be expressed as

$$Y_{e,j}(X) = \frac{1}{M}\sum_{i=1}^{M} y_{i,j}(X) \quad (1)$$

where the subscript *e* denotes the prediction by the new ensemble model.

The final classification label of the ensemble model for image input *X* is generated as

$$\hat{Y}_e(X) = class(\max(Y_{e,1}(X), Y_{e,2}(X), \dots, Y_{e,C}(X))) \quad (2)$$

2) Majority Voting

In this method, the individual model predictions are first used to generate classification labels. For each output label $\hat{y}_{i,j}(X)$ generated by a base model corresponding to full support to j^{th} class, the vote $V_j(X)$ of the j^{th} class increases by 1. The class which gains the highest votes is taken to be the final predicted class by the ensemble model.

The final classification label of the majority voting ensemble model can be represented as

$$\hat{Y}_e(X) = class(\max(V_1(X), V_2(X), \dots, V_C(X))) \quad (3)$$

3) Weighted Voting

In this method, the votes of a model to a certain label are weighted in proportion to the performance of the model. Equivalently, the vote of a model with higher accuracy is given more preference.

The individual model predictions are first used to generate classification labels. For each output label $\hat{y}_{i,j}(X)$ generated by a base model corresponding to full support to j^{th} class, the vote $V_j(X)$ of the j^{th} class increases by w_i.

The symbol w_i denotes the weight factor assigned to the vote of i^{th} model and is given as

$$w_i = \frac{a_i}{\sum_{i=1}^{M} a_i} \quad (4)$$

The term a_i is the validation accuracy of the i^{th} model.

The final classification label of the weighted voting ensemble model can be represented as

$$\hat{Y}_e(X) = class(\max(V_1(X), V_2(X), \dots, V_C(X))) \quad (5)$$

V. DATASET AND TRAINING

For training and validation, concrete crack dataset [11] is used. This dataset [11] for training and validation was built out of 1250 images of bridge towers and anchor chambers of a suspension bridge in Dalian, Liaoning, China. The images were captured using a smartphone at a distance of 0.5-1.0m to the surface and were cropped into 256x256 pixel dimension images. Finally, a dataset of 60,000 images was prepared after manual classification.

The images include cracks in varied lighting conditions and situations for enhanced robustness of model. The dataset specifications are given in table I. Sample figures from the dataset are shown in Fig.2.

TABLE I

SPECIFICATION OF THE DATASET USED

Type	Training	Validation	Total
Positive	24k	6k	30k
Negative	24k	6k	30k
Total	48k	12k	60k

VI. EXPERIMENTS AND RESULTS

The models have been trained using the fastai library with Tesla P100-PCie GPU for acceleration on Google Colab, which is a cloud computing platform for machine learning.

The best ensemble model in our experiments outperforms the previous best results as shown in table II.

Let TP, TN, FP and FN denote the true positives, true negatives, false positives and false negatives for the model. Then the performance metrics may be expressed in these terms. The metrics used are listed below.

A. Accuracy

It is a measure of the number of correct predictions made over all kinds of predictions made.

$$Accuracy = \frac{TP + TN}{TP + FP + FN + TN} \quad (6)$$

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 28,2020 at 05:00:11 UTC from IEEE Xplore. Restrictions apply.

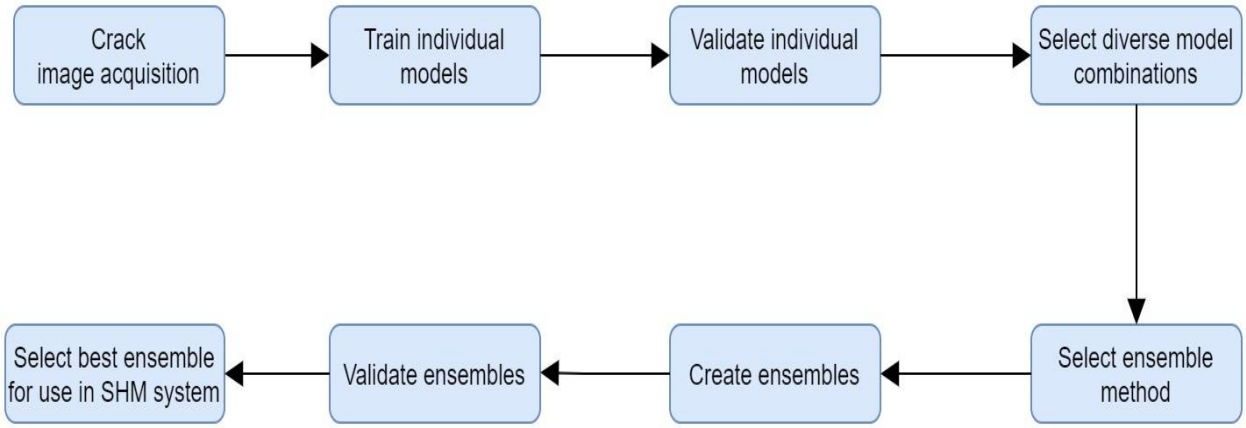

Fig. 1. Flow Diagram for the technique

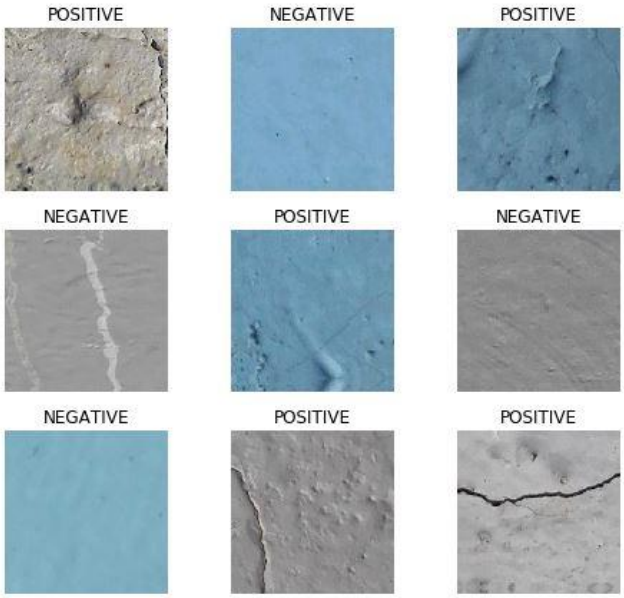

Fig. 2. Sample Images from the dataset

B. Precision

Precision is a measure of what proportion of predicted positives were truly positive.

$$Precision = \frac{TP}{TP + FP} \tag{7}$$

C. Recall

Recall is a measure of what proportion of actual positives were classified correctly.

$$Recall = \frac{TP}{TP + FN} \tag{8}$$

D. Matthews Correlation Coefficient (MCC)

MCC is a correlation between observed and predicted binary classifications.

$$MCC = \frac{(TP.TN) - (FP.FN)}{\sqrt{(TP + FP)(TP + FN)(TN + FP)(TN + FN)}} \tag{9}$$

E. AuROC

AuROC is a measure of how well the probabilities of the positive classes are separated from the negative classes.

F. F1 Score

F1 score is the harmonic mean of recall and precision. It maintains a balance between recall and precision.

$$F1\ Score = 2\,.\frac{Precision.Recall}{Precision + Recall} \tag{10}$$

TABLE II
PERFORMANCE COMPARISON ON DATASET WITH PREVIOUS WORK

Work	**Accuracy**
Li et al. [8]	99.39
Li et al. [11]	99.06
Proposed Ensemble Model	99.67

Results based on the ensembling method are shown for various models in table IV, V, VI and VII.

VII. DISCUSSION

The comparative studies in the form of tables provide a deep insight for analysis. The results are discussed based on the three ensemble methods used. The model combinations are indexed in table III. The models m1-m5 are the individual constituent models. The models m6-m11 are the combinations of two models. Similarly models m12-m14 represent the three-model combinations and m15-m16 are the four-model combinations. Model m17 is the total-ensemble model built using all of the models m1-m5. All ensemble combinations (m6-m17) have been implemented using the three ensembling techniques of averaging, majority voting and weighted voting. Table IV shows the performance of the base models. The results based on the ensembling methods are discussed below.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 28,2020 at 05:00:11 UTC from IEEE Xplore. Restrictions apply.

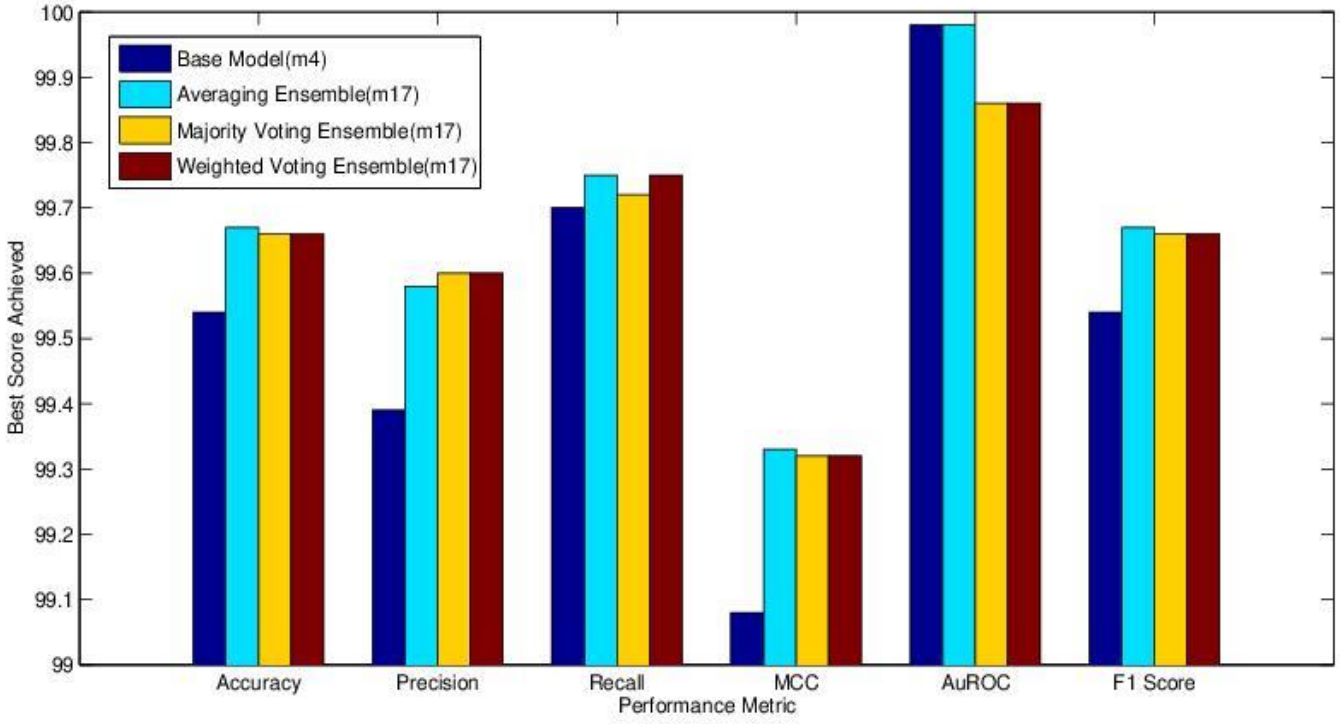

Fig. 3. Performance improvement of ensemble model m17 over the best single model m4

TABLE III

MODEL COMBINATIONS LIST

Model Index	Base Models
m1	ResNet 34
m2	VGG 19
m3	SqueezeNet
m4	DenseNet
m5	AlexNet
m6	DenseNet, SqueezeNet
m7	ResNet, DenseNet
m8	DenseNet, VGG
m9	VGG, ResNet
m10	ResNet, SqueezeNet
m11	SqueezeNet, VGG
m12	ResNet, VGG, DenseNet
m13	DenseNet, VGG, SqueezeNet
m14	SqueezeNet, ResNet, DenseNet
m15	DenseNet, ResNet, VGG, AlexNet
m16	SqueezeNet, AlexNet, VGG, ResNet
m17	Total-ensemble

A. Averaging Based Ensemble Models

The results on the concrete crack dataset can be assessed very well by accuracy since this dataset is balanced in terms of number of images of both classes. Accuracy helps to determine the degree of correct prediction of a model. This includes correct prediction efficiency for both classes-positive and negative. From table IV, it has been noted that, the maximum accuracy for any single model is 99.54 for m4 (DenseNet). However, the top accuracy of 99.67 is achieved using ensembling as shown in table V. Almost all averaging-based ensembles perform better than the best model in the combination.

The top precision of 99.60 is achieved by model m16 which is an improvement over the 99.52 precision value of m1 (ResNet). The improvement in precision value implies that the false alarms in the system are brought down. This helps to reduce the efforts of the visual inspection team which will be given lesser false alarms hence leading to better utilization of resources. Among the single models, the recall value of 99.73 is highest for m2 (VGG19) while ensemble models m8 and m13 have recall of 99.75. Since recall represents the ratio of predicted cracks out of total cracks, a high value of recall is very important. The F1 score presents a combined perspective of precision and recall, and hence higher F1 score is generated when model provides lesser false alarms and is able to detect most of the cracked images correctly. The highest value for F1 score among the single models is that by m4 (DenseNet) with a value of 99.54. This value is significantly improved to 99.67 in the total-ensemble model (m17). The AuROC metric helps to understand the quality of the predictions of the model and how well it can differentiate the two classes. The AuROC value of 99.98 of m4 is maintained in most of the ensemble models. This shows that the models are confident of the predictions they make. The MCC metric may be used when detection of both classes is to be given equal importance. It represents the correlation between the predicted and true classes and is very useful when the dataset is unbalanced. The model m4 provides the best value of 99.08 among the individual models, while the total-ensemble achieves the MCC score of 99.33.

B. Majority Voting Based Ensemble Models

Table VI shows the performance of ensemble models based on majority voting. In this method, the class label which obtains maximum votes from all the models is termed as the true label for the given data sample.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 28,2020 at 05:00:11 UTC from IEEE Xplore. Restrictions apply.

TABLE IV

PERFORMANCE OF INDIVIDUAL MODELS

Model	Accuracy	Precision	Recall	MCC	AuROC	F1 score
m1	99.48	**99.52**	99.43	98.95	99.97	99.47
m2	99.42	99.12	**99.73**	98.85	99.97	99.43

TABLE VIII

TABULAR COMPARISON FOR PERFORMANCE IMPROVEMENT IN METRICS

Model Type	Accuracy	Precision	Recall	MCC	AuROC	F1 score
Single Model	99.54(m4)	99.52(m1)	99.73(m2)	99.08(m4)	99.98(m4)	99.54(m4)
Averaging Ensemble	99.67(m16,m17)	99.60(m16)	99.75(m8,m13,m17)	99.33(m16,m17)	99.98(most models)	99.67(m16,m17)
Voting Ensemble	99.66(m17)	99.60(m17)	99.75(m8,m13)	99.32(m17)	99.86(m15,m17)	99.66(m17)
Weighted Voting Ensemble	99.66(m17)	99.60(m17)	99.75(m13)	99.32(m17)	99.86(m15,m17)	99.66(m7)

It can be observed that for even number of models in an ensemble, there is a chance of a tie for the number of votes that each label gets. Hence, the confidence of prediction to the given label is considered to resolve such a tie. No such corrective measure is required for voting ensembles with an odd number of models. As can be seen, almost every ensemble model outperforms the individual best model in the combination.

As can be seen from table VI, the maximum performance is again achieved by the total-ensemble model (m17) on all the parameters except the recall metric. The individual maximum recall of 99.73 for model m2 is outperformed by voting based m8 and m13 models with 99.75 recall score. The recall value for m17 is 99.72 which is almost the same as that of m2. The AuROC value of the best voting ensemble at 99.86 (for m15 and m17) is lower than the individual best of 99.98(for m4). However, the value is still very high and can be termed as a confident distinction ability between the two classes.

The voting ensembles improve the accuracy of 99.54 (for m4) to 99.66 (for m17), the precision of 99.52 (for m1) to 99.60 (for m17), the recall value of 99.73 (for m2) to 99.75 (for m8 and m13), f1 score of 99.54 (for m4) to 99.66 (for m17) and the MCC value of 99.08 (for m4) to 99.32 (for m17).

C. Weighted Voting Based Ensemble Models

The weighted voting method provides higher vote value to model with better accuracy. The results are tabulated in table VII. As expected, the weighted voting results of ensembles with 2 constituent models (m6-m11) are the same as that of the better performing model among the two in the ensemble. For three or more model combinations(m12-m17), the weighted voting ensemble outperforms the best model in the combination.

The weighted voting ensembles improve the accuracy of 99.54 (for m4) to 99.66 (for m17), the precision of 99.52 (for m1) to 99.60 (for m17), the recall value of 99.73 (for m2) to 99.75 (for m13), f1 score of 99.54 (for m4) to 99.66 (for m17) and the MCC value of 99.08 (for m4) to 99.32 (for m17). It is observed that the best AuROC value of 99.86 (for m15 and m17) is lower than the individual best of 99.98 (for m4). However, the value is still very high and demonstrates a good confidence in the predictions.

Hence, it can be concluded that the ensemble models markedly improve the performance than the individual models and the total-ensemble model (m17) shows best results for most of the performance metrics.

D. Comparative analysis of ensemble methods for crack detection

Since the concrete crack dataset is a balanced one, the accuracy provides a good direct estimate of performance. The performance improvement in the metrics by various ensemble methods is compared in table VIII. Among the constituent models, DenseNet (m4) is the best performing, while the total-ensemble model (m17) is the best among the ensembles. The accuracy improvement is from 99.54 to 99.67. The recall improvement is from 99.73 to 99.75 in the m13 model based on all the three methods of ensemble. The precision value is improved by all the three ensemble methods from 99.52(for m1) to 99.60 (for m17). The f1 score is again improved best by averaging method from 99.54 (for m4) to 99.67 (for m16, m17). The MCC metric which gives equal focus to both class labels without any bias, is improved from 99.08 (for m4) to 99.33 (for m16, m17) in the averaging ensemble. The AuROC value is already high and maintained in averaging ensembles which denotes the quality of the classifying decision.

It is observed that the best performing single base model on the given dataset is DenseNet (m4). The total-ensemble model(m17) achieves improvement in almost all the metrics. The performance improvement of the total-ensemble model (m17) over the best single model m4 is shown in Fig.3.

It is important to note that roughly all the parameters are boosted the most by the averaging method of ensemble. This is intuitively expected as the algebraic aggregation of predictions is done and then converted to class labels. It is observed that m16 and m17 based on averaging perform the same on most of the metrics except precision and recall. However, m17 outperforms m16 in other ensembling methods. This shows the strength of the averaging method which helps to achieve improved results. Owing to the simplicity and the algebraic nature of combination, for most of the cases, a simple averaging method may be used to build an optimal ensemble model with a number of diversified models.

VIII. CONCLUSION

In this paper, ensemble learning has been proposed for the problem of concrete crack detection. The individual CNN models are trained and then various ensemble models based on ensemble methods are built. The ensemble models have shown to boost the performance of the individual models. The best ensemble model gives benchmark results with an accuracy of 99.67% on 12k images used for validation. The results offer promising scope of application of more ensemble-based algorithms for crack detection.

***Abstract*— Nowadays, Internet is facing an exponential increase in the number of electronic devices interfaced through it. Previously, there is a limit of connecting only mobile and PCs (personal computer) with the internet but now millions of devices can be connected using the concept of IoT (internet of things). Hence, IoT is able to communicate data between machine to machine and the data that is previously available to private server now easily available to the internet so that it can be accessed efficiently. This paper show the increase in the usage of IoT in monitoring like applications. Smart farming is the technique which intend to provide all the necessary resources for the specified amount of time. These resources required are light intensity, ambient temperature required, relative humidity, soil moisture content, pH reading of the soil. The central idea is to sense all these parameters one by one and take the final decision accordingly. A sensor node should be developed for sensing all the required resources parameters and subsequently send the data to the cloud for further processing. After getting all the required resources values our final aim is to predict the crop production using various data mining techniques. As the human lives are primarily depended on the food resources, the agricultural process need to be efficient and this efficiency can be enhanced if there is an accurate amount of resources. By getting the accurate amount of resources, Data mining techniques such as Random forest, KNN, SVM are used to analyze the crop production in advance such that farmer always have an upper hand on it and by comparing with the previous trend he will be able to detect which kind of parameter is accurate and which is not. A User defined site is designed to monitor all these values of agricultural process.**

I. INTRODUCTION

Agriculture is the foremost only field industry where the recent improvement in technology has not been welcomed in huge number. One of the main reason regarding this issue is poor lethargic condition of the farmers in developing countries say India. The scarcity of agricultural products is also increasing day by day due to two main reasons, first one is overpopulation and the second one is urbanization. Considering the case of overpopulation, it increases the demand of agricultural resources and with the case of increasing population it emphasis the better growth of farming products but due to globalization the most of agricultural land is taken by big industries and they convert these land into non-agricultural land. Basically the rural area for farming is decreasing day by day and with that decrease the agricultural resources are also decreasing. Therefore, the need of an hour is to take a look at the situation carefully and emphasis is given to improve the crop production by consuming the resources conservatively without wasting the existing resources. Smart farming is one such methodology to do it. In this type of farming the crop is fed up with the sufficient quantity of resources required for it to grow and by taking the calculated amount of time. In normal Traditional farming method, there is a time based irrigation system i.e. farmer know exactly that after certain limited time (few days) he needs to irrigate his crop. But due to the lack of knowledge farmer is not capable of irrigating his/her field at the exact duration of time which significantly lead to a wastage of water. Hence to overcome such issue smart farming method is employed. To overcome the issue of traditional farming, a soil moisture detection sensor is implanted at the observation site to get the soil moisture content and with this the crop is irrigated accordingly. Similarly, soil moisture sensor, temperature sensor, Humidity sensor and pH sensor are used around the plant to get the desired value, which helps in reducing the exploitation of extra resources used initially in traditional farming. Soil moisture is important in determining the physical

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:57:29 UTC from IEEE Xplore. Restrictions apply.

structure of the plant whereas all the other sensors play a major role in photosynthesis. This paper basically suggest an idea to generate the sensor node which is able to send the data to the central node i.e. to the thing speak cloud. This paper consist of methodology used in smart farming and after visualizing the exact percentage of resources required for crop to appropriately predict the crop yield using various data mining techniques. Data Mining [1] is a procedure to retrieve useful information from very enormous datasets. This technique is used to predict the crop production in advance so that the farmers could take an immediate measures accordingly as the crop demands. It also helps government to get the value of exact MSP (minimum selling price) for farmers. It aims to predict the crop prediction by using various regression and classification methods like multiple linear regression, SVM, Random forest, KNN etc. With these techniques of data mining, the effect of various parameters (sensor node parameters in general) on the prediction of crop production has been studied.

II. LITERATURE SURVEY

In paper [2] author tries to explains the requirement of WSN in agricultural field so as to increase the crop productivity. This paper [2] also give emphasis on the need of smart farming techniques in today's scenario which ultimately analyze the architecture of proposed system by monitoring the environment parameters. The paper [3] suggest the usage of IoT in the field of agriculture. It basically shows how the intermediate chains of agriculture are connected and how IoT can be useful in doing it. It also tell us about all the technologies that are designed by using the concept of IoT. In paper [4] author explained the system using the feature of GPS to monitor the agricultural field. The prime aim of GPS is to look at the data sensed at sensor node and transfer this data using RS232 that are obtained from sensor node to the central node. The proposed system in paper [5] shows the data of light intensity factor around the crop and saving it in a excel sheet. The data stored in database is further used to compare and analyze it later on. In this system only the light intensity parameter is targeted as their only parameter to control the crop production. The author in paper [6] tried to sort out the problem of unequal rain distribution in crop production by controlling the parameters like soil moisture sensor and pH sensor. Arduino is used as a controlling unit which is further also used to communicate the values to the cloud part. The paper [7] shows the problem of food scarcity in Africa. It significantly put forward a schematic way which would predict total crop production needed to meet the African native citizens' needs. The model of Artificial Neural Network is built and subsequently the prediction is done. It helps in predicting the annual amount of crops needed by 2021. The paper [8] defined the comparison algorithms which one can use to make a prediction of kharif crop in suburban zones of India. The algorithms is being executed on an open source platform named WEKA. Afterwards the various type of error is calculated of all the algorithms and being compared individually. In paper [9] author proposed smart agriculture based on IoT and cloud computing methods therefore the agriculture information cloud is constructed with different dynamic resources so as to achieve load balancing. Large amount of data obtained through RFID, and wireless communication are supported through the agriculture information cloud schematic model. In paper [10] the limitation of IoT is discussed. Actually there is communication delay between the cloud server and the end user application. So, paper proposes the model of AI-enabled edge computing to work for IoT applications. It improves the speed and range for the IoT applications. In paper [12] author tries to convey the various data mining techniques one can use while dealing with concept of IoT techniques and provide an overview of what is data mining and different techniques one must use while dealing with it having maximum efficiency.

III. PROPOSED WORK

Our proposed work is divided mainly into two broad categories. First is getting the sensor data from senor node used at the data transmission end and uploading each senor value to thingspeak so as to monitor it for further evaluation. Secondly, after getting sensor data values utilizing it for analyzing the crop yield production will have an upper hand on the future prediction of crop production.

A. Working with sensor node and thingspeak

The main central idea of the work is explained in Fig.1 given below which contains various components namely Relative humidity & ambient air temperature sensor, Soil Moisture content sensor, ph sensor, CO2 sensor, Microcontroller Unit (MCU) along with Wi-Fi module, Wi-Fi router, and thingspeak cloud. Finally the user defined website to monitor the details. Moisture content of the soil is measured with the use of electrode fabricated in it. The main responsible factor through which the soil moisture content changes is the resistance between the two terminals of the electrode. Whenever the soil moisture changes the resistance between the terminal changes. The change in the value of resistance and is the amount of soil moisture content percentage in the soil. A chip is also fabricated inside it which is used to convert the change in resistance to some analog voltage. It is fed with 3.3v input to give an output voltage in the range 0-3.3v. Output voltage signal is fed to MCU unit respectively. Soil moisture sensor have working voltage less than 5V DC and current limit is < 20mA. DHT11 is multivariable sensor which shows the reading of the relative humidity content in percentage and temperature of the atmosphere. It is capable of measuring both the humidity and temperatures single handedly. It senses the relative humidity using capacitors and temperature using the temperature dependent resistors through which change in the output voltage of the resistance gives the relative change in temperature from the previous value. The output waveform of this sensor is digital in nature hence noise must be removed

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:57:29 UTC from IEEE Xplore. Restrictions apply.

subsequently to protect the actual output wave from getting distorted. The digital nature of output pulse force the connection of the sensor to one of the input pins of MCU which is digital in nature. As the resulting output wave is of digital in nature, hence the data is updated after every 2 seconds timeframe. Humidity range of this sensor is 20-80% with 5% accuracy and temperature range of DHT11 is 0-50 degree Celsius with 2 degree accuracy. The sampling rate of DHT11 is 1 Hz and current limit of sensor is 2.5mA. MQ-2 sensor is used to sense the amount of CO2 in surrounding atmosphere. It is metal oxide semiconductor type gas sensor also known as chemiresistors as the sensing is based upon the change in the value of resistance as the gas comes directly in contact with the sensor material. Using the voltage divider rule, the concentration of gas can be found later on in voltage terms. It can detect gas concentration at 200pm-1000pm. It is fed with 5V dc input.

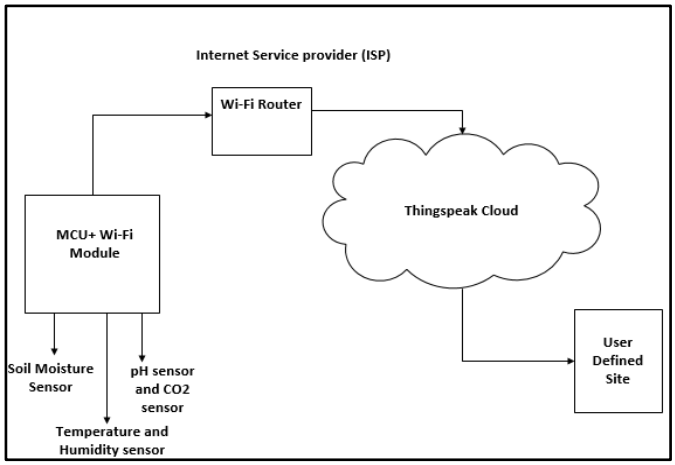

Fig 1. Block Diagram of proposed System

NodeMCU is microcontroller unit here. It is a board which functions on ESP8266 Wi-Fi module. Apart from General pins input-output it also come with additional feature i.e. Pulse Width Modulation capability and analog-digital converter (ADC) all these components are embedded in a single piece of board. NodeMCU basically collects the data from all the sensors that are mentioned above at its GPIOs pins. Data from humidity and temperature sensor is given at GPIO 0 while analog data from the soil moisture sensor is given at the analog input pin of the NodeMCU which having 10 bit of inbuilt ADC. As 10 bit gives a maximum count of 1023 units so it basically mapped the 0-3.3v value to 0-1023 count. It is based on Tensilica 32-bit RSIC microcontroller. The clock speed of the NodeMCU is 80MHz. The SRAM capacity of the device is 80KB. To code the MCU unit Arduino IDE software is used. To connect the NodeMCU board with Wi-Fi, hotspot of the cell phone could also be used which worked as router. Id and password are entered corresponding to the hotspot so that it can connected to the active internet connection.

Thingspeak is used as a cloud source in the above mentioned system. It is basically a platform service which allows you to visualize and analyze live data in the cloud. Certain number of channels are created in this platform where it analyzes the raw data obtained from sensors. Initially, 5 fields are created to analyze the data. The field names are soil moisture content, surrounding temperature, relative humidity content, CO2 and ph. correspondingly, API key is required to code the board that is used in our system. But with the help of thingspeak they are generate automatically. All the data are send in the form analog values so that the graphical representation of the sensor data can be plotted effectively.

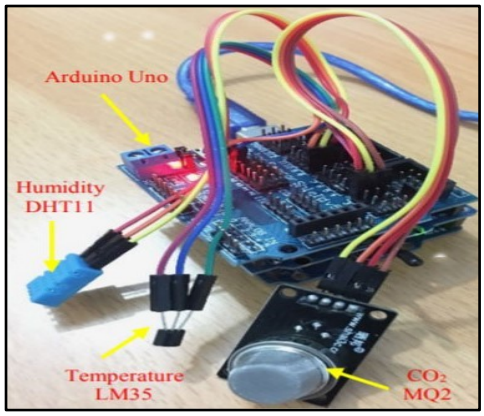

Fig 2. Interfacing of sensors

B. Implementation of Data mining

After sensing the values of all the sensors used above, the measurements of each parameters are stored in the form of datasets. After storing the value, various data mining techniques are used to predict the exact crop production in future. To predict the Crop production three major steps have to be done. These are datasets details, data preprocessing and building prediction model.

1. Datasets used

All the datasets were collected from the previously sensed value from the sensors used at observation site. Temperature, humidity, soil moisture, CO2 percentage and pH value are the common datasets used in the analysis. In addition to these values monthly rainfall dataset is taken from the publicly available records issued by Indian government. Area needed for crop production is also available at the government records. In addition to all these values yield of the crop is also taken under consideration so as to compare it with predicted value with per year yield (in tonnes/hectare).

2. Datasets preprocessing

Datasets preprocessing was done to collect all the datasets of the sensors and additional parameters in Microsoft excel. For every crop it consists of various columns namely: temperature, pH, Soil moisture, relative humidity, CO2 percentage, monthly

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:57:29 UTC from IEEE Xplore. Restrictions apply.

rainfall. By dividing the value of production by area under production, a value is obtained as somehow close to yield. Therefore, by removing the production column and adding yield column or vice-versa and finally saving the file in .csv extension.

3. *Data mining techniques*

Regression is the process performing a statistical modelling through which one can estimate the dependence of dependent variable over one or more than one independent variable. Predictant is the name given to dependent variable and predictors to independent variable. Considering production as dependent (target) variable and all others parameters whether it is area, temperature, soil moisture etc. as independent variables. Now, regression is somewhat similar to classification techniques. Algorithms used in this research paper are Random forest classification, KNN (K-Nearest neighbor) classification and SVM (Support Vector machine) classification.

4. *Constructing the prediction model using sci-kit learn libraries*

This paragraph discuss the building of prediction model of various data mining techniques namely multiple linear regression, K-nearest neighbor (KNN), Support vector machine (SVM) and random forest regression as discussed above using sci-kit learn and py-earth libraries. Sci-kit learn is an open source platform tool for data mining and data analysis via interfacing with python [10]. It provides classification, clustering and regression algorithms. Fig 3. Shows how to construct a prediction model for various data mining techniques as discussed above using sci-kit learn.

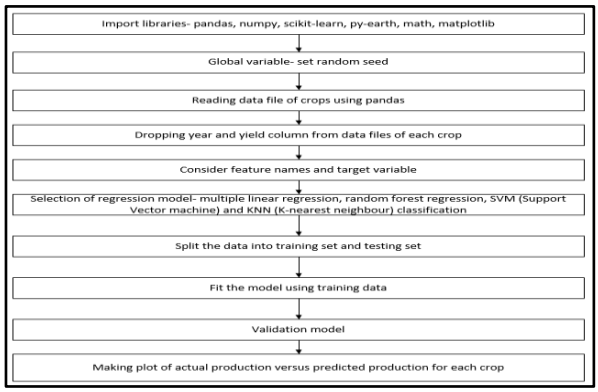

Fig 3. Procedure to construct the prediction model

In prediction model first of all the libraries are imported and then the global variable is created by random seeding method. As our dataset contain year and yield column but it also has production column which is Yield/Area. Hence, both these column are dropped. Now the code of above three classification is added and the data is divided inti training and testing data. Now training data is considered for evaluation and then respective algorithm is added to the data values and plot of actual vs predicted plot is created at last.

IV. RESULTS AND OBSERVATIONS

In the above mentioned work the output of the above methodology depicted in part A of the proposed work is depicted as the variation of values vs observation time and is monitored in thingspeak cloud server. The matlab representation of data sensed at the agricultural field is shown in the form of fields in channel. In fig 4, Temperature is plotted at thingspeak server, similarly in subsequent figures from 5-8 all remaining sensors plot have been obtained.

The plot of ambient temperature of surrounding and time interval is plotted and the values of temperature is recorded in Fahrenheit.

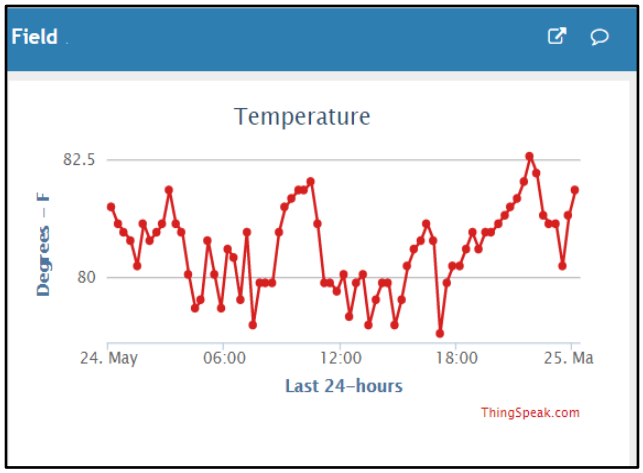

Fig 4. Surrounding air temperature

The plot of relative humidity and time interval is plotted and it is observed that maximum value recorded is 40 percent in humidity.

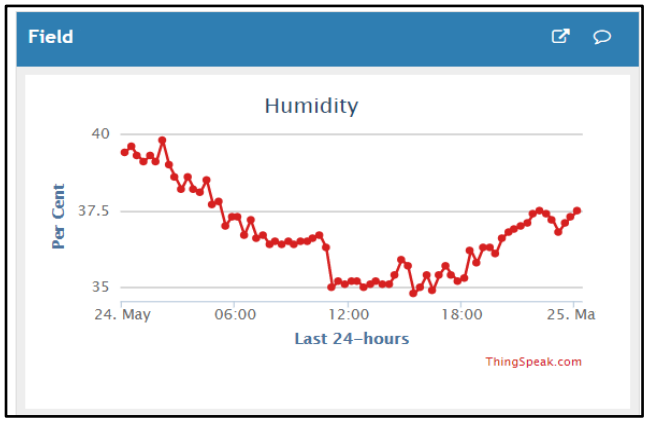

Fig 5. Surrounding air relative humidity

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:57:29 UTC from IEEE Xplore. Restrictions apply.

The plot of soil moisture content vs time interval is plotted and it is noted that soil moisture content is also in percentage.

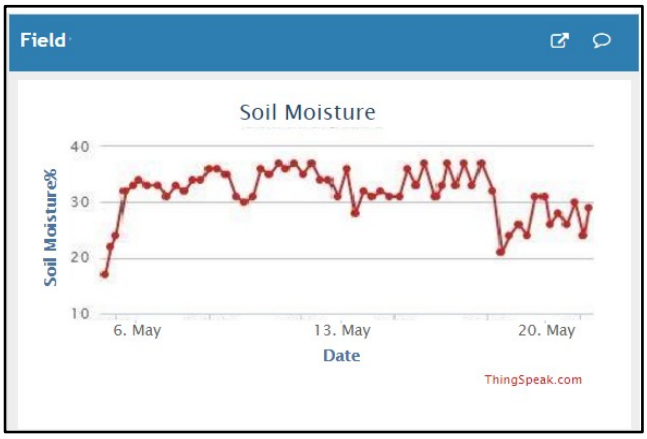

Fig 6. Soil moisture reading

The plot of CO2 vs. time interval is plotted and it is observed that maximum concentration of gas reaches at midway between 3-4 pm.

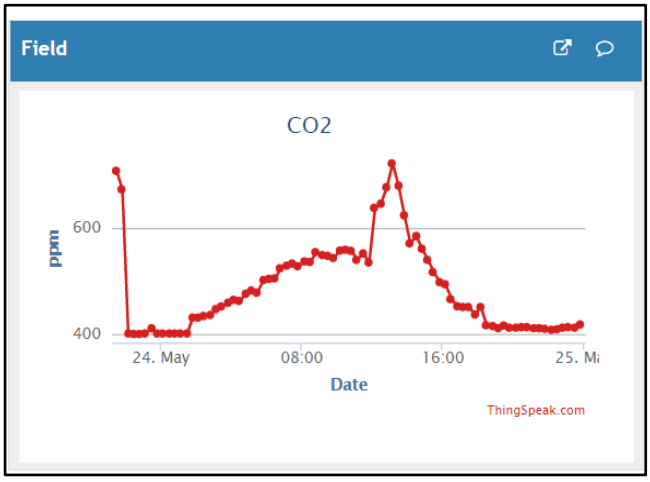

Fig 7. CO2 content in surrounding air

The plot of pH values vs. time interval is plotted and it is concluded that soil is alkaline in nature coz majority of time the value crosses 7.

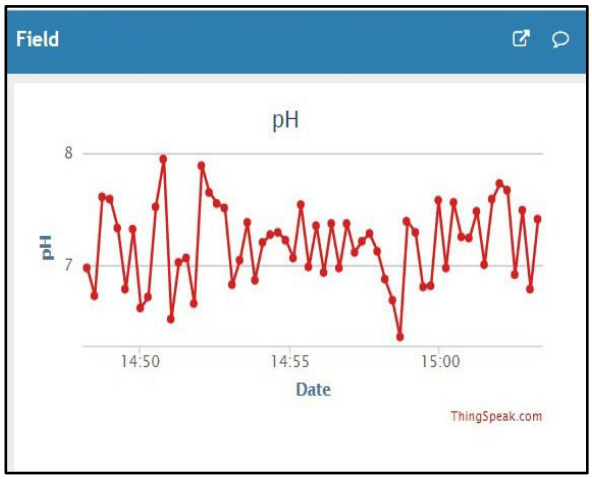

Fig 8. pH of soil

The result of the proposed work done in part-B i.e. visualization of predicted crop production using various data mining techniques mentioned above is shown in the form of plot between actual vs. predicted crop production. Each algorithms are applied on the given datasets and corresponding comparison plot is drawn as shown below.

The plot correspond to SVM is drawn and as SVM gives accurate data for more than 10000 data values peak is observed at this stage.

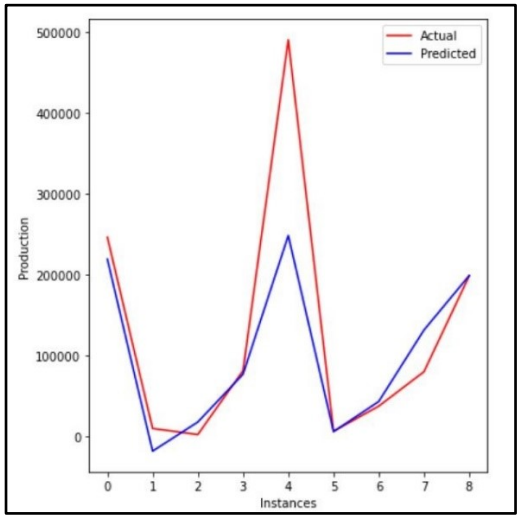

Fig 9. SVM classification- comparison between predicted and actual value of crop production

The plot correspond to KNN is drawn between the actual and predicted crop production. At small value instances the actual and predicted graph is exact replica but it fail to do so at higher values.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:57:29 UTC from IEEE Xplore. Restrictions apply.

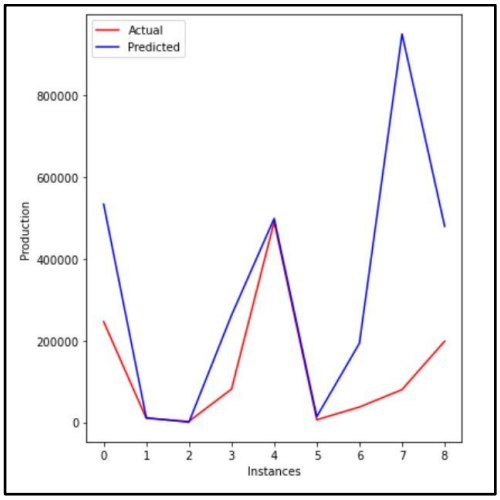

Fig 10. KNN classification- comparison between predicted and actual value of crop production

The plot correspond to Random forest classification which from graph it is concluded that it gives better accurate results on the small data values due to its accuracy in measurement of lower order data values as compared to higher values in actual vs. predicted crop production.

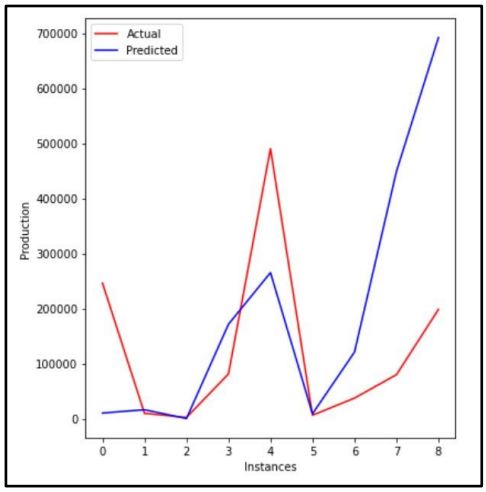

Fig 11. Random Forest- comparison between predicted and actual value of crop production

Based on the results of all three techniques an observation is done showing the accuracy percentage of calculated values with that of theoretical values. The result of observation is thus noted of various data values of dataset and are compared. A total of 11000 data values records are taken for observation.

TABLE I. ACCURACY COMPARISON OF RANDOM FOREST, SVM, KNN

NO OF DATA VALUES USED	Percentage of Accuracy of shown algorithms		
	Random Forest	SVM	KNN
0	0	0	0
2000	70.18	67.13	66.01
3000	70.56	65.4	67.49
4000	70.88	58.34	49.9
5000	68.46	61.58	56.6
6000	55.97	62.92	58.9
7000	63.89	63.01	62.0
8000	58.79	64.79	60.0
9000	60.25	65.25	78.69
10000	59.54	66.23	81.3
11000	56.2	68.8	87.9

In this table it is inferred that on the small number of data the random forest classification is the best to apply for prediction and for large no of data values KNN is recommended.

At the end a custom made webpage is designed having login page and crop prediction page. In crop prediction page after entering all the values of parameters and selecting the type of technique will get the content of Nitrogen, Potassium and phosphorus in soil related to that specific technique.

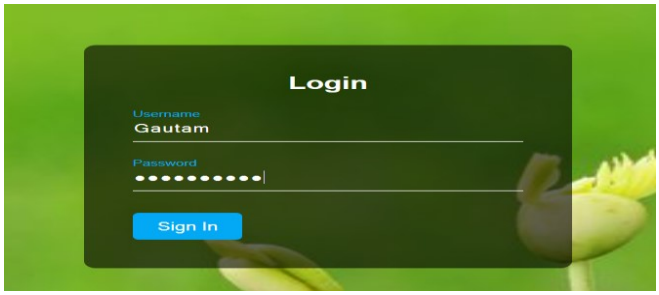

Fig 12. Login page of user defined site

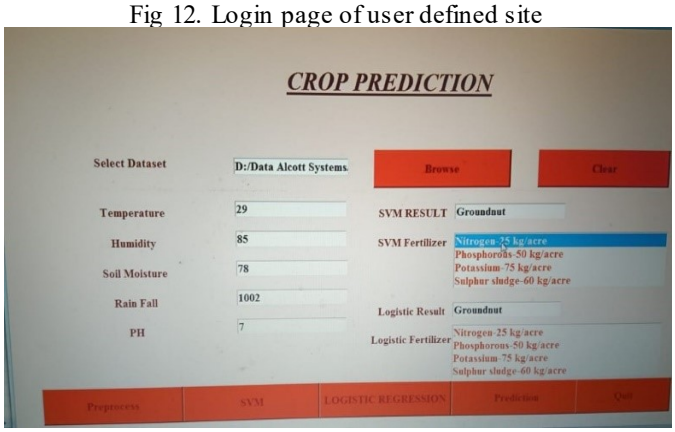

Fig 13. Crop prediction web page

V. CONCLUSION AND FUTURE SCOPE

This paper showed the transformation of system which is capable of collecting the data from senor node with the help of IoT in the field of agriculture. This system successfully able to sense the data and sending the data locally to thingspeak cloud which is further access by user in his/her custom made website. Data mining techniques are used to predict the crop production in advance so that farmer always got to know the extent of accuracy of their farming techniques. Various methods of regression and classification to get the output and their plot are plotted successfully. In future whether showing the data in custom made website can show the data in mobile app. Further, it detects the disease of the crop by using the concept of image detection. With that suitable type of fertilizer and pesticides is used to eliminate the disease. Artificial Intelligence and neural network could also be used as a regression method that promises to give more precise results.

ACKNOWLEDGMENT

We would like to thank Mrs. Bhavnesh Jaint, for his constant motivation and guidance during the project. Without his timely help and support, the completion of this paper wouldn't have been possible. We would also like to thank the publisher of the research papers from where we have taken references.

Estimation of COVID-19 Prevalence under Closed Population using Capture-Recapture approach

Rakesh Kumar[1], R.S.Mishra[2]

Delhi Technological University, Delhi, India

Abstract: ***The nation-wide lockdown due to COVID-19 created the situation of closed population. This paper presents a general theory for estimating the size of a closed population. The theory is based on a log-linear model, with model parameters representing the natural logarithm of subpopulation size and the natural logarithm of subpopulation capture probabilities. Lastly the paper contains illustration of use of log-linear to closed population.***

Keywords: COVID-19, log-linear, capture-recapture

1. Introduction

Estimating population sizes has long been of interest, from the estimation of the human or ecological population size within regions or countries to the hidden number of corona patients in the state. Total enumeration of the population, for example, via a census, is often infeasible or simply impractical. However, a series of partial enumerations or observations of the population is often possible. This has led to the ideas of capture-recapture methods, which have been extensively used within ecology to estimate the size of wildlife populations, with an associated measure of uncertainty, and are most effectively applied when there are multiple capture occasions. The capture-recapture technique originally developed for animal studies and later has been applied by practitioners and researchers to human populations under the term `multiple-record system' for an arbitrary number of lists and under the term `dual-system especially for two lists. The earliest references to such applications can be traced back to Sekar & Deming (1949) for two samples, Wittes & Sidel (1968) for three samples, Wittes (1974) for four samples and Fienberg (1972) for five samples.

Since state circumstances will vary in terms of disease activity and capacity to respond, caution should be exercised in directly linking severity assessment at a global to national level to actions at the state level. It is likely that information will be limited early in the pandemic while the demand for information simultaneously escalates. If pandemic surveillance is to provide sufficient information and data to assess severity, country/state need to review their existing surveillance procedure and capacity to address the weaknesses to be prepared for pandemic surveillance. Essential components of an effective pandemic corona surveillance system will include: early detection and investigation; comprehensive assessment; and Monitoring. Delhi government launched 5T plan to stop the spread of the novel corona virus. The 5T plan includes Testing, Tracing, Treatment, Teamwork and Tracking based on the South Korean strategy Test, Trace and Isolate. But the step testing requires basis. India's apex medical body Indian Council of Medical Research (ICMR) intensified the random sampling of people who display flu-like symptoms but don't have any history of travel to outbreak zones to determine whether community transmission is taking place. Later ICMR experts aren't convinced about following South Korea's strategy, which has reported more recoveries from Covid-19 than new infections through aggressive testing without lockdowns. Indian experts said they will revise the testing protocol depending on the situation. The ICMR in its study highlighted that Covid-19 containment activities need to be targeted in districts reporting positive cases among Severe Acute Respiratory Infections (SARI) patients and stated that intensifying sentinel surveillance for Covid-19 among SARI patients may be an efficient tool to effectively use resources towards containment and mitigation. Testing: Until now testing was very limited. Only symptomatic people who had history of travel were tested. But now Delhi government plans to aggressively start, testing drives in Delhi areas which are being seen as Corona virus hot spot. Also there is going to be random testing of one lakh people in the next few days. Delhi is the first state to carry out random testing. Second T - Tracing as testing ramps up every single contact of positive cases through cellphone triangulation will be traced. Twenty four hour tabs will be kept on those who are in quarantine to ensure it's being followed. Such focused actions will help in staying at least two steps ahead of virus.
ICMR (Indian Council of Medical Research) conducted a test in few states of country and its research shown that there are many cases of corona virus where it is difficult to find the source i.e. they have no travel history and not get in contact with any such person who has travel history. The Ministry of Home Affairs (MHA) of India stated that the government has adopted a special strategy to fight coronavirus, with specific instructions for the district and state authorities. The strategic approach for COVID-19 containment broadly involves defining the area of operation, applying perimeter control, delineating containment and buffer zones. Besides, there is active search for cases, contact tracing, quarantine, clinical management and awareness generation among public.

Without discussing the methodology, It is estimated by Indian professor Ramanan Laxminarayan, Director and Senior Fellow, The Center for Disease Dynamics, Economics & Policy that by July 2020, 300 to 500 million Indians will get infected and a couple of million Indians can die of corona virus cases and fatalities. A data journalist Rukmini S. Has also presented her observation on projections of corona virus cases concluded that if the rate of COVID-19 spread continues, 30,000 deaths can occur in

Licensed Under Creative Commons Attribution CC BY

India by May 2020 and also mentioned that various variables like lockdowns in India and the enforcement of them are great challenges that statisticians cannot deal with.

Random Sampling

Random sampling is basic to many computing applications in science, statistics, and engineering. Random sampling is used on those occasions when processing the entire dataset is unnecessary and too expensive in terms of response time or resource usage. The savings generated by sampling may arise either from reductions in the cost of retrieving the data from the database or from subsequent "post-processing" of the sample. Sampling is useful for applications which are attempting to estimate some aggregate property of a set of records, such as the total number of records which satisfy some predicate. Thus random sampling is typically used to support statistical analysis of a dataset, either to estimate parameters of interest or for hypothesis testing. Random sampling has three common justifications: reduced database retrieval costs (or time), reduced "post-processing" computational costs, or reduced cost of physical inspections. So, random sampling is a basic sampling technique through which each individual is chosen entirely by chance and each member of the population has an equal probability of being included in the sample. It is the only way to be sure that the sample is not biased and is representative of the population as a whole, and even more complex sampling schemes such as systematic and stratified sampling are based on this basic scheme. ICMR's testing of a small random sample may not be able to capture it. As India is divided its 755 districts into green, orange and red zones. It will entail making sure that green zones are indeed green by deploying testing strategies. Delhi government announced a five-point action plan of "five Ts -- testing, tracing, treatment, team-work and tracking -- and monitoring" to contain the virus spread and said one lakh random rapid anti-body blood tests for COVID-19 tests will be conducted in the city's hotspot areas, the similar plan is followed by other states also.

2. Literature Review

The past literature is reviewed keeping in view for this study is concerned as well as COVID-19. Pandemic is not new for the world, but the lockdown concept is new for country like India experience in year 2020. Estimating population sizes has long been of interest, from the estimation of the human or ecological population size within regions or countries to the hidden number of corona patients in the state. Total enumeration of the population, for example, via a census, is often infeasible or simply impractical. However, a series of partial enumerations or observations of the population is often possible. This has led to the ideas of capture-recapture methods, which have been extensively used within ecology to estimate the size of wildlife populations, with an associated measure of uncertainty, and are most effectively applied when there are multiple capture occasions.

Capture-recapture methods are used in various areas, from epidemiology (Coeli et al., 2000) to zoological studies of populations (Fernandez, 1995) or even in the analysis of the variation of measurement intervals of closed communities of diverse magnitudes (Cormack, 1992). The capture-recapture techniques are used for closed populations, where the effects of birth rate or mortality and migration are not taken into account, in this case it is considered no change in population size. They can also be used for open populations, where population changes caused by birth rate, mortality and migration are taken into account (Cormack, 1989). Sekar and Deming (1949) proposed their research concerned with estimating birth and death rates in an area near Calcutta, India. The research based report of Robles, S. C. et al. (1988) described about usefulness of capture-recapture methods used to estimate completeness at the Ontario Cancer Registry. The method was applied in two fashions; first, using three data sources in a modeling approach and second, using two data sources and standard, simple capture-recapture methods. The modeling approach is more flexible, since several variables that influence cancer registration can be considered and can be used to identify reporting patterns of different data sources. Wittes, J. T (1974) in his paper considered the problem of estimating the total size of a target population from which a study sample has been obtained by merging names from several routinely collected lists. Each list is assumed to be a simple random sample from the target population and all lists are assumed independent. Hook, E. B. (1980) presented his work with goal to compare various methods for estimating the live-birth prevalence of spina bifida (cystica) using Bernoulli census analysis, allowing for under ascertainment in the sources used, and to determine if a stable estimate or at least a useful confidence boundary on the population live-birth prevalence rate could be derived from prenatal diagnosis of spina bifida undertaken as part of a cost-benefit analysis. Brenner, H. (1994) highlighted the drawback of routine systems of disease monitoring, such as morbidity registries, are often prone to specific threats of validity, such as in imperfect diagnoses or imperfect record linkage. Through quantitative assessment of the performance of the two-source capture-recapture method for disease monitoring in the presence of imperfect record linkage. International Working Group for Disease Monitoring and Forecasting (1995) evaluates the potential epidemiologic uses of capture-recapture, which include the primary area of determining disease frequency. Capture-recapture may be a means to effectively "count" new cases (incidence) or count existing cases (prevalence). In addition to generating an estimate of population size, another application of capture-recapture is to assess the costs of ascertainment relative to the degree of accuracy. Fisher N. et al. (1994) worked on routinely collected data from local agencies to provide a reliable estimate of the size and psychiatric morbidity of the homeless population of a given central London by using capture-recapture analysis. A multiple sample, log-linear capture-recapture method was applied to a defined geographical area during 6 months. The method calculates the total homeless population from the sum of the population actually observed and an estimate of the unobserved population. Sheila M. Bird and Ruth King (2018) with changed name of Capture-Recapture Estimation with Multiple Systems Estimation (MSE) advocated that the MSE approach has been preferred when estimating "capture-shy" or hard to-reach populations, including those caught up in the criminal justice system; or homeless; or trafficked; or civilian casualties of war. The paper focuses on whether the uncertainty which qualified their estimates was sufficiently narrow to orient public policy or not, if not, what options

Licensed Under Creative Commons Attribution CC BY

were available and/or taken to reduce the uncertainty or to seek external validation. *Jones H.E.et al.(2016) by using* Capture–recapture analysis recommended for estimating the prevalence of problem drug use or people who inject drugs .The work aim to demonstrate how naive application of Capture–recapture can lead to highly misleading results, and to suggest how the problems might be overcome. The method further validated by a case study of estimating the prevalence of people who inject drugs in Bristol, UK, using Capture–recapture. *Leclerc, P. (2014) already published similar type of work as Jones H.E.et al.(2016) carried but study area was* Island of Montréal, Canada, Using a Six-Source Capture-Recapture Model.

Even after worthiness of this method Stephen N Jarvis et al. (2000) stated with prior proof in his research paper with illustration that there is also serious drawbacks in the use of the mark/recapture technique when applied to injuries. Through example of two sample mark/recapture estimation in an epidemiological setting it is shown to violate virtually all the requirements for valid use of the technique. Further mentioned that very little can be deduced accurately about the scale or characteristics of an unobserved group by the use of mark/recapture applied to two overlapping health event registers. Begon, M. (1983) as a critic to the methods of Jolly he mentioned that there has also been a consistent interest in the method on the part of statisticians, a sporadic interest in field-based critiques of the method, and a considerable tendency, especially since the mid-seventies, to refer to Jolly's paper but make no use of its contents.

3. Capture-Recapture Method and Log-Linear Model

Pierre Simon Laplace (1749-1827) used similar to capture-recapture approach to estimate the size of human population of France. Further Lincoln-Peterson develop a technique with the name capture-recapture

Closed Population: A closed population is one in which the total number of individuals is not changing through births, deaths, immigration or emigration. But in practice, most real populations are not closed, it's a chance the in complete lockdown, the population is definitely closed. An open population is one that is (or could be) changing during the course of study, because of any combination of births, deaths, immigration or emigration. The 'closed captures' data types all assume the population of interest is closed during the sampling period (White *et al*. 1982). Meaning, the models assume that no births or deaths occur and no immigration or emigration occurs. Typically, we refer to a closed population as one that is free of unknown changes in abundance, as we can usually account for known changes.

The assumption is in context of human being is differ from animals in that way that- human being are self conscious and able to report about their illness and checked (tagged), human being always available whenever called for recounting. But this COVID-19 effected the mind and thought of people in such a way that people use to hide themselves from the society and that become a challenging task to the health department to do mapping to identify them from the huge crowd of population, even if it is closed due to lockdown. The 'closed captures' data types all assume the population of interest is closed during the sampling period (White *et al*. 1982). Meaning, the models assume that no births or deaths occur and no immigration or emigration occurs. Typically, we refer to a closed population as one that is free of unknown changes in abundance, as we can usually account for known changes.

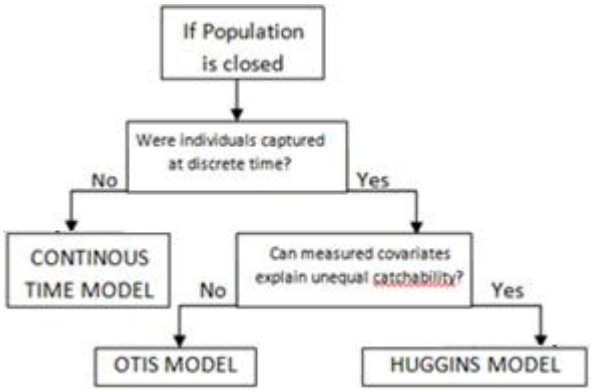

Figure 1: Flow Chart of the methods of CAPTURE-RECAPTURE

Consider a closed population with size N and the people are indexed by 1,2,. . . , N in any arbitrary fashion. In a usual t-sample capture-recapture experiment, people are captured and marked in each trapping sample (or trapping occasion), and we only notice in each sample whether each person was captured or not without recording the sequential order or the time when it was captured. Thus the capture history can be expressed as a N x t matrix (X_{ij}), where X_{ij} = I [the i^{th} person was caught in the j^{th} sample], i = 1, 2,. . . , N, j = 1, 2.. . , t. Extensive models have been discussed for the above discrete-time type data.

If the capture time and the sequential order for each individual can be recorded, then a continuous-time model is needed. Anderson and Wilson (1989) have done some simulation to compare the existing estimators for continuous-time models. Becker (1984), Becker and Heyde (1990) proposed an estimation procedure using a martingale approach.

In the complete lockdown situation the whole population is considered as closed population and the new birth in this period is neglected because the record is unavailable for this period. A closed population is one in which the total number of individuals is not changing through births, deaths, immigrations and emigrations and all these were not in assumption in corona period. In practice, most real populations are not closed. Sometimes, however, the changes over the time period of interest are small enough that the assumption of closure is a reasonable approximation, and the effects of violating that assumption are minimal. For that reason, the analysis of capture-recapture data from closed populations continues to be a topic of interest to researchers.
However closure is subdivided into two components: (i) geographic and (ii) demographic. The geographic closure of population by a boundary, which limits the population, and demographic is about birth, death, immigration and emigration.

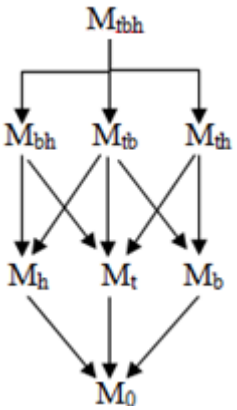
The models of Otis et al.(1978) denoted M_0, M_t, M_b, M_h, M_{bh}, M_{tb}, M_{th}, and M_{tbh}.



Model M_0 assumes a single common probability of capture. The subscripts t, b, and h correspond to temporal variation in common probability of capture, behavioral response to common probability of capture, and individual response to capture, respectively. Multiple subscripts indicate a combination of capture responses.

The above mentioned eight models summarised by symbol, source of variation in capture probabilities , and the associated estimators, if any , program CAPTURE uses theses names for estimators.

Table 1: Discrete-Time Models and Associated Appropriate Estimator with Log Linear form

Model	Source of variation in capture probabilities	Appropriate estimator	Log Linear form
M_0	None	Null (All estimators given below are valid)	$log\ (P_{ij}) = \alpha$
M_t	Time	Darroch (1958)	$log\ (P_{ij}) = \mu_j$
M_b	Behaviour	Zippin (1956)	$log\ (P_{ij}) = \alpha + \gamma\ Y_{ij}\ (\alpha_i = \alpha)$
M_h	Heterogeneity	Jackknife (1978)	$log\ (P_{ij}) = \alpha_i$
M_{bh}	behaviour heterogeneity	Generalized Removal (Otis et al. 1978)	$log\ (P_{ij}) = \alpha_i + \gamma\ Y_{ij}$
M_{tb}	time behaviour	None	$log\ (P_{ij}) = \mu_j + \gamma\ Y_{ij}$
M_{th}	time heterogeneity	None	$log\ (P_{ij}) = \alpha_i + \mu_j$
M_{tbh}	time behaviour heterogeneity	None	$log\ (P_{ij}) = \alpha_i + \mu_j + \gamma\ Y_{ij}$

Relation of the model

Each arrow points from one model to an immediate special case of the model. Test of assumptions are based partly on these relations among the model

Figure 2: Relation of the Model

There are also capture-recapture models available for the open population like Jolly-Seber model, Modern open population model, Multi State Model, Target Recovery Model and Joint modeling of live and dead recovery, with different assumptions. These models are widely used by researchers to count the animal populations as well as human also.

Log-Linear Models

The log-linear model approach was originally proposed by Fienberg (1972) and has been widely used in many applications (Cormack 1989; Agresti 1994; Evans, Bonett, and McDonald 1994; Coull and Agresti 1999; IWGDMF 1995). In this approach, the data are regarded as a form of an incomplete 2^t contingency table (t is the number of lists) for which the cell corresponding to those individuals uncaptured by any of the samples is missing. Then various log-linear models are fitted to the observed cells and the chosen model is projected onto the unobserved cell by assuming that there is no t-sample interaction. We use the three-sample case as an illustration. There are seven observed cells: z_{111}, z_{110}, z_{101}, z_{100}, z_{011}, z_{010}, and z_{001}, where z_{100} is the number of individuals captured in sample 1 only and z_{011} is the number of individuals caught in samples 2 and 3 but not in sample 1. A similar interpretation pertains to other capture histories. The missing cell z_{000} denotes the number of missed individuals. The log-linear approach models the logarithm of the expected value of each observable category. The most general log-linear model for the three-sample case is

$$log\ E(z_{ijk}) = u + u_1 I(i = 1) + u_2 I(j = 1) + \underline{u}_3 I(k = 1) + u_{12} I(i = j = 1) + u_{13} I(i = k = 1) + u_{23} I(j = k = 1) + u_{123} I(i = j = k = 1); \quad \text{----------(1)}$$

where I(A) is an indicator function for event A. The above is a reparameterization of the eight expected values. We have seven observed cells, whereas there are eight parameters in the right-hand side of equation (1). Therefore, a commonly adopted assumption is that there is no three-sample interaction term, i.e., $u_{123} = 0$, which allows an extrapolation formula for the missing cases using the fitted values of the observable cells. The independent model with main effect terms is equivalent to model M_t in Table 1. The log-linear models corresponding to the multiplicative models M_b and M_{tb} are discussed in Cormack (1989), who also showed how to t various models using the GLIM package (GLIM is a statistical package(marketed by NAG) which analyses generalised linear models by iterated reweighted least squares). Many authors stated that random sampling is required in capture studies. This assumption stems from ball and urn experiments, in which marked and unmarked balls are shaken completely, and a random sample is taken at the end of each sampling occasion. Traditional sampling methods include procedures for drawing random samples. Uses of the procedures require knowledge of the sampling probabilities (for finite populations). Deliberate control over the elements to be sampled is required. It is unrealistic to think that if any COVID patient is captured (marked) in one corner of the trapping grid may be captured subsequently in the opposite corner of the boundary. The concept of random sampling does not apply to situations assumed in Models M_b, M_h, M_{bh}, M_{tb}, M_{th}, and M_{tbh}. The goal of these models is to provide an analysis of the sampled data in the face of behavioural response and heterogeneity, both of which are contrary to the traditional role of random sampling.

4. Data Source For Illustration

According to ICMR the data of the following people should be considered for COVID-19 testing.

1) Symptomatic (fever, sore throat, running nose, dyspnea, etc) individuals who have travelled to affected countries

Licensed Under Creative Commons Attribution CC BY

(China, Hong Kong, Japan, South Korea, Singapore, Iran, Italy etc.)
2) Close contacts of confirmed positive cases of COVID-19 infection.
3) All individuals evacuated and quarantined from Wuhan, China and Diamond Princess ship, Japan.

It includes information on COVID-19 service activities by private and public hospitals and community health services from 25th March 2020 to 31st May 2020 (Lock-down period in India). This study may be use to estimate the number of people who were infected by the corona virus (COVI-19) in an outbreak in whole India and for more accuracy study area may be carried out at state wise. For example if the study area is Delhi selected with approximately 16787941 population in 11 different districts. Our data are restricted to census records of government. In total, 271 cases were reported from the following three sources. (1) A-list: records based on Symptomatic (fever, sore throat, running nose, dyspnea, etc) individuals who have travelled to affected countries (China, Hong Kong, Japan, South Korea, Singapore, Iran, Italy etc.) . There were 135 ascertained cases. (2) B-List: records provided by Close contacts of confirmed positive cases of COVID-19 infection. The records included 122 cases reported by doctors in local hospitals. (3) C-list: records based on All individuals evacuated and quarantined from Wuhan, China and Diamond Princess ship, Japan.. A total of 126 cases were in the C-list.

Table 2: Data on corona virus infection

A	B	C	Data
1	1	1	Z_{111}= 28
1	1	0	Z_{110}= 21
1	0	1	Z_{101}= 17
1	0	0	Z_{100}= 69
0	1	1	Z_{011}= 18
0	1	0	Z_{010}= 55
0	0	1	Z_{001}= 63
0	0	0	-----

The data are given in Table 2 Several log-linear models were fitted to these data. Except for the saturated model, the log-linear models, which do not take into account heterogeneity (i.e. models (AC, B), (BC, A), (AB, C), (AB, BC), (AB, AC) and (BC, AC)), do not fit the data well. The quasi-symmetric and three partial quasi-symmetric models (see Darroch *et al*., 1993), which incorporate heterogeneity effects, fit the data well. The four adequate models produce approximately the same estimates, 1300, with an approximate estimated s.e. of 520. This relatively large estimated i.e. shows the data are actually insufficient to model the heterogeneity effect.

Estimation Procedure

$$\hat{C} = 1 - \frac{1}{t} \sum_{k=1}^{t} \frac{S_k}{n_k}$$

Equation for estimator of sample coverage ----------(2)

The singletons cannot contain any overlap information. Therefore, the sample coverage can be Interpreted as a measure of overlap. When neither dependence exists, it follows from the definition of C that $C = D/N$, where D denotes the average of overlapped cases, i.e.

$$D = \frac{1}{t} \sum_{k=1}^{t} \{ \sum_{k=1}^{N} I [\sum_{j \neq k} Xij > 0] = M - \frac{1}{t} \sum_{k=1}^{t} S_k$$

----------(3)

Here, M denotes the number of different cases identified in at least one of the lists. Hence, in the independent case, a valid estimator is

$$N_0 = D/\hat{C} \qquad \text{----------(4)}$$

the sample coverage is estimated to be $\hat{C} = 51.27\%$ and the average of the overlapped cases is D= 208.67. If we incorrectly assume that the three samples are independent, then from (4) an estimate would give $N_0 = D/\hat{C} = 407$, which is slightly larger than the estimate of 388 based on an independent log-linear model. We feel these data, with estimated sample coverage of 51%, do not contain enough information to correct for undercount. Thus, this example presents a very valuable data set with the advantage of a known true parameter.

5. Discussion

We discuss first the extent to which this study provides evidence for or against the use of mark/recapture techniques in the epidemiological setting. We then consider the relationship of these findings to other similar studies. To what extent then does the present study meet the "requirements" for the mark/ recapture method? As far as possible, the study has attempted to define a "closed" population—Otis condition "a". Note here that "closed" does not infer that the COVID-19 patient population of Delhi is unchanged—rather that the reference population for individual cases is the same for both lists. In this study the reference population is COVID-19 patients from Delhi addresses with following people should be considered for COVID-19 testing.
1) Symptomatic (fever, sore throat, running nose, dyspnea, etc) individuals who have travelled to affected countries (China, Hong Kong, Japan, South Korea, Singapore, Iran, Italy etc.)
2) Close contacts of confirmed positive cases of COVID-19 infection.
3) All individuals evacuated and quarantined from Wuhan, China and Diamond Princess ship, Japan.

Indian Council of Medical Research (ICMR) affirms, while there is no readily available test kit to detect coronavirus infection, doctors and researchers go by a series of tests to confirm the infection i.e. Swab test, Nasal aspirate and tracheal aspirate test. Indian Council of Medical Research (ICMR) suggests that anyone with a recent travel history to COVID-19 affected countries or someone who has been in close contact with infected patients is also advised screening. Despite the extended time over which our lists are compiled, an individual's availability for both lists is almost concurrent. The crucial assumption, that an individual in the population from which one list is a sample, is also in the population from which the other list is a sample, is thus

Licensed Under Creative Commons Attribution CC BY

satisfied. In any area of epidemiology or, in fact, any human monitoring system involving population estimates of the number of people who have a certain characteristic, capture-recapture should be considered a complementary or an alternate approach to traditional counting technology. One application of capture-recapture, in addition to generating an estimate of population size, is to assess the costs of ascertainment relative to the degree of accuracy obtained. A primary goal of monitoring is the ability to obtain accurate and timely incidence rates at a reasonable cost. The more expensive it is to accurately estimate the counts of disease, the less likely it is to assess that disease and the smaller the geographic coverage. When setting out to determine incidence rates, therefore, one should first determine the amount of precision desired, as greater degrees of precision are likely to be more expensive. The appropriate degree of precision required for estimating incidence rates will vary by the use(s) to which the data are put. There are no right or wrong decisions as to how many samples should be examined, or the degree of ascertainment needed, as this is a function of both the acceptable degree of precision and the amount of resources available to carry it out.

We strongly believe that with any disease monitoring system, whether communicable or non-communicable, there should be the means to formally evaluate the degree of undercount. With capture-recapture, we have this technology. All disease monitoring systems should be able to estimate the proportion of the diseases diagnosed in the community, region, or nation that were identified by the monitoring system. Without this information, it is difficult, if not impossible, to determine the degree to which the rates of disease are compromised by missing cases. Capture-recapture is not a panacea. However, it offers public health officials the opportunity to get closer to the truth if the methods are used appropriately. There is much to be learned in the development of capture-recapture models for use in epidemiology. The assumptions need to be assessed and the models tested. Epidemiologists and biostatisticians working with human disease need to continue the dialogue with those who have developed the approaches using capture-recapture. Much remains to be learned, and there is great potential. As indicated by the IWGDMF (1995), the log-linear model approach has many advantages as follows: (a) all models are under a unified framework; (b) model selection can be easily implemented and carried out in a flexible fashion, based on data and guided by prior information; (c) tests are available for comparing models; (d) dependence can be incorporated by adding proper interactions; and (e) all inference is within the mainstream of statistical data analysis. An untestable assumption involved is that the highest-order interaction does not exist. The IWGDMF commented that the existence of heterogeneity in three-list data might result in the lack of a reliable estimate. Another concern is that two equally fitted models might produce quite different estimates. As the number of lists increases, the number of adequate models increases rapidly and thus model selection causes further problems.

Irreversibility analysis

ABSTRACT

This paper is to study the thermal analysis of vapor compression refrigeration system using R134a in primary circuit and Al_2O3-Water based nano-fluids in secondary circuit. The study provides the information of the secondary fluids input conditions, Performance parameters of vapour compression refrigeration system using eco-friendly refrigerants and without nano materials, Effect of overall evaporator heat transfer coefficient using different nano particles mixed with R718 in the secondary evaporator circuit and R134a in primary circuit, the compressor power consumption and the system overall energy performance. Such an analysis with the help of engineering equation solver software (EES) tool can be conveniently useful to compare the thermal performance of different nano-particles (i.e., Al_2O3, TiO_2) based nano fluid as a secondary fluid in a vapor compression refrigeration system.

1. Introduction

Nanofluids are a new class of fluids engineered by dispersing nanometer-sized materials (nanoparticles, nanofibers, nanotubes, nanowires, nanorods, nanosheet, or droplets) in base fluids. In other words, nanofluids are nanoscale colloidal suspensions containing condensed nanomaterials. Nanofluids have been found to possess enhanced thermophysical properties such as thermal conductivity, thermal diffusivity, viscosity, and convective heat transfer coefficients compared to those of base fluids like oil or water. It has demonstrated great potential applications in many fields. For a two-phase system, there are some important issues we have to face. One of the most important issues is the stability of nanofluids, and it remains a big challenge to achieve the desired stability of nanofluids (Fig. 1).

1.1. Brief literature review

Lots of research work has been done for replacing "old" refrigerants with "new" refrigerants Ahamed et al. [1] emphasized on use of hydrocarbons and mixture compressor shows much higher exergy destruction as compared to rest of components in the vapour compression refrigeration system and this exergy destruction can be minimized by using of nanofluid and nanolubricants in compressor. Anand [2] did detailed exergy analysis of 2 ton of refrigeration capacity window air conditioning test rig with R22 as working fluid and reached to the conclusions , that irreversibility in system components will be highest when the system is 100% charged and lowest when 25% charged and irreversibility in compressor is highest among system. Arora et al. [3] developed numerical model of actual vapour compression refrigeration system with liquid vapour heat exchanger and did energy and exergy analysis on the same in the specific temperature range of evaporator and condenser and concluded that R502 is the best refrigerant compared to R404A and R507A and compressor is the worst component and liquid vapour heat exchanger is best component of the system in case of exergy transfer. Bolaji et al. [4] had done experimentally comparative analysis of R32, R152a and R134a refrigerants in vapour compression refrigerator and concluded that R32 shows lowest performance whereas R134a and R152a showing nearly same performance but best performance was obtained of system using R152a. Chopra et.al [5] carried out analysis of energetic and exergetic based comparison Multiple Evaporators with

Das, Experimental studies of vapour compression refrigeration system with eco-Friendly primary refrigerant and brine mixed with nano particles as secondary refrigerant, Materials Today: Proceedings, https://doi.org/10.1016/j.matpr.2020.06.083

Fig. 1. (a) VCRS setup.

compound compression and flash intercooler with individual and multiple throttle valves and find out the effect of flash intercooler on second law performances. Han et al. [6] Under different working conditions experimental results revealed that there could be replacement of R407C in vapour compression refrigeration system having rotor compressor with mixture of R32/R125/R161 showing higher COP, less pressure ratio and slightly high discharge compressor temperature without any modification in the same system. Mishra et al. [7–9] performed numerical analysis of vapour compression refrigeration system using R134a, R143a, R152a, R404A, R410A, R502 and R507A, and discussed the effect of evaporator temperature, degree of subcooling at condenser outlet, superheating of evaporator outlet, vapour liquid heat exchanger effectiveness and degree of condenser temperature on COP and exergetic efficiency. They reported that evaporator and condenser temperature have significant effect on both COP and exergetic efficiency and also found that R134a has the better performance while R404a has poor performance in all respect (Table 1).

1.2. Problem statement

From the above literature review following points are left by different authors-

- Different arrangements & combinations of refrigerants with nano particles are still left for research.
- Al_2O_3 , TiO_2 & CuO response is better and they may improve the COP of refrigerator by introducing a secondary circuit in the evaporator unit.

But still there is vast area is to explore for performance improvement in VCRS at low cost and low input (Table 2).

Table 1
Performance parameters of vapour compression refrigeration system using eco-friendly refrigerants and without nano materials.

Refrigerants	COP	ED_Ratio	ETA_Second
R134a	2.973	2.447	0.2901
R404a	2.705	3.158	0.2717
R407a	2.754	2.333	0.30

Table 2
Effect of overall evaporator heat transfer coefficient using different nano particles mixed with R718 in the secondary evaporator circuit and R134a in primary circuit.

Nano particles	Overall heat transfer coefficient (U_e)	Difference in water temperature (°C)	Difference in brine temperature (°C)
Copper oxide	1372.14	15.71	11.58
Copper	1367.18	14.55	11.44
Al_2O_3	1318.0	14.62	11.5
Ti_2O_3	1242.43	14.43	11.32
Without nano particles	691.04	12.24	9.29

1.3. Materials and methodology

To improve thermal performance of vapour compression air conditioning systems by improving:

- First law efficiency- According to first law of thermodynamic energetic efficiency /COP is defined as the ratio of net air conditioning effect to the per unit power consumed. First law analysis restricted to calculate only coefficient of performance of the systems and,
- Second law efficiency- The concept of exergy was given by second law of thermodynamics. Second law efficiency is the exergy of the heat abstracted in to the evaporators from the space to be cooled and exergy of fuel is actual compressor work input.

In this paper our main focus on performance of three suspended nano particles i.e., Al_2O_3, TiO_2, & CuO in water based refrigerant in secondary circuit and in primary circuit we are using eco-friendly refrigerants (Table 3).

Table 3
Effect of overall evaporator heat transfer coefficient using different nano particles mixed with R718 in the secondary evaporator circuit and R134a in primary circuit.

Nano particles	Overall heat transfer coefficient (U_e)	% improvement
Copper oxide	1325.7	91.41
Copper	1324.25	91.4099
Al_2O_3	1318.70	90.6077
Ti_2O_3	1242.43	79.6
Without nano particles	691.04	—

Das, Experimental studies of vapour compression refrigeration system with eco-Friendly primary refrigerant and brine mixed with nano particles as secondary refrigerant, Materials Today: Proceedings, https://doi.org/10.1016/j.matpr.2020.06.083

1.4. Results

In this paper, first law and second law analysis of vapour compression refrigeration systems using multiple evaporators and single compressor and single expansion valve with eco-friendly refrigerants in the system and secondary refrigerant (water used in secondary circuit with and without nano-particles mixed with water used as refrigerant) have been presented with the help of EES software results.

1.5. Conclusion

Various nano-particles with R134a refrigerant can be used as an excellent refrigerant to improve the heat transfer characteristics in a refrigeration system. A successful model has been designed and the basic theoretical heat transfer analysis of the refrigeration system has been done.

Experimental Validation of Fully Informed Particle Swarm Optimization Tuned Multi-Loop L-PID Controllers for Stabilization of Gantry Crane System

Sudarshan K. Valluru, Madhusudan Singh, Daksh Dobhal, Kumar Kartikeya, Manpreet Kaur and Arnav Goel

Abstract Linear PID controllers are commonly used as an electrical component to decrease the error between anticipated set value and actual measured values for control of various benchmarked systems. The Multi-Loop Linear PID (ML-PID) controller, gives a robust and efficient performance in most of the situations. This paper presents the implementation of linear PID controller to stabilize and control the Gantry Crane System. Optimal performance is obtained for a few specific combinations of the proportional, integral, and derivative gains, which makes it essential to tune these values through Optimization techniques. The Fully Informed Particle Swarm Optimizer (FIPSO) is used to tune the gain values of the ML-PID controlled Gantry Crane System. These values are validated experimentally, and obtained results prove that the FIPSO tuned multi-loop linear PID controller quickly stabilizes the system subjected to external disturbances.

1 Introduction

The Linear PID is one of the most widely used electrical component in the systems industry [1, 5]. It provides efficient solutions while being computationally inexpensive and simple to implement and simulate. The Linear PID can control and modulate responses of benchmarked dynamical systems [11, 12]. Though, if the system has nonlinearities, the controller may produce unsatisfactory response including high peak overshoot and large settling time, but still, it has limitations like optimality and tuning [10]. Thus, the difficulty of tuning is to be challenging particularly if the multi PID controllers have more than three objectives. The three terms in the controller namely Proportional, Integral, and Derivative can be varied to get an optimal response which is calculated according to the external disturbances by evolutionary computation [8].

In recent years, Particle Swarm Optimization has gained much attention of researchers as a bio-inspired algorithm for the optimization techniques especially for the multimodal and multi-output functions [6, 13]. Although the standard PSO showed better results and faster convergence time to reach global optima for unimodal objective functions, it suffers from falling of local minima problem for nonlinear, multimodal objective functions [6]. This paper addresses the simultaneous tuning of ML-PID controllers using a new variant of FIPSO [2, 4], and the obtained gain values are tested to control and stabilize the Gantry Crane System [3].

The rest of the paper is organized as following sections. Section 2 describes the design of a Multi-Loop Linear PID Controller. Mathematical modeling of the Gantry Crane system is presented in Sect. 3. The tuning of the Controller using FIPSO is presented in Sect. 4. Experimental results and discussions are given in Sect. 5, and finally, Sect. 6 outlines the conclusion of the paper.

2 Design of Multi-Loop L-PID Controllers

The linear proportional integral derivative controller operates upon the error term $\varepsilon(t)$, the mismatch between the real time output and reference input signals to generate the correction signal $\alpha(t)$. The correction signal is obtained as the sum of the error, derivative of the error, and integral of the error multiplied by their respective coefficients. Usually, the three coefficients are denoted by P, I, and D respectively. Hence the expression for the correction signal is obtained as (1):

$$\alpha(t) = K_p \varepsilon(t) + K_i \int_{t1}^{t2} \varepsilon(t) \cdot dt + K_d \frac{d\varepsilon(t)}{dt} \tag{1}$$

The primary task is determining the optimal combinations of the coefficients which yield the best performance. The term proportional to the error reduces the system response time as it is increased till a maximum allowed value above which

sustained oscillations are introduced in the system response. In reducing the steady state error, the major part is played by the integral term. The derivative term leads to a reduction of the corrected signal if the error is increasing.

3 Gantry Crane System

The crane system, in spite of its simple structure, is a complex system owing to its nonlinear nature [7]. Because of this, it is considered to be one of the under accutated benchmark of control systems. If it is assumed that the payload is a lumped-mass distribution rather than a distributed-mass system, the gantry crane can be modeled as a simple pendulum. Utilizing the assumptions of payload being a point mass distribution, massless cable, the cable of fixed length and not flexible and neglecting the damping coefficient of the cable, the free body diagram of the crane and functional diagrams are shown in Fig. 1 and Fig. 2 respectively. Consider M, m, l, b, and I to be the mass of the trolley, mass of the pendulum bob, length of the cable, the coefficient of friction of cart, and the MOI of the bob respectively.

The variables x and θ are the position of trolley along the belt and angular position of the pendulum. The equations of motion obtained for the system are (2) and (3):

$$F = (M+m)\cdot \acute{x} + b\acute{x} - mlsin\theta \cdot \acute{\theta}^2 + mlcos\theta \cdot \acute{\theta} \tag{2}$$

$$0 = \left(I + ml^2\right)\cdot \acute{\theta} - mglsin\theta + mlcos\theta \cdot \acute{x} \tag{3}$$

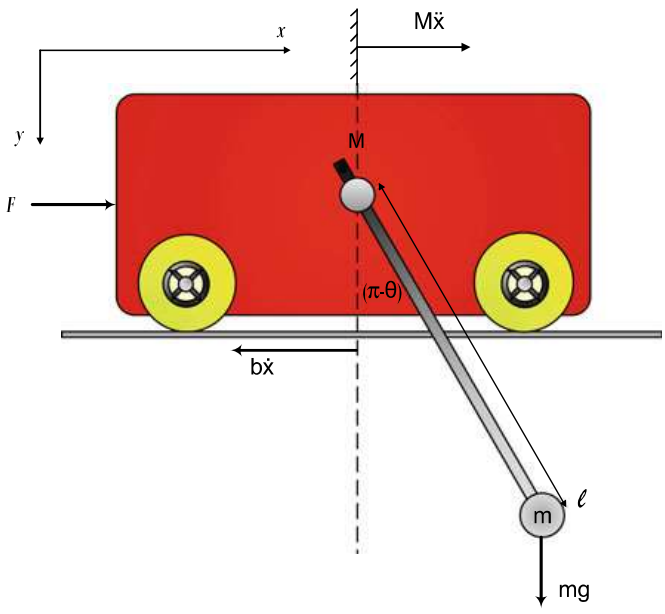

Fig. 1 FBD of gantry crane system

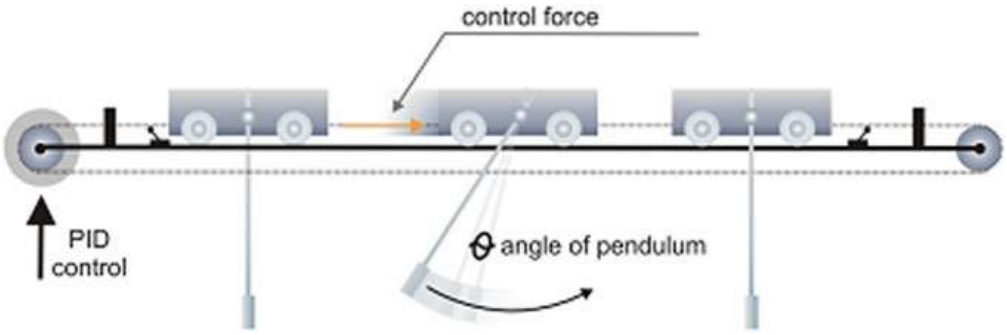

Fig. 2 Functional Diagram

Table 1 Gantry crane system parameters

S. No.	Parameters	Value
1	Mass of the cart (M)	2.4 kg
2	Mass of the pole (m)	0.23 kg
3	Cart friction coefficient (b)	0.05 Ns/m
4	Length of the pole (l)	0.32 m
5	Pendulum moment of inertia (I)	0.099 kg m^2
6	Gravity constant (g)	9.81 ms^{-2}
7	Range of operating voltage of D.C. servo motor (V)	±24 V

For $\theta \rightarrow 0$: $sin\theta \approx \theta$, $cos\theta \approx 1$, $\acute{\theta}^2 \approx 0$

For the simpler understanding of carrying out the stability analysis of the dynamics of the system, the linearized system Eqs. (4) and (5) as

$$F = (M + m) \cdot \acute{x} + b\acute{x} + ml \cdot \acute{\theta} \tag{4}$$

$$0 = \left(I + ml^2\right) \cdot \acute{\theta} - mgl\theta + ml \cdot \acute{x} \tag{5}$$

The system parameters as specified in Eqs. (4) and (5) are given in Table 1.

4 Tuning of ML-PID by FIPSO Algorithm

The PSO algorithm mimics the flocking of birds and the schooling of fishes to find the optimal value of the given target function [9]. The Fully Informed Particle Swarm Optimization takes into account the influence on each particle in a swarm by the mean of its nearest neighbor. Therefore, it has the advantage of fast convergence, escaping

the tendency to fall in local minima and ability to optimize complex functions when compared to Standard PSO algorithm.

The important variables associated with particles in the swarm in FIPSO are x_i (position), v_i (instant velocity), Pb_i (Present Personal best), and Gb_i (Global Position best). Each particle is updated on the basis of above parameters in the above-defined pop size (iteration) for which cost Function (F_{cost}) is to be minimized. For the Gantry Crane Benchmark, x_i can be comprehended as (6)

$$x_i = [K_{P1}, K_{I1}, K_{D1}, K_{P2}, K_{I2}, K_{D2}] \tag{6}$$

where x is the position of the particle, K_{P1}, K_{I1}, K_{D1} are PID constants for the cart's position controller and K_{P2}, K_{I2}, K_{D2} are for the angle controller of the gantry crane system. Particles in a swarm were initialized using the Eq. (7)

$$x_i = unifrnd(PosLL_i, PosUL_i, npop, 1) \tag{7}$$

where $unifrnd$ function generates uniform random numbers in the range ($PosLL_j$,$PosUL_j$). $PosLL$ And $PosUL$ are the lower and upper decision boundary variables respectively, $npop$ is the population (swarm) size and jth represents one of the PID constants shown in above equation.

The updated velocity and position of each particle in an iteration can be calculated as in Eqs. (8) and (9)

$$v_{i+1} = w * v_i + c_1 * (Pb_i - x_i) + c_2 * (Gb_i - x_i) + chi * (x_i - \mathrm{NN}_i) \tag{8}$$

$$x_{i+1} = x_i + v_{i+1} \tag{9}$$

where NN_i is the Nearest Neighbor, defined as the mean of the personal best position of the nearest five particles w is the inertial weight, c_1, c_2 are personal and global learning coefficients respectively and chi is the constriction coefficient. Finally, the innovative Global Best and Personal Best are updated as (10) and (11):

$$Pb_{i+1} = \begin{matrix} \{Pb_i, & Fcost(x_i) > Fcost(Pb_i) \\ x_i, & otherwise\} \end{matrix} \tag{10}$$

$$Gb_{i+1} = \min\{Fcost(Pb_{i+1})\} \tag{11}$$

4.1 Implementation of FIPSO for ML-PID Tuning

The overall FIPSO pseudo code to tune the ML-PID controller for gantry system is summarized as follows:

```
  FCost- call the function whose variables are to be
  tuned
  nVar- no. of variables to be tuned
  NoVar- row vector defining size of the decision
  variable matrix
  PosLL- minimum values of decision variables
  PosUL- maximum value of decision variables
  VelUL-maximum value of velocity
  VelLL- minimum value of velocity
  Setting required PSO parameters:
  Gen- maximum no of iterations to be undergone by the
  code
  PopSize- size of the swarm
  Km- No. of nearest neighbours considered
  NN- Best position closest of neighbours
  Initialisation of swarm parameters
  global best- array of size NoVar containing zeros
  fori=1: PopSize
      initialize position of particle assigning it random
      value;
      set velocity of particle zero;
      evaluate cost function for particle;
      set personal best position and cost equal to
      initial position and cost for each particle;
       if personal best cost of particle i> global best
       cost
          global best=personal best of i;
      end
  end

  Main Loop of PSO
  for it=1: Gen
      fori=1: PopSize
          update velocity using FIPSO innovative vector
          formula;
          apply velocity limits so that velocity remains
          between VelLL and VelUL;
          update position;
      apply position limits so that position remains
      betweenPosLl and PosUL;
          calculate value of cost function;
          if cost of i< personal best cost of i
              personal best position of i= position of i;
              personal best cost of i= cost of i;
          end
          if global best cost < best cost of i
              global best= personal best of i;
          end
      end
end
  apply position limits so that position remains between
  VarMin and VarMax;
  calculate value of cost function;
  if cost of i< personal best cost of i
  personal best position of i= position of i;
  personal best cost of i= cost of i;
  end
  if global best cost < best cost of i
  global best= personal best of i;
  end
  end
end
```

Table 2 ML-PID gain parameters

S. No	Gain co-efficient	Optimal value
1	K_{P1}	4.8590
2	K_{I1}	0.4918
3	K_{D1}	4.0352
4	K_{P2}	4.9101
5	K_{I2}	0.0973
6	K_{D2}	0.3000

The swarm size, iteration, w, c_1, c_2, chi values used in the experiment for the optimization of ML-PID controller for the gantry crane system are 50, 30, 0.7298, 1.4962, 1.4962, 0.7298 respectively. Two main objectives for control of Gantry Crane System, namely, swing minimization of pendulum and tracking of input voltage signal, were achieved using two separate PID controllers. The optimal gain values obtained at 30th iteration with minimum cost function is given in Table 2.

5 Experimental Results

The cart was required to track a sinusoidal trajectory of amplitude 0.3 V and a frequency of 0.1 Hz. A sample time of 100 s was chosen to operate the system. Small manual perturbations of increasing magnitude were given to pendulum for every 20s intervals. Cart Position Response, Pendulum Angle Response, and Control Signal depicting the performance of ML-PID were obtained and validated extensively for stabilizing the Gantry Crane System as shown in Fig. 3. The measure of performance

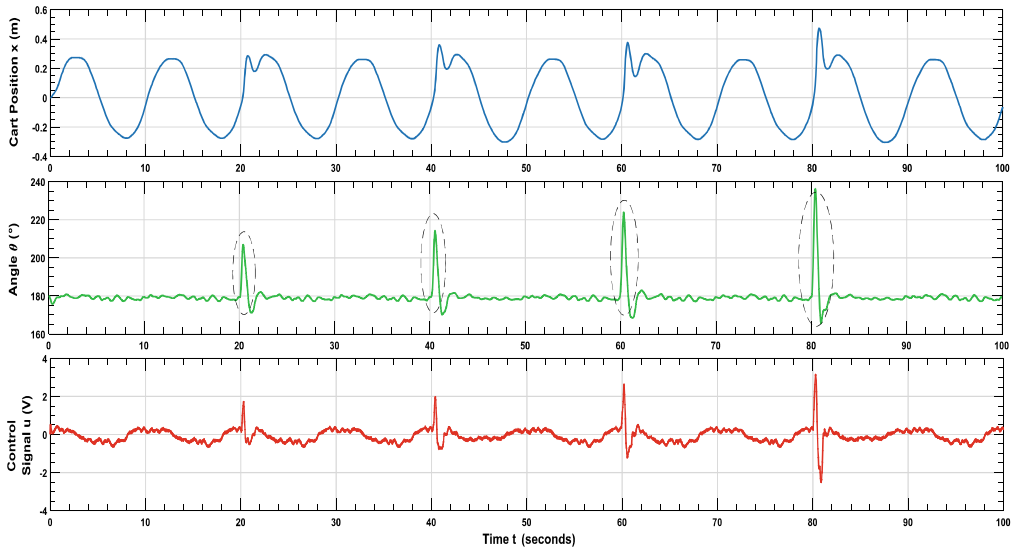

Fig. 3 Performance of Multi-Loop L-PID controller

Table 3 Pendulum angle stabilization response

S. No.	Instant of disturbance initiation (s)	Instant of stabilization (s)	Amplitude of disturbance (°)	Time taken to stabilize (s)
1	20.11	21.57	26.9	1.46
2	40.4	41.7	34.3	1.3
3	59.96	61.58	43.9	1.72
4	80.06	81.67	56.3	1.61

was time taken for stabilization after an external disturbance was given. The instant of stabilization was determined according to the 3% settling time stability condition.

The ML-PID responds to stabilization of the pendulum angle against the external noise/disturbance is given in Table 3. It is observed that as the magnitude of disturbance increases, the time taken for stabilization also increases.

6 Conclusions

In this paper, ML-PID controllers were designed, and the optimal gain parameters are obtained by using the FIPSO algorithm. The controllers were validated to stabilize the benchmarked gantry crane system. It is observed that the ML-PID controller brings the pendulum to the desired position under the perturbations in an average time of 1.522 s.

***Abstract*—With the advancements in technology, the ease of interconnectedness among devices has increased manifold, leading to the widespread usage of Internet of Things. Internet of Things has also reached our homes, often referred to as domestic Internet of Things. However, the security aspect of domestic Internet of Things has largely been under question as the increase in inter-device communication renders the system more vulnerable to adversaries. Largely popular blockchain technology is being extensively researched for integration into the Internet of Things framework in order to improve the security aspect of the framework. Blockchain, being a cryptographically linked set of data, has a few barriers which prevent it from being successfully integrated to Internet of Things. One of the major barrier is the high computational requirements and time latency associated with it. This work tries to address this research gap and proposes a novel scalable blockchain optimization for domestic Internet of Things. The proposed blockchain model uses a flow based filtering technique as an added security layer to facilitate the scenario. This work then evaluates the performance of the proposed model in various scenarios and compares it with that of traditional blockchain. The work presents a largely encompassing evaluation, explanation and assessment of the proposed model.**

***Index Terms*—blockchain, internet of things, flow policies, IoT security, scalable blockchain**

I. Introduction

Blockchain, with the potential to revolutionize modern technological communication, is being rapidly amalgamated into a number of modern architectures such as smart-grid [1], healthcare [2], fintech [3] etc. By primarily providing transparency, security and decentralization to the host architecture, blockchain improves the overall functioning of the network. One such framework in which the applicability of Blockchain is being optimistically considered is the Internet of Things [4]. This paper addresses the scenario of Blockchain in domestically deployed Internet of Things and proposes a feasible novel blockchain communication methodology.

Traditionally, domestic Internet of Things have comprised of a simple permission-based security model, in which, after a user grants the IoT system permission to use a particular data, it can use the data in every possible way [5]. No further insights are usually provided into how the data is being used or the online sinks for data transfer. Such a scenario could possibly result in a massive security breach, compromising a user's private data, such as security camera footage, thermostat readings, schedule notes etc. Such a scenario necessitates additional security mechanisms to secure domestic Internet of Things [6].

Since the popularization of bitcoin and the conceptualization of blockchain technology, extensive research is underway to effectively integrate blockchain communication to Internet of Things [4]. This is due to the possibility that blockchain can potentially improve the communication nuances involved in Internet of Things [20]. Cryptographic links between blocks of data, in blockchain, impart enhanced integrity and immutability [7] to the system, thus adding on to the security layer. The distributed framework of blockchain provide decentralization [7] to the system, thus avoiding single points of failure. Blockchain works in a transparent manner [8], with every transactional record present throughout the system, thus suitable for untrusted environments. However, there are certain hurdles to efficient deployment of blockchain in Internet of Things, which translate to the increased resource consumption and added latency in the system. Domestic IoT devices, often being compact, with certain specialized tasks, do not contain adequate computational power to sustain cryptographic mining, necessitated in traditional blockchain [9]. As the cryptographic hashes grow more and more complex, the temporal aspect of the transactional processes rise, thus causing a large delay and forcing the system to lag. Addressing these issues, this paper proposes a modification for blockchain, in context of domestic Internet of Things, which outperforms the existing blockchain systems in terms of resource consumption and latency, while preserving the security aspects of the system. A detailed analysis of the comparison of performance is also

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:47:47 UTC from IEEE Xplore. Restrictions apply.

presented to illustrate the improvement achieved.

The remainder of the paper is organized as follows: Section II explains the background, Section III presents the proposed approach and Section IV reports the results. Conclusions are presented in Section V.

II. Background

Internet of Things is an interconnected network of devices communicating with one another for the exchange of some sort of information. Various devices can be part of the network such as smartphones, sensors, hubs, etc. These devices exchange information with each other to complete a particular task. Information is transferred, processed and analysed among devices in the network. It is not a necessity that the Internet of Things is always a part of the Internet as the name suggests. A few of the major components which define the overall functioning of the infrastructure are:

- Devices: Connecting devices are the basic building blocks of Internet of Things. These devices can be sensors or actuators. Different devices such as mobile camera, accelerometer, proximity detector, pressure sensors, etc can be the part of IoT.
- Connection: The basic blocks, devices in Internet of Things are connected with each other and with the Internet via some means. They may be connected through standard Wi-Fi, Bluetooth, wired LAN (Local Area Network).
- Data Processing: Data Processing is done by the software. It can be identifying a person using a camera or measuring the temperature of the room. The software processes data and gives appropriate results to the user.
- User Interface: User Interface is responsible to show the results processed by the applications to the user in a very suitable manner. It can be showing continuous results over a mobile application or giving an alert via notification on mobile phone to the user.

The process begins with the sensors and chips that are embedded in the physical things that surround us, each of which transmits valuable data. All these devices having sensors are connected with one another. There are IoT platforms which store the relevant data transmitted by the connected devices. IoT platform analyses the data received from various devices. After analysis, important data is transferred to the real time applications. The application will then show the results of analysis to the user. In this way, IoT helps us to interact with machines and devices.

With sophistication of technology, security has become a cardinal issue in modern day Internet of Things [9]. The devices in IoT are connected with each other and the Internet. The data exchange taking place between these devices over the network must be safe and secure. The inter-connected nature of this setup makes it exceptionally prone to attacks such as:

- Cryptanalysis Attacks [10]: In cryptanalysis attacks, the focus is to find the encryption key and to break the encryption. It refers to the act of breaking ciphers. The attacker will study and analyse the ciphers to break the encryption and will break into the system.
- Software Attacks [11]: In software attacks, viruses, trojan horse programs or worms are used to inject malicious code into the system. The malicious code will then destroy the software. An attack on software of IoT device may lead the attacker to steal the user's personal credentials.
- Network Attacks [11]: IoT is vulnerable to network attacks because the transmission of data takes place in a broadcast manner. As soon as an attacker hacks a device in the network, he can easily break into other devices present in the same network. Hence, it is important to keep the network safe. Network attacks can be active or passive.
  - Passive Attack: In passive network attacks, attacker attacks the functioning components of the network. The attacker attacks the network in a concealed manner and try to gather important information of the user. Traffic analysis, node destruction, node malfunctioning, node outage can be some passive attacks.
  - Active Attack: In active network attacks, the attacker tries to make the network services complex and destroy the function and operation of the network. Jamming, flooding, Denial of Service (DoS), wormhole, blackhole, sinkhole are some active attacks.
- Denial-of-Service (DoS) Attack [12]: In DoS attack, the attacker makes the IoT devices and services unavailable. It is very difficult to detect DoS attacks. The attacker makes unnecessary requests to the services which reduce the capacity of the network. The attacker generally tries to flood the centralized resources with requests such that it is unavailable for the other nodes in the network. In Distributed Denial-of-Service (DDoS) Attack, multiple attackers from multiple sources try to flood the requests to a single resource. It can neither detect the attack beforehand nor can stop it by just blocking a single source as it is originated by multiple sources.

Blockchain is an inter-connected list of time-stamped series of secure and immutable records which is distributed in nature [14]. As highlighted in the previous section, integration of blockchain communication into IoT infrastructures effectively enhances the security aspect of IoT infrastructures and protects the system from the above-mentioned threats [4]. Each and every block in this list or chain uses cryptographic methods to stay connected. All these blocks together provide security to each other and also prevents any form of modification to the data. This chain has no central authority. Due to absence of any central power, this distributed ledger is open to each and everyone to see and add. It is by its very nature a transparent entity and every node involved in it is accountable for its actions. The blockchain is a simple yet ingenious way of passing information from system X to system Y in a highly safe and secure manner. One party creates an initialization

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:47:47 UTC from IEEE Xplore. Restrictions apply.

block, it is then verified by millions of other distributed systems [13]. After the verification, the block is added to the chain which consists of previously added blocks.

The three primary factors that impart this high security to the blockchain setup are:

- Decentralization [7]: The system follows a decentralized computational approach in which every involved entity performs some computation locally. This system eliminates a single point of failure and increases the efficiency.
- Transparency [8]: The system is transparent as the blockchain contains every record in an encrypted manner and a record of it is present in each node. This increases the accountability in the system and enhances the security.
- Immutability [7]: Immutability of this system ensures that the encapsulated data is not tampered with. The hashing ensures that any change in the underlying data renders the entire blockchain invalid.

Despite the benefits of amalgamating blockchain to IoT, the integration is not usually feasible in real world scenarios [19]. This is due to the high latency and computational constraints that accompany the setup [9]. This work, in the following section, attempts to address this research gap and proposes an optimized filtering technique to enhance blockchain performance in domestic Internet of Things.

III. Proposed Model

Modern day Internet of Things are prone to security breaches as the devices store a huge variety of crucial personal and institutional data [9]. Several attacks, such as DDoS (Denial of Service), Side Channel Attacks or Man in the Middle attack can cause immense harm by breach of data or rendering the devices useless. For instance, in 2016, Dyn, an American DNS provider faced a large scale DDoS attack, which originated from millions of IP addresses. Several of these IP addresses belonged to IoT devices such as sensors, printers, routers, monitors etc which were infected with Mirai Malware [15]. Similar circumstances necessitate the improvement of security mechanisms in these devices. Integration of blockchain technology to the Internet of Things may provide a solution, as explained in the earlier sections. However, a major obstacle in the adoption of blockchain by IoT devices is the high computational requirements of blockchain. IoT devices are usually small, with limited resources and computation at their disposal. This work tries to close this gap in the case of domestic Internet of Things by providing a case specific solution.

In traditional blockchain scenarios which have been integrated in the Internet of Things, every transaction initiated in the system, whether genuine or not, is being competed for by miners to validate [14]. The process of validation of a transaction is extremely bulky in nature and thus, utilizes a huge chunk of the computational power, thereby, increasing the processing time and resource usage [16]. This work designs a preliminary selective mechanism to identify the predicted authenticity of a transaction before the mining initiates. This mechanism eliminates a set of transactions before the mining process. The blockchain model uses the selective mechanism for the filtering of transactions, thus eliminating the need for validating a number of transactions which do not fit the selection criteria. This subsequently saves computational time of the system and thus, aids the scalability of blockchain in domestic Internet of Things.

The selectivity of transactions in the proposed blockchain model is based on the idea of flow policies [17] [18]. Flow Policies, in simple words are the underlying principles in a system that govern the flow of data. In domestic Internet of Things, the flow pattern of data files between devices are fairly static in nature, in the sense that any particular device has a predefined set of data flow paths. Under normal circumstances, the devices do not usually defy these predefined pathways and almost always confirm to them. For instance, a thermostat might send its data to a hub processor in the network, but it will never have to send the collected data to a bitmap image processor in the same network under normal circumstances. Similarly, a security camera might send a jpg file to a bitmap processor in the network, but might never have to send it directly to an untrusted online sink, while securely functioning. These predefined path structures in domestic Internet of Things have been researched previously and have also been successfully implemented in traditional security architectures. This paper leverages this attribute of domestic Internet of Things and amalgamates it with blockchain to improve the security architecture of the system, while maintaining the scalability of the associated blockchain framework in terms of time and resource consumption.

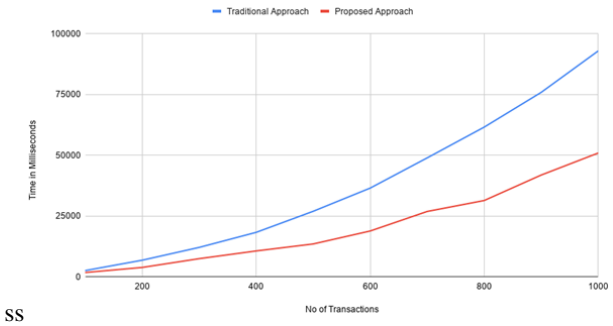
Every transaction necessitates the involvement of at least two devices. In the presented model, every device has an associated list of flow policies, defining which devices can send or receive data from them. In order to identify if the transaction is in accordance with the user defined flow policies, an intersection is performed between the associated flow policies of the involved devices and the resulting set of flow policies are used to evaluate the authenticity.

In the presented model, the user defines a set of flow rules for every device in the network, i.e. which devices can send in or receive data from that particular device. Every transaction, upon initiation by a sender is flooded into the blockchain network. In the network, every miner has the flow policies of the network. Upon receiving a transactional data packet, duly stamped with the sender's and receiver's IPs, the miner first checks the fulfilment of the associated flow policies. If the transaction is in accordance to the defined flow policies of both the sender and the receiver, the miner proceeds to the validation process. The miners then compete to validate the transaction and mine a block. This block is then added to the blockchain and the transaction is complete. If the transaction violates the flow policies, the data packet is dropped and the transaction cancelled. The flow policies in this model, thus, act like a primary security layer to filter out invalid transactions which do not follow the rudimentary flow patterns acceptable to the user. For a flow policy violation, no major computation is performed in this model, saving a certain

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:47:47 UTC from IEEE Xplore. Restrictions apply.

amount of computational power and time. In scenarios when the system is under attack, this filter thus considerably reduces the chances of the system being overwhelmed by adversaries generating fake requests in the system.

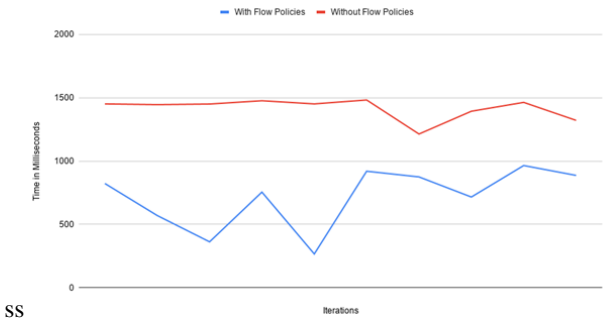
In real world scenarios, under normal circumstances, devices usually function without any interference, following those user-defined paths. During an attack by an adversary, a burst of faulty transactions of data are initiated with the intention of interrupting the functioning of the model. If processing those faulty transactions consume too much of the system resources or time, the system starts to fall apart and eventually, fails. The proposed model protects an IoT establishment from such scenarios in which a system is under constant attack by a particular device or application, initiating multiple bogus transactions to create bottlenecks in the system and slow it down, ultimately resulting in a system failure.



IV. Results

A simulation environment is developed to conduct these runs and only generalized average scenarios are taken into consideration in order to account for the usual trend observed. However, as pointed out earlier, in real world scenarios, the occurrence of fraudulent transactions are often concentrated in short periods of time in which a malicious entity attempts to impair the system. In usual circumstances, the system functions without the presence of any malicious entities without any fraudulent transactions. This work presents scenarios encompassing all possible scenarios.

The first set of simulations are performed on a randomized set of data transactions in the underlying IoT ecosystem in which the flow policies are defined in a probabilistic manner. The flow policy for every pair of device has a defined probability which determines if that particular transactional flow will be valid or not. In real world scenarios, the user directly interacts with the system to explicitly state the flow policies. Thus, the probabilistic method used in this work is merely an attempt to simulate the real world user interaction. The system then generates completely randomized data transactions in the IoT simulation. Blockchain Nodes are subsequently invoked to initiate these transactions. Depending upon the percentage of faulty transactions, the performance evaluation changes.



In the particular case of Fig. 1, the probability for every pair of node was set to be 0.5 and since the transactions initiated were randomized, the scenario translated to almost 50% of the transactions being faulty. As visible in the graph presented, the proposed method significantly outperforms the existing approach as almost half the transactions are invalidated by the flow policies, thus, saving the time otherwise required in mining. The presented graph represents an averaged out scenario of multiple iterations of simulation, with data values being reset at every iteration.

The “difficulty” in these blockchain simulations represent a quantized value of the string length of the initial cryptographic challenge which is required to be solved in order to block a mine and validate transactions. In simple words, “difficulty” of the blockchain system is representative of the difficulty of the

SS

Fig. 1. Comparison of traditional and proposed approach

SS

Fig. 2. Difficulty of encryption: 2

cryptographic mining. While for cryptocurrencies, this number is very large, in the case of domestic Internet of Things, this number is relatively smaller. This is due to the disparity in use case, security requirements and time constraints.

The simulations work on “difficulties” ranging from 2 to 5. In other words the length of the initial cryptographic challenge is varied from 2 to 5 in order to give an idea of how this factor affects the time considerations of the implementation. For various difficulty levels, graphs are presented portraying the changes in timing between traditional blockchain approach and the presented approach enhanced with flow policies. It can be seen in Fig. 2, Fig. 3, Fig. 4 and Fig. 5 that as the difficulty in the blockchain method is increased the associated time of transactions also increase. It is evident that the proposed approach provides a huge temporal benefit in optimizing the operation of the Internet of Things Infrastructure of domestic use case scenario. For difficulty levels of 2, 3, 4 and 5, the performance of all the iterations are clearly better for the proposed approach, as compared to the traditional blockchain approach.

This work also encompasses the evaluation of the proposed method in scenarios with different percentages of invalid transactions. Fig. 6 represents the performance of the model in the above-mentioned scenario. It can be observed that as the percentage of invalid transactions increases, the time consumption of the system reduces. This is due to the fact that invalid transactions are rejected in the filtering phase and are thus, not mined at all. This saves the computational time otherwise wasted in their validation. However, even when

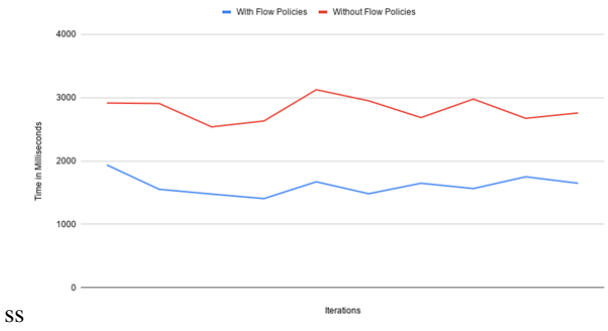

Fig. 3. Difficulty of encryption: 3

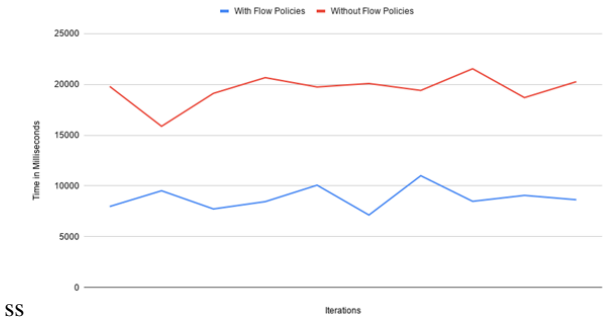

Fig. 4. Difficulty of encryption: 4

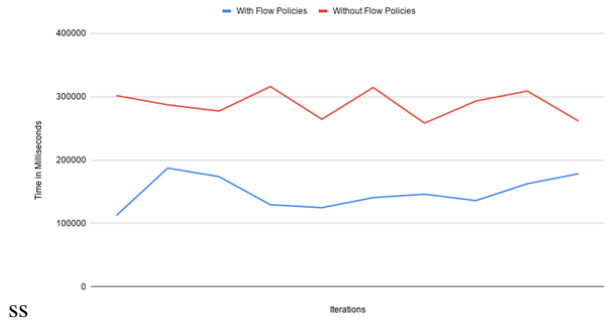

Fig. 5. Difficulty of encryption: 5

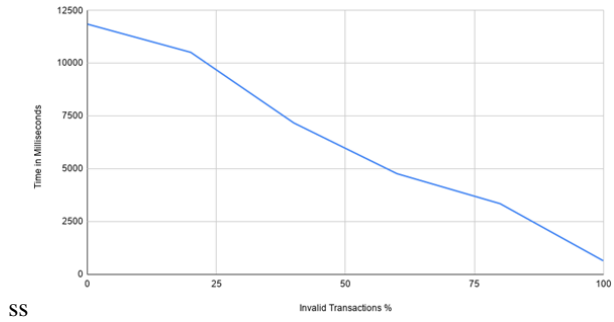

Fig. 6. Variability in Percentage of Invalid Transactions

100% of the transactions are invalid, The time does not reduce to 0. This is because some computation is still required by the system to run processes other than mining. When 0% of the transactions in the system are invalid, the system requires a lot of time as all the transactions are mined as usual and no apparent optimization is achieved.

V. Conclusion

This work navigates through the blockchain mechanism of operation and analyses the scope of integrability to domestic Internet of Things (IoTs). While navigating through the use case scenario of modern Blockchain Technology, the work considers as to how blockchain is suitable for domestic Internet of Things and the benefits that the integration of blockchain provides by enhancing the security and reliability of blockchain by imparting decentralization, immutability and transparency.

One of the major barriers in scaling blockchain into domestic IoTs is the immense latency which comes along with the blockchain technology. Primarily, the Proof of Work (PoW) consensus algorithm associated with blockchain is responsible for the latency caused as the cryptographic challenge presented before miners are time consuming. However, it is also crucial to impart security to the process of validation of transactions. Intensive and inclusive literature review and research led us to an optimizing technique, which when integrated to traditional blockchain led to a significant decline in time considerations. This technique requires installation of entity specific traffic flow policies which are defined for each entity in the IoT infrastructure. This optimization is very specific to the use case of domestic Internet of Things in which data flow paths are relatively static. In other scenarios, such as cryptocurrency, this is not viable owing to the variable data flow paths and the unpredictable nature of transactional packet flow.

This work then conducts an analytical simulation in order to assess the performance metrics by varying the user specific parameters. A few parameters such as percentage of malicious transactions, “difficulty” of the mining and overall number of transactions are varied and the corresponding data sets are used to obtain performance graphs. These graphs indicate the performance improvement achieved and discusses the implication of this improvement in real world scenarios.

Abstract— **Sunlight is always a great asset for human beings. Among various systems available to access solar power, the most well known innovation is the photovoltaic(PV) transformation of daylight into electricity. Regardless of its benefits, sunlight based PV innovation has issues such as bulky and less efficiency. The most precious process of photosynthesis, the sun catching nature of trees is an inventive thought of light catching cells. The idea of a sun oriented flexible tree is fit for tending to these issues adequately with polish. In this paper efforts have been made to audit the parts of the sun based tree and its energy harvesting capability. The different energy enhancement structures are additionally talked about alongside utilizations of the sun powered tree. The paper additionally addresses the difficulties engaged with this innovation and proposes future research heading.**

Keywords— **Photovoltaic, Solar tree, Solar Energy, Renewable Energy**

I. INTRODUCTION

The journey for green and supportable energy sources has gotten probably the greatest test for our time, because of exhaustion of fossil energy products, environmental challenges, an Earth-wide temperature boost and perpetually developing energy demands. Energy from the sun comprises light and warmth from the Sun, it is being utilized via different advancing technologies. Few of them are like sunlight based heat collectors, sun oriented photovoltaic, sun based heat power, sun based electricity powerhouse, sun-powered building design and counterfeit photosynthesis [1].

The most well-known use of the sun is electric energy generation through the photovoltaic (PV) frameworks. Sun based PV execution is reliant on the nearby climatic conditions and accessibility of sun-powered radiation. Sun based radiation appraisal and estimation is particularly useful for the appropriate structure of sun based energy change frameworks. The trap frequency and intensity of the Sun beams vacillate for the duration of the day and throughout the year. In this manner, sun-powered modules fixed at a specific point may not be completely advanced. Sun following PV frameworks can be structured, however they essentially raise the all-out expense of energy generation as they are exorbitant and require support. Another, encouraging approach to coordinate sun oriented PV into the developed condition is through multidimensional Photovoltaic frameworks [6-8]. One of the essential installation components for the establishment of all such sun based PV modules is land Rooftop sun oriented PV is an alluring choice, however, it has constrained space for modules to be masterminded in a cluster or multistoried building particularly inland limited urban territories. The Sun following PV frameworks can be a possible solution but they fundamentally raise the all out expense of energy as they are exorbitant and require support. Another challenge in this encouraging solar powered PV execution deals with issues like installation space requirement, low PV efficiency, approach to coordinate sun based PV frameworks etc.

Significant cost reductions have been observed in the past few decades along with high efficiency in photovoltaic based solar cells with strong increase in people acceptability. The PV technology now positioned to provide low-cost energy options and have enormous capacity for future energy generation. Improvement in energy-conversion efficiency reduces such costs, with mass manufacturing likely to bring down the additional costs associated for achieving higher efficiencies. This suggests that the industries will evolve beyond the conventional single-junction solar cells that presently dominate commercial production, where energy-conversion efficiencies are constrained by practical values of Shockley–Queisser limits to below 30%. Contrary to that nature's solar capturing technology, plants exploit the Sun more effectively [3]. The low effectiveness is due to associated losses like spectrum loss, reflection loss and heat generation and so forth.

In this article the overall prospects for a range of approaches that can potentially exceed these limits are based on ultimate efficiency prospects, material requirements and installations outlook. The challenges involved in this technique are considered and suggestions are proposed to overcome them. Finally the concept of solar trees is discussed to overcome above losses through law of conservation and minimization process.

II. SIMILARITIES BETWEEN SOLAR CELL AND PHOTOSYNTHESIS

Like plants, solar cells gather their energy from sunlight. Plant leaves collect sunlight and transform this energy into

chemical energy. Similarly, photovoltaic solar cells convert the sun's energy into electricity. They perform the same function but in different senses. The main resemblance between the two is that both photovoltaic and photosynthetic plants are supposed to absorb photons.

This task of absorption of sunlight is carried out by a molecule called chlorophyll in nature (plants). In the case of photovoltaic, scientists have designed materials where the electrons can absorb the energy of the sun's photons. In both cases, photons are absorbed by electrons, which take up the extra energy and get excited to a higher energy state known as excited electron. The process of conversion of the energy absorbed by excited electrons should be fast before they lose their energy and go back to their initial state. In the case of photosynthesis, this issue is resolved by moving the electron from one molecule to another until it finally settles in a molecule that can store this energy for a long time. In photovoltaic, the excited electrons are carried off into a circuit, where they are either used to operate directly or are routed into a battery for storage [4].

There is a type of solar cell that is designed to be as analogous to photosynthesis. This is a non-conventional photovoltaic cell that tries to reproduce the way photosynthesis works. Instead of moving an electron as quickly as possible through a crystal of identical atoms, this dye-sensitized solar cell absorbs energy in a dye molecule, then transfers the excited electron into another material located adjacent to the dye molecule. This technique makes sure that the electron doesn’t lose its energy ineffectively. When connected to a circuit, this electron makes its way through the second material without risking losing its energy.

III. PLANT ARCHITECTURE INSPIRE SOLAR CELL DESIGN

Plants exhibit a variety of systematic structures and structures, which are difficult to explain. Plants are dependent on the light energy they receive from photosynthesis, and strong sunlight is the most important factor in photosynthetic influence, but in addition the leaf temperature, leaf water status, and many other physiological procedures of the plant also influence photosynthesis. There are no fixed configuration rules in all conditions.

Geometrically it is determined by only two parameters: the propagation limit and the branch length. They are undoubtedly more cohesive and consistently attracted to authors of plant conditions and development models. In trees, the leaves outside the hiding place are different from those inside the tree cover. The outer leaves are called "sun leaves," and the inner leaves are "secret leaves." These leaves contain differences such as fiddle, internal structures of life, and science that enable the translation of certain energy to use different types of solar radiation more effectively. The leaves of the sun are generally normal, prolonged and larger than the secreted leaves, which contain many layers of chlorine-containing tissue and are very broad within the arteries. It is believed that the sun's leaves are better adapted to capture and use direct sunlight (if not too different to even think of causing heat and pressure related damage). Its long position is connected in parallel with the most important levels of sunlight reaching the inner cover where the foliage is located. Shaded leaves appear to make good use of sunlight, reaching into the inner shelter after exposure to different substances, such as outer leaves, in the form of direct light. Leaves of similar color can be found in an outdoor shelter such as the color towards the subtle sun. The leaf level of photosynthesis depends on the biomass of the leaf biomass as the emission of light into the leaf area. The scattering and course of leaf functioning within a tree can completely alter the effectiveness of a good harvest. The leaf area all tightened to a given plant is a very important aid that contributes to the partitioning of edible radiation. When the point from the light of the sun decreases from the equator to the highest positions, the trees of different lengths and widths have effectively changed the light capture technique. All kinds in a variety of colors to add an effort to capture a quick glow through the whole tree.

The leaf must "absorb" sunlight, water from the inside and carbon dioxide from the air that combines photosynthesis. Leaf photosynthesis, meanwhile, is influenced by these carefully regulated materials: enough sunlight and carbon dioxide for photosynthesis, yet not all that closely related heat storage or water misery. The leaves found on the Nature Trail trees are expensive and adequate or molded with a needle that is ideal for their water-conserving weather conditions and high maintenance during the day is an important way to persevere.

Plants show a striking assorted variety of structures and structures, which are hard to decipher. Plants rely upon the light energy that they catch by photosynthesis, and sun-powered radiation is the significant main impetus influencing photosynthetic movement, yet in addition leaf temperature, leaf water status, and numerous others. because nobody configuration rules in all conditions. The geometrically dictated by only two parameters: spreading edge and branch length. are undoubtedly multi-fractals and have consistently pulled in mathematicians for plant shape and development models. In trees, the leaves on the outside of the tree shelter contrast from those inside the tree covering. The outside leaves are alluded to as "sun leaves," while the inside leaves are "conceal leaves." These leaves have contrasts fit as a fiddle, interior life structures, and science that make an interpretation of specific capacities to utilize various types of sun based radiation successfully. Sun leaves are normally littler, progressively prolong, and thicker than concealed leaves, with more layers of chlorophyll-containing tissues and increasingly broad inside vascular frameworks. It is believed that sun leaves are better adjusted to catch and utilize direct

sunlight based radiation (when it isn't too exceptional to even think about causing heat and different pressure related harm). Their lengthened shape is likewise connected with more significant levels of sunlight based radiation arriving at the inward covering where the shade leaves are found. Shade leaves appear to successfully utilize diffuse sun oriented radiation, which arrives at the internal shelter in the wake of having been dissipated by different items, similar to the external sun leaves, in the way of direct light. Shade leaves can likewise be found on the outside shelter as an afterthought that faces from the overarching sun. The leaf photosynthesis rate relies upon the biochemical limits of the leaf just as a light appropriation on the leaf surface. The dispersion and course of action of leaves inside a tree can firmly change the light reaping effectiveness. The all-out leaf zone bolstered by a given plant is the most essential auxiliary property that influences the division of consumed radiation. As the sunlight based tendency point diminishes from the equator to higher scopes, trees with contrasting stature to width proportion have inalienably changing efficiencies of light capture. Every single such variety to augment the immediate light capture attempt by the whole tree.

A leaf must "catch" sunlight, water from inside and carbon dioxide from the encompassing air by means of pores for photosynthesis. The leaf photosynthesis, at that point, is influenced by these exercises in careful control: enough daylight and carbon dioxide to run photosynthesis, yet not all that much-related warmth retention or water misfortune. The leaves found on the trees of the Nature Trail are either expensive and level or needle-moulded which appropriate to its climatic conditions for cautious preservation of water and most extreme daylight retention is a significant endurance system. A significant result of variety in a leaf design, its shape and size is the general light gathering and the proficiency factor for photosynthesis.

IV. SOLAR POWER TREE

Nature motivation centres around profoundly requested little bent surface geometry which follows the most extreme snare of daylight and water protection through photosynthesis. Likewise between a sun oriented cell and a tree is that both attempt to catch the most extreme sunlight based energy with least water misfortune or warmth age. At present utilization of PV, frameworks increment quickly because of ceaseless decrease in costs of sun based cells. Still, there are a few obstacles for the appropriation of this innovation like low productivity and enormous space necessities. Different methodologies [6] have been done to improve sun oriented energy factors, for example, low ingestion coefficient, heat loss, reflection coefficient and so forth, The charge bearer age and conduction impact the light conversion proficiency of a sunlight based cell. This is a roundabout way that relies upon the quantity of sun-powered cells introduced and their energy change limit.

Recently inspired by natural heat-trapping technology - photosynthesis, a new concept solar tree is introduced by many researchers [3,4]. Nature centres around profoundly requested little bent surface geometry like tree geometry. So a gathering of cells which are littler might be prolonged, a little bent and have a multilayer structure. The new idea- Solar Tree is a natural venture, an environmental model, a counterfeit sun based structure that seems as though sculptural trees exist from little scope (size of a bonsai tree) to enormous scope (about the size of a breeze turbine) power plant. In sun based trees, PV boards or cells are orchestrated in a Fibonacci arrangement design rather than leaves. It is an independent unit that produces green energy and provides a place of comfort and energy for a wide variety of services.

The structure is a ground-mounted solar system with a pole that supports many individual panels up in the air. The performance of sunlight based trees vary and they have been intended to give the capacity to face various situations. Sunlight based tree has remarkable properties as far as structure and multi-edge direction parameters. By utilizing the tallness parameter, the sun-powered tree requires less space utilization which can lessen the installation cost. Such a mix of the sun oriented cell should be possible on common trees to lessen the expense of mounting. Contrasted with the customary sun based PV homestead which is situated a solitary way, the multi-edge direction parameter from the sun based tree boards yields the potential ability to retain higher daylight force prompting higher yield vitality. Simultaneously, this parameter disposes of the need to introduce a sun oriented tracker which can decrease the operational expense. To build the assortment Generation of 1MW force from PV module framework requires the space of around 5-6 Acres for lodging the boards as it whereas a solar tree would take just 1% of the land territory in contrast with general PV lodging. So it is appropriate for places where there is a shortage of land. It can likewise be bolted at any situation to withstand the wind pressure because of substantial tempest influencing over the fundamental shaft/trunk. The boards will be normally looking with least block from different towards the sun at an edge as required so they can gather the greatest sun-powered energy in a daytime.

Sun-powered trees are actually a functional answer for household use. In this setting utilization of PV innovation for the local necessity as the sun oriented tree is the acceptable option when contrasted with traditional level or housetop mounting PV panels. Solar trees can be introduced close, before the house or on a porch, where there is no concealing consistently. To build assortment efficiency, the nanowire cell can be used rather than present PV cells. The Nanowire cells can gather multiple times progressively sun based vitality

International Journal of Engineering Applied Sciences and Technology, 2020
Vol. 5, Issue 2, ISSN No. 2455-2143, Pages 217-221
Published Online June 2020 in IJEAST (http://www.ijeast.com)

when contrasted with regular cells. The idea of nano leaf is a plan to expand the different types of energies, for example, sunlight based, warm and piezoelectric force by stalks, branches, and twigs of a tree.

Solar trees are really a practical solution for domestic use . In this context use of Photovoltaic technology for the domestic applications in the form of the solar tree is the good alternative when compared with conventional rooftop mountings. Solar trees can be installed in front of the houses, at the terrace, in streets or where there is no shading throughout the day.

V. Minimization of Solar Energy Loss

Sunlight increases temperature which affects photovoltaic conversion. This does not significantly affect the light generated current of the cell but reverse saturation current increases exponentially with temperature and also reduces open circuit voltage with temperature. Furthermore, it has been experimentally observed that temperature drops the efficiency of solar cell. It is imperative to reduce the heat build-up in the cell in order to improve conversion efficiencies. Recently, it is seen that solar tree energy conversion efficiency increases through minimizing the chlorophyll antennae [6]. Similarly to keep the heating impact of a solar cell low , various approaches are possible. The approaches are possible such as use of multispectral cells for low heat production, reduction in energy loss through current loss and the use of thermal generators for energy harvesting. The reduction in size expected a reduction in current with less utilization time. Recent quantum level technology developed tuneable band gaps across a wide range of energy levels by changing their size, whereas the bandgap is fixed by the choice of bulk materials. This reduces semiconducting particles below the size of the exciton Bohr radius. The quantum nature of existing particles set electron energies finite alike energies in an atom. The developed Quantum dots methodology is referred to as artificial atoms and energy levels are tuneable by changing their size, which in turn defines the bandgap [1]. The dots can be grown over a range of sizes, allowing them to express a variety of band gaps without changing the construction techniques. This makes it attractive for multi-junction solar cells and use of a variety of materials to improve efficiency by harvesting multiple parts of the solar spectrum. To increase the collecting efficiency of cell, the nanowire cells can be used instead of present Photovoltaic cells. The Nanowire cell can collect 15 times more solar energy as compared to conventional cells [1].

VI. Flexible Solar Tree

From the previous section, it is found that the natural light conversion technology photosynthesis is similar to solar cell technologies. Rather the natural conversion technology is found higher than solar cell light conversion technology [3,6]. These natural processes suggest various different possible solutions to these energy losses in a solar cell. The laws of science put some limits on such power conversion, but also leave some scope for improvement through multiple loss minimizations. Section II shows that sun spectrum absorption varies with nature and configuration of leaves, so give an idea of multi-spectrum material for solar cell construction. Also leaves shape, size effect light inclination and efficiency for light energy conversion. This inspiration focuses on small curved surface geometry to capture more sunlight. The multilevel solar cell - tandem cell can be fabricated to drastically reduce the transmission losses. The efficiency of natural photosynthesis also depends on water evaporations; similarly, heat dissipation play is a key factor in solar cell light conversion. .From the previous section, it is also clear that scaling down also affects efficiency drastically.

All these ideas include a modified version of the solar tree which is discussed in section II. The advancement of technology has reduced the size of solar panels to a size of 0.6 x 2.55 inches . This is comparable to the size of plant leaves and their individual identity power varies from 0.5 to 4 W. The cumulative power output will be quite high for various

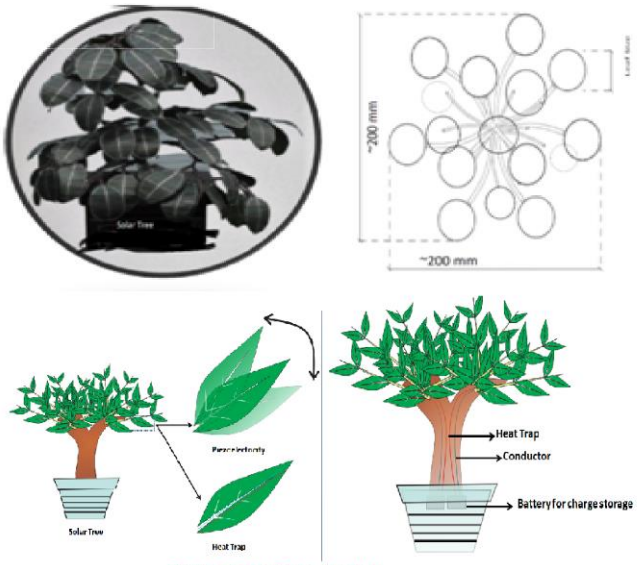

Fig 1 : Solar Tree Model

domestic applications. The concept of nano solar material solar tree leaf that would maximize the light conversion [1,5]. In order to trap maximum solar energy, the use of quantum wire PV boards is orchestrated in a Fibonacci arrangement design. One such plant pot size is proposed is shown in figure1. In this novel solar tree design, multispectral cell junctions can be fabricated to drastically reduce the transmission losses. On top of the leaves, the anti-reflective coating can be used to reduce reflection losses. Leaves are the independent unit that produces green energy and provides a place of comfort and energy for a wide variety of services. This kind of texturing of the rear surface will not be required

to achieve total internal reflection as the surface of flexible materials is already rough.

The leaf photosynthesis is also influenced by these exercises in careful control of carbon dioxide or too much-related water retention. In photosynthesis, this problem of heat generation is solved by molecules energy transfer to another until it settles in a molecule that can store energy for a long time. The conductive branches of photovoltaic solar trees can trap excited electrons into a battery for storage. This leaf-like structure acts as a thermionic generator thereby leading to the enhanced sensitivity. This design ensures the enhanced performance of a solar cell as a reduction in heat-up leads to higher efficiency. In addition to this the flexible nature of leaves also helps in harvesting wind energy. The various forms of energies such as solar, thermal and piezoelectric power by stalks, branches, and twigs of a tree. The amount of energy generation varies with the size/shape of leaves, the number of leaves etc. The flexible nature of coated piezoelectric solar cells helps in harnessing the wind energy throughout day and night. A significant amount of wind power is also generated due to wind-generated movement of small light weighted leaves. The heat energy can be converted simultaneously into electric energy using thermal converters. the energy of radiations. The various designs of flexible trees can be possible depending on geographical conditions and demands. The synchronization of solar energy with heat energy and wind energy supply continuous supply of energy even at night or when the sun is covered with clouds.

VII. CONCLUSIONS

The The sunlight based tree idea is effective to satisfy the expanding energy demands of the individuals, sparing area, and ought to be executed to give power without the issue of intensity cut-off. The concept of nano leaf is an idea to maximize the various forms of energies such as solar, thermal and piezoelectric power by stalks, branches, and twigs of a tree.

All this energy waste harvesting converts it into grid power. The adaptable nature and nano-size leaf fit it into a beautiful small size pot plant and a valuable device. This superb plant that requires no watering and sustains. The beginning venture cost of the sun based tree is likewise equivalent to the same limit PV frameworks as other framework parts are similar. The restitution time of proposed framework is by all accounts high yet because of persistent increment in the expense of network force and decrease in the expense of PV cell because of mechanical progression long recompense period can be compensated. The same photosynthesis move configuration can be reached out to different areas and applications including higher energy utilizations. At the last, Solar Tree front line eco-perfect innovation and should work in agreement with common trees.

ABSTRACT: A fuzzy model for forecasting the probability of cost overrun risk for Indian construction project is developed by identifying, classifying and ranking the cost overrun factors of the construction industries. Fifty five cost overrun factors are identified, classified into eleven clusters through a detailed literature review process and discussion with experts from the Indian construction industry. A questionnaire survey in Indian construction industry was conducted for data collection to calculate Relative Importance Index (RII) of the factors and clusters. On the basis of the relative importance index of the factors and clusters, a model is developed using the fuzzy logic tool box of MATLAB program software. The model is developed in two stages. First the probability of cost overrun due to the clusters of cost overrun factors is determined and the final cost overrun risk probability of the project is determined taking into consideration the probability of all the clusters. Applicability of the fuzzy model has been tested on a real case study in India. With the help of the proposed model, it is possible to guide project managers and decision makers to make more informative decisions such as contingency estimation, mark-up estimation, bid price, selection of optimum procurement route, evaluation of different projects and preparation of project portfolios.

Keywords: Construction industry, Cost overrun, Probability, MATLAB, Fuzzy logic, India.

I. INTRODUCTION

To complete a construction project within stipulated budget is an important factor among all the norms required for the success of the project [1-3], yet construction projects are found to be suffering from the issue of cost overrun. Cost overrun is defined as the increased costs over estimated cost [4]. This issue of cost overruns is critical both for developed as well as developing countries [5-13]. Indian construction projects are also suffering from the problem of cost overrun. A joint study was conducted by PMI and KPMG with the support of MOSPI in India on infrastructure projects in which a total cost overrun of Rs 2.19 lakh crore for 1304 projects was reported in 2018 [14]. Generally the cost overrun risk analysis is ignored in the projects and the cost of a project is determined just by adding some contingency charges, consequently many projects fail to complete the project in stipulated budget. Therefore it is essential to estimate the probability of cost overrun risk for Indian construction projects to determine a reliable cost of the project.

Several theories and methods have been proposed for risk analysis for construction projects. Zhi, (1995) [15] used qualitative method by using P-I matrix of for risk analysis of overseas construction project, Baccarini and Archer (2001) [16] Computed a risk score for cost, time or quality of project by employing P-I model. Hull (1990) [17] proposed various models by using Monte Carlo Simulation (MSC) and PERT theory for the risk analysis of cost, schedule and technical performance. Özta & Ökmen (2004) [18] presented Monte Carlo simulation technique for determining the risks and uncertainties associated with project cost and duration. Thomas *et al.*, (2006) [19] used a Fault tree method to model risky scenarios by utilizing linguistic variables to evaluate risk likelihood and impact. Dey (2001) [20] presented risk analysis model based on AHP and decision trees. Dikmen and Birgonul (2006) [21] used AHP for risk and opportunity estimation of international construction projects. Nasir *et al.*, (2003) [22] used belief network and MCS for estimating activity duration. Kangari and Riggs (1989) [23] proposed a model for risk analysis by using FST. Tah and Carr (2000) [24] presented a model for hierarchical risk breakdown structure for qualitative risk assessment through the concepts of fuzzy association, fuzzy composition and application of fuzzy logic.

According to a study by Sharma and Goyal [25], it was concluded that each theory has its own advantages, disadvantages and no theory seems to be complete for handling the uncertainty. However, based on the work done earlier it may be suggested that fuzzy theory is more suitable for handling the complex problems in construction industry as the process is based upon experience, assumptions and human judgment. The fuzzy theory has been applied in the different areas of construction projects as decision support tool, enhancing the performance, evaluation and assessment, forecasting and modeling construction risks [26-35, 40].

The previous studies of cost overrun risk analysis in India were very few in which fuzzy techniques were applied. Therefore in this study a fuzzy model for forecasting the probability of cost overrun risk in Indian construction project is developed by identifying, classifying and ranking the cost overrun factors of the construction industries. The construction industry caters to building and other infrastructure development project. Data for the cost overrun factors are collected from medium to large construction industry with turnover varying from 50 crores to 600 crores. Collected data through questionnaire are validated from sample verification technique and expert opinion. Only reliable data are used in the proposed model. With the help of the proposed model, it is possible to guide project managers and decision makers to make more informative decisions such as contingency estimation, mark-up estimation, bid price, selection of optimum procurement route, evaluation of different projects and preparation of project portfolios.

II. METHODOLOGY

The adopted methodology for the development of the model and for obtaining the results of interest is explained diagrammatically in Fig. 1. This model is developed in two stages as shown in Fig.1. First the probability of cost overrun due to each cluster is assessed by the probability level of the factors of respective cluster. The probability of cost overrun of project is assessed by the probability output of each cluster as determined in the previous step. Major components of the methodology are explained in the following sections.

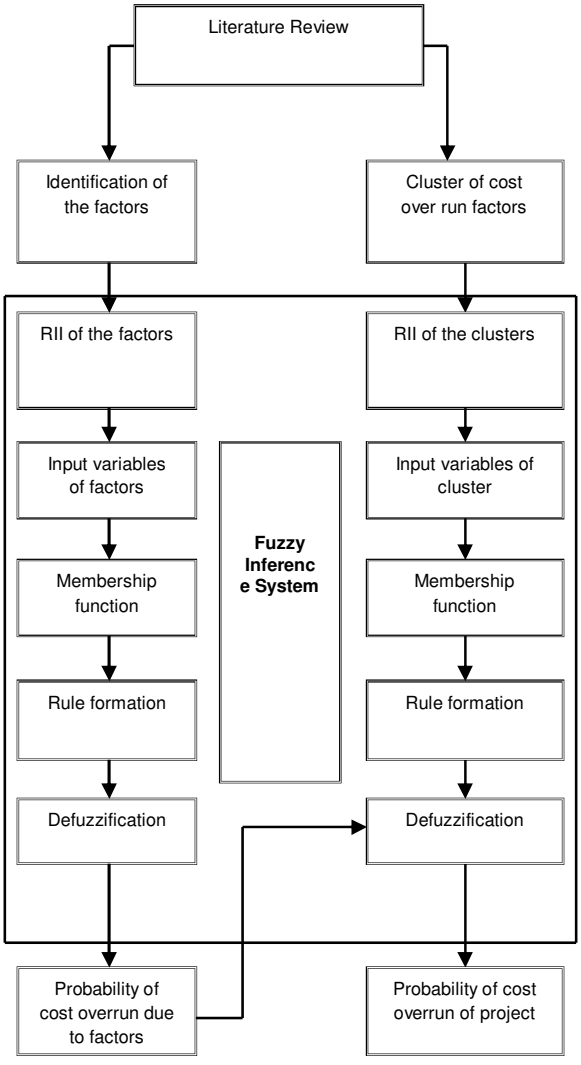

Fig. 1. Methodology.

A. Identification and classification of cost overrun factors

A number of studies conducted on the factors responsible for cost overrun in the construction projects are reviewed [6-14]. The cost escalation causes and their classification are given by Sharma and Goyal (2014) [25] for the construction industry. Fifty five important factors, responsible for cost overrun are identified through intensive literature review. These factors are grouped in eleven clusters named as 'Cluster Owner', 'Cluster Contractor', 'Cluster Consultant', 'Cluster Design', 'Cluster Project', 'Cluster

Material', 'Cluster Labor', 'Cluster Equipment', 'Cluster Contract', 'Cluster Coordination/communication' and 'Cluster External'.

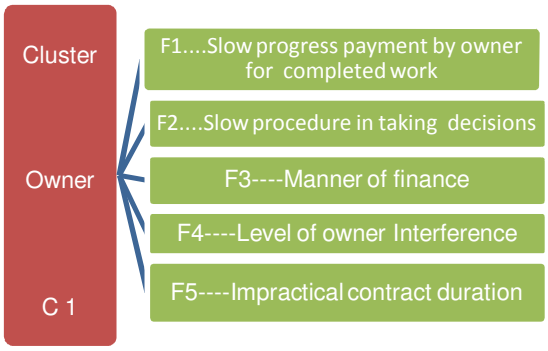

Fig. 2. Cost overrun factors of 'Cluster Owner'.

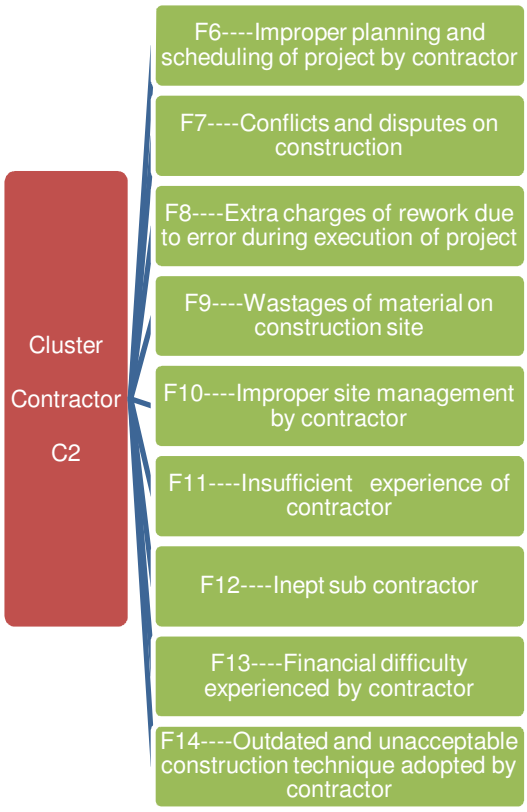

Fig. 3. Cost overrun factors of 'Cluster Contractor'.

All the factors are represented as F1, F2, F3 etc. and clusters are represented as C1, C2, and C3 etc. slow progress payment by owner for completed work, slow procedure in taking decisions, manner of finance, level of owner interference and impracticable contract duration are the factors of 'Cluster Owner' as shown in Fig. 2. improper planning and scheduling of project by contractor, conflicts and disputes on construction sites, extra charges of rework due to error during execution of project, wastages of material on construction site, improper site management by contractor, insufficient experience of contractor, inept sub contractor, financial difficulty experienced by contractor and outdated and unacceptable construction technique adopted by contractor are the factors of 'Cluster Contractor' as shown in Fig. 3.

In correct estimation of time and cost, contract management, delay in inspecting of work, quality assurance & quality control and experience level of consultant are the factors of 'Cluster Consultant' as shown in Fig. 4. In a similar manner all the factors of 'Cluster Design', 'Cluster Project', 'Cluster Material', 'Cluster Labor', 'Cluster Equipment', 'Cluster Contract', 'Cluster Coordination/communication' and 'Cluster External' are shown in Fig. 4-12.

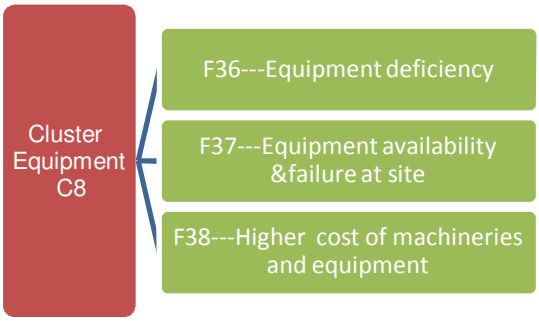

Fig. 9. Cost overrun factors of 'Cluster Equipment'.

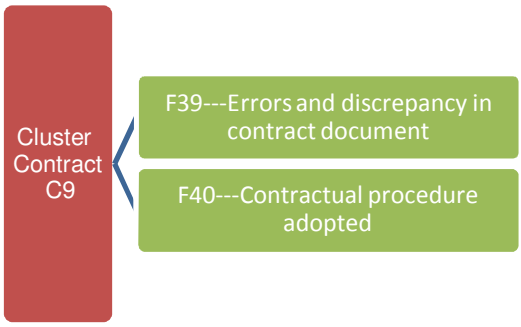

Fig. 10. Cost overrun factors of 'Cluster Contract'.

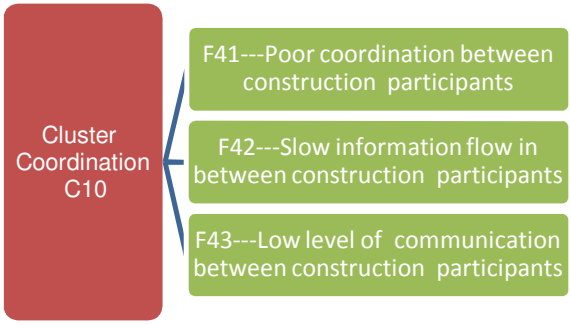

Fig. 11. Cost overrun factors of 'Cluster Coordination'.

B. Relative importance index of factors and clusters

For ranking the cost overrun factors and cluster relative importance index (RII) is calculated by collecting data through a questionnaire survey in Indian construction. The population for survey was drawn from the practitioners of the Indian construction industry, which included owners comprising government sectors (key decision makers), contractors and consultants. A non-probability sampling technique known as convenience and snow ball is used to collect the sample. The questionnaire was distributed through friend and referral network. Personal interviews were also conducted for obtaining the response quickly. Total 250 questionnaires were distributed to the potential respondents within the Indian construction company comprising owner, contractor and consultant. 100 questionnaire set to owner, 100 questionnaire set to contractor and 50 questionnaire set to consultant were distributed. Out of 250 questionnaire set, only 135 responses were returned. Out of total respondents, 62 (45%) of the respondents are working in clients' organization while 47 (34.81%) and 26 (19.2%) respondents are professionals that work in contracting and consulting organizations respectively.

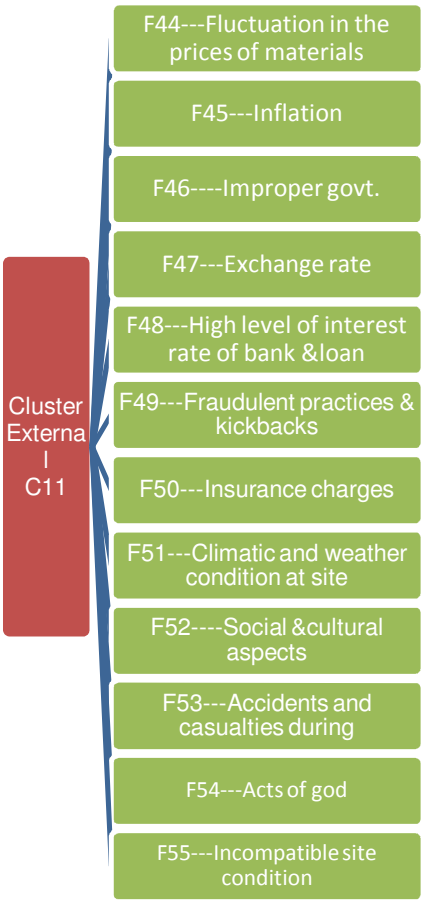

Fig. 12. Cost overrun factors of 'Cluster External'.

The respondents were asked for judging the importance level of identified cost overrun factors. A likert scale of 1 to 5 was used to evaluate the importance level of each factor. These numbers were allocated to the respondents' score as '1 = Very low; 2=Low; 3=Medium; 4=High; 5=Very high'. For ranking these cost overrun factors and clusters the following relation was used to determine the relative importance index (RII)

$$RII = \sum W / (A*N) \quad (1)$$

where W is the weighting for each factor provided by the respondent (it ranges from 1 to 5), A is the maximum weight and N is the number of overall respondents.

C. Model development using fuzzy theory

The fuzzy model to assess the probability of cost overrun is developed in fuzzy inference system (FIS) of MATLAB [36]. Fuzzy inference is a procedure where application of fuzzy logic is employed for mapping from a set of given input to obtain an output. The important features of fuzzy inference system have been explained here in brief.

Fuzzy set. The notion of fuzzy logic was originally pioneered by Zadeh in a seminal article on fuzzy sets theory in 1965 [37]. The concept of the theory is founded on multiple-valued logic; it processes and introduces interpretations which are expressed in vague linguistic terms rather than exact and precise crisp value. The theory is very useful for handling the partial truth issues.

A fuzzy set A of a universe of discourse X can be defined through Eqn. (2):

$$A = \{(x, \mu_A(x)) \mid x \in A, \mu_A(x), \in [0, 1]\} \quad (2)$$

where μ_A (x) is the membership function which provides X a membership values in the interval of 0 to 1.

Fuzzy inference system. As per litreture review Mamdani and Sugeno type of fuzzy inference methods are generally employed. For this research study, Mamdani type fuzzy inference is used because of its wide application [38]. The system of fuzzy inference is basically a rule-based. The crisp input members are fuzzified first to convert them into fuzzy sets by defining the membership functions. After that inference engine of the fuzzy logic system repossesses the knowledge contained in a rule-base where all inputs are combined as per the constructed fuzzy rules. The output fuzzy sets obtained through this process then aggregated and defuzzified where they are converted from a fuzzy set to obtain a crisp number.

The model is developed in two stages as shown in Fig. 2. First the probability of cost overrun due to each cluster is assessed by the probability level of the factors of respective cluster. The probability of cost overrun of project is assessed by the probability output of each cluster as determined in the previous step. The process of fuzzy inference system is applied for both the stages.

The various steps of fuzzy inference process employed for model development are outlined below:

1. The first step of fuzzy inference system is to define all input and output variables for model development. For the first stage of model development the various 'factors' are taken as the input variables and output is the 'probability of cost overrun due to cluster'. For the second stage various clusters are taken as the input variables and 'Probability of cost overrun of project' which is abbreviated as 'PCOP' is defined as the output variable.
2. The input variables are then fuzzified with the help of membership function in this step. The membership function is the fuzziness degree and gives a mathematical value to all input variables. Different shapes of membership functions such as trapezoidal, triangular, bell-shaped, piecewise-linear, Gaussian, g bell-shaped etc. can be used. in this study, g bell-shaped are used as Gaussian and bell membership functions have the advantage of being smooth and nonzero at all points [39]. It can be graphically represented as shown in Fig. 13.

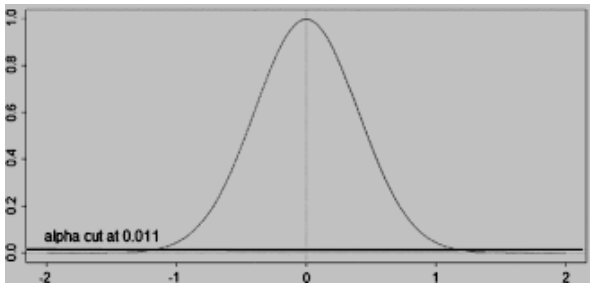

Fig. 13. Gbell-shaped fuzzy membership functions.

3. Fuzzy rules are defined in this step to perform the inference. Fuzzy rules are logical inference and connect

the input variables to output variables. IF-THEN forms of fuzzy rules are used here in this research study. Fuzzy rule for the input linguistic variables x_1, x_2 with their corresponding fuzzy values A_1, A_2 and output linguistic variable y with B as its fuzzy value, can be explained as follows.

If x_1 is A_1 AND x_2 is A_2 then y is B

If part of this rule "x_1 is A_1 AND x_2 is A_2" is called antecedent and then part of the rule "y is B" is known as consequent.

Fuzzy operators "AND", "OR" and "NOT" are also incorporated to construct fuzzy rules.

The estimated values of relative importance for the cost overrun factors are allocated as fuzzy rules weight. An interview was developed with the experts of construction industry in India for the construction of fuzzy rules for forecasting the probability of cost overrun.

4. Defuzzification process takes place finally, where the fuzzy results of the inference engine are converted into a crisp one. Different types of defuzzification methods have been recommended in literature. In this study 'centroid of area' method is applied to forecast 'the probability of cost overrun of the project'. This method of 'centroid of area' calculates the weighted average of a fuzzy set. The outcome of defuzzification to a fuzzy conclusion by using this method can be expressed by the formula

$$Z_{COA} = (\int_Z \mu_A (Z)\, Z\, dz) / (\int_Z \mu_A(Z)\, dz) \quad (3)$$

where Z_{COA} is the crisp output, μ_A (Z) is the aggregated membership function and z is the output variable.

D. Model validation

To test the reliability of the proposed fuzzy cost overrun assessment model, it is tested in a real case study. For this purpose an interview was conducted with a team of the experts of a leading Indian construction company. The panel of the experts included top 10 executive engineers, project managers and site engineers of the company. The experts were requested to examine the cost overrun factors considered for this research and filled in the required information regarding cost overrun factors to assess the proposed model. They were also requested to estimate the cost risk level of the project.

III. NUMERICAL STUDY AND RESULTS

The summary of the calculated, relative importance index (RII) of the cost overrun factors in Indian construction industry and the proposed fuzzy model for these factors has been discussed in the following sections:

A. RII of cost overrun factors and important cost overrun factors in Indian construction industry

The data collected in the questionnaire are analyzed from owner, contractor and consultant's perspective**.** The relative importance index (RII) is computed for each factor causing cost overrun to determine the important factors causing cost overrun in Indian construction industry.

RII of Cluster Owner. RII of the factors slow progress payment by owner for completed work, slow procedure in taking decisions, manner of finance, level of owner interference and impracticable contract duration are 0.498, 0.522, 0.425, 0.357 and 0.676 respectively as shown in Fig. 14.

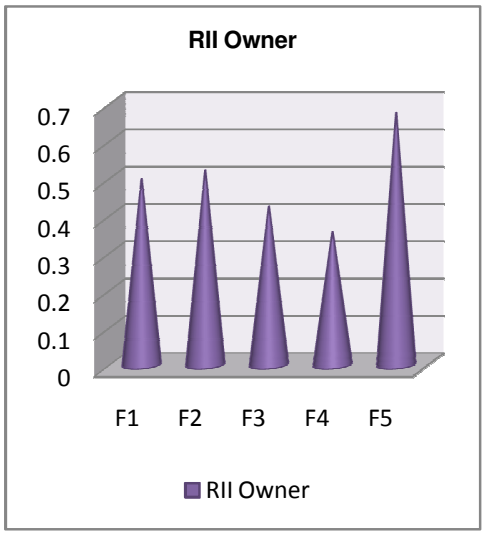

Fig. 14. RII of cluster owner.

RII of Cluster Contractor. RII of the factors improper planning and scheduling of project by contractor, conflicts and disputes on construction sites, extra charges of rework due to error during execution of project, wastages of material on construction site, improper site management by contractor, insufficient experience of contractor, inept sub contractor, financial difficulty experienced by contractor and outdated and unacceptable construction technique adopted by contractor are 0.670, 0.548, 0.495, 0.445, 0.385, 0.352, 0.413, 0.675 and 0.320 respectively as shown in Fig. 15.

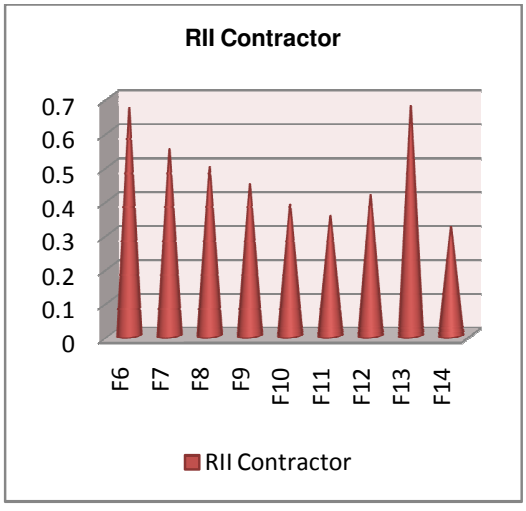

Fig. 15. RII of cluster Contractor.

RII of Cluster Consultant. RII of the factors incorrect estimation of time and cost, contract management, delay in inspecting of work, quality assurance & quality control and experience level of consultant are 0.742, 0.556, 0.391, 0.430 and 0.394 respectively as shown in Fig. 16.

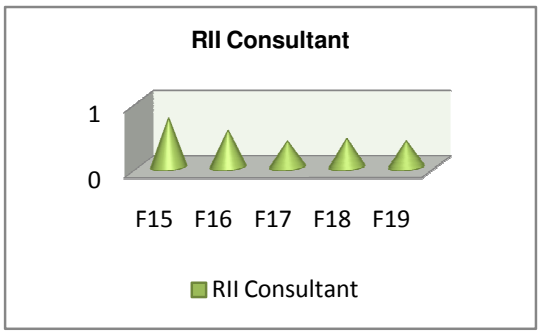

Fig. 16. RII of cluster Consultant

RII of Cluster Design. RII of the factors delay in design approval, inappropriate design & delay in making design document and frequent modification in design are 0.442, 0.478 and 0.704 respectively as shown in Fig. 17.

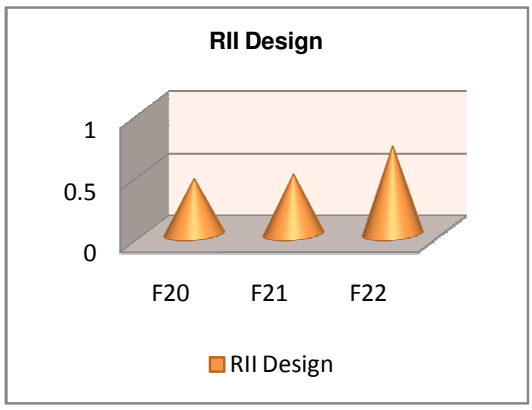

Fig. 17. RII of cluster Design.

RII of cluster Project. RII of the factors modification in the scope of the project, lowest possible bid procurement policy and quantity of extra work done are 0.556, 0.800 and 0.724 respectively as shown in Fig. 18.

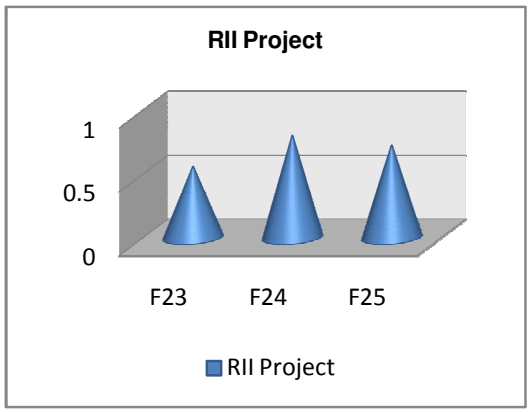

Fig. 18. RII of cluster Project.

RII of cluster Material. RII of the factors material cost, delay in delivery of material, delay in material procurement, material shortage at site and modification in material specification are 0.565, 0.343, 0.317, 0.371 and 0.411 respectively as shown in Fig. 19.

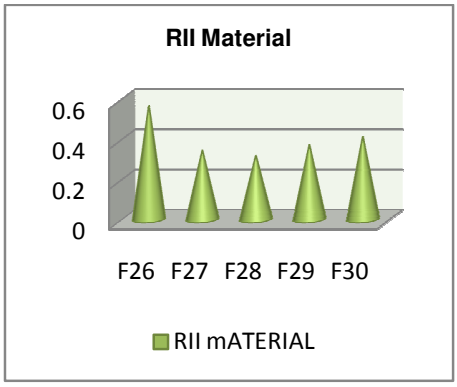

Fig. 19. RII of cluster Material.

RII of cluster Labor. RII of the factors poor qualification level of labor, dispute and strikes of labor, Less productivity level of labor, project labor charge and deficiency of labor for project are 0.341, 0.328, 0.352, 0.628 and 0.370 respectively as shown in Fig. 20.

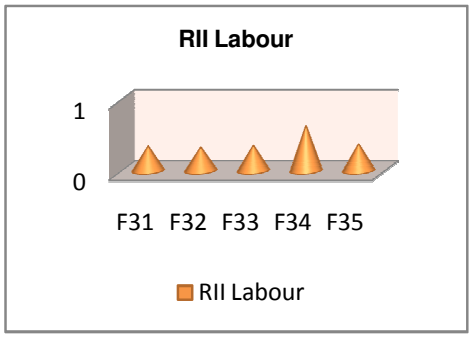

Fig. 20. RII of cluster Labour.

RII of cluster Equipment. RII of the factors equipment deficiency, equipment availability & failure at site and higher cost of machineries and equipment are 0.317, 0.302 and 0.582 respectively as shown in Fig. 21.

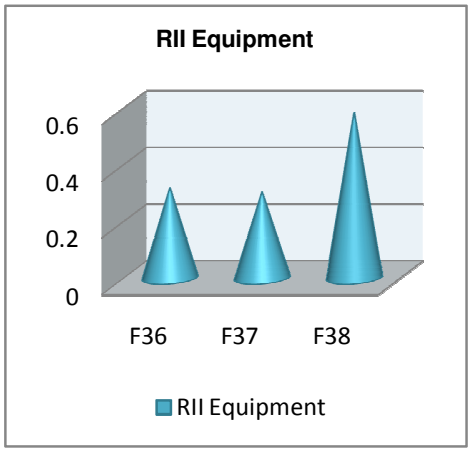

Fig. 21. RII of cluster Equipment.

RII of cluster Contract. RII of the factors errors and discrepancy in contract document and contractual procedure adopted are 0.728 and 0.410 respectively as shown in Fig. 22.

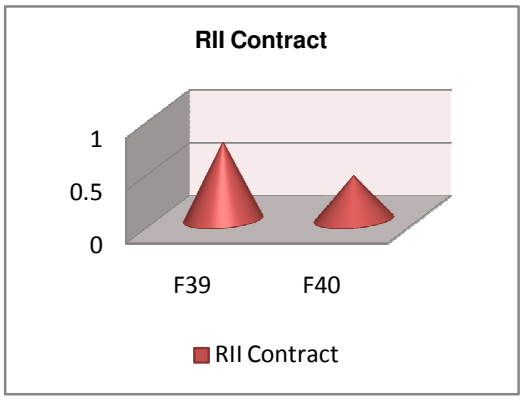

Fig. 22. RII of cluster Contract.

RII of cluster Coordination. RII of the factors are Poor coordination between construction participants, slow information flow in between construction participants and Low level of communication between construction participants are 0.659, 0.440 and 0.430 respectively as shown in Fig. 23.

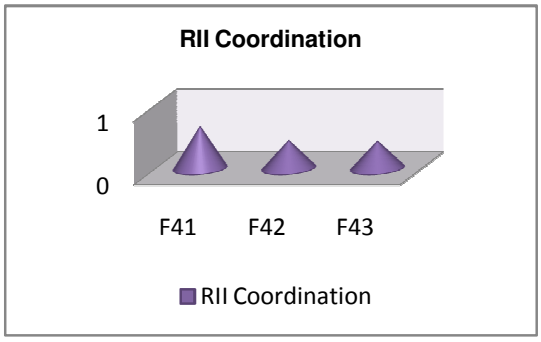

Fig. 23. RII of cluster Coordination.

RII of cluster External. RII of the factors fluctuation in the prices of materials, inflation, improper govt. policy, exchange rate, high level of interest rate of bank &loan, fraudulent practices & kickbacks, insurance charges of project, climatic and weather condition at site, social & cultural aspects, accidents and casualties during construction period, acts of god and incompatible site condition are 0.829, 0.788, 0.780, 0.621, 0.560, 0.520, 0.490, 0.485, 0.423, 0.370, 0.321 and 0.665.

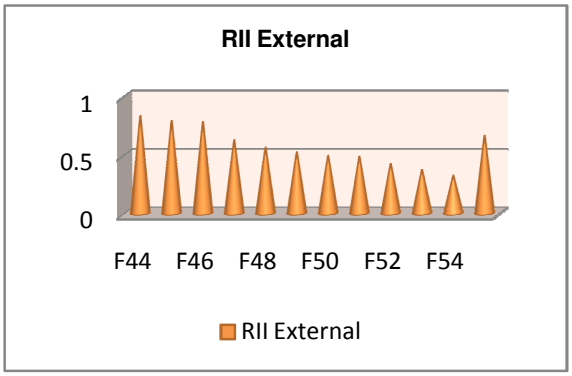

Fig. 24. RII of cluster External.

RII of the clusters. The RII of the clusters is shown in Fig. 25. RII of the clusters of ' Cluster Owner', 'Cluster Contractor', 'Cluster Consultant', 'Cluster Design', 'Cluster Project', 'Cluster Material', 'Cluster Labor', 'Cluster Equipment', 'Cluster Contract', 'Cluster Coordination/communication' and 'Cluster External' are 0.495, 0.477, 0.502, 0.541, 0.693, 0.401, 0.391, 0.4, 0.569, 0.509 and 0.570 respectively.

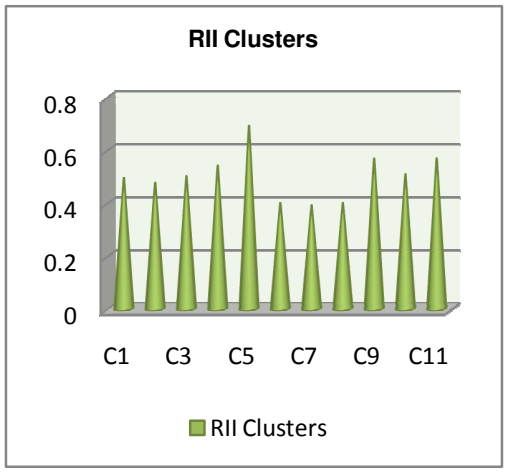

Fig. 25. RII of clusters.

B. Model development

The model is developed in two stages. First the probability of cost overrun due to each cluster is assessed by the probability level of the factors of respective cluster such as the probability of cost overrun due to the 'Cluster Owner' is estimated by probability of cost overrun due to the factors of 'Cluster Owner'.

The probability of cost overrun of project is then assessed by the probability output of each cluster as determined in the previous step.

Define input and output variables. For the first stage of the model development the cost overrun factors are taken as the input variables and output probability of cost overrun due to the cluster is determined from the model. The input and output variables for 'Cluster Owner' are described in Table 1. The various factors of cost overrun of 'Cluster Owner' are Slow progress payment by owner for completed work, Slow procedure in taking decisions, Manner of finance, Level of owner interference and Impracticable contract duration. These factors are considered as input variable for determining the output 'the probability of cost overrun due to the 'Cluster Owner'. During model development these factors are considered as F1, F2, F3, F4, and F5. And the output variable is abbreviated as 'POC1'. Similarly, probability of cost overrun due to the 'Cluster Contractor', 'Cluster Consultant', 'Cluster Design', 'Cluster Project', 'Cluster Material', 'Cluster Labor', 'Cluster Equipment', 'Cluster Contract', 'Cluster Coordination/communication' and 'Cluster External' is determined using factors related to that cluster.

As mentioned earlier the cost overrun probability of the project is determined taking into consideration the probability of all the clusters. Therefore for the second stage of model development clusters such as 'Clusters Owner', 'Cluster Contractor', 'Cluster Consultant', 'Cluster Design', 'Cluster Project', 'Cluster Material',

'Cluster Labor', 'Cluster Equipment', 'Cluster Contract', 'Cluster Coordination/communication' and 'Cluster External' are considered as input variables.

Table 1: Input and output variables for determining 'probability of cost overrun due to cluster 'Owner'.

Input variables		Output variable
F1	Slow progress payment by owner for completed work	probability of cost overrun due to cluster' C1 (Owner) POC1
F2	Slow procedure in taking decisions	
F3	Manner of finance	
F4	Level of owner interference	
F5	Impracticable contract duration	

And the output variable is 'probability of cost overrun of project' as shown in Table 2. During model development these clusters are considered as C1, C2, C3, C4, C5, C6, C7, C8, C9, C10 and C11.and the output variable is 'Probability of cost overrun of project' which is abbreviated as **'PCOP'.**

Table 2: Input and output variables for determining the probability of cost overrun of project.

Input variables		Output variable
C1	Owner	Probability of cost overrun of project (PCOP)
C2	Contractor	
C3	Consultant	
C4	Design	
C5	Project	
C6	Material	
C7	Labour	
C8	Equipment	
C9	Contract	
C10	Coordination	
C11	External	

The input variables in the form of factors and output probability of owner related 'POC1' cluster are shown in the FIS Editor window of Fuzzy Logic tool box of MATLAB Program Software in Fig. 26.

Fuzzy Membership Functions. The membership function of input variables in the form of factors and clusters of factors and output variable Probability of cost overrun of project 'PCOP 'were generated using the membership function editor in the Matlab fuzzy logic toolbox as shown in Fig. 27.

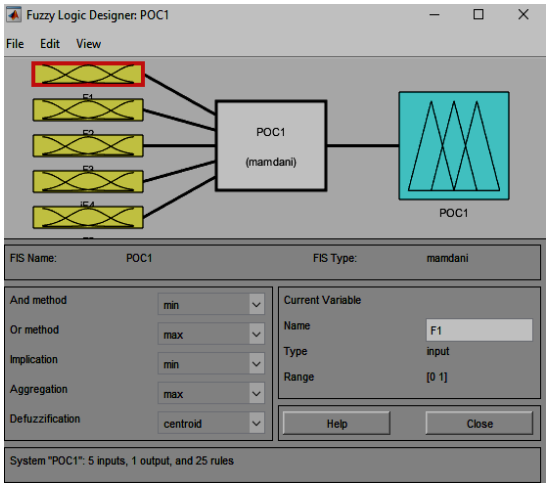

Fig. 26. Defining Input and output variables.

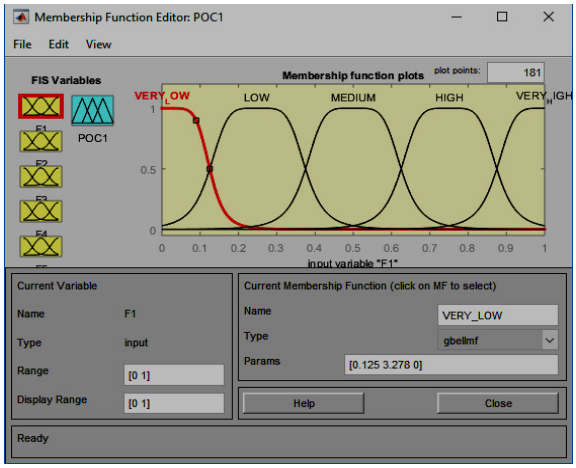

Fig. 27. Defining membership of Input and output variables.

Fuzzy rules and weighting of rules. Considering 55 cost overrun factors, total 275 rules are formed. Samples of the fuzzy rules of cluster 'Owner' are presented in Table 3.

Table 3: Sample fuzzy rules of factors of 'Cluster Owner'.

Rule	Antecedent	consequence	weighting
1	If the probability of cost overrun due to the factor 'Slow progress payment by owner for completed work ' is very low	Then the probability of cost overrun due to Cluster 'owner' is very low	0.498
6	If the probability of cost overrun due to the factor 'Slow procedure in taking decisions' is very low	Then the probability of cost overrun due to Cluster 'owner' is very low	0.522
11	If the probability of cost overrun due to the factor 'Manner of finance ' is very low	Then the probability of cost overrun due to Cluster 'owner' is very low	0.425
16	If the probability of cost overrun due to the factor 'Level of owner interference' is very low	Then the probability of cost overrun due to Cluster 'owner' is very low	0.357
21	If the probability of cost overrun due to the factor 'Impracticable contract duration' is very low	Then the probability of cost overrun due to Cluster 'owner' is very low	0.676

Table 4: Sample Fuzzy rules for estimating the probability of cost overrun of the project.

Rule	Antecedent	Consequence	Weighting
1	If the probability of the cost overrun due to 'Cluster Owner' is very low	Then the 'probability of cost overrun of the project' is very low	0.495
6	If the probability of the cost overrun due to the 'Cluster Contractor' is very low	Then the 'probability of cost overrun of the project' is very low	0.477
11	If the probability of the cost overrun due to the 'Cluster Consultan' is very low	Then the 'probability of cost overrun of the project' is very low	0.502
16	If the probability of the cost overrun due to the 'Cluster Design' is very low	Then the 'probability of cost overrun of the project' is very low	0.541
21	If the probability of the cost overrun due to the 'Cluster Project' is very low	Then the 'probability of cost overrun of the project' is very low	0.693
26	If the probability of the cost overrun due to the 'Cluster Material' is very low	Then the 'probability of cost overrun of the project' is very low	0.401
31	If the probability of the cost overrun due to the 'Cluster Labour' is very low	Then the 'probability of cost overrun of the project' is very low	0.391
36	If the probability of the cost overrun due to the 'Cluster Equipment' is very low	Then the 'probability of cost overrun of the project' is very low	0.4
41	If the probability of the cost overrun due to the 'Cluster Contract' is very low	Then the 'probability of cost overrun of the project' is very low	0.569

Since the probability of cost overrun due to the cluster 'Owner' is directly related to the probability of cost overrun due to slow progress payment by owner for completed work, slow procedure in taking decisions, Manner of finance, Level of owner interference and Impracticable contract duration, therefore the probability of cost overrun of these factors will influence the probability of cost overrun due to the cluster 'Owner'. The calculated RII of the factors are the weighting of the rules.

Considering 11 clusters of cost overrun factors, total 55 rules are formed. Since the probability of cost overrun of the project is directly related to the probability of cost overrun due to the 'Clusters Owner', 'Cluster Contractor', 'Cluster Consultant', 'Cluster Design', 'Cluster Project', 'Cluster Material', 'Cluster Labor', 'Cluster Equipment', 'Cluster Contract', 'Cluster Coordination/communication' and 'Cluster External'. Therefore the probability of cost overrun due to these clusters will influence the probability of cost overrun of the project. Fuzzy rules for estimating the probability of cost overrun of the project are presented in Table 4.

For fuzzy inference the rules are made as follows:

If F1 is 'very low' then POC1 is 'very low': Which means that if the probability of cost overrun due to the factor 'slow payment of complete work by owner' is 'very low' then the probability of cost overrun due to Cluster 'Owner' is 'very low'. The rule editor window of Fuzzy Logic tool box of MATLAB Program Software is shown in Fig. 28.

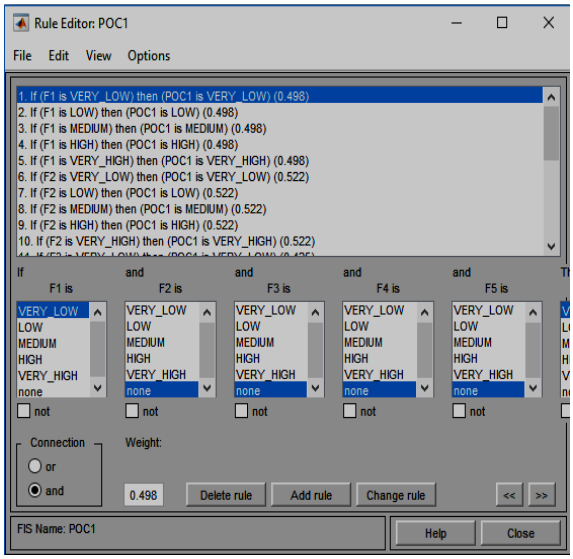

Fig. 28. Rule formation.

Defuzzification. Finally the 'probability of cost overrun due to Cluster 'Owner' PCO1 and 'probability of cost overrun' of project' is estimated by defuzzification by 'centroid of area' method as shown in Fig. 29.

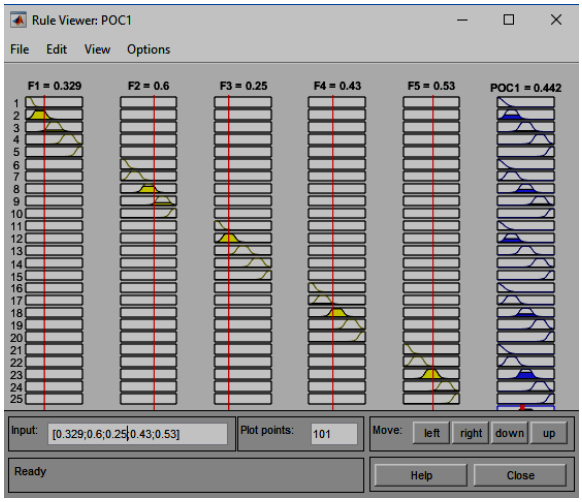

Fig. 29. Defuzzification process.

C. Testing of the model

To test the reliability of the proposed fuzzy cost overrun assessment model, an interview has been conducted with a team of the experts of a leading Indian construction company. The panel of the experts consists of the top 10 executive engineers, project managers and site engineers of the company. The experts were requested to examine the cost overrun factors considered for this research and filled in the required information regarding cost overrun factors to assess the proposed model. They were also requested to estimate the probability of cost overrun of the project. The information provided by the group of the experts are presented as shown in the following table in the Table 5.

Table 5: Information provided by the group of the expert.

S.No.	Factors	Probability of occurrence of factor
1	F1	0.329
2	F2	0.6
3	F3	0.25
4	F4	0.43
5	F5	0.53
6	F6	0.4

The determined probabilities of cost overrun due to clusters by model are given in Table 6.

Table 6: Probability level of clusters.

S.No.	Cluster	Name of cluster	Probability of cost overrun due to cluster	Probability of cost overrun of the project
1	C1	Owner	0.442	0.435
2	C2	Contractor	0.405	
3	C3	Consultant	0.406	
4	C4	Design	0.476	
5	C5	Project	0.524	
6	C6	Material	0.436	
7	C7	Labour	0.289	
8	C8	Equipment	0.26	
9	C9	Contract	0.263	
10	C10	Coordination	0.465	
11	C11	External	0.609	

The probability of cost overrun of the project was calculated by the experts was in the range of 0.35-0.50. Provided information was tested using the proposed model and The probability of cost overrun of the project obtained was 0.435 as shown in Fig. 30, which is much closer to the estimated cost risk level of the project estimated by the panel of the experts of the company.

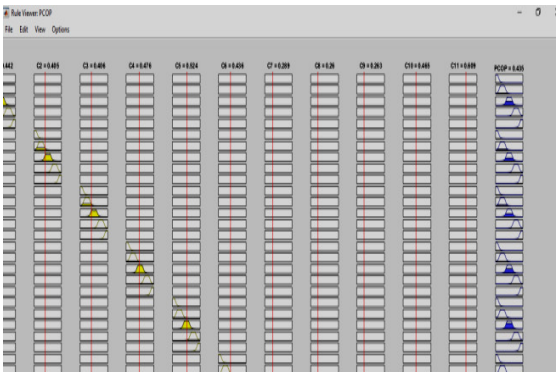

Fig. 30. Probability of cost overrun of the project.

V. CONCLUSION

It is observed that very few projects get completed within stipulated costs in India, despite the importance of economy in construction projects. The cost of a project is calculated just by adding some contingency charges and proper analysis of cost overrun risk is ignored, consequently many projects fail to complete the project in stipulated budget. Therefore in this study a fuzzy model for forecasting the probability of cost overrun risk in Indian construction project is developed by identifying, classifying and ranking of the factors responsible for the cost overrun in the construction industries. The fuzzy theory is chosen for developing the model as the theory is found suitable for quantifying the probability of cost overrun risk of the construction project when the variables regarding the cost overrun factors are expressed in linguistic terms. The fuzzy set theory (FST) is equipped to take care of imprecise, incomplete and uncertain data expressed in linguistic form. Through an extensive literature survey and discussion with the experts of the Indian construction industry, fifty five cost overrun factors were identified and then classified into eleven clusters. A questionnaire survey was conducted in Indian construction industry for data collection to calculate relative importance index (RII) of the recognized factors causing cost overrun and clusters. Total 250 questionnaires were distributed to the potential respondents within the Indian construction company comprising owner, contractor and consultant. Out of 250 questionnaire set, only 135 responses were returned. The calculated relative importance index of the factors and clusters was used to develop model using the fuzzy logic tool box of MATLAB program software. First the probability of cost overrun due to the clusters of cost overrun factors is determined. The final cost overrun risk probability of the project is then determined taking into consideration the probability of all the clusters. For all input and output linguistic variables five membership functions are defined using g-bell shaped fuzzy numbers. Fuzzy rules for estimating the probability of cost overrun of the project are constructed with the discussion of experts of the Indian construction industry in the simple forms of the Mamdani-style. The calculated RII of the factors and clusters are taken as the weighting of the rules. Centre of area (COA) method is chosen for defuzzification. The model has been tested by taking into consideration a real case study in India. To test the model an interview was conducted with a team of the experts of a leading Indian construction company. The panel of the experts consisted of the top 10 executive engineers, project managers and site engineers of the company. The experts were requested to examine the cost overrun factors considered for this research and filled in the required information regarding cost overrun factors to assess the proposed model. They were also requested to estimate the cost risk level of the project. The probability of cost overrun of the project was calculated by the experts was in the range of 0.35-0.50. Provided information was tested using the proposed model and The probability of cost overrun of the project obtained was 0.435, which is much closer to the estimated cost risk level of the project estimated by the panel of the experts of the company. With the help of the proposed model, it is possible to guide project managers and decision makers to make more informative decisions such as contingency estimation, mark-up estimation, bid price, selection of optimum procurement route, evaluation of different projects and preparation of project portfolios.

VI. LIMITATION OF APPROACH AND FUTURE SCOPE

The following are the limitations of the proposed model: The sample size of population for the identification cost overrun factors is very small as compared to the size of construction industry. Therefore the calculated the relative importance index (RII) does not represent a true picture of actual cost overrun scenario. The model can differ as per the shapes and number of membership function adopted in fuzzy logic tool. The constructed rules for fuzzy model are based on expert opinion. It is based on subjectivity. For different attitudes of the experts rules can also be changed and in this condition the model will produce different result. Results can vary according to the defuzzification method adopted for obtaining output. Fuzzy rules are based on literature survey findings expert judgment and, it is clear that a completely different model may be proposed by other researchers based on different expert opinions. The model could also be developed for estimating the performance and delay probability in construction and other industrial projects using fuzzy logic theory.

***Abstract*— Automatic Generation Control (AGC) is a controlling technique used in electrical power generation to maintain a constant nominal frequency and power interchange with other linked systems by creating a balance of the generation of the system with system load losses. The frequency of the system deviates from its desired value if there is any sudden load change. If the frequency deviates in a large amount the system may get collapsed. Hence, a fast and accurate controller action is required to maintain stability and nominal frequency. For AGC many controlling techniques have been studied. In this paper, a PI controller is compared with a fuzzy controller. A two area system is considered both being thermal. Different step load changes have been considered and the performance of both the controllers has been observed in different load conditions. Simulation results have been brought up to show the better working of the fuzzy controller than the PI controller.**

Keywords— AGC, area control error, fuzzy logic controller, pi controller, two area system

I. INTRODUCTION

The purpose of electrical power generating units is to generate a certain amount of power that fulfills the required amount of load in a specific region. These generating units are referred to as power plants. There are different types of plants like a thermal plant, hydro plant, nuclear plant, etc. The load conditions do not remain the same throughout the time. It changes very rapidly and not only in one direction but in both directions that is it may go higher or lower than the normal demand. It depends on the consumers how much they are utilizing the load. Due to these variations in load demand the system frequency gets affected. It deviates from the nominal frequency. The deviation of frequency from its nominal value is undesirable as it affects the speed of the machine. The speed of a synchronous machine which is used as in generating units directly depends on the frequency. Therefore, as the frequency fluctuates, the speed of machines also fluctuates due to which the output of the machine is inconsistent. Hence the frequency of the system must remain constant.

To maintain a constant frequency of the system a control scheme is known as Automatic Generation Control (AGC) is used that controls the amount of the steam entering the turbine [1]. The primary purpose of the controller is to set the frequency of the system uniform whatever the changes in load demand may be [7]. As the load demand changes the frequency suddenly increases or decreases, immediately the current frequency is compared with a reference frequency or nominal frequency and according to it an error signal is sent to the controller which the takes adjust the amount of steam valve to be open or closed. Certain limits of load fluctuation are controlled by the controller or AGC but if load fluctuations are very high then the controllers need to be reset either manually or automatically [1]. The controller has a very vital role in AGC, and its proper and fast functioning is a must.

There are a lot of controllers that are used like P, PI, PID, fuzzy, genetic algorithm, PSO, etc [8-10]. Different controllers have different advantages. Many works have been followed out for inspecting different controller's behavior by considering a certain load change in a certain area. In this paper different performance of conventional PI controller has been contrasted with the fuzzy logic controller. A two area system is simulated in MATLAB Simulink. Different load changes are given to area 1 of the two area system. First taking the PI controller and then fuzzy controller the system is simulated and frequency variations and power variations are plotted. These plots are presented to show a comparative analysis of both the controllers.

II. CONTROL AREA CONCEPT

A power system in which a common generation control technique is used is known as a control area [2],[9]. Many control areas are attached through tie-lines [3]. In a control area, the action of a controller is to regulate the amount of inlet of the steam valve so that the amount of steam input to the turbine is regulated. The controller uses Area Control Error to bring the frequency at a nominal value [4].

Area Control Error (ACE) is the variation between actual and scheduled power generation in a control area considering frequency bias setting [1],[2]. In this paper two area thermal-thermal system is considered.

Mathematically ACE is given as:

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:53:05 UTC from IEEE Xplore. Restrictions apply.

For area 1: $ACE_1 = \Delta P_{12} + B_1 \Delta f_1$
For area 2: $ACE_2 = \Delta P_{21} + B_2 \Delta f_2$

where:

ΔP_{12} and ΔP_{21} denotes the departures from the scheduled interchange
B_1 and B_2 denotes frequency bias coefficient of area 1 and area 2 individually.
Δf_1 and Δf_2 area frequency deviation of area 1 and area 2 individually.

III. TWO AREA SYSTEM

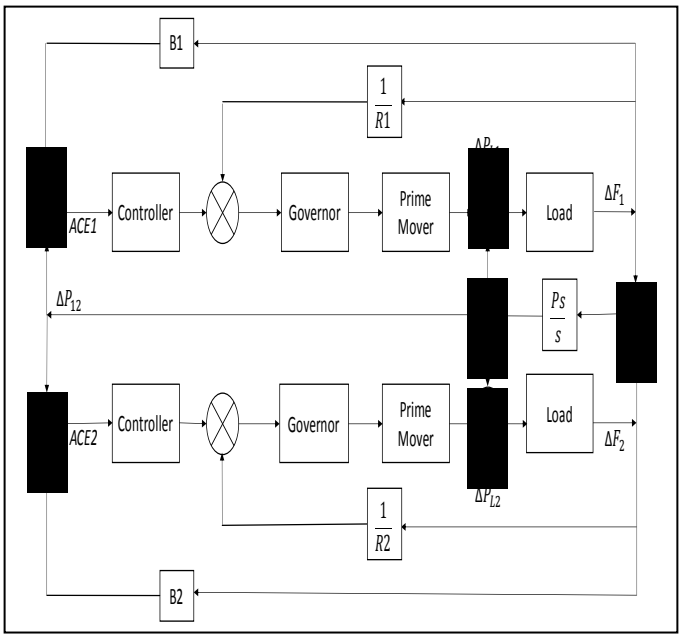

Fig 1: Two area thermal-thermal system block diagram

As shown in the above figure each area of the two-area system has its own controller and both are connected through a tie-line. Load changes (ΔP_L) may occur in any of the area which results in the frequency variations of area 1 i.e. ΔF_1 and in area 2 i.e. ΔF_2.
In this paper load changes of 0.1 per unit (pu), 0.2 pu and 0.3 pu have been considered in area 1. The controllers are first taken as PI controller and then fuzzy logic controller and then the system is simulated in MATLAB Simulink.

A. Parameters used

Time constant of turbine= 0.5 s
Time constant of governor = 0.2 s
Inertia constant of governor = 5 s
Speed regulation of governor= 0.05
Rated output of turbine = 250 MW

IV. FUZZY LOGIC CONTROLLERS

The fuzzy system is one of the key agents of computational intelligence. Prof. A Zadeh proposed the idea of a fuzzy system in 1965. A Fuzzy system differs from conventional computing as conventional computing involves Boolean logic whereas a fuzzy system involves multivalued logic. It deals with uncertainties due to ambiguity, imprecision, and vagueness. Fuzzy logic is much more general than conventional logic systems. It is mostly used in the systems with uncertainties due to ambiguity, imprecision, vagueness ambiguity, randomness, partial truth, and approximation.
The fuzzy logic controller has three steps [5],[6]:

1. Fuzzification
2. Inference rule
3. Defuzzification

It takes input variables in the form of membership functions. Membership functions can be of various types like triangular, Gaussian, trapezoidal, etc. Here, a triangular membership function is used. Every input variable is assigned with a specific number of membership functions that contain values of certain limits. These values are assigned with some linguistic terms [6]. This step is known as fuzzification.
After fuzzification there comes the rule base of the fuzzy logic controller. In the rule base, rules are assigned formulated on the knowledge of the system. Outputs are also given linguistic terms and input variable mapping is done to assign a particular output linguistic variable following the given matching of input linguistic variables. The full rule base considered in the system is mentioned in the following section.
In the final step that is defuzzification, the output linguistic variables are changed to corresponding numbers which decide the controlling action accordingly.

A. Membership functions

The following variables are created using MATLAB fuzzy command with five membership functions each.

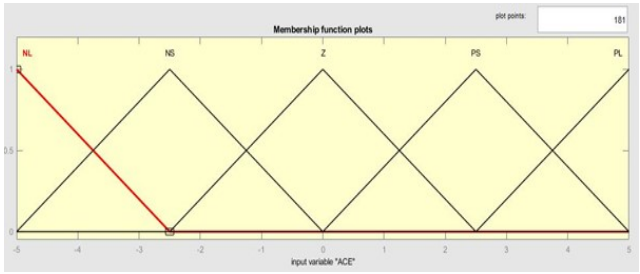

Fig 2: Input variable ACE

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:53:05 UTC from IEEE Xplore. Restrictions apply.

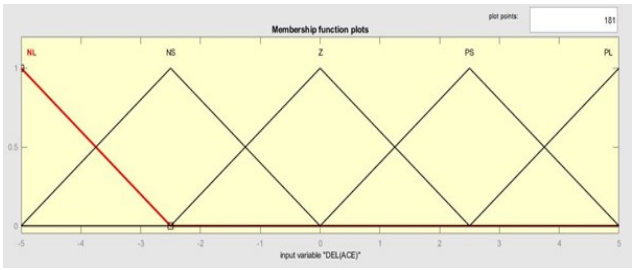

Fig 3: Input variable del(ACE)

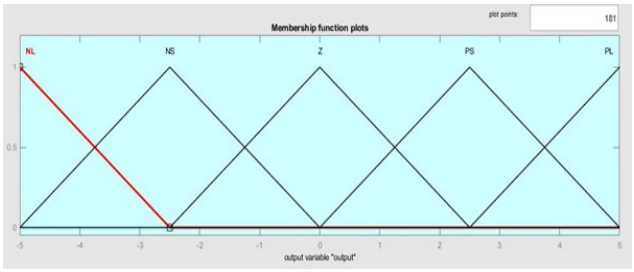

Fig 4: Output variable

B. Fuzzy Rule Base

The rules are assigned with the help of MATLAB fuzzy toolbox. Following table displays the rules that are set for input variables ACE and del(ACE) in order to give necessary output. Here the ACE and del(ACE) are used as input variables and assigned with values from -5 to 5 and given linguistic terms : More negative (NL), Less negative (NS), Zero (Z), Less positive(PS), More positive (PL).

TABLE I. RULE BASE [4]

		ACE				
		NL	**NS**	**Z**	**PS**	**PL**
DEL(ACE)	**NL**	NL	NL	NS	Z	Z
	NS	NL	NL	NS	PS	Z
	Z	NS	Z	Z	PS	PS
	PS	NS	Z	PS	PL	PL
	PL	Z	Z	PS	PL	PL

V. SIMULATION AND RESULTS

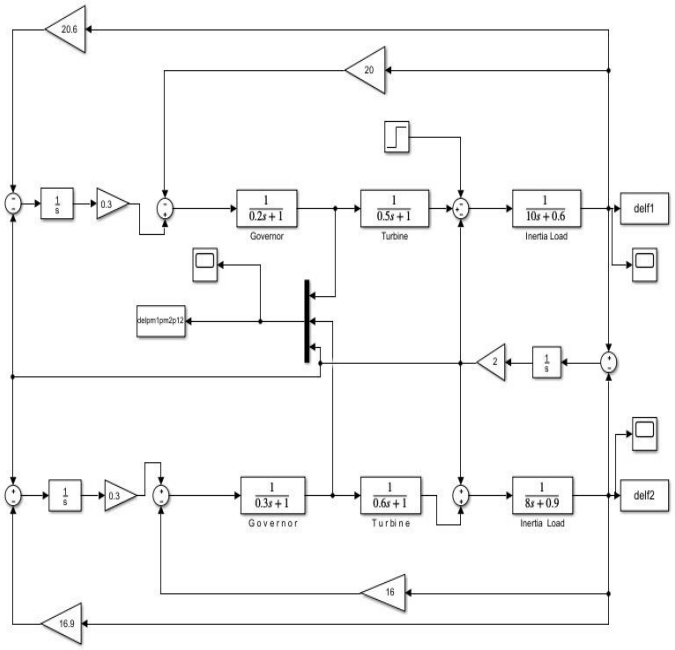

Fig 5: Two area system Simulink model by using PI control

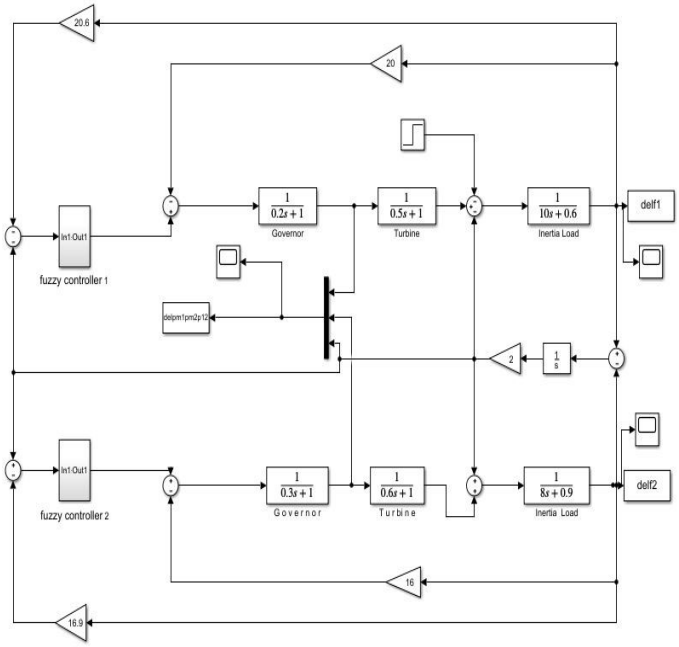

Fig 6: Two area system Simulink model by using fuzzy control

The following plots show the behavior of frequency as well as power fluctuations in both areas using a fuzzy controller and PI controller. For each load change, four plots are shown in the following sections.

A. Results for 0.1 pu load change

A change of 0.1 pu load is applied in area1 and the following results have been obtained.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:53:05 UTC from IEEE Xplore. Restrictions apply.

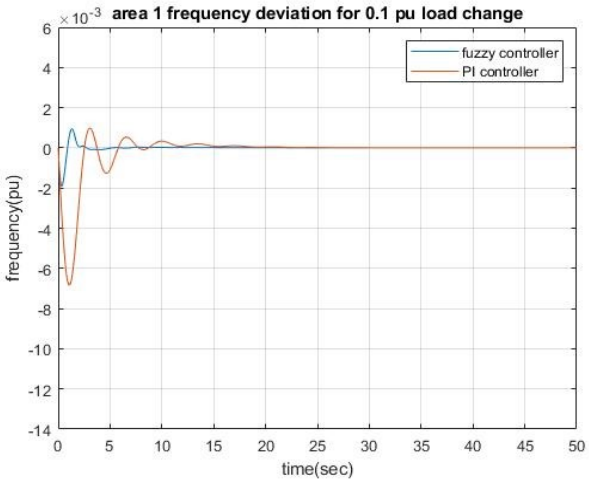

Fig 7: Area 1 frequency variations

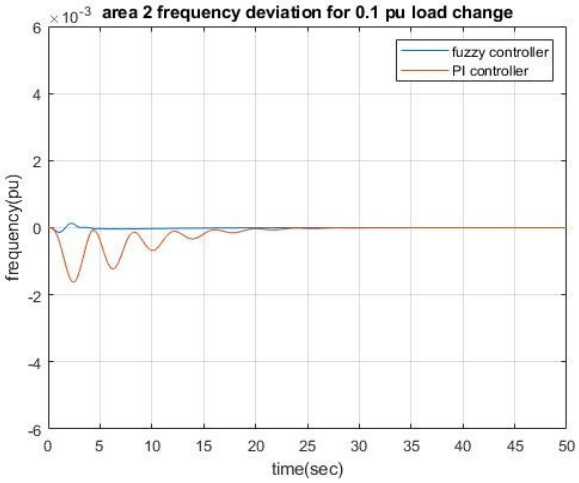

Fig 8: Area 2 frequency variations

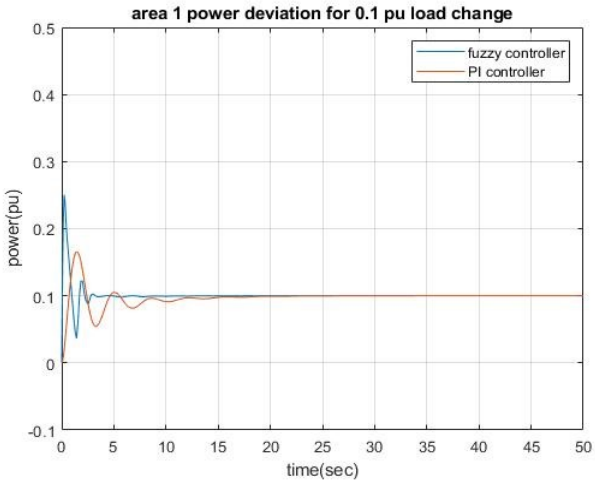

Fig 9: Area 1 power variations

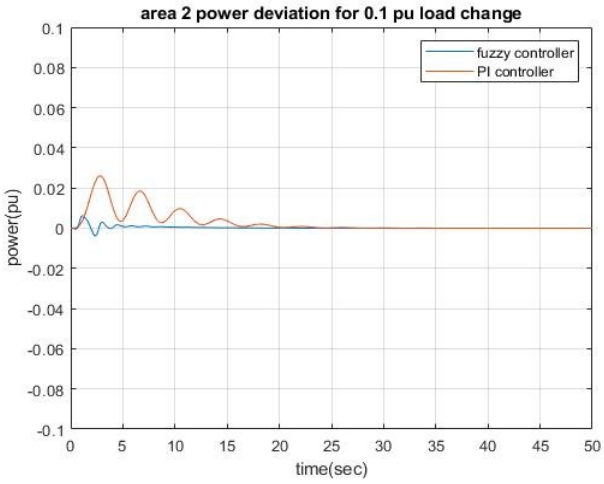

Fig 10: Area 2 power variations

B. Results for 0.2 pu load change

A change of 0.2 pu load is applied in area1 and the following results have been obtained.

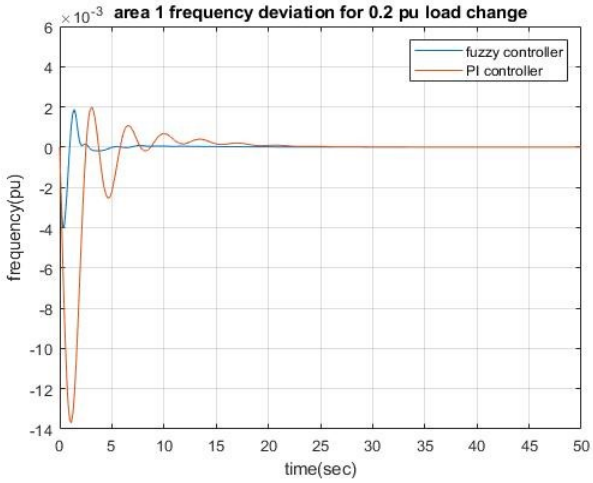

Fig 11: Area 1 frequency variations

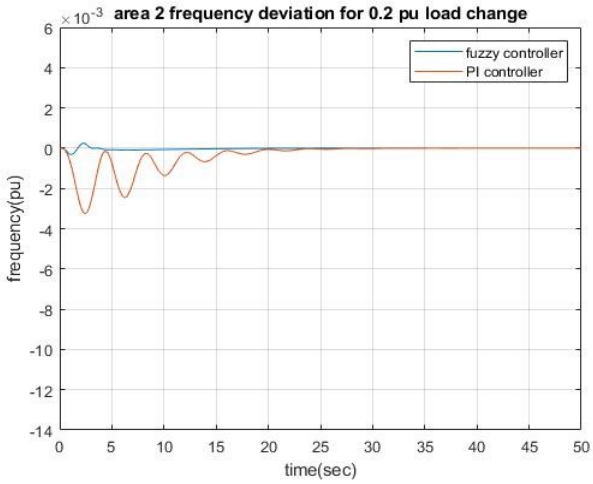

Fig 12: Area 2 frequency variations

C. *Results for 0.3 pu load change*

A change of 0.3 pu load is applied in area1 and the following results have been obtained.

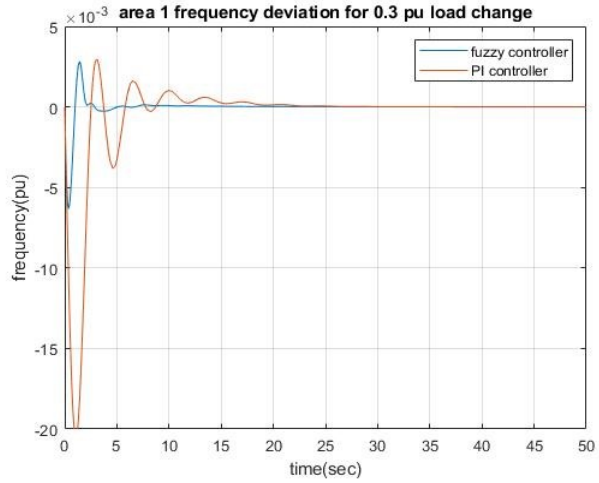

Fig 15: Area 1 frequency variations

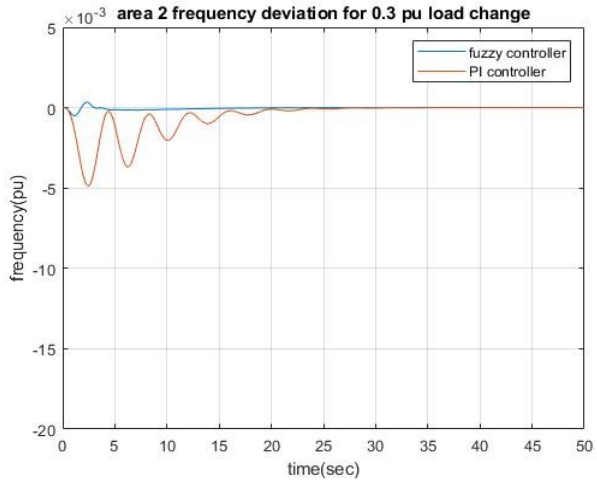

Fig 16: Area 2 frequency variations

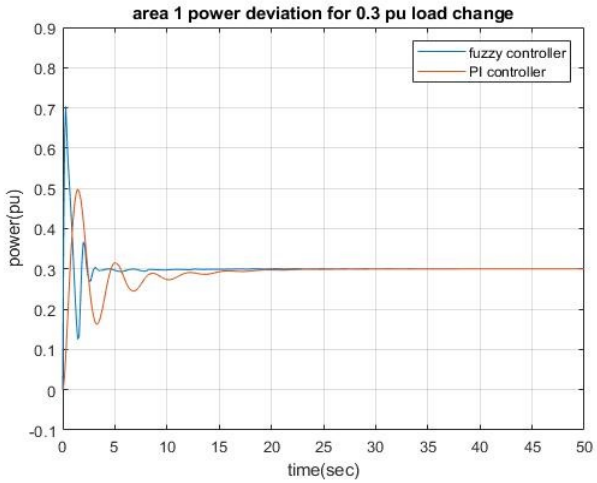

Fig 17: Area 1 power variations

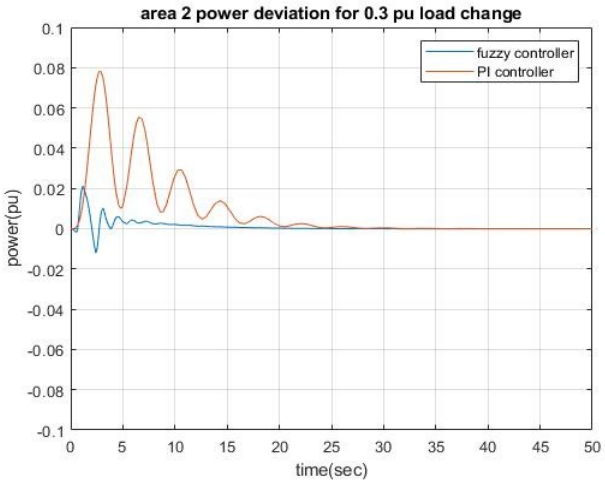

Fig 18: Area 2 power variations

From all the above plots the settling time and maximum deviation have been calculated with the help of MATLAB and following table is prepared which shows settling time and maximum fluctuation of frequency change in area 1 (ΔF1), frequency change in area 2 (ΔF2), power change in area 1 (ΔP1), power

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:53:05 UTC from IEEE Xplore. Restrictions apply.

change in area 2 (ΔP2) for all three load changes.

TABLE II. COMPARATIVE RESULT OF SETTLING TIME AND MAXIMUM DEVIATION OF FREQUENCY AND POWER

1% change	PI		Fuzzy	
	Settling time(sec)	max fluctuation (pu)	Settling time(sec)	max fluctuation (pu)
ΔF1	18.3083	0.0068	9.1211	0.0037
ΔF2	23.3675	0.0016	14.6863	0.000345
ΔP1	18.124	0.1647	11.7476	0.2463
ΔP2	23.8816	0.0261	13.8683	0.002
2% change	PI		Fuzzy	
	Settling time(sec)	max fluctuation (pu)	Settling time(pu)	max fluctuation (pu)
ΔF1	22.2716	0.0136	10.2409	0.0078
ΔF2	27.3657	0.0032	17.8777	0.0012
ΔP1	23.041	0.3282	12.7378	0.4925
ΔP2	26.8495	0.0501	16.4937	0.0039
3% change	PI		Fuzzy	
	Settling time(sec)	max fluctuation (pu)	Settling time(pu)	max fluctuation (pu)
ΔF1	23.3151	0.0201	13.4343	0.0075
ΔF2	31.3705	0.0049	18.7375	0.0017
ΔP1	22.012	0.4907	13.7400	0.7087
ΔP2	27.8761	0.0778	19.6394	0.0065

VI. CONCLUSION

By observing all the plots of frequency and power deviations of both the areas using two controlling techniques for a particular load change the frequency returns to its nominal value in lesser time in case of the fuzzy logic controller in contrast to the traditional PI controller and also power deviations are less in case of fuzzy logic controller. Moreover, due to the increased the amount of step load change, the deviation of transients of frequency and power in the conventional controller are increased much before coming to its nominal value whereas in the case of the fuzzy logic controller the deviations are not much increased by increasing the load changes. Hence fuzzy logic is a more reliable and effective controller as compared to the traditional PI controller.

LIMITATIONS AND FUTURE SCOPE

In the fuzzy controller, a triangular membership function is used. In place of triangular other membership functions can be considered like trapezoidal, Gaussian, etc. In place of fuzzy control more advanced artificial intelligence techniques can be used.

***Abstract*—Thermal Infrared cameras have a unique set of capabilities that enables them to see and capture images in situations where vision is severely obscured, including dark, shade, and foggy conditions. Conversion of TIR image to visible spectrum makes them more interpretable, but automating transformation is a challenging task as it requires estimation of both chrominance and luminance for each pixel, posing the need for a more complex model that is capable of capturing higher-level semantics of a TIR image to generate a perceptually realistic RGB image.The use of Conditional Generative Adversarial Networks (cGANs) is proposed with a combination of content and adversarial losses to tackle this problem. The proposed cGAN uses a U-Net auto-encoder network as generator, and a patch based discriminator for adversarial training. The cGAN learns the most effective loss function during training, producing state-of-the-art perceptually realistic outputs. Qualitative and quantitative analyses show that our approach outperforms existing methods.**

***Index Terms*—Conditional Generative Adversarial Networks, Deep Learning, Image to Image Transformation, Thermal Infrared Imaging**

I. Introduction

Thermal infrared imaging technology originally found applications in the fields of Military and Intelligence [8]. Thermal infrared cameras capture images and videos in the thermal spectrum, which is invisible to the human eye. Infrared radiation is reflected and emitted by all objects, even in the dark. Thus, thermal infrared cameras can capture images in the dark, and in conditions where visibility is obscured e.g. foggy conditions. In recent years, the technology has significantly improved. Resolution of thermal sensors has increased, and thermal infrared cameras have become less expensive. This has led to the application of thermal infrared cameras in entirely new fields like; automotive computer vision systems, surveillance systems, medical imaging and specialized equipment for various scientific and industrial applications including archaeology, geology, mining etc. Other significant advantages of thermal cameras are that they can capture images even in very low light, they are robust to extreme changes in light and shade conditions, and they preserve the anonymity of the subjects being captured in surveillance systems. As the use of thermal infrared cameras becomes more common, there is a growing need to develop efficient and accurate methods to transform thermal infrared (TIR) images to visible spectrum (RGB) images. Perceptually realistic visible spectrum (RGB) images are more intuitive to interpret and easier to understand for the untrained human eye, and will help improve the viewing performance of the human operator that operates a thermal infrared imaging system.

Transformation of black and white (grayscale) images into colored (RGB) images is a similar problem that has been well researched before [2]–[6]. Autoencoder networks have been used to obtain impressive results in grayscale colorization e.g. the "Colorful Image Colorization" [19] and "Let there be color!" [18]. When colorizing grayscale inputs, a given pixel of the input grayscale image can correspond to many different colors in the colorized output. As each pixel in a grayscale image only captures brightness (luminance), the color (chrominance) of the output remains ambiguous. An input grayscale pixel intensity can map to an infinite number of combinations of red, green and blue intensity values that produce the same luminance as the input but output very different colors. This is known as chrominance ambiguity in colorization methods. The problem of transforming thermal infrared images to visible spectrum images poses an entirely new challenge. A thermal infrared image captures intensities of infrared radiation only. There is no way to estimate visible spectrum intensities knowing only the thermal infrared intensi-

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:49:24 UTC from IEEE Xplore. Restrictions apply.

ties, as they both lie in different radiation spectra. Therefore, it has been required to resolve not only chrominance ambiguity, but also luminance ambiguity for generating a perceptually realistic visual spectrum image from thermal infrared input. Colorization methods have previously been researched that utilise autoencoder Convolutional Neural Networks (CNN), as they are able to extract a semantic representation of input and then generate an appropriate output. This approach was used by Berg et al. (TIR2Lab) [17] for thermal infrared colorization and Limmer et al. [20] for near infrared colorization. However, the images generated using this approach were distorted and blurred Therefore, a more complex system is needed that is able to generate the visible spectrum image from a more abstract representation of the input image.

II. Method

The use of a Conditional Generative Adversarial Network (cGAN) [16] is proposed for generating visible spectrum images from thermal infrared input. This is an image to image transformation problem, a class of problems which has previously been approached using autoencoder networks. Such networks must train on carefully hand engineered loss functions to work effectively. An ill-engineered loss will eventually result in blurry and unrealistic output, which is a common problem in autoencoder models. The proposed Conditional Generative Adversarial Network architecture not only learns the input-output mapping, but also learns the loss function that trains the complete network resulting in clearer and more realistic looking output image.

A. Conditional Generative Adversarial Networks

Conditional Generative Adversarial Networks provide an architecture for effective training of generator networks to learn a conditional mapping from given input image, to a target output image. The generator, a deep convolutional neural network, first extracts the relevant semantic features from the input infrared image, and generates colorized output from that abstract semantic representation. This generator network trains on a combination of adversarial and content losses, in parallel with a discriminator, using the cGAN architecture. Our cGAN was trained on a large dataset (50,184 images) of pairs of thermal infrared and visible spectrum images.

A cGAN consists of two primary components, a generator network (G), and a discriminator network (D). The generator model is an autoencoder network that maps the input image to its corresponding output. With each training iteration, it adjusts it's weights to produce a more realistic image, that is closer to the actual output provided in the dataset. The discriminator model is typically a convolutional neural network that is trained to correctly identify original output images (output images sampled from the dataset) from fake output images (output images generated using the generator model). Unlike in traditional GANs, in cGANs, the discriminator receives both the input image and the target image as input, and it predicts whether the output is a valid transformation of the given input. This aids in learning a conditional mapping between the input and the output. The training process of a GAN is a min-max game, with an objective function as given in eq. 1

$$\min_G \max_D V(D,G) = \mathbb{E}_{x\sim p_{data(x)}}[\log D(x)] + \mathbb{E}_{x\sim p_z(x)}[\log(1 - D(G(x))] \quad (1)$$

Here, G and D are the generator and discriminator network respectively. $D(x)$ represents the discriminator prediction for the given input image (x), $D(G(x))$ represents the discriminator prediction for the generated image ($G(x)$) for the given input image. With the objective of averting detection by generating more realistic outputs, the generator aims to increase the discriminator's classification error, while the discriminator trains to better classify real and fake samples, decreasing the classification error. This min-max game drives the training of a GAN, and adversarial competition trains the generator to produce more genuine looking images.

B. Network Architecture

The generator of the cGAN architecture proposed is an autoencoder network with skip connections that has previously been used for image segmentation and image synthesis (U-Net) [15]. Our discriminator is a convolutional neural network that classifies 70x70 sized patches of the image as real or fake (PatchGAN), producing a tensor as output.

1) Generator Architecture: U-Net consists of a contracting encoder network (left) and an expanding decoder network (right)(see Fig. 1). The encoder network uses convolution operation to downsample the image and obtain an abstract representation of the image at the bottleneck. The decoder network then generates the output image from this feature map by means of upsampling.

2) Encoder: The encoder resembles most Convolutional Neural Networks, with added skip connections to aid in direct transfer of low level information directly from initial layers towards the output layers. The entire encoder section consists of 8 stages. With each encoding stage, two convolutions using a 3x3 filter is applied. The activation function used is Rectified Linear Unit (ReLU). The convolution layer is followed by a 2x2 max pooling layer that has a stride of 2 for downsampling. This downsampling is what lends the encoder network it's contracting path shape. With each stage, the number of channels is doubled at the downsampling step.

3) Decoder: The decoder network consists of 8 decoding stages. Each stage of the decoder applies a simple 2D up sampling operation to the feature map, expanding the map. After that, a 2x2 up convolution is applied, that halves the number of channels in the feature map. A skip connection then concatenates the resulting feature tensor with the output from a corresponding encoding stage. This is followed by application of two 3x3 convolutions, using Rectified Linear

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:49:24 UTC from IEEE Xplore. Restrictions apply.

Unit (ReLU) activation.

4) Discriminator Architecture: The PatchGAN discriminator [9] is another unique element of the proposed architecture (Fig. 2). The function of the discriminator is to correctly classify the given images as being original or fake. Our discriminator classifies patches of the image of NxN size, instead of making predictions for the entire image at once. The primary benefit of using a patch based discriminator is that there are fewer parameters to train in the discriminator network, resulting in faster training. Using a patch based discriminator also encourages sharper detail in generated images [10], [11]. When using a Patch discriminator, the image is essentially modeled as a Markov field, where pixel values are separated by more than a span of N can be considered to be conditionally independent. Through extensive parameter tuning, it has been discovered that a patch size of 70x70 pixels is optimal, making fast discriminator predictions without much loss in image quality. With a patch size of 70x70, there are 900 patches of an output image to predict, resulting in an output tensor of 30x30.

C. Objective Functions

The use of a combination of per-pixel content loss, and the cGAN adversarial loss, are used to train the network. Through the adversarial loss, the high level semantic structure of the input image can be captured, while content loss aids in the capture of low frequency details in the input.

1) Content Loss: This is a per-pixel loss. It evaluates the average difference between each pixel of the target image and the generated image, thus effectively minimizing the per-pixel error in generated images. The L1 content loss is used as it has been observed that use of L2 content loss tends to generate blurry output images.

$$L_{content} = \frac{1}{WH}\sum_{i=1}^{W}\sum_{j=1}^{H}||y_{i,j} - G(x)_{i,j}||_1 \quad (2)$$

where W and H denote the height and width of the image respectively, and $||.||_1$ denotes the L1 norm. $y_{i,j}$ and $G(x)_{i,j}$ represent the pixel values for the sample output image(y) and the generated image ($G(x)$) respectively.

2) Adversarial Loss: Adversarial loss in a cGAN can be expressed as:

$$L_{adversarial}(G, D) = \mathbb{E}_{x,y}[\log D(x, y)] + \mathbb{E}_{x,z}[\log(1 - D(G(x), z))] \quad (3)$$

Equation 3 represents a quantitative measure of the classification error of the discriminator. G, the generator network, and D, the discriminator network are involved in a two player min-max game, with the objectives of respectively maximising and minimising this classification error.

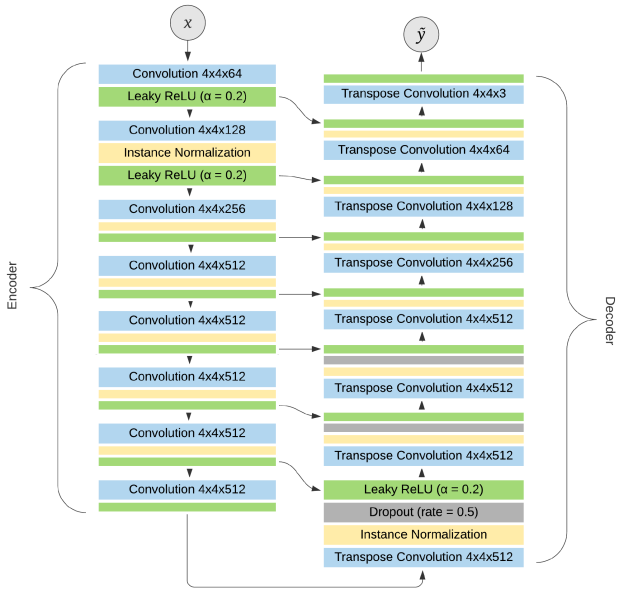

Fig. 1. Generator Architecture

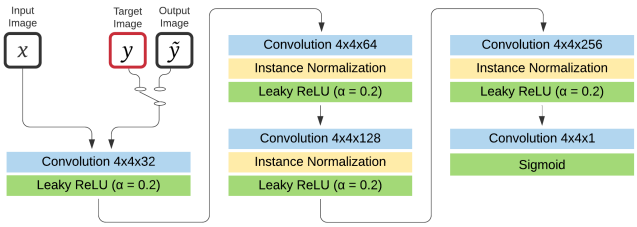

Fig. 2. Discriminator Architecture

3) Final Objective: The final objective function is a weighted sum of the content loss and the adversarial loss.

$$L_{total} = \lambda_{content} L_{content} + \lambda_{adversarial} L_{adversarial} \quad (4)$$

After experimenting and fine tuning parameters on the training data-sets, the optimal values of the weights are obtained as: $\lambda_{content} = 1, \lambda_{adversarial} = 100$

III. Experiments

The model is trained on the publicly available KAIST-MS dataset [7], which is benchmark dataset used for training and testing multi-spectral image transformation models. The dataset consists of 50,184 sample mappings of visible spectrum RGB images and their corresponding TIR images. All images were resized to 256x256 three channel RGB with a train-test split ratio of 80:20. The generator network was initialized with random weights, with a normal distribution $N(0, 0.02)$. The dimensions of the patch discriminator were set to 70x70 after fine-tuning. Training was done with a

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:49:24 UTC from IEEE Xplore. Restrictions apply.

learning rate of 0.0002, $\beta_1 = 0.5$ and $\beta_2 = 0.9$, using the Adam Optimizer. Publicly available Nvidia Tesla P100 (15.9 GB) GPUs were used to train the model on Kaggle.

IV. Results

There is no single widely accepted technique to evaluate the quality of computer generated images, and a variety of multiple methods and measures have been used by researchers working in this field. The quality of our results are evaluated using a number of such quantitative measures in IV-A, and also compared them with baseline results for a subjective qualitative analysis in IV-B.

A. Quantitative Analysis

The model is also compared to its contemporaries on the basis of relevant quantitative metrics. The metrics used will also include the structure similarity index (SSIM) [14], multiscale structure similarity index (MSSIM) [13] and peak signal-to-noise ratio (PSNR). Higher values indicate better quality of generated images. Comparing our method with the Naive and TIR2Lab methods, both trained on the same KAIST dataset, it has been observed that our model outperforms these baselines. Average scores for the compared methods are presented in table I.

1) Structure Similarity Index (SSIM): Structure Similarity Index is a measure used to estimate the perceived quality of cinematic movies and television picture, as well as various types of digital images and videos. The index is calculated on a number of windows of the image. The SSIM for two image windows p and q, having size $N \times N$ is:

$$SSIM(x,y) = \frac{(2\mu_p\mu_q + c_1)(2\sigma_{pq+c_2})}{(\mu_p^2 + \mu_q^2 + c_1)(\sigma_p^2 + \sigma_q^2 + c_2)} \quad (5)$$

Where μ_p is mean, σ_q is standard devation, and σ_{pq} is co-variance.

2) Peak Signal-to-Noise Ratio (PSNR): PSNR is a mathematical ratio between the maximum power of a given signal and the power of noise error. It is commonly used to measure the image reconstruction quality of lossy compression methods. PSNR is used to compare the quality of the generated RGB image with the actual visual spectrum image sample. A simple PSNR can be defined by mean squared error.

$$\frac{1}{WH}\sum_{x=1}^{W-1}\sum_{y=1}^{H-1}(P(x,y) - Q(x,y))^2 \quad (6)$$

Where the images P and Q are $W \text{x} H$ sized.

3) Multi-scale SSIM (MSSIM): Multi-scale SSIM calculates the structural similarity index by calculating the SSIM index for several differently scaled versions of an image, and then combining them. The MS-SSIM index is more robust than SSIM index.

TABLE I
AVERAGE RESULTS OF ALL THE TEST IMAGES OF THE KAIST DATA-SET.

Method	PSNR	SSIM	MSSIM
Naive	9.15	0.32	0.13
TIR2Lab	14.6	0.52	0.51
Proposed	**16.12**	**0.55**	**0.53**

B. Qualitative Analysis

Fig. 3 shows the results generated using our proposed model. Comparing them with the TIR2Lab baseline in Fig. 4, It can also be seen that the obtained results are highly detailed, and perceptually realistic. Our model is robust and correctly generates outputs for both day time, and night time inputs. This was ensured by training the cGAN on day and night images separately.

V. Conclusion

In this paper, a deep learning approach is proposed to solve the colorization problem of thermal infrared images. In particular, a multi-term objective function associated with conditional generative adversarial networks is used to learn the mapping for this image to image translation task. Our method has been evaluated on a publicly available dataset. Our qualitative results produce perceptually realistic images, while retaining the high level information of the given input. When tested on quantitative measures, our model gave a comparable SSIM score, as well as a better PSNR value. Both qualitative and quantitative analysis methods demonstrate that our proposed work outperforms all previous traditional approaches such as the use of a Convolutional Neural Network as an auto-encoder network.

GloVeInit at SemEval-2020 Task 1: Using GloVe Vector Initialization for Unsupervised Lexical Semantic Change Detection

Vaibhav Jain
Delhi Technological University

vaibhav29498@gmail.com

arXiv:2007.05618v1 [cs.CL] 10 Jul 2020

Abstract

This paper presents a vector initialization approach for the SemEval2020 Task 1: Unsupervised Lexical Semantic Change Detection. Given two corpora belonging to different time periods and a set of target words, this task requires us to classify whether a word gained or lost a sense over time (subtask 1) and to rank them on the basis of the changes in their word senses (subtask 2). The proposed approach is based on using Vector Initialization method to align GloVe embeddings. The idea is to consecutively train GloVe embeddings for both corpora, while using the first model to initialize the second one. This paper is based on the hypothesis that GloVe embeddings are more suited for the Vector Initialization method than SGNS embeddings. It presents an intuitive reasoning behind this hypothesis, and also talks about the impact of various factors and hyperparameters on the performance of the proposed approach. Our model ranks 13th and 10th among 33 teams in the two subtasks. The implementation has been shared publicly.[1]

1 Introduction and Background

Lexical Semantic Change (LSC) Detection is an active research topic in the field of natural language processing, and has been applied for diachronic (across time) and synchronic (across domains) tasks (Schlechtweg et al., 2019). Previously limited to manual "close-reading" approaches, the availability of large-scale corpora have allowed the use of computational methods for this task (Tahmasebi et al., 2018). This topic has found various applications in various disciplines such as improving information retrieval from historical documents (Morsy and Karypis, 2016), preventing cross-domain ambiguity in requirements elicitation interviews (Jain et al., 2020), and studying the impact of societal and cultural changes on word meanings and usage (Tahmasebi and Risse, 2017).

LSC detection involves the use of two corpora C_1 and C_2 which, in the diachronic case, belong to different time periods t_1 and t_2 respectively. The various approaches found in the literature usually involve the construction of a word embedding space specific to each corpus. The embeddings can be constructed through count-based methods such as Positive Pointwise Mutual Information and Random Indexing, or predictive methods such as Skip-Gram with Negative Sampling (SGNS). Most of these models are stochastic in nature which means that separately trained embedding models live in their own space. In order to project them onto a *unified space*, alignment techniques such as vector initialization and orthogonal Procrustes are used. The LSC of a word is then quantitatively determined by measuring the contextual dissimilarity between the word's representations (Tahmasebi et al., 2018).

Recently, there have been efforts to evaluate these various methods by comparing their results with manually-annotated data (Schlechtweg et al., 2019; Ahmad et al., 2020). The SemEval-2020 Task 1 is one such effort which is based on LSC detection in corpora of English, German, Latin, and Swedish languages (Schlechtweg et al., 2020). Its aim is to provide an evaluation framework for unsupervised LSC detection systems by comparing their results against a ground truth, as annotated by native speakers or scholars. It consists of two subtasks: *Given two corpora C_1 and C_2 (for time periods t_1 and t_2), for a set of target words,*

1. *decide which words lost or gained senses between t_1 and t_2, and which ones did not; as annotated by human judges.*

2. *rank them according to their degree of LSC between t_1 and t_2 as annotated by human judges. A higher rank means stronger change.*

2 System Overview

2.1 Vector Initialization

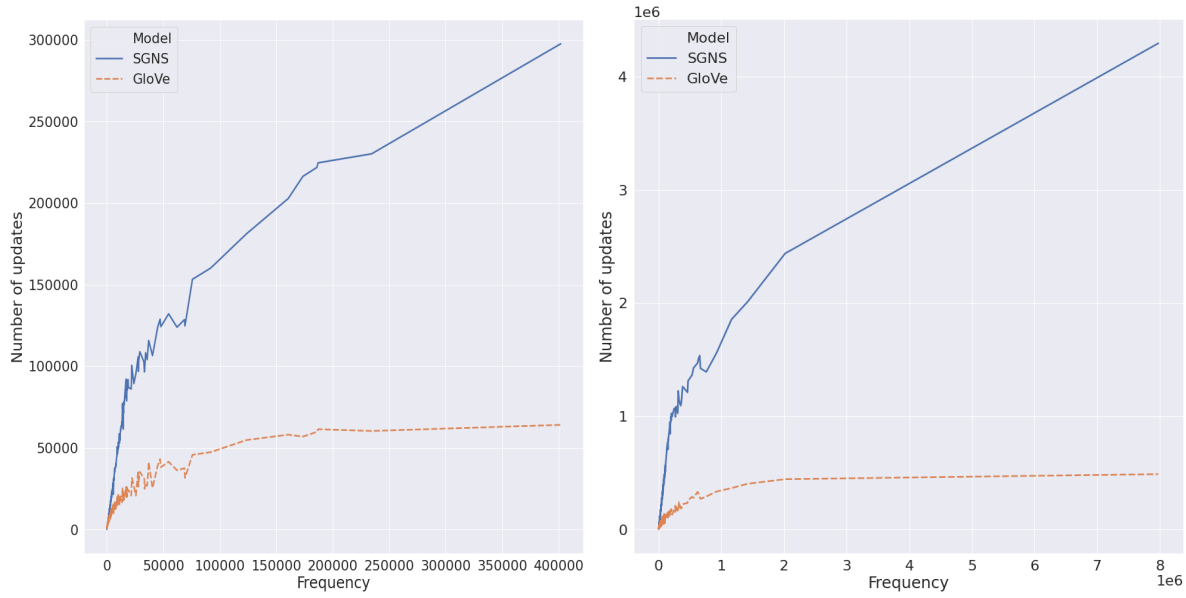
The Vector Initialization (VI) alignment method, which was first used by Kim et al. (2014), involves the embedding space for t_1 to be trained independently on C_1. It is then used to initialize the embedding space for t_2 which is then subsequently trained from C_2. The underlying idea is that the embedding for a word w will get considerably updated if it is used within different contexts in C_1 and C_2, otherwise it will receive only a slight update. A study by Schlechtweg et al. (2019), which applied the VI method on SGNS embeddings, found it to perform significantly weaker on LSC detection tasks than other methods such as orthogonal Procrustes (OP). They attributed this to the sensitivity of the VI method to the frequency of a word in C_2. The high frequency of a word in C_2 will result into the word's embedding getting frequent updates away from its initial state. This leads to a large divergence between the word's representations even if it does not undergo any LSC from t_1 to t_2.

In a recent shared task on LSC detection in the German language, a modified VI approach achieved the third-best result and outperformed certain OP approaches (Ahmad et al., 2020). Instead of only initializing on the word embeddings obtained from C_1, the modified approach initializes on the complete SGNS model which includes the hidden layer. However, it also theoretically suffers from sensitivity to high frequency.

2.2 Comparison of GloVe and SGNS

GloVe (Global Vectors) and SGNS are unsupervised algorithms for obtaining word embedding spaces (Pennington et al., 2014; Mikolov et al., 2013). GloVe makes use of co-occurrence matrix X; its (i, j) entry, X_{ij} is the number of times the word w_j appears in the context of the word w_i (as defined by the window-size L). It trains the word embeddings by minimizing the cost function

$$J = \sum_{i=1}^{V} \sum_{j=1; j \neq i}^{V} f(X_{ij})(u_j^T v_i - \log X_{ij})^2, \tag{1}$$



where V is the vocabulary size and $u, v \in \mathbb{R}^D$ are the word and context word vectors respectively. The final word embeddings can be obtained by summing or averaging the two.

On the other hand, SGNS is a predictive model which relies on a shallow two-layer neural network which, given a word, predicts the set of its context words. To avoid the expensive softmax function in the training objective, negative sampling is used by drawing a few negative samples from a noise distribution.

An important distinction between GloVe and SGNS from this paper's point of view is the number of updates that are made to a word embedding during training. In a single epoch, the number of updates to the SGNS embedding of a word is roughly equal to the number of words that appear in its context throughout the corpus. Hence, the number of updates is proportional to the frequency of the word which has an upper-bound of the total number of words in the corpus. However, this relationship is not exactly linear because of downsampling of frequent words and negative sampling. In the GloVe model, the number of updates received in a single epoch is equal to the number of *distinct* context words. This number is limited by an upper-bound of vocabulary size V, which is usually much less than the total number of words in the corpus.

As discussed in Section 2.1, the VI method can falsely give a high LSC score to words with high frequency. Our hypothesis is that the GloVe model is more suited for the VI method due to its lesser sensitivity to high frequency. To give an indication of the extent of this difference, the relationship between a word's frequency and the number of updates to its embedding is depicted in Figure 1 for both GloVe and

SGNS models trained on the C_2 corpora of all the four languages. These results are based on the official GloVe implementation[2] and the `gensim`[3] implementation of SGNS. The models were trained for a single epoch and only words with a frequency of greater than or equal to 5 were considered. It is clear that the proportion of updates for frequent and rare words is comparatively more balanced in the case of GloVe. On the other hand, there is a high rate of growth in the number of updates with respect to the frequency in the case of SGNS, which indicates that it is biased towards estimating a high LSC for frequent words.

3 Results and Experimental Setup

The dataset provided by the competition organizers consists of the corpora C_1 and C_2, and the list of target words for four languages: English, German, Latin, and Swedish (Schlechtweg et al., 2020). All of the corpora were already prepossessed: they were in tokenized and lemmatized form with punctuation marks and one-word sentences removed.

Subtask 1 is concerned with identifying the loss or gain of one or more word sense(s), where subtask 2 tests a model's ability to detect fine-grained changes in the two sense frequency distributions. For example, consider the word *cell* which historically referred to either a chamber or the smallest unit of an organism. However, the relative usages of both these senses have decreased with time, with mobile phone being the predominant meaning now. For subtask 2, the ground-truth ranking of the target words is determined by calculating the Jensen-Shannon divergence between their normalized sense frequency distributions from t_1 and t_2 (Donoso and Sánchez, 2017). A submission is scored by its Spearman's rank-order correlation coefficient against the ground-truth ranking.

We used cosine distance as the metric to calculate the distance between a word's vectors in diachronic spaces, and every word with a distance of more than 0.55 (for German) or 0.45 (for other languages) were classified to have gained of lost word sense(s).

In all of our experiments, only words having a frequency of at least 5 were considered. Our best-performing solution during the evaluation phase achieved an accuracy of 60% in subtask 1 and a score of 0.352. It was obtained by training word embeddings with a dimensionality of 50 on both C_1 and C_2 for 60 epochs each with a window-size of 10. The subtask-2 score was close to but less than the modified SGNS-based VI approach discussed in Section 2.1, which was proposed by the team *IMS* and received a score of 0.372. We ranked 13th and 10th out of 33 participants in the two subtasks respectively.

Further experiments on subtask-2 were conducted after the competition for analyzing the impact of hyperparameters like window-size L and embedding dimensionality d and are reported in Table 1. Number of training epochs was limited to 20 for models with window-size 10 because of their high computational requirements. The results suggest that training the models for higher number of epochs can produce better results if the embedding dimensionality is high, but can backfire in the opposite case. Using a larger window-size improves the average result in most cases.

L	**Epochs**	***d***	**Scores**				
			English	**German**	**Latin**	**Swedish**	**Average**
5	20	5	0.012	0.366	0.391	0.15	0.23
		10	-0.144	0.362	0.394	0.114	0.182
		20	0.193	0.402	0.368	0.244	0.302
		50	**0.278**	0.446	0.315	0.229	0.317
		100	0.226	0.312	0.254	0.186	0.244
	60	5	-0.018	0.354	0.432	0.121	0.222
		10	-0.095	0.283	0.379	0.108	0.169
		20	0.212	0.41	0.377	0.324	0.331
		50	0.228	0.464	0.329	**0.366**	**0.347**
		100	0.269	0.312	0.276	0.309	0.291

		10	-0.036	0.351	0.409	0.146	0.218
		20	0.144	**0.479**	0.397	0.187	0.302
		50	0.198	0.477	0.275	0.267	0.304
		100	0.199	0.349	0.257	0.227	0.258

Table 1: Results of the post-evaluation experiments

3.1 Error Analysis

We defined the ranking error for each target word as the difference between its predicted rank and its true rank divided by the total number of target words. It lies in the range $(-1, 1)$ and has an ideal value of zero. A positive value indicates that the model overestimated the LSC for a word, and a negative value indicates otherwise. A regression plot between the relative frequency of the target words and their ranking error as per our best performing model is depicted in Figure 2. A word's relative frequency is defined as its frequency divided by the total frequency of all words in the corpus.

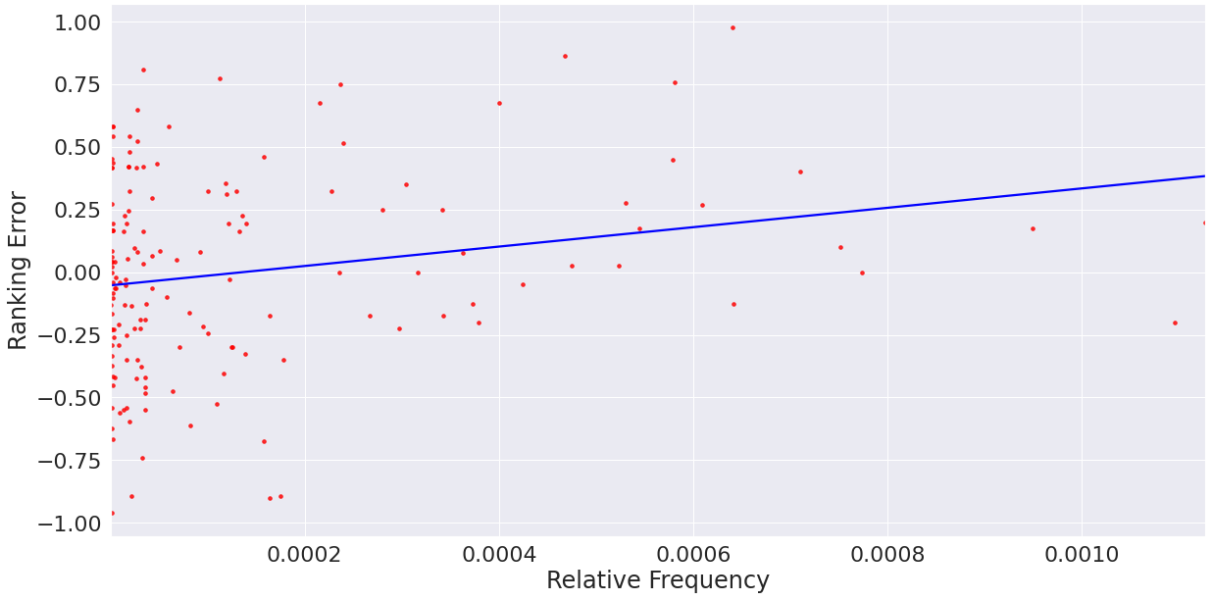

Figure 2: Regression plot between the frequency of the target words and their ranking error

There is a statistically significant correlation between the ranking error and the relative frequency, with the result of the Spearman's rank-order correlation test being $\rho = 0.186$ and $p = 0.020$. This indicates that the GloVe model's relative insensitivity to high frequency can lead to it assigning a rank lower than the true rank to such words. We believe that the frequency of the target words is not large enough for SGNS' sensitivity to high frequency to have a major impact on the results. This explains our model's inferior performance as compared to SGNS-based model in this task.

4 Conclusion and Future Work

In this paper, we reported our work in the SemEval2020 Task 1. We proposed a GloVe-based VI approach which achieved the 11th rank out of 32 participating teams. We gave a theoretical reasoning behind why GloVe is less sensitive towards high frequency than SGNS and thus more suited for VI method, and empirically showed the magnitude of the difference between the number of updates to word embeddings in the two models. We believe that despite a lower-than-expected performance in this competition, our work presents a good case for the suitability of GloVe model when corpora of larger size are involved. However, proving this quantitatively is a challenging task because of the limitations associated with manual annotation-based evaluation.

Planned future work includes the study of how techniques such as dimension-wise mean-centering and length normalization, which have proved beneficial in OP-based approaches, can be applied for VI method.

Acknowledgments

We would like to thank the task organizers for preparing the dataset and organizing the competition, Jens Kaiser (member of the team *IMS*) from University of Stuttgart for sharing the results from his work on the SGNS-based VI alignment method, and the anonymous reviewers for their detailed and helpful feedback.

Abstract

Purpose – The purpose of this study is to investigate the linkage between gratitude and leadership among university teachers. It also tended to examine mediating and moderating effect of social intelligence amidst the relationship between gratitude and leadership. As social intelligence is a multi-dimensional concept, this paper explored mediating and moderating effect of three dimensions of social intelligence, i.e. social awareness, social skills and social information processing.

Design/methodology/approach – Mediation effect was examined with help of Baron and Kenny's (1986) technique, Sobel test and bootstrapping estimates. Significance of interaction between independent variable (gratitude) and moderator (social intelligence) was investigated for moderation analysis.

Findings – The findings reported partial mediating effect of all three dimensions of social intelligence. No significant moderation effect was observed.

Originality/value – This is one of the pioneer studies that explored interrelationship between gratitude, social intelligence and leadership among Indian University teachers.

Keywords Gratitude, Social intelligence, Leadership, Mediation, Moderation

Paper type Research paper

Introduction

A growing number of researchers in positive psychology have proved that gratitude improves well-being (Emmons and McCullough, 2003; Watkins *et al.*, 2014; Wood *et al.*, 2010), facilitates life satisfaction (McCullough *et al.*, 2002; Garg, 2017a), elicits prosocial behavior (Bartlett and DeSteno, 2006) and reduces aggression, envy and narcissism (Froh *et al.*, 2011). However, researchers still believe that the domain of gratitude is yet to be explored adequately. Emmons and Crumpler (2000) highlighted the scarcity of studies on gratefulness in the sphere of social science and organizational psychology. Only handfuls of researchers have investigated the role of gratefulness in modern organizations (Waters, 2012; Grant and Wrzesniewski, 2010).

DOI 10.1108/IJOA-01-2020-2016

According to Emmons and McCullough (2003), gratitude directly influences organizations through improving organizational climate. It also enhances employee's well-being and reduces negative emotions like resentment and envy at the workplace. Also, Fehr *et al.* (2017) proposed that gratitude may play an essential role in various prominent organizational phenomena such as leadership, organizational citizenship and customer service. The feeling of thankfulness may also promote employee efficiency, success, productivity and loyalty (Grant and Wrzesniewski, 2010; Garg, 2018). Previous studies support the positive association of gratitude with organizational citizenship behaviors (Dik *et al.*, 2014; Spence *et al.*, 2013; Garg *et al.*, 2019), prosocial work behaviors (Grant and Gino, 2010), altruism (Spence *et al.*, 2013) and social support at the workplace (Kaplan *et al.*, 2014). In a critical study, Edmondson (2002) reported that gratitude facilitates psychological safety at the workplace, which promotes trust, faith and courage to take interpersonal risks. It influences the attitude of employees toward their colleagues, superiors and management, which enhances their job satisfaction by facilitating better interpersonal relationships (Hu and Kaplan, 2014; Giles and Yates, 2014). Gratuitous organizational culture ensures the recognition of employees' contributions to the workplace. Authors also reported that grateful employees approach their colleagues in a more positive note, which leads to more magnificent team spirit and altruistic behavior.

Although these studies have highlighted the potential benefits of gratitude for modern organizations, they are often criticized for three main reasons. Firstly, most of the studies are theoretical; thereby, the domain calls for empirical investigation of these hypothesized relationships. Secondly, a theoretical explanation of gratitude (see broaden-and-build theory of positive emotions, social-cognitive theory of gratitude and find, remind and bind theory of gratitude) is primarily based on western context and researchers advocate the application of these theories in eastern countries for better acceptability and research rigor. Then finally, research studies are yet to explore the direct impact of gratitude on individual and organizational outcomes such as motivation, morale, intelligence, customer satisfaction and profitability (Fredrickson, 2004; Fehr *et al.*, 2017). Fredrickson (2004) highlighted the need to investigate the role of gratitude in organizations. "In organizations, does gratitude lead to lower employee turnover, more customer loyalty, higher net sales or more profitable outcomes?" (Fredrickson, 2004, p. 160). Unfortunately, the research gap highlighted by Fredrickson is yet to be fully answered. Other researchers, including Grant and Wrzesniewski (2010), Watkins *et al.* (2003), Garg (2020) and Garg and Gera (2019), have also called for more empirical researches on gratitude, especially in the modern organization.

While explaining the broaden-and-build theory of positive emotions in the context of gratefulness, Fredrickson (2004) suggested an investigation of the mechanism through which gratitude strengthens organizations. Probably, the author was aspiring for future researchers to examine moderating and mediating variables amidst the relationship between gratitude and proposed organizational outcome variables. Algoe and Stanton (2012) find, remind and bind the theory of gratitude and Watkins's *et al.* (2014) amplification theory of gratitude also reiterated the same research gap. Based on these theories, this study proposes a model that tends to examine mediating and moderating social of social intelligence in the relationship between gratitude and leadership. The mediating variable explains the mechanism through which the effect of independent variables transmits to the dependent variable. In other words, the independent variable influences the mediating variable, which ultimately influences the dependent variable. Then, the moderating variable influences the relationship between predictor and criterion variable. The moderators act as a catalyst that either increases or decreases the intensity of association between two variables. Following a section of this paper reviews previous literature on gratitude, social intelligence

and leadership. Next, several hypotheses regarding the relationship between gratitude, three dimensions of social intelligence (social awareness (SA), social skills (SS) and social information processing), and leadership are proposed in Section 2. Propositions of mediating and moderating effects of three dimensions of social intelligence are also introduced here. Then, the methodology, sample, questionnaires and findings of the study are discussed in Section 3. This paper ends with a discussion on the theoretical and practical implications of the study in Section 4. The limitations of the study, along with scope for future researchers, were also discussed in Section 5 of the paper.

Theory and conceptual framework

Gratitude

Gratitude has been conceptualized in several forms, including emotion, trait, virtue, habit and coping mechanism (Emmons and McCullough, 2003). "In various contexts, gratitude can refer to an emotional state, an emotional expression, a character trait or even a virtue" (Watkins *et al.*, 2014, p. 13). Researchers suggested that Rosenberg's (1998) "level of analysis" is helpful for an adequate understanding of various facets of gratitude (Watkins *et al.*, 2014). Rosenberg (1998) argued that an affective phenomenon could be divided into three levels of analysis, namely, emotion, mood and trait. Similarly, gratitude could also be approached using this typology, which assists researchers to conceptualize gratefulness appropriately.

As emotions, gratitude may be experienced when people feel "that something good has happened to them, and they recognize that someone else is largely responsible for this benefit" (Watkins *et al.*, 2014, p. 17). Moral affect theory of gratitude (McCullough *et al.*, 2001) reported that gratitude is an honest emotion in three ways. Firstly, it acts as a moral barometer. A barometer is an instrument that indicates a change in atmospheric pressure. In the same way, gratitude represents the emotional response of beneficiary toward benefactor's intentional act of benevolence. Secondly, gratitude acts as a moral motivator. A grateful individual is more likely to act morally and pro-socially. Previous researches (Peterson and Stewart, 1996; Graham, 1998) specially elaborated that a beneficiary possesses a higher probability of contributing to the welfare of the benefactor or even to the third party. Then finally, it can reinforce moral behaviors. A benefactor who receives sincere gratitude is more likely to help their beneficiary again, and thereby, gratuitous behaviors are reinforced (Watkins *et al.*, 2014).

As an affective trait, it is defined as a "general tendency to recognize and respond with grateful emotions to the roles of other people's benevolence in the positive experiences and outcomes that one obtains" (McCullough *et al.*, 2002, p. 112). This approach considers gratitude as a personality trait of an individual. "Trait gratitude may be viewed more as the being of gratitude, whereas gratitude emotion is related to the feelings of gratitude" (Watkins *et al.*, 2014, p. 22). Watkins (2009) defined three essential components of trait gratitude and termed them as "three pillars of gratitude." Firstly, grateful people are poised to have a strong *sense of abundance* or lack of *sense of deprivation*. A sense of abundance or lack of sense of deprivation allows an individual to acknowledge and appreciate all physical and material things that a person possess. Such persons start appreciating previously unnoticed blessings such as a human body, sound mind, three square meal, family, friend, job and home. Although these items seem quite reasonable and insignificant, a mere realization that a large number of people still dreams of having a life similar to them does the miracle. This realization helps a grateful person to acknowledge the fact that he is far more blessed than most of the others. Appreciation of simple pleasure is expressing thankfulness for mundane aspects of life such as a pleasant meal, excellent weather, sudden and

unplanned meeting with an old friend. Secondly, grateful people have a strong sense of *appreciation for the simple pleasures* of life. Even mundane, routine, and day-to-day benefits are cheered by people possessing trait gratitude. Appreciation of simple pleasure is expressing thankfulness for all aspects of life such as a pleasant meal, excellent weather, sudden and unplanned meeting with an old friend, etc. Then finally, grateful people are also characterized by *social appreciation* or *appreciation of others*: they appreciate the contribution of others in their life. This component of trait gratitude also values the importance of expression of appreciation to others.

In addition to these pillars of gratitude, McCullough *et al.* (2002) elaborated four facets of trait gratitude, namely, *intensity*, *frequency*, *span* and *density*. Frequency is the number of times an individual experiences gratitude in a given set of time. Span refers to several events for which one feels gratefulness in a given period. Density involves the number of persons for which an individual experiences gratefulness regarding one particular positive outcome. Then finally, intensity refers to a degree of experience of gratefulness. To summarize, people high in trait gratitude should show facets of intensity, span, frequency and density of gratitude. Little work has investigated gratitude as mood probably because emotion and mood states are not appreciatory distinguished in previous researches (Watkins *et al.*, 2014). However, Rosenberg's approach clarified that moods are longer in duration and are more rooted in awareness than emotions. Grateful moods are not about something particular. Then they are assumed to facilitate grateful emotions. In a nutshell, researchers hailed gratitude as a multidimensional concept that can take several forms (Alkozei *et al.*, 2017). Although researchers have discussed several perspectives of gratitude, they broadly agree on four facets of gratefulness. These facets are, firstly, benefactor favors beneficiary intentionally without being bound of duty; secondly, the gift has certain utility for the receiver; thirdly, the recipient recognizes the goodness of favor/gift and finally, the receiver aspires to reciprocate the gift received from the giver.

Social intelligence

Social intelligence is defined as "the capability to understand and manage humanity to act wisely in human relations (Thorndike, 1920, p. 228). According to Marlowe (1986), social intelligence is one's capability to understand the feelings, thoughts and behaviors of self and others in social circumstances and consequently act according to that understanding. It is accessed with the help of the Tromso Social intelligence scale (TSIS) that investigates three dimensions of social intelligence, namely, SA, SS and Social Information Processing (SIP). SA refers to one's ability to sense social cues about another person's thoughts, aspirations, and emotions. It helps an individual to understand the social situation appropriately (Goleman, 2006). Goleman (2006) empathized that the empathic acknowledgment of other's feelings and roles is the basis of SA. Further, SS are competencies that promote interaction and communication with others. They are cumulative inherent and learned behaviors that influence one's relationship with others (Agran *et al.*, 2016; Davies *et al.*, 2015). Examples of such behaviors are praising and appreciating others, cooperation, helping and seeking help from others, collaborating with others. Then finally, SIP describes the process of cognitive and behavioral response generation is affected by the SIP mechanism. It refers to the ability to understand social cues and other's feelings and aspirations. It helps an individual to predict one's beliefs, expectations, wishes and behavior through observing their facial expression, gestures, eye movement and body language. In a nutshell, it sensitizes employees for their and other feelings.

Leadership

Northouse (2007) defines leadership as "a process whereby an individual influences a group of individuals to achieve a common goal" (p.75). Also, Greer ad Plunkett (2000) stated that "leadership is an art that can be acquired and developed by anyone with the motivation to do so." (p. 157). Researchers have propagated various theories to explain how people become leaders. One of the most eminent scholars, Bass (1990) contributed greatly in the development of three leadership theories. Firstly, trait theory acknowledged the contribution of certain desirable personality traits in evolution of a leader. Secondly, situational theory gave credit to a situation or event that provided an opportunity to rise above the occasion. Such situations are so stimulating and challenging that they elicit extraordinary leadership skills from an ordinary-looking man. Then finally and most importantly, transformational leadership theory emphasized on four essential dimensions of leadership i.e. individualized consideration, intellectual stimulation, inspirational motivation and idealized influence. The theory stated that "transformational leaders are people with a vision who demonstrate the ability to accomplish greatness, are capable of obtaining results through the injection of energy and enthusiasm, and are generally trusted, respected and admired by their followers" (pp. 23–25). The underlying premise of the present study is based on the transformational theory of leadership. Here, gratitude is proposed to have influence over four inherent dimensions of transformational leadership. Garg (2020) also supported the association between gratitude and different constructs of leadership. The theoretical premise of the interrelationship between gratitude, social intelligence and leadership are explained in the following paragraphs.

Gratitude, social intelligence and leadership

Proposed associations between gratitude, social intelligence and leadership are theoretically based on Fredrickson's (1998) *broaden-and-build theory of positive emotions*, and Algoe and Stanton (2012) *find, remind and bind argument of gratitude*. According to Fredrickson, positive emotions like gratitude "broaden people's momentary thought-action repertoires and build their enduring social resources" (Fredrickson, 2004, p. 147). She elaborated that positive emotion broadens thought-action tendencies in three broad ways, namely, through broadening the scope of attention, the range of cognition and scope of action. It is reported that positive emotions elicit a well-thought response from beneficiary instead of a narrow tit-for-tat reaction. Grateful people creatively explore several activities as probable reflections of their gratitude. They tend to think consciously about how to meet the needs of their benefactor, which broadens their attention toward the giver's needs (Watkins *et al.*, 2014). Several studies, including Peterson and Stewart (1996), Graham (1998), McCullough *et al.* (2001), also favored the broad perspective of the theory.

Fredrickson also argued that gratitude builds resources in at least four ways. Firstly, gratitude is assumed to develop and strengthen social bonds. Secondly, in addition to establishing a connection between benefactor and beneficiary, gratitude also strengthens one's relationship with the divine. Several researchers, including Uhder *et al.* (2010), Watkins *et al.* (2014), also supports the fact that gratitude builds and strengthens spirituality. Thirdly, gratitude promoted civil communities and organizations. Then finally, gratitude is poised to expand one's "more general skills for loving" (Fredrickson, 2004, p. 152). In a nutshell, gratitude is poised to transform both at individual and organizational levels. Following the same analogy, this study proposed that gratitude broadens one's social intelligence, and it builds leadership skills.

Now, this study proposes that gratitude improves SA, SS, and social information processing. Broaden perspective of positive emotion elaborated expansion of thought-action

repertoires, the scope of attention, cognition and action and awareness of other's needs. Then, these expanded repertoires seem to have a direct bearing on the social intelligence of the employees. Few researchers, including Covey (1996), Boyatzis and Saatcioglu (2008) reported a positive relationship between gratitude and some elements of social intelligence. Further, banking on Fredrickson's explanation, it is proposed that gratitude broadens social intelligence, which builds leadership resources (skills) for a manager.

The proposed association between gratitude and leadership could also be hypothesized based on Algoe and Stanton (2012) *find, remind and bind theory of gratefulnes*s. Algoe's work is an extension of Fredrickson's philosophy, and it tends to explain the mechanism through which gratitude builds resources for an individual. According to this theory, gratitude helps one find new relationships in social and organizational settings. A grateful person creates and avails more opportunities to initiate a social exchange with others, which facilitates the establishment of a new connection. It also maintains an ongoing relationship by reminding the blessing of association with others. A grateful person cherishes the social context, and thus, makes conscious and consistent efforts to manage them. This effort tends to bind these social affiliations and makes them long-standing. Again, based on this explanation of Find, Remind and Bind theory of gratitude, it could be proposed that gratitude works on one's social intelligence, which bestows them with permanent and favorable social affiliation. Then, good social association with colleagues and followers is the hallmark of success for a leader.

Garg and Gera (2019) explored the mediating effect of social intelligence amidst the relationship between gratitude and leadership. They explained that social intelligence partially mediates the intended association. The current study aspired to further strengthen the findings of the authors by exploring the mediating effect of three constructs of social intelligence. It has also been argued that an individual's personality traits like social intelligence may influence the relationship between gratitude and leadership. Accordingly, the present tends to investigate both mediation and moderation effect with the help of the following theoretical models (Figures 1 and 2) and hypotheses.

H1. Gratitude is positively related to leadership.

H2. Gratitude is positively related to SA.

H3. Gratitude is positively related to SS.

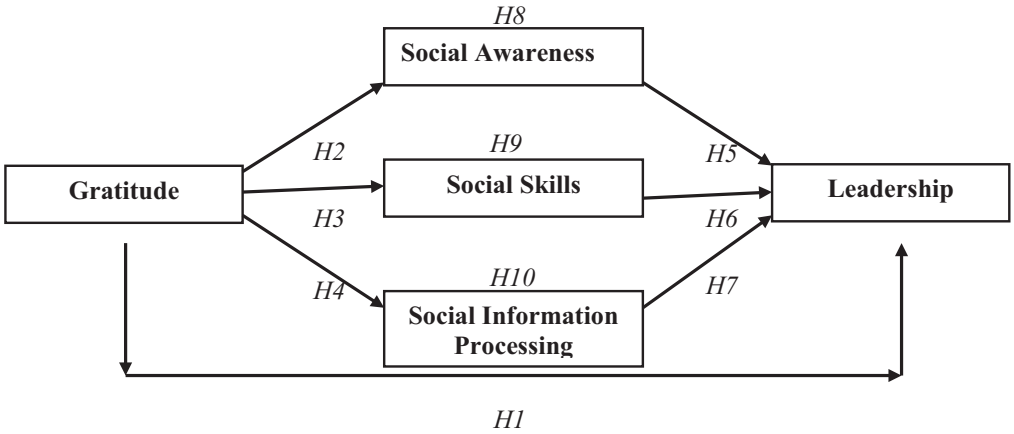

Figure 1.
Mediation model

H4. Gratitude is positively related to social information processing.

H5. SA is positively related to leadership.

H6. SS is positively related to leadership.

H7. SIP is positively related to leadership.

H8. SA mediates the relationship between gratitude and leadership.

H9. SS mediates the relationship between gratitude and leadership.

H10. SIP mediates the relationship between gratitude and leadership.

H11. SA moderates the relationship between gratitude and leadership.

H12. SS moderates the relationship between gratitude and leadership.

H13. SIP moderates the relationship between gratitude and leadership.

Methodological framework

Objectives, sample and procedures

The principal aim of this study was to investigate the linkage between gratitude and leadership among university teachers. It also tended to examine the mediating and moderating effect of social intelligence amidst the relationship between gratitude and leadership. As social intelligence is a multi-dimensional concept, this paper explored the mediating and moderating effect of three dimensions of social intelligence, i.e. SA, SS and social information processing. The sample comprised of 252 university professors teaching across various private, government, and autonomous institutes across Delhi- National Capital Region (NCR), Haryana and Punjab. Respondents were approached either personally or through emails. A total of 300 University teachers were approached and 255 teachers reverted. Three questionnaires were discarded for being incomplete. Now, colleagues of these 252 teachers were approached. Respondent was asked to respond to gratitude questionnaire (GQ-6) and TSIS and one of the colleagues of the respondent was approached to access leadership skills of respondent through multifactor leadership questionnaire (MLQ-5X). The convenience sampling method was used to reach out to these 300 respondents. Respondents were assured regarding the anonymity of responses and for strictly academic usage of collected data. Out of 252 respondents, 124 (49%) were male and 128 (51%) were female. Also, 19% of teachers were below 25 years, 26% were between 26-35 years, 21% were between 36-45 years, 16% were between 46-55 years and the remaining 18% were above the age of 55 years. Finally, the majority of respondents (51%) were from Delhi-NCR.

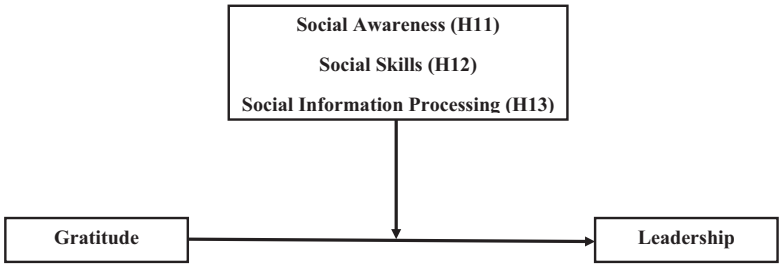

Figure 2.
Moderation model

Measures

Gratitude. It was measured with the help of a GQ-6, a self-report instrument developed by McCullough *et al.* (2002). This scale has six items rated on a seven-point scale ranging from 1 (strongly disagree) to 7 (strongly agree). Out of six items, two items are reverse scored on this scale. GQ-6 is one of the most practiced gratitude scales in academic researches (Froh *et al.*, 2008; Yüksel and Oguz Duran, 2012; Sun and Kong, 2013; Kong *et al.*, 2015; Caputo, 2016; Langer *et al.*, 2016). The six items include "If I had to list everything, I felt grateful, it would be a very long list," "I have so much in life to be thankful for" and "Long amounts of time can go by before I feel grateful to something or someone" (reverse-scored).

Social intelligence. Social Intelligence was measured with the 21 items TSIS developed by Silvera *et al.* (2001). TSIS accesses three dimensions of social intelligence, namely, SA (SA), SS (SS) and SIP. Seven statements are reverse scored, and each statement is measured on the seven-point rating scale. SA is measured with items like "Other people become angry with me without me being able to explain why" and "I have often hurt others without realizing it." Examples of items included to measure SS are "I fit in easily in social situations" and "I have a hard time getting along with other people." SIP is accessed with items like "I know how my actions will make others feel" and "I understand others' wishes."

Leadership. Leadership is measured with the help of the 21 items MLQ-5X developed by Rowold (2004). It accesses seven dimensions of leadership (inspirational motivation, idealized influence (attributed), idealized influence (behavior), individualized consideration, intellectual stimulation, contingent reward and management by exception) rated on a five-point rating scale ranging from 1 (strongly disagree) to 5 (strongly agree).

Reliability and validity

Reliability refers to the consistency of a measure. It is the degree to which similar results are obtained under consistent conditions (Malhotra and Dash, 2018). In this paper, internal consistency reliability, which is the consistency of the respondent's response across different items of the scale, is accessed Cronbach's alpha. It measures split-half correlation through splitting items into two sets, and Cronbach's alpha represents mean of all possible split-half correlations for a set of items. According to George and Mallery (2003), Cronbach's alpha should be greater than 0.70 to confirm reliability. All measures which confirm internal consistency reliability are reported in Table 1 (Cronbach's alpha value for gratitude = 0.877, SA = 0.748, SS = 0.709, SIP = 0.736 and leadership = 0.778). It is suggested to calculate composite reliability along with Cronbach's alpha (Cronbach and Shavelson, 2004). Composite reliability estimates should also be greater than 0.70 to reaffirm reliability (Hair *et al.*, 2010). Also, Convergent and Discriminant validity is determined with average variance extracted (AVE), which was calculated by summation of square of each factor

Variable	Mean	S.D.	α	CR	AVE	VIF
Gratitude	4.68	1.231	0.888	1.270	0.877	1.396
Social awareness	3.83	0.565	0.800	0.584	0.748	2.062
Social skills	3.51	0.643	0.782	0.633	0.709	2.727
Social information processing	3.34	0.761	0.794	0.764	0.736	2.475
Leadership	3.65	0.732	0.773	0.713	0.778	1.231

Notes: S.D. – Standard deviation; α – Cronbach's alpha; CR – Composite reliability; AVE – Average variance extracted; VIF – Variance inflation index
Source: Primary data

Table 1.
Descriptive statistics

loading divided by the number of indicators. AVE must be greater than 0.50 for convergent validity (Fornell and Larcker, 1981). AVE values are reported in Table 1. Discriminant validity indicates distinctiveness. It reflects the degree to which one construct is different from another construct (Bryman and Bell, 2014). Fornell and Larcker (1981) suggested a simple method to ensure Discriminant validity i.e. AVE's value should be higher than the squared inter-correlations of constructs. Table 3 depicts the results of Fornell and Larcker's (1981) results. AVEs were compared (highlighted in bold in the diagonal) with the squared intercorrelations (non-bold entries and below the diagonal). It was found that AVE was greater than the squared correlations, and thereby, it supports the existence of discriminant validity.

Multicollinearity and common method bias

According to Kline (2009), the problem of multi-collinearity surfaces when the correlations among variables are high. In this study, multi-collinearity was explored with the variance inflation factor (VIF), which should be less than five (Kline, 2009). The present study did not have an issue with multi-collinearity, as all VIF values are less than five (Table 1). Detrimental effects of method variance include biased estimates of reliability and validity, inflated or deflated estimates of the relationship between two constructs, affect hypothesis testing, lead to Type I or Type II error and deflated interaction effect (Podsakoff *et al.*, 2012). To minimize common method bias, this study adopted both procedural and statistical remedies. Firstly, pre-validated measurement scales with a different rating scale for predictor (seven-point) and criterion (five-point) were used. Secondly, the anonymity of the respondents was assured and strictly maintained. Also, respondents (university teachers) were explained how the study and its findings might be useful for them. It motivates respondents to respond more accurately and positively (Podsakoff *et al.*, 2012). Also, the independent variable and dependent variables were measured from two different sources. Respondent was asked to respond to GQ-6 and TSIS, and one of the colleagues of the respondent was approached to access the leadership skills of the respondent through MLQ-5X. Apart from these procedural methods, the Harman one-factor was also used to check common method bias. More than one factor was reported when items of different measures were subjected to factor analysis.

Statistical tools

The collected data is analyzed with the help of different statistical tools such as the measure of central tendency, standard deviation, correlation, hierarchical regression, Sobel test and bootstrapping.

Data analysis and interpretation

Table 1 shows means, standard deviations, and reliability, validity and multicollinearity estimates of variables of the study (Tables 1 and 2). Table 2 elucidates the correlation among variables of the study. Results suggest that gratitude is positively associated with the leadership of the teacher and with three dimensions of social intelligence. Hence, *H1–H4* are supported. Also, SA, SS, and SIP are positively correlated with leadership. Thus, *H5–H7* are confirmed (Tables 3 to 5).

Now, mediating effect of SA, SS and SIP on the relationship between gratitude and transformational leadership is explored with Baron and Kenny's (1986) four-step approach, in a combination of "Sobel test" and "bootstrap of the indirect effect" as suggested by Zhao *et al.* (2010). As per Baron and Kenny (1986), the first three conditions for mediation are significant regression between an independent variable and dependent variable,

independent variable and mediator and mediator and dependent variable. In the fourth step, a mediator is controlled, and the independent variable is again regressed on the dependent variable. Complete mediation is present when the predictor variable no longer predicts criterion variable and partial mediation is present when the influence of the independent variable on the dependent variable is reduced on the controlling effect of the mediating variable.

Table 4 presents path coefficients and significance levels for the proposed mediation hypotheses using hierarchical regression. It is argued that Baron and Kenny's (1986) method provides a fair idea about mediation, but the statistical significance of the mediator could be examined using a Sobel test (Yay, 2017). It is also argued that both these methods assume a normal distribution of data. Thus, researchers advocate the bootstrapping process, which is resampling with a replacement for large times such as 5,000 or 10,000 times, to confirm the mediation effect. Bootstrapping method is increasingly gaining acceptance among researchers (Shrout and Bolger, 2002; Fritz *et al.*, 2012). Table 5 shows the result of the Sobel and bootstrapping method. Results of Tables 3 and 4 suggest that SA, SS and SIP partially mediate the relationship between gratitude and transformational leadership. Hence, *H8–H10* are supported.

Finally, the moderation effect of three dimensions of social intelligence was analyzed by calculating the interaction effect of an independent variable (gratitude) and proposed moderators. It is being suggested that significant interaction confirms the moderation effect. Results of Table 6 show that none of the three dimensions of social intelligence (SA, SS and social information processing) moderates the relationship between gratitude and leadership. Hence, *H11*, *H12* and *H13* are rejected. Findings are discussed in the next section of the paper.

Discussion

In one of the most popular articles, 'grateful leaders make the best leaders,' Nieuwhof (2017) discussed five essential reasons for leaders to cultivate and cherish the virtue of gratitude.

Variables	1	2	3	4	5
Gratitude	1				
Social awareness	0.507**	1			
Social skills	0.454**	0.652**	1		
Social information processing	0.376**	0.620**	0.753**	1	
Leadership	0.549**	0.629**	0.736**	0.654**	1

Notes: **Correlation is significant at the 0.01 level (two-tailed)
Source: Primary data

Table 2. Correlation matrix

Variables	1	2	3	4	5
Gratitude	0.877				
Social awareness	0.257	0.748			
Social skills	0.206	0.426	0.709		
Social information processing	0.141	0.384	0.567	0.736	
Leadership	0.301	0.395	0.541	0.427	0.778

Source: Primary data

Table 3. Discriminant validity results

Firstly, he argued that gratitude impacts the overall attitude of a human being. It makes a person more compassionate, kinder, less suspicious and less resentful. Then all these qualities are essential traits of a good leader. Secondly, a sense of abundance allows a grateful leader to see and use an opportunity where other misses. According to Nieuwhof, this abundance thinking develops an abundance mentality that enables leaders to realize immense prospects of growth and development. Thirdly, gratitude may fuel generosity among leaders, which wins the hearts and souls of the followers. Also, people desperately wish to work with a grateful leader. In other words, gratitude attracts people to work in a team for larger organizational goals. The author claims that employees are ready to accept lower wages or even pay cuts to work under a grateful senior. Then finally, gratitude neutralizes anger and jealousy of a leader. Then, a calm and compose leader can easily touch the skies of success.

Table 4. Mediation analysis (results of hierarchical regression)

Hypothesized relationships	IV to DV	IV to Med	M to DV (with mediator)	IV to DV	Hypotheses support
G→ SA →L	0.549*	0.507*	0.629*	0.472*	*H8*
G →SS →L	549*	0.454*	0.736*	0.499*	*H9*

Source: Primary data

Considering such expert opinions, objects of a broaden-and-build theory of positive emotions, attachment perspective of a social cognitive theory of gratitude, Fredrickson's theoretical predictions, previous literature and advice of practitioners, this study hypothesized that gratefulness influences leadership. It is revealed that gratitude is positively associated with leadership. The present study also suggests a statistically robust and positive relationship between gratitude and SA, SS and social information processing. Also, the mediation and moderation effect of three dimensions of social intelligence (SA, SS and SIP) are explored. It reports that all these three dimensions of social intelligence partially mediate the relationship between gratitude and transformational leadership. The findings suggest that cultivating gratitude broadens one's social intelligence, which builds leadership skills. These findings are consistent with the broaden-and-build theory of positive emotions and also with a prediction of Fredrickson.

SA refers to one's ability to emphatically sense social cues about another person's thoughts, aspirations and emotions, which helps them to understand others appropriately. Then, here gratitude hits the bull's eye. A grateful leader is presumed to analyze others' contributions correctly and then acknowledge their efforts through grateful and appreciative behaviors at an appropriate public forum. Leaders generally resort to the oral expression of thankfulness, appreciation note, reward, promotion and challenging assignment to express their gratitude toward their subordinates.

SS are competencies that promote interaction and communication with others. Then, researches suggested that managers who express gratitude make their subordinates more comfortable for voicing their concerns. Grateful people appear more warmth and responsive to others, and hence, they command their trust and faith (Fredrickson, 2004), which makes them easy to approach. This easiness and comfort of subordinates allows free flow of interaction between two parties and thereby facilitates SS. As far as SIP is concerned, it is one's ability to regulate negative emotions such as anxiety, nervousness, etc. in social situations. This study reports that gratitude influence the SIP capacity of leaders. The findings could be understood with the help of the "undoing effect" of positive emotions. Several studies, including Sansone *et al.* (2010), Allen (2018) and Jans-Beken (2018) reported the undoing effect of gratitude through neutralizing stress, anxiety, nervousness and depression.

The findings of the present study complement the results of previous studies. Garg and Gera (2019) also reported a positive association between gratitude and leadership. Afterward on, Garg (2020) advocated that gratitude is both necessary and sufficient conditions for the development of seven essential constructs of educational leadership. Waters and Stokes (2015) also reported that an effective school leader attends both emotion-gratitude and action-gratitude. The authors also supported that gratuitous behaviors of leaders reciprocate, and it is equally effective in good and challenging time. Howells (2013) discussed the importance of gratitude for school leadership in great length. The results of the present study support her qualitatively researched propositions.

Conclusion

Theoretical contribution of the study

The study makes a few significant contributions to the existing literature. Firstly, the current study aspires to address the scarcity of gratitude studies in organizational contexts. Fredrickson (2004), in her famous book *The Psychology of Gratitude,* suggested an exploration of gratitude for workplace betterment. She promoted future researchers to investigate the association between gratitude and employee performance, leadership skills, employee satisfaction level and profitability of the firm. Unfortunately, her call has not been

attended enough in past 15 years. Then, this is one of the few studies in the direction enlightened by Fredrickson. Secondly, findings of the study provide an alternate explanation of broaden-and-build theory. It could be inferred that gratitude as positive emotions broadens one's SS, which build resources in terms of leadership skills. Further, the study stresses the significance of gratitude in the context of leadership. Probably, this is the first empirical study to investigate the relationship between gratitude and leadership. Previous researchers have discussed the role of leaders' emotions in the staff's performance and productivity (Humphrey, 2002; Garg, 2017b). Combining the results of these studies with the findings of this study reveals that gratitude can be doubly beneficial for leaders. Firstly, gratitude can sharpen leadership skills and secondly, as emotion, gratitude can influence subordinates' performance. Future researchers can undoubtedly investigate the impact of grateful leaders on follower's performance. Positive emotions are contagious (Hatfield *et al.*, 1993), and feelings of organizational leaders are especially contagious (George, 1995). Thus, the gratuitous behavior of leaders may produce a cascading effect through eliciting a similar response from subordinates.

Fourthly, this resolves the "black-box" of a path through which the effect of gratitude transmits to leadership. The results show that SA, SS and SIP partially mediate the relationship between gratitude and leadership. In summary, gratitude influences social intelligence, which horns one's leadership skills. Again, this study is one of the first explorations to explore the mediating and moderating effect of social intelligence amid the relationship between gratitude and transformational leadership. Then finally, this study is conducted in Indian settings, and most of the previous studies on gratitude were conducted in western contexts. As discussed, the findings of this study are complementing the broaden-and-build theory and social attachment perspective of a social cognitive theory of emotions. These theories were developed in non-eastern conditions. Given vast cultural differences, this study provides an appropriate avenue of application of these theories in Indian states.

Practical implications of the study

The findings of this study provide several practical implications for practitioners too. Firstly, leadership skill trainers can help participants in cultivating gratitude to promote leadership skills. Trainers may use different gratitude practices and interventions including "gratitude journals" (Froh *et al.*, 2008; Froh *et al.*, 2007), "gratitude letters" (Seligman, 2002; Sergeant and Mongrain, 2011), "gratitude letters visits" "cultivating mindfulness" (Langer, 2014; Langer *et al.*, 2010), "gratitude collages" (Reivich, 2009), "sharing positive events" (Gable *et al.*, 2004), "acts of kindness" (Sheldon *et al.*, 2013) and "meditation and progressive muscle relaxation techniques" (Shapiro, Schwartz and Santerre, 2002). Secondly, as discussed, leaders' expression of gratefulness is not only beneficial for leaders; it also influences subordinates' performance too. Thus, organizations are suggested to motivate their line managers to cultivate the virtue of gratitude. This could quickly be done by imbibing gratuitous behavior in organizational culture. Again as suggested by previous researchers that positive emotions are contagious, gratuitous behavior by top management will motivate line managers to follow suit. Thirdly, findings suggest that social intelligence is a significant predictor of leadership. Although more researches are required for generalization, a recruiter may start discussions and debates on the inclusion of social intelligence test for the selection of managers.

Also, Fehr *et al.* (2017) proposed a multilevel model of gratitude in organizations. According to this model, gratitude could be observed at three levels in the workplace, namely, episodic gratitude ("feeling grateful in response to a particular experience"),

persistent gratitude ("a stable tendency to feel grateful within a particular context") and collective gratitude ("persistent gratitude that is shared by the members of an organization"). The authors also argued that these different forms of gratitude complement and support each other. If an organization facilitates institutionalization of gratitude at organizational level, then it facilitates cultivation of both episodic and persistent gratitude at individual level. Thus, the present study recommends organizational level gratitude programs such as "Formal appreciation program," "Thanks-giving day or week," and "Personalized gratuitous letters from managers and leaders." In recent commendable initiatives, contemporary organizations have started paid leaves to employees to serve the needy people. Under the Corporate Social Responsibility initiative, these companies allow a group of employees to submit a socially-beneficial project. If such a project is approved, the organization not only funds the project, but employees are also given paid leaves. Such schemes foster an organizational culture based on gratitude and trust.

Limitations, scope for future studies and conclusion

The present study provides an empirical model of gratitude, social intelligence, and transformational leadership. However, these contributions come in light of a few limitations. Firstly, this study is based on a cross-sectional research design, and also data is collected using self-reported measures. Thus, there are chances of common method variance (CMV). Although CMV was not reported in this study, a longitudinal study is required to conclude any causal and hypothesized relationships. Future researchers may conduct longitudinal studies to confirm the findings of this study. Secondly, the present study is based on a sample of 252 employees only. A larger sample comprising of respondents from diverse industries would be appropriate for generalization of the results. Future research should explore a larger sample spread over different companies. Thirdly, this study examined the mediating effect of social intelligence only. Future researchers may test a range of variables such as contentment, satisfaction perceived organizational support for possible mediation effect. Also, gratitude is measured with the help of a one-dimensional scale (GQ-6). Future researchers may use multidimensional scales like GRAT for better results. The present has considered consolidated values of gratitude and leadership measures, and future researchers may opt for in-depth analysis by considering different constructs of gratitude and leadership. It would be interesting to examine

In conclusion, the study provides empirical evidence supporting a positive association between gratitude and transformational leadership. Moreover, all three dimensions of social intelligence proved to be partially mediators of the relationship between gratitude and leadership. Besides, SS were also reported as moderator of a hypothesized relationship. As this study is a pioneer study in the field of gratitude, social intelligence and leadership, the results bring significant contributions that enhance understanding and support further research in this specific area of study.

Appendix. Questionnaire

Gratitude scale

(1) I have so much in life to be thankful for.
(2) If I had to list everything that I felt grateful for, it would be a very long list.
(3) When I look at the world, I do not see much to be grateful for.*
(4) I am grateful to a wide variety of people.
(5) As I get older I find myself more able to appreciate the people, events, and situations that have been part of my life history.
(6) Long amounts of time can go by before I feel grateful to something or someone.

* *Items 3 and 6 are reverse-scored.

Social intelligence scale

(1) I can predict other people's behavior.
(2) I often feel that it is difficult to understand other's choices.
(3) I know how my actions will make others feel.
(4) I often feel uncertain around new people who I do not know.
(5) People often surprise me with the things they do.
(6) I understand other people's feelings.
(7) I fit in easily in social situations.
(8) Other people become angry with me without me being able to explain why.
(9) I understand other's wishes.
(10) I am good at entering new situations and meeting people for the first time.
(11) It seems as though people are often angry or irritated when I say what I think.
(12) I have a hard time getting along with other people.
(13) I find people unpredictable.
(14) I can often understand what others are trying to accomplish without the need for them to say anything.
(15) It takes a long time for me to get to know others well.
(16) I have often hurt others without realizing it.
(17) I can predict how others will react to my behavior.
(18) I am good at getting on good terms with new people.
(19) I can often understand what others really mean through their expression, body language etc.
(20) I frequently have problems finding good conversation topics.
(21) I am often surprised by others' reactions to what I do.

Leadership scale

(1) I make others feel good to be around me.
(2) I express with a few simple words what we could and should do.
(3) I enable others to think about old problems in new ways.
(4) I help others develop themselves.

(5) I tell others what to do if they want to be rewarded for their work.
(6) I am satisfied when others meet agreed-upon standards.
(7) I am content to let others continue working in the same way as always.
(8) Others have complete faith in me.
(9) I provide appealing images about what we can do.
(10) I provide others with new ways of looking at puzzling things.
(11) I let others know how I think they are doing.
(12) I provide recognition/rewards when others reach their goals.
(13) As long as things are working, I do not try to change anything.
(14) Whatever others want to do is O.K. with me.
(15) Others are proud to be associated with me.
(16) I help others find meaning in their work.
(17) I get others to rethink ideas that they had never questioned before.
(18) I give personal attention to others who seem rejected.
(19) I call attention to what others can get for what they accomplish.
(20) I tell others the standards they have to know to carry out their work.
(21) I ask no more of others than what is absolutely essential.

Implementation Strategy for Resource Optimization of FPGA-Based Adaptive Finite Control Set-MPC using XSG for a VSI System

Vijay Kumar Singh, Ravi Nath Tripathi, and Tsuyoshi Hanamoto

***Abstract*— Finite control set-model predictive control (FCS-MPC) for power electronic systems has been implemented using field-programmable gate array (FPGA) considering an alternative solution to handle the computational burden of the control algorithm. However, FPGA resource utilization is a concern for optimum design and development of the FCS-MPC. This paper presents, an analytical approach based implementation strategies using the Xilinx system generator (XSG) considering the real-time operation of the FCS-MPC for a three-phase voltage source inverter (VSI). Moreover, an adaptive prediction model is proposed to adapt to the change in load current. The percentage THD, dynamic response, and steady-state error are evaluated for system performance analysis. The implementation strategies are compared based on FPGA resource utilization for the FCS-MPC in stationary *αβ* and rotating *dq* frames considering fixed, approximated and adaptive values of a coefficient used for current prediction. The look-up tables (LUTs), flip-flops and DSP slices have opted as utilization indices of FPGA resources for comparative analysis. The optimum design based controller model is used for FPGA-based experimental system implementation. The simulation and experimental results are used for the performance evaluation of the FCS-MPC in both *αβ* and *dq* frames. Moreover, change in switching state constraint is included in the cost function and controller performance is evaluated corresponding to the weighting factor for approximated and adaptive coefficient values.**

***Index Terms*— finite control set-model predictive control, field-programmable gate array, model-based design, voltage source inverter, Xilinx system generator.**

I. INTRODUCTION

MODEL predictive control (MPC) possesses appealing characteristics such as explicit use of a system model, flexibility of simultaneous handling of multiple constraints and easy inclusion of nonlinearities [1]–[4]. These distinctive features of MPC have created considerable attention towards researcher and MPC has been applied to a wide variety of power converter and drive applications. For instance, two-level voltage source inverter (VSI) [5], [6], three-level neutral-point clamped converter (NPC) [7], active front end rectifier [8], [9], cascaded H-Bridge inverter [10], three-phase direct matrix converters [11], [12], predictive control for UPS applications [13], predictive torque control (PTC) and field-oriented control (FOC) of an induction machine [2], [14], just to name a few.

The fundamental principle of the MPC is to have a plant or system model that is used for the prediction of the future behavior of control parameters and the control action is selected based on an optimization function or cost function in each sampling interval. Finite control set-model predictive control (FCS-MPC) is one of the classifications of MPC that uses the discrete-time model of a power converter. The cost function is computed based on the finite number of switching states of the power converter and the control action is directly applied to the converter. As compared to the generalized MPC method, the computational requirement is reduced in the FCS-MPC by using the discretized power converter model and a small prediction horizon (N_P = 1). The computations required during the implementation of predictive controls for power converters are accomplished by the microprocessor and digital signal processor (DSP) [3], [4], [14].

The prediction and cost function computations required for the algorithm in the practical implementation should strictly complete within a given sampling interval. However, the computational task is a concern especially for complex converter systems and creates a delay issue that deteriorates the quality of waveforms [5], [15]. This issue has been addressed and some methodologies for delay compensation have been presented to compute the optimum switching state within the specified sampling interval [16], [17]. However, delay compensation techniques have to deal with the increased computational burden and average switching frequency [16].

Field programmable gate array (FPGA) is a pragmatic choice for the implementation of MPC because of parallel processing capability [18]–[24]. In [18], a comparative analysis among various digital control platforms is presented for the implementation of model predictive control including FPGA. Moreover, the different approach is adopted for FPGA-based system implementation. In [19], an FPGA platform of NI-CRIO

reconfigurable system is used to implement MPC for a back-to-back converter. The FPGA implementation of MPC is performed using a model-based design (MBD) through MATLAB/Simulink in [20], [21] and FPGA code was obtained using hardware description language (HDL) coder functionality of Simulink. In [22], a high-speed FCS-MPC implementation is presented with a control algorithm coded in C++ using PROTOIP toolbox and HDL code was generated through Xilinx Vivado HLS. Xilinx system generator (XSG) as a digital simulator adopting the MBD platform was used to implement an FPGA-based predictive current controller in [23]–[26]. XSG is an integrated platform with MATLAB/Simulink and facilitates the HDL code generation for the developed system.

In addition to the implementation approach, resource utilization is another key aspect of FPGA-based system control implementation. The system control implementation based on FPGA resource utilization is compared in [22] and [25] for Xilinx FPGA. In [22], the prediction horizon is considered for the comparison of FPGA resource utilization. In [25], semi-parallel and fully serial implementation approaches for MPC are adopted and resource utilization is compared for the same. The look-up tables (LUTs), flip-flops and DSP slices are the main digital logic indices considered for resource utilization in the aforementioned papers.

There is a possibility to adopt different implementation strategies for an FPGA implementation to enhance resource utilization. In this way, the MBD approach can be advantageous by allowing different implementation strategies under the same environment and to compare the FPGA resource utilization. Moreover, the MBD approach provides better system visualization and easy debugging that is appealing for rapid controller prototyping.

This paper presents analytical implementation strategies using an MBD approach considering the reduction in the FPGA resource utilization for fully parallel implementation of the FCS-MPC algorithm. The predictive model coefficient computed using load parameters is one of the significant factors that influence system performance. Furthermore, an adaptive predictive model is proposed to compensate for the effect of change in load parameters by using simple mathematical relation of the three-phase inverter output voltage, dc voltage supply, and modulation index. The unity and non-unity modulation index is also included to investigate the proposed adaptive model design considering system performance.

A comparative analysis of FPGA resource utilization using analytical implementation strategies is considered corresponding to the predictive model coefficient of the FCS-MPC for a three-phase VSI system with RL load. Moreover, resource utilization for controller implementation using stationary $\alpha\beta$ and rotating dq reference frames is used for in-depth analysis. In general, the cost function is formulated based on stationary $\alpha\beta$ coordinates [27], [28]. Considering current control with the FCS-MPC, the sinusoidal future current references need be predicted accurately using an extrapolation method, however, the extrapolated reference causes unwanted oscillations that influence transient response [7], [9], [27]. Considering the above issue, the cost function can be designed using a rotating dq frame that does not require the extrapolation method due to continuous current references [27]. However, the comparative analysis based on design constraints and performance indices is required to be addressed for two frames. Furthermore, the computational burden, as well as the FPGA resource requirement corresponding to each coordinate system, is crucial for practical system implementation.

The FPGA-based implementation of the FCS-MPC is performed using the MBD approach provided by the XSG integrated to MATLAB/Simulink. The system performance is analyzed based on the implementation of the FCS-MPC using optimum FPGA resource utilization in $\alpha\beta$ and dq frames for the adaptive predictive model (unity and non-unity modulation index). The dynamic behavior and steady-state error are considered for analysis of system performance. Furthermore, a constraint of change in switching state [2], [29] is considered to analyze the performance of average switching frequency reduction and the current harmonics for the adaptive predictive model.

The paper is organized as follows: Section II describes the algorithm of the FCS-MPC for both stationary $\alpha\beta$ as well as rotating dq frames considering the discrete-time mathematical model of the three-phase VSI system. In Section III, the model-based design and development of the controller in the digital simulator are explained. Section IV covers the different implementation strategies considered for the development of the FCS-MPC algorithm and the comparative FPGA resource utilization. The simulation and experimental results are presented with detailed discussion in Section V. Finally, appropriate conclusions are drawn in Section VII.

II. Finite Control Set-MPC

The power circuit of a three-phase VSI with *RL* load is shown in Fig. 1 where R is the load resistance and L is the load inductance. The switching states of the converter are determined by the switching signals S_a, S_b, and S_c as shown in Table I. Considering all possible switching combinations of the switching signals, eight switching states $\boldsymbol{S}$ ($\boldsymbol{S}_0$–$\boldsymbol{S}_7$) and hence, eight voltage vectors $\boldsymbol{v}_i$ ($\boldsymbol{v}_0$–$\boldsymbol{v}_7$) are obtained as shown in Table II.

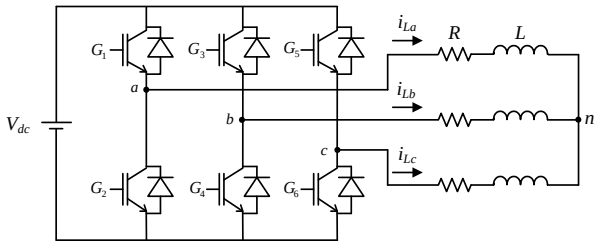

Fig. 1. Power circuit of three-phase VSI with RL load.

$\boldsymbol{S}_7 = [1 \ 1 \ 1]$	$\boldsymbol{v}_7 = [0, 0]$

The FCS-MPC based on the current control objective uses a discrete-time model of the load current for the formulation of the control algorithm and deals only with a limited number of possible switching states of the power converter. The discrete-time model can be obtained from the dynamics of the load current. The dynamics of the load current $\boldsymbol{i}_L$ (i_{La}, i_{Lb}, i_{Lc}) can be described by the vector differential equation as below:

$$\boldsymbol{v_i} = R\boldsymbol{i_L} + L\frac{d\boldsymbol{i_L}}{dt} \tag{1}$$

A. Discrete-time Predictive Model

The discrete-time model of the load current dynamics (1) for a sampling time T_S represents the predictive model. It will be used to predict the future value of load currents considering each voltage vector listed in Table II. The discrete-time model can be obtained by an approximation of load current derivative $d\boldsymbol{i}_L/dt$ using the forward Euler discretization method given as:

$$\frac{d\boldsymbol{i_L}}{dt} \approx \frac{\boldsymbol{i_L}(k+1) - \boldsymbol{i_L}(k)}{T_S} \tag{2}$$

After substituting (2) into (1), an expression of predicted future load current at sampling interval k+1 is obtained for each of the seven different voltage vectors $\boldsymbol{v_i}(k)$ in $\alpha\beta$ frame as:

$$\begin{aligned} i_{L\alpha}^{p}(k+1) &= k_1 i_{L\alpha}(k) + k_2 v_{i\alpha}(k) \\ i_{L\beta}^{p}(k+1) &= k_1 i_{L\beta}(k) + k_2 v_{i\beta}(k) \end{aligned} \tag{3}$$

$$\text{where } k_1 = \left(1 - \frac{RT_S}{L}\right),\ k_2 = \frac{T_S}{L}$$

$i_{L\alpha}(k)$, $i_{L\beta}(k)$ and $i^p{}_{L\alpha}(k+1)$, $i^p{}_{L\beta}(k+1)$ denote the measured load currents at instant k and the predicted future load currents at instant k+1, respectively. The coordinate transformations from abc to $\alpha\beta$ are computed using mathematical relation defined by Clarke transformation as

$$\begin{bmatrix} x_\alpha \\ x_\beta \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1/\sqrt{3} & -1/\sqrt{3} \end{bmatrix} \begin{bmatrix} x_a \\ x_b \\ x_c \end{bmatrix} \tag{4}$$

where x can be any quantity voltage or current.

The voltages and currents in dq coordinates can be transformed from $\alpha\beta$ components using Park transformation relation given as:

$$\begin{bmatrix} x_d \\ x_q \end{bmatrix} = \begin{bmatrix} \cos\theta^* & \sin\theta^* \\ -\sin\theta^* & \cos\theta^* \end{bmatrix} \begin{bmatrix} x_\alpha \\ x_\beta \end{bmatrix} \tag{5}$$

where θ^* is the reference phase angle for the coordinate conversion. The predicted load currents in rotating dq-frame can also be obtained using forward Euler discretization considering feed-forward terms for the decoupling of the d and q components of the current as given below:

$$\begin{aligned} i_{Ld}^{p}(k+1) &= k_1 i_{Ld}(k) + k_2 \left\{ v_{id}(k) + k_3 i_{Lq}(k) \right\} \\ i_{Lq}^{p}(k+1) &= k_1 i_{Lq}(k) + k_2 \left\{ v_{iq}(k) - k_3 i_{Ld}(k) \right\} \end{aligned} \tag{6}$$

$$\text{where } k_1 = \left(1 - \frac{RT_S}{L}\right),\ k_2 = \frac{T_S}{L},\ k_3 = \omega^* L$$

ω^* is an angular frequency of the current reference and calculated as $\omega^* = d\theta^*/dt$.

B. Adaptive Predictive Model

The predictive model depends on the coefficients k_1, k_2, k_3, for current prediction and computed using the load parameters (R, L). Any change in load parameters disturbs the accuracy of the predictive model, which ultimately affects the performance of the FCS-MPC. The value of a coefficient can be updated to compensate for the effect of change in load parameters. In this paper, an approach to update the coefficient k_1 (adaptive k_1) corresponding to the change in load resistance R is considered by assuming unchanged load inductance L.

According to the phase voltage and line current relationship, the load impedance Z can be calculated as given below:

$$Z = \frac{v_{ph,rms}}{i_{L,rms}} \tag{7}$$

where $v_{ph,rms}$ is the rms values of voltage in any phase and $i_{l,rms}$ is the rms value of the load current. The $v_{ph,rms}$ can be simply obtained using the relation between the phase voltage and a dc supply to an inverter given as:

$$V_{dc} = \frac{2\sqrt{2}v_{ph,rms}}{m} \tag{8}$$

where m is a modulation index.

By substituting the value of $v_{ph,rms}$ from (8) into (7), the value of Z can be updated as follows

$$Z = \frac{mV_{dc}}{2\sqrt{2}i_{L,rms}} \tag{9}$$

The load impedance Z contains resistance (R) and inductive reactance (X_L) as given below

$$Z = \sqrt{R^2 + (X_L)^2},\ \text{where } X_L = \omega L \tag{10}$$

R can be computed by putting the value of Z from (9) to (10) and represented as:

$$R = \sqrt{\left(\frac{mV_{dc}}{2\sqrt{2}i_{L,rms}}\right)^2 - (X_L)^2} \tag{11}$$

R can be updated by (11) according to the change in load current. Further, the coefficient k_1 used for current prediction in (3) and (6) can be automatically updated by putting the value of

This article has been accepted for publication in a future issue of this journal, but has not been fully edited. Content may change prior to final publication. Citation information: DOI 10.1109/JESTPE.2020.2999267, IEEE Journal of Emerging and Selected Topics in Power Electronics

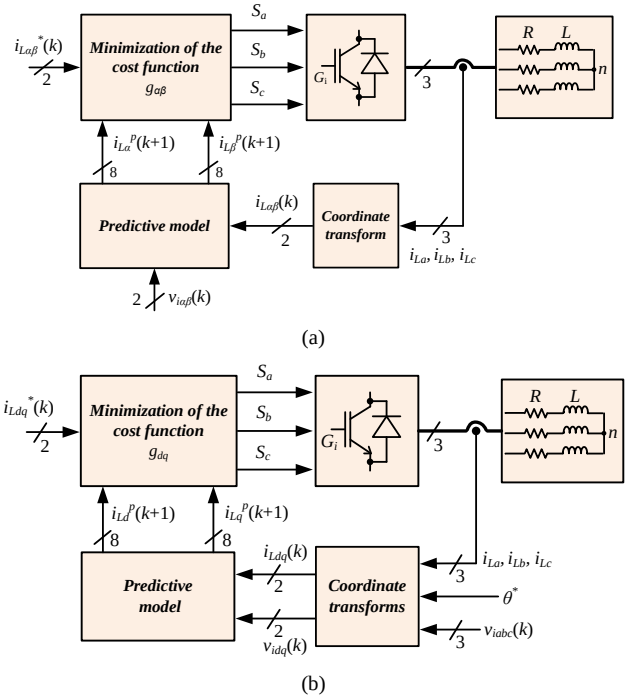

Fig. 2. Schematic diagram of load current control using the FCS-MPC in (a) $\alpha\beta$-frame and, (b) dq-frame.

the updated R from (11) and an expression for adaptive k_1 can be written as follows:

$$k_1 = \left(1 - \frac{T_S}{L}\sqrt{\left(\frac{mV_{dc}}{2\sqrt{2}i_{L,rms}}\right)^2 - \left(X_L\right)^2}\right) \tag{12}$$

Considering any system parameters, $\left(\frac{mV_{dc}}{2\sqrt{2}i_{L,rms}}\right)^2 \gg \left(X_L\right)^2$.

Thus, the expression for adaptive k_1 is approximated as:

$$k_1 \approx \left(1 - \frac{mV_{dc}T_S}{2\sqrt{2}Li_{L,rms}}\right) \tag{13}$$

The values of V_{dc}, T_S, and L are known and $i_{l,rms}$ can be obtained from the reference load current.

C. Cost Function

To select an optimum switching state according to the optimum voltage vector in each sampling and to minimize the current error for the next sampling interval, selection criteria is required to be defined considering control objectives.

The simple selection criteria i.e cost function can be expressed in orthogonal $\alpha\beta$ coordinates as follows:

$$g_{\alpha\beta} = \left|i^*_{L\alpha}\left(k+1\right) - i^p_{L\alpha}\left(k+1\right)\right| + \left|i^*_{L\beta}\left(k+1\right) - i^p_{L\beta}\left(k+1\right)\right| \tag{14}$$

where $i^*_{L\alpha}$ and $i^*_{L\beta}$ are the real and imaginary components of the reference current. The future reference current value required by (14) has to be predicted using the Lagrange extrapolation method discussed in [5]. However, for sufficient small T_S, a simple approximation $i^*_L(k+1) \approx i^*_L(k)$ can be used and no extrapolation is required. The same approximation is considered in this paper.

The cost function for the control of dq coordinate is formulated as:

$$g_{dq} = \left|i^*_{Ld}\left(k+1\right) - i^p_{Ld}\left(k+1\right)\right| + \left|i^*_{Lq}\left(k+1\right) - i^p_{Lq}\left(k+1\right)\right| \tag{15}$$

where i^*_{Ld} and i^*_{Lq} are the reference currents for d and q components respectively. The block diagram of the load current control using the FCS-MPC with stationary $\alpha\beta$ and rotating dq reference frames are depicted in Fig. 2(a) and Fig. 2(b) respectively.

The cost functions expressed in (14) and (15) are based on the primary control objective that is current control. Furthermore, the cost function with a constraint of change in switching state of the inverter is considered to compare the system performance for the FCS-MPC. The inclusion of this constraint reduces the number of commutations of power switches that leads to a reduction in switching frequency. Present switching state $\boldsymbol{S}(k)$ is compared with previously applied switching state $\boldsymbol{S}(k\text{-}1)$ to ensure fewer switching commutations for each phase. The cost function with the constraint is formulated as

$$g = g_{\alpha\beta/dq} + \lambda \cdot p \tag{16}$$

where λ is the weighting factor and p is the number of switching commutations defined as

$$p = \sum_x \left|S_x\left(k\right) - S_x\left(k-1\right)\right|, \quad x = a,b,c \tag{17}$$

III. Model-Based Design of the FCS-MPC

A low-level digital code (VHDL/Verilog) of the desired control system is required to program an FPGA device for the FPGA-based system implementation. The developments in the system implementation facilitate the generation of low-level code for FPGAs using the functionality of a model-based design approach [20], [23]. The XSG, an MBD platform, provides the Xilinx blockset for the MATLAB/Simulink to develop a virtual model of digital circuits specifically for Xilinx FPGAs. Xilinx blockset consists of the fundamental mathematical blocks, a block for the inclusion of low-level VHDL code (Blackbox) and a block for the inclusion of MATLAB code (MCode). During implementation, the Blackbox is used for the analog-to-digital converter (ADC) and digital-to-analog (DAC) interfaces.

The modeling of the FCS-MPC is performed based on the schematic diagram shown in Fig. 3. This is a fully parallel implementation approach and the control algorithm is divided

This article has been accepted for publication in a future issue of this journal, but has not been fully edited. Content may change prior to final publication. Citation information: DOI 10.1109/JESTPE.2020.2999267, IEEE Journal of Emerging and Selected Topics in Power Electronics

into three steps: prediction of future load currents, computation of cost functions, and selection of optimum switching state. The cost function without constraint is opted to demonstrate the modeling steps and FPGA resource utilization based on implementation strategies considering equal resource requirements by the constraint during the FCS-MPC implementation with $\alpha\beta$ as well as dq-frames.

The prediction of future load currents is performed firstly using (3) and (6) corresponding to the FCS-MPC in $\alpha\beta$-frame and dq-frame respectively. Further, the cost functions are computed using (14) and (15) for both the frames described in section II. The future current predictions and cost functions are computed on the parallel basis for each inverter voltage vectors ($\boldsymbol{v}_0$–$\boldsymbol{v}_7$) defined for corresponding switching states (S_a, S_b, S_c) as given in Table II.

The modeling for the prediction and cost computation can be performed using only fundamental mathematical blocks based on (3), (14) and (6), (15) for $\alpha\beta$ and dq-frame respectively. However, there is a possibility to perform the same operation using other blocks of the Xilinx blockset. The following strategies are considered for the modeling of the FCS-MPC algorithm for both $\alpha\beta$ and dq frame:

- Fundamental mathematical blocks for the current prediction and cost function computation
- MCode block for the current prediction and cost function computation
- Approximation for the coefficient k_1
- Adaptive k_1

IV. FPGA Implementation Strategy and Resource Utilization

A. Implementation Strategy

The implementation strategy is crucial for the time required for computation and resource utilization. There is a possibility to reduce the required FPGA resources significantly by using an appropriate implementation strategy that may create the possibility of system implementation using smaller FPGAs. The following are the objectives of analytical implementation strategies mentioned in Section III:

- FPGA resource: minimization of resource utilization (LUTs, flip-flops, DSP slices) required for fully parallel implementation.
- Usability: the implementation strategy with minimum resource utilization can be used for semi-parallel/sequential implementation.
- Trade-off: maintaining appropriate control quality and computational speed with reduced resource utilization.

Besides, the optimum strategy can be beneficial to develop various controllers for the FPGA-based system implementation. The implementation strategies are described as follows:

1) Fundamental mathematical blocks

In this strategy, the future current predictions and cost function computations are performed using fundamental mathematical XSG blocks: AddSub, CMult, Mult, Absolute. AddSub block performs the addition and subtraction for two inputs, CMult block performs the function of gain multiplier for a single input, Mult block performs the function of multiplication for two inputs and Absolute block performs the function of absolute value computation for real and imaginary quantities in (14) and (15). The coefficients (k_1, k_2, k_3) used for future current predictions are provided by Xilinx Constant blocks with an appropriate number of bits and binary point settings for fixed-point number representation.

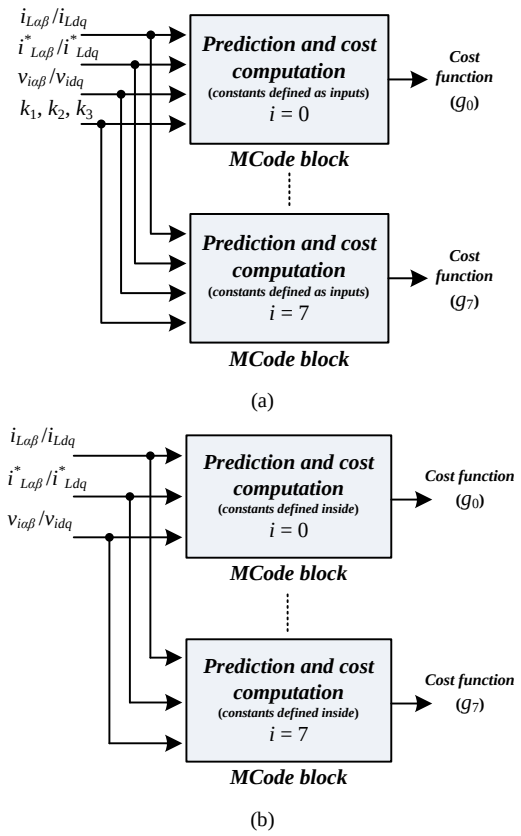

Fig. 4. Development methodologies for the FCS-MPC in XSG using MCode block (a) case-I, (b) case-II.

2) MCode blocks

In this strategy, the future current predictions and cost function computations are performed together through a single MCode block corresponding to each voltage vector using MATLAB code. This strategy is further subdivided into two cases based on the coefficients (k_1, k_2, k_3):

Case-I: coefficients defined as inputs to MCode blocks

Case-II: coefficients defined inside MCode blocks

The development methodologies are presented in Fig. 4 for case-I (Fig. 4(a)) and case-II (Fig. 4(b)). An additional case (case-III) is considered for the resource utilization in the current prediction using adaptive k_1 where other coefficients defined inside the MCode block like case-II.

The MATLAB code for the prediction (Ipred_real and Ipred_img) and cost computation using current errors (x and y) in $\alpha\beta$-frame for case-I and case-II is as follows:

2168-6777 (c) 2020 IEEE. Personal use is permitted, but republication/redistribution requires IEEE permission. See http://www.ieee.org/publications_standards/publications/rights/index.html for more information.
Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 06,2020 at 05:20:42 UTC from IEEE Xplore. Restrictions apply.

This article has been accepted for publication in a future issue of this journal, but has not been fully edited. Content may change prior to final publication. Citation information: DOI 10.1109/JESTPE.2020.2999267, IEEE Journal of Emerging and Selected Topics in Power Electronics

MATLAB code: **Case-I**

```
function [cost] = mpc_case-I (Im_real, Im_img,
Iref_real, Iref_img, k1, k2, v_real, v_img)
Ipred_real = k1*Im_real + k2*v_real;
Ipred_img = k1*Im_img + k2*v_img;
x = Iref_real – Ipred_real;
y = Iref_img – Ipred_img;
    if (x<0)
        mod_x = – x;
    else
        mod_x = x;
    end
    if (y<0)
        mod_y = – y;
    else
        mod_y = y;
    end
cost = mod_x + mod_y;
end
```

MATLAB code: **Case-II**

```
function [cost] = mpc_case-II (Im_real, Im_img,
Iref_real, Iref_img, v_real, v_img)
k1 = xfix({xlSigned, 10, 8, xlRound, xlWrap}, 0.95);
k2 = xfix({xlSigned, 13, 13, xlRound, xlWrap},
0.005);
Ipred_real = k1*Im_real + k2*v_real;
Ipred_img = k1*Im_img + k2*v_img;
x = Iref_real – Ipred_real;
y = Iref_img – Ipred_img;
    if (x<0)
        mod_x = – x;
    else
        mod_x = x;
    end
    if (y<0)
        mod_y = – y;
    else
        mod_y = y;
    end
cost = mod_x + mod_y;
end
```

The values of k_1, k_2 are defined inside the MATLAB code in case-II using a command xfix that is used for the fixed-point number representation. Similarly, the MATLAB codes for the case-I and case-II of the FCS-MPC in *dq*-frame are designed using the coefficients k_1, k_2, and k_3 according to the codes designed for the FCS-MPC in $\alpha\beta$-frame mentioned above. An additional case (case-III) is considered for the resource utilization in the current prediction using adaptive k_1 where other coefficients defined inside the MCode block like case-II.

B. Resource Utilization

Every FPGA has a set of programmable logic, I/O, and memory resources. The FPGA resources consist of configurable logic blocks (CLBs) which are the main constituent to implement code on the FPGA. A CLB element comprises of a pair of slices and a slice contains LUTs and flip-flops [30], [31]. According to the family of the FPGA chip, the number of LUTs and flip-flops in a single slice are different. For instance, there are four LUTs and eight flip-flops in a slice considering Zynq-7000 series FPGAs [31]. In addition, there is a major component of the FPGA resources, called DSP slices that are mainly used to implement digital signal processing functions. The main constituents of a DSP slice are signed multipliers, adder/accumulator, arithmetic logic unit (ALU) logic functions and many more [32], [33].

The FPGA resource utilization considering implementation strategies mentioned in the previous section are listed in Table III and IV for the FCS-MPC in $\alpha\beta$-frame and *dq*-frame respectively. To select the optimum design strategy, only two logic indices LUTs and DSP slices need attention because the number of Flip-flops are the same considering $\alpha\beta$-frame as well as *dq*-frames.

1) Coefficient k_1 (k_1 = 0.95, k_1 = 1)

The coefficient k_1 is used in future current prediction using (3) and (6) as mentioned in Section II. The value of k_1 depends on the load parameters (R, L) and sampling time (T_S). The exact value of k_1 is 0.95 based on the parameters (R = 10 Ω, L = 10 mH and T_S = 50 μs) considered for simulation and experimental validations. In the case of k_1 = 0.95, the number of bits 10 and binary points 8 are specified and provides the coefficient value of 0.9492187 that utilizes significant FPGA resources. The approximation (k_1 = 1) can be opted considering the reduction in FPGA resource utilization due to the omission of the required bits and the multiplier used to multiply the exact value of k_1. Consequently, the required bits and the multipliers directly reduce the LUTs and DSP slices, respectively. However, the

performance with $k_1 = 1$ is required to be analyzed through simulation as well as the experiment.

In case-II of MCode block, the equal number of DSP slices are required for both the subcases $k_1 = 0.95$ and 1, however, the required number of LUTs for $k_1 = 0.95$ is slightly higher as required for $k_1 = 1$. In the case of the FPGA implementation using controller development in $\alpha\beta$-frame, both cases (case-I and II) of MCode with $k_1 = 1$ are the optimum solutions, however, considering better controller performance based on current prediction using an exact value of k_1 with the cost of slightly increased LUTs, case-II of MCode block with $k_1 = 0.95$ can be the optimum choice.

On the other hand, for the controller development in *dq*-frame, case-II of MCode block is an optimum strategy due to the least percentage utilization of DSP slices among all the individual resource indices. Although the LUTs requirement has reduced significantly in the case of the development using fundamental mathematical blocks, the required DSP slices have increased approximately 3 times. Furthermore, the FPGA resource utilization for the development of the FCS-MPC in *dq*-frame is even higher as compared to $\alpha\beta$-frame due to the additional coordinate transformation ($\alpha\beta$ to *dq*) for voltage vector including measured current, reference phase angle θ^* generation using CORDIC SINCOS and an extra effort for computation of feed-forward term used for decoupling.

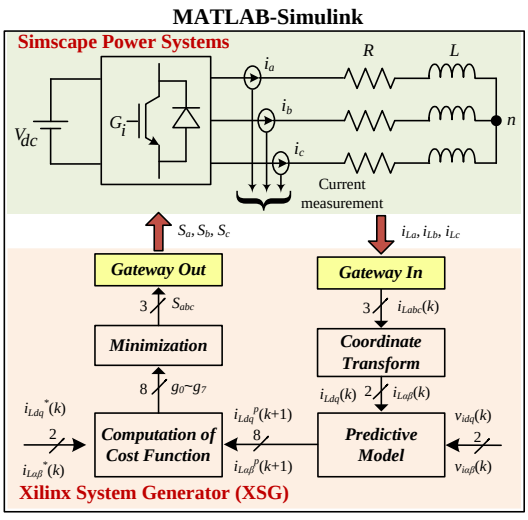

Fig. 5. Block diagram representation of methodology for simulation.

2) Adaptive k_1 (m = 1, 0.95, 0.9)

The adaptive k_1 is used for future current prediction using (3), (6) and (13) as mentioned in Section II. The adaptive k_1 depends on the modulation index (m) for a fixed dc supply. The unity value (m = 1) and non-unity value (m = 0.95, 0.9) are opted for system performance analysis as well as resource utilization.

In the case of the controller development using adaptive k_1, resource utilization is significantly higher than the optimum design cases (MCode block: case-II) in both $\alpha\beta$-frame as well as *dq*-frames. However, considering the updated predictive model corresponding to the load changes, the controller performance needs to be investigated for the controller development using adaptive k_1. Moreover, a trade-off between controller performance and the FPGA resource utilization can be a better choice to decide an appropriate implementation strategy corresponding to the system application.

An optimum implementation strategy corresponding to the minimum resource utilization is further utilized for the prediction and cost computation in both the frames. After the completion of current prediction and cost computation, the minimum cost function g_{min} and an optimum switching state $\boldsymbol{S}_{opt}$ are selected using a pipelining method for all three implementation strategies. The logic for the selection of g_{min} and $\boldsymbol{S}_{opt}$ are developed in XSG using a multiplexer (Mux block) and comparator (Relational block) based on the XSG diagram depicted in [26].

V. RESULTS AND DISCUSSION

Simulation methodology in Fig. 5 is represented using a block diagram to express the development approach of the controller. The power circuit of three-phase VSI is developed in MATLAB/Simulink using simscape toolbox, whereas the controller is developed in the digital environment of XSG using Xilinx toolbox. Due to the non-identical platforms, a signal from simscape to XSG is interfaced using Xilinx "Gateway In" block and a signal from XSG to simscape is interfaced using Xilinx "Gateway Out" block.

The FPGA architecture of the FCS-MPC with the schematic block diagram representation of the experimental setup in Fig. 6 is developed for a complete understanding of the FPGA-based implementation of the system. An adequate latency is provided to blocks used to predict load current and to compute cost

function for proper completion of the computational task by the corresponding block. To ensure the selection of the optimum switching state in the given sampling interval, the sampling clock is generated as a synchronizer. The sampling clock is used as an enabling signal and given to the multiplexer that is used for the selection of optimum switching state. Before sending switching signals directly to the VSI, the isolator circuit is used for electrical isolation of the FPGA board and inverter board considering safety precautions of the FPGA board (Zynq-XC7020). The FPGA code was generated through the modeled controller in XSG and programmed using dedicated software (Xilinx Vivado Design Suite) for the real-time implementation of the VSI system with the FCS-MPC. The laboratory prototype of the experimental setup is shown in Fig. 7. The experimental system components used for the development of laboratory prototype are listed in Table V.

TABLE V
DISCRIPTION OF COMPONENTS SPECIFICATIONS FOR THE EXPERIMENTAL SYSTEM

S.No.	Components	Specifications
1.	Three-phase VSI	STEVAL-IHM023V3, 1 kW
2.	DC supply	THDSHVMTRPFCKIT
3.	Current transducer	LA 25-NP
4.	Op-amp IC for level shifter	LM385N
5.	Isolator IC	ADuM3440
6.	ADC	Digilent Pmod AD1
7.	DAC	Digilent Pmod DA4
8.	FPGA board	Zedboard Zynq Evaluation and Development Kit

TABLE VI
PARAMETERS FOR SYSTEM IMPLEMENTATION

Parameter	Symbol	Value
Supply dc voltage	V_{dc}	145 V
Load resistance	R	10 Ω
Load inductance	L	10 mH
System frequency	f	50 Hz
Sampling frequency	f_S	20 kHz
FPGA clock frequency	f_{CLK}	100 MHz

The performance of the FCS-MPC in $\alpha\beta$ and dq frames was experimentally evaluated and the experimental data are obtained through HIOKI 8855 Memory Hicorder. Further, the data are plotted with the help of MATLAB plotting tool for demonstration and analysis of experimental results. The system parameters considered for the simulation and the experimental validation are listed in Table VI. The validation and analysis of FPGA-based FCS-MPC are performed using the implementation strategy having the optimum resource utilization.

A. *Effect of Predictive Model Coefficient*

The performance of the FCS-MPC in $\alpha\beta$ and dq frames is analyzed for the predictive model with exact (k_1 = 0.95), approximated (k_1 = 1) as well as the adaptive values of coefficient k_1 considering unity (m = 1) and non-unity (m = 0.95, 0.9) values of 'm'. Moreover, the simulation and experiment were carried out considering the cost function without constraint for reference

currents with low load ($\boldsymbol{i}_L$ = 2.5A) and high load ($\boldsymbol{i}_L$ = 4A) conditions. To investigate the quality of the load current and the switching stress on the power devices, the harmonic content in the load current corresponding to the average switching frequency (f_{sw}) is also analyzed considering both the frames. The results obtained during the simulation as well as an experiment are listed in Table VII and VIII for the FCS-MPC in *αβ* and *dq* frames respectively. The harmonic content in the load current during the experiment was measured through HIOKI 3390 power analyzer and current clamp sensor.

1) Coefficient k_1 (k_1 = 0.95, k_1 = 1)

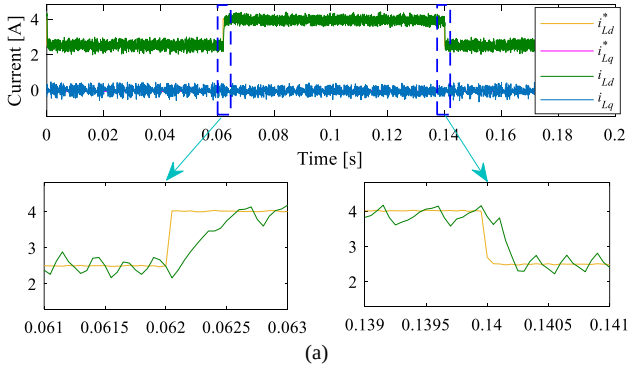
During the simulation, there is a slight difference in percentage THD for the FCS-MPC in *αβ* and *dq* frames corresponding to the coefficient k_1, however, the performance is almost similar during the experiment for both frames. The percentage THD is less in the case of high load with the cost of slightly higher switching stress as compared to low load during the simulation. However, a significantly high current THDs are observed during the experiment for the low load as compared to high load condition. The percentage THD of the load currents in the experiment is higher as compared to the simulation that is because of the simplified model of the VSI and the load used for the simulation study.

2) Adaptive k_1 (m = 1, 0.95, 0.9)

In this case, there is a slight difference in percentage THD for the simulation as well as the experiment in *αβ* and *dq* frames. This difference is more pronounced for low load current as well as non-unity values of '*m*'. In addition, percentage THD for adaptive k_1 with m = 1 is slightly better as compared to m = 0.95 and 0.9. Compared to the other cases of coefficient k_1 (k_1 = 1, 0.95), the controller performance is slightly better for current prediction with adaptive k_1 in both low load as well as high load conditions for unity value of '*m*', however, implementation with adaptive k_1 requires highest FPGA resources amongst the cases of k_1.

B. Dynamic Performance (k_1 = 0.95, 1; *adaptive* k_1: m = 1, 0.95, 0.9)

To investigate the dynamic performance of the FCS-MPC for the three-phase VSI system, the step change in the reference current is considered for current tracking during the transients. The comparative analysis for the system implementation using k_1 = 0.95, 1 and adaptive k_1 (m = 1, 0.95, 0.9) is performed considering simulation as well as experimental results. The tracking performance of the load current is demonstrated for the change in reference current from 2.5A to 4A at instant 0.062s and from 4A to 2.5A at instant 0.14s.



The dynamic performance of FCS-MPC in *αβ* and *dq* frames is represented in Table IX and X considering the settling time during transients for the cases of the coefficient k_1. The settling time for a step change at 0.062s ($\boldsymbol{i}_L$ = 2.5A to 4A) is significantly lower in *dq*-frame as compared to *αβ*-frame. Moreover, the proposed adaptive k_1 case demonstrates the fastest settling time amongst in simulation as well as experiment. The settling time for a step change at 0.14s ($\boldsymbol{i}_L$ = 4A to 2.5A) is slightly better for

This article has been accepted for publication in a future issue of this journal, but has not been fully edited. Content may change prior to final publication. Citation information: DOI 10.1109/JESTPE.2020.2999267, IEEE Journal of Emerging and Selected Topics in Power Electronics

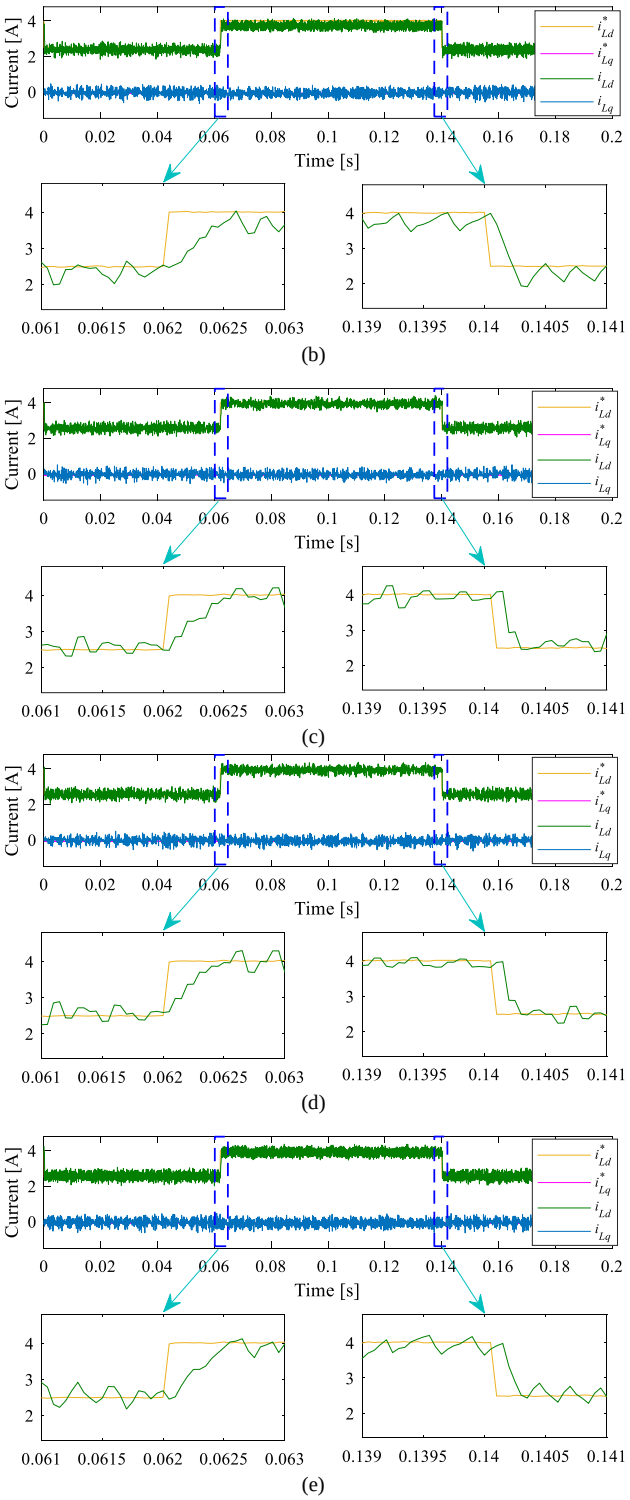

Fig. 8. Experimental results of load current dynamic performance for the FCS-MPC in *dq*-frame (a) coefficient k_1: k_1 = 0.95 (fixed), (b) coefficient k_1: k_1 = 1 (approximated), (c) adaptive k_1: m = 1, (d) adaptive k_1: m = 0.95, and (e) adaptive k_1: m = 0.9.

dq-frame as well as adaptive k_1 case as compared to *αβ*-frame and other cases of k_1.

The current tracking in Fig. 8 are depicted for the controller performance in *dq*-frame for coefficient k_1 = 0.95, 1 as well as adaptive k_1 with m = 1, 0.95, 0.9. In *dq*-frame, the step changes are applied in the *d*-axis component of the reference current, keeping *q*-axis reference current zero. The time axis is enlarged to demonstrate the current tracking during the transient caused by step changes in reference current. The transient response is almost the same for the current prediction using k_1 = 0.95 and 1. In addition, the transient response for adaptive k_1 with m = 1 is almost the same for m = 0.95 and 0.9 and slightly better as compared to k_1 = 0.95 and 1. However, the current tracking performance of adaptive k_1 with m = 1 is best amongst the aforementioned cases.

C. *Steady-state Error*

The steady-state error (SSE) is analyzed through the simulation as well as experiment for load current tracking considering adaptive k_1 (m = 1, 0.95, 0.9) and coefficient k_1 (k_1 = 1, 0.95). The comparative SSE analysis is performed for the $\boldsymbol{i}_L$ = 4A and $\boldsymbol{i}_L$ = 2.5A in Fig. 9 and Fig. 10 respectively using bar graphs for the FCS-MPC in both frames. The comparative analysis demonstrates a similar trend for the $\boldsymbol{i}_L$ = 4A and $\boldsymbol{i}_L$ = 2.5A in simulation as well as experimental results. The SSE

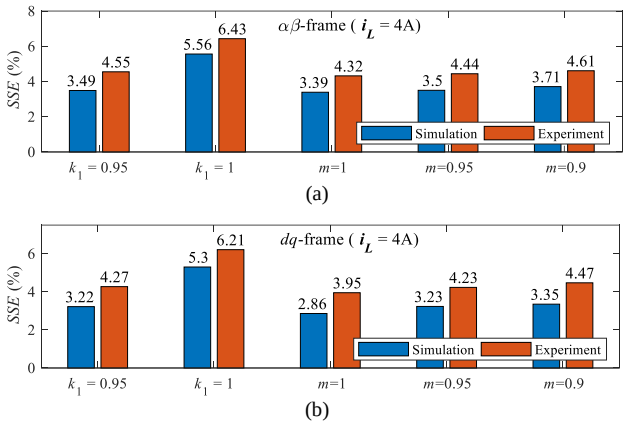

Fig. 9. Steady-state error performance for $\boldsymbol{i}_L$ = 4A with the current prediction using coefficient k_1: k_1 = 0.95 (fixed), k_1 = 1 (approximated) and adaptive k_1: m = 1, 0.95, 0.9 through the simulation as well as experiment for the FCS-MPC in (a) *αβ*-frame, and (b) *dq*-frame.

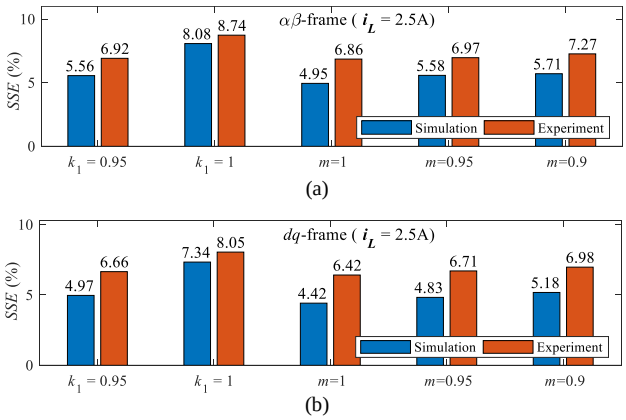

Fig. 10. Steady-state error performance for $\boldsymbol{i}_L$ = 2.5A with the current prediction using coefficient k_1: k_1 = 0.95 (fixed), k_1 = 1 (approximated) and adaptive k_1: m = 1, 0.95, 0.9 through the simulation as well as experiment for the FCS-MPC in (a) *αβ*-frame, and (b) *dq*-frame.

This article has been accepted for publication in a future issue of this journal, but has not been fully edited. Content may change prior to final publication. Citation information: DOI 10.1109/JESTPE.2020.2999267, IEEE Journal of Emerging and Selected Topics in Power Electronics

performance for adaptive k_1 with m = 1 is better as compared to other cases and it is more pronounced for the low load current $\boldsymbol{i}_L$ = 2.5A. Moreover, the SSE performance in *dq*-frame is better as compared to *αβ*-frame for the considered cases of coefficient k_1 as well as both load current conditions.

D. Switching State Constraint

The system performance is investigated for the cost function with the switching state constraint (16) as discussed in section II during the simulation and experiment. The constraint of change in switching state provides a reduction in the switching frequency corresponding to the variation in weighting factor λ. The system performance with varying λ is examined for average switching frequency f_{sw} as well as percentage THD in the load current considering the case of best system performance (adaptive k_1: m = 1) and poor performance (coefficient k_1 = 1).

1) For condition $\boldsymbol{i}_L$ = 4A (adaptive k_1: m = 1 and k_1 = 1)

The performance of the FCS-MPC in *αβ*, as well as *dq* frames for $\boldsymbol{i}_L$ = 4A, are depicted in Fig. 11 and Fig. 12 for the simulation and experiment results respectively. The average f_{sw} decreases corresponding to an increase in λ, consequently, the harmonic

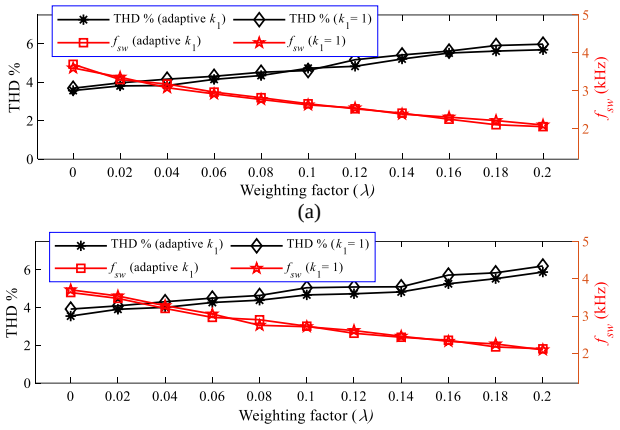

Fig. 11. Average switching frequency (f_{sw}) and percentage THD in load current for $\boldsymbol{i}_L$ = 4A during simulation with the FCS-MPC in (a) *αβ*-frame, and (b) *dq*-frame.

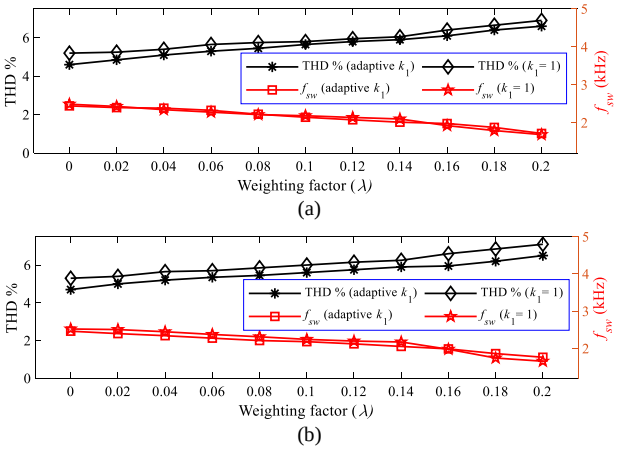

Fig. 12. Average switching frequency (f_{sw}) and percentage THD in load current for $\boldsymbol{i}_L$ = 4A during experiment with the FCS-MPC in (a) *αβ*-frame, and (b) *dq*-frame.

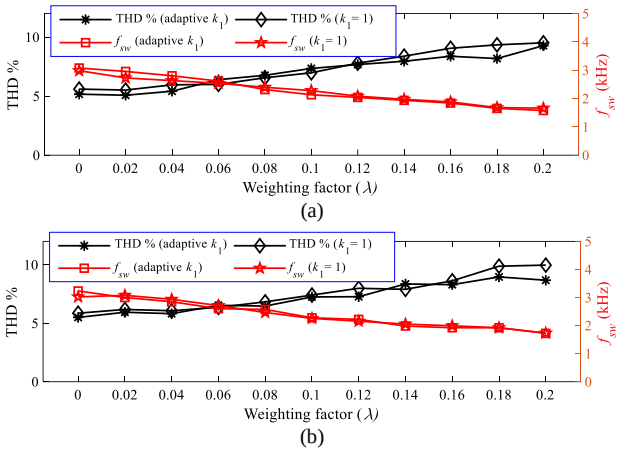

Fig. 13. Average switching frequency (f_{sw}) and percentage THD in load current for $\boldsymbol{i}_L$ = 2.5 A during simulation with the FCS-MPC in (a) *αβ*-frame, and (b) *dq*-frame.

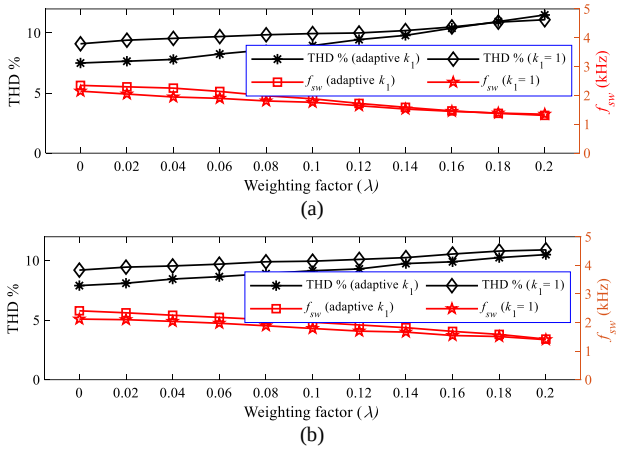

Fig. 14. Average switching frequency (f_{sw}) and percentage THD in load current for $\boldsymbol{i}_L$ = 2.5 A during experiment with the FCS-MPC in (a) *αβ*-frame, and (b) *dq*-frame.

content in the load current increases. A slightly higher percentage THD is observed corresponding to λ for k_1 = 1 as compared to the adaptive k_1 during the simulation as well as the experiment. However, THD is almost the same especially for the value of λ = 0.1 to 0.14 in the simulation as well as the experiment for both the frames.

2) For condition $\boldsymbol{i}_L$ = 2.5A: Adaptive k_1 (m = 1) and k_1 = 1:

Similar to the previous case, the performance in both the frames for $\boldsymbol{i}_L$ = 2.5A is presented in Fig. 13 and Fig. 14 for simulation and experiment respectively corresponding to the same range of λ.

In the case of the simulation, the gap between THD lines for adaptive k_1 and k_1 = 1 is negligible corresponding to variation in λ. However, the gap between THD lines decreases with the increase in λ for both the frames in the case of the experiment. And, similar to the case of $\boldsymbol{i}_L$ = 4A, the THD is almost the same for value λ = 0.1 to 0.18. This trend of THD is authenticated through the average f_{sw} corresponding to change in λ and THD increases with the reduction in average f_{sw}.

The controller performance is significantly changed

This article has been accepted for publication in a future issue of this journal, but has not been fully edited. Content may change prior to final publication. Citation information: DOI 10.1109/JESTPE.2020.2999267, IEEE Journal of Emerging and Selected Topics in Power Electronics

TABLE XI
FPGA RESOURCE UTILIZATION FOR THE DEVELOPMENT OF THE FCS-MPC WITH SWITCHING CONSTRAINT

Logic utilization indices	FCS-MPC in $\alpha\beta$-frame		FCS-MPC in dq-frame	
	adaptive k_1: $m = 1$	$k_1 = 1$	adaptive k_1: $m = 1$	$k_1 = 1$
LUTs (53200)	5763 (11%)	4074 (8%)	9405 (18%)	8352 (16%)
Flip-flops (106400)	2617 (2%)	1005 (1%)	2262 (2%)	1260 (1%)
DSP slices (220)	38 (17%)	26 (12%)	43 (20%)	31 (14%)

considering the percentage THD in load current for current prediction using fixed, adaptive and approximated value of coefficient k_1 as summarized in Table VII and Table VIII. In addition, the performance is dependent on constraint for switching frequency reduction that ultimately results in higher percentage THD. However, the switching constraint almost compensates for the effect of current prediction using the approximated value of coefficient k_1 for the higher value of λ.

3) FPGA resources

The FPGA resource utilization in the case of the FCS-MPC development with the change in switching state constraint using adaptive k_1 (MCode block: case-III) as well as $k_1 = 1$ (MCode block: case-II) is also listed in Table XI for both the frames. The FPGA resource utilization is minimum for the implementation strategy using MCode block: case-II, $k_1 = 1$. So, a trade-off between the FPGA resource utilization and controller performance can be opted considering the requirement of the system application using an appropriate implementation strategy.

VI. CONCLUSION

This paper presented analytical implementation strategies for the development of FCS-MPC using a fully parallel approach considering conventional current prediction and proposed adaptive current prediction for $\alpha\beta$ and dq coordinates. A significant reduction is achieved (around 65% in DSP Slices) in overall FPGA resource requirement in dq coordinate for system development through MCode block case-II (coefficients defined inside the MATLAB code) of Xilinx blockset. Especially, system development through an approximated value of a coefficient ($k_1 = 1$) provides a further reduction in FPGA resources. Furthermore, resources are optimized using case-II for adaptive current prediction (around 50% reduced DSP Slices) for unity and non-unity modulation index. However, a trade-off between the controller performance and optimum resource utilization is vital for the cost-performance ratio.

The FCS-MPC performance for percentage THD, dynamic behavior, and SSE is investigated for conventional current prediction and proposed adaptive current prediction in $\alpha\beta$ and dq frames using implementation strategy with optimum FPGA resources. The system performance for adaptive k_1 with $m = 1$ is significantly better for all performance indices under high as well as low current operation in both the frames. The performance for coefficient k_1 ($k_1 = 1$) is poor amongst all the case of current predictions and become quite poorer for the low current operation. Furthermore, change in switching state constraint considered for the in-depth analysis lead to an interesting conclusion that percentage THD performance for coefficient $k_1 = 1$ and adaptive k_1 with $m = 1$ become almost similar corresponding to the change in weighting factor under high as well as low current operation. However, for this case, the SSE performance is not investigated and considered as possible future work. This overall system implementation and performance analysis will be vital for achieving a trade-off between controller performance and FPGA resource utilization. The effect of inductive load parameter variation on controller performance is a possible future work considering constraint as well for FPGA-based FCS-MPC implementation using optimum resources.

Vijay Kumar Singh received his B.Tech. degree from the Department of Electronics and Communication Engineering, United College of Engineering and Research, Allahabad (under UPTU Lucknow), Uttar Pradesh, India, in 2008 and M. Tech. degree (Power Electronics and ASIC Design) from the Department of Electrical Engineering, Motilal Nehru National Institute of Technology, Allahabad, Uttar Pradesh, India in 2012. He completed Ph.D. degree course from the Department of Life Science and Systems Engineering, Kyushu Institute of Technology, Kitakyushu, Fukuoka, Japan in 2020. His research interests include model predictive control, design, modeling, and development of control techniques for power electronic converters.

Ravi Nath Tripathi received his B.Tech (Electrical and Electronics Engineering) degree in 2011 from Graphic Era Institute of Technology (GEIT), India and M.Tech (Power Systems) degree in 2013 from Delhi Technological University (formerly Delhi College of Engineering), Delhi, India. He completed doctoral degree course in 2017 from Kyushu Institute of Technology. He has worked as Post-Doctoral Researcher on NEDO project from 2017-2020 and currently working as a researcher in Next Generation Power Electronics Research Center, Kyushu Institute of Technology, Japan. His research interest is design and development of Gate Drive Control for power semiconductor devices, design and development of controller for power electronic converters, Grid-integration of Solar PV system and motor drives.

Tsuyoshi Hanamoto was born in 1961. He received an M.S degree from Kyushu Institute of Technology, Japan in 1986 and then joined Kobe Works of Kobe Steel, Ltd. In 1990, he joined the Center for Cooperative Research of Kyushu Institute of Technology. From 1997 to 2000 he was with Department of Electrical Engineering and since April 2000, he has been with the Graduate School of Life Science and Systems Engineering, Kyushu Institute of Technology, where he is presently a Professor. His research interests include motor control, power electronics, and FPGA-based system development.

Modelling and optimisation of magnetic abrasive finishing process based on a non-orthogonal array with ANN-GA approach

S. Ahmad, R. M. Singari and R.S. Mishra

Department of Mechanical, Production & Industrial, Automobile Engineering, Delhi Technological University, New Delhi, India

ABSTRACT

Magnetic abrasive finishing (MAF) is an advanced precise finishing method that achieves micro-level to nano-level surface roughness. In industries, MAF is highly recommended where zero or negligible post-process surface defects are an obligatory requirement. In the same context, process optimisation is essential for making it commercially viable. This study presents an artificial neural network and genetic algorithm (ANN-GA), a robust modelling and optimisation tool (applicable to any sort of data set orthogonal array design or non-orthogonal array design) that is applied to scrutinise and improve the performance of the magnetic abrasive finishing of stainless steel SS302. In addition, the results from ANN-GA modelling and optimisation have been compared with conclusions drawn from conventionally used Taguchi-ANOVA analysis. An L_{27} non-orthogonal array design has been opted for as per machining set-up restriction. Abrasive size, voltage, machining gap, and rotational speed were the design variables considered in the present research work. It was found that the parametric design used in this study provides a straightforward, methodical, and proficient method of modelling and optimisation of change of surface roughness or finishing behaviour during the MAF process. Modelling and optimisation done with ANN-GA show a maximum value of $(\Delta R_a)_{max}$ equal to 0.256 µm, which is 7% better than the result obtained from Taguchi-ANOVA analysis.

1. Introduction

Expeditious advancements of latest materials with properties like high hot hardness, toughness, fragility, strength-weight ratio, etc. are becoming worthy of attention. These significant properties of such advanced materials have made them more demandable in various industrial and research applications. The processing of these materials by traditional manufacturing processes always has been a challenge. Also, the quality of surface finish always has a consequential effect on the functionality of any mechanical component.[1,2] For example, frictional power losses, wear, tear, and component fatigue life have a great dependency on surface quality and surface integrity.[3]

In recent times, a few non-traditional finishing and polishing processes have evolved. These processes are capable enough to process advanced material such as NiMoC alloys, silicon wafers, carbide, and CBN cutting tools, etc. as well, as they can obtain micro to a nano-level range of surface finish.[4–6] Abrasive flow machining (AFM), chemo-mechanical polishing (CMP), magnetic float polishing (MFP), magneto-rheological finishing (MRF), and magnetic abrasive finishing (MAF), etc., are some such non-traditional finishing and polishing processes.[3,7–10]

In the MAF process, application of gentle forces by using a flexible magnetic abrasives brush (FMAB) for removing surface unevenness has been a really innovative idea. During MAF, the magnetic forces allow the FMAB to shear off the material from the surface in the form of micro-chips.[11–15] Many authors have studied various control factors, and optimisation techniques to accomplish the best surface finish on different advanced materials using the MAF manufacturing processes. However, these optimisation techniques lack intelligent iterative optimisation methodology for better performance of the process.

Yamaguchi *et al.*[6] used diamond paste for the finishing of an uncoated carbide tool (UCT) surface using MAF to get better tool wear characteristics. Finishing time, pole tip feed, spindle speed, machining gap, steel grits mean-diameter, diamond abrasive, lubricant, were chosen as control factors. It was reported that roughness less than 25 nm could be achieved. Tool life of MAF processed UCT had been doubled compared to UCT not processed with MAF, when it was used in turning of titanium (Grade 5) rods. It is vital for coated tool finishing to use different sizes of the abrasive particle simultaneously adjusting magnetic force for desired finishing and less material removal.[16] Amineh *et al.*[1] utilised MAF to remove the recast layer formed by wire electro-discharge machining (WEDM). The MAF was able to shear off the recast layer generated during WEDM without any micro-cracking. It was found that increasing abrasive particles causes higher recast layer removal, and improved the surface roughness. In another study, Amnieh *et al.*[17] examined the effectiveness of finishing parameters such as tool rotational speed, abrasive mesh number, and finishing time. Jiang Guo *et al.*[2] found that the MAF was an effective finishing operation for a flat workpiece of polyamide 12 (PA12) 3-D printed parts under constant magnetic field. The process leaves no visible chemical change within the 10 µm subsurface level. Jiang Guo *et al.*[18] investigated the tribological performance of RSA-905 after finishing the surface by magnetic field-assisted finishing (MFAF). Magnetic abrasive (SiC, Al_2O_3, Carbonyl Iron Powder) was used for finishing and achieved the desired finish without any post-process subsurface defect. Tribological performance was improved, and

surface residual stresses were released. However, a small decrement in hardness was noticed. Yuewu Gao *et al.*[19] studied the influence of various process variables on the polish quality and compared the surface roughness of Cu-27400 and SS316 flat workpiece. An Al_2O_3 based atomised magnetic abrasive tool was selected for processing under the control of a permanent magnet (Nd-Fe-B). Shadab Ahmad *et al.*[20] examined the consequence of sintered magnetic abrasive (SMA) on the MAF process. The process parameters considered were voltage, machining gap, and rotational speed. There were three experimental arrays designed according to the L_9 orthogonal array. The Taguchi-ANOVA method was used to find the optimised surface roughness change and corresponding values of the parameter with their quantitative effect. The most influential parameter was voltage followed by machining gap and rotational speed, respectively and it was found that the abrasive size has a significant role in the MAF process.[20,21]

The application of different optimisation methods like Taguchi, Response Surface, Fuzzy Logic, Genetic Algorithm, Moth Flame Algorithm, and Particle Swarm Algorithm for the effective utilisation of the MAF process, is increasing.[22,23] The influence of voltage, machining gap, abrasive size, and rotational speed on surface roughness during the MAF process was studied by employing various methods by many researchers. Table 1 shows the finishing parameters and optimisation techniques employed in the research.

The above literature survey shows that many researchers have analysed the effects of process parameters and optimised the process with different techniques. In addition, very few researchers have employed an iterative optimisation method for more effective utilisation of the MAF process. Artificial neural networks (ANNs) have solved various parametric based problems in manufacturing processes, like pattern finding and learning in a set of data, developing the ability of pattern classification, forecasting, clustering, or modelling.[31–33] Genetic algorithms (GAs) can perform a global search, optimisation, and generalisation.[34,35] The neural network solves the problems where modelling by mapping input patterns to output results is important. However, to perform computational optimisation, tools like GAs are used and need a single stature of merit as a fitness function.

This current research study explains the development and application of an artificial neural network and genetic algorithm (ANN-GA) as a modelling and optimisation tool that is used to improve the performance of the magnetic abrasive finishing of SS302. In addition, the results from ANN-GA modelling and optimisation have been compared with conclusions drawn from conventionally used Taguchi-ANOVA analysis. The Taguchi-ANOVA method is used to analyse the data for comparison.

2. Magnetic abrasive finishing (MAF)

Magnetic Abrasive Finishing (MAF) is an advanced finishing operation to produce an efficient and excellent surface finish quality on a cylindrical surface, flat surface, and externally and internally in tubes.[36,37] This process has the flexibility to work without the restriction of workpiece material characteristics (physical and mechanical properties). The workpiece material could be electrically conductive or non-conductive, magnetic or non-magnetic.[5,16,36] Thus, there is no restriction if material is made of ferrous or non-ferrous. Conventionally

in MAF, magnetic abrasives particles (MAPs) composed of ferromagnetic material with abrasive particles are employed as cutting tools to shear-off the material from the target surface. But this material removal is greatly affected by finishing pressure, which works on the influence of a magnetic field across the machining gap.[38] The schematics of the MAF process are illustrated in Figure 1 representing the equipotential lines across which magnetic abrasive is arranged on the work surface to remove material.[20,38] The rotational motion causes the cutting force parallel to the targeted surface, and abrasive penetration inside the workpiece is due to the normal force generated by the magnetic field intensity.[39] MAPs become arranged with each other magnetically along a line of magnetic force.[9] A Fishbone diagram representing all the factors that affect the MAF process is shown in Figure 2.

3. Materials and method

3.1 Material and tools

Stainless steel grade 202 was the workpiece material for the study of this particular finishing operation. Sintered magnetic abrasive (SMA) was working as many tiny cutting tools with random cutting edges in simultaneous action. These abrasives performed shearing operation to remove the material from the targeted surface in the form of microchips.[40] The constituent of SMA was alumina powder, and cast iron powder sintered together in 40/60 by weight ratio, its preparation techniques have been discussed in the literature.[20,21] An electromagnet (32 mm pole diameter) mounted on a lathe tool post connected to a DC Supply produces a static magnetic field, as shown in Figure 3. Various independent control factors influence the performance of the MAF process, including abrasive size, voltage, machining gap, and rotational speed.

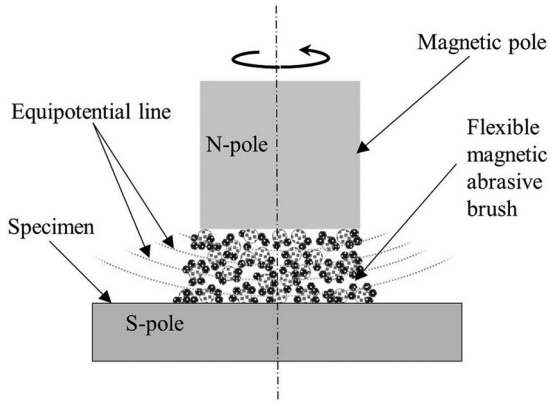

Figure 1. Schematic of the MAF process.

3.2 Experimental detail

The Taguchi technique is a prevailing tool for designing, arrangement, and collection of experimental data in a controlled way. It also tells us the effects of process variables over some particular variables for the design of efficient systems, and simultaneously, it reveals the effects of uncontrolled factors.[41,42]

The L_9 orthogonal array for three levels and three factors was used by Ahmad *et al.*[20]; each row of each array (three different arrays set for three different abrasives sizes, for investigation of a good range of abrasive size) represents the trial situation with a combination of factors. Columns were corresponding to each control parameter or process variable in the array, and there were nine combinations, as it is in the L_9 orthogonal array. The response parameter was Change in Surface Roughness (ΔR_a). This technique has been effectively utilised by numerous researchers to understand the finishing impacts during the MAF process.[4,20,21] Nevertheless, the satisfactory decision of the researched parameters (control factors) is fundamental.

The observations in this examination were led according to a non-orthogonal array[43,44] as per machining set-up restrictions. The determination of the non-orthogonal array depends on relying on the prerequisite that did not fit by the orthogonal array. Table 2 shows the control factors, their units, definition, and levels. It is notable that the control factors level is non-uniform for abrasive size because of sieve size restriction. The experimental data[20] presented in Table 3 have been used to develop the ANN model. The following observations were set in a fashion using an L_{27} non-orthogonal array with four inputs and one output. The input parameters

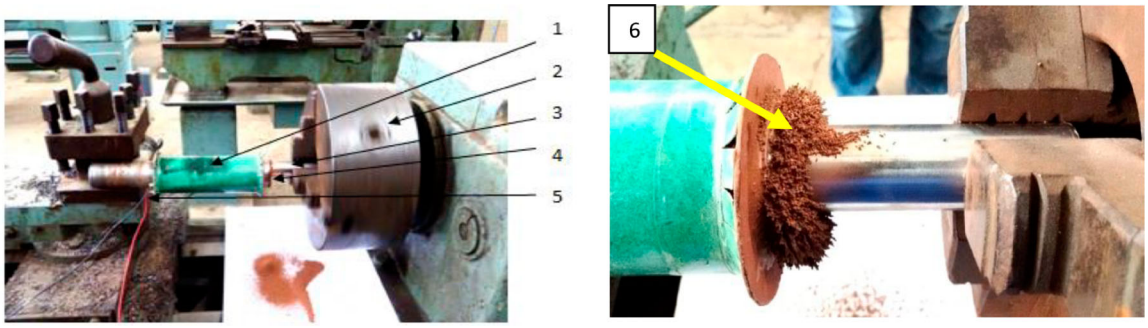

Figure 3. Images of the MAF setup: (1) Electromagnet (2) Chuck, (3) Workpiece, (4) Flexible Magnetic Abrasive Brush (FMAB), and (5) D.C. Power supply (6) FMAB in a closer view.

Table 2. Control factors, units, definition, and levels.

Control factor	Unit	Definition	Level 1	Level 2	Level 3
Abrasive Size (*d*)	µm	The average size of abrasive particles	90	150	300
Voltage (*V*)	Volts	Voltage applied to electromagnet to alter magnetic intensity	6	12	18
Machining Gap (*x*)	mm	The gap between the electromagnetic tool and workpiece	1	1.5	2
Rotational speed (*S*)	rpm	The relative rotational motion between tool and workpiece	60	90	120

Time 20 min for each run.

were abrasive size, voltage, machining gap, and rotational speed. The Change in Surface Roughness (ΔR_a) was an output/response parameter, measured in microns (µm).

In the Taguchi method, the signal-to-noise (S/N) ratio response has been formed corresponding to each observation, and 'larger-the-better' quality characteristic was targeted in this assessment, as more difference in surface roughness required. The control factors and the process response were taken as inputs to calculate the S/N ratio. Moreover, ANOVA analysis was carried out to scrutinise which controlling factor was statistically significant, so the best combination of the control factors, i.e. optimal combination, can be forecasted.[42] The S/N ratio (larger the better quality) for the change of surface roughness given by the Taguchi method is given below:

$$S/N = -10\log\frac{1}{n}\left(\frac{1}{y_1^2}+\frac{1}{y_2^2}+\cdots+\frac{1}{y_n^2}\right)$$

where $y_1, y_2, \ldots, y_n$ are the responses of the change of surface roughness and n is the number of observations. For each level, the average of selected characteristics of the factor has been shown in Table 3 (see *S/N* ratio). The response, *S/N* ratio, merges the reiterations, and the impact of noise levels into one whole coherent information. ANOVA for the *S/N* ratio was carried out for the classification of the significant factor.[45] The mean-response graphs were plotted, whereas the percentage contribution of factors was resolved by ANOVA.

4. Results and discussion

The prime motive of this study was to calculate the maximum Change in Surface Roughness $(\Delta R_a)_{max}$ and optimal values of factors correspondingly that have the most significant influence. Experimental data, which connect the influence of abrasive size, voltage, machining gap, and rotational speed, are shown in Table 3. These factors have a vital impact on the MAF process.

4.1 Analysis of variance (ANOVA)

For the computation of the process quality and its characteristics, the experimental data has been converted into S/N ratio. Based on S/N ratio, a ranking of control factors have been shown in Table 4. It is clear from Table 4 that the prevailing factor that affects the ΔR_a is voltage, and then machining gap, followed by abrasive size and rotational speed, respectively. Also, the variations in S/N ratio are shown in the main effects plot (Figure 4) where the most optimum result by Taguchi analysis is observed as abrasive size, voltage, machining gap, and rotational speed at 150 µm, 18 V, 1 mm, and 90 rpm respectively.

The analysis of the experimental data was carried out using ANOVA. The ANOVA analyses of the ΔR_a for all the analysed factors are shown in Table 5. The factors, having *P*-value less than 0.05 show a statistically considerable effect on the process performance. Also, Table 5 shows the percentage contribution of all factors in the overall result.

By scrutinising the results from Table 5, it can be noticed that voltage has the biggest influence on ΔR_a (% contribution = 41.60%), so much so, that this factor should be the centre of attention. Besides voltage, the change in surface roughness is also affected by machining gap (% contribution = 27.98%), abrasive size (% contribution = 10.95%), and rotational speed (% contribution = 9.39%).

The calculated S/N ratio was satisfactory because of the points on the normal probability plot in Figure 5 showing the approximate linear pattern with normal distribution having small disintegration.[19,45] Also, frequency versus residual plot Figure 5 confirms better the data variation as there were no outliers, and the negatively skewed histogram shows the initial observed S/N ratio has more impacts on results. The plot of residuals versus fitted value shows a random pattern (illustrated in Figure 5), which means residuals have approximately constant variance, and the residuals versus order plot shows that the data collected can be used to find the non-random error.

4.2 Interaction plot and the effect of factors on the change in surface roughness

The effect of the various process factors (Data means) on ΔR_a is shown in Figure 6. Factors corresponding to near-

2	−15.47	−16.41	−16.83	−15.93
3	−17.27	−14.73	−17.85	−15.91
Delta	1.80	3.60	3.06	1.73
Rank	3	1	2	4

horizontal line show insignificant effect, whereas factors corresponding to the highest inclined lines have the most significant effect. The most effective factor on ΔR_a was Voltage as its increment was highest, while the other factors show a lesser impact. ΔR_a increases with the increase of Voltage and Rotational Speed. Simultaneously, ΔR_a decreases with the increase of Machining Gap and Abrasive Size. The highest ΔR_a was found for the highest Voltage and the highest Rotational Speed.

4.3 Linear regression model

The linear dependence between the value of controlling factors (Abrasive Size, Voltage, Machining Gap, and Rotational Speed) and ΔR_a was obtained. Using MINITAB 17 software, the linear regression equation was derived from set values of abrasive size, voltage, machining gap, and rotational speed and ANOVA. However, a linear regression model was obtained as following to predict ΔR_a. A linear dependence between parameters and the unknown quantity is provided by the

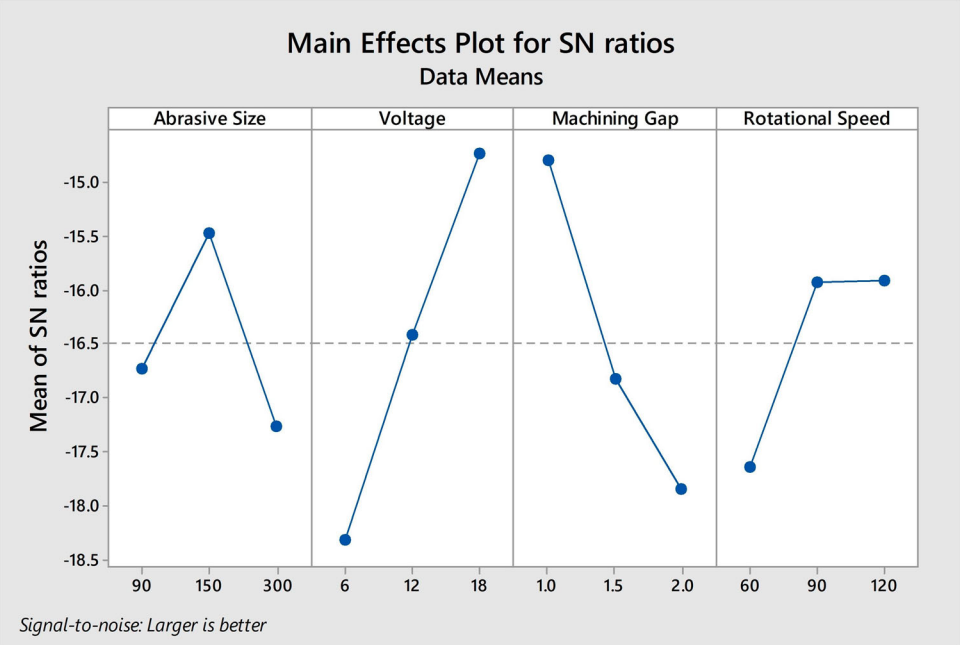

Figure 4. Main effects plot for S/N Ratio for ΔR_a.

Table 5. Analysis of variance for S/N ratio for change in surface roughness

Source	DF	Adj SS	Adj MS	*F*-value	*P*-value	% contribution
Abrasive size	2	15.350	7.6748	14.44	0.000	10.95
Voltage	2	58.344	29.1718	54.88	0.000	41.60
Machining gap	2	39.225	19.6126	36.89	0.000	27.98
Rotational speed	2	13.165	6.5826	12.38	0.000	9.39
Error	18	9.569	0.5316			6.80
Total	26	140.238				

developed model.

$$\text{Experimental } \Delta R_a(A) = 0.1511 - 0.000080d + 0.005370X_1 - 0.0549X_2 + 0.000403X_3 \quad (1)$$

$\Delta R_a = 0.23938$ (at abrasive size $d = 150$ µm, voltage $X_1 = 18$ V, machining gap $X_2 = 1$ mm, rotational speed $X_3 = 90$ rpm)

The developed linear regression equation with the help of MINITAB 15 for the ΔR_a (particularly for 150-micron size abrasive particle) is as below.[20]

$$\Delta R_a = 0.1850 + 0.00556X_1 - 0.0646X_2 + 0.00021X_3 \quad (2)$$

$\Delta R_a = 0.21713$ (at $d = 150$ µm, $X_1 = 18$ V, $X_2 = 1$ mm, $X_3 = 90$ rpm)

Based on the above Equations (1) and (2), a difference has been shown between non-orthogonal array and an orthogonal array, and it applied for the chosen controlling factors and their values. However, from Equations (1) and (2), coefficients showed that each factor has individual impacts, on ΔR_a which were dissimilar. The ΔR_a increases with increasing

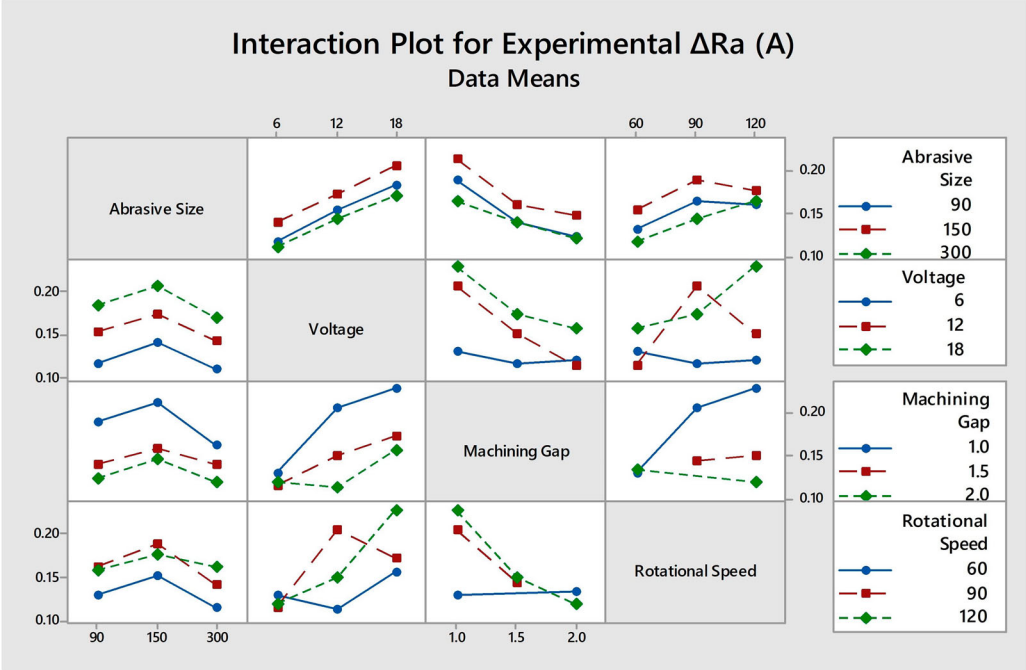

Figure 6. Interaction plot for ΔR_a.

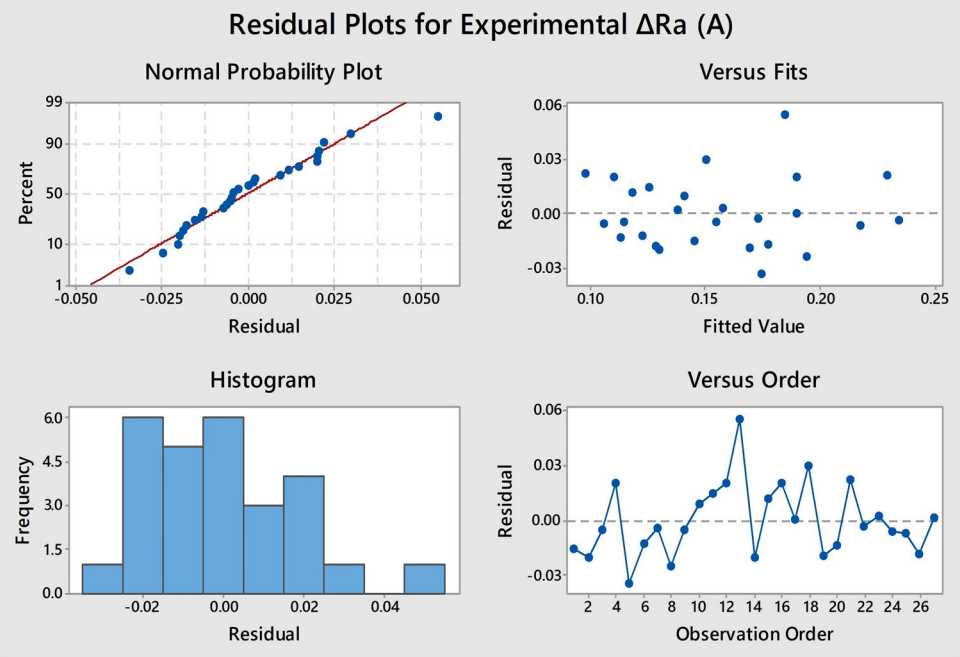

Figure 7. Residual plot for the change of surface roughness (ΔR_a).

Voltage and Rotational Speed, and decreases with increasing Machining Gap and Abrasive Size. The model formulated for prediction of ΔR_a, represented by Equation (1) was satisfactory because of the points on the normal probability plot in Figure 7 showing the approximate linear pattern with normal distribution having small disintegration.[44,45] In Figure 7 the plot of residuals versus fitted value shows a random pattern, which suggests that residuals have approximately constant variance, and the residuals versus order plot shows that the data collected can be used to find the non-random error. Also, the frequency versus residual plot in Figure 7 confirms the finer data variation as there were no outliers; however, the histogram is negatively skewed showing that the initial observations have more weight on the overall results.

4.4 Artificial Neural Network (ANN)

Artificial Neural Networks (ANN), normally referred to as Neural Networks, are analogous to biological neural networks. These networks have been used to approximate a function (in mathematical model form) that depends on a huge number of inputs. Due to the highly complex nature of calculations involved during the development of the network, software is normally used.[46] For data training and testing, MATLAB R2015a software has been used in this work.

Neural networks contain an input layer which is composed of neurons corresponding to the various process parameters. The experimental or realtime data (x_i) related to these parameters are subsequently fed into the neurons of the input layer. Input data are transferred to the hidden layer and output layer by multiplying weights (w_{ij}) between two neurons and adding using a summation function as shown in Equation (3). The feed-forward ANN model developed for modelling of ΔR_a (response or output) contains 4 different input layers of neurons equal to four input parameters (in this case, abrasive size, voltage, machining gap, and rotational speed). The developed ANN architecture was 4-10-8-1, i.e. four inputs, two hidden layers (10 and 8 neurons, respectively), and one output, as illustrated in Figure 8. This ANN architecture (4-10-8-1) has been found more appropriate for the modelling of data for which error is nearly zero as shown in Figure 9(c). For the present data, the ANN training algorithm was '*trainlm*' (trainlm is often the fastest backpropagation algorithm in the toolbox). The activation transfer functions (mathematical function that converts and processes the input data of each

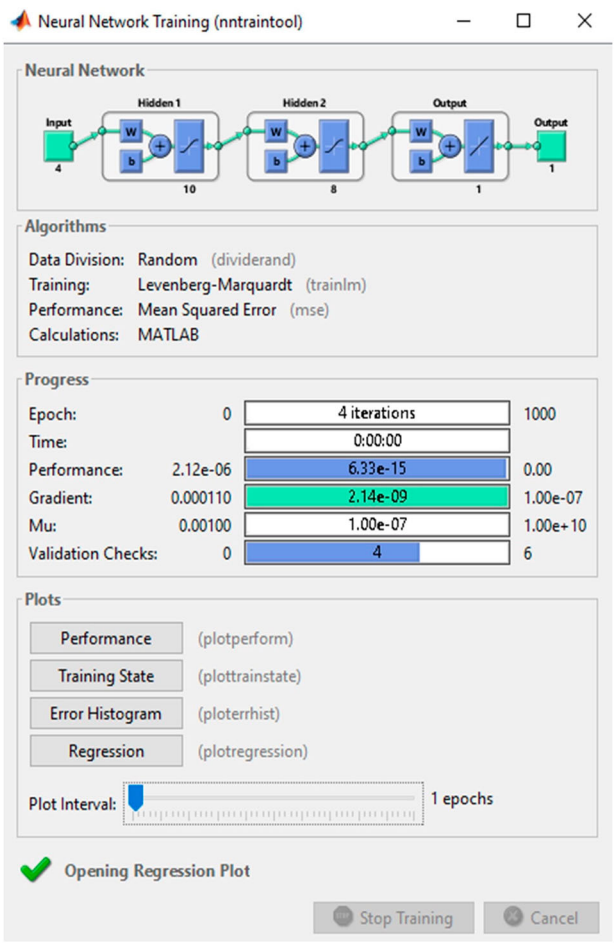

Figure 8. Neural network training.

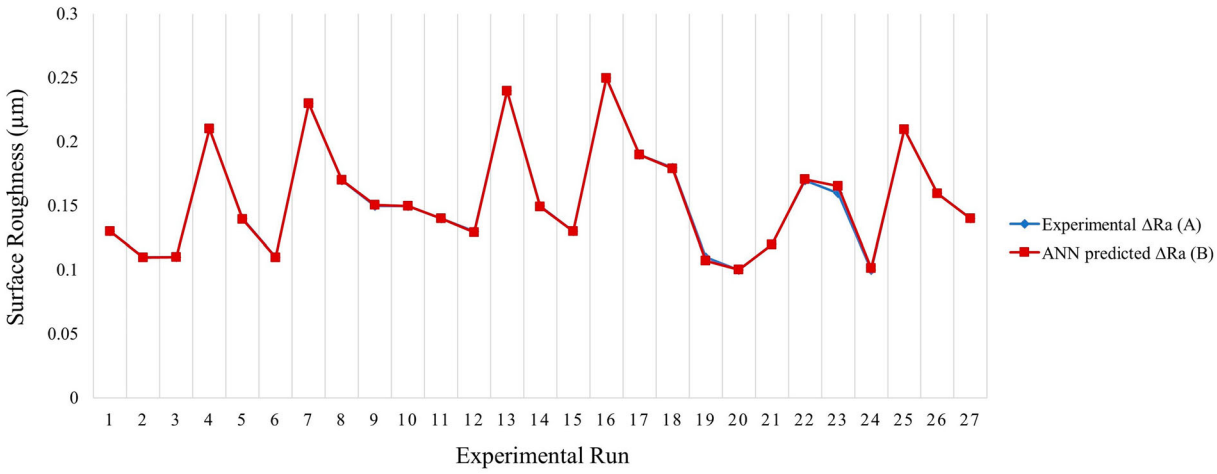

Figure 10 Comparison for surface roughness.

layer to outputs) '*logarithmic sigmoid logsig*' and the linear transfer function '*purelin*' were used as they offer better predictions.[31,32] This training algorithm updates weights and biases in pursuance of '*Levenberg–Marquardt*' optimisation (used to solve non-linear least squares problems). For the training, testing and validation of ANN, 70%, 15%, and 15% data are used, respectively. Regression coefficients can be acquired for the training, validation, and testing after ANN

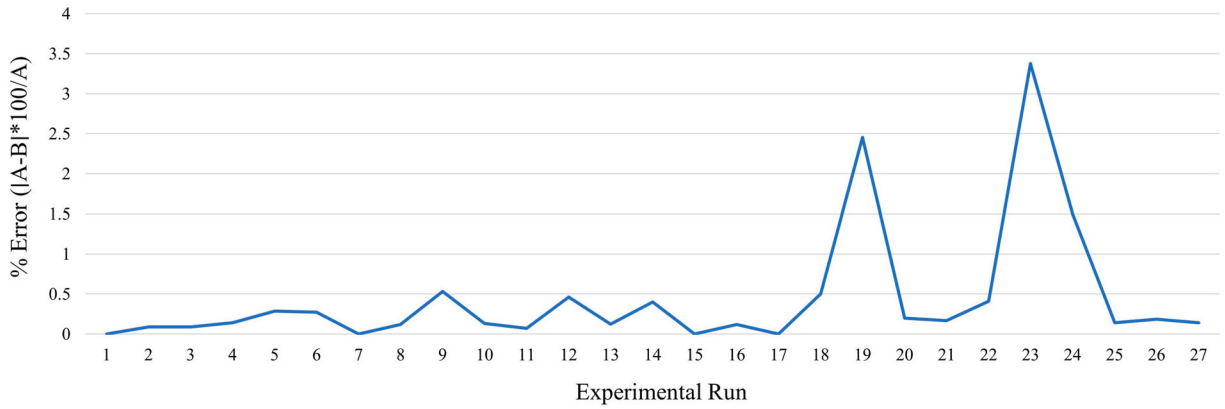

Figure 11 Percentage error plot between experimental and ANN predicted result.

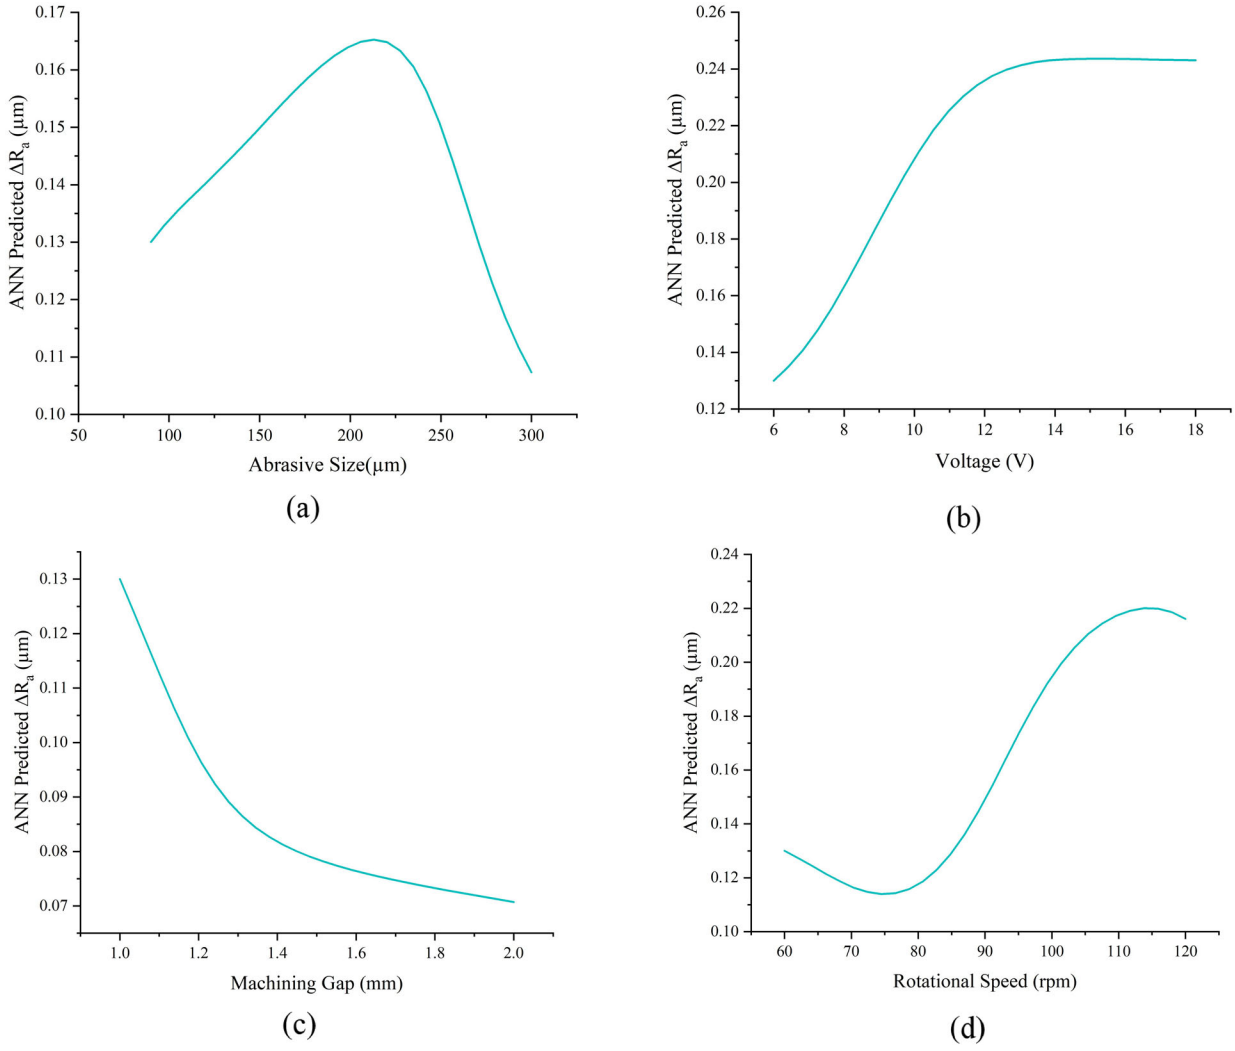

Figure 12. ANN predicted the individual effect of process variables (a) effect of abrasive size on ΔR_a (b) effect of voltage on ΔR_a (c) effect of machining gap on ΔR_a (d) effect of rotational speed on ΔR_a.

training.[32,33,46]

$$\text{Output} = f\left(\sum_{i=1}^{n} b + x_i w_i\right) \tag{3}$$

where, b is bias, experimental or realtime data (x_i), corresponding weights (w_{ij}), and f is activation function.

The trained ANN performance is shown in Figure 9(a), which points to the rationally good performance of trained ANN because the validation and test curves are perfectly on line; the error histogram also confirms this fact in Figure 9(c). It cannot be ignored that the best validation performance has attained zero epoch (which shows the number of passes the ANN training has performed over the entire training dataset) with the value of $6.4892*10^{-7}$, where the training persists until the 4th epoch, Figure 9 (b), showing the best validation performance. Figure 9(d) shows the training state of ANN, where the gradient

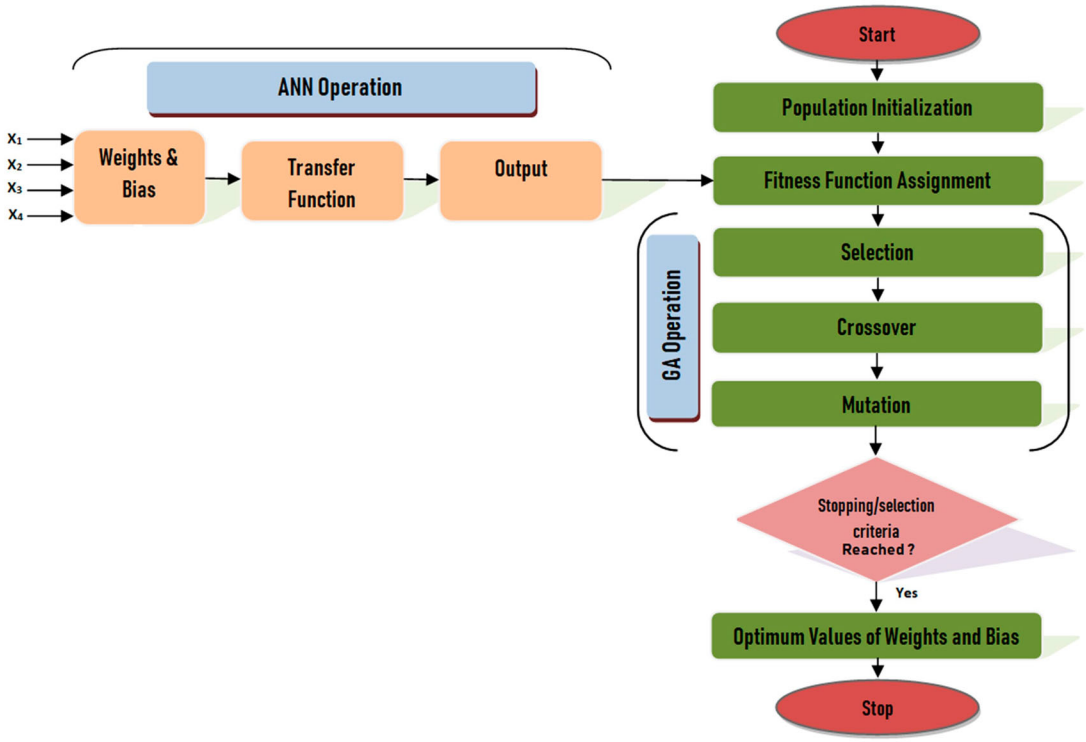

Figure 13. Flow chart of ANN-GA model.

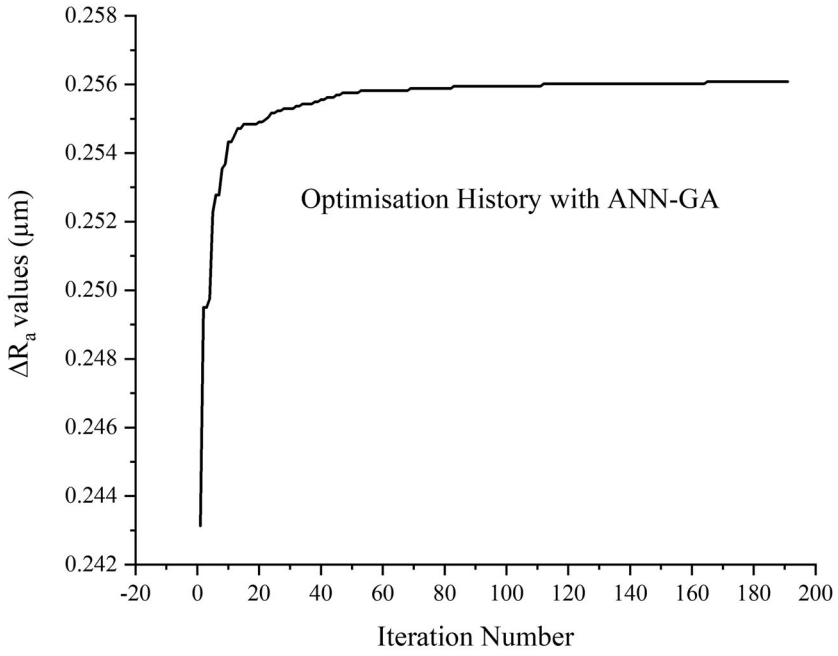

Figure 14. Optimisation history plot.

coefficient's final value is $2.14*10^{-9}$, approximately zero at the 4th epoch. Also, a diminishing value of gradient can be seen with the increase of epochs number. From Figure 10, it is clear that the ANN predicted and experimental values of ΔR_a between initial, and final states conform with each other to a very high degree, with the maximum error equal to 3.43%, and the other errors are negligible. Figure 11 shows the percentage error plot. Hence, it is certain that the developed ANN model has effectively learned the relationship between the input values and ΔR_a values, and thus can be used for maximising the change in surface roughness.

4.5 The individual effect of process parameters predicted by ANN Training

ANN training has predicted the relationship between the ΔR_a with controlling factors by varying the value of one factor, keeping constant value of other factors.

A relationship between the ΔR_a with abrasive size is shown in Figure 12(a). Initially, the trend is increasing until a certain limit, then it decreases. Due to the weaker magnetic bond formation on the edge of an irregularity,[39] the abrasive particles which are tinier than the peaks of irregularities get detached and cannot perform the shearing action satisfactorily. The

Table 6. Parameters of selection

Population size	Population type	Crossover fraction	Mutation rate	Max. generations	Initial population	Initial scores
50	Double vector	0.8	0.01	191	50	50

increasing size of the abrasive particles improves the shearing action and starts removing irregularities. The particles of size bigger than the irregularities shear-off the irregularities of the surface with a ploughing action. These ploughing actions further cause higher surface roughness by removing the material from the root.[47]

Since voltage increase causes an increase in the strength and contact area of the magnetic brush with the target surface, this escalates the normal magnetic force (F_n); consequently, the cutting force (F_c) increases.[4] This increased F_c helps the magnetic abrasive particles to remove irregularities of the surface more efficiently. Hence, the increase in voltage causes an increase in ΔR_a and the same trend has been predicted by ANN as illustrated in Figure 12(b).

When the face of the electromagnet comes closer to the targeted surface, then dense electromagnetic flux causes a higher magnetic force which controls the magnetic abrasive particles to perform more intensely, and vice-versa when further away. Thus, ΔR_a decreases when the machining gap increases, the relationship illustrated in Figure 12(c).

Figure 12(d) shows an increase in ΔR_a when rotational speed in most of the ranges increases; initially it decreases slightly because the normal magnetic force marginally decreases with increase in speed.[4,48]

4.6 Optimisation

The optimal selection of parameters has been carried out to increase the utility and commercial viability of manufacturing processes. Genetic Algorithms (GAs) solve optimisation problems that depend on several variables. Using an input-output pattern of data from the MAF process, by combining the capability of ANN and GA, can solve both the modelling and the optimisation problems.[46]

The basic optimisation problem for this ANN-GA approach is as in the following Equation (4):[49]

$$\text{Optimise } y = f(x, w) \tag{4}$$

where y represents the response or outcome of GA iteration, such as a change in surface roughness; x is a variable (instantaneous process factor during iteration) in the neural network, and w represents weights that evolve in the network training process. $f(.)$ is a fitness function that depends on the nature of input–output relation.

For the accomplishment of the target, a two-phase process has been applied. These two phases are modelling phase and optimisation phase. Conventionally, the standard optimisation problem is to be defined as an objective function. In this surface finishing operation, the difference between the initial and final roughness has to be maximum to achieve minimum surface roughness.

Thus, the present problem is the maximisation of ΔR_a and the objective function can be expressed as:

$$\left.\begin{array}{l}\text{Find values of:(V, x, S, d)for which, } \Delta R_a\text{is maximum}\\ \text{Subjected to range of magnetic abrasive finishing parameters:}\\ 6\text{ Volts} \le \text{V} \le 18\text{ Volts}\\ 1\text{ mm} \le \times \le 2\text{ mm}\\ 90\text{ rpm} \le \text{S} \le 120\text{ rpm}\\ 90\,\mu\text{m} \le \text{d} \le 300\,\mu\text{m}\end{array}\right\} \tag{5}$$

where ΔR_a is change in the surface roughness, 'V' is voltage, 'x' is maching gap, 'S' is rotational speed and 'd' is abrasive size. ΔR_a is a function of the affecting parameters, trained by neurals network.

An effective global optimisation method genetic algorithm (GA) can be used to solve the optimisation problem expressed by Equation (4). GA is a search algorithm, analogous to the process of natural selection that belongs to the class of evolutionary algorithms (EA). Genetic algorithms optimise the problems using methods motivated by the phenomenon of reproduction, mutation, crossover (recombination), and selection.[50] Manufacturing problems that contain data sets as information and defining a continuous and smooth mathematical formula is not possible for 'optimisation objective function,' these can be modelled by ANN and optimised by GA. Figure 13. shows a methodology for the ANN-GA operation.

The decisive parameters of GA optimisation operations are the population size, crossover fraction mutation rate, iterations number (i.e. generations). The opted initial population size was 50, the crossover rate of 0.8, the mutation rate of 0.1, and a number of iterations of 191 were utilised; the optimisation was terminated, and the optimisation history plot up to 191 iterations is shown in Figure 14. Parameters of selection for GA operation are illustrated in Table 6.

The optimisation problem in Equation (4) has been solved with the constraint (lower and upper limits of controlling factors) to search the optimum values of finishing parameters. The contribution of the optimisation process in maximising the ΔR_a is evident when compared with the Taguchi-ANOVA optimised result. From Table 7, ANN-GA shows $(\Delta R_a)_{max}$ of 0.256 µm, whereas Taguchi and ANOVA analysis find $(\Delta R_a)_{max}$ of 0.239 µm.

Table 7. Comparison of results obtained from the Taguchi method and ANN-GA Optimisation

Control factor	Taguchi predicted	ANN-GA Predicted
Abrasive Size/µm	150	105.158
Voltage/V	18	17.999
Machining Gap/mm	1	1.001
Rotational Speed/rpm	90	91.890
Change in Surface Roughness/µm	0.239	0.256

5. Conclusions

Based upon the above results and discussion the following conclusions can be made-

1. ANN-GA is a robust modelling and optimisation tool for any sort of data set (orthogonal array design or non-orthogonal array design) appropriate to scrutinising the finishing of SS302, and it was noticed that the parametric design used in this study provides a straightforward, methodical, and proficient method of modelling and

optimisation of change of surface roughness or finishing behaviour during the MAF process.
2. Modelling and optimisation done with ANN-GA show a maximum value of $(\Delta R_a)_{max}$ equal to 0.25610 µm, which is 7% better than the result obtained from Taguchi-ANOVA analysis.
3. From the regression analysis, ΔR_a increases with the increase of Voltage and Rotational Speed and decreases with increasing Machining Gap and Abrasive Size, whereas the ANN modelling predicts the same results except for the effect of abrasive size, i.e. ΔR_a increases then decreases over the range, and this argument is justified by the optimum value of abrasive size (between the lower and upper limits) obtained from both the optimisation techniques.
4. Voltage has the highest influence on ΔR_a, i.e. 41.60%, followed by Machining Gap (27.98%), while Abrasive Size (10.95%) and Rotational Speed (9.39%) show almost four times lower effect.
5. An ANN model for predicting ΔR_a was developed, and a linear regression equation was developed, where ΔR_a depends on abrasive size, voltage, machining gap, and rotational speed at a confidence level of 99.5%. By comparing the results obtained from ANN methods, and ANOVA, it can be concluded that the ANN model is capable of predicting with very high accuracy and is more efficient.

Abstract-- **An early analysis of growth dynamics for infectious diseases, like COVID-19, is needed to dissect the crucial driving factors that result in rapid disease transmission, refine the measures taken to control the pandemic and improve disease forecast. The phenomenological models are used to identify the initial climbing growth period of COVID-19 outbreak in India and have modelled 3 major epidemic growth models: Generalized logistic growth, Logistic growth and Generalized growth, to predict the growth in the total number of positive cases, daily increase in the number of positive tested cases and the daily growth rate in confirmed positive cases, dated from Apr 10, 2020, to Apr 20, 2020. The bootstrap resampling method is applied for data prediction to process the sample data, dated from Jan 31, 2020, to Apr 10, 2020, and to calculate the 3 major growth parameters: r (Rate of growth at an early stage), K (Final epidemic size) and C(Number of aggregate cases at time t), which are used to calculate confidence intervals which predict the future direction of the curve and increase in the number of confirmed cases with 95% accuracy for the interval Apr 10, 2020, to Apr 20, 2020. Our models predict exponential and sub-exponential spread rate in the number of positive cases in India from Apr 10, 2020, to Apr 20, 2020. Our findings reveal that significant measures are needed to control the transmission rate of the virus in the community, as the models predict sub-exponential growth in India.**

Keywords – COVID-19; Phenomenological models; Epidemic Growth Models; Logistic Growth; Bootstrap Resampling Method; Growth parameters; Confidence Intervals; Data Prediction.

I. INTRODUCTION

In the early stages of an epidemic, the growth rate of the infection spread follows an exponential path. Extrapolation of available data is the most crucial method used to depict the growth dynamics of the epidemic. The predicted data help the policymakers to take preventive measures in the right direction to curb the spread of disease in the community.[11] In case of an epidemic, epidemic growth models are constructed to extrapolate the rate at which the disease might spread in the community. These epidemic growth models are constructed using the parameters obtained by exploring available data, using bootstrap resampling methods. In the bootstrap resampling method, multiple simulations run on the available dataset. In consecutive simulations, parameters are adjusted to extrapolate the most precise estimates that are further used to plot the respective epidemic growth models.[12] COVID-19 disease is now proclaimed as a pandemic around the globe. India comes among one of the few countries in the world which have implemented complete lockdown as a preventive measure to decrease the growth in positive cases of COVID-19 disease at an early stage of an outbreak. It has now spread across the whole world, badly affecting nations like the USA, Italy and Spain. This paper focuses on extrapolation of available data for India to construct early-stage epidemic growth models to dissect the crucial driving factors that are resulting in the rapid spread of disease, to refine the measures taken by authorities to control the pandemic and improve disease forecast.[4,5].

Logistic growth model construction is favourable and can unravel the growth and fall in the number of cases around the inflection point. If the logistic curve converges at an early stage, it means the pandemic is under control, suggesting that the steps taken to control the pandemic are working. Whereas, if the logistic curve does not converge and shows an exponential growth even after the occurrence of the inflection point, then it indicates that the measures taken in order to manage the pandemic are not working, and the epidemic is still in its early growth stage. Logistic models also involve calculation of important feature parameters like rate of growth at early stage(r), final epidemic size (K) and the number of aggregate cases at time t (C), growth deceleration (p), disease turning point(t)

which helps in accurate modelling of curve. Hence, the proposed method of logistic modelling is meritorious over conventional methods.

I. LITERATURE SURVEY

Novel coronavirus (COVID-19) belongs to a family of coronaviruses, which can cause various illness like SARS and MERS.[9] According to the World Health Organization, COVID-19 first appeared in the city of Wuhan, Hebei province, in China in December 2019. SARS-CoV-2 is a new mutation Coronavirus, which is identified as the cause of coronavirus disease of 2019.[8]This pandemic has now affected almost every country on the planet, and researchers around the world are racing to find a cure (or vaccine) for this virus.[9] USA, Italy and Spain are the worst hit nations.The situation in USA is very severe, because more than 50,000 people have lost their lives to this virus.[8] Active research in the field of Computers and Mathematics has helped researchers and doctors, to track the rate of growth of this virus in different countries.[1] Research referenced in [1] has shown that the rate of growth of virus in every country follows the same pattern, that is exponential in nature.

II. METHODS AND THEORY

A. DATASET SOURCES

This report is focused on daily data for the number of positive recorded cases from India. The dataset is sourced from the COVID-19 Patient Database[4] which consists of total confirmed cases state wise consisting of patient number, patient gender, age-bracket, travel history,detected city and current status for all cities in India. The data is updated daily. In this report the data from Jan 31 is used when the first case in India was reported to Apr 10 and used the models to forecast outbreak for next 5 to 10 days.

B. EPIDEMIC GROWTH MODELS

India is currently at the initial stage of the spread, that is, the number of positive cases has not reached a saturation peak yet, and the daily increase is still widening.

In the present scenario, the general epidemic growth models like Richards model and complete interval epidemic curves which constitute an extra variable 'α' signifying the imbalance between rise and sink for the growth frequency curve, cannot be constructed as the amount of data is very limited.

Early epidemic growth models usually result in an 'S' shape when they reach saturation stage. This happens when the epidemic is at an early stage and the data available for processing the model is limited.

Hence, this research focuses on 3 major models, which are constructed using few parameters:

1. Logistic Growth Model

$$\frac{dC(t)}{dt} = r(1 - \frac{C(t))}{K})C(t) \quad (1)$$

2. Generalized Logistic Growth Model(GLM):

$$\frac{dC(t)}{dt} = r(1 - \frac{C(t))}{K})C^p(t) \quad (2)$$

3. Generalized Growth Model (GGM):

$$\frac{dC(t)}{dt} = rC^p(t) \quad (3)$$

Here, the following main parameters are calculated to construct accurate growth models:

1. R : Rate of growth at early stage.
2. K : Final epidemic size.
3. C(t) : Number of aggregate cases at time t.
4. p : Signify profile of distinct growth.

Parameter p lies from 0 to 1, where if:

a. p = 0 : Implies constant growth rate.
b. 0 < p < 1 : Implies sub-exponential growth rate.
c. p = 1 : Implies exponential growth rate.

The 2 basic models, which are derived from Richard's model keeping the parameter α equal to 1 (α=1) and p=1, result in logistic development and generalized logistic development models. The development rate for these models deteriorates proportionally to the number of days. These curves tend to saturate the development in the figures for positive cases at an early juncture of epidemic resulting in optimistic results.

The (3) generalized growth model (GGM) allows for a steady increase in outbreak in the early phase (p<1), but it is unable to explain the decomposition of the frequency rate at advanced stages. Therefore, it acts as an upper barrier, or the worst case scenario that is obtained on the presumption that the upsurge will continue to develop following an expanding pattern as before.Logistic development (1) and Generalized Logistic development (2) usually result in an 'S' shaped curve, when the growth in the number of confirmed cases saturates. They predict very optimistic results, which can be seen as the best case scenario in the early stage analysis of the pandemic.

The generalized logistic growth model (2) results in sub-exponential development rate at a preliminary phase, hence it is preferred to study the imbalance between decay and growth dynamics. These three models are constructed using the available data for the total number of actual recorded cases in India.

C. PARAMETER ESTIMATION

For the parameter estimation stage, the Damped least square method, also known as Marquardt-Levenberg algorithm has been used to resolve the problem of least square nonlinear regression for curve fitting. In order to fit the normal function of normal growth in generalized case of Richard's model (α =1, p = 1), commence the starting spike and permit the algorithm to

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:55:03 UTC from IEEE Xplore. Restrictions apply.

calculate one of the 3 parameters optimally. Since, the early phase of growth models does not observe the logistic rate of development, hence to calculate the variability in our model variables, bootstrap resampling method along with a Poisson function is utilized for error estimation $f(\lambda)$, where λ is the expected value of the distribution as in prior inspections [2].

D. *CONFIDENCE INTERVAL*

The confidence interval mean is calculated for parameter estimation developed for Models (1), (2) and (3) by iterating 200 sets of realizations using parametric bootstrap resampling technique as used in prior studies [2].Parameters were then estimated from the realizations to construct 95% accurate Confidence Intervals. A Poisson error structure was used in the parametric bootstrap method for confidence interval estimation. Problems with the appropriate procedure occur when the model cannot be specified separately from the data resulting in unstable variations of the estimated parameters.The models parameters were evaluated for accurate identification using the simulations.

III. RESULTS

The Generalized linear model parameter p, which signifies the distinct profile growth of infected population is estimated to be 0.99 (95% Confidence Interval: [0.98, 1]). This high value of parameter p signifies that the growth rate is heading towards an exponential trend, and major preventive measures need to be enforced at the earliest.

On the contrary, the logistic model depicts a very optimistic best-case scenario , forecasting the total number infected population at 9,547 (95% Confidence Interval: [9349, 9746]) after 5 days (April 15), and 10,723 (95% Confidence Interval: [10514, 10933]) after 10 days.It might be a very optimistic result if the actual infected cases follow the logistic growth model. India announced their confirmed case for the first time on Jan 30. Since 10 April 2020, according to Indian administration, there were 206 deaths in India and 7,062 cases of infection, indicating that the mortality rate stands at 2.91% among the infected population.

While the growth rate of the infected population is slowing as predicted in Figure 5. , future conditions stay undetermined as the total number of infected individuals is close to the tip of inflection. Also, there is a possibility of new major outbursts to occur in the near future.

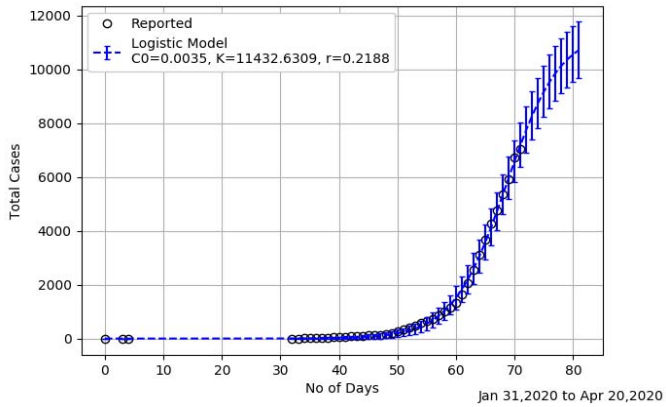

Figure 1. Estimation of Logistic Model to total cumulative confirmed cases in India since Jan31. The error bar is 95% CI extracted from 200 simulations using a poisson error structure.

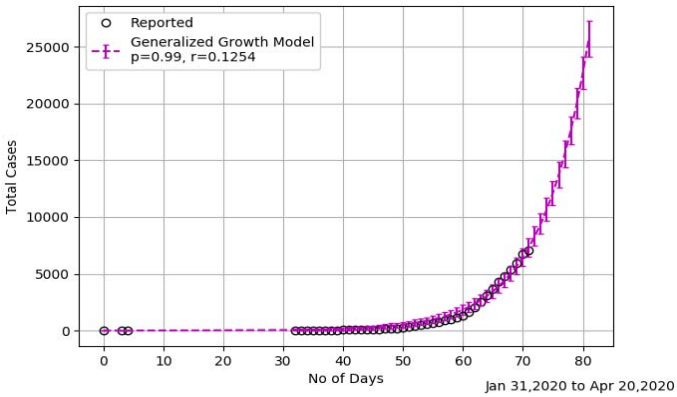

Figure 2. Estimation of Generalized Growth Model to total cumulative confirmed cases in India since Jan31. The error bar is 95% CI extracted from 200 simulations using a poisson error structure

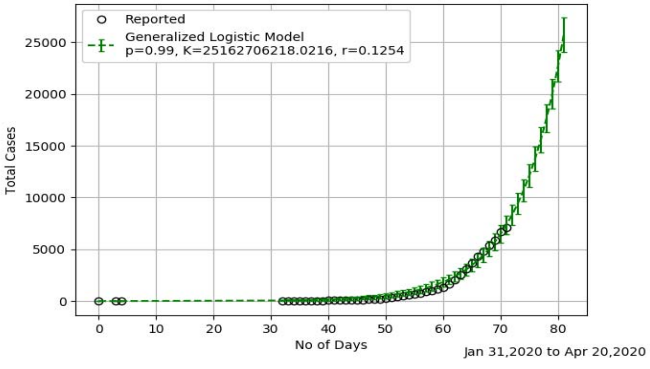

Figure 3. Estimation of Generalized Logistic Model in green to total cumulative confirmed cases in India since Jan31. The error bar is 95% CI extracted from 200 simulations using a poisson error structure.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:55:03 UTC from IEEE Xplore. Restrictions apply.

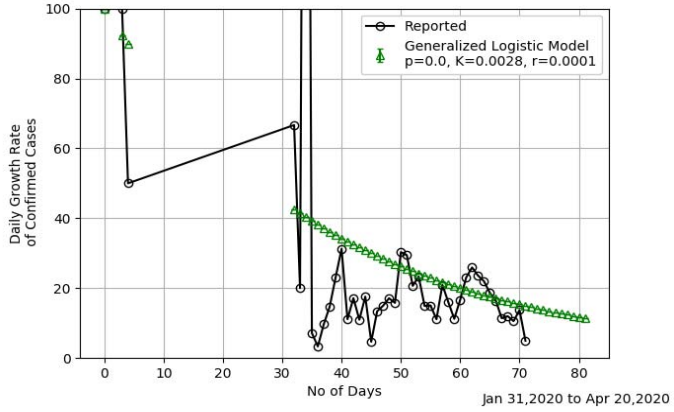

Figure 4. Estimation of models[3](*Generalized Logistic Development Model[1] (in green)*) to rate of daily development of infected population in India since Jan 31. The error bar is 95% CI extracted from 200 simulations using Poisson Error structure[1]

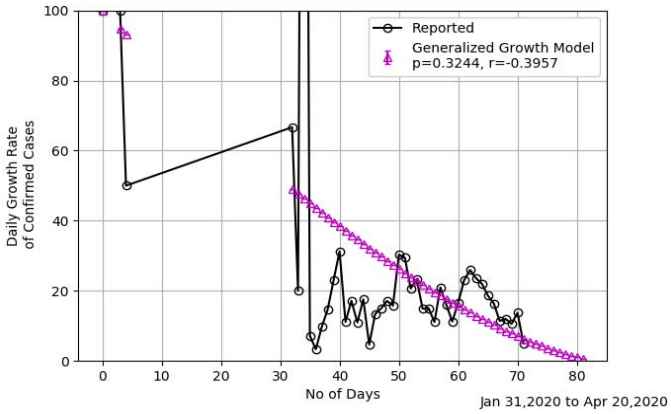

Figure 6. Estimation of models[3](*Logistic Development Model[1] (in blue*),Generalized Growth Model (*in pink*) to rate of daily development of infected population in India since Jan 31. The error bar is 95% CI extracted from 200 simulations using Poisson Error structure[1]

The probability is that the growth rate can keep on fluctuating at current levels for sometime, where the generalized growth model tends to be more favorable for drawing inferences. In this case, the infected population will increase to 13735 (95% CI: [13499, 13970]) in 5 days (April 15th), also to 25706 (95% CI: [25377,26034] within next 10 days (April 20th).

Figure 7. predicts that the point of inflection was passed a few days back, and also the daily number of confirmed infections has started decreasing. This seems to be a positive indication suppose the disease to break out following the logistic depreciation in cases in the following days, presuming the absence of other major public transmission, as was witnessed during phase III of most hotspots in China's research [1].

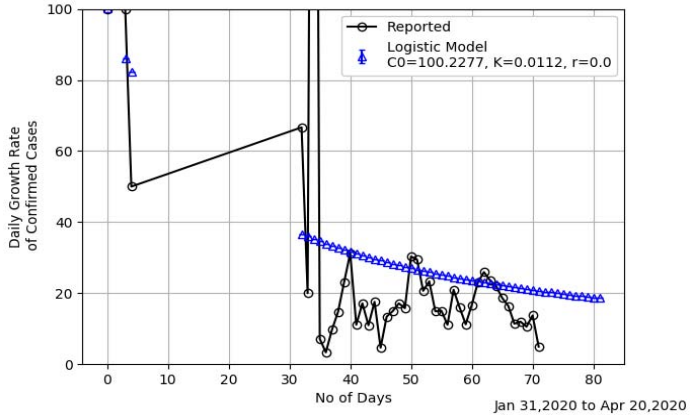

Figure 5. Estimation of models[3](*Logistic Development Model[1] (in blue*),Generalized Growth Model (*in pink*)to rate of daily development of infected population in India since Jan 31. The error bar is 95% CI extracted from 200 simulations using Poisson Error structure[1]

The daily development in the infected population is likely to deteriorate from this junction with an estimated daily surge of 603 (95% Confidence Interval:[550,655]) in 10 days(Apr 20) as predicted by the Logistics Model.

A pessimistic result is obtained from the Generalized Logistic model and Generalized Growth model. Both models estimate the daily increase of infected cases to be : 1355 (95% Confidence Interval: [1279, 1431]) from GLM and 1780 (95% Confidence Interval: [1697,1862]) from GGM, both of which could be predicted to be attained within 10 days

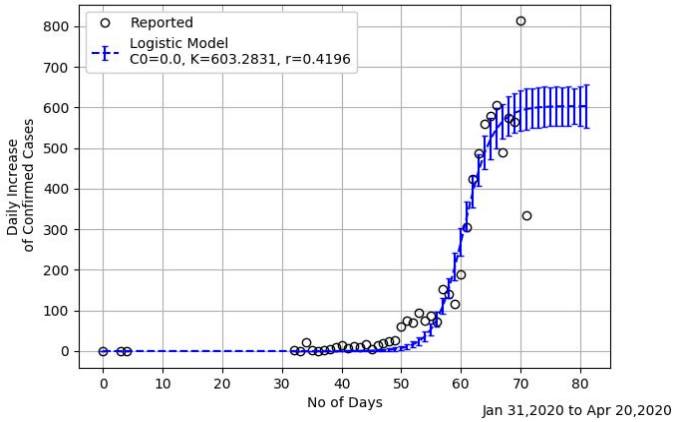

Figure 7. Estimation of models[3] (*Logistic Development Model[1] (in blue)*) to daily increase of infected population in India since Jan 31.The error bar is 95% CI extracted from 200 simulations using Poisson Error structure[1]

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:55:03 UTC from IEEE Xplore. Restrictions apply.

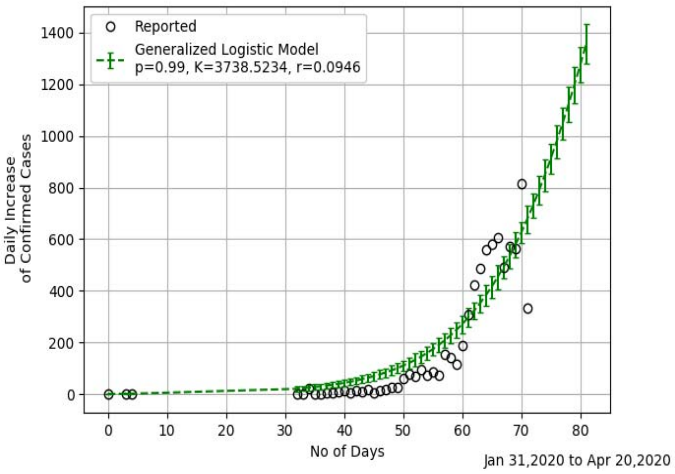

Figure 8. Estimation of models[3](*Generalized Logistic Development Model*[1] *(in green)*) to daily increase of infected population in India since Jan 31. The error bar is 95% CI extracted from 200 simulations using Poisson Error structure[1]

As shown in Figure 4. and Figure 6. the daily growth rate of the confirmed positive cases is definitely not growing exponentially, because the growth rate reduced notably from 40% in February to 1.5% by April 10.The initial period of the Indian outbreak occurred on Jan 30, where most cases are admitted to have a clear travel history to infected places.Although, it is observed from the results that the surge in figures is approaching a constant trend, the uncertainty in future cases might occur.

IV. CONCLUSION AND FUTURE WORK

In this research paper, uniquely introduced variations of logistic models to data of covid-19 pandemic in India and have employed a special 3 parameter Generalized Logistic Model and 2-parameter Generalized Growth Model to model the spread of this outbreak in India. Levenberg–Marquardt algorithm is used for parameter estimation to carry-out least square nonlinear minimization for curve fitting in Python and have calculated confidence intervals with 95% average accuracy, using bootstrap resampling method , where 200 simulations are performed using Poisson error structure. For some days, the number of total cases is predicted with more than 97% of accuracy, which shows the reliability of the models constructed.

With this research paper, tried to model the following growth models: (1)logistic growth development model, the (2)generalized growth development model,(3)generalized logistic growth model to the actual infected population of Covid-19 pandemic from Jan. 30 to Apr 10 of India. Our analysis tries to discover the growth of the covid-19 pandemic in India and the influence of National Lockdown at the average level.

On the grounds of experience in China[1], a high level risk in India is predicted with approximate total actual cases on April 14 to be 12116 (i.e. 95 % CI: [11895, 12336]), 25706 (i.e. 95 % CI: [25337, 26034]) by April 20.The GLM parameter p is around 0.99 (95% Confidence Interval: [0.98, 1]). This indicates that domestic transmission sources in India are out of control as growth is nearing an exponential one.On the contrary, the best case scenario would be the one described in the logistic model, giving the total infected population as 9547 (95% CI: [9349, 9746]) after 5 days (April 15), and 10723 (95% CI: [10514, 10933]) after 10 days. It might be a very good result if the actual infected cases follow the logistic model.Extrapolation of data for India has helped to determine the course of future measures that need to be taken in order to curb the development in COVID-19 disease in India. National lockdown has definitely helped to curb the surge in positive cases in India, but the infection might start spreading rapidly if the lockdown is lifted without prior precautions.

Accuracy of results depends proportionally on the size of the sample data collected. In our research, modelling logistic growth models for COVID-19 pandemic in its most nascent early stages, inferring that the size of sample data available for data extrapolation is very small. Hence, as the sample data size is very limited, saw differences between actual and predicted forecasts using the proposed method.Some external factors also might have resulted in mis-reporting of actual cases.

Table I: Short Term Forecast for daily increase of confirmed cases as predicted by GLM along with actual data and accuracy(%)

Day	Date	Actual	Predicted	Accuracy (%)
72	11 April 2020	854	677	79.27
73	12 April 2020	758	730	96.30
74	13 April 2020	1243	787	63.31
75	14 April 2020	1031	847	82.15
76	15 April 2020	886	911	97.25
77	16 April 2020	1061	978	92.17
78	17 April 2020	922	1188	77.6
79	18 April 2020	1371	1268	92.48
80	19 April 2020	1580	1274	80.63

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:55:03 UTC from IEEE Xplore. Restrictions apply.

Under-testing due to unavailability of testing kits in India might have also resulted in mis-reporting in actual recorded cases, which further resulted in deviation from actual figures in India.

Also, new hotspots might have originated in most affected states like Maharashtra, which might have led to sudden disruptions in the number of reported cases in April 2020.

Regression convergence depends significantly on preliminary values of parameters K, r and p, it might fail to converge accurately for a limited sample dataset.

Therefore, logistic models are highly data-driven in nature and the accuracy in predicted data depends on how well can the data collected mimic the actual dynamics of the pandemic.

The logistic models constructed mimic both the spread of epidemic and also the control in epidemic (S-shaped curve). Curve starts to converge after inflection point, predicting the control in the epidemic. Non-convergence of logistic models implies that the pandemic is not in control and further measures need to be undertaken.

ABSTRACT: Synergistic use of superabsorbent hydrogels has vital contribution to the daily life. This work gives an account of a facile approach to synthesize superabsorbent hydrogels based on *Moringa oleifera* gum and polyvinyl alcohol cross-linked with borax. Fourier transform infrared, X-ray diffraction, and scanning electron microscopy were employed to characterize the structure, crystallinity, and surface morphologies of the samples. The cross-link density, swelling ratio, reswelling, water retention properties, and salt sensitivity of hydrogels were investigated. Reaction parameters for the hydrogel synthesis were optimized on the basis of water absorbency, and the reaction condition of greater water absorbency after 12 h at room temperature was taken as an ideal condition. Optimum conditions were obtained as [poly(vinyl alcohol) PVA] = 10% (w/v) and [borax] = 1.05×10^{-3} mol/L. Under the optimized conditions, the maximum swelling ratio of MOG/PVA hydrogel reached 1163 g/g in deionized water and 290 g/g in 0.9 wt % NaCl solution. Furthermore, all hydrogels exhibited salt sensitivity and excellent water retention capacity under the high temperature state and displayed smart swelling behaviors in physiological saline solutions. The water absorbency, reusability, and salt sensitivity of the hydrogels give these smart polymer wide promising applications.

1. INTRODUCTION

Superabsorbent hydrogels (SHs) are three-dimensional networks of linear (or branched) hydrophilic polymers interconnected by chemical and/or physical cross-linking. They can absorb and retain large quantities [swelling ratio (SR) > 100] of liquids,[1] blood solutions,[2] and bodily fluids.[3] SHs are broadly used in agriculture,[4] biomedical applications,[5] personal care products,[6] and even in sewage treatments.[7] Moreover, on the basis of their functional groups including −COOH, −OH, $-CONH_2$, $-SO_3H$, and their cross-linking nature,[8] SHs may perform by various stimuli factors such as osmotic pressure, pH, and temperature, which results in a gradual or sudden variation in the SR.[9]

Commonly, water-absorbing gels experience swelling in various phases. Initially, the gel outside comes in contact with water molecules and become wetted through hydrophilic groups present on the gel surface.[10] Second, the water molecules enter in polymer matrices through micropores, which leads in the expansion of gel molecular volume.[11] Lastly, the osmotic pressure of water and the binding force of the molecular matrices reached to equilibrium, as a result, the most extreme water absorbency is achieved.[12] However, the polymer hydrophilic groups tie salt constituent particles effectively by a mechanism similar to complexation.[13] Therefore, the gel structures got blocked, obstructing the entrance of water molecules in the initial phases and volume expansion of the gel in the last phase. Therefore, the swelling capacity decreases abruptly in aqueous fluids, such as blood,[14] urine,[15] and soil solutions.[16] To fulfil these gaps, a simple tactic applied to synthesize superabsorbent materials depends upon natural polysaccharide such as natural gums, cellulose, chitosan, and starch, which might rise their biocompatibility, biodegradability, and swelling capacity.[12]

Moringa oleifera (family: Moringaceae) is a wild plant that grows in many countries of tropics and subtropics. The stem of the *M. oleifera* tree exudes a gum commonly known as *M. oleifera* gum (MOG), which is initially white in color but changes to brownish black and reddish brown on exposure. It gives a highly tacky solution when dipped in water.[17] It is composed of D-galactose, D-mannose, D-glucoronic acid, D-xylose, L-arabinose, and L-rhamnose.[18] All the parts of *M. oleifera* are nontoxic and beneficial for human health and contain minerals, nutrients, and various antioxidants.[19,20] In India, MOG is usually known as sajna gum.

Polymer like poly(vinyl alcohol) (PVA) has fair reputation as a biocompatible and nontoxic linear biopolymer.[21] We selected PVA as the other component because of its fair adhesive properties and water solubility.[22]

The aim of this work was to develop natural gum-based SH with better swelling, physicochemical, and reswelling properties that can vie with synthetic counterparts concerning to the environmental problems. The hydrogel was synthesized using biodegradable and cheap materials: MOG and PVA. The synthesis procedure is aqueous-based, catalyst-free, and environmentally friendly. Here, we described its advantages, procedure, and swelling properties to evaluate its promising application.

2. RESULTS AND DISCUSSION

2.1. Fourier Transform Infrared Spectra. Fourier transform infrared (FTIR) analysis (Figure 1) of MOG/PVA hydrogel displayed a strong absorption band in the region 3401 cm^{-1}, which can be assigned to stretch vibrations of O−H. The band in the region at 2906 cm^{-1} is because of C−H symmetric stretching vibrations. Further a wavenumber at about 1663 cm^{-1} represents hydroxyl bending mode. The characteristic absorption bands at 1163 and 1457 cm^{-1} correspond to C−O−C stretching and CH_2 bending vibrations, respectively. In case of cross-linked hydrogel, the strong absorption band of MOG[17] at 3403 cm^{-1} and PVA[23] at 3400 cm^{-1} was less pronounced and slightly moves to longer wavelength. The appearance of bands around 1429 and 1343 cm^{-1} is because of asymmetric stretching of B−O−C, and also, a wavenumber around 1661 cm^{-1} corresponding to H−OH bending has weakened, and a wavenumber around 837 cm^{-1} corresponding to C−H bending has almost disappeared, which provides evidence that the cross-linking between hydroxyl groups of MOG and PVA by borax.[24]

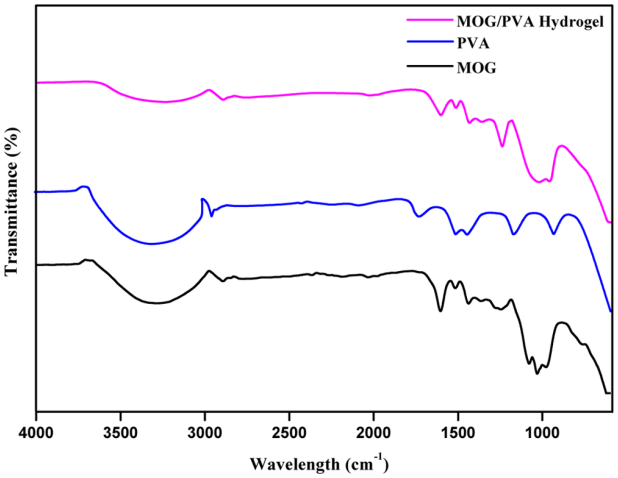

Figure 1. FTIR spectra of MOG, PVA, and MOG/PVA hydrogel.

2.2. X-ray Diffraction Studies. The X-ray diffraction (XRD) pattern (Figure 2) of MOG exhibits a broad peak around 2θ = 10−28°, which corresponds to the amorphous nature of pure MOG.[17] The PVA showed two typical peaks[25] at 2θ of 19.4 and 41°. In case of MOG/PVA hydrogel, the intensity of diffraction peaks at 2θ = 21.9° decreases with slight change in position, suggesting decomposition of semi-crystalline and amorphous nature of PVA and MOG, respectively, which indicates that MOG and PVA were chemically cross-linked.

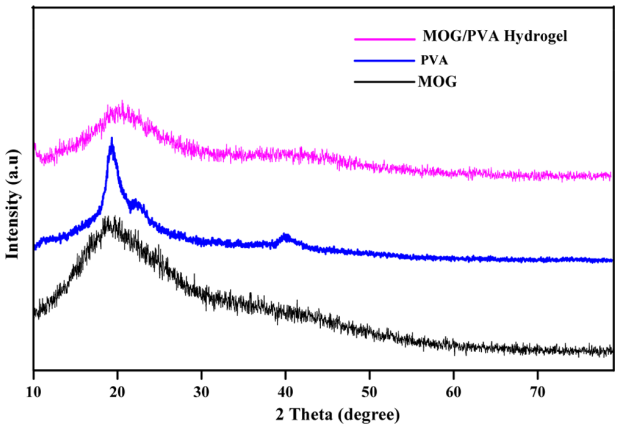

Figure 2. XRD of MOG, PVA, and MOG/PVA hydrogel.

2.3. Scanning Electron Microscopy. Scanning electron microscopy (SEM) images of MOG, PVA, and borax cross-linked MOG/PVA hydrogel are presented in Figure 3a−c, respectively. The MOG exhibited a smooth and compact surface, as shown in Figure 3a. PVA has a smoother and sheet-like morphology, as shown in Figure 3b, whereas the cross-linked hydrogel exhibited a fractured and scaly surface with significant pore spaces, as shown in Figure 3c. These pores are the regions for water permeation and interaction sites of external stimuli with the hydrophilic groups, which leads to increase in SR.

2.4. Swelling in Deionized Water. Figure 4 shows the SR of MOG/PVA hydrogels at different concentrations of PVA and borax at room temperature in deionized water. The water absorbency of hydrogels increases sharply during the first 120 min and afterward turned out to be slower until reaching a plateau. The swelling ability of hydrogels decreases with increasing cross-linker borax concentration, owing to the reason that the increase of cross-linking density makes polymer chains self-entangled, resulting in more compact structure. However, when the PVA content increases, the swelling of hydrogels first increased and then decreased, and the initial increase in swelling may be because of the increase in hydrophilicity and the formation of network of optimum pore size. Thereafter, further increase in PVA concentration has led to decrease in swelling of hydrogels, this may be because of the blocking of active sites on polymer chains, leading to decrease in the hydrophilic groups. The best result was obtained with SR 1163 (g/g), which was in agreement that the MOG/PVA hydrogels were superabsorbent.

2.5. Swelling in Various Saline Solutions. Figure 5 shows the equilibrium swelling capacity of MOG/PVA hydrogels in various saline solutions (D-glucose, urea, physiological saline water, and synthetic urine). The order of equilibrium swelling capacity for SHs in above solutions in the decreasing order was ranked as urea solution > D-glucose solution > physiological saline water > synthetic urine. The equilibrium swelling capacity of SHs in D-glucose solution was found to be slightly lower compared to the values measured in deionized water, whereas the equilibrium swelling capacity subsequently decreases in synthetic urine and in physical saline water. The shrinking behavior of hydrogels in synthetic urine and physiological saline water is because of the charge-

ACS Omega XXXX, XXX, XXX−XXX

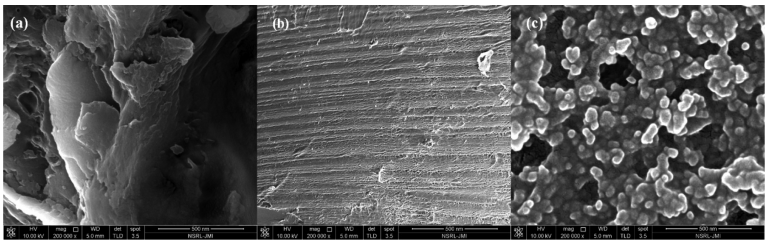

Figure 3. SEM images of (a) MOG, (b) PVA, and (c) MOG/PVA hydrogel.

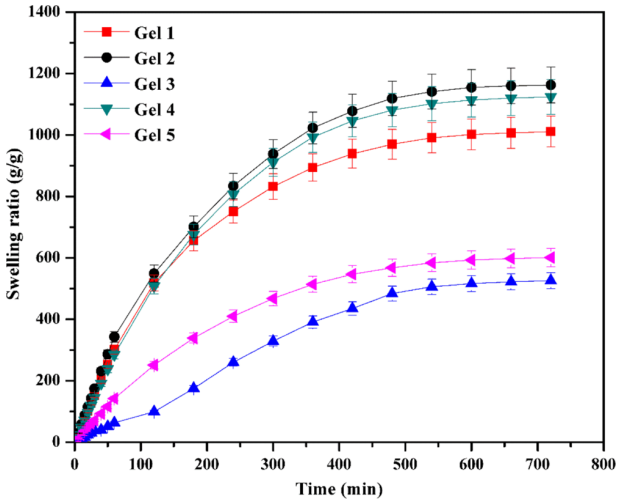

Figure 4. SR of MOG/PVA hydrogels in deionized water at room temperature.

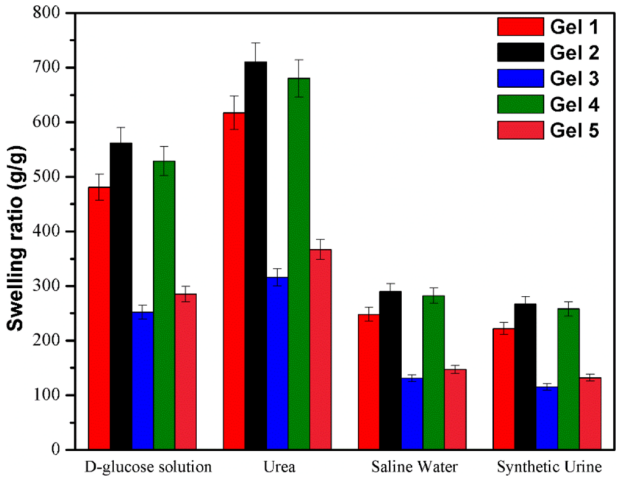

Figure 5. SR of MOG/PVA hydrogels in various saline solutions.

screening effect of the counterions (Na^+, K^+, Ca^{2+}, and Mg^{2+}) resulting in the decline of anion−anion repulsions, which reduces the osmotic pressure between the internal hydrogel network and the external solution.[26]

2.6. Water Retention Capacity. Figure 6 depicts the water retention capacity of the equilibrium swollen MOG/PVA hydrogels. As can be seen from the curves, the water retention capacity decreases with increasing time. After dehydration, gel samples became plastic-like; moreover, water retention decreases with increasing borax amount. GEL 3 losses water rapidly compare to GEL 2, and became

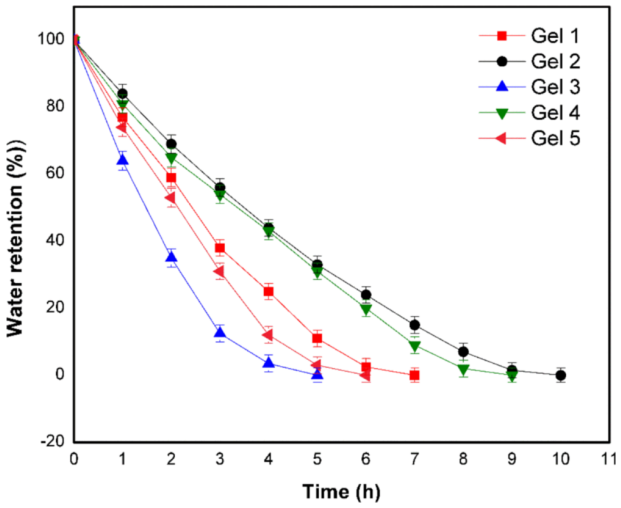

Figure 6. Water retention capacity of the MOG/PVA hydrogels at constant temperature (60 °C).

highly dehydrated after 5 h, while water retention capacity of GEL 2 was reached to 31% at this time interval. This may be because of the H-bonding interactions and van der Waals forces between water molecules and hydrogel matrices, which directly affect the water retention capacity of hydrogel.[27] Considering the above, MOG/PVA hydrogels have outstanding water retention capacity, which allows for a further application prospects in agriculture.

2.7. Reswelling Capability Studies. The reswelling capability of hydrogels in deionized water following five consecutive swelling/drying cycles is depicted in Figure 7. The enormous weight and larger pressure inside the hydrogel system are caused by absorbed water molecules, resulting in the breaking of polymer networks.[28] Thus, the voids in the hydrogel porous structure collapses slowly, resulting in the reduced swelling capability. The equilibrium swelling capacity of bone-dried GEL 2 was 1035 g/g for cycle 1 and remained at 756 g/g for cycle 5, exhibiting swelling capability loss to 35%. The swelling capability of GEL 4, GEL 1, GEL 5, and GEL 3 after five reswelling cycles decreased to 40, 49, 58, and 72%, respectively. These results infer the reason of hydrogen-bonding interactions among MOG and PVA that arisen during the drying process.

2.8. Salt-Sensitivity Analysis. To examine the salt-sensitivity factor (f) of the MOG/PVA hydrogels, the swelling capacity at equilibrium (W_s) in various salt solutions (NaCl, KCl, NH_4Cl, $CaCl_2$, and $AlCl_3$) at 0.15 mol/L concentration is given in Table 1. In NaCl, KCl, and NH_4Cl solutions, the equilibrium swelling capacity W_s of all hydrogels increased in the following ascending order: $Na^+ < K^+ < NH_4^+$ (Table 1).

https://dx.doi.org/10.1021/acsomega.0c01023
ACS Omega XXXX, XXX, XXX−XXX

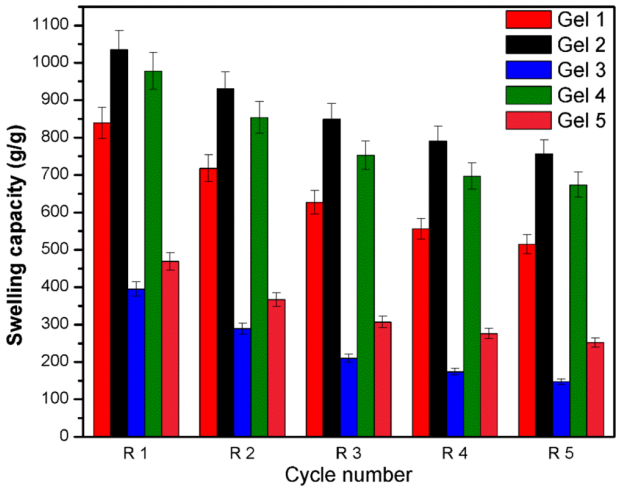

Figure 7. Reswelling capability of MOG/PVA hydrogels during consecutive swelling/drying cycles.

This may be because of the charge screening effect of these cations on the W_s values increased in the same order. The equilibrium swelling capacity in NaCl, $CaCl_2$, and $AlCl_3$, decreases with the increasing of cationic charge (Na^+ < Ca^{2+} < Al^{3+}) (Table 1), which might be elucidated by the Donnan equilibrium theory.[29,30] According to Donnan, the shrinking and swelling behavior were ascribed to the decrease osmotic pressure difference between the interior hydrogel and the external solution.[31]

2.9. Network Parameters. The gel content influences the cross-link density (CD) of the hydrogel network and it rely upon the composition of the reaction mixture. Higher swelling capacity is because of low CD of hydrogels, and at lower CD, the water permeation into the hydrogel matrix becomes easier, resulting in the increment in gel-swelling capacity. Table 2 shows with the increase in borax concentration, the CD of the forming gel gets increased while M_c decreased, this may be because of the number of efficient cross-links per unit volume increases in the hydrogel network, leading to a reduction in pore size of the voids present in the network chains. CD of gel 2 is lower than gel 4 and gel 5 because of the presence of hydrophilic functional groups and adequate pore size. Moreover, the network parameters influence the hygroscopicity, strength, and integrity of hydrogels.

3. CONCLUSIONS

In this research work, a series of borax cross-linked MOG/PVA hydrogels were developed and optimized as the water conservation material in agriculture. The procedure for hydrogel synthesis is ecofriendly as it employs biodegradable, catalyst-free, and inexpensive materials. The SRs of MOG/PVA hydrogels changed dramatically from 526 to 1163 g/g, depending upon the composition of the reaction mixture (borax and PVA). The swelling and shrinking behavior of MOG/PVA hydrogels were influenced by inorganic salt aqueous solutions. The water retention test confirms the good water holding property of the MOG/PVA hydrogel. This biobased SH has great potential for large-scale commercial applications including agriculture and hygienic products.

4. EXPERIMENTAL SECTION

4.1. Materials. MOG (Nutramine Life Sciences, Delhi), polyvinyl alcohol (SD Fine Chemicals India, M_w 85,000−125,000, alcoholysis degree 98−99%), and borax (Qualigens Fine Chemicals) are used. Deionized water was used throughout the experimentation. The solvents and chemicals were used without any further purification.

4.2. Preparation of the MOG/PVA Hydrogel. For the preparation of MOG/PVA hydrogel, definite concentration of MOG (4% w/v) was hydrated and stirred at 200 rpm with a overhead stirrer for 6−8 h at room temperature. PVA solutions of different concentrations (8% (w/v), 10% (w/v), and 12% (w/v)) were prepared separately by dissolving required quantity of PVA in deionized water at 80 °C. The cross-linker borax was separately dissolved in the calculated amount in deionized water (Table 2) and was added to the reacting solution mixture and again stirred for 30 min and kept aside for another 4 h without stirring for proper cross-linking. To remove unreacted borax, the hydrogels were rinsed with deionized water and soaked overnight in acetone for dehydration. Dehydrated hydrogels were filtered through a nylon sieve and dried in an oven at 45 °C till constant weight was obtained. The procedure for the synthesis of MOG/PVA hydrogel is described in Figure 8a, whereas dried and swollen hydrogels are depicted in Figure 8c,d, respectively.

4.3. Characterization of the MOG/PVA Hydrogel. FTIR spectra of MOG, PVA, and MOG/PVA hydrogel were recorded on a FTIR spectrophotometer (model: Tensor 37 spectrophotometer), within the frequency range of 4000−500 cm^{-1} by the KBr pellet method. XRD patterns of MOG, PVA, and MOG/PVA hydrogel were collected using an X-ray diffractometer (model: Bruker) with Cu Kα radiation (λ = 1.54 Å) at a voltage of 40 kV and a current of 40 mA in the 2θ range of 10−80°. The surface morphology of MOG, PVA, and MOG/PVA hydrogel was observed by SEM (model: S-4800 Hitachi, Japan). Before the analyses, a thin layer of gold was sputter-coated on the sample surface.

4.4. Swelling Measurements. A series of accurately weighed bone-dried hydrogel samples (0.1 ± 0.0001 g) was dipped entirely in deionized water or various saline solutions [urea solution: 50 g urea in 1000 mL deionized water; 0.9 wt % NaCl aqueous (saline) solution; D-glucose solution: 50 g D-glucose in 1000 mL deionized water; synthetic urine: 0.6 g

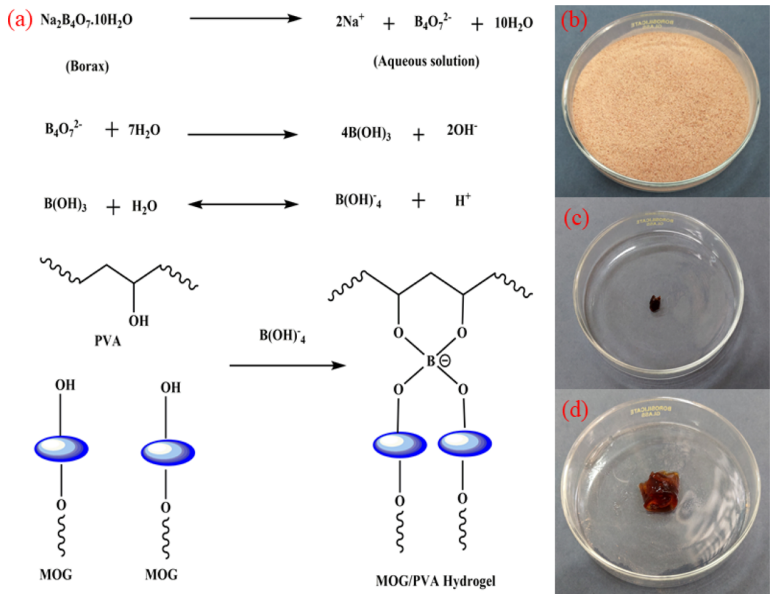

Figure 8. (a) Schematic representation for the synthesis of MOG/PVA SHs, (b) MOG powder, (c) dried hydrogel, and (d) swollen hydrogel.

$CaCl_2$ + 1 g $MgSO_4$ + 8 g NaCl + 20 g urea in 1000 mL deionized water] and allowed to achieve swelling equilibrium at room temperature.

At certain time intervals, swollen hydrogels were withdrawn from the swelling medium, and later, excess surface water (or salt solution) was removed by filter paper and weighed accurately (W_t). This process was repeated until the weight of the swollen hydrogel sample remained constant (W_e), which demonstrated that the hydrogel had reached its equilibrium swelling capacity. The water absorbency of hydrogel (SR; g/g) was calculated by using eq 1, where (W_d) is the weight of the dry hydrogel samples. The equilibrium swelling capacity (W_{eq}, g/g) was calculated using eq 2, where (W_d) is the same as eq 1.

$$\mathrm{SR} = \frac{W_t - W_d}{W_d} \tag{1}$$

$$W_{eq} = \frac{W_e - W_d}{W_d} \tag{2}$$

4.5. Water Retention Measurement. To study the percentage water retention of hydrogel samples under constant temperature, a certain quantity of water-swollen hydrogel was placed in a vacuum oven at high temperature (60 °C) and weighed every 1 h. The percentage water retention (W_R) was detected by the following eq 3

$$W_R = \frac{W_i - W_d}{W_e - W_d} \times 100\% \tag{3}$$

where W_i is the weight of the swollen hydrogel and W_d and W_e are the same as eq 2.

4.6. Reswelling of Cross-Linked Hydrogels. A preweighted dry hydrogel sample was immersed in deionized water to ensure that the swelling equilibrium was achieved and weighted. The swollen hydrogels were bone-dried in a vacuum oven at 80 °C. The dried hydrogel sample was soaked again in deionized water to determine its equilibrium swelling capacity. This swelling/drying cycle was repeated five times using the same hydrogel, and finally losses of equilibrium swelling capacity were measured for each hydrogel sample.

4.7. Salt-Sensitivity Factor (*f*). The effect of ions (anions and cations) on the swelling capacity of the hydrogels was evaluated in various salt solutions as described by Rodrigues et al.[32] The dimensionless salt-sensitivity factor (f) was determined using eq 4:

$$f = 1 - \left(\frac{W_s}{W_w}\right) \tag{4}$$

where W_s and W_w are the equilibrium swelling capacity in saline solution and in deionized water, respectively. All salts were used at concentration of 0.15 mol/L.

4.8. Network Parameters. Some important network parameters used to characterize the network structure of hydrogel were determined. The hydrogel cross-linking density (CD) is obtained by the average molar mass (M_c) entrapped between two neighboring cross-linking points of the polymer chain contained in the gel. The CD value is inversely proportional to M_c, as the higher the M_c, the lower the CD. According to the Flory–Huggins theory[33] and a previously developed method,[34,35] the M_c value of any hydrogel can be determined using eq 5

https://dx.doi.org/10.1021/acsomega.0c01023
ACS Omega XXXX, XXX, XXX−XXX

$$M_c = Q^{5/3}(D_2V_1/(0.5 - X_1)) \quad (5)$$

where Q represents the equilibrium water absorption of the hydrogel, D_2 denotes the hydrogel density, V_1 is the solvent volume used for swelling, and X_1 is the Flory−Huggins interaction parameter between the solvent and hydrogel. The mean pore size or mesh size of the polymeric network of the hydrogels (ξ) broadly defines the linear distance between the macromolecular chains in a cross-linked network and is estimated using eq 6.[36−38]

$$\xi = 0.071(M_c)^{1/2}/(\phi)^{1/3} \quad (6)$$

Here, (ϕ) is the polymer volume fraction in the swollen state.

ORIGINAL RESEARCH

Multi-dimensional aggregation: a viable solution for interval data

Shailender Kumar[1]

Received: 22 November 2019 / Accepted: 21 April 2020
© Bharati Vidyapeeth's Institute of Computer Applications and Management 2020

Abstract Now a day multi-dimensional data modeling and aggregate query processing which are key assets of business intelligence solutions are being frequently realized to the unorthodox data. For interval values which are recorded when the data is on hold, multidimensional aggregation is the only viable solution and the author emphasizes over this aspect in this paper. Actually, such intervals reflect the state of reality of either current data or such data which were part of the present database. Every possible challenge which interval data throws upon is resolved in this paper through introduction of aggregation operator. Although the intervals are unknown at first but they eventually depend on the actual data and it turns out to be quiet handy while associating them with the resulting tuples. Only those result groups are selected for this purpose, which are specified partially. The interval data signifies that data holds either for each interim in the interval or entire interval and in both of these two cases it faces contention with the operators. In this paper, the author presents the empirical analysis of the aggregation operator after its implementation over the huge industrial data sets and claims that it holds an edge over the other temporal aggregation algorithms.

Keywords Aggregates · Databases · Query processing · Static · Stable

1 Introduction

In most of the present reality database employments, e.g., in the fiscal, medicinal, and systematic spheres, handle time-oriented data, which is raw facts with linked time-phases that holds certain time-varying feature of the facts, classically at the point when the certainties were or is right in the displayed veracity or when the realities was or is section of the contemporary condition of the database. In distinction to this, contemporary database administration delivers valuable tiny integral query language support for time-varying facts administration [1]. In phase through the growing dispersion of professional aptitude, collective calculation turn out to be significant. An aggregate operator transfigures a reflection temporal arrangement into a prompt upshot arrangement [2]. Ordinarily, this is accomplished by principal part the contention transient connection into bunches of lines with undistinguishable esteems for more than one components, then appertain an aggregate procedure, e.g., max or min, to every cluster in one go. For time-traverse esteemed time-arranged databases, total is exceptionally testing on the grounds that the time-traverse esteems can likewise be utilized for portraying the bunches of contention columns [3].

In this paper, the author proposes a novel time-oriented aggregation operator which is employed to perform multi-dimensional aggregation [4]. It improves a decent variety of prior proposed conglomeration operator and gives multi-dimensional help to two periods of total: (a) the elucidation of point assemblies for which to report more than one amassed esteems and (b) the elucidation of amassing assemblies, i.e., gathering of transient contention pushes that are associated with the item bunches and over which the time-situated total methods are assessed [5]. The author constructs the elementary structural chunk on

Published online: 02 May 2020

contemporary developments in multi-dimensional query process and is the central exertion to dynamism these approaches to phase-esteemed data that are proven by time-oriented facts [6]. The paper covenants a well-organized employment of the aggregation operator with an average density of order $n \log z.$, where z signifies the number of product clusters and n signifies the figure of time-oriented aspects rows [7]. In investigational estimations on huge records, the time-oriented aggregation operator display nearly undeviating performance.

Aggregation of time-oriented facts presents complex trials [8]. Most significantly, the stint-phases of product rows can hinge on the authentic records and are not acknowledged in advancement [9]. As a result, the clustering of the artifact tuples can only be quantified moderately. Following, accumulation should provision what is named persistent, flexible, and fissile semantics of the connotation among records and time-intervals [10]. For instance, the quintessence of a retro juncture with a record adjust is static, hugeness that the adjust grasps for every single sub-periods of the traverse [11]. In deviation, contemplate the association of an exacting month with the numeral of periods operated by a demonstrative amid that period, e.g., 150 periods. The stint-relationship is malleable, by way of 150 periods are well-thoroughly deliberated a total of the periods functioned by the wage earner amid every day amid that month. A stint-relationship is fissionable if the realities can't be connected with changed time–values [12]. All techniques so far offer help for static practices. In conclusion, a period arranged accumulation final product may be more noteworthy than the contention time-situated connection [13]. Explicitly, for instant time-oriented aggregates that are gathered to form a static span, the product stint-relation scope can be double that of the time-oriented reflection [14]. To enumerate the product scope, the paper outlines the concept of a time-oriented aggregation aspect; and to regulate the time-oriented aggregation, the capability to state immobile time-span for the product rows is comprised [15].

The paper is organized in the following manner: Sect. 2 crisply explicates the literatures available in the domain of temporal databases and temporal aggregate operators. Section 3 includes key concepts and basic parameters. In Sect. 4, the author explains and introduce aggregation operator. Section 5 gives a brief overview about the employment of the operator. Section 6 reports on an empirical evaluation and Sect. 7 sum up the things by providing the concision the beneficiation of this article.

2 Background

The notion of hasty as well as amassed time-oriented aggregate operators has been, as of now, expressed by a few authors [16]. The importance of a rapid time-oriented amassed at stint 'st' is assumed by capturing the cluster of rows that confiscation at 'st' [17]. The implication of an amassed time-oriented accumulative at stint 'st' is assumed by capturing the cluster of rows that seizure in the progressive span [st − s, st], s ≥ 0. Misty amassed upshots with uninterrupted stints are amalgamated into static time spans. Most analysis has been improved the situation moment time-arranged totals, e.g. [4, 6], and accumulative aggregates [5, 18] and time-oriented aggregates with auxiliary succession predicates [7, 14] have acknowledged slender contemplation.

An introductory plan by Tuma [8, 19] for presuming time-oriented aggregates entails two examinations of the response stint-oriented schema—one for the assessment of the stint-interims of the item lines and the assessment of the time-arranged totals. A scheme by Kline and Snodgrass [4, 20] look at the info time-arranged connection just a single time, development of an accumulation sequencing tree in principle memory. In the interim, the sequencing tree isn't steady, the most pessimistic scenario time intricacy is $O(n^2)$ where cardinality of a relation is n. A rise, giving under the indistinguishable most pessimistic scenario unpredictability, is the k-ordered conglomeration sequencing tree [21]. A methodology deeds fractional congregation of columns for junk get together of timeworn protuberances.

A steady tree, for collection in principle memory, is grounded on the requested entire sign of time [4, 22]. This elucidation performs for the total capacities like summation, average, and count; for minimum and maximum, a merge-sort like procedures are planned. The two calculations have a most pessimistic scenario. For minor stockpiling, a procedure of bucket calculation is advocated over the information columns to mic-buckets giving to a dividing of the time reflections and furthermore figures out how to pay for enduring lines particular administration. Conglomeration is then accomplished on every single mic-bucket in partition. The calculation includes right to utilize the complete databank thrice.

The disk-grounded calculation, preservation of prompt and cumulative time-oriented conglomeration [6, 23] has already been carried out. A SB-tree encompasses a step of traverses related with modestly figured totals. With the SB-tree, total questions are practical to a complete base assembly—it isn't conceivable to grasp gathering establishes. The multilevel-styled SB-tree [23] emphases on arrangement total explorations amalgamated with go

predicates. The two strategies are focused on to spread grounds, the stint-interim of the info row is erased; thus the outcome isn't a stint situated connection.

The overall strategies portions three aspects. To begin with, the time-arranged gathering process combines the subdividing of the course of events with the array of the info lines [21]. The course of events is isolated into ranges, and an info push fit into an express board if its entire sign of time associate that panel. Second, the item pushes are very much characterized for stint-focuses and not after some stint-interims. Third, they permit the exploitation of at utmost one non-time-situated trait for time-arranged congregation.

Our opportunity arranged collection administrator, which spreads the multi-dimensional crease administrator to engage time-situated total, overpowers these limits and rearranges the conglomeration administrators pondered [3, 16]. It de-couples the isolating of the timetable from the collection of the info columns, consequently allowing to require item pushes over likely covering ranges and to control the degree of the item connection. Furthermore, it bolsters various characteristic highlights [17]. For a viable commercial the creators deed the classification of the info connection.

3 Preliminaries

3.1 Temporal aggregates

The paper commences a divergent stint sphere, where the modules are entitled stints (or stint-facts), well-found with a whole request $<$ T, and the author employs these as our stint-sphere. A whole mark of stint (or stint-facts) is a curled cluster over the stint-sphere and is signified by two stints, $[T_{start}, T_{end}]$, signifying its universal initial and absolute end facts, consistently. The author employs T as shorthand for [T_start, T_end]. For whole mark of time, the author presents numerous schemas: st $\in$ sT represents the stint 'st' is incorporated over the whole mark of stint sT. For two whole mark of stint sT and sT′, sT′ $\subseteq$ sT iff every stints in sT′ are also included in sT, and sT $\cap$ sT′ yields the group of stints over the whole mark of time. If sT $\cap$ sT′ $\neq \varnothing$, the paper states that the binary segments transect.

A time-oriented schema is a multi-tuple Schema = (ψ, ς, dom), where ψ is a determinate regular group of time-oriented attributes, ς is a determinate group of spheres, and sphere: $\rightarrow \varsigma$ is a procedure that links a sphere with every time-oriented attribute. A time-oriented schema is a schema with single whole mark of stint valued attribute (the sphere of whole mark of time corresponds to ς). For the determination of this paper, the author expresses time-oriented stint-relation schemas $V = (w_1, w_2, w_3, \ldots, w_n, \text{Timestamp})$ and $Z = (u_1, u_2, u_3, \ldots, u_n)$. Note that the statement that time-oriented schemas have a whole mark of time attribute. Timestamp is only for appropriateness. There is no concealed time-oriented property, and all clarifications are parameterized with a settled characteristic. Generally, the retitle administrator μ can be utilized to direct schemas as reasonable.

3.2 Attribute characteristics

The paper differentiates amongst three semantics of the stint-relationship of a standard attribute with a whole mark of time attribute. For a time-oriented stint-relation with schema $(w_1, w_2, w_3, \ldots, w_n, Timestamp)$ the attribute features. Timestamp are assumed as $vt = (v_1, v_2, v_3, \ldots, v_n)$, where $v_i \in \{v, m, a\}$. The values v, a, and m represent persistent, flexible, and nuclear features, correspondingly. For example, $vt = (v, m)$ for the schema (X, Y, Timestamp) represents that X has a persistent features and Y has a flexible features. If numerous time-oriented properties are employed, e.g., substantial stint and exchange stint, a standard characteristics enhanced the highlights over more than one stint. The rest of the paper utilizes just a single stint property T, and V denotes to the features associated with sT.

Definition 1 (*Modification of aspect values*). Let $t = (v_1, v_2, v_3, \ldots, v_n|T)$. be a super tuple over time-oriented schema $(w_1, w_2, w_3, \ldots, w_n, \text{Timestamp})$., U be a whole mark of time, and let $Z = (u_1, u_2, u_3, \ldots, u_n)$. be the aspect value features. The alteration in the aspect values is demarcated as streams:

$$\begin{aligned} &\text{adjct}\ (t, U, Z) = (\text{adjct}\ (t.w_1, t.T, U, u_1), \\ &\ldots, \text{adjct}(t.w_n, t.T, U, u_n), U). \end{aligned} \tag{1}$$

Considering the features Z, the adjct procedure alters every standard aspect value of t to the stint-sphere U and produces the tuple which associates T. For example, for the tuple (Apr, 1000, [2004/03, 2004/12]), the features (v, m), and the time-sphere [2004/05, 2004/06] the adjct procedure yields (Apr, 1000, [2004/05, 2004/06]).

4 Multi-dimensional aggregate operator

4.1 Aggregation clusters

A common time-oriented conglomeration operator should handle the dimension of two orthogonal individualities of conglomeration. Categorization of the artifact assemblages

is done on the basis of fallouts in time-oriented aggregate. The clusters of rows which are named as aggregation cluster significantly represents the stint-relationship with product cluster. Every product cluster can be characterized as a row in a time-oriented stint-relation R with schema $(k_1, k_2, k_3, \ldots, k_n|T)$.. Each k_i. is an element of the time-oriented stint-relation which reflects the reflection of the conglomeration operator; tuples undertake standards from k_i. that ensue in the reflection schema. For the whole mark of time, there are two scenarios: static spans and stable spans. With static spans, the whole mark of time attribute undertakes as values the utmost, non-intersecting spans over which the group of reflection rows is persistent. Intervals to aggregate are represented in Fig. 1.

Definition 2 (*Static spans*). Let v be a time-oriented stint-relation with whole mark of time attribute T. The paper describes the static span of v as:

$$\mathrm{SS(v)} = \{\mathrm{sT}|\forall \mathrm{v} \in \mathrm{v}(\mathrm{v.sT} \supseteq \mathrm{sT''} \vee \mathrm{r.sT} \cap \mathrm{sT'} = \emptyset) \wedge \forall \mathrm{sT'} \supset \mathrm{sT}\left(\exists \mathrm{v} \in \mathrm{v}\left(\mathrm{v.sT} \not\supseteq \mathrm{sT''} \wedge \mathrm{r.sT} \cap \mathrm{sT'} \neq \emptyset\right)\right)\Big\}. \tag{2}$$

The leading portion of the equation confirms that product spans do not cross margins of reflection spans and the subsequent portion of the equation confirms that the product spans are uttermost. The static spans for any time-oriented stint-relation are clustered by its sub-group.

Theorem 1 (Cardinality of static spans). *For a time-oriented stint-relation v with m rows, $m > 0$, the cardinality of static spans is partial by the following equation*:

$$|SS(v)| \leq 2m - 1 \tag{3}$$

Proof The end-points of the rows with whole mark of time can be undeviatingly wl-ordered giving at most 2 m time-points. 'm' time-points yields at most m − 1 successive time spans.

Definition 3 (*Stable spans*). Let v be a time-oriented stint-relation with whole mark of time attribute T. The Stable-span(v), has been described as a user-specified group of time-stamps, that fulfills thetandard temporal

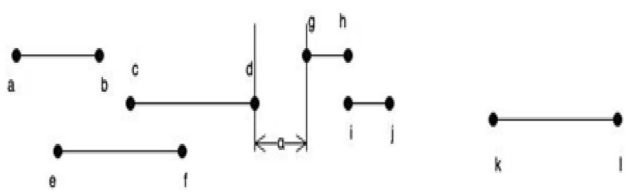

Fig. 1 Intervals to aggregate

statements. These statements describe that stable spans must overlaps with other spans in the time-oriented reflection stint-relation. The categorical ordering of product clusters with stable spans permits control of the cardinality of the artifact schema.

Definition 4 (*Partially quantified product clusters*). A product cluster with schema $(k_1, k_2, k_3, \ldots, k_n)$ is moderately quantified iff the standard of the whole mark of time attribute is not quantified properly. The paper characterizes a partially quantified product row as $v = (k_1, k_2, k_3, \ldots, k_n, [*, *])$.

With partially quantified product clusters in place, the author pushes the conclusion of the product clusters with static spans into the algorithm for the estimation of the time-oriented multi-dimensional conglomeration operator. The incompletely evaluated item pushes are simulated to every single static span for the predictable conglomeration clusters. The cross connection from proclamation that assigns the huge information columns to the static spans is utilized certainly by the estimation of a calculation.

5 Employment of the aggregation operator

5.1 Notion and outline

The work of the collection administrator for static spans is grounded on the various articulations: on the off chance that we analyze the time-situated contention connection, which is very much requested by the span begin time estimations of the lines, whenever point 'pt' assess the item pushes in advance to the point 'pt' (supposing, no columns that begin next to 'pt' added to the item group). Consequently, time-arranged contention connection is being scrutinized, item bunch are framed, and obsolete-columns are also isolated from primary memory. Just the columns those are legitimate at point-stint 'pt'. For the utilization with stable spans, the entire characteristic of time of the item group is measured in the gathering connection. Thus, it isn't compulsory to protect the information pushes in primary memory, however can assess them and refresh the total esteems as we filter the information connection. Data flow of the employment is clearly represented in Fig. 2.

5.2 Algorithm for static span

The algorithm employed for aggregation has five input elements: the cluster stint-relation c, the time-oriented reflection stint-relation t, a list of aggregate procedures $P = \{ p_1, p_2, \ldots, p_n. \}$, a assortment base α, and trait features F. The yield is a period situated connection that incorporates c delayed by the estimations of the total

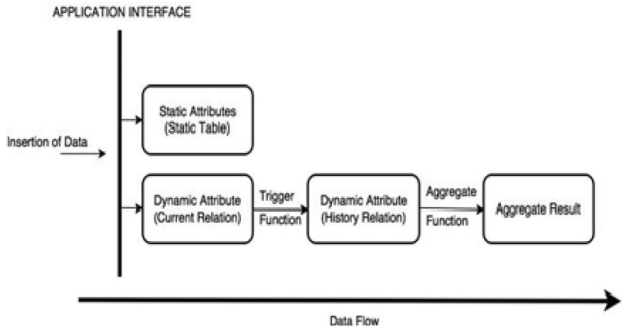

Fig. 2 Data flow

techniques in P. The calculation utilizes two sorts of information assemblies.

The initial step of the calculation is to instate the cluster reflection ct. In the event that c is a proj-reflection over relation, the gathering reflection is at first vacant and will be occupied while scrutinizing the time-situated contention rows. Else, ct is introduced with c, with the begin stint of the records settled to $-\infty$. In conclusion, a record over the non-fleeting properties is created. T succeeding advance is to assess the time-situated contention connection r sequentially on the premise of begin time of the lines. On the off chance that the gathering connection is a social variable based math articulation, we may need to spread the assemblage table with another section before as far as possible all product groups to which information tuple r contributes.

5.3 Algorithm for stable span

The algorithm for the assessment of administrator CT with stable traverse semantics. The key information configuration is the assemblage relation ct that holds the cluster connection c and has a supplementary section named Pi for each time-situated total methods Pi $\in$ P. The item groups, involving their entire sign of time, are entirely measured. The information rows cannot be kept in an end-point assemblage tree.

5.4 Complexity

For the complexity examination of time-oriented aggregate operator, the treatment of the information connection r is proper, which is isolated into four stages: query in the record, manufacture of result lines, refresh of the list and inclusion of the tuple at last point assemblage tree. A refresh list and the query related to the clter reflection have multifaceted nature and order of complexity $\log n_c$, the number of tuples present in the cluster relation is reflected by n_c. The development of a performance outcome push is undeviating as related to the uncovered columns. The support for different trait highlights infers at a cost. For every outcome, it needs a sweep over the entire E-point assemblage tree as well as a change in the characteristic esteems. On the off chance that exclusive static qualities were utilized, the total esteems could be assessed incrementally.

6 Experimental results and analysis

The author executed a number of trials with the static span and stable span algorithms, investigative their presentation for numerous backgrounds. All trials were track on an Intel core i3 with a 1.8 GHz processor and 2 GB memory. The author uses facts stint-schema that comprise from 20,000 to 1, 00,000 entries. The lifecycle of the facts stint-relations is about [0, 2^{20}]. The bunch connection holds one of a kind record. This is a vilest incident since all entire characteristic of time wind up on the comparable E-point assemblage tree. A cluster reflection with extra columns constructed over minor E-point assemblage trees and perform superior. Group partitioning scheme is represented in Fig. 3.

The primary trial examines the versatility of the static spans. The time intricacy depends on the quantity of unclog-tuples and the accumulation encouragement. Connection r-most noticeably awful with the major comprehensible number of unclog-tuples and the most extreme accumulation encouragement for static span has a handling stint that is quadratic in the extent of the information connection. For every other datum gatherings, the preparing stint divulges an undeviating execution. Connection r-measure up to have a collection perspective near 0 despite the fact that the quantity of open tuples is most extreme.

The routine of stable spans isn't misrepresented by crossing columns since the total result is computed augmentation. The indispensable limitation as far as execution is the quantity of upshot assemblages and the efficacy of the current query hone (for every single tuple in r, we should discover all bunches that gratify the standard state

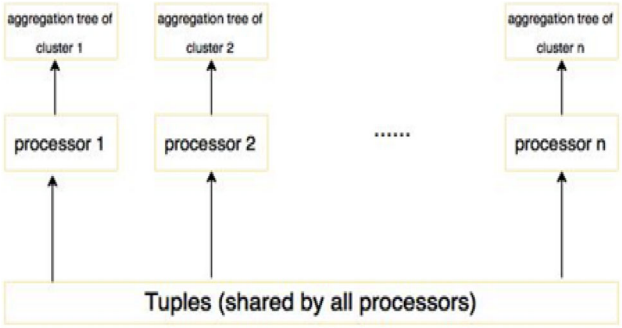

Fig. 3 Group partitioning scheme

and along these lines must be refreshed). Since we utilize AVL-trees for ordering item bunches, the execution increments steeply alongside the quantity of groups. In the event that we utilize hashing, the query time would be stable. In any case, the hashing just backs the fairness conditions.

The execution impact of variable key components on the algorithms utilized by the information connection r-rand is explored. The preparing time of dynamic number of open-tuples is high when contrasted with static one. The execution decays bit by bit since with adaptable properties, all open-tuples must be kept at last point tree. When a static span has been build up, the end-point tree is navigated, the eminence esteems are attuned, and the preceding total strategy is assessed. We have likewise fused the execution of a digressed static spans that backings static characteristics as it were. Static spans are incrementally figures out the totals, and its accomplishment is self-representing the quantity of unclog-tuples as in Fig. 4.

6.1 Static span versus stable span

The result of evaluating aggregates with static span semantics is represented in two ways: (1) with moderately quantified outcome clusters, and (2) a priori calculation of static spans by consuming SQL. The results confirm that static span with moderately quantified outcome clusters is certainly an effective way of evaluating aggregates with static span semantics. The performance of stable span declines as the number of clusters rises as clearly shown in Table 1. Nonetheless, up to an aggregation part of very nearly 46% Stable span outflanks static spans. In this manner, stable spans are effective for sensible aggregation elements, and it licenses to unequivocally control the aggregation factor.

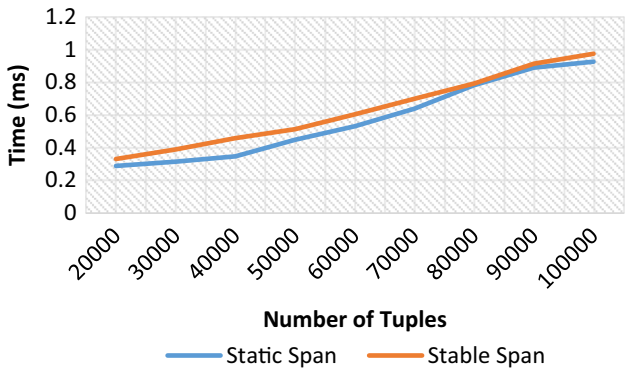

Fig. 4 Performance comparison of static span versus stable span

Table 1 Perfromance comparison of static span vs stable span at each tuple value

Static span		Stable span	
No. of tuples	Time (ms)	No. of tuples	Time (ms)
20,000	0.286	20,000	0.329
30,000	0.312	30,000	0.388
40,000	0.344	40,000	0.457
50,000	0.447	50,000	0.511
60,000	0.529	60,000	0.603
70,000	0.638	70,000	0.698
80,000	0.782	80,000	0.793
90,000	0.889	90,000	0.914
100,000	0.926	100,000	0.975

6.2 Static span versus balanced tree

The very last trial equates static span over the weighted balanced assemblage tree quantified in [3, 5]. The utmost operational procedure come into play, but prompt that it provisions summation, count, or average—it provisions stretchy aspects. Static span supports only static aspects and consents incremental calculation of aggregate standards. While stable span has the similar presentation as the balanced tree algorithm, the trials demonstrate that the provision for numerous stint-aspects features in static span is expensive and the DBMS should recognize circumstances which do not include flexible aspects and stable spans are employed. The recollection investigation of static span hinges on the numeral of unclog-rows.

7 Conclusion and future scope

This paper exhibits a novel time-oriented total administrator that controls most recent headway in multiple dimension query processing to relate with span-esteemed information. The conglomeration administrator streamlines an assorted variety of formerly proposed time-arranged collection administrators. It splits the portrayal of artifact stint-clusters from the explanation of conglomeration assemblages, i.e., the congregations of stint-oriented valued tuples that are linked with the artifact clusters and over which the time-oriented conglomeration procedures are evaluated. This prompts a definite informative system that licenses additionally to direct the extent of the result connection. Consequently, the conglomeration operator provision multiple time-oriented aspect features, embracing stretchy values which embrace aspect standards have to be attuned if the rows time-value altered. Lastly, the author delivers two dissimilar algorithms for the assessment of the

aggregation operator with static span and stable span, correspondingly. Comprehensive trial evaluated over the procedures which are climbable with reverence to facts group extent and associate well with other time-oriented aggregation algorithms. The appraisal additionally exposes that the help for several property determines at a cost. Future work includes various enhancement phases in static and stable span calculations, containing the following ones: improvement procedures for stint-relational algebra expressions that interrelate with the conglomeration administrator, the introduction of the cluster relation on the fly, indexes on the cluster relation, and a variety of the E-point assemblage tree that does not entail a completely arranged information connection.

***Abstract*—Node classification is a technique to assign node labels using the network topology and various node features. Many techniques like random walk-based method, label propagation graph regularizations are proposed in this research. Network embedding is a popular method to capture graph structure in low dimensional vector space and can capture the features of the nodes properly. In this paper, the popular embedding techniques are visualized on various data-sets and introduce the idea of network embedding techniques to perform the node classification task.**

***Index Terms*—Label propagation, Network embedding, Node classification, Online Social Networks, Random walk.**

I. INTRODUCTION

Node classification [1,2,3] is one of the most popular techniques, which is aimed to determine the labels of the vertices (nodes) of the network according to the other labelled vertices (nodes) and the structure of network graph. Many times, in a network, only a part of total nodes is labelled. There can be many reasons behind the unknown labels for a larger number of nodes so it becomes extremely essential to classify these nodes to acquire knowledge about their characteristics and behaviour. The labelled nodes and the links can be used to infer the missing labels.

The Node Classification problem can be stated as: providing a social network (or any other network structure) where some of the nodes are labeled and rest unlabeled, in what way estimate a good quality labeling for each node of the network. This problem is called the "node classification problem", fundamental problem being providing labeling for each node in a network.

Problem Statement:

Given a graph **G (V, E, W)**

V is the set of all nodes in the graph (—V— = n)

E is the set of edges in the graph

W is the weight matrix of the graph

Let **Vl** represent the labelled subset of V

Vu = (V - Vl) represents the set of unlabelled nodes

Let **Y** represent the set of all possible labels (be m)

Let **Yl** be the set of initial labels given on nodes of set Vl. To solve the problem, our method uses the information already available in the partly labeled network to predict labels for the rest of the nodes. Our goal is to train the classifier using the nodes that are pre labeled. Then the trained classifier is used to label the unlabeled nodes and also to nodes that already have some labels to augment their existing labels.

II. NETWORK OR GRAPH EMBEDDING

Transforming graph properties into vector space is Graph Embedding. Embedding must capture the geometric structure of graph, its vertex-to-vertex connection, and all other appropriate information about the graph and its vertices.

A. Methods used for Graph Embedding

1) DeepWalk[9]

DeepWalk is a random-walk based network embedding procedure. Random walks begin from a chosen node then moving to random neighbors at each step for a defined number of times. DeepWalk consists of 3 basic steps:

a) Sampling (Sampling of graph with random walks)

b) Training the skip-gram network (Skip-Gram network accepts node as one-hot-vector and maximizes the chances of predicting its neighbor nodes)

c) Computing the Embeddings (the hidden layer of the trained network is used as the embedding)

2) LINE [10]

Large-scale Information Network Embedding (LINE) defines two basic functions for first and second order proximity. These are explained below:

a) First Order Proximity refers to similarity between two nodes if they are connected by an edge.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 16,2020 at 05:51:46 UTC from IEEE Xplore. Restrictions apply.

b) Second Order Proximity refers to similarity of two nodes' neighborhood's structure.

3) Node2Vec [11]

Node2Vec is similar to DeepWalk with the addition of biasing in random walks over the discovery of larger neighborhood or discovery of microscopic view around the node. Two parameters P and Q were introduced to control the probability of returning to the previous node and discovering the undiscovered part of the network respectively. All other steps (Training, computing Embeddings) is same as DeepWalk.

4) SDNE [12]

Structural Deep Network Embedding (SDNE) does not use random walks and is designed to preserve the first and second-order proximity on nodes in the embeddings.

SDNE uses an autoencoder neural net consisting of two parts Two (left and right) Vanilla auto encoders which accepts node adjacency vectors and learn the second order proximity.

5) Struc2Vec [13]

Struc2Vec embeds a network using node's structural identity. The idea is to construct a meta-graph which encodes the structural information of the graph of interest, and then use random walks from every node in this meta-graph to determine the contexts.

Struc2Vec has four basic steps:

a) Determine the structural similarity between every pair of nodes of the network, over different neighborhood sizes.

b) Construct a weighted multi layered graph where each layer of this graph relates to a level in hierarchy determining the structural similarity.

c) Use this multi layered graph to generate context for every node in the network based on biased random walks.

d) Use standard techniques to learn a latent representation from this context.

III. METHODOLOGY

A. Algorithm

Using the idea of network embedding techniques followed by label propagation and regression for classification and a proper mixture of test and training data, an algorithm for node classification is proposed which works as follows:

Input: Graph (G)
Output: Accuracy Score, F1_score

NodeClassification(G)
G ← DiGraph(edge_list)
model ← EmbeddingTechnique(G)
model.train(window_size, iter)
embeddings ← model.get_embeddings()
for embedding in embeddings
evaluate_embedding(embedding)
plot_embedding(embedding)
evaluate_embeddings(embedding):
X, Y ← read_node_labels(label _list)
tr_frac ← 0.8
clf ← classifier(embedding, clf = LogisticRegression())
clf.evaluate(Y_test, Y_predicted, trac_frac)
label_propagation(G)
label_prop_model←labelPropagation()
label_prop_model.fit(X_train,y_train)
prediction ← label_prop_model.predict(X_test)
evaluate(Y_test, prediction)

The graph is given as an input to the algorithm in step 2, which is converted to lower dimensions using different graph embedding techniques in step 3 and 4. Step 4 trains the model to evaluate embeddings. Plot_embedding is used to plot the reduced vector form in pictorial form. Evaluate_embeddings function in step 9 is used to classify nodes by logistic regression in which tr_fact is the fraction of pre-labelled dataset that is the number of nodes which are already labelled. Step 13 evaluates the predicted labels and gives accuracy and f1_score as output. Similarly, in function 'label_propagation' (step 14), 80% nodes are used to predict the labels of remaining nodes and again the predicted labels are evaluated in step 18.

A directed graph is constructed using the edge list for various datasets like karate, wiki etc and have used 80% of the nodes for training our model and then used it to classify the remaining 20% nodes using various methods. Initially, classified using label propagation in which each node checks for the labels of its neighbors and then adopts the label with highest frequency.

Then tried to classify nodes using feature- based methods and then applying logistic regression to classify them. In non-embedded graph the neighbor list is considered as the features of the node, however in embedded graph the dimensionality is used a feature list and then after the again using 80% of the classified nodes have tried to classify the rest 20% of the nodes. In order to classify using logistic regression, used OneVsAll classifier in which one classifier is fitted per class. Interpretability is the main advantage of this classifier as the inspection of classifier will give the knowledge of the class as each class is represented by one classifier.

A comprehensive comparison of various classification techniques is shown and suitability of different embedding techniques for different datasets and have also proved the scalability problem of old classifying methods as the size of dataset increases the gap between the evaluation score of embedded and non-embedded graph also increases substantially, however the evaluation score was quite compa-rable in smaller datasets.

B. Evaluation Metrices

- **Accuracy score:** In classification, this function computes subset accuracy: the set of labels predicted for a sample must exactly match the corresponding set of labels in y true i.e. true labels.
- **F1 score** F-score or F-measure are the equivalent terms of F1 score. The weighted average of the recall and precision is interpreted as F1 score. The best value of F1_ score is 1 whereas worse is 0. Equal weightage is given precision and recall. Mathematically, it can be stated as:

F1 = (recall * precision) * 2 / (recall + precision)

a) Micro Metrics are calculated over the global domain by counting the total number of false negatives, false positives and true positives.
b) Macro Metrics are calculated for every label and their unweighted mean is found. The label imbalance is not taken into account

IV. Result

Evaluation and comparisons of node classification using both non-embedded and embedded graphs. The graph was embedded using different techniques mentioned above in Section 2.1. The metrics mentioned in Section 3.2 are used to evaluate and compare the results obtained.

Application of Label Propagation on various datasets without the use of any embedding techniques produced results shown in Table 1. The values obtained are one of the lowest showing limitations of Label Propagation on big datasets. Using Logistic Regression on non-embedded graphs shows slight improvement over previous Label Propagation, shown in Table 2.Various graph embedding techniques are used in the proposed algorithm and results are obtained showing improvements over previous approaches. Results with graph embeddings are shown from Table 3 through Table 8.

Traditional methods of node classification may not scale well with the increasing size of the network. This is also evident by observing the value of F1_score and accuracy below as they are comparable in smaller datasets such as karate and flight but as the size of the dataset increases the F1_score and accuracy of embedded graphs is much better than that of non-embedded graphs like in wiki data set, classification using logistic regression gave 32.6% better results when applied on embedded graph(LINE embedding technique) than non-embedded graph by considering neighbors as features. Classification of wiki data set using logistic regression on embedded graph gave 86.4% better results than label propagation on non-embedded graph. Similarly, on comparing the struc2vec embedding of flight (Brazil) dataset and found that the accuracy score is 61.36% better than that of non-embedded one.

CONCLUSION AND FUTURE WORK

In this paper, various approaches to node classification techniques are analyzed using label propagation on non-embedded graphs and logistic regression on both embedded and non-embedded graphs. Node classification using logistic regression on embedded graphs gives better results than both logistic regression and label propagation on non-embedded graphs. Various embedding techniques work best for different data sets because of their methods of feature generation i.e., dimensionality. For example, struc2vec works best on flight networks which are identified by the network structure however LINE, SDNE and node2vec gave better results on large data sets such as wiki dataset. The results obtained after embedding are quite significant and give commendable results. The embedding techniques can be further used for link prediction i.e., predicting the missing links which can be used for building a recommendation engine, Graph reconstruction. The node classification efficiency can be further enhanced using a neural network, which can greatly capture the characteristic dynamics of the network, by training the network data-sets.

ORIGINAL PAPER

Nonlinear dynamics of a time-delayed epidemic model with two explicit aware classes, saturated incidences, and treatment

Kanica Goel · Abhishek Kumar · Nilam

Received: 28 April 2020 / Accepted: 10 June 2020

Abstract Whenever a disease emerges, awareness in susceptibles prompts them to take preventive measures, which influence individuals' behaviors. Therefore, we present and analyze a time-delayed epidemic model in which class of susceptible individuals is divided into three subclasses: unaware susceptibles, fully aware susceptibles, and partially aware susceptibles to the disease, respectively, which emphasizes to consider three explicit incidences. The saturated type of incidence rates and treatment rate of infectives are deliberated herein. The mathematical analysis shows that the model has two equilibria: disease-free and endemic. We derive the basic reproduction number R_0 of the model and study the stability behavior of the model at both disease-free and endemic equilibria. Through analysis, it is demonstrated that the disease-free equilibrium is locally asymptotically stable when $R_0 < 1$, unstable when $R_0 > 1$, and linearly neutrally stable when $R_0 = 1$ for the time delay $\varrho > 0$. Further, an undelayed epidemic model is studied when $R_0 = 1$, which reveals that the model exhibits forward and backward bifurcations under specific conditions, which also has important implications in the study of disease transmission dynamics. Moreover, we investigate the stability behavior of the endemic equilibrium and show that Hopf bifurcation occurs near endemic equilibrium when we choose time delay as a bifurcation parameter. Lastly, numerical simulations are performed in support of our analytical results.

1 Introduction

The last two decades have seen several large-scale epidemics outbreaks such as Ebola, SARS, Zika virus, and swine flu, which leads to low socioeconomic status and inadequate access to health care. People get information about these outbreaks quite quickly due to significant advances in social media, which can have an insightful effect on the actual epidemic dynamics [17,31]. Therefore, at the beginning of an epidemic outbreak, the initial step is to make the individuals aware of the disease and its preventive methods. Awareness programs can alert the susceptible population toward the

Published online: 04 July 2020

contagious disease [23]. If susceptible individuals have adequate knowledge and proper information about the infection, then they take precautionary measures such as regular hand sanitization, the use of face masks, wear hand gloves, vaccination, and even quarantine, which can reduce the impact of illness, for instance, ranging from the plague outbreak in the English village of Eyam in 1665–1666 [9], where the town completely sealed itself off to prevent further transmission of plague, to more recent outbreaks of swine influenza [17] and Ebola [31]. In the situation of rural health services, the challenge of government health-care scheme is that there are numerous gaps in primary health services, and the health-care facilities are mainly urban centric. The rural residents may have low health knowledge awareness, and their receiving way of health knowledge can be traditional and straightforward. Knowledge level increases with higher education levels; therefore, one of the main factors is their education level. Therefore, a lot of people are not fully but partially aware of the spread and control of infectious diseases. Due to partial awareness, some individuals often medicate themselves adopting antibiotics, even when advised against doing so which weakens their immune system makes them at a high risk of catching the infection [18]. Therefore, complete awareness about the cycle of disease, along with the utilization of appropriate precautions and adequate decontamination procedures, is vital. Full awareness of the disease in humans develops a habit of taking precautionary measures against it, and they follow the instructions given by health workers and government and lower their risk of becoming infected.

In the study of the transmission of infectious diseases, the incidence rate has a vital role as it determines the number of infectives per unit of time. In 1927, Kermack Mckendrick considered the bilinear incidence rate, which follows the law of mass action [1]. In the bilinear incidence rate, the number of infectives linearly increases, which might be real for a small population of infected individuals, but it is impractical for a large number of infectives. Therefore, several studies are devoted to consider nonlinear incidence rate for disease transmission dynamics (e.g., [2,3,15,16,26,34–40]. In the present study, we have incorporated the nonlinear saturated incidence rate, where the interaction term is of the form $Sg(I)$, $g(I) = \beta I/(1 + \varepsilon I)$. Here, βI measures the force of infection, and $1/(1 + \varepsilon I)$ measures the inhibition effect of the behavioral change of the susceptibles when their number increases and crowding effect of the infective individuals [2,22]. In this incidence rate, the number of infectives depends on the nonlinear bounded map $g(I)$, which tends to saturation level β/ε when I gets large. It prevents the unboundedness of the contact rate as it includes the psychological effects and, thus, more realistic than the bilinear incidence rate.

Treatment is vital to cure the infection and prevent the development of resistant bacteria. Therefore, consideration of the treatment rate in the epidemic model is of great importance. In 2004, Wang and Ruan [10] studied the SIR epidemic model with the constant treatment rate and showed various bifurcations. The consideration of constant treatment rate might be real when there are small infected populations because there are limited medical resources available in society. Therefore, in 2012, Zhou and Fan [24] improved the treatment rate by considering Holling type II functional response as given below:

$$h(I) = \frac{\beta I}{1 + \alpha I}, \quad I \geq 0, \quad \beta \geq 0, \quad \alpha \geq 0.$$

and explore the SIR epidemic model to understand the effect of the limited medical resources and their supply efficiency on the transmission of infectious diseases. Motivated by the work mentioned above, we deliberate the Holling type II treatment rate (also called saturated treatment rate) and study the effect of treatment rate with limited medical resources in the current epidemic model.

The inclusion of time delay in the study of epidemiology is an important aspect. Persons with asymptomatic infections play an essential role in the spread of infectious disease, especially as they are unaware of their infection and therefore take no special hygiene precautions. Thus, the study of epidemiology involves time delay, which needs to be considered for practical purposes. The inclusion of time delay may arise due to delays caused by the latency in a vector and delay caused by a latent period in the host [4]. Recently, many mathematical models studied the impact of time delay in their epidemic model [7,13,35–37,40].

The impact of information and awareness on the spread of epidemics has been studied by many authors [14,19–21,27–29,33,34]. Funk et al. [19] considered the aware susceptible and aware infected populations in their epidemic model, on the assumption that the

aware susceptibles will be at a lower rate of catching the infection than the unaware susceptibles, and studied that disease dynamics in a well-mixed population. Kiss et al. [20] studied the effect of information transmission on the dynamics of sexually transmitted diseases. They assumed that the entire population is aware of the risk of infection; however, only a specific portion decides to react by constraining their contact with contaminated people. Misra et al. and Dubey et al. [21,34] investigated the impact of awareness programs on the transmission dynamics of infectious diseases in their nonlinear epidemic models. Some researchers studied the impact of awareness on the disease transmission dynamics along with the influence of time delay. Zuo et al. [29] introduced a time delay in the media variable to emphasize the delay in reporting cases of infections. Zhao et al. [27] studied the SIRS epidemic model by incorporating time delay in media coverage. Zuo and Liu [28] studied the effect of awareness programs driven by media and the delay on the prevalence of the infectious disease. In all these models, the study reveals that the disease-free equilibrium (DFE) is stable when a basic reproduction number R_0 is less than one, unstable when $R_0 > 1$, irrespective of the value of the time delay, and has a stable endemic equilibrium for time delay equals to zero. In the study of Zuo et al. [29], Zhao et al. [27], and Misra et al. [21], the occurrence of Hopf bifurcation is shown for the particular value of the time delay. Greenhalgh et al. [33] included two delays, one in reporting of infected cases and another delay representing the loss of disease awareness after a fixed period. Their study reveals the reduction in infected individuals with an increment in the duration of awareness. It is also shown that both the time delays can produce oscillations and destabilize the endemic equilibrium.

The public is a coalition of many subgroups of individuals with vastly different social, educational, and economic backgrounds. During an outbreak, people adopt full or partial awareness, depending on the understanding of how they perceive risks, and communicate about the effectiveness of protective measures. Therefore, instead of going directly from susceptible to infected class, we introduce fully aware and partial aware susceptible compartments into the SIR epidemic model due to heterogeneous protection level and extend the epidemic model to include the behavioral change of susceptibles, which can change the transmission patterns and reduce the prevalence of disease to the more extent. The precaution level of susceptible individuals is heterogeneous as they may take different levels of precautions to protect themselves from being infected based on the severity of epidemics or their characteristics. We consider three specific nonlinear incidence rates of unaware susceptibles, fully aware susceptibles, and partially aware susceptible, respectively, with the inclusion of time delay as a latent phase having a fixed duration. Also, with awareness, treatment to infectives is essential to mitigate the infection. Therefore, we consider the nonlinear saturated treatment rate, which includes the fact of limitation in the availability of resources. We formulate the nonlinear time-delayed mathematical epidemic model and perform the stability analysis to demonstrate the eradication or persistence of the disease with the help of the basic reproduction number R_0 for the time delay $\varrho \geq 0$. The bifurcation theory approach using the center manifold theory is performed, revealing the existence of backward and forward bifurcations, which shows that reducing R_0 below unity is not sufficient to eradicate the disease due to the presence of backward bifurcation, which has an important implication in the study of disease dynamics. Further, choosing time delay as a bifurcation parameter, the periodic and oscillatory solutions appear via Hopf bifurcation. Moreover, the numerical experiments show the importance of considering full and aware susceptible individuals and nonlinear terms such as time delay, incidences, and treatment.

The rest of the manuscript is organized as follows: The model and its basic properties are presented in Sect. 2. In Sect. 3, the existence of disease-free and endemic equilibria is presented, and stability analysis is performed using the basic reproduction number. The conditions for the backward and forward bifurcations are derived. Also, the existence of stability switches is shown via the presence of Hopf bifurcation by choosing the time delay as a bifurcation parameter. In Sect. 4, numerical simulations are presented to signify the theoretical results. Lastly, Sect. 5 is devoted to a brief discussion.

2 Mathematical model and basic properties

We assume that N denotes the total constant population, and it is divided into five compartments according to the disease status: unaware susceptible class $S(t)$, fully aware class $A_F(t)$, partially aware class $A_P(t)$, infected individuals class $I(t)$, and removed individu-

als class $R(t)$. The unaware susceptible class consists of those individuals who are vulnerable to the disease and taking no precautions against it. A fully aware susceptible class involves those individuals who have adequate knowledge and proper information about the spread of the disease and taking precautionary measures against it. Partially aware susceptibles consist of those individuals who have an incomplete understanding of the spread and prevention of the disease and have low resources available to escape from the infection. Including a behavioral response among unaware susceptibles would unavoidably call for response among fully aware susceptibles and partially aware susceptibles. Therefore, we have considered three explicit same functional types of saturated incidence rates described below:

(i) $F_1(S(t-\varrho), I(t-\varrho)) = (\beta_1 S(t-\varrho) I(t-\varrho))/(1+\varepsilon I(t-\varrho))$, representing the saturated incidence rate among unaware susceptibles,

(ii) $F_2(A_F(t-\varrho), I(t-\varrho)) = (\beta_2 A_F(t-\varrho) I(t-\varrho))/(1+\varepsilon I(t-\varrho))$, representing the saturated incidence rate among fully aware susceptibles,

(iii) $F_3(A_P(t-\varrho), I(t-\varrho)) = (\beta_2 A_F(t-\varrho) I(t-\varrho))/(1+\varepsilon I(t-\varrho))$, representing the saturated incidence rate among partially aware susceptibles,

where ϱ denotes the time delay, representing the latent period. The latent period is defined as the period between exposure and infection, since the pathogen is present in a latent stage, without clinical symptoms or signs of infection in the host. The delay term in $S(t)$, $A_F(t)$, and $A_P(t)$ is introduced because people, who are unaware, fully aware, or partially aware of the disease may consider themselves in their respective classes after becoming infected. We assume that such individuals are in the latent period.

Let κ denote the constant rate of inflow of new unaware susceptibles due to the recruitment of new members by the current members or immigration. Let δ_1 denote the rate at which unaware susceptibles $S(t)$ become fully aware. δ_2 denotes the rate at which $S(t)$ becomes partially aware of the disease. The parameters β_1, β_2, and β_3 are the transmission rates of infection of unaware, fully aware, and partially aware susceptible populations, respectively. We suppose that all the susceptible classes can become infected by contact with infected individuals, but the fully aware class has less chance to be infected as compared to the unaware susceptible and partially aware susceptible individuals [33]. Therefore, it is assumed that β_1 and β_3 are greater β_2. The parameter ε represents the behavioral changes or measures of inhibition adopted by infectives. ϑ denotes the natural mortality rate of all individuals, whereas d and θ denote the disease-induced mortality rate and recovery rate of the infectives, respectively. The function $h(I(t)) = aI/(1+bI)$ represents the treatment rate of infectives, where a and b denote the cure rate and limitation rate in the availability of resources, respectively. The symbols and description of the parameters and state variables are given in Table 1 briefly.

The flow diagram of the proposed epidemic model is given in Fig. 1, and model is represented mathematically under the following system of delay differential equations:

$$\begin{aligned}
\frac{\mathrm{d}S}{\mathrm{d}t} &= \kappa - \delta_1 S - \delta_2 S - \frac{\beta_1 S(t-\varrho) I(t-\varrho)}{1+\varepsilon I(t-\varrho)} - \vartheta S,\\
\frac{\mathrm{d}A_F}{\mathrm{d}t} &= \delta_1 S - \frac{\beta_2 I(t-\varrho) A_F(t-\varrho)}{1+\varepsilon I(t-\varrho)} - \vartheta A_F,\\
\frac{\mathrm{d}A_P}{\mathrm{d}t} &= \delta_2 S - \frac{\beta_3 I(t-\varrho) A_P(t-\varrho)}{1+\varepsilon I(t-\varrho)} - \vartheta A_P,\\
\frac{\mathrm{d}I}{\mathrm{d}t} &= \frac{\beta_1 S(t-\varrho) I(t-\varrho)}{1+\varepsilon I(t-\varrho)} + \frac{\beta_2 I(t-\varrho) A_F(t-\varrho)}{1+\varepsilon I(t-\varrho)}\\
&\quad + \frac{\beta_3 I A_P(t-\varrho)}{1+\varepsilon I(t-\varrho)} - (d+\theta+\vartheta) I - \frac{aI}{1+bI},\\
\frac{\mathrm{d}R}{\mathrm{d}t} &= \theta I + \frac{aI}{1+bI} - \vartheta R.
\end{aligned} \tag{1}$$

Suppose that the initial conditions of the model (1) take the form

$$\begin{aligned}
&S(\nu) = \chi_1(\nu),\ A_F(\nu) = \chi_2(\nu),\ A_P(\nu) = \chi_3(\nu),\\
&I(\nu) = \chi_4(\nu),\ R(\nu) = \chi_5(\nu),\\
&\chi_i(\nu).\ \nu \in [-\varrho,\ 0],\ \chi_i(0) > 0\ (i = 1, 2, 3, 4, 5),
\end{aligned} \tag{2}$$

where $(\chi_1(\nu), \chi_2(\nu), \chi_3(\nu), \chi_4(\nu), \chi_5(\nu)) \in C([-\varrho, 0], \mathbb{R}^5_+)$, which is the Banach space of continuous functions mapping the interval $[-\varrho, 0]$ into $\mathbb{R}^5_+$, where

$$\begin{aligned}
\mathbb{R}^5_+ = \{&(S, A_F, A_P, I, R)\,/S \geq 0, A_F \geq 0,\\
&A_P \geq 0, I \geq 0, R \geq 0\}.
\end{aligned}$$

Using Proposition 2.3 in [32] and Proposition 2.1 in [25], it follows that all state variables of the model (1) are nonnegative, i.e., $(S, A_F, A_P, I, R) \in \mathbb{R}^5_+$. For

Table 1 Notations of model variables and parameters

Symbol	Description
N	Total constant population
$S(t)$	Unaware susceptibles
$A_F(t)$	Fully aware susceptibles
$A_P(t)$	Partially aware susceptibles
$I(t)$	Infected population
$R(t)$	Removed population
ϱ	Latent period (time delay)
κ	Constant recruitment rate of unaware susceptibles
β_1	Transmission rate of susceptibles to infected individuals
β_2	Transmission rate of fully aware to infected individuals
β_3	Transmission rate of partially aware to infected individuals
ε	Inhibition measures by infectives
δ_1	Rate of full awareness in unaware susceptibles
δ_2	Rate of partial awareness in unaware susceptibles
ϑ	Natural death rate
d	Disease-induced death rate
θ	Recovery rate
a	Cure rate
b	Rate of limitations in treatment availability

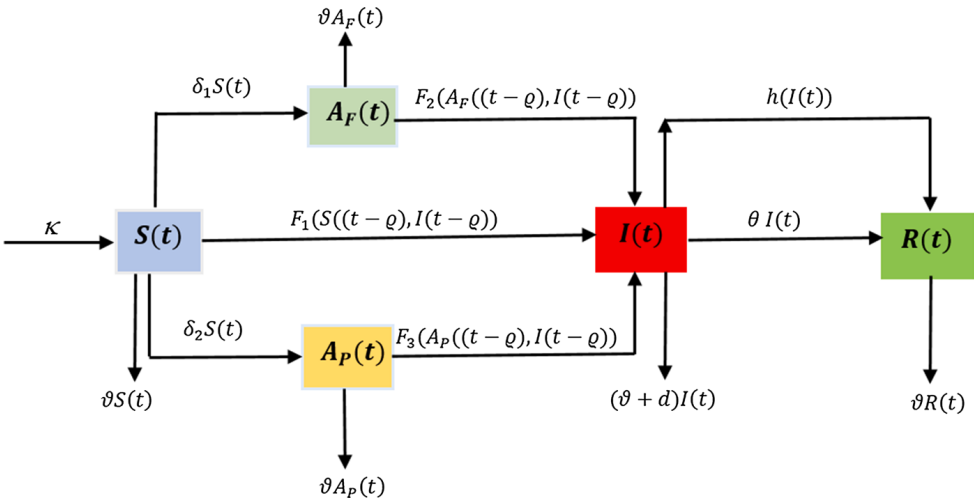

Fig. 1 Flow diagram of the model (1)

biological reasons, we assume that the model parameters κ, δ_1, δ_2 β_1, β_2, β_3, ε, ϑ, θ, d, a, b are positive. By the fundamental theory of functional differential equations [6], the model (1) has a unique solution $(S(t)\, A_F(t), A_P(t), I(t), R(t))$ satisfying the initial conditions (2).

Lemma 1 *The compact set*

$$\Omega = \left\{(S(t), A_F(t), A_P(t), I(t), R(t)) \in \mathbb{R}^5_+ : S(t) + A_F(t) + A_P(t) + I(t) + R(t) \leq \frac{\kappa}{\vartheta}\right\}$$

is invariant for the solutions of the model (1).

Proof Since the right-hand side of the model (1) and its derivatives are continuous, it assures the well-posedness of the model (1).

On adding the equations of the model (1), we get

$$\begin{aligned}&\frac{\mathrm{d}}{\mathrm{d}t}\left(S(t)+A_F(t)+A_P(t)+I(t)+R(t)\right)\\&=\kappa-\vartheta\left(S(t)+A_F(t)+A_P(t)\right.\\&\quad\left.+I(t)+R(t)\right)-dI\\&\leq\kappa-\vartheta\left(S(t)+A_F(t)+A_P(t)+I(t)+R(t)\right).\end{aligned}\tag{3}$$

Thus, the invariant region for the existence of the solutions is given as

$$0<\lim_{t\to\infty}\left(S(t)+A_F(t)+A_P(t)+I(t)+R(t)\right)\leq\frac{\kappa}{\vartheta}.\tag{4}$$

Hence, the solution of the model (1) is compact. □

In the next section, we obtain the model's equilibria and perform stability analysis to investigate the behavior of the equilibrium points.

3 Mathematical Analysis

Since $R(t)$ does not appear in the first four equations of the model (1), without loss of generality, it is sufficient to consider first four equations of the model for the analysis purpose:

$$\begin{aligned}\frac{\mathrm{d}S}{\mathrm{d}t}&=\kappa-\delta_1S-\delta_2S-\frac{\beta_1S(t-\varrho)I(t-\varrho)}{1+\varepsilon I(t-\varrho)}-\vartheta S,\\\frac{\mathrm{d}A_F}{\mathrm{d}t}&=\delta_1S-\frac{\beta_2I(t-\varrho)A_F(t-\varrho)}{1+\varepsilon I(t-\varrho)}-\vartheta A_F,\\\frac{\mathrm{d}A_P}{\mathrm{d}t}&=\delta_2S-\frac{\beta_3I(t-\varrho)A_P(t-\varrho)}{1+\varepsilon I(t-\varrho)}-\vartheta A_P,\\\frac{\mathrm{d}I}{\mathrm{d}t}&=\frac{\beta_1S(t-\varrho)I(t-\varrho)}{1+\varepsilon I(t-\varrho)}+\frac{\beta_2I(t-\varrho)A_F(t-\varrho)}{1+\varepsilon I(t-\varrho)}\\&\quad+\frac{\beta_3IA_P(t-\varrho)}{1+\varepsilon I(t-\varrho)}-(d+\theta+\vartheta)I-\frac{aI}{1+bI}.\end{aligned}\tag{5}$$

For the existence of model equilibrium, we set the right-hand side terms of the (5) to zero and obtain that the model (5) has two equilibria given below:

1. Disease-free equilibrium $E_0(S_0, A_{F_0}, A_{P_0}, 0)$ (represents the eradication of infected individuals, i.e., $I\equiv 0$ for all $t>0$), discussed in Sect. 3.1.
2. Endemic equilibrium $E_e(S^*, A_F^*, A_P^*, I^*)$ (represents the persistence of infected individuals above a certain positive level, i.e., $I>0$ for all $t>0$), discussed in Sect. 3.2.

3.1 Disease-free equilibrium

The system (5) has a disease-free equilibrium of the form $E_0(S_0, A_{F_0}, A_{P_0}, 0)$, where

$$S_0=\frac{\kappa}{\delta_1+\delta_2+\vartheta},\ A_{F_0}=\frac{\delta_1\kappa}{\vartheta(\delta_1+\delta_2+\vartheta)},$$
$$A_{P_0}=\frac{\delta_2\kappa}{\vartheta(\delta_1+\delta_2+\vartheta)}.$$

The characteristic equation of the system (5) at disease-free equilibrium is obtained as

$$\begin{aligned}&(-\vartheta-\lambda)^2\left(-\delta_1-\delta_2-\vartheta-\lambda\right)\left(\lambda+(\vartheta+d+\theta+a)\right.\\&\left.-\left(\beta_1S_0+\beta_2A_{F_0}+\beta_3A_{P_0}\right)\mathrm{e}^{-\lambda\varrho}\right)=0.\end{aligned}\tag{6}$$

Equation (6) is fourth-degree transcendental equation in λ with roots $\lambda_1=-\vartheta$, $\lambda_2=-\vartheta$, $\lambda_3=-(\delta_1+\delta_2+\vartheta)$, and the other roots are the solution of

$$\begin{aligned}&\lambda+(\vartheta+d+\theta+a)\\&-\left(\beta_1S_0+\beta_2A_{F_0}+\beta_3A_{P_0}\right)\mathrm{e}^{-\lambda\varrho}=0.\end{aligned}\tag{7}$$

On simplification, Eq. (7) can be written as

$$\begin{aligned}X(\lambda):=\lambda+(\vartheta+d+\theta+a)\\-\frac{\kappa\left(\beta_1\vartheta+\beta_2\delta_1+\beta_3\delta_2\right)}{\vartheta\left(\delta_1+\delta_2+\vartheta\right)}\mathrm{e}^{-\lambda\varrho}=0.\end{aligned}\tag{8}$$

The term $\frac{\kappa(\beta_1\vartheta+\beta_2\delta_1+\beta_3\delta_2)}{\vartheta(\vartheta+d+\theta+a)(\delta_1+\delta_2+\vartheta)}\mathrm{e}^{-\lambda\varrho}$ at $\varrho=0$ is defined as the basic reproduction number of the system (5). Thus, the basic reproduction number of the system (5) is

$$R_0=\frac{\kappa\left(\beta_1\vartheta+\beta_2\delta_1+\beta_3\delta_2\right)}{\vartheta\left(\vartheta+d+\theta+a\right)\left(\delta_1+\delta_2+\vartheta\right)}.$$

The basic reproduction number R_0 is the average number of secondary infections caused by a single infected agent, during his/her entire infectious period, in an entirely susceptible population [8].

3.1.1 Analysis for $\mathbf{R_0\neq 1}$

As mentioned above, Eq. (6) has three negative real roots $\lambda_1=-\vartheta$, $\lambda_2=-\vartheta$, $\lambda_3=-(\delta_1+\delta_2+\vartheta)$, and other roots are the solutions of Eq. (8).

Note that

$$X(0)=(\vartheta+d+\theta+a)\,(1-R_0).\tag{9}$$

If $R_0 > 1$, then $X(0) < 0$. Also,

$$X'(\lambda) = 1 + \frac{\kappa\,(\beta_1\vartheta + \beta_2\delta_1 + \beta_3\delta_2)}{\vartheta\,(\delta_1 + \delta_2 + \vartheta)}\mathrm{e}^{-\lambda\varrho}\varrho > 0. \quad (10)$$

Thus, $\lim_{\lambda\to\infty} X(\lambda) = +\infty$.

Hence, $X(\lambda) = 0$, $X(0) < 0$, $X'(\lambda) > 0$, and $\lim_{\lambda\to\infty} X(\lambda) = +\infty$ indicate that there always exists a unique and positive real root of $X(\lambda) = 0$ if $R_0 > 1$.

Now, if $R_0 < 1$, then

$$\begin{aligned}\mathrm{Re}\ \lambda &= \frac{\kappa\,(\beta_1\vartheta + \beta_2\delta_1 + \beta_3\delta_2)\,\mathrm{e}^{-(\mathrm{Re}\ \lambda)\varrho}\cos(Im\lambda)\varrho}{\vartheta\,(\delta_1 + \delta_2 + \vartheta)} \\ &\quad - (\vartheta + d + \theta + a) \\ &< \frac{\kappa\,(\beta_1\vartheta + \beta_2\delta_1 + \beta_3\delta_2)}{\vartheta\,(\delta_1 + \delta_2 + \vartheta)} - (\vartheta + d + \theta + a) \\ &= (\vartheta + d + \theta + a)\,(R_0 - 1) \\ &< 0. \end{aligned} \quad (11)$$

Therefore, $R_0 < 1$ implies that λ is a root of Eq. (6) with negative real part.

3.1.2 Analysis at $\mathbf{R_0 = 1}$

In this subsection, the system (5) is analyzed at $E_0(S_0, A_{F_0}, A_{P_0}, 0)$ and $R_0 = 1$ for the time delay $\varrho \geq 0$.

Case (i) $\varrho > 0$

If $R_0 = 1$, then $\lambda = 0$ is a simple characteristic root of Eq. (8). Note that $R_0 = 1$ implies that $\kappa\,(\beta_1\vartheta + \beta_2\delta_1 + \beta_3\delta_2) = \vartheta\,(\vartheta + d + \theta + a)\,(\delta_1 + \delta_2 + \vartheta)$.

Let $\lambda = r + is$ be any of the other solutions, then (8) becomes:

$$\begin{aligned} &r + \mathrm{i}s + (\vartheta + d + \theta + a) \\ &\quad - (\vartheta + d + \theta + a)\,\mathrm{e}^{-r\varrho}\,(\cos s\varrho - \mathrm{i}\sin s\varrho) = 0. \end{aligned} \quad (12)$$

By applying Euler's formula and splitting real and imaginary parts, Eq. (12) can be written as

$$\begin{aligned} r + \vartheta + d + \theta + a &= (\vartheta + d + \theta + a)\cos s\varrho\ \mathrm{e}^{-r\varrho}, \\ s &= -(\vartheta + d + \theta + a)\sin s\varrho\ \mathrm{e}^{-r\varrho}. \end{aligned} \quad (13)$$

On squaring and adding both the equations of Eq. (13), we obtain

$$\begin{aligned} &(r + \vartheta + d + \theta + a)^2 + s^2 \\ &\quad = (r + \vartheta + d + \theta + a)^2\,\mathrm{e}^{-2r\varrho}. \end{aligned} \quad (14)$$

If there exists a root satisfying both the equations of (13), then this root also satisfies Eq. (14) obtained by squaring and adding these equations. For Eq. (14) to be verified, we must have $r \leq 0$. Therefore, E_0 is linearly neutrally stable.

Case (ii) $\varrho = 0$

We now analyze the qualitative behavior of the system (5) without time delay, i.e., we take $\varrho = 0$. This analysis has an interest in itself and will also allow getting some information on the stability of the coexistence equilibrium in the case with delay [30]. The bifurcation theory approach obtained in [11], which is based on the center manifold theory [5], has been used to decide the local stability of a nonhyperbolic equilibrium (i.e., linearization matrix has at least one eigenvalue with zero real part) near the criticality E_0 and $R_0 = 1$. It allows us to clarify the direction of the bifurcation and describes the local behavior of disease-free equilibrium near $R_0 = 1$. For simplicity, we redefine the state variables as $S = x_1$, $A_F = x_2$, $A_P = x_3$, and $I = x_4$. So, the system (5) takes the form:

$$\begin{aligned} \frac{\mathrm{d}x_1}{\mathrm{d}t} &= \kappa - \delta_1 x_1 - \delta_2 x_1 - \frac{\beta_1 x_1 x_4}{\varepsilon x_4 + 1} - x_1\vartheta \equiv g_1, \\ \frac{\mathrm{d}x_2}{\mathrm{d}t} &= -\frac{\beta_2 x_2 x_4}{\varepsilon x_4 + 1} - \vartheta x_2 + \delta_1 x_1 \equiv g_2, \\ \frac{\mathrm{d}x_3}{\mathrm{d}t} &= -\frac{\beta_3 x_3 x_4}{\varepsilon x_4 + 1} - \vartheta x_3 + \delta_2 x_1 \equiv g_3, \\ \frac{\mathrm{d}x_4}{\mathrm{d}t} &= \frac{\beta_1 x_1 x_4}{\varepsilon x_4 + 1} + \frac{\beta_2 x_2 x_4}{\varepsilon x_4 + 1} + \frac{\beta_3 x_3 x_4}{\varepsilon x_4 + 1} \\ &\quad - (d + \theta + \vartheta)x_4 - \frac{a x_4}{b x_4 + 1} \equiv g_4. \end{aligned} \quad (15)$$

We observe that when $R_0 = 1$, the chosen bifurcation parameter β_2 takes the form

$$\begin{aligned} \beta_2 &= \beta_2^* \\ &= \frac{\delta_2\,(\vartheta(a + d + \theta + \vartheta) - \beta_3\kappa) + \vartheta\,(\delta_1 + \vartheta)\,(a + d + \theta + \vartheta) + \beta_1\kappa(-\vartheta)}{\delta_1\kappa}. \end{aligned}$$

The Jacobian matrix $J(E_0,\ \beta_2^*)$ of the system (15) obtained at criticality (that is, at E_0 and β_2^*) is

$$J(E_0, \beta_2^*) = \begin{pmatrix} -\vartheta - \delta_1 - \delta_2 & 0 & 0 & -\frac{\kappa\beta_1}{\vartheta + \delta_1 + \delta_2} \\ \delta_1 & -\vartheta & 0 & -\frac{\kappa\beta_2^*\delta_1}{\vartheta\,(\vartheta + \delta_1 + \delta_2)} \\ \delta_2 & 0 & -\vartheta & -\frac{\kappa\beta_3\delta_2}{\vartheta\,(\vartheta + \delta_1 + \delta_2)} \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

The eigenvalues of the Jacobian matrix $J(E_0, \beta_2^*)$ are $\lambda_1 = -\vartheta,\ \lambda_2 = -\vartheta,\ \lambda_3 = -\vartheta - \delta_1 - \delta_2,\ \lambda_4 = 0$. We see that λ_1, λ_2, and λ_3 are real and negative eigenvalues and $\lambda_4 = 0$ is a simple zero eigenvalue (since the algebraic multiplicity of $\lambda_4 = 0$ is 1) of $J(E_0, \beta_2^*)$. Thus, when $R_0 = 1$, the DFE E_0 is a non-hyperbolic equilibrium.

The right eigenvector $v = (v_1, v_2, v_3, v_4)$ of $J(E_0, \beta_2^*)$ corresponding to $\lambda_4 = 0$ is obtained as

$$
\begin{aligned}
v_1 &= -\frac{\beta_1 \kappa}{(\delta_1 + \delta_2 + \vartheta)^2},\\
v_2 &= -\frac{\delta_1 \kappa\,(\beta_2\,(\delta_1 + \delta_2 + \vartheta) + \beta_1 \vartheta)}{\vartheta^2\,(\delta_1 + \delta_2 + \vartheta)^2},\\
v_3 &= -\frac{\delta_2 \kappa\,(\beta_3\,(\delta_1 + \delta_2 + \vartheta) + \beta_1 \vartheta)}{\vartheta^2\,(\delta_1 + \delta_2 + \vartheta)^2},\\
v_4 &= 1.
\end{aligned}
$$

The left eigenvector $w = (w_1, w_2, w_3, w_4)$ of $J(E_0,\ \beta_2^*)$ corresponding to $\lambda_4 = 0$ is obtained as

$$
\begin{aligned}
w_1 &= 0,\\
w_2 &= 0,\\
w_3 &= 0,\\
w_4 &= 1.
\end{aligned}
$$

Let g_k's, $k = 1, 2, 3, 4$, denote the right-hand side of the system (15). The bifurcation coefficients a_1 and b_1 defined in Theorem 4.1 of [33] are given by:

$$
\begin{aligned}
a_1 &= \sum_{k,i,j=1}^{4} w_k v_i v_j \left(\frac{\partial^2 g_k}{\partial x_i \partial x_j}\right)_{E_0},\\
b_1 &= \sum_{k,i=1}^{4} w_k v_i \left(\frac{\partial^2 g_k}{\partial x_i \partial \beta_2^*}\right)_{E_0}.
\end{aligned}
$$

The nonzero partial derivatives of the functions g_k's at E_0 are evaluated as

$$
\begin{aligned}
\left(\frac{\partial^2 g_4}{\partial x_4 \partial x_1}\right)_{E_0} &= \beta_1, \left(\frac{\partial^2 g_4}{\partial x_4 \partial x_2}\right)_{E_0} = \beta_2^*,\\
\left(\frac{\partial^2 g_4}{\partial x_4 \partial x_3}\right)_{E_0} &= \beta_3, \left(\frac{\partial^2 g_4}{\partial x_1 \partial x_4}\right)_{E_0} = \beta_1,\\
\left(\frac{\partial^2 g_4}{\partial x_2 \partial x_4}\right)_{E_0} &= \beta_2^*,\\
\left(\frac{\partial^2 g_4}{\partial x_3 \partial x_4}\right)_{E_0} &= \beta_3, \left(\frac{\partial^2 g_4}{\partial x_4^2}\right)_{E_0}\\
&= -\frac{2\varepsilon\beta_1\kappa}{\delta_1 + \delta_2 + \vartheta} - \frac{2\varepsilon\beta_2^*\delta_1\kappa}{\vartheta\,(\delta_1 + \delta_2 + \vartheta)}\\
&\quad -\frac{2\varepsilon\beta_3\delta_2\kappa}{\vartheta\,(\delta_1 + \delta_2 + \vartheta)} + 2ab, \textit{and}\\
\left(\frac{\partial^2 g_4}{\partial x_4 \partial \beta_2^*}\right)_{E_0} &= \frac{\delta_1\kappa}{\vartheta\,(\delta_1 + \delta_2 + \vartheta)}.
\end{aligned}
$$

The bifurcation coefficients a_1 and b_1 are calculated at the bifurcation parameter β_2^* as follows:

$$
\begin{aligned}
a_1 &= -\frac{2}{\delta_1\kappa\vartheta^2\,(\delta_1 + \delta_2 + \vartheta)}\Big(\delta_1(\delta_2(\vartheta^2\,(\kappa(a(\varepsilon - b)\\
&\quad +\varepsilon(d + \theta + \vartheta)) + 2(a + d + \theta + \vartheta)^2\Big)\\
&\quad + \beta_3\kappa\,(\beta_3\kappa - 2\vartheta(a + d + \theta + \vartheta)))\\
&\quad + \vartheta^3\,(\kappa(a(\varepsilon - b) + \varepsilon(d + \theta + \vartheta))\\
&\quad +2(a + d + \theta + \vartheta)^2\Big))\\
&\quad + \delta_1^2\vartheta^2\,(\kappa(a(\varepsilon - b) + \varepsilon(d + \theta + \vartheta))\\
&\quad +(a + d + \theta + \vartheta)^2\Big)\\
&\quad + (\delta_2\,(\vartheta(a + d + \theta + \vartheta) - \beta_3\kappa)\\
&\quad + \vartheta^2(a + d + \theta + \vartheta))^2\\
&\quad - \beta_1\kappa\vartheta\,(2\delta_2\,(\vartheta(a + d + \theta + \vartheta) - \beta_3\kappa)\\
&\quad +\vartheta\,(\delta_1 + 2\vartheta)\,(a + d + \theta + \vartheta))\\
&\quad + \beta_1^2\kappa^2\vartheta^2\Big)\\
&= -\frac{2}{\delta_1\kappa\vartheta^2\,(\delta_1 + \delta_2 + \vartheta)} \times G(\beta_3),\\
b_1 &= \frac{\kappa}{\delta_1 + \delta_2 + \vartheta}.
\end{aligned}
$$

where

$$
G(\beta_3) = \left(\zeta_2\,\beta_3^2 + \zeta_1\,\beta_3 + \zeta_0\right), \tag{16}
$$

where the coefficients $\zeta_0,\ \zeta_1$ and ζ_2 are

$$
\begin{aligned}
\zeta_2 &= \delta_2\,(\delta_1 + \delta_2)\,\kappa^2,\\
\zeta_1 &= 2\delta_2\kappa\vartheta\,(\beta_1\kappa - (\delta_1 + \delta_2 + \vartheta)\,(a + d + \theta + \vartheta)),\\
\zeta_0 &= \vartheta^2\Big(\big(\delta_1 + \delta_2 + \vartheta\big)\big(\delta_1\big(\kappa(a(\varepsilon - b)\\
&\quad + \varepsilon(d + \theta + \vartheta))\\
&\quad + (a + d + \theta + \vartheta)^2\big)
\end{aligned}
$$

$$+\big(\delta_2+\vartheta\big)(a+d+\theta+\vartheta)^2\big)$$
$$+\beta_1\delta_1\kappa(a+d+\theta+\vartheta)$$
$$+\beta_1\kappa\big(\beta_1\kappa-2\big(\delta_1+\delta_2+\vartheta\big)(a+d+\theta+\vartheta)\big)\big). \tag{17}$$

It can be seen that the bifurcation coefficient b_1 is always positive and the sign of a_1 depends the sign of $G(\beta_3)$, given in Eq. (16). If $G(\beta_3) < 0$, then $a_1 > 0$, whereas if $G(\beta_3) > 0$, then $a_1 < 0$.

The discriminant of quadratic polynomial $G(\beta_3)$ is obtained as

$$D = a\big(\delta_1+\delta_2\big)\kappa(b-\varepsilon)\big(\delta_1+\delta_2+\vartheta\big)$$
$$+\big(-\delta_1-\delta_2-\vartheta\big)\big(\big(\delta_1+\delta_2+\vartheta\big)(a+d+\theta+\vartheta)^2$$
$$+\varepsilon\big(\delta_1+\delta_2\big)\kappa(d+\theta+\vartheta)\big)$$
$$+\beta_1\kappa\big(\delta_1+\delta_2+2\vartheta\big)(a+d+\theta+\vartheta)$$
$$+\beta_1^2\big(-\kappa^2\big). \tag{18}$$

Let β_3^* and β_3^{**} be two roots of Eq. (16), then we get

$$\beta_3^* = \frac{-\zeta_1+D}{2\zeta_2}, \text{ and } \beta_3^{**} = \frac{-\zeta_1-D}{2\zeta_2}. \tag{19}$$

Using Theorem 4.1(iv) in [11], the type of bifurcation is governed by the sign of a_1 and hence by the sign of $G(\beta_3)$. If $G(\beta_3)$ is of positive sign, then forward bifurcation occurs, whereas if the sign of $G(\beta_3)$ is negative, then the system (15) reveals a backward bifurcation. The study of forward and backward bifurcation is important in the study of epidemiology as they play a relevant role in disease control and eradication. In the case of forward bifurcation, the condition $R_0 < 1$ is a necessary and sufficient condition for disease eradication, whereas reducing R_0 below unity is no longer sufficient for disease eradication when a backward bifurcation occurs. These behavior differences are essential in planning how to control a disease; a backward bifurcation at $R_0 = 1$ makes control more difficult. These two cases are discussed below separately.

(I) Forward bifurcation: When there is a forward bifurcation at $R_0 = 1$, it is not possible for a disease to invade a population if $R_0 < 1$ because the system will return to the disease-free equilibrium $I = 0$ if some infectives are introduced into the population. For values of R_0 slightly greater than 1, E_0 changes its stability from stable to unstable and the model admits a unique endemic equilibrium, which is locally asymptotically stable [11]. Therefore, it is imperative to find the range for which forward bifurcation occurs. The range of forward bifurcation is governed by the positivity of $G(\beta_3)$. Thus, there are two cases in which $G(\beta_3)$ is found to be positive. These are given as follows:

$$\begin{cases} \zeta_1 > 0, \\ \zeta_0 > 0. \end{cases} \tag{20}$$

or

$$\begin{cases} D > 0, \\ \text{either of } (\zeta_1 > 0,\ \zeta_0 < 0),\ (\zeta_1 < 0.\ \zeta_0 > 0),\ \text{or } (\zeta_1 < 0,\ \zeta_0 < 0) \text{ holds}, \\ \beta_3 < \beta_3^* \text{ or } \beta_3 > \beta_3^{**}. \end{cases} \tag{21}$$

(II) Backward bifurcation: The backward bifurcation is characterized as when $R_0 < 1$; a small unstable endemic equilibrium appears while the disease-free equilibrium and a larger endemic equilibrium are locally asymptotically stable. When $R_0 > 1$, then an unstable disease-free equilibrium and a stable endemic equilibrium exist [11]. It is illustrated in Fig. (4). The range of existence of backward bifurcation (i.e., when $G(\beta_3) < 0$) as follows:

$$\begin{cases} D > 0, \\ \text{either of } (\zeta_1 > 0,\ \zeta_0 < 0),\ (\zeta_1 < 0.\ \zeta_0 > 0),\ \text{or } (\zeta_1 < 0,\ \zeta_0 < 0) \text{ holds}, \\ \beta_3^{**} < \beta_3 < \beta_3^*. \end{cases} \tag{22}$$

Based on the analysis above, we state the following theorems:

Theorem 1 *The disease-free equilibrium* $E_0(S_0, A_{F_0}, A_{P_0}, 0)$ *of the delayed system (5) is asymptotically stable if* $R_0 < 1$ *and unstable if* $R_0 > 1$ *for* $\varrho > 0$.

Theorem 2 *The disease-free equilibrium* $E_0(S_0, A_{F_0}, A_{P_0}, 0)$ *of the delayed system (5) at* $R_0 = 1$ *is linearly neutrally stable for* $\varrho > 0$.

Theorem 3 *When* $R_0 = 1$, *then the undelayed system (15) reveals a backward (forward) bifurcation at disease-free equilibrium* $E_0(S_0, A_{F_0}, A_{P_0}, 0)$ *if and only if* $G(\beta_3) < 0\ (> 0)$.

The graphical presentations of the forward and backward bifurcations are shown in Figs. 2, 3, and 4 for the experimental data mentioned below: $\kappa = 2$, $\varepsilon = 0.1$, $\vartheta = 0.01$, $d = 0.001$, $b = 0.8$, $\theta = 0.01$, $a = 0.9$, $\beta_1 = 0.004$, $\delta_1 = 0.01$, $\delta_2 = 0.009$. At these values of parameters, we evaluate that the range of β_3 is $\beta_3^{**} = 0.00098164 \leq$

$\beta_3 \leq 0.0088652 = \beta_3^*$. The cases of occurrence of forward and backward bifurcations, given in the inequalities (20), (21), and (22), are illustrated from (1)–(3) as below:

(1) If we take $\beta_3 = 0.00008$, then we obtain that $\zeta_2 = 0.000522$, $\zeta_1 = 1.242 \times 10^{-6} > 0$, and $\zeta_0 = 7.75344 \times 10^{-9} > 0$. This case illustrates the inequality (20), and the graph is shown in Fig. 2.
(2) On considering $\beta_3 = 0.01$, we obtain that $\zeta_2 = 0.000522$, $\zeta_1 = 1.242 \times 10^{-}6 > 0$, $\zeta_0 = -5.44699 \times 10^{-8} < 0$, and the discriminant $D = 1.15276 \times 10^{-10} > 0$. It illustrates the inequality (21), and the graph is shown in Fig. 3.
(3) If we take $\beta_3 = 0.006$, which lies between β_3^{**} and β_3^*, then we obtain that the coefficients $\zeta_2 = 0.000522$, $\zeta_1 = 1.242 \times 10^{-6} > 0$ and $\zeta_0 = -4.05047 \times 10^{-8} < 0$, and the discriminant $D = 8.61164 \times 10^{-11} > 0$. This case illustrates the inequality (22), and the graph is shown in Fig. 4.

In Figs. 2, 3, and 4, the solid lines show stability and the dashed lines show instability.

3.2 Endemic equilibrium and stability

Assuming that $S,\ A_F,\ A_P,\ I \neq 0$. To determine the conditions for the existence of endemic (positive) equilibrium $E_e(S^*, A_F^*, A_P^*, I^*)$, we put the right-hand side of the system (5) to zero. We get:

$$\kappa - \delta_1 S - \delta_2 S - \frac{\beta_1 S I}{1+\varepsilon I} - S\vartheta = 0, \tag{23}$$

$$-\frac{\beta_2 A_F I}{1+\varepsilon I} - \vartheta A_F + \delta_1 S = 0, \tag{24}$$

$$-\frac{\beta_3 A_P I}{1+\varepsilon I} - \vartheta A_P + \delta_2 S = 0, \tag{25}$$

$$\frac{\beta_1 S I}{1+\varepsilon I} + \frac{\beta_2 A_F I}{1+\varepsilon I} + \frac{\beta_3 A_P I}{1+\varepsilon I} - (d+\theta+\vartheta)I - \frac{aI}{1+bI} = 0. \tag{26}$$

Solving for S, A_F and A_P in terms of I, from Eqs. (23), (24), and (25), respectively, and substituting the resulting expression in Eq. (26), after simplification, we obtain the following equation in I:

$$P(I) := A_0 + A_1 I + A_2 I^2 + A_3 I^3 + A_4 I^4 = 0, \tag{27}$$

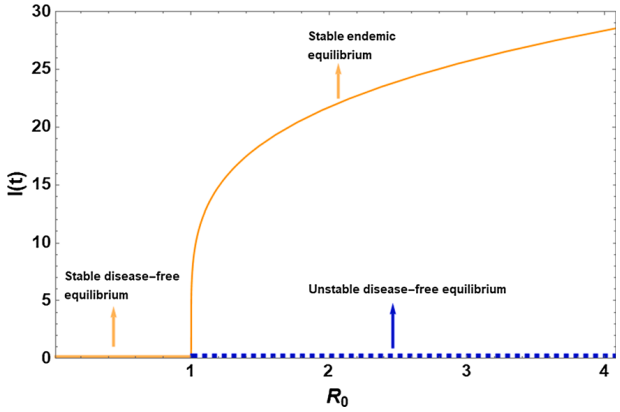

Fig. 2 Plot of R_0 versus $I(t)$, showing the occurrence of forward bifurcation

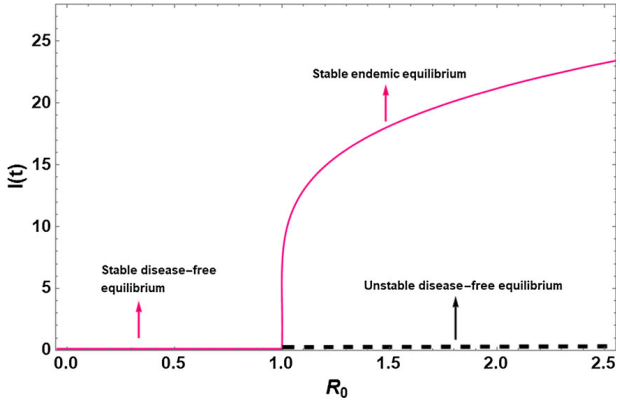

Fig. 3 Plot of R_0 versus $I(t)$, showing the occurrence of forward bifurcation

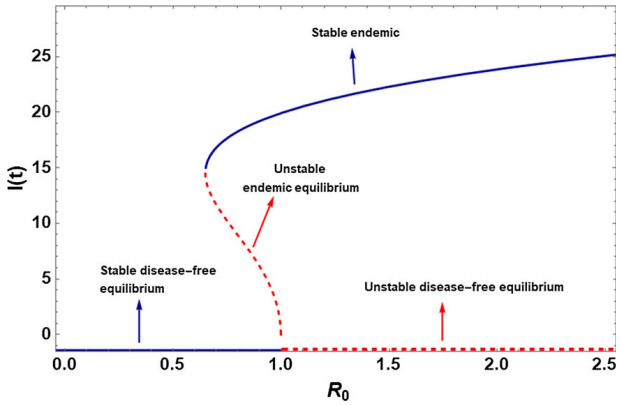

Fig. 4 Plot of R_0 versus $I(t)$, showing the presence of backward bifurcation

where

$$
\begin{aligned}
A_0 &= \vartheta\,(\delta_1+\delta_2+\vartheta)\,(a+d+\theta+\vartheta)(1-R_0),\\
A_1 &= \vartheta\,((\delta_1+\delta_2+\vartheta)\,(3\varepsilon\vartheta+\beta_2+\beta_3)+\beta_1\vartheta)\\
&\quad (a+d+\theta+\vartheta)-\beta_2\delta_1\kappa\vartheta\,(2\varepsilon+b)\\
&\quad -\beta_3\delta_2\kappa\vartheta\,(2\varepsilon+b)\\
&\quad -\beta_1\kappa\vartheta^2(2\varepsilon+b)+b\vartheta^2\,(\delta_1+\delta_2+\vartheta)\\
&\quad (d+\theta+\vartheta)-\beta_2\beta_3\delta_1\kappa-\beta_2\beta_3\delta_2\kappa\\
&\quad -\beta_1\,(\beta_2+\beta_3)\,\kappa\vartheta,\\
A_2 &= \vartheta\Big(\beta_3\,(\delta_2(2a\varepsilon-\varepsilon\kappa(\varepsilon+2b)+(2\varepsilon+b)(d+\theta+\vartheta))\\
&\quad +(\delta_1+\vartheta)\,(2a\varepsilon+(2\varepsilon+b)(d+\theta+\vartheta)))\\
&\quad +3\varepsilon\vartheta\,(\delta_1+\delta_2+\vartheta)\,(a\varepsilon+(\varepsilon+b)(d+\theta+\vartheta))\Big)\\
&\quad +\beta_2\Big(\beta_3\Big(\,(\delta_1+\delta_2)\,(a-\kappa(\varepsilon+b)+d+\theta+\vartheta)\\
&\quad +\vartheta(a+d+\theta+\vartheta)\Big)+\vartheta\big(\delta_1(2a\varepsilon-\varepsilon\kappa(\varepsilon+2b)\\
&\quad +(2\varepsilon+b)(d+\theta+\vartheta))\\
&\quad +(\delta_2+\vartheta)\,(2a\varepsilon+(2\varepsilon+b)(d+\theta+\vartheta))\big)\Big)\\
&\quad -\beta_1\Big(\beta_2\,(-\vartheta(a+d+\theta+\vartheta)+\kappa\vartheta(\varepsilon+b)+\beta_3\kappa)\\
&\quad +\vartheta\,(\vartheta(-2a\varepsilon+\varepsilon\kappa(\varepsilon+2b)\\
&\quad -(2\varepsilon+b)(d+\theta+\vartheta))\\
&\quad -\beta_3(a-\kappa(\varepsilon+b)+d+\theta+\vartheta))\Big),\\
A_3 &= -\,(\varepsilon\vartheta+\beta_3)\,((\varepsilon\vartheta+\beta_2)\,(-a\varepsilon\vartheta-\beta_1(a-b\kappa))\\
&\quad -\varepsilon\delta_1\,(a\varepsilon\vartheta+\beta_2(a-b\kappa)))+\varepsilon\delta_2\,(\varepsilon\vartheta+\beta_2)\,\big(a\varepsilon\vartheta\\
&\quad +\beta_3(a-b\kappa)\big)-(d+\theta+\vartheta)\big(\beta_1\,(\vartheta\,(-\beta_3(\varepsilon+b)\\
&\quad -\varepsilon\vartheta(\varepsilon+2b))-\beta_2\,(\vartheta(\varepsilon+b)+\beta_3))\\
&\quad -(\delta_1+\delta_2+\vartheta)\,(\beta_2\,(\beta_3(\varepsilon+b)+\varepsilon\vartheta(\varepsilon+2b))\\
&\quad +\varepsilon\vartheta\,(\beta_3(\varepsilon+2b)+\varepsilon\vartheta(\varepsilon+3b)))\big),\\
A_4 &= b\,(\varepsilon\vartheta+\beta_2)\,(\varepsilon\vartheta+\beta_3)\,(d+\theta+\vartheta)\\
&\quad (\varepsilon\,(\delta_1+\delta_2+\vartheta)+\beta_1)\,.
\end{aligned}
\tag{28}
$$

For a positive root of I^* of the polynomial $P(I)$, we have

$$S^* = \frac{\kappa+\varepsilon\kappa I^*}{(\delta_1+\delta_2+\vartheta)\,(\varepsilon I^*+1)+\beta_1 I^*}, \tag{29}$$

$$A_F^* = \frac{\delta_1 S^*(\varepsilon I^*+1)}{\varepsilon I^*\vartheta+\beta_2 I^*+\vartheta}, \tag{30}$$

$$A_P^* = \frac{\delta_2 S^*(\varepsilon I^*+1)}{\varepsilon I^*\vartheta+\beta_3 I^*+\vartheta}. \tag{31}$$

So, $E_e(S^*, A_F^*, A_P^*, I^*)$ is a positive equilibrium of the system (5).

Theorem 4 *When $R_0 > 1$, then there is either a unique or three positive endemic equilibria if all equilibria are simple roots.*

Proof Let $R_0 > 1$. We see that the coefficient A_4 is always positive. On the other hand, $A_0 < 0$ when $R_0 > 1$. From Eq. (27), we have a fourth-degree polynomial in I, given below:

$$P(I) := A_0 + A_1 I + A_2 I^2 + A_3 I^3 + A_4 I^4 = 0.$$

The following possibilities for the signs of A_1, A_2, and A_3 exist:

$$
\begin{aligned}
&\mathbf{V}_1 : A_1 > 0,\ A_2 > 0,\ \text{and } A_3 > 0,\\
&\mathbf{V}_2 : A_1 < 0,\ A_2 < 0,\ \text{and } A_3 > 0,\\
&\mathbf{V}_3 : A_1 < 0,\ A_2 > 0,\ \text{and } A_3 > 0,\\
&\mathbf{V}_4 : A_1 < 0,\ A_2 < 0,\ \text{and } A_3 < 0,\\
&\mathbf{V}_5 : A_1 > 0,\ A_2 > 0,\ \text{and } A_3 < 0,\\
&\mathbf{V}_6 : A_1 > 0,\ A_2 < 0,\ \text{and } A_3 > 0,\\
&\mathbf{V}_7 : A_1 > 0,\ A_2 < 0,\ \text{and } A_3 < 0,\\
&\mathbf{V}_8 : A_1 < 0,\ A_2 > 0,\ \text{and } A_3 < 0.
\end{aligned}
$$

Using Descartes' rule of signs [12], $P(I)$ can have either a unique or three positive roots. If any of the conditions $\mathbf{V}_1$–$\mathbf{V}_4$ holds, then there is unique endemic equilibrium, whereas for the existence of three endemic equilibria, any one of the conditions $\mathbf{V}_5$–$\mathbf{V}_8$ must satisfy. □

For the present study, we consider the case of unique endemic equilibrium only. **H1:** Suppose that any of the conditions ($\mathbf{V}_1$–$\mathbf{V}_4$, and $R_0 > 1$) holds, then the system (5) admits a unique endemic equilibrium.

Now, we study the local stability behavior of endemic equilibrium $E_e(S^*, A_F^*, A_P^*, I^*)$. For this, we obtain the characteristic equation of the system (5) at $E_e(S^*, A_F^*, A_P^*, I^*)$ as given below:

$$P_0(\lambda)+\mathrm{e}^{-\lambda\varrho}P_1(\lambda)+\mathrm{e}^{-2\lambda\varrho}P_2(\lambda)+\mathrm{e}^{-3\lambda\varrho}P_3(\lambda)=0, \tag{32}$$

where,

$$
\begin{aligned}
P_0(\lambda) &= \lambda^4+K_1\lambda^3+K_2\lambda^2+K_3\lambda+K_4,\\
P_1(\lambda) &= K_5\lambda^3+K_6\lambda^2+K_7\lambda+K_8,\\
P_2(\lambda) &= K_9\lambda^2+K_{10}\lambda+K_{11},\\
P_3(\lambda) &= K_{12}\lambda+K_{13}.
\end{aligned}
\tag{33}
$$

where the coefficients K_i, $i = 1$ to 13 are given in Appendix. For $\varrho = 0$, the characteristic equation becomes:

$$\lambda^4 + Q_3\lambda^3 + Q_2\lambda^2 + Q_1\lambda + Q_0 = 0, \tag{34}$$

where $Q_i's$, $i = 0, 1, 2, 3$, are given in Appendix.

Based on Routh–Hurwitz criterion, it can be concluded that all the roots of Eq. (34) have negative real parts if the following inequalities hold:

H2: $Q_i > 0$ $(i = 0, 1, 2, 3)$, $Q_3Q_2 - Q_1 > 0$, and
$$Q_3Q_2Q_1 - Q_1^2 - Q_3^2Q_0 > 0. \tag{35}$$

Thus, we state the following theorem:

Theorem 5 *At $\varrho = 0$, the endemic equilibrium $E_2(S^*, A_F^*, A_P^*, I^*)$ is locally asymptotically stable if **H2** holds.*

Now multiplying by $e^{-\lambda\varrho}$ on both sides of the characteristic equation (32), we get:

$$P_0(\lambda)e^{\lambda\varrho} + P_1(\lambda) + e^{-\lambda\varrho}P_2(\lambda) + e^{-2\lambda\varrho}P_3(\lambda) = 0. \tag{36}$$

Change of stability and hence the existence of oscillatory solution may appear if the roots of the characteristic equation are purely imaginary. Therefore, to study the stability of E_e, assuming that $\lambda = i\omega$, $(\omega > 0)$ is a root of Eq. (36). Then, Eq. (36) becomes:

$$P_0(i\omega)e^{i\omega\varrho} + P_1(i\omega) + e^{-i\omega\varrho}P_2(i\omega) + e^{-2i\omega\varrho}P_3(i\omega) = 0. \tag{37}$$

Equation (37) can be rewritten as

$$\begin{aligned}&(M_0 + iN_0)(\cos\omega\varrho + i\sin\omega\varrho) + (M_1 + iN_1)\\ &+ (M_2 + iN_2)(\cos\omega\varrho - i\sin\omega\varrho)\\ &+ (M_3 + iN_3)(\cos 2\omega\varrho - i\sin 2\omega\varrho) = 0,\end{aligned} \tag{38}$$

where M_0, M_1, M_2, M_3, N_0, N_1, N_2 and N_3 denote the real and imaginary parts of $P_0(i\omega)$, $P_1(i\omega)$, $P_2(i\omega)$ and $P_3(i\omega)$, respectively, given as:

$$\begin{aligned}&M_0 = \omega^4 - K_2\omega^2 + K_4,\ N_0 = -K_1\omega^3 + K_3\omega,\\ &M_1 = -K_6\omega^2 + K_8,\ N_1 = -K_5\omega^3 + K_7\omega,\\ &M_2 = -K_9\omega^2 + K_{11},\ N_2 = K_10\omega,\\ &M_3 = K_{13},\ N_3 = K_{12}\omega.\end{aligned}$$

When Eq. (38) splits into its real and imaginary parts, we get

$$M_1 + M_4\cos\omega\varrho + V_4\sin\omega\varrho = -N_3\sin 2\omega\varrho - M_3\cos 2\omega\varrho, \tag{39}$$

$$N_1 + N_5\cos\omega\varrho + M_5\sin\omega\varrho = -N_3\cos 2\omega\varrho + M_3\sin 2\omega\varrho, \tag{40}$$

where $M_4 = M_0 + M_2$, $N_4 = N_2 - N_0$, $M_5 = M_0 - M_2$ and $N_5 = N_2 + N_0$.

On squaring Eqs. (39) and (40) and then adding, we obtain

$$(M_1 + M_4\cos\omega\varrho + N_4\sin\omega\varrho)^2 + (N_1 + N_5\cos\omega\varrho) + M_5(\sin\omega\varrho)^2 - N_3^2 - M_3^2 = 0. \tag{41}$$

On substituting $\sin\omega\varrho = \sqrt{1 - \cos^2\omega\varrho}$ in Eq. (41), we obtain

$$L_1\cos^4\omega\varrho + L_2\cos^3\omega\varrho + L_3\cos^2\omega\varrho + L_4\cos\omega\varrho + L_5 = 0, \tag{42}$$

where

$$\begin{aligned}&L_1 = p_1^2 + 4p_5^2,\ L_2 = 4p_1p_2 + 8p_4p_5,\\ &L_3 = 4p_2^2 + 2p_1p_3 + 4p_4^2 - 4p_5^2,\\ &L_4 = 4p_2p_3 - 8p_4p_5,\\ &L_5 = p_3^2 - 4p_4^2,\\ &p_1 = M_4^2 + N_5^2 - N_4^2 - M_5^2,\ p_2 = M_1M_4 + N_1N_4,\\ &p_3 = M_1^2 + N_4^2 + N_1^2 + M_5^2 - N_3^2 - M_3^2,\\ &p_4 = M_1N_4 + N_1M_5,\\ &p_5 = M_4N_4 + M_5N_5.\end{aligned}$$

Let $\cos\omega\varrho = x$, then Eq. (42) can be written as

$$f(x) := L_1x^4 + L_2x^3 + L_3x^2 + L_4x + L_5 = 0. \tag{43}$$

From Eq. (43), we obtain

$$f'(x) = 4L_1x^3 + 3L_2x^2 + 2L_3x + L_4 = 0. \tag{44}$$

For convenience, we assume that $x = y - L_2/4L_1$. Then, Eq. (44) becomes:

$$y^3 + Ay + B = 0, \tag{45}$$

where

$$A = \frac{L_3}{2L_1} - \frac{3}{16}\left(\frac{T_2}{T_1}\right)^2,$$

$$B = \frac{1}{32}\left(\frac{L_2}{L_1}\right)^3 - \frac{L_2L_3}{8L_1^2} + \frac{L_4}{4L_1}.$$

Now, roots of Eq. (45) are given as

$$y_1 = \sqrt[3]{-\frac{B}{2} + \sqrt{O}} + \sqrt[3]{-\frac{B}{2} - \sqrt{O}},$$

$$y_2 = \eta_1 \sqrt[3]{-\frac{B}{2} + \sqrt{O}} + \eta_2 \sqrt[3]{-\frac{B}{2} - \sqrt{O}},$$
$$y_3 = \eta_2 \sqrt[3]{-\frac{B}{2} + \sqrt{O}} + \eta_1 \sqrt[3]{-\frac{B}{2} - \sqrt{O}},$$

where $\eta_1 = \frac{-1+\sqrt{3}\mathrm{i}}{2}$, $\eta_2 = \frac{-1-\sqrt{3}\mathrm{i}}{2}$ and $O = \frac{B^2}{4} + \frac{A_3}{27}$.

It follows from $\cos \omega\varrho = x$ and $x = y - L_2/4L_1 = F_1(\omega)$ that

$$\cos \omega\varrho = F_1(\omega). \tag{46}$$

On substituting Eq. (46) in Eq. (41) and solving for $\sin \omega\varrho$, we obtain

$$\sin \omega\varrho = F_2(\omega). \tag{47}$$

From Eqs. (46) and (47), we get

$$F_1^2(\omega) + F_2^2(\omega) = 1. \tag{48}$$

Assume that **H3:**, Eq. (48) has at least one positive root ω_0, such that the characteristic equation (32) has a pair of purely imaginary roots $\mathrm{i}\omega_0$.

For ω_0, the corresponding critical value of time delay ϱ_k can be obtained as:

$$\varrho_k = \frac{1}{\omega_0}\left(\arccos F_1(\omega_0) + 2k\pi\right), \ k = 0, 1, 2, \ldots. \tag{49}$$

Assume that ϱ is a bifurcation parameter and ϱ_0=min ϱ_k, $k = 0, 1, 2, \ldots$ is the critical value.

To establish the Hopf bifurcation, we show that $Re\left[\frac{\mathrm{d}\lambda}{\mathrm{d}\varrho}\right]^{-1}\Big|_{\lambda=\mathrm{i}\omega_0} \neq 0$.

Differentiating Eq. (32) with respect to ϱ, we obtain:

$$\begin{aligned}
&\frac{\mathrm{d}\lambda}{\mathrm{d}\varrho}\left(P_0'(\lambda) + \mathrm{e}^{-\lambda\varrho}P_1'(\lambda) - \varrho\mathrm{e}^{-\lambda\varrho}P_1(\lambda) + \mathrm{e}^{-2\lambda\varrho}P_2'(\lambda) - 2\varrho P_2(\lambda)\mathrm{e}^{-2\lambda\varrho} + \mathrm{e}^{-3\lambda\varrho}P_3'(\lambda) - 3\varrho P_3(\lambda)\mathrm{e}^{-3\lambda\varrho}\right)\\
&\quad - \lambda\mathrm{e}^{-\lambda\varrho}P1(\lambda) - 2\lambda P_2(\lambda)\mathrm{e}^{-2\lambda\varrho} - 3\lambda P_3(\lambda)\mathrm{e}^{-3\lambda\varrho} = 0.\\
&\Longrightarrow \frac{\mathrm{d}\lambda}{\mathrm{d}\varrho}\left(P_0'(\lambda) + \mathrm{e}^{-\lambda\varrho}P_1'(\lambda) - \varrho\mathrm{e}^{-\lambda\varrho}P_1(\lambda) + \mathrm{e}^{-2\lambda\varrho}P_2'(\lambda) - 2\varrho P_2(\lambda)\mathrm{e}^{-2\lambda\varrho} + \mathrm{e}^{-3\lambda\varrho}P_3'(\lambda) - 3\varrho P_3(\lambda)\mathrm{e}^{-3\lambda\varrho}\right)\\
&\quad = \lambda\mathrm{e}^{-\lambda\varrho}P1(\lambda) + 2\lambda P_2(\lambda)\mathrm{e}^{-2\lambda\varrho} + 3\lambda P_3(\lambda)\mathrm{e}^{-3\lambda\varrho}.\\
&\Longrightarrow \frac{\mathrm{d}\lambda}{\mathrm{d}\varrho} = \frac{\lambda\left(P_1(\lambda) + 2P_2(\lambda)\mathrm{e}^{-\lambda\varrho} + 3P_3(\lambda)\mathrm{e}^{-2\lambda\varrho}\right)}{\left(P_0'(\lambda)\mathrm{e}^{\lambda\varrho} + P_1'(\lambda) - \varrho P_1(\lambda) + \mathrm{e}^{-\lambda\varrho}\left(P_2'(\lambda) - 2\varrho P_2(\lambda)\right) + \mathrm{e}^{-2\lambda\varrho}\left(P_3'(\lambda) - 3\varrho P_3(\lambda)\right)\right)}.
\end{aligned}$$

Thus, we get

$$\left[\frac{\mathrm{d}\lambda}{\mathrm{d}\varrho}\right]^{-1} = \frac{\left(P_0'(\lambda)\mathrm{e}^{\lambda\varrho} + P_1'(\lambda) + \mathrm{e}^{-\lambda\varrho}P_2'(\lambda) + \mathrm{e}^{-2\lambda\varrho}P_3'(\lambda)\right) - \left(\varrho P_1(\lambda) + 2\varrho P_2(\lambda)\mathrm{e}^{-\lambda\varrho} + 3\varrho P_3(\lambda)\mathrm{e}^{-2\lambda\varrho}\right)}{\lambda\left(P_1(\lambda) + 2P_2(\lambda)\mathrm{e}^{-\lambda\varrho} + 3P_3(\lambda)\mathrm{e}^{-2\lambda\varrho}\right)}.$$

$$\text{i.e.,} \left[\frac{\mathrm{d}\lambda}{\mathrm{d}\varrho}\right]^{-1} = \frac{\left(P_0'(\lambda)\mathrm{e}^{\lambda\varrho} + P_1'(\lambda) + \mathrm{e}^{-\lambda\varrho}P_2'(\lambda) + \mathrm{e}^{-2\lambda\varrho}P_3'(\lambda)\right)}{\lambda\left(P_1(\lambda) + 2P_2(\lambda)\mathrm{e}^{-\lambda\varrho} + 3P_3(\lambda)\mathrm{e}^{-2\lambda\varrho}\right)} - \frac{\varrho}{\lambda}.$$

$$Re\left[\frac{d\lambda}{d\varrho}\right]^{-1}\Big|_{\lambda=\mathrm{i}\omega_0} = \frac{X_1X_2 + Y_1Y_2}{X_2^2 + Y_2^2},$$

where

$$
\begin{aligned}
X_1 &= -\sin\omega_0\varrho_0\left(-4\omega_0^3+2K_2\omega_0\right)\\
&\quad+\cos\omega_0\varrho_0\left(-3K_1\omega_0^2+K_3\right)+\left(-3K_5\omega_0^2+K_7\right)\\
&\quad+\left(K_{10}\cos\omega_0\varrho_0+2\omega_0K_9\sin\omega_0\varrho_0\right)\\
&\quad+K_{16}\cos 2\omega_0\varrho_0,\\
X_2 &= K_5\omega_0^4-K_7\omega_0^2-2K_{10}\omega_0^2\cos\omega_0\varrho_0\\
&\quad+2\left(-K_9\omega_0^2+\omega_0K_{11}\right)\sin\omega_0\varrho_0\\
&\quad-3\omega_0^2K_{12}\cos 2\omega_0\varrho_0\\
&\quad+3\omega_0K_{13}\sin 2\omega_0\varrho_0,\\
Y_1 &= \cos\omega_0\varrho_0\left(-4\omega_0^3+2K_2\omega_0\right)\\
&\quad+\sin\omega_0\varrho_0\left(-3K_1\omega_0^2+K_3\right)+2\omega_0K_6\\
&\quad+2\omega_0K_9\cos\omega_0\varrho_0-K_{10}\sin\omega_0\varrho_0\\
&\quad-K_{16}\sin 2\omega_0\varrho_0,\\
Y_2 &= -K_6\omega_0^3+\omega_0K_8+2\left(-K_9\omega_0^3+\omega_0K_{11}\right)\cos\omega_0\varrho_0\\
&\quad+3\left(\omega_0^2K_{12}\sin 2\omega_0\varrho_0+\omega_0K_{13}\cos 2\omega_0\varrho_0\right)\\
&\quad+2\omega_0^2K_{10}\sin\omega_0\varrho_0.
\end{aligned}
$$

Obviously, if **H4:** $X_1X_2+Y_1Y_2\neq 0$, then $Re\left[\frac{d\lambda}{d\varrho}\right]^{-1}\Big|_{\lambda=i\omega_0}\neq 0$.

Thus, we state the following theorem:

Theorem 6 *For the system (5), if the conditions (**H1–H4**) hold, then the endemic equilibrium* $E_e=(S^*, A_F^*, A_P^*, I^*)$ *is locally asymptotically stable when* $\varrho\in[0,\varrho_0)$*; the system (5) undergoes a Hopf bifurcation at* $E_e=(S^*, A_F^*, A_P^*, I^*)$ *when* $\varrho=\varrho_0$*, and a family of periodic solutions bifurcate from* $E_e=(S^*, A_F^*, A_P^*, I^*)$.

4 Numerical simulation

In this section, numerical experiments are presented to show the analytical results using Mathematica 11.

We have considered the following set of experimental data: $\kappa=2$, $\vartheta=0.01$, $\beta_1=0.02$, $\beta_2=0.006$, $\beta_3=0.008$, $\delta_1=0.1$, $\delta_2=0.02$, $a=0.04$, $d=0.009$, $\theta=0.004$, $\varepsilon=0.5$, $b=0.09$.

At these parameters values, the endemic equilibrium is $E_e(S^*, A_F^*, A_P^*, I^*)=(11.903, 55.602, 9.443, 38.504)$ with $R_0>1$.

Figure 5 shows the behavior of different subpopulations for the time delay $\varrho=1$. Evidently, as time increases, unaware susceptibles decrease, and the fully aware and partially aware, infected, and removed individuals population increase and then start decaying and settle down to steady state $E_e(11.903, 55.602, 9.443, 38.504)$.

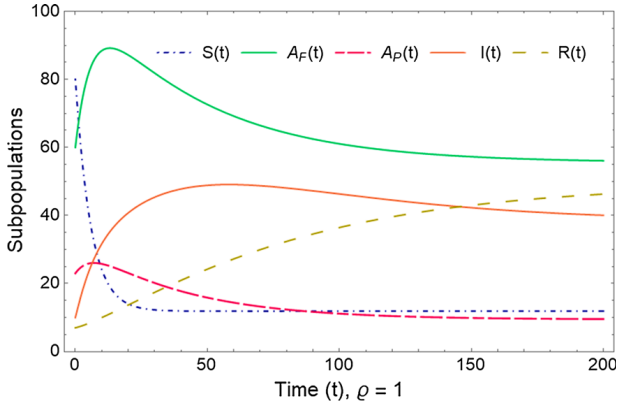

Fig. 5 Subpopulations $S-A_P-A_F-I-R$ at $\varrho=1$

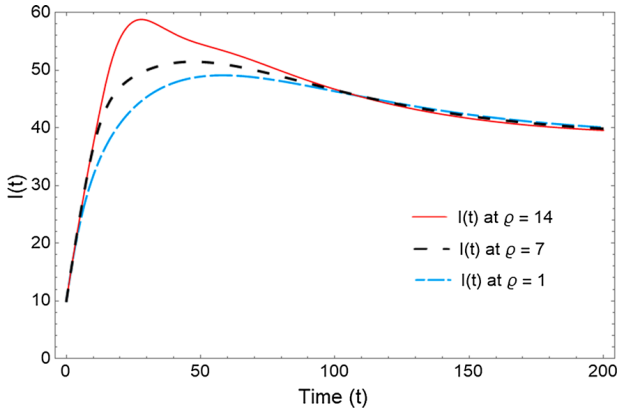

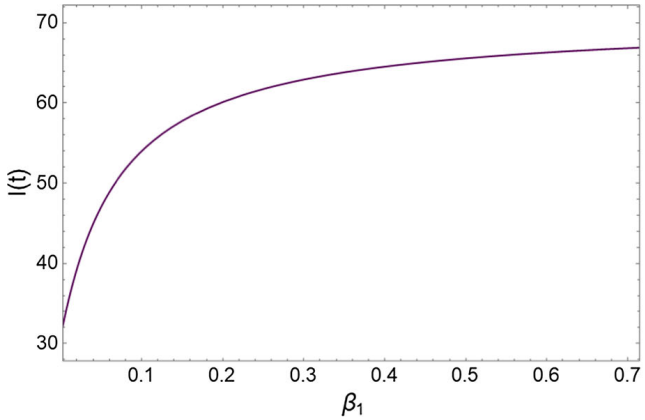

Fig. 6 Infected population $I(t)$ at different values of time delay ϱ

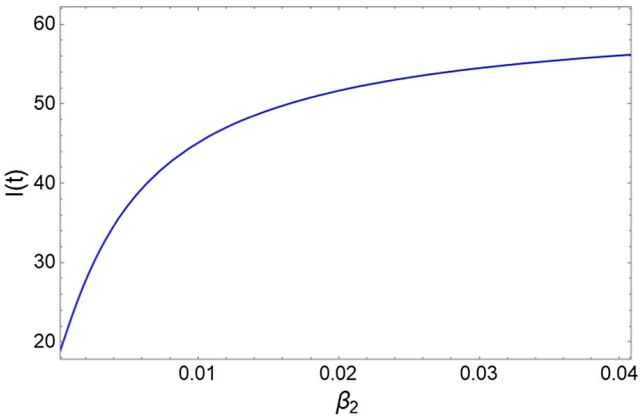

Figure 6 depicts the effect of time delay on the infected population. We plot the infected population for different values of time delay $\varrho=1, 7$, and 14, respectively. It reveals that the large value of time delay causes an increment in the infected population.

Figure 7a–c shows the influence of different transmission rates on infected population $I(t)$. It validates the increment in the number of infected population as the transmission rates increase, which is biologically true.

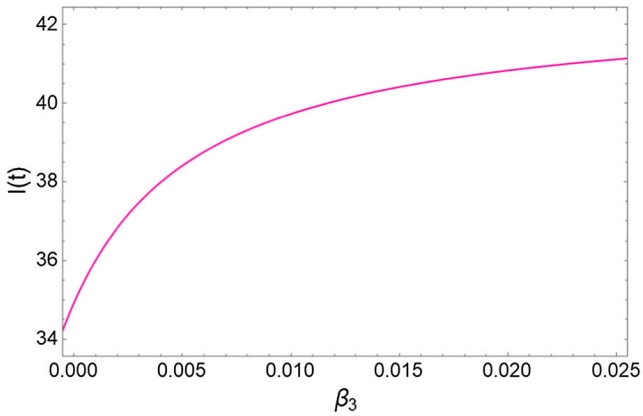

Figure 8a, b shows the impact of full and partial awareness rates (δ_1 and δ_2) on the infected population for the time delay $\varrho=1$. It is evident that if the full awareness rate is high, then infection diminishes at a high level. Partially awareness in humans also helps

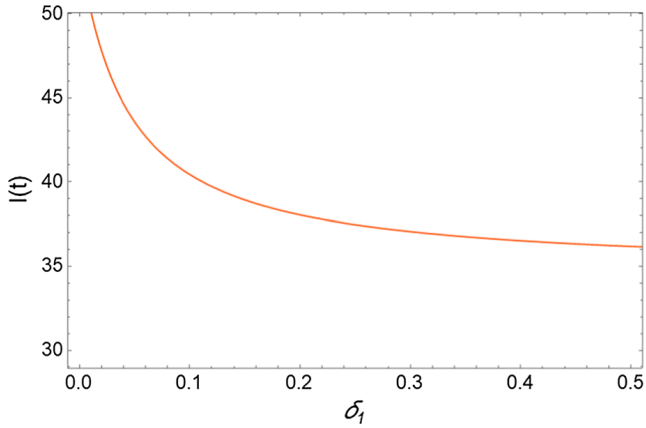
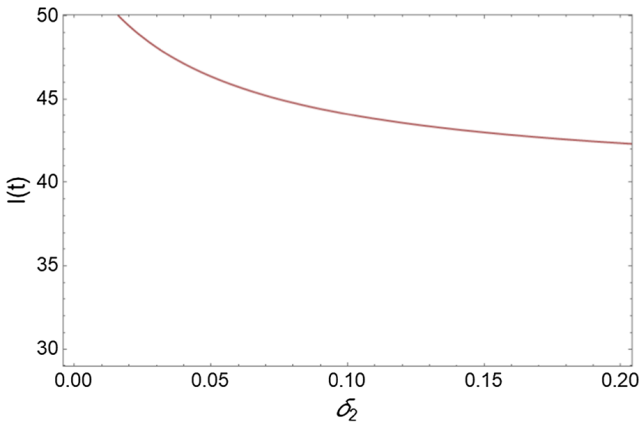
(a) Infected population $I(t)$ when β_1 varies.



(b) Infected population $I(t)$ when β_2 varies.



(c) Infected population $I(t)$ when β_3 varies.

Fig. 7 Infected population for the transmission rates of unaware, fully aware, and partially aware susceptibles for the time delay $\varrho = 1$

(a) Infected population $I(t)$ for δ_1.

(b) Infected population $I(t)$ for δ_2.

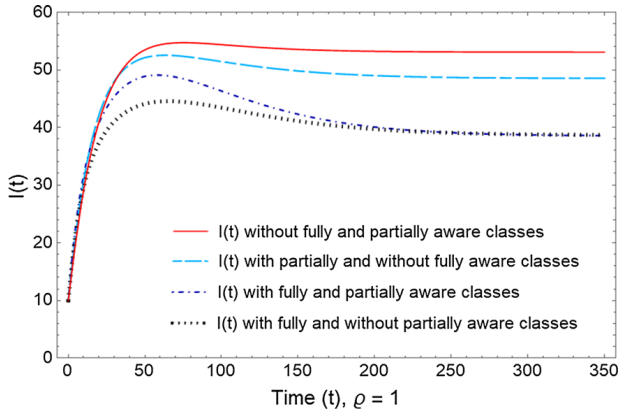

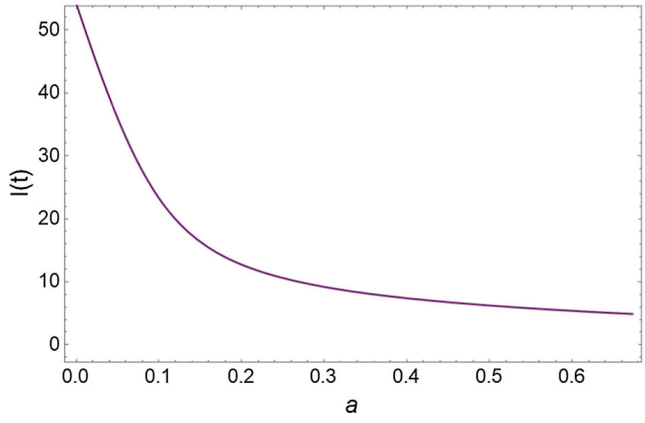

Fig. 9 Dynamics of infectious diseases showing the impact of aware classes on infected individuals $I(t)$ for the time delay $\varrho = 1$

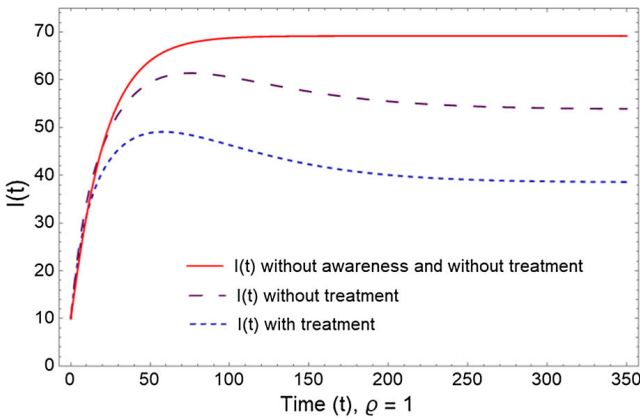

them to escape from the infection, as depicted in Fig. 8b. Thus, more efforts should be put to spread full awareness among people.

Figure 9 examines the potential of fully and partially aware classes in minimizing the impact of an epidemic. From the graph, it is evident that when people are not aware of the spread of disease at all (shown by a solid red line), then the infection occurs at a higher rate. Awareness in humans motivates them to escape from the infection. By the full and right information about a disease, individuals change their attitudes and actions to reduce their chances of becoming infected, spreading the disease further, or experiencing prolonged periods of medical treatment. Attempts to raise awareness of an infectious disease may also build a sense of threat in individuals who are inadequately informed. When there is only partial information available, then infection reduces, but a low level (as shown by the dashed green line). Because of weak, inaccessible, and absence of education, uneducated individuals are rarely formally trained in the process of handling diseases, its prognosis, and diagnosis, preventions, and cures. They take preventive measures by word of mouth or by social media, which leads to a reduction in the infection at a low level. Also, if people are partially mindful, then there are chances that they can take unnecessary medications due to fear of catching the infection, which can weaken their immune system. So those people are at more risk of getting infected (shown by the dot-dashed blue line). Therefore, the absence of partial awareness and presence of full awareness about the spread and prevention of disease are leading to a reduction in the range of illness at the high rate (shown by the dotted black line).

Figure 10a shows that the increase in the cure rate can increase the reduction in infected individuals. Figure 10b shows the influence of saturated treatment rate on infected population $I(t)$. We have plotted the infected population when there is neither treatment nor awareness available. Clearly, in this case, infection is spreading at a very high rate. Purple dashed line shows the infected population when people are aware, but treatment is not available, and the solid red line shows the infected population in the absence of awareness and treatment. The major difference can be seen between these two lines. Blue dashed line shows

(a) Effect of cure rate a on Infected population $I(t)$ for the time delay $\varrho = 1$.

(b) Infected individuals $I(t)$ with and without saturated treatment rate and aware classes for the time delay $\varrho = 1$.

Fig. 10 Impact of cure rate, awareness, and saturated treatment on the infected population for $\varrho = 1$

the infected population when both awareness and treatment are present, which is stabilizing at the lowest level among three lines. Thus, the treatment rate with awareness helps in reducing infection at a faster rate.

To show the presence of Hopf bifurcation, we take the following experimental data: $\kappa = 10$, $\varepsilon = 0.92$, $\beta_1 = 0.2$, $\beta_2 = 0.02$, $\beta_3 = 0.04$, $\delta_1 = 0.05$, $\delta_2 = 0.03$, $\vartheta = 0.1$, $a = 0.2$, $b = 0.5$, $\theta = 0.01$, $d = 0.01$.

We obtain that $E_e(S^*, A_F^*, A_P^*, I^*) = (25.5152, 10.5267, 5.37598, 42.1257)$, at these values of parameters.

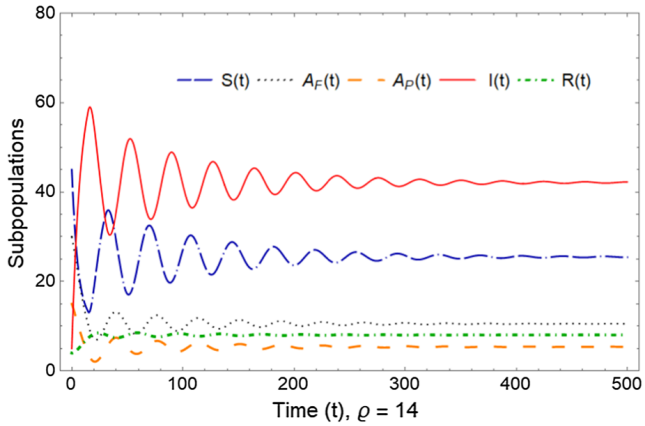

Figure 11 depicts the time series solutions of the model (1) with their respective SIR phase plot for distinct values of time delay ϱ. It is observed that the spread of infectious disease can be controlled for $\varrho = 14$, and $\varrho = 21$. That is, Fig. 11a–d shows that initially periodic solutions appear but after a time; the endemic equilibrium E_e reached to its steady state. Figure 11e–h shows the unstable limit cycle around the endemic equilibrium when time delay $\varrho > \varrho_0 = 24$.

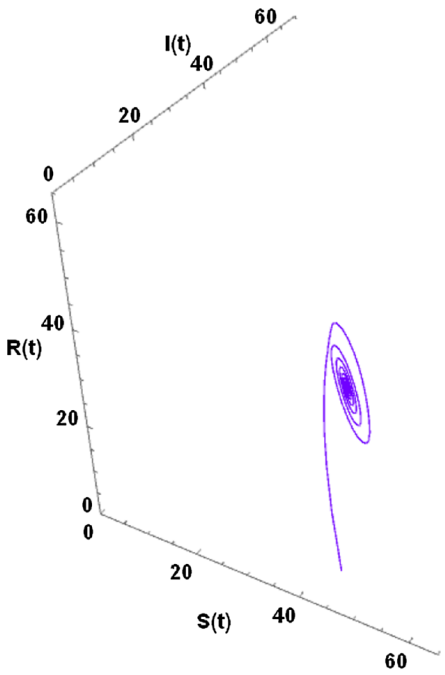
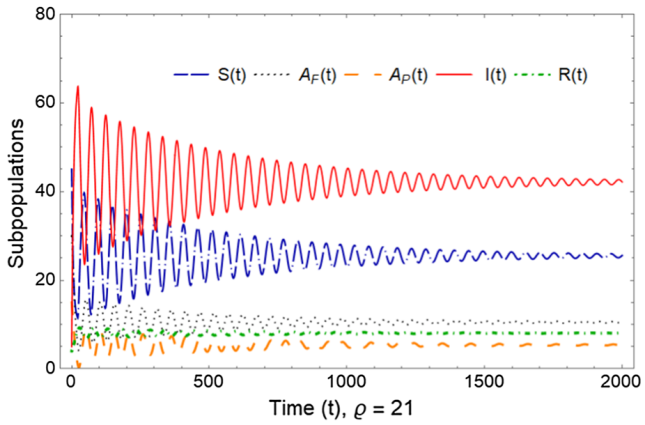
5 Discussion



In the present article, we divide the total population into five compartments: unaware susceptibles, fully aware susceptibles, partially aware susceptibles, infected, and removed individuals and study a time-delayed epidemic model with the inclusion of saturated incidences and treatment rates. We analyze the model mathematically and study the dynamic behaviors of the epidemic model with and without time delay ϱ. The mathematical analysis of the model shows that it exhibits two equilibria: disease-free and endemic. By deriving the basic reproduction number R_0, we prove that the disease-free equilibrium is locally asymptotically stable when $R_0 < 1$, unstable when $R_0 > 1$, and linearly neutrally stable when $R_0 = 1$ for the time delay $\varrho > 0$. When we don't consider the time delay, then using the center manifold theory, it is obtained that the forward or backward bifurcation occurs when $R_0 = 1$. We obtain the bifurcation range of forward and backward bifurcations, given in the inequalities (20), (21), and (22), respectively. In the presence of forward bifurcation, as R_0 increases through unity, the disease-free equilibrium loses its stability, and a stable endemic equilibrium appears. In contrast, the presence of backward bifurcation shows that a stable endemic equilibrium coexists with a stable DFE when $R_0 < 1$. It has an important implication as it fails the ideal condition of reducing R_0 below unity to eradicate the diseases from society. Thus, the control programs must reduce R_0 further than below unity to eliminate the disease. Schematic diagrams of forward and backward bifurcation are depicted in Figs. (2), (3), and (4). Further, the local stability of the endemic equilibrium has been studied, which demonstrates that by choosing time delay as a bifurcation parameter, the Hopf bifurcation occurs near the endemic equilibrium, revealing the presence of oscillatory and periodic solutions.

The numerical simulations show the graphical representation of the effectiveness of theoretical results. We see that the consideration of time delay has a significant role as it has an impact on the number of infectives. It is seen that when the time delay is high, then infection spreads at a higher rate. The periodic and oscillatory solutions have been plotted near endemic equilibrium, which shows the presence of Hopf bifurcation at different values of time delay ϱ. As the delay ϱ passes through the critical value ϱ_0, the endemic equilibrium loses its stability, and an unstable limit cycle appears. When there is no treatment available, then knowledge about the spread of disease is the main focus. The role of full and partial awareness in susceptibles, with and without saturated treatment, has been shown numerically. When treatment is not given to infected individuals, then only susceptibles' full or partial awareness shows the significant difference in the number of infectives (Figs. 9, 10b), whereas if we consider saturated treatment rate along with awareness in the susceptibles, then the transmission pattern of infectious diseases changes more effectively, and the reduction in the prevalence of the disease can be seen to the more extent.



The findings of the model, consisting of explicit saturated incidences with latent period and saturated treatment rate, are capable of demonstrating the significant role of the latent period, the behavior of susceptibles through different subclasses, and limitation in available facilities of treatment. The results are capable of understanding the role of varying protection levels of susceptibles in the transmission pattern of the infectious diseases and hence further suggesting the control strategies to prevent the spread of infections at a massive scale. The full awareness about the spread of infectious disease increases public perception to avert infection and willingness to adopt prevention methods, which mitigates the transmission of disease. Due to the

different social, educational, and limited information resources, some people may have incomplete information. Therefore, these partially aware individuals adopt insufficient preventive methods, through which infection reduces but at a low level. Public health initiatives can put extra effort into making individuals fully aware by enhancing health literacy and providing sufficient information resources. It can contribute to early case detection and help in reducing the transmission of infection. Thus, for the eradication of the disease, programs related to regular knowledge, full information, education, and communication, concerning the spread of infectious diseases and its importance to the public and health-care workers, will help them in improving their general attitude toward it. Timely disease pieces of information updates are highly needed. Together with awareness, appropriate treatment to infectives and the availability of health resources will help in diminishing the infection from society, effectively.

Appendix

Using Mathematica 11, we obtain the coefficients of the characteristic equation (32) as follows:

$$K_1 = \frac{a + (1+bI^*)^2(d+\theta+4\vartheta) + \delta_1(1+bI^*)^2 + \delta_2(1+bI^*)^2}{(1+bI^*)^2},$$

$$K_2 = \frac{(\delta_1+\delta_2)\left(a+(1+bI^*)^2(\theta+d+3\vartheta)\right) + 3\vartheta\left(a+(d+\theta+2\vartheta)(bI^*+1)^2\right)}{(1+bI^*)^2},$$

$$K_3 = \vartheta\left((\delta_1+\delta_2)\left(2a+(1+bI^*)^2(2(d+\theta)+3\vartheta)\right) + \vartheta\left(3a+(bI^*+1)^2(3(d+\theta)+4\vartheta)\right)\right),$$

$$K_4 = \frac{\vartheta^2(\delta_1+\delta_2+\vartheta)\left(a+(d+\theta+\vartheta)(1+bI^*)^2\right)}{(1+bI^*)^2},$$

$$K_5 = \frac{\beta_3\left(-A_P^* + \varepsilon I^{*2} + I^*\right) + \beta_2\left(-A_F^* + \varepsilon I^{*2} + I^*\right) + \beta_1\left(-S^* + \varepsilon I^{*2} + I\right)}{(\varepsilon I^*+1)^2},$$

$$\begin{aligned}
K_6 = {} & \frac{1}{(1+bI^*)^2(1+\varepsilon I^*)^2}(\beta_3(I^*(\varepsilon I^*+1)\\
