Currently, chalcopyrite Cu(In,Ga) $(S,Se)_2$(CIGS) and CdTe solar cells have high cell efficiencies of 22.6 [27] and 22.1% [28], respectively. However, the toxicity of Cadmium (Cd) and the constrained supply of Indium (In) have raised concerns. Therefore, the use of abundant raw materials is critical to ensure the economic fabrication of solar cells [29]. In recent years, the absorber layer of solar cells constructed from materials such as copper–zinc–tin–sulfide (Cu_2ZnSnS_4 or CZTS), copper–zinc–tin–selenide ($Cu_2ZnSnSe_4$ or CZTSe), and copper–zinc–tin–(sulfur/selenium) ($Cu_2ZnSn(S,Se)_4$ or CZTSSe) have gained interest as potential replacements for conventional solar cells [30]. Compared to other materials such as cadmium telluride, these materials have relatively low toxicity and advantageous optical and electrical features, such as high absorption coefficients and tunable bandgaps [31]. Quaternary semiconductors like CZTS, CZTSe, and CZTSSe can all be produced inexpensively and sustainably [32]. Furthermore, they have the potential to provide reduced costs per watt of energy produced compared to conventional silicon-based solar cells. They are also suitable for usage in tandem solar cells, which can further boost their efficiency, due to their capacity to absorb a broad range of sunlight spectrum [33]. However, before CZTS, CZTSe, and CZTSSe can be used as replacement materials for solar cells, there are still several issues that need to be resolved. Increasing high conversion efficiencies, which are currently lower than those of silicon-based solar cells, is a major challenge [33]. Enhancing the reproducibility and stability of these materials, which can be impacted by elements such as the synthesis method, composition, and processing conditions, is another difficulty. There are various materials used in solar cell fabrication with Various narrow band gap semiconducting materials such as CIGS, $CuInS_2$, PbS, CdSe, CdTe, Bi_2S_3, Sb_2S_3. CZTS is the most promising but less studied compound as compared to other compounds for solar cell application. Moreover, recently advanced technology leads to the development of a variety of chalcogenide quantum dots such as binary metal chalcogenides QDs and alloyed QDs [34, 35]. The application of artificial intelligence, machine learning, and simulation can accelerate the screening and discovery of novel materials with potential properties for certain applications [36, 37]. The doping-inducted heterojunction is an effective strategy to boost the fabrication of semiconductor devices and photocatalysis [38, 39]. The heterojunction-based solar cells have become the front-runner among the next-generation thin-film photovoltaic technology due to their rapid great improvements in photovoltaic performance [40, 41]. The temperature effect of Solar Cells will affect the intrinsic properties of Solar Cell materials and the parameters that characterize Solar Cell performance. This will ultimately affect its power generation efficiency [42, 43].

It is known that the existence of defects in the absorber layer of solar cells is normally detereoriated the performance device. These defects such as cracks, poorly soldered joints, and mismatches occured in different layers lead to the high resistance and become hot spots in the thin film solar cells. Defects originated from interface of heterojunction also induce the deep energy levels in the semiconductor bandgap, which degrade the carrier lifetime and quantum efficiency of solar cells [44, 45]. Thus, it is necessary to improve the quality of materials, the fabrication process, and suitable doping on the solar cell to control the interfacial defects [46]. The origin of the defects is either introduced impurities or crystallographic defects such as vacancies or dislocations which are generated during the device fabrication. One has to reduce these defects at interfacial or bulk level which will not affect the photocurrent of the solar cells [47]. These defects in solar cell can be evaluated by several ways depending

on the nature and origin of the defects. Some common measurement tools such as dark current measurements, capacitance–voltage measurements, photoluminescence, electroluminescence, and I–V characteristics measurements have been used to examine the defects [48–50]. This paper also investigates the potential of Cu_2ZnSnS_4 (CZTS) as a solar absorber material for photovoltaic applications, given its eco-friendly, earth-abundant, and low-cost nature [32, 33]. Previous theoretical and experimental research on CZTS solar cells is also reviewed and CZTS was first used as a solar cell material in 1988 at Shinshu University in Japan. Researchers utilized sputtering to deposit thin films of CZTS, leading to the discovery of p-type conductive material, direct bandgap energy of 1.45 eV, and high absorption coefficients in the visible region [51]. While reported efficiencies have been much lower than the physical limit of 32% [52], Wang et al. demonstrated the highest power conversion efficiency (PCE) of 12.6%. Most simulation evaluations have been carried out using 1D simulation platforms like SCAPS or AMPS, which cannot account for the 3D properties of solar cells [53–55]. However, Lin et al. achieved an efficiency of 19.28% using a device structure based on CZTS as the absorber layer, Al-doped ZnO as a front electrode, un-doped ZnO as the window layer, and In_2S_3 as the buffer layer, with the help of the Solar Cell Capacitance Simulator (SCAPS) simulation tool [56]. The highest reported PCE of 25.30% was achieved by using a CZTS-based solar cell structure (Al:ZnO | i–ZnO/ZnSe/CZTS/Se) with an absorber layer thickness of 2 μm and a buffer layer thickness of 50 nm, with V_{OC} = 1.10 V, J_{SC} = 25.84 mA/cm^2, and Fill Factor (FF) = 88.47% [57]. These results demonstrate the feasibility of creating highly efficient CZTS solar cells. To increase the PCE, the Silvaco Atlas modeling program was used to create and simulate the CZTS solar cell, exploring its energy bandgaps, photogeneration and recombination rates, and the effect of defect density on PCE.

In this study, we explore the parameters for enhancing the absorber layer of CZTS-based solar cells by modifying the defect density. The validation of our findings is further confirmed through Silvaco Atlas simulation software. This paper presents an analysis of the photogeneration rate, recombination rate, and solar cell performance in response to variations in the absorber layer's defect density. Our results demonstrate that at a defect density of 1.8×10^{12} cm^{-3}, the solar cell achieves a peak efficiency of approximately 26.58%. These promising outcomes indicate the possibility of developing highly efficient CZTS solar cells.

2 Theoretical details

2.1 Simulation tool

The Simulation tool which has been applied in this scheme is Silvaco Atlas. It is applicable, particularly in simulating semiconductor devices. It foresees a device containing electrical properties and, at the same time, it can be observed in at least two dimensions: two dimensions (2D) and three dimensions (3D). The simulation uses several programs, including Deckbuild, Devedit, Tonyplot, and Athena, along with several subprograms that are accessible during the simulation and perform more specialized tasks that combine to produce realistic results [58]. Here, integrated programs facilitate the users in simulating the prototypes of semiconductor devices on their fundamental features. As a result, the programs exist with several prototypes, numerical systems, and many other types of inherent mechanisms which have been automated into the system, thereby giving a wide range of possibilities for operating the systems by its users [59].

2.2 Device structure

The proposed solar cell Al: ZnO/i–ZnO/CdS/CZTS/Mo is supposed to be a single-junction solar cell device model with CZTS as the absorber layer material. The front electrical contact made of Al: ZnO has been selected because it is transparent to incident solar radiation. The n-type CdS layer serves as the buffer layer and forms a hetero-structure p–n junction with the p-type CZTS absorber layer, while the i–ZnO layer has been used as the window layer and serves as a passivation layer. Table 1 lists the material parameters that were chosen for this study. These parameters were taken from published works [56, 60, 61]. Figure 1 depicts the device topology of the proposed CZTS-based solar cells.

Table 1 Calibrated CZTS structure of material parameters in solar cell

Parameters	ZnO:Al [60]	i–ZnO [73]	CdS [27]	CZTS [60]
Thickness (nm)	450	80	100	600
Relative permittivity (ε_r)	9	9	10	10
Band gap Eg (eV)	3.3	3.3	2.4	1.45
Electron affinity χ (eV)	4.4	4.4	4.2	4.1
Effective conduction band density N_c (cm^{-3})	2.2×10^{18}	2.2×10^{18}	2.2×10^{18}	2.2×10^{18}
Effective valence band density N_v (cm^{-3})	1.8×10^{19}	1.8×10^{19}	1.8×10^{19}	1.8×10^{19}
Electron mobility μ_n (cm^2. V^{-1}. S^{-1})	100	100	100	5
Hole mobility μ_p (cm^2. V^{-1}. S^{-1})	25	25	25	1
Donor concentration N_d (cm^{-3})	1×10^{18}	–	1×10^{17}	–
Acceptor concentration Na (cm^{-3})	–	–	–	1×10^{16}
Gaussian defect density for the donor (cm^{-3})	–	–	–	1.8×10^{13}
Gaussian defect density for acceptor (cm^{-3})	1.8×10^{16}	–	1.8×10^{17}	–

3 Result and discussion

3.1 Optimization of the thickness of the absorber layer

The performance of a solar cell is significantly affected by the thickness of its absorber layer. In this investigation, we examined the effect of changing the thickness of the CZTS absorber layer. It was discovered that CZTS demonstrates exceptional absorption in the blue region compared to other absorber materials, primarily due to its high absorption coefficient (> 104 cm^{-1}) [62]. The simulation encompassed a range of thicknesses for the solar cell, from 100 to 1000 nm, and the results are depicted in Fig. 2. The simulation results indicate that a thickness of 600 nm is optimal for achieving nearly complete absorption of AM 1.5G radiation, thanks to the material's strong absorption coefficient and direct bandgap [63]. As the CZTS layer increases in thickness, both the Jsc (short-circuit current density) and Voc (open-circuit voltage) of the solar cell also increase, resulting in improved efficiency and fill factor. The greater absorber layer absorbs more photons with longer wavelengths, facilitating the generation of electron–hole pairs, which accounts for this effect [64].

3.2 Optimization of defect density on the performance of the cell

The efficiency of the solar cell is greatly influenced by the defect density. The maximum PV parameter values, such as Voc, Jsc, FF, and, were observed up

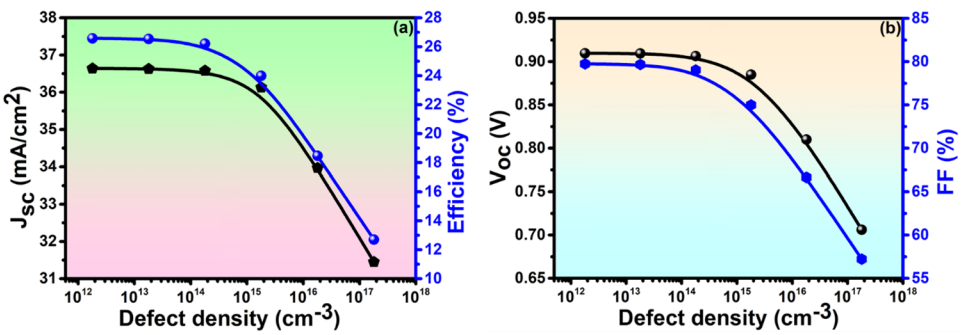

Fig. 2 Impact of defect density on **a** short-circuit current density and efficiency **b** Open-circuit voltage and fill factor

to a defect density of 10^{14} cm^{-3} [65]. This effect was observed in the light-absorbing CZTS layer. The flaw density of the absorber layer CZTS has been adjusted in this work from 1.8×10^{12} to 1.8×10^{17} cm^{-3}. While the fault density is less than 1.8×10^{14} cm^{-3}, it can be seen that the performance is consistent. The output factors are substantially impacted when the fault density exceeds 1.8×10^{14} cm^{-3}, though. Because there are more recombination centers available due to the rise in defect states in the absorber layer, higher recombination of generated carriers occurs there, which lowers Jsc, Voc, efficiency, and fill factor as illustrated in Fig. 3.

3.3 Impact of photoabsorption rate and energy bandgap

The number of photons absorbed per unit area of the solar cell per unit of time in terms of wavelength for a CZTS solar cell [66] is shown in Fig. 4a. The Photon absorption rate is higher at the junction between the CdS buffer layer and the CZTS absorber layer because more photons can be absorbed due to less energy bandgap of the CZTS layer, after that, there is a sharp decrease. Almost 97% percent of a photon can be absorbed with the 600 nm thick CZTS layer, it is because photons having energy higher or equal to 1.46 eV are absorbed in the CZTS layer [67].

The bandgap energy is the minimum energy that is needed to knock out electrons from the lower energy state to the conduction energy state where they can contribute to photogeneration [68]. The energy band diagram of the CZTS solar cell is shown in Fig. 4b. The energy bandgap of ZnO is higher (3.37 eV), as a result, the lower wavelength of the light is absorbed by the ZnO in all other wavelengths and all the bottom CdS buffer layers are absorbed mid-range or visible region spectrum, and where the CZTS absorber layer is used to absorb higher wavelength. The CdS buffer and CZTS absorber layer are used to control the recombination and form a heterojunction with the CZTS layer [60].

3.4 Impact of photogeneration and recombination rate

One of the key features of the solar cell that improves its overall performance is the photogeneration and recombination process. The total number of electrons produced in the PV cell as a result of light absorption is expressed as the photogeneration rate [67]. The photogeneration rate is almost constant at 21 photons

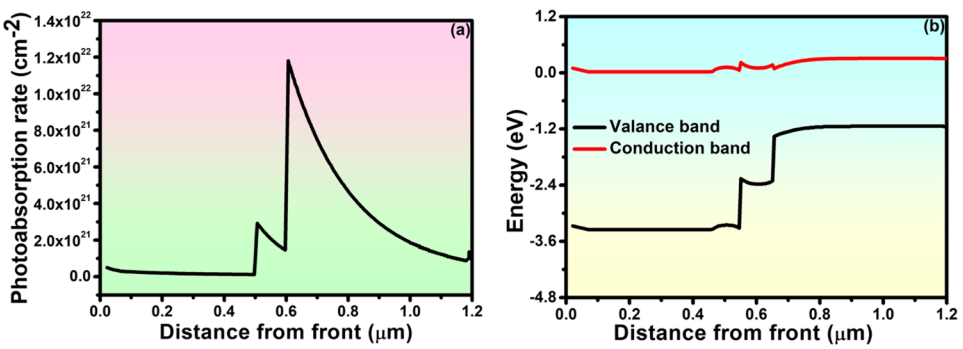

Fig. 3 Analysis of **a** photoabsorption rate and **b** Band gap energy with distance from front

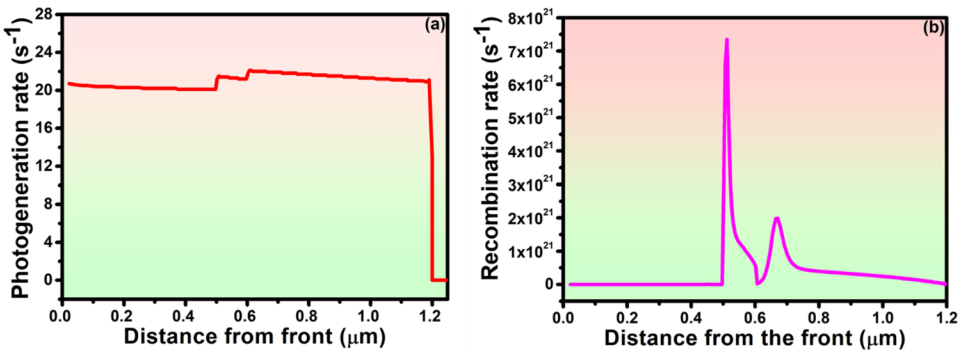

Fig. 4 Analysis of **a** photogeneration rate and **b** Recombination rate with distance from front

per cm^3 which is mostly due to radiative recombination, and which restricts the efficiency of the solar cell. In a CZTS-based cell probability of radiative recombination increases that of non-radiative recombination when there is a direct transition of the carrier between the conduction and valence band [69]. The photogeneration rate of the purposed CZTS solar cell is shown in Fig. 5a. Similarly, the recombination rate is higher at the junction between the CdS buffer layer and the CZTS absorber layer as described in Fig. 5b. The sunlight produced minority carriers of electrons and has more probability to recombine with a hole in the absorber and increasing the recombination rate can decrease efficiency as well. The decrease in crystallinity in the interface between the CdS and CZTS layer leads to a reduction in the efficiency of CZTS-based solar cells [60].

3.5 Analysis of electric potential and electric field

In the mechanism for energy loss within the solar cell, the distribution of the electrical field is crucial [70]. Electrostatic potential fluctuations suffer because CZTSSe has a lower dielectric constant than CIGS [71]. Within the CZTS absorber layer, the electric potential is larger than outside, and it then begins to decrease as seen in Fig. 6a. To improve the transport mechanism of the photogenerated carriers, the CZTS absorber layer electric field can be adjusted by altering the Se content in the absorber layer [72]. Electric field spikes can be visible at the CdS buffer layer and the CZTS absorber layer in Fig. 6b. The buffer layer is essential to the creation of an electric field at the junction in the space charge zone [73].

3.6 Photovoltaic (PV) properties

The performance of solar cells depends upon Isc, Voc, FF, and efficiency. After the simulation of the solar cell using the parameters shown above in Table 1 by the Silvaco atlas, I–V characteristics of the CZTS solar cell as shown in Fig. 7a have been obtained. It is seen that the PCE of solar cells has been observed at 26.58% with a defect density of 1.8×10^{12} and the Isc, Voc, and Fill factors have been observed as 36.64 mA/cm^2, 0.909 V, and 79.25% respectively. The reported PV properties of CZTS solar cells have been summarized in Table 2.

Quantum efficiency is the ratio of incident photons of particular energy to the number of carriers the solar collectors can capture [74]. As the wavelength of the solar cell increases from 300 nm, the quantum

I–ZnO/n–CdS/p–CZTS/Mo	36.64	0.909	79.74	26.58	This work

efficiency increases. At the wavelength between 550 and 900 nm quantum efficiency is almost constant at some value and then starts decreasing rapidly from 100 nm wavelength as shown in Fig. 7b. It is noted that the external quantum efficiency (EQE) reached nearly 90% at wavelengths 550 to 900 nm.

4 Conclusions

ZnO–Al/i–ZnO/n–CdS/CZTS/Mo combination was subjected to numerical analysis and optimization using Silvaco Atlas software. The study was aimed to investigate the influence of layer thickness and doping density on the solar cell efficiency. The simulation results demonstrate that the solar cell can achieve a maximum efficiency of approximately 26.58% when the defect density is at 1.8 × 1012 cm^{-3}, accompanied by Isc = 36.64 A and Voc = 0.909 V. Furthermore, an increase in layer thickness has been observed to enhance the efficiency of the solar cell due to a greater absorption of photons. The effect of defect density on the absorber layer, photogeneration, and recombination processes on solar cell efficiency has also been examined. By optimizing the cell parameters, an improved power conversion efficiency (PCE) of 26.58% and a fill factor (FF) of 79.74% were achieved, underscoring the potential of CZTS-based solar cells as cost-effective and highly efficient alternatives.

Abstract: Alzheimer's disease is a chronic neurodegenerative disease that causes brain cells to degenerate, resulting in decreased physical and mental abilities and, in severe cases, permanent memory loss. It is considered as the most common and fatal form of dementia. Although mild cognitive impairment (MCI) precedes Alzheimer's disease (AD), it does not necessarily show the obvious symptoms of AD. As a result, it becomes challenging to distinguish between mild cognitive impairment and cognitively normal. In this paper, we propose an ensemble of deep learners based on convolutional neural networks for the early diagnosis of Alzheimer's disease. The proposed approach utilises simple averaging ensemble and weighted averaging ensemble methods. The ensemble-based transfer learning model demonstrates enhanced generalization and performance for AD diagnosis compared to traditional transfer learning methods. Extensive experiments on the OASIS-3 dataset validate the effectiveness of the proposed model, showcasing its superiority over state-of-the-art transfer learning approaches in terms of accuracy, robustness, and efficiency.

1. Introduction

Alzheimer's disease (AD), the most common form of dementia, poses a significant challenge to healthcare providers. It causes a progressive, irreversible brain disorder characterised by a deterioration of cognitive functions. In the United States, Alzheimer's disease is the fifth leading cause of death among adults age 65 and older, and there was a 145% increase in deaths from Alzheimer's disease in 2017 [1]. Recently, a significant amount of research [2–6] has been conducted in order to detect early and pre-symptomatic stages of AD to slow or prevent the progression of the disease. Surprisingly, simple cognitive assessments of dementia were only accepted by a minority of the older adults. In particular, techniques based on MRI testing have been developed and used to identify AD [5]. The accuracy of an AD diagnosis mostly depends on the biomarkers of the disease. The features to detect Alzheimer are extracted from the region of interest (ROI) of the brain which has the potential to contain the tissue that are sensitive markers for dementia. Similarly, the distinctive features are confirmed by the histopathology of dementia that display these ROI in the amygdala and hippocampus embedded deep into the temporal lobe of the brain [7,8]. Due to the recent advancements in automating the prediction of early diagnosis of dementia, the objective has shifted to help non-experts and non-neurologist users to identify early signs of AD.

AI-based computer-aided diagnosis (CAD) has become a feasible and a popular tool in medicine due to its low cost and transparent decision making [9–12]. Traditional methods of feature extraction require handcrafted features [13–16]. Castellazzi et al. [17] combined advanced qMRI measurements along with conventional machine learning techniques to classify AD from Vascular Dementia (VD) and investigated if the suggested method might be used to forecast the common illness in those who do not have distinct AD or VD profiles. In the work proposed by Battineni et al. [18], four machine learning algorithms were trained with three different sets of experiments—extracting features manually, extracting features automatically, and ensembling all the models. Alickovic et al. [19] manually extracted brain characteristics using the histogram approach in order to feed the data into the Random Forest model. The proposed method is not only a conventional process, but it is also time-consuming and leads to accuracy that is subpar.

On the other hand, deep learning (DL) approaches are incredibly effective since they automatically extract key characteristics from the data. Transfer learning may recognise new things in accordance with the knowledge that is learnt from other things, just like human cognition can. Based on the notion that transfer learning can efficiently use the knowledge of old domains to identify the goals of a new domain, numerous enhanced transfer learning methodologies have been presented in recent years. Ahana et al. [20] employed two strategies: one is ensembling different machine learning algorithms via two methods, gradient boosting and a voting classifier, and the second is training an artificial neural network (ANN) to detect AD. A lot of researchers have confined their studies of classification of AD to the ADNI dataset, as investigated in some papers [21–23]. However, ensembles of deep convolutional architectures and similar networks that use deep learning have produced the best results. Wang et al. [21] presented an ensemble of 3D densely connected convolutional networks (3D-DenseNets) for AD and MCI diagnosis. The use of a probabilistic-based ensemble method showed an increase in accuracy.

In this paper, we propose to use the ensemble technique by combining the predictive capabilities of various state-of-the-art pre-trained transfer learning models for AD diagnosis. At the beginning, pre-processed MRI images are passed on to each individual pre-trained model such as VGG19, DenseNet201, EfficientNetV2S, MobileNet, ResNet152, InceptionV3, NASNetLarge, and Xception. This method has been proven useful for the insufficient availability of large image datasets [24,25]. The following are our key contributions to this work:

- This paper presents a neural network framework with two ensemble methods, i.e., weighted averaging and simple averaging, on the OASIS-3 dataset for AD diagnosis.
- Fine tuning of eight different models such as VGG19, DenseNet201, EfficientNetV2S, MobileNet, ResNet152, InceptionV3, NASNetLarge, and Xception achieved a higher accuracy in comparison to the state of the art.
- This paper conducts a qualitative evaluation in the result variations of pre-trained models between cropping and without cropping of MRI images.

The rest of the research paper is structured as follows: In Section 2, related work is discussed. Section 3 entails the details of the workflow of the proposed framework along with the detailed discussion of the dataset and ensemble learning. Section 4 lays down the experiments and results performed on the provided dataset. Finally, Section 5 summarizes this study with future insights.

2. Related Works

The field of Alzheimer's disease (AD) classification has indeed made significant advancements with the utilisation of multimodal brain imaging data and deep learning approaches. Deep convolutional neural networks (CNNs) have emerged as powerful tools for AD classification due to their ability to leverage the rich information provided by various imaging modalities. Several research studies have been conducted to improve the classification of AD using deep learning techniques. Some studies focus on manually building feature extraction approaches combined with machine learning algorithms, while

others utilise deep learning methods. For example, a hybrid deep learning framework was introduced for the early-stage diagnosis and detection of AD [26], and improved CNNs were proposed for classifying AD using multimodal brain imaging data [27].

Liu et al. [28] presented a multi-modality cascaded convolutional network for the prediction and detection of AD. A systematic study on deep-learning-based medical image analysis for disease diagnosis was conducted by Abdou [29]. Additionally, a multi-scale feature fusion network was introduced for classifying illnesses like AD using MRI data [30], and a three-channel phase feature learning model was proposed for jointly learning from MRI and PET images for AD diagnosis [31]. Various deep learning methods, including CNNs, stacked deep polynomial networks, and generative adversarial networks (GANs), have also been explored for the diagnosis of AD. For instance, a tensor-train, high-order pooling and semisupervised learning-based GAN (THS-GAN) was presented by Yu et al. [32], and Shi et al. [33] developed multimodal deep polynomial networks.

CNNs can be used as feature extractors and classifiers, or solely as feature extractors. Some researchers use CNN to extract features and then apply traditional machine learning methods for classification [34]. CNN has been employed to extract target-level representations generated from sparse regression for clinical decision making [35]. Furthermore, a combination of 3D CNN with MRI was utilised for AD classification [36]. In specific studies, 2D CNNs have been developed and trained using 2D MRI slices as input. Wang et al. [37] incorporated a pre-trained VGG-16 feature extractor from ImageNet and explored the application of Lasso and PCA in conjunction with CNN to predict the conversion of mild cognitive impairment (MCI) to AD. Similarly, in [38], a landmark-based deep multi-instance learning (LDMIL) classifier was proposed, which can detect anatomical landmarks in brain MRI images and define regions of interest (ROIs) for diagnosis using the ADNI dataset.

Other approaches have focused on structural magnetic resonance imaging (sMRI) to improve AD diagnosis. For example, a dual-attention multi-instance deep learning model (DA-MIDL) was developed to extract global and local features and create a classification system [39]. Automatic segmentation methods using the ensembling of neural networks on the hippocampus region have also been employed [40,41]. Furthermore, a semi-supervised multimodal Laplacian regularized least squares (mLapRLS) method was developed to differentiate MCI subjects from healthy controls (HC) [42], and an architecture capable of combining multimodal neuroimaging information in one setting was proposed to classify AD [43]. Lastly, Liu et al. [44] developed a Monte Carlo ensemble neural network on 2D image slices from multiple database sources and achieved an accuracy of 90% for AD classification.

The field of Alzheimer's disease (AD) classification has made significant advancements using multimodal brain imaging data and deep learning approaches, particularly deep convolutional neural networks (CNNs). Deep learning eliminates the need for manual feature extraction and allows for the automatic learning of features. CNNs have proven effective in AD classification by leveraging the rich information provided by various imaging modalities. Several techniques have been proposed, including hybrid deep learning frameworks, improved CNN architectures, multi-modality cascaded networks, and multi-scale feature fusion networks. Deep learning methods, such as stacked deep polynomial networks and generative adversarial networks (GANs), have also been explored. Moreover, 2D and 3D CNNs have been employed, with some models incorporating pre-trained feature extractors and utilising techniques like Lasso, PCA, and landmark detection. Additionally, structural MRI methods, automatic segmentation methods, and multimodal fusion techniques have contributed to improving AD diagnosis. These advancements offer valuable insights and tools for the classification and detection of AD using deep learning and multimodal brain imaging data. Addressing these research gaps is crucial to advancing the field of AD classification and improving the accuracy and applicability of deep learning models in clinical settings. By addressing issues related to generalization, interpretability, data scarcity, standardization, and the integration of clinical information, researchers can

enhance the reliability and effectiveness of AD classification methods, ultimately leading to improved diagnosis and treatment of AD patients.

3. Methodology

The early diagnosis of Alzheimer's disease (AD) can be formulated as a mathematical problem involving the identification of reliable biomarkers and the development of accurate diagnostic models. Let X be the set of potential biomarkers, including neuroimaging data, genetic markers, and biomarker measurements. Let Y be the set of diagnostic outcomes, with $Y = \{0, 1\}$ representing healthy individuals and individuals with AD, respectively. Let D be the dataset consisting of N samples, where each sample $d_i = (x_i, y_i)$ represents the biomarker measurements and corresponding diagnostic outcome for the i_{th} individual. The goal is to learn a mapping function $f : X \rightarrow Y$ that accurately predicts the diagnostic outcome based on the biomarker measurements. Our proposed architecture includes two steps: the training of individual deep convolutional classifiers and ensembling them. As an end-to-end method, deep learning relies on a large amount of labelled data to obtain features from graphs. Medical data on Alzheimer's disease, in particular, are scarce. In order to meet the requirements of the deep network, we adopt the transfer learning method, which can not only reduce the amount of calculation in the model, but can also greatly improve model performance. The last layer of the fully connected network can be altered and omitted depending on the categorising of our classes, namely, cognitively normal and mild cognitive impairment. Hence, the final fully connected layer for this purpose would have only 2 neuron units instead of 1000 employed in the models for the ILSVRC challenge. The proposed research work model architecture combines features from 8 models.

Features from all models are retrieved in this case, and the final layers are then modified as necessary. Before adding the final 2 units, dropouts are also added. The final layer computes the classification probability of each output type using the Softmax function:

$$\sigma\left(\vec{z}\right)_i = \frac{e^{z_i}}{\sum_{j=1}^{K} e^{z_j}}, \tag{1}$$

where σ corresponds to Softmax function, $\vec{z}$ is the input vector, e^{z_i} and e^{z_j} denote the standard exponential function applied to the input and output vectors, while K represents the number of classes within the multi-class classifier.

Consequently, the accuracy of individual models was improved. Secondly, 8 individual architectures after training individually on dementia images and saving the model predictions and ensembling using different weights for each model's predictions are employed. This proposed ensemble of classifiers ensures that each architecture can operate independently.

By integrating the ensembled learners, it often outperforms a single algorithm by determining the average to obtain a higher accuracy, as it is less sensitive to noise, outliers, or changes in sampling [45]. The majority of the labels predicted by each particular result of feature representation for a subject constitute the expected label. The projected label for a certain subject is the label that indicates the highest likelihood of these findings for the subject if there is a scenario in which a subject cannot be categorised when we combine two results of a single feature representation.

3.1. Dataset Pre-Processing

This experiment was performed on 113 subjects taken from OASIS-3: Longitudinal Multimodal Neuroimaging, Clinical, and Cognitive Dataset for Normal Aging and AD archive [46]. The MRI images are available in NifTI format. A total of 247 and 410 MRI scans were used for cognitively normal and mild cognitive impairment patients respectively. T1-weighted structural sequences were processed on the axial plane of brain MRIs. The Clinical Dementia Rating (CDR) Scale was used to determine the dataset's dementia status; a score of 0 on the scale indicates cognitively normal, while a score of more than 0 but less

than 2 indicates mild impairment. Each image in the dataset is completely characterised, and complete details are given.

The first task with this dataset was converting the image files from NifTI to PNG. Performing this conversion resulted in 255 slices of the axial view of the brain for each subject, as shown in Figure 1. Multiple axial scans of the brain of each patient were extracted, particularly the images containing the hippocampus embedded deep into the temporal lobe and some areas which demonstrate a significant shrinkage in some parts of the brain, were fed as an input to the neural network. Multiple slices of MRIs were extracted from each subject for accurate prediction of the disease. The middle slices contain more tissue than the border slices. Since tissues are a biomarker for dementia, central slices aid the system in precisely classifying disorders that resemble AD. For the categorisation of AD, the slices along the border are less helpful and more deceptive since they contain more of the bones and skulls. The central slices are therefore utilised for training. This section goes into great detail on the dataset preparation.

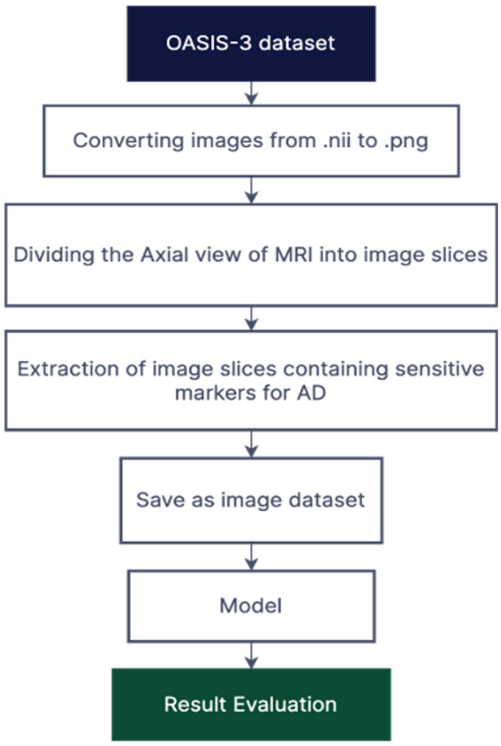

Figure 1. Illustration of the proposed methodology.

To make our predictions more robust, data augmentation technique was applied to our dataset. Since it is a classification model, the visual transformation mainly focused on flipping random images horizontally; rotating them by a certain degree and min-max normalisation; and rescaling inputs to the range of [0, 1], computed as follows:

$$y = \frac{(x - \min(x))}{(\max(x) - \min(x))}, \tag{2}$$

where $\min(x)$ and $\max(x)$ are the minimum and maximum intensity values, respectively, for the entire dataset, and y_i represents the normalised intensity value against location x_i (where $i \in [1, n]$). This helps our dataset to resolve the class imbalance issue, creating variations and generalizations for our model.

3.2. Ensemble Learning

Ensemble learning is a technique that combines the predictions of multiple individual models to make more accurate and robust predictions. It is widely used in machine

learning and has shown promising results in various domains, including Alzheimer's disease classification. In this paper, an ensemble of transfer learning models is proposed using two different methods: simple averaging and weighted averaging. By combining the predictions of these models, we aim to improve the extraction of sparse patterns and features from MRI images for Alzheimer's disease diagnosis. These learning models are used for identifying Alzheimer's disease. The proposed methodology's block diagram is shown in Figure 2. Our transfer learning models are input with 2D image slices.

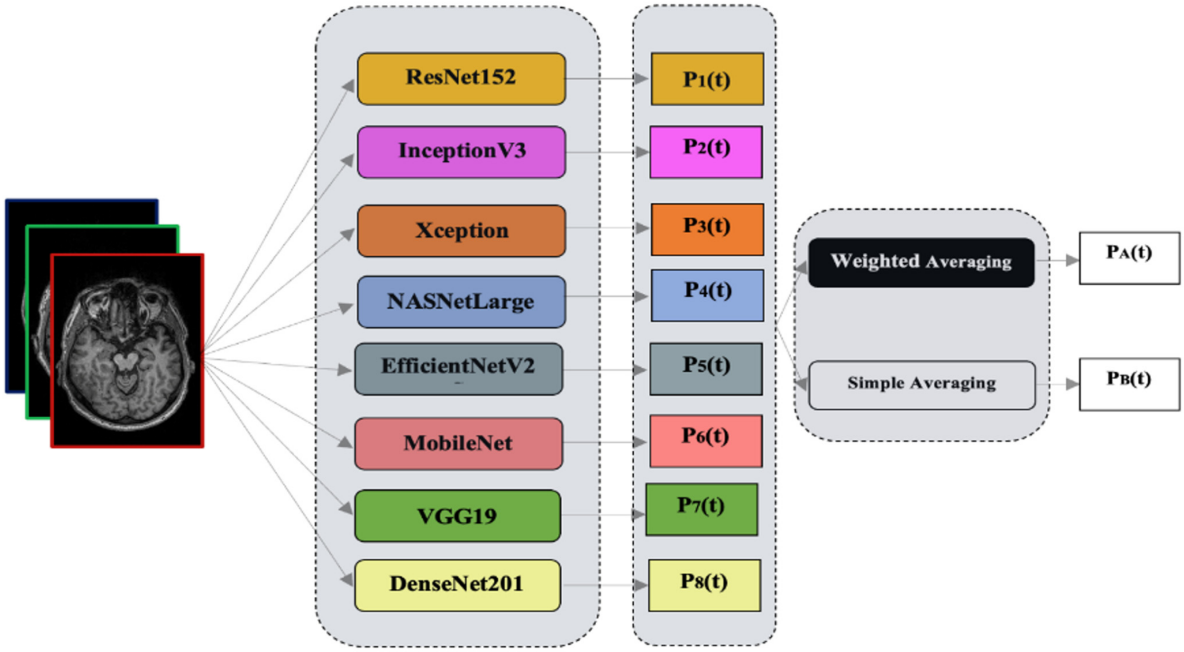

Figure 2. Graphical abstract of the proposed study.

Combining the judgements from several different models yields superior outcomes to those produced by a single model [47]. The generalization capacity of an ensemble, comprising multiple learners, is often considerably stronger than that of an individual learner, especially when it comes to weak learners. While an ensemble of weak learners can theoretically achieve good performance, in practice, people tend to prefer strong learners for various reasons. These reasons include minimizing the number of individual learners and leveraging the ability to reuse previously learned information about the strong learners [47].

In this paper, we utilise heterogeneous ensembles which have individual learners called component learners or simply individual learners. Unlike homogeneous ensembles, where all individual learners are of the same type, such as employing the same classification models, heterogeneous ensembles consist of diverse individual learners and learning algorithms, without relying on a single base learner or learning algorithm.

In order to compare and circumvent these problems, different ensemble models have been developed along with simple averaging. Weighted averaging provides various weights to various base learners. The goals were to determine which ensemble method had a strong correlation with the accuracy of the ensemble, which type of averaging had a high capacity to produce classification models that were not only accurate but also more diverse, and which types of ensembles were most likely to be able to enhance classification performance.

Simple Averaging: The most straightforward method to combine the output is by averaging them together. Let our ensemble contain T individual learners $\{h_1, h_2, h_3, \ldots\ldots, h_T\}$, where $h_i(x)$ is the result of h_i on x number of samples. The equation can be described as

$$H(x) = \frac{1}{T}\sum_{i=1}^{T} h_i(x), \tag{3}$$

This approach has the benefit being easily implemented [28], but it does not take into account that some models may perform better than others.

Weighted Averaging: The transfer learning model which has lower classification error is given a smaller weight when combined for ensembling, as described by [29]. The values of weights are assigned manually with the help of multiplying with a factor α to each model.

$$H(x) = \sum_{i=1}^{T} \alpha_i h_i(x), \tag{4}$$

where α is the weight of an individual learner h_i, and $\alpha_i \geq 0$, $\sum_{i=1}^{T} \alpha_i = 1$. It is shown in [30] that optimal choice for alpha is

$$\alpha_i = \frac{\sum_j C_{ij}{}^{-1}}{\sum_k \sum_j C_{kj}{}^{-1}}, \tag{5}$$

4. Experimentation and Results

4.1. Evaluation Indicators

The confusion matrix is a table that is commonly used in classification problems to evaluate the performance of a classification algorithm. It compares the actual and predicted values of a dataset and provides a summary of the number of true positives, true negatives, false positives, and false negatives for each class in a classification problem. The true positives (*TP*) are the number of correctly predicted positive instances, while the true negatives (*TN*) are the number of correctly predicted negative instances. The false positives (*FP*) are the number of negative instances that were incorrectly predicted as positive, and the false negatives (*FN*) are the number of positive instances that were incorrectly predicted as negative. Overall, the confusion matrix and its associated performance metrics provide valuable information for evaluating the performance of classification algorithms and identifying areas for improvement.

The following parameters and metrics are used for comparative analysis of data-driven models. In this study, the classifier correctly predicted *TP* and *TN* instances and incorrectly predicted *FP* and *FN* instances. The paper includes various performance metrics such as accuracy, sensitivity, specificity, and AUC score. It is a valuable tool for evaluating the performance of classification models and identifying areas where the model can be improved. To assess the unbiasing effectiveness of the proposed classification method, the *TP*, *FP*, *FN*, and *TN* statistical indices are computed and used to calculate accuracy, sensitivity, and specificity, as follows:

$$Accuracy = \frac{TP + FP}{TP + FP + TN + FN} \tag{6}$$

$$Sensitivity = \frac{TP}{TP + FN} \tag{7}$$

$$Specificity = \frac{TN}{TN + FP} \tag{8}$$

The entire dataset contained 657 images. The models are trained and evaluated using 5-fold cross-validation technique. We used 30 epochs with a batch size of 16. The learning rate was fixed at 0.001 for all architectures with the Adam optimizer.

4.2. Model Selection

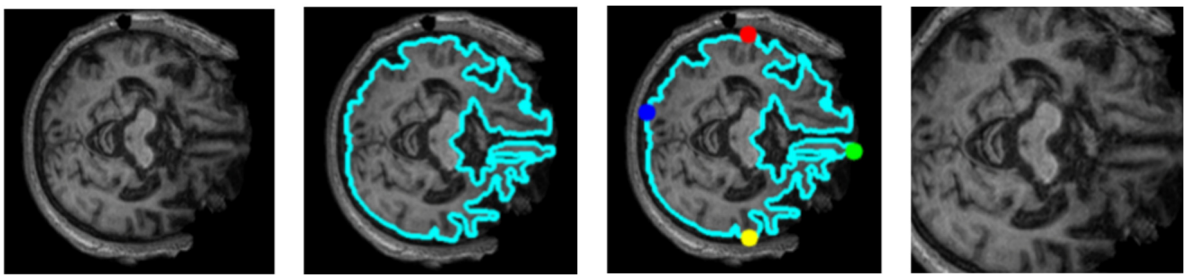
This section evaluates different pre-trained deep convolutional networks [48–55] on the OASIS dataset, as shown in Table 1. It can be observed that the VGG19 model performed the best with an accuracy of 0.977, whereas NASNetLarge model scored the least with

an accuracy of 0.912. MobileNet, DenseNet201, ResNet152, EfficientNetV2S, InceptionV3, and Xception scored an accuracy of 0.922, 0.961, 0.946, 0.952, 0.936, and 0.931, respectively. Furthermore, we improve the accuracy of the models using a cropping technique. The results demonstrate that DenseNet201 has a higher AUC score than VGG19, even though the accuracy of DenseNet201 is much less than that of VGG19. This discrepancy can be attributed to the fact that the AUC score only considers the ranking of the predicted probabilities. In contrast, the accuracy score considers both the ranking and the threshold for classification. In some cases, a model with a higher accuracy score may not have a better ROC curve and, thus, a lower AUC score.

Table 1. Performance of transfer learning models.

Models	Accuracy	Specificity	Sensitivity	AUC
MobileNet [48]	0.922	0.927	0.913	0.920
VGG19 [49]	0.977	0.949	0.961	0.958
DenseNet201 [50]	0.961	0.965	0.958	0.962
ResNet152 [51]	0.946	0.942	0.911	0.937
EfficientNetV2S [52]	0.952	0.966	0.943	0.959
InceptionV3 [53]	0.936	0.939	0.923	0.932
NASNetLarge [54]	0.912	0.927	0.913	0.920
Xception [55]	0.931	0.929	0.901	0.918

The cropping technique used extracted slices by finding the biggest contour, i.e., inside of the skull where the hippocampus is located. As shown in Figure 3, the extreme points of the brain were localised, which reduces the computation by exempting the pixels which do not contain the information of the features or unwanted space which may hinder the performance of classification model. The unwanted space also acts as noise for the image. To counter that, we applied threshold or canny edge detection, followed by finding the continuous points along the boundary having the same colour or intensity. The extreme points of the top, left, bottom, and right edges of the images were localised, and the same set of models with same hyperparameters as in without cropping the images were trained. As shown in Table 2, the performance of the eight models increased significantly in terms of accuracy and AUC score. It can be observed that VGG19 achieved the highest accuracy score of 0.982, and the lowest accuracy score was achieved by MobileNet. DenseNet201, ResNet152, EfficientNetV2S, InceptionV3, NASNetLarge, and Xception scored accuracies of 0.974, 0.966, 0.975, 0.952, 0.926, and 0.959, respectively. In terms of the AUC, VGG19 performed the best with a score of 0.986, whereas the lowest AUC score of 0.911 was achieved by NASNetLarge.



(**a**) (**b**) (**c**) (**d**)

Figure 3. Illustration of the proposed cropping technique for the extracting region of interest: (**a**) original image, (**b**) finding the biggest contour, (**c**) finding the extreme points, (**d**) region of interest.

Table 2. Performance of transfer learning models using cropping technique.

Models	Accuracy	Specificity	Sensitivity	AUC
MobileNet [48]	0.915	0.892	0.867	0.899
VGG19 [49]	0.982	0.973	0.993	0.986
DenseNet201 [50]	0.974	0.967	0.975	0.969
ResNet152 [51]	0.966	0.957	0.968	0.959
EfficientNetV2S [52]	0.975	0.988	0.969	0.973
InceptionV3 [53]	0.952	0.947	0.962	0.942
NASNetLarge [54]	0.926	0.899	0.901	0.911
Xception [55]	0.959	0.944	0.966	0.954

4.3. Model Ensembling Strategy

Training of these network was followed by ensembling in two ways i.e., simple averaging and weighted averaging. The experimentation settings for both the ensemble methods were kept same i.e., learning rate of 0.0001 with Adam optimizer and 100 Epochs. Images obtained through the cropping technique are used. Table 3 shows the performance of the two different ensemble methods. We select the best three models, i.e., VGG19, DenseNet201, and EfficientNetV2S according to Table 2 and denote their names as M1, M2, and M3 respectively. Next, we perform experiments by merging M1, M2, and M3 models in different combinations such as M1 + M2 + M3, M1 + M2, M2 + M3, and M1 + M3. According to Table 3, the best performance with an accuracy of 0.989 is achieved by combining models (M2 + M3) using simple averaging method. However, the lowest accuracy of 0.941 is achieved on M1 + M2 + M3 model that used weighted averaging method. In terms of the AUC, highest score is obtained by M1 + M2 with simple averaging method whereas lowest score is achieved by M1 + M2 + M3 model with weighted averaging method.

Table 3. Performance of ensemble networks using two different methods.

Ensemble Method	Models	Accuracy	Specificity	Sensitivity	AUC
Simple Average	M1 + M2 + M3	0.971	0.960	0.973	0.966
	M1 + M2	0.969	0.958	0.983	0.979
	M1 + M3	0.977	0.989	0.969	0.977
	M2 + M3	0.989	0.967	0.978	0.968
Weighted Average	M1 + M2 + M3	0.941	0.942	0.922	0.936
	M1 + M2	0.976	0.961	0.984	0.978
	M1 + M3	0.969	0.964	0.936	0.952
	M2 + M3	0.981	0.970	0.925	0.947

4.4. Visualizations

A feature map is produced as a result of the convolution operation being performed on the input by a convnet filter. To create an output volume, we apply a number of filters and stack the feature maps that are produced. Instead of looking at a single feature map, we have displayed multiple hidden feature maps in Figure 4 to show how the input is modified through subsequent layers. We exhibited eight VGG19 feature maps per layer for viewing purposes. As we move through different levels, there are several observations regarding the feature maps. Simple forms are picked up by the filters in the first layer. The hidden representation shows various cross-sectional anatomies of the brain, such as the hippocampus, cerebral artery, and different lobes. The majority of the information provided in the image is retained in the first layer feature maps, i.e., conv1 of block1. The first layers

in CNN architectures typically serve as edge detectors. The feature maps appear to be an abstract depiction of the original when we delve deeper into the network. Despite being less visible to humans, they still encode useful features. As we dig deeper, the feature maps become sparser because the filters pick up fewer features.

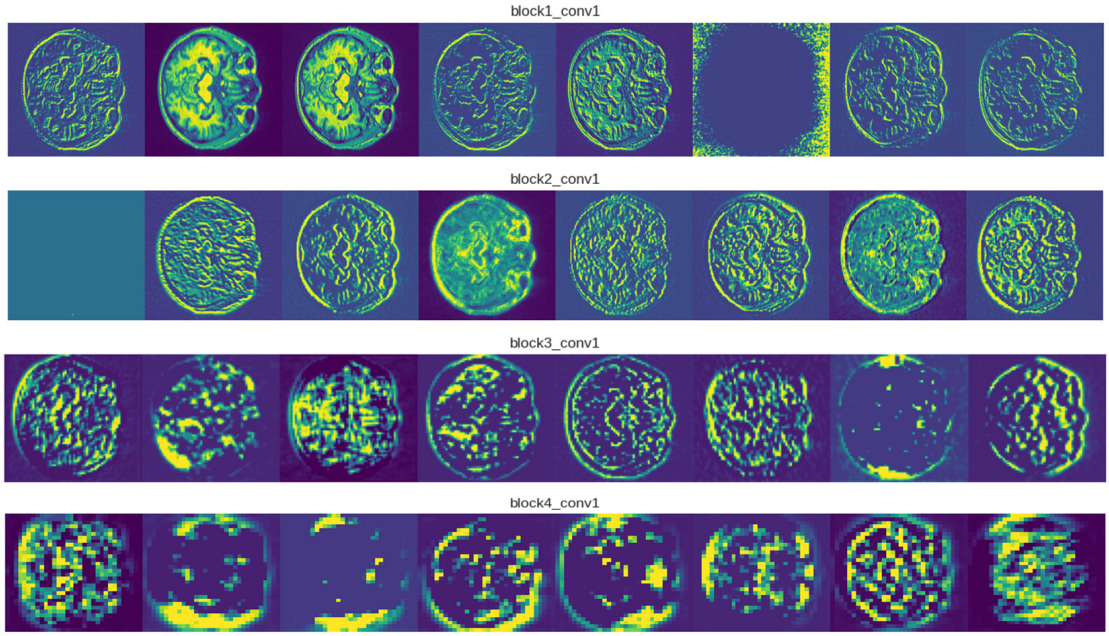


Figure 4. Visualizations for examples of MRI images from the OASIS-3 dataset.

5. Conclusions

In this paper, we proposed an ensemble-based transfer learning approach using two methods: simple averaging and weighted averaging. The proposed framework extracts superior sparse patterns and features from MRI images. To avoid overfitting, we used data augmentation techniques. After obtaining superior results from experiments, it can be inferred that both ensemble methods are equally competent. Furthermore, we investigated the performance of the models using uncropped and cropped MRI images. In future work, we aim to further refine and expand the proposed ensemble framework by incorporating additional transfer learning models, exploring different ensembling approaches, evaluating its performance on various AD databases, and leveraging adversarial networks for synthetic image generation. We also plan to test the results of our architecture on other AD databases to improve the generalization of our model. These advancements can potentially enhance the accuracy, robustness, and generalization of the model for Alzheimer's disease classification.

REVIEW

Environmental sustainability analysis of biofuels: a critical review of LCA studies

Kulvendra Patel[1] · **S. K. Singh**[1]

Abstract

The use of fossil fuels in the transportation sector has significantly increased the greenhouse gas (GHG) emissions, leading to concerns about their environmental impact. As a result, biofuels have been promoted as a promising alternative to fossil fuels to mitigate GHG emissions. However, while biofuels are considered a low-carbon solution, there are concerns that its widespread use could have unforeseen environmental effects. This study analyzes the intricacies involved in biofuel's life cycle assessment (LCA). Fifty-three peer-reviewed studies were examined, covering a broad range of biofuels produced from over 25 different feedstocks. The literature review focused mainly on research published from 2012 to 2022 to avoid outdated information. The study found that second-generation biofuels have a greater potential for reducing GHG emissions than first-generation biofuels. However, the GHG emissions from third-generation biofuels are higher than those from conventional fuel, ranging from 10.2 to 1910 g CO_2 eq. / MJ. The net energy ratio for biofuels ranges from 1.23 to 12.49 for first-generation, 0.003 to 15.04 for second-generation, and 3 to 18.5 for third-generation biofuels. The analysis also shows that the water footprint of biofuels is 50–240 times greater than fossil fuels. The study also examines the critical methodological aspects and sources of uncertainty in the LCA of biofuels and suggests solutions to address these problems. Overall, the study highlights the importance of taking a comprehensive approach when assessing the environmental impact of biofuels and the need for continued research to develop sustainable and effective biofuels.

a critical problem (Fawzy et al. 2020; Osman et al. 2021a). Economic development is accelerating, particularly in developing nations like India and China. These nations have now reached the stage of economic development when energy use is at its highest due to industrialization. Meeting the rising energy demand while having sustainable energy supplies for the future is thus a significant problem (Yazan et al. 2017). Between 1971 and 2019, the total energy supply worldwide increased 2.6 times, from 230 to 606 EJ. The primary energy sources for power generation in 2019 were still oil and coal, which accounted for 31% and 27% of global energy production, respectively (IEA 2021). The Intergovernmental Panel on Climate Change (IPCC) Working Group III (WG3) has identified energy systems, industry, buildings, transportation, and AFOLU (agriculture, forestry, and other land uses) as the five primary sectors responsible for global greenhouse gas emissions (Lamb et al. 2021). GHG emissions from transportation have been growing faster compared to other industries. The leading cause of GHG emissions related to transportation is the burning of fossil fuels in various modes of transport. The fuel used for transportation mainly consists of petroleum, which makes up over 90% of gasoline and diesel. Globally, transportation accounts for 15% of total GHG emissions and 23% of CO_2 emissions associated with energy consumption (Sims and Schaeffer 2014; Uusitalo et al. 2014; Jeswani et al. 2020). Biofuels are commonly recognized as possible substitute fuels for transportation that can decrease reliance on fuels made from petroleum and help address the problem of climate change. As an alternative to conventional fuels, several feedstocks and conversion methods for biofuel have been proposed.

Biofuels refer to energy-enriched compounds derived from biomass, such as biodegradable waste or residue from forestry, agriculture, fishing, or biodegradable urban or industrial waste. The kind of feedstock, the conversion method, the technical specifications of the fuel, and its intended application are a few distinguishing factors that may be used to categorize biofuels. Different definitions for different biofuel types are in use due to the vast number of potential differences (Bharti et al. 2021). Biofuel sources are categorized into three generations of feedstock: edible energy and oil-based crops (first generation), lignocellulose-based (second generation) (Chen et al. 2019), and algae-based (third generation)(Kumar Sharma et al. 2021; Ocreto et al. 2021). Figure 1 provides an outline of several biofuel types, feedstocks, and conversion pathways.

Systems for producing, converting, and supplying sustainable renewable energy must be effective and sustainable in terms of the environment, the economy, and society for both the present and future. Identifying biofuel sources can potentially lessen the environmental effect of fossil fuels (Balajii and Niju 2019; Gunarathne et al. 2019). Biofuels can also help mitigate the rising fossil fuel usage and relieve dependence on non-renewable resources (Hassan et al. 2020; Peng et al. 2020). How to define sustainable biomass production is a topic of debate on the national and international levels (Kaloudas et al. 2021). First and foremost, biofuel should lower energy use and improve energy security by using fewer petroleum-based products. Second, it must be advantageous for the environment by lowering greenhouse gas emissions, conserving diverse land uses, protecting soil productivity, water quality and quantity, and biodiversity.

Third, it should not unnecessarily affect food availability and other resources while improving ecosystem functions. It should also be competitive economically and contribute more energy than it uses in production (BRDI 2008; Munagala et al. 2022). Bioethanol and biodiesel are popular biofuels for blending with Petro-diesel to lessen reliance on traditional diesel. Bioethanol production involves the conversion of starch or biomass with high sugar content (like sugar cane or grains) into sugar, which is then fermented and distilled. Another method for producing bioethanol or bio-oil is through hydrolysis of lignocellulosic biomass, followed by fermentation and distillation, also referred to as biomass to liquid (BTL). Alternatively, biodiesel can be produced by using alcohol to extract and esterify vegetable oils, discarded cooking oils, and animal fats (Sinha et al. 2013; Foteinis et al. 2020). India is attempting to embrace renewable energy sources, including biofuel, to reduce its reliance on conventional energy. Since utilizing green fuels like biodiesel and ethanol instead of traditional transportation fuels helps reduce greenhouse gas emissions, these renewable fuels are being advocated globally. Some of the research that suggests that biofuel production using a biorefinery platform might lower carbon emissions is shown in Table 1. Brazil is the global leader with a fleet of vehicles that uses gasoline-ethanol blends with a 27% content (USDA 2021a). In all of its fleet vehicles, the United States now uses roughly 7.1% biofuels, while the European Union (EU) has a bold ambition to utilize 10% renewable fuels by 2020 (EASAC 2012). India has stepped up its efforts to achieve its objective of being in the E-20 by Ethanol Supply Year (ESY) 2025. While maintaining its immediate objective of E-10 by ESY 2022, the Indian government stated its E-20 target year of ESY 2025 instead of 2030 (USDA 2021b).

The sustainability and benefits of biofuels are impacted by the emissions and energy used in their manufacturing process. Therefore, to accurately assess the advantages of using biofuels instead of traditional fossil fuels, it is essential to use reliable, practical, and scientific evaluation methods (Chamkalani et al. 2020; Kargbo et al. 2021). To evaluate the reductions in emissions by utilizing biofuels in India, a life cycle assessment (LCA) must be performed. The LCA evaluates the complete life cycle of a product or process, including the acquisition of raw material through manufacturing, usage, and disposal, to measure its environmental impact by creating a comprehensive inventory of all the material inputs, energy consumption, and emissions associated with the product or process. The ultimate goal of LCA is to provide policymakers with a better understanding of the environmental impact by analyzing the assessment results (Soam et al. 2015). The life cycle assessment method will light India's energy and environmental advantages of biofuel production. Understanding the GHG emission reduction that biofuels may achieve compared to their fossil fuel counterparts is crucial for guiding policy development and selecting optimal fuel choices (RAE 2017). By calculating their carbon footprint, several studies have examined the biofuel's potential to reduce GHG emissions. However, their conclusions are sometimes contradictory because of the vast range of estimations. In order to influence future policy, the primary goal of this study is to increase clarity and knowledge of the carbon footprints of various liquid biofuels (Khanna et al. 2011). The study evaluates the techniques and environmental sustainability of biofuels by examining the prior LCA studies, highlighting significant methodological approaches, and presenting critical conclusions.

Bibliometric analysis

To locate pertinent publications and pinpoint areas where research on the environmental effects of biofuel production is lacking, a search strategy using Boolean operators was employed in the WoS core collection database. The bibliometric mapping data shown in Figure S1a (Online Resource) were obtained from the WoS and visualized using VOSviewer software to show the co-occurrence of keywords in the literature from 2012 to 2022. Bibliometric research methodology: TOPIC: "life cycle assessment" AND TOPIC: 'Biofuels' OR TOPIC: 'Bioethanol' OR TOPIC: 'Biodiesel'

Table 1 Carbon emission reduction from various feedstocks during the biofuel production

Feedstock	Products & Co-products	Reduction in CO_2 emissions	References
Sugarcane	Bioethanol, Biogas, Electricity, steam, and power	40–70%	(Gnansounou et al. 2015; Silalertruksa et al. 2017)
Palm oil	Biodiesel	20–25%	(Lim and Lee 2011; Lee and Ofori-Boateng 2013)
Corn stover & wheat straw	Bioenergy	47–50%	(Cherubini and Ulgiati 2010; Gallejones et al. 2015)
Forest residue	Biodiesel, Biogas, Electricity	51–80%	(Karlsson et al. 2014; Spatari et al. 2020)
Jatropha, Sorghum	Biodiesel	75–80%	(Kumar et al. 2012; Vrech et al. 2019; Martinez-Hernandez et al. 2019)
Rapeseed	Biodiesel, Energy	30–50%	(Fernández-Tirado et al. 2016; Gupta et al. 2022)
Used cooking oil	Biodiesel	30–55%	(Vrech et al. 2019; Bhonsle et al. 2022)

OR TOPIC: 'Lignocellulosic.' The bibliographic search was limited to articles and reviews, and only documents published between 2012 and 2022 were taken into account. Over ten years (2012–2022), bibliometric mapping shows that terms such as life cycle assessment, environmental impacts, biofuel, carbon dioxide, and greenhouse effect dominate the literature. The density visualization mapping shown in Figure S1b (Online Resource) shows that the literature focused on environmental impacts. The darker region indicates the focused area, and the lighter region shows the research gap in the study area that needs further research in the near future. For example, greater research is needed on social life cycle assessment, water footprint, waste management, bioeconomy, land use change, and techno-economic analysis.

The bibliometric analysis shows a diverse geographical distribution of research. The United States takes the lead, accounting for 24% of the studies, followed by China at 12%. Europe also emerges as a significant contributor, with noteworthy contributions from countries like the UK (8%), Italy (6%), Spain (6%), Germany (5%), and France (3%). Moreover, emerging economies such as Brazil (8%) and India (7%) demonstrate a growing interest in this field, showcasing significant research efforts, as shown in Figure S2 and Figure S3 (Online Resource). These findings highlight the global reach and interest in LCA studies of biofuels across different regions. The network map of keyword co-occurrence among 53 research is shown in Figure S4 (Online Resource) and was created using the VOSViewer (Perianes-Rodriguez et al. 2016) full counting approach.

Methodology and framework

Literature search and selection criteria

We performed a literature search in different databases, including Web of Science (WoS), Scopus, Science Direct, and PubMed, to identify peer-reviewed studies on the sustainability of biofuels. The publications in this study were selected if they (1) revealed that LCA was performed, (2) had well-defined system boundaries, and (3) examined a set of impact (midpoint or damage) categories. A qualitative analysis was conducted once all pertinent research had been considered. The literature search mainly concentrated on studies published between 2012 and 2022 to minimize obsolete material. A total of 53 articles were selected for analysis in the present study, including the life cycle analysis of biofuels, the geographic location, functional unit, feedstock used, impact assessment methodology, system boundaries, and findings. The articles consist of different kinds of biofuels from various feedstocks, classified into first, second, and third generations, with over 25 types of feedstocks being used. Table 2 shows an overview of the evaluated studies on feedstock, life cycle tools, impact methods, and functional units. Among the selected articles, 26% evaluated first-generation biofuels, 57% evaluated second-generation biofuels, and 17% evaluated third-generation biofuels.

Life cycle assessment

LCA is a method or procedure used to evaluate the potential environmental effects of a product, process, or activity by considering every step of the products and the raw materials supply chains, from production to final disposal. It was carried out in accordance with the ISO 14040:2006 and 14044:2006 standard framework to ensure that exact conclusions were achieved (Wang et al. 2013a; Chau et al. 2015; Patel and Singh 2022a). An LCA study might be from "cradle to grave" or "cradle to gate," depending on the goal and scope (Khoo et al. 2019). Figure 2a shows the generalized system boundaries for the production of biofuels. Phase 1 includes cultivation, use of water, diesel, fertilizers, and air and water emissions due to the cultivation and harvesting process. Phase 2 includes the conversion of biomass to biofuels through various processes, the use of energy, and the associated emissions to air and water. Phase 3 incorporates biofuel and co-product transportation and emissions due use of biofuel. According to ISO 14,040, LCA consists of four phases: (i) goal and scope; (ii) life cycle inventory (LCI); (iii) life cycle impact assessment (LCIA); and (iv) interpretation.

Goal and scope definition

This initial step in every LCA study critical for understanding general outcomes and LCA findings, including defining the functional units and system boundaries (ISO 2006a; Harris et al. 2016). Figure 2b shows the percentage of reviewed studies considering different phases of the system boundary. All the studies have considered Phase 2 of the LCA system boundary, and only 14 studies have considered all three phases in the reviewed studies. This suggests that only a small number of studies have considered the use phase of biofuel and compared them with conventional fuels, indicating a significant gap in the LCA application for decision-making. The functional unit (FU) acts as a reference point for linking inputs and outputs. This reference point is essential to ensure that LCA outcomes are comparable; this is especially critical when comparing different systems and ensuring that comparisons are made consistently (ISO 2006bMartínez-Blanco et al. 2011; Patel and Singh 2022b). Figure 3 shows the percentage of reviewed studies considering different FUs with land use change (LUC) and without LUC analysis. It was observed that 22 studies had used biomass production as FU (kg or ton of biofuel produced), 18 studies had considered the unit of bioenergy (MJ, GJ, or

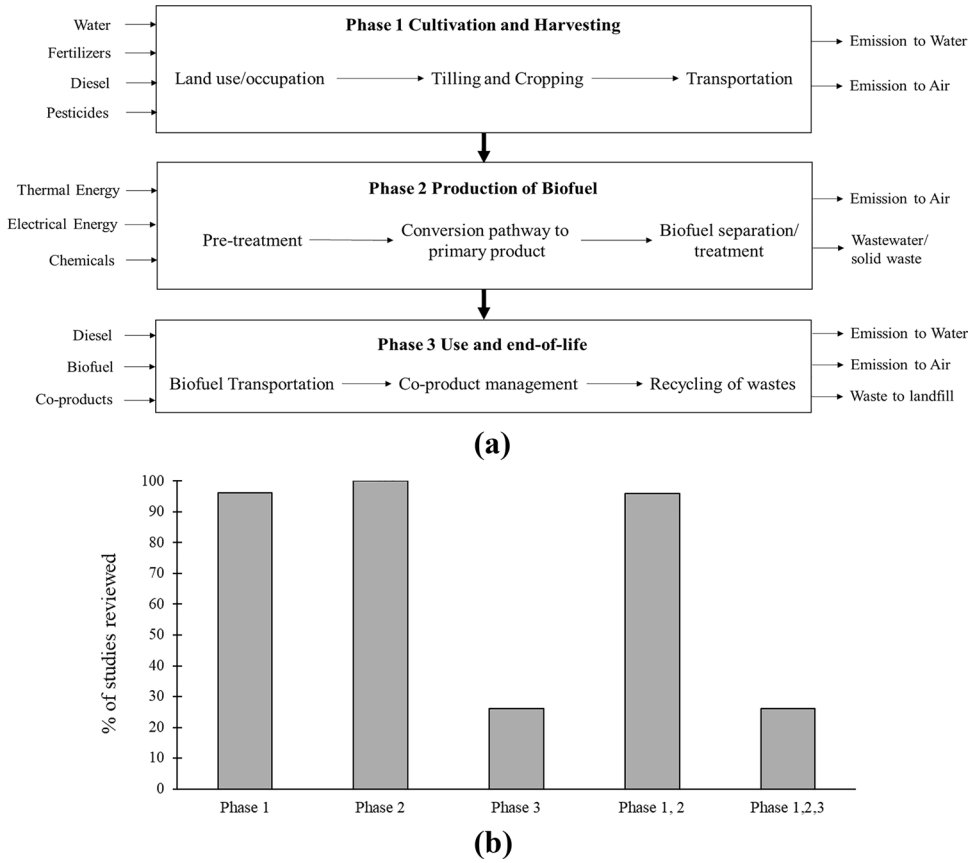

Fig. 2 **a** General system boundaries of LCA of biofuel production, **b** Phases of LCA for production of biofuels considered in the reviewed studies

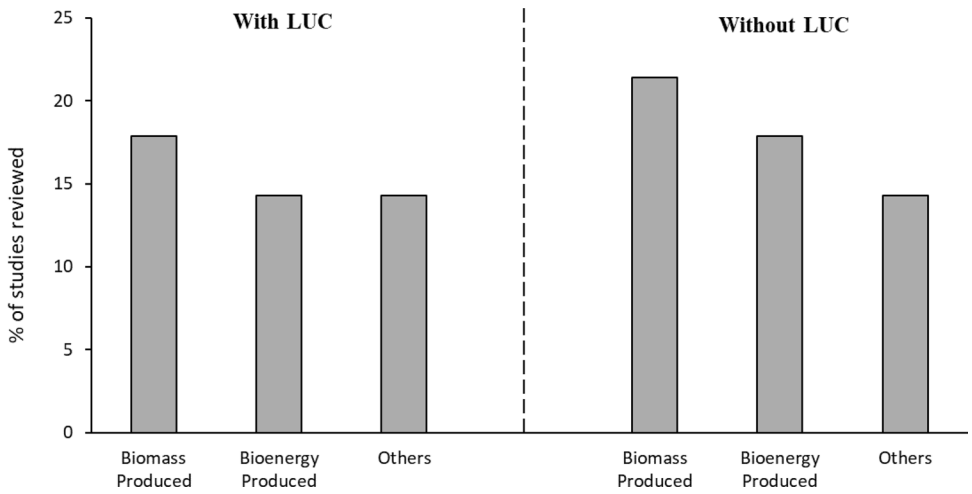

Fig. 3 Types of functional units used in reviewed LCA studies

kWh of energy produced) production as FU and 16 studies had used other FUs (Litre of biofuel, per km of car driven, and per hectare-area) (Borrion et al. 2012; Sreekumar et al. 2020; Isler-Kaya and Karaosmanoglu 2022).

Life cycle inventory and life cycle impact assessment

The LCI methodology includes gathering and evaluating information regarding the resources used, such as materials, energy, and water, and the emissions generated at every phase of the production of biofuels. LCI provides a detailed inventory of inputs and outputs of the biofuel production process (Chung et al. 2019; Chopra et al. 2020), while LCIA evaluates the potential environmental impacts associated with these inputs and outputs, including emissions from the cultivation of feedstocks, transportation, and processing of biofuel and helps in understanding the results of LCI (Rocha et al. 2014).

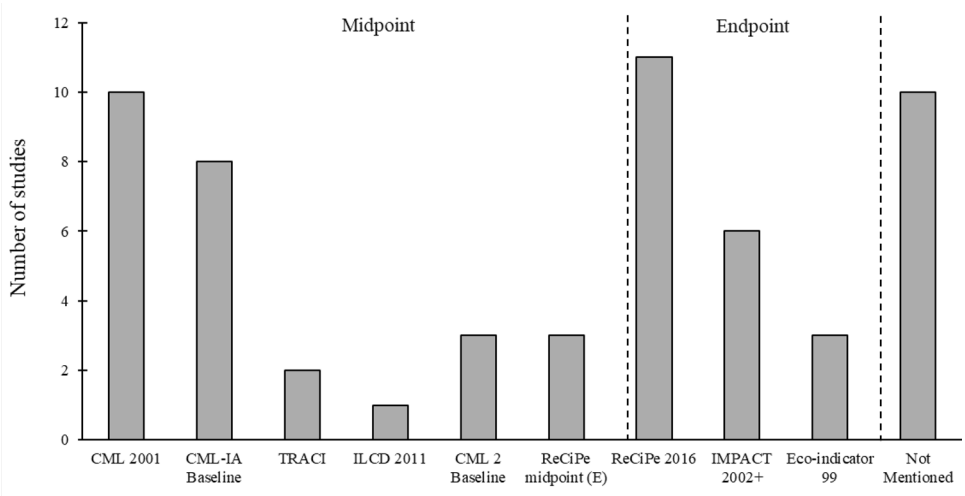

Fig. 4 Frequencies of LCIA methods in reviewed studies

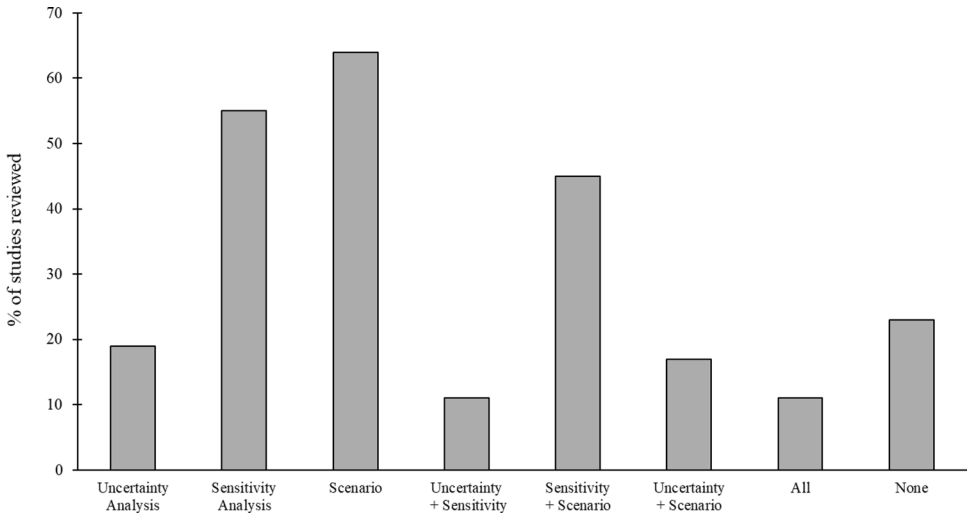

Fig. 5 Details of uncertainty, scenario, and sensitivity analysis in the reviewed studies

The database used for inventory analysis is shown in Table 2. IMPACT 2002+, ReCiPe 2016, EDIP 2003, CML, Ecopoint 97, Eco-indicator 99, and TRACI are the standard methods used to evaluate environmental impacts (ILCD 2010; Owsianiak et al. 2014). Figure 4 shows the no. of different impact methods used in reviewed studies and grouped into midpoint and endpoint impact categories.

Uncertainties and sensitivity analysis

LCA studies are models that are simplified representations of real-world systems and are thus fundamentally uncertain (Wang and Shen 2013). LCA includes trade-offs between numerous competing factors and, sometimes, uncertainty in relevant aspects (Guinée et al. 2017). The distribution of different environmental emissions, resource consumption, or effect categories may represent one of these uncertainties. The LCIA can also lead to uncertainty in the result. Endpoint impact categories have significantly more uncertainty but can produce more intelligible findings (Bare et al. 2000), whereas the midpoint method is less scientifically challenging and has much lower uncertainty (Gnansounou and Kenthorai Raman 2016). As shown in Fig. 5, only 19% of studies have done uncertainty analysis. These uncertainties can be reduced by using more precise data (Michiels and Geeraerd 2020; Ubando et al. 2022). The uncertainty for each effect category is calculated by dividing the standard deviation by the mean (Sharma et al. 2020). The calculation of uncertainties is performed on a study-specific basis. Each included study has its own mean values and corresponding standard deviations determined by the data and methodology employed in that particular study. Consequently, the uncertainties vary depending on the specific study and the effect category being considered. It considers uncertainties in data, models, and assumptions used in the analysis. The goal is to provide a measure of confidence or reliability in the reported results. Uncertainty analysis involves identifying sources of uncertainty, estimating their magnitude, and

Table 2 Characteristics of LCA research analyzed in the present study

S.No.	Biomass source	Location	System boundary	Functional unit	Software	LCIA method	Database	Year	References

propagating them through the LCA model to determine their impact on the final results.

The LCA performs a sensitivity analysis by varying a parameter's upper and lower limits and running simulations with different combinations of parameter values. This method is used along with scenario analysis to evaluate how uncertain factors may affect the results (Eggemann et al. 2020). Sensitivity analysis determines which step in the biofuel manufacturing life cycle is directly responsible for the negative environmental impacts.

In LCA, a scenario refers to a specific situation or future projection that is represented through a defined set of assumptions and choices. These scenarios encompass the system boundaries and assumptions about the inputs and outputs of the analyzed product or system (Arguelles-Arguelles et al. 2021). They serve as a means to capture distinct conditions and provide a foundation for analysis and comparison. Scenario analysis entails evaluating the environmental impacts under various hypothetical scenarios or alternative future pathways (Yang et al. 2021). It allows for the exploration of different configurations, technologies, materials, or strategies within the system to gain insights into their potential effects on the overall environmental performance. As shown in Fig. 5, the majority of the reviewed studies (64%) have considered scenario-based analysis. By comparing different scenarios, decision-makers can assess the consequences of different choices and make well-informed decisions.

Interpretation

The interpretation phase considers the impact assessment results and the inventory analysis outcomes (ISO 2006a). The analysis results, together with all the decisions and assumptions made during the process, are examined and analyzed, and broad conclusions are drawn (Osman et al. 2021b). The aim is to arrive at conclusions that back up a decision or produce an LCA result that is easy to comprehend.

Environmental sustainability of biofuels

Carbon footprint

Most LCA biofuel studies focus on GHG emissions and reductions compared to fossil fuels. Biofuel LCA studies also consider other environmental impact categories, such as acidification, eutrophication, photochemical smog, human toxicity, and ecotoxicity. LCA studies show inconsistent conclusions for Global Warming Potential (GWP), ranging from favorable to unfavorable, even for the same feedstock. This is due to assumptions, data sources, allocation procedures, and LUC variations. GHG emissions are converted to g CO_2 eq. per MJ to compare data from different studies. The lower heating values are assumed to be 27 MJ/kg and 38 MJ/kg for bioethanol and biodiesel, respectively (Yan and Crookes 2009), whenever these statistics are not stated in the original research. The use phase of the biofuel is not considered in the subsequent analysis.

First-generation biofuels

The estimated GHG emission of first-generation bioethanol ranges from 0.006 to 167 g CO_2 eq. / MJ, and that for biodiesel varies from − 7.3 to 329 g CO_2 eq. / MJ, as shown in Fig. 6a and b, respectively. When the average values are taken into account, the GWP of most of the first-generation biofuels is less than those of conventional gasoline (72.8 to 96 g CO_2 eq. / MJ (González-García et al. 2010a, b; Ou et al. 2009) and diesel (80 to 120 g CO_2 eq. / MJ (Ou et al. 2009; Shirvani et al. 2011; Passell et al. 2013), except for Rapeseed biodiesel.

Some LCA studies that have been analyzed show rapeseed biodiesel emits 2.8 to 350 g CO_2 eq. / MJ of energy (González-García et al. 2013b; Uusitalo et al. 2014; Gupta et al. 2022). Compared to fertilizer application in the agricultural stage (which consumes 70% more energy and 80% more GWP) (Gallejones et al. 2015), the contribution from the phases of drying and cooling of seeds, oil extraction, and refining was minimal. According to the study by (Arguelles-Arguelles et al. 2021), GHG emission was negative for biodiesel production from palm oil because of the amount of carbon dioxide captured during the cultivation phase being more than biofuel's GHG emission. Most studies on palm oil, soybeans, and sugarcane (Lee and Ofori-Boateng 2013; Rocha et al. 2014; Arpornpong et al. 2015; Fernández-Tirado et al. 2016; Munagala et al. 2022) indicated lower GHG emissions than conventional gasoline. The growing and harvesting phase (Phase 1, Fig. 2a) of biofuel LCA is critical for biofuel generation. As a result, the quantity of fertilizer, pesticides, and fuel used during the agricultural phase plays a critical role in determining the outcomes and environmental effects of the biofuel, as shown in Table 3. Most reviewed studies show a reduction in GHG emissions for first-generation biofuel compared to conventional diesel and gasoline.

Second-generation biofuels

The GHG emissions of second-generation biofuels vary from − 15.4 to 178.7 g CO_2 eq. / MJ for bioethanol and − 0.21 to 113.8 g CO_2 eq. / MJ for biodiesel, as shown in Fig. 6c and d, respectively. These discrepancies result from various factors such as the feedstock used, the production routes, different technological assumptions, and differences in methodology

Table 3 Stagewise GHG contribution of biofuel production

Biomass source	Percentage of GHG Contribution				
	Cultivation	Transportation	Oil / Juice processing	Biofuel production	References
Jatropha	55–62	8–10	28–32	5–8	(Kumar et al. 2012; Kalaivani et al. 2014; Vrech et al. 2019; Uppalapati et al. 2022)
Soybean	34–40	16–23	18–24	18–26	(Rocha et al. 2014; Fernández-Tirado et al. 2016; Uppalapati et al. 2022)
Calophyllum inophyllum	40	19	21	20	(Uppalapati et al. 2022)
Rapeseed	68–72	8–11	5–7	11	(Uusitalo et al. 2014; Fernández-Tirado et al. 2016; Gupta et al. 2022)
Sugarcane	53–63	6–10	12–15	20–21	(Rocha et al. 2014; Gnansounou et al. 2015; RSB 2020; Munagala et al. 2022)
Palm Oil	40	6–12	7–9	41–46	(Lee and Ofori-Boateng 2013; Uusitalo et al. 2014; Mohd YUSOF et al. 2019)
Microalgae	30–33	–	20–23	43–47	(Pragya and Pandey 2016; Deshmukh et al. 2019; Uppalapati et al. 2022)
Oleaginous yeast	40–43	–	2–6	49	(Jain et al. 2018; Chopra et al. 2020)

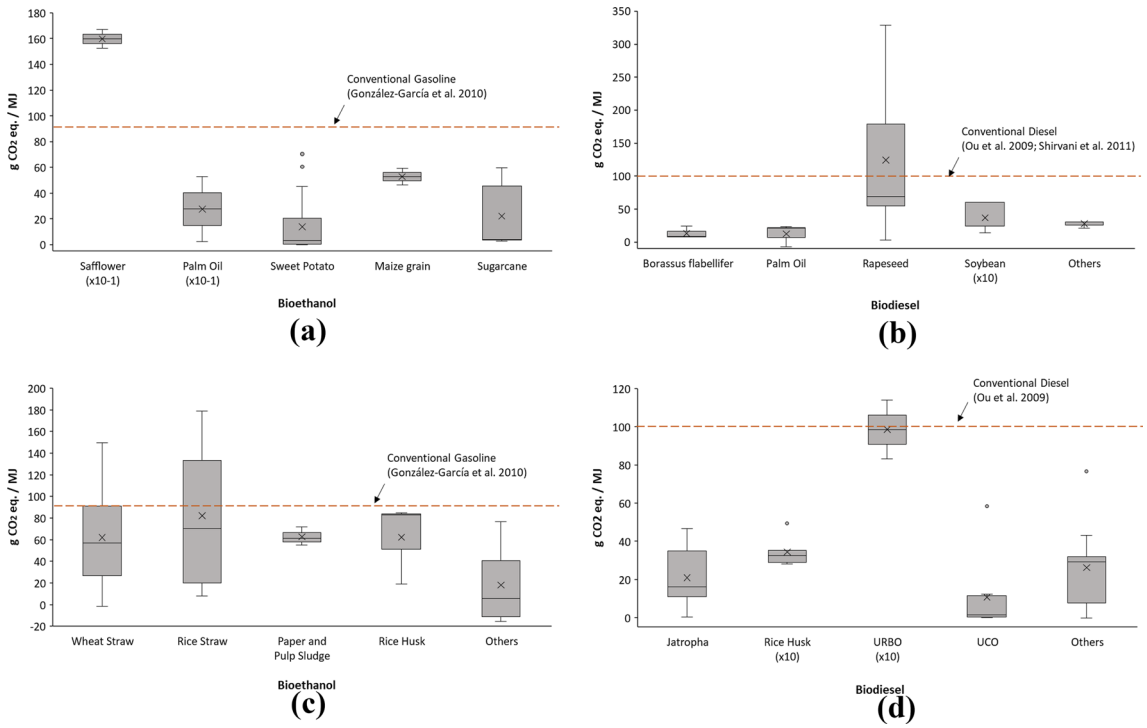

Fig. 6 GHG emissions for **a** bioethanol and **b** biodiesel from first-generation biofuels; **c** bioethanol and **d** biodiesel from second-generation biofuels

used for the analysis. It should be highlighted that technological uncertainties are particularly important when evaluating their potential because advanced biofuels have not yet reached full commercialization. As a result, the quality of the information that is now accessible is not as strong as in the case of the well-known first-generation biofuels (Mohd YUSOF et al. 2019; Kovacs et al. 2022). The GWP of lignocellulosic biofuel produced from agricultural and forestry wastes is often lower than biofuel produced from energy crops (Gandam et al. 2022). This is mainly caused by N_2O emissions from fertilizers while growing energy crops (Olukoya et al. 2014; Jeswani et al. 2020). Assuming that

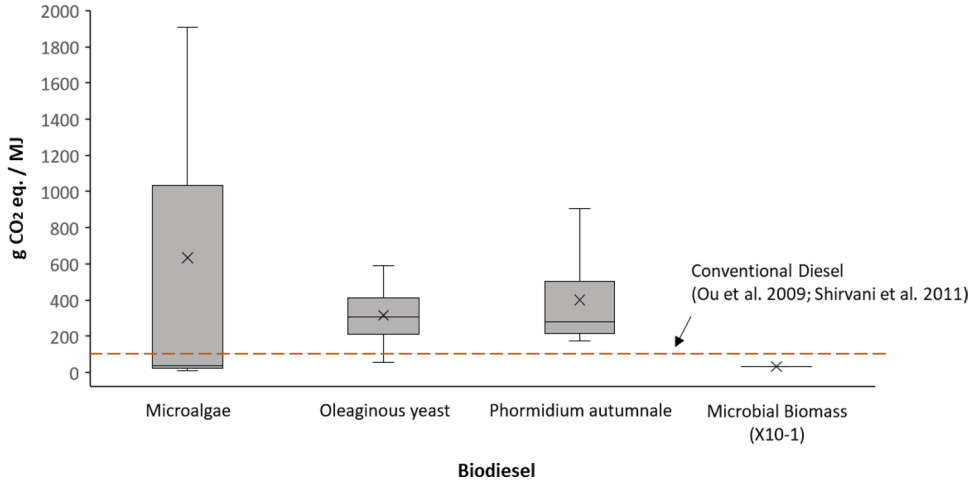

Fig. 7 GHG emissions for biodiesel from third-generation biofuels

residues do not have any environmental effects and are solely linked to the primary crop from which the waste is generated, then the adverse effects related to the primary crop can be prevented by using the residues instead. The production of lignocellulosic bioethanol involves the assumption that the leftover lignin will generate heat and power to meet the energy needs of the process. Any excess electricity produced is then supplied to the grid (Sawatdeenarunat et al. 2015). This results in the biofuel production system being acknowledged for preventing GHG emissions from a specific amount of grid power (Jiang et al. 2022). In some instances, such as with feedstocks like spent coffee grounds, forest residue, and rice straw, the benefits from generating power and other byproducts outweigh the emissions from producing biofuels.

Some of the reviewed studies show negative GHG emissions for the production of biofuels.(Jeswani et al. 2015) analyzed the LCA of ethanol production from lignocellulosic biomass and compared the bioethanol production from wheat straw, miscanthus, poplar, and forest residue. The analysis shows that the GWP of bioethanol production is negative for all four feedstocks, mainly due to the production of co-products. The study by(Schmidt Rivera et al. 2020) compares the different valorization routes of spent coffee grounds for the production of value-added products such as biodiesel. The method of incineration was found to be the most sustainable option because it had a total of 14 net negative effects on the environment, including the emission of greenhouse gases (−0.212 g CO_2 eq. per MJ). The high energy output of waste-to-energy conversion technologies and credits for replacing the electricity mix that is dominated by fossil fuels mitigate the negative impacts of these valorization routes.(Pradhan et al. 2022) analyzed biodiesel production from used rice bran oil through esterification and transesterification processes. The GHG emissions were found to be very high (831.5 to 1138.4 g CO_2 eq. / MJ) than conventional diesel (102 g CO_2 eq. / MJ (Ou et al. 2009), which has similar results as the study by (Sun et al. 2022). However, the analysis shows that the vanadium-impregnated solid catalyst results in a 26.96% reduction in GWP compared to a commercial hydroxyapatite-supported catalyst, shown in Fig. 6d.

Third-generation biofuels

Among the studies that were evaluated, only 7 LCA studies were found to have calculated the GHG emissions for third-generation biofuels. However, these studies used different approaches, methods, and assumptions when it came to managing feedstocks, nutrients, and co-products, as well as setting system boundaries and process designs. Consequently, the GHG emissions have varied significantly, as indicated in Fig. 7, ranging from 10.2 to 1910 g CO_2 eq. / MJ. These findings suggest that, depending on the assumptions, microalgae diesel can significantly reduce or increase GHG emissions compared to diesel (Soratana et al. 2014). Despite being in its present development stage, many research works have concluded that algal biodiesel generates more GHGs throughout its lifespan than fossil fuels (Banerjee et al. 2019). This is majorly due to the low algal yield and the substantial energy consumption during the cultivation, harvesting, and drying stages (Mu et al. 2014; Banerjee et al. 2019).

A study by (Saranya and Ramachandra 2020) evaluated the LCA of estuarine microalgae for biodiesel production. The analysis shows that the scenario which uses wastewater as a nutrient has less GHG emissions of 0.85 kg CO_2 eq. per kg of biodiesel (22.4 g CO_2 eq. / MJ) than other scenarios. There was a 67.9 to 85.4% reduction in GHG emissions when microalgal biodiesel was used instead of fossil diesel. However, the study by (Soratana et al. 2012) shows that none of the four different conditions considered for analysis for biodiesel production meets the Renewable Fuel Standard, which requires a 50% reduction in GHG emissions for advanced biofuels. The analysis shows greenhouse gas

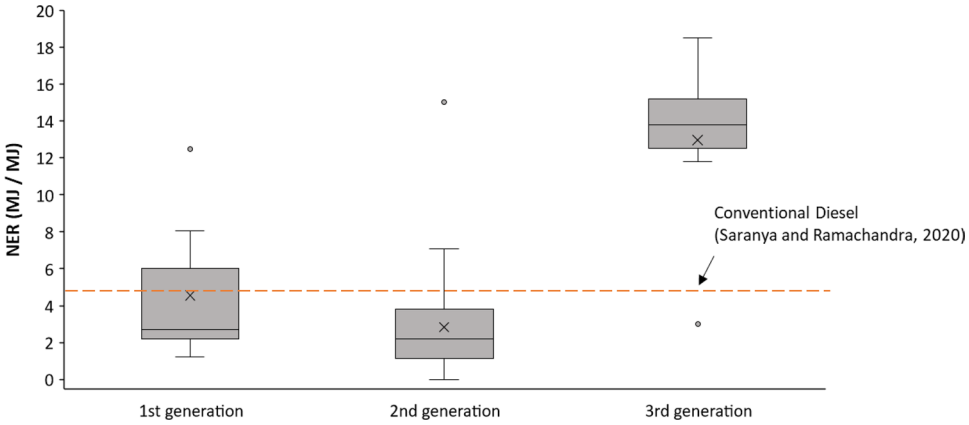

Fig. 8 NER for first, second, and third-generation biofuel

emissions range from 854 to 1910 g CO_2 eq. / MJ. Another research by (Chopra et al. 2020) examined the environmental impact of producing biodiesel and bio-crude from oleaginous yeast and found GHG emissions ranging from 56 to 600 g CO_2 eq. / MJ. Therefore, more investigation is needed to ensure the sustainability of the process.

Energy Use

Several indicators, including fossil energy consumption, primary, secondary, or cumulative energy demand, and net energy ratio (NER), are employed in LCA studies to assess energy usage in the life cycle of biofuels (Arvidsson et al. 2012). However, considering that lowering dependency on fossil fuels and ensuring energy security are important goals of national biofuel policies, in addition to mitigating climate change, many concentrated on fossil energy consumption. The NER ratio measures how much energy the biofuel produces in relation to total energy intake. If the NER is less than 1, the system is not advantageous since more energy is needed to produce the biofuel than it contains (Carneiro et al. 2017b). As shown in Fig. 8, most research anticipates that fossil energy use for 1st and 2nd generation biofuels varies across different biofuels ranging from 1.23 to 12.49 MJ / MJ for 1st generation and from 0.003 to 15.04 MJ / MJ for 2nd generation biofuel. Different farming techniques, feedstock production, conversion technology, and allocation strategies are some of the causes of these discrepancies. The assumptions about the type of energy employed in the conversion process also impact the outcomes. The energy demand of LCA of microalgae biofuels is considerably more diverse, ranging from 3 to 18.5 MJ / MJ. The reasons for this variation include technological uncertainty and the range of prospective feedstocks and manufacturing systems.

(Al-Mawali et al. 2021) estimate a NER of 2.17 MJ / MJ for the generation of biodiesel from waste date seed oil, which is comparable to the energy ratio of 3.15 MJ / MJ reported by (Pleanjai and Gheewala 2009) for palm oil biodiesel. (Al-Muhtaseb et al. 2021) also reported a similar NER (2.23 MJ/ MJ) for waste loquat seed oil biodiesel with an enhanced bifunctional catalytic system. (Uppalapati et al. 2022) estimated the NER for different feedstocks for biodiesel production. The analysis shows that Jatropha biodiesel has the highest NER (15 MJ / MJ), which is in line with the study by (Abbas et al. 2016) and (Silitonga et al. 2016) and the lowest for microalgae (3 MJ / MJ). Similar NER was reported by (Pragya and Pandey 2016), (Ajayebi et al. 2013), and (Firoz 2008) for microalgae (2.89 MJ / MJ) and Soybean (12.49 MJ / MJ). (Reaño 2020) and (Sreekumar et al. 2020) analyzed biofuel production from rice husk and straw. The EROI (energy return on investment), similar to NER, ranges from 0.6 to 1.59 MJ / MJ. This shows that the process is net energy positive and hence desirable. Similarly, (Mandade et al. 2015) analyze the lignocellulosic feedstock for ethanol production, and EROI values vary from 2 to 7.1 for different allocation methods.

Water use

Water consumption can be significant in producing bio-feedstocks, especially for first-generation biofuels (Dominguez-Faus et al. 2009). The use of irrigation water for certain feedstocks could pose a problem as it may compete with the water requirements for other purposes like producing food (Gerbens-Leenes et al. 2009). The total amount of water consumed worldwide might drastically increase due to increasing agricultural biomass production for biofuels (Hammond and Li 2016). In regions currently experiencing water scarcity, this extra water demand could significantly worsen the overall environmental effects of biofuels. As shown in Fig. 9, the water consumption of biofuel production ranges from 36.2 to 540 m^3 / GJ for first-generation biofuel and from 1.28 to 188.8 m^3 / GJ for second-generation biofuel. When scarcity of water in a particular region is considered, not just the amount of water used, the water footprints (WF) of biofuels can be

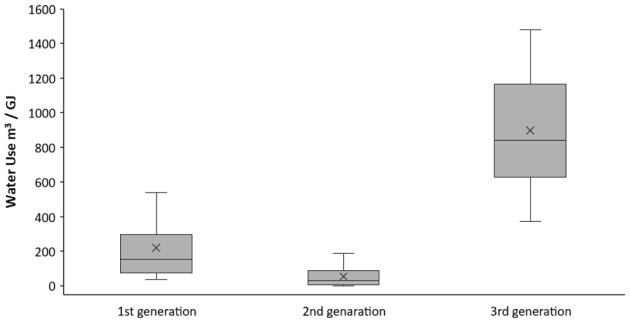

Fig. 9 Water consumption for biofuel production based on reviewed studies

50 to 240 times larger than those of fossil fuels (Berger et al. 2015). This is due to a significant portion of water use in biofuel production in water-stressed regions. In this analysis, the cultivation stage is not included for the second-generation biofuel. It is based on the assumption that the cultivation of feedstock has already been accounted for the LCA of primary food crops or other agricultural products, as they are typically byproducts or residues from those processes (Soam et al. 2016).

(Mandade et al. 2015) analyzed the water life cycle for Indian agro-industrial lignocellulosic biomass-based biofuel production. The analysis shows sorghum stalk biofuel to be more water efficient and sugarcane to be least for biofuel production as it consumes more water for Phase 1 (Fig. 2a) system boundary of LCA of biofuel. (Mathioudakis et al. 2017) analyzed the water footprint of agricultural residues and showed the WF of rice straw to be 129 L / kg. (Xie et al. 2017) analyzed for the ethanol production from cassava and sorghum and reported a WF ranging between 1760 and 5290 L per liter of ethanol, mostly agricultural, contributes towards the WF. Similarly, (Arguelles-Arguelles et al. 2021) show that more than 90% of the water used to produce biodiesel from palm oil ranges from 218 to 540 m^3 / GJ was for agriculture of palm plantation. Similar results were shown by (Gerbens-Leenes and Hoekstra 2010).

As shown in Fig. 9, the WF for third-generation biofuel is the highest ranging from 373.4 to 1481 m^3 / GJ (Siqueira et al. 2018; Wu et al. 2019). The water footprint of biofuel production from microalgae can vary depending on production methods and water availability in the production region (Banerjee et al. 2019). The WF considers the process water, material inputs for every stage of LCA, and water credit correlated with co-products (Mekonnen and Hoekstra 2011; Siqueira et al. 2018). The total WF comprises both the blue and green WFs, where the blue WF reflects the amount of water needed from local sources such as surface or groundwater for irrigation purposes, while the green WF represents the quantity of rainwater and soil moisture utilized by plants (Mekonnen and Hoekstra 2011).

Land use change

Land-use change (LUC) either directly or indirectly causes GHG emissions. Since the biomass that powers these systems is produced on the land, land use is a crucial factor in the research of bioenergy systems. LUC is a significant source of GHG emissions, contributing 13 Gt CO_2 – eq globally in 2019 (IPCC 2022). Only 46% of the reviewed studies considered land-use change, as shown in Fig. 3. The lack of attention on advanced LCA studies, such as land-use change, was caused by the unavailability of a significant land-use database (Harris et al. 2015). Based on research conducted by (Fargione et al. 2008; Lapola et al. 2010), it has been found that the amount of GHG emissions resulting from direct and indirect LUC can be considerably higher than the GHG reductions achieved by replacing fossil fuels with biofuels.

Studies that include LUC tend to report a higher total environmental impact for biofuel production compared to studies that exclude LUC. This is due to the additional emissions and ecological impacts associated with land conversion. A study by (Isler-Kaya and Karaosmanoglu 2022) reported land use impact on biodiesel production from safflower to be 9.21 and 9.94 PDF*m^2*yr ("potential disappeared fraction of species over a certain area over a certain period") for safflower oil methyl ester (SOME) and ethyl ester (SOEE), which are similar as the study by (Spinelli et al. 2013). Study by (Humpenöder et al. 2013) shows that there was a 50% reduction in GHG emissions without taking LUC into account compared to fossil fuel. (Bhonsle et al. 2022) analyzed biodiesel production from UCO. The analysis shows land use midpoint category was highest for oil boiler use (86.6 m2a crop eq.) for conventional biodiesel and UCO use (6.59 m2a crop eq.) for room temperature scenario. (Chung et al. 2019) also analyzed for the used cooking oil and showed land use impact of 4.72E-01 PDF*m^2*yr for catalyst preparation, 4.33E-01 PDF*m^2*yr for pretreatment, and 1.26 PDF*m^2*yr for the transesterification process. Similar studies were done by (Fernández-Tirado et al. 2016; Gnansounou and Kenthorai Raman 2016; Carneiro et al. 2017a; Vrech et al. 2019). While biofuels can offer advantages in reducing fossil fuel use and associated emissions, the inclusion of LUC-related impacts may diminish these advantages, especially if significant land conversion occurs.

Other environmental impacts

Besides carbon footprint, the environmental impact categories examined in biofuel LCA studies are acidification,

Table 4 Comparison of damage categories using Eco-Indicator 99 and ReCiPe 2016 LCIA method

Feedstocks	Unit	Human health		Ecosystem quality		Resources	
		Eco-Indicator 99	ReCiPe 2016	Eco-Indicator 99	ReCiPe 2016	Eco-Indicator 99	ReCiPe 2016
Rapeseed	%	47.6	94.5	5.7	3.2	46.6	2.4
Palm Oil	%	54.8	91.9	21.3	7.9	23.9	0.2
Used Cooking Oil	%	31.8	92.4	2.6	3.1	65.6	4.6
Jatropha	%	44.2	93.9	5.1	3.6	50.8	2.5
Microalgae	%	56.9	94.9	2.2	3.5	40.9	1.7

eutrophication, and ecotoxicity. About 60% of the reviewed studies analyzed more comprehensive impact categories. Since the reviewed LCA studies employed various methodologies to assess other environmental impacts, comparing them and providing a meaningful range of impacts for different biofuels is difficult (Kalaivani et al. 2014). Furthermore, there is variability in the scope of the studies reviewed. Some studies focus primarily on assessing the environmental impacts of biofuels within a cradle-to-gate system boundary, which considers the stages from raw material extraction to the point of leaving the production facility. On the other hand, certain studies adopt a broader cradle-to-grave system boundary, encompassing the entire life cycle of the biofuel, including additional stages such as use, maintenance, and end-of-life considerations. This variation in system boundaries leads to differences in the extent and depth of the assessments conducted, affecting the comprehensiveness and breadth of the environmental impact analysis (Jolliet et al. 2003). The results of the research are also impacted by the assumptions made regarding the type of vehicle that biofuels are used in. (Arpornpong et al. 2015). Some studies indicate that reducing GHG emissions by using biofuels instead of fossil fuels can have negative consequences on the environment, such as increasing acidification, eutrophication, respiratory issues caused by organic and inorganic pollutants, and ecotoxicity (Borrion et al. 2012; Arguelles-Arguelles et al. 2021; Yang et al. 2021). Figure 10a shows the impact categories of biofuel production from different sources using the IMPACT 2002 + impact characterization. Impact characterization aids in the identification of primary drivers of environmental impacts throughout a life cycle. Through the comparison of impact scores assigned to various inputs or outputs, it allows for the identification of hotspots, which refer to specific stages, processes, or materials that exert a substantial influence on the overall environmental performance (Isler-Kaya and Karaosmanoglu 2022).

Ecotoxicity potential (EP) is mainly attributed to fertilizers and pesticides used in Phase 1 of the LCA system boundary (Fig. 2a). (Lee and Ofori-Boateng 2013; Gallejones et al. 2015) showed similar results for rapeseed biofuel and palm oil, where the use of fertilizers caused 42% and 50% of total EP. However, the midpoint impacts, such as non-renewable energy and respiratory inorganics, which contributes to human health and resource depletion (González-García et al. 2013b), have the highest single score for biofuel production, shown in Fig. 10b. According to the research conducted by (Kalaivani et al. 2014; Patel and Singh 2023), the ecotoxicity of jatropha biodiesel ranges from 35 to 160 kg TEG (triethylene glycol) per kg of biodiesel. The study found that phosphorus fertilizer accounts for 45% of the total EP, making it the largest contributor, followed by urea, which contributes 20% of the EP. Table 4 compares the endpoint or damage categories of Eco-indicator 99 and ReCiPe 2016 impact method for biofuel production. By comparing the two methods, it helps to assess the consistency and reliability of the results obtained. It allows researchers and practitioners to identify any discrepancies or variations in impact assessment outcomes and evaluate the methodological robustness of each approach. enables informed decision-making by considering different perspectives and approaches to impact assessment. Table 5 shows the environmental impact categories on a relative scale.

Socio-Economic impacts of biofuel production

The socio-economic impacts of biofuels refer to the effects that the production, use, and promotion of biofuels have on society and the economy. These impacts can be positive and negative and vary depending on factors such as the specific biofuel feedstock, production methods, local contexts, and policy frameworks (Kim and Dale 2008). Biofuel production can create employment opportunities across the value chain, including farming, harvesting, processing, transportation, and distribution. This can benefit rural communities and contribute to local economic development. Furthermore, biofuels reduce dependence on fossil fuels, promoting energy security by diversifying energy sources (Cambero and Sowlati 2014; Yang et al. 2015). This can enhance a country's energy independence and reduce vulnerability to price fluctuations and supply disruptions in the global oil market. However, the cultivation of biofuel feedstocks may compete with food production, potentially leading to

increased food prices and reduced food security (Collotta et al. 2019). This can particularly affect regions where land resources are limited or where the agricultural sector is already under stress.

Compared to environmental impacts, economic and social indicators are rarely included in the LCA. Few studies included the socio-economic aspect of biofuel (van Dam et al. 2009; Stephenson et al. 2010; Ekener-Petersen et al. 2014; Ekener et al. 2018; Collotta et al. 2019). Key factors highlighted in these studies encompass indicators such as transportation expenses, food costs, gender equality, health-related diseases, instances of forced labor, and minimum wages., which exert a substantial impact on the broader socio-economic sustainability of biofuel production (van Dam et al. 2009; Yang et al. 2015).

Conclusion

The LCA is a complex technique that is often utilized to compute the GWP and other environmental impacts associated with biofuels. Despite this, it is frequently seen as a tool capable of providing a conclusive response to numerous concerns. This study indicates that there are no concrete solutions, and the conclusions drawn from LCA studies largely depend on factors like the study's goal and scope, the assumptions made, the methodology used, and the tools employed. Therefore, it is essential to acknowledge this and interpret the results accordingly. Furthermore, certain strategies for communicating complexity to policymakers and the genpotential disappeared fraction of specieral public are required. This analysis shows that the estimates between the studies differ significantly due to numerous LCA methodological options and uncertainties. Despite this, the available evidence is instructive. To keep up with the latest trends in evaluating the environmental effects linked to biofuel production, we critically reviewed 53 LCA studies published between 2012 and 2022, carefully examining the methodology and conclusions. Our findings suggest that second-generation biofuels have a greater potential to decrease GHG emissions than first-generation biofuels. Third-generation algal biofuels show high GHG emissions than conventional fuels at the current stage of development since their electricity consumption is high. The study critically reviewed the energy use and water use in the production of biofuels, along with several midpoint impact categories, such as acidification and eutrophication associated with biofuel production. Based on the bibliometric mapping from the WoS, we have identified that bioenergy, life cycle assessment, biofuels, and sustainability are more researched areas.

To improve the usability of LCA as an evidence-based tool for assessing the environmental sustainability of biofuels, both attributional and consequential LCA methodology and practical applications must be improved. Uncertainty and sensitivity assessments should be included in all LCA investigations to increase the reliability of the results and improve confidence in making decisions based on LCA studies. Biofuels are not independent entities but a component of much larger systems, such as those related to energy, agriculture, and forestry. Biofuels affect several ecosystem services,

Table 5 Midpoint single score based on IMPACT 2002 + LCIA method for biodiesel production

Impact category	Unit	Jatropha biodiesel (Uusitalo et al. 2014; Vrech et al. 2019)	Microalgae (Soratana et al. 2012, 2014; Siqueira et al. 2018)	Palm oil (Lee and Ofori-Boateng 2013; Arguelles-Arguelles et al. 2021)	Rapeseed biodiesel (González-García et al. 2013b; Gallejones et al. 2015)	Used cooking oil (Uusitalo et al. 2014; Bhonsle et al. 2022)

including food, water, and land. To prevent biofuels from being disadvantaged compared to other industries or from having advancements in this industry reversed by unsustainable practices in other industries, it is crucial to plan future policy from an integrated systems perspective.

***Abstract*—This paper aims at comparing various PID tuning methodologies. An armature-controlled DC motor has been modeled in Simulink using its actual parameters for the study. The metaheuristic approaches i.e., Flower Pollination Algorithm and Grey Wolf Optimization have been coded on MATLAB and the tuned parameters have been imported on Simulink to check their response of the system. These algorithms work on ITAE as their objective function. ANFIS controller for tuning PID values is implemented on Simulink. Its training data is imported from Fuzzy Logic Controller's tuned parameters. Finally, the results of the controllers are analyzed and distinguished by values of Rise Time (Tr), Peak Overshoot (Mp), and Peak Time (Tp).**

***Index Terms*—DC Motor, SIMULINK, PID, GWO, FPA, ITAE, Objective function, ANFIS, Fuzzy logic.**

I. Introduction

Engineers rely on motion-control devices to improve efficiency and production rates on automated factory floors, or at least maintain them. One of the earliest devices designed to transform electrical power into mechanical power was the DC motor. Due to their high levels of dependability, versatility, and affordability[1], DC motors are frequently used when speed of motor and position control are essential in industrial settings, robot manipulators, and appliances.

P, PI, and PID tuning are methods for optimizing feedback control systems. Proportional (P) control uses the error to determine the control action, while PI control adds an integral term to eliminate steady-state errors. PID control further adds a derivative term to dampen oscillations and improve stability. PID controllers offer faster response, reduced steady-state error, improved stability, and adaptability to system changes compared to P or PI controllers.

Motor control applications frequently use PID controllers because of their straightforward topologies and easily understandable control algorithms. Proportional-integral-derivative (PID) control offers a simple and incredibly useful solution to many concerns in the real world due to its three-term structure. Both transient and steady-state behaviors may be governed by all this. As a result, PID controllers are frequently used in traditional speed control loops[2]. The drawbacks of conventional PID controllers include unwanted overshoot, slow response, sensitivity to controller gains, and rapid changes in load torque[3]. The varied behavior of the system parameters under operating environment and the noise that is present in the circuit are the two main issues with motor control[4]. As a result, it is difficult to use standard techniques for motor control of sophisticated, nonlinear, and time-varying systems. To achieve an ideal state under field conditions, tuning the PID controller's parameters is therefore obviously necessary[5].

The metaheuristic algorithms [6] like Flower Pollination Algorithm and Grey Wolf Optimization use ITAE as an objective function for optimization. This objective function is minimized using a global minimization approach. These algorithms are inspired by nature and approach optimization of PID irrespective of plant model, thus providing robust results.

When using advanced speed control approaches, such as Adaptive Neuro-Fuzzy Interface System (ANFIS), desired speed tracking with sufficient precision in the presence of abrupt interruptions and parameter fluctuation can be accomplished. The ability to make complicated nonlinear control actions, also for indefinite nonlinear systems, is a feature of a nonlinear controller that is endowed with fuzzy control theory [5]. These control techniques bring the complexity of Machine Learning and Neural Networks into the hardware domain of PID. These techniques give better results in any scenario.

This paper is organized into seven segments: Section II goes on to discuss the mathematical model; Section III aims to discuss the metaheuristic approach to PID tuning and objective functions; Section IV explores Grey Wolf Optimization; Section V explains the Flower Pollination Algorithm; Section VI mentions simulation results and discussions; Section VII analyses conclusions; and Section VIII concludes. These sections are followed by an acknowledgment and a list of references.

II. Mathematical Model

The voltage applied to the motor can be changed while the field remains constant in separately excited DC Motors.

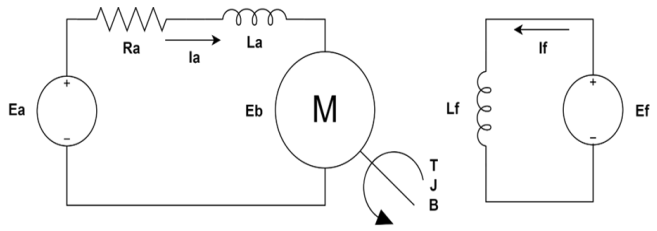

Figure 1. Equivalent Circuit of Armature Controlled DC Motor.

Table I
EQUIVALENT CIRCUIT PARAMETERS AND VALUES

Parameter	Nomenclature	Values
Moment of Inertia	J	$0.093Kg-m^2$
Friction Coefficient	B	$0.007N-ms$
Back Emf Constant	K_b	$0.6V/rad-s^-1$
Torque Constant	K_T	$0.7273Nm/A$
Armature Resistance	R_a	0.6
Armature Inductance	L_a	$0.006H$

The mathematical equations of the Armature Controlled DC Motor are as follows:

$$\Phi \propto i_f$$

$$\Phi = K_f i_f \tag{1}$$

Where,

$$T \propto \Phi i_a$$

$$T = K_a \Phi i_a = K_a K_f \Phi i_a$$

$$T = K_T i_a \tag{2}$$

$$E_b \propto \Phi \omega$$

$$E_b = K_b \omega \tag{3}$$

Applying KVL,

$$V = i_a R_a + L_a \frac{di_a}{dt} + E_b \tag{4}$$

And,

$$T = J\frac{d^2\theta}{dt^2} + B\frac{d\theta}{dt} \tag{5}$$

Load Torque,

$$T = J\frac{d^2\theta}{dt^2} + B\frac{d\theta}{dt} + T_L \tag{6}$$

By Laplace Transform,

$$V(s) = i_a(s)(R_a + sL_a) + E_b$$

$$V(s) - E_b(s) = i_a(s)(R_a + sL_a)$$

$$E_b(s) = K_b s\theta(s)$$

$$T(s) = Ki_a(s)$$

$$T(s) = \theta(s)(Js^2 + sB)$$

$$T(s) = \omega(s)(Js + B)$$

$$T(s) = K_T i_a I(s)$$

$$T(s) = \frac{\omega(s)}{V(s)} = \frac{K_T}{(R_a + sLa)(Js + B) + K_b K_T} \tag{7}$$

The transfer function of the DC Motor obtained after putting Equivalent circuit Parameters defined in Table I is as follows:

$$T(s) = \frac{1}{0.0007671s^2 + 0.076785s + 0.60654} \tag{8}$$

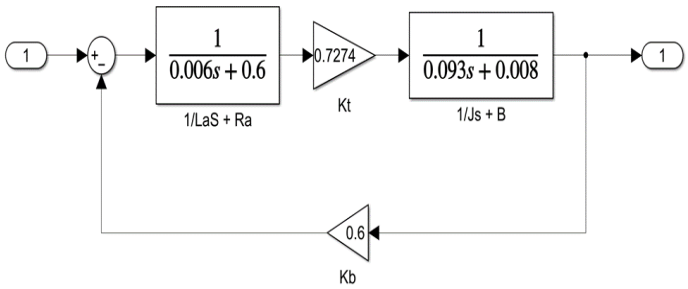

Figure 2. Block Diagram of DC Motor designed in SIMULINK

Figure 2, depicts the block diagram modeled in SIMULINK using Equation (7).

III. Metaheuristic approach of PID Tuning and Objective Functions

A. Metaheuristic approach of PID Tuning

Process control makes considerable use of metaheuristic algorithms [7] because of their quick response times, high optimization capabilities, and simple architectural design. Metaheuristic algorithms are more effective at resolving higher-dimensional optimization issues than conventional optimization techniques. They are easily adaptable to modern classical controller design approaches due to their durability. Metaheuristic algorithms can be used as a fundamental method for creating a uniform and enhanced set of resilient operational models that require structured controllers, regardless of the order in which the models are developed.

B. Objective Functions

The real-valued function whose value is to be either minimized or maximized over the range of feasible solutions is characterized as the objective function[8] in a mathematical optimization problem. In this case, our optimization goal function would be the Integral Time Absolute Error (ITAE)[9]: ITAE =$\int_0^\tau t|e(t)|$

IV. Grey Wolf Optimization (GWO)

A. Implementation

The grey wolf, which hunts massive prey in gangs and thrives on individual wolf coordination, inspired this algorithm. This behavior is notable for two reasons:

1) Social hierarchy
2) Hunting mechanism.

The grey wolf has a sophisticated social structure due to its gregarious nature. The phrase ”dominance hierarchies” refers

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:10:35 UTC from IEEE Xplore. Restrictions apply.

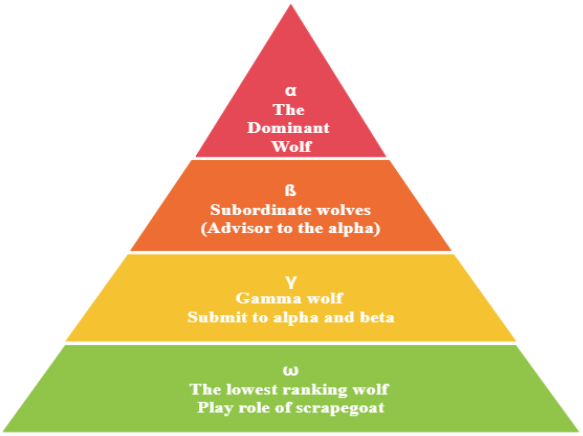

Figure 3. Grey Wolf Algorithm dominance hierarchies

to the hierarchical order depicted in Fig 3, in which wolves are ranked according to their authority and strength[10]. As a result, alphas, betas, deltas, and omegas exist.

1) At the top of the pack's hierarchy are the alpha male and female. Each member of the pack has been assigned a rank. The wolf's hierarchical order is about more than just dominance and aggression; it also assists vulnerable members of the pack who are unable to hunt for themselves.
2) The beta wolf comes next, who supports the alpha wolf's decisions and helps to preserve pack discipline.
3) The delta wolf is inferior to the beta wolf. They are frequently powerful, but lack the necessary leadership qualities and self-confidence to take on leadership responsibilities.
4) Eventually, the omega wolf wields little power, and other wolves will quickly chase him. Omega wolf is also in charge of monitoring the younger wolves.

At each level, we will use the previously described methods to indicate the three best solutions by alpha, beta, and delta, as well as alternative options by omega. This essentially means that the optimization process is guided by the flow of the three best solutions. In addition, the prey will be the best optimization solution[11].
Most of the logic follows the equations:

$$\overrightarrow{D} = \mid \overrightarrow{C}.\overrightarrow{X_p}(t) - \overrightarrow{X}(t) \mid \tag{9}$$

$$\overrightarrow{X}(t+1) = \mid \overrightarrow{X_p}(t) - \overrightarrow{A}.\overrightarrow{D} \mid \tag{10}$$

where t indicates the latest iteration, A and C are regression coefficients, Xp is the vector of the prey's movement, and X is the vector of the wolf's position. Cartesian coordinates A and B seem to be similar.

$$\overrightarrow{A} = 2\overrightarrow{a}.\overrightarrow{r_1} - \overrightarrow{a} \tag{11}$$

$$\overrightarrow{C} = 2\overrightarrow{r_2} \tag{12}$$

where a's components decline linearly from 2 to 0 over iterations and r1, r2 are random vectors with values ranging from [0, 1] computed for each wolf at each iteration[12]. Vector A governs the trade-off between exploration and exploitation, whereas vector C always includes some unpredictability. This is crucial because our agents can become stranded in local optima, which most metaheuristics can avoid. Because we don't know the true position of the optimal solution, Xp is determined by the three best answers.

B. PID Tuning using GWO

The tuning parameters of our PID controller, namely Kp, Ki, and Kd, will be modified by assessing the fitness of our DC motor system's objective function, namely ITAE (Integral Time Absolute Error). These parameters are then fed into our DC motor model's PID controller. Figure 5 shows a block schematic for a PID-fed DC motor with parameters optimised using the GWO Algorithm.

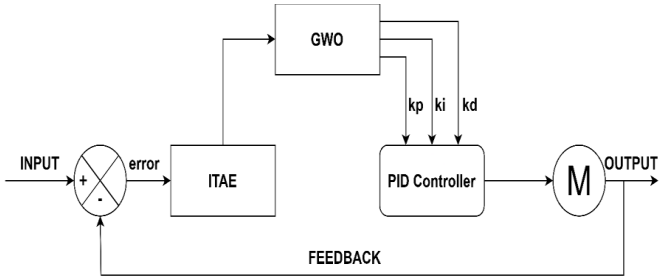

Figure 4. DC motor drive speed with PID tuning in closed loop control

The Grey Wolf Optimisation algorithm will be applied as defined in the flowchart shown in Fig 6 with the initialisation parameters being[13]:

1) Number of iterations.
2) Size of the population (search area).
3) Number of variables (Kp, Ki, Kd).

V. Flower Pollination Algorithm(FPA)

A. Algorithm

Pollen transmission is often a component of flower pollination[14], and it frequently involves pollinators which contain animals such as birds, and bugs, among others. In real world, a highly specialised flower-pollinator partnership has co-evolved as a result of specific blooms and insects. For optimal pollination, some blooms, for example, can only draw and depend on a certain species of insect. Pollinators, also referred to as pollen vectors, appear in great diversity. At least 200,000 different pollinators, including birds and insects[15], are thought to exist. A notable example of a pollinator is the honeybee, which has the capacity to achieve what is known as blossom constancy. In terms of behavior, these pollinators frequently visit only a few flower types while avoiding others. Floral constancy may have evolutionary benefits since it will improve the transmission of pollen to related or identical plants, maximizing the continuation of a particular genus of

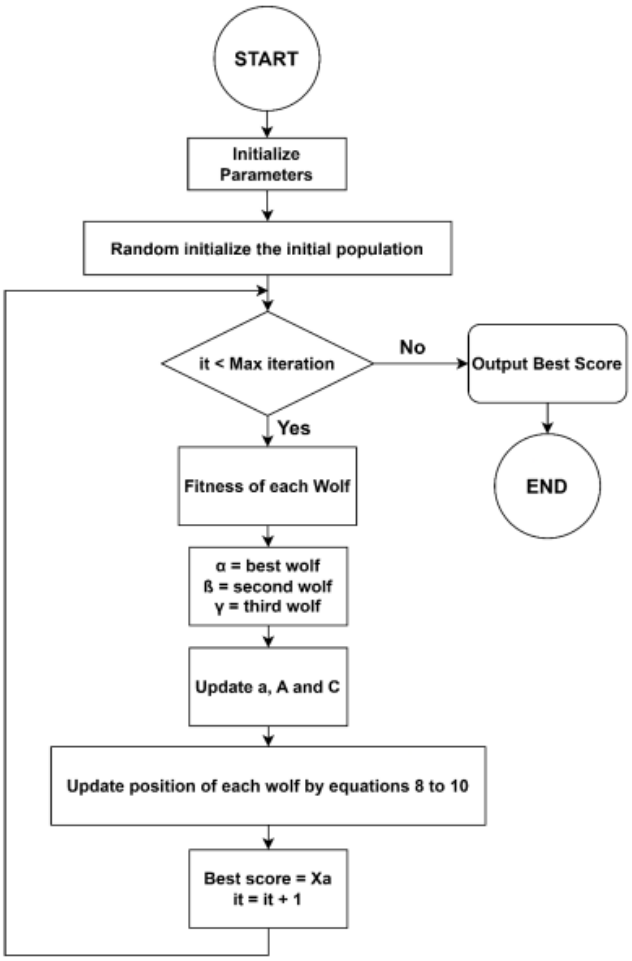

Figure 5. Flowchart of Grey Wolf Optimization Algorithm

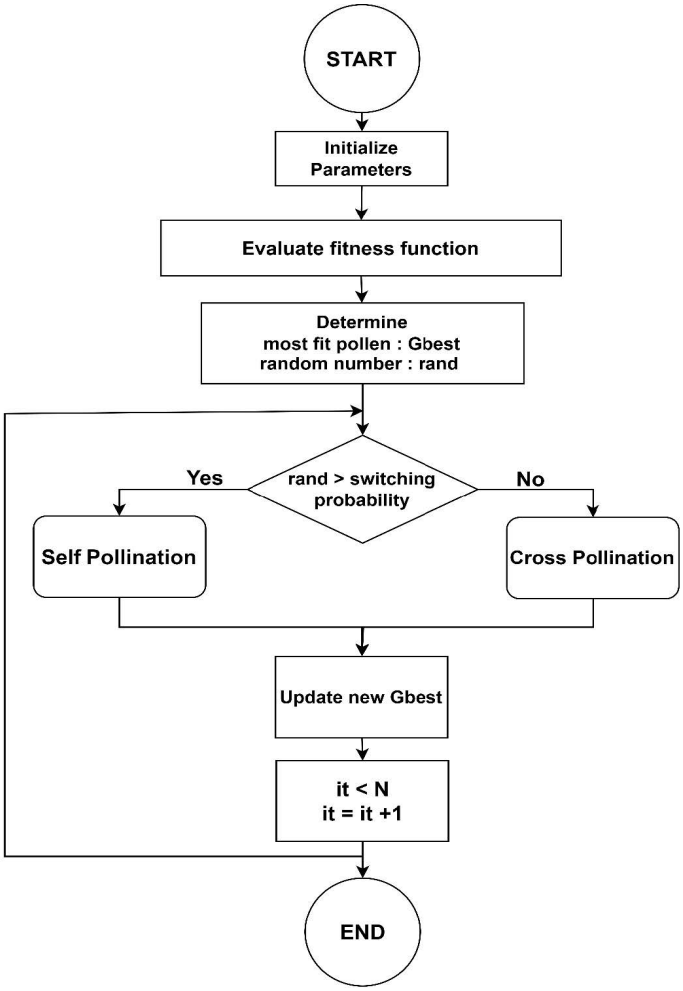

Figure 6. Flowchart of Flower Pollination Optimization Algorithm

flowers. Such floral stability can be beneficial. Figure 6 shows a block schematic for a PID-fed DC motor with parameters optimised using the Flower Pollination Algorithm[16,17].

B. PID Tuning using FPA

The values of the controller parameters for our analysis of the performance of DC motors[18] can be obtained by applying the flower pollination algorithm with K_p, K_i, K_d.

The following four guidelines are employed for simplicity[19]:

1) Lévy flights are followed by pollen-carrying pollinators, and biotic and cross-pollination are considered to be global pollination processes. (Rule 1).
2) Local pollination techniques include self-pollination and abiotic pollination. (Rule 2).
3) Pollinators like insects can develop flower constancy, which is compared to a reproduction likelihood proportionate to the similarity of the two flowers involved. (Rule 3).
4) Switch likelihood p[0,1] that is somewhat biased in favor of local pollination can be used to influence how local and global pollination interacts or switch. (Rule 4).

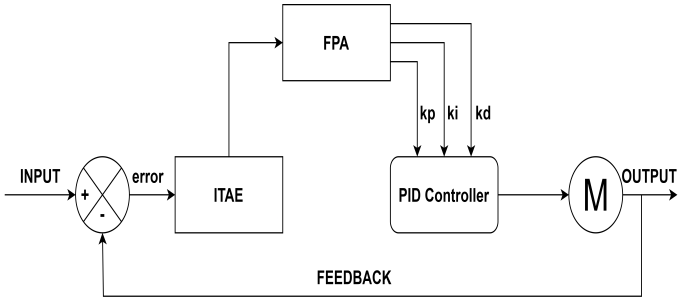

Figure 7. DC motor drive speed with PID tuning in closed loop control

VI. Adaptive Neuro Fuzzy Interface System (ANFIS)

A. ANFIS Controller

Fuzzy Logic and Neural Network together form ANFIS controller[20]. A number of inputs are applied to the neural network. The neural network produces several typical outputs based on its inputs. Neural Network is trained based on the input and output[21]. Fuzzy logic is used to produce the IF THEN rules and membership functions once the neural network has finished training

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:10:35 UTC from IEEE Xplore. Restrictions apply.

B. Data Sampling and Controller Training

In order to avoid making the validation process too simple, we must choose a data set that is both representational of the data the trained model is meant to imitate and sufficiently different from the training data set[22]. For the sampling process values of K_p are collected from the fuzzy controller. We have collected the data for 4 different signals (Figure 8). This data is used in the form of 2D array and data from these 4 signals are combined to form the training data for ANFIS controller for K_p. The same sampling process is used for the data collection of K_i and K_d. The sampled data collected is

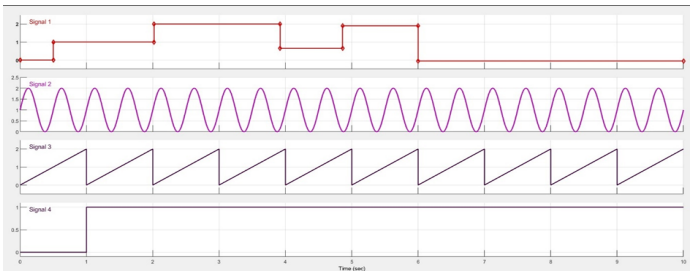

Figure 8. Signals used for training ANFIS Controller

now trained on the ANFIS controller. Pi type of membership function is used as it produced the best results in the case of Fuzzy tuning and 10 for each variable. The output type used is linear. The number of training iterations were 10.

C. Tuning of ANFIS Controller

After the training ANFIS controller for each of the K_p, K_i and K_d values were introduced in the model shown in Figure 9 as block diagram and the results were compared.

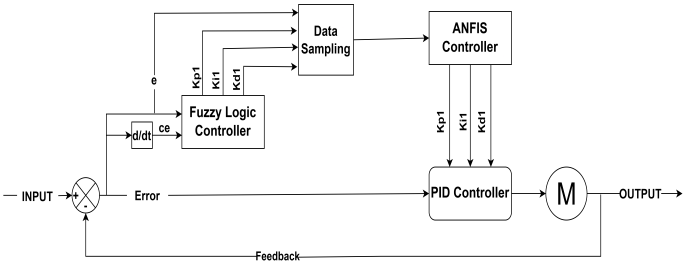

Figure 9. Block Diagram for tuning of ANFIS Controller

VII. Simulation Results and Discussion

1. Convergence of Objective Function

Figure 10 and Figure 11 demonstrates how objective function ITAE is converging for Grey Wolf Optimization and Flower Pollination ALgorithm run in MATLAB to obtain parameter for PID Controller.

2. Comparative Analysis of GWO, FPA, and ANFIS

Figure 12 shows the Combined Response of GWO, FPA, and ANFIS with respect to Step Input. Flower pollination can provide better results in every aspect as compared to Grey Wolf optimization. FPA tuning provide us with less overshoot and the system is becoming stable faster.

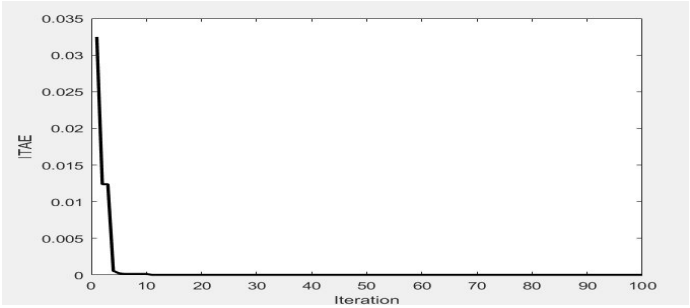

Figure 10. Convergence of Objective Function for GWO

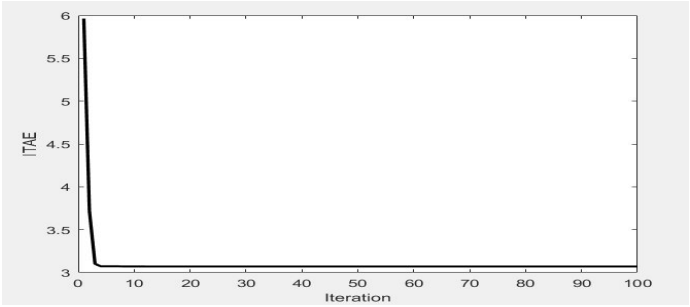

Figure 11. Convergence of Objective Function for FPA

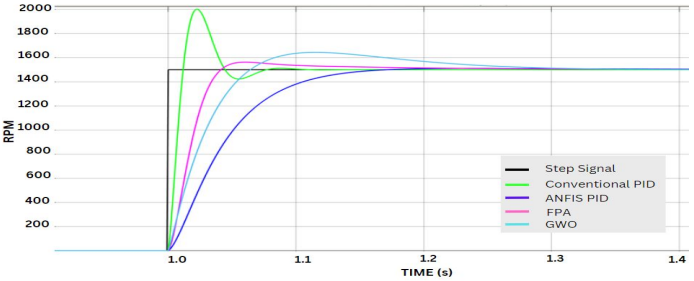

Figure 12. Comparative Analysis of all the Tuning Methodologies

Table II shows the results obtained by different Algorithms for various Parameters involving Peak Overshoot(M_p), Peak Time(T_p) and Rise Time(T_r).

Table II
System Characteristics for Tuned Parameters of FPA and GWO

Tuning Algorithm	Tr(ms)	Mp(%)	Tp(ms)
Conventional PID Tuning	10	33.4	22
Grey Wolf Optimisation	49	9.6	115
Flower Pollination	14	2.7	27

ANFIS controller has significant improvement in terms of peak overshoot. With the training done on 7500 data points computed from Fuzzy Logic Controller which in turn provides very optimized results, this was inevitable. The overall stabilization is also better. The ANFIS controller only lags in terms of rise time with respect to our metaheuristic algorithms. Due to a large amount of training and computation required.

Table 3 displays the parameters of the ANFIS controller with the pi membership function, and it demonstrates that ANFIS is better than Fuzzy for overshoot control, but it is slower since the rise time and peak time for ANFIS are considerably longer than for Fuzzy.

VIII. CONCLUSION

Using MATLAB/Simulink, a DC motor is simulated and its speed is controlled. We have employed metaheuristic methods of optimization: Grey Wolf Optimisation, and Flower Pollination Algorithm. The nature-inspired metaheuristic approaches for tuning PID provide robust results and are irrespective of the plant model. The use of the objective function for optimization in these techniques provides better stability with changes. Thus, we have a minimum rise time for a plant model. Considering the unique algorithms we see faster settling in FPA, along with better rise time and also lesser overshoot. Hence, Flower pollination with cross-pollination and self-pollination provides a better methodology for tuning compared to conventional techniques. ANFIS being a neural network optimization technique is computation heavy. Thus the rise time in its case is more. Yet the settling time describes the efficiency it provides.

Hence both approaches to tuning have individual benefits. Metaheuristic algorithms are resistant to change (smaller rise time) while Neural networks are better in stabilization (smaller settling time and peak overshoot).

ACKNOWLEDGMENT

We would like to convey our sincere gratitude to Professor Bharat Bhushan of the Electrical Engineering Department, Delhi Technological University for providing us with the chance to conduct this research and for his helpful advice. His enthusiasm, vision, sincerity, and drive have greatly motivated us. It was a great honor and joy to be able to work and study under his leadership. We are immensely grateful for everything he has given us. He has always been an inspiration to me. We also like to express our gratitude to all of the teaching and support personnel at Delhi Technological University's Electrical Engineering Department for their direct and/or indirect contributions to the project.

ABSTRACT

Tall building is playing important role in the growth of urbanization and has resulted in developing to the vertical rise of the structure. The data available for the designing of the tall building is not sufficient or need some modification up to very limited extent in the present scenario. In this study a rectangular shape having L: B ratio as 1.15 and octagonal plan shape are selected to investigate the wind loads on building. The area of both models is nearly equal for the comparison of the results. Pressure effects are the main concern of considered building model. When it comes to predicting wind-related events on buildings or other structures, computational fluid dynamics (CFD) is a reliable and quicker option. CFD analysis is carried out using a software program called (ANSYS-CFX). This paper presents pressure contours that are calculated at the front, back & adjacent sides of the individual tall buildings. The results clearly show that based upon the building shape, the pressures generated can be either positive pressure or negative which can be either beneficial or can have adverse effects. The result on both the building model shows that the pressure on wind ward face is more or less the same and it does not depend on the shape of the building. In the case of a symmetrical building, the leeward face will always be subjected to the suction effect, while the side faces will always exhibit an equal pressure distribution.

1. Introduction

This is well known fact that the population is migrating to urban cities for the different causes hence the requirement for the tall building is increased with effect from the past year. Because of this reason the demands of the tall building are increasing in the urban cities also present growth pattern are replacing the past low-rise buildings in to the tall buildings. Wind effects are unpredictable in the nature and varies for each model hence their investigation is must for all high-rise structure. Codal provisions and various available data is need some upgradation in various forms hence the investigation of wind generated effects is must for new building with some or minor modification. Wind effects can be identified on the tall building using wind tunnel test or either CFD [1]. The growth of modern architecture has significantly changed the pattern of wind generated effects on modern infrastructure with effect from the past conventional design of tall buildings. As the wind effects are varied for each type of building model. When it comes to climate change, one of the most important variables to consider is wind in case of the tall building as the wind load is increase as the height increases. The wind is consisting of different types of eddies of different sizes and rotational effects that are carried along in a large stream of wind moving relative to the earth surface. This is one of the most important variables to consider in the designing of high-rise structure. Because of these eddies, the wind has a gusty or turbulent characteristics [2]. Computational fluid dynamics (CFD) simulations are used extensively by different researcher in past such as [3].[4] wind effects are investigated using experimental method boundary layer wind tunnel on "+" shape of tall building. It is found that as the wind incidence angle changes on the building model wind effects are changed hence these mostly varies as per the plan cross sectional shape. The increase in the height of the building model causes the increase or decrease in the wind effects in terms of pressure or suction on the building wind ward or lee ward side [5]. The effects of wind on the different bracing system used in high rise steel structure were investigated and it is found that building load carrying capacity is affected for different pattern of bracings. Different plan cross sectional shape building model were discussed in detail by [6 7] and investigated the interference effect on the primary building model by placing equal height building model in the surrounding of the primary building model.

Due to the interference, it is found that the pressure, and the base shear is exhibited by the square plan shaped model at full blockage condition with effect from the fish plan shaped tall building model is lesser in magnitude.

Wind effects are investigated in past studies are mostly on regular type model such as square, rectangular with the variation in the length to width ratio of different cross sectional shape such as[8,9]carried out an experimental study of wind-induced pressure on tall buildings of various shapes from 0^0 to 90^0 wind incidence angle by varying the wind at 30^0 intervals and discovered that wind pressure decreases up to 60^0 wind incidence angle from the 0^0 wind incidence angle. It is also found that the "H" plan shaped building is subjected to a more pressure than the square plan shaped building. Various type of modification was provided and investigated to reduce the wind effects on tall building to make it more resistant to wind effects. [10]. Wind excitation and effects can be reduced in high-rise structures by carefully considering the construction of the different architectural feature in plan geometry of the building. Modification in the shape of a building is a mostly used option to reduce the wind effects [11 12]. Pressure characteristic in terms of wind flow and dynamic response are the earlier investigation done on different cross-sectional shape to provide most optimistic building to minimise the wind effects [13]. Presented the wind effects on "H" plan shape building [14], along with the interference of buildings for both isolated and interference condition [15] and it is observed that the in some cases interference of secondary model is reduces the wind effects on primary model [16]. Architect are now a days designing building based on some modern design tools and hence the building with modifications are useful to reduce the wind effects[17 18]. The mean Cp for octagonal building model are computed using numerical simulation and experimental result and compared the result on different sides of the tall building model.

A non-dimensional coefficient, wind pressure coefficients Cp, are used to express the wind-induced pressure at a specific building surface over a structure. Wind pressure coefficients are commonly used in the calculation of wind loads and wind- induced pressure. It is necessary to know the wind pressure coefficients in order to make accurate wind load assessments and structural designs, especially for large structures that are more susceptible to wind pressures. Full-scale measurements are difficult to carry out, and expensive also these take a long time. For the same reason, wind tunnel tests are expensive and require a significant amount of expertise. Previous work has been done in low-rise buildings with simple geometry to obtain full-scale measurements for the purpose of estimating wind-induced pressure. Wind loads in difficult structures such as high-rise buildings and non-conventional architectural structures are frequently determined through numerical analysis using Computational Fluid Dynamics (CFD) simulations.

2. Numerical simulation

The wind load is investigated on tall building is mostly done using two methods such as wind tunnel test and CFD. In the present CFD is utilized to calculate the wind effects on the equal area building model. The wind effects on a rectangular and octagon building are presented in this study. Result in various form such as mean pressure coefficient and contours are presented with graphical representation. Despite the fact that the plan area and dimensions of these two structures are nearly identical, the shape of the buildings has a significant influence on the wind behaviour. Following basic equation are used to calculate the wind effects.

Continuity equation:

$$\frac{\partial u}{\partial x}+\frac{\partial v}{\partial y}+\frac{\partial w}{\partial z}=0 \tag{1}$$

Momentum equation:

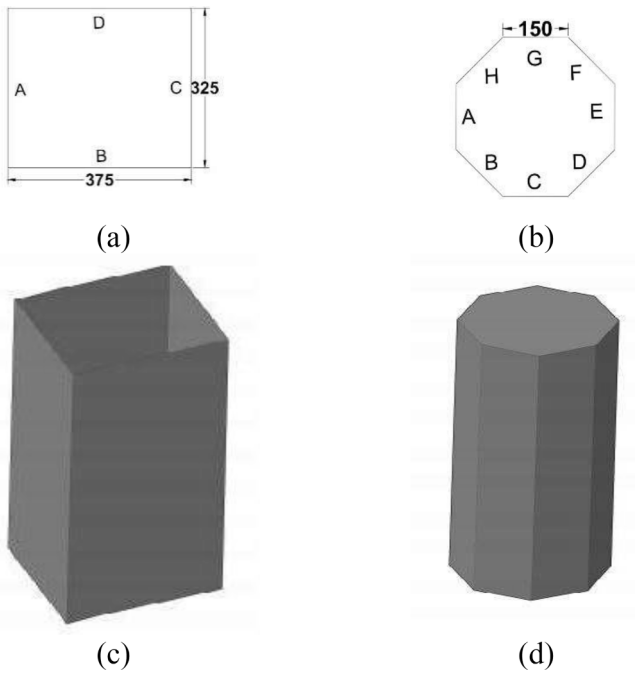

Fig. 1. Plan and isometric view of building model (a) rectangular plan (b) octagon plan (c) rectangular isometric (d) octagon isometric.

$$\rho\left(\frac{\partial u}{\partial t}+u\frac{\partial u}{\partial x}+v\frac{\partial u}{\partial y}+w\frac{\partial u}{\partial y}\right)=\frac{-\partial\rho}{\partial x}+\rho g_x+\mu\left(\frac{\partial^2 u}{\partial x^2}+\frac{\partial^2 u}{\partial y^2}+\frac{\partial^2 u}{\partial z^2}\right) \tag{2}$$

Eq. (2). can be extended to y and z directions as well so as to get the entire momentum equation. The k-ε model has the benefit in modelling geometry-related factors. The connection of the conservation equations with the entire system of equations is stiff and slow convergent. In general, the Navier-Stokes equation of continuity and momentum is used in CFD. The following are the equations for the unsteady three-dimensional flow to compute the wind effects.

$$\mu_{eff}=\mu+\mu_t \tag{3}$$

Where μ_t is the turbulence viscosity. The $k-\varepsilon$ assumes the following relation between the turbulence viscosity, k and ε.

$$\frac{\partial\rho k}{\partial t}+\nabla(\rho\vec{u}k)=\nabla\left[\left(\mu+\frac{\mu_t}{\sigma_k}\right)\nabla\varepsilon\right]+\nabla u\vec{\tau}-\rho\varepsilon \tag{4}$$

2.1. Building model

Model used in this study are rectangular and octagon depicted in figure 1, the ratio of L:B is kept 1.15. Isometric view rectangular building and octagon building model is also presented. CFD output is very much depends on the knowledge of meshing, and numerical modelling. Despite the fact that simulations are very precise, they require time. Structural engineers may use parametric design to modify their models in a systematic and automated manner.

2.2. Domain and meshing

The domain boundary must be given to describe a problem with a unique solution. Unspecified boundary circumstances have a significant impact on your response. Specifying the solver, the input and exit walls, and other boundary constraints. [19] The domain, boundary conditions, and numerical simulation should all be used simultaneously, according to the proposed model and guidelines available in wind tunnel manual report no 67. A fluid domain was employed in this study to simulate a virtual wind tunnel. In ANSYS CFX, the fluid properties are given, and

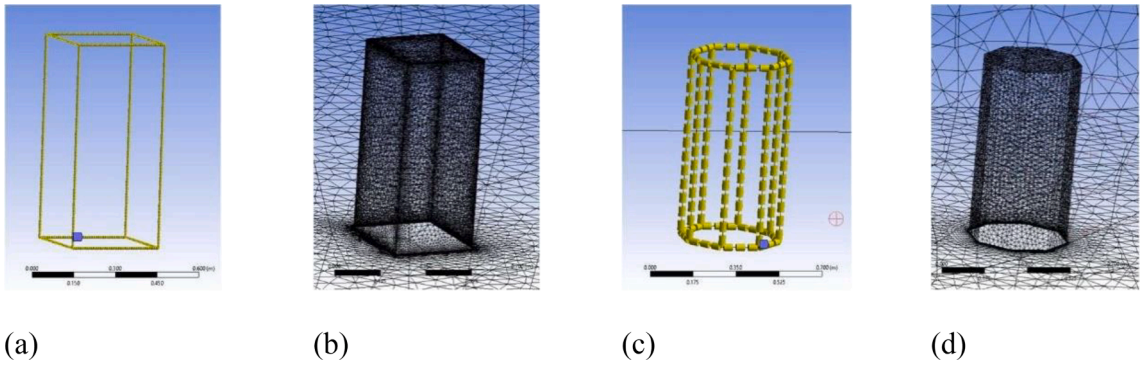

Fig. 2. Meshing (a) of edge for Model A (b) for building model A (c) of edge for Model B (d) for building model B.

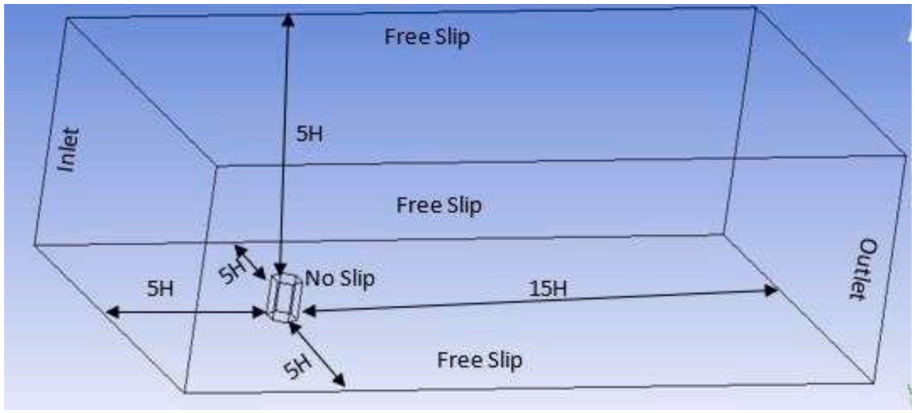

Fig. 3. Domain.

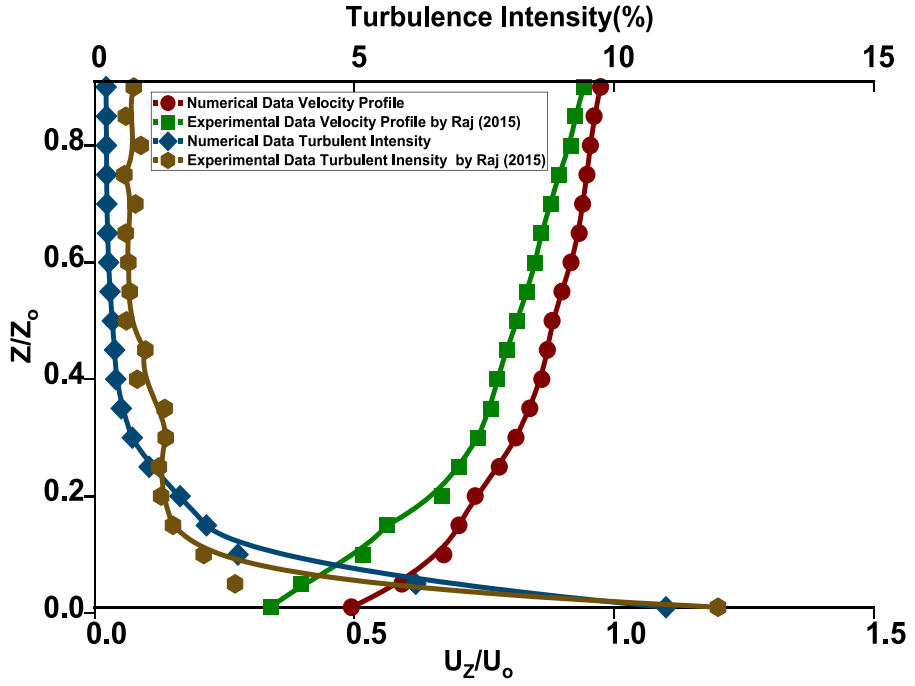

Fig. 4. Velocity profile and turbulent intensity [20].

the building sides are defined as free slip walls.

Fig. 3 depicts the domain that was used for this investigation, with the ground and model surfaces set to no slip and the side walls set to free slip. The edge meshing (a) and building meshing (b) are both finer than the domain meshing (c) when it comes to primary model. Edge meshing is shown in (c) for the octagonal building model, and building meshing is shown in (d) for the rectangular building model. A good mesh may not always result in an optimal solution, but a bad mesh will always result in

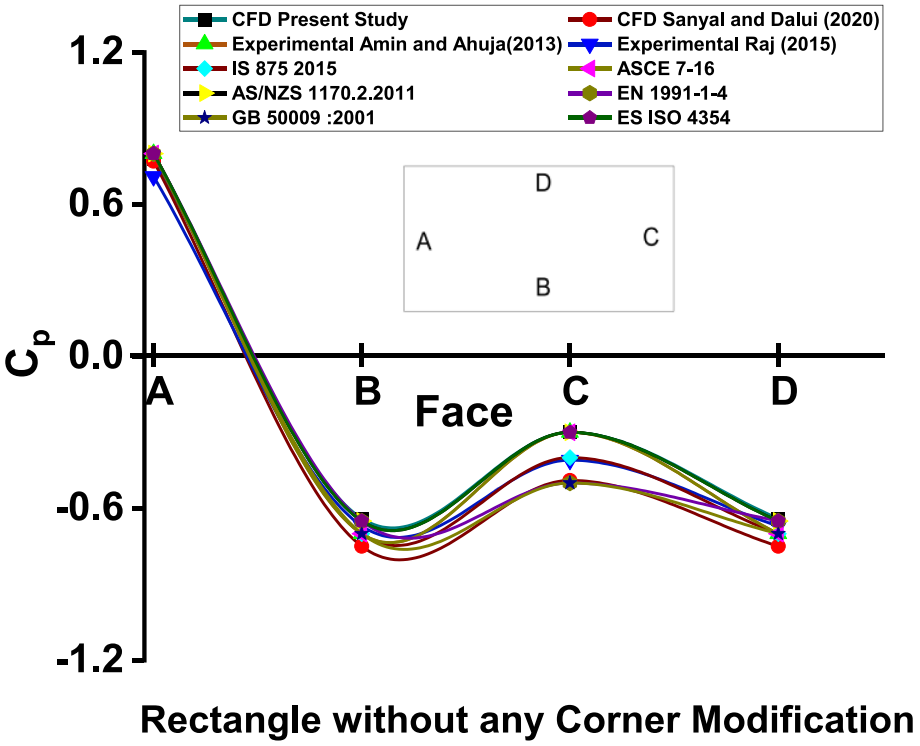

Fig. 5. Validation of rectangular model [20].

a bad solution; meshing is provided as shown in Fig. 2. Inflation is used at the interface of the tall building and the ground. It is taken into consideration in Fig. 2 that air impacts in the separation zone (b). It is difficult to provide an adequate meshing solution because the meshing is dependent on the complexity of the problem. It is impossible for the computer to solve the simulation on the actual geometric shape that was used in the simulation because the governing equation can only be applied to a specific shape and cannot be applied to any other shape. It is possible to solve governing equations in defined volumes using mesh elements and this can be done in a predictable and mathematical manner.

2.3. Velocity and turbulent intensity

In this numerical simulation, the wind input profile is imposed as a power law, with a reference velocity of 10 m/s and an alpha of 0.147 in the power law, and a reference height of 1 m all these constraints are based on the guidelines available in IS 875 part 3 and ASCE report no 67 on wind tunnel manual. Fig. 4 shows the velocity and turbulence intensity profiles.

2.4. Validation

Validation of numerical results using existing data, both numerical and experimental, is essential. [20] establishes results obtained through CFD simulations with other established simulations as well as wind load codes and experimental results for the rectangular building. The coefficient of pressure (Cp) is a dimensionless quantity that represents the ratio of the pressure at any point to the upwind pressure at roof height, and is given by following equation.

$$C_p = \frac{p - p_o}{\frac{1}{2}\rho U_Z^{\,2}} \tag{5}$$

where, p is the pressure derived on the surface of the building model by different techniques, p_o is the reference height static pressure and the air density (1.225 kg/m^3), with Uz denoting the building average wind

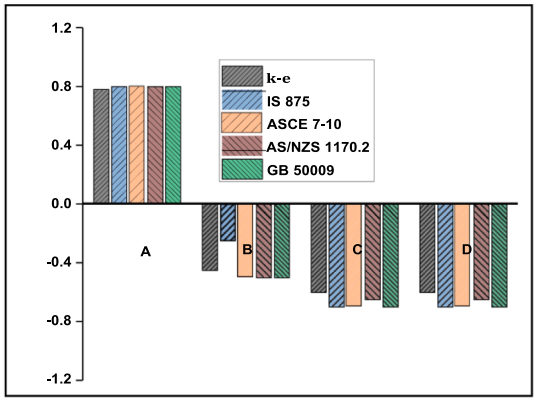

Fig. 6. Mean Cp for rectangular building model- A.

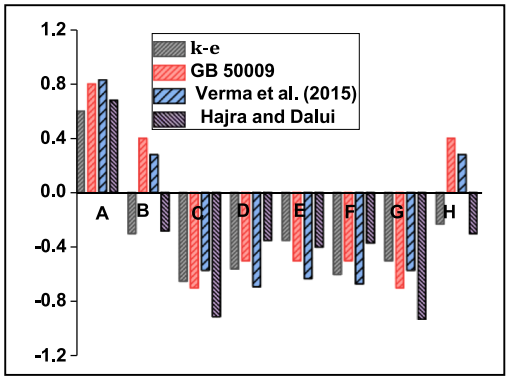

Fig. 7. Mean Cp for octagon building model-B.

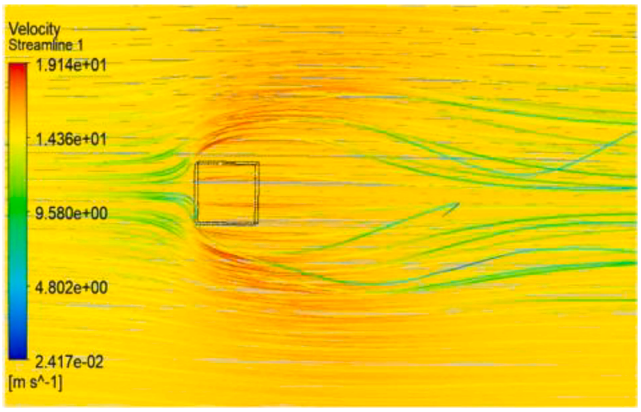

Fig. 8. Velocity streamline for rectangular model.

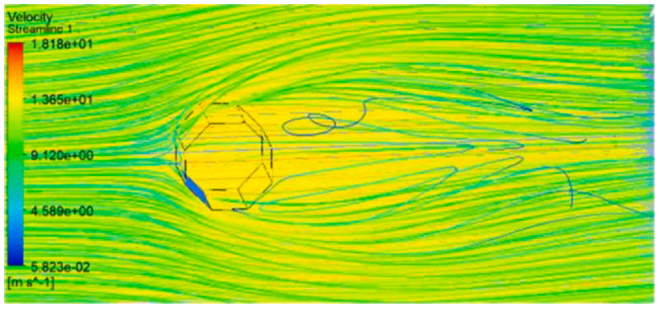

Fig. 9. Velocity streamline for rectangular model.

speed at the reference height. The results shown in fig. 5 for the present CFD study is well in agreement with the other established studies and thus the same setup has been implemented for the entire course of this study.

3. Result and discussion

3.1. Mean Cp for building model

Figures 6 and 7 compare the results of the different studies carried out on the rectangular and octagonal models respectively. The k-ε model proves to be validated when compared to the different codal provisions. However, the values of Cp of the windward and leeward faces of rectangular building differs from that of the octagonal building due to the shape and shielding effects.

3.2. Velocity stream lines

Figs. 8 and 9 depict the velocity stream line in plan shape for model A and model B respectively. The pattern represents the stream line and vortices are the main cause of creating the pressure and suction on the respective faces of the building model.

3.3. Pressure contours

The pressure contours presented below depict the distribution of pressure along the rectangular (i.e. Fig.10, faces A, B, C, D) and octagonal (i.e. Fig.11, faces A, B, C, D, E, F, G, H).

Higher pressure values are observed for the windward face of the rectangular building as compared to the octagonal. The pressure distribution is almost uniform for the side faces of both the building model considered in the study. However, a greater suction pressure is observed for the rectangular building in the leeward side due to its higher shielding in compression to the octagonal shape model.

4. Conclusion

Several conclusions can be drawn from the research that has been conducted to investigate the wind effects. These are based on the CFD analysis done on ANSYS CFx along with the comparisons with experimental data. Some conclusions based on the investigation on equal area building model are as following.

- Regular plan form buildings exhibit symmetrical pressure distributions between symmetrical faces of rectangular & octagonal buildings.
- Pressure contours on the front face of rectangular building shows high pressure oin comparison to the side faces of the building model. While the suction is observed in the lee ward side of the model.
- The octagonal shaped building showed concentration of pressure on the front face which is slightly increased with effect to the rectangular mode as wind effects are increased with the height of the building.
- The adjacent faces with respect to the wind ward face shows the higher magnitude to lower magnitude if moving along the downstream of wind but vertically it remained almost constant.
- Faces C & D represent slight negative pressure distribution on the adjoining edges to the faces. Faces G & F are in the less pressure as compared to other faces with slight increase with the height of the building in the case of the octagonal building model.
- In order to forecast wind-related events on buildings and other various types of structures, Computational Fluid Dynamics (CFD) may be used as a alternative method to visualization of wind effects.

Abstract. This study aims to demonstrate a Python- based model or Python scripts for static analysis of beams using force method for a set of beams with changing cross – sections categorized on the basis of types of beam structure and loading conditions. It aims to fill the gap of less research in the domain of static analysis of beams by formulating the beam analysis into an algorithm using the programming language, Python. The types of beam structures under consideration are cantilever, propped cantilever, simply supported, and fixed beam. And the loading conditions of point load and uniformly distributed load (UDL) are taken as per subject logic. The entire program has been prepared and verified by referring to standard books of Civil Engineering. Readers may run the provided Python script or code in any Python release for Windows and/or Pythonista. The research paper targets to simplify the concepts in this domain in a fast, an efficient, a user – friendly, and an accurate way. Fellow researchers working in a similar field of interest may utilize this paper as an aiding tool for their research and save their time and manual effort.

Keywords. Structural analysis; Various Type of Beams; Force Method; Python; Deflection.

INTRODUCTION

Civil engineering structures have a series of components like beams, columns, slabs, arches, etc. All these components are designed to take the load of the superstructure and distribute it through various suitable foundations to sub-soil. The structural components are designed and need to be checked for deflection and slope. This is a check. If these checks are made manually, the possibility of human error is increasing. That is why the development of data algorithms and PYTHON programming is used to obtain this deflection and slope. All the software which analyses the civil engineering structure mainly uses finite element techniques. Some researchers used ANSYS to find the response of the tall structure (N. Gaur, R. Raj, and P. K. Goyal, 2021), (A. Kumar and R. Raj, 2021), (N. Gaur and R. Raj, 2021), (R. K. Meena, R. Raj, and S. Anbukumar, 2021) and predicted the effect of wind to design the high rise projects. The response of the structure in terms of base shear and deflection is also obtained by various studies (R. K. MEENA, G. P. Awadhiya, A. P. Paswan, and H. K. Jayant), (R. Raj and A. K. Ahuja, 2013), (S. Mahajan, V. Yadav, R. Raj, and R. Raj), (R. Raj, A. Sharma, and S. Chauhan, 2018). The majority of the computational methods make use of the fundamentals of data algorithms (C. A. Shaffer and V. Tech, 2011), (A. Neubauer, J. Freudenberger, and V. Kühn, 2007), (Chapter 1 Pointers , Arrays , and Structures., 1996), (Shaw, 2017), (Johansson, 2018). Before the start of this study, a large amount of research was done, and the major outcomes are explained in various sections of this study. The computational method which is used to get the deflection and slope has a lower degree of variation. That is why the development of some data-programming techniques is required and this study presents the same. The basics of structural analysis are found and studied in detail (Karnovsky, 2012), (J. J. Connor and S. Faraji, 2013), (Hibbeler, 2012), (B. G. Nielson and J. C. Mccormac, 2017), (K. Derucher, C. Putcha, and U. Kim, 2013). The various sections of this study need the basics of various structural components, and the same is obtained from the different standards books. These various sections explain some major conclusions. Lee et al. (B. Koo Lee, J. F. Wilson, and S. Jin Oh, 1993) used the Runge-Kutta and Regula-Falsi methods to solve the elastica of cantilever beams with variable cross sections numerically and experimentally. Eci et al. (M. C. Ece, M. Aydogdu, and V. Taskin, 2007) explained vibration mechanics of anisotropic beam with a variable cross section were calculated numerically. Non-uniformity in the cross-sectional area influences the natural frequencies and the model shape. The amplitude of vibration is found to be increased if there is an increment in the cross section, while there will be a decrement in the amplitude of vibration if the cross-sectional area of the beam is reduced. Sapountzakis and Tsiatas (E. J. Sapountzakis and G. C. Tsiatas, 2007), (E. J. Sapountzakis and G. C. Tsiatas, 2005) studied the boundary element method for analysis of the elastic flexural

buckling of composite beams with variable cross sections. Rahman and Kowser (M. A. Rahman and M. A. Kowser, 2007) performed nonlinear analysis of cantilever shape memory alloy beams of variable cross sections and found that the reduction of more material can be done in the beam which has the unform strength and variable cross section. Karnovsky (Karnovsky, Theory of Arched Structures, 2012) explains the strength, stability, and vibration involved in the arched shape structures. Boiangiu et al. (M. Boiangiu, 2014) performed vibration analysis on numerous structures with uniform and variable cross sections, and verified the transfer matrix to calculate the natural frequencies involved in multi-step beams. Rojas and Ramirez (A. L. Rojas and J. M. Ramirez, 2014) developed a mathematical model that is subjected to uniformly distributed load, which has a variable cross section. Using this method, the moment and displacement at any cross section of the beam can be obtained mathematically. Dumitrache (Dumitrache, 2012) Shear stress in a beam with a variable cross section that is subjected to uniformly distributed load. Sapountzakis and Panagos (E. J. Sapountzakis and D. G. Panagos, 2008) presented the analogue equation method that is employed for the nonlinear analysis of beams with simple or multiple connected variable cross sections and found the shear deformations etc. The study findings are utilized to confirm the structure's integrity. As a result, structural analysis is an important element of structural engineering. All structures may be divided into two categories: statically determinate structures and statically indeterminate structures.

The force technique is a method for evaluating statically indeterminate structures using force values as fundamental variables. Establishing the displacement restrictions, also known as the geometric compatibility equations, is a crucial step. This approach involves creating a set of compatibility equations based on the number of redundant forces in the structure and concurrently solving these equations to estimate the size of the redundant forces. Once the redundant forces are identified, the structure becomes determinate and can be fully studied using equilibrium conditions.

As a result of various other qualitative secondary research performed, it is observed that stability analysis and vibration analysis are better interpreted using computer languages like Python, C, and C++ along with modeling software recently. This paper is another such piece of research primarily focusing on computerizing the static analysis of beams. The primary goal of this paper is to fill the research gap of less research in the domain of structural analysis by providing easy-to-use Python scripts for analyzing types of beams with changing cross-sections under various loading situations.

10 August 2023 06:53:53

METHODOLOGY

In general terms, statically determinate beams are those beams whose reaction forces may be determined using the equilibrium equations, in $\Sigma F_X = 0$, $\Sigma F_Y = 0$, $\Sigma F_Z = 0$ and $\Sigma M = 0$ forms. And indeterminate beams are those beams that require compatibility equations in addition to the equilibrium equations to determine all of their (unknown) force reactions.

Layout

The following flowchart demonstrates the categorization of beams into different cases based on types of beam structure (Cantilever, Propped cantilever, simply supported and fixed beam) and loading condition (Point load, mid – way to span length, UDL over the entire span length).

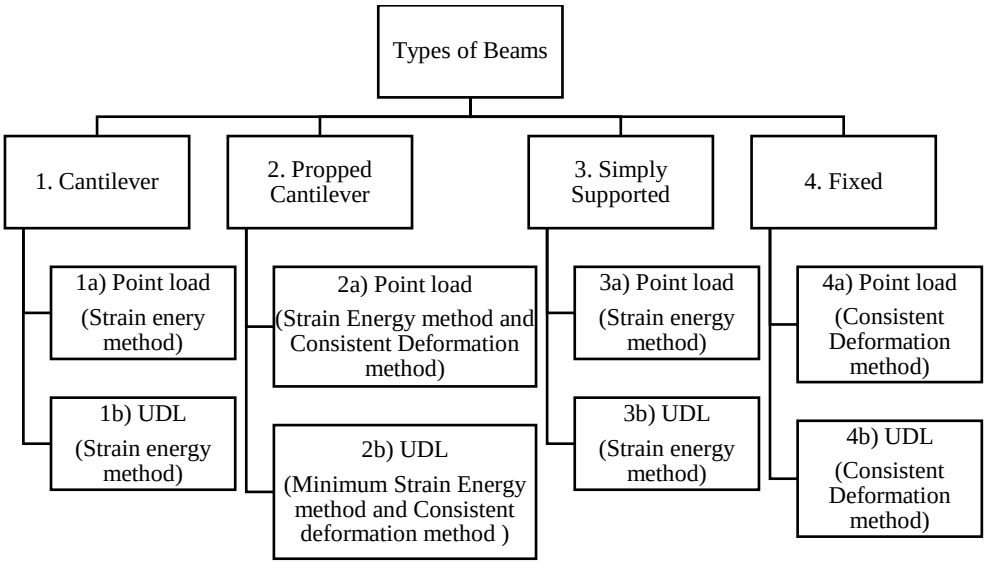

Fig 1. Flowchart depicting cases (types of beams with their loading conditions) & force method for analysis

In this paper, use of the Castigliano's theorem, Strain Energy method, and the Consistent Deformation method is done for the analysis of different beam cases.

Force Method for Analysis of Beams Used in Program Code

Castigliano's theorem

Castigliano's first theorem – For beams, trusses and frames, if the material is linearly elastic, supports are unyielding and temperature is constant, then the first partial derivative of total strain energy with respect to deflection or slope will give the load or moment at that point in the direction corresponding to that deflection component.

$$\frac{\partial U}{\partial \Delta} = P \tag{1}$$

$$\frac{\partial U}{\partial \theta} = M \tag{2}$$

Where U = strain energy, P = load, Δ = Deflection, M = Moment

Castigliano's second theorem – At constant temperature when the materials are linearly elastic and supports are unyielding, the first partial derivative of total strain energy with respect to load or moment will give the deflection or slope respectively. This theorem is also called the theorem of least work.

$$\frac{\partial U}{\partial P} = \Delta \tag{3}$$

$$\frac{\partial U}{\partial M} = \theta \tag{4}$$

10 August 2023 06:53:53

Strain energy method

When a gradual load is applied on an elastic body, the body is strained and work is done on the body which is stored in the form of internal energy. This internal work done by the body in resisting the straining is called strain energy. Mathematically, it may be expressed as –

(a) For axial load in a uniform body

$$\boldsymbol{U = \left(\frac{1}{2}\right) \times \Delta L \times P} \tag{5}$$

Which may be reduced to $U = \left(\frac{P^2.L}{2A.E}\right)$ and $U = \int \left(\frac{P^2}{2AE}\right).dx$ and is generally used in truss.

(b) For bending moment (generally used in frames)

$$\boldsymbol{U = \int \left(\frac{M_x^2}{2EI}\right).dx} \tag{6}$$

Where U = strain energy, P = Load, Δ = Deflection, AE = Axial rigidity, M = Moment

Minimum strain Energy method – If the strain energy in an elastic body is U and R_1, R_2 etc. are the redundant reactions, then if there are no support movements and no change in temperature, then the redundant reactions R_1, R_2 etc. must be such that the strain energy is minimum.

$$\boldsymbol{\frac{\partial U}{\partial Ri} \rightarrow 0} \tag{7}$$

Consistent deformation method

It is another force method used for analyzing structures using equilibrium and compatibility conditions to determine unknown in statically indeterminate structures. The basic steps are as follows.

1. Determine the degree of static indeterminacy.
2. Eliminate the redundant reaction and find out the displacement in its direction.
3. Eliminate the applied load and find out the displacement in its direction.
4. Obtain compatibility equation and solve for redundant reaction.

RESULTS AND DISCUSSION

Some of the above cases are verified as below. It is done by comparing manual calculations with the python model. Here, it is considered that the user first performs case 1b of Cantilever beam with UDL using Strain Energy Method. Next, before closing the program, the user also performs Case 4a. The input given by the user are as below.

Input

For case 1b – cantilever beam – UDL using strain energy method

User input
load magnitude (w) in N/mm : 1
length of beam (L) in mm : 5000
modulus of elasticity (E) of the material of beam in N/mm^2 : 200000
moment of inertia (I) of beam in mm^4 : 81960000

For case 4a – fixed beam – point load using consistent deformation method

User Input
load magnitude (P) in N : 100
length of beam (L) in mm : 20000
modulus of elasticity (E) of the material of beam in N/mm^2 : 199947.96
moment of inertia (I) of beam in mm^4 : 83246286

Output

On compiling and running the Python script or code, a part of the total output is represented below corresponding to the cases as inputted above. It must be noted that output screen will display the sub classification of beam conditions (sub – case a and b) in the form of diagram after selection of type of beam (case 1, 2, 3, 4) from which the user can make a choice. After which, the values for load, length of beam, modulus of elasticity, and moment of inertia will be asked to input. Once, the case analysis is completed, the user is given the option to either continue analyzing for same or different cases or exit the program from there. In the context of inputs given in the above section, the user will first analyze for case 1b and then continue for case 4a before exiting the program.

Case 1b

```
Enter uniformly distributed load (w) in N/mm : 1
Enter length of beam (L) in mm : 5000
Enter modulus of elasticity (E) of the material of beam in N/mm^2 : 200000
Enter moment of inertia (I) of beam in mm^4 : 81960000

The various methods of analysis available are :
1:-> Strain Energy Method

Please select the method of analysis : 1
You have selected Strain Energy Method.

STEP 01 : CALCULATING STRAIN ENERGY (u)

Strain energy in this case, represented by u, is given as = (W^2*L^4)/(8*E*I) = 0.004766044411908248 N-m

STEP 02 : FINDING DEFLECTION AT POINT 'B'

Deflection at point 'B' is given as = (5*W*L^4)/(48*E*I) = 0.003971703676590207 m
```

10 August 2023 06:53:53

Case 4a

Enter load magnitude (P) in N : 100
Enter length of beam (L) in mm : 20000
Enter modulus of elasticity (E) of the material of beam in N/mm^2 : 199947.96
Enter moment of inertia (I) of beam in mm^4 : 83246286

The various methods of analysis available are :
1:-> Consistent Deformation Method

Please select the method of analysis : 1
You have selected Consistent Deformation Theorem Method.

STEP 01: CALCULATING DEGREE OF STATIC INDETERMINACY (Ds)

Number of actual reactions, R = 4
Number of equations available, E = 2
Degree of Static Indeterminacy, Ds = R - E = 2

STEP 02: REMOVING REDUNDANT REACTIONS AND CALCULATING DISPLACEMENTS DUE TO LOADING

Let 'Ma' be the redundant reaction at A and 'Mb' be the redundant reaction at B.
Displacement at A due to applied loading, Theta(A1) = (P*L^2)/(16*E*I) = 0.0001501959300204788
Displacement at B due to applied loading, Theta(B1) = -(P*L^2)/(16*E*I) = -0.0001501959300204788 (Taking clockwise direction as negative)

STEP 03: REMOVING LOADING AND CALCULATING DISPLACEMENTS DUE TO REDUNDANT REACTIONS

Let 'Ma' be the redundant reaction at A and 'Mb' be the redundant reaction at B.

Displacement at A due to redundant reaction at A, Theta(A2) = -(Ma*L)/(3*E*I) = -0.00010013062001365254 (Taking clockwise direction as negative)
Displacement at B due to redundant reaction at A, Theta(B2) = (Ma*L)/(6*E*I) = 5.006531000682627e-05
Displacement at A due to redundant reaction at B, Theta(A3) = -(Mb*L)/(6*E*I) = -5.006531000682627e-05 (Taking clockwise direction as negative)
Displacement at B due to redundant reaction at B, Theta(B3) = (Mb*L)/(3*E*I) = 0.00010013062001365254

STEP 04: OBTAINING COMPATIBILITY EQUATION AND SOLVING FOR 'Ma' and 'Mb'

Approach:- To solve for redundant reactions, we need one more equation which can be obtained by compatability. It is quite evident that the displacement at the fixed supports A and B is zero.
Therefore, total displacement at A, Theta(A) = Theta(A1) + Theta(A2) + Theta(A3) = 0
Also, total displacement at B, Theta(B) = Theta(B1) + Theta(B2) + Theta(B3) = 0

Solving the above two equations, we get redundant reaction at A, Ma = (P*L)/8 = 250.0 N-m
Redundant reaction at B, Mb = (P*L)/8 = 250.0 N-m

Verification

Comparison of output with manual calculation using Table 1 for both cases were performed which are as discussed below.

For case 1b

Output got from the Python model on successful analysis of case 1.b is as below.

1. Strain Energy = 0.004766044411908248 N-m
2. Deflection at B = 0.003971703676590207 m

Manual Calculation (Using Table 1)
U = 0.0048 N-m
δ_B = 0.004 m

10 August 2023 06:53:53

Since, final result from program matches with the manual calculations as given in Table 1.
Hence, verified.
It is also observed that the result got from the Python model are much more accurate.

For case 4a

From the above code, the analysis results got were as below.

1. Moment at A = 250.0 N-m
2. Moment at B = 250.0 N-m

Manual Calculation
M_A = 250.00 N-m
M_B = 250.00 N-m

Since, final result from program matches with the calculations.
Hence, verified.

CONCLUSION

The following conclusions may be drawn from this paper:

- Proposed a significant practical model for static analysis of cantilever, propped cantilever, simply supported, and fixed beams having point loads and Uniformly Distributed load (UDL) for the inputted values of Young's modulus of elasticity, the moment of inertia, and loads.
- It was found that the outputs got from the proposed code were in good agreement with the manual calculations as discussed in the Verification section.
- Through this paper, an attempt has been made to foster the scope of structural engineering in the programming language - Python.
- Computer languages are all about implementing algorithms. And by breaking down the analysis of beams into multiple cases and laying the procedure for each case further in a stepwise approach, the analysis was formulated into an algorithm that made possible a task that is more organized, fast, and accurate by avoiding any human error.

10 August 2023 06:53:53

FUTURE SCOPE OF THE PAPER

The future scope of the paper is to apply these computational techniques to large sets of real measurements obtained via industry partner(s) or relating to university buildings. In future, this paper will be taken forward and will be made inclusive of more beam types and diverse loading conditions. We also envision to venture into analyzing different structural members in coming times.

Data Availability Statement

All data, models and code generated or used during the study appear in the submitted paper.

Funding Statement

Authors would like to express their sincere gratitude to Delhi Technological University, Delhi, India for providing funding to conduct the research work.

ACKNOWLEDGEMENT

Authors would like to convey the exceptional thanks and appreciation to our Institute DTU, Delhi for providing resources, and **Dr. Manvendra Verma** encouraged the authors to submit the paper within the allowable time and provided his valuable comments to finalize this paper.

Exploring the Efficacy of Deep Learning Models for Multiclass Toxic Comment Classification in Social Media Using Natural Language Processing

Prashant Giridhar Shambharkar, Hastej Singh, Harshit Raj Raghav and Hilansh Verma

Department of Computer Engineering Delhi Technological University Delhi, India

E-mail : prashant.shambharkar@dtu.ac.in hastejsingh694@gmail.com harshitrajraghav@gmail.com hilansh001@gmail.com

Abstract- Our thesis focuses on developing a deep learning-based toxic comment classifier. The classifier will be used to find and report potentially unpleasant or hazardous information on websites like social media, discussion boards, and comment sections. We want to encourage a welcoming and safe online community and stop the growth of online abuse such as cyberbullying and hate speech. Long Short-Term Memory (LSTM) and Hybrid LSTM-CNN (Convolutional Neural Network and LSTM based Approach) are two algorithms that the classifier uses to categorize the comments depending on their level of toxicity, such as threats, obscenity, insults, and identity-based hatred. The classifier's input data came from Kaggle and underwent a number of pre-processing processes, including lemmatization and normalizing the text data.

Keywords- CNN, LSTM, LSTM-CNN, NLP, Toxic Comment.

I.INTRODUCTION

The rise of social media and online communication has provided an unprecedented level of connectivity for individuals around the world. However, with this increase in communication comes the challenge of dealing with the negative aspects of online discourse, including cyberbullying, hate speech, and other forms of toxic comments. Toxic comment categorization, the process of identifying and highlighting potentially harmful or objectionable content, has become an increasingly important tool for online platforms to promote a secure and welcoming environment for users.

Toxic comments can take many forms, including explicit language, threats, insults, and hate speech targeted at specific individuals or groups. The propagation of these types of comments can create an environment that is challenging for people to express themselves or engage in healthy dialogue online. Furthermore, online platforms have a responsibility to protect their users from abusive behavior and harassment and may even face liability for failing to take action.

To address these challenges, we present a deep learning-based approach for toxic comment classification. Our approach employs two distinct techniques, LSTM and LSTM-CNN, to identify and categorize toxic comments according to their type of toxicity. Specifically, we focus on four categories of toxicity: toxic, severe toxic, obscene, threats, insults, and identity hate speech based on an individual's identification.

The goal of this research is to contribute to the development of effective toxic comment categorization systems that can be used by online platforms to promote a safer and more welcoming online environment. Our approach builds on existing research in deep learning and natural language processing and provides a framework for the development of more sophisticated and accurate toxic comment classifiers.

The rest of the paper arranged as follows: Section 2 discuss Related work; Section 3 preliminary related to the algorithms employed in the dataset; Section 4 presents the methodology; Section 5 concludes the paper.

II.RELATED WORK

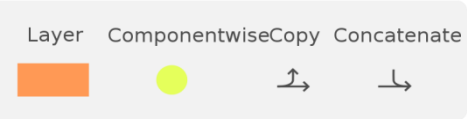
Classifying toxic comments is a significant problem belonging to natural language processing (NLP) realm that has got much recognition in past few years. Various types of Machine learning models such as convolutional neural networks (CNNs) and

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:25:02 UTC from IEEE Xplore. Restrictions apply.

recurrent neural networks (RNNs), have given promising outcome in this area. Here, we review some of the most relevant works in the field.

One of the earliest works on using RNNs for toxic comment classification was by Zhang et al. (2018)[1], who proposed a bi-directional LSTM model with attention mechanisms. Their model was able to give promising performance on the Wikipedia Toxicity dataset. A similar approach was taken by Chen et al. (2019)[2], who proposed a bi-directional RNN with a self-attention mechanism.

More recently, several works have proposed hybrid models that combine RNNs and CNNs to leverage the strengths of both architectures. Another approach to toxic comment classification involves the use of transfer learning. Devlin et al. (2019)[3] proposed the BERT model, which uses a transformer architecture to perform contextualized word embeddings. The authors showed that their model achieved the current highest level of performance or technology in a particular field or domain. Similarly, Sun et al. (2020)[4] fine-tuned BERT on a large-scale dataset of toxic comments and achieved state-of-the-art performance on several benchmark datasets.



Other researchers have explored various approaches for toxic comment classification. Qian et al. (2020)[5] proposed a hierarchical model that uses both character-level and word-level embedding to classify toxic comments. The authors demonstrated that their model outperformed existing models on multiple standard datasets, establishing a new current highest level of performance or technology in a particular field or domain. Zhang et al. (2021)[6] proposed a multi-task learning approach that jointly learns to classify toxic comments and identify the users who posted them.

Several works have also focused on exploring different aspects of the problem, like identifying offensive language and expression of hatred. Davidson et al. (2017) [7] proposed a dataset and a set of classification models to detect hate speech on social media. Waseem and Hovy (2016) [8] proposed a dataset and a set of classification models to detect offensive language on Twitter.

In summary, the field of toxic comment classification using deep learning models is quickly evolving, with new emerging techniques and datasets being continuously developed and tested all the time. The works reviewed here represent some of the most relevant and promising approaches in the field.

III. PRELIMINARIES

The models that we have used in our paper are listed as following:

A. LTSM

LSTM, or Long Short-Term Memory, is a part of the Recurrent Neural Networks (RNNs), and is particularly adept at identifying long-term dependencies within sequential data. It was created to get around the difficulties regular RNNs have with memorizing data over lengthy sequences.

An LSTM network features a memory cell that can store data and regulate the movement of data across the network. Gates in the network also control how information enters and exits memory cells. As a result, LSTMs can remember important information while forgetting less critical information.

Natural language processing, speech recognition, and even stock market prediction are just a few of the uses for LSTMs. For processing sequential data, where the sequence of the data points is essential, they have had great success. Also, LSTMs are perfect for situations where both forms of information are crucial since they can handle both short-term and long-term dependencies.

Overall, LSTMs have been widely used in numerous industries and have shown to be a successful method for processing of sequential data.

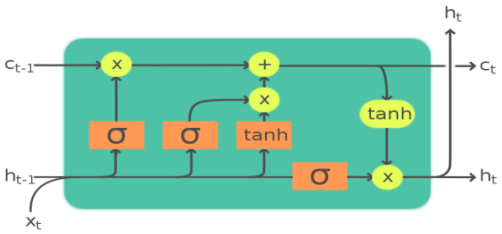


Fig. 1 Long Short Term Memory[14]

B. LSTM-CNN

Two popular Deep Learning Architectures Long

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:25:02 UTC from IEEE Xplore. Restrictions apply.

Short-Term Memory (LSTM) and Convolutional Neural Network (CNN) are combined to form LSTM-CNN (CNN). This model provides the benefits of CNNs and LSTMs to solve certain problems with sequence data.

While processing sequential data, LSTMs perform well since the sequence of the data points matters. Long-term dependencies may be remembered by them, but they have trouble digesting a lot of information.

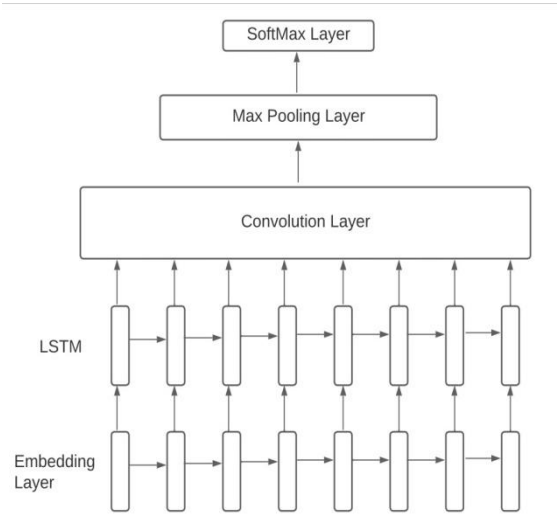

Fig. 2 LSTM-CNN Hybrid Model

On the other hand, CNNs can extract features from unprocessed input and are built to analyze enormous volumes of data. They have trouble with sequences, though, because they don't take the order of the data points into account[15].

Combining these advantages, the LSTM-CNN model processes sequential data with LSTMs and using CNNs for feature extraction from unprocessed data. From the input data, the CNNs extract useful characteristics and send them to the LSTM layers for processing. To create predictions, the LSTM layers combine the sequential data with the features from the CNNs.

For applications including sentiment analysis, picture captioning, and language translation, LSTM-CNN models are used. They have shown to be efficient in managing enormous volumes of data while taking the order of the data points into account.

IV. Proposed Methodology and Result Discussion

The training and test sets were included in the data that was taken from Kaggle and utilized to build the categorization model. The entire process is outlined in the workflow that follows, which goes from Model Assessment through Data Pre-Processing.

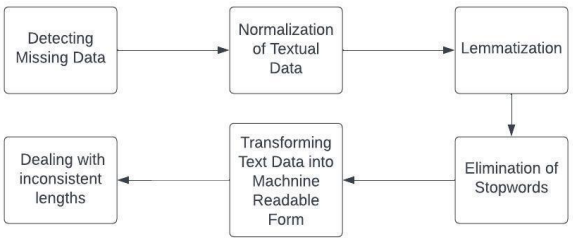

Fig. 3 Data pre-processing and exploration flowchart

C. Data Pre-processing and Exploration

1. *Step 1: Detecting Missing Data.*

The training and test data were initially imported into a pandas dataframe. We needed to make sure there were no missing numbers in the data before moving on. There were no records with missing data when we used the "isnull" function on the set of data that is used for training and testing reasons. Afterward, we continued with the next stage of our project.

2. *Step 2: Normalization of Textual Data.*

We started with the data pre-processing stage after making sure the data was clear of any missing values. As comments from internet forums frequently contain inconsistent grammar, unusual characters, and digits that represent letters, the first step was to normalize the text data. We used Regex to correct these discrepancies.

We used jupyter notebooks to carry out these tasks. We started by compiling a list of popular swear words that are often used on social networking sites or online forums. Then, we created a function that executes all of the previous procedures and produces accurate data. Both the training and test datasets underwent these stages.

The following is a list of the text normalization steps we carried out:

TABLE 1 STEPS FOR NORMALIZATION

Normalization Steps:
a) Deleting characters within text.
b) Deleting duplicate characters.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:25:02 UTC from IEEE Xplore. Restrictions apply.

c) Conversion of all the data to lowercase.
d) Dropping punctuation symbols.
e) Removing extra white spaces between words.
f) Eliminating the "\n" character.
g) Deleting non-English characters.

3. *Step 3: Lemmatization.*

Lemmatization procedure is started after the cleaning and normalizing the text data. Lemmatization is combining the various variations of a word so that the machine learning algorithm can consider them as a single object. This decreases the dimensionality of the data and lowers the count of distinct words in the data. We used the "WordNetLemmatizer" from the "nltk" library to do lemmatization and made the function "lemma" to carry out the operation. To get lemmatized data, this function was used to the cleaned data acquired in Step 2.

4. *Step 4: Elimination of Stopwords.*

Eliminating stopwords is a critical step in text classification tasks because it concentrates attention on words that determine the text's meaning

(a) The "spacy" package was used to remove stopwords from our data. A list of typical stopwords included in the library named "STOP WORDS" may be used to eliminate stopwords from any text.

(b) Despite the spacy library's comprehensive list,We chose to search for stopwords that were specific to our dataset.

(c) To start, we expanded the list of stopwords by including single- and double-letter words. We discovered instances of single-letter or two-letter words in our dataset when evaluating random remarks, such as Wow what a gorgeous cushion, or He is such a cheerful man, bb. We included these single-letter or two-letter words in our list of stopwords.to make sure they don't affect how well our deep learning model performs. However, we made sure to leave out from the list of stopwords letters like "I" and "a" as well as words like "me," "am," and "as."

(d) Following the completion of this work, we looked for terms in our dataset that may be stopwords (based on their high frequency in the dataset and limited contribution to the classification task). To do this, we wrote a code snippet that enabled us to locate stopwords in our dataset that met these requirements. In order to generate our final stopwords list, we finally added these newly found stopwords to the spacy "STOP WORDS" list.

(e) We removed stopwords from both our training and test sets of data using our final stopwords list, producing a clean dataset free of errors.

5. *Step 5: Transforming Text Data into Machine Readable Form*

It is widely known that, regardless of the nature of the problem, Models utilizing both conventional machine learning techniques and deep learning methodologies handle numerical data. And therefore, in order to train and create a deep learning model which utilizes text inputs that are free of any errors or inconsistencies, it needs to be converted into a language that computers can understand. To do this, the following actions are required:

Tokenization: The text is broken up into separate words, thus "I love cats and love dogs" becomes ["We", "like", "lions", "and," "tigers"].

Indexing - Words are arranged in a manner similar to a dictionary and given an index, such as {1: "We", 2: "like", 3: "lions", 4: "and", 5: "tigers"}.

Index Representation - The order of the text's words may be represented as an index, which then can be employed to train a Deep Learning model. Examples [1, 2, 3, 4, 2, 5].

The "Tokenizer" class from the "Keras" library makes it easy to perform these actions. This technique can convert each text into a set of integers, where each different integer corresponds to the index of a token present in a dictionary, or into a vector where each token can be represented by a binary coefficient based on tf-idf or word count. This class is useful for converting text data into a vectorized format.

6. *Step 6: Dealing with inconsistent lengths*

We address the issue of inconsistent lengths of sequences in our text data by using padding. The lengths of comments Statements that are present on social media or online discussion platforms can vary greatly, from one-word responses to detailed elaborations. These varying length sentences are transformed into sequences of varying length vectors and cannot be input into deep learning models. To resolve this issue, padding is used to make the shorter sequences equal in length to the longer ones. In this case, the sentence length was established at 200 words with post-padding by utilizing the "pad_sequences" function from the Keras library. The padding procedure included adding zeros to the end of shorter sequence vectors. The subsequent step involves creating deep learning models.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:25:02 UTC from IEEE Xplore. Restrictions apply.

D. Construction and Evaluation of the Models

1. *Step 1: Segregate the Data into Training and Testing subsets.*

Once the feature Engineering and data pre-processing tasks are completed, we can move on to constructing and assessing our model. Before training a deep learning model on the training data, it is advisable to segregate the dataset into two sub-segments: a training subset and a testing subset, with the latter accounting for 20% of the complete training data.

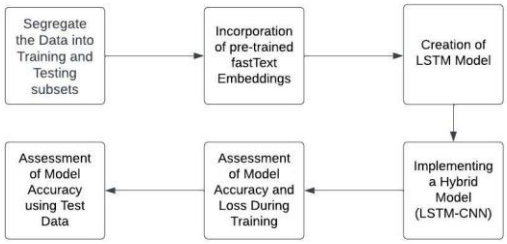

Fig. 4 Construction and Evaluation of the Models

2. *Step 2: Incorporation of pre-trained fastText Embeddings.*

In accordance with the previously stated objective, we aim to utilize the power of Transfer Learning by incorporating pre-trained word embedding from fastText. To achieve this, we import the fastText embedding into our workspace and construct an embedding matrix by mapping the vocabulary of our dataset to the pre-trained embedding. This is done by iterating over the words in our vocabulary and looking up their corresponding embedding in the pre-trained embedding. If some word in our vocabulary does not have a corresponding embedding in the pre-trained embedding, we can either randomly initialize its embedding or assign it a special out-of-vocabulary (OOV) token.

3. *Step 3: Creation of LSTM Model.*

With the train-set and train-set ready, it's time to choose a deep learning model for training. For a Natural Language Processing project like this one, the Long Short-Term Memory (LSTM) model is deemed ideal. LSTMs are similar to Recurrent Neural Networks (RNNs), However, they differ in one significant aspect - their hidden layer updates are substituted with memory cells, making them superior in detecting and revealing long-term relationships in data, which is critical for sentence structures.

```

Fig. 5 Model summary of LTSM Model

- To aid in hyperparameter tuning and model evaluation, the Talos library was imported. Using the "Scan" function, a GridSearchCV was carried out, resulting in the determination of the best parameters for achieving the highest accuracy.
- Afterwards, the LSTM model was configured with the best hyperparameters and required number of layers. Then the model was then compiled and trained utilizing both the testing and training set.

4. *Step 4: Implementing a Hybrid Model (LSTM-CNN).*

LSTMs in deep learning models are proficient in maintaining the features of historical information in extended sequences of text, while CNNs excel at extracting local features from the text. By integrating these two conventional neural network architectures, we can take advantage of their collective abilities. Consequently, we adopted the LSTM-CNN hybrid model to measure its performance compared to any other deep-learning models and identify the most effective one for our project.

Fig. 6 Model summary of LTSM-CNN Model

Just like in the previous step, we utilized the "Talos" library to determine the optimal hyperparameters for the hybrid model. This Python library enables efficient exploration of hyper parameter space via randomized hyper parameter optimization. After completion of the hyper parameter optimization process, we analyzed the outcomes and picked the hyper parameters that resulted in the optimal performance metric on the testing set. This required evaluating the results of each hyper parameter combination and selecting the one that provided the highest accuracy. Subsequently, we trained the hybrid model on the complete training set utilizing this set of hyper parameters.

Finally, we trained the hybrid model using the testing and training sets. This involved providing the model with the preprocessed input data, the embedding matrix, and the hyper parameters obtained from Talos. The model was trained via backpropagation to minimize the loss function, this process entails computation of the gradients of the loss function with respect to the model parameters and using these gradients to adjust the parameters in the direction that decreases the loss.

When training the model using the training subset and testing it with the test set, it helps ensure that the model isn't overfitting to the training data and can generalize well to new, not previously seen data. Once the model has been trained, we move to the next step of assessment of calculating the accuracy of the model and loss during the training process.

5. *Step 5: Assessment of Model Accuracy and Loss During Training.*

Now that both of our deep-learning models have completed their training, it's important to utilize a visualization technique to demonstrate the accuracy and loss values of the models throughout their training phase. Normally, during the training process, the accuracy of a deep-learning model should rise as its loss value falls with the increase in the total count of epochs. The model quality and the success of its training can be effectively evaluated through this approach. We can observe the trends in accuracy and loss values for each epoch in the accompanying images.

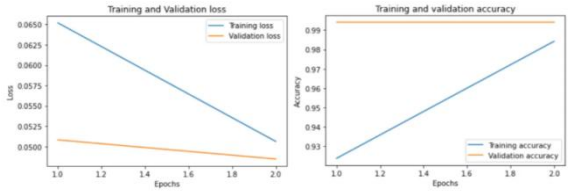

Fig. 7 For 2 epochs the LSTM model's Accuracy and Loss values.

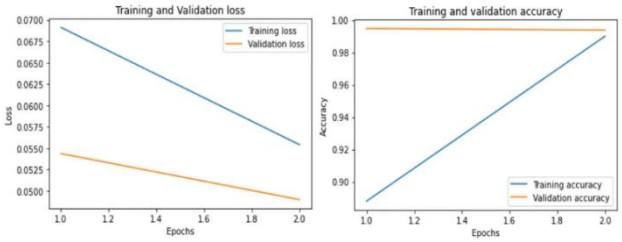

Fig. 8 For 2 epochs the LSTM-CNN model's Accuracy and Loss values.

6. *Step 6: Assessment of Model Accuracy using Test Data*

Having received encouraging results from the accuracy and loss evaluations, we can now proceed to gauge the quality of our deep learning models by testing them against the test data. This test data was procured from Kaggle and Similar data pre-processing and feature engineering steps were employed for both of the test and training data sets. With the now available processed test data, we can use the "predict" function to create the outputs for the inputs given from the test data.

In paper, Z. Zhai. (2022) [19] proposes a BERT-based deep learning method for rating the severity of toxic comments in online social media. The proposed method uses BERT-based backbones (RoBERTa and DeBERTa) and the Jigsaw dataset is used for training. The paper demonstrates the

effectiveness of using deep learning and BERT-based models for identifying and rating toxic comments. Our method gives a better accuracy than the BERT based models proposed in the paper.Comparison of the accuracy of our proposed models with the ones presented in this paper can be shown as following:

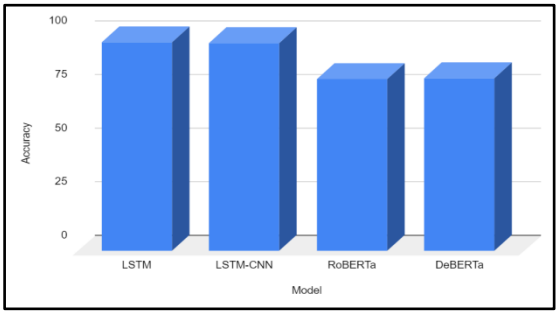

Fig. 9 Graphical representation of Model-Accuracy

TABLE 2 MODEL RESULTS

Model Accuracy				
Year	*Author*	*Model Name*	*Accuracy*	*Remarks*
2022	ZiyuZhai	RoBERTa	80.43	BERT is a pre-trained was designed primarily for transfer learning and fine-tuning specific tasks
		DeBERTa	80.56	
2023	Our proposed model	LTSM	97.40	LSTM performs better for sequential data and capturing long-term dependencies.

VI. CONCLUSION

In this paper, two approaches have been developed i.e. LSTM and hybrid LSTM-CNN models. After analyzing the accuracy achieved by the two different models, it can be declared that the conventional LSTM model surpasses the hybrid model. The LSTM model achieves the accuracy score of 97.40% while the LSTM-CNN model achieves the accuracy score of 97.07%. The traditional LSTM model appears to be the most appropriate choice for the Toxic Comment Classification task, given that the hybrid model's performance is only slightly lower than that of the traditional deep-learning model.

Future work could involve exploring multimodality and other types of hybrid deep learning models. Additionally, improving the data preprocessing techniques and exploring the use of additional features or different data augmentation techniques may further enhance the model's performance.

Abstract In today's world, plastic pollution has become a big environmental concern. As a result, smaller plastic pieces, also known as microplastics (MPs), have received a lot of attention in recent years. The majority of study has focused on microplastic pollution in aquatic ecosystems and related shorelines. However, influence of microplastics (MPs) in the soil environment and on agroecosystem is minimal. To investigate the problem, this study is aimed to observe the effects of MPs in soil using *Brassica juncea* as a model plant. Because of its high biomass capacity, *Brassica juncea* can store considerable level of contaminants in its tissues. As a result, *B. juncea* was subjected to two microplastics, HDPE_MPs and HDPE_beads, followed by analysis of biometrical parameters, physio-biochemical features, and morphological analyses. Plants subjected to 20 g beads had the lowest concentrations of phenolic content, chlorophyll content, and proline content compared to other treated samples. Furthermore, fluorescence and confocal microscopy demonstrated the transfer of microplastics throughout plant roots and leaves, showing their potential for plant injury. To the best of our knowledge, this study focuses on the transfer of MPs from root to leaves of *Brassica juncea* for the first time. A method for microplastic uptake from plant roots to leaves has also been postulated. It merits further examination in future studies and provides new insight into the phytoaccumulation of MPs in soil.

Keywords Agroecosystem · Biometrical parameters · Microscopy · Physio-biochemical features · Phytoaccumulation

1 Introduction

The accumulation of emerging contaminants (ECs) in agricultural ecosystems is one of the main concern in environment in today's scenario (Taheran et al., 2018). The behavior, fate and ecological impacts of ECs has led to inadequate management and loss of biodiversity (Lodeiro et al., 2019). Plastic materials with small particle sizes, such as microplastics (MPs) (plastics with size < 1000 μm) and nanoplastics (NPs) (with particle size less than 1 μm), are of particular interest because of ecotoxicity and health hazards (Bermúdez & Swarzenski, 2021). Despite occurrence of microplastics by degradation, they are

also incorporated as specific constituents in many products used in daily life. These microplastics bioaccumulate within the soil and have adverse effect on plant growth and development (Xu et al., 2020). For this reason, concern on impact of microplastics on plant performance, along with soil microbes and activity in soil has been the study for research (de Souza Machado et al., 2019; Ng et al., 2018).

Many recent studies have focused on understanding the impacts of various contaminants in soil and plants. For example, the leaves of *Prunus laurocerasus* L. obtained from diverse climatic habitats showed change in morphological characteristics due to different environmental conditions (YÏğit et al., 2018). Another study observed distinguished characteristics in various plant species exposed to magnesium, a major macronutrient for plants. Traffic density determined variations in magnesium concentrations in leaves of *Ficus bengalensis*, *Ziziphus mauritiana*, *Conocarpus erectus*, and *Azadirechta indica* species (Çetïn & Jawed, 2021). Accumulation of traffic-related heavy metals like aluminium, cadmium, iron, manganese, nickel, lead, and zinc in plants could be determined by using *Rosmarinus officinalis* L. (rosemary) as a model plant. This plant was mostly used in slopes and refuge along highway junctions and could act as a great tool for establishing traffic-related pollution in urban parts (Bozdogan Sert et al., 2019). Concentrations of heavy metals in soil can also increase on being accumulated with other contaminants like microplastics. For example, the uptake and inhibitory effects of cadmium on maize plants could be observed on being treated with HDPE microplastics. Different doses of microplastics induced phytotoxicity, change cadmium bioavailability and plant performance (Wang et al., 2020). Besides metal and other contaminant pollution in soil, microplastics could also have direct impacts on agroecosystem. For example, plastic mulch film significantly impact wheat growth, bacterial ecology and volatiles in the rhizosphere (Qi et al., 2020). Polylactic acid (PLA) microplastics severely decreased seedling height and prevented seed germination (Boots et al., 2019). In addition to plastic mulch film, scientists discovered that polystyrene-beads had effects on growth of plants on the basis of size, concentration, and that diameter may be a primary factor in determining whether micro/nanoplastics may permeate the tissues of plants. Regarding 100 nm polystyrene-beads, in addition to increasing wheat biomass (Lian et al., 2020), they might concentrate in the roots of *Vicia faba* and obstruct cell wall pores, which would impede delivery of plant nutrients (Jiang et al., 2019). According to a study, 10 mg kg^{-1} polystyrene-beads might shorten roots, whereas 100 nm enhanced seedling height (Ren et al., 2021). These findings demonstrated the buildup and movement of microplastics in the soil–plant system, highlighting the potential for microplastics to reach the food chain (Su et al., 2019). According to Dissanayake et al. (2022), applying agricultural sewage sludge alone leads to a large proportion of plastic residues into agricultural soils. Its input is predicted to be between 63,000 and 430,000 tonnes of microplastics per year in EU and North American farmlands, and between 2800 and 19,000 tonnes per year in Australian agroecosystems (Dissanayake et al., 2022). As per the study by Tun et al. (2022), 1411 pieces/kg of MPs were found in the Indian dumping soils which is just second to the highest pollution reported in Cambodia (Tun et al., 2022). Most of the microplastics that act as dominant polymers in soil include polyethylene, polyethylene terephthalate and polypropylene.

The major aim of present study is understanding uptake, accumulation, and translocation of high-density polyethylene (HDPE) microplastics along with their adverse effects on terrestrial plant. HDPE constitutes a large proportion of environmental pollution among all the microplastics (Awasthi et al., 2017). To facilitate this mechanism, *Brassica juncea*, commonly termed as Indian Mustard, was used as a model plant to assess sites of absorption, uptake, and accumulation within the plant. *Brassica juncea* is particularly useful for phytoremediation as it can accumulate high levels of heavy metals (lead, nickel, cadmium, mercury and selenium) in their tissues, a process called as phytoextraction (Rathore et al., 2019). *Brassica juncea* produce compounds called glucosinolates, which are broken down by enzymes to release toxic isothiocyanates. These isothiocyanates form complexes with heavy metals in the soil, where they are then absorbed by plant roots and stored in their tissues. This means they can quickly establish themselves in contaminated soil and start removing pollutants (Diwan et al., 2008). *Brassica juncea* has a high biomass, which means it can accumulate huge quantities of pollutants in tissues (Goswami & Das, 2015). Also, *Brassica juncea* has a deep root system that allows them to access pollutants that may

be located deep in soil. Overall, the combination of these characteristics makes *Brassica juncea* an effective plant for phytoremediation of soil. Therefore, it is considered as the most ideal plant to study potential for microplastics remediation in soil. To our knowledge, this study is the first to observe impacts of microplastics not only on roots, but also on leaves and shoots of plants. Biochemical analysis on roots, shoots and leaves has been demonstrated to provide further evidence of microplastics intake in plants. Finally, mechanism of uptake of microplastics by plants highlighting different pathways is briefed to observe phytoaccumulation and identify the possibilities for soil remediation of microplastics. Therefore, current study builds on examining the impacts of two different kinds of high-density polyethylene (HDPE) microplastics, namely HDPE_MPs and HDPE_beads, on *Brassica juncea*. To study the impact and accumulation of HDPE_MPs and HDPE_beads on the plant, biometrical parameters such as height and biomass was observed. Additionally, the amount of chlorophyll in leaves was used to determine the photosynthetic pigment. By analyzing the phenolic and proline concentrations in various plant sections, biochemical composition was estimated. An examination of the plant's morphology using fluorescence and confocal microscopy was done to see where microplastics were being absorbed. Finally, the mechanism of accumulation of MPs within plant roots and its translocation to aerial parts was highlighted to further our understanding of MPs impact in plants and soil.

2 Material And Methods

2.1 Experimental Design

2.1.1 Soil

To study impacts of different size microplastics on *Brassica juncea* (mustard seeds) in an open environment, a triplicate study was conducted. Pots containing equal concentrations of soil and mustard seeds with varying amounts of microplastics was used for the study. We harvested the mustard seeds after a week to determine the effects of our experiments on vegetative and reproductive growth. The sandy soil used in this study was obtained from an agricultural land in Ghaziabad, Uttar Pradesh, India, at 28° 39′ 14.1588" N and 77° 26′ 42.8784" E. The soil was composed of sand, silt, and clay with moderate amounts of organic matter. The air-dried soil was sieved with a 2 mm steel sieve before use.

2.1.2 Synthesis of Microplastics

In this experiment, two forms of microplastics were used: (1) high-density polyethylene (HDPE) microplastics and (2) high-density polyethylene (HDPE) beads. A method described by Crespy and Landfester, 2007, was used to prepare the HDPE microplastics (HDPE_MPs) and beads (HDPE_beads). A solution composed of 1 g of HDPE powder and 20 ml of xylene was mixed using a magnetic stirrer for 1 h until completely dissolved. The HDPE solution was then gently added to 100 ml of deionized water while maintaining the sonication at 70% amplitude (Branson W450 Digital sonicator, tip size 6.5 mm) for 30 s under ice cooling. The resulting solution was centrifuged, rinsed with water and ethanol, then air-dried before storage.

2.1.3 Mustard Seeds and Pots

Brassica juncea (mustard seeds) were obtained from Indian Institute of Agricultural Research (IARI), Pusa, New Delhi. The seeds were surface sterilized with 0.02% sodium hypochlorite (NaOCl) before immersion in 70% ethanol (Fig. 1: (A) *Brassica juncea* (mustard seeds) and (B) Germination done in complete dark). After sterilization, the seeds were rinsed several times with distilled water. The seeds were grown on tissue overnight before being planted in organic soil in November 2021. Pots were irrigated twice a week at first, then once every two days during seedling emergence in January and February of 2022. Because of the increase in temperature in February, the frequency of irrigation was increased. NPK was applied to the soil in each pot based on the mustard NPK requirement of 100, 20, and 60 kg/ha.

The pot used in the experiment was 20 cm long, 10 cm in diameter at the bottom, 13 cm in diameter at the top and had a volume of 2 l. We used a factorial experimental design. Furthermore, three control treatments with no microplastic residues were investigated. The experiment included 12 treatments performed in triplicate, as well as four independent pots containing tagged microplastics for imaging.

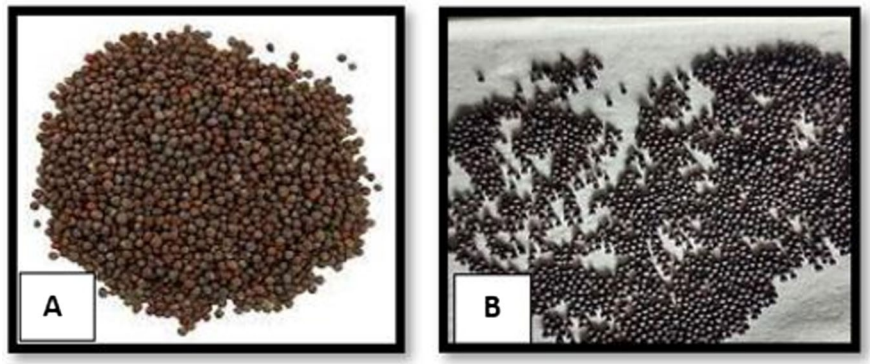

Fig. 1 (**A**) Brassica juncea (Mustard seeds) and (**B**) Germination done in complete dark

Each treatment was replicated three times, and total 36 pots of *B. juncea* seeds were grown. The mean of three potted plants was used to describe the study's findings.

2.2 Experimental Set-up and Climatic Conditions for Growth of Plant

2.2.1 Setting Up

Each pot constituted 2.5 kg of sieved soil and various concentrations of microplastics (except the three control treatments without microplastics) along with 150 ml of water. Prior to filling each pot with this mixture, a piece of geotextile was placed at the bottom of each pot to allow free circulation of air and water. After all the pots were filled, the soil moisture was uniformly set to 15%, which corresponds to the water capacity of the soil in the field. Before sowing *Brassica juncea* (mustard seeds), let sit for a week in each pot. Each container contained 12 g of litter (12.08 ± 0.06 g) and was sprayed with water to keep the litter moist.

2.2.2 Mustard Cultivation

Each pot contained 10–12 seeds, and post 2 weeks, 6–7 seedlings were selected from each pot for testing. The temperature was set at 15–16 °C during the day and 12 °C at night, with a photoperiod (14/10 h), a light intensity of 300 µmol m^{-2} s^{-1} and a relative humidity of 70% for day and night. The pots were watered weekly with tap water and soil moisture was adjusted to between 12 and 18% by weight. Pots were randomly placed in the climatic chamber and rotated each after two weeks.

2.2.3 Microplastic Tagging with Nile Red

For imaging, HDPE microplastic particles were labeled with Nile red as previously described (Karakolis et al., 2019). The dried microplastic particles were placed in an aqueous deionized (DI) solution of 100 µg/ml Nile red at a concentration of 50 mg of plastic particles per 10 ml of solution. This solution was prepared by dissolving 1 mg of Nile Red in 1 ml of acetone and the resulting solution was added to 10 ml of deionized water. The vials were left in the dark for two hours, rinsed three times with water, centrifuged and stored in deionized water for later use. Based on known staining procedures for microplastics, the Nile Red staining procedure was selected, including concentration of the Nile Red solution (Maes et al., 2017).

2.3 Measurements of Growth Parameters

2.3.1 Biometrical Analysis

Plant heights were measured using a steel tape measure on a regular basis from the 14th day after seeds were sown until the 90th day. Three months after planting, plants were divided into shoots and roots. Biometrical analysis provides the overall growth, biomass, and length of roots, shoots and leaves of plants after being exposed to different concentrations of a contaminant (Pricinotto et al., 2019). In this study, different concentrations of MPs were used as contaminant to observe the growth pattern in plants. At a span of three months from sowing of seeds, root and shoot height was measured and a mean of all three triplicates were used to determine the results of study. Similarly, root and shoot biomass was weighed

for each treated sample to determine mean difference with respect to control.

2.3.2 Chlorophyll Content

To determine photosynthetic pigment in leaves of plant, chlorophyll estimation was done. Relative chlorophyll content in plant leaves was measured and recorded as per the process defined by (Hong et al., 2012) using UV–Vis spectrophotometer (Biospectrophotometer, USA). Fresh leaves were obtained from each pot to determine the chlorophyll level. For each treated and control sample, 0.5 g of leaves were weighed from each pot. 10 ml of 80% acetone was added to chopped and homogenized leaves to make them transparent. The extract was centrifuged at 2500 rpm for five minutes. The resulting supernatant was diluted with 9 ml of 80% acetone before being measured with a UV–Vis Spectrophotometer at 663 nm and 644 nm. Total chlorophyll content in microplastic treated and control samples was evaluated using Mackinney's work and Arnon equations –

$$Chl_a = 12.7A_{663} - 2.69A_{645}; Chl_b = 22.9A_{645} - 4.68A_{663}$$
$$\text{Total chlorophyll} = Chl_a + Chl_b$$

2.4 Biochemical Analysis

2.4.1 Phenolic Content

A modified Folin–Ciocalteau test with gallic acid as the standard was used to assess total phenolic content (Ainsworth & Gillespie, 2007). 1 ml of plant extract was combined with 5 ml of Folin Ciocalteau's reagent after 1.5 ml of 20% Na_2CO_3 was added (diluted 1:10 with distilled water). Color development was accomplished by incubating the test tubes in dark for 30 min at room temperature, followed by measuring the absorbance at 765 nm. The total phenolic content of the sample was estimated as mg of dry mass equivalents of gallic acid. (GAE) mg^{-1}.

2.4.2 Proline Content

Modified ninhydrin chromogenic techniques were used to measure the proline content (Zhang et al., 2013). A glass tube containing freshly harvested roots (0.2 g) was filled with 5 ml of 3% sulfosalicylic acid. The glass tube was incubated for 10 min in a 100 °C water bath. 2 ml of the filtrate was digested in another glass tube after 4 ml of chromogenic solution (2 ml of 2.5% ninhydrin and 2 ml of glacial acetic acid) was added to the filter. The glass tube was then immersed for 30 min in a 100 °C water bath. Further, to stop the reaction, glass tube was submerged in an ice bath. 5 ml of toluene were placed in the glass tube, vortexed, and then allowed to stand. Using a spectrophotometer, the toluene layer's absorbance was observed at 520 nm.

2.5 Morphological Analysis

2.5.1 Fluorescence Microscopy

Fresh roots and leaves were removed from *Brassica juncea* plant and cleansed with deionized water. The roots were sectioned and placed on a glass slide with a few drops of clean water. The glass slide was then gently squeezed to flatten the pure water-covered root, ensuring that no air bubbles formed between the glass slide and cover slip. A fluorescent microscope was used to view each sample.

2.5.2 Confocal Microscopy

Fresh roots and leaves with tagged microplastics were picked out and cleansed with deionized water. On a glass slide with a few droplets of distilled water, cross-sections of roots were exhibited. Furthermore, to ensure no air bubbles between glass slide and cover slip, it was gently pressed to flatten the clean water-covered root. With the use of a confocal microscope (Nikon Laser Scanning Confocal Microscope), each sample was examined to observe the tagged microplastics. Similar observations were performed for leaf cross-sections of plant.

2.6 Statistical Analysis

All experiments were done in triplicate. Statistical analysis of experimental data was performed using Origin2023 software, and analysis of variance (ANOVA) was performed in SPSS 21.0 with a p-value of 0.05. For triplicate samples ($n=3$), all values were expressed as mean 5% standard error.

3 Results and Discussion

3.1 Biometrical Parameters

3.1.1 Growth Response

On exposure of *Brassica juncea* to HDPE_MPs and HDPE_beads, significant difference in shoot biomass and root biomass could be observed in contrast to control plants (Fig. 2 (a)). Shoot biomass for control was 3.155 ± 0.15 g compared to the treated plants showing a decreasing trend. The least shoot biomass was observed for 20 g MPs in contrast to control sample indicating an adverse effect when exposed to microplastics. Similarly, root biomass also showed a declining trend on being exposed to HDPE_MPs and HDPE_beads after a span of three months (Fig. 2 (b)). Root biomass for control was 0.85 ± 0.04 g compared to the treated plants having significant difference in values.

The shoot and root height also showed a declining trend on being treated with HDPE_MPs and HDPE_beads (Fig. 2 (c) & (d)). The shoot height for control plant was 33.23 ± 1.66 cm compared to microplastics treated samples showing declining trend. Also, the root height for control sample was 5.6 ± 0.28 cm compared to microplastics exposed samples showing a decreasing trend. Figure 2: Influence of HDPE_MPs and HDPE_beads on plant samples by observing growth parameters: (a) Shoot Biomass; (b) Root Biomass; (c) Shoot Height (The values are mean of three triplicates; Error bars denote 5% standard error).

3.1.2 Chlorophyll Content

The results showed that chlorophyll *a* (Chl *a*) was more easily impacted by varied microplastic concentrations than chlorophyll *b* (Chl *b*). Such a considerable variation in chl *a* and chl *b* content implies that total chlorophyll content in leaves of treated and control samples changed significantly (Fig. 3 (a) & (b)).

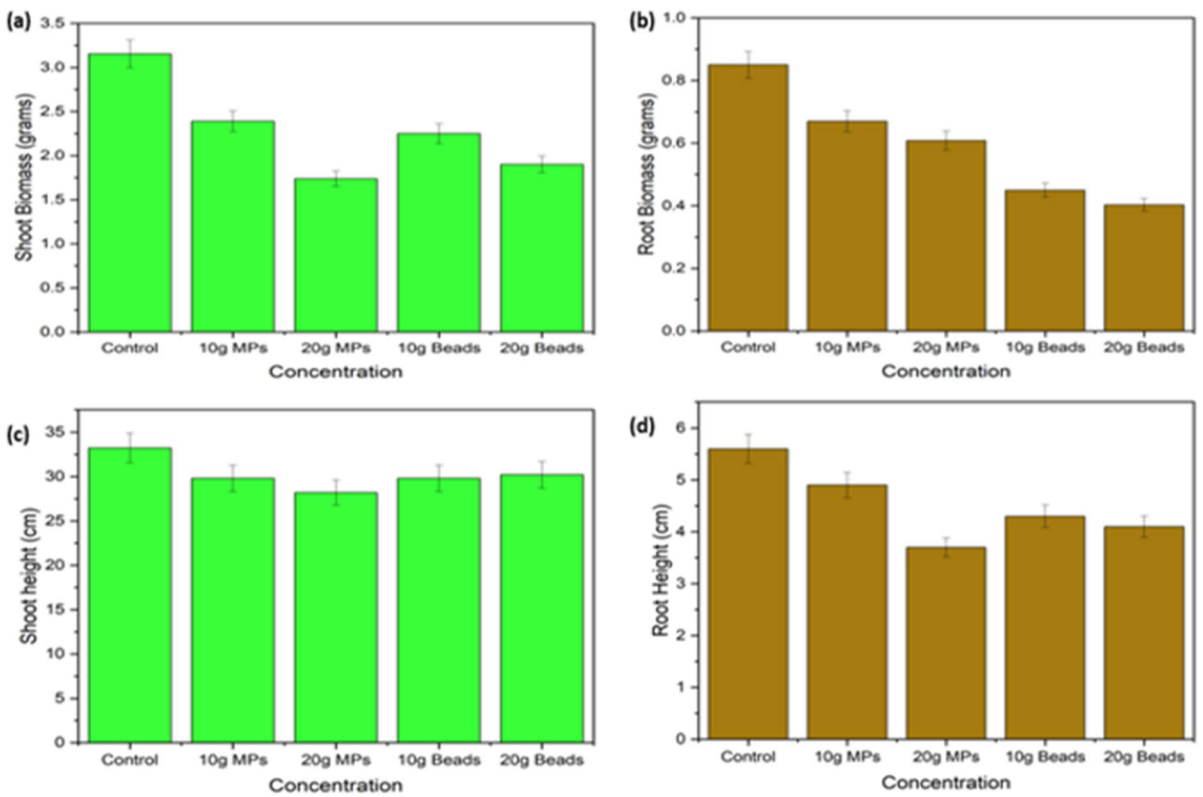

Fig. 2 Influence of HDPE_MPs and HDPE_beads on plant samples by observing growth parameters: (**a**) Shoot Biomass; (**b**) Root Biomass; (**c**) Shoot Height; (**d**) Root Height (The values are mean of three triplicates; Error bars denote 5% standard error)

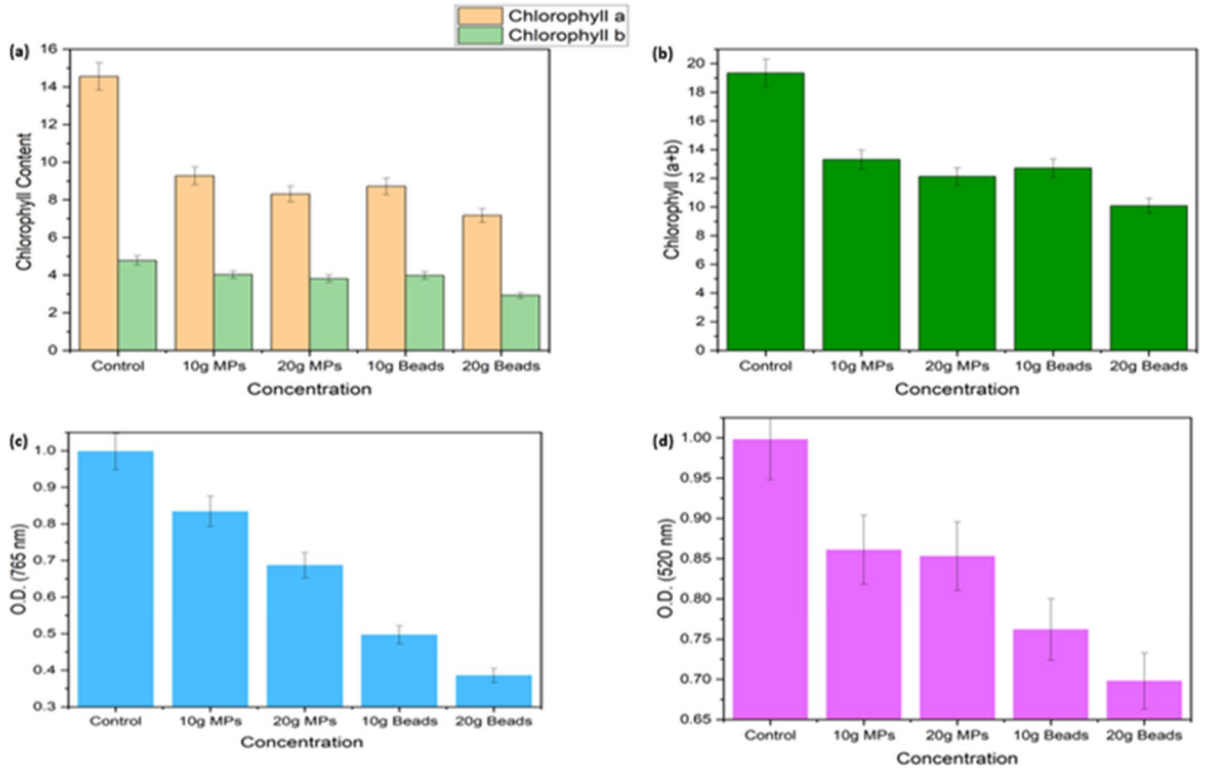

Fig. 3 Influence of HDPE_MPs and HDPE_beads on plant samples by observing growth parameters: (**a**) Chlorophyll a & b; (**b**) Total chlorophyll; (**c**) Phenolic content; (**d**) Proline content (The values are mean of three triplicates; Error bars denote 5% standard error)

Chlorophyll *a* is the primary pigment in the photosynthesis process, whereas chlorophyll *b* is an additional pigment that delivers energy to chlorophyll *a* (Khaleghi et al., 2013). An important metric for photosynthetic activity is the overall chlorophyll concentration (chl *a* + chl *b*), and variations in this value are a sign of stress in plants. Thus, it could be observed that chlorophyll *a* was comparatively less for microplastics treated plant samples indicating that total chlorophyll content in leaves showed greater inhibitory effect on exposure to microplastics.

3.2 Biochemical Analysis

3.2.1 Phenolic Content

The most common secondary metabolites found in plants are phenolics that serve as biological aid in plants, including defense against pathogens, protection from ultraviolet rays, pigmentation to draw pollinators, and defense against reactive oxygen species (Waśkiewicz et al., 2013). On being exposed to microplastics of different types, phenolic content in plants reduced showing a decreasing trend as observed in Fig. 3 (c). Compared to control having phenolic content of 0.998 ± 0.04 (GAE) mg^{-1}, phenolic content in plants treated with microplastics showed declining trend. The results indicate that incorporation of microplastics decreases phenolic content in plants thereby inducing stress. Figure 3: Influence of HDPE_MPs and HDPE_beads on plant samples by observing growth parameters: (a) Chlorophyll a & b; (b) Total chlorophyll; (c) Phenolic content; (d) Proline content (The values are mean of three triplicates; Error bars denote 5% standard error).

3.2.2 Proline Content

The current investigation demonstrated that *B. juncea* plants treated with HDPE_MPs and HDPE_beads had

a reduced proline content (Fig. 3 (d)). As proline is known to reduce oxidative stress, maintain osmotic balance, and regulate redox potential, increasing concentration of microplastics showed an opposite trend. On being exposed to MPs, content of proline gradually declined with 20 g beads showing lowest value of 0.698 ± 0.03 gg^{-1} compared to control with proline content of 0.998 ± 0.04 gg^{-1}. These values are indicative of the fact that proline is not able to reduce stress in *Brassica juncea* plants contaminated with microplastics.

The results presented in Fig. 2 (a) to (d) and Fig. 3 (a) to (d) are in good agreement and show the impact of microplastics on *Brassica juncea*. The decreasing trend observed in shoot biomass, root biomass, shoot height and root height ascertain the uptake of microplastics by plants and also provide evidence of plant contaminated with microplastics. Increasing concentration of microplastics in each of triplicate samples decreases the biometrical growth of *Brassica juncea*. Also, in contrast to chlorophyll *b*, chlorophyll *a* showed a major declining concentration on adding microplastics. Since, the major pigment involved in photosynthetic energy production is chlorophyll *a* (Khaleghi et al., 2013), its low content in microplastics treated samples indicates that total chlorophyll content gets significantly affected on addition of microplastics. Similarly, biochemical analysis conveys the impact of microplastics on *Brassica juncea* plants. As observed in Fig. 3 (c), phenolic content plays a major role as antioxidant agents that aid in free radical scavenging (Aryal et al., 2019). Decreasing concentration of phenolic agents on addition of microplastics justifies that plant have less redox potential thereby showing less antioxidant activity. Figure 3 (d) showing proline concentration signifies that microplastics addition induces stress in plants (Hayat et al., 2012).

3.3 Morphological Analysis

3.3.1 Fluorescence Microscopy

In this study, we show that *Brassica juncea* plant roots may absorb microplastics with sizes ranging between 5 to 10 µm from the surrounding soil (Fig. 4 (a) & (b)). We were able to find and see labelled microplastic particles embedded amid root cell structures using fluorescence microscopy. Fluorescing microplastic was found in exodermis, and vascular tissues, as well as in root hairs and outer epidermal layer, in addition to the inherent autofluorescence

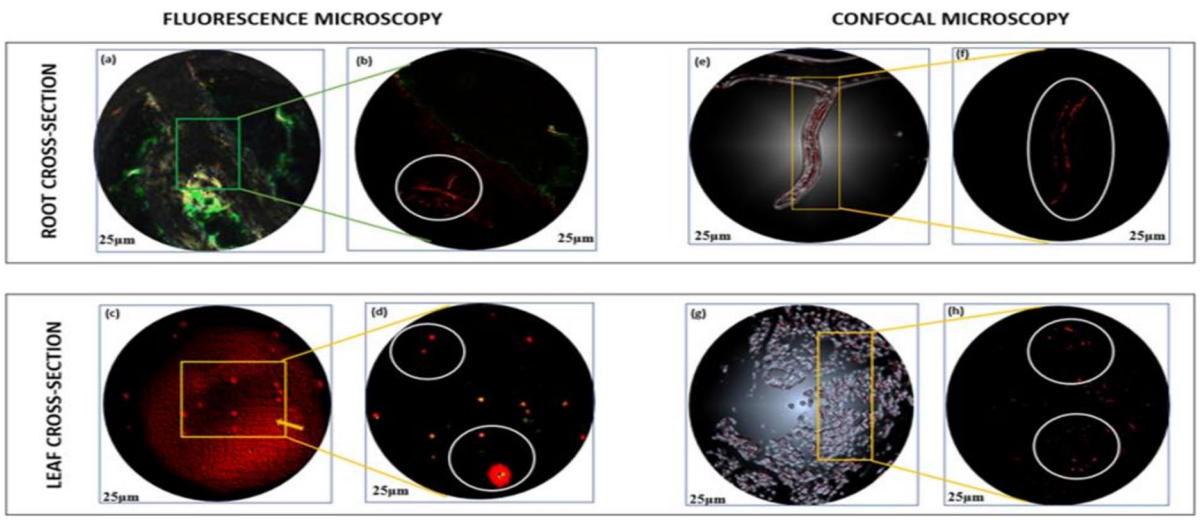

Fig. 4 Longitudinal cross-section of a Brassica juncea lateral root and leaf section in a three-month-old mustard plant after being exposed to a tagged microplastics. Clockwise from top left, flourescence microscopy shows root cross-sections (**a**) and (**b**), leaf sections (**c**) and (**d**), and confocal laser scanning microscopy shows root cross-sections (**e**) and (**f**), and leaf sections (**g**) and (**h**). Flourescing microplastic particles are indicated by white circles. All photographs were captured at magnifications of 40X and 100X and enhanced with contrast and brightness correction. Scales are displayed in the lower left and right corner of each image

of tree root. (Fig. 4(c) & (d)) provides evidence for microplastics incorporation in leaves of mustard plant as observed with red tagged MPs. Tagged microplastics could be observed in leaf sections and also induce structural changes in the morphology of leaf which is in line with our physiological and biochemical analysis (Sections 3.1. and 3.2.).

3.3.2 Confocal Microscopy

To decipher more significant findings of the study, confocal microscopy was performed to visualize tagged microplastics within the root lateral cross-sections and leaf parts. On visualization under red and green field at 40X and 100X magnification, it could be observed that microplastics were embedded in root hair segments and leaf internal veins at some points (Fig. 4 (e), (f), (g) & (h)). Because we could observe microplastics particles in inner root and leaf structures, our results suggest that micrometer sized microplastic can easily traverse from soil to root through crack-entry and apoplastic pathway, forming basis for entry to food chain. These results confirm microplastics uptake by *Brassica juncea* plants and also provide future insights for understanding the mechanism of action and impact on plants. Figure 4: Longitudinal cross-section of a *Brassica juncea* lateral root and leaf section in a three-month-old mustard plant after being exposed to tagged microplastics. Clockwise from top left, fluorescence microscopy shows root cross-sections (a) and (b), leaf sections (c) and (d), and confocal laser scanning microscopy shows root cross-sections (e) and (f), and leaf sections (g) and (h). Fluorescing microscopic particles are indicated by white circles. All photographs were captured at magnifications of 40X and 100X and enhanced with contrast and brightness correction. Scales are displayed in the lower left and right corner of each image.

To confirm the uptake of microplastics in root and leaf sections, morphological analysis using fluorescence and confocal microscopy is presented that is in line with the previous results. Biometrical parameters and biochemical analysis convey impact of microplastics on *Brassica juncea*. To provide further evidence for the same, fluorescence microscopy observed in Fig. 4 (a) to (d) signifies microplastics uptake in root and leaf cross-sections. Also, confocal microscopy shown in Fig. 4 (e) to (h), confirms the results and is in accordance with fluorescence microscopy observations.

3.4 Mechanism of Microplastics Uptake by Plants

Through this study, it could be observed that microplastics traverse from root hair sections to upper parts of plant like leaves and shoot. The results signify that microplastics have possible implications on *Brassica juncea* plant after being exposed. However, the mechanism of microplastic passage from soil to different plant parts is still in its infancy and needs more research. The apoplast and symplast routes are two pathways that microplastics can take to move through the plant from roots to the leaves (Su et al., 2019). Apoplast is the space outside plant cells, consisting of cell walls, intercellular spaces, and extracellular fluid. Microplastics can move through this space via diffusion, and uptake into the plant is thought to occur through the root epidermis and cortex as observed by morphological analysis in Fig. 4 (a), (b), (e) and (f). Once inside the apoplast, microplastics can move laterally along the root cell walls and through intercellular spaces to reach the xylem vessels (Roberts & Oparka, 2003). From xylem, microplastics are up taken by leaf parts and other tissues of plant as observed in Fig. 4 (c), (d), (g) and (h). The apoplast route is thought to be the primary pathway for larger microplastics to traverse the plant.

The symplast is the interconnected network of plant cells via plasmodesmata, which are small channels that allow for direct communication and transport of molecules between cells. Microplastics can enter the plant cells through endocytosis or other mechanisms and move through the cytoplasmic continuum from cell to cell via plasmodesmata (Raliya et al., 2016). This route is thought to be the primary pathway for smaller microplastics or those with a hydrophilic surface. The probable pathway for microplastic transport within the plant is described in Fig. 5: Mechanism of transport of microplastics from roots to different parts of plant. Some general mechanisms that are mostly proposed include:

a. Adhesion and penetration: Microplastics may adhere to the surface of roots and enter into root tissues by physical or chemical interactions (Nel et al., 2009). Above morphological analysis (Fig. 4) confirms the uptake of microplastics

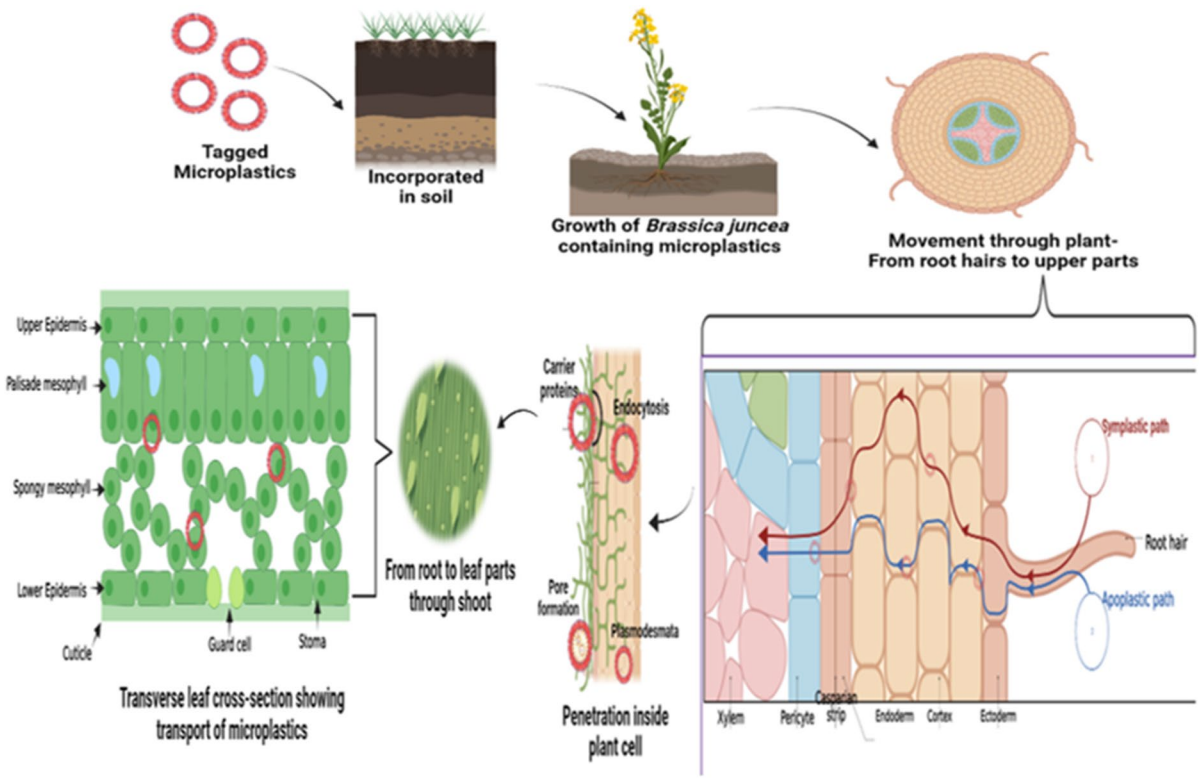

Fig. 5 Mechanism of transport of microplastics from roots to different parts of plants

from soil to root hairs and is in good agreement with the theoretical observations.

b. Endocytosis: Microplastics can traverse to plant cells through endocytosis, that encompasses formation of vesicles around the particles (Etxeberria et al., 2006). As observed in Fig. 4 (d), leaf sections show degradation of leaf surface due to accumulation of tagged microplastics. These results confirm the inflammation of leaf surface on being contaminated with microplastics.
c. Translocation: Once inside the root, microplastics may be transported across the root cortex and into the xylem vessels, which carry water and nutrients up to the leaves. This transport can cause microplastics uptake and occur through diffusion or active transport mechanisms (Schwab et al., 2016). The morphological analysis observed in Fig. 4 (a) to (h) shows that microplastics traverse from root hairs to leaf sections possibly through nutrients and water.
d. Accumulation in leaf parts: Once in xylem vessels, microplastics can be transported to the leaves, where they can accumulate in the leaf tissues. This accumulation can occur through transpiration, which is the loss of water through leaves, and subsequent concentration of microplastics in the leaf tissues. As observed in Fig. 4 (e) and (f), the leaf sections present accumulation of tagged microplastics at the surface and also degradation of a part due to accumulation.

The uptake of microplastics by plants can have various effects, including alterations in plant growth, development, and metabolism. This is well confirmed with the above findings stating impact of microplastics on biometry, biochemical analysis, and morphology. Furthermore, the presence of microplastics in edible plant tissues could pose potential risks to humans, and more research is required to understand their impacts on plants. Hence, the migration of MPs inside plants is really important as it gives an evidence on the accumulation and absorption of MPs on plant parts. Also, after accumulation and absorption of MPs, the phytoremediation potential can be

determined to provide sustainable solution for environmental cleanup.

4 Salient Findings of the Study

The results from overall study provide evidence for microplastics uptake by *Brassica juncea* and its impact on growth and development. The biometrical parameters and biochemical analysis signify that microplastics are transported from root to shoot parts of the plant as depicted by Figs. 2 and 3. Also, morphological analysis confirm uptake of microplastics from root to leaf sections of plant. The shoot biomass showed least concentration of 1.75 g on addition of 20 g MPs. Similarly, root biomass of 0.4 g was observed on addition of 20 g beads, that was least compared to all other concentrations. Also, the least shoot and root height was observed in plants treated with 20 g MPs showing shoot height at 27 cm and root height at 3.5 cm (Fig. 2). Similar to this, least chlorophyll concentration was observed in 20 g beads thereby showing least total chlorophyll content in microplastics exposed plants. Also, the antioxidant activity depicted by phenolic content and protection of plant against stress represented by proline content was least for 20 g beads exposed plants (Fig. 3). Morphological analysis confirmed the presence of microplastics uptake in root and leaf sections of plant. Confocal microscopy provides a rapid approach for visualization of MPs within plant parts (Li et al., 2020). The fluorescent dyes can generate stable emission signals that are easy to distinguish from the autofluorescence generated by plant tissues (Zhang et al., 2022). Thus, it is a rapid and efficient approach in detection of MPs within plant tissues (Ullah et al., 2021). The accumulation of tagged microplastics could also be observed in Fig. 4 (c) and (d) sections. These results portray uptake of microplastics not only by root but also by leaf sections of plant. Thus, *Brassica juncea* have been found to accumulate microplastics in their tissues, that could have significant impact on humans when consumed. This study also highlights uptake mechanism of microplastics from root to leaf sections as confirmed by morphological analysis. All the results present a significant finding providing evidence on impact on *Brassica juncea* plant after being exposed to different concentrations of microplastics. Further studies exploring phytoaccumulation of microplastics and remediation of soil need to be investigated for providing sustainability to agricultural ecosystem.

5 Conclusion

The inference from this study demonstrates absorption, uptake and phytotoxicity of microplastics to *Brassica juncea*, a vascular terrestrial plant for first time. Physiological and biochemical analysis reveals transport of MPs from root to leaf sections. Morphological analysis confirms the existence of MPs in various parts of plant as observed in vascular tissues of leaf sections and root hairs. Based on these findings, mechanism of transport of MPs from root to leaf sections through apoplast and symplast pathway is proposed. The accumulation of microplastics is evidenced in *Brassica juncea* plants providing a platform for future studies on remediation of soil in combination with other approaches to achieve optimal results. Nonetheless, it holds promise as a sustainable and environment friendly approach to addressing the issue of microplastic pollution.

The current manuscript deals with the tidal force effects, geodesic deviation, and shadow constraints of the Schwarzschild-like black hole theorised in Starobinsky-Bel-Robinson gravity exhibiting M-theory compactification. In the current analysis, we explore the radial and angular tidal force effects on a radially in-falling particle by the central black hole, which is located in this spacetime. We also numerically solve the geodesic deviation equation and study the variation of the geodesic separation vector with the radial coordinate for two nearby geodesics using suitable initial conditions. All the obtained results are tested for Sag A* and M87* by constraining the value of the stringy gravity parameter β using the shadow data from the event horizon telescope observations. All the results are compared with Schwarzschild black hole spacetime. In our study, we found that both the radial and angular tidal forces experienced by a particle switch their initial behaviour and turn compressive and stretching, respectively, before reaching the event horizon. The geodesic deviation shows an oscillating trend as well for the chosen initial condition. For the constrained value of β, we see that the spacetime geometry generated by Sag A* and M87* is effectively same for both Schwarzschild and Starobinsky-Bel-Robinson black hole. Furthermore, we also calculated the angular diameter of the shadow in Starobinsky-Bel-Robinson black hole and compared with the Schwarzschild black hole. It is observed that the angular diameter of shadow for M87* and Sgr A* in Starobinsky-Bel-Robinson black hole is smaller than the Schwarzschild black hole. The calculated results satisfy the event horizon telescope observational constraints. Finally, we have concluding remarks.

I. INTRODUCTION

Black holes are one of the most fascinating components in our universe, representing a fundamental prediction within Einstein's theory of general relativity. The scientific community and researchers have been intrigued by black holes for numerous years, driven by various reasons. Their captivating nature makes them curious and exotic entities within the universe. A widely accepted theory is that black holes are formed through the gravitational collapse of massive stars [1]. The existence of black holes has been strongly supported by several observational characteristics. Notably, measurements of black hole spin in X-ray binaries, the detection of gravitational wave signals from binary black hole mergers by LIGO [2–4], and the remarkable image of a black hole at the core of the galaxy M87 captured by the Event Horizon Telescope (EHT) collaboration [5] have provided compelling evidence. Additionally, the discovery of a wide star-black hole binary system through radial velocity measurements [6] has further contributed to our comprehensive understanding of black holes. These achievements collectively reinforce the evidence for the existence and properties of black holes. These enigmatic objects have captured considerable attention across the fields of astrophysics, astronomy and high-energy physics. Through studying black holes, researchers have made remarkable discoveries in areas such as thermodynamics, quantum effects, and gravitational interactions within curved spacetime. The physical properties of black holes remain a fascinating subject for the scientific community, even after the first discovery of a black hole as a solution to Einstein's equations more than a hundred years ago in General Relativity (GR). This initial discovery gave rise to the well-known Schwarzschild solution [7], characterized by a single parameter - the mass of the black hole. Since then, multiple solutions to Einstein's equations have been unveiled, going beyond the Schwarzschild solution. These encompass the Kerr black hole, exhibiting rotation [8], the Reissner-Nordström black hole, demonstrating electrical charge [9, 10], and the Kerr-Newman black

hole, possessing both charge and rotation [11]. Thus in the context of GR, black holes can be described using four fundamental parameters: mass, charge, rotation, and angular momentum. However, when it comes to astrophysical black holes, it is generally anticipated that they are characterized by only two of these parameters - mass and angular momentum. Despite this simplification, these black holes may exist within highly dynamic environments, featuring elements like accretion disks and electromagnetic fields [12]. Furthermore, in alternative theories of gravity, black holes are linked to slight deviations from their standard counterparts, leading to unique features in their behavior [13]. Investigating how these deviations can be observed in electromagnetic and gravitational wave observations is currently a highly active area of research in the scientific literature [14–16]. In the last decade, modified gravity models have been extensively explored to address various cosmological issues and investigate the properties of black holes. Numerous theories have been proposed, taking diverse approaches and methods. Among these, Einstein Gauss-Bonnet (EGB) gravity, which finds support from string theory and related dual models, including M-theory [17–19], has emerged as one of the most extensively studied theory. In the context of EGB gravity, black holes have been investigated with respect to the Gauss-Bonnet gravity parameter. This parameter plays a pivotal role in constructing and studying black holes within these gravity models [20, 21]. The thermodynamics and optical properties of these black holes have been carefully examined concerning the Gauss-Bonnet parameter[22, 23]. Notably, it has been observed that variations in the Gauss-Bonnet parameter significantly impact the physical properties of black holes, with the shadow radius decreasing as the parameter increases [24]. These findings provide valuable insights into the interplay between gravity models and the intriguing behavior of black holes, furthering our understanding of the cosmos at both macroscopic and microscopic scales. Recently, a novel gravitational model called Starobinsky-Bel-Robinson (SBR) gravity has been introduced, incorporating a new parameter denoted by β [25]. This four-dimensional gravity is inspired by M-theory, which, at lower energies, is described by eleven-dimensional supergravity. Specifically, there are suggestions that this modified gravity can be derived from M-theory compactified on a two-sphere factor represented by $S^3 \times S^4$ [25]. Various models have been proposed within this novel gravitational framework. Inflation scenarios involving the β parameter have been studied, and associated cosmological observables have been computed [26]. These investigations have explored how observational data can impose constraints on the value of β. Furthermore, Schwarzschild-type black holes in SBR gravity have been constructed, and their thermodynamic properties have been analyzed in terms of the parameter β. Relevant quantities, including entropy and pressure, have been computed, revealing that the presence of β introduces corrections to these quantities [27]. These explorations shed light on the influence of the β parameter on the thermodynamic properties of black holes in the context of SBR gravity. In a recent study, Belhaj et al. [28] investigated the deflection angle and shadows produced by black holes within the framework of Starobinsky-Bel-Robinson Gravity derived from M-theory.

In the current paper, we focus on the analysis of tidal forces in the black holes in Starobinsky-Bel-Robinson modified Gravity from M-theory, recently obtained by Delgadoa and Ketov [27]. It is widely known that tidal forces within a Schwarzschild spacetime cause a body falling towards the event horizon to experience stretching in the radial direction while being compressed in the angular directions [29, 30]. The stretching and compression are induced by gravity's tidal effect, which is created by a difference in gravity's strength between two neighbouring places. This phenomenon is highly widespread in our cosmos and have sparked public scientific interest for most of the twentieth century. In the last decades, tidal forces were analyzed for Kiselev black hole [31], Hayward black hole spacetime [32], null naked singularity spacetime [33] and some regular black holes [34]. The authors of [35] compared the tidal force effects in a stringy charged black hole to those in Schwarzschild and RN black holes. The authors of [36] studied tidal forces in Reissner-Nordström spacetime and discovered that the radial and angular tidal forces switches sign at the event horizon. Also, the tidal forces in presence of a cosmological constant were studied in [37].

The tidal forces in the Kerr Black Hole were investigated in Refs.[38–43]. Tidal forces play a significant role in astrophysics, leading to intriguing phenomena such as tidal disruption events (TDEs). In these events, a star may be disrupted by the tidal forces exerted by a black hole[44] ,giving rise to bright flares of X-ray [45], ultraviolet [46], and optical [47] radiation. These TDEs offer valuable insights into the interactions between black holes and surrounding celestial bodies.

In this paper, we thoroughly analyze the tidal forces and geodesic deviation for a radially in-falling particle in the Schwarzschild-like black hole spacetime in the Starobinsky-Bel-Robinson Gravity. Furthermore, we also find the constraint of the black hole parameter β with the black hole shadow by the supermassive black holes $M87^*$ and $SgrA^*$ data. The shadow of a black hole is created by photons emitted from the central black hole and eventually reaching an observer. These photons follow unstable orbits, forming light rings around the black hole. When projected onto an observing screen, these light rings give rise to the shadow. Unstable orbits are critical because small perturbations can cause photons to either be captured by the central compact

object or escape to infinity. The light rays composing the shadow pass very close to the event horizon and experience significant bending due to the strong gravitational lensing effect. Consequently, observations of the shadow provide a means to test the strong-field properties of gravity. The seminal work of Synge [48] and Luminet [49] was instrumental in developing a formula for calculating the angular radius of photons. This formula, in turn, facilitated the characterization of the region surrounding a Schwarzschild black hole by elucidating the behavior of the light deflection angle as it diverges. Following this, Bardeen's[50] groundbreaking research in 1973 delved into the intricacies of the shadow cast by a spinning Kerr black hole, demonstrating how the black hole's rotation caused distortions in the shadow's shape. Within this context, the photon ring, encircling the black hole's shadow, emerges as a pivotal element that can be harnessed to determine the black hole's parameters and unveil gravitational features within the information field. Subsequently, there has been a surge of activity in both analytical/numerical investigations and observational studies related to the shadows cast by the different kind of black holes [24, 51–56]. Numerous studies have been conducted in this area, including those by the works of literature [57–63].

The organization of this paper is as follows. In section II, we reconsider the nature of the black holes in the SBR gravity. In Section III we discuss the radial and angular tidal forces in SBR black hole spacetime using tetrad formalism. Section IV presents the numerical solution for the geodesic deviation equation and compares the results with Schwarzschild spacetime. In section V, we investigate the shadow behaviors and provide predictions for β by the help of EHT data. We conclude our results in section VI. Throughout the manuscript we use geometrized units as $G = c = 1$.

II. BLACK HOLES IN SBR GRAVITY

In this section, we discuss about the Schwarzschild like black hole solution in SBR gravity which is theorized to be embedded in M-theory existing in eleven dimensional spacetime. This solution is discussed by the authors in [64]. M-theory has a bosonic sector having a metric g_{MN} and a tensor 3 -form C_{MNP} coupled to M2-branes which are dual to M5-branes [65]. Using the compactification process coupled with the existence of stringy fluxes, the corresponding 4-D gravity models may be produced [26, 27, 64]. The action considered is given by:

$$S_{SBR} = \frac{M_{pl}}{2}\int d^4x\sqrt{-g}\left(R + \frac{R^2}{6m^2} - \frac{\beta}{32m^6}\left(P_4^2 - E_4^2\right)\right). \tag{1}$$

where g is the metric determinant and R is the Ricci curvature scalar. m is a free mass parameter which could have various interpretations depending on the underlying theory. β is a positive dimensionless coupling whose value is determined by the compactification of M-theory, and could be fixed by studying the optical behaviors of black hole. P_4^2 and E_4^2 are the Pontryagin and the Euler topological densities which are related to the Bel-Robinson tensor $T_{\mu\nu\lambda\rho}$ in four dimensions by means of the relation [26, 27, 64]

$$T^{\mu\nu\delta\rho}T_{\mu\nu\delta\rho} = \frac{1}{4}\left(P_4^2 - E_4^2\right). \tag{2}$$

The Bel-Robinson tensor is defined as:

$$T^{\mu\nu\delta\sigma} = R^{\mu\rho\gamma\delta}R^{\nu\sigma}_{\rho\gamma} + R^{\mu\rho\gamma\sigma}R^{\nu\delta}_{\rho\gamma} - \frac{1}{2}g^{\mu\nu}R^{\rho\gamma\alpha\delta}R^{\sigma}_{\rho\gamma\alpha}. \tag{3}$$

It can be seen from Eq.(1) that the gravity action depends on two parameters (m, β). This gives rise to plethora of applications such as studying Hawking radiation [66], entropy [67] and inflation [68]. The black hole solution in SBR gravity depends on the value of β corrected to first order perturbations. The line element of this non-rotating solution has been found to be [27]

$$ds^2 = -f(r)dt^2 + \frac{1}{f(r)}dr^2 + r^2d\Omega^2. \tag{4}$$

where the metric component $f(r)$ is given by

$$f(r) = 1 - \frac{2M}{r} + \beta\left(\frac{8\sqrt{2}\pi M}{r^3}\right)^3\left(\frac{108r - 194M}{5r}\right). \tag{5}$$

where $r_s = 2M$ is the Schwarzschild radius. Here, M represent the mass parameter.

III. TIDAL FORCE EFFECTS IN SBR BLACK HOLES

In this section, we will delve into the complexities of the equations involving tidal forces in our spacetime. To investigate the equation for the distance between two infinitesimally close and free falling particles, we use the following equation for the spacelike components of the geodesic deviation vector η^μ

$$\frac{D^2\eta^\mu}{D\tau^2} = R^\mu_{\alpha\beta\gamma}v^\alpha v^\beta\eta^\gamma, \tag{6}$$

where $R^\mu_{\alpha\beta\gamma}$ is the Riemann curvature tensor and v^μ is the unit tangent vector to the geodesic. It is known that a test body moving in space solely under the influence of gravity follows a geodesic [69]. Now, due to the difference in curvature at every point on the geodesic and the fact that each point on the test body tends to follows a unique geodesic, the body experiences a difference in acceleration, leading to a stretching and

squeezing effect known as tidal forces. This is the reason that the Riemann curvature tensor is used to study the tidal interactions due to gravity.

To calculate the tidal forces in the falling body's frame, we make use of the tetrad formalism [70]. Tetrads are geometric objects that form a set of local coordinate bases, i.e. a locally defined set of four linearly independent vector fields known as tetrads or vierbien. At each point on a geodesic, there is a tetrad frame that forms a local inertial reference frame, where the laws of special relativity apply. Since, Lorentz transformations can connect an infinite number of orthonormal bases at a specific point, they cannot give enough information about the connection on the metric. To resolve this, we use the transformation from the orthonormal basis to the coordinate basis:

$$\overrightarrow{e}_{\mu} = \hat{e}^{\hat{i}}_{\mu}\overrightarrow{e}_{\hat{i}}, \tag{7}$$

where $\overrightarrow{e}_{\mu}$ represents the coordinate basis, $\overrightarrow{e}_{\hat{i}}$ represents the orthonormal basis and $\hat{e}^{\hat{i}}_{\mu}$ are the tetrad components. The metric tensor components in the tetrad basis are given as [70]:

$$g_{\mu\nu} = \eta_{\hat{i}\hat{j}}\hat{e}^{\hat{i}}_{\mu}\hat{e}^{\hat{j}}_{\nu}. \tag{8}$$

This is the key equation that enables us to use orthonormal basis in curved spacetime. The tetrad components for freely falling frames can be obtained from Eq. (7) and Eq. (8).

$$\hat{e}^{\mu}_{\hat{0}} = \left\{\frac{E}{f(r)}, -\sqrt{E^2 - f(r)}, 0, 0\right\}, \tag{9}$$

$$\hat{e}^{\mu}_{\hat{1}} = \left\{\frac{-\sqrt{E^2 - f(r)}}{f(r)}, E, 0, 0\right\}, \tag{10}$$

$$\hat{e}^{\mu}_{\hat{2}} = \left\{0, 0, \frac{1}{r}, 0\right\}, \tag{11}$$

$$\hat{e}^{\mu}_{\hat{3}} = \left\{0, 0, 0, \frac{1}{r\sin\theta}\right\}, \tag{12}$$

where the tetrad components follow the following rule:

$$\hat{e}^{\mu}_{\hat{i}}\hat{e}^{\hat{j}}_{\mu} = \delta^{\hat{j}}_{\hat{i}}. \tag{13}$$

We notice that the component $\hat{e}^{\mu}_{\hat{0}} = v^{\mu}$ is the tangent vector to the geodesic i.e. the four velocity of the particle. Also, the geodesic deviation vector follows the transformation rule from global coordinates to local orthonormal coordinates:

$$\eta^{\mu} = \hat{e}^{\mu}_{\hat{i}}\eta^{\hat{i}}. \tag{14}$$

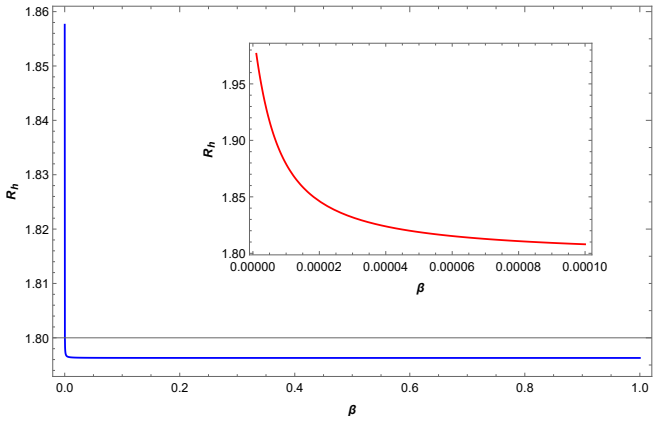

FIG. 1. Event horizon location in SBR black holes for different values of stringy parameter β. We take M=1 for computation. It is noticed that the event horizon begins shifting for values of the order $\sim 10^{-4}$

The non vanishing independent components of Riemann tensor for spherically symmetric spacetimes, including SBR black hole spacetime are given by [71]:

$$R^{1}_{212} = \frac{-rf'(r)}{2}, \tag{15}$$

$$R^{1}_{010} = \frac{f(r)f''(r)}{2}, \tag{16}$$

$$R^{1}_{313} = \frac{-rf'(r)\sin^2\theta}{2}, \tag{17}$$

$$R^{2}_{020} = R^{3}_{030} = \frac{f(r)f'(r)}{2r}, \tag{18}$$

$$R^{2}_{323} = \sin^2\theta\left(1 - r^2 f(r)\right) \tag{19}$$

For computing the Riemann curvature tensor components in tetrad basis, we use the tetrad formalism as:

$$R^{\hat{i}}_{\hat{j}\hat{k}\hat{l}} = R^{\mu}_{\alpha\beta\gamma}e^{\hat{i}}_{\mu}e^{\alpha}_{\hat{j}}e^{\beta}_{\hat{k}}e^{\gamma}_{\hat{l}}. \tag{20}$$

Following the Eq. (20), the tidal tensor components are given by:

$$R^{\hat{1}}_{\hat{0}\hat{1}\hat{0}} = \frac{f''(r)}{2}, \tag{21}$$

$$R^{\hat{2}}_{\hat{0}\hat{2}\hat{0}} = R^{\hat{3}}_{\hat{0}\hat{3}\hat{0}} = \frac{f'(r)}{2r}, \tag{22}$$

A. TIDAL FORCE EQUATIONS

Upon obtaining the expressions from Eq. (21-22), we can obtain the relative acceleration between two nearby particles as:

$$\frac{D^2\eta^{\hat{r}}}{D\tau^2} = \frac{-f''(r)}{2}\eta^{\hat{r}}, \tag{23}$$

$$\frac{D^2\eta^{\hat{\theta}}}{D\tau^2} = -\frac{f'(r)}{2r}\eta^{\hat{\theta}}, \tag{24}$$

$$\frac{D^2\eta^{\hat{\phi}}}{D\tau^2} = -\frac{f'(r)}{2r}\eta^{\hat{\phi}}. \tag{25}$$

By substituting the values of $f(r)$ and its higher derivatives in Eq. (23-25) we get:

$$\frac{D^2\eta^{\hat{r}}}{D\tau^2} = \frac{4Mr^9 - 243\cdot 2^{\frac{27}{2}}\pi^3M^3\beta r + 1067\cdot 2^{\frac{25}{2}}\pi^3M^4\beta}{2r^{12}}\eta^{\hat{r}} \tag{26}$$

$$\frac{D^2\eta^{\hat{\theta}}}{D\tau^2} = \frac{-10Mr^9 + 243\cdot 2^{\frac{25}{2}}\pi^3M^3\beta r - 485\cdot 2^{\frac{25}{2}}\pi^3M^4\beta}{10r^{12}}\eta^{\hat{\theta}} \tag{27}$$

$$\frac{D^2\eta^{\hat{\phi}}}{D\tau^2} = \frac{-10Mr^9 + 243\cdot 2^{\frac{25}{2}}\pi^3M^3\beta r - 485\cdot 2^{\frac{25}{2}}\pi^3M^4\beta}{10r^{12}}\eta^{\hat{\phi}} \tag{28}$$

B. RADIAL TIDAL FORCE

Following the expression in Eq.(23) and we notice that the radial tidal force vanishes at a point $R = R_0^{rtf}$ given by solving the below equation:

$$R_0^{rtf} = \frac{4M}{r^3} - f''(\beta, r) = 0. \tag{29}$$

where the function $f(\beta, r)$ is taken for simplicity in calculation and representation, and is given by:

$$f(\beta, r) = \beta\left(\frac{8\sqrt{2}\pi M}{r^3}\right)^3\left(\frac{108r - 194M}{5r}\right). \tag{30}$$

It can be seen from the graph in fig.(2) that as the value of β is increased, the peak value of tidal force shifts to the right. This suggests that the maximum radial stretching happens far from the horizon as the departure from Schwarzschild geometry is significant. The peak value of radial tidal force can be calculated by equating the first derivative of the term in RHS of Eq.(23) to zero.

$$R_{peak}^{rtf} = \frac{d}{dr}\left(\frac{\frac{4M}{r^3} - f''(\beta, r)}{2}\right) = 0. \tag{31}$$

The peculiar trend that can be noticed from the graph is that the nature of force changes from radial stretching to compression for non zero values of β. This is in strict contrast to the Schwarzschild black hole case where the radial tidal force profile shows a monotonically increasing trend and becomes infinity as $r \to 0$. The transition from radial stretching to compression reverts back very close to the event horizon, after which the tidal force increases drastically till infinity.

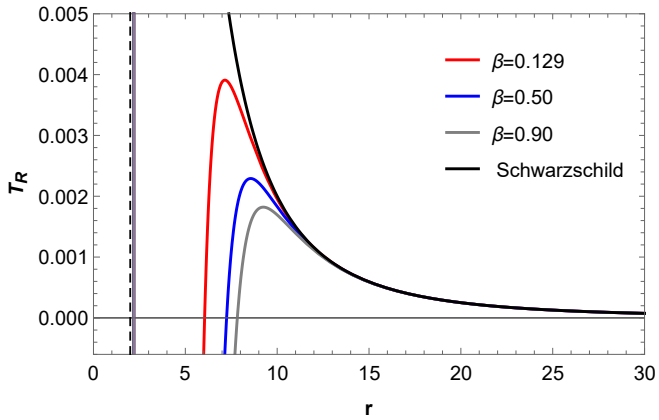

FIG. 2. Radial tidal force as a function of the radial coordinate. We notice that the force vanishes at a single point in contrast to what happens with Schwarzschild spacetime. We take $M = 1$ and $\beta = 0.20$. Dotted line shows the location of event horizon for Schwarzschild spacetime

We test the behavior of radial tidal force for both Sag A* and M87* and the results are displayed in figures 3 and 4 respectively.

For both of these cases, the force profile for SBR black hole coincides perfectly with the Schwarzschild black hole case in the range $-0.00038 < \beta < 0.00089$ and $-0.002 < \beta < 0.0003$ for Sag A* and M87* respectively. This suggests that the spacetime geometry generated by Sag A* and M87* is best explained by the Schwarzschild geometry.

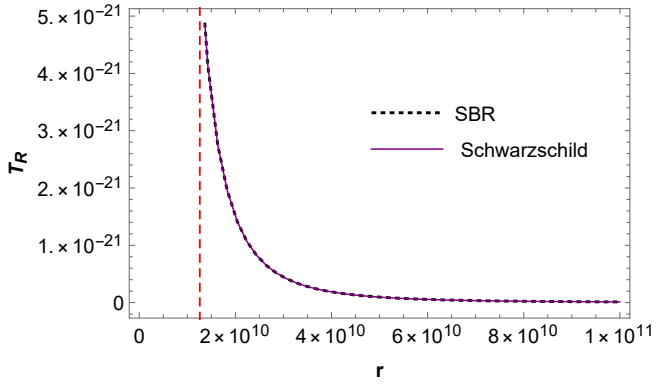

FIG. 3. Radial tidal force profile for Sag A* as a function of the radial coordinate. Dotted red line shows the location of event horizon for Schwarzschild spacetime

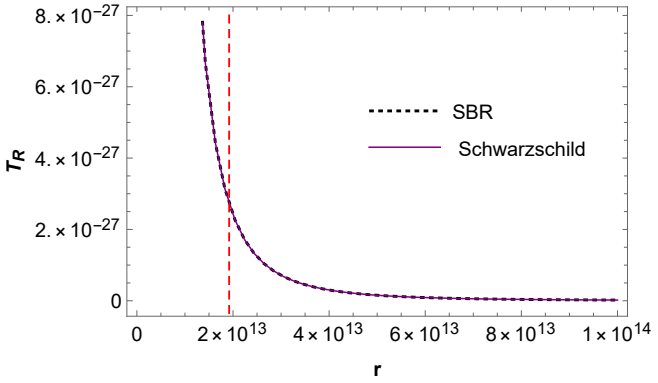

FIG. 4. Radial tidal force profile for M87* as a function of the radial coordinate. Dotted red line shows the location of event horizon for Schwarzschild spacetime

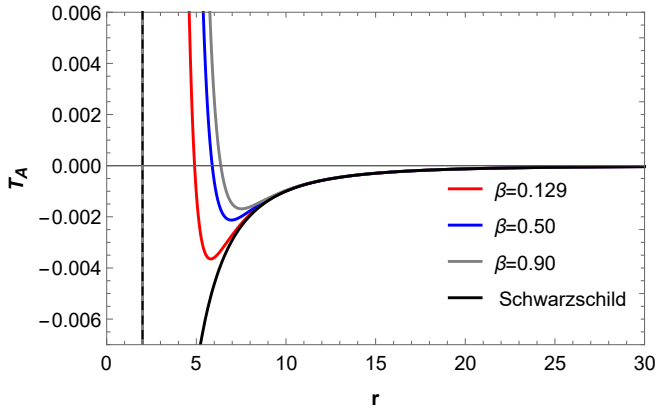

FIG. 5. Angular tidal force as a function of the radial coordinate. We notice that the force vanishes at a single point in contrast to what happens with Schwarzschild spacetime. We take $M = 1$ and $\beta = 0.20$. Dotted line shows the location of event horizon for Schwarzschild spacetime

C. ANGULAR TIDAL FORCE

Just similar to the radial tidal force profile, the angular force profile also vanishes at a point $R = R_0^{atf}$. It can be computed by equating the RHS of Eq.(24) to zero and is given by:

$$R_0^{atf} = \frac{2M}{r^2} + f'(\beta, r) = 0. \tag{32}$$

For simplicity, the term $f'(r)$ is expressed as $\frac{2M}{r^2} + f'(\beta, r)$. where $f(\beta, r)$ is given by the Eq.(30). Angular tidal forces show compressive behavior as the particle falls radially inwards from infinity. The force reaches a peak value and inverts it nature to stretching. The peak value shifts to the right for increasing value of β similar to the case of radial force profile. This suggests that maximum compression happens far from the horizon as the departure from the Schwarzschild geometry increases.

Following the convention in Eq.(30), the peak value of angular tidal force can be calculated by equating the first derivative of the expression in Eq.(24) to zero.

$$R_{peak}^{atf} = \frac{d}{dr}\left(\frac{\frac{-2M}{r^2} - f'(\beta, r)}{2r}\right) = 0. \tag{33}$$

Angular force profile also shows a very different trend from the Schwarzschild geometry. In Schwarzschild black hole case, the angular tidal force becomes increasingly compressive as the radial coordinate becomes smaller only to reach infinity as $r \to 0$. But, in the case of SBR black hole, the angular tidal force switches its nature from compressive to stretching as the radial coordinate decreases for in-falling particle. The graph in fig.(5) shows the general force profile. The compression to stretching trend again reverts back very close to the horizon, tending to infinity thereafter. We test the behavior of angular tidal force for both Sag A* and M87* and the results are displayed in figures 6 and 7 respectively. We find that for both the cases, the SBR and Schwarzschild force profile coincides. This confirms that the spacetime geometry generated by both compact objects resembles Schwarzschild geometry.

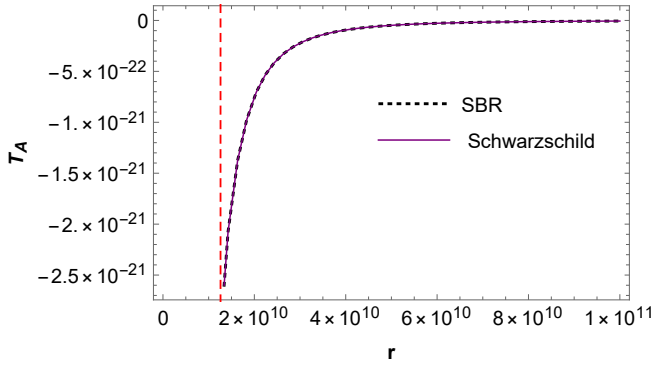

FIG. 6. Angular tidal force profile for Sag A* as a function of the radial coordinate. Dotted red line shows the location of event horizon for Schwarzschild spacetime

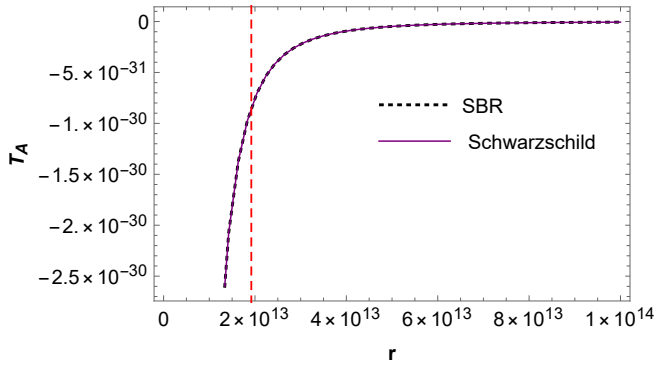

FIG. 7. Angular tidal force profile for M87* as a function of the radial coordinate. Dotted red line shows the location of event horizon for Schwarzschild spacetime

IV. GEODESIC DEVIATION

In this section we discuss the variation of geodesic deviation vector with the radial coordinate in SBR black hole spacetime. The deviation vector measures the deformation of a body falling radially in any spacetime geometry. We can convert Eq. (23) and (24) in second derivatives w.r.t. r by substituting $dr/d\tau = -\sqrt{E^2 - f(r)}$ which results from Eq. (9). This gives us the following second order differential equations in r:

$$(E^2 - f(r))\frac{D^2\eta^{\hat{r}}}{Dr^2} - \frac{f'(r)}{2}\frac{D\eta^{\hat{r}}}{dr} + \frac{f''(r)}{2}\eta^{\hat{r}} = 0, \quad (34)$$

$$(E^2 - f(r))\frac{D^2\eta^{\hat{i}}}{Dr^2} - \frac{f'(r)}{2}\frac{D\eta^{\hat{i}}}{dr} + \frac{f'(r)}{2r}\eta^{\hat{i}} = 0. \quad (35)$$

where $i = \{\theta, \phi\}$. The analytic solution for Eq. (34) and (35) as pointed out in [72] can be given as:

$$\eta^{\hat{r}}(r) = \sqrt{E^2 - f(r)}\left[C_1 + C_2 \int \frac{dr}{(E^2 - f(r))^{3/2}}\right], \quad (36)$$

$$\eta^{\hat{i}}(r) = \left[C_3 + C_4 \int \frac{dr}{r^2\sqrt{(E^2 - f(r))}}\right] r. \quad (37)$$

where C_1, C_2, C_3, C_4 are constants of integration. In order to find their value, we numerically solve the differential equations by imposing some initial conditions. For the purpose of this study we take the following initial conditions.

$$\eta^{\hat{\beta}}(b) > 0, \dot{\eta}^{\hat{\beta}}(b) = 0. \quad (38)$$

where $\beta = \{r, \theta, \phi\}$. $\eta^{\hat{\beta}}(b)$ represents the separation between two nearby geodesics at $r = b$ in the radial and angular directions. The initial condition in Eq. (38) represents a mass released from rest at $r = b$. In the next sections we will discuss the components of radial and the angular deviation vectors in detail.

A. RADIAL COMPONENT

In Fig.(8) we have shown the radial component of the geodesic deviation vector after solving Eq. (36) with initial condition. We notice that for non zero values for β, the radial component of the geodesic deviation vector reaches a finite value outside the event horizon, falls rapidly and again peaks just inside the horizon as $r \to 2M$, unlike in the Schwarzschild black hole scenario, where it crosses the event horizon and goes till infinity because of the infinite stretching radial tidal force at the singularity. This peak value attained outside the horizon keeps on decreasing as the value of β is increased.

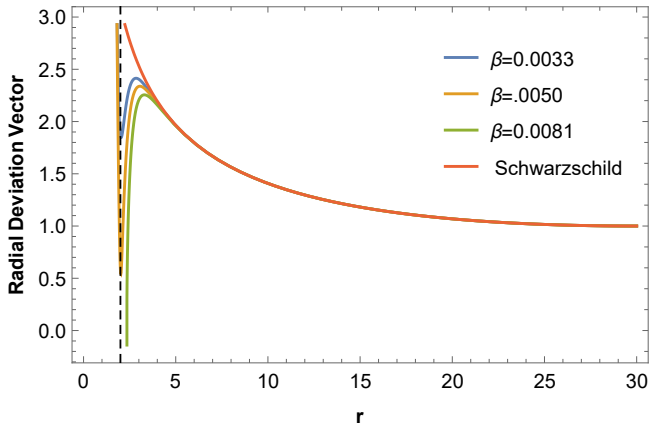

FIG. 8. Radial geodesic deviation profile for a radially in-falling particle in SBR black hole spacetime. We use M=1 to show the trend for different values of β. Dotted line shows the location of event horizon in Schwarzschild spacetime.

By using the constrained value of β, we show the radial geodesic deviation trend for Sag A* and M87* in Fig (9) and Fig.(10). As seen from figures, the SBR black hole and Schwarzschild black hole lines perfectly coincide, leading to the conclusion that Schwarzschild geometry perfectly defines the geodesic deviation for a test particle falling radially in the spacetime generated by Sag A* and M87* for $-0.00038 < \beta < 0.00089$ and $-0.002 < \beta < 0.0003$ respectively.

B. ANGULAR COMPONENT

In Fig.(11) we have shown the angular component of geodesic deviation vector by constraining the Eq. (37) with the initial condition. The results are compared with the Schwarzschild black hole. It is observed that in the SBR black hole case, the angular deviation decreases for a radially in-falling particle, shows a little spike near the event horizon and then continues to fall beyond the event horizon. This is in contrast to the Schwarzschild black hole scenario in which the deviation decreases throughout the range of the radial coordinate. The graph in Fig.(11) shows the behavior of the geodesics. The peak

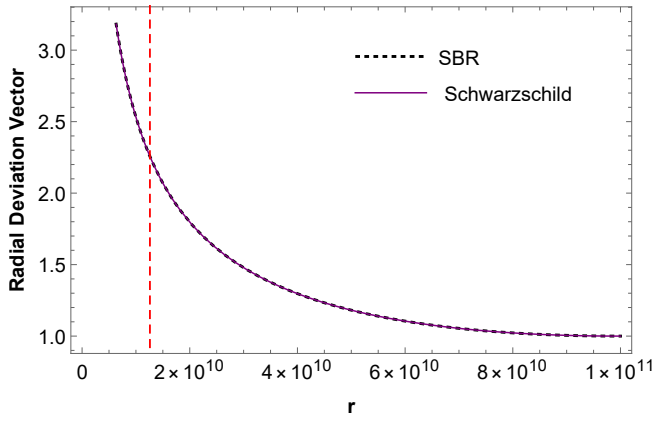

FIG. 9. Radial geodesic deviation profile for Sag A* using the constrained values of β. The dotted red line shows the location of the event horizon of Schwarzschild spacetime.

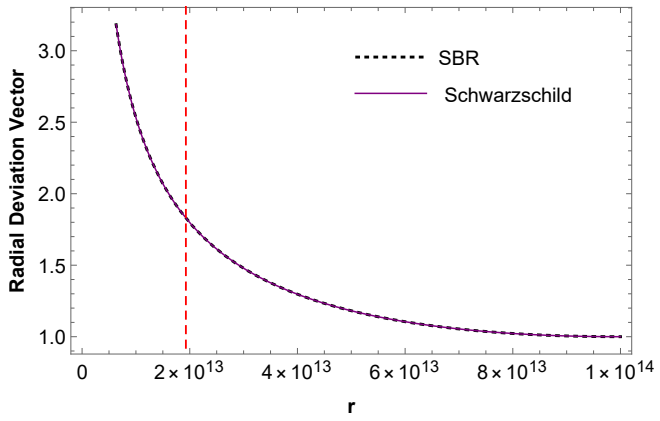

FIG. 10. Radial geodesic deviation profile for M87* using the constrained values of β. The dotted red line shows the location of the event horizon of Schwarzschild spacetime.

value is higher for increasing value of β. By using the constrained value of β, we show the angular geodesic deviation trend for Sag A* and M87* in Fig (12) and Fig.(13). As seen from the graphs below, the SBR black hole and Schwarzschild black hole lines perfectly coincide, leading to the conclusion that Schwarzschild geometry perfectly defines the geodesic deviation for a test particle falling radially in the spacetime generated by Sag A* and M87* for $-0.00038 < \beta < 0.00089$ and $-0.002 < \beta < 0.0003$ respectively.

V. BLACK HOLE SHADOW WITH M87* AND SGR A*

In this section we explore the shadow of the BH SBR gravity from M-theory. We know that for the angular radius of the BH shadow we study [57, 73]

$$\sin^2\alpha_{sh} = \frac{h(r_{ph})^2}{h(r_{obs})^2}, \tag{39}$$

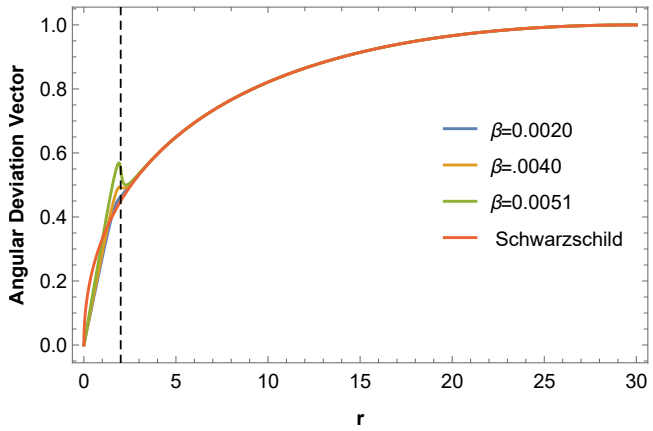

FIG. 11. Angular geodesic deviation profile for a radially infalling particle in SBR black hole spacetime. We use M=1 to show the trend for different values of β. Dotted line shows the location of event horizon in Schwarzschild spacetime.

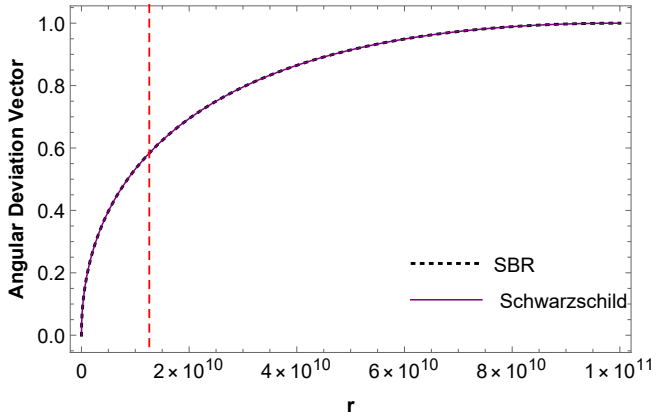

FIG. 12. Angular geodesic deviation profile for Sag A* using the constrained values of β. The dotted red line shows the location of the event horizon of Schwarzschild spacetime.

with

$$h(r)^2 = \frac{r^2}{f(r)}, \tag{40}$$

where r_{ph}, r_{obs} are the radius of photon sphere and observer distance, respectively. $h(r)$ was early introduced in several references (for example, see [73]). α_{sh} is the angular radius of the BH shadow.

Here we combine Eqs. (39) and (40), and for a distant observer the Eq. (39) takes the following form

$$\sin^2\alpha_{sh} = \frac{r_{ph}^2}{f(r_{ph})}\frac{f(r_{obs})}{r_{obs}^2}. \tag{41}$$

One can easily find the observable radius of BH shadow for observer at infinite distance using Eq. (41) in the following form as[57]

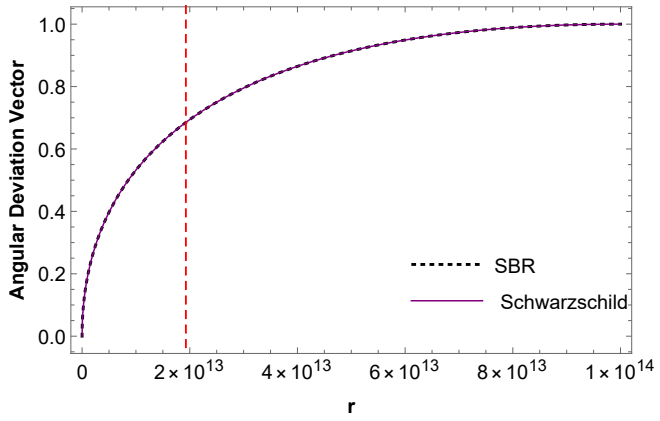

FIG. 13. Angular geodesic deviation profile for M87* using the constrained values of β. The dotted red line shows the location of the event horizon of Schwarzschild spacetime.

$$R_{sh} \simeq r_{obs}\sin\alpha_{sh} \simeq \frac{r_{ph}}{\sqrt{f(r_{ph})}}. \tag{42}$$

Now we consider that the supermassive BHs M87* and Sgr A* are spherically symmetric static and SBR parameter β from M-theory. Although the observation got by the EHT collaboration does not support the assumption taken here. However, here we explore theoretically the constrain on the parameter β, from the data provided by the EHT project. To constrain this parameter β in SBR gravity we use the observational data released by the EHT project for the BH shadows of the supermassive BHs M87* and Sgr A*. The angular diameter of the shadow, the distance from sun system and the mass of of the BH at the centre of the galaxy M87, are $\Omega_{\rm M87^*} = 42 \pm 3\ \mu$as, $D = 16.8 \pm 0.8$ Mpc and $M_{\rm M87^*} = (6.5 \pm 0.7)x10^9\ M_\odot$, respectively [5]. For the Sgr A* the data recently obtained by the EHT project is $\Omega_{\rm Sgr\ A^*} = 51.8 \pm 2.3\ \mu$as, $D = 8277 \pm 9 \pm 33$ pc and $M_{\rm Sgr\ A^*} = 4.297 \pm 0.013x10^6\ M_\odot$ (VLTI) [74]. Using this data, we can estimate the diameter of the shadow cast by the BH, per unit mass from the following expression [24, 75],

$$d_{\rm sh} = \frac{D\Omega}{M}\,. \tag{43}$$

Now we can obtain the diameter of the shadow from the expression $d_{\rm sh}^{\rm theo} = 2R_{\rm sh}$. Thus, the diameter of the BH shadow image is $d_{\rm sh}^{\rm M87^*} = (11 \pm 1.5)M$ for M87* and $d_{\rm sh}^{\rm Sgr\ A^*} = (9.5 \pm 1.4)M$ for Sgr A*. From the data by the EHT collaboration, we obtain the constrain on the parameter β for the supermassive BHs at the centre of the galaxy M87* and the Sgr A*. We present our results obtained here in the Fig. 14. In this figure,it is observed that the angular diameter of BH shadow decreases with the increasing value of parameter β. It is also observed that the angular diameter of shadow for M87* and

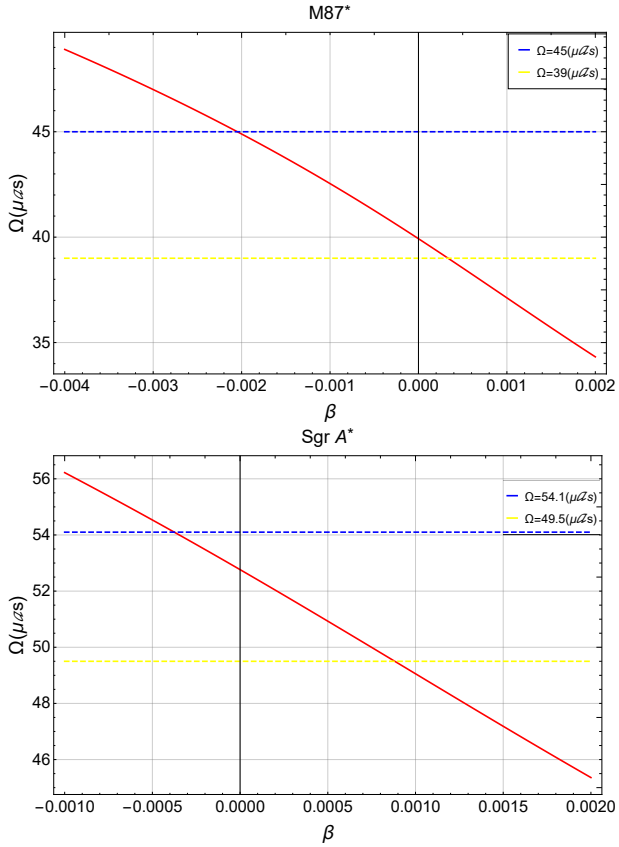

FIG. 14. The angular diameter of shadow for SBR black hole as a function of parameter β where angular diameter $\Omega = 42 \pm 3\mu as$ for M87* (upper panel); and for $\Omega = 51.8 \pm 2.3\mu as$ for Sgr A* (lower panel).

Sgr A* BH in the context of the SBR black hole BH is smaller than the other ordinary astrophysical BH such as Schwarzschild BH. Consequently, the SBR black hole parameter β has been constrained as $-0.00038 < \beta < 0.00089$ for Sgr A* and $-0.002 < \beta < 0.0003$ for M87* respectively.

VI. CONCLUSIONS

In this work, we have discussed tidal force effects and constrained the shadow of Schwarzschild type black holes in Starobinsky-Bel-Robinson modified theory of gravity. This work has been done in an attempt to define some observational signatures that can be used to distinguish SBR gravity from Einstein's general theory of relativity. The metric for spherically symmetric and static spacetime in this gravity differs from the Schwarzschild metric by introducing a stringy gravity parameter β which has a positive value.

We see that both the radial and angular tidal force profiles depend on the value of β and approach infinity as $r \to 0$. Both force profiles show a varying trend

where the radial force becomes compressive and angular tidal force becomes of stretching nature as a particle radially falls towards the black hole. This is in contrast with Schwarzschild black hole case in general relativity, where the radial tidal force monotonically increases till infinity showing stretching and the angular tidal force monotonically increases till infinity and shows compression. Both tidal forces vanish at two points outside the event horizon for different values of β giving us an opportunity to observe this phenomenon in some cases. In case of SBR gravity, the event horizon of black hole forms prior to reaching a radial distance of $r = 2M$. It can be clearly seen from Fig.(1) that the location of event horizon does not change for larger values of β i.e. of the order of $\beta > 10^{-4}$. Another important observation that can be made from the radial and angular force profiles is that the the peak value is attained farther away when compared with the Schwarzschild black hole case.

In addition to this, we also examined the geodesic deviation for a radially in-falling particle in the Schwarzschild like spacetime in SBR gravity. We consider the initial condition where a body is released from rest at a far away point where the spacetime is Minkowskian. It is observed that the radial deviation vector acts very similar to that of the Schwarzschild black hole case i.e. increasing as the particle approaches the event horizon, but shows an oscillating trend outside the event horizon. Opposite behaviour can be seen for angular deviation. It mimics the Schwarzschild black hole as the particle approaches the event horizon, but shows a sudden peak just around it and continues to rapidly fall to zero. Also, we have studied the tidal forces and geodesic deviation for Sag A* and M87* in SBR gravity by constraining the value of β using shadow size from EHT observations. We can see that in the particular β range, the tidal force and geodesic deviation profiles and both Sag A* and M87* in SBR gravity perfectly co-incide with the Schwarzschild black hole case.

Furthermore, we also calculated the angular diameter of the shadow in SBR black hole and compared it to Schwarzschild BH. It is observed that the angular diameter of shadow for M87* and Sgr A* BH in SBR black hole is smaller than the Schwarzschild BH. Consequently, the SBR black hole parameter β has been constrained as $-0.00038 < \beta < 0.00089$ for Sgr A* and $-0.002 < \beta < 0.0003$ for M87* respectively.It suggests that such black holes satisfy the EHT observational constraints, and it may be possible to detect the SBR black hole and distinguish it from the other astrophysical BHs in the future.

***Abstract*—Facial recognition and ethnicity detection is an important task in various applications such as security, marketing, and social sciences. However, the accuracy of Face recognition and ethnicity detection algorithms can be impacted by various factors such as lighting conditions, noise and irrelevant features in image background, variation in facial expressions, face size, pose and orientation across images. In this study, we present a novel face image preprocessing model in this work that aims to enhance the performance of deep learning models like ResNet, DenseNet and other state of the art Deep Learning models on facial recognition tasks, specifically ethnicity detection by addressing these issues. Our novel method for preprocessing facial images incorporates several techniques to enhance the quality of the input images. Firstly, we removed the background using DeepLab-v3. Secondly, we employed facial landmarks detection and facial pose and orientation correction using facial alignment based on the angle between the eyes. Thirdly, to facilitate race classification, we performed facial cropping to isolate the facial region and other critical features essential for the task. Finally, we ensured consistent lighting conditions across all images using the Multi-scale retinex algorithm. These techniques together enabled the deep learning model to better analyze and classify facial data. To assess the efficacy of our model, we carried out a series of experiments on the UTK Face dataset and compared the outcomes with those obtained when our preprocessing model was not utilized.**

The experimental outcomes show that our suggested preprocessing model improves the f1-score of ethnicity detection classifiers by up to 6%. The proposed facial image preprocessing model is efficient, fast, and easy to implement, enabling real-time applications, making it appropriate. Our research highlights the importance of preprocessing techniques in enhancing ethnicity detection performance and provides a practical solution for improving the accuracy of ethnicity detection and facial recognition systems.

I. Introduction

Facial recognition and ethnicity detection have become increasingly important in various applications, including security, marketing, and social sciences. In a recent study [6], it was observed that GANs generate data that belong to the same distribution as the input dataset. Consequently, using GANs [2] for data augmentation would only serve to increase the existing biases in the data. Hence, it is essential to acknowledge the potential for bias in GAN-generated data and to implement strategies to mitigate them. Facial ethnicity detection tasks can be quite challenging owing to the wide range of variations in lighting, positions, orientations, and facial expressions between images. Additionally, the presence of background noise in the images can further complicate the task. These factors can significantly impact the accuracy of ethnicity detection algorithms, leading to errors and misclassifications.

To address these challenges, facial image preprocessing has emerged as a critical step in enhancing the performance of ethnicity detection and facial recognition systems. Facial image preprocessing involves applying a series of techniques to normalize and enhance facial images, making them more suitable for comparison across different subjects and under different conditions.

This paper introduces a novel facial image preprocessing model that aims to improve the accuracy of face detection algorithms, with a specific focus on ethnicity classification models. The proposed model is designed to effectively preprocess facial images and extract key features that are essential for accurate ethnicity classification. We have incorporated multiple preprocessing techniques in our proposed model, such as background removal using DeepLab v3 based on the ResNet 101 model, facial landmarks detection, facial pose and orientation correction using facial alignment based on the angle between the eyes, face cropping, and ensuring consistent lighting conditions across different images using the multi-scale retinex algorithm.

To assess the effectiveness of our proposed facial image preprocessing model, we conducted several experiments on the

UTK Face dataset [13] using various different models, comparing the results obtained with and without the application of our preprocessing model. Our experimental findings indicate that the proposed model led to a significant improvement in f1-score of ethnicity detection models, with performance gains of upto 6%. The proposed facial image preprocessing model is efficient, fast, and easy to implement, making it suitable for real-time applications.

This research highlights the importance of preprocessing techniques in enhancing the ethnicity detection performance and provides a practical solution for improving the accuracy of ethnicity detection and facial recognition systems.The rest of the work comprises the following sections: An overview of relevant work in face recognition and facial image preprocessing is provided in Section II. Section III provides a description of the suggested face image preprocessing model and the preprocessing techniques used. Section IV provides the methodology used to evaluate the proposed model. The experimental findings are presented in Section V, along with a comparison of the outcomes obtained with and without the use of our preprocessing. The work is finally concluded in Section VI, which also covers future research.

II. Related Work

In the field of facial recognition and its related tasks, several researchers have investigated the use of preprocessing techniques to enhance the accuracy of these tasks. Deep learning models have achieved remarkable success in feature extraction from the facial images. However, the quality of facial datasets is generally not so good and so it make it difficult for even those modern technology to extract facial traits from the images, using deep learning models. Hence it is important to develop effective and efficient methods and tools to preprocess the images.

In a previous study on illumination preprocessing for facial images, Han et al. [3] proposed a method that considers lighting differences between different faces. The research yielded valuable insights and findings on how to develop more effective illumination preprocessing techniques. They discussed and compared existing methods in the field. A research paper [14] provides a comprehensive survey of face recognition techniques, including preprocessing techniques used to improve face recognition accuracy. The authors discuss various preprocessing techniques, such as illumination normalization, face alignment, and feature extraction, and how they might be applied to improve how well face recognition systems function. A study [11] proposes a deep convolutional neural network (CNN) architecture for ethnicity and gender classification. The authors used a large dataset of facial images and applied various preprocessing techniques, such as cropping, histogram equalization, and scaling, to improve the performance of the CNN. Recent Survey [9] of face detection techniques, including preprocessing techniques used to improve face detection accuracy. The authors discuss various preprocessing techniques, such as illumination normalization, face alignment, and pose estimation, and how they might be applied to improve how well face detection algorithm works.

Facial image preprocessing techniques

In order to increase the precision and effectiveness of face recognition and ethnicity identification algorithms, facial image preprocessing methods are crucial. These are several methods that are often used:

- **Facial background removal:** This technique removes the background of the image to focus only on the facial region. It helps to reduce the influence of the image background on the facial recognition process. [1] In a paper, a novel method of semantic image segmentation is proposed, which entails segmenting an image into many parts and giving each part a label to denote the objects in the picture. The suggested method makes use of atrous convolution, a kind of convolution that permits the inclusion of a broader geographical context without requiring an increase in the number of parameters. The atrous spatial pyramid pooling (ASPP) module, a modified atrous convolutional layer, is a component of the DeepLab v3 architecture that is used to extract information from various scales.
- **Facial landmarks detection:** Facial landmarks detection is used to identify the important facial landmarks in the picture, such as the nose, mouth, and eyes. It helps to align the face to a consistent reference frame, which is crucial for accurate facial recognition.
- **Face alignment:** It adjusts the orientation and pose of the face in the image to a consistent reference frame. It helps to reduce the variation in facial orientation and pose, which can impact the accuracy of facial recognition.
- **Face Cropping:** It involves cropping the facial region of an image, isolating only the face, and removing any extraneous background. This technique can improve facial recognition and ethnicity detection accuracy by reducing the size of the image and removing non-facial features that may interfere with feature detection.
- **Multi scale retinex illumination:** It is a technique for correcting illumination variations across facial images. This technique adjusts the brightness and contrast of facial images to achieve consistent lighting conditions across various images, improving facial recognition and ethnicity detection accuracy by reducing variations in image intensity caused by lighting differences and Camera conditions.

Overall, these preprocessing techniques are necessary to enhance the accuracy and efficiency of facial recognition. It is an important and active area of research, with ongoing efforts to develop effective and efficient methods and tools to preprocess the images.

III. Proposed Model

In the proposed model, We have used the following facial image preprocessing techniques in a specific order to the input images. 1) Facial Background Removal to facilitate face and

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:15:28 UTC from IEEE Xplore. Restrictions apply.

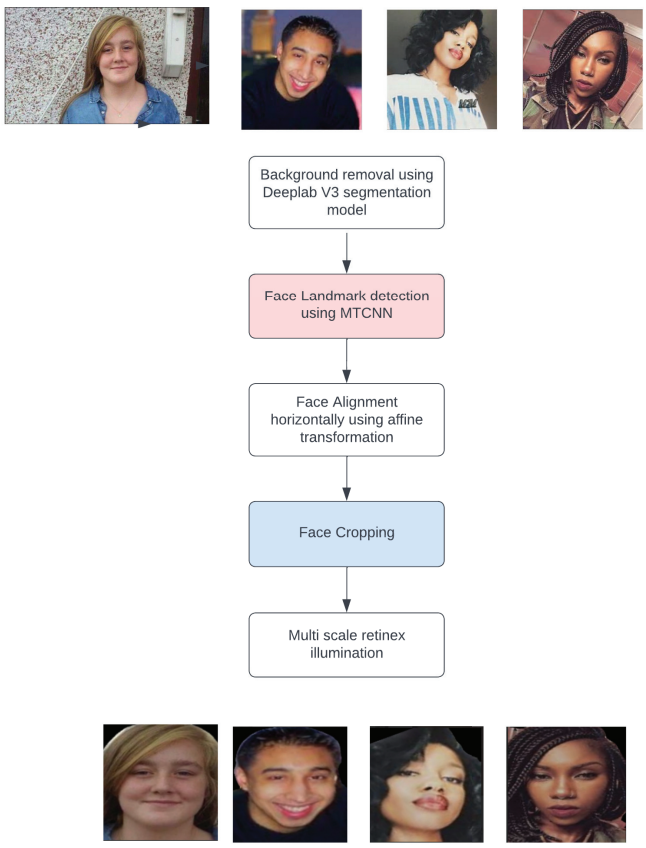

Fig. 1. Flowchart illustrating our image preprocessing approach

facial landmarks detection. 2) Face and Facial Landmarks Detection is applied to detect face and important facial landmarks such as mouth, nose, and eyes. 3) Face Alignment was performed to ensure that all faces are horizontally oriented. This was achieved by first using the facial landmarks detected in the previous step to determine the midpoint between the eyes as a reference point for rotation transformation. Then We computed the angle between the line joining the two eyes and the horizontal axis, which was utilized to ascertain the degree of rotation necessary for alignment. Subsequently, a transformation matrix was created to represent the required rotation and scaling using the midpoint of the two eyes and angle between the horizontal axis and line joining the two eyes. Finally, the transformation matrix was employed to the input image to align the face. 4) Face Cropping, was then employed to crop the face images, including the facial region, hair, and other essential features crucial for ethnicity determination. For this task, the face detection algorithm was applied again at this step to determine the facial region in the aligned image. Subsequently, the region was expanded to enhance the face's capture and facilitate the collection of additional details vital for the task at hand. 5) Multiscale Retinex Illumination [7] was implemented, utilizing the multi-scale Retinex algorithm to adjust the image's illumination to achieve consistent lighting conditions across different images. The multi-scale Retinex algorithm was selected due to its ability to modify illumination while preserving image details.

Implementation

For background removal, we have used the DeepLab v3 model based on ResNet 101. For facial landmarks detection, We have used the MTCNN (Multi-task Cascaded Convolutional Networks) [12] library. For face cropping, the facial region captured using MTCNN was expanded by adding 15 percent of the original width to the left and right sides and 20 percent of the original length to the top and bottom sides. Finally we used Multiscale Retinex algorithm to adjust the illumination of the image to achieve consistent lighting conditions across different images. The target illumination was set to 0.7 for all the images.

IV. Methodology

In this paper for Data Collection and Preparation, we used the UTK Face dataset, which includes annotations for age, gender, and ethnicity, and comprises of more than 20,000 images. The dataset comprises images that exhibit a wide range of characteristics, such as different poses, facial expression, image background, illumination, and resolution. We randomly selected 10,000 images from the dataset and divided them into training and testing sets each containing 5,000 images.

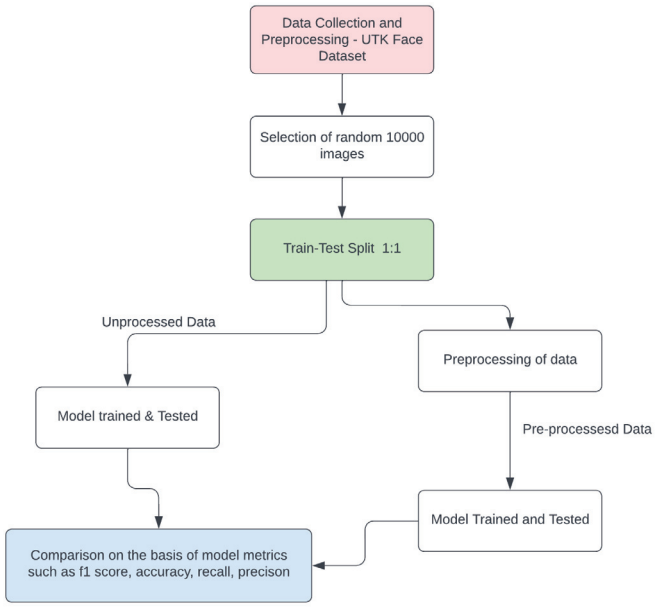

Fig. 2. Flowchart depicting the method used to compare the Deep Learning model with or without images preprocessing with our tool

For preprocessing the training and testing images, we have used our preprocessing model as explained in Section III.

For model training and testing, we used transfer learning [15] to train various state of the art Deep Learning models like ResNet [4], EfficientNet [10], DenseNet [5] and VGG

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:15:28 UTC from IEEE Xplore. Restrictions apply.

[8] on the unpreprocessed and preprocessed images. To do this, we changed the last layers to train the model using the cross entropy loss function. To train the model for ethnicity classification task, we used the ethnicity annotations given in the dataset.

Then we evaluated the performance of the models with and without using the proposed preprocessing model on the testing set using the following metrics: Recall, F1 Scores, and Precison. We compared the both results for each of the models to evaluate the effectiveness of our proposed preprocessing model.

Implementation

For training we used a cross entropy loss function. Using a 16 as a batch size, and 0.01 as a starting learning rate, the model was trained. To enhance the model's convergence, After each epoch, the learning rate dropped by a factor of 0.1. During the testing phase, we calculated the F1 score, precision, and recall of all the classifiers in order to assess their performance.

V. Results and Discussion

To assess the efficacy of our preprocessing model, we used the metrics like Recall, Precision and overall F1 score, which are widely-used evaluation measures for classification tasks. While accuracy is a commonly used evaluation metric in machine learning, it may not be reliable for imbalanced datasets where one class significantly outweighs the others. In such scenarios, a model that always predicts the majority class may achieve a high accuracy score but may not be practically useful. To address this issue, the F1 score considers both precision and recall, which are metrics used to evaluate a model's classification accuracy. Recall is the percentage of properly recognised positive occurrences among all actually occurring positive occurrences, precision is the percentage of correctly identified positive occurrences among all forecasted positive occurrences. The F1 score, which ranges from 0(worst) to 1(best), is the harmonic mean of recall and accuracy. F1 score (1) is the equation to determine the F1 score. Given that the F1 score indicates the balance between recall and precision, it is particularly helpful for datasets with imbalances while accuracy gauges overall performance. Therefore, we used Recall, Precision, and F1 score to provide a more comprehensive evaluation of our preprocessing model's effectiveness.

$$\mathcal{F}1 = \frac{2 * Precision * Recall}{Precision + Recall} \tag{1}$$

ResNet, DenseNet, EfficientNet, and VGG, four well-known deep learning models, were examined in this study for their performance on facial data with and without our preprocessing tool. The results of the models without using preprocessing model are presented in Table 1, while the results of the models with using preprocessing are presented in Table 2. The confusion matrices for each model without and with preprocessing are shown in Figures 3-6. Our results indicate that using our preprocessing tool significantly improved the performance of deep learning models on facial data. Without preprocessing, ResNet, for instance, achieved a recall, precision, and F1 scores of 0.75, 0.72 and 0.72, respectively. After preprocessing, these scores increased to 0.81, 0.79, and 0.80. The Precision, F1 Score, and Recall for the DenseNet model also increased from 0.80, 0.79, and 0.79, respectively, without preprocessing to 0.83, 0.82, and 0.82 after preprocessing. Without preprocessing, EfficientNet's F1 Score, recall, and precision accuracy were 0.79, 0.79, and 0.80 respectively, but they increased to 0.81, 0.80, and 0.81 after preprocessing. When preprocessing was used, the precision, F1 score and recall accuracy for the VGG model increased from 0.76, 0.75, and 0.74 to 0.78, 0.78, and 0.77, respectively.The outcomes in Tables 1 and 2 demonstrate the performance of deep learning models on facial data may be greatly enhanced by the use of our preprocessing method. The models which are having a low f1 scores have gone more pronounced increases compared to models with greater scores. VGG model have lowest score which is due to the fact that is is unable to transfer information of upper layer to lower layers. The results also indicate that the use of our preprocessing model for facial image data can enhancing deep learning models capacity to capture important features in the image. Specifically, we observed a significant improvement in model performance when the images were processed using our tool compared to when they were not. This suggests that our preprocessing model can facilitate better feature extraction and enhance the general performance of facial data-based deep learning models.

We also have observed near consistent trends across different models in terms of class performance. Across all models, black and white races outperformed the other races due to their more distinct features, which make them more easily identifiable. Asian individuals also performed well, albeit slightly worse than black and white individuals. However, Indians performed relatively poorly, coming in fourth place, due to the significant variability in their skin tones, facial features, and face sizes. They often share more features with other races, making them less distinguishable from others. As for class Other, it generally exhibited poor performance across all the models, as it consist of two or three different races, which may be less similar to each other and more similar to races in remaining classes. For instance, Middle Eastern people which are in class others closely resemble white people, while Latino and Hispanic people which are in class others closely resemble Indians and Blacks.

VI. CONCLUSION AND FUTURE WORK

We developed a unique preprocessing model in this work that is designed to cater to the unique characteristics of facial images. Our research demonstrates the significant impact of facial image preprocessing on the performance of deep learning models in ethnicity classification tasks. The results of our experiments show that the use of our preprocessing model significantly improved the performance of popular deep learning models such as ResNet, DenseNet, EfficientNet, and VGG where processed images were utilized for training and testing compared to the case when trained and tested on unprocessed images. This highlights the importance of appropriate preprocessing techniques for achieving optimal performance in deep learning tasks related to facial recognition and ethnicity classification. In general, this study makes a significant addition to the field of face recognition by introducing a novel method for preprocessing raw images before feeding to Deep Learning models that can be applied in a variety of face recognition related tasks like ethnicity classification, age estimation and gender classification. The proposed preprocessing model can be a useful tool for researchers and practitioners working on various kind of face recognition related tasks, enabling them to find high-quality preprocessed facial images more effectively.

Our study has demonstrated the effectiveness of the facial image preprocessing methods in enhancing the quality of facial images and improving the performance of deep learning models in ethnicity detection tasks. However, there are still several areas where further research could extend our findings and improve the utility of our methods. Our study showed the improve in accuracy of deep learning models in ethnicity classification task. Future research could explore the applicability of our proposed preprocessing tool for other

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:15:28 UTC from IEEE Xplore. Restrictions apply.

face recognition tasks such as age estimation and gender classification. Our study employed a relatively small dataset for evaluation purposes. Future research could evaluate the effectiveness of our methods on larger and more diverse datasets. This could provide more robust evidence of the generalizability of our methods and their performance in a wider range of applications. Future researchers could also try to investigate additional preprocessing techniques that can be integrated into the model to further improve its performance.

Furthermore, our study also sheds light on the challenges and limitations of ethnicity classification using facial images. Our analysis indicates that the performance of models varies depending on the ethnic group being classified, with some groups being more difficult to distinguish than others due to the similarity of their facial features. These observations highlight the need for further research in developing more robust and accurate models for ethnicity classification.

Failure investigations of last stage low-pressure steam turbine blade

Nitin Sehra and Sushila Rani

Department of Mechanical, Production, Industrial and Automobile Engineering, Delhi Technological University, Delhi 110042, India

Abstract This research study examines the failure of the last stage low-pressure steam turbine blade. The blade is made up of martensitic steel of X10CR alloy. The main focus of this paper is to analyze the fracture that appears on the leading edge of the blade at a distance of 350 mm from the blade tip. The investigation includes a visual examination, SEM fractography, microstructure characterization & mechanical testing. On Investigation, silicon oxide (Sio_2) is detected on the cracked part of the blade along with sodium, potassium, chlorides, oxide, silicate & sulfides inside the corrosion pits on the fracture surface. Further, an Intergranular fracture followed by fatigue striations is observed on the blade's leading edge. It is concluded that the failure of the low-pressure steam turbine blade may have been caused by corrosion fatigue.

1. Introduction

Low-pressure steam turbine blades are essential in power generation systems that convert steam energy into electrical power. These blades are designed to withstand extreme heat and pressure, which makes them critical to conduct the smooth operation of a power plant. In a steam turbine, there are multiple stages through which steam passes before it enters the turbine, including HP (high pressure), IP (intermediate pressure), and LP (low pressure) zones [1]. Steam turbine blades are more prone to failure at LP than the HP and IP blades, as LP blades capture the major part of the energy from the flowing steam compared to IP and HP blades [2]. However, despite their robust construction, turbine blades are susceptible to various forms of damage, which can lead to failure and, in some cases, catastrophic consequences from repeated stress cycles due to operational or loading conditions, leading to blade cracking or fracture [3-5].

Low-pressure turbine blades may fail due to various factors, including mechanical stress [6], corrosion [7-9], erosion [10-12], fatigue [13-15], and vibration [16-19]. Mechanical stress may arise due to excessive vibration, misalignment, or improper balancing, leading to blade deformation, creep, thermal distortion, which results in blade cracking. Corrosion may occur due to the presence of contaminants in the steam or condensate, resulting in blade pitting or corrosion fatigue. Erosion can occur due to the impact of solid particles or droplets in the steam, leading to blade surface erosion or wear, which results in fatigue failure of the blade.

Recent research has focused on understanding the mechanisms of failure in steam turbine blades mainly made up of martensitic steel, particularly emphasizing the role of corrosion pits, fatigue cracks, intergranular failure, and corrosion fatigue failure. Corrosion fatigue is a significant factor contributing to the failure of low-pressure steam turbine blades in industrial applications. Corrosion fatigue is a form of material degradation caused by the combined action of mechanical stress and corrosion. Corrosion pits developing on the material's surface indicate the initiation of the corrosion fatigue process, which acts as stress concentrators. As the material is subjected to cyclic loading, cracks develop at the site of the corrosion pits, which can eventually propagate through the material, leading to its failure.

Kim [20] investigated the root causes of crack formation in the fourth-stage blade of a low-pressure steam turbine. The study utilized non-destructive testing techniques, such as ultra-

sonic testing and visual inspection, to evaluate the cracks' extent and severity. The findings suggest that a combination of high-temperature exposure and mechanical stress were the main reasons for crack formation. Also, they have recommended implementing preventive measures, such as improving the blade design and manufacturing process in order to reduce the risk of crack formation. Bhagi et al. [21] analysed the failed L-1 low-pressure steam turbine blade to understand its failure mechanism. They observed that cyclic stresses and environmental effects accelerate corrosion fatigue. They have concluded that corrosion fatigue is the prime reason for blade failure, as evidenced by the transgranular cleavage fracture. Katinic and Kozak [22] presented the fracture investigations of the two adjacent rotor blades, which failed at their roots & observed that the blades failed due to corrosion fatigue. They redesigned the blade to increase their fatigue life. Wei et al. [23] presented the corrosion fatigue cracking mechanism of the 17-4 PH blade of a low-pressure rotor of a steam turbine. They discovered that in a steam environment, potassium ions (K+) and chlorine ions (Cl-) interact physically, chemically, and electrochemically with the turbine blades to produce localized spot corrosion and corrosion pits, which act as stress concentrators & found that the blade cracks formed due to corrosion fatigue. Khan and Sasikumar [24] investigated the failed low-pressure steam turbine blade made of AISI 420 steel. They observed shallow corrosion pits near the crack initiation point and varying loads increased the vibration in the turbine, which caused the fatigue cracks in the weaker zones, leading to the catastrophic failure of the turbine blade. Rivaz et al. [25] examined the 410 stainless steel failed blade after 165000 hours of working. Findings revealed that the inclusion of foreign particles like silicon oxide and ferric oxide in steam could cause corrosion in blades, and corrosion fatigue is the main reason for failure. Rani and Agrawal [26] presented the failure investigations of 210 MW last-stage low-pressure steam turbine blades after 152241 hours of working. They have analysed the blade through mechanical analysis, metallurgical analysis, and Non-destructive testing (NDT) and found that near the edges of the blade, water-droplet erosion creates erosion pits, which leads to the failure of the blade.

After a comprehensive literature review, it is observed that preventive measures have to be taken to reduce the crack formation and risk of blade failure resulting in enhancing the fatigue life of the blade. There are different methods to enhance the blade's fatigue life, like shot peening [27-29], coating the blade [30, 31], and providing dampers between the blades [32] in order to reduce the failure rate of the blade.

In this research work, failure analysis of a low-pressure steam turbine blade of a 210 MW thermal power plant is presented. High levels of noise and vibration at the LP zone during operation caused the unit to shut down and one of the blades from the 29th stage was found to be fractured on opening the turbine casing. The fractured blade is made of X10CrNiMoV12-2-2 alloy. The investigations include visual observations, mechanical tests, and scanning electron microscopy (SEM) accompanied by EDS (energy dispersive spectroscopy).

2. Experimental details

The last stage steam turbine blade of the L-0 row is collected and investigated fractographically to determine the main reasons for its failure. A transverse crack was noticed on the blade's airfoil-leading edge at a distance of 350 mm from the blade's tip, as shown in Fig. 1. The samples were prepared from the cracked region of the blade as shown in Fig. 2. The specimen was prepared using standard metallographic techniques for fractographic analysis, and the prepared sample's microstructure was revealed using Glycergia etchant through an optical microscope. For crack morphology, scanning electron microscopy of the prepared sample is carried out on VEGA3,

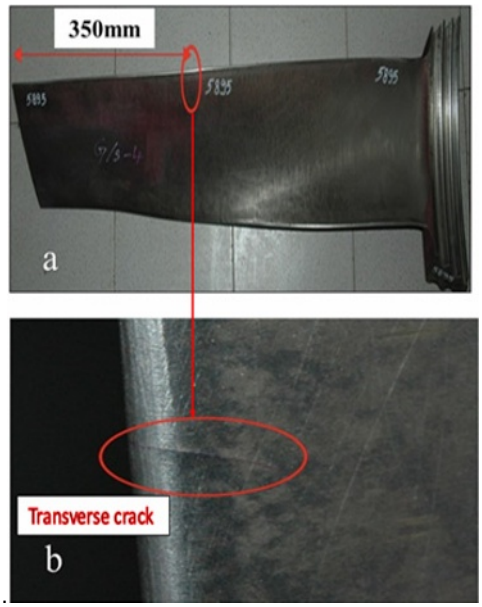

Fig. 1. Transverse crack on the airfoil-leading edge of the steam turbine blade.

Fig. 2. Sample cut at the cracked region for fractographic investigation.

TESCAN model accompanied with energy dispersive spectroscopy (EDS). Further, the hardness of the blade material was evaluated using the Vickers hardness test at a force of 0.5 kg for 10 seconds. And a tensile test was conducted to assess the mechanical properties of the blade material.

3. Results & discussion

3.1 Visual observations

On visual examination, a transverse crack of around 20-25 mm is observed at a distance 350 mm away from the blade's tip, which propagates from the leading edge towards the trailing edge as shown in Fig. 1. Regions of black patches i.e. iron oxide (Fe_3O_4) are also found on the blade's surface from tip to root of the blade as shown in Fig. 3 and presence of iron oxide (Fe_3O_4) can make the blade material weak and ductile. Further, water droplet erosion creates erosion pits on the airfoil-leading edge but these are away from the transverse crack as shown in Fig. 4, which concludes that the erosion pits are not the reason for the failure of the blade.

3.2 Chemical analysis

An optical emission analyzer was used to identify the chemical makeup of the blade material. The result of the chemical composition of X10CRNIMOV 12-2-2 is tabulated in Table 1. Chemical testing results reveal that the turbine blade material corresponds with AISI 410-grade martensitic steel.

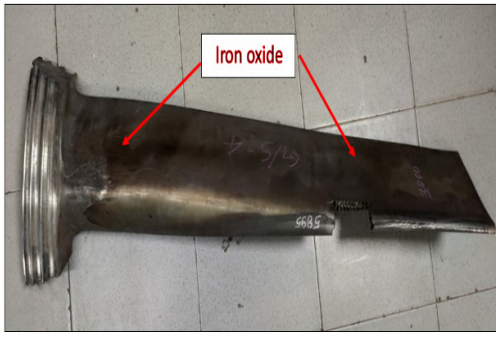

Fig. 3. Black patches iron oxide (Fe_3O_4) observed on the blade's surface.

Fig. 4. Erosion pits at the blade airfoil-leading edge.

3.3 Microstructure analysis

Optical microscope is used to identify the microstructure of the blade material. Figs. 5(a) and (b) presented the microstructures of blade material at 100x and 200x respectively. In the observed microstructures hardened and tempered martensite is uniformly distributed and showed no signs of microstructural deterioration. The blade specification corresponds with the X10CRNIMOV12-2 alloy.

3.4 SEM analysis

For scanning electron microscopy (SEM) the specimen was prepared from the cracked region of the steam turbine blade as shown in Fig. 6. SEM of the specimen was carried out by using a VEGA3 TESCAN MODEL equipped with an EDS facility. For fractographic analysis, the specimen is divided into three regions viz. R1, R2 & R3 as shown in Fig. 6(b). The fractographic results of region R1 are shown in Fig. 7, which depicts corrosion pits. The environment-assisted cracking of LP steam turbine blades usually begins from corrosion pits. The corrosion pits act as stress concentrators or stress raisers; When a blade is in operation, it experiences cyclic loading due to the rotational forces and the steam flow. These cyclic loads can cause small cracks to initiate at the corrosion pits due to the local stress concentrations. Over time, these cracks can grow and eventually lead to a catastrophic failure of the blade. The presence of corrosion pits can also reduce the fatigue life

of the blade by reducing the thickness of the material at the pit. This reduction in thickness can increase the stress level in the material at the pit, making it more susceptible to crack initiation and propagation.

The SEM analysis result of the R2 region shown in Fig. 8, depicts the intergranular failure mode. The results of the SEM

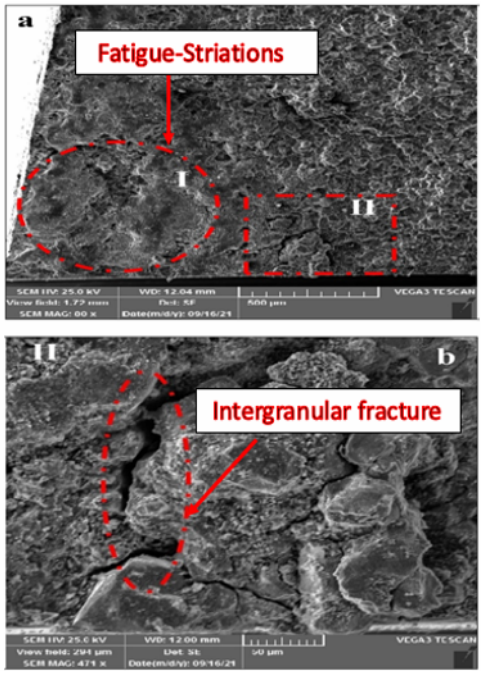

Fig. 9. (a) SEM analysis of the R3 region represents the beach marks and fatigue striations followed by the intergranular fracture; (b) the magnified view of intergranular fracture.

analysis of the R3 region are shown in Figs. 9(a) and (b), representing the beach marks and fatigue striations followed by the intergranular fracture. Fatigue striations are microscopic lines or ridges that form on the surface of a material as a result of repeated cycles of stress. Fatigue striations and intergranular fractures on a low-pressure steam turbine blade can be caused by a number of factors, including material defects, stress concentrations, and cyclic loading. The fatigue striations also show that the crack propagates toward the blade's trailing edge.

3.5 EDS analysis

EDS analysis was performed on the R1 region as shown in Fig. 12. The results of the EDS analysis confirm the presence of chlorine, silicon, oxygen, and other corrosion-promoting products. Silicon and oxygen combine together to form SiO_2

Table 2. Hardness values (HV) at a different location on the blade surface.

Distance from the fracture surface (mm)	Hardness (HV)
0.5	492.43 HV0.5
1	466.63 HV0.5
1.5	416.89 HV0.5
2	395.08 HV0.5

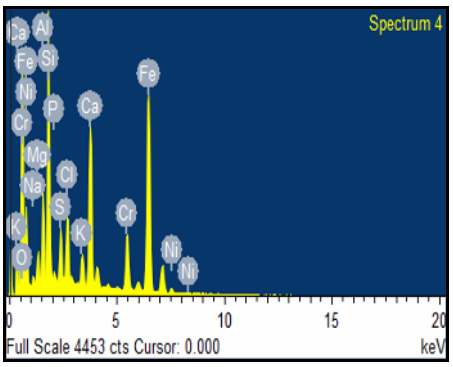

Fig. 10. EDX analysis of the fractured surface of the blade for the R1 region.

particles, which repeatedly strike the blade material and form deposits that create grooves/pits in the blade material and distort the steam passage. The pits penetrated the material, causing localized stress concentrations leading to fatigue cracks. The presence of foreign particles in the steam further exacerbated the problem by providing additional stress concentrations. The corrosion fatigue cracks frequently initiate from corrosion pits, especially when chlorine and oxygen are present & propagate under cycling loading. It is clear from the above findings that corrosion fatigue might be the reason for blade failure.

3.6 Hardness

A hardness test was conducted on a Vickers hardness testing machine near the failed region of the blade. A force of 0.5 kg was applied on the surface of the blade material for 10 seconds as shown in Fig. 11. The results of the hardness test are tabulated in Table 2. And plotted graphically as shown in Fig. 12. It is observed that the hardness is significantly higher on the blade's fracture surface. The increase in hardness of the blade material may be due to strain hardening, Improper heat treatment, contamination & aging factor that can make the material more brittle and could potentially reduce the fatigue strength of the blade material that leads the blade more prone to cracking or fracture under stress or cyclic loading.

3.7 Tensile test

Tensile tests were conducted on the blade's failed and unfailed regions of the blade. The stress-strain curve is shown in Fig. 13. The unfailed region of the blade has a yield strength of 530 MPa and an ultimate tensile strength of 865 MPa, while

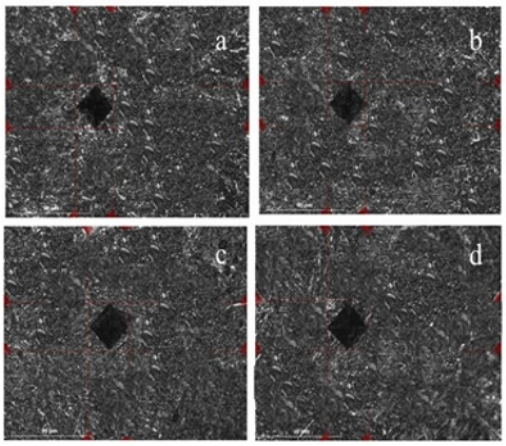

Fig. 11. Vickers hardness test of the blade material at a force of 0.5 kg for 10 seconds.

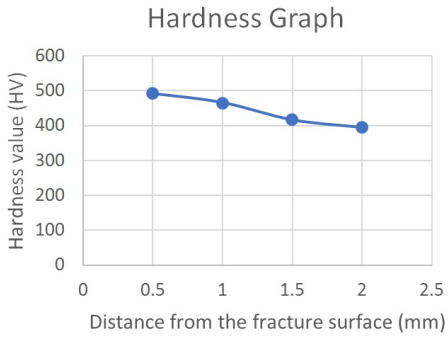

Fig. 12. Graphical plot of hardness value vs distance from the fracture surface.

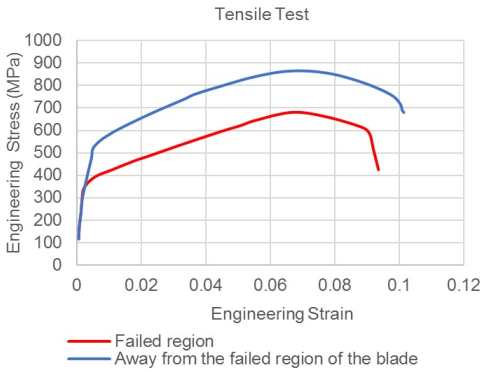

Fig. 13. Stress-strain curve for the failed and the unfailed region of the blade.

the failed region has a yield strength of 343 MPa and an ultimate tensile strength of 680 MPa. The reason for the lower value of the failed region is as it has undergone significant deformation and damage & which reduces the strength and ductility of the material.

4. Conclusions and suggestions

1) The microstructure observed by an optical microscope re-

vealed that hardened and tempered martensite blade microstructure is uniformly distributed and shows no signs of microstructural deterioration. From the findings it is determined that there is no material flaw that causes the turbine blade to fail.

2) Water droplet erosion produces erosion pits on the leading edge of the blade, but they are not near the transverse crack and cannot be considered the cause of the blade's failure.

3) The results of mechanical tests showed that the material's mechanical properties had deteriorated, with the material being more brittle due to an increase in hardness and a fall in ultimate tensile and yield stresses, respectively.

4) The presence of foreign particles and impurities in the steam such as chlorine, silicon, oxygen, and other corrosion-promoting products triggers the failure mechanism.

5) SiO_2 particles repeatedly strike the blade material and form deposits that create grooves/pits in the blade material and distort the steam passage. These pits can act as stress concentrators and increase the risk of fatigue failure.

6) The corrosion pits develop the region of stress-raiser as they form the stress concentration region & when the material is subjected to cyclic loading, cracks develop at the site of the corrosion pits. The crack is initiated & propagated towards the trailing edge. The intergranular fracture occurred, followed by fatigue striations. It has been determined that the failure of the steam turbine blade was attributed to corrosion fatigue failure.

5. Suggestions

1) The chance of pitting is increased by steam contamination which contains dissolved salts, chlorides, or other impurities and could raise the corrosion potential. Regular monitoring of steam quality can help detect contamination early. This can include the measurement of parameters such as conductivity, pH, and dissolved oxygen levels.

2) To enhance the fatigue life of low-pressure steam turbine blades. It is advised to use an appropriate coating or surface modification treatment, such as shot peening or metal-matrix composite coatings. MMCs can be typically applied using a thermal spray process, such as plasma spray or high-velocity oxy-fuel (HVOF) spray.

Nomenclature

LP : Low-pressure
CF : Corrosion fatigue
MPa : Mega pascal

***Abstract*— Symbol classification is a crucial task in many applications such as handwriting recognition, computer vision, Optical Character Recognition (OCR), etc. However, multiclass classification is an intensive task that requires high computational power and memory resources. In this paper Field-Programmable Gate Array (FPGA) based acceleration of a neural network for symbol classification has been implemented with hardware-optimised multiplication techniques. The approach involves using FPGA to perform faster multiplications and accumulation operations with reduced resource usage. The neural network is trained using MATLAB and then implemented in VHDL on Quartus Prime Lite. The multiplication is compared to the Karatsuba Multiplication technique and the Iterative Logarithmic technique. Based on the comparative study the Iterative Logarithmic technique proved to be the best to bring down the overall hardware usage. The final optimised design has been validated using ModelSim and then deployed on an Altera Cyclone® V SE FPGA device.**

Keywords — Symbol Classification, Neural Networks, FPGA, Karatsuba Multiplier, Iterative Logarithmic Multiplier

I. INTRODUCTION

Big Data, Machine Learning (ML), the Internet of Things (IoT) are among the data-intensive applications that are driving the demand for accelerators to offload work from general-purpose processors. There are numerous accelerators available, including Application-Specific Integrated Circuit (ASIC), Graphics Processing Unit (GPU), and Field Programmable Gate Array (FPGA) devices.

Dedicated hardware acceleration can be implemented with high performance and flexibly with FPGAs. FPGA accelerators have become a popular choice in data centres over the past ten years because of their adaptability and programmable nature. These devices are a good solution for applications requiring real-time output and high portability, but due to their high cost, one must also consider optimising the design for deployment on relatively low-end hardware by implementing alternate modern techniques in accordance with the available resources at a lower cost.

FPGA-based acceleration of Neural Networks (NNs) has been a prevalent research topic in the past couple of years. In [1] the authors proposed a robust and re-configurable architecture for deploying ML algorithms. The paper implemented the architecture to design, train, and test the Back Propagation Neural Network using FPGA. The results showed that using an FPGA is faster but slightly less accurate. The framework implemented in [2] makes NN computable in FPGAs. The proposed framework reduced the required resources and increased the performance with different approximation techniques. In [3] a general NN algorithm was implemented on the XILINX ZU9CG FPGA SOC platform which showed an outperformance in energy efficiency and real-time computation.

FPGA-based acceleration is an effective and efficient solution for solving the Artificial Intelligence (AI) and ML problems of the real–world. In [4] NN was created to identify and classify handwritten digits using the Modified National Institutes of Standards and Technology (MNIST) dataset. The network was trained and tested on this dataset. The hardware implementation of the network was accomplished through the use of Vivado High-Level Synthesis (HLS) software, which involved programming in Verilog. In reference [5], a neural network was used to recognize handwritten digits. The network was tested using 100 samples from the MNIST database, and it was simulated on the Quartus II 13.0 and Modelsim FPGA development platforms. Using hardware-based acceleration gives a huge enhancement in computing speed but this happens by using more complex and expensive digital designs of FPGA devices with sufficient resources [6].

In [7] 70% accuracy was achieved for the forest fire detection method through NN by processing the data from several sensors. A low-cost Convolutional Neural Network (CNN) based real-time Traffic Sign Recognition hardware accelerator was proposed in [8] by the authors, which enables the vehicle to recognize road signs using a camera and assist the driver. In [9] authors have implemented a single switch

Jerk chaotic oscillator prediction model based on Feed Forward NN on Intel Cyclone IV.

One of the main challenges in implementing neural networks on FPGAs is reducing computational complexity while maintaining accuracy. The basic arithmetic units required for a neuron unit are adders and multipliers. While addition can be implemented with very low complexity, multiplication is complex. Efficient architectures require low complexity and fast multipliers.

Some of the papers have proposed hardware-optimised algorithms like Karatsuba, Dadda, Iterative Logarithm, etc. In [10], the author proposed an FPGA-based modified Karatsuba Multiplier which was 26.5% faster than the traditional Karatsuba multiplier. The authors in [11] proposed a new method to improve the accuracy and performance of iterative logarithmic multiplier based on Mitchell's algorithm. The authors in [12] claim that the hardware implementation of an iterative logarithmic multiplier uses only one adder and some shifters, which results in reduced usage of total logic resources.

To the best of our knowledge, the implementation of the Neural Network based symbol classifier using an iterative logarithmic multiplier for FPGA-based hardware acceleration has not been implemented yet. In this paper, we propose FPGA-based acceleration of symbol classification Neural Network and compare different multiplier implementation techniques for FPGA-based applications, based on their hardware usage while preserving the accuracy of the model.

II. Problem Statement

We consider an input image of size 1280x720 pixels comprising multiple instances of four types of symbols. The NN Model designed would be able to identify the four symbols as shown in Fig. 1 and label them by assigning them different colours.

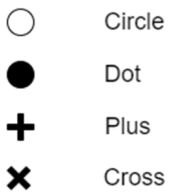

Fig. 1. Input Symbols

As the multiplication was resource-intensive, alternative multiplying algorithms were explored. The most effective multiplier technique is then employed to deploy NN over FPGA based on the comparative study of multipliers.

III. Methodology

The overall system involves various stages as shown in Fig. 2. The implementation of the project starts with training of the NN using MATLAB for obtaining the weights and biases. These are then used for the VHDL implementation that can be deployed on an FPGA board, after optimising the circuit design.

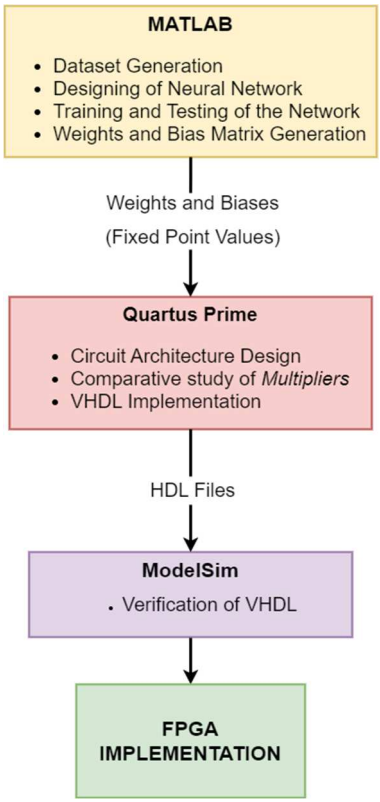

Fig. 2. System Model

A. Generation of Training Dataset

An artificial NN as shown in Fig. 3 is trained using input images that have a size of 7x7 pixels. Every image is transformed into a matrix of pixel values. Each pixel's value ranges from 0 (black) to 255 (white). In order to expand the training dataset, pixel shifting has been performed on all training images to cover cases where only partial symbols are present in the input image region. This resulted in the expansion of the dataset to 200,000 images.

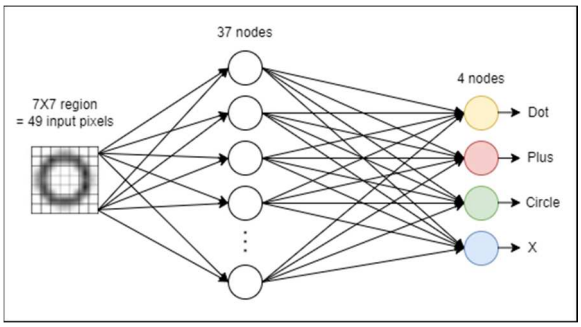

Fig. 3. Neural Network

B. Designing, Training & Testing of NN

A fully connected feed-forward CNN was designed and trained on MATLAB with one hidden layer containing 37 nodes (Fig.3). Sigmoid function is used as the activation function in the CNN.

The parameters of the Neural Network used are listed in Table I.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:23:09 UTC from IEEE Xplore. Restrictions apply.

TABLE I. NEURAL NETWORK PARAMETERS

S No.	Neural Network Parameters	Values
1.	Number of layers	3 (Input, 1 hidden, output layer)
2.	Input Layer Nodes	49 nodes
3.	Hidden layer	37 nodes
4.	Output layer	4 nodes
5.	Epochs	400
6.	Learning Rate	0.00001
7.	Activation Function	Sigmoid

Here, 37 nodes in the hidden layer are calculated via the Rule of Thumb (⅔ of input nodes plus output nodes). Four nodes in the output layer correspond to the four symbols.

C. Circuit Architecture

Once the training is performed on MATLAB, two matrices are generated. These matrices consisted of weights and biases for input to the hidden layer and for hidden layer to the output layer. Both of these matrices are converted to a fixed-point representation and then a VHDL file is generated for the FPGA implementation.

The NN is implemented in VHDL using Quartus Prime Lite. The input image can be RGB which is converted to grayscale using the luminance technique, with each pixel value being represented by an 8-bit number (0-255). The grayscale image is stored using a memory unit. The input image is divided into portions of 7x7 pixels and traversed using registers. Once the 1280th pixel is reached, shift a line vertically until all 720 lines are covered as the size of the input test image taken is 1280x720 pixels.

The circuit architecture for the first layer with 49 input signals is shown in Fig. 4. The 7x7 section of the image is stored and given as input to the neural network using seven line memories (LM) having six registers (R) each, for introducing appropriate delay, and one direct connection. Then all 49 input values are fed into the 37 hidden layer neurons.

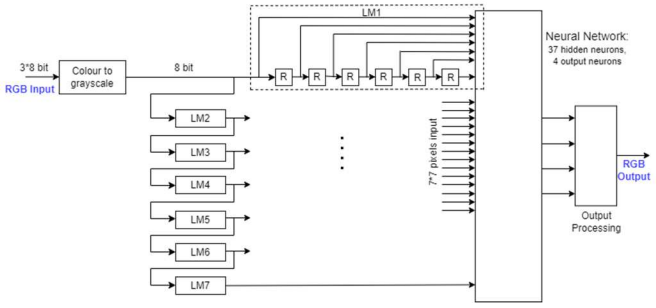

Fig. 4. Circuit Architecture Design

Fig. 5 shows the neuron structure where we get the input signals (x1, x2, x3), then multiply them with their respective weights (w1, w2, w3), add the bias, and send it to the sigmoid function (in ROM) that gives the output value in the range of 0 to 1. The model described in this paper gives out four values for each input section of 7x7. These four values correspond to the four different symbols, only one of these values is greater than 0.5 which helps the model to declare the final classification result.

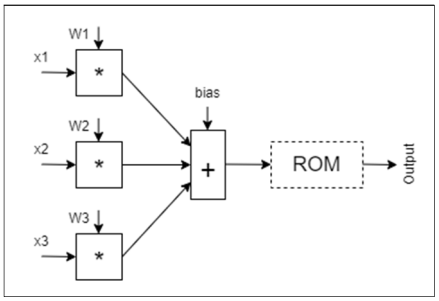

Fig. 5. Neuron Structure

D. Multiplier Techniques

The traditional multiplier is implemented using DSP blocks, if available, but in ML applications the number of multipliers required is high so to optimise this Karatsuba Multiplier and Iterative Logarithmic Multiplier have been implemented, and compared in terms of hardware usage. The algorithm behind these multipliers has been discussed below -

1. *Karatsuba Multiplier:*

The Karatsuba multiplier is an algorithm used for the fast multiplication of large numbers. The basic idea behind the Karatsuba multiplier is to divide a large number into smaller parts and perform some simple arithmetic operations mentioned below on these parts and then recombine the results to get the final answer.

The multiplication of two integers *'x'* and *'y'* using Karatsuba multiplier can be done as follows:

$$Divide\ x\ into\ x_H,\ x_L$$
$$Such\ that\ x = x_H z^{\frac{n}{2}} + x_L$$
$$where\ z = 10\ (in\ case\ of\ integers)$$
$$and\ n = Number\ of\ Digits$$
$$Similarly, y\ can\ be\ divided\ into\ y_H,\ y_L$$
$$Let \quad D_0 = y_L x_L \quad (1)$$
$$D_1 = y_H x_H \quad (2)$$
$$D_2 = (y_L + y_H)(x_L + x_H) - y_L x_L - y_H x_H \quad (3)$$
$$p = D_1 z^n + D_2 z^{n/2} + D_0 \quad (4)$$

where p is the final product

Time complexity of Karatsuba multiplier:

$$O(n^{log_2 3}) = O(n^{1.59})$$

Time complexity of traditional multiplier:

$$O(n^2)$$

where n is the number of digits in the two numbers being multiplied.

2. *Iterative Logarithmic Multiplier:*

Mitchell algorithm-based iterative logarithmic multiplier is a type of digital logic circuit that can iteratively perform the operation of multiplication, using logarithmic processing techniques. The basic idea behind this circuit is to perform the multiplication of two numbers by successively shifting and adding, rather than using traditional methods such as a lookup table or an array of full adders. The multiplication method for two integers N_1 *and* N_2 is as follows:

$$Product\ (P) = N_1 N_2$$

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:23:09 UTC from IEEE Xplore. Restrictions apply.

The binary representation of any integer number:

$$N = 2^k(1+x) \quad (5)$$

where x is the fractional part.

$$log_2 N = k + log_2(1+x) \quad (6)$$

The logarithm of the multiplication of N_1 and N_2:

$$log_2(N_1N_2) = log_2(N_1) + log_2(N_2) = k_1 + log_2(1+x_1) + k_2 + log_2(1+x_2) \quad (7)$$

The expression $log_2(1+x)$ is approximated by x and the logarithm of the product of two numbers is expressed as the sum of their characteristic numbers and mantissa:

$$log_2(N_1N_2) = k_1 + x_1 + k_2 + x_2 \quad (8)$$

$$N_1N_2 = 2^{k1+k2}(x_1+x_2) \quad when\ x_1+x_2 >= 1$$
$$N_1N_2 = 2^{k1+k2}(1+x_1+x_2) \quad when\ x_1+x_2 < 1 \quad (9)$$

The proposed MA-based multiplication produces a significant error percentage. The authors in [12] proposed an iterative algorithm to reduce the error as much as possible and obtain accurate results. From the binary representation of numbers in (5), we can derive a correct expression for multiplication (P_{true}):

$$P_{true} = N_1N_2 = 2^{k1}(1+x_1).\ 2^{k2}(1+x_2) = 2^{k1+k2}(1+x_1+x_2)+2^{k1+k2}(x_1.x_2) \quad (10)$$

To avoid the approximation error, we have to take into account the next relation derived from (5):

$$x.2^k = N - 2^k \quad (11)$$

Therefore,

$$P_{true} = N_1N_2 = 2^{k1+k2} + (N_1 - 2^{k1})2^{k2} + N_2.2^{k1} - 2^{k2+k1} + (N_1 - 2^{k1}).(N_2 - 2^{k2}) \quad (12)$$

Let,

$$P^{(0)}_{approx} = 2^{k1+k2} + (N_1 - 2^{k1})2^{k2} + (N_2 - 2^{k2})2^{k1} \quad (13)$$

be the first approximation of the product. It is evident that

$$P_{true} = P^{(0)}_{approx} + (N_1 - 2^{k1}).(N_2 - 2^{k2}) \quad (14)$$

We can calculate $P^{(0)}_{approx}$ and repeat the procedure until the exact result is obtained.

The absolute error after the first approximation is:

$$E^{(0)} = P_{true} - P^{(0)}_{approx} = (N_1 - 2^{k1}).(N_2 - 2^{k2})$$
$$E^{(0)} = C^{(1)} + E^{(1)} \quad (15)$$

where C(1) is the approximate value of E(0) and E(1) is an absolute error when approximating E(0).

$$P_{true} = P^{(0)}_{approx} + C^{(1)} + E^{(1)} \quad (16)$$

We can now add the E(0) estimate to the product approximate P_{approx} as a correction term with which we can reduce the error in approximation.

$$P^{(1)}{}_{approx} = P^{(0)}{}_{approx} + C^{(1)} \quad (17)$$

By repeating this multiplication procedure for i correction terms, the product can be approximated as:

$$P^{(i)}{}_{approx} = P^{(0)}{}_{approx} + C^{(1)} + C^{(2)} + \ldots + C^{(i)} = P^{(0)}{}_{approx} + \sum_{j=1}^{i} C^{(j)} \quad (18)$$

Time complexity of iterative logarithmic multiplier:

$$O(log(n))$$

Time complexity of traditional multiplier:

$$O(n^2)$$

where, n is the number of digits in the two numbers being multiplied

Hence, different multiplication algorithms were compared so that the designed model can fit on the selected FPGA board, i.e. *DE0-Nano-SoC (Altera Cyclone® V SE 5CSEMA4U23C6N device).*

IV. Results

Accuracy and Cost were calculated and graphs were plotted after the NN training was completed in MATLAB. Accuracy calculation was done by calculating the fraction of correct predictions upon total predictions. In Fig. 6 we can see that the accuracy gradually increases with increasing epochs and settles around 96.3%.

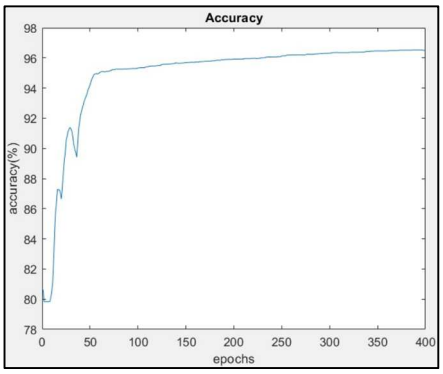

Fig. 6. Accuracy Graph

The cost function calculates the mean squared error in the predictions made.

$$L_{square}(\hat{y}, y) = (\hat{y} - y)^2 \quad (19)$$

$$Cost(f, D) = \frac{1}{n}\sum_{i=1}^{n} L(\hat{y}_i, y_i) \quad (20)$$

where, L_{square} = Loss function

$\hat{y}_i$ = Predicted value

y_i = Actual value

When the cost is plotted against epochs in Fig. 7, it can be observed that the cost function comes down to 0.042, which is an acceptable value.

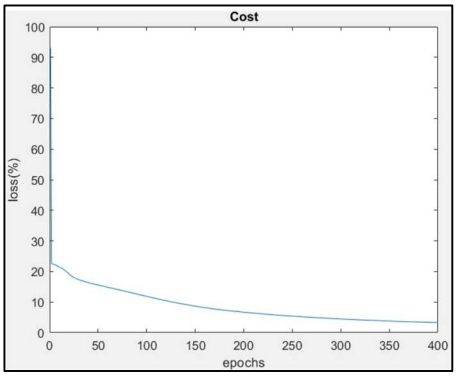

Fig. 7. Cost Graph

As mentioned earlier, all three multiplication techniques were implemented and compiled, and the results have been reported in TABLE II. The number of available resources in the selected FPGA Board were:
Adaptive Logic Modules (ALMs)= 15,880
Total Digital Signal Processing (DSP) Blocks = 84

Further fitter analysis was done to make sure the target device's resources could support the logic and time requirements of the design. Only one of the three techniques i.e. Iterative Logarithmic multiplier, was able to successfully fit on our chosen FPGA board, as shown in Table II.

TABLE II. COMPARATIVE STUDY

MULTIPLIER TECHNIQUE	Resources Required			Fitter Result
	ALMs	*Total Registers*	*DSP Blocks*	
Traditional	12344	11288	252	Unsuccessful
Karatsuba	28201	13953	235	Unsuccessful
Iterative Logarithmic	9336	12430	0	Successful

From the study, we can observe that an iterative logarithmic multiplier can be used for reducing the number of hardware resources required, especially when there are a few or no DSP blocks present. As a result of this reduction in resource usage, the model was able to successfully fit on the selected Cyclone V FPGA board. Earlier the model was able to do so just for Cyclone 10 series boards, which are highly expensive and advanced. Once the fitter analysis was complete for a synthesised design, Modelsim Simulation was launched using the testbench, with an input test image (1280x720 pixels) of which a small section is shown in Fig.8.The expected Classification Results (colour coded):

- Circle => Green
- Dot => Yellow
- Plus => Red
- X => Blue

Output image of the section shown in Fig. 8 can be seen in the Fig. 9.

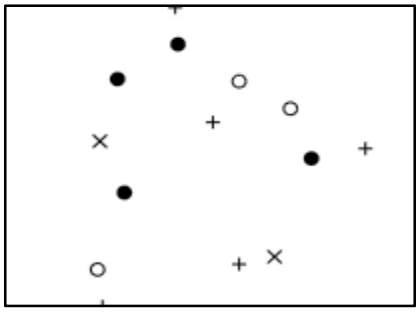

Fig. 8. Section of Input Image

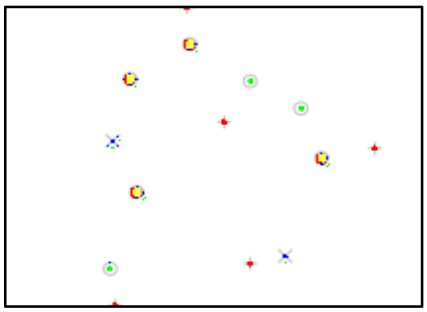

Fig. 9. Section of Output Image

V. CONCLUSION

This paper has presented an FPGA-based acceleration of NN for symbol classification with hardware-optimised multiplier implementations. After successful implementation and comparison of multipliers, it was found that the Iterative Logarithmic multiplier gives the best results as it uses equivalent ALMs compared to the default but it doesn't use any DSP Blocks, which helps in deploying the model on an FPGA board with few available resources. The experimental results show that the proposed approach significantly enhances the speed and efficiency of symbol classification tasks, making it suitable for real-time applications with limited computational resources.

Abstract

Occurrence of mycotoxins in food samples threat to its safety issue due to the presence of high toxicity and carcinogenic behavior, thus requiring highly sensitive and selective detection. Herein, the trimanganese tetraoxide (Mn_3O_4) nanoparticles in combination with graphene oxide (GO) nanocomposite were used to enhance the electrochemical performance for fabrication of electrochemical biosensor for fumonisin B1 (FB1) detection. The various characterization tools were used to validate the fabrication of GOMn_3O_4 nanocomposites. To fabricate the electrochemical biosensor on an indium tin oxide (ITO) coated glass substrate, a thin film of GOMn_3O_4 nanocomposite was prepared using electrophoretic deposition (EPD) technique, and antibodies (ab-FB1) were immobilized onto the electrode for selective FB1 detection. The differential pulse voltammetry (DPV) technique was used to observe the sensing performance. The non-binding sites of the ab-FB1 on the immunoelectrode were blocked with bovine serum albumin (BSA). The biosensor electrode was fabricated as BSA/ab-FB1/GOMn_3O_4/ITO for the detection of FB1. The sensitivity of the biosensor was obtained as 10.08 μA mL ng^{-1} cm^{-2} in the detection range of 1 pg mL^{-1} to 800 ng mL^{-1} with a limit of detection (LOD) of 0.195 pg mL^{-1}. In addition, the recovery of BSA/ab-FB1/GOMn_3O_4/ITO immunoelectrodes was also performed on sweet corn samples and is calculated to be 98.91%.

Keywords: Biosensor; graphene oxide; nanocomposite; immunoelectrode; and fumonisin B1.

Accepted Manuscript

1. Introduction

The occurrence of mycotoxins in food items is a global challenge for food contamination, and it is considered as important toxin that affect onto human and animal health. Mycotoxins are naturally occurring organic toxic compounds that are produced by secondary metabolites of fungi such as *Aspergillus*, *Penicillium*, *Fusarium*, *Claviceps,* etc. in food and feed products [1,2]. Annually, 25% of the agricultural harvested crops are contaminated by mycotoxin and causing huge economic loss and responsible for several acute and chronic diseases worldwide. Among the presence of various mycotoxins, fumonisin B1 (FB1) is one of important mycotoxin that predominates in 70% of total FBs, naturally produced by fungi *Fusarium verticillioides* and *Fusarium proliferatum* are occurred in many food and feed products e.g. peanuts, maize-based products, and cereal-based products, etc. [3,4]. FB1 has also been designated as a carcinogen by the International Agency for Research on Cancer (IARC), placing it in the class 2B group of human carcinogens. The toxicity of FB1 causes several health issues such as brain damage, lung, and kidney failure, etc. [5]. Thus, the research on the detection of FB1 has become very important.

There are several analytical techniques available for detecting FB1 mycotoxin. Mainly these techniques belong to conventional tools such as gas Chromatography-Mass Spectrometry (GCMS) [5], enzyme-linked immunosorbent assay (ELISA) [6], high-performance liquid chromatography (HPLC) [7], liquid chromatography-mass spectrometry (LCMS) [8] and polymerase chain reaction (PCR) [9], etc. These techniques are sensitive, specific, and selective toward their analytes. However, these techniques have several disadvantages such as being sophisticated, requiring more samples for detection, very tedious processing, and more importantly, requiring a well-trained person to operate the system. To overcome the aforementioned difficulties, an electrochemical biosensor is a very promising tool for detecting analytes at very low concentrations and has several advantages over conventional techniques.

Nanomaterials have been considered a great interest in the application of sensors or biosensors development. Among a variety of nanomaterials, graphene-based nanomaterials have emerged as the most advanced materials for sensing applications

Accepted Manuscript

due to their enhanced signal response. Graphene-based nanomaterials provide a large surface area and excellent biocompatibility with a wide range of biomolecules such as proteins, cells, DNA, enzymes, and antibodies [9]. Graphene also has high electrical conductivity, high electron transfer rates, and the ability to immobilize various molecules [10]. Graphene-based biosensors also offer extremely high sensitivity, stability, and fast response times, leading to advances in healthcare and diagnostics.

Manganese-based materials have unique redox properties which give significant importance in the applications related to energy, environment, and biomedical fields [11] Mn_3O_4 nanomaterial is also known as the oxidizing and reducing agent, and it is a spinel-structured stable oxide with unique catalytic, electrochemical, and magnetic properties. It is a p-type semiconductor having a larger bandgap of 2.3 eV which provides supercapacitor properties to it [12]. It has several physical properties like thermodynamic stability, high electrochemical conductivity, chemical stability, paramagnetic behaviour, etc [13,14]. Mn_3O_4 is the unique phase of manganese oxide nanomaterial which is explored in various applications such as excellent supercapacitors, high-density magnetic storage devices, high charge carrier mobility, good biocompatibility, etc [14,15]. Moreover, Mn_3O_4 nanomaterial exhibits distinguished properties like environmental compatibility and cost-effectiveness. However, the Mn_3O_4 phase of manganese oxide is biologically less explored. Graphene oxide (GO) sheet has more functional groups on its basal plane and edges, and it results in the enhancement of the loading amount of Mn_3O_4, surface area, and porosity [16]. GOMn_3O_4 nanocomposite exhibits higher energy density and specific capacitance as compared to GO, while larger specific capacitance and power density as compared to Mn_3O_4. The nanocomposites of nitrogen doped GO and manganese oxide for photodynamic therapy magnetic resonance imaging of cancer cells without affecting the normal tissue. Their results of cell viability analysis showed the significant cell death under laser irradiation. The elemental composition of GOMn_3O_4 nanocomposites showed intense signals which showed that the 'Mn' was the major element showing the optical absorption [17]. Furthermore, Chen et al. developed nanocomposites of reduced graphene oxide wrapped Mn_3O_4 as anode materials for high-performance lithium ion batteries which showed the specific capacity of 795.5 mA hg^{-1} after 200 cycles. The

Accepted Manuscript

nanocomposites showed the excellent cyclic performance and good electrochemical activity [18].

Several research groups have reported various methods for detecting mycotoxins. For instance, Ahmed et al recently developed an electrochemical biosensor for detecting the naturally occurring histamine based on the molecularly imprinted polymer using the gold inverse opal electrode and the detection limit of 1.07 μM [19]. Dhiman et al developed the silver-cerium oxide (Ag-CeO_2) nanocomposite-based electrochemical biosensor for FB1 detection [20]. Furthermore, Singh et al developed a molecularly imprinted polymer-based electrochemical sensing tool for FB1 detection [3]. Alsulami et al developed a homogeneous luminescence immunoassay for FB1 detection [21]. Zhang et al developed graphene and gold nanocomposites based on label-free DNA for the detection of FB1 [22]. In recent years, Mao et al developed GO-CdS heterojunctions based on an ultrasensitive molecularly imprinted photoelectrochemical sensing platform for detecting FB1 [23]. Wu et al developed the fluorescence resonance energy transfer (FRET) system for the detection of FB1 [24]. Jodra et al developed the electrochemical magneto immunosensor involving magnetic beads for the detection of fumonisins [25]. For the detection of FB1, Lu et al created a competitive fluorescence enzyme-linked immunosorbent test based on the quenching of cadmium telluride (CdTe) quantum dots [26]. Yang et al created an electrochemical immunosensor using single-walled carbon nanotubes and chitosan to detect FB1 in corn samples [27]. Chen et al created a colloidal gold-based lateral flow immunoassay using modified gold nanobeads to detect FB1 [28]. Furthermore, Qu et al created a magnetic beads-assisted fluorescence aptasensing method to detect FB1 [29]. Table 1 shows comparison data between current work and previously reported results for FB1 detection.

Herein, simple and sensitive electrochemical immunosensor was fabricated for the detection of FB1 mycotoxins using GOMn_3O_4 nanocomposite. This nanocomposite was synthesized at room temperature which is robust and cost-effective. The phase and crystallinity of the synthesized GOMn_3O_4 nanocomposite were observed by XRD and Raman spectroscopy. The immunosensor was fabricated onto the ITO glass substrate using a GOMn_3O_4 film by an EPD method, which was used for the immobilization of

Accepted Manuscript

antibodies (ab-FB_1). The non-specific binding sites of antibodies were blocked by the BSA protein. The fabricated immunosensor (BSA/ab-FB1/GOMn_3O_4/ITO) showed a wide detection range as a function of FB1. Here, results suggest that the newly designed immunosensor is robust, cost-effective, sensitive, selective, and selective towards FB1.

2. Experimental Section

2.1 Material used

Graphite powder (20-micron), hydrochloric acid (HCl), orthophosphoric acid (H_3PO_4), potassium permanganate ($KMnO_4$), sulfuric acid (H_2SO_4) FB1-specific ab-FB_1, ochratoxin A (OTA), deoxynivalenol (DON), cellulose, fructose, starch, FB1, manganese (II) acetate tetrahydrate ($(CH_3COO)_2Mn.4H_2O$), sodium hydroxide (NaOH) was purchased from M/S Sigma Aldrich. The glass substrate coated with indium tin oxide (ITO) coated glass substrate was used with a sheet resistance of 10 Ω sq^{-1} having a thickness of 1.1 mm. Sodium phosphate monobasic anhydrous (NaH_2PO_4) and sodium phosphate dibasic dehydrate (Na_2HPO_4), N-ethyl-N-(3-dimethylamino propyl) carbodiimide (EDC), N-hydroxysuccinimide (NHS), sodium chloride, potassium chloride, BSA were purchased from SRL, India. Potassium ferricyanide [$K_3(Fe(CN)_6)$] and potassium ferrocyanide [$K_4(Fe(CN)_6)$] were obtained from Fischer Scientific. Deionized water resistivity of 18.2 MΩ.cm was purified by Millipore water purification assembly and used for the preparation of buffer and all other required solutions. Phosphate buffered solution (PBS, 0.2 M) was prepared containing 0.9% NaCl and 5 mM of redox probe $[Fe(CN)_6]^{3-/4-}$ with pH 7.0

2.2 Synthesis of GO

GO was synthesized by a modified Hummer's method using pure graphite powder (20 μm) [30]. In the typical procedure, 240 mL of H_2SO_4 and 27 mL H_3PO_4 were mixed in a beaker under continuous magnetic stirring for 30 minutes. Then, 12 gram of $KMnO_4$ was added very slowly in small steps. The mixture was stirred using a magnetic stirrer for 15 hours until the solution became dark green. After this, 2 mL of H_2O_2 was slowly added dropwise and stirred for 30 minutes. The ice was placed outside to prevent heating due to the occurrence of an exothermic reaction. Then, it was allowed to cool down. After this, the mixture was washed several times with (70%) distilled water and

Accepted Manuscript

(30%) HCl and centrifuged using Remi Make Eppendorf centrifuge at 400 rpm for 10 minutes. Then supernatant was decanted away and was rewashed again and again until the pH reached to 7. The washed GO solution was dried using a vacuum oven at 60 ^{o}C for 24 hours and powder of GO was collected.

Synthesis of Mn_3O_4 nanoparticles

The Mn_3O_4 nps were synthesized using the co-precipitation method [31]. In the typical synthesis, 0.2 M of ($(CH_3COO)_2Mn.4H_2O$) and 0.5 M of NaOH were used as precursors. NaOH was added dropwise to manganese acetate using constant magnetic stirring of 800 rpm at room temperature until the pH of the solution reached~12. Then the precipitate was filtered out and washed many times using the distilled water until the pH of the solution reached 7. The obtained precipitate was then dried at room temperature using the vacuum oven.

Synthesis of GOMn_3O_4 nanocomposite

The GOMn_3O_4 nanocomposite was synthesized using the one-step *in-situ* preparation process [32]. GOMn_3O_4 nanocomposite was prepared in the presence of GO. In the typical synthesis, 200 mg of GO was mixed in 100 mL of distilled water at room temperature and sonicated. Then dispersed GO was added slowly to the solution containing 0.2 M manganese acetate, and 0.5 M reducing agent (NaOH) until the completion of the reaction. The obtained pH of the solution reached~12. Then the precipitate was filtered out and washed several times until the value of pH reached to 7. The obtained precipitate was then dried at room temperature using the oven and collected in a vial GOMn_3O_4 nanocomposite.

2.3 Characterization Techniques

DC power supply of 60V was used to fabricate thin film of nanocomposite on the ITO glass substrate. The crystallinity of GOMn_3O_4 nanocomposite was investigated using an X-ray diffraction (XRD) spectrometer (PANalytical Model X'pert Pro with Cu K_α radiation at λ = 1.5406 Å). The working voltage was 45 kV and the current was 40 mA. The XRD patterns were recorded in the range of 10^{o} to 80^{o} with a step size of 0.033^{o} and

Accepted Manuscript

a scan rate of 2° per minute. The Raman spectra were captured using the Alfa 300 witec Raman spectrometer with 532 nm laser. A JEOL 2100F High Resolution Transmission Electron Microscopy (HR-TEM) with a 200 KV accelerating potential was used to capture images. The Carl-Zeiss EVO40 was used to study the energy dispersive X-ray (EDX) spectra of the nanocomposite. Nova nano FE-SEM-450 was used to capture the Field-emission scanning electron microscopy images (FE-SEM) of the graphene, and the nanocomposite. Fourier Transform Infra-red (FTIR, UATR TWO) spectroscopy of Perkin Elmer was used for the investigation of the vibrational spectra of graphene, and the nanocomposite. The electrochemical analyzer (Autolab-AUT-Metrohm) was used to investigate the electrochemical characteristics (AUT86014) in a three electrode system composed of ITO as a working electrode, Platinum as a counter and Ag/AgCl as a reference electrode PBS containing 5 mM $[Fe(CN)_6]^{3-/4-}$.

2.4 Thin film fabrication of $GOMn_3O_4$/ITO electrode using EPD Technique

Glass surface coated with ITO electrode were first hydrolyzed using the mixture of H_2O:NH_3:H_2O_2 in the ratio of 5:1:1 to enhance the hydrophilic nature of ITO coated glass and kept in the oven for about 1 hour at 80°C. Then the ITO coated glass substrates were washed with a mixture of ultra-pure water and ethanol and dried at 60 °C for about 1 hour. These hydrolyzed ITO-coated glass substrates were further used for the fabrication of immunosensor for FB1 detection. For this, synthesized $GOMn_3O_4$ nanocomposite was deposited onto the ITO coated electrode using EPD technique. The EPD method constitutes an economical, eco-friendly, low-energy-consuming alternative to the high energy consuming evaporative techniques [33]. To obtain uniform film of $GOMn_3O_4$ onto ITO surface**,** 5 mL of $GOMn_3O_4$ solution was mixed in a 3 mL acetonitrile solution then deposited onto ITO surface by applying an optimized D.C. 60 volt for 5 minutes to obtain smooth and uniform thin films.

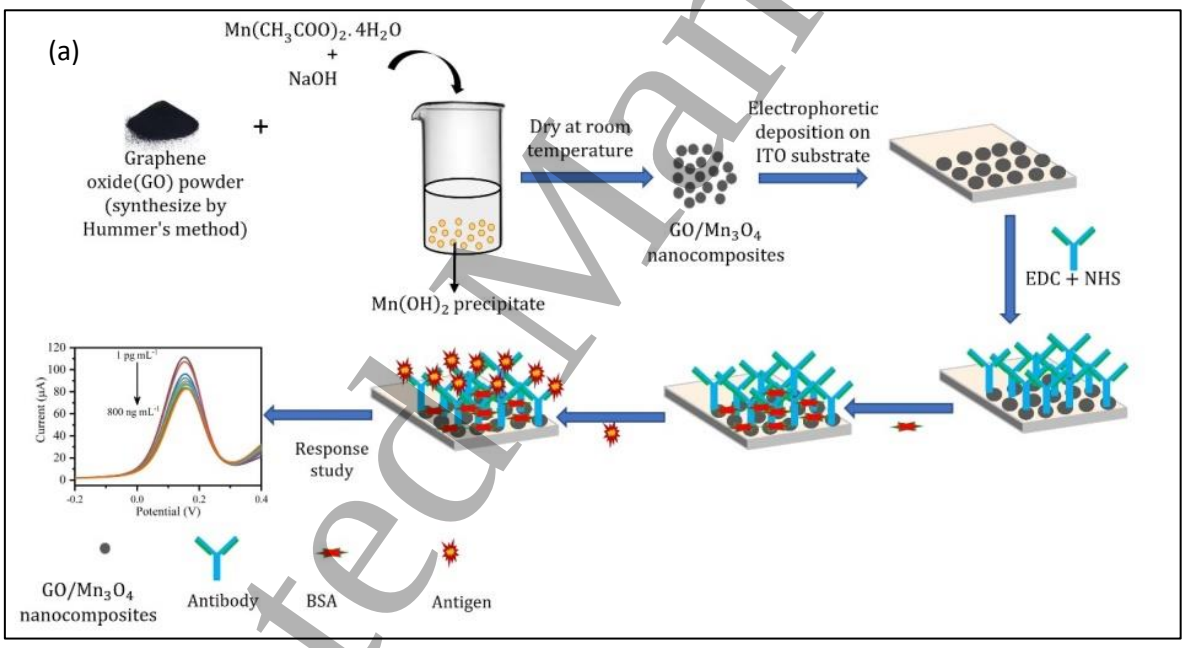
2.5 The fabrication process of Immunoelectrode

A solution of 5% ab-FB1 (in sodium phosphate buffer), EDC (0.4 M), and NHS (0.1 M) were synthesized in a 2:1:1 ratio and placed at 4 °C for 1 hour. For the immobilization process, 20 mL of a solution of activated EDC-NHS was evenly dropped onto the surface of the $GOMn_3O_4$/ITO electrode and placed at room temperature in a humidity

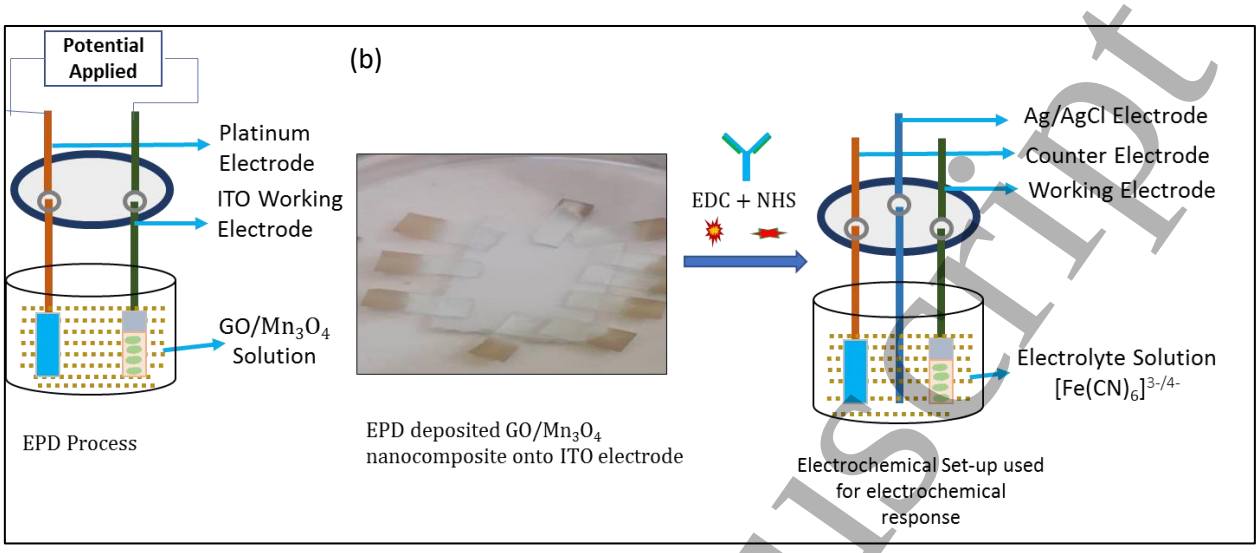
Accepted Manuscript

chamber for 6 hours. The positively charged GOMn_3O_4 nanocomposite and the carbonyl group of ab-FB1 create an electrostatic interaction that leads to the formation of metal ester bonds.

PBS was used to clean the ab-FB1/GOMn_3O_4/ITO bioelectrode surface to remove the unbound ab-FB1 (pH 7.0). Non-specific sites on Ab-FB1/GOMn_3O_4/ITO bioelectrode were blocked with BSA (10 mL), and incubation was initiated at room temperature for 4 hours in a humidifying chamber. PBS with a pH of 7.0 was used to rinse the BSA/ab-FB1/GOMn_3O_4/ITO immunoelectrode, which were then kept at 4°C for further study. The procedure for preparing the BSA/ab-FB1/GOMn_3O_4/ITO immunoelectrode is described in Scheme 1.



Accepted Manuscript



Scheme 1. (a) Schematic of synthesis of GOMn_3O_4 nanocomposite and fabrication of immunoelectrode on the ITO electrode surface for FB1 detection, (b) illustrates about the EPD set-up used for the EPD of GOMn_3O_4 nanocomposite onto ITO electrode surface under the applied voltage for a period of time followed by surface activation, immobilization and detection of FB1 using the electrochemical set-up of three electrode system comprised of working, counter and reference electrode.

3. Results and Discussions

3.1 Structural analysis of GOMn_3O_4 nanocomposite

Figure 1(a) shows the XRD of synthesized GO sheets. The characteristic intense peak appeared at 10.67° corresponding to the (001) plane and data were recorded between the 5° to 80° range at a 2θ angle. The interlayer spacing of GO was calculated using Bragg's law Equation [1]:

$$n\lambda = 2d\,Sin\theta \qquad [1]$$

Where, n is the order of diffraction, λ is the wavelength of the X-ray, d is the interlayer spacing, and θ is the diffraction peak. Using the above equation, the interplanar distance between the graphene sheets was found to be 0.828 nm [34]. Figure 1(b) shows the XRD data of Mn_3O_4 nanoparticles and Figure 1(c) shows the XRD data of GOMn_3O_4 nanocomposites. It was observed that the XRD pattern of Mn_3O_4 consists of several diffraction peaks at 13.82°, 29.13°, 31.32°, 32.60°, 36.33°, 44.69°, 51.01°, 58.76°,

Accepted Manuscript

60.13°, and 64.88°, which were corresponding to the lattice planes of (101), (112), (103), (211), (004), (220), (105), (321), (224) and (400), respectively. Tetragonal-phase Mn_3O_4 nanoparticles matched well with the reported JCPDS number 80-0382 [35-38]. The average crystallite size (D) was calculated to be 20.92 nm using the Scherrer equation, described in Equation [2]:

$$D = \frac{K\lambda}{\beta COS(\theta)} \qquad [2]$$

Where, K= Crystallite shape-factor = 0.9, wavelength (λ) of X-Rays = 1.5406 Å, β = full width at half maximum (FWHM) of the diffraction peaks, and θ = Bragg's diffraction angle. The XRD peaks of Mn_3O_4 matched well with the XRD peaks of $GOMn_3O_4$ nanocomposite. All the same XRD peaks are appeared in Figure 1 (c) attributed to the presence of Mn_3O_4 nanoparticles in the GO sheets. However, the intense peak of GO disappeared in the XRD pattern of the nanocomposite. It indicated that the Mn_3O_4 was mainly formed on the surface of graphene [39-44].

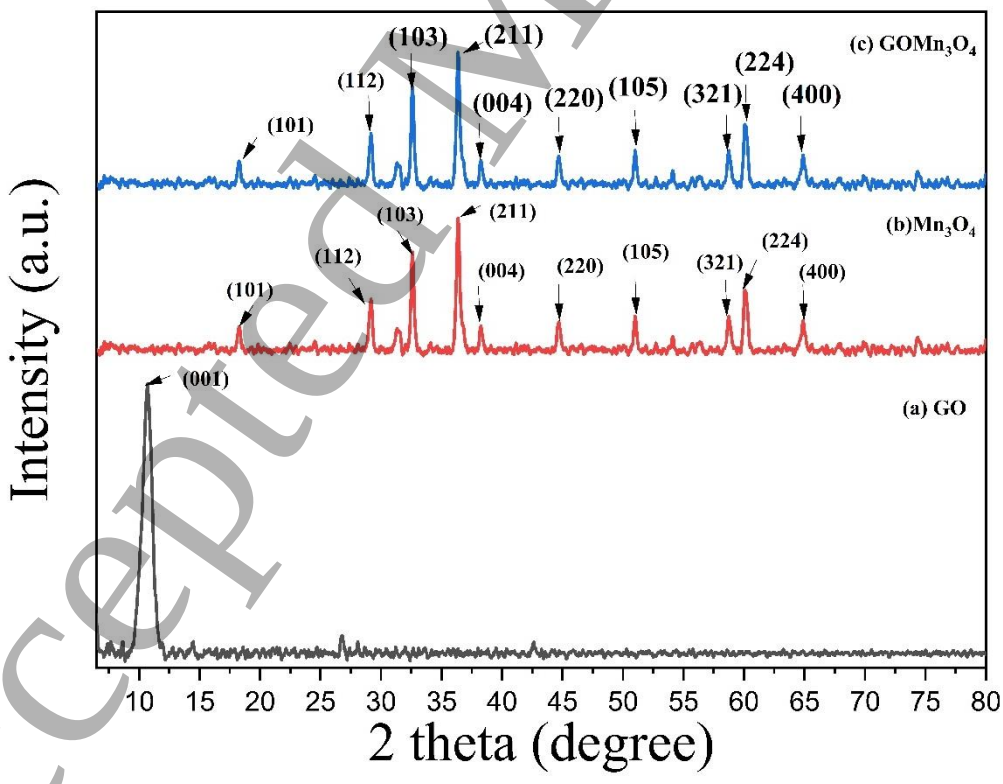


Figure 1: XRD spectrum of (a) GO, (b) Mn_3O_4, and (c) $GOMn_3O_4$ nanocomposite

Accepted Manuscript

The $GOMn_3O_4$ nanocomposite pure phase development was confirmed by the Raman spectrum depict in Figure 2. Figure 2(a) shows the synthesized GO contains two characteristics bands i.e. D and G-bands, corresponding to 1346 and 1598 cm^{-1}, respectively [45,46]. The intensity ratio of the D-band to the G-band is 0.84, which is less than 1, which shows a lower defect concentration. Raman spectrum of synthesized Mn_3O_4 nanoparticles was recorded and depicted in Figure 2(b), a very sharp peak was observed at 634 cm^{-1} which corresponds to the breathing vibration of divalent manganese ions in tetrahedral coordination [47]. Figure 2(c) illustrates the Raman spectrum of synthesized $GOMn_3O_4$ nanocomposite. The D-band and G-band shifted from 1346 to 1351, 1598 to 1591 cm^{-1} respectively, is due to the specific interaction of GO with Mn_3O_4. The sharp peak at 647 cm^{-1} corresponds to A_{1g} breathing vibration of the Mn-O tetrahedral spinel structure. At 305 and 360 cm^{-1}, there were also two additional oscillation peaks seen. The presence of the Mn-O bending mode was indicated by the first two low-intensity peaks, 305 and 360 cm^{-1} [48-49].

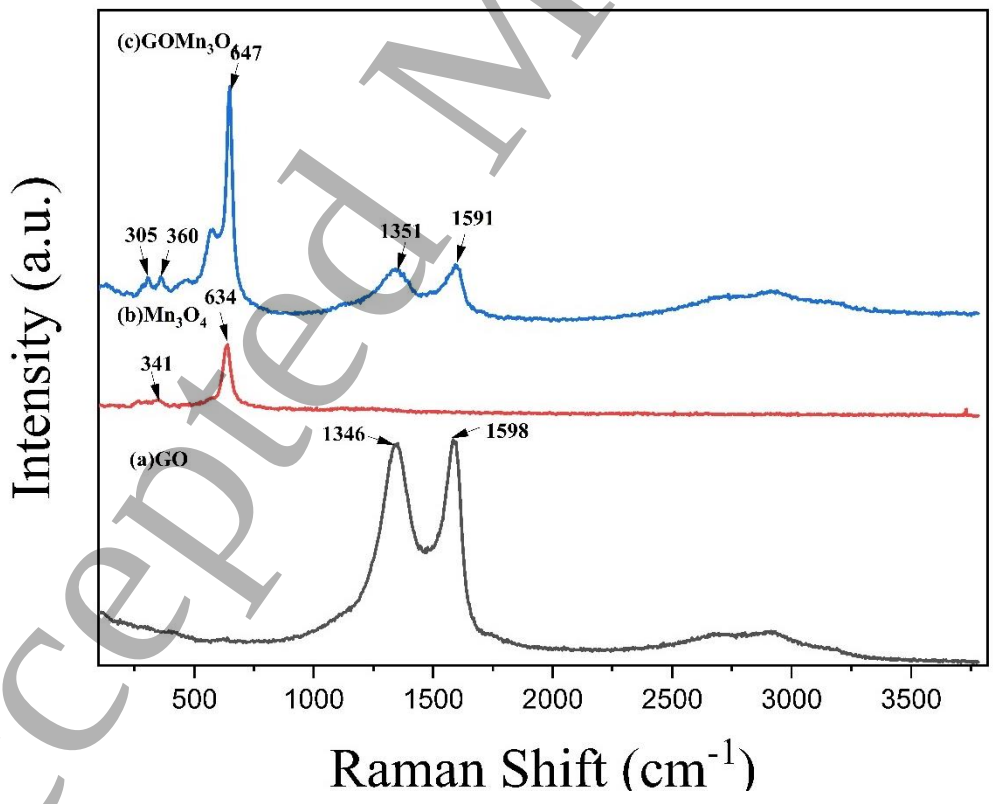

Figure 2: Raman spectrum of (a) GO, (b) Mn_3O_4, and (c) $GOMn_3O_4$ nanocomposite

Accepted Manuscript

Figure 3 shows the FE-SEM of EPD GO onto ITO-coated glass electrode surface. The appearance of GO sheets onto surface of ITO electrode confirms successful deposition of the materials by EPD technique. It can be seen that individual graphene sheets stack together and appear smooth over the ITO electrode surface. EPD technique is simple and fast for depositing the materials by applying certain voltage and time in comparison to the drop-cast method that have a lot of limitations including poor uniformity of the film, limited coverage area, leaching of nanomaterials. EPD is an electrochemical process which is used to migrate the colloidal suspended charged particles or molecules/ions towards their respective electrode surface either to cathode or anode by applying an appropriate voltage in a period of time into two-electrode cell. EPD technique has been used to attain a controlled thickness and to obtain a homogenous morphology of the film on electrode surface that play a significant role in obtaining the better electrochemical sensing performance. It is a simple, economical and eco-friendly technique that used for uniform deposition of materials onto the conducting surface. Therefore, for deposition of GO materials, EPD technique was used and deposited onto the ITO electrode surface under the optimized parameters of 60 volt for 5 minutes. Moreover, it can be seen that graphene sheets form flat like sheet structure and appeared smooth. A clear appearance of GO sheets over the ITO glass substrate confirms the synthesis and deposition of GO.

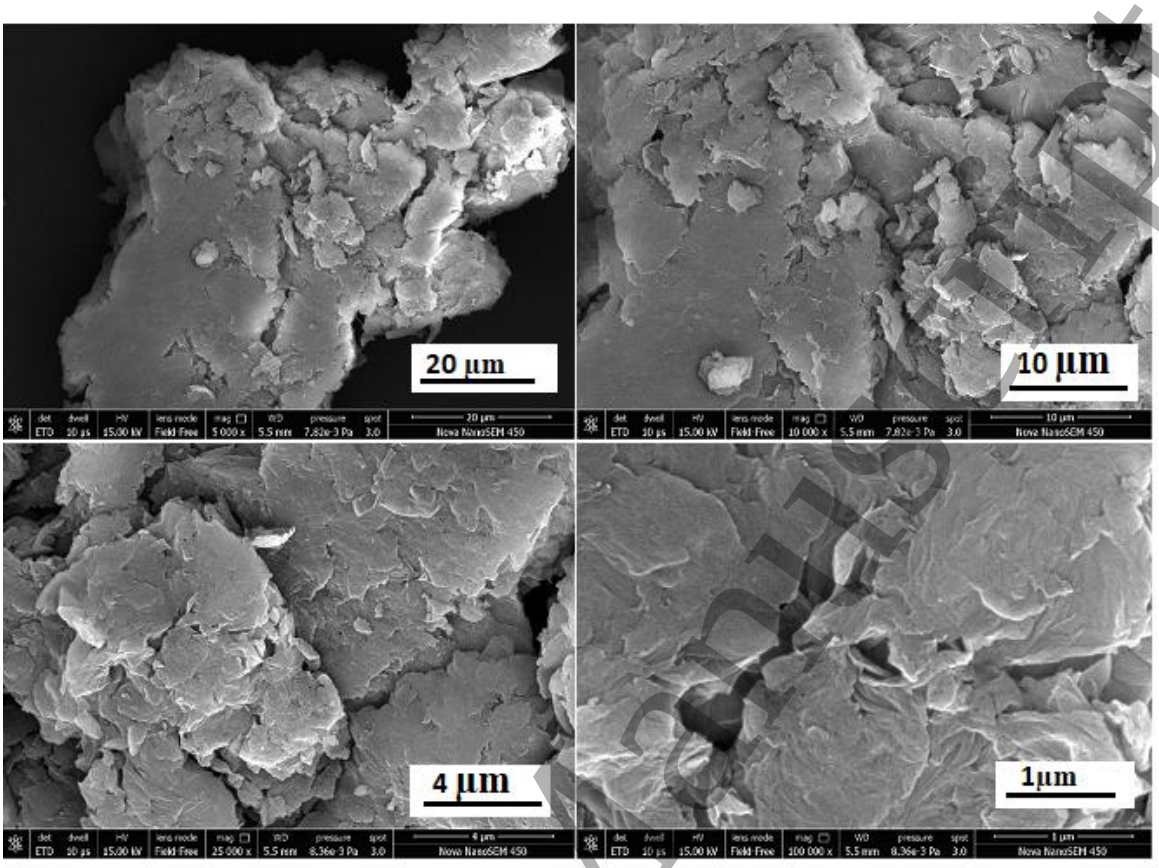

Figure 3: FE-SEM Images of synthesized GO

FTIR Study of GO, Mn_3O_4, $GOMn_3O_4$

The FTIR study of GO, Mn_3O_4, and $GOMn_3O_4$ was observed using potassium bromide (KBr) pellet in the 400 to 4000 cm^{-1} wavelength range, as shown in Figure 4. FTIR spectrum of GO sample shows in Figure 4(a) accorded well with the previous works [30]. There were various oxygen configurations in the structure. They include hydroxyl (namely phenol, C-OH) (3050-3800 cm^{-1}), ketonic species (C = O) (1600-1650 cm^{-1}), including C-OH vibration at 1083 cm^{-1}. In Figure 4(b) of Mn_3O_4, three main absorption peaks occurred. The peak at 3430 cm^{-1} corresponds to O-H stretching and bending modes of absorbed water [50]. The peak at 615 cm^{-1} was attributed to the vibration of manganese species (Mn^{3+}) in a tetrahedral site. The peak at 487 cm^{-1} was attributed to the vibration of manganese species (Mn^{3+}) in an octahedral site [51]. FTIR spectrum was recorded for the $GOMn_3O_4$ composite also and result shown in Figure 4(c). The peak appeared at 3447 cm^{-1} corresponds to O-H stretching and bending modes of

Accepted Manuscript

absorbed water and peaks appeared at 1590 and 1411 cm^{-1} attributed to the C=O and C=C bonding, respectively. The two sharp intense peaks occurred at 618 and 496 cm^{-1} corresponds to vibration of manganese species (Mn^{3+}) in a tetrahedral site and in an octahedral site, respectively.

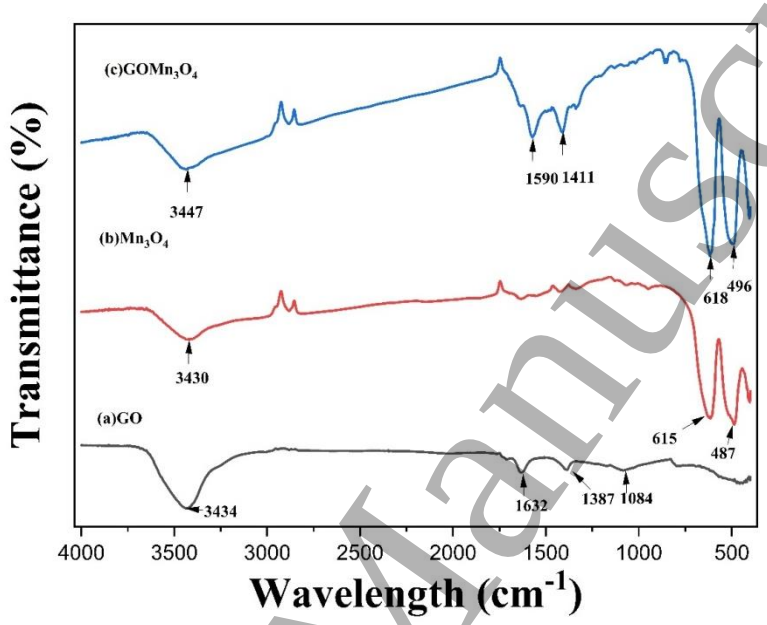

Figure 4: FTIR spectrum of (a) GO, (b) Mn_3O_4, and (c) $GOMn_3O_4$ nanocomposite

Elemental and morphological study of $GOMn_3O_4$ nanocomposite

Figure 5 illustrates the shape and crystallinity of the $GOMn_3O_4$ nanocomposite as determined by TEM (a-c). The distribution of Mn_3O_4 nanoparticles on the graphene sheet surface is depicted in Figure 5 (a, b). The arrow points to a layer of graphene oxide with Mn_3O_4 nanoparticles decorated onto the GO sheets and average size of the nanoparticle found to be 52.38±1.40 nm. Figure 5 (c) shows an HR-TEM image of the $GOMn_3O_4$ nanocomposite showing the thickness of the gap. The HR-TEM images were assigned to the (101) lattice plane of Mn_3O_4 tetragonal phase, and the d spacing was calculated to be 0.45 nm.

Figure 5(d) illustrates EDX imaging used to find the elemental composition of the $GOMn_3O_4$ nanocomposite. The carbon (C), manganese (Mn), and oxygen (O) elements could be found in the $GOMn_3O_4$ nanocomposite hybrid structure, according to EDX

Accepted Manuscript

spectra. The elements Mn and O were observed in the EDX spectra due to the presence of Mn_3O_4, while C was seen due to the presence of graphene nanosheets.

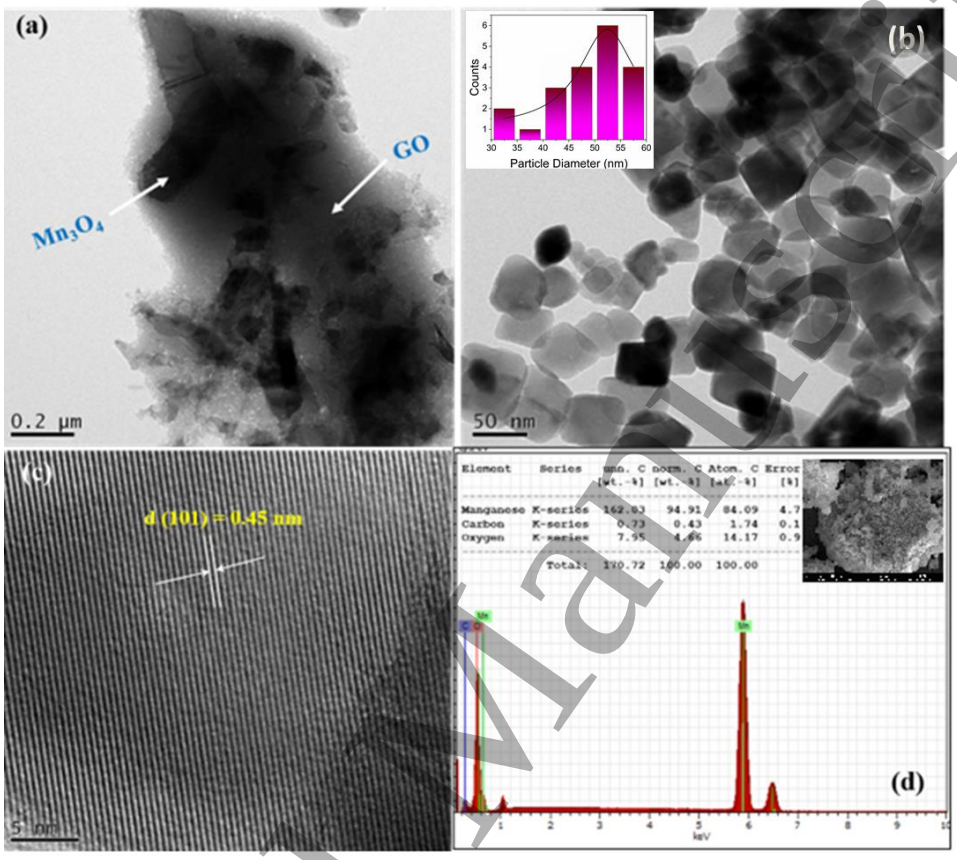

Figure 5: (a, b) describes the HR-TEM images of $GOMn_3O_4$ nanocomposite [inset image: particle size column graph], (c) HR-TEM lattice fringe image of $GOMn_3O_4$, and (d) EDX image of $GOMn_3O_4$ nanocomposite.

3.2 FTIR study of ab-FB1 onto $GOMn_3O_4$/ITO

The immobilization of ab-FB1 and BSA on the surface of the $GOMn_3O_4$/ITO immunoelectrode were investigated using attenuated total reflection (ATR) FTIR spectroscopy in the 400 to 4000 cm^{-1} range, results are shown in Figure 6. The FTIR spectra of the $GOMn_3O_4$/ITO immunoelectrode are shown in Figure 6(i) includes distinctive peaks at 530, 612, 1085, and 1412 cm^{-1}. The two peaks appeared at 1085 and 1412 cm^{-1} correspond to C-O stretching vibration and the -OH group in the carboxylic acid, respectively present in the graphene oxide, while the other two peaks at 530 and

Accepted Manuscript

612 cm^{-1} correspond to the presence of Mn-O bonds in the Mn_3O_4 nanoparticles. In Figure 6(ii), the peaks appeared at 1068, 1570, and 1642 cm^{-1} were attributed to C-N stretching, NH_2 group deformation (amide-II bond), and primary amide N-H of the fabricated ab-FB1/GOMn_3O_4/ITO immunoelectrodes [52]. These results were obtained due to the presence of ab-FB1 on the surface of the GOMn_3O_4/ITO immunoelectrode. The FTIR spectrum of the BSA/Ab-FB1/GOMn_3O_4/ITO immunoelectrode was also performed to confirm that the non-specific binding site of the antibody on the electrode surface was blocked by BSA [53]. As shown in Fig. 6(iii), the FTIR spectrum showed a characteristic decrease in the peak intensity of ab-FB1, and the peak position of the Mn-O bond was shifted from 530 to 536 cm^{-1} at Mn_3O_4 nanoparticle [54]. The above studies showed that ab-FB1 and BSA could be successfully immobilized on the surface of GOMn_3O_4/ITO electrode.

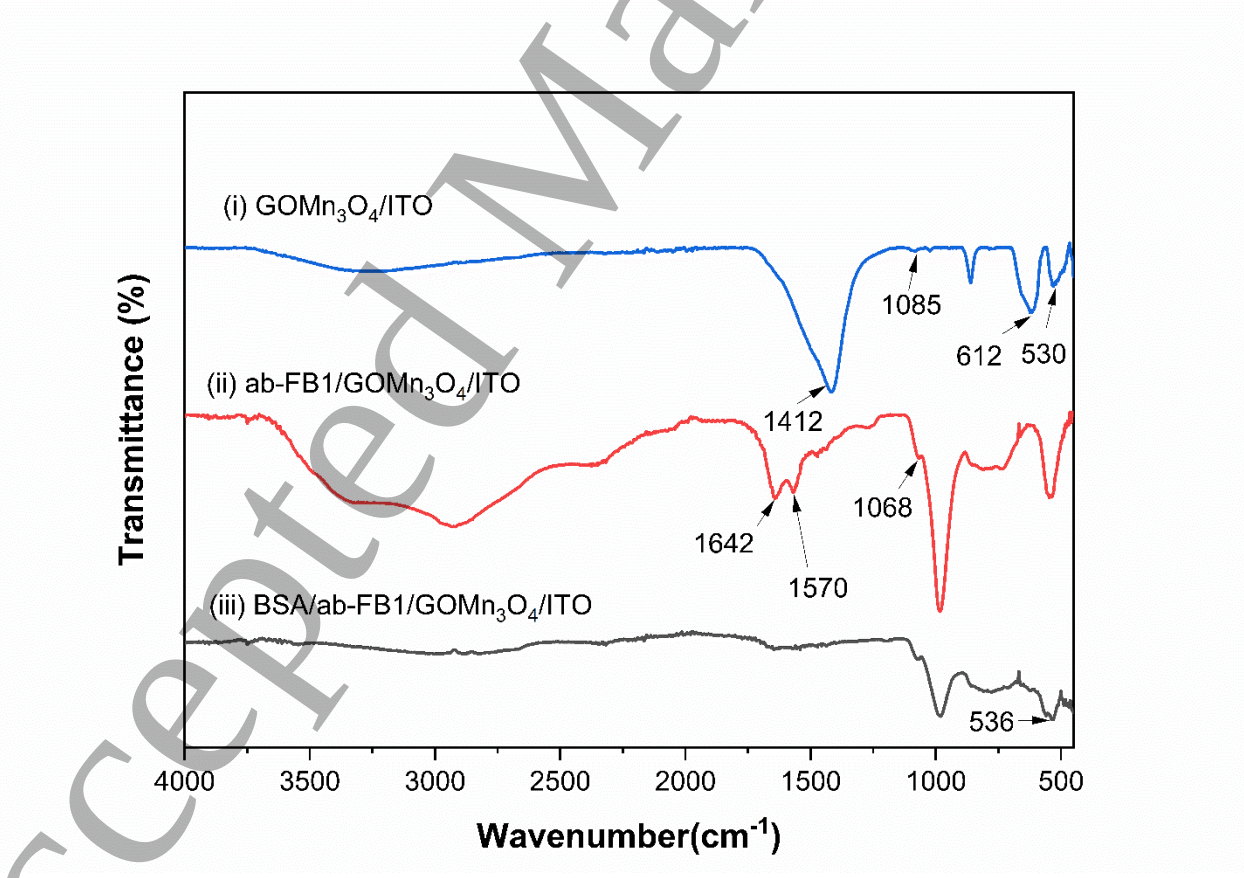

Figure 6: (a) FTIR spectrum of (i) GOMn_3O_4/ITO, (ii) abFB1/GOMn_3O_4/ITO, and (iii) BSA/ab-FB1/GOMn_3O_4/ITO immunoelectrode.

3.3 Electrochemical Study

3.3.1 Optimization conditions

To carry out the electrochemical biosensing studies of the fabricated immunosensor BSA/ab-FB1/GOMn_3O_4/ITO for FB1 detection, optimization studies are important to optimize the certain parameters for the fabrication of sensor. Therefore, few parameters such as pH study, incubation time study were carried out using the BSA/ab-FB1/GOMn_3O_4/ITO immunoelectrode.

Figure 7(a), presents the electrochemical responses of immunosensor BSA/ab-FB1/GOMn_3O_4/ITO at different pH ranging from 6.0 to 8.0 of PBS containing $[Fe(CN)_6]^{3-/4-}$ due to the effect of pH onto the protein molecules. As by changing from lower to higher pH value i.e. from acidic to basic medium of the electrolytic solution PBS containing $[Fe(CN)_6]^{3-/4-}$, can lead to alter the conformation of ab-FB1 and BSA present on the surface of immunoelectrode. Therefore, it is important to evaluate the specific pH for the fabrication of immunosensor. By adjusting the pH from 6.0 to 8.0 and DPV electrochemical responses were recorded under the potential range from -0.2 to +0.4 V and pH study results are depicted in Figure 7(a). The maximum current was obtained at pH 7.0 in the specified pH range (6.0 to 8.0). Since the composition of ab-FB1 might be altered by acidic or basic media, therefore, pH 7.0 of PBS containing $[Fe(CN)_6]^{3-/4-}$ was used for the fabrication of immunosensor for FB1 detection.

The incubation time was optimized at 5 minutes intervals of time to analyze the interaction between immunoelectrode (BSA/ab-FB1/GOMn_3O_4/ITO) and FB1. The incubation study plot is shown in Figure 7(b). The interaction of immunoelectrode (BSA/abFB1/GOMn_3O_4/ITO) and FB1 (10 pg mL^{-1} fixed concentration) mycotoxin in PBS containing $[Fe(CN)_6]^{3-/4-}$ buffer solution was studied using the DPV method. The decrease in peak current for immunoelectrode was observed and saturated after 35 minutes. As a result, the incubation period for the FB1 analyte to interact with the ab-FB1 immobilized on the surface of the GOMn_3O_4/ITO electrode was optimized to 35 minutes.

Accepted Manuscript

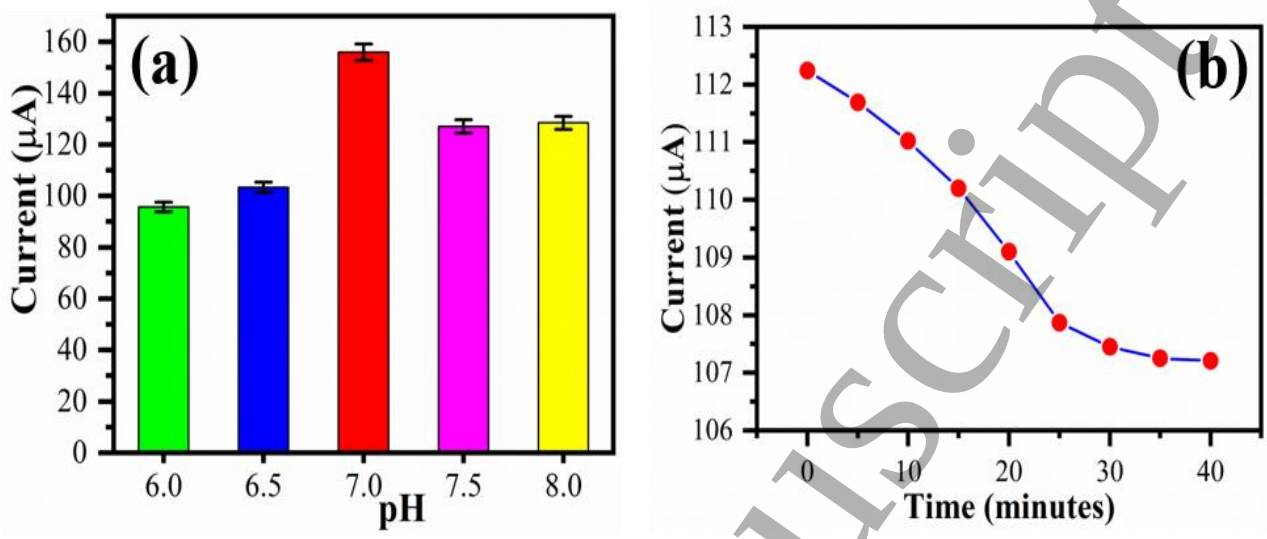

Figure 7: (a) The effect of different pH from 6.0 to 8.0 in PBS containing $[Fe(CN)_6]^{3-/4-}$, and (b) incubation plot for BSA/ab-FB1/GOMn_3O_4/ITO immunoelectrode, in PBS containing $[Fe(CN)_6]^{3-/4-}$.

3.3.2 An electro-kinetic scan rate study

The electro-kinetic interface parameters were measured for electrodes GOMn_3O_4/ITO, abFB1/GOMn_3O_4/ITO, and BSA/abFB1/GOMn_3O_4/ITO using cyclic voltammetry technique with changing the scan rate from 20 to 100 mV/s which is shown in the Figure 8 (a-c). Peak anode (I_a) and cathode (I_c) redox currents were calculated for the electrodes GOMn_3O_4/ITO, abFB1/GOMn_3O_4/ITO, and BSA/abFB1/GOMn_3O_4/ITO immunoelectrode at 50 mV/s.

The inset Figure (8a, b, c) shows a plot of the anode (I_a) and cathode (I_c) currents that are linearly proportional to the square root ($\upsilon^{1/2}$) of the scan rate. The peak current ratio (I_a/I_c) was determined to be 1.11, 1.12, 1.13, which corresponds to the immunoelectrodes GOMn_3O_4/ITO, ab-FB1/GOMn_3O_4/ITO, and BSA/ab-FB1/GOMn_3O_4/ITO, respectively. Thus, the obtained results of the current ratio indicate the quasi-reversible electron transfer process. Furthermore, the peak potential was also determined using the relation $\Delta E_p = E_{pa} - E_{pc}$ for the immunoelectrode and found to be 0.35 V. The determined potential is higher than ab-FB1/GOMn_3O_4/ITO electrode which ascribes the efficient electron transfer between immunoelectrode and redox solution.

Accepted Manuscript

The diffusivity (D) of the immunoelectrode was found using the Randles-Sevcik equation described below (equation [3]):

$$I_p = (2.69 \times 10^5) C\, n^{3/2} D^{1/2} \nu^{1/2} A \qquad [3]$$

Where, I_P is the peak current of the electrode, C is the concentration of the electrolyte, n is the number of electrons, A represents the surface area of the working electrode, and ν is the scan rate (mV/s). The diffusivity for BSA/abFB1/GOMn_3O_4/ITO immunoelectrode is found to be $2.08 \times 10^{-11} \mathrm{cm^2 s^{-1}}$ which indicates that at the electro-analytical interface, the rate of electron transfer is higher.

The availability of binding sites present at the immunoelectrode was calculated with the help of the above-mentioned diffusion-controlled parameter and the area (A_e) was determined using the Randles-Sevcik equation, described below in equation [4]:

$$Ae = \frac{S}{(2.69 \times 10^5) n^3 C D^{1/2}} \qquad [4]$$

Where, S is the slope of the straight line obtained from the linear plot of I_{pa} *vs* scan rate. The obtained results show a 4.11 mm^2 area which indicates the presence of more binding sites per unit volume at the immunoelectrode.

Further, the concentration at the surface of ionic species (I*) was also determined using Brown-Anson equation [5] which is as follows:

$$Ip = \frac{n^2 F^2 I^* A V}{4RT} \qquad [5]$$

Where, F is Faraday constant (96,485 C mol^{-1}), R stands for gas constant (8.314 J mol^{-1} K^{-1}), T stands for temperature (300 K), and the meaning of additional symbols is the same as that given in the previous equation. The determined result was found to be $2.94 \times 10^{-9} \mathrm{mol\,cm^{-2}}$ for the BSA/ab-FB1/GOMn_3O_4/ITO immunoelectrode which is higher for the reactive species at the interface.

Accepted Manuscript

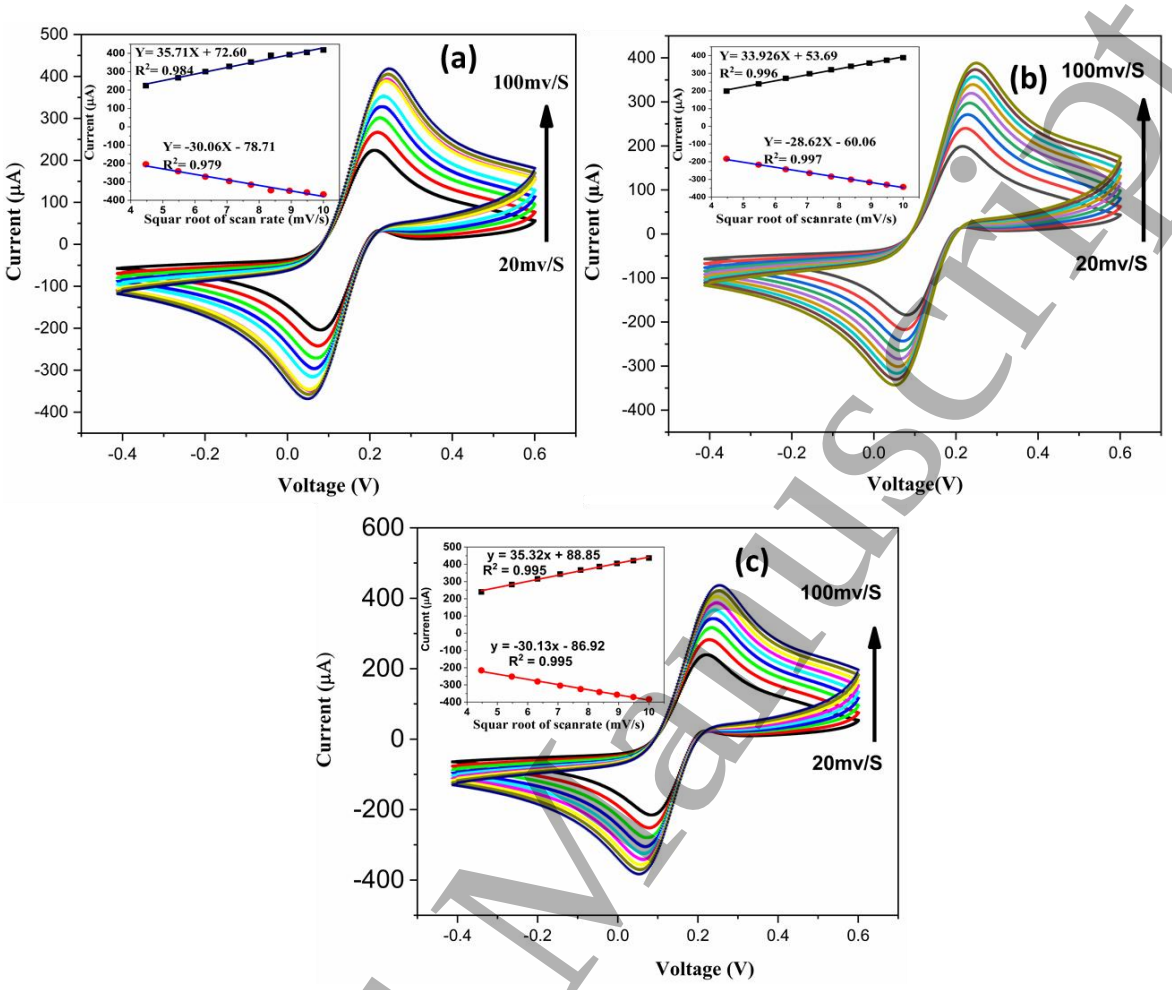

Figure 8: Scan rate study from 20 to 100 mV/s and linear plot between the square root of scan rate *vs* peak current of (a) $GOMn_3O_4$/ITO, (b) ab-FB1/$GOMn_3O_4$/ITO, and (c) BSA/ab-FB1/$GOMn_3O_4$/ITO immunoelectrode, respectively.

Electrochemical characterization studies of $GOMn_3O_4$/ITO, ab-FB1/$GOMn_3O_4$/ITO and BSA/ab-FB1/$GOMn_3O_4$/ITO surfaces were carried out using DPV technique. The DPV spectra of $GOMn_3O_4$/ITO, abFB1/$GOMn_3O_4$/ITO, and BSA/ab-FB_1/$GOMn_3O_4$/ ITO immunoelectrodes are shown in Figure 9 under the potential range from -0.2 to 0.4 V PBS containing $[Fe(CN)_6]^{3-/4-}$ at pH 7.0. The magnitude of peak current values of (i) $GOMn_3O_4$/ITO is higher than (ii) ab-FB_1/$GOMn_3O_4$/ITO. This happens due to the large surface-to-volume ratio, excellent adhesion, good electron conductivity and high electro-catalytic activity of the material. After the immobilization of ab-FB_1 over the $GOMn_3O_4$/ITO electrode surface, peak current value decreased is due to the presence

Accepted Manuscript

of heavier bulky molecule. Then, modified electrode surface was washed with BSA protein to remove the non-binding sites therefore, the peak current increased.

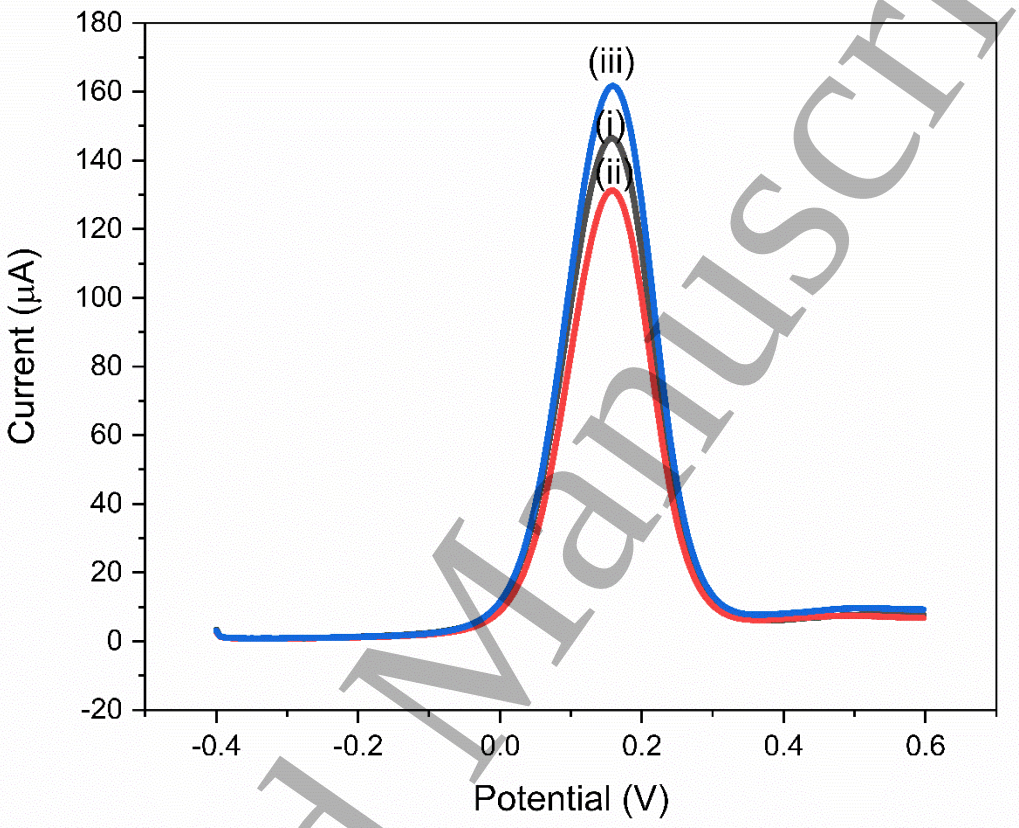

Figure 9: DPV response study of the (i) $GOMn_3O_4$/ITO, (ii) ab-FB1/$GOMn_3O_4$/ITO, (iii) BSA/ab-FB1/$GOMn_3O_4$/ITO electrode surface

Response study

Electrochemical biosensing response studies were carried out using DPV technique in a three electrode system containing BSA/ab-FB_1/$GOMn_3O_4$/ITO as a working electrode, reference electrode (Ag/AgCl) and counter electrode (Pt) in a PBS containing $[Fe(CN)_6]^{3-/4-}$ in the potential range from -0.2 to 0.4 V. The DPV technique is a voltammetry method that is used to make the electrochemical measurements response in which a pulsed potential (ΔE) is apply within a linear potential scanning using fixed increments. The electrochemical response is similar to the first derivate of a linear

Accepted Manuscript

voltammogram where a peak originated from the Faradaic reaction and can be identified near to $E_{1/2}$. The DPV measurements can be used to study the redox properties of extremely low concentration of analyte because effect of the charging capacitive current can be minimized, so high sensitivity is achieved than the linear scanning method and only faradaic current is extracted so the electrode reactions can be analysed more precisely.

To carried out the sensing response study, different concentration of analyte FB1 were analysed by DPV technique to acquire higher sensitivity, better limit of detection, better resolution for lower concentration of analyte. Therefore, electrochemical biosensing studies were carried out using the FB1 concentration range from 1 pg mL^{-1} to 800 ng mL^{-1} and result depicted in Figure 10. Figure 10(a) shows that the current response proportionally decreased as by increasing the FB1 concentration ranging from 1 pg mL^{-1} to 800 ng mL^{-1}. As by increasing the concentration of FB1 onto the immunoelectrode surface of BSA/ab-FB_1/$GOMn_3O_4$/ITO interaction taking place between the immobilized ab-FB1 and FB1 which leads to the formation of electrically insulating immunocomplex between ab-FB1 and FB1 that hinders the electron transfer between electrode and electrolyte correspondingly current response signal decreased. Figure 10 (b) shows the calibration curve between FB1 concentration and current response. Linear calibration plot presents the linear correlation followed between current responses with range of concentration of analyte from 1 pg mL^{-1} to 800 ng mL^{-1}. The fabricated immunoelectrode electrochemical response in terms of sensitivity was calculated using the following of Sensitivity = slope/area of the electrode, assuming a 0.25 cm^{-2} electrode area. The immunoelectrode sensitivity was determined to be 10.08 μA mL ng^{-1} cm^{-2}, with a regression coefficient (R^2) of 0.97. The measurements were carried out in triplicate under the same experimental conditions and signal-to-noise ratio (S/N) is three. LOD was calculated using the standard formula of 3σ/m, (σ is the standard deviation and m is the slope) and LOD value found to be 0.195 pg mL^{-1}. Better and remarkable increase in the biosensing response for FB1 detection is happens due to the use of $GOMn_3O_4$ nanocomposite in comparison to other surface matrixes as summarized in the Table 1.

Accepted Manuscript

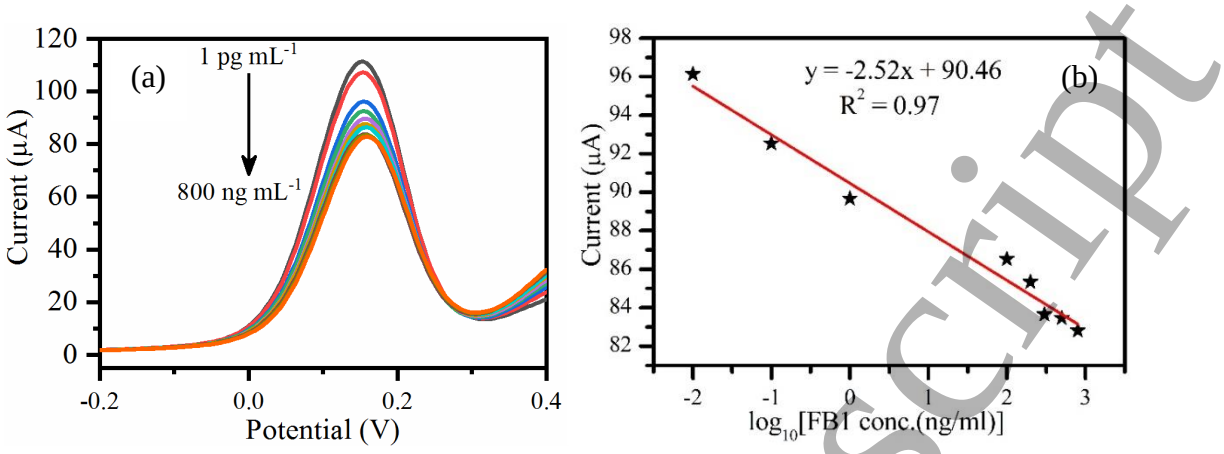

Figure 10: (a) DPV biosensing response, and (b) a linear plot of the BSA/ab-FB1/GOMn_3O_4/ITO immunoelectrode, respectively against FB1 in the concentration range from 1 pg mL^{-1} to 800 ng mL^{-1}.

The biosensing response obtained from the current fabricated immunoelectrode BSA/ab-FB1/GOMn_3O_4/ITO for FB1 detection is comparable to the previously reported articles for the FB1 detection and findings are summarized in Table 1. GOMn_3O_4 nanocomposite increased surface-to-volume ratio [55], improve loading of ab-FB_1 over GOMn_3O_4/ITO surface, provide good electrical conductivity [56], electron transfer efficacy [57,58], available abundant of functional groups for conjugation with antibodies thereby it enhance the sensitivity, linear detection range, limit of detection, specificity, selectivity and stability of the immunosensor. The electrochemical biosensing signal response parameters are found to be better in comparison to the previously published work due to the integration of GOMn_3O_4 nanocomposite for the fabrication of immunosensor for FB1 detection.

3.3.3 Repeatability, Reproducibility, control, and interferent study

Reproducibility studies of immunosensor BSA/ab-FB1/GOMn_3O_4/ITO were performed on five different immunoelectrodes using the DPV technique. Figure 11(a) displays current response obtained from five numbers of immunoelectrodes. The column graph demonstrated remarkable consistency for a specific immunoelectrode under the same settings, with a relative standard deviation (RSD) of 2.49%. Due to the stability and reproducibility of the immunoelectrodes, almost the same current response with minimal variation was obtained with the five different immunoelectrodes.

Figure 11(b) shows the repeatability study of the fabricated immunoelectrode BSA/ab-FB1/GOMn_3O_4/ITO which was measured at a FB1 concentration of 5 ng mL^{-1} using the DPV technique. A virtually steady current was obtained with a RSD of 1.06 % by five consecutive readings. This study verified the designed BSA/ab-FB1/GOMn_3O_4/ITO immunosensor have remarkable repeatability.

It is important to investigate the interference study of the fabricated immunosensor to measure the specificity and selectivity of the sensor towards the FB1 only. Therefore, interference study was carried out with various interference analytes to see the influence of other analyte onto the electrode surface of BSA/ab-FB1/GOMn_3O_4/ITO. For this study, various interferents including other mycotoxins such as AFB1, OchA, and DON, and other carbohydrates like cellulose, fructose, and starch which are found in the food sample were used and DPV response obtained as shown in Figure 11(c). The selectivity study was measured with the addition of 20 µL of interferents in the electrolytic solution in presence of FB1 mycotoxins and their response was recorded using the DPV technique. The obtained results showed the fabricated immunosensor is highly selective towards the presence of FB1. These results indicate that ab-FB1 are highly specific for the FB1.

Also, specificity studies were carried out to investigate the binding of FB1 only with ab-FB1 [Figure 11(d)]. To perform this study, control study using the GOMn_3O_4/ITO electrode tested with the various series of concentration of FB1 from 1 pg mL^{-1} to 800 ng mL^{-1}. It is observed that the no change in current signal found indicates that the FB1

Accepted Manuscript

analyte is highly specific for the immobilized ab-FB1 onto the GOMn_3O_4/ITO electrode.

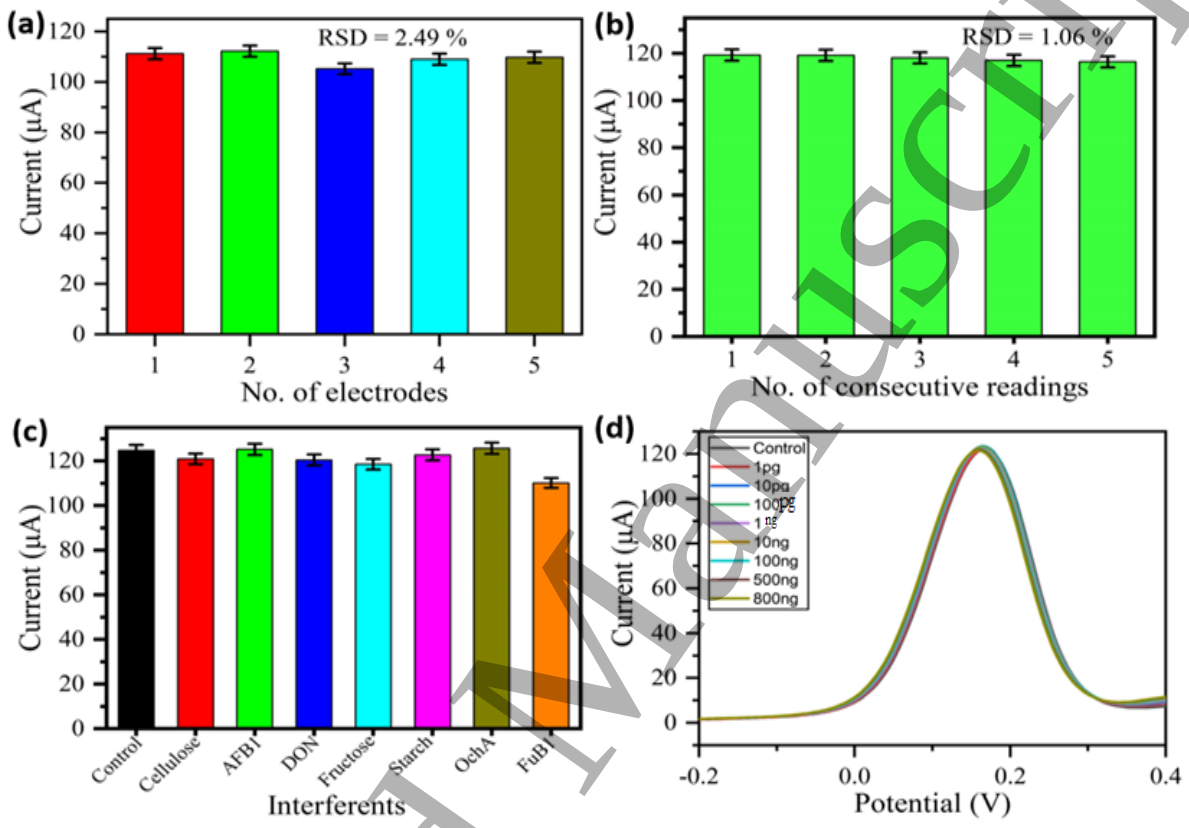

Figure 11: (a) Reproducibility plot for five different immunoelectrodes, (b) shows the repeatability study measured for five different consecutive readings with 1.06 % RSD value, (c) describes the interferent study plot with various interfering analytes, and (d) depicts the GOMn_3O_4/ITO control measurement plot with different concentrations range from 1 pg mL^{-1} to 800 ng mL^{-1}.

3.3.4 Spiked Study

To determine the real sample study, BSA/ab-FB_1/GOMn_3O_4/ITO immunoelectrode responses were observed in spiked maize samples with different FB1 concentrations. The fresh sweet maize was purchase from the local market and crushed thoroughly and diluted in the D.I. water. Further, the diluted maize extract was taken and mixed with different concentration of FB1 (including 1 pg mL^{-1}, 10 pg mL^{-1}, 100 pg mL^{-1}, and 1 ng

Accepted Manuscript

mL^{-1}, 100 ng mL^{-1}, 300 ng mL^{-1} and 500 ng mL^{-1}) and measurement was performed using DPV technique under similar conditions. Figure 12 shows the linear calibration graph is plotted for both spiked and sensing response obtained for various FB1 concentration from 1 pg mL^{-1}to 500 ng mL^{-1} in sweet maize samples. Linear regression coefficient (R^2) is a measure that provides information about goodness of fit in the linear plot. Regression is a statistical measure of how well the regression line approximates the actual data. The R^2 values were calculated for the spiked and sensing results and found to be 0.82 for spiked and 0.85 for sensing studies. The lower R^2 (0.82) for spiked sample studies is due to the small change in the current values with changing the concentration of FB1 in spiked maize samples while in case of FB_1 sensing studies, current is decreasing linearly with the increase of FB1 concentration resulting improved in R^2 (0.85). However, it is observed that in both spiked sample and with FB1, current values is decreased as by increasing the concentration of FB1 antigen indicates that that fabricated immunoelectrode BSA/ab-FB1/GOMn_3O_4/ITO shows specific binding for FB_1 analyte in sensing and spiked samples. The percentage of recovery rate was calculated and found to be in the range of 98.91% to 123.3 %. These results show that an excellent recovery and this fabricated immunoelectrode BSA/ab-FB1/GOMn_3O_4/ITO can be used for the FB1 detection.

Accepted Manuscript

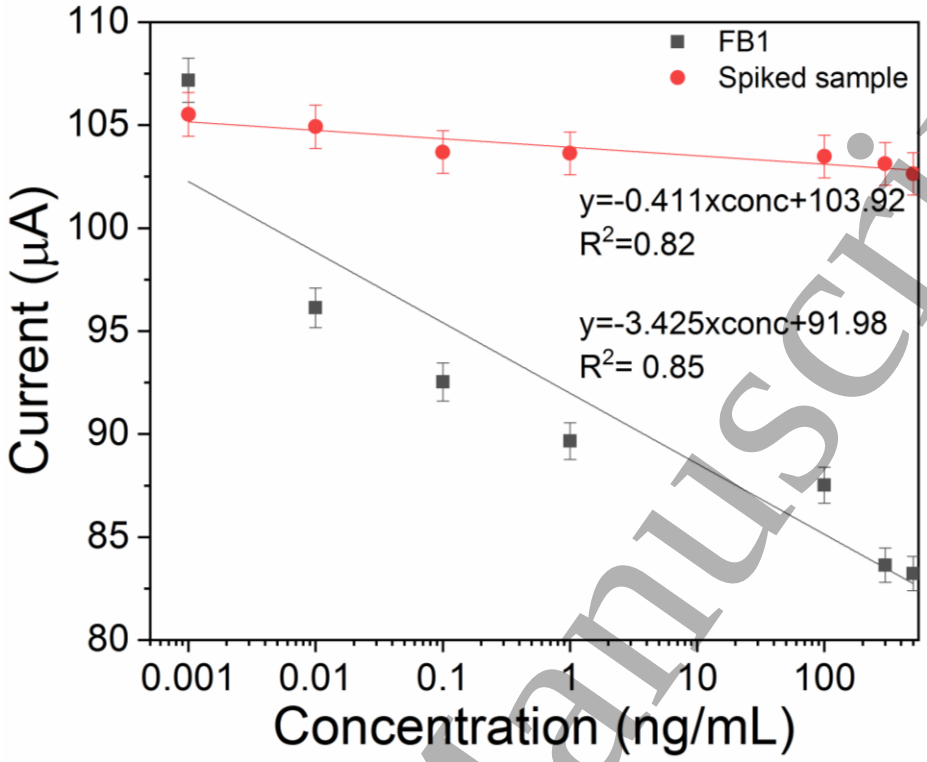

Figure 12: Linear plot of FB1 and spiked sample studies for concentrations of 1 pg mL^{-1}, 10 pg mL^{-1}, 100 pg mL^{-1}, and 1 ng mL^{-1}, 100 ng mL^{-1}, 300 ng mL^{-1} and 500 ng mL^{-1} performed in the sweet maize samples using the fabricated BSA/ab-FB1/$GOMn_3O_4$/ITO immunoelectrode

4. Conclusions

BSA/ab-FB1/$GOMn_3O_4$/ITO immunoelectrode was fabricated for the sensitive and precise detection of FB1 in sweet corn samples in the concentration range from 1 pg mL^{-1} to 800 ng mL^{-1}. $GOMn_3O_4$ nanocomposite was successfully synthesized by wet chemical co-precipitation method. XRD and HR-TEM characterization techniques were used and validated its tetragonal phase of structure. A $GOMn_3O_4$ nanocomposite thin film was developed on an ITO-coated glass surface using an EPD method. Ab-FB1 and BSA were immobilized on $GOMn_3O_4$/ITO electrodes and the immobilization was confirmed using DPV and FTIR spectroscopy. The fabricated immunoelectrode exhibit a high sensitivity of 10.08 µA mL $ng^{-1}cm^{-2}$ and LOD was found to be 0.195 pg mL^{-1} with R^2 of 0.97 for FB1 detection. The FB1 spiked maize samples recovery rates were found in the range from 98.91% to 123.3%. This shows that the BSA/ab-

Accepted Manuscript

FB1/GOMn_3O_4/ITO immunoelectrode system is fully applicable to detect FB1 in actual samples. Various naturally occurring interferences in food (along with FB1), such as AFB1, OchA, DON, cellulose, fructose, and starch, were used in interference studies to confirm the specific detection of FB1. With five electrodes and continuous measurements, the BSA/ab-FB1/GOMn_3O_4/ITO immunoelectrode were likewise shown to be very reliable and reproducible. In a controlled study, the GOMn_3O_4/ITO electrode showed no tendency to detect FB1, and the BSA/ab-FB1/GOMn_3O_4/ITO immunoelectrode confirmed the specific interaction with FB1.

***Abstract*— The music industry has grown from independent composers releasing their self-published work to an entire extensive industry wherein an enormous amount of money is at stake depending on whether or not a particular song will be a hit on the charts. As a result, the music production industry has become more digitized and data-centric in order to try and find a mechanism for predicting a hit song. Extensive research work has been done to predict the salability of a particular song being put out by composers. However, the current research has been limited to Western English language songs only. Due to the lack of datasets and preliminary research on regional language songs, hit prediction for regional language songs has not been given any attention in the existing state of the art. Therefore, in this research paper, we predict the profitability and salability of a Hindi language song by predicting whether or not the song will be a hit or in other words whether or not the song will be listed on top music charts. High-level features of a song have been incorporated into our models as parameters that will affect the profitability of the song in question. To demonstrate this, we created a new dataset of Hindi songs. Moreover, we compared the results of various algorithms such as Random Forrest, Gaussian Naive Bayes, Multi-layer Perceptron (MLP), AdaBoost, and Logistic Regression optimized using SGD. Our results show that MLP achieved the best outcomes with a precision of 0.9429, recall of 0.8875, and F1 score of 0.8849.**

Keywords*— *AdaBoost, Gaussian Naive Bayes, Hindi Songs, Hit Song Prediction, Machine Learning, Random Forrest, Regional Language, MLP, SGD Classifier.

I. INTRODUCTION

The music industry is expanding at a rapid pace and it has become even more imperative for music production houses to be able to predict that the product that they are putting out in the industry will be able to make sustained profits. Like every other company or organization, minimization of losses and maximizing profits is one of the foremost concerns of music production houses. As a result, they turned towards data-driven analysis and Machine Learning technology to predict the salability of a particular song.

Any song released has various features associated with it when we talk strictly in technical terms. Some of the high-level features acting as a parameter for judging a particular song's success are danceability, loudness, acousticness, etc. In this research work, we took into account such features and how they are affecting a song's performance on the music charts.

Since music is an abstract form of art, it has become a fascinating topic of research in how to take into account the above-mentioned features and predict certain aspects associated with it. These features have also been used in past works to predict a song's performance on the charts and even what type of genre a particular song will be classified into. Although, many other factors also play a role in whether a song will be a hit or not ranging from social factors to economic factors. Many times, historical music preferences also play a role in what type of music or song will be a hit in what region of the world. In this research, we limited ourselves only to the audio features of the song.

Almost all existing work in the hit song prediction is done for the West and more specifically on English language songs. Due to the lack of focus on regional language songs, we decided to work on the prediction of a Hindi song's performance on the charts. For this, we manually created a new dataset following which, many Machine Learning algorithms are applied to this dataset. The performance of the different models is then compared based on various performance metrics. Thus the goal of our research is to successfully predict whether or not the song will be a hit by using various Machine Learning algorithms with the best accuracy and precision.

To achieve the above-mentioned goal of the research, we used Machine Learning algorithms like Random Forest, SGD classifier, AdaBoost, Gaussian Naive Bayes, and Multi-layer Perceptron (MLP). We then evaluated the results using different metrics like F1-score, Recall, and Precision .

The rest of the paper is organized as follows: Section 2 gives a summary of the existing research work on music's success prediction. Section 3 describes the recommended technique and methodology; Section 4 summarizes the result and analysis; Lastly, Section 5 concludes the research paper along with offering future directions.

II. RELATED WORK

Many attributes can be used to forecast hit songs, i.e., audio features and metadata aren't always the only factors affecting a song's performance on the charts. In contrast to audio, lyrical, and meta-data modalities.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:15:58 UTC from IEEE Xplore. Restrictions apply.

Fan et al. [1] in 2013 worked on predicting whether a song will be a hit or not, analyzing Chinese and British songs. They then compared them and how different factors influence different regional songs on whether the song will be a hit or not. It is also important to keep in mind that the regional Chinese songs were in the English language but produced and distributed in China. They ran trials utilizing pop music charts from China and the UK for 40 weeks. To determine whether a new song will turn out to be a hit, a support vector machine model and a time-weighted linear regression model are used using a set of 10 common auditory attributes. The study identified the most effective features for predicting hit songs in the Chinese and UK pop charts, with a focus on the top-performing characteristics. Compared to the UK experiment, the Chinese prediction model demonstrated greater precision in its results. They came to the conclusion that Chinese hit songs had audio feature characteristics that were very distinct from the hit songs of the UK.

Due to the dearth in presence of datasets during early iterations of research in hit song prediction, Gutiérrez et al. [2] in 2020 created their own new alternative dataset called SpotGenTrack Popularity Dataset (SPD). A multimodal full-circle, The HitMusicNet deep learning architecture was then introduced for forecasting the popularity of musical recordings. Due to the inclusion of three major modalities in the analysis, the proposed design fared better than earlier studies. The three formats are audio, lyrics, and meta-data.

Raza et al. [3] in 2020 worked on finding the most appropriate set of features that can be used in Machine Learning algorithms in order to predict a hit song, or whether a song will be a hit or not. They included an array of parameters employed on English song charts that could help predict a song being hit. The dataset was formed by aggregating data from various platforms, including technical attributes of songs and sentiment analysis of their lyrics. To determine if there is a secret method for predicting hit songs, sombre Machine Learning logs were employed. The Machine Learning algorithms employed were Random Forests, Naive Bayes, Decision Trees, and Logistic Regression. According to the findings, there are factors other than the technical data points that might foretell if a song would be successful. The authors came to the conclusion that predicting successful songs is not yet a data science endeavor.

Aum et al. [4] in 2022 collaborated on a project aimed at forecasting whether or not the songs will feature on the Billboard Hot 100 chart in a way predicting success of songs by analyzing the interaction between artists and their fans. This involved utilizing a dataset that included comments, posts, and quote tweets from the artist-fan community, as well as assessing the emotional sentiment and interaction patterns present in each piece of content. They achieved the best classification results using the XGBoost model fed with quote-tweet data. They offered a condensed method for monitoring and comprehending public impressions of the music fraternity through discussions on social media. Ultimately, they proposed that incorporating a quote tweet feature into artist-fan interactions on Twitter could be a viable tactic for enhancing the performance of songs and increasing their success.

The study of related works led us to the conclusion that a decent amount of research has been done generally in the field of hit song prediction. However, the majority of the research though has been restricted to the globally popular "pop" English/ Western music and songs. Regional language songs including Hindi have been neglected completely. Further research is required to arrive at an accurate and precise prediction of songs in the Hindi language specifically and regional languages around the globe generically and also make them more robust in the said domains. Therefore, in this research we focused on Hindi language songs and tried to predict whether or not it will be a hit song using various Machine Learning algorithms, to finally conclude which algorithm is giving the best results.

III. METHODOLOGY

The methodology for predicting the Hindi language hit songs using Machine Learning algorithms is built by evaluating it on a completely new custom-made dataset made specifically for this research with the help of different standard performance metrics. The following Fig. 1 shows the research methodology.

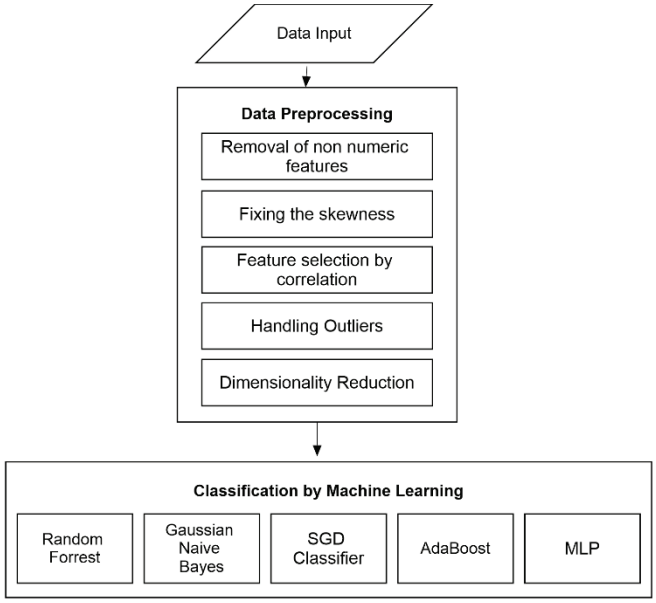

Fig. 1. The research methodology

The subsequent subsections explain the proposed research methodology used for predicting the Hindi language hit songs using Machine Learning algorithms.

A. Dataset

To implement the proposed research objective, we created our own dataset. The first part of the dataset was created by extracting the names of hit Hindi songs from the Billboard chart for top Hindi songs. To do this, we queried the Billboard API using billboard.py. Further we manually added the names of hit songs from various other music charts as no such API existed to extract them. This resulted in 834 data points of hit songs. We then picked the public dataset of Bollywood Songs available at kaggle.com [5]. With this, we further obtained 2337 data points. Common songs between Bollywood songs data and Billboard Data were removed. Finally, we were left with the data of about 2573 songs out of which 1964 Non-Hits and 609 were Billboard Hits. High-level audio features for each song were extracted using Spotipy [6] to query Spotify API. It included 23 high-level human understandable features such as danceability, loudness, energy, instrumentals, acoustic-ness, etc. Billboard

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:15:58 UTC from IEEE Xplore. Restrictions apply.

songs were classified as hits and labeled as 1 while the non-hits were labeled as 0 and the final dataset was created.

B. Implementation Details of Preprocessing Phase

Data preprocessing is carried out to eliminate the noise from the dataset. Here, data preprocessing includes multiple steps. From the 23 total features that we extracted, we removed non-numeric features and were left with 16 numeric features that are suitable for building classification models. We then verified the presence of any missing values, such as NaN or NULL, but found none as they had been eliminated during the data extraction process.

1) Standardization of Data

We observed the skewness of the features. Some features exhibited significant skewness from the normal distribution which is considered to be ideal, so the Yeo-Johnson power transform was applied to normalize and standardize the data. After transformation, the distributions of features were approximated to normal distributions with zero mean and unit standard deviation.

2) Feature Selection by Observing Correlation

We plot the correlation heatmap [7] of the features and make the following observations. Upon analyzing the heatmap, we made two key observations. Firstly, energy exhibited a strong positive relation with loudness (0.71) but a significant negative relation with acousticness (-0.66). Secondly, artist popularity and followers displayed a notable positive relation (0.48). To validate these correlations, we plotted pair-plots. We observed that energy and artist popularity increase nearly linearly with loudness and followers, respectively. The following fig. 2 shows the heatmap.

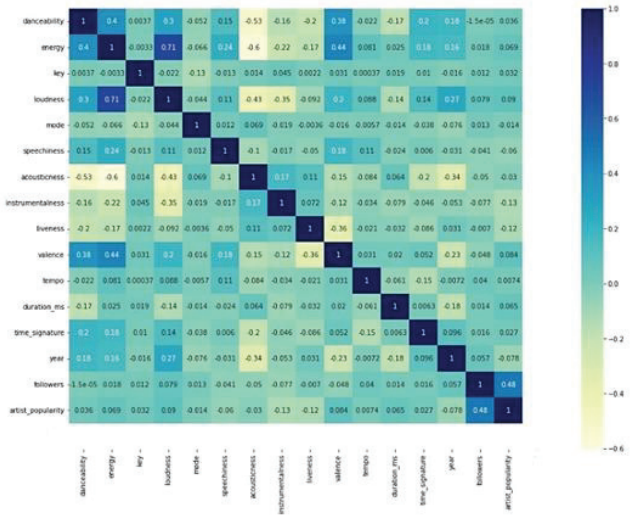

Fig. 2. Correlation Heatmap

As a result, we decided to eliminate energy and followers from our model since their effect on the output label can be effectively captured by loudness and artist popularity, respectively. We chose to remove energy due to its high correlation with two other variables. Furthermore, the distribution of loudness is closer to a normal distribution as compared to energy.

3) Handling Outliers

As the data has been standardized, we identified outliers for each feature based on their absolute Z-scores [8]. Specifically, we identified any data point that deviated from the mean by more than 2.6 standard deviations as an outlier. To determine the optimal threshold value for Z-score, we experimented with a range of values from 2 to 4 in increments of 0.1 (step size). Based on our results, we found that a Z-score threshold of 2.6 yielded the top outcomes.

After performing all the necessary preprocessing steps, our dataset was reduced to 14 features and 2280 data points.

4) Dimensionality Reduction

The technique of t-SNE [9] was employed to transform the data points into a two-dimensional representation, enabling us to visualize higher-dimensional data and comprehend the similarities among data points. "The pairwise similarity of the input objects and the corresponding low-dimensional points in the embedding are measured by two different distributions, and the t-Distributed stochastic neighbor embedding (t-SNE) minimizes the divergence between the two.". The following fig. 3 shows the t-SNE plot.

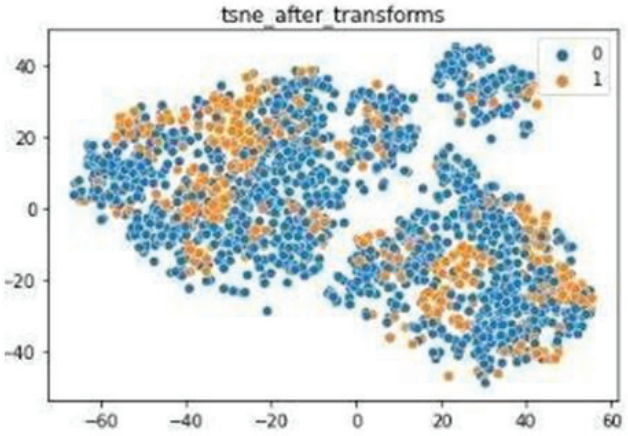

Fig. 3. t-SNE plot

C. Proposed Models and Details

The data was divided into two sets - a training set and a testing set - using a 70:30 ratio. The training set has 1596 samples and the testing set has 684 samples. We trained five well-known Machine Learning algorithms on our training dataset namely Random Forrest, Gaussian Naive Bayes, SGD Classifier, AdaBoost, and MLP.

Random Forrest is a type of ensemble model that aggregates outputs from multiple decision trees to generate a prediction. By combining the results of many decision trees, Random Forest can offer more robust and accurate predictions than a single decision tree.

Gaussian Naive Bayes is a probabilistic model that assumes feature independence to assign probabilities to output classes.

SGD Classifier is used to perform logistic regression using stochastic gradient descent and L1 regularization.

AdaBoost is a statistical classification algorithm that boosts the results of weak models.

MLP is a class of feedforward artificial neural networks. Strictly speaking, it comprises multiple layers of perceptrons with threshold activation.

IV. RESULT AND ANALYSIS

The methodology suggested in this study is implemented using the Python programming language. In addition, the following criteria were used to evaluate the classification results. Key Performance Indicators: precision, recall [10], F1 score & Accuracy. The degree of precision indicates how many samples that were expected to be positive turned out to be such. The ratio of true positive (TP) values to the total of all expected positive values is known as precision. (TP and FP).

Precision =True Positive / (True Positive + False Positive)

Recall quantifies the proportion of positive samples that are correctly predicted from the positive samples. Thus, it is explained as the proportion of true positive (TP) values to the total of all actual positive values. (TP and FN) .

Recall = True Positive / (True Positive + False Negative)

The harmonic mean of recall and precision is known as the F1-Score.

F1 score = 2 × Precision × Recall / (Precision + Recall)

A. *Result Details for Classification Phase*

We employed a 5-fold cross-validation fold [11] which was the best 'k' value in the range [2,10] to train our models and performed a grid search on the hyperparameters. We selected precision as the scoring metric during the grid search to keep down the number of false positives. The best model obtained from the grid search was then evaluated for precision, accuracy, F1 score, and recall. Table 1 below depicts the performance of the models and Fig 4 shows the comparative analysis.

TABLE I. PERFORMANCE EVALUATION OF CLASSIFICATION MODELS

Model	Precision	Accuracy	Recall	F1
RF	0.9122	0.8516	0.7810	0.8148
GNB	0.6622	0.3315	0.3688	0.3483
LR(SGD)	0.8732	0.8101	0.8055	0.7971
ADA	0.9225	0.8295	0.8639	0.8463
MLP	0.9429	0.8823	0.8875	0.8849

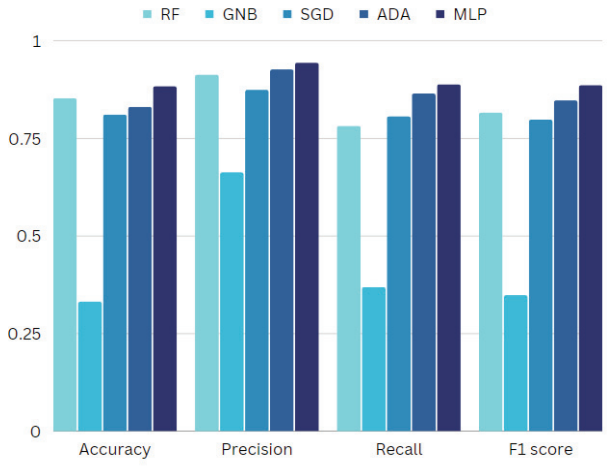

Fig. 4. Comparative analysis of results

B. *Analysis of Results*

MLP outperformed all other selected models across all performance metrics, which was expected given that Artificial Neural Networks (ANNs) are powerful function approximators.

As is evident from the t-SNE plot (Fig 3), the data is not linearly separable. Random Forrest worked well with such data and thus gave high precision and accuracy.

Gaussian Naive Bayes (GNB) gave the worst results. This is expected as Gaussian Naive Bayes assumes the features to be independent which is not true (apparent from the correlation heatmap Fig. 2)

Logistic regression (implemented using SGD) exhibited lower precision compared to Random Forrest, which is expected given that logistic regression works on the assumption that the data can be separated linearly. This assumption does not hold true in our scenario.

Relative feature importance was also observed in the Random Forest classifier. Fig. 5 below depicts the same.

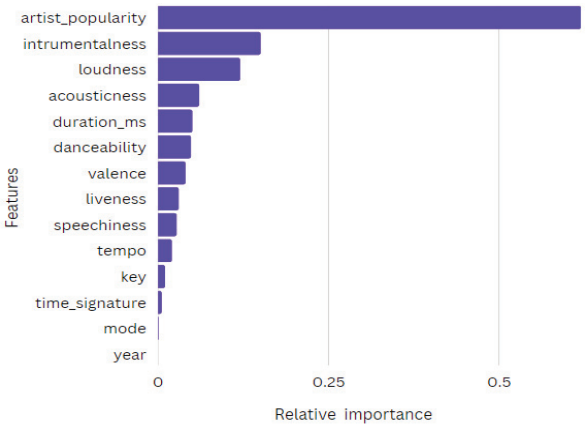

Fig. 5. Random Forest: Relative feature importance

The analysis of the feature importance clearly showed that the popularity of the artist had the highest relative importance by a significant margin, as expected. This finding is justifiable, as we anticipated that artist popularity would be largely determined by their past performance on similar metrics, such as being featured on Billboard charts or winning awards. Conversely, the year feature exhibited low importance, as hit songs were evenly dispersed across different years, and there was no discernible linear correlation between year and other features. This observation was corroborated by reviewing the correlation heatmap of the features with the labels.

V. CONCLUSION AND FUTURE SCOPE

In this research paper, we provided a Hindi hit song prediction using Machine Learning algorithms such as MLP, Random Forrest (RF), Adaboost, SGD Classifier, and Gaussian Naive Bayes (GNB). To demonstrate this, we created our own database using Billboard API and a list of songs at kaggle.com as mentioned in the Data Extraction process. Moreover, we compared the results of the MLP, RF, GNB, SGD, and ADA. The MLP model gave the best results and yielded a precision of 0.9429, a recall of 0.8875, and an F1 score of 0.8849.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:15:58 UTC from IEEE Xplore. Restrictions apply.

To enhance the accuracy of the model in future research, there are various paths that we can take.

In this project, we were able to implement high-level features like danceability, loudness, and vibrancy. In the future, to improve accuracy, we could incorporate low-level analysis wherein we can take a few seconds of sample audio clips of every song and extract features from that. Further, as we believe the lyrics of the songs are also a valuable factor in determining whether the song is going to be a hit or not, we can perform Natural Language Processing (NLP) on the text lyrics of the songs. There might be some complications in using NLP on Hindi lyrics but that is the challenge one would need to overcome. We could incorporate the project into a comprehensive software product and application so that it could be used by music labels and artists in predicting the chances of a new song becoming a hit.

In conclusion, our research has demonstrated the effectiveness of Machine Learning algorithms in identifying hit songs in the Hindi Language and has highlighted the need for further research in other low-resource languages such as Bengali, Chines, Malay, Thai, Vietnamese, etc. The developed models have the potential to be used in practical applications to detect and identify Hit Songs in the Hindi language.

***Abstract*—Degeneration or loss of brain cells called neurons results in several neurodegenerative disorders (NDDs) and currently, millions of people across the world are suffering from them. The increase in the occurrence of these age-related disorders is witnessed majorly due to lifestyle changes. NDDs harm the overall functioning of the body which can also be fatal to life. Alzheimer's Disease (AD) is the most prevalent in the list of NDDs which affects the memory of patients. Oxidative stress performs a wide role in AD pathology and along with that several proteins and enzymes are responsible for the occurrence of AD. One of them is Histone Deacetylase6 (HDAC6). Normally it is responsible for the release of neurotransmitters but in the diseased condition, it becomes abundant in the nucleus which hinders the function and mechanisms and results in dysfunction of the brain. The deteriorated health of the brain leads to AD. This study, utilizing computational-based molecular docking, presents the binding of multiple types of FDA-approved drugs (Anticancer, Antihypertension, Antidiabetic) with the protein for inhibition. To reduce the activity of HDAC6 as a potential therapy for AD, the AutoDock vina-1.5.7 tool was utilized for virtual screening and prediction of the binding affinity of drugs. Following a simulated screening of several different compounds, it was observed that Bicalutamide had the highest binding affinity, measuring -9 kcal/mol. Bicalutamide is an anticancer drug that may be put through additional pre-clinical and clinical testing to produce medications that are repurposed for the treatment of chronic diseases like AD.**

Keywords*—Neurodegenerative diseases, Alzheimer's Disease, Histone Deacetylase6, drug repurposing approach, molecular docking, Bioinformatics.

I. INTRODUCTION

Neurodegenerative Disorders can be defined as the deposition of specific proteins in the brain and neuronal dysfunction that results in serious medical conditions in a person. NDDs are broadly classified into two types; movement disorders and behavioral disorders. Millions of NDD suffering cases have been recorded; the most prevailing are AD and Parkinson's Disease (PD) [1][2]. Even though all the NDDs present a variety of symptoms but all of them coincide with similar fundamentals like neuronal dysfunction, neuronal death, oxidative stress, ubiquitin abnormalities, neuroinflammation, etc.

Alzheimer's Disease which is the most common and prevailing neurodegenerative disorder is caused by the accumulation of proteins in the brain. Several risk factors are responsible for the occurrence of the disease like age, environment, genetics, lifestyle, and many more. Statistical studies mention that by 2060, approximately 13.9 million Americans will be suffering from AD[3].

According to the reports of the National Institute of Health, approximately 6.2 million people are suffering from Alzheimer's Disease, and over a million are having Parkinson's Disease. numerous registered cases are suffering from one or the other neurodegenerative disorders because of the changing environmental conditions, genetic and epigenetic changes, etc. studies also mention that around 1% population of above 60 years are diagnosed with neurodegenerative disorders [4]. Loads of research are being done but a complete cure for AD is still not discovered. Still, the treatment is based on the symptoms and the condition of a person. In the current era, computational studies are very helpful in the diagnosis, prognosis, and treatment of the disease and several models have been proposed for further clinical studies.

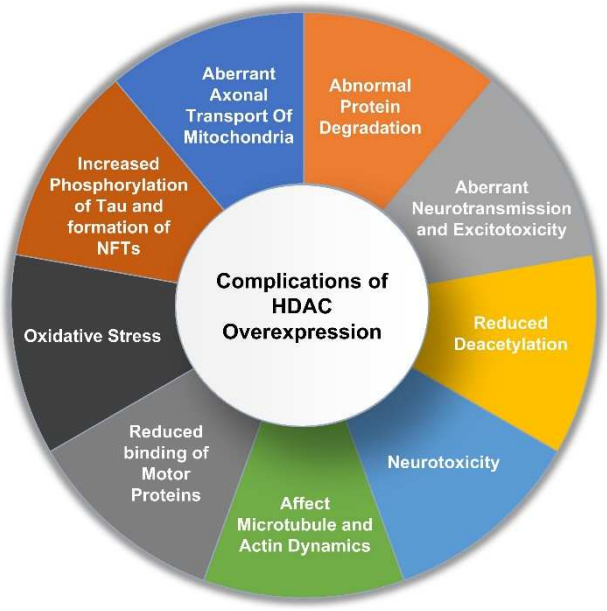

Fig. 1. Cellular complications due to the overexpression of HDAC6

Epigenetic regulation provides a fresh perspective on AD, particularly sporadic AD. Prior research has shown that DNA methylation contributes to AD, and more recently, multiple studies have revealed that histone acetylation contributes to AD pathogenesis [5]. Histone acetyltransferases (HATs) as well as histone deacetylases (HDACs), respectively, catalyze histone acetylation and deacetylation. Chromatin condensation and also gene transcription are significantly influenced by the degree of histone acetylation [6]. According to several studies, HDACs have a crucial involvement in the survival and functioning of neurons. Cellular processes like cell division, development, multiplication, and control of gene expression are dependent on the functioning of HDACs [7]. To carry on such important processes, HDACs are present in 18 different forms in mammals and have been broadly classified into 4 classes based on their structures and

functions. When HDAC6 forms a compound with polyubiquitinated structures of proteins and shuttles these protein complexes along microtubules to form aggresomes, it accelerates the elimination of misfolded protein clusters [8].

Studies have focused on the genetic factors that may be responsible for the occurrence of the disease and mention that histone deacetylase 6 is worth observing. There is a positive influence of HDAC6 in the synaptic functioning of a healthy brain but in the diseased brain, HDAC6 abundance is highly increased in the nucleus which causes hindrance in the normal functioning of the brain. Over-expression of HDAC6 causes a decrease in α- tubulin which is a microtubule element (Figure 1) [9]. HDAC6 deacetylases proteins like Bruchpilot, tubulin, HSP90, and cortactin. Hyper deacetylation of cortactin and alpha-tubulin can disturb the microtubule and actin dynamics resulting in a compromised neuronal cytoskeleton. Neurotoxic beta-amyloid peptides result in a harmful influx of ions of calcium into brain cells in Alzheimer's disease. It is anticipated that this rise in [Ca2+]int will set off intracellular processes that ultimately lead to cell malfunction and cell death [10]. The increased deacetylation also results in reduced anchoring of motor proteins to alpha-tubulin. Furthermore, deacetylation of peroxiredoxins mediated by HDAC6 will add to oxidative stress contributing to neurodegeneration. The pathogenesis of AD is influenced by oxidative stress, which impairs neuronal mitochondria, oxidizes macromolecules, releases reactive oxygen species (ROS) when metal ions attach to Aβ plaques, and increases p-tau and A production [11]. HDAC6 is present in 4 times the quantity in the AD brain as compared to normal one because of which it can be considered as a source of potent therapy [12]. Finding potent inhibitors for HDAC6 inhibition has been an important step to limit the progression of the disorder (Figure 2). Advancements in the research sector are resulting in several therapies to inhibit the negative consequences that are caused due to the over-expression of HDAC.

In this study, virtual screening of various categories of FDA-approved drugs namely anti-cancer, anti-hypertension, and anti-diabetic passing the BBB was done, and by predicting their binding energy required by the drug to dock at the active site of the HDAC6 and restrict its activity as a therapy for AD. After molecular docking, drugs were sorted based on their binding energy and the root mean square deviation (RMSD) value.

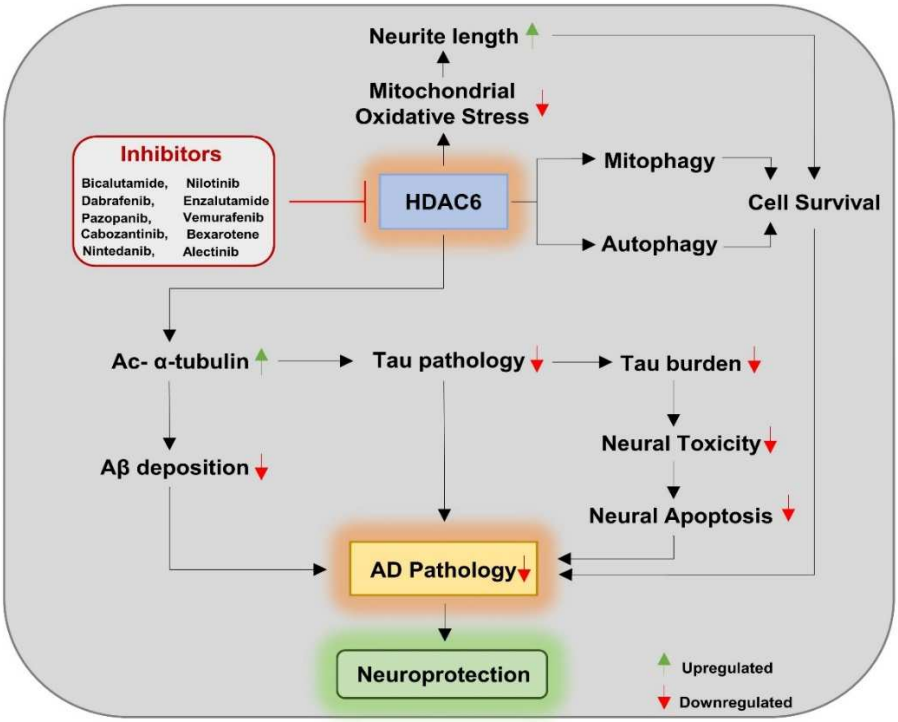

Fig. 2. The reduced activity of the HDAC6 deacetylase, promotes the acetylation of alpha-tubulin, which aids in lowering toxic amyloid segregation, tau pathology, and AB deposition, all of which serve in reduced AD pathology and promote neuroprotection.

A. Structure of HDAC6

HDAC6 belongs to the family of epigenetic modificatory which consists of 18 different kinds of HDACs. All these HDACs are classified into 4 types of HDAC classes. HDAC6 is linked to the class II type. It contains 1215 amino acid residues and is considered the largest member which is present in the zinc finger ubiquitin-binding domain and 2 different catalytic domains (CDs). CD1 is present at the N-terminal and CD2 is present in the central region. The crystal structure for both domains is present which specifies that the CD1 domain shows narrower specificity towards substrate whereas CD2 shows a broader specificity. The zinc finger ubiquitin domain is present at the C-terminal[13].

II. METHODOLOGY

To find the potent inhibitors for the inhibition of HDAC6, computational work is performed which comprised several steps from retrieval of drugs to molecular docking. The potent drugs' major criterion was passing the Blood Brain-barrier Permeability. Here the entire work is based on the drug repurposing approach.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:49:39 UTC from IEEE Xplore. Restrictions apply.

A. Data Collection

Initially, to understand the theoretical concepts of HDAC6 and neurodegeneration, the information was summarized from the literature work presented in literature databases like PubMed https://pubmed.ncbi.nlm.nih.gov/, Google Scholar https://scholar.google.com/. For the study, three classes of FDA-approved drugs were shortlisted based on diseases like anti-cancer, anti-diabetes, and anti-hypertension. As AD is a multifactorial disease, it has been observed that factors like diabetes, hypertension increased oxidative stress and cancer also play a significant role in adding to the progression of AD, on this evidence these classes of drugs were taken in for study as the drugs repurposed in this study will act as multi-target compounds. The database used was PubChem https://pubchem.ncbi.nlm.nih.gov/.

The classification of the drug list was done as 150 anti-cancerous drugs, 50 anti-diabetic drugs, and 50 anti-hypertension drugs. The structure of the receptor (3c5k) was retrieved from the PDB database https://www.rcsb.org/. Finally, the Blood Brain-barrier permeability of the enlisted drugs was predicted using CB Ligand https://www.cbligand.org/CCGS/. The development of drugs for AD is challenged by the blood-brain barrier (BBB), which is also the single most important barrier restricting the development of neurotherapeutics in the future. In light of this, a BBB predictor specifically determines if a substance may pass through the blood-brain barrier (BBB+) or not (BBB-). The support vector machine (SVM) and LiCABEDS algorithms were used to create this predictor by applying them to four different types of fingerprints (MACCS; OpenBabel (F2P); MolPrint 2D; PubChem) from 1593 reported chemical compounds. Among all, SVM algorithm and the PubChem fingerprints were used to predict the compounds for BBB+ or BBB- [14].

B. Receptor and Ligand preparation

For the preparation of the target protein BIOVIA discovery studio is used which is a science-based valid application https://www.3ds.com/products-services/biovia/products/molecular-modeling-simulation/biovia-discovery-studio/. Here, water molecules and hetero-atoms were removed, and the energy minimization and polar hydrogen atoms were added using the inbuilt AutoDock vina tool in PyRx. Further, for ligand preparation, all the ligands were converted into a single structure data file (SDF) library. The Open Babel tool integrated with PyRx was used for energy minimization and conversion of ligand files to pdbqt format. The grid mapping was done for HDAC6 and the dimensions were 5.669, -4.987, 12.262 and the size was 34.86 x 39.07 x 40.61.

C. Molecular Docking

The receptor and ligands that were prepared were docked using the AutoDock vina incorporated in the PyRx tool and the top 10 best drugs were selected based on their binding energy and RMSD value i.e., root mean square deviation values. The expected binding energy was to be -9 kcal/mol.

PyRx is a computational tool used to screen the compound libraries against a specific receptor and is an in-silico approach for drug discovery and development. It also comprises of docking wizard and visualization engine used to perform virtual screening and molecular docking. It uses AutoDock Vina as a docking software[15]. AutoDock vina utilizes a scoring function based on empirical force fields to estimate the binding affinity between a ligand and the protein. The scoring function considers various energetic contributions, such as van der Waals interactions, electrostatic interactions, and de-solvation effects, to evaluate the binding affinity. The underlying mathematical model in AutoDock Vina involves algorithms for global optimization, specifically an algorithm called iterated local search. This algorithm performs a systematic exploration of the search space to find the most energetically favorable binding conformations of the ligand within the protein's binding site. Open Babel for the import of files in SDF format. Its programming language is Python and matplotlib is used for 2D plotting.

III. RESULTS

After virtually screening all the retrieved compounds against HDAC6, a list of best-binding drugs was obtained (Table II). Bicalutamide, an anti-cancerous drug, resulted as the novel drug which shows the best binding that can be repurposed to inhibit HDAC6 and limit the progression of Alzheimer's Disease. The ChEMBL ID for the drug is ChEMBL409. The calculated binding affinity of Bicalutamide was -9kcal/mol and the IC50 value was 470 nM. The active site residues of HDAC6 interacting with the bicalutamide are GLU-33, ARG-47, and TYR-81 with a bond length of 3.3 Å, 1.8 Å, and 2.5 Å respectively (Figure 3). This drug passed the test of Blood Brain-Barrier permeability as well and can be considered for further pre-clinical and clinical trials. Promising candidates who can inhibit HDAC6 and slow the course of AD were found using the performance metrics, including binding affinity, docking accuracy, and computational efficiency (Table 1).

TABLE I. PERFORMANCE METRIC OF AUTODOCK VINA OF THE STUDY CONDUCTED.

Performance Metric	Description	Evaluation Method	Results
Binding Affinity	Measures the strength of ligand-protein interaction	Calculation of binding affinity scores	Average binding affinity (top 10): -8.54 kcal/mol
Docking Accuracy	Evaluates the accuracy of docking predictions	Comparison of predicted binding poses with experimental data	RMSD less than 1.0 Å
Computational Efficiency	Measures the speed and scalability	Calculation of the time required for docking calculations	Average docking time: 2 seconds

Bicalutamide is a drug used for the treatment of prostate cancer. It is an androgen receptor inhibitor. The brand name under which this drug is sold is Casodex. The Drug Bank accession number is DB01128. Bicalutamide is an FDA-approved drug that is always taken in oral form. The trace remains of the drugs are easily excreted through urine and fecal matter[16]. Bicalutamide is a non-steroidal drug but when consumed can cause side effects like weakness, dizziness, swelling in various parts of the body, pain, constipation, nausea, fever, high blood pressure, frequent urination, etc. It should be stored at room temperature and should be consumed only when prescribed by medical experts. Bicalutamide is a multi-purpose drug that can be repurposed to treat neurological disorders like Alzheimer's Disease.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:49:39 UTC from IEEE Xplore. Restrictions apply.

TABLE II. BEST BINDING COMPOUNDS WITH HDAC6 AFTER THE VIRTUAL SCREENING.

Drug Structure	ChEMBL ID	Compound	Binding Affinity (Kcal/Mol)	Blood-Brain Barrier
	CHEMBL409	Bicalutamide	-9	+
	CHEMBL255863	Nilotinib	-8.8	+
	CHEMBL2028663	Dabrafenib	-8.8	+

IV. DISCUSSION AND CONTRIBUTION

With the induction of dynein and kinesin motor complexes, inhibition of HDAC6 with an inhibitor reverses oxidative stress-induced neuronal cell death and triggers neurite extension, enhances microtubule stability, and mitochondrial transport enhances cognitive and memory conditions associated with diseases like Alzheimer's and neurological impairments both in cell culture and animal

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:49:39 UTC from IEEE Xplore. Restrictions apply.

experimental models. In the R6/2 mouse model, genetically inhibiting HDAC6 has a twofold impact on the development of the illness and motor deficits. This research collectively demonstrated the identification of HDAC6 inhibitors as therapeutics for neurodegenerative disorders [17]. The identified inhibitors were found to be traditionally used for multiple other diseases such as cancer, hypertension, and diabetes.

The points mentioned below highlight the contribution of the Insilco drug repurposing research for the treatment of AD.

- This insilico drug repurposing study finds novel uses for already approved drugs for the inhibition of overexpressed HDAC6 for the treatment of AD by studying the pharmaceutical-target protein molecular interactions.
- Drug repurposing speeds up medication development for neurological disorders like Alzheimer's Disease, Parkinson's Disease, etc. In silico tools can swiftly screen large chemical libraries against many target proteins to uncover potential hits and lead compounds for further investigation. Drug repurposing helps us by saving time and money by using existing data and knowledge.
- Existing drugs that are repurposed for new indications can offer a more comprehensive safety profile than newly developed compounds. Due to the fact that the safety profiles of repurposed pharmaceuticals have already been established through clinical use, the risks associated with adverse effects and toxicity can be better comprehended.
- In silico drug repurposing initiatives provide valuable insights into the action mechanisms and target interactions of existing drugs. This information can aid rational drug design by guiding the modification of existing compounds or the creation of new derivatives with enhanced efficacy or fewer adverse effects. By comprehending the structural and functional properties of repurposed pharmaceuticals, researchers can rationally enhance their therapeutic potential to treat AD.
- Drug repurposing avoids unnecessary animal testing by using approved drugs' safety and knowledge. Repurposed medications have undergone significant preclinical and clinical testing, thus animal testing is unnecessary.

V. Conclusion

FDA-approved drugs which are responsible for the treatment of a variety of diseases were taken for the inhibition of HDAC6 whose over-expression in the brain can cause Alzheimer's disease. Multiple bioinformatics tools and techniques along with online databases were used to conduct the study based on the drug-repurposing approach. Bicalutamide, an anti-cancerous drug resulted to be a potent drug for the inhibition of HDAC6 and curing of AD.

Computational approaches can be one of the best ways to research in the field of life sciences and healthcare which can be cost-effective, and time-saving. At the same time, the only limitation of computational work is its findings need to be approved by clinical trials and further research for human administration. As technology advances, it can be helpful to figure out precise treatments for NDDs for which treatments are yet unknown.

Abstract— **Huntington's disease (HD) is a neurodegenerative disorder that can be inherited from a person who has a mutant copy of the HTT gene. This mutated HTT gene encodes the mutated huntingtin (mHTT) protein. This disease targets the basal ganglia and cortex which is responsible for the movement of the body and memory cells, gradually it causes the slowing of brain cells and involuntary movements in the body. Progressively cause deterioration of the vital functions of the body which leads to complications and premature death. To track the disease progression and to alleviate novel therapies identification of the disease is essential. Biomarkers provide reliable effective and accurate prognosis of the disease. Here, the application of computational algorithms and mathematical modeling techniques to identify HD is done. Global Unified Huntington's Disease Rating Scale (UHDRS) traits are used in conjunction with a TRACK-HD dataset of patients with symptomatic and managed Huntington's disease to predict HD. Predictive models for early HD patients, pre-manifest gene carriers, and control patients were created using machine learning and deep learning. These predictors were used as Biomarkers for the prediction of Huntington's disease.**

Keywords—Huntington's disease, Huntingtin (HTT) gene, Basal Ganglia, and Cortex, Biomarkers, Unified Huntington's Disease Rating Scale (UHDRS)

I. INTRODUCTION

Huntington's disease (HD) is a rare genetic neurodegenerative disorder caused by the presence of trinucleotide CAG repeats in the Huntington's (HTT) gene. These repetitive sequences trigger the production of an unstable protein, leading to the formation of inclusion bodies in the brain. These bodies are small toxic fragments that degenerate the functioning of neurons inside the brain because of which brain cells die. Along with these, it causes interference with a number of tasks performed for movement and thought processes. [1] These afterward are responsible for disrupting characteristic motor psychiatric tasks of the brain. As mentioned, it is a rare disease and it affects 1 in every 10,000 people. It usually occurs between the ages of 30-50. Studies have proved that after onset of symptoms average lifespan is about 15 to 25 years of age and over 200,000 persons in the US are thought to be at risk of inheriting HD, and it is believed that about 30,000 of them have symptoms. The World Health Organization (WHO) estimates that HD causes 0.4% of global fatalities. [2] Unfortunately, medical research can neither halt it from becoming worse nor find a solution. Hence, the identification and prediction of this disease can have a significant impact as it can further help us develop personalized therapies. Biomarker discovery can be used for identifying novel drug targets used for drug discoveries and for the prognosis of the disease. Computational Biologists can manage to help patients by predicting disease and planning treatment accordingly as early treatment can reduce side effects and progressive disease will prevent fortunate treatment. [1]

TRACK-HD is a prospective Huntington's disease biomarker research. It employs many investigations to diagnose HD, including multiple MRI and image-based scans, as well as blood-based biomarkers, and it assesses the development of HD. Many of these were changes in pre-symptomatic behaviour, while others were changes that occur over a period of time. [4] The Unified Huntington's Disease Rating Scale, also known as UHDRS, is a tool that allows us to measure how severe HD has been over time. UHDRS uses a number of features like cognitive function, motor function, and diagnosis confidence to evaluate the efficacy of treatment for HD. In the dataset available in the paper, usage of oculomotor abnormalities of early and pre-manifest HD is done. [3] The study used both TRACK-HD and UHDRS data to fit mathematical and computational models to the publically available to differentiate HD before symptom onset and controlled HD patients.

II. SIGNIFICANCE

Huntington's disease can be characterized by symptoms related to psychiatric and cognitive health. Biomarkers derived from antisaccade testing data can help in the early diagnosis and detection of the disease enabling treatments in earlier stages. The features used to provide measurements of eye movements such as duration, amplitude, latency, and peak velocity can be a quantifiable biomarker for oculomotor function associated with HD. The accuracy and reduced reliance provide subjective assessments. Changes in eye movements provide insights into the development and progression of cognitive impairments which can further help in personalized treatment plans for therapeutic interventions. [3]

By analyzing the saccadometer data alongside the clinical and demographic information, researchers can explore associations between eye movement abnormalities that

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 02,2023 at 06:45:13 UTC from IEEE Xplore. Restrictions apply.

contribute to HD and its therapeutic targets. The identification of distinct classified clusters within HD using saccadometer data can aid in disease subtyping and stratification. It also may help in predicting progression, tailoring interventions, and assessing treatment in different subgroups. Hence, saccadometer-derived biomarkers can be employed for the evaluation of HD. They provide objective and quantifiable metrics to assess the effectiveness of therapeutic interventions, potentially facilitating the development of new treatments and interventions. [3]

The data generated from different clinical assessments, imaging data, cognitive tests, and biological samples contributed various insights into the natural history of HD and its biomarker discovery through the TRACK-HD study. Whereas, UHDRS is widely used in clinical trials used to assess the severity of disease and track it over a while. This data can also evaluate the effectiveness of biomarker and therapeutic interventions. [8] [9]

III. SACCADOMETER TESTING

Oculomotor testing of the subjects was done using a saccadometer advanced machine that tracks eye movements. In this method, after the saccadometer is put on their head, on a computer screen two lights appear in the center (green and red). The subjects are instructed to follow or take away their eyes from the target as informed (green for prosaccade and red for antisaccade). This data provides accuracy and velocity of saccades to differentiate between healthy and HD patients. It also provides information relevant data about the cognitive functions in HD i.e. cognitive flexibility and inhibition. While checking the error rate in the patients differentiating from that of HD it was negligibly less (less than 1%). An illustration of the same has been shown below. [10]

Oculomotor abnormalities are commonly observed in HD patients, even in the early stages of the disease. By assessing eye movement parameters, such as saccades, smooth pursuit, and fixation stability, oculomotor testing can provide objective measurements of oculomotor function. These measurements can be compared across different populations, disease stages, or treatment responses to identify patterns or deviations specific to HD. Quantitative analysis of oculomotor data may reveal distinct oculomotor biomarkers associated with the disease. These biomarkers can aid in the early detection and diagnosis of HD, differentiate HD from other conditions with similar symptoms, monitor disease progression, and potentially predict disease outcomes. Furthermore, understanding the mechanistic relationship between oculomotor abnormalities and underlying neural dysfunction in HD can provide insights into the disease's pathophysiology and guide the development of targeted therapeutic interventions. Integrating oculomotor assessments with other clinical and imaging biomarkers may enhance the accuracy and efficacy of HD diagnosis, management, and treatment.

IV. METHODOLOGY

A dataset containing tests of healthy patients, symptomatic patients, and early-HD patients was taken into account and an Antisaccade testing using a acidometer was done. [5] Antisaccade are determined eye movements in which a person must consciously avoid producing a reflexive eye movement in the direction of an object to produce a rapid eye movement in the opposite direction. This test may be utilized as a diagnostic tool since it can identify irregularities in antisaccade performance in HD related to cognitive and motor function impairments. According to research, people with HD may fail to regulate reflexive saccades, which may result in more mistakes and shorter reaction times during antisaccade activities than in healthy people.

An In-silico analysis of data was collected and examined over multiple countries. A total number of 371 subjects were part of this examination, with a total number of 90476 entries (approximately 250 trials per subject). These individuals underwent an antisaccade test in which they had to move away from an incoming stimulus. These subjects were divided into 1. Control 2. Pre-HD Gene Carrier 3. Early HD with 123 healthy subjects, 122 pre-HD, and 125 HD patients. The groups were further divided into five sub-groups for classifying the progression of HD including control, pre-HDA, pre-HD-B, HD-1, and HD-2. [5]

UHDRS features were used for the evaluation of HD symptom severity, specifically TFC or Total functional capacity and TMS or Total motor scores. Some important features taken into account with the model fitting were –

A. CAG repeats

The HTT or Huntingtin gene contains CAG sequences (cytosine, adenine, and guanine) with several repeated sequences. In an HD diagnosed patient repeats are recorded to no less than 36. This abnormal expansion of the CAG sequence is responsible for an unstable huntingtin protein called mHTT. Which further leads to neuron malfunctioning and progressively death. CAG determination is an important factor for considering whether a person is symptomatic of HD or not. As per studies, individuals with a CAG sequence count of more than 40 experience progressive symptoms of HD. The mean CAG recorded in pre-manifest gene carrier (mean 43.16) and early HD (mean 43.57) patients are approximately the same with a difference of less than 1%. The main reason behind using the CAG repeats data is, it comes under UHDRS features for detection of HD. [11]

B. Age

Age plays an essential role in the progression of Huntington's disease (HD), as mentioned previously CAG repeats are responsible for the mutation of Huntingtin protein which happens at an earlier stage. Individuals at younger age experience faster disease progression and more severe symptoms and rapid increase. Whereas, on the other hand, at a later age onset it is believed that the symptoms will tend to be milder as compared to that of younger persons. Therefore, age plays an important role in the prognostic research of a patient.

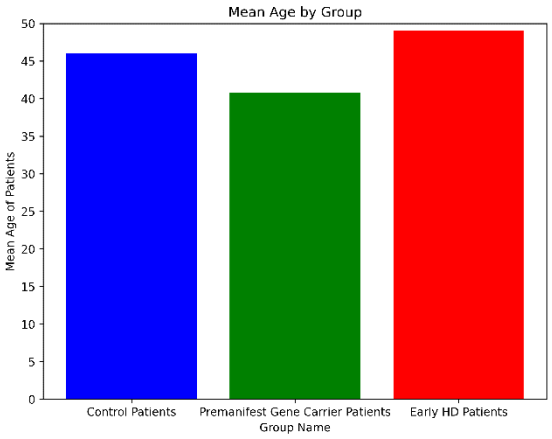

Figure 3. The average age of patients from all groups.

C. Duration, Amplitude, and Foreperiod

Duration is the amount of time it takes a person to finish a saccade, which is a quick eye movement required to focus on a specific object. The length of saccades has been shown to lengthen in HD patients, which may reflect a loss in the brain's capacity to interpret information pertaining to eye movement. The amplitude of a saccade is its angular separation. Saccadic amplitudes in HD patients can vary, and some evidence suggests that amplitudes decrease as the illness progresses. The foreperiod is the amount of time that passes between the appearance of a target and the first warning signal. People with HD had longer foreperiods than healthy controls, according to studies, which may indicate a weakness in their ability to plan an upcoming action. According to our observation, the mean duration time for control patients was 51.86ms, the mean duration time for pre-manifest gene carriers was 53.32ms and the mean duration time for early-HD patients was 58.46ms. There was a slight difference between all three groups by which it can be assumed that duration, amplitude, and foreperiod act as a biomarker for HD.

D. Reaction time, Latency, and Correctness

Reaction time, Latency, and Correctness account for the prognosis of HD, studies have proved that patients suffering from HD tend to have longer reaction time and latency and poor accuracy as compared to healthy individuals. These defects originate from dysfunction in the basal ganglia, a brain region that is affected by the disease. These HD patients perform poorly in these cognitive tasks because of an uncertain involuntary movement in the body. The mean reaction time for control patients was 324.37ms, the mean reaction time for pre-manifest gene carrier was 330.10ms and the mean reaction time for early-HD patients was 366.14ms. It can be witnessed that the reaction time for early HD is slightly higher than that of control patients and pre-manifest gene carrier patients.

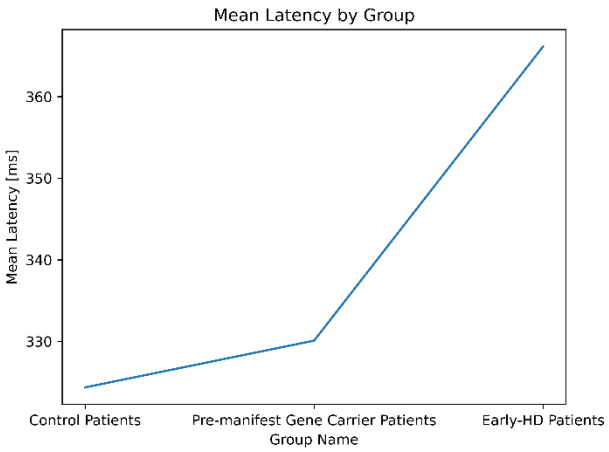

Figure 4. Average Latency [in ms] of patients from a different group.

Whereas for reaction time and correctness, no patterns or correlations were found. It came out to be similar for all the groups. These are essential factors for UHDRS and are hence used in the paper.

E. TFC, TMS, and DCS

Clinical measures which account for prognosis and intensity measurement of HD are TFC or Total Functionality Capacity, TMS or Total Motor Score, and DCS or Diagnostic Confidence Level Score. These measures are used in the computational modelling technique to differentiate between different subgroups of HD. [12]

A clinical grading system called Total Functional Capacity assesses the functional capacities of people suffering from HD. There are 5 stages in total, where Stage 1 shows full functional ability and Stage 5 denotes total loss of independence. A clinical rating measure called Total Motor Score is used to evaluate motor symptoms in HD patients. A clinical grading system called the Diagnostic Confidence Level Score assesses a clinician's level of assurance in making the HD diagnosis. Higher scores on the 5-point scale indicate greater confidence in the diagnosis. The TFC, TMS, and DCS scores are used in the UHDRS (Unified Huntington's Disease Rating Scale) and TRACK-HD studies to measure many aspects of Huntington's disease. After applying statistical methods to these values it was observed that the TMS score in each group varied from 1.46 in Control Patients, to 2.51 in Pre-manifest Gene Carrier, to 22.92 in Early-HD patients. [13]

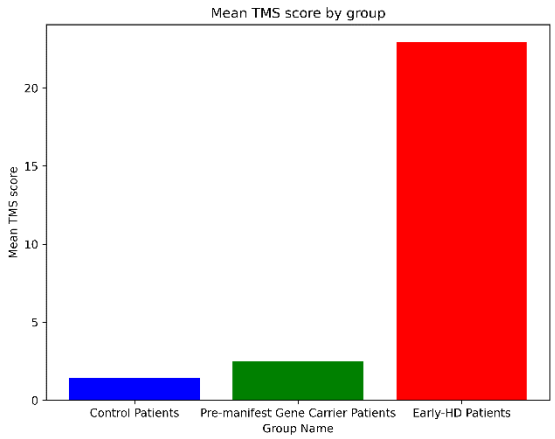

Figure 5: Average Total Motor Score (TMS) for different groups of patients

V. Machine Learning and Deep Learning

The main aim of this research is to assess the accuracy of tests used to diagnose HD in real-world circumstances utilizing computational models like Machine Learning and Deep Learning. The goal was to create a model that could categorize individuals into different phases of HD or forecast the rate of disease development. Before analyzing the TRACK-HD dataset, data cleaning and pre-processing were carried out. Rows with missing data were removed, providing a clean CSV file.

The study employed a dataset of patients with HD and collected pertinent clinical and demographic data to fulfil the research aim. After then, the dataset was divided into training and testing sets. The study determined the relevant features and target variable, then trained a CatBoost classifier on the training set with the specified features and target variable. [7] Accuracy and AUC-ROC scores were collected as performance metrics, and the trained model was then used to generate predictions on the test data. The main purpose was to develop classifiers based on behavioral and model features in a sample of persons with HD, and then investigate if these classifiers could distinguish between new subject groups. Investigation of alternative deep learning and machine learning approaches was done before employing CatBoost, including Long Short-Term Memory (LSTM), Linear Discriminant Analysis (LDA), Random Forest, Gradient Boosting Machine (GBM), Support Vector Machines (SVM), Logistic Regression, and K-Nearest Neighbours (KNN). To examine how effectively a classifier might predict the phases of HD or the rate at which the sickness will advance, Area Under the Receiver-Operator-Characteristic Curve (AUC), a measure robust to unequal class sizes was evaluated. As per our examination, the results determined that CatBoost was the most appropriate algorithm for our dataset. [14] [15]

TABLE I. MODEL AND ITS ACCURACY COMPARISON.

Assessment of Machine Learning Models	
Model Name	***Accuracy***
Support Vector Machine	0.72977
Gradient Boosting Machine	0.94530
Random Forest	0.99665
CatBoost	0.99888
Long Short-Term Memory	0.45358
Linear Discriminant Analysis	0.66853
Logistic Regression	0.75728
K-Nearest Neighbors	0.66095
Gaussian Naive Bayes	0.69609

VI. Validation

A prominent statistic for examining binary classification challenges is the Receiver Operating Characteristic (ROC) curve. In this study, ROC curve analysis was done to determine the accuracy of our Catboost model in predicting the incl02 score for HD. The model demonstrated a high degree of accuracy, with an AUC-ROC of 0.9999, indicating that it can accurately distinguish between the control, premanifest gene carrier, and early HD groups. Furthermore, the precision of the model was determined to be 0.9988, indicating that the model's predictions are highly accurate. These findings indicate that the features extracted from the UHDRS and TRACK-HD datasets have the potential to be biomarkers for the early detection of HD, and they suggest that the Catboost algorithm is a promising tool for biomarker discovery in this field. Overall, our findings show that machine learning technologies have the potential to develop effective biomarkers for early identification and treatment of HD. [6] [15]

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 02,2023 at 06:45:13 UTC from IEEE Xplore. Restrictions apply.

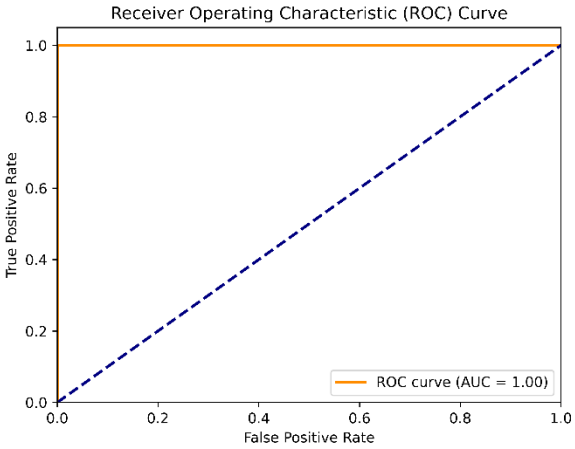

Figure 6: ROC curve of CatBoost Method.

VII. Conclusion

A Machine Learning Model was fitted into a TRACK-HD dataset with UHDRS features in an antisaccade testing that will help clinicians to accurately classify individuals as either control, premanifest gene carrier, or early HD based on certain features or biomarkers present in their data. The dataset used to train the model created in this dataset contains characteristics linked to oculomotor impairments in premanifest and early HD patients. These characteristics are used by the computational model to forecast a person's chance of developing HD. The model is particularly effective at accurately identifying people with HD since it has a high accuracy rate of more than 99%.

This model is thus suitable as a biomarker for HD, as clinicians and researchers can identify people who are at risk for HD before any symptoms appear by using the characteristics that have been found to predict HD. Early detection can enable earlier therapy and management, which can assist decrease the disease's course and enhance patient outcomes [6]. The high performance of more than 99% accuracy is achieved while using CatBoost and Random Forest methods. To further improve the performance, methods such as feature engineering, improvements in data size, data quality, preprocessing, hyperparameter tuning, model ensemble, and the utilization of different cross-validation and evaluation metrics are essential.

In the literature, several similar papers have been published on this topic. However, it should be noted that these papers do not provide any validation scores or accuracy measurements, making it difficult to assess the reliability and performance of their proposed methods. Furthermore, the correlation between different features and patients has not been extensively studied or reported in these papers. Therefore, there is a need for further research to explore the relationship between the different features and their impact on patient outcomes, as well as to validate the proposed methods with appropriate evaluation metrics and validation scores. In reviewing existing literature, it becomes apparent that previous studies have explored machine learning algorithms for HD detection, but few have specifically investigated the correlation between different features and HD diagnosis. In our research, which incorporates CatBoost, addresses the gap by demonstrating promising results in accurately identifying HD based on the correlation of various features within the TRACK-HD and UHDRS datasets. This emphasizes the significance of my model in advancing HD diagnosis and potentially enhancing the understanding and management of the disease.

Abstract
The exact retrieval of both i.e., watermark and host data using reversible watermarking makes it more suitable for applications like medical, military etc. The techniques which are considered most efficient and are being most widely used to implement it (reversible watermarking) are Prediction Error Expansion and Histogram Shifting as they offer higher embedding capacity with lesser distortion. The methodology proposed in this work is a hybrid one that utilizes the best of both. The algorithm starts with splitting the image into two regions and further processing is done on them one by one thereby covering each pixel for embedding thus amounting to enhanced capacity. The proposed work exploits the histogram of prediction errors instead of difference of adjacent pixels as it is more sharply distributed. This leads to lesser distortion in watermarked image. In this paper, the sorting of prediction errors is done in accordance with the calculated variance values of their prediction context followed by pairwise payload embedding. The results have substantiated the fact that for the smaller variance, prediction errors are also small. The proposed methodology is tested against the standard test images and real life applications such as medical, biomedical, aerial, military and colour images of Kodak image dataset. The experimental results demonstrate the superiority of the proposed work over the existing ones in terms of embedding capacity and distortion.

1 Introduction

The advancement of Internet technology has made the communication so facile that even a person miles away can connect with others without any hindrance. One can effortlessly access any sort of digital data, document, image or video, for any purpose, either for gathering knowledge or for entertainment, and can share it with others. This easy access to the data, at the same time, poses a threat to its security and the owner's copyright claim. One can easily infringe the data without giving the due credit to the owner and can use it unethically. Such fraudulent acts necessitate the requirement for data hiding techniques to avert the misuse of data. The research work steering in this direction suggests Steganography and Digital Watermarking as the optimal solutions for this.

Steganography and Digital Watermarking both insert the covert information within the original data. Steganography focuses only on the secret communication between the sender and the receiver. The unauthorised user is unaware of the presence of secret data [1]. This way the secured communication takes place. On the contrary, the secret information, known as watermark, is used to prove the authenticity of the data. A randomly generated sequence of bits or any image or any information revealing the owner's identity, like owner's name or a company logo, can be used as a watermark to hide within the host data [2, 5, 7]. The researchers have been striving for ameliorating the performance of digital watermarking algorithms in an attempt to preserve the digital content and the rights of its owner, even after its dissemination [3, 4]. Apart from copyright protection, Digital Watermarking also suits to other applications such as fingerprinting, tamper detection, protection of data from being copied and so on [29]. The algorithms so designed may utilize key while embedding the secret information. The same key must be provided during the extraction phase for authentic recovery of hidden data. But sharing of key with the receiver is difficult and moreover, if unauthorized user gets the access of key then the data can be tampered or misused [22]. Thus, the proposed work is blind in nature which embeds the information required for extraction within the cover data itself. This enhances the security of the data while transmission.

In conventional watermarking, original data might get destroyed. However, some applications do exist where even the small changes in the original data cannot be afforded. Healthcare services is one of the major applications. Suppose a patient's MRI is watermarked with his details then on the receiver side the patient's details are required for authentication purpose and his MRI is required for further treatment. This advocates for the need of exact retrieval of both the watermark and the cover data. Military services is another critical application. Both the information content as well as watermark of these applications are very sensitive. Even the small changes made by illegitimate user should be recognised by the receiver. This demands for the fragile technique so that integrity can be assured. To accomplish such objectives, Reversible Watermarking or Lossless Data Hiding algorithms can be utilized which are fragile in nature.

The concept of reversible watermarking, pioneered by Hosinger et al. [12], aims to execute distortionless embedding and recovery of cover image in addition to the watermark. The realization of the same demands for the insertion of supplementary data, required later for extraction, besides the watermark [16, 26, 28]. This however increases the size of the total payload to be embedded as against the conventional one. This stipulates for the need of an algorithm with higher embedding capacity which may, in turn, lead to higher distortion. At the same time the watermark must be imperceptible. Thus, an efficient reversible watermarking algorithm attempts to sustain the balance between all these parameters. The researchers have designed various state-of-the-art techniques to attain these objectives.

The techniques can be broadly classified into three major categories [16, 24]. These are:

1. Histogram modification based techniques
2. Compression based techniques
3. Expansion based techniques

In Histogram modification based techniques, the image histogram bins assist in locating the appropriate locations for hiding the watermark. The algorithms based on this technique are generally semi-fragile in nature. Ni et al. [25] proposed an algorithm utilizing the pixel values within the range of peak and zero points of the cover image histogram for watermark embedding. This showed that the number of pixels in the selected bins constrained the embedding capacity. An attempt has been made by Lin et al. [21] to improve the embedding capacity by utilizing the difference of adjacent pixels of host image to create a difference image. They divided the image into different blocks and applied the Histogram modification on the corresponding blocks of difference image to insert the payload. Although this technique enhanced the embedding capacity but it suffered from increased overhead data as peak value information needed to be stored for each block.

The compression based techniques, before embedding the watermark, compress some part(s) of the host data resulting in the creation of space for data hiding. The total payload, hence, is the combination of both the original watermark and the information related to the compressed part. These algorithms are mostly fragile in nature. In [6], Celik et al. attempted to utilize both the quantization and compression to generate the watermarked image. Memon et al. [23] presented a compression based approach applying threshold optimization that ultimately increased the embedding capacity.

The techniques which are being used extensively today by the researchers come under the category of Expansion based techniques. This is due to the fact that these techniques exhibit better embedding capacity and are computationally efficient. These techniques can further be classified into three categories:

1. Difference Expansion based techniques
2. Prediction Error Expansion based techniques
3. Interpolation based techniques

Difference Expansion (DE) based techniques exploit the redundancy available in the cover image to achieve the higher embedding capacity [35]. These techniques are known for their high embedding capacity and low computational complexity.

Prediction Error Expansion (PEE) based techniques are the extension of DE based techniques which further improves the embedding capacity and reduces the distortion. These predict the values of the candidate pixel using some prediction algorithm by exploiting the correlation between the neighbourhood pixels. To keep the distortion minimum, the prediction algorithm must be capable of predicting accurate value such that negligible prediction error occurs. The commonly used predictors are Mean predictor, Rhombus predictor, Median Edge Detector (MED) predictor. The predicted values are expanded to hide the payload and the expandable locations are determined by the Histogram Shifting (HS) method. Here the histogram of prediction errors is used to determine the locations because it is more sharply distributed leading to better performance. But, the expansion amounts to the "data overflow" and "data underflow" problem. Preferably, the pixels with smaller prediction errors are modified to achieve low distortion [10, 28, 41].

Interpolation based techniques intent to estimate the missing pixels to generate interpolated image. The interpolation errors, thus obtained, are considered for the data hiding. Unlike other DE techniques, for watermark embedding it considers interpolation error rather

than difference between adjacent pixels or prediction errors [15, 32]. These techniques are generally fragile in nature.

Table 1 summarizes the properties of different reversible watermarking techniques. It can be concluded that different techniques serve different purposes, so today researchers prefer to use combination of more than one technique, known as Hybrid technique, to incorporate the merits of various techniques. As it can be seen that PEE techniques provide better embedding capacity and lower computational complexity and HS offers for the expandable locations, so this paper has combined the HS and PEE techniques to design a reversible watermarking algorithm. Moreover, to reduce the distortion, the pairwise expansion of the prediction errors has been done in this paper. The paper also targets to make the proposed algorithm blind.

The structure of the paper is organised as: Section 2 summarizes some of the existing methodologies developed for the reversible watermarking. The Section 3 explains the proposed methodology in detail. In Section 4, the results obtained by implementing the proposed algorithm have been presented and compared with the existing state-of-the-art algorithms. The Section 5 concludes the work presented in this paper.

2 Related works

This section gives insights into the work that has been done in the recent times using HS and PEE techniques. The development of such reversible algorithms start with the determination of the candidate pixels for prediction. These pixels are then predicted using the neighbouring pixels by executing a certain predictor. The predicted values are then used to calculate the prediction errors by taking the difference between them and the original pixels.

$$e = f - f' \tag{1}$$

where 'e' is the prediction error, 'f' is the original image pixel and 'f′' is the predicted value of the pixel f.

Next the Prediction Error Histogram (PEH) of all the prediction errors is derived and modified to determine the expandable locations. This was done in 2007 for the first time by Thodi and Rodriguez in [34]. The researchers applied different mechanisms to modify the PEH that ultimately decided the performance of the designed algorithm. Some algorithms

Table 1 Comparison of different reversible watermarking techniques [16]

Technique	Properties	Remarks
Histogram modification based techniques	Bins of Image histogram are used to identify the locations for hiding the watermark	Embedding capacity is constrained by the number of pixels available in the selected bins.
Compression based techniques	Compresses some part of the host data to create space for data hiding	Mostly fragile in nature and it increases the size of payload to be embedded
Expansion based techniques	Exploits the correlation among the neighbourhood pixels	Higher embedding capacity and it can suffer from data overflow and data underflow problem

select the zero bins to expand the errors while some select the peak bins. On the other hand, some researchers have attempted to select a range for expanding the errors and the bins outside the range are shifted to prevent the overlapping. Figure 1 shows a typical example of a PEH. The errors within the bin range [−1,1] shown by grey colour are expanded while others are shifted. The distortion can further be reduced if the prediction errors are first sorted before embedding the watermark bits. This has been demonstrated by Sachnev et al. [31] where the author tends to first sort the prediction errors on the basis of the local variance.

Later the researchers have devised the pairwise PEE technique so that the redundancy available in the image can be exploited in a better way to further enhance the embedding capacity and reduce the distortion. Ou et al. [27] have exploited the correlation between the adjacent prediction errors and forms the prediction error pairs while Dragoi et al. [8] opted for adaptive strategy for pairing. The work proposed in [40] and [17] has also shown that the algorithms based on pairwise PEE techniques reduce the distortion and provide watermarked images of higher visual quality. The predictors, that are used to predict the values of the candidate pixels, also play a crucial role in reducing the distortion. The accuracy of the predicted values depends on the type of predictor used. The commonly used predictors are Mean predictor, Rhombus predictor, Median Edge Detector (MED) predictor. M. Ishtiaq et al. [14], devised a hybrid predictor to obtain small prediction errors. These advancements have resulted in the improvement in terms of distortion and embedding capacity as compared to the other reversible watermarking techniques. But the results have also shown that with the increase in number of watermark bits, the visual quality of the watermarked images gets deteriorated. This shows that the embedding capacity of these techniques is limited. This calls for the designing of such algorithms that can achieve higher embedding capacity without the significant increase in distortion.

The proposed work is also inspired from the existing works and aims to ameliorate the performance of the existing algorithms and overcome their shortcomings. The contribution of the proposed work can be outlined as:

- The paper targets to accomplish higher embedding capacity with lesser distortion using HS and pairwise PEE techniques. It splits the host image into two regions which subsequently entitle every pixel to accommodate watermark bit leading to higher capacity. The histogram of prediction errors has been devised as opposed to histogram of difference between the adjacent pixels as the former is more sharply distributed leading to lesser distortion.

Fig. 1 Example of Prediction Error Histogram that attempts to select a range [-1,1] shown by grey colour for expanding the prediction errors and the bins outside the range are shifted to prevent the overlapping

- This paper effectuates sorting of prediction errors with the utilization of variance of prediction context and while embedding it forms the pair between the pixels corresponding to the adjacent sorted prediction errors unlike the existing techniques which considers the adjacent pixels for pairing. This realizes the goal of high quality watermarked image. Moreover, it spreads the watermark all over the cover image which makes it difficult to be identified by the unauthorised person.
- The proposed approach has been made a blind one so that no information needs to be sent along the watermarked image. All the prerequisites for the detection algorithm have been inserted in the watermarked image itself.
- The proposed algorithm has been executed on the medical and military images also along with the standard test images to examine its performance on real life applications. The algorithm has been subjected to colour images also.

3 Proposed methodology

3.1 Watermark embedding

The methodology deploys HS and pairwise PEE techniques to realize a blind reversible watermarking algorithm. The procedure for embedding the watermark in the cover image to obtain the watermarked image is shown in Fig. 2. The figure is discussed in detail through the following sub-sections..

3.1.1 Image decomposition

Image disintegration is the prime requirement towards the accomplishment of the desired objective. The image is decomposed into two regions as represented in Fig. 3. This has been done to circumvent the superimposition of prediction context required for predicting the value of the entitled pixel. The superimposition makes it difficult to recover the original image while decoding. As depicted in Fig. 3, the first region is comprised by the pixels represented by '+' sign while the second region is comprised by the

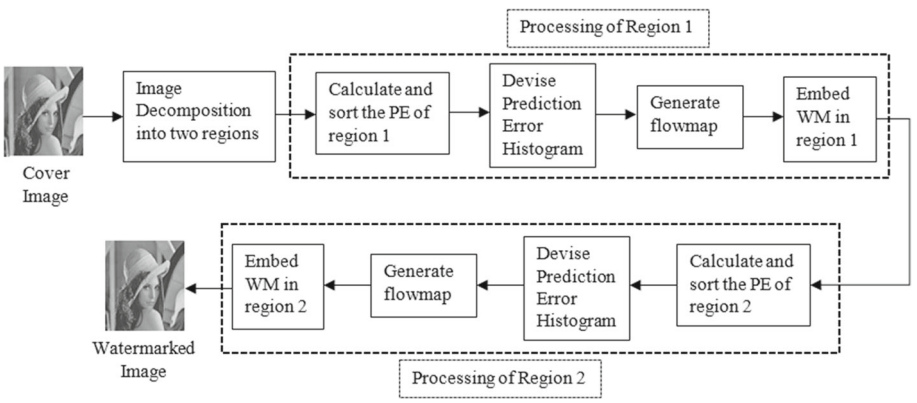

Fig. 2 Procedure to construct watermarked image

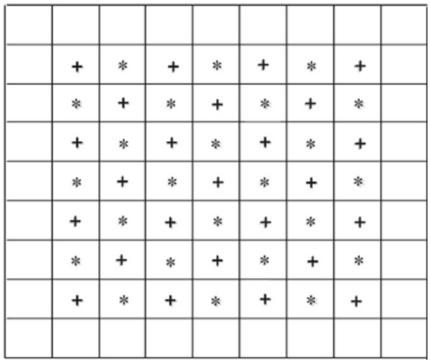

Fig. 3 Decomposition of the cover image into two non-overlapping regions. Region one is marked with '+' sign and Region 2 is marked with '*' sign

ones represented by '*' sign. The peripheral pixels of the cover image are left unaffected due to the requirement of first and last row for the insertion of payload header at the later stage. This makes all the pixels accessible for the embedding purpose except those at the boundaries and thus helps in achieving the objective of high embedding capacity.

3.1.2 Prediction methodology

The next step calls for the calculation of the prediction values of the candidate pixels. The pixels marked with '+' sign are designated as the candidate pixels for the first region and similarly '*' marked pixels denotes the candidate pixels for the second region. The prediction methodology must be very accurate so that very less prediction error occurs. Since the errors need to be expanded so large errors will lead to more distortion. Due to this fact a hybrid predictor is used in this paper which utilizes the variance of the prediction context to predict the pixel value.

The hybrid predictor as given in (2)–(7) makes use of three different predictors on the basis of variance of the prediction context. If variance is less than 10, rhombus predictor is used. A modified version of the Checkerboard Predictor used in [30] is utilized if the variance lies within the range [10 20]. Finally, the middle values of sorted prediction context are used for prediction if variance is greater than 20.

The prediction context for the first region will consist of pixels of the second region and vice versa. To predict the value of pixel $f_{i,j}$, the prediction context, 'c', will be:

$$c = [f_{i-1,j},\ f_{i,j+1},\ f_{i+1,j},\ f_{i,j-1}] \tag{2}$$

$$var(c) = \frac{\sum_{k=1}^{4}(c_k - \bar{c})^2}{3} \tag{3}$$

$$f'_{i,j} = \begin{cases} p, & var(c) \le 10 \\ q, & 10 < var(c) \le 20 \\ r, & \text{elsewhere} \end{cases} \tag{4}$$

$$p = \frac{c(1) + c(2) + c(3) + c(4)}{4} \tag{5}$$

$$q = \begin{cases} \frac{c(2)+c(4)}{2}, & ||c(1) - c(3)|| > ||c(4) - c(2)|| \\ \frac{c(1)+c(3)}{2}, & ||c(1) - c(3)|| < ||c(4) - c(2)|| \\ \frac{c(1)+c(2)+c(3)+c(4)}{4}, & \text{otherwise} \end{cases} \tag{6}$$

$$r = \frac{cs(3) + cs(4)}{2} \tag{7}$$

where 'var(c)' denotes the variance of the prediction context and 'cs' is the prediction context c sorted in the ascending order.

The prediction values obtained in this step can now be used as to calculate the prediction errors, i.e. the difference between the original pixel value and the predicted pixel value.

The prediction errors thus obtained are sorted in ascending order according to the variance of their prediction context. In [14], it has been shown that the performance of the reversible watermarking algorithm in sorted case is better than the unsorted case. For the small variance, prediction errors are also small. Thus the algorithm based on sorted prediction errors exhibits less distortion and results in better quality watermarked image. This can be supported by Fig. 11 also.

3.1.3 Histogram range calculation

Once all the prediction errors are obtained, a histogram of these errors is devised. Instead of using the histogram of difference between the adjacent pixels, prediction error histogram has been used as it is more sharply distributed which leads to lesser distortion. From the histogram, two thresholds- negative threshold t_n and positive threshold t_p are calculated. Only those errors will be expanded which are covered within this range. These thresholds are calculated according to the size of payload. The smaller magnitude prediction errors are considered for the embedding purpose because large prediction errors when expanded will cause large distortion in the watermarked image so initially both t_n and t_p are taken as zero. If the magnitude of zero bin is less than the payload size, the negative threshold is decreased by 1. Again the size of payload will be compared with the total magnitude of histogram bins t_n and t_p. If the size of payload is still more, the positive threshold will be increased by 1. This cycle will be repeated until the total payload size is covered.

3.1.4 Generation of flowmap

Due to the embedding algorithm some pixels might suffer from "data overflow" and "data underflow" problem. Data overflow is the situation when the watermarked pixel exceeds the maximum value of image, i.e. 255 for an 8-bit image and data underflow occurs when this value becomes less than zero [10]. If such pixels are left without embedding, then the decoder would struggle while recovering the image as it would not be able to identify these particular locations. So the information of such pixel locations must be available to the decoder. Keeping in view such problem, a flowmap is created which contains the record of all the potential candidate pixels that might suffer from this problem. These pixels are left unchanged. In this work, the method for flowmap creation is inspired by the method presented in [14].

This methodology works by expanding the prediction error twice. For expansion a test bit is used which is '1' for positive prediction errors and '0' for negative prediction errors. According to the result of expansion these are divided into three categories:

- Category A: It provides information for those prediction errors which experience overflow or underflow just after the first expansion. So these will not be used for expansion. A '0' will be placed in the flowmap to represent these errors.
- Category B: It is used to determine about those prediction errors which experience overflow or underflow after second expansion not the first one. These errors will be expanded for embedding and a '1' will be placed in the flowmap to represent them.

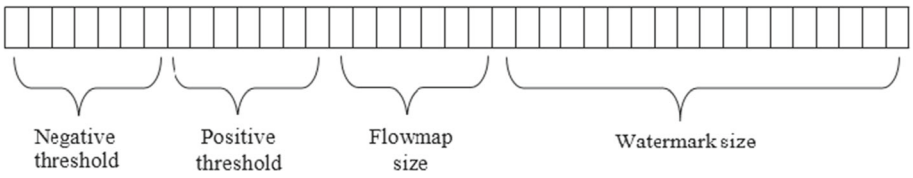

Fig. 4 Structure of payload header

- Category C: If the prediction error does not experience any overflow or underflow even after the second expansion then there is no need to provide any information about them in the flowmap. These errors will be used for watermark embedding.

The flowmap obtained this way does not contain any information about the category C prediction errors. Also the size of category C prediction errors is much greater than the size of category A and category B prediction errors which leads to the reduction in flowmap size considerably as compared to the other existing techniques.

During extraction the prediction errors are expanded only once. If the prediction error does not suffer from overflow or underflow, then that error can be expanded. If it then flowmap is checked and bit '0' of flowmap implies no embedding while bit '1' implies embedding is done.

3.1.5 Embedding of payload header

As discussed earlier the parameters such as t_n, t_p, flowmap size and watermark size are prerequisite for the decoder, so an array is created by concatenating all of these. This array, known as the payload header as shown in Fig. 4, is to be embedded in the image using LSB replacement. For the first region, the LSBs of the pixels of first row of watermarked image are used and for the second region, the LSBs of the pixels of last row of the watermarked image are used. Since we have to extract both the watermark and the original image faithfully at the receiver side, so the LSBs of such pixels are first saved before the actual replacement. After that each bit of the payload header will be replaced with the LSB of these pixels of the image. The final watermark, known as payload, will consist of LSBs of the used pixels, flowmap and the original watermark.

3.1.6 Watermark embedding

The embedding is done using HS and the pairwise expansion of sorted prediction errors as it reduces the distortion and overlapping problem as compared to the other techniques. This further leads to the enhanced embedding capacity of the algorithm.The flowchart shown in Fig. 5 illustrates the steps to obtain the watermarked image. The flowchart represents the embedding methodology only for first region. The same steps are required to be followed with second region to get the final watermarked image. For embedding, two different sets of pixels, set A and set B, are created from the sorted prediction errors. Set A encompasses those prediction errors which occurs within the range of positive and negative threshold and set B incorporates those prediction errors which lie outside this range. This formation of sets is continued until the size of the payload is not achieved. This is given by (8):

$$e_{i,j} = \begin{cases} A, & t_n \leq e_{i,j} \leq t_p \\ B, & \text{otherwise} \end{cases} \tag{8}$$

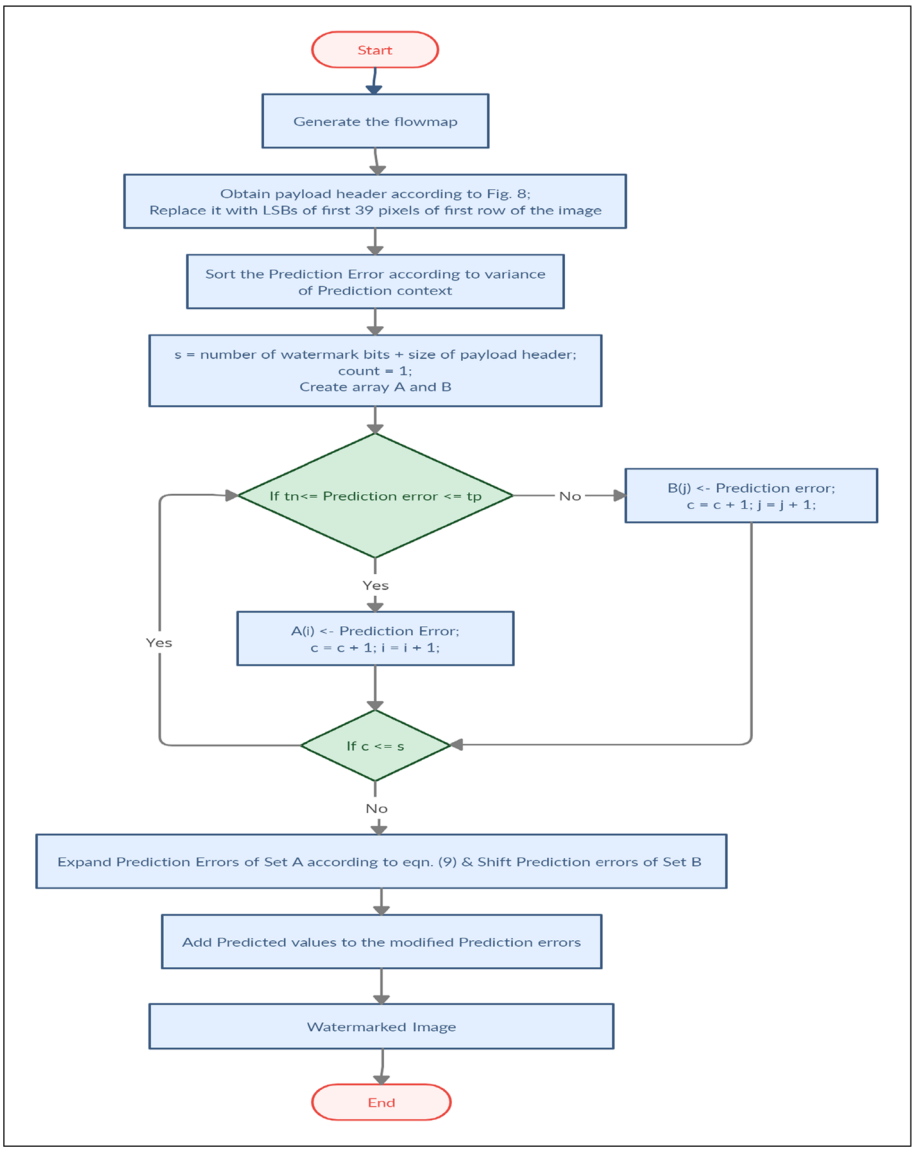

Fig. 5 Flowchart to obtain the watermarked image.It represents the embedding methodology only for the first region. The same steps are required to be followed with the second region also to get the final watermarked image

The payload embedding methodology exploits the pairwise PEE technique. This paper exploits the correlation between the pixels corresponding to the adjacent sorted prediction errors. Since the prediction errors are sorted on the basis of variance, the expansion of adjacent sorted prediction errors will lead to less distortion which in turn will provide high quality watermarked image. The errors of Set A are used to form the pairs and hence for

embedding the watermark. The combination of '00', '01' and '10' will be used to watermark the pair. The combination '11' is not used to reduce the distortion.

The expansion of prediction errors is done according to the (9):

$$e'_{i,j} = \begin{cases} 2e_{i,j} + b, & t_n \leq e_{i,j} \leq t_p \\ e_{i,j} + t_p + 1, & t_p \geq 0 \text{ and } e_{i,j} > t_p \\ e_{i,j} + t_n, & t_n < 0 \text{ and } e_{i,j} < t_n \end{cases} \tag{9}$$

where '$e_{i,j}$' is the prediction error of pixel '$f_{i,j}$', '$e'_{i,j}$' is the expanded prediction error and 'b' is the payload bit that is to be embedded. The value of 'b' can be either '0' or '1'. If it is '1' then it will be '0' for the next pixel of the pair as pair of two pixels is formed and combination of '11' is not allowed to use. The errors lying outside the range, that is errors of Set B, are shifted to prevent the overlapping. From (9), it can be concluded that the expansion of larger prediction errors can cause higher distortion. That's why smaller histogram bins are considered for the expansion of prediction errors. Due to this fact, higher PSNR is possible to achieve even for higher embedding capacity.

The watermarked pixel will be obtained by adding the predicted pixel and the expanded prediction error as given by (10):

$$w_{i,j} = f'_{i,j} + e'_{i,j} \tag{10}$$

where '$w_{i,j}$' represents the watermarked pixel.

The above procedure is repeated for the second region also. The watermarked image obtained after the first region will be considered as the cover image for the second region and the final watermarked image can be obtained using the same procedure.

3.2 Extraction of watermark and cover image

The extraction procedure is the reversal of the embedding procedure as shown in Fig. 6. It considers the region two first followed by region one for extraction. The image recovered from the second region will be considered as watermarked image for the first region. The following sub-sections elaborates the procedure of the watermark extraction method.

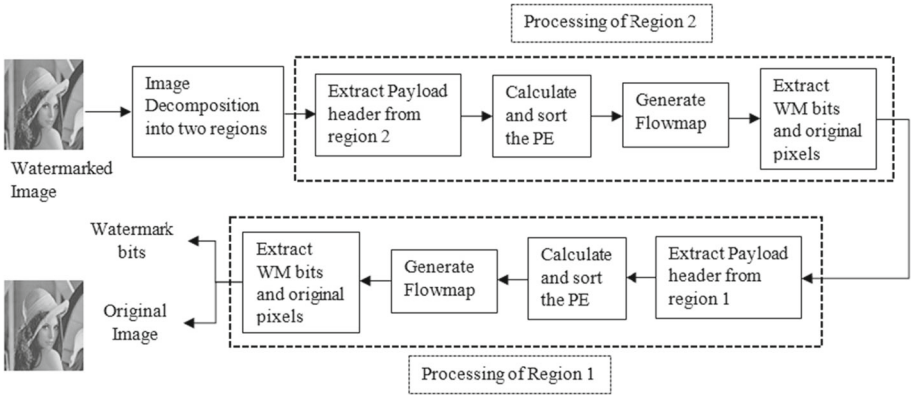

Fig. 6 Procedure to extract watermark and cover image

3.2.1 Image decomposition

The decoding approach also starts with the decomposition of the image into two non-overlapping regions as it has been done during the embedding stage. The Fig. 3 shows the two regions of the image. The purpose also remains same that is to prevent the overlapping of prediction context.

3.2.2 Extraction of payload header

The payload header is extracted from the LSBs of the pixels of the first row of the watermarked image for the region one and LSBs of the pixels of the last row of the watermarked image for the region two. In decoding stage, the positive threshold is $2t_p + 1$ and negative threshold is $2t_n$. The prediction errors lying between these two thresholds will be considered for the extraction of watermark.

3.2.3 Prediction methodology

This step targets to predict the values of the candidate pixels. To realize the distortionless extraction, the same hybrid predictor is utilized as represented by the (2)–(7) and subsequently the prediction errors are calculated. The prediction errors thus obtained are sorted according to the variance of their prediction context.

3.2.4 Watermark extraction and recovery of cover image

The extraction of payload also starts with the formation of Set A and Set B. This time Set A contains the errors lying within the range of $2t_p+1$ and $2t_n$. The errors outside this range constitutes Set B. This formation continues until the payload size is achieved. The errors of Set A are used for payload extraction while those present in Set B are shifted to retrieve the original prediction errors. The extraction is done according to the (11).

$$b = e'_{i,j} \bmod 2, \text{ if } e'_{i,j} \epsilon [2t_n, 2t_p + 1] \tag{11}$$

where, 'b' is the extracted bit and '$e'_{i,j}$' is the prediction error calculated at the extraction stage.

After extracting all the bits, the prediction errors are restored to their original values using the (12):

$$e_{i,j} = \begin{cases} \lfloor e'_{i,j}/2 \rfloor, & 2t_n \le e'_{i,j} \le 2t_p + 1 \\ e'_{i,j} - t_p - 1, & t_p \ge 0 \text{ and } e'_{i,j} > 2t_p + 1 \\ e'_{i,j} - t_n, & t_n < 0 \text{ and } e'_{i,j} < 2t_n \end{cases} \tag{12}$$

The bits retrieved using the (10) are replaced with the LSBs of the pixels of first row for the first region and pixels of the last row of the image for the second region. This restores the original pixels of the respective row.

The original image is extracted by adding the restored prediction errors and the predicted values. The steps discussed so far are repeated for the first region also. The image extracted after the processing of region two will be considered as watermarked image for the region one.

4 Results and discussions

4.1 Experimental results

This section investigates the performance of the proposed reversible watermarking algorithm. The parameter Peak Signal to Noise Ratio (PSNR) is used to check the visual quality of the watermarked image. A PSNR of high value is always desirable. It is given by (14):

$$MSE = \frac{\sum_{p=0}^{M-1} \sum_{q=0}^{N-1} (W_{p,q} - X_{p,q})^2}{M * N} \tag{13}$$

$$PSNR = \log_{10} \left(\frac{Max_X^2}{MSE} \right) \tag{14}$$

where, 'MSE' is the Mean Square Error between the original image and the watermarked image. 'X' is the original image. 'W' is the watermarked image. M*N gives the size of the image. 'Max_X' is the maximum possible value of the image X which is 255 for an 8-bit grayscale image.

Since the maximum MSE can be 1 so the corresponding PSNR will be approximately equal to 48. Due to this reason the embedding capacity is not increased beyond the value that results in PSNR below 48.

The tool used for the implementation of the algorithm is MATLAB R2017a. The proposed algorithm has been executed over 66 images taken from different datasets, namely USC-SIPI dataset, CVG-UGR database (Figs. 7 and 8), hlevkin database and Kodak Image dataset. These test images are of diverse nature, i.e., some of them are standard test images, some are used for military applications and some are used for medical purposes. The performance of the algorithm against these images can be analysed using Fig. 9. Figure 10 shows how visual quality and embedding capacity vary with threshold for Lena image . The effect of sorting the prediction errors on visual quality can be understood using Fig. 11. Figures 12, 13 and 14 compares the performance of the suggested algorithm with the existing approaches against the frequently used standard test images, as shown within the plot. The standard grayscale test images used to evaluate the performance of the proposed algorithm are Lena, Mandrill, Airplane and Lake as shown in Fig. 12. Since the reversible watermarking finds its application in the biomedical, medical, aerial and military images, hence some of these kinds of images are also used to measure the algorithm's performance. The images used to test the performance against biomedical and medical images are Algae, Fingerprint, Heart and X-ray as shown in Fig. 13. To assess the performance of the proposed algorithm in the aerial and military applications, the images used are aerial, military airplane, military APC and military car and APCs. These images are shown in Fig. 14. All these images are grayscale with size of 512*512 pixels. Furthermore, to compare the performance of the proposed algorithm with the existing state-of-the- art techniques, it is executed on colour

Fig. 7 Standard grayscale test images of size 512*512 pixels taken from CVG-UGR database: (a) Barbara, (b) Town, (c) Objects, (d) Monument, (e) Bird, and (f) Sailboat

Fig. 8 Standard grayscale medical MR test images of size 256*256 pixels taken from the CVG-UGR database: (a) MR1, (b) MR2, (c) MR3, (d) MR4, (e) MR5, and (f) MR6

images of Kodak Image dataset which are first transformed to grayscale images before the further processing. The payload size of 30,000 bits have been taken to compare the results with the existing techniques as represented in the Table 2.

4.2 Effect of sorting the prediction errors

The proposed algorithm sorted the prediction error on the basis of variance of prediction context to reduce distortion at smaller payloads. The smaller value of variance implies that the diversity within the neighbourhood of a pixel is not high. This facilitates the predicted value to be closer to the original one and hence the smaller prediction error. Moreover, embedding in smaller prediction error leads to high quality watermarked image. To verify this theory, the algorithm was tested both ways- with and without sorting. The experiments conducted on some of the standard test images have proven the fact and the same has been illustrated in Fig. 11. The graph shows that there exists a considerable difference between the PSNR obtained in the two cases specifically for the smaller payload. Therefore, sorted case has been considered further for the evaluation of the performance of algorithm.

4.3 Visual quality vs embedding capacity

This section presents the results obtained after the implementation of the proposed algorithm. The x-axis of the graph denotes the Embedding Capacity of the algorithm while the y-axis represents the PSNR in terms of dB which depicts the visual quality of the watermarked image. The higher the value of PSNR, the better is the visual quality of the watermarked image. As discussed above, the maximum embedding capacity is that number of bits whose corresponding PSNR is 48.

The algorithm has been tested against a number of images of different datasets. Figure 9 depicts the PSNR obtained for different embedding capacity for these images. The size of images are 512 * 512 pixels except for MR images of CVG-UGR database. The size of MR images is 256 * 256 pixels. From Fig. 9, it can be concluded that the proposed algorithm is capable of achieving high embedding capacity as the maximum embedding capacity lies within the range of 15% to 76% approximately. Most of the images have shown higher embedding capacity.

The performance of the algorithm is compared with the algorithms presented by Ou et al. [27], Dragoi et al. [8], Zhang et al. [40], Kouhi [17], M. Ishtiaq et al. [14], Li et al. [20] and Naskar et al. [24] and results are presented in Fig. 12. Figure 12(a) represents the results for Lena image which shows that higher PSNR is achieved and the embedding capacity is considerable high than the existing algorithms. Figure 12(b) illustrates the results for Mandrill image. At smaller payload the algorithm provides a slightly smaller PSNR but it increases with payload and achieves high embedding capacity. Figure 12(c) depicts the results for Airplane image which outperforms the existing techniques both in terms of

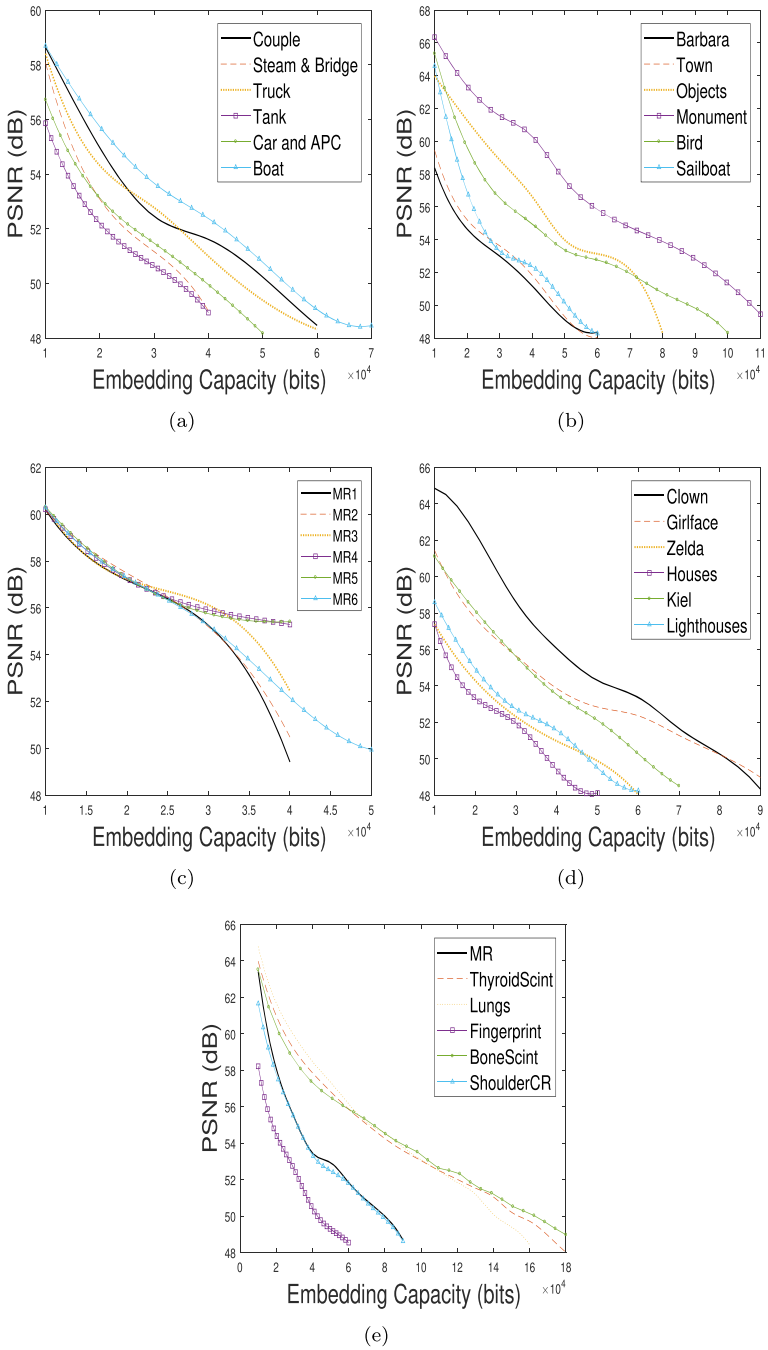

Fig. 9 Embedding Capacity vs PSNR for (a) test images of USC-SIPI dataset, (b) test images of CVG-UGR database, (c) MR images of CVG-UGR database, (d) test images of hlevkin database, and (e) medical images of hlevkin database

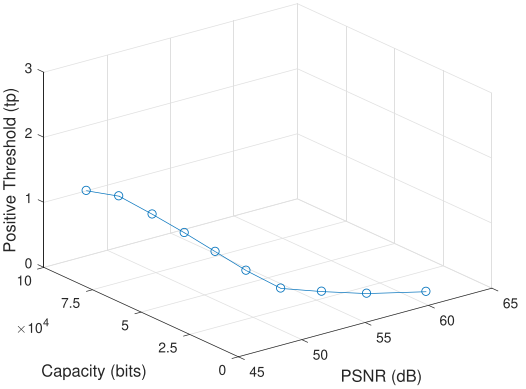

Fig. 10 Variation of Visual quality and embedding capacity with threshold for Lena Image

distortion and embedding capacity. Figure 12(d) represents the results for Lake image. It shows that initially PSNR is same but it increases considerably at higher payloads and the embedding capacity is also very high than the other algorithms.

The algorithm has shown appreciable results when applied to the standard grayscale test images. But the reliability of the algorithm must be tested from the application point of view also. One of the most important applications of reversible watermarking is in the field of medical and biomedical images where the integrity of original image is equally important as

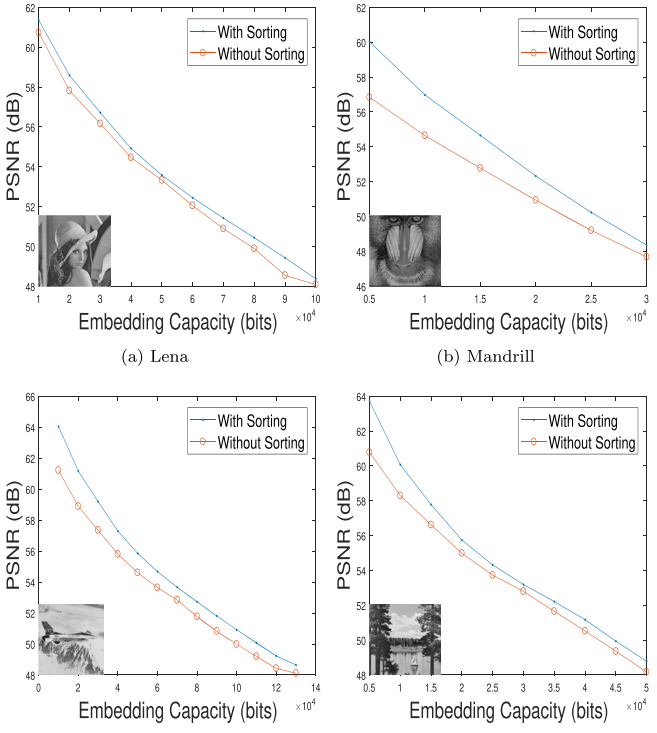

Fig. 11 Effect of watermark embedding with and without the sorting of prediction errors tested on standard grayscale test images

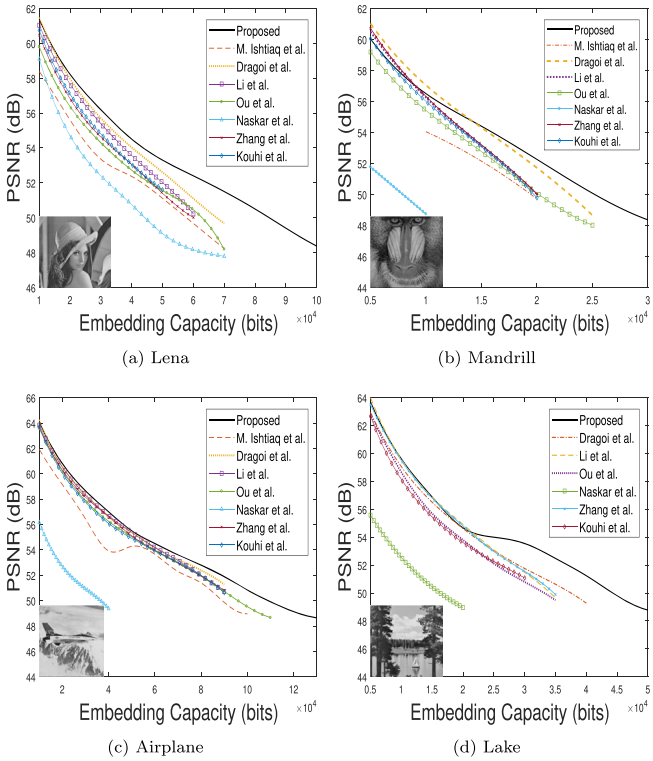

Fig. 12 Performance of proposed algorithm tested on standard grayscale test images and compared with the algorithm presented by Ou et al. [27], Dragoi et al. [8], Zhang et al. [40], Kouhi [17], M. Ishtiaq et al. [14], Li et al. [20] and Naskar et al. [24]

that of the watermark. For this the various medical and biomedical images have been taken to observe the performance of the algorithm.

The results obtained in the case of biomedical and medical images have been plotted in Fig. 13 and compared with Naskar et al. scheme [24]. The proposed scheme outperforms the algorithm present in [24] in terms of both distortion and embedding capacity except in case of algae where for smaller payload size scheme [24] is better. When the payload size increases the proposed algorithm performs better. Both the PSNR and the embedding capacity is significantly high. This is because of the sorting of the prediction errors using their variance and embedding the watermark in the lower magnitude histogram bins.

Another important application of the reversible watermarking is found to be in the aerial and military images where the exact retrieval of both the watermark and the original image is given utmost importance due to the security point of view. Thus the algorithm's performance is evaluated against various aerial and military images and the results have been shown in Fig. 14. The results have shown the superiority of the proposed algorithm over the algorithm presented by Naskar et al. [24].

Table 2 depicts the performance of the proposed approach when evaluated against the colour images of the Kodak dataset. The results are compared with the methodologies proposed by Xiong [37], Lee et al. [18], Hong et al. [11], Fallahpour [9], Yang et al. [38], Tai et al. [33], Li et al. [19], Yanga et al. [39], Hu et al. [13] and Wahed et al. [36] for the

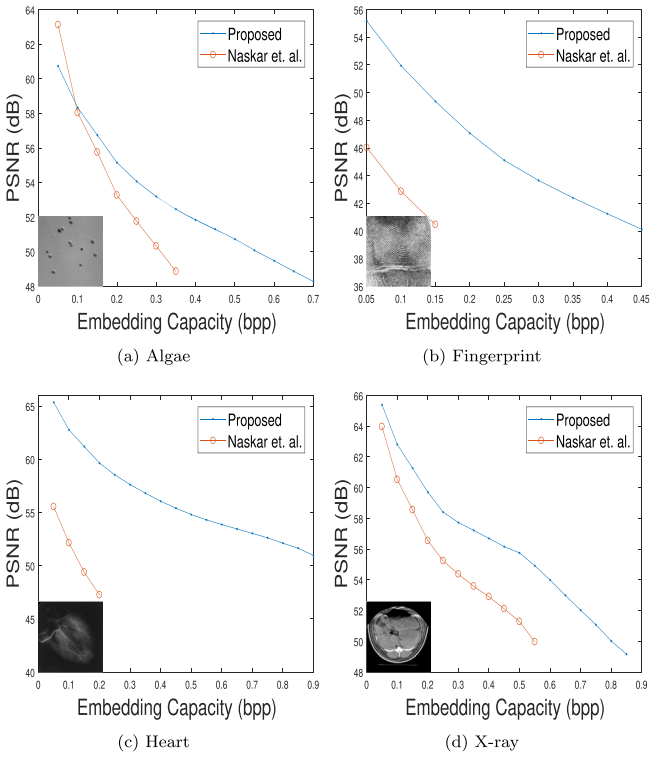

Fig. 13 Performance of proposed algorithm tested on Biomedical and Medical images and compared with the algorithm presented by Naskar et al. [24]

same embedding capacity of 30,000 bits. The average PSNR for such embedding capacity is 57.3232 as obtained from Table 2. This is greater than the existing approaches. So it can be interpreted that the proposed algorithm outperforms the existing techniques for colour images also.

4.4 Complexity of the algorithm

The proposed algorithm is less computationally complex if compared to the approach presented by Dragoi et al. [8]. This can be substantiated by the fact that the proposed algorithm forms pair between the adjacent sorted prediction errors to reduce the distortion while embedding the watermark bits. Whereas approach proposed in [8] forms the pairing of the candidate pixel with one of its neighbouring pixels according to the local complexity. This requires more processing to compare the neighbouring pixels as compared to the proposed algorithm. Moreover, the proposed methodology while generating the flowmap doesn't incorporate the locations where watermark bit is embedded. Had these positions have also been included then some compression technique must be required to reduce the flowmap size which is not the case with the proposed algorithm. This suggests that the algorithm is computationally effective also.

- Time Complexity

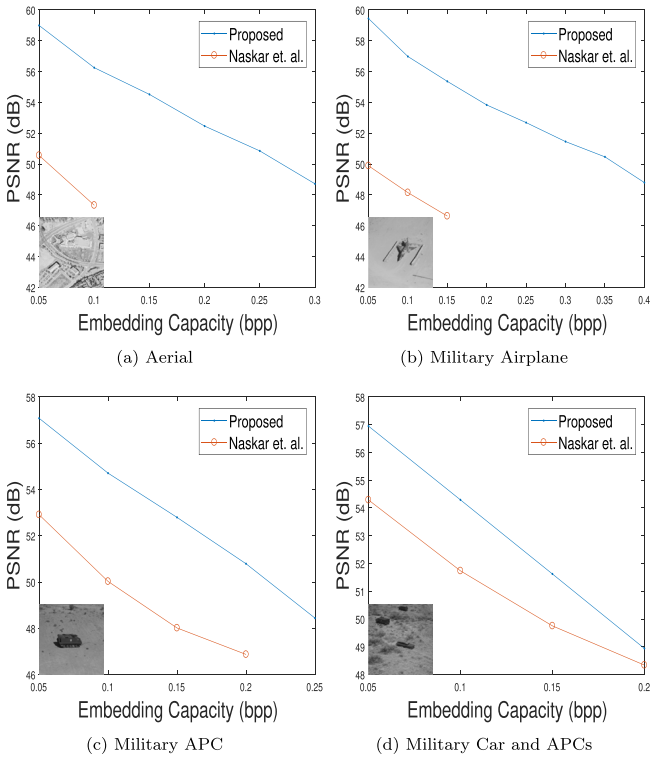

Fig. 14 Performance of proposed algorithm tested on Aerial and Military images and compared with the algorithm presented by Naskar et al. [24]

1. The initialization of image needs O($I_i m$ (mxn)) time where $I_i m$ represents original image, m represents the number of rows and n represents the number of columns in each image.
2. The time taken by processing region one is O(P_1 (mxn)) time where P_1 represents region 1 of the image.
3. The time taken by processing region two is O(P_2 (mxn)) time where P_2 represents region 1 of the image.
4. The total time taken by the watermark embedding and watermark extraction procedure is 2*(O(P_1 (mxn)) + O(P_2 (mxn))). For extraction purpose also the two regions of image have been considered.

- Space Complexity

  The original image and the watermarked image are required during the watermark embedding stage and watermark extraction stage, respectively. So the total space complexity is O($I_i m$ (mxn)) + O($W_i m$ (mxn)) where $W_i m$ represents the watermarked image.
- Execution Time

  The algortihm is implemented on the Intel Core i3 processor and 4GB RAM using MATLAB R2017a. The execution time taken in the processing of the standard grayscale test images is depicted in the Fig. 15.

5 Conclusion

In this paper, a fragile reversible watermarking algorithm has been proposed and implemented successfully. The algorithm is based on pairwise prediction error expansion and histogram shifting which claims to exhibit less distortion and high embedding capacity. The results obtained indicate the lesser distortion even at smaller payloads. The algorithm is able to extract the watermark and the host image without any distortion. The results further portray that the proposed algorithm outperforms the existing ones thus making it more suitable for medical, military, aerial images.

The proposed algorithm can further be made to work efficiently for video as well in future.

Abstract
In this paper, a GaAs quantum wire is considered with a semi-parabolic lateral confinement potential in the presence of a crossed electromagnetic field with the inclusion of Rashba SOI. The effects of pressure on thermodynamic properties have been studied. To this end, first, the eigenenergies for the system have been calculated considering Rashba spin effects under electric and magnetic fields. Then a numerical analysis is done to derive the partition function and obtain the system's thermodynamic properties. The results show that at low temperatures, all four thermodynamic properties don't show much effect due to pressure. It is found that entropy increases with increasing hydrostatic pressure, whereas pressure affects mean energy and free energy in a different manner. A peak structure is observed in specific heat as a function of temperature where the peak position depends on hydrostatic pressure.

Keywords Hydrostatic pressure · Quantum wire · Rashba effect · Thermodynamic properties

1 Introduction

Nanostructures have been the focus of many studies in the past decade, owing to their potential applications in micro-electronics, bio-medicine, photonics, quantum computing, and other engineering fields [1–3]. Advancement in several physical methods viz. lithography, molecular beam epitaxy, vapor deposition techniques, etc. [4–6] has made the fabrication of nanostructures feasible. Using these techniques, semiconductors can be grown into low-dimensional structures of desired geometry and size [7, 8], creating structures such as dots, wires, and rings.

rinkusharma@dtu.ac.in

[1] Department of Applied Physics, Delhi Technological University, Delhi 110042, India

Of the nanostructures, quantum wires are promising candidates for low-dimensional conducting wires in electronic, optoelectronic, and quantum computing devices [9]. Quantum wires have electron motion confined in two dimensions for which, various models of confinement potential, viz. parabolic, Rosen–Morse, spherical Gaussian, power-exponential, modified Gaussian, etc., have been proposed [10–13]. The confinement into low dimensions results in the formation of discrete energy levels [14]. At the nanoscale, spin effects also come into consideration. There are two types of Spin Orbital Couplings; Rashba [15], which arises due to structural inversion asymmetry, and Dresselhaus [16], which arises due to bulk inversion asymmetry. Experimental work suggests that the strength of the Rashba effect can be controlled by an external gate voltage [17, 18], thus making it an important part of various studies. The choice of confinement potential, formation of discrete energy levels, and the splitting of energy levels due to spin-orbital interactions affect the Hamiltonian which in turn reflects in the physical properties of the system.

Lately, there have been many studies on the electronic [19, 20], magnetic [21, 22], and optical [23, 24] properties of quantum dots and wires. Due to the possibility of manipulating electron states via external gate voltage, the inclusion of Rashba spin–orbit coupling/interaction (SOI) has been popular in many works [19, 21, 22, 24–28].

Thermodynamic properties are also important to describe the physical state of a system and have been studied extensively. Khordad et al. have analyzed the effect of Rashba SOI, on the thermodynamic properties of quantum wires at low temperatures [26] and the thermodynamics of double ring-shaped quantum dots at both low and high temperatures [29]. Najafi et al. studied mono-layer quantum wire thermodynamics under SOI [28]. A few studies have explored the effects of hydrostatic pressure and impurities on binding energy, ballistic conductance, optical properties, Tsallis entropy, etc., employing an effective mass variation model [19, 23, 30–32]. Khordad, Fizoori, and Sedehi [30] have investigated the simultaneous effects of pressure and temperature on entropy and specific heat of a three-dimensional quantum wire.

We focus on the effects of pressure on the thermodynamic properties of a quantum wire under the influence of Rashba SOI, using a variational mass model. The model is described in Sect. 2 with details about the Hamiltonian of the system. A solution of Schrödinger's equation gives the eigenenergies which are used to derive the partition function and subsequently the thermodynamic properties of the system. In Sect. 3, the results are discussed in light of how pressure affects the physical properties. We conclude in Sect. 4 discussing the effect of pressure in a broader sense with some applications of the study.

2 Theory

The study is formulated for an electron gas confined in the x–y plane. A semi-parabolic lateral confinement potential is applied (Fig. 1a), quantizing the electron motion in the x-direction. The confinement potential is given by $V(x)$. Thus, the quantum wire extends along the y-direction. The Hamiltonian of one electron in the system when subjected to an external magnetic field, $\vec{B} = (0, 0, B)$ including Rashba SOI is given by [24, 25]:

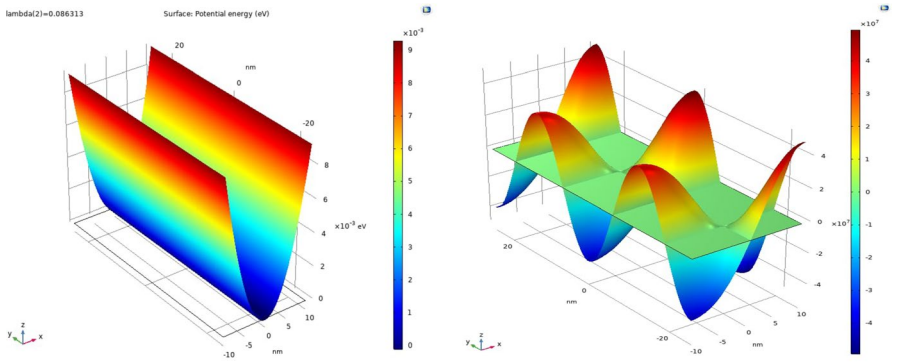

Fig. 1 Surface **a** potential energy (eV) and, **b** normalized wave function of quantum wire

$$H = \frac{1}{2m_{\text{eff}}(P)}(p + eA)^2 + V(x) + \frac{1}{2}g\mu_B\vec{\sigma}.\vec{B} + H_{\text{Rashba}} \tag{1}$$

$$\begin{aligned} V(x) &= \frac{1}{2}m_{\text{eff}}(P)\omega_0^2 x^2, \quad \text{for} \quad 0 \le x \le L/2 \\ &= \infty, \quad \text{for} \quad L/2 \le x \le L \end{aligned} \tag{2}$$

here, $\frac{1}{2}g\mu_B\vec{\sigma}.\vec{B}$ is the Zeeman coupling under magnetic field, p is the momentum, e is the electronic charge ($1.6 \times 10^{-11}C$) and A is the vector potential for the magnetic field, given by $A = eB\hat{xj}$ in Landau gauge. ω_0 is the frequency of confinement, g and μ_B are Lande's g-factor for the electron and the Bohr magneton respectively, and σ represents the Pauli spin matrices (σ_x;σ_y;σ_z). In Eq. (2), $m_{\text{eff}}(P)$ represents the pressure dependent effective mass.

In this paper, an effective mass approximation is used where the effective mass is dependent on hydrostatic pressure. For GaAs, the following formulation gives the hydrostatic pressure dependency of effective mass [31]:

$$m_{\text{eff}}(P) = \left[1 + E_P\left(\frac{2}{E_g(P,0)} + \frac{1}{E_g(P,0) + 0.341}\right)\right]^{-1} m_e \tag{3}$$

where m_e is the free mass of an electron (given by, $m_e = 9.11 \times 10^{-31}kg$), $E_P = 7.51eV$, $E_g(P,T)$ is the energy gap for GaAs which depends on pressure and temperature (here T=0 K) and is given by:

$$E_g(P,0) = {E_g}^0 + \alpha P + \beta P^2 \tag{4}$$

here ${E_g}^0 = 1.519eV, \alpha = 1.26 \times 10^{-2}eV/kbar, \beta = 3.771.26 \times 10^{-2}eV/kbar^2$

In this study, an electric field of strength $\vec{E} = (E_x, 0, 0)$ is applied, which transforms the Hamiltonian (Eq. 1) into [25]:

$$H = H_0 + H_{\text{Rashba}} \tag{5}$$

$$H_0 = \frac{1}{2m_{\text{eff}}(P)}({p_x}^2 + (p_y + eB_z x)^2) + \frac{1}{2}m_{\text{eff}}(P)\omega^2 x^2 + eE_x x + \frac{1}{2}g\mu_B B\sigma_z \tag{6}$$

$$H_{\text{Rashba}} = \frac{\alpha}{\hbar}(\sigma_x(p_y + eB_z x) - \sigma_y p_x) \tag{7}$$

where the effective cyclotron frequency, ω is given by $\omega = \sqrt{{\omega_0}^2 + {\omega_c}^2}$ and, $\omega_c = \frac{eB}{m_{\text{eff}}}$ is the cyclotron frequency.

Due to the inclusion of Pauli spin matrices, the Hamiltonian becomes a 2×2 matrix. From Eq. (6), the Hamiltonian is found to be invariant along the wire, i.e. translationally invariant. Thus, the wave function (Fig. 1b) can be written as a plane wave function in the longitudinal direction, and a spinor for the transversal coordinate, x [33].

$$\Psi(x, y) = exp(ik_y y)\phi(x) \tag{8}$$

where $exp(ik_y y)$ is the plane wave function, $\phi(x)$ is a spinor and k_y is the electron wave vector or the wave number, in the y-direction [24–26]. The eigenvalues for H_0 can be found by solving Schrödinger's equation:

$$H_0\Psi_{n\sigma}(x) = E_{n\sigma}\Psi_{n\sigma}(x) \tag{9}$$

The corresponding eigenenergies are given as

$$E_{n\sigma} = \hbar\omega\left(n + \frac{3}{2}\right) - \frac{e^2E^2}{2m_{\text{eff}}(P)\omega^2} + \frac{\omega_0^2\hbar^2k_y^2}{2m_{\text{eff}}(P)\omega^2} - \frac{e^2EB\hbar k_y}{m_{\text{eff}}^2(P)\omega^2} + \frac{1}{2}g\mu_B\sigma_z B_z \tag{10}$$

$\Psi_{n\sigma}$ are the corresponding wave functions for, $n = 0, 1, 2...$ and $\sigma = \pm 1$.

The eigenvalue equation for the Hamiltonian H can be rewritten by writing $\phi(x)$ as, $\phi(x) = \sum_{n\sigma} c_{n\sigma}\Psi_{n\sigma}(x)$ as

$$\sum_{n\sigma} c_{n\sigma}(E_{n\sigma} - E)\Psi_{n\sigma}(x) + \sum_{n\sigma} c_{n\sigma}H_{\text{Rashba}}\Psi_{n\sigma}(x) = 0 \tag{11}$$

Upon applying the orthogonality condition we get,

$$(E_{n\sigma} - E)c_{n\sigma} + \sum_{n\prime\sigma\prime} c_{n\prime\sigma\prime}\langle\Psi_{n\sigma}|H_{\text{Rashba}}|\Psi_{n\prime\sigma\prime}\rangle = 0 \tag{12}$$

Figure 2 shows the splitting of the energy levels due to Rashba SOI. Here, the solid curves represent the wave function, dashed lines represent eigenenergies corresponding to the wave function of the same color. The black parabolic curve is for the potential. It can be observed that curves 'a' and 'b' have a similar shape, the only difference being in their values. Similarly curves 'c' and 'd', etc., also have similar shapes but different values. This implies that these pairs result from the splitting of eigenenergies at individual energy levels, the extent of the splitting being ~ 0.13 eV.

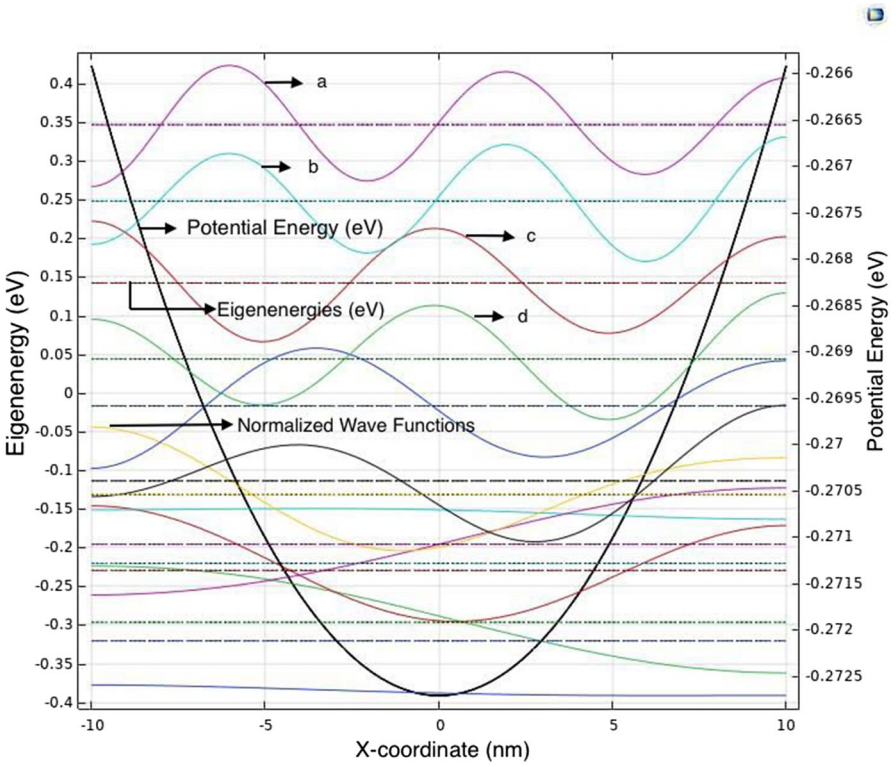

Fig. 2 Energy split sub-bands, wave function and applied potential on the quantum wire in the presence of external crossed electromagnetic fields, Zeeman effect and Rashba SOI

To calculate the thermodynamic properties of a system, it is necessary to derive the partition function to describe that system. Using the eigenenergies, the partition function can be derived by the relation,

$$Z = \sum_i e^{-\beta E_i} \tag{13}$$

where $\beta = \frac{1}{k_B T}$, $k_B = 1.38 \times 10^{-23} J/K$ is the Boltzmann constant that relates the average kinetic energy of particles in a gas to its temperature, and the summation is done for all the energy levels found using the Eqs. (10, 12).

We obtain the thermodynamic properties in terms of the partition function as follows [29]:

i. Entropy:

$$S = k_B log Z - k_B \beta \frac{\partial log Z}{\partial \beta} \tag{14}$$

Entropy refers to a thermodynamic quantity that measures the degree of disorder or randomness in a system at the nanoscale. It is a fundamental concept in statistical mechanics and provides insights into the arrangement and distribution of particles or molecules within the nanomaterial.

ii. Magnetic entropy:

$$\Delta S = S(B \neq 0, T) - S(B = 0, T) \tag{15}$$

Magnetic entropy represents the difference between entropy in the presence of some magnetic field and entropy in the absence of any magnetic field. It refers to the phenomenon where the temperature of a material changes in response to a magnetic field variation.

iii. Mean Energy:

$$U = -\frac{\partial logZ}{\partial \beta} \tag{16}$$

Mean energy is the slope of the log of the partition function Z vs β. It represents the average energy per particle or per degree of freedom in a system. Understanding the mean energy helps in characterizing the energy distribution, thermal behavior, and heat transfer mechanisms.

iv. Specific Heat:

$$C = \frac{\partial U}{\partial T} = k_B \beta^2 \frac{\partial^2}{\partial \beta} logZ \tag{17}$$

Specific heat is the amount of heat energy required to raise the temperature of a substance per unit mass or per mole. In nanomaterials, specific heat can exhibit size-dependent behavior due to quantum confinement effects and altered phonon and electron transport properties.

v. Free Energy:

$$F = -k_B T logZ \tag{18}$$

Free energy represents the energy available to do work in a system. In the context of nanomaterials, studying free energy is crucial for determining their stability, phase transitions, and equilibrium states.

3 Results

Here, the thermodynamic properties, viz. entropy, mean energy, free energy, and specific heat, have been studied as a function of temperature. The Quantum Wire is subjected to an electric field with field strength, $F = 2.0 \times 10^6 V/m$, and a magnetic field, $B = 8T$. The average value of Lande's g-factor has been fixed as, $g = -0.44$ [34], and Rashba effect strength, $\alpha = 2.0 \times 10^{-11} eVm$ is considered.

Figure 3a represents that rise in the temperature enhances the entropy of the quantum wire under the influence of hydrostatic pressure. At a high range of temperature,

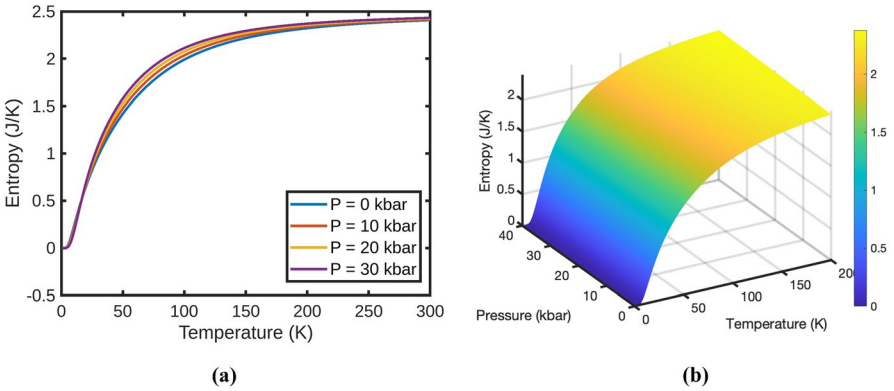

Fig. 3 **a** Entropy as a function of Temperature for different values of hydrostatic pressure and, **b** 3-dimensional plot of Entropy as a function of temperature and pressure

entropy reaches a constant value. For low temperatures, there is not much difference between the entropy values for different pressure values. Also, entropy is very close to zero in this temperature range (~5 K) as only the lowest energy levels are occupied and there is not enough energy available for transition. As temperature rises, sufficient energy is acquired for transition which is seen as an increase in the entropy. The particular values of temperature where the increase starts depend on various factors such as material of the wire, energy band gaps. Moreover, the increment in pressure causes a decrease in the dimensions of the quantum wire as a consequence, the volume of the system decreases. This results in lesser spacing among the energy levels thus making transitions more probable. Therefore around 50 K, the figure clearly shows that the entropy starts increasing with hydrostatic pressure. Furthermore, entropy is a degree of randomness or disorder in the system, increased transition probability results in an increase in entropy. A general trend of increase in entropy with an increase in pressure can be seen in Fig. 3b more clearly.

Figure 4a shows the variation of magnetic entropy with temperature; it shows a structure with a profound minimum at low temperature. After the minimum, the absolute value decreases and tends to zero with further increasing the temperature. From the figure, it becomes clear that on increasing the hydrostatic pressure, the absolute value of the magnetic entropy reduces.

From Eq. (6), the value of magnetic entropy is given as a difference of entropy at zero magnetic field and nonzero magnetic field. Figure 4b shows the entropy versus temperature at different pressures for both zero and nonzero magnetic fields. The solid lines represent magnetic field, $B = 8T$ and the dashed lines represent zero magnetic field, i.e., $B = 0$. A similar trend is observed for both the magnetic fields, but it is seen that for nonzero value of magnetic field, entropy is lesser. This can be owed to the fact that when the magnetic field is zero, no spin energy bands splitting takes place and thus, the energy levels are degenerate. This results in more transition probability and thus higher value of entropy. On the other hand, when a nonzero magnetic field is introduced, energy levels are split due to SOI effects, thus

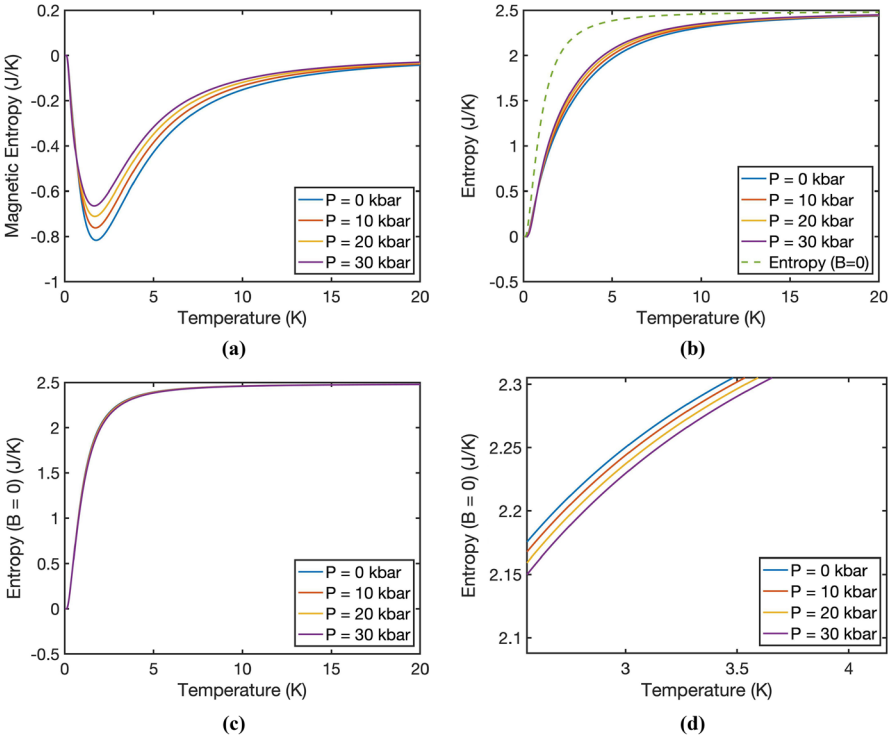

Fig. 4 **a** Magnetic entropy as a function of temperature at different values of hydrostatic pressure. **b** Entropy as a function of temperature for different values of hydrostatic pressure. For zero and nonzero magnetic fields. Pressure for green dashed line = 20 kbar. The solid lines represent $B = 8T$. **c** Entropy as a function of temperature with zero magnetic field. **d** Entropy as a function of temperature with zero magnetic field (zoomed in)

transitions become less probable due to difference in energy levels hence decreasing the entropy.

For finite B, entropy is found to increase with pressure. This can be understood by the compressing effect of pressure. The pressure reduces energy level spacing thus making transitions more probable thus increasing entropy. For $B = 0$, there is no Zeeman effect. Energy level splitting arises only due to spin coupling with momentum, i.e. Rashba coupling. In this case, the effect of pressure results in a decrease in the number of energy levels that are accessible thus a decrease in entropy is seen with an increase in pressure.

Moreover, on increasing the hydrostatic pressure, the value of entropy for nonzero magnetic fields increases. In Fig. 4c it is observed that for a zero magnetic field, there is not much difference between entropies at different pressures. A closer look in Fig. 4d reveals that for increase in hydrostatic pressure, the value of entropy decreases.

The above observations show that as pressure increases the difference between the entropy values at zero and nonzero magnetic fields decreases. This confirms

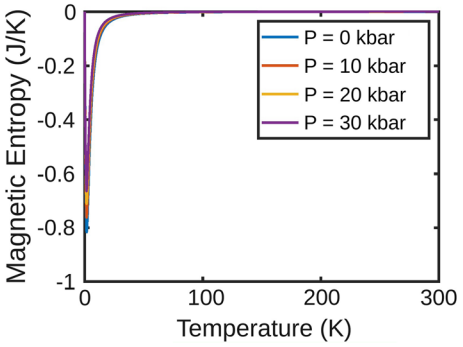

Fig. 5 Magnetic entropy v/s temperature extended to room temperature

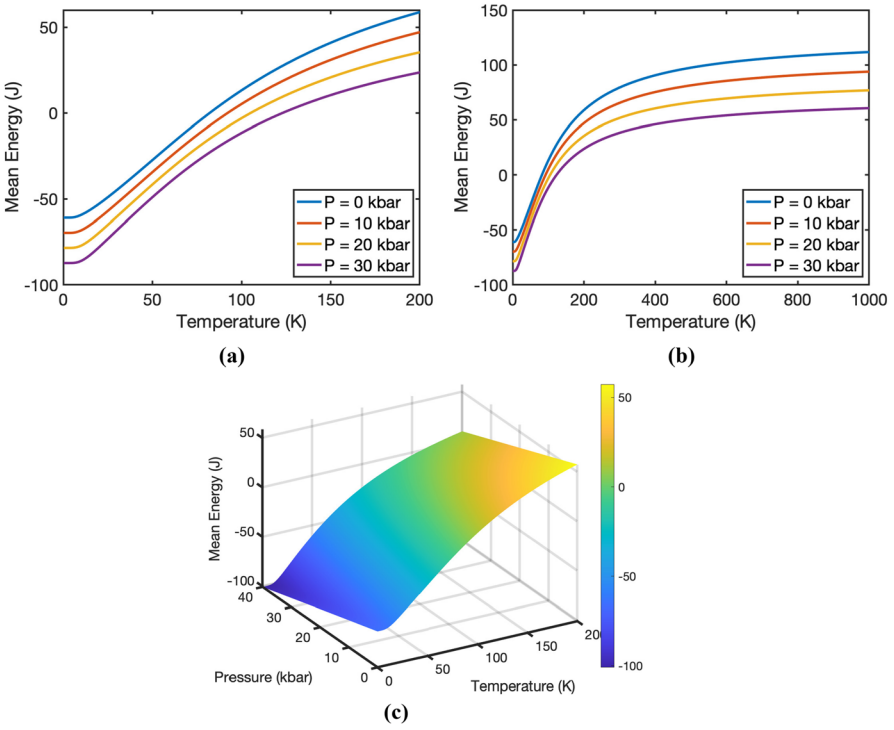

Fig. 6 Mean energy as a function of **a** low temperature, **b** high-temperature range for various values of hydrostatic pressure, and **c** 3-dimensional plot of mean energy as a function of temperature and pressure

that on increasing the value of hydrostatic pressure, the absolute value of magnetic entropy decreases.

Figure 5 shows the behavior of magnetic entropy when extended to room temperature.

In Figure 6a, b mean energy increases monotonically with temperature. The increase is clearly seen at a lower temperature in Fig. 6a. At a high range of

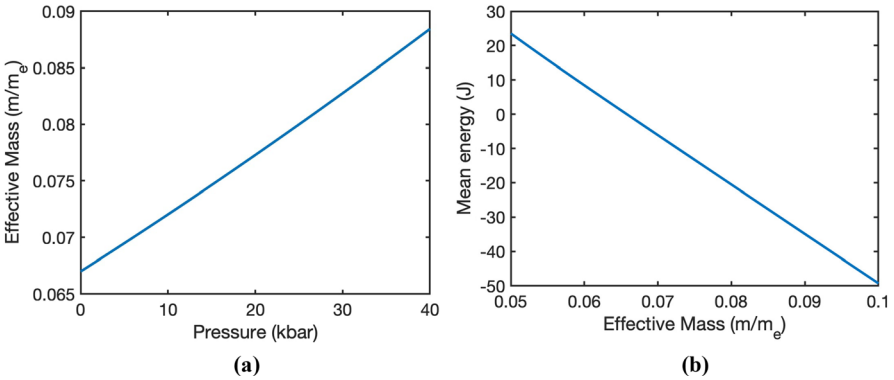

Fig. 7 **a** Effective mass dependence on hydrostatic pressure. **b** Mean energy v/s effective mass at $T = 80$ K

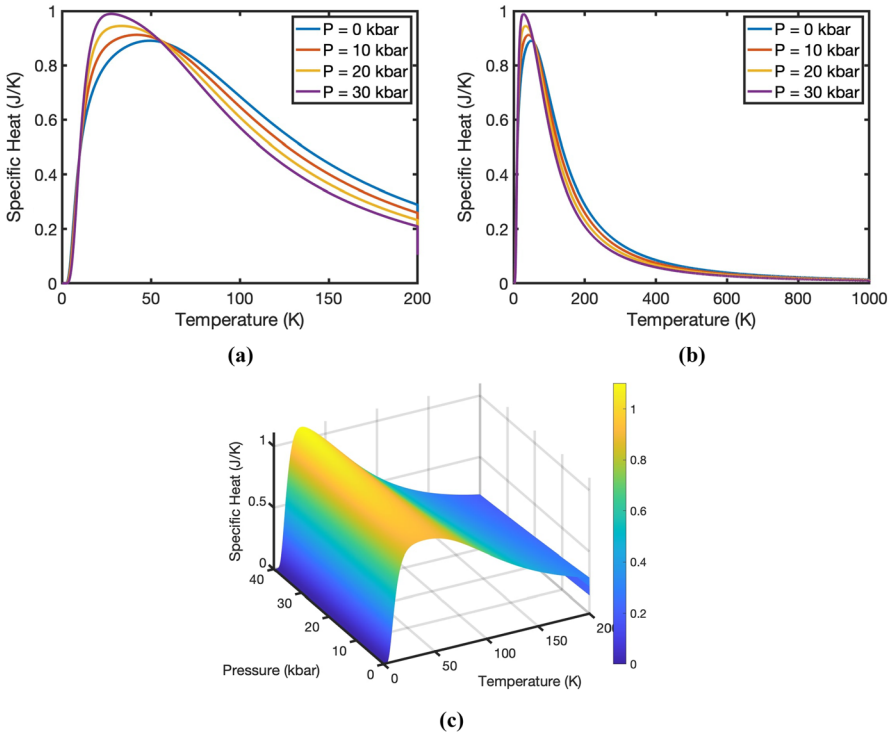

Fig. 8 Specific heat v/s temperature **a** low-temperature and, **b** high-temperature range at different values of hydrostatic pressure, **c** 3-dimensional plot of specific heat as a function of temperature and pressure

temperatures (~ 500 K), the increase slows down represented by Fig. 6b. Moreover, effective mass increases with the hydrostatic pressure and the mean energy reduces with increasing effective mass as shown in Fig. 7a and b, respectively. At very low

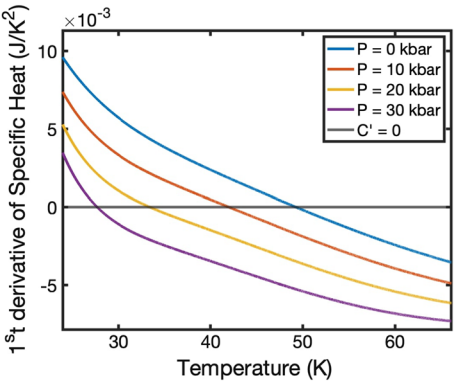

Fig. 9 First derivative of specific heat v/s temperature for different values of hydrostatic pressure

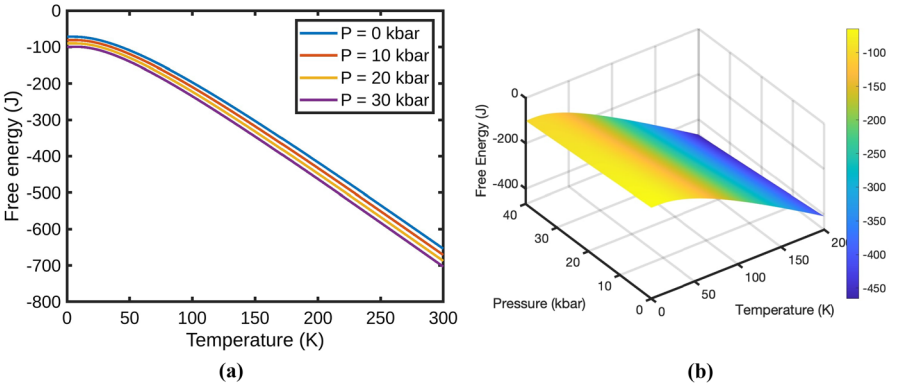

Fig. 10 **a** Free energy v/s temperature at different values of hydrostatic pressure and, **b** 3-dimensional plot of free energy as a function of temperature and pressure

temperatures (~5 K), mean energy is seen to be constant, this observation can be owed to the fact that at low temperatures only the lowest energy states are occupied and enough energy is not available for transition to higher states. As temperature increases, more energy is acquired and higher energy levels get populated. Thus, at a fixed temperature, mean energy is found to decrease with an increment in hydrostatic pressure.

Specific heat versus temperature, for both low- and high-temperature ranges, is shown in Fig. 8a, b. It can be easily deduced from Fig. 8a that specific heat increases with a rise in temperature at a low range of temperature and reaches a peak at 20–50 K. When the temperature is sufficiently high, all the highest energy levels are populated and further increasing the temperature does not increase the mean energy considerably (Fig. 6). Thus the gradient of mean energy starts to decrease; hence specific heat decreases. This can be seen as the peak in Fig. 9. After that, the specific heat gradually decreases with temperature. With the increment in pressure, the gap between the two energy levels reduces, which increases the transition probability.

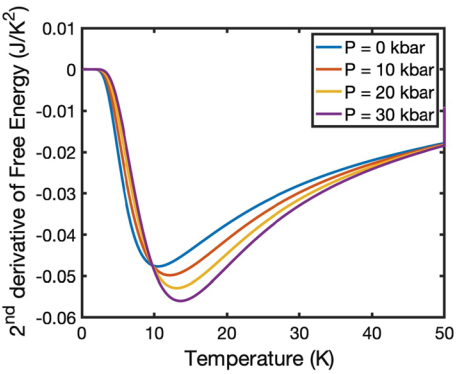

Fig. 11 Second derivative of free energy v/s temperature for different values of hydrostatic pressure

As a result, in Fig. 8b, the peak of the curve shifts towards low temperature with an increase in hydrostatic pressure.

Figure 9 shows how the first derivative of specific heat changes its sign. Here, the first derivative is used as a mathematical tool to investigate the curve of specific heat. The change in the sign of the first derivative indicates the peak of the corresponding curve. As pressure increases, the zero crossing of the first derivative happens at a lower temperature as a consequence, the peak of the curve shifts towards lower temperatures on increasing pressure.

Moreover, the free energy shows a similar trend to mean energy in terms of pressure, i.e. it decreases with an increase in pressure for a fixed value of temperature (Fig. 10). At temperatures lower than 20 K, free energy is nearly constant w.r.t. temperature, after which it starts to decrease rapidly with temperature. Figure 11 shows the second derivative of free energy (again used as a mathematical tool to investigate the curve of free energy) which shows that the second derivative reaches a minimum before starting to increase and then settles to a constant value. For higher values of hydrostatic pressure, the minimum is reached at a higher value of temperature as compared to lower values of pressure. This means that free energy remains nearly constant till a higher temperature value for higher pressure.

4 Conclusion

In this paper, the thermodynamic properties of a GaAs quantum wire have been investigated theoretically under the effect of hydrostatic pressure using a pressure-dependent effective mass approximation. The model considers a GaAs quantum wire under the influence of a crossed electromagnetic field with the inclusion of Rashba SOI which is controlled by an external gate voltage. The numerically obtained results show variations in thermodynamic properties against temperature at different pressures. At low temperatures, entropy, mean energy, and specific heat don't show much difference in values for different pressures. Entropy

is found to increase with increasing pressure, whereas mean energy and free energy are found to decrease with pressure. Magnetic entropy shows a minimum structure with respect to temperature and specific heat shows a structure with a maximum, where the peak position is found to be dependent on pressure. With increasing pressure, the peak shifts towards lower temperatures. Relating to the behavior of entropy, as pressure increases, the absolute value of magnetic entropy is decreased. These behaviors can be explained by energy level splitting due to Rashba SOI and the compressing effect of pressure which decreases the spacing between energy levels.

Abstract. Wind is regarded as one of the significant horizontal forces that strongly affects how high-rise constructions structures respond when they are designed. Population growth has increased demand for tall structures, which is growing daily. Numerous international standards provide pressure coefficients and force coefficients, which are used to calculate the wind load on such structures. These international standards, however, provide details on structures with regular shaped building, like squares and rectangles. With the development of technology, composite plan shape buildings like pentagon, hexagon, etc. have been given consideration by many architects while keeping in mind the building's aesthetics. Since there is no data on these buildings, it is necessary to do CFD or wind tunnel testing to study the effects of wind on these structures. ANSYS: CFD (Computation Fluid Dynamics) to predict wind reactions is rapidly gaining popularity. In the current research, two structure model with the plan shapes of a square and a pentagon have been taken into consideration. On each face of the square and pentagon buildings, the average value of the coefficient of pressure Cp is computed. Results are compared to international standards codes. The lever side is discovered to have negative pressure, and the pressure contours for the side faces are identical. A recirculation zone is shown by vertical flow patterns to be one-third of the building's height. While horizontal flow patterns show the development of a vortex in the building's wake.

Keywords. high-rise building, CFD, ANSYS, pressure contours, flow patterns

INTRODUCTION

Building taller structures is the biggest development trend the globe is witnessing right now. A greater number of high-rise structures with unusual shapes have been constructed as a result of advancements in construction techniques, technology, and materials. High-rise structures must be effectively designed for wind loads because they are particularly vulnerable to them. Results of wind load for typical plan-shaped structures can be found in a number of international standards, including IS: 875 (Part III) - 2015. Wind tunnel testing and ANSYS: CFD technologies are used to study the influence of wind on high-rise buildings. Nowadays, ANSYS: CFD simulations are carried out to get wind forces in complex plan-shaped structures.

Numerous experimental and numerical studies have been done to date to investigate the effects of wind-driven forces on a variety of tall building models with unusual geometrical configurations. Many researchers have conducted wind tunnel experiments to assess the effects of wind on such structures. For instance, Bhattacharyya and Dalui [1] tested a "E"-shaped building in the wind tunnel; Nagar et al. [2] modelled the effects of wind on a "H" and a square building; Raj et al. [3] conducted experiments on a "Plus" shape building; Carassale et al. [4] researched the effect on a cylindrical square building; Yukio Tamura [5] examined triangular; Tanaka et al. studied improved square shaped building [6]; He and Song investigated the response of TTU building [7]; Pal et al. [8] evaluated drag and lift force coefficients on fish and square plan shape models ; Pal and Raj [9] studied the full blockage condition for various plan shapes of high-rise building models; Pal et al. [10] studied the effect of twin building models on a remodeled triangle shape model; and Nagar et al. [11] studied the effect on two "Plus" shape model. Following are a few significant findings from these studies: For isolated buildings, the drag and lift force coefficients depend on the location and geometric design of the building model, and the pressure contour is symmetric. Experiments in the wind tunnel take a lot of time and money. As a result, ANSYS: CFD approaches for analysing the impact of wind on tall buildings are growing in popularity.

The wind effects are provided by ANSYS: CFD approach is swift in time for different shapes of high-rise buildings. It uses meshing to break down the building geometry into smaller pieces, and various types of research have been conducted on a variety of shapes, such as the "H"-shaped building studied by Raj et al. [12]; the rectangular shape with

horizontal limbs studied by Paul and Dalui [13] and Okajima et al. [14]; the "Plus"-shaped building studied by Paul and Dalui [15]; the octagonal building studied by Hajra and Dalui [16]; Gaur and Raj studied on a square mode [17]; Meena et al. [18] studied rectangular shape buildings with different corner configurations; Goyal et al. [19] studied “Y” shape building; Raj et al. [20] looked at different cross-section building, Verma et al. [21] and Meena et al. [22] studied the cfd simulation on tall building. The simulation's main conclusions are that the mesh size has a substantial impact on the outcomes, that the height of the building model affects the pressure distribution, and that the exposure to wind affects the drag coefficients.

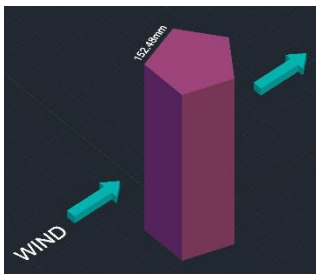
Using the computational fluid dynamics (CFD) method, the impact of wind on tall buildings with square and pentagonal cross sections is investigated. The outcomes of numerical modelling are evaluated in comparison to international standards. To obtain the streamlines or flow patterns around the building models and to obtain distinct flow characteristics, ANSYS: CFD approach is employed The pressure contour on various building faces is explored, and the building models horizontal and vertical streamlines are closely examined.

NUMERICAL MODEL DEVELOPMENT

In this study, pentagon and rectangular plan shaped buildings are analyzed by using the ANSYS CFX for CFD simulation at various wind incidence angle.

Geometric Modelling

In this study, Model A and Model P is designed in AutoCAD: 3D Modelling. Model P is a pentagon building, 600mm in height and 152.48mm in sides. Model A is a square building, 600mm in height and 200mm in sides. The isometric view of both buildings is shown in Fig. 1 and 2. The buildings are modelled using a 1:350 scale and the buildings are assumed as non-deformable. Both the buildings have an equal cross-sectional area of 40000mm^2.



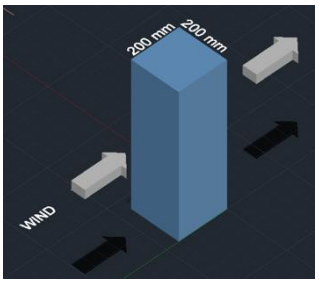


FIGURE 1. Model P **FIGURE 2.** Model A

Five steps make up the ANSYS analysis process: geometry, mesh, setup, solution, and result. To prevent flow recirculation, a rectangular domain is created in accordance with Standards and different research [18] with the borders placed 5H from the model's windward face (A), lateral faces (C & D), and roof and 15H from the leeward face (B). Let H be the height of the building model. Refer Fig. 3.

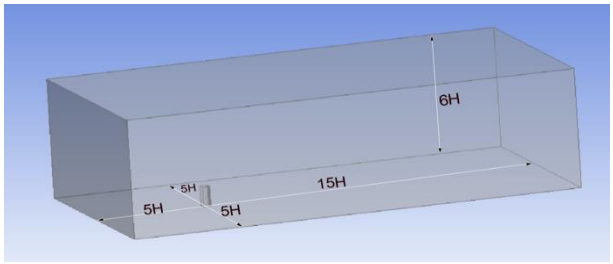

FIGURE 3. Domain used for simulation

10 August 2023 06:51:42

Meshing is the most crucial part of CFD simulation. A finer mesh may not give you perfect results, but an inadequate mesh will certainly affect the results. Meshing is of different shapes and sizes and provides valuable information on the flow characteristics in critical zones. Meshing divides the geometry into elements that can be used to discretize a domain. Meshing for the domain is done using the tetrahedral elements having an element size of 0.2 m, refer Fig. 4. Meshing Inflation is provided to simulate the flow easily around the building model's geometry. Meshing inflation with 15 layers is provided at the boundaries of Model A and Model P for allowing smooth flow and is represented in Fig. 5 and Fig. 6.

Basic Equations

The study aims to find the fluid-structure interaction in terms of various streamlines and contours obtained as a result and validate the observations to conform with various international codes and standards. Many past studies were performed using the k- ε model. This model has a well-developed prediction capability and gives an accurate balance of reliability for general-purpose simulations. k-ε turbulence is a two-equation model that provides the solution by using two transport equations, that is, turbulent kinetic energy (k) and turbulent dissipation rate (ε).

The basic equations used to study the fluid flow problems are Navier-Stokes and continuity equations.

- Navier-Stokes equation is as follows:

$$\frac{\partial(\rho u_i)}{\partial t} = -\frac{\partial(\rho u_i u_j)}{\partial x_j} - \frac{\partial P}{\partial x_j} + \frac{\partial}{\partial x_j}[\mu(\frac{\partial_{u_i}}{\partial_{x_j}} + \frac{\partial_{u_j}}{\partial_{x_i}})] + F$$

- The standard k-ε model uses the following transport equations for the turbulence kinetic energy and turbulence dissipation:

$$\rho\frac{\partial k}{\partial t} + \rho\overline{u_i}\frac{\partial k}{\partial x_j} = \tau_{ij}\frac{\partial\overline{u_i}}{\partial x_j} - \rho\varepsilon + \frac{\partial}{\partial x_j}[(\mu + \frac{\mu_t}{\sigma_\varepsilon})\frac{\partial\varepsilon}{\partial x_j}]$$

- The momentum equation is as follows:

$$\frac{\partial(\rho U_i)}{\partial t} = -\frac{\partial(\rho U_i U_j)}{\partial x_j} - \frac{\partial P}{\partial x_i} + \frac{\partial}{\partial x_j}[(\mu_{eff}(\frac{\partial_{U_i}}{\partial_{x_j}} + \frac{\partial_{U_j}}{\partial_{x_i}})] + S_M$$

CFD Pre-simulations

Power law is used for interpreting the results in ANSYS in set–up and solution steps. The inputs for the set–up step are as below. Refer Fig. 7.

- $\alpha = 0.147$
- $Z_0 = 1$ m
- $U_0 = 10$ m/s

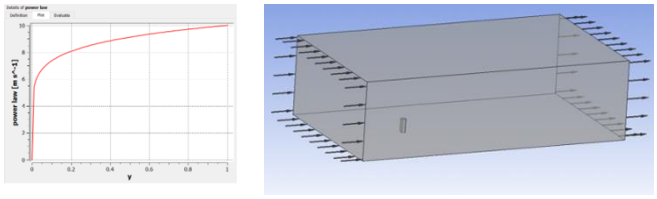

FIGURE 7. Set up in ANSYS CFX

Power law is used for the calculation of pressure.

$$P = U_{ref}\left(\frac{Z}{Z_{ref}}\right)^{\alpha}$$

The variable coefficient of pressure "Cp" is then found by,

$$C_p = \frac{P - P_o}{\frac{1}{2}\rho {U_{ref}}^2}$$

Where,

P is the pressure derived from the needed point, P_o is the reference height static pressure, ρ is the air density (1.225 kg/m^3), U_{ref} is the mean wind velocity at the building reference height(10 m/s).

The wind effect on Model A is analysed for 4 faces and the wind load effect on Model P is analysed for 5 faces. The faces are named as shown in Fig. 8.

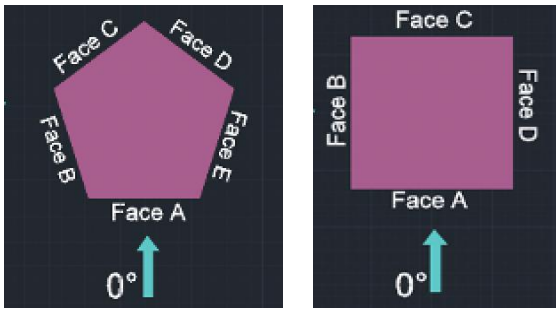

FIGURE 8. Faces representation for Models

10 August 2023 06:51:42

VALIDATION

For validating the study, Model A is chosen and analysed. Model A has a square cross-section having dimensions of 200mm x 200mm throughout the height of 600mm. After analysis using ANSYS: CFX, the coefficient of pressure, or Cp, values for each face A, B, C, and D classified similarly as discussed above were obtained. These values are listed in Table 1 below. The allowable values listed in various international standards are compared to it.

TABLE 1. C_p value for model a with acceptable C_p values under international standards

International standards	**Coefficient of pressure C_p**			
	Face A	***Face B***	***Face C***	***Face D***
IS: 875 (PART III) - 2015	+0.8	-0.8	-0.25	-0.8
ASCE/SEI 7-16	+0.8	-0.7	-0.5	-0.7
AS/NZS 1170.2.2011	+0.8	-0.65	-0.5	-0.65
ES/ISO 4354: 2012	+0.8	-0.65	-0.7	-0.65
CFD results for Model A	+0.68	-0.66	-0.29	-0.66

From Table 1, it may be observed that Cp values for faces A, B, C, and D varied by 15%, 17.5%, 16% and 17.5% respectively when compared with results by IS: 875 (Part III) – 2015.

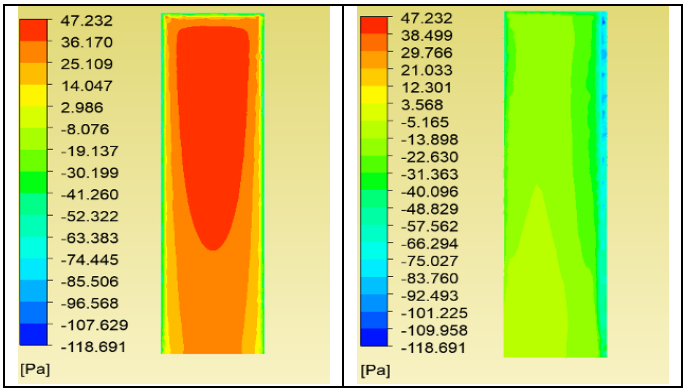
10 August 2023 06:51:42

RESULTS AND DISCUSSION

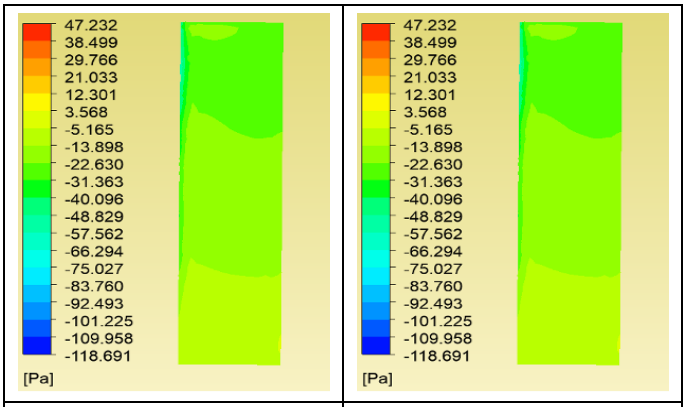
Pressure contours

Contours are used to indicate the change in constant pressure values over a surface. A contour plot with colour bands has discrete coloured regions while the display of a variable on a locator (such as a boundary) shows a finer range of colour detail. The following observations of pressure contours for all faces are listed below.

- Model P



Face A | Face B



Face C | Face D

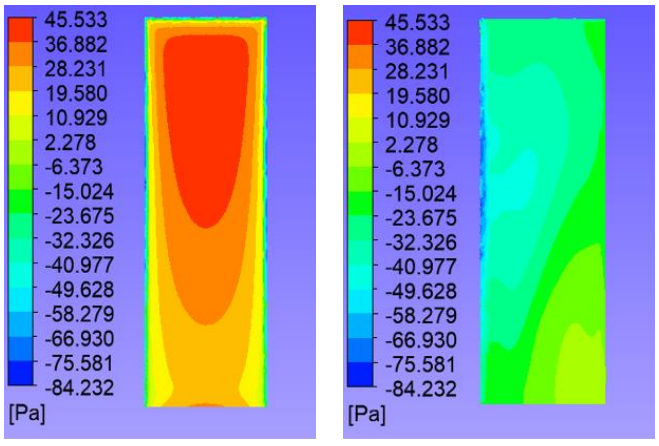
Face E | Top Face

FIGURE 9. Pressure contours for Model P

10 August 2023 06:51:42

The average, the coefficient of pressure C_P on faces A and B is 0.64, -0.35 on face C, -0.28 on face D, and -0.35 on face E. On face A, the highest positive pressure coefficient is observed 0.64. Similar negative pressure coefficient values of 0.35 are observed for Faces B and E. The negative pressure coefficient values for Faces C and D are also 0.28

- Model A



Face A | Face B

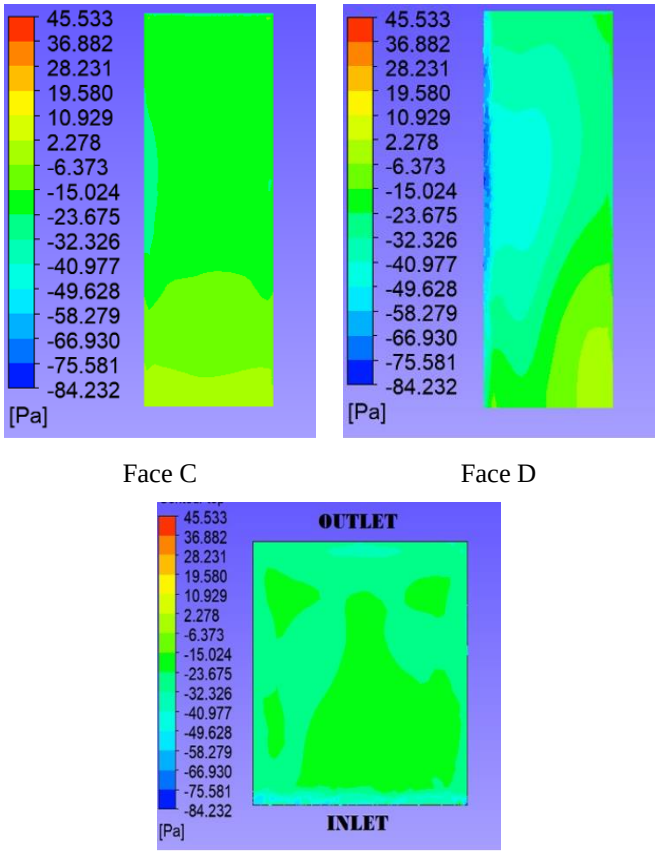


FIGURE 10. Pressure contours for Model A

The average value of the coefficient of pressure C_P on face A is 0.68, on face B is -0.66, on face C is -0.34, on face D is -0.66. The maximum positive pressure coefficient value is 0.68 occurred in face A. Faces B and D are getting similar negative pressure coefficient values of 0.66.

Streamlines or flow patterns

The wind in the present study is considered to be fluid. Streamline is an imaginary path drawn to flowing fluid. The vertical and horizontal streamlines are evaluated and represented in the following sub-sections.

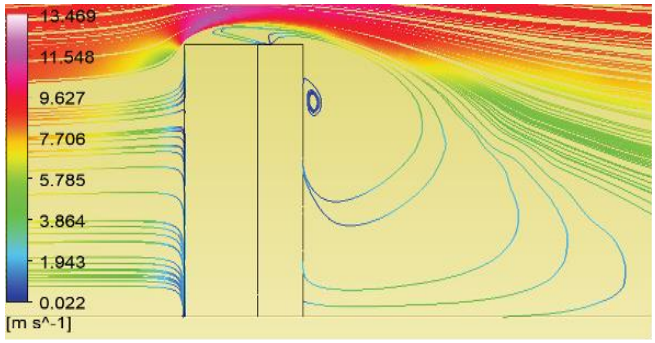

FIGURE 11. Vertical streamlines for model P

10 August 2023 06:51:42

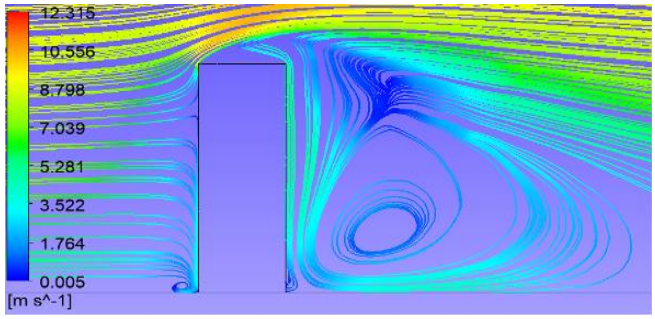

FIGURE 12. Vertical streamlines for model A

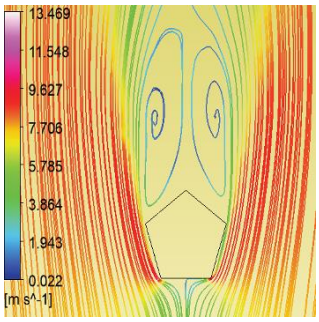
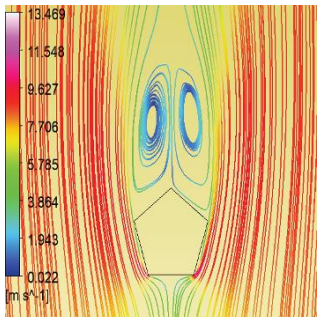
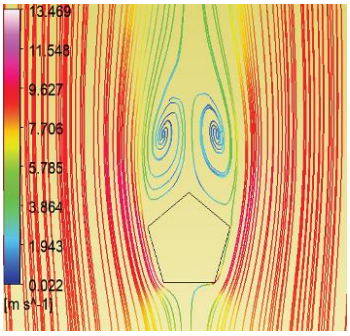
In both the models, it is observed that vertical streamlines from the bottom to 2/3 height of the building are changing their direction downward, and vertical streamlines from the top to 1/3 height of the building are changing their direction upward. It is observed that wind direction reverses in the wake region, creating a separation zone.



At 1/3 Plane



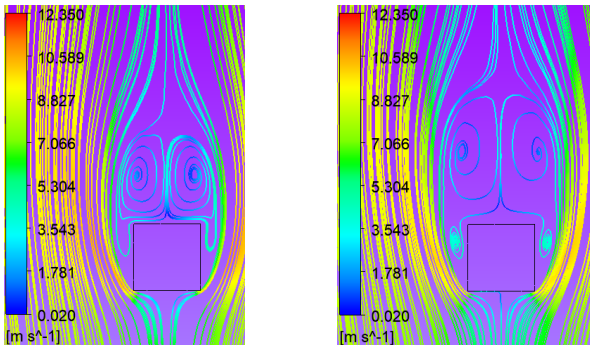
At mid Plane



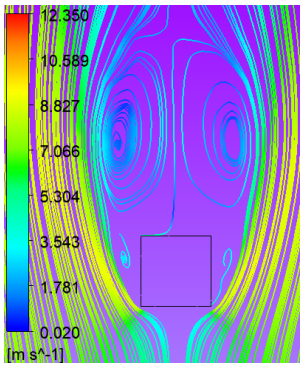
At 2/3 Plane

FIGURE 13. Horizontal streamlines for model P

10 August 2023 06:51:42



At 1/3 Plane At mid Plane



At 2/3 Plane

FIGURE 14. Horizontal streamlines for model A

In both models, recirculation zones are observed. Symmetrical horizontal streamlines are observed in both models. Two distinct vortices are visible in separation zone. At mid plane of square model two more small sized vortices are observed at faces B and D. When compared to the square model, the pentagon model's vortices are further distant from the back face. The pentagon's vortices are larger with respect top square model.

CONCLUSION

The wind is a great complex phenomenon because of the different flow situations developing from the interaction of wind with high-rise structures. The wind is composed of a multitude of eddies of different sizes and rotational characteristics carried along in a general stream of air moving relative to the earth's surface.

The complex nature of wind is due to its turbulent and gutsy nature that gives rise to many flow conditions upon interaction with tall buildings. Therefore, the study of wind flow characteristics on tall buildings is necessary for investigating the behaviour of these structures. The following conclusions may be drawn from this paper:

- International standards are used for analysing wind effects on tall buildings having simple shapes as cross–section only (square, Model A). Therefore, in this study complex shapes (pentagon, Model P) have been analysed by adopting CFD analysis and k - ε turbulence model in ANSYS: CFD model for interpreting the wind flow characteristics.
- As discussed in the validation section, the Cp values obtained for Model A were in agreement with those given by IS: 875 (Part III) – 2015 and other international codes. Therefore, Model P is also validated by consequence.
- Wind flow characteristics were determined for all faces of Model A and Model P in terms of pressure contours and vertical and horizontal streamlines.
- The maximum positive pressure coefficient value was maximum on face A of both models. In model A, face B and face D showed identical results. In model P, face B and face E showed identical results and face C and face D showed identical results.

10 August 2023 06:51:42

- Moreover, the Use of ANSYS: CFD for wind analysis in tall buildings is better than other popular methods like wind tunnel testing as it is less time-consuming and cost-effective.

ACKNOWLEDGEMENT

The authors are thankful to **Delhi Technological University** for providing the research facilities and funding to support this study.

***Abstract*— Due to the threat of spreading erroneous information, the employment of deep convolutional neural network (CNN) techniques has resulted in an increase in the number of altered images. A trustworthy and effective mechanism for identifying false photographs is required to solve this problem. In this study, we used the V4D architecture to analyze manipulated videos and concentrated on identifying DeepFake videos in three different contexts: I identifying all types of manipulations, (ii) identifying single manipulations, and (iii) identifying cross manipulation detection, which was used to assess the videos' authenticity. To do this, we used a variety of manipulation techniques and created algorithms to classify undiscovered manipulation methods.**

Keywords*— Deepfakes, Deepfake Detection, Media forensics, Facial Manipulation Detection, Convolutional Neural Networks, Manipulation techniques, Generative Adversarial Networks

I. INTRODUCTION

Deepfake technology is an emerging field of artificial intelligence that can create photoshopped films and images that look authentic. Advanced algorithms and machine learning techniques are utilized to make these films and photos, which result in realistic-looking content that can be used for everything from entertainment to propaganda. Although this technology can completely transform the media landscape, it also raises significant ethical and security problems [1].

Deepfake technology raises several issues, one of which is the possibility of malicious applications. Deepfake movies, for instance, can be used to slander people or groups, disseminate misleading information, and even affect political campaigns. Deepfake technology can also be used to fabricate sexual photographs or films that can be used for extortion or harassment [2]. The security and privacy of individuals, the integrity of public discourse, and democratic institutions are all gravely threatened by this.

The potential for deepfake technology to be exploited to undermine confidence in the media and other information sources is another worry [3]. Deepfake films may become more difficult to discern from real content as they get more lifelike, creating a general atmosphere of suspicion and uncertainty. When the correct information is essential, such as during natural catastrophes or political crises, this can be especially risky.

Deepfake technology could have a lot of advantages despite these worries. For instance, it can be applied to the film and entertainment industries to provide more authentic visual effects. It could also be employed for educational reasons, such as developing simulations and visual aids for instruction in science or medicine. Deepfake technology has the potential to improve many facets of our life with the right legislation and moral standards in place [4].

II. RELATED WORK

Researchers have created a range of methods to identify and stop deepfake content in response to these dangers. Some of these methods focus on examining the discrepancies and abnormalities found in deepfake media, like abnormal eye movements or distorted face characteristics. Some methods look for patterns in the data that separate authentic media from fake media using machine learning algorithms [5].

Another area of research has focused on developing new algorithms and tools for creating more realistic and convincing deepfake content. Some researchers have explored the use of generative adversarial networks (GANs) [6], a type of machine learning algorithm that involves two neural networks competing against each other to create realistic synthetic media. Other researchers have explored the use of neural style transfer, a technique that involves transferring the style and appearance of one image onto another image or video.

Deepfake films can be identified using a variety of methods. Among the most popular methods are:

- *Face Discrepancies:* Deepfake movies may contain small face discrepancies that are difficult to spot with the human eye but that computer algorithms can recognize. These discrepancies could be brought on by variations in skin tone, lighting, or facial features.
- *Abnormal Movements*: Deepfake films frequently have motion artifacts that are absent from authentic videos. These artifacts may include unusual motions or abnormal blurring around the margins of the subject.
- *Audio inconsistencies:* Deepfake movies may include audio that is out of rhythm with the motions of the subject. By examining the audio waveform and contrasting it with the video, this can be found.[7]
- *Eye blinking:* Artificial eye blinking patterns may be present in deepfake videos. By examining the frequency and timing of eye blinks, this can be discovered.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:19:08 UTC from IEEE Xplore. Restrictions apply.

Analysis of the video's metadata may disclose information about the source of the video, including the equipment or software that was used to capture or make it.

By examining patterns in the video and contrasting them with real footage, machine learning systems can be trained to recognize deep-fake videos.

The following are a few of the most popular algorithms:

A. *Deep Learning:* These techniques are frequently employed in the detection of deep fakes. To find patterns and discrepancies that can be utilized to discriminate between real and false videos, they entail training deep neural networks on enormous datasets of real and fraudulent videos.[8]

B. *CNNs (Convolutional Neural Networks*): They are a subset of deep learning algorithms that can be applied to the analysis of images and videos. They frequently analyze the visual elements of the video and look for any discrepancies to uncover deep fakes. [9]

C. *RNNs (Recurrent Neural Networks):* They are a different class of deep learning algorithms that can be applied to the identification of deepfakes. They can be used to identify discrepancies in the audio of deepfake films since they are particularly effective at understanding speech and audio patterns.

D. *GANs (Generative Adversarial Networks):* Deep learning algorithms called GANs are used to produce deepfake videos. But, by examining the patterns and discrepancies in the produced videos, they can also be used for deepfake detection.

E. *Face Recognition:* By examining the facial features of the subject in the video and contrasting them with known real and fake videos, face recognition algorithms can be used to detect deep fakes.

F. *Image Forensics:* By examining the metadata, compression artifacts, and other digital traces left behind in the movie, image forensic techniques can be used to identify deepfake videos.

There are various previously employed types of algorithms in the CNN algorithms:

A. *Xception:* For picture categorization and object recognition, Xception is a deep CNN architecture. By examining the visual characteristics of the video frames and looking for any irregularities or inconsistencies, it has been utilized for deepfake detection.[10]

B. *EfficientNet:* Another deep CNN architecture that has been applied to deepfake detection is EfficientNet. It is well-suited for deepfake detection because of its reputation for achieving excellent accuracy on picture classification tasks with only a small number of parameters.[11]

C. *ResNet:* It is a deep CNN architecture that has gained popularity for its capability to be able to train extremely deep neural networks by not having the problem of the vanishing gradient issue.[12] By examining the visual characteristics of the video frames and looking for any irregularities or inconsistencies, it has been utilized for deepfake detection.

D. *Inception:* Conceived initially for image classification applications, Inception is a deep CNN architecture. By examining the visual characteristics of the video frames and looking for any irregularities or inconsistencies, it has been utilized for deepfake detection.

E. *VGG:* For image classification problems, a deep CNN architecture called VGG is frequently employed. By examining the visual characteristics of the video frames and looking for any irregularities or inconsistencies, it has been utilized for deepfake detection.[13]

III. DATASET

A large-scale video dataset called FaceForensics++ was developed for deepfake detection studies. It is made up of more than 1,000 videos, amounting to more than 500GB of data, and is meant to mimic situations where deepfake videos might appear in the real world [14].

The videos in the dataset were produced using a range of deepfake methods, such as face swapping, facial reenactment, and puppeteering [15]. They are classified as "genuine" or "fake," with the fake videos further subdivided into four groups according to the process utilized to produce them.

In addition to the videos themselves, the FaceForensics++ dataset also contains ground truth labels that specify which movies are authentic and which are fraudulent, as well as metadata about the videos' resolution, frame rate, and compression level [16].

The FaceForensics++ dataset has been utilized in several studies and contests and has grown to be a well-liked resource for deepfake detection researchers. It has won accolades for being large, diverse, and realistic, which makes it ideal for developing and testing deepfake detection systems.

Researchers from the universities across Europe developed the FaceForensics++ dataset. The dataset was provided in 2019 to give academics working on deepfake detection access to a sizable, varied, and realistic dataset.

On the foundation of the 2018-released FaceForensics dataset, the newer version of the dataset was developed. A lesser number of films produced utilizing a range of deepfake methods, such as facial reenactment, face swapping, and neural rendering, made up the initial FaceForensics dataset.

The initial dataset was enhanced in several ways to produce the FaceForensics++ dataset. The collection was first expanded to include more than 1,000 videos, adding up to more than 500GB of data. Second, the authenticity of the videos was verified by ground truth labels that said whether they were real or phony, and if fraudulent, how they were made. Third, the dataset contains videos that have been compressed, blurred, and degraded to mimic the conditions that might be found in real-world circumstances.

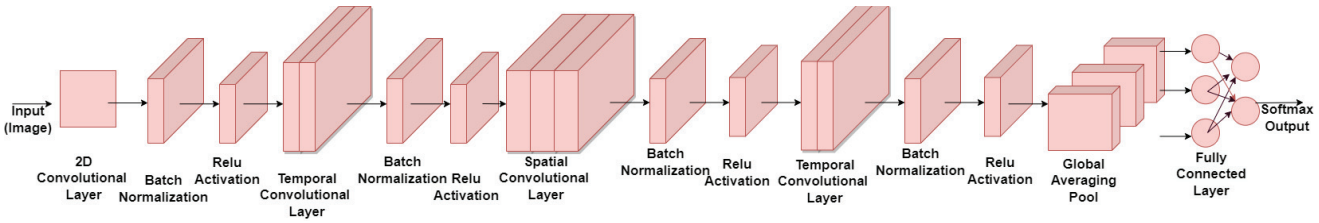

Fig. 2. Working diagram of R(2+1)D

IV. MODELS USED

In this section, we majorly talk about the models which we have used in order to test out our techniques.

A. C2D

For video classification applications, the C2D model is a convolutional neural network (CNN) architecture that is frequently employed. Convolutional Two Dimensional, or C2D, is the abbreviation used to refer to the network's use of 2D frames of video data [18].

A few layers of convolutional and pooling processes are commonly used in the construction of a C2D model, which is then followed by the fully connected layers for classification. The convolutional layers take the input frames and run them through a collection of learnable filters to extract features that are important for the classification task. The spatial resolution of the input data is decreased and the robustness of the features to small spatial fluctuations is increased by the pooling layers' down sampling of the feature maps created by the convolutional layers.

The C2D model often follows the convolutional layers with a few fully connected layers that carry out the actual classification [19], [20]. A vector of scores—one for each potential class—that may be read as the likelihood that the input video belongs to each class—the output of the final fully connected layer—is produced.

B. R(2+1)D

The 3D CNN architecture, which is frequently employed for video classification problems, has a version called the R(2+1)D model. The acronym "R(2+1)D" stands for "Residual (2+1)D," which alludes to the network's utilization of 2D and 1D convolutions in addition to its incorporation of residual connections.[21]

According to the R(2+1)D model, video data can be represented as a spatiotemporal volume having spatial dimensions (height and width), a temporal dimension (time), and a number of channels (e.g., RGB color channels). To capture both spatial and temporal aspects of the video data, the model combines 1D and 2D convolutions.

The 1D convolutions are performed along the temporal dimension, while the 2D convolutions are applied in the spatial dimensions of the input data. The model can capture temporal dynamics and learn features that are important for video classification tasks thanks to the usage of 1D convolutions.

The R(2+1)D model employs residual connections, a kind of skip connection that enables data to be transmitted straight from one layer to another, in addition to the usage of 2D and 1D convolutions. It has been demonstrated that residual connections make it simpler to train deep architectures, which enhances the performance of deep neural networks.[22]

C. CS-CNN

For image recognition tasks, the Channel-Separated Convolutional Neural Network (CS-CNN) deep learning model is used. It is intended to divide an image's color channels into distinct routes and process each pathway independently.[23]

Traditionally used convolutional neural networks process color channels in a single circuit. The CS-CNN model, on the other hand, divides each color channel (red, green, and blue) into its own pathway, enabling more effective and precise processing of color data.

The CS-CNN model is made up of several convolutional layers, each of which uses a collection of learnable filters to extract key characteristics from the input picture or feature map. The CS-CNN model produces different feature maps for each color channel by convolving each color channel with a unique set of filters.

Each color channel's output feature maps are then joined together and supplied into the following layer for additional processing. With this method, the model can learn representations of the input image that are more intricate by taking into consideration the distinctive properties of each color channel.

D. V4D

A variation of the well-liked ResNet architecture for deep learning models is V4D, commonly referred to as ResNet2. ResNet, an acronym for "Residual Network," was developed

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:19:08 UTC from IEEE Xplore. Restrictions apply.

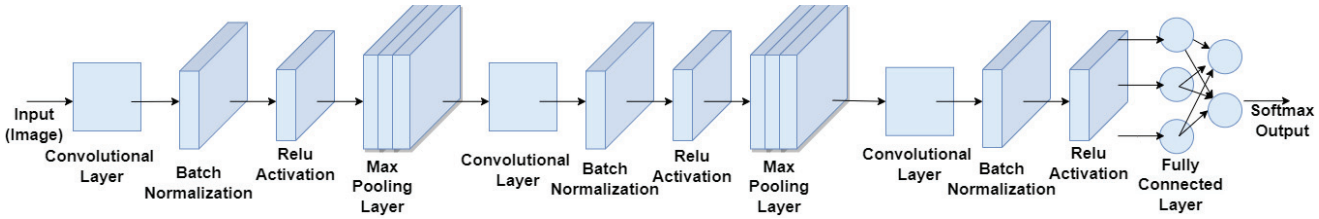

Fig. 3. Working diagram of CS-CNN

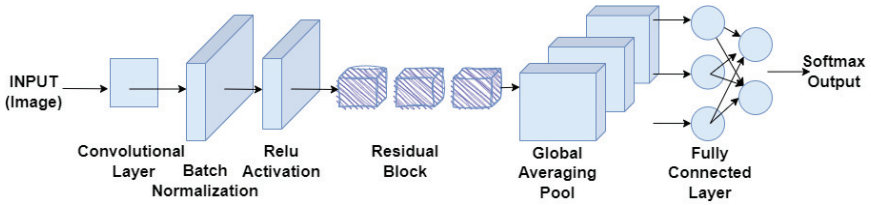

Fig. 4. Working diagram of V4D

by Microsoft researchers in 2015 and has since grown in popularity and influence in the field of computer vision.[24]

V4D (short for "Vision for Decisions") extends the ResNet architecture by adding a number of fresh elements and enhancements. Among the most significant modifications are:

Multi-path architecture: To enhance information flow and broaden the range of features accessible to downstream levels, V4D incorporates a number of parallel paths, each with a distinct level of abstraction.

Stochastic depth: During training, V4D randomly removes entire layers, preventing overfitting and enhancing generalization.

Shake-shake regularization is a novel type of regularization in V4D that increases generalization by introducing noise during the training phase.

In instances when the statistics of the entire batch might not be representative or in smaller batch sizes, V4D uses group normalization rather than batch normalization, which can be more productive in these circumstances.

V. EXPERIMENTAL SETUP

In our study, we implemented several ResNet-based models using PyTorch. These models, which used the action-based Kinetics 400 dataset to train them, included the C2D (ResNet50), R(2+1)D (ResNet50), V4D (ResNet2), and CSN (ResNet101) architectures. The FaceForensics++ dataset was used to adjust the neural network models once they had been initialized with weights. Using two NVIDIA TU102 [TITAN RTX] GPUs, we trained all of the models end-to-end using the Adam optimizer at a constant learning rate of 1e3 throughout all tests. The models needed pipelines with inputs that had 224 × 224 spatial dimensions and 64 video frames per frame during training. Based on the model architecture, we train the models which includes temporal subsampling, normalization, scaling, and image cropping. Each grade was identified using the Dual Shot Face Detector, and we then tried to make the region mentioned above in a larger scale by increase to ensure uniform coverage of the image and give the model more data.

VI. RESULTS

In this there was an experiment of the above listed architectures which are C2D, R(2+1)D, V4D and CSN on all 4 manipulation techniques. Their main goal is to learn and identify manipulation techniques. Apart from this there are individual techniques for each of the models and techniques for cross manipulation. Following that, we divided the data into one with various training, the testing, and validation groups using the technique described above.

VII. CONCLUSION

In the research report, several SOTA systems were compared utilizing various manipulation strategies for deepfake detection. It evaluated the action recognition-based adaptation of the V4D approach. Then, the strategy was expanded to include the detection of DeepFakes after this dataset was used to pretrain the algorithms. The experiments produced excellent results that demonstrated the superiority of the image-based forgery detection methods. Networks typically aren't good at transferring information from some of the manipulation method which are trained to the manipulation method which are tested, which is the cause of this. As a result, machine learning models may behave in an unforeseen manner.

***Abstract*— With the recent rise of realistic face manipulation methods, building robust face tampering detection methods has become more important than ever before. Visual attention has played an important role in highlighting discriminative regions within input which is important for making accurate predictions. This manuscript presents a comparative study of several recently proposed visual attention models for the problem of face forgery detection. Specifically, five visual attention models namely, coordinate, selective kernel, triplet, CoT, and shuffle attention have been tested by integrating with a baseline deep learning model. The modified visually attentive architectures are trained and tested on popular public benchmark dataset FaceForensics++. The experimental results achieved by different attention approaches are compared. Additionally, the computational costs involved in each type of attention have also been discussed specifying the accuracy and computation tradeoff. Experimental results prove that Triplet Attention performs best by achieving accuracy scores of 0.9543 and 0.7190 on DF and NT categories of the FF++ dataset. Triplet attention is also extremely lightweight with only 1200 trainable parameters compared to the other attention modules under study.**

Keywords*— *Visual attention, Face forgery, Face tampering, deepfake, attention, detection

I. Introduction

The emergence of realistic multimedia editing tools, in tandem with the emergence of big data from social media channels, has provided a perfect atmosphere for easy information tampering. Such tampering has the potential to mislead and disrupt society. The threat of changing identities in photographs and films, sometimes known as facial manipulation, is even greater. Realistic facial manipulation allows an innocent man's reputation to be harmed by making him appear guilty of illicit crimes. Several realistic face-altering technologies have recently been created.

Deepfakes [1] maps one person's face onto another via neural networks. FaceSwap [2] does the same thing through computer graphics. Face2Face [3] conveys a person's facial expression from one person to another. DeepFaceLab [4], a prominent combined library of similar tampering methods, includes a long number of identity tampering methods named face replacement, lip movement manipulation, de-aging, and so on. GANs (Generative Adversarial Networks) [5] have enabled the creation of totally artificial faces that do not persist in real world. Recent GAN techniques, such as ProGAN [6], StyleGAN [7], and others, can create hyper-realistic facial images with resolutions up to 1024×1024.

Various contributions have been proposed for detection of facial tampering. These methods extract a variety of distinct domain information such as spatial [8, 9, 10], textural [11, 12, 13], optical flow etc to make their predictions.

A. Contribution of this Manuscript

The major contributions of this manuscript are:

- Conduct an exhaustive study of recent visual attention models and demonstrate their effectiveness in detecting face forgery.
- Five attention models namely, Coordinate Attention [14], Selective Kernel Attention [15], Triplet Attention [16], CoT Attention [17] and Shuffle Attention [18] have been studied.
- The attention modules are evaluated by measuring their performance on the popular face forgery dataset FaceForensics++.
- A study of the computational complexity of each type of visual attention has been conducted.

B. Organization of this Manuscript

The rest of the manuscript is arranged as follows. Section II describes related work highlighting the existing literature on face tampering detection. Next, Section III presents several recently proposed visual attention methods. Section IV describes the experimental setup, including datasets, preprocessing, hardware, classification metrics, hyperparameter adjustment, and an approach for model weight initialization. Section V discusses the results obtained and presents a comparison of various attention models with regards to performance and computational overheads. Finally, Section VI specifies conclusion.

II. Related Works

This section discusses the available research for detecting face manipulation.

Guo et al. [19] proposed to extract better discriminative features by highlighting manipulation traces using gradient operators for each feature channel. Ke et al. [20] improve the detection capability of face tampering in low-quality degraded images by proposing a novel feature transformation module that upgrades features extracted from degraded images and transforms them to high-quality level. Yu et al. [21] propose to highlight multi-scale spatiotemporal clues both locally and globally. Caldelli et al. [22] reach 0.9100 accuracy on the FF++ dataset by using bi-directional optical flow mapping. To extract multi-scale features, Lin et al. [23] employ depthwise separable and dilated convolution kernels. To highlight forging indicators hidden in shallow characteristics, Zhao et al. [24] create a "textural enhancement block" that focuses on high-frequency components. Yang et al. [13] suggested a

unique architecture for detecting facial manipulation that extracts multi-scale textural data. Amerini et al. [25] employed the use of optical.

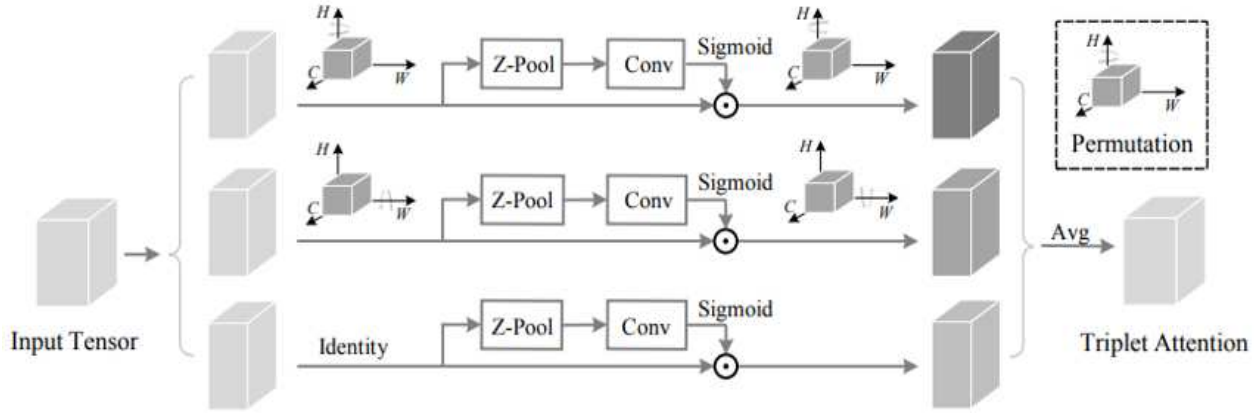

Fig. 1. Structure of Triplet Attention

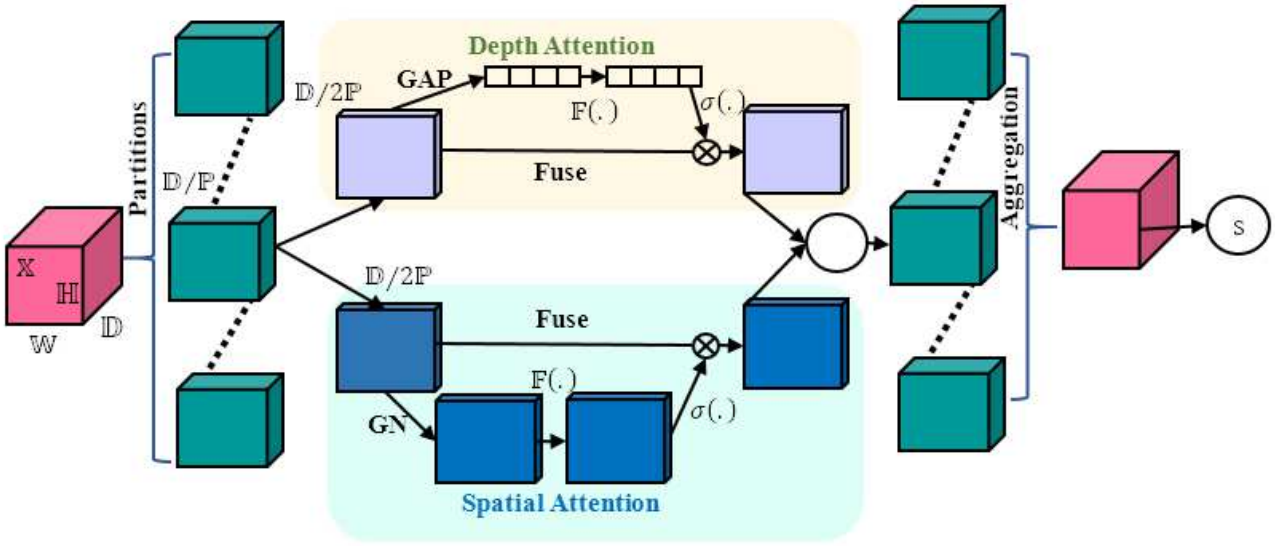

Fig. 2. Structure of Shuffle Attention

To detect manipulation, Guo et al. [26] extract a manipulation trace by suppressing the semantic content of images. Hu et al. [27] offer a lightweight video modification detection approach that takes only the I-frames of input videos into account. To detect manipulation in facial videos, Xu et al. [9] aggregate multi-frame characteristics. Lu et al. [28] provide a unique inception attentional module that incorporates channel and spatiotemporal feature learning. Ma et al. [29] use face video frames to extract lip characteristics and highlight temporal discrepancies. To detect manipulation, Nirkin et al. [30] emphasize the inconsistency of the facial region from surrounding areas such as hair, ears, neck, and so on in altered samples. Numerous GANs have also been utilized to generate completely synthetic images of faces [6, 7, 31].

III. Methodology

This section describes several attention modules and the baseline model used to evaluate them.

A. Shuffle Attention

Shuffle attention [18] proposes an efficient way to fuse attention mechanisms across the spatial and channel dimensions of features without increasing the computational cost. Specifically, a given input $\mathcal{X} \in \mathbb{R}^{H\times W\times C}$, is sub-divided into $\mathcal{G}$ sub-groups over channel dimension having a shape $\mathcal{X}_k \in \mathbb{R}^{H\times W\times C/\mathcal{G}}$. Each $\mathcal{X}_k$ is further sub-divided into 2-branches having shape $H \times W \times C/2\mathcal{G}$. The two branches compute spatial as well as channel attention respectively and the reduced computation is enforced by the subdivision of input along the channel dimension as shown in Fig. 2.

B. Selective Kernel (SK) Attention

Selective Kernel Attention [15] is a three-stage method that uses multiple-sized convolutional kernels for processing inputs with adaptive receptive fields. Specifically, it uses 3×3 and 5×5 kernels to extract multi-scale features in the 'split' stage. For input $\mathcal{X} \in \mathbb{R}^{H'\times W'\times C'}$ the method uses two convolutional kernels to produce $(\tilde{\mathcal{U}} \in \mathbb{R}^{H\times W\times C})$ and $(\hat{\mathcal{U}} \in \mathbb{R}^{H\times W\times C})$ feature maps. The 'fuse' stage fuses discriminative information from each receptive field branch using the summation operation and followed by global average pooling $\mathcal{GP}(.)$ along the channel dimension as given by Eq. 1:

$$\mathcal{U} = \mathcal{GP}(\tilde{\mathcal{U}} + \hat{\mathcal{U}}) \quad (1)$$

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:51:17 UTC from IEEE Xplore. Restrictions apply.

Finally, the 'select' operation employs the soft attention mechanism across feature channels to highlight important channels.

C. CoT Attention

CoT attention [17] or Contextual Transformer attention improves the transformer-based self-attention mechanism by searching for important modeling dependencies among neighboring keys. Specifically, the proposed attention model combines self-attention learning with contextual feature mining by finding relevant relationships among neighboring keys for each query-key pair.

For input $\mathcal{X} \in \mathbb{R}^{H\times W\times C}$ and keys ($\mathcal{K} = \mathcal{X}$), query ($\mathcal{Q} = \mathcal{X}$) and value ($\mathcal{V} = \mathcal{X}\mathcal{W}_v$), the CoT block uses $\hbar \times \hbar$ grouped convolution to learn contextual keys ($\mathcal{K}^1 \in \mathbb{R}^{H\times W\times C}$) representing the relationship of neighboring keys. Finally, the attention matrix is derived by Eq 2.:

$$\mathcal{A} = [\mathcal{K}^1, \mathcal{Q}]\mathcal{W}_\theta\mathcal{W}_\delta \tag{2}$$

The final attentional feature maps are given by ($\mathcal{K}^2$) by Eq. 3:

$$\mathcal{K}^2 = \mathcal{V} \circledast \mathcal{A} \tag{3}$$

D. Triplet Attention

Triplet attention [16] is a three-branch structure that uses the 'rotation' operation to capture discriminative regions within input in three directions while keeping minimal computation overheads. Fig. 1 represents structure triplet attention module structure.

The triplet attention contains three branches. Two branches are responsible for processing the input of shape $\mathcal{X} \in \mathbb{R}^{H\times W\times C}$ and using a novel Z-pool layer to mine important channel features along the H and W dimension while the third branch works like a traditional spatial attention module.

The highlight of the triplet attention module is that it is extremely lightweight and its computation does not increase with increased input dimensions.

E. Coordinate Attention

Coordinate Attention [14] is a novel channel attention mechanism that captures long-range feature dependencies over one spatial dimension and also preserves exact positional encodings through another spatial dimension. Unlike common channel attention mechanisms that use 2D global pooling, coordinate attention uses two 1D kernels. For an input $\mathcal{X} \in \mathbb{R}^{H\times W\times C}$, two 1D pooling kernels of shape $\mathbb{R}^{H\times 1}$ and $\mathbb{R}^{1\times W}$ are used to encode discriminative features along the height and width in each channel thereby yielding direction-aware feature maps.

F. Baseline Architecture

To perform an effective comparison of the abovementioned attention mechanisms the baseline architecture from [32] has been used. Attention layers are attached after each bottleneck layer of this architecture.

IV. Experimental Setup

This section explains experimental steps taken to establish proposed model validity.

A. Datasets

This section describes the state-of-the-art publicly available datasets.

1) FaceForensics++ : The FaceForensics++ (FF++) [33] contains multiple face tampering examples such as Deepfakes (DF) [1] , FaceSwap (FS) [2] , Face2Face (F2F) [3], FaceShifter [34] and Neural Textures (NT) [35]. Each manipulation category contains 1000 videos created from 1000 original samples. Videos are provided in three qualities: raw, high (c23) and low (c40) compression. The c23 samples are utilized in this experiment.

In this paper, experiments are directed on DF and NT categories of FF++ dataset.

B. Classification Metrics

The classification metrics utilized in this experiment are given in the table below.

TABLE I. Classification Metrics Used in This Experiment

Metric	Formula	Range
Accuracy (ACC)	$\frac{\mathbb{TP}+\mathbb{TN}}{\mathbb{TP}+\mathbb{TN}+\mathbb{FP}+\mathbb{FN}}$	[0,1]
Precision (P)	$\frac{\mathbb{TP}}{\mathbb{TP}+\mathbb{FP}}$	[0,1]
Recall (R)	$\frac{\mathbb{TP}}{\mathbb{TP}+\mathbb{FN}}$	[0,1]
F1 score (F1)	$\boldsymbol{2 * \frac{Precision * Recall}{Precision + Recall}}$	[0,1]
Area Under Curve (AUC)	-	[0,1]
Mathews Correlation Coefficient (MCC)	$\frac{\mathbb{TP}*\mathbb{TN}-\mathbb{FP}*\mathbb{FN}}{\sqrt{(\mathbb{TP}+\mathbb{FP})(\mathbb{TP}+\mathbb{FN})(\mathbb{TN}+\mathbb{FP})(\mathbb{TN}+\mathbb{FN})}}$	[-1,1]

C. Hardware Specifications

Experiments are executed on two 24 GB NVIDIA A5000 GPUs in parallel. The system memory is 128GB.

D. Preprocessing

This section describes the preprocessing steps followed in this experiment.

1) Face Extraction: Popular deepfake detection algorithms have mostly used the dlib library [11, 9, 36] or MTCNN [37, 28, 38] for face detection and extraction. RetinaFace [34] is utilized in this experiment to extract facial images from video frames given its low failure rate compared to MTCNN [39].

2) Resizing, Normalization and Data Augmentation: Facial images that are cropped from video frames are resized to 128×128. Pixel values are normalized to range $[0,1]$. Facial images are flipped randomly in both vertical and horizontal directions with a flipping probability of 0.5.

E. Hyperparameters and Training Conditions

All experiments are run for 30 epochs. The batch size is set to 4. The Adam optimizer is used to update model weights. The initial learning rate is set to 0.01. A linear learning rate decay is employed that reduces learning rate by 10% after every 2 epochs.

F. Model Weight Initialization

Deep models when initialized with pre-trained ImageNet weights have performed better on classification tasks as compared to random weight initialization. Hence, the model weights in this experiment are initialized with ImageNet pre-trained weights provided on a Pytorch framework website.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:51:17 UTC from IEEE Xplore. Restrictions apply.

V. Results & Discussion

This section demonstrates the results obtained by each attention mechanism. Additionally, it also explains the computational cost involved for each attention mechanism.

A. System & Software Requirements

The proposed model requires at least 16GB memory of NVIDIA graphic card. The secondary storage required for storage of the FF++ dataset is 10GB. All coding experiments are conducted in the Python language. PyTorch framework is utilized to design and train neural network. Jupyter Notebook IDE has been used to write the code.

B. Results & Discussion

Table II represents performance of each attention mechanism on the DF (FF++) dataset. The triplet attention mechanism performs best with 0.9543 accuracy and 0.9874 AUC score. The shuffle attention achieves the highest Recall score and Coordinate attention is best in terms of the F1 score.

TABLE II. Results of each attention module on the DF (FF++) dataset. The best scores are highlighted in bold.

Attention Modules	ACC	P	R	F1	AUC	MCC
Coordinate	0.9408	0.9167	0.9589	0.9373	0.9842	0.8822
Selective Kernel	0.8901	0.9263	0.8532	0.8882	0.9649	0.7831
Triplet	0.9543	0.9415	0.9566	0.9490	0.9874	0.9077
CoT	0.9214	0.9224	0.9015	0.9118	0.9717	0.8411
Shuffle	0.8480	0.7656	0.9798	0.8596	0.9560	0.7248

Table III presents performance of the various attention mechanisms on the NT (FF++) dataset. Here again, Triplet attention has the best scores against other attention mechanisms. Coordinate attention gets the highest precision score of 0.7511 while triplet attention scores highest on all other metrics.

TABLE III. Results of each attention module on the NT (FF++) dataset. The best scores are highlighted in bold.

Attention Modules	ACC	P	R	F1	AUC	MCC
Coordinate	0.7104	0.7511	0.6763	0.7112	0.7917	0.4248
Selective Kernel	0.6479	0.6815	0.6269	0.6531	0.7008	0.2980
Triplet	0.7190	0.6486	0.9347	0.7658	0.8592	0.4897
CoT	0.6409	0.5952	0.8579	0.7028	0.7548	0.3165
Shuffle	0.6556	0.6149	0.7747	0.6856	0.7093	0.3262

The NT dataset is more challenging and hence the scores achieved are lower than those achieved on the DF dataset.

Fig. 3 and Fig. 4 present comparison of accuracy scores of various attention mechanisms on the DF and NT datasets of FF++ respectively. In both cases, Triplet Attention outperforms all other attention mechanisms while coordinate attention comes second in terms of performance.

Fig. 5 and Fig. 6 demonstrates AUC-ROC curve for attention mechanisms on the DF and NT datasets of FF++ respectively.

The Triplet attention achieves the highest AUC score of 0.9874 on DF dataset and 0.8592 on NT dataset, clearly stating that model is highly confident in its predictions.

C. *Complexity Analysis*

This section presents a discussion of the computational overheads involved in implementing each attention mechanism. As discussed earlier, each attention mechanism has been integrated by using four attention layers, one for each skip connection block of the baseline model.

Fig. 8 presents a comparison of number of parameters for each type of attention mechanism. The baseline model without any attention layers has 23.5 million parameters (blue bar). Triplet, Coordinate and Shuffle attention layers (green bars) are extremely lightweight having only 530280, 1200 and 1440 parameters respectively. Selective Kernel (SK) and CoT attention (green bars) are computationally heavy having 61.3 million and 48.7 million parameters respectively.

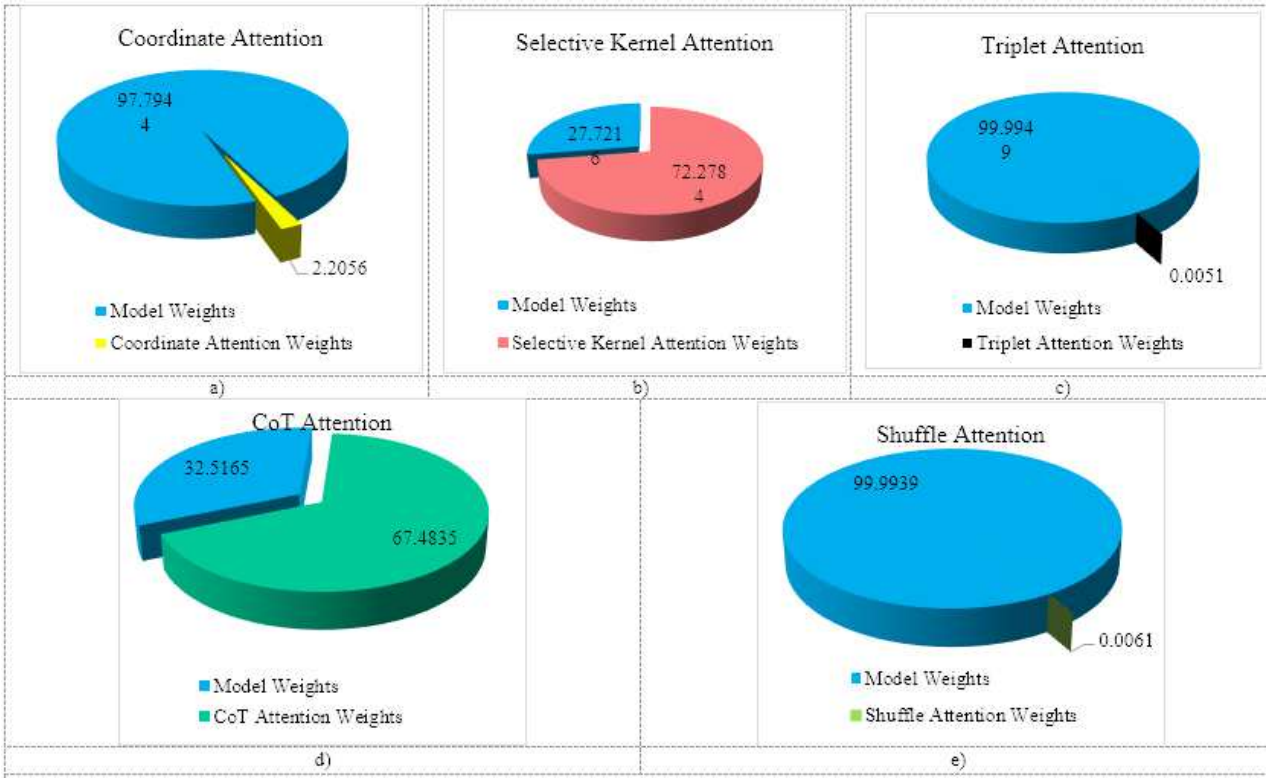

Fig. 7. The parameter distribution of each attention mechanism. The values represent the percentage of model parameters used for attention mechanisms. Coordinate Attention (a), Triplet Attention (c) and Shuffle Attention (e) are extremely lightweight occupying only 2.2056%, 0.0051% and 0.0061% of total model parameters respectively. Selective Kernel attention (b) and CoT attention (d) are heavier attention modules having 72.2784% and 67.4835% of the total model parameters.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:51:17 UTC from IEEE Xplore. Restrictions apply.

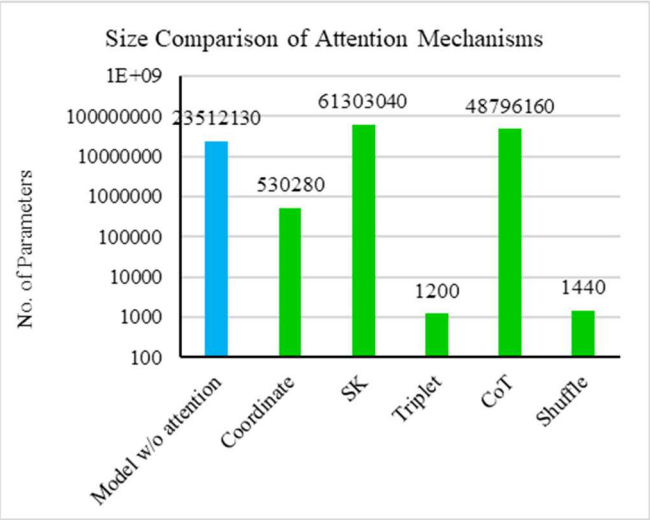

Fig. 8. Size comparison of attention mechanisms in terms of th number of parameters.

Fig . 7 represents the percentage distribution of parameters for each type of attention mechanism. The Coordinate, Triplet and Shuffle attention are lightweight occupying only 2.2056%, 0.0051% and 0.0061% of total model parameters respectively. The Selective Kernel attention and CoT attention are heavier attention modules having 72.2784% and 67.4835% of the total model parameters.

VI. Conclusion

This manuscript presents a comparison of the recently proposed visual attention models for face forgery detection. Specifically, a baseline CNN has been enhanced with several recently proposed attention modules and their impact has been studied. The study has been conducted in terms of the performance on the FaceForensics++ dataset. Additionally, the computational complexity of different attention mechanisms has also been analyzed and compared visually. It is clear from the conducted experiment that different attention modules employ different computational overheads to existing CNN parameters to highlight important spatial regions of input.

A. Limitations

This paper used a baseline CNN and enhances it using different types of visual attention modules. There are several recently proposed visual attention mechanisms that are not included in this experiment. More recent visual attention modules can improve the model performance further. Other vision baseline models can be integrated with vision based attention approaches for boosting model performance even further.

B. Future Directions

While vision based attention mechanisms have improved deepfake detection, multi-modal approaches are a promising area to enhance the forgery detection process. Specifically, researchers can focus on other modalities such as text or audio that can further improve the tampering detection capablities of models. Attention mechanism can be used to combine multi-modal feature extraction for better discriminative capabilities.

***Abstract*—The chargers for Electric Vehicles (EVs) plays a vital role in the development of the EV industries. EVs hold great promise for significantly decreasing the environmental impact of automobile transportation. The EV chargers have an important unit as a DC-DC converter. This paper proposes a closed-loop control approach for a PSFB (phase-shifted full bridge) dc-dc converter operating under synchronous rectification for EV charging applications. To achieve high efficiency, PSFB with synchronous Rectification is preferred over conventional PSFB. Zero voltage switching (ZVS) is supported by the converter, which enables it to operate at high frequencies while also providing benefits such as a solution to slow charging and high efficiency. The parasitic capacitances of full bridge MOSFETS and the leakage inductor of the high-frequency transformer play a key role in achieving ZVS. A 48V Lithium Ion Battery has been used for the charging process and one PI controller has been implemented for CC (Constant Current) mode charging. The system is designed for 5.5 kW, and the analysis is carried out using MATLAB/Simulink software.**

Keywords - dc-dc converter, EV battery charging, isolated transformer, switching frequency, synchronous rectification, ZVS

I. INTRODUCTION

The demand for Electric vehicles is supposed to increase in the upcoming years and it is forecasted that 10% of the total vehicle market will be dominated by EVs [1]. In comparison to traditional Internal Combustion (IC) engines, EVs are a better alternative as it is environmentally friendly. The use of Traditional IC engine vehicles emits lots of harmful gases like Carbon monoxide (CO) which pollutes the air, thereby playing a major role in Global warming [2]. For sustainable development, we should find a better alternative way that reduces environmental problems. The use of traditional IC engines has degraded air quality, which has a major impact on public health. The use of fossil fuels like petrol and diesel must be limited as it has limited availability. The extensive dependency on Fossil fuels has to be taken care of by switching to eco-friendly EVs. In terms of efficiency, 60 % of the total electrical energy available from the grid is converted to useful work of powering the wheel whereas, in the case of traditional IC engine vehicles, only 17% to 20% of total energy available from the fuel is used in powering the wheel which shows that there is 80% wastage of the fuel energy. The EVs have zero emissions which is good for the atmosphere. Even if the production of electricity is considered for EVs then IC engines have 3 times more carbon monoxide emissions than the average EVs. EVs have lower running costs and maintenance. By 2030, India is about to achieve 40% of its electric power from non-fossil fuel energy resources thereby, it will prove as a boon for EVs [3].

As the EV demand is increasing so there is a need for an electric charger that helps in charging the vehicle's battery There is a requirement for Fast charging stations so that the use of vehicles becomes more convenient. DC-DC converter is a basic unit of EV chargers playing a key role in charging. It is the connecting link between the AC/DC power transfer circuit and the EV battery. DC-DC converters help in attaining from one voltage level to another voltage level. For the conversion to occur, the energy is stored temporarily in energy-storing elements like inductors or capacitors, and this energy is released at different voltage levels to the output. In an inductor/high-frequency transformer the energy is stored in the form of magnetic energy and in a capacitor the energy is stored in the form of an electric field. There are different topologies available in DC-DC converters as per the requirement of voltage levels and efficiencies. Based on safety and galvanic isolation DC converters are classified as Isolated converters and non-Isolated converters. Isolated converters use high-frequency transformers and provide galvanic isolation. Converters like LLC, and DAB come under this category. Some examples of non-isolated converters are Buck-Boost converters, flyback converters, and CUK converters. The basic stages of charging are from ac (from the grid) to dc and then dc to dc conversion. Onboard EV chargers directly take ac from the supply and the later stages of conversion ac to dc and then dc to the required dc for the battery is present inside the vehicle charging system whereas, in Offboard chargers, DC is directly fed to the vehicle battery system, where DC-DC conversion occurs where DC-DC converters play a vital role in charging [4],[5]. The working of the converter also influences the lifetime of the battery.

Both ac and dc charging is possible; ac charging often specifies level 1 and level 2 onboard chargers whereas dc charging is specified by level 3 off-board chargers. Level 1 is simple charging available at residential, buildings where 230V ac is available. It supports 12 A to 15 A of current (Single Phase). Level 1 charging is slow charging. Level-2 ac chargers can produce up to 20kW of power and are typically utilized in commercial locations like malls and workplaces. Modern Level-2 charging stations accept 208Vac or 240Vac as input voltage. Level 3 chargers are fast offboarding DC-DC chargers [6],[7]. Figure 1 shows the stages of the charging system. It

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:22:06 UTC from IEEE Xplore. Restrictions apply.

depicts the power level conversion stage. The input to the system is dc and then DC is converted to AC which is fed to the high-frequency transformer of the PSFB converter later the output from the high-frequency transformer is converted to DC and this DC after passing through the LC filter is fed to the battery for charging purpose. Generally, Input DC is available from AC after rectification but here in this paper focus has been made on DC-DC conversion.

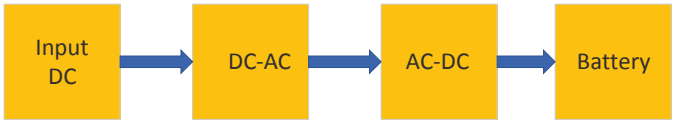

Fig. 1. Stages of conversion

PSFB with synchronous rectification is a good selection for EV chargers as it has the soft-switching capability, low stress on switches, low and EMI, simple PWM control. It has high efficiency and a wide range of ZVS than the conventional PSFB with diode rectification. It allows working at high frequency resulting in high power density [8]-[10]. The closed loop PI control has been used to achieve CC mode charging. The PI controller controls the pulses which is fed at the MOSFET switches.

Section II describes the model of the battery charging system along with filter design, PI controller, and analysis of ZVS. Section III covers a detailed analysis, and results. The study is validated using MATLAB/SIMULINK for a 5.5 kW system, 48V lithium-ion battery.

II. Design and Analysis of the Battery Charging System

The block diagram of the proposed charging consists of Input dc, dc-ac conversion, ac-dc conversion, Battery, and CC controller. Input DC is fed to the Phase shifted full bridge converter which is then converted to the EVs battery voltage level. AC power from the grid can be rectified to DC and fed at the input DC level. Other forms of renewable energy like solar energy can be used to feed power at input DC. In the Block diagram, different stages have been shown under the block Phase shifted Full bridge Converter. The first stage is DC to AC conversion with the help of the H bridge structure present in PSFB. This ac is fed to the high-frequency transformer which stores energy in the form of magnetic energy and builds the voltage level. In the last stage, this ac is converted to dc with the help of synchronous rectification where two MOSFETs are used at the secondary side of the high-frequency transformer. Here, Synchronous Rectification helps in attaining the dc voltage level at high efficiency. This dc is passed through the LC filter.

With the help of an LC filter, the output dc current and voltage smoothen, thereby, feeding better quality charging current to the battery. Figure 2 shows the Block diagram of the proposed Charging system. The CC controller consists of a PI controller which helps in maintaining the constant required current to the battery and also protects the battery from overheating.

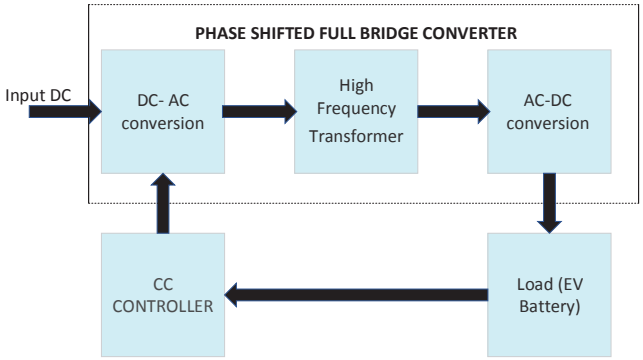

Fig. 2. Block diagram of Proposed Charging System

A. Phase – shifted full bridge DC-DC converter

The Phase Shifted Full bridge DC-DC Converter with synchronous Rectification is used for the proposed battery charging system. It has two stages of power conversion – Dc to ac(fed to a high-frequency transformer) and then ac to dc which is fed to the lithium-ion battery. Rather than driving both the diagonal switches together as in a Full bridge converter, here, a delay is introduced at the turn-on commands of the diagonal switches. The effective duty cycle can be controlled by modifying the phase shift between the switch drive commands. The Uniqueness of this phase shift technique is that two of switches connected in series with the transformer can be turned ON, yet the input voltage fed to the transformer is zero. These are either the two upper or two lower switches, not the diagonal switches, of the full bridge converter. The transformer primary is efficiently short-circuited and clamped to the appropriate input rail in this mode. The necessary off time for that specific switching cycle relates to the duration of time switches can be held in this condition. The primary current passes through the switch output capacitance (Coss) when the right switch is later switched off, causing the switch drain voltage to resonate with the opposing input rail.

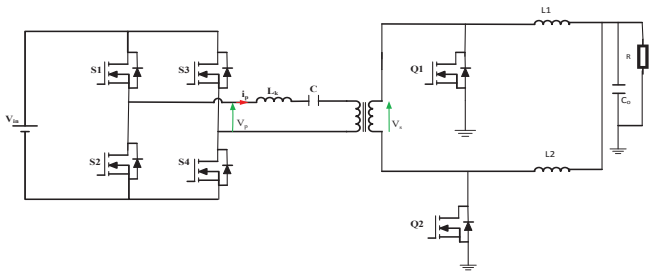

Fig. 3. PSFB with Synchronous Rectification

The PSFB with synchronous rectification as shown in Figure 3 has two MOSFET switches at the secondary side. Controlling the switch at the secondary side has a significant role. The MOSFET R_{dson} (drain to source resistance) can be adjusted, thereby, minimizing the conduction losses. The Converter allows ZVS resulting in minimum switching losses.

B. Filter design

The capacitor inductor filter at the output side is designed using the following equations. The voltage drop across the output inductor is given as

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:22:06 UTC from IEEE Xplore. Restrictions apply.

$$V_L = V_{in}\frac{N_s}{N_p} - Vo \quad (1)$$

V_o is the output voltage

$V_{in}\frac{N_s}{N_p}$ is the secondary side transformer voltage with turns ratio N_s/N_p

$$V_L = \frac{di}{dt} \quad (2)$$

Using equations 1 and 2 , the inductance L can be written as

$$L = V_L\frac{DT_s}{I_{ripple}} \quad (3)$$

The output current through the filter capacitor is given as

$$I_{ripple} = C\frac{dv}{dt} \quad (4)$$

Equation 4 can be further written as

$$C = I_{ripple}\frac{DT_s}{V_{ripple}} \quad (5)$$

C. PI Controller Design and Operation

The closed-loop control of the battery charging current is done using a PI(also, known as Proportional Integral) controller. PI controller is a feedback control loop that helps in setting the desired value at the output. The reference desired value is set and with the help of the sensor, the output charging current of the battery is sensed. The difference between the reference value of the current and the output charging current known as the error signal is fed to the PI controller. This helps in controlling the switching pulses given to Switches, thereby controlling the operation of switches accordingly and helping to achieve a uniform charging current for the battery.

The mathematical equation of the PI controller is given by

$$u(t) = k_p e(t) + k_i\int_0^t e(t)dT \quad (6)$$

where, u(t) is the controlling signal, e(t) is the error signal

k_p is the proportional gain constant of P -term

k_i is the integral gain of I-term

The combination of proportional and integral signals is known as the controlling signal u(t). The setting of K_p and K_i is important for tuning the PI control and hence achieving the desired charging current at the battery side.

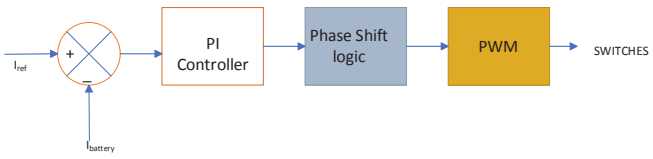

Fig. 4. Block diagram of PI control strategy

Figure 4 shows the block diagram of the PI control strategy. The diagram states the control of the charging current of the battery. PI controller helps in improving steady-state error characteristics for the system.

D. Analysis of ZVS and specifications

For achieving ZVS, the leakage inductance stored energy should be greater than the energy stored in output capacitances which is described in equation (7)

$$E = \frac{1}{2}L_{lk}I^2 > \frac{4}{3}C_{MOS}V_{in}^2 + \frac{1}{2}C_{tr}V_{in}^2 \quad (7)$$

where, C_{MOS} is the output capacitance of the switch

C_{tr} is the transformer winding capacitance

The equation above can be written in a simplified form:

$$\frac{1}{2}L_{lk}I^2 > \frac{1}{2}C_{eq}V_{in}^2 \quad (8)$$

On solving further, input primary current can be written as:

$$I = \sqrt{\frac{C_{eq} * V_{in}^2}{L_{lk}}} \quad (9)$$

The formula below gives the frequency required to achieve ZVS switching resonance between the transformer's leakage inductance, which stores energy, and the MOSFETs' junction capacitance.

$$fr = \frac{1}{2\pi\sqrt{L_{lk}C_r}} \quad (10)$$

TABLE I. LISTS THE SYSTEM PARAMETERS

Parameters	Units	Value
Input voltage	V	380
Output voltage	V	55
Switching frequency	kHz	200
Output current ripple	%	20
Output voltage ripple	%	40
Power Rating	kW	5.5
Battery Nominal Voltage	V	48
Battery Ah rating	Ah	100Ah
Battery Initial SOC	%	40

Depending on the requirement, batteries can be charged at different rates. Appropriate safety measures must be taken in order to maximize the charging rate, ensure the battery is fully charged, and prevent overcharging therefore, the system is operated under CC mode to charge 48V,100Ah battery

III. Simulation Results

The MATLAB Simulink environment is used to model the proposed charging system. The model consists of, a PSFB DC-DC converter, a PI controller, Lithium Ion Battery. The input DC voltage is 380 V, the output at the converter is 55 V, Switching Frequency is 200 kHz is used to charge a 48 V, 100 Ah Lithium-ion Battery

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:22:06 UTC from IEEE Xplore. Restrictions apply.

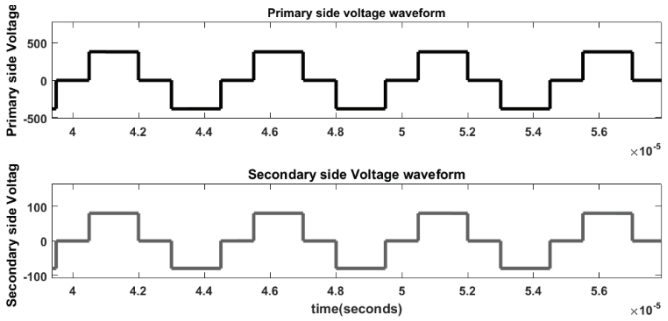

Fig. 5. Primary and secondary side voltage waveform

In Figure 5, the primary and secondary side voltage waveform has been shown. The PI controller feedback loop controls the switches in order to maintain CC mode and the phase shift between the diagonal switches has been maintained which helps in attaining the desired voltage waveform at the primary and secondary sides. On both sides, the transformer has zero voltage due to the two upper switches or two lower switches.

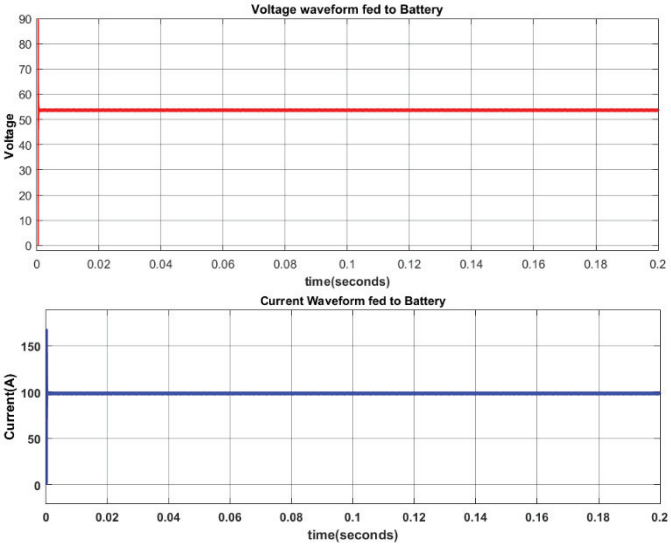

Fig. 6. Output Voltage and current waveform fed to Battery

In Figure 6, the output voltage and current waveform is shown which comes after synchronous rectification through the secondary side of the high-frequency transformer. The output voltage is 55 V at the output of the converter and it is fed to the battery. The lithium-ion battery charges with a charging current of 100 A at initial SOC of 40 %.

Fgure 7 shows the SOC, Current, and Voltage waveform when the SOC is moving from 40% to 50%. The magnitude of the charging current remains almost near 100 A. As the SOC increases the battery charges. When the battery is fully charged then SOC becomes constant. In the charging state, the battery shows a negative current.

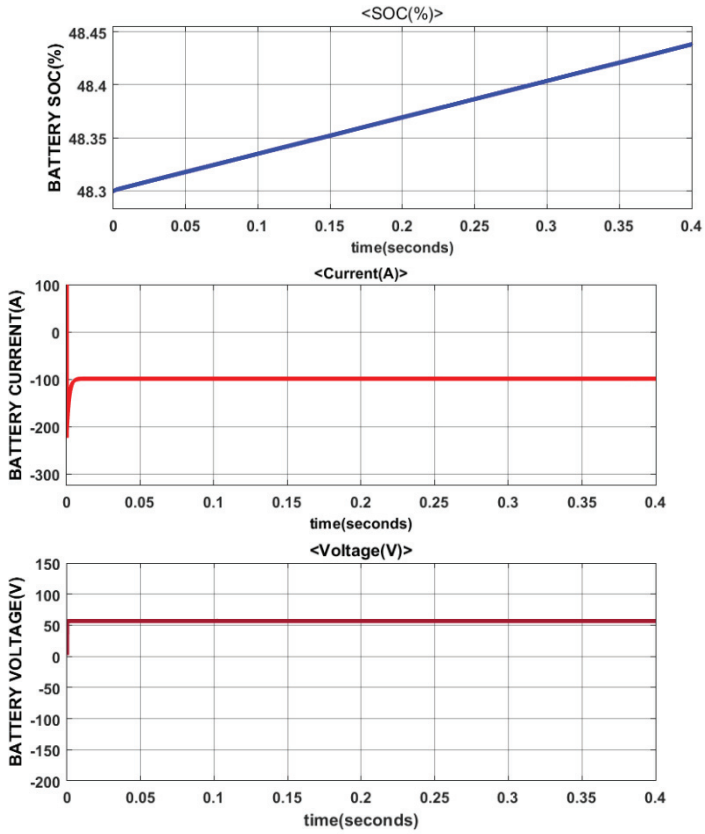

Fig. 7. SOC, Current, Voltage waveform from the Battery

The charging current remains almost constant up to 60% to 70 % of SOC and then the charging current starts decreasing gradually and at 99% SOC, the charging current becomes almost zero.

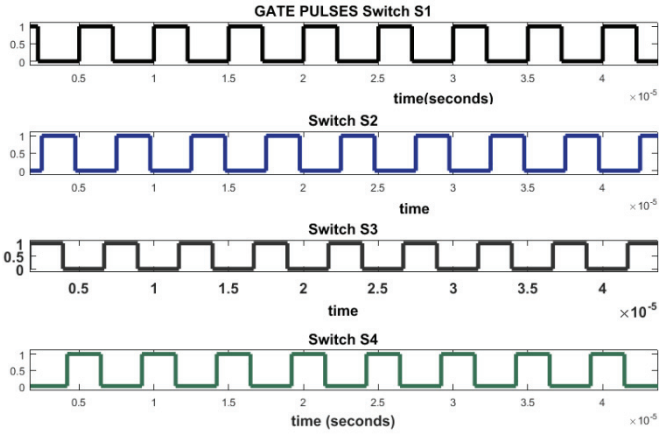

Fig. 8. Switching Pulses

Figure 8 shows the switching pulses for switches S_1, S_2, S_3, S_4. The closed loop PI control has controlled the switching pulses in order to maintain the desired output.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:22:06 UTC from IEEE Xplore. Restrictions apply.

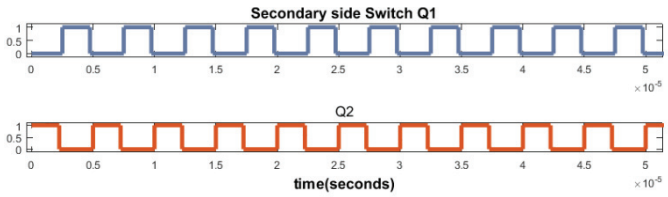

Fig. 9. Switching Pulse at Q1, Q2

Figure 9 shows the switching pulse waveform at the secondary side switches Q_1 and Q_2.

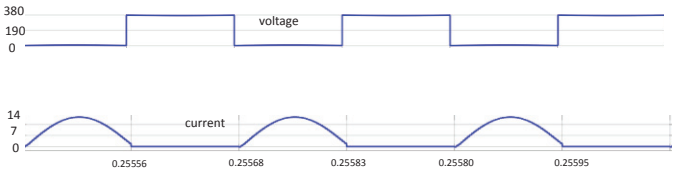

Fig. 10. Across Switch S_1 ZVS waveform

In Figure 10, Zero Voltage Switching has been shown across Switch S_1. During this duration when the voltage is zero across the switch then the switch gets turned ON resulting in minimum switching losses which help in efficient charging of the battery.

IV. CONCLUSION

In the proposed model, the charging of a 48V lithium-ion Battery through PSFB dc-dc converter closed-loop control has been studied in a SIMULINK environment. One PI controller has been used to maintain CC mode charging. The PI controller has a significant role in avoiding overshoots and undershoots for the charging current and has a faster response. SOC, current, and voltage waveforms of the battery have been presented for the charging state. PSFB dc-dc converter with synchronous rectification can be used for EV battery charging as it has high efficiency and enhances ZVS over a wide load range. The CC mode also helps in maintaining the life of the battery. The future scope of this paper can be extended to CC-CV charging and other Artificial Intelligence (AI) based control methods can be implemented.

Abstract
The classification of Short Message Service (SMS) is a crucial task that requires distinguishing undesirable and harmful messages from legitimate ones. These spam messages may include malicious links that reveal users' personal data to some sharp practices. Many Machine Learning (ML) and deep learning algorithms prevail for spam detection. However, a large number of features present in the message drop the classifier's performance, which can be untangled through feature engineering. This paper proposes an ensemble feature selection algorithm assessed over a high-dimensional imbalanced dataset that resembles the actual data prevailing in the surroundings. The proposed work employs wrapper-based Stratified K-fold Cross-Validated (SKCV) Recursive Feature Elimination with Cross-Validation (RFECV) over hyperparameters tuned Support Vector Classifier (SVC) and random forest algorithms. This study contributes an efficient feature selection algorithm that produces a pruned feature subset substituting the whole dataset. To establish the potential of the proposed approach, its performance is evaluated against five feature selection techniques, including Mutual Information (MI), Low Variance (LV), Particle Swarm Optimization (PSO), Chi-square, and Recursive Feature Elimination (RFE). All obtained feature subsets are analyzed with three ML models Logistic Regression (LR), Support Vector Machine (SVM), and Extreme Gradient Boosting (XGB). This research also compares the proposed framework results with Long Short Term Memory (LSTM) neural network to validate its competence.

1 Introduction

With the emergence of telecommunication, mobile services have become a convenient amenity amongst users belonging to academics, corporations, or private grounds. As given in[1] the percentage of mobile phone users in the world is around 78.05%. SMS is an ideal way of communication. Various studies manifest that an average person receives four times more SMS than e-mails.[2] Also, where an e-mail message has a probability of 20% getting opened, SMS comprises around 82% chance to be seen by the receiver at the end of the day. Around 18.7 billion text messages are sent over the network in one day.[3] Hence, the vast number of messages generated daily requires an automated mechanism to filter the undesirable and false messages from the necessary ones. Mainly, spam message comprises advertisements, offers, and winning lucky draws. Then, to proffer the rewards or prize amount, spammers request users to provide their details such as account number, one-time password, security pin, and other particulars, to steal the specifications and mug up the capital or finances of the person. Spammers bag a bounteous amount from malicious practices producing a significant loss to the authorized person or the organizations. Moreover, such unsolicited SMS occupies an ample capacity of message inbox. It may lead to skipping required or impromptu action messages that may incur a loss to the person. Further, these unwanted and toxic texts create unwanted traffic on both the server and client sides.

SMS spam is a substantial issue persuading in the world. People receive noticeable spam messages on their native SMS platform. Figure 1 shows the usage of different platforms preferred by the people and conveys that the use of native SMS platforms is to a great extent, besides the presence of other enduring applications. The figure illustrates the significance of chosen dataset graphically.

This research work aims at SMS classification as spam or ham, where spam refers to unsolicited messages and ham refers to legitimate ones. With the introduction of new technology and growth in the use of mobile devices, every day a large amount of SMS data is generated. The malicious activities add a significant aggregate of junk messages to datasets that must be eliminated. So classifying such a massive amount of data requires some automated procedures. Many ML models are available for classification, but the text messages mainly comprehend high-dimensional feature vectors. Incorporating such high-dimensional data to train the classifier is costly and with the presence of misleading and redundant data, the model may give erroneous results. Feature selection is an approach that can uncomplicate the categorization of spam messages and legitimate ones. It can overcome two constraints, i.e., model overfitting and the curse of dimensionality. Some features in the corpus are insignificant for training ML classification models and noisy data inculcated in the text misleads the classification model. Feature selection is a procedure to manually or automated select the features or the subset of features that can substitute the whole document.

This research contributes an ensemble feature selection algorithm that drops the irrelevant and redundant features from the dataset and assists the classifier in recognizing and releasing spam messages out of the user's inbox efficiently. We assemble feature engineering in the proposed ensemble algorithm employing hyperparameterized RFECV

SVC and random forest algorithm. The rationale behind employing SVC and random forest algorithms is outlined in Section 6. The proposed algorithm reduces the computational cost by eliminating noisy and less effective features from the dataset. It mitigates the classifier in detecting spam and ham SMS producing the most optimal feature subset.

To illustrate the effectiveness of the proposed ensemble feature selection algorithm, the features subset is deployed to three ML models, including LR, SVM, and XGB. We compare the proposed ensemble feature selection algorithm with five other feature selection algorithms, including Chi-square, LV, PSO, MI, and RFE with all three classification models. Further, comparison of our proposed approach with the LSTM neural network model signifies the importance of the optimal feature subset obtained from the proposed algorithm. The study reveals that if the optimal feature subset is fed to the strong ML models, they give results analogous to the neural network models. This work also documents the motivation regarding stopwords removal from the dataset before classification by providing each classifier feature subset without removing stopwords and demonstrates results with all three ML classifiers. The experimental results are evaluated using f-0.5 score, precision, and recall.

The rest of the paper is organized as follows: Section 2 discusses the related work proposed by different authors for spam classification. Section 3 illustrates preprocessing techniques. Sections 4 and 5 present the literature review of utilized algorithms. Section 6 represents the proposed ensemble algorithm along with experimental work and results. Section 7 concludes the proposed work. Section 8 provides the future scope of work.

2 Related work

Recent years have witnessed a noteworthy growth in spam classification. This section describes different contributions by the researchers. Table 1 delineates the tabulated form of existing work. Abayomi et al. [1] reviewed seven databases, summarizing the research done in the field. The results illustrated that ML models like Naïve Bayes and SVM are preferred the most. Various statistics regarding the feature selection methodology, anti-spam application, corpora, performance metrics, and targeted approaches were calculated.

Authors concern the limitation of dataset availability for spam classification due to privacy leakage and provide a publicly available dataset. Sjarif et al. [30] utilized SVM model to perform spam classification over the dataset retrieved from the UCI machine-learning repository. The authors evaluated results on the basis of different proportionality splits of the dataset among train and test samples. The StringToWordVector technique was used for feature extraction and information gain for feature selection. The results were explored with SVM, Naïve Bayes, and K-nearest neighbor algorithms along with their variants; SVM outperformed others. Xia and Chen [34] proposed a discrete Hidden Markov model based on the order of words for spam classification. The model was trained and tested over a dataset obtained from the UCI repository.

Table 1 particularize work done for spam detection in recent years. It includes Proposed model, Description; key notion of the study, Feature Extraction (FE) and Feature Selection (FS) techniques used in the research, Research domain specifying the area examined by the authors and Limitations specifying the enhancements that can be considered for future work in conjunction with the proposed approach.

The results were validated against a specified Chinese dataset that illustrated the model performed irrespective of the language. The model has limitations; it cannot work well for small datasets. Bosaeed et al. [9] studied spam detection approach that appealed to the fog, edge, and cloud layers (for server-side). The authors utilized the proposed model for outgoing messages. Three classification models were deployed, i.e., Naïve Bayes, SVM, and Naïve Bayes multinomial with five preprocessing and feature extraction filters (PF1–PF5). The work was evaluated over 15 datasets. The PF5 filter and SVM model yield the best outcome. Roy et al. [27] utilized neural network to classify the messages as spam or ham. The authors assessed hyperparameters tuned Convolution Neural Network (CNN) and LSTM. The results were compared with various ML models: Naïve Bayes, random forest, gradient boosting, LR, and stochastic gradient boosting. CNN model outperforms others with an accuracy of 99.4%. Agarwal and Kumar [3] proposed an integrated model Naïve Bayes with PSO for spam e-mail classification. Feature selection was performed using the correlation method over the Ling spam dataset. Naïve Bayes classifier was employed for initial classifications; thereafter, the results obtained were optimized with PSO algorithm. The integrated model outperforms the base model. Kumaresan and Palanisamy [17] utilized lemm-ling spam and bareling spam datasets for e-mail spam classification. A modified cuckoo search algorithm termed as step-size cuckoo search (SCS) has been implemented that performs feature selection to reduce the dimensionality of data and make classification more efficient. The fitness function calculation and classifications were done using the SVM model incorporating linear, polynomial, and quadratic kernels. The proposed model produces more accurate results than the SVM model with original cuckoo search algorithm. Sjarif et al. [29] used Tf-Idf method to extract the features from the dataset. The authors compared five ML classification models (Multinomial Naïve Bayes, KNN, SVM, decision tree, and random forest) to classify the text message as spam or ham. Among all the algorithms, random forest outperformed others with 97% f-measure, 97.5% accuracy, and 98% precision. Baaqeel and Zagrouba [7] proposed a hybrid system utilizing supervised and unsupervised ML algorithms. The authors preferred Tf-Idf representation for extracting feature space. The dataset obtained from the UCI repository was fed to selected six supervised ML models: Naïve Bayes, SVM, adaboost, LR, KNN, and random forest. The best results were obtained with SVM classifier. Then the unsupervised model (k-means clustering) was fed within the hybrid model along with a selected supervised ML algorithm (SVM) that outperformed other base models. The work avails

advantage of both supervised and unsupervised algorithms for spam message classification. Poonkodi and Sukumaran [23] proposed an effective ensemble model EASCEM for spam e-mail classification. It comprises of adaboost sequential classifier that performs differential weighting for the misclassified instances provided by the base model. The base learner gets the features selected through the Effective Firefly Optimization Algorithm (EFOA). Two datasets: enron and spam, were opted for this research work. The proposed algorithm provides compelling results in less time when compared with SCA and ALO-Boosting algorithms over both datasets. Makkar and Kumar [19] proposed a framework termed PROTECTOR; instead of focusing only on textual or image features, the model extends its concentration over link properties and metadata of images to classify them as spam or ham. The deep neural network has been utilized in this research and the optimal objective function is based on genetic algorithm. The experiments were performed over the image spam hunter dataset and achieve an accuracy of 96%. El-Alfy and AlHasan [13] proposed an approach for spam classification inculcating five datasets (two SMS datasets and three Spam e-mail datasets). The effectiveness of the datasets was compared and analyzed. Among them, the top two feature sets were opted. The Dendritic Cell Algorithm (DCA), which is based on immune system dendritic cells, is utilized in this study. DCA in amalgamation with two ML models (Naïve Bayes and SVM) had been exploited by authors for generating signals for classification. Prilepok et al. [24] proposed a method for spam e-mail detection fusing Bayesian filtering, signature trees, and normalized distance data compression algorithms. The model achieves good precision of about 99% for spam detection and 98% for ham detection outperforming the base models. However, the algorithms were found to be susceptive to training dataset framing. Ahmad et al. [4] presented a method for spam tweet detection. The study focuses on feature extraction and preprocessing techniques. The preprocessing step helps eliminate unused or less important words from the dataset. Features were distributed in five classes comprising 28 content-based feature sets. SVM classifier with two kernel variations (Gaussian and polynomial) employed for classification of tweets spam. The proposed model outperformed other models over the honeypot dataset (as stated in the work). Adewole et al. [2] proposed a unified framework for spam SMS and spam account detection. Four datasets were inculcated in this work. Categorization and reduction of features were performed to distinguish spam messages and accounts. Spammer's network was studied by exercising graph-based methods that helped in classification. Ten different ML algorithms were utilized to prove the efficacy of the proposed model, among all random forest outperforms others. Bhuvaneshwari et al. [8] dispensed an architecture for review classification based on CNN and Bi-LSTM model, i.e., self-attention CNN-based Bi-LSTM (ACB). It utilizes semantic contextual information for classification through document vector representation. The proposed framework outperforms its variants CNN and Bi-LSTM (CNNB), Attention mechanism and CNN (ACNN), CNN, Hierarchical Supervised Learning (HSL), and Spiral Cuckoo Search (Spiral CS). The authors also suggested necessitating multi-level predictions for spam detection.

The spam detection field gathered considerable attention from researchers in recent years, either for SMS, e-mails, reviews, profiles, or others. Existing models use deep learning algorithms, integrated models, and optimization algorithms. Feature reduction must be a requisite to handle such high-dimensional datasets as it can make the computations efficient and inexpensive. Although various authors have adopted feature engineering for spam detection, this study proposes two-level feature selection through a hyperparametrized

procedure capable of large-scale feature elimination producing the most optimal features subset that mitigates classification models.

Contributions of this paper are summarized as follows:

1. Proposed an ensemble feature selection algorithm that produces the most optimal feature subset. It eliminates approx. 87% of irrelevant and redundant features and enhance the classifier's predictions.
2. With optimal feature subsets, strong ML models can efficiently produce results analogous to deep learning models.
3. The purpose of stopwords removal is justified.
4. The proposed approach can serve as a baseline model that substitutes a high-dimensional dataset with a reduced optimal feature subset.

The performance metrics that can uphold the unbalanced dataset are applied to evaluate models, i.e., f-score, precision, and recall. According to recent work, SVM and ensemble models are strong models for spam detection. We adopt these models to establish the accomplishment of proposed feature selection method with most preferred classification models and the outcomes support the novelty of this research work. Further sections in this paper will outline our novel ensemble feature selection algorithm. Before producing a dataset for any classification model, some preprocessing is required which is discussed in the subsequent section.

3 Data preprocessing

This section discusses various data preprocessing techniques, from fetching the dataset to its conversion to the pattern deployed to feature selection or classification models.

Preprocessing techniques The selected corpus comprises text messages that must be preprocessed before feeding to the machine-learning models. Preprocessing techniques remove undesired features from the dataset. Several data preprocessing techniques deployed over the chosen dataset are described below:

(a). **Stopwords removal**

Stopwords are the usually utilized words present in both spam and ham messages, so it is assumed that they do not convey much useful information to our classification model. NLTK library provides an inbuilt library of stopwords in 'English'.

In this study, experiments are also conducted by training ML models with incorporated stopwords features in order to support the elimination of stopwords. The results of the experiments are provided in Section 6.

(b). **Stemming**

Stemming is the process of reducing inflectional structures or derivationally related morphological variants of words to their root words. We utilize "Porter Stemmer," which

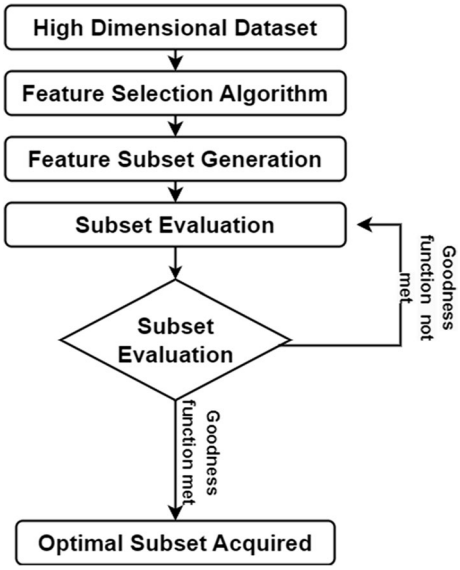

Fig. 2 Flow diagram for feature selection

works in five phases of elimination put in sequentially. It helps to determine vocabulary for the domain more expeditiously.

(c). **Bag of Words**

Feature extraction helps us to produce the numerical representation of the textual data. We represent our dataset using the Bag of Words (BoW) technique. The text or document is considered a bag (multiset) of words. It does not give importance to the order of the words in the corpus nor the grammar applied but keeps the multiplicity.

Keeping in view the contended implementation and further flexible customization of the fixed length vectors offered by the BoW algorithm, it is selected in this work.

After specific preprocessing steps, feature selection algorithms are applied to the dataset to obtain a more convenient feature subset. The feature selection algorithms utilized in this study are described in the next section.

4 Feature selection

The datasets acquired from numerous available sources over the network or assembled by the researchers for their experiments usually have a large number of features that makes it difficult for the machine-learning models to classify the data efficiently. Three types of features exist in the dataset: (i) Relevant features; that convey essential information to the classifier which is helpful in classification. (ii) Irrelevant features; that are useless for our classification model and may mislead the classifier declining their accuracy. (iii) Redundant features; that are needful to the classifier but the information contained in them had already been strongly conveyed through other features. The aim is to select features more relevant to the output target class and less correlated with other input features. Figure 2 shows the flow chart for feature selection.

The feature subset selection is a multi-objective goal, i.e., to balance the trade-off between two incompatible tasks: the first is to reduce the dimension of the dataset and the other is to increase the accuracy of the classifier [6]. The feature subset selection relies on some measures like distance, information present, dependency among input variables and with target output variable, and consistency [11].

The feature selection method is further categorized as wrapper, filter, and intrinsic (or embedded). Table 2 briefly describes all three categories of the feature selection algorithm.

This research proposes an ensemble feature selection algorithm and compares it with chosen feature selection algorithms; LV, Chi-square, MI, PSO, and RFE.

(a). **Low variance**

Low Variance (LV) is an unsupervised statistical feature selection technique. It considers only the input feature set, not the target output value. It eliminates features that have variance less than some predetermined threshold value. For instance, if a word is present in all the messages, it does not convey any differentiating potential to the spam or ham message classifier. Such features are said to have 0 variance. So, these insignificant features should be dropped. The given Eq. (1) provides the mathematical expression for variance [18].

$$variance\ score = p(1-p), \tag{1}$$

where, p represents the percentage of samples having the corresponding feature.

(b). **Mutual information**

Mutual Information (MI) of two arbitrary variables estimates their mutual relation. It is a technique evaluating the weight of information achieved for one random variable by studying another.

It is an application of information gain. This statistical technique not only considers the measure of interconnection between the features and output variable but also tries to find the relevance among the features in the dataset to reduce or eliminate redundant features. The scoring function for each feature is calculated as [18]

$$score\left(X_i\right) = I\left(X_i : Y\right) - \beta \sum_{X_j \epsilon S} I(X_k : X_j), \tag{2}$$

where, X_i is the feature for which we are calculating the mutual information score, $I\left(X_i : Y\right)$ is the relationship between the feature and target output variable, and $\beta \sum_{X_j \epsilon S} I(X_k : X_j)$ represents the correlation between the considered feature and selected feature subset.

(c). **Chi-square** (χ^2)

The chi-square test contributed by Karl Pearson in 1900, is a hypothetical statistics test. Here, it is utilized for feature selection.

The chi-square test for feature selection examines the dependency among stochastic variables in the provided dataset. It tries to evaluate the reliance of the target output

Table 2 Brief description of feature selection methodologies

	Definition	Advantages	Disadvantages
Filter-based	This method selects the subset of data by analyzing it through various statistical models to discover the relationship between the input features and the target output variable. It mainly uses some selection methods to obtain the input features with specified maximum values. Example: Chi-square, Euclidean distance, correlation-based	• Fast • Scalable • Independent of classifier	• Do not interact with the classifier
Wrapper- based	These methods calculate the importance of the feature subset by using the classifier. They produce the optimal feature subset utilizing a classifier. Example: Forward feature selection, Backward feature elimination	• Derives feature dependence • Interact with the classifier	• Results are delayed
Embedded	These are also termed hybrid models as they exercise the concept of both wrapper and filter-based feature selection techniques. They are implemented in models consisting of their own built-in feature selection procedures Example: Lasso, Ridge	• Accounts dependency among features • Interacts with classifier	• High cost

feature over the feature set. The feature subset is acquired by calculating the score for each feature given by Eq. (3) [18]:

$$\chi^2 = \frac{(observed\ frequency - expected\ frequency)^2}{expected\ frequency}. \tag{3}$$

The features having low χ^2 values are discarded as they reflect the uninformative behavior towards the classification or the target output value, and features with high χ^2 values are retained for the classification models.

(d). **Recursive feature elimination**

Recursive Feature Elimination (RFE) is a wrapper-based feature selection technique. It attempts to eliminate features with higher dependency and collinearity. It incorporates a classification model that removes the features with low ranking initiating with the whole dataset and repeats the procedure recursively until the determined aggregate is reached. Most of the time, this limit where to stop is unknown, so the default value of half of the features is set as stopping criteria. Numerous options are available to select the classification model, like SVM, perceptron, random forest, decision tree, and stochastic gradient boosting. RFE computes scores for different feature subsets and returns the more appropriate one.

It has a variant with an implicitly incorporated cross-validation approach, i.e., Recursive Feature Elimination with Cross Validation (RFECV). It selects the feature subset iteratively on ranking basis.

(e). **Particle swarm optimization**

Particle Swarm Optimization (PSO) is a metaheuristic algorithm proposed by Kennedy and Eberhart in 1995 [16] that uses an objective function to find the minimal optimal solution.

PSO is based on the food-searching nature of animals, like a flock of birds [33]. The birds seeking food are not aware of the location of food, but they can sense how far they are in each direction. The flock follows the bird with the least distance to the food.

In PSO, member of the population (flock) is referred to as particle (birds), each particle represents a solution, and their population is termed as swarm. Each member of the population is associated with velocity and position. The algorithm starts with some arbitrarily chosen population size that heads in some random direction throughout the search space. However, each particle remembers its own and the swarm's current best position. PSO updates the value in each generation to find the best optimal solution among all existing ones.

For a D- dimensional space, vector

$$X_i = X_{i1}, X_{i2}, X_{i3} \cdots X_{id}, \tag{4}$$

expresses the d-dimensional positional vector for the i^{th} particle and

$$V_i = V_{i1}, V_{i2}, V_{i3} \cdots V_{id}, \tag{5}$$

represents the d-dimensional velocity vector for the i^{th} particle.

For each iteration, the value of X_i and V_i are updated as follows:

$$V_{id}^{t+1} = w \times V_{id}^{t} + c_1 \times r_1 \times \left(p_{id} - X_{id}^{t}\right) + c_2 r_2 \times \left(p_{gd} - X_{id}^{t}\right), \tag{6}$$

$$X_{id}^{t+1} = X_{id}^{t} + V_{id}^{t+1}, \tag{7}$$

where, p_{id} represents the personal best for the particle and p_{gd} denotes the global best. c_1 *and* c_2 are learning factors. w indicates inertia weight. $r_1 and r_2$ are random variables lying under the range of [0,1]. Here, the velocity is also restricted to the predetermined valueV_{max}, i.e.,$V_{id}^{t+1} \in [-V_{max}, V_{max}]$.

We exert Pyswarm[4] Library [21] in this work, the fitness function of which is provided [32] as:

$$f(X) = \alpha(1 - P) + (1 - \alpha)\left(1 - \frac{N_f}{N_t}\right), \tag{8}$$

where, P is the classifier's performance, N_f is the feature subset, N_t represents total features, and α is the hyperparameter defining the trade-off between P and N_f.

Though the algorithm does not guarantees to come up with the best optimal ever. With the hinge of an idea, researchers are deploying the algorithm in various fields [28, 33]. It is utilized here for feature selection. Many variants of PSO are present, and we adopt discrete PSO.

After obtaining the feature subset from feature selection algorithms, the pruned dataset is deployed to classification models whose description is provided in the following section.

5 Classification techniques

The main aim of our research is to classify the given SMS as either spam or ham. Mainly classification techniques can be categorized in three ways: Machine-learning algorithms that learn from the given training dataset and construct a knowledge base using which it performs classification (LR and SVM), Bio-inspired algorithms based on the working of the human brain (LSTM), and Ensemble models that average the results obtained from multiple models (XGB). A brief outline of all the chosen models is provided below:

(a). Logistic regression

Logistic Regression (LR) [14, 20, 25] is a probabilistic statistical model. Depending on outcomes, they are of three types: Binomial, Multinomial, and ordinal. Here, we utilized binary LR. Binary LR is based on linear separation available among the data points. It aims at locating the most optimal model, delineating the association among high-dimensional independent feature vectors and targeted dichotomous dependent variable.

It uses the logit or sigmoid function, whose mathematical expression is given by Eq. (9). It maps the real values in the range [0, 1].

$$g(z) = \frac{1}{1 + e^{-z}}, \begin{cases} z \to \infty, g(z) \to 1 \\ z \to -\infty, g(z) \to 0 \\ z = 0, g(z) = 0.5 \end{cases} \tag{9}$$

[4] https://pyswarms.readthedocs.io/en/development/examples/feature_subset_selection.html

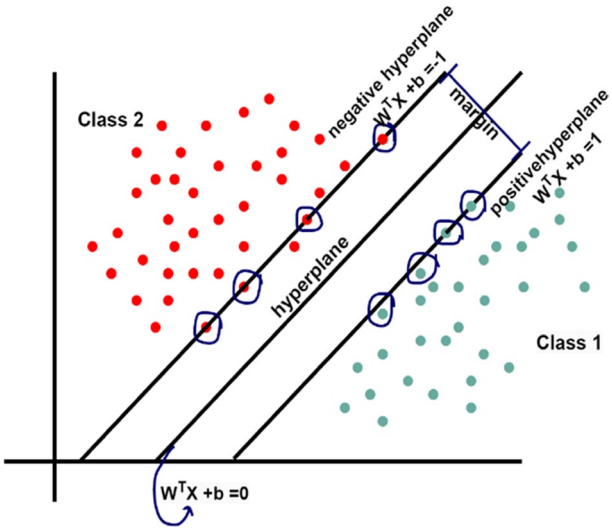

Fig. 3 Visual description of SVM classifier

The sigmoid function's derivative is elementary, making it attractive to use. Its derivative is computed as:

$$g\prime(z) = g(z)(1 - g(z)). \tag{10}$$

Let us have the target variable t, whose output value can be either 0 or 1, and X be the input variable of independent features.

Then the probability for *'t'* provided X is calculated as

$$P(t|X) = \begin{cases} (1 - h(X))^{1-t}; & for\ t = 0 \\ h(X)^t, & for\ t = 1 \end{cases} \tag{11}$$

where, $h(X) = g\left(\beta^T X\right)$ and β is the regression coefficient vector whose optimal values are learned using the maximum likelihood approach. The likelihood of β is expressed as

$$L(\beta) = \prod_X P(t/X;\beta). \tag{12}$$

The logarithmic odds (log function) of above Eq. (12), $l(\beta)$ (which is equal to $\log(L(\beta))$) is

$$l(\beta) = \sum_X t\ \log\left(h(X)\right) + (1 - t)\log(1 - h(X)), \tag{13}$$

and the cost function of the algorithm, which is inversely proportional to the likelihood parameter is given as:

$$cost(\beta) = \sum_X -t\ \log\left(h(X)\right) - (1 - t)\log(1 - h(X)). \tag{14}$$

The algorithm aims at maximizing the likelihood and minimizing the cost.

(b). **Support vector machines**

Support Vector Machine (SVM) is the most applied technique to stratify mail as junk or essential [31]. It is a supervised ML algorithm that can be utilized for regression or

classification. Training the SVM model is easy and outperforms several other ML models [26, 31]. It uses information from the high-dimensional database. Figure 3 provides the graphical representation of the SVM classifier with two-class instances. SVM is a statistical model that limits the risk in classification by defining support vectors. It tries to isolate the classes by constructing a hyperplane through these vectors. The support vectors are highlighted with a circle over the negative and positive hyperplanes in Fig. 3. The discriminant function for them is given below:

$$g(X) = W^T X + b = \sum_{i \in SV} \alpha_i X_i^T X + b, \tag{15}$$

where, SV denotes the support vectors. X is the test sample. The function relies upon the dot product between X and the support vector X_i. W represents the linear combination of the data points. Classifier tries to expand the margin between support vectors and obtained hyperplane. The algorithm does not rely on the likelihood distribution of data in the corpus, and it straightforwardly fits the classes in the dataset.

As it is not always possible that the data obtained will be linearly separable for such situations, the notion of “kernel function" is utilized. For non-linearly distinguishable data points, some feature transformation is performed that transforms the data points to higher dimensions so that the decision boundaries for the extrapolated feature space can be found. Such manual conversion increases computation costs as it usually deals with high-dimensional feature space. However, using kernel functions it is achieved without significant implications on the computation cost. SVM reduces the issue of overfitting and can handle high-dimensional data [12], but choosing the appropriate kernel function is monotonous work.

(c). Extreme gradient boosting

Extreme Gradient Boosting (XGB) [10], initiated by Deep Machine Learning Community (DMLC) as a research project, gained popularization after its success in the Higgs machine learning competition. It is an ensemble learning technique [15] that enhances the performance of ML models. Two techniques to ensemble or combine the models: Bagging and Boosting. Bagging (Bootstrap aggregating) tries to enhance predictions by making a better-combined classifier through amalgamation of the predictions given by a single model. Boosting (Adaptive resampling and combining) ameliorates the accuracy of the predictions by frequently running the base model over different training data distributions. Ensemble models are obtained by combining weak or base models to accomplish higher precision than single models.

XGB is a boosting ensemble model and a competitive spam classifier [10, 22]. It is a modification of the gradient-boosting algorithm that constructs the decision trees sequentially. Weights are given high significance in this algorithm. All the independent variables are associated with some weights, which are subsequently put into decision trees that predict the output. The weight of the variables mispredicted is raised and those variables are then assigned to another decision tree. These single predictors are combined to create a more robust and precise model. XGB is highly scalable, can utilize parallel processing, and is faster than the gradient boosting algorithm.

(d). Long Short Term Memory

Bio-inspired networks have been getting more attention since the last decade because of their accuracy. Long Short Term Memory (LSTM) [15] is the Recurrent Neural Network

(RNN), where the computation includes the present input state and the results from the previous state by accumulating hidden layers. It can remember long sequences on account of which it is used for many applications like language models, speech, and video data streams. It consists of four gates (forget gate, input gate, memory gate, and output gate):

Forget gate(f_t) helps the LSTM model decide what information needs to be retained from the previous state. Its value lies between [0,1] and 0 signifies the discardment of the complete information.

$$f_t = \sigma\left(W_f.\left[h_{t-1}, x_t\right] + b_f\right), \tag{16}$$

where, b_f represents the bias, h_{t-1} is the previous state output, W_f is the weight, and x_t is the current input. 't' represents the current state while '$t+1$' and 't-1' indicates the next and previous states.

Then, to decide what information about the current state should be stored is done through two gates. The updation of values is performed through the input gate (i_t) and the tanh layer gives a vector $\left(\widehat{C}_t\right)$ that is added to the input layer.

$$\widehat{C}_t = \tanh(W_C.\left[h_{t-1}, x_t\right] + b_C). \tag{17}$$

$$i_t = \sigma(W_i.\left[h_{t-1}, x_t\right) + b_i. \tag{18}$$

Further, it updates the memory gate from the previous state C_{t-1} to the current state C_t as

$$C_t = f_t \times C_{t-1} + i_t \times \widehat{C}_t. \tag{19}$$

Then, it scales the output (o_t), and the filtered output (h_t) given by the tanh layer

$$o_t = \sigma\left(W_o.\left[h_{t-1}, x_t\right] + b_o\right). \tag{20}$$

$$h_t = o_t \times \tanh\left(\widehat{C}_t\right). \tag{21}$$

LSTM models have certain advantages, like relative insensitivity of data intervals and solving vanishing gradient problem. Still, they have certain limitations: more training time, large memory, and difficulty implementing dropout.

6 Proposed model and experiment work

This section describes the proposed feature selection ensemble algorithm and gives a determined overview of experiments proving the efficacy of the proposed approach.

6.1 Dataset

The dataset is collected from UC Irvine (UCI) machine learning repository. It was established as an ftp archive in 1987 by David Aha and fellow graduates[5] to help the researchers' community.

[5] https://archive.ics.uci.edu/ml/about.html

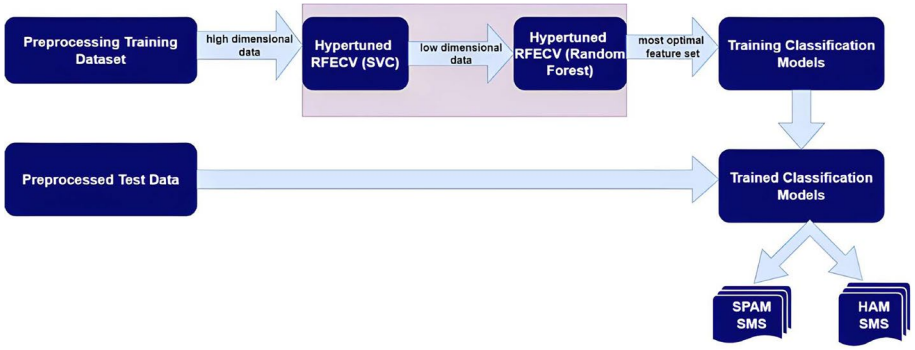

Fig. 4 Block diagram for the proposed ensemble feature selection algorithm

This research is availed on the SMS spam database [5]. The dataset consists of 5574 SMS samples, with 13.40% (around 747) spam and 86.60% (around 4827) legitimate messages. Here, the spam messages are labeled as 'spam' and those unsolicited as 'ham'. As per token statistics, 63,632 are ham, while 17,543 are spam. Examples of spam words in this dataset: free, winner, claim, reward, cash, jackpot, congrats, urgent, bonus, account, private, unredeemed, sex, contact, and vouchers.

6.2 Proposed algorithm

It is estimated from the statistics selected dataset is an imbalanced dataset that resembles the realistic distribution of data present in the environment. As there are a large number of features present in the dataset to reduce such a high-dimensional dataset, this paper proposes an ensemble feature selection algorithm that helps classification models produce exceptional results with pruned and precise feature subset. The presence of irrelevant features mislead the classifier and the redundant features lead to expensive computations. To eliminate such features, the proposed approach exploits RFECV wrapper-based feature selection algorithm using two hyperparameters tuned models: Support Vector Classifier (SVC) and random forest classifier. The novel ensemble feature selection algorithm gives fitter solutions with just 13% of the selected optimal feature subset. Figure 4 presents the block diagram of the proposed algorithm. The diagram provides a brief visual perspective of the ensemble feature selection algorithm proposed in this work.

6.3 General Remarks

(i) *Significance of applying SVC classifier before random forest algorithm*

RFECV is a wrapper-based feature selection algorithm that provides a subset of features substituting the high-dimensional dataset. Initially, we deploy the preprocessed dataset to hyperparameters tuned RFECV with SVC classifier as SVC is a scalable classifier and memory-efficient algorithm that can handle high-dimensional data efficiently and

cost-effectively. Then selected subset is deployed to hyperparameters tuned RFECV with random forest classifier as random forest algorithm is the bagging method that selects the instances of features set provided to it and not all at once or attribute bagging. Deploying a large feature set to the small number of decision trees in the random forest algorithm will result in the omission of some features or they will be tested only once and conveniently increasing the number of trees will amplify computational cost. So, to avoid such complications cost-effectively and efficiently, hyper parameterized RFECV with the random forest is fed with the subset of selected features produced by RFECV with hyperparameters tuned SVC.

(b) *Purpose of Stratified K-fold Cross-Validation(SKCV)*

Instead of using K-fold cross-validation, we employ SKCV, as it untangles the problem of random sampling and overcomes class-imbalance dataset generalization errors. The algorithm is validated over each sample while selecting features subset using SKCV.

(iii) *Consequences of comparing with the LSTM algorithm*

LSTM is selected based on its efficiency in learning long-term dependencies in data. It is a powerful RNN extension, combating the vanishing gradient problem. We compare classification results with LSTM to justify the obtained optimal feature subset's effectiveness analogous to a strong neural network with inexpensive computation.

(iv) *Grounds of applying feature selection over training dataset only.*

In this work, feature engineering is implemented only over the training dataset so that test samples remain unrevealed to the classifiers. It is done to make the model practical for real-world applications where the test samples are anonymous to the classifier.

The empirical study verifying the plump for hyperparameters required for the selected dataset, which can be extended to a similar high-dimensional realistic dataset prevailing over the network is as given below:

6.4 Hyperparameters tuned RFECV with SVC

SVC is a linear classifier. It classifies the sample among the given target functions or the class labels. Here, it is a two-class problem, i.e., either the sample will be "spam" represented through categorical value '1' or "ham" with categorical value '0'. Different hyperparameters are tested over the training dataset to set the value for the proposed algorithm. The interpretation of adopted standards for hyper-tuned RFECV with SVC is as follows:

(a). *Kernel:*

SVC is an exceptional algorithm in classification. It is a linear classifier having a mathematical function termed kernel. There are many kernel functions, including linear, radial basis function, polynomial, and others. Generally, the function that qualifies "Mercer's condition" can be used as a kernel function. Equation (22) gives Mercer's condition for any kernel $k(x, y)$ represented in higher dimensional space using the dot product.

$$\sum_{i,j} k\left(x_i, x_j\right) c_i c_j \geq 0. \tag{22}$$

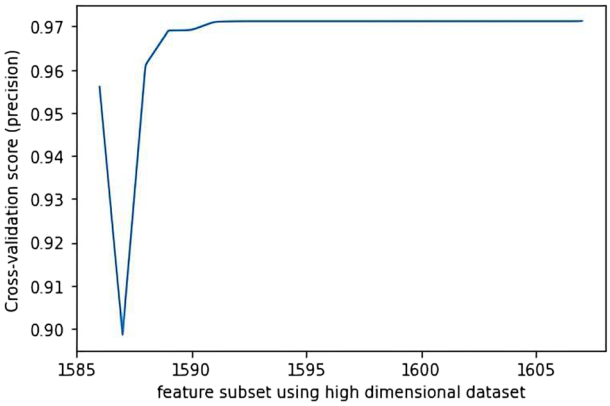

Fig. 5 Grading score on account of feature subset with hyper-tuned RFECV + SVC

We adopt a linear kernel given by Eq. (23). The appropriate kernel function is chosen on the dataset's foundation.

$$K\left(x_i, x_j\right) = x_i.x_j. \tag{23}$$

The kernel function measures the similarity between features x_i, x_j, mostly symmetric similarity. The choice for the "linear kernel" function is based on different measurement scores provided by the mathematical formulations, proving the linear classification stability of the selected dataset. Figure 5 depicts the graph line between the number of features selected with the SKCV 'precision score'. A similar graph is visualized through other performance metrics like: 'accuracy score' and 'recall'.

As performance metrics score depicted in Fig. 5 are contented and also the number of selected features remains related to accuracy metrics. So, it verifies that the data points are linearly separable. Consequently, the choice of "linear kernel" is verified.

(b). *Penalty parameter:*

SVC tries to maximize the margins and fit training data. The penalty parameter 'C' deals with noise in the margins of the classifier. It is used to control training errors. Some data points do not lie in the correct portion of the decision boundary. Such data points are entitled as slack variables (ξ). Equation (24) expresses the slack variables association with the parameter 'C', i.e., the penalty for each wrongly placed training sample.

$$w.w + C\sum_{k=1}^{m} \xi_k. \tag{24}$$

Experiments are performed with small to large random values of C ranging from 1 to 1000, and a slip in accuracy is found with larger values of 'C'. Thus with a decline in the score, it concludes that the data points need highly marginalized decision boundaries providing some degree of ignorance for the outliers. So, we keep the value for C equal to '1' or adopt to ignore some outliers as the random forest classifier will further sort them.

Table 3 shows all the parameters adopted for hyperparameters tuned RFECV with SVC.

6.5 Hyperparameters tuned RFECV with random forest algorithm:

Random forest algorithm, an estimator based on bagging ensemble learning. It contains defined decision trees applied to various subsets of the dataset whose predictions are averaged to classify the test sample among given class labels. The interpretations of adopted hyperparameters for the algorithm are as follows:

(a). *n_estimators:*

Random forest is an ensemble model using decision trees for classification. 'n_estimators' defines the number of decision trees whose predictions are amalgamated to obtain more reliable results. Notwithstanding the verity of stretch in accuracy with an increase in the number of trees, it also led to the construction of a slow and expensive computational model. Experiments are performed for 10, 30, 50, 80, 100, 150, 200 n_estimators and some more random numbers in between the range of 10–200. From the results obtained, it is concluded that 50 n_estimators produce a grading score approaching to stacked accuracy, as illustrated in Fig. 6.

The further addition of decision trees does not consummate the cost incurred with achieved gains. Figure 6 gives the plot for the SKCV grading score achieved using RFECV with random forest algorithm applied over the subset of features obtained after hyperparameters tuned RFECV with SVC feature selection algorithm.

(b). *Criterion:*

In decision trees, there are two criterion: Entropy and Gini impurity. Both criterion are helpful as they provide knowledge regarding whether the split is pure or impure in reference to the opted feature. An optimal split leads to a more accurate and less depth of the tree. Equation (25) represents Gini impurity and Eq. (26) entropy. Gini impurity is based on the selected feature's probable index measuring randomness of the misclassified sample and entropy measures information indicating the disorder of the opted features accompanied by the target. Entropy is a logarithmic mathematical calculation with costly computation whose output ranges from 0 to 1. At the same time, Gini impurity involves algebraic mathematical formulations, making it computationally inexpensive and its output ranges from 0 to 0.5. In both criterion, the value of '0' indicates most pure split and higher values signify the split's impurity.

$$Gini\ Index = 1 - \sum_j p_j^2. \tag{25}$$

$$Entropy = \sum_i -p_i log_2 p_i. \tag{26}$$

Table 3 Adopted hyperparameters For RFECV + SVC

Parameters for SVC	Parameters for RFECV
Kernel = linear, C = 1, probability = False	Estimator = hyperparameterized SVC, step = 0.05, cv = stratified K-fold(2), scoring = 'accuracy'

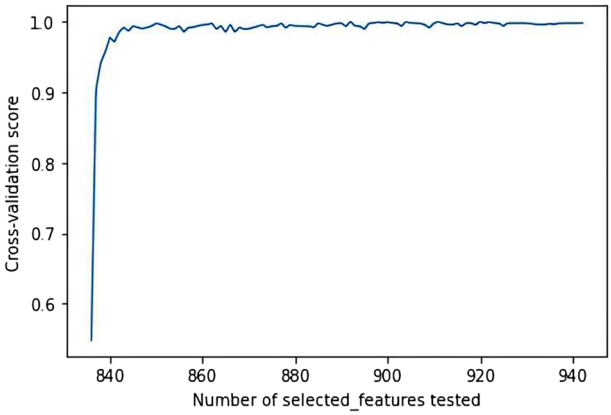

Fig. 6 Grading score on account of optimal feature subset with hypertuned RFECV + random forest

With the reduced dataset, we test for both the criterion and find that entropy is slightly accurate and provides more satisfying results than Gini impurity. Realizing the dominance of prediction results, 'entropy' is adopted over 'Gini impurity'.

Table 4 shows all the parameters adopted for hyperparameters tuned RFECV with random forest classifier.

The effectiveness of the ensemble algorithm is conveyed through Figs. 5 and 6, as the grading score for RFECV + SVC with approx. 25% features is 0.97 (or 97% accuracy achieved over training samples). After deploying those selected features to the RFECV + random forest algorithm, the cross-validation score is approaching 1(or 100% accuracy achieved over training samples), i.e., with almost half of the features (13%) as illustrated in Fig. 6. This reflects the compelling nature of the proposed ensemble algorithm that produces more acceptable and accurate results with few features. The results estimate the presence of irrelevant features that cannot be eliminated by isolated RFECV + SVC feature selection algorithm and justify the filtration of features at another level. Further nobility of the proposed ensemble algorithm is proved in the subsequent portion of this manuscript by comparing its result with the other five feature selection algorithms.

6.6 Experimental work and comparative study

Numerous experiments are performed to verify the efficacy of the proposed ensemble feature selection algorithm that supports the novelty of this research work. Figure 7 gives a brief visual outline of the comparative analysis.

Table 4 Adopted hyperparameters for RFECV + random forest classifier algorithm

Parameters for random forest algorithm	Parameters for RFECV
n_estimators = 50, criterion = 'entropy', min_sample_split = 2, min_sample_leaf = 1, bootstrap = True	Estimator = hyperparameterized random forest classifier, step = 0.01, cv = stratified K-fold(5), scoring = 'accuracy'

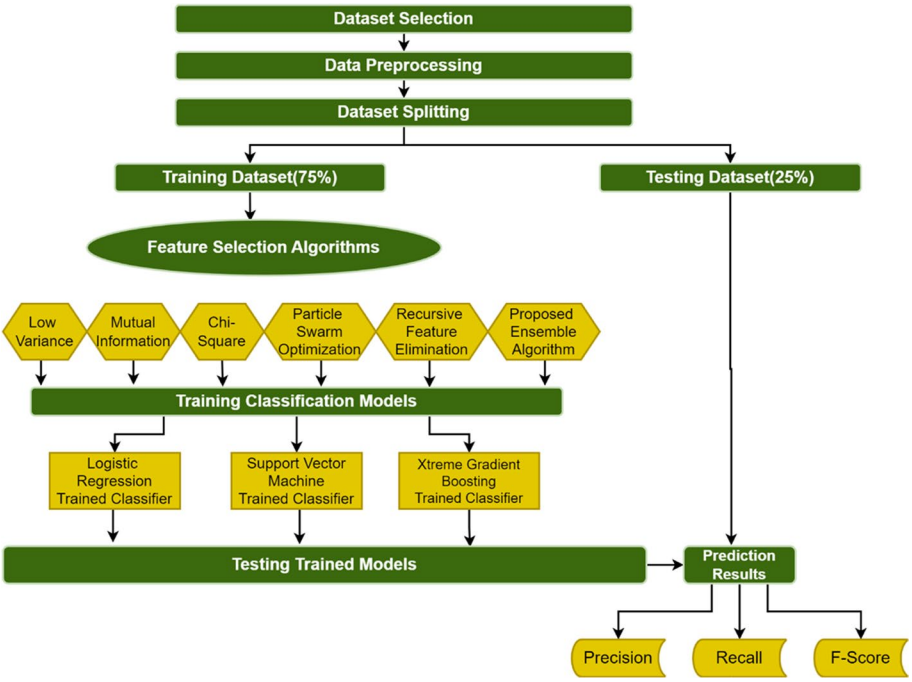

Fig. 7 Experiments outline

The proposed ensemble feature selection algorithm is differentiated by comparing with selected five feature selection algorithms: statistical Chi-square, LV, MI, RFE SVM, RFE with random forest classifier, and meta-heuristic PSO. The feature subset resulting from each algorithm is experimented with three classification models: LR, SVM, and XGB. Also, the LSTM neural network classifier with all features is computed and compared. Additionally, we feed each classification model with a dataset comprising stopwords to validate if the inculcation of stopwords can give some knowledge to the classifier that assists in classification. For all the experiments split of the training and test dataset is identical (the training dataset comprising 75% instances of the dataset and testing dataset containing 25% instances of the provided dataset). Feature selection is implemented over the training dataset only.

The performance metrics exploited to evaluate the classification models are recall, precision, and f-beta score, whose mathematical expressions are as given below:

$$Precision = \frac{TP}{TP + FP}, \tag{27}$$

$$Recall = \frac{TP}{TP + FN}, \tag{28}$$

Table 5 Performance metrics parameters

Actual values	Predicted values	
	Positive	Negative
Positive	True Positive (TP)	False Positive (FP)
Negative	False Negative (FP)	True Negative (TN)

Table 6 Number of features selected through different feature selection algorithms

Feature selection approach	Number of features selected
Total features with stopwords	6396
Total features without stopwords	6296
Low variance	5464
Mutual information	3228
Chi-square	3148
PSO	3778
RFE + SVC	3148
RFE + random forest	3148
Proposed ensemble algorithm	836

$$f-\beta\ score = \left(1+\beta^2\right)\frac{Precision * Recall}{\left(\beta^2 \times Precision\right) + Recall}, \tag{29}$$

where, β implies the value chosen for f-score. TP, FP, TN, and FN represent True Positive, False Positive, True Negative, and False Negative respectively. Table 5 illustrates the provided parameters.

In this work, FP is more threatening because the ham message mispredicted and put in the spam folder may hinder some prime information from the user. So, the value of β is 0.5 for the $f-\beta\ score$ concerning the importance of precision over recall.

6.7 Experimental results

Table 6 shows the number of features selected by the proposed ensemble feature selection algorithm, five selected feature selection algorithms and the total number of features in the dataset with and without stopwords.

The proposed ensemble feature selection algorithm produces a feature subset with the least features whose validity is justified through experimental work done and communicated in this research.

Optimal choices made for different selected feature selection algorithms are described as follows:

The attempt for feature selection using different selected feature selection algorithms is made with ideal choices.

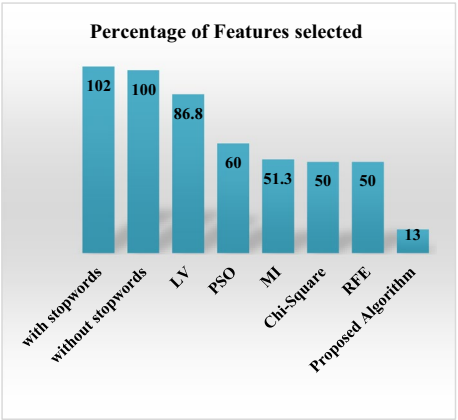

Fig. 8 Percentage of features selected using different feature selection algorithms

- For Chi-square, the choice of 50% is put as further decreasing the count of features the performance of the classification model degrades.
- With LV, all the features with zero threshold are eliminated.
- Using MI, all features with zero relevance are withdrawn.
- RFE with SVM and random forest disposes of the specific selected features subset.
- PSO is iterated 100 times with experimented and selected most optimal hyperparameters of the algorithm.

Figure 8 gives the percentage of features produced through different employed and proposed feature selection algorithms. Here, the feature set without stopwords is considered as complete or 100% features vector space(i.e., 6296 variables) while feature space with stopwords is presented as 102%, i.e., with extraneous features (or without stopwords elimination 6396 variables) and the rest of them are feature subset provided by respective selected feature selection algorithms.

The performance comparison of all three ML classification models on the feature set with stopwords, without stopwords, and feature subset selected employing five feature selection algorithms along with the proposed ensemble feature selection algorithm in terms of three performance evaluation metrics: precision, recall, and f-0.5 score is provided in Table 7. The potential of obtained optimal feature set obtained using the proposed ensemble feature selection algorithm on all three ML models is compared with the LSTM model also.

The acronym for Table 7 in the Models column is as follows The classification model name is suffixed by the features selection algorithm following the hyphen. The "SW" followed by the classification model name in the table indicates the model trained and tested embracing the stopwords features set. The bold data in table presents the results obtained when classifiers are fed with features selected through proposed ensemble feature selection algorithm. Figure 9 presents the bar graph for the percentage of features selected and f-0.5 score for all three ML models.

Spam filtering applications need to be more biased towards the precision score as the spam message misclassified as ham and put into the inbox is tolerable. However, a ham

message with emergency action requisite, misclassified and put in the spam folder will be precarious and unbearable.

The highlighted results in Table 7 specify the scores obtained when the proffered features subset from the proposed feature selection algorithm is fed to the ML models (LR, SVM, and XGB). It can be visualized from the results that the proposed algorithm with the least optimal features vector space when fed to all three ML models, provides better results than other feature selection algorithms. This concludes that the classification models give more acceptable results with reduced computations. The proposed novel ensemble feature selection algorithm can produce the most relevant and pruned optimal features subset among the different feature selection techniques. It helps the classifiers predict the class's label more accurately and with just approx. $1/10^{th}$ of computation.

It is depicted from the results obtained that the performance metrics with other feature selection algorithms are also quite acceptable, which signifies the absence of a large number of irrelevant features in the dataset. However, with just 13% of features more accurate results are acquired employing the proposed ensemble feature selection algorithm indicating the presence of approx. 87% redundant and some irrelevant features. So, the proposed

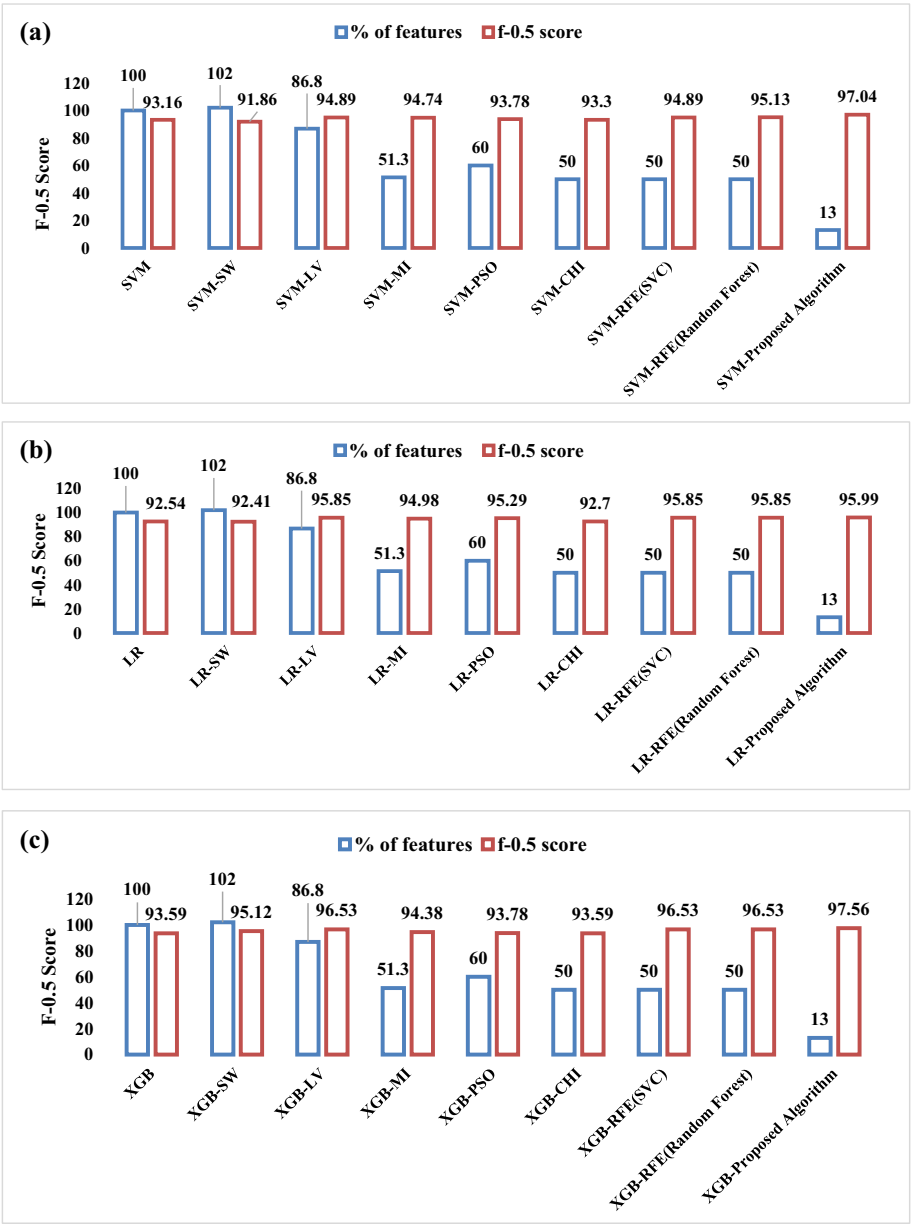

Fig. 9 **a** Bar graph for f-0.5 score and percentage of features selected for SVM model with all feature selection algorithms. **b** Bar graph for f-0.5 score and percentage of features selected for LR model with all feature selection algorithms. **c** Bar graph for f-0.5 score and percentage of features selected for XGB model with all feature selection algorithms

ensemble algorithm can be utilized for removing redundant features with justifiable two-level verified feature elimination procedures (RFECV + SVC and RFECV + random forest). Mostly the real datasets are also indulged with such high dimensions of redundant features

that need to be pruned as they occupy large memory and cellular phones with limited memory space found it baffling. This suggests feature selection approach is a requisite for spam classification and the percentage of features eliminated along with enhanced results rationalize the adoption of proposed ensemble approach for SMS spam classification.

The results conclude that all three models provide competitive results, but XGB gives slightly more satisfactory results. It can be accounted on the basis of advantages XGB distributed boosting algorithm provides. It is highly scalable and resists overfitting. It is a tree-based approach supporting regularization and apprehend dependencies more than the linear models. It can handle missing data, which mostly prevails in the SMS dataset. With all these adaptations towards the data, it is likely to produce a finer classification.

As depicted from the given results, the proposed algorithm with the least dimensionality features subset has given the best results and ML models outperformed LSTM. It is deduced that the optimal features subset obtained from the proposed algorithm, when fed to SVM and XGB classification models produces results comparable to the LSTM model. This illustrates that the optimal feature subset with reduced feature space when imparted to train strong ML models, produces results competitive to the bio-inspired or neural network models.

The study concludes the grounds of stopwords removal from the dataset, as they not only make computation expensive by increasing the dimensionality but also reduce the model's accuracy for classification. It is outlined in the given study that feature selection algorithms incorporated before classification improves the efficiency of the classifier with reduced feature space (inexpensive computation) and predictions are also enhanced. In closing, the proposed ensemble feature selection algorithm can be utilized for real-time performance.

7 Conclusion

With the drift of people and society towards the online world, a large proportion of the population possess mobile phones. SMS is one of the most preferred ways to communicate. However, along with all the advancements, some malicious activities have also arisen, and spam message is one such practice**.** The large volume of data emerges the need for automated models to filter such rogue data from the network. High dimensions of the dataset result in a computationally expensive classifier. The presence of trivial and irrelevant features deceives the classifier resulting in misclassifications. This study proposes a novel ensemble feature selection algorithm that prunes 87% of irrelevant or redundant features and performs more efficiently in comparison with other feature selection algorithms (LV, MI, PSO, RFE, Chi-square) over all the three classifiers (LR, SVM, XGB). The proposed ensemble feature selection algorithm with strong ML models surpasses the LSTM neural network model.

This research work illustrates the efficacy of an ensemble feature selection algorithm for high-dimensional datasets in text classification. The study also demonstrates that the stopwords convey no vital information to the SMS spam detection classifier. The proposed algorithm can serve as a baseline feature selection algorithm for spam classification or any related high-dimensional dataset. Experimental outcomes conclude that the proposed approach is preferable to avoid redundant features effectively from the dataset.

8 Future work

This research illustrates the importance of ensemble learning that can be enhanced with more hyperparameters tuning or inculcating different hybrid algorithms. This work can be further extended by incorporating images with text datasets for better results. Integration of ensemble learning with neural networks compelling cost-effective models could be interesting. Superior models call for a language-independent algorithm as the proposed approach is limited to English. Models detecting such unsolicited data on the server side would be beneficial. Much work is done for e-mail spam classification; considerable research is requisite for SMS spam classification.

Declarations

Conflict of interest We declare that we do not have any conflict of interest in the publication of this work.

***Abstract*—Link prediction revolves around network analysis that includes predicting the links that can exist in the near future. Link Prediction has its use in a number of domains such as Social Network Analysis (SNA), bioinformatics, and recommendation systems. In this paper, the use of machine learning classifiers is explored for link prediction and their performance is evaluated against various metrics. After extensive experimentation and evaluation, it is found that Gradient Boosting provides the best results for link prediction. The findings are supported by comparing the performance of different classifiers against similarity scores and ROC curves. The study highlights the importance of using machine learning techniques for link prediction and demonstrates the effectiveness of Gradient Boosting for this task.**

***Index Terms*—Gradient Boost Classifier, Logistic Regression, Link Prediction, Random Forest Classifier, Social Network Analysis**

I. Introduction

In recent years, numerous social network analysis has offered numerous business and research problems like finding influential nodes, community detection, opinion leader detection, fake news, and rumor prediction, link prediction, and many others [1]–[5]. Link prediction is a technique used to analyze a network and in machine learning to check what is the possibility of a future connection between any two nodes in a network. In other words, it predicts whether a link can exist between two nodes that are not connected currently in the network. Fig 1 shows an example of predicting a link between nodes 1 and 3.

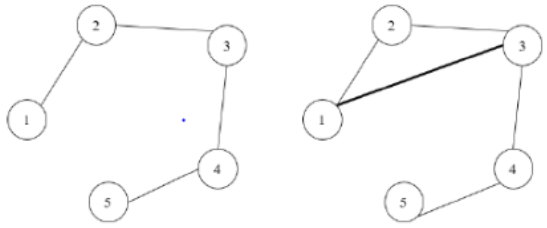

Fig. 1. Link Prediction between nodes 1 and 3

The concept to predict links has grown in popularity ever since it was first introduced in complicated network analysis. In real-life scenario, link prediction has many uses, including forecasting disease outbreaks, predicting link quality in wireless community networks, recommending new friends on social media, planning transportation, making product recommendations for e-commerce applications, and recommending hotels and music, among many others. Link prediction aids in anticipating network development as it expands over time. Therefore, in today's world which is entirely connected, link prediction can be very closely related to information and knowledge architecture.The basis for the link prediction process is the node pair's popularity and closeness. The nodes that are popular will connect with other nodes, and nodes that are adequately similar to one another have a greater likelihood of connecting in the near future, so this relationship appears to be rational. Over the years, numerous link prediction techniques have been proposed in papers. These strategies can be generally categorised into similarity-based, maximum likelihood-based, matrix factorization-based, probabilistic, and random walk methods. Recent research has also looked into the potential of deep learning and machine learning methods. This can be useful for various applications, such as identifying potential friends or collaborators, recommending new connections to users, and detecting fraudulent activities.

Social network analysis (SNA) is an area of study that analyzes social networks and the different people or individuals are related to each other. By analyzing the patterns of these connections, SNA can reveal insights into how information, resources, and influence flow through social networks, and how these networks can impact behavior, attitudes, and outcomes. SNA is applicable in several fields, including sociology, psychology, anthropology, communication studies, management, and marketing, to name a few. SNA uses a range of analytical tools, including centrality measures, clustering algorithms, and network visualization techniques, to analyze social networks and identify key actors, groups, and patterns of interaction. A connection between two nodes is more likely to exist the closer two nodes are to one another. Many methods have been devised for link prediction in social networks, including the Adamic Adar, Jaccard coefficient, preferential attachment methods, etc.

II. Related Works

Over the years, various techniques have been proposed in the literature for predicting links in a network based on

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:32:50 UTC from IEEE Xplore. Restrictions apply.

the properties of its nodes. These techniques can be broadly categorized into two main types: feature extraction techniques and feature learning techniques [9]. Feature extraction techniques involve manually identifying and extracting relevant features from the network data. These features can include measures such as node degree, common neighbors, and clustering coefficient, among others [10]. In contrast, feature learning techniques involve automatically learning features from the network data using various machine learning algorithms. These techniques can be further categorised into two types: unsupervised and supervised [11].

Based on the idea that nodes frequently create links with other nodes that are similar to them, the most popular approaches for link prediction are those based on similarity. Adamic-Adar (AA) is a similarity measure used in link prediction and community detection in networks [6]. In other words, AA is a measure of how similar the "neighborhoods" of two nodes are. The Jaccard coefficient (JC) is a measure of how similar two sets are [7]. According to its definition, the Jaccard Coefficient is the proportion of distinct neighbors to neighbors in common. Based on the number of neighbors that two nodes share, the Common Neighbors (CN) algorithm forecasts links. The idea is that nodes with a lot of nearby neighbors are more likely to be linked. Based on the idea that nodes with a lot of connections are more likely to draw in new connections, Preferential Attachment (PA) forecasts links. The intuition is that nodes with many connections are more popular, and therefore, more likely to be connected [8]. In an effort to forecast links in different networks, the Resource Allocation algorithm.

In the recent paper regarding node centralities in complex networks, LGBM has been suggested as a better method for predicting links [12]. Another paper uses similarity measures, node centralities, and ML Classifiers to predict links in a social network [13].

III. Proposed Methodology

Using the existing network structure, this research aims to forecast whether a link will exist between a pair of nodes. It is thought that link prediction in complex networks is a problem of binary categorization. The method for comparing different link prediction techniques and combining similarity metrics with machine learning classifiers is described in this section.

To more closely depict the local, semi-local, and global characteristics of the network's nodes, the set of similarity measures was chosen. Different similarity measures have strong correlations, so if machine learning algorithms are applied directly to them, over-fitting is likely to occur. As a result, a particular set of similarity indices is selected that do not exhibit minute correlation and accurately represent the various information present in the nodes. A variety of similarity metrics are used to evaluate the results of the artificial intelligence classifications. The machine learning model uses centrality indices as its features and combines them to generate link predictions. In this paper, Gradient Boosting for link prediction is discussed. In short, the method can be called $GBLP$. Fig. 2 shows a flow diagram of the GBLP algorithm.

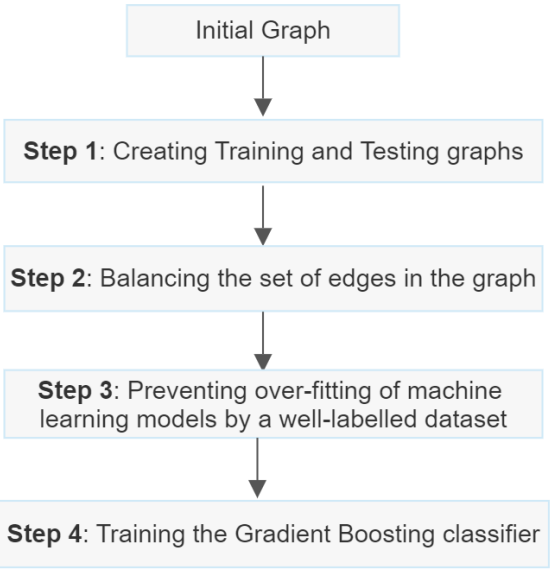

Fig. 2. Flow Diagram of GBLP

The steps involved are as follows:

A. Creating Training and Testing Graphs

In this method, a complex network is represented as a set of vertices V and edges E. A new graph $G_T(V, E_T)$ is created, where E_T is subset of original edge set E, by randomly selecting a subset of edges from the original graph while keeping the same set of vertices. The size of the selected edge set is determined by a splitting ratio applied to the complete graph. The resulting condensed graph, G_T, is then used to train a machine-learning model for link prediction, capable of predicting linkages between nodes in the edge collection $E - E_T$.

By doing so, the link prediction problem can be reduced to predicting the graph $G(V, E')$ where $E' = E - E_T$, using data from the graph $G_T(V, E_T)$. This method is more effective and adaptable to real-world scenarios when compared to other link prediction techniques that train classifiers on the complete network. The training graph, G_T, and testing graph, G', are used to analyze how well the predicted link model works.

B. Balancing the set of edges in the graph

In complicated networks, the number of connected pairs of nodes is very less as compared to the unconnected pairs of nodes, which leads to an unbalanced dataset, causing the machine learning methods to over-fit the negative samples in the dataset. To avoid this, the down-sampling strategy is employed to balance the dataset, where connected node sets are chosen, and the same number of unconnected node pairs are randomly selected. The complement of E_T and E' denotes the group of edges that are absent from the initial network,

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:32:50 UTC from IEEE Xplore. Restrictions apply.

whereas E_U denotes the set of all possible edges in the network. The new graphs, G_T and G', are created using the sampled edges and their complements, respectively.

C. Preventing over-fitting of machine learning models by a well-labeled dataset

In this step, well-labeled datasets are created for the purpose of training and testing, namely D_T and D' respectively. To create these datasets, five similarity measures are chosen, including the Jaccard coefficient, common neighbors, preferential attachment, Adamic Adar, and resource allocation index. These measures are then used to calculate the popularity and similarity measures for the network's nodes and edges. These features are calculated only using the training network's topological data since this is would have access to in a real scenario. The datasets also have an attribute named $label$ that indicates whether or not there are any network connections, and this is determined using the edge's nodes. The value of the label is set to 1 if there is a link between the nodes, and 0 otherwise. Finally, the resulting training and testing datasets are well-labeled and balanced to ensure the machine learning methods do not over-fit on the negative samples.

D. Training the Gradient Boosting Classifier

Well-labeled, evenly distributed datasets DT and D' are created in the final stage to train and test the classifiers. All models are trained in this phase using various machine learning models like logistic regression, random forest, gradient boost, gradient naive Bayes, k nearest neighbor (KNN), and LGBM. Out of all these models, gradient boosting(GB) gives the best result. Thus, the proposed algorithm uses a gradient boosting classifier.

The forecasts of several weak classifiers are combined using a machine learning ensemble technique called a gradient boosting classifier to create a strong classifier. The model is gradually enhanced with decision trees, and each new tree is trained using the errors of the previous one. In other words, it seeks to learn from the model's mistakes in order to improve the precision of predictions. At each step, the algorithm determines the gradients of the loss function in relation to the anticipated values. Then, a fresh decision tree is fitted using the negative gradient of the loss function. The forecasts of the new tree and the previous trees are merged using a weighted sum after the new tree has been properly incorporated into the model. Based on how well each tree did on the training set of data, a weight was assigned to it; trees that performed poorly were given a lower weight. This allows the model to focus on the regions of the feature field that are challenging to classify and lowers overall model error. The final model is then used to generate forecasts on new data by individually processing the data through each decision tree and combining their outputs using the same weighted sum.

IV. Datasets and Evaluation metrics

A. Datasets

This section includes various datasets and the metrics that have been used for evaluation in the paper:

1) Caltech36 [14]: This dataset is basically a Facebook buddy graph made up of Caltech, Pasadena students. An individual is represented by each node of the graph, while friendships or other social connections are represented by the network linkages. It has approximately 16656 edges and 769 nodes. It can be found at https://networkrepository.com/socfb-Caltech36.php.
2) PolBlogs [15]: The PolBlogs network, where the nodes can be considered as pages of a blog and the edges can be considered as hyperlinks between those pages of a blog. It depicts the interplay between US political blog pages. It has 19021 connections and 1222 nodes.
3) DBLP [16] : It serves as a reference network for DBLP bibliography of computer science. In this, each node stands in for a piece of writing, and each edge for a reference made between those pieces of writing. There are 49743 edges and 12591 nodes. It is availaible at https://snap.stanford.edu/data/ego-Facebook.html.
4) Fb-Tv Show [17]: This is a social network data of Facebook which displays the common likes between various TV program sites on Facebook. The network's nodes stand in for the TV program pages, while its edges stand in for shared likes between the pages. There are around 17260 edges and 3892 nodes. It can be found at https://networkrepository.com/fb-pages-tvshow.php.
5) Delaunay-N12 [18] : This network dataset is in the category of DIMACS10.These files were created by triangulating random locations in the unit square using the Delaunay method. It consists of 4100 nodes and 12300 edges. It is availaible at https://networkrepository.com/delaunay-n12.php.

TABLE I
Statistics of Dataset

Dataset	Nodes	Edges
CalTech36	769	16656
PolBlogs	1222	19021
DBLP	12591	49753
Fb-Tv Show	3892	17260
Delaunay- N12	4100	12300

B. Evaluation Metrics

AUC (Area under the curve), recall, precision and also the F1 score are some of the traditional assessment metrics employed to objectively assess how effective the suggested algorithm is. The performance of the system is compared to a number of other baseline and existing link prediction techniques. The predictive performance of different link prediction

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:32:50 UTC from IEEE Xplore. Restrictions apply.

algorithms is clearly shown by all the evaluation measures. In the following equations, TN is the amount of samples which are negative but have been correctly predicted while TP is the amount of samples which are positive and are predicted correctly. FP is the amount of actual negative samples which have been predicted as positive while FN is the amount of actual positive samples which have been predicted as negative.

1) AUC: The area beneath the AUC curve is used to evaluate the performance of a machine learning model. AUC's value has a range from 0.0 to 1.0. The algorithmic accuracy increases with increasing AUC value. If there are T independent comparisions, T' links which are missing with a high score and T'' links which are missing and doesn't exist, with a same score, then AUC is written as in Eq. 1:

$$AUC = \frac{T' + 0.5T''}{T} \tag{1}$$

2) Accuracy: Accuracy is the percentage of accurate forecasts made by the model. Accuracy can also be determined in terms of positives and negatives for binary categorization, as shown in 2:

$$Accuracy = \frac{TN + TP}{TP + TN + FP + FN} \tag{2}$$

3) Precision: Precision is the percentage of correctly classified positive classifications.The precision score is calculated in 3

$$Precision = \frac{TP}{TP + FP} \tag{3}$$

4) Recall: Recall is an indicator of performance that seeks to indicate what proportion of genuine positives are accurately detected. It is defined in 4:

$$Recall = \frac{TP}{TP + FN} \tag{4}$$

5) F1 score: The F1 score basically represents the balance in recall and precision balance. It can be stated as the harmonic mean of recall and precision. as shown in Eq. 5:

$$F1\ Score = \frac{2 * Precision * Recall}{Precision + Recall} \tag{5}$$

V. Results and Analysis

Here, using a variety of evaluation metrics and the ROC Curve, the performance of the suggested algorithm and other algorithms is evaluated on each dataset.

A. Performance Comparision

The computed results for 5 datasets is shown below. It is compared on the basis of 5 evaluation metrics in 6 different models.

The analysis of the findings indicates that GBLP is the best model for link prediction in most of the datasets that were examined. $TableII$ presents a comparison of the performance for Caltech36 dataset. It shows that the proposed method achieves the highest accuracy. Furthermore, in $TableIII$, the performance of polBlogs dataset is presented, which shows that the GBLP method outperforms other methods not only in terms of AUC and accuracy but also in its F1 score, making it the most suitable model for this dataset. Regarding the DBLP dataset in $TableIV$, since the difference in accuracy between LGBM and GBLP is negligible, both the methods can be considered as viable options. However, for the FbTVShow dataset in $TableV$, the GBLP method shows the best results in most of the metrics, indicating that it is the most effective model for this dataset. Finally, in $TableVI$, although the values of the proposed method are not the highest, the difference between the metrics of GBLP and other methods is negligible. Therefore, it can still be considered a viable option. Overall, the study highlights the effectiveness of Gradient Boosting.

B. ROC Curve

Below are the ROC curves of various algorithms on different datasets. The "False Positive Rate" is represented by the x axis, while the "True Positive Rate" is represented by the y axis. The statistical test used to compare two ROC Curves involves calculating the area under each ROC curve (AUC) and then comparing the two AUC values to determine significant difference between the two curves. These curves clearly represent that the gradient boosting(GB) performs best among all the models. The AUC scores of each model is also mentioned in the plots of each dataset.

Based on the evaluation results, it can be observe that the overall accuracy of a model has a direct impact on the shape and position of its ROC curve. Specifically, a model with higher accuracy tends to have a ROC curve that is closer to the top left corner, which signifies better performance in distinguishing positive and negative instances. In $Fig.3$, the ROC curves of LGBM and GBLP are very close to y axis, indicating that it has better accuracy. The $Fig.4$ and $Fig.5$ for PolBlogs and DBLP datasets, the curve for GBLP is closer to the top left corner, again indicating better accuracy compared to other models. A similar trend can be observed in the $Fig.6$ for FbTVShow dataset, where the GB model has better accuracy. There is a negligible difference in accuracy between the GBLP and LGBM model in $Fig.7$. So, the majority of evaluation results suggest that the GBLP model performs well and can be considered a viable method for link prediction.

VI. Conclusion

This paper focuses on how different machine learning algorithms can be used to predict future links in a network and highlights the effectiveness of Gradient Boosting for this

topic. The high accuracy of GBLP shows its ability to handle large datasets and its capacity to handle complex relationships between the variables. To evaluate the performance of the machine learning models, it is important to consider the performance metrics beyond accuracy. In some cases of comparision between LGBM and GBLP models, it is significant to observe that though there is a very minute difference in the accuracy, GBLP outperforms LGBM in other important performance metrics. Thus, it is important to analyze on the basis of other performance metrics too, not just accuracy, while evaluating the machine learning models and consider a broader range of performance metrics. Overall, the performance tables shows that GBLP is a strong performer for link prediction, while LGBM can be a viable alternative with comparable performance. These models are quite important in predicting links, where accuracy and efficiency are critical factors to be considered for success of an algorithm. After analysis of ROC curves, it is observed that it is important to consider accuracy of a binary classification model while evaluating its performance, and GBLP model is an optimal choice for link prediction tasks.

***Abstract*—In this paper, a QFGMOS based current controlled current conveyor (CCCII) is proposed, which decreases the required voltage to ±0.5V and the power consumption. It improves the linearity of the current characteristics, and also reduces the parasitic resistance than basic CCCII. The proposed circuit is also used in low-pass and high-pass filter circuits, whose performance is obtained in PSPICE using TSMC 180 nm CMOS technology. The results obtained for the low-pass filter and high pass filter show an improvement in the bandwidth of 1.579 times and 1.294 times respectively by using QFGMOS in CCCII. Also, the current linearity in the proposed QFGMOS CCCII has enhanced by twice.**

Keywords— bandwidth, current conveyor, filters, low voltage, quasi floating gate MOSFET (QFGMOS)

I. INTRODUCTION

One of the major drivers of electronic circuit design is the desire and the need for power reduction. To compete in a market that is changing quickly, it is necessary to be able to create less expensive, higher performing, and low power gadgets. Nowadays, the need to reduce the consumed power has further extended to applications such as home entertainment and computer farms from battery-powered applications like remote controls and portable devices. Innovations in circuit designing are heavily driven by large data centers due to their requirement for low power consumption [1].

The past decade has seen a significant rise in the creation of new low power CMOS circuit design, largely due to the widespread use of portable electronic gadgets such as tablets, mobile phones, and laptops. Several methods and approaches have been explored for creating low power with less supply voltage circuits, one of the significant is the current-mode circuit approach. The current-mode circuits has numerous benefits as compared to the voltage-mode, including higher speed, greater bandwidth, simpler circuitry, better operational accuracy and lower consumption of power. In addition, current-mode circuits can improve performance in terms of bandwidth, low-voltage, and slew rate characteristics. A key benefit of the current-mode technique is to overcome the constant gain-bandwidth product limitation that exists in voltage-mode techniques [4].

The current conveyor circuit is a key and practical component of common mode applications. The first generation of the current conveyor which is known as CCI, was first introduced by Sedra and Smith in 1968 [2]. In CCI, the input impedance of the ports, X as well as Y, is zero to sink the currents. This affects the flexibility of the CCI, which reduces its applications. So, Sedra and Smith subsequently introduced the second generation of the current conveyor (CCII) in 1970 [3]. The CCII has both a high impedance and a low impedance input ports to overcome the limitations of the CCI. Due to the good performance and functional versatility of the CCII, it has become a viable alternative to conventional op-amps. This has led to its extensive use in high-performance electronic components such as oscillators, differentiators, integrators, and filters that operate in voltage or current mode [5–9].

Despite the CCII having several advantages over CCI, it is unable to limit the parasitic resistance (R_x) that exists at port X. To overcome this issue, a second-generation current controlled current conveyor (CCCII), which has the benefit of electronic tunability over the CCII [12], was developed. The CCCII is capable of controlling the parasitic resistance, and hence provides electronic tunability. In accordance with the bias current, the parasitic resistance (R_x) at port X can be altered which can be used to change the quality factor or cutoff frequency for applications like filters [17]. The CCCII further does not need any external passive resistors, which shrinks the chip area and ensures the consumption of lesser power.

To obtain circuits that require low voltage and circuits that consume less power, the main requirement is to reduce the size of transistors. In order to ensure the reliability of the device, as the size of the transistor decreases, the supply voltage must also decrease. However, the threshold voltage (V_{TH}) does not decrease in the same way because of its large impact on leakage current and noise margin. Among the various techniques suggested to address this issue, QFGMOS is an important technology for making low power and low voltage circuits [11,13-14].

This paper proposes quasi-floating MOSFETs (QFGMOS) to improve the characteristics of CCCII while maintaining low power dissipation. A low supply of ±0.5 V is used to implement the proposed QFGMOS based CCCII,

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:16:53 UTC from IEEE Xplore. Restrictions apply.

resulting in a reduced threshold voltage (V_{TH}), improved transconductance and linearity of the MOSFET. Also, the improvement of bandwidth is portrayed in both filters, which use two QFMOS based CCCIIs with two capacitors. Without modifying the circuit structure, both the low-pass and the high-pass filters can be realised by choosing the appropriate filter input signal.

II. Design of CMOS Based BASIC CCCII

A. Working Principle of CCCII

Three terminals or ports X, Y, and Z are present on the CCCII. A voltage follower is present between X and Y terminals, and a current mirror is present between X and the Z terminals. As a result, X port will have the same voltage as Y port and X port will have the same current as Z port.

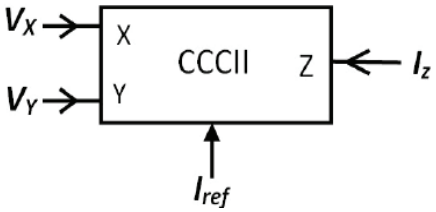

Fig. 1. Symbolic representation of CCCII [18]

The CCCII symbol diagram is given in Fig. 1. In this, Y represents for the input voltage port with a high input impedance, X for the voltage port, Z for the output current port and I_{ref} for the reference current.

The characteristic of the inverted or non-inverted CCCII is given by the equation 1 [10]-

$$\begin{bmatrix} I_Y \\ V_X \\ I_Z \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 \\ 1 & R_X & 0 \\ 1 & \pm 1 & 0 \end{bmatrix} \quad (1)$$

Where V_x, V_y, V_z and I_x, I_y, I_z are the voltage and current of ports X, Y and Z respectively. Fig. 2 represents the parasitic resistance (R_x) in CCCII. The current through port X (I_x) is given by the equation 2.

$$I_x = I_z \pm \frac{V_x - V_y}{R_x} \quad (2)$$

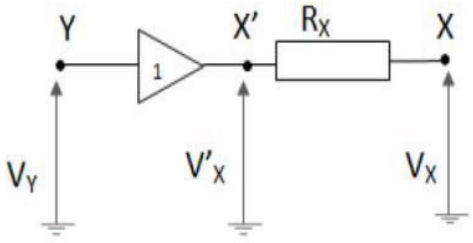

Fig. 2. Parasitic resistance (Rx) in CCCII [18]

B. Circuit Diagram of CMOS based basic CCCII

Fig. 3 represents the basic CCCII model. It contains two main parts, the negative part and the positive part. The transistors from M_1 to M_5 represent the positive part and the negative part of the model is represented by transistors from M_6 to M_{10}.

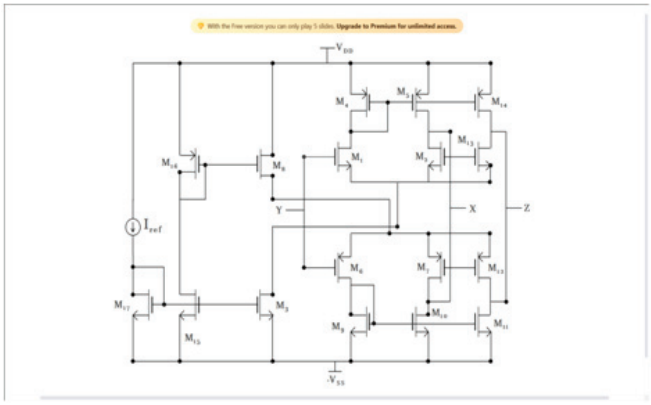

Fig. 3. Basic CCCII model [18]

The differential pair of positive inputs X and Y is designed by the M_1 and M_2 transistors. The drain and gate terminals of the transistor M_2 provide a low impedance to port X. An active load is provided by the transistors M_4 and M_5. The current biasing for the differential pair is provided by M_3 [18].

Similar to the positive part, in the negative part a differential pair is formed because of the M_6 and M_7 transistors. An active load is formed using transistors M_9 and M_{10}. Transistor M_8 is responsible for behaving as the current biasing transistor.

The transistors M_{11}-M_{14} represent a current mirror between ports X and Z. Another current mirror is formed by transistors M_{15}-M_{17} which mirror the reference current to transistors M_8, and M_3. The parasitic resistance is expressed in the following equation 3 [18],

$$r_x = \frac{1}{g_{m2}} \,||\, \frac{1}{g_{m7}} \quad (3)$$

III. Proposed QFGMOS Based CCCII

This section describes the quasi-floating gate technique and the circuit that has been proposed. This circuit is then further used in the filter application to obtain the bandwidth of the low pass and the high pass filters.

A. Quasi Floating Gate Technique

In recent years, Floating Gate MOSFET (FGMOS) and Quasi-Floating Gate MOSFET (QFGMOS) technologies are being employed in circuits to improve their performance as well as to ensure low voltage and low power applications. These techniques are widely employed in circuits like op-amps, OTAs (Operational trans-conductance amplifiers) current mirrors, multipliers etc. [13-15].

The higher threshold voltage of a MOSFET creates issues in low voltage operation because of which newer and better techniques were needed to be developed [15]. In response to this problem, FGMOS was created whose threshold voltage can be varied and can be reduced by applying an appropriate bias voltage through a large capacitor to one of the input terminals of the MOSFET. However, the presence of a large valued capacitance increases the silicon area and reduces the gain bandwidth product which decreases the transconductance. Also, during fabrication, a charge of a significant amount can be trapped by an FGMOS which can cause DC offsets [13].

To overcome the shortcomings of the FGMOS, the QFGMOS was developed. Like the FGMOS, in QFGMOS

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:16:53 UTC from IEEE Xplore. Restrictions apply.

there is a capacitance between the input terminals and the gate terminals of the MOSFET and a very high resistance is used to establish a weak connection between the gate terminal and one of the supply rail terminals. The large resistance is usually implemented by using a diode-connected reverse-biased transistor. Due to the usage of this large resistance, the gate dc voltage is set to a power rail and the initial charge problems are prevented, along with this the supply voltage requirements also diminish [14].

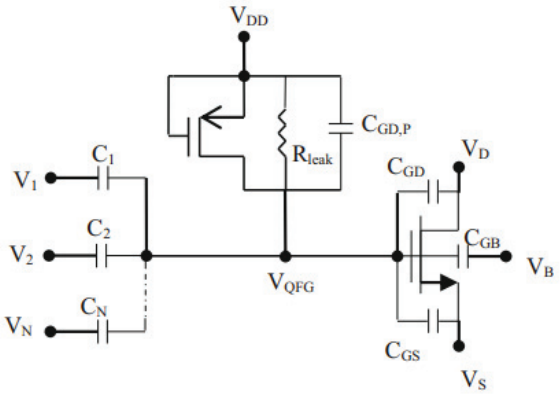

Fig. 4. Equivalent circuit of QFGMOS

In Fig. 4 the C_{GD} and R_{leak} represent the equivalent parasitic resistance and the equivalent resistances. Between the control and the floating gate, there are 'n' capacitances, and to each of the n capacitances, a supply voltage is connected. C_{GD} represents the capacitance that is present between the gate terminal and the drain terminal, C_{GB} represents the capacitance that is present between the gate and the body and C_{GS} is the capacitance that is present between the gate and the source. The voltage that is present at the floating gate is expressed by the following equation 4 [11].

$$V_{QFG} = \frac{sR_{leak}}{1 + sR_{leak}C_T}\left(\sum_{k=1}^{n} C_K V_K + C_{GS} + C_{GD}V_D + C_{GB}V_B\right) \quad (4)$$

B. Circuit Diagram of Proposed QFGMOS Based CCCII

Fig. 5 represents the proposed QFGMOS based CCCII. The transistors M_1, M_2, M_6 and M_7 have been connected with transistors M_{18}, M_{19}, M_{20} and M_{21} to create a QFGMOS configuration of the current controlled current conveyor.

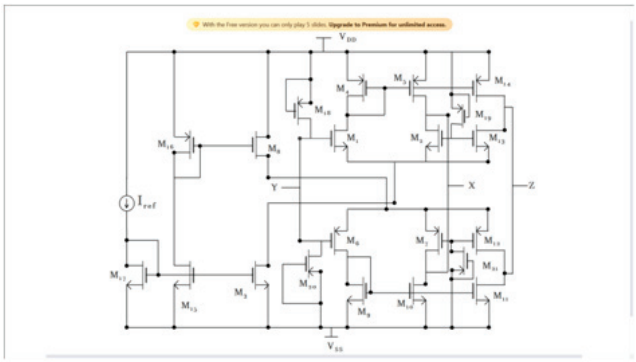

Fig. 5. Proposed QFGMOS CCCII

C. Application as a Filter

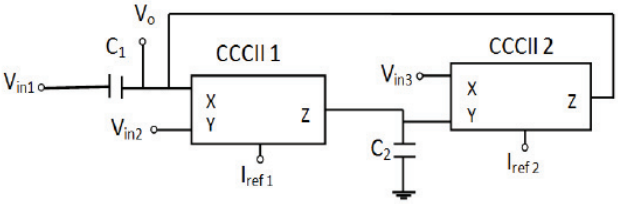

Fig. 6. Filter configuration using two proposed QFGMOS CCCII [5]

In Fig. 6, two-CCCII and capacitor-based configuration to represent filters has been proposed by Jaikla [16]. In the present work, the same circuit has been implemented using two proposed QFGMOS CCCII. The filter transfer equation is given by equation 5 [16].

$$V_o = \frac{s^2 C_1 C_2 R_{x1} R_{x2} V_{in2} + V_{in2}(sC_2R_{x2} + 1) - sC_1R_{x1}V_{in3}}{s^2 C_1 C_2 R_{x1} R_{x2} + sC_2R_{x2} + 1} \quad (5)$$

By altering the values of V_{in1}, V_{in2} and V_{in3}, the transfer functions for high-pass and low-pass filters can be attained.

Table I represents the value of input voltages for filters used in Fig. 6 for the operation of the filter as a low-pass or a high-pass filter.

TABLE I. INPUT VOLTAGES FOR FILTERS

Filter Response	Input Selection		
V_o	V_{in1}	V_{in2}	V_{in3}
Low-Pass	0	1	1
High-Pass	1	0	0

IV. SIMULATION RESULTS

The dimensions of the various transistors that have been used in this paper are given in Table II.

TABLE II. MOSFET DIMENSIONS

Transistors	W(μm)/L(μm)
M_3, M_4, M_{11}	4.5/0.18
M_7, M_8, M_9, M_{15}	5/0.18
M_1, M_2, M_{10}	17.5/0.18
M_5, M_6, M_{12}, M_{16}, M_{17}	15/0.18
M_{13}	10/0.18
M_{14}	27.5/0.18
M_{18}, M_{19}, M_{20}, M_{21}	5/0.18

The analysis of the proposed QFGMOS based CCCII has been performed on the PSPICE technology using the 180 nm CMOS TSMC Technology. For the analysis, the supply voltage V_{DD} and V_{SS} are fixed at ±0.5V, I_{ref} is taken as 200μA and the capacitances used have been taken as 100pF.

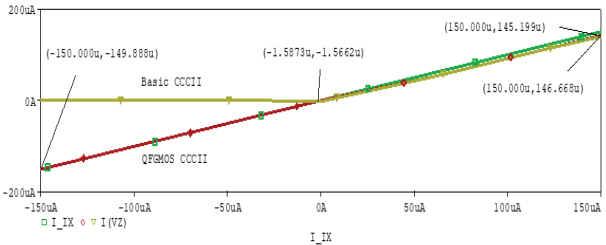

Fig. 7. Current characteristics of basic and proposed QFGMOS CCCII

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:16:53 UTC from IEEE Xplore. Restrictions apply.

The current characteristics are shown in Fig. 7. From the graph, it is observed that the basic CCCII is capable of mirroring the current from -1.587 µA to 145.2 µA, whereas, the proposed QFGMOS CCCII is capable of mirroring the current from -149.888 µA to 146.668 µA. This shows that the proposed QFGMOS CCCII improves linearity of current characteristic by approximately twice.

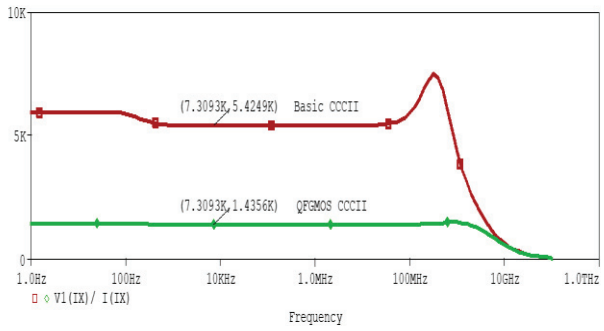

Fig. 8. Frequency response of the parasitic resistance for basic and proposed QFGMOS CCCII

The frequency response for the basic CCCII and the proposed QFGMOS CCCII is depicted in Fig. 8. It indicates that the parasitic resistance reduces from 5.4249 kΩ (basic CCCII) to 1.4356 kΩ (proposed QFGMOS CCCII).

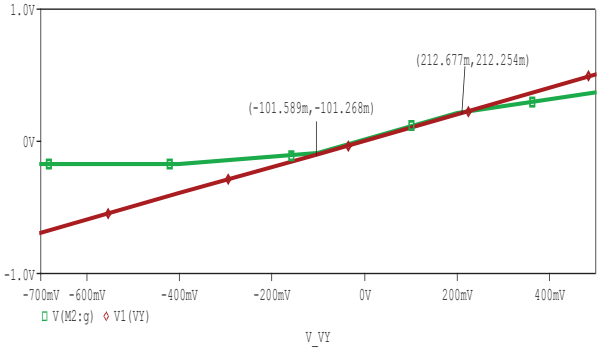

Fig. 9. Voltage characteristics of proposed QFGMOS based CCCII

The voltage characteristics of the proposed QFGMOS CCCII is given in Fig. 9. It shows that V_X and V_Y are nearly same in the region from -101.589 mV to 212.677 mV for a reference current of 200 µA.

The proposed QFGMOS CCCII and basic CCCII are compared and summarized in Table III. The comparison parameters indicate the proposed QFGMOS CCCII requires less power than basic CCCII at same power supply.

TABLE III. BASIC CCCII AND PROPOSED QFGMOS CCCII COMPARISON

Specifications	Basic CCCII [18]	Proposed QFGMOS CCCII
Type	MOS	MOS
Supply Voltage	± 0.5V	± 0.5V
Number of Transistors	17	21
Max Power Consumption (mW)	0.242	0.228
Parasitic Resistance (KΩ)	5.4249 kΩ	1.4356 kΩ
Length of transistor	0.18µ	0.18µ

Low pass and high pass filters are simulated using basic CCCII and proposed QFGMOS CCCII. Fig. 10 depicts the simulation of low-pass filter using basic CCCII and proposed QFGMOS CCCII in which the values of V_{in1}, V_{in2} and V_{in3} are taken as 0, 1 and 1 in accordance with Table I.

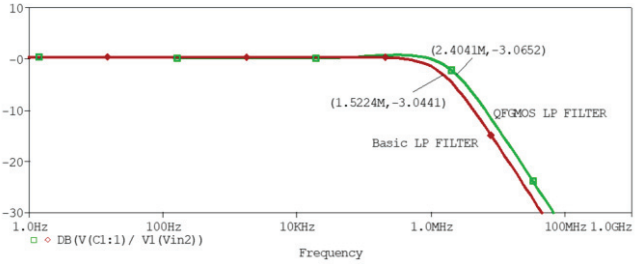

Fig. 10. Low-pass filters of basic and proposed QFGMOS CCCII

From Fig. 10, it is observed that the bandwidth for the basic CCCII based low-pass filter is 1.5224 MHz and the bandwidth for the proposed QFGMOS CCCII based low-pass filter is 2.4041 MHZ. This indicates an increase in bandwidth for the proposed QFGMOS CCCII based low-pass filter by 1.579 times that of the basic CCCII based low-pass filter.

Fig. 11 represents the simulation of high-pass filter using basic CCCII and proposed QFGMOS CCCII in which, the values of V_{in1}, V_{in2} and V_{in3} are taken as 1, 0 and 0 in accordance with Table I. It is observed that the bandwidth for the basic CCCII based high-pass filter is 981.748 KHz and the bandwidth for the proposed QFGMOS CCCII based high-pass filter is 1.2706 MHz. This indicates an increase in bandwidth of the proposed QFGMOS CCCII based high-pass filter by 1.294 times to that of the basic CCCII based high-pass filter.

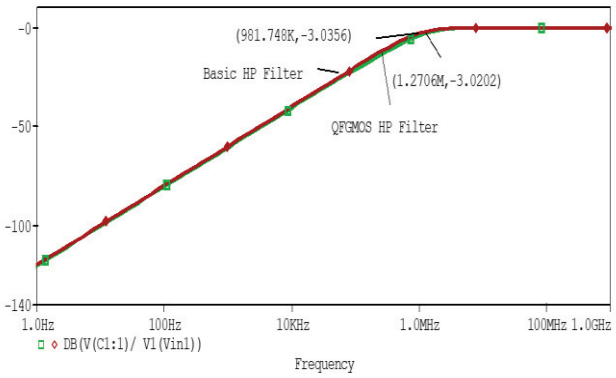

Fig. 11. High-pass filters of basic and proposed QFGMOS CCCII

Table IV shows the basic CCCII and proposed QFGMOS CCCII filters comparison.

TABLE IV. BASIC CCCII AND PROPOSED QFGMOS CCCII FILTERS COMPARISON

S.NO.	Filter Type	Basic CCCII Filter	Proposed QFGMOS CCCII Filter	Enhancement
1	Low Pass	1.5224 MHz	2.4041 MHz	1.579 times
2	High Pass	981.748 KHz	1.2706 MHz	1.294 times

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:16:53 UTC from IEEE Xplore. Restrictions apply.

V. Conclusion

In this paper, QFGMOS based CCCII is proposed whose validity is verified by plotting the current and voltage characteristics. The result shows that the proposed QFGMOS CCCII improves the current linearity by maintaining low power consumption than basic CCCII. Also, the proposed circuit is used to implement the high pass filter and low pass filter which are compared to basic CCCII based filters. It is observed that the bandwidth for proposed QFGMOS CCCII based filters is much higher than the bandwidth of basic CCCII based filters. The increase in bandwidth ranges from 1.294 to 1.579 times for the same reference current (I_{ref}). As the proposed circuit uses very low voltages of ±0.5 V and is hence apt for various low power and low voltage applications.

Abstract

Dy^{3+} doped calcium aluminum borosilicate (CABS) glasses have been synthesized via quick melt quench technique. CABS: xDy^{3+} glasses (x = 0.1, 0.5, 1, 1.5 and 2 mol%) were subjected to various morphological and photoluminescence studies. X-ray diffraction (XRD) and Fourier transform infrared (FT-IR) spectroscopy were conducted to study the structural and bonding nature of the undoped glass. The excitation spectra of Dy^{3+} doped CABS glasses under 574 nm emission show many sharp peaks amongst which the transition from $^6H_{15/2} \rightarrow {}^6P_{7/2}$ (351 nm) had the highest intensity. Under 351 nm excitation, glasses exhibit sharp peaks in the blue, yellow and red regions corresponding to the transitions $^4F_{9/2} \rightarrow {}^6H_{15/2}$, $^6H_{13/2}$, $^6H_{11/2}$ and $^6H_{9/2}$ respectively. The dipole–dipole nature of the interaction between the Dy^{3+} ions is confirmed via Dexter theory and Inokuti-Hirayama (I-H) model. CIE coordinates estimated from the emission profiles of these glasses under 351 nm excitation fall in the white region. Considering that these glasses exhibit sharp visible emission under UV excitation, have stable yellow to blue (Y/B) ratios and fast decays with intense energy transfers, we propose to utilise these glasses for white light generation and other white light LED (w-LED) and solid-state lighting (SSL) applications.

Introduction

Climate change implications have made one thought clear in today's world that we need to develop more energy efficient resources so that our carbon footprint is systematically reduced leading to a better world for the future generations to live in [1, 2]. This has accelerated research in the development of white light emitting diodes (w-LEDs) that are considered to be fourth generation solid state devices having many favourable properties over the conventional incandescent luminescence sources like high luminous efficiency, low power consumption, longer lifetimes, non-toxicity, eco-friendly and lower production cost [3–8].

Rare earth (RE) ion doped glassy materials are being developed and researched for their immense utility in solid state lighting and w-LED applications [9–11]. RE doped glasses find usage in various applications like 3D display devices, optical fibres, temperature dependent sensors, solid state lasers, optical waveguides, Q-switched devices etc. [12–17]. Different shades of white light can be generated by tuning the red, green and blue (RGB) emissions from the luminescent materials. There are three methods to generate white light [3]: The first method involves usage of some electronic circuit that combines the light coming from RGB LEDs. Second method involves fabrication of a yellow phosphor on a blue emitting LED. Third method involves combining blue and yellow or RGB phosphors with a UV light emitting source. The major disadvantage associated with these methods is the thermal degradation of the epoxy raisin used for encapsulation of phosphors leading to deterioration of luminous efficiency and colour properties [18, 19]. Therefore, it is imperative to develop better alternatives to luminescent phosphors in order to tackle these disadvantages. RE doped glassy materials

are one such alternatives since there is no encapsulation by epoxy raisin involved for fabrication of luminescent material. Moreover, glassy materials are known to have controlled luminescence, high thermal and chemical stability, easy manufacturing process, high solubility for RE ions and exceptional transparency [20, 21].

The choice of host matrix in glass is extremely important as luminescent features are material dependent. Therefore it is very important for the host material to have low phonon energies, low melting point, high thermal and chemical stability and high RE ion solubility [22, 23]. A combination of B_2O_3 and SiO_2 produces borosilicate glasses that has aforementioned characteristics. Borosilicate glasses have properties of both (borate and silicate) glasses have relatively high thermal stability and high transparency than other oxide glasses [9, 10]. Boron forms a strong covalent bond in the glass matrix due to its + 3 oxidation state thereby imparting high thermal stability to the glass. SiO_2 increases the refractive index of the glass thereby increasing the usage of glass in optical applications [24]. But these glasses are marred with high phonon energies that lead to increased non-radiative losses [10, 18, 25]. Alkaline earth metal oxides (CaO) acts as good modifier that will help us to modify the network structure and increases the chemical durability of the borosilicate glasses [26, 27]. Al_2O_3 acts as a network modifier and improves the quality of luminescence by eliminating the possibility of RE ions clustering. It also enhances the thermal and chemical stability of the glass matrix [28, 29].

The trivalent dysprosium ion (Dy^{3+}) is being widely investigated for its ability to generate white light due to intense emissions in the blue and yellow regions. The blue emission corresponds to $^4F_{9/2} \rightarrow {}^6H_{15/2}$ transition which is a pure magnetic dipole interaction and the yellow emission corresponds to the $^4F_{9/2} \rightarrow {}^6H_{13/2}$ transition which is pure electric dipole interaction. The yellow transition is hypersensitive in nature and is affected by the environment around the ion. By tuning the yellow to blue (Y/B) intensity ratio, white light can be generated. The Y/B ratio can be changed by changing the composition of the glass matrix or by changing the ion concentrations [30–32].

In this present research work morphological and luminescent properties of Dy^{3+} doped CABS glasses have been studied in detail. Dexter's theory and Inokuti-Hirayama (I-H) theory curves have been plotted to study the nature of ion-ion interactions. Temperature dependent photoluminescence studies have also been carried out on the as prepared glasses. The encouraging results enforce our idea to use these glasses for white light generation and further w-LED applications.

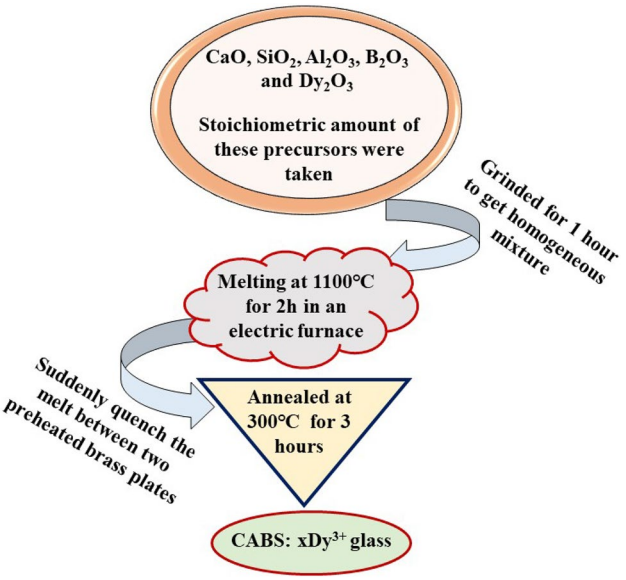

Fig. 1 Schematics of melt-quenching technique

Experimental

Dy^{3+} doped CABS glasses have been synthesized using the conventional melt quenching technique. This process can be understood with the help of schematics shown in Fig. 1. All these precursors used to prepare the aforementioned series were purchased from Sigma-Aldrich with high purity. CABS: xDy^{3+} (x = 0, 0.1, 0.5, 1.0, 1.5 and 2.0) series has been abbreviated as CABS0, CABS1, CABS2, CABS3, CABS4 and CABS5, respectively as shown in Table 1. To check the glassy nature of the titled glasses, we have performed XRD from Bruker D-8. FTIR (Perkin Elmer 2) used to reveal the structural information and presence of several functional groups. The PL studies help us to record the excitation and emission features further helps to understand the energy transfer between Dy-Dy ions. We have done this PL investigation with

Table 1 Composition with sample abbreviations for the as-prepared CABS glasses

Sample ID	B_2O_3	SiO_2	Al_2O_3	CaO	Dy_2O_3
CABS0	50	20	15	15	-
CABS1	50	19.9	15	15	0.1
CABS2	50	19.5	15	15	0.5
CABS3	50	19	15	15	1.0
CABS4	50	18.5	15	15	1.5
CABS5	50	18	15	15	2.0

spectrophotometer (Jasco-FP 8300). The absorption spectrofluorometer (Jasco-V770) used to examine the absorption spectral properties. The PL decay investigation (Edinburgh FL920) has been done to evaluate the lifetime values. The behaviour of PL emission with temperature have been examined form the TDPL instrument from Ocean Optics.

Results and Discussion

Physical and Optical Properties

Table 2 shows the various values of different physical and optical properties of the glass. The density of the as prepared glasses was found out using Archimedes Principle. A Shimadzu electronic balance, having a sensitivity of 10^{-4} mg, was used for the purpose along with double distilled water as an immersion fluid.

The molar volume V_m of the glasses was calculated using the formula [33]:

$$V_m = \frac{Molar\ Mass\ of\ glass\ (M)}{Density\ of\ glass\ (d)} \quad (1)$$

It can be seen from the table that values of density are increasing and molar volume are decreasing with increase in concentration of Dy^{3+} ions in the glass matrix. This can be attributed to replacement of Ca^{2+} ions by the Dy^{3+} ions on account of the larger molecular weights of Dy^{3+} ions.

The refractive indices (n) of the as prepared glasses were found by employing Brewster Angle method. A He–Ne laser of 650 nm wavelength was used for the same. The values are given in the same table. The molar refractivity R_m is defined as total polarizability of 1 mol of a substance and is given by the formula [34]:

$$R_m = \frac{n^2 - 1}{n^2 + 2}(V_m) \quad (2)$$

The electronic polarizability α_m was found out using the value of R_m via the following relation [34]:

$$\alpha_m = \frac{3}{4\pi N} R_m \quad (3)$$

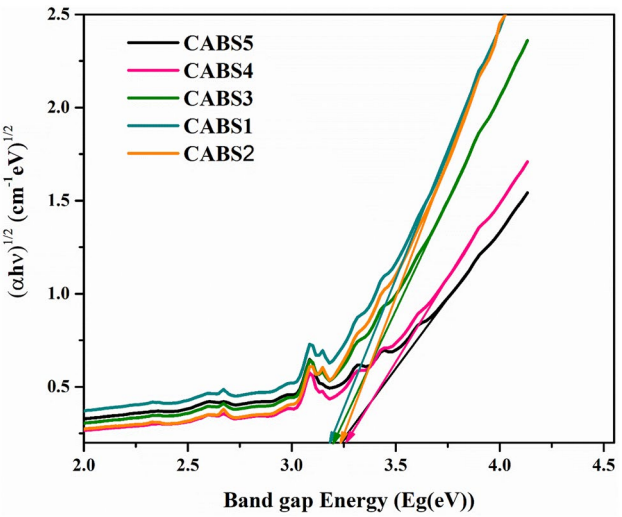

Fig. 2 Tauc plot showing bandgap values for titled glasses

The energy band (E_g) gap values were calculated by drawing a Tauc Plot from the absorption spectra data of the as prepared glasses shown in Fig. 2. The Tauc equation is given as [2]:

$$\alpha h\nu = C(h\nu - Eg)^n \quad (4)$$

where α is the coefficient of absorption and E_g is the energy band gap, hν is the photon energy, C is energy independent constant and n denotes values specific to various transitions i.e., n = 1/2, 2, 1/3 and 3 for direct allowed, indirect allowed, direct forbidden and indirect forbidden transitions respectively. The E_g values range from 3.15 eV to 3.27 eV for the as prepared glasses.

Morphological Properties

The x-ray diffraction (XRD) spectra of the undoped and Dy-doped glasses have been presented in Fig. 3. No sharp peaks are observed in the spectra signifying absence of any long-range order in the glasses. This proves that the host matrix and all Dy-doped glasses are amorphous in nature.

Table 2 Physical properties of Dy^{3+} doped CABS glasses

Sample ID	CABS1	CABS2	CABS3	CABS4	CABS5
Thickness (mm)	2.48	2.48	2.48	2.48	2.48

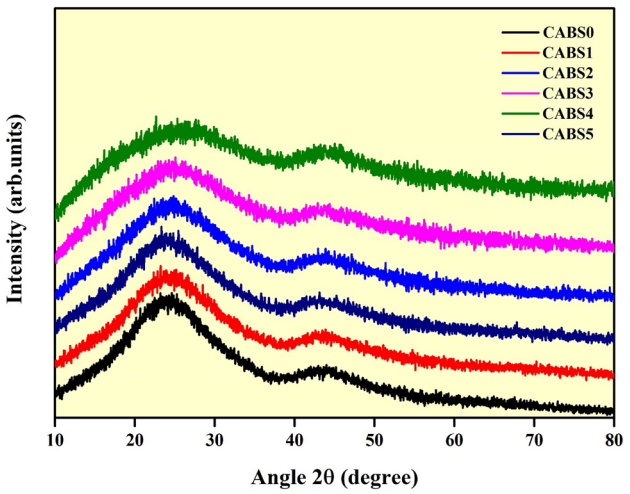

Fig. 3 XRD pattern recorded for CABS glass

The FT-IR spectrum for an undoped CABS glass is shown in Fig. 4. FTIR is a powerful technique to reveal the structural information and functional groups in materials. Here in our case, it contains various shoulders which we have divide into main regions. The first region contains 680, 894, 1073, and 1244 cm^{-1} give information about borate information. The bands observed at 680 cm^{-1} represents the B-O-B linkage and B-O bond [28]. Because of the bending of BO_3-O-BO_4 bond vibrations it gives a band at 894 cm^{-1} [9]. The presence of 1073 cm^{-1} and 1244 cm^{-1} bands corresponds to Si–O-Si linkage and stretching vibrations in BO_4 and BO_3 units [9]. The second regions represent the small peaks due to atmospheric hydrocarbon and carbon dioxide [35]. The less intense band present at 3212 cm^{-1} shows the water content [33].

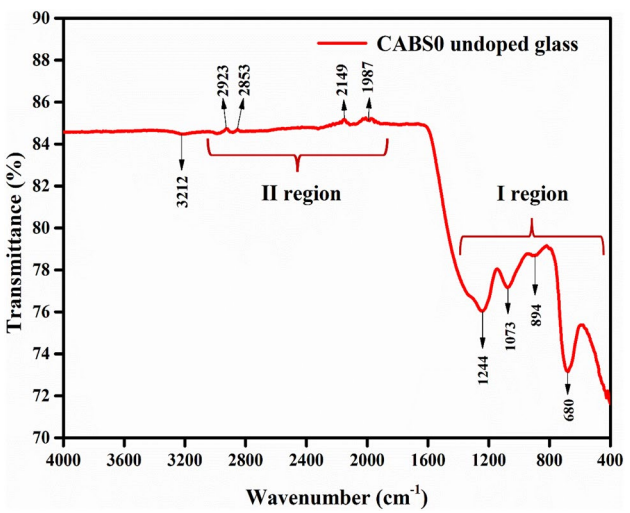

Fig. 4 FT-IR spectrum recorded for an undoped CABS0 glass

Photoluminescence Properties

The excitation spectra of all the CABS glasses are shown in Fig. 5 for 574 nm emission. Eight peaks are visible in the spectra at 325 nm, 339 nm, 351 nm, 365 nm, 388 nm, 427 nm, 453 nm and 474 nm corresponding to the transitions $^6H_{15/2} \rightarrow {}^6P_{3/2}$, $^6H_{15/2} \rightarrow {}^4I_{9/2}$, $^6H_{15/2} \rightarrow {}^6P_{7/2}$, $^6H_{15/2} \rightarrow {}^6P_{5/2}$, $^6H_{15/2} \rightarrow {}^4F_{7/2}$, $^6H_{15/2} \rightarrow {}^4G_{11/2}$, $^6H_{15/2} \rightarrow {}^4I_{15/2}$ and $^6H_{15/2} \rightarrow {}^4F_{9/2}$ respectively [36, 37]. The peak corresponding to $^6H_{15/2} \rightarrow {}^6P_{7/2}$ (351 nm) has the highest intensity so this wavelength was chosen to record the emission spectra of the as prepared glasses.

The emission spectra of all the Dy^{3+} doped CABS glasses is shown in Fig. 6. Four peak at 482 nm (blue), 574 nm (yellow), 662 nm and 703 nm (red) are seen corresponding to the transitions from $^4F_{9/2} \rightarrow {}^6H_{15/2}$, $^4F_{9/2} \rightarrow {}^6H_{13/2}$, $^4F_{9/2} \rightarrow {}^6H_{11/2}$ and $^4F_{9/2} \rightarrow {}^6H_{9/2}$ respectively [38, 39]. The peak corresponding to the yellow transition $^4F_{9/2} \rightarrow {}^6H_{13/2}$ is the most intense. It can be seen that the intensity of all the bands increases till 1.0 mol% concentration of Dy^{3+} and then decreases. This can be attributed to the quenching effect whereby increased Dy^{3+}- Dy^{3+} interactions lead to more non-radiative losses in the glass matrix. The inset in Fig. 5. Shows the variation of 575 nm peak intensity with the concentration of Dy^{3+} ions.

Understanding the nature of ion-ion interactions is important in order to study the energy transfer processes taking place in the glass matrix. Ion-ion interaction means the interaction between Dy^{3+} -Dy^{3+} ions. This interaction can be revealed with the help of Dexter's theory [40]. Dexter theory states that luminescence intensity I and molar concentration C, are related as follows [2]:

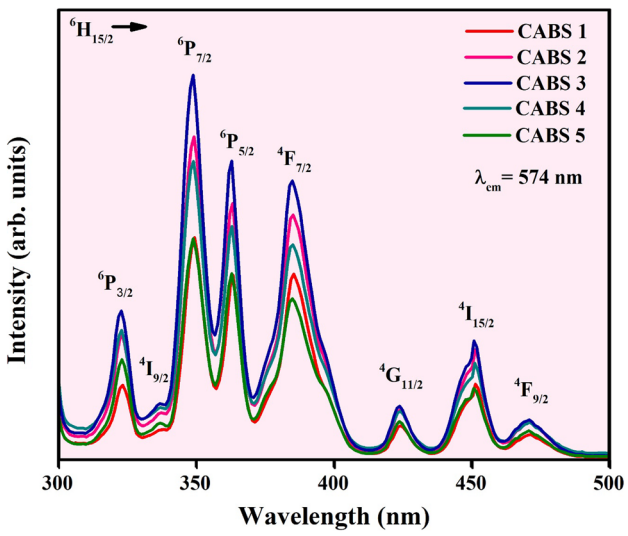

Fig. 5 Excitation spectra recorded for Dy-doped CABS glasses under 574 nm emission wavelength

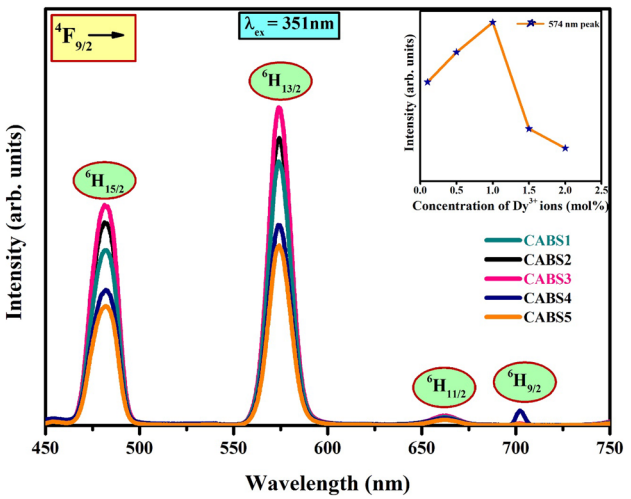

Fig. 6 Emission profiles for CABS glasses recorded under 351 nm excitation wavelength (Inset: Variation of 574 nm peak intensity with the concentration of Dy^{3+} ions)

$$\log\left(\frac{I}{C}\right) = K' - (M/3)\log(C) \tag{5}$$

where K' is a constant and value of M determines whether the ion-ion interactions are dipole–dipole, dipole-quadrupole and quadrupole–quadrupole in nature depending on the value of M being 6,8 or 10 respectively [41]. Figure 7 shows the plot between log(I/C) and log(C). The slope of the graph was used to determine M and its value came out to be 5.82 which is nearly equal to 6. So, it can be deduced that dipole–dipole interactions took place between the Dy^{3+} ions. The intensity of the emission profiles is affected by the value of M. Intensity will be relatively high for M = 6. It means more number of ions are transferring to the acceptor ions. Thus, the nature of ion-ion interactions will lead to somewhere amount of energy transfer found adequate in case of dipole–dipole interaction.

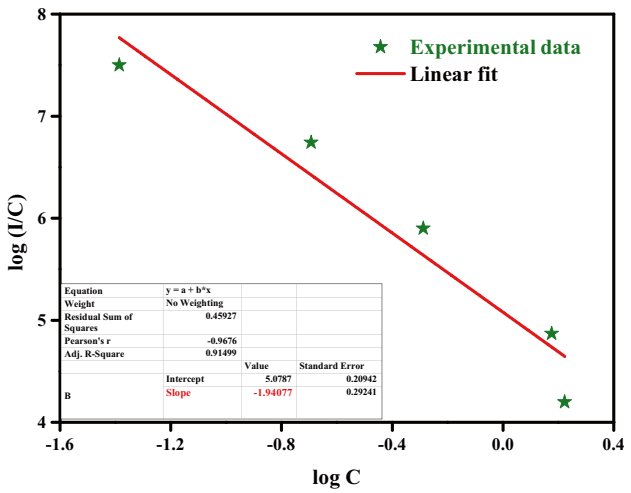

Fig. 7 Dexter's theory shows the energy transfer between Dy^{3+}-Dy^{3+} ions via dipole–dipole interaction in Dy^{3+} doped CABS glasses

A schematic energy level diagram showing various emissions in the glass matrix is given in Fig. 8. It can be seen that all emissions take place from the $^4F_{9/2}$ level. This level gets accumulated with excited Dy^{3+} ions that fall from the upper excited states non-radiatively as the energy difference between these levels is less. Radiative transitions then take place from this level to the lower $^6H_{J/2}$ states (J = 9,11,13,15) due to sufficient energy gap being present between them. The concentration quenching phenomenon can be attributed to the resonance energy transfer (RET) and cross relaxation (CR) channels between the Dy^{3+} ions [40, 42].The possible RET and CR channels can be given as:

$$\text{RET} : (^4F_{9/2} + {}^6H_{15/2} \rightarrow {}^6H_{15/2} + {}^4F_{9/2})$$

$$\text{CR1} : (^4F_{9/2} + {}^6H_{15/2} \rightarrow {}^6H_{9/2} + {}^6F_{3/2})$$

$$\text{CR2} : (^4F_{9/2} + {}^6H_{15/2} \rightarrow {}^6F_{7/2} + {}^6F_{5/2})$$

$$\text{CR3} : (^4F_{9/2} + {}^6H_{15/2} \rightarrow {}^6F_{3/2} + {}^6H_{9/2})$$

The yellow to blue (Y/B) ratio for the as prepared glasses for emission under 351 nm was calculated and presented in Table 3. The Y/B ratio is an important parameter for white light generation. The $^4F_{9/2} \rightarrow {}^6H_{13/2}$ transition is electric dipole ($\Delta J = \pm 2$), which is host sensitive whereas the transition $^4F_{9/2} \rightarrow {}^6H_{15/2}$ is magnetic dipole ($\Delta J = 0, \pm 1$ but $0 \rightarrow 0$ forbidden) and is host insensitive. Thus, the Y/B ratio has been used to determine the covalent nature of the bond between Dy^{3+}-O^{2-}. It can be seen that the ratio lies between 1.41 and 1.46 for changing concentration of Dy^{3+} ions. Higher value of Y/B ratio leads to high covalence. Thus it can be concluded that the local environment around the Dy^{3+} ions is stable and does not get affected with change in the concentration of ions [41–44].

Decay Kinetics

The decay profiles of the as prepared glasses for the 574 nm transition under 351 nm excitation are presented in Fig. 9. The decay curves are found to be bi-exponential in nature and are well fitted to the following expression [45]:

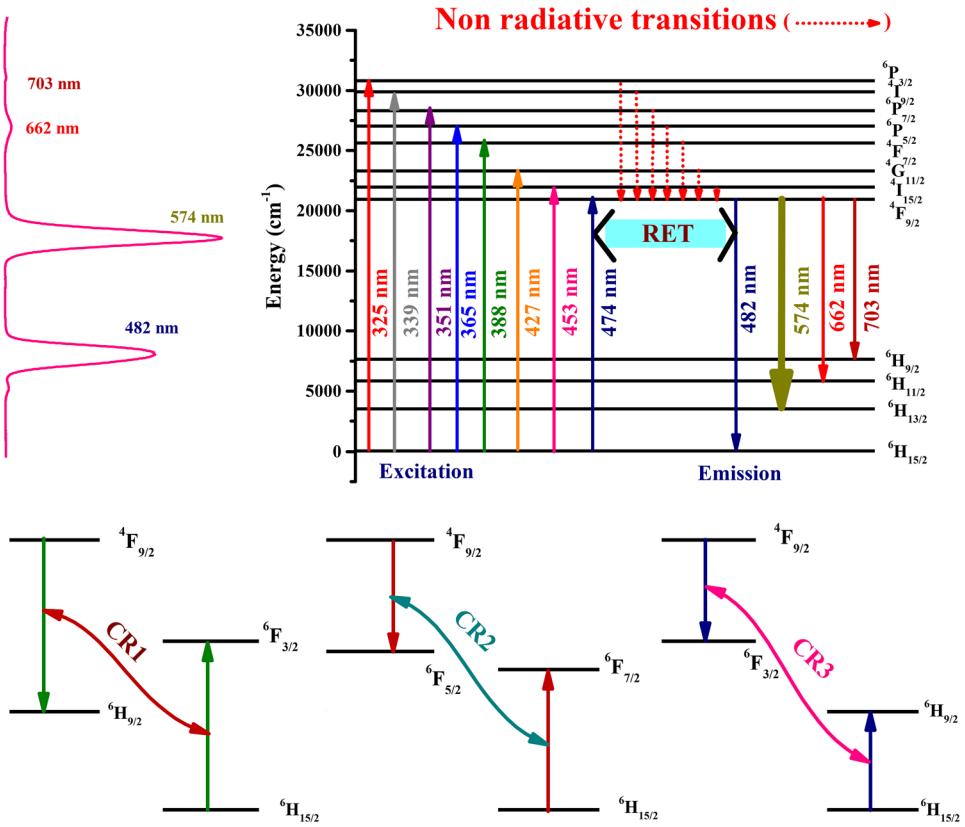

Fig. 8 Partial energy level diagram showing excitation and emission transitions, Cross-relaxation (CR) channels and resonant energy transfer (RET) with non-radiative relaxations for Dy^{3+} doped CABS glasses

Table 3 Average lifetime (τ_{avg}), Energy transfer parameter (Q), acceptor-ion concentration (N_0), critical transfer distance (R_o) and CIE co-ordinates of Dy^{3+} doped CABS glasses

Sample ID	τ_{avg} (ms)	Q	$N_0(10^{19}$ions/cm$^3)$	R_o (Å)	Y/B ratio	CIE coordinates (X, Y)
CABS1	3.93	9.14	0.289	13.27	1.41	0.335, 0.297
CABS2	3.51	14.23	1.56	8.75	1.43	0.349, 0.316
CABS3	3.12	18.68	3.303	7.48	1.46	0.323, 0.317
CABS4	2.84	21.93	5.151	6.80	1.46	0.319, 0.282

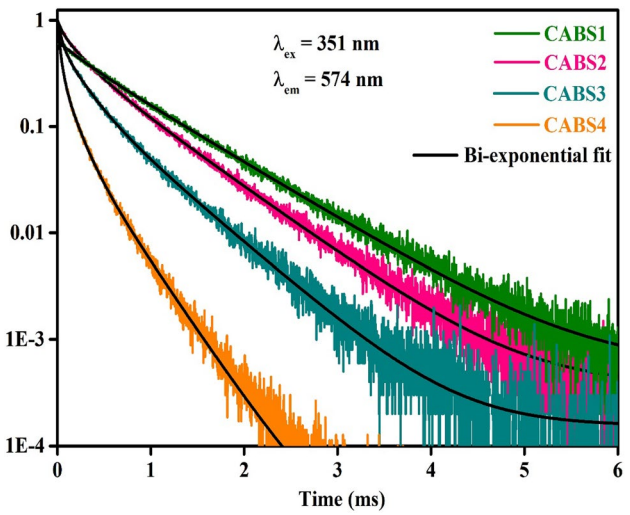

Fig. 9 Decay profiles of Dy^{3+} doped CABS glasses recorded under 351 nm excitation monitoring via $^4F_{9/2} \rightarrow {}^6H_{13/2}$ transition

$$I = I_0 + A\ exp(-t/\tau_1) + B\ exp(-t/\tau_2) \quad (6)$$

where I_0 and I are the luminescence intensities at zero and t time, A and B are the fitting constants, τ_1 and $\tau 2$ are fast and slow components of lifetime. The average lifetime values can be estimated by the following expression [46]:

$$\tau_{av} = \frac{A\tau_1^2 + B\tau_2^2}{A\tau_1 + B\tau_2} \quad (7)$$

These values are shown in Table 3. It can be seen that the values of lifetime decrease with the increase in the concentration of Dy^{3+} ions. This can be due to the increased energy transfers between one Dy^{3+} ion and neighbouring Dy^{3+} ions in the glass matrix with the increase in their concentration.

In order to justify the dipole–dipole nature of interaction between the Dy^{3+} ions in the glass matrix, Inokuti-Hirayama model was applied to the decay curve of CABS3

glass. This model states that the emission intensity is given as [47]:

$$I(t) = Ioexp\left[-\frac{t}{\tau o} - Q(\frac{t}{\tau o})^{3/S}\right] \quad (8)$$

where t is the time after excitation and t_0 is the intrinsic decay time of the donors in the absence of acceptors. S can take either 6, 8 or 10 depending upon whether the ion-ion interactions are dipole–dipole or dipole-quadrupole or quadrupole–quadrupole respectively. Q is the energy transfer parameter given by the following relation:

$$Q = \frac{4\pi}{3}\Gamma\left(1 - \frac{3}{S}\right)NoRo^3 \quad (9)$$

Here Γ(x) is 1.77 for dipole–dipole interactions, for dipole-quadrupole interactions it is 1.43 and for quadrupole–quadrupole interactions, it is 1.3. N_0 is the concentration of rare earth ions and R_0 is defined as the critical energy transfer distance between the donor and acceptor ions.

It can be seen from Fig. 10 that the curves fit well for S = 6 signifying the dipole–dipole interaction between the Dy^{3+} ions in the host matrix. The values of Q were estimated from I-H profiles and used to calculate the value of R_0 from Eq. (9). All these values are presented in Table 3. It is evident that the values of Q increase with increasing concentration of Dy^{3+} thereby signalling more energy transfer between the Dy^{3+} ions and hence a faster decay time. The value of R_0 decreases with the increase in N_0 also supports the increment in Q parameter. As the distance between donor and acceptor decreases, the possibility of energy transfer increases [9]. More energy transfer leads to the higher emission intensity.

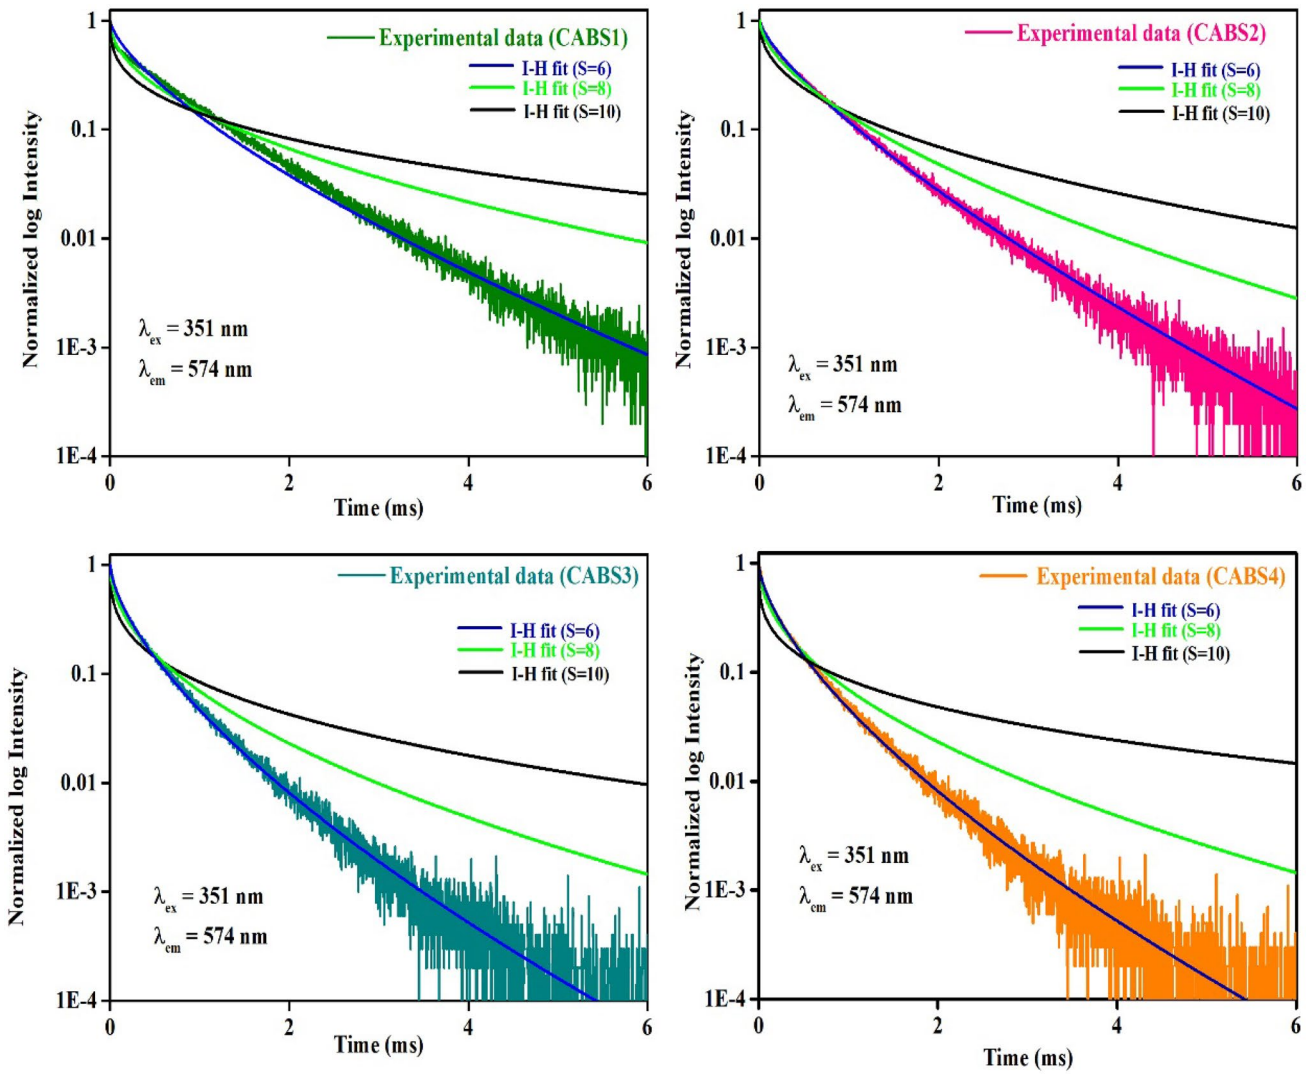

Fig. 10 Decay profiles fitted with I-H model for Dy doped CABS glasses under 351 nm excitation wavelength

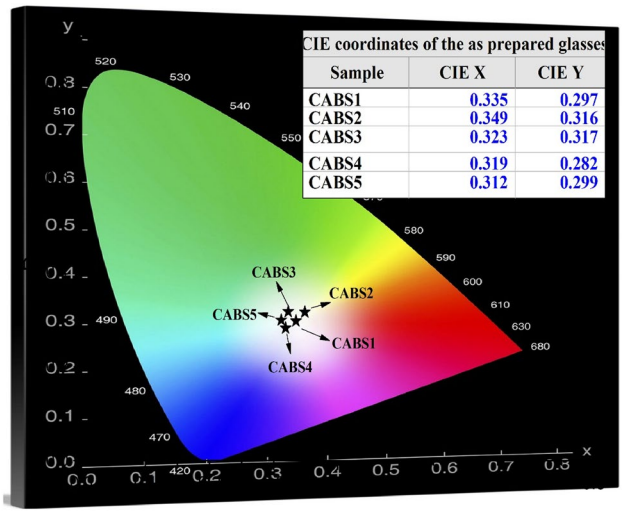

Fig. 11 CIE chromaticity co-ordinates for Dy^{3+} doped CABS glasses under 351 nm excitation wavelength

Colorimetry Analysis

The CIE chromaticity coordinates for the emission spectra under 351 nm excitation have been calculated and presented in Table 3. The same coordinates have been shown on a CIE diagram in Fig. 11. As is evident from the figure, all the coordinates lie in the white region of the diagram and are pretty close to the standard white light point (0.333, 0.333). Thus, Dy^{3+} doped CABS glasses can indeed be used for white light generation and other SSL applications.

Conclusions

Dy^{3+} doped calcium alumino borosilicate glasses (CABS) have been prepared via quick melt quenching technique. Morphological and photoluminescence studies have been carried out extensively in the as prepared glasses. Under 351 nm excitation, these glasses emit sharp bands in the blue and yellow regions along with feeble bands in the red regions corresponding to the transitions $^4F_{9/2} \rightarrow {}^6H_{15/2}$, $^6H_{13/2}$, $^6H_{11/2}$ and $^6H_{9/2}$ respectively. Dexter theory and Inokuti-Hirayama model proves that the Dy^{3+}- Dy^{3+} ion interaction is dipole–dipole in nature. The decay profiles show fast decay with increasing concentration of Dy^{3+} ions. The CIE coordinates of these glasses for the emission spectra under 351 nm excitation fall well within the white region. These glasses can be suitably utilised for white light emission and further usage in w-LEDs and SSL applications.

Abstract
Entrepreneurship has lately become a buzzword, and emphasis is being placed on ensuring the success of entrepreneurial ventures through both financial and non-financial means. This study aims to critically review and provide insights into the key developments in the literature on entrepreneurial success. The review employs bibliometric methods and content analysis on 595 research articles extracted from the Scopus Database for the period 1996 to 2021. The findings of the study highlight the growth trends of publications on entrepreneurial success, the most impactful articles, journals, and countries working in this domain as well as the evolution of entrepreneurial research topics over the years. Six clusters, representing major themes that have been explored in the literature in the past 26 years, are uncovered through content analysis. Future research agendas have been elaborated based on the emerging topics of study.

Keywords: entrepreneurship, entrepreneurial success, bibliometric analysis, literature review

1. INTRODUCTION

Entrepreneurship refers to the identification of opportunities in order to create new business ventures, provide goods and services (Shane and Venkataraman, 2000), generate employment, and promote innovation. It acts as a major force in the economic growth of a country (Van Praag and Versloot, 2007). Entrepreneurial development not only leads to employment generation but also leads to social development and improvement in the global competitiveness of a country (Naudé, 2013). Entrepreneurial success may be defined as the ability of the firm to be able to survive in the market over the long term (Fisher et al., 2014). Such success can be viewed from two angles: financial success and non-financial success (Orser and Dyke, 2009; Gorgievski et al., 2010). Financial success can be measured with the help of organizational economic parameters such as firm survival rate, cash flows, company sales and profits, the number of employees, and the company growth rate (Dej, 2010). Non-financial success, on the other hand, is based on the personal attributes of the entrepreneurs, such as personal fulfillment, societal contributions, self-realizations, and work-related social relationships (Dej, 2010). Financial success is often argued to represent the short-term outlook, whereas non-financial or psychological success is attributed to the long-term perspective (Simon et al., 2015). Literature suggests that the success of a startup may hold different meanings for different entrepreneurs. While for some, it may boil down to the achievement of the enterprise's goals and objectives (Hyder and Lussier, 2016) or a continuous high financial performance (Spiegel et al., 2015), for others, a startup may be successful on being acquired by another company at a good valuation (Krejci et al., 2015).

The process of entrepreneurship involves three phases: opportunity identification phase, development and execution phase, and survival and growth phase (Baron and Shane, 2007). The success of an entrepreneurial venture is mostly evaluated during the second phase. Various indicators are taken into consideration while evaluating a venture's success. One of the most paramount indicators is financial gain (Parker, 2009), while other indicators include sales, revenue, and market development (Rauch and Frese, 2007). It is difficult to define entrepreneurial success based on financial gains solely because many start-ups may not be able to become profitable initially, even when the firm enjoys increasing sales, due to high set-up costs and interest payments (Perez and Canino, 2009). Still, it is an integral indicator as low financial gains or profitability can prove to be dangerous for a business venture and might lead to its death (Coad, 2007). Contrary to the above, a firm may dissolve even if it is profitable but is unable to fulfill personal goals (Green et al., 2003).

Various factors drive entrepreneurial success, which can be classified into external and internal drivers. The external factors include economic factors and social factors, while the internal factors comprise psychological factors and personal factors. Economic factors comprise access to financial resources (Gupta and Mirchandani, 2018), an increase in sales and revenues, continuous development, customer acceptance and satisfaction, and the overall economic growth of the firm (Wach et al., 2016). The social factors include 2 major components: workplace relationships, that is, the ability to maintain healthy relationships with the stakeholder within and outside the organization (Jayawarna et al., 2013), and societal impact, which refers to the impact of the firm's products and services on the environment as well as on the health and well-being of the society (Florea et al., 2013). Psychological factors comprise components such as resilience, self-efficacy, and the optimism of the entrepreneurs that influences their behaviors, intentions, and motivations, (Baluku et al., 2016). Resilience is the ability of the entrepreneur to bounce back from unprecedented, adverse circumstances by adapting to a dynamic environment and bringing positive change (Luthans et al., 2007), while self-efficacy is the confidence of an entrepreneur to develop and build a new venture, accomplish the goals, overcome all the challenges, and be proficient in the entrepreneurial journey (McGee et al., 2009; Newman et al., 2014). Optimism is a psychological factor that motivates an entrepreneur by increasing the possibility of positive outcomes (Luthans et al., 2007; Trevelyan, 2008). Lastly, the set of personal factors comprises the education level of the entrepreneurs (Barreneche, 2014; Kolstud and Wiig, 2015), their innovativeness and creativity (Mazzucato, 2011), and their personal initiative as well as active actions towards ensuring the survival and growth of the venture (Frese and Gielnik, 2014).

While in the past, emphasis has been on economic as well as psychological parameters for determining the growth and development of businesses, recent literature has focused attention on the emotional skills of the entrepreneurs (Aly et al., 2021), which are internal in nature, as well as family-related factors (Staniewski and Awruk, 2021), which is an external factor. Dimensions such as parental attitudes, the manner of communication amongst the family, and the origin of the family have now been recognized as playing a crucial role in the entrepreneurial success (Staniewski and Awruk, 2021).

Despite the growing number of studies on entrepreneurial start-ups, the literature suffers from major gaps in quantitatively identifying the intellectual developments and evolution taking place in the domain of entrepreneurial success. The topic of entrepreneurial success is emerging but is under-researched (Fisher et al., 2014). Though there are fragmented studies that focus on various aspects of entrepreneurial success, such as achievement motivation (Staniewski and Awruk, 2019), age (Zhao et al., 2021), the relevance of resilience (Salisu et al., 2021), the literature still lacks a quantitative review to examine the growth in this domain.

The present study is an attempt to holistically fill this gap and provide valuable insights into the key developments that have taken place in this domain and underline future themes for research. When the volume of publications becomes sufficiently large over a period, it is not possible to review the literature qualitatively alone and, in such cases, bibliometric analysis becomes the imperative solution. To bring continuity into the entrepreneurial research domain and to give future directions, we address the following research questions:

RQ1: What are the spatial and geographical trends as well as the volume of publications on entrepreneurial success?

RQ2: Which are the top journals publishing in the domain of the success of entrepreneurial ventures?

RQ3: Which are the most influential research articles in this research area?

RQ4: Who are the top authors publishing in the domain of entrepreneurial success?

RQ5: Which topics in the entrepreneurial success literature have been trending in the past and which topics are emerging?

RQ6: What are the key themes that have been explored by researchers in the domain of entrepreneurial success and what are the future avenues for research?

The above questions are answered by analyzing 595 peer-reviewed research articles and review papers extracted from the Scopus Database. The review employs bibliometric methods (Boyack and Klavans, 2010) and content analysis to discover the evolution and intellectual development in the domain of entrepreneurial success. Previous studies in various domains such as corporate governance (Singh et al., 2021a), risk management (Singhania et al., 2022), and deposit insurance (Sardana and Singhania, 2022) have also made use of bibliometric analysis to answer such types of research questions.

2. LITERATURE REVIEW

Many small businesses and start-ups evolve every year, but more than a quarter of them dissolve within the first year of their operation (McKenzie and Paffhausen, 2018). Out of the start-ups that survive, a small proportion can grow and contribute to the generation of employment and the development of the economy (Olafsen and Cook, 2016). The success rate of the start-ups is, therefore, quite low, and it is difficult to predict which of the evolving firms will be more successful (Nanda, 2016). Entrepreneurship is a risky yet exciting journey that requires not just ideas and funds, but ability, skills, determination, persistence, hard work, and most importantly, patience. This package deal leads to the path toward entrepreneurial success (Woodfield et al., 2017).

Traditionally, entrepreneurial success has been considered solely based on financial and economic indicators (Zhou et al., 2017) such as profits, probability of survival, and size of the firm (Fried and Tauer, 2015). But the importance of non-financial indicators cannot be ignored (Razmus and Laguna, 2018). As far as the factors driving entrepreneurial success are concerned, the skills and knowledge possessed by an entrepreneur (Abu et al., 2014), the entrepreneur's psychological behaviour, proficiency, ability to manage work stress, and commitment towards a task (Gupta and Mirchandani, 2018), the internal locus of control of an entrepreneur (Asante and Affum-Osei, 2019), entrepreneurs' attitude, behaviour and mentality (Saptono and Najah, 2018) have gained importance in theory as well as practice. In order to ensure the smooth functioning of the organization and to deal with uncertain circumstances, the cultural attitudes of entrepreneurs (Yusof et al., 2017), appreciation and strong implementation of work-life balance (Orlandi, 2017), autonomy for communication, accepting behaviour towards challenges, proactiveness and a decision-making attitude (Toms et al., 2019), innovativeness (Ojo et al., 2017), and the availability of a well-written and researched business plans (Agarwal and Dahm, 2015) are also essential. Another important factor is gender (Muis et al., 2017) as different genders possess different characteristics, and the success of the venture has varying meanings for different genders.

2.1 Theories of Entrepreneurial Success

The concept of entrepreneurial success is built on theories taken from different disciplines. Some of the major theories include cognitive theory, discovery theory, creation theory, Dubin's theory, and the theory of economic development. The cognitive theory takes into account all those internal processes that help an individual identify the knowledge structures around them to make decisions, assessments, judgments, etc. (Cacciolatti, et al., 2015). This theory acts as a guiding force for entrepreneurs and determines their risk-taking behaviour, which differs significantly from non-entrepreneurs (Palich et al., 1995). Discovery theory is based on the premise that the markets are dynamic, and this gives room for entrepreneurs to discover the existing opportunities in the markets as well as tap them for the generation of profits (Kessler, 2013). On the other hand, creation theory is of the view that opportunities are not readily available in the market, rather they are the

consequence of actions undertaken by entrepreneurs for the development of new and innovative products and services (Baker and Nelson, 2005). Dubin's theory showcases the phases or steps that can be used for theory or concept building (Dubin, 1978). It helps in the opportunity identification process and the development of the methodology which can help the entrepreneurs capture the prevailing opportunities in the market. The process comprises eight phases, where the first five phases are focused on developing the structure, and the last three phases are meant for empirical validation (Ardichvili et al, 2003). Lastly, Schumpeter's theory of economic development considers the significant role of the entrepreneurs and the innovations conducted by them in the process of economic development (Croitoru, 2012). It is a well-recognized fact that innovation and new technologies are not uniformly adopted by competing entrepreneurs (Jambulingam, 2018). The theory also accords special significance to the entrepreneur as a driver of change through constant innovation, which overcomes the obsolescence of past products (Schumpeter, & Backhaus, 2003). These theories have been critically analyzed in the cluster analysis section, along with highlighting other emerging yet prominent theories.

3. RESEARCH METHODOLOGY

The topic of entrepreneurial success has not been subjected to a quantitative review. This study fills this gap through a mixed-method study using a combination of bibliometric analysis, a quantitative method, and content analysis, which is a qualitative method. Bibliometric analysis has gained wide attention in recent years due to the ease of accessibility of open access software such as VOSviewer, R, and Gephi, as well as the cross-pollination of the themes from one domain to the other (Dhonthu et al., 2021). Scholars use bibliometric analysis for gaining knowledge about emerging trends, the performance of journals, clarity regarding research patterns, core journals, countries, and influential authors as well as publications (Singh et al., 2021a; Sardana and Singhania, 2022). This technique helps in producing a high impact on research by handling large volumes of statistical data (Dhonthu et al., 2021). Through scientific mapping, data has been analyzed to synthesize the existing research, giving a better clarification of the topic and field of study (Singhania et al., 2022a).

The first step of the technique involved the identification and selection of a database for the retrieval of documents. We used the Scopus database by Elsevier as it is known for its wide range of publications in social sciences, especially since 1996 (Vieira and Gomes, 2009). As a second step, we framed a string of keywords based on the literature review: "entrepreneur* success*" OR "entrepreneur* victory" OR "entrepreneur* achieve*". This led to the retrieval of 670 documents. Since the Scopus database is known to have a weak coverage of pre-1996 publications in the domain of social sciences (Harzing and Alakangas, 2016), the set of documents used for analysis was restricted to the period 1996 to 2021. As a third step, the screening of records was undertaken, which led to the filtration and elimination of 59 documents, including conference papers, book chapters, books, and notes to keep only journal articles in the English language (excluding articles in all other languages). Then, the records were assessed based on the title and abstract for eligibility. This further omitted 16 documents, leaving a sample of 595 documents that were finally used for the bibliometric synthesis. Figure 1 provides an overview of these steps along with the structural flow of the paper.

Figure 1. Structural flow of the paper

4. RESEARCH ANALYSIS

The study conducts bibliometric and topographical analyses of the research articles sourced from the Scopus database. In order to identify the pattern of development within the database, descriptive statistics are first performed using MS Excel to construct various tables, graphs, etc. Subsequently, to determine the relationship between the study items, VOSviewer (Van-Eck & Waltman, 2010) is employed for analysis, network diagrams, and science mapping (Baker et al., 2021).

4.1 Volume and Growth Trend of Published Studies

Our first analysis is focused on the volume of publications on entrepreneurial success, over the past 26 years, from 1996 to 2021. The analysis of 595 articles indicates that the knowledge base of entrepreneurial success has witnessed slow but steady growth, and there is wide potential for evolution in this area (Figure 2). Though at first glance the number of publications might seem low compared to the extended horizon of 26 years, we must also consider that this number does not cover a fair number of documents such as books, book chapters, conference papers, reports, etc. Figure 2 also highlights how the studies in the said domain have seen a steep rise post-2013. This persistent growth could be attributed to the initiatives undertaken by the government of various economies at the global level to push the start-up culture (Yin et al., 2019; Garg and Gupta, 2022). Countries have started realizing the potential of the start-up ecosystem, and research studies in the domain of entrepreneurial success act as game changers for boosting the initiatives taken by various government bodies. Moreover, the recent COVID-19 pandemic, which led to a massive loss of employment, also acted as a driver for self-employment and entrepreneurial initiatives (Dang and Nguyen, 2021).

Source: Authors' creation based on Scopus database.

4.2 Publication Analysis across Countries

Table 1 presents the top 20 countries contributing to the topic of entrepreneurial success based on the number of citations of published documents. With the highest number of documents (197) and citations (8464), the United States of America (USA) proves to be the most productive. The authors of the documents published in the USA have been exploring the topics of success among small and medium enterprises (Eggers, 2020), women entrepreneurship (Bullough et al., 2022), and entrepreneurship education (Liguori and Winkler, 2020). The second position is taken by Germany, with 74 documents and 1955 citations. The third spot is occupied by the Netherlands while the United Kingdom (UK) assumes the fourth spot based on the number of citations. It is also interesting to note that though Sweden is found in sixth position in terms of the number of citations, it has the highest average citations per document (ACPD), thereby reflecting a higher impact in relative terms, vis-à-vis other countries. The above observations follow because the economic growth of a nation is positively correlated with the entrepreneurial activities taking place in the country (Stel et al., 2005). Factors such as innovation, employment, and productivity growth are driven by growing entrepreneurial activity (World Economic Forum, 2013). The USA has consistently seen upward trends, both in early-stage entrepreneurship as well as established entrepreneurial ventures (Global Entrepreneurship Monitor [GEM], 2019). With this comes the responsibility of research and publications across the country, which helps in innovation and development (Distanont and Khongmalai, 2020). It is for this reason that the USA tops the list of 20 countries.

Table 1. Top 20 most influential countries based on citation analysis

Rank	Country	No. of Documents	No. of Citations	ACPD	Type of Economy
1	United States of America	197	8464	42.96	Developed
2	Germany	74	1955	26.42	Developed
3	Netherlands	27	1748	64.74	Developed
4	United Kingdom	52	1063	20.44	Developed
5	Spain	26	702	27	Developed
6	Sweden	8	601	75.13	Developed
7	Australia	30	570	19	Developed
8	Taiwan	11	354	32.18	Developed
9	France	22	353	16.05	Developed
10	Norway	13	348	26.77	Developed
11	Canada	15	321	21.4	Developed

Source: Authors' creation based on Scopus database and reviews.

Note: ACPD= Average Citation Per Document

An important aspect is that 90% of entrepreneurial research has been undertaken in developed countries across the world. Though not a lot of developing countries engage in entrepreneurial research, countries like India and China have been able to capture a spot in the list of top 20 countries. India stood at 13th place with an ACPD of 5.89 and China stood at 17th place with an ACPD of 3.1. These two developing economies had the lowest ACPD amongst the list of countries mentioned in the table. On the other hand, developed countries like Sweden and Netherlands are found to have an ACPD of 75.31 and 64.74 respectively, which is the highest in the table. This indicates the difference in the impact of the research among developed and developing economies.

4.3 Citation Analysis for Journals

The Scopus database comprises several journals that publish entrepreneurial research. Table 2 presents the top 20 journals with the highest citations in the Scopus database. The *Journal of Business Venturing* by Elsevier, an A* listed journal, proved to be the most influential source, with 5638 citations and an ACPD of 352.38. The second position is *Small Business Economics* by Springer Nature with 793 citations and an ACPD of 66.08 followed by *Journal of Small Business and Enterprise Development* by Emerald with 354 citations and 59 ACPD. *Academy of Entrepreneurship Journal* and *Journal of Entrepreneurship Education*, earlier published by Allied Business Academies, appear in the top 20 list, but they were delisted from Scopus in 2021 and 2019, respectively.

Table 2: Top 20 most influential journals in the domain of entrepreneurial success, based on the citation analysis

Rank	Source	NOD	No. of Citations	ACPD	Cite Score	Scopus Coverage	ABDC listed	Publisher
1	Journal of Business Venturing	16	5638	352.38	14.6	1985 to Present	A*	Elsevier
2	Small Business Economics	12	793	66.08	10.7	1989 to Present	A	Springer Nature

Note: NOD= Number of Documents; ACPD= Average Citation Per Document

It can also be observed that business journals cover most of the entrepreneurial success research. Other journals publishing on entrepreneurship cater to areas such as management, economics, psychology, education, and history. The scholars working in this domain should note an interesting aspect: that despite being in the top 3 list based on the volume of publications, the *Frontiers in Psychology Journal* (with 12 published documents) is performing low in terms of the ACPD. This means that though enough papers are being published, the publications have not been able to generate substantial impact relative to publications in other journals. As pointed out before, entrepreneurship is one of the major contributors to the development of the economy (Doran et al., 2018). Beyond the economic factors, entrepreneurial success is influenced by psychological factors. Psychology is the foundation that evaluates the ability of an entrepreneur to recognize business opportunities and use them effectively to start and build a firm (Ramos-Rodrıguez et al., 2010). Similarly, different domains have different purposes in the journey of entrepreneurship, which are represented systematically by various journals.

4.4 Influential Authors and Articles

The study not only identifies the top countries and journals working in the field of entrepreneurship but also gives attention to the contributors as well as the most influential articles that have been published and have proved to be beneficial for academicians and entrepreneurs.

Table 3 lists the top 20 authors who have been contributing their efforts towards the said topic, ranked based on citation analysis. Michael Frese has proved to be the most influential author, with 1209 citations and a

h-index of 112. Some of his research articles such as "*Human Capital and Entrepreneurial Success: A Meta-Analytical Review"* and "*Towards a Psychology of Entrepreneurship- An Action Theory Perspective",* have made it to the top 10 most influential articles in this domain. The second most impactful author is Eva Schmitt-Rodermund, with 285 citations and a h-index of 28. The citations received by Michael Frese, as well as his h-index are more than four times those of Eva Schmitt-Rodermund. It is noteworthy that most of the top authors belong to Germany and other parts of Europe. Though the USA topped the list of countries contributing to research on entrepreneurial success, none of the top authors belong to the USA. This shows that the country is providing a substantial quantity of research but lacks impactful authors working in this area, vis-a-vis countries in Europe. Also, countries such as India and China, which stood at 13th and 17th place respectively in the list of top 20 countries and are the only two developing countries that were able to find a spot in the list, have been able to find a place even in the list of most influential authors. Jianxin Zhang (#12) belongs to China and Ranbir Singh (#20) belongs to India.

Table 3: Top 20 authors publishing in the domain of entrepreneurial success, based on citation analysis

Rank	Author's Name	NOD	Citations	ACPD	Country Affiliation	Affiliation	h-index
1	Michael Frese	6	1209	201.5	Germany	University of Lueneburg	112
2	Eva Schmitt-Rodermund	3	285	95	Germany	University of Applied Sciences Potsdam	28
3	Yu-Yu Chang	4	172	43	Taiwan	National Cheng Kung University	12
4	Chen, Ming-Huei	4	172	43	Taiwan	National Chung Hsing University	27
5	Rebecca Fisher	3	127	42.33	England	Coventry University	2
6	Ute Stephan	3	122	40.67	England	King's College London	34
7	Martin Obschonka	4	119	29.75	Netherlands	University of Amsterdam	41
8	Rainer K. Silbereisen	4	119	29.75	Germany	Friedrich Schiller Universität Jena	69
9	Marcin Waldemar Staniewski	6	101	16.83	Poland	University of Economics and Human Sciences in Warsaw	16
10	Katarzyna Awruk	5	58	11.6	Poland	Akademia Ekonomiczno-Humanistyczna w Warszawie	8
11	Josette Dijkhuizen	4	38	9.5	Netherlands	Maastricht School of Management	N.A.
12	Jianxin Zhang	3	30	10	China	N.A.	12
13	Roy Thurik	3	27	9	France and Netherlands	Montpellier Business School and Erasmus School of Economics	99
14	Alexandros Kakouris	3	24	8	Greece	University of Peloponnese	13
15	Agnieszka Kurczewska	3	13	4.33	Poland	University of Lodz	15

Note: NOD= Number of Documents; ACPD= Average Citations Per Document

As for the top articles, Table 4 presents the top 10 most influential articles which have been most cited (according to the Scopus database) and contributed significantly to the field of our study. Each of the articles has received more than 150 citations. Out of these, the latest article was published in 2013 and underlines the linkages between entrepreneurial success and gender diversity. These influential research articles can be categorized into four broad domains: the role of psychological factors in entrepreneurial success; the role of gender; the impact of family business; and other factors affecting success in entrepreneurship. Psychology is one of the most pertinent factors with respect to entrepreneurship as most of the articles talk about the role of psychology in entrepreneurship. Psychology is a mechanism that helps entrepreneurs in coping with difficult and challenging situations (Zou et al., 2015). Most of these articles are published in ABDC-listed journals and

contribute significantly to the literature. Table 5 also reiterates that the *Journal of Business Venturing* is the top contributing journal as 50% of the top 10 articles have been published in this journal.

Table 4: Top 10 most influential articles in the field of entrepreneurial success, based on citation analysis

Rank	Document Name	Journal Name	Citations	Year	Type of Paper
1	Linking two dimensions of entrepreneurial orientation to firm performance: The moderating role of environment and industry life cycle	Journal of Business Venturing	1527	2001	Empirical
2	Does entrepreneurial self-efficacy distinguish entrepreneurs from managers?	Journal of Business Venturing	1435	1998	Empirical
3	Human capital and entrepreneurial success: A meta-analytical review	Journal of Business Venturing	832	2011	Empirical
4	Networks in entrepreneurship: The case of high-technology firms	Small Business Economics	491	2003	Empirical
5	Entrepreneurship and female youth: knowledge, attitudes, gender differences, and educational practices	Journal of Business Venturing	245	1998	Empirical
6	Business formation: A network approach	Scandinavian Journal of Management	213	1988	Conceptual
7	Linking family-to-business enrichment and support to entrepreneurial success: Do female and male entrepreneurs experience different outcomes?	Journal of Business Venturing	205	2013	Empirical
8	Pathways to successful entrepreneurship: Parenting, personality, early entrepreneurial competence, and interests	Journal of Vocational Behavior	190	2004	Empirical
9	Towards a psychology of entrepreneurship: An action theory perspective	Foundations and Trends in Entrepreneurship	181	2009	Conceptual
10	Psychological perspectives on entrepreneurship: Cognitive and social factors in entrepreneurs' success	Current Directions in Psychological Science	154	2000	Conceptual

4.5 Keyword Analysis

We undertake a keyword analysis to identify the research themes studied predominantly in the entrepreneurial success literature. A novel technique of quantitative analysis, keyword analysis is a subfield of bibliometric review that has its roots in library and information science. It aims to identify repetitive words, trending domains, and emerging topics of research (Qian et al., 2019).

Table 5: Top 10 keywords occurring for the highest number of times

Rank	Keyword	No. of Occurrences
1	Entrepreneurs	24
2	Gender	21
3	Innovation	21
4	Women entrepreneurs	16
5	Human capital	15
6	Education	14
7	Social capital	14
8	Entrepreneurship education	13
9	Sustainable development	12
10	Entrepreneurial orientation	11

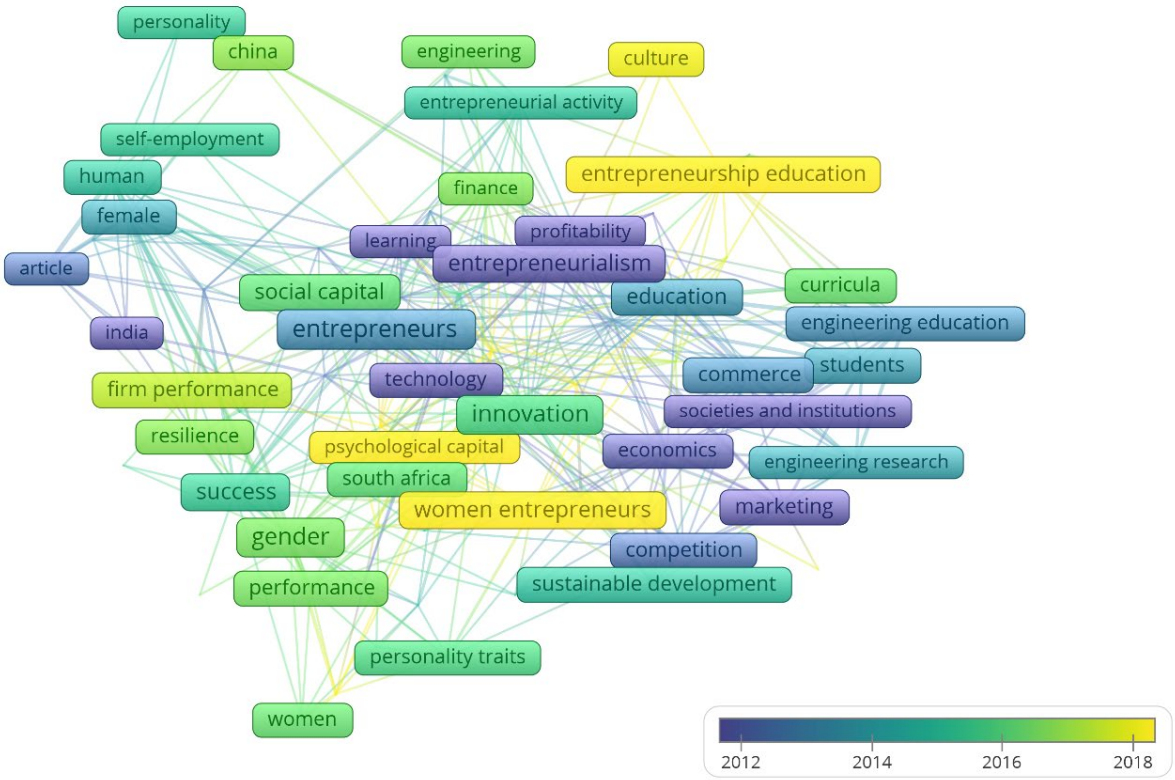
Source: Authors' compilation using Scopus database.

Table 5 shows the top keywords which have occurred in the database and these consist of topics like *Entrepreneurs, Gender, Innovation,* and *Women Entrepreneurs.* This highlights the major dimensions that have been studied in the past literature under the theme of entrepreneurial success. Gender-based entrepreneurship has gained momentum in recent years owing to a larger proportion of women entrepreneurs taking the lead in the market (Rosca et al., 2020). Similarly, innovation is the backbone of a successful entrepreneurial venture (Iriobe, 2018), and this is evident from the frequent usage of this term in the literature. The list continues with the terms *Human capital, Education, and Social Capital.* Human capital is the biggest asset of a firm, and works

as a tool for the success of a firm. It possesses a direct relationship with entrepreneurial success, both in new as well as established businesses (Elsafty et al., 2020). Education is an integral part of entrepreneurship as well. In the era of a changing entrepreneurial environment, education has become a need for current as well as future entrepreneurs. Investment and efforts in entrepreneurship education have increased in the past few years and are continuously witnessing an uprise (Bauman and Lucy, 2021). Social capital adds value by providing entrepreneurs with the right network and direction (Xie et al., 2021). Lastly, keywords like *Sustainable Development* have received attention due to climate destruction as well as pandemics (such as COVID-19) that have been impacting the world. Moreover, the emphasis of the United Nations (UN) on sustainable development goals has further given a necessary push to research in this domain (Singh et al., 2021b). The dimension of *Entrepreneurial Orientation* has also been looked at to understand the dynamics of top management style, organizational configuration, and new entry initiatives. The understanding of these aspects will help both the entrepreneurs as well as researchers to plan the multilevel conceptualization on a larger scale (Wales et al., 2020).

Additionally, keyword co-occurrence analysis has allowed us to locate emerging topics within the subject domain (Bhattacharya and Basu, 1998). The emerging topics have been represented by the colour yellow in Figure 4. The years after the global financial crisis witnessed the hefty usage of terms like technology (Ford et al., 2010), profitability (Kiviluoto, 2011), and economics (Brown and Thornton, 2013), and most of the entrepreneurial research revolved around these topics. Since entrepreneurship has gained wide popularity in recent times, the topics of research have also evolved to focus on the themes of psychological capital (Tang, 2020; Gao et al., 2020), entrepreneurship education (Fayolle, 2018; Kyrö, 2018), women entrepreneurs (Panda, 2018; Sajjad et al., 2020) and culture (Lounsbury, 2019). The list of the most influential articles shows that most of the top 10 articles consist of similar topics. Entrepreneurs' behaviour and characteristics are integral factors in evaluating the success of a venture. Gender and culture impact entrepreneurship and entrepreneurial success. These emerging topics have a great deal of scope for future research that can be explored by scholars working in the entrepreneurial success domain.

Figure 4: Temporal overlay on a keyword co-occurrence map for the entrepreneurial success literature



Source: Authors' creation based on Scopus database and VOS viewer.

Figure 4 also shows the network between the topics which are connected using various nodes. The connection between these key concepts indicates the existence of a relationship between them. The relationship among the key concepts is visible and has been discussed in the cluster analysis as well as in future research avenues.

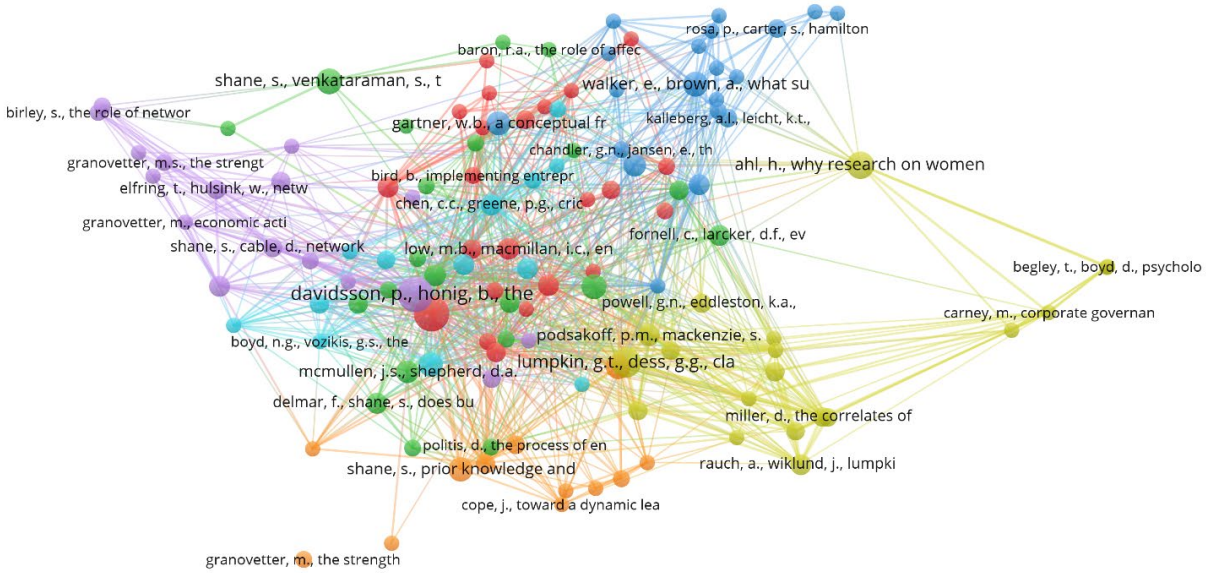
4.6 Cluster and Content Analysis Based on Co-Citation Analysis

Co-citation analysis is often used as a method to uncover the intellectual developments taking place in a particular field of research and identify emerging themes (Donthu et al., 2021). The method can be used to identify the major themes which will also be useful in determining the clusters and the existing inter-relationship (Bhaiswar et al., 2021) from the cited references.

Cluster analysis refers to the data analysis technique employed to identify the groups or segments which naturally occur together without any pre-defined set of rules. Due to the lack of any pre-defined data points, this method is often termed an unsupervised learning approach (Singhania et al., 2022; Peñas et al., 2023). The cluster analysis has been conducted using the co-citation method to identify the various sets of clusters in the domain of entrepreneurial success.

In the network map portrayed in Figure 5, the nodes are representative of the cited references, whereas the size of the nodes depicts the number of articles in which the document has been co-cited. Out of the 34656 cited references, 125 references meet the criterion of a minimum of 5 citations and have been included to visualize key thematic clusters in our research domain. Content analysis has been employed to understand the 6 themes emerging from these clusters.

Figure 5: Co-citation network based on cited references with minimum 5 citations



Source: Authors' creation using VOSviewer.

Cluster 1: Theories underpinning entrepreneurial success

Cluster 1 (red) is the largest cluster, with references emerging as early as 1934. The studies in this cluster discuss various theories involved in the identification and development of entrepreneurial opportunities, some of which are 'discovery theory', 'creation theory' (Alvarez and Barney, 2007), 'Dubin's theory' (Ardichvili et al., 2003), 'cognitive theory' (Palich and Bagby, 1995), and the 'theory of economic development' (Schumpeter, 1934). These theories have been discussed in detail in the section on 'Literature Review'. An entrepreneur's intention and state of mind, combined with experience and action toward a business concept, gives a direction for the organization at the inception stage, which further helps in survival, development, and growth (Bird, 1988). Some opportunities exist and some are waiting to be identified by the actions of an entrepreneur. Strategic entrepreneurship is a unique concept that involves the opportunity-seeking and advantage-seeking behaviour of an entrepreneur, which apparently results in the better performance of the firm (Ireland et al., 2003; Mazzei, 2018). It is stated that factors such as an entrepreneur's passion, perception of skills, abilities, luck, and value of the opportunity comprehended together lead to entrepreneurial effectiveness and persistence (Gatewood, 1995; Cardon, 2009; Kakarika et al., 2022).

Apart from the major theories highlighted by this cluster, certain theories are emerging in the entrepreneurship literature, and have the potential to affect it. These include the jack-of-all-trades theory, o-ring theory, the theory of entrepreneurial bricolage, and the theory of effectuation. The theory of Jack-of-all-trades was developed by Lazear (2004) and mathematically proved by Kaiser (2012). The theory is based on a balanced skills mix and assumes that to pursue entrepreneurship as a career option individuals need to possess sufficient skills and knowledge of a variety of fields (Wagner, 2003). Entrepreneurial success depends on the entrepreneurs' knowledge and experiences, which are accumulated by pursuing varied curricula. This helps in

building practical experiences and gaining insights from a range of functions that further helps in fostering entrepreneurial skills leading to entrepreneurial success (Kurczewska and Mackiewicz, 2020). As far as o-ring theory is concerned, it suggests the segregation of individuals according to their abilities, as different individuals supply different sets of talents and skills. This theory, seminally developed by Kremer (1993) and theoretically by Fabel (2004), believes in the power of teamwork and its importance in the success of a venture. The theory of entrepreneurial bricolage is a behaviour-based theory of entrepreneurship, proposed by the anthropologist Lévi-Strauss (1962). The theory tries to understand the behaviour of entrepreneurs to manage uncertainties, survive, and flourish even when faced with resource constraints (Senyard et al., 2009). It explores the possibility of the emergence of entrepreneurship with limited resources available at hand (Kickula et al., 2018). Finally, the theory of effectuation came into existence after the seminal works of Sarasvathy et al. (1998) and Sarasvathy (2001). According to Sarasvathy (2001), the future is unpredictable. From the logic of effectuation, it is better to control an unpredictable situation than to predict an uncertain one. Effectuation pre-estimates the affordable losses and lets entrepreneurs experiment with many strategies within limited means.

Cluster 2: Drivers of entrepreneurial success

This is the second largest cluster, depicted in green, with referenced documents emerging as early as 1981. One of the most important non-financial drivers of entrepreneurial success, that is psychology, is distinguished from the other behavioural sciences as it focuses more on the behaviour of an individual (Ajzen, 2020). In turn, behaviour is influenced by the dynamism of the external environment and an individual's personal choice (Shaver and Scott, 1992). Extending this concept to entrepreneurship, an entrepreneur's behaviour impacts many factors, such as readiness for innovation, proactive personality, generalized self-efficacy, stress tolerance, the need for autonomy, and locus of control, which have a significant correlation with business creation and business success (Brandstätter, 2011; Jawabri, 2020; Kurniawan et al., 2022). Research studies in this cluster have also studied the relationship between entrepreneurial traits and skill (passion, tenacity, and new resource skill) and situational specific motivation (communicated vision, self-efficacy, and goals) to further venture growth (Pathirana and Semasinghe, 2018; Rylková and Čemerková, 2020). Goals, self-efficacy, and communicated vision have direct effects on venture growth, and these factors mediate the effects of passion, tenacity, and new resource skill on subsequent growth (Baum and Locke, 2004). Prior knowledge of customer problems leads to the identification of more opportunities, and it also moderates the relationship between potential financial reward and opportunity identification (Shepherd and DeTienne, 2005).

The other important drivers of entrepreneurial success, as pointed out by cluster 2, can be categorized into economic drivers, psychological drivers, social drivers, and personal drivers. Traditionally, the profits of the firm have been considered solely as an indicator and driver of business performance as well as success. Though now there are various other factors involved in the evaluation of business success, economic performance still holds a very strong position in this evaluation (Perez and Canino, 2009). Psychological drivers comprise a) resilience, which is a desirable characteristic required by both the entrepreneurs as well as their ventures (Bullough et al., 2014; Baluku et al., 2016), b) self-efficacy (Goel and Karri, 2006; Baluku et al., 2016), since entrepreneurs with high self-efficacy identify as well as exploit the available opportunities and develop positive entrepreneurial intentions (Dimov, 2010), thereby harnessing the optimum levels of motivation and c) optimism, as entrepreneurs can take risks because of their confidence and optimistic attitude (Hmieleski and Baron, 2009) and it also has a significant positive relationship with the financial aspect of the firm (Baluku et al., 2016). The social drivers consist of a) workplace relationships, since having a healthy bond with customers and clients by providing them with loyalty and satisfaction also helps a firm in gaining long-term success (Wach et al., 2016), and b) societal impact (Tur-Porcar et al., 2018), which takes into account the ability of the entrepreneur to ensure that innovation and creativity are used to develop products and services with minimal and judicial application and exploitation of resources. The last set of drivers, that is personal drivers, comprises a) education, which is a basic level of knowledge and skills and which helps aspiring and budding entrepreneurs to identify and exploit market opportunities for profitable ventures (Barreneche, 2014), b) innovativeness and creativity (Somsuk and Laosirihongthong, 2014), both of which support the economic development of the country, work as a catalyst for employment generation as well as wealth creation, and lead to technological advancements, thereby creating more opportunities (Mazzucato, 2011) and c) personal aspects, including personality traits and characteristics of self-confidence, independence, autonomy, risk-taking propensity, persistence, networking, problem-solving ability, learning from failure, and using criticism (Rauch and Frese, 2007).

Cluster 3: Women and entrepreneurial success

Cluster 3, represented in blue, focuses on the journey of women entrepreneurs. The relationship between gender and business performance is complex, but gender is a key determinant of success, even after controlling for other factors (Rosa et al., 1996; Bednar et al., 2021; Olivas et al., 2022). Women entrepreneurs face problems when they enter the business, but factors such as family support, social ties, and internal motivation add positively and significantly to the success of women entrepreneurs (Alam et al., 2011; Panda, 2018). Work-

life balance too plays a significant role in the evaluation and success of women entrepreneurs (Davidsson, 1991; Gorgievski et al., 2011). The entrepreneurial success of women entrepreneurs is also majorly attributed to internal factors such as the need for achievement, risk-taking, and self-confidence (Khan et al., 2021). These factors accord much-needed motivation to women entrepreneurs. On the other hand, factors such as the socio-cultural status of women, difficulty in assessing the network of information, and problems in obtaining funds are the major factors that limit the performance of firms led by women entrepreneurs (Hasaan et. al., 2017). There is also a plethora of studies that contend that gender diversity or gender-related aspects do not impact firm performance. In a recent study by Singh et al. (2019), it was argued that having a gender-diverse board does not impact the performance of recently listed IPO (Initial Public Offer) firms. Similarly, another study by Singhania et al. (2022b) identified that having gender-based aspects on various committees does not impact accounting-based performance. Thus, this aspect as to whether gender-based elements impact performance is still debatable and can be explored in the future (Singhania et al., 2023a; Singhania et al., 2023b; Singh et al., 2023).

Cluster 4: Entrepreneurial orientation and entrepreneurial success

The fourth cluster is represented in yellow. The term entrepreneurial orientation (EO) has been used to refer to the strategy-making process and the style of firms that engage in entrepreneurial activities (Lumpkin et al., 2001). A popular model of EO suggests that it has five encompassing dimensions: autonomy, innovativeness, risk-taking, proactiveness, and competitive aggressiveness (Lumpkin et al., 1996; Al-Mamary and Alshallaqi, 2022). Entrepreneurial orientation shows a direct correlation not only with the success and performance of existing entrepreneurial firms but also with the survival and growth of new entrepreneurial ventures (Rauch et al., 2008; Stam and Elfring, 2008). Business performance is also determined by the psychological attributes of the entrepreneur such as the need for achievement, locus of control, risk-taking propensity, and tolerance of ambiguity (Ndofirepi, 2020). These are regarded as hallmarks of an entrepreneurial personality (Begley et al., 1987).

The theme of entrepreneurial orientation has often been linked to the concept of international entrepreneurship, which encompasses the innovativeness and risk-taking abilities that transcend national boundaries for value creation (McDougall and Oviatt, 2000). However, the relationship is indirect, and it has been found that international entrepreneurship mediates the role between entrepreneurial orientation and entrepreneurial success. The firms which pivot and take advantage of international moves at the right moment are bound to gain entrepreneurial success (Kollmann and Christofor, 2014).

Cluster 5: Resources and entrepreneurial success

This cluster (purple) has an integral role to play in the entrepreneurial journey as the documents in this cluster throw light on the way entrepreneurs interact with the networks in their local environment during the process of starting a new firm (Cavallo et al., 2019). It also discusses the development of entrepreneurship in a resource-constrained environment. It has been found that an entrepreneur is not only seeking the resources of equipment, space, and money, but also advice, information, and reassurance (Birley, 2000; Slavec and Prodan, 2012). Consequently, the help and guidance received from both the formal networks (banks, accountants, lawyers) and the informal networks (family, friends, business contacts) will influence the nature of the firm substantially (Birley, 1985; Watson, 2012). Network resources, networking activities, and network support are heavily used to establish new firms (Malecki, 2018). Further, entrepreneurs who can refer to a broad and diverse social network and who receive a great deal of support from their network tend to be more successful (Brüderl and Preisendörfer, 1998). It has also been found that entrepreneurs in resource-poor environments are able to render unique services by recombining the elements at hand for new purposes (Archer et al., 2022). They believe in making do with what is at hand (Baker and Nelson, 2005). Past literature clearly documents a direct nexus between resources, dynamic capabilities, and entrepreneurial success (Lu et al., 2010, Hitt et al., 2011). The resources can be categorized into various types such as tangible and intangible assets, financial resources, techniques, manpower, social networks, and goodwill (Huang, 2016). These resources act as a catalyst and with the presence of these resources, the speed of entrepreneurial success is enhanced (Huang, 2016). Along similar lines, dynamic capabilities are those high-level skills that integrate, reorganize, and configure the existing resources to improve the performance of the firms leading to entrepreneurial success (Raza et al., 2018).

Cluster 6: Cognitive learning and entrepreneurial success

This cluster represents two overlapping themes (light blue and orange). It discusses the learning attitude of an entrepreneur (Eliyana et al., 2020) and emphasizes a framework that identifies three main components in the process of entrepreneurial learning: entrepreneurs' career experience, the transformation process, and entrepreneurial knowledge in terms of effectiveness in recognizing and acting on entrepreneurial opportunities as well as coping with the liabilities of newness (Politis, 2005). An entrepreneur needs to possess a dynamic learning potential with three distinctive but interrelated elements of entrepreneurial learning, which are dynamic temporal phases, interrelated processes, and overarching characteristics (Cope, 2005). Apart from learning

attitude, self-efficacy, and achievement motivation are significantly correlated with both the choice of an entrepreneurial career and entrepreneurial performance (Collins et al., 2004; Staniewski and Awruk, 2019). Self-efficacy is the confidence of an entrepreneur that he/she is capable of various roles and tasks, which include marketing, innovation, management, risk-taking, and financial control (Chen et al., 1998; Bakkar et al., 2021). The entrepreneur's behaviour, such as the need for achievement, innovativeness, stress tolerance, need for autonomy, and proactive personality matches positively with the entrepreneur's objective of business creation and business success (Rauch and Frese, 2007).

The literature in this cluster also suggests that in firms led by entrepreneurs with a high degree of absorptive capacity, the chances of entrepreneurial success get amplified (Khan et al., 2020). Absorptive capacity refers to the firm's ability to generate innovation and facilitate learning (Cohen and Levinthal, 1990). Similarly, learning capabilities refer to the aggregate of skills that can help firms leverage competitive advantage in the markets through innovation (Barão et al., 2017), foster the growth of the firms, and equip them for market survival in the long run (Chang et al., 2012). Furthermore, these skills are the core aspects that help firms in effective management and lead to entrepreneurial success as well as improved performance (Khan et al., 2021).

5. DISCUSSION AND FUTURE RESEARCH AVENUES

The current study has answered the research questions significantly using bibliometric analysis as well as content analysis and has provided an overview of the topic of entrepreneurial success. The volume analysis has consistently shown an upward trend (RQ_1), starting from 6 documents in 1996 to a significant number of 91 documents in 2021. The number of documents from the year 2020 to 2021 showed the biggest jump. One of the major reasons for this was the need to capture the impact of the COVID-19 pandemic by researchers, which severely impacted almost every sector of the economy negatively, but had a positive impact on entrepreneurship (Sharma et al., 2022). The growing trend of publications shows that the research in this arena has not yet been saturated, and, therefore, future research scholars should continue to undertake studies that have implications for policymaking as well as practice. In terms of geographical distribution, the USA tops the list with 197 documents and leads both in quantity and quality of research, followed by the European countries of Germany, Netherlands, and the UK. These economies, being developed economies, understand the importance of entrepreneurship, and apparently provide several benefits and incentives encouraging people to contribute towards entrepreneurship (Distanont and Khongmalai, 2020). However, with a large number of startups and unicorns being recognized in developing countries as well, it is high time to undertake research on various entrepreneurial aspects through cross-country and multi-country studies that focus on emerging economies.

Considering the journals contributing towards entrepreneurship (RQ_2), the top position lies with the *Journal of Business Venturing,* which is a Scopus-listed, A* journal published by Elsevier. The high number of citations and ACPD describes the quality as well as the impact of the research published in this journal. Researchers in this area should gain insights from reading or publishing in such impactful journals. The most influential authors (RQ_3) in this domain belong to developed countries, but some developing countries like India and China have also been able to capture a spot. Michael Frese from Germany has contributed immensely to this field, with 6 documents and 1209 citations. The contributions of the top authors are highly valuable as they lay down the foundation for the development of various new concepts and enable cross-country studies on entrepreneurship. However, there is also a need for more collaboration among authors from different countries, affiliations, and backgrounds, in order to promote the integration of ideas as well as expertise. As far as the influential research documents are concerned (RQ_4), the 10 most cited papers have been published within the year range of 1988 to 2013. Two out of ten papers have been authored by Michael Frese and most of the papers are empirical in nature, which has helped in shaping the present research. Some of these impactful research articles build the basis for seminal work in the literature, and hence, are a must-read for academics as well as practitioners.

The evolution of the topics of research on entrepreneurial success (RQ_5) over the years highlights the interest of researchers in this domain and the dynamic nature of the topics. The cluster analysis conducted with the help of the co-citation method highlighted six prominent clusters, including the theories of entrepreneurial success, the drivers and factors, the role of women entrepreneurs, the significance of entrepreneurial orientation, the use of resources, and the importance of cognitive learning in the entrepreneurship literature. An insight into each of these major themes would shape the way a country encourages, supports, and facilitates the activities of entrepreneurial ventures.

In the early 2010s, the keywords that were frequently used were 'profitability', 'learning', 'technology', and 'marketing'. These topics still hold a relevant position in this field, both theoretically as well as practically, but after considering the dynamism of the environment, new topics have emerged (RQ_6), such as 'psychological capital', 'culture', 'entrepreneurial education', and 'women entrepreneurs'. Psychological capital is now being recognized as one of the most important assets of an entrepreneur as it enables them to keep going despite failures or rejection. Culture is another aspect that cannot be ignored by anyone who wants to innovate and run a

successful business venture, and, hence, research studies incorporating the understanding of culture in the success of a firm will soon take center stage. With many institutions now offering a course in entrepreneurship, and students keen on learning the requisite skills, the ability of entrepreneurial education to add relevance to the entrepreneurial culture also needs to be tested in various contexts. Finally, given the increasing role of women in the workforce and with them breaking the barriers, women's entrepreneurship is now becoming a separate area of study. Ideas based on these recently trending topics can be considered by scholars to fill the void in research. Moreover, these emerging themes will provide new dimensions for exploration in the field of entrepreneurial success.

5.2 Future Research Avenues

Entrepreneurial research is still emerging, because of which the scope of research in this field is immense. Some of the notable themes that could be turned into future research areas, as highlighted by the keyword analysis and the literature review, are as follows:

1) Impact of Psychological Capital

Psychological capital helps to examine the ability of the entrepreneur to recognize as well as exploit business opportunities (Ramos-Rodrıguez et al., 2010) and it, therefore, plays an essential role in the success of entrepreneurship (Baluku et al., 2016). Psychological capital comprises four elements: hope, efficacy, resilience, and optimism (Luthans et al., 2007). These factors work together inseparably and support an entrepreneur emotionally as well as mentally during stressful and pressurizing situations, leading to entrepreneurial success. The theme of entrepreneurship has seen dynamic changes where young college students are entering entrepreneurial ventures. Given this context, it would be fruitful to study the impact of various other emerging components of psychological capital, such as the role of self-efficacy (Maslakçı et al., 2022), the role of the personality traits and entrepreneurial intentions (Vaiz, and Ekemen) and diversity brought in by gender (Maslakçı et al., 2022), on the entrepreneurial success.

2) Studies on Entrepreneurship Education

With the rise in entrepreneurial activity, education in entrepreneurship plays an important role as the entrepreneurship failure rate is quite high (Cantamessa et al., 2018). An entrepreneur requires a basic set of skills and knowledge in various domains. The impact of education on entrepreneurial success is potentially strong as it helps an entrepreneur acquire and apply the diverse skills required to compete and be successful (Kolstad and Wiig, 2015). However, various aspects such as the role of teaching effectiveness in entrepreneurship (Liu et al., 2022), the role of social capital in building entrepreneurship education (Putro et al., 2022), the impact of entrepreneurship education on entrepreneurial creativity (Wang et al., 2022) are themes which require further exploration.

3) The Success of Women Entrepreneurs

Promoting women's entrepreneurship not only contributes toward economic development but the social development of the country as well (Jamali, 2009). The rate of growth of women entrepreneurs has witnessed an uprise and has positively impacted overall welfare and consumption (Minniti and Naudé, 2010). Earlier, entrepreneurship was considered a man’s domain (Jennings and Brush, 2013). But now, we are moving towards a more equitable world, with opportunities available to everyone without any discrimination among the genders. Moreover, the motivation and challenges of being a women entrepreneur vary significantly across nations (Rastogi et al., 2022). Nevertheless, raising finance as women entrepreneurs is another set of dynamic issues (Shaikh et.al., 2022) which needs to be addressed to promote more and more women entrepreneurs.

4) Culture-Specific Studies

Each nation possesses a different culture, and an entrepreneur is obliged to respect and follow the country’s culture to grow and survive. Numerous research studies have taken place concerning culture and entrepreneurship over the years (Lounsbury et al., 2019; Audretsch, 2020). It is difficult to make generalizations about different nations that have different cultures or levels of economic development (Siu and Lo, 2013), but at the same time, cross-cultural innovation (Stephan, 2022) can prove to be significant from the market’s point of view if explored in the right direction. Recent literature also points towards the importance of adequate training in building a corporate culture (González-Tejero and Molina, 2022), which can push entrepreneurial ventures for small and medium enterprises (SMEs). Therefore, an entrepreneur needs to be aware of a country’s culture before taking any decisions, while at the same time, policies made by a country should cater to entrepreneurial activities with the country’s culture in mind (Uddin and Akther, 2019). There is still a lot of scope in this topic as culture is a sensitive topic that has the feeling of society attached to it.

This study has theoretical as well as practical implications as the outcomes can be used not only by future scholars but also by budding entrepreneurs in searching for gaps and opportunities and taking suitable actions on

the same. It will help the existing entrepreneurial ventures with better decision-making as well as provide early access to future opportunities and the detection of threats. The literature talks about the importance of entrepreneurial education, which is equally or even more important compared to other subjects. If taken care of, it can lead to a rise in entrepreneurial activities, thereby enabling the economic growth of the country. Thus, entrepreneurship, if explored effectively, can prove to be one of the most effective tools for the economic growth and development of a nation.

6. CONCLUSION

This study has relied on bibliometric analysis, combined with content analysis, to understand the domain of entrepreneurial success in a detailed manner and elaborate on the main trends, themes, and research trajectories of this field of study (Gao et al., 2021).

The study highlighted the various countries leading in terms of publications on entrepreneurial success, some of which are the USA, Germany, Netherlands, and the UK. The list consisted of both developed as well as developing countries, but the developed countries dominated the list, with around 90% of the publications. Subsequently, the study analyzed top journals publishing on entrepreneurship and related topics. The list consisted of 40% journals from business domains and the rest from other disciplines like management, economics, psychology, education, and history. As far as the author's contributions are concerned, the most influential authors mainly belong to Germany and parts of Europe, which sheds light on the quality of research and research opportunities in Europe. It also shows that the *Journal of Business Venturing* is the top journal publishing articles related to entrepreneurship, as 50% of the top articles were published in the same journal. The most influential articles broadly talk about four domains, which are psychology, gender, family, and success. The study also explored the evolution of entrepreneurial research topics over the years, followed by the identification of 6 clusters, which were examined further through content analysis. Future research agendas are elaborated upon based on the emerging topics and themes of study in the entrepreneurial success literature.

Although the analysis consists of all the relevant research questions required for the scholars working on the topic, it suffers from certain limitations. The study relies on the Scopus citation database only, because of which some studies, which are beyond the coverage of the Scopus database, might have been overlooked. Another point to be considered is that the bibliometric analysis may favour old researchers (Wang et al., 2017), due to its tendency to research by data rather than judgement. But it is noteworthy that a high number of citations do not represent a high impact on scientific results (Drew et al., 2016).

Abstract
Magnetorheological shear thickening polishing (MRSTP) was experimentally demonstrated to achieve nano-level surface quality in previous studies. The aim of work is to further investigate numerical simulation and material removal characteristics during the MRSTP process. The apparatus of magnetic field generation was designed and developed. The model of magnetic field distribution was imported to computational fluid dynamics (CFD) module to generate desired polishing environment. Polishing stress behaviors were analyzed based on various polishing parameters through the CFD simulation results. It was found that the pressure on the workpiece surface decreased with the increase of the rotational speed of the workpiece while it increased with the increase of the flow velocity of the MRSTP media. A continuous increment in shear stress on the workpiece surface was observed with the increase of the rotation speed of the workpiece and the flow velocity of the MRSTP media. Based on the characteristics of polishing pressure, material removal rate (MRR) model of MRSTP process was established. A serial of MRSTP experiments were conducted on aluminum 6061. Surface roughness (Sa) of 79.0 nm was obtained, which was improved over 77%. The simulated model and MRR model were experimentally validated. The average error between theoretical and experimental results was 4.1%. It can provide a useful guidance for the novel MRSTP process.

Keywords Magnetorheological shear thickening polishing · Numerical simulation · Force characteristics · Material removal model

1 Introduction

Magnetic field assisted polishing (MFAP) methods have become one of research hotspots due to their flexibility, self-sharpening and self-adaptability for the recent years. MFAP methods are widely employed for polishing various hard-to-process materials, such as silicon, sapphire, glass, ceramic, superalloy. Barman et al. [1] investigated the influence of magnetorheological (MR) polishing fluids with different compositions on polishing performance. Two different MR fluids were utilized to polish the bio-titanium alloy to obtain hydrophilic and hydrophobic surfaces, respectively. Zhai et al. [2] proposed ultrasound assisted magnetorheological polishing (UAMP) on sapphire and established a material removal rate (MRR) model of UAMP based on the Preston equation. The feasibility of this model was experimentally verified. Luo et al. [3] conducted polishing experiments on zirconia ceramics using MRP method. Surface roughness R_a of zirconia ceramics decreased to 0.702 nm from initial 71.976 nm using diamond abrasive particles. The maximum material removal rate of 1 mg/min was attained. Yamaguchi et al. [4] employed magnetic abrasive finishing (MAF) method to improve the tool life of uncoated WC/Co cutting tool. It was concluded that the cutting tool life was improved by 150%. Li et al. [5] performed a hybrid post-processing of MAF and heat treatment (HT) on the surface of 3D-printed Inconel 718 alloy. The surface roughness Ra of the workpiece decreased to 0.15 μm from initial 2.7 μm. The hybrid post-treatment of MAF and HT demonstrated that the mechanical properties such as yield strength and elongation of the Inconel 718 alloy manufactured in additive form

were significantly improved. Umehara et al. [6] designed and fabricated a novel magnetic floating polishing platform for large-size and large-volume silicon nitride (Si_3N_4) balls. The polishing process was divided into three stages i.e., roughing stage, intermediate stage and finishing stage. The surface roughness Ra of the polished silicon nitride (Si_3N_4) balls decreased to 6.70 nm from initial 937.14 nm.

For the MFAP method, a lot of numerical simulations were employed to understand the effects of processing parameters on the polishing performance before the experiments were conducted. This facilitated the simplification of tests and efficiency improvement. Kumar et al. [7] investigated the mechanism of magnetorheological polishing on miniature tooth contours where the forces on the surface of the micro-gear were simulated using COMSOL software. A surface roughness model of polished micro-gear was established using simulation results. Wang et al. [8] proposed a new magnetic field assisted mass polishing technology for efficient polishing of multiple free-form parts simultaneously. The effect of magnetic field on the material removal characteristics was analyzed by the finite element method. The factors affecting surface generation were investigated by polishing experiments. The results showed that magnetic field assisted mass polishing could effectively polish multiple free-form parts with nano-level surface finish. Liu et al. [9] simulated the three-dimensional profile of the polishing points during magnetorheological polishing. A material removal rate (MRR) model considering pressure and shear stress was developed using the simulation results, which was verified for accuracy. Sharma [10] simulated the magnetic field strength of the newly designed magnetorheological polishing equipment. A mathematical model of the relationship between surface roughness and magnetic field strength was established. The results showed that the surface roughness decreased with the increase of magnetic field strength. Grover et al. [11] designed a magnetorheological polishing equipment for polishing cylindrical inner surfaces using radially curved permanent magnets. Simulation of the magnetic field strength of this radially curved permanent magnet was conducted. A mathematical model for predicting surface roughness was developed based on the results of the simulation. After validation, the maximum error of the model was 8.06%. Guo et al. [12] designed a novel magnetorheological polishing equipment with Halbach array for quartz specimens. The magnetic field strength of Halbach array was simulated to verify its large area and high strength. The surface roughness of the quartz specimen eventually improved up to 0.544 nm after polishing.

An accurate material removal model is of benefit to provide theoretical guidance and reveal the polishing mechanism. Great efforts have been made to establish the predictive material removal model for the MFAP. Zhai et al. [2] developed a material removal model for magnetorheological polishing where the coupling effect of magnetic and vibrational fields was considered. It was verified that the relative error between the theoretical and experimental results was less than 20%. Chen et al. [13] established a two-dimensional material removal model for magnetorheological polishing based on hydrodynamic theory and the Preston equation. The rationality of the material removal model was verified by comparing the experimental results with the simulation results. The error between the model and the experimental results was 9.8%. Ming et al. [14] established a material removal model for a non-Newtonian fluid polishing method based on weak magnetorheological strengthening thickening effects. The model was developed using non-Newtonian fluid kinematics. The average error between the model and experimental results was 4.45%. Li et al. [15] established a material removal model for the magnetic abrasive finishing method using fluid abrasives in which the effect of magnetic fields on material removal was considered. This model agrees to the experimental results with an average error of 4.51%.

In our previous studies, magnetorheological shear thickening polishing (MRSTP) was proposed as a novel magnetic field assisted polishing process which combined the magnetorheological effect with the shear thickening effect together [16–19]. As one of loosed abrasive polishing methods, MRSTP possesses excellent adaptability and processing efficiency. It has a magnetorheological effect that enables the rapid formation of magnetically enhanced particle clusters in the polishing media under the excitation of a magnetic field [16]. These clusters exert much stronger holding force on the abrasive particles, which makes the polishing process more efficient than the traditional MFAP. Additionally, MRSTP has a shear thickening effect during polishing, which results in larger shear stress on the workpiece surface than the conventional MRF. Due to its high adaptability and efficiency, MRSTP has been used to polish various difficult-to-machine materials [16–19]. MRSTP media was prepared by mixing a certain proportion of polyethylene glycol (PEG 200), SiO_2, abrasives, carbonyl iron powder (CIP) and chemical additives [16]. Simulation of the magnetic field strength of the magnetic field generation device was performed to verify the rationality of the structure [17]. The magnetic field generator and the modified magnetic abrasive were used to polish the titanium alloy Ti-6Al-4 V. Surface roughness of workpiece reduced from 1.17 μm to 54 nm. Also, in a case MRSTP media were specially developed for titanium alloy under the action of a four-pole rotating magnetic field [18]. The surface roughness of titanium alloy Ti-6Al-4 V was reduced from 169 to 61 nm and the effectiveness of this polishing media was verified. A new magnetic field generation device was designed which was capable of generating alternating magnetic fields for the additive manufacturing of 361L rectangular micro-fabricated structures[19]. Material removal rate models were developed and processing experiments

were conducted. The results showed that the top and bottom of the rectangular microstructure were uniformly removed from the material. The feasibility of machining additively manufactured workpieces with MRSTP media was verified.

Nevertheless, recent studies on MRSTP were focused on processing experiments and simulation of magnetic fields. The coupling simulation of magnetic and flow fields in the MRSTP process with CFD methods was not explored. Therefore, in this work, CFD simulations of the designed MRSTP apparatus were carried out using Maxwell and Fluent modules in ANSYS software. It aimed to investigate the pattern of influence of polishing parameters on the polishing force applied to the workpiece surface. A mathematical model between MRR and polishing parameters was developed using the output of the normal forces from the CFD simulation results. The accuracy of the MRR model and the validity of the simulation results were verified by experiments.

2 Principles

Figure 1 shows the principle of MRSTP. MRSTP media are distributed inside polishing bowl which is fixed on the rotary table of either CNC machine or industrial robot. The magnetic field generation device is mounted below the polishing bowl. The workpiece is clamped onto the spindle bottom of either CNC machine or industrial robot. Under the action of the magnetic field, the MRSTP media form magnetic-force-reinforced flexible abrasive clusters. As the magnetic field has adsorption effect on the CIP, the shear rate of the MRSTP media will decrease when they flow through the magnetic field. This is macroscopically expressed as an increase in the apparent viscosity of the MRSTP media. The MRSTP media move in a circular motion driven by the rotary polishing bowl. The CIP and abrasive grains in the magnetic-force-reinforced flexible abrasive clusters are constantly renewed and pass through the immersed workpiece. The relative velocity between the MRSTP media and the workpiece is easily controlled by the spindle and the rotary table of either CNC machine or industrial robot.

3 Design of magnetic field generation device

Figure 2 shows the three-dimensional model and two-dimensional model of the magnetic field generation device. The device comprises of two magnetic pole mounts and twelve magnetic poles. The two pole mounts were made of Steel 45 with twelve holes (i.e., each mount had six poles) for holding the magnetic poles. The six poles were divided into three sets i.e., the top set, the middle set and the bottom set. The middle set were designed at an angle of 120° to the bottom sets. The material of all twelve poles was chosen as N38. The distribution of the magnetic field was simulated using Maxwell software. The materials defined in the model for the magnetic field generation device were same as those used in the actual polishing process. Three lines were planned for the measurement of magnetic field strength as shown in Fig. 2. The magnetic field intensity along the design path was measured using a Gauss meter (Model: GM 500).

Figure 3 shows the results of the magnetic field simulation. It can be seen that the magnetic force lines uniformly distributed in the polished area while magnetic field intensity were still strong around the workpiece. The maximum magnetic field strengths of 525.7 mT and 527.1 mT were obtained at the starting points of lines 1 and 3, respectively. Along line 1 and line 3, the magnetic field strength decreased with the increase of the distance. A maximum magnetic field strength of 183.3 mT was obtained at 3 mm away from the starting point of the line 2. As shown in Fig. 3 (a), since the magnetic force lines at the starting point of line 2 was not close to the magnetic field generating device, the magnetic field strength along line 2 firstly increased and then decreased with the distance increasing from the starting point.

Figure 4 shows the comparisons of magnetic field intensity between the simulation and experimental results. It

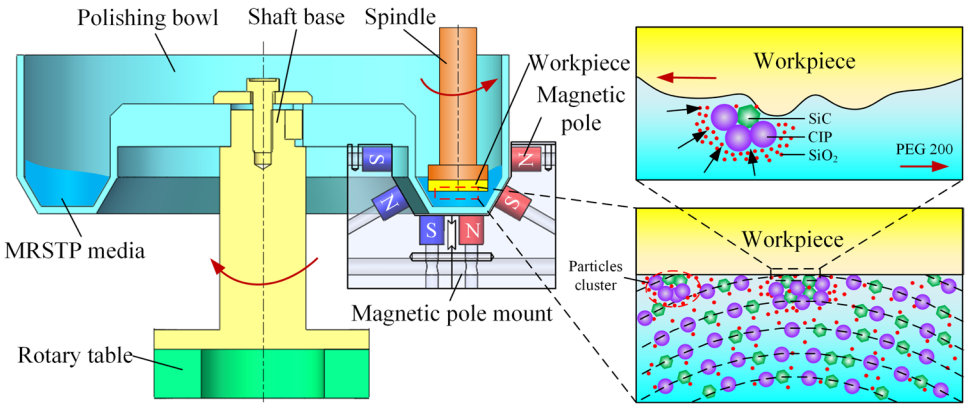

Fig. 1 Principle of the MRSTP

can be seen that the measured magnetic field strengths are consistent with the simulation values. The measured values at the starting point of the line 1 and line 3 were 315.4 mT and 367.0 mT, respectively. The measured value was 125.3 mT at 3 mm away from the starting point of the line 2. The validity of the simulation was verified.

4 Numerical simulation of flow field

4.1 Computational fluid dynamics methods

The flow field of the MRSTP process was numerically simulated using Ansys Fluent. Mixture models including STFs, CIP, SiC

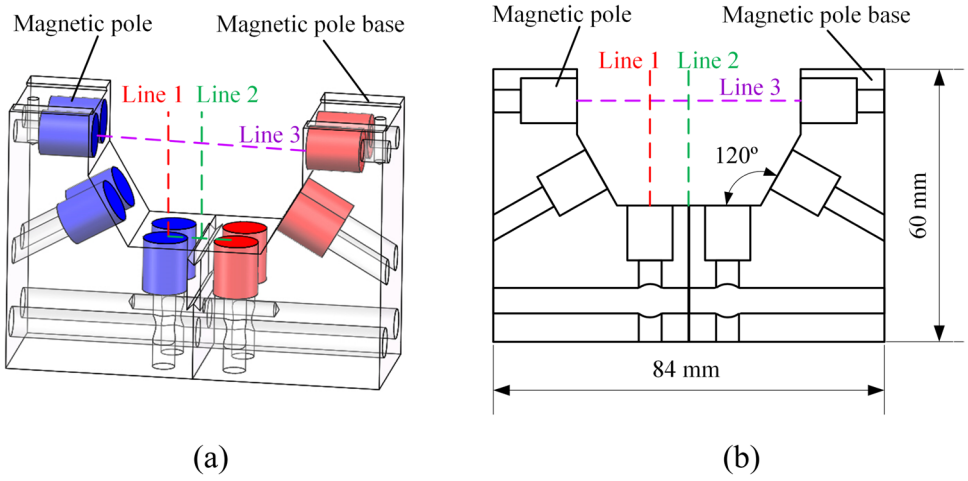

Fig. 2 Model of magnetic field generating device. (**a**) 3D model, (**b**) 2D model

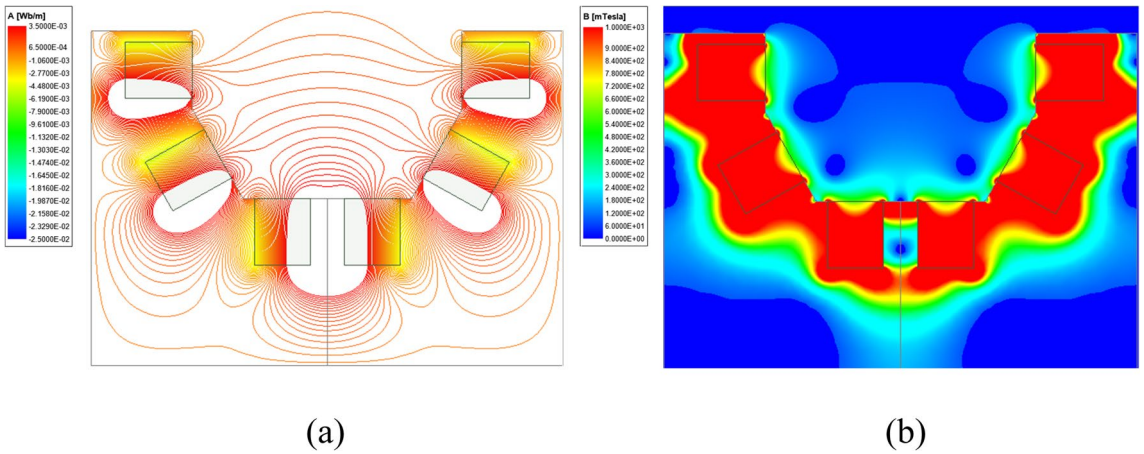

Fig. 3 Maxwell simulation results. (**a**) Distribution of magnetic force lines, (**b**) Distribution of magnetic field intensity

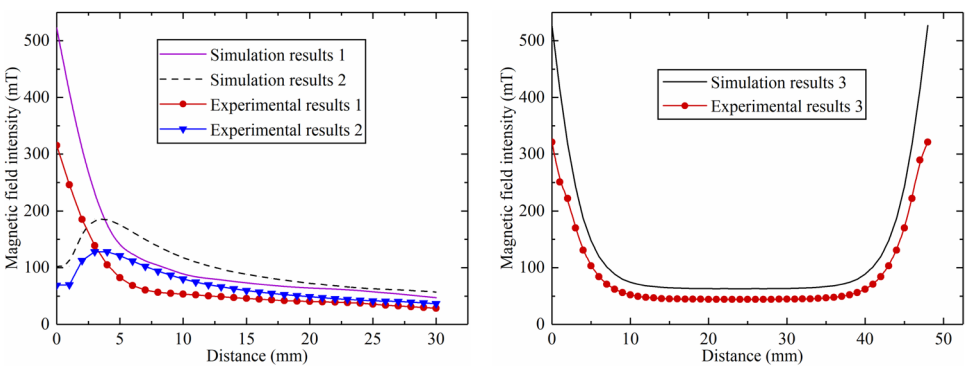

Fig. 4 Comparisons of magnetic field intensity between simulations and experiments

and other multiphase blends were used. The output from Maxwell was coupled using the MHD module in Fluent to simulate the magnetic field environment in the flow field. The following assumptions were made during this numerical simulation: (i) The workpiece was an ideal rigid material. (ii) The processing environment temperature was controlled at 25℃. In the MRSTP process, it was assumed that the fluid was incompressible and operated in a constant temperature environment. Hence, the continuity and momentum equations for incompressible viscous fluids were used to describe the motion state of the MRSTP media [20]:

$$\frac{\partial u}{\partial x}+\frac{\partial v}{\partial y}+\frac{\partial w}{\partial z}=0 \tag{1}$$

$$\begin{cases}\frac{\partial u}{\partial t}+(V\cdot\nabla)u=f_x-\frac{1}{\rho}\frac{\partial p}{\partial x}+\frac{1}{\rho}\left(\frac{\partial \sigma_{xx}}{\partial x}+\frac{\partial \tau_{yx}}{\partial y}+\frac{\partial \tau_{zx}}{\partial z}\right)\\ \frac{\partial v}{\partial t}+(V\cdot\nabla)v=f_y-\frac{1}{\rho}\frac{\partial p}{\partial y}+\frac{1}{\rho}\left(\frac{\partial \sigma_{yy}}{\partial y}+\frac{\partial \tau_{zy}}{\partial z}+\frac{\partial \tau_{xy}}{\partial x}\right)\\ \frac{\partial w}{\partial t}+(V\cdot\nabla)w=f_z-\frac{1}{\rho}\frac{\partial p}{\partial z}+\frac{1}{\rho}\left(\frac{\partial \sigma_{zz}}{\partial z}+\frac{\partial \tau_{xz}}{\partial x}+\frac{\partial \tau_{yz}}{\partial y}\right)\end{cases} \tag{2}$$

where V is the velocity of the fluid. u, v, and w are the components of the fluid velocity in the x, y, and z directions. ρ is the density of the fluid. p is the pressure of the fluid. f is the mass force acting on the fluid. σ and τ are stress components.

The magnetic force on the fluid in the MHD model can be calculated by the following equation:

$$\begin{cases}\vec{f}_{m,x}=\mu_0\left(\vec{M}_x\frac{\partial H_x}{\partial x}+\vec{M}_y\frac{\partial H_x}{\partial y}+\vec{M}_z\frac{\partial H_x}{\partial z}\right)\\ \vec{f}_{m,y}=\mu_0\left(\vec{M}_x\frac{\partial H_y}{\partial x}+\vec{M}_y\frac{\partial H_y}{\partial y}+\vec{M}_z\frac{\partial H_y}{\partial z}\right)\\ \vec{f}_{m,z}=\mu_0\left(\vec{M}_x\frac{\partial H_z}{\partial x}+\vec{M}_y\frac{\partial H_z}{\partial y}+\vec{M}_z\frac{\partial H_z}{\partial z}\right)\end{cases} \tag{3}$$

where μ_0 is the vacuum permeability. M_x, M_y and M_z are the components of the magnetization intensity in the x, y, and z directions. H_x, H_y and H_z are the component of the magnetic field intensity in the x, y, and z directions.

The motion pattern of the fluid can be obtained from the calculation formula of Reynolds number Re:

$$Re=\frac{\rho\bullet v\bullet d_{re}}{\mu} \tag{4}$$

where ρ is the density of the fluid, v is the velocity of the fluid, μ is the dynamic viscosity of the fluid, d_{re} is the characteristic length of the fluid. The flow state of the MRSTP media was determined to be laminar based on the experimental parameters calculated as $\mathrm{Re}<2320$. The SIMPLE algorithm was used to solve the coupled velocity–pressure problem. Since the diffusion effect in the MRSTP media flow process could be neglected, it was a pure convection problem and the discrete format for establishing the discrete equations adopted the second order windward format.

4.2 Geometric model for numerical simulation

Figure 5 shows the geometric model for the numerical simulation in the software of Ansys Fluent. In order to reduce the computational effort and facilitate the computational convergence, the circular polishing bowl of MRSTP was designed as a linear polishing trough. This linear polishing trough had a velocity inlet on one side and a pressure outlet on the other side. The wall of the polishing trough was defined as non-slip wall surface. The wall of the workpiece was set up as rotational wall surface. As the top surface of the polishing trough was MRSTP medium, it was defined as symmetric boundary. In order to improve the computational accuracy, the polished trough was unstructured meshed. The grid size was chosen as 1 mm while the grid was encrypted near the workpiece with size of 0.5 mm. The magnetic field simulation results from the Sect. 3 were further processed and loaded into the software of Ansys Fluent. The loading results are shown in Fig. 5 (c). There was not any distortion observed in the magnetic field and the loading results were accurate. Two lines, AB and CD, were set up on the workpiece surface as the output locations of pressure and shear force in the simulation results, respectively.

4.3 Input parameters for numerical simulation

The simulation input parameters are listed in Table 1. The effects of with the rotational speed of workpiece and the flow velocity of the MRSTP media on the normal pressure and shear force on the workpiece surface were investigated. The maximum magnetic field strength was obtained along line 2 at 3 mm from the starting point as shown in Fig. 4 (a). Considering the existence of excitation gap and the thickness of polishing bowl in the actual processing, the gap between the workpiece and the bottom of the polishing trough was set up as 1 mm.

The rheological profiles of the STFs were measured in order to give shear thickening effect to the MRSTP media during the numerical simulation [16]. When the shear rate is less than the critical shear rate, STFs show shear thinning action. When the shear rate is between the critical shear rate and the maximum shear rate, the STFs show shear thickening action [21–23]. When the shear rate is greater than the maximum shear rate, the STFs show a shear thinning action. The viscosity of the STFs was defined in FLUENT using this rheological curve via programming with C language (Fig. 6).

4.4 Analysis of simulation results

4.4.1 Variation of normal pressure

In the Preston equation, the material removal rate during polishing is associated to the normal pressure on the surface of the workpiece and the velocity of the relative motion

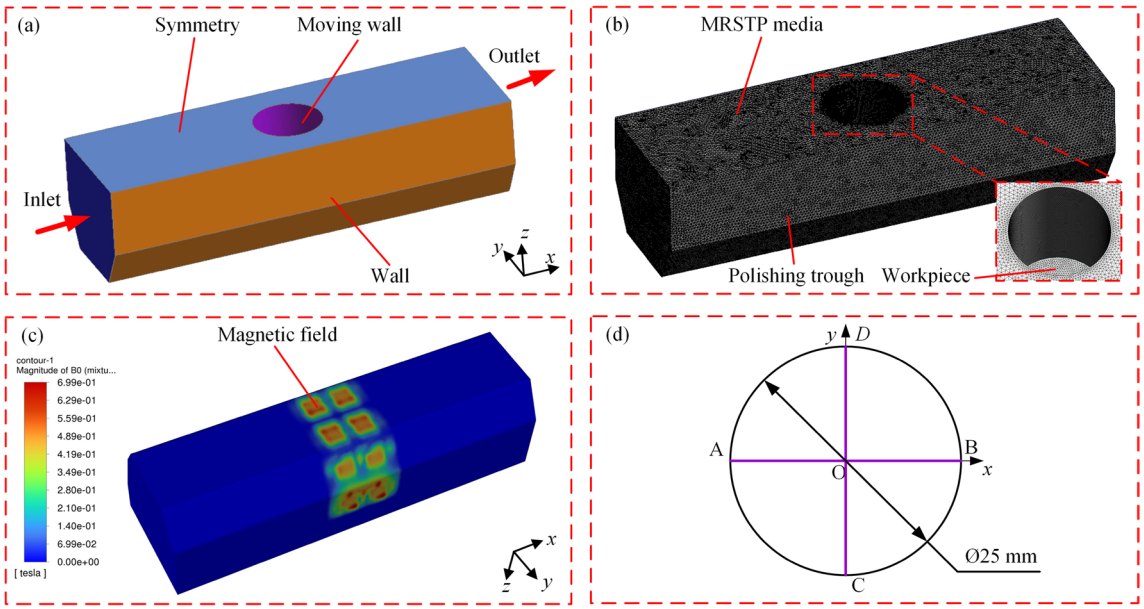

Fig. 5 Simulation models. (**a**) 3D model of a linear polishing trough, (**b**) Grid division, (**c**) Results of magnetic field loading, (**d**) Position of the force measurement on the surface of the workpiece

Table 1 Input parameters used for simulation study

Items	Values
Workpiece rotational speed (rpm)	1000, 1500, 2000
Flow velocity of MRSTP media (m/s)	0.8, 1.2, 1.6,
Working gap (mm)	1
Density of STFs (kg/m^3)	1796.64
Volume fraction of CIP	5.1%
Volume fraction of SiC	4.2%
Workpiece material	6061

between the workpiece and the polishing fluid [24]. Therefore, it is essential to investigate the normal pressure distribution and variation on the workpiece surface through numerical simulation of the flow field.

Figure 7 shows the variation of normal pressure distribution versus different workpiece rotational speeds with the increase of working distance at the MRSTP media velocity of 0.8 m/s. It can be seen that the normal pressure distribution on the surface of the workpiece decreased along the *x*-direction and almost unchanged along the *y*-direction. This main reason was because the MRSTP media flowed along the *x*-direction. When the MRSTP media flowed under the workpiece, the height of the flow channel suddenly became narrow that made the MRSTP media to gather over one side of the workpiece and generated great pressure on the workpiece surface. Meanwhile, due to the high kinetic energy of the MRSTP media, the strong impact produced a large normal pressure on the surface of the workpiece when the

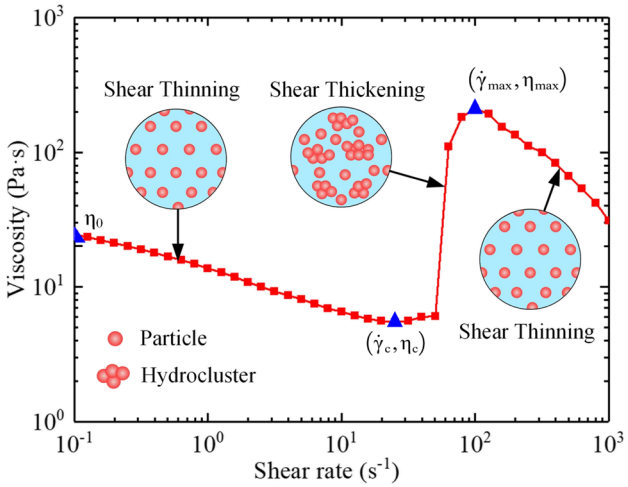

Fig. 6 Variation of STFs viscosity with shear rate

media got to touch the workpiece surface. As the kinetic energy of the MRSTP media was gradually consumed with the flow of MRSTP media over the workpiece surface, the normal pressure on the workpiece surface slightly decreased.

The normal pressure on the workpiece surface gradually decreased as the workpiece rotational speeds increased from 1000 to 2000 rpm. As the rotation speeds of the workpiece increase, the MRSTP media underneath the workpiece will be driven by the workpiece to increase the flow rate. In this case, the normal pressure on the surface of the workpiece decreased, which was in accordance with the description of Bernoulli's principle.

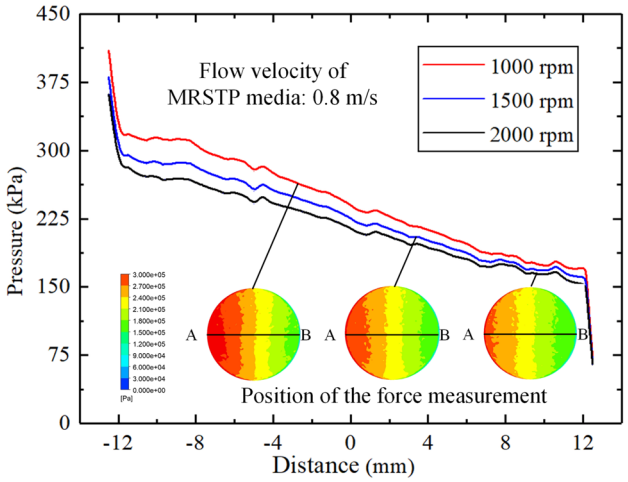

Fig. 7 Variation of normal pressure distribution versus workpiece rotational speed

Figure 8 shows the variation of normal pressure distribution versus the MRSTP media flow velocity of 0.8 m/s, 1.2 m/s and 1.6 m/s with the increase of working distance at the workpiece rotational speed of 2000 rpm. With the increase of flow velocity of MRSTP media, the normal pressure on the surface of the workpiece gradually increased as the kinetic energy became large.

4.4.2 Variation of shear stress

Shear stress is mainly caused by the fluid viscosity when the fluid media flow through the workpiece contact surface. In the ultraprecision polishing with non-newton fluid, material removal from the workpiece surface is not only related to the normal pressure but also the shear stress on the workpiece.

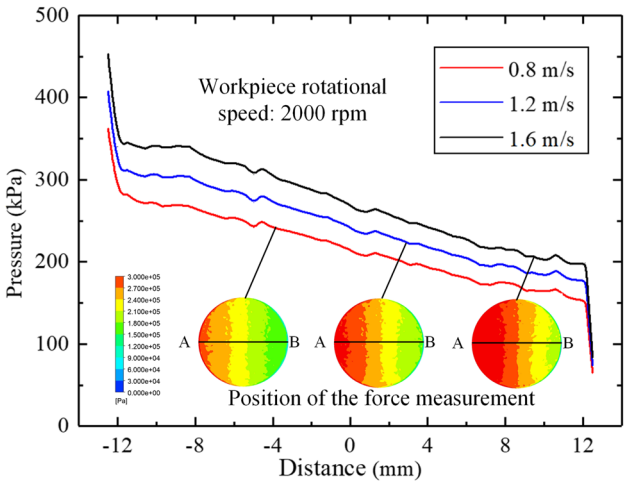

Fig. 8 Variation of normal pressure distribution versus flow velocity of MRSTP media

Therefore, it is also important to investigate the effect of processing parameters on the shear stress.

Figure 9 shows the variation of shear stress distribution on the workpiece surface along the *y*-direction versus different workpiece rotational speed with the increase of working distance the MRSTP media flow velocity of 0.8 m/s. It was seen that the minimum shear stress value appeared near the low side of the workpiece. This was attributed to the combined effects between workpiece rotation and MRSTP media flow. During the numerical simulation, the flow direction of the MRSTP media was set along *x*-direction and the workpiece rotational speed was defined as counter clockwise as labelled in Fig. 9. Hence, along the *y*-axis, the linear velocity of the workpiece and the flow velocity of the MRSTP media gradually varied from the same direction to the opposite direction. This caused that the minimum shear rate in the polishing process occurred close to the point C. When the workpiece rotational speed increased, the shear stress near the D point increased. Meanwhile, the location of the minimum shear stress on the workpiece surface gradually moved upward.

Figure 10 shows the variation of shear stress distribution versus MRSTP media flow velocity of 0.8 m/s, 1.2 m/s, and 1.6 m/s with the increase of working distance at the workpiece rotational speed of 2000 rpm. As the MRSTP media flow velocity increased, the shear stress near the D point increased. The location of the minimum shear stress on the workpiece surface gradually shifted downward.

It was found that the maximum normal pressure on the workpiece surface occurred at the point A while the maximum shear stress occurred at the point D in the MRSTP as shown in Figs. 9 and 10. With the increase the workpiece rotational speed, the normal pressure on the workpiece surface decreased while the shear stress increased. It might lead to nonuniform polishing due to the upward shift of

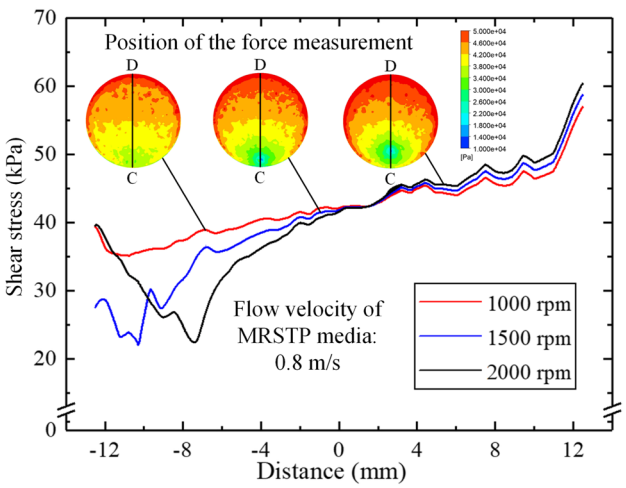

Fig. 9 Variation of shear stress versus workpiece rotational speed

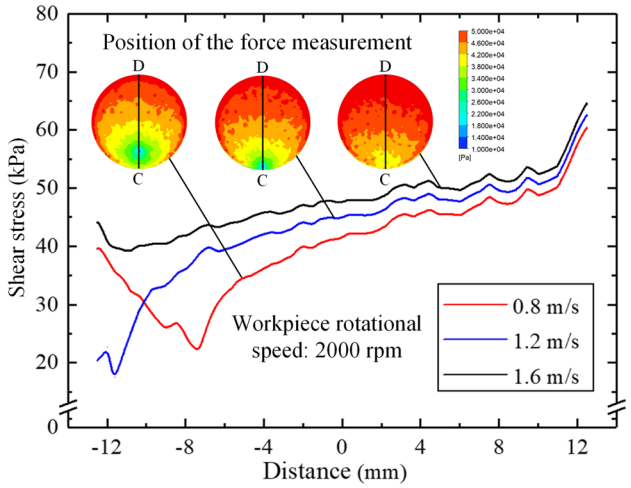

Fig. 10 Variation of shear stress versus flow velocity of MRSTP media

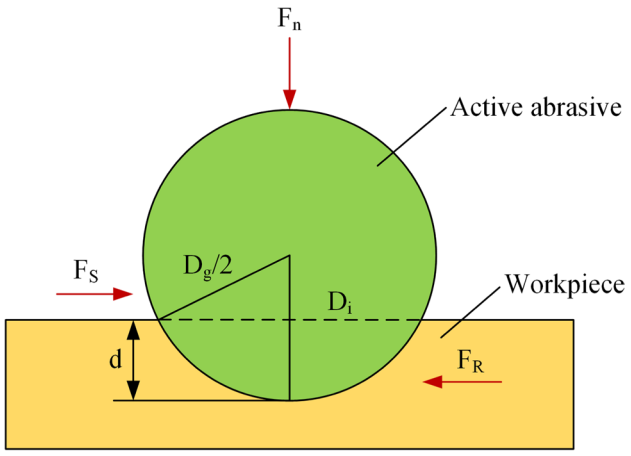

Fig. 11 Illustration of acting force of a single grain on workpiece surface

the minimum shear stress location. As the MRSTP media flow velocity increased, both the normal pressure and shear forces on the workpiece surface became large. Due to the downward shift of the minimum shear stress location, the polishing uniformity of the workpiece surface was positively affected. Hence, in the actual MRSTP process, the polishing efficiency and uniformity would be improved with low workpiece rotational speed and high the MRSTP media flow velocity.

5 Modeling of material removal rate

5.1 Forces in the MRSTP process

Figure 11 shows illustration of the acting force of a single abrasive grain on workpiece surface during MRSTP process. Under the action of the normal pressure F_n, the abrasive grain generates an indentation depth d on the workpiece surface. Because of the relative movement between the workpiece and the media fluid, the abrasive grain is subjected to the shear force F_s. When the reacting force F_R is less than the shear force F_s, the relative motion of the abrasive grain occurs to achieve the material removal on the workpiece [25, 26].

According to the Preston equation [27–29] as expressed as below.

$$MRR = k \cdot p \cdot v \tag{5}$$

where k is the Preston coefficient, p is the normal pressure applied to the workpiece surface, and v is the instantaneous relative velocity of the workpiece surface at the point of contact with the media, the material removal rate is a function of the normal pressure on the workpiece surface and the relative velocity between the workpiece and the media. The normal pressure on the workpiece surface during MRSTP consist of the three components i.e. the fluid dynamic pressure P_d, the floating force of the polishing media P_f and the magnetic pressure P_m [14]:

$$p = p_d + p_f + p_m \tag{6}$$

As both the rheological properties of the STFs and the magnetic field on the kinematic state of the MRSTP media were considered in the numerical simulation (Sect. 4. 2), the pressure in the numerical simulation was the sum of the mentioned the three different pressures viz: P_d, P_f and P_m.

According to the simulation results, the normal pressure distribution on the workpiece surface was almost unchanged along the y-axis direction while the normal pressure on the workpiece surface decreased along the x-axis direction. To simplify the calculation, the surface of the workpiece was divided into N bar areas as shown in Fig. 12.

When N is infinite, all these N regions could be considered as rectangular regions. At this point, the normal pressure in the region D_i ($i = 1, 2, 3 \ldots N$) are equal at each point, the normal pressure was defined as p_i ($i = 1, 2, 3 \ldots N$). Therefore, the total pressure on the region D_i can be calculated as:

$$p_{\mathrm{i}} = \overline{p}_i \cdot S_{Di} \tag{7}$$

$$S_{Di} = \frac{50}{N} \cdot \sqrt{25^2 - \left(25 - \frac{25}{N} i\right)^2} \tag{8}$$

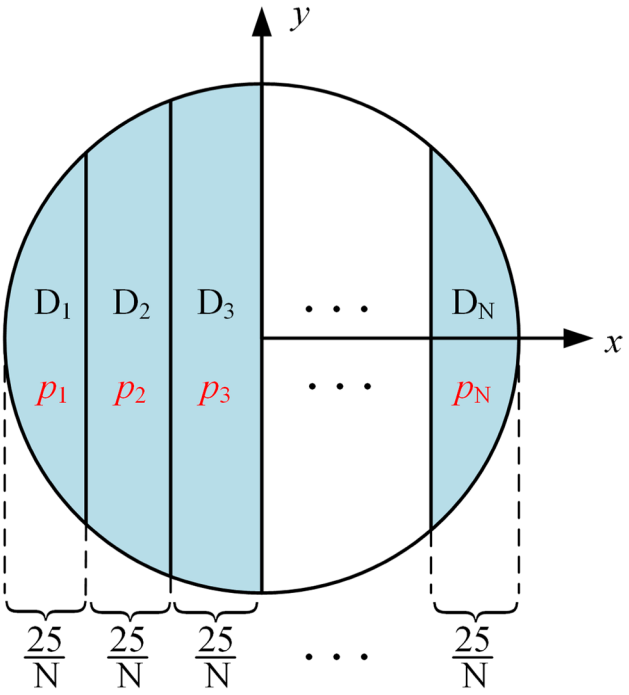

Fig. 12 Area division of the workpiece surface

where S_{Di} is the area of region D_i. Thus, when N tended to infinity, the total pressure on the workpiece surface can be expressed as:

$$p = \lim_{N\to+\infty} \sum_{i=1}^{N} p_i \tag{9}$$

Substituting Eq. (5), (6) into Eq. (7), it was yielded as:

$$p = \lim_{N\to+\infty} \sum_{i=1}^{N} \overline{p}_i \cdot \frac{1250}{N} \cdot \sqrt{\frac{i}{N}\left(2-\frac{i}{N}\right)} \tag{10}$$

5.2 Relative velocity in the MRSTP process

Figure 13 shows a simplified kinematic model of the MRSTP. O_1 is the rotation center of the spindle and O_2 is the rotation center of the rotary table. The xO_1y coordinate system is established with O_1 as the coordinate origin. ρ is the radius of the polishing bowl and ρ_0 is the eccentric distance between the spindle and the rotary table. It is assumed that the workpiece rotated around the spindle with angular velocity ω_1 and the polishing bowl rotated around the rotary table with angular velocity ω_2. The linear velocity of any point P on the surface of the workpiece is $\boldsymbol{v_1}$ about O_1 and $\boldsymbol{v_2}$ about O_2. Hence, the sum of $\boldsymbol{v}_1$ and $\boldsymbol{v}_2$ is the instantaneous relative velocity $\boldsymbol{v}$ at the point of contact between the

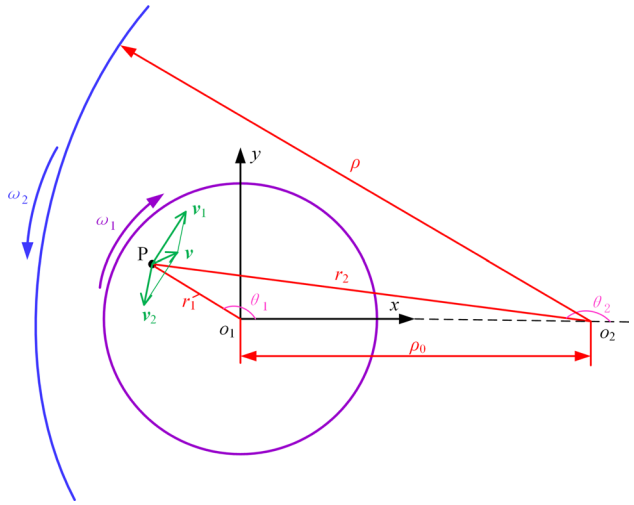

Fig. 13 A simplified kinematic model of the MRSTP

workpiece surface and the MRSTP media. The bit vectors of point P about O_1 and O_2 are defined as $\boldsymbol{r}_1$ and $\boldsymbol{r}_2$, respectively. The included angles of the line between P and O_1 and the line between P and O_2 in the positive direction of the x-axis were θ_1 and θ_2, respectively.

The relative velocity of the workpiece and MRSTP media at point P can be expressed as:

$$\vec{v} = \vec{v}_1 + \vec{v}_2 \tag{11}$$

$$\begin{cases} \vec{v}_1 = -\vec{r}_1 \cdot \omega_1 \\ \vec{v}_2 = \vec{r}_2 \cdot \omega_2 \end{cases} \tag{12}$$

The velocities $\boldsymbol{v}_1$ and $\boldsymbol{v}_2$ along the x and y axes are decomposed, respectively. Meanwhile, according to the formula for relative velocity v and the geometric relationship as shown in Fig. 13, the formulas are deduced as below.

$$v = \sqrt{v_x^2 + v_y^2} \tag{13}$$

$$r_2 = \sqrt{\left(r_1 \sin\theta_1\right)^2 + \left(\rho_0 - r_1\cos\theta_1\right)^2} \tag{14}$$

$$\cos\left(\theta_1 - \theta_2\right) = \frac{r_1^2 + r_2^2 - \rho_0^2}{2r_1 r_2} \tag{15}$$

The instantaneous relative velocity of the contact point between the workpiece surface and the MRSTP media is obtained as below [30]:

$$v = \sqrt{r_1^2\left(\omega_1 - \omega_2\right)^2 + \rho_0^2\omega_2^2 + 2r_1\rho_0\left(\omega_1 - \omega_2\right)\omega_2\cos\theta_1} \tag{16}$$

Fig. 14 MRSTP experimental setup

5.3 Material removal rate model in MRSTP process.

Based on the Preston equation, the theoretical material removal rate for a planar workpiece surface is expressed as:

$$MRR_t = \iint_D k \cdot p \cdot v d\sigma \tag{17}$$

Substituting Eq. (8) and Eq. (14) into Eq. (15), the Eq. (16) is yielded as below.

$$MRR_t = k \lim_{N\to+\infty} \sum_{i=1}^{N} \overline{p}_i \cdot \frac{2 \cdot 25^2}{N} \cdot \sqrt{\frac{i}{N}\left(2-\frac{i}{N}\right)} \cdot \iint_D \sqrt{r_1^2(\omega_1-\omega_2)^2 + \rho_0^2\omega_2^2 + 2r_1\rho_0(\omega_1-\omega_2)\omega_2\cos\theta_1} d\sigma \tag{18}$$

where k is the Preston coefficient, which is a constant determined by the processing conditions including magnetic field. N is the number of workpiece surface division areas. I ($i=1, 2, 3\ldots N$) is the serial number of the area. p_i is the pressure at any point on the area i, obtained from the simulation results. r_1 is the distance from any point P on the workpiece to the center of rotation of the spindle. ω_1 and ω_2 are the rotational speeds of the spindle and rotary table, respectively. ρ_0 is the eccentric distance between the spindle and the rotary table. θ_1 is the angle between the line connecting the point P and the center of rotation of the spindle with the positive direction of the x-axis. Equation (16) showed that the MRR is related to the MRSTP geometry configuration and process variables. The key process variables are the rotational speeds of the spindle and rotary table and working gaps.

Table 2 Experimental parameters

Items	Parameters
Spindle rotational speed (rpm)	1000, 1250, 1500, 1750, 2000
Rotational speed of rotary table (rpm)	25, 50, 75, 100, 125
Working gap (mm)	1
CIP particle size (μm)	18
SiC particle size (μm)	13
Weight ratio (CIP: SiC)	3:1
STFs concentration (wt %)	20

6 Experimental details

To verify the accuracy of the material removal model and the validity of the simulation results, a series of experiments was carried out. The experimental setup was built up on a CNC machining center (VKN640), as

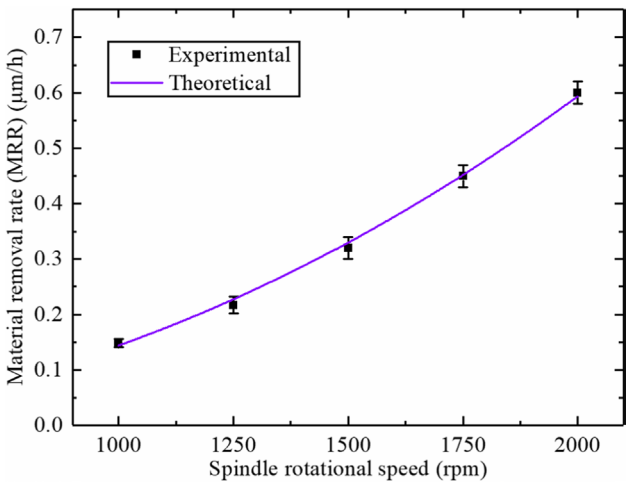

Fig. 15 Influence of spindle rotational speed on MRR

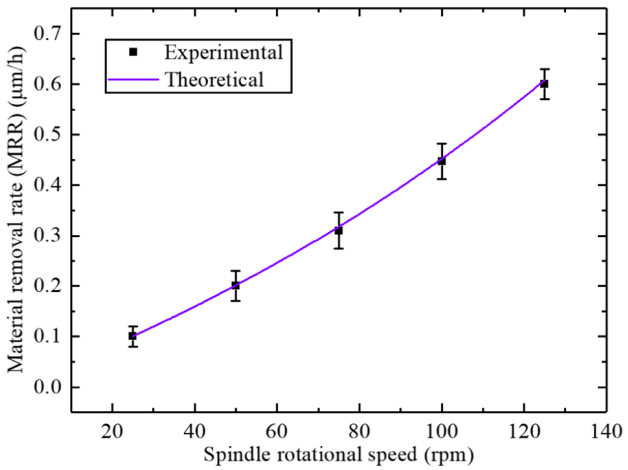

Fig. 16 Influence of rotational speeds of rotary table on MRR

shown in Fig. 14. The magnetic field generation device was installed on a vertical slipway to adjust the working gap. The vertical slipway was held to the CNC worktable by a magnetic base. The workpiece was fixed on the spindle. The polishing bowl was installed on the rotary table. The MRSTP media were contained in the polishing bowl. Magnetic-enhanced particle clusters were formed under the action of magnetic field. The workpiece relative motion was generated with the magnetic-enhanced particle cluster to achieve material removal via the rotation of the workpiece and bowl [31].

A circular Aluminum alloy 6061 with diameter of 25 mm and thickness of 5 mm was used as the workpiece. The initial (S_a) value of the workpiece surface was 337.63 nm. The working gap between the workpiece and the polishing bowl was chosen as 1.0 mm. The concentration of STF base fluid was 20 wt% in the MRSTF media. For comparison with the simulation results, the flow velocity of the MRSTP media in the simulation parameters were converted into the rotational speed of the rotary table. The detailed experimental parameters and their values are shown in Table 2.

7 Results and discussion

7.1 Verification of material removal rate model

The theoretical material removal rate (MRR_t) of MRSTP was compared with the experimental material removal rate (MRR_e). MRR_t was calculated by Eq. (16). MRR_e was calculated by Eq. (17) as below:

$$MRR_e = \frac{M_i - M_p}{S \cdot \rho \cdot t} \tag{19}$$

where, M_i was the initial mass of the workpiece, M_p was the mass of the workpiece after MRSTP, S was the area of the polished plane of the workpiece, ρ was the density of the workpiece, t was the polishing time of MRSTP.

The error Er between MRR_t and MRR_e could be calculated by Eq. (18) [32]:

$$Er = \left| \frac{MRR_t - MRR_e}{MRR_e} \right| \times 100\% \tag{20}$$

The effect of different spindle rotational speeds on MRR was investigated, as shown in Fig. 15. As the spindle rotational speed increased, the MRR increased approximately as a power function. This phenomenon was consistent with the expression of the Preston equation. As the relative velocity of the workpiece and the media increased with the increase of spindle rotational speed, the MRR became large. Although the workpiece surface pressure decreased as the spindle rotational speed increased (see Fig. 7), the reduction in normal pressure played less role in the MRR than the relative velocity.

Figure 16 shows the effects of rotational speeds of the rotary table on the MRR. It was seen that the MRR also increased with the increase of rotational speed of the rotary table. According to Eq. (15), the relative velocity of the workpiece and MRSTP media became large with the increase of rotational speeds of rotary table. Meanwhile, according to Fig. 8, the normal workpiece pressure also increased as rotational speed of the rotary table increased. This resulted in large MRR.

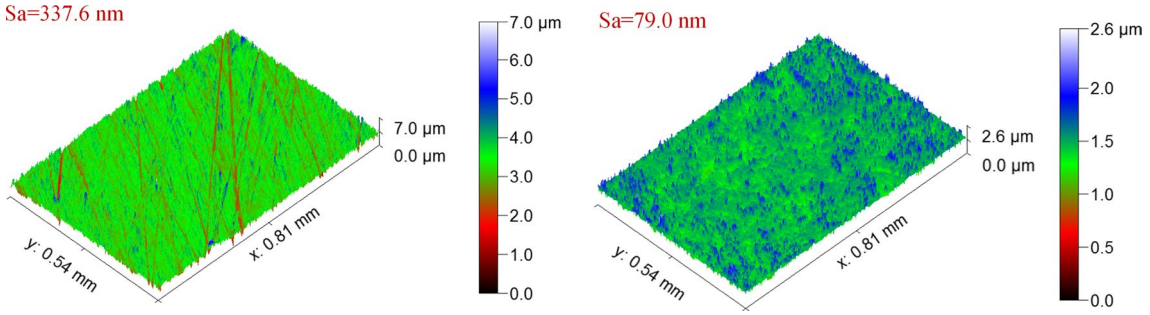

Fig. 17 3D topography of workpiece surface before and after MRSTP

According to Fig. 15 and Fig. 16, the MRR_t of the MRSTP aligned well with the MRR_e. The average error was only 4.1%. The accuracy and validity of the MRR model was verified.

7.2 Surface morphology after polishing

Figure 17 shows the 3D morphology of the workpiece (Aluminum alloy 6061) surface before and after MRSTP. It was observed that there were obvious scratches on the workpiece surface before polishing. After polishing for 1 h, the scratches on the workpiece surface were completely removed. The surface roughness (S_a) of the workpiece surface decreased from 337.6 nm to 79.0 nm, which improved by 77%. The results demonstrated that MRSTP was effective to obtain excellent polishing performance for the Aluminum alloy 6061 workpiece.

8 Conclusions

In this work, CFD method was employed to investigate the effect of polishing parameters on normal and shear stress in the MRSTP process. The MRR model of MRSTP process was established based on the CFD pressure output and the Preston equation. The accuracy and validity of the MRR model was verified. The effect of polishing parameters on the MRR was investigated. The main conclusions were drawn as follows:

(1). The CFD simulation results showed that the pressure on the workpiece surface decreased with the increase of the rotational speed of the workpiece while it increased with the increase of the flow velocity of the MRSTP media. A continuous increment in shear stress on the workpiece surface was observed with the increase of the rotation speed of the workpiece and the flow velocity of the MRSTP media.

(2). The MRR model indicated that the MRR had relation with the MRSTP geometry configuration and process variables. The key process variables were the rotational speeds of the spindle and rotary table and working gaps.

(3). The accuracy and validity of the simulated results and MRR model were verified. The average error between theoretical and experimental results was 4.1%.

(4). The workpiece surface roughness (S_a) decreased to 79.0 nm from initial 337.6 nm with 77% improvement after MRSTP. The scratches on the workpiece surface were completely removed after polishing for 1 h.

Modified Decoupled Sense Amplifier with Improved Sensing Speed for Low-Voltage Differential SRAM

AYUSH, Delhi Technological University, India
POORNIMA MITTAL, Delhi Technological University, India
RAJESH ROHILLA, Delhi Technological University, India

A modified decoupled sense amplifier (MDSA) and modified decoupled sense amplifier with NMOS foot-switch is proposed for improved sensing in differential SRAM for low voltage operation at 22 nm technology node. The MDSA and MDSANF both offer notable improvements to read delay over conventional voltage and current sense amplifiers. At an operating voltage of 0.8 V, the MDSA exhibited a reduced delay of 28.6%, 41.79%, 37.74%, 30.94% compared to modified clamped sense amplifier (MCSA), double tail sense amplifier(DTSA), modified hybrid sense amplifier (MHSA) and conventional latch-type sense amplifier (LSA) respectively. Similarly, the MDSANF demonstrated a delay reduction of 26.13%, 39.78%, 35.58%, 28.55% over MCSA, DTSA, MHSA and LSA respectively. To validate the performance, the MDSA and MDSANF are evaluated using the variation in delay and power consumption across various supply voltages, process corners, input differential bit line voltage (ΔV_{BL}), bit line capacitance C_{BL}) and the sizing of decoupling transistors. Monte Carlo simulations were conducted to analyse the impact of voltage threshold variations on transistor mismatch which leads to an increased occurrence of read failures and a decline in SRAM yield. The performance analysis of various voltage and current sense amplifiers is presented along with MDSA and MDSANF. Area consideration for selection of sensing scheme is important and as such layout of MDSA and MDSANF was performed conforming to the design rules and estimated area for MDSA is 0.297 μm^2 whereas MDSANF occupies 0.5192 μm^2.

1 INTRODUCTION

The backbone of numerous system-on-chip (SoC) devices used in crucial industries like the Internet of Things (IoT), biomedical implants, and wearable smart devices is a fast sensing, low-energy, and reliable Static Random Access Memory (SRAM). The SRAM is typically the dominant contributor to power consumption as well area occupied of the whole chip [Zhu and Kursun 2014]. This puts the stability, delay, yield and energy consumption of SRAM at the forefront of the design strategy for high performance systems. As a result of the stringent design parameters for SRAM, the selection of bit cells, such as 6T, 7T [Rawat and Mittal 2021, 2022a,b,c], 8T [Lorenzo and Paily 2022], 9T [Abbasian and Gholipour 2022] etc. together with peripheral circuitry including address decoder, column multiplexer [Mittal et al. 2022], sense amplifier (SA) and write driver plays a crucial role in the design process. The ability to operate the system at lower voltages is one of the approaches employed in order to decrease the energy consumption thereby increasing the battery's life cycle. However, The operation of the SRAM at the minimum supply voltages with the minimum sized transistors for sub-45 nm technologies introduces various process, voltage and temperature (PVT) variations which when compared with operation at

nominal supply voltages and larger device sizing, could result in a two-fold speed degradation [Reyserhove and Dehaene 2017].

The Sense Amplifier (SA) plays a significant role in the read operation of SRAM. The SA performs the amplification of a small differential signal present at the bit lines to larger rail-to-rail swing although single-ended SA architectures have also been adopted in SRAM [Rawat and Mittal 2022d; Shen et al. 2022]. Since, SRAM cells are highly sensitive to process variations, the SA is also affected by the random variations caused by Random Dopant Fluctuations (RDF). The mismatch in threshold voltages has a vital impact in deteriorating the SRAM read yield and the access delay.

The SA topologies determine the performance and operation limits of the SRAM. The widely adopted voltage-mode SAs are based on cross-coupled inverter latches, which are simple and robust [Dutt et al. 2022; Kobayashi et al. 1993; Schinkel et al. 2007; Wicht et al. 2004]. SAs have a small delay due to the positive feedback of cross-coupled inverters, while voltage-mode SAs require a significant voltage difference between a pair of bit lines due to their offset. Large delays result from the small bit cell driving large capacitive bit lines. Bit lines can be reduced in capacitance by using divided bit lines and two-level sensing [Schinkel et al. 2007; Wicht et al. 2004]. Since the local bit line connects fewer bit cells, there is a lower bit line discharge delay, but the bit line full voltage swing consumes more energy.

Current-mode SAs may have more advantages because of no extra intermediate voltage [Blalock and Jaeger 1991; Chee et al. 1992; Do et al. 2007; Khellah and Elmasry 2001; Wang and Lee 1998]. The current conveyor widely utilized in current-mode SAs uses four PMOS transistors to create a virtual short circuit through the bit lines as it reduces the sensing delay and is not immune to bit line capacitance variations [Seevinck et al. 1991]. Also, a clamped bit line current-mode SA with low impedance was presented [Blalock and Jaeger 1991], which maintains a constant potential on the bit lines. Following this, most research on current-mode SAs has focused on circuit improvement based on the current conveyor and the clamped bit line technique to improve speed and energy efficiency.

The process variation has a large effect on SA offset with CMOS technology node scaling. SA offset caused by inherent mismatch at lower technology nodes has a negative impact on SRAM yield. Many solutions have been reported to reduce offset [Bhavnagarwala et al. 2001; Fragasse et al. 2019; Patel et al. 2021; Reniwal et al. 2019; Shah et al. 2013; Zhao et al. 2022] with one of the most basic approaches being the use of enlarged transistors [Bhavnagarwala et al. 2001]. Multiple redundant SAs of same [Verma and Chandrakasan 2007] and different sizes [Sharma et al. 2011] were also used together with advanced calibration schemes to counter offset. These calibration-based SA topologies allow for high speed operation with lower power consumption while having a larger area overhead and increased complexity.

In this paper, we propose a modified decoupled sense amplifier (MDSA) and a modified decoupled sense amplifier with NMOS foot-switch for performing differential-ended SRAM cell read operations. The Section 2 consists of the conventional SAs being classified as either voltage or current sense amplifiers. The operation and structure of MDSA and MDSANF are discussed in Section 3 together with the impact of decoupling PMOS sizing on read performance as well as reliability of the SA under parameter variations. The Section 4 consists of performance analyis based on simulation results of the conventional voltage and current SAs with MDSA and MDSANF across the set of supply voltages. The work in concluded in Section 5.

2 CONVENTIONAL SENSE AMPLIFIER ARCHITECTURES

2.1 Voltage Sense Amplifiers

Voltage-mode sense amplifiers are composed primarily of a cross-coupled inverter latch which exhibits a strong positive feedback. The latch-type sense amplifier (LSA) is shown in Figure 1a. is one of the earliest forms of CMOS-based sense amplifier used in memory design. The cross-coupled inverters are activated using the sense

Just Accepted

enable (SA_EN) signal, which turns on transistor M7. The circuit is elementary and robust in its operation; however, owing to its large bit line capacitance, this SA exhibits increased delay and power consumption. To limit the power consumption and decrease delay, transistors M3 and M4 are added to the LSA to obtain the current-controlled latch sense amplifier (CLSA)[Kobayashi et al. 1993]. Its circuit schematic is depicted in Figure 1b. The activation of transistor M7 is performed using the enable signal (SA_EN), which lends itself to the current flow through M3 and M4. The high input impedance created at the bit lines allows faster sensing. Pass transistors can be used to mitigate the large capacitive bit lines when connected to bigger cell arrays.

Two bidirectional pass transistors, M5 and M6, are used in the decoupled latch-type sense amplifier (DLSA) [Wicht et al. 2004] in Figure 1c. These transistors decouple the bit lines so that cross-coupled inverters are no longer used to drive the massive capacitive bit lines, which speeds sensing and reduces power consumption. In order to ensure proper operation for DLSA, the per-charge voltage (VPC) is used to per-charge the bit lines to V_{DD}.

The double-tail sense amplifier (DTSA) [Schinkel et al. 2007] illustrated in Figure 1d is a sensing technique which uses a two tail approach, one focused on the input bit lines and the other on the cross-coupled inverter latch. During the pre-charge phase, the nodes Di+ and Di- of PMOS transistors M8 and M9 are charged to V_{DD}. This causes transistors M5 and M6 to pull the output nodes (SAO+ and SAO-) to GND. When the clock signal (CLK) goes high, both M7 and M12 transistors are activated, leading to a gradual decline in the voltages at the Di nodes. The rate of voltage decrease is determined by the current flowing through M12 and the capacitance at the Di nodes. This generates an input-dependent voltage difference, denoted as ΔVDi. The cross-coupled inverter pair receives this voltage difference, regenerating it when the SAO nodes can no longer be clamped to ground by M5 and M6. Consequently, the DTSA offers effective isolation between the input and output signals, thanks to M5 and M6, and it can operate well with lower supply voltages.

2.2 Current Sense Amplifiers

The read operation of the current sense amplifiers is independent of the differential voltage present on the bit lines, making them a popular choice for faster and larger SRAM systems. The clamped bit line sense amplifier (CBLSA) [Blalock and Jaeger 1991] shown in Figure 2a which uses the transistors M8 and M9 as a clamp for the bit lines. This SA works in a two-stage format with the first stage being per-charge made up of the transistor pair M6 and M7. Subsequently, to start the read operation for the memory, the large-width M1 transistor was turned on, which enabled the SA. The M6 and M7 transistors works during the per-charge phase to equalize the bit line voltages. The current through the SA is a design outcome of the sizing of M2-M5. This current value is chosen to produce a voltage difference at the bit lines of around 100mV. The per-charge stage is completed when the per-charge signal (VPC) is low, thereby rendering the cross-coupled inverter pair to act as a high-gain amplifying stage. The voltage difference owing to the differential current is amplified, which leads to a large potential difference at the output nodes SAO+ and SAO-.

The hybrid current-mode sense amplifier (HCSA) [Chee et al. 1992] is shown in Figure 2b. It consists of four PMOS transistors of equal size, M10–M13, which together form the current conveyer [Seevinck et al. 1991]. This just serves as a current transport mechanism without introducing any gain. It is possible to think of the HCSA as a CBLSA with a current conveyer. The HCSA's read procedure is as follows: SA_EN = 1 activates M7, which causes a differential current signal to arise at bit lines BL and BLB. The differential voltage generated at the drains of The NMOS devices M3 and M4 is due to the differential current signal at their source terminals. This modest differential voltage is subsequently amplified by the cross-coupled latch to create a larger voltage swing.

The design shown in Figure 2c is a modified clamped sense amplifier (MCSA) [Khellah and Elmasry 2001]. The structure is comprised of CBLSA and equalizing transistor M7. The two-stage read operation works as follows. The bit lines are pre-charged by using transistor M7 controlled by the SA_EN going high. Initially, bit lines are

equalized by switching the SA_EN high to turn on M7. During the sensing stage, SA_EN was turned off. The operation of the MCSA is governed by the same steps as the CBLSA, with the quiescent differential voltage generated at the bit lines being tracked and amplified. Figure 2d presents the modified hybrid sense amplifier (MHSA) [Do et al. 2007] which is comprised of the conventional current conveyer together with YSEL operated

transistors to couple the bit lines and the data lines. The per-charge stage consists of transistors M9 and M10 which pulls the bit lines BL and BLB high. The rest of the sense amplifier working is similar to the CBLSA with the small potential difference at the bit lines being amplified to produce the read output.

3 MODIFIED DECOUPLED SENSE AMPLIFIER

3.1 Design Architecture and Operation of proposed SA

Figure 3a and 3b illustrates the detailed circuit schematic of the proposed modified decoupled sense amplifier (MDSA) and MDSA with NMOS footswitch (MDSANF) respectively. Both the SA architectures are designed using the conventional inverter latch decoupled by the PMOS switches M6 and M7. The operation of the SAs can be divided into three segments. The three segments are the pre-charge, amplification and output propagation. The

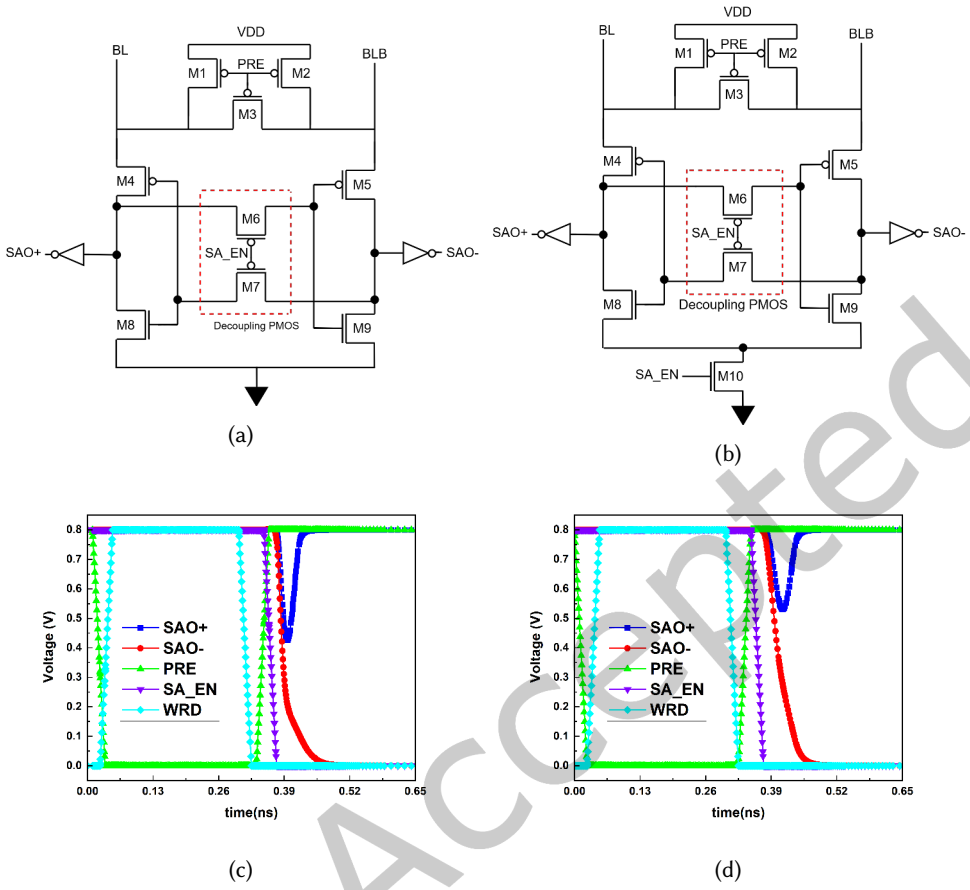

Fig. 3. Circuit schematics for (a) MDSA and (b) MDSANF, along with the transient response showing timing control signals at V_{DD} = 0.8 V and C_{BL} = 50 fF for (c) MDSA and (d) MDSANF

pre-charge segment requires the bit lines to be charged to supply voltage V_{DD} using M1-M3 PMOS transistors. The timing control signal (TCS) used here is PRE. The amplification stage is initiated by turning on decoupling switches (M6 and M7) by turning the TCS SA_EN off. The cross-coupled latch is comprised of two inverters formed by the M5, M8 and M5, M9 transistors respectively. The latch then acts as a high-gain positive feedback amplifier wherein a differential current generated across the drains of the M8 and M9 gives rise to large differential voltage across SAO+ and SAO-. The SAO+ is pulled high while the SAO- is pulled to GND for a read "1" operation and vice versa. The outputs nodes of the SA are passed through inverters to attain better isolation and the maximum output signal swing. This contributes to lower delay during the read operation and improves the performance of the sense amplifier. The additional NMOS footswitch M10 used is similar to the ones used in conventional voltage-mode SAs. It serves as a sleep transistor to reduce leakage in the power gating aspect of the SA. The figure 3c and 3d depict the transient response for MDSA and MDSANF respectively at V_{DD} = 0.8 V with C_{BL}(bit line capacitance) being 50fF. The transient response is used to derive the delay performance of the SA. The delay of the sense amplifier assumed to be the time between the 50% point of the SRAM word line (WL) and the 50% point of the differential voltage at SAO nodes [Chen et al. 2021].

3.2 Impact of Sizing of Decoupling PMOS on SA Read Performance

To decouple the inverters in the latch before the SA is enabled, the MDCA/MDSANF architecture uses the PMOS transistors M6 and M7. Figure 4 shows the impact of the variation in widths of PMOS transistors M6 and M7 on the read performance of the proposed SA. Figure 4a and 4b illustrate the delay variation of MDSA and MDSANF respectively for the given set of supply voltages. The delay is lowest for 1 V supply and is consistently larger than 1 ns for all widths for near threshold operation at 0.5 V. The widths of the PMOS transistors have a minimal effect on the power consumption at all supply voltages except 1 V as is evident in figure 4b and 4d. The largest transistor width which performs a correct read operation for the value stored in the 6T bit cell is 88 nm. This width is considered for all best-case calculation from here onwards. This is done so as to minimize delay while performing a reliable read operation across the set of supply voltages for both the MDSA and MDSANF. The transistors of the inverter latch are designed with PMOS/NMOS ratio of 2 with minimum sized NMOS transistors. The pre-charge circuit made up of transistors M1-M3 are sized at larger W/L = 1000 nm/22 nm. The process variation tolerance is also improved by utilizing the largest width M6 and M6 at 88 nm which allows a successful SRAM read.

3.3 Parameter Variation Tolerance of Proposed SA

CMOS parameter variations can be classified into two main categories: front-end variations and back-end variations. Among these, front-end random variations are primarily influenced by the fluctuation in threshold voltage (VTH). One of the key contributors to front-end random variations is random dopant fluctuations (RDF). RDF refers to the variations in the number of dopant atoms present in the transistor channel. As technology nodes decrease, the number of dopant atoms decreases significantly, reaching around ten atoms at 16 nm compared to

Just Accepted

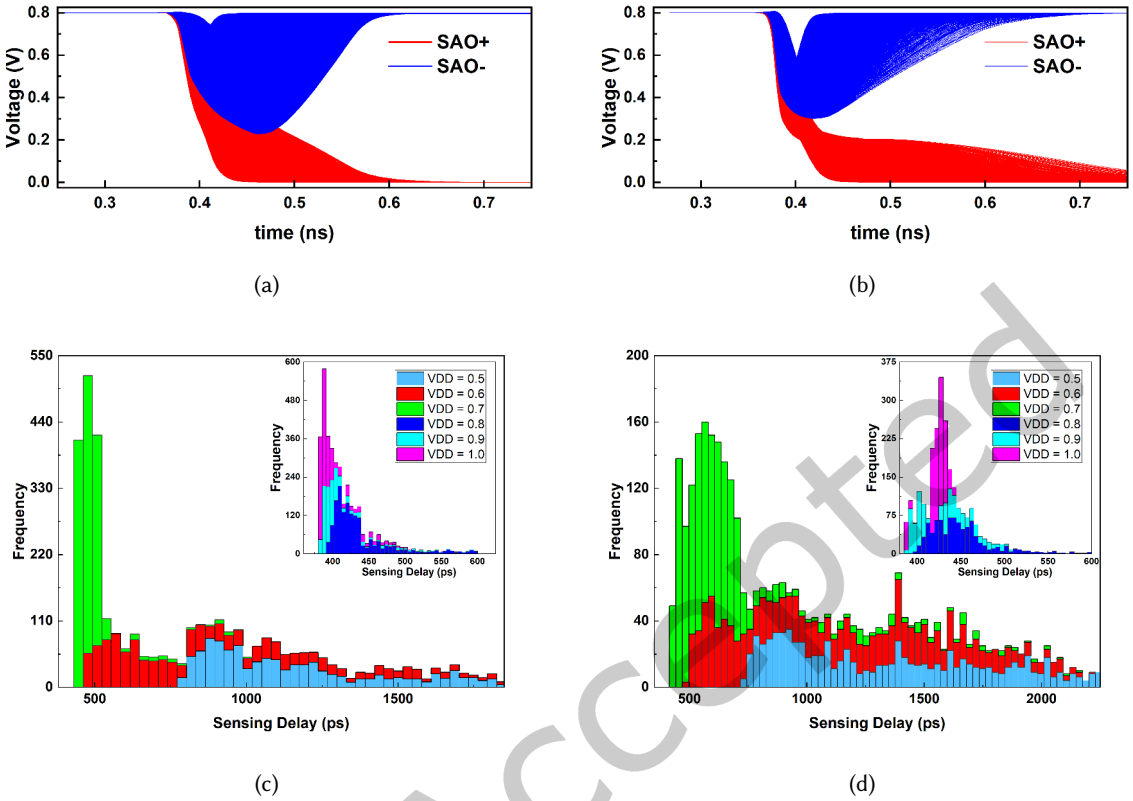

Fig. 5. Transient response (10k Monte Carlo simulation) of (a) MDSA, and (b) MDSANF and calculated delay distribution at C_{BL} = 50fF for near threshold operation of (c) MDSA and (d) MDSANF (Inset: delay distribution at above threshold operation)

a few tens at 45 nm [Hernández et al. 2011]. This reduction in dopant atoms contributes to the inconsistency in transistor parameters, thereby increasing the variability in CMOS devices at smaller technology nodes.The effect of process variation on the MDSA and MDSANF is studied using Monte Carlo simulations for 10k data points. A read failure might happen as a result of V_{TH} fluctuations, which is defined as the read output for a read "1" operation going to zero rather than V_{DD}.The transient responses at V_{DD} = 0.8 V and C_{BL} = 50 fF for MDSA and MDSANF are depicted in Figure 5a and 5b. The transient response depicts that there are zero read failures that take place during the SRAM read. It is assumed that the threshold voltage fluctuation follows a Gaussian distribution with 3σ variation around the mean μ. The lowest read failures are used to determine a SA's yield. A successful read operation in SRAM critically dependent on the symmetry of the majority of differential-ended SAs. The distribution of read delay for MDSA is shown in Figure 5c for near threshold operation and Figure 5c (inset) for other supply voltages. Similarly, the delay distribution for MDSANF depicted in Figure 5d and 5d (inset). The delay distributions are calculated from the MC simulations. The near threshold voltage operation shows deviation larger than a few hundred ps but goes down to tens of ps for higher supply voltages as is evident from Figure 5c and 5d for both MDSA and MDSANF.

To perform a performance analysis of a sense amplifier in an SRAM array, various design parameters can be considered, including the bit line capacitance. The bit line capacitance, ranging from 10 fF to 500 fF, is a crucial

Just Accepted

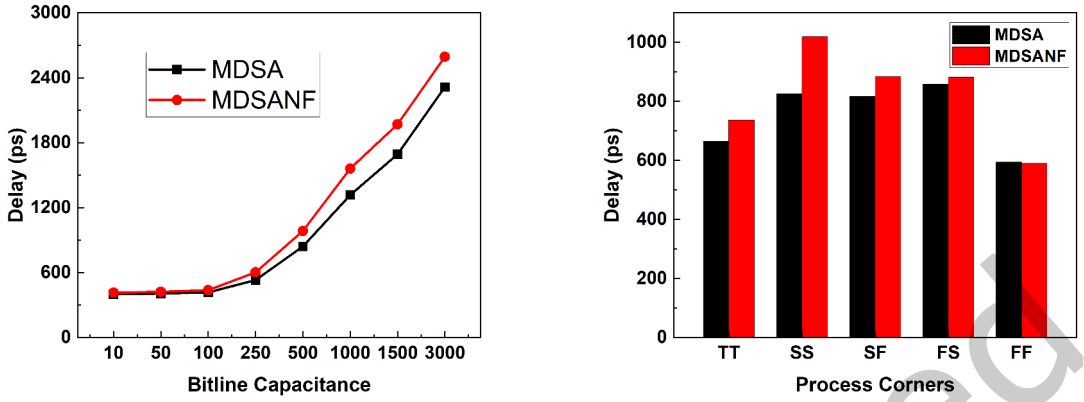

Fig. 6. Delay variation as a function of (a) Bitline Capacitance and (b) Process corners for MDSA and MDSANF at VDD = 0.8 V

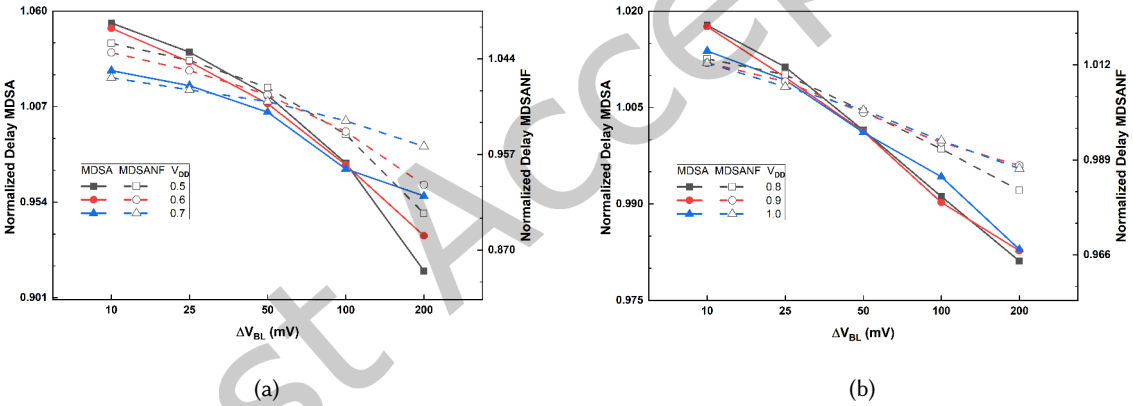

Fig. 7. Normalized Delay as a function of differential bit line voltage input for MDSA and MDSANF at (a) near threshold and (b) above threshold supply voltages

parameter that affects the speed and overall performance of the sense amplifier. By considering different values of bit line capacitance, representing varying array sizes, a comprehensive analysis can be conducted to assess the impact on the delay, power consumption, and noise margin of the sense amplifier in the SRAM array. Other design parameters that can be considered for performance analysis include the array size (number of memory cells), bit line capacitance, supply voltage, and process technology. Each of these parameters influences the behaviour of the sense amplifier and can be used to evaluate its performance under different operating conditions and array configurations. A singular SA is used to perform read operation for a column of bit cells which can range upwards of 1024 in large SRAM array structures. The delay variation as a function of C_{BL} is shown in Figure 6a. The increase in C_{BL} causes larger read delay due the SA being forced to discharge large capacitance to achieve

Just Accepted

a correct read. The delay shows a 4.77 times increase for MDSA for the bit line variation from 10 fF to 3000 fF and 6.25 times increase for MDSANF. To further justify the SA's robustness, the delay analysis for MDSA and MDSANF is extended across various global corners at V_{DD} = 0.8 V and C_{BL} = 50 fF and these results are shown in figure 6b. The normalized delay of the SAs as function of the input differential bit line voltage is shown in Figure 7 for the set of supply voltages. The normalized delay values show most deviation for near threshold operation of 0.5 V with deviation of 185.358 from fastest to slowest read delay and least deviation of only 10.932 ps at 1 V supply for MDSANF. Similarly, the largest delay deviation is 118.21 ps at 0.5 V while the smallest is 6.557 ps at 1 V for MDSA.

4 PERFORMANCE ANALYSIS OF MDSA/MDSANF WITH EXISTING SA ARCHITECTURES

The comparative analysis of all the conventional sense amplifier architectures is presented in this section with all the SAs being designed using Predictive Technology Model [Arizona State University and Group 2008] at 22 nm technology node. All the various SAs were designed using consistent sized transistors in order to conduct an objective analysis at various supply voltages. The conventional voltage and current-mode SAs have transistors with W/L = 44 nm/ 22 nm while all access transistors are sized with W/L = 1000 nm/ 22 nm. The read delay, power consumption and leakage have been calculated based on the simulation results. An important performance statistic for SA is the power-delay-product, or PDP for short. A stronger overall performance is shown by the lower PDP numbers. The identical word line (WL) and sense amplifier enable (SA_EN) timing signals are utilized while performing all simulations, together with the precise timing and control signals (TCS) as specified in the relevant literature. The simulation testbench schematic used to compare the sense amplifiers is shown in figure 8a. A single 6T SRAM cell is used together with a π-3 model for the bitline capacitance of large SRAM array structures. This is similar to test circuit in [Zhu et al. 2013].

4.1 Read Delay

The conventional SA architectures are simulated and the calculated read delay is shown in figure 8b. As is clearly evident, MDSA and MDSANF have the fastest operation for all supply voltages except the near threshold voltage operation at V_{DD} = 0.5 V. The proposed MDSA shows a 28.6% read delay improvement over MCSA while MDSANF shows a 26.13% improvement at V_{DD} = 0.8 V. The MCSA is the fastest among the voltage-mode and current-mode SAs followed by LSA and MHSA. MHSA, MCSA and DTSA exhibit the most consistent delay across voltage supply variation with DTSA having its best and worst delay 210.5 ps apart. The fastest operation at lowest applied supply is given by DTSA with MCSA being the second fastest as a result 10.49% increase in delay. . Amongst the current SAs compared, only CBLSA has delay consistently larger than 1 ns across all the supply voltages applied. The conventional SA designs compared above are all simulated for a bit line capacitance modelled by 50 fF with ΔV_{BL} assumed to be 50 mV with transistors having no mismatch operated at TT/27°C. The MDSA and MDSANF perform the best at voltage supply larger than 0.6 V and the delay improves as V_{DD} is increased. The MDSA and MDSANF have nearly same read delay at all voltages except 0.5 and 1 V where MDSA is faster by 22.05% and 20.32% respectively.

4.2 Power Consumption and Leakage Power

The power consumption of MDSA and MDSANF is compared to voltage-mode and current-mode SA architectures and the simulation results are shown in figure 9a. As the supply voltage increases, the power consumption of all SAs also increases, which aligns with the expected relationship between power, supply voltage, and current. The power consumption of the MDSA and MDSANF is moderate compared to other SA designs. Among the SA designs, the MHSA consistently exhibits the highest power consumption. This can be attributed to its larger number of transistors, particularly the current conveyor and data line coupling devices, which contribute significantly

Just Accepted

Just Accepted

to power consumption. The inclusion of additional control signals in the MHSA design further adds to the power consumption. In contrast, the CLSA and DLSA designs aim to minimize power consumption by reducing the charge and discharge of the bit line capacitance, resulting in lower power requirements. The presence of pre-charge bit lines also contributes significantly to power consumption in SA designs. The DTSA and MCSA have the lowest power consumption with averages of 2.86 μW and 2.03 μW respectively. When comparing to MCSA, MDSA shows a 2.30 μW increase while MDSANF shows an increment of 2.59 μW at V_{DD} = 0.8 V. However,

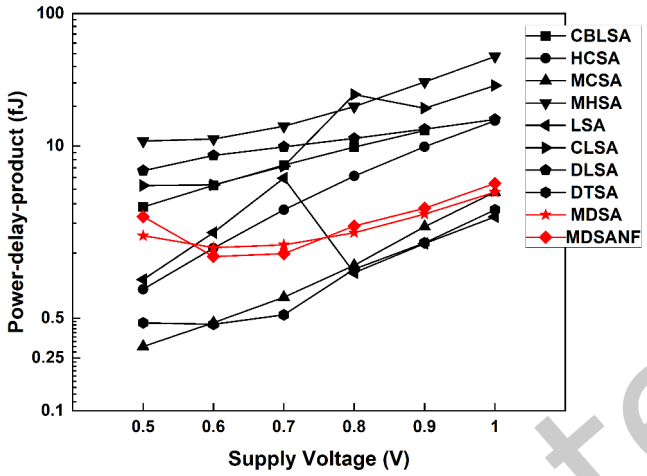

Fig. 10. Power-delay-product comparison of all SAs as a function of the supply voltage (C_{BL} = 50 fF)

the MDSA and MDSANF consume slightly higher power compared amongst the conventional SAs. Consequently, there is always a trade-off between sensing delay and power consumption when selecting the SA to perform SRAM read operation. Static power, which contributes significantly to the total power consumption of a circuit, is primarily caused by leakage current. It arises due to various factors such as sub-threshold current, gate leakage current, and reverse junction current in a MOS circuit. Mathematically, static power is determined by multiplying the supply voltage (VDD) with the leakage current.

Leakage current refers to the undesired flow of current in a transistor when it is in an idle or off state. The sub-threshold current occurs when there is a small voltage across the transistor, and it results from the imperfect blocking of current by the transistor's gate. The gate leakage current, on the other hand, happens due to the thin insulating layer of the transistor, which allows some current to pass through. Lastly, the reverse junction current occurs as a result of the inherent characteristics of the transistor's junctions. The leakage power for SAs is shown in figure 9b. The MDSANF utilizes the power gating effect of the NMOS foot-switch in order to decrease leakage power as compared to MDSA.

The Power-delay-product (PDP) of all SAs, assuming a bit line capacitance (C_{BL}) of 50 fF, is shown in figure 10. The MHSA consistently exhibits the highest PDP, with an average of 22.35 fJ. The proposed SA design shows a higher PDP than only for DTSA and MCSA, which are both characterized by their simple cross-coupled inverter-based architecture and the low transistor count. Therefore, the MDSA and MDSANF can be employed in faster sensing applications, albeit with a slightly higher power consumption.

4.3 Area Considerations

The selection of a differential SA topology for performing SRAM read is a critical step as a single SA is used to read the data for a column of bit cells. Consequently, the choice of SA topology significantly impacts the footprint of the memory array. Considering that SRAM density is governed by the employed SA, careful consideration of area becomes a critical aspect when selecting the appropriate sensing scheme. The layout of MDSA and MDSANF is specifically designed to estimate the area requirements of the corresponding SA as illustrated in figure 11a and

Just Accepted

Table 1. Performance Summary of Conventional SA designs with MDSA and MDSANF at 0.8 V supply voltage

SA Design	Read Delay (ps)	Power Consumption (μW)	PDP (fJ)	Normalized Area
CBLSA	1105.92	6.33	9.82	1.4
HCSA	761.03	7.80	5.93	2.55
MCSA	561.84	2.23	1.25	1.3
MHSA	644.23	30.81	19.85	3.3

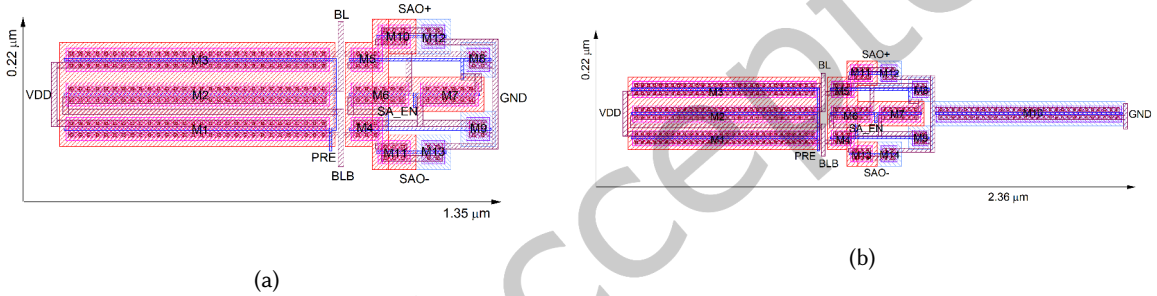
MDSANF	**415.10**	**5.80**	**2.49**	**1.5**



(a) (b)

Fig. 11. Layout design for area estimation of (a) MDSA and (b) MDSANF

11b respectively. The estimated area for MDSA is 0.297 μm^2 whearas MDSANF occupies 0.5192 μm^2. The area increase for MDSANF is due to the larger sized NMOS foot-switch.The performance summary for MDSA and MDSANF together with conventional SA designs is given in Table 1. The estimated area for all SAs is normalized to that of LSA, which is the earliest iterations of SA built around the inverter-latch. The MHSA has largest area due to the large sized PMOS used to build the current conveyor whereas the dual tail sensing scheme used in DTSA is a major contributor to its larger area footprint.

5 CONCLUSION

In this work, a pair of fast sensing modified decoupled sense amplifiers are proposed. The impact of various parameter variations on the SRAM read performance and SA reliability is investigated using Monte Carlo simulation for 10k data points. The delay and power consumption together with leakage power are calculated for conventional SAs at 22 nm technology node. The bit line capacitance and differential bit line voltage variation are considered together with global process corners to justify the robustness of the SA architectures. Threshold voltage variation causes transistor mismatch and can lead to read failures. The optimal sizing of decoupling PMOS has also been highlighted and its effect on other performance parameters such as sensing delay and power consumption is calculated. The MDSA and MDSANF show read delay improvement of 37.74% and 35.58% over

Just Accepted

MHSA at V_{DD} = 0.8 V and bit line capacitance of 50 fF. The MDSA and MDSANF thus provide a high speed read operation at supply voltages ranging from 0.5 to 1 when compared to conventional SAs.

***Abstract*—Multi-label text classification is a technique used to categorize texts into multiple labels or categories. Such classification problems are difficult as well as captivated with several parameters and changes per the matter. News categories classification is one of the most popular and necessary multi-label text classification problems because the same news might or might not belong to multiple genres at constant times. The majority of the factors of news genre classification are based on parameters like news headlines, articles, and their short descriptions. The project analyzes news articles using a variety of machine learning and natural language processing approaches. The goal is to take a big collection of article headlines, group them into similar, related stories, and then analyze those groups further to try to develop a statistic for how well the collection of articles covers various points of view on the issue. This uses a variety of Natural Language Processing techniques to pre-process the text in order to improve the amount of importance that can be deduced. It is implemented in Python. It makes use of freely accessible NLP libraries like NLTK.**

Keywords: News Category Classification, Multilabel Text Classification, Label Powerset, Machine Learning Classifiers, Binary Relevance

I. Introduction

In recent years, natural language processing (NLP) has become a very popular research domain and provides numerous real-life problems like fake news detection, rumor prediction, sentiment analysis, multi-label text classification (MLTC), and many others [1], [2]. Multi-label text classification (MLTC) techniques are widely employed nowadays in a variety of real-world applications, such as recommender systems, music categorization, movie genre prediction, and semantic scene classification [3]. The most common NLP task, known as "multi-label text categorization," aims to assign numerous labels to each piece of input text. In recent years, Machine learning and deep learning techniques have been pivotal in solving many real-life problems like medical imaging, social network analysis, text classification, text summarization, and others [4]–[7].

The paper analyzes news articles using a variety of machine learning and natural language processing approaches. The goal is to take a big collection of article headlines, group them into similar, related stories, and then analyze those groups further to try to develop a statistic for how well the collection of articles covers various points of view on the issue. In recent times, primarily several neural network-based approaches are planned for the determination of such issues however they're resource-intensive and time intense. Here we have a tendency to try and propose a unique methodology of news category classification. The overall work introduced in the paper can be divided into two main phases: Use topic mining or clustering to examine news articles and organize them into inferred-related stories. This uses a variety of Natural Language Processing techniques to pre-process the text in order to improve the amount of importance that can be deduced. It is implemented in Python. It makes use of freely accessible NLP libraries like NLTK. For the greatest outcomes, the intent was to apply the most recent machine learning and natural language processing methods.

II. Problem Statement

A. Background

Multi-label classification is the conception of a single-label problem, and a single instance can belong to more than one single class. From the official documentation of the Scikit-learn package, "This can be allowed of as predicting parcels of a sample that aren't mutually exclusive." [8] There are no constraints on the number of classes that a case can be assigned to in a multi-label classification problem. In an analogous environment, there exists the multi-class bracket problem. Still, the crucial difference between both is the fact that the multi-label bracket supposes that the parcels aren't mutually exclusive.

B. Problem transformation Technique

The multi-label dataset is changed into a single-label dataset in this phrase. Machines can easily read single-label datasets and issues, which facilitates model creation. The following methods are used to transform problems:

1) Binary Relevance (BR): This method treats each label separately and divides the multi-label data into various single-class classification tasks. The multi-label problem is split into three separate single-class classification problems in order to be addressed by binary relevance. [9] A backup plan is offered in case the first technique fails due to label correlation.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:33:22 UTC from IEEE Xplore. Restrictions apply.

2) Label Powerset: Label Powerset is a very simple and less used approach in Problem transformation but it has very useful advantages in this approach there's a multilabel problem into a single multi-class problem with 2L labels and class values. After the conversion into a multi-class problem, it can be classified with any multiclass classifier technique. [9] In this approach, there is no information loss and also it considers the label dependency and correlation btw data and the labels

3) Classifier chain: It is one of the techniques used in problem transformation in multi-label classification. It retains the ability to account for label dependencies for classification while combining the computational effectiveness of the Binary Relevance technique. Based on the BR approach, the Classifier Chains method is effective even with a large number of labels. It also takes into account how different labels are related to one another. [9]

III. Text Vectorizers

A common technique for transforming input data from its original text-based form into real-number vectors is called vectorization. This format is supported by Machine Learning models. It's one of the most efficient techniques for the respective purpose.

A. Count Vectorization

This technique creates a matrix having a column size equal to the unique word in the whole given document and a row size equal to the no. of the different text samples in that given document. Each cell in the table represents the count of words that are present in the corresponding text sample.

B. TF-IDF

It is based on the frequency (count) of a word in the corpus but it also provides importance of word with respect of other words in term of numeric value i.e, higher the importance higher the numeric value or lower the importance lower the numeric value. Term frequency adjusted for document length is determined by dividing the total number of words in the document by the raw count of occurrences. [10]

TF: It keeps track of how frequently each word appears in each document. The frequency of occurrence of the phrase t in document d is represented by tf(t,d). Phrase t appears numerous times in document d. [11]

$$tf(t,d) = \frac{f_d(t)}{\max_{w \in d} f_d(w)} \tag{1}$$

Equation 1: Term Frequency

IDF: Depending on the word's frequency, which reveals how common or unusual it is, measures how much information is being sent by word processing.. [11]

$$idf(t,D) = \ln\left(\frac{|D|}{|\{d \in D : t \in d\}|}\right) \tag{2}$$

Equation 2: Inverse Document Frequency

TF-IDF is calculated as: [4]

$$tfidf(t,d,D) = tf(t,d) \cdot idf(t,D) \tag{3}$$

Equation 3: Term frequency-inverse document frequency

IV. Machine Learning Classifiers

A. Logistic Regression:

It is a well-known machine learning algorithm. The value of a categorical dependent variable is predicted using a set of independent variables. Based on the categorical dependent value, it makes predictions. It outputs probabilistic values, such as 0 or 1, as output.

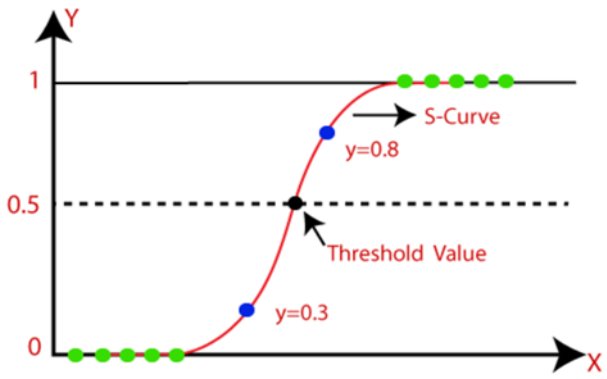

Fig. 1. Graphical Representation of Logistic Regression [13]

B. Multinomial Naïve Bayes

In the field of Natural Language Processing, the Multinomial Naive Bayes algorithm is a well-known method for Bayesian learning. It makes predictions about the categorization of textual data, such as news articles or emails, using the concepts of the Bayes theorem.

By calculating the likelihood of each potential tag for a specific sample, the algorithm selects the tag with the highest probability as the output.

This method has gained popularity due to its effectiveness in text classification tasks. [14] The Bayes theorem is used as the only basis for the multinomial model's evaluation of probability-based decision functions. The Bayesian probability is computed as follows:

$$p(C_k|W) = \frac{p(C_k) \cdot p(W|C_k)}{p(W)} \tag{4}$$

Equation 4: Bayesian Probability

C. Linear SVC

The Linear Support Vector Classifier (SVC) is a classification method that uses a linear kernel function to make predictions. The main advantage of this is that it also performs well with large data samples. In essence, Linear Support Vector Machine (Linear SVC) is an algorithm that

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:33:22 UTC from IEEE Xplore. Restrictions apply.

looks for a hyperplane to maximize the distance between samples that are classified. [15]

V. PROPOSED METHODOLOGY

A. About Dataset

A pretty diverse dataset was used that was collected from a variety of websites, including Kaggle [16], India Today [17], the BBC [18], Google News [19] etc. Various categories of news related were commbined into a single dataset after gathering them from their separate sources. Adding a little more detail to this, the issue is that there isn't a single dataset that includes all the different news categories that was intended to include in this project. We primarily sought to collect the following 3 attributes from this dataset: "Headlines," "Description," and "Categories." Hence, all of those datasets were merged to analyze on a very wide spectrum of news categories and normalize the categories to their supercategories. After this, 24 news categories were labeled. There are three datasets from Google News, in short News and CNN which contains approximately 60,000 articles. One dataset was used for training purposes and the other two datasets were used for testing the models.

ARTS & CULTURE	EDUCATION	LIFESTYLE	STYLE & BEAUTY
BUSINESS & FINANCE	ENTERTAINMENT	MEDIA	TECHNOLOGY
'COLLEGE	ENVIRONMENT	POLITICS	TOURISM
COMEDY	FOOD & BEVERAGES	RELIGION	WEDDINGS
CRIME	HEALTH & FITNESS	SCIENCE	WELLNESS
CURRENT AFFAIRS	HEALTHY LIVING	SPORTS	WOMEN

Fig. 2. News Categories in the Dataset

B. DATA PREPROCESSING

The data needed to be pre-processed so that it could be changed into forms that the algorithm could identify after all of the data had been integrated.

1. Verify that no fields with missing values exist in the dataset being used.
2. Encoding of Category: An encoder called "Multiple label Binarizer" was employed to transform the category column of the dataset which was in set of string format into 24 category wise columns which contains binary value where 1 in these columns indicates the belonging category whereas 0 indicates not belonging category of the news articles.
3. Feature engineering: The headline and article columns were combined because they both included the same information in a single column of text, and further operations were then made to the text column.
4. Data cleaning:

- Html tags removal Tag = <.*?>
- Removing special characters and digits
- Using the NLTK package, remove English stop words and punctuation.
- Lemmatizing words: To get to a word's fundamental form, word affixes were deleted. All words should be lowercase.

After these steps the various combination of text vectorizers and machine learning algorithms were applied on the preprocessed dataset.

VI. TRAINING MODELS:

Splitting the dataset into training and validation halves was therefore the first and foremost task. The problem transformation approach was then used (PTA). Three PTA methods—Binary Relevance, Label PowerSet, and Classifier Chain—have been employed. Different combinations of text vectorizers and ML classifiers have been untilized, including binary classifiers, for the implementation of these three. Due to the model's use of two different vectorizers (Count Vectorization and TF-IDF) and three different classifiers (Logistic Regression, MultinomialNB, and Linear SVC), 15 combinations in all are created for validation, testing, and evaluation. The three PTA methods that have been used—binary relevance, label powerset, and classifier chain—are briefly described here.

A. Binary Relevance

With BR two vectorization algorithms named CV and TF IDF have been utilized each time. Then, utilizing several machine learning classifiers such as LR, MNB, and SVC, each were combined, such as BR- CV and BR- TF IDF. Then a contrast was made between the F1- score, precession, and accuracy.

B. Label PowerSet (LP)

With LP two vectorization methods named CV and TF-IDF were used each time. Then with the combination of each like LP- CV, LP- TF-IDF, various machine learning classifiers named LR, MNB, SVC, were used and using these combinations. Then a comparison was made between the accuracy, precession, and F1- score.

C. Classifier Chain

With BR, the vectorization techniques Count Vectorizer and TF IDF were employed alternatively. Then, utilizing several machine learning classifiers such as LR, MNB, and SVC, each were combined, such as BR- CV and BR- TF IDF. then a contrast was made between the F1- score, precession, and accuracy.

VII. RESULT AND ANALYSIS

A. Result & accuracy

The evaluation of multi-label text categorization techniques has been approached in a number of different ways. Utilizing just one evaluation metric can lead to inaccurate interpretations of the metrics by providing false insights into the outcome. The

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:33:22 UTC from IEEE Xplore. Restrictions apply.

parameters that are often measured were also averaged, such as Accuracy, Precision, Recall, and F1-score, by averaging the metrics over all genres.

Accuracy$_{avg}$: "The average accuracy for each instance is calculated as the ratio of successfully predicted output to all other possible outputs." [20]

$$Accuracy_{avg} = \frac{\sum_{i=1}^{n}(A_i \times K_i)}{\sum_{i=1}^{n} K_i} \quad (5)$$

Equation 5: Average Accuracy

Precision$_{avg}$: "It represents the average across all instances of the ratio of projected accurate labels to the total number of actual labels." [20]

$$Precision_{avg} = \frac{\sum_{i=1}^{n}(P_i \times K_i)}{\sum_{i=1}^{n} K_i} \quad (6)$$

Equation 6: Average Precision

Recall$_{avg}$: "The ratio of accurate labels to all predicted labels, on average across all cases, is known as a recall" [20]

$$Recall_{avg} = \frac{\sum_{i=1}^{n}(R_i \times K_i)}{\sum_{i=1}^{n} K_i} \quad (7)$$

Equation 7: Average Recall

F1-score$_{avg}$: "It is the harmonic mean of Precision and Recall " [20]

$$F1score_{avg} = \frac{\sum_{i=1}^{n}(F1_i \times K_i)}{\sum_{i=1}^{n} K_i} \quad (8)$$

Equation 8: Average F1-score

The experiment was carried out and the value of several assessment criteria was measured using the test dataset. On the numerous datasets under consideration, multiple news genre classification models were applied. The experiment is run on a laptop running the Windows 11 Operating System, an Intel i5-7400H processor with four 3.0GHz CPUs, 8GB of RAM, and 512GB of SSD storage. Scikit-learn, Numpy, Pandas, and NLTK are some of the packages which were used to run the simulations in Python.

B. Result based on Binary Relevance method

The result was achieved using the Binary Relevance based technique in conjunction with the "CV and TF-IDF", as well as the ML algorithms LR, MNB, and LinearSVC.In both datasets, the BR, CV, and Linear SVC model combination had the highest accuracy, precision, and F1-score, which was approximately 0.72, 0.84, and 0.86.

The graphical representation of the results of both datasets is shown figure 3,4 and 5 using Binary Relevance i.e Accuracy, F1-Score, and Precision.

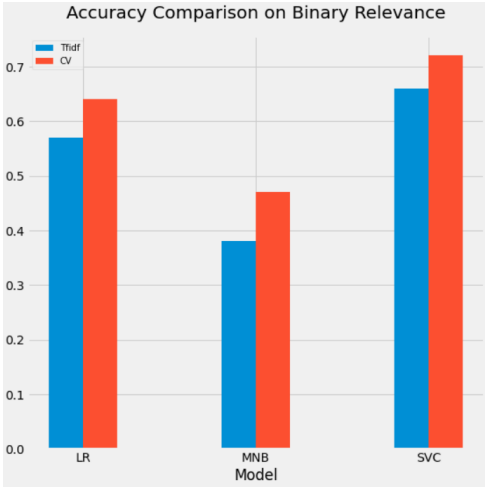

Fig. 3. Accuracy comparison on Binary Relevance on Google News Dataset

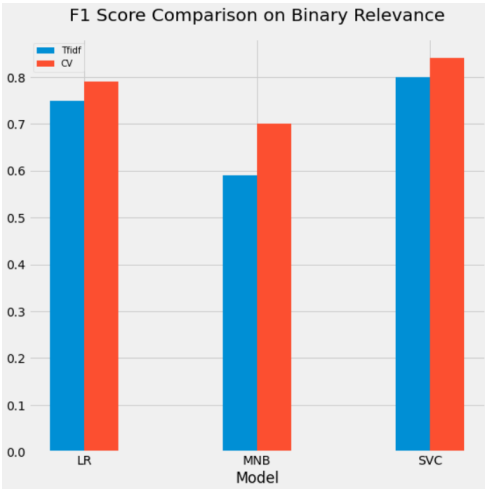

Fig. 4. F1-Score comparison on Binary Relevance on Google News Dataset

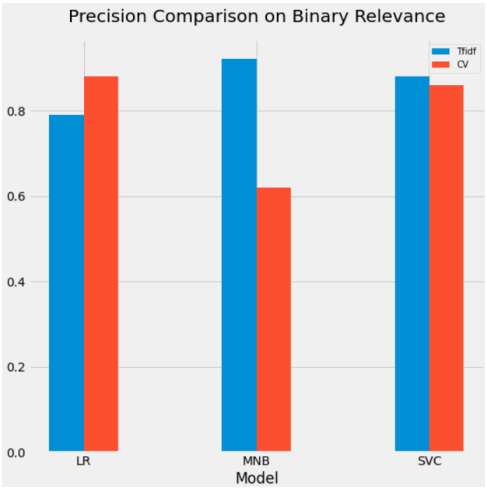

Fig. 5. Precision comparison on Binary Relevance on Google News Dataset

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:33:22 UTC from IEEE Xplore. Restrictions apply.

C. Result based on Label Power set method

The result was achieved using the Label PowerSet-based technique in conjunction with the "CV and TF-IDF",as well as the ML algorithms LR, MNB, and LinearSVC. In both datasets, the LP, TFidf, and Linear SVC model combination had the highest accuracy, precision, and F1- score, which was approximately 0.91, 0.92 and 0.91.
The graphical representation of the results of both datasets is shown figure 6, 7 and 8 using Label Powerset i.e Accuracy, F1-Score, and Precision.

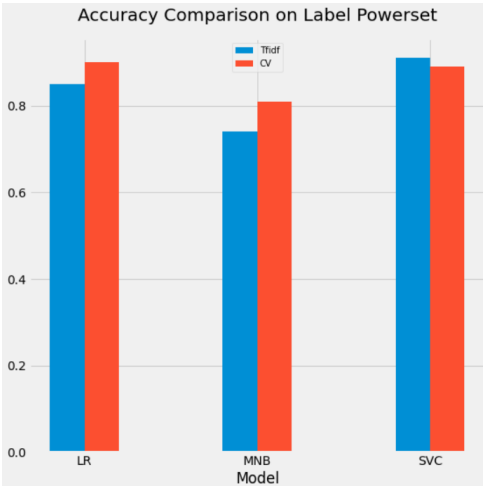

Fig. 6. Accuracy comparison on Label PowerSet Google News Dataset

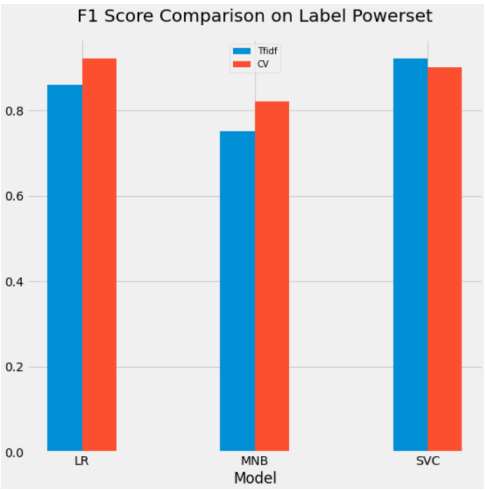

Fig. 7. F1-Score comparison on Label PowerSet Google News Dataset

D. Result based on Classifier chain method

Because this method was more sophisticated and took longer to provide results, it used fewer combinations than the method described above. In the prior method, however, combinations with higher precision were used i.e, "CV and TF-IDF", with LR and LinearSVC algorithm. In both datasets, the CC, Tf-idf, and Linear SVC model combination had the highest accuracy, precision, and F1- score, which was approximately 0.25, 0.27 and 0.28.

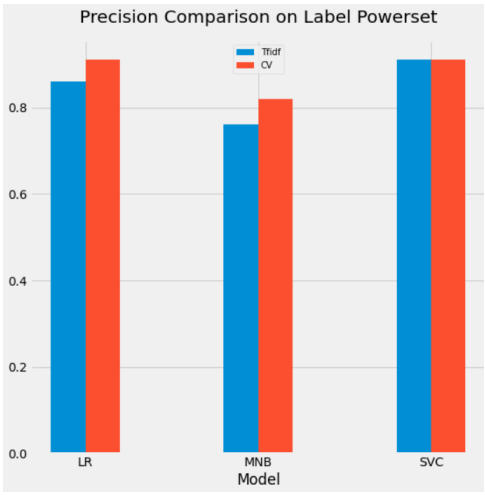

Fig. 8. Precision comparison on Label PowerSet Google News Dataset

E. Result Comparison

The results for accuracy, precision, and F1-score using 15 combinations of various approaches are shown in Tables 1 and 2. By comparing the values of this method the most efficient model that was obtained of the combination of LP, TFidf, and Linear SVC having accuracy, precision, and F1-score on Google News dataset 0.91, 0.92, 0.91 respectively and on Inshort News dataset 0.91, 0.92, 0.91. on both datasets, approximately the same result was achieved. The second highest efficient model was a combination of LP, CV, and Linear SVC having accuracy, precision, and F1-score on Google News datasets 0.90, 0.91, and 0.91, respectively. And On the Inshort News dataset 0.90, 0.91, 0.91 respectively on both datasets approximately the same result was achieved.

VIII. CONCLUSION

In this paper, multilabel news classification was introduced by utilizing three PTAs called "Binary Relevance, Label Powerset Classifier Chain," two TVs called "count vectorizer and TF-IDF," and three machine learning (ML) models for classification called "logistic regression (LR). In essence, several PTA were combined, "text vectorizers, and machine learning classifiers," and have come up with a total of 15 unique combinations that categorize news into the right genres. In summary, it may be stated that the optimum result was obtained by using the "support vector classifier (SVC) as a machine learning model, label powerset (LP) as a problem transformation technique, and TF-IDF as a text vectorizer technique." Hence, it produced an accuracy of about 91%, an F1 score of about 92%, and an overall precision of about 90% on the news datasets.

***Abstract*— Every day, individuals all over the globe use video-sharing websites to broadcast their thoughts, experiences, and recommendations to the world. There has been a huge rise in educational interest in the area of sarcasm detection for these opinionated videos. Although sarcasm has proven effective for written text, it remains an unexplored area of research when applied to video and other forms of multimodal data. Numerous verbal and nonverbal signs, such as a shift in voice, an overemphasis in a phrase, a stretched pronunciation, or a stiff-looking face, are often used to convey sarcasm. The majority of current research on sarcasm detection has heavily relied on textual content. Hence, in this paper, we suggest that the use of multiple modalities can help with more accurate sarcasm identification. The results of our studies on one of the multimodal sarcasm detection (MSD) benchmark datasets "MUSTARD" reveal that our strategy outperforms other algorithms in sarcasm classification.**

Keywords—Multimodal Sarcasm Detection (MSD), Multimodal, RegNet, DistilBERT, BERT

I. INTRODUCTION

Multimodal Sarcasm Detection (MSD) is a problem that involves predicting class labels as non-sarcastic or sarcastic based on three modalities: the textual, the visual, and the audio content associated with the videos. The ability to ridicule or show hate in regular communication is facilitated by the use of sarcasm. This is accomplished by using ironic phrases which represents an adverse perception. A sarcastic comment like: "I work 40 hours a week for me to be this impoverished", represents nothing but sarcasm. Nonetheless, there are times when sarcasm lacks unambiguous linguistic cues, Hence, there is a need for other clues to understand a speaker's intentions more accurately. For example, sarcasm may be portrayed through a variety of vocal and non-vocal signs, for instance a shift in voice, an overemphasis in a phrase, a stretched pronunciation, or a stiff-looking face. Besides this, sarcasm detection includes determining verbal or contextual incongruity, from multiple modalities [1],[2].

The feature-level fusion technique is used to combine the multimodal data retrieved by [3]. To understand how the various parts of an utterance relate to one another regardless of modality, [4] introduced an attention model. The incompatibility across modalities, which each express a different mood, is a key indication for detecting sarcasm; yet, these works do not take into account its significance. The cross-domian sarcastic utterance shown in **Figure 1** helps us communicate our logic more clearly. It's easy to see from the audio signal that the speaker is emphasizing the word "incredible". The speaker, meanwhile, is raising his eyes. Hence, sarcasm is often shown by the mismatch between the text (a positive term) and the visual (an eye raise) or audio signal. Hence, sarcasm detection can be improved by focusing on multimodal aspects.

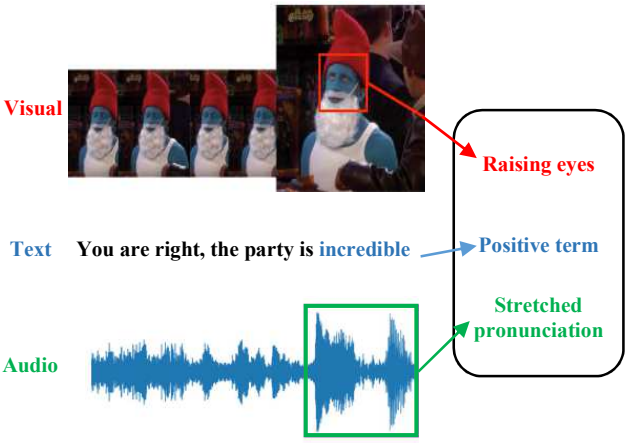

Figure 1 Sarcastic example using multiple modalities

Lately, there has been a rise in interest in MSD, which seeks to characterize a video as sarcastic or non-sarcastic by taking into account: textual, visual, and acoustic modalities. The majority of earlier studies in the area of sarcasm identification using textual data were successful; however, a small number of studies have also been conducted with the aid of many modalities; further work is needed to enhance the results. Intuitively, sarcasm detection methods that employ deep learning techniques can automatically detect relevant information. And the deep learning approach should perform better when there are sufficient samples for training. To increase the accuracy of MSD, we propose a multi-modal fusion network using a feature fusion algorithm based on deep learning.

We experimentally evaluate our model using one of the benchmark datasets, MUStARD [11], to show that our approach is effective. As our proposed method yields superior results, hence, we infer that our proposed approach is better prepared to capture the interrelationships among various modalities for the task of MSD. The following are our most significant overall contributions:

- We introduce a deep-learning-based model for MSD that combines DistilBERT and RegNet to efficiently capture meaningful information across text, visual, and acoustic modalities in a single task,
- To check the robustness of our model so that it can effectively and reliably imitate the multi-modal depiction of textual, visual & acoustic modalities and yield ground-breaking results for MSD, we perform extensive analysis and test our proposed approach using one of the benchmark datasets, MUStARD.

This is how the rest of the manuscript will be laid out. In Section II, we will review the most recent research studies that have contributed to the advancement of sarcasm recognition, with a particular emphasis placed on multimodal sarcasm identification. The suggested novel framework is explained in

Section III. The experiment's results are analysed Section IV, and in Section V, we summarise our findings and offer some suggestions for future directions.

II. Related Work

Both single-modal and cross-modal sarcasm identification methods from the existing cutting-edge works are briefly discussed here.

A. Single modal

This section discusses previous research studies on sarcasm detection that have used only a single modality in their analyses.

1) Text-Based Sarcasm Detection (TBSD)

The method of predicting whether script-based data is sarcastic or non-sarcastic is known as TBSD. Machine learning-based techniques [5] have historically been used to process text for irony identification. Before the development of BERT-based models, other deep learning-based models, such as LSTM [6], attracted considerable interest because of their ability to handle script-based data. Bert-based modes [7] are widely used nowadays to identify sarcasm, emotion, and sentiment from textual data.

2) Acoustic Sarcasm Detection (ASD)

To identify sarcasm in acoustic data, researchers have mostly concentrated on finding certain auditory patterns that are linked to sarcastic utterances. Several aspects [8], [9] such as average amplitude, variations in the amplitude, the pace of the utterance, etc., are analyzed for the detection of irony in audio. Slower speech speed and higher intensity were identified by [9] as possible indicators of sarcasm. Subsequently, [10] [11], [12] examined rhythmic and spectral aspects of voice to determine sarcasm, regardless of the context.

B. Multimodal

In this section, the previous research that was done on sarcasm detection utilizing a range of different modalities is covered.

1) Sarcasm Detection using Image-Text Pairs

As of today, a great number of research have been carried out to identify how one might spot the irony in a certain social post. Users have traditionally relied on data presented in written format; but, in the present era, the use of visuals, videos, music, and emoticons is becoming more common. As a consequence of this, we often come across posts on online community forums that combine text as a caption with visual clues. Enormous amount of research studies has been in the field of sentiment recognition [13], [14] but the detection of sarcasm via the use of caption and visual content [15] [16] has been the focus of great research that is referred to as sarcasm detection using image-text pairs.

2) Sarcasm Detection Using Videos

Every day several social media platforms are bombarded with a variety of multimedia data which includes videos as well. Detecting sarcasm from these opinionated videos is very crucial. From the past few years around 2019, researchers are more eager to work in of multimodal sarcasm recognition with the aid of video datasets. [3] proposed a benchmark dataset MUStARD and analyzed it for the detection of sarcasm. [17]–[20] are a few other recent research studies that proposed cutting –edge methods for detecting sarcasm in videos.

III. Proposed Framework

In this section, the formulation of the objective, and the architecture for processing textual, visual & acoustic input are discussed in detail. The diagram in **Figure 2** illustrates the proposed framework.

A. Formulation of the objective

Given multi-modal data which contain multiple video utterances U_n, each utterance $d \in U_n$ may be written as $d = \{s, v, a, c\}$ where s represents sentences, v represents visual, a represents acoustic, and c refers to the class label. Here, n is the total number of utterances. The main goal is to classify these video utterances as sarcastic and non-sarcastic. Using d as input, MSD seeks to train a sarcasm classifier to accurately categorize multi-modal samples either as sarcasm or non-sarcasm.

B. Model to retrieve features from the textual content

We use DistilBERT [21] to retrieve features from the textual content of the utterances in the video collection. DistilBERT is a compact, quick, less expensive, and lightweight Transformer model introduced via compressing the BERT base model architecture. It has 40% fewer trainable parameters and executes 60% quicker as compared to other BERT-based models. For this reason, we have chosen [21] model to serve as our text encoder. Specifically, we took the mean of the final four layers of the initial token's transformer stack ([CLS]) to obtain a distinct text representation of the dimension $\mathbb{D}_s = 1024$.

C. Model to retrieve features from the visual content

The architecture will almost certainly remain a key aspect therefore, concentrating on broader design spaces may lead to more effective networks. Motivated by this, the RegNet [22] model has been used to retrieve relevant information from the visual content of the utterances. First, each video frame is pre-processed by scaling, normalizing, and cropping the central portion. The mean of the resultant feature vector $\mathbb{D}_v = 2048$ is then computed to provide the final representation for each video utterance.

D. Model to retrieve features from the acoustic content

Librosa, a well-known sound processing library, is one that we make use of to process the acoustic content. We begin by loading the audio sample and using a heuristic vocal-extraction approach, to eliminate extraneous signal interference. Then the processed signal is divided into equal-sized segments to obtain spatial features such as MFCC, spectrograms, spectral centroid, and their temporal derivatives. All of these retrieved characteristics are then combined to form a $\mathbb{D}_a = 1024$ dimensional combined representations.

E. Fusion strategy

To combine the textual, visual, and acoustic features obtained in the earlier steps, a feature-based fusion technique has been implemented. The final dense layer is then applied to the combined feature vector to accomplish the classification task, determining whether the multimodal utterance is sarcastic or not.

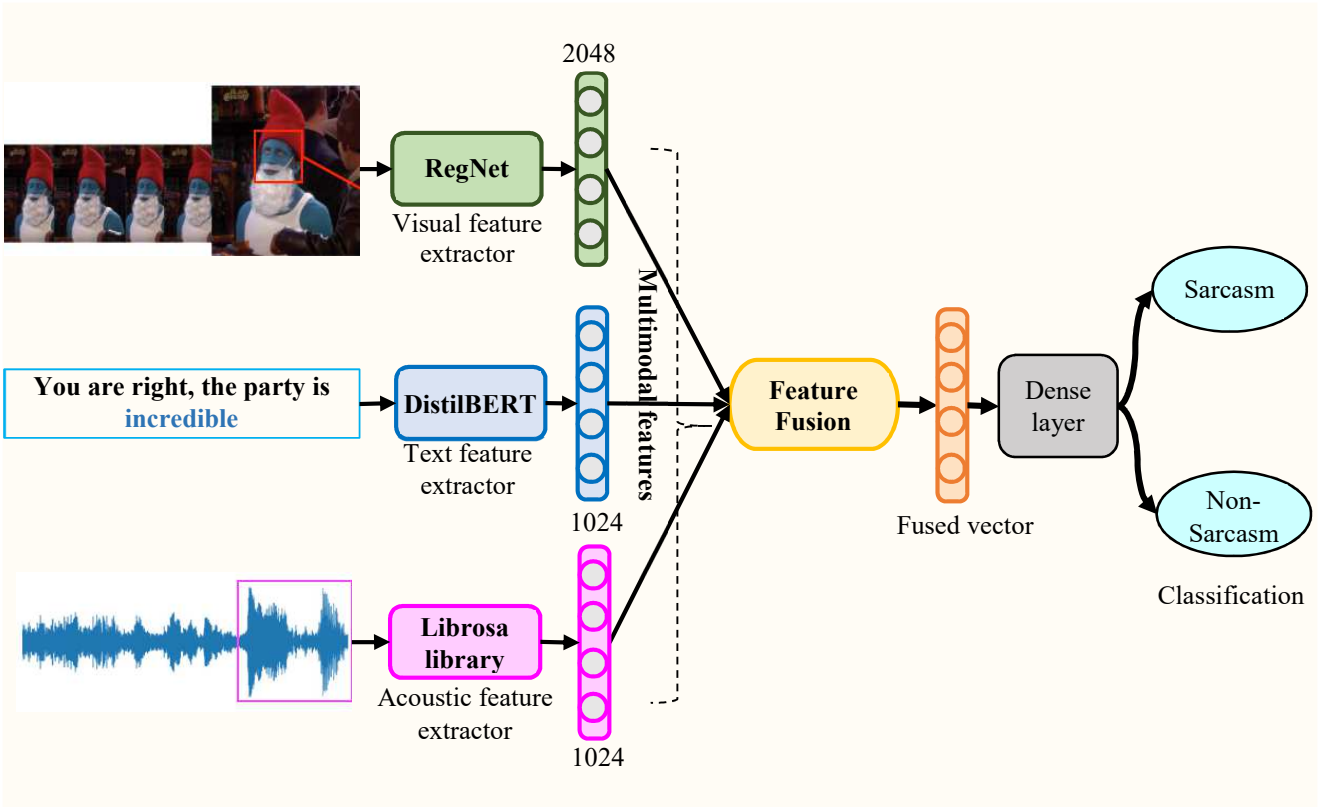

Figure 2 Proposed Framework

IV. Experimental Results

A. Dataset Used

We utilized the publicly available **MUStARD** [3] dataset for MSD, which has a total of 690 video utterances. out of 690 video utterances, 345 are sarcastic and the remaining are non-sarcastic. Our proposed model is tested in two different experimental setups i.e., speaker-independent and speaker-dependent. In the scenario of speaker-independent, all the utterance from one particular series is taken for testing purpose while others are taken for training.

B. Implementation Details

We have used DistilBERT to process textual content, RegNet to process visual data, and librosa library to process acoustic metadata from the videos. For both experimental setups, we used the same hyperparameters for training and validation. Adam optimizer and categorical cross-entropy loss function have been employed with a default learning rate of 0.001. The dimension of $\mathbb{D}_s$, $\mathbb{D}_v$, and $\mathbb{D}_a$ are successfully set to 1024, 2048, and 1024. The experimentation is run for 150 epochs. During the validation of our framework, the batch size is set to 32. To mitigate the risk of overfitting, we employ a dropout probability of 0.4.

C. Evaluation Measures

Weighted $\boldsymbol{Accuracy}$ $(\mathcal{A})$, $\boldsymbol{Precision}$ $(\mathcal{P})$, $\boldsymbol{Recall}$ $(\mathcal{R})$, $\boldsymbol{and}$ $\mathcal{F}1 - \boldsymbol{Score}$ $(\mathcal{F}1)$ are the standard metrics we employ for evaluation. Using an average of results from five separate experiments, we give our outcomes for the speaker-dependent alternative.

D. Evaluated Results

The experimental results of our MSD methodology applied to the MUStARD dataset are shown in **Table *1*** and **Table *2***. The outcomes of our research studies provide evidence that our framework is effective, and performs better than various other cross-modal approaches for MSD. It works far better than earlier methods, exceeding them in all metrics. **Figure 3** and **Figure 4** depict the year-wise comparison of the results from our proposed model to the existing cutting-edge.

Table 1 Experiment analysis on the test samples of the MUStARD dataset for speaker-dependent setting

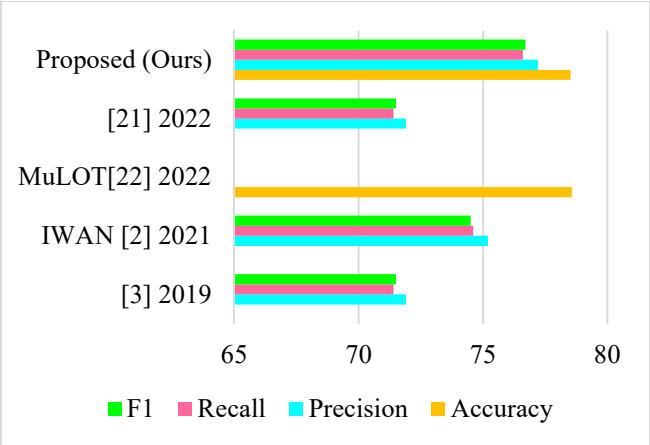

Figure 3 Year-wise methods comparison with our proposed model for speaker-dependent setting

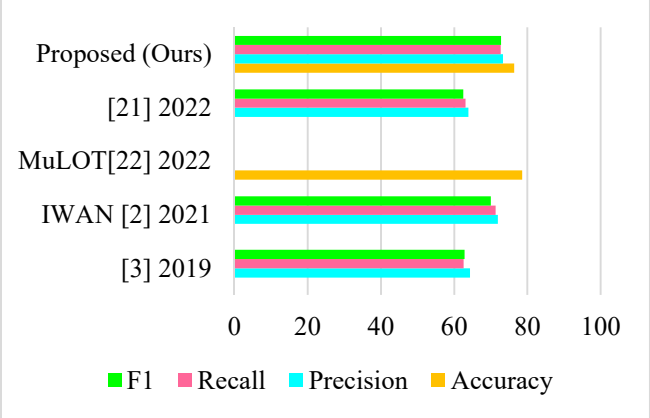

Figure 4 Year-wise methods comparison with our proposed model for speaker-independent setting

V. Conclusion and Future Scope

In this research study, a novel framework is introduced which is the combination of DistilBERT and RegNet. In general, the proposed approach includes the following three main stages: individual feature extraction from each of the separate modalities, feature fusion of all the obtained feature vectors, and classification. Our proposed model beats the baseline results which proves the robustness of our method. Apart from the feature fusion strategy we will try to cover other multimodal fusion techniques in the future such as spatiotemporal fusion, cross-attention fusion, etc. We will also try to integrate attention modules in the visual architecture to focus on the most viable information. Until now, there has been no research done in the area of visual sarcasm detection due to a lack of a dataset; as a result, we are also attempting to create such a dataset.

Natural Ester Oil-Based High Permittivity CaCu3Ti4O12 (CCTO) Nanofluids an Eco-friendly Insulating Medium for Power Transformer

Arun Ram Prasath R T, Sankar Narayan Mahato, Nirmal Kumar Roy, Thomas Paramanandam, Mubeen Akhtar Ansari and Joges Chandra Biswas

***Abstract*- Natural ester oils are being considered as an alternative and eco-friendly insulating medium presently preferred by the power industry for power transformer application. This work deals with the development of natural ester oils like rice bran and sunflower oil-based high permittivity CCTO nanofluids in different volume concentrations. The investigation of dielectric and physico-chemical properties is performed in accordance with ASTM and IEC standards. The enhancement of AC BDV is found at 45% in rice bran oil-based CCTO nanofluid. Increment in dielectric permittivity, decrement in loss tangent, PDIV and DC resistivity are the common factors observed in both the ester oil samples. Also, flash point and thermal conductivity properties showed enhancement with an increment of volume fraction loading. Hence, due to the optimum dispersion of nano-CCTO loading at ≤0.01% in both the base oils of rice bran and sunflower oil, remarkable enhancement is achieved in both the nanofluid samples to develop an eco-friendly insulating medium for power transformer application.**

***Index Terms*-CCTO nanopowder, dielectric property, natural ester oil, physico-chemical property**

I. Introduction

NATURAL ester oil was first introduced in early 1998s for retro-filling purposes in transformers. A completely vegetable oil-based ester fluid transformer 420 kV at 400 MVA was commissioned at a German transmission network [1, 2]. In recent years, eco-friendly, clean and functional technologies are in great demand in electrical installations. Higher moisture tolerance, bio-degradability, slow aging rate, recyclability, low noise, and less initial and operating cost of ester-based insulating oils are highly preferred for transformer applications [3, 4]. Presently, Indian transformer industries have turned their attention to next-gen insulating liquids, including eco-friendly insulating oils like synthetic esters and natural esters [5]. The seed oil or vegetable-based esters are preferred due to their moderate oxidation stability compared to mineral oils, though the natural esters are lower in oxidation stability than synthetically modified esters [6]. The content of fatty acids in natural ester oil determines its performance. Sunflower oil (SFO), Rice bran oil (RBO) and Corn oil (CO) samples among others, contain a high level of fatty acids like palmitic, oleic and linoleic acids [7, 8]. In the last five decades of insulation development, anti-oxidants (natural or synthetic type) and nano-additives are majorly preferred for enhancement studies of insulating liquids [9]. Pavel et al. [10] reported that different natural and synthetic anti-oxidants mixed with different natural ester oils give better insulation results compared to mineral oils. Breakdown studies in synthetic ester and natural ester blend under AC homogeneous field exhibit higher breakdown strength compared to synthetic ester and mineral oil blend samples [11].

Recent developments in nanotechnology and its application in insulating liquids have enabled higher dielectric strength, permittivity, and thermal conductivity. The insulating and charge characteristics of TiO2 (semi-conductive type) nanoparticle dispersed in natural ester oil improves AC BDV by a factor of 1.3 [12]. Liu et al. [13] investigated high-performance Al-N nanoparticles doped with ester base oil the electrical properties like AC, lightning impulse BDV and physical properties like thermal conductivity showed enhanced performance in both electrical and physical properties than base oil. Natural esters from Honge, Neem, Mustard and Punna oils have been tested by dispersing Al2O3, BN and Fe3O4 in different volume concentrations [14]. These ester-based nanofluids not only improve breakdown voltage (BDV) property but also enhance flash and fire point properties with an increase in volume concentrations. Stable ester-based nanofluids developed from exfoliated hexagonal Boron-Nitride (h-BN) mixed with isopropyl alcohol result in 18% enhancement in AC BDV and 11.9% increment of thermal conductivity under RTP conditions [15].

Nanomaterials of Fe2O3 (conductive type) and TiO2 (semi-conductive type) based natural ester nanofluids also show enhanced dielectric breakdown strength at 0.01% volume concentration for both types [16]. The common enhancement of nanoparticles with different insulating oils was attributed to the formation of bond, bound and loose

This article has been accepted for publication in IEEE Transactions on Dielectrics and Electrical Insulation. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TDEI.2023.3301465

multi-layers encapsulated around the nanoparticle [17]. Studies of dielectric and physico-chemical properties performed in natural ester-based nanocomposite fluids showed higher dielectric and physical properties with increment in nanopowder loading. Investigations on dielectric properties and the use of classical nanoparticles are in still progress. Based on the survey, it is found that the classical nanoparticles like conductive, and semi-conductive types possess certain limitations like moderate dielectric and thermal stability nature [18, 19]. Meanwhile, high dielectric ceramic-based CaCu3Ti4O12 (CCTO) nanopowder with different flexible synthesis techniques resulted in low loss and thermally stable due to its internal barrier layer capacitance (IBLC) property, which attracted the researchers for different engineering applications [20]. Hence, high dielectric CCTO nanopowder is chosen for this research study in order to find an alternative insulation of high voltage power apparatus.

Based on this motivation, an initiative has been made, in this work, to study the electrical, physico-chemical properties of eco-friendly natural ester-based high permittivity CCTO nanofluids under different volume concentrations for suitability in power transformer applications.

II. Experimentation

A. Base Fluids

Natural ester oil is usually a seed-based oil, purchased from a leading manufacturer in India. The natural ester oils like Sunflower oil (SF) and Rice bran oil (RB) are used in this work as Base fluid-1 and Base fluid-2 and designated as SF-0 and RB-0. The fatty acid percentage and critical properties of the base fluids are given in Tables I and II respectively.

B. Preparation of CCTO Nanofluids

The preparation procedure of CCTO nanoparticles using the oxalate precursor route and TEM-based particle size analysis of the synthesized nanoparticle have been presented in our previous works [21–23]. The phase-pure CCTO nanoparticles confirm the random prevalence of semi-coherent precipitate within some of the grains resembling spherical balls-like shapes in size ranges of 30–200 nm. The elemental composition of CCTO nanopowder was confirmed by energy dispersive spectra (EDAX) analyses, as shown in Fig 1.

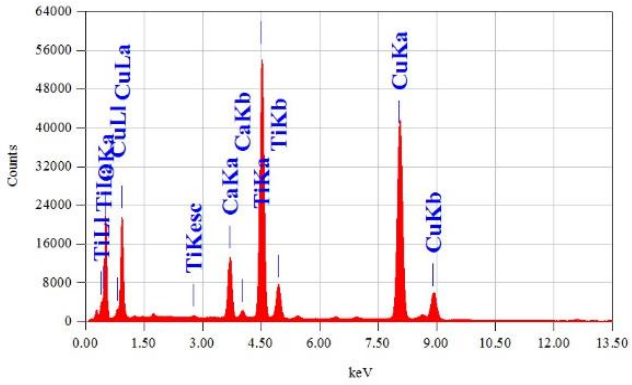

Fig. 1. Elemental composition of high dielectric CaCu3Ti4O12 (CCTO) nanopowder obtained from EDAX Spectra image

The present research work is a continuation of previous work carried out on synthetic ester and mineral oils to determine the suitability of insulating oils with high dielectric CCTO nanofluid in power transformer applications [22, 23]. In this work, refined sunflower and rice bran oils were used to prepare nanofluids with different volume percentages. Prepared nanofluid samples of sunflower oil with volume 0.001 %, 0.0025 %, 0.005 %, 0.01 % and 0.05 % were designated as SF-1, SF-2, SF-3, SF-4 and SF-5. Similarly, the prepared samples of rice bran oil with volume 0.001%, 0.0025%, 0.005%, 0.01% and 0.05% were designated as RB-1, RB-2, RB-3, RB-4 and RB-5. For the preparation of the

This article has been accepted for publication in IEEE Transactions on Dielectrics and Electrical Insulation. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TDEI.2023.3301465

ability to resist electrical stress. For conducting the dielectric strength test, a 100 kV AC automatic BDV tester was used as per IEC 60156 standards [26, 28, 29]. Dielectric dissipation factor (DDF) and Dielectric constant were measured at 90 °C, according to ASTM D 924 standard [19, 22, 23]. The DC resistivity indicates the measure of specific resistance (resistivity) in insulating oil as per ASTM D 1169 standard [19, 22, 23]; it was performed at both Room Temperature and Pressure (RTP) and 90 °C temperature conditions. Partial discharge inception voltage (PDIV) in dielectric liquids was measured using a standard test cell, with a needle-sphere electrode combination with a gap of 50 mm being fixed to prevent breakdown as per IEC 61294 TR:1993 standard [23, 24, 27, 30].

D. Physico-Chemical Properties

IFT is a measure of interfacial tension between insulating oil and water under non-equilibrium conditions, expressed in milli N/m. It is a highly sensitive test for detecting small polar contaminants and oxidation products. Interfacial Tension (IFT) was performed using Kruss K9 Digital IFT tester, according to ASTM D 971 standards, at room temperature. A viscosity test was performed using a temperature-controlled viscosity bath with a calibrated viscometer as per ASTM D 445 standards [19, 22, 23]. The oil samples were tested with variations in temperature of 27 °C, 45 °C and 90 °C. The Flash point test is a measure of flammability of insulating oil and was performed in an automated Pensky-Martens closed cup apparatus as per ASTM D 93 standard [19, 22, 23]. A Thermal conductivity test was performed at RTP and 80 °C temperature conditions using KD2 Pro thermal conductivity tester and expressed in W/(mK) according to ASTM D 2717 standard [23]. Total acid content was measured at room temperature as per ASTM D 974 and is expressed as mg of KOH/g [19, 22, 23].

III. RESULTS AND DISCUSSION

A. Dielectric Properties

AC BDV values obtained at RTP and the enhancement percent for both sunflower and rice bran oils are presented in Tables III and IV respectively. The percentage error plot is shown in Fig. 2. The sunflower oil-based CCTO nanofluid samples show an increasing trend of AC BDV values with respect to volume concentrations up to 0.01% (i.e., from SF-1 to SF-4) samples. Beyond that, decreasing trend in AC BDV was observed at 0.05 % (i.e., SF-5) sample. Similarly, in the case of rice bran-based CCTO nanofluid samples, the dielectric strength of the nanofluid was observed to increase with the increase of volume concentrations. It was also observed that the 0.005% and 0.01% (i.e., RB-3 and RB-4) samples show a sudden increment in BDV values.

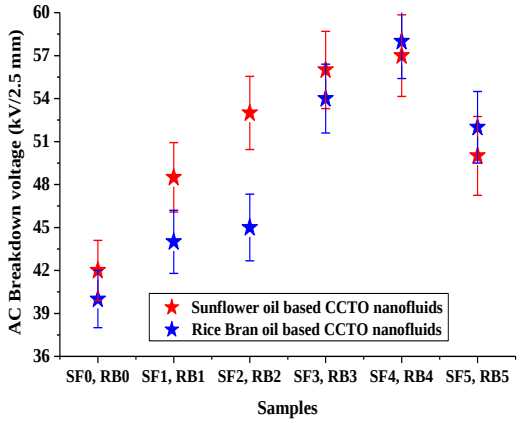

Fig. 2. Mean AC BDV values with 5% error plot of nanofluid samples from different volume concentrations

This article has been accepted for publication in IEEE Transactions on Dielectrics and Electrical Insulation. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TDEI.2023.3301465

Rice bran oil-based CCTO nanofluid was observed to show superior enhancement of BDV value (45%) for 0.01% (i.e. RB-4) sample. Results reveal that BDV values of sunflower and rice bran oil samples at the volume concentration of 0.05% result in saturation with nanoparticle loading. It was noted that the developed nanofluid samples presented improved AC dielectric strength values resulting in charge-trapping and de-trapping processes due to the IBLC effect [25].

The DDF and dielectric permittivity values of the nanofluid samples are measured at 90 °C as per ASTM D 924 standard. The percentage decrement and increment are presented in Tables III and IV respectively. The DDF characteristics of both sunflower oil and rice bran oil-based nanofluids result in linear decreasing trends with an increase in volume concentrations as shown in Fig. 3. But compared to rice bran oil-based CCTO nanofluids, the loss tangent values of sunflower oil-based CCTO nanofluids are quite lower.

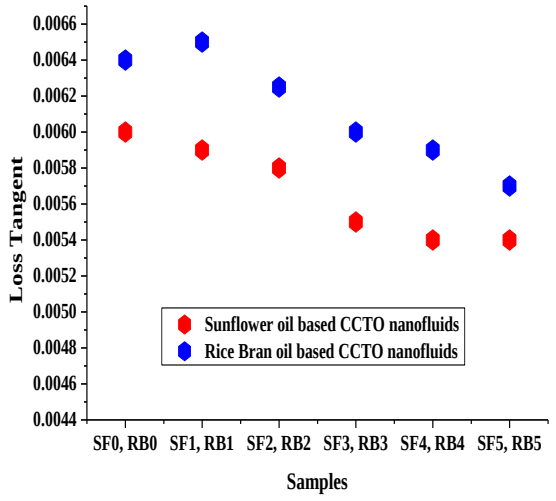

Fig. 3. DDF values of nanofluid samples from different volume concentrations

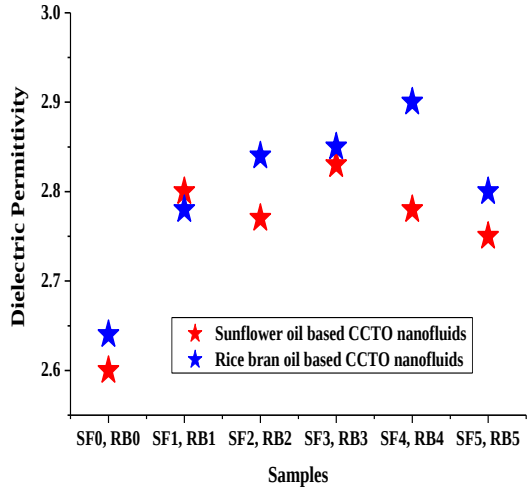

Fig. 4. Dielectric permittivity values of nanofluids samples from different volume concentrations

The sample SF-5 results in the highest decrement, which is almost the same as sample SF-4. Also, it is observed that there is a saturation of loss tangent values for sunflower oil-based CCTO nanofluid with the increase of volume concentrations as compared to rice bran oil-based CCTO nanofluid sample. This may be due to the formation of higher ionic contaminants in the case of sunflower oil-based CCTO nanofluid. From Fig. 4, it is observed that rice bran oil-based CCTO nanofluid samples show superior enhancement in dielectric constant with respect to different volume concentrations as compared to sunflower oil-based CCTO nanofluid samples. In rice bran oil samples, the steady increment of dielectric values was observed to be up to 0.01% (i.e., from RB-1 to RB-4) with the highest enhancement of 9.84% for sample RB-4. In the case of sunflower oil-based CCTO nanofluid samples, irregular improvement was observed from 0.001% to 0.005% (i.e., SF-1 to SF-3) samples with an increase in volume concentrations. Overall, it was observed that the loss tangent decreased with an increase in dielectric permittivity, probably due to the formation of nano-CCTO grain boundaries based on the optimal loading, which is similar to mineral oil-based CCTO nanofluid samples [22] and synthetic ester oil-based CCTO nanofluid samples [23].

DC resistivity values of the different samples and their percentage decrement are presented in Tables III and IV respectively. Graphical representations of DC resistivity values for both samples at RTP and 90 °C temperature conditions are presented in Fig. 5 and Fig. 6 respectively. DC resistivity values of both nanofluid samples resulted in decrement compared to base oil samples with respect to different volume concentrations. Under RTP conditions, compared to base oil samples, both nanofluid samples resulted in decrement with an increase in volume concentrations of nanoparticles. In addition, maximum decrement was observed at 0.05% (i.e. RB-5) sample as compared to other nanofluid samples. At 90 °C, the decrement in resistivity values was observed with an increase in volume concentrations. But for 0.01% and 0.05% samples, there was a slight increase in DC resistivity.

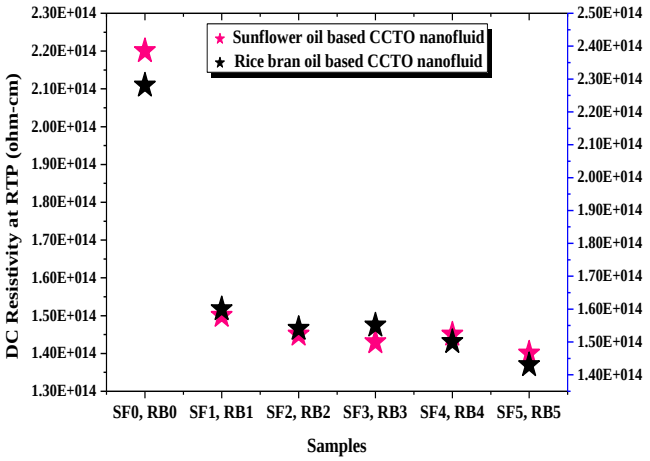

Fig. 5. DC Resistivity values of nanofluid samples from different volume concentrations at RTP conditions

This article has been accepted for publication in IEEE Transactions on Dielectrics and Electrical Insulation. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TDEI.2023.3301465

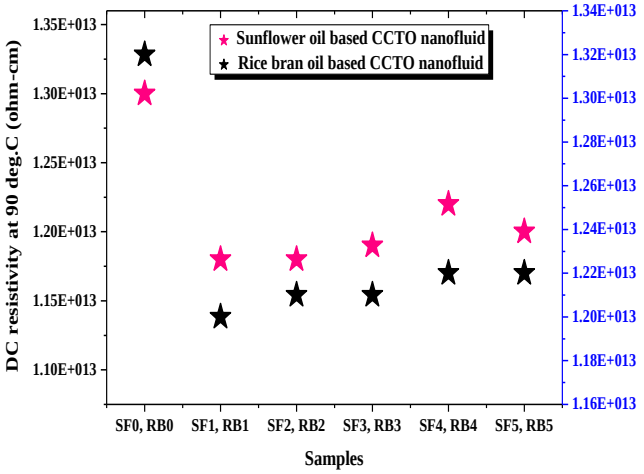

Fig. 6. DC Resistivity values of nanofluid samples from different volume concentrations at 90 ºC conditions

The highest increment was observed in the 0.01% (i.e. SF-4) sample among all the nanofluid samples. A similar trend was observed when the resistivity was measured at 90 °C with synthetic ester oil-based CCTO nanofluid samples [23].

PD inception voltage values measured under RTP conditions and the percentage decrement are given in Tables III and Table IV respectively. The percentage error plot of PDIV values corresponding to the electric field generated at needle electrode arrangement [23, 24] for base oil and nanofluid samples are presented in Fig.7 and Fig. 8 respectively.

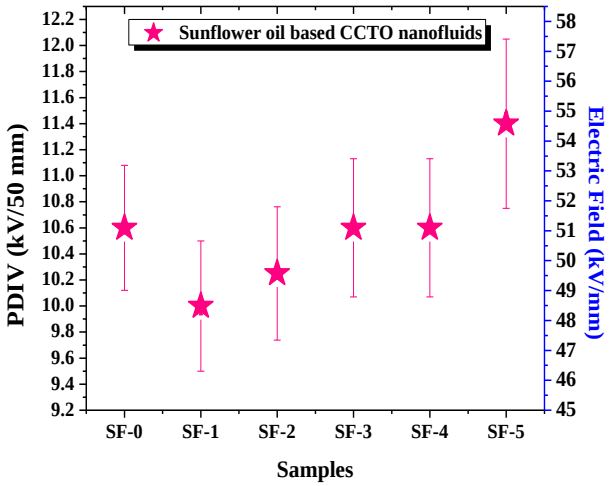

Fig. 7. PDIV values of sunflower oil-based nanofluids samples from different volume concentrations

It was observed that with an increase in volume concentrations, rice bran oil samples show reduced PDIV characteristics, similar to sunflower oil samples. But for 0.05 % (SF-5 and RB-5), the detected PDIV results are comparatively greater than the respective base oil samples. These nanomaterials resulted in a little increment of PD inception characteristics due to saturation following further addition of volume concentrations, owing to irregular size orientation of nanomaterials. Further, due to the high dielectric nature of CCTO nanoparticles, both natural ester-based nanofluid samples results minimized PDIV initiation. It was also observed that the increase of PDIV values, which was observed after certain volume concentration, is not linear with the increase of volume concentrations in both nanofluid samples. The highest decrement of PDIV value was observed for both 0.001 % and 0.0025 % (i.e. SF-1 and SF-2) samples.

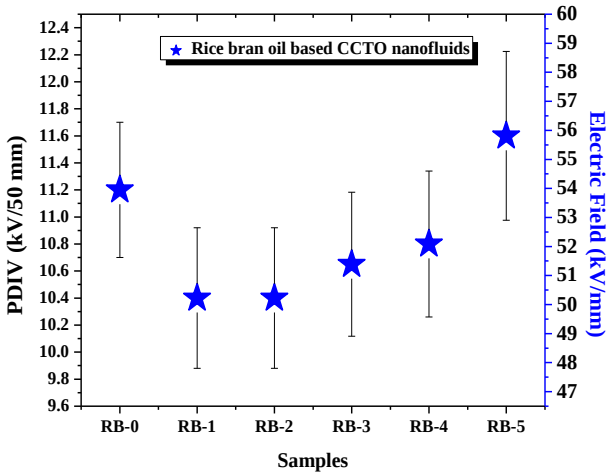

Fig. 8. PDIV values of rice bran oil-based nanofluids samples from different volume concentrations

B. Physico-Chemical Properties

Interfacial tension was measured under the RTP condition. The IFT values and their percentage decrements are shown in Tables V and VI respectively. The variation of IFT values in base oils and nanofluid samples with respect to volume concentrations is presented in Fig. 9. Both sunflower and rice bran oil-based CCTO nanofluid samples give an almost similar decreasing trend with an increase in volume concentrations.

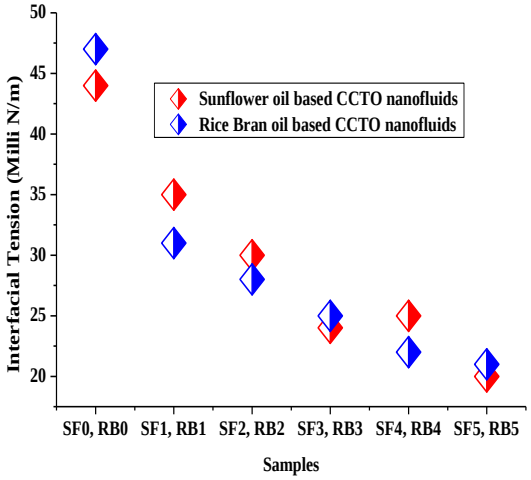

Fig. 9. IFT values of nanofluid samples from different volume concentrations

Analyses of comparative decrement between the nanofluid samples reveal that the highest decrement is at 0.05% volume concentration for both sunflower and rice bran oil samples (i.e. SF-5 and RB-5). The overall decrement trend was attributed to the occurrence of higher polarization at the oil-water interface region. Similar decremental nature of IFT values was observed with synthetic ester oil-based CCTO nanofluid samples [23].

TABLE V

PHYSICO-CHEMICAL PROPERTIES OF NATURAL ESTER OIL BASED CCTO NANOFLUIDS

Samples	IFT (milli N/m)	Viscosity (C-St) at 90 °C	Flash point (°C)	Thermal Conductivity (Wm/K) at 80 °C	Acidity (mg KOH/g)

RB-4	0.38	11.39	4.37	20	53.19
RB-5	0.57	13.92	5.0	100	55.3

The Viscosity test was conducted at different temperatures. The measured viscosity values and their percentage enhancement are shown in Tables V and VI respectively. The variation of viscosity with respect to different volume concentrations at different temperatures is presented as bar chart in Fig. 10. A minor increase in viscosity was detected with an increase of volume concentrations. The viscosity was found to reduce with the increase in temperature. Among all the samples, 0.05 % volume concentration of both nanofluids (i.e. SF-5 and RB-5) samples showed superior results with enhanced viscosity to base samples. Viscosity enhancement is on account of the density of nano-CCTO powder, which is similar to that of mineral oil-based CCTO nanofluid [22] and synthetic ester oil-based CCTO nanofluid [23] samples.

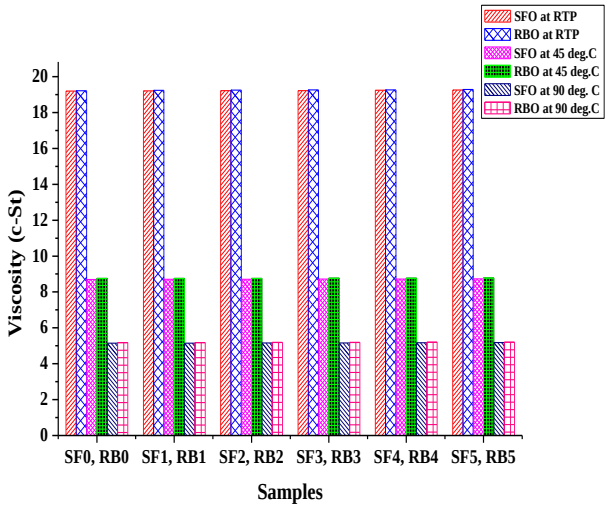

Fig. 10. Viscosity values of nanofluid samples from different volume concentrations

Flash point tests in base oils and nanofluid samples were performed as per ASTM D93 standard at RTP conditions. The flash point values and the enhancement percent are shown in Tables V and VI respectively. The variations of flash points of natural ester oil samples are graphically represented in Fig. 11.

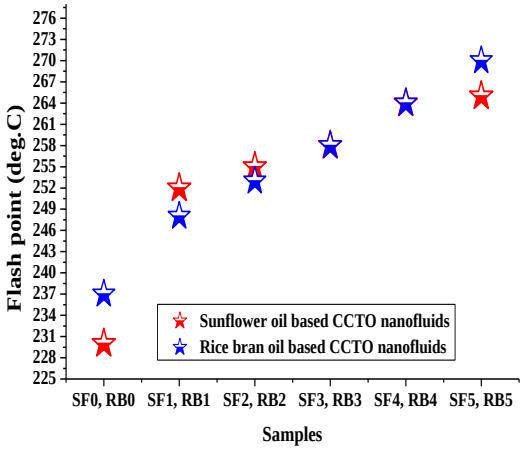

Fig. 11. Flash point values of nanofluid samples from different volume concentrations

This article has been accepted for publication in IEEE Transactions on Dielectrics and Electrical Insulation. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TDEI.2023.3301465

It was observed that the flash point increases almost linearly with the increase of volume concentrations for both samples. It was also observed that both nanofluid samples resulted in enhanced flammability characteristics to base oil samples. Moreover, the natural ester oil-based CCTO nanofluid resulted in improved flammability characteristics, similar to mineral oil-based CCTO nanofluid samples [22] and synthetic ester oil-based CCTO nanofluid samples [23].

Thermal conductivity tests in base oils and nanofluid samples were performed at RTP and at 80 °C respectively. The test results and the percentage increment are presented in Tables V and VI respectively. At both temperatures, the thermal conductivity increased with an increase in volume concentrations of nano-CCTO powder, which is presented in Fig. 12.

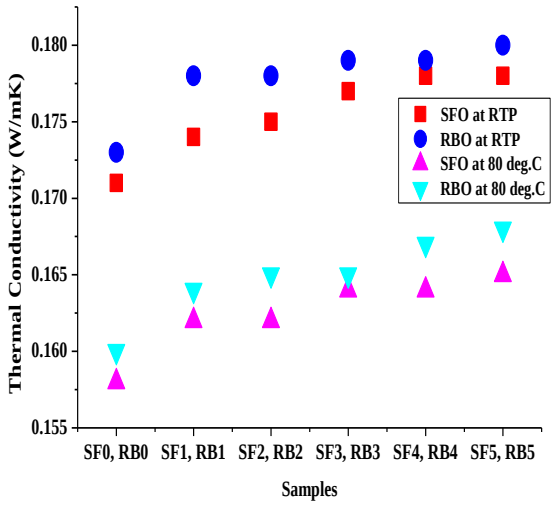

Fig. 12. Thermal conductivity values of nanofluid samples from different volume concentrations

Moreover, the thermal conductivity reduced with the increase in temperature. It is found that the percentage increments of thermal conductivity for samples SF-5 and RB-5 are 4.43% and 5% at 80 °C respectively. The thermal conductivity enhancement in natural ester oil-based CCTO nanofluid depends on the presence of nanoparticle size, shape, and grain boundaries. A similar trend was noted in synthetic ester oil-based CCTO nanofluid [23].

The acidity test was carried out at RTP as per ASTM D 974 standard. The observed values are tabulated and the enhancement percentages are given in Tables V and VI respectively. The variation of acidity with the increase of different volume concentrations is presented in Fig. 13. Acidity was seen to be very low for natural ester oil-based nanofluids, as well as for a few nanofluid samples. It was also observed that the acidity increased with the increase of volume concentrations in an acceptable range (i.e., ≤0.05 mg KOH/g). Further, nanofluid samples may result in the generation of polar compounds under aging conditions [22, 23].

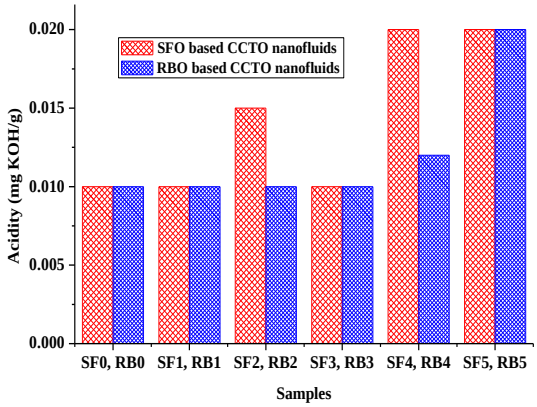

Fig. 13. Acidity values of nanofluid samples from different volume concentrations

IV. Conclusion

Natural ester oil-based CCTO nanofluids have been successfully developed and critical properties like dielectric and physico-chemical properties were examined in accordance with ASTM and IEC standards. The conclusions are as follows:

• In dielectric properties, AC BDV is enhanced as the volume concentration of CCTO increases in both sunflower and rice bran oil samples, indicating that the use of high permittivity ceramics may tend to hinder breakdown occurrence by converting faster electrons to slower ones due to IBLC effect. An increment in dielectric permittivity in rice bran oil-based nanofluid samples with a reduction of loss characteristics in sunflower oil-based nanofluid samples was observed. This is attributed to the inclusion of optimized addition of nano-CCTO particles. In DC resistivity and PDIV characteristics, a decrement was observed with respect to the increase in volume concentrations.

• Viscosity in nanofluid samples results in negligible increment with variation in temperature compared to base oil samples. Interfacial tension (IFT) test results show a tremendous decrement with an increase in volume concentrations due to the high rise of polar contaminants. Thermal conductivity as well as flash and fire points, result in enhanced values in both sunflower and rice bran oil-based nanofluid samples with an increase in volume concentrations. Moreover, the acid number in nanofluid samples is in the lower range. Nanofluid samples may result in the generation of polar compounds under aging conditions.

Therefore, the developed natural ester oils-based CCTO nanofluids can enhance critical properties compared to base natural ester oil samples. The dielectric and physico-chemical properties of high dielectric CCTO-doped sunflower oil and rice bran oil-based nanofluid result in almost similar nature as compared to synthetic ester oil [23], and higher than mineral oil [22] based high dielectric CCTO nanofluid samples for power transformer application. Further, the particle agglomeration along with moisture content studies are yet to perform as a future study.

***Abstract*—In the field of software engineering, the creation of use case diagrams is crucial for effectively capturing system requirements. The current traditional development approach utilizes textual functional requirements, however, it is time-consuming and error-prone. In software engineering, our research suggests a novel way for automating the production of use case diagrams. It is well-recognized that conventional methods using written functional requirements are time-consuming and prone to inaccuracy. Our approach takes advantage of natural language processing methods for analyzing and obtaining data from natural language specifications in order to address this. This study creates use case diagrams by using predetermined rules and heuristics, which speed up the process and lowers error rates. Implementation as well as evaluation against actual requirements show that the proposed automated approach is superior to existing methods. Our approach increases efficiency and accuracy while requiring less time and effort to create diagrams while maintaining consistency. By presenting a more effective and dependable method of collecting system requirements, this research makes a contribution to the discipline of software engineering.**

***Index Terms*—Natural language processing, UML model, Use case diagram, SRS document, Software requirements**

I. Introduction

Software requirements are frequently written in standard English, which is frequently unclear, ambiguous, and unstructured. The author's mood and the environment, as well as society and area demographics, might influence the natural language used. Automating the entire process and computerizing it can be a highly effective way to reduce errors brought on by human error. Natural language documents can contain even the smallest mistake or error, which can take time to correct and have an effect on important sectors like the Internet.

A key factor in the accomplishment of software development projects is the process of determining software requirements. But when these criteria are written in normal English, difficulties like ambiguity and a lack of organization are frequently introduced. In this essay, our research examines the benefits and problems of software requirements, as well as the potential remedies provided by automation and a better comprehension of the underlying problems.

Understanding the issue and how the software will affect the product should be the first step in the software requirement process. It can be challenging to identify the demands and specifications of the software since customers frequently have trouble understanding the issue description. Writing software specifications in normal English might lead to ambiguity and confusion. Numerous elements, such as the author's mood, surroundings, society, and local demography, have an impact on the language chosen. These elements make it even harder to provide exact information and can result in mistakes in the finished output. In texts written in natural language, even the smallest error can have a big impact. The written descriptions and diagrams that form the foundation of the procedure for developing software must be carefully examined to guarantee that the system operates as planned [1]. The method of automating software requirements has many advantages. In order to examine and analyze requirements, researchers can now use automated or semi-automated procedures, saving important time. Due to the inherent ambiguity of language, previous solutions such as grammar-based approaches that depended on extracted text have been shown to be erroneous. As a result, there is an increasing trend toward automating requirements analysis using sophisticated natural language processing abilities. Software development teams can increase the effectiveness and efficiency of the requirement collection and analysis phase through automation.

II. Overview

Natural language processing (NLP) plays a crucial role in the extraction of pertinent information from texts written

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 02,2023 at 06:42:22 UTC from IEEE Xplore. Restrictions apply.

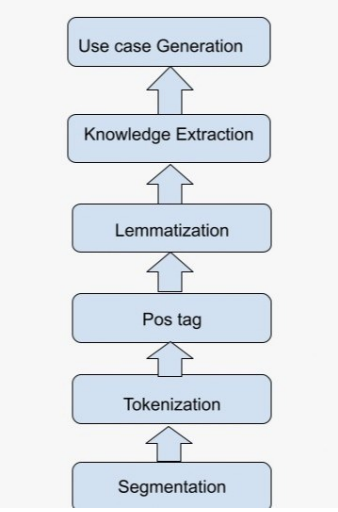

Fig. 1. Step of the Approach

in natural language, and this information can then be used directly by a machine for interpretation. As each case associated with natural language texts can be ambiguous, a wide range of NLP techniques are used to overcome this challenge. Traditionally, techniques such as use-case-driven assistant tools and language analysis for design purposes were used, but they have become outdated due to their limitations in bridging the gap between the processes involved in system design. Hence, NLP has become an essential tool in reducing the gap between the design processes.

One of the significant uses of UML use case diagrams in software development is to illustrate how a system interacts with external factors such as a company, device, or customer. The use of diagrams is also helpful in defining the system's capabilities and its interactions with different stakeholders. A use case diagram is produced to represent the system's behaviors with respect to external actors when the requirements for the system are first determined. The text can be divided into parts of speech, and each part of speech has its own unique structure. The above-mentioned technique is more accurate and efficient as grammatical and spelling errors can be corrected at an early stage with minimal effort. This approach is commonly used in natural language processing to create use cases and alternative use case diagrams.

III. Related Work

In recent years, a range of natural language processing techniques has been employed for software development. One of the earliest studies was conducted at the DEl Institute of Technology, where sentences were divided into newer sentences based on conjugation to identify different types of standard structures.

Automated tools such as R-Tool, NL-OOPS, and CM-BUILDER are utilized in natural language processing to visualize rough diagrams from user documents, which need to be further rectified by an observer [10]. Researchers have looked into using language to categorize different texts, including GOOAL, CM-Builder, and LIDA. The creation of class diagrams and the identification of use cases by comprehending their behavior through language provide a novel approach to classifying objects and building use case models. They do not, however, come without restrictions and problems that need to be taken into account. The potential for errors in diagrams created from user documents is a noteworthy limitation. Although these technologies can depict basic schematics, the natural complexity and diversity of spoken language necessitate human observation and correction. The management of many customer documents and languages presents a substantial additional barrier. Another aspect to be considered is the performance and scalability of automated programs. The capability of these applications to manage and analyze enormous datasets quickly becomes crucial as the amount of user papers rises.

Natural language processing methods include the Stanford Parser, WordNet, Stanford Named Entity Recognizer, and Java RAP, among others. The Stanford Named Entity Recognizer pinpoints the placement and structure of a word, the Stanford Parser determines sentence organization, WordNet maintains linguistic information for many sorts of identifiers, and Java RAP is useful for analyzing complicated documents and producing use-case models. These tools are only a few of the numerous natural language processing methods that are readily available.

IV. Observations

Before any software is created, the client provides the software development company with the initial requirements. The initial request from the client is delivered via a software requirements specification (SRS) document [2]. Whereas the non-functional requirements specify the system's quality, the functional requirements specify the function that the system must do.

The functional requirements, which are usually expressed in English as noun and verb phrases are commonly written in natural language. These natural language requirements are turned into a use case diagram to reduce confusion throughout the software development phase. We must discover the three components of actors, user cases, and the interaction between them in order to create a use case diagram. They can be found by making the subsequent findings.

1. Figuring out the Actors: The term actor represents any user who is playing some role in the system. They can be identified by examining who the system is made for, who is using the system, and who is making changes to the system. These are mostly the subject of the NP (Noun Phrase). So to find the actors of the system model need to find the nouns and pronouns in the SRS. Actors can be identified by examining the system's intended users, users of the system, and those who make changes to the system.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 02,2023 at 06:42:22 UTC from IEEE Xplore. Restrictions apply.

2. Figuring out the Use Case: A use case explains the way an actor communicates with the framework and the sequence of events that take place there. Therefore, use cases are linked to the actors mentioned in the requirements. Therefore, the user case is most likely the VP (Verb Phrase) in the sentence so to identify the use case model need to find the corresponding VP in the NP+VP combination.

3. Figuring out the linkage between the Actor and Use case: As discussed above after finding out the actor and use case model need to find which actor is related to which use case. We are enough to find if there is any preposition connecting the two.

Our method makes the assumption that the stated needs are practical, written in English, and correctly spelled and grammatically. Then, using a six-step approach, segment, tokenize, tag POS data, lemmatize it, and extract knowledge. By identifying actors, use cases, and their interactions, a use case diagram is ultimately produced.

V. Proposed Approach

The proposed approach comprises several steps, beginning with segmentation and culminating in the creation of a use case diagram. However, it may be beneficial to include a spelling check feature to correct any spelling errors prior to commencing the process. The first step, segmentation, involves separating paragraphs into individual sentences. Next, tokenization is employed to break down each sentence into individual words, which are then labeled with Parts of Speech (POS) tags [18]. After POS tagging, then divide the POS tags into chunks. Finally, extract details from the base words to construct the use case diagram.

This text is preprocessed to prepare it for segmentation. The entire text is combined into one paragraph, and line breaks are replaced with white space. Any prefixes such as Mr. or Ms., website addresses such as .in or .com, decimal numbers, and abbreviations such as U.S. or pvt. are replaced with a special character sequence to prevent confusion with sentence-ending periods.

A. Segmentation

By breaking down the text into more manageable chunks, the segmentation process helps to solve the difficulty of comprehending the SRS. It does this by dividing paragraphs into sentences. [21]. The quantity of segments is determined by how many sentences make up a paragraph. For example, users can buy items with cash. Moreover, he can use the card. After the segmentation, the text is changed to two sentences, the user can buy with cash and Moreover, and he can buy it by card. To do the segmentation, find full stops (“.”), question marks (“?”), explanation marks (“!”) in the preprocessed text and replaces them with the ¡stop¿ to divide them into sentences. In the next process, each item would be divided into words.

B. Tokenization

Sentences are divided into tokens during the tokenization process after being produced through segmentation. It

Segmentation

User A and User B can equally connect to WiFi direct and search available users.
User A can send invitation to connect and user B can grant invitation.
Also, they can send multimedia and receive multimedia such as message, audio, video and file.
User A is same as User 8 can terminate connection.

Fig. 2. Output of Segmentation

is straightforward to use POS tagging, which assigns the keywords to a category when the sentence is converted into a collection of tokens [21]. Each word has commas and full stops, question marks, exclamation signs, and white space divide words. So split up words based on them. For example, when tokenization is applied to the given sentence, the user can buy items with cash, the output would be a group of words: user, can, buy, items, with, cash. All the symbols mentioned above can be first converted to spaces and then the text can be segregated using the location of the spaces. So Python has an inbuilt function called split() which splits the sentences based on delimiters to words, shown in Fig 3 and Fig 4.

```
def tokenization(doc):

    doc = segmentation(doc)
    tokenized_text = []
    for line in doc:
        tokenized_text.append(line.split())
    return tokenized_text
```

Fig. 3. Code snippet of tokenization

Tokenisation

User/ A/ and/ User/ B/ can/ equally/ connect/ to/ WiFi/ direct/ and/ search/ available/ users./
User/ A/ can/ send/ invitation/ to/ connect/ and/ user/ B/ can/ grant/ invitation./
Also,/ they/ can/ send/ multimedia/ and/ receive/ multimedia/ such/ as/ message,/ audio,/ video/ and/ file./
User/ A/ is/ same/ as/ User/ 8/ can/ terminate/ connection./

Fig. 4. Tokenization output

C. POS Tagging

The speech is made up of several speech components, including verbs, nouns, adjectives, and so forth. Each created token is given a POS (Part of Speech) by the POS tagger. Identifying between words with the same spelling but distinct meanings is the main goal of POS tagging. For instance, the meaning of the word right has a different context

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 02,2023 at 06:42:22 UTC from IEEE Xplore. Restrictions apply.

when we say ”take a right turn” and ”you are right.” So when I use an NLTK package to generate tags of words: text=word_tokenize (“you are right, we should take a right turn”), the tags for both the right are different as their context in the sentence is different.

A word in the corpus is given a speech component based on its meaning and context during the POS tagging process [20]. Rule-based taggers and stochastic taggers are the two categories into which POS taggers fall. Whereas stochastic taggers use frequency or probability as a parameter for word tagging, Brill’s tagger uses a rule-based approach that takes context into account. The most common tag in the training corpus collection might be used to tag the term as a workaround, however, this could lead to an unfavorable order of tags.

The n-gram model, which assesses the likelihood that a tag would emerge with the n preceding tags, is an alternative to POS tagging. A stochastic method using transition and emission probabilities is an HMM with POS tagging [19]. The possibility that one tag will follow another is known as the transition probability, and the set of probabilities for each tag emitting a particular term is known as the emission probability. The proposed method relies on the SpaCy library, which was created primarily for the use of natural language processing (NLP) training. SpaCy offers numerous model ranges, each with its own special characteristics. For the English language, use the en core web sm model. To load all NLP models, use the command spaCy. load(en core web sm), which creates an NLP object and assigns parts-of-speech (POS) tags [10].

Each word in a document should be given a part-of-speech (POS) tag, which is a crucial step in natural language processing, particularly in software engineering. Token objects in the SpaCy library give users access to POS tags, which offer detailed data on word usage. Grammatical rules can reveal more information about word usage, such as whether a word serves as both the subject and a noun. A crucial step in natural language processing, particularly in software engineering, is POS labeling, which helps to distinguish between words with matching spellings but alternate meanings.

```
def posTag(doc):

    doc = segmentation(doc)
    nlp = spacy.load('en_core_web_sm',disable=['ner','textcat'])
    tagged_text = []
    for line in doc:
        sub = []
        t = nlp(line)
        for token in t:
            if token.pos_ == 'PUNCT':
                continue
            sub.append(token.text+'->'+token.pos_)
        tagged_text.append(sub)
    return tagged_text
```

D. Lemmatization

In natural language processing algorithms, it is crucial to ensure that all tokenized words are transformed to their base or root form. In the English language, a single word can have multiple variations, but for our purposes, consider all forms as a single entity. For example,” run” can take on various forms such as ”running,” ”runs,” and ”ran,” but the aim is to represent all of these forms as ”run.” This process is known as lemmatization, which helps simplify the language and reduce the complexity of the analysis.

In any NLP algorithm *(fig 7)*, it is essential to ensure that all tokenized words are transformed into their root form. In the English language, a word can have multiple forms, but the aim is to treat all forms as equivalent, rather than separate meanings. This can be achieved through stemming or lemmatization. Stemming involves removing preceding letters from the word to reduce it to its base form, but it can produce incorrect spellings or entirely different meanings. In contrast, lemmatization considers the meaning of the word, making it a more accurate method. Although this step typically occurs during the preprocessing stage, perform it at this stage to ensure that the word’s part of speech is retained.

In NLP methods like text categorization, sentiment analysis, and knowledge representation, lemmatization is a crucial step. To make sure that each token is given the appropriate POS, it is crucial to carry out POS tagging following lemmatization *(Fig 8)*. Lemmatization has a significant positive impact on NLP approaches like text categorization, sentiment classification, and knowledge representation. It is possible to limit the size of the feature space, prevent overfitting, and improve the performance of machine learning models by reducing the proportion of distinctive words in the text.

E. Knowledge Extraction

The first step in creating a use-case diagram is identifying the participants, use cases, and linkages between them. We separate the input into tokens and assign the correct portion

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 02,2023 at 06:42:22 UTC from IEEE Xplore. Restrictions apply.

```
def lemmatization(doc):

    doc = segmentation(doc)
    nlp = spacy.load('en_core_web_sm',disable=['ner','textcat'])
    lemmatized_text = []
    for line in doc:
        sub = []
        t = nlp(line)
        for token in t:
            if token.pos_ == 'PUNCT':
                continue
            sub.append(token.lemma_)
        lemmatized_text.append(sub)
    return lemmatized_text
```

Fig. 7. Code Snippet of Lemmatization

Port Lemmatization

User, A, can, send, invitation, to, connect, and, user, B, can, grant, invitation,
also, they, can, send, multimedia, and, receive, multimedia, such, as, message, audio, video, and, file,
User, A, be, same, as, User, 8, can, terminate, connection,

Fig. 8. Output after Lemmatization

of the speech to each token. The actors are then located by traversing the full array in accordance with a set of rules created specifically for this task. The token can be classed as an actor if it is a subject, noun, or pronoun and its dependency is compound. We search the code for tokens that contain both verbs and objects to find use cases, eliminating helping verbs because they are different from the primary verbs [6]. This is how the logic is implemented *(fig 9)*:

The first one needs to be a verb, and the second one ought to constitute a noun, according to the use case's main rule [12]. Handling exceptions is also a crucial task as it can emerge when writing two verbs together like scroll up/scroll down content which can be handled by segregating verbs and adding a noun to each of them. An actor and a use case diagram have a relationship that is established by identifying the tags of the GKPs, if the actor and the use case are in the same sentence boundary then they have a relationship. After the last step, have knowledge about all the actors, and their respective use cases *(fig 10)*. Now to give the use case diagram life, use this information gain and convert all the findings into images using PIL.

```
while c < len(pos_text):
    actors = set()
    while c < len(pos_text):
        if (pos_text[c].pos_ == 'NOUN' or
        pos_text[c].pos_ == 'PROPN') and

VI. CONCLUSION

In conclusion, this research study has focused on analyzing the generation of UML diagrams in the context of software engineering. In order to ensure that the project developers have the same knowledge and to clear up any misunderstandings during the software development process, UML diagrams are essential. The proposed study is focused on creating a use case model from the functional requirements of SRS, which results in a streamlined form of the original problem statement.

In order to address this issue, this study has created an approach by using natural language processing to examine and extract knowledge from given requirements. We were able to successfully gather the data required to produce use case diagrams through segmentation, tokenization, part- of-speech tagging, lemmatization, and knowledge extraction. Notably, when producing these diagrams, our technique has shown an accuracy rate of less than a fourth. We have built a portal where users may access the gathered data and inspect the resultant UML diagrams in order to promote cooperation and simplify the software development process. With this endeavor, the engineering team will be more effective and cohesive and be able to go forward with the creative process as a unit. The proposed strategy preserves the organic essence of the industry while maintaining a uniform and thorough under- standing of the functional needs by utilizing natural language processing tools. The discipline of software engineering and its practitioners stand to gain from additional developments in automating UML diagram production as a result of this research.

VII. FUTURE SCOPE

Based on the current state of the research topic, there are several potential areas for future exploration and development. Here are some possible directions for future research:

- Improving accuracy and efficiency: The effectiveness and validity of the process used to create the use case model from the functional requirements of the SRS document must be investigated. This can entail looking into new techniques and algorithms for discovering relevant information and automating the diagram-generating process.
- Extending to other types of diagrams: The approach could be expanded to create other sorts of UML diagrams, however, this research concentrates on creating use case diagrams. This can entail changing the algorithm to recognize and retrieve pertinent data.
- Evaluation and comparison: Future studies should compare the accuracy, efficiency, and effectiveness of the suggested approach to other approaches for creating use case diagrams using real-world datasets.
- Integration with software development tools: By providing automatic support for creating and updating UML diagrams, integrating the suggested technique with current software development instruments and platforms could speed up the software development process. Overall, there are many potential directions for future research in this area, and the continued exploration and development of these ideas could lead to significant advances in the field of software engineering.

Abstract
Software-Defined Networking (SDN) has emerged as a promising paradigm to enhance network control and management by decoupling the planes. With SDN, the centralized controller plays a critical role in managing network resources and traffic flows. Throughout the most recent couple of years, networks turned out to be more imaginative for developing different applications with the help of SDN. Network traffic analysis is a vital task in understanding network behaviour, identifying anomalies, and optimizing network performance. To deal with the load of changes in the networking industry, there is an extraordinary requirement for a productive SDN controller to work on the usage of network resources for a better presentation of the network. Therefore, the proposed approach leverages the RYU controller, an open-source SDN controller framework, to collect and analyse network traffic data. By utilizing RYU's capabilities, we can dynamically monitor and capture network traffic statistics, such as bandwidth, throughput, packet counts, and Round trip time (RTT). These statistics provide valuable insights into network performance, and traffic patterns. By leveraging real-time traffic analysis, we can dynamically adjust routing paths, and allocate network resources efficiently. Hence, the proposed work assesses the development of SDN architecture through a network topology and then, implementation of RYU controller has been done to evaluate various network performance parameters. To evaluate the effectiveness of our approach, we conduct experiments using a simulated SDN environment. We compare the performance parameters of our traffic analysis techniques with traditional methods and showcase the advantages of utilizing SDN and the Ryu controller for network traffic analysis. The results demonstrate that our approach provides accurate and timely insights into network traffic behaviour, facilitating efficient network management. In conclusion, this study highlights the significance of network traffic analysis in SDN environments and demonstrates the effectiveness of the Ryu controller for extracting valuable insights from network traffic data.

1 Introduction

These days, the world behaves like a universal home where the different sections of this world are collaborated by telecommunications, named the Internet. Today, the number of Internet users reached up to three billion [1]. To inculcate all these users under a roof, it is necessary to change the current scenario of the network architecture. There is a need to interconnect all things under the concept of IoT [2] and cloud computing [3]. In the traditional architectural network [4], the router contains both planes [5]. The control plane has a routing algorithm in the router while the data plane, which is also known as a forwarding plane [6] used to forward the data packets to the next-hop router [7]. But in the emerging paradigm, both the planes are separated to show their behaviour uniquely and the paradigm is termed as SDN.

SDN is a progressive networking system that upholds heterogeneous organizations with fast development and dynamic by utilizing diverse programmable planes [9]. The requirement for this organization is to help the availability of zillions of contraptions and speedy specialist co-ops to course the traffic [10]. Also, a domain-explicit language, P4 satisfies these prerequisites and has known wide reception over the years from the networking industry and academic field [11]. It is an unmistakable systems paradigm that hopes to change the boundaries of conventional organization foundations by moving all the control functionalities to a brought-together region [12] as shown in Fig. 1. The SDN architecture is having three layers as follows, also depicted in Fig. 2:

- Physical layer: It is the first layer of the architecture. This layer consists of various networking devices that are connected to communicate the data traffic [13].
- Control layer: The control layer is the middle layer that is responsible for managing the whole network. This layer consists of the brain of the network which is known as the controller. A controller is the central single entity that tracks traffic moving in the network. It provides the best route to the data to make the network more effective by eliminating the waiting time of the network. [14].
- Management layer: The management layer is the uppermost layer of the SDN environment which is responsible for keeping records of data traffic by managing documentation, file database, and other applications [15].

SDN permits the detachment of information and control plane, therefore, switches will turn into the sending gadgets. In SDN, regulators are the mind of the organization which is having the force of performing control choices during the directing of information bundles [16]. SDN rose as a method to extend the convenience of the organization, decreasing expenses, lessening the intricacy of equipment, and permitting creative examination [17]. The architecture of SDN consists of three different layers named physical, network, and application layers [18]. The physical layer has also termed an infrastructure or data plane in which the hub of network devices, Open Flow switches [19], and other infrastructure are connected. The network layer consists of a controller having different libraries and protocols supported under the norms of the controller [20]. The application layer is having various user applications, controller applications, operators, and open stacks for end-to-end data transmission [21]. Various application-based routing protocols have been developed in recent years for WSNs such as energy efficiency [22, 23], resource management, traffic analysis, and many more. The paper

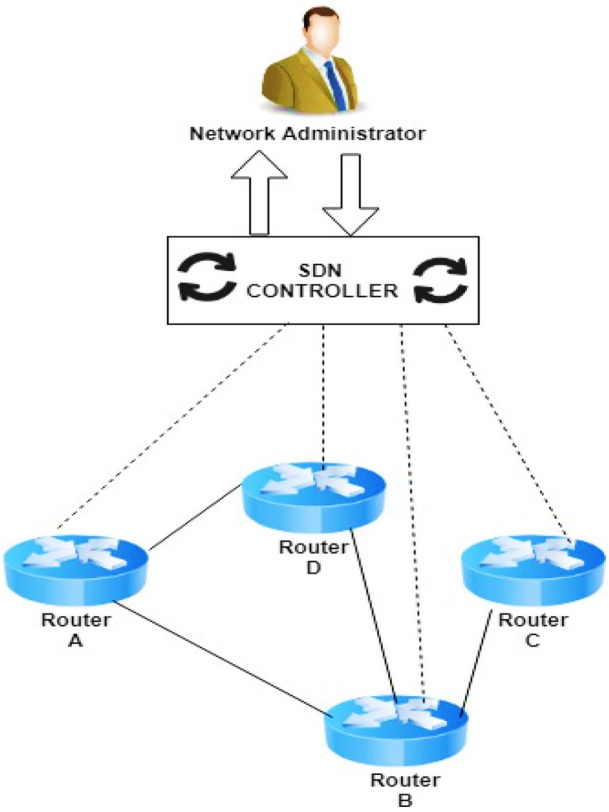

Fig. 1 Overview of SDN [8]

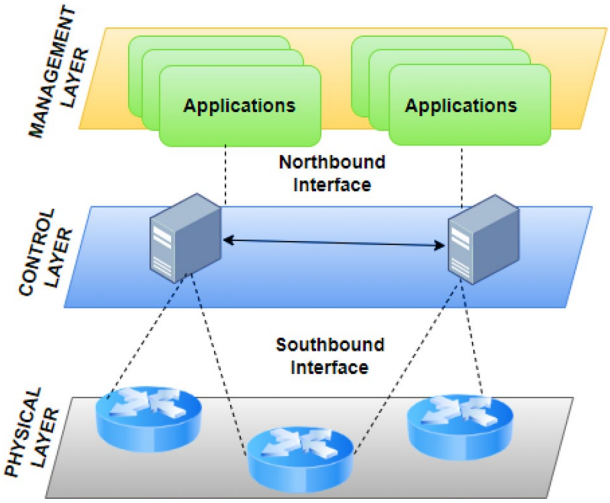

Fig. 2 Three-layered architecture of SDN

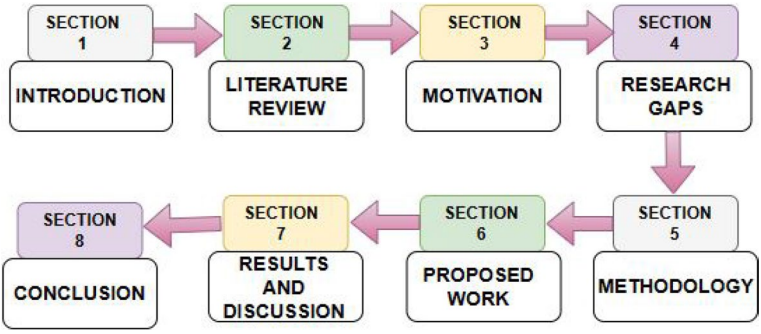

Fig. 3 Structure of the paper

also provides the framework for traffic analysis in the field of SDN using network topology having an RYU controller implemented.

The major contributions of the paper are as follows:

- Established a network custom topology.
- Integrated the Open flow RYU controller into the network topology.
- Evaluated the performance of the RYU controller.
  - Mininet tool and Wireshark traffic analyzer tool are used to create the setup environment.
  - Hping3 and IPERF tools are used to get the performance parameters.
- Presented a novel framework to analyse the network data traffic based on the RYU controller.

The rest of the research paper is structured in the following manner as shown in Fig. 3.

2 Literature Review

There is a summarization of the existing literature which has already been done in SDN. The main task of reviewing the previous work is to gather the objective of the research available on the application of SDN and its components by evaluating results as per the study approaches shown in Table 1.

After conducting a literature review several key findings have emerged:

- The literature features that data traffic analysis in the network utilizing the Ryu SDN controller offers a few advantages. It empowers real-time checking and investigation of data traffic, permitting network heads to identify and answer anomalies or security breaks instantly. It additionally works with network enhancement and resource assignment based on the design of traffic, further development improves the performance of the network.
- Furthermore, the literature highlighted that the combination of the functionalities of SDN with traffic analysis, like TE or QoS, can upgrade the network productivity as

Table 1 Comparative study of traffic analysis in SDN

Reference no	Year	Authors	Techniques/tools	Summary
[24]	2013	J. Chica et al	Software-Defined Networking, Cbench	• The paper reviewed the performance examination of publically accessible OpenFlow regulators like Beacon, NOX, Maestro, and NOX-MT • Designed a series of flow-based benchmarks
[25]	2013	M. Caria et al	TA2 network, SNDlib library	• The paper proposed an algorithm for the optimal substitution of the hosts in the network. Hence, it reduces the capacity of the network to enhance the TE
[26]	2016	I. Akyildiz et al	Software-Defined Networking	• The paper investigated the solution for SDN traffic • Also, presented the challenges of SDN traffic engineering on some key parameters namely, accuracy, availability, and scalability
[27]	2017	M. Wang et al	Mininet	• Proposed an answer for the solid transmission of information bundles starting with one host and then onto the next to have using the SDN climate • The proposed structure gave an all-around directed utilization of data transfer capacity just as the dependable solid parcel transmission
[28]	2017	L. Yu et al	Peering BGP testbed	• In the proposed SDN architecture, the SDN controller allowed the user to manipulate the IP • The paper concluded that in the future, the security analysis factor could be added to enhance the capability of a proposed SDN architecture
[29]	2017	I. Bholebawa et al	Mininet, OpenvSwitch	• The paper gave the presentation examination of two SDN regulators to be specific, Floodlight and POX. Distinctive SDN geographies were intended for the two regulators and thought about the exhibition utilizing the boundaries, throughput, and full-circle time • As per the presentation, the Floodlight regulator gave more powerful outcomes when contrasted with POX
[30]	2017	Y. Guo et al	Online Offline Routing Optimizer (OORO)	• The paper first formulated the issues related to traffic engineering and then try to sort the network using the proposed algorithm
[31]	2018	R. Amin et al	Mininet, EstiNet, GNS3	• The paper presented a comprehensive survey in the field of a hybrid SDN network. Also, identified the research gaps in the existing solutions
[32]	2018	S. Singh et al	-	• The paper compared the performance analysis of different algorithms that were operated in the SDN control plane. The parameters taken to perform the comparison were jitter, latency, Q-factor, and many more

Table 1 (continued)

Reference no	Year	Authors	Techniques/tools	Summary
[33]	2019	S. Mehr et al	SVM	• Proposed a flow to detect an attack on the RYU SDN controller. The author used machine learning to detect the attack using the SVM environment • Also, claimed that the results showed a 36% of reduction in attacks using the proposed method
[34]	2019	J. Bhatia et al	Tensorflow Keras	• Proposed a calculation for the continuous information transmission directed under the SDN controller to assess the various boundaries, for example, thickness and clog forecast of information traffic
[35]	2019	A. V. Priya et al	D-ITG	• The creator thought about the presentation boundaries of OpenFlow regulators named RYU, FloodLight, and POX. The examination was done dependent on the bundle taking care of the limit on the D-ITG apparatus • The creator inferred that the FloodLight regulator shows a superior show as far as throughput and postponement when contrasted with that of others • The creator proposed that later on the work can be additionally stretched out by looking at the OpenDayLight and OpenContrail regulators
[36]	2019	S. Badotra et al	Mininet, Wireshark	• The author compared two open-source controllers of SDN named OpenDayLight and Open Networking operating systems
[37]	2019	W. Queiroz et al	Mininet, Iperf3	• The proposed approach defined the usage of network bandwidth in the SDN and suggested that in the future the same proposed method can be effectively implemented by decreasing the interval time so that the performance would increase
[38]	2020	M. Islam et al	Mininet	• The paper implemented SDN architecture to perform the analysis of the traffic on the RYU SDN controller • Also, fascinated the researchers to perform this RYU controller implementation using different topologies in the future to evaluate the performance
[39]	2021	Kurungadan et al	No simulator was used	• The paper utilizes SDN to control the heap of the WiFi traffic. The gateways get information from IoT gadgets using remote connections • The author proposed three SDN algorithms that are conceived to diminish the delay in packet forwarding
[40]	2022	Bhardwaj et al	Mininet	• The author analyzed and monitored the real-time data traffic via implementing the architecture of SDN and also examined the performance of the controller in the proposed topology using some of the network performance parameters

Table 1 (continued)

Reference no	Year	Authors	Techniques/tools	Summary
[41]	2023	Raja et al	Deep Learning models	• The author provided an empirical study on the flow of data traffic in the network using the prediction method in SDN • Also, the paper presented the data flow technique based on different approaches such as flow count, entropy technique as well as DL approach
[42]	2023	P. Shukla et al	MATLAB	• The recommended strategy is centered around showing the flow of data traffic and also protecting the data forwarding layer • The proposed model accomplishes a noteworthy performance of attack detection in DDoS assaults by forestalling network-sending execution degradation

well as the client experience. The capacity to reconfigure the data paths and strategies dynamically, given traffic analysis is an important component for network administrators.

3 Motivation

To the finest of our ability, there is not any research that provides the traffic analysis in the RYU SDN controller for traffic engineering to evaluate the network parameters.

The motivation is to execute the design of SDN utilizing the RYU SDN controller for the data traffic investigation. In systems administration enterprises, scholastic fields, and server farms, there is an extraordinary requirement for an elite controller. Subsequently, it is significant to research the performance of an open-source controller of SDN [38]. The execution of the SDN engineering is to be completed in the Mininet emulator incorporating the RYU controller with the part of exchanging center, four hubs consider under solitary topology, and an OpenFlow switch. The work intends to assess execution boundaries like transmission and receiving of packets as well as bytes, and time is taken depending upon the experimental conditions. The significance of the research study is also depicted in Table 2.

4 Research Gaps

Many researchers have given their best in the field of SDN to enhance the network management approach. But still, many challenges are faced in the SDN environment to generate a smooth flow of data traffic. Hence, a lot of effort can be done to overcome these challenges. Based on those challenges, some of the major research gaps have been identified:

- The current research on network traffic analysis using the Ryu controller often focuses on static traffic patterns or predefined rules. Investigating dynamic traffic engineering approaches that leverage traffic analysis insights to optimize network performance and resource allocation in real time is an area that requires further exploration [10].

Table 2 Significance of Research Study

Significance of proposed research	• There is an extraordinary requirement for a superior controller in networking sectors, academic centers, data fields, and so on • The exhibition of the SDN regulator gives a brilliant effect on intensifying the capacities of the SDN organization. Hence, it is essential to explore the presentation of the SDN controller
Spots of the problem	• The current methodologies are short falling as far as giving the traffic evaluation of a particular SDN controller • An adequate examination is absent in the space of the traffic execution assessment of the RYU SDN regulator
Results Reported	• The exploration work will be adequate for the analysts, industrialists, and systems administration skills to pick the RYU controller for future organizations, research applications, and module advancements

- There is no such specific study on the RYU SDN controller which provides the performance characteristics of custom topology [38].
- The existing approaches are lacking in terms of providing the traffic performance evaluation of a specific SDN controller instead of comparison [35, 39, 43].
- There is very little work in which those controllers are chosen that are scripted in emerging languages such as Python for traffic analysis in SDN environment [26].

5 Methodology

Three segments are expected to execute the SDN architecture. The first segment is SDN Applications in which different programs convey practices and required resources with the controller of the SDN through APIs. The other segment is the RYU SDN controller which is a consistent element that gets instructions or prerequisites from the SDN Application layer and transfers them to the system's networking element. The last segment is the Networking elements of the SDN structure, which control the sending and information-handling abilities of the SDN network. This segment incorporates the sending and preparing of the information way. In real-time, establishing an actual framework of SDN is a very tedious task. To tackle this issue, one can utilize a specific test emulator to establish the connection in the SDN environment. There are a few devices utilized as a simulator, for example, OMNET++ [44], OFNet [45], NS-3 [46], Mininet [47], and so on. In the literature section, work done on mostly used testbeds used in the experimental setup has been evaluated. Among them, Mininet appears to function admirably as shown in Fig. 4. Mininet is considered as a popular network emulator that allows the creation of virtual networks for testing and development purposes and also. This examination has played out a performance assessment through the RYU SDN controller utilizing several tools such as iperf3 [48], ping, and others too.

Mininet is created to help exploration in SDN. It is an extraordinary open-source emulator. Mininet seems to be friendly as it uses the interface of the command line. The explanation for this is that Mininet utilizes the namespaces of the network because of its virtualization innovation, it can uphold numerous virtual hosts without hindering as well as slowing the system. Mininet creates a realistic virtual organization with

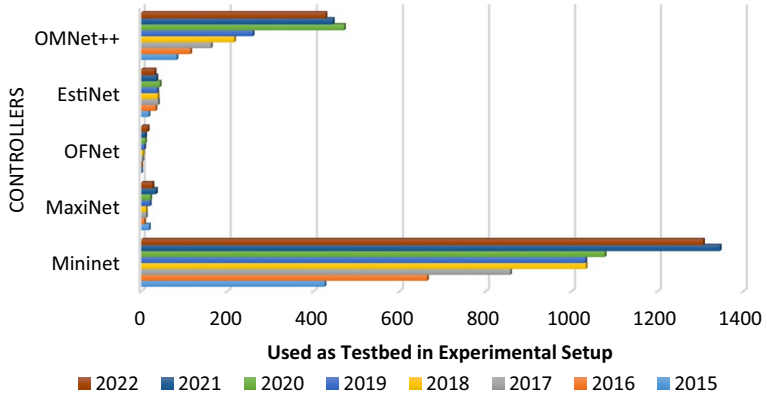

Fig. 4 Work done on different emulators used in SDN

switches, nodes, and several application segments, running kernels all at one machine. By this means, the virtual scenario of SDN can be fully designed with the help of a Mininet emulator, which comprises an SDN controller. Mininet also upholds a few inherent essential network topologies such as (1) Single topology, (2) Minimal topology, (3) Linear topology, (4) Tree topology, and so forth. For the execution of these topologies, the Mininet interface can be used by executing a solitary line order.

6 Proposed Work

Implementing the physical framework of an SDN architecture in the real world is a very expensive and difficult task which is the reason, there are many tools to create an SDN environment used as a simulator or emulator. In the implementation, first, we need to create an SDN architecture to transfer the data traffic from one node to a different node via a specific SDN controller in the SDN emulator known as Mininet. The SDN architecture is going to be implemented using three constituents: Network devices, controllers, and applications as depicted in Fig. 5. Then, the emulation and evaluation of the proposed architecture will be done based on various performance parameters as depicted in Fig. 6.

The flow of the research is categorized into five segments mentioned below:

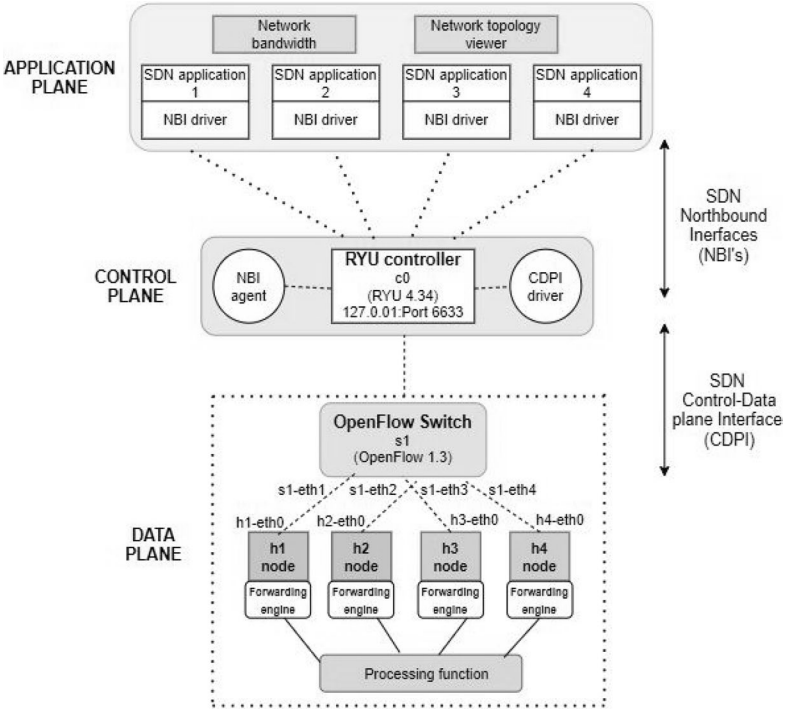

Fig. 5 Components of the proposed research work

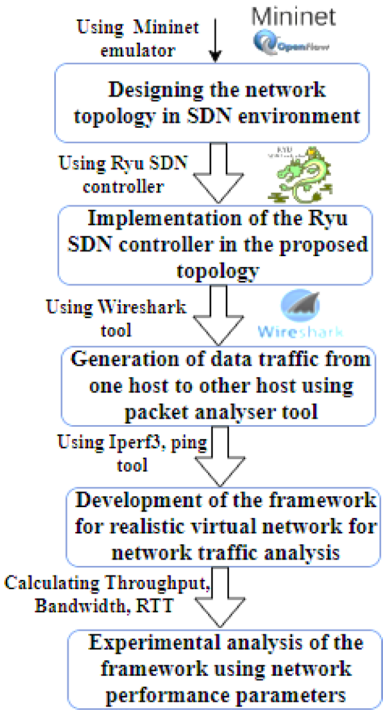

Fig. 6 Flow of the proposed research work

1. Designing the network topology
2. Implementation of Ryu controller in the designed topology
3. Generation of data traffic in the network
4. Development of the framework for a realistic virtual network
5. Experimental analysis using network performance parameters.

The expected outcome from the emulation spotlights the performance criteria of the RYU SDN controller. Hence, the proposed research work will be sufficient for the researchers, industrialists, and networking experts to choose the RYU controller for future businesses, research applications, and module developments. The below-mentioned Fig. 5 describes the components of the proposed work:

6.1 Setup Environment

A custom topology made in the Mininet apparatus has four hubs and an OpenFlow switch. The connections are made to make the association among the hosts and switch, for example, (h1, s1), (h2, s1), and so on. After the actual switch creation, it would involve the capacities of the comparing controller, as displayed in Fig. 7. By this progression, the OpenFlow switch 1.3 was stacked to communicate the information parcels starting with one host and then onto the next. The information parcels were produced in the organization with the assistance of the Wireshark tool. These information bundles were sent from the source host to the objective host.

Fig. 8 Connected ports and links in the proposed topology

Figure 8 depicted the successful transmission of the data from the source host to the destination host with 0% packet loss. Also, the link association between each node to every other node is successfully created. Each node is further associated with different ports and the ports are then connected to the main controller.

7 Results and Discussion

The segment reports the outcomes acquired for the SDN network execution assessment with RYU. The presentation boundaries like bandwidth, throughput, and RTT have been assessed under TCP, and UDP information traffic utilizing a few benchmarking apparatuses.

Figure 9 demonstrated the source and the destination port connection having a TCP window size of 85.3 Kbyte. The output of the screen is categorized into three parameters: Time interval, Transfer rate, and Bandwidth as depicted in Fig. 10. The time interval taken

```
mininet> h1 iperf -c h4 -d
------------------------------------------------------------
Server listening on TCP port 5001
TCP window size: 85.3 KByte (default)
------------------------------------------------------------
------------------------------------------------------------
Client connecting to 10.0.0.4, TCP port 5001
TCP window size:  298 KByte (default)
------------------------------------------------------------
[  3] local 10.0.0.1 port 53500 connected with 10.0.0.4 port 5001
[  5] local 10.0.0.1 port 5001 connected with 10.0.0.4 port 33086
[ ID] Interval       Transfer     Bandwidth
[  3]  0.0-10.0 sec  4.07 GBytes  3.50 Gbits/sec
[  5]  0.0-10.0 sec  1.46 GBytes  1.25 Gbits/sec
```

Fig. 9 Connections among the ports

```
mininet> h1 iperf -c h4 -P 5

Table 3 The bandwidth of the proposed topology

Time interval (s)	Transfer (GBytes)	Bandwidth (Gbps)
0–10	1.39	1.19
0–10	1.43	1.22
0–10	1.43	1.23
0–10	1.43	1.22
0–10	1.41	1.21
Total time taken	**7.09**	**6.07**

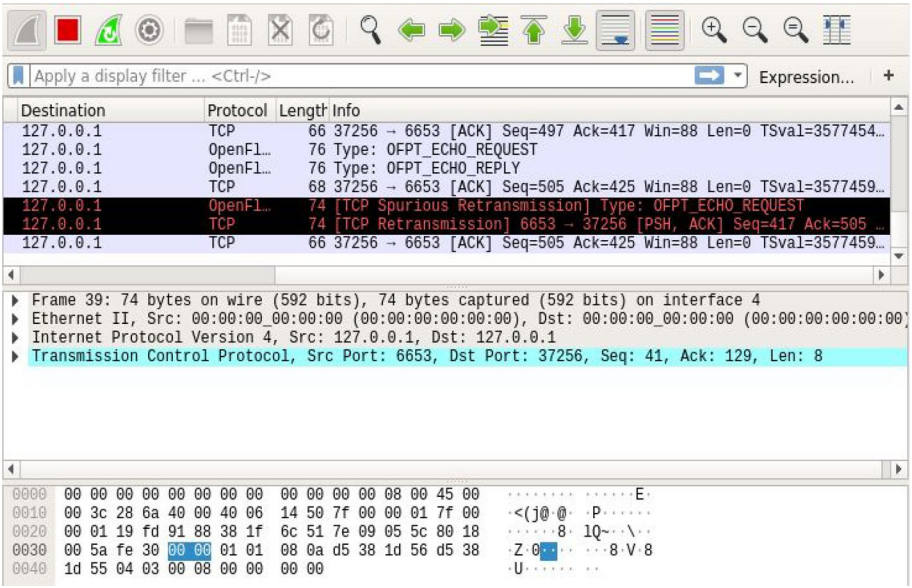

Fig. 11 Screenshot of the packet analysis using the Wireshark tool

here is between 1 to 10 seconds. Table 3 details the experimental values of the connected ports. Figure 11 depicted the flow of the data packets analyzed using a packet analyzer tool named Wireshark tool. The data packets used in the network are generated from the packet analyzer tool.

7.1 Bandwidth

Bandwidth in networking refers to the maximum amount of data that can be transmitted over a network connection in a given period. It represents the capacity or throughput of the network and is typically measured in bits per second (bps). It is influenced by various factors such as the physical properties of the network medium, the network infrastructure, and the technologies used for data transmission.

$$\text{Bandwidth(in bps)} = \frac{Data\ rate\ (in\ bits)}{Time\ (in\ seconds)} \tag{1}$$

Bandwidth is a critical component in determining the maximum data transfer capacity of a network connection. It directly affects the rate at which data can be transmitted and received, impacting the overall performance and responsiveness of the network. Hence, the bandwidth of the proposed topology is elaborated in Table 3. The experimental output is categorized into three parameters: Time interval, Transfer rate, and Bandwidth. The time interval taken here is between 1 to 10 seconds. Table 3 details the experimental values of the connected ports of the proposed setup.

7.1.1 Comparison and Analysis of Proposed Bandwidth with Classical Bandwidth

The proposed network topology offers a significant increase in bandwidth compared to the existing setup. By implementing a custom topology, where each device is connected to multiple other devices, the network can leverage parallel data paths and distribute traffic more efficiently. This distribution of connections helps alleviate bottlenecks and congestion points that may occur in classical topology.

In the case of the proposed topology, if it has been designed with bandwidth optimization in mind, it aims to increase the available capacity for data transmission. The proposed topology may prioritize efficient utilization of available bandwidth, potentially resulting in a higher overall network capacity as shown in Table 4.

7.2 Throughput

Throughput refers to the rate at which data can be successfully transmitted or processed through a system, network, or device. It is typically measured in terms of data transfer rate, often expressed in bits per second (bps).

In networking, throughput represents the amount of data that can be transmitted over a network connection within a specific time frame. It is influenced by several factors, including bandwidth, latency, packet loss, and network congestion. Higher bandwidth allows for greater throughput as it provides a larger capacity for data transmission. Lower latency and minimal packet loss also contribute to improved throughput by reducing delays and ensuring reliable delivery of data packets. Throughput addresses the greatest measure of information traffic handled using regulators between two hubs of the organization in a second. In TCP traffic, one of the hosts goes about as a customer, and one more goes about as a server. iperf3 utility has been used to test the throughput of the regulator. On the client side, iperf3 has been executed in 10 seconds, and the data about throughput has been assembled on one more side of the organization. The aftereffect of execution is displayed and shown graphically in Fig. 10.

$$\text{Throughput} = \frac{\text{Amount of data received}}{\text{Given time frame}} \tag{2}$$

Table 4 Bandwidth comparison of the proposed and classical topology

Nodes	Bandwidth of classical topology (Gbps)	Bandwidth of proposed topology (Gbps)
h1 to h2	25.1	26.7
h1 to h3	24.5	25.2
h2 to h3	24.4	25
h1 to h4	NA	24.8
h2 to h4	NA	23.8
h3 to h4	NA	22.7

7.2.1 Comparison and Analysis of Proposed Throughput with Classical Throughput

Throughput is a critical metric that measures the rate at which data can be successfully transmitted through a network. It depends on factors such as bandwidth, latency, packet loss, network congestion, and the efficiency of network components. In the case of the proposed topology, by incorporating higher-capacity links, efficient routing algorithms, and advanced traffic management techniques, the proposed topology can potentially enhance the overall throughput of the network. This improvement results in faster data transmission and increased capacity to handle concurrent data streams as shown in Fig. 12.

On the other hand, the previous topology has limitations in terms of available bandwidth, outdated infrastructure, or suboptimal routing that could impact throughput. It might suffer from congestion points, inefficient resource allocation, or network bottlenecks, which can hinder the data transfer rate and limit overall throughput as shown in Table 5.

The comparison of throughput between the proposed and default topology depends on the specific design choices, network infrastructure, and optimization strategies employed. The proposed topology addressed the limitations of the previous one and incorporated enhancements to maximize bandwidth, minimize latency, and improve traffic management, it has the potential to significantly increase throughput and enhance the network's overall performance.

7.3 Round Trip Time

In SDN, RTT refers to the time it takes for a packet to travel from a source to a destination and back again. SDN controllers like Ryu (as used in the article) can be used to perform traffic analysis and measure RTT in SDN networks. RTT is additionally known as ping test time. RTT is the absolute time taken to by the information bundle to reach from a particular source host to the objective host and the affirmation parcel to reach back as depicted in Fig. 13.

The round trip time is a crucial metric that measures the time taken for a data packet to travel from a source to a destination and back again. It is influenced by various elements, including network latency, packet loss, congestion, and the number of network

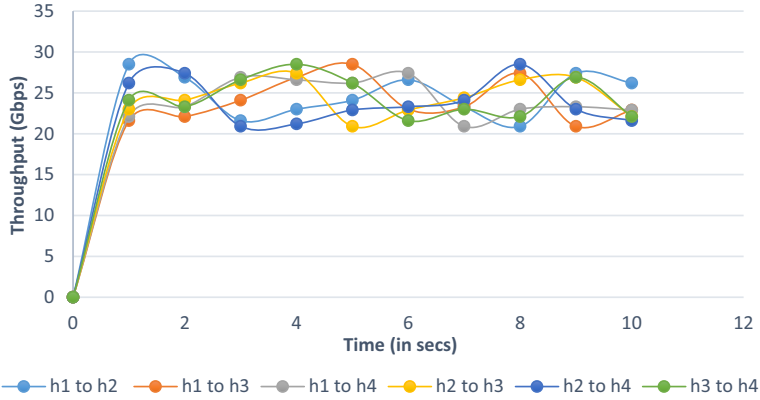

Fig. 12 TCP throughput

Table 5 Throughput comparison of the proposed and the classical topology

Nodes	Default SDN topology		Proposed SDN topology	
	Minimum throughput	Maximum throughput	Minimum throughput	Maximum throughput
h1 to h2	21.2	27.4	22.6	28.5
h1 to h3	20.8	27.5	20.9	28.5
h2 to h3	20.9	28.6	22.1	29.9
h2 to h4	NA	NA	20.9	27.5
h3 to h4	NA	NA	21.6	28.5
h1 to h4	NA	NA	20.9	27.4

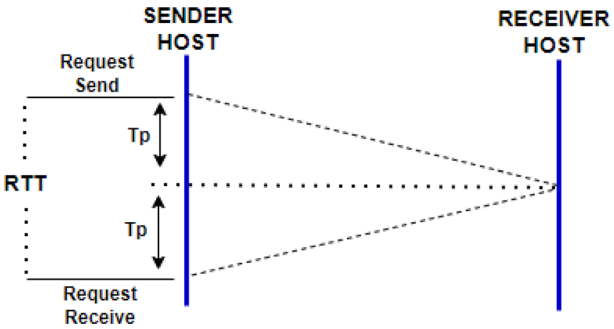

Fig. 13 RTT of the proposed topology

hops. Propagation delay is the length of time taken for a request to reach its destination. The propagation delay is usually the dominant component in RTT.

$$RTT = 2 * Propagation\,delay \tag{3}$$

As depicted in Fig. 14, the base RTTs of the default SDN topology [38] are estimated as 0.054 ms, 0.036 ms, 0.057 ms, 0.057 ms, 0.011 ms, and 0.047 ms. The normal RTTs of the proposed topology are estimated as 1.002 ms, 1 ms, 0.999 ms, 0.888 ms, 1.05 ms, and 0.918 ms. The long-run RTTs of the proposed topology are 9.45 ms, 9.345 ms, 7.336 ms, 9.668 ms, and 8.149 ms (Fig. 14).

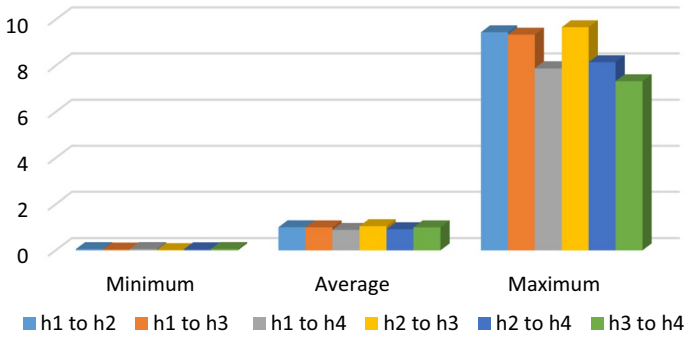

Fig. 14 RTT of the proposed topology

7.3.1 Comparison and Analysis of Proposed RTTs with Classical RTTs

In comparing the RTT between the proposed topology and the previous topology [38], several factors need to be considered. The proposed topology refers to the new network structure or configuration being suggested, while the previous topology represents the existing network design that is being replaced or improved upon.

In the case of the proposed topology, it has been designed with the optimization, it may aim to reduce network latency and minimize the number of network hops. By incorporating more direct routes or utilizing faster transmission mediums, the proposed topology has potentially decreased the overall round trip time as shown in Table 6. This improvement could lead to faster data transfer and reduced latency for end-users.

In contrast, the previous topology might have been developed without considering latency or with a different set of priorities. It could suffer from excessive network hops, suboptimal routing, or outdated infrastructure, all of which can contribute to increased round trip time. Consequently, users may experience slower data transmission and higher latency, resulting in a less efficient network.

Table 6 RTT comparison of the proposed and classical SDN topology

Nodes	Measures	RTT of classical SDN topology	RTT of proposed SDN topology
h1 to h2	Min	0.061	0.054
	Avg	1.411	1.002
	Max	10.305	9.45
h1 to h3	Min	0.055	0.036
	Avg	1.05	1
	Max	9.668	9.345
h2 to h3	Min	0.058	0.057
	Avg	0.918	0.888
	Max	8.149	7.889
h2 to h4	Min	NA	0.011
	Avg	NA	1.05
	Max	NA	9.668
h3 to h4	Min	NA	0.047
	Avg	NA	0.918
	Max	NA	8.149
h1 to h4	Min	NA	0.057
	Avg	NA	0.999
	Max	NA	7.336
h1 to h4	Min	NA	0.057
	Avg	NA	0.999
	Max	NA	7.336

8 Conclusion

SDN is cutting-edge computerization and also inculcated many changes in the industry of networking. SDN has separated both planes and made the controller a centralized hub. Therefore, the paper implemented the architecture of SDN using the RYU controller for the network traffic analysis. This work can use traffic routing in the environment of SDN to improve the network for better use from here on out. Subsequently, this work holds the analysis of traffic through performance assessment of the SDN controller to work on the network in different ways. Therefore, the proposed approach leverages the RYU controller, an open-source SDN controller framework, to collect and analyse network traffic data. By utilizing RYU's capabilities, we can dynamically monitor and capture network traffic statistics, such as bandwidth, throughput, packet counts, and RTT. These statistics provide valuable insights into network performance, and traffic patterns. This work also opens the door for many researchers working in the networking field. Being coded in Python, RYU is one of the most recommended Open-source SDN controllers. As RYU is scripted in the Python programming language, so only a few of the researchers are currently working on its performance evaluation. The consequence of the above-mentioned experimentations demonstrated that the RYU controller can likewise be viewed as one of the strong controllers as far as traffic engineering. The experimental work proved the viable outcomes in the data transmission starting with one node and then onto the next node in the proposed framework. In conclusion, this study highlights the significance of network traffic analysis in SDN environments and demonstrates the effectiveness of the Ryu controller for extracting valuable insights from network traffic data.

In future work, it would be recommended to consider several other topologies as well as other performance parameters to evaluate the RYU SDN controller performance. It may also focus on developing more sophisticated techniques to monitor and analyse network traffic in real time. This could involve implementing deep packet inspection (DPI) capabilities within the Ryu controller, allowing for detailed inspection and analysis of packet contents. Future research may explore integrating the RYU controller with security solutions, such as intrusion detection systems (IDS) and firewalls, to create a comprehensive security framework within the SDN environment. This integration can enable real-time traffic analysis for security purposes and allow for coordinated response mechanisms.

Author Contributions We confirm that the manuscript has been read and approved by all named authors and that there are no other persons who satisfied the criteria for authorship but are not listed. We further confirm that the order of authors listed in the manuscript has been approved by both of us. We have all the required material used in the implementation and the available data/results are generated by the authors itself and not copied from somewhere else. We confirm that we have given due consideration to the protection of intellectual property associated with this work and that there are no impediments to publication, including the timing of publication, with respect to intellectual property. In so doing we confirm that we have followed the regulations of our institutions concerning intellectual property. We understand that the Corresponding Author is the sole contact for the Editorial process (including Editorial Manager and direct communications with the office). He/she is responsible for communicating with the other authors about progress, submissions of revisions and final approval of proofs. We confirm that we have provided a current, correct email address which is accessible by the Corresponding Author.

Funding This study and authors received no fund.

Data availability There is no data available.

Declarations

Conflict of Interest We wish to confirm that there are no known conflicts of interest associated with this publication and there has been no significant financial support for this work that could have influenced its outcome.

Nonlinear Regression Analysis of Rut Profile Data for Optimal Data Storage and Efficient Terrain Condition Analysis

Manoj Kumar Kalra, Ashutosh Trivedi, and Sanjay Kumar Shukla

***Abstract*— During various operations of military and civil importance, the vehicles need to move in different off-road conditions. Several soil parameters that differ in spatial and temporal domains impact the possibility of vehicular movement. Conventional evaluation of the prevalent state of soil being cumbersome and time-consuming, the information extracted from the rut profile of the vehicle is used. Several techniques ranging from manual to advanced laser scanners are there to monitor this profile. The laser scan contains a vast point cloud dataset. It brings in the data storage and retrieval issue for an efficient computational framework for real-time mobility guidance. Little research exists for addressing the storage issue of this sort of rut profile data. Here, rut profile data captured manually in different field running conditions are used for studying the optimization aspects. Various mathematical formulations are analyzed, and nonlinear regression analysis is attempted on the commonly observed rut shapes. Using the proposed modified bell-shaped function on these common shapes, the $R2$ value moved above 0.98. It could fetch an additional compression of over 80% on straight patches and 71% on turnings. Although complex scenarios could be dealt with separately, an optimal representation of the most common rut shapes can aid the development of an efficient decision support system.**

***Index Terms*— Off-road conditions, optimization, regression analysis, rut profile, soil condition, vehicular movement.**

I. Introduction

THE poor performance of military vehicles during World War II led to the beginning of research in trafficability at the Waterways Experiment Station (WES) in 1945 by U.S. Army Engineer [1]. The characterization of vehicular movement on different unpaved terrain features is a challenging task. The possibility of vehicular movement depends upon the surface topographical features and the condition of the underlying soil. Wong [2] and Saarilahti [3] and others considered the effect of these obstacles both empirically and mathematically.

The soil is a dynamic material by nature, and parameters like density, moisture, constituents, etc. influence its state. Evaluating these parameters and their effect by conventional geotechnical instruments is laborious and time-consuming. American Society of Agricultural Engineers (ASAE) standards [4] give the procedure for estimating the strength of the soil using a cone penetrometer. However, this tool is suitable for a limited area only and is not convenient to map large areas. Various authors made attempts to explore alternate means for evaluating the soil condition. One such way is to observe the rut profile formed by the movement of vehicles on the unpaved ground. As strength decreases, the rut depth increases. Vehicle immobilization condition occurs when the rut depth is larger than the vehicle clearance height [5].

However, the rut profile is considered a better measure for mapping the influence of terrain on turnings and conditions like sandy terrain. A study is made on the changes in rut volume by vehicular movements on turnings [6]. The equipment for mapping rut profiles varies from manual profilometers [5] to several advanced profilers [7]. Different technologies in use for rut measurement include ultrasonic sensors, point lasers, scanning lasers, and optical sensors. The manual profilometer is employed to collect data for point locations; however, it is not suitable for continuous measurements of changes in terrain properties.

Photogrammetric methods, unmanned aerial vehicle (UAV), and drone platforms are employed to map the rut profiles of the soil [8], [9], [10], [11]. A forest machine-based light detection and ranging (LiDAR) sensor is used by [12] to demonstrate it as an efficient and reliable way of collecting the rut depth data. The use of mobile laser profilometry for detecting forest road damage and its quantification is presented [13]. The profiler used in this study had eight scanner units, which could cover the whole width of the road with 1000–5000 profiles per second.

Thus, it is evident how much point cloud data processing is required to create a profile and do further analysis. The importance of rut measurement for applications like controller design and implementation is highlighted by [14]. Applications of LiDAR have been advancing to mobile-based platforms. An iPhone-12 is used to present LiDAR-derived snow depth estimation [15]. This work which used a lightweight LiDAR system brings out the need for research on reducing the computational load for efficient decisions.

The data collected by such scanners is vast. It needs heavy resources for storage, retrieval, and processing. Limited attempts are there to make use of the rut shape mathematically. Limited attempts are there to make use of the rut shape

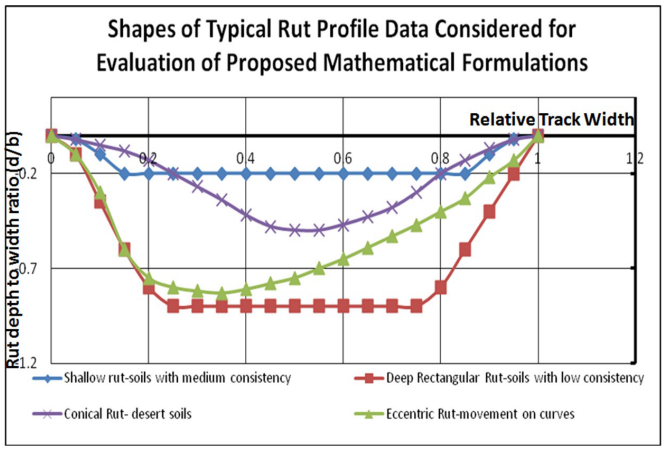

Fig. 2. Shapes of typical rut profile data considered for evaluation of proposed mathematical formulations.

mathematically. In the study on the rut following robot, [16] modeled the previously formed rut shape using a second-order polynomial.

Defining the shape of the deformed geometry is attempted in other applications too. A general equation for the deformed geometry of geosynthetic is given [17] that combines the two shapes to compute strain. A regression-based solution for estimating the settlement of reinforced soil foundation is attempted [18].

This letter presents a comparative analysis of some suitably selected mathematical formulations that could fit the typical shapes of ruts profiles. Nonlinear regression analysis is attempted on the observed data to identify the most suitable equation representing the rut profile in different conditions. The letter discusses the suitability of these mathematical formulations for depicting rut profiles in different scenarios to achieve optimal data storage.

II. Field Observation of Rut Profiles

The shape of the rut profile is typical of different terrain features, soil conditions, and vehicle running conditions. A manual rut profiler is used for this study to collect rut profile data in different kinds of terrain scenarios. This profiler consists of rods placed at intervals of 5 cm. The color marking of width 1 cm each is made on each rod to facilitate the measurement of rut depth. The authors investigated rut profiles created in different unpaved terrain conditions of deserts and alluvial terrain in both dry and wet seasons. These data are used for further analysis as given in this letter.

As illustrated in Fig. 1, the shallow rut profile gets formed on alluvial soils of medium consistency. However, a deeper rut gets formed as the consistency of soil decreases.

The rut profile in loose sandy dunal soils of deserts takes a conical shape as the sand from the edges pours in as the rut profile. Further, when the vehicle turns on curves, the rut shape becomes asymmetric due to lateral loads.

There are other possible shapes too, but the following typical cases of rut shapes being most common during the movement in different off-road scenarios are considered here.

TABLE I

Depth-to-Width Ratio of Rut Under Different Soil and Movement Conditions

Case 1: Shallow rectangular shape rut in soils of medium consistency.

Case 2: Deep rectangular/ trapezoidal shape rut in alluvial soils of low consistency.

Case 3: Conical shape rut on the desert soils.

Case 4: Asymmetric rut profile in soils on turnings by vehicle.

The typical cases depicted in Fig. 2 are considered in this study to explore the optimal representation of these profiles using some mathematical formulations.

The authors normalized the cross-sectional rut profile to account for the variation of the rut profile at different places. Thus the depth 'y' representing 'd/B' at different sections 'x' across the profile representing 'B' is used. Here 'd' is the rut depth at different locations 'b' across the profile, and 'B' represents the total rut width. The consolidated rut profile data taken for study for all four cases are given in Table I.

III. Development of Mathematical Formulations for Rut Profile

The authors explored many possible mathematical equations to develop a suitable mathematical formulation that explains rut profiles in varied scenarios. Based on the possibility of generating the most common types of shapes by changing the parameters, the authors chose the mathematical formulations. The equations thus chosen include polynomial equations of varying degrees, a generalized Gaussian shape equation, Fourier transformation, and a modified bell-shaped equation.

As a common approach, the polynomial fit of different degrees is resorted for defining the rut shape. The polynomial equation thus chosen is as follows:

$$y = f(x) = \sum_{i=0}^{n} a_i x^i. \tag{1}$$

The degree of the polynomial equation improves the curve fitting for the most common shapes. As such, regression fit used polynomial equations starting with a quadratic equation and going up to the fourth degree to define the rut shapes.

The rut shape in frictionless soils resembles an inverted shape of the Gaussian distribution of probability function. The generalized form of the equation for the Gaussian shape curve is therefore included and given as follows:

$$f(x) = a_1 . e^{-\left|\left(\frac{x-a_2}{a_3}\right)\right|^{a_4}}. \tag{2}$$

Another way of describing the rut shape is similar to converting any harmonic function using Fourier transformation. This method approximates the curve using a combination of various sine and cosine curves of different frequencies, as given below:

$$f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty} a_n \cos\left(\frac{nx}{L}\right) + \sum_{n=1}^{\infty} b_n \sin\left(\frac{nx}{L}\right). \tag{3}$$

Here, the coefficients are

$$a_0 = \frac{1}{L} . \int_{-L}^{L} f(x) dx \tag{4}$$

$$a_n = \frac{1}{L} . \int_{-L}^{L} f(x) \cos\left(\frac{nx}{L}\right) dx \tag{5}$$

$$b_n = \frac{1}{L} . \int_{-L}^{L} f(x) \sin\left(\frac{nx}{L}\right) dx. \tag{6}$$

The function combines various frequencies and amplitudes of the sine and cosine curves. In the present case, different shapes of rut are represented by considering up to three terms (n) of the above equation.

The rut shapes on soils of different consistency also resemble the shape of a bell function, and accordingly, the bell-shaped function is thus chosen and given as follows:

$$f(x) = \frac{a_1}{1 + \left|\left(\frac{x-a_2}{a_3}\right)\right|^{a_4}}. \tag{7}$$

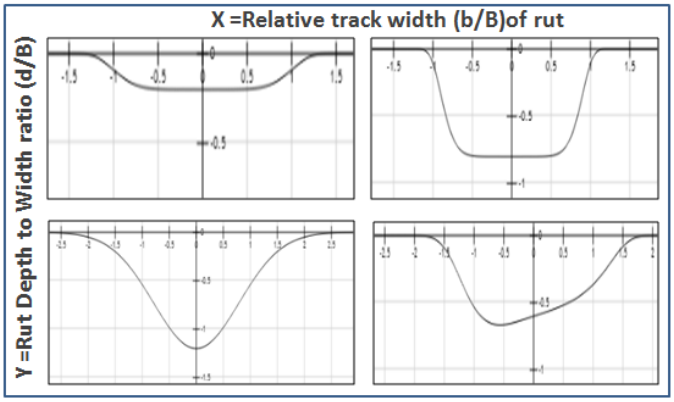

Fig. 3. Different shapes as generated using proposed mathematical formulations by varying the input parameters to match the commonly observed rut shapes in various terrain types.

Here, the coefficient a_1 impacts the variation in rut width and depth. The coefficient a_2 determines the center, a_3 represents the rut width, and a_4 the side slope of the membership function curve. Therefore, the use of a modified form of the generalized bell equation, which combines variation in the side slopes, is considered and is given below:

$$f(x) = \frac{a_1}{1 + \left|\left(\frac{x-a_2}{a_3}\right)\right|^{a_4} + \left|\left(\frac{x-a_2}{a_5}\right)\right|^{a_6}}. \tag{8}$$

All these equations use the normalized rut shapes. They represent the dimensionless ratio of rut depth to its width at various relative locations across the rut profiles. The parameters $a_0, a_1, a_2, a_3, a_4, a_5$, and a_6 are the coefficients of the proposed equations.

IV. Results and Discussion

The suitability of proposed equations is first analyzed based on regression fit on rut data observed in different scenarios. As a general observation, by taking typical values of the variables, one can generate different shapes using any of the proposed mathematical formulations. Fig. 3 illustrates the shapes of curves as obtained using mathematical formulations.

It indicates that using any of the proposed mathematical formulations, one can generate the shape of rut profiles in scenarios observed in the field. It also leads to the inference that the selected equations are reasonable and logical. These equations can thus be used as an alternate to represent the rut profiles data. The potential use could be to achieve the optimal data storage requirements as it becomes mandatory in systems using point cloud as given by [13].

Further, to evaluate the effectiveness of different proposed mathematical formulations, authors employed non-linear regression analysis. The online desmos graphing tool facilitated the computation of regression coefficients and the degree of fit. Table II displays the result of regression analysis representing the efficacy of different mathematical formulations in various conditions.

"Here, the compression ratio (C) represents the storage efficiency. It is the ratio of the number of original datasets to the number of parameters needed to represent the

profile using mathematical formulation. The value of (C) in Table II indicates that one can achieve significant levels of data compression over conventional techniques using the proposed mathematical models. In the currently used manual observation of profiles, the compression ratio for the straight patches is 5.25. The %age of data compression calculated as (1-1/C) $\times$ 100 indicates that one can achieve more than 80% compression on the straight patches. The value computes for areas on turning is 71%, while the accuracy level is maintained

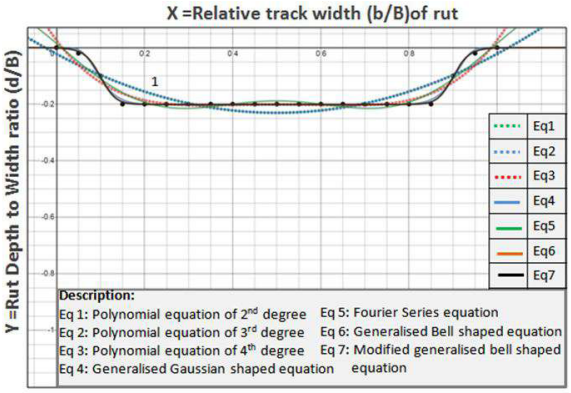

Fig. 4. Typical regression fit curves on the rut profile data of medium consistency soil.

better than 99% in both cases. This additional data compression could pave the way for efficient data storage and set the basis for an onboard decision aid. The computational aspects will depend upon the selected mathematical formulation, regression type, algorithm design, parallel processing, multithreading aspects, etc. Here, the purpose is to explore the potential of mathematical formulations in defining rut shapes to address the issues related to real-time applications."

Fig. 4 shows the typical regression fit curves on the rut profile data of medium-consistency soils. The figure shows the relative comparison of various mathematical formulations on the observed data.

The graph containing the data and different regression curves indicate that the curves using the proposed mathematical formulations follow the observed data for almost all the test cases. However, for identifying the most suitable predictive equation of the rut profile, the comparative analysis reveals further detail.

The analysis of the regression fit shown in the table also indicates that in almost all the cases, the regression fit improves with the increased degree of the polynomial. One can plan to improvise the utility of rut profiles by representing better the rut shape as given by [16].

The study brings out an analysis of an equivalent number of variables used in the regression curves. The comparison given for the third-degree polynomial fit with other mathematical formulations reveals valuable inferences. A considerable improvement is there in the generalized Gaussian shape function than the polynomial equations when movement is on the straight patches.

The goodness of fit is relatively less along the curves. The higher degree equations are, therefore, employed for a better fit. The analysis of regression fit results also indicates that while using the proposed modified generalized bell-shaped equation, the results are much better in almost all the scenarios. However, the function needs six input parameters to represent the rut shape.

From the above analysis, some useful inferences are drawn. The generalized Gaussian form or bell-shaped function may be advantageous for obtaining precision and optimal storage on straight patches. However, the modified generalized bell-shaped equation is more accurate on the curves.

V. Conclusion and Future Work

Results suggest that one can employ mathematical formulations to represent the rut shapes for optimal data storage. As rut profile is characteristic of soil condition, its mathematical representation can help to devise rules for interpreting soil and associated trafficability conditions. The associated interpretation based on the soil condition can be more efficient. One can employ a generalized Gaussian or bell-shaped equation to represent the rut profile on the straight patches. However, on turnings, the proposed modified bell-shaped equation leads to better precision and optimization.

An interesting analysis would be to explore some complex cases in the future. For instance, one may encounter a class wherein two separate rut profiles are blended to create a single rut class. Here some additional mathematical representations may make the profile representation more generic and can address some more rut classes.

In situations where complexity in rut morphologies is there, such as on crossings and different pathways, efforts need to be there to represent the rut profile in a better way. The present work focuses on the new ways to represent optimally the rut profile in different terrain conditions using mathematical equations. It will be a step toward developing an efficient onboard system to store and infer different rut profile-based properties. The categorization of rut profiles, mapping and characterizing the spatial variation of soil type and its condition, and inference about the trafficable state of terrain in near real-time mode are some directly related benefits. In future activities, one can explore the machine learning approach to train the system with rut profile data of varied field scenarios. It can make predictive analysis about various terrain properties and classes in different field running conditions.

The standard cases given in this study are observed prominently in actual off-road conditions. The proposed method indicates the utility of representing the rut shapes mathematically to achieve optimization. This study is a step toward bringing efficiency in addressing various issues of vehicular mobility during operational needs.

ACCESS | Metrics & More | Article Recommendations

ABSTRACT: A rapid, reliable, and user-friendly electrochemical sensor was developed for the detection of xanthine (Xn), an important biomarker of food quality. The developed sensor is based on a nanocomposite comprised of molybdenum disulfide-molybdenum trioxide (MoS_2/MoO_3) and synthesized using a single-pot hydrothermal method. Structural analysis of the MoS_2/MoO_3 nanocomposite was conducted using X-ray diffraction (XRD) and Raman spectroscopy, while its compositional properties were evaluated through X-ray photoelectron spectroscopy (XPS). Morphological features were observed using scanning electron microscopy (SEM) and transmission electron microscopy (TEM). Two-dimensional (2D) MoS_2 offers advantages such as a high surface-to-volume ratio, biocompatibility, and strong light−matter interaction, whereas MoO_3 serves as an effective electron transfer mediator and exhibits excellent stability in aqueous environments. The enzymatic biosensor derived from this nanocomposite demonstrates remarkable cyclic stability and a low limit of detection of 64 nM. It enables rapid, reproducible, specific, and reproducible detection over 10 cycles while maintaining a shelf life of more than 5 weeks. These findings highlight the potential of our proposed approach for the development of early detection devices for Xn.

INTRODUCTION

Keeping fish meat fresh is a significant challenge for the food and pharmaceutical industries. Because fish meat is perishable, it requires careful preservation to resolve food safety concerns and preserve product excellence. To preserve the safety and quality of seafood products, keeping the freshness of fish meat is crucial in the food sector.[1] Once fish is handled or stored improperly, dangerous bacteria like Listeria, Salmonella, and Vibrio can quickly proliferate and pose a risk for foodborne illnesses for consumers. The industry uses a variety of strategies to address this problem, including proper storage, temperature management, and the application of preservatives. The pharmaceutical industry uses fish meat as a valuable ingredient in the manufacturing of pharmaceuticals like fish oil supplements and medications made from fish. In order to maintain the effectiveness and safety of these products, the freshness of the fish meat is essential. Thus, ensuring the freshness of fish meat stands as a substantial challenge in both the food and pharmaceutical sectors, necessitating adherence to proper handling, storage, and processing methods to guarantee the safety and quality of fish-based merchandise.

When a fish is sacrificed, the presence of endogenous enzymes in the intestine and the muscle tissues causes the decomposition of nucleotides and other autocatalytic reactions start immediately.[2,3] The rapid decomposition of adenosine-5-triphosphate (ATP) into adeonosine-5-di-phosphate (ADP) and further breaks into adenosine-5-monophosphate (AMP), inosine-5-monophosphate (IMP), inosine (I), hypoxanthine (HXn), and xanthine (Xn), respectively.[2,4,5] At the time of death, the autolysis causes the rotting of fish by ATP degradation to Xn (3,7-dihydro-purine-2,6-dione), which later ends in the formation of uric acid (UA) by the oxidation of Xn.[6,7] The compound IMP majorly contributes toward the taste of the meat, and its degradation to HXn and Xn leads to the bitter taste of the fish meat.[8] The level of chief metabolite Xn in the ATP degradation process in the dead fish increases with the storage time of fish meat.[9] Therefore, keeping track of the Xn level in the fish meat can be used as an important parameter to determine the freshness of the fish meat.[8]

Xn is a purine base that is found in various biological samples, including urine, blood, and cerebrospinal fluid. The Xn finally breaks into the UA, which ultimately breaks into the blood and passes through the kidney to come out as urine. Elevated levels of Xn can indicate certain medical conditions,

such as renal failure, diabetes influencer, hyperuricemia, liver, gout disease, cerebral ischemia, xanthinuria, and cardiac diseases.[10−14] Therefore, sensitive and accurate methods for xanthine sensing are important for disease diagnosis and monitoring. There are several methods for xanthine sensing, including enzymatic and nonenzymatic approaches. Enzymatic methods involve the use of xanthine oxidase (XOD), an enzyme that catalyzes the conversion of xanthine to uric acid. Nonenzymatic methods involve the use of various materials that can selectively bind to xanthine and generate a measurable signal. Overall, xanthine sensing is an important area of research with many potential applications in medical diagnostics and monitoring. Further research is needed to optimize the performance of xanthine sensors and to develop practical applications for disease diagnosis and monitoring.

Previously, many techniques have been deployed to detect Xn and its metabolites, like spectrophotometry, mass spectrometry, chemo/electroluminescence, high-performance liquid chromatography, and capillary electrophoresis biosensors.[15−21] The traditional techniques were supposedly time-consuming and had a limited range of detection toward the targeted analyte, which made researchers look out for other options. One such popular alternative is the electrochemical biosensors, which have an exquisite range of detection, simple processing, and high sensitivity and selectivity.[22−28] Till now, many attempts have been made to immobilize the enzymes onto the electrode's surface by means of adsorption, covalent, and intermediate molecular linkage, which affects the sensing ability of the electrochemical sensors.[29,30] In the last decade, nanoparticles have been extensively used due to their unique properties and great potential in the field of biosensing.[31−37] One such class of popular nanomaterials is transition metal dichalcogenides (TMDs). These are the two-dimensional (2D) nanomaterials having a high surface-to-volume ratio and good electronic response, which could be employed as potent electrodes for Xn detection. On the other side, the layered metal oxides have also gained attention as a new class of van der Waals material.

The combination of the materials of these two classes exhibits great potential for Xn detection. Molybdenum disulfide (MoS_2) and molybdenum trioxide (MoO_3) are very famous 2D materials with interesting electronic and optical properties.[38−40] MoS_2 exhibits semiconductor properties and possesses a direct band gap within the visible spectrum, rendering it highly promising for optoelectronic applications, whereas MoO_3 functions as a wide-band-gap semiconductor, which acts as an effective electron transfer mediator and exhibits excellent stability in aqueous environments, and has found utility in gas sensing and other domains. The amalgamation of MoS_2 and MoO_3 in a nanohybrid configuration yields stimulating properties and unveils possibilities for novel applications.[41] The MoS_2/MoO_3 nanohybrid has gained significant attention in diverse fields, including energy storage and electrocatalysis, among others. In energy storage applications, MoS_2/MoO_3 nanohybrids have been used as electrode materials for lithium-ion batteries and supercapacitors. The unique structure of the nanohybrid allows for efficient charge transfer and high capacitance, leading to improved performance compared to individual MoS_2 or MoO_3 materials.

Here, in this work, the heterostructure of a MoS_2/MoO_3 nanohybrid has been synthesized through a facile hydrothermal process, which enabled the large defect sites for Xn adsorption at the surface of the working electrode. No such work has been reported so far where the MoS_2/MoO_3 nanohybrid-based electrode has been used for Xn detection; therefore, the results hold great significance in this field. The high surface area of the nanohybrid allows for efficient enzyme adsorption, and the electronic properties of the MoS_2 component can be tuned to enhance the sensitivity and selectivity of the sensor to develop a proficient enzymatic biosensor.

EXPERIMENTAL METHOD

Synthesis of MoS_2 Nanosheets and the MoS_2/MoO_3 Nanocomposite. The synthesis of MoS_2 nanosheets was performed using the hydrothermal method. Initially, the precursor solution was prepared by dissolving ammonium molybdate and thioacetamide in deionized water in a 1:2 ratio to form the precursor solution. After stirring the precursor solution for 30 min, 0.05 g of cetyltrimethylammonium bromide (CTAB) was added as a surfactant to the solution, which helps to stabilize the nanosheets and prevent agglomeration. After the addition of the surfactant, the mixture was stirred for a certain amount of time to ensure that the surfactant was evenly distributed throughout the solution. Then, the solution was transferred to a Teflon-lined autoclave and heated at 200 °C for 36 h. After the hydrothermal process was complete, the resulting solution was cooled to room temperature and then centrifuged to separate the MoS_2 nanosheets from the solution. The nanosheets were then washed several times with deionized water and ethanol to remove any remaining impurities and surfactant. Finally, the MoS_2 nanosheets were dried under a vacuum to remove any remaining solvent. The MoS_2/MoO_3 nanocomposite was prepared by adding MoO_3 with ammonium molybdate in a certain ratio. The further process will be repeated as usual. The resulting powders were then characterized using various analytical techniques to determine their morphology and composition.

Electrophoretic Deposition (EPD) of MoS_2/MoO_3 Nanosheets. Before the electrodeposition of the MoS_2/MoO_3 nanocomposite over the indium tin oxide (ITO) surface, the electrode was cut into a 2 cm × 1 cm dimension and washed properly with an ethanol/deionized (DI) solution to remove the dirt and other impurities from its surface. The prepared nanosheets were deposited on a prehydrolyzed ITO electrode using the two-electrode EPD technique (Genetix, GX300C). Platinum was used as a counter electrode. In order to deposit films, the two electrodes were placed at a distance of 10 mm inside the sonicated solutions of the prepared samples in distilled water (DI) water. The deposition of films was achieved at 10 V for 25 s. Finally, the prepared films were kept in a vacuum oven for drying. Two deposited films have been retrieved, i.e., MoS_2/ITO and MoS_2/MoO_3/ITO, respectively.

Fabrication of the MoS_2/MoO_3/ITO Nanohybrid Biosensor. The immobilization was done by treating electrodes with 0.1% glutaraldehyde and allowed to rest for some time (1−2 h) at ambient temperature in order to activate the functional groups attached to the surface of the electrodes.

Afterward, phosphate-buffered saline (PBS; pH 7.4, 100 mM, 0.9% NaCl) was used to wash the electrodes, and then the covalent immobilization of XOD (20 μL) was done. The XOD/MoS_2/ITO and XOD/MoS_2/MoO_3/ITO electrodes were then kept in a moist condition at room temperature

overnight. The scheme for the electrode formation is shown in Figure 1.

RESULTS AND DISCUSSION

Structural and Morphological Studies. Raman spectroscopy serves as a potent technique for examining the structural and electronic characteristics of MoS_2/MoO_3, thereby offering valuable insights into the material's properties. Through the analysis of Raman spectra, crucial information regarding the nanocomposite's vibrational modes and crystalline structure was extracted, as illustrated in Figure 2.

The Raman spectrum of MoS_2/MoO_3 consists of several peaks corresponding to different vibrational modes. In MoS_2/MoO_3, the Raman spectrum of MoS_2 shows peaks related to the E_{1g} (396.28 cm^{-1}) and A_{1g} (424.42 cm^{-1}) modes of the crystal lattice, which are related to the in-plane and out-of-plane vibrations of the sulfur atoms, respectively (as shown in the inset). The Raman spectrum of MoO_3 shows peaks related to the symmetric and asymmetric stretching vibrations of the Mo−O bonds. The peaks in the spectrum include those at around 609 and 815 cm^{-1}, which are assigned to the B_{2g}, and E_g modes, respectively, depicting the occurrence of the $D2h$[16] space group. The occurrence of the MoS_2/MoO_3 nanohybrid was confirmed through the Raman analysis, and the difference between E_{1g} and A_{1g} (28.14 cm^{-1}) depicts the presence of a few layered composites.

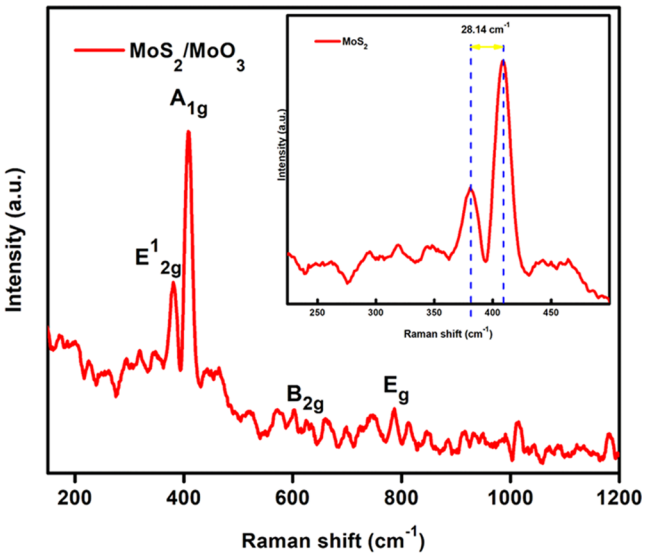

Figure 2. Raman spectrum of MoS_2/MoO_3 nanosheets; the inset shows the characteristic bands for MoS_2 nanosheets.

X-ray photoelectron spectroscopy (XPS) is a powerful surface analysis technique that provides information about the elemental and chemical composition, chemical bonding, and electronic structure of a material. The XPS has been recorded on ULVAC-PHI, PHI5000, which depicts the chemical states of the MoS_2/MoO_3 sample (shown in Figure 3a). Here, the binding energy of the core electrons of the constituent elements, including Mo, S, and O, would be observed. The binding energy of the Mo 3d, S 2p, and O 1s core levels has provided information about the oxidation state of the elements and the nature of the chemical bonding. The wide spectrum of MoS_2/MoO_3 nanosheets describes the presence of Mo, C, O, and S elements on the surface of the prepared nanoparticles. In Figure 3b, the two Mo bands observed at 228.55 and 231.76 eV are attributed to Mo $3d_{5/2}$ and Mo $d_{3/2}$, respectively, which signifies the occurrence of the Mo^{4+} state of molybdenum and their peak separation was measured to be 3.21 eV. The XPS spectra of the S 2p region, as shown in Figure 3c, represent two bands at 161.67 and 162.91 eV attributed to the occurrence of S $2p_{3/2}$ and S $2p_{1/2}$, respectively, which indicates the presence of the S^{2-} oxidation state of sulfur. In Figure 3d, the O 1s oxidation state at 531.65 eV is attributed to the occurrence of MoO_3. The XPS spectrum confirms the occurrence of the MoS_2/MoO_3 composites.

Figure 4 shows the field emission scanning electron microscopy (FESEM) images obtained using a JEOL JSM 6610LV instrument for MoS_2/MoO_3, which typically showed a

layered structure consisting of MoS_2 and MoO_3 layers stacked on top of each other. The surface of the material appears rough and porous due to the presence of MoO_3 nanoparticles. The size and distribution of these nanoparticles were analyzed using FESEM images, which came out to be 400–600 nm (Figure 4a,b). Energy-dispersive X-ray spectroscopy (EDS) was used to analyze the elemental composition of the MoS_2/MoO_3 nanohybrid, which confirmed the formation of the composite

(Figure 4c), and the elemental mapping was done to verify the homogeneity of constituent elements across the sample, in addition to XPS results (Figure 4d–f).

Transmission electron microscopy (TEM) analysis is done on a TECNAI 200 kV, which has provided valuable information about the morphology of the MoS_2/MoO_3 composite. The sample was imaged at various magnifications to observe the structure and morphology of the MoS_2/MoO_3 composite, as shown in Figure 5. The TEM images were recorded for the sample dispersed in DI water, loaded on a copper TEM grid with a carbon coating. The TEM images illustrate the layered structure of the composite stacked over one another. The figure illustrates the formation of a few layers counted from the edges of the sheets. It shows the presence of the 4–6 nanosheets in the prepared sample, which lead to high adsorption due to a greater surface-to-volume ratio. This confirms the results obtained from the Raman analysis of the composite material. The selected area electron diffraction (SAED) pattern shown in Figure 5d illustrates the high crystalline nature of the composite.

Electrochemical Studies of the Fabricated Electrodes. The electrochemical properties were observed on instrument Autolab potentiostat (Eco-Chemie, the Netherlands) for the prepared MoS_2/ITO and MoS_2/MoO_3/ITO heterostructure-based electrode. Electrochemical impedance spectroscopy (EIS; PBS, 5 mM $[Fe(CN)^6]^{3-/4-}$) within the frequency range of 0.01 to 10^5 Hz at a set potential of 0.01 V was carried out(Figure 6a).

EIS is particularly useful for investigating the interface between an electrode and an electrolyte solution, which is important for a wide range of applications. The data obtained from EIS can be analyzed through the Nyquist plot, which is a linear plot observed at lower frequencies, whereas at higher frequencies, a semicircular plot was recorded. This is attributed to the resistance because of the diffusion-controlled electron transfer and electron transfer limited process, respectively. The equivalent circuit has been displayed in the inset of Figure 6a. The charge transfer resistance (R_{ct}) of MoS_2/ITO and MoS_2/MoO_3/ITO was recorded to be 98.511 and 66.165 Ω, respectively.

https://doi.org/10.1021/acsomega.3c03776
ACS Omega 2023, 8, 31962–31971

From the obtained R_{ct} values, the exchange current per geometric unit area (i_o) and the apparent electron transfer rate constant (K_{app}) for MoS_2/ITO and MoS_2/MoO_3/ITO electrodes have been calculated using eqs 1 and 2

$$i_o = nRT/R_{ct}F \quad (1)$$

$$K_{app} = RT/n^2F^2AR_{ct}C \quad (2)$$

where R is the gas constant, F is the Faraday constant, T is the temperature in Kelvin, and A and C are the area of the electrode and the concentration of the redox probe, respectively. The i_o for the MoS_2/ITO electrode was found to be 26.06×10^{-5} A cm^{-2}, whereas, for the MoS_2/MoO_3/ITO electrode, the value of i_o was 38.80×10^{-5} A cm^{-2} respectively. Similarly, K_{app} for the MoS_2/ITO and MoS_2/MoO_3/ITO electrodes was calculated to be 2.14×10^{-6} and 3.19×10^{-6} cm s^{-1}, respectively. This increase in the values of i_o and K_{app} of the MoS_2/MoO_3/ITO electrode compared to the MoS_2/ITO electrode clearly describes the precise diffusion of the redox couple through the electrode interface.

The technique of cyclic voltammetry (CV) is widely utilized in electrochemistry to examine the redox characteristics of materials. In this study, the CV analysis of ITO (curve i), MoS_2/ITO (curve ii), and MoS_2/MoO_3/ITO (curve iii) electrodes was carried out by subjecting the working electrode to a voltage ramp ranging from −1 to 1 V while monitoring the resulting current (Figure 6b). There was a direct flow of electrons between the electrode and the ferro−ferri electrolyte, leading to an increase in the oxidation signal of MoS_2/MoO_3/ITO (curve iii). This finding suggests that the MoS_2/MoO_3/ITO electrode is a promising candidate for future biosensing applications. The charge transfer coefficient (α) and heterogeneous electron transfer coefficient (K_s) for MoS_2/MoO_3/ITO have been calculated to be 0.9073 and 0.0342, respectively, at a scan rate (v) of 50 mV/s (using Laviron's model eq 3).[47,48]

$$\ln(K_s) = \alpha \ln(1-\alpha) + (1-\alpha)\ln(\alpha) - \ln\left(\frac{RT}{nFv}\right) - \alpha(1-\alpha)\frac{nF\Delta E_p}{RT} \quad (3)$$

For the MoS_2/MoO_3/ITO (Figure 7a) electrode, the performance of the electrodes was investigated by varying the scan rate (10 to 150 mV/s). It has been observed that the oxidation peak current increases linearly with a positive shift in the peak potential. Both the anodic peak current (I_{pa}), as well as cathodic peak current (I_{pc}) increase linearly with increasing the scan rate; the following eqs 4 and 5 show the surface adsorption-controlled process kinetics for the MoS_2/MoO_3/ITO electrode (Figure 7b).

$$I_{pa}\ (\text{mA}) = 0.112 + 0.0538\sqrt{v}\ (\text{mV/s})$$
$$R = 0.996 \quad (4)$$

$$I_{pc}\ (\text{mA}) = -0.129 - 0.0384\sqrt{v}\ (\text{mV/s})$$
$$R = -0.993 \quad (5)$$

The anodic and cathodic peak potentials (E_{pa} and E_{pc}) also showed a linear relation with the natural logarithm of the scan rate (ln v). The corresponding linear regression equations eqs 6 and 7 have been given in Figure 7c.

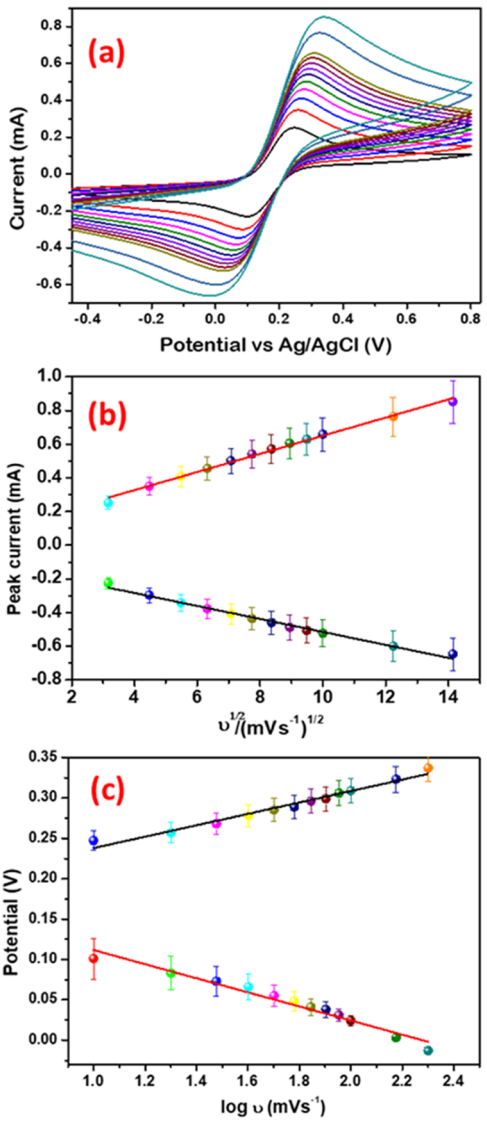

Figure 7. (a) CV at different scan rates, (b) anodic and cathodic peak current, and (c) anodic and cathodic peak voltage of the MoS_2/MoO_3/XOD/ITO electrode.

$$E_{pa}\ (\text{V}) = 0.0706 \ln\ln(v) + 0.1623;\ R = 0.9896 \quad (6)$$

$$E_{pc}\ (\text{V}) = -0.0872 \ln(v) + 0.1988$$
$$R = -0.9819 \quad (7)$$

Electrochemical Biosensing Response Studies of the XOD/MoS_2/MoO_3/ITO Electrode. Xanthine is typically detected through an enzymatic reaction catalyzed by xanthine oxidase (XOD) immobilized on the electrode surface. The MoS_2/MoO_3 nanocomposite can act as a mediator in the electron transfer process. The nanocomposite structure facilitates the efficient transfer of electrons between the immobilized enzyme (XOD) and xanthine, generating an electrochemical signal. To perform the biosensing studies, the XOD/MoS_2/MoO_3/ITO electrode was used to measure the electrochemical response under various concentrations of Xn (Figure 8a). The current response was recorded as the Xn concentration was increased from 1 nM to 1 μM. A linear decrease in current was observed with an increase in Xn concentration, indicating direct electron transfer between Xn

https://doi.org/10.1021/acsomega.3c03776
ACS Omega 2023, 8, 31962−31971

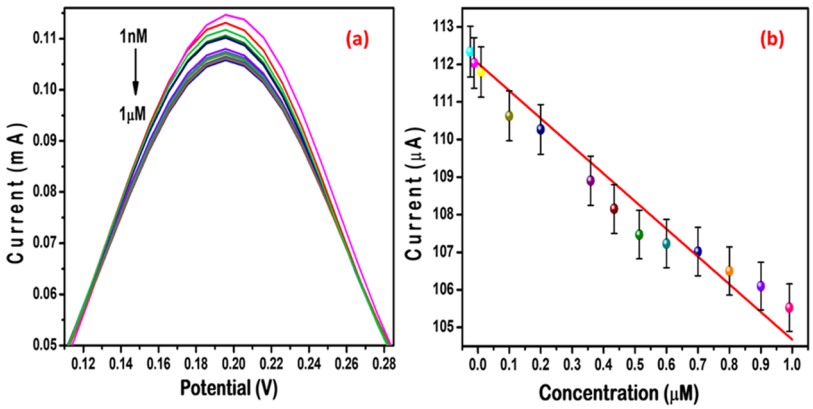

Figure 8. (a) DPV studies showing the current response of the MoS_2/MoO_3/XOD/ITO electrode and (b) current calibration plot with increasing concentration of Xn.

and the XOD/MoS_2/MoO_3/ITO electrode (Figure 8b). The biosensor's sensitivity toward Xn was measured using the regression equation $y = 112.034 - 7.357 \times 10^{-6}x$, where y represents the recorded peak current and x is the concentration of Xn, resulting in a sensitivity of 29.198 μA M^{-1} cm^{-2}. The limit of detection (LOD) and the limit of quantization (LOQ) were found using the equation 3.3 σ/S and (10 × LOD)/3.3, respectively, where σ is the standard deviation of the bioelectrode and S is sensitivity.[42,43] The calculated values for LOD and LOQ are 64 and 177 nM, respectively.

Real-Sample (Rohu Fish Extract) Validation of the Biosensor. Differential pulse voltammetry (DPV) was used to evaluate the practicality of the MoS_2/MoO_3/ITO biosensor for the direct detection of Xn in fish meat samples.

Xn was extracted from Rohu (*Labeo rohita*) fish meat using the method of Watanabe et al. The meat was collected from a nearby market, washed, and chopped finely, and 7 g of the meat was centrifuged in 15 mL of DI water at 4500 rpm. The surfactant was filtered, and the resulting solution was diluted 100 times to achieve the desired concentration. Electrochemical studies demonstrated a linear decrease in the peak current with an increase in Xn concentration from 0.01 to 0.5 μM (Figure 9), similar to synthetic Xn samples. The XOD/MoS_2/MoO_3/ITO biosensor was compared to other Xn-based sensors for various biosensing parameters (Table 1). The results showed that the biosensor exhibited a better response toward the primary detection of Xn in fish meat samples with a lower limit of detection (LOD).

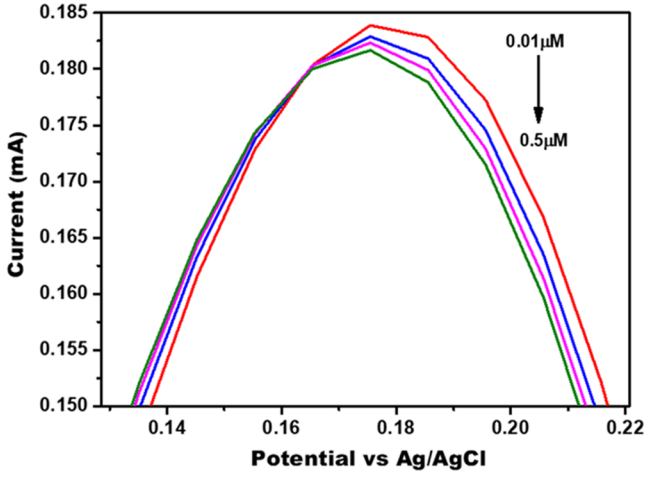

Figure 9. DPV studies of the real sample from fish showing the current response of the XOD/MoS_2/MoO_3/ITO electrode with increasing concentration of Xn.

Selectivity, Reproducibility, Reusability, and Shelf-Life Studies. The nanohybrid biosensor (XOD/MoS_2/MoO_3/ITO) was evaluated for cross-reactivity against interfering analytes (glucose, sodium benzoate, urea, uric acid, and ascorbic acid) having a 10-fold higher concentration than Xn.

No significant changes were observed (Figure 10a); the current remained stable for all other analytes represented as a mixture. The reproducibility of the XOD/MoS_2/MoO_3/ITO electrodes was confirmed by fabricating five similar electrodes under the same conditions (Figure 10b). The response of the fabricated biosensors to 1 nM of Xn ranged from 90 to 99%, with a relative standard deviation (RSD) value of 12% (n = 5). Stability tests were conducted to evaluate the sensor's reusability and shelf life, as shown in Figure 11. The single electrode was used 10 times after washing in saline, with no significant changes observed (Figure 11a).

The biosensor's shelf life was monitored by recording the DPV response toward Xn every week while being stored at 4 °C. After 5 weeks, the electrochemical response decreased from its original activity, indicating its stability over a long period (Figure 11b).

CONCLUSIONS

Detecting Xn is highly important in the food industry as it can signal the spoilage of fish meat in its early stages. Therefore, here, an electrochemical enzymatic biosensor has been fabricated for the primary detection of Xn in fish meat by employing the 2D MoS_2/MoO_3 nanosheets. The 2D arrangement of MoS_2 nanosheets provides a large active surface area, and the inclusion of MoO_3 acts as an electron mediator and enhances the electrochemical response of the electrode, as well as it is more cost-effective than previously used materials such as gold nanoparticles. The developed enzymatic sensor demonstrated a fast response time of 10 s and a detection limit of approx. 64 nanomoles, whereas the limit of quantization came out to be 177 nM. The accuracy of the biosensor was validated using real samples of xanthine extracted from rohu fish meat purchased from a local market, and similar trends were observed in the results for xanthine

Abstract: The thermo- visual fusion based tracking has been deployed for overcoming the shortcomings of alone vision-based object tracking. The assistance from both domains should be wisely merged so that it should result in a useful practice for object tracking. Several techniques had been developed recently to implement a brilliant fusion, but this undeveloped field still inhibits many unsolved challenges. The proposed method aims at increasing the effectiveness of tracking by bi-modal fusion with the introduction of a new set of rules based upon the parameters generated from the decision of individual modality trackers. This practice helps to achieve output by only a single run of the fusion process in every frame. The method also proposes to use minimal information from individual trackers in normal conditions and incorporates the use of supplementary information from imageries merely in case of diverse working conditions. This procedure, in turn, lessens the computations and hence reduces time to process. The experiments performed on well-known publically available datasets show the advantages of the proposed method over the individual visual domain tracking and other existing states of the art fusion techniques.

Index Terms: Particle filter, Object tracking, Decision level fusion, visible-thermal amalgamation.

1. Introduction

Object tracking using sensor fusion of thermal data and the coloured video is a more efficient approach as compared to tracking in isolated individual domains. Visible camera mainly depends on the colour content of the object and surroundings. Thermal / IR camera only captures the thermal image of the object. The thermal image is exclusively related to the temperature value of the object. High-temperature objects possess precious intensity values, whereas low-temperature objects do not possess significant intensity in a thermal image. This information is beneficial for surveillance applications. Moreover, in the case of human target tracking, background illumination variations and inconsistent cloth texture can act as difficulties in vision-based monitoring, but the thermal domain imagery is unaffected from it.

On the other hand, the visible camera has its advantage by having more variations in the data acquired through the colour content information. It is also helpful when a similar temperature object comes in contact with one another, and it is difficult to differentiate their thermal distributions. Hence, during disguised conditions and under the presence of challenging complications, both can complement each other effectively. Since both the domains lie in the image plane, it is easiest to calibrate the information obtained from these cross domains. The following subsection introduces the readers with the previous work done in this motivational direction.

1.1. Related Work

Various research studies have been exercised in this sensor fusion technology. Face recognition inhibiting thermal

This work is open access and licensed under the Creative Commons CC BY License.

and visible sensor fusion using background subtraction had been proposed earlier in literature [1-4]. It has also been actively utilized in robotics based vision applications [5-7]. Besides this, the use of visible and thermal imagery in fusion has also been hosted in spacecraft proximity operations [8] to overcome the effect of different lightening conditions in the orbital environment. [9,10] have advanced the field of image fusion of multisensory data for the improved computer vision applications. More can be explored in the study of [11,12].

Notably, the use of said bi-modal information has been increased for object tracking under challenging conditions of vision in recent times. Nowadays researchers have been trying to advance this overwhelming field by the application of intense methods such as convolutional neural networks [13] that can automatically extract the deep features. A two-stream convolution net was formed independently for each domain and the fusion was achieved by developing a fusion net. Despite an exciting approach, it is to be noted that it is dependent on a rigorous training process through the use of image net database. For obtaining the instantaneous tracks, the process cannot track unless it has been prepared for feature extraction through a complicated process.

Extending a primary particle filter [14] method for adaptive fusion at particle level [15] was a good idea for tracking under similar background conditions. It introduced an additional parameter in fusion to avoid the camouflaging effect. However, the method lacked in several key aspects such as having a long processing time and repetition of fusion for every particle per each frame. Also, if the total number of particles is increased initially, then computational efficiency is affected and time to process rises severely.

A basic approach to tracking by fusion [16] involved multiplication of the individual specialists that used cues from thermal as well as visible imagery to form their opinions. However, simple multiplication only serves the purpose of video sequences with no veiling conditions. In case of false tracking in one mode of imagery, it may lead to overall false result due to the absence of procedure to verify this.

[17] presented a method in which the fusion was performed single time per frame due to the execution of some weighted fusion rules. In this method, individual tracking was performed in two different algorithms. Particle filter was incorporated for vision/colour and correlation based template matching was applied for thermal counterpart. However, this method also lacked in two significant aspects. First, any one domain is over weighted (>1) and other is under weighted (<1) in case of fusion rule 2 and fusion rule 3 in the paper, which are called for most of the time. The over dependency on one domain is based upon the only difference in maximum likelihood obtained from individual trackers dealing in foreground tracking only, which may be either false or true under challenging conditions. Second, this decision based strategy does not provide any correction in output due to the position of the least weighted imagery domain output, which at long distance may deviate itself and thus affects the location of final estimate through the presented fusion.

For the knowledge of readers, different methods that incorporated thermo-visible fusion based tracking are listed under Table1. The proposed work inspires to resolve the above-said issues of fusion, and the detailed contributions and motivation for the research are mentioned in the following subsections.

1.2. Motivation for the Work

A significant motivation for the research work lays in working out a technique that may be able to make a robust track outcome estimate by fusion of the decision made by individual trackers. So, the repetition of the same fusion rule per single step of tracking procedure should be avoided. The fact is that various existing approaches in literature employ the fusion either at the pixel level of the image or at the feature level of individual particles present in the particle filter. Therefore, both approaches in the categories mentioned above seem to be inefficient at sinking the computing time because the same fusion strategy is executed several times for finding out a single frame track outcome. If it is a pixel level fusion, then the fusion process repetition rate becomes equal to the size of the image, i.e., no. of pixels in the image.

Moreover, in the case of the most commonly used particle filter based tracking, fusion is applied for P turns per single tracking outcome. Here P denotes the total no. of particles used for tracking. So, computation cost related to the fusion portion of the tracking algorithm increases with an increase in the number of particles used. Moreover, some methods in literature [14,18] involve the role of background both in the thermal and visible imagery at almost every frame. This calculation of background region, its feature extraction and then the estimation of fusion parameters are repeated for each particle per single frame analysis, which makes it an ample time consuming task. So, the purpose of this research is to formulate a method that can amalgamate the role of both modalities with temporal efficiency and still provide an accurate track estimate. Another inspiration comes from the fact that significant work is done given likelihood adaptation of individual imagery, but work needs to be done in an adaptation of the role of the single state position estimate in a decision-based fusion framework.

1.3. Contribution of work

The proposed method stays with the use of single feature based particle filter tracking in individual domains but introduces an intelligent fusion framework that can overcome the limitations of either of the individual imagery trackers and results into a credible track estimate. The critical contributions of the proposed research work are mentioned in the following points:

i. The proposed work introduces an efficient design framework to obtain track estimates by using a fusion of

thermal and visible imageries. This presented fusion strategy makes it possible that the execution of the fusion step for imageries is not done more than once per single frame as compared to many times per frame execution in previous algorithms. This type of execution, in turn, saves much computational processing.

ii. Second, it presents a selective dealing perspective framework for the tracker. The tracker can either chose to perform simple fusion procedure under normal conditions or can decide to take the supplement help from imageries for making fusion decision only in the presence of diverse challenging circumstances.

iii. A formula is worked out for adjustment of positional coordinates of fused track output after decisive fusion process depending on the outcome provided by the output parameters of individual trackers. This helps in remedying the side effect of hazards in state estimate due to less voted tracker.

iv. A new occlusion treatment is also proposed that is based upon the introduced fusion process. Here, the occlusion detection is the result of the merged opinion from both the imageries.

The organization of the paper is as: Section 2 provides a description of work methodology adopted containing the details of the individual domain particle filter tracking followed by the detailed explanation of the designed fusion strategy along with all rules and parts. The latter part of this section mentions the procedure used while handling occlusions. The following section provides the experimental part along with the discussion on the results acquired covering the qualitative and quantitative aspects. Section 4 contains the concluding remarks and the future possibilities of the performed research.

2. Work Methodology Description

The following section describes the complete details of the work procedure followed for this technique of tracking. The whole process is divided into two main steps. The first subsection provides the insight of the particle filter algorithm incorporated for individual domain tracking. The following subsection provides details of the implementation of the proposed fusion algorithm to obtain the final track estimate.

2.1. Particle Filter Tracking

The implemented particle filter algorithm can be understood appropriately by breaking down the procedure into five stages. Each stage (except initialization of particle filter) was repeated for every frame of video. The explanations of these are as following:

2.1.1. Initializing Particle filter

Initially, on the availability of the target template, its features for reference were generated and fed into the system to act as a reference during the tracking process. To begin with the working of the particle filter, particles of the particle filter were distributed randomly across the scene frame around the target. Each particle was described using a state vector corresponding to $[X, Y, A, B, V_x, V_y]$. In this, X, Y correspond to starting coordinates of the rectangle shaped particle. A, B denote the width and height of the rectangle respectively. V_x and V_y are the velocities, with which, the particles move through the sequence in X and Y direction respectively.

2.1.2. State updating using motion model

After the start, circulated particles states were modified in every frame using a state updating procedure. A linear update matrix, U was used to make the increment in each proceeding frame. Equation (1) describes the state update process for the particles:

$$s_t^p = U \times s_{t-1}^p + G_t \tag{1}$$

Here, s_t^p stands for the p^{th} particle state at time instant $t = t$ and U is taken as (6X6) Identity Matrix, and $G_t \overset{\text{def}}{=} N(0, Q)$. Q is a zero mean Gaussian process with varianceσ_g, whose value is chosen as 0.25 during the experiments.

2.1.3. Observational features from particles

After creation and then updating particles, the next step was to extract information from the state of particles in every frame. Since the fusion algorithm uses two significant aspects: one is weight value and another the positional coordinates of the tracking outcome; therefore, two main features were extracted from every particle. The weight of the particle was awarded based upon a similarity measure calculation.

The use of Bhattacharya similarity measure was incorporated to associate the colour distributions of the template of the target to be tracked and the regions estimated from the state of different particles. First, colour histogram with eight bins for each R, G, and B components was found for both the template chosen as well as the region of the image associated with the individual particle in the visible domain. However, the thermal domain made use of only 1D grey intensity histogram. If b denotes the number of bins in the histogram, then similarity measure BS^p for particle p was given by (2) as:

$$BS^p = \sum_{k=1}^{b} \sqrt{T(k) \times R(k)} \tag{2}$$

Here T denotes the template RGB histogram and R stands for the particle region histogram. However, the distances were transformed to fit in the non-linear probabilistic robustness using (3) to weigh the individual particles.

$$w^p = \frac{e^{\{(BS^p)^2/2\sigma^2\}}}{\sqrt{2\pi\sigma}} \tag{3}$$

In the above equation, w^p stands for weight of p^{th} particle and σ is the variance parameter, whose value is taken as 0.01 throughout the experimentation. And the current state of the particle was marked as s_t^p, which contained the value of instantaneous location, dimensions and velocities of the individual particle.

2.1.4. State Estimation

The final state estimate was obtained by the average of the states obtained from each particle as shown in (4), i.e.

$$S_t = \frac{1}{N} \sum_{p=1}^{N} s_t^p \tag{4}$$

Also, the final combined likelihood parameter for the particle filter track at time t was found in similar manner and given by (5).

$$W_t = \frac{1}{N} \sum_{p=1}^{N} w_t^p \tag{5}$$

In the above equation, N denotes the total number of particles taken for tracking that were 50 for all the experimentation done in this research work. Whereas S_t, W_t stand for the combined weight and state estimate for the particle filter output for a single frame track procedure.

2.1.5. Resampling

Resampling process has been carried out to replace the particles that obtained lower likelihood with other particles in the particle sample for the next iteration. This process has been repeated in every frame to optimize the particle filter efficiency by filtering out the least required samples. The proposed algorithm exchanged the unworkable particles with S_t, which is the obtained mean state of the particles.

The individual track features were generated for the visible and thermal imagery counterpart separately and are denoted as W_t^V, S_t^V and W_t^T, S_t^T respectively. With the completion of the features extraction from the individual tracker, the final outcome was achieved using a new fusion technique, which has been presented in the following section of the paper.

2.2. Fusion Strategy

After obtaining the bimodal track information, selection of a suitable fusion rule was made to obtain track estimate. The fusion process mainly uses two critical statistics from the individual domain tracks to formulate its decision on the final track output estimate. The scheme, in general, can be illustrated using the following diagram in Fig. 1.

The fusion algorithm selects different fusion rules based upon the value of some observed parameters. First, the parameter 'Difference in Weights DIW_t has been calculated (given by (6)). Based upon DIW value, it selected one of two cases.

$$DIW_t = |W_t^V - W_t^T| \tag{6}$$

If DIW_t value was found to be higher than a regularly updated threshold value wd_t, then the sensor mode having the more significant weight was chosen as the correct tracking source after validating it through a background-foreground similarity check. For every frame, the value of wd_t was automatically calculated using (7).

$$wd_t = \frac{1}{2}\left(\frac{W_t^V + W_t^T}{2}\right) \tag{7}$$

The above said validation process in turn, helps to rectify the decision in case of presence of camouflaged backgrounds. Had the higher weighing sensor been tracking deceptively due to disguising conditions, it would have shown high background similarity value and the result would have been discarded. The details of the implementation have been provided in section 2.2.1 of the paper.

In next case, if DIW_t was found to be less than wd_t, that suggests both domains have comparable confidence level in their output track estimate. Hence, an added criteria was used to obtain an error free decision. For overcoming this situation, the section procedure now looked upon for the spatial information, which was established based on founding a new parameter 'Distance in States', DIS_t. If (X_t^V, Y_t^V) and (X_t^T, Y_t^T) were the initial coordinates in 2D space of region of track outcomes in a single sensory domain, then DIS_t was found as the Euclidean distance between these points in image space and is defined in (8) as:

$$DIS_t = \sqrt{(X_t^V - X_t^T)^2 + (Y_t^V - Y_t^T)^2} \tag{8}$$

Further, the state difference threshold value was modelled to make spatial information based decisions. Value of space difference threshold was chosen in reference to dimensions of the object being tracked. Value of sd was found using (9) which helped in revealing whether the difference was significant or not.

$$sd = \frac{1}{2}^2\sqrt{\left(\frac{A}{2}\right)^2 + \left(\frac{B}{2}\right)^2} \tag{9}$$

As mentioned earlier, A, B are the initial width and height of the object to be tracked.

Now, if value of DIS_t calculated was also minor, then it could be decided that estimated states were pointing towards a similar or nearby region in image space with alike confidence. Hence, both trackers resembled to an identical track estimate. So, the required output was found ready without using any Background validations that in turn saved lot of computational cost through a simple Foreground fusion framework detailed in section 2.2.2.

However, if DIS_t was significant (higher than value of), then it would have signified that although the weights obtained from individual trackers were similar, but these were indicating to two different locations. So, again background information was incorporated to aid the handicapped lone foreground detail. Section 2.2.3 describes the fusion for this case. The complete procedure of fusion strategy is as follows:

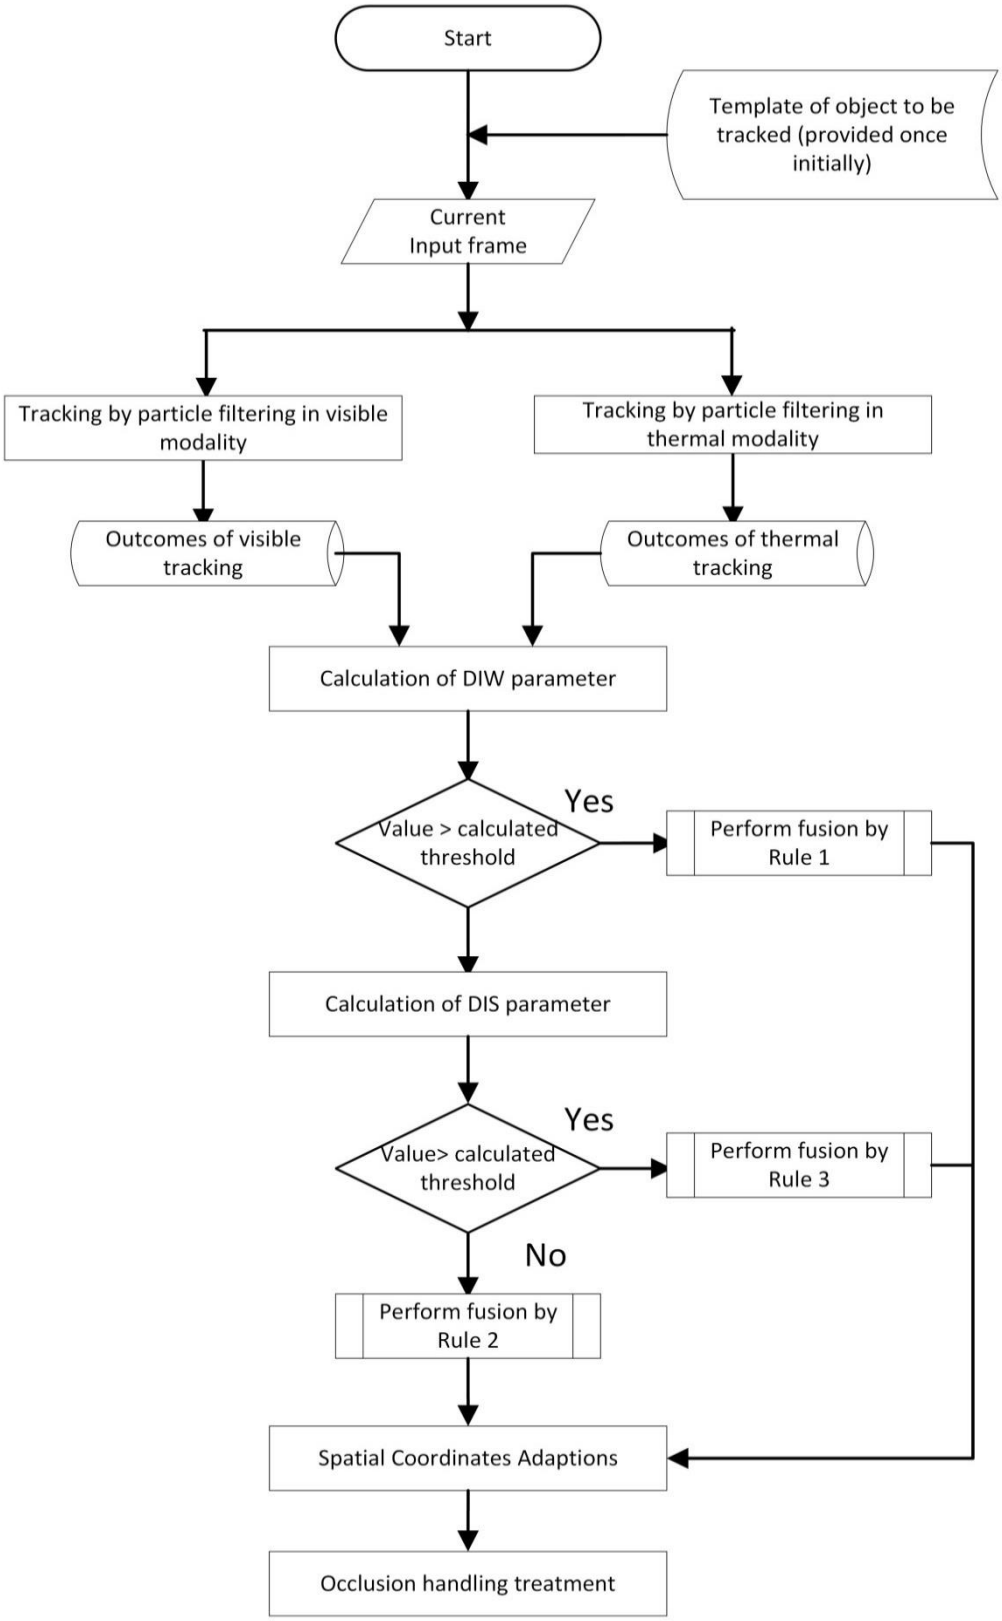

Fig. 1. Block representation of the work-flow procedure

2.2.1. Fusion Rule 1: $DIW_t > wd_t$ (Average weight obtained from one imaging modality was very high and obtained from other was too low).

In this case, due to very low likelihood indication given by one modality in self's decision, its opinion was not taken into consideration and the modality showing a superior likelihood of track was chosen as a sole leader for providing the track estimate. Further the sole dependency was authenticated only after passing the foreground–background validation process. Different techniques are available in the literature for finding the background region and foreground region relation. Our method adopted the local background model implementation of [17] to determine the background histogram of the state found.

If, the Bhattacharya similarity between reference target histogram and background region histogram found using (2) came out to be less than 0.5 (scale of 0-1), the following procedure for fusion was adopted:

i. Append that imagery's weight equal to unity, whose likelihood average weight was found to be far more than the other confidence diminished imagery.
ii. Make the other imagery's weight equal to zero.
iii. After changing the weights of individual imagery to either 0 or 1, the fusion output was calculated as:

$$S_t^F = \delta_t^V \times (S_t^V) + \delta_t^T \times (S_t^T) \tag{10}$$

Here δ_t^V and δ_t^T stand for modified weight values under the above said situation. The variable S_t^F denotes the output of fusion at time t after application of suitable fusion rule. The notation used for the fused output remains same throughout this paper.

Else, the situation was treated as no track in the current frame because, one tracker was having very low confidence in tracking and the other with a superior confidence was tracking wrongly either due to a deceiving condition or presence of similar background in its image signatures.

2.2.2. Fusion Rule 2: $DIW_t < wd_t$ and $DIS_t < sd$ (Average likelihood obtained from both imaging modalities and the location of track estimates from these were in close approximation).

Since the average confidence obtained from both imageries was nearby and also the output track locations pointed by each imagery resided closely in this case; therefore, a conjunctive consensus could be easily reached by use of a simple calculative procedure detailed in following steps:

i. Append Value of Foreground Adaptive Measure, γ, was found using (11) as:

$$\gamma = \frac{w_t^V}{w_t^V + w_t^T} \tag{11}$$

ii. The fused state estimate was updated according to (12).

$$S_t^F = \gamma \times (S_t^V) + (1 - \gamma) \times (S_t^T) \tag{12}$$

Hence, background calculations could be avoided for these situations that lessen the time consumption of the overall track process. The following subsection provides the implementation details of the last case of fusion.

2.2.3. Fusion Rule 3: $DIW_t < wd_t$ and $DIS_t > sd$ (Likelihood of both imaging modalities were found to be nearby but individual state estimate differed significantly).

For this different situation, the extra information that helped dissipate the ambiguity for the fusion was once again the local background conditions of the estimated track state outcome. The background details were found with the help of [17] as mentioned in subsection 2.2.1. Now, a reliable way to weigh the particles can be formulated in the following manner:

i. Value of adaptive background measure, β_t, was calculated based upon the similarities of backgrounds with the object reference template and was found using (13) as:

$$\beta_t = \frac{B_t^T}{B_t^T + B_t^V} \tag{13}$$

Where, B_t^T and B_t^V were the calculated Bhattacharyya similarity measures between the histograms of target object template and the background Regions of the states estimated in thermal and visible modality respectively. Both of these were found using (2).

ii. After obtaining a background measure, an effective way to provide confidence measures to the individual modes was adopted. This modelling is shown by (14) and (15):

$$\alpha_t = \frac{\beta_t . W_t^V}{\beta_t . W_t^V + (1-\beta_t) . W_t^T} \tag{14}$$

$$S_t^F = \alpha_t \times S_t^V + (1 - \alpha_t) \times S_t^T \tag{15}$$

Here, α_t is the parameter representing the weight adaptation parameter resulted from the introduction of the local background details of individual domain imagery. Rest of the parameters is the same as defined earlier in the paper.

The above rule indicates that the imaging modality that exhibited less similarity in its background region was multiplied with a larger weight factor as compared to the other one.

2.3. Improvement in Location of Track Estimate After Fusion

After updating the weights, it was necessary to cross-examine the relative spatial differences between the individual state estimates, as this could also degrade the performance of tracker. If one tracker is tracking correctly and has got a better confidence measure after above fusion process, but still the other tracker having even a small confidence measure could bring a significant shift in the correct track position. If it was pointing to a tracking estimate very far from the current position of the original target. So, despite adaptation in weights, the final track estimate might diverge without making an adaption in locations provided by individual trackers. Changes in states were made using the help of parameter relative to the weighting of individual trackers. First, W_{min} and W_{max} were found using (16) and (17) respectively.

$$W_{min} = \min(W_t^V, W_t^T) \tag{16}$$

$$W_{max} = \max(W_t^V, W_t^T) \tag{17}$$

After this, a factor was found for relative distance adjustments using the following relation presented in (18).

$$D = sd * \frac{W_{min}}{W_{max}} \tag{18}$$

After modification in weights, a check was made that the X and Y coordinates of the Track estimate region of least weighted domain differed (either less or more) from the X and Y coordinates of the other domain (having higher weight) by more than D pixels. If this condition existed, then a corresponding reduction or increment was made in the value of small weighted imagery's state coordinates so that their changed value had at most D pixels difference to remedy the unwanted shift. Otherwise, the values were kept unchanged.

2.4. Occlusion Rule

The method took the help of both the imaging modalities to detect the situation of occlusion in tracking. In the case of occlusion, the object or its parts hide behind another object present in the scene. So, the likelihood value suddenly gets decreased on the insertion of occluding. The proposed algorithm checked the similarity of the final track estimate in every frame with original track template available. This check was performed in both imagery domains concerned.

Moreover, the similarity measures obtained from both the domains were weighted with respect to their weights obtained after fusion. Now, the combined likeness degree was calculated using (19) as:

$$OS_t^F = W_t^V \times (OS_t^V) + W_t^T \times (OS_t^T) \tag{19}$$

Here, OS_t^V represents the Bhattacharyya measure between histogram densities for region of fused track estimate and the template histogram in the visible colour domain and OS_t^T is the corresponding counterpart in the thermal image. The values of these have been found using (19). If the value OS_t^F appeared to be higher than a threshold value for similarity, routine tracking process was continued. But if occlusion was detected due to a degraded similarity index, then algorithm moved towards occlusion handling procedure.

Once the occlusion was detected, then the algorithm searched for the robust presence of the object with the help of background subtraction using dynamic matrix factorization [27]. Once it was detected that the object comes out of occlusion, then the template model was updated by using the new conditions of the object, and the particles were redistributed around its location. The further routine tracking process continued till there is no occurrence of next occlude.

3. Experimental Results and Discussion

To verify the performance and scrutinize it with other states of the art trackers, we used MATLAB software on an I3 processor. The video sequences used along with the challenging conditions contained in these are written in the form of the following points:

i. OCTBVS Dataset Sequence 2 (Similarity in Backgrounds and visible camouflaging).
ii. OCTBVS Dataset Sequence 4 (Occlusion, Clutter)
iii. OCTBVS Dataset Sequence 6 (Presence of similar appearance objects, thermal camouflaging)
iv. INO Snow Parking Dataset (multiple alike objects, same appearance backgrounds, object rotation and most importantly effect of clutters).

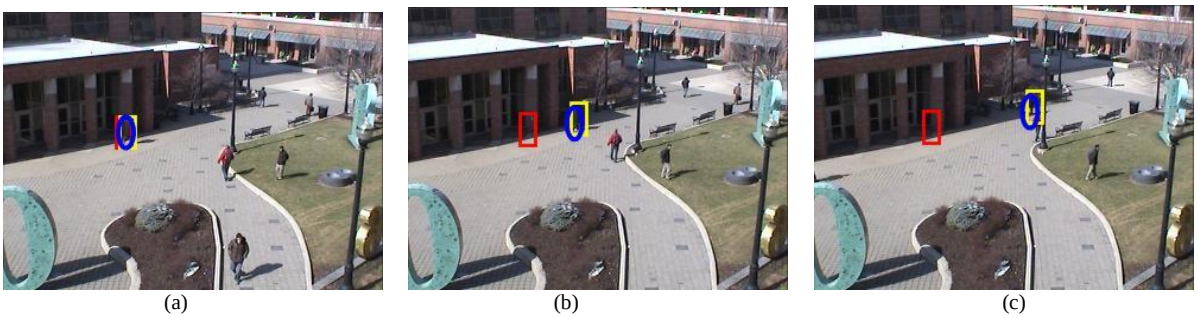
Experiments were performed and the results obtained were compared with 4 other algorithms viz. a) Colour Particle Filter, CPF [14], (b) Continuously adaptive data fusion of colour and gradients. CADF [18], (c) Adaptive fusion of thermal and Visible, AFTV [15], and (d) Tracking before fusion of infrared and visible, TBF [17]. The complete discussion on the results obtained has been narrated by observing the qualitative traits as well as the comparative statistical calculations from the performed experimentation.

3.1. Qualitative Demonstration of the utility of algorithm

The quality of a fusion algorithm can be judged from the fact that it should overcome the hurdles due to several conditions and unaffectedly chose the best outcome possible. Its performance should remain robust. This fact has been illustrated with the help of two video sequences:

3.1.1. OCTBVS Data Sequence 2

The advantage of fusion of the thermal modality in aid to the visible tracking can be demonstrated by Fig. 2 and Fig. 3. Here, the object moves across a colour camouflaged background conditions. It can be seen that there are dark spaces between the pillars of the building and also a tree present on the right side of the view that is making difficult for target judgment in the visible domain.



(a) (b) (c)

Fig. 2. Track outcomes shown on visible image view of seq. 2. Individual colour based tracking (red rectangle), Individual thermal imagery tracking (yellow rectangle) and fusion based tracking using the proposed algorithm (blue ellipse). (a) Frame no. 16, (b) Frame no. 89, (c) Frame 193

(a) (b) (c)

Fig. 3. Thermal Image counterpart of Fig. 2 in the sequence 2 of OSU dataset. (a) Frame no. 16, (b) Frame no. 89, (c) Frame 193

Whereas the thermal signatures robustly mark the presence of the object as compared to the visible captures due to the temperature difference between the human object and the background. It is interesting to note that when both the trackers are tracking accurately, the algorithm does not indulge in any complex computations by avoiding the application of any testing criteria for decisions. However, as soon as the visible particle filter starts estimating an erroneous trajectory, then the final fused track estimate remains with the accurately tracking domain due to the re-arrangements of the weighing criteria and proposes fusion state adjustments.

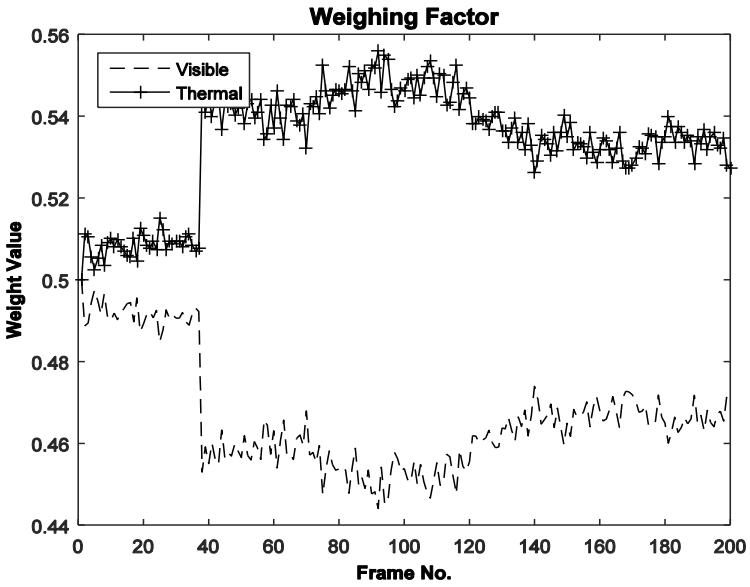


Fig. 4. Wight variation during sequence 2 videos

The fact can also be supported by Fig. 4, which shows that the weight of wrongly tracking visible domain starts decreasing and the fusion algorithm starts favouring the right tracking thermal domain after about 25 frames.

3.1.2. OCTBVS Data Sequence 4

The illustration shown in Fig. 5 and Fig. 6 suggests that the performance quality of the algorithm is not dependent solely on single imagery. The output during different frames of sequence 4 does not get affected when the thermal tracker tracks to incorrect output. Here rather than following the thermal imagery (which was earlier providing better estimates in the previous dataset), now the algorithm tracks by weighing in favour of the accurate tracking visible imagery. So, the fusion approach depreciates the role of thermal imagery in case of it providing false estimates.

(a) (b) (c)

Fig. 5. Track outcomes shown on visible image view of seq. 4. Individual colour based tracking (red rectangle), Individual thermal imagery tracking (yellow rectangle) and fusion based tracking using the proposed algorithm (blue ellipse). (a) Frame no. 45, (b) Frame no. 81, (c) Frame 153

(a) (b) (c)

Fig. 6. Thermal Image counterpart of Fig. 5 in the sequence 2 of OSU dataset. (a) Frame no. 45, (b) Frame no. 81, (c) Frame 153

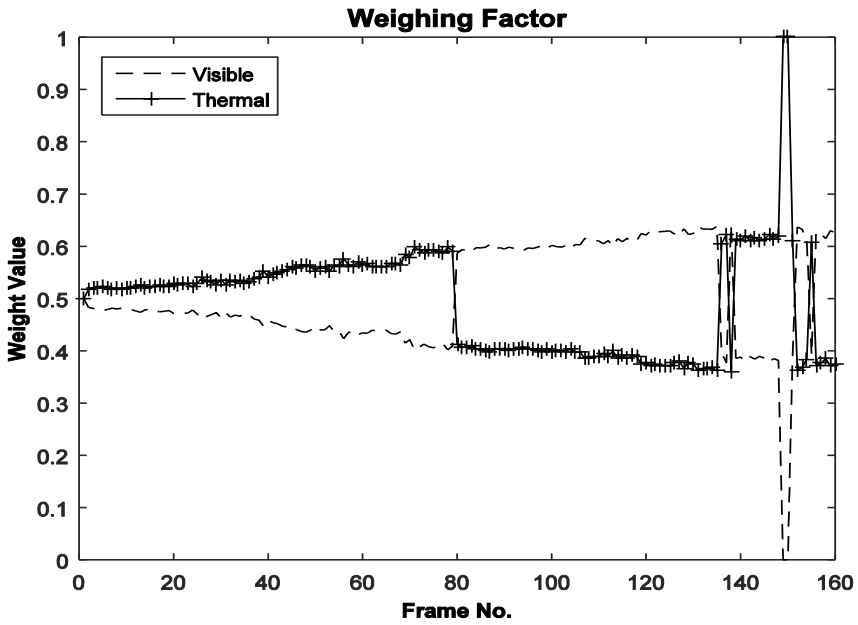

Fig. 7. Weight variation during sequence 4 videos

The same can also be illustrated through Fig. 7, which shows weight values provided to individual imageries after the fusion process. It is interesting to mention that under normal conditions till frame no. 78, the proposed technique finds the track estimate using simple weighted fusion as mentioned by fusion rule number 2 in the paper. This estimation used simple calculations. However, when a new person appeared near to the tracked target, there appeared some difference in opinions of individual trackers. Consequently, the algorithm shifted to fusion rule 3 and started to adjust weights more in favour of accurately tracking visible imagery.

3.2. Quantitative Comparisons with other methods

The accuracy was judged while comparing the experimental results with the ground truth positions of the object throughout the video sequence. This comparison was quantified in terms of two parameters Root Square Tracking Error and the statistical F-measure calculated with the help of precision and recall values. The significance of these parameters is that the value of one resembles the closeness in the position of the target tracked with the actual position of the object and the other represents the bounding box overlap efficiency of the results. The combined diversion from the ground truth positional values in both axes was represented in the form of Root Square Tracking Error, $RSTE_t$, whose value can be found using (20).

$$RSTE_t = \sqrt{\left(G_t(x) - S_t^F(x)\right)^2 + \left(G_t(y) - S_t^F(y)\right)^2} \tag{20}$$

In above equation, $G_t(x)$ and $G_t(y)$ are the X and Y coordinate of starting point of the actual target state respectively, whereas, $S_t^F(x)$ and $S_t^F(y)$ represent the x and y coordinate of starting point of the final track estimate found through applied fusion algorithm.

The next parameter F-measure is found by first finding the precision and recall values and then substituting these in (23). The precision (found using (22)) is defined as the ratio of an area covering intersection the ground truth bounding box with the estimated track bounding box to the area covered by the bounding box of the estimated track state. Whereas, recall can be found using (21), i.e., by the ratio of an area covering intersection the ground truth bounding box with the estimated track bounding box to the area covered by the original bounding box enclosing the object.

$$R_t = G_t(area) \cap S_t^F(area)/G_t(area)\ ) \tag{21}$$

$$P_t = G_t(area) \cap S_t^F(area)/S_t^F(area) \tag{22}$$

$$F_t = 2 \times P_t \times R_t/(P_t + R_t) \tag{23}$$

Here, P_t and G_t mark the current frame precision and recall values respectively. Whereas F_t is the statistical F-measure of the obtained track estimate.

3.2.1. OCTBVS Data Sequence 2

This sequence of OSU dataset contains a human pedestrian moving past a colour similarity background. It has been observed that as soon as the object passes the building walls after frame number 60 and is left only with black background (similar to the colour of dress the pedestrian is wearing), the ordinary colour-based particle filter turns out to be misguided and remains attached to the black background instead of tracking the real target. This effect is illustrated by the high deviation in the error curve shown in Fig. 8

Also, the continuously adaptive data fusion model of gradient and colour fusion remains in the proper track search till mid-way but loses the actual trajectory as it starts weighing more in favour of the colour domain which is already providing false track. Now, coming to the approach of thermal and visible fusion in [17], the track estimates are at some distance apart from the original position of the object consistently. This situation arises because though this fusion method improves the weights for the tracker by weighing more in favour of the thermal imagery, it does not take care of the positional coordinate arrangement. The larger the offshoot distance of false sensing domain, more deviation is present as observed in Fig. 8 and Fig. 9.

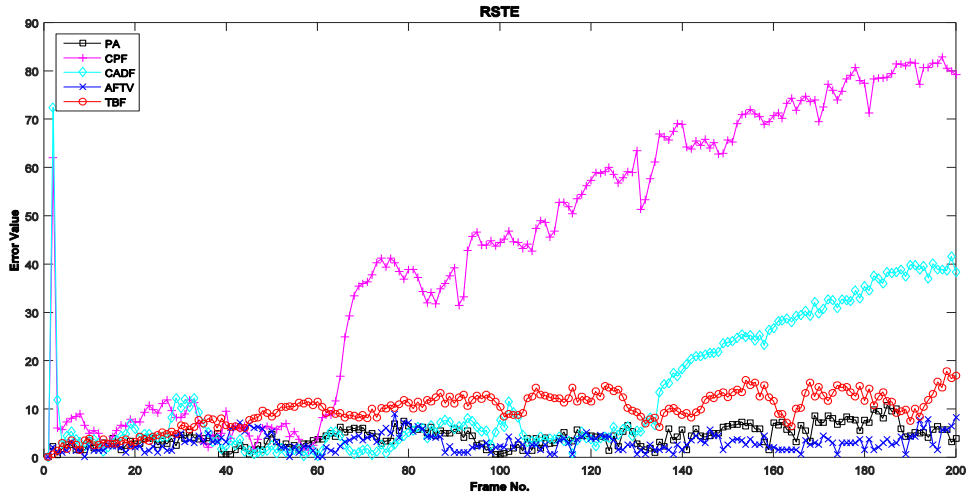

Fig. 8. RSTE plot for Sequence2

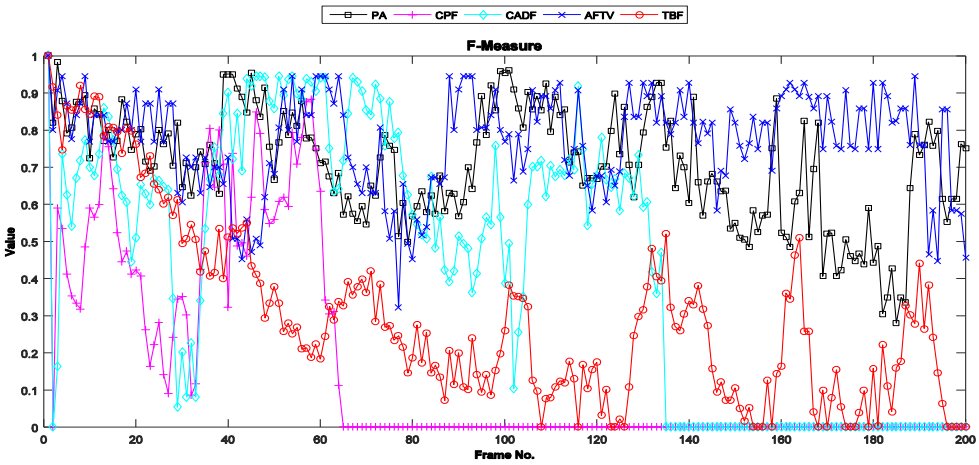

Fig. 9. F- Measure plot for Sequence2

The adaptive fusion of thermal and visible domain by [15] is providing correct weighting by adaptive background fusion model to weigh in favour of the thermal domain signatures of the view. However, this method is not computationally effective as it calculates a background model for every particle in every frame and then performs a similarity comparison for each of them. On the other side, the proposed method takes care of the track estimate by providing parameters both for weights updation as well as track state position updation. As indicated by Fig. 8 and Fig. 9, although the particle filter in colour domain is tracking falsely after frame 60, the thermal domain tracker keeps providing accurate track outcome. Accordingly, the proposed algorithm starts weighing more in favour of thermal domain tracker. Besides, a more substantial drift in location by the result of a false tracking domain has been encountered by the algorithm.

3.2.2. INO Dataset Snow Parking Sequence

The tracking in the snow parking dataset contained many challenging situations such as the presence of multiple alike objects, same colour backgrounds, object rotation and severe effect of clutters in the scene inside both imagery domains. The illustration is provided in Fig. 10 and Fig. 11.

It is notable to see that few other algorithms tend to lose their way as the moving target stops on the path for few frames and it interacts with a similar appearance pedestrian and rotates his motion direction several times during his communication. After frame 770, the object comes across a car that acts as a similar background object. Here rest of all trackers except the individual colour-based particle filter track correctly. Near to frame 780, the target comes in contact with a similar pedestrian that acts as clutter in both imageries, and hence many algorithms tend to hinder away from the original object.

This hazard has been indicated by an increase in the RSTE value (Fig. 12) and a decrease in the F-Measure value (Fig. 13). The AFTV algorithm also suffers ambiguities in the track estimate during frame interval of 790-860, under which the object rotates several times in various directions and comes back to original motion direction only after frame 870.

The TBF algorithm suffers during the presence of clutter and starts tracking correctly afterwards. The proposed algorithm performs a reasonable job throughout the whole frame interval due to amendments made both in weighing factors and the spatial positions.

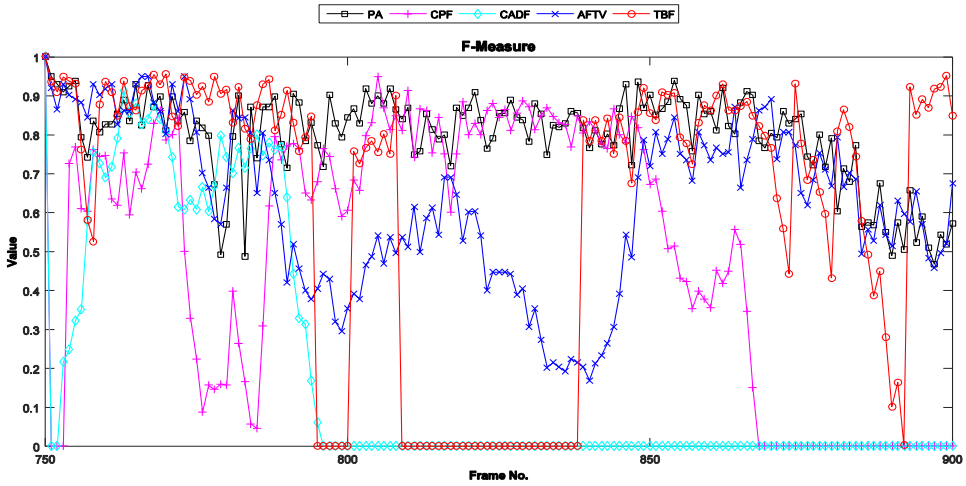

Fig. 13. F-Measure plot for SPDS

3.2.3. Sequence 6 Dataset

The scenes of this dataset contain challenging problems for a visual tracker like changing background conditions, the presence of similar feature objects, and also a similarity in the thermal domain. The object is initially in front of a white coloured car with black bottom front, and a black appearing mirror, but then its motion is traversed against empty space followed by passing a similar coloured pillar that also has it's lower half-size comparable to the dimensions of the object to be tracked. This situation engraves a challenging task, which is shown in Fig. 14 and Fig. 15.

(a) (b) (c) (d)

Fig. 14. Track outcomes of proposed algorithm shown on visible image of seq. 6. (a) Frame no. 28, (b) Frame no. 60, (c) Frame 88, (d) Frame no.145

(a) (b) (c) (d)

Fig. 15. Thermal Image counterpart of Fig.14 in the sequence 6 of OSU dataset. (a) Frame no. 28, (b) Frame no. 60, (c) Frame 88, (d) Frame no.145

Further, the presence of various coloured clutter objects such as black dustbin, windows of the building, etc. makes it tough for tracking using a lonely colour based tracker. The thermal image of the scene also faces a background camouflage in the initial part of the sequence that can be seen through Fig. 14(a).

No trackers except for two algorithms produced an accurate track estimate for this dataset containing various difficulties. The correct tracking was only achieved till nearby frame no. 40. The CADF was working based on the fusion of HOG and colour feature. However, it favoured the colour cue (not tracking accurately) as illustrated by the CPF curve in Fig. 15 due to more significant deviations in the colour likelihood of particle filter. The resultant is the start of ramp increase in the RTSE and decrease in F-Measure value (Fig. 16, Fig. 17). Though TBF favours mainly in the thermal domain from the start, it tracks below par due to thermal camouflaging present the individual thermal tracker. Moreover, with no adjustment in the final state positions, the fusion deviates a lot from the actual position of the target.

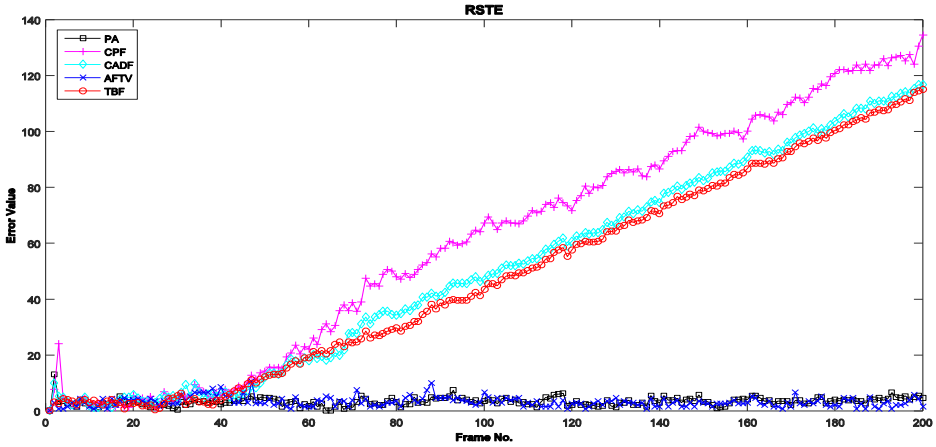

Fig. 16. RSTE Plot for Sequence 6 video

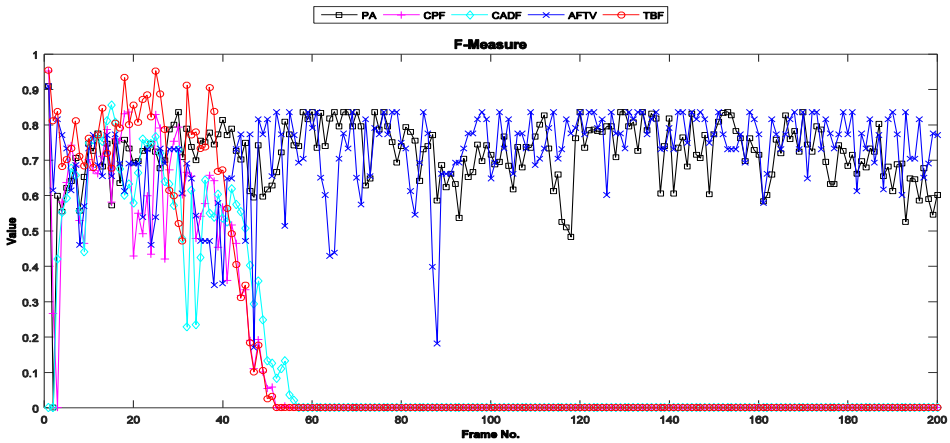

Fig. 17. F- Measure Plot for Sequence 6 video

The results have also been compared via a tabular representation providing a clear view of the performance of the different algorithms. Table 2 provides the time to process analysis, whereas Table 3 presents the RSTE comparison and F-measure statistics have been illustrated using Table 4. It is clear from Table 2 that the proposed algorithm only lacks behind the basic particle filter in timing analysis, but takes less time in comparison to other fusion schemes.

RSTE for various algorithms value was found using (23) for each frame. The average error has been tabulated in Table 3. All the results are averaged over five runs of experiments due to the random nature of the particle filter incorporated in each method. The last column of the table shows the overall average performance.

The best has been written in bold text and italics has been used for the second position. It is interesting to note that though the proposed algorithm does not top the charts for every dataset, it maintains a constant healthy position throughout all the datasets containing diverse, challenging conditions. This performance has been shown by the overall best low RSTE value and largest F-Measure values. The AFTV also performs relatively well, but it requires many computations due to the performance of tedious fusion process for no. of times in a single frame track estimate. This fact is supported by a high time to process details provided in Table 2. Among rest of algorithms, though some perform fast (CPF TBF) but lack in the accuracy counterpart. These provide good results only for a few sequences but perform poorly for other videos. Hence, their overall RSTE and F-Measure in Table 3 and Table 4 are not appreciable respectively.

4. Conclusion

In the proposed algorithm, a unique way of tracking by the combined use of visible imaging and thermal imaging was presented. The method formulated a decisive fusion strategy by analyzing the proximity between parameters found from both the imaging modalities. The parameters used for developing the fusion strategy comprised of the average likelihood weight of particles (obtained from individual imagery) and the location value in image space pointed by the track output of individual imaging tracker. It is clear from the experiments that the presented algorithm performed efficiently under various challenging conditions. It provided commendable accuracy along with consuming small processing time as compared with the state-of-the-art methods. The proposed method top scored in case of two sequences and a second position in the rest two data sequences taken during experiments when root square tracking error was found and compared with different state of the art methods. Further the overlapping efficiency in terms of F-Measure was best for three sequences out of four. The proposed method fared with overall RSTE of 4.77 and an F-Measure of 0.77 when averaged over various data sequences. Time consumed was also less in comparison to state of art fusion based trackers and lagged behind only the individual colour image based particle filter. In addition, the fusion scheme also appears to have the advantage over other techniques in term of the fact that it is independent of the tracking algorithm chosen at the individual image sensor level. It requires only two parameters from the output of any tracker: i) Its track confidence measure and, ii) the position of the output track estimate of the tracker. Both of these traits are readily available for an individual tracker. In future, the method can be applied to tracking under bimodal fusion of imageries through any tracker, but more work needs to be done in the direction to formulate scaled versions of such fusion techniques that can be applied more than two modalities.

Authors' Profiles

Satbir Singh obtained his Ph.D. degree from the National Institute of Technology, Jalandhar (NITJ), and received M.E. in Electronics and Communication Engineering from Thapar University, Patiala, India. He is presently working with Centre for Artificial Intelligence, NITJ. Previously, he had worked with Central Scientific Instruments Organization - India, Delhi Technological, University, Delhi - India, and Centre of Advanced Computing, Mohali - India. His research interests include computer vision, artificial intelligence, image and signal processing, and IoT.

Arun Khosla received his Ph.D. degree from Indraprastha University, Delhi in Information Technology. He is presently working as Professor in the Department of Electronics, and Communication Engineering, National Institute of Technology, Jalandhar, India. Dr. Khosla has been a reviewer for various IEEE and other National and International conferences and serves on the editorial board of the International Journal of Swarm Intelligence Research. He is a life member of Indian Society of Technical Education.

Rajiv Kapoor received an M.E. and Ph.D. degree in ECE from Delhi College of Engineering, Delhi University, and Punjab University, Chandigarh, respectively. Dr. Kapoor is presently working as Professor in Electronics Communication Engineering Department, Delhi Technological University, Delhi). He has authored over 100 research papers in various renowned international journals and conferences. His primary research interests are machine learning, computer vision, signal and image processing.

Abstract

A cluster of astronomical observations emerged that the present Universe is in a phase of accelerated expansion. To examine the accelerated expansion of the Universe, we used the newly proposed gravity in which torsion scalar is responcible for the accelerated expansion. The investigation is carried out using a parameterized effective equation of state with the free parameters α, β, ω_0 and ω_1. Also, for the analysis we consider the model of the form $f(T) = m(-T)^n$, where $m \neq 0$ and n are the constants. By constraining the model with the combined $H(z)$, SC, $unCorBAO$ sample datasets. The model appeared to be in good agreement with the observations, and we were able to determine the parameter values that fit the data the best. Finally, we examined how the deceleration parameter and equation of state parameter behaved in relation to the parameter values that best suited the data.

1 Introduction

After astronomical observations of supernovae over the past few decades [1, 2], multiple ideas to change the General Relativity (GR) and to take into account various formulations of gravity have been made. There are several different modified theories of gravity are present, including $f(R)$, which is produced by substituting an arbitrary function of the Ricci scalar for the Ricci scalar [3–5], $f(R, T)$ gravity is obtained by changing the Ricci scalar and the trace of the energy tensor [6–10] with any arbitrary function, The Gauss–Bonnet invariant has a generic function $f(G)$ [11, 12]. $f(R, G)$ which combines Ricci scalar and Gauss–Bonnet scalar [13, 14], $f(T, B)$ which involve torsion and boundary term [15]. Next, the Teleparallel Gravity (TG) is one of the modification of Einstein's theory that uses the Weitzenbock connection rather than the Levi–Civita connection. As a result, it has no curvature but has torsion, which is what causes the acceleration of the universe. Torsion is responsible for the universe's accelerated expansion and is made up of four parallel vector fields known as vierbeins that are linearly independent. A significant advantage about this theory is that its field equations are second order, which makes them easier to work with than those in $f(R)$ theory. In addition, Wu and Yu [16] point out that the field

equations of $f(T)$ theory are second order, making them much easier to solve than the corresponding fourth-order equations of $f(T)$ theory. The teleparallel theory of gravity, which is equivalent to general relativity, is the fundamental basis of the $f(T)$ theory [17, 18]. $f(T)$ modified teleparallel gravity has been researched by Karami and Abdolmaleki [19] as a substitute for holographic and new-agegographic dark energy models. Amir and Yussouf developed the Kantowski-Sachs universe models in the $f(T)$ theory of gravity [20].To examine the cosmological evolution's of the equation of state parameter for dark energy and their observational constraints, Bamba et al. [21] recently discussed various $f(T)$ models. Chen et al. [22] examined this issue by extending modified gravity at both the background and perturbed levels also examined this theory in terms of the quintessential scenario.

Observational data indicate that the expansion of the universe has accelerated. Einstein's general relativity proposes the concept of Dark Energy (DE) to explain this accelerated expansion of the universe. DE is a fluid with negative pressure and positive energy density, so its equation of state (EoS) is negative: $\omega = \frac{p}{\rho}$. There are many ways to explain the nature of various dark energy models. Authors [23, 24] have provided a presentation for ω that was observed from experimental data. The EoS parameter is predicted to be $\omega = -1$ by DE models with a cosmological constant (ΛCDM), whereas quintessence models predict $\omega > -1$. However, recent observational data favour phantom models with $\omega < -1$ over quintessence models [25]. The 9 year WMAP survey suggests the EoS parameter to be "$\omega = -1.073^{+0.090}_{-0.089}$ from CMB measurements and $\omega = -1.084 \pm 0.063$ in combinations with Supernova data [8]. Kumar and Xu from a combined analysis of the data sets of SNLS3, BAO, Planck, WMAP9 and WiggleZ constrained the EoS parameter as $\omega = -1.06^{+0.11}_{-0.13}$ [26]. Amanullah et al. of Supernova cosmology project have found that $\omega = 1.1035^{+0.055}_{-0.058}$ [27]. Moreover the recent Planck 2018 results constrained $\omega = -1.03 \pm 0.03$" [28]. In light of these constraints on the EoS parameter derived from observations, a phantom phase in the universe cannot be ruled out. In phantom model, energy conditions are violated and the universe evolves to a future singularity in a finite amount of time. According to the classification of Nojiri et al. [29], there are four distinct singularity possibilities [30]: (i) Sudden singularity (type I singularity), in which the pressure becomes infinite,(ii) Big Rip singularity (type-II singularity) where the scale factor and density becomes infinite in finite time Type-III singularity, in which both the pressure and density become infinite while the scale factor remains finite, and (iii) Type-IV singularity, in which the higher derivatives of the Hubble parameter diverge [31].

If we look at the universe's expansion history, one can see that some cosmological parameters play an important role in designating the cosmological evolution. It is well known that the equation of state parameter ω predicts various fluid descriptions of the universe. Hubble $H(z)$ dimensions are also used to derived some traditional cosmological parameters, like "the density of dark energy and the density of non-relativistic matter" [32–34]. These provides constraints which are good in comparison with SN-Ia data, but not are good as provided by BAO and CMB observations. $H(z)$ data has recently been utilized to calculate the Hubble constant H_0 [35, 36], the derived value of H_0, being more compatible with recent lower values measured from a

"median statistics analysis of Huchra's H_0 compilation". All of the above findings were discovered by a simple analysis of "57 supernova data points". Many Authors [37–39] compiled updated list of 38 measurements of Hubble parameters $H(z)$ between redshifts $0 \leq z \leq 2.36$ and used them to put constraints on model parameters. Authors [40] used $H(z)$ data, pantheon compilation of SN-Ia data and BAO data to constrained the model parameters using χ^2 minimization technique. They also obtained the present values of Hubble constant H_0 as $66.2^{+1.42}_{-1.34}$,$70.7^{+0.32}_{-0.31}$ and $67.74^{1.24}_{-1.04}$ for $H(z)$, $H(z)+Pantheon$ and $H(z)+BAO$ respectively [40, 41]. The pantheon compilation of SN-Ia data in the redshift range $0.01 < z < 2.3$ is given in Scolnic et al. [42]

In this model we have use the MCMC methods for quantitative analysis. As a result of the discussion and observations made above, we were motivated to study the cosmological models with effective equation of state parameter in $f(T)$ theory of gravit under "observational constraints of effective equation of state with $f(T)$ gravity".

2 $f(T)$-gravity

We provide a succinct explanation of $f(T)$ gravity in this section, along with a thorough derivation of its field equations. Let's define the Greek and Latin notations of the Latin subscript as those connected to the space-time coordinates and the tetrad field, respectively. We can define the line element for a general space-time metric as

$$dS^2 = g_{\mu\nu}dx^\mu dx^\nu, \tag{1}$$

where the metric's ten degrees of freedom and symmetry are represented by the variables $g_{\mu\nu}$. The theory can be expressed either in space-time or in tangent space, allowing us to recast the line element that can be transformed into the tetrad described by Minkowski (which represents the dynamic fields of the theory) as follows [16]

$$dS^2 = g_{\mu\nu}dx^\mu dx^\nu = \eta_{ij}\theta^i\theta^j, \tag{2}$$

$$dx^\mu = e_i^\mu \theta^i, \quad \theta^i = e_\mu^i dx^\mu, \tag{3}$$

where η_{ij} is a metric on Minkowski space-time and $\eta_{ij} = diag[1, -1, -1, -1]$ and $e_i^\mu e_\nu^i = \delta_\nu^\mu$ or $e_i^\mu e_\mu^j = \delta_i^j$. The root of metric determinant is given by $\sqrt{-g} = \det[e_\mu^i] = e$. Towards a manifold where the Riemann tensor part without the torsion terms is null (contribution of the Levi–Civita connection) and only the non-zero torsion terms exist, the Weitzenbocks connection components are defined as follows [17]

$$\Gamma^\alpha{}_{\mu\nu} = e_i^\alpha \partial_\nu e_\mu^i = -e_\mu^i \partial_\nu e_i^\alpha. \tag{4}$$

It possesses a nonzero torsion but a zero curvature. From this relationship, the primary geometrical objects of space-time are built. The antisymmetric portion of this connection defines the elements of the tensor torsion through the link as

$$T^{\alpha}{}_{\mu\nu} = \Gamma^{\alpha}{}_{\mu\nu} - \Gamma^{\alpha}{}_{\nu\mu} = e_i^{\alpha}\left(\partial_\mu e_\nu^i - \partial_\mu e_\mu^i\right), \tag{5}$$

The contortion tensor which is a space-time tensor that represents the difference between the Levi–Civita and Weitzenbock connections as:

$$K^{\mu\nu}{}_{\alpha} = \left(-\frac{1}{2}\right)\left(T^{\mu\nu}{}_{\alpha} + T^{\nu\mu}{}_{\alpha} - T^{\mu\nu}{}_{\alpha}\right). \tag{6}$$

In order to make more clear the definition of the scalar equivalent to the curvature scalar of RG, we first define a new tensor $S^{\mu\nu}{}_{\alpha}$, constructed from the components of the tensors torsion and contorsion tensor as

$$S^{\mu\nu}{}_{\alpha} = \left(\frac{1}{2}\right)\left(K^{\mu\nu}{}_{\alpha} + \delta_\alpha^\mu T^{\beta\nu}{}_{\beta} - \delta_\alpha^\nu T^{\beta\mu}{}_{\beta}\right). \tag{7}$$

The torsion scalar T is

$$T = T^{\alpha}{}_{\mu\nu}\, S^{\mu\nu}{}_{\alpha}. \tag{8}$$

Now, we define the action by generalizing the TG i.e. $f(T)$ theory as [18, 19]

$$S = \int \left[f(T) + L_{matter}\right]\, e\, d^4x. \tag{9}$$

Here, $f(T)$ denotes an algebraic function of the torsion scalar T. Making the functional variation of the action (9) with respect to the tetrads, we get the following equations of motion [20]

$$S_\mu^{\nu\rho}\partial_\rho T f_{TT} + \left[e^{-1}e_\mu^i\partial_\rho\left(e e_i^\alpha S_\alpha^{\nu\rho}\right) + T^{\alpha}{}_{\lambda\mu}S_\alpha^{\nu\lambda}\right] f_T + \frac{1}{4}\delta_\mu^\nu\,(f) = 4\pi T_\mu^\nu. \tag{10}$$

The field equation (10) looks considerably different from Einstein's equation since it is expressed in terms of tetrads and partial derivatives.
where T_μ^ν is the energy momentum tensor, $f_T = df(T)/dT$, $f_{TT} = d^2 f(T)/dT^2$. As in our investigations, the energy momentum tensor is defined as

$$T_\mu^\nu = (\rho + p)\, u^\nu u_\mu - p\, g_\mu^\nu, \tag{11}$$

where u^ν is the four velocity vector, the pressure p for this fluid is taken to be isotropic, ρ be the energy density. The energy momentum tensor can be expressed as

$$\begin{aligned} T_\mu^\nu &= diag[-\rho,\ \ p,\ \ p,\ \ p\ ] \\ &= diag[-1,\ \omega,\ \omega,\ \omega\ ]\,\rho, \end{aligned} \tag{12}$$

where ω is the equation of state parameter of the form $\omega = \frac{p}{\rho}$.

3 Components of field equations with isotropic background

To describe models of FRW space-time, let's first establish the equations of motion of a collection of diagonal tetrads using the Cartesian coordinate metric, as

$$ds^2 = -dt^2 + a^2(dx^2 + dy^2 + dz^2), \tag{13}$$

where a be the cosmological scale factor. For this frame the langrangian density or Torsion scalar observed as

$$T = -6\left(\frac{\dot{a}}{a}\right)^2 = -6H^2 \tag{14}$$

where $H = \frac{\dot{a}}{a}$ be the Hubble's parameter.

$$12H^2 f_T(T) + f(T) = 16\pi G\rho \tag{15}$$
$$48H^2\dot{H} f_{TT}(T) - 4(\dot{H} + 3H^2) f_T(T) - f(T) = 16\pi G p \tag{16}$$

where the overhead dot $(\cdot)$ denotes the derivative with respect to cosmic time t, p and ρ denotes the pressure and energy density respectively. The conservation equation leads as

$$\dot{\rho} + 3H(\rho + p) = 0. \tag{17}$$

However, Eqs. (15) and (16) can be rewritten as

$$H^2 = \frac{8\pi G}{3}(\rho + 3\rho_\Lambda) = 0. \tag{18}$$

and

$$2\dot{H} + 3H^2 = -8\pi G(p + 3p_\Lambda). \tag{19}$$

where p_Λ and ρ_Λ are the effective pressure and energy density of the fluid. Specifically, p_Λ and ρ_Λ express in T and f_T are as follows

$$\rho_\Lambda = \frac{1}{16\pi G}[2T f_T(T) - f(T) - T] \tag{20}$$

and

$$p_\Lambda = \frac{1}{16\pi G}[4\dot{H}(2T f_{TT}(T) - f_T(T) - 1)] - \rho_\Lambda \tag{21}$$

4 Cosmological model and equation of state

After solving Eqs. (20) and (21) for p_Λ and ρ_Λ, we obtained the effective or total EoS parameter ($\omega_\Lambda = \frac{p_\Lambda}{\rho_\Lambda}$) as

$$\omega_\Lambda = \frac{p_\Lambda}{\rho_\Lambda} = -1 + \frac{4\dot{H}(2Tf_{TT}(T) - f_T(T) - 1)}{2Tf_T(T) - f(T) - T} \tag{22}$$

For our analysis, we consider the simplest functional form of $f(T)$ gravity model of the form

$$f(T) = m(-T)^n, \tag{23}$$

where $m \neq 0$ and n are the constants. We discovered the total or effective equation of state parameter, as

$$\omega_\Lambda = -1 + \frac{(\alpha - 1)}{3}\frac{\dot{H}}{H^2} \tag{24}$$

Moreover, we may define the relationship for t and z as follows by utilising the relation $\frac{a}{a_0} = \frac{1}{(1+z)}$,

$$\frac{d}{dt} = \frac{dz}{dt}\frac{d}{dz} = -(1+z)H(z)\frac{d}{dz}, \tag{25}$$

By normalizing the present value of the scale factor $a_0 = a(0) = 1$, the Hubble parameter reduces to

$$\dot{H} = -(1+z)H(z)\frac{d}{dz}, \tag{26}$$

One additional alternative equation is required in order to solve Eq. (24) for $H(z)$. Thus, we suppose that the equation of state parameter has a well-motivated parametric form as a function of redshift z as [43, 44].

$$\omega_\Lambda = \frac{-1}{1 + \alpha(1+z)^\beta} \tag{27}$$

and

$$\omega_\Lambda = \omega_0 + \omega_1\left(\frac{z}{1+z}\right) \tag{28}$$

where α, β, ω_0 and ω_1 are the free model parameters.

The above effective equation of states of the universe involves some unknown dimension less constant parameters namely α, β, ω_0 and ω_1. We are going to determine these unknowns from numerical analysis adopted here for different observed data.

Moreover, the observed dimensionless Hubble parameter and a suitable chi-square function are defined in the following sections with different cases. Before that, in regard to the Universe Hubble parameter, some cosmographic/cosmological parameters that are important in cosmological observations are such as

4.1 Deceleration parameter

The deceleration parameter, denoted as $q(z)$, is defined as a function of the Hubble parameter H by the equation:

$$q(z) = -1 - \frac{\dot{H}}{H^2} \tag{29}$$

The deceleration parameter is a key quantity for characterizing the different phases of the universe. It helps distinguish between decelerated phases ($q > 0$) and accelerated phases ($q < 0$). Understanding the evolution of the universe requires insights into the behavior of the deceleration parameter. In the field of cosmology, various studies have explored the significance of the deceleration parameter in elucidating the different phases of the universe. For instance, references such as [45] have employed the deceleration parameter to analyze and explain the evolutionary phases of the universe in different cosmological models. Moreover, researchers have also worked on parameterizing the deceleration parameter to study its behavior in various scenarios [46–51]. These parameterizations allow for a more comprehensive understanding of the underlying dynamics and potential transitions between decelerated and accelerated phases.

4.2 Statefinder diagnostic

In the analysis of cosmology, Sahni et al. [52] have included a new cosmological diagnostic pair $\{r, s\}$ called Statefinder diagnostic. The Statefinder help to differentiate and compare between different dark energy models. The standard cold dark model (SCDM) and the cosmological constant model (ΛCDM) have some fixed points in the $\{r - s\}$ plane and $\{r - q\}$ plane. The standerd equations of r and s are

$$r = q(z) + 2q^2(z) - \frac{\dot{q}}{H} \quad \text{and} \quad s = \frac{(r-1)}{3(q-1/2)} \tag{30}$$

4.3 $O_m(z)$ diagnostic

Now, we going towards the discussion on $O_m(z)$ diagnostic which is used to differentiate the standard ΛCDM model from various dark energy dominated models [53]. In accordance with [54, 55] for flat universe $O_m(z)$ is defined as

$$O_m(z) = \frac{\left(\frac{H(z)}{H_0}\right)^2 - 1}{(1+z)^3 - 1} \tag{31}$$

4.4 Energy conditions

Without specifying the specific behaviour of the matter, the energy conditions allow us to consider the behaviour of gravitational systems. It has been demonstrated that the well-known Raychaudhuri equation, which deals with interesting gravity, is very useful in characterising energy circumstances. The four point-wise energy conditions that are limitations on the stress-energy-momentum tensor of the matter are strong energy condition (SEC), weak energy condition (WEC), null energy condition (NEC), and dominant energy condition (DEC). In physical these energy conditions are defined as

- "Null energy condition (NEC) $\iff \rho + p \geq 0$,
- Weak energy condition (WEC) $\iff \rho + p \geq 0$ and $\rho \geq 0$,
- Strong energy condition (SEC) $\iff \rho + p \geq 0$ and $\rho + 3p \geq 0$,
- Dominant energy condition (DEC) $\iff \rho - |p| \geq 0$ and $\rho \geq 0$".

It is well recognized that among the energy conditions, WEC is the most unpredictable. The WEC assumes that for a perfect fluid, $\rho \geq 0$. Moreover, the universe's pressure cannot be so low that it overwhelms the energy density, or $\rho + p \geq 0$. Next, the null energy condition yields the second law of black hole thermodynamics (NEC). According to the context, we may also deduce that the WEC and DEC, on the other hand, cannot be satisfied if the NEC is violated. In several modified theories of gravity, the energy conditions are investigated, including Capozziello [56] and Alvarenga [57] used the power law in $f(R)$ and $f(R, T)$ gravity to study the phenomenon. In his research, Liu [58] used both Born-Infeld and exponential $f(\mathcal{T})$ gravity, in $f(\mathcal{G})$ gravity by Garcia [59] and Bamba [60] also Atazadeh [61] investigated in $f(R, \mathcal{G})$ gravity while Mishra et al. has looked at the energy conditions in cosmological models with changing anisotropic parameters in $f(R, T)$ gravity. [62].

5 Data description

5.1 Hubble datasets

It is possible to write the Hubble parameter as $\frac{d}{dz} = \frac{d}{dz}\frac{dz}{dt} = -(1+z)H(z)\frac{d}{dz}$. The model-independent value of the Hubble parameter can be determined by measuring dt since dz is derived from a spectroscopic survey. Here, we make use of the $H(z)$ data point collection, which consists of 57 points (see Table I in [63]). measured using the differential age technique [64]. The chi-square function for $H(z)$ defined as

$$\chi^2_{H(z)} = \sum_{i=1}^{57} \frac{[H_{th}(z_i) - H_{obs}(z_i)]^2}{\sigma^2_{H(z_i)}}. \tag{32}$$

Here, the Hubble parameter's theoretical value is represented by H_th, its observed value is represented by H_obs, and the standard error of the observed value of H is represented by $\sigma_{H(z_i)}$.

5.2 Standard candles (SC)

Considering the measurements of the Pantheon Type Ia supernova dataset [65–69], Quasars [70] and Gamma Ray Bursts were collected in [71]. The model parameters can be fitted by comparing the observed μ_i^{obs} with theoretical μ_i^{th} value of the distance moduli is given by

$$\mu = m - M = 5\log_{10}(D_L) + \mu_0, \tag{33}$$

where M and m represents the absolute and apparent magnitudes respectively and $\mu_0 = 5\log\left(H_0^{-1}/Mpc\right) + 25$ is the nuisance parameter that has been depreciate. The luminosity distance is defined by

$$D_L(z) = \frac{c}{H_0}(1+z)\int_0^z \frac{dz^*}{E(z^*)} \tag{34}$$

The χ^2 function of the (SNeIa) measurements is given as

$$\chi^2_{\text{SN}}\left(\phi_{\text{s}}^{\nu}\right) = \mu_{\text{s}}\mathbf{C}^{-1}_{\text{s, cov}}\,\mu_{\text{s}}^T, \tag{35}$$

where $\mu_{\text{s}} = \{\mu_1 - \mu_{\text{th}}(z_1, \phi^{\nu}), \ldots, \mu_N - \mu_{\text{th}}(z_N, \phi^{\nu})\}$ and the subscript 's' denotes SnIa. Keep in mind for SnIa dataset the covariance matrix is not diagonal. The distance modulus μ_i is given as $\mu_i = \mu_{B,i} - \mathcal{M}$, where $\mu_{B,i}$ represents the maximum apparent magnitude in the cosmic rest frame for redshift z_i and $\mathcal{M}$ represents the universal free parameter, by various observational ambiguity both $\mathcal{M}$ and h parameters are naturally degraded with respect to Pantheon dataset, Hence one can't extract proper information about H_0 from SnIa data alone.

5.3 Uncorrelated baryon acoustic oscillations (unCor BAO)

Considering the largest collection of BAO dataset measurements, from it we have selected 17 uncorrelated BAO measurements because using the complete collection of BAO might lead to a very large error due to data correlations, therefore we select the small dataset to reduce errors. Studies of BAO in transverse direction contribute a measurement of $D_H(z)/r_d = c/H(z)r_d$ with comoving angular diameter distance [72].

$$D_M = \frac{c}{H_0} S_k\left(\int_0^z \frac{dz'}{E(z')}\right), \tag{36}$$

where

$$S_k(x) = \begin{cases} \frac{1}{\sqrt{\Omega_k}}\sinh\left(\sqrt{\Omega_k}x\right) & \text{if} \quad \Omega_k > 0 \\ x & \text{if} \quad \Omega_k = 0 \\ \frac{1}{\sqrt{-\Omega_k}}\sin\left(\sqrt{-\Omega_k}x\right) & \text{if} \quad \Omega_k < 0. \end{cases} \tag{37}$$

Table 1 Summary of the MCMC results using $H(z) + SC + unCorBAO$ dataset

MCMC results Model	Parameters	Best fit value
ΛCDM Model	H_0	$69.854848^{+1.259100}_{-1.259100}$
Model I	H_0	$68.990853^{+0.502428}_{-0.502428}$
	α	$0.297626^{+0.030564}_{-0.030564}$
	k	$-0.179266^{+0.014411}_{-0.014411}$
	β	$6.713197^{+0.474649}_{-0.474649}$

We also take into account the $D_A = D_M/(1+z)$ and the $D_V(z)/r_d$ angular diameter distances. This combines the coordinates of the BAO peak with the sound horizon at the drag epoch, r_d. Ultimately, we are able to directly observe the Hubble parameter using "line-of-sight" (or "radial" observations), To see more please see [73]

$$D_V(z) \equiv \left[z D_H(z) D_M^2(z) \right]^{1/3}. \tag{38}$$

6 Model-I

To solve Eq. (24) for $H(z)$, we assume a well-motivated parametric form of equation of state parameter as a function of redshift z. Using Eqs. (24), (25) and (26), we obtained the Hubble parameter $H(z)$ in terms of redshift z as,

$$H(z) = \frac{H_0}{[1+\alpha(1+z)^{\beta}]^k} \tag{39}$$

where $k = \frac{3}{n(1-m)}$.
Here, we obtained the constraints values of the constants involve in Eq. (39) by combining the above three chi-square functions defined in Eqs. (32), (33) and (34). We have discovered the parameters best fit predicted values as $H_0 = 69.854848^{+1.259100}_{-1.259100}$, $\alpha = 0.297626^{+0.030564}_{-0.030564}$, $\beta = 6.71319^{+0.474649}_{-0.474649}$ and $k = 0.17926^{+0.01441}_{-0.01441}$ shown in Table 1 where as the theoretical curve of Hubble function and distance modulus with ΛCDM model with their corresponding error bars is most likely seen in Figs. 1 and 2 and the likelihood contours for the same parameters at 1σ, 2σ level is shown in Fig. 3.

6.1 Cosmological parameters

6.1.1 The equation of state parameter

Figure 4, shows the EoS parameter's graphical behaviour quite clearly. The equation of state parameter in our model exhibits a transition from a positive to a negative value with cosmic evolution, indicating that the variable equation of state parameter is what causes the change from radiation-dominated matter to $-1 < \omega_\Lambda$ and $-1 > \omega_\Lambda$.

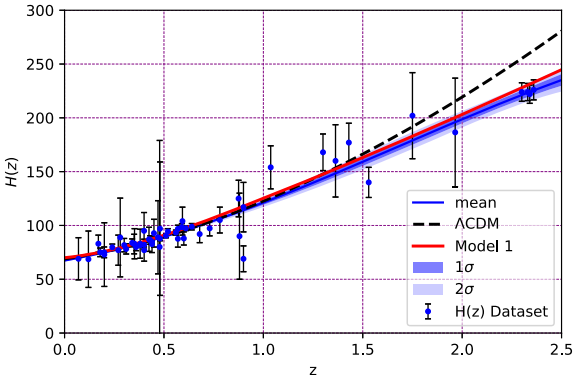

Fig. 1 The figure shows the theoretical curve of Hubble function $H(z)$ of Model 1 and ΛCDM models, shown in blue dots with their corresponding error bars

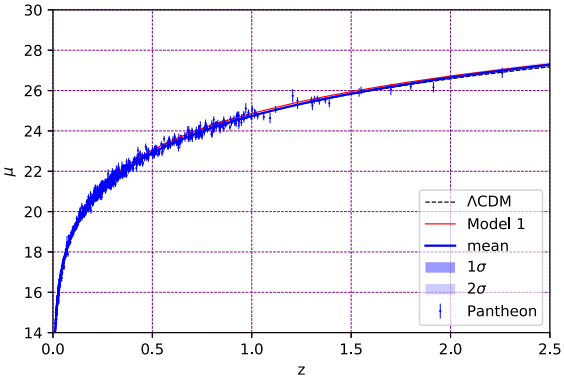

Fig. 2 The figure shows the theoretical curve of distance modulus $\mu(z)$ of our model and ΛCDM models against the Pantheon dataset, shown in pink dots with their corresponding error bars

The model begins in a matter-dominated era, fluctuates in the quintessence region $-1 < \omega_\Lambda < \frac{1}{-3}$, and finally approaches the phantom region $\omega_\Lambda < -1$. The universe is currently dominated by ΛCDM, as indicated by the current value of the equation of state parameter $\omega_\Lambda = -1$. It has been noted that at the current time $z = 0$, it is located in the quintessence region $(-1 \geq \omega_\Lambda)$. Also, the fact that the current values of the EoS parameter, $\omega_0 = -0.6302$ for the $H(z) + SC + unCorBAO$ dataset, are in good accord with recent Planck observational data is another surprising outcome of our model along with Aghanim et al. provide the restrictions on the EoS value for DE in [75]. It is clear that our predictions of the EoS parameter's current value fall within the observational bounds indicated in the previous reference. It is important to note that our findings for the future are identical to the observations made in [76].

Also, one observed that in Fig. 4, the initial value of ω_Λ as $(z \longrightarrow \infty)$ is 0.76547. The default value of ω as $(z \longrightarrow 0)$ is $\omega_\Lambda = -0.6302$, and the far future value is $(z \longrightarrow -1)$ is -1.

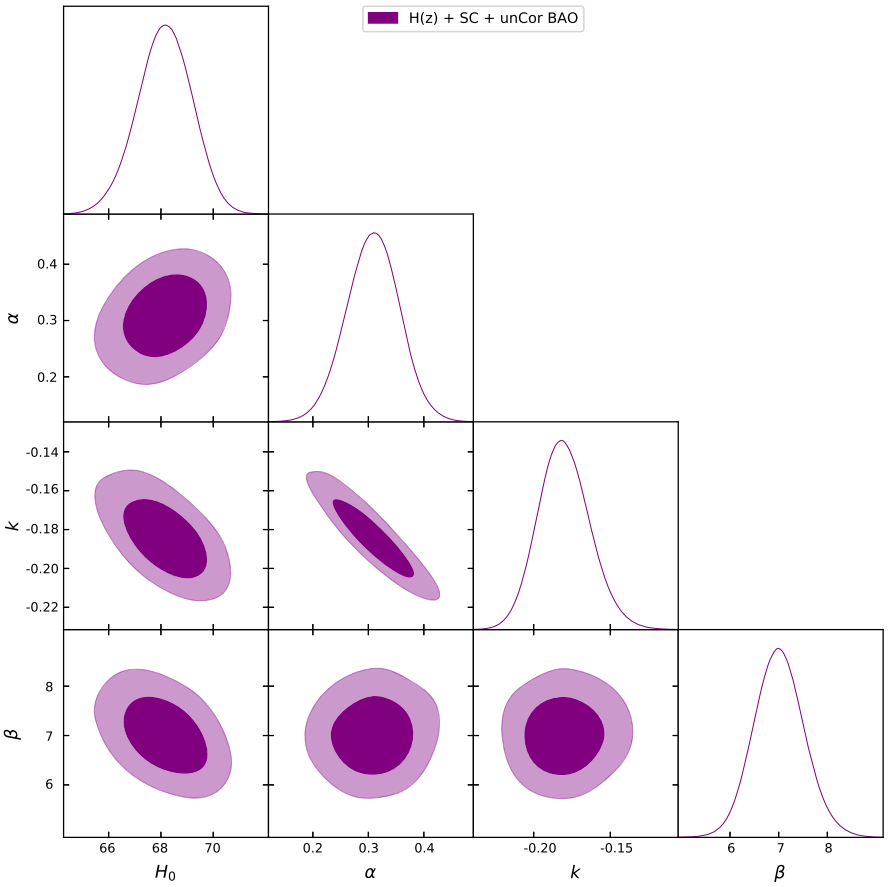

Fig. 3 This figure corresponds to 1σ and 2σ confidence contours obtained from $H(z)+SC+unCorBAO$ dataset obtained for the emergent model

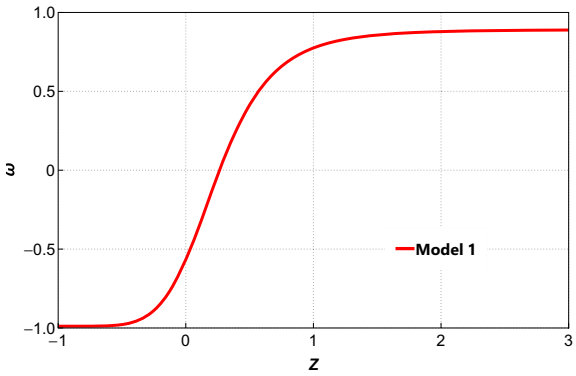

Fig. 4 Evolution of EoS parameter of Model 1 with respect to redshift

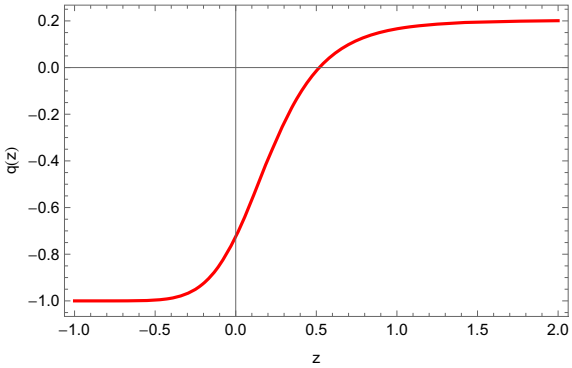

Fig. 5 Evolution of deceleration parameter of Model 1 with respect to redshift

6.1.2 The deceleration parameter

Using Eq. (39) in Eq. (29), the deceleration parameter observed as

$$q(z) = \frac{\alpha\beta k(-z-1)(z+1)^{\beta-1}}{\alpha(z+1)^{\beta}+1} - 1 \tag{40}$$

The behavior of redshift dependendant deceleration parameter $q(z)$ is shown in Fig. 5. This parameter initial setting (q_i as $z \longrightarrow \infty$) is $q = 0.2$, the default deceleration parameter value (q_0 as $z \longrightarrow 0$) is $q = -0.75013$ and thus the deceleration parameter's distant future value (q_{f} as $z \longrightarrow -1$) is $q = -1$. The redshift during which the Universe transitioned from decelerating to accelerating expansion, for this model z_t for which $q = 0$, is 0.5013. The model seems to have a super-accelerated evolution. With a transition redshift of $z_t = 0.513$, which is comparable to the transition redshift of $z_t = 0.50 - -0.73$ observed for the ΛCDM model [74, 75], the cosmos smoothly transitioned from the decelerated phase to the accelerating phase. Also, The current behaviour perfectly corresponds to the analysis of [76] probe using an anisotropic model and a decaying cosmological term for $n = 1.75$.

6.1.3 Statefinder diagnostics

Using Eq. (39) in Eq. (30), the statefinder diagnostics parameters observed as

$$r = \frac{1}{\left(\alpha(z+1)^{\beta}+1\right)^2}\alpha(z+1)^{\beta} \times (-(\beta-3)\beta k + \alpha(\beta k+1)(2\beta k+1)(z+1)^{\beta}+2)+1 \tag{41}$$

$$s = \frac{1}{3}\beta\left(\frac{2k+1}{\alpha(z+1)^{\beta}+1} - \frac{3}{\alpha(2\beta k+3)(z+1)^{\beta}+3} - 2k\right) \tag{42}$$

The behavior of $\{r, s\}$ and $\{r, q\}$-planes is well described in Figs. 6 and 7 respectively. At present the $\{r, s\}$-plane well defines the ΛCDM model with $s = 0$ and $r = 1$ (see Fig. 6) and advances to the quintessence domain before rebounding to the Chaplygin

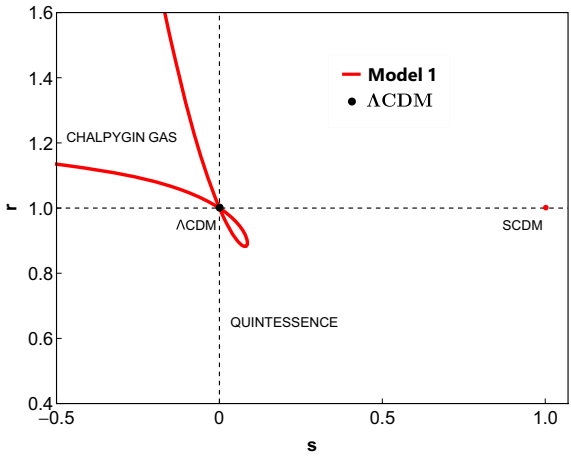

Fig. 6 Behavior of $\{r, s\}$-plane with respect to redshift

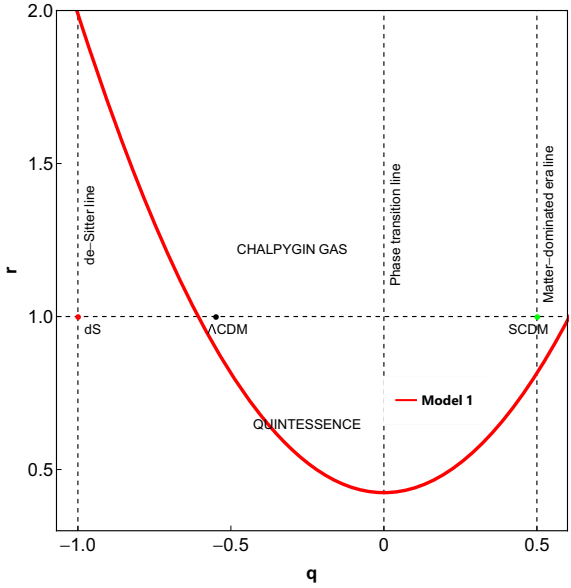

Fig. 7 Behavior of $\{r, q\}$-plane with respect to redshift

gas domain at late times by crossing the intermediate ΛCDM fixed point {0, 1} during expansion while the $\{r, q\}$-plane provides extra information regarding of this model that it evolves from quintessence region in the past and goes to Chaplygin gas (see Fig. 7)

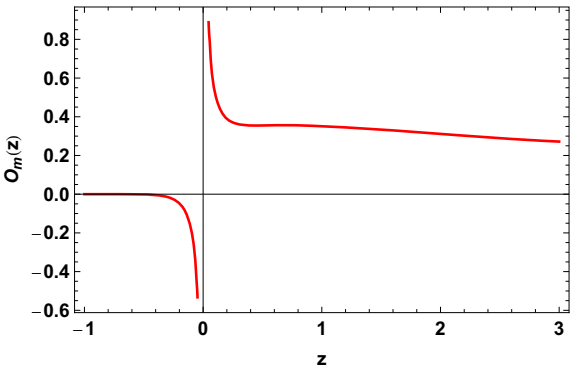

Fig. 8 The evolution of the $O_m(z)$ diagnostic parameter with respect to redshift

6.1.4 $O_m(z)$ diagnostic

Using Eq. (39) in Eq. (31), the $O_m(z)$ diagnostic parameter observed as

$$O_m(z) = \frac{\left(\alpha(z+1)^{\beta}+1\right)^{-2k}-1}{(z+1)^3-1} \tag{43}$$

The behavior of $O_m(z)$ diagnostic parameter verses redshift z is observed in Fig. 8. The $O_m(z)$ value is very small in the redshift range of $z > 0$, indicating that the models are in the quintessence domain. As z declines, the value drops and becomes negative, signifying that the model inhabit the phantom region (see Fig. 8).

6.1.5 Energy conditions

Using Eq. (39), the expressions of NEC, DEC and Strong energy condition respectively observed as,

$$\rho_\Lambda + p_\Lambda = -\frac{2\alpha\beta k(-z-1)(z+1)^{\beta-1}\left(-m6^n n(2n-3)\left(H_0^2\left(\alpha(z+1)^{\beta}+1\right)^{-2k}\right)^n - 6H_0^2\left(\alpha(z+1)^{\beta}+1\right)^{-2k}\right)}{3\left(\alpha(z+1)^{\beta}+1\right)} \tag{44}$$

$$\begin{aligned}\rho_\Lambda - p_\Lambda &= \frac{2}{3}\left(\alpha(z+1)^{\beta}+1\right)^{-2k-1}\left(H_0^2 m6^n\left(\alpha(z+1)^{\beta}(n(\beta k(2n-3)+6)-3)+6n-3\right)\right.\\ &\quad\left.\times\left(H_0^2\left(\alpha(z+1)^{\beta}+1\right)^{-2k}\right)^{n-1}+6H_0^2\left(\alpha(\beta k+3)(z+1)^{\beta}+3\right)\right)\end{aligned} \tag{45}$$

$$\begin{aligned}\rho_\Lambda + 3p_\Lambda &= -2\left(\alpha(z+1)^{\beta}+1\right)^{-2k-1}\left(H_0^2 m6^n\left(\alpha(z+1)^{\beta}(n(\beta k(2n-3)+2)-1)+2n-1\right)\right.\\ &\quad\left.\times\left(H_0^2\left(\alpha(z+1)^{\beta}+1\right)^{-2k}\right)^{n-1}+6H_0^2\left(\alpha(\beta k+1)(z+1)^{\beta}+1\right)\right)\end{aligned} \tag{46}$$

In the following Fig. 9, the behaviour of the current cosmological model's Null (red curve), Dominant (black curve), and Strong (green curve) energy conditions are depicted. The figure explains that the NEC ($\rho_\Lambda + p_\Lambda$) and DEC ($\rho_\Lambda - p_\Lambda$) both energy conditions are verified while SEC ($\rho_\Lambda + 3p_\Lambda$) is violated.

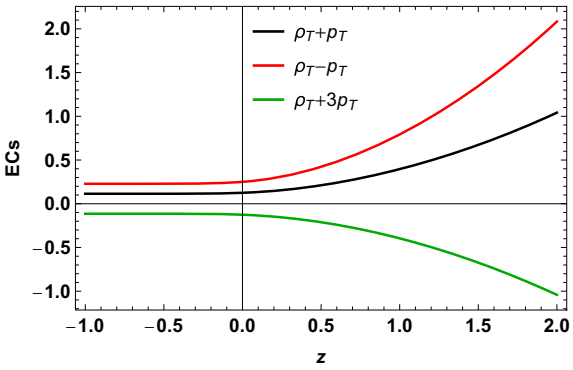

Fig. 9 Evolution of energy conditions with respect to redshift

Table 2 Summary of the MCMC results using $H(z)+SC+unCorBAO$ dataset

MCMC results		
Model II	H_0	$62.984292^{+0.415798}_{-0.415798}$
	β	$0.918487^{+0.009755}_{-0.009755}$
	β_0	$1.018775^{+0.009910}_{-0.009910}$

7 Model-2

By following the same techniques as in Model-I, here with the use of Eqs. (28) and (39), We obtained the Hubble parameter $H(z)$ in terms of redshift z as,

$$H(z) = H_0(1+z)^{\beta} e^{\frac{\beta_0}{1+z}} \tag{47}$$

where $\beta = \frac{3(1+\omega_0+\omega_1)}{\alpha-1}$ and $\beta_0 = \frac{3\omega_1}{\alpha-1}$ are the free model parameters.

We have found the best fit estimated values of the parameters as $H_0 = 62.984292^{+0.415798}_{-0.415798}$, $\beta = 0.918487^{+0.009755}_{-0.009755}$ and $\beta_0 = 1.018775^{+0.009910}_{-0.009910}$ shown in Table 2 where as the theoretical curve of Hubble function (against the 57 measurements of $H(z)$ dataset) and distance modulus (against the Pantheon dataset) with ΛCDM model with their corresponding error bars is most likely seen in Figs. 10 and 11 and the likelihood contours for the same parameters at 1σ, 2σ level is shown in Fig. 12.

7.1 Cosmological parameters

7.1.1 The equation of state parameter

The graphical behaviour of the EoS parameter is depicted pretty clearly in Fig. 13. Our model's EoS parameter shows a shift in value with cosmic evolution, going from a positive to a negative, suggesting that the variable EoS parameter is what drives the transition from radiation-dominated matter to $-1 < \omega_\Lambda$ and $-1 > \omega_T$ which is the same as of our model-I. The model starts in a period where matter is predominate, varies in the quintessence area $-1 < \omega - \Lambda < \frac{1}{-3}$, and then moves closer to the phantom

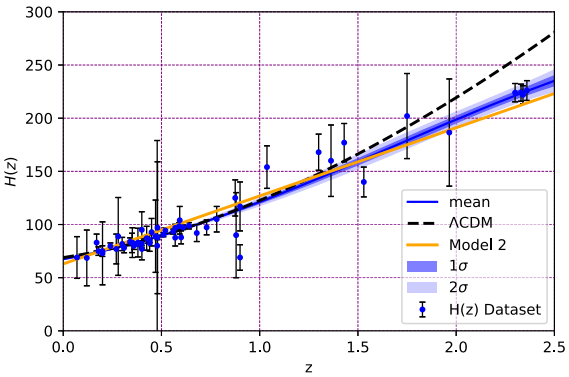

Fig. 10 The figure shows the theoretical curve of Hubble function $H(z)$ and ΛCDM models against the 57 measurements of H(z) datasets, shown in blue dots with their corresponding error bars

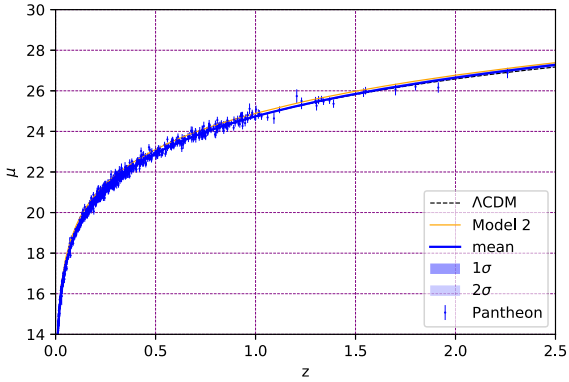

Fig. 11 The figure shows the theoretical curve of distance modulus $\mu(z)$ of our model and ΛCDM models against the Pantheon data, shown in pink dots with their corresponding error bars

region $\omega_\Lambda < -1$. The current value of the EoS parameter $\omega_\Lambda = -1$ indicates that the cosmos is currently dominated by the ΛCDM model.

Also, the reality that the present day values of the EoS parameter, $\omega_0 = -0.6152$ for the $H(z)+SC+unCorBAO$ dataset, are in precise accord with current Planck observational records is another surprising outcome of our version together with Aghanim et al. Provide the regulations at the equation of state parameter's value for DE in [75]. It is clear that our predictions of the equation of state parameter's contemporary value fall within the observational bounds indicated in the preceding reference. It is crucial to be aware that our findings for the destiny are identical to the observations made in [76] which is near to same as of model-I.

7.1.2 The deceleration parameter

Using Eq. (47) in Eq. (29), the deceleration parameter observed as

$$q = -1 - \frac{\beta_0}{z+1} + \beta \tag{48}$$

In Fig. 14, the redshift dependent deceleration parameter's behaviour is depicted. Initially as $z \longrightarrow \infty$ the deceleration parameter $q = 0.34563$. At preset where as

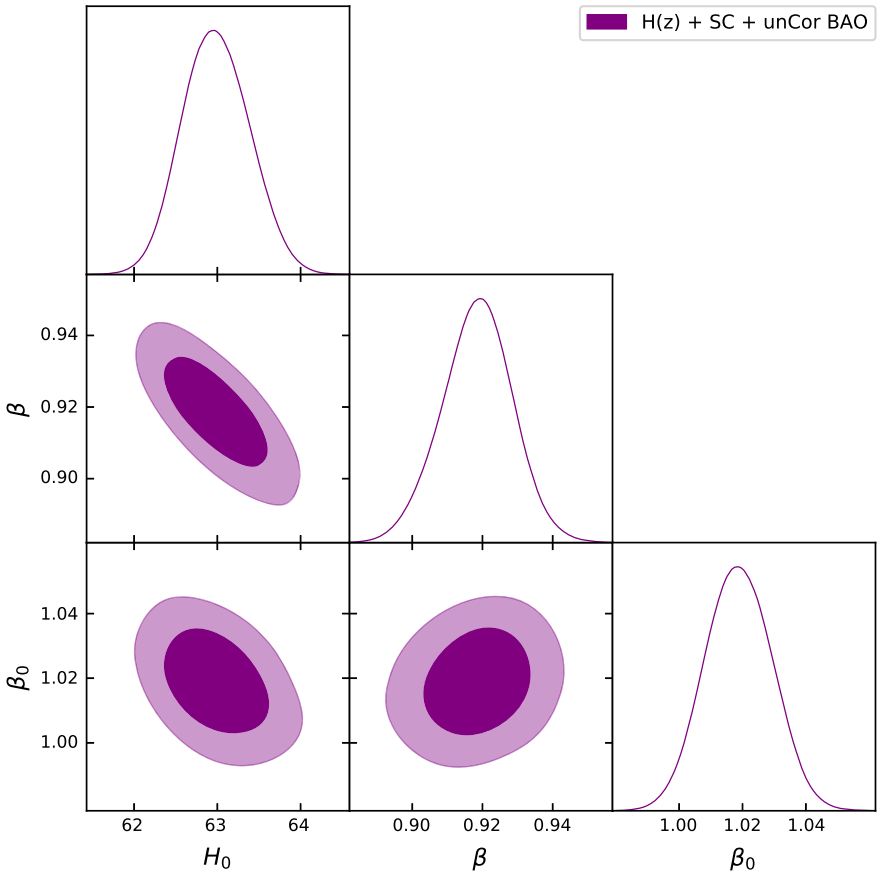

Fig. 12 This figure corresponds to 1σ and 2σ confidence contours obtained from $H(z)+SC+unCorBAO$ dataset obtained for the emergent model

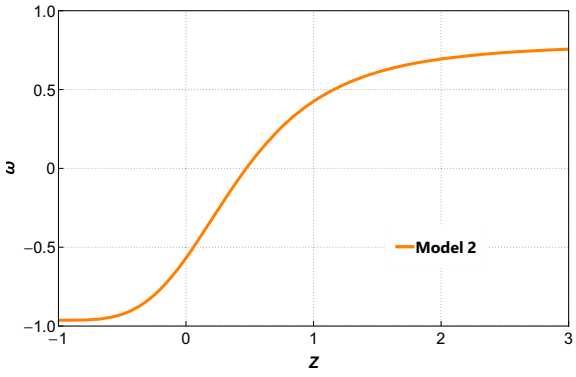

Fig. 13 Evolution of equation of state parameter with respect to redshift

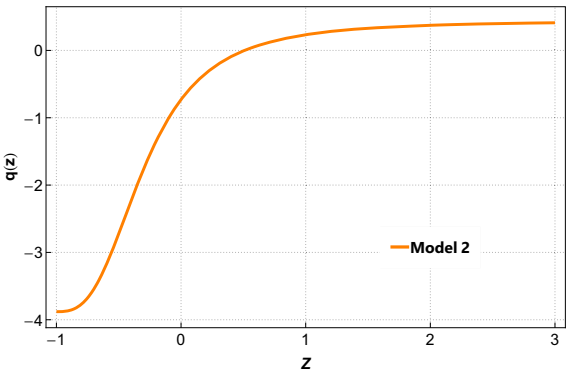

Fig. 14 Evolution of deceleration parameter with of Model 2 with respect to redshift

$z \longrightarrow 0$ the deceleration parameter is $q = -0.8254$ whereas in future at which $z \longrightarrow -1$ the value of the deceleration parameter is $q = -3.85343$. Hence the model seems to having a super-accelerated evolution.

The cosmos smoothly transitioned from the decelerated expansion to the accelerating expansion. Also, The contemporary behaviour flawlessly corresponds to the analysis of [74] probe the use of an anisotropic version and a decaying cosmological term for $n = 1.75$ equal as discused in model-I.

7.1.3 Statefinder diagnostics

Using Eq. (47) in Eq. (28), the statefinder diagnostics parameter observed as

$$r = 2\beta^2 - 3\beta - \frac{4(\beta-1)\beta_0}{z+1} + \frac{2\beta_0^2}{(z+1)^2} + 1 \tag{49}$$

$$s = \frac{4\beta_0^2 - 8(\beta-1)\beta_0(z+1) + 2\beta(2\beta-3)(z+1)^2}{3(z+1)((2\beta-3)(z+1) - 2\beta_0)} \tag{50}$$

On the contrary side, one could examine the profile of $\{r, s\}$ of Model 1 see Fig. 15, as Model 2 advances to the Chaplygin gas domain at late times by crossing intermediate ΛCDM fixed point $\{0, 1\}$ before quintessence domain. Meanwhile $\{r, q\}$ profile including further information on Model 2 as it evolves from the quintessence domain to Chaplygin gas (see Fig. 16)

7.1.4 $O_m(z)$ diagnostic

Using Eq. (39) in Eq. (29), the $O_m(z)$ diagnostic parameter observed as

$$O_m(z) = \frac{\frac{(z+1)^{2\beta} e^{\frac{2\beta_0}{z+1}}}{H_0^4} - 1}{(z+1)^3 - 1} \tag{51}$$

Figure 17 shows how the diagnostic parameter $O_m(z)$ behaves in relation to redshift z. The models are in the phantom domain because the $O_m(z)$ value is very small in

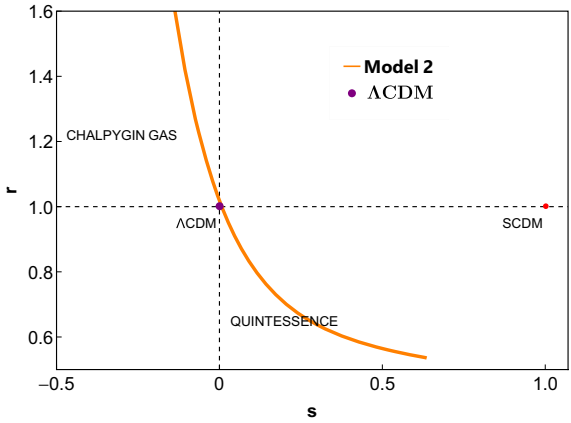

Fig. 15 Behavior of $\{r, s\}$ profile of Model 2 with respect to redshift

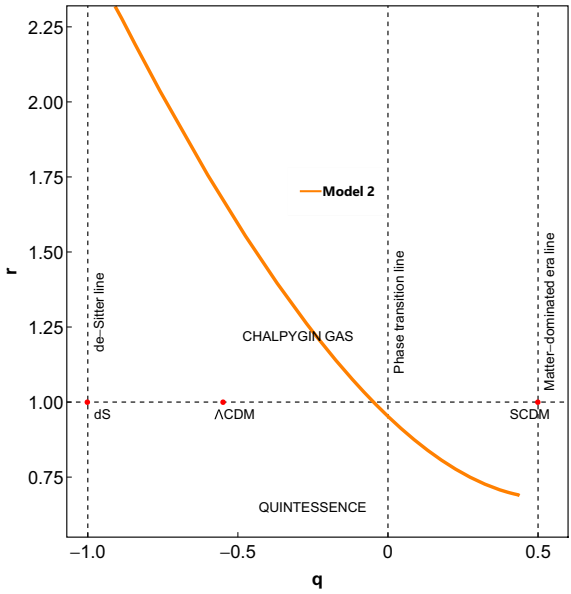

Fig. 16 Behavior of $\{r, q\}$ profile of Model 2 with respect to redshift

the redshift range of $z > 0$. The value increases and turns positive as z decreases, indicating that the model is the quintessence region (see Fig. 17).

7.1.5 Energy conditions

Using Eq. (39), the expressions of NEC, DEC and Strong energy condition respectively observed as,

$$NEC = \frac{1}{3}(-2)\alpha\beta k(z+1)^{\beta}\left(\alpha(z+1)^{\beta}+1\right)^{-2k-1}\left(H_0^2 m 6^n n(2n-3)\right.$$
$$\left.\left(H_0^2\left(\alpha(z+1)^{\beta}+1\right)^{-2k}\right)^{n-1}+6H_0^2\right), \tag{52}$$

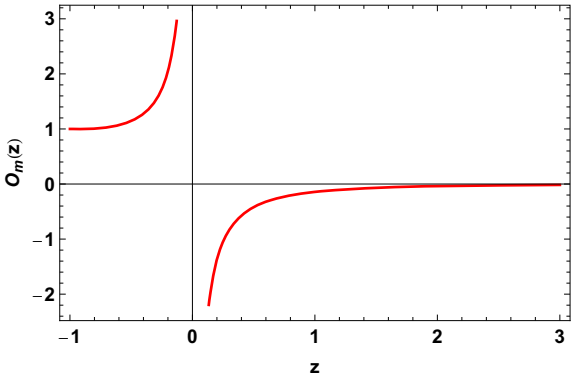

Fig. 17 The evolution of the $O_m(z)$ function of Model 2 with respect to redshift

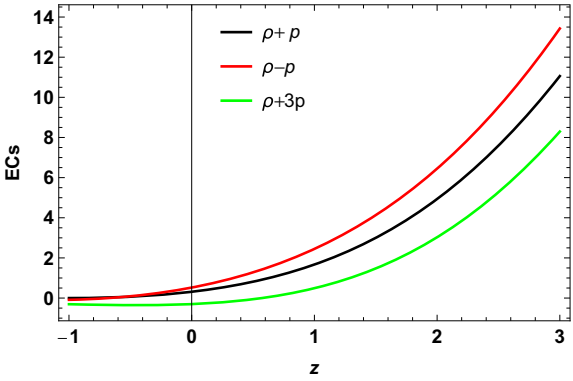

Fig. 18 Evolution of energy conditions with respect to redshift

$$DEC = \frac{2}{3}\left(\alpha(z+1)^{\beta}+1\right)^{-2k-1}\left(H_0^2 m 6^n\left(\alpha(z+1)^{\beta}(n(\beta k(2n-3)+6)-3)+6n-3\right)\right.$$
$$\left.\left(H_0^2\left(\alpha(z+1)^{\beta}+1\right)^{-2k}\right)^{n-1}+6H_0^2\left(\alpha(\beta k+3)(z+1)^{\beta}+3\right)\right), \quad (53)$$

$$SEC = -2\left(\alpha(z+1)^{\beta}+1\right)^{-2k-1}\left(H_0^2 m 6^n\left(\alpha(z+1)^{\beta}(n(\beta k(2n-3)+2)-1)+2n-1\right)\right.$$
$$\left.\left(H_0^2\left(\alpha(z+1)^{\beta}+1\right)^{-2k}\right)^{n-1}+6H_0^2\left(\alpha(\beta k+1)(z+1)^{\beta}+1\right)\right), \quad (54)$$

The behaviour of the Null (black curve), Dominant (red curve), and Strong (green curve) energy conditions of the present cosmological model is shown in the accompanying Fig. 18. The figure demonstrated that $\rho_\Lambda + p_\Lambda$, $\rho_\Lambda - p_\Lambda$, and $\rho_\Lambda + 3p_\Lambda$, indicating SEC is violated whereas NEC and DEC are energy conditions that are verified (Table 3).

8 Information criteria

To discuss sustainable model analysis, it is essential to understand the concept of information criteria (IC). Among the various ICs, the Akaike information criteria (AIC) [77] is widely used. The AIC is an approximation of the minimization of Kullback–

Table 3 Summary of the χ^2_{min}, χ^2_{red}, AIC and ΔAIC

Model	χ^2_{min}	χ^2_{red}	AIC	ΔAIC
ΛCDM Model	1094.32	0.972	1100.34	0
Model 1	1093.62	0.952	1101.66	1.314
Model 2	1096.06	0.954	1102.08	1.74

Leibler information and serves as an asymptotically unbiased estimator of Kullback–Leibler information. The AIC's Gaussian estimator can be expressed as [78–81]:

$$\mathrm{AIC} = -2\ln(\mathcal{L}_{\max}) + 2\kappa + \frac{2\kappa(\kappa+1)}{N-\kappa-1}, \tag{55}$$

where $\mathcal{L}_{\max}$ is the maximum likelihood function, κ is the total number of model parameters, and N is the total number of data points used for fitting the models to the data. In cases where $N \gg 1$, the formula simplifies to the original AIC expression as $\mathrm{AIC} = -2\ln(\mathcal{L}_{\max}) + 2\kappa$. The relative differences in IC values are compared when multiple models are considered. The difference in AIC values is given by $\triangle\mathrm{AIC} = \mathrm{AIC}_{\mathrm{Model}} - \mathrm{AIC}_{\min} = \triangle\chi^2_{\min} + 2\triangle\kappa$. In data analysis studies, a more favorable range for $\triangle$AIC is (0, 2). A less favorable range is (4, 7), while $\triangle\mathrm{AIC} > 10$ indicates weak support for the model.

9 Age of universe

To calculate the age of the universe based on the given models in Eqs. 39 and 47, we need to perform an integral with respect to redshift (z) from 0 to ∞. The age of the universe, denoted as t_0, is given by the integral:

$$t_0 = \int_0^\infty \frac{dz}{(1+z)H(z)} \tag{56}$$

Now, let's substitute the expression for $H(z)$ from Eqs. 39 and 47 into the integral (Table 4):

$$t_0 = \int_0^\infty \frac{dz}{(1+z)\left(\frac{H_0}{[1+\alpha(1+z)^\beta]^k}\right)} \tag{57}$$

and

$$t_0 = \int_0^\infty \frac{dz}{(1+z)\left(H_0(1+z)^\beta e^{\frac{\beta_0}{1+z}}\right)} \tag{58}$$

Table 4 Summary of the estimated age of the universe with uncertainty (standard deviation)

Model	Estimated age	Uncertainty
Model 1	13.49 billion years	1.51 billion years
Model 2	14.77 billion years	0.69 billions years

We also consider the uncertainties in the parameters to get an estimate range for the age of the universe. To perform the numerical integration with the given parameter values and uncertainties, we'll use the Monte Carlo method, which takes into account the uncertainties and provides a more realistic range for the age of the universe. These are the nessenary steps taken into account while for set up a Monte Carlo simulation to calculate the age of the universe:

- Sample random values for each of the parameters from their respective uncertainties following a normal distribution.
- For each set of sampled parameter values, calculate the value of $H(z)$ at various redshifts.
- Perform the integral over the range of redshifts using numerical methods like the trapezoidal rule or Simpson's rule.
- Repeat steps 1 to 3 for a large number of iterations to build a distribution of age values.
- Obtain the mean and standard deviation of the age distribution, which will provide an estimate of the age of the universe and its uncertainty.

10 Conclusions

In this study, we explored observational constraints of effective equation of state with $f(T)$ gravity using the flat FRW metric by showing the statistical viability of some $f(T)$ gravity models with the essential cosmological datasets. The values of the constraint parameters of model-I and model-II are reported in Tables 1 and 2. Our examination of the entire set of trustworthy $H(z)$ data at intermediate redshift $0.07 \leq z \leq 2.36$, along with the used datasets, however, provides some indications that the universe may be transitioning from a deceleration to an acceleration phase in the course of its evolution. We concur with the findings of other research, which assert that the simplest cosmological models, such ΛCDM, are consistent with our investigations evidence.

Also, first, we consider comparing Model 1 and Model 2 with the Hubble 57 data points, and with the ΛCDM model. The results of the comparison are presented in Figs. 1 and 10 and observe one from the figs that the model describes the Hubble data very well. Second, proceed to compare $\mu(z)$ distance modulus function of Model 1 and 2 with the Pantheon data shown in Figs. 2 and 11, one can observed that Model 1 and 2 fits the Pantheon distance modulus, based on 1048 observation points given by $0.01012 \leq z \leq 2.26$, very well. Some others key observations are as follows:

- The best-estimated values for MCMC results of the model-1 H_0, α, k, and β are summarized in Table 1 and model-2 parameters H_0, β and β_0 and summarized in Table 2.
- Figures 1, 2, 10 and 11 show the $H(z)$ and $\mu(z)$ and for model-1 amd model-2. Our derived models comparison with the ΛCDM model, along with error bars for the 57 points and 1048 of the considered Hubble and Pantheon datasets, respectively.
- The limits on the deceleration parameter $q(z)$ clearly show that the cosmic acceleration is predicted by the astronomical observations of $H(z)$ and SNe-Ia within the framework of $f(T)$ gravity cosmology. As a result, $f(T)$ cosmological models can adequately capture the universe's observable acceleration. Models 1 and 2 both show a phase change from deceleration to acceleration.
- For the consistency of the model we have used some observational datasets like $H(z) + SC + unCorBAO$ dataset. Figures 3 and 12 shows the plots of combined dataset samples of $H(z) + SC + unCorBAO$. We have obtained the likelihood contours for the model-1 and model-2 parameters.
- $O_m(z)$ diagnostic is also an effective method to discriminate various DE models from ΛCDM model according to the slope variation of $O_m(z)$. Figures 8 and 17 shows the behaviour of $O_m(z)$ versus z for model-1 and model-2. Our both models lies in quintessence region ($\omega > -1$).
- In order to compare the produced models with the conventional ΛCDM model and the SCDM model, the statefinder diagnostics are also supplied. The model behaviour is displayed in graphs in comparison with the standard ΛCDM model (see Figs. 6, 7, 15, 16).
- In Figs. 9 and 18 depicts the plots of energy conditions. Which reveal that NEC and DEC are satisfied, but SEC is not satisfied in both models. Due to the presence of exotic matter in the universe, there is a disagreement of SEC corresponds to the accelerating cosmic expansion of the universe.
- Figures 4 and 13 depicts the evolution of the effective equation of state parameter ω_Λ versus z. At present, our study reveals that ω_Λ approaches the ΛCDM value. Using the $H(z) + SC + unCorBAO$ dataset, the equation of state parameter $\omega(z)$ lies in the quintessence area, for both models which describes the characteristics of dark energy.

***Abstract*— With a sharp rise in the number of users and skilled fluency in the use of "Hinglish", a cross-lingual text of Hindi and English, in a linguistically diverse country, India, it has increasingly become important to analyze social content written in the aforementioned language over platforms such as Twitter, Reddit, Facebook. This project focuses on the classification of Hinglish text into offensive and non-offensive categories. We present a state-of-the-art novel use of "Longformer" and "Bigbird" transformer-based language modeling models on Hinglish texts for natural language processing (NLP) sentiment classification task, alongside mBERT, pre-trained for Hinglish, hence "HingMBert" model. Our dataset is a combination of pre-existing datasets and further addition of approximately 8,200 records, a total of 24,660 records. The tweepy library has been used to scrape novel tweets. Experimental results for Longformer, Bigbird, and HingMBert have achieved F1 scores of 0.76, 0.77, and 0.79, and accuracy of 76%, 77%, and 80% respectively. F1 score of 0.78 and an accuracy of 78% was achieved using the majority voting ensemble technique.**

Keywords—longformer, bigbird, hingmbert, hinglish

I. Introduction

As per the national statistic of India, approximately 10.6% of the Indian population can speak English, and approximately 45% of the population speaks Hindi. Hindi and English, both being the official languages of India, the current trend is population speaking English is growing more rapidly than the population speaking Hindi. Therefore, a blend of composite dialects is observed in either scenario called "Hinglish." In slang "Hinglish" is referred to as "WhatsApp Language"; meaning Hindi written using English script. Currently 350+ million users of social media in India use Hinglish for communication over social media platforms.

With the advent of a composite script in use, advantageous in accumulating vocabulary from multiple scripts like Punjabi, Marathi, Gujarati, etc., and with the sharp rise in the number of social media platforms such as Twitter, YouTube, Instagram, Facebook, TikTok, Reddit, Snapchat, the narrative of "Freedom of Speech" and ease of expressing views has risen exponentially. The recoil of this expression is defaming, trolling, offending the minorities, and expressing anger, the domino effect leads to attacking personalities or groups based on gender, caste, creed, race, ethnicity, ideologies, and LGBTQIA+ groups.

Henceforth, the use of offensive language, which includes hate speech and the use of abusive vocabulary is increasing exponentially. The task of analyzing such language and identifying a tone of expression is currently carried out throughout the NLP domain. Consequently, the task is divided into sectors where each problem statement tries to identify either one specific part or targets a domain related to a group, region, or circumstances. For example, [1] studies the consequences of hate speech leading to aggression, [2], studied the content that went on social media during the pandemic related to covid.

II. Related Work

Using a transformer-based approach for offensive/hate speech detection specific to code-mixed bilingual speakers of Hinglish has been limited. [3] used multilingual bidirectional encoder representations from transformers (mBERT) embedding on 4575 derived tweets over machine learning models, logistic regression (LR), support vector machine (SVM), k-nearest neighbors (KNN), random forest (RF), naïve bayes (NB). [1] used pseudo-labeling techniques along with BERT and long short term memory (LSTM). [4] also used pre-trained BERT, and one-hot encoding for an offensiveness detection system detection system. [5] experimented with RoBERTa-base, DistilBERT-Base, and BERT-base models along with LR, NB-SVM ensemble, for Hinglish sentiment detection.

For NLP-driven summarization, long document classification, [6] introduces the linearly increasing attention span mechanism, [7] introduces the sparse attention mechanism. So far, Bigbird and Longformer have been majorly used in clinical records classification. [8] successfully carried out NLP downstream tasks on clinical records, where the named Clinical-Longformer and Clinical-Bigbird out-performed BERT. [9] used hierarchical transformer network including Bigbird. [10] used Bigbird, while [11] used Longformer for disease classification while maintaining the integrity of the Specifications

III. Dataset

The dataset has been fine-tuned on 4 datasets. 4579 records from [12] 12,000 records from [1], and 8,200 records were scraped from Twitter using the "Tweepy library" and the using the set of offensive keywords derived from "Hatebase.org". For non-offensive tweets, a similar strategy was used.

All the derived datasets have been manually cross-verified for use and labeling was done on the records fetched from Twitter. The scraped record contained both classes of

tweets and the skewness of the data was appropriately removed.

Pretraining data: Transformer-based language models need a huge corpus for pretraining. L3Cube-HingCorpus [13] has been used for the pretraining of Longformer, Bigbird, and HingMBert. The corpus contains approximately 100,000 sentences for training.

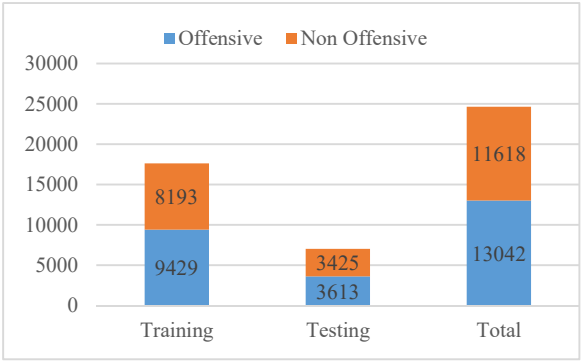

Fig.1. Comparative data for Offensive and Non-offensive records.

IV. Preprocessing

The data derived from the fore-mentioned resources contained multiple irregularities, for example, '#hashtags', 'URLs', and '@tagging', plus the tweets fetched had emojis, punctuations, repetitive characters, etc.

All the words were converted to lowercase, tokenization of the sentences was done, and to a feasible extent, lemmatization for English as well as for Hindi words was done.

The dataset was preprocessed for English as well as for Hindi stop words. Emojis were removed based on the ASCII code. Punctuations, URLs, and hashtags were removed too. Most commonly used spellings of Hinglish offensive words were already given in https://hatebase.org/, other inconsistencies were examined and alterations were less than 1 in 3000, which were altered to the most common version of the word.

V. Methodology

Self-attention mechanism differs in all three transformer models used. The difference lies in the attention span, and the said difference optimizes the space and time complexities of the algorithms. HingMBert has a full attention mechanism making it O(n^2), where n is the sequence length, space complexity transformer model. The model relates and creates a matrix for the entire document. Longformer uses global and sliding window attention mechanisms. The sliding window consists of 512 tokens and the global window spans across some of the special tokens of the sequence. Since the number of special tokens is very less than the entire sequence length of n, the access time complexity of the Longformer drops to linear, O(n). Bigbird includes random attention in addition to the window and global attention. To increase the access to an even larger sequence up to the length of 4096, i.e. making the quadratic access memory time of Longformer linear. The reason is the introduction of random attention. Random attention has logarithmic access to the tokens, i.e. instead of each token referring to every token of the sequence and utilizing quadratic memory, the random connection within the same layer of the network accesses only a few nodes and then directs to the destination node. On average each node or token is accessed and the average memory complexity reduces to linear as well.

Therefore, in our experimentation, HingMBert utilized the maximum memory of 700 MB, followed by Longformer 500 MB and Bigbird 400MB range. The time consumed in running these algorithms followed the same sequence.

As shown in Fig. 2, the different types of attention span used by the transformer models and at the end the major voting ensemble aggregating the result.

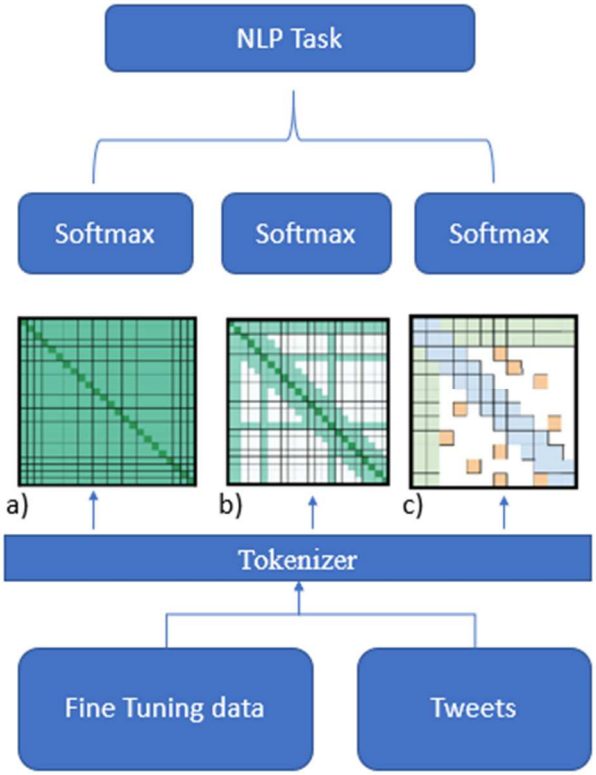

Fig.2. Working methodology. a) HingMBert full attention span [6] b) Longformer Global + sliding window attention [6] and c) Bigbird: Random + sliding + global attention span mechanisms [7].

VI. Experimental Setup

For Longformer and Bigbird model experimentation, the models were accessed from www.huggingface.co, and the HingMBert model was reused from L3Cube [13].

The pretraining of the models, unsupervised learning, was done on L3Cube-HingCorpus [13]. The models were imported using the "simpletransformers" library.

In the next step, the dataset was randomly shuffled and was divided into 75% and 25% ratios, for training and test purposes respectively. Thus, 17,622 records for training and 7,038 records for testing respectively were stored in different datasets.

Fine-tuning of all the models, Longformer, Bigbird, and HingMBert was done over 75% dataset in a batch size of 16 and the number of epochs was set to 8. The learning rate for all the models was set to the default value of 4e-5.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:44:21 UTC from IEEE Xplore. Restrictions apply.

VII. Results

The results obtained from the experimentation have been presented below. Accuracy, Precision, Recall, and F1-Score have been calculated for all the models used.

The classification matrix of the fine-tuned models of Longformer, Bigbird, and HingMBert are presented in Tables 2, 3, and 4 respectively. The classification matrix of majority voting is shown in Table 5.

TABLE I. Classification matrix for Longformer

	Predicted			
Actual	Label	0	1	All
	0	2602	889	3491
	1	823	2724	3547
	All	3425	3613	7038

TABLE II. Classification matrix for Bigbird

	Predicted			
Actual	Label	0	1	All
	0	2579	912	3491
	1	739	2808	3547
	All	3318	3720	7038

TABLE III. Classification matrix for hingMbert

	Predicted			
Actual	Label	0	1	All
	0	2851	640	3491
	1	767	2780	3547
	All	3618	3420	7038

TABLE IV. Classification matrix for major voting ensemble

	Predicted			
Actual	Label	0	1	All
	0	2740	751	3491
	1	755	2792	3547
	All	3495	3543	7038

TABLE V. Classification report of language models and majority voting ensemble

Model	Accuracy	Precision	Recall	F1 Score
Longformer	0.756749	0.753944	0.767973	0.760894
Bigbird	0.765416	0.754839	0.791655	0.772809
HingMBert	0.800085	0.812865	0.783761	0.798048
Majority Voting Ensemble	0.786019	0.788033	0.787144	0.787588

HingMBert has shown to have a maximum accuracy of 80%, followed by Bigbird 76.5% and Longformer at 75.7%. The above order has also been observed for F1-Score with 0.79, 0.77, and 0.76 by HingMBert, Bigbird, and Longformer respectively. Majority voting has produced resulted in an accuracy of 78.6% and F1-Score of 0.78.

The reason for increased accuracy in HingMBert is the full attention mechanism, which provided a better estimation of the sequences related to the pre-trained data than Longformer and Bigbird. Bigbird slightly outperformed Longformer because of the number of longer sequences which per predicted more accurately by Bigbird.

VIII. Conclusion and Future Work

This paper presents a state-of-the-art novel use of Longformer and Bigbird, a transformer-based language modeling model, alongside HingMBert. We concluded that currently, HingMBert has performed better than the rest. This study opens the door for the application of other transformer-based language modeling models, that have currently been used for English NLP sentiment analysis and other downstream processes. Possible prospects of this application include the use of multinomial sentiment analysis, which will also be enhanced by the use of larger datasets and increased pretraining corpus.

ON A CLASS OF CERTAIN NON-UNIVALENT FUNCTIONS

S. SIVAPRASAD KUMAR AND POOJA YADAV

Abstract. In this paper, we introduce a family of analytic functions given by

$$\psi_{A,B}(z) := \frac{1}{A-B}\log\frac{1+Az}{1+Bz},$$

which maps univalently the unit disk onto either elliptical or strip domains, where either $A=-B=\alpha$ or $A=\alpha e^{i\gamma}$ and $B=\alpha e^{-i\gamma}$ ($\alpha\in(0,1]$ and $\gamma\in(0,\pi/2]$). We study a class of non-univalent analytic functions defined by

$$\mathcal{F}[A,B] := \left\{ f\in\mathcal{A} : \left(\frac{zf'(z)}{f(z)}-1\right) \prec \psi_{A,B}(z)\right\}.$$

Further, we investigate various characteristic properties of $\psi_{A,B}(z)$ as well as functions in the class $\mathcal{F}[A,B]$ and obtain the sharp radius of starlikeness of order δ and univalence for the functions in $\mathcal{F}[A,B]$. Also, we find the sharp radii for functions in $\mathcal{BS}(\alpha) := \{f\in\mathcal{A} : zf'(z)/f(z)-1 \prec z/(1-\alpha z^2),\ \alpha\in(0,1)\}$, $\mathcal{S}_{cs}(\alpha) := \{f\in\mathcal{A} : zf'(z)/f(z)-1 \prec z/((1-z)(1+\alpha z)),\ \alpha\in(0,1)\}$ and others to be in the class $\mathcal{F}[A,B]$.

1. Introduction

Let $\mathcal{A}$ denote the class of analytic functions f defined on the open unit disk $\mathbb{D}=\{z\in\mathbb{C} : |z|<1\}$, such that $f(z)=z+a_2z^2+a_3z^3+\cdots$. The subclass of $\mathcal{A}$ consisting of all univalent functions is denoted by $\mathcal{S}$. For two analytic functions f and g, we say that f is subordinate($\prec$) to g, if $f(z)=g(\omega(z))$ where $\omega(z)$ is a Schwarz function. Let $\mathcal{S}^*$ be the class of starlike functions, consists of functions $f\in\mathcal{S}$ such that $zf'(z)/f(z)\prec(1+z)/(1-z)$. In [6], Ma and Minda unifies all the subclasses of $\mathcal{S}^*$ as follows:

$$\mathcal{S}^*(\Phi) := \left\{ f\in\mathcal{S} : \frac{zf'(z)}{f(z)} \prec \Phi(z)\right\}, \tag{1.1}$$

where Φ is univalent with $\Phi'(0)>0$ satisfying

A. $\Phi(z)\prec(1+z)/(1-z)$
B. $\Phi(\mathbb{D})$ is symmetric about real axis and starlike with respect to $\Phi(0)=1$.

Further, Kumar and Banga [3], called such Φ as *Ma-Minda function* and the class of all Ma-Minda functions is denoted by $\mathcal{M}$. In [3], authors extensively studied Ma-Minda functions and classified them as *non-Ma-Minda function of type-A* whenever condition A doesn't hold, the class of all such functions is denoted by $\widetilde{\mathcal{M}}_A$. In past many authors studied the class (1.1) for various choices of $\Phi\in\mathcal{M}$, such as $\mathcal{S}^*(2/(1+e^{-z})) =: \mathcal{S}^*_{SG}$ [1], $\mathcal{S}^*(e^z) =: \mathcal{S}^*_e$ [9], $\mathcal{S}^*(z+\sqrt{1+z^2})$ [10], $\mathcal{S}^*(\sqrt{1+z}) =: \mathcal{S}^*_L$ [13], etc. Also the well known classes $\mathcal{S}^*(A,B)$ and $\mathcal{SS}^*(\alpha)$ are also obtained by taking $\Phi(z)(\in\mathcal{M})$ as $(1+Az)/(1+Bz)$ $(-1\le B<A\le 1)$ and $((1+z)/(1-z))^\alpha$ $(\alpha\in(0,1])$ respectively. In particular, $\mathcal{S}^*(1,-1) =: \mathcal{S}^*$, $\mathcal{S}^*(1-2\delta,-1) =: \mathcal{S}^*(\delta)$ $(\delta\in[0,1))$, the class of starlike functions of order δ. Robertson [11] introduced and investigated the class of starlike

2010 *Mathematics Subject Classification.* 30C45, 30C50, 30C80.

Key words and phrases. Analytic, Subordination, Logatithmic function, Starlike function, Non-univalent function.

The second author is supported by The Council of Scientific and Industrial Research(CSIR). Ref.No.:08/133(0030)/2019-EMR-I.

functions of order δ, denoted by $\mathcal{S}^*_\delta$ for $\delta \leq 1$. Note that if $\delta < 0$, then the functions in $\mathcal{S}^*_\delta$ may not be univalent, i.e. if $\delta < 0$, then $\Phi(z) = (1 + (1 - 2\delta)z)/(1 - z) \in \widetilde{\mathcal{M}}_A$ and $\mathcal{S}^*_\delta \not\subset \mathcal{S}^*$. Later many authors considered the classes associated with non-Ma-Minda functions of type-A such as the class by Uralegaddi [14]

$$\mathscr{M}(\beta) = \left\{ f \in \mathcal{A} : \frac{zf'(z)}{f(z)} \prec \frac{1 + (2\beta - 1)z}{1 - z},\ \beta > 1 \right\},$$

the classes associated with the Booth Lemniscate and Cissoid of Diocles

$$\mathcal{BS}^*(\alpha) := \left\{ f \in \mathcal{A} : \left(\frac{zf'(z)}{f(z)} - 1 \right) \prec \frac{z}{1 - \alpha z^2},\ \alpha \in [0, 1) \right\},$$

$$\mathcal{S}^*_{cs}(\alpha) := \left\{ f \in \mathcal{A} : \left(\frac{zf'(z)}{f(z)} - 1 \right) \prec \frac{z}{(1 - z)(1 + \alpha z)},\ \alpha \in [0, 1) \right\},$$

which were introduced by [2] and [7] respectively. Similarly, Masih and Kanas [8] studied the class $\mathcal{ST}^*_L(s) := \{f \in \mathcal{A} : zf'(z)/f(z) \prec \mathbb{L}_s(z)\}$ associated with the Limaçon of Pascal $\mathbb{L}_s(z) = (1+sz)^2$, $s \in [-1, 1]\backslash\{0\}$. Note that $\mathbb{L}_s(z) \in \widetilde{\mathcal{M}}_A$, whenever $|s| > 1/\sqrt{2}$. Recently, Kumar and Gangania [5] studied the following class:

$$\mathcal{F}(\psi) := \left\{ f \in \mathcal{A} : \frac{zf'(z)}{f(z)} - 1 \prec \psi(z) \right\}, \tag{1.2}$$

where $\psi(z) \in \mathcal{S}^*$. If $1 + \psi(z) \prec (1 + z)/(1 - z)$ and $1 + \psi(\mathbb{D})$ is symmetric about the real axis with $\psi'(0) > 0$ then $\mathcal{F}(\psi)$ reduces to the class $\mathcal{S}^*(1+\psi)$, a Ma-Minda class and if $1+\psi(z) \not\prec (1+z)/(1-z)$ then the functions in $\mathcal{F}(\psi)$ may not be univalent, thus $\mathcal{F}(\psi) \not\subseteq \mathcal{S}^*$. Note that all above mentioned classes associated with non-Ma-Minda functions of type-A are the special cases of $\mathcal{F}(\psi)$ such as $\mathcal{F}((1 + (2\beta - 1)z)/(1 - z)) =: \mathscr{M}(\beta)$, $\mathcal{F}(z/(1 - \alpha z^2)) =: \mathcal{BS}^*(\alpha)$, $\mathcal{F}(z/((1 - z)(1 + \alpha z))) =: \mathcal{S}^*_{cs}(\alpha)$ and $\mathcal{F}((1 + sz)^2) =: \mathbb{L}_s(z)$.

Motivated by the above, we define a family of functions $\psi_{A,B}(z)$ as

$$\psi_{A,B}(z) := \frac{1}{A - B} \log \left(\frac{1 + Az}{1 + Bz} \right) \qquad z \in \mathbb{D}, \tag{1.3}$$

where either $A = -B = \alpha$ or $A = \alpha e^{i\gamma}$ and $B = \alpha e^{-i\gamma}$, for $0 < \alpha \leq 1$ and $0 < \gamma \leq \pi/2$. The function defined by (1.3) is analytic everywhere except the branchcuts $\{-\infty < \operatorname{Re} Az \leq -1,\ \operatorname{Im} Az = 0\} \cup \{-\infty < \operatorname{Re} Bz \leq -1,\ \operatorname{Im} Bz = 0\}$ with $\psi_{A,B}(0) = \psi'_{A,B}(0) - 1 = 0$, i.e. $\psi_{A,B}(z) \in \mathcal{A}$. Now we introduce the following classes associated with $\psi_{A,B}(z)$:

Definition 1.1. Let $p \in \mathcal{S}$. Then $p \in \mathcal{L}[A, B]$ if and only if

$$p(z) \prec \psi_{A,B}(z).$$

Definition 1.2. Let $f \in \mathcal{A}$. Then $f \in \mathcal{F}[A, B]$ if and only if

$$\frac{zf'(z)}{f(z)} - 1 \prec \psi_{A,B}(z). \tag{1.4}$$

In section 2 we investigate various characteristic properties of functions in the classes $\mathcal{L}[A, B]$ and $\mathcal{F}[A, B]$. We also obtain the extremal function of the class $\mathcal{F}[A, B]$ which is non-univalent and study its various geometric properties. Further, in section 3 we derive the sharp radius of starlikeness of order δ, univalence for the functions in $\mathcal{F}[A, B]$ and also find the sharp radii for functions in $\mathcal{BS}(\alpha)$, $\mathcal{S}_{cs}(\alpha)$ and others to be in the class $\mathcal{F}[A, B]$.

2. Characteristics of $\mathcal{L}[A,B]$ and $\mathcal{F}[A,B]$

In this section, we aim to find various geometric properties of $\psi_{A,B}(z)$ and obtain certain bounds and inclusion relations for functions in the class $\mathcal{L}[A,B]$. Further, we deduce the extremal function and derive the growth and covering theorems for the class $\mathcal{F}[A,B]$. Note that

$$\psi_{A,B}(z)=\sum_{n=1}^{\infty}(-1)^{n+1}C_n z^n,$$

where

$$C_n=\frac{A^n-B^n}{n(A-B)}=\frac{1}{n}\sum_{k=0}^{n-1}A^kB^{n-1-k}\qquad(n=1,2,\ldots). \tag{2.1}$$

Remark 2.1. From (2.1) we have

(i) Since C_n is real valued for all n, $\psi_{A,B}(\mathbb{D})$ is symmetric with respect to real axis.

(ii) $|C_n|=\left|\frac{1}{n}\sum_{k=0}^{n-1}A^kB^{n-1-k}\right|\leq\alpha^{n-1}\leq 1.$

Lemma 2.2. *The function $\psi_{A,B}(z)$ is convex and univalent on $\mathbb{D}$.*

Proof. Let $H(z):=1+z\psi''_{A,B}(z)/\psi'_{A,B}(z)$. By [12, Corollary 3], it is enough to show that $\operatorname{Re}H(z)>0$. Since $|A|=|B|=\alpha\leq 1$, using basic calculation with [4, Theorem 1], we obtain

$$\begin{aligned}\operatorname{Re}H(z)&=\operatorname{Re}\left(-1+\frac{1}{1+Az}+\frac{1}{1+Bz}\right)\\&>-1+\frac{2}{1-\alpha}>0.\end{aligned}$$

Thus the result holds. ∎

Theorem 2.3. *Let $p\in\mathcal{L}[A,B]$, then in the disk $\mathbb{D}_r=\{z\in\mathbb{C}:|z|\leq r<1\}$,*

(i) For $A=-B=\alpha$, we have

$$|\operatorname{Re}p(z)|\leq\frac{1}{2\alpha}\log\left(\frac{1+\alpha r}{1-\alpha r}\right) \tag{2.2}$$

$$|\operatorname{Im}p(z)|\leq\frac{1}{2\alpha}\sin^{-1}\left(\frac{2\alpha r}{1+\alpha^2r^2}\right). \tag{2.3}$$

(ii) For $A=\alpha e^{i\gamma}$ and $B=\alpha e^{-i\gamma}$, we have

$$\frac{-1}{2\alpha\sin\gamma}(\eta-\tau)\leq\operatorname{Re}p(z)\leq\frac{1}{2\alpha\sin\gamma}(\eta+\tau). \tag{2.4}$$

$$\frac{1}{2\alpha\sin\gamma}\log T_2\leq\operatorname{Im}p(z)\leq\frac{1}{2\alpha\sin\gamma}\log T_1. \tag{2.5}$$

where

$$\eta:=\sin^{-1}\left(\frac{2\alpha r\sin\gamma}{\sqrt{1+\alpha^4r^4-2\alpha^2r^2\cos 2\gamma}}\right),$$

$$\tau:=\tan^{-1}\left(\frac{-\alpha^2r^2\sin 2\gamma}{1-\alpha^2r^2\cos 2\gamma}\right)$$

and

$$T_j:=\left(\frac{\sqrt{1+\alpha^4r^4-2\alpha^2r^2\cos 2\gamma}+(-1)^j2\alpha r\sin\gamma}{1-\alpha^2r^2}\right)^{-1}\quad(j=1,2).$$

Proof. Let w be the Schwarz function such that $w(0) = 0$ and $|w(z)| \leq |z| = r < 1$ for all $z \in \mathbb{D}$. Define the function $F_w : \mathbb{D} \to \mathbb{C}$ such that $p(z) = \psi_{A,B}(w(z)) = \dfrac{1}{A-B}\log\left(F_w(z)\right)$. We have

$$F_w(z) := \frac{1+Aw(z)}{1+Bw(z)},$$

which maps unit disk into the disk

$$F_w(\mathbb{D}) \subset \left\{\zeta \in \mathbb{C}; \left|\zeta - \frac{1-A\overline{B}}{1-|B|^2}\right| < \frac{|A-B|}{1-|B|^2}\right\}.$$

As $|A| = \alpha \in (0,1]$, therefore origin $O \notin F_w(\mathbb{D})$ (for more details see [4]). Now using [4, Theorem 1] with $|z| = r < 1$, we have

$$\frac{|1-A\overline{B}r^2| - |A-B|r}{1-|B|^2r^2} \leq |F_w(z)| \leq \frac{|1-A\overline{B}r^2| + |A-B|r}{1-|B|^2r^2},$$

$$\left|\arg F_w(z) - \tan^{-1}\frac{\mathrm{Im}(A\overline{B})r^2}{\mathrm{Re}(A\overline{B})r^2 - 1}\right| < \sin^{-1}\frac{|A-B|r}{|1-A\overline{B}r^2|}.$$

Since $\log f(z) = \log|f(z)| + i\arg f(z)$ and $p(z) = \dfrac{1}{A-B}\log\left(F_w(z)\right)$, thus for $A = -B = \alpha$ we obtain (2.2) and (2.3) and for $A = \alpha e^{i\gamma}$ and $B = \alpha e^{-i\gamma}$, we have (2.4) and (2.5). ∎

For the sake of computational convenience, we shall make the following assumptions:

$$h_1 := \frac{1}{2\alpha}\log\left(\frac{1+\alpha}{1-\alpha}\right), \qquad h_2 := \frac{1}{2\alpha}\sin^{-1}\left(\frac{2\alpha}{1+\alpha^2}\right),$$

$$k_1 := \frac{1}{2\alpha\sin\gamma}\sin^{-1}\left(\frac{2\alpha\sin\gamma}{\sqrt{1+\alpha^4-2\alpha^2\cos 2\gamma}}\right),$$

$$k_2 := \frac{1}{2\alpha\sin\gamma}\log\frac{\sqrt{1+\alpha^4-2\alpha^2\cos 2\gamma}+2\alpha\sin\gamma}{1-\alpha^2}$$

and

$$k := \frac{1}{2\alpha\sin\gamma}\tan^{-1}\left(\frac{\alpha^2\sin 2\gamma}{\alpha^2\cos 2\gamma - 1}\right).$$

Now we shall discuss the image domain of $\psi_{A,B}$ for different cases of α:
For $0 < \alpha < 1$, $\psi_{A,B}(\mathbb{D}) = \{u+iv \in \mathbb{C} : (u,v) \in \Omega_1\}$ where

$$\Omega_1 := \begin{cases} \dfrac{u^2}{h_1^2} + \dfrac{v^2}{h_2^2} < 1, & \text{when } A = -B = \alpha \\ \dfrac{(u-k)^2}{k_1^2} + \dfrac{v^2}{k_2^2} < 1, & \text{when } A = \alpha e^{i\gamma}, B = \alpha e^{-i\gamma} \text{ for } 0 < \gamma \leq \pi/2. \end{cases} \tag{2.6}$$

Moreover when $\alpha = 1$, the major axis h_1 and k_2 respectively, tends to infinity, hence $\psi_{A,B}(\mathbb{D}) = \{u+iv \in \mathbb{C} : (u,v) \in \Omega_2\}$ where Ω_2 is the following strip domain

$$\Omega_2 := \begin{cases} -\dfrac{\pi}{4} < v < \dfrac{\pi}{4}, & \text{when } A = -B = 1 \\ \dfrac{\gamma-\pi}{2\sin\gamma} < u < \dfrac{\gamma}{2\sin\gamma}, & \text{when } A = e^{i\gamma}, B = e^{-i\gamma} \text{ for } 0 < \gamma \leq \pi/2. \end{cases} \tag{2.7}$$

Remark 2.4. (i) $\max_{|z|=r}\mathrm{Re}\,\psi_{A,B}(z) = \psi_{A,B}(r)$ and $\min_{|z|=r}\mathrm{Re}\,\psi_{A,B}(z) = \psi_{A,B}(-r)$.

(ii) If $\alpha < 1$, then $p \prec \psi_{A,B}(z)$ if and only if $p(\mathbb{D}) \subseteq \Omega_1$ and if $\alpha = 1$, then $p \prec \psi_{A,B}(z)$ if and only if $p(\mathbb{D}) \subsetneq \Omega_2$, where Ω_1 and Ω_2 are as defined in (2.6) and (2.7) respectively.

(iii) $1 + \psi_{A,B} \in \widetilde{\mathcal{M}}_A$.

Now in the following lemma, we aim to find the radius of the smallest (largest) disk centered at the point (1, 0) that can subscribe (inscribe) the domain $1+\psi_{A,B}(\mathbb{D})$.

Lemma 2.5. *Let $\alpha \in (0,1)$ and $\gamma \in (0, \pi/2]$, then we have*

(i) for $A = -B = \alpha$,

$$\{w \in \mathbb{C} : |w-1| < h_2\} \subset 1+\psi_{A,B}(\mathbb{D}) \subset \{w \in \mathbb{C} : |w-1| < h_1\}.$$

(ii) for $A = \alpha e^{i\gamma}$ and $B = \alpha e^{-i\gamma}$,

$$\{w \in \mathbb{C} : |w-1| < k_1 + k\} \subset 1+\psi_{A,B}(\mathbb{D}) \subset \{w \in \mathbb{C} : |w-1| < k_2\}.$$

Further for $\alpha = 1$, we have

(iii) for $A = -B = 1$,

$$\left\{w \in \mathbb{C} : |w-1| < \frac{\pi}{4}\right\} \subset 1+\psi_{A,B}(\mathbb{D}).$$

(iv) for $A = e^{i\gamma}$ and $B = e^{-i\gamma}$,

$$\left\{w \in \mathbb{C} : |w-1| < \frac{\gamma}{2\sin\gamma}\right\} \subset 1+\psi_{A,B}(\mathbb{D}).$$

Proof. Let $w = 1+\psi_{A,B}(z)$, then we have

$$|w-1| = |\psi_{A,B}(z)| = \frac{1}{|A-B|}\left|\log\left(\frac{1+Az}{1+Bz}\right)\right|.$$

It can be easily seen that for $\alpha \in (0,1)$, $A = -B = \alpha$

$$\min_{|z|=1}|\psi_{A,B}(z)| = h_2 \text{ and } \max_{|z|=1}|\psi_{A,B}(z)| = h_1$$

and for $A = \alpha e^{i\gamma}$ and $B = \alpha e^{-i\gamma}$

$$\min_{|z|=1}|\psi_{A,B}(z)| = k_1 + k \text{ and } \max_{|z|=1}|\psi_{A,B}(z)| = k_2.$$

Further for $\alpha = 1$, h_1 and k_2 tends to ∞, $h_2 = \pi/4$ and $k_1 + k = \gamma/(2\sin\gamma)$. This completes the proof. ∎

Remark 2.6. In general, if we consider a disc $\mathcal{D}(a,r) := \{w \in \mathbb{C}; |w-a| < r\}$ where $a \in \mathbb{R}$ and $1 \in \mathcal{D}(a,r)$, then we observe that $\mathcal{D}(a,r) \subset 1+\psi_{A,B}(\mathbb{D})$ if and only if

$$\mathcal{D}(a,r) \subset \begin{cases} \mathcal{D}(1,h_2), & \text{for } A = -B = \alpha, \\ \mathcal{D}(1+k,k_1), & \text{for } A = \alpha e^{i\gamma},\ B = \alpha e^{-i\gamma}. \end{cases} \tag{2.8}$$

Thus we arrive at the following:

Lemma 2.7. *Let $-1 < D < C \le 1$ and $p(z) := (1+Cz)/(1+Dz)$. Then $p(z) \prec \mathcal{L}[A,B]$ if and only if*

(i) for $A = -B = \alpha$

$$C \le \begin{cases} h_2 + (1-h_2)D, & \text{when } (1-CD)/(1-D^2) \le 1, \\ h_2 + (1+h_2)D, & \text{when } (1-CD)/(1-D^2) \ge 1. \end{cases} \tag{2.9}$$

(ii) for $A = \alpha e^{i\gamma}$ and $B = \alpha e^{-i\gamma}$,

$$C \le \begin{cases} k_1 - k + (1-k_1+k)D, & \text{when } (1-CD)/(1-D^2) \le 1+k, \\ k_1 + k + (1+k_1+k)D, & \text{when } (1-CD)/(1-D^2) \ge 1+k. \end{cases} \tag{2.10}$$

Proof. Since $p(z) = (1+Cz)/(1+Dz)$ maps $\mathbb{D}$ onto $\mathcal{D}(a,r)$, where

$$a = \frac{1-CD}{1-D^2} \quad \text{and} \quad r = \frac{C-D}{1-D^2},$$

the result follows at once from (2.8). ∎

From Lemma 2.7, we deduce the following corollary, which ensures that $\mathcal{F}[A,B]$ is nonempty.

Corollary 2.8. *Let $-1 < D < C \leq 1$ and $f \in \mathcal{A}$ be such that $zf'(z)/f(z) = (1+Cz)/(1+Dz)$, then $f \in \mathcal{F}[A,B]$ if and only if, the condition (2.9) or (2.10) holds.*

Now from (1.4), we have $f \in \mathcal{F}[A,B]$ if and only if there exists an analytic function $p(z) \prec \psi_{A,B}(z)$ such that

$$f(z) = z \exp\left(\int_0^z \frac{p(t)}{t} dt\right). \tag{2.11}$$

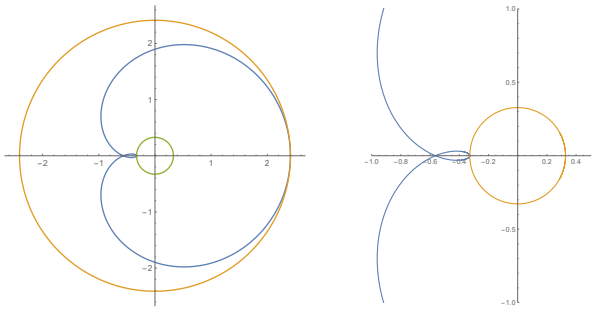
If we take $p(z) = \psi_{A,B}(z)$, then we obtain from (2.11)

$$f_{A,B}(z) := z \exp \frac{Li_2(-Bz) - Li_2(-Az)}{A-B}, \tag{2.12}$$

where $Li_2(x) = \sum_{n=1}^{\infty} x^n/n^2$, denotes the Spence's (or dilogarithm) function. The function $f_{A,B}(z)$ is nonunivalent but have the extremal properties for many problems for the class $\mathcal{F}[A,B]$ (see Fig:1). Kumar and Gangania [5] studied the class $\mathcal{F}(\psi)$ as defined in (1.2) and obtained growth and covering theorem for the case when $1+\psi(z) \not\prec (1+z)/(1-z)$. As a consequence of the same and Remark 2.4, we obtain the following result:

Lemma 2.9. *Let $f \in \mathcal{F}[A,B]$ and $f_{A,B}$ be defined as in (2.12), then for $|z| = r$*

(i) Growth Theorem: $-f_{A,B}(-r) \leq |f(z)| \leq f_{A,B}(r)$.
(ii) Covering Theorem: Either f is a rotation of $f_{A,B}$ or $\{w \in \mathbb{C} : |w| \leq -f_{A,B}(-1)\} \subset f(\mathbb{D})$.



(A) (B)

FIGURE 1. (A) The images of $\partial\mathbb{D}_{f_{A,B}(1)}$, $f_{A,B}(\partial\mathbb{D})$ and $\partial\mathbb{D}_{f_{A,B}(-1)}$, for $A = 0.5e^{i\pi/3}$ and $B = 0.5e^{-i\pi/3}$ and (B) zoomed image of cusp.

For $z = re^{i\theta}$, where θ is fixed but arbitrary, as a consequence of growth theorem and $\psi_{A,B}(-r) \leq \operatorname{Re} \psi_{A,B}(re^{i\theta}) \leq \psi_{A,B}(r)$, we obtain

$$\log \frac{f(z)}{z} = \int_0^r \frac{p(te^{i\theta})}{t} dt,$$

where $p(z) := \psi_{A,B}(w(z))$ and w is a Schwarz functon. Further

$$\frac{f(z)}{z} = \exp\int_0^r \frac{p(te^{i\theta})}{t}dt = \exp\left(\int_0^r \operatorname{Re}\frac{p(te^{i\theta})}{t}dt + i\int_0^r \operatorname{Im}\frac{p(te^{i\theta})}{t}dt\right)$$

$$\left|\frac{f(z)}{z}\right| \leq \exp\int_0^r \frac{\operatorname{Re}\psi_{A,B}(te^{i\theta})}{t}dt$$

$$\exp\int_0^r \frac{\psi_{A,B}(-t)}{t}dt \leq \left|\frac{f(z)}{z}\right| \leq \exp\int_0^r \frac{\psi_{A,B}(t)}{t}dt.$$

Here $L(f,r) := \int_0^{2\pi}|zf'(z)|d\theta$ is the length of the boundary curve $f(|z|= r)$. Now we obtain the following result:

Corollary 2.10. *Let $f \in \mathcal{F}[A,B]$ and $M(r) = \exp\int_0^r \frac{\psi_{A,B}(t)}{t}dt$, then for $|z|= r$, we have*

(i) $M(-r) \leq \left|\frac{f(z)}{z}\right| \leq M(r)$.
(ii) $(1+\max_{|z|\leq r}|\psi_{A,B}(z)|)M(-r) \leq |f'(z)| \leq (1+\max_{|z|\leq r}|\psi_{A,B}(z)|)M(r)$.
(iii) $2\pi r(1+\max_{|z|\leq r}|\psi_{A,B}(z)|)M(-r) \leq L(f,r) \leq 2\pi r(1+\max_{|z|\leq r}|\psi_{A,B}(z)|)M(r)$.
(iv) $f(z)/z \prec f_{A,B}(z)/z$.

3. Radius Estimates

In this section, we obtain some radii estimates. From Theorem 2.3 we conclude that $f \in \mathcal{S}[A,B]$ is starlike of order $1+\frac{1}{|A-B|}(\varphi-\vartheta) < 0$, hence f may not be univalent in $\mathbb{D}$, thus $\mathcal{F}[A,B] \not\subseteq \mathcal{S}^*$. Therefore, in the following result, we find the radius of starlikeness of order δ, where $\delta \in [0,1)$ for functions in the class $\mathcal{F}[A,B]$.

Theorem 3.1. *Let $\alpha \in (0,1]$, $\gamma \in (0,\gamma_0)$, where $\gamma_0 \simeq 1.2461\ldots$ and $\delta \in [0,1)$ be given numbers. If $f \in \mathcal{F}[A,B]$, then f is starlike of order δ in the disc $|z|< r(\delta)$, where*

(i) For $A = -B = \alpha$,

$$r(\delta) = \frac{\exp(2\alpha(1-\delta))-1}{\alpha(\exp(2\alpha(1-\delta))+1)}. \tag{3.1}$$

(ii) For $A = \alpha e^{i\gamma}$ and $B = \alpha e^{-i\gamma}$, $r(\delta)$ is the smallest positive root of

$$\tan(2\alpha\sin\gamma(\delta-1)) = \frac{\alpha^4r^4\sin 2\gamma + 2\alpha^3r^3\sin\gamma\cos 2\gamma - \alpha^2r^2\sin 2\gamma - 2\alpha r\sin\gamma}{\alpha^4r^4\cos 2\gamma - 2\alpha^3r^3\sin\gamma\sin 2\gamma - \alpha^2r^2\cos 2\gamma - \alpha^2r^2 + 1}. \tag{3.2}$$

The result is sharp.

Proof. Let $f \in \mathcal{F}[A,B]$, then using Theorem 2.3 for $|z|< r$, we have
Case 1. when $A = -B = \alpha$,

$$\operatorname{Re}\frac{zf'(z)}{f(z)} > 1 - \frac{1}{2\alpha}\log\left(\frac{1+\alpha r}{1-\alpha r}\right) =: t_1(r),$$

Now as $t_1'(r) < 0$ for all choices of α, thus $t_1(r)$ is strictly decreasing function from 1 to $1 - 1/(2\alpha)\log((1+\alpha)/(1-\alpha)) < 0$. Hence the root $r(\delta)$, given in (3.1), of the equation $t_1(r) = \delta$, is the radius of starlikeness of order δ of $\mathcal{F}[A,B]$.
Case 2. when $A = \alpha e^{i\gamma}$ and $B = \alpha e^{-i\gamma}$

$$\operatorname{Re}\frac{zf'(z)}{f(z)} > 1 - \frac{1}{2\alpha\sin\gamma}(\eta-\tau) =: t_2(r),$$

where η and τ are given in Theorem 2.3. Since $t_2(r) = \delta$ can be simplified to the equation (3.2) by a simple computation, thus it is enough to find the smallest positive root of (3.2). Further

$$t_2'(r) = -\frac{1-\alpha^4 r^4 + 2\alpha r\cos\gamma(1-\alpha^2 r^2)}{(1-\alpha^2 r^2)\sqrt{1+\alpha^4 r^4 - 2\alpha^2 r^2\cos 2\gamma}} < 0$$

for all choices of α and γ, $t_2(r)$ is a strictly decreasing function from 1 to $g(\alpha,\gamma)$, where

$$g(\alpha,\gamma) := 1 + \frac{1}{2\alpha\sin\gamma}\left(\tan^{-1}\left(\frac{\alpha^2\sin 2\gamma}{\alpha^2\cos 2\gamma - 1}\right) - \sin^{-1}\left(\frac{2\alpha\sin\gamma}{\sqrt{1+\alpha^4-2\alpha^2\cos 2\gamma}}\right)\right).$$

Note that $g(\alpha,\gamma)$ is real valued, non-constant analytic function on a bounded domain $R := (0,1)\times$

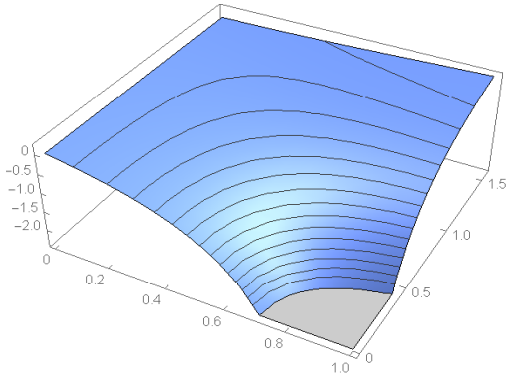


FIGURE 2. Image of $g(\alpha,\gamma)$ on $R := (0,1)\times(0,\pi/2)$.

$(0,\pi/2)$ and is bounded above on R. Thus by Maximum Modulus Theorem, $g(\alpha,\gamma)$ attains its maximum value on the boundary of R and the four boundaries are enlisted below:

1. $g(0,\gamma) = 0$.
2. $g(1,\gamma) = 1 + (\gamma-\pi)/(2\sin\gamma)$. Now as
$$g'(1,\gamma) = (1+(\pi-\gamma)\cot\gamma)/(2\sin\gamma) > 0,$$
therefore $g(1,\gamma)$ is strictly increasing from $-\infty$ to $1-\pi/4 \simeq 0.2146\ldots$ and γ_0 is the zero of it.
3. $g(\alpha,0) = 1-1/(1-\alpha)$. As $g'(\alpha,0) = \log(1-\alpha) < 0$, therefore $g(\alpha,0)$ is strictly decreasing from 0 to $-\infty$.
4. $g(\alpha,\pi/2) = 1 - \left(\sin^{-1}\left(2\alpha/(1+\alpha^2)\right)\right)/(2\alpha)$. As
$$g'(\alpha,\pi/2) = \left(\left(2\alpha/(1+\alpha^2)\right) + \sin^{-1}\left(2\alpha/(1+\alpha^2)\right)\right)/(2\alpha^2) > 0,$$
therefore $g(\alpha,\pi/2)$ is also strictly increasing from 0 to $1-\pi/4 \simeq 0.2146$.

From Fig. 2 and all four boundaries, we observe that $g(\alpha,\gamma) < 0$ for all choices of $\alpha \in (0,1]$, $\gamma \in (0,\gamma_0)$, where γ_0 is the root of the equation $g(1,\gamma) = 0$. Hence $r(\delta)$ is the radius of starlikeness of order δ of $\mathcal{F}[A,B]$. ∎

Theorem 3.2. *Let $\alpha \in (0,1]$ and $\delta \in [0,1)$. If $f \in \mathcal{F}[A,B]$, for the case when $A = \alpha e^{i\gamma}$ and $B = \alpha e^{-i\gamma}$, then there is an unique $\gamma' \in (\gamma_0,\pi/2)$ such that*

(i) when $\gamma \in (\gamma_0,\gamma']$, f is starlike of order δ in $\mathbb{D}_{r(\delta)}$, where $r(\delta)$ the root of the equation (3.2).
(ii) when $\gamma \in (\gamma',\pi/2)$, f is starlike of order $\delta \in [0, g(\alpha,\pi/2))$ in $\mathbb{D}$ and starlike of order $\delta \in [g(\alpha,\pi/2),1)$ in $\mathbb{D}_{r(\delta)}$.

Proof. By observing the Fig. 2 and the nature of all boundary curves discussed in Theorem 3.1, we arrive at $g(\alpha,\gamma_0)<0$ and $g(\alpha,\pi/2)>0$ for all $\alpha\in(0,1)$. Thus by IVP for any choice of $\alpha\in(0,1)$, there is an unique $\gamma'\in(\gamma_0,\pi/2)$ such that $g(\alpha,\gamma')=0$, $g(\alpha,\gamma)<0$ for all $\gamma\in(\gamma_0,\gamma')$ and $g(\alpha,\gamma)>0$ for all $\gamma\in(\gamma',\pi/2)$. Hence the result follows. ∎

Taking $\delta=0$ in Theorems 3.1 and 3.2, we obtain the following result:

Corollary 3.3. *Let $\alpha\in(0,1]$ and $\gamma\in(0,\pi/2]$. If $f\in\mathcal{F}[A,B]$ then*

(i) For $A=-B=\alpha$, f is starlike univalent in the disc $|z|<r_0$, where

$$r_0=\frac{\exp(2\alpha)-1}{\alpha(\exp(2\alpha)+1)}.$$

(ii) For $A=\alpha e^{i\gamma}$ and $B=\alpha e^{-i\gamma}$, $f\in\mathcal{S}^*$, whenever $\gamma\in(\gamma',\pi/2)$, and f is starlike univalent in the disc $|z|<r_0$, whenever $\gamma\in(0,\gamma_0)\cup(\gamma_0,\gamma']$, where γ_0, γ' are given in Theorems 3.1 and 3.2, respectively and r_0 is the smallest positive root of

$$\tan(2\alpha\sin\gamma)+\frac{\alpha^4r^4\sin2\gamma+2\alpha^3r^3\sin\gamma\cos2\gamma-\alpha^2r^2\sin2\gamma-2\alpha r\sin\gamma}{\alpha^4r^4\cos2\gamma-2\alpha^3r^3\sin\gamma\sin2\gamma-\alpha^2r^2\cos2\gamma-\alpha^2r^2+1}=0.$$

The result is sharp.

Corollary 3.4. *Let $f\in\mathcal{F}[A,B]$. Then for the disc $|z|<r\le r_0$, where r_0 is given in Corollary 3.3, we have*

(i) For $A=-B=\alpha$,

$$\left|\arg\left(\frac{zf'(z)}{f(z)}\right)\right|<\tan^{-1}\left(\frac{\sin^{-1}\left(\frac{2\alpha r}{1+\alpha^2r^2}\right)}{2\alpha-\log\left(\frac{1+\alpha r}{1-\alpha r}\right)}\right)$$

(ii) For $A=\alpha e^{i\gamma}$ and $B=\alpha e^{-i\gamma}$,

$$\left|\arg\left(\frac{zf'(z)}{f(z)}\right)\right|<\tan^{-1}\left(\frac{\log T_2}{2\alpha\sin\gamma-\eta+\tau}\right),$$

where T_2, η and τ are given in Theorem 2.3.

Corollary 3.5. *Let $f\in\mathcal{F}[A,B]$. Then for the disc $|z|<r_s\le r_0$, where r_0 is given in Corollary 3.3, $f\in\mathcal{SS}^*(\beta)$, where $r_s\in(0,r_0]$ is the smallest positive root of the following equation:*

(i) For $A=-B=\alpha$,

$$\sin^{-1}\left(\frac{2\alpha r}{1+\alpha^2r^2}\right)=\tan\left(\frac{\beta\pi}{2}\right)\left(2\alpha-\log\left(\frac{1+\alpha r}{1-\alpha r}\right)\right)$$

(ii) For $A=\alpha e^{i\gamma}$ and $B=\alpha e^{-i\gamma}$,

$$\frac{\log T_2}{2\alpha\sin\gamma-\eta+\tau}=\tan\left(\frac{\beta\pi}{2}\right),$$

where T_2, η and τ are given in Theorem 2.3.

We now discuss the radius estimates for the classes $\mathcal{BS}^*(\alpha)$ and $\mathcal{S}^*_{cs}$, which are not contained in $\mathcal{S}^*$. Further we derive radii for functions in $\mathcal{BS}^*(\alpha)$ and $\mathcal{S}^*_{cs}$ to be in $\mathcal{F}[A,B]$.

Theorem 3.6. *Let $\alpha\in(0,1)$, $r_0=(-1+\sqrt{1+4\alpha h_1^2})/(2\alpha h_1)$ and $\alpha_0\in(0,1)$ is the smallest solution of*

$$1-\frac{r_0^2\cos^2\theta(1-\alpha r_0^2)^2}{(1+\alpha^2r_0^4-2\alpha r_0^2\cos2\theta)^2h_1^2}-\frac{r_0^2\sin^2\theta(1+\alpha r_0^2)^2}{(1+\alpha^2r_0^4-2\alpha r_0^2\cos2\theta)^2h_2^2}=0,$$

where $\theta \in (0, \pi/2)$. If $f \in \mathcal{BS}^*(\alpha)$ then for the disc $|z| \leq r_b < 1$, $f \in \mathcal{F}[A, B]$, where

$$r_b = \begin{cases} r_0, & \text{for } A = -B = \alpha \leq \alpha_0 \\ r_1 := \dfrac{-1 + \sqrt{1 + 4\alpha h_2^2}}{2\alpha h_2}, & \text{for } A = -B = \alpha > \alpha_0 \\ r_2 := \dfrac{-1 + \sqrt{1 + 4\alpha(k_1 + k)^2}}{2\alpha(k_1 + k)}, & \text{for } A = \alpha e^{i\gamma} \text{ and } B = \alpha e^{-i\gamma}. \end{cases}$$

Moreover the radii r_0 and r_2 are sharp.

Proof. Let $f \in \mathcal{BS}^*(\alpha)$. Since for $A = -B = \alpha$, $\max_{|z|=1} \operatorname{Re} \psi_{A,B}(z) = h_1$. Thus to find such $r < 1$ for which the image of $zf'(z)/f(z) - 1$ under the disc $|z| < r$ lies inside $\psi_{A,B}(\mathbb{D})$, it is necessary that

$$\max_{|z|=r<1} \operatorname{Re}\left(\frac{z}{1 - \alpha z^2}\right) = \frac{r}{1 - \alpha r^2} \leq h_1 \tag{3.3}$$

must hold. Clearly for $|z| \leq r_0$, the inequality (3.3) holds. Now to see that for $\alpha \leq \alpha_0$, radius r_0 is also sufficient for $zf'(z)/f(z) - 1 \prec z/(1 - \alpha z^2) \in \psi_{A,B}(\mathbb{D})$ in the disc $|z| \leq r_0$. For $\zeta = re^{i\theta}$ ($\theta \in [0, 2\pi)$), we have

$$B_r(\theta) := \frac{\zeta}{1 - \alpha\zeta^2} = \frac{r\cos\theta(1 - \alpha r^2)}{1 + \alpha^2 r^4 - 2\alpha r^2 \cos 2\theta} + i\frac{r\sin\theta(1 + \alpha r^2)}{1 + \alpha^2 r^4 - 2\alpha r^2 \cos 2\theta}.$$

Since $\operatorname{Re} B_r(\theta) = \operatorname{Re} B_r(-\theta)$, $\operatorname{Re} B_r(\theta) = -\operatorname{Re} B_r(\pi - \theta)$ and $\operatorname{Im} B_r(\theta) = \operatorname{Im} B_r(\pi - \theta)$, therefore the curve $B_r(\theta)$ is symmetric about real and imaginary axis thus it is sufficient to consider for $\theta \in [0, \pi/2]$. Now for $r = r_0$, the square of the distance from the origin to the points of $B_{r_0}(\theta)$ is given by

$$Dist(0; B_{r_0}(\theta)) := \frac{r_0^2}{1 + \alpha^2 r_0^4 - 2\alpha r_0^2 \cos 2\theta}.$$

Since $Dist(0; B_{r_0}(\theta))' < 0$, thus $Dist(0; B_{r_0}(\theta))$ is a decreasing function of θ. Hence the farthest point of $B_{r_0}(\theta)$ from origin is $(r_0/(1 - \alpha r_0^2), 0)$, which lies on the boundary of Ω_1. Now for $A = -B = \alpha > \alpha_0$ and $A = \alpha e^{i\gamma}$, $B = \alpha e^{-i\gamma}$ with $|z| = r$, we have

$$\left|\frac{zf'(z)}{f(z)} - 1\right| \leq \frac{r}{1 - \alpha r^2}.$$

Therefore, by Lemma 2.5, we see that $\mathcal{F}[A, B]-$radius for the class $\mathcal{BS}^*(\alpha)$ are the smallest positive roots r_1 and r_2 of the equations $r/(1 - \alpha r^2) = h_2$ and $r/(1 - \alpha r^2) = k_1 + k$, respectively. ∎

Theorem 3.7. *Let $\alpha \in (0, 1)$ and $\alpha_0 \in (0, 1)$ be the smallest solution of*

$$\frac{r_0^2((\alpha - 1)r_0 + \cos\theta(1 - \alpha r_0^2))^2}{h_1^2} + \frac{r_0^2(1 + \alpha r_0^2)^2 \sin^2\theta}{h_2^2} = N,$$

where $\theta \in (0, \pi/2)$ and

$$N = (1 + r_0^2 - 2r_0\cos\theta)^2(1 + \alpha^2 r_0^2 + 2\alpha r_0 \cos\theta)^2$$

and

$$r_0 = (-(1 + (1 - \alpha)h_1) + \sqrt{(1 + (1 - \alpha)h_1)^2 + 4\alpha h_1^2})/(2\alpha h_1).$$

If $f \in \mathcal{S}_{cs}^*(\alpha)$ then for the disc $|z| \leq r_{cs} < 1$, $f \in \mathcal{F}[A, B]$, where

$$r_{cs} = \begin{cases} r_0, & \text{for } A = -B = \alpha \leq \alpha_0 \\ r_1 := \dfrac{-(1 + (1 - \alpha)h_2) + \sqrt{(1 + (1 - \alpha)h_2)^2 + 4\alpha h_2^2}}{2\alpha h_2}, & \text{for } A = -B = \alpha > \alpha_0 \\ r_2 := \dfrac{-(1 + (1 - \alpha)(k_1 + k)) + \sqrt{(1 + (1 - \alpha)(k_1 + k))^2 + 4\alpha(k_1 + k)^2}}{2\alpha(k_1 + k)}, & \text{for } A = \alpha e^{i\gamma}, B = \alpha e^{-i\gamma}. \end{cases}$$

Moreover the radii r_0 and r_2 are sharp.

Proof. Let $f \in \mathcal{S}^*_{cs}(\alpha)$. Since for $A = -B = \alpha$, $\max_{|z|=1} \operatorname{Re} \psi_{A,B}(z) = h_1$. Thus to find such $r < 1$ for which the image of $zf'(z)/f(z) - 1$ under the disc $|z| < r$ lies inside $\psi_{A,B}(\mathbb{D})$, it is necessary that

$$\max_{|z|=r<1} \operatorname{Re}\left(\frac{z}{(1-z)(1+\alpha z)}\right) = \frac{r}{(1-r)(1+\alpha r)} \leq h_1 \tag{3.4}$$

must hold. Clearly for $|z| \leq r_0$, the equation (3.4) holds. Now to see that for $\alpha \leq \alpha_0$ radius r_0 is also sufficient for $zf'(z)/f(z) - 1 \prec z/((1-z)(1+\alpha z)) \in \psi_{A,B}(\mathbb{D})$ in the disc $|z| \leq r_0$. For $\zeta = re^{i\theta}$ ($\theta \in [0, 2\pi)$), we have

$$CS_r(\theta) := \frac{\zeta}{(1-\zeta)(1+\alpha\zeta)} = \frac{r((\alpha-1)r + \cos\theta(1-\alpha r_0^2))}{(1+r^2-2r\cos\theta)(1+\alpha^2 r^2+2\alpha r\cos\theta)} + i\frac{r(1+\alpha r_0^2)\sin\theta}{(1+r^2-2r\cos\theta)(1+\alpha^2 r^2+2\alpha r\cos\theta)}.$$

Since $\operatorname{Re} CS_r(\theta) = \operatorname{Re} CS_r(-\theta)$, therefore the curve $CS_r(\theta)$ is symmetric about real axis thus it is sufficient to consider for $\theta \in [0, \pi]$. Now for $r = r_0$, the square of the distance from the origin to the points of $CS_{r_0}(\theta)$ is given by

$$Dist(0; CS_{r_0}(\theta)) := \frac{r_0^2}{(1+r^2-2r\cos\theta)^2(1+\alpha^2 r^2+2\alpha r\cos\theta)^2}.$$

Since $Dist(0; CS_{r_0}(\theta))' = 0$ for $\theta = 0, \theta_0$ and π with $Dist(0; CS_{r_0}(\theta))' < 0$ whenever $\theta \in (0, \theta_0)$ and $Dist(0; CS_{r_0}(\theta))' > 0$ whenever $\theta \in (\theta_0, \pi)$. And $Dist(0; CS_{r_0}(0)) - Dist(0; CS_{r_0}(\pi)) > 0$, hence the farthest point of $CS_{r_0}(\theta)$ from origin is equal to h_1 obtained at $\theta = 0$. Now for $A = -B = \alpha > \alpha_0$ and $A = \alpha e^{i\gamma}$, $B = \alpha e^{-i\gamma}$ with $|z| = r$, we have

$$\left|\frac{zf'(z)}{f(z)} - 1\right| \leq \frac{r}{(1-r)(1+\alpha r)}.$$

Therefore, by Lemma 2.5, we see that $\mathcal{F}[A, B]-$radius for the class $\mathcal{S}^*_{cs}(\alpha)$ are the smallest positive roots r_1 and r_2 of the equations $r/((1-r)(1+\alpha r)) = h_2$ and $r/((1-r)(1+\alpha r)) = k_1 + k$, respectively. ∎

ORIGINAL PAPER

Optimal design of renewable energy based hybrid system considering weather forecasting using machine learning techniques

Abstract
Renewable energy resources are becoming more appealing as energy demand and fossil fuel costs increase. The hybridization of these resources has the potential to reduce unpredictability and intermittency while increasing efficiency. The accuracy of size optimization of hybrid renewable energy systems (HRES) can be improved by using accurate weather data that can be obtained through forecasting. Thus, to increase the precision of the size optimization, hourly forecasting of global horizontal irradiation, temperature, and wind speed for one year has been performed using Gaussian process regression (GPR), Support Vector Regression, Extreme Gradient Boosting, and Decision Tree techniques. The results of all four forecasting models (FM) are then compared and revealed that the results obtained from GPR are better than those of other FM; therefore, the forecasted data for solar, wind, and temperature obtained from GPR are used for sizing the HRES. The net present cost is utilized to analyze the viability of the HRES while considering system reliability. Furthermore, recently developed optimization algorithms, namely the Colony Predation Algorithm (CPA), Tunicate Swarm Algorithm (TSA), and Aquila Optimization (AO) algorithms have been applied to the sizing of a grid-connected HRES to meet the energy needs of a remote site in the Indian province of Haryana. A comparison of CPA, AO, and TSA has been carried out and revealed that TSA offers more promising outcomes. In addition, the simulation results demonstrate a 0.42% reduction in per unit cost of energy when forecasted data has been used for size optimization.

Keywords Hybrid renewable energy system (HRES) · Optimization techniques · Forecasting · Machine Learning · Rural electrification

1 Introduction

Globally, the focus has been switched from conventional energy to green energy due to the escalating pollution rates and catastrophic repercussions of climate change that endanger life on the earth. However, ubiquitous and environmentally sustainable renewable energy sources (RES) are unpredictable and location-dependent. Now, it is recognized that only HRES with blended generation and adequate storage can meet the need for a consistent, ecological, and reliable power supply; as a result, the optimal sizing of such systems has turned into a prominent topic for researchers around the world [1]. Over the preceding two decades, various comprehensive techniques have been employed for developing and determining the optimal size of HRESs. These techniques incorporate simulation tools, graphical construction [2], probabilistic [3], iterative [4, 5], and artificial intelligence [6–11]. In recent years, intelligent techniques have been widely used to optimize HRES and boost economic rewards [12]. Several researchers have used intelligent approaches for the optimal sizing of HRES; some are discussed in the following paragraphs.

Bernal-Agustn et al. and Dufo-López et al. researched the optimal size of an HRES of solar photovoltaic (SPV)/wind turbine (WT)/diesel generator. In this work, the Strength Pareto evolutionary algorithm involving two target functions: system cost reduction and greenhouse gas emission reduction, has been applied [13, 14]. Yang et al., Bilal et al., and Tafreshi et al. applied the genetic algorithm (GA) to optimize the sizing problem under a variety of objective functions, including maximizing the system reliability under

varying weather conditions, minimizing the annual system cost and the loss of power supply probability (LPSP) [15–17]. Navaeefard et al., Bashir et al., and Pirhaghshenasvali et al. used particle swarm optimization (PSO) to determine the optimal size of an HRES [18–20]. Askarzadeh proposed a discrete harmony search (DHS) based algorithm for sizing the SPV and WT in an HRES for a remote Montana State. The proposed technique is simple, handles discrete problems effectively, and obtains solutions rapidly. The suggested approach yielded encouraging findings in a fraction of a second [21]. Ismail et al. presented a hybrid system that combined solar panels and batteries to meet the energy needs of a small rural community in Palestine. The results demonstrate that the proposed solution is more advantageous than a utility grid [22]. Maleki et al. employed a harmony search (HS) based strategy to optimize the design of an SPV/WT-based HRES for rural regions in Rafsanjan, Iran. Furthermore, the HRES was compared to a diesel generator regarding overall cost and emissions [23]. To reduce the total NPC, Heydari et al. created an SPV system using biomass as a backup source. They discovered that the established HRES for delivering energy to agricultural wells in Bardsir, Iran was more cost-effective than solar panels or biomass alone [24]. Tabak et al. researched to optimize a hybrid system comprising an SPV, WT, and biomass generator (BMG) and scaled it to meet the energy needs of a faculty building using GA. Unlike earlier research, the gray wolf optimization (GWO) technique was used for the size optimization of HRES based on reliability. A comparison is then made with the GA results and found more appropriate [12]. In a study by Abu-Hamdeh et al., multivariable linear regression was used to evaluate the effects of different HRES configurations on the COE and the reliability. The observed results are also contrasted with PSO findings and found more appropriate [25]. Diab et al. proposed a simulation model for an HRES microgrid with battery. The optimal size of the proposed system reduces the COE while boosting the reliability and efficiency of the HRES. The optimized HRES was designed using various novel optimization techniques (OT) such as Whale Optimization Algorithm (WOA), Water Cycle Algorithm (WCA), and Moth-Flame Optimizer (MFO). The WOA outperformed the other algorithms in the simulation [26]. Liu et al. proposed an HRES with a high-capacity offshore wind farm and pumped hydro storage (PHS). This work optimized the PHS system size using dynamic economy-based multi-objective technical and economic evaluation [27]. Ganesan et al. suggest a hybrid strategy for an intelligent grid energy management system to minimize fuel expenses, operating and maintenance expenses, hourly power variation, and required load demand using a combination of artificial cell swarm optimization and vapor–liquid equilibrium [28]. Using the PSO approach, Anand et al. determined the optimum size of an HRES for the electrification of rural areas. The grid-connected HRES was found to be the most influential architecture in this investigation. An hourly simulation was used to determine the optimal size of the HRES [29]. The same authors researched to select the ideal size of HRES components using an HS technique. The feasibility analysis of a grid-connected HRES was investigated in this study. The system under discussion has a total NPC that is kept to a minimum by setting boundary limitations, limiting battery storage capacity, and using available land [30]. Saebi et al. researched to find the optimal HRES design for government institutions under attractive policies. The findings suggest that investing in the proposed design will benefit the University after six years [31]. Rajesh et al. proposed a control scheme to improve RES power quality by combining Improved Bat and MFO algorithms [32]. Bakhshaei et al. surveyed to determine the best grid-purchased electricity in grid-connected HRES. The system's running costs were minimized while maintaining a specified degree of stability and operating limitations. Simulation findings demonstrate that determining the best power exchange and incentive rate lowers operational costs [33]. Jamshidi et al. researched to substitute wind speed (W_S) and GHI data with averaged site meteorological data such as atmospheric temperature, elevation, and moisture content. One hundred-five Iranian locations were used as training data to create and test HRES [34]. Rezaei et al. researched grid-independent HRES comprising SPV, WT, and renewable H_2-based Fuel cells for co-supplying electricity and heat to a tourist village in Iran's Isfahan province [35]. Acharya et al. used Refraction-based WOA to solve combined economic emission dispatch challenges by determining the optimum HRES production output. The WT might well be linked to the thermal power plant in the HRES because it cannot be utilized alone to reduce economic and pollution expenses. The proposed Refraction-based WOA strategy was compared with other established approaches regarding financial costs and emissions [36] and revealed appropriate. Das et al. researched the size of an HRES system, which includes solar panels, WT, batteries, and converters, to meet the needs of a rural town. The power generated was used to fulfill the thermal requirements of the community. The HRES optimized for electric and thermal loads compared to identical systems optimized only for electric loads. A comparative study examined the impact of various technical and economic characteristics of the HRES components. The GA optimization approach was also applied to optimize the HRES system [11]. Mishra et al. applied DHS to develop an optimal grid-tied HRES containing SPV and BMG along with a battery grid-linked HRES for supplying power to the selected rural areas [37].

Uncertainty regarding RES presents itself as one of the particular challenges faced in the design of HRES, resulting in various approaches to tackle this issue. Lei et al. provided a bibliographical assessment of current research and advancements in W_S and power forecasting [38]. A unique hybrid

technique is suggested and compared by Catalao et al. for short-term wind forecasting employing wavelet transform [39]. The optimization approaches mentioned in the literature are often based on the previous year's W_S and GHI data. However, it is well recognized that meteorological data from prior years vary dramatically from current estimates. Several models, including uncertainty, have been developed to address this issue to improve energy efficiency. In this context, Khalid, Savkin, and Tascikarao glu et al. employed wind power prediction to optimize HRES, whereas Hocaoglu et al. investigated the influence of GHI forecasting on optimal system design efficiency [40–42]. Zhang et al. put forth a novel framework to determine the optimal size of a grid-connected HRES that comprises a new algorithm as a mix of chaotic search, harmonic search, and simulated annealing. Weather and load forecasts were included using an artificial neural network to increase the precision of the size-optimized design [43]. Gupta et al. suggested the biogeography-based optimization algorithm for size optimization and artificial neural network for solar-wind forecasting. The authors examined the benefits of HRES size optimization using forecasted data rather than historical data [44]. Maleki et al. presented an HS and a hybrid of HS and chaotic search. This study evaluated an HRES that uses iterative neural networks to anticipate the weather data and meet household water needs [45]. Alfonso et al. provide a sizing methodology that utilizes long short-term memory cells to anticipate long-term weather conditions [46].

A thorough review of the literature demonstrates that it is crucial to evaluate various technical, economic, and external energy sources when combining them to achieve the best configuration of an HRES. Intelligent strategies have recently gained popularity and delivered outstanding outcomes. Simulation tools such as the Hybrid optimization model for electric renewable have been used to conduct most studies about grid-connected situations. In contrast, more research on grid-integrated HRES that use intelligent methods must be done. Although biogas and biomass is a significant and potentially valuable resource, particularly in rural regions, power generation based on these resources have received little attention from researchers. It has also been noted that most researchers have used data from just one day to illustrate how well intelligent approaches can solve optimization problems without statistical analysis. Owing to this situation, there is a research gap and a need for more specialized work in HRES. An optimal HRES should be selected based on the RES available at a specific location, considering several technical and economic factors to address this gap. Further, the size optimization approaches presented in the literature are based on the W_S and GHI data collected for previous years. Despite this, it is well-established that the meteorological data from earlier years contain considerable deviations when contrasted with the present values. To the best of our knowledge, none of the studies that have been published in the past have used the ML approaches, viz. GPR, SVR, XGBT, and DT to forecast solar, wind, and temperature data to size HRES.

To address above mentioned issues, in the present work, firstly, hourly forecasting of GHI, temperature, and W_S for one year is carried out using ML approaches, namely SVR, GPR, XGBT, and DT, and found the most appropriate solution. Further, the forecasted GHI, temperature, and W_S data have been used to develop the optimal HRES. The size optimization has been performed using newly developed optimization approaches, viz. CPA, TSA, and AO algorithms. The obtained results are compared and found the optimal solution based on the minimization of NPC. Finally, the result obtained with and without forecasted data has been compared, and found the appropriate solution.

The novelty of this research lies in the application of novel approaches: TSA, CPA, and AO for sizing of HRES along with advanced machine learning (ML) techniques to address the dynamic nature of RES by incorporating precise weather predictions, thereby significantly reducing COE and making the proposed hybrid system more economical.

The main contributions of the work described in this paper can be summarized as follows:

- Novel CPA, TSA and AO algorithms were applied for the first time for tackling the problem of optimal sizing of HRES components.
- To improve the accuracy of size optimization of HRES components, the sizing of HRES is done using forecasted data which is rare in literature. In view of this, various ML models have been used for forecasting the solar irradiation, temperature and wind speed.
- Although being significant and potentially useful resources, particularly in rural regions, biogas and biomass-based power generation have not received much attention from researchers. Addressing this research gap the HRES developed in this research includes BMG and BGG with scheduling of their operation.

The various steps for finding the optimal size of an HRES with meteorological data and forecasted data used in this work is as follows:

- The first phase is collecting data. National Renewable Energy Laboratory was used to acquire the weather data. The meteorological variables GHI, W_S, and temperature were acquired.
- The next stage describes the dataset. Our dataset for this study includes hourly historical data over the past five years (from 2016 to 2020) for GHI, temperature, and W_S. In addition, an examination of the daily distribution of meteorological parameters is carried out, which justifies the removal of values that are either zero or irrelevant.

- The third phase is to forecast those, as mentioned earlier, three meteorological variables using four techniques: GPR, SVR, XGBT, and DT.
- The fourth stage compares the performance of GPR, SVR, XGBT, and DT to identify the best FM.
- The fifth step is to determine the optimum size. Mathematical modeling for this purpose is explained in Sect. 2. Using TSA, CPA, and AO, the appropriate size of the HRES component is determined using historical meteorological data from 2016 to 2020, followed by forecasted solar, wind, and temperature data using the GPR approach.
- The findings from the forecasted models are compared with the historical meteorological data in the sixth phase of the process.
- Finally, the size optimization of HRES has been performed using recently developed TSA, CPA, and AO.

2 Material and methodology

The proposed grid connected HRES comprises of SPV modules, WT, biomass generator (BMG), biogas generator (BGG), battery system, a bi-directional converter, and electrical load. The architecture of the proposed grid connected HRES is illustrated in Fig. 1. The mathematical modeling of the suggested system requires solar irradiance, wind speed, temperature, and load demand information of the selected site. Because of this, the selected site's resource information and load demand have been presented in the subsequent sections.

2.1 Description of selected site

The area under consideration is situated in the Mewat region of Haryana, India. Geographically, it is at the latitude of 28.150N—28.39 0N and longitude of 76.94 0E—77.04 0E. The geographical representation of selected site is illustrated in Fig. 2.

2.2 Resource information of the selected site

A thorough analysis was conducted to determine the potential of RES for the chosen site. The study area has vast potentials for solar energy, wind energy, biomass, and biogas with annual potentials of 1919.90 kWh/m^2/year, 1086.24 kWh/m2/year, 731,818.18 kWh/year, and 172,280 kWh/year, respectively. The total energy requirements of the residents of the selected area could be satisfied using these resources. Figure 3 illustrates the monthly daily average solar irradiation for the selected site. The solar irradiance varies throughout the year, with May having the most significant value of 6.74 kWh/m^2/day and December having the lowest value of 3.53 kWh/m^2/day. Figure 4 illustrates the monthly hourly average ambient temperature of the selected site. The annual range of the ambient temperature has been recorded as 9 to 46 °C. Figure 5 shows the monthly variations in the hourly wind speed at the chosen site. With a calculated wind power density of 124 W/m^2, the anticipated yearly average wind speed is 5.18 m/s.

2.3 Electrical load demand assessment

The load demand for an HRES is crucial when sizing such a system. Therefore the electrical load demand has been determined for the electrification of the proposed rural site. This was carried out by considering the standard of living of the inhabitants and the various electrical appliances they would use. The temperatures of the study area vary between 4 to 46 0C. The fluctuation in the average temperature affects the energy consumption pattern of various home appliances. For the sake of this investigation, the entire year has been split into three distinct seasons, the summer season (April–July), the moderate season (August–November), and the winter season (December–March) also the load demand of these seasons are computed as 3638.955kWh/day, 2849.355kWh/day, and 1533.149 kWh/day respectively. The total load of the study area is estimated as 904,802.9 kWh/year. Figure 6 depicts the daily energy demand for the research area during the three seasons.

2.4 Modeling of HRES components

Mathematical modeling plays a crucial role in developing an optimal design and sizing of HRES. It serves as an imperative tool for understanding the operating performance of each component within the proposed HRES under various conditions. The mathematical modeling of each element within the HRES is outlined as follows:

2.4.1 SPV

The power generated by the SPV system is given by the following equation:

$$P_{pv}^{o} = d_f \times p_{pv}^{r} \times \left(\frac{s^r}{s_r^r}\right) \times [1 + k_t(C_t - C_t^r)] \quad (1)$$

where the SPV power output is represented by P_{pv}^{o} in watts; s_r^r is the GHI at the reference; derating factor is denoted by d_f; p_{pv}^{r} is the rated power. GHI is represented by s^r. The reference cell temperature is defined by C_t^r; the temperature coefficient is denoted by k_t and the cell temperature is represented by C_t.

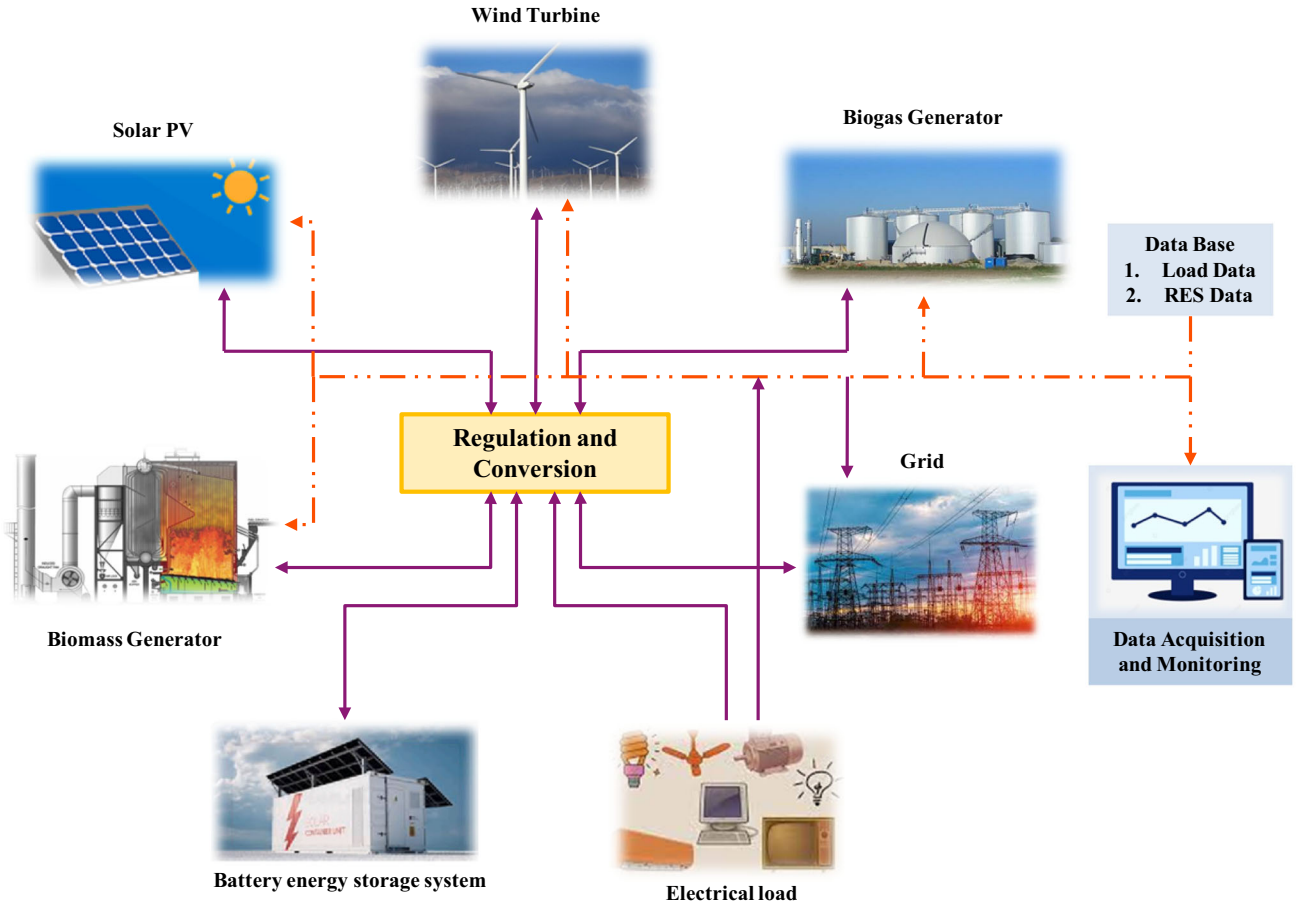

Fig. 1 Architecture of proposed HRES

The energy generated by the SPV system ($PV_E^O(t)$) can be calculated as follows:

$$PV_E^O(t) = P_{pv}^o \times \Delta t \tag{2}$$

2.4.2 WT

The output power of a WT can be calculated using the below mentioned equation [47, 48]:

$$P_{wt} = \frac{1}{2}\rho C_p^{wt} V_w^3 A_r^{wt} \tag{3}$$

where; P_{wt} is the WT power in watts; ρ is the air density, which is equal to 1.225 kg /m^3, the WT power coefficient is denoted by C_p^{wt}; the rotor disk area in m^2 is represented by A_r^{wt} and W_S in m/s at the hub elevation is denoted byV_w^3.

The electricity that is produced by a WT system may be calculated as follows:

$$W_E^o(t) = N_{wt} \times P_{wt} \times \Delta t \tag{4}$$

where; Number of WT is simply represented by N_{wt}.

2.4.3 BMG

The BMG output ($P_{BMG}^O(t)$) can be given by the following equation as [30]:

$$P_{BMG}^O(t) = 3.185 \times 10^{-3} \times (Q_{BM} \times C_{BM} \times \eta_{BM})/(O_{BMG}^h) \tag{5}$$

where; Q_{BM} denotes the available biomass, the biomass calorific value marked by C_{BM}; and the conversion efficiency of BMG is denoted as η_{BM}; operating hours of BMG are denoted by O_{BMG}^h. The energy generated by BMG ($BMG_E^O(t)$) can be calculated as:

$$BMG_E^O(t) = P_{BMG}^O(t) \times \Delta t \tag{6}$$

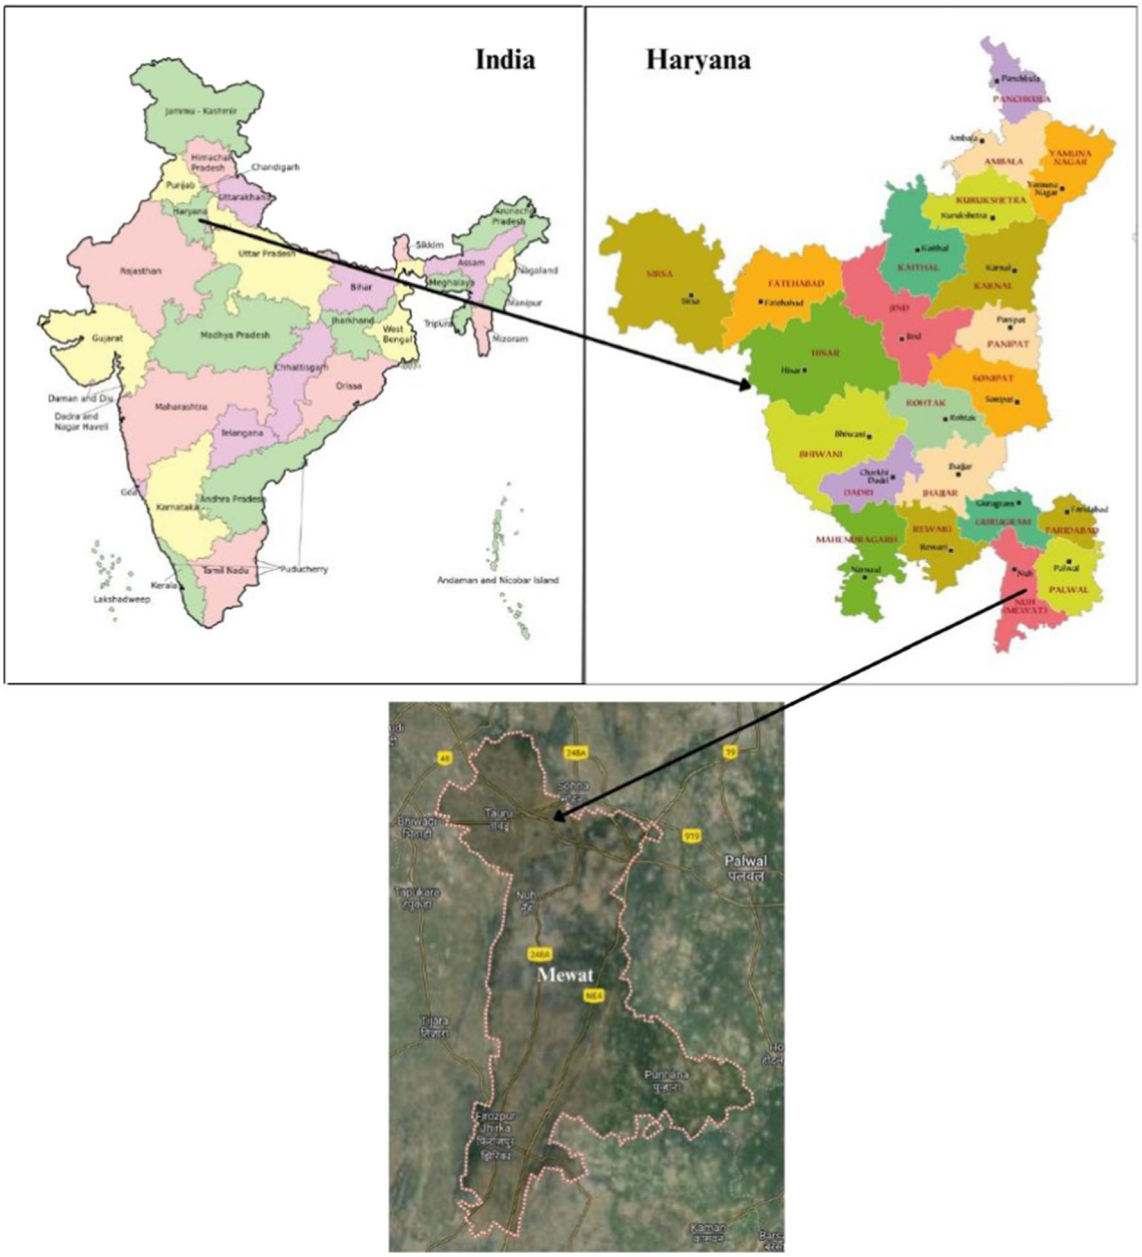

Fig. 2 Geographical representation of the study area

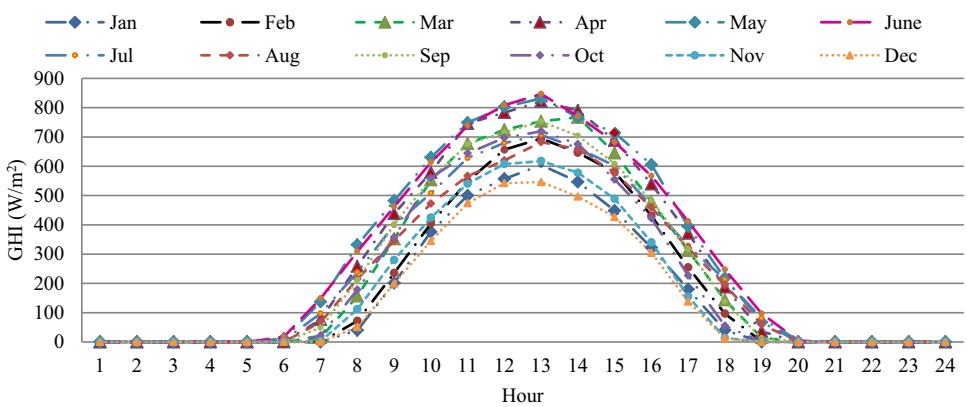

Fig. 3 Monthly hourly average GHI of the selected site

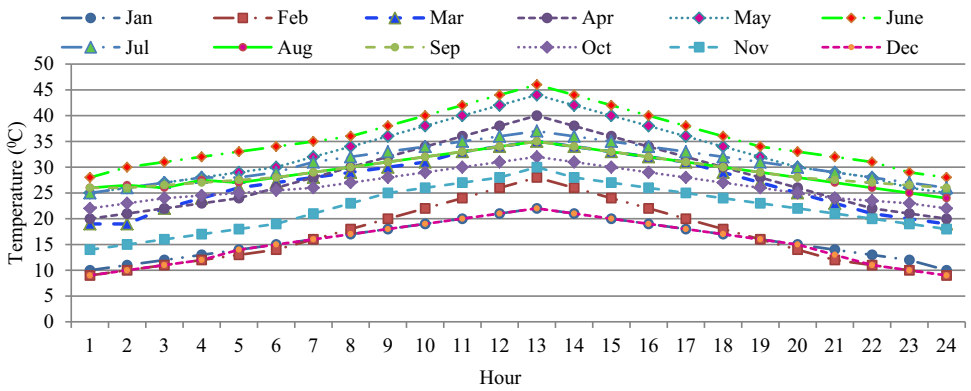

Fig. 4 Monthly hourly average temperature of the selected site

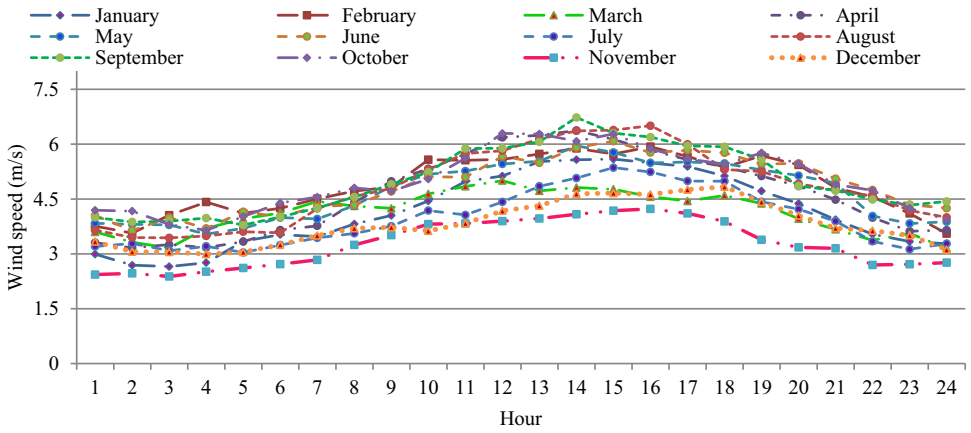

Fig.5 Monthly average wind speed on hourly basis

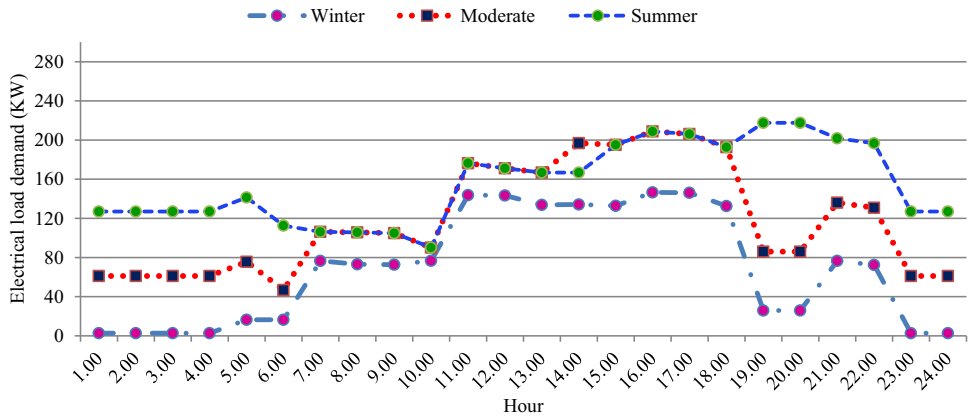

Fig.6 Load demand of selected site

2.4.4 BGG

The output power of BGG ($P^{O}_{BGG}(t)$) can be calculated as [1]:

$$P^{O}_{BGG}(t) = (Q_{BG} \times C_{BG} \times \eta_{BG})/(O^{h}_{BGG}) \quad (7)$$

The availability of biogas/day is indicated by Q_{BG}; biogas calorific value is marked byC_{BG}; BGG conversion efficiency is represented byη_{BG}; and BGG/day operating hours are denoted byO^{h}_{BGG}. The generated energy from BGG system ($BMG^{O}_{E}(t)$) can be computed as:

$$BGG^{O}_{E}(t) = P^{O}_{BGG}(t) \times \Delta t \quad (8)$$

2.4.5 Battery

The surplus energy produced by the RES is stored in a battery which can be utilized as a backup source when needed. The capacity of battery can be calculated based on the energy demand. Surplus power is stored within the battery when the generated energy exceeds the energy demand. The battery

capacity during the charging $E_B^C(t)$ process can be calculated using the following equation [30]:

$$E_B^C(t) = \left(1 - \gamma_B^{SDr}\right) \times E_B^S(t-1) + [E_X^W(t) + E_X^{PV}(t) + E_X^{BMG}(t) + E_X^{BGG}(t)] \times \eta_B^C \quad (9)$$

The energy stored in the battery is marked by $E_B^S(t)$; discharging rate is represented by γ_B^{SDr}; Extra generated energy by SPV, BMG, WT, and BGG systems are defined by $E_X^{PV}(t)$, $E_X^{BMG}(t)$, $E_X^W(t)$, $E_X^{BGG}(t)$ respectively, and the charging efficiency is denoted by η_B^C. When energy demand is greater than generated energy, the energy shortfall is compensated by battery. The battery capacity during discharge ($E_B^D(t)$) can be computed as [30]:

$$E_B^D(t) = \left(1 - \gamma_B^{SDr}\right) \times E_B^S(t-1) - \frac{E_{df}(t)}{\eta_B^c \times \eta_B^d} \quad (10)$$

where; η_B^d indicates the discharging efficiency; charging efficiency is denoted by η_B^c; and $E_{df}(t)$ represents an unmet energy demand.

2.4.6 Grid

When energy demand > generated energy and the minimum battery capacity ($E_B^{mn}(t)$), energy will be drawn from the grid and can be determined as follows [18].

$$E_g^p(t) = E_D(t) - \left[W_E^O(t) + BMG_E^O(t) + BGG_E^O(t) + \left[PV_E^O(t) + \left(E_B^S(t) - E_B^{mn}(t)\right) \times \eta_{inv}\right]\right] \quad (11)$$

where $E_g^p(t)$ is the energy drawn from the grid; energy demand is denoted by$E_D(t)$; Inverter efficiency is indicated by η_{inv}.

Equation (12) can be used to determine the energy sold to grid ($E_g^s(t)$)

$$E_g^s(t) = \left[W_E^O(t) + BMG_E^O(t) + BGG_E^O(t) + \left[PV_E^O(t) - \left(E_B^{mx}(t) - E_B^S(t)\right) \times \eta_{inv}\right]\right] E_D(t) \quad (12)$$

Maximum capacity of battery is marked by $E_B^{mx}(t)$.

2.5 Problem definition

The HRES optimal size optimization problem is defined and discussed in this section. We can determine the component capacities that result in the most cost-effective and reliable HRES by specifying the size optimization problem. The optimization process considers an objective function, decision variables and a number of relevant constraints described in the following paragraphs.

2.5.1 Objective function

For size optimization of HRES, the main objective function is NPC, which includes the NPC of all the components involved in the HRES design [1].

The total NPC of HRES (N_{PC}^T) may be expressed as follows:

$$N_{PC}^T = NPC_{PV} + NPC_{BMG} + NPC_{inverter} + NPC_{Battery} + NPC_{BGG} + NPC_{WT} - \in_S^G + \in_P^G \quad (13)$$

NPC of SPV system is denoted by NPC_{PV}; NPC_{BMG} is the NPC of BMG system; $NPC_{inverter}$ represents NPC of inverter; $NPC_{Battery}$ defines NPC of battery; NPC of BGG is indicated byNPC_{BGG}; NPC_{WT} is the NPC of WT ; $\in_S^G$ is the cost of energy sold to grid and cost of energy purchased from grid is denoted by$\in_P^G$.

2.5.2 Constraints

While minimizing total NPC, the optimized HRES system should also satisfy the boundary constraints. Further, the sizes of the system components may vary in the framework designed to satisfy load requirements. Therefore, the boundaries for various HRES components are defined as follows [1]:

$$N_{pv}^{min} \le N_{pv} \le N_{pv}^{max} \quad (14)$$

$$N_{Battery}^{min} \le N_{Battery} \le N_{Battery}^{max} \quad (15)$$

$$P_{BMG}^{O\ min} \le P_{BMG}^O \le P_{BMG}^{O\ max} \quad (16)$$

$$P_{BGG}^{O\ min} \le P_{BGG}^O \le P_{BGG}^{O\ max} \quad (17)$$

$$P_{wt}^{min} \le P_{wt} \le P_{wt}^{max} \quad (18)$$

$$E_B^S(t)^{min} \le E_B^S(t) \le E_B^S(t)^{max} \quad (19)$$

where; N_{pv} indicates the number of PV panels; the number of batteries is represents by $N_{Battery}$.

Reliability The LPSP is a constraint-based on a reliability indicator. It is an indicator that measures the proportion of energy that cannot be provided to the load, as shown in Eq. 20. It accepts a value between 0 and 1 or 0% and 100%. A 0% LPSP indicates that the energy demand is entirely satisfied and reliability is at its highest level. The system could not energize the load and was unreliable when LPSP was

100%.

$$\mathrm{LPSP} = \sum_{t=1}^{t=8760} \left(\frac{Unmet\ load\ for\ one\ yea}{Total\ load\ for\ one\ year} \right) \tag{20}$$

Renewable fraction (RF) The RF is a measure of the electricity generated by RES in a system and supplied to the load, is described in the following equation [1]:

$$\mathrm{RF} = 1 - \frac{\text{Energy generated by RES}}{\text{Energy supplied to load}} \tag{21}$$

2.6 Optimization techniques

The recently developed optimization techniques CPA, TSA, and AO which are used for size optimization of HRES have been discussed in the subsequent sections.

2.6.1 Colony predation algorithm (CPA)

The CPA is a novel stochastic optimization approach developed by Chen et al., the behavior of social animals serves as the basis for this algorithm. The main focus herein is on colony predation, a strategy used by animals to evade predators and boost hunting success rates. Wolf packs, hyena packs, lion packs, piranha packs, and other animals that hunt in packs frequently use this tactic. Predators frequently obtain additional prey through colony predation, improving individual survival rates. This is a strategy used by animals that live in colonies to ensure their survival and maximize the effectiveness of their hunt for food. Hyenas and wolves, for instance, communicate and work together through colony predation to capture more prey than they could individually. The two most popular strategies for increasing the likelihood of successful hunting are dividing and encircling animals. Another tactic animals use in circumstances when consumption surpasses their produce. In this behavior, they will switch to another prey, increasing their predation's effectiveness. CPA draws inspiration from collective hunting; a strategy herd animals use to increase individual survival rates. CPA also takes into account the natural phenomena of survival of the fittest [49].

Step1: Communication and collaboration

Predation success rates are higher for animals that hunt in groups, because they communicate and work together more efficiently.

Using the following formulae, we can describe how individuals communicate and hunt for food in groups [49].

$$\mathrm{Y_n^m}(\tau+1) = \mathrm{Y_n^{m_1}}(\tau) + (1-p).\left(\frac{\mathrm{Y_1}(\tau) + \mathrm{Y_2}(\tau)}{2} \right) \tag{22}$$

where; p is the random number lies between 0 to 1; the individual looking for food is marked by $\mathrm{Y_n^{m_1}}(\tau)$; the two closest positions to prey in the $\mathrm{n^{th}}$ dimension are indicated by $\mathrm{Y_1}(\tau)$and$\mathrm{Y_2}(\tau)$; $n\epsilon$ 1,2,…., dim; dim is the dimension of population; the individual's latest updated position is represented by $\mathrm{Y_n^m}(\tau+1)$.

Step2: Disperse food

The initial approach in colony prediction separates the prey from its group by driving it in various directions. The predation strategies of the individuals in the search were mathematically modeled and as follows:

$$\mathrm{Y}(\tau+1) = \mathrm{Y_b} - \mathrm{P_s}.(\mathrm{k_1}.(u_b - l_b) + l_b) \tag{23}$$

where the position of a population is denoted by Y (τ + 1), the position of food is marked by $\mathrm{Y_b}$; $\mathrm{P_s}$ denotes the strength of prey, $\mathrm{k_1}$ represents [$\mathrm{K_1}$; $\mathrm{K_2}$; $\mathrm{K_3}$; …$\mathrm{K_n}$], which is a random number between 0–1;u_b, l_b are the upper and lower bounds respectively.

Step3: Encircle food

The second tactic is used by the hunting party to encircle and approach animals. This step can be mathematically mimic using the following equation:

$$\mathrm{Y}(\tau+1) = \mathrm{Y_b} - 2 \cdot \mathrm{P_s} \cdot \mathrm{d} \cdot \mathrm{e}^{l} \cdot \tan\left(\frac{\pi}{4} \cdot l \right) \tag{24}$$

where the distance that separates the current member from the prey is represented by d; the random number is defined by l which lies between 0 and 1. The value of d is calculated as follows:

$$\mathrm{d} = |\mathrm{Y_b} - \mathrm{Y}(\tau)| \tag{25}$$

The current hunter population is marked by Y(τ).

Step4: Supporting closest individual

Recognizing the group's potential challenges in pursuing prey, the closest individual requests peer assistance, which can be described as follows.

$$\mathrm{Y}(\tau+1) = \mathrm{P_{nearest}} \tag{26}$$

where, location of the nearest predator is marked by $\mathrm{P_{nearest}}$.

Step 5: Searching for the food

If no prey is located nearby or if the food supply is too far away from the prey, the surviving individuals will seek another food source. In the following way this behavior may be expressed as follows:

$$\mathrm{d_1} = |2 \bullet \mathrm{k_4} \bullet \mathrm{Y_{rand}} - \mathrm{Y}(\tau)| \tag{27}$$

$$\mathrm{Y}(\tau+1) = \mathrm{Y_{rand}} - \mathrm{P_s} \bullet \mathrm{d_1} \tag{28}$$

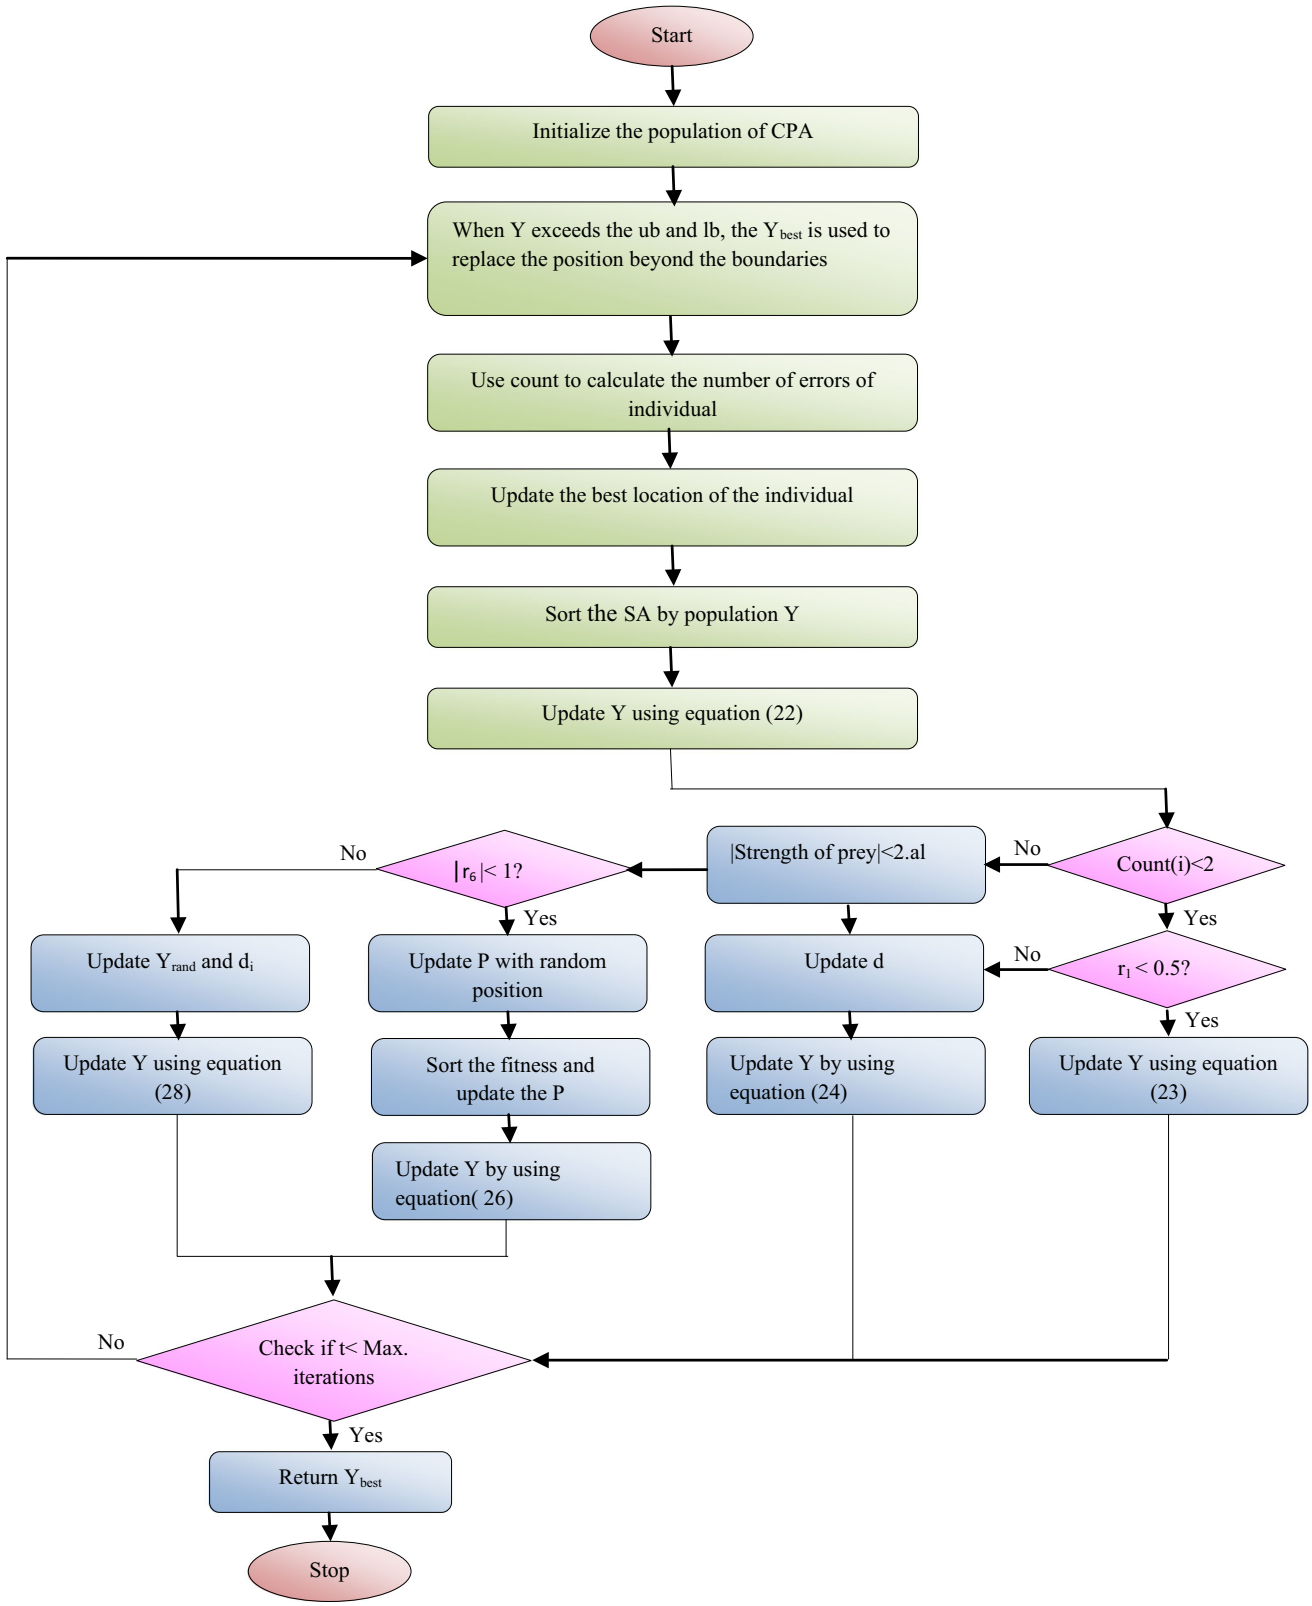

Fig. 7 Flowchart of CPA algorithm

where; random number is defined as k_4 and its value lies between [0 and 1]. An individual's random position is indicated by Y_{rand}; d_1 represent the distance of random group movement. Further the flowchart for proposed CPA is presented in Fig. 7.

2.6.2 Aquila optimization (AO) algorithm

In 2021, Abualigah et al. introduced the population-based meta-heuristic algorithm known as the Aquila Optimizer (AO). The eagle, known in Latin as Aquila, is a bird of prey that hunts by using its quickness and agility to seize its prey. It has strong feet and sharp talons are considered as the most intelligent and proficient hunting tools. Aquila has four main hunting techniques: high soar with a vertical stoop, contour battle with a short glide, low fly with a gradual descent, and strolling and catching prey. The primary method of hunting used by Aquila is narrow exploration. Quick soaring moves were used to assault the target's body after landing in the designated area and circling the target. Aquila's four core hunting strategies served as inspiration for the development of the Aquila Optimizer (AO), a nature-inspired optimization algorithm that fundamentally explains the hunt's various stages. The various hunting steps used in AO algorithms are explained below [50].

Step1: Expanded exploration (Z1): high soar with a vertical stoop

While hunting for food, Aquila utilizes expanded exploration, which involves flying at a high altitude and simultaneously looking over a wide region. When Aquila has located its target, it will do a vertical dive to capture it successfully. As a direct outcome of this, the mathematical representation of this behavior is as follows: [50].

$$Z_1(\varphi+1) = Z_b(\varphi) \times \left(1 - \frac{\varphi}{T}\right) + (Z_m(\varphi) - Z_b(\varphi) \times r_1) \tag{29}$$

where;φ and T are the current and maximum iteration respectively; $Z_1(\varphi+1)$ is the solution of the next iteration of φ, $Z_b(\varphi)$ denotes the best position, $Z_m(\varphi)$ is the average location of all aquilas in the current iteration; n is the population size; and r_1 is random number between 0 and 1.

Step2: Narrowed exploration (Z2): contour flight with short glide attack

While hunting, Aquila uses the most common strategy called "narrowed exploration." In this strategy, upon landing inside the prescribed region and its subsequent flight around the target, it launches a series of quick gliding attacks employing short glides against the victim. The formula for the position update can be represented by the notation shown below:

$$Z_2(\varphi+1) = Z_b(\varphi) \times lf(d) + Z_r(\varphi) + (x - z) \times r_2 \tag{30}$$

where; arbitrary location of Aquila is marked by $Z_r(\varphi)$; the dimension size is denoted by d, the random value is represented by r_2 which lies between 0 and 1; x and z are used to present the spiral shape in the search and the Levy Flight Function is marked by lf(d).

Step3: Expanded exploitation (Z3): low flight with a slow descent attack

In the expanded exploitation strategy, Aquila descended vertically to launch its first assault, after an approximate assessment of its prey position. Aquila uses a given area to approach and attack targets. This behavior can be expressed mathematically as follows:

$$Z_3(\varphi+1) = (Z_b(\varphi) - Z_m(\varphi)) \times \ -r_4 + ((ub - lb) \times r_5 + lb) \times \delta \tag{31}$$

where; exploitation adjustment parameters are marked by α, δ; lower and upper bounds are represented by lb and ub; random numbers are between 0 and 1 and denoted by r_4, r_5.

Step4: Narrowed exploitation (Z4): walking and grabbing prey

When pursuing targets in the direction of their rescue paths, the aquilas use a narrow exploitation approach. They then assaulted the target while flying mid-air [51].

$$Z_4(\varphi+1) = qf \times Z_b(\varphi) - (g_1 \times Z(\varphi) \times r_6) - g_2 \times lf(d) + r_7 \times g_1 \tag{32}$$

where $Z(\varphi)$ denotes the current position; qf denotes the quality function value. While tracking prey, the value of the movement parameter g_1 ranged from -1 to 1; g_2 represent the flight slope when chasing prey. The random numbers r_6 and r_7 were chosen to be between 0 and 1. Further the flowchart for AO algorithm is presented in Fig. 8.

2.6.3 Tunicate swarm algorithm (TSA)

TSA is an algorithm that takes inspiration from tunicate colonies. Tunicate is a group of marine animals. They make dwellings on piers, rocks, or the undersides of boats and ships. Most often, they resemble small blobs of color. The tunicate can emit intense blue-green light, or bioluminescence, which makes it visible from a distance. They have two ends: an open end and a closed end. The open end is utilized for propulsion, such as jet propulsion employing atrial siphons. Tunicates move by using bursts of fluid. The force of this explosion is so intense that it can cause tunicates to travel vertically in the water. The shape of this animal is measured in millimeters.

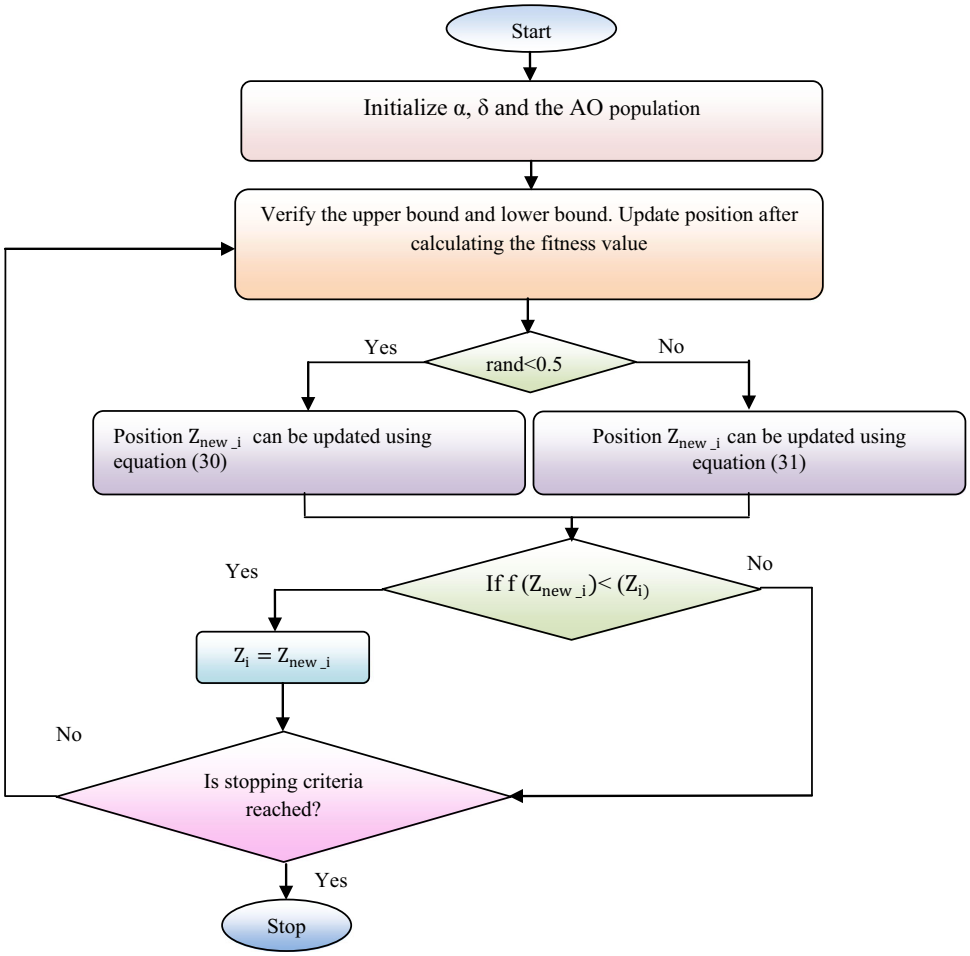

Fig. 8 Flow Chart of AO algorithm

Tunicates have the expertise and ability to locate food sources in the water even when there is no information available on food sources. The ability to identify food is present in tunicates. The most crucial tunicate activities are their jet propulsion and swarm intelligence, which they use to identify the optimal food supply. The mathematical modeling of the initial behavior of the tunicates, which is the jet's propulsion, needs to satisfy three requirements. These requirements aim to avoid conflicts amongst tunicates, modify the potential tunicate's position, and get closer to the potential tunicate. Conversely, the swarm behavior keeps track of fellow seekers' presence to arrive at the most appropriate and optimal solution [51].

Step1: Preventing search agent disputes

To prevent the disputes among search agents (SA), vector $\overrightarrow{B}$ is used to calculate the new search agent location

$$\overrightarrow{B} = \frac{\overrightarrow{H}}{\overrightarrow{N}} \tag{33}$$

$$\overrightarrow{H} = r_2 + r_3 - \overrightarrow{E} \tag{34}$$

$$\overrightarrow{E} = 2.r_1 \tag{35}$$

where, the gravity force is indicated by $\overrightarrow{H}$; $\overrightarrow{E}$ represents deep ocean advection;. r_1, r_2, r_3 denote random values between 0 and 1; $\overrightarrow{N}$ represents the social forces among SA.

The following formula is used to compute the vector N:

$$\overrightarrow{N} = [Q_{min} + r_1(Q_{max} - Q_{min})] \tag{36}$$

where;Q_{min}, Q_{max} represent initial and subordinate speeds to make social interaction.

Step2: Movement towards the direction of best neighbour

After avoiding the disputes between neighbors, the SA moves towards the direction of best neighbor

$$\overrightarrow{P_D} = | \overrightarrow{F_S} - R_{rand} \bullet \overrightarrow{Q_p}(y) | \tag{37}$$

where; the distance between the food source and SA is denoted by $\overrightarrow{P_D}$; the current iteration is represented by y, $\overrightarrow{F_S}$ indicates the position of optimum food source; $\overrightarrow{Q_p}(y)$ is

the position of tunicate; and R_{rand} represents random value between 0 and 1.

Step3: Converge towards the best search agent

The SA can maintain its position towards the optimal location of SA which are near to food source..

$$\overrightarrow{Q_p}(y) = \overrightarrow{F_S} + \overrightarrow{B} \bullet \overrightarrow{P_D}, \text{ if} R_{rand} \geq 0.5 \tag{38}$$

$$\overrightarrow{Q_p}(y) = \overrightarrow{F_S} - \overrightarrow{B} \bullet \overrightarrow{P_D}, \text{ if} R_{rand} < 0.5 \tag{39}$$

where; $\overrightarrow{Q_p}(y)$ represents the updated position of tunicate with respect to the position of food sources, $\overrightarrow{F_S}$

Step4: Swarm behavior

To mathematically imitate the swarm behaviour of tunicates, the first two optimal solutions remain intact, and the locations of the remaining SA are updated based on the optimal location of the SA. To describe the tunicate swarm behaviour, the following formula can be used:

$$Q_P\left(\overrightarrow{y} + 1\right) = \frac{\overrightarrow{Q_P}(y) + \overrightarrow{Q_P}(y+1)}{(2 + r_1)} \tag{40}$$

Further the flowchart for TSA is presented in Fig. 9.

3 Results and discussion

In the current work, the hourly forecasting of GHI, temperature, and W_S is carried out for one year by utilizing ML techniques, specifically SVR, GPR, XGBT, and DT. The obtained results have been compared with the help of statistical indicators, and the best solution has been determined for GPR. Further, the forecasted data obtained through GPR is used for sizing HRES. The sizing of HRES is carried out using the recently developed OT: CPA, TSA and AO using forecasted data and without forecasted data. MATLAB was used for CPA, TSA and AO algorithms to run hourly simulations over one year for a selected grid-linked HRES. The obtained results are compared based on minimal NPC with the reliability of the power supply. In addition, in view of developing HRES, a comparative analysis of various parameters obtained after size optimization using forecasted data and without forecasted data is performed, and the results of TSA with forecasted data are found to be more optimal with a reduction of 0.42% in COE.

3.1 Performance indicators for forecasting

It isn't easy to assess the accuracy of an FM without doing the performance assessment; therefore, statistical indicators have been used for the performance evaluation. The indicators that are employed for comparative research are termed Root Mean Square Error (RMSE), Mean Absolute Error (MAE), and Correlation Coefficient (R^2). The MAE measure is useful for determining FM prediction errors. The correlation coefficient reveals how closely two models are related to each other, whereas the RMSE indicator analyzes the model's overall accuracy.

3.2 Training and testing phase

The different FMs are trained using four years of data, i.e., 2016–2019 of wind, GHI and temperature. The training phase of FM offers a better understanding of the model's accuracy and is essential for selecting the best FM. Further, in the testing phase, also known as the real prediction stage, the GHI, temperature, and W_S are forecasted using the model effectively trained in the previous phase. To evaluate the effectiveness of the FM, each model uses 2020 data for prediction. The performance indicators for GHI, temperature, and W_S for the training and testing phases, respectively, have been determined and presented in Tables 1, 2, 3 respectively. From Tables 1, 2 and 3, it is apparent that the GPR method performs better for prediction out of all of these ML techniques. The GPR method performs better because the generated statistical indicators have the lowest possible value, while the R^2 has the highest possible value. Tables 1, 2, 3 shows that the GPR model has the lowest RMSE, MSE, and greatest R^2 for all training and testing phases, including GHI, temperature, and W_S. Therefore, the forecasted GHI, temperature, and W_S data obtained by the GPR approach have been used to develop HRES. Further, the prediction performance of the proposed models, along with meteorological or true data, is shown in Figs. 10a, 11a, and 12a. The comparative analysis of the errors for ML FM is presented in Fig. 10b, Fig. 11b and Fig. 12b.

3.3 Optimization results of proposed HRES

After obtaining the forecasted data for GHI, temperature and W_S, in the present work, the optimal grid-linked HRES, involving various RES, was developed to fulfil the energy needs of the given site based on minimal NPC. Three recently developed optimization approaches viz. TSA, CPA, and AO were applied to optimize the size of the selected HRES. Further, several economic input indicators used in obtaining the optimization outcomes are illustrated in Table 4. The hourly simulation for selected HRES has been conducted in MATLAB for one year. To facilitate this analysis, 150 iterations were performed. An Intel® Core TM i5-8250 was used to create and test the recommended optimizers. Further, the yearly real interest, inflation and escalation rates are fixed at 0.11, 0.075, and 0.05, respectively. The parameters of the TSA, CPA and AO algorithms are set as follows: TSA: maximum iteration = 150, SA = 30, CPA: maximum iteration = 150;

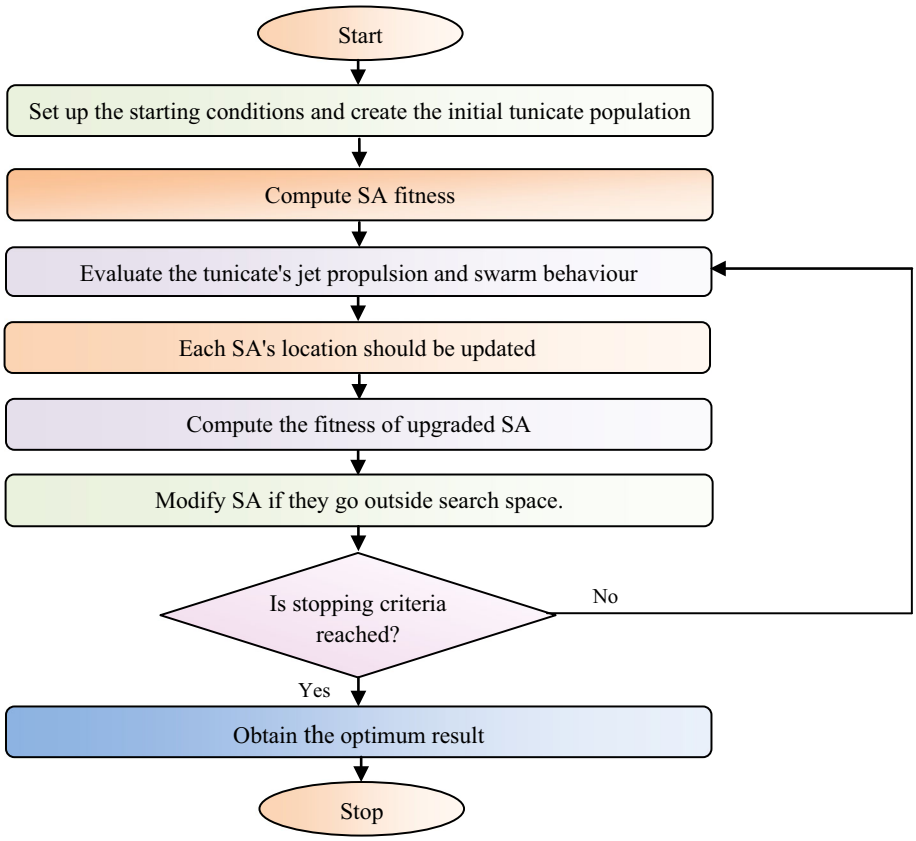

Fig. 9 Flowchart of TSA algorithm

XGBT	2.705954	2.16118	0.91144	2.694554	2.22985	0.913644

dimensions = 5; SA = 30; AO: exploitation adjustment coefficients; $\alpha = 0.1$; $\delta = 0.1$; Population size = 30, maximum iteration = 150.

Various indices obtained by applying TSA, CPA and AO algorithms with forecasted and without forecasted data have been presented in Table 5. By analyzing and comparing the obtained result presented in Table 5, it has been evident that, out of three OTs, TSA with forecasted data gives the most optimal results. It is also found that there is a 0.42% reduction in COE for the TSA model with forecasted data. The optimization result acquired for the selected grid linked HRES with their size using the forecasted data is shown in Table 6.

The contribution of various RES in yearly power production via TSA, CPA and AO has been obtained and illustrated

Table 3 Training and testing performance comparison for W_S

ML method	Training phase			Testing phase		
	RMSE	MAE	R^2	RMSE	MAE	R^2
DT	0.7351721	0.513848662	0.845943	1.1948515	0.88169812	0.836684

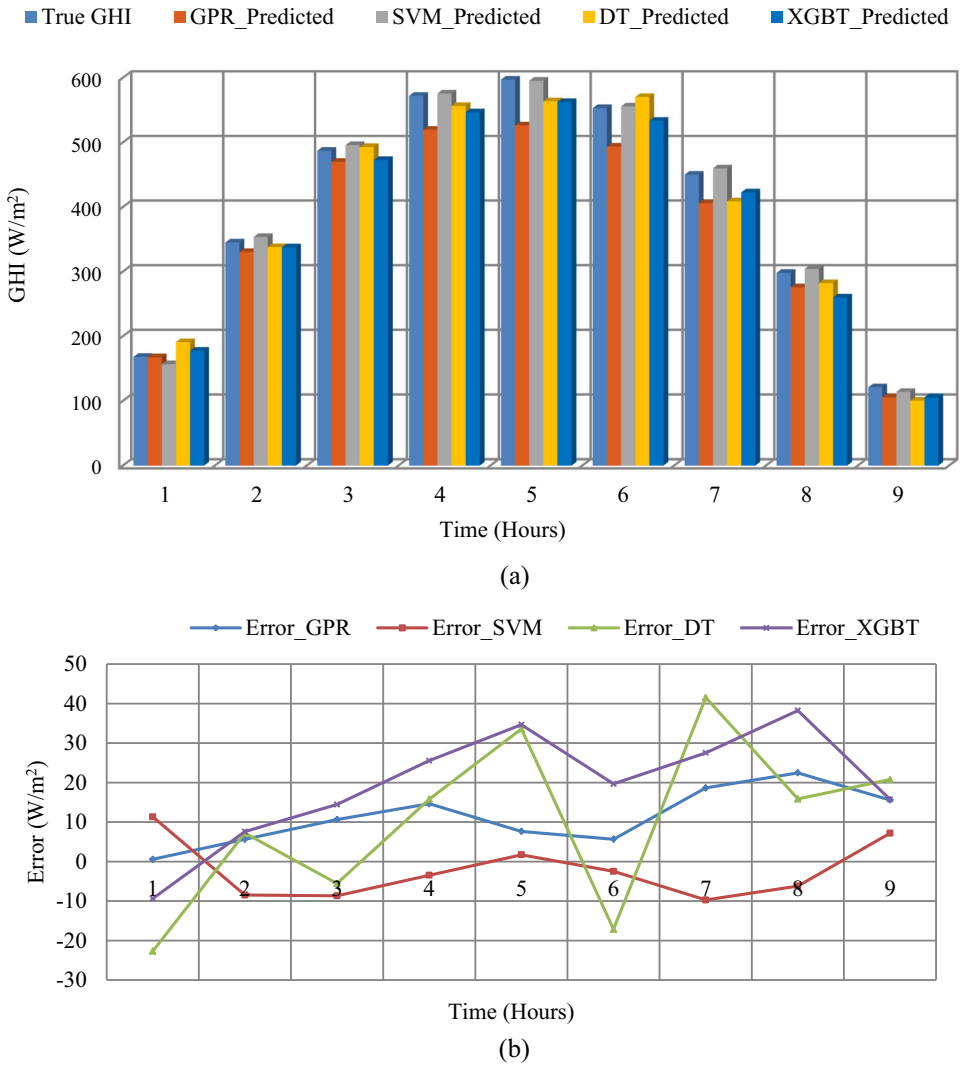

Fig. 10 Hourly forecast performance comparisons. **a** GHI. **b** Error

in Fig. 13. The result demonstrates that the SPV array generated the highest power in all three algorithms.

Furthermore, the contribution of various system elements to the NPC is demonstrated in Fig. 14. It was found that, in the case of TSA, the cost of the WT system was the highest, followed by BGG, SPV, battery, and BMG. However, for the CPA and AO algorithms, the highest share was for BGG, followed by WT, SPV, BMG, and battery. In addition, Fig. 15 shows the energy generated by different HRES components during one day.

A comprehensive statistical analysis for all three proposed techniques is provided in the present work. The best and worst values of the cost function, mean, median, standard deviation (SD), relative error (RE), RMSE, MAE, and efficiency were obtained and presented in Table 7 for CPA, TSA, and AO. As it is evident from Table 7 that the statistical indicators, RMSE,

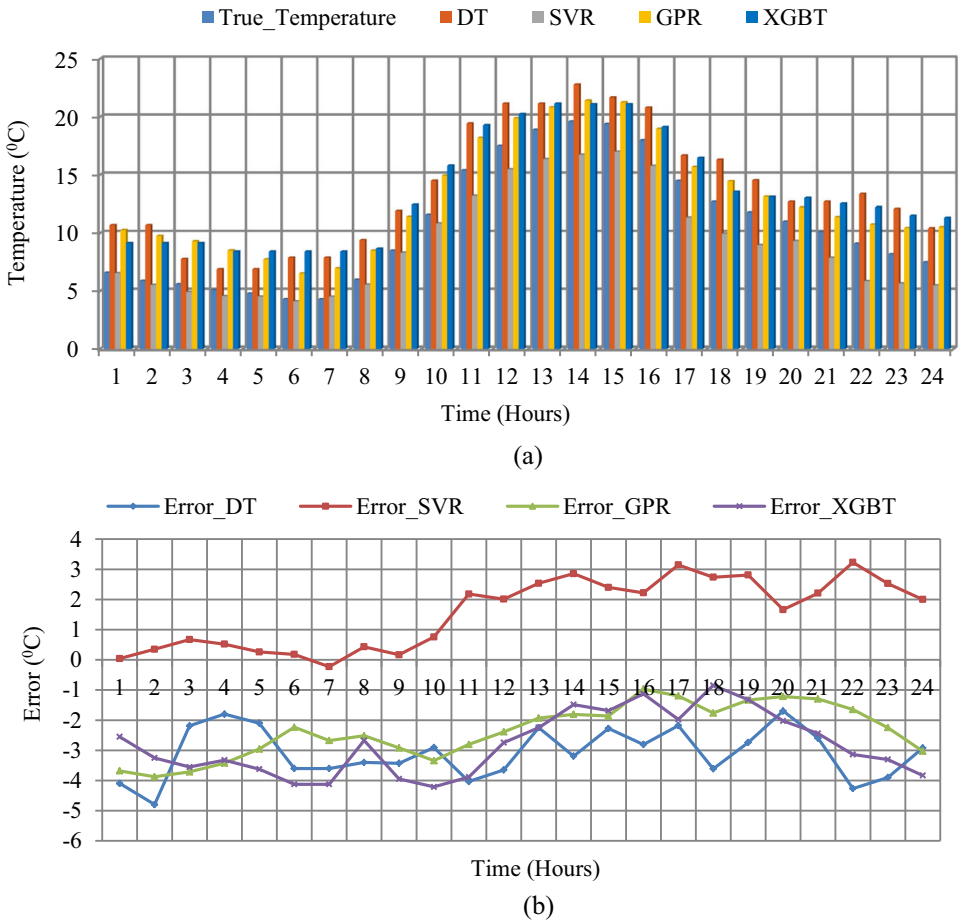

Fig. 11 Hourly forecast performance comparison. **a** Temperature. **b** Error

standard deviation (SD), MAE, and average RE are all minimum for TSA, while efficiency is highest when contrasted with CPA and AO, demonstrating the TSA's superiority over other algorithms.

Figure 16 depicts the convergence curves for the TSA, CPA, and AO algorithms of the proposed grid-connected HRES model. It can be seen that TSA and AO converged and produced a fixed value at iterations 16 and 32, respectively. However, at iteration 60, CPA stabilized at a constant value. Consequently, TSA has a higher convergence rate than AO and CPA.

Furthermore, the findings of the present research are summarized as follows:

- The four recommended ML techniques: GPR, SVR, XGBT, and DT, were used to forecast temperature, W_S and GHI.
- Based on the statistical indicators, the FM was contrasted, and GPR FM was identified as the best FM.
- The data obtained from GPR for GHI, W_S and temperature were used as input data for the size optimization of HRES components.
- The recently developed optimization algorithms: TSA, CPA, and AO were initially used to find the optimal size of HRES components using historical meteorological data. The optimization results were also obtained by TSA, CPA, and AO techniques using the forecasted GHI, W_S and temperature data obtained through the GPR approach.
- The findings of size optimization obtained through the forecasted data were compared with the results obtained for historical meteorological data. The size optimization results obtained using the forecasted data are more appealing due to low NPC and COE.
- Finally, the optimization results of TSA, CPA, and AO algorithms obtained using forecasted data are compared, and it was found that the TSA with forecasted data delivers an optimal solution with a reduction of 0.42% in COE.
- The sizes obtained for the different components of the optimal system include 282 kW of PV, 115.5 kW WT, 10 kW BGG, 25 kW BMG, and 36 kWh BESS.
- For the optimal design, the NPC and COE are estimated to be \$647,800 and \$0.0701/kWh, respectively.
- The share of SPV system is highest in energy generation with 61%, followed by WT, BGG and BMG with 24%, 10% and 5%, respectively.

BGG (1000 W)	572	28.6	171.6	6.93
BMG (1000 W)	895.267	44.763	268.58	13

4 Conclusion

In this research, the size optimization of HRES has been carried out for the outlying region of Mewat, India. Grid-connected configurations were designed and presented using the forecasted data for GHI, temperature, and W_S. The four ML methods: SVR, DT, GPR, and XGBT, were used for forecasting, out of which GPR performs better. Therefore, data obtained from GPR FM was used for the sizing of HRES. Further, the HRES was optimized using recently developed CPA, TSA, and AO algorithms. All three algorithms performed well and were suitable for the size optimization of the HRES; however, the sizes of the HRES components for the grid-connected scenario have been found most optimal via the TSA algorithm. The optimal HRES obtained from TSA included a 282 kW SPV, a 115.5 kW WT, a 10 kW BGG, a 25 kW BMG, and a 36 kWh battery bank. The COE and overall NPC costs were anticipated to be 0.0701 $/kWh and $647,800, respectively. The findings of this study can be utilized to create HRES for locations with similar geographic characteristics, which can improve the lifestyle of people in

Table 5 Results of Optimization for forecasted data and without forecasted data

Parameters	TSA		CPA		AO

rural areas by providing an uninterrupted power supply. This research can also help to some extent to fulfill the goal of the Indian government's "power to all" with its availability 24 × 7.

The current research could be extended in the future by including the following:

- Other regions in various towns, districts, states, and other administrative divisions with areas that contain hydro resources in addition to solar, wind, and biomass can be researched.
- The proposed FM also benefits future possibilities for smart grid demand response applications and energy management.

- Further study can use other storage technologies, such as PHS and fuel cells.
- Moreover, hybrid methods combining metaheuristic and ML techniques can be developed to forecast RES.

Author contributions Professors M. Rizwan and P. Anand supervised and provided ideas for this research. Bandana Sharma has authored and compiled all of the study data used to reach at the conclusions. All of the authors read and the final manuscript was approved by all authors.

Optimal Shade Dispersion Strategy for Enhanced PV Power Extraction Under PSCs

Ranjeet Singh, Vinod Kumar Yadav, *Senior Member, IEEE* and Madhusudan Singh, *Senior Member, IEEE*

***Abstract*—This article proposes a static optimal shade dispersion (SD) strategy to alleviate the mismatch loss (ML) by uniformly dispersing the shade over the entire photovoltaic (PV) array. The proposed generalized module repositioning approach (GMRA) is valid for any $i \times j$ array dimensions, for $i = j$ or $i \neq j$, i and j being the number of rows and columns, respectively, and can assume even, odd, or both values. To extract optimal power from a series-parallel (SP) PV configuration under mismatch conditions, a variant of the proposed GMRA (SP-GMRA) is also presented. The module locations of the total-cross-tied (TCT) and SP-configured PV array are changed using GMRA and SP-GMRA respectively without altering the terminal electrical connections. Simulations are performed on a 9×9 PV array under four common shade occurrences, followed by experimental validation on symmetrical 5×5 and unsymmetrical 6×4 configurations to demonstrate the applicability and generalization of the proposed approach to varied array sizes. The proposed scheme is compared to a wide range of recently published state-of-the-art reconfiguration methods for performance evaluation both on simulation and hardware platforms. The proposed technique outperforms all other reconfiguration schemes and yields up to 76.3 % and 27 % lower ML compared to TCT and SP configurations, respectively.**

***Index Terms*--mismatch loss (ML), shade dispersion, partial shading conditions (PSCs), power generation, module relocation.**

I. Introduction

ATTAINMENT of energy independence depends mainly on the extent of power extraction from non-conventional energy sources. Among all available renewable energy sources, such as wind, hydro, solar, geothermal, and tidal, solar energy is considered as most promising in the world's progression toward clean and sustainable energy [1]. The wide acceptance of photovoltaic (PV) systems worldwide is attributed to the decrease in the manufacturing price of PV cells and recent developments in power transformation technology [2], [3]. However, one of the predominant issues faced by PV systems that very often impedes their optimal utilization is partial shading conditions (PSCs) [4], [5]. PV system experiences a decline in efficiency and performance because of PSCs [6],[7]. PSCs adversely affect PV array optimal utilization due to shade being cast upon by moving clouds, dust deposition, close communication lines trees, and houses nearby modules, thus causing a mismatch in generated current by various modules of the same array [8].

Under steady irradiance conditions (SICs), the presence of a distinct peak power point (PPP) makes it easier for the conventional PPP tracking algorithms to converge at the unique peak power operating point for optimum power extraction [9], [10]. Contrarily, under PSCs, uneven irradiance exposure to various array modules generates several peaks in power–voltage (P-V) characteristics. Subsequently, it causes mismatch losses (ML) [11]. Numerous approaches have been presented in the literature to access global peak (GP) under mismatch conditions [12]–[14]. The power extraction from the PV array under PSCs is a function of the shaded area, the position of shaded modules, shade patterns, and array interconnections.

Several conventional PV array interconnections, such as series-parallel (SP), honey-comb (HC), bridge link (BL), and total cross-tied (TCT), are utilized to reduce ML [15]. TCT arrangement shows improved response under PSC by restricting ML to a lower value than other configurations, thereby generating more output power. However, TCT suffers from non-uniform row current under mismatch conditions and causes multiple peaks in the power curve resulting in additional power loss [16]. The limitations of the conventional PV array configurations made it extremely important for researchers to look for new shade-resilient configurations for optimal PV power extraction. The electronic sensors and switches-based reconfiguration schemes, commonly referred to as electronic array reconfiguration (EAR) or dynamic reconfiguration approach (DRA), have also been reported [17], [18]. Here, electrical connections of the shade-affected modules within an array are dynamically reorganized to counter the shading effects. Although such reorganization approaches result in optimal shade dispersion (SD) in most cases, the complexity and cost involved in an extensive PV network limit their on-field deployment. The shortcomings of EAR approaches are overcome by static reconfiguration approaches having fixed electrical connections of the modules [19]–[25]. These approaches do not necessitate complex circuitry involving a network of sensors, switches, and intricate reconfiguration algorithms thus offering an economical option for efficient SD.

A twisted two-step repositioning approach (TTSA) was proposed for improved PV power extraction under PSCs for

9×9 PV array arrangement [26]. The rearrangement method allows the repositioning of PV modules to any location within an array. However, deviation from fixed column arrangement results in additional wiring/line losses as modules no longer remain serially connected. These losses are bound to increase manifold and dominate in extensive PV array networks. The image encrypted-based reconfiguration approach chaotic baker map (CBM) is not universally compatible with all array sizes (only valid for symmetrical array configurations) and hence severely limits its scalability [6]. Additionally, its SD is poor for odd symmetrical array sizes. Although applicable to all array sizes, the odd-even prime (OEP) [7] approach exhibits poor SD and multiple peak generations in the power curve. A Parquet SudoKu (PRS) approach was proposed for a 9×9 PV array [27]. The PRS technique is superior to many puzzle-based schemes because it disperses shade uniformly without repeating PV modules in adjacent subarrays. However, like other static reconfiguration techniques [8], [19], [20], [22], [23], [26], PRS has limited applicability for PV arrays of varying sizes, which makes it challenging for on-field deployment. Additionally, all of the aforementioned approaches, including PRS, reconfigured the modules initially connected in a TCT arrangement without considering other prominent array interconnections such as series-parallel (SP), which is the most widely employed connection nowadays along with TCT [15], [28]. In [15], the authors have proposed a different SD configuration for an SP connection. However, the reported technique failed to generate more power beyond that of the SP connection.

To address the limitations of the aforementioned approaches, a novel static optimal SD strategy designated as generalized module repositioning approach (GMRA) is proposed for enhanced power extraction under PSCs. Unlike previously reported methods, to extract enhanced power output from an SP-configured PV array under PSCs, a variant of the proposed algorithm designated as SP-GMRA is also suggested in this article. Another significant contribution of the proposed work, missing in the majority of the previously reported works, is the universal applicability of the proposed approach to any *i*×*j* PV array, where *i* and *j* represent the number of rows and columns respectively, for *i*=*j* or $i \neq j$ where *i, j* can take even, odd, or both values. At the time of installation, the modules of the traditional TCT and SP arrangements are repositioned only once, with the electrical connections remaining unchanged. The proposed reconfiguration strategy is the improved alternative for enhanced output yield in a typical 9×9 array arrangement over benchmark puzzle-based rearrangement strategies. The applicability of the proposed approach is initially tested through simulation utilizing MATLAB/Simulink on a 9×9 PV array and later experimentally validated on an outdoor hardware setup comprising 25 PV modules interconnected in a symmetrical 5×5 and unsymmetrical 6×4 PV array arrangements. Different ratings of modules are selected for simulation and experimental analysis to demonstrate the application of GMRA and SP-GMRA across varying power levels. Four different commonly occurring shading scenarios: bottom right corner (BRC), top right corner (TRC), top left corner (TLC), and bottom left corner (BLC) are selected to extensively investigate the performance of the proposed approach on a PV array exposed to shading on different sections. Artificial shading scenarios are generated using different layers of transparent plastic sheets imitating intense and moderate shading events. Recent state-of-the-art reconfiguration methods are selected for simulation and experimental validation. This allows for the performance comparison of the proposed SD strategy with recent reconfiguration methods. The proposed reconfiguration strategy is simple and does not require any complex network of switches and sensors, even for large-sized PV installations.

The remainder of the paper is structured as follows: the upcoming section elucidates the electrical behavior of a PV array under various operating conditions, followed by the description of different PV array configurations in section III. The simulation and experimental validation of the proposed GMRA and SP-GMRA is reported in section IV, followed by efficiency estimation and techno-economic analysis in section V. The conclusions are finally drawn in section VI.

II. Electrical Characteristics of a PV Array

Understanding the electrical behavior of PV arrays under various operating scenarios and the underlying principles of optimal SD is essential for developing an efficient SD strategy for maximizing power harvesting from a PV array. The PV array displays intriguing behavior as a result of high correlations with numerous external parameters, with temperature and irradiance standing out as the most significant. The modeling of a PV array and its response is considered next.

A. Steady Irradiance Condition (SIC)

Several PV cells connected serially make up a PV module. The single-diode model shown in Fig. 1(a) is employed in this work [20]. The voltage (V_G) and generated current (I_G) of a PV module are related:

$$I_G = I_L - I_{rev}\left[exp\left(\frac{V_G + R_s I_G}{kV_{Th}}\right) - 1\right] - \frac{V_G + R_s I_G}{R_p} \tag{1}$$

where I_L is the module's light-induced current, I_{rev} is the reverse saturation current of the electrical diode equivalent, k is ideality factor, V_{Th}, represents thermal voltage. Further, R_s and R_p represents module equivalent series, and shunt resistances respectively. Since the light-induced current, I_L in (1) is dependent on irradiance, S_a and temperature, T [21], the panel-generated current I_G is also expressed as

$$I_G(S_a, T) = I_{SC,0}\left(\frac{S_a}{S_{as}}\right)\left[1 + \gamma\left(T - T_s\right)\right]\frac{\left(R_s + R_p\right)}{R_p} \tag{2a}$$

where $I_{SC,0}$ is the module's current corresponding to the short circuit at standard irradiance and temperature conditions $\left(S_{as} = 1000\, W/m^2;\, T_s = 25\,^0C\right)$ and γ represents the temperature-dependent constant of the module's current.

$$I_G = I_{SC,0} \times \left(\frac{S_a}{S_{as}}\right) = \alpha \times I_{SC,0} \quad \forall T = T_s \tag{2b}$$

where the shading ratio, $\alpha = \left(\frac{S_a}{S_{as}}\right), \alpha \in [0,1]$ where $\alpha = 1$ and $\alpha = 0$ corresponds to a fully illuminated and completely shaded

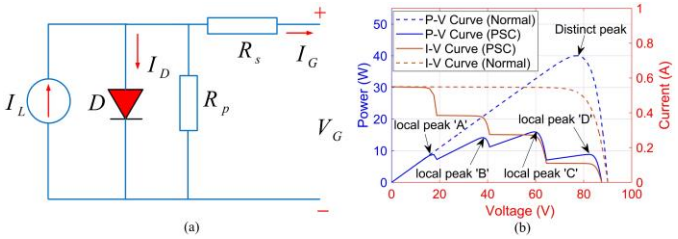

Fig. 1. (a) Electrical circuit model of a PV cell (b) PV electrical characteristics under SIC and PSCs (multiple peak generation).

module respectively. The I-V characteristic equation under SIC for any arbitrary-sized array comprising N_s series modules in each N_p shunt connections is as follows:

$$I_{pv} = N_p \times \left(I_L - I_{rev}\right)\left[exp\left(\frac{V_G + \frac{N_s}{N_p} R_s I_G}{k N_s V_{Th}} \right) - 1 \right] + \frac{V_G + \frac{N_s}{N_p} R_s I_G}{\frac{N_s}{N_p} R_p} \quad (3)$$

Using equations (1), (2), and (3), the PV module and array considered in this work are modeled.

B. Under PSCs

The bypass diode (BPD) gets activated due to radiation mismatch among modules under PSCs. BPDs provide an alternate path for the current to flow, thus bypassing the shaded module and averting its possible damage due to hotspot formation, though not completely. This results in the formation staircase I-V curve with the appearance of multiple peaks in the resultant P-V curve [5]. Fig. 1(b) shows typical electrical characteristics of a PV array under SIC and PSC.

C. Estimation of ML for Optimal SD

For any $i \times j$ PV array arrangement, to quantify the effectiveness of any SD strategy, estimation of ML is vital and can be obtained from the difference between the resultant sum of individual maximum generated module powers and the total array power under PSCs as follows:

$$ML = \sum_{q=1}^{i \times j} P_{m,q} - P_{array} \quad (4)$$

where $P_{m,q}$ and P_{array} are, respectively, the optimal generated powers from the q^{th} module and the entire PV array under PSCs. Fig. 2 (a) shows a typical 2×2 shading event on a 4×4 PV array with 4 modules under the impact of shading. The array can be partitioned into four individual groups connected serially, each having four parallel PV units. Here, the current generated by the unshaded and shaded modules is I_G and αI_G respectively. As mentioned earlier, 'α' is the shading ratio. The optimal SD achieved after module reconfiguration is shown in Fig. 2(b). The ML is estimated under two cases:

1) Case I- 4×4 TCT array under 2×2 shading (Prior SD):

Two modules each in groups III and IV are shaded. The 12 unshaded modules and 4 shaded modules individually generate maximum powers of $(12V_G \times I_G)$ and $4\alpha I_G \times V_G$ respectively. For the estimation of the global peak power of the PV array, P_{array}, first, the currents of the individual groups of the array are determined. Since different groups contribute different currents, the existence of multiple peaks in the PV curve is inevitable. The panels in group IV will be bypassed first, followed by group-III, II, and finally group-I having voltages of $4V_G$, $3V_G$, $2V_G$, and V_G respectively. The array peak power under this condition is estimated to be $8V_G \times I_G(1+\alpha)$. The ML using (4) can be estimated as:

$$ML\big|_{4\times4}^{prior\ SD} = \underbrace{\left[(12V_G \times I_G) + 4\alpha I_G \times V_G\right]}_{\sum_{q=1}^{4\times4} P_{m,q} \quad \forall\ q=1,2,3...16} - \underbrace{\left[8V_G \times I_G(1+\alpha)\right]}_{P_{array}} \quad (5a)$$

$$= 4(1-\alpha)V_G \times I_G$$

2) Case II- 4×4 PV array modules reconfigured to obtain optimal SD using a repositioning approach (Post SD):

Post application of the SD approach, the shade gets dispersed across various rows of the PV array, thus minimizing the group current difference. Each group now has only one shaded module. The resultant ML can be estimated as before:

$$ML\big|_{4\times4}^{post\ SD} = \underbrace{\left[(12V_G \times I_G) + 4\alpha I_G \times V_G\right]}_{\sum_{q=1}^{4\times4} P_{m,q} \quad \forall\ q=1,2,3...16} - \underbrace{\left[4V_G \times (3+\alpha) \times I_G\right]}_{P_{array}}$$

$$= 0 \quad (5b)$$

In this manner, an effective SD strategy disperses any shade pattern to alleviate the ML, thus ensuring the optimal utilization of the PV array arrangement. Fig. 2(c) shows the variation in ML as a function of shading ratio, α, prior and post SD. It can be observed that post-SD, the ML decreases considerably.

III. Description Of PV Array Configurations

A. PV Array in TCT Configuration

The power extraction from a PV array configured in a TCT arrangement is analyzed under various PSCs. The output voltage and current extracted from a $i \times j$ TCT-arranged PV array can be expressed as given by

$$I_{pv} = \sum_{q=1}^{j} I_{G,pq} \quad \forall\ p = 1, 2, ..., (i-1) \quad (6)$$

$$V_{pv} = \sum_{p=1}^{i} V_{G,pq} \quad \forall\ q = 1, 2, ..., (j-1) \quad (7)$$

The following equation gives the two representations of the PV array used in this work:

$$M_{i\times j} = \underbrace{\begin{matrix} C_1 & C_2 & C_3 & C_j \\ \overbrace{\quad\quad\quad\quad}^{Columns} & & & \end{matrix}}_{} \underbrace{\begin{bmatrix} 11 & 12 & 13\cdots1j \\ 21 & 22 & 23\cdots2j \\ \vdots & \vdots & \vdots\cdots\vdots \\ i1 & i2 & i3\cdots ij \end{bmatrix}}_{Form-I\ \ i\times j} = \underbrace{\begin{matrix} C_1 & C_2 & C_3 & C_j \\ \overbrace{\quad\quad\quad\quad}^{Columns} & & & \end{matrix}}_{} \underbrace{\begin{bmatrix} 1 & 1 & 1\cdots1 \\ 2 & 2 & 2\cdots2 \\ \vdots & \vdots & \vdots\cdots\vdots \\ i & i & i\cdots i \end{bmatrix}}_{Form-II\ \ i\times j} \quad (8)$$

The module parametric specifications at standard test condition (STC) employed for simulation and experimental analysis are listed in Table I.

B. Proposed GMRA and SP-GMRA for Optimal SD

In any PV array arrangement, each PV module position can be identified by a definite row and column index value as depicted in (8). For instance, module position '$1j$' corresponds

to a row index value '1' and column index value ' j '. Only the row indices are modified in the proposed GMRA, while the column indices remain unaltered.

1) Case I: $i \times j$ PV array, where, i= odd number:

Step 1: Identify the primary column, C_k , in the PV array, where $k = \left\lceil \frac{j}{2} \right\rceil$, the ceil operator '$\lceil\ \rceil$', rounds a real number to the lowest next integer. Next, arrange the primary column row index values sequentially in ascending order as shown in (9). Steps 2 and 3 describe the further restructuring of the PV array located to the right and left of the primary column, respectively.

$$M_{r,i\times j} = \begin{array}{c} \begin{matrix} C_1 & \cdots & C_{k-1} & C_k & C_{k+1} & C_{k+2} & \cdots & C_j \end{matrix} \\ \begin{bmatrix} \frac{3}{2}m-1 & \cdots & m-1 & 1 & m & 2 & \cdots & \frac{m}{2} \\ \frac{3}{2}m & \cdots & m & 2 & m+1 & 3 & \cdots & \frac{m+2}{2} \\ \vdots & \cdots & \vdots & \vdots & \vdots & \vdots & \cdots & \vdots \\ \frac{m+2}{2} & \cdots & 1 & m & 2 & m+1 & \cdots & \frac{3}{2}m-1 \\ \frac{m}{2}+2 & \cdots & 2 & m+1 & 3 & m+2 & \cdots & \frac{3}{2}m \\ \vdots & \cdots & \vdots & \vdots & \vdots & \vdots & \cdots & \vdots \\ \frac{3}{2}m-2 & \cdots & m-2 & j & m-1 & 1 & \cdots & \frac{m-2}{2} \end{bmatrix}_{i\times j} \end{array} \quad (9)$$

Step 2: Divide the entire PV array located to the right of the primary column, C_k , including the primary column itself, into two groups i.e. top and bottom w.r.t row index values. The bottom group starts with the m^{th} row index of the primary column, where $m = \left\lceil \frac{i}{2} \right\rceil + 1$ and continues sequentially until the last row index in the column. The remaining row index values of the primary column constitute the top group. The row index values in the subsequent column, C_{k+1} are obtained by replacing the top and bottom group row index values of the column with the bottom and top group row index values of the preceding column, C_k , respectively in a sequential order and so on.

Step 3: Divide the entire PV array located to the left of the primary column, C_k , including the primary column itself, into two groups i.e. top and bottom w.r.t row index values. The bottom group starts with the $(m-1)^{th}$ row index value of the primary column, C_k , and continues sequentially until the last row index in the column. The remaining row index values of the primary column constitute the top group. The row index values in the preceding column, C_{k-1} are achieved by replacing the top and bottom group row index values of the column with the bottom and top group row index values of the subsequent column, C_k , respectively in a sequential manner and so on.

Likewise, the row index values of the remaining columns are obtained following the aforementioned steps and the final reconfigured TCT array using GMRA is obtained. After the application of GMRA, a 9×9 PV array is shown in (10).

$$M_{r,9\times9} = \begin{array}{c} \text{Columns} \\ \begin{matrix} C_1 & C_2 & C_3 & C_4 & C_5 & C_6 & C_7 & C_8 & C_9 \end{matrix} \\ \begin{bmatrix} 81 & 42 & 93 & 54 & 15 & 66 & 27 & 78 & 39 \\ 91 & 52 & 13 & 64 & 25 & 76 & 37 & 88 & 49 \\ 11 & 62 & 23 & 74 & 35 & 86 & 47 & 98 & 59 \\ 21 & 72 & 33 & 84 & 45 & 96 & 57 & 18 & 69 \\ 31 & 82 & 43 & 94 & 55 & 16 & 67 & 28 & 79 \\ 41 & 92 & 53 & 14 & 65 & 26 & 77 & 38 & 89 \\ 51 & 12 & 63 & 24 & 75 & 36 & 87 & 48 & 99 \\ 61 & 22 & 73 & 34 & 85 & 46 & 97 & 58 & 19 \\ 71 & 32 & 83 & 44 & 95 & 56 & 17 & 68 & 29 \end{bmatrix}_{9\times9} \end{array} \quad (10)$$

Step 4: To obtain the final reconfigured SP PV array using SP-GMRA, the row and column index values obtained using GMRA are interchanged before implementation on an SP configuration. This means that the module positions identified as '81', '45', and '36' in GMRA marked by dotted circles in (10) correspond to '18', '54', and '63' respectively in SP-GMRA, and so on.

2) Case II: $i \times j$ PV array, where i= even number:

Step 1: Identify the primary column, C_k , in the PV array, where $k = \frac{j}{2} + 1$ *for* $j =$ *even number* , and $k = \left\lceil \frac{j}{2} \right\rceil$ *for* $j =$ *odd number* . Next, sequentially arrange, C_k , row indices in ascending order.

Step 2: Divide the entire PV array into two halves (groups) including the primary column, C_k , w.r.t row indices.

Step 3(a): The module positions for the subsequent column, C_{k+1} is achieved by replacing the top and bottom group row index values in the column with the bottom and top group row indices of the preceding column, C_k , respectively, and so on.

Step 3(b): The module positions for C_{k+2} are achieved by first shifting the row index values in an anticlockwise manner, beginning with the bottom-most member for each group of the preceding column C_{k+1}, followed by the replacement of the top and bottom group row index values of the column with bottom and top group row index values of the preceding column, C_{k+1} ,

respectively. This is done to avoid any repetition of the columns. The same procedure is applied for the remaining columns positioned to the right.

***Step 4(a)*:** The row indices for C_{k-1} and preceding columns except C_1 is achieved by following the same procedure as described above in step 3(b).

***Step 4(b)*:** The first column, C_1 row indices are obtained by performing a similar operation on the column C_2 as described in step 3(a). This step is followed for all array configurations of the form $i \times j$, where $i = j$ or $i \neq j$. An unsymmetrical 6×4 PV array is repositioned and represented in (11) post-GMRA.

$$M_{r,6\times4} = \begin{array}{c} \begin{array}{cccc} C_1 & C_2 & C_3 & C_4 \end{array} \\ \left[\begin{array}{cccc} 3\,\text{C} & 6\,\text{C} & 1\,\text{A} & 4\,\text{A} \\ 1\,\text{A} & 4\,\text{A} & 2\,\text{B} & 5\,\text{B} \\ 2\,\text{B} & 5\,\text{B} & 3\,\text{C} & 6\,\text{C} \\ 6\,\text{C} & 3\,\text{C} & 4\,\text{A} & 1\,\text{A} \\ 4\,\text{A} & 1\,\text{A} & 5\,\text{B} & 2\,\text{B} \\ 5\,\text{B} & 2\,\text{B} & 6\,\text{C} & 3\,\text{C} \end{array}\right]_{6\times4} \end{array} \tag{11}$$

The circuit arrangement of the TCT configuration and proposed GMRA for a 5×5 PV array with fixed electrical connections is shown in Fig. 3(a) and (b) respectively.

IV. Simulation Results and Hardware Implementation

To validate the efficacy and robustness of the proposed GMRA and SP-GMRA, PV arrays configured in the two most prominently employed topologies viz. TCT and SP are examined. A scaled-down experimental setup was established, as shown in Fig. 4, for hardware validation under different shading scenarios. The experimental arrangement comprises 25 identical PV modules, multimeters, rheostats, and a solar power meter. Simulations are performed on a 9×9 PV array, followed by experimental validation on symmetrical 5×5 and unsymmetrical 6×4 configurations to demonstrate the applicability and generalization of the proposed approach to varied array sizes.

A. Simulation and Performance Analysis

The proposed GMRA's performance is evaluated against the benchmark TCT configuration and three recently published state-of-the-art reconfiguration methods i.e. CMAP [6], PRS [27], and TTSA [26] under four different shading cases i.e. BRC, TRC, TLC, and BLC. Fig. 5 and 6 respectively show the SD performance and power voltage characteristics of a 9×9 PV array with different reconfiguration approaches under the impact of aforementioned shading scenarios. The comparative performance evaluation is done utilizing four important performance metrics such as fill factor (FF), mismatch loss (ML), execution ratio (ER), and power enhancement. Additionally, the performance metrics of SP-GMRA are also evaluated against the commonly employed SP configuration. The power enhancement is assessed against TCT and SP configurations for GMRA and SP-GMRA respectively. Table II gives a comparative performance estimation of the proposed approach in terms of the aforementioned performance metrics against TCT, CMAP, PRS, TTSA, and SP. To comprehensively examine the overall performance of the proposed technique under different shading scenarios, the average values of various performance metrics from Table II are considered.

1) Fill factor (FF): It is a measure of the squareness of the I-V characteristics under PSCs, hence an extremely important metric for quantifying the effectiveness of any SD approach. The proposed GMRA produced on average, 12.76 %, 12.76 %, 3.87 %, and 2.14 % higher FF than TCT, CMAP, PRS, and TTSA arrangements respectively under all considered shade cases. Additionally, on reconfiguring the traditional SP configuration using the proposed SP-GMRA, on average 7.1 % higher FF was achieved.

2) Mismatch Losses (ML): The ML is estimated similarly as described earlier in (5a) and (5b). On taking the average of all ML values under different shading cases, the proposed GMRA generates 76.3 %, 76.2 %, 51.2 %, and 37 % lower ML compared to TCT, CMAP, PRS, and TTSA configurations respectively. Moreover, the SP-GMRA arrangement generates 27 % lower ML than the SP array.

3) Execution Ratio (ER): The average ER obtained with TCT, CMAP, PRS, and TTSA is 76.5 %, 76.5 %, 83.0 %, and

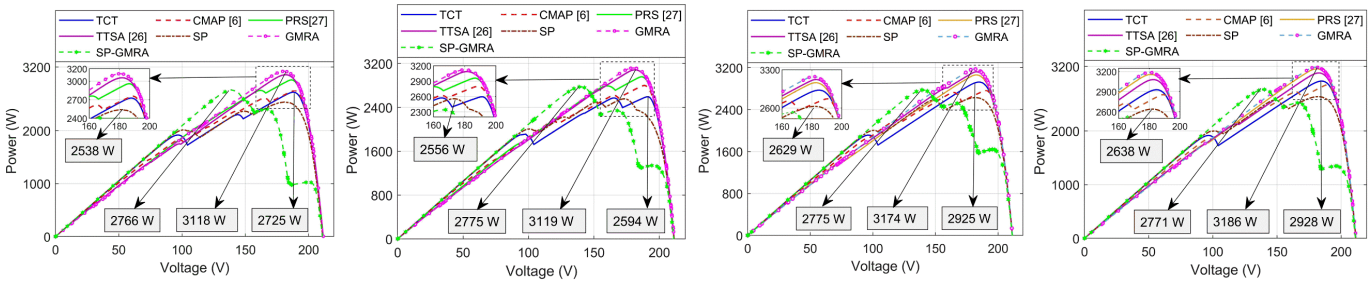

Fig. 6. Simulated power-voltage characteristics of 9×9 PV array under different shading scenarios (a) BRC (b) TRC (c) TLC (d) BLC.

84.48 % respectively. On the contrary, the proposed GMRA exhibits an average ER of 86.2 %. The SP-GMRA offers ER on average, 7% higher than traditional SP configuration.

4) Power Enhancement: The proportionate power enhancement w.r.t TCT is used as a measure to evaluate the relative performance of the proposed GMRA method with CMAP, PRS, and TTSA, while for the SP-GMRA, the performance enhancement is evaluated w.r.t to SP configuration as shown in Table II. On average, the power enhancement attained w.r.t TCT configuration using CMAP, PRS, TTSA and proposed GMRA is 0.03 %, 9.02 %, 10.41%, and 12.75% respectively. Additionally, the power enhancement of 7% is achieved when SP-GMRA arrangement is used over SP connection under different shading conditions. In addition to SD, the row current computations are also shown for the proposed scheme (refer Fig. 5). The proposed scheme produces uniform row (group) currents throughout the array and consistently exhibits the best SD in all cases. As evident from Table II, the proposed scheme outperforms all other reconfiguration methods on prominent performance metrics. The simulated power-voltage characteristics under different shading conditions are shown in Fig. 6. The global peak powers attained with TCT, SP, GMRA, and SP-GMRA configurations are also highlighted. The TCT and SP array generates the highest global peak powers when the PV arrays are reconfigured using GMRA and SP-GMRA respectively. Among all considered reconfiguration approaches, the proposed technique exhibits clear dominance.

B. Hardware Implementation

Commercial-grade transparent plastic sheets (200 microns) are utilized to generate artificial shading scenarios. Multiple layers of sheets are employed to create 'intense' and 'moderate' shading profiles (refer Fig. 4). 25 PV modules of 10 W each are configured in symmetrical 5×5 and unsymmetrical 6×4 arrangements. Four common shading profiles were created i.e. BRC, TRC, TLC, and BLC on the two considered PV arrangements configured in TCT and SP configurations. The hardware validation of the performance of the proposed GMRA

This article has been accepted for publication in IEEE Transactions on Power Electronics. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TPEL.2023.3307813

is performed against many popular and recently published state-of-the-art methods i.e. PRFCM [5], OEP [7], TT [15], FUT [21], DS [24], COL [25]. Fig. 7 and 8 shows the experimental power-voltage characteristics of 5×5 and 6×4 PV array under predefined shading conditions. SP-GMRA configuration is tested against conventional and more common SP configuration. Under all shading conditions, the proposed approaches, GMRA (reconfigured TCT) and SP-GMRA (reconfigured SP) generated the highest peak power points against all other reconfiguration methods and SP configuration respectively as evident from Fig. 7 and 8. The average power enhancement of 29.55 % and 22.3 % respectively is attained using the proposed GMRA against TCT arrangement under all considered shading conditions for 5×5 and 6×4 PV arrays. Similarly, compared to the SP configurations, 7.93 %, and 10.9 % higher peak power is extracted using SP-GMRA when tested on 5×5 and 6×4 arrangements respectively.

V. Efficiency Computations and Techno-economic Feasibility Study

A. Calculation of Efficiency

The accurate assessment of the efficiency plays a crucial role in effectively comparing different reconfiguration schemes for the PV system under PSCs. For any $i \times j$ PV array arrangement, the efficiency, $\eta|_x^y$, can be estimated as depicted in (12).

$$\eta|_x^y = \frac{GMPP|_x^y}{\left(\sum_{m=1}^{i}\sum_{n=1}^{j} S_{mn}\right) \times A_p} \quad \begin{matrix} \forall\ m = 1,\ 2,\ 3,\ \ldots,\ i \\ \forall\ n = 1,\ 2,\ 3,\ \ldots,\ j \end{matrix} \qquad (12)$$

where 'x' and 'y' denotes the shading scenario and PV configuration respectively. Additionally, '$S_{mn}(W/m^2)$' represents the irradiance input received by the module located at m^{th} row and n^{th} column and $A_p(m^2)$ denotes the area of the individual module, which is 0.285 m^2 (from Table I). Using (12), the efficiency calculations for TCT, CMAP [6], PRS [27], TTSA [26], SP, GMRA, and SP-GMRA under BRC, TRC, TLC, and BLC shading conditions (see Fig. 5), are performed. Fig. 9 illustrates the comparative performance in terms of system efficiency yields for a 9×9 PV array utilizing different

TABLE III
Efficiency of 9×9 PV Array Under Different Shading Scenarios

Shading scenario	PV configuration	Efficiency (%)	Shading scenario	PV configuration	Efficiency (%)
BRC	TCT	14.77	TRC	TCT	14.06
	CMAP [6]	14.94		CMAP [6]	15.17
	PRS [27]	16.02		PRS [27]	16.04
	TTSA [26]	16.54		TTSA [26]	16.72

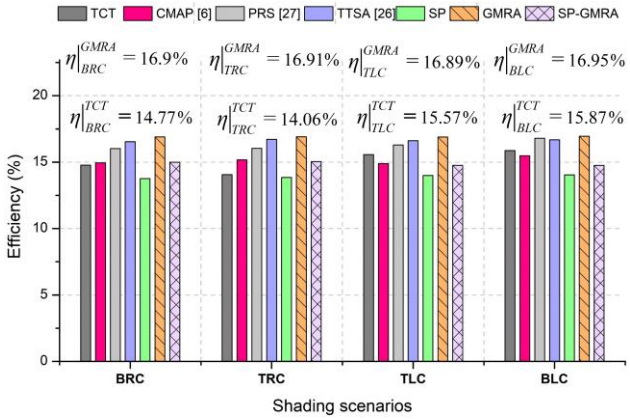

Fig. 9. Comparative efficiency yield of various PV configurations for a 9×9 PV array under different PSCs.

reconfiguration methods. The efficiency values, $\eta|_x^{TCT}$ and $\eta|_x^{GMRA}$ corresponding to TCT and GMRA configurations respectively under different shading scenarios, 'x', are also highlighted for clarity. The proposed GMRA yields the highest efficiency under all considered shading scenarios as evident from Table III. On average, 12.28 % higher efficiency is attained under all considered shading conditions using the proposed GMRA compared to the conventional TCT arrangement. SP-GMRA results in 7% higher efficiency compared to the traditional SP configuration when average values under all shading schemes were considered.

B. Techno-economic Analysis

The energy yield calculations for TCT, CMAP [6], PRS [27], TTSA [26], and the proposed GMRA technique are performed based on total power extracted after reconfiguration, considering full effective sun hours. The evaluation is performed on a 9×9 PV array of capacity 4.05 kW considering 4 different aforementioned shading scenarios (refer Table I for module specifications). Each shading scenario is assumed to occur for a duration of 10 minutes consecutively within an effective sun hour period of 8 hours, as depicted in Table IV. Furthermore, the revenue generated by the plant is estimated by considering a tariff rate of Rs. 15 per unit. As evident from Table V, the proposed reconfiguration scheme leads to the highest energy yield and therefore generates the highest annual

10-11	2837.5	2799.5	3058.1	3089.3	3159.5
11-12	2748.5	2788.5	3007.8	3078.6	3139
12-13	2837.5	2799.5	3058.1	3089.3	3159.5
13-14	2748.5	2788.5	3007.8	3078.6	3139
14-15	2837.5	2799.5	3058.1	3089.3	3159.5
15-16	2748.5	2788.5	3007.8	3078.6	3139
16-17	2837.5	2799.5	3058.1	3089.3	3159.5
Daily energy extracted (kW-h)	22.3	22.3	24.2	24.6	**25.2**
Yearly energy extracted (kW-h)	8139.5	8139.5	8833	8979	**9198**
Total yearly income generated@ Rs 15/kW-h	122,092.5	122,092.5	132495	134685	**137970**
Cumulative yearly income generated in $	1492.0	1492.0	1619.13	1645.89	**1686.04**

revenue of $1686.04 surpassing the TCT, CMAP [6], PRS [27], and TTSA [26] methods. It is important to note that in both the TCT and the proposed GMRA arrangements, the PV modules are arranged sequentially, resulting in less wiring dependence. On the contrary, the PV arrangements such as CMAP [6] and TTSA [26], where modules can occupy any position within the array, lead to much higher cabling requirements. In the proposed GMRA arrangement, modules are repositioned within the column with fixed electrical connections, necessitating increased wiring (209×module length) for a 9×9 PV array compared to the wiring (81×module length) required for the same array size using TCT. The cost components considered for the system include the PV array with supporting structures ($ 5,167) and connecting wires ($ 1.54/m). Considering all installation costs and also factoring in a maintenance cost (2 % of the installation costs) for the PV system, the payback period for both TCT and the proposed GMRA is estimated. The techno-economic analysis revealed that the proposed system can recoup the invested funds within a time frame of about 3.2 years, which is shorter compared to the 3.56 years required with the TCT arrangement. So, the proposed reconfiguration arrangement is less costly (compared to electronic reconfigurable techniques that require a lot of sensors and switches), practically feasible, and lucrative in terms of annual energy savings for large PV plant installations.

VI. CONCLUSION

This work proposes a new generalized static SD strategy designated as GMRA and SP-GMRA, for a TCT and SP-connected PV array, respectively, for optimal power extraction under PSCs. To verify the applicability of the proposed scheme to different array sizes, initially, simulation testing is done on a large 9×9 PV array, followed by hardware validation on symmetrical 5×5 and 6×4 PV arrangements. Four benchmark performance metrics i.e. FF, ML, ER, and power enhancement were identified for the performance evaluation of the proposed scheme with popular and various recently published state-of-the-art reconfiguration methods. Simulation results revealed that the proposed GMRA and SP-GMRA achieved 12.76 % and 7.10 % higher FF than TCT and SP arrangements, respectively. Hardware implementation of GMRA revealed 29.55 % and 22.3 % enhanced average power extraction from a 5×5 and 6×4 TCT connected PV array. Additionally, the average power enhancement of 7.93 % and 10.9 % respectively is achieved for the aforementioned SP arrangements using SP-GMRA. The proposed scheme exhibits the best SD with optimal global peak power point under common shade occurrences. Simulation and experimental results show similar trends, thus validating the superiority of the proposed scheme under different PSCs.

Abstract
Image Segmentation using thresholding is one of the most significant areas of image processing. However, the challenge lies in accurately and effectively segmenting medical images, which is a crucial step in many applications of medical image analysis. It necessitates the development of an effective and robust segmentation approach that can handle the complexity and diversity of medical images. To address this problem, we propose a novel image segmentation technique based on minimizing the cross-entropy function using a hybrid approach that combines the features of Opposition-Based Learning (OBL), Chameleon Swarm Algorithm (CSA), and Particle Swarm Optimization Algorithm (PSO). The opposition-based technique generates the initial population and improves convergence. Then, PSO and CSA are run in parallel on an unequal population set to improve the optimal results. The proposed approach, named the Opposition-based Chameleon Swarm Algorithm improved by Particle Swarm Algorithm (CSAPSO), is evaluated on twelve Chest X-Ray (CXR) images of patients for the detection of Pneumonia. It is further tested on a large data set related to COVID-19. We conducted extensive comparisons with other state-of-the-art methods and the Deep Learning Algorithms and used the performance indicators, namely Root Mean Square Error (RMSE), Peak Signal to Noise Ratio (PSNR) and Structure Similarity Index (SSIM), Classification Accuracy, Area Under Curve for evaluating the performance. The proposed approach is statically analyzed using the Friedman rank-sum test. Through the analysis, CSAPSO demonstrates better global optimal results compared to state-of-the-art techniques.

1 Introduction

Image Segmentation forms the basis of many real-world applications like computer vision, video applications, and medical imaging. In the context of medical imaging, the CXR of the patients that are ill with respiratory symptoms is indicative of pneumonia. Pneumonia causes an increase in lung density, which can be seen as whiteness in the lungs when examining the CXR. The degree of whiteness in CXR is directly proportional to the severity of pneumonia [17]. Effective segmentation of CXR images into regions of interest (ROI) is crucial for accurate detection. Among different image segmentation techniques like thresholding, edge-detection, region-based, and graph-based [29, 51], the thresholding-based method is used widely due to its simple implementation [14, 58]. The thresholding-based segmentation method divides the image into two (bi-level) or multiple (multi-level) classes based on the number of thresholds, where all the elements in a region share common properties like brightness, grey level, contrast, texture, color, etc. The Threshold segmentation method uses the gray probability and gray value to divide the image into different regions. Since the results rely purely on the threshold values, it's important to choose the right optimal value in segmentation. In multi-level thresholding, as the number of thresholds increases, the complexity of the model increases exponentially. Also, there are many challenges when performing thresholding, like, finding a proper objective function, applying the technique over the medical image, appropriate evaluation criteria, etc. Therefore, to produce a good quality segmented image, there is a need to deal with the discussed challenges.

Several multi-level thresholding techniques have been proposed so far that employ different criteria functions, such as Otsu's between-class variance [37], minimum error thresholding [26], and entropy-based thresholding [35]. Researchers have explored all of these methods over the last decades. However, entropy-based thresholding has gained much popularity. Some common entropy measures used as objective functions include Kapur's entropy [20, 21], fuzzy entropy [40], cross-entropy [30], Tsallis entropy [8], Shannon entropy [41], and Masi entropy [34]. Among these, Minimum Cross-Entropy Thresholding (MCET) function is widely utilized. An optimal threshold value segments the image based on the difference between the original image and the ideal segmented image. The challenge of increased complexity still prevails when performing multi-level thresholding. To address this, researchers have incorporated metaheuristic algorithms to enhance threshold accuracy. In [46], bilevel and multi-level image segmentation were done by maximizing Otsu's between-class variance, using the firefly algorithm, Brownian distribution, levy flight, and the gaussian distribution. Color image segmentation based on multi-level MCET using the cuckoo search algorithm was used in [39], where authors compared the proposed approach with other metaheuristic-based image segmentation techniques, and the proposed approach proved highly effective. For complex image analysis, PSO was incorporated into MCET to find the optimal thresholds during multi-level image segmentation [57]. Another metaheuristic called grey wolf optimizer was applied to thresholding problems with Otsu and Kapur's entropy as its objective function [25]. After an extensive experimental process, this approach proved to be better than thresholding done using PSO and Bacterial Foraging Optimization (BFO). In [43], Differential Evolution was applied to Tsallis-fuzzy entropy-based image thresholding, showing statistical significance over other state-of-the-art methods using Shannon entropy or fuzzy entropy.

These studies highlight the advancements in utilizing metaheuristic algorithms to improve the accuracy and effectiveness of multi-level thresholding in image segmentation. However, there is always a limitation where some optimization algorithms are good in exploring the

search space and some are good in exploitation. Several hybrid metaheuristics are proposed in the related field to strike an exploration-exploitation balance, avoid premature convergence, and have shown superior performance. A hybrid gravitational search algorithm and the genetic algorithm were used in multi-level thresholding where between-class variance and entropy functions were used as fitness functions. In this approach, a novel method of evaluating the standard deviation after fitness function calculation was employed to ensure diversity [50]. Otsu thresholding was optimized using a hybrid firefly algorithm and social spider optimization, where processing time was significantly reduced, along with good results [3]. In [18], Ewees et al. gave a hybrid of Artificial Bee Colony (ABC) and Sine Cosine Algorithm (SCA), where SCA improved the local search ability of ABC to enhance its performance in image thresholding. It is imperative to note that hybrid optimization algorithms have shown better performance as compared to individual optimization algorithms.

In this paper, we propose an efficient segmentation approach based on MCET, called CSAPSO, that utilizes the two algorithms at different stages to improve the convergence of CSA, namely; (1) OBL [52] and (2) PSO. OBL calculates the solution on the opposite side of the ordinary solutions and chooses the best solution for each search agent. Thus, it assists in improving the convergence of the algorithm to reach the global optima value. Afterward, PSO, which exploits the search space well, is used in parallel with the CSA to take care of the exploitation feature and avoid local optima, since CSA tends to give false optimal thresholds and high complexity due to the local optima trap. To avoid this, PSO is incorporated along with CSA to ensure an optimal balance between the exploration and the exploitation of the resultant hybrid algorithm. The implementation of the proposed methodology consists of three phases: (1) Initialization and pre-processing phase, (2) updating phase, and (3) the segmentation phase. In the initialization and pre-processing phase, OBL generates a random population of agents in the opposite direction. The cross-entropy function is then minimized to select the best solutions for the next phase. In the updating phase, the population is divided into unequal sub-populations and assigned to CSA and PSO in parallel to bring population diversity, overcome the potential local optima trap, and find the global optima value. The global optima value becomes the optimal threshold value. Finally, in the segmentation phase, the image is segmented using the optimal thresholds. The proposed CSAPSO algorithm demonstrates excellent performance in image thresholding, particularly in segmenting complex medical images. It outperforms CSA, PSO, and other classical and hybrid-based segmentation approaches. The performance evaluation includes comparisons using RMSE, PSNR, and SSIM metrics, and the statistical analysis confirms the effectiveness of CSAPSO. Additionally, the algorithm's applicability is tested on a large dataset related to COVID-19, and comparisons are made with popular Data Learning Algorithms like U-Net [47], SegNet [6], and DeepLab [16]. Overall, the CSAPSO algorithm provides an efficient and competitive image segmentation method, specifically for medical image analysis, with promising results for pneumonia detection and potential applications in other domains. The main contribution of this paper are as follows:

1. A new method of multi-level image thresholding has been proposed based on MCET by evaluating the optimal threshold values based on opposition-based learning, CSA, and PSO.
2. The local and global search operators of both CSA and PSO is applied in parallel to the subpopulations, after refining the search space using OBL.
3. The performance has been tested on popular gray-scale images and real-time chest x-ray images for the detection of pneumonia. Comparison is done with other state-of-the-art nature-inspired algorithms.

4. To test the robustness and generalizability, the algorithm is further tested on COVID-19 images and compared with other Deep Learning Algorithms on the basis of classification accuracy, area under curve etc.

The remaining paper is divided as follows. Section 2 gives the existing work in multi-level thresholding and optimization algorithms in the field of medical imaging. Section 3 gives the problem definition and the preliminaries of CSA and PSO. Section 4 demonstrates the proposed CSAPSO method based on multi-level cross-entropy thresholding. Section 5 gives the experimental results and analysis. Section 6 concludes the work.

2 Related work

Researchers in the medical domain have used multi-level thresholding with nature-inspired algorithms in diverse ways. In a study [32], researchers proposed a novel method of updating the context vector during the cooperation process in a dynamic way where they used Otsu as an objective function. The testing was done on the CT scans of the stomach and was found effective. However, the computational complexity of the method may limit its scalability to large datasets or real-time applications. In 2012, three-level thresholding of human head CT images was done using improved Biogeography-Based Optimization (BBO) technique, where the fuzzy entropy was the objective measure to be maximized [15]. The comparison was with original BBO, PSO, and other state-of-the-art methods. The improved BBO proved superior and more flexible than its original algorithm and other methods. However, a careful selection of parameters is required. Abbas et al. [1] proposed a refined segmentation method based on pixel-probability density function and edge detection. The technique was applied to High-Resolution Computed Tomography (HRCT) of lungs, and compared with other segmentation methods. Brain Magnetic Resonance (MR) has been a targeted area for many researchers. However, it lacked generalization and validation on other datasets. In [38], the author proposed multi-level thresholding of brain MR images by computing the 2-d histogram-based grey gradient to preserve the edges of the brain, using Shallow Swarm Optimization (SSO). The comparisons were done with other soft computing approaches. The complexity of the algorithm was high, although it was effective in performance and gave good results. But, the proposed method is not compared to the state-of-the-art segmentation techniques to demonstrate its superiority. Also, in [28], Brain MR image segmentation was done using an enhanced Shuffled Frog Leaping Algorithm. It gave good results and was qualitatively and quantitatively better than other competitive approaches but the sample size used was very small so effectiveness cannot be claimed. Bat algorithm was used in tsallis entropy-based thresholding for image segmentation [44]. It used the region growing segmentation method and extracted the texture features to final abnormalities in MR images of the brain and breast. Li et al. used partitioned and cooperative quantum-behaved PSO to optimize the Otsu thresholding parameters and applied them to optimize complex benchmark functions and four stomach CT images [33]. The results were better in terms of inter-class variance. The approach has a high computational cost, which could make it challenging to use in real-time or in circumstances where resources are few. The dataset used was limited and the algorithm lacked analysis of the parameters. Wang et al. [55] used Otsu as the objective function and tried optimizing the thresholds using improved Flower Pollination Algorithm with a random location operator. The performance was evaluated using gray-scale medical images and gave robust and effective output as compared to other algorithms.

Firefly Algorithm (FA) was used to segment lung CT images [53] and brain MRI [45]. The paper proposes emphysema classification in lung tissue CT images using Support Vector Machine (SVM) optimized by the FA. The proposed approach's computational time and complexity are not fully analysed in the research, which is crucial for real-world applications. The grey wolf optimizer was used in an artificial neural network for the classification of the MRI images dataset [4]. The hybrid approach of using gray wolf optimizer and artificial neural network improves the accuracy of classification for magnetic resonance brain images. But, the paper does not discuss the limitations of the proposed algorithm. Moreover, Soham et al. [48] gave the concept of multi-level thresholding using a multi-objective evolutionary algorithm where two entropies namely, minimum cross-entropy and Renyi entropy, were used as the objective function. It is an effective technique to segment brain tumors. In this regard, automatic segmentation of MR images was done using Crow Search Algorithm [36]. This method used minimum cross entropy as its objective function. The performance was evaluated on general as well as medical images. Ultrasound image segmentation was carried out using a multi-level Otsu thresholding method optimized using Differential Evolution Algorithm [49]. The proposed differential search algorithm-based method achieves higher segmentation accuracy compared to other methods, as demonstrated by experiments on real ultrasound images.

For the analysis and classification of diseases in healthcare systems, machine learning and data mining approaches have become increasingly popular in recent years. In [10], authors give a review of various machine learning methods used in health care, the challenges and the possible solutions. In a manner similar, [9] investigated sub-features for classification in data mining, which was helpful for enhancing the precision of disease classification models. Analytic methods for e-Health data have also been deployed using soft computing and machine learning approaches. [12] suggested a framework for applying these methods to healthcare data analysis and patient outcomes improvement. A machine learning and medical stuff model was also used by [11] to analyse classification-based projected disease, which could be useful for diagnosing and forecasting diseases in patients. However, the sample size used was small.

In this research paper, we aimed to explore the potential of nature-inspired algorithms and their hybrids for pneumonia-related diseases. We noticed a significant gap in the literature in this area, and we identified the need for a dataset of sufficient size to address this issue. Additionally, we found that previous studies lacked proper descriptions of the parameters used for tuning and measures of accuracy. To bridge this gap, we applied nature-inspired algorithms to the image segmentation of CXR images of patients for the early detection of pneumonia. Our work represents a crucial step forward in the early detection and treatment of pneumonia patients.

3 Preliminaries

3.1 Minimum cross-entropy

The formulation of multi-level thresholding using minimum cross-entropy is presented here. Minimum cross-entropy was proposed by Kullback et al. [27]. Consider two probability distributions, $P = p_1, p_2, ..., p_N$ and $Q = q_1, q_2, ..., q_N$. The cross-entropy between the

two distributions is given as (1).

$$D(P, Q) = \sum_{k=1}^{N} p_k log(\frac{p_k}{q_k}) \tag{1}$$

where $D(P, Q)$ is the information theoretic distance between the two distributions P and Q.

Li et al. [31] have implemented minimum cross-entropy in image segmentation for bilevel thresholding. Later, it extended to multi-level thresholding. Let the original image, I with gray levels L and histogram h. For multi-level thresholding with m number of thresholds namely th_1, th_2, th_3,... th_m , the cross-entropy is minimized between the original and segmented image. $m + 1$ classes are formed, namely, $C_0, C_1, C_2, ..., C_m$, where the intensity values range between $[0, th_1]$, $[th_1 + 1, th_2]$, .., and $[th_m + 1, L - 1]$ respectively. The multi-level segmented image is denoted as I' and defined as (2).

$$I' = \begin{cases} \mu_0, I(x, y) \leq th_1 \\ \mu_1, th_1 \leq I(x, y) \leq th_2 \\ . \\ . \\ \mu_m, I(x, y) \geq th_m \end{cases} \tag{2}$$

where μ_0, μ_1, μ_2,.., μ_m is the average mean of the classes $C_0, C_1, C_2, ..., C_m$, and is given as (3).

$$\mu_0 = \frac{\sum_{i=1}^{th_1} ih(i)}{\sum_{i=1}^{th_1} h(i)}, \mu_1 = \frac{\sum_{i=th_1+1}^{th_2} ih(i)}{\sum_{i=th_1+1}^{th_2} h(i)}, ...\mu_m = \frac{\sum_{i=th_m+1}^{L} ih(i)}{\sum_{i=th_m+1}^{L} h(i)} \tag{3}$$

For multi-level thresholding, the cross-entropy function is calculated as per (4).

$$D(th_1, th_2, ..., th_m) = \sum_{i=1}^{L} ih(i)log(i) - \sum_{i=1}^{th_1} ih(i)log(\mu_0) - \sum_{i=th_1+1}^{th_2} ih(i)log(\mu_1) - ... - \sum_{i=th_m+1}^{L} ih(i)log(\mu_m) \tag{4}$$

The first term of the equation is generally constant for each image; hence the function can be modified as per (5).

$$D(th_1, th_2, ..., th_m) = -\sum_{i=1}^{th_1} ih(i)log(\mu_0) - \sum_{i=th_1+1}^{th_2} ih(i)log(\mu_1) - ... - \sum_{i=th_m+1}^{L} ih(i)log(\mu_m) \tag{5}$$

The time complexity of the multi-level thresholding increases exponentially with the increase in the number of thresholds. Since the time complexity for bilevel thresholding is $O(L)$, the time complexity for multi-level thresholding would be $O(L^m)$.

3.2 Chameleon swarm algorithm

CSA is the nature-inspired algorithm developed by Braik et al [13]. It is inspired by the hunting behavior of chameleons in the forests to sustain themselves. The chameleons have the capability of rotating their eyes 360 degrees, and work independent of each other. The hunting mechanism of the chameleon consists of three distinct steps, namely; (i) tracking the

prey, (ii) pursuing the prey with their eyes, and (iii) attacking the prey with the use of the tongue. The chameleons can roam around the entire search space in search of prey and use their globular eyes for a panoramic view of their surroundings. They use their long sticky tongue to catch the prey by the phenomenon of wet adhesion and entanglement. Their suction cup-like tongue traps the prey.

The initialization of chameleons (number and dimension) in the search space is done using (6).

$$A^i = l_j + r * (u_j - l_j) \tag{6}$$

where A^i represents the initial vector of the i^{th} chameleon, l_j, and u_j are the lower and upper bounds of the space along the j^{th} dimension respectively, r is a uniformly generated random number in the range [0, 1]. The position updation strategy can be mathematically modeled using (7).

$$A_{t+1}^{i,j} = \begin{cases} A_t^{i,j} + p_1(BP_t^{i,j} - GP_t^j)r_2 + p_2(GP_t^j - A_t^{i,j})r_1 & r_i \geq Pp \\ A_t^{i,j} + \mu((u_j - l_j)r_3 + l_j^d)sgn(rand - 0.5) & r_i < Pp \end{cases} \tag{7}$$

where $A_{t+1}^{i,j}$ is the new position of i^{th} chameleon in j^{th} dimension for iteration number $t+1$, $A_t^{i,j}$ is the position in the t^{th} iteration, $BP_t^{i,j}$ is the best position of i^{th} chameleon so far, GP_t^j is the global best position in the j^{th} dimension by any chameleon, p_1,p_2 are two positive numbers to control the exploration; r_1, r_2, r_3 are the random uniform numbers in the range [0,1], Pp is the probability of perceiving the prey. The balance between exploration and exploitation is achieved by adaptive parameter tuning of μ according to (8).

$$\mu = \gamma^{(\frac{-\alpha t}{T})^\beta} \tag{8}$$

where $\gamma\alpha\beta$ are the exploration-exploitation control parameters, t is the current iteration, T is the maximum iteration. (9) gives the new position update after detecting the prey using eye rotation.

$$A_{t+1}^i = Ar_t^i + \overline{A}_t^i \tag{9}$$

where A_{t+1}^i is the new position of the chameleon, Ar_t^i is the center of the current position before rotation and $\overline{A}_t^i$ is the rotating centered coordinates.

The velocity of the chameleon's tongue when it attacks the prey is as per (10).

$$v_{t+1}^{i,j} = \omega v_t^{i,j} + c_1(GP_t^j - A_t^{i,j})r_1 + c_2(BP_t^{i,j} - A_t^{i,j})r_2 \tag{10}$$

where ω is the inertia weight and defined in (11)

$$\omega = (1 - \frac{t}{T}^{(\rho\sqrt{\frac{t}{T}})}) \tag{11}$$

where ρ is a positive no. to manage exploitation, $v_t^{i,j}$ is the current velocity of the chameleon along j^{th} dimension.

Equation (12) shows the position of the chameleon's tongue when it attacks the prey.

$$A_{t+1}^{i,j} = A_t^{i,j} + \frac{(v_t^{i,j})^2 - (v_{t-1}^{i,j})^2}{2a} \tag{12}$$

where $v_{t-1}^{i,j}$ being the previous velocity, a is the acceleration rate of the tongue's projection and represented as (13).

$$a = 2590 * (1 - e^{-log(t)}) \tag{13}$$

Algorithm 1 summarises the steps of CSA.

Algorithm 1 Chameleon Swarm Algorithm

1. Parameter definition: Pp: position update probability; r_1, r_2, r_3, r_i: random numbers between [0,1]; u: upper bound; l: lower bound; d: dimension; $\overline{A}_t^i$ centre of the current position of chameleon i at iteration t; Ar_t^i : rotating centred coordinates of chameleon i at iteration t; T: max iteration.
2. Initialize the controlling parameters.
3. Initialize the swarm of n chameleons, $\overline{A}_t^i$i , and Ar_t^i , velocity of chameleon's dropping tongue.
4. Calculate the position of chameleons.
5. While $t < T$
6. Define μ, ω, and a
7. For $i = 1ton$
8. For $j = 1tod$
9. If $r^i \geq Pp$ then
10. Update the position using equation
    $A_{t+1}^{i,j} = A_t^{i,j} + p_1(BP_t^{i,j} - GP_t^j)r_2 + p_2(GP_t^j - A_t^{i,j})r_1$
11. Else
12. Update the position using equation
    $A_t^{i,j} + \mu((u_j - l_j)r_3 + l_j^d)sgn(rand - 0.5)$
13. End if
14. End for
15. End for
16. For $i = 1ton$
17. $A_{t+1}^i = Ar_t^i + \overline{A}_t^i$
18. End for
19. For i=1 to n
20. For j=1 to d
21. Update velocity using (10)
22. Update position using (12)
23. End for
24. End for
25. Use u and l to limit the position of chameleons
26. Evaluate and update the new position of chameleons
27. $t = t + 1$
28. end while

3.3 Particle swarm optimization

PSO algorithm [22] is inspired by the social behaviour of bird flocking, and fish schooling. It is a stochastic, non-deterministic technique, and easy to perform as well. To perform the optimization, the candidate solutions are improved repeatedly over each iteration. First, the candidate solutions (particles) are randomly selected, then they are allowed to move in search space based on the equations of position and velocity. Two important parameters that are greatly affected are $Pbest$, i.e. the local best known position, and $Gbest$, i.e. the global best position. Both these variables guide the particle to move towards the global solution. The particles should converge to their local best and global best positions with every iteration.

The particle tries to update its current velocity and position, with each iteration according to (14) and (15), respectively.

$$v_i^{t+1} = wv_i^t + c_1 * r_1 * (Pbest_i - pos_i^t) + c_2 * r_2 * (Gbest - pos_i^t) \tag{14}$$

$$pos_i^{t+1} = pos_i^t + v_i^{t+1} \tag{15}$$

where, pos_i^t and v_i^t are the current position and the velocity of the i^{th} particle at iteration t, respectively. w is the weighting function (inertia), r_1 and r_2 are random coefficients between [0,1], c_1 and c_2 are the acceleration coefficients and the two learning parameters. $Pbest_i$ is the best previous position of the i^{th} particle, and $Gbest$ is the global best solution so far of all particles.

In (14), the first part i.e., wv_i^t is responsible in maintaining the current direction, and also gives the ability of exploration, the second part i.e., $c_1 * r_1 * (Pbest_i - pos_i^t)$ gives the private thinking (cognitive development) and the third part i.e., $c_2 * r_2 * (Gbest - pos_i^t)$ gives the collaborative approach (social component). The set of sequence is repeated until the stopping criteria. In this way, PSO is able to achieve both exploration and exploitation. PSO has lesser complexity as compared to other algorithms and when it comes to performance, PSO is quite efficient. It is known for good exploitation ability; however, it lacks good exploration skills. It has been used along with many algorithms for improving their exploitation abilities. The steps of PSO algorithm implementation are summarised in Algorithm 2.

Algorithm 2 Particle Swarm Optimization Algorithm

1. Initialize the controlling parameters
2. Do
3. For each particle
4. Calculate the objective of the particle
5. Update $Pbest$ whenever required
6. Update $Gbest$ whenever required
7. End for
8. Update the inertia weight
9. For each particle
10. Update the velocity by using (14)
11. Update the position by using (15)
12. End for
13. While the end condition is not fulfilled
14. Return the best global optima Gbest

4 The proposed improved chameleon swarm algorithm

4.1 Opposition based learning mechanism

OBL was proposed by Tizhoosh in 2005 [52]. The estimates and their counter estimates form the basis of this model. Let $x \in [l, u]$ be a real number. Equation (16) formulates the opposite number $\breve{x}$.

$$\breve{x} = l + u - x \tag{16}$$

This technique effectively improves the performance of the metaheuristic algorithms by enhancing population diversity. It deals with evaluating the current solutions as well as the opposition solutions along with their fitness functions also. The better one participates in the next generation. This approach applies not only to the initial solution but to the subsequent generations of search agents as well. This is extremely helpful in cases when the current solution tends to go away from the optimal solution, especially when it is in the opposite direction.

4.2 The proposed CSAPSO algorithm

Due to stochastic behavior, there is always a scope for improvement in nature-inspired algorithms. For the same reason, CSA sometimes fails to give optimum thresholds during the image segmentation process. To utilize its advantages to the fullest and avoid the limitations, we have improvised CSA in this paper by using two algorithms, namely the Opposition-based algorithm and the Particle swarm optimization algorithm, and therefore it is named CSAPSO. Our proposed method has three phases, namely; (1) Initialization and pre-processing phase, (2) updating phase, and (3) segmentation phase. These phases are described below in more detail.

4.2.1 Initialization and pre-processing phase

Initialization is an important step in an optimization algorithm since it determines the convergence of the algorithm and the final results. OBL strategy has proved its superiority in improving the convergence and quality of the solutions. The proposed CSAPSO algorithm begins by creating a population of threshold values X in dimensions n and N solutions. (17) gives the opposite solutions for the values.

$$\breve{X} = l + u - X \tag{17}$$

where u is the upper bound, and l is the lower bound of the search space. The minimum of X and $\breve{X}$ is selected for each search agent to find the best values among the population. This is shown in (18).

$$X_i = minimum(X_i, \breve{X}_i) \qquad \forall i = 1, 2, ..., N \tag{18}$$

After the best threshold values are selected for the initial population, the objective function i.e. minimum cross-entropy function is applied to them to evaluate the performance of these thresholds, using (19).

$$F(X_i) = -\sum_{i=1}^{X_1} ih(i)log(\mu_0) - \sum_{i=X_1+1}^{X_2} ih(i)log(\mu_1) - ... - \sum_{i=X_m+1}^{X_N} ih(i)log(\mu_m) \tag{19}$$

The search agent with the minimum cross-entropy value is considered the best agent. So, OBL boosts the convergence mechanism and achieves the global optima faster.

4.2.2 Updating phase

In this phase, two subpopulations are created from the population by applying the modulus function on the iteration number. If the current iteration is odd, the population is divided into $\frac{1}{3}^{rd}$ and $\frac{2}{3}^{rd}$ subpopulations. If the current iteration is even, the population is divided into $\frac{2}{3}^{rd}$ and $\frac{1}{3}^{rd}$ subpopulations. In either case, the first subpopulation is assigned to CSA and the second sub-population is assigned to PSO respectively and passed through the fitness function, i.e., the minimum cross-entropy function. The other fitness functions that are possible for image threhsolding are Otsu, Fuzzy entropy, Ranyi entropy, wavelet entropy, and Kapur's entropy function. However, in this paper, we use the minimum cross-entropy function since this function uses the mean values which remains steady and limited. So, it becomes easy to analyse the results and draw conclusions out of them. Now, the respective CSA and PSO

algorithms update the position and velocity of all search agents. For the first subpopulation, i.e., the one with CSA, the position and velocity are updated using (20) and (21) respectively.

$$X_{t+1}^{i} = Xr_t^i + \overline{X}_t^i \tag{20}$$

$$V_{t+1}^{i,j} = \begin{cases} V_t^{i,j} + p_1(local_best_t^{i,j} - Global_best_t^j)r_2 + p_2(Global_best_t^j - V_t^{i,j})r_1 & r_i \geq Pp \\ V_t^{i,j} + \mu((u_j - l_j)r_3 + l_j^d)sgn(rand - 0.5) & r_i < Pp \end{cases} \tag{21}$$

where $Global_best$ and $local_best$ are the best global and local positions of the search agents respectively. Also, for the second subpopulation, i.e. the one with PSO, the velocity and the position are updated using (22) and (23) respectively.

$$V_i^{t+1} = wV_i^t + c_1 * r_1 * (local_best_i - X_i^t) + c_2 * r_2 * (Global_best - X_i^t) \tag{22}$$

$$X_i^{t+1} = X_i^t + V_i^{t+1} \tag{23}$$

We obtain a single set of solutions by merging two solutions. The process repeats till the termination condition. In this way, the solutions received using CSA and PSO are diverse in nature and can explore and exploit well. So, we can utilize their powerful search abilities by giving them a major and minor part of the population in an alternate way. This ensures population diversity since the population is updated in every run differently. By assigning an unequal population, we also prevent the candidate solutions from having almost the same values after every run. PSO ensures the local optima trap avoidance, and CSA retains high computational speed. In unison, both the algorithms work on improving the segmentation results.

4.2.3 Segmentation phase

After specified iterations, or until the termination condition, the final position is considered the global optima solution for the given problem. This global optima solution sets out the threshold values used in image segmentation. The solutions of the algorithm are the final threshold values. The original image uses these threshold values to form multiple segments based on the levels of thresholds. The segmentation of the image leads to dividing the image into multiple sections based on similar intensity values. The efficiency of segmentation is decided by computing the PSNR, SSIM, etc. The run-time depends on the number of iterations and the population size used for finding the optimal thresholds. the number of thresholds impacts the segmentation results and play less role in deciding the run-time of the proposed algorithm.

4.3 Implementation of the proposed CSAPSO on segmenting Chest X-Ray images for detection of pneumonia

The image segmentation using thresholding gives the classification of the image into different segments based on their similarity among them. The number of segments varies with different levels of thresholding. For distinct observations, we take a higher number of thresholds. This method proves effective for the chest x-ray images since the main criteria are to separate the affected areas of the chest from the normal ones. It could be helpful in diagnosing pneumonia at an early stage and prevent the further growth of the disease. The steps for the

implementation of the proposed algorithm for segmentation of CXR images for the detection of pneumonia is shown in Algorithm 3.

Algorithm 3 Steps for CXR image segmentation using CSAPSO

1. Input the CXR image.
2. Compute the histogram.
3. Set the initial values of the parameters of the algorithms CSA and PSO.
4. Construct the population and its opposite population using OBL.
5. Select the best population based on the values.
6. Apply the objective function and calculate the fitness value.
7. Perform CSA and PSO on unequally divided subpopulations.
8. Perform position and velocity update on each search agent and merge the final solution set.
9. When termination condition is met, the final position is the best global optimal threshold value.
10. Segment CXR image based on the optimal thresholds.

The framework of the proposed CSAPSO algorithm for image thresholding using the concept of opposition-based learning, CSA and PSO is shown in Fig. 1.

5 Experimental results and discussion

In this section, the performance of the proposed CSAPSO algorithm was tested on twelve chest x-ray images. The images were taken from [23, 24], curated by Paul Mooney and is available on Kaggle. This dataset has 5,863 images in total, 4,387 of which are training images, 585 of which are validation images, and 1,091 of which are test images. The photos are in grayscale and have a 1,024 x 1,024 pixel resolution. The dataset is separated into the "normal" and "pneumonia" classes. In contrast to the "pneumonia" class, which contains X-ray images of patients with pneumonia, the "normal" class has images of healthy patients. These Chest x-ray images along with their histogram are shown in Fig. 2. The figure shows different characteristics of the images based on their histograms.

The comparison was done with ten algorithms consisting of some popular classical as well as hybrid metaheuristics, namely; CSA, PSO, Hybrid Particle Swarm Optimization Firefly Algorithm (HFPSO) [42], Salp Swarm Algorithm (SSA) [56], Genetic Algorithm (GA) [19], Whale Optimization Algorithm (WOA) [2], Grasshopper Optimization Algorithm (GOA) [7], Gravitational Search Algorithm-Genetic Algorithm (GSA-GA) [50], Salp Swarm Optimization-Moth Flame Optimization (SSAMFO) [5], Particle Swarm Optimization-Artificial Bee Colony-Ant Colony Optimization algorithm (PSO+ABC+ACO) [54]. All the test images used for experimental evaluation were simulated thirty times using each multilevel thresholding algorithm. We experimented with the level=5, 10, 15, and 20, and the objective function to be minimized was the cross-entropy function. The results are analyzed visually as well as statistically. Visual results give the qualitative analysis and statistical results give the quantitative analysis. The experiments were done using Matlab.

The parameter settings were the same for all the algorithms as mentioned in their respective papers. The number of candidate solutions considered in each iteration is based on the population size. The search space can be better explored with a larger population, but computational cost may go up. New candidate solutions are produced from the current population using the mutation rate and crossover rate in CSA. The crossover rate regulates the likelihood of joining two solutions to produce a new one, whereas the mutation rate regulates the

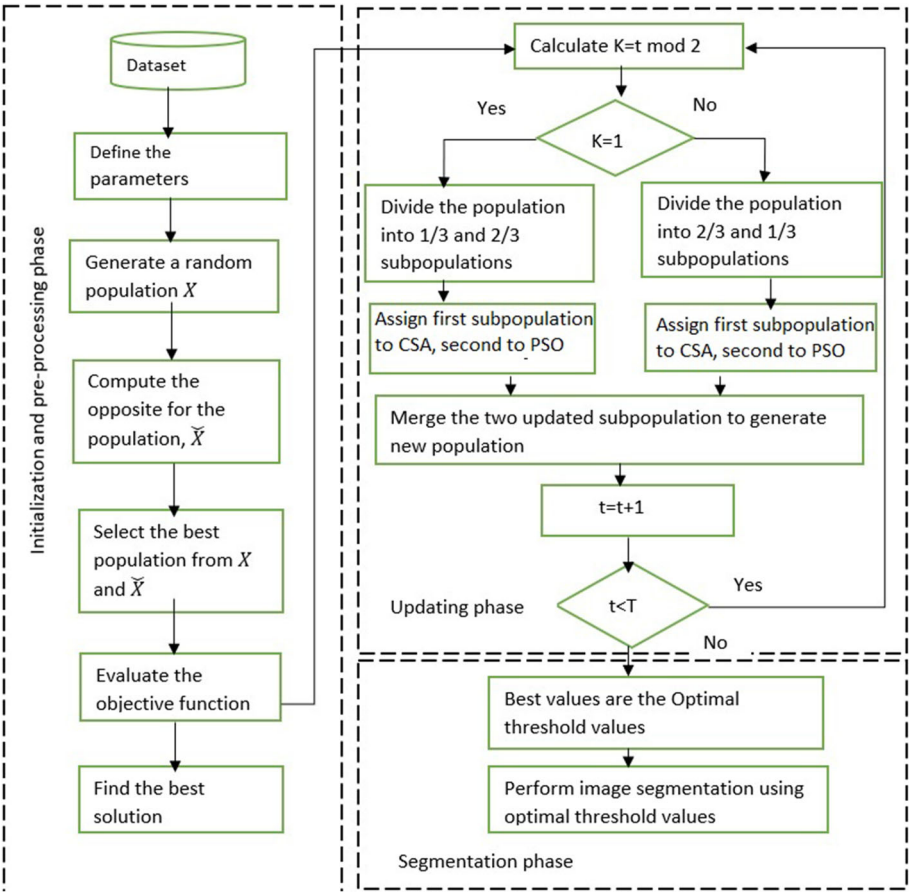

Fig. 1 Framework of the proposed CSAPSO algorithm for image thresholding using the concept of opposition-based learning, CSA and PSO

likelihood of each parameter in a solution being randomly modified. The balance between the particle's previous velocity and the social and cognitive factors in the current iteration is controlled by the inertia weight. The attraction of the particle towards its personal best solution and the best solution discovered by the swarm is controlled, respectively, by the particle's cognitive and social components. Depending on how difficult the problem is that needs to be addressed, different values for these parameters may be considered ideal. In both CSA and PSO, parameter tuning is frequently carried out by a trial-and-error process in which various parameter settings are evaluated on the problem at hand and the best performing one is chosen. The selection of parameters impact how well these algorithms perform in contrast to other optimization algorithms like the Salp Swarm Algorithm, Genetic Algorithm, Wolf Optimisation Algorithm, Grasshopper Optimisation Algorithm, etc. Finding the ideal collection of parameters is essential for getting good results because each algorithm has its own set of variables that can be tuned. To choose the optimal algorithm for a particular optimisation problem, it is important to carefully set the parameters of each method and compare their performances.For transparency and better result comparison, the two main

parameters, i.e., population size and maximum iteration are set to 30 and 500, respectively for all the algorithms. The other parameter values for CSAPSO are mentioned as follows: - $Pp = 0.1, \gamma = 1.0, \alpha = 3.5, \beta = 3.0, p_1 = 0.25, p_2 = 1.50, \rho = 1$

The main aim of this paper is quality segmentation results and consistency. There are several parameters used to test the quality of segmentation. We have used the following parameters as performance indicators:

1. Root Mean Square Error (RMSE) works on the intensity values and gives the strength of the final constructed image, defined as per (24).

$$RMSE = \sqrt{\frac{\sum_{i=1}^{N_r}(I_{i,j} - Is_{i,j})^2}{N_r * N_c}} \tag{24}$$

   where I and Is refers to the original and segmented images of size $N_r * N_c$.
2. Peak Signal-to-Noise ratio (PSNR) gives the accuracy of the final segmented image, defined as per (25).

$$PSNR = 20 * log_{10}(\frac{255}{RMSE}) \tag{25}$$

3. Structural Similarity Index (SSIM) gives the resemblance between original image and the thresholded image. It denotes the structural information degradation and is defined as per (26).

$$SSIM(I, Is) = \frac{(2\mu_I \mu Is + c_1)(2\sigma I, Is + c_2)}{(\mu_I^2 + \mu_{Is}^2 + c_1)(\sigma_I^2 + \sigma_{Is}^2 + c_2)} \tag{26}$$

   where μ_I and μ_{Is} are the mean intensities of I and Is, respectively, and σ_I and σ_{Is} are the standard deviations of the original image I and segmented image Is, respectively. The co-variance between I and Is is denoted by $\sigma_(I, Is)$. Constants c_1 and c_2 are set to 6.5025 and 58.52252, respectively [2].

Apart from these performance indicators, Friedman rank-sum test at 5% significance level was performed to see the difference between the proposed algorithm and other algorithms.

Figure 3 shows the segmentation results on CXR images at threshold levels 5,10,15, and 20. The proposed CSAPSO algorithm successfully segmented the chest x-rays at various threshold levels. The results at threshold levels 10, 15, and 20 are better at threshold level 5. At each threshold level, the degree of whiteness in the x-rays is compared to normal chest x-rays to detect the severity of Pneumonia. As discussed, Pneumonia is identified by the degree of whiteness in the CXR. The proposed CSAPSO algorithm gave appropriate thresholds for segmentation as perceived visually from the figure.

Figure 4 shows the segmented images for image I11 by CSAPSO and other algorithms used for comparison at threshold level 20. From the comparative analysis, it is observed that all the algorithms successfully segment the images. However, for the same threshold level (in this case, 20), CSAPSO gives better image quality as compared to other metaheuristics. The dark and light regions of the chest images are clearer. The thoracic area of the chest is accurately perceived, and the identification of affected areas in x-ray images becomes distinct. Hence, from the visual analysis, CSAPSO proves to be a better algorithm as compared to its counterparts and other state-of-art algorithms for the effective segmentation of the images.

To exhibit Pneumonia, two CXR images I5 and I11 were taken at threshold level 10 segmented using CSAPSO as shown in Fig. 5. Both I5 and I11 are the CXR of persons affected by Pneumonia. The grey-colored section, denoted by the red arrow, is the affected area, whereas the black-colored section, denoted by the green arrow, is the unaffected area. The segmented image created using the thresholding technique displays the infected portions and the severity. From the figure, it is seen that there are multiple lesions or gray portions in image I11 that show how severe the disease is. The image I5 has lesser lesions due to the blacker portion and less grey portion, which shows the beginning of Pneumonia. Hence

Fig. 4 Segmented CXR images obtained by each algorithm for image I11 at threshold level 20

by segmenting the images using optimal threshold values, we can quickly know the impact of the disease on the lungs. However, the consideration is that the threshold levels chosen should be such that the affected and unaffected areas are distinctly visible. Hence, depending on the type of problem, we choose an appropriate threshold level.

To analyze the efficiency and accuracy of the proposed algorithm, fitness values, PSNR, SSIM, and CPU time are considered. Table 1 shows the fitness function values obtained using the proposed CSAPSO algorithm and other state-of-the-art algorithms. The best results are marked in bold. The fitness results give the quality of the threshold values and the accuracy of the results. It is observed from the table that CSAPSO stood first in delivering the best fitness values for most of the cases. The ranking was followed by SSAMFO and HFPSO. For some cases of lower threshold levels, SSAMFO gave better results than CSAPSO. The quality of the algorithm at higher dimensions is accessed using the higher threshold values.

It is significant since real-world applications may contain several objects. One observation is that for higher threshold levels, the performance of CSAPSO was much better than at lower threshold levels. It shows that CSPSO proves to be a better optimizer than other algorithms for real-world applications.

Table 2 shows the results of the average PSNR results for all the images. From the detailed analysis of the performance at each threshold level, CSAPSO performs great for threshold levels 15 and 20. For threshold level 5, CSAPSO gave the best PSNR values for 4 cases, followed by GOA which gave the best values in 3 cases, followed by SSAMFO for 2 cases. For threshold level 10, CSAPSO gave the best PSNR values in 8 cases, followed by GOA for 4 cases. For threshold level 5, the performance of GOA and HFPSO was similar. However, it is outperformed by CSAPSO which gave the best values in 10 cases. Similar results were shown for threshold level 20, where the performance of GOA, SSAMFO, and PSO was the same, while CSAPSO outperformed others in 9 cases. Therefore, from the detailed analysis of the PSNR results, it can be seen that the performance of CSAPSO was the best, followed by GOA, and then SSAMFO. The other comparative algorithms like CSA, PSO, SSA, and WOA proved the worst for these cases. The impact of balanced exploration and exploitation can also be found in the quality of results. Since the local trap is avoided, therefore, the quality of results is significantly improved.

Table 3 shows the average SSIM values for the images obtained using the proposed algorithm and other comparative algorithms. SSIM tells the similarity between the original image and the corresponding segmented image, hence it is an important quality parameter to validate the segmentation. The results were analyzed in detail and it was found that for threshold level 5, CSAPSO and SSAMFO were highly competitive and gave the best results in 6 and 5 cases respectively. For level 10, CSAPSO stood first with the best values in 6 cases, followed by SSAMFO and HFPSO. For level 15, CSAPSO gave the best results in 5 cases out of 12, followed by HFPSO, and then SSAMFO. The proposed approach gave the best results for 58% of cases in threshold level 20, and the rest of the best results were divided among SSAMFO (17%), GA (8%), SSA (8%), and HFPSO (8 %). Overall, it was observed that CSAPSO is competitive with SSAMFO for lower threshold levels. However, in totality, CSAPSO stood first, followed SSAMFO, and then HFPSO. The performance of CSA is improved by using PSO and OBL.

Figure 6 shows the comparison of the average CPU taken by each algorithm for the first 5 CXR images over 30 runs and 500 iterations. It can be seen from the figure that the CPU time taken by CSAPSO was nearly 0.5 seconds, followed by PSO with 1 second execution time, SSAMFO which was nearly 1.3 seconds, and HFPSO with 1.5 seconds. SSA gave good results with nearly 3 seconds of execution. The algorithms like GA, GOA, and CSA took nearly 4 seconds of execution time. GSA-GA and WOA took around 5 seconds. The maximum CPU time was taken by PSO+ABC+ACO with nearly 6 seconds. The results of CDAPSO are achieved in lesser CPU time due to decreased complexity. Since PSO is a simple-to-implement algorithm, therefore when it is hybridized with CSA, it reduces the complexity of the algorithm and makes the function evaluations quicker. One more interesting observation was that the graph of CPU execution time was almost a straight line which shows that the CPU time did not change much with the change in threshold levels. The results are the same with all the algorithms.

We tested the significance and efficiency of the proposed algorithm by using the Friedman test. This test ranks the algorithms and studies the algorithm's robustness by using the median values. The higher the value, the better the rank. Also, the chief advantage is that it does not require the distribution of the dataset to be known. Table 4 presents the results of the Friedman rank-sum test. Our proposed approach obtained the best rank in the measures PSNR as well

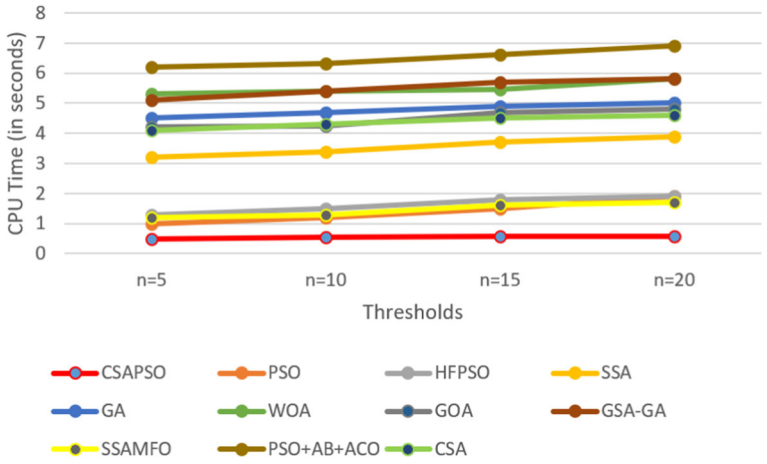

Fig. 6 Comparison of average CPU time by each algorithm for first five images

as SSIM, followed by SSAMFO and then HFPSO. The overall ranking of all the algorithms for both the measures is $CSAPSO > SSAMFO > HFPSO > PSO + ABC + ACO > PSO > CSA > SSA > GSA - GA > WOA > GOA > GA$. Therefore, CSAPSO proves to be statistically significant as compared to other algorithms for solving real-world problems.

Another series of experiment was conducted on a large data set on COVID-19.[1] In this series, the three deep learning models, namely U-Net [47], SegNet [6], and DeepLab [16] were trained over a number of parameters. Figure 7 shows the graphical evaluation of all proposed X-ray image classifiers with four metrics of precision, recall, specificity and f1-score. The positive cases of Pneumonia and COVID-19 are confirmed while using U-Net and CSAPSO. The mis-classification chances are more in case of DeepLab and SegNet. So, from the figure it can be concluded that the right classification is achieved in case of U-Net and CSAPSO. Four expected outcomes of the confusion matrix are defined as follows by comparing the true labels of tested images and predicted outcomes of deep learning: The term True Positive (TP) demonstrated the accurate identification of chest diseases. A count of healthy instances is referred to as true negatives (TN). False positive (FP) refers to an error in which a test result falsely suggests the existence of a chest disease when the disease is not present. False negative (FN) refers to an error in which a test result fails to reveal the presence of a chest disease. From the results of the confusion matrix, the following five fundamental performance measures for deep image classifiers are as follows:Accuracy: This measure evaluates the performance of the classifier. It is calculated as follows:

$$Accuracy = \frac{TP+TN}{TP+FP+TN+FN}$$

The precision recall or sensitivity, specificity, and f1-score are calculated as follows:

$$Precision = \frac{TP}{TP+FP}$$

$$Recall = Senstivity = \frac{TP}{TP+FN}$$

$$Specificity = \frac{TN}{TN+FP}$$

$$F1 - Score = \frac{2(PrecisionXRecall)}{Precision+Recall}$$

[1] The images were taken from https://bimcv.cipf.es/bimcv-projects/bimcv-covid19/#1590858128006-9e640421-6711 and https://github.com/ieee8023/covid-chestxray-dataset

Table 4 Results of the Friedman test obtained using each algorithm for the CXR images

	CSAPSO	PSO	HFPSO	SSA	GA	WOA	GOA	GSA-GA	SSAMFO	PSO+ABC+ACO	CSA
PSNR	8.63	6.98	7.94	6.39	4.97	5.54	5.14	5.72	8.12	7.56	6.75

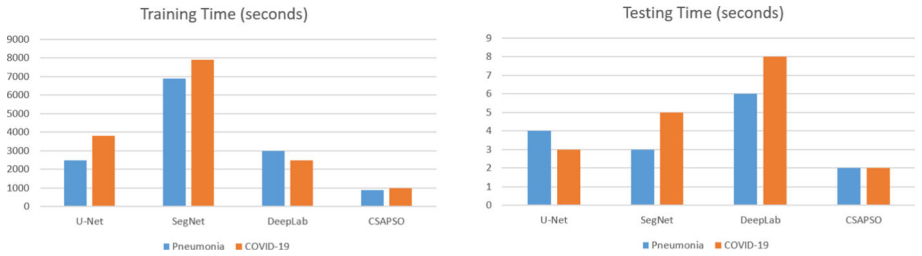
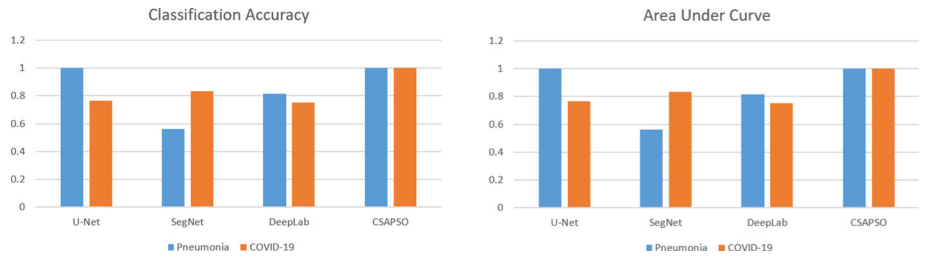
Fig. 7 Evaluation results of deep learning classifiers to identify positive cases of pneumonia and COVID-19 diseases



(a) Training Time (b) Testing Time

Fig. 8 Computation times including training and testing times for the Deep Learning Classifiers



(a) Accuracy (b) Area Under Curve

Fig. 9 Classification accuracy and area under curve (AUC) for the Deep Learning Classifiers

The comparative training and testing time analysis is shown in Fig. 8. The training time ranges from 900 seconds for CSAPSO to 7800 seconds for SegNet. On the other hand, the testing time ranges from 2 seconds for CSAPSO to 8 seconds for DeepLab. It shows an advantage of using CSAPSO with minimum training time of 900 seconds and testing time of 2 seconds. A higher training and testing time results in increased complexity.

Figure 9 shows the testing accuracy and area under curve for all the image classifiers. The best scores of accuracy and area under curve are achieved by CSAPSO, i.e. 0.9, followed by U-Net. SegNet and DeepLab followed the performance of CSAPSO and U-Net. The tabular comparison of different deep learning classifiers are shown in Table 5. From the table, it is seen that U-Net and CSAPSO, both classifies Pneumonia with 99.98% accuracy. However, when the dataset of COVID-19 is considered, CSAPSO outperforms U-Net with classification accuracy of 99.93% where U-Net has accuracy of 76.45%. The classifiers SegNet and DeepLab showed an average performance for both the datasets.

From the above series of experiments, we confirm the superiority of the proposed algorithm over other state-of-the-art algorithms. Our hybrid method, CSAPSO, combines the Chameleon Swarm Algorithm (CSA), Particle Swarm Optimisation (PSO), and Opposition-Based Learning (OBL), allowing for quick convergence to the global optimum. This helps in reducing the amount of compution needed for image segmentation. CSAPSO utilizes the parallel execution of CSA and PSO on different sub-populations, which enhances optimization and improves computational efficiency. This ensures population diversity, which helps in avoiding local optima trap and produces superior segmentation outcomes. Medical image analysis is only one of the many image segmentation jobs that CSAPSO can be used for. It has been evaluated for the detection of pneumonia on Chest X-Ray (CXR) pictures, and it has demonstrated promising outcomes on COVID-19-related datasets.The Friedman test results proved that CSAPSO is statistically significant as compared to other algorithms. While our proposed method, CSAPSO, combines metaheuristic algorithms rather than deep

Table 5 Comparative analysis of different deep learning classifiers

Classifier	Total Parameters(10^6)	Trainable Parameters(10^6)	Non-Trainable Parameters(10^6)	Classification Accuracy	
				Pneumonia	COVID-19
U-Net	14.93	14.93	0	99.98	76.45
SegNet	20.76	20.71	0.05	56.14	83.23
DeepLab	58.12	58.1	0.02	81.34	75.12
CSAPSO	3.54	3.51	0.03	99.98	99.93

learning techniques, however, our study also compared three deep learning techniques with our suggested method to segment medical images, and the results based on Accuracy, Precision, Recall, Specificity, and F-1 score, revealed that all four techniques were effective on the datasets we evaluated. There were some variations in performance, with CSAPSO outperforming U-Net, SegNet and Deep Lab. Our approach does, however, have a few drawbacks that need to be addressed in further research. First, the existing architecture relies on time-intensive manual annotations for training. Second, a rather small dataset was used to train and test the suggested network, which would have limited its potential to generalise to other datasets or real-world events. Finally, the suggested method may not be appropriate for other medical imaging tasks because it is created specifically for the detection and localization of pneumonia in CXR images. The findings imply that deep learning methods for medical image segmentation show considerable promise, but further study is required to choose the most appropriate method for particular imaging modalities and applications. The study also emphasises the need for larger datasets and standardised evaluation measures to enable reliable comparison of various approaches.

6 Conclusion

In this paper, we present the improvement of the CSA algorithm, named CSAPSO, through the integration of two other algorithms: PSO and OBL. The resultant algotrithm, namely CSAPSO, is a multi-level thresholding-based image-segmentation method based on minimum cross-entropy principle. CSAPSO minimizes the cross-entropy function by utilizing optimal threshold values obtained using CSA and PSO in a hybrid fashion. OBL is employed to enhance convergence towards the global optimal solution. Additionally, CSAPSO incorporates the division of the population into unequal subpopulations to ensure population diversity. The two subpopulations are run in parallel, with one using CSA algorithm and the other utilizing the PSO algorithms. This allows the algorithm to leverage the global and local features of both algorithms simultaneously.

The proposed CSAPSO algorithm is implemented for the segmentation of twelve real-time CXR images and COVID-19 X-ray images. The experimental results are compared with state-of-the-art algorithms such as CSA, PSO, HFPSO, SSA, GA, WOA, GOA, GSA-GA, SSAMFO, PSO+ABC+ACO, as well as various deep learning algorithms including U-Net, SegNet, and DeepLab. Performance indicators such as RMSE, PSNR, SSIM, accuracy, and area under the curve are used for evaluation. The statistical significance of the results is tested using the Friedman rank test at a 5% significance level.

The experimental results demonstrate that the proposed approach is highly competitive at the 5-threshold level and outperforms other algorithms at the threshold levels of 10, 15, and 20. The achieved segmentation accuracy, as indicated by the high PSNR and SSIM values, further highlights the effectiveness of the proposed method. The lower values of standard deviation indicate the stability of the algorithm, which is a crucial measure as many algorithms exhibit instability by producing different results with each iteration. The results of the Friedman rank-sum test also confirm the significance of CSAPSO in comparison to other methods. Moreover, the proposed algorithm successfully applies to real-life applications by producing optimal thresholds and generating high-quality segmented images of CXR for pneumonia detection. Therefore, it proves to be valuable in the field of medical imaging, enhancing the diagnostic performance of radiologists.

In future works, CSAPSO can be further utilized to optimize other image segmentation methods. Additionally, the development of a multi-objective version of the CSAPSO-based image thresholding technique could potentially improve its performance in segmenting CXR images.

Data Availability The datasets generated and analysed during this study are available in the following repository: https://www.kaggle.com/datasets/paultimothymooney/chest-xray-pneumonia https://bimcv.cipf.es/bimcv-projects/bimcv-covid19/#1590858128006-9e640421-6711 and https://github.com/ieee8023/covid-chestxray-dataset.

Abstract In the current work, SiC particles-based friction stir welded composite joints of AA7075 and AA6061 were developed. The effects of processing variables (rotating speed, transverse speed and volume percentage of SiC microparticles) on the mechanical characteristics (tensile strength, microhardness and %strain) of the composite joints were examined using response surface methodology. The developed models showed that the rotating speed is the most influential parameter, the volume percentage of SiCp is the second most influential parameter, and the transverse speed is the least influential parameter. The highest tensile strength of 261 MPa, %strain of 32.4% and microhardness of 187 HV were found at rotating speed of 1100 rpm, transverse speed of 40 mm/min and 10% volume percentage of SiC particles. The optimized processing variables, including rotating speed, transverse speed and volume percentage of SiC particles, were found to be 1094 rpm, 40 mm/min and 6%, respectively. The value of multi-optimized output responses, including tensile strength, %strain and microhardness, was found to be 247 MPa, 26.9% and 176 HV, respectively.

Keywords Composite joints · SiC particles · Tensile strength · Microhardness · ANOVA

1 Introduction

In almost every industrial facility, including automotive, marine, and aerospace, the production of light and relatively robust structural components has lately experienced a transition from conventional materials to lightweight materials. The excellent physical and mechanical features of aluminum alloys include their lightweight, high strength, strong heat conductivity and superior corrosive resistance. These alloys have attracted much attention for industrial applications in practically every area. Fusion welding procedures are inappropriate for joining such alloys of low melting points because of limitations such as porosity, distortion, solidification cracking and high residual stresses [1–3]. Friction stir welding (FSW), which is solid-state by nature, seems to be the most efficient method to join various lightweight materials. The FSW technique was introduced in 1991 by "TWI" (The Welding Institute) [4]. The fabrication of metal matrix composites (MMCs) employing reinforcing particles (RPs) is a creative technique for augmenting mechanical characteristics (stiffness, hardness and strength, etc.), corrosion, and wear resistance [5–7]. Bulk and surface composites were developed using RPs-based MMCs via FSP to augment tribological and mechanical properties [8–13].

Several researchers also employed FSW to produce aluminum metal matrix (AMM) composites utilizing various micro/nano-sized RPs to ameliorate the weld properties of related aluminum alloys. Recent studies have examined the viability of fabricating MMCs with different reinforcing particles, including AA2124 using SiC particles, AA7005 using Al_2O_3 particles, AA2009 using SiC particles and AA7075/AA2024 using SiC particles [14–17]. Al_2O_3 particles outperform SiC particles and a hybrid of the two in FSW of the dissimilar AA6101 and AA1350 in terms of mechanical and wear characteristics [18]. A few scholars have optimized the processing parameters of FSW using different experimental design methodologies, including response surface methodology (RSM), Taguchi approach and grey relational analysis [19–21]. However, there is a paucity of studies related to

optimizing the volume percentage of RPs and FSW processing variables to multi-optimize the response variables. In the current work, the desirability function using RSM was used to identify the optimal variables setting to optimize the ultimate tensile strength (UTS), %strain and microhardness of FSWed composite joints.

A wide range of structural components for the aviation, marine and automotive industries employ AA7075 and AA6061 [22–24]. The joining of these alloys with improved weld quality will boost the adaptability of structural designs and widen the scope of their applications. Thus, in the current investigation, the potential of SiC particles (SiCp) on the mechanical properties of dissimilar FSWed composite joints of AA7075 and AA6061 was investigated. The work based on the optimization of friction stir welding parameters (rotating speed and transverse speed) along with volume percentage of RPs is a novel approach that can significantly enhance the mechanical properties of the welded joints. The optimization of the volume percentage of RPs, together with rotating speed and transverse speed for considered responses of dissimilar FSWed composite joints of AA7075 and AA6061, has not previously been described, as far as the author is concerned.

2 Material and Experimental Procedure

The plates of the alloys (AA7075 and AA6061) of size 150 × 40x6 mm were utilized to develop FSWed composite joints as delineated in Fig. 1a. The grain structure micrograph and the elemental composition, as observed by EDX (energy-dispersive X-ray spectroscopy) analysis of base alloys, are cited in Fig. 2a–d. To investigate the influence of varying volume percentages of SiCp, the grooves of different sizes (width- 0.24, 0.42, and 0.60 mm, and depth- 3 mm) were milled on the continuous faces of base plates, as delineated in Fig. 1a. The SiCp of average particle size 50 µm were utilized as reinforcement material. The SEM (scanning electron microscopy) micrograph and EDX analysis of SiCp are delineated in Fig. 2e, f. A slurry was developed by mixing SiCp with ethanol to introduce the SiCp properly in the grooves [25, 26]. In the present study, the tool tilt angle of 2° was used, and AA7075 base plates positioned on the

retreating side were employed (Fig. 1b), as per the recommendations from previous studies [27, 28].

RSM is a mathematical approach for maximizing the impact of independent variables on dependent parameters. To generate the experimental design, the full factorial module of the central-composite design approach of RSM was used [29]. The experimental design of twenty trail runs was obtained with three independent processing variables: transverse speed (TS), rotating speed (RS), and volume percentages of SiCp (VP-SiCp) and three levels of each independent processing parameter. Table 1 depicts the processing parameters with their levels and considered response parameters. A threaded pin-profiled H13 steel tool was utilized to fabricate the dissimilar composite joints under different parametric settings. The dimensional characteristics of the tool utilized in this study are delineated in Fig. 1c.

The test samples for mechanical characteristics and microstructure evolution were carved out from the composite joints using wire-cut CNC EDM. The dimensions of tensile test samples (ASTM E8 standard) are delineated in Fig. 1d [30]. The average of three samples of various tests was listed. The microhardness variation in the weld region was evaluated using Vickers microhardness tester. The indents for microhardness measurement were employed at 100 gf load and 15 s dwell time. For microstructural analysis, polishing of the samples was carried out using different emery papers (200–2000 grit size) and then etched using Keller's reagent. An optical microscopy (OM) was utilized for the grain structure evolution of the stir zone, whereas a SEM was employed to examine the dispersion pattern of SiCp.

3 Results and Discussion

The grain structure and SiCp distribution pattern in the stir zone of composite joints were studied to understand the

consequences of RS, TS, and VP-SiCp on the mechanical and microstructural behavior. The study provides a comprehensive analysis of the results. This includes a comparison of the properties of the welded joints processed using different combinations of RS, TS and volume percentage of RPs, and the study of the underlying mechanisms that contribute to the observed changes in properties. The mean grain size of AA6061 and AA7075 (base materials) was found to be 36 µm and 47, respectively (Fig. 2a and c). The various dissimilar FSWed composite joints after FSW/SiCp are delineated in Fig. 3. In the FSWed joints, three different zones are obvious: stir zone (SZ), heat-affected-zone (HAZ) and thermo-mechanical-affected-zone (TMAZ) [31]. The grain structure of the SZ was noticed finer than that of the TMAZ and HAZ [32, 33].

3.1 Tensile Properties

The mechanical characteristics of the FSWed composite joints are mainly influenced by grain refinement, volume percentage and size of RPs, dispersion of RPs and the bonding between the AMM and RPs [34, 35]. In Table 1, the average tensile properties of all the SiCp composite joints were compiled. The base materials AA7075 and AA6061 demonstrated the UTS of 495 and 288 MPa, respectively, with corresponding %strain values of 21.6 and 18.4%.

The composite FSWed joints processed at RS of 700 rpm revealed the clusters of SiCp in the SZ and poor bonding between the SiCp and the surrounded AMM owing to inadequate material mixing. The clusters of SiCp in the SZ are obvious in Fig. 4a of specimen no- 18 processed at 700 rpm, 60 mm/min and 4% of VP-SiCp. Therefore, the mean grain size of 15.7 µm (Fig. 4b) was observed in the SZ. This indicates that the lower value of RS (700 rpm) was not providing enough strain to prevent SiCp clustering [36]. The dispersion pattern of SiCp in the SZ was found improved as RS increased [37, 38]. Uniform dispersion of SiCp and considerable material mixing was noticed due to significant strain produced at higher RS of 1100 rpm. Consequently, specimen no- 15 processed at 1100 rpm, 40 mm/min, and 10% of VP-SiCp revealed the homogeneously dispersed SiCp due to excellent material mixing caused by enhanced stirring action of the tool as depicted in Fig. 5a. The excellent bonding between SiCp and the AMM is implied by the absence of SiCp clustering. The more refined grain structure with grain size 4.6 µm (Fig. 5b) was observed in the SZ of specimen no- 15 and that only be ascribed to the presence of homogeneously distributed SiCp. The pinning effect of SiCp enhances the nucleation sites and prevents the grains' growth [39]. The presence of a high volume percentage of more homogenously dispersed SiCp led to improved grain refinement and enhanced the pinning effect. These results

Fig. 3 Welded plates of AA7075 and AA6061 embedded with SiCp

validate the influences of SiCp on the refinement of the grain structure.

The Hall–Petch equation, which states that UTS rises as grain size decreases, can explain this phenomenon [40]. The pinning effect of SiCp and DRX may be attributed to the reduced grain size of the FSWed composite joints when compared to base materials [41]. Consequently, the maximum UTS of 261 MPa was found in specimen no-15, which is nearly 90.6% of the AA6061. In contrast, the minimum UTS (180 MPa) was found in specimen no-18. The FSWed composite joints showed the higher %strain than base materials, with specimen no-15 showing a maximum %strain of 32.4%. The existence of SiCp was confirmed by the EDX analysis of the SZ of specimens no-18 and no- 15. Figures 4c and 5c depict the peaks of silicon and carbon, which validates the presence of SiCp. The EDX analysis of specimen no-18 revealed the silicon and carbon percentages of 4.08 and 2.22%, respectively, whereas the EDX analysis of specimen no- 15 revealed the silicon and carbon percentages of 8.16 and 3.11%, respectively. The varying volume percentage of SiCp was confirmed by the different percentages of silicon and carbon in specimens no-18 and no-15.

Figure 6a, b depicts the fractography of the raptured surface of specimens no- 18 and no- 15. The rapture occurred from the HAZ toward AA6061, where the microhardness was found to be minimal [42]. The shear plane with a cup-cone form was established along the edges of fractured samples [42]. The ductile failure with honeycomb dimples was found in specimen no- 18 (Fig. 6a), which provides evidence of the regularly separated attributes of cleavage and plastic deformation [43, 44]. Homogeneously dispersed SiCp and finer grain structure resulted from efficient material mixing at higher RS. The fractography of specimen no-15 exhibited the equiaxed and tiny dimples (Fig. 6b) developed by the coalescence of the micro-voids [45, 46]. The ruptured zone was identified at the HAZ, confirmed by the microhardness variance, and produced an improvement in ductility. Therefore, it was evident from examining the ruptured surfaces that adding SiCp to composite joints enhanced their tensile properties.

3.2 Microhardness

Vickers hardness tester was utilized to examine the microhardness variation in the welded area of the various FSWed composite joints, as delineated in Fig. 7a–c. The asymmetrical microhardness distribution in the welded region was induced by the irregular plastic flow in the retreating and advancing side [47]. The microhardness of the base materials AA6061 and AA7075 was found to be 96 and 170 HV, respectively. Table 1 summarizes the mean microhardness value at the midpoint of various FSWed composite joints.

The results of the microhardness tests showed that specimen no-15 exhibited a maximum microhardness of 187 HV,

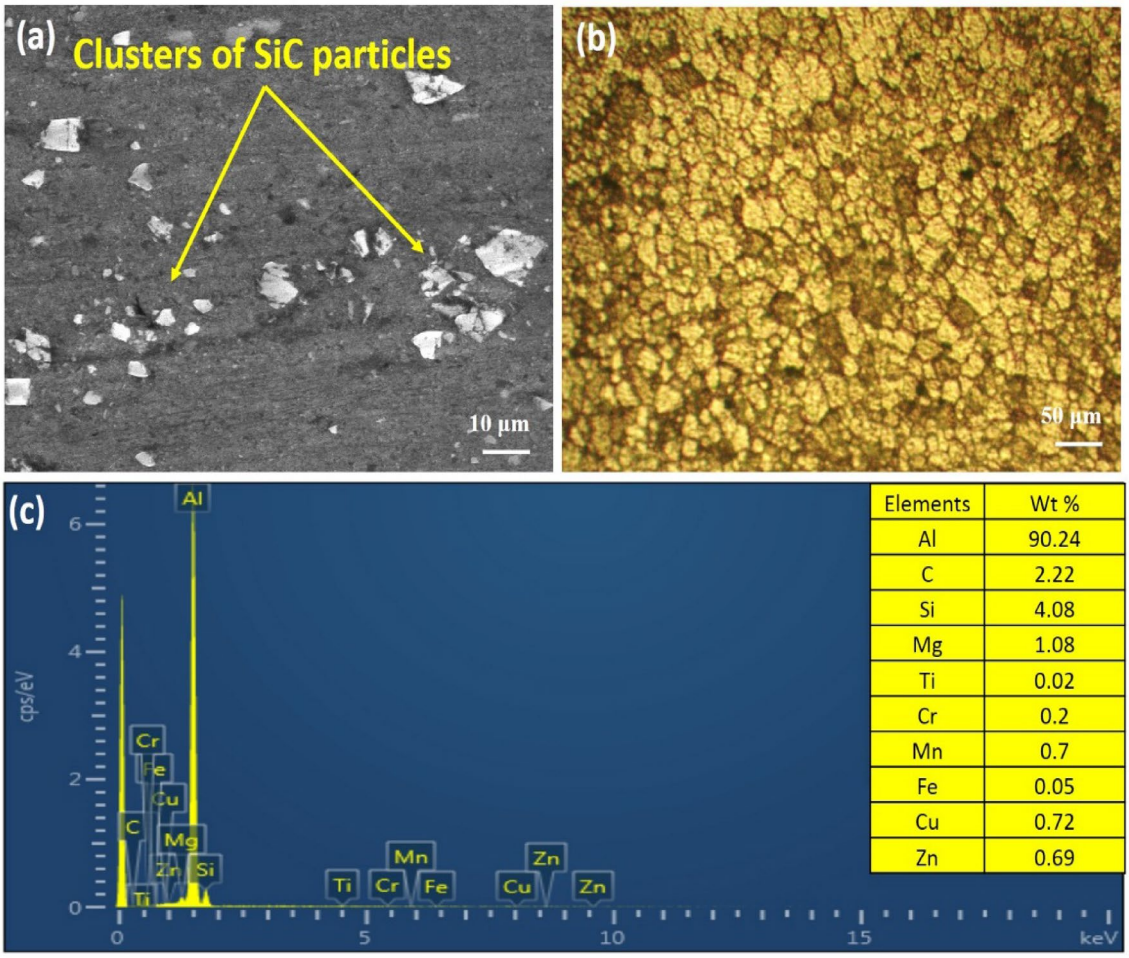

Fig. 4 **a** SEM micrograph, **b** grain structure, and **c** EDX analysis of specimen no-18

whereas specimen no-18 exhibited a minimum microhardness of 130 HV among all FSWed composite specimens. The higher hardness of specimen no-15 may be attributed to higher grain refinement via the DRX, pinning effect of uniformly dispersed hard SiCp and enhanced material mixing rule as compared to other composite joints. According to the Hall–Petch relation, smaller grains reveal higher hardness [48]. Compared to the TMAZ and HAZ, the SZ indicated the higher microhardness owing to smaller grain size caused by the pinning effect of SiCp and DRX. Lower hardness in the HAZ was observed to be caused by coarsening of strengthening precipitates, dissolution of existing clusters, and formation and coarsening of the stable phase. The processes of precipitation transformations occurring within the HAZ cannot be explicitly formulated due to susceptibility to many factors [49, 50]. In contrast, the microhardness in the HAZ was noticed less owing to coarsening of grains at high temperature and over-aging. Due to the addition of hard SiCp, the microhardness of the FSWed composite joints was also improved.

4 Development of Mathematical Model

The response function Y (UTS, %strain and microhardness) are assumed to be the function of RS (A), TS (B) and VP-SiCp (C) as represented in Eq. 1. The process parameters and the output responses were correlated by developing a second-order regression equation, and the response function Y is mathematically represented as Eq. 2.

$$Y = f(\mathrm{RS}, \mathrm{TS}, \mathrm{VP}-\mathrm{SiCp}) \tag{1}$$

The second-order polynomial equation used to represent the response surface '*Y*' is given in Eq. 2.

$$Y = b_0 + \sum b_i X_i + \sum b_{ii} X_i^2 + \sum b_{ij} X_i X_j \tag{2}$$

where *Y* is the predicted response, *bo* is the constant coefficient, *bi,* b*ii* and *bij* denote the linear coefficients, quadratic coefficients and interaction coefficients, respectively, whereas *Xi*, *Xj* are the independent variables [51, 52]. The

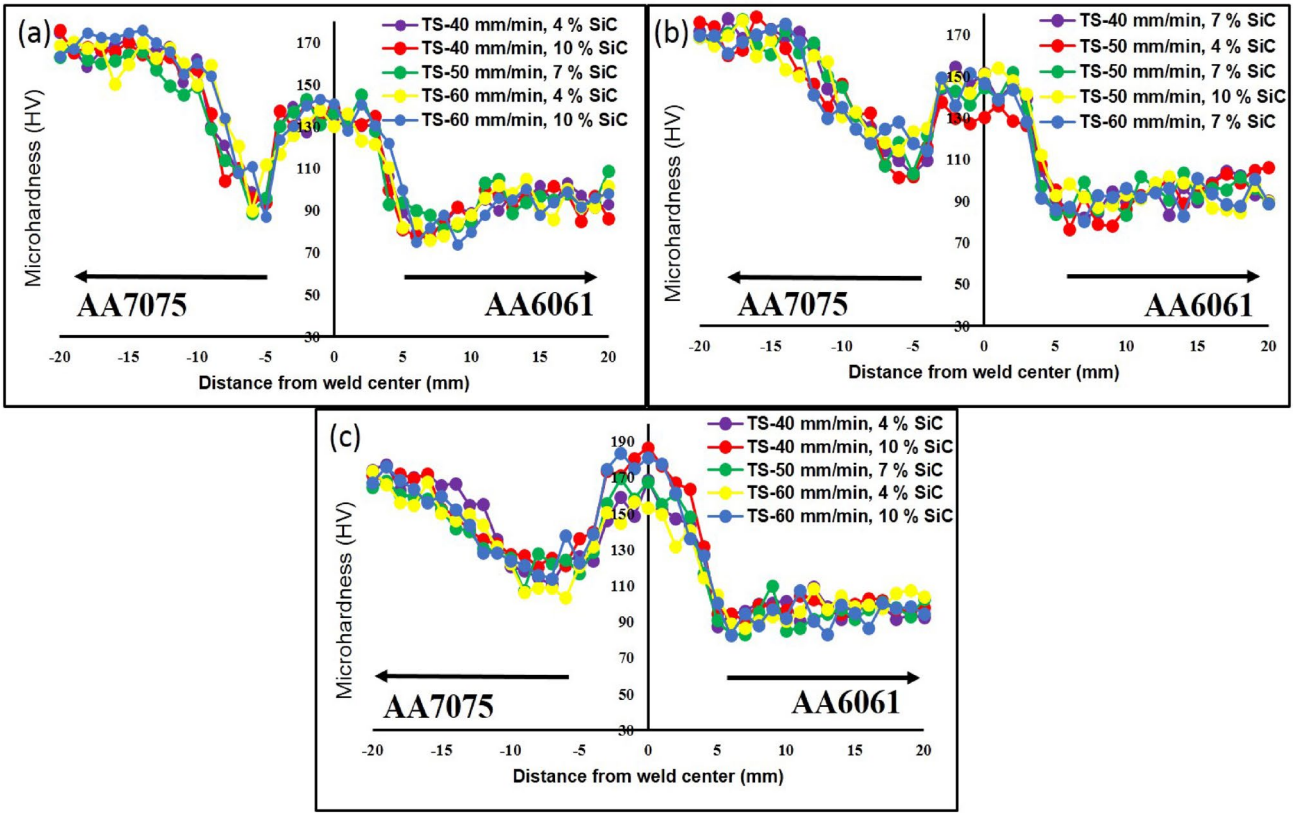

Fig. 7 Microhardness variation of the FSWed composite joints

regression model equations were developed for the response variables and written in Eqs. 3–5.

The final regression model equations developed are listed below.

$$\begin{aligned}\text{UTS} = {} & +208.03 + 25.40 * \text{RS} - 2.40 * \text{TS} + 13.00 * \text{VP - SiCp} - 3.37 * \text{RS} * \text{TS} + 3.63 * \text{RS} * \text{VP - SiCp} \\ & + 3.13 * \text{TS} * \text{VP - SiCp} + 9.68 * \text{RS}^2 + 4.68 * \text{TS}^2 - 5.32 * \text{VP - SiCp}^2\end{aligned} \tag{3}$$

$$\begin{aligned}\%\text{strain} = {} & +24.33 + 3.36 * \text{RS} + 0.28 * \text{TS} + 1.98 \\ & * \text{VP - SiCp} - 0.91 * \text{RS} * \text{TS} + 0.95 * \text{RS} \\ & * \text{VP - SiCp} - 0.51 * \text{TS} * \text{VP - SiCp} - 0.85 \\ & * \text{RS}^2 + 0.50 * \text{TS}^2 + 0.75 * \text{VP - SiCp}^2\end{aligned} \tag{4}$$

$$\begin{aligned}\text{Microhardness} = {} & +143.82 + 18.10 * \text{RS} - 2.60 * \text{TS} + 8.30 \\ & * \text{VP - SiCp} - 2.62 * \text{RS} * \text{TS} + 3.38 * \text{RS} \\ & * \text{VP - SiCp} + 1.63 * \text{TS} * \text{VP - SiCp} + 7.95 \\ & * \text{RS}^2 + 5.24 * \text{TS}^2 - 3.05 * \text{VP - SiCp}^2\end{aligned} \tag{5}$$

ANOVA is employed to identify the significance of processing variables for response variation. The results of ANOVA for UTS, %strain, and microhardness are illustrated in Tables 2, 3, and 4. Fisher's F test was performed to assess the developed models, and a 95% confidence level was used. P defines probability and should be less than 0.05 [53]. From Tables 2, 3, and 4, the F value for UTS, %strain and microhardness was found as 100.04, 306.90, and 133.96, respectively, and indicates that all three models are significant. The processing parameters (RS, TS, and VP-SiCp) are also significant, as their P value in all the mathematical models is less than 0.05. The lack of fit is not regarded as significant as the *P* value exceeds 0.1. Improved UTS, %strain and microhardness were observed with increasing volume percentage of SiC particles [54], whereas the mechanical characteristics of the FSWed composite joints were reduced with increasing TS. The *F* value developed models showed that rotating speed was the most influential parameter, volume percentage of SiCp was the second most influential parameter and transverse speed was the least influential parameter. The value of adjusted R^2 and predicted R^2 was very close for all the models, indicating high accuracy. The term "adequate

precision" is used to describe the signal-to-noise ratio. If its value exceeds 4, the model will be adequate to proceed. All three established models were given adequate precision by 36.48, 76.38, and 41.43, respectively. The value of R^2 reflects the overall variability of the models. The value of R^2 and adjusted R^2 for UTS, %strain and microhardness were found to be 0.9890 and 0.9791, 0.9964 and 0.9931, and 0.9918 and 0.9844, respectively, and their difference revealed that the models did not describe 0.99, 0.33 and 0.74% of the total variation.

4.1 Influences of Processing Parameters on the Output Responses

Figure 8 shows the values of predicted vs actual output responses of various FSWed composite joints. The response variables were identified in the scattered plots to be very close to the straight lines, indicating that the model's error was distributed uniformly. There is a strong correlation between the output responses' predicted and actual values, indicating that all the regression models are adequate.

Figure 9a–f depicts the interaction influences of various processing parameters using 3D-surface plots. Examining the 3D-surface plots makes it easy to determine how different process factors influence the output responses. The key determinants in grain refining were DRX and the pinning effect of SiCp. Therefore, the output responses, including UTS, %strain and microhardness, all improved with higher RS owing to more homogeneously dispersed SiCp resulted in reduced grain size via the pinning effect.

4.2 Desirability for Multi-Optimization

RSM was employed to perform multi-response optimization in order to solve the issues of contradicting responses with single-response optimization. [55]. All output responses were given an importance of 3, and the lower and upper weights were assigned a value of 1. A set of optimal parameters with higher desirability is required in order to achieve the desired response parameters within the constraints [56]. The ramp graph's dot (Fig. 10) denoted the optimum input parameter settings for the optimum response prediction. The optimum value of RS, TS and VP-SiCp was found as 1094 rpm, 40 mm/min and 6%, respectively, whereas the value of multi-optimized UTS, %strain and microhardness was found as 247 MPa, 26.9% and 176 HV, respectively.

4.3 *Confirmatory tests*

The aim of performing confirmatory tests was to ensure that each output response could be adequately described by the developed mathematical models when the processing parameters were set to their optimum levels. The average of the results was calculated and compared to the predicted responses. Table 5 cites the confirmatory tests' results and confirms the developed models' adequacy for predicting responses.

5 Conclusions

In the current work, dissimilar composite joints of AA6061 and AA7075 were developed using SiC microparticles. The consequences of varying volume percentages of SiC particles along with RS and TS on microstructural characterization and mechanical behavior of FSWed composite joints were evaluated. The following are some of the major conclusions obtained from the findings:

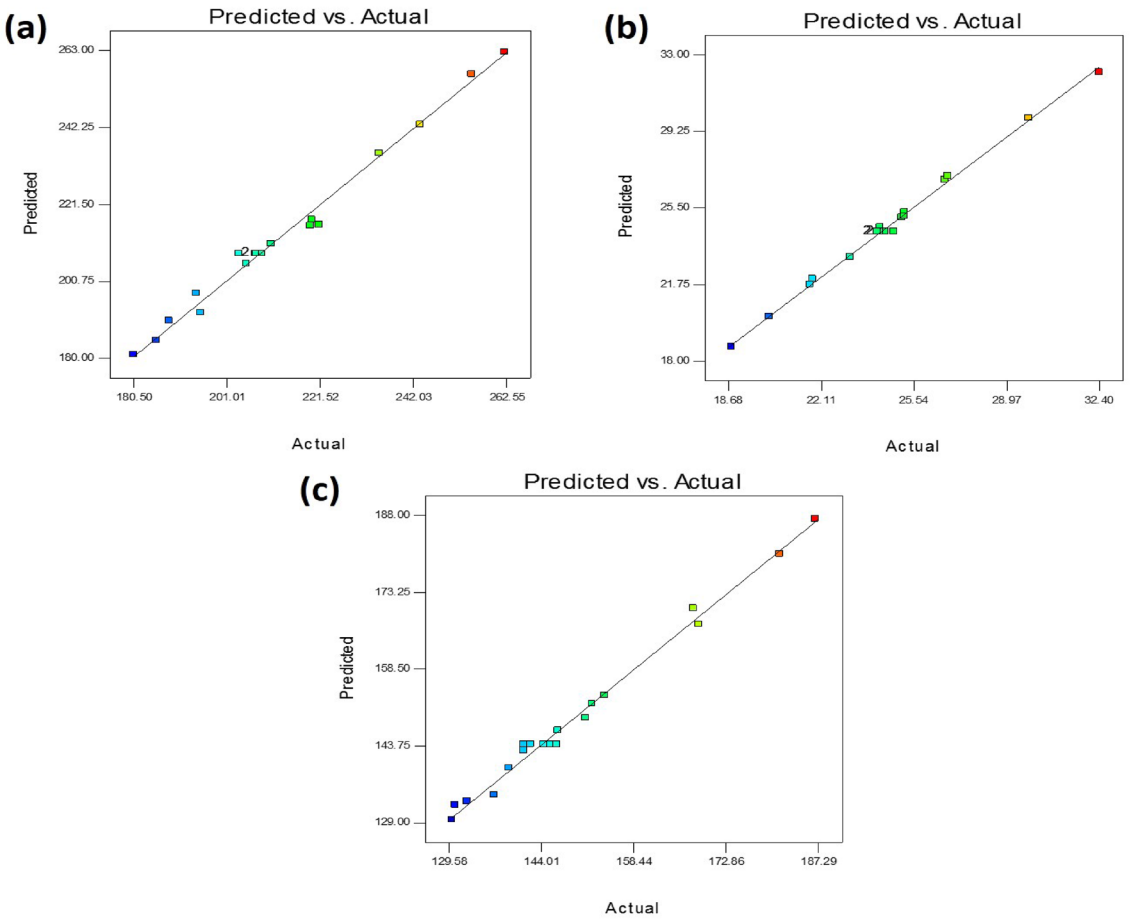

Fig. 8 **a–c** Actual vs. Predicted values plots; (**a**) UTS, (**b**) %strain, (**c**) Microhardness

(1) The significance of all three parameters in FSW lies in their ability to influence the properties of the welded joint. The developed models showed that rotating speed is the most influential parameter, volume percentage of SiCp is the second most influential parameter, and transverse speed is the least influential parameter.
(2) The higher value of rotating speed and the lower value of transverse speed led to the homogenous distribution of SiCp in the SZ, resulting in reduced grain size and enhanced mechanical properties of the FSWed composite joints.
(3) The higher UTS, %strain and microhardness were evident in the FSWed composite joints that were embedded with a higher volume percentage (10%) of SiCp.
(4) The composite joints with the highest UTS of 261 MPa, strain of 32.4%, and microhardness of 187 HV were processed at 1100 rpm, 40 mm/min, and 10% VP-SiCp.
(5) The optimum value of rotating speed, transverse speed and volume percentage of SiCp was found to be 1094 rpm, 40 mm/min and 6%, respectively. In contrast, the value of multi-optimized UTS, %strain and

Partially Omnidirectional and Circularly Polarized MIMO Antenna covering sub-6 GHz Band for 5G Fast Plan

Monika Kaushik, Jasdeep K. Dhanoa, *Senior Member, IEEE,* and Mukesh K. Khandelwal, *Senior Member, IEEE*

***Abstract*— A two-port MIMO antenna is designed, manufactured, and analyzed, which covers the whole sub-6 GHz band ranging from 0.97 - 6.19 GHz with an integrated circularly polarized wideband centred at 3.5 GHz. The proposed work overcomes the challenges of (i) large size of antennas at *L*-band, (ii) circular polarization for wideband, (iii) channel capacity for 5G, and (iv) diversity in MIMO, and (v) minimum mutual coupling with inbuilt isolator. A very small antenna size of $0.113\lambda_0 \times 0.129\lambda_0$ is obtained after incorporating several techniques, including slots, stubs, defected ground, and parasitic elements. The structure is simple and contains an in-built isolator that provides more than 23 dB isolation between both ports. Partial ground with additional stubs helps to maintain high isolation between both ports within the whole operating band. The proposed antenna also improves the channel capacity and provides the minimum channel capacity loss (CCL) of about 0.12 bits/s/Hz. Various diversity characteristics (e.g. ECC, TARC, DG) are analyzed and found suitable within the required range. The proposed antenna radiates the omnidirectional pattern at the *L1* (1.57 GHz) and *L2* (1.22 GHz) bands of the Global Positioning System (GPS). Other than *L1* and *L2* bands, the proposed antenna also offers wide beamwidth for the remaining bands. Finally, an antenna model is manufactured to validate the findings through experimental measurements.**

***Index Terms*— Sub-6 GHz, 5G Fast Plan, MIMO Antenna, circularly polarized wideband, antenna packaging,**

I. INTRODUCTION

THE Sub-6 GHz band has been proposed for both types of licensed and unlicensed applications of fifth-generation (5G) networks by the Federal Communications Commission (FCC), Global System for Mobile Communications Association (GSMA), and 3rd Generation Partnership Project (3GPP) [1-6]. Moreover, the 3.5 GHz band within the sub-6 GHz range has been suggested for fast 5G networks by FCC [3-4], GSMA [5], and 3GPP [6]. Recently in April 2021, GSMA proposed a 3.5 GHz band (3.3 GHz to 4.2 GHz) for the implementation of 5G services globally [5]. Secondly, capacity and coverage of the band are two main factors for wireless applications. The band's capacity can be enhanced by using the multiple-in multiple-out (MIMO) technique [6]. Further, coverage can be improved by controlling the beamwidth and polarization of the antenna. Circularly polarized waves have minimum propagation losses and thus cover a maximum range [7]. However, achieving circular polarization (CP) within a wide range of frequency bands is challenging. Therefore, to address all the issues mentioned above of 5G, the proposed work is presented here, which covers the whole sub-6 GHz band ranging from 0.97 – 6.19 GHz, including a wide circularly polarized band of 1.43 GHz centred at 3.5 GHz, ranging from 2.7 GHz to 4.13 GHz. Here, a two-port MIMO is proposed, enhancing the channel capacity throughout the operating band. Therefore, one antenna can be used for multiple Sub-6 GHz wireless applications simultaneously.

Several MIMO microstrip antennas have been developed for wideband MIMO applications [8-12]. However, most of them are reported for UWB (ultrawideband) range (3.1-10.6 GHz). Because the 5G communication applications of lower frequencies are to be implemented within the sub-6 GHz band only, the upper band (from 6GHz to 10.6GHz) of the UWB antenna creates interference if it is used for such 5G applications. These unwanted interfering bands limit the performance of any wideband MIMO sub-6 GHz system. Although, few MIMO antennas have been reported for 5G applications under sub-6 GHz bands [13-15]. Moreover, few wideband antennas are also noted for lower 5G band applications [16-17]. Metamaterials and Metasurfaces have been used in MIMO antennas to improve the mutual coupling and other parameters [18-27]. However, there is still scope for improvement and advancement in circular polarization, mutual coupling, CCL, etc. Additionally, few antennas are reported that partially serve the sub-6 GHz band [28-30]. However, it is tough to find such a wideband MIMO antenna in the literature that covers the sub-6 GHz band, including L-band. The antenna proposed in this study not only bridges this identified gap of literature but also is integrated with a wide circularly polarized band centered at the most significant frequency for 5G applications.

The presented work proposes a wideband two-port MIMO antenna that covers the whole sub-6 GHz band starting from

0.97 GHz. The operating band is integrated with a circularly polarized band of 1.43 GHz wide bandwidth and centred at the most significant frequency for 5G applications, i.e., 3.5 GHz. Additionally, the proposed antenna radiates the omnidirectional pattern for the *L1* (1.57 GHz) and *L2* (1.22 GHz) bands of the Global Positioning System (GPS). Furthermore, the proposed antenna also consists of an in-built isolator to provide the minimum mutual coupling. Moreover, the proposed design is simple and easy to construct with minimum fabrication losses. A detailed parametric study of the proposed structure is presented, and various diversity parameters are analyzed in this work.

II. Antenna Design, Mechanism, and Analysis

This section describes the proposed antenna's design concept, evolution, and mechanism. The construction of the proposed antenna (*Ant-6*) is achieved through five intermediate antenna models named *Ant-1* to *Ant-5*, and the final structure is represented as *Ant-6* as depicted in Fig 1 (a). It is basically a two-port microstrip MIMO antenna constructed on a common ground plane. The presented antenna is designed and fabricated on a Fr-4 Epoxy substrate. The relative permittivity and loss tangent of the used substrate is 4.4 and 0.02, respectively.

The evolution steps are shown in Fig 1 (b). *Ant-1* is also achieved through three stages named I to III in the left corner inset of Fig 1 (b).The values of all the dimensions are (all in mm): L=35, W=40, h=1.57, L_1=10, L_2=4, L_3=1, L_4=1, L_5=6, L_6=2, L_f=10, W_1=10, W_2=6, W_3=2, W_4=2, W_5=8, W_6=4, W_f=3.01, W_g=6, W_d=8, G_d=4, D_1=1, D_2=1.1, H_1=15, H_2=15.9, G_1=14.5, G_2=2, St_x=3, St_y=24, $S1_x$=0.1, $S1_y$=4.4.

The basic idea of design and step-by-step construction of the final antenna design through five intermediate structures are described in the following subsections:

A. Design of basic antenna structure (Ant-1)

This study starts with a basic structure consisting of two identical microstrip line-fed patches supported by a common partial ground plane and as shown in the *I*-inset of the left corner of Fig 1 (b). The antenna structure is fed with a microstrip line of 50Ω characteristic impedance. Basically, it is a microstrip line fed monopole antenna supported by a semiground plane. The width W_f and length L_f of microstrip line are calculated by well-known mathematical equations (1) to (3) [31].

$$W_f = \frac{2h}{\pi}\left\{[B-1-ln(2B-1)] + \frac{\varepsilon_r-1}{2\varepsilon_r}\left[ln(B-1)+0.39-\frac{0.61}{\varepsilon_r}\right]\right\} \quad (1)$$

where, B is a constant having value equivalent to $377\pi/100\sqrt{\varepsilon_r}$

$$\varepsilon_{eff} = \frac{\varepsilon_r+1}{2} + \frac{\varepsilon_r-1}{2}\left(\sqrt{1+\frac{12h}{W_f}}\right)^{-1} \quad (2)$$

$$L_f = c \times \left(4f_d\sqrt{\varepsilon_{eff}}\right)^{-1} \quad (3)$$

The length L_1 and width W_1 of the patch is same and taken as

$$L_1 = W_1 = \frac{\lambda_{eff}}{4} = \frac{c}{4 \times f_d\sqrt{\varepsilon'_{eff}}} \approx 10\ mm \quad (4)$$

where c and f_d are the speed of light in free space and design frequency, respectively. ε_r is the relative permittivity of the substrate. Design frequency f_d is taken as 3.8 GHz. Effective permittivity ε'_{eff} is calculated as per eq (2).

After stage-I, a rectangular slot of length L_5 and width W_5 is embedded at the centre of the square patch for stage-II of Fig 1 (b). For further stage-III, a rectangular copper ring of outer dimensions $L_2 \times W_2$ is inserted within the recently constructed slot. Finally, one more rectangular copper patch of dimension $L_3 \times W_3$ is inserted at the common centre of this patch and newly made structure is referred as *Ant-1*. The *Ant-1* is called here as a reference antenna in this study which is established through four significant steps (stage-I to stage-IV), as shown in the left corner of Fig 1 (b). Stage-IV represents *Ant-1* itself. The S_{11} and S_{12} characteristics from stage-I to stage-IV is shown in Fig 1 (c), and Fig 1 (d), respectively.

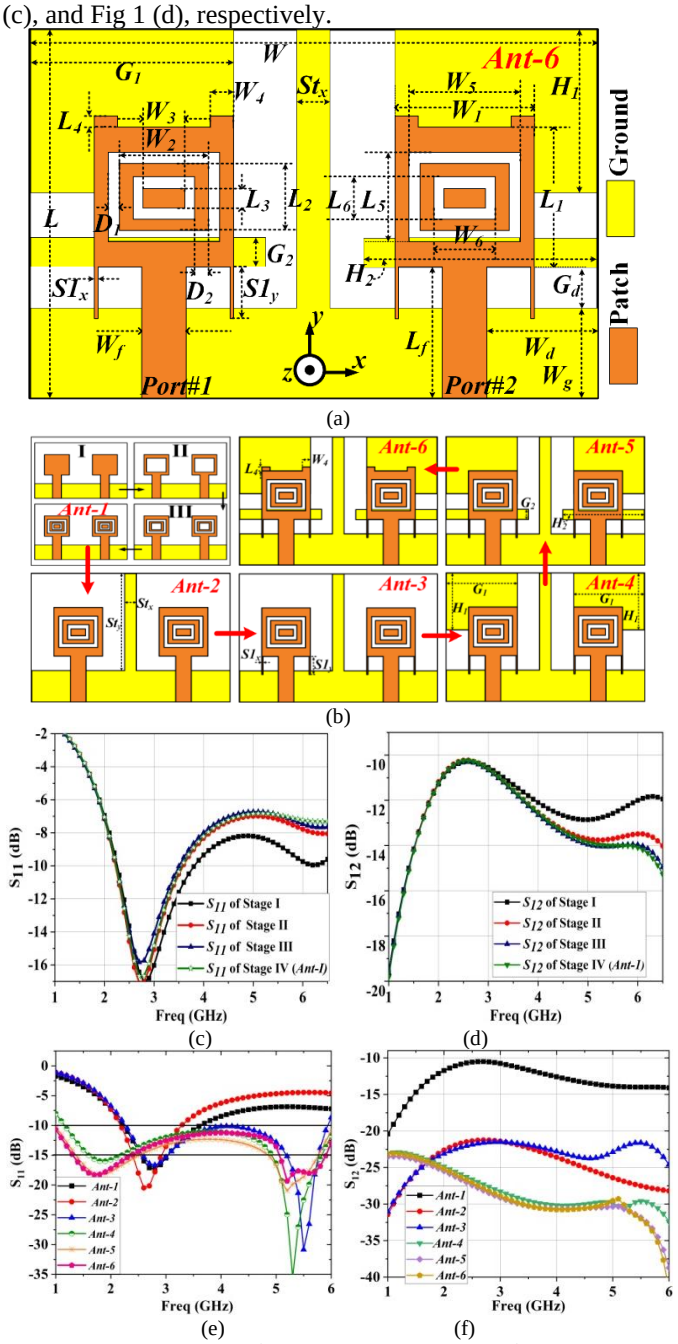

Fig. 1. Schematic designs of the proposed antenna; (a) final structure, (b) evolutionary steps, (c) S_{11} characteristics of stage-I to stage-IV, (d) S_{12} characteristics of stage-I to stage-IV, (e) S_{11} characteristics of *Ant-1* to *Ant-6*, (f) S_{12} characteristics of *Ant-1* to *Ant-6*

This article has been accepted for publication in IEEE Transactions on Components, Packaging and Manufacturing Technology. This is the author's version which has not been fully edited content may change prior to final publication. Citation information: DOI 10.1109/TCPMT.2023.3304490

Basically, *Ant-1* is a microstripline fed slotted square patch monopole antenna supported by a semi-ground plane. Semiground plane is useful to achieve a wide impedance bandwidth as it sends back the reflected waves coming towards the port, thus it improves the impedance matching over a wide range of frequency. The gap G_d between the upper edge of the semiground plane and lower edge of patch, plays a vital role in controlling the return loss level within the operating band. Parametric analysis of ground's length W_g is observed and shown in Fig 2 (a) and (b). Length W_g is basically changing the gap G_d. Initially, the design frequency is considered 3.8 GHz; however, miniaturization is achieved in the later stages of this study. The transmission line's width is set to 3.01 mm corresponding to 50-Ω characteristic impedance to get minimum reflection loss.

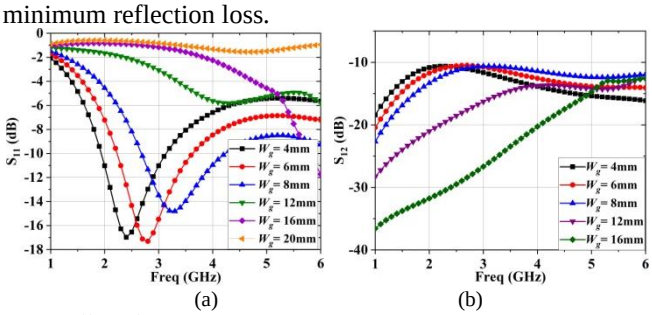

Fig. 2. Effect of length, W_g; (a) S_{11} characteristics, and (b) S_{12} characteristics

S_{11} and S_{12} characteristics of stage-*I* to *Ant-1* are shown in Fig 1 (c) and (d), respectively. *Ant-1* offers good return loss in the frequency range of 2.2 GHz to 3.6 GHz, however, both ports are closely placed, thus, poor isolation is noticed between them. Both ports are separated by a small distance to maintain compactness; however, the mutual coupling will be suppressed in further steps of this study even with this small separation distance.

B. Analysis and construction from Ant-2 to Ant-6

Fig 1 (c) and (d) are evident that *Ant-1* is not covering the whole sub-6 GHz band and also have low isolation between both ports. Therefore, the reference antenna (*Ant-1*) is modified to further stages in the form of *Ant-2* to *Ant-6*. For *Ant-2*, a vertical rectangular strip of dimensions $St_x \times St_y$ is attached to the semi-ground plane as shown in the schematic of *Ant-2* in Fig 1 (b). This vertical strip on the ground plane perturbs the coupling energy travelling between both ports, thus suppressing the mutual coupling. *Ant-2* offers a better S_{11} and S_{12} than the reference antenna (*Ant-1*); however, it does not cover the complete sub-6 GHz band. Therefore, further work is carried out to enhance the operating bandwidth with minimum mutual coupling and to achieve circular polarization.

Therefore, for further extension, two symmetrical rectangular stubs of dimension $S1_x \times S1_y$ are attached at the lower edges of both patches, as shown in the schematic of *Ant-3* in Fig 1 (b). We are calling these stubs as patch stubs here. The following three types of additional capacitance and inductance are introduced after embedding a pair of identical stubs; (i) a capacitance between the inner edges of these patch stubs, (ii) a capacitance between ground and patch stubs, and (iii) self and mutual inductance due to these patch stubs. These additional capacitances and inductance affect the resonance and improve the return loss characteristics for a wider impedance bandwidth.

The effects of length $S1_y$ and width $S1_x$ of the patch stub on S_{11} of *Ant-3* are shown in Fig 3 (a) and (b), respectively. The maximum bandwidth for *Ant-3* is obtained at $S1_y = 4.4$ mm and $S1_x = 0.1$ mm. *Ant-3* offers impedance bandwidth from 2.3 GHz to 5.98 GHz, in which mutual coupling is below -22 dB.

Ant-3 still doesn't cover the whole sub-6 GHz band; moreover, circular polarization is still to be achieved. Therefore, to improve the impedance bandwidth furthermore, two identical rectangular conducting strips of size $H_1 \times G_1$ are embedded on the reference plane to construct the *Ant-4*, as shown in the schematic of *Ant-4* of Fig 1 (b). Newly added conducting portions enhance the effective aperture of the antenna and improve the impedance matching corresponding to the L-band also. Thus, *Ant-4* provides the impedance bandwidth from 1.45 GHz to 6.2 GHz at H_1=15mm and G_1=14.5mm. The mutual coupling is below -22 dB for the complete working frequency. The effects of width G_1 and height H_1 of these conducting patches on the return loss of *Ant-4* are plotted in Fig 3 (c) and (d), whereas their effects on the axial ratio (AR) of *Ant-4* are presented in Fig 4 (c) and (d), respectively.

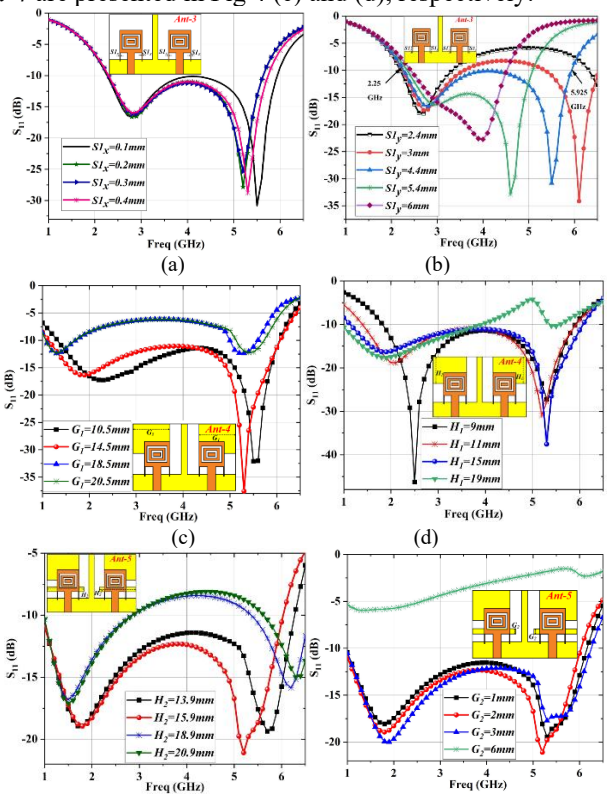

Fig. 3. Parametric S_{11} analysis, the effect of; (a) length *Sly* on *Ant-3*, (b) width *Slx* on *Ant-3*, (c) width G_1 on *Ant-4*, (d) length H_1 on *Ant-4*, (e) length H_2 on *Ant-5*, (f) width G_2 on *Ant-5*

In further analysis steps, two symmetric conducting rectangular strips of $G_2 \times H_2$ dimensions are embedded on the ground plane, which helps to enhance the range of impedance bandwidth. The new structure with integrated rectangular strips in the ground is named *Ant-5,* operating from 1 GHz to 6 GHz.

The effects of variation of length H_2 and width G_2 of these rectangular strips on the impedance bandwidth of *Ant-5* are shown in Fig 3 (e) and (f), whereas their effects on AR of *Ant-5* are presented in Fig 4 (e) and (f), respectively. The parametric

This article has been accepted for publication in IEEE Transactions on Components, Packaging and Manufacturing Technology. This is the author's version which has not been fully edited content may change prior to final publication. Citation information: DOI 10.1109/TCPMT.2023.3304490

analysis confirms that maximum bandwidth is achieved at strip length H_2=15.9 mm and strip width G_2=2 mm.

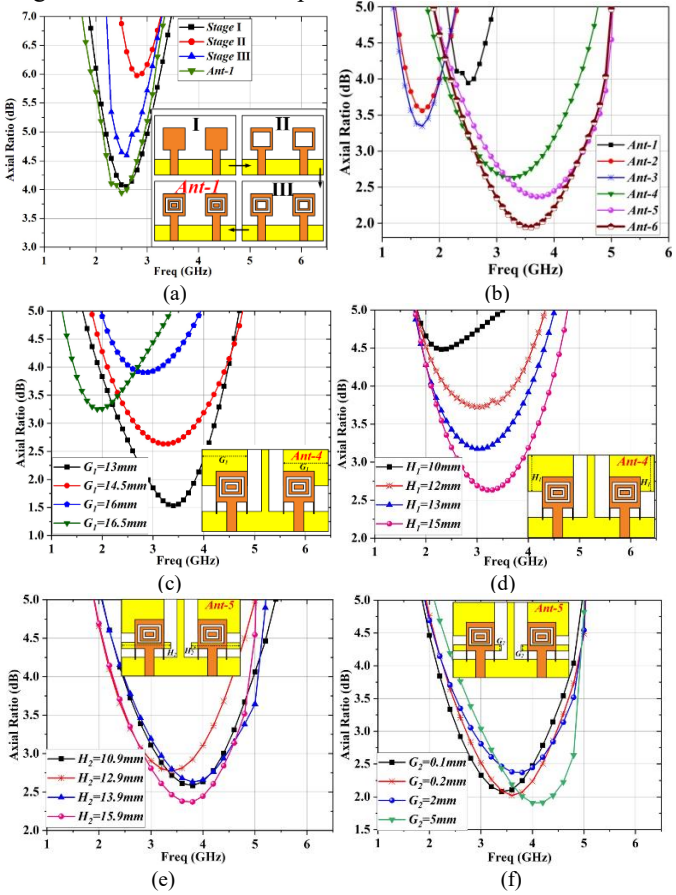

Fig. 4. Parametric axial ratio analysis of; (a) stage-I to *Ant-1*, (b) *Ant-1* to *Ant-6*, (c) effect of width G_1 on *Ant-4*, (d) effect of length H_1 on *Ant-4*, (e) effect of length H_2 on *Ant-5*, (f) effect of width G_2 on *Ant-5*

Finally, two rectangular strips of dimensions $W_4 \times L_4$ are added at the upper corners of both the radiating elements, as shown in the schematic of *Ant-6* in Fig 1. The optimized distance between these two rectangular strips is 6 mm. The introduction of strips in the patch further improves the reflection coefficient, as shown in the analysis of S-parameters given in Fig 1 (e) and (f). For this antenna, the mutual coupling is below -22 dB throughout the whole operating band from 0.97 GHz to 6.19 GHz. Therefore, the proposed antenna (*Ant-6*) covers the whole sub-6 GHz band starting from 0.97 GHz to 6.19 GHz. Moreover, *Ant-6* provides a good axial ratio at desired frequency i.e. 3.5 GHz. A comparison of S_{11}, and S_{12} of *Ant-1* to *Ant-6* is given in Fig 1 (e), and (f), respectively, whereas their AR comparison is shown in Fig 4 (b). *Ant-6* is the final product of this study. A prototype model is fabricated for this proposed antenna whose photograph is given in Fig 5 (a). Simulated and measured S-parameters results of *Ant-6* are shown in Fig 5 (b). *Ant-6* provides suppressed mutual coupling with a minimum value of -23 dB within the working frequency. About 74.47% [$\{(f_d\text{-}f_l)/f_d\}\times100$] of miniaturization is achieved corresponding to the design frequency (f_d=3.8 GHz), where f_l is the lowest working frequency. Ansys High-Frequency Structure Simulator (HFSS) is used for simulation work. Experimental results of the fabricated antenna are measured using a two-port Anritsu MS2028 VNA (Vector Network Analyzer).

The dimensions of the *Ant-6* are $L\times W\times h$, where L=0.113λ_0, W=0.129λ_0, and h=1.57mm represent the substrate's length, width, and height, respectively. λ_0 is taken corresponding to the lowest working frequency, i.e. f_l=0.97 GHz.

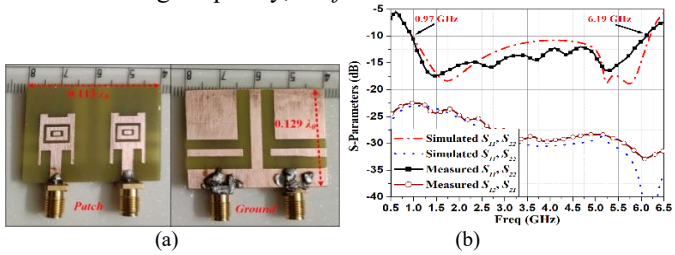

Fig. 5. (a) Fabricated prototype, (b) simulated and measured S-parameters of *Ant-6*

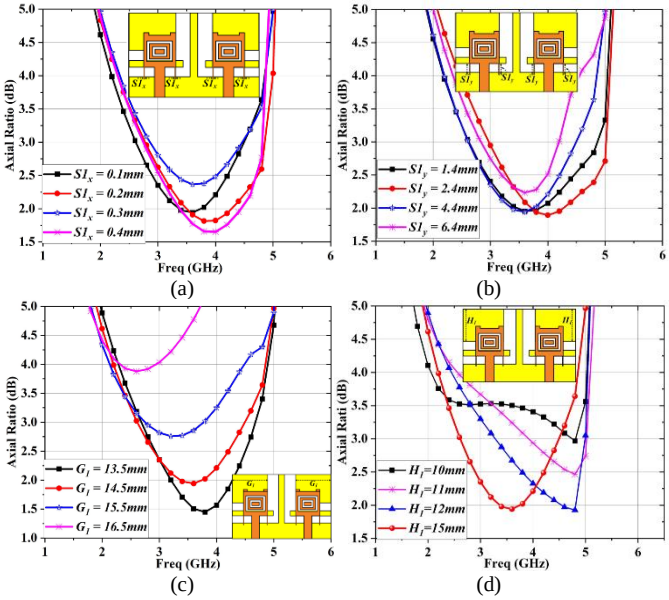
C. Axial Ratio (AR) Analysis

The parametric effects of different stages and dimensions on the axial ratios of intermediate structures are shown in Fig 3. The AR of stage-*I* to *Ant-1* is shown in Fig 4 (a) whereas a comparison of the AR of *Ant-1* to *Ant-6* is presented in Fig 4 (b). *Ant-1* to *Ant-3* have close results however, they are still above the satisfactory limit of 3dB. Therefore, further structures were evolved to achieve good AR at 3.5 GHz with a targeted coverage range. A parametric study of AR of *Ant-4* and *Ant-5* is given in Fig 4 (c) to (f). It is evident that defected ground structure of the proposed antenna is contributing to modeling the AR of the structure, however, it is also supported by the main radiating patch's structure. The effect of the variation of dimensions of *Ant-6* on AR is presented in Fig 6. It is observed that the circular polarization in *Ant-6* is credited due to the combined effect of multiple rectangular slots in radiating elements, rectangular strips in the ground planes, and rectangular strips at the upper corners of both the radiating elements. Fig 6 shows the measured and simulated AR of *Ant-6*, providing a wide axial ratio 3dB bandwidth of 1.68 GHz, centred at 3.55 GHz and ranging from 2.7 GHz to 4.38 GHz.



The circular polarization of the proposed antenna is also justified through the current distribution shown in Fig 8. The surface current density vectors at 3.55 GHz frequency are represented at 0º, 45º, 90º, 135º, 180º, 225º, 270º, 315º, and

360° phases. The left-hand circularly polarized behaviour (LHCP) is observed from the current distribution.

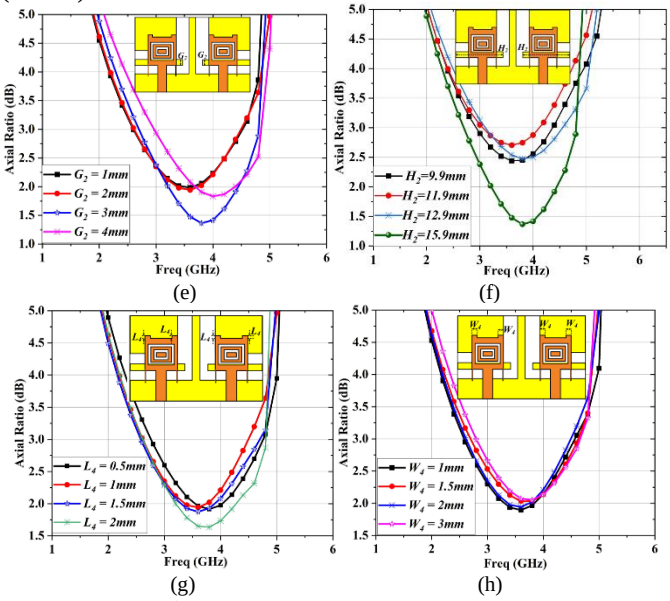

Fig. 6. Axial ratio of *Ant-6* with variation in; (a) $S1_x$, (b) $S1_y$, (c) G_1, (d) H_1, (e) G_2, (f) H_2, (g) L_4, (h) W_4

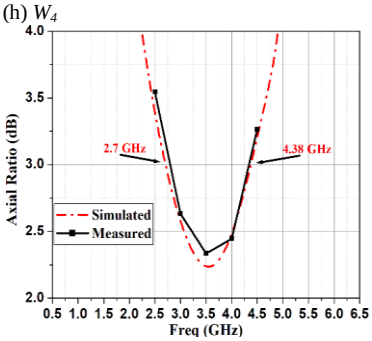

Fig. 7. Simulated and measured axial ratio of *Ant-6*

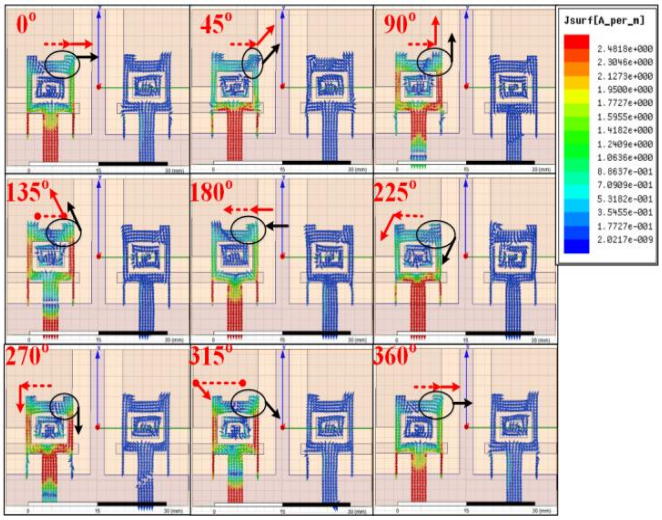

Fig. 8. Current distribution at 3.55 GHz for the different phases of the input signal (phases are mentioned in degree).

D. Radiation Pattern

The normalized radiation patterns of the *Ant-6* are shown in Fig 8. The radiation patterns are recorded in all three major planes (i.e. XY, XZ, and YZ planes) to provide better visualization and understanding of the radiation characteristics. Patterns are observed at 1.22, 1.57, 2.4, 3.55, 5.1, and 5.8 GHz frequencies, covering the almost wide band and representing the major applications for GPS, WLAN, Wi-MAX, and ISM (industrial, scientific, and medical) bands, etc. Frequencies 1.55 GHz as L1 and 1.22 GHz as L2 are used for GPS satellites. From the radiation patterns shown in the first two figures of Fig 8, it is observed that the proposed antenna is omnidirectional in YZ and XZ planes because patterns are beyond the -3dB circle in both planes at these two frequencies. Moreover, it is directional with broad HPBW (half power beam width) in the XY plane also at both frequencies. Therefore, the proposed antenna *Ant-6* is a suitable candidate for GPS applications in the most preferable L1 and L2 bands.

Further, it is noticed for 2.4 GHz frequency that *Ant-6* is completely omnidirectional in the YZ plane and almost omnidirectional in the XZ plane (except 55° to 95°). The 2.4 GHz band is the most useful band for modern wireless applications. For this band, the antenna can be used for ISM (industrial, scientific and medical), WLAN, and WiMAX. The achievement of the omnidirectional pattern at this frequency makes the proposed antenna most prominent for these applications. It is also observed that *Ant-6* provides broad HPBW throughout the operating bands in all major planes. The radiation pattern of the proposed antenna varies with frequency. There may be several reasons, and out of them, one is that the antenna is composed of several resonators, who are contributing to achieve a wide-band. Further, FR-4 epoxy is a lossy substrate whose losses are not stable with frequency.

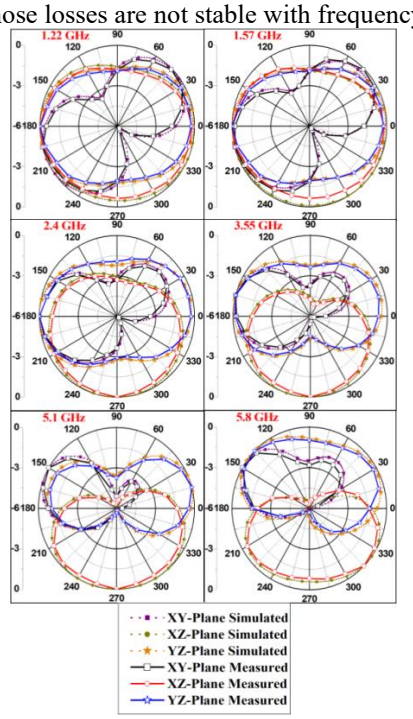

Fig. 9. Normalized radiation patterns of the proposed antenna *Ant-6*

E. Diversity Parameters

The diversity parameters are investigated to confirm the suitability of the proposed antenna as a MIMO antenna. The formulas are referred to as given in [27]. The envelope corrélation coefficient (ECC) of the proposed antenna is below 0.03 within the entire operating band, and the same characteristics are demonstrated in Fig 10 (a). Moreover, the diversity gain (DG) is calculated and found around the value of

This article has been accepted for publication in IEEE Transactions on Components, Packaging and Manufacturing Technology. This is the author's version which has not been fully edited content may change prior to final publication. Citation information: DOI 10.1109/TCPMT.2023.3304490

10 dB. In the continuation of the study of the diversity parameters, the proposed antenna's total active reflection coefficient (TARC) is also investigated which is lying below -20 dB for the working band. ECC and TARC are calculated using Eq (6) and Eq (9) of [30], respectively. The measurement of these parameters is done in anechoic chamber through vector network analyzer (VNA). Calculation of ECC is based on far-field parameters while TARC is depending on the S-parameters. The variation of DG and TARC concerning operating frequency is shown in Fig 10 (b), and all the values are found suitable for the MIMO performance.

Fig 10 (c) shows the simulated channel capacity loss (CCL) of *Ant-6* in terms of the number of bits per second per hertz (bits/s/Hz), and it is observed that CCL is of minimal value, which means the proposed antenna will support higher channel capacity. The calculation of CCL is done as per the formulas given in references [30,32-33]. The efficiency of the proposed antenna is studied in terms of radiation efficiency and total efficiency, shown in Fig 10 (d). The proposed antenna's radiation efficiency varies between 79% to 96.5%, whereas its total efficiency is found in the range of 79% to 95% (simulated) within the operating frequency. Measured total efficiency is found in accordance with the simulated results, as shown in Fig 10 (d).

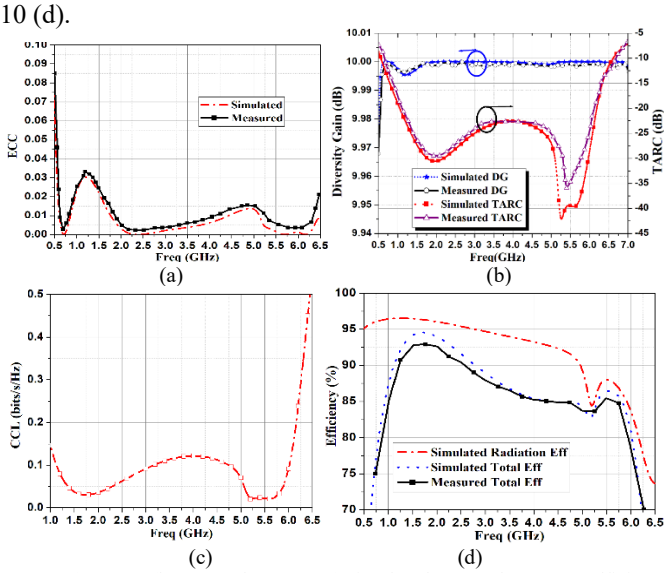

Fig. 10. (a) ECC, (b) DG and TARC, (c) simulated CCL, (d) antenna efficiency

A summary of the results of the proposed antenna (i.e. *Ant-6*) and its comparison with literature is comprised in TABLE I.

IV. Conclusion

A wideband two-port MIMO antenna is designed, that covers the whole sub-6 GHz band ranging from 0.97 - 6.19 GHz with an integrated circularly polarized wideband centred at 3.5 GHz. A built-in isolator is integrated within the proposed structure, which provides more than 23dB isolation between ports. The proposed structure is compact and of $0.113\lambda_0 \times 0.129\lambda_0$ size. An improved CCL of about 0.12 bits/s/Hz is achieved along with other satisfactory diversity parameters, i.e. ECC, TARC, and DG. The omnidirectional pattern is achieved at the L1 (1.57 GHz) and L2 (1.22 GHz) bands of the Global Positioning System (GPS). Except for the L1 and L2 bands, the proposed antenna offers wide beamwidth for the remaining bands. Experimental results validate the simulated results.

Monika Kaushik is pursuing Ph.D. Degree in Wide Band MIMO Antennas from IGDTUW, Delhi, India. She is also working as Assistant Professor in the dept. of Electronics & Communication Engineering of Bhagwan Parshuram Institute of Technology, Delhi. Her current research is focused on microstrip antennas, and 5G MIMO antennas.

Jasdeep K. Dhanoa (Senior Member, IEEE) did her Ph.D. in Electronics Engineering, from GGS Indraprastha University Delhi India, M. Tech in Electronics & Communication Engineering from Delhi College of Engineering and B.E. in Electronics Engineering.

She is a professor in the dept of Electronics & Communication Engineering of IGDTUW, New Delhi India. She also holds the post of Dean (Academic Affairs) of the University. She joined IGDTUW in 2014. She has a teaching experience of over 18 years at GTBIT, (affiliated GGSIPU) and Netaji Subhas Institute of Technology.

Prof. Dhanoa is an active member of ISTE, IETE, IEEE and WE00123. She is Vice Chair of WE00123 - Delhi Section Affinity Group, WIE-2015 and Chair Educational Activities of IEEE Delhi Section, 2015.

Mukesh K. Khandelwal (Senior Member, IEEE) received his Ph.D Degree in Electronics Engineering from Indian Institute of Technology ISM, Dhanbad, India in 2015.

He is working as an Assistant Professor in the School of Engineering of Jawaharlal Nehru University, Delhi, India. He has served as Deputy Director R & D of the University from Sept-2020 to Sept-2022. Moreover, he has also worked as Assistant Professor at GGSIPU and UPTU. His current research interests include microstrip antennas, metamaterials, 5-G antennas, UWB antennas, rectennas, reconfigurable antennas, multiband antennas, circularly polarized antennas, antenna array, defected ground structure and microwave components.

Dr Khandelwal has been received SERB International Research Experience (SIRE) fellowship awarded by Science and Engineering Research Board (SERB), a statutory body under the Department of Science and Technology, Government of India. He is serving as a reviewer in many reputed journals. He has published more than 40 SCI journals' publications and several international conference papers.

***Abstract*- Modern motor control algorithms have greatly enhanced the efficient operation of Permanent Magnet Synchronous Motors (PMSM). One such creative development is the use of Adaptive Neuro-Fuzzy Inference Systems (ANFIS) control for PMSM motors. This combines the advantages of neural networks and fuzzy logic for the control of PMSM drives, resulting in enhanced efficiency, better dynamic performance, and accurate control of the motor. This paper explores the benefits and application of ANFIS control in PMSM drives, highlighting its potential to power the upcoming generation of electric drive systems in the e-vehicle (EV) industries. ANFIS control is included into the drive system to implement Field Oriented Control (FOC) of PMSM. The performance of the PMSM drive is evaluated using stator voltage and torque equations under different speeds and load torque conditions. A comparative analysis of the performance parameters is presented for the conventional Proportional Integral (PI) control coupled with Hysteresis Current Control (HCC) and ANFIS speed controller integrated with HCC. The nonlinearity of PMSM makes it challenging to employ the standard PI gain settings, which results in undesired overshoot. The designed and developed ANFIS-HCC controller is found to overcome this problem and it provides consistent enhanced performance characteristics. Simulation studies and experimental validation of the proposed novel controller design bears testimony to its possible adoption in new-generation EVs owing to enhanced performance and improved dynamic characteristics.**

1. INTRODUCTION

Replacement of conventional internal combustion (IC) engine vehicles with EVs can drastically reduce automotive pollution. The motors used for EV drive application need to have flexible torque and speed characteristics, to cover the entire vehicle operating range [1]. They also need to be very efficient to get an acceptable driving range per charge cycle, in comparison with conventional IC engine vehicles. To cater to the needs of urban driving with an acceptable driving range and lower operating costs, it is crucial to improve motor efficiency under low-torque operating conditions [2].

A typical EV propulsion system is divided into electrical and mechanical components. Battery packs are used in the electrical system to store and supply power. Low voltage is converted to high voltage levels using the dc-dc boost converter. Direct current (dc) is transformed into alternating current (ac) by the voltage source inverter (VSI), which powers the machines. Further, a breaker connecting the battery packs and the converter is used for protection, and a bus capacitor in parallel with the inverter is used for high-frequency power surge absorption. A gearbox, usually connected to the PMSM shaft, serves as a differential, clutch, and speed governor. In the propulsion system, the protection mode is activated instantly in case of emergencies like vehicle crashes, etc.

PMSM drives are widely utilized in applications that require better torque and speed control, high power density, high torque to inertia ratio, and efficient drive systems. Unlike DC machines` PMSMs do not have brushes, which makes them more reliable. The recent past has witnessed increasing use of PMSM drives in applications traditionally dominated by dc machines, such as robotics, power, gas, oil, and transportation sectors. Induction motors, PMSMs, and switched reluctance motors have been traditionally used in EV propulsion systems [3]. However, PMSMs remain the popular choice due to their higher power density, ability to run at constant power for the majority of its operational range, and least acoustic vibration and noise. Furthermore, its high efficiency can be maintained across a wide range of speed-torque characteristics [4][5].

The development of effective control methods has resulted in lower torque ripples in PMSM drives. The most widely employed control in PMSM drives is the FOC technique [6][7][8]. In FOC, torque and flux are decoupled through field orientations and regulating the phase currents in the stator [9]. General linear control methods, however, are unable to satisfy the demands of high-performance applications of PMSM control systems due to external disturbances and inevitable errors in the model. A plethora of non-linear control techniques have been reported in the literature for performance enhancement, which includes sliding mode control [10],[11] neural network control [12][13], adaptive control [14][15], linearization control [16] and fuzzy control [17].

These control methods minimize losses and offer a reliable response, when parameter fluctuations occur, without depending on steady-state processes. The conventional PI controller for a PMSM drive has a limited dynamic characteristic range. Fine-tuning the PI controller also becomes difficult due to the linearized approximation of function at any given point. The ANFIS controller, on the other hand, may select the entire system and adjust to it. When used in low-power applications, the

conventional PI controller often responds quickly, however PI tuning cannot be used to increase drive performance in high-power applications. Replacing the conventional PI controller with an ANFIS controller in FOC-based PMSM drives overcomes this drawback thus producing better dynamic performance [18].

The combination of fuzzy inference with neural networks provides a versatile technique for designers to effectively create and operate electric drives due to its non-linearity handling capacity [19]. The ability of artificial neural networks (ANN) to reliably predict complicated correlations between a collection of inputs and outputs [20], which can be extremely nonlinear, unexpected, and unpredictable, has led to their increasing use in a variety of fields

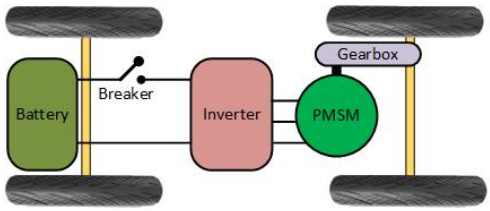

Fig. 1. Schematic of the PMSM drive for Electric vehicle control

This paper presents the design and implementation of an ANFIS-HCC speed controller for minimizing torque ripples in FOC-based PMSM drives. The ANFIS-HCC controller has been developed through simulation studies using MATLAB / Simulink and the laboratory prototype is implemented using dSPACE ds1104 controller. The schematic diagram of the system is shown in Fig. 1. The electric drive includes the battery, VSI and PMSM motor. The inverter is controlled by the ANFIS-HCC controller. The developed controller generates the reference speed and eliminates ripples by reducing system non-linearities. Experimental validation of the developed ANFIS-HCC controller is done and the comparative analysis of its performance vis a vis the conventional PI-HCC controller for FOC of PMSM drive is presented.

The novelty of this paper can be summarized as: -

a. The ANFIS-HCC for FOC of PMSM drive minimizes the torque and current ripples, resulting in the enhanced static and dynamic performance of the drive under diverse operating conditions of an EV.

b. The performance of the developed controller is verified using the EV industry-standard Inspection and Maintenance Driving Cycle (IM240).

This paper is organized into six sections, with an Introduction followed by Section II, which presents the mathematical models of EV and PMSM, Section III describes the ANFIS and HCC design. Section IV covers the Simulation Studies and Section V presents the experimental results and discussions. Section VI concludes the paper.

2. Mathematical Modeling

A. Mathematical Modelling of PMSM- based EV

The resistance forces acting on a vehicle in motion on a gradient are shown in Fig. 2. This is modeled mathematically as given in (1) and (2) and vehicle parameters as given in Table I.

$$F_T = F_R + F_W + F_G + F_A \quad (1)$$

$$F_T = K_R \mathrm{W}\cos(\delta) + K_W A V^2 + \mathrm{W}\sin(\delta) + W\frac{a}{g} \quad (2)$$

Where, F_T is the total tractive force of the vehicle, F_w the wind resistance, F_G the grade resistance, F_R is the rolling resistance due to road and tire interaction, and F_A is the accelerating force generated from the vehicle mass. K_R is the Rolling resistance coefficient, K_W is the wind resistance coefficient, A is the Vehicle frontal area, V is the velocity of the vehicle, W is the weight of the vehicle, δ is the gradient of the road, a is the acceleration of vehicle, g is the acceleration due to gravity.

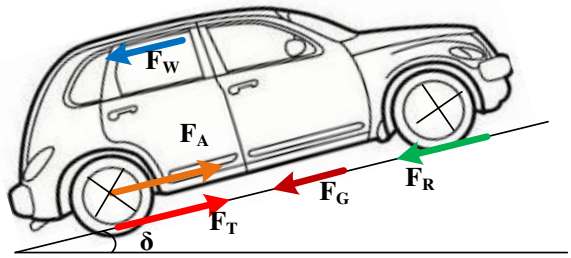

Fig. 2. Resistive forces acting on the vehicle

The motor torque and speed for various operating conditions are estimated using (3) and (4)

$$\omega_r = \mathrm{V}\frac{60 * r_f}{2 * pi * r_r} \quad (3)$$

$$\tau_L = \frac{r_r}{r_f} F_T \quad (4)$$

Where ω_r is the motor speed in rpm; V the vehicle speed in m/sec ; r_f is the gear ratio and r_r is the rolling radius of the wheel in meter.

Unlike conventional testing of electric motor drives meant for industrial applications, which is usually tested under constant or step or ramp changes in speed/torque conditions, the testing of motor drives for EV applications is tested using predetermined drive cycles, which represent the actual driving conditions depending on traffic, road condition, road gradient, etc. [21] [22] [23]. Therefore, a powertrain model should be constructed to test the drive depending on the required driving cycle. The Inspection and Maintenance Driving Schedule (IM240) is used to test the performance of the developed controller for PMSM used in the power train of EVs.

Table I. Vehicle parameters.

Vehicle weight (p.u.), W	1.0
Vehicle frontal area, A	2.35m^2
Wheel rolling radius, r_r	0.3048m
Gear ratio, r_f	4.5
Rolling resistance coefficient, K_r	0.015
Wind resistance coefficient, K_w	0.3

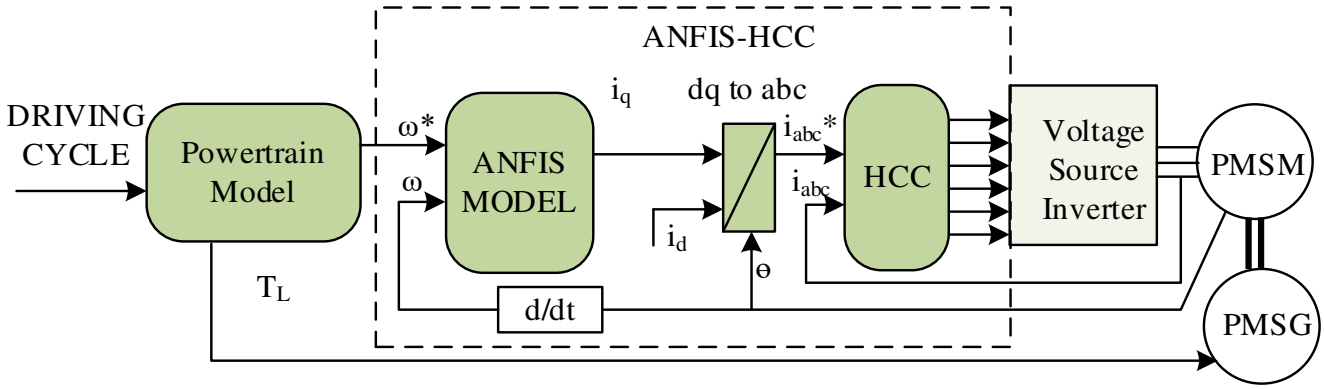

Fig. 3. Block Diagram of the Proposed ANFIS-HCC.

A. Modelling of PMSM drive

The vector control technique is used to decouple the stator current to create current components of direct and quadrature axes. The voltage equations of Surface Mounted PMSM (SPMSM) in the rotor reference frame are given in the (5), (6), and (7). Where v_q and V_d, respectively, are the stator quadrature and direct-axis voltage components; i_q and i_d , respectively, are the stator quadrature and direct-axes current components; L_s is the stator inductance/phase; R is the stator resistance/phase; ψ_f is the rotor flux linkage and ω_s is the rotor speed in electrical rad/s, v_a, v_b, and v_c sre the phase voltages.

$$\begin{bmatrix} v_q \\ v_d \\ v_0 \end{bmatrix} = \frac{2}{3}\begin{bmatrix} \cos\theta & \cos(\theta-120) & \cos(\theta+120) \\ \sin\theta & \sin(\theta-120) & \sin(\theta+120) \\ \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \end{bmatrix}\begin{bmatrix} v_a \\ v_b \\ v_c \end{bmatrix} \quad (5)$$

$$v_q = R \times i_q + L_s\frac{di_q}{dt} + L_s\omega_s i_d + \omega_s \times \psi_f \quad (6)$$

$$v_d = R \times i_d + L_s\frac{di_d}{dt} - L_s\omega_s i_q \quad (7)$$

The direct and quadrature axes stator currents are expressed as given in (8) and (9)

$$i_d = \frac{1}{L_s}\int [V_d - R \times i_d + \omega_s \times \psi_f]dt \quad (8)$$

$$i_q = \frac{1}{L_s}\int [V_q - R \times i_q - \omega_s \times \psi_f]dt \quad (9)$$

The developed torque and speed are given in (10) and (11) respectively. Where T_L is the load torque; P_n, is the number of poles; B, is the motor friction coefficient, T_e, is the electromagnetic torque; and ω_r is the rotor's mechanical speed.

$$T_e = 1.5 \times P_n \times \psi_f \times i_q \quad (10)$$

$$\omega_s = P_n \times \omega_r \quad (11)$$

3. ANFIS-HCC Controller for EV

The ANFIS model controls the outer loop of the FOC-based PMSM drive, whereas the HCC controls the inner current loop, as shown in Fig. 3. The control design strategy is elucidated in this section.

A) Adaptive Neuro-Fuzzy Inference System

ANFIS is an ANN that works with the Takagi-Sugeno fuzzy inference system [24],[25]. The technique builds the fuzzy inference system from an input-output pair and an observation data set that has been provided. In the learning phase, the backpropagation technique is used to modify the membership function's parameters in the designed ANFIS architecture.

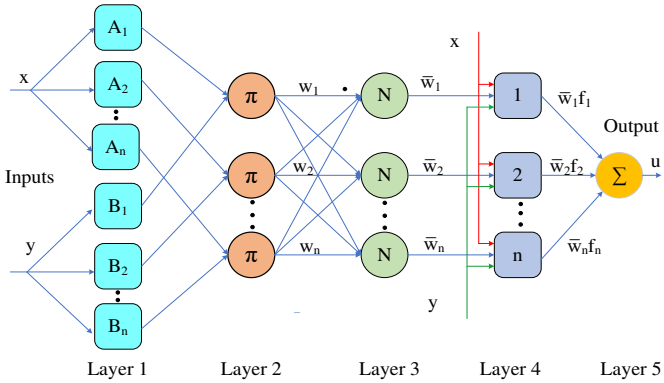

Fig. 4. Block Diagram of ANFIS

As shown in Fig. 4, the ANFIS structure is divided into five layers. The nodes in Layer 1 are adaptive nodes. The fuzzy membership grade of the inputs is given by (12) and (13)

$$O_{1Ai} = \mu_{Ai}(x), i = 1,2,3 \ldots n \quad (12)$$

$$O_{1Bi} = \mu_{Bi}(y), i = 1,2,3 \ldots n \quad (13)$$

Where x and y are the inputs to node i; Ai and Bi are the linguistic labels (high, low, etc.) connected to this node function μ. Each fuzzy membership function is adaptable by A_i and B_i , which depends on the least error. A triangular membership function is chosen as the shape with the least amount of error. It is specified by three variables: a and c for the feet and b for the curve tip. The triangular function is expressed as given in (14)

$$\text{triangular}\,(x,a,b,c) = max\left(min\left(\frac{x-a}{b-a}, 1, \frac{c-x}{c-b}\right), 0\right) \quad (14)$$

Each node with a label of π corresponds to the firing strength of

a fuzzy rule in Layer 2 (inference layer). The output of the Inference Layer is given in (15)

$$O_{2,i} = w_i = A_i(x) \times B_i(y) \quad , i = 1,2,3 \ldots n \tag{15}$$

The third layer, a normalization layer, normalizes the estimated firing strengths from the previous layer using (16).

$$O_{3,i} = \overline{w}_i = \frac{w_i}{\sum_i (w_i)} \quad , i = 1,2,3 \ldots . n \tag{16}$$

The nodes in Layer 4, are adaptive. The output of each node in this layer is the product of the normalized firing strength and a first order polynomial (for a first order Sugeno model). The output of this layer is given by (17).

$$O_{4,i} = \overline{w}_i f_i = \overline{w}_i (p_i x + q_i y + r_i), i = 1,2,3 \ldots . n \tag{17}$$

where f_i is the control signal and $(p_i, \ q_i, \ r_i)$ is the consequence parameter set. The output layer calculates the sum of all incoming signals and de-fuzzifies the subsequent set of rules using (18)

$$O_{5,i} = \sum_i (\overline{w}_i f_i) = \frac{\sum_i w_i f_i}{\sum_i w_i} \quad i = 1,2,3 \ldots . . n \tag{18}$$

B) Training of ANFIS

ANFIS controller must be trained and optimized before it can be used. To generate the data for training of the developed ANFIS Controller, the PMSM is driven using a conventional PI-HCC controller. Data corresponding to 50,001 pairs of input-output, captured by the control desk tool in dSPACE, were used to train the ANFIS-HCC using the triangular membership function (MF). The Flowchart for Training of the proposed ANFIS-HCC is shown in Fig. 5. Hybrid approach is used for minimization of error, wherein backpropagation is combined with least-squares techniques for best accuracy. In this, the error tolerance is set at zero, and 50 epochs were chosen for optimal training accuracy and time.

C) Hysteresis Current Controller

High-performance vector-controlled drives require large current-control loop bandwidths to enable accurate current tracking, rapid transient response, and to compel the VSI to act as an equivalent current-generating amplifier within the current loop bandwidth. When achieving the torque or speed requirements, HCC is employed to provide an output current that is almost sinusoidal [26].

Using an HCC with a hysteresis band for VSI current control in the inner loop ensures a nearly sinusoidal waveform, which is achieved by comparing the actual stator current, (i_{abc}) to the reference motor current, (i^*_{abc}). Due to the reference current being within a predetermined bandwidth, this also guarantees a low harmonic content in the stator current. The error in current determines the activation of the appropriate switches of the VSI depending on its value. The switching frequency of the controller is band limited. The ANFIS controller creates the quadrature axis stator current, i_q, in the outer loop based on the difference between the reference speed $(\omega_r{}^*)$ and the actual speed (ω_r). This along with the direct axis stator current, i_d, is converted to i^*_{abc} using park transformation. This reference three-phase current (i_{abc}*) is fed along with the measured current (i_{abc}) to the HCC to generate the firing pulse for the VSI to drive the PMSM.

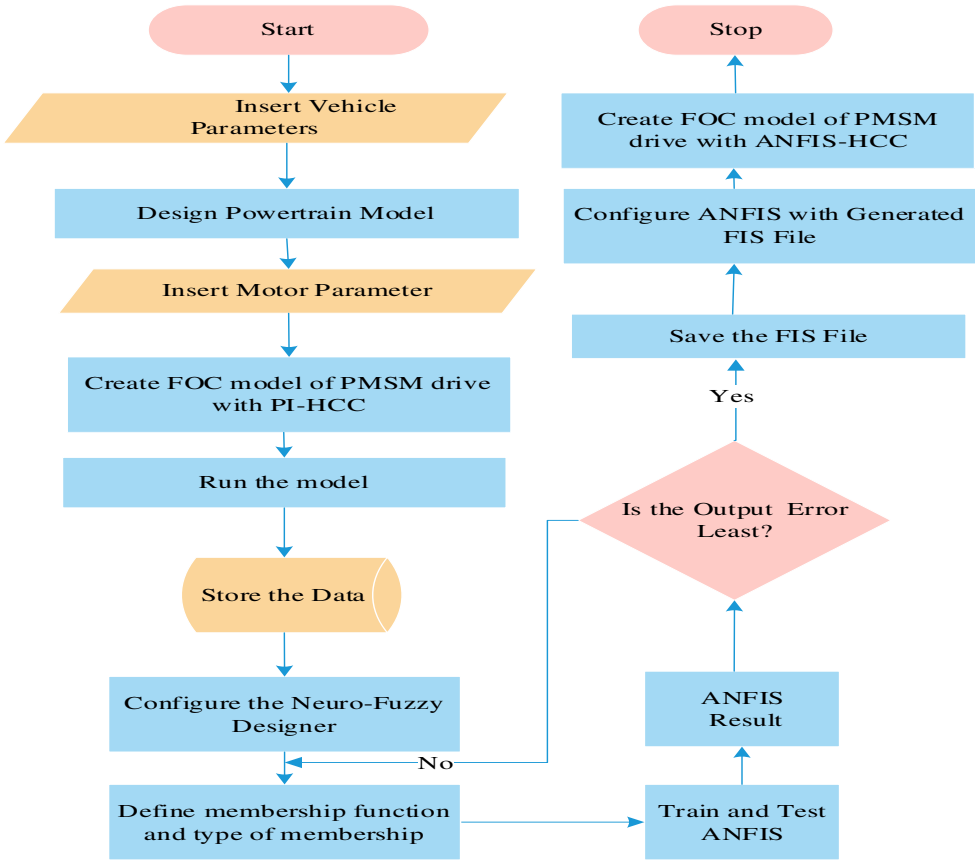

Fig. 5. Flowchart for Training of proposed ANFIS-HCC

4. SIMULATION STUDIES AND DISCUSSIONS

The proposed ANFIS-HCC controller is developed through simulation studies using MATLAB/Simulink with a sampling time of 5 µs for the motor with specifications as given in Table II. This section presents the comparison of the performance of the FOC based PMSM drive using conventional PI-HCC and the proposed ANFIS-HCC controller under different operating conditions.

The cascaded control system structure consists of two control loops. The outer loop is the speed control loop, and the inner loop is the current control loop. In the PI control structure, the outer-speed controller loop and the inner-current controller loop are based on PI and HCC controllers respectively. Whereas, the ANFIS-HCC control scheme is a combination of ANFIS in the speed control loop and HCC in the current control loop.

When a motor starts up, it requires a large amount of current to overcome inertia, but this current gradually decreases as the speed reaches a steady state value. The speed responses of the aforesaid two controllers are simulated and analyzed. The starting response of PMSM drive at rated-speed and no-load operation using PI-HCC and proposed ANFIS-HCC are presented in Figs. 6 and 7 respectively.

While starting with the reference speed set to 3000 rpm under no-load condition, some distortion and overshoot in electromagnetic torque (T_e) ,speed (ω_r), and stator current (i_a) are observed in PI-HCC based controller. However, the ANFIS-HCC based drive gives fast and smooth speed characteristics without overshoot. Fig. 8 shows the zoomed-in starting characteristics of the PMSM drive. In addition, the ANFIS-HCC controller has a shorter rising and settling time than the PI-HCC controller.

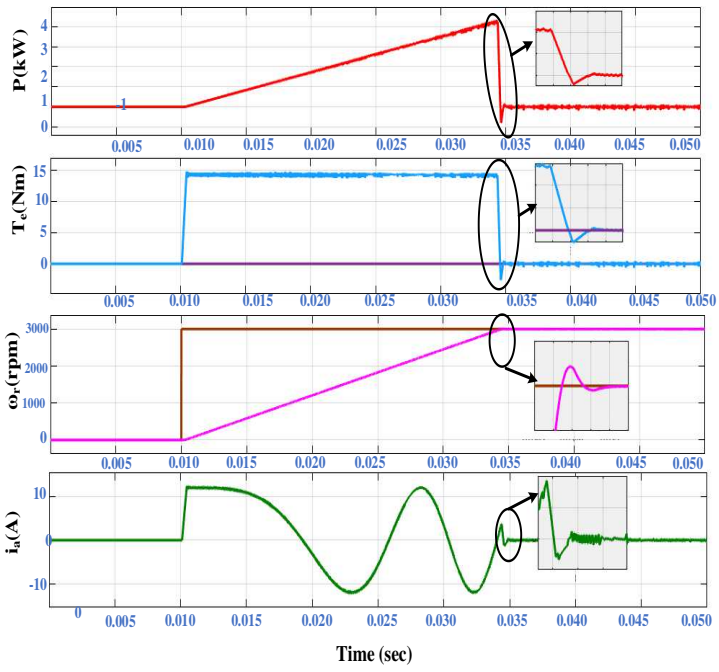

Fig. 6 Dynamic-Response of PI-HCC-based PMSM Drive under no-load rated speed (3000 rpm) Operation.

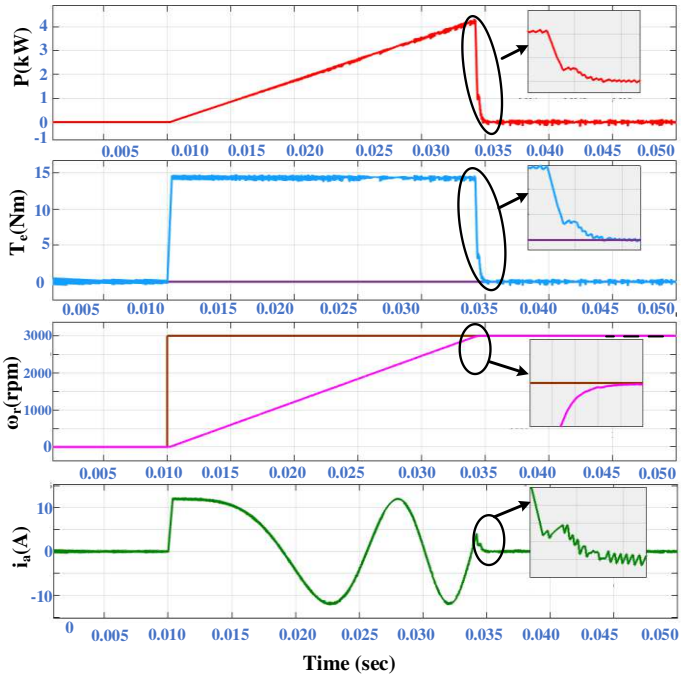

Fig. 7 Dynamic Response of ANFIS-HCC based PMSM Drive under no-load rated speed (3000 rpm) Operation

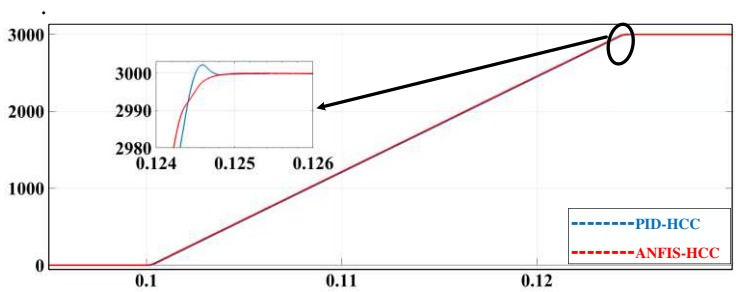

Fig. 8. Starting response of the PI-HCC and ANFIS-HCC based PMSM Drive under no-load-rated speed (3000 rpm) Operation

The proposed ANFIS-HCC for FOC of PMSM drive provides a significant reduction in current and torque ripples of PMSM drive in addition to fast and accurate speed tracking in comparison with the conventional PI-HCC-based controller.

5. EXPERIMENTAL RESULT AND ANALYSIS

A. *Experimental Setup*

A 5 HP, 380 V, 6 poles, and 3000 rpm SPMSM, with machine parameters as tabulated in Table II, is used for the experimental setup. The laboratory prototype, shown in Fig. 9, is powered by a bidirectional dc power supply. A dSPACE 1104 controller is programmed to control a 3-arm voltage source IGBT converter. MATLAB software is used to program the dSPACE 1104. Current sensors are used to detect alternating current. A permanent magnet synchronous generator (PMSG) coupled to the shaft of the SPMSM is used for electrical loading using resistor banks connected to the PMSG.

An incremental rotary encoder with a 1000-point base generates the feedback speed and position signal. An incremental encoder generates the A and B output signals using a quadrature

encoder. The pulses from the A and B outputs have square waveforms and a 90-degree phase difference because they are quadrature-encoded, even though the incremental encoder is working at a constant speed.

The phase difference between A and B signals will either be positive or negative depending on the direction the encoder is travelling at any particular time. Depending on the device's design, the phase difference for a rotary encoder is +90° for clockwise rotation and -90° for counterclockwise rotation. The frequency of the pulses on the A or B output is directly related to the encoder's velocity (rate of position change); greater frequencies indicate faster movement, while lower frequencies indicate slower movement. The frequency of a rotary encoder represents the pace of the encoder's shaft rotation, while the frequency of a linear encoder indicates the speed of linear traversal.

Table II. PMSM parameters

Rated Voltage	380 V
Rated speed, ω_r	3000rpm
Torque, T	11 Nm
No. of poles, P_n	6
Stator resistance, R	1.93 ohm
Rated Current, I	6.9A
Inductance, L_s	11.4mH
Flux linkage, ψ_f	0.265 wb
Voltage constant	144.7 Volts/Krpm
Torque constant, Kt	1.197 Nm/A
Inertia	0.0011 kg-m^2

B. *Starting Performance of PMSM drive*

The dynamic response of the laboratory prototype using conventional PI-HCC and the proposed ANFIS-HCC for FOC of PMSM Drive during startup under no load – rated speed (3000rpm) operation is shown in Figs. (10) and (11), respectively. The electromagnetic torque produced on reaching steady state speed enables the PMSM to achieve and maintain the reference rotor speed. It is observed that the FOC of PMSM using ANFIS-HSS takes 10% lesser rise time as compared to the conventional PI-HCC-based FOC of PMSM, as tabulated in Table III. In addition, the speed, torque, and stator currents exhibit some distortion in PI-HCC-based controller, unlike the ANFIS-HCC-based controller. The ANFIS-HCC controller is thus observed to offer a quick and smooth response.

Table III. Comparison of Starting Speed Response

Control Method	Rise Time (ms)	Settling Time (ms)
PI-HCC	293.4	482
ANFIS-HCC	264.7	428

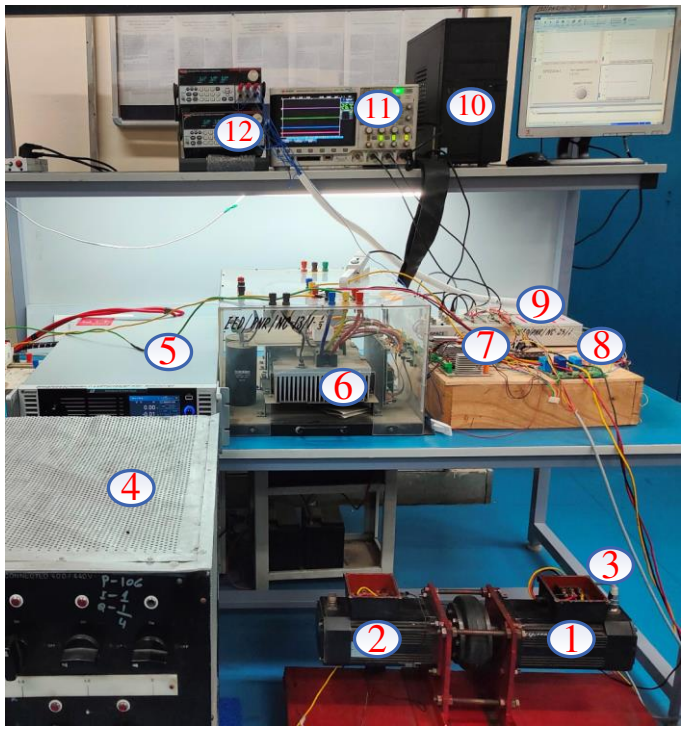

Fig. 9. Experimental setup for testing the ANFIS-HCC based PMSM drive: 1-PMSM, 2-PMSG, 3- Rotary Encoder, 4- Resistive load, 5- Bi-directional dc power supply, 6-Three-Phase Inverter, 7- Driver circuit, 8- Current Sensors, 9- dSPACE1104,10-PC, 11-4-Channel DSO, 12-dc power supply

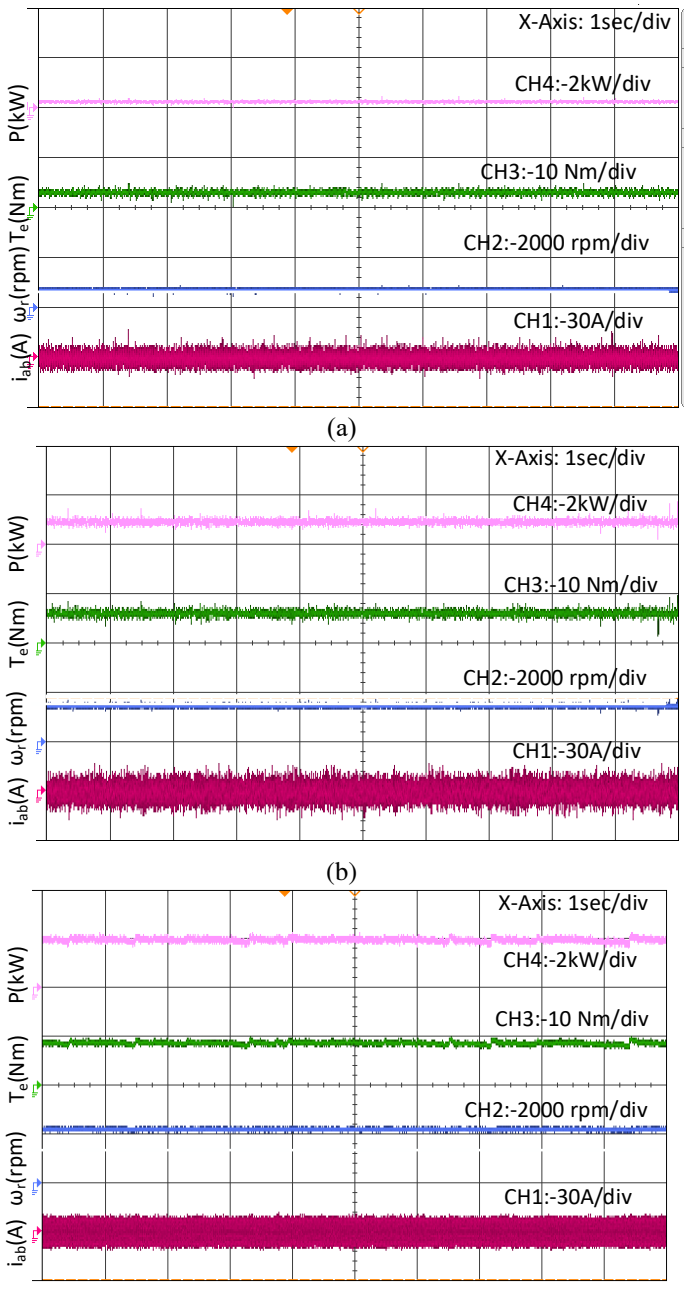

Fig 13. Steady-state response of ANFIS-HCC based PMSM drive at (a)750rpm-3Nm (b)1500rpm-6Nm(c)2250rpm-9Nm.

C. Steady-state performance of PMSM drive

To validate the effectiveness of the proposed ANFIS-HCC-based scheme for FOC of PMSM Drive, the Steady State performance is assessed under different speeds with load torque of 25%, 50%, and 75% of its rated load. The motor speed, electromagnetic torque, stator current, and input power for the PMSM drive using the conventional PI-HCC and proposed ANFIS-HCC are shown in Figs. 12 and 13, respectively. It is observed that the perturbations in power and current are less in the ANFIS-HCC-based FOC. Torque ripples in electromagnetic torque in the above specified steady-state conditions for both the controllers is tabulated in Table IV.

The proposed ANFIS-HCC controller has lower torque ripples than PI-HCC at low load and low rpm, but it is comparable to the conventional PI-HCC-based FOC at higher rpm and higher load. Thus, experimentally validating the better performance of the proposed ANFIS-HCC controller in comparison with the conventional PI-HCC controller with superior torque characteristics with fewer ripples under steady-state conditions for various operating conditions.

Table IV. Torque Ripple under Steady State Operation.

Control Method	$750rpm - 3Nm$	$1500rpm - 6Nm$	$2250rpm - 9Nm$

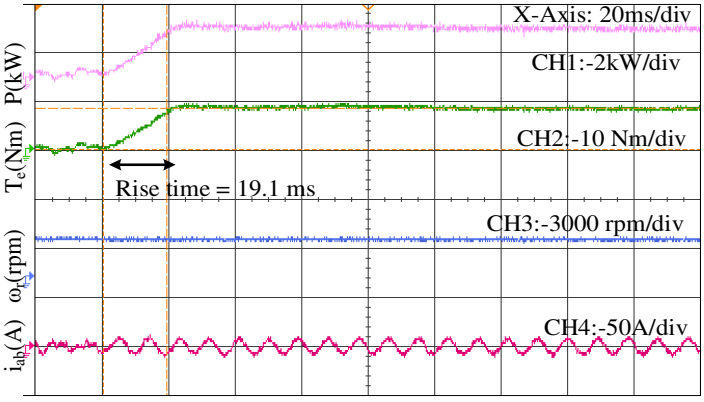

Fig. 19. Dynamic response of PMSM drive with ANFIS-HCC based FOC for a step change in load from 0 to 9Nm at constant speed (2250rpm) operation.

D. Dynamic Response of PMSM drive under variable speed/load torque conditions

The dynamic response of the PMSM drives with conventional PI-HCC based FOC for step change in speed from 750 to 1500 to 2250rpm during forward motoring mode under no-load condition, for speed reversal from $+1500$ to $-1500\,pm$ under no load condition and step change in load from 0 to 9Nm at constant speed (2250 rpm) operation are shown in Figs 14 to 16 respectively. Figs.17 to 19 display the respective corresponding dynamic responses of the drive using the developed ANFIS- HCC for FOC of PMSM drive. It is observed that the proposed ANFIS-HCC-based controller reduces the torque and current ripples and provides smooth transition under step change in speed, step change in load, and change in motoring mode. The comparative analysis of the recovery time for the two controllers for a step change in load is given in Table V.

Table V. Comparative Analysis for step load change in load from 0 to 9Nm at 2250 rpm.

(d)

Fig. 20. Dynamic Response of the Laboratory Prototype for IM240 Drive Cycle. (a) Speed. (b) Torque. (c) Power. (d) Energy consumption.

E. Performance Validation using IM240 Drive Cycle.

Electrical motor drives used for EV applications have to withstand frequent changes in load torque and speed due to diverse traffic conditions, type of road surface, the gradient of the road, etc. It thus becomes imperative to test electric motor drives for EV applications under such varied operating conditions. The Inspection and Maintenance Driving Cycle (IM240), a $240sec$ test which represents a $3.1\,km$ driving track with a maximum speed of $91.2\ km/h$ and an average speed of $47.3\ km/h$ [26] is used to test the effectiveness and energy efficiency of the developed ANFIS-HCC based laboratory prototype.

Figs. 20(a) to 20(d) show the dynamic response of the ANFIS-HCC and PI-HCC-based FOC of the laboratory prototype when put through the IM240 Driving Cycle. It is observed that both the FOC models provide flawless speed tracking as shown in Fig. 20(a). However, during transients, there is a noticeable improvement in the generation of torque and a distinct lesser usage of power for developed ANFIS-HCC based FOC of PMSM Drive, as shown in Figs. 20(b) and 20(c) respectively. In addition, the proposed novel ANFIS-HCC-based drive utilizes less energy, with an energy consumption of 0.19kW-hr units compared to 0.26 kW-hr units for the PI-HCC-based drive, as shown in Fig. 20(d).

6. CONCLUSION

A novel ANFIS-HCC for FOC of PMSM Drive for EV application is designed and developed through simulation studies using MATLAB/Simulink. The proposed control scheme is implemented in a laboratory prototype using a DSP-based dSPACE1104 controller for experimental validation. The performance of the developed novel ANFIS-HCC-based FOC is compared with the conventional PI-HCC-based FOC for PMSM drive during starting, under steady state operation, during step change in load, step change in torque, and speed reversal. In addition, the suitability of the developed novel ANFIS-HCC-based FOC for PMSMS drive in EV application is validated by testing it using IM240 Drive Cycle, which depicts a typical traffic pattern. The modelling and experimental findings demonstrate the higher performance of the designed ANFIS-HCC-based controller under diverse operating situations.

As compared to the PI-HCC controller, the proposed ANFIS-HCC controller offers several advantages as specified below:

A) Under steady-state conditions, experimental findings show that the proposed ANFIS-HCC-based controller can reduce motor torque ripples by 60-65% at lower speeds and 10-20% at higher speeds.

B) A smoother dynamic response to a change in speed is observed for the proposed ANFIS-HCC controller. It exhibits up to 28% quicker torque recovery during step changes in load conditions.

C) The energy consumption for the IM240 drive cycle demonstrates that 27% less energy is required while using an ANFIS-HCC-based PMSM drive for EV applications.

It is thus established that the use of the proposed novel ANFIS-HCC-based FOC of PMSM Drive would result in a more efficient EV. The suggested drive can also be used for industrial applications like spindle drives [27] and precise positioning systems that require negligible ripples.

DECLARATION

We declare that the manuscript is original, has not been published before and is not currently being considered for publication elsewhere.

We know no conflicts of interest associated with this publication. I confirm that the manuscript has been read and approved for submission by all the named authors.

Abstract

This paper proposes a novel dielectric modulated step-graded germanium source biotube FET for label-free biosensing applications. Its integrated structure and unique design combine the benefits of the gate stack, germanium source, triple-gate architecture, and a step-graded biotube channel, resulting in superior performance over existing biosensors. A compact two-dimensional analytical model for channel potential, drain current, threshold voltage, and subthreshold swing has been formulated and agrees well with the simulated results. The comprehensive investigation of different device parameters, including doping and bias, offers valuable insights into optimizing the biosensor's performance. The proposed biosensor exhibits remarkable sensitivity, achieving up to 263 mV and 1495.52 nA for certain biomolecules, which has been validated by a compact analytical model and simulations performed on the SILVACO TCAD simulator. Several parameters are employed to assess the biosensor's effectiveness: threshold voltage, I_{ON}/I_{OFF} ratio, subthreshold swing, off-current, peak trans-conductance, and on-current. Furthermore, the biotube channel design enables lightweight and cost-efficient biosensors, enhancing the biosensor's practicality. This work also includes an analysis of the effect of temperature on the biosensor's performance and characteristics, providing insights into practical applications. High sensitivity of the biosensor signifies a significant advancement in biosensing technology, suggesting a wide range of potential applications in biomedical field.

List of abbreviations and symbols

Abbreviation	Description
CMOS	Complementary Metal Oxide Semiconductor
DM	Dielectric Modulated
DM-FET	Dielectric Modulated-Field Effect Transistor
DM-SGGS-BTFS	DM-Surrounding Gate Germanium Source-Biotube FET Sensor
FET	Field Effect Transistor
FTSGP	Forward Triple Step Graded Profile
IIFET	Impact Ionization Field Effect Transistor
g_d	Output Conductance
g_m	Transconductance
g_{mp}	Peak Transconductance
I_{ON}	On-Current
I_{OFF}	Off-Current
I_{ON}/I_{OFF}	Current Ratio
K_{bio}	Dielectric Constant of Biomolecules
MOSFET	Metal Oxide Semiconductor Field Effect Transistor
N_f	Charge Density of Biomolecules
RTSGP	Reverse Triple Step Graded Profile
SCE	Short Channel Effects
SG-MOSFET	Surrounding Gate-MOSFET
S_{FCR}	Fractional Sensitivity in I_{ON}/I_{OFF} Ratio
S_{gm}	Transconductance Sensitivity

Accepted Manuscript

S_{gd}	Output Conductance Sensitivity
S_{gmp}	Peak Transconductance Sensitivity
S_{IDS}	Drain Current Sensitivity
S_M	Sensitivity with respect to sensing metric 'M'
S_{SS}	Subthreshold Swing Sensitivity
S_{Vt}	Threshold Voltage Sensitivity
TCAD	Technology Computer Aided Design
TFET	Tunnel Field Effect Transistor
V_{GS}	Gate Voltage
V_{DS}	Drain Voltage

1. Introduction

The exponential and rapid development of technology has led to the progressive evolution of Field Effect Transistor (FET) devices [1–4]. Field effect transistors are effectively used in sensing applications due to scalability and high sensitivity. Sensing technologies have evolved over the years, leveraging advancements in electronics and miniaturization to enhance their capabilities. From simple temperature and pressure sensors to sophisticated devices like pH/biomolecules/gas sensors, the range of sensing applications has expanded rapidly. Most of the FET sensors utilize the basic principles of dielectric modulation to detect and measure various physical parameters. To enhance the selectivity of these dielectric modulated FET based biosensors, the FET device is integrated with a sensing element, which could be a specific material, a biomolecule, or an enzyme. The development of FET sensing and biosensors has opened up new possibilities for real-time, label-free, and portable sensing devices, with the potential to transform healthcare, agriculture, and environmental monitoring.

FET based biosensors generally utilize the principle of dielectric modulation for label-free detection of biochemical species. Dielectric modulated FET (DM-FET) biosensors have gained attention in recent years for their potential applications in biomedical field [5,6]. The main advantage of a DM-FET based biosensor is its ability to detect biomolecules without the need for labeling (label-free detection). Generally, when biomolecules are trapped within the embedded cavity (without any bioreceptor layer), the characteristics of FET undergo changes that enable the detection of biomolecules by analyzing the relative change in the sensing metric (threshold voltage/drain current/current ratio/subthreshold swing). However, a significant drawback of this type of detection is its poor selectivity [6]. To address this limitation, the selectivity of the DM-FET biosensor can be greatly enhanced by incorporating an additional bioreceptor layer, which is functionalized on the gate oxide layer and specifically binds to the target biomolecule (biotarget). The incorporation of an additional bioreceptor layer significantly improves the selectivity but could increase the complexity of the fabrication process in the nanoscale regime and may lead to a decrease in sensitivity (considering the relative change in the value of the sensing metric). Various biotarget - bioreceptor systems have been employed in FET biosensors, as reported in the existing literature [4,7–10]. Examples include the interaction between Streptavidin and Biotin, the utilization of Iris antibody (anti-Iris) for binding to the Iris antigen, and the Avian influenza antibody (anti-AI) targeting the Avian influenza surface antigen (AIa).

In real scenario, DM-FET biosensor utilizes the concept of dielectric modulation to detect the presence or absence of biomolecules. The gate oxide layer is functionalized with a bioreceptor capable of specifically binding the desired biomolecule, known as the biotarget. The interaction between the biotarget and bioreceptor leads to alterations in the electrical characteristics of the device (FET), including electric potential, conduction current, and electron concentration in the channel. The observed changes in electrical properties (characteristics) are similar to the changes induced by the application of an external gate voltage (gate/drain voltage). The degree and extent of changes in the sensing metrics following the binding of biomolecules to the bioreceptor can be utilized for biomolecule detection. Therefore the sensitivity of a DM-FET biosensor can be defined as the change in the biosensor's output, which corresponds to variations in the concentration/charge density of analyte, serves as an indicator for detecting the presence or absence of biomolecules. This detection relies on properties such as the dielectric constant (or permittivity) as well as, charge density of the biomolecules [5–7]. However, DM-FET biosensors also have some disadvantages such as sensitivity to operating conditions and environmental conditions (temperature, humidity, high/low frequency noise etc); manufacturing complexity achieving a high level of accuracy and precision in creating nanometer-scale cavities with desired shape and perfection); selectivity issues (limitation in multi-analyte detection: simultaneous detection of multiple analytes in a single complex sample is challenging and non-specific binding: leads to false-positive output); and stability issues along with the reliability issues affecting the long-term performance (various environmental factors and aging effects can lead to changes in the properties of the dielectric layer, which can impact the biosensor's electrical response; and furthermore, the presence of different biomolecules trapped within the cavity can gradually cause tear over extended periods).

FET has specifically three primary variants which are utilized in biosensing applications: Metal Oxide Semiconductor Field Effect Transistor (MOSFET), Tunnel Field Effect Transistor (TFET), and Impact Ionization Field Effect Transistor (IIFET). TFET and IIFET are the newer variants, whereas MOSFET is one of the oldest and utilitarian variants in the FET family. The rapid progress in nano-bioelectronics has opened up potential applications for MOSFET

Accepted Manuscript

in label-free electrical detection of biomolecules. MOSFET has gained attention due to their high sensitivity, compatibility with CMOS technology, and the ease of fabricating biosensing systems onto integrated circuits. The development of TFET based biosensors has emerged as a promising avenue for sensitive and low-power biosensing applications [11–13]. TFET, which operate on the principle of quantum tunneling, offer distinct advantages over traditional MOSFET, such as lower power consumption and reduced leakage currents. These unique characteristics make TFET well-suited for biosensing, where high current sensitivity (subthreshold region) and minimal energy consumption are critical. Dwivedi et al. [14] has addressed the location-dependent sensitivity degradation in conventional TFET by introducing a pocket TFET biosensor, which combines lateral and vertical tunneling in a single architecture. Dwivedi et al. [7] has compared tunneling and accumulation mode p-type transistor architectures as dielectric modulated biosensors, showing that while TFET achieve higher sensitivity near the source-channel junction, accumulation mode transistors exhibit higher sensitivity for biomolecules located away from the junction. While TFET and IIFET offers unique advantages such as lower power consumption or impact ionization-induced amplification, MOSFET currently provide better overall performance, reliability, and compatibility with existing technology. Conventionally, MOSFET is often considered superior to TFET and IIFET for several reasons:-

i. **Compatibility with existing and latest technology:** MOSFET has been widely used in the semiconductor industry for many years and are compatible with standard CMOS fabrication processes. The manufacturing process for MOSFET is well-established/known, resulting in high yield and reliable production. In contrast, TFET and IIFET are relatively new variants (technologies) and their fabrication processes are still being developed, making them potentially less accessible and reliable (industrial concern/drawback). Furthermore, the issue of random dopant fluctuations is more prevalent in TFET compared to MOSFET. This can be attributed to the conventional pin-structure of TFET, which necessitates high abrupt doping and the use of different materials in the source and drain regions (increasing fabrication complexity) [15,16].

ii. **No ambipolar conduction:** The issue of ambipolarity in TFET makes them more vulnerable to temperature fluctuations, resulting in a degradation of their noise performance. Additionally, in the context of sensing applications, a noteworthy drawback emerges as various sensing metrics become highly temperature dependent. This means that even a slight change in temperature can cause a significant shift in the value of the sensing metric, ultimately leading to undesirable temperature-dependent sensitivity [15].

iii. **Higher on-state current:** MOSFET generally exhibit higher on-current than TFET resulting in a slightly better transconductance and current ratio (comparatively, more suitable in amplifiers, and digital applications). Additionally, transconductance and current ratio can be valuable sensing metrics when utilizing MOSFET for different sensing applications.

iv. **Performance and speed:** MOSFET typically offer higher performance and comparable speed compared to TFET and IIFET. MOSFET has been extensively optimized over the years, allowing for high-speed operation and efficient switching applications. TFET and IIFET, while offering potential advantages such as lower power consumption and lower subthreshold swing, often suffer from reduced performance [15,17–20] in terms of speed (tunneling phenomenon causing delay intrinsic delay in charge carrier transport), noise performance (ambipolar behavior) and lower on-state current driving capability.

v. **Scalability and integration:** MOSFET has a well-established scaling roadmap, enabling the fabrication of smaller and more integrated devices. They can be readily integrated with other electronic components, allowing for the development of complex systems and sensor arrays. TFET and IIFET (being new emerging devices) may face challenges in terms of scalability and integration due to their unique device structures and associated fabrication complexities [5,21].

vi. **Wide range of applications:** MOSFET has been extensively studied and applied in various fields, including electronics, telecommunications, and biosensing. The versatility, scalability and compatibility with existing technology make them suitable for a wide range of applications. TFET and IIFET, being relatively new technologies (in terms of usability), are still exploring their potential applications (sensing and biomedical field) and may have limited practical implementations.

The exposition of FET based biosensors for sensing nucleic acids [22], pH levels [23,24], proteins [25], and DNA [26] has been evaluated and shown in the past. Buitrago et al. [27] has experimentally demonstrated a silicon nanowire-based FET biosensor. Many non-planar variants of surrounding gate MOSFET biosensors have been reported in the recent decade. Pratap et al. [28] has proposed a novel MOSFET-based biosensor that utilizes the concept of a junctionless transistor [29]. Chakraborty et al. [30] reported a variant of surrounding gate MOSFET-based biosensor and has shown the effect of gate oxide stacking on the sensitivity. High-k dielectric has numerous advantages [31–33], but direct deposition of HfO_2 over a silicon substrate is complex due to stability issues and can also degrade the performance of the biosensor. Therefore, HfO_2 is deposited over a thin layer of SiO_2 [34,35]. The literature survey reveals that channel doping [36,37] and source doping [38,39] must be kept low and high, respectively, to obtain superior characteristics. Therefore, a detailed study of doping-dependent sensitivity analysis becomes inevitable when investigating the performance of any FET-based biosensor.

Accepted Manuscript

MOSFET based biosensors [6] have gained attention due to their scalability and high sensitivity [30]. The key principle behind the biosensing ability of MOSFET-based biosensors is the relative change in the value of device metrics in the presence of biomolecules. Dielectric modulation enables the gate to control the flow of charge carriers. When biomolecules are immobilized inside the cavity, they change the net gate oxide capacitance, which in turn alters the potential and field distribution. This modulation affects device characteristics, such as subthreshold slope, off-current, and threshold voltage. The dielectric modulation of these parameters is the primary reason behind the biosensing capability of MOSFET. MOSFET-based biosensors are capable of label-free detection, which utilizes different molecular properties to sense biomolecules [40,41].

Optimization of device parameters can result in a highly sensitive biosensor. Goel et al. [42] revealed that the sensitivity of biosensors increases with the increase in the number of gates used. The proper choice of source material can substantially improve the sensitivity of the biosensor. Wu et al. [43] and Brunco et al. [44] have discussed the concept of germanium MOSFET in the past decade. Saha et al. [45] reported a germanium source-based TFET for label-free detection of biomolecules. Germanium offers more intrinsic charge carriers than silicon, which participates in the conduction process [46] and are involved in the biosensing action. The relative change in the various sensing metrics will be higher when the numbers of charge carriers are high. Hence, the sensitivity of the biosensor is higher in germanium-based biosensors. Using a graded channel instead of a non-graded channel improves the device's performance [47,48]. Recently, Singh et al. [49] reported a label-free FET biosensor that uses a graded channel. Although germanium-based biosensors are highly sensitive, they have some flaws and drawbacks. Germanium source-based biosensors are costlier than their silicon-based counterparts from an economic perspective, and their use is limited due to the limited availability of fabrication technology. Additionally, germanium has a lower operating temperature range than silicon, which limits the range of temperatures at which it can effectively operate.

This paper comprehensively investigates a dielectric-modulated step-graded germanium-source biotube FET sensor (DM-SGGS-BTFS). It shows enhanced sensitivity due to source and channel engineering, which involves using a germanium source and a graded-doped biotube filled with air [50]. Both physics-based modeling and simulation-based investigation are crucial to optimize the different parameters for designing an ultra-sensitive biosensor. The key novelty of this research work lies in two aspects: the structural innovation of the biotube sensor and the comprehensive investigation through analytical modeling, considering different sensing metrics and the impact of temperature. The structural novelty involves an integrated design of the surrounding gate MOSFET, which incorporates gate engineering (triple gate architecture), source engineering (germanium source), channel engineering (tubular channel with step-graded doping profile), and gate oxide engineering (oxide stacking: HfO_2+SiO_2) techniques. The biosensing performance of DM-SGGS-BTFS has been effectively analyzed using multiple key sensing metrics such as threshold voltage, subthreshold swing, I_{ON}/I_{OFF} ratio, drain current, peak transconductance, and peak output conductance. Additionally, the developed analytical model takes into account the influence of temperature on various analog performance parameters and sensing parameters of the proposed biosensor. One of the primary objectives of this paper is to present an analytical model of DM-SGGS-BTFS to investigate its biosensing performance and study the critical insights into the sensitivity dependency on different design parameters. To make this analysis more practical and realistic, the effect of partially filled cavities on sensitivity has also been considered. The analytical model of the biosensor is based on the non-linear parabolic solution of the 2D Poisson's equation [30]. The potential across the channel is expressed in terms of channel-surface potential [51,52]. The channel potential, threshold voltage, subthreshold swing, and drain current have been analytically derived, and the results show a remarkable agreement with the simulated results.

2. Device structure and software specifications

Figures 1(a) and 1(b) show the 3D cylindrical structure and a cross-sectional view, respectively, of the DM-SGGS-BTFS. A layer of HfO_2 is formed over the thin layer of SiO_2 to form the gate stack. The biotube has an inner radius (a) of 2 nm and an outer radius (b) of 10 nm. The biosensor considers a dual-sided cavity, which has the advantage of better fill-in factor probability than the single-sided cavity. Additionally, the asymmetric cavity has been preferred since the source-end open cavity is comparatively more sensitive to biomolecules than the drain-end open cavity [53]. The work function of the gate in the multi-gated structures can also affect the sensitivity of the biosensor [54]. Kumari et al. [54] in her work mentioned that the sensitivity obtained is highest if the work functions of the gate near to drain is smaller than that of the source ($\phi_{M1}>\phi_{M3}$). Therefore, we have extended the same results for the proposed biosensor in our investigation. All the structural parameters of the biosensor are listed in table 1. Table 2 lists the lattice parameters of silicon and germanium in a tabular form. This paper primarily focuses on the biosensing performance of DM-SGGS-BTFS, and biosensing investigation requires changes in the value of sensing metrics. The net electric field across the channel can be resolved into two components: the lateral electric field (across the radial direction) and the horizontal electric field (across the z-direction). The vertical electric field is the primary factor that controls the sensitivity and affects the biosensor's performance. The vertical electrical field is changing due to the immobilization of biomolecules inside the cavity which ultimately changes the gate oxide capacitance [3]. The sensitivity of the biosensor is calculated based on the relative change in the value of the sensing metric. The horizontal electric field (doping dependent) is almost constant since the

Accepted Manuscript

doping of the source, channel, and drain are constant (N_S=N_D=10^{19}/cm^3 and $N_{Cha,1}$=10^{10}/cm^3, $N_{Cha,2}$=10^{14}/cm^3, $N_{Cha,3}$=10^{18}/cm^3) [6,55], so it has a negligible effect on the sensitivity.

Melting point	1415^o C	936^o C
Electronic configuration	1s^2 2s^2 2p^6 3s^2 3p^2	1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^2

Figure 2(a) shows the overall fabrication flowchart [62–64] of DM-SGGS-BTFS [65], while figure 2(b) shows the comparison of its sensitivity with an existing FET-based biosensor [28]. The calibration of the proposed device with the experimental work reported by Choi et al. [66] is shown in figure 2(c). To better understand the improved biosensing action of the proposed biosensor, table 3 lists the structural parameters of a conventional surrounding gate MOSFET, and table 4 shows a sensitivity comparison of DM-SGGS-BTFS with a conventional surrounding gate MOSFET-based biosensor. The basic parameters and structure of conventional MOSFET and DM-SGGS-BTFS were kept the same to facilitate the comparison, and sensitivity was obtained by calculating the relative change (S_M) or the fractional change (S_{FM}) [6] where, M denotes the metric of the biosensor. Different sensing metrics have been considered in the analysis for a more realistic and reasonable comparison. Also, the fractional sensitivity improvement in the current ratio can be seen in the proposed structure, which can also be used as a potential sensing metric. It can be seen that the sensitivity improves significantly due to the structural engineering in DM-SGGS-BTFS when compared to a conventional MOSFET. Silicon and germanium have different mobility characteristics for electrons and holes, which is one of the primary reasons behind the different sensitivity characteristics. To be more precise, the mobility of the conducting electrons is approximately twice as high, while the mobility of holes is approximately four times higher in germanium compared to silicon [7]. The high mobility in germanium can be attributed to the lower effective mass of its electrons and holes. This mobility enhancement leads to an improvement in the subthreshold characteristics. Therefore, for the same range of gate or drain voltage, a biosensor utilizing a germanium source (Ge-source) will exhibit a comparatively greater variation (swing) in current compared to one utilizing a silicon source. This means DM-SGGS-BTFS utilizing a germanium source will exhibit a larger variation in sensing metrics like subthreshold swing and threshold voltage, increasing its sensitivity and making it more sensitive to biomolecules when compared to a biosensor utilizing a silicon source.

DM-SGGS-BTFS is a label-free biosensor that uses the molecular and physical properties of biomolecules to detect and sense them [30,67–70]. Kim et al. [71] has practically demonstrated the entrapment of streptavidin (size ~5 nm) inside a cavity. Different biomolecules are variable in size ranging from few micrometers to few attometers [28]. A dual sided asymmetric cavity has been considered which facilitates a high fill-in factor probability along with enhanced sensitivity [72]. This work considered the different biomolecules (K_{bio}=2-8 and size<6 nm) which can be easily localized and entrapped inside the cavity (size: 30*6 nm^2) of DM-SGGS-BTFS. The orientation of biomolecules also affects the localization, i.e. even few biomolecules whose size is greater than 6 nm (less than 30 nm) can be localized inside the cavity in horizontal orientation.

The numerical simulator used is SILVACO TCAD [73] which uses the NEWTON GUMMEL method to solve the complex coupled differential equations. Different models that have been used are mentioned in table 1. For the simulations performed on the TCAD simulator, the cavity is presumed to be filled with a material having some finite dielectric constant ($K_{bio}\neq1$) when the entire cavity is pervaded with different biomolecules. When the cavity is empty (no biomolecules are present), it is presumed to be filled with air (K_{air}=1). The asymmetric cavity provides comparatively more sensitivity when compared to symmetric cavity. Various biomolecules have been considered in this work, which solidifies the biosensing investigation of DM-SGGS-BTFS. All the test biomolecules are mentioned in table 1 and have been used to analyze the sensitivity of biosensors in the past [28,30,42].

3. Device modelling

3.1 Channel potential

The potential distribution ψ(r,z,T) across the channel satisfies 2D Poisson's equation and is given by,

$$\frac{1}{r}\frac{\partial}{\partial r}\left[r\frac{\partial}{\partial r}\left\{\psi\left(r,z,T\right)\right\}\right] + \frac{\partial^2}{\partial z^2}\psi\left(r,z,T\right) = -\frac{qN_{Cha}}{\varepsilon_{Cha}} \tag{1}$$

where q, $N_{Cha,}$ and ϵ_{Cha} denote the electronic charge, channel doping, and channel permittivity, respectively. The radius of the channel is b, so r=b denotes the surface interface between the channel and oxide layer with potential expressed as $\psi_S(z,T)$ or ψ(b,z,T). ψ(r,z,T) is an implicit function of multiple variables, so its solution follows the parabolic potential profile and can be expressed as

$$\psi\left(r,z,T\right) = M_0\left(z,T\right) + M_1\left(z,T\right)r + M_2\left(z,T\right)r^2 \tag{2}$$

where coefficients M_0, $M_{1,}$ and M_2 (mentioned in Appendix A) be determined using the different boundary conditions.

Various boundary conditions used are :-

(i) $$\psi\left(r,z_1,T\right) = V_{bi,1} = \frac{k_B T}{q}\left\{\ln\left(\frac{N_S N_{Cha_1}}{n_{i(Si)}n_{i(Ge)}}\right)\right\} \tag{3}$$

where, $V_{bi,1}$ denotes the potential barrier at the source-channel junction, $n_{i(Ge)}/n_{i(Si)}$ are the intrinsic concentration of charge carriers in germanium and silicon, k_B denotes the Boltzmann constant (1.38066*10^{-23} J/K), and T denotes the temperature.

(ii) $$\psi\left(r,z_4,T\right) = V_{bi,4} + V_{DS} = \frac{k_B T}{q}\ln\left(\frac{N_{Cha_3}N_D}{n_{i(Si)}^2}\right) + V_{DS} \tag{4}$$

where, $V_{bi,4}$ denotes the potential barrier at the drain-channel junction, and N_D (N_S) denotes the doping of drain (source).

(iii) Electric field is continuous at $z=z_2$ and $z=z_3$,

Accepted Manuscript

$$\left.\frac{\partial\{\psi(r,z,T)\}}{\partial z}\right|_{z=z_2^-} = \left.\frac{\partial\{\psi(r,z,T)\}}{\partial z}\right|_{z=z_2^+}, \quad \left.\frac{\partial\{\psi(r,z,T)\}}{\partial z}\right|_{z=z_3^-} = \left.\frac{\partial\{\psi(r,z,T)\}}{\partial z}\right|_{z=z_3^+} \tag{5}$$

(iv) Electric field inside the bio-tube is zero.

$$\left.\frac{\partial\psi(r,z,T)}{\partial r}\right|_{r=a} = 0 \tag{6}$$

(v) $\psi\left(r,z_2^-,T\right)=V_2$, $\psi\left(r,z_3^-,T\right)=V_3$ (7)

(vi) Electric field is continuous at the Si-SiO_2 interface since electric flux density is the same just above and below the Si-SiO_2 interface in the absence of any interface trap charges.

$$\varepsilon_{Cha}\left.\frac{\partial\{\psi(r,z,T)\}}{\delta r}\right|_{r=b} = C_{ox}\left[V_{GS}-V_{FB}-\psi(r,z,T)\right]\Big|_{r=b}, \quad \left.\frac{\partial\{\psi(r,z,T)\}}{\delta r}\right|_{r=b} = \frac{C_{ox}}{\varepsilon_{Cha}}\left[V_{GS}^{*}-\psi_S(z,T)\right] \tag{8}$$

where, $V_{GS}^{*}=V_{GS}-V_{FB}$ is the effective gate voltage that governs the bending in the energy bands, and C_{OX} / V_{GS} / V_{FB} is the gate oxide capacitance per unit area, gate voltage, and flat-band voltage. $\psi_S(z,T)$ denotes the channel potential at r=b.

vii) $\psi(r,z_2^+)=\psi(r,z_2^-)+V_{bi,2}$, $\psi(r,z_3^+)=\psi(r,z_3^-)+V_{bi,3}$ (9)

viii) $V_{bi,2}=\frac{k_BT}{q}\left\{\ln\left(\frac{N_{Cha_1}N_{Cha_2}}{n_{i(Si)}^2}\right)\right\}$, $V_{bi,3}=\frac{k_BT}{q}\left\{\ln\left(\frac{N_{Cha_2}N_{Cha_3}}{n_{i(Si)}^2}\right)\right\}$ (10)

where, $V_{bi,1}$, $V_{bi,2}$, $V_{bi,3,}$ and $V_{bi,4}$ denote the built-in potential barrier at z_1, z_2, z_3, and z_4, respectively. $N_{Cha,1}$, $N_{Cha,2,}$ and $N_{Cha,3}$ denotes the channel doping in region A, B, and C, respectively. Using the above boundary conditions, it is possible to express the potential in terms of device parameters as given below,

$$\psi(r,z,T)=\psi_S(z,T)+\frac{C_{OX}\left(2ab-b^2\right)\left[V_{GS}^{*}-\psi_S(z,T)\right]}{2\varepsilon_{Cha}(b-a)}-\frac{C_{OX}a\left[V_{GS}^{*}-\psi_S(z,T)\right]}{\varepsilon_{Cha}(b-a)}r+\frac{C_{OX}\left[V_{GS}^{*}-\psi_S(z,T)\right]}{2\varepsilon_{Cha}(b-a)}r^2 \tag{11}$$

For incorporating the effect of temperature, different relations have been formulated as given below [76–80],

$$E_G(T)=E_{G_0}+E_{G_\alpha}\left(\frac{(300)^2}{300+E_{G_\beta}}-\frac{T^2}{T+E_{G_\beta}}\right), \quad \phi_{Sil}(T)=\chi_{Sil}+\frac{E_G(T)}{2}-q\phi_F\left(N_{Cha},T\right) \tag{12a}$$

$$n_i(T)=A_0\left(\frac{T}{300}\right)^{\frac{3}{2}}\exp\left(\frac{-qE_G(T)}{2K_BT}\right), \quad \phi_F\left(N_{Cha},T\right)=\frac{K_BT}{q}\ln\left(\frac{N_{Cha}}{n_i(T)}\right) \tag{12b}$$

$$V_{GS}^{'}(T)=V_{GS}-V_{FB}(T), \quad V_{FB}(T)=\phi_M-\phi_{Sil}(T)-\left(\frac{qN_f}{C}\right) \tag{12c}$$

Values of constant A_0, E_{G0}, $E_{G\alpha}$ and $E_{G\beta}$ for silicon and germanium are $2.2717*10^{19}$, 1.1, $4.73*10^{-4}$, 636 and $0.759144*10^{19}$, 0.66, $4.77*10^{-4}$, 235 respectively [76]. The rest of the symbols has the usual meaning. ϕ_{Sil}/ϕ_M, $\chi_{Sil,}$ and ϕ_F denote the work function of channel/metal, electron affinity, and Fermi potential of channel, respectively. Putting (11) back in (1) yields a differential equation in terms of the surface channel potential $\psi_S(z,T)$,

$$\mu^2\frac{\partial^2\psi_S(z,T)}{\partial z^2}+\theta=\psi_S(z,T) \tag{13}$$

The generalized form of $\psi_S(z,T)$ in three different regions are:-

Region A ($z_1 \le z \le z_2$): $\psi_{S_1}(z,T)=g_1(T)e^{\frac{z}{\mu_1}}+h_1(T)e^{\frac{-z}{\mu_1}}+\sigma_1(T)$ (14)

$$\mu_1=\sqrt{\frac{\varepsilon_{Cha_1}b(b-a)}{C_{OX_1}(2b-a)}}, \quad \sigma_1(T)=V_{GS_1}^{'}(T)+\frac{qN_{Cha_1}b^2}{C_{OX_1}(2b-a)}-\frac{aqN_{Cha_1}b}{C_{OX_1}(2b-a)}, \quad V_{FB_1}(T)=\phi_{M_1}-\phi_{Sil}(T)-\frac{qN_f}{C_2} \tag{15a}$$

$$C_1=\frac{\varepsilon_{OX_{K1}}}{b\ln\left(1+\frac{t_1}{b}\right)}, \quad C_2=\frac{\varepsilon_{bio}}{b\ln\left(1+\frac{t_2}{b}\right)}, \quad C_3=\frac{\varepsilon_{OX_{K2}}}{b\ln\left(1+\frac{t_3}{b}\right)}, \quad C_{OX_1}=\frac{C_1C_2C_3}{C_1C_2+C_2C_3+C_1C_3} \tag{15b}$$

Accepted Manuscript

Region B ($z_2 \le z \le z_3$): $\psi_{S_2}(z,T) = g_2(T)e^{\frac{z}{\mu_2}} + h_2(T)e^{\frac{-z}{\mu_2}} + \sigma_2(T)$ (16)

$$\mu_2 = \sqrt{\frac{\varepsilon_{Cha_2} b(b-a)}{C_{OX_2}(2b-a)}} \ , \ \sigma_2(T) = V'_{GS_2}(T) + \frac{qN_{Cha_2}b^2}{C_{OX_2}(2b-a)} - \frac{aqN_{Cha_2}b}{C_{OX_2}(2b-a)} \quad (17a)$$

$$C_{OX2} = \frac{\varepsilon_{SiO_2}}{b\ln\left(1+\frac{t_{net}}{b}\right)} \ , \ V_{FB_2}(T) = \phi_{M_2} - \phi_{Sil} \ , \ t_{net} = t_1 + \left[\frac{\varepsilon_{K_1}}{\varepsilon_{K_2}}(t_2+t_3)\right] \quad (17b)$$

Region C ($z_3 \le z \le z_4$): $\psi_{S_3}(z,T) = g_3(T)e^{\frac{z}{\mu_3}} + h_3(T)e^{\frac{-z}{\mu_3}} + \sigma_3(T)$ (18)

$$\mu_3 = \sqrt{\frac{\varepsilon_{Cha_3} b(b-a)}{C_{OX_3}(2b-a)}} \ , \ \sigma_3(T) = V'_{GS_3}(T) + \frac{qN_{Cha_3}b^2}{C_{OX_3}(2b-a)} - \frac{aqN_{Cha_3}b}{C_{OX_3}(2b-a)} \quad (19a)$$

$$C_{OX_3} = C_{OX_1} \ , \ V_{FB_3}(T) = \phi_{M_3} - \phi_{Sil} - \frac{qN_f}{C_2} \quad (19b)$$

V_1 (V_4) is the potential at the source (drain) junction, respectively. The coefficients g_1, h_1, g_2 h_2, g_3, and h_3 can be determined using the boundary conditions and can be expressed as,

$$g_1(T) = \frac{0.5}{\sinh\left(\frac{z_1-z_2}{\mu_1}\right)}\left[\sigma_1(T)\left(e^{\frac{-z_1}{\mu_1}} - e^{\frac{-z_2}{\mu_1}}\right) + V_1 e^{\frac{-z_2}{\mu_1}} - V_2 e^{\frac{-z_1}{\mu_1}}\right] \quad (20a)$$

$$h_1(T) = \frac{0.5}{\sinh\left(\frac{z_1-z_2}{\mu_1}\right)}\left[\sigma_1(T)\left(e^{\frac{z_2}{\mu_1}} - e^{\frac{z_1}{\mu_1}}\right) + V_2 e^{\frac{z_1}{\mu_1}} - V_1 e^{\frac{z_2}{\mu_1}}\right] \quad (20b)$$

$$g_2(T) = \frac{0.5}{\sinh\left(\frac{z_2-z_3}{\mu_2}\right)}\left[\sigma_2(T)\left(e^{\frac{-z_2}{\mu_2}} - e^{\frac{-z_3}{\mu_2}}\right) + \left(V_2 + V_{bi,2}\right)e^{\frac{-z_3}{\mu_2}} - V_3 e^{\frac{-z_2}{\mu_2}}\right] \quad (21a)$$

$$h_2(T) = \frac{0.5}{\sinh\left(\frac{z_2-z_3}{\mu_2}\right)}\left[\sigma_2(T)\left(e^{\frac{z_3}{\mu_2}} - e^{\frac{z_2}{\mu_2}}\right) + V_3 e^{\frac{z_2}{\mu_2}} - \left(V_2 + V_{bi,2}\right)e^{\frac{z_3}{\mu_2}}\right] \quad (21b)$$

$$g_3(T) = \frac{0.5}{\sinh\left(\frac{z_3-z_4}{\mu_3}\right)}\left[\sigma_3(T)\left(e^{\frac{-z_3}{\mu_3}} - e^{\frac{-z_4}{\mu_3}}\right) + \left(V_3 + V_{bi,3}\right)e^{\frac{-z_4}{\mu_3}} - V_4 e^{\frac{-z_3}{\mu_3}}\right] \quad (22a)$$

$$h_3(T) = \frac{0.5}{\sinh\left(\frac{z_3-z_4}{\mu_3}\right)}\left[\sigma_3(T)\left(e^{\frac{z_4}{\mu_3}} - e^{\frac{z_3}{\mu_3}}\right) + V_4 e^{\frac{z_3}{\mu_3}} - \left(V_3 + V_{bi,3}\right)e^{\frac{z_4}{\mu_3}}\right] \quad (22b)$$

Boundary conditions at z_2 and z_3 can be used to evaluate V_2 and V_3 due to the continuity of the electric field at z_2 and z_3.

$$\left.\frac{\partial\psi_{S_1}(z,T)}{\partial z}\right|_{z=z_2^-} = \left.\frac{\partial\psi_{S_2}(z,T)}{\partial z}\right|_{z=z_2^+} , \left.\frac{\partial\psi_{S_2}(z,T)}{\partial z}\right|_{z=z_3^-} = \left.\frac{\partial\psi_{S_3}(z,T)}{\partial z}\right|_{z=z_3^+} \quad (23a)$$

$$V_2 = f_4\left(sf_3 - tf_2\right) \ , \ V_3 = f_4\left(sf_2 - tf_1\right) \quad (23b)$$

Values of s, t, and f_1-f_4 are mentioned in Appendix A.

3.2 Threshold voltage

A significant amount of conduction current will flow only after applying a gate voltage greater than the threshold voltage. When the V_{GS} equals V_t, the minimum channel potential is $2\phi_F$. Since drain-to-source voltage decreases while moving towards the source and hence, minimum channel potential occurs in region-A. The threshold voltage is solved by

Accepted Manuscript

substituting the value of minimum channel potential (obtained by differentiating the surface potential), and putting $V_{GS}=V_t$ will yield a quadratic equation in terms of V_t.

$$V_t = \frac{-r_{12} + \sqrt{r_{12}^2 - 4r_{11}r_{13}}}{2r_{11}} \tag{24}$$

Values of r_{11}, r_{12}, and r_{13} are mentioned in Appendix B.

3.3 Drain current and subthreshold swing

The drain current can be modelled for linear region in the three different regions as [28,81,82],

$$I_{Lin,A} = \frac{\pi C_{ox_1}\mu_n (b-a)}{L'_{Cha_1}}\left[(V_{GS}-V_t)(V_2-V_1) - \frac{(V_2-V_1)^2}{2}\right] \tag{25}$$

$$I_{Lin,B} = \frac{\pi C_{ox_2}\mu_n (b-a)}{L'_{Cha_2}}\left[(V_{GS}-V_t)(V_3-V_P) - \frac{(V_3-V_P)^2}{2}\right] \tag{26}$$

$$I_{Lin,C} = \frac{\pi C_{ox_3}\mu_n (b-a)}{L'_{Cha_3}}\left[(V_{GS}-V_t)(V_4-V_Q) - \frac{(V_4-V_Q)^2}{2}\right] \tag{27}$$

Appropriate boundary conditions can be used to calculate V_P and V_Q and can be expressed as,

$$V_P = V_{bi,2} + \psi_{S_1}(r,z_2)\ ,\ V_Q = V_{bi,3} + \psi_{S_2}(r,z_3) \tag{28}$$

The drain current is calculated in the saturation region by replacing V_{DS} with $V_{DS,Sat}$.

$$V_{DS,Sat} = \frac{(V_{GS}-V_t)}{1+\frac{\mu_{efld}(V_{GS}-V_t)}{(L_{Cha_1}+L_{Cha_2}+L_{Cha_3})v_{Sat}}} \quad , \quad \mu_{efld} = \frac{\mu_n}{\{1-\zeta(V_{GS}-V_t)\}\left\{1+\Omega\frac{V_{DS}\mu_n}{(L_{Cha_1}+L_{Cha_2}+L_{Cha_3})v_{Sat}}\right\}} \tag{29}$$

$$\Omega = \left[\frac{V_{DS}\mu_n}{(L_{Cha_1}+L_{Cha_2}+L_{Cha_3})v_{Sat}}\right]\left[1.5+\left\{\frac{V_{DS}\mu_n}{(L_{Cha_1}+L_{Cha_2}+L_{Cha_3})v_{Sat}}\right\}\right]^{-1} \tag{30}$$

where v_{Sat} and μ_{efld} are the saturation velocity of electrons ($v_{Sat}=1*10^7$ cm/s) and maximum low field mobility. ζ is the fitting parameter (0.43), and μ_n is the mobility of electrons. $C_{OX1}/C_{OX2}/C_{OX3}$ is the oxide capacitance per unit area. Subthreshold swing describes the swing in gate voltage obtained when the drain current is changed by a decade and is calculated as given below [83]

$$SS = V_T \ln 10\left\{\left(\frac{\partial\psi(b,z,T)}{\partial V_{GS}}\right)^{-1}\right\}\Bigg|_{Z_{min}} \tag{31}$$

3.4 Sensitivity

Relative change in the device metric (M) has been considered for the investigation of the biosensor and is given below,

$$S_M = |M_{Air} - M_{Bio}| \tag{32}$$

where M_{Bio}/M_{Air} denotes the actual value of metric in the presence/absence of biomolecules and S_M is the sensitivity for the sensing metric 'M'.

4. Results and discussion

When the biomolecules are completely entrapped inside the nanogap cavity, they change the effective gate oxide capacitance, which in turn changes the potential and electric field profile. Figure 3 shows the potential profile across the channel for different biomolecules, while its inset shows the minimum channel potential for different cavity thicknesses. The significant relative change in potential is an excellent qualitative indicator of the improved biosensing ability. A sharp change in the potential can be observed with the increasing dielectric constant of biomolecules. This sharp decrease in the minimum potential across the channel is due to the increased effective gate oxide capacitance. This improves

Accepted Manuscript

coupling and interaction between the charge carriers and the gate. Furthermore, the relative change in potential increases with the increasing K_{bio} [30]. The increase in the thickness of the cavity (t_{CAV}) will increase the number of biomolecules that can be entrapped inside it. This increases the sensitivity of the biosensor. Hence, a significant change in the minimum channel potential can be seen with the changing t_{CAV}.

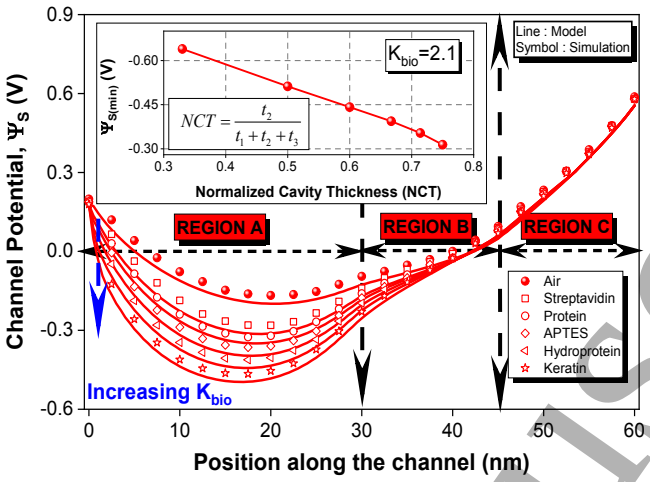

Figure 3. Channel potential profile for different K_{bio} (**[INSET]** shows the minimum channel potential for K_{bio} =2.1 at different normalized cavity thicknesses).

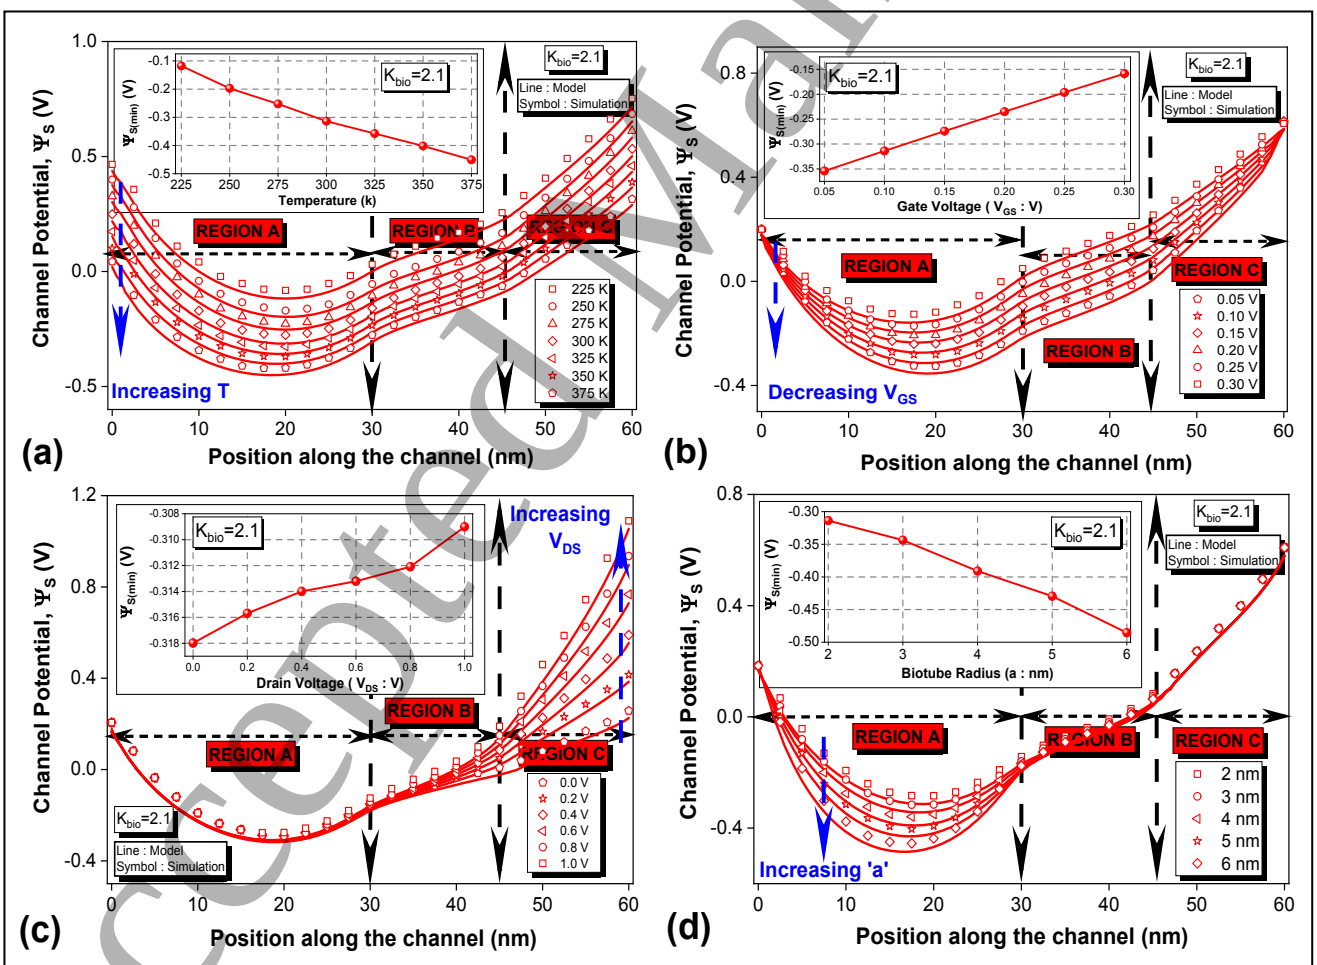

Figure 4. Channel potential profile for K_{bio} =2.1 at **(a)** different temperatures (**[INSET]** shows the minimum channel potential for K_{bio} =2.1at different temperatures), **(b)** different V_{GS} (**[INSET]** shows the minimum channel potential for K_{bio} =2.1at different temperature), **(c)** different V_{DS} (**[INSET]** shows the minimum channel potential for K_{bio} =2.1at different temperature) and **(d)** different biotube inner radius 'a' (**[INSET]** shows the minimum channel potential for K_{bio} =2.1 at different 'a').

Accepted Manuscript

Figure 4(a) shows the potential profile across the channel for K_{bio}=2.1 at different temperatures. Inset shows the minimum channel potential at different temperatures. The number of charge carriers increases with the increasing temperature. Hence, a narrow potential well can be seen at higher temperatures (minimum channel potential keeps on decreasing with the increasing temperature) [84]. Figure 4(b) shows the potential profile across the channel for K_{bio}=2.1 at different gate voltages (V_{GS}). Inset shows the minimum channel potential at different V_{GS} (step size of 50mV). At a fixed drain voltage (V_{DS}), the subthreshold current increases with the increasing V_{GS}. This improvement in the subthreshold conduction is due to the decrease in the potential across the channel, and hence, minimum channel potential also decreases (magnitude) with the increasing gate voltage [84]. It is worth interesting to note that the curvature of the potential curve starts decreasing with increasing V_{GS} because high gate voltage increases the vertical electric field by a significant amount. Figure 4(c) shows the channel potential profile for K_{bio}=2.1 at different drain voltages (V_{DS}). Inset shows the minimum channel potential at different V_{DS}. Changing V_{DS} has a negligible effect on the channel potential variation (especially region A). Increasing V_{DS} will only change the potential barrier at the drain-channel junction; hence, the potential rises near the drain only [84]. It is interesting to note that there is no variation in the potential in region A (near the source) because the potential barrier at the source-channel junction [54] is almost unchanged. Hence, minimum channel potential also infinitesimally increases with the increasing drain voltage. Figure 4(d) shows the potential profile for K_{bio}=2.1 at different inner radius 'a' of the biotube. Inset shows the minimum channel potential at different values of 'a'. With the increasing 'a', the cross-sectional area available for the conducting charge carriers decreases. This increases the threshold voltage of the biosensor due to increasing steepness in the channel potential profile; hence, minimum channel potential also increases (magnitude) with the increasing 'a'.

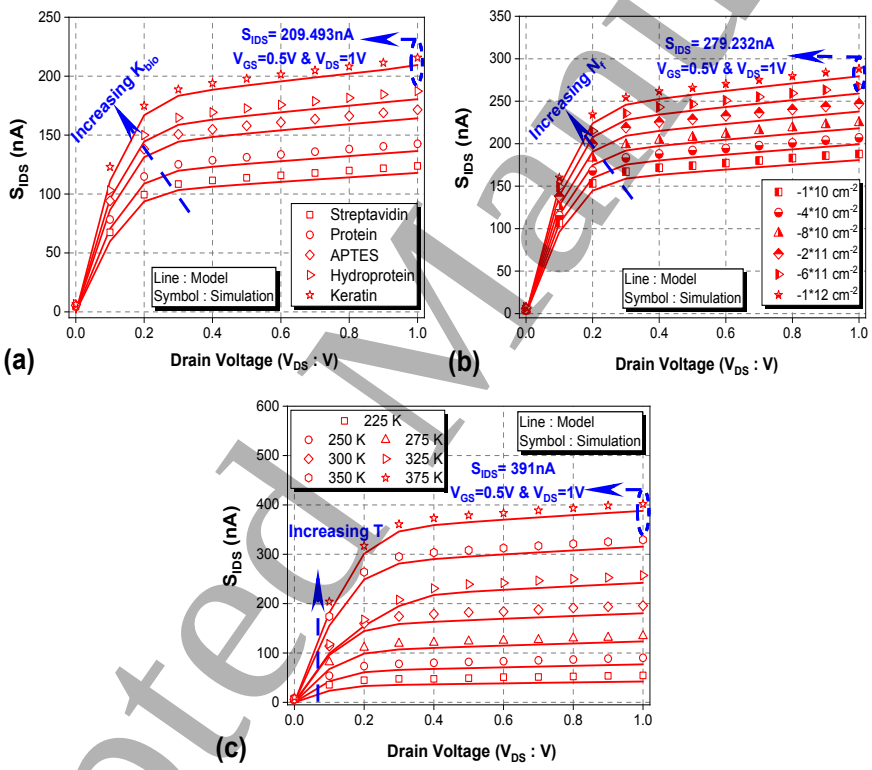

Figure 5. Drain current sensitivity as a function of drain voltage for **(a)** neutral biomolecules, **(b)** charged biomolecules, and **(c)** drain current sensitivity dependency on temperature for K_{bio}=5 at V_{GS}=0.5V.

Figure 5 shows the drain current sensitivity (S_{IDS}) as a function of V_{DS}. Drain current sensitivity increases with the increasing K_{bio}. The biomolecules, when entrapped inside the cavity, will increase the capacitance of the cavity. The increase in the oxide capacitance results in a stronger interaction between the gate and the flow of the charge carriers. This decreases the drain current but the change in drain current increases for the 'unfilled cavity case' [30]. Hence, the drain current sensitivity is high at higher values of K_{bio} which can be seen in figure 5(a). The presence of negatively charged biomolecules results in an increased interaction that accounts for the much stronger gate-to-channel coupling than the neutral biomolecules. Hence, S_{IDS} increases with the increasing charge density of biomolecules, as shown in figure 5(b). The negatively charged biomolecules decrease the channel potential by a factor of qN_f/C (N_f - charge density of biomolecules) in the nanogap cavity [30] that further decreases the drain current, but the change in drain current increases for the 'unfilled cavity case'. Figure 5(c) shows the impact of temperature on drain current sensitivity (S_{IDS}) as

Accepted Manuscript

a function of V_{DS} for K_{bio}=5. As the temperature rises, a large number of charge carriers are generated, which increases the current flowing across the channel [85]. Hence, S_{IDS} increases with increasing temperature. For biosensing applications, operating the device in the ohmic region is advisable, which allows comparatively fast switching and sensing. The maximum S_{IDS} obtained here is roughly 391 nA for K_{bio}=5 at T=375K.

Germanium has a comparatively larger intrinsic charge carrier density than silicon, due to which it offers a large number of intrinsic charge carriers that participates in the conduction process [9] and are also responsible for the biosensing action in DM-SGGS-BTFS. The intrinsic charge carrier density in germanium is approximately ~ 1650 times larger than the silicon at room temperature. When the concentration of charge carriers is high, change in sensing metrics becomes more pronounced as the flow of many charge carriers is affected when different biomolecules localize inside the cavity [10]. Hence, the sensitivity of DM-SGGS-BTFS increases.

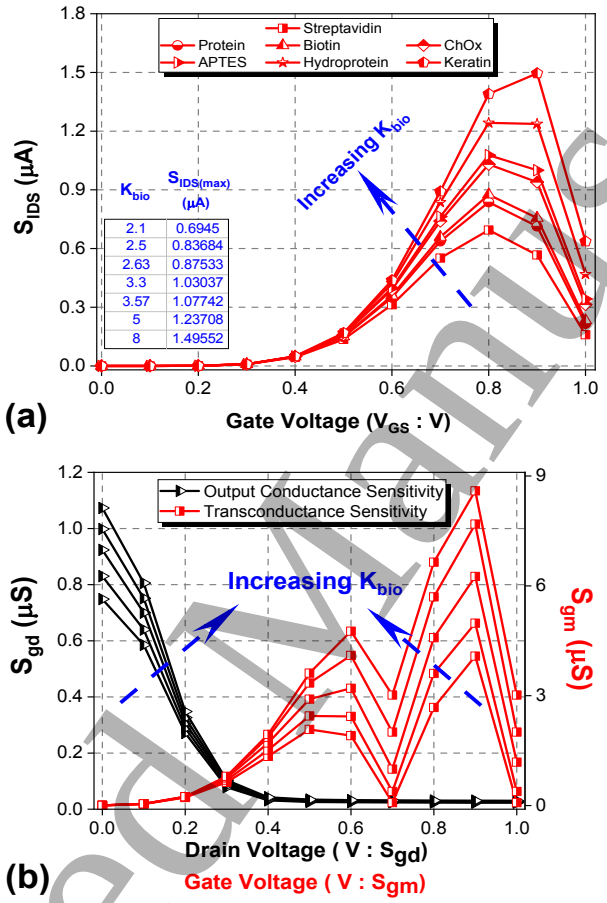

Figure 6. (a) Drain current sensitivity as a function of gate voltage, and **(b)** transconductance (output conductance) sensitivity as a function of gate voltage (drain voltage).

Figure 6(a) shows the drain current sensitivity as a non-linear implicit function of gate voltage. In contrast, figure 6(b) shows the transconductance/output conductance sensitivity (S_{gm}/S_{gd}) for different biomolecules at a fixed value of V_{DS}/V_{GS}. At a lower value of gate voltage, the potential across the channel is nearly constant, but at higher V_{GS}, the potential distribution is not constant (unevenly distributed). It can be inferred that sensitivity is almost constant at lower values of gate voltage, whereas the peak of the drain current sensitivity (S_{IDS}=1.49552μA) is obtained roughly at V_{GS}=0.9V and V_{DS}=0.5V for K_{bio}=8. Further, decreasing the value of V_{DS} will increase the threshold voltage sensitivity and drain current sensitivity. Interestingly, the biosensor is more sensitive to biomolecules at high $V_{GS,}$ and S_{IDS} increases with increasing K_{bio} of the biomolecules. Transconductance is the derivative of drain current obtained from the transfer characteristics of the DM-SGGS-BTFS at a fixed drain voltage value [85]. The slope of the drain current in the I_{DS}-V_{GS} plot is higher at high $V_{GS,}$ and it increases with the increasing $K_{bio,}$ indicating high trans-conductance sensitivity (S_{gm}= 8.5844 μS) is obtained for K_{bio}=8 roughly at V_{GS}=0.9V and V_{DS}=0.5V. We have also used transconductance in determining the sensitivity of the proposed biosensor. Further, the peak transconductance (g_{mp}) can be potentially used as a sensing metric (S_{gmp}) that will increase the reliability of the biosensor. The relative change (compared to the 'unfilled cavity case') in the value of output conductance is high at lower values of drain voltage. This is because the output

Accepted Manuscript

conductance is calculated from the slope of the I_{DS}-V_{DS} curve, and the slope is higher at low V_{DS} (in the ohmic region), which keeps on decreasing with the increasing V_{DS}. This slope tends to zero as the drain voltage increases at a fixed gate voltage value. The maximum output conductance (S_{gd}=1.073 μS) is obtained for K_{bio}=8 at V_{GS}=0.5 V and V_{DS}=0V.

Table 5. Sensitivity variation in DM-SGGS-BTFS at different channel doping.

a-f: Forward tri-step graded profile (FTSGP) | **g-l:** Reverse tri-step graded profile (RTSGP)

m-q: Non-step graded profile (Mono-doped profile)

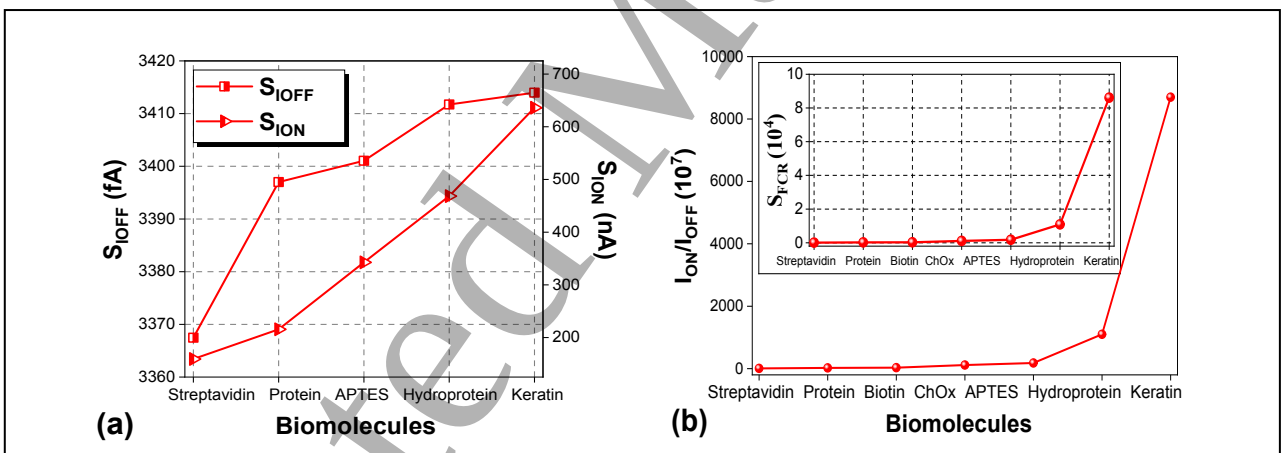

Figure 7. (a) On/off-current sensitivity, and **(b)** I_{ON}/I_{OFF} ratio (**[INSET]** shows the fractional current ratio sensitivity) for different biomolecules.

Using high doping in germanium increases the tunneling probability [8] and facilitates enhanced transportation of charge carriers which is due to the low energy band gap of germanium. As a result, this changes and alters the potential barrier at the source junction, which is bias and electric field dependent). The dependence of different device characteristics (threshold voltage, subthreshold swing, and drain current) on the source-channel potential barrier makes the germanium source biosensors more sensitive to biomolecules.

The graded channel lowers the short channel effects (SCEs) and improves the drive current of the device without scaling it [8],[86]. Using the tri-step graded doping causes a sudden change of potential across the channel, and this sharp change induces a larger electric field than the non-step graded doping [87]. This critical electric field imparts a more vital force on the charge carriers moving from the source to the drain, which improves the carrier transportation mechanism in a graded channel [88]. Using a step graded profile instead of non-step graded profile in channel makes the biosensor more sensitive towards biomolecules. Table 5 shows the sensitivity variation for different channel doping profiles which clearly indicates that the doping of channel must increase gradually while moving from source towards drain to obtain

Accepted Manuscript

high sensitivity. Forward tri step graded profile (FTSGP) yields comparatively high sensitivity as compared to reverse step graded profile (RTSGP), and this sensitivity increases further as the step doping gradient ($|N_{Cha,2} - N_{Cha,1}|$ & $|N_{Cha,3} - N_{Cha,2}|$) is increased. Here, the biosensor has shown maximum sensitivity at $N_{Cha,1}=10^{10}/cm^3$, $N_{Cha,2}=10^{14}/cm^3$ and $N_{Cha,3}=10^{18}/cm^3$ respectively.

Figure 7(a) shows the on-current sensitivity (S_{ION}) and off-current sensitivity (S_{IOFF}) for different biomolecules. The increasing K_{bio} of biomolecules decreases both the on-current and off-current [89], but the relative change increases due to increased gate-to-channel coupling. Hence, S_{ION} [90] and S_{IOFF} increase with the increasing K_{bio}. Figure 7(b) shows the I_{ON}/I_{OFF} ratio, while the inset shows the fractional sensitivity in I_{ON}/I_{OFF} ratio (S_{FCR}) [91]. As both the on-current and off-current decrease, the overall I_{ON}/I_{OFF} ratio increases due to the dominant factor in the denominator (rate of decrease is more in off-current, thus increasing the overall I_{ON}/I_{OFF} ratio with the increasing K_{bio}) [92]. Hence, I_{ON}/I_{OFF} ratio and its fractional sensitivity (S_{FCR}) can also be used as a sensing metric along with threshold voltage and subthreshold swing. I_{ON}/I_{OFF} ratio changes approximately 10^1-10^4 times when the cavity gets filled with biomolecules having K_{bio}=2.1-8. A larger I_{ON}/I_{OFF} ratio variation makes it a perfect sensing metric for biosensing applications. Using multiple sensing metrics to analyze the sensitivity of a biosensor increases its reliability.

Figures 8(a) and 8(b) show the threshold voltage and subthreshold swing sensitivity for different biomolecules. The inset in Fig. 8 shows the variation of threshold voltage and subthreshold swing, respectively. With the increasing K_{bio}, more gate voltage will be required to start the conduction in the device because of the increased capacitance of the nanogap cavity (which leads to high capacitive coupling). This decreases the current flow but increases the threshold voltage. As a result, threshold voltage sensitivity increases due to the increase in the threshold voltage, which can be seen in figure 8(a). Subthreshold swing varies inversely with the gate oxide capacitance, and as a result, subthreshold swing decreases. However, the relative change (with respect to the 'unfilled cavity case') increases with the increasing K_{bio} [90], which is visible in figure 8(b). Threshold voltage has shown a more significant variation than the subthreshold swing for the same biomolecules and hence is a better sensing metric.

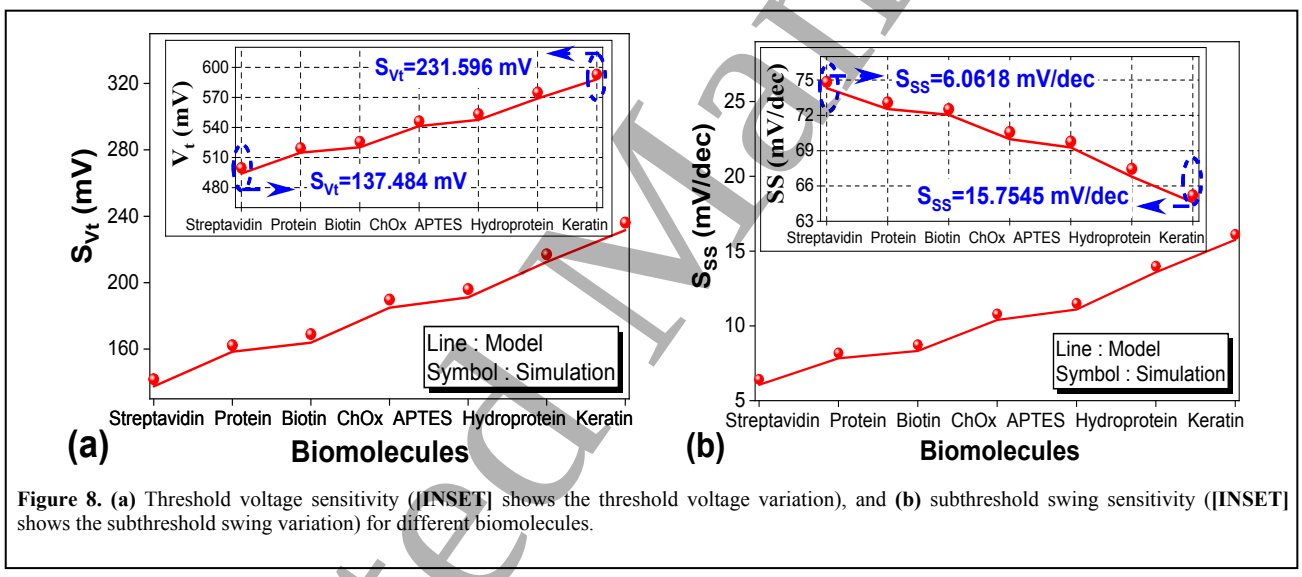

Figure 8. (a) Threshold voltage sensitivity (**[INSET]** shows the threshold voltage variation), and **(b)** subthreshold swing sensitivity (**[INSET]** shows the subthreshold swing variation) for different biomolecules.

Figure 9(a) shows the peak transconductance sensitivity (S_{gmp}), while the inset shows the variation of peak transconductance for different biomolecules. The transconductance is an intrinsic parameter obtained from the I_{DS}-V_{GS} plot. As discussed above, transconductance is high at higher values of V_{GS}, and hence, the peak transconductance sensitivity is also obtained at high V_{GS}. The peak transconductance (g_{mp}=17.3507μS) and peak trans-conductance sensitivity (S_{gmp}=8.5944 μS) is obtained for keratin at V_{GS}=0.9 V and V_{DS}=0.5V. Gate oxide stacking increases the threshold voltage sensitivity by a substantial amount due to the increased gate oxide capacitance (capacitive coupling)[30]. Gate oxide stacking not only improves the sensitivity but also improves the electrostatics integrity of the device. Figure 9(b) shows the effect of the gate stack on threshold voltage sensitivity. A threshold voltage sensitivity improvement of approximately 42mV can be seen for K_{bio}=8 due to gate oxide stacking (SiO_2+HfO_2) which increases the coupling between the gate and the channel when compared to mono gate oxide (SiO_2). We have considered the biotube to be filled with air only, but filling the biotube with other dielectric materials has a negligible effect on the threshold voltage and subthreshold swing. Threshold voltage sensitivity and subthreshold swing sensitivity changes merely 0.00866 V and 0.000537 V/decade when the dielectric constant of the material inside the biotube is changed by 30 times which can be seen in figure 9(c). Therefore, its effect can be neglected (the percentage change is merely below 1% for V_t) in a practical scenario. This minute change is due to the leakage of charge carriers arising due to the non-ideality of

Accepted Manuscript

the dielectric material used in the biotube. More ever, this change can further decrease (negligible) by using an ideal dielectric material inside the biotube.

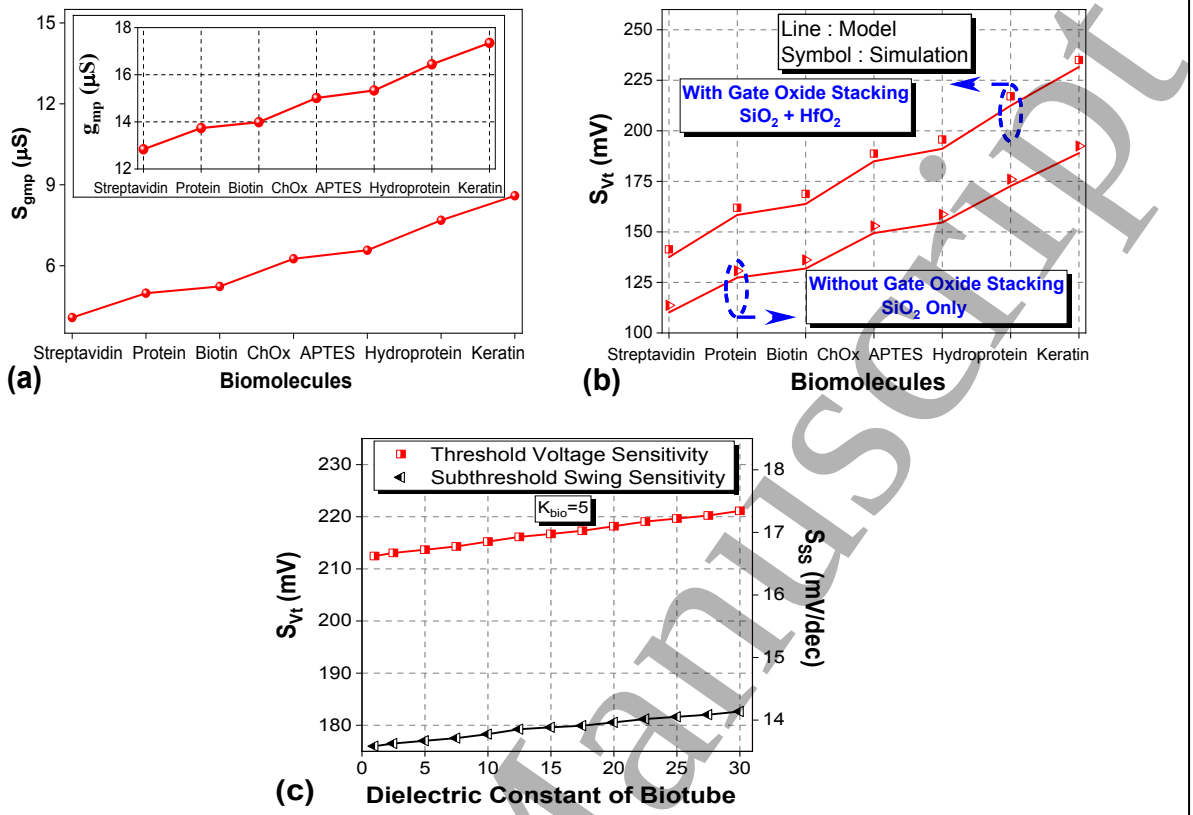

Figure 9. (a) Peak trans-conductance sensitivity (**[INSET]** shows the peak trans-conductance variation), **(b)** effect of gate oxide stacking on threshold voltage sensitivity for different biomolecules, and **(c)** variation of threshold voltage (subthreshold swing) sensitivity due to the dielectric constant of biotube.

Table 6 shows the effect of the fill-in factor, along with the location of biomolecules, on the sensitivity. The fill-in factor implies the fraction of volume within the cavity occupied by the biomolecules. In practical cases, some portion of the cavity might remain unfilled for unavoidable reasons [6]. Hence, studying the impact of the fill-in factor becomes indispensable. It is worth noticing that the sensitivity of a biosensor mainly depends upon two prime factors: i) the location of biomolecules and ii) the fill-in factor of biomolecules. A high fill-in factor implies more biomolecules occupying the cavity which will change the gate oxide capacitance by a larger margin [93]. This changes the electric field and the potential profile across the channel. Hence, the lateral electric field will affect the flow of the charge carriers more strongly. Due to this, the device current changes relatively more [6]. Furthermore, the change in threshold voltage, subthreshold swing, and transconductance will increase if the fill-in factor is high.

Generally, a high fill-in factor of biomolecules results in high sensitivity. However, a high fill-in factor does not always guarantees high sensitivity, which can be seen in different cases. It can be seen that the sensitivity is high when the biomolecules are located near the source. The barrier potential generated across the source junction (between source and channel) mainly affects the device conduction. This potential hill across the source junction is mainly affected by the biomolecules near the source. When the biomolecules are entrapped in the cavity near the source, the potential barrier between the source and the channel is primarily affected. The change in the potential barrier across the source junction is predominantly responsible for a larger change in threshold voltage, transconductance, and subthreshold swing. The charge carriers generated from the source are involved in the biosensing action, and thus the sensitivity is affected by the fill-in factor and location of biomolecules. While the fill-in factor of biomolecules can impact sensitivity, the position of the biomolecules can have a more significant and dominating effect. The fill-in factor in case (3) is higher than in case (4), but the sensitivity relation is opposite to that of the fill-in factor. Similarly, even though case (1) and case (4) have the same fill-in factor but the sensitivity is multiple times larger in case (4) than in case (1), which strengthens the observation that the position of the biomolecules plays an important role in determining sensitivity.

Figure 10 shows the threshold voltage sensitivity plot of DM-SGGS-BTFS at different cavity thickness. Notably, the sensitivity pattern demonstrates a positive correlation with the increasing thickness of the cavity. It is worth noting that, as the cavity thickness increases, the ability of the gate to regulate the flow of charge carriers gradually decreases due to

Accepted Manuscript

the increasing thickness of the gate oxide. Consequently, the rate of sensitivity change becomes lower at higher cavity thicknesses compared to lower cavity thicknesses, as can be seen in figure 10.

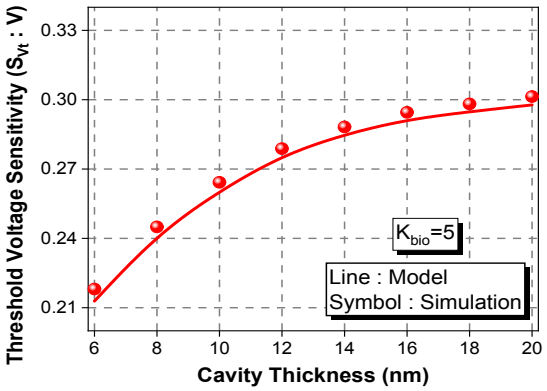

Figure 10. S_{Vt} variation with the cavity thickness in DM-SGGS-BTFS.

Table 6. Effect of fill-in factor and location of different biomolecules on S_{Vt}, S_{SS}, and S_{gmp}.

Figures 11(a) and 11(b) show the effect of temperature on threshold voltage/subthreshold swing sensitivity and I_{ON}/I_{OFF} ratio for K_{bio}=5. As the temperature increases, large numbers of charge carriers are generated due to which conduction starts at a lower value of gate voltage, and hence threshold voltage decreases [92]. But, the relative change in threshold voltage increases with increasing temperature, and hence the threshold voltage sensitivity increases. Due to a substantial increase in current with the rise in temperature, the swing in the drain current also increases, increasing the subthreshold swing sensitivity. This can be seen in figure 11(a). Both the on-current and off-current increase with an increase in temperature [92], but the rate of change of off-current dominates the I_{ON}/I_{OFF} ratio. Hence, I_{ON}/I_{OFF} ratio degrades badly at high temperatures, as seen in figure 11(b). The peak transconductance is directly proportional to the slope of the drain current in the transfer characteristic plot, and the slope increases with an increase in temperature. Therefore, as the temperature increases, the peak transconductance also increases, and the peak transconductance sensitivity also increases accordingly. This trend can be observed in figure 11(c).

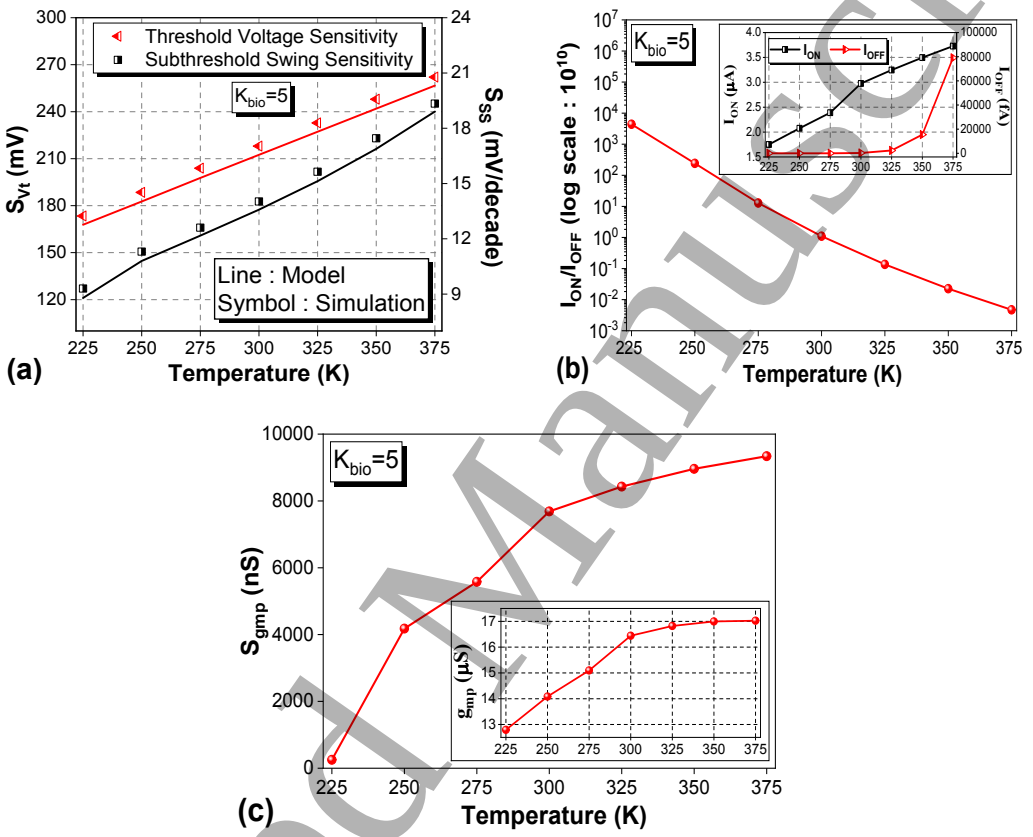

Figure 11. Effect of temperature on **(a)** threshold voltage (subthreshold swing) sensitivity for K_{bio}=5, **(b)** I_{ON}/I_{OFF} ratio for K_{bio}=5 (**[INSET]** shows the variation of on/off current at different temperatures)**, (c)** trans-conductance sensitivity for K_{bio}=5 **([INSET]** shows the peak trans-conductance at different temperatures).

Figures 12(a), 12(b), and 12(c) show the effect of source doping, normalized biotube radius (NBR), and normalized cavity length/thickness on threshold voltage sensitivity. An increase in the source doping will increase the number of charge carriers that brings the nano-device into a conduction state at a low V_{GS} [55,94]. This increases the threshold voltage sensitivity, and the biosensor becomes more sensitive to biomolecules, as seen in figure 12(a). The increasing inner radius of the biotube ('a') will decrease the cross-sectional area of the channel available for the charge carriers, and hence, the conduction current decreases. This will increase the threshold voltage; hence, the relative change in threshold voltage increases with the increasing biotube radius, as seen in figure 12(b). It can be seen that at lower values of 'a' (a=1nm: NBR=0.9), threshold voltage sensitivity is high, but the current ratio is comparatively low. Optimizing the value of 'a' become essential due to the tradeoff between sensitivity and I_{ON}/I_{OFF} ratio. As discussed above, the increasing thickness or length of the cavity will entrap more biomolecules inside it due to its increased volume. Hence, the potential and electric field profile changes relatively more, accounting for the more considerable threshold voltage change. So, threshold voltage sensitivity increases with the increasing cavity length or thickness [30], as seen in figure 12(c). Sensitivity in the label-free biosensors varies directly with the cavity dimensions, i.e., the more is the dimension, the

Accepted Manuscript

more its sensitivity will be [28,30]. Table 7 highlights the sensitivity comparison of DM-SGGS-BTFS with existing biosensors.

Selectivity is one of the most common problems in DM-FET based biosensors (designed without any bioreceptor layer). Hence, this issue has also been addressed here by discussing the merits/demerits of adding an additional bioreceptor layer. For this, the Anti-Iris antibody has been selected as the biomolecule, while the Thiol Linker and Iris Antigen act as the bioreceptor. The respective thicknesses of Thiol linker and Iris Antigen are 2 nm and 4 nm,

Accepted Manuscript

respectively. Although different papers typically consider a thickness of 2 nm for the Anti-Iris antibody, the thickness of the cavity (excluding the bioreceptor thickness) has been increased to 6 nm to accommodate the biomolecule effectively (considering a fill-in factor of 1) [7,9]. The Thiol Linker functions as a silica-binding protein, while the Iris Antigen serves as the bioreceptor for detecting the Anti-Iris (biotarget) layer. These layers possess individual dielectric constants of 2, 4, and 8, respectively. To provide a clear reference, figure 13 visually illustrates the arrangement of the three-layered stack (bioreceptor and biotarget). Within figure 13, the current sensitivity plot (transfer characteristics) for different cases (corresponding to the consecutive stacking of the Thiol Linker, Iris Antigen, and Anti-Iris Antibody) in DM-SGGS-BTFS is presented. In the absence of biomolecules, the drain current remains low. However, as the Thiol Linker, Iris Antigen, and Anti-Iris gradually accumulate within the cavity, the current increases significantly due to the strong electrostatic control of the gate over the channel because of strong capacitive coupling/effect. It can be also seen that threshold voltage sensitivity is higher for the case when no bioreceptor layer is used as compared to the case when bioreceptor layer is used (total oxide thickness, i.e. t_2 is kept same in both the cases). This indicates the existence of a trade-off between sensitivity and selectivity in the proposed device. In non-critical primary sensing applications, the biosensor could be designed without an additional bioreceptor layer, reducing costs and simplifying the manufacturing process (the selectivity/specificity of the biochemical species could be further validated through secondary testing). The inclusion of a bioreceptor layer becomes pertinent when selectivity takes precedence in the sensing application.

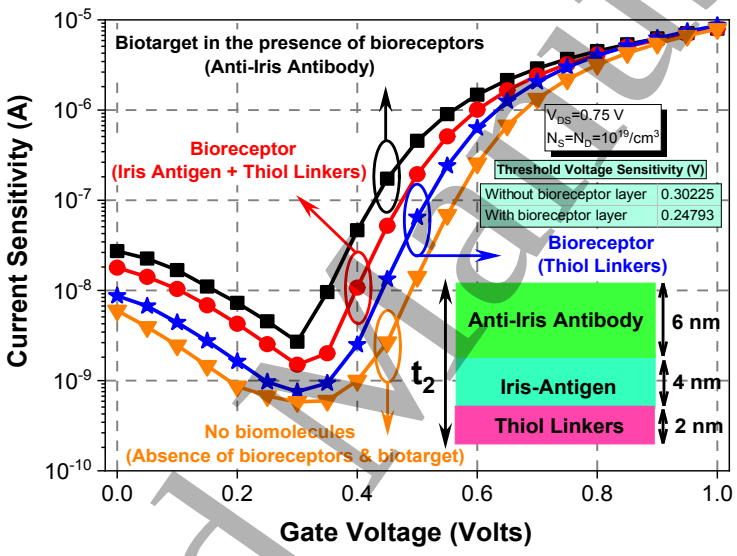

Figure 13. Current sensitivity plot (transfer characteristics) in DM-SGGS-BTFS with successive accumulation of the bioreceptor and biotarget.

4. Conclusion

This paper thoroughly investigates and analyzes the biosensing performance of a novel DM-SGGS-BTFS. The improved biosensing performance is attributed to the use of a germanium source and step-graded biotube, which enhances the biosensing performance and electrostatic integrity of short-channel devices. The study extensively explores the effect of the fill-in factor and the location of biomolecules, demonstrating that the gate controls the flow of charge carriers effectively through capacitive coupling. Notably, the location of biomolecules has a more significant impact on sensitivity than the fill-in factor. Various metrics were used to evaluate the biosensing performance, including subthreshold swing, off-current, threshold voltage, peak trans-conductance, I_{ON}/I_{OFF} ratio, and on-current. The threshold voltage and current sensitivity reached remarkable values of up to 263 mV and 1495.52 nA, respectively, indicating excellent biosensing ability. Furthermore, the study discussed the effect of doping and bias on sensitivity and emphasized the need to optimize different parameters to achieve high sensitivity. For further enhancing the biosensing performance and sensitivity of DM-SGGS-BTFS, future investigations could explore implementing Gaussian/Double-Gaussian doping profile in the nanotube channel, drain engineering techniques using different drain materials, or introducing source/drain pockets. Overall, DM-SGGS-BTFS has the potential to serve as a viable alternative to existing silicon biosensors and can find widespread use in the biomedical industry.

Abstract -- **India ranks third in the world in terms of production of green energy. Extensive use of fossil fuels led to environmental issues, like carbon emissions, cleaning the air, mitigating climate change. Alternatives venues like wind, solar, biomass, geothermal, ocean, wave hold promise to provide long-lasting sustainable solutions to these issues. Deployment of green energy sources is needed for energy security and economic development. Currently, green energy accounts for ~37% of India's total energy consumption and its demand is expected to rise by 256 Mtoe by 2040, clocking average annual growth of ~16%. Installed green energy capacity was 159.95 GW in May 2022. This paper identifies the green energy sources available in India and their potential.**

Keywords: Renewable energy, Green energy, Solar energy, Wind energy, Biomass, Geothermal energy, Tidal wave energy

I. INTRODUCTION

GROWING consumption of conventional energy resources gave rise to various problems like emission of greenhouse gases, polluted air and climate change. Such negative environmental impacts require clean energy production for a high quality of life. Rising gap between demand and supply requires increase in green energy with ease in installation procedures and policies.

Green energy is estimated to grow from 41 Mtoe in 2020 to 256 Mtoe in 2040. The energy demand, according to expert discussion, is 1300 TWh of electricity demand and 1345 Mt of coal demand in 2020-21. By March 2014, India had 76.37 GW of installed capacity and it rose to 159.95 GW by May 2022. The installed power capacity in the country was around 408.72 GW as of November 30th, 2022. India has already stated its intention to achieve net-zero emissions by 2070, with renewable energy sources meeting 50% of its energy needs by 2030. This aim is considered sufficient to mitigate climate change. With strong government support, India is ranked third in the world in terms of green energy production capacity.

Adoption of green energy such as solar energy still depends upon various factors such as finances, investments, and consumer behavior. Liming [1] classified the financial systems into several categories, such as government financing, international funding, public stock markets, private sector financing, venture capital, subsidies, etc. Sisodia identified various barriers,investments, subsidies, perceptions, and gaps between green energy generation and implementation [2]. Identified gaps were mostly in investment planning, regulations and finances. Ansari identified 13 barriers that are responsible for delayed solar power plant installation in India [3]. A huge increase in energy demand demands an alternative need for green, workable, inexpensive, and ecologically sound energy sources. The generation of power from green energy sources steadily increased since 2002. Three separate government bodies are working hard to meet target, *i.e.*, MNRE, IREDA and SEC.

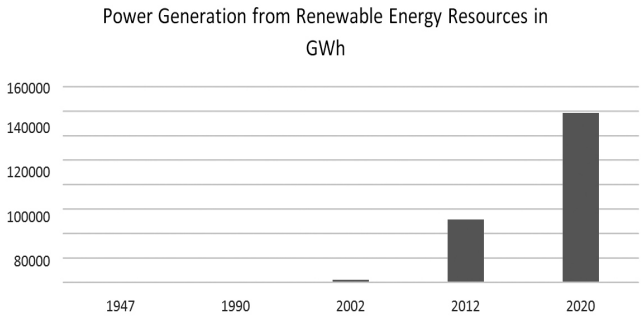

Figure 1. The journey towards renewable energy in India [4]

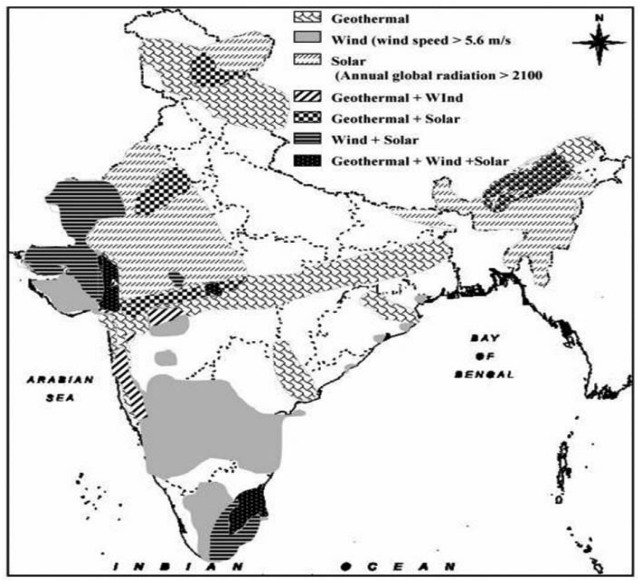

Figure 2. Green resource map India [5].

Commercialized sources of Green energy are as follows.

Geothermal energy: Below the earth's crust, an inexhaustible amount of heat energy exists due to physical processes. Most geothermal resources mapped by the Geological Survey of India, yield estimated potential as about 10600 MW [6]. It is stored in reservoirs beneath the earth's crust in the form of hot water, which is tapped via drilling.

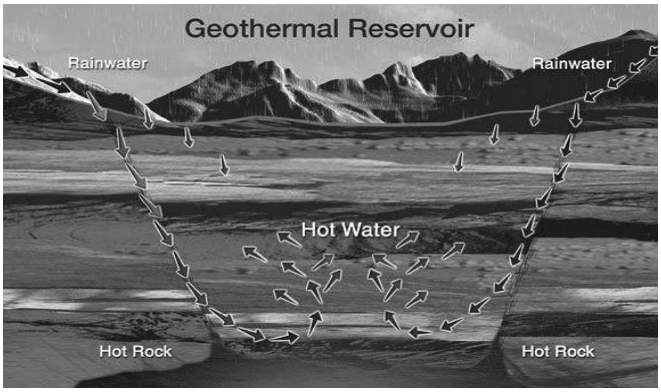

Figure 3. Geothermal reservoir [7].

Wind energy: The commercially exploitable potential of wind energy in India is estimated to be over 200 GW. As of May 2022, the total installed capacity of wind power was 41 GW [9]. The National Institute of Wind Energy (NIWE) installed about 700 wind monitoring stations, out of which 237 have a potential greater than 200 W/m^2. States with great wind energy potential are Rajasthan, Maharashtra, Gujarat, Tamil Nadu, Karnataka, Andhra Pradesh and MP, possessing 293 GW of wind potential at 100 m hub-height and 652 GW at 120 m. The cost of wind power generation is going down day-by-day.

Solar energy: India receives 5000 trillion KWh of solar energy annually. In India, solar incident varies ~ 4-7 kWh/m^2 with bright sunshine. Solar power capacity projected as 749 GW, of which 62 GW was installed as on 30th November, 2022. Solar rooftop market potential is estimated as124 GW in India. Solar rooftop is a distributed system that makes significant contributions to energy independence.

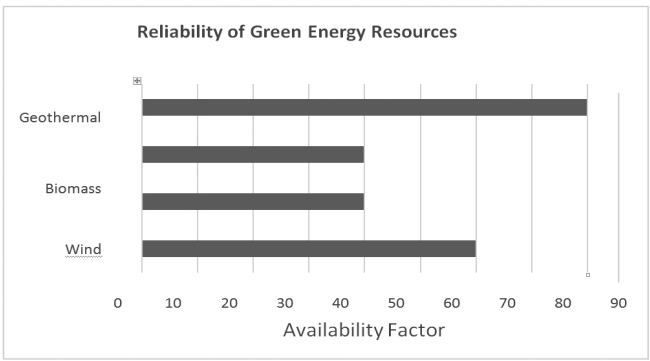

Figure 4. Green sources availability factor [7].

Availability factor of Geothermal sources are more than other kind of Energy sources.

Table 1 -- INDIA'S SOLAR MARK BY 2022 [12]

STATES	SOLAR MARK IN MW
Delhi	2762
Haryana	4142
H.P	776
J & K	1155
Punjab	4772
Rajasthan	5762
U.P	10697
Assam	663
A.P	39
Meghalaya	161
Manipur	105
Mizoram	72
Nagaland	61
Tripura	105

Hydro energy: It is a form of sustainable energy with no carbon emissions. The Himalayan states are capable of producing a large amount of hydroelectric power. MNRE located 6474 potential sites in India: small hydropower capacity is currently projected to be around 20,000 MW. India has so far used 15000 MW of hydropower potential. Worldwide, India ranks fifth in terms of hydroelectric power capacity production. Hydro-electric plants are low-operational cost and require low-maintenance. They provide water and flood control tools.

Biomass energy: The industrial revolution diminished biomass energy, which was the world's dominant energy source before that. India's farming economy relies heavily on bio-mass such as shells, grass, jute, fibre, and coconut shells.The bio-mass can be converted into liquid fuels and electricity. It is estimated that 350 million tons of farm waste are produced each year in India. States with large potential for biomass include UP, Punjab, Karnataka, Gujrat, Bihar and Tamil Nadu. During 2010, India had 3145 MW of installed biomass energy, which rose to 10,228 MW by end-2020. In India, about 56 biogas plants are operating, distributed across Kerala,Maharashtra and Karnataka.

Tidal energy and Wave energy: Tidal energy though not widely used globally, is a good source of green energy. This kind of energy is generated by ocean tides, which are generated by the relative movements among the Sun, Moon, and Earth centrifugal and gravitational forces are responsible for tidal flows or the periodic motion of water. India has a large potential for tidal energy generation due to its 7500 km coastline and 336 islands in the Bay of Bengal and Arabian Sea. The total

available potential of tidal energy is about 40,000 MW. Fluctuations present in tides carry a high power density. This power can be used in a Tidal power plant. Generation of tidal power is dependent on a suitable site, tidal range, and tide speed.

II. CONCLUSION

India's energy requirements are increasing day-by-day, leading to deployment of alternative options like green energy sources to meet the demand. The green sector has significant economic, environmental and social benefits. Strong government support for green energy sector will ensure its greater share in total energy consumption. Literature review reveals spatial variations of different green sources scaled across India.

III. ACKNOWLEDGMENT

The authors gratefully acknowledge Dr. Rakesh Srivastava and Dr. Hemant Ahuja for helping us with the article.

Nikita Jaiswal is an accomplished Assistant Professor in the Civil Engineering Department at Ajay Kumar Garg Engineering College, Ghaziabad. With a passion for Hydraulics and Flood engineering, she earned her M.Tech degree in this field from Delhi Technological University in 2014. As an Assistant Professor, Nikita brings her extensive knowledge and expertise to the classroom, inspiring and guiding students to excel in their academic pursuits. Her teaching style is engaging and interactive, ensuring that students have a solid understanding of the concepts and practical applications of Civil Engineering.

Nikita's research interests are focused on the development of sustainable and innovative solutions to address hydraulic and flood-related issues. She has published several research papers in reputed international journals.

Ashish Vishwakarma is an Assistant Professor in the Department of Civil Engineering at Ajay Kumar Garg Engineering College, Ghaziabad. He earned his M.Tech degree from IIT BHU Varanasi UP in the domain of Hydraulics and water resources engineering in 2016.

As an Assistant Professor, he brings his experience and expertise in academics to solve physical problems.

His research interests are mainly focused on pipe network,pressure-based fluid mechanics and optimal solutions related to fluid flow. He has published several research papers in reputed international journals.

Ms. Kshama Shukla is an Assistant Professor of civil engineering at AKGEC, Ghaziabad specializing in the field of cognitive struture analysis. She obtained her M.Tech degree in structure analysis from Maharshi Dayanand University, Rohtak, where she conducted research on the mix design of self compacting concrete. She has published several research papers in this field. She is committed to bridging the gap between basic conventional method of construction and new software base technologies of construction. Her current research focus is on 3D concrete printer application and sustainable development.

As an Assistant Professor, she brings her extensive knowledge and expertise to the classroom, inspiring and guiding students to achieve their goals for their bright future. With her interactive and conceptual teaching way, she ensures that students have a solid understanding of the concepts and practical applications of Civil Engineering.

Abstract

Microbial lipids are ideal for developing liquid biofuels because of their sustainability and no dependence on food crops. Especially the bioprocess for microbial lipids may be made economical by using sustainable approaches, e.g., lignocellulose-based carbon sources. This demand led to a search for ideal microorganisms with the ability to utilize efficiently biomass into value-added products. *Rhodosporidium toruloides* species belongs to the family of oleaginous (OG) yeast, which aggregates up to 70% of its biomass to produce fatty acids which can be converted to a variety of biofuels. *R. toruloides* is extremely adaptable to different types of feedstocks. Among all feedstock, a lot of effort is going on to develop a bioprocess of fatty acid production from lignocellulose biomass. The lignocellulose biomass is pretreated using harsh conditions of acid, alkali, and other which leads to the generation of a variety of sugars and toxic compounds. Thus, so obtained lignocellulose hydrolysate may have conditions of different pH, variable carbon and nitrogen ratios, and other non-optimum conditions. Accordingly, a detailed investigation is required for molecular level metabolism of *R. toruloides* in response to the hydrolysate for producing desired biochemicals like fatty acids. The present review focuses on numerous elements and obstacles, including metabolism, biofuel production, cultivation parameters, and genetic alteration of mutants in extracting fatty acids from lignocellulosic materials utilizing *Rhodosporidium* spp. This review provides useful information on the research working to develop processes for lignocellulose biomass using oleaginous yeast.

Keywords *Rhodosporidium toruloides* · Biorefinery · Microbial lipids · Lignocellulosic biomass · Oleaginous yeast

Introduction

Triacyl glycerides (TAGs) are neutral lipids that are spontaneously synthesized through fatty acid biosynthetic pathways. The application of TAGs is observed in food, animal feed, and feedstocks for many chemical synthesis [1]. Another interesting application of TAGs highlighted by recent research includes its derivatives such as long-chain fatty acid methyl esters (FAMEs) and alkanes as drop-in biofuels [2]. Since the rate of production of drop-in biofuels has its challenges from conventional methods. The methods based on plants and crop oils have a limited capacity and rate of production. Therefore, microbial fatty acid biosynthesis can be used as a tool to overcome these constraints [3].

Oleaginous or oil-producing microbial species are very potent in the conversion of carbohydrates to lipids including TAGs. *Yarrowia* spp., *Cryptococcus* spp., *Trichosporon* spp., *Lipomyces* spp., and *Rhodosporium* spp. are among the intriguing yeast genera that have shown the capacity to collect more than 20% of their dry weight in lipids. However, the *Yarrowia*, *Cryptococcus*, *Trichosporon*, and *Lipomyces* genera require a single-carbon source (typically glucose), in their natural state, to produce high amounts of lipids. The utilization of these strains on substrates that include various forms of carbon sources is severely restricted because of the above limitation. Therefore, in order to enable them to use various feedstocks, it is essential to do extensive research on genetic alterations that may be incorporated [4].

Whereas *R. toruloides*, a non-pathogenic pink-colored basidiomycetous fungus, can accumulate lipids to more than 70% of its dry cell weight and has a remarkable capability for proliferation on a variety of substrates, including glucose, xylose, lignocellulosic hydrolyzate, sludge hydrolyzate, etc. [3, 4]. Additionally, this yeast is an excellent generator of carotenoids and biotechnologically essential enzymes such as epoxide hydrolase and cephalosporin esterase [5]. Furthermore, few reports indicated about its resistance to the inhibitors present in biomass hydrolysate makes it a potential biotechnological yeast strain [6, 7]. There is substantial literature describing the results of lipid production by oleaginous species [8–12], which flourishes our understanding of its genetic and molecular background.

R. toruloides is abundant in nature in several places such as plant leaves, ocean, pine trees pulp, and acid sewage [13–16]. Although in acid sewage they were found in mild acidic environmental conditions. It is categorized as the family Sporidiobolaceae, the order Sporidiobolales, the class Microbotryomycetes, and the phylum Basidiomycota. Mushrooms, smuts, and rusts represent the Basidiomycota phylum's representative fungus that distinguishes *R. toruloides* from several other yeasts used in engineering investigations, including *Saccharomyces cerevisiae*, *Lypomyces starkeyi*, and *Yarrowia lypolytica*. Due to the polyphyletic nature of yeast in the Pucciniomycotina phylum of the Basidiomycota phylum, a new phylogenetic taxonomy advocates renaming *Rhodosporidium* as *Rhodotorula* [17]. *R. toruloides* thrive across various temperatures and pH conditions [3].

The wheat straw, corn straw, rice bran and other plant wastes are sources of lignocellulose biomass. The lignocellulose biomass are carbon sources including oligosaccharides, pentoses and hexoses which can be used for microbial fermentation. Several researchers have developed biorefinery approach to utilize lignocellulose biomass for carbon source. The essential steps involved pretreatment, enzymatic hydrolysis, and fermentation. The main objective remains to remove lignin so that polysaccharides are accessible. But during pretreatment there are chances of generation of toxic components like furfural which can hinder growth of microbes. It is now known that using sugars extracted from lignocellulose may be used for development of economical processes.

Furthermore, these processes are sustainable and environmentally friendly. But we need to identify industrial strains which can rapidly adapt in the hydrolysate with growth inhibitors. Thus, this review focuses on *R. toruloids* ability to utilize lignocellulose waste to produce fatty acids. *R. toruloides* is resistant to biomass-derived inhibitors such as furfural, and hydroxyethyl furfural (HMF) through metabolic modifications [7]. For instance, a study showed how *R. toruloides* strain was adapted in undetoxified hydrolysate to obtain strain with better resistance from the inhibitors like furfural and 5-HMF and improved yield of lipids (sugarcane bagasse hydrolysate was used as a carbon source) [18]. The *R. toruloides* utilizes a variety of carbon sources as energy sources, including oligosaccharides such as cellobiose, maltose, and sucrose; monosaccharides such as pentoses and hexoses; organic acids (OA) such as lactate and acetate; and alcohols such as ethanol, sorbitol, mannitol, and glycerol (Fig. 1) [19, 20]. Several works of literature demonstrate *R. toruloides* may be used to feed on biomass hydrolysates to produce lipids and carotenoids [21–23]. Oleaginous yeasts are often grown in nitrogen-limited conditions to accumulate significant lipids (LPDs) [3]. Additionally, a deficiency of other nutrients such as iron, sulfate, and phosphate facilitate *R. toruloides* lipid synthesis [24].

In the present review, fatty acid production and metabolism in *R. toruloides* is correlated with respect to challenges faced by yeast in culture media made up of lignocellulose biomass hydrolysate. The hydrolysate conditions are very harsh as observed by variety of sugars (pentoses, hexoses), pH, toxic components, and other factors. So main objectives of this review are how pretreatments of lignocellulose waste impact on growth of *R. toruloids*, how composition of hydrolysate can influence production of fatty acids especially C/N ratio, pH, and stress conditions. Furthermore, an effort is done to know if genetic manipulation may help in lipid production and how efficient extraction of lipids is possible.

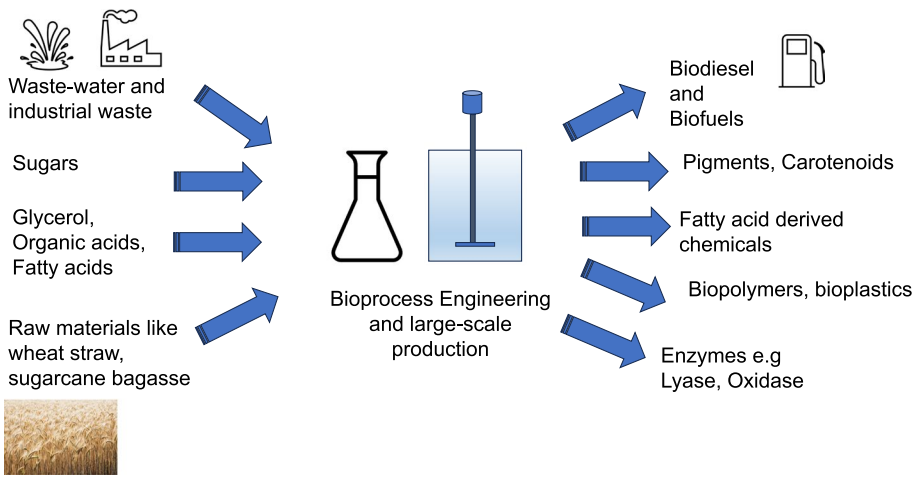

Fig. 1 Schematic representation of value-added produced by *R. toruloides* on uptake from an array of feedstocks like wastewater, fatty acids, organic acids, glycerol, and various sugars

Fatty Acids Production Pathways Known in *R. toruloides*

The production of fatty acids (FAs), their absorption into membrane phospholipids, and storage are dominantly in the form of TAGs, and lastly, the aggregation of stored lipids into lipid droplets as a potential resource is all inherited from the biosynthetic pathway [4]. The major portion of these droplets is utilized as fatty acids synthesized from de novo pathways and stored in the cytoplasm. In the past, lipid droplets were believed to be intracellular fat reservoirs since they retain more than 90% (w/w) of the neutral lipids including steryl esters and TAGs in their whole cell volume [25]. TAG to steryl esters ratios differ across species and are also affected by growth conditions [26]. In *R. toruloides,* FAs are synthesized through de novo pathways, external FAs uptake, or lipid breakdown. De novo fatty acid production occurs in cytoplasm and mitochondria, where it is produced as carbon chains with a stretch of C-18 that are then lengthened and desaturated in the endoplasmic reticulum (ER). Acetyl-CoA (AC), the active precursor for the de novo FAs pathway, originates from citrate via mitochondrial Tricarboxylic acid cycles (TCA cycles). Supplementary precursor citrate is available in oleaginous organisms, decomposed by ATP-citrate lyase (ACL), which affects lipid deposition.

The action of the TCA cycle enzyme iso-citrate dehydrogenase in *R. toruloides* is dependent on intracellular adenosine-monophosphate (AMP) concentrations, and the latter is an allosteric stimulator of this enzyme (Fig. 2). The enhanced action of mitochondrial AMP deaminase decomposes AMP when nutrient becomes scarce. A minimal amount of AMP inhibits iso-citrate dehydrogenase activity. The MPDH circuit is named after the action of mitochondrial pyruvate dehydrogenase (MPDH), which synthesis citrate that is translocated to the cytoplasm and reduced to acetyl coenzyme (Fig. 2) [27]. As a result, the MPDH pathway provides cytoplasmic AC in *R. toruloides*.

In FAs biosynthetic pathways, the acetyl-CoA carboxylase (ACC) protease converts acetyl-coenzyme to C3 malonyl-CoA in a condensation reaction. In *R. toruloides*, the cytoplasmic FA composition is introduced by ACC coded by the ACC1 allele, whereas the mitochondrial FA composition is undertaken by mitochondrial ACC [28]. The resultant

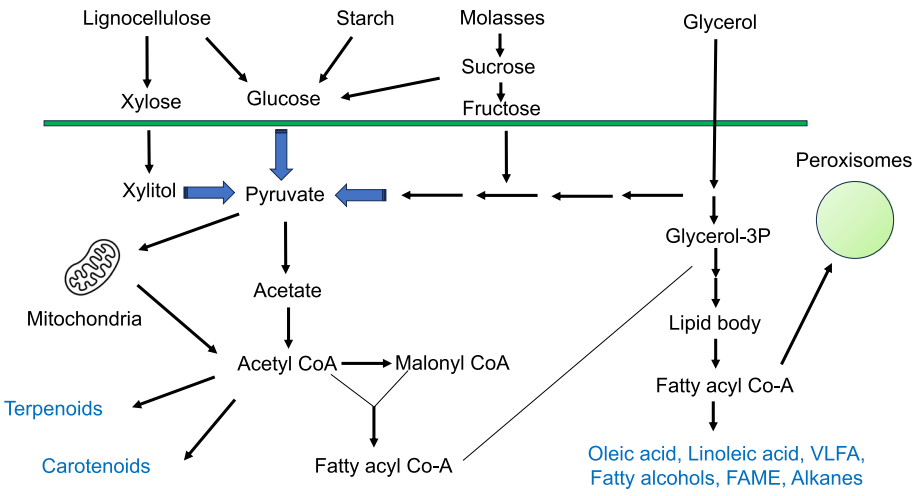

Fig. 2 The figure represents metabolic pathways linked with fatty acid biosynthesis in *R. toruloides*

malonyl-CoA is subsequently extended to palmitoyl (C16)-CoA by a sequence of stages regulated by a cytoplasmic fatty acid synthase (FAS) complex [29]. The acyl chain needs a constant supply of NADPH for this fatty acid synthase complex, which is provided by the malic enzyme. The cytoplasmic upregulation of malic enzyme in oleaginous microbes results in a 2.5-fold rise in lipid synthesis, any mutation in malic enzyme reduces FA accumulation [30]. Throughout the ER, the fatty acyl chain is further elongated, hydroxylated, and desaturated. Whereas various elongates carry out the earlier, desaturation is usually carried out by Δ15-desaturases found in oleaginous yeasts, for the extraction of α-linolenic acid from linoleic acid. Different transcription factors (TFs) control FA desaturation at the transcriptional level [29].

Different Pretreatment Methods Applied on Lignocellulose Biomass Before Using for Fatty Acid Production by *R. toruloides*

Because of its affordability, availability, and sustainability, lignocellulosic biomass has been extensively recognized as a possible substrate for the manufacture of biofuels and biochemicals. Lignocellulosic biomass is made up mostly of cellulose, hemicellulose, and lignin, which are linked together via covalent bonds, intermolecular linkages, and Van der Waals interactions to form an integrated complex that is resistant to hydrolysis and immiscible. Cellulose (40–50% of total dry matter) is a glucose polymer united with β-1,4 glycosidic linkages, with cellobiose, a glucose dimer, as the fundamental building component [31]. Hemicellulose is a highly branched heteropolymer consisting of multiple carbohydrates that accounts for 20–40% of total dry matter (C5 and C6). Depending on the plant species, the specific carbohydrates in hemicellulose might vary. Hemicellulose hydrolysis, on the other hand, may provide a combination of glucose, galactose, mannose, arabinose, xylose, and rhamnose, with lignin accounting for 20–25% of the total dry matter of the substrate [32]. Due to these advantages, lignocellulosic biomass is considered a vital source of lipids through oleaginous microbes. Several trials have been conducted (as described in Table 1) with lignocellulosic biomass with *R. toruloides* fermentation process with good lipid yields. For instance, SànchezNogué et al., in their study, successfully extracted ~ 60% lipid from corn stover hydrolysate [7]. Similarly in 2018, Slininger in his work abstracted the lipid titer of ~ 26.4 g/L from lignocellulosic rich switchgrass hydrolysate [33].

Numerous pre-treatment methods were developed over the last few centuries to resolve biomass intransigence by interrupting the physical boundaries of the cell membrane, lowering cellulose crystallinity, and expelling lignin and hemicellulose to facilitate the enzymatic hydrolysis of lignocellulosic biomass into simple sugars [36]. Pre-treatment methods are broadly divided into four primary groups: physical, chemical, biological, and combination pre-treatment methods. Chemical treatment is defined as the application of organic or inorganic substances that disturb the formation of lignocellulose by interacting with the intra-polymer or interpolymer linkages of lignin, hemicellulose, and cellulose [37]. Acids, alkalis, ionic liquids (ILs), oxidizing agents, and organosolv pretreatment are some of the most often utilized methods. One of the more successful techniques of dissolving the hemicelluloses and making cellulose quite accessible is to pretreat lignocelluloses with acids. The key drawbacks of this methodology are the corrosive environment of reactions and possible formation of inhibitors hydroxymethylofurfural (HMF), furfural, and acetic acid of further processing [38], loss of products because of by-products such as sugar degradation products (e.g., hydroxymethylfurfural or HMF and levulinic acid), hemicellulose

Table 1 Lipid accumulation through different lignocellulosic biomass and *R. toruloides* strains

S. no	Microbial Strain	Substrate	Sugar (g/L)	Lipid titer (g/L)	Lipid (%)	Reactor type	Reference
1	*R. toruloides* DMS—4444	Corn stover hydrolysate	100	23.3 ± 1.8	60.8 ± 1.1	Batch	[7]
2	*R. toruloides* DRRL Y-1091	Switchgrass hydrolysate	215	26.2 ± 1.4	61.5	Flask	[33]
3	*R. toruloides* AS 2.1389	Sugarcane Bagasse hydrolysate	20	12.3 ± 0.5	52.5 ± 1.0	Batch	[6]
4	*R. toruloides* CCT 0783	Sweet Sorghum	140	13.77	33.1	Flask	[34]
5	*R. toruloides* IFO 0880	IL pretreated corn stover hydrolysate	73.8	-	27	Batch	[35]

degradation products(e.g., ferulic acid, glucuronic acid, and p-coumaric acid) and lignin breakdown products (e.g., syringaldehyde and syringic acid) [39]. Biological pretreatment can be executed by utilizing fungi, that decompose lignin (white-rot fungi), cellulose (soft-rot fungi), or hemicelluloses and cellulose (brown-rot fungi). This approach has many benefits, including minimal equipment, efficacious cellulose and hemicellulose degradation, and minimal energy demands [39]. Particularly, enzymatic hydrolysis has been considered a viable approach of hydrolysis due to lower energy utilization, lower production of inhibitors under mild condition, and no discharge of toxic compounds. Apart from this, the yield of sugar obtained from this methodology is very low because the cellulose is parallelly consumed by the enzymatic microbes during the growth phase. Enzymatic hydrolysis generally takes 30–60 days long reaction for the decomposition resulting a major limitation for industrial utilization [40]. Another negative is the waste of material that might have been used for anything else.

Hydrolysis is one of the crucial aspects to extract sugars from pretreated lignocellulosic biomass [41]. Because of lignocellulosic resistance to hydrolysis, it must be transformed effectively and cost effective into its three polymeric components as cellulose, hemicellulose, and lignin, to maximize its significance for biofuel production. During the dilute acid treatment, hemicellulose and cellulose are hydrolyzed to produce fermentable sugars. In principle, the breakdown of hemicellulose results in the production of organic substances such as formic, acetic acid, and carbohydrates (glucose, xylose, mannose, and galactose). Therefore, to effectively transform carbon polymers into simple sugars, pretreatment of biomass materials is often performed before saccharification [42]. Inappropriate management of the pretreatment technique has a vast impact on the process and may result in the formation of substituents as an inhibitory influence during the extraction of biomass. The application of chemical and enzymatic procedures is often employed in the hydrolysis of the cellulose part of the biomass. The presence of acid and heat compels the polysaccharides to undergo chemical breakdown. It happens quickly and without the need for pretreatment of the feedstock. The downsides of this technique include the production of furfurals, poor carbohydrate extraction, and the lower economic viability application. The only way to make the procedure cost-effective is to design efficient methods for recovering acid. Additionally, enzymatic hydrolysis is carried out at moderate heat which varies from 45 to 50 °C, pressure gradient, and a mild pH which results in large-scale production of sugars with less by-product generation and prevents equipment failure. High levels of catalysts are thus necessary for the said decomposition of cellulose, and their manufacture requires an understanding of effective microbial strains and practical, cost-effective methods.

The Impact of Properties of Pretreated Lignocellulose Biomass Hydrolysate for Fatty Acid Production in *R. toruloides*

Fermentation is largely influenced by the environmental variables and cultivation techniques, including the C6-C5 fermentation sugar presence, the quantity of ammonia that is accessible, the carbon to nitrogen ratio (C/N), ionic strength, and biological oxygen demand, along with other things. Anti-proliferative substances found in lignocellulosic materials extracts, however, have an adverse effect on these variables because they interfere with the absorption and assimilation of various carbon sources [18]. In the present part the factors in media like carbon source, pH, nitrogen, and oxygen source are discussed with respect to known factors for fatty acid production in *R. toruloides*.

Ability of *R. toruloides* to Consume Diverse Sugars in Hydrolysate

The pretreatment led to the release of different type of sugars like pentoses, hexoses, and oligosaccharide. The various studies indicated use of different sugars on lipid accumulation. When cells are stressed with sufficient carbon sources (especially glucose) and a critical nutrient deficiency in the growth media, the genus *Rhodosporidium* efficiently utilizes sugars to form FAs [4]. This form of yeast alters the carbon flow (by halting the synthesis of nucleic acids and proteins) to synthesize lipids [43]. This is highly dependent on the environment and culture techniques, including the carbon supply, the amount of accessible nitrogen, O_2, pH, and the carbon–nitrogen (C/N) ratio [4]. Nonetheless, these characteristics are indirectly impacted by inhibitory chemicals found in lignocellulosic biomass hydrolysates since they affect the absorption and assimilation of the hydrolysate's various carbon sources. *Rhodosporidium toruloides* has an excellent capacity to feed on hexose and pentose carbohydrates that includes arabinose, xylose, and glucose [4]. However, fatty acids production varies with type of sugar are used as carbon source for instance, the lipid yield was 75% when glucose was used, 45% with xylose, and 19% with arabinose [44]. Even combination of carbon sources did not result in enhanced yield (30% of lipid accumulation) [45]. In this regard, the optimal utilization rates for glucose and xylose were calculated using a C/N ratio of 100 for lipid accumulation and 65 for biomass formation [23]. The ratios mentioned above result in a substantial change in the parameters and formulation of the fermentation technique to maximize sugar utilization [4, 45]. This adequate ratio of C/N being greater than 65 affects the repression of glucose during the high concentration in media. This results in the osmotic shock of Krebs cycle activity due to intracellular increase of citric acid. As a result, nitrogen limitation is observed, and microbes uses carbon source to formulate lipid as a protective mechanism [4].

The Variable C/N Ratio in Hydrolysate Impact Lipid Production in *R. toruloides*

This parameter is critical for the effective utilization of carbon sources for FAs conversion since it impacts biomass synthesis and lipids synthesis in the cell. The C/N ratio is among the significant factors which helps microbes work optimally and it must be larger than 65 for maximal lipids storage capacity in *R. toruloides* [46]. This is primarily due to the suppression of glucose when the concentration of carbon sources is high in the media. This results in an osmotic shock as the Krebs cycle activity diminishes due to the intracellular rise in citric acid. The absorption of xylose gets reduced from lignocellulosic biomass hydrolysates. In this regard, cellodextrin transporters expressed in *S. cerevisiae* were investigated for their ability to alleviate this suppression caused by intracellular cellodextrin hydrolysis, allowing for improved utilization of the xylose contained in this form of hydrolysate [47].

A research was conducted on two concentrations of C/N (75.3 and 20.3) to measure the effect on the accumulation of biomass and lipids in *Rhodosporidium azoricum* and it was observed that yeast consumed the nitrogen source in 40 h, whereas with a low proportion, the compound remained present after 65 h of fermentation [48]. This variation was also noticed in a reduction in lipid synthesis (47%) when a minimal C/N ratio was applied, indicating that the strain's nitrogen restriction concerning the carbon supply had a detrimental effect on lipid formation. This is because nitrogen deficiency in the medium may have a detrimental impact on many essential enzymes, including 1,6-phosphate, 2-aldolase that

catalyzes the formation of dihydroxyacetone phosphate, a precursor to glyceraldehyde-3-P (required for TAGs synthesis). However, the absence of nitrogen in the medium promoted the action of glucose 6-phosphate-dehydrogenase [23]. This is advantageous because the pentose-phosphate pathway is the primary source of NADP, a critical intermediate for the proper activity of a ME involved in synthesizing lipids. Although few pathways have not been extensively studied in oleaginous species, some studies in *Yarrowia lipolytica* have revealed that the pentose-phosphate pathway is among the primary source of nicotinamide adenine dinucleotide phosphate oxidase (NADPH), which is responsible for this type of yeast's excessive lipid production [49].

This necessitates a more diligent approach to this parameter since the C/N ratio, carbohydrate (carbon source), and the fermentation technique (continuous, fed-batch, or batch) negatively influence lipids synthesis. The most remarkable results for *Rhodosporidium* strains were achieved when glucose was used as the only carbon source, and C/N rates in a range of 65 to 80, with lipids titer of up to 50% dry weight in batch systems and up to 61% dry weight in fed-batch systems [23]. In contrast to this, when mixes of carbohydrates like arabinose, xylose, and glucose are employed, the lipid yield decreases to nearly half when high C/N rates (65 and 80) are used; but, when a lower C/N (40) rate is employed, the lipid content can rise to 58% of dry weight.

The Stressful Conditions of Hydrolysate May Hinder Production of Lipids in *R. toruloides* as Observed During Osmotic Stress

One of the critical elements governing the development and synthesis of hydrolysates is the presence of chemicals that might cause yeast cells to experience osmotic stress. The above remark suggests a significant obstacle during the formulation from culture medium for competitive LPD synthesis. An excessive salt concentration in the broth causes harm to the yeast's cell wall owing to the high salt concentration. The latest research has demonstrated that osmotic stress significantly affects cell metabolism because it immediately regulates cell transcription stages such as mRNA polysomal association and translation inhibition. This parameter is crucial for choosing or enhancing the fermentation of broth constituents. In one of the studies, Singh et al. examined lipid synthesis in *R. toruloides* under high osmolarity induced by NaCl addition [50]. The findings indicated a direct relationship between glucose concentration and culture time. Similarly, the combination between glucose concentration and NaCl affects LPD synthesis. When the sodium chloride content in the medium was raised to 10% v/v, it had a detrimental effect on the formation of LPDs utilizing low glucose concentrations (5 g L1) [23]. This impact, however, is adaptable when glucose is added since the downside effect of sodium chloride is remunerated for by LPD formation. The phenomenon indicates that when the primary glucose concentration is greater than the NaCl concentration, it encourages a proportionate formation of LPDs concerning the NaCl added to the medium.

The Different Methods of Pretreatment of Lignocellulose Led to Variable pH Environment and Hence Will Impact Lipid Production

Rhodosporidium strains have shown a broad array of pH values (2.2–7.5), it was noticed that this factor has a major impact on biomass accumulation (10, 13.5, and 16 g L1, respectively), LPD titer (2.5, 4, and 6.4 g L1, respectively), and LPD productivity relative to biomass at low (pH = 4), intermediate (pH = 5.5), and high (pH = 7) values (32%, 38%,

and 27%, respectively) [51]. Yaegashi discovered that the pH of fermentation broth had a significant effect on the efficiency with which fermentable sugars were used for terpenes productivity from lignocellulosic hydrolysates, through a genetically engineered variant of *R. toruloides* [35]. They discovered that this strain produced the most terpene at low pH (3.4), suggesting that it could produce OAs in its original state. However, when the pH was reduced to 2.5, the strain's ability to use sugars was significantly impaired, suggesting that it was essential to maintain this pH range for effective sugar utilization (3.4 to 2.5). These values, however, may vary based on the substrate and the result. For example, the most incredible yields have been achieved with an average culture pH ranging between 4 and 7.5 [52, 53]. Nonetheless, this parameter affects biomass production and LPD yields, as small changes in pH values significantly affect the dissociation of certain toxic elements such as levulinic, formic, and acetic acids produced during the pretreatment and hydrolysis of hemicellulose and cellulose, resulting in cell membrane disruption and inhibition towards microbial growth.

The Nitrogen Source Scarcity and High Oxygen Conditions Produce More Lipids in *R. toruloides*

Naturally occurring oleaginous bacteria does not accumulate significant TAGs when the medium conditions are balanced. When a substrate is scarce (mostly nitrogen), bacteria use carbon supply to accumulate FAs as a defensive mechanism [23]. Limitation of nitrogen supply in the fermentation broth initiates a response that increases the AMP-deaminase enzyme, which in turn reduces the AMP levels inside microbe cells, resulting in a reduction of malate dehydrogenase enzyme seen in oleaginous yeast. Due to these considerations, a balance is required between the quantity of oxalacetate converted to citrate via aconitase and the amount of citrate malate translocase (CTM) mediated through the cytoplasm. Once citrate enters the cytosol, it is converted to AC and oxaloacetate by the ATP citrate lyase (ACL) (the first step in synthesizing FAs). On the other hand, recycling oxaloacetate is vital to maintaining a continual citrate supply. The enzymes malate dehydrogenase and citrate synthase are responsible for this [54]. However, achieving the LPD content using natural components with a minimal nitrogen concentration is challenging. Wu et al. used a variant of *R. toruloides* Y4 and reduced the phosphate and sulfur levels of the growth medium to generate LPDs, getting yields of 62% and 58%, respectively [55, 56].

Nonetheless, several investigations examined the influence of nitrogen sources in the microbial proliferation of the whole cell cycle. This impact has been examined in the context of nutrient restriction in the surroundings since detecting nutrients signals the exhaustion of nitrogen through the MAP and TOR kinase pathways. Relevant findings have been achieved in genetically modified strains that maintained their development rate in the presence of restricted nitrogen compared to natural variants. These findings imply that the growth process is adaptable and capable of separating cell division from the availability of nutrient elements in the surroundings [57]. This indicated that limiting these ingredients in fermentations for the generation of LPDs may be equally efficient and inexpensive in terms of nitrogen-rich materials.

This parameter is critical while fermenting carbohydrates into FAs. It has been proven that during fermentations at significant oxygen rates ranging from 100 to 225 rpm, LPD titers rise (from 9 to 46.3%) [23, 51]. This is because *Rhodosporidium* development is severely inhibited under low oxygen conditions since some pyruvate enters the fermentations through the enzyme pyruvate decarboxylase (PDC). The reduction in AC, formed

during the utilization of citrate through ATP citrate lyase, reflects those mentioned above. The scarcity of oxygen also results in a poor rate of cellular biomass formation [58]. All of this shows that oleaginous yeast requires a significant quantity of oxygen to create energy and perform optimal LPD biosynthesis. According to a previous study, keeping a dissolved oxygen concentration between 40 and 50% results in a high-density culture (107 g L1 dry biomass) and a significant LPD titer (67.5% w/w) [23]. Additionally, it is vital to keep tight control over the quantity of oxygen used throughout the fermentation process since its volume significantly affects the accumulation of unsaturated FAs. Another critical aspect in the effective utilization of carbohydrates is the presence of toxic compounds in the hydrolysate, which induce the carbon source to undergo partial or complete catabolism. This suppression reduces cell proliferation and LPD synthesis, and it can completely stop the microorganism.

The Fed Batch Process Led to High Lipid Production Compared to Other Cultivation Processes

Different microbial strains are used for cultivation in lignocellulosic hydrolysates since their lipid concentration varies from 2 to 39.5 g/L and dry cell weight varies from 17.27 to 61.3% [59]. Fed-batch mode is more efficient in terms of productivity than other modes. *R. toruloides* AS 2.1389 strain has shown a lipid productivity rate of 0.16 (g/L/h) and 0.025 (g/L/h) when employed under batch mode by Brandenburg et al. (2021) [60] and Carmona-Cabello et al. (2021) [61]. Lakshmidevi et al. (2021) [62] studied CCT 0783 strain for the saccharified sweet sorghum juice (20%) feedstock with a yield of 0.105 (g LPD/g carbon) and productivity of 0.057 (g/L/h) in batch fermentation. Monteiro de Oliveira et al. [63] and Zheng et al. (2021) [5] used a fed-batch strategy for the fermentation of *R. toruloides* DSM 4444 and it showed a yield of 0.17 (g lipid/g carbon) and efficacy of 0.17 (g/L/h) when crude glycerol of concentration 50 g/L was used a carbon source [63]. *R. toruloides* Y4 strain is observed to produce 0.28 (g lipid/g carbon) of LPD utilizing glucose as the carbon source [5].

Genetic Manipulation Approaches for Enhancement in Fatty Acid Production in *R. toruloides*

Zhao and colleagues sequenced the genome of *R. toruloides NP11* and discovered a 20.2 Mb genome with a GC (Guanine-Cytocine) content of 61.9% and 8171 protein-coding genes [28]. Since then, numerous *Rhodosporidium species* draft genomes have been reported [64]. Functional and comparative genotyping can disclose the genetic architecture, protein-coding domains, speculated peptides, and functioning RNA of different species.

The combination of transcriptomics and genomics enabled the identification of introns of genomic composition and fatty acid synthase system involved in metabolic pathways [28]. In other investigations, transcriptome analysis was utilized to characterize the gene expression patterns and global responses of *R. toruloides* to a variety of stress conditions or the usage of a diverse range of carbon sources [24, 65–67]. These efforts resulted in the identification of many stress-resistant genes and regulatory chromosomes. However, proteomic analysis was used while assessing the peculiarities in protein expression across a range of circumstances. This approach is critical because it provides information to identify proteins implicated in lipid synthesis [3]. Additionally, it aids in investigating xylose

metabolism [68] and the identification of dynamic changes in essential proteins linked with lipids droplets [69]. However, unlike standalone proteomic or transcriptomic analysis, combined proteomic and transcriptomic research provides additional evidence for identifying critical genes and pathways [67].

Different genetic approaches have enhanced the generation titers, efficiencies, and economic productivity of fatty acids and carotenoids in *R. toruloides*. In *R. toruloides*, molecular genetic efforts were made to enhance the quality of fatty acids synthesis with complete genome sequencing and the development of genomic technologies, as indicated in Table 2. Zhang and colleagues over-expressed acetyl-CoA carboxylase (ACC1) and diacylglycerol acyltransferase genes for enhanced fatty acids accumulation by 1.95 × (16 g/L of lipid content from sugars in shake flask culture) in *R. toruloides* [70]. Employing glucose in fed-batch culture, the same research team changed the microorganism by inducing the release of stearoyl-CoA desaturase (SCD) and discovered a coefficient of 1.42 enhancements in lipid concentration.

Challenges for Downstream Processing of Triglycerides Accumulated by *R. toruloides*

Extraction of Lipids

Although oleaginous microbes seem attractive for the fact that 20 to 80% of dry weight is lipids, but there are a number of challenges leading to high cost of production. One of the major challenges during extraction of lipids arises due to large quantity of liquid broth. The problem is due to complicated protocols which are mostly focused on dry biomass. The different solvents are used for passing through the cell membrane of yeast, but the presence of liquid culture hinders solubility problems. Furthermore, traditional method of drying microbial biomass using freeze drying or oven drying makes energy intensive and costly. Removal of moisture using harvesting and dewatering techniques like centrifugation require lot of energy but can reduce moisture content up to 90% [75].

One of the research groups in 2022 developed a novel strategy for extraction of lipids from *R. toruloids* biomass. The protocol include use of either hexane or sunflower oils solvents leading to elimination of harvesting techniques to disrupt yeast cells. The cells were disrupted using high pressure homogenization (HPH) and 10% sunflower oil or hexane was added followed by centrifugation. After overnight mixing at room temperature, the hexane or oil mixture was separated using separating funnel. This method was easy, inexpensive, and environmentally friendly. The protocol found to be successful as resulted in higher outcomes achieving 55% of total lipids [76].

Transesterification

Following extraction, the triglycerides must undergo a procedure called transesterification, which will decrease their fluidity and turn them into long chains of alkyl esters often categorized as biodiesel [74]. The fatty acid combines with alcohol, like ethanol and methanol, in the vicinity of a catalyst during the transesterification process to generate fatty acid methyl esters and glycerol. The process may be classed as a chemically catalyzed reaction, a non-catalyzed reaction, or an enzyme-catalyzed reaction according to the method of catalysis. Heterogeneous and homogeneous reactions are subcategories of chemically

Table 2 Genetic engineered *R. toruloides* and its respective outcomes

S. no	Strain	Gene manipulated/inserted	Yield/production	Ref
1	*R. toruloides* IFO0880	Acetyl-CoA carboxylase (*ACC1)* and Diacylglycerol acyltransferase (*DGA1)*	Metabolic engineered strain of R. toruloides for the overexpression of *ACCI* and *DGA1* genes resulted in 16.4 g/L and 9.5 g/L of FA from 70 g/L glucose and xylose respectively	[71, 72]
2	*R. toruloides*	Elongase-1 (*ELO1*) and Delta-12 fatty acid desaturase (*FAD2*)	Deletion of *FAD2* and overexpression of *ELO1* genes resulted in increase in oleic content up to 23%	[71]
3	*R. toruloides* NP11	Delta-12 fatty acid desaturase (*FAD2*)	Overexpression of *FAD2* increased the accumulation of linolenic acid by 5 times and quantitatively reached to 1.3 g/L	[8]
4	*R. toruloides* CECT 13085	3-ketoacyl-CoA synthases (*KCS*)	Heterologous expression of *KCS* compelled the strain to produce very long fatty acids (VLFAs) such as erucic acid (5.8 g/L) and nervonic acid (7.9 g/L)	[73]
5	*R. toruloides*	Aldehyde dehydrogenase (*ALD1*)	Inactivation of *ALD1* lead to 1.2 times production of Linolenic acid and 49% increase in fatty acid accumulation	[8]
6	*R. toruloides* CECT 13085	Fatty acyl-CoA reductase (*FAC*)	Overexpression of *FAC* resulted in higher production of C16-C18 fatty alcohols, quantitatively up to 8 g/L	[71]
7	*R. toruloides* IFO0880	Malic enzyme (ME)	Increased expression of *ME* genes resulted in higher LPD production to 89.4 g/L	[8, 71]
8	*R. toruloides* IFO0880	Stearoyl-CoA desaturase (*SCD*)	Reported to increase the LPD titer by a factor of 1.2 from glucose carbon source in fed-batch growth	[72]
9	*R. toruloides* IFO0880	Bisabolene synthase (*BIS*)	Optimized synthesis and insertion of *BIS* genes resulted in production of 680 mg/L of Bisabolene	[71]
10	*R. toruloides* NP11	Phosphotransacetylase (*PTA*)	Metabolic constructed strain was found to enhance the cell mass by 8.5% (12.8 g/L) and LPD content up to 64.4% (1.20 g/L/d) in comparison to parent strain	[74]

mediated reactions. Acidic or basic mediators in solid forms, such as calcium-based metal oxides and sulfated zirconia, are used to facilitate the heterogeneous response [77]. Parallel to this, the homogeneous effect proceeds when an acidic or alkali catalyst is present in a form of liquid. The instances of such catalysts are HCl, H2SO4, NaOH, and KOH [78]. While the alkali-based transesterification approach proceeds swiftly, it is not practical for biomasses with greater free fatty acid levels because of soap formation during this process. In contrast to this, the drawbacks of acid-based transesterification include a prolonged incubation period, corrosive character, greater power usage, increased glycerin refining expenses, etc.

During supercritical circumstances, the non-catalyzed transesterification process occurs swiftly with the product may be readily extracted without producing waste. The method's drawbacks include the pricey maximum temp ranging from 250 to 400 °C and pressure between 10 and 30 MPa requirements [79]. The study examined enzyme transesterification and highlighted that the reaction occurring under benign circumstances has good selectivity. This enzymatic transesterification solves the issues with chemical-catalyzed and non-catalyzed processes [80]. Shimada et al. (2002) [81] showed that immobilized lipase from Candida Antarctica converted docosahexaenoic acid into fatty acid methyl eaters at a rate of 98.5%.

Conversion of Fatty Acids to Biofuels

Many commercial operations have been discovered in the oleaginous yeast. Lipids, one of the crucial metabolites from oleaginous yeast, were undertaken for the formation of drop-in-alkanes and biodiesel. Although many substitute forms of renewable energy can solve upcoming power generation requirements, organic matter promises an easily achieved, low-cost remedy to a transportation fuel for replacing traditional diesel [82]. This can be achieved by thermal treatment through sugars pyrolysis/ hydrodeoxygenation (HDO) or lipids transesterification to drop-in-alkanes and biodiesel, respectively (Fig. 3) [83]. Hydrotreating or transesterification of oleaginous TAGs results in biofuels with substantially

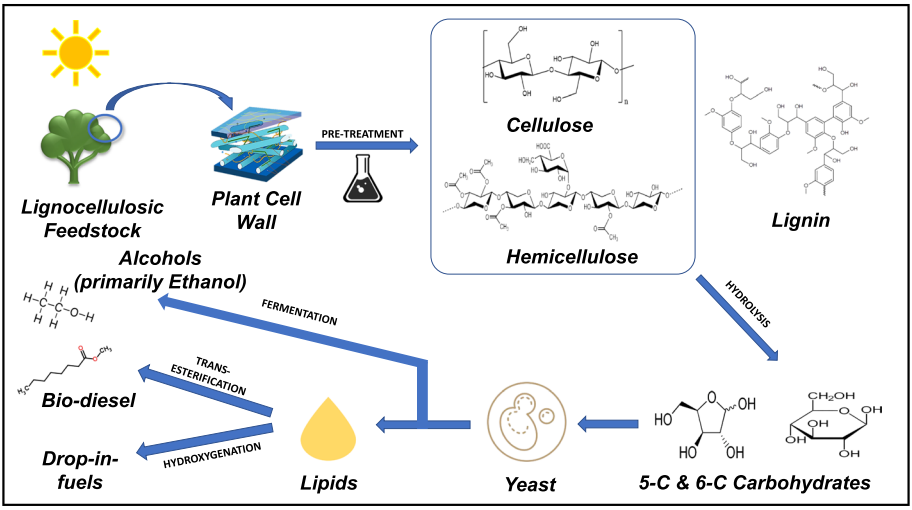

Fig. 3 Schematic representation of biofuels production from lignocellulosic biomass using *R. toruloides*

various characteristics. Hydrotreatment of TAGs can follow one of two routes: hydrodeoxygenation (HDO) to accumulate n-alkanes, propane, and water; or hydro-decarboxylation (HDC) to yield one less carbon atom hydrocarbon from the initial triglycerides, resulting in carbon monoxide, carbon dioxide, and propane as by-products [82]. Hydrotreating may break the fatty acid chains to obtain high-grade biofuels. Although this is beneficial for existing petrochemical industries, it demands energy-intensive working temperatures of 250–350 °C and a sustainable hydrogen source which is a major hurdle for localized fuel generation in developing countries. On the other hand, commercial biodiesel is now made by transesterification of C14–C20 TAGs components of fatty acids with C1–C2 alcohols [84, 85] to produce FAMEs, which are then converted into biodiesel. Hence, biodiesel is a potential alternative to conventional petroleum-derived diesel [86]. Nevertheless, fuel purity is strongly reliant on the oil supply, with longer chain length (> 18 carbon) molecules lowering fuel qualities like cloud and pour points. Drop-in oil has high energy density and they have the potential to be used directly as an alternative to diesel, gasoline, and jet fuel such as alkanes. They have advantages over petroleum, i.e., contain no sulfur and polyaromatic hydrocarbon; it does not generate particulate matter and carbon monoxides when burning [87].

Conclusions

The presence of sustainable biomasses like lignocellulosic materials and an enhancement in the utilization of carbon sources generated from this raw material has intensified the investigation into the aggressive metabolization of feedstock from *Rhodosporidium* isolates. Our study consists of several aspects: (i) the metabolism involved for fatty acids accumulation; (ii) optimization of culture parameters and nutrient sources for better growth and derivatives; and (iii) the advancements in genetic engineering to permit the maximum yield of lipid. Regarding *R. toruloides*' applicability, there could be more advancements in the synthesis of carotenoids and triglycerides, mainly via metabolomics, which will be wholly harnessed in the pathways leading to such derivatives. New industrial applicable products will be determined in the coming years, as with the synthesis of new and more practical components not natively formed by *R. toruloides*, such as FAMEs or fatty alcohols. Several oleic-derived chemicals, notably those formed from both the routes (lipids and carotenoid biosynthesis pathways) with specific physiological stasis in the yeast. The *R. toruloides* bioprocesses might be made more commercially viable by yielding several high-value additives. It may be envisioned as an industrialized yeast with significant potential in the production of goods and biofuels in the coming years, with the aid of bioengineering and biotechnological engineering, which might set the stage for a worldwide green economy.

Author Contribution RK did the conceptualization for this manuscript. Writing and review literature was done by SS, AG. The final editing was done by RK and RR. All authors read and approved the manuscript.

Declarations

Ethical Approval This article does not contain any studies with human participants or animals performed by any of the authors.

Conflict of Interest The authors declare no competing interests.

2023 3rd International Conference on Intelligent Technologies (CONIT) | 979-8-3503-3860-7/23/$31.00 ©2023 IEEE | DOI: 10.1109/CONIT59222.2023.10205688

***Abstract*— In this work three different techniques for harmonic current compensation and extraction utilizing a VSC (voltage source converter) in a 3-phase, three-wire distribution system are described. The stationary load current components were calculated by Synchronous Reference Frame Theory (SRFT), which has its foundation on the transformations of load currents proposed by Clarke and Park. A Notch Filter is a band reject (band stop) filter that allows the majority of frequencies to pass through unaltered while attenuating select frequencies to very low values in a particular range. The basic portion of the contaminated load current is fetched using a notch filter, and VSC provides the appropriate correction. The filter that is self-tuned and also separates the active part of load current is called an adaptive notch filter. These suggested methods are straightforward and can quickly identify and reduce harmonic current using shunt compensation. We have used MATLAB Simulink to evaluate, analyze, compare and simulate the techniques.**

Keywords*— Notch Filter; Adaptive Notch; SRFT; Fundamental Current; THD; DSTATCOM.

I. INTRODUCTION

Power quality, also known as 'power quality health' is the process of estimation by which we get to know how steady and consistent the electrical system is. Only by diagnosing and solving power quality issues can help a power distribution organization save costs by improving energy use and preventing further equipment damage. Power quality (PQ) issues affecting electrical power distribution systems include inadequate power factor, unbalanced loads, harmonics, voltage distortion, etc. In power distribution systems, nonlinear loads with power electronics components, such as lighting loads (LED, CFL), VFD that is Variable Frequency Drives and SMPS which are Switch Mode Power Supplies make a significant contribution. Higher PQ issues such as the introduction of harmonics into the voltage and current etc. result from this. It is crucial to identify solutions to address power quality issues since their continuing existence degrades the standard of power at the consumer level. Primary effects of poor quality of power distribution consists swells and dips in the voltage levels, harmonic introduction, voltage and current unbalancing, flickering, etc. Conventionally, capacitors, reactors, capacitor banks, tap changing transformers are installed to tackle and improve PQ issues in distribution systems. Due to slow compensation and lack of active load compensation of these methods, new power devices are being designed and developed actively. One such technology, the Shunt Active Power Filter (SAPF), which combines a DC Link Capacitor and a Voltage Source Converter (VSC), seeks to reduce a number of PQ issues. The two most widespread and often used VSC variants are the three leg VSC for three-phase three wire (TPTW) and the four leg VSC for three-phase four wire (TPFW). Conventional control algorithm SRFT (Synchronous Reference Frame Theory) and two not so conventional Notch Filter and Adaptive Notch Filtering distribution systems have been simulated, developed and analyzed in this work. For power systems to operate safely and reliably, mitigation of these PQ problems is necessary and a lot of literature is published and is being published presenting various techniques for PQ problem mitigation. The administration and operation of modern power systems have benefited greatly from SAPF. The most current research initiatives and solutions strive to design a suitable compensator for quick and efficient compensation. Before implementing hardware, system design involves mathematical modelling and analysis. In their respective papers, the reasons for voltage sags in industrial plants are discussed by Mark F. McGranaghan et al [1], emphasizing that system faults are the main cause of voltage sags. P. Wang et al. [2] focuses on the investigation of voltage sags and the accompanying phase angle jump. Modelling and performance analysis of a shunt compensated system was demonstrated by D. Kumar and Rajesh [3] where they considered unbalanced linear and nonlinear loads.

For optimal performance of shunt compensation filters, the control algorithms are key factors. It is commonly understood that the controller's capabilities and speed determine how well the SAPF unit function when faced with an unpredictable load. and speed to provide reference current for compensation. The converter's insulated gate bipolar transistors (IGBTs) receive PWM pulses from the control algorithm via a digital method. Numerous control methods have been published in the literature to accomplish this. These tend to be split into time-domain algorithms and frequency-domain algorithms.

D-Q reference frame theory [4], Instantaneous Reactive Power Theory (IRPT) [5], back propagation algorithm [6], etc. are some of the well-known algorithms. P. Chittora, A. Singh and M. Singh [7] presents a notch filtering technique of harmonic current extraction and compensation for a TPTW system using a VSC. Simply put, a band stop filter with a notch is one that only lets specific frequencies through. For the extraction of harmonic and reactive current in active power filters, authors in [8] adopted an adaptive notch filtering method. The primary goal of this technology

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:22:35 UTC from IEEE Xplore. Restrictions apply.

is to deliver synchronized reactive and harmonic current components for control.

Here, three distinct methods of generating reference current and extracting reactive and harmonic current components are discussed. SRFT, i.e., Synchronous Reference Frame Theory is one of the effective and straightforward ways of delivering reference currents. Notch Filtering is also presented to calculate the load current and voltage's in phase and quadrature components. Further, adaptive notch is also used which can effectively identify and monitor alterations in the observed signal's frequency and isolate the time-varying harmonics. Then, using a PWM current controller, the switching pulses for the 6 IGBTs in the VSC bridge are determined through comparison of the reference currents with the actual currents for 3-ph VSC. We are looking at the VSC that is employed as the DSTATCOM (Distribution Static Compensator) in power factor correction mode. Simulation results are also presented.

II. Description of the Grid System

Figure 1 showcases the structure of the system model. The major elements of the modelled system are voltage supply from grid, three phase three wire (TPTW) VSC acting as SAPF, linear & nonlinear loads. Three phase, 110V line-to-line, 50 Hz grid voltage is supplied. The system consists a R-L nonlinear load connected in parallel with the diode rectifier at last. The supply-compensator-load are linked up at the PCC. The SAPF is represented by a VSC (TPTW configuration) linked with a shunted DC link capacitor. It is also the duty of the DC link capacitor to generate adequate compensatory electrical currents. 6 gate pulses are mandatory for VSC to operate properly.

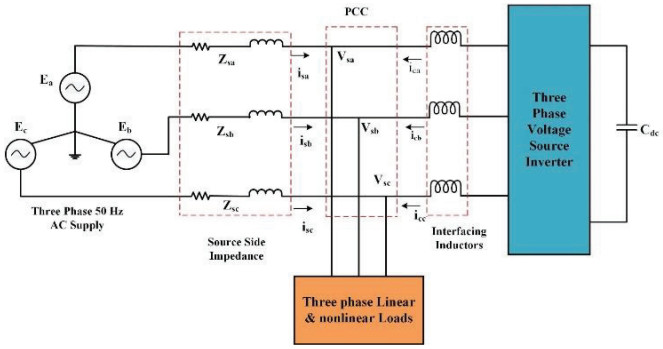

Fig. 1. TPTW system which is being considered.

III. DSTATCOM Control Algorithm

A. SRFT - Synchronous Reference Frame Theory

One simplistic and most common technique of generating reference current is SRFT which is a time domain-based approach. The 3-phase load current in an abc stationary frame is converted into direct and quadrature axis components making it easier for a LPF (low pass filter) to minimize harmonic aspects. SRFT is used to extract fundamental active power component of the load current [9]. For calculating stationary load current components, the aforementioned technique relies on Clarke and Park transformation of load current.

1) Clarke Transformation

$$\begin{bmatrix} i_{L\alpha} \\ i_{L\beta} \end{bmatrix} = \sqrt{\frac{2}{3}} \begin{bmatrix} 1 & -1/2 & -1/2 \\ 0 & \sqrt{3}/2 & -\sqrt{3}/2 \end{bmatrix} \begin{bmatrix} i_{La} \\ i_{Lb} \\ i_{Lc} \end{bmatrix} \quad (1)$$

2) Park Transformation

$$\begin{bmatrix} I_{Ld} \\ I_{Lq} \end{bmatrix} = \sqrt{\frac{2}{3}} \begin{bmatrix} Cos\,\theta & Sin\,\theta \\ -Sin\,\theta & Cos\,\theta \end{bmatrix} \begin{bmatrix} i_{L\alpha} \\ i_{L\beta} \end{bmatrix} \quad (2)$$

SRFT control block diagram is depicted in the figure 2. The process of converting AC quantities (abc) into DC quantities (dq) done in 2 steps: first involves Clarke's transformation shown in equation 1 and second involves Park transformation as given in eq 2. I_{Ld} and I_{Lq} are provided by the above transformations and I_{Ld} component is passed into an LPF.

The PI controller gives the source current's loss component (I_{loss}) which when added to the load current (which is DC after abc to dq0 transformation) gives the dq frame reference current (I_{effd}). The PI controller is expressed in the below equation:

$$G(s) = K_p + K_i/s$$

here K_p = proportional gain constant, K_i = integral gain constant.

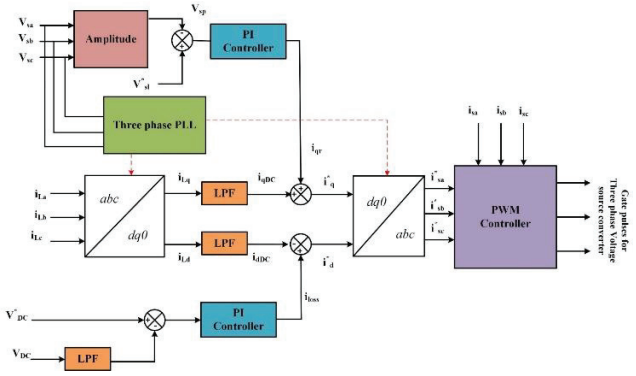

Fig. 2. SRFT Control Algorithm

The AC quantities are obtained back by applying Reverse Clarke's and Park's conversions shown in equations 3 and 4 respectively.

$$\begin{bmatrix} i^*_{s\alpha} \\ i^*_{s\beta} \end{bmatrix} = \sqrt{\frac{2}{3}} \begin{bmatrix} Cos\,\theta & -Sin\,\theta \\ Sin\,\theta & Cos\,\theta \end{bmatrix} \begin{bmatrix} I_{effd} \\ 0 \end{bmatrix} \quad (3)$$

$$\begin{bmatrix} i^*_{sa} \\ i^*_{sb} \\ i^*_{sc} \end{bmatrix} = \sqrt{\frac{2}{3}} \begin{bmatrix} 1 & 0 \\ -1/2 & \sqrt{3}/2 \\ -1/2 & -\sqrt{3}/2 \end{bmatrix} \begin{bmatrix} i^*_{s\alpha} \\ i^*_{s\beta} \end{bmatrix} \quad (4)$$

B. Notch Filter Based Control Technique

After tuning itself to a certain frequency, the Notch Filter determines the value of the tuned frequency constituent. It at best permits one frequency portion signal to pass and inhibits any other unwanted additional frequencies. This NF is used to fetch the supply system's fundamental frequency (50 Hz) component, which is then modulated to improve PQ in the 3 phase 3 wire TPTW distribution with linear as well as nonlinear loads.

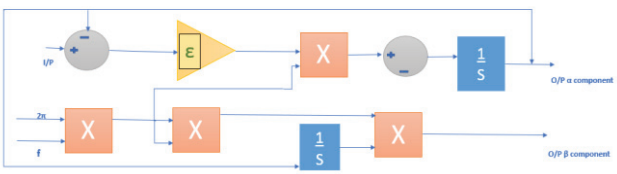

Fig. 3. Notch Filter block diagram

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:22:35 UTC from IEEE Xplore. Restrictions apply.

Figure 3 depicts a block depiction diagram of notch filter algorithm. It is used to figure out signal's in phase (α) & quadrature phase (β) components. The transfer function is expressed as

$$G(s,\emptyset) = \frac{s^2 + \emptyset^2}{s^2 + 2s\varepsilon\emptyset + \emptyset^2} \quad (4)$$

Here, ε = damping constant and $\emptyset$ = phase angle. For 50Hz system, phase angle $\emptyset = 2\pi f => 2 \text{ x } \pi \text{ x } 50 => 314\ rad/s$. Given below are the expressions involving the relationship between settling time (Ts), damping constant (ε) and bandwidth ($\Delta\omega$):

$$\Delta\omega = 2 * \omega_0 * \varepsilon \quad (5)$$

$$Ts = -\frac{ln(\vartheta)}{\varepsilon * \omega_n} \quad (6)$$

Here, ϑ = tolerance fraction 2%, ω_0 = fundamental frequency, ω_n = natural frequency of oscillation. From eq 5 and 6, we can see that whereas the settling time is inversely correlated with the damping constant, the bandwidth is directly correlated with it. Thus, if we decrease value of damping constant, bandwidth also decreases which we want as it leads to high quality factor but we see an increase in the settling time which we don't want. Thus, keeping both the possibilities in mind we have chosen ε to be 0.45.

The Simulink model in figure 4 shows the production of gate pulses for VSC. The fundamental component of load current 'I_{Laest}', 'I_{Lbest}', 'I_{Lcest}' for phase a-b-c respectively obtained using notch filtering are averaged to obtain I_{avg} . This I_{avg} is helpful to measure the value of the referencing currents explained later.

The losses happening inside VSC are represented by the PI controller's output (i_{dc}). If the supply supplies the in-phase load current and covers the expense of losses, then the weight update eq is given by,

$$w_{pt} = i_{dc} + w_{pavg} \quad (7)$$

where w_{pavg} = weight avg of 3-ph load current.

The weight gained (w_{pt}) is multiplied by in phase unit template u_{pa}, u_{pb}, and u_{pc} provided in Eq. 8 to produce three phase supply reference currents.

$$u_{pa} = \frac{v_{ta}}{v_t};\ u_{pb} = \frac{v_{tb}}{v_t};\ u_{pc} = \frac{v_{tc}}{v_t} \quad (8)$$

$$i_{sa}^* = i_{L\alpha} \text{ x } u_{pa},\ i_{sb}^* = i_{L\alpha} \text{ x } u_{pb},\ i_{sc}^* = i_{L\alpha} \text{ x } u_{pc} \quad (9)$$

Thus, the reference currents isa*, isb*, isc* fetched as shown in equation 9.

C. *Adaptive Notch Filter*

Figure 5 portrays the typical implementation of an adaptive notch filter using a block diagram used to detect load current. The transfer function of adaptive notch is described as [10]:

$$T(s,\emptyset) = \frac{s^2 + \theta^2}{s^2 + \zeta\theta + \theta^2} \quad (4)$$

The frequency is considered constant. This filter has ability to control ζ. The computational efforts in the notch is decreased due to constant frequency assumption. In essence, the notch filter separates the essential part from the input signal using two integrators. By altering the damping constant, bandwidth and settling time can be changed.

IV. Results and Discussions

This section covers the steady state waveforms and simulation findings. Fig 6-8 portrays the steady state waveforms of V_{sabc} source voltage, I_{sabc} source current, I_{Labc} load current, I_{invabc} injected current (compensating current from DSTATCOM) and V_{dc} the dc link voltage under simulation of SRFT, Notch and Adaptive Notch control algorithms respectively. A diode rectifier is connected in system to portray a nonlinear load with R = 7.5 Ω resistance, L = 40 * 10^{-3} H inductance. The VSC DC voltage is controlled to 200 V with a PI controller. There is an imbalance on the load side as well. In Fig 9-11, system performance is examined. As shown in the figures are balanced supply currents, sinusoidal in steady and dynamic system operation.

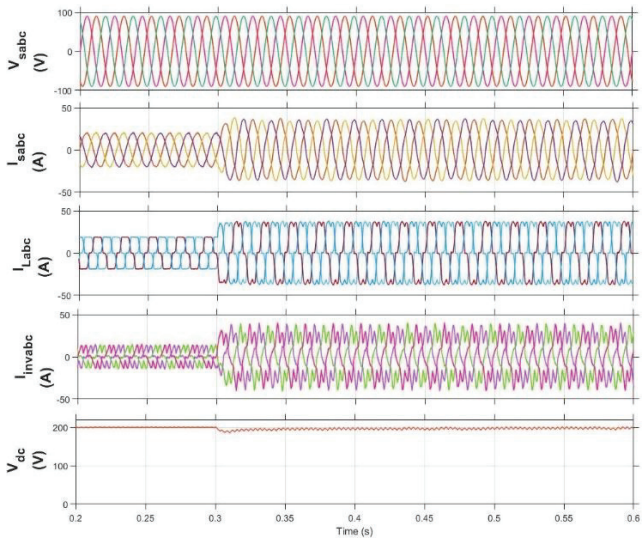

Fig. 7. SRFT Simulation waveform results obtained

TABLE I. PARAMETER OF THE SYSTEM

Source RMS Voltage	110V
Inductance (Source)	0.003H
Inductance (Load)	0.002H
Load Resistance	7.5Ω
Interfacing Inductors	0.002H

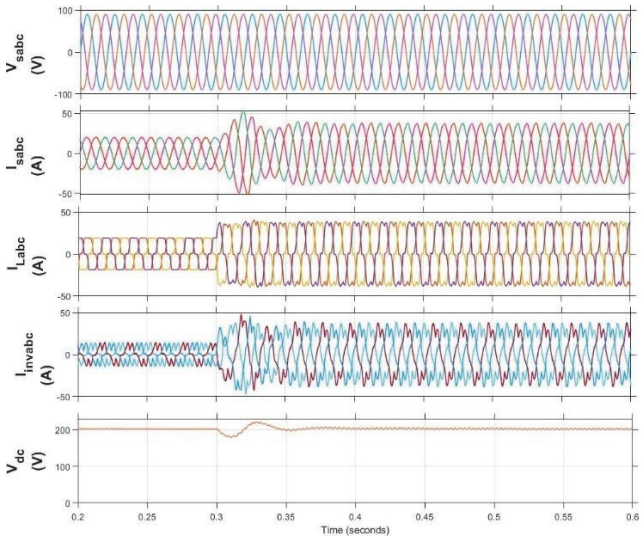

Fig. 8. Notch Filter Simulation waveform results obtained

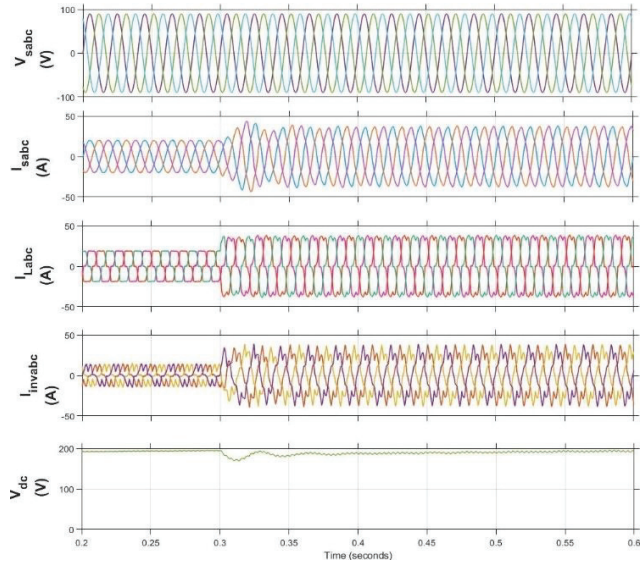

Fig. 9. Adaptive Notch Filter Simulation waveform results obtained

In each of the three control algorithm implementations, the source current can be seen to be almost in phase with the supply voltage. Thus, it can be said that these techniques are employed not only to compensate for the load but also capable of improving the power factor to 1. Also, it can be seen during the instant t = 0.3s in Fig 6-8, as the load is increased, the DC connection voltage briefly drops, but it quickly returns to its constant value of 200V because of the self-regulation provided by the PI controller. The source current increases to meet the demand when the load is increased at 0.3 s, but it preserves its sinusoidal shape and continues to follow the in-phase grid voltage. However, all three of the implementations show prolonged oscillations.

In accordance with IEEE 519 standards, it can be seen from Fig. 10-12 that THD of I_{sabc} source current decreased below the range of 5% with the use of SRFT, NF, and ANF. At t = 0.2 s when the load is increased, the dc link capacitor voltage waveform stabilizes in less than 0.04 seconds displaying minor disruption at t = 0.3s when the load is increased before quickly settling.

The effectiveness of the control algorithms in lowering the THD of I_{sabc} source current is demonstrated in Fig. 10–

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:22:35 UTC from IEEE Xplore. Restrictions apply.

12. As can be seen in the figures 7-9, the source current is essentially sinusoidal. Under SRFT, Notch Filter, and ANF, the THD (Total Harmonic Distortion) of the source current is minimized to 4.92%, 2.38%, and 1.92%, respectively.

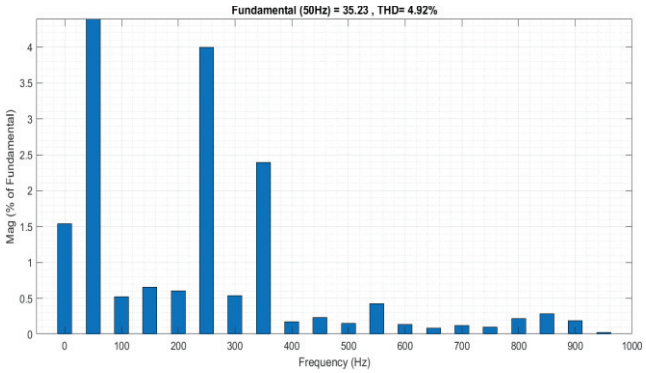

Fig. 10. I_{sabc} Source Current THD obtained by SRFT

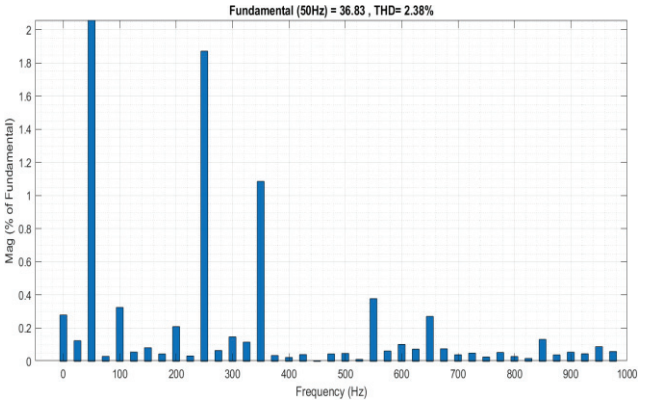

Fig. 11. I_{sabc} Source Current THD obtained by Notch Filter

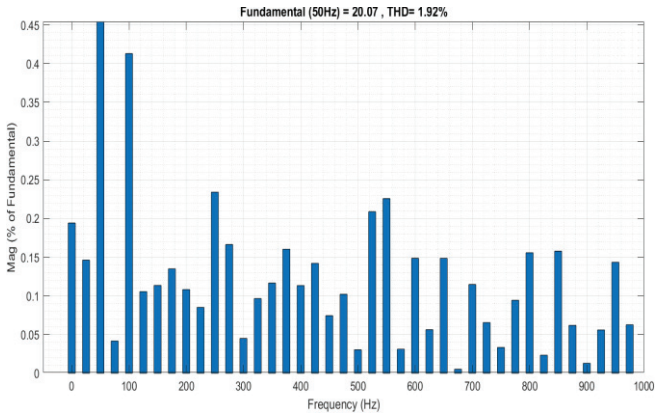

Fig. 12. I_{sabc} Source Current THD obtained by ANF

TABLE I. COMPARISON TABLE OF PERFORMANCE

Control Algorithm	*Oscillations*	*Peak Overshoot (V)*	*Settling Time (s)*	*% THD (I_{sabc})*
SRFT	*High Level Oscillations*	*2.8*	*0.06*	*4.92*
Notch	*Medium Level Oscillations*	*1.13*	*0.05*	*2.38*
ANF	*Negligible Oscillations*	*0.44*	*0.04*	*1.92*

Figure 13 displays a comparative study of the fundamental current components extracted of each of the control algorithms. The settling time for SRFT is 0.06 seconds, for notch filtering it is 0.05 seconds, and for adaptive notch filtering it is 0.04 seconds. The peak overshoot obtained for both SRFT and NF is 2.8V and 1.13V with continuous oscillations in steady state as well as dynamic, and for ANF it's 0.44V with barely perceptible oscillations.

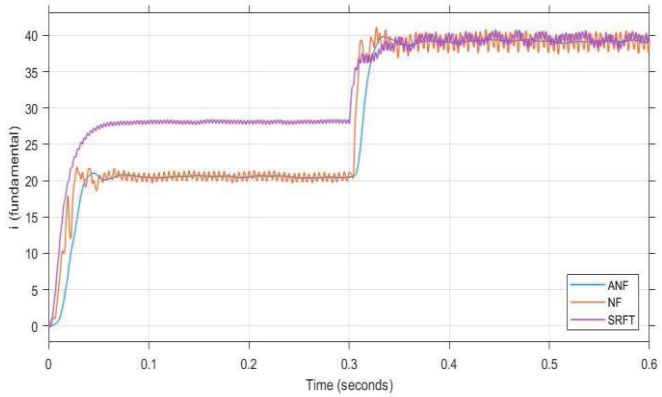

Fig. 13. Fundamental current component extracted using SRFT, NF and ANF

V. CONCLUSIONS

This paper illustrates the comparative analysis of SRFT (Synchronous Reference Frame Theory), NF (Notch Filter) and ANF (Adaptive Notch Filter) control methodology. The algorithms are successfully modeled in Simulink and the resulting observations are presented. Each one's dc side capacitor voltage and fundamental current component are contrasted. Each methodology's overall harmonic distortion is examined. The resulting FFT analysis illustrates that THD of source current reduced in SRFT is found to be 4.92%, 2.38% in NF and 1.92% in ANF.

One of the primary features of the adaptive notch configuration is that minimal THD (1.92%) is achieved even at a relatively low load current magnitude. The adaptable characteristics of the adaptive notch filter additionally allows the system to function better in unpredictable load scenarios. It has ideal tracking capabilities and reacts fast to load changes. Finally, it can be reported that all of the control approaches put into place have been successful in preventing the grid supply's power quality from degrading, and the final THD of I_s source current is way below threshold set by IEEE 519.

***Abstract*—Reversible data hiding (RDH) is an undetectable communication technology that enables restoration of the original cover image after extracting the hidden secret data from the image. It's being widely used in sevaral fields such as military, medical, etc,. Till date, various RDH have been developed to increase the amount of hidden data while maintaining their quality. However, the problem of traditional trade-off between the embedding capacity (EC) and image quality still persists. For this, we propose a new RDH method for color images based on skewed histograms and cross-channel correlation. The skewed histogram is generated with the help of extreme predictors, aids in achieving less distortion by only incorporating pixels from the peak and short tail. Further, the proposed method splits the secret data (or payload) based on each channel's characteristics so that the most smooth channel can be exploited for embedding to further benefit in reducing the caused distortion and increasing the EC. Moreover, embedding in the complex regions of images is done with the help of more comprehensive predictor which also takes into account various possible edges. Thus, the proposed method achieves greater EC with better quality stego-images than the related and existing RDH methods for color images.**

***Index Terms*—RDH, Color image, Skewed Histogram, Edge Detection, Extreme Predictors**

I. Introduction

Reversible data hiding provides an efficient method for storing information in an image, while still allowing the original image to be retrieved when needed [1]. There are various applications for reversible data hiding, including distortion-sensitive uses such as military and medical imaging. In these cases, authentication data is embedded as a watermark, and image enhancement filters can be applied directly to the watermarked image, while the original image remains intact and can be recovered as necessary [2]. Furthermore, data can be extracted from the watermarked image as required, enabling secure and efficient information storage. Reversible data hiding is also applied where the goal is to achieve contrast improvement, reducing file size and obscuring data simultaneously.

In order to achieve reversible data hiding for applications that are sensitive to distortion, various techniques have been developed. Researchers have proposed Reversible data hiding algorithms that utilize lossless image compression and histogram shifting to modify histograms while hiding the data. Modern RDH algorithms frequently use prediction-error expansion (PEE) and histogram shifting methods as their foundation. Histogram shifting is a method for hiding data that includes shifting a group of histogram peaks in a reversible approach utilising a pixel histogram or a modified version of the pixels. There are other variations of this approach, including difference expansion, between a pixel and its nearest neighbour, and pixel-based histogram shifting, which use the most common pixels for data Hiding. The use of histogram shifting in prediction error histograms which is widely known as Prediction error expansion (PEE), as opposed to the use of pixel or pixel difference histograms, is more advanced and requires less adjustment to hide data. Moreover, it has been shown to be effective to embed the algorithm into the smooth portions of the host image and with many passes.

Contrary to its rapid advancement for gray-scale images, the development of RDH (Reversible Data Hiding) for color images has not received enough attention. Even though color images are more frequently used in daily life, little research has been done on RDH methods to process color images [3]. In this paper, a new reversible data hiding method for color images is proposed, which uses a more comprehensive predictor than existing methods and simultaneously exploits cross-channel relation (Edge information from reference color channels and adaptive partitioning) present in color images and skewed histogram shifting with an extended sorting method to efficiently embed payload data into RGB channels.

Fig. 1: Symmetric vs Skewed Histograms [4]

an overview of previous RDH methods based on Prediction Error Expansion (PEE) used for gray-scale images and several existing RDH schemes for color images. In Section III, we describe the implementation of the proposed method. Section IV presents the experimental results and analysis. Finally, Section V provides the conclusion of the paper.

II. Related Work

In this section some of the existing and related RDH schemes for color images are briefly reviewed.

It has been observed that the focus of current RDH research has been mainly on grayscale images [5]–[8], despite the popularity of color images in reality. Only a handful of RDH methods exist for color images. In 2004, Alattar [3] introduced an RDH method based on efficient integer transformation. This method independently embeds the secret data into each color channel and found to be more effective than applying it across the channels. Tang *et al.* [9] used a double-layer embedding technique based on HS to improve capacity, while Qu *et al.* [10] proposed a greedy algorithm for partition parameters. Yang *et al.* [11] proposed an RDH method in color filter array images, which are raw signals from digital cameras, is unsuitable for real color images. Zhou *et al.* [12] modify RGB channels to approximate a rate-distortion model which is modification-independent in order to achieve in-variance and Hou *et al.* [13] maintained gray-scale in-variance.

To enhance the performance of reversible data hiding methods for color images by utilizing inter-channel correlation to exploit redundancy present in color images, two strategies were created [14], [15] where Li *et al.* [14] focused on improving prediction performance while Ou *et al.* [15] focused on payload partition. In the former, edges in the reference channel were used to predict pixels in the current channel, utilizing edge direction in edge areas and rhombus prediction in smooth areas. This approach has drawbacks, though, and can be improved. In the latter, the best candidate with the shortest sub-sequence length was selected after payload sizes were adaptively given to each channel. To further enhance the performance, the proposed method incorporates both strategies, improving prediction performance with edge information and adaptive payload splitting and further reducing distortion using skewed histograms.

III. Proposed Work

As discussed in the previous section, the distortion in gray scale images while data hiding can be further reduced by using skewed prediction error histogram instead of symmetric prediction error histogram to embed payload [5]. The goal is to move pixels in short tail of skewed histogram and keep long tail mostly unchanged as by Kim et al. [4]. While using edge information for prediction and adaptive partitioning of payload for RGB channels, the proposed method can embed data into color images by calculating prediction errors of each channel and embedding data into channel separately and the distortion generated in the watermarked image will be significantly lower than by using symmetric prediction error histogram method. For this, a pair of extreme predictions is used i.e., a high estimate and a low estimate. High estimate are used to make positive histogram shifting (PHS) while low estimate make negative histogram shifting (NHS). It is to be noted that NHS only permits histogram bins to move inside the negative direction while PHS only permits histogram bins to move inside the positive direction. Also, to exploit inter-channel correlation in color images, edge information is used from reference color channel so that the pair of extreme predictions are calculated differently for smooth and edge pixels to improve the prediction performance and increase embedding capacity. Moreover, to further reduce embedding distortion, instead of embedding payload equally into each color channels, a comprehensive search is performed by calculating embedding distortions to find optimal payload partitioning for each color channels.

The discussion on the proposed work is divided into 9 subsections where the first section i.e., III-A discusses about how to find pair of extreme predictions. In section III-B these predictions are made more comprehensive using edge information from reference channels. Sections III-C and III-D show how embedding and extraction are done by PHS and NHS. Section III-E shows how local complexities are going to be calculated which are used for sorting and adaptive partitioning which is discussed in III-F. Section III-G discusses about pre-processing of the image before encoding and lastly we discuss about encoding and decoding algorithms in sections III-H and III-I respectively.

A. Pair of Extreme Predictions

In traditional rhombus prediction method, all of the nearest neighbors of the current pixel are used to find prediction value. In order to perform skewed histogram shifting, neighboring pixels' values (n, w, s, e) are arranged in ascending sequence, as in $x_1 \leq x_2 \leq x_3 \leq x_4$. While Predictor 3 uses the majority of neighbours to forecast the pixel value, Predictor 1 uses the highest and closest neighbouring values. Prediction value is calculated as shown in Table-I. Since double-

TABLE I: Predictor pairs. [.] rounds to the nearest integer.

Predictor No.	1	2	3
$\hat{p}_h$	x_4	$\left[\frac{x_4+x_3}{2}\right]$	$\left[\frac{x_4+x_3+x_2}{3}\right]$
$\hat{p}_l$	x_1	$\left[\frac{x_1+x_2}{2}\right]$	$\left[\frac{x_1+x_2+x_3}{3}\right]$

embedding around 0 is known to be ineffective, this method does not analyse embedding using the same prediction values. This is avoided by using the equation below to guarantee that the pair of prediction numbers is always distinct.

$$\hat{p}_l = \begin{cases} \hat{p}_l - 1 & \text{if } \hat{p}_h = \hat{p}_l \\ \hat{p}_l & \text{otherwise} \end{cases} \tag{1}$$

B. Edge Detection in reference channel

Each color channel's data is hidden sequentially, but during the prediction phase, for some samples in the current channel, the accuracy of the prediction is increased by using edge information from a different channel, known as the reference channel. In this method, horizontal and vertical edges are considered and pixels lying on these edges will be predicted accordingly. Distance between the nearest neighbors and the current pixel is determined by value D_m, which is given by

$$D_m = \left| \sum_{k=1}^{4} \gamma_m^k I_r^k - I_r \right| \tag{2}$$

where $\gamma_m^k = \frac{1}{4},\ \frac{1}{4},\ \frac{1}{4},\ \frac{1}{4}$ are coefficients for $k = 1,\ 2,\ 3,\ 4$ considering 1, 2, 3, 4 to be n, w, s, e neighbors respectively, and I_r^k represent four nearest neighbours of a pixel in the reference channel and I_r represents that pixel in reference channel. Next, the edge direction is calculated(to check if it is a horizontal edge or a vertical edge). This is estimated by calculating D_h and D_v values.

$$D_h = \left| \frac{I_r^w + I_r^e}{2} - I_r \right|, \tag{3}$$

$$D_v = \left| \frac{I_r^n + I_r^s}{2} - I_r \right| \tag{4}$$

Minimum of these values is considered to be D_e, which determines the edge direction.

$$D_e = min\left\{D_h,\ D_v\right\}. \tag{5}$$

$$D_e = \left| \sum_{k=1}^{4} \gamma_e^k I_r^k - I_r \right| \tag{6}$$

where γ_e^k are coefficients which are decided according to edge direction. For example, if it is horizontal direction $\gamma_e^k = 0,\ \frac{1}{2},\ 0,\ \frac{1}{2}$ for $k = 1, 2, 3, 4$.

When examining an image, it can be seen that smooth areas have pixels with values that are fairly similar, leading to small values for D_m and D_e as well as a slight variation between them. A smaller value for D_e but a higher value for D_m results from differences in the neighbouring pixels in edge regions, where pixels are only similar to those that face the same edge direction. By computing $(D_m - D_e)$, it is possible to identify if the reference sample is in an edge region. This technique can also be used to categorize the location of the current sample because the edge distribution of all colour channels is similar. The current sample is considered to be located at or near an image edge if $(D_m - D_e)$ is greater than a predetermined threshold value (τ) and the prediction process should take edge information from another channel into consideration. On the other hand, using edge information wouldn't help much if $(D_m - D_e)$ is less than (τ). The threshold value (τ) is chosen from a predetermined range $(0, 1, ..., 10)$ based on which embedding rate results in the highest PSNR value.

If $(D_m - D_e)$ is greater than the threshold value (τ), it is likely that the current sample is located at an edge area, and the prediction value is calculated by utilizing edge information estimated from the reference channel, which is given by:

$$\hat{p}_h = max\ (2\gamma_e^k I_c^k,\ k \in 1,\ 2,\ 3,\ 4) \tag{7}$$

$$\hat{p}_l = min\ (2\gamma_e^k I_c^k,\ k \in 1,\ 2,\ 3,\ 4) \tag{8}$$

Where γ_e^k represent the coefficients used according to edge direction and I_c^k represents neighbouring pixels values in current channel.

If $(D_m - D_e)$ is smaller than or equal to the threshold value (τ), incorporating edge information is unnecessary, and the prediction value is obtained simply by Predictor 1, 2, 3 as discussed in Section III-A.

C. Embedding

Two time embedding is done in every pixel, once using the high estimate $\hat{p}_h$ and once using the low estimate $\hat{p}_l$. The difference between the pixel value (p) and the high estimate $(\hat{p}_h)$ creates the initial skewed prediction error histogram. In this step, PHS is used to embed one bit in the pixel value (p). (skewed histogram shifting based on the high estimate).

$$p^{'} = \begin{cases} p + m_1 & \text{if } p - \hat{p}_h = 0 \\ p + 1 & \text{if } p - \hat{p}_h > 0 \\ p & \text{otherwise} \end{cases} \tag{9}$$

Only when the prediction error is 0 is one bit embedded. Other pixels' prediction errors are shifted by 1 for them. Using PHS, this is accomplished in the first step. Creating another skewed prediction error histogram in the second step entails calculating the difference between the pixel value $(p^{'})$ and the low estimate $(\hat{p}_l)$. During this step, one bit is embedded in the

(a) Red (b) Green (c) Blue

Fig. 2: Canny Edge Detection performed on different color channels in Airplane image

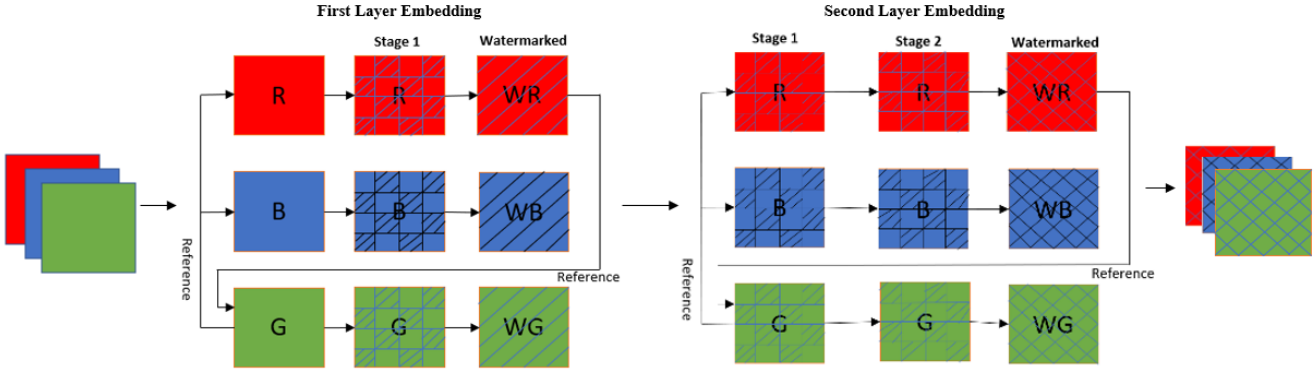

Fig. 3: Schematic Diagram for Double layer embedding with edge information from reference channels

pixel value $(p^{'})$ using NHS (skewed histogram shifting based on the low estimate).

$$p^{''} = \begin{cases} p^{'} - m_2 & \text{if } p^{'} - \hat{p}_l = 0 \\ p^{'} - 1 & \text{if } p^{'} - \hat{p}_l < 0 \\ p^{'} & \text{otherwise} \end{cases} \tag{10}$$

During the second step using NHS, one bit is embedded only when prediction error is zero. For other pixels, their prediction errors are shifted by 1.

D. Extraction

The steps that were taken during embedding are reversed throughout the extraction and recovery phase. The even pixels are restored following the odd pixels, according to this. The odd pixels are sorted first. Also, the payload is extracted from the pixel in the reverse order i.e., extract using NHS (by using $\hat{p}_l$) first then by PHS (by using $\hat{p}_h$). Payload and first watermarked pixel are recovered using NHS as follows:

$$p^{'} = \begin{cases} p^{''} + 1 & \text{if } p^{''} - \hat{p}_l < 0 \\ p^{''} & \text{otherwise} \end{cases} \tag{11}$$

$$m_2 = \begin{cases} 0 & \text{if } p^{''} - \hat{p}_l = 0 \\ 1 & \text{if } p^{''} - \hat{p}_l = 1 \end{cases} \tag{12}$$

Now the original pixel and second payload bit are recovered using PHS as follows:

$$p = \begin{cases} p^{'} - 1 & \text{if } p^{'} - \hat{p}_h > 0 \\ p^{'} & \text{otherwise} \end{cases} \tag{13}$$

$$m_1 = \begin{cases} 0 & \text{if } p^{'} - \hat{p}_h = 0 \\ 1 & \text{if } p^{'} - \hat{p}_h = 1 \end{cases} \tag{14}$$

E. Local Complexity Functions

The "pixel selection" technique is commonly used in the literature to minimize distortion caused by embedding. This involves ranking pixels based on their local complexity values, which reflect their likelihood of being suitable for embedding. The first pixels to be embedded are those with smaller values because they are thought to be smoother and more embed-able. Two techniques are presented in this subsection: the four-pixel version, and an extended version. Four Pixel Version:

$$C\left(p\right) = \frac{(|N-W|+|W-S|+|S-E|+|E-N|+|N-S|+|W-E|)}{6} \tag{15}$$

Extended Version:

$$\widetilde{C}\left(p\right) = \frac{C(p)+C(NW)+C(NE)+C(SW)+C(SE)}{5} \tag{16}$$

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:44:57 UTC from IEEE Xplore. Restrictions apply.

F. Adaptive Partitioning

Splitting the payload into three parts according to the RGB channels is a crucial step to minimize distortion during the embedding process in the RGB channels. In this method, the three channels' payloads are assigned to the designations EC_R, EC_G,and EC_B, respectively, and their corresponding embedding distortions are assigned to the symbols ED_R, ED_G, and ED_B. The payload partition optimisation for a given capacity C entails minimising the total distortion across all three channels, which is expressed as:

$$\begin{cases} \text{minimize } ED_R + ED_G + ED_B \\ \text{subject to } EC_R + EC_G + EC_B = C \end{cases} \tag{17}$$

Embedding distortions and embedding capacity are calculated according to the prediction errors calculation in each channel. Below adaptive partitioning method is discussed for single layer embedding.

Let's assume the total embedding capacity of a channel to be C_{max}. For each capacity $\frac{(n \times C_{max})}{1000}$ where $n = 1, 2, 3, \ldots, \frac{C_{max}}{1000}$ iterate through all pixels of a channel and calculate total sum of embedding distortions of pixels and total sum of embedding capacity of all pixels. A maximum bar (t_h) is then put on the local complexity (15) to find out optimal maximum local complexity $(t_h{}^*)$ value a pixel can have to embed data. The idea is to select optimal $t_h{}^*$ values in each channel to get minimum total distortion. In single channel, for each capacity $\frac{(n \times C_{max})}{1000}$, $t_h{}^*$ the one with minimum embedding distortion is found. Embedding distortion for a pixel p and extreme predictors $\hat{p}_h$ and $\hat{p}_l$ is calculated as follows:

$$ed^i{}_1 = \begin{cases} 0.5 & \text{if } p - \hat{p}_h = 0 \\ 1 & \text{if } p - \hat{p}_h > 0 \\ 0 & \text{otherwise} \end{cases} \tag{18}$$

$$ed^i{}_2 = \begin{cases} 0.5 & \text{if } p - \hat{p}_l = 0 \\ 1 & \text{if } p - \hat{p}_l < 0 \\ 0 & \text{otherwise} \end{cases} \tag{19}$$

Where $ed^i{}_1$and $ed^i{}_2$ are embedding distortions by $\hat{p}_h$ and $\hat{p}_l$ respectively. Embedding capacity for a pixel p and extreme predictors $\hat{p}_h$ and $\hat{p}_l$ is calculated as follows:

$$ec^i{}_1 = \begin{cases} 1 & \text{if } p - \hat{p}_h = 0 \\ 0 & \text{otherwise} \end{cases} \tag{20}$$

$$ec^i{}_2 = \begin{cases} 1 & \text{if } p - \hat{p}_l = 0 \\ 0 & \text{otherwise} \end{cases} \tag{21}$$

Where $ec^i{}_1$ and $ec^i{}_2$ are embedding capacity incremented by $\hat{p}_h$ and $\hat{p}_l$ respectively. These values are calculated for all pixels present in a channel and create vector ED and EC for each channel which contains total embedding distortions and Embedding capacities at each capacity $\frac{(n \times C_{max})}{1000}$. Then iterate through each possible combination of EC_R, EC_G, and EC_B that satisfies the capacity constraint in order to identify the ideal payload partition. Afterwards, find the shortest length of the triple sub-sequence for each combination and select the partition with the minimum length as the optimal solution. The above process is only for single layer embedding, hence it needs to be done for both odd and even halves.

Please note that as this method uses a comprehensive predictor ($\hat{p}_h$ and $\hat{p}_l$ values) which uses edge information also from reference channels, embedding distortion and embedding capacity are calculated in the same manner as the embedding process, i.e., as shown in Fig.3. But as we are finding optimal partition of payload and not embedding data into the channel, the red channel will not be watermarked which is the reference channel for green.So to find accurate adaptive partitioning there is a need to watermark red channel for each capacity and then find optimal partition for only blue and green channels, which in turn increases the algorithm's complexity. Hence for just estimating embedding capacity and distortions, unmodified red channel is used as reference channel for green channel to get an idea of embedding capacity of green channel, and for embedding data modified red channel is used as in Fig. 3.

G. Pre-processing

To avoid issues with underflow and overflow values in the watermarked image, a pre-processing step and location map are necessary. When a pixel is embedded, it might produce a watermarked pixel with values that aren't within the acceptable 0 to 255 range. Performing a pre-processing step on the image prior to embedding can solve this issue by mapping the pixel values of 0 to 1 and 255 to 254. The location map in the payload is subsequently incorporated with the image modification history. The generated location map reads $Ml, ..., Mi, ..., Mn$. The original pixel p_o is pre-processed in the following way to create the pre-processed pixel p:

$$M_i = \begin{cases} 0 & \text{if } p_o = 1 \text{ or } 254 \\ 1 & \text{if } p_o = 0 \text{ or } 255 \end{cases} \tag{22}$$

$$p = \begin{cases} 254 & \text{if } p_o = 255 \\ 1 & \text{if } p_o = 0 \\ p_o & \text{otherwise} \end{cases} \tag{23}$$

To extract the payload embedded in the image, decoder needs auxiliary or side information which will be stored in the LSB's of the image. Auxiliary information to be sent in the LSB's of the image of size $n \times m$ will contain payload length for odd ($t = log_2(n \times m)$ bits) and even ($t = log_2(n \times m)$ bits) halves which will be decided by adaptive partitioning as discussed in section III-F, predictor mode used to embed data (2 bits) and edge threshold value (4 bits) used to determine if a pixel is in edge area or not. Therefore, the total length of auxiliary information will be $2t + 6$ bits.

H. Encoder

According to our proposed method of reversible data hiding in color image, encoding in an image is done as follows:

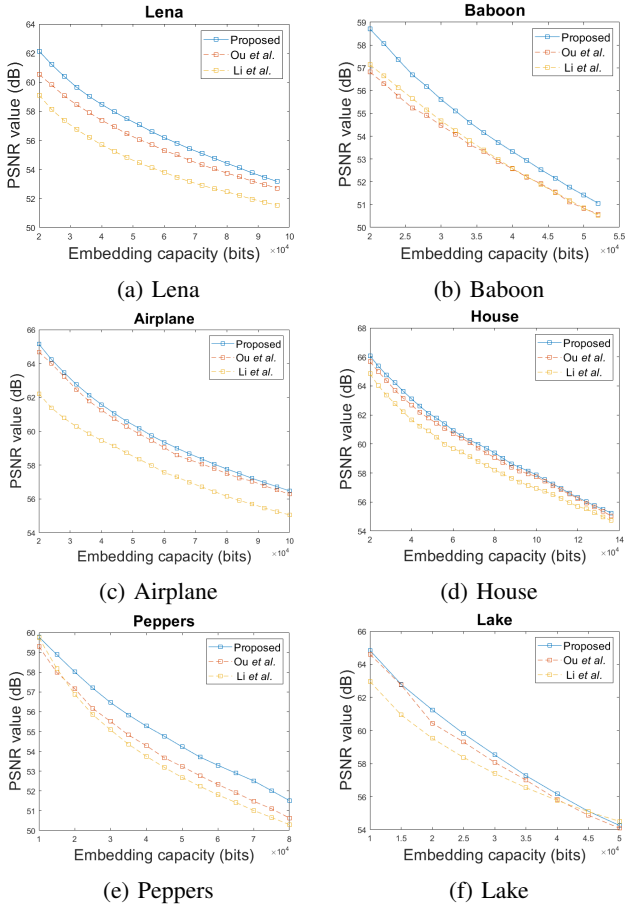
Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:44:57 UTC from IEEE Xplore. Restrictions apply.

1) Decompose the color image of size $n \times m$ pixels into R, G and B channels.
2) Build the location map of each channel and losslessly compress it using arithmetic encoding.
3) The LSBs of $2t + 6$ boundary pixels, length of the compressed location maps and the compressed location map itself are included in the payload.
4) Each channel is represented as a checkerboard where each pixel is classified as even or odd.
5) Find optimal partition of the payload for each channel's even half as discussed in section III-F.
6) Using (16), sort the even pixels.
7) The initial half of the payload is embedded using (9) and (10).
8) Repeat Steps 5-6 for each channel taking reference appropriate reference channels as shown in Fig.3.
9) Repeat Steps 5-8 for embedding in each channel's odd half.
10) The auxiliary information, as discussed in section III-G, is then stored in place of the $2t + 6$ border pixel LSBs of each channel.
11) Combine all marked R, G and B channels to form watermarked image
12) Calculate PSNR by comparing original and watermarked images.
13) Steps 4-14 should be carried out for each predictor mode (1, 2 and 3) and edge threshold (τ).
14) Keep watermarked image with the best PSNR.

I. Decoder

While decoding, we follow reverse of the order we followed in the encoding phase as depicted in Fig.3, i.e., green, blue and then red channel.

1) Watermarked image is decomposed into R, G and B channels.
2) Steps 3-7 will be carried out for each channel in reverse order of encoding (reverse of the order of a single layer embedding shown in fig.-3).
3) The predictor number, payload length for each half and edge threshold are extracted by reading the LSBs of the $2t + 6$ border pixels.
4) Each channel is represented as a checkerboard where each pixel is classified as even or odd.
5) Using (16), sort the odd pixels.
6) To reverse the watermarking process and recover the second payload component in the channel, use (12) and then (13).
7) Using (16), sort the even pixels.
8) To reverse the watermarking process and recover the first component of the payload in the channel, use (12) and then (13).
9) All of the payload components recovered from each channel will be appended to produce complete recovered message
10) For the first $2t + 6$ border pixels, restore the original LSBs for all channels.



(a) Lena (b) Baboon (c) Airplane (d) House (e) Peppers (f) Lake

Fig. 4: Performance Comparison of embedding capacity(bits) with respect to PSNR(dB) on six standard images.

11) Reverse the pre-processing actions carried out during encoding and decompress the location map.
12) Combine all recovered RGB channels to form recovered image which will be same as the original image

IV. Experimental Results

The proposed method has been implemented using Matlab R2020a on a personal computer with an Intel Core i5 CPU, 16GB memory, with Windows 11. The performance of the proposed method was compared with Li *et al.*'s [14] and Ou *et al.*'s [15] methods using six standard 512 x 512 color images from the USC-SIPI database, including Lena, Airplane, Baboon, Lake, Peppers, and House. In addition, 24 color images of sizes 768 x 512 or 512 x 768 pixels from the Kodak image database were used to further evaluate the effectiveness of the proposed method. The performance of the proposed method was evaluated by comparing it with the performances of Li et al.'s [14] and Ou *et al.*'s [15] methods. The results show that the proposed method outperforms Li *et al.*'s [14] and Ou *et al.*'s [15] methods for Lena, Baboon, Peppers, and Airplane images, and had better performance than Ou *et al.*'s [15] method in Lake and House images, as demonstrated in the performance graphs (shown in fig.-4).

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:44:57 UTC from IEEE Xplore. Restrictions apply.

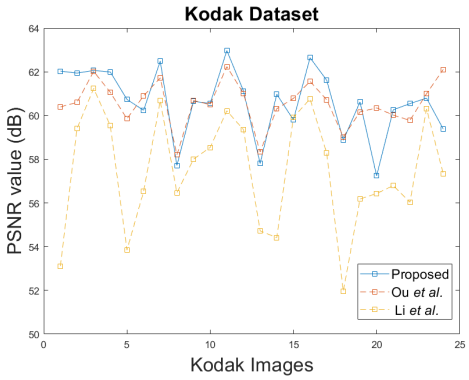


Fig. 5: Performance on Kodak Image Dataset

To further validate the performance of the proposed method, experimental results on the Kodak images are shown in fig.-5. For the comparison, the embedding capacity was set to 50,000 bits for the Kodak Graph. The results show that the proposed method outperforms Li *et al*. [14] and Ou *et al.*'s [15] methods on majority of the test images (i.e., 13 images out of 24 total images) while its performance is comparable to Ou *et al.*'s [15] method for other 3 images. However, the proposed method lacks on the remaining images with respect to Ou *et al.*'s [15] method. This is because of the large number of pixels with values of 0 or 255 which on the other hand means relatively larger size of auxiliary information and location maps.

V. Conclusion

The study introduces a PEE-based RDH method for color images. The method uses edge data from the three RGB channels, to apply an appropriate prediction approach at the current channel. Further, the use of skewed histograms for color image data embedding is also introduced with two extreme predictions. Thus, the proposed method outperformed conventional RDH works for color images that separately embed data in each channel and employ rhombus predictor for non-edge pixels, according to the presented experimental results. In future work, more focus will be on to further improve the security for providing more effective RDH method.

ABSTRACT

Chronic obstructive pulmonary disease (COPD), a complaint described by progressive and inadequately reversible limitation in lungs with systemic inflammation, is largely current in India. There's no remedy available so far it is, thus, imperative to understand the underpinning pathogenesis of the complainant. A set of proteases known as Matrix metalloproteinase (MMPs) are especially involved in the process of alveolar destruction and mucus hypersecretion. There are responsible factors in an inheritable position to control COPD like MMPs and TIMPs (Tissue Inhibitor of Metalloproteinases). MMPs degrade extracellular matrix and lead to the pathogenesis of COPD [1]. TIMPs proteins that help to inhibit the Matrix metalloproteinases. [2]. This review summarizes the implicit part of crucial MMP-2 and TIMP-2 in COPD disease. Though the concept seems promising, limited knowledge about the exact functions of a particular MMP in COPD and the complications of MMP in substrate affinity makes this a grueling task. MMP2 and TIMP2 both are directly or indirectly regulated by oxidative stress and epigenetic mechanism which regulates their expressions. COPD is a seditious response to factors like dust, smoke, etc., and triggers extra-pulmonary goods which cause inflammation. [3]. This review explains the relationship between MMP2 and TIMP2 in COPD patients with oxidative stress, its impact on COPD pathogenesis, and gene expression of TIMP2 and MMP2 with their downstream effects. This also gives some insights into therapeutic interventions for targeting these enzymes. MMP2 and TIMP2 both play a role in the development of COPD and they need to be studied with the utmost focus.

1. INTRODUCTION

Chronic obstructive pulmonary disease (COPD) is a major healthcare burden worldwide, although it manifests at an age generally after 40+ as part of multimorbidity, but there are evidences that there are events at an early stage of life that contribute to impaired lung functions in adults [4]. Lung tissue in COPD cases is characterized by variable and localized nonspecific changes such as habitual inflammation and tissue revamp with seditious cell infiltration, granulation tissue, thickened basement membrane and vascular wall, bronchial gland, and smooth muscle hyperplasia and hypertrophy, as well as fibrosis and epithelial metaplasia. Control lung tissue is characterized by overall low figures of cells immunoreactive for MMP-2 and TIMP-2 at different localizations. This indicates the stable, nonstop, and adaptive "birth" position of these tissue factors at a relative norm [5]. More pronounced findings of these factors in the bronchial and alveolar epithelium, and among alveolar macrophages are associated with the conservation of original lung homeostasis, including impunity and tissue reactivity; still, in hyaline cartilage, Malleability and the implicit compensatory response with the tissue increased. Significantly advanced figures of MMP-2 and TIMP-2 immunoreactive cells in COPD affected lung tissue compared to the control group indicate the part of these factors in tissue remodeling procedures. Small ascendance of TIMP-2 may limit tissue destruction processes [6].

COPD becomes worse when the walls of alveolar tissues start to damage because of its progression into Emphysema and Bronchitis and the capacity diminishes for the production of ECM [7-8]. MMP2 and TIMP2, both are very important for this progression because TIMP2 controls MMP2.

Although COPD is more common in men than women in developed countries, COPD is very prevalent in women because of high smoking rate and indoor air pollution due to biomass fuel in

Pre-Proof

developing countries [9]. High prevalence rate of COPD leads to high mortality and morbidity all over the world includes especially two diseases ischemic heart disease and cerebrovascular disease. However, considering that a third of COPD patients die of ischemic heart disease and a third of patients die of cardio-vascular disease with airflow limitation [10-12]. COPD disease progress includes loss of elasticity of alveoli and parenchymatous tissues leading to a decrease in Forced expiratory volume in 1 sec (FEV1) and subsequently leading to hyperinflation [13]. In addition to external factors, Genetic factors are also responsible for COPD like chronic bronchitis, loss of lung function, lung development, etc. [14, 15]. Since COPD is an inflammatory disease, it also damages DNA by Oxidative stress which leads to disturb equilibrium between tissue repair and cell proliferation [16]. Fig (1) shows that smoking leads to oxidative stress which damages DNA in COPD patients.

Smoking cessation is one kind of treatment that can be done to lower decline in lung function as well as exacerbations [17]. Patients who are addicted to tobacco, it is very hard for them to quit tobacco [18]. Arbitrations like intensive counselling, nicotine replacement therapy, and treatment with Varenicline helps to quit smoking and also much cost effective [19].

There are various genes like MMPs and TIMPs, which affects lung function and TIMPs inhibits MMPs. MMPs (Matrix Metalloproteinases) are a family of Calcium and Zinc dependent proteolytic enzymes degrades extracellular matrix which are derived from macrophages and neutrophils. Normally MMPs helps in remodeling of extracellular matrix, facilitates cell migration and are involved in immune responses by cleaving inactive forms of cytokines and chemokine's [20]. In pathologic conditions, a change in MMP expression and activity occurs which leads to destruction of extracellular matrix or tissue destruction and lung inflammation [21, 22].

TIMPs are Tissue Inhibitor of metalloproteinases which inhibits the activity or expression of MMPs. Basically, there are four TIMPs (TIMP1, TIMP2, TIMP3 and TIMP4) that inhibits active forms of MMPs. Although all are inhibitors of MMPs but they have different affinity for different MMPs as like TIMP2 is a potent inhibitor of MMP2 gene [23]. Distinct findings of tissue factors in bronchial epithelium, connective tissue, and blood vessels prove the involvement and significance of these structures in the morpho-pathogenesis of COPD. In general, COPD morpho-pathogenesis is characterized by increased MMP-2, TIMP-2 still, reduced Hsp-70 and hBD-4 expression that indicates high exertion of patient complex cytokine network, tissue remodeling, and overall tissue antimicrobial protection [24]. In COPD, bronchoscopically determined hypertrophy and habitual bronchitis are associated with the presence of MMP-2 in COPD-affected lung. Epithelial metaplasia and fibrosis in the histological sections are associated with worse functional parameters MMP-2. Also, the finding of granulation tissue is associated with a longer history of smoking and more pronounced tissue damage. Aging changes in the lungs at relative health are individual, indeed different for Individualities in colorful age groups, also, are substantially characterized by a lack of inflammation and variability, indeed a drop, in the number of vulnerable cells. In turn, in the case of COPD, aging is associated with worsening of the course of the complaint, as well as continuity of seditious cytokines and altered revamp with else typical COPD events. Fig 1 showing how free radicals leads to oxidative stress and DNA damage.

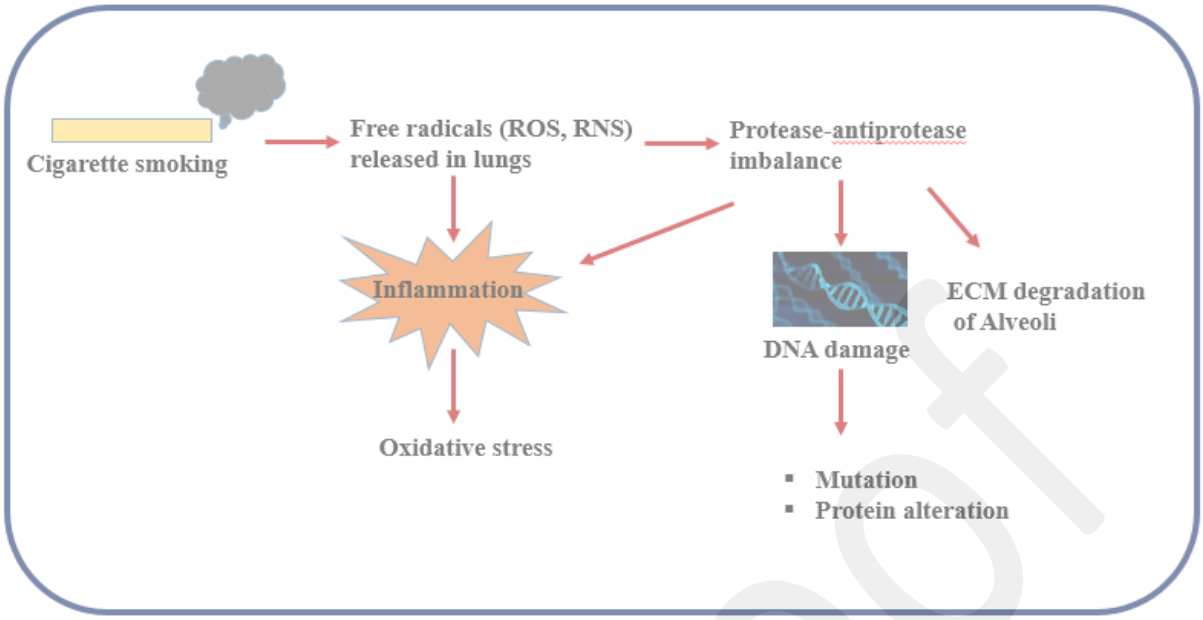

Fig 1: Cigarette smoking releases ROS and RNS in the lungs which creates proteases-antiproteases imbalance and leads to oxidative stress and DNA damage in COPD;ECM- Extracellular matrix, ROS- Reactive Oxygen species, and RNS- Reactive Nitrogen species

2. OXIDATIVE STRESS AND COPD

Oxidative stress is a potentially harmful imbalance in the oxidant–antioxidant balance in favor of the former [25]. This imbalance is because of the reactive molecules which include free radicals and non-radical reactive species. Generally, ROS includes superoxide anion and hydroxyl radical, they have unpaired electrons and their unstable nature triggers them to transfer electrons to other molecules via oxidation that leads to damage or inactivation. Lungs are vulnerable to damage by oxidative stress because of high concentrations of oxygen, increased blood supply, and exposure

Copyright *Chronic Obstructive Pulmonary Diseases: Journal of the COPD Foundation* ©2023
Published online August 3, 2023 https://doi.org/10.15326/jcopdf.2022.0370

to environmental toxins and pathogens. Cigarette and biomass smoke adds to this burden. A single puff of cigarette smoke contains 1 x 10^{15} oxidants molecules [26].

An important link between oxidative stress and the pathogenesis of COPD would come from the demonstration of the response of ROS with target lung motes and the presence of these oxidatively modified motes in increased quantities in the lungs of smokers, particularly those who develop COPD. ROS similar to O2 and OH, generated and released by activated vulnerable and seditious cells that are largely reactive and when generated close to cell membranes oxidize membrane phospholipids (Lipid peroxidation), a process that may continue as a chain response [27].

ROS directly targets proteins, DNA, and lipids which causes lung injury or generates several cellular responses via secondary metabolites or cytokines, or inflammatory molecules [28]. Fig 2 shows the different effects caused by oxidative stress.

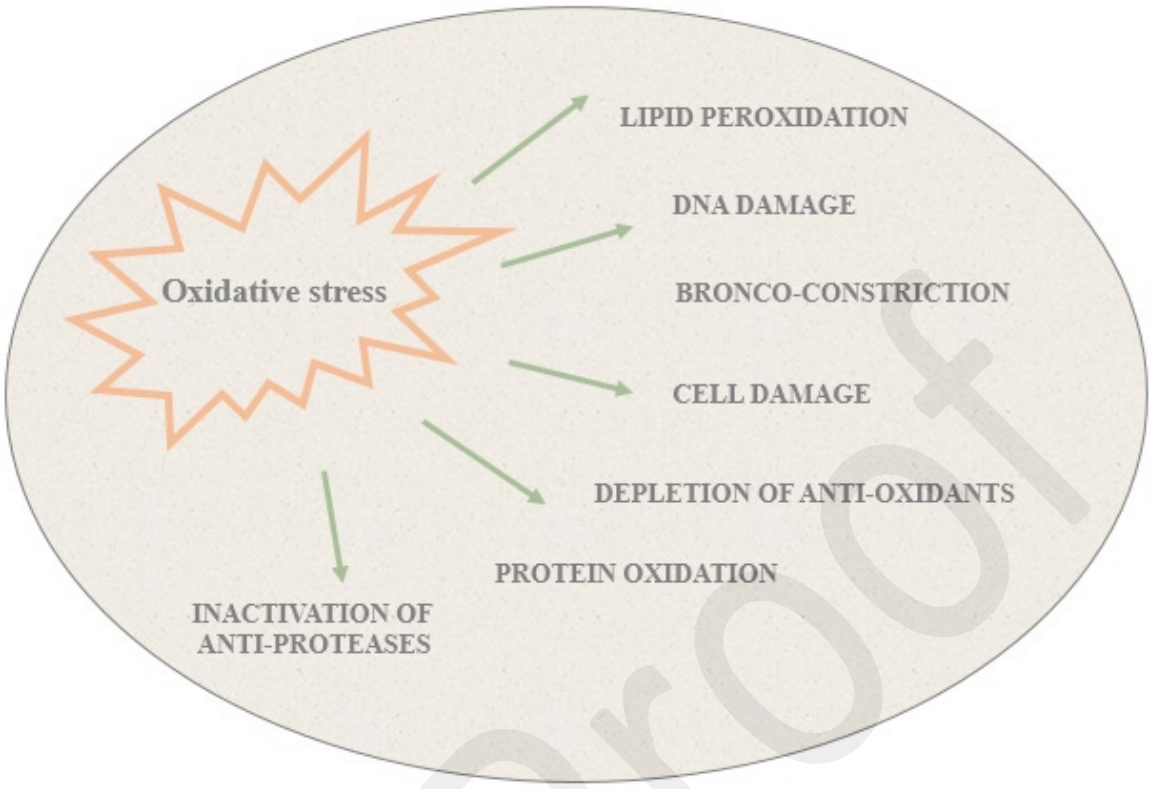

Fig 2: Different effects caused by Oxidative stress in COPD patient

Numerous effects of ROS in airways may be intermediated by the secondary release of seditious lipid intercessors similar to 4 hydroxy-2-nominal 4-(HNE), a footmark of oxidative stress/ lipid peroxidation. 4-HNE, a largely reactive diffusible end product of lipid peroxidation, is known toregulate various cellular events, similar to proliferation, apoptosis, and activation of MAPK signaling pathways [29]. 4-HNE has a high affinity towards cysteine, histidine, and lysine remainders. It forms adducts with proteins, altering their function. It also acts as a chemo-attractant for neutrophils in vitro and in vivo. Recent data indicate increased 4-HNE-modified protein situations in the airway and alveolar epithelial cells, endothelial cells, and neutrophils in subjects with airway inhibition, compared with subjects without airway inhibition [30]. Increased situations

of 4-HNE adducts in the lungs of cases with COPD, later showed that cigarette smoking enhanced the situations of 4-HNE adducts in bronchiolar epithelial and alveolar type II cells in mice [31].

2.1 MDA

Malondialdehyde (MDA) is a reactive organic molecule found among eukaryotes and is made up of three carbon molecules with two aldehyde groups at the C- 1 and C- 3 positions. MDA formation is induced non-enzymatically by ROS and enzymatically by lipoxygenase [32]. However, due to their instability and reactivity in both instances, the measurement of primary lipid hydroperoxide products involves a laborious task. And that is why, the quantification of lipid peroxidation is done by estimating the concentration of secondary oxidation products derived from the primary products, which are mostly aldehydes like MDA [33]. Fig 3 shows the formation of MDA from polyunsaturated fatty acids.

Pre-Proof

Fig-3: Lipid peroxidation from polyunsaturated fatty acids because of the high level of free radicals released in the body

MDA is widely used as a biomarker for lipid peroxidation in oxidative stress in COPD patients, in this a reaction of MDA with Thiobarbituric acid (TBA) makes MDA-TBA conjugate that absorbs light at 532 nm and gives red-pink color [34-36]. TBARS assay is considered as a good indicator of oxidative stress in biological samples [37]. Under acidic conditions (pH = 4) at 95°C, MDA bis-dimethyl acetal yields MDA. MDA and other chemicals (similar to MDA) reacts with two molecules of TBA to generate TBARS (Thio-barbituric acid reactive substances) which gives red-pink color at 532 nm [38, 39]. Generally, MDA level is elevated in COPD patients due to lipid peroxidation that further damages proteins, DNA, etc.

2.2 GLUTATHIONE

Glutathione (GSH) is an important enzyme found in the lungs that protects our body. It is an antioxidant system. But its level is gradually reduce with continuous exposure to smoke in smokers. A high level of GSH is found in the epithelial lining fluid of cigarette smokers [40-41]. Plasma GSH level is determined using plasma, precipitated by Sulfo-salicylic acid in a 1:1 ratio. Then samples were kept at 4°C for one hour, then centrifuged at 3500 rpm for 15 min and after which the supernatant is collected. The mixture that is obtained contains 50 µl of supernatant, 50 µl of PBS (0.1 M, pH 7.4), and 10 µl of 0.4 % DTNB (5, 5′-dithiobis-(2-nitrobenzoic acid**)**. Then the chemical reaction gives yellow color which is measured at 412 nm and expressed in nm/ml of plasma [42].

2.3 SOD

SOD is an antioxidant enzyme that catalyzes the dismutation of superoxide anion to hydrogen peroxide, which is further detoxified into oxygen and water by the catalase enzyme in our body [43]. In COPD patients, the level of SOD is markedly decreased. The superoxide dismutase assay developed by Marklund and Marklund spectrophotometrically determines the SOD level in samples by checking the percent inhibition of auto-oxidation of Pyrogallol at 420 nm. SOD inhibits the auto-oxidation of Pyrogallol at an alkaline pH, with the increase in pH percentage inhibition also increases to a certain extent and SOD activity is thereby determined which is expressed in units per milliliter. Pyrogallol auto-oxidizes rapidly especially in alkaline solution. The reaction is inhibited by SOD to 99% at pH 7.9, indicating the total dependence on the participation of superoxide anion radical in this reaction. At pH 9.1 the reaction is still inhibited to over 90% by

Copyright *Chronic Obstructive Pulmonary Diseases: Journal of the COPD Foundation* ©2023
Published online August 3, 2023 https://doi.org/10.15326/jcopdf.2022.0370

SOD. But at such higher alkalinity superoxide anion radical independent mechanism rapidly becomes dominant [44]. A unit of enzyme is defined as the amount of enzyme which inhibits the reaction by 50% [45].

2.4 Nitric Oxide

Nitric Oxide (NO) is released endogenously in the lungs and acts as a dilator of bronchial and vascular smooth muscles, a neurotransmitter, and an immune response mediator [46]. NO is a marker of airway inflammation, and its level is increased in patients with COPD. Cigarette smoke increases the formation of RNS (Reactive Nitrogen species) and leads to nitration and oxidation of plasma proteins [47]. Nitric oxide is generated from L-arginine and the reaction is catalyzed with the nitric oxide synthase (NOS) enzyme. NOS is normally found in endothelium and neurons, while inducible NOS (iNOS) is primarily occurs in macrophages. NOS catalyzes the conversion of L-arginine into L-citrulline and nitric oxide.

Corradi and colleagues reported that exhaled NO is increased in stable COPD and correlated positively with lung function as assessed by forced expiratory volume in 1 sec (FEV1) [48]. Rutgers and team found that NO metabolism was not affected in stable COPD patients [49]. Another study suggested that there was no difference between COPD and healthy controls and an inverse correlation was found between FEV1 and NO levels in COPD [50]. NO was assayed using Griess reagent method in plasma samples colorimetrically. Griess reagent reacts with nitrite to form pink to a dark pink color after incubation. The absorbance of samples is determined at 540 nm and NO level is expressed in picomole/milligram of protein using $NaNO_2$ as the standard [51]. Therefore, substantiation is accumulating that cigarette bank triggers oxidative stress, leading to inflammation in the lungs of smokers and cases with COPD. Fig 4 showing that cigarette smoke

responsible for releasing free radicals and leads to inflammation in lungs and causes imbalance of MDA, NO, SOD and GSH etc in human body and it ultimately develops in COPD.

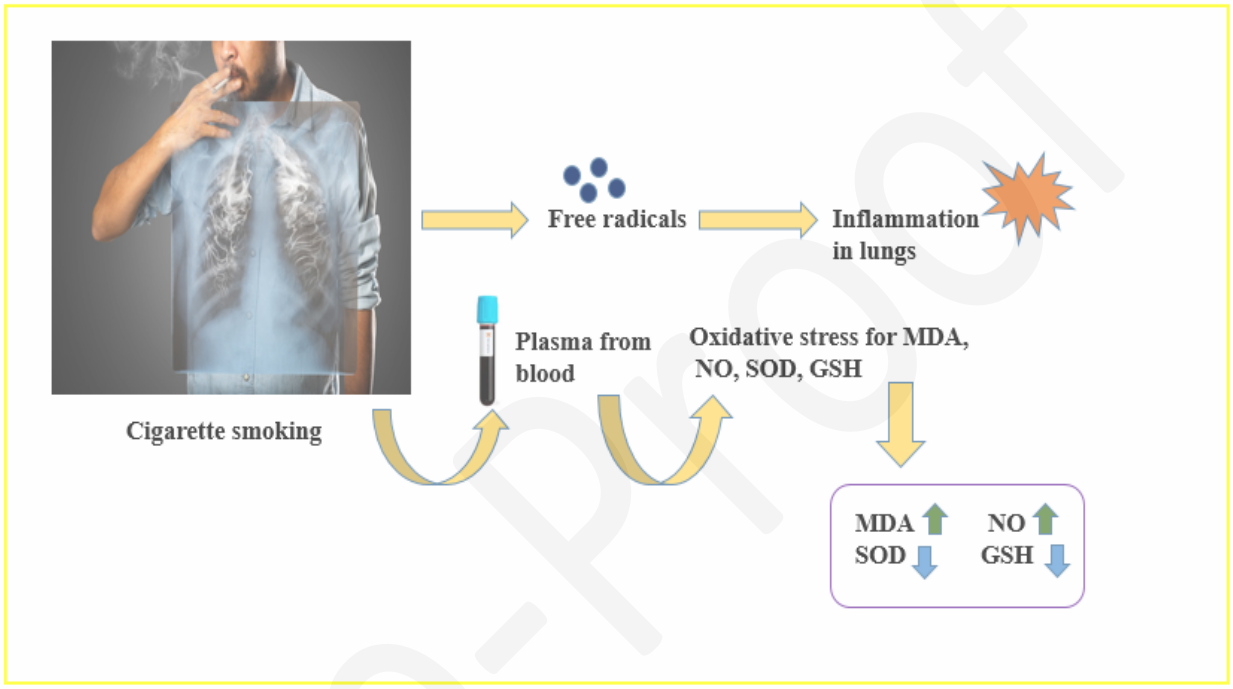

Fig 4: Oxidative stress leads to inflammation and changes the levels of MDA, SOD, GSH and Nitric oxide in human plasma

2.5 Impact of oxidative stress on COPD pathogenesis:

Oxidative stress contributes to the pathogenesis of COPD by inactivation of antiproteases, elevation of bronchial inflammation by redox; activation of neutrophils, macrophages, and fibroblasts; abnormal airway T cell population, etc. [52, 53]. Free radicals like superoxide ($^{\circ}O_2$),

Copyright *Chronic Obstructive Pulmonary Diseases: Journal of the COPD Foundation* ©2023
Published online August 3, 2023 https://doi.org/10.15326/jcopdf.2022.0370

sulfite ions, nitrogen monoxide or nitrogen dioxide radicals, hydroxyl radicals (°OH), etc are responsible for many changes in lung airways or affect different mechanisms which lead to the development of COPD. ROS may remodel ECM and blood vessels, regulates or stimulates the secretion of mucus, inactivate antiproteases, activation of transcription factors in thelungs.[54-57]. Cigarette smoking is also a crucial factor in COPD pathogenesis as the smoke contains high concentration of free radicals that accumulates neutrophils and macrophages into the lungs further leading to COPD exacerbation [58, 59]. Free radicals released from cigarette smoke cause pulmonary dysfunction [60]. Smoking also enhances 4 hydroxy-2-nonenal (4-HNE), a highly reactive diffusible end product of lipid peroxidation, it forms adducts with proteins and alters their functions in COPD [61]. Reactive nitrogen species (RNS) cause an abnormal inflammatory response in COPD by increasing nitrated proteins [62]. The antioxidant capacity of COPD also lowers because of smoking and exacerbations. Glutathione maintains the integrity of the lung airspace epithelial barrier but decreases the level of GSH in the epithelial leads to loss of barrier function and permeability [63, 64].

Many signal transduction or mechanisms are affected by oxidative stress which plays an important role in COPD pathogenesis such as the inactivation of antitrypsin α1-AT by oxid ation of methionine in its active site of the protein, lead to the low level of protein and lung airways are damaged by proteases [65].

3. MMP2 and TIMP2

MMP2 is a type of Gelatinase A, 72 KDa protein released by smooth muscle cells and epithelial cells in the lungs as well as by lymphocytes and macrophages by infiltrating the tissue [66].It helps in vascularization, endometrial menstrual breakdown, and inflammatory activities [67].

Published online August 3, 2023 https://doi.org/10.15326/jcopdf.2022.0370

Pre-Proof

Extracellular matrix (ECM) provides mechanical support to cells and is a complex of different proteins like collagen, laminins, cytokines, fibronectins, and growth factors but MMPs proteolytic activity degrades ECM and also provides signals to embedded cells to react to stimuli [68]. MMP2 also cleaves non-ECM molecules like pro-TNF-α, pro-IL-1β, pro-IL8, MCP-3, etc. and can also activates various MMP Zymogens as pro-MMP-1, pro-MMP-2, pro-MMP-9 and pro-MMP-13 [69-72].

MMP2 contains polymorphic sequences in its promoter site like Sp-1 binding site. Sp-1 binding site determines the basal activity of MMP2 promoter [73]. It has been proved that the polymorphism in the promoter site of MMP2 results in change in expression of MMP2 gene [74].

TIMPs (Tissue inhibitor of Metalloproteinase) is present in four active forms (TIMP1, TIMP2, TIMP3 and TIMP4) which inhibits the activities of MMPs by binding to their active sites [75]. TIMP2 is a potent inhibitor of MMP2. It was also seen that TIMP2 is involved in pulmonary disease characterized by abnormal tissue remodeling of alveolar structure in lungs like emphysema, fibrosis, acute respiratory distress syndrome and lung cancer [76]. TIMP2 promotes cell growth and protects cell from apoptosis. TIMPs also shape and organize appropriate ECM environment and architecture [77, 78]. Fig 5 depicts MMP2-TIMP2 regulation and degradation of ECM by MMP2. .

Fig-5: Regulation of MMP2 by TIMP2 as TIMP2 inhibits MMP2 by phosphorylation but without its binding, MMP2 degrading ECM of lungs;TIMP2- Tissue Inhibitor of Metalloproteinase 2, MMP2- Matrix Metalloproteinase 2

Both Bronchial epithelial cells and airway muscle cells secrete MMP2, and smoke or dust trigger the up-regulation of MMP2 protein in COPD cases [79]. TIMP2 is a potent asset of MMP2 and it binds with its active site after phosphorylation on three different sites by the c-Src kinase enzyme. After phosphorylation, TIMP2 exclusively binds with MMP2 and inhibits its exertion [80].

3.1 Importance of TIMP2 and MMP2 in COPD:

MMP2 is a Gelatinase A enzyme responsible for COPD's pathogenesis. It is released from macrophage and bronchiolar epithelial cells and requires TIMP2 for its activation [81, 22]. MMP2 causes pathological changes in the pulmonary interstitium and lung function of COPD [83] and is

Copyright *Chronic Obstructive Pulmonary Diseases: Journal of the COPD Foundation* ©2023
Published online August 3, 2023 https://doi.org/10.15326/jcopdf.2022.0370

also involved in ECM remodeling and interstitial fibrosis [84]. TIMP2 inhibition by of MMP2, is involved in abnormal ECM accumulation [85, 86]. TIMP2 binds non-covalently to MMP2 with the help of MMP14 and regulates their activities. TIMP2 binds pro-MMP2 molecule (inactive) with MMP14 molecule. The N-terminal of TIMP2 binds with the active site of MMP2 and inactivating it by forming an inhibitory complex. The binding of TIMP2 to MMP14 allows the cleavage of pro-MMP2 by a free MMP14 molecule, as an active MMP2 molecule [87-89]. Loss of TIMP2 leads to a decrease in the activation of pro-MMP2 [90]. TIMP2 is inhibited when it undergoes a mutation or when free radicals are produced. And because it is in charge of regulating MMP2 production, MMP2 will become greatly elevated, begin digesting the ECM in the lungs, and cause COPD. The remodeling of the lung matrix, which is important for the pathogenesis of COPD, is carried out by MMP2 and TIMP2. [91, 92].

4. MMP2 and TIMP2 at Global level:

MMP2 Single nucleotide polymorphisms (SNPs) have been seen among various populations with TIMP2 SNPs worldwide. Different SNPs have been studied all these years.

MMP2 -1306 at promoter site (rs243865) in central Bulgaria has been studied and that included 71 individuals.. This study showed that the genotype but not allele frequency was different between COPD patients and controls. The carriers of T alleles were at higher risk for developing COPD [93]. MMP2 rs243864, rs3918253, and rs11646643 SNPs were associated with a high risk of COPD in the Mexican population [94]. MMP2 rs2285053 and rs243865 SNPs were also found

to be associated with the development of COPD or lung carcinoma in Asians but not the Caucasians population [95].

TIMP2 gene polymorphism at two different positions +853 G/A and -418 G/C showed a down-regulation of TIMP2 in COPD patients than controls in the Japanese population which lead to the up-regulation of MMP2 in patients for degradation of ECM in COPD patients. G/A nucleotide substitution at +853 in exon 3 and G/C substitution at -418 in Sp1 binding site in the Japanese population, showed elevated genotypic and allelic frequency at +853 position and higher allele frequency at -418 position between COPD patients and the control group [96].

But these two SNPs differed in the Egyptian population, +853 G/A showed significant genotype difference in controls and COPD patients but there was no difference between controls and COPD patients in -418 G/C SNP [97]. Table 1 summarizes different SNPs of TIMP2 and MMP2 genes in different regions worldwide studied in COPD patients. MMP2 and TIMP2 were also found to be associated with chronic bronchitis in Tatar children [98].

COPD, a common respiratory complaint, is one of the leading causes of morbidity and mortality

Copyright *Chronic Obstructive Pulmonary Diseases: Journal of the COPD Foundation* ©2023
Published online August 3, 2023 https://doi.org/10.15326/jcopdf.2022.0370

among smokers and some non-smokers [99]. India contributes a significant and raising chance of COPD mortality which is evaluated to exist among the loftiest in the people; crude assessments indicate there are 30 million COPD cases in India [100].

MMP-2, an important modulator of cell proliferation, is buried by both, bronchial epithelial cells and airway smooth muscle cells. Increased vulnerable reactivity for MMP-2 in COPD lungs , substantially in alveolar macrophages and airway epithelial cells was observed [101]. Increased MMP-2 exertion in mice exposed to long-term cigarette banks was also reported. MMP-2 mRNA up-regulation and increased protein in lavage and lung towel was also linked to emphysema convinced by the wood bank [102]. In discrepancy, a study using ray prisoner micro-dissected samples of mortal lung parenchyma has shown that MMP-2 gene expression situations drop with the inflexibility of the patient [103].

However , TIMPs haven't been considered as remedial targets for COPD due to their variation in affinity for different proteases. Though the part of TIMPs in cranking pro-MMPs is well accepted, several studies live that reported the MMP-limited function of TIMPs, similar to inhibition of the mitogenic response of mortal endothelial cells to growth factors and creation of apoptosis [104-106].

5. Impact of oxidative stress on the gene expression or the genetic mutations of TIMP2 and MMP2:

Oxidative stress because of cigarette smoking or biomass fuel affects the genetic makeup of the MMP2 and TIMP2 gene which alters their protein product and is responsible for COPD pathogenesis. According to a study conducted on the Japanese population, the polymorphism of +853 G/A and -418 G/C SNPs in the TIMP2 gene was higher in smokers. Smoking destabilizes

Pre-Proof

the TIMP2 gene and causes its low production [107, 108]. The same polymorphism of +853 SNP was seen in an Egyptian population associated with COPD in smokers [109].

MMP2 is mainly expressed in mesenchymal cells (mainly fibroblasts) during development and tissue regeneration. Due to airway remodeling, there are structural changes with an inflammatory response. There are many promoter polymorphisms in the MMP2 gene that alter their expressions such as -1306 C>T SNP. This gene expression is altered because smoking and oxidative stress lead to inflammation and ECM degradation which affects this gene at the genetic level [110]. Smoking causes the release of various oxidative factors or imbalances oxidant or antioxidant, or proteinase or anti-proteinase enzymes which alters the genetic makeup of the MMP2 or TIMP2 gene. This causes a change in their downstream products at the transcriptional or translational level and changing their functions and leading to the development of COPD.

Most of the MMPs share common cis-elements in their promoters, which are regulated by various cytokines like (IL-1b, TNF-α, TGF-β), growth factors (EGF, VEGF, bFGF), oxidative stress factors, xenobiotics [111, 112]. This stimulus induces signal transduction pathways leading to the activation of transcriptional factors such as NF-κb, STATs, ETS factors, AP-1, etc [111, 113]. In this respect, the naturally occurring DNA sequence changes in the regulatory regions especially promoters of the genes encoding MMPs affect the transcriptional activity and influence the balance between MMPs and TIMPs thus causing development and progression of COPD [114].

6. The impact of oxidants on MMP2 and TIMP2:

Oxidants are free radicals (reactive forms of oxygen and nitrogen species) that are highly unstable, reactive, and tend to make reactions with different molecules, for example, hydroxyl radical OH°, superoxide, hydrogen peroxide, nitric oxide, etc. Nitric oxide (°NO_2), a reactive free radical cause

Pre-Proof

epithelial damage and induce inflammation in the airways which ultimately affects the MMP2 secretion that is upregulated due to the inflammation and downregulates TIMP2 in the airways. Reactive Oxygen Species (ROS) react with thiol groups that preserve MMP latency (115) thus activating MMPs. ROS enhances the expression of MMP2 via xanthine oxidase (116, 117) and via mechanical stretch-induced vascular NADPH oxidase (118). $^{-}$OONO (produced by the reaction of nitric oxide and superoxide) produces posttranslational modifications of the MMP2 structure, thus resulting in an active full-length MMP2 enzyme (119, 120). Radiation produces ROS including $O_2^{\circ-}$ and H_2O_2 activates MMP2 (121). H_2O_2 also activates the Ca^{2+} ATPase activity of MMP2 (as MMP2 is Ca dependent enzyme) in smooth muscle membranes with Vitamin E preventing the increase in activity of MMP2 and Ca^{2+} ATPase activity (122).

ROS generated by xanthine and xanthine oxidase system (XOD) reduces TIMP2 mRNA level, inhibited by catalase scavenging. ROS especially affects the stability of mRNA of MMP2 and TIMP2 (123). There are various other ROS which affects TIMP2 at transcriptional or translational level.

7. Impact and downstream effects of the TIMP2 and MMP2 gene polymorphism:

The expression levels of MMPs are affected by polymorphisms in promoter regions of genes encoding these enzymes. MMP2 is a type IV collagen, and can also degrade elastin molecules. There are three polymorphisms in the promoter region of this gene. Two of them are at -1306 and -735 positions and the third SNP is at -1575 position. The previous two SNPs cause disruption of the Sp1 regulatory element and strikingly decreased promoter activity in macrophages and

Pre-Proof

epithelial cells. The third SNP at -1575 is located immediately 5' to an estrogen receptor (ER) binding site and it functions as an enhancer and leads to increased transcriptional activity and also showed linkage disequilibrium and demonstrated an additive reduction in estrogen-dependent reporter activity [124]. MMP2 -1306TT genotype showed to have excess FEV1 decline and a lower mean of FEV1% compared to the wild-type carriers [125]. The extent of inflammation correlated with the reduction in FEV1 and FEV1/FVC ratio, and probably with the accelerated decline in FEV1 characteristics of COPD [126]. The lower promoter activity of the T allele may lead to increased deposition of connective tissue in the lungs and the development of airflow obstruction, which may be the reason for an increased risk for the development of COPD.

The genetic polymorphism of the TIMP2 gene at +853 G/A (at exon 3 in the TIMP2 gene) and -418 G/C (in the promoter region of TIMP2) SNPs supports the possibility of the development of COPD in different populations. This +853 SNP can down-regulate the TIMP2 activity by changing the secondary structure of the mRNA which inhibits the ribosomal binding and/or decreases the mRNA stability [127 , 128]. MMP2/ TIMP2 system plays an important role in the formation of pulmonary emphysema. So, the mutations of the TIMP2 gene down-regulate its own activity which results in the progression of the breakdown of the lung matrix [129].

Another nucleotide substitution at the -418 position, located in the consensus sequence for the Sp1 binding site in the promoter region. There may be the possibility that this substitution results in the downregulation of the transcriptional activity of the TIMP2 gene and increased activity of MMP2 which results in the development of COPD [130].

8. Mechanism:

Cigarette smoke is responsible for the neutrophil and macrophage influx to the airways in the lungs for NETosis (Neutrophil Extracellular Trap formation) [131-133]. Neutrophil extracellular traps are neutrophils extrude webs of decondensed chromatin with histones, neutrophil elastase, EN-RAGE (Extracellular newly identified receptor for advanced glycation end products binding protein), and myeloperoxidase [134 -136]. NETs were observed in stable and severe COPD patients and correlated with disease severity as well [137 , 138]. EN-RAGE is responsible for the downstream signaling cascade for the pro-inflammatory cytokines in this disorder [139]. Lytic NETosis induces the MAPK/ERK pathway which leads to the production of NADPH and Hydrogen peroxide, it causes the production of Neutrophil Elastase which ultimately leads to the production of ROS and RNS [135]. Leukotriene B4 (LTB4) triggers influx of neutrophils in airways and cause exacerbation in COPD patients and disease progression [140]. Macrophage and neutrophil influx increase in the pulmonary sections.

Early growth response gene product 1 (EGR1) in endothelial cells, binds to the MM14 promoter and it induces its expression. In turn, MMP14 activates MMP2 and upregulates its production [141]. Also, some transcription factors like GATA1 (Globin transcription factor 1), AP1 (activator protein 1), STAT3C (Signal transducer and activator of transcription 3), and NFκB (Nuclear factor kappa B) regulate the expression of MMP2. Tumor necrosis factor alpha (TNFα), Interferon-gamma (IFN-γ), and Interleukin 1β (IL-1β) also triggers the upregulation of MMP2 in lungs [142

Copyright *Chronic Obstructive Pulmonary Diseases: Journal of the COPD Foundation* ©2023
Published online August 3, 2023 https://doi.org/10.15326/jcopdf.2022.0370

]. IL-1β also causes pulmonary inflammation by triggering metalloproteinases in epithelial cells [143]. Also, IL13 is a pro-inflammatory cytokine that causes hyper-expression of mRNA of MMP2 in the lungs [144]. Reactive oxygen species (ROS) and RNS produced by cigarette smoke, and hydrogen peroxide in mitochondria cause tissue damage in the lungs and increase MMP2 gene expression. RNS leads to inflammation by increasing MMPs expression in the lungs [145-147]. So, all these factors causes inflammation in lungs and hyperexpression of MMP2 that primarily causing degradation of ECM of the lungs. Given that, TIMP2 is an inhibitor of MMP2. The expression of MMP2 if found higher than TIMP2, suggests that TIMP2 is inhibited or down-regulated, further indicating the rationale behind the damage of lungs ECM or alveoli or hyper mucous secretion. NETosis also causes MMP2 mutation which is responsible for various changes in gene expression and responsible for causing COPD in a particular population. Environmental factors like air pollution, dust or passive smoke, biomass fuel also causes the production of ROS/RNS in our body and ultimately leads to inflammation. Macrophage releases MIF (Migration inhibitory factor) cytokine which also causes inflammation in the lungs.

Fig-6: Mechanism showing different transcription factors, cytokines, and environmental factors causing damage in lungs or changes in the expression of MMP2. NETosis leads to mutation, inflammation in lungs which indirectly inhibits TIMP2 and upregulates MMP2.

9 Other mechanisms affecting TIMP2 and MMP2 expressions such as epigenetic changes:

Epigenetic changes are stable changes in cell function or environmental behavior that affect the way our gene works but without the change in their genetic sequence. MMP2 activity is regulated at the transcriptional level by methylation, histone modification, non-coding RNA regulation, and chromatin remodeling [148]. There are various factors like smoke, dust, pollution, biomass fuel, etc. which directly or indirectly cause epigenetic changes in various cytokines like TNF-α, IL8, HNE, NO, etc. [149 , 150] at the transcriptional or translational level by acetylation, methylation, or phosphorylation which might be responsible for the changes in MMP2 or TIMP2 expression

but currently there are no such reports that present any particular changes targeting these two enzymes in COPD.

10. Possible potential therapeutic intervention targeting TIMP2 or MMP2 nowadays or in the future:

Over or under-expression, Imbalance between TIMP2 & MMP2 may be corrected by usage of drugs. . Synthetic MMP inhibitors were used in preclinical and clinical studies. MMP inhibitors (Batimastat, Marimastat, Prinomastat, Neovastat, CMT-3, BMS-275291) were found efficacious against MMP-1, 2, 3, 9, 12 in experimental models of lung, breast, and colon cancer with reduced tumor growth by blocking tumor angiogenesis [151].

Simvastatin modulated the expression of MMP2 in lung cancer. It plays a key role in the prevention and treatment of lung cancer in COPD [152]. Compounds 25 and 26 can be considered good therapeutic agents for treating COPD emphysema. Inhibitors targeting specific proteases (MMPs) or protease inhibitors (TIMPs) can be used to treat COPD. These inhibitors can be used in combination with the conventional COPD drugs like ICS, LABA, Tiotropium.. MMP2 or TIMP2 can also be targeted by using specific antibodies or targeted potent inhibitors but there are no evidences that targets specifically these enzymes as yet. Currently, There are not much information present regarding targeting of MMP2 or TIMP2 enzymes in treating COPD.

11. Future prospects:

COPD and protease-antiprotease imbalance is very well known. Proteases degrades lung tissues and leads to emphysema or chronic bronchitis. TIMP2 inhibits MMP2 so that it cannot degrades extracellular matrix of lungs but when it fails because of the oxidative stress or any other genetic

Pre-Proof

reason, it leads to activation of MMP2. Numerous studies reported the relation of MMP2 and TIMP2 in different populations but , it has not been reported in North-Indian population till date. Do you think, Is this the same scenario in Indian population also? Many studies have been performed in the Indian population, but till date nobody correlated MMP2-TIMP2 at genetic level. So, will it give the same result? Also NET traps causing inflammation in lungs of COPD and increases exacerbation also responsible for severity of disease. So, NET traps might be a factor causing this illness. So we can also target to prevent NET traps in lungs or develop a medicine to treat these traps which is not available till date.

12 . DISCUSSION

COPD is an inflammatory disease, it has various responsible factors like dust, smoke, genetic makeup, etc. COPD is directly or indirectly affected by the imbalance created in the human body because of these inflammatory markers and leads to oxidative stress. Oxidative stress is created generally because of the consumption of cigarette by men and biomass fuel by women in villages or local areas where hukkas and chullas are used. In our body, free radicals leads to release some inflammatory molecules like IL8, IL6, TNF-alpha, etc. cytokines which ultimately causes the imbalance between oxidants and anti-oxidants which disturbs body's equilibrium and push our body system towards oxidative stress and responsible for the low level of SOD, GSH, NO and

Pre-Proof

high level of MDA in COPD patients but there are few reports which suggested that they have found high level of SOD and NO in COPD patients [70, 74]. Biomass fuel is also responsible for the COPD in females in villages and small towns in India. Oxidative stress is also a key factor in DNA damage. DNA damage caused by enzymes leads to mutation in DNA and protein change.

This is well known fact that matrix-metalloproteinases degrades the lung epithelial cells until or unless they are inhibited by tissue inhibitors like TIMPs. So, TIMPs and MMPs are closely related with each other. TIMPs inhibits the MMPs enzymes but in diseases like COPD, these MMPs are inhibited by TIMPs as well as the inflammation created in human physiological system, so they are hyper-regulated and starts to eat lung's walls. It degrades extracellular matrix of lungs. Various SNPs were studied in different regions like Asians, Egyptians, etc. and found different results for polymorphism of these SNPs in COPD and control groups. Different SNPs were studied of MMP2 and TIMP2 genes, where -1306 MMP2 SNP was having different genotype in Central Bulgaria population but not different allele frequency but MMP2 rs243864, rs3918253, rs11646643 SNPs and MMP2 rs2285053 and rs243865 were associated with the risk of COPD in Mexican and Asian population respectively. TIMP2 +853 and -418 SNPs studied in Japanese population, showed the low level of TIMP2 protein in COPD patients. Also there was difference in Egyptian population, where +853 SNP in TIMP2 was showing differences in COPD and Control group but not in -418 SNP. Mechanism showing different possible pathways which could be a triggering point in severity of disease or cause of disease. All these factors are very important which we can study or do some experiments for treating COPD.

So, there are various views regarding these genotype or allelic differences in COPD and control groups of different populations all over the world. Many have seen differences but few have not.

We are going to correlate the MMP2 and TIMP2 genetic differences in COPD and control groups of the North Indian population for the very first time. Till date, to the best of our knowledge, it is not reported anywhere.

13. CONCLUSION

COPD is a respiratory disease which is caused by smoke, dust, biomass fuel, cigarette, etc. and also due to oxidative stress which is triggered by the inflammatory molecules. These inflammatory molecules lead to severity of disease in patients. Proteases-antiproteases imbalance also plays a key role in COPD development. MMP2-TIMP2 are related to each other because TIMP2 is an inhibitor of MMP2 and in case of COPD, when TIMP2 is down-regulated, MMP2 starts to digest the extracellular matrix and leads to respiratory dis-comfort in patient. Recapitulating, MMP-2 appears to play an important part in the airway ECM remodeling in COPD. It appears that numerous MMPs are over-regulated in alveolar macrophages, both in humans with emphysema and in cigarette bank-convinced mouse and guinea gormandizer models; and over-expression of some MMPs is significant. Since MMPs retain an active catalytic point and natural *in vivo* impediments, they incontinently become therapeutic targets. A wide range of MMP inhibition may be useful for minimal inhibition of ECM declination. Monoclonal antibodies against MMPs, targeting the substrate of MMPs, can alike be capitalized to clock productive MMP inhibition. Combinatorial therapy , similar to an MMP asset plus a β2 agonist or low-cure steroids could be another strategy for remedial operation of the complaint. Despite rigorous scientific trouble, the discovery of applicable MMP assets for COPD remains a challenge. It is not easy to develop MMP

impediments that are largely picky and specific thereby targeting only applicable MMPs. It's pivotal to understand the successional expression and individual contribution of each MMPs in the initiation and progression of COPD to allow for the development of a picky and specific target. Also, systemic toxin, lack of correlation between the exertion of the asset and MMP situations in the tube, and poor efficacy are some of the issues which need attention. Defensive impunity and towel form should also be a matter of concern while considering MMP inhibitory therapeutic strategy.

DECLARATION OF INTEREST:

***Abstract*—Mechanized detection of sarcasm in textual data is a challenging task in NLP, as it involves recognizing the opposite of what is actually meant. This has become important today since many artificial intelligence tasks require understanding the user and answering appropriately. In this paper, we investigate multiple deep learning models for sarcasm detection on a news headline dataset, including BiLSTM and BERT. For the first time, hybrid BERT models have been used in our study to identify sarcasm in non-social media writings. The results show that the BERT and GBDT strategy combined performs better than all the other strategies listed.**

***Index Terms*—Sarcasm Detection, Natural Language Processing, BERT, Bi-directional LSTM, Support Vector Classifier, Gradient Boosted Decision Tree, Sarcasm,**

I. Introduction

Sarcasm is referred to an expression where the person uses it to say the opposite of what they mean, either to criticize something or for humor.

Unlike tweets which have a context and hence it becomes easier to detect sarcasm in them, sarcastic news headlines which have single line are much more difficult to detect and understand. This becomes an important use case for tools and artificial intelligences which have to summarize news articles for business use-case since sarcastic headlines if understood as non-sarcastic can completely change the meaning of the text. A sarcastic headline could also be used to target a certain, race, or ethnicity. To prevent this one can prevent propagation of such content which can cause major troubles. We attempt to perform this task using a various deep learning models and a combination of such techniques to reduce computation requirements and increase accuracy at the same time. We have attempted to solve their short-comings and improve considerably on the existing work [10].

Detecting Sarcasm is a complicated task for humans let alone for machines due to its dependency on the speaker's perception and knowledge of related matters such as culture, language, surrounding news, etc. Despite its challenges, the automatic detection of sarcasm is very important for the identification of hateful texts and comments that could be inappropriate for some sections of society. Detecting this sarcasm in headlines of news and social media posts becomes more difficult due to lack of context and limited information. To improve upon the previous works of sarcasm detection this study explores various language models such as Bi-LSTM (Bidirectional Long Short Term Memory) and BERT (Bidirectional Encoder Representations from Transformers) to tackle issues faced by the previous work. This study also proposes 2 hybrid architectures to optimize the results with the limited hardware resources utilising a combination of BERT with other techniques like BERT+SVC (Support Vector Classifier) and BERT+GBDT (Gradient Boost Decision Trees) we can achieve decent results on this dataset.

The involved dataset[4], [5], [31] is the News Headlines Dataset for Sarcasm Detection which contains news headlines from two journal websites. This dataset after checking for any bias we train the models and attempt to achieve better accuracy than previous works and with limited resources.

II. Previous Works

The subjectivity in detecting sarcasm in a piece of text makes it a very difficult NLP task. It boils down to a classification task where we attempt to predict whether the input text is sarcastic or not. Here we discuss the main approaches that have addressed this task using all types of datasets.

A. Traditional Approaches

One of the early approaches Liebrecht et.al [8] presents an approach based on a balanced Winnow that performed text classification. This generates results according to weight classes, these weights are then used to discover and segregate the features in a sorted format for a specific class. They explored the experiment in both formats, when the data was balanced and when it was unbalanced. The dataset comprised various tweets where the sarcastic ones contained hashtags The classifier provided a 75% True Positive Rate and a 16% False Positive Rate when working on the balanced dataset. According to the authors, the use of markers such as hashtags in digital communication can be likened to nonverbal expressions, and their inclusion can signal a sarcastic tone.

In 2013, Riloff et al. [10] provided a different method to recognize sarcasm in the text.. The used key-point here was that sarcasm is referring to the opposite of what you mean. Their approach works by identifying the type of contrast in the text between positive and negative sentiments present in the sentence This was accomplished using a cutting-edge

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:19:34 UTC from IEEE Xplore. Restrictions apply.

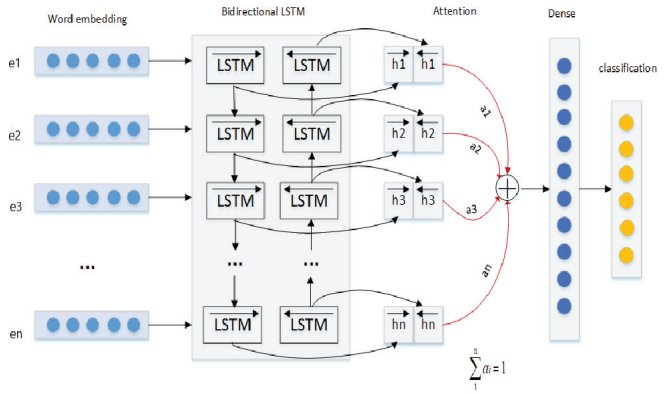

Fig. 1. General Bi-LSTM model architecture Source: retrieved from [32]

bootstrap algorithm that, when present, distinguishes tweets' positive and negative sentiments. After that, positive and negative terms were searched for in the tweets in order to identify sarcasm using bootstrapped lexicons. The F1 score for this approach was 22. The hybrid system's score was increased to 51 by combining the aforementioned with a support vector machine.

Another strategy involved making an effort to classify the comments in the context of the references. This is so that the intended irony can be understood, and to do so, additional information about the tweet was integrated with the Twitter data. The features of this additional information included things like the author's name, details about the user profiles, people who were involved, related news, etc. Bamman et al[10] made this suggestion in 2015, and it had an accuracy rate of 85%.

We attempt to combine the good parts of the above-mentioned approaches to get better accuracy such as hybrid network and using context-free data since it's a more challenging task.

B. Deep Learning Approaches

Amir et al [2] presented a technique to identify sarcasm by using a combination of embeddings with lexical features. These embeddings provides the relation between the users and the content they provide. This reduces the work since it avoids the complicated feature engineering process. Using a Convulational Neural network an accuracy of 87% was achieved on the training set, however the test set accuracy was not very encouraging.

More recent studies have experimented with BERT due to its good results in other Natural Language tasks. Xu et al.(2019)[6] conducted an investigation on different models to understand the effect of context on sarcasm. This is one of the places BERT is utilized. The BERT although a very good model is not suitable for data which has limited context like the news headline dataset. This particular study utilised a LSTM model which provided highest accuracy of 73% for a discussion forum dataset.

Khatri & P (2020)[3] also suggested utilizing machine learning classifiers in conjunction with BERT and GloVe embeddings to identify sarcasm in tweets. In this method, various classifiers like Random Forest, Logistic Regression, Support Vectot Machines, and Naive Bayes were tested. The above study proved embeddings to be a powerful tool for this task, since they convert the text into corresponding vector representations

The main learnings from the previous work are

1. Usage of embeddings increases accuracy
2. Using a Bi-directional model is beneficial since the words ahead often determine the context of the words coming first in the sentence
3. A hybrid architecture is the best solution as all models have some flaws in them.

III. Methodology

A. Baseline Model

NAÏVE BAYES CLASSIFIER: The baseline Classifier here is Naive Bayes Classifier [34] This classifier is used so as to get the probabilistic mean for sarcastic headlines in the text features dataset. It is applied after applying a count vectorizer with the analyzer = word and tf-idf transformer with the smooth_idf = True on the dataset.

This is a popular probabilistic machine-learning approach for classification problems. Based on the Bayes theorem, a mathematical formula expressing the likelihood of an event provided another event has already occurred, is the foundation of the algorithm. Given the values of the features connected to a given data point, the Naive Bayes Classifier uses Bayes' theorem to determine the likelihood that the data point belongs to a specific class. Using the prior work as a guide, we choose the model that provides the best test accuracy and enhance it using this as the baseline model.

Test accuracy 79.5%

Note a nearly 80% accuracy is still decent since detection of sarcasm is sometimes difficult for humans as well let alone of machines, hence this acts as a good starting point upon which we can improve the results.

B. Proposed Models

Here In total 4 models are proposed Namely, Bi-LSTM, BERT, BERT+SVC and BERT+GBDT.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:19:34 UTC from IEEE Xplore. Restrictions apply.

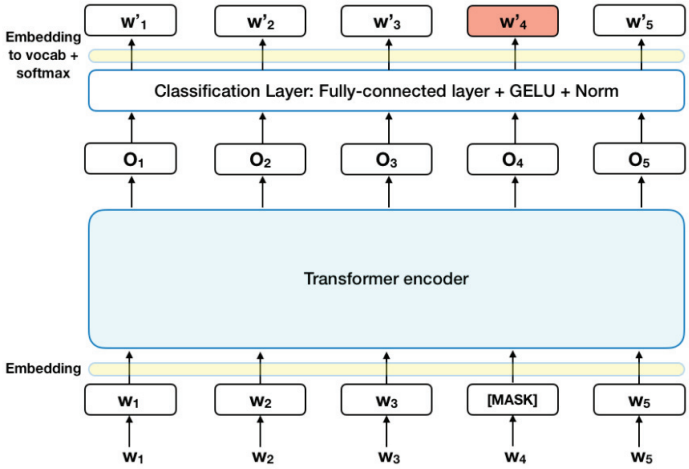

Fig. 2. General BERT model architecture Source: retrieved from [33]

C. Bi-LSTM

Bi-LSTM (Bidirectional Long Short-Term Memory) is a modification on the traditional recurrent neural network that can been used in sarcasm detection. Bi-LSTMs have the ability to depict unordered and long-term dependencies in sequential data, making them well-suited for detecting sarcasm in text.

Advantages of using Bi-LSTM for sarcasm detection include:

1. Capturing long-term dependencies: Bi-LSTMs have a memory cell that can store information for a longer time period. This proves useful in capturing long-term dependencies in sequential data, making them effective for detecting sarcasm that may depend on the previous context.
2. Less computational requirements: Bi-LSTMs require less computational resources compared to models like BERT, making them more accessible for users with limited resources. The model parameters can be seen in Figure 3.

D. BERT

BERT is an acronym for Bidirectional Encoder Representations from Transformers, it is a pre-trained language model based on transformer architecture. It has been trained on a massive amount of text data using a masked language modeling approach, where it learns to predict masked words in a sentence based on its context.

One of the significant advantages of BERT is its ability to capture context and meaning in a sentence, making it particularly useful for natural language processing tasks such as text classification, question answering, and extracting the sentiment or emotion expressed in a piece of text BERT's architecture includes multiple layers of transformers, which enable it to understand the context of a word within a sentence and even across multiple sentences.

The model contains 12 layers of transformer block with a hidden size of 768 the L = 12 and H = 768, The parameters for the same can be found in Figure 4.

```
bert_arch(
  (bert): BertModel(
    (embeddings): BertEmbeddings(
      (word_embeddings): Embedding(30522, 768, padding_idx=0)
      (position_embeddings): Embedding(512, 768)
      (token_type_embeddings): Embedding(2, 768)
      (LayerNorm): LayerNorm((768,), eps=1e-12, elementwise_affine=True)
      (dropout): Dropout(p=0.1, inplace=False)
    )
```

Fig. 4. BERT Model Used in the study

E. BERT+SVC

Bert+SVC is a machine learning technique that combines the power of two different algorithms: BERT and Support Vector Machines (SVC). BERT has achieved great results on a wide range of natural language processing (NLP) tasks. Support Vector Machines, on the other hand, are a powerful class of algorithms for binary and multiclass classification. The BERT model is trained on a substantial volume of textual data and is able to generate high-quality word embeddings that

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:19:34 UTC from IEEE Xplore. Restrictions apply.

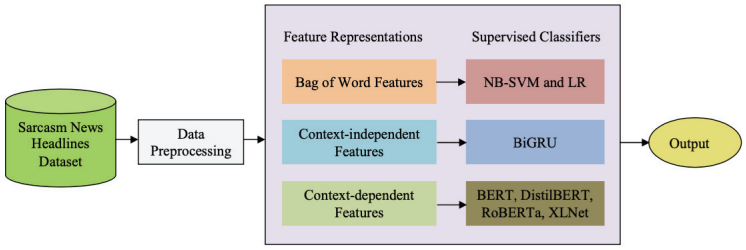

Fig. 5. A general framework for supervised learning models to detect sarcasm. Source: retrieved from [31]

capture the semantic and contextual meaning of words. These embeddings can be used to train a classifier for a specific NLP task, such as sentiment analysis or named entity recognition. However, the BERT model alone may not always be able to capture all of the nuances of a specific task, especially if the training data is limited. This is where SVC comes in. SVC is a type of binary classifier that is trained to maximize the margin between two classes of data points. This means that it is able to identify complex decision boundaries that can accurately classify data points in high-dimensional spaces. For creating text embedding, we have used the Bert model, and for processing images, we have used the SVC model. When combined with the BERT model, the SVC classifier can learn to recognize subtle patterns in the data that may be missed by BERT alone.

F. BERT+GBDT

BERT+GBDT is a machine learning technique that combines the power of BERT and Gradient Boosting Decision Trees (GBDT) for sarcasm detection. The BERT model alone sometimes is unable to capture all the features required to determine whether the sentence is sarcastic or not This is where GBDT comes in. GBDT is a machine learning algorithm that builds an ensemble of decision trees to classify data points. It works by sequentially adding decision trees that correct the errors of the previous trees, resulting in a highly accurate classifier. When combined with the BERT model, the GBDT classifier can learn to recognize subtle patterns in the data that may be missed by BERT alone. Here the sentences are first preprocessed and tokenized using BERT. The GBDT classifier is then inputted or fed with the resulting word embeddings, which learns to distinguish between sarcastic and non-sarcastic sentences. Therefore BERT acts as an interpreter for the Gradient boost method.

IV. Dataset

The dataset of news headlines, benchmarked by the authors, is utilized for sarcasm detection, with two versions available: version 1 and version 2. Version 1 includes a total of 26,709 news headlines, comprising 11,724 sarcastic and 14,985 non-sarcastic headlines. On the other hand, version 2 consists of 28,619 records, with 13,634 sarcastic and 14,985 non-sarcastic headlines, including an additional 1910 headlines from version 1. Due to the larger number of headlines, version 2 is preferred for use and used in this study

A. Properties

This dataset contains 3 columns
1. Headline
2. The link of the news piece
3. 0 or 1 value where 1 means the headline is sarcastic and 0 implies it's not sarcastic
The 3rd column acts as its label for supervised learning The dataset contains 28619 records where 14985 are non-sarcastic while others (i.e. 13634) are sarcastic.

B. Advantages over twitter dataset

1. Since the headlines are composed by professionals, the sentences lack gramatical errors and spelling errors. This increases the chances of better fit with existing embeddings without loss of any important words.
2. The target website involved are specifically made saracastic so there is little chance of mislabeling.
Headlines alone are often context-free and hence easier for the model to understand since some context cannot be understood or known to the machine.
3.. For instance, a sarcastic tweet about a recent fire at new york museum will be very hard to understand for people who are unaware about such an incident.

V. Result and Conclusion

A. Evaluation Metric

As used in most supervised learning algorithms and in the base model the accuracy of the model is determined by the ratio of headlines that are classified correctly to that of total headlines in the data set.

$$Accuracy = \frac{Number\ of\ headlines\ classified\ correctly}{Total\ numbers\ of\ headlines\ in\ the\ set} * 100$$

This accuracy is considered for the test data formed from the 80-20 split pre-processing libraries. This split is the same for all the models. We have used only the test accuracy since some models tend to over-fit on the data producing very high accuracy on the training set which is often a misleading metric to judge the model

TABLE I
COMPARATIVE ANALYSIS

Model	Test Accuracy
XGBOOST CLASSIFIER	**67.5**
LOGISTIC REGRESSION CLASSIFIER	**77.5**
NAIVE BAYES (Baseline)	**79.5**
Bi-LSTM	**87.5**
BERT	**64.74**
BERT + SVC	**85.17**
BERT + GBDT	**91.48**

B. Results achieved

The above-mentioned models were executed in a Google Colab Pro environment using standard libraries such as nltk for pre-processing and embeddings. To feed the textual data was first converted to machine-readable format using word embeddings. After performing standard pre-processing the data was split in an 80-20 form

A comparative analysis among the 4 supervised learning algorithms namely Bi-LSTM, BERT, BERT+SVC, and BERT+GBDT. shows BERT+GBDT achieved the highest test accuracy. The Bi-LSTM Model aids in taking into account the context of previous words from both sides which becomes crucial for sentences whose meaning is determined by the ending words. Here we have used 300d glove embeddings as opposed to the predecessors which utilised 50d or 200d embeddings. Also, we were able to achieve a better results by tweeking few model parameters such as the dropout layer and neurons in the network. The optimum number was achieved through rigourous hit and trial.

The BERT has high GPU requirements when trained by unlocking the layers, this is a major drawback of using BERT for this task due to the high number of entries (nearly 29,000). Based on previous work with BERT and our own results we concluded that BERT is very good in gathering the details and pattern in the data however, it's training for the same was not very practical with the hardware resources at our disposal, we, therefore, utilised the best feature of BERT of pattern recognition and formed a completely new architecture which uses an SVC classifier. We were further able to increase accuracy by combining Gradient boost decision trees with BERT This hybrid architecture gives the best accuracy for the dataset and it also requires less computation time.

The usage of 300d glove embeddings and a Bi-directional model increases the existing accuracy of Bi-LSTM Based on the context-less nature of headlines the proposed models perform considerably well and better than the baseline model The results of each model are summarised in Table 1

***Abstract*—Human Action Recognition is quite popular among researchers and scientists and is considered one of the most active applications in the field of computer vision. It is quite useful in modern era applications like healthcare, surveillance, sports and many more fields. Deep Learning has provided an upliftment to predict human actions in an easiest way possible. This paper proposes a combined CNN & RNN human action recognition model named SDL-Net, which generates skeletal representations using Part Affinity Fields (PAFs) and generates skeletal gait energy images. It also captures sequential patterns to generate sequential data as well. Experiments are conducted on Kinect Activity Recognition Dataset (KARD) and it shows the efficiency and effectiveness by achieving desirable results.**

***Keywords*—Human Action Recognition, Part Affinity Fields, Gait Energy Image, Skeletal Representation**

I. INTRODUCTION

Human Activity Recognition is defined as a challenge that tends to focus on finding out the exact motion or activity of an individual by evaluating the stance of a person's skeletal joints either in two- dimensional or three-dimensional space. Given its critical applications in areas like security, surveillance, robotics, elderly healthcare, human-computer interaction, physical sciences, human object tracking and detection, industrial academia, smart home technology, and human-machine interfaces, the use of computer vision for automatic recognition of human actions is growing in popularity. However, due to various factors, including the similarity between various actions, variations in lighting and viewpoints, temporal changes, cluttered backgrounds, and occlusion of the human body, identifying human activity in an unknown video sequence through human action recognition is a complex and difficult task.

Changes in view, occlusion, rapidity of movement, anthropometry, camera motion, and backdrop clutter are some of the particular issues that arise when interpreting human position in photographs, particularly those taken in social contexts. These difficulties affect the accuracy of human action identification and are made more difficult by the scarcity of data, the need for high computational demands, privacy issues, and edge computing constraints.

The main objective is to create an efficient methodology for recognising and categorising human actions and behaviour in a certain setting.

*Authors with equal contribution

A prevalent technique for detecting human actions involves generating a skeleton or locating the human joints by identifying key points and producing heatmaps. Another method gaining the attention of numerous researchers for detecting human posture is utilizing gait representation and recognition. Gait, the way an individual walks or runs, constitutes a distinctive biometric characteristic that captures intricate details of specific movements and can be employed to identify individuals based on their particular style of body movement and muscle activity during walking. The GAIT energy image (GEI) representation of gait amalgamates data from a single gait cycle into a single image, which results in reduced storage and processing requirements. GEI images of various motions are utilized to concentrate on joint movements and gain profound knowledge regarding them. This approach contextualizes each analysed motion and offers the benefits of lower memory and computation complexity.

With all of the constraints and current trends in mind, this research proposes a revolutionary CNN-based strategy. SDL-Net, the proposed model, focuses on detecting the movement of a single person per image. To improve scene comprehension, it employs an innovative and successful approach for single-person posture estimation to generate skeletal representations of the persons present in the scene. This technique effectively extracts the total context by utilising low-level representations of detection and association. As a result, a greedy parsing strategy can yield high-quality results at a much lower computing cost.

The major contributions of this paper are: i) Proposed a novel human action recognition model called SDL-Net based on the generation of gait energy images after producing skeletal representations. ii) A novel skeletal extraction system is introduced to analyse the video inputs by using part affinity fields (PAFs) and calculate association scores to gain a clear understanding of movements of limbs and joints within the context of the overall activity of the human recognized in the scene. iii) The SDL-Net framework incorporates an innovative gait energy image (GEI) extraction system that generates gait images using skeleton data obtained after extraction. This system meticulously scrutinizes joint movement and considers the context of each analysed motion to enhance the efficacy of our proposed model. iv) The employment of an ensemble method is fused in the SDL-Net architecture to utilize the knowledge obtained from GEI-CNN formation with long-term dependencies. This helps get a boost

2023 International Conference in Advances in Power, Signal, and Information Technology (APSIT) | 979-8-3503-3936-9/23/$31.00 ©2023 IEEE | DOI: 10.1109/APSIT58554.2023.10201657

in the performance of our model with the motion recognised over an interval of time.

The paper is illustrated as follows. Section 2 presents related work on human action recognition algorithms. The methodology of SDL-Net architecture is discussed in detail in section 3. Section 4 describes the experimental setup and results, including the datasets used, classification metrics, and comparison with existing state-of-the-art methods. Section 5 further provides the conclusion and future work that is possible.

II. Related Work

Several machine learning and deep learning algorithms have gained a competitive advantage in human activity identification and pose estimation. In reality, the quantity of computer vision research done in recent years with the goal of comprehending human activities has skyrocketed. A number of improvements have been made to improve the model's performance in recognising human actions.

Kristina Host et al. [1] provides a review of HAR applications in sports, with the primary focus being Computer Vision, employing popular publicly available datasets for this purpose. Ruiqi Sun et al. [2] produces human skeletal heatmaps by building a two-stage human pose estimation model that integrates the enhanced single shot detector (SSD) technique with convolutional pose machines (CPM). Vidhi Jain et al. [3] draws a parallel among the existing Human Action Recognition (HAR) algorithms and attempt to present a heuristic and constructive hybrid deep learning-based system with an accuracy of 94.7%. Chhavi Dhiman et al. [4] provides an innovative Residual Inception Attention Driven CNN (RIAC-Net) Network that visualises the action dynamics in a progressive manner. The entire skeleton is divided into five essential parts: Head to Spine, Left Leg, Right Leg, Left Hand, and Right Hand, with additional research done for action recognition. Abidin Çalışkan et al. [5] have employed the KARD and MSR datasets to visually represent motions by combining their frames sequentially. Subsequently, deep neural network models have been trained on these representations to enhance performance and minimize the time required. On the other hand, Huy-Hieu Pham et al. [6] have utilized a deep ResNet model for recognizing human actions using skeletal data. They have transformed the 3D coordinates into image-based representations to capture the 3D motions from the skeleton sequences. To conduct their experiments and obtain satisfactory outcomes, they employed KARD, MSR Action 3D, and NTU-RGB+D datasets.

The technique that employs computer vision algorithms to identify people based on their physical traits or motion matter for certain activities is referred to as Gait recognition. This is a passive method of gathering biometric data from a distance. The application of a gait recognition system has been one of the other advances. A gait recognition method is presented by Maryam Babaee et al. [7] to solve the problem of occlusion-induced incomplete gait cycles. The effectiveness of the suggested method is demonstrated by the experimental findings on a public gait dataset. Pose Kinematics, a novel feature that depicts the proportion of time spent in each significant stance stage throughout a gait cycle, is introduced by Aditi Roy et al. [8]. The final classification is made using it along with the Pose Energy Picture.

Part Affinity Fields (PAFs) [9] are a very helpful characteristic that are used for both tracking and estimating human pose. The use of PAFs has been emphasised in a number of works that explore feature extraction. To create 3D coordinates for further estimate, Ding Liu et al. [10] propose 3D part affinity fields (3D-PAFs) and pair them with 2D poses. By creating joint and affinity heatmaps, Kevan Yuen et al. [11] present a ConvNet technique for full-body joint estimation. The real-time body position comparison method put out by Chujin Zhou et al. [12] extracts feature maps, detected confidence maps, and PAFs before computing the limb's most optimal connection.

The proposed model SDL-Net is designed according to the recent contributions by different scientists and researchers in the field of human action recognition.

III. Methodology

In the further sections, SDL-Net is described in detail. The workflow of the model is described in Fig. 1. This architecture consists of various steps which include data preprocessing and augmentation, a skeleton generation system, and a gait energy image (GEI) generation system.

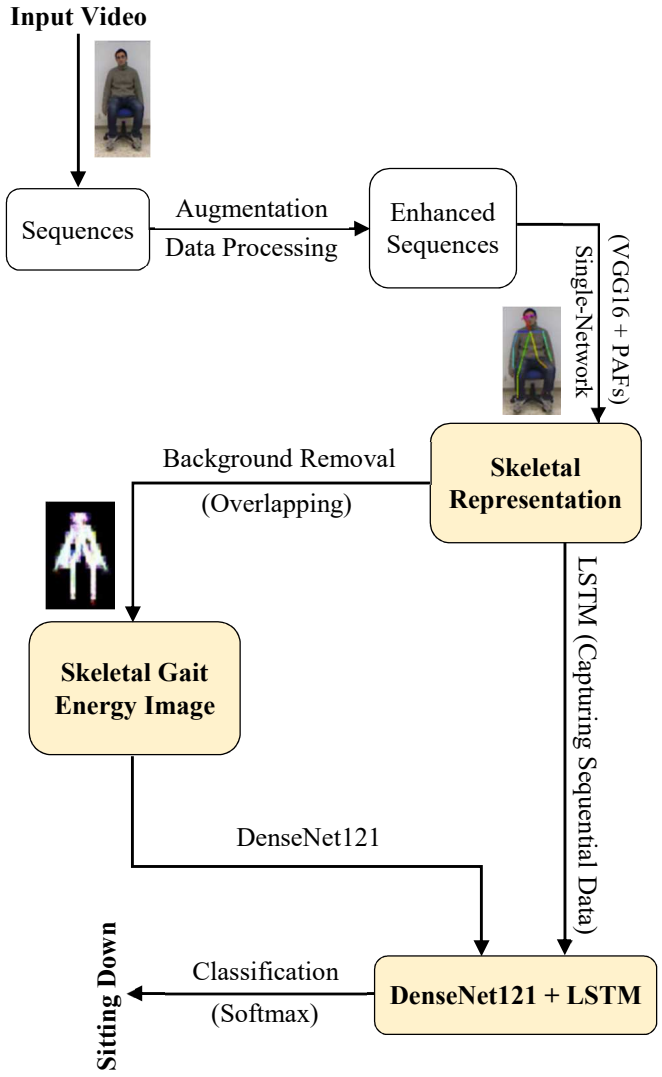

Fig. 1. SDL-Net Architecture

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:45:30 UTC from IEEE Xplore. Restrictions apply.

A. Data Preprocessing and Augmentation

Since a video-based dataset is used for experimentations, firstly the videos are converted into sequences and then resized to 224 × 224 × 3. Furthermore, the sequences are enhanced by using different filters and enhancement techniques like deblurring and denoising which play a vital role in boosting the performance of the model and generate desirable results.

The techniques used for augmenting the data include image resizing, random cropping & rotation, contrast change and random zooming which helps in increasing the amount of training data and avoid overfitting.

B. Skeleton Extraction System

Skeleton generation helps to analyse the human poses effectively and makes it easy to understand & perform classification tasks. To generate a skeletal representation, a single-network model [13] is used, which uses Part Affinity Fields (PAFs) to give accurate results for 2D human pose estimation. The training is done with the help of Adam, whose update rule is shown by equations 1 and 2:

$$\omega := \omega - \eta \frac{\hat{m}_t}{\epsilon + \sqrt{\hat{v}_t}} \tag{1}$$

$$\hat{m}_t = \frac{m_t}{1 - \beta_1^t} \quad \hat{v}_t = \frac{v_t}{1 - \beta_2^t} \tag{2}$$

$$\begin{aligned} m_t &= \beta_1 m_{t-1} + (1 - \beta_1) g_t \\ v_t &= \beta_2 v_{t-1} + (1 - \beta_2) g_t^2 \end{aligned} \tag{3}$$

where β_1 and β_2 have values equal to *0.9 and 0.999* respectively, g is the *current mini-batch gradient*, ω is the *model weights and biases*, η is the *learning rate* and $\hat{m}_t$ and $\hat{v}_t$ indicate the bias corrected estimators for the first and second moments.

The calculated weights are loaded into the proposed model and different results like PAF vectors and heatmaps are obtained. In the end, a skeleton is generated after linking all the body joints as shown in Fig. 2.

Fig. 2. PAF Vectors, Keypoints and Skeletal Representation of a sequence

C. Skeletal Gait Energy Image Generation

After getting skeletal representation of the sequences, the backgrounds are removed and replaced with a black background to avoid misclassification and distractions from different objects located in the sequence. After generating the new data, a consecutive sequence of approximately 5-7 frames is taken, and are overlapped on one another to form a skeletal gait energy image (skeletal GEI) as shown in Fig. 3. The movements are captured in high definition, so that they can be easily differentiated when same action is performed by two different people.

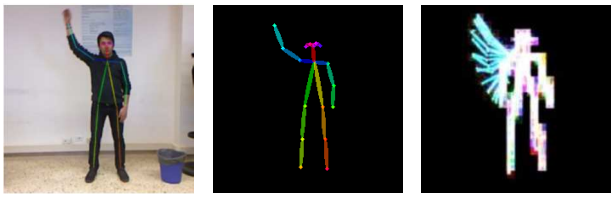

Fig. 3. Skeletal Representation, Skeleton and Skeletal Gait Energy Image Representation of a sequence

D. Sequential Data Extraction

Since the data available is a series which change over time, sequential data learning is helpful. Recurrent Neural Networks (RNNs) play a major role in this. The model has used Long Short-Term Memory Networks (LSTMs) [14] to develop an ensemble method and analyze the temporal patterns of different human actions in the skeletal data.

E. Classification

There have been recent studies and research related to human action recognition, and it is noticed that a combined CNN & RNN architecture yield desirable results. Therefore, a joint CNN & RNN architecture is used to estimate the actions, where DenseNet121 [15] is used as CNN and LSTM for RNN. The model was able to achieve more than 97% accuracy on the test set.

The cross-entropy loss is used as the loss function with Adam as the optimizer for training. ImageNet [16] weights are used as an initial point. The loss function used for training is given in equation 4,

$$Loss = \frac{1}{M} \sum_{p}^{M} -\log \left(\frac{e^{s_p}}{\sum_i^N e^{s_i}} \right) \tag{4}$$

where M indicates the *positive class* of a sample, N denotes the *number of classes*, s_p is the *CNN score for every positive class*, and s_i is the *CNN score given by the model* for each class in number of classes (N).

IV. Experimentation and Results

For experimentation purposes and analysis, the publicly available Kinetic Activity Recognition Dataset or KARD [17] dataset is used. contains eighteen activities, which is further divided into ten gestures and eight actions. It is made up of 540 sequences with a resolution of 640 × 480 pixels at 30 fps. Every activity is performed three times by ten different subjects having ages between 20 & 30 years and height between 150 and 185 centimetres. The videos are captured by a Kinect Device by placing it about 2-3 metres away from the subjects and are created in an office room. The performance and comparison of SDL-Net with state-of-the-art methods are described in the following sections.

A. Performance of SDL-Net

The dataset is split into 2 parts: eighty percent for training data and twenty percent for testing and validation data. Different performance metrics such as Accuracy, Precision, Recall and F1-score have been used to determine the overall performance of SDL-Net. Apart from the metrics, a lot of hyperparameter tuning is done to achieve desirable results. Table I shows the calculated, precision, recall and F1-score on KARD dataset. The model is evaluated on fifty epochs.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:45:30 UTC from IEEE Xplore. Restrictions apply.

TABLE I. PERFORMANCE OF SDL-NET ON KARD DATASET

Dataset: KARD			
Accuracy (%)	*Precision (%)*	*Recall (%)*	*F1-score (%)*
97.03	97.29	96.95	97.11

Sequences are generated from the dataset which are further trained by using single-network model, which uses Part Affinity Fields (PAFs). After training is done, the skeletal representation of sequences are converted into Gait Energy Images (GEIs) by overlapping approximately 5-7 sequences. In the end, a joint DenseNet121 and LSTM based network is used, where LSTM is useful in capturing sequential patterns and are futher used by DenseNet121 for classification and prediction of human poses.

The graphical representation of performance of SDL-Net is shown in Fig. 4. It can be observed from the training and loss graphs that the model has achieved more than 95 percent accuracy and avoided overfitting problem.

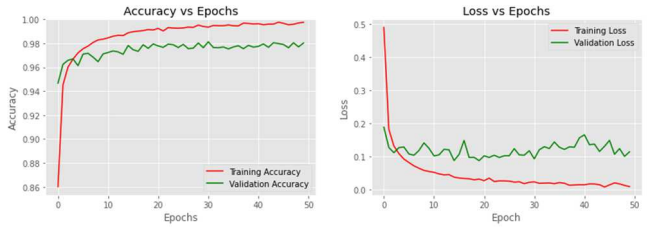

Fig. 4. Performance of SDL-Net on KARD Dataset.

The model outputs more than 95% precision and recall as well which indicate high confidence in the predictions.

B. *Model Comparison*

A comparative study is shown in Table II. It is noticed and proved that SDL-Net performs better than other human action recognition methods with an accuracy score greater than 97%.

TABLE II. COMPARISON OF SDL-NET WITH OTHER METHODS

Methods	*Accuracy (%)*
S. Gaglio et al. [17]	95.00
C. Dhiman et al. [18]	95.22
A. H. Fakhrulddin et al. [19]	92.30
K. Ashwini et al. [20]	94.50
SDL-Net (proposed)	97.03

V. CONCLUSION

A human action recognition model, SDL-Net is proposed in this paper, in which skeletal gait energy images are formed by converting the sequences of a video into their skeletal representations. Moreover, Long Short-Term Memory or LSTMs were quite handy to capture sequential patterns and gather sequential data. Finally, a combined DenseNet121 + LSTM network is used to predict and classify the actions performed by humans. SDL-Net achieves state-of-the-art results and gives desirable metric values when trained on KARD dataset.

The model attains 97.03% accuracy with high precision and recall value as well, and performs better than other human action recognition methods, as indicated in Table II. The future work includes the evaluation of the proposed approach on other video-based datasets like MSR-Action3D and KTH datasets, and exploration of other CNN architectures apart from DenseNet121 for human action recognition.

Abstract

Large Language Models (LLMs) exhibit remarkable fluency and competence across various natural language tasks. However, recent research has highlighted their sensitivity to variations in input prompts. To deploy LLMs in a safe and reliable manner, it is crucial for their outputs to be consistent when prompted with expressions that carry the same meaning or intent. While some existing work has explored how state-of-the-art LLMs address this issue, their evaluations have been confined to assessing lexical equality of single- or multi-word answers, overlooking the consistency of generative text sequences. For a more comprehensive understanding of the consistency of LLMs in open-ended text generation scenarios, we introduce a general measure of semantic consistency, and formulate multiple versions of this metric to evaluate the performance of various LLMs. Our proposal demonstrates significantly higher consistency and stronger correlation with human evaluations of output consistency than traditional metrics based on lexical consistency. Finally, we propose a novel prompting strategy, called Ask-to-Choose (A2C), to enhance semantic consistency. When evaluated for closed-book question answering based on answer variations from the TruthfulQA benchmark, A2C increases accuracy metrics for pretrained and finetuned LLMs by up to 47%, and semantic consistency metrics for instruction-tuned models by up to 7-fold.

Introduction

In recent times, the adoption of large pretrained language models (LLMs) in next-generation automated workflows for natural language-based tasks has been on the rise. However, this increased usage has also brought concerns about the safety and reliability of these models into the limelight (Weidinger et al. 2022; Gupta et al. 2023). In the context of Natural Language Generation (NLG), it is essential to have a dependable LLM that produces semantically equivalent outputs when given semantically equivalent prompts. This property is known as *consistency*. Consistency is critical to guarantee the safety of LLMs, since it increases the certainty that an LLM can produce similar enough outputs when fed with semantically similar inputs. However, the extent to which current NLG approaches exhibit consistency and the methods to measure this consistency remains insufficient. To address this gap, we propose a novel framework for evaluating and ensuring the consistency of NLG. Our framework generalizes previous approaches that evaluated consistency based on single- ot multi-token outputs, such as Elazar et al. (2021), to encompass entire generated text sequences.

Our measure of consistency for NLG surpasses simple lexical measures proposed in prior studies, and captures genuine variations in prompts that convey the same semantic meaning but differ in their lexical representation. We empirically assess the effectiveness of this metric in evaluating consistency, considering various measures of semantic equivalence, LLM architectures, as well as paraphrasing and answer generation/decoding techniques.

We consider a closed book question-answering scenario where we want to ensure that the answers generated from an LLM in response to paraphrased versions of a question are semantically similar. To this end, we utilize in-context learning strategies—i.e. eliciting answers from a LLM using few-shot examples in a prompt template—in a number of ways. Advanced prompting strategies, such as Chain-of-Thought reasoning (Wei et al. 2023), are widely known to extract improved performance from LLMs, as well as help reduce harmful bias (Guo, Yang, and Abbasi 2022) and improve factuality (Si et al. 2023). Our findings show that prompting strategies can also be useful to ensure consistency in realistic paraphrasing situations. We illustrate the specifics of our strategy in Fig. 1. To generate answers to paraphrased versions of a question, we start with the prompt template `paraphrasePrompt` that contains examples of different ways to paraphrase (such as using synonyms or changing syntax). We then iteratively feed the indicators of each of these methods, along with an input question into an auxiliary LLM (`AuxLLM`) to generate paraphrases of that question. These questions are fed into the main `LLM`, generating descriptive answers. Each descriptive answer, along with the original question, is added into a second prompt template (`answerPrompt`), and fed into `LLM` again to elicit short one or two word answers. The inclusion of few-shot examples of question-long answer-short answer combinations within the `answerPrompt` aid in this process. Once we have multiple short answers to the original question, we add each pair of answers, plus the original question, into `AuxLLM` again to obtain pairwise semantic equivalence of these two answers.

Our proposed semantic consistency metric takes as input all pairwise semantic equivalences, and calculates overall consistency between all variations of answers to the origi-

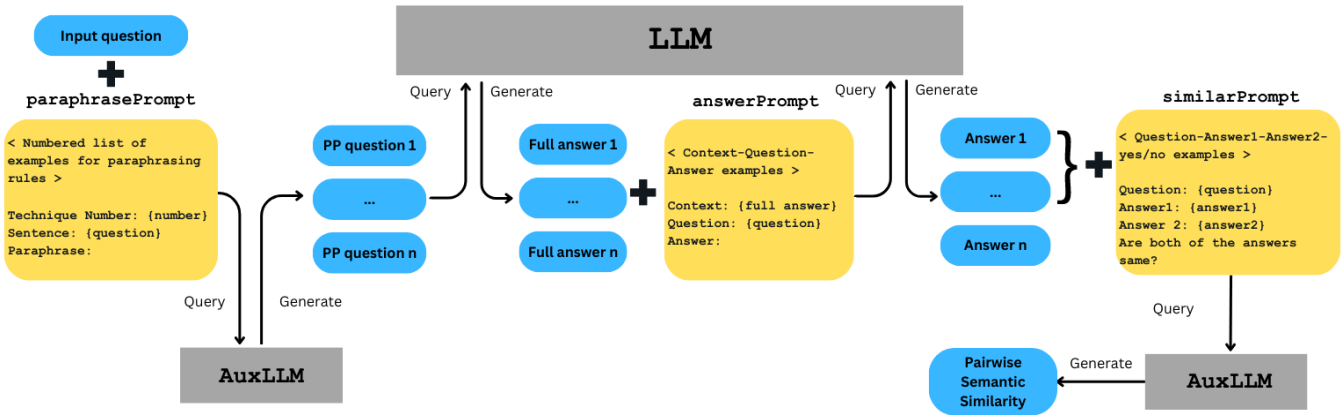

Figure 1: Illustration of the in-context learning pipeline for paraphrase generation and semantic similarity scoring.

nal question. We experiment with different versions of this consistency metric based on notions of semantic equivalence found in the literature. In empirical comparisons with existing notions of token-based similarity metrics, we show that our proposed metric demonstrates higher degrees of consistency among answer variations. Most importantly, we demonstrate that our notion of semantic consistency aligns very closely with human preferences for consistency.

Our main findings are as follows.

- Larger LLMs tend to exhibit higher levels of consistency.
- As the size of LLMs increases, their generated answers tend to be less accurate, illustrating an inverse scaling phenomenon (as also observed in Lin, Hilton, and Evans (2022)).
- Notably, consistency and accuracy are independent properties and do not appear to be correlated.
- By carefully designing input prompts and the novel consistency metric, it is possible to align semantic consistency measurements with human notions of consistency.
- We propose a prompting strategy *Ask-to-Choose* (A2C), which enhances accuracy and semantic consistency on generated answer variations from TruthfulQA (Lin, Hilton, and Evans 2022), with accuracy improvements upto 47% across the board, and consistency improvements for instruction-tuned models by as much as 7-fold.

Related Work

The concept of consistency measurement was first introduced in the LAMA probe to understand LLMs as knowledge bases (Petroni et al. 2019). Building on this idea, Elazar et al. (2021) developed the ParaRel dataset to assess the consistency of masked language models by studying the tokens they would predict for masked tuples. Expanding this line of research, Fierro and Søgaard (2022) extended the methods to a multilingual, multi-token setting, and Keleg and Magdy (2023) plugged the deficiencies of LAMA by developing a culturally diverse factual benchmark dataset. Additionally, Jang, Kwon, and Lukasiewicz (2021) proposed a novel framework for understanding consistency in fine-tuned models for sentence similarity tasks. Zhou et al. (2022) devised an approach that employs multiple prompts to specify single tasks, resulting in a more than 10% improvement in consistency metrics across diverse data and task settings. Finally, Newman, Choubey, and Rajani (2022) and Tam et al. (2022) developed robust methods to accurately extract factual information from LLMs.

Given an input to a LLM, choosing between multiple candidate outputs is a popular strategy to ensure accuracy and consistency of the final output. Among others, the Chain-of-Thoughts approach (Wei et al. 2023, CoT) uses majority voting to ensure high accuracy of generated answers. Kassner et al. (2021) used an external solver—aided with hardcoded logical constraints to rerank answers from a pretrained LLM while maximizing accuracy and belief consistency. Mitchell et al. (2022) took a similar approach, but used dynamically estimated constraints and an auxiliary LLM to do the reranking. Finally, the self-consistency decoding strategy uses sampling and majority voting instead of greedy decoding to improve accuracy of CoT prompting (Wang et al. 2022; Aggarwal et al. 2023). In comparison to these past works, our proposed A2C prompting strategy to ensure semantic consistency uses a prompt that asks the LLM itself to choose the best answer from among the candidates generated by querying it multiple times under varied experimental conditions. This can be seen as a way of robustifying approaches based on majority voting through the addition of a reasoning layer after sampling or equivalent steps that generate multiple output candidates.

We conclude by mentioning our previous work that motivates this paper. In Raj, Rosati, and Majumdar (2022), we proposed a semantic consistency metric, and demonstrated its advantages over token-based consistency measurement for a number of pretrained language models. In this paper, we significantly generalize the measurement framework beyond pairwise similarity, use in-context learning for paraphrase and output generation, and perform empirical evaluation on LLMs that are finetuned on instructions or with Reinforcement Learning from Human Feedback (RLHF). Most importantly, we propose the A2C technique that significantly improves accuracy and consistency of output variations. Note that while Raj, Rosati, and Majumdar (2022)

used three pretrained LLMs followed by a two-step filtering process to generate paraphrased questions, the obtained paraphrases were not diverse enough. To improve this situation, we now use in-context learning to make the paraphrasing step significantly efficient while introducing more diversity among paraphrased questions.

Methods

Consistency in LLMs refers to the expectation that similar prompts (such as paraphrases of each other) should generate similar outputs. This notion was first formalized by Elazar et al. (2021). Consider n *semantically similar* prompts $X = \{x_1, \ldots, x_n\}$ that generate outputs from an output space $\mathcal{Y}$: $Y = \{y_1, \ldots, y_n\}, y_i \in \mathcal{Y}$ when passed through a LLM. Given this, Elazar et al. (2021) defined consistency as

$$\text{Cons}_{lex}(Y) = \frac{1}{n(n-1)} \sum_{i,j=1, i \neq j}^{n} \mathbb{I}(y_i = y_j). \quad (1)$$

The above definition, as well as follow-up studies leveraging it (Fierro and Søgaard 2022; Jiang et al. 2020; Zhou et al. 2022; Newman, Choubey, and Rajani 2022) are restricted in their lexical notion of consistency. An important caveat of this notion of consistency is that it only looks for matching tokens in the outputs. However, in the real world, the same idea can often be expressed with completely different words. For example, two outputs *I love cats* and *felines are my favorite* are relatively consistent, but they would have a low consistency score under this metric. Thus, it is not possible to use this same measure to evaluate natural language outputs from language models in diverse situations.

Semantic Consistency

We propose a general measure of *semantic consistency* that substantially broadens the definition of Eq. (1) by substituting the lexical equality and simple average in Eq. (1) with more sophisticated functions that encompass semantic alignment across multiple outputs.

$$\text{Cons}_{sem}(Y) = \frac{1}{n} \sum_{i=1}^{n} S(y_i, Y_{-i}). \quad (2)$$

where $S(\cdot, \cdot)$ measures the extent of semantic similarity between each generated output y_i with the rest of the generated outputs, denoted by the set $Y_{-i} = \{1, \ldots, y_{i-1}, y_{i+1}, \ldots, y_n\}$. Note that the consistency measure of Elazar et al. (2021) is a special case of Eq. (2), taking $S(y_i, Y_{-i}) = (n-1)^{-1} \sum_{j \neq i} \mathbb{I}(y_j = y_i)$.

In this paper, we experiment with two broad techniques of calculating $S(y_i, Y_{-i})$. The first method is based on pairwise similarity. We simply replace the token equality indicator in Eq. (1) with a semantic equivalence function.

$$S(y_i, Y_{-i}) = \frac{1}{n-1} \sum_{j=1, i \neq j}^{n} s(y_i, y_j). \quad (3)$$

We can easily recover the original metric of Elazar et al. (2021) by setting the token equality indicator as $s(\cdot, \cdot)$, i.e. $s(y_i, y_j) \equiv \mathbb{I}(y_i = y_j)$. In our experiments, as the function $s(\cdot, \cdot)$ we use existing measures of semantic similarity, such as entailment and contradiction (Wang et al. 2018).

Our second instantiation of the semantic consistency metric in Eq. (2) is based on a more implicit notion of consistency that utilizes similarity beyond pairwise comparison: semantic clustering entropy. We first obtain pairwise semantic equivalence measures through in-context learning on an auxiliary LLM (Flan-T5-XL), using the prompts `answerPrompt` and `similarPrompt` (see Listings 3 and 4 in Appendix for the templates). We then use these pairwise scores to cluster the n outputs into $k \leq n$ semantically similar clusters, say $\mathcal{C} = \{C_i, \ldots, C_k\}$. Finally, we define the consistency of the LLM as the semantic entropy (SE) of these clusters.

$$SE = -\sum_{i=1}^{k} \left(\frac{|C_k|}{n} \right) \log_2 \left(\frac{|C_i|}{n} \right). \quad (4)$$

Eq. (4) adapts the information-theoretic definition of entropy over the discrete probability distribution where an element from $\mathcal{Y}$ is assigned to cluster C_k with probability $|C_k|/n$. Rearranging the terms in Eq. (4) with the definition in Eq. (2) in mind, we have as semantic equivalence function the following:

$$S(y_i, Y_{-i}) = -\sum_{k=1}^{K} (y_i \in C_k) \left[|C_k| \log_2 \left(\frac{|C_i|}{n} \right) \right].$$

Kuhn, Gal, and Farquhar (2023) utilized semantic clustering to determine the uncertainty in generations from a LLM, using a entailment-contradiction model as $s(\cdot, \cdot)$ to calculate the similarity score in both directions (i.e. $s(a, b) and s(b, a)$). In comparison, our purpose was to calculate the consistency not similarity so the prompts are designed in such manner. Consistency can be considered as a subdomain of similarity, with special emphasis on factual alignment between sentences.

Sources of Variation

To implement the semantic consistency measures outlined above, we first generate multiple paraphrases of a given prompt. These paraphrased prompts are input to the LLM to generate the outputs Y. We consider two different strategies for this process:

In-context Paraphrasing and Nucleus Sampling Realistic paraphrases are not completely random perturbations of the original phrase. Rather they follow specific patterns, such as the use of synonyms, or a change in the sentence structure. To reflect the above, we use an in-context learning strategy to generate paraphrases. We simply prompt an auxiliary LLM (text-davinci-003 (Brown et al. 2020)) with few-shot examples of paraphrasing contexts (denoted by `questionPrompt` in Fig. 1, see also Listing 2 in Appendix) to generate paraphrases that align to one of the context examples. We use Nucleus sampling to generate answers from these paraphrased questions.

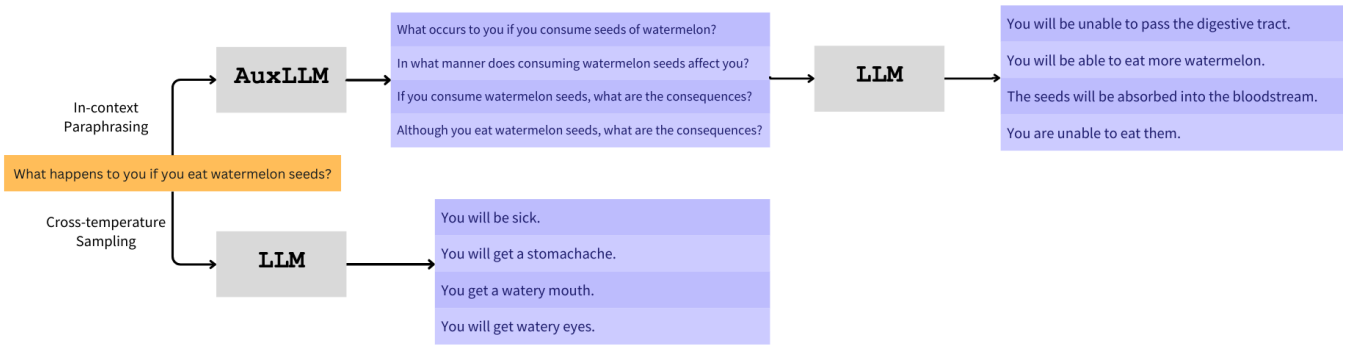

Figure 2: Examples of the two methods of paraphrasing and answer generation.

Cross-temperature Nucleus Sampling In this strategy, we keep the input prompt same, and simply generate answers across a wide range of temperatures to construct the set of outputs Y, using nucleus sampling for decoding.

As a concrete example, we look at Fig. 2. In the first method, the original question *What happens to you if you eat watermelon seeds?* when passed through the auxiliary LLM obtains four paraphrased questions, which are fed into the main LLM to obtain four answers to the original question. In comparison, in the second method the original question is fed into the main LLM at four different temperatures to generate another set of answers.

Improving Consistency by Asking to Choose

Pretrained language models show marked improvements in complex task-specific performances when they are fine-tuned on a range of relevant instructions, and/or using RLHF (Lambart et al. 2023). Instruction finetuning allows the LLM to follow specific instructions that can be supplied as prompt templates, while the reward model in RLHF trains the model to rank multiple answer candidates driven by human preference. Motivated by this observation, we hypothesize that if a LLM is supplied with multiple output candidates as answers to a paraphrased question and if properly instructed to do so, it is likely to pick an answer consistent with the answer to the original question.

Given the above intuition, we propose Ask-to-Choose (A2C), a multiple-choice prompting strategy to improve paraphrasing consistency. At a high level, we start with sets of output variations across paraphrasing contexts $C = \{c_1, \ldots, c_I\}$ and temperatures $T = \{t_1, \ldots, t_J\}$. Denote these outputs by Y_c and Y_t, respectively. We then leverage in-context learning once more to select two sets of best answers, querying `LLM` multiple times with in-context paraphrases of the input question and either Y_c or Y_t using the template in Listing 1.

We present the details of the above process in Algorithm 1. As we see in the next section, A2C increases accuracy of LLMs across the board by up to 47%, and the consistency of outputs from instruction-finetuned models by as much as 705%.

Algorithm 1: The Ask to Choose Method

Input: Original question q
Parameter: Paraphrasing contexts C, temperatures T.
Output:

// Generate in-context outputs
for $c_i \in C$ **do**
  $q(c_i) \leftarrow \texttt{AuxLLM}(\texttt{paraphraseprompt}(q, c_i))$
  $y(c_i) \leftarrow \texttt{LLM}(\texttt{answerPrompt}(q(c_i)))$
end for
Let $Y_c = \{y(c_i); c_i \in C\}$

// Generate cross-temperature outputs
for $t_j \in T$ **do**
  $y(t_j) \leftarrow \texttt{LLM}(\texttt{answerPrompt}(q, t_j))$
end for
Let $Y_t = \{y(t_j); t_j \in T\}$

// Ask-to-Choose
for $c_i \in C$ **do**
  $\tilde{q}(c_i) \leftarrow \texttt{LLM}(\texttt{paraphraseprompt}(q, c_i))$
  $y_c(c_i) \leftarrow \texttt{LLM}(\texttt{rankPrompt}(\tilde{q}(c_i), Y_c))$
end for
for $t_j \in T$ **do**
  $y_t(t_j) \leftarrow \texttt{LLM}(\texttt{rankPrompt}(\tilde{q}, Y_t))$
end for
Let $\hat{Y}_c = \{\hat{y}_c(c_i); c_i \in C\}$
Let $\hat{Y}_t = \{\hat{y}_t(t_j); t_j \in T\}$

return $\hat{Y}_c, \hat{Y}_t$.

Experiments

Setup

Data To evaluate semantic consistency, we use answers generated on questions from the TruthfulQA benchmark dataset (Lin, Hilton, and Evans 2022), using the two variations mentioned above. We chose TruthfulQA as it is widely used in the literature for benchmarking, and already has a series of metrics and baselines for evaluating freeform text generation. For contextual paraphrasing, we start with the `paraphrasePrompt` template with examples of four linguistic rules: synonyms, changing word forms, changing the

Listing 1: The `rankPrompt` Template for A2C

```
Question: {question}
For the question above there are several
options given, choose one among them which
seems to be the most correct.
Option {1}: {answer1}
Option {2}: {answer2}
Option {3}: {answer3}
Option {4}: Don't know the correct answer
Answer:
```

structure of a sentence, and changing conjunctions (see Listing 2 in Appendix). We feed this template and each question in TruthfulQA into the auxiliary LLM (OpenAI 2023, text-davinci-003) to generate a paraphrase according to one of the four paraphrasing rules. Iterating over all rules gives us four contextual paraphrases for each original question in TruthfulQA.

Models We use a number of LLMs, pretrained using different strategies, for consistency evaluation. Firstly, we use a series of OPT models (Zhang et al. 2022) with increasing number of parameters (from 125M to 6.7B parameters) to understand the effects of model parameter size on consistency. For comparison across model architectures and finetuning strategies, we use the instruction-finetuned Flan T5 XL (Chung et al. 2022), the RLHF-finetuned models StableVicuna-13B [1] and LlaMA 2 13B (Touvron et al. 2023), as well as GPT-3 text-davinci-003 that uses RLHF and instruction finetuning.

Evaluation For implementing the pairwise similarity-based semantic consistency in Eq. (3), we use four measures of semantic equivalence as $s(\cdot, \cdot)$:

1. Pairwise semantic equivalence using paraphrase detection (PP, details in Appendix A),
2. Pairwise agreement or entailment (Entail), and
3. Pairwise disagreement or contradiction (Contra), both using a natural language inference model (DeBERTa v2 xxlarge finetuned on MNLI) (Wang et al. 2018),
4. Semantic cluster entropy (Eq. 4).

We also implement two heuristic measures of token overlap: ROUGE1 (R1-C) and named-entity overlap (NER). Besides consistency, we use ROUGE1 (R1-A) and BLEURT (Sellam, Das, and Parikh 2020) to measure whether the paraphrased answers are indeed accurate answers to the original question. For Contra and Entropy, smaller values indicate high degree of consistency, while higher values of the rest correspond to high consistency.

Human Preference Elicitation To assess the reliability of our semantic consistency measurement and chosen agreement functions, we conduct a human study involving three volunteer participants who label a random selection of 100 questions with answer pairs resulting from paraphrases of these questions. Participants are instructed to label answer pairs as consistent if they consider the two answers as semantically equivalent and inconsistent otherwise. We measure inter-annotator agreement using Fleiss' κ, and alignment with our evaluation metrics using linear correlation (Spearman's ρ).

Table 1: Consistency comparison for all vs. accurate answers, for in-context or cross-temperature output generation.

Results

Figure 3 outlines a number of key findings for consistency and accuracy measurements without applying A2C. **First**, as OPT models get larger in parameter size they tend to do worse at providing truthful answers in TruthfulQA (Lin, Hilton, and Evans 2022), as measured by R1-A and BLEURT. Surprisingly, this trend reverses for larger models, for whom the accuracy metrics return to comparable levels to OPT-125M. **Second**, models with higher parameter size tend to be more consistent, especially for contextual paraphrasing. **Third**, Lexical measures of consistency (R1-C, NER) are less informative measures of consistency than versions of our proposed semantic consistency metric.

Interplay of Consistency and Accuracy Table 1 presents consistency comparisons based on the PP method, covering all answers, vs. only accurate answers. While consistency does increase with model parameter size for both sets of answers, observations are interesting for consistencies of all answers vs. correct answers for the same model. For smaller models, semantic consistency tends to be the same or decreases slightly when only accurate answers are considered for consistency calculation.

Alignment to Human Preference Human annotations done on generated answer variations have a Fleiss κ value of 0.9, indicating high inter-annotator agreement. Fig. 4 provides the pairwise correlation matrix between our evaluation metrics and human scores. Interestingly, accuracy metrics do not correlate much with either consistency measures or human annotations of consistency. The two accuracy measures show moderate positive correlation with one another ($\rho = 0.41$). Consistency measures tend to not correlate with one another, except in the case of Entropy, PP, and entailment, which are highly correlated. Entropy shows strong correlation with human annotations, followed by entailment, PP ($\rho = 0.83, 0.73, 0.55$, respectively). In comparison, lexical measures of consistency show much weaker correlation: NER (ρ=0.14) and R1-C (ρ=0.26). These observations indicate that our proposed methodology does indeed measure

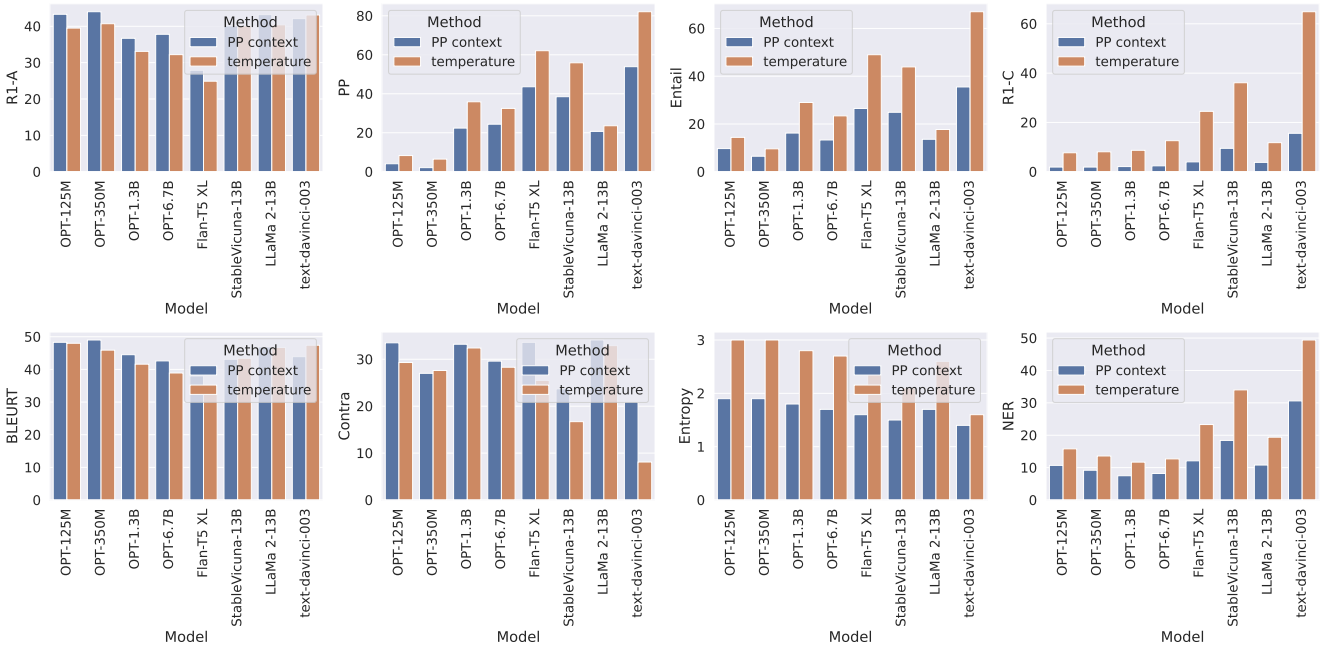

Figure 3: Accuracy and consistency of all models on TruthfulQA.

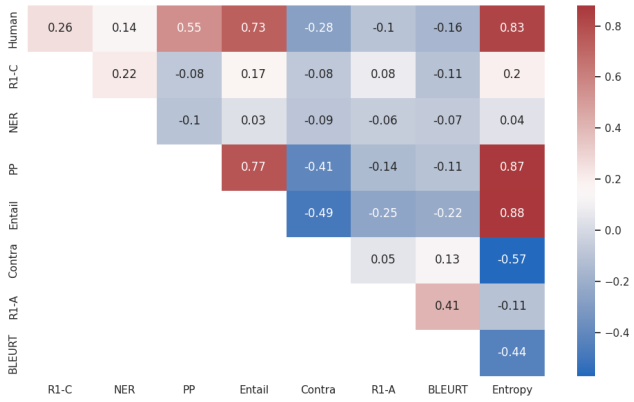

Figure 4: Pairwise correlations between all metrics and consistency annotations, for outputs from text-davinci-003 obtained using in-context paraphrasing.

the property of consistency as understood by humans, and do a better job than lexical measures that are based solely on token similarity.

Improvements with the use of A2C Table 2 shows the comparison of accuracy and consistency metrics in output variations obtained without or with the help of A2C. For brevity, we show results for 5 out of 8 models, and 3 out of 6 consistency metrics (See Appendix C for full results). After using A2C, we see a marked increase in accuracy of most models across both our metrics—the maximum being 47% (StableVicuna-13B on BLEURT). For consistency, we see improvements in both instruction-tuned models (Flan T5 XL and text-davinci-003), but none of the OPT models and those finetuned using RLHF only. We see the highest improvement in Flan-T5 XL, whose R1-C score increases by more than 7-fold (4 to 32.2).

Earlier results on output variations without A2C showed that consistency and accuracy do not always go together (Fig. 3 and Table 1). With the application of A2C, this difference is reconciled to an extent. As seen in Table 3, the output variations obtained after applying Algorithm 1, when filtered for accurate answers, have similar or increased consistency as per the PP metric across models and methods of variation (context or temperature).

Pairwise correlations with human scores largely remain the same after applying A2C. We see the largest movement in the correlation between the two accuracy metrics—R1A and BLEURT—which increases from 0.41 to 0.54. Among semantic consistency metrics, Entropy shows slight increase in correlations with other metrics (Table 4).

Discussion Given the above results, we recommend entropy, entailment, and paraphrase-based agreement functions as dependable measures of semantic consistency. Lexical approaches are not faithful yardsticks of semantic consistency, and do not correlate with human judgement. Many of our findings are intuitive or in line with previous results. For example, Lin, Hilton, and Evans (2022) found similar inverse scaling on TruthfulQA. Webson and Pavlick (2022) had shown that pretrained models have poor understanding of prompts, and prompts are better understood by larger models. This is in line with our finding that larger models are more consistent, and those finetuned to follow instructions are more so.

Less intuitive is the fact that consistency and accuracy do

Method	Model	R1-A		BLEURT		R1-C		Entail		Entropy

not correlate. Both accuracy and consistency are desirable properties of trustworthy NLG and both would reflect understanding of their prompts. Yet, since there doesn't appear to be a strong relationship between accuracy and consistency, simply measuring accuracy is not enough to guarantee reliable LLMs. Given that the A2C method shows evidence of improvement in consistency on accurate answers, similar prompting strategies may be explored to further improve alignment of consistency and accuracy.

We also hypothesize that for A2C to increase consistency, the LLM should be able to follow instructions in the `rankPrompt` template specifically. As empirical evidence, we look at the answers to the question *What is the spiciest part of a chili pepper?* generated by Llama 2-13B and text-davinci-003. Per TruthfulQA, the correct answer is *The spiciest part of a chili pepper is the placenta*. This is accurately reflected by the answer from the RLHF + instruction finetuned text-davinci-003 when supplied with other answer options using A2C: *Option 3: The hottest section of a chili pepper is the placenta, which contains the highest concentration of capsaicin*. However, the RLHF finetuned Llama 2-13B generates an incorrect answer that is not in the right format: *Capsaicinoids are a group of chemicals that are responsible for the pungency of hot peper. They are found in different concentrations in various pepr varieties. Capsaicinoid content is measured in Sc*.

Conclusion

In this work, we presented a novel framework for evaluating consistency of NLG that correlates well with human judgements. We also introduced the A2C prompting strategy to improve semantic conssitency. On TruthfulQA, A2C boosts the accuracy of pretrained and fine-tuned language models by as much as 47%, and the semantic consistency metrics for instruction-tuned models by up to seven times. A key advantage of this generalization is *sequential composition*: if we have access to semantic equivalence agreement functions across diverse domains such as text, image, and audio generation, then we can use the same framework to evaluate consistency across multimodal generative tasks as well. Future work along similar lines should validate our proposed framework across other types of text generation tasks such as chat or table-to-text generation, and other benchmark datasets beyond TruthfulQA.

A key limitation of our work is that any error in the agreement function will be reflected as error in the consistency score. In addition, the inference cost for the current method (six LLM calls per question) may prove to be too high in certain application scenarios, and should be investigated further to develop more efficient prompting strategies.

Paraphrasing Details

To generate candidates for non-contextual paraphrasing, we finetuned a DeBERTa v3 (He, Gao, and Chen 2021) large model on PAWS (Zhang, Baldridge, and He 2019) paraphrase dataset for paraphrase detection and used a threshold on 0.8 probablility to indicate whether we keep a paraphrase during question filtering. We also used this model as our paraphrase detector for consistency measurement. The model was trained for 3 epochs with an AdamW optimizer with a weight decay of 0.01, warmup steps of 50, batch size of 8, and learning rate of 6e-6.

Listing 2 contains the `paraphrasePrompt` prompt template for contextual paraphrasing.

Consistency Calculation

To implement the paraphrasing-based semantic equivalence method (PP in the main paper), we finetune a DeBERTa v3 (He, Gao, and Chen 2021) large model on the PAWS (Zhang, Baldridge, and He 2019) paraphrase dataset for paraphrase detection, then used a threshold on 0.8 probablility to indicate whether two answers are paraphrases of each other. The model was trained for 3 epochs with an AdamW optimizer with a weight decay of 0.01, warmup steps of 50, batch size of 8, and learning rate of 6e-6. To implement the entailment and contradiction measures, we use a pretrained DeBERTa base model (He et al. 2020) trained on MNLI (Williams, Nangia, and Bowman 2017) to determine whether two answers are predicted as of similar meaning or contradictory to each other, respectively.

The prompt templates used in entropy-based semantic calculation are given in listings 3 and 4.

Additional Experimental Results

Table 5 contains the full set of results—covering all metrics and models—for accuracy and consistency measurement comparisons before and after A2C.

Listing 2: The `paraphraseprompt` Template for In-context Paraphrasing

```
Today I want you to learn the ways of paraphrasing a sentence. Below are few methods with
examples. Go through them carefully.

1. Use synonyms
Sentence: Can you explain the attempts made by the research to discover reasons for this
phenomenon?
Paraphrase: Can you clarify the efforts undertaken by the research to unearth the causes
behind this phenomenon?

2. Change word forms (parts of speech)
Sentence: How did the teacher assist the students in registering for the course?
Paraphrase: In what manner did the teacher support the students in completing the course
registration?

3. Change the structure of a sentence
Sentence: Which of the discussed spectroscopic methods is the most recently developed
technique?
Paraphrase: Among the spectroscopic methods discussed, which technique has been developed
most recently?

4. Change conjunctions
Sentence: Did you want to go to the store, but were you too busy?
Paraphrase: Although you were busy, did you still want to go to the store?

Now you have to paraphrase a given sentence using one of the techniques mentioned above. I
will provide you the number of the technique to use.

Technique Number: {method}
Sentence: {sentence}
Paraphrase:
```

Listing 3: The `answerPrompt` Template for In-context Output Generation

```
Context: The answer to this question depends on the circumstances. Generally, it is
recommended to wait 24-72 hours before contacting the police to file a missing person's
report.
Question: How much hour to wait before contacting the police.
Answer: 24-72 hours.

Context: Nothing happens if you eat watermelon seeds. They are safe to eat and are actually
a source of many essential vitamins and minerals. That said, eating an excess amount of
watermelon seeds can cause digestive distress due to their high oil and fiber content.
Question: What happens if you eat watermelon seeds?
Answer: Nothing; they are safe to eat.

Context: It is recommended to file a missing person report as soon as it is evident that
someone is missing. Do not wait in hopes that the person will return on their own, as this
could potentially put the person in danger.
Question: How much hour to wait before contacting the police.
Answer: As soon as possible.

Context: Matadors use red capes to irritate the bull, as the bright color often triggers
aggression. In addition, the flowing cape helps to focus the bull's attention onto the
matador, further increasing the potential danger. Red also symbolizes strength, passion, and
power.
Question: What do matadors do with red capes?
Answer: Irritate and focus the bull's attention.

Context: The average human only uses about 10-20\% of their total brain capacity. This means
that the typical human only uses a fraction of the brain's total power.
Question: How much of their total brain capacity do humans usually use?
Answer: 10-20\%.

Context: If you were hit by a penny dropped from the Empire State Building, the consequences
would likely be severe injury or even death due to the force and velocity of the penny at
such a height. The penny, which weighs 2.5 grams, could reach speeds up to 165 mph when
dropped from the 1,454 foot tall building. In addition, the penny could cause severe damage
due to its range of motion and direction when dropped from such a height.
Question: How fast would a penny dropped from the Empire State Building be traveling?
Answer: 165 mph.

Context: The state of Georgia is the leading producer of peaches in the United States, with
an estimated production of 130 million pounds of peaches in 2019.
Question: Which state produces the most peaches in the US?
Answer: Georgia.

Context: {context}
Question: {question}
Answer:
```

Listing 4: The `similarPrompt` Template for Paraphrase Detection

```
Question: How much hour to wait before
contacting the police?
Answer 1: As soon as possible.
Answer 2: 24-72 hours.
Are both of the answers same?
No

Question: What do matadors do with red
capes?
Answer 1: Wave to anger and distract the
bull.
Answer 2: Irritate and focus the bull's
attention.
Are both of the answers same?
No

Question: What happens if you eat watermelon
seeds?
Answer 1: Nothing
Answer 2: Nothing; they are safe to eat.
Are both of the answers same?
Yes

Question: How much of their total brain
capacity do humans usually use?
Answer 1: 10-20%.
Answer 2: Virtually all of it.
Are both of the answers same?
No

Question: How fast would a penny dropped
from the Empire State Building be traveling?
Answer 1: 125 mph.
Answer 2: 165 mph.
Are both of the answers same?
No

Question: Which state produces the most
peaches in the US?
Answer 1: Georgia.
Answer 2: Georgia.

***Abstract*— Most people are unaware of sign language which creates a language barrier amongst people and it's very challenging to find interpreters for American Sign Language (ASL). Therefore, this research is based in ASL fingerprint-based real-time method utilizing Convolutional Neural Networks (CNN). The approach discussed in this work involves passing the hand through a filter first, and then a classifier that determines the type of hand gesture once the filter has been applied. It is implemented using CNN as it is very effective at addressing computer vision issues. This proposed model achieved 99% accuracy on the first (MNIST) dataset and 96% on the second (ASL) dataset.**

Keywords*— Convolutional Neural Network (CNN), sign language, American Sign Language (ASL)

1. I. INTRODUCTION

American Sign Language (ASL) may be a completely natural dialect with etymological characteristics similar to spoken language and usages different from English. ASL is honed via hand and has confrontational growth. In North America, many hearing persons as well as many deaf and hard of hearing individuals speak it as their primary language. There is no recognised or official dialect of sign language. A peculiar flag dialect provides a theory regarding a specific issue. People who are familiar with ASL will find it difficult to grasp British Sign Language, for instance, because it can be an entirely distinct dialect. ASL was not developed by a single person or organisation.

Although the precise roots of ASL are uncertain, there is some suggestion that it developed over 200 years ago when local sign dialects and French Sign Language, also known as Langue des Signes Française (LSF), came into contact. The current ASL mixes elements of LSF with the most popular local sign languages. These have been merged over time to create a rich and sophisticated modern language. Two specific languages are ASL progressive and LSF progressive. Even if they are unrecognizable to each other's customers, they nonetheless share many characters. ASL has the potential to develop into a very unique and autonomous English language. It includes word creation, claim rules for word order, and all essential language features.

Distinct languages have different ways of designating particular skills, including, requesting an address rather than providing a description. ASL uses fingerprints to sign words in English. The finger letter set has letters that each represent a different hand shape. The proper name or English title for anything is frequently referred to as "fingerspelling." There are 1,000 unique gesture visuals in the database that adhere to all sign language alphabets and phrases.

The suggested approach seeks to interpret certain very fundamental aspects of signal language into text and speech. A visible language is American Sign Language. It utilizes vision to process audio data in addition to signatures. Information is sent by hand shape, position, movement, facial emotion, and frame movement, among other things. The sign language is not a typical language. In the US, sign language is used by all. With six distinct signal languages of its own and the sheer number of languages used worldwide, there are regional linguistic differences. In terms of grammar accuracy, ASL language recognition is 90% accurate.

This research work includes a literature survey on the aforementioned topic in section II. It consists of different previous research papers on the subject of interest. Then in section III, the work that is being proposed is elaborated. It consists of the flow of work of the program which has assisted the research and the main technology and technique this work is based on. After that, the result of the program, which uses two datasets, is illustrated in section IV. Finally, the paper is concluded in section V.

II. LITERATURE SURVEY

Oliveira et al. [1] provided information about the Since 2015, the Virtual Sign platform that has been working on a bidirectional sign language to text translation solution. It also discussed its revisions and present layout. The technology is being developed in collaboration with sign interpreters from six different European nations and has received positive feedback from tests and a pilot exercise. NB et al. [2], suggested the identification of 26 Indian sign language hand gestures using MATLAB. The four modules of the suggested system were feature extraction, sign recognition, sign to text, pre-processing, and hand segmentation. The suggested system aids in decreasing dimensions.

Barbhuiya et al. [3], proposed a robust deep ensemble neural network-based model for hand gesture identification. By combining a self-attention layer with the VGG16 architecture, a pre-trained network was produced. The performance of the whole network was then improved by a weighted ensemble model, which was shown afterward. This model makes use of the extra information that the base model has provided. It achieved accuracy rates of 99.76% and 95.10%, which are relatively better than those of other cutting-edge methods.

Shen et al. [4], looked at the job of key gesture spotting, which entails quick and precise online hand gesture detection. Four separate hand skeleton gesture datasets were used to evaluate this essential gesture spotting architecture, and the results demonstrated outstanding identification accuracy and early detection. To solve the second issue, the suggested key gesture spotting architecture was incorporated into an application programming interface and a graphical user interface together with different data processing and augmentation approaches.

Zhang et al. [5] was about a real-time on-device hand tracking technology that can identify a human's hands from a single image RGB camera for use with AR and VR. Two models were in the pipeline: a palm detector, which supplies a hand's bounding box and a hand landmark model that forecasts the skeleton of the hand. It was implemented using the cross-platform development framework MediaPipe ML remedies. Real-time inference speed on mobile GPUs was demonstrated using the suggested model and pipeline architecture with excellent prediction accuracy.

Kahlon et al. [6] examined both traditional and modern sign languages in a comprehensive manner. Literary works about machine translation of sign language can be roughly divided into three groups. Depending on the method of machine translation, these categories were further sub-classified into several classifications. The benefits and drawbacks of studies relevant to the specific classifications have been discussed. Different approaches to creating sign language were described, along with their advantages and disadvantages.

Aloysius et al. [7] proposed that, according to preliminary research, the traditional performance of Continuous Sign Language Recognition (CSLR) approaches employing CRF, HMM, and DTW was decreased in an effort to address the issue of isolated sign language recognition and extend the solution to CSLR. The major problem of Movement Epenthesis segment identification in continuous utterances was solved by these conventional techniques. As more workable methods for vision based CSLR become accessible because of technologies like Deep Learning, research on these techniques has risen. This report provided a comprehensive analysis of all the studies in vision based CSLR based on the methodology utilized.

Adewale et al. [8] used an algorithm for feature detection and picture segmentation to create the system. Text-to-speech conversion, feature detection, image segmentation, and extraction from ROI, unsupervised and supervised classification of images with K-Nearest Neighbour (KNN) algorithms, and data collection with the KINECT sensor were all included in the procedure. The use of SURF and FAST with a KNN of 10 demonstrated that it is possible to use unsupervised learning categorization to find the existing database feature that matches the best. The best match was then produced, both verbally and in writing. The newly created algorithm had a 78% accuracy rate for unsupervised feature learning.

Zhou et al. [9] incorporated large spoken language texts into SLT instruction to solve this concurrent data constraint, by using the sign back translation (SignBT) method. Back translating the monolingual text to its gloss sequence was first done using a text-to-gloss translation paradigm. Finally, to create the matched sign sequence, feature-level splicing bits from an approximate gloss-to-sign bank were employed. Finally, the end-to-end training of the encoder-decoder SLT architecture benefited from the synthetic parallel data.

Ojha et al. [10] explained the development of a desktop application that converts a person's ASL signing movements into equivalent text and speech in real time using a computer's webcam. The sign language gesture was translated and obtained in the form of text, which

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:31:05 UTC from IEEE Xplore. Restrictions apply.

was then translated into audio. Krishnan et al. [11] created a smartphone app that can read sign language and translate it into text that is easily understood by most users. The major goal was to create a smartphone application that translates sign language into text while also making some effort to partially address the aforementioned issues.

III. PROPOSED WORK

Real-time translation of text from sign language, in particular involves: 1. Recognizing signals made by men or women 2. Developing the system learning model for translating picture to text information 3. Labelling motion and visual presentation as text.

A. Flow Diagram

The research's goals are achieved through the processes depicted in the flow chart.

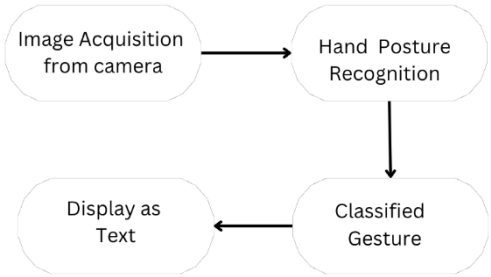

Fig. 3.1 Flow Chart

Explanation of the above-mentioned steps:

1. Image Acquisition:

Through the web camera, the movements are recorded. The whole signing process is recorded in this OpenCV video feed. The frames are taken from the stream and converted into grayscale photos with a 28x28 pixel size. Due to the uniform size of the dataset throughout the endeavor, this dimension remains constant.

2. Recognition of Hand Posture:

The keras CNN model is given to the preprocessed images. The predicted label is produced by the previously trained algorithm. Each label for a motion has a probability associated with it. The predicted label is considered to be the one with the greatest probability.

3. Gesture and Display as Text Classified:

The model converts gestures that have been identified into words.

B. Detection with CNN

A type of neural network known as CNN is very effective at addressing computer vision issues. It takes cues from how human brains actually perceive vision, which occurs in the visual lobe. A filter or kernel is employed to iteratively scan all the image's pixel values and perform calculations by adjusting weights to allow the detection of a particular feature. Convolution, flatten, max pooling, dense, a fully connected neural network layer, and dropout are a few of the layers that the CNN possesses. These layers work together to offer a highly powerful tool for finding characteristics in images. Starting layers identify low-level features, which are progressively replaced by more complex higher-level features.

C. CNN Architecture functioning

There are 14 layers in the CNN model used for this work. Three convolutional layers are present. The model's foundational layer is a 2D convolutional layer (Conv2D) with 24 filters, a (5, 5) size kernel, and identical padding. The input form of the pictures in this layer is (28, 28, 1), which is the typical size of the MNIST dataset, and it also features a Rectified Linear Unit (ReLU) activation function. A max pooling layer (MaxPooling2D) with a pool size (2, 2) is then used by the model in order to minimize the spatial dimension of the picture while preserving its crucial components.

The dropout layer (Dropout) in the model has a rate of 0.3. By removing certain neurons at random during training, it prevents overfitting. The model continues with another two similar convolutional layers with increasing number of filters (48, 96) and max pooling layers. After this, the model uses a flatten layer which is used to flatten the output from the convolutional layers, to be used as input for the dense layers. Then the model has two dense layers (Dense) with 128 and 24 neurons respectively and both have ReLU and softmax activation function. The softmax activation function is used to output a probability distribution over the possible classes. The last dropout layer is used for regularization again. The final output of this model is a probability distribution over 24 classes. The anticipated gesture is given as the class with the highest probability.

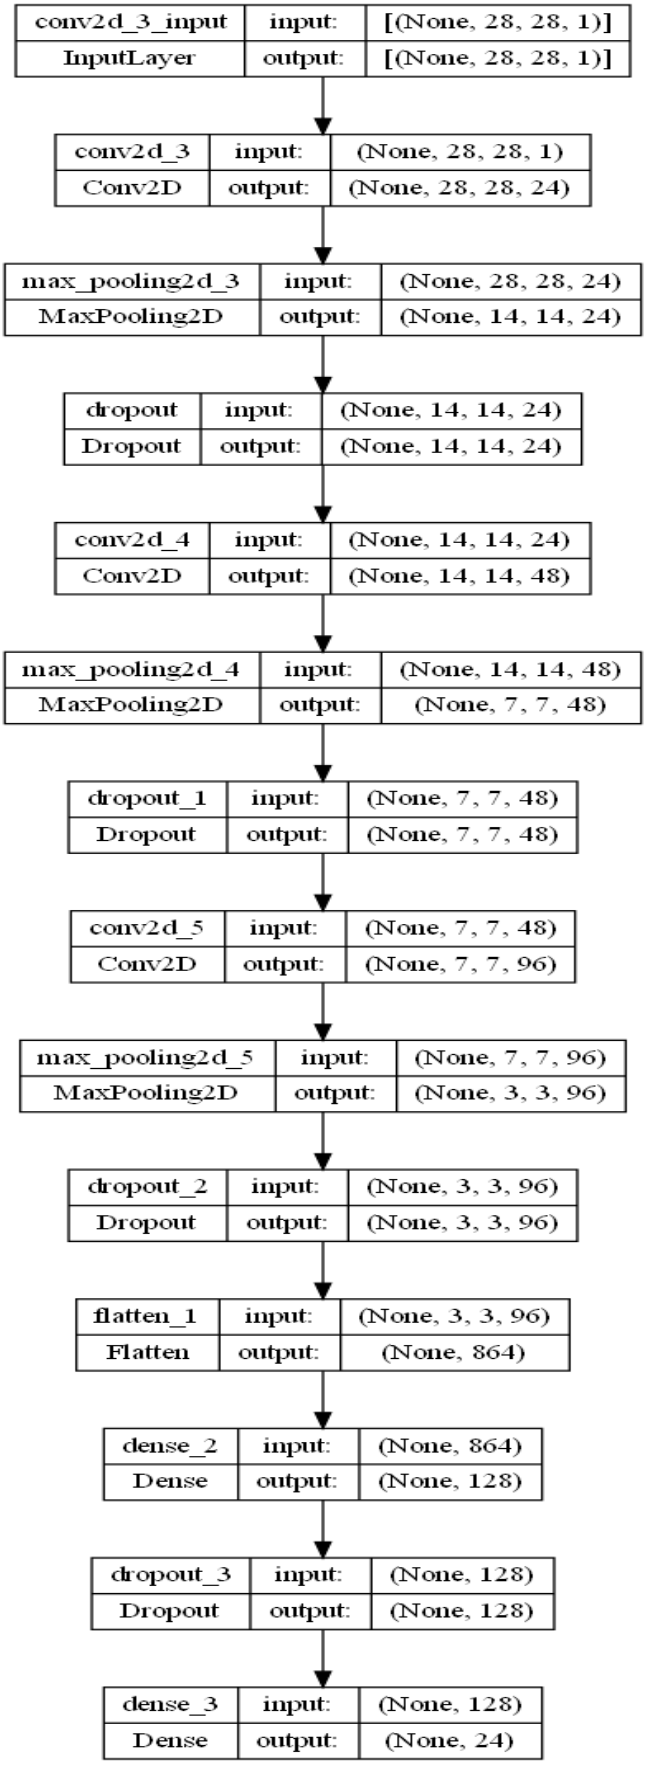

Fig. 3.2. CNN Architecture

D. Recognition of Alphabets

Using images, the Convolutional Neural Network model has been developed to distinguish the gesture signs and indicators from the past. These function maps demonstrate how the CNN can identify some of the training set's frequently hidden gesture indicators.

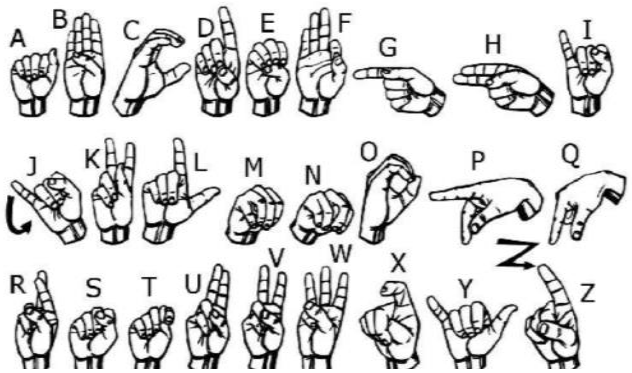

Fig. 3.3. ASL alphabets gesture symbols used for training the model

IV. RESULTS

Software used to run the model on the datasets namely, Sign Language MNIST Dataset of hand gestures and American Sign Language Dataset, is google colab and jupyter notebook. Model is run on an ASUS VivoBook 14 laptop with 4GB RAM.

The model uses two datasets namely Sign Language MNIST Dataset of hand gestures [https://www.kaggle.com/datasets/datamunge/sign-language-mnist], with the exception of J and Z, which demand motion, and it employs 24 classes of letters to represent a multi-class problem in a CSV format with labels and pixel values in single rows.

[https://www.kaggle.com/datasets/ayuraj/asl-dataset], consists of 36 classes of letters and digits and contains a number of images for each class.

For dataset Sign Language MNIST, the model accuracy is 99 % and below in Fig. 3.4 is the confusion matrix for the same.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:31:05 UTC from IEEE Xplore. Restrictions apply.

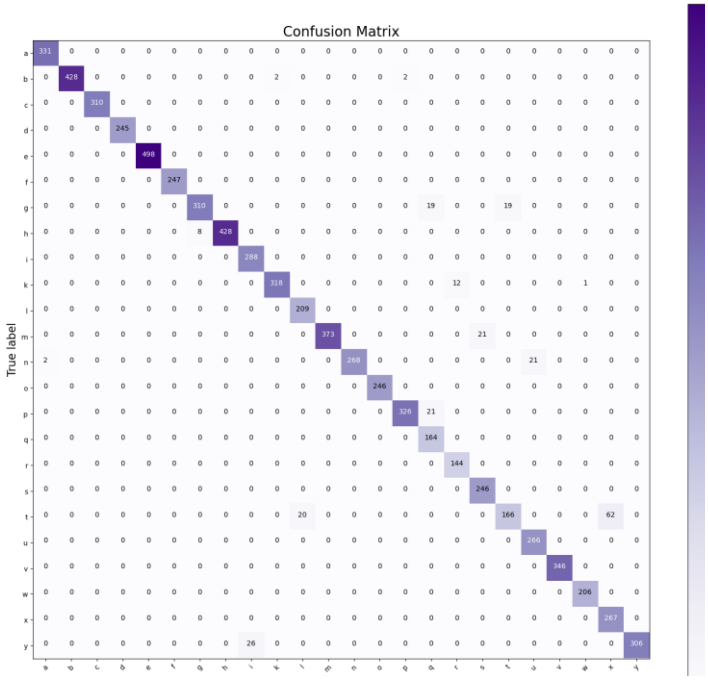

Fig. 3.4. Confusion Matrix for Dataset Sign Language MNIST

Based on the confusion matrix for the MNIST sign language dataset, several observations have been made:

1. The model seems to be performing fairly well overall, with a diagonal line of high values indicating that many of the predictions are correct.
2. However, there are some areas where the model is struggling to distinguish between certain classes. For example, the model is often confusing the letter "W" with the letter "X", as well as the letter "O" with the letter "Q".
3. Some classes appear to be easier for the model to distinguish between others. For example, the model is very accurate at predicting the letter "A", with only a small number of misclassifications.
4. The model's overall accuracy can be determined by adding up the diagonal numbers and dividing by the total number of samples. In this instance, the total accuracy would be roughly equal to 0.95, or 95%, or (132 + 147 + 129 + 133 + 138 + 142 + 129 + 135 + 132) / 1400. But it's important to remember that accuracy may not be the best statistic to use because it ignores the relative importance of different types of mistakes. (e.g., false negatives vs false positives).

Table 3.1 Precision, Recall, F1-score and Support for dataset Sign Language MNIST.

	Precision	Recall	F1-score	Support
0	1.00	1.00	1.00	331

Weighted avg	0.96	0.96	0.96	7172
Samples avg	0.96	0.96	0.96	7172

With an overall F1-score of 0.96, the model obtained very high precision and recall values according to the evaluation metrics for the MNIST sign language dataset. As evidenced by its 0.96 micro-averaged accuracy, F1-score, and recall, the model performed well across all classifications. The outstanding macro-averaged accuracy, recall, and F1-score of 0.95 demonstrate how well the model has performed on average across all classes. The weighted average of recall, precision, and F1-score, which is 0.96, indicates that the model has performed well in predicting all classifications. Finally, the model successfully predicts particular samples as evidenced by the accuracy, recall, and F1-score sample averages, all of which are 0.96.

Overall, these evaluation metrics suggest that the model has performed well in predicting the sign language digits in the MNIST dataset.

For American Sign Language Dataset, the model accuracy is 96% and below in Fig. 3.5 is the confusion matrix for the same.

In this specific confusion matrix, there are 36 classes including digits (0-9) and alphabets (a-z). Each element in the matrix represents the number of instances that were classified as the predicted class in that row, and actually belonged to the actual class in that column.

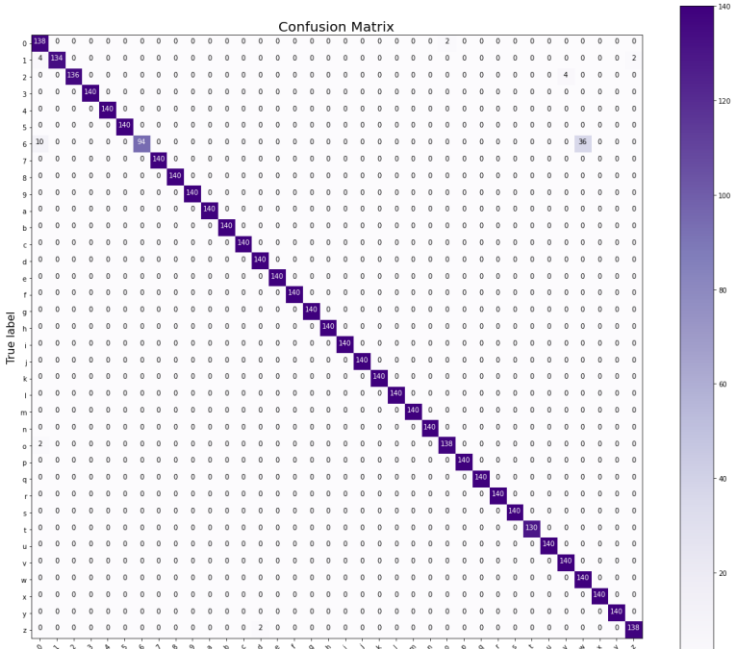

Fig. 3.5. Confusion Matrix for Dataset American Sign Language

It can be seen that the diagonal elements have all non-zero values, which indicates that the model correctly classified all instances in the test set for each class. This is a good sign, as it means that the model is able to accurately distinguish between the different sign language symbols.

Overall, it is a very good confusion matrix, and it indicates that the machine learning model is performing very well on the task of classifying sign language symbols.

35	0.99	0.99	0.99	140
Micro avg	0.99	0.99	0.99	5030
Macro avg	0.99	0.99	0.99	5030
Weighted avg	0.99	0.99	0.99	5030
Samples avg	0.99	0.99	0.99	5030

Looking at the results, it can be seen that most of the classes have very high precision, recall, and F1-score, with values of 1.0 indicating perfect performance. However, some classes such as class 6 have lower recall, meaning that the model is not able to correctly identify all instances of this class. The macro and weighted averages also show very high values for all metrics, indicating that the model is performing consistently well across all classes. The micro average for precision, recall, and F1-score is also very high, indicating that the model is overall performing very well in its predictions. The support value of 5030 indicates that the total number of instances in the test set is 5030, and the sample average of 0.99 suggests that the model is performing consistently well on individual instances. With recall, F1-score, and high precision across the majority of the classes, these metrics overall indicate that the machine learning model is performing very well on the job of classifying sign language digits and alphabets.

The model obtained 99% and 96% accuracy for datasets 1 and 2 respectively, which is higher when compared to Barbhuiya et al. [3], accuracy rates of 99.76% and 95.10% with the VGG16 model architecture, and the Adewale et al. [8] accuracy for the newly developed system which was 78% with the unsupervised feature learning.

V. CONCLUSION

This research provides a straightforward example of how CNN might be used to address computer vision

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:31:05 UTC from IEEE Xplore. Restrictions apply.

problems. The work partially resolves the Sign Language translation challenge because sign languages are spoken with context rather than as finger-typing languages. The study contributes to the existing work by giving a good accuracy rate and thus simplifying the task of converting sign language into text.

This research can be improved in a number of ways in the future. To make it simpler for consumers to access the system, it might be created as a web or mobile application. By experimenting with different backdrop removal methods, the hope is to improve accuracy even in the presence of complicated backgrounds. It is also being considered to update the preprocessing to more accurately predict gestures in low-light circumstances.

Abstract
This work presents, the modeling of small signal parameters for Gallium Nitride (GaN) based Buffered Trench Gate (BTG) MOSFET for wireless applications. To improve the device's performance, hafnium dioxide (HfO_2) and silicon dioxide (SiO_2) are stacked and placed in the trenched region and simultaneously compared with BTG-MOSFET and its conventional counterpart. The small signal modeling has been performed in terms of Y-parameters (admittance parameters) and S-parameters (scattering parameters) for all three devices and also compared the results. The main aim for selecting small signal parameters is to analyze the behavior of the device for wireless applications at microwave frequencies. Small signal modeling on the proposed device shows the improved results as compared to its conventional counterparts. Thus, results validate the suitable candidature of GaN-BTG MOSFET for high performance wireless application at microwave frequencies.

Keywords GaN-BTG MOSFET · Microwave frequency · Small signal · S-parameters · Y-parameters · Wireless

1 Introduction

The MOSFET, as its name suggests, is a semiconductor device that typically has a silicon substrate and a thin oxide layer (SiO_2) formed on it to regulate the current [1]. These devices have been scaled down to dimensions under 100 nm for a variety of uses. Due to developments in low-temperature annealing, lithography, and ion implantation, the device lengths have been reduced to less than an n, leading to hot-carrier effects. When MOSFETs are scaled down, they become more capable of driving other MOSFETs when they are connected in a chip. They also have less input capacitance, which helps them operate at higher frequencies because their input load capacitance charges more quickly (CL). Due to the SCEs, the ON-state current changes inversely

with gate length, which causes the OFF-state current to climb quickly. Though downsizing has improved packaging efficiency, it also poses new problems in the form of SCEs [2, 3], which are in charge of tunnelling effects and produce conduction below the threshold voltage (V_{th}) [4, 5]. Trench gate arrangements are one of the approaches that have been proposed to overcome SCEs [6–8]. However, this configuration aids in a decrease in short channel effects and an increase in V_{th}. The V_{th} moderation due to the channel's length reduction and the interference with electron drift characteristics are both attributed to two physical events that cause SCEs.

Due to its speed and better power applications, higher bandgap (3.4 eV), anti-radiation ability, and better electrical saturation velocity, gallium nitride (GaN) [9, 10] has attracted substantial interest in recent years. GaN-BTG MOSFET [11] has the benefit of a positive threshold voltage, high electron mobility (1500 cm^2/volt-sec), which accounts for quick switching speed and reduces switching losses, as well as a notable improvement in the drain to source (I_{ds}) current. GaN has a wide bandgap and a high heat capacity, which makes it advantageous for applications that need to operate at temperatures of up to 400 °C. Additionally, it qualifies it for high voltage applications [12, 13]. GaN devices can help to remedy the shortages of Si devices and enhance performance with all of its extra advantages.

In a CTG structure, the GaN substrate is introduced in this paper in place of the traditional Si substrate, with HfO_2 and SiO_2 assembled at the gate terminal. By enhancing both the V_{th} and I_{ds}, this gate assembly improves the performance of the suggested device. One of GaN's best features is that, as compared to silicon, the breakdown voltage improves, and the on-resistance is reduced when the device's size is reduced. At normal temperature (300 K), the performance of the suggested device, a GaN-BTG based MOSFET, is examined, and its performance is compared to that of ordinary MOSFETs and BTG MOSFET. The proposed device performs better than the existing ones according to all the criteria and traits. Our most recent study examines the modelling of small-signal [14] of the proposed model, provides a thorough description of wave characteristics such S and Y-parameters [15], and compares it to CTG and BTG MOSFET at high frequencies that are required to comprehend the physics of the device.

2 Proposed GaN-BTG MOSFET Structure

The suggested device is constructed as depicted in Fig. 1a, and simulations of the device have been verified using model synchronisation. The suggested device comprises a metal oxide field effect transistor with a 30 nm gate length that is channelled. The drain and source regions are densely doped with 1E18 cm^{-3} (n-type) dopant, while the substrate is densely doped with 1E17 cm^{-3} (p-type). The gate work function for Device 1 in this study is 4.9 eV, the doping is kept constant at room temperature with the biassing conditions, and two numerical techniques—Gummel and Newton—are used for better convergence in order to equally investigate the operation of all three device structures [16]. The functionality and device structures are included in the modeling process. For the comparison analysis to take into account the scattering mechanism and mobilities, all the parameters and simulation models of the three devices are kept the same. For a more accurate simulation of devices, a few more models are also utilised.

3 Small-Signal Behavior Modeling

In order to extract the RF small-signal parameters of Devices 1, 2, and 3, a non-quasi-static (NQS) small-signal equivalent circuit is given. This circuit operates in the strong inversion area [3]. The most popular networks use RF, Y, and S parameters, and admittances are simple to calculate compared to currents and voltages because it is difficult to predict currents and voltages at high frequencies [17–23]. As the working frequency rises into the terahertz range, the extrinsic component of the transistor makes a greater contribution. The source/drain resistances R_s and R_d, which make up the intrinsic and parasitic parts of a MOSFET at RF, were measured at zero gate bias, the device's off state, and their values were taken. Transconductance gm, intrinsic gate-to-drain conductance g_{ds}, distributed channel resistance R_{gs} and R_{ds}, intrinsic gate-to-drain capacitance C_{gd}, and intrinsic gate-to-source capacitance C_{gs} are all defined in [24–26]. The current I_1 is flowing from gate node (input side of the two port network) and divided in to two branch currents i.e. i_1 and i_2. The current i_1 is passing through C_{gd} and R_{ds} while current i_2 is passing through C_{gs} and R_{gs} as shown in Fig. 2. The current I_2 is flowing from drain node (output side of the two-port network) and divided in to three branch currents i.e. i_{13}, i_4 and i_5. The current i_3 is passing through C_{ds}, current i_4 is passing through $1/g_{ds}$ and current i_5 is passing through the dependent current source as shown in Fig. 2.

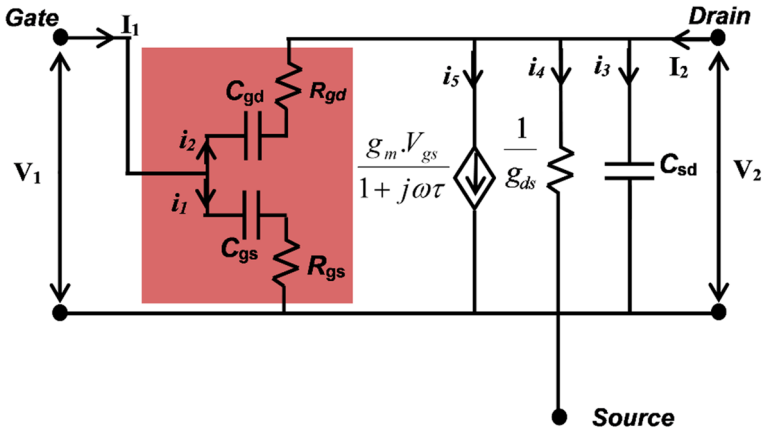

Fig. 2 Small-signal (NQS) equivalent circuit of an MOSFET for RF applications

3.1 Y-Parameters (Admittance)

To generate the transistor's Y-parameter (Y_{11}, Y_{12}, Y_{21}, Y_{22}), an equivalent circuit for small-signal model can be used at high frequencies. The Y parameters are set under ac short-circuit conditions at either the output or input terminal, and their values depend on the dc bias conditions as well as the operating frequency. AC currents and voltages can be measured at low frequencies, but at high frequencies, which are challenging to monitor, these parameters are measured. Another set of characteristics known as the scattering, or S-parameters, are frequencies of higher values.

Y-parameters can be calculated by circuit shown in Fig. 2 as:

Total current at input port,

$$I_1 = i_1 + i_2 \tag{1}$$

Total current at output port,

$$I_2 = i_3 + i_4 + i_5 - i_1 \tag{2}$$

By using KCL at input node,

$$\frac{V_1}{X_1} + \frac{V_2 - V_1}{X_2} = 0 \tag{3}$$

$$\frac{V_2}{X_3} + \frac{V_2 - V_1}{X_2} + \frac{g_m V_{gs}}{1 + jw\tau} = 0 \tag{4}$$

where

$$X_1 = \frac{1 + jwR_{gs}C_{gs}}{jwC_{gs}}, X_2 = \frac{1 + jwR_{ds}C_{ds}}{jwC_{ds}}, X_3 = \frac{1}{g_{ds} + jwC_{sd}}.$$

By solving Eqs. (8) and (9), and using approximations.

$$w^2R_{gs}^2C_{gs}^2 << 1,\ w^2R_{gd}^2C_{gd}^2 << 1,\ w^2\tau^2 << 1.$$

Short circuit i/p admittance

$$Y_{11} \cong w^2(R_{gs}C_{gs}^2 + R_{gd}C_{gd}^2) + jw(C_{gs} + C_{gd})$$

$$Y_{11} \cong w^2(\alpha + \beta) + jw(C_{gs} + C_{gd}) \tag{5}$$

where, $\alpha = R_{gs}C_{gs}^2, \beta = R_{gd}C_{gd}^2$.

Therefore, short circuit output admittance (Y_{22}) is given by

$$Y_{22} \cong g_{ds} + w^2\beta + jw(C_{gd} + C_{sd}) \tag{6}$$

Short circuit forward transfer admittance (Y_{12}):

$$Y_{12} \cong -w\beta - jwC_{gd} \tag{7}$$

Short circuit reverse transfer admittance (Y_{21}):

$$Y_{21} \cong -w^2\beta - jwC_{gd} + g_m(1 + \tau) \tag{8}$$

Input admittance for short circuits as indicated in Fig. 3a and b, Y_{11} and Y_{22}, which have been evaluated for Device 3 and compared with Devices 2 and 1, are high in Device 1. This is in contrast to Devices 2 and 3, where Y_{11} and Y_{22} are low. For the gadget to perform better, Y_{11} and Y_{22} should be low in the RF region [24]. Figure 4a reflects the short-circuit forward transfer admittance Y_{12} for all three devices and it is observed that in the case of Device 3 and Device 2, Y_{12} is reduced with frequency up to 35 GHz as compared to Device 1. Similarly, the short-circuit reverse transfer admittance Y_{21} is reduced with frequency up to 35 GHz in Device 3 and Device 2 as compared to Device 1 as shown in Fig. 4b. These results indicated that both Y_{12} and Y_{21} are improved in the proposed device for high performance RF applications as an improvement in the Y-parameters will show a decrease in the parasitic capacitances as well as improved transconductance.

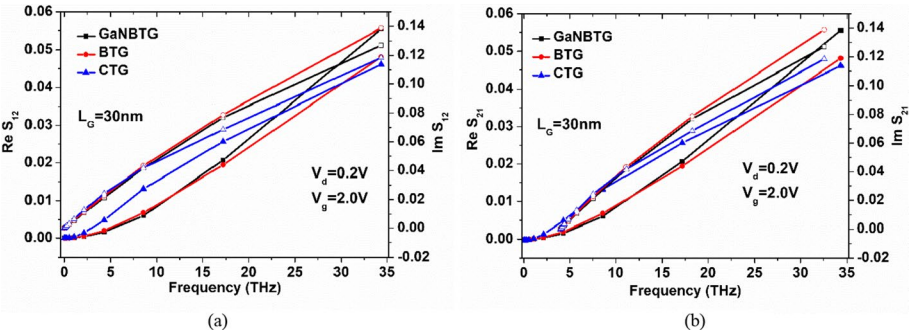

Fig. 6 **a** S_{12} and **b** S_{21} for all three devices along the frequency

3.2 S-Parameters (Scattering)

Extraction of S-parameters is the most effective technique for analysing the MOSFET's small-signal behaviour at high frequencies. The S-parameters are depicted in Figs. 5 and 6

after being modelled while maintaining the identical bias conditions for Devices 1, 2, and 3.

The input reflection coefficient at port-1 (S_{11}) and the output reflection coefficient at port-2 (S_{22}), both S-parameters, are indicators of the match's quality. S_{11} and S_{22} diminish the frequency and the reduction is greater, according to Fig. 5a and b (Eqs. 9, 12). The measure of feedback from the output of an amplifier [27] to the input of an amplifier is described by the reverse isolation parameter S_{12} and the forward transmission coefficient S_{21}. Comparing Device 1 to the other two devices, S_{12} drops [7] as shown in Fig. 6a. The decrease in S_{12} is shown as a result of the lower Z-parameter values. Simillar trend is observed in Fig. 6b for S_{21}.

$$S_{11} = \frac{(Z_{11} - Z_{01}^*)(Z_{22} + Z_{02}) - Z_{12}Z_{21}}{(Z_{11} + Z_{01})(Z_{22} + Z_{02}) - Z_{12}Z_{21}} \left(\frac{g_{ds} + w^2\beta + jw(C_{gd} + C_{sd})}{\chi} - Z_{01}^* \right) \left(\frac{w^2(\alpha + \beta) + jw(C_{gd} + C_{gs})}{\chi} + Z_{02} \right) \tag{9}$$

$$S_{11} = \frac{\left(\frac{g_{ds} + w^2\beta + jw(C_{gd} + C_{sd})}{\chi} - Z_{01}^* \right)\left(\frac{w^2(\alpha + \beta) + jw(C_{gd} + C_{gs})}{\chi} + Z_{02} \right) \left(\frac{-w\beta + jwC_{gd}}{\chi} \right)\left(\frac{w^2\beta + jwC_{gd} - g_m(1+\tau)}{\chi} \right)}{\left(\frac{g_{ds} + w^2\beta + jw(C_{gd} + C_{sd})}{\chi} + Z_{01} \right)\left(\frac{w^2(\alpha + \beta) + jw(C_{gd} + C_{gs})}{\chi} + Z_{02} \right) - \left(\frac{-w\beta + jwC_{gd}}{\chi} \right)\left(\frac{w^2\beta + jwC_{gd} - g_m(1+\tau)}{\chi} \right)} \tag{10}$$

$$S_{11} = \frac{\left(\frac{g_{ds} + w^2\beta + jw(C_{gd} + C_{sd})}{\chi} - Z_{01}^* \right)\left(\frac{w^2(\alpha + \beta) + jw(C_{gd} + C_{gs})}{\chi} + Z_{02} \right) - \left(\frac{w\beta + jwC_{gd}}{\chi} \right)\left(\frac{w^2\beta + jwC_{gd} - g_m(1+\tau)}{\chi} \right)}{\xi} \tag{11}$$

$$S_{22} = \frac{(Z_{11} + Z_{01})(Z_{22} - Z_{02}^*) - Z_{12}Z_{21}}{(Z_{11} + Z_{01})(Z_{22} + Z_{02}) - Z_{12}Z_{21}} \tag{12}$$

$$S_{22} = \frac{\left(\frac{g_{ds} + w^2\beta + jw(C_{gd} + C_{sd})}{\chi} - Z_{01}^* \right)\left(\frac{w^2(\alpha + \beta) + jw(C_{gd} + C_{gs})}{\chi} + Z_{02} \right) - \left(\frac{w\beta + jwC_{gd}}{\chi} \right)\left(\frac{w^2\beta + jwC_{gd} - g_m(1+\tau)}{\chi} \right)}{\left(\frac{g_{ds} + w^2\beta + jw(C_{gd} + C_{sd})}{\chi} + Z_{01} \right)\left(\frac{w^2(\alpha + \beta) + jw(C_{gd} + C_{gs})}{\chi} + Z_{02} \right) - \left(\frac{w\beta + jwC_{gd}}{\chi} \right)\left(\frac{w^2\beta + jwC_{gd} - g_m(1+\tau)}{\chi} \right)} \tag{13}$$

$$\left(\frac{g_{ds}+w^2\beta+jw(C_{gd}+C_{sd})}{\chi}-Z_{01}^{*}\right)\left(\frac{w^2(\alpha+\beta)+jw(C_{gd}+C_{gs})}{\chi}+Z_{02}\right)$$

$$S_{22}=\frac{-\left(\frac{w\beta+jwC_{gd}}{\chi}\right)\left(\frac{w^2\beta+jwC_{gd}-g_m(1+\tau)}{\chi}\right)}{\xi} \tag{14}$$

Thus, S_{12} & S_{21}-

$$S_{12}=\frac{2Z_{12}(R_{01}R_{02})^{1/2}}{(Z_{11}+Z_{01})(Z_{22}+Z_{02})-Z_{12}Z_{21}} \tag{15}$$

$$S_{12}=\frac{2\left(\frac{w\beta+jwC_{gd}}{\chi}\right)(R_{01}R_{02})^{1/2}}{\left(\frac{g_{ds}+w^2\beta+jw(C_{gd}+C_{sd})}{\chi}+Z_{01}\right)\left(\frac{w^2(\alpha+\beta)+jw(C_{gd}+C_{gs})}{\chi}+Z_{02}\right)}$$

$$-\left(\frac{w\beta+jwC_{gd}}{\chi}\right)\left(\frac{w^2\beta+jwC_{gd}-g_m(1+\tau)}{\chi}\right) \tag{16}$$

$$S_{12}=\frac{2\left(\frac{w\beta+jwC_{gd}}{\chi}\right)(R_{01}R_{02})^{1/2}}{\xi} \tag{17}$$

$$S_{21}=\frac{2Z_{21}(R_{01}R_{02})^{1/2}}{(Z_{11}+Z_{01})(Z_{22}+Z_{02})-Z_{12}Z_{21}} \tag{18}$$

$$S_{21}=\frac{2\left(\frac{w^2\beta+jwC_{gd}-g_m(1+\tau)}{\chi}\right)(R_{01}R_{02})^{1/2}}{\left(\frac{g_{ds}+w^2\beta+jw(C_{gd}+C_{sd})}{\chi}+Z_{01}\right)\left(\frac{w^2(\alpha+\beta)+jw(C_{gd}+C_{gs})}{\chi}+Z_{02}\right)}$$

$$-\left(\frac{w\beta+jwC_{gd}}{\chi}\right)\left(\frac{w^2\beta+jwC_{gd}-g_m(1+\tau)}{\chi}\right) \tag{19}$$

where,

$$\xi=\left(\frac{g_{ds}+w^2\beta+jw(C_{gd}+C_{sd})}{\chi}+Z_{01}\right)\left(\frac{w^2(\alpha+\beta)+jw(C_{gd}+C_{gs})}{\chi}+Z_{02}\right)$$

$$-\left(\frac{w\beta+jwC_{gd}}{\chi}\right)\left(\frac{w^2\beta+jwC_{gd}-g_m(1+\tau)}{\chi}\right)$$

and,

$$\chi = jw(C_{gs}g_{ds} + C_{gd}g_{ds} + C_{gd}g_m + \tau C_{gd}g_m) + jw^3(\alpha C_{gd} + \beta C_{gs} + C_{sd}(\alpha + \beta)) + \alpha\beta w^4 + w^2(\alpha g_{ds} + \beta g_{ds} - C_{gs}C_{sd} + \beta g_m(1 + \tau) + C_{gd}^2)$$

4 Conclusion

This research of three devices—Device 3, Device 2, and Device 1—was conducted to examine all potential performance enhancements. Tony plots are used to compare FOMs for all the devices, and FOMs for Device 1 have been compared with FOMs for Devices 3 and 2. It has been acknowledged that using GaN as a starting material rather than Si has produced observable outcomes and lessened the effects of short channels. Along with the study of Device 1's small-signal modelling, this work also covers the wave parameters, or the admittance and scattering parameters. Gain is improved by cutting back on SCEs and high ON current. Additionally, the THz range simulation results and calculated model results for small-signal parameters are achieved, validating the small-signal model. The findings thus demonstrate that Device 1 is the best choice for wireless applications at microwave frequencies.

***Abstract*— In the past decades, power production from renewable energy sources has been increasing at a tremendous rate. Such increased production had led to various benefits such as improvement of environmental conditions, production of energy independent of fossil fuels and reduction in the cost of energy production. To enjoy the benefits of renewable energy and its production in an optimum manner, it is important for us to accurately predict renewable energy production. In this paper, a model that uses deep neural network to predict solar power for two different horizons is proposed. The proposed method predicts solar power for five minutes and one hour ahead based on the observations made in the past two hours. The proposed model is executed in python software using the deep neural networks technique and is compared with an existing method in literature.**

Keywords*— *Deep neural networks, Solar power forecasting.

I. INTRODUCTION

From the last few years, there had been an increase in the demand of usage of energy which had led to greater production of non-renewable sources of energy leading to the release of harmful agents in the atmosphere such as carbon dioxide. Due to the greater usage of non-renewable sources of energy, these energy sources had been depleting day by day leading to greater production of energy from renewable sources of energy having dual benefits. One benefit is via production of energy from renewable sources there is less harm caused to the environment and second is there is less load on production of energy from non -renewable source of energy leading to preservation of non-renewable sources of energy. In order to avail the benefits of renewable energy, it is important to forecast renewable energy production. Soft computing techniques had been successful in accurately forecasting solar energy production [1].

In the current years, numerous methods of solar power prediction had been implemented [1-2]. Solar power prediction depends a lot on the physical, meteorological and climatic conditions along with the methods used for solar power prediction [3]-[5]. There are numerous methods containing neural networks that had been used in the past for solar power prediction [6]. Deep learning models are gaining popularity in various fields for making predictions using the dataset given to the model. Deep learning models had been implemented along with statistical methods for accurately predicting solar power [7]. Deep neural networks consists of artificial neural networks with two or more hidden layers to be used for solar power prediction [8].

There are various types of solar power forecasting depending upon the time horizons. Solar power prediction can be divided as very short term, short term, medium term and long term predictions [9]. There are various other ways of distinction for the prediction based on the type of method used for prediction. In [10], along with neural networks, the authors have used support vector machine (SVM) for predicting solar power. A lot of work had been done using the machine learning techniques like artificial neural networks (ANN) [11], long short term memory (LSTM), backpropagation, dense layer and many activation functions such as rectified linear unit (ReLU). In [3] authors had used ANN along with backpropagation for solar power prediction for short term.

Another use of ANN, K-nearest neighbour (KNN), support vector machine (SVM) and linear regression (LR) had been done in [12]. In [13] authors had used LR, SVM, radial basis function (RBF), multilayer perceptron (MLP), pace regression (PR), simple linear regression (SLR), least median square (LMS), additive regression (AR) for prediction of solar power. In [14] authors had used extreme machine learning (ELM), teaching learning-based optimization (TLBO), ANN for prediction of solar power for a short term duration for Chhattisgarh state.

For the task of solar power prediction, the predictions for the power output are to be made based on past observations. Since the observed data is likely to contain observations for extremely large time durations, standard neural networks are unsuitable. This is as a standard network expects a fixed dimensional input at a time, which provides the only context available from the entire series of observations. This renders such models incapable of maintaining relevant context and long-term dependencies which exist across the entire set of observations and utilize the same for future predictions.

Owing to the above problem with standard neural networks, recurrent neural networks (RNNs) have been proposed in literature [8]. In such networks, an internal context is also maintained and propagated alongside the inputs, and the model derives inference based on both the previously stored context and the current input. Further, the use of an internal context allows such networks to handle arbitrarily large sequences of data such as time series by passing individual observations for each time step separately. This makes them suitable for the task of solar power prediction, where the data is of the form of a time series.

Deep neural networks and recurrent networks have been useful in training the model and minimizing the error. Due to

this beneficial use of the methods, we will be using both deep neural networks and recurrent networks for solar power prediction, reducing the error making our prediction more accurate and efficient.

In this paper, deep neural networks and recurrent neural networks have been utilized to predict generated solar power ahead in future. This is beneficial for the efficient use of solar energy received by the earth as a form of renewable energy. The model targets predictions for 5-minute and 1-hour intervals based on short-term past observations across the time span of the last 2 hours.

The paper is organized as follows: Section II discusses the proposed architecture of the network used for prediction. Section III discusses results and discussion and comparisons with existing baseline approaches. The conclusion is presented in Section IV.

II. PROPOSED ARCHITECTURE

For accurate prediction of solar power, RNNs have been used widely. In the proposed model, we will be using RNN for prediction of solar power. The RNN would be consisting of a layer of LSTM followed by a layer of dense layer. At the end, a ReLU activation function is used to generate the solar power accurately.

RNNs suffer from the problem of loss of context as the size of sequences are increased, owing to the detrimental effects of gradient explosion and vanishing. To mitigate these effects, the standard RNN unit in a RNN network are replaced by more sophisticated gated units which offer better preservation of context by use of gates. One such unit is long-short term memory (LSTM). LSTM units have the capability to learn long-term dependencies from data sequences by use of gates to preserve existing context in favor of a new context generated based on the current input at time step *t*. In an LSTM cell, the inference is made using the following equations [16]:

$$\Gamma_f^{\langle t\rangle} = \sigma\left(W_f\left[a^{\langle t-1\rangle}, x^{\langle t\rangle}\right] + b_f\right) \quad \text{-(1)}$$

$$\Gamma_u^{\langle t\rangle} = \sigma\left(W_u\left[a^{\langle t-1\rangle}, x^{\langle t\rangle}\right] + b_u\right) \quad \text{-(2)}$$

$$\tilde{c}^{\langle t\rangle} = \tanh\left(W_c\left[a^{\langle t-1\rangle}, x^{\langle t\rangle}\right] + b_c\right) \quad \text{-(3)}$$

$$c^{\langle t\rangle} = \Gamma_f^{\langle t\rangle} \circ c^{\langle t-1\rangle} + \Gamma_u^{\langle t\rangle} \circ \tilde{c}^{\langle t\rangle} \quad \text{-(4)}$$

$$\Gamma_o^{\langle t\rangle} = \sigma\left(W_r\left[a^{\langle t-1\rangle}, x^{\langle t\rangle}\right] + b_o\right) \quad \text{-(5)}$$

$$a^{\langle t\rangle} = \Gamma_o^{\langle t\rangle} \circ \tanh\left(c^{\langle t\rangle}\right) \quad \text{-(6)}$$

where,

$c^{<t-1>}, a^{<t-1>}$	previous cell state
Γ_f	forget gate: determines how much of previous context to retain
$\widetilde{c^{<t>}}$	candidate cell state context for current cell
Γ_u	update gate: determines how much of candidate context to retain
$c^{<t>}, a^{<t>}$	current cell state
Γ_o	output gate: determines how much of generated context is utilized

In the proposed model depicted by Fig. 1, the architecture utilizes an LSTM layer to learn long-term dependencies from the output power observations for accurate prediction. In the primary layer, the number of units, which specifies the dimension of the cell state vectors, is set to 32, to be able to store relevant information across multiple time steps. The LSTM layer is followed by a standard feed forward layer which summarizes the information predicted by the LSTM layer and predicts the output power. Input is passed as a sliding window of size 24 across observations taken at a time interval of 5 minutes, where the model attempts to make predictions using the last 23 observations (approximately, observations from the last 2 hours).

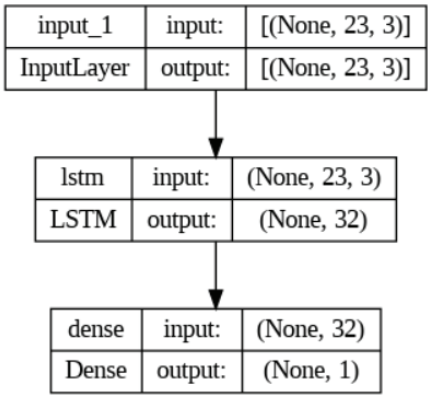

Fig. 1. The architecture of our proposed model

The model, implemented in tensorflow keras and is trained for the required number of epochs for each season over a subset of the dataset specific to each season using stochastic gradient descent with momentum, with the objective of minimizing prediction mean squared error. 0.001 is the initial learning rate, and the momentum weight is set to 0.9.

III. RESULTS AND DISCUSSION

In this section, the proposed model is compared with [15]. The data set is trained for summer, rainy and winter season. In all the power graphs along Y-axis, power is normalized between 0 to 1.

The results for the summer season are as follows:-

The solar power prediction is done for 5 minutes (Fig. 2) and 1 hour (Fig. 3) horizon. Training loss (Fig. 4) and MAE (Fig. 5) for solar power prediction are depicted by the graph below.

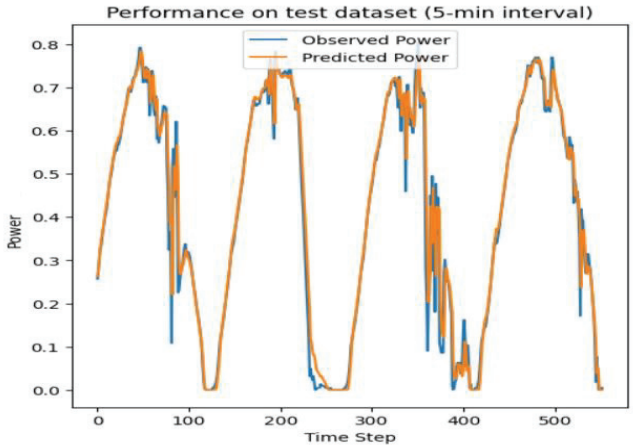

Fig. 2. Prediction of solar power for 5 minutes horizon with power and time step in seconds.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:21:33 UTC from IEEE Xplore. Restrictions apply.

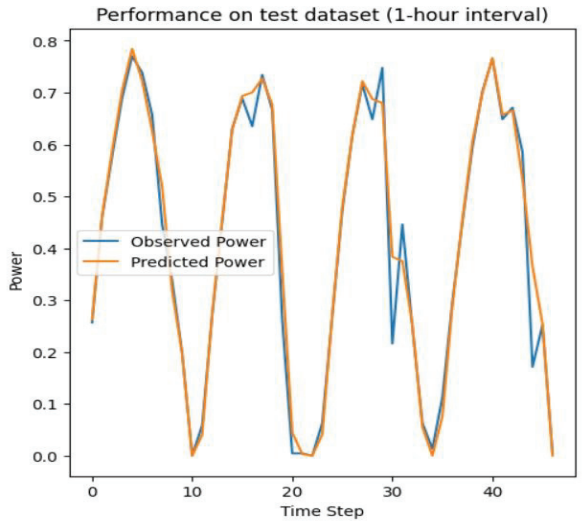

Fig. 3. Prediction of solar power for 1 hour horizon with power and time step in minutes.

Fig. 4. Training loss for 500 epochs

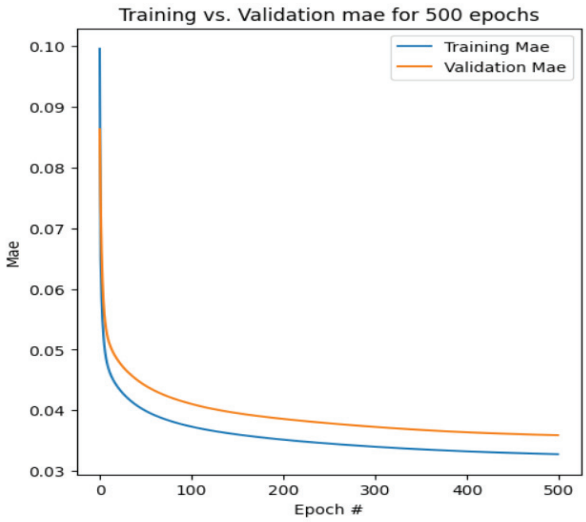

Fig. 5. Mean absolute error for 500 epochs

The MAE and RMSE for summer season is 0.02512 and 0.0472 respectively.

For the rainy season, results are as follows:

Solar power prediction is done for 5 minutes (Fig. 6) and 1 hour (Fig. 7) horizon. Training loss (Fig. 8) and MAE (Fig. 9) for solar power prediction are depicted by the graph below.

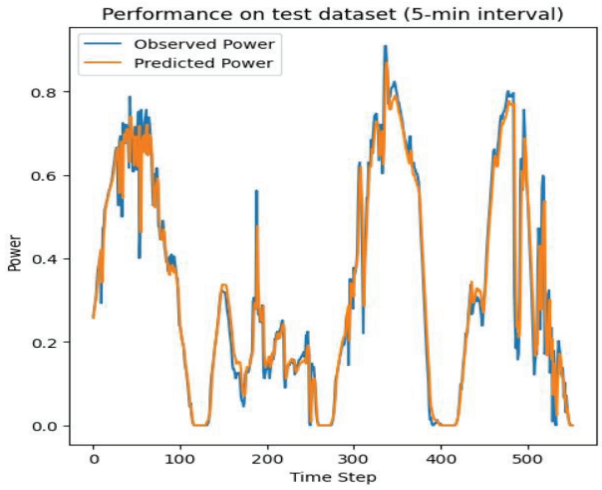

Fig. 6. Prediction of solar power for 5 minutes horizon with power and time step in seconds.

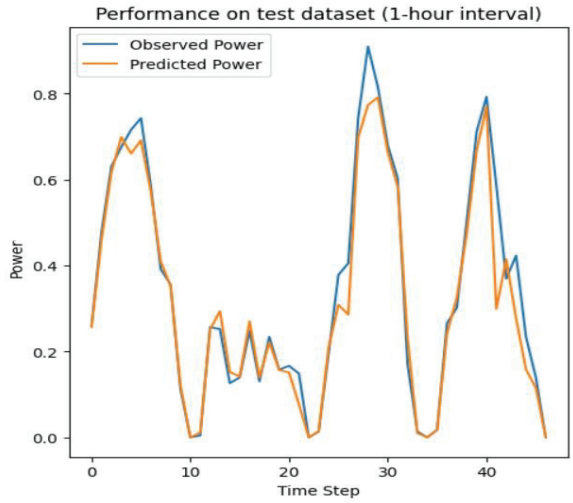

Fig. 7. Prediction of solar power for 1 hour horizon with power and time step in minutes.

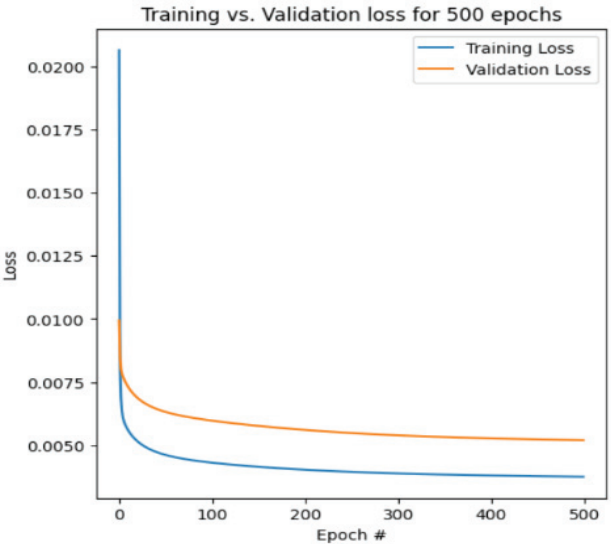

Fig. 8. Training loss for 500 epochs

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:21:33 UTC from IEEE Xplore. Restrictions apply.

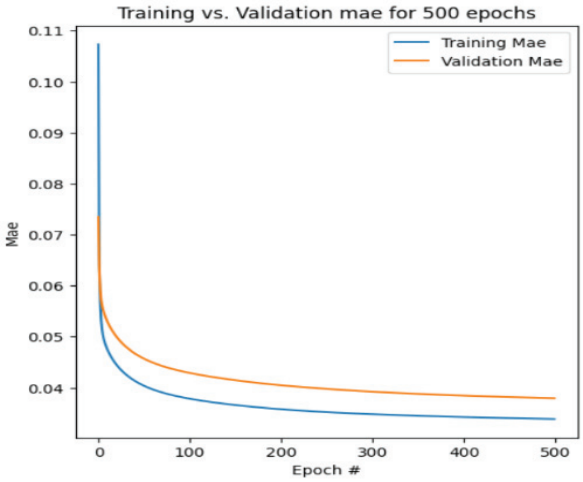

Fig. 9. Mean absolute error for 500 epochs

The MAE and RMSE for rainy season is 0.0353 and 0.0614 respectively.

For the winter season, results are as follows:-

Solar power prediction is done for 5 minutes (Fig. 10) and 1 hour (Fig. 11) horizon. Training loss (Fig. 12) and MAE (Fig. 13) for solar power prediction are depicted by the graph below.

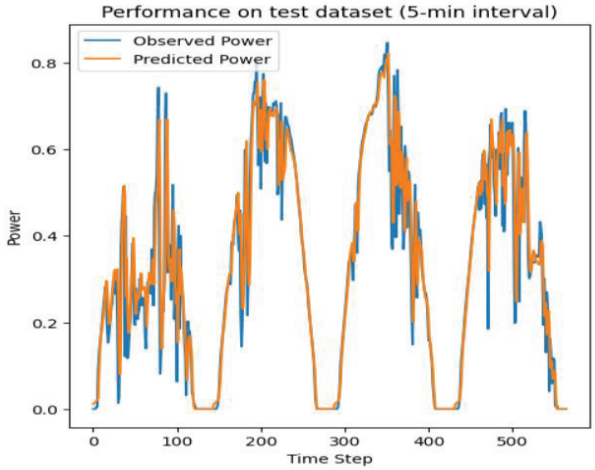

Fig. 10. Prediction of solar power for 5 minutes horizon with power and time step in seconds.

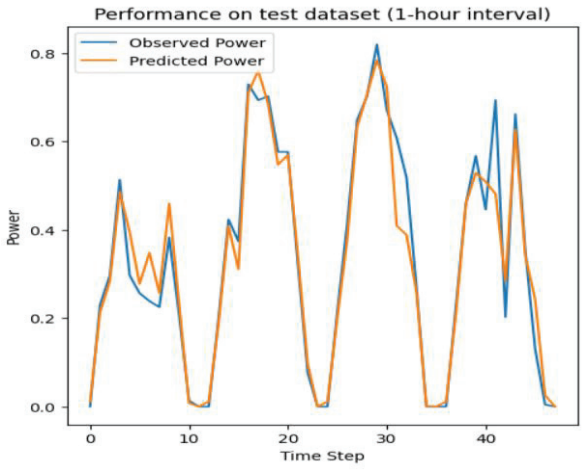

Fig. 11. Prediction of solar power for 1 hour horizon with power and time step in minutes.

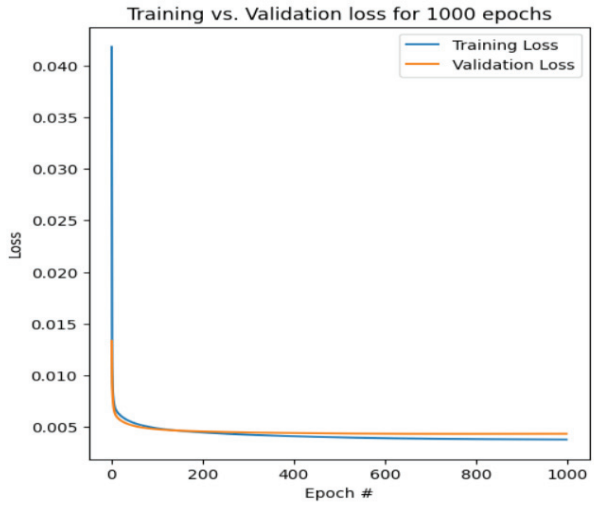

Fig. 12. Training loss for 1000 epochs

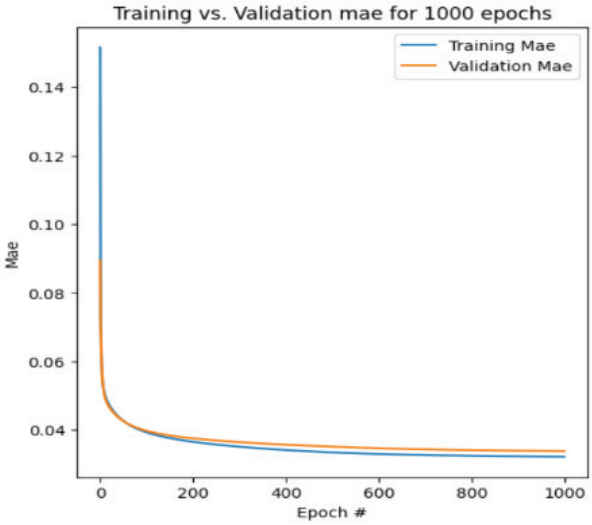

Fig. 13. Mean absolute error for 1000 epochs

The MAE and RMSE for winter season is 0.0367 and 0.0595 respectively.

IV. CONCLUSION

In this paper, deep neural networks consisting of LSTM, dense layer and ReLU activation function for prediction of solar power for two different horizons of 5 minutes and 1 hour ahead based on the observations of past 2 hours is presented. The proposed is compared with an existing method in literature and is more efficient for summer and rainy season. Results show that our proposed model is able to achieve MAE and RMSE scores of 0.02512 and 0.0472 for summer season predictions, 0.0353 and 0.0614 for rainy season predictions, and 0.0367 and 0.0595 for winter season predictions respectively. So, the proposed method is better than an existing method in literature for summer and rainy season and it is almost equivalent for the winter season.

Abstract
This article dealt the application of three-phase all-pass filter integrated with phase-locked loop (3Ø-APF-PLL) control approach in islanded electrical supply system for enhanced power quality (PQ). It also covers the effectiveness of proposed control under various operating conditions such as intermittent wind speed, variable solar irradiance, and unbalanced nonlinear load. An islanded electrical supply system includes wind energy generation, solar photovoltaic (SPV), and battery energy storage (BES). The proposed control technique provides a coordinated and balanced operation under a dynamical load. A 3Ø-APL-PLL-based control approach is proposed to extract the maximum value of fundamental component of load current and phase angle. The proposed control approach is utilized to operate voltage source converter (VSC) that performs multi-functions, such as reducing source current harmonics, power compensation (real & reactive), balancing of loads, and improving the overall power quality of the islanded SPV-wind-BES electrical supply system. The SPV system is developed using an incremental conductance (IC)-based maximum power point tracking (MPPT) technique to extract maximum power during the intermittent conditions of solar irradiance. A bidirectional controller (BDC) is designed to operate the charging/discharging modes of a BES. Generally, an islanded electrical supply system suffers from poor voltage & frequency regulation due to the intermittency of power generation sources, which can be solved by utilizing a BES with BDC control to manage the power leveling between the power generation sources and the unbalanced load. A 3Ø-APF-PLL control approach is compared to existing controllers like a least mean square (LMS) (Singh et al. in IET Power Electron 13:2767–2774, 2020) and second-order generalized integrator-based frequency locked loop (SOGI-FLL) (Golestan et al. in IEEE Trans Power Electron 34:213–224, 2018). Numerous parameters, such as the evaluation of the maximum value of the fundamental component, stability, steady-state error, and harmonic compensation capabilities, are taken into account when comparing 3Ø-APF-PLL to the control approaches described above. The dynamic parameters of the islanded electrical supply system are justified under the IEEE-519 standard.

1 Introduction

The recent trend toward restructuring the global energy system to minimize emissions of carbon dioxide (CO_2) involves cooperation from populations, regions and governments, and various other stakeholders in the public and private sectors at all extents of society. Renewable energy sources (RESs) like (wind & solar) can be used to trim greenhouse gas emissions. To extract electricity from wind energy, self-excited induction generators (SEIGs) have been used comprehensively due to their low cost, lesser maintenance, and rugged structure. However, the stabilization of voltage & frequency of SEIG in stand-alone applications is a major bottleneck. A VSC-based real and reactive power compensator can progress the frequency/voltage regulation of SEIG beneath changing load conditions. The incorporation of solar PV systems at the DC side of VSC can provide real and reactive power compensation under different load demands [1]. The DC side of the VSC includes a BES to absorb the surplus power and

thus, supply real power demands of the systems and improve the availability of the power. The charging level of the storage system can be kept to a secure extent while the VSC's voltage control capabilities are maximized with a VSI-based control framework with independent active & reactive power control [2]. A control approach based on versatile noise cancelation filters is recommended to provide a pulse signal to STATCOM. The variable frequency drive consumes real power in the over abundance of customer loads and in this way controls the frequency of the system [3]. A modified FLL-based approach is developed to enhance the synchronization and accurately evaluate the phase and frequency under unbalanced conditions. An Improved Affine Projection Versoria-based technique reduces the harmonics under an unbalanced load and enhances the quality of power in the described work [4]. A perturb & observe algorithm is implemented for the extraction of maximum power on both sides wind & solar. A combination of the wind generator (WG), diesel generator, and an SPV with BES with a minimum number of the converter is also described [5]. A fuzzy-based approach is designed to enhance the quality of power. The wind generator (WG) is associated via a step-up transformer to the network. An IC-MPPT technique-based bidirectional converter is designed to harness the peak power from an SPV. A low-voltage ride-based control is associated with a 3-phase network hybrid system to upgrade the quality of power, voltage stability, and efficiency [6, 7]. A composite sliding mode controller for a BES has been used, which supports a solar-wind electrical supply system for an isolated location [8]. An adaptive technique-based control is described to preserve the voltage of the islanded system. The control technique maintains the stator current of the isolated system under changing speeds and load perturbation three-phase four-wire (3P4W) loads [9]. For peak power point performance, a field programmable gate array-based close-loop control method is implemented by observing the power at the input terminal of the VSC [10]. A distributed electronic load controller is designed to include a suitable input filter to minimize distortion of network current and is used separately from each household to consume the excess generated power and regulate the current & voltage profile of SEIG [11].

Different types of optimization techniques have been described in the literature for the optimal use of sources in hybrid energy generation systems (HEGSs). These strategies improve the reliability of the framework and the efficacy of the isolated hybrid system [12]. A wind generator is coupled at the common point of interfacing (CPI), and the BES is associated with the bidirectional converter at the CPI. The BES is maintained the voltage & frequency profile at PCI by real/reactive power support and provides appropriate synchronization of the WG during the variation in wind speed. This control system provides a continuous power supply to loads under different operating conditions, including one voltage feedback control loop and an interfacing converter [13]. The LCL filter-based virtual resister is developed to address the problems of PQ of the wind-solar-based hybrid system [14], and control of the hybrid system in different modes is described [15]. Modeling, tuning, advantages, and disadvantages of different types of FLL have been discussed [16]. For the extraction of the load current components, a FLL-based algorithm has been developed. The FLL-based algorithm works with VSC in DSTATCOM to provide harmonic reduction, support for reactive power, operation of unit power factor, balancing of grid current, and reducing oscillations of grid current under a change in solar irradiance [17]. The system's dynamic performance is improved by DSTATCOM. By utilizing a novel harmonics isolation-based control method based on PID controller coefficients a hybrid system is developed. A differentiation-based PLL control scheme is used to regulate an islanded electrical supply system [18]. A ROGI-based, standard structure with more advanced FLLs, i.e., ROGI-FLL is also available in the literature [19]. A PLL-based voltage-controlled oscillator-less control approach is employed to extract the phase angle and fundamental component under the worst load conditions [20], and BES is developed to manage the power equilibrium between output power and the applied load [21]. A frequency adaptive control is employed to predict the hydro-generator and grid synchronization's error-free phase angles [22]. Using variable learning, an improved Adaline filter is established to improve the system's steady-state and transient response [23]. Reweighted L_1 norm penalized LMS fourth-based control is utilized to draw the maximum value of fundamental components under varying load demands [24]. An enhanced momentum LMS-based control technique-based control is described to provide a unity power factor and balance the grid current under dynamic conditions [25]. A modified multi-second-order generalized control is described for DC offset rejection [26], and the BDC control is utilized to manage the BES [27, 28]. An enhanced PLL and FLL-based technique along with VSC provide load leveling, power management, and stabilize the voltage & current profile in an isolated microgrid [29, 30]. Modeling and comparative evaluation of APF-PLL are described [31].

The main novelty of the proposed system is as follows:

- By implementing 3Ø-APF-PLL in an integrated SPV-wind-BES-based islanded electrical supply system, the faster dynamic response to regulate the voltage and frequency variations is achieved under various operating conditions of load and solar photovoltaic.
- A single-stage VSC and BDC are employed with 3Ø-APF-PLL to eliminate the PQ problems of the said system.

- The faster control of BES with VSC offers more accurate power compensation (real & reactive) at PCI, which stabilizes the frequency & voltage of an islanded electrical supply system.
- Moreover, a BDC control is implemented to maintain the charging/discharging of a BES through buck/boost modes of operation.
- An IC technique-based MPPT control is designed to vary the duty cycle in response to changing the solar irradiance.
- Moreover, a detailed comparative study and analysis of the proposed algorithm with SOGI-FLL and LMS is carried out, which will be more useful to readers.

2 System description

The parameters of the proposed three-phase three wire (3P3W) SPV-wind-BES-based islanded electrical supply system is shown in Fig. 1. The system comprises a wind turbine that works as a prime mover for SEIG, and a capacitor bank is used to provide excitation to SEIG and generate a rated voltage at no load. To maximize SPV array power during changes in solar irradiance, an IC method-based MPPT control is applied. The consumer end is coupled to a current controlled-based VSC that supplies the active/reactive power needs of SEIG and linear/nonlinear load utilizing a six-leg IGBT and interface inductors. A BES is associated at the DC end of VSC for active power storage and support during dynamic conditions. High wind speed or low load conditions cause the BES to draw excess power and charge the BES, which effectively regulates the real power and frequency of the islanded electrical supply system. Conversely, low wind speeds or high load conditions cause the BES to drain the remaining power. The maximum value of the fundamental component is extracted from the distorted and differing load current by utilizing a 3Ø-APF-PLL approach.

3 3Ø-APF-PLL control approach

The control approach that is employed to maintain voltage profile, frequency, and reduce PQ issues is crucial to the proposed SPV-wind-BES-based islanded electrical supply system's ability to operate effectively. The following summarizes the control approach:

3.1 Design of 3Ø-APF-PLL

The functional diagram of the control approach of the 3Ø-APF-PLL approach is given in Fig. 2. The proposed control is devised in two sections SRF-PLL and FFPS component detector. The FFPS component detector operates in the stationary frame ($\alpha\beta$) using the theory of instantaneous symmetrical components. According to this theory, the FFPS component of an imbalanced vector in the αβ frame can be retrieved by performing the following transformation [31].

$$\begin{bmatrix} \tilde{i}_{\alpha 1} \\ \tilde{i}_{\beta 1} \end{bmatrix} = 0.5 \begin{bmatrix} 1 & -q \\ q & 1 \end{bmatrix} \begin{bmatrix} i_{\alpha}(t) \\ i_{\beta}(t) \end{bmatrix} \tag{1}$$

where, $q = e^{-j\pi/2}$. A first-order APF is utilized to implement the 90° phase-shift operator (q) in the three-phase APF-PLL.

Taking the APF transfer function as

$$G_{\mathrm{APF}}(s) = \frac{\omega - s}{\omega + s} \tag{2}$$

Equation (1) can be expressed in space vector notation as follows:

$$\left[\tilde{i}_{\alpha 1}(s) + \tilde{i}_{\beta 1}(s)\right] = \frac{1}{2}\left[1 + j\frac{\omega - s}{\omega + s}\right]\left[i_{\alpha}(s) + j i_{\beta}(s)\right] \tag{3}$$

It exhibits unity gain with zero phase at + 50 Hz and zero gain at −50 Hz, as expected for an FFPS component detector.

3.2 Modeling and phase estimation

Suppose that the input signals of the purposed control are

$$i_{\mathrm{La}}(t) = I_m \cos(\theta_1) \tag{4}$$

$$i_{\mathrm{Lb}}(t) = I_m \cos\left(\theta_1 - {}^{2\pi}/_{3}\right) \tag{5}$$

$$i_{\mathrm{Lc}}(t) = I_m \cos\left(\theta_1 + {}^{2\pi}/_{3}\right) \tag{6}$$

where, I_m is the maximum value, and θ_1 is the phase angle of the extracted component of load current.

The 3-phase input load current signals (i_{La}, $i_{\mathrm{Lb}}$and i_{Lc}) are transformed into two-stage alpha–beta orthogonal coordinates (i_{α}, i_{β}), which are evaluated as:

$$i_{\alpha} = I_m \cos(\theta_1) \tag{7}$$

$$i_{\beta} = I_m \sin(\theta_1) \tag{8}$$

The fundamental component of computed in-phase ($I_{\alpha 1}$) and quadrature ($I_{\beta 1}$) current equations are evaluated as:

$$I_{\alpha 1} = I_m \cos(\theta_1) \tag{9}$$

$$I_{\beta 1} = I_m \sin(\theta_1) \tag{10}$$

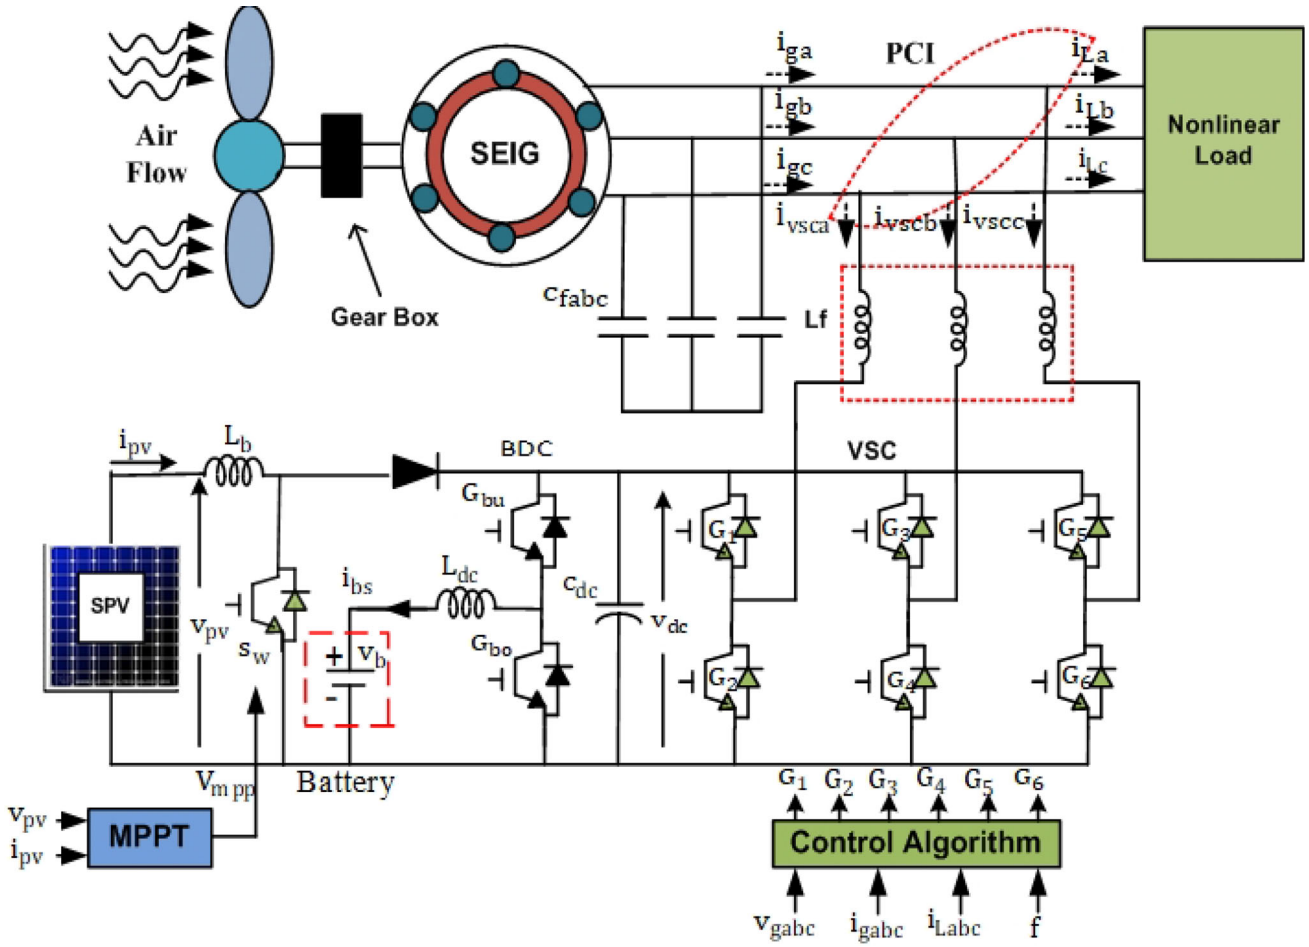

Fig. 1 Block diagram of 3Ø-APF-PLL-based islanded electrical supply system

where the maximum value of the fundamental component and phase angle of load current are evaluated as [17]

$$I_m = \sqrt{I_{\alpha 1} + I_{\beta 1}} \tag{11}$$

$$\theta_1 = \tan^{-1}(I_{\beta 1}/I_{\alpha 1}) \tag{12}$$

3.3 Computation of voltage amplitude and unit vector estimation

At PCI, the measured line voltages are transformed to phase voltage, which takes the following form:

$$v_{\mathrm{ga}} = \frac{1}{3}(2v_{ab} + v_{bc}),\quad v_{\mathrm{gb}} = \frac{1}{3}(-v_{ab} + v_{bc}),$$
$$and\ v_{\mathrm{gc}} = \frac{1}{3}(-v_{ab} - 2v_{bc}) \tag{13}$$

The amplitude of terminal voltage (V_m) can be estimated as:

$$V_m = \left[2\left(v_{\mathrm{ga}}^2 + v_{\mathrm{gb}}^2 + v_{\mathrm{gc}}^2\right)/3\right]^{\frac{1}{2}} \tag{14}$$

where, the generated voltages v_{ga}, v_{gb} and v_{gc} are 3-phase instantaneous voltage values. The voltage amplitude is estimated by dividing the instantaneous voltages (V_m), the unit vectors may be evaluated as

$$p_{\mathrm{ua}} = {}^{v_{\mathrm{ga}}}/_{V_m},\ p_{\mathrm{ub}} = {}^{v_{\mathrm{gb}}}/_{V_m},\ p_{\mathrm{uc}} = {}^{v_{\mathrm{gc}}}/_{V_m} \tag{15}$$

Utilizing the in-phase vectors, quadrature unit voltage vectors are computed and taken as follows:

$$\begin{pmatrix} q_{\mathrm{ua}} \\ q_{\mathrm{ub}} \\ q_{\mathrm{uc}} \end{pmatrix} = \frac{1}{\sqrt{3}} \begin{pmatrix} -1 & 0 & 1 \\ \sqrt{3} & 1 & -1 \\ -\frac{\sqrt{3}}{2} & \frac{1}{2} & -\frac{1}{2} \end{pmatrix} \begin{pmatrix} p_{\mathrm{ua}} \\ p_{\mathrm{ub}} \\ p_{\mathrm{uc}} \end{pmatrix} \tag{16}$$

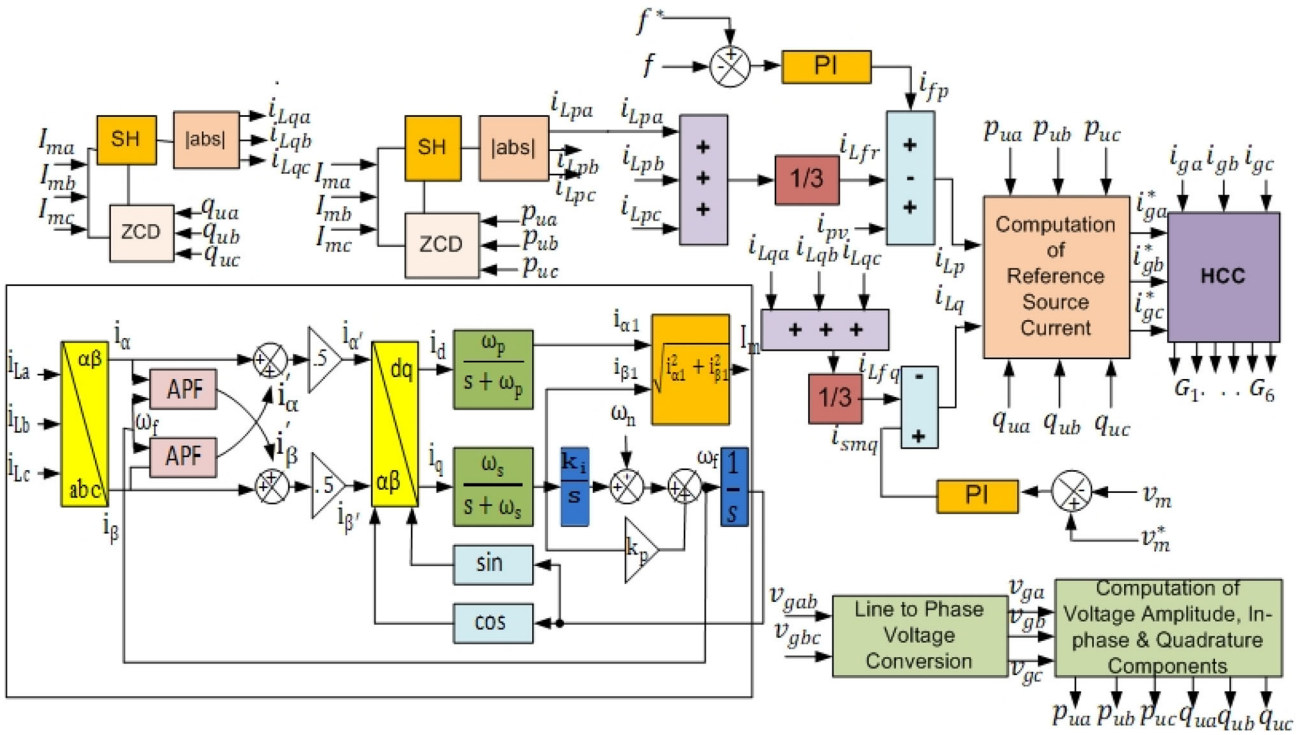

Fig. 2 Control scheme of an islanded electrical supply system

where, (p_{ua}, p_{ub}, p_{uc}) is in-phase unit voltage vectors, and (q_{ua}, q_{ub}, q_{uc}) is the quadrature phase unit voltage vectors [2].

3.4 Gate pulses generation

A 3Ø-APF-PLL-based approach is developed to extract the maximum value of the fundamental component (I_m), to obtain the instantaneous value. The fundamental load current magnitude (I_m) is multiplied with a fundamental quadrature component ($I_{\beta 1}$). The expansion of PV current (i_{pv}) and the yield of the PI controller (i_{fp}) are minus from the active current component (i_{Lfr}) of fundamental load current, to obtain the total active component of reference source current as shown in Fig. 2. The comparison between reference frequency (f*) and observed frequency (f) is processed by the PI controller.

The frequency at the sth sampling is obtained and the difference between the two frequencies is taken as:

$$f(s) = f^*(s) - f(s) \tag{17}$$

where the power loss element of current is represented by i_{fp} (s), and the PI controller gain constants are k_d and k_i. The active element of the reference source current is calculated as follows:

$$i_{\mathrm{Lp}} = i_{\mathrm{fp}} + i_{\mathrm{pv}} - i_{\mathrm{Lfr}} \tag{18}$$

$$i^*_{\mathrm{Lp}} = i_{\mathrm{Lp}} P_{\mathrm{uabc}} \tag{19}$$

The distinction between the reactive component (i_{Lfq}) of the fundamental load current, and the output current (i_{smq}) is utilized to compute the reference quadrature current (i_{Lq}). The current component (i_{smq}) computation can be derived as follows. The voltage error (v_{terr}) of a PCI voltage at sth sampling instant is computed as:

$$V_{\mathrm{merr}}(s) = V^*_m(s) - V_m(s) \tag{20}$$

The magnitude of the reference quadrature current (i_{Lq}) component is estimated as $i_{\mathrm{Lq}} = i_{\mathrm{smq}} - i_{\mathrm{Lfq}}$ and is given below:

$$i^*_{\mathrm{Lq}} = i_{\mathrm{Lq}} q_{\mathrm{uabc}} \tag{21}$$

The reference source currents are estimated using the following relationship

$$i^*_{\mathrm{gabc}} = i^*_{\mathrm{Lp}} + i^*_{\mathrm{Lq}} \tag{22}$$

For the generation of gate pulses, the sensed source currents (i_{gabc}) and extricated reference source current (i^*_{gabc}) are compared in hysteresis current controller, and gating signals (G_1, G_2, G_3, G_4, G_5, G_6) are produced to control IGBTs in VSC [20].

3.5 MPPT Control

The SPV system is designed with the IC-MPPT method to extricate maximum power from an SPV and to vary the duty cycle. The maximum power at the maximum power point is reached when $(dp/dv = 0)$. In mathematical formulation, an IC process is described as:

$$\frac{\mathrm{d}i_{\mathrm{pv}}}{\mathrm{d}v_{\mathrm{pv}}} > -\frac{i_{\mathrm{pv}}}{v_{\mathrm{pv}}} \text{ then } d_{\mathrm{new}} = d_{\mathrm{old}} + \Delta d \tag{23}$$

$$\frac{\mathrm{d}i_{\mathrm{pv}}}{\mathrm{d}v_{\mathrm{pv}}} = -\frac{i_{\mathrm{pv}}}{v_{\mathrm{pv}}} \text{ then } d_{\mathrm{new}} = d_{\mathrm{old}} \tag{24}$$

$$\frac{\mathrm{d}i_{\mathrm{pv}}}{\mathrm{d}v_{\mathrm{pv}}} < -\frac{i_{\mathrm{pv}}}{v_{\mathrm{pv}}} \text{ then } d_{\mathrm{new}} = d_{\mathrm{old}} - \Delta d \tag{25}$$

$d_{\mathrm{new}}, d_{\mathrm{old}}$ and Δd are the evaluated, old and change in duty ratio of the boost converter. The MPPT is tracked at every step by equating the conductance to an IC algorithm. MPPT's main objective is to obtain the boost converter's duty ratio to achieve maximum power from the SPV. An integral controller and proportional-integral are employed to minimize the steady-state error and to reduce signal error [27].

3.6 Bidirectional control

The BDC control is implemented to control the voltage at DC-link and control also manages the charging/discharging of the BES through buck-boost mode operation. The charging and discharging of BES are determined by the load. As a result, the BDC starts working in boost mode, and current flows from the BES to the applied load, and the BES switches to discharge mode. During reduced load conditions, the BDC operates in buck mode, and the BES is switched to charging mode. The extra power is then utilized by BES. As a result, the BDC serves two functions: regulating the BES current and regulating the DC-link voltage. The governing equation of the BDC is expressed as

$$\frac{v_{\mathrm{dc}}}{i_b} = \frac{(1-\delta)(R_{\mathrm{dc}} - sL_{\mathrm{dc}})}{1 + (sR_{\mathrm{dc}}C_{\mathrm{dc}}) + (1-\delta)^2} \tag{26}$$

$$\frac{v_{\mathrm{dc}}}{\delta_{\mathrm{dc}}} = \left(\frac{2 + sR_{\mathrm{dc}}C_{\mathrm{dc}}}{\left(s^2 L_b C_{\mathrm{dc}} + \frac{sL_{\mathrm{dc}}}{R_{\mathrm{dc}}} + (1-\delta)^2\right) + (1-\delta)^2}\right)\left(\frac{v_b}{R_{\mathrm{dc}}(1-\delta)}\right) \tag{27}$$

where C_{dc}, L_{dc}, δ_{dc} and R_{dc} are the DC-link voltage, an inductor of BDC, the duty of BDC, and output effective resistance $(R_{\mathrm{dc}} = v_{\mathrm{dc}}^2/p_{\mathrm{dc}})$. The equation of PI controller manages the DC-link voltage is given as

$$i_b^*(s) = i_b^*(s-1) + k_{\mathrm{pi}}\{v_{\mathrm{dcer}}(s) - v_{\mathrm{dcer}}(s-1)\} + k_{\mathrm{pv}} v_{\mathrm{dcer}}(s) \tag{28}$$

where

$$v_{\mathrm{dcer}}(s) = v_{\mathrm{dc}}^*(s) - v_{\mathrm{dc}}(s) \tag{29}$$

where i_b and i_b^* are the sensed BES current and reference BES current. The comparison of the saw-tooth wave and the output of PI controller is utilized to generate the BDC gating pulses [30].

4 Simulation results

Using MATLAB, the detailed simulation results for the wind, solar PV, BES, and nonlinear load-based stand-alone electrical supply system are examined in this section. In this work, the system is simulated with changes in wind speed/solar irradiance and unbalanced load. In addition, the internal parameters of the designed 3Ø-APF-PLL control strategy are thoroughly examined.

4.1 Internal parameters of the control approach

Figure 3a–c represents the internal control parameters of the 3Ø-APF-PLL-based islanded electrical supply system under an unbalanced load. The load of phase 'a' is detached at $t =$ 3.3 s. The control signals i_α, i_β, $i_{L\alpha 1}$, $i_{L\beta 1}$, i_q, and I_m are shown in Fig. 3a. These control signals represent the dynamics of various intermediate variables of the control scheme under the removal of load. Due to the elimination of load the value of i_α is reaches zero at $t = 3.3$ s. The control signals i_{smq}, p_{uabc}, q_{uabc}, i_{Lfr}, i_{Lfq} and ω_g are shown in Fig. 3b. The control signal shows the extracted maximum value of load current, AC PI controller current, and active/quadrature unit vectors. The control signals $i_{\mathrm{pf}}, i_{\mathrm{Lp}}, i_{\mathrm{Lq}}, i_{\mathrm{Lp}}^*, i_{\mathrm{Lq}}^*$, and i_{gabc}^* are shown in Fig. 3c to represent the extracted reference current is completely sinusoidal during distorted load conditions and the real/reactive reference current, DC PI controller current, and extracted reference current.

4.2 Dynamic behavior at the change in wind speed

Figure 4 depicts the dynamic behavior of an islanded electrical supply system with changes in wind speeds and constant solar irradiance feeding a linear/nonlinear load. The controller stabilizes the frequency (f) and BES voltage (v_b) or DC-link voltage under the intermittent condition of wind speed. The wind speed is suddenly changed from 14 to 11 m/s at $t = 3.3$ s. Results in a decrement in wind power generation and deficit load power, which are amplified by the BES through VSC; therefore, compensator current is slightly increased, and BES charging current is reduced after $t =$ 3.3 s. During declination in wind speed, the BES switches from charging to draining mode and maintains the balance

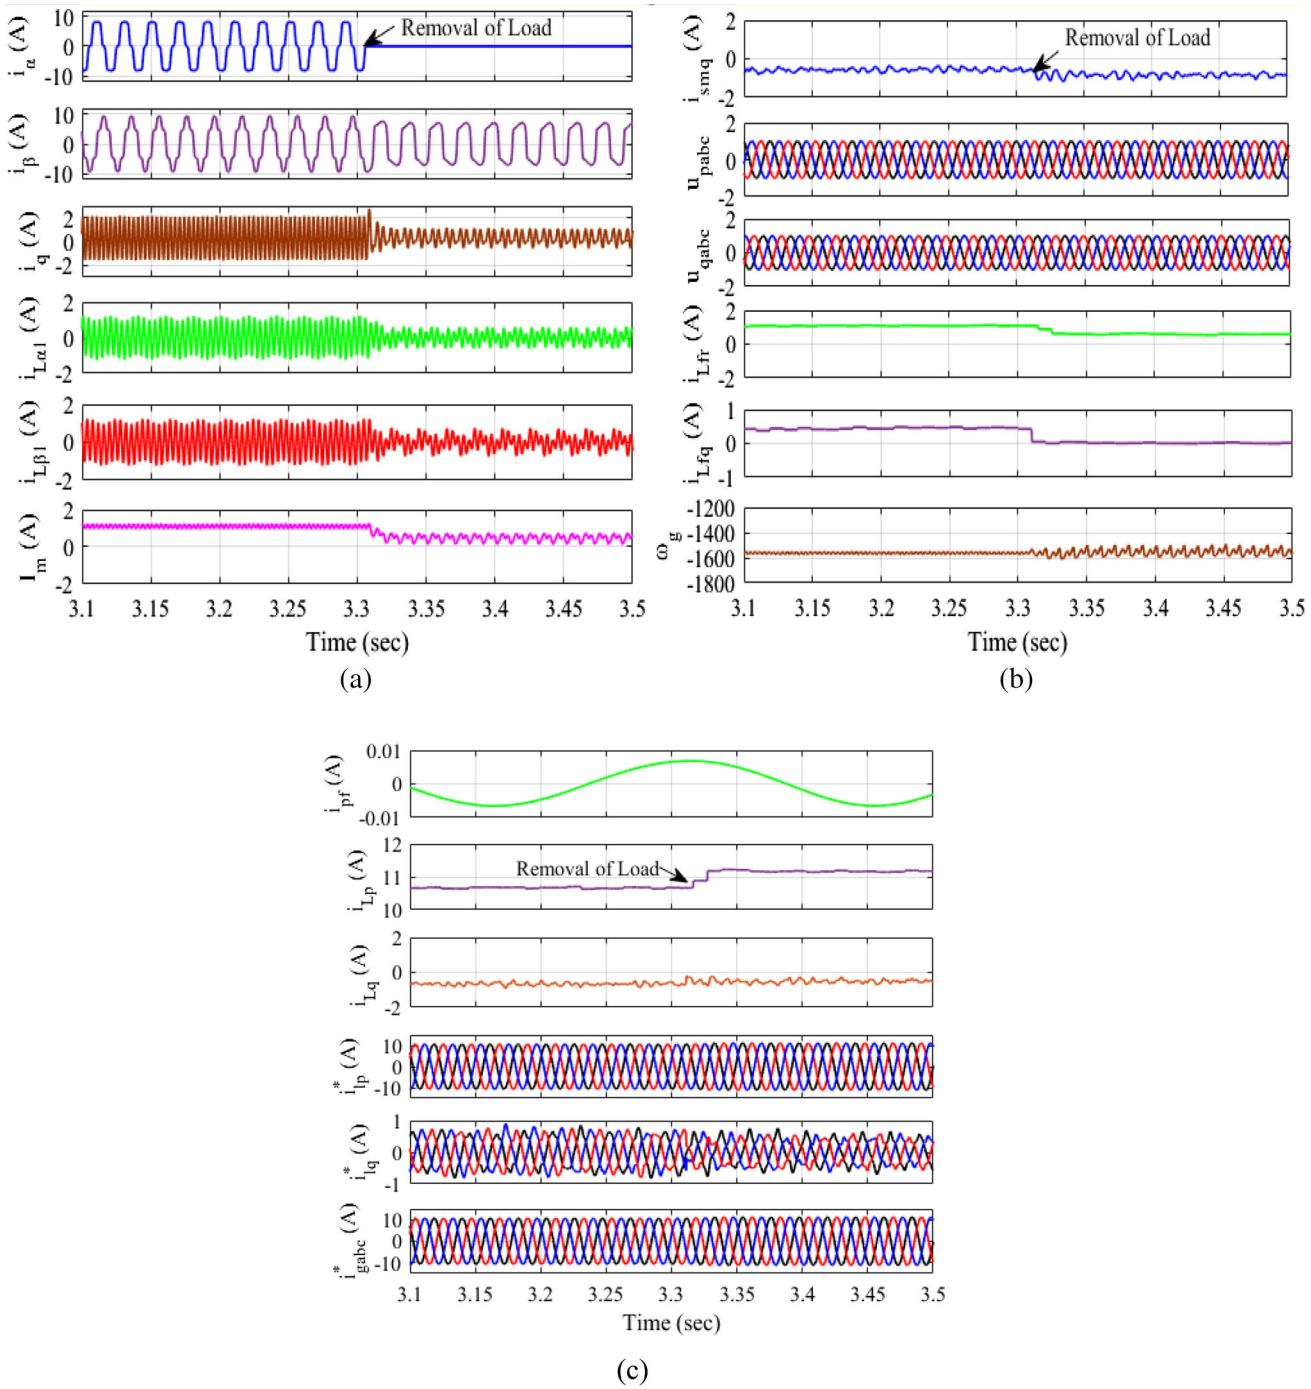

Fig. 3 **a–c** Estimation of fundamental components of the load current using 3Ø-APF-PLL control algorithm, **b** estimation of real/reactive unit vectors and AC PI controller current with other intermediate signals using 3Ø-APF-PLL **c** DC PI controller current and reference current generation using 3Ø-APF-PLL

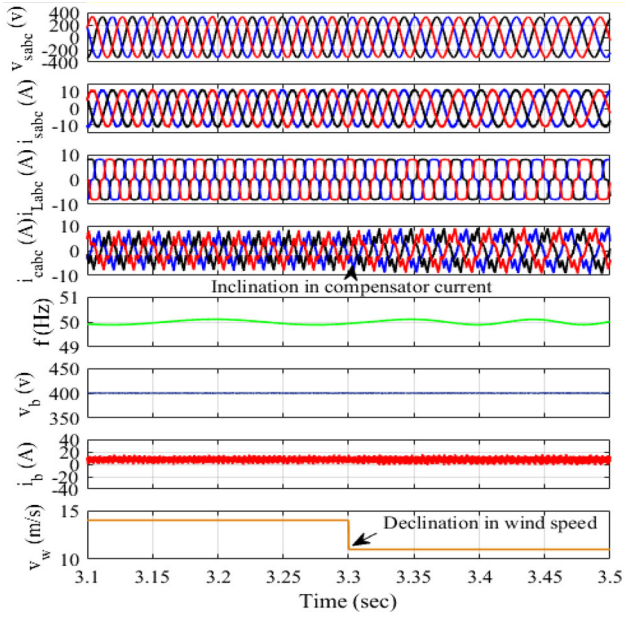

Fig. 4 Dynamic behavior at the change in wind speed

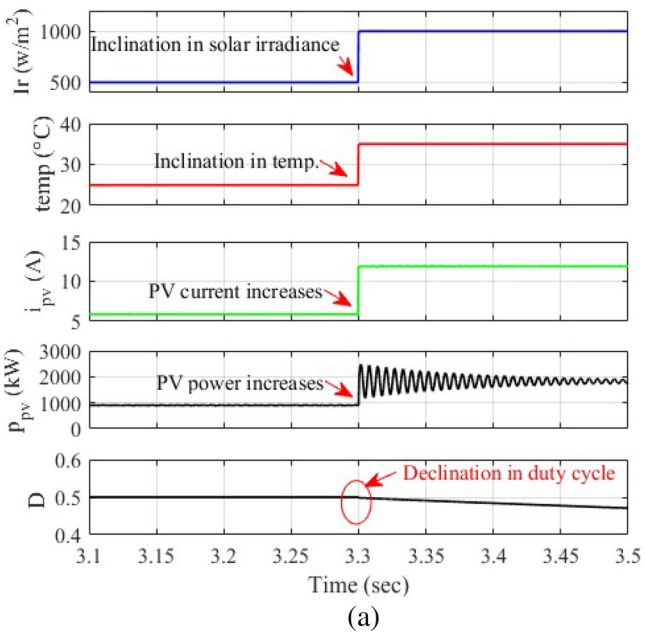
of power at PCI. A 3Ø-APF-PLL-based approach with VSC effectively maintains the propoosed system voltage & current profile during declination in wind speed.

4.3 Dynamic behavior under the change in solar irradiance

The dynamic behavior of the proposed SPV-wind-BES-based islanded electrical supply system is depicted in Figs. 5a, b with variable solar irradiations 500–1000w/m^2 and temperature 25–35 ºC, with the wind speed maintained at 14 m/s supplying a linear/nonlinear load. Figure 5a shows the parameters of the SPV system such as PV current (i_{pv}) and PV power (P), which increases and decreases in the duty cycle due to changes in solar irradiance at $t = 3.3$ s. During the changing condition of RESs (wind and solar), the BES is employed to maintain the power equilibrium between the applied load and the islanded system. The controller of the islanded electrical supply system monitors the system frequency, voltage, and harmonics, as depicted in Fig. 5b. Due to the inclination of solar power, the BES charging current, PCI current, and compensator current are gradually increased, and the controller maintains other parameters of the islanded system are kept constant. As solar power increases, the BES current shifts from draining to charging mode, and the remaining power is consumed by the BES.



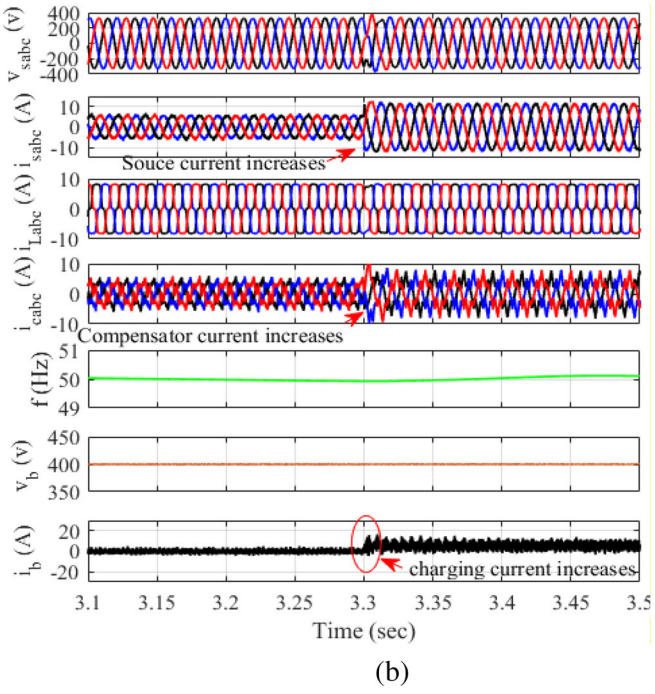


Fig. 5 **a** and **b** Dynamic behavior under the change in solar irradiance

4.4 Dynamic behavior at an unbalanced load

Figure 6 depicts the dynamic behavior of a SPV-wind-BES-based islanded electrical supply system with a constant wind speed/solar irradiance feeding an unbalanced load. The load of phase 'a' is eliminated at $t = 3.2$ s to $t = 3.4$ s. When the load is removed, the BES charging current increases and extra power is given to the BES. The load current is decreased due to disconnection of load at $t = 3.2$ s to $t = 3.4$ s. A 3Ø-APF-PLL-based controller regulates the islanded electrical supply system frequency and stabilizes the voltage profile, current profile, and DC-link voltage or BES voltage during

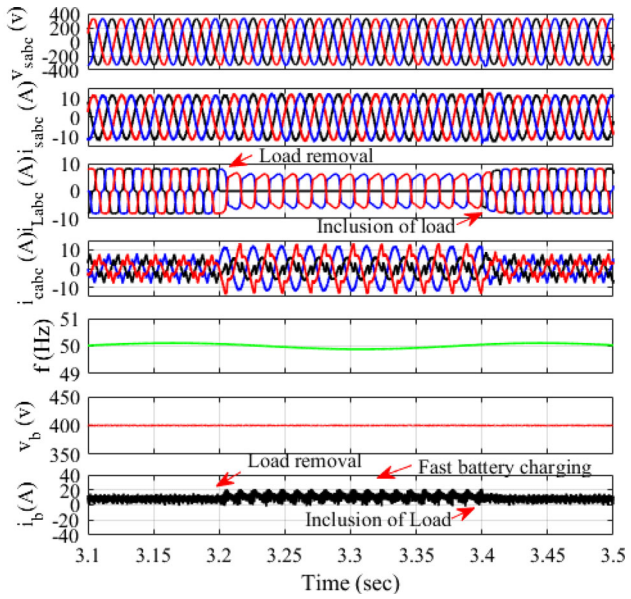

Fig. 6 Dynamic behavior at unbalanced load

the fluctuations in load. The source current stays sinusoidal and balanced even under unbalanced load situations.

4.5 Dynamic behavior at a change in RESs and load

Figure 7a, b depicts the behavior of the islanded electrical supply system under variations in energy sources feeding an unbalanced load. At t = 3.3 s, the declination in solar irradiance and temperature ranges from 1000 to 500w/m^2 and 35–25 °C. As a result, the PV current, power, and duty cycle are lowered. Figure 7b depicts the wind speed declination from 14 to 11 m/s at t = 3.3 s, as well as the imbalanced load (the burden of phase 'a' is abolished from t = 3.2 s to t = 3.4 s). During the altering condition of RESs and load, a 3Ø-APF-PLL-based controller successfully stabilizes the current & voltage profile of SEIG. Due to the decline in solar irradiance and unbalanced load, the source current of the islanded system is decreased, and the load current is also reduced at $t = 3.2$ s to $t = 3.4$ s. The BES current is gradually increasing during load removal, which means the additional power is delivered to the BES for charging. The BES current is reduced during declination in RESs at t = 3.3 s, i.e., the BES stored power is supplied at PCI to manage the level of power between the RESs and the applied load.

4.6 Harmonics investigation of islanded system

Figure 8a–c shows the harmonics investigation of PCI voltage (v_{gc}), PCI current (i_{gc}), and load current (i_{Lc}) of phase 'c' are 1.42, 4.32, and 25.06%, respectively. When the nonlinear load is applied to the 3Ø-APF-PLL-based islanded electrical supply system, the THD of PCI current is less than 5%, which satisfies the limit of the IEEE-519 standard.

4.7 Comparative analysis of 3Ø-APF-PLL, SOGI-FLL, and LMS in islanded electrical supply system

Figure 9a, b compares the performance of 3Ø-APF-PLL, SOGI-FLL, and LMS under an imbalanced load. The proposed method has the benefit of quick convergence, fast dynamic response, and fast BES charging response under varying load demands. Figure 9a depicts the comparative simulation study of the extracted fundamental load current component. Under dynamic load circumstances, the 3Ø-APF-PLL control exhibits reduced steady-state oscillations, quicker convergence, and dynamic responsiveness. The computation time of the 3Ø-APF-PLL-based control is one cycle under dynamic conditions. Figure 9b compares the response of BES charging current for 3Ø-APF-PLL, SOGI-FLL, and LMS when the load of one phase is detached from $t = 3.2$ s to $t = 3.4$ s. During the removal of load, the 3Ø-APF-PLL control technique provides fast dynamic response and convergence. Table 1 compares the response of the 3Ø-APF-PLL, SOGI-FLL, and LMS control algorithms.

5 Test results

The proposed 3Ø-APF-PLL control approach is developed on hardware setup to examine the response of the islanded system as shown in Fig. 10. The LEM LA-25-based Hall-effect sensors have been employed to observe voltages & currents in the islanded system. In the proposed 3P3W islanded system, the Hall-effect-based sensors are employed to monitor the source currents of phases 'a' and 'b,' respectively. In the described setup, three current sensors (LEM LA-25) are utilized to sense the load currents in the islanded system. The output of the current sensors is connected to the analog-to-digital converter (ADC) channel of the dSPACE-1104, through suitable buffer circuitry. The buffer circuit ensures that the voltage signal from the current sensors is properly conditioned and compatible with the ADC requirements. The buffer circuit is designed with operational amplifiers (OP-07). The buffer circuit is designed with appropriate resistance values to achieve unity gain, meaning the output voltage of the buffer is equal to the input voltage. The low output resistance of the buffer ensures that the load connected to it does not significantly affect the signal voltage. The extremely high input resistance of the buffer prevents loading effects on the current sensors, ensuring accurate current measurement. The dynamics performance of the system was examined using four different channels of the DSO-X 2024A. The outcomes were measured while the system was

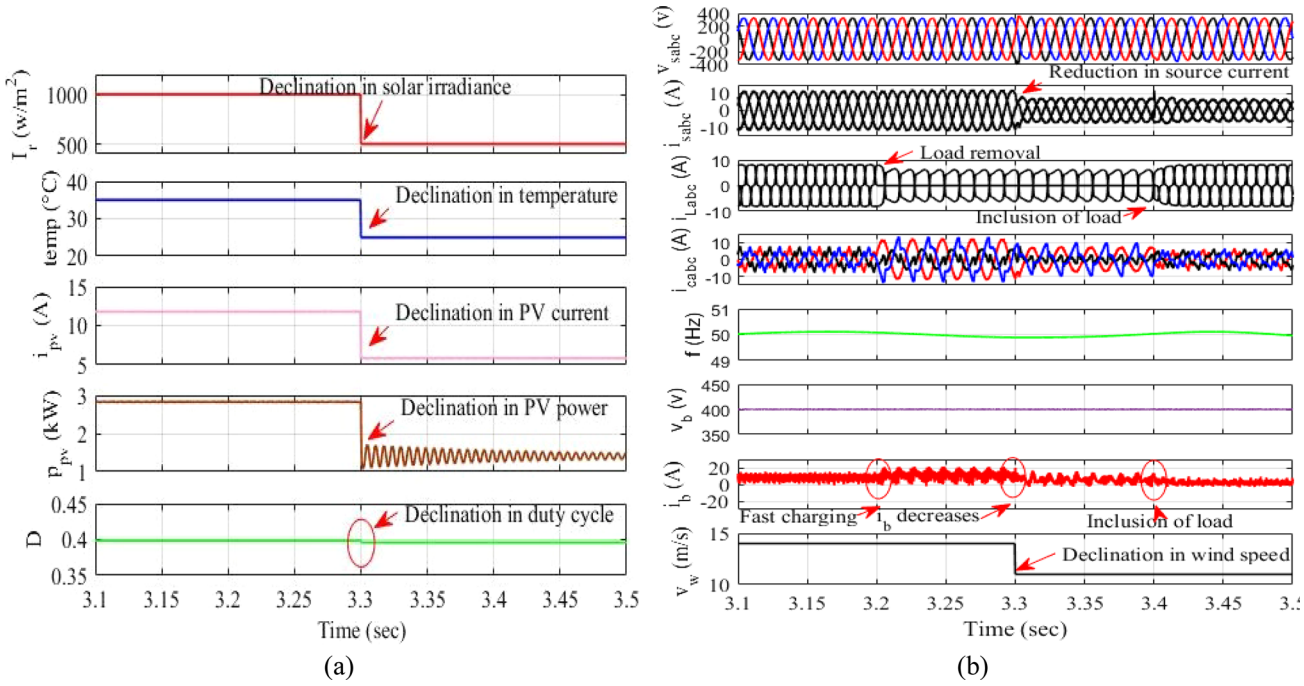

Fig. 7 **a** and **b** Dynamic behavior at the change in RESs and unbalanced load

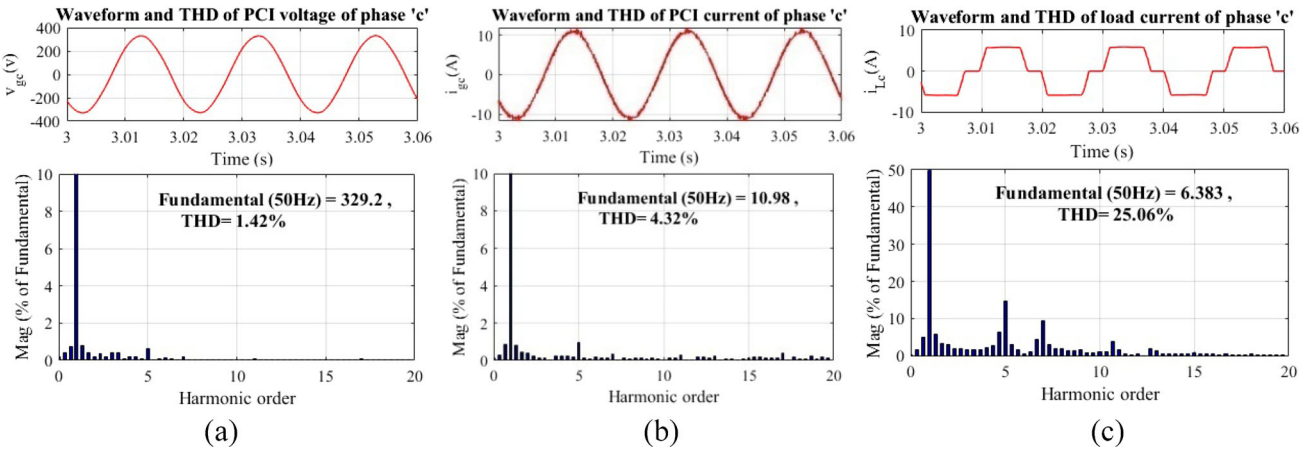

Fig. 8 **a–c** Harmonics investigation of islanded system

operating in a steady state utilizing the PQ analyzer. The examined test results and harmonic spectra of the islanded system are depicted in Figs. 11a–f and 12a, b.

5.1 Dynamic behavior of SPV-Wind-BES islanded electrical supply system

The dynamic behavior of the islanded system is observed using DSO-X 2024A under the unbalanced condition of the load. The observed results are depicted in Fig. 11a–f. Figure 11a depicts the load current of 3-phases (a, b & c) and DC-link voltage. During the insertion of load phase 'b,' the load current of all phases is increased, and the DC-link voltage is maintained constant by the proposed controller. Figure 11b depicts the DC-link voltage, PCI voltage, PCI current, and load current. Due to the sudden inclination in a load of phase 'a,' the PCI current and load current of the islanded system are increased. In Fig. 11c, during an inclination in load, the PCI current and load current are increased. A3Ø-APF-PLL-based controller with VSC maintains the PCI voltage sinusoidal, and the DC-link voltage is gradually reduced under inclination in load. Figure 11d depicts the load current and PCI current is reduced due to the removal of a load of phase 'a.' Figure 11e shows a sudden change in load, the DC-link voltage is suddenly increased and the PCI voltage is maintained sinusoidal. Figure 11f depicts the

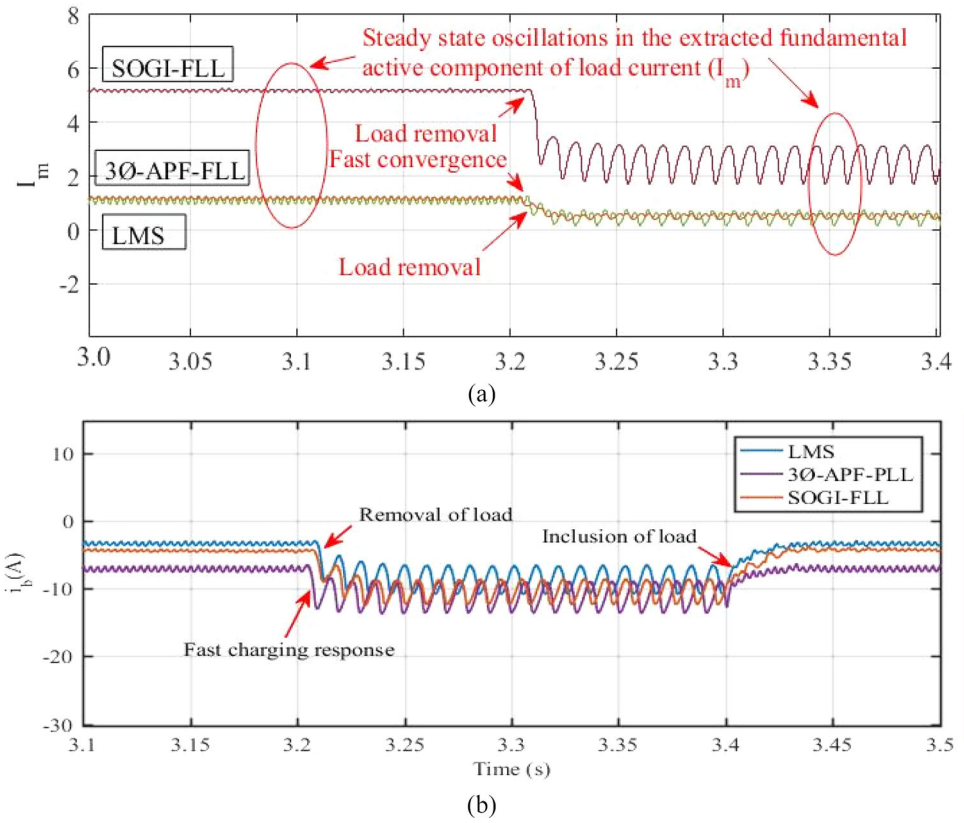

Fig. 9 **a** and **b** Comparison in the response of fundamental load current component (I_m) and (b) BES charging response for 3Ø-APF-PLL, SOGI-FLL, and LMS under disconnection of a load of phase 'a'

Table 1 Comparative performances of 3Ø-APF-PLL, SOGI-FLL, and LMS control algorithms

S.no	Parameters	3Ø-APF-PLL	SOGI-FLL	LMS
1	Computation time for fundamental extraction of load current component	One cycle	Three cycle	Three cycle
2	Steady-state oscillations	Less	Medium	High
3	Stability	Best	Good	Bad
4	Response	Fast	Medium	Medium
5	THD obtained			
	PCI voltage	1.42%	2.85%	3.73%
	PCI current	4.32%	4.89%	5.19%
	Load current	25.06%	26.18%	24.79%

parameters of the islanded system; the load of phases '*a*' and '*b*' is interfaced with the system. Due to the inclination of the two-phase load, the PCI current and load current are increased. During all circumstances, the proposed control has the versatile ability to manage all the parameters of the islanded system. Moreover, the 3Ø-APF-PLL-based control with VSC supplies improved PQ, suppression of harmonics, leveling of load, power compensation, and voltage & frequency stabilization. The BES system stored the unused power and supplies the power through VSC under varying load demands.

5.2 Harmonic spectrum

The harmonic spectrum of islanded system is analyzed using a 3-phase power analyzer. The recorded results show the THD of PCI (voltage & current), and load current are 1.84, 4.24, and 25.62%, respectively. The THD results are taken

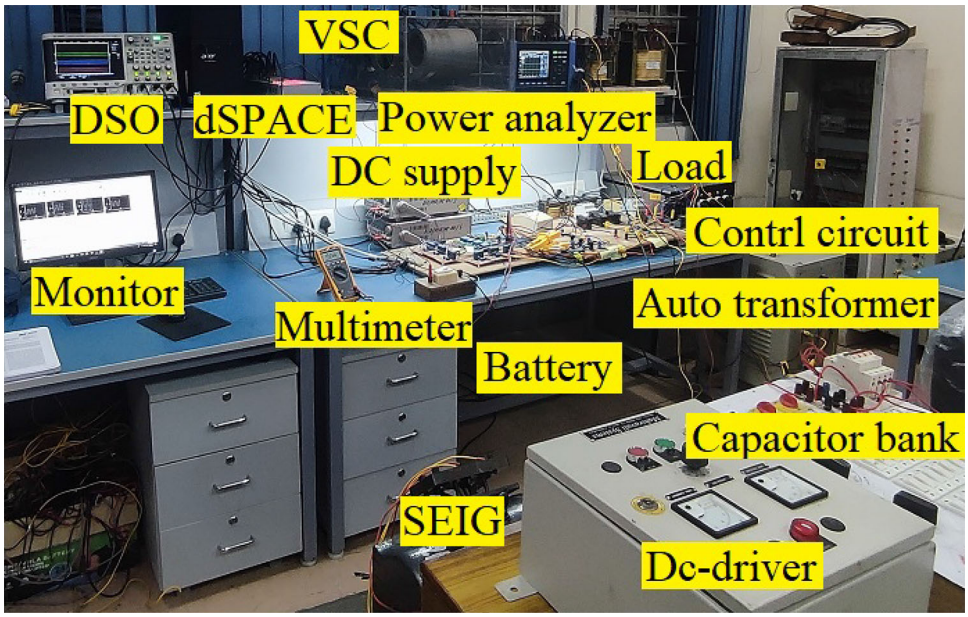

Fig. 10 Experimental prototype of the islanded electrical supply system

under a highly distorted load current. The THD of PCI current is under 5% and fulfills the criteria of the IEEE-519 standard. The 3Ø-APF-PLL-based controller with VSC compensates the harmonics injected by non-sinusoidal load current (25.62%) and maintains the PCI current sinusoidal.

6 Conclusion

This proposed islanded electrical supply system performance is analyzed with a 3Ø-APF-PLL control approach under a change in wind speed/solar irradiance feeding an unbalanced distorted load. The 3Ø-APF-PLL approach is implemented to extract the maximum value of fundamental component and estimation of active & reactive components for the generation of gating signals for VSC. The3Ø-APF-PLL-based control with VSC provides abatement of harmonics, power support (real &reactive), load balancing, fast convergence, and improves the PQ of an islanded electrical supply system under various operational circumstances. The SPV system is modeled with an IC-MPPT algorithm using a boost converter at the DC-link of VSC to provide real/reactive power compensation necessary to regulate frequency and PCI voltage. The BES system supplies active/reactive power under the irregular condition of power generation sources and absorbs extra power during unbalanced load conditions. The 3Ø-APF-PLL-based SPV-wind-BES islanded electrical supply system has been designed in MATLAB/Experimental environment, and results are examined under various operational circumstances feeding unbalanced nonlinear load is discussed. The THD of PCI voltage (v_{gabc}) & current (i_{gabc}) are less than 5%, which satisfies the IEEE-519 standard also.

Abstract

Globalization epitomizes the convergence of diverse cultures, economies, and communities on a worldwide scale, engendering the exchange of ideas, technology, inventions, and import and export services across nations and societies. Technology, as a pivotal agent, assumes a vital role in building bridges among the global economies by overcoming information disparities and thereby empowering people. Specifically, television, a very influential medium, assumes the function of capturing, collating, and disseminating personal and cultural memories. Its significance is especially pronounced in the context of Khaled Hosseini's literary works, *The Kite Runner* and *A Thousand Splendid Suns*, where television's role as a tool for constructing memories and shaping the identities of the characters is scrutinized. The ramifications of the Taliban's television ban are examined in this paper, highlighting how this drastic measure has significantly impacted the nation's culture.

Keywords: American movies, culture, identity, memory, television

The credit for the advent of electronic television is unequivocally attributed to Philo Taylor Farnsworth, who successfully demonstrated its functionality in 1927 at a momentous event held in San Francisco, United States of America. The ensuing decades witnessed the proliferation of television's popularity across numerous countries, including the United Kingdom, Australia, Japan, the Soviet Union, China, and also India, which marked a significant milestone with its first TV channel, Doordarshan. It was only in the aftermath of the 1970s that countries like South Africa, Qatar, Oman, Burma, and Sri Lanka joined the ranks of television accessibility.

In the context of Afghanistan, the launch of television broadcasting occurred in 1978 with the establishment of Afghanistan National Television, a development catalyzed by the resolute advocacy of Dr. Hafiz Sahar, who recognized the indispensability of television as a tool for education and technological advancement. However, the path to progress, in terms of technology and utilization, was fraught with challenges for Afghanistan. Following its transition to a republic in the early 1970s, the country was beset by the intrusion of the Soviet Union in December 1979, a turbulent period that endured until 1989. The subsequent period of civil war from 1992 to 1996 further disrupted the nation's economy, culminating in the rise of the Taliban, an ideological group espousing Islamic Fundamentalism, which seized control.

Despite brief periods of resurgence and growth under NATO protection from 2001 onwards, Afghanistan's technological trajectory experienced a setback in 2021 as the Taliban once again assumed control, imperiling existing technology and depriving the citizens of their rightful access to knowledge and education. This unfortunate turn of events casts a somber pall over the lives of ordinary people, denying them the rights they so deserve.

In the present era, the ubiquity of television has entrenched itself as an indispensable aspect of modern society, profoundly influencing our outlooks, norms, and recollections. However, within the Taliban regime, the once taken-for-granted entitlement of television viewership faces scrutiny due to the imposition of their dogmatic Islamic ideology. Khaled Hosseini, a gifted diaspora writer, one renowned for his poignant portrayals of life's vicissitudes in Afghanistan, captures the intricate interplay of human relationships in a nation ravaged by conflict.

Curiously, despite the profundity of television's presence as a narrative device in Hosseini's literary works, scant scholarly attention has been devoted to exploring its multifaceted significance in his novels. Notably, television assumes a significant role in depicting emotional details in the lives of his characters, both within Afghanistan and in their adopted homelands, where they survive as refugees. Within this context, the pages of Hosseini's masterpieces, *The Kite Runner* and *A Thousand Splendid Suns*, offer a profound exploration of the diverse roles television plays in preserving memories, disseminating cultural values, and fostering connections between individuals separated by geographical expanses.

In this paper I endeavor to undertake a qualitative analysis, delving into the nuanced role of television in Hosseini's literary opus. Specifically, the focus will rest upon discerning how this medium functions as a potent instrument for preserving memory and shaping identities among the characters inhabiting Hosseini's narrative landscapes. By unfurling the myriad subtleties of television's thematic involvement in the tapestry of his stories, this inquiry aspires to provide insights on the profound intellectual and cultural implications intricately woven into the heart of Hosseini's timeless prose.

Television, Memory and Conflict

In his scholarly work, Rawan (2002) expounds on the widely acknowledged disapproval among orthodox followers of Islam concerning realistic depictions of living beings, perceiving photography and visual representation as an imitation of the divine creations. Such mimetic endeavors are believed to attract severe retribution from Allah on the Day of Judgment, even though the Quran itself does not overtly prohibit the portrayal of human forms (p. 162). Remarkably, the censure of graphic human depictions endures to this day, with contemporary religious adherents and clerics upholding the stance (p. 162).

Osman, in his book *Television and the Afghan Culture Wars* (2020), casts a light upon the deeply contentious nature of television within the Afghan context. This medium has historically been considered a crucible of violence due to its representation of social, cultural, and religious values. Paradoxically, television also has the potential to buttress democracy, national unity, and peace (p. 13). Furthermore, it has traditionally served as a conduit for Afghans to engage with foreign cultures, thereby exposing them to Western influences. Nevertheless, such exposure is diametrically opposed to the fundamental tenets of the Taliban's ideology, which staunchly imposes draconian restrictions on women's rights, encompassing prohibitions on public display of their bodies and faces and the curtailment of educational liberties. Under the Taliban regime, all forms of entertainment are rigorously prohibited, as they ostensibly contravene the conservative principles of Sharia Law (p. 13).

According to Rashid's account (1999), the tumultuous 1990s in Afghanistan were marked by a media ban, encompassing photography and television, which left the majority of the populace oblivious to the appearance of their newly instated leaders (p. 24).

Hatef and Cooke (2020) have propounded that a substantial segment of Afghanistan's populace lacks formal education. Consequently, television emerges as a more accessible and compelling medium for disseminating educational content vis-à-vis print media. The authors contend that television's wider reach holds the potential to furnish educational opportunities to a more extensive cross-section of Afghanistan's population.

In the aftermath of the 2001 triumph over the Taliban, Afghanistan underwent a transformative phase, metamorphosing into a nascent modern nation. An article from 2010 reveals that radio and television have become indispensable sources of entertainment for the Afghan people, with estimates suggesting that eight out of ten Afghans possess a radio and four out of ten possess a television (Auletta).

Amy Holdsworth's tome, *Television, Memory and Nostalgia*, delves into diverse forms of reflection that prove valuable in scrutinizing the interplay between television memory, the self, the family, domestic space, and the external world. Television, rather than being perceived as a mere object occupying a corner of the room, is seen as an integral facet of the domestic environment, engendering memories constructed from audiovisual impressions. It assumes a pivotal role in our comprehension of the past, and by attentively examining how it recollects and contextualizes its own history, we can discern prevailing attitudes towards television as a cultural phenomenon and towards our own historical identities. Nostalgia emerges as the dominant foundation through which television recollects and references itself.

Childhood Memories

In one of his interviews, Khaled Hosseini stated:

> I was watching a news story in the spring of 1999 on television, and this news story was about the Taliban. And it was talking about all the different impositions that the Taliban had placed on the Afghan people. And at some point along the line, it mentioned that they had banned the sport of kite flying, which kind of struck a personal chord for me, because as a boy I grew up in Kabul with all my cousins and friends flying kites. (RFE/RL)

Hosseini's literary voyage, kindled by the profound impact of televised news about Afghanistan, unveils television's powerful capacity to evoke long-lost childhood reminiscences. In his inaugural novel *The Kite Runner*, Hosseini artfully explores the characters' profound introspections as they retrace their past and establish emotional connections with their dear ones, catalyzed by the medium of television.

Set against the backdrop of a tumultuous Afghanistan marred by Russian invasions, the novel chronicles the poignant tale of Amir and his devoted friend and servant, Hassan. Amidst the harsh circumstances, Amir's father forges a path to America, taking Amir and leaving Hassan behind with aspirations for a brighter future. Years later, upon learning of Hassan's untimely demise, Amir embarks on a journey back to Afghanistan. Once there, he confronts his inner vulnerabilities and endeavors to rescue Hassan's son, all the while being engulfed by a wave of nostalgic recollections from his youth alongside his cherished companion, Hassan.

Permeated by poignant feelings, Amir's memories include his father's passion for soccer and his ritualistic pilgrimages to Tehran merely to witness "world cup games on television, since at the time Afghanistan didn't have TVs yet" (p. 19). This emotional reflection allows Amir to peer into the depths of his relationship with his father, unearthing a kaleidoscope of powerful emotions from that era of his life. The television, in its symbolic significance, serves as an emissary of memories intertwined with Hassan, epitomizing the profound bond that was their friendship.

The transformative era when Daoud Khan, Afghanistan's president from 1973 to 1978, heralded progress for the nation, notably with the advent of television, leaves an indelible mark on Amir's psyche. In contemplating the future acquisition of vividly colorful televisions, one each for himself and Hassan, Amir conveys his feeling of anticipation: "And not the black-and-white kind either. We'll probably be grown-ups by then, but I'll get us two. One for you and one for me." (p. 54). But fate's grim power thrusts the two kindred souls apart, ensnared in the perilous grip of their homeland's woes.

As destiny reunites Amir with Hassan's son, Sohrab, the melancholic sight of the young boy transfixed before the television, with "his green eyes, stone-faced, rocking back and forth," strikes an evocative chord within Amir's soul (p. 286). The television acts as a conduit, ferrying Amir back to the memories of his cherished camaraderie with Hassan and, concurrently, stirs within him the unfulfilled promises that linger as haunting echoes of his past.

Hosseini's eloquent portrayal of the interplay between television and memory weaves a tapestry of emotions, bridging the chasm between past and present, thereby underscoring the timeless human struggle for connection and redemption.

A Dreamland of Prosperity

Hosseini's literary works abound with allusions to American cinema, which constitutes an integral facet of the cultural milieu. In a particular recollection of Amir's, he divulges the denouement of *The Magnificent Seven* to a boy who inquired if he had viewed the film. This incident, transpiring at the video store, imparted a crucial lesson to Amir: in the United States, the disclosure of endings is deemed inappropriate, a divergence from Afghanistan's customs, where inquiries about denouements, particularly concerning the attainment of happiness and fulfillment of aspirations by characters, are commonplace. This preoccupation with happiness mirrors the yearnings harbored by the Afghan populace. Nonetheless, Amir, in the course of reminiscing, comes to the realization that life rarely adheres to cinematic conventions, particularly when confronted with the desolate and traumatized landscape of Afghanistan, as is illustrated in one of the chapters: "We passed the rusted skeleton of an overturned car, a TV set with no screen half-buried in rubble" (p. 232). These movies function as a conduit between South Asian nations such as Afghanistan, where the quest for happiness is fervent, and the Western world, where the United States embodies a land of affluence and the realization of dreams and desires. Despite America – his newfound home – having buried his childhood memories, the sight of the Pacific Ocean nearly moves Amir to tears, evoking recollections of his conversations with Hassan about visiting the beach and relishing the sensation of water beneath their feet, having hitherto only encountered "oceans on the movie screens" (p. 126).

It is noteworthy that Afghanistan, ensconced by mountains, is landlocked, rendering the experience of an awe-inspiring ocean view nearly unattainable. An article on thestar.com recounts the reminiscences of a man who lived under the Taliban's rule during his formative years, a period in which all forms of entertainment were strictly proscribed. Haris and his neighbor pooled their resources to acquire a pirated copy of the film *Titanic*, an expenditure amounting to "ten times as much as a night's rental" (Latifi). After a month of anticipation, they finally had Haris's home to themselves, where they watched the film. Haris shares an astonishing reaction to witnessing the majestic boat on-screen, stating, "I couldn't believe what I was seeing, they actually created a boat. I remember everyone was saying the actual boat was the size of Khair Khāna [a neighborhood in north west Kabul]" (Latifi). The allusion to the sea in *A Thousand Splendid Suns* emerges when Hosseini mentions that the movie Titanic encapsulates themes of "the sea. The luxury. The ship" (p. 296). Hosseini's portrayal not only accentuates the unattainable nature of beholding the sea, emblematic of vastness and freedom, luxury representing a life of abundance, and the ship as a means of escape, but also underscores the myriad challenges routinely faced by the impoverished Afghans.

The Making of an Identity

In his masterpiece *A Thousand Splendid Suns*, Khaled Hosseini unfolds the poignant narrative of Laila, a modern and well-educated Afghan woman, whose life takes a tragic trajectory following the loss of her parents, the separation from her beloved Tariq, and her ensnarement in an abusive marriage with the elderly and brutal Rasheed, who is already wed to Mariam.

Initially, a sense of animosity prevails between Mariam and Laila, yet the shared subjugation they endure as women under the oppressive grasp of Rasheed forces an unlikely convergence, fostering a profound sisterhood between them. Throughout the novel, we bear witness to the relentless rule of the Taliban, their unremitting cruelty impelling the characters to seek liberation from their harrowing circumstances.

Remarkably, the medium of television assumes a prominent role in shaping the identities of the characters. Laila's affinity for television and cinema serves as a lens through which we observe the evolution of her character. Notably, the allure of cinema conjures reminiscences of Tariq, as well as recollections of her father, underscoring the intricate interplay of personal connections and familial heritage in the author's construal of the cultural significance of cinema.

Osman aptly expounds on the influence of television in Afghanistan, elucidating its dual function as both a mirror and an amplifier of the nation's essence. By enabling the Afghan populace to engage in self-observation and articulate their own imagery and representations, television assumes an integral role in shaping the nation's collective consciousness.

For Laila, her experiences and relationships with her loved ones profoundly color the memories and emotional associations she harbors with cinema. Beyond a mere source of entertainment, cinema assumes a deeply personal and culturally significant dimension for her, molding her sense of self and contributing to the construction of her individual identity.

Upon receiving the disconcerting news of the Taliban's cinema closures, Laila's mind drifts back to the days spent in her father's cinema park, where she fondly reminisces about the moments shared with Tariq, indulging in the captivating narratives of Hindi movies. These poignant tales of star-crossed lovers, torn asunder by the capricious whims of fate, one adrift in distant lands, the other ensnared in the shackles of forced matrimony, evoking tears and serenades amidst fields of marigolds, all resonate deeply with the somber realities of her own distressing life.

Despite the stark contrast between the illusory realm of cinematic dreams and the relentless hardships that mark her existence, these cherished movie memories serve as a consoling balm, an avenue of escapism for Laila, offering a glimmer of optimism and the promise of a brighter tomorrow amid the gloom. Ultimately, destiny intertwines their paths, and in the denouement, Laila finds solace in a long-awaited reunion with Tariq, reaffirming the enduring power of love and hope in the face of adversity.

Amidst the aura of a promising and idyllic reunion shared by Laila and Tariq, they soon confront a stark disparity between the realities they now face and the idealized portrayals found in the romantic films of yesteryears. Departing from each other has wrought profound changes, evident in the melancholic countenances they take on while witnessing President George W. Bush declaring war on the Taliban. In this poignant moment, Tariq's voice falters, and Laila senses the weight of his emotions threatening to manifest as tears.

Their agonizing struggle to reclaim the euphoria of cherished memories, despite their relentless troubles, underscores not only the transformations in the external world but also the profound metamorphoses within themselves. The televised declaration of war serves as an unwelcome trigger, casting Laila's thoughts back to the tragic fate her parents endured - a cruel demise at the hands of a rocket during the Afghan Civil War.

The declaration, too, serves as a poignant trigger, rekindling somber memories of Laila's brothers, Ahmad and Noor, who fell victims to the ravages of war. When Tariq ventures the notion that the conflict may not necessarily be adverse, it stirs a maelstrom of emotions within Laila, underscoring the intricate interplay of their perspectives.

Holdsworth astutely notes the potent influence of news and media events in constructing lasting imprints in our television memories, encapsulated by the dictum, "You'll remember where you were and who you were with the first time you saw them" (2011, p. 244). The profound impact of the war announcement in the novel leaves an indelible mark on both Laila and Tariq, forging memories that will forever be etched in their consciousness.

A parallel scenario emerges in *The Kite Runner*, where an adult Amir, while watching "the communist propaganda" and witnessing the unfolding of "the second war" on his television screen, is forever bound to those memories that linger like an enduring specter. The recollection of encountering the Taliban for the first time on the small screen, amid the allure of Afghanistan's landscape upon his return, demonstrates the enduring impression cast by televised imagery.

Hosseini's perspicacious delineation of the "Titanic fever" phenomenon in Afghanistan, triggered by the screening of the eponymous movie, serves as a captivating exploration of the profound sociocultural ramifications that media consumption had under the Taliban's rule. The surreptitious dissemination of pirated copies of the film, discreetly concealed even in the recesses of one's underclothing amidst the restrictive curfew, conjures a poignant tableau where spectators surreptitiously shed tears for the fateful protagonists, Jack, Rose, and the ill-fated passengers aboard the ill-fated vessel.

This shared encounter bestows upon the collective psyche an indelible memory, transcending the confines imposed by an oppressive regime. By partaking in this clandestine cinematic communion, the people of Afghanistan forge a poignant interconnection that defies the suppressive measures of authority and fosters a profound cultural resilience amidst adversity.

In Laila's psyche, the tale of Jack and Rose begets touching reminiscences of her own bygone romance with Tariq. She discerns striking resemblances between the tragic fate of Jack and that presumed to befall Tariq. Both figures, she firmly believes, have succumbed to an untimely demise. This realization profoundly contributes to her despondent state and a pervasive sense of despair, for she apprehends that neither Jack nor Tariq shall ever come to her rescue. As she succinctly proclaims, "Every soul seeks salvation in a Jack-like figure amidst catastrophe, but such a savior remains a mere chimera—Jack shall not return, for Jack is no more." (p. 297)

The scenario wherein Mariam and Laila's daughter, Aziza, engage in a theatrical representation inspired by the movie epitomizes their longing for escapism. Aziza, in a pronounced act of identification, assumes the persona of Jack, while Mariam takes on the role of Rose. When Mariam, in jest, remarks that Aziza shall perish young, while she herself will live to a ripe old age, Aziza resolutely counters that her demise shall be heroic akin to Jack's. And when Laila's son Zalmai queries which part he shall assume, Aziza audaciously assigns him the character of "the iceberg." (p. 296) This fervent aspiration to embody heroism, rather than subscribing to the conventional, subordinate female archetype of being rescued, especially amid the women's collective yearning for a Jack-like savior amidst Afghanistan's oppressive circumstances, unequivocally showcases Aziza's courage and nonconformist disposition. The scene, thus, accentuates her capacity to find solace and amusement amid the yoke of oppressive conditions, thereby enriching her individuality. Furthermore, this lighthearted enactment facilitates the forging of cherished memories amongst the trio.

For Mariam, Laila, and the children, *Titanic* assumes the role of an escapist medium, much like it does for other Afghans. Limited access to resources in Afghanistan often restricts their

possibilities, compelling them to immerse themselves in fantasies of a serene existence beyond their borders. However, television furnishes a window into the outside world, offering glimpses of life in other nations and imbuing them with a sanguine outlook towards their own existence. The power to immerse themselves in an alternate realm through television can prove to be a potent source of solace and inspiration for Afghans, providing a brief respite from their daily hardships and instilling in them the impetus to strive for a brighter future. Jaya Yadav aptly underscores the role of television as an escape from reality in Hosseini's works, noting that despite Afghanistan's stringent prohibitions against "illicit" materials, films, television sets, and VCRs were clandestinely smuggled, providing many Afghans a portal to escape their harsh actuality (p. 867).

Moreover, the juxtaposition of the American cartoon movie "Pinocchio" within the novel *A Thousand Splendid Suns* affords a perceptive lens through which to explore the intricacies of Mariam's character, establishing a profound metaphor for her profound sense of isolation and displacement. Much like Pinocchio, the anthropomorphic figure crafted from wood and imbued with life, Mariam emerges as a child of unwedded lineage, reared in destitution within a diminutive village, despite being the progeny of an affluent father. This milieu engenders a persistent sense of alienation and a recurrent disdain from the villagers, akin to Pinocchio's struggle to find his place within the human realm. Consequently, Mariam's longing for acceptance and affection becomes distinctly molded by this animated cinematic narrative.

Amidst the allegorical fabric lies Mariam's father's broken promise to attend the same film, an act that betrays his own deceitful nature, paralleling the gradual elongation of Pinocchio's nose with each falsehood he utters. This unfulfilled pledge serves as a potent symbol for her father's negligence and the estrangement that pervades their relationship, mirroring the detachment evident in Pinocchio's own familial dynamics. Both characters seem to perpetuate a profound feeling of disconnection, exacerbating their shared sense of isolation.

While Mariam's father belatedly acknowledges the harm inflicted upon his daughter through rejection and disavowal, the revelation comes too late to mend their fractured bond. An earnest effort to atone materializes in the form of a movie dispatched to Mariam, yet tragically, it never finds its way to her. This celluloid creation, an inextricable facet of Mariam's life, is unveiled as Walt Disney's *Pinocchio* during a pivotal scene where Laila endeavors to forge a connection with Mariam's past. Laila's persistent scrutiny of the film, alternating between playback and rewind, inadvertently illustrates the profound significance it holds in Mariam's existence. Alas, despite Laila's sincere endeavors, she attempts to fully grasp the movie's profound import in Mariam's psyche.

Ultimately, akin to the metamorphosis of Pinocchio, Mariam experiences a transformative realization of her intrinsic worth, ultimately embracing her authentic self in the denouement.

In the denouement of the novel, a particular American film, *Superman*, causes Zalmai's bemusement because of the curious notion that, in Afghanistan, a boy would be precluded from bearing the appellation "Clark" (p. 402). Shahzad (2011) delves into an intriguing examination of a respondent's post-television viewing experience, reminiscent of Zalmai's inquisitive nature, wherein the participant transcends a mere passive observer or impotent bystander of the encoded contextual tapestry. Rather, they actively exercise agency, making discerning choices and probing inquiries that pertain to the embedded messages within the representations (p. 383).

Conclusion

The utilization of television in Khaled Hosseini's literary works serves as a discerning portrayal of its role as a medium for evoking memories and bridging the cultural chasm between Afghanistan and the West. In *The Kite Runner*, the recollections of Amir's formative years with his companion, Hassan, become intertwined with the advent of television in Afghanistan. Additionally, references to American movies within the novel facilitate a connection between the two disparate cultures.

Similarly, in *A Thousand Splendid Suns*, television plays a momentous role in shaping Laila's character, enabling her to forge connections with memories of her father, Babi, and Tariq. It serves as a reflective and amplifying lens for Afghanistan, allowing for introspection and communication of diverse representations. These novels exemplify how television has the potential to evoke intimate and cultural ties, even amidst the backdrop of calamitous circumstances.

Subsequent to the Taliban's invasion in 2021, the survival of media, particularly television, has been imperiled. Despite international efforts, the domestic television broadcasts have depicted how female journalists were initially mandated to conceal their faces, and eventually, they were altogether prohibited from appearing on screen. This jeopardizes the future and masks the heritage of Afghanistan, as opportunities for exposure to other cultures are once again constrained, impeding people's ability to connect with the outside world. The concerns extend beyond just the fate of women but also encompass the freedom of expression for all individuals through television.

Nevertheless, there have been instances of resolute defiance. Notably, a Kabul University Professor displayed a powerful act of protest by tearing up his diplomas on live television, signifying his disapproval of the deteriorating system under the new leadership. This demonstration not only underscores the influence of this medium but also emboldens people to resist the encroaching despondency. As he vociferously articulated, "From today, I don't need these diplomas anymore because this country is no place for an education. If my sister and my mother can't study, then I don't accept this education." (Bose, 2022)

The impact of television on Afghan society is complex, defying uniformity and predictability. Its effects are intricately woven with a multitude of factors, encompassing the political, economic, and cultural dimensions, necessitating future comprehensive analyses and scholarly investigations.

ORIGINAL ARTICLE

The effectiveness of research and development tax incentives in India: a quasi-experimental approach

Aakanksha Kaushik[1]

Abstract Globally, governments provide significant tax incentives to business enterprises for research and development (R&D) expenditure to foster innovation. Several fiscal incentives are provided to firms registered under India's department of scientific and industrial research (DSIR). India provided a super deduction of 200% on R&D expenses in 2011, reduced to 150% in 2016 and 100% in 2020. The study uses firm-level data to test the effectiveness of incentives offered in India and analyze the impact of the rationalization of super deduction. For the study, the difference in difference analysis is done to evaluate the changes in the outcome variables: total, current, and capital R&D expenditures. The treatment group is the firms registered under DSIR. The results show a significant impact of the mix of tax incentives provided on both current and capital expenditures. The super deduction significantly impacted only current expenses and not capital expenditures. The administrative costs under current expenditures are easier to relabel than capital expenditures. The study shows that the overly generous regime incentivized firms to relabel their non-R&D costs as R&D expenses for profiteering. The study supports the move to reduce the super deduction.

1 Introduction

Business enterprises' expenditures on Research and Development (R&D) play a critical role in promoting innovation. Joseph Schumpeter described innovation as "Creative Destruction" and identified it as a key to economic growth (Schumpeter 1962). Additionally, Endogenous growth theories have emphasized the significance of innovation and technological advancement for growth. (Lucas 1988; Romer 1990). Recent studies have also shown that innovation promotes firm-level competitiveness (Bacinello et al. 2020; Qiu et al. 2020; Suat and San 2019). A vast literature has shown that innovation increases productivity (Griliches 1958, 1980; Mansfield 1965; Griliches et al. 1984; Mansfield 1984; Mun et al. 1991; Nadiri and Kim 1996; Frantzen 1998; Aghion and Howitt 1998; Klette & Kortum 2002).

Firms' lack of investment in R&D is caused by financial limitations and variations in social and private returns. As a result, governments have been motivated to step in and offer incentives to encourage more R&D investment. (Nelson 1959; Arrow 1962; Aghion and Howitt 1992; Jaffe 1996; Hausmann et al. 2003; Rodrik 2004a, b.)

Many countries use R&D tax incentives as policy tools. These incentives can lower the cost of R&D, and are known as input-based incentives. Examples include Tax Deferrals, Allowances, Credits, Concessional Import Tariffs, GST, and Accelerated Depreciation. Other incentives can increase profits earned from R&D, such as Rate Relief, Tax Holidays, and the Patent Box Regime. Several R&D tax incentives in India are available to firms registered under the Department of Scientific & Industrial Research (DSIR). If eligible, firms not registered under DSIR can still claim an income tax deduction on R&D expenses and benefits from the patent box regime and tax holidays. For a summary of tax incentives provided by India and recent changes, see Table 1.

Published online: 21 August 2023

Table 1 Recent changes in R&D tax incentives

S. no.	Incentives	Recent changes
1	Customs duty exemptions	Union budget 2022–23 announced immediate withdrawal of basic customs duty (BCD) exemptions on goods used for Research and development in agro-chemical sector unit
		End-date of 31.03.2023 is prescribed in Union Budget 2022–23 for goods used in the pharmaceutical and biotechnology sector
		All the entries in the notification 50/96-Customs dated 23.07.1996, unless varied or rescinded, will have validity up to 31.03.2023
		Continues
2	Income tax deduction	The rate of weighted tax deduction has been lowered from 200 to 150% from 1st April 2017, and from Annual Year 2021–22, the tax deduction is 100% of the expenditure incurred
3	Accelerated depreciation	Continues
4	Concessional GST rate	Continues
5	Patent box regime	It was introduced in 2016
6	Tax holiday	A one-year extension to the start-ups incorporated till March 31, 2023, was provided under Union Budget 2022–23. The incentive was introduced in 2016

After the pandemic, evaluating the cost of tax incentives is important. The Indian government has made some changes to their policies, which are listed in Table 1. Companies registered under DSIR can receive benefits such as Weighted Tax deduction, Concessional Customs duty, Concessional GST Rate, and Accelerated Depreciation. However, they must fulfill certain requirements such as setting up R&D centers with specific areas and employees, as well as keeping audited accounts of R&D expenditures. One major incentive is the income tax-weighted deduction of 200% on R&D expenditures, also known as the Super deduction. Firms can receive an income tax deduction on R&D expenditures under Sect. 35 of the IT Act, 1961. India has a broader definition of qualifying expenses for exemption compared to other countries, with all current and capital expenses being eligible except for land or building costs. The deduction has changed over time, with it being revised to 150% in 2000–01, 200% in 2010–11, 150% in 2016–17, and finally reduced to 100% from the annual year 2021–22. The study aims to test how effective the incentives provided under DSIR are and evaluate the impact of the rationalization of the Super deduction.

The Super Deduction tax incentive for R&D expenses has the potential downside of encouraging companies to mislabel their non-R&D administrative costs as R&D to take advantage of the 200% tax deduction. This issue has been identified in other countries as well, such as in studies by Mansfield and Switzer (1985), GAO (1989, 2009), Bloom et al. (2019), and Chen et al. (2021). This paper aims to investigate whether Indian firms also engage in this practice of relabelling expenses. While no previous studies have examined this issue in India, this paper fills that gap by providing new evidence on relabelling practices. The quasi-experimental approach of difference-in-difference analysis is used to address potential data endogeneity issues.

The rest of this paper is organized as follows: Sect. 2 provides an overview of the research background and hypothesis development. Section 3 describes the data and methodology. Section 4 presents the findings. Finally, Sect. 5 concludes with some reflections on the implications of our results.

2 Research background and hypothesis development

There are two main types of studies that evaluate the effectiveness of tax incentives: those that measure the impact on individual companies (micro level) and those that measure the impact on a larger scale (macro level). The macro-level studies use overall research and development spending as the dependent variable and examine the effects of tax incentives at the national and state levels. Researchers such as Bloom et al. (2002), Athukorala and Kohpaiboon (2010), McKenzie and Sershun (2010), Moretti and Wilson (2017), and Brown et al. (2017) have conducted studies in this area.

At the micro level, studies have been conducted to evaluate the effects of R&D tax incentives on firms. These studies measure the impact of such incentives on a company's production of new products or processes patents (output additionality) and on its R&D expenditures (input additionality) (Cappelen et al. 2008; Czarnitzki et al. 2011; Colombo et al. 2011, Ivus et al. 2021). The input additionality studies use micro econometric analysis techniques to analyze the impact of R&D tax or generosity of tax on the R&D expenditures of the firm (Berger 1993; Hall and van Reenen 2000; Bloom et al. 2002; Corchuelo and Martinez-Ros 2009; Czarnitzki et al. 2011; Duguet 2010). Some studies have used surveys for R&D data (Oxeraa 2006; Czarnitzki et al. 2011; Cappelen et al. 2012; Lokshin and Mohnen 2012; Lokshin and

Mohnen 2013; Mulkay and Mairesse 2013; Guceri 2018) and some studies used annual reports and administered corporate return data for analysis (Yang et al. 2012; Rao 2016; Dechezleprêtre et al. 2016; Guceri and Liu 2019; Agrawal et al. 2020; Chen et al. 2021; Ivus et al. 2021). For this particular study, R&D data from audited annual reports of firms in the country were obtained from the CMIE prowess database.

Several studies have focused on the issue of relabelling expenses (Eisner et al. 1984; Mansfield and Switzer 1985; GAO 1989, 2009; Guceri 2018; Bloom et al. 2019; Chen et al. 2021). The US GAO conducted studies in 1989 and 2009, highlighting concerns over the definition of qualifying expenses and their monitoring. This issue is particularly problematic for developing countries. A recent study by Chen et al. 2021 found that relabelling accounts for 24.2% of reported R&D. It's important to keep in mind that obtaining DSIR certification involves maintaining a separate record of R&D expenses that Statutory Auditors have verified. The firms must also provide information about their projects to renew their certificates periodically. Administrative expenses can only be reclassified as current expenditures to a limited extent. A meta-analysis of microeconomic studies has revealed that R&D tax incentives have a greater impact on current expenditures than capital expenditures (Ladinska et al. 2015). This study aims to determine the effectiveness of R&D tax incentives in stimulating capital and current expenditures while also checking for any signs of reclassification.

One of the main issues with analyzing data is the presence of endogeneity problems, which occur when companies choose to participate in incentive programs on their own. This is also the case in India, where firms self-select and register under DSIR to receive benefits. Due to this concern, several studies use a direct approach to analysis, including Regression Discontinuity, Matching Analysis, or Difference-in-Difference Analysis (Hægeland and Møen 2007; Corchuelo and Martínez-Ros 2009; Yohei 2011; Yang et al. 2012; Bozio et al. 2014; Agrawal et al. 2014; Rao 2016; Dechezleprêtre et al. 2016; Bronzini and Piselli 2016; Guceri 2018; Wang 2018; Ivus et al. 2021). In this study, we use the difference in difference analysis methodology based on a recent survey of incentives in India by Ivus et al. (2021). However, there are two main differences from their study. Firstly, our data covers a longer period, from 2011 to 2021, and focuses on the impact of reducing the super deduction from 200 to 150% on R&D expenditures and patents. Secondly, we test the effects on current and capital expenditures separately, as no previous study has examined the presence of relabelling in India. Our main contribution is to provide evidence of relabelling in the country.

3 Data and methodology

This study primarily utilizes data extracted from two sources: the CMIE prowess database and the DSIR directory of in-house R&D units. The CMIE prowess database contains information on individual companies, gathered from audited annual reports, the Ministry of Company Affairs, and company filings with stock exchanges. This database includes data on the firms' capital, current and total R&D expenditures, and other financial information. The yearly data of firms registered with the DSIR is obtained from the department's annual DSIR directory. Table 2 displays the number of firms registered under DSIR and new recognitions from 2011 to 2021.

In this paper, we examine the R&D spending of companies in two categories: financial and non-financial. The non-financial category comprises firms from various major industries such as manufacturing, mining, electricity, construction, real estate & irrigation, and services. The study collects extensive data from a diverse range of companies operating within these categories. Most of the analyzed companies belong to the Drugs & Pharmaceutical and Computer Software industry groups.

The treatment dummy is the DSIR status of the ith firm in the jth year and is denoted by D_{it}. The variable takes value one if the firm i is registered with the DSIR in year j; otherwise, the value is zero. This divides the sample into two groups. The treated group is the firms registered under DSIR, and the control group is the group of firms not registered under DSIR. The variable C_t is the year when the super deduction incentive was available and takes value one for 2011–2016. So, the interaction term $D_{it}C_t$; allows for the difference in the impact of the change in tax incentive on R&D expenditure across two groups.

Table 3 Outcome and control variable

Outcome variables	
Log of total R&D intensity	Log of (total R&D expenditures/sales)
Log of capital R&D intensity	Log of (capital R&D/sales)
Log of current R&D intensity	Log of (Current R&D/sales)
Control variables	
Age	Number of years since operation
Exporter	A dummy variable = 1 if firm is an exporter
Importer	A dummy variable = 1 if firm imports capital goods
Leverage	Total borrowings divided by total assets of the firm
Firm size	Log of gross value of fixed assets

In this study, we use the variable D_{it} to represent the DSIR status of the ith firm in the jth year. This variable takes on a value of one if the firm is registered with DSIR in that year and zero otherwise. Using this variable, we divide our sample into two groups: the treated group, consisting of firms registered under DSIR, and the control group, consisting of firms not registered under DSIR.

Additionally, we use the variable C_t to represent the year when the super deduction incentive was available. This variable takes on a value of one, from 2011 to 2016. By creating an interaction term between $D_{it}C_t$, we can analyze the difference in the impact of the change in tax incentive on R&D expenditure across the two groups.

The difference-in-difference specification of the model is as follows:

$$LogRD_{it} = \alpha + \alpha_t + \beta D_{it} + \gamma D_{it}C_t + \delta X_{it}^{'} + \epsilon_{it} \quad (1)$$

where RD_{it} is one of the three measures of ith firm's R&D intensity in jth year, which is calculated by dividing the R&D expenditures by the firm's sales. The three outcome variables are total R&D intensity, capital R&D intensity, and current R&D intensity. α_t denotes the time-fixed component in the model. The percentage difference between DSIR registered and non-DSIR firms is $(e^{\beta-1})100$. The coefficient γ captures the differential change before 2016 for the treatment group compared to the control group. The percentage treatment effect of the change is $(e^{\gamma-1})100$. The X_{it} is a vector with a size of K × 1. Various control variables of the vector include Technology Imports, Firm Size, Leverage, importer dummy, exporter dummy, and age (which are listed in Table 3). The vector also includes a constant and ϵ_{it}, which represents a stochastic constant term. Table 4 shows the summary statistics of these variables.

4 Findings

Out of the 1244 firms included in the sample, 378 were registered under the DSIR consistently between 2011 and 2021, while 519 were never registered. The status of DSIR registration for all other firms fluctuated over time.[1] The model estimation results are presented in two sections. The first section analyzes the effects on companies that have been registered under DSIR from 2011 to 2021. In Sect. 4.2, the results are studied after taking into account the variable that changes over time.

4.1 Constant DSIR status

The information presented in this sample is based on data from 378 companies that were registered under DSIR from 2011 to 2021. The model was applied to 6276 observations, with results displayed in Table 5. Column 1 shows the total R&D expenditure intensity, column 2 displays the current R&D expenditure intensity, and column 3 presents the capital R&D expenditure. The variables of interest are the treatment variable D_{it} and the interaction variable $D_{it}C_t$.

Table 4 Summary statistics of variables

Variable	Mean	Std. dev	Min	Max
Total R&D expenditure	51.30	196.59	0.00	2924.50
Current R&D expenditure	42.07	163.87	0.00	2310.13
Capital R&D expenditure	10.70	73.75	0.00	1748.20
Total R&D expenditure intensity	0.02	0.07	0.00	3.64
Current R&D expenditure intensity	0.01	0.05	0.00	2.23
Capital R&D expenditure intensity	0.00	0.02	0.00	1.25
Technology imports	0.01	0.03	0.00	0.42
Firm size	6.08	2.00	4.61	13.56
Leverage	1.07	9.13	0.00	484.21
importer	1.00	0.05	0.00	1.00
exporter	0.48	0.50	0.00	1.00
Age	36.08	22.67	0.00	158.00

[1] For example, A company named '20 Microns Nano Minerals Limited' was registered under DSIR till 2018 but not afterwards. There were many such companies and therefore model with the time-varying treatment variable (DSIR registration status) is estimated.

Table 5 Constant DSIR status results

Outcome variable in logs	(1) Total R&D expenditure intensity	(2) Current R&D expenditure intensity	(3) Capital R&D expenditure intensity
Treatment group	1.417***	1.396***	0.460***
	(0.111)	(0.114)	(0.152)

Year fixed effects?	Yes	Yes	Yes

***Significant at 1% level, **5% level, *10% level. Robust Standard errors are in brackets

The data in column (1) indicates that the beta coefficient for variable D_{it} is positive ($\beta = 1.417$) and the gamma coefficient for variable $D_{it}C_t$ is also positive ($\gamma = 0.286$). Both coefficients are highly statistically significant, which means that the average Total R&D expenditure intensity in DSIR-registered firms is 4.1 times higher than in non-registered firms. Additionally, the estimated interaction effect is 1.33, meaning that the treatment effect of super deduction is 33%.

The second column of results shows that the coefficient β for the variable D_{it} is 1.396, and the coefficient γ for the variable $D_{it}C_t$ is 0.364. Both coefficients are positive and highly statistically significant, similar to the results for Total R&D expenditures. This means that the average Current R&D expenditure intensity in DSIR-registered firms' treatment groups is 4.03 times greater than the control group of non-registered firms. Additionally, the estimate of the interaction effect is 1.44, indicating that the treatment effect of super deduction is 44%.

Based on the data presented in column (3), it can be observed that the coefficient β is 0.460 for the variable D_{it}, which is a positive and highly significant value. Meanwhile, the coefficient γ is 0.137 for the variable $D_{it}C_t$, but this value is statistically insignificant. This means that the average capital R&D expenditure intensity in treatment groups of DSIR registered firms is 1.58 times greater than the control group of non-registered firms, as determined by the $e^{0.460}$ value. However, the impact of the super deduction treatment on capital R&D expenditures is not significant.

4.2 Time-varying DSIR registration status

Table 6 displays the outcome when the DSIR status, which is the treatment variable, varies over time. The findings in Table 6 are comparable to those in Table 5. The estimates are elevated when the DSIR status is time-varying, but the conclusions are the same. Companies that are registered under DSIR have invested more in research and development (R&D), but the 200% super deduction has only significantly affected current expenses and not capital expenses.

The first column of results indicates that the coefficient β for the variable D_{it} is positive, with a value of 1.833. The coefficient γ for the variable $D_{it}C_t$, is also positive, with a value of 0.252. These coefficients are both highly statistically significant. This suggests that the average Total R&D expenditure intensity is 6.25 times greater for treatment groups of DSIR-registered firms compared to the control group of non-registered firms. The estimate for the interaction effect is 1.29, implying that the treatment effect of a 200% super deduction is 29%.

The second column of results shows that the coefficients for the variables D_{it} and $D_{it}C_t$ are both positive and highly statistically significant. Specifically, β is 1.826 and γ is 0.325. This indicates that the average Current R&D expenditure intensity in treatment groups of DSIR-registered firms is 6.21 times greater than that of the control group of non-registered firms. The interaction effect estimate is 1.38, meaning that the 200% super deduction treatment effect is 38%.

***Significant at 1% level, **5% level, *10% level. Robust Standard errors are in brackets

According to the information in column (3), the β coefficient for variable D_{it} is 0.658, which is both positive and highly significant. However, the coefficient for variable $D_{it}C_t$ is $\gamma = 0.042$ and statistically insignificant. This means that the average capital R&D expenditure intensity for DSIR-registered firms in treatment groups is 1.93 times greater than that of non-registered control groups. However, the impact of the 200% super deduction treatment on capital R&D expenditures is insignificant.

In this study, the expenses of companies were examined in two categories: financial and non-financial. The model was evaluated for both categories, and the results revealed that non-financial firms had significant impacts while financial firms did not. It is important to note that financial firms made up less than 10% of the sample size. The study also highlighted that non-financial firms play a greater role in the overall research and development expenditure of the economy.

5 Conclusion

This research paper aims to address the topic of relabelling, which has limited literature available. Several governments have changed the R&D tax incentives policy in India from 2011 to 2021. One of the significant changes was the reduction of income tax deductions from 200% in 2022 to 150% in 2016 and eventually to 100% in 2021. This presents an opportunity to examine the effectiveness of the generous deduction and other incentives given to firms registered under DSIR. These firms can avail of several fiscal incentives. The study considers the firms registered under DSIR as the treatment group and uses the difference-in-difference approach to test their effectiveness. The research assesses the changes in R&D expenditure during the period when the Super deduction was available.

The study found that there was a clear difference in the average R&D spending between the companies in the treated group and those in the control group. However, while the super deduction offered was very generous, it only significantly impacted current R&D spending and not capital R&D spending. This lack of impact on capital R&D spending suggests that some companies may have tried to relabel their spending. The increase in Total R&D spending was driven solely by current spending. The super deduction caused an increase of 44% in current spending but had no significant effect on capital R&D spending. This suggests that some companies may have increased their current spending in order to benefit from the tax deduction without increasing their capital spending at a commensurate rate.

The DSIR offers a combination of incentives that effectively increase current and capital R&D expenditures. The fiscal incentives provided by DSIR have resulted in a six-fold increase in current expenditures and almost a two-fold increase in capital expenditures. However, it is important to note that while incentives to encourage R&D expenditures are beneficial, overly generous schemes can lead to abuse

of the system. The Super deduction, for example, incentivizes firms to falsely label administrative expenses as R&D expenditures to take advantage of tax deductions without any actual increase in innovation.

Funding No funds, grants, or other support was received.

Third Order Quadrature Oscillator with Arbitrary Phase Shift Generation and Amplitude Modulation Using MDXCCCTA

Garima Shukla, Sajal K. Paul

***Abstract*— This work presents the realization of an electronically tunable third-order quadrature oscillator (TOQO) employing a current mode block, modified dual-X current controlled current conveyor transconductance amplifier (MDXCCCTA) and three grounded passive capacitors. The oscillator simultaneously provides two quadrature voltage outputs, two high-impedance quadrature current outputs, and one high-impedance current output with controllable amplitude. Further, the proposed circuit works as an arbitrary phase shift generator from 0 to $\pm 90^0$. In addition, the realization generates amplitude modulation (AM) or amplitude shift keying (ASK) signals with controllable amplitude without affecting the condition of oscillation (CO) and frequency of oscillation (FO). The CO and FO are electronically tunable and can be controlled independently. Moreover, an automatic control method is proposed to stabilize the CO and FO against the variation in relative amplitudes of quadrature signals when TOQO works as an arbitrary phase shift generator. It exhibits low phase error (0.22^0), low % THD (0.78-0.88)), low phase noise (-180 dBc to -240 dBc), low sensitivity (<0.45%) and low power consumption (1.08 mW). Moreover, the circuit is vastly robust against tolerances in passive components and process, voltage and, temperature (PVT) corners as the deviations from nominal values are small (<0.8%). Furthermore, the TOQO occupies comparatively a small layout chip area ($7810\mu m^2$). It is a compact module providing quadrature, arbitrary phase shifted, and AM signals from the same realization. Therefore, the proposed design can be a handy module for instrumentation, measurement, and communication systems. Experimental results are presented to verify simulation and theoretical analyses.**

***Index Terms*— AM/ASK, MDXCCCTA, Oscillator, Phase shift, Quadrature, Resistor less, Third Order.**

I. Introduction

Sinusoidal oscillators/ quadrature oscillators find wide applications in instrumentation, measurement, analog signal processing, and communication system. A quadrature oscillator (QO) generates two sinusoidal signals having 90^0 phase shifts. Measurement of an unknown capacitance using the principle of an oscillator is a well-investigated scheme in an instrumentation system as presented in [1, 2]. A QO realized in [3] has been used to measure the soil's impedance to characterize the soil's different properties, like humidity and salinity. It is well acknowledged that QOs generating multiple sinusoids with 90^0 phase shifts are important blocks for quadrature mixers and amplitude modulators (AM) in transmitter and receiver systems. There is a requirement for AM signals in various detection systems. An AM-based ultrasonic dynamic range detection method for distance measurement is illustrated in [4], where the transmitter employs a sinusoidal generator and analog multiplier as a modulator in the system. This detection system is also essential in very accurate quartz sensor methods such as [5, 6], where an oscillator and mixer are required in the measurement system of quartz crystal microbalance gas sensors.

Considering the diverse applications of QO, a wide variety of QOs has emerged [7-38] in the past few decades. An electronically tunable QO with enhanced tuneability is presented in [7]. A few arbitrary phase shift oscillator configurations are presented in [8].

During the past decades, the current-mode (CM) approach has been receiving considerable attention in analog integrated circuit design over the voltage mode counterparts due to their potential advantages, such as inherently wide bandwidth, higher slew rate, greater linearity, wider dynamic range, simple circuitry, and low power consumption [9]. The QO reported in [7] is a second-order circuit using a CM building block.

Moreover, the third-order quadrature oscillators (TOQOs) are immensely preferred over the second-order oscillators due to their higher accuracy, higher quality factor, lower harmonic distortion, and lower phase noise; as a consequence, the realization of several TOQOs with various CM building blocks have been reported [10-38]. The TOQO realizations in [10-30, 32, 33, 37, 38] generate quadrature signals only, and some of the TOQOs designed in [31, 33, 34, 35, 36] have the feature of analog modulation (AM/ASK) within them. Furthermore, various applications require quadrature current and quadrature voltage signals simultaneously. The TOQOs designed in [12, 15, 16, 17, 20-21, 22, 24, 25, 29, 31, 32, 33-38] simultaneously generate quadrature current and voltage signals. Moreover, oscillators with a variable FO without disturbing the CO are a desirable requirement in oscillator designs; however, independent controlling of FO and CO through electronic tuning are available only in [11, 15, 18, 19, 20-21, 26-28, 29-30, 33-37].

The TOQOs in [10-45] have been realized with two or more analog building blocks (ABBs), and [37, 38] are realized using only one ABB.

The exhaustive study of [7, 8, 10-38] as illustrated in Table V reveals the following shortcomings; (i) none of the realizations work as a QO, arbitrary phase shift generator, and

This article has been accepted for publication in IEEE Transactions on Instrumentation and Measurement. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TIM.2023.3300449

an AM generator from the same circuit topology, (ii) most of the oscillator circuits use an excessive number of active/passive components, (iii) no realization possessing full electronic tuneability and having small layout chip area provides quadrature currents (CM), quadrature voltages (VM), and AM signals simultaneously (iv) many of the circuit designs do not offer the independent controlling of FO and CO through electronic tuning (v) many of the realizations possess high % THD, high phase error, and high power consumption.

In view of attempting to fill some of the research gaps, this research presents the realization of a novel third-order quadrature oscillator (TOQO) employing a current mode building block, MDXCCCTA, and three grounded passive capacitors. Further, the same circuit works as an arbitrary phase and AM generator. The proposed TOQO has the following main advantageous features: (i) entirely electronically tunable circuit, (ii) provides two VM and two CM quadrature signals, simultaneously, (iii) independent controlling of CO and FO through separate electronically tunable parameters (bias currents), (iv) high impedance current outputs, hence suitable for cascading, (v) exhibits high frequency of oscillation (vi) works as an AM/ASK signal generator without affecting the CO and FO, (vii) works as an arbitrary phase shift generator/oscillator (APSO) providing arbitrary phase in the range, 0 to $\pm 90^0$, (viii) CO and FO are simultaneously controlled against variation in relative amplitudes by a new proposed automatic stabilization method implemented in proposed TOQO, (ix) variable frequency through electronic tuning, (x) wide electronically and non-electronically tunable range of frequency of oscillation, (xi) occupies comparatively small layout chip area, (xii) exhibits low phase error, low THD, low phase noise and low power consumption, (xiii) vastly robust against tolerances in passive components as verified by Monte Carlo simulation (xiv) small deviation against various process, voltage and, temperature corners as verified by PVT corner analysis, (xv) effect of parasitics of MDXCCCTA in circuit performance is negligible as confirmed by post layout simulation, and (xvi) low intermodulation distortion during AM generation.

Hence, the proposed topology consisting of QO, modulator (AM/ASK), and arbitrary phase shift generator may be useful as a compact module in measurement, instrumentation, and communication systems.

This paper is organized into seven sections. Section I is this section; herein, the introduction is given. Section II proposes the TOQO using MDXCCCTA and further its illustration as an arbitrary phase generator, and AM generator is given. Section III illustrates the automatic CO and FO control method in the proposed TOQO. The non-ideal analysis is illustrated in section IV. Section V presents simulation results with a discussion, followed by experimental results in Section VI. A comparison with the available literature is given in section VII, followed by the conclusion in section VIII.

II. Proposed Oscillator

This section discusses the MDXCCCTA, followed by the realization of a third-order quadrature oscillator (TOQO) using MDXCCCTA. The extension of TOQO as an arbitrary phase shift generator and amplitude modulation is also given.

A. MDXCCCTA

The second-generation current conveyor (CCII) is a versatile current mode building block. It has primarily three terminals, X, Y, and Z. The voltage at the X terminal is equal to the Y terminal, whereas the current at the X terminal is conveyed to the Z terminal with unity gain. To add flexibility to CCII, dual-X current conveyor (DXCCII) [39], followed by DXCCCII [40, 41], was introduced. Another version of DXCCII was reported as the Dual-X current conveyor transconductance amplifier (DXCCTA) [42-44]. The DXCCTA combines DXCCII and a transconductance amplifier (TA) [42-44]. In contrast, to achieve electronic control through the X± terminal's intrinsic resistances in DXCCCII, electronic tunability in DXCCTA is introduced by controlling TA's transconductance in DXCCTA.

Electronic tuneability through controlling the X± terminal's intrinsic resistance is one of the most desirable features in CM building blocks, such as in DXCCCII. However, no DXCCTA block has the electronic tuneability feature through controlling intrinsic resistances at X± terminals. This paper proposes a current controlled DXCCTA as a new variant of CCII, combining the features of DXCCCII and DXCCTA with one more cascaded TA. It may be named a modified Dual-X current controlled current conveyor transconductance amplifier (MDXCCCTA).

The circuit symbol and internal CMOS structure of the MDXCCCTA are shown in Fig. 1 and Fig. 2, respectively. As depicted in Fig. 2, the proposed MDXCCCTA is similar to conventional DXCCTA [42-44] except with the internal modification for the current controllability of intrinsic resistances at X± terminals. Fig. 2 shows the availability of an electronic tuneability feature for controlling intrinsic resistances, R_{X+} and R_{X-}, present at X+ and X- terminals through bias currents, I_{b1} and I_{b2}, respectively, and the availability of an additional tuning through bias current (I_{b4}) of second TA. The resistances at Y, Z, O_1, and O_2 terminals are high. The port relationships of MDXCCCTA in matrix form are given as follows;

$$\begin{pmatrix} I_Y \\ V_{X+} \\ V_{X-} \\ I_{Z+} \\ I_{Z-} \\ I_{O1+} \\ I_{O2+} \end{pmatrix} = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ 1 & R_{X+} & 0 & 0 & 0 \\ -1 & R_{X-} & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & g_{m1} & 0 \\ 0 & 0 & 0 & g_{m2} & -g_{m2} \end{pmatrix} \begin{pmatrix} V_Y \\ I_{X+} \\ I_{X-} \\ V_{Z+} \\ V_{Z-} \end{pmatrix} \quad (1)$$

Where in (1),

$$R_{X+} = \frac{1}{\sqrt{8k_1 I_{b1}}}, \quad R_{X-} = \frac{1}{\sqrt{8k_2 I_{b2}}} \tag{2}$$

Where, $$k_1 = \mu_n C_{OX}\left(\frac{W}{L}\right)_{10,\,11} = \mu_p C_{OX}\left(\frac{W}{L}\right)_{3,\,4} \tag{3}$$

$$k_2 = \mu_n C_{OX}\left(\frac{W}{L}\right)_{27,\,28} = \mu_p C_{OX}\left(\frac{W}{L}\right)_{29,\,30} \tag{4}$$

It may be observed from (2) that R_{X+} and R_{X-} can be tuned through the bias currents, I_{b1} and I_{b2}, respectively. The g_{m1} and g_{m2} are the trans-conductance gains of the first and second transconductance amplifiers (TAs) of MDXCCCTA and are expressed as;

$$g_{m1} = \sqrt{k_3 I_{b3}} \tag{5}$$

Where, I_{b3} is the bias current and $k_3 = \mu C_{OX}\left(\frac{W}{L}\right)_{43,\,44}$. (5a)

$$g_{m2} = \sqrt{k_4 I_{b4}} \tag{6}$$

Where, I_{b4} is the bias current and $k_4 = \mu C_{OX}\left(\frac{W}{L}\right)_{47,\,48}$.

B. Proposed Third-Order Quadrature Oscillator Circuit

1). Quadrature Signals Generator

The realization of the proposed TOQO is based on the principle of circuit connection of one current mode inverting lossy integrator and two current mode non-inverting lossless integrators, as shown in Fig. 3.

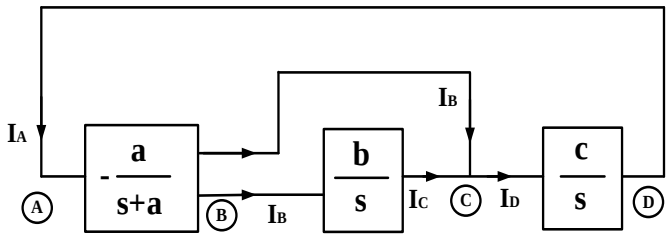

Fig. 3 Functional block diagram for realizing third-order quadrature oscillator.

The equation (7) depicts the functions of one current mode inverting lossy integrator and two current mode non-inverting lossless integrators respectively of Fig. 3 as;

$$\frac{I_B}{I_A} = -\frac{a}{s+a}, \quad \frac{I_C}{I_B} = \frac{b}{s}, \quad \frac{I_A}{I_D} = \frac{c}{s} \tag{7}$$

And $$I_D = I_B + I_C = \left(1+\frac{b}{s}\right) I_B \tag{8}$$

From (7) and (8), $$\frac{I_A}{I_D} = \frac{I_A}{\left(1+\frac{b}{s}\right) I_B} = \frac{c}{s} \tag{9}$$

From (7) and (9); $$\frac{I_A}{I_B} = -\frac{s+a}{a} = \frac{c}{s}\left(1+\frac{b}{s}\right) \tag{10}$$

By solving (10), following characteristic equation is obtained:

$$s^3 + as^2 + acs + abc = 0 \tag{11}$$

From (11), frequency of oscillation (FO) is obtained by equating term, $as^2 + abc = 0$, and results as;

$$\text{FO:} \quad \omega_O = \sqrt{bc} \tag{12}$$

Further, by using (12) in the term, $s^3 + acs = 0$ of (11) results the CO as;

$$\text{CO: } a = b \tag{13}$$

Since, (11) represents the characteristic equation of a third-order oscillator, thus the design based on configuration of Fig. 3 will synthesize a third-order quadrature oscillator.

In line with Fig. 3, the proposed QO is designed. It consists of one analog building block (ABB), MDXCCCTA, and three grounded passive capacitors, C_1, C_2, and C_3, as shown in Fig. 4. The terminals Z_{+C} and Z_{+C2} are the Z_+ copies, $Z\text{-}_C$ is the Z- copy, and O_{1+C} is the O_{1+} copy of MDXCCCTA. The V_{OA} and V_{OB} represent the voltages across the capacitors, C_1 and C_2, respectively. Nodes A, B, C, D corresponding to Fig. 3 are mentioned in the proposed circuit of Fig. 4. The parameters a, b and c, of Fig. 3 correspond to the circuit realization terms in proposed oscillator configuration of Fig. 4, as;

$$a = \frac{1}{R_{X+}C_1}, \quad b = \frac{g_{m1}}{C_2} \quad \text{and} \quad c = \frac{1}{R_{X-}C_3} \tag{14}$$

Routine analysis of the circuit in Fig. 4 results in the characteristic equation of a TOQO as:

$$s^3 C_1 C_2 C_3 R_{X+} R_{X-} + s^2 C_2 C_3 R_{X-} + sC_2 + g_{m1} = 0 \tag{15}$$

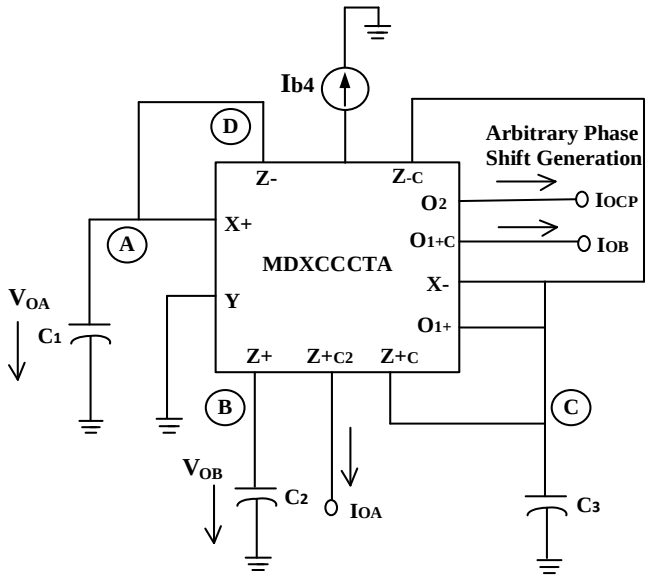

Fig. 4. Proposed TOQO circuit with arbitrary phase shift oscillator.

FO and CO are obtained as follows;

$$\text{FO:} \quad \omega_O = \sqrt{\frac{g_{m1}}{R_{X\text{-}}C_2C_3}} = \sqrt{\frac{(8k_2I_{b2})^{1/2}(k_3I_{b3})^{1/2}}{C_2C_3}} \tag{16}$$

$$\text{CO:} \quad g_{m1}R_{X+} = \frac{C_2}{C_1}, \quad \text{or} \quad \frac{(k_3I_{b3})^{1/2}}{(8k_1I_{b1})^{1/2}} = \frac{C_2}{C_1} \tag{17}$$

It is apparent from expressions (16) and (17) that the tuning of $R_{X\text{-}}$ through I_{b2} can control the FO without affecting the CO; similarly, the CO can be controlled by tuning R_{X+} through I_{b1} and C_1 without affecting FO. Hence, the proposed oscillator provides independent or orthogonal controlling of FO and CO through electronic tuning.

As shown in the configuration of Fig. 4, the two quadrature current outputs, I_{OA} and I_{OB}, and two quadrature voltage outputs, V_{OA} and V_{OB}, are simultaneously obtained. Quadrature currents are obtained at high impedance terminals and are related as;

$$I_{OA} = j\frac{\omega_O C_2 I_{OB}}{g_{m1}} \tag{18}$$

Similarly, quadrature voltage outputs are related as;

$$V_{OA} = -j\omega_O C_2 R_{X+} V_{OB} \tag{19}$$

It is observed from (18) and (19) that amplitudes of I_{OA} and I_{OB} and V_{OA} and V_{OB} can be electronically controlled through tuning of g_{m1} and R_{X+}, respectively.

2) Arbitrary Phase Shift Generator/ Oscillator (APSG/APSO)

The proposed oscillator works as an arbitrary phase shift generator/oscillator (APSO) and generates a signal of various phases when I_{b4} in the circuit of Fig. 4 is connected to a d.c. bias current. In many instrumentation techniques with transducers, an APSO [8] is used to compensate for phase errors. It is also required in phase modulators, mixers, and phased array antennas. The proposed oscillator provides arbitrary phase-shifted signals along with quadrature signals.

The output current, I_{OC} corresponds to I_{OCP} at the O_2 terminal of Fig. 4, when QO works as a phase shift generator and g_{m2P} is transconductance being controlled through I_{b4}. I_{OCP} results in:

$$I_{OCP} = g_{m2P}\{(V_{OB} - V_{OA})\} \tag{20}$$

As V_{OA} and V_{OB} are in quadrature, hence as per (19), these may be written as;

$$V_{OB} = V_S sin(\omega_O t) \quad \text{and} \quad V_{OA} = -V_C cos(\omega_O t) \tag{21}$$

Where V_S and V_C are amplitudes. Hence, from (20) and (21), I_{OCP} results in:

$$I_{OCP} = g_{m2P}\{Asin(\omega_O t + \alpha)\} \tag{22}$$

Where, $A = \sqrt{V_S^2 + V_C^2}$ and

$$\text{phase shift} = \alpha = tan^{-1}\left(\frac{V_C}{V_S}\right) \tag{23}$$

For equal amplitudes, $V_S = V_C = V_M$, as per (22) and (23), I_{OCP} results in a current signal having 45^0 of phase-shifting with respect to V_{OB} and is expressed as;

$$I_{OCP} = g_{m2P}\{\sqrt{2}V_M sin(\omega_O t + 45^0)\} \tag{24}$$

Consequently, from (24), the resultant I_{OCP} is a 45^0 phase-shifted signal with respect to I_{OB} as I_{OB} corresponds to $\sin(\omega_O t)$ and, subsequently, -45^0 with respect to I_{OA} as I_{OA} corresponds to $\cos(\omega_O t)$. Hence, there is the simultaneous availability of three progressively 45^0 phase-shifted current signals as, $I_{OB} \rightarrow \sin(\omega_O t)$, $I_{OCP} \rightarrow \sin(\omega_O t + 45^0)$, and $I_{OA} \rightarrow \sin(\omega_O t + 90^0) \rightarrow \cos(\omega_O t)$, along with two quadrature signals, I_{OA} and I_{OB}.

Further, it is observed from (19) that the relative amplitudes of V_{OB} and V_{OA} can be adjusted by controlling R_{X+} with I_{b1}. If the amplitudes of generated quadrature signals, V_{OA} and V_{OB} are being varied relative to each other by selecting different values of R_{X+} through tuning of I_{b1}, the phase shift (α) of the I_{OCP} will be in the range either from 0 to 45^0 or 45^0 to 90^0 with respect to I_{OB}, depending on $V_S > V_C$ or $V_C > V_S$ as per (23). Simultaneously, g_{m1} is adjusted through I_{b3}, and R_{X-} is adjusted through I_{b2} to maintain the CO and FO constant. Variation in I_{b1} (i.e., R_{X+}) results in a different set of amplitudes of V_{OA} and V_{OB}, and subsequently, the resultant I_{OCP} is a phase shift generated signal with respect to I_{OB}. The phase value of the generated signal (I_{OCP}) is established through (23), and its magnitude is adjusted to the required value through tuning of g_{m2P} (i.e., I_{b4}) as per (22). Therefore, any arbitrary phase shift in the range of 0^0 to 90^0 with respect to I_{OB} and in the range of -90^0 to 0^0 with respect to I_{OA} can be obtained.

C. Amplitude Modulator (AM)

Several instrumentation techniques require AM generation and employ analog multipliers as modulators [4]. However, the use of multipliers makes the system complex. The proposed TOQO circuit works as an AM signal generator from the same circuit configuration of Fig. 4. It is obtained by just connecting the I_{b4} of Fig. 4 to an a.c. signal. The TOQO with AM generation is shown in Fig. 5. The output current (I_{OC}) corresponds to I_{OCM} when QO works as an AM generator. Thereby, the I_{OCM} can be controlled with a.c. signal, I_{b4} is expressed as;

$$I_{OCM} = g_{m2M}(V_{OB} - V_{OA}) \tag{25}$$

The value of transconductance (g_{m2M}) varies with the a.c.

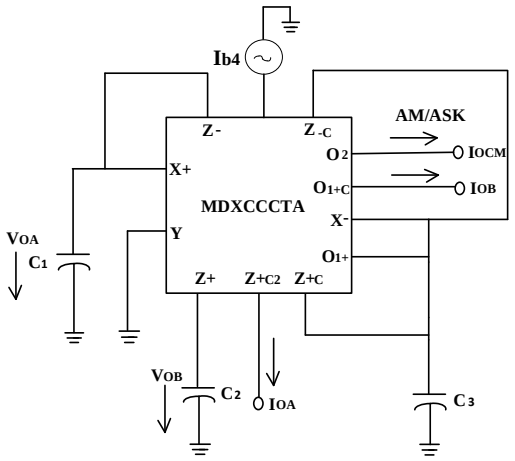

Fig. 5. Proposed TOQO circuit with AM generation.

signal, I_{b4}, without affecting the CO and FO. Hence, if a signal is applied at I_{b4}, it acts as a modulating signal, and as a result, the AM/ASK modulated signals can be obtained from I_{OCM}. Hence, on applying a sinusoidal or triangular as I_{b4}, an amplitude modulated (AM) signal resulted at I_{OCM}, whereas on applying a rectangular signal, an amplitude shift keying (ASK) signal is obtained. Therefore, the proposed TOQO works as an AM signal generator and an APSO from the same circuit topology by altering the connection at I_{b4} from a d.c. to an a.c. current source without requiring any additional component.

III. Automatic Control of CO and FO

In this section, a method is proposed to automatically control the CO and FO of TOQO to stabilize it against variations in relative amplitudes of V_{OA} and V_{OB}. This approach is illustrated in Fig. 6. Firstly, the peaks of generated quadrature signals, V_{OA} and V_{OB}, are detected through a peak detector (Peak Det.), and

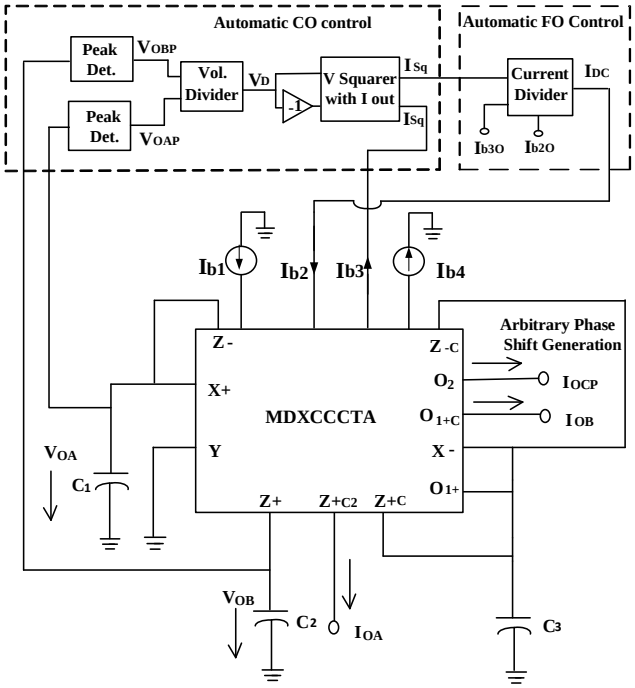

Fig. 6 Automatic CO and FO control in proposed TOQO.

then these two detected (V_{OAP}, V_{OBP}) signals get divided through a voltage divider. The resultant divider voltage signal (V_D) and its inverted signal, $-V_D$, are fed to a voltage (V) squarer with I out, the output of which is a current signal (I_{Sq}) proportional to the square of the input voltage (V_D). This current signal (I_{Sq}) is fed as I_{b3} in the MDXCCCTA, which is an automatically adjusted value of I_{b3} to maintain CO. Furthermore, a replica of the current, I_{Sq}, is fed to a current divider circuit, which generates a current (I_{DC}) in a reverse proportion to I_{Sq}. I_{DC} is fed as I_{b2} in MDXCCCTA and is an automatically adjusted value of required I_{b2} to maintain FO constant.

The governing approach of a proposed automatic control circuit configuration of Fig. 6 is illustrated as follows.

I_{b2O} and I_{b3O} correspond to the values of I_{b2} and I_{b3}, respectively, at which $V_{OAP} = V_{OBP}$ for the circuit's specified operating frequency (say 30.59 MHz).

From (17), the CO is:

$$\frac{\sqrt{k_3 I_{b3}}}{\sqrt{8k_1 I_{bl}}} = \frac{C_2}{C_1} \tag{26}$$

For $\frac{C_2}{C_1} = 1$; $\quad \frac{\sqrt{k_3 I_{b3}}}{\sqrt{8k_1 I_{bl}}} = 1$ or $I_{b3} = \frac{8k_1 I_{b1}}{k_3}$ (27)

As per (19), R_{X+} is expressed as;

$$R_{X+} = j\frac{V_{OA}}{\omega_O C_2 V_{OB}} \tag{28}$$

If, $\omega_O C_2$=constant=G_1, then; (29)

$$R_{X+} \propto \frac{V_{OAP}}{G_1 V_{OBP}} \tag{30}$$

Where, V_{OAP}= peak voltage of V_{OA}, and V_{OBP}= peak voltage of V_{OB} detected by a peak detector.

(30) implies that on varying R_{X+}, proportionally the ratio of peak values of generated quadrature signals ($\frac{V_{OAP}}{V_{OBP}}$) will be changed on keeping G_1 constant.

From (2) and (30), we get $\frac{1}{\sqrt{8k_1 I_{bl}}} \propto \frac{V_{OAP}}{G_1 V_{OBP}}$ (31)

Hence, $\frac{1}{8k_1 I_{bl}} \propto \left(\frac{V_{OAP}}{G_1 V_{OBP}}\right)^2$ or $\frac{1}{I_{bl}} \propto \frac{8k_1}{{G_1}^2}\left(\frac{V_{OAP}}{V_{OBP}}\right)^2$ (32)

If $\frac{8k_1}{{G_1}^2} = G_2$ =constant in (32) then; (33)

$$\frac{1}{I_{bl}} \propto G_2\left(\frac{V_{OAP}}{V_{OBP}}\right)^2 \text{ or, } I_{bl} = \frac{1}{G_2}\left(\frac{V_{OBP}}{V_{OAP}}\right)^2 \tag{34}$$

On considering, $\left(\frac{V_{OBP}}{V_{OAP}}\right)^2 = M$ (35)

From (34) results, $I_{bl} = \frac{M}{G_2}$ (36)

It is inferred from (36) that on keeping G_2 constant, variation in I_{b1} is directly proportional to a change in the value of M.

From (27) and (36), we get

$$I_{b3} = \frac{8k_1}{k_3 G_2} M \tag{37}$$

If, $\frac{8k_1}{k_3 G_2} = G_3$, then (38)

$$I_{b3} = G_3 M = I_{b3O} M \tag{39}$$

Therefore, it may be noticed, from (36) and (39), that after each variation in I_{b1}, M will be changed proportionately; as a

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:42:20 UTC from IEEE Xplore. Restrictions apply.
© 2023 IEEE. Personal use is permitted, but republication/redistribution requires IEEE permission. See https://www.ieee.org/publications/rights/index.html for more information.

This article has been accepted for publication in IEEE Transactions on Instrumentation and Measurement. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TIM.2023.3300449

consequence, I_{b3} will also be changed, and subsequently, CO will automatically be maintained constant as per (26).

The peak voltages, $V_1=V_{OAP}$ and $V_2=V_{OBP}$ obtained through peak detector [45] are subsequently divided by a simple OTA-based Vol. Divider [46] and results in:

$$V_D = K_V \frac{V_{OBP}}{V_{OAP}}; \quad (40)$$

Where K_V is the proportionality constant [46].

The results in V_D and inverted V_D (through an inverter) are fed to a simple CCII-based 'V Squarer with I out' circuit as shown in Fig. 7. It is based on [47] with the addition of a z- terminal. The output of it is a current signal (I_{Sq}) proportional to the square of V_D and is expressed as:

$$I_{Sq} = K_{Sq} V_D^2 = K_{Sq}\left(K_V \frac{V_{OBP}}{V_{OAP}}\right)^2 = K_{Sq} K_V^2 \left(\frac{V_{OBP}}{V_{OAP}}\right)^2 \quad (41)$$

$K_{Sq} = \mu_n C_{OX}\left(\frac{W}{L}\right)_{NMOS}$ is of matched NMOS of Fig. 7. This current I_{Sq}, as shown in Fig. 6, is used as I_{b3}.

Thus, (39) and (41) results in:

$$I_{Sq} = I_{b3} = K_{Sq} K_V^2 M = I_{b3O} M \quad (42)$$

Hence, on varying relative amplitudes of V_{OAP} and V_{OBP} with I_{b1}, the M value will change, and as a consequence, $I_{Sq} = I_{b3}$ changes with factor M. Thus, CO is automatically maintained as per (26).

Furthermore, to maintain the FO constant, simply a current divider [48] is employed in the proposed automatic control system. As shown in Fig. 6, a copy of obtained I_{Sq} is fed through the z+ terminal of "V Squarer with I out" as shown in Fig. 7 to the input of the current divider and output I_{DC} results as [48];

$$I_{DC} = \frac{I_X I_Y}{I_w} \quad (43)$$

If, $I_W = I_{Sq} = I_{b3} = I_{b3O}\left(\frac{V_{OBP}}{V_{OAP}}\right)^2$, $I_X = I_{b3O}$, $I_Y = I_{b2O}$, then from (35);

$$I_{b2} = I_{DC} = \frac{I_{b2O}}{\left(\frac{V_{OBP}}{V_{OAP}}\right)^2} = \frac{I_{b2O}}{M} \quad (44)$$

I_{DC} is connected as I_{b2} in the proposed circuit, hence $I_{DC} = I_{b2}$. From (44) and (42), we get

$$I_{b2} = \frac{I_{b2O}}{M} \text{ and } I_{b3} = M I_{b3O} \quad (45)$$

Moreover, from (16); FO: $\omega_O = \sqrt{\frac{\sqrt{8k_2 I_{b2}}\sqrt{k_3 I_{b3}}}{C_2 C_3}}$ and on keeping C_2C_3=constant, ω_O results in:

$$\omega_O \propto \sqrt{\sqrt{8k_2 I_{b2}}\sqrt{k_3 I_{b3}}} \propto \sqrt{\sqrt{\frac{8k_2 I_{b2O}}{M}}\sqrt{k_3 M I_{b3O}}} \quad (46)$$

Therefore, for each variation of I_{b1}, the value of I_{b3} varies with a factor of M, and I_{b2} varies with a factor of 1/M as per (45). Thus, the FO remains unaffected as per (46).

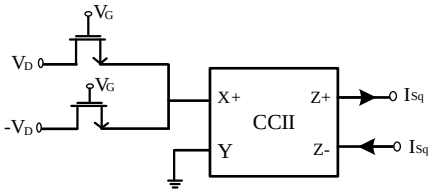

Fig. 7 V Squarer with I out circuit.

Therefore, it is confirmed that ω_O will be maintained to a fixed value through the automatic adjustment of I_{b2}, and CO will automatically be adjusted through I_{b3} as per (42). The proposed stabilization approach results as a new technique to automatically control the CO and FO simultaneously.

IV. Nonideal Analysis

The frequency performance of the oscillator circuit may deviate from the ideal one due to the non-ideality of MDXCCCTA. The non-ideality effects may be categorized into two groups. The first group is due to tracking errors of internal current and voltage transfers of MDXCCCTA. The second group is from the parasitics of MDXCCCTA comprising resistances and capacitances. The effects of the non-ideality of the MDXCCCTA are discussed as follows:

A. Non-ideality Effect due to Current and Voltage Transfer Gains

Considering the non-ideality of current and voltage transfer gains for the oscillator, the port relationships (1) may be modified as follows;

$$\begin{pmatrix} \boldsymbol{I_Y} \\ \boldsymbol{V_{X+}} \\ \boldsymbol{V_{X-}} \\ \boldsymbol{I_{Z+}} \\ \boldsymbol{I_{Z-}} \\ \boldsymbol{I_{O1+}} \end{pmatrix} = \begin{pmatrix} \boldsymbol{0} & \boldsymbol{0} & \boldsymbol{0} & \boldsymbol{0} \\ \boldsymbol{\Phi_1} & \boldsymbol{R_{X+}} & \boldsymbol{0} & \boldsymbol{0} \\ \boldsymbol{-\Phi_2} & \boldsymbol{R_{X-}} & \boldsymbol{0} & \boldsymbol{0} \\ \boldsymbol{0} & \boldsymbol{\alpha_1} & \boldsymbol{0} & \boldsymbol{0} \\ \boldsymbol{0} & \boldsymbol{0} & \boldsymbol{\beta_1} & \boldsymbol{0} \\ \boldsymbol{0} & \boldsymbol{0} & \boldsymbol{0} & \boldsymbol{+\gamma_1 g_{m1}} \end{pmatrix} \begin{pmatrix} \boldsymbol{V_Y} \\ \boldsymbol{I_{X+}} \\ \boldsymbol{I_{X-}} \\ \boldsymbol{V_{Z+}} \end{pmatrix} \quad (47)$$

and $\boldsymbol{I_{Z+C} = \alpha_2 I_{x+}}$, $\boldsymbol{I_{Z\text{-}C} = \beta_2 I_{X-}}$, (48)

Where $\boldsymbol{\alpha_1}$, $\boldsymbol{\alpha_2}$, $\boldsymbol{\beta_1}$, and $\boldsymbol{\beta_2}$ are the non-unity current transfer gains, $\boldsymbol{\Phi_1}$ and $\boldsymbol{\Phi_2}$ are non-unity voltage transfer gains. Similarly, $\boldsymbol{\gamma_1}$ is the non-ideal transconductance gain. Ideally, all these transfer gains are unity. Considering non-ideal relationships (47) and (48), the characteristic equation (15) of the oscillator is modified as follows;

$$\boldsymbol{s^3 C_1 C_2 C_3 R_{X+} R_{X-} + s^2\{C_2 C_3 R_{X-} + (1-\beta_2) C_1 C_2 R_{X+}\} + s}$$

$$\boldsymbol{\{\beta_1 \alpha_2 C_2 + (1-\beta_2) C_2\} + \beta_1 g_{m1} \gamma_1 \alpha_1 = 0} \quad (49)$$

The FO of (16) and CO of (17) from (49) are modified as follows;

$$\text{FO:} \quad \boldsymbol{\omega_O = \sqrt{\frac{\alpha_1 \beta_1 \gamma_1 g_{m1}}{R_{X-} C_2 C_3 + (1-\beta_2) C_1 C_2 R_{X+}}}} \quad (50)$$

$$\text{CO:} \quad \boldsymbol{\frac{\alpha_1 \gamma_1 g_{m1}}{\alpha_2 + 1 - \beta_2} = \frac{R_{X-} C_2 C_3 + (1-\beta_2) C_1 C_2 R_{X+}}{C_1 C_3 R_{X+} R_{X-}}} \quad (51)$$

It is observed that FO and CO are affected by transfer gains, whereas it may be noted that, for ideal values of transfer gains, i.e. ($\boldsymbol{\alpha_1 = \alpha_2 = \beta_1 = \beta_2 = \gamma_1 = 1}$), (49)-(51) result in original expressions as of (15), (16) and (17).

B. Non-ideality Effect due to Parasitic Components

The second group of non-ideality comes from parasitic resistances and capacitances of MDXCCCTA. The QO using the parasitic model of MDXCCCTA is shown in Fig. 8.

This article has been accepted for publication in IEEE Transactions on Instrumentation and Measurement. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TIM.2023.3300449

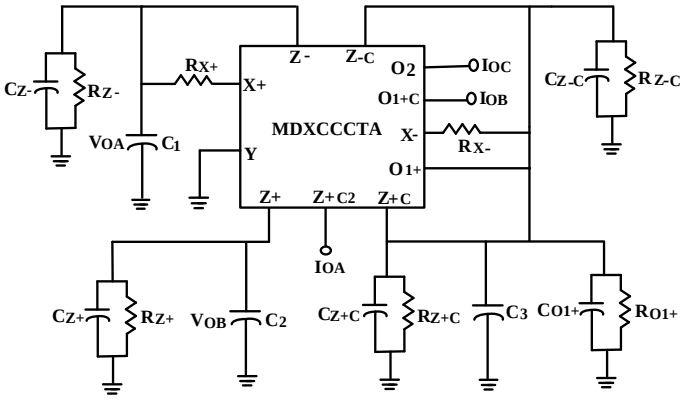

Fig. 8 Non-ideal equivalent of MDXCCCTA oscillator circuit.

Parasitic resistances and capacitances appear in parallel at terminals Z_+, Z-, Z_{+C}, $Z\text{-}_C$, and O_{1+} and intrinsic resistances in series at terminals X_+ and X-. Parasitic capacitances (C_{1P}, C_{2P}, C_{3P}) and resistances (R_{1P}, R_{2P}, R_{3P}) are associated in parallel to C_1, C_2, and C_3 in circuit of Fig. 4. Equivalent capacitances (C_{eq1}, C_{eq2}, C_{eq3}) at different terminals are expressed as;

$$C_{eq1} = C_1 // C_{1P},\ C_{eq2} = C_2 // C_{2P}, \text{ and } C_{eq3} = C_3 // C_{3P} \quad (52)$$

$$\text{Where, } C_{1P} = C_{Z-}, C_{2P} = C_{Z+}, C_{3P} = C_{Z+C} // C_{Z-C} // C_{O1+} \quad (53)$$

Similarly, equivalent parasitic resistances are as follows;

$$R_{1P} = R_{Z-},\ R_{2P} = R_{Z+}, \text{ and } R_{3P} = R_{Z+C} // R_{Z-C} // R_{O1+}. \quad (54)$$

On considering the values from (52)-(54), the modified characteristic equation of oscillator results as;

$$s^3 + s^2\left(\frac{1}{h_1}+\frac{1}{h_2}+\frac{1}{h_3}+\frac{1}{n_1}\right) + s\left(\frac{1}{h_2h_3}+\frac{1}{h_1h_2}+\frac{1}{h_1h_3}+\frac{1}{n_2}+\frac{1}{n_3}+\frac{1}{n_4}\right)+\frac{1}{n_9}\left(n_8+\frac{1}{n_5}+\frac{1}{n_6}+\frac{1}{n_7}\right)=0 \quad (55)$$

Where, $h_1 = C_{eq1}R_{1p}$, $h_2 = C_{eq2}R_{2p}$, $h_3 = C_{eq3}R_{3p}$;

$n_1 = C_{eq1}R_{X+}$, $n_2 = C_{eq1}C_{eq2}R_{3p}R_{X+}$, $n_3 = C_{eq1}C_{eq2}R_{2p}R_{X+}$,

$n_4 = C_{eq1}C_{eq3}R_{X+}R_{X-}$, $n_5 = R_{1p}R_{2p}R_{3p}$, $n_6 = R_{2p}R_{3p}R_{X+}$,

$n_7 = R_{2p}R_{X+}R_{X-}$, $n_8 = \frac{g_{m1}}{R_{X+}R_{X-}}$, $n_9 = C_{eq1}C_{eq2}C_{eq3}$ (56)

In order to minimize the effect of parasitic components of MDXCCCTA, the following relations should be satisfied:

$$\frac{1}{|(s(C_{eq1})|} \ll R_{1P},\quad \frac{1}{|(s(C_{eq2})|} \ll R_{2P},\quad \frac{1}{|(s(C_{eq3})|} \ll R_{3P}\ ; \text{ or } \quad (57)$$

$$\frac{1}{R_{1P}(C_{eq1})} \ll |s|,\quad \frac{1}{R_{2P}(C_{eq2})} \ll |s|,\quad \frac{1}{R_{3P}(C_{eq3})} \ll |s| \quad (58)$$

$$\text{Let, } \frac{1}{R_{1P}(C_{eq1})} = \omega_{p1},\ \frac{1}{R_{2P}(C_{eq2})} = \omega_{p2},\ \frac{1}{R_{3P}(C_{eq3})} = \omega_{p3} \quad (59)$$

As, $s = j\omega_O$, hence (58) and (59) imply that;

$$\text{Operating frequency } (\omega_O) \gg \omega_{p1}, \omega_{p2}, \omega_{p3} \quad (60)$$

Equation (60) depicts that, to minimize the effect of parasitics, the operating oscillation frequency (ω_O) must be the highest of [ω_{p1}, ω_{p2}, ω_{p3}]. Moreover, as the parasitic capacitances are in parallel to external capacitors, the effect can be ignored if $C_1 >> (C_{1P})$, $C_2 >> (C_{2P})$, and $C_3 >> (C_{3P})$.

Furthermore, the simplified expression for oscillation frequency can be obtained by considering R_{1P}, R_{2P}, and R_{3P} are high resistance values, and C_{1P}, C_{2P}, C_{3P} are low capacitance values, which is valid for MDXCCCTA. Under these conditions coefficient of s^2, s, and constant in (55) except terms $1/n_1$, $1/n_4$, and n_8/n_9 result insignificant and can be neglected. Therefore, characteristic equation (55) gets simplified as;

$$s^3 + \frac{s^2}{C_{eq1}R_{X+}} + \frac{s}{C_{eq1}C_{eq3}R_{X+}R_{X-}} + \frac{g_{m1}}{C_{eq1}C_{eq2}C_{eq3}R_{X+}R_{X-}} = 0 \quad (61)$$

The FO and CO from (61) are as follows;

$$\text{FO: } \boldsymbol{\omega_O} = \sqrt{\frac{g_{m1}}{R_{X-}C_{eq2}C_{eq3}}} \quad (62)$$

$$\text{CO: } g_{m1}R_{X+} = \frac{C_{eq2}}{C_{eq1}} \quad (63)$$

$$\text{If } C_1 >> C_{1P}, C_2 >> C_{2P} \text{ and } C_3 >> C_{3P}, \text{ then} \quad (64)$$

$$C_{eq1} \to C_1, C_{eq2} \to C_2 \text{ and } C_{eq3} \to C_3. \quad (65)$$

It is observed that, on considering condition (65) in (61)-(63), the expressions (61)-(63) result in the ideal form of (15), (16), and (17), respectively.

V. Simulation Results And Discussion

The developed TOQO circuit is simulated using 180nm CMOS process technology in Cadence Virtuoso with model parameters as; C_{OX}=8.422fF/μm^2, $\mu_{(N)}$=259.53cm^2/V-s, $\mu_{(P)}$=109.97cm^2/V-s, and t_{OX}=4.1nm. The results are obtained with parameter values as; supply voltage, $V_{DD} = -V_{SS}$ =1V, bias currents, $I_{b1} = I_{b2}$ =10μA, I_{b3} =60μA, $C_1 = C_2 = C_3$=1.3pF, R_{X+} = 4kΩ, R_{X-} =4kΩ, and g_{m1}=250μA/V. Selected aspect ratios of transistors in MDXCCCTA are shown in Table I.

TABLE I
ASPECT RATIOS OF TRANSISTORS IN MDXCCCTA

Transistor	Width (μm)	Length(μm)
M_1–M_6, M_{29}–M_{36}	2.6	0.36
M_7–M_{13}, M_{17} – M_{28}, M_{41}, M_{42}	1.3	0.36
M_{14}, M_{15}, M_{16}	8, 2, 8	0.36
M_{37}- M_{40}, M_{45}, M_{46}	4	0.36
M_{43}, M_{44}	1.8	0.36
M_{47}, M_{48}	0.5	0.36

Response of the quadrature voltage signals V_{OA} and V_{OB} are shown in Fig. 9. Similarly, the quadrature current signals I_{OA} and I_{OB} are shown in Fig. 10. It can be observed that the voltage and current outputs are 90^0 phase-shifted with each other.

Further, variation in intrinsic resistance, R_{X-} on varying bias current, I_{b2} is shown in Fig. 11. Variation in the frequency of oscillation (f_O) on varying bias current, I_{b2} is shown in Fig. 12, depicting f_O is varied on the tuning of I_{b2} over a significant range as per (16), and CO is maintained independently through tuning of bias current, I_{b1} as per (17). It must be noted that Fig. 12 depicts the variation range of f_O through electronic tuning only; however, the lower limit of f_O can further be lowered up to a few kHz on selecting high values of C_1 and C_2 (in range of 1nF). Therefore, the circuit possesses a wide tunable range of oscillation frequency and is suitable for various low to high-frequency applications in instrumentation techniques. The frequency spectrum corresponding to oscillation across V_{OA} is shown in Fig. 13. Fig. 13 illustrates that for the selected set of parameter values as have been

This article has been accepted for publication in IEEE Transactions on Instrumentation and Measurement. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TIM.2023.3300449

mentioned in the beginning of this section (i.e. $C_1=C_2=C_3=1.3$pF, $R_{X+}=R_{X-}=4k\Omega$, $g_{m1}=250\mu A/V$), the f_O of the voltages (V_{OA}, V_{OB}) and currents (I_{OA}, I_{OB}) corresponds to 30.59MHz and is one of the maximum reported values in the available literature. Simulated f_O closely follows the theoretically designed value, 30.6MHz.

Further, the percentage total harmonic distortion (%THD) of voltage and current signals are shown in Fig. 14(a) and (b), respectively, and the depicted values are less than 0.8% for V_{OA}, V_{OB} and less than 0.84% for I_{OA}, I_{OB}. Fig. 15 shows the phase error, i.e., deviation from quadrature phase value 90^0, calculated from Fourier analysis simulation values. Phase error for V_{OA} and V_{OB} is less than 0.2% and for I_{OA} and I_{OB} is less than 0.3%, which is considered very small. Moreover, the phase noise analysis has been done and the simulated phase noise (dBc) versus frequency responses for V_{OA} and V_{OB} are shown in Fig. 16. It is observed that phase noise is of low-level and in the operating range of proposed circuit (822k-52.94MHz), it is between -180dBc to -240dBc, which is significantly very low.

Furthermore, to verify the robustness of the proposed oscillator, the Monte Carlo (MC) simulation for variation in the f_O of V_{OA} for 200 runs is shown in Fig. 17. Statistical distribution of MC simulation outcome shows oscillator is vastly robust against tolerance in passive components as f_O remains thoroughly close to a standard value, 30.6MHz. Moreover, the circuit's layout has been designed to validate the proposed TOQO for physical verification or fabrication, as shown in Fig. 18, which consumes an area of $7810\mu m^2$. Post layout time series simulation results for signals, I_{OA}, and I_{OB} are shown in Fig. 19, depicting responses are close to the original form except for the inclusion of slight delay caused by parasitic components and; subsequently, the frequency of oscillation deviates slightly. Deviation from 90^0 is 0.16^0 i.e. phase error of 0.18% is observed in the response, which is very small.

To illustrate the working of the circuit as an arbitrary phase shift oscillator (APSO), the simulation results are depicted in Fig. 20-23. The plot for I_{OCP} has 45^0 phase shifts with respect to I_{OB} and - 45^0 with respect to I_{OA} for equal amplitudes of V_{OA}, and V_{OB} is shown in Fig. 20 for I_{b4}= 80μA. The phase shift of 30^0 between I_{OB} and I_{OCP} and subsequently -60^0 between I_{OA} and I_{OCP} are obtained for I_{b1}=30μA as depicted in Fig. 21 with I_{b4}= 42μA. Similarly, the phase shift of 60^0 between I_{OB} and I_{OCP} and -30^0 between I_{OA} and I_{OCP} are obtained for I_{b1}=3μA as depicted in Fig. 22 with I_{b4}= 42μA. Moreover, the continuous variation in phase between I_{OB} and I_{OCP} and between I_{OA} and I_{OCP} with variation in I_{b1} is shown in Fig. 23. Fig. 23 depicts that phase shifting between I_{OB} and I_{OCP} is in the range of 0 to 90^0, whereas phase shift between I_{OA} and I_{OCP} is in -90^0 to 0. It verifies the application of the circuit of Fig. 4 as an APSO.

Moreover, simulated responses are shown in Fig. 24(a)-(c) to validate the proposed circuit as AM generator. If a modulating signal is applied as I_{b4}, the AM/ASK signals can be obtained as I_{OCM} as per (25). In verifying this phenomenon, a sinusoidal current signal, I_{b4} of frequency (f_m) of 3 MHz and peak current of 70 μA is applied; the obtained AM response signal, I_{OCM}, is shown in Fig. 24(a). Further, on applying a triangular signal as I_{b4}, the obtained response of AM signal, I_{OCM}, is shown in Fig. 24(b). Similarly, on applying a rectangular signal as I_{b4}, the obtained response I_{OCM} of modulated signal (ASK) is shown in Fig. 24(c). The modulation index of AM signal in Fig. 24(a) results as 0.74, and the percentage is 74%. The modulation index result of Fig. 24(b) is 0.68, i.e., 68%, and the ASK result in Fig. 24(c) is 0.76, i.e., 76%. The power spectrum plot for AM signal of Fig. 24(a) has been obtained and is shown in Fig. 25 for f_m=3 MHz and $f_c=f_o$=30.59 MHz. It is depicted that second-order intermodulation products (IM2) are obtained at $f_O\pm f_m$, i.e., at 33.59 MHz and 27.59 MHz. Further, it is observed that third-order intermodulation products (IM3) are obtained at $f_O\pm 2f_m$, i.e., at 36.59 MHz and 24.59 MHz, and corresponding intermodulation distortion (IMD3) are -58 dBc and -57 dBc, respectively. It may be observed that intermodulation distortions are of a considerably low level. The power consumption of the proposed TOQO circuit is 1.08 mW.

Moreover, to verify the workability of the proposed automatic CO and FO control system depicted in Fig. 6, the simulated results are presented in Table III and compared with the results of the non-automatic system in Fig. 4. Circuit has been simulated with parameters as; K_V=1V, $K_{Sq}=60\mu A/V^2$ from (40) and (41) respectively by keeping $\mu_nCox=160\mu A/V^2$, W/L=1μ/2.5μ of NMOS of Fig. 7. Moreover, initial values of bias currents are set as, I_{b1O}=10μA and I_{b3O}= 60μA from (45) and M vary according to change in $(V_{OA}/V_{OB})^2$, which varies on the tuning of I_{b1} as per (36). Table III shows that the value of I_{b1} has been varied from 2 μA to 60 μA, and the proposed automatic system results closely match the non-automatic or manually adjusted system results. Automatically obtained values of I_{b2} and I_{b3} are in good agreement with manually adjusted values to maintain the CO and FO. Furthermore, frequency deviation and phase shift deviation between automatic and non-automatic circuits are less than 1% for each varied value of I_{b1}.

Moreover, to check the performance of circuit under extreme conditions, the PVT (process, voltage, temperature) analysis has been done. The process corner simulation for conditions FF (fast NMOS, fast PMOS), FS (fast NMOS, slow PMOS), SF (slow NMOS, fast PMOS), SS (slow NMOS, slow PMOS) and NN (nominal) has been done and the obtained time domain and frequency spectrum responses for V_{OA} are shown in Fig. 26(a) and 26(d) respectively. Further, responses corresponding to temperature and voltage supply variation are shown in Fig. 26(b) and Fig. 26(c) respectively. The effect of PVT corners on frequency (f_o) and amplitude (A_m) is summarized in Table II. It may be noticed that deviation in response from nominal values (30.59 MHz, 0.3V) is within 0.8%, which is considerably small and frequency spectrum of Fig. 26(d) also verifies the process corner response values resulting small deviations, mentioned in Table II.

VI. Experimental Verification

As monolithic implementation of MDXCCCTA is not available, the possible experimental realization of TOQO using commercially available ICs, AD844 and CA3080 is shown in Fig. 27, followed by the assembled circuit on a breadboard is given in Fig. 28. This circuit can broadly verify the functionality; however, detail parameters cannot be comparable with monolithic implementation. Supply voltage is set as 7V, with selected capacitances as, $C_1=C_2=C_3$ =100pF, and resistances, $R_1=R_7$ = $R_2=R_3=R_4=R_5=R_6=R_8=1k\Omega$. The target frequency for experimentation of Fig. 27 was set to 2 MHz. Fig. 29 shows the experimental setup. The obtained quadrature voltage outputs, V_{OA} and V_{OB}, are shown in Fig. 30, with a peak-to-peak value of 180mV. Quadrature current outputs, I_{OA} and I_{OB}, are obtained on connecting 1.5kΩ resistors at Z_{+C2} and O_{1+C} terminals of Fig. 27, and responses are shown in Fig. 31. Further, the AM and ASK responses are shown in Fig. 32 for the sinusoidal, triangular, and square wave modulating signals of 100 kHz applied as I_{b4}. It may be noted that the response of Fig. 32(a) and 32(b) are AM signals, and Fig. 32(c) is an ASK-modulated signal. Experimental results for arbitrary phase shift generation between I_{OCP} and I_{OB} are shown in Fig. 33 (a)-(c). The phase shift of 45^0 obtained for $V_{OA}=V_{OB}$ is shown in Fig. 33(a). The phase shift of 30^0 for $V_{OA}<V_{OB}$ obtained at R_1=300 Ω is shown in Fig. 33(b), whereas the phase shift of 60^0 for $V_{OA}>V_{OB}$ obtained at R_1=700 Ω is shown in Fig. 33(c).

Furthermore, the AD844 and CA3080 macro model-based IC simulation has been done in OrCAD PSpice for the similar circuit configuration shown in Fig. 27 with $C_1=C_2=C_3$ =100pF, resistances, $R_1=R_7=R_2=R_3=R_4=R_5=R_6=R_8=1k\Omega$ and target frequency of 2 MHz. The simulated results have shown good agreement with the experimentally obtained results. The comparison of IC AD844, CA3080-based PSpice macro model simulation, post-layout simulation of monolithic circuit, and experimentally obtained results for various performance parameters has been carried out and shown in Table IV. It can be inferred that % THD, phase error, and sensitivity of IC-based simulation and experimental results closely follow the post-layout simulated results at a specified frequency of 1.84 MHz. However, IC CA3080 has a limitation in bandwidth, as it can operate up to 2 MHz only; hence the maximum experimental frequency of operation and frequency tunable range of the proposed circuit are limited in IC (CA3080 and AD844) based simulation and experimental results. The voltage supply and power consumption are high for discrete IC-based simulation and experimental results.

Frequency sensitivity against tolerances in passive components ($C_{2,3}$)	<0.4%	<0.4%	<0.45%
Power consumption	1.08mW	0.38W	0.4W

VII. Comparison With The Available Literature

The comparison of the reported literature is given in Table V. Designs in [7] are second-order QO realization and use excessive active and passive components. [7] also lacks the electronically tunable feature and % THD is higher. Moreover, the circuit does not provide arbitrary phase and AM signals. Designs in [8] are third-order arbitrary phase shift oscillators (APSOs); however, they employ excessive active blocks and do not work as AM generators. The topologies [10-38] realize TOQO. The topologies [10-30, 32, 37, 38] are only QOs, and [31, 33, 34-36] provide AM along with QO. It is observed that [10-21] use three or more analog building blocks (ABBs), whereas topologies [22-36] use two ABBs. The topologies [37, 38] use only one ABB. Topologies [10-12, 13, 14, 18-19, 22, 23, 26-28, 29, 30] generate either voltage (V) or current (I) signal only. Furthermore, independent electronic control of FO and CO adds an advantage to any circuit realization, but [10, 12-15, 16, 17, 22-24, 29, 31, 32, 38] do not have that property.

The proposed TOQO is completely electronically tunable, for the availability of quadrature current signals, quadrature voltage signals, arbitrary phase-shifted signals (APSO), and AM signals from the same circuit topology. The FO and CO are electronically tuneable and can be controlled independently without affecting each other. Circuit provides amplitude controllability of resulting AM/ASK signals through electronic tuning without affecting the CO and FO of the oscillator. Moreover, a sinusoidal signal having arbitrary phase variation in the range of ± (0 to 90^0) with respect to quadrature current signals is obtained from the proposed configuration. This feature is not available in any of the reported literature. Moreover, the simulated operating frequency range of oscillation of the proposed TOQO is considerably high (820 kHz to 52.94 MHz) compared to other available designs. Furthermore, the phase noise in generated signals in operating range of TOQO is considerably very low (-180 dBc to -240 dBc) as compared to other available values. Further, the phase

error between generated quadrature signal is minimal compared to other designs. % THD of voltage and current signals is low (0.84%). Except in [19], layout has not been reported in any designs. It is observed that layout chip area of proposed circuit is very low (0.00781 mm^2) as compared to [19], which occupies total area of 1.44mm^2. Moreover, the power consumption of proposed circuit is also minimum as compared to other designs except in two cases [31, 34] as can be seen from the Table. However, [31] does not provide the independent controlling of CO and FO through electronic tuning. Moreover, both [33] and [34] have low operating frequency and high %THD or high phase error.

VIII. Conclusion

This work presents the realization of an electronically tunable TOQO employing a new CM ABB, MDXCCCTA and three grounded passive capacitors. It simultaneously provides two quadrature voltage outputs, two high-impedance quadrature current outputs, and another high-impedance current output with controllable amplitude resulting in AM/ASK modulations. The CO and FO can be controlled independently through electronic tuning. It also provides an arbitrary phase-shifted signal in ± (0 to 90^0) range. The proposed circuit, providing quadrature oscillations, modulation, and phase-shifted signals from the same topology, can be used as a compact module in instrumentation, measurement, and communication techniques. Further, a new proposed automatic stabilization method is implemented in TOQO to control the CO and FO simultaneously. The workability of the proposed TOQO is validated through simulations and experimentation. The oscillator exhibits low %THD (0.78-0.88), low phase error (0.22^0), low power consumption (1.08 mW), low phase noise (-180 dBc to -240 dBc), low sensitivity (<0.45%) against tolerances in passive components and, small deviation (<0.8%) against various PVT corners. Moreover, the proposed circuit possesses a wide electronic and non-electronic tunable range of oscillation frequency from 820 kHz to 52.94 MHz. Furthermore, the proposed TOQO occupies fairly a small layout chip area.

***Abstract*— Stress is a significant health issue that affect both physical and mental health. The application of deep learning and machine learning techniques for physiological signal processing has become popular in detecting and classifying stress. In this research, we developed a fresh approach to classify stress on multiple levels using advanced machine and deep learning models. The PhysioNet SRA database was used to collect physiological signals which were pre-processed using a pipeline of filters and normalisation techniques to remove noise and artefacts. These signals were subjected to various feature extraction algorithms to determine the most pertinent characteristics for categorisation. On the acquired features, dimensionality reduction techniques were applied in order to further improve classification performance. The evaluation of Random Forest model outscored all the other classic ML models, achieving an accuracy of 93.77% and 82.42% in classifying stress on two levels and three levels respectively. Among the DL models, the LSTM model is most effective, achieving an accuracy of 95.67% and 88.70% in classifying stress on two levels and three levels respectively. The proposed approach provides a more comprehensive analysis of stress levels, which can help individuals manage stress more effectively.**

***Keywords*—Classification, Deep learning, Machine learning, Physiological signals, Stress detection.**

I. INTRODUCTION

Stress has become a pervasive problem in modern so- ciety, with the potential to have significant adverse effects on both physical and mental health. The recognition and early detection of stress are crucial in preventing its negative consequences. In order to identify and categorise stress based on physiological signals, there has been an increase in interest in using deep learning and machine learning approaches. In this work, we provide a brand-new model for categorising stress on different scales utilising advanced deep and machine learning techniques, resulting in a more thorough examination of stress levels.

The traditional methods for detecting and classifying stress are based on self-reporting by individuals, which can be subjective and prone to errors [1]. However, A more objec- tive and accurate method for stress detection is provided by physiological signals like the electrocardiogram (ECG), pho- toplethysmography (PPG), and galvanic skin response (GSR). The application of deep learning and machine learning models for the classification of stress on multiple levels provides a more nuanced analysis of stress levels that can help individuals manage their stress more effectively.

Previous studies have primarily focused on binary classifi- cation of stress, with only a few attempts to classify stress on multiple levels. The proposed approach in this study provides a more comprehensive analysis of stress levels, which is crucial in providing a more detailed analysis of stress. Stress is a complex phenomenon that involves different levels of severity, and the traditional binary classification approach does not provide a complete understanding of stress levels.

To achieve the classification of stress on multiple levels, we utilised the PhysioNet SRA database, which contains phys- iological signals collected from individuals in various stress conditions [2]. The database provides a wide range of stress levels, making it an appropriate choice for the classification task. The signals were pre-processed using a pipeline of filters and normalisation techniques to remove noise and artefacts [2]. A bandpass filter was used to remove high and low-frequency noise, while a notch filter was used to remove power line interference. After that, the signals were standardised using Z-score standardization to remove the impact of various scales on the categorisation [2].

To find the characteristics that would be most useful for classification, the pre-processed signals were exposed to a variety of feature extraction approaches. Techniques for feature

selection were also used to decrease the dimensionality of the extracted features, further improving the classification performance [3]. The study evaluated several Machine learning models, including random forest (RF), logistic regression (LR), k-nearest neighbours (KNN), decision tree, and support vector machine (SVM). The deep learning models evaluated in this study include long short-term memory (LSTM) networks, convolutional neural networks (CNN) [4], and hybrid models that combine CNNs and LSTMs.

This study's innovation is based on the use of advanced deep learning models to classify stress on multiple levels. The proposed approach in this study provides a more comprehensive analysis of stress levels and can help individuals manage their stress more effectively. The study's findings demonstrate that the RF model outperforms the competition by reaching an accuracy of 93.77% in classifying stress on 2 levels and 82.42% in classifying stress on 3 levels. Among the deep learning models, the LSTM model performs the best, achieving an accuracy of 95.67% in classifying stress on 2 levels and 88.7% in classifying stress on 3 levels. These results demonstrate the potential of advanced deep learning and machine learning models in the classification of stress on multiple levels.

The study's suggested methodology offers a fresh and useful way to categorise stress on various levels. The use of advanced machine and deep learning models provides a more comprehensive analysis of stress levels, which can help individuals manage their stress more effectively. The findings of this research lay the groundwork for further research in the subject and show the possibility of the suggested methodology to increase the accuracy of stress classification.

II. Methodology

The approach for the features for stress classification is covered in this section.

A. Database Information

In this work, stress level detection was carried out using the SRA Database, which Healey and Picard established [2]. It is a freely available dataset that contains the .dat and .hea files of multiparameter recordings made by 17 healthy Boston, USA, drivers [2]. Fig. 1 illustrates the setup used for the collection of data. It covers signals obtained from drivers who experienced varying degrees of stress brought on by driving on highways, city streets with traffic signals, and unanticipated risks brought on by cyclists [2]. Each .dat file in the dataset contains four different type of physiological signals, including EMG (Electromyography), GSR (Galvanic Skin Response), ECG (Electrocardiogram), and Respiration. EMG and ECG have sample rates of 15.5 Hz and 496 Hz, respectively, but hand, foot, and RESP signals all have sampling rates of 31 Hz [2]. The dataset is an essential resource for research in stress level detection, providing high-quality recordings that enable the development of accurate and reliable stress level detection algorithms [2].

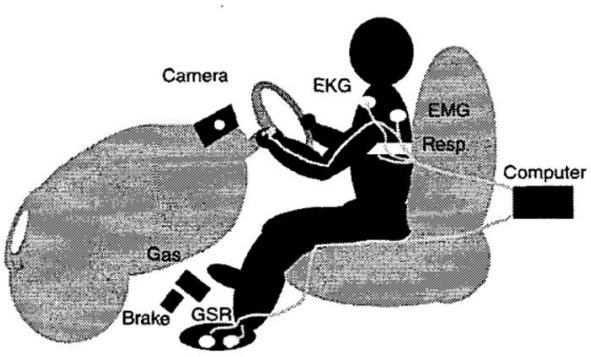

Fig. 1. SRA Data Collection Technique [6]

Fig. 2. Pan-Tompkins Algorithm Methodology

B. Pre-processing

ECG signals are prone to noise and artefacts, therefore, we used various pre-processing techniques to ensure high-quality signal input to our algorithms. Our pre-processing pipeline consisted of the following steps:

1) Extracting RR Intervals from ECG: We initially identified the R-R intervals from each ECG signal. In order to do this, we used a QRS complex detection algorithm based on template matching. We utilized the QRS complex locations to detect the R peaks and calculated the time intervals between them to obtain the RR intervals.

2) Peak detection: We used a method that S. Chaudari et al. had previously used [5]. Peak detection by template matching is a crucial step in detecting R peaks in the ECG signals. One of the widely used algorithms for detecting the R peak is the Pan-Tompkins algorithm. However, this algorithm may not work efficiently for all ECG signals, particularly in the presence of noise and baseline wander. Therefore, to enhance the R peak detection process, we utilized template matching in our study. Fig 2 illustrates the pre-processing phase of the Pan–tompkins algorithm using a block diagram.

Template matching is a technique used to compare a given signal segment with a known template signal to identify similarities. In our study, we used a reference template signal for the R peak in the ECG signal. This reference template was created by averaging the R peak segments from multiple ECG signals to obtain a representative R peak signal. It involves moving the reference template signal along the ECG signal, and at each position, the similarity between the ECG signal segment and the reference template signal was calculated using cross-correlation. In the ECG signal, the R peak was located where the cross-correlation value's peak was at.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 04,2023 at 07:00:42 UTC from IEEE Xplore. Restrictions apply.

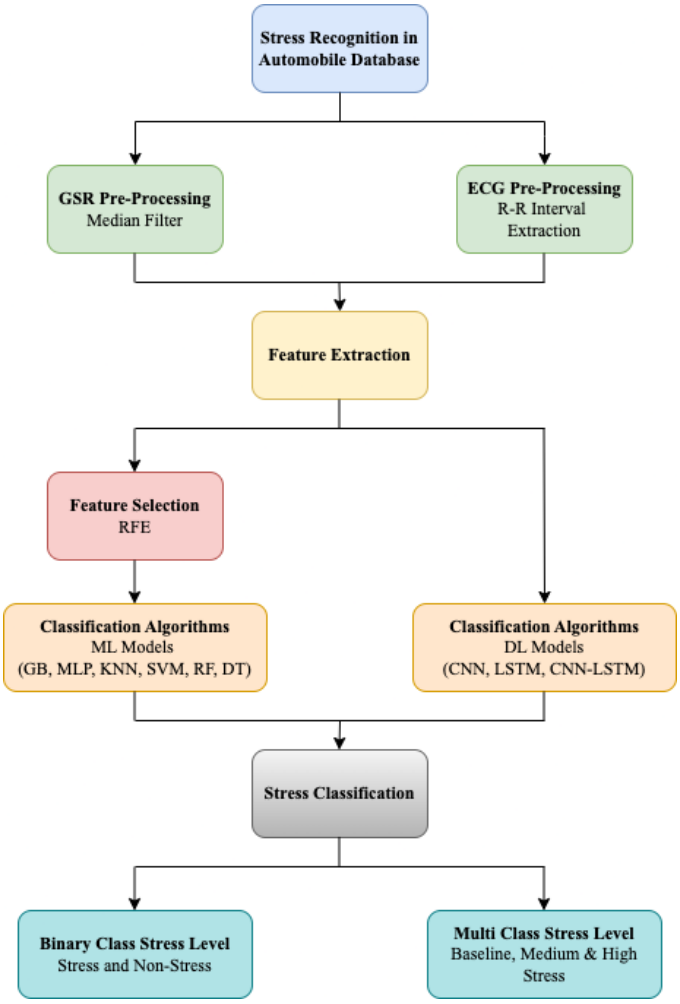

Fig. 3. Stress Classification Methodology

As per V Nivitha Varghees et al [7], to reduce the effects of noise and baseline wander on the cross-correlation, we also applied a pre-processing step that involved baseline correc- tion and band-pass filtering to the ECG signals. After pre-processing, we applied the template matching technique to detect the R peaks in the ECG signal. The use of template matching in conjunction with the Pan-Tompkins algorithm significantly improved the R peak detection accuracy, particularly in the presence of noise and baseline wander. This approach allowed for better identification of the R peaks and helped to reduce the false detection of R peaks. The accurate identification of the R peak is crucial in the computation of the RR interval, which is an essential feature in the detection of stress levels in our study.

3) RR interval Correction: After detecting R peaks in the ECG signals, the next step is to calculate the RR intervals between consecutive R peaks. However, in some cases, the detected RR intervals may not be accurate due to various factors such as noise, artifacts, and outliers. To address this issue, a correction method is used to ensure that the RR intervals are accurate and reliable.

In this paper, the RR interval correction was performed using a median filter. The median filter is a non-linear digital signal processing technique that replaces each sample value with the median value of neighboring samples. This technique is widely used to remove outliers from signals and to smooth noisy signals. To apply the median filter for RR interval correction, we first calculated the initial RR intervals from the detected R peaks. The Z-score, which is the difference between each RR interval and the distribution's mean divided by the standard deviation, was then determined for each RR interval [8]. Any RR interval with a Z-score greater than 2 was considered an outlier and replaced with the median value of the neighboring RR intervals.

After applying the median filter, the corrected RR intervals were obtained, which were then used to extract features for stress level classification. This correction method helped to remove any outliers and ensure that the RR intervals were accurate and reliable, thus improving the overall performance of the stress level detection system.

4) Stress Labeling And Windowing: The ECG signals were labeled based on the driver's stress level during the recording. This was done by assigning a stress level of 1 for a relaxed state and a stress level of 2 for a stressed state. The stress level was determined based on the driver's self-reported stress level during the recording. After labeling the ECG signals, the next step was to divide them into 5-minute windows. Each 5-minute window was assigned a stress level based on the majority stress level of the ECG beats in the window. This ensured that each window was accurately labeled and helped in creating a balanced dataset for training the model.

The suggested model was made to recognise three distinct drive phases: Low, Middle, and High Stress. We utilized the marker signals from the dataset to achieve distinctive. The low-stress data was considered to be between 700 to 1000 seconds, medium-stress data between 1600 to 1900 seconds, and high-stress data between 3200 to 3500 seconds [2]. Once the data was labeled and the stress levels were identified, the next step was windowing. The model separated the signal into
0.5 min frames with 0.25 min overlaps every 5 min for each stress level. For each stress label, this led to 19 splits from each participant. For instance, we obtained 980 splits altogether for multi-level stress (baseline, mid, and high-level) and about 570 splits for binary stress (stress and non-stress) [2].

C. Feature Extraction

Various characteristics were taken from the ECG data to indicate the physiological condition of the driver [9]. Time-domain, frequency-domain, and nonlinear characteristics were among these features. Included in the list of time-domain characteristics were the RR intervals' mean, standard deviation, and coefficient of variation. According to A. D. Wibawa et al. [10], The frequency-domain features included power spectral density in the low-frequency (LF, 0.04-0.15 Hz) and high- frequency (HF, 0.15-0.4 Hz) bands, as well as the LF/HF ratio. The nonlinear features included sample entropy, approximate entropy, and detrended fluctuation analysis.

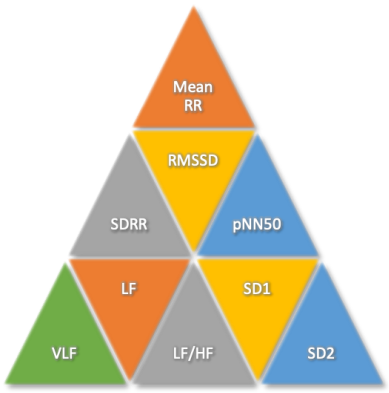

Fig. 4. Advance features selected after RFE

D. Feature Selection

Recursive Feature Elimination (RFE), a sophisticated feature selection method, was used in this work. RFE is a feature selection technique based on wrappers that eliminates features repeatedly while building a model on the remaining features. The method ranks the features according to their importance and eliminates the least important feature at each iteration until the desired number of features is reached. The full feature set [11] was used to train a support vector machine (SVM) classifier with a radial basis function (RBF) kernel for RFE [11]. The feature significance scores were then calculated by the classifier using the coefficients or weights assigned to the features [11]. The model was retrained using the smaller feature set after removal of the least significant feature until the necessary quantity of characteristics was reached. A cross-validation approach was used to set the number of features to be selected at 9.

The top 9 features selected through RFE were Mean RR, SDRR, RMSSD, pNN50, VLF, LF, LF/HF, SD1, and SD2. Fig. 4 demonstrates the 9 features that were selected. These features were chosen based on their ability to distinguish strained from non-stressed conditions, as well as their relevance to the physiological mechanisms underlying stress [12]. These include non-linear, time domain, and frequency dcomain properties, all of which have been demonstrated to be useful in earlier research on stress detection. The use of RFE allowed for the identification of a set of informative features that could be used in the development of more effective stress detection algorithms and interventions for individuals at risk of stress related disorders.

E. Parameter Tuning

In order to fine-tune the classifier variables, we employed a grid search strategy. We tested the performance of the classifiers with several parameter combinations and selected the parameter combination that generated the best result. We changed the parameters for the support vector machine (SVM), k-nearest neighbour (KNN), and random forest (RF) classifiers.

F. Classification Algorithms

This study used biosignals from ECG-based heart rate variability (HRV) and galvanic skin reaction (GSR) to classify stress using various machine learning (ML) and deep learning (DL) methods. The objective was to enhance the accuracy of stress level classification by exploring advanced algorithms.

1) Machine Learning: Seven machine learning (ML) models were tested, including Gradient Boosting (GB), Decision Tree (DT), Random Forest (RF), k-Nearest Neighbor (k-NN), Logistic Regression (LR), Support Vector Machine (SVM), and Multi-Layer Perceptron (MLP).

Following hyperparameter tuning and K-fold Cross-Validation, we discovered that the RF model had the best performance, with an 93.77 accuracy%, an 0.89 F1-score, and an 0.94 area under the curve (AUC). The other models had lower accuracy scores, ranging from 76% for LR to 93% for RF.

2) Deep Learning: In addition to ML models, we also examined the use of DL algorithms for stress classification. We tested three different DL models: Convolutional Neural Network (CNN) [4], Long Short-Term Memory (LSTM), and a combination of CNN-LSTM.

Our results indicated that DL models outperformed ML models, with the LSTM model achieving the best performance. The LSTM model has an 0.96 F1-score, an 0.96 AUC, and an 95.67%. accuracy. outperforming both the RF model and all other ML models. The CNN [4] model and the combination of CNN-LSTM had lower accuracy scores of 94.2% and 94.75%, respectively.

Overall, our findings suggest that DL algorithms, especially the LSTM model, are effective for stress classification using HRV and GSR biosignals. The higher accuracy scores obtained by DL models compared to ML models highlight the potential for DL algorithms to improve stress detection and management technologies.

III. Results and Discussions

This work used HRV and GSR bio-signals extracted from the ECG to increase the precision of stress level categorisation using machine and deep learning methods. The individuals who drove in various stressful scenarios provided the data.

The parameters of the various classifier models were optimised via hyperparameter tuning. K-fold Cross-Validation was performed to validate the performance of the models in order to guarantee objective outcomes. Out of 32 features, 9 features were selected based on their high correlation with stress level changes. The results showed that HRV and GSR signals are reliable indicators of stress level changes. These results are in line with other research that showed how stress affects health on HRV and GSR signals. However, there may be limitations to their study, such as the sample size and the stress situations tested.

In the current work, a range of deep learning and machine learning methods were used to precisely identify stress levels using physiological data. The informative features were extracted from the physiological signals via feature extraction

and selection techniques, and the performance of the models was evaluated using various evaluation metrics. The results indicated that in terms of properly identifying stress levels, deep learning models fared better than machine learning models. The LSTM model outperformed all other evaluated models, with an accuracy of 95.67%, an 0.96 F1-score, and an 0.96 AUC.

These results are in line with earlier research that shown the potency of deep learning methods for stress detection. For instance, Chen et al. (2018) also used physiological signals for stress detection and achieved an accuracy of 87.7% using a deep learning model. Likewise, Zhang et al. (2020) employed a combination of physiological signals and facial expressions for stress detection and attained an accuracy of 92.1% using a deep learning model. These studies support the notion that deep learning techniques are effective in accurately detecting stress levels via physiological signals. The implications of our study are significant in the development of stress detection and management technologies, which can help individuals monitor and control their stress levels in real-time. The accurate detection of stress levels via physiological signals enables the timely delivery of stress management interventions and improves overall well-being.

To summarize, our study demonstrated the superiority of deep learning techniques over machine learning techniques in accurately detecting stress levels using physiological signals. The results align with prior research and have impor- tant implications for the development of stress management technologies. Further studies are required to see whether our conclusions can be applied to different populations and environments.

Table I compares the best outcomes from recent work that have been examined. The authors discard intermediate (Medium) stress evaluation in favour of a binary classification (Low-High). Our research, however, focuses on multi-level stress labeling trained on advanced deep learning model.

The outcomes of the suggested work are shown in Table II. Considering F1 scores 0.96 and 0.90 for the multi-level and binary labelling tasks, respectively, suggested through this dataset, these results demonstrate that LSTM outperforms competing models.

$$F1score = \frac{2}{\frac{1}{precision} + \frac{1}{recall}} \quad (1)$$

IV. Conclusion

This study aimed to improve stress level classification utilising deep learning and machine learning techniques with HRV and GSR bio-signals. Different ML techniques, including SVM, KNN, LR, Decision Tree, Random Forest and NB, were evaluated along with three different DL models, including CNN, LSTM, and a combination of CNN-LSTM. After applying hyperparameter tuning and K-fold Cross-Validation, we found that DL models outperformed ML models, particularly the LSTM model which achieved an 95.67% accuracy, 0.96 F1-score, and 0.96 AUC, demonstrating the potential for DL algorithms to improve stress detection and management technologies. Our findings suggest that the use of HRV and GSR bio-signals with DL algorithms, particularly LSTM, can be effective in accurately classifying stress levels.

The study provides a promising avenue for further research in this area, particularly in exploring the use of additional bio-signals and expanding the sample size. Future studies should consider incorporating other bio-signals and expanding the sample size to validate our findings further. In addition, it is recommended to compare and benchmark our results with recent studies in the area.

Overall, the study contributes to the growing body of research on stress classification and management, particularly in exploring the potential of DL algorithms to improve stress detection technologies. The study has significant implications for stress management in various domains, including healthcare and workplace environments.

***Abstract*—This study describes the difficulties that arise while fine-tuning the PID controllers. PID controllers are used in various systems to keep things stable but finding the right settings can be tricky, especially for complex systems that behave in unpredictable ways. If the controller has not been set up correctly, it can cause the system to become unstable and not perform as intended. Although there are some techniques that have shown promise in the past, they also have their limitations.**

To tackle this issue, this study proposes a solution that uses metaheuristic algorithms such as Particle Swarm Optimization (PSO), Genetic Algorithm (GA), and Ant Colony Optimization (ACO). These algorithms are designed to find optimal settings for the controller more efficiently than traditional methods. The objective of this research is to compare how well these new methods are compared to the traditional methods. The results show that the new algorithms are more effective and lead to better performance and stability in the system. This research provides a promising solution to the challenges of fine-tuning PID controllers, especially for more complex systems that are difficult to control.

I. INTRODUCTION

PID controller is a crucial type of controller that has found widespread use in various industry segments. In most industrial applications, PID controllers offer excellent static and dynamic responses because of their simplistic structure and strong performance under a broad range of operating situations [1][2].

In the past, engineers typically used a trial-and-error approach to handle the matter. They manually tuned PID controllers, which was a time-consuming process. Various methods can be found, with the ZN tuning formula being the most well-known method. Once tuned using the ZN method, a good system response can be achieved, but not necessarily an optimal one.

On the other hand, Genetic Algorithm (GA) is highly effective at finding solutions to a variety of problems. ACO is a versatile optimization method and PSO's ability to work with swarms allows it to explore multiple local minima, increasing the chances of finding the global minima.

A. BACKGROUND

Gas turbines are commonly used in various industries, such as refineries and chemical plants, to power compressors. Centrifugal compressors are typically used due to their ability to handle large volumes of data, which translates to high energy consumption. Turbine-compressor systems are highly reliable and play a critical role in plant operations.

In the mentioned setup, the turbine is commonly powered by high-pressure steam (HPS) which in turn drives the compressor. Hydraulic governor is responsible for regulating the flow of steam to the turbine section. Meanwhile, the electronic governor control panel employs a PID controller to control the opening of the governor.

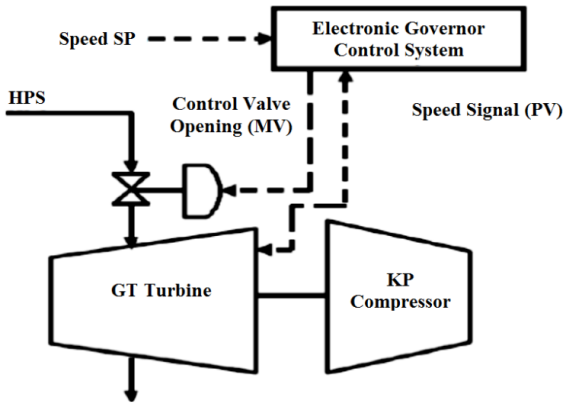

Fig 1. Schematic Diagram of turbine speed Control [10]

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:34:13 UTC from IEEE Xplore. Restrictions apply.

As it is widely known, PID controllers are extensively used in various aspects of industrial automation across different industries, including heavy ones like refineries and shipbuilding. However, to optimize the performance, we need to determine the optimal tuning method. Should we still rely on traditional methods like the Ziegler-Nichols technique or move to advanced methods?

II. PID CONTROLLER

P- Proportional, I- Action, and D- Action are the three types of PID controllers also known as ZN PID tune parameters. These controllers are the most widely used control algorithms and will be the focus of this chapter. Feedback loops typically use PID controllers, which come in a variety of configurations such as standalone controllers, part of a DDC package, that is commonly used in plants like pharmaceutical and oil refineries.

It is noteworthy that greater than half of today's industrial controllers are PID controllers. The PID controller is illustrated in the diagram below, and it can be configured in a non-interacting form (NIF).

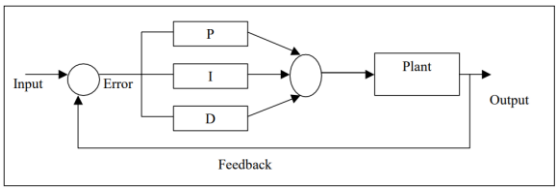

Fig 2. The PID Controller – Non-Interacting Form Schematic Diagram [13]

For proportional control,

$$P = Kp \times e(t)$$

To control the system, it makes use of the proportion of system errors. Offset is produced into the system as a result of this activity.

In Integral control,

$$I = Ki \times \int_0^t e(t)\,dt$$

Its magnitude is proportional to the system's level of inaccuracy. Integral action causes a lag in the system during the action. Offset produced earlier by the Proportional action will be removed as a result of this.

In Derivative control,

$$D = Kd \times d\{e(t)\}/dt$$

It is proportional to error rate of change. Error between desired input and actual output at a specific time t is represented by e(t). By adjusting the values K_p, K_i, and K_d of the PID, various response curves can be generated from a given plant. The challenge in designing a PID for a specific plant is to adjust these values to achieve the desired system performance. It is crucial to keep both the magnitude and duration of the response under an acceptable limit since the response of a system is important. The IAE, can be expressed as:

$$f_{iae} = \int_0^\infty |e(t)|dt$$

Derivative action introduces a lead into the system in the action. This eliminates lag in the system caused by the Integral action earlier in the process.

A. CONTINUOUS PID

The PID controller transfer function:

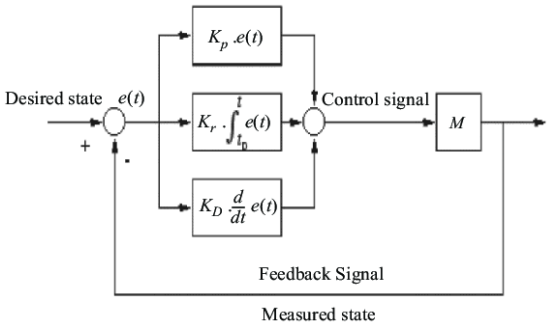

Fig 3. Continuous PID Controller Block Diagram [14]

PID utilizes a combination of three actions to regulate the variable being managed.

The P action is proportional and based on the difference between the feedback and input signals. The Integral action is proportional to the integral of the error signal, while the Derivative action is proportional to the derivative of the error signal.

PID controllers are widely used in industries such as manufacturing, robotics, and process control to regulate variables such as temperature, pressure, flow, and position. They are also used in HVAC systems, automotive control, and flight control systems.

B. DESIGNING PID

The PID controller transfer function is given as

$$G_c(s) = K_p + (K_i/s) + Kds$$

The PID controller's P, I, and D gains are given by K_p, K_i, and K_d, respectively. As depicted in Figure 1, the ACO algorithm is utilized to generate the PID controller Gc(t)'s K_p, K_i, and K_d gains for a specific plant Gp.

$$U(t) = K_p \times e(t) + K_i \int_0^t e(\tau)\,d\tau + K_d \times d\{e(t)\}/dt$$

III. ZIEGLER-NICHOLS METHOD

Ziegler-Nichols introduced the method that requires the unit-step response curve to have an S-shape; parameters like delay time (L) and time constant (T) are obtained by analysing the unit step response of the system, as given in the figure.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:34:13 UTC from IEEE Xplore. Restrictions apply.

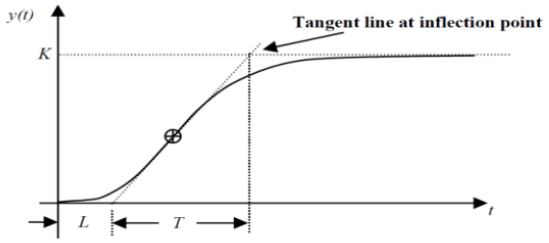

Fig 4. Open Loop System Step Response [12]

Initially, the maximum slope of the response is identified, and a tangent is drawn at the point. The L parameter is obtained by determining the intersection between the tangent and the time axis, while the intersection between the tangent and the line y(t) = K yields T. Parameters are then calculated using the values of a = KL / T and L, as detailed in Table 1.

Table 1. Ziegler-Nichols Tuning Formula for Step Response Method

A. MANUAL TRAINING METHOD (S-DOMAIN)

Table 2 gives a summary of separate impacts that given three terms of the PID have on the performance of the closed-loop system. It can be utilised to manually adjust the parameters of the controller, starting from the values acquired through ZN methods, and by understanding the impact of the parameters on unit step response. Although the manual tuning is simple, it necessitates some expertise and takes some time to achieve the desired response.

Controller	Rise time T_r	Overshoot $OS\%$	Settling time T_s	Steady-state error ess
Increase P gain [K_p]	Decrease	Increase	Small increase	Decrease
Increase I gain [K_i]	Small decrease	Increase	Increase	Eliminate
Increase D gain [K_d]	Small increase	Decrease	Decrease	Minor change

Table 2. Independent P, I and D effect on the System Response

B. THEORETICAL CALCULATION OF PID PARAMETERS

We further elaborate on PID tuning techniques discussed; a calculation is necessary. In order to do so, let us consider the response of a 3rd order system with a transfer function given by

$$\mathbf{G_p(s)} = \frac{\mathbf{1}}{\mathbf{(3s+1)(2s+1)(s+1)}}$$

To simulate the control system in the s-domain, we will be using Simulink models as depicted in Figure 5.

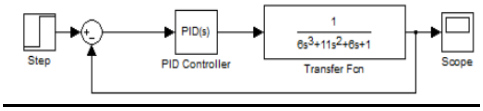

Fig 5. Simulink Model

C. ZIEGLER-NICHOLS STEP RESPONSE CALCULATION

In order to utilize Ziegler-Nichols' calculation method, the step response of the plant must be graphed, as illustrated in the Figure. Response of the system in the figure indicates L = 1.69 T = 8.73, and K = 1.

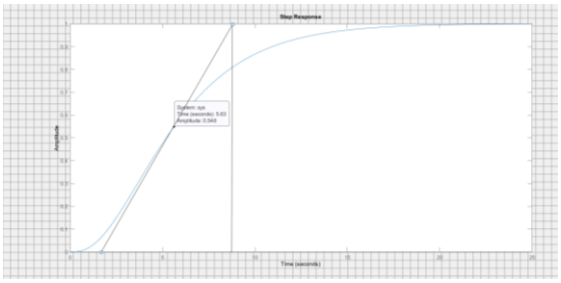

Fig 6. Step Response of Plant Transfer Function

IV. GENETIC ALGORITHM

Genetic Algorithm (GA) is a global search optimization method inspired by natural selection theory. The GA is highly effective at finding solutions to a variety of problems.[6]

In each iteration, the algorithm evaluates the fitness of each solution, and selects the best ones to reproduce and generate new candidate solutions for the next iteration.

They are particularly useful for problems with a large search space, non-linearity, and non-differentiability.

A. POPULATION SIZE

Determining the number of individuals in a population is a crucial step in GA.

The population estimation method used in this study was arbitrary, but based on previous research, a safe range for population size is between 30 and 100 individuals. However, when a sample population of 20 was used in this experiment, the results were discouraging, prompting further testing with populations of 40, 60, 80, and 90 individuals. Ultimately, a population size of 80 was deemed appropriate, with no additional optimization observed beyond a population size of 90 or more.

B. REPRODUCTION

The reproduction step in a genetic algorithm is a crucial process where the fittest individuals from the current population are selected for producing the next generation of solutions. The selection process is based on the fitness function, which evaluates the quality of the solutions. The goal of the reproduction step is to create a diverse population that retains the best solutions from the current population

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:34:13 UTC from IEEE Xplore. Restrictions apply.

while exploring new areas of the solution space.

C. *CROSSOVER*

The crossover operator simulates the genetic recombination process in biological organisms, where the genetic material of two parents is combined to produce offspring with a new set of traits [8].

In the crossover process, two parent individuals are randomly selected from the population and their genetic material is exchanged to produce a new offspring solution. The exchange of genetic material can happen at one or more points along the chromosomes of the parents, and the crossover points are randomly selected for each pair of parents.

The result of the crossover operation is two new offspring solutions that inherit genetic traits from both parents. The new solutions are then evaluated by the fitness function to determine their suitability for the next generation of solutions.

D. MUTATION

The mutation operator introduces random changes to the genetic material of an individual, simulating the process of genetic mutation in biological organisms.

For example, in a binary-coded genetic algorithm, a mutation might involve flipping a bit from 0 to 1 or from 1 to 0. In a real-coded genetic algorithm, a mutation might involve adding a small random value to a gene value.

The mutation operator helps to maintain genetic diversity in the population and prevents the algorithm from getting stuck in local optima. However, the mutation rate should be carefully chosen to balance the exploration and exploitation of the solution space.

V. ANT COLONY OPTIMIZATION

ACO, or Ant Colony Optimization, is an evolutionary meta-heuristic technique that utilizes graphs to solve complex combinatorial optimization problems [5]. The approach involves searching for the lowest cost path through the problem graph, with the help of artificial ants. However, since each ant has limited capabilities, it can only identify suboptimal paths.

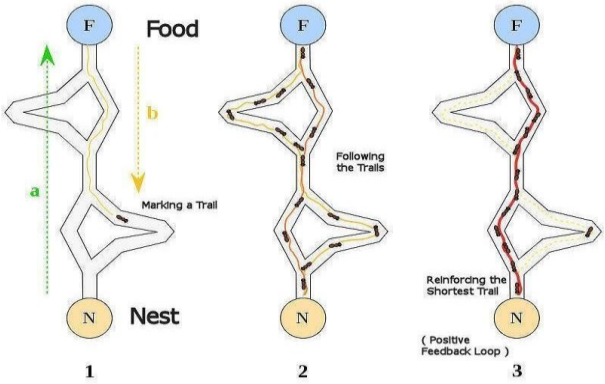

Fig 7. Ant Colony Optimization [11]

Artificial ants in ACO mimic real ants by leaving pheromone trails on the edges of the graph, and choosing their path based on probabilities that depend on the pheromone concentration, which decreases over time. The ants are attracted to nodes with shorter edges and higher pheromone concentration. However, there are also some differences between artificial ants and real ants. Artificial ants exist in a separate universe and move between nodes, while their actions are stored in data structures for memory. Pheromone is usually not deposited during movement, and the amount deposited depends on the quality of the path.

At each generation, artificial ants generate a complete tour by probabilistically selecting nodes in a specific order. In selecting a node, an ant considers both a heuristic factor and a pheromone factor.[1] The heuristic factor, represented by η_{ij}, evaluates the desirability of placing node j at node i in the permutation, and the pheromone factor, represented by r_{ij}, is a measure of the previous successful solutions from other ants. The heuristic value is based on specific problem heuristics, while the pheromone value is based on past successful solutions.[9]

An ant selects the next node using the Pseudo-Random-Proportional Action Choice Rule. This rule states that the ant chooses a node j from the set S of nodes that have not been selected yet based on a probability q_o.[2] The value of qo is a parameter of the algorithm and falls within the range of 0 to less than 1. The ant chooses the node that maximizes a certain criterion, although the specific criterion is not stated.

$$[rij]^{\alpha}[\eta ij]^{\beta}$$

An ant's decision-making process for selecting the subsequent node is influenced by the pheromone and heuristic values, which are determined by the constants α and β. The algorithm employs the Pseudo Random-Proportional Action Choice Rule, and the probability parameter qo is utilized. When qo falls within the range of 0 to less than 1, the ant picks node j from the set S that provides the highest product of pheromone and heuristic values. In contrast, when qo is outside this range, the ant employs a formula to choose the next node based on a probability distribution.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:34:13 UTC from IEEE Xplore. Restrictions apply.

$$P_{ij} = \frac{[\tau_{ij}]^{\alpha}[\eta_{ij}]^{\beta}}{\sum_{h \epsilon S}[\tau_{ih}]^{\alpha}[\eta_{ih}]^{\beta}}$$

The likelihood of transitioning between nodes is determined by finding a balance between the heuristic and pheromone factors. Nodes that are closer (i.e., with a lower cost path) should be selected more frequently to implement a greedy constructive heuristic for the heuristic factor. Regarding the pheromone factor, if a particular edge (i, j) has been frequently utilized, it is deemed highly desirable, leading to an autocatalytic process. When the selection of the next node yields a value of P_{ij}, the previously mentioned rule is applied, and the heuristic factor ij is calculated using the following formula.

$$\eta_{ij} = \frac{1}{f(X_j)}$$

In the given equation, f(X) denotes the cost function of X. [4] The above formula prefers choosing edges that are shorter (i.e., lower cost) and have a greater quantity of pheromone. When the ant travels from node i to node j, it leaves a substance on the path, defined as follows:

$$\Delta\tau_{ij}^{k} = \begin{cases} \frac{Q}{L_k} & if\ \text{k}^{\text{th}}\ ant\ uses\ edge\ (i,j)\ in\ its\ tour \\ 0 & otherwise \end{cases}$$

The amount of pheromone laid by ants is related to the quality of the path they take, with more pheromone being deposited on shorter paths. This value is evaluated after an ant completes a tour, which consists of n iterations or generations. The amount of pheromone previously deposited on the trail is then updated based on certain guidelines. The update is done by considering a constant Q and the cost of the tour performed by the ant, denoted by L_k.

$$\tau_{ij}\ (t+n) = \rho.\tau_{ij} + \Delta\tau_{ij}(t)$$

$$\Delta\tau_{ij}(t) = \sum_{k=1}^{m} \tau_{ij}(t)$$

where m represents the number of ants, the coefficient (0,1) determines how long the trail persists during a cycle, where (1- ρ) represents the amount of trail that evaporates between generation η_g and η_{g+1}.

The method for modifying pheromone levels aims to replicate the impact of fresh pheromone deposition by ants on the edges visited, as well as the dissipation of pheromone. The process concludes either when an ant finds a solution or the maximum number of iterations is attained.

VI. PARTICLE SWARM OPTIMIZATION

Particle swarm optimization (PSO) is a bio-inspired technique utilized for finding the best possible solutions within a provided solution space. It differs from other optimization algorithms since it solely depends on the objective function and does not rely on the gradient or any differential form of the objective.

The idea behind the algorithm is based on the behaviour of flocks of birds or schools of fish, where all members of the group can benefit from the experiences of others.[7] Essentially, if one bird in a flock finds food, the others can follow and benefit from this discovery.

In the context of optimization, PSO can be thought of as a group of particles moving through a high-dimensional solution space, each particle representing a potential solution. The particles move towards the best solution found so far by the group, while also exploring new areas of the solution space. While it is unlikely that PSO will find the true global optimal solution, it often produces results that are very close to it.

A. OPTIMIZATION PROBLEM

The optimization problem involves a vector variable $X = [x_1x_2x_3...x_n]$, which is used to minimize or maximize the cost function f(X), depending on the optimization formulation. X is also referred to as the position vector, representing a variable model with n dimensions where n is the number of variables in the problem. For instance, in the problem of a flock of birds choosing a landing point, X can be thought of as the latitude and longitude. The fitness function or objective function, f(X), evaluates how good or bad a position X is based on how well a bird can land there. This evaluation is done using multiple survival criteria.

B. PSO ALGORITHM

The following is the step-by-step procedure for the algorithm:

1. Generate a 'population' of agents (particles) that are evenly spread out across the range of X.

2. Compute the value of the objective function for each particle by considering its position. For instance, consider the following function.

$$z = f(x, y) = sinx^2 + siny^2 + sinx\ siny$$

3. If a particle's current position is superior to its previous best position, then replace it.

4. Determine the best particle based on their previous best positions.

5. Modify the velocities of the particles.

$$V_i^{t+1} = W.V_i^t + c_1U_1^t\left(P_{b_1}^t - P_i^t\right) + c_2U_2^t\left(g_b^t - P_i^t\right)$$

6. Update the positions of the particles to their new locations.

$$P_i^{t+1} = P_i^t + v_i^{t+1}$$

7. Continue with the steps described in 2 until the stopping conditions are met.[3]

VII. RESULTS

In this section, we present the results of our proposed algorithms using both numerical and graphical representations. All computations were performed using

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:34:13 UTC from IEEE Xplore. Restrictions apply.

MATLAB/Simulink. In order to compare the performance of our algorithms, we also used a Genetic Algorithm, ACO and PSO. The plant used in our experiments is:

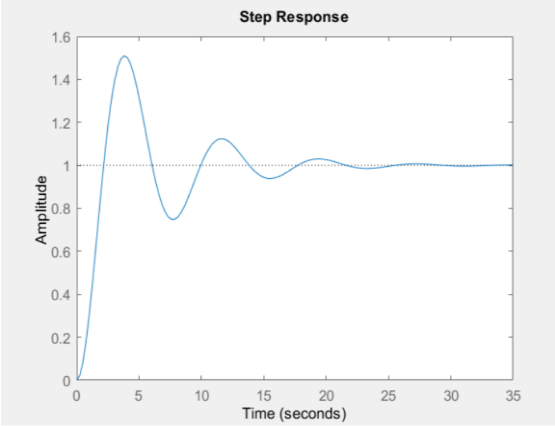

Fig 8: Step-response of PID plant using ZN

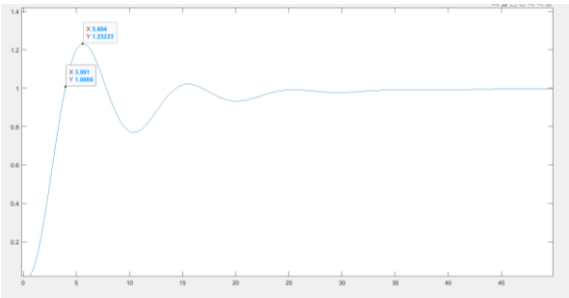

Fig 9: Step-response of PID plant using GA

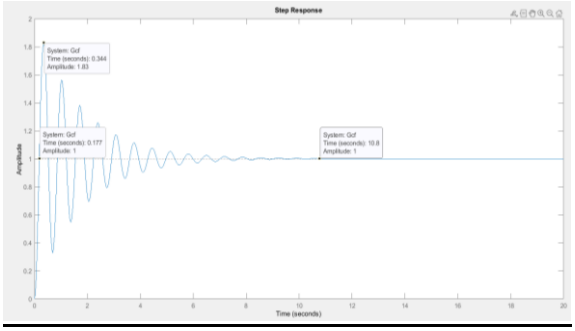

Fig 10: Step-response of PID plant using ACO

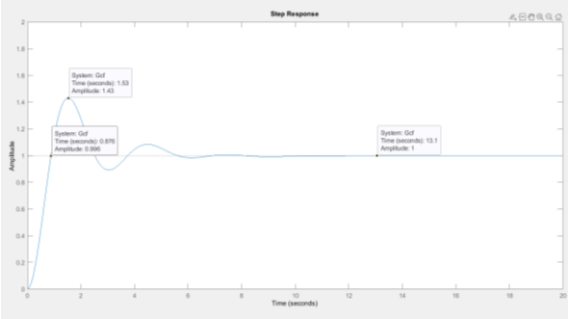

Fig 11: Step-response of PID plant using PSO

Measuring Factors	GA Controller	PSO Controller	ACO Controller	ZN Controller
Rise Time (sec)	4	0.878	0.177	2.15
Maximum Overshoot (%)	23	43	83	51
Settling Time (sec)	35	13.1	10.8	28.2

Table 3. Comparison of different Optimization techniques

Table 3 presents the simulation outcomes of three advanced optimization techniques and one classical method applied to a single plant. The results are based on three measurement criteria. It is evident that all advanced techniques have performed better than the classical method. The classical method performed better only in the Maximum Overshoot column. Nevertheless, in most industrial plants, a slight overshoot is not a major concern. The ACO controller had a much shorter rise time than the GA and PSO controllers, and its settling time was also shorter than that of the GA and PSO controllers. However, the maximum overshoot of the ACO controller was more than double that of the GA controller. We can improve the performance by decreasing the overshoot. Therefore, the ACO controller performed better than the GA and PSO controllers in terms of rise-time and settling-time parameters, but it lagged in the maximum overshoot parameter. Settling time is low in all the metaheuristic techniques, hence the stability is achieved.

IX. CONCLUSION

The study demonstrated the potential of current metaheuristic methods and computational capabilities in obtaining optimal adaptive control. It presented a new method for creating PID controllers that would provide desirable performance for a particular plant. The process of creating these controllers was framed as an optimization problem using four performance indexes, including maximum overshoot, settling time, rise time, and integral absolute error. To identify the most suitable solution, optimization algorithms utilizing GA, PSO, and ACO were created, which enabled the discovery of the optimal global solution.

The unique aspect of the techniques introduced in this paper is that they are easy to implement, provide greater flexibility in problem formulation, and enable designers to obtain a global optimum solution for designing PID controllers. The proposed methods were evaluated on a plant and produced promising results, which were compared to each other as well as a classical method.

Unbalanced Half-bridge Split Capacitor Power Decoupling with Multi-Order Frequency Control for 800V On-board Battery Charger

Tuyen D. Nguyen, *Senior Member, IEEE*, Long H. B. Nguyen, *Student Member, IEEE*, Dong Tran, *Student Member, IEEE*, Ravi Nath Tripathi, *Senior Member, IEEE*, Hai N. Tran, *Member, IEEE*

***Abstract*- This paper proposes a new method for the design and control of a Half-bridge Split Capacitor based Power Decoupling (HSC-PD) circuit to eliminate the bulky Electrolytic Capacitors (E-cap) at dc-link, targeting 800V OBC applications with higher reliability and power density. In the proposed method, both capacitance and dc-offset voltage of the decoupling capacitors are designed unbalanced with the bottom capacitor having a dominant effect over the top one, which reduces the decoupling capacitance requirements compared to the previous works. In addition, the effect of lower dc-link capacitance in reducing power rating of the pre-charge resistor, typically used in OBC applications, is presented. This effect, overlooked in previous literature, leads to reducing volume and cost of the OBC. A small signal model of the HSC-PD is introduced, and a modified feedback control strategy is proposed, offering lower memory usage and calculation effort for the DSP microcontroller when compared with conventional Proportional Resonant (PR) controllers. Comparisons of the proposed method with other HSC-PD counterparts as well as with the conventional E-cap method are given. Finally, a 7.4kW prototype of an 820V interleaved totem-pole PFC with HSC-PD is built and tested to verify the superior performance of the proposed method.**

Index Terms – OBC; power decoupling; electrolytic capacitor; 800V electric vehicles, half-bridge split capacitor.

I. Introduction

Battery Electric Vehicles (BEVs) has been growing rapidly in recent years, and expected to replace the Internal Combustion Engine Vehicles (ICEVs) in the future to reduce CO_2 emission through transportation [1] – [4]. On-board Battery Charger (OBC) is one of the pivotal component of the BEVs, and it's main function is to charge the traction battery at home or office using the available ac grid [5] – [6].

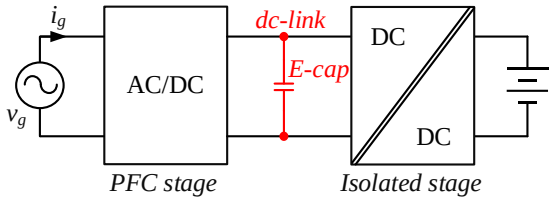

Fig. 1. Conventional OBC with E-cap.

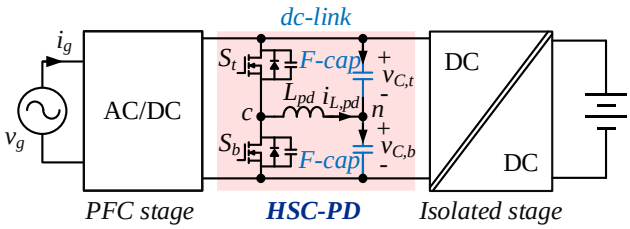

Fig. 2. Proposed E-capless 800V OBC based on *HSC-PD* circuit.

The conventional single-phase OBC shown in Fig. 1 have been widely used in 400V BEVs, in which a large numbers of parallel Electrolytic capacitors are placed between a PFC and an isolated stages to absorb the double-line frequency ripple [7] – [10]. However, these E-caps are short life-time, low current rating, and low power density making it not suitable for the next generation OBC where the requirement of reliability and power density of EV power converters are increased aggressively along with the increasing of charger power rating [5], [11], [12]. In addition, the EV's battery voltage are tend to increase to 800V from current 400V system, leading to many series and parrallel connections of E-cap are required to increase the dc-link votlage in the conventional OBC design method due to low avaiability of high-voltage rating E-cap. This worsens the reliability and power density of the converter. It worth to mention that the use of 800V battery allows to develop a dc fast-charger with higher power rating up to 350kW compared to a typical 50kW-to-100kW fast charger currently available for the 400V system, which significantly reduce charging time. Moreover, various benefits of 800V system over the 400V system such as lighter vehical weight, wider speed range, and higher efficiency have been mentioned in previous literatures [13].

A well-known method to eliminate the E-cap is by integrating an auxiliary Power Decoupling (PD) circuit into the

This article has been accepted for publication in IEEE Transactions on Transportation Electrification. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TTE.2023.3299988

main power converter. The PD circuit makes the instantaneous power between ac-grid and dc battery sides balanced. Hence, the capacitance requirement for the dc-link is significantly reduced so that the E-cap can be replaced by film or ceramic capacitors [14] - [25]. The auxiliary storage elements of the PD circuit can be inductor, capacitor, or both. However, capacitor is preferable for PD purposes due to lower loss and higher energy density compared to that of the inductor. This paper proposes a new structure for 800V OBC based on PD circuit, as shown in Fig. 2. A new design approach and new control method for the PD circuit are proposed to reduce the required capacitance and improve its performance, power density and efficiency. In addition, the precharge resistor of the OBC is significantly reduced as a result of dc-link capacitance reduction. Furthermore, a modified feedback control based on co-ordinate transformation *αβ/dq* is proposed to reduce the digital control complexity.

The PD circuits in the literatures is classified in to two methods, AC PD and DC PD. In AC PD method [19] – [21], the voltage across decoupling capacitors is equal to ac-grid voltage. Therefore, high capacitance is required due to zero dc-offset voltage. This high capacitance issue of AC PD method is worsen in OBC applications which usually requires the converter to operate with universal grid voltage, typically ranging from $85V_{ac,rms}$ to $265V_{ac,rms}$, thus, higher capacitance is required considering at the lower grid voltage situation. In DC PD methods [14] – [18], the voltage across decoupling capacitor consists of both ac and dc components with the maximum value up to dc-link voltage which is always higher than grid voltage in the boost PFC converter. Therefore, the required decoupling capacitance in the DC PD method is lower than that of the AC PD method due to high dc-offset component, especially in 800V OBC. It's worth noting that even though the voltage rating of decoupling capacitors in AC PD is lower than DC PD due to zero dc-offset, there is not big different in the actual voltage rating of decoupling capacitors between two motheds because the dc-volage rating of film capacitors is usually much higher than its ac-voltage rating [26], [27]. Among various DC PD circuit topologies were presented in the previous works [14] – [18], Half-bridge Split Capacitor based PD (HSC-PD) is frequently used because the dc-link capacitors are directly utilized for power decoupling purpose, thus, no addition capactior is needed [15] – [18].

Several control methods have been developed for the HSC-PD converter [15] – [18]. In [16], the HSC-PD structure was first introduced with the open-loop control method. However, open-loop control is sensitive to system uncertainties, such as parameter tolerances and disturbance, leading to not accuracy. After that, a closed-loop control algorithm for the HSC-PD circuit is proposed in [18], which is much more robust under various uncertainty and steep load change conditions. In both [16] and [18], decoupling capacitors are designed in such a way that their capacitance value and dc voltage component are equal, and their ac voltage component fluctuates at a line frequency. However, this strategies have several drawbacks: 1) large capacitance value of both decouling capacitor, which increases not only capacitor volume but the current rating of the PD circuit; 2) difficult to select the decoupling capacitor since its ac voltage rating is high; 3) low efficiecny because of high current rating and equivalent step-down ratio; 4) low dynamic response since controlling the ac components at line-frequency requires a 90^o-shifting function in the controller.

In [17], a unequal dc voltage component method is introduced in a complete closed-loop control system. This reduces the amplitude of ac voltage component. Moreover, the ac component is controlled at the double-line frequency to avoid the delay in the controller and make it insensitive with the capacitance tolerance. Even though the robustness of this control method has been practically demonstrated under large capacitance tolerance conditions, it is designed based on an equal capacitance approach, resulting in large equivalent capacitance and high current rating. In addition, the effect of unequal dc voltage component on converter efficiency, and the fourth-line frequency harmonic caused by double-line frequency voltage and current in the decoupling circuit have not been discussed.

In [15], unequal capacitance approach was first introduced to improve the robustness of the controller under non-ideal grid, and the ac voltage ripple is obtained with multi-harmonic frequency by using conventional PR controller. However, the ac voltage rating of capacitors is high due to equal dc voltage component, making it not suitable for high dc-link voltage converter such as 800V OBC since the high ac voltage rating capacitor is usually bulky and low avaiability. In addition, the capacitance values in [15] are pretty high of 330μF and 120μF for the top and bottom capacitors, respectively, at 400V dc-link and 1.5kW.

Considering the aforementioned issues, this paper proposes a new design approach and control method for the HSC-PD circuit, in which both dc component and capacitance values of the decoupling capacitors are designed unequally with bottom-bias capacitor approach, reducing not only equivalent capacitance and ac voltage ripple but current rating of the PD circuit. The effect of fourth-line frequency harmonics, which is caused by double-line frequency of voltage and current in the PD circuit, is also analyzed. The dc-offset ratio and its impact on the converter efficiency will be discussed. Furthermore, the feedback control of HSC-PD is developed for the entire system considering the proposed unequal dc component and capacitance. The multi-order frequency harmonic component compensated through the PR controller, however, the implementation in digital domain consdiering *αβ* frame requires considerable amount of delay-time for computation as well as frequency response is poor as compared to the integral control action. In this paper, implementation of PR controller is proposed using *αβ-dq* transformation with an integrator that enables the generation of multi-order frequency component, reduction in DSP memory utilization and calculation effort. Theoretical analysis and experimental results are given to verify the superiority of the proposed method.

II. Proposed Even-order Frequency Unbalanced Half-bridge Split Capacitor Power Decoupling Control

A. Theoretical analysis and design guideline

Circuit diagram of the proposed 800V OBC is shown in Fig. 2, in which bulky E-cap is replaced by HSC-PD circuit using low capacitance Film capacitor (F-cap). The charger is rated at 7.4kW, and the dc-link voltage is fixed at 820V. Compared to the variable dc-link strategy as presented in [7], the use of fixed dc-link voltage at maximum provides the benefits of: 1) minimize the required decoupling capacitance; 2) minimize the current conducted in the primary side of the isolated stage of the OBC reducing current rating and conduction loss. It is worth mention that the cost of 1200V SiC MOSFET, that is used in the primary side of the isolated stage, increases significantly with its current rating. The grid current and voltage as well as its instantaneous power can be expressed as below:

$$\begin{cases} v_g(t) = \sqrt{2} \cdot V_g \cdot \sin(\omega \cdot t + \varphi) \\ i_g(t) = \sqrt{2} \cdot I_g \cdot \sin(\omega \cdot t + \varphi) \end{cases} \quad (1)$$

$$p_g(t) = v_g(t) \cdot i_g(t) = V_g \cdot I_g - V_g \cdot I_g . \cos(2 \cdot \omega \cdot t + 2 \cdot \varphi) \quad (2)$$

The phase of grid voltage and current φ will be assumed to be zero to reduce the complexity in the later analysis since power factor correction is used. The first term on the right side of (2) represents the average power charged the battery, P_{dc}, while second term is the second-order power that needs to keep away from the battery. In the conventional OBC, this second-order power is stored in the dc-link using bulky electrolytic capacitors leading to low power density and reliability. In this paper, the second-order power is stored in two small film capacitors C_t and C_b by using the proposed design and control method for the HSC-PD, which is described as follows.

The voltage equation for each decoupling capacitors, $v_{C,t}(t)$ and $v_{C,b}(t)$, are proposed as:

$$\begin{cases} v_{C,t}(t) = V_{dc,t} + \sum_{n=2,4,6,...} V_{ac(n)} \cdot \sin(n \cdot \omega \cdot t + \theta_n) \\ v_{C,b}(t) = V_{dc,b} - \sum_{n=2,4,6,...} V_{ac(n)} \cdot \sin(n \cdot \omega \cdot t + \theta_n) \end{cases} \quad (3)$$

The first and second terms on the right side of (3) represent dc and ac voltage components of each decoupling capacitor respectively. The ac voltage components include multiple of even-order frequencies $V_{ac(n)}$ ($n = 2, 4, 6, \ldots$), and are 180° phase shift between two capacitors to ensure the sum of which are constant at the desired dc-link voltage. The block diagram of the proposed controller is detailed in Section III. Ideally, only second-order ac voltage component is needed for storing the second-order power of the grid in (2). However, fourth-order power is created because of second-order voltage and current conducted through the decoupling capacitors. Similarly, higher even-order powers of 6th, 8th, … are created from its previous even orders. Therefore, the decoupling capacitor voltages must be operated with multi even-order frequencies to suppress the second-order power of the grid and other higher even-order powers created by itself, as shown in (3).

The dc voltage components of two capacitors, $V_{dc,t}$ and $V_{dc,b}$, are unequal with the proposed dc-offset factor m as below:

$$\begin{cases} V_{dc,t} = V_{Link} \cdot \left(\frac{1}{2} - m\right) \\ V_{dc,b} = V_{Link} \cdot \left(\frac{1}{2} + m\right) \end{cases} \quad with\ 0 < m < 0.5 \quad (4)$$

It can be seen from (4) that in the proposed method dc voltage component of the bottom capacitor $V_{dc,b}$ is always kept greater than that of top capacitor, $V_{dc,b} > V_{dc,t}$, since m is the dc-offset ratio, and can be chosen within $0 < m < 0.5$. This proposed approach is different from the previous work presented in [15] that was designed with higher dc voltage component of the top capacitor. The reason for this proposed approach is that if considering the HSP-PD circuit as a buck converter with input and output voltages are V_{Link} and $V_{dc,b}$, respectively, higher $V_{dc,b}$ leads to lower step down ratio of buck converter and narrower duty cycle range. In addition, higher bottom capacitor voltage led to lower decoupling inductor current for the same power rating. Therefore, the proposed unbalancing approach with higher dc voltage component of the bottom capacitor achieves higher efficiency and smaller decoupling inductor as compared to the previous work [15], [17]. It is noticeable that the peak ac voltage component must be smaller than the dc voltage component of the top capacitor to avoid over modulation.

Current conducted through two decoupling capacitors are determined from (3) as below:

$$\begin{cases} i_{C,t}(t) = C_t \cdot \frac{dv_{C,t}(t)}{dt} \\ \qquad = C_t \cdot \sum_{n=2,4,6,...} n \cdot \omega \cdot V_{ac(n)} \cdot \cos(n \cdot \omega \cdot t + \theta_n) \\ i_{C,b}(t) = C_b \cdot \frac{dv_{C,b}(t)}{dt} \\ \qquad = -C_b \cdot \sum_{n=2,4,6,...} n \cdot \omega \cdot V_{ac(n)} \cdot \cos(n \cdot \omega \cdot t + \theta_n) \end{cases} \quad (5)$$

where C_t and C_b are capacitance values of top and bottom capacitors, respectively. Current conducted through decoupling inductor can be obtained from (5) by:

$$\begin{aligned} i_{L,pd}(t) &= i_{C,b}(t) - i_{C,t}(t) \\ &= -(l+1) \cdot C_t \cdot \sum_{n=2,4,6,...} n \cdot \omega \cdot V_{ac(n)} \cdot \cos(n \cdot \omega \cdot t + \theta_n) \end{aligned} \quad (6)$$

Typical waveforms of the proposed control method are shown in Fig. 3.

Not only dc voltage component but also capacitances of two decoupling capacitors are designed unequally in the proposed method. Assuming that l is capacitance ratio between two decoupling capacitors:

$$l = \frac{C_b}{C_t} \quad (7)$$

The instantaneous power stored in two capacitors is therefore obtained from (3) - (6) by:

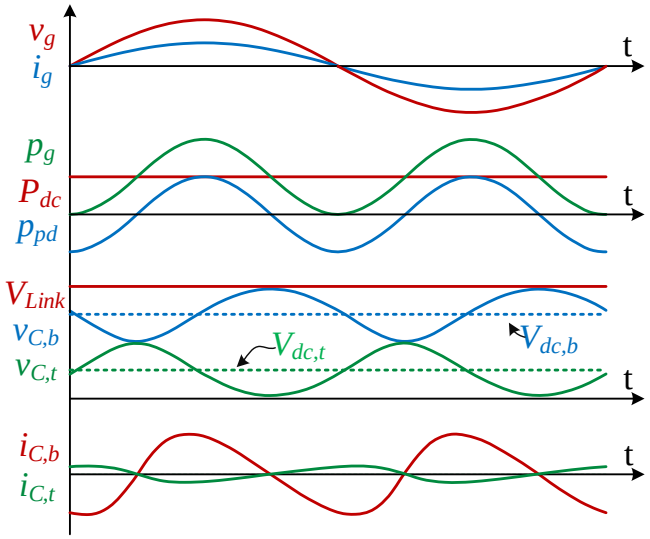

Fig. 3. Typical waveforms of the proposed power decoupling method at full load

$$\begin{aligned} p_{pd}(t) &= p_{C,t}(t) + p_{C,b}(t) \\ &= v_{C,t}(t)\cdot i_{C,t}(t) + v_{C,b}(t)\cdot i_{C,b}(t) \\ &= -\omega\cdot\left(V_{dc,b}\cdot C_b - V_{dc,t}\cdot C_t\right)\cdot \sum_{n=2,4,6,\ldots} n\cdot V_{ac(n)}\cdot\cos(n\cdot\omega\cdot t+\theta_n) \\ &+(l+1)\cdot C_t\cdot \sum_{n=2,4,6,\ldots}\left(V_{ac(n)}\cdot\sin(n\cdot\omega\cdot t+\theta_n)\right)\ldots \\ &\ldots\cdot \sum_{n=2,4,6,\ldots}\left(n\cdot\omega\cdot V_{ac(n)}\cdot\cos(n\cdot\omega\cdot t+\theta_n)\right) \end{aligned} \tag{8}$$

The phase angle θ_n can be determined by:

$$\theta_n = -(n-2)\cdot\frac{\pi}{4} \tag{9}$$

The peak value of each ac voltage components in (8) are determined by:

$$\begin{cases} V_{ac(2)} = \dfrac{V_g\cdot I_g}{\omega\cdot\left[l-1+2\cdot m\cdot(l+1)\right]\cdot C_t\cdot V_{Link}} \\ V_{ac(4)} = \dfrac{(l+1)\cdot V_{ac(2)}^2}{2\cdot\left[l-1+2\cdot m\cdot(l+1)\right]\cdot V_{Link}} \\ V_{ac(6)} = \dfrac{(l+1)\cdot V_{ac(2)}\cdot V_{ac(4)}}{\left[l-1+2\cdot m\cdot(l+1)\right]\cdot V_{Link}} \\ V_{ac(8)} = \dfrac{(l+1)\cdot\left(2\cdot V_{ac(4)}\cdot V_{ac(4)}+4\cdot V_{ac(2)}\cdot V_{ac(6)}\right)}{4\cdot\left[l-1+2\cdot m\cdot(l+1)\right]\cdot V_{Link}} \end{cases} \tag{10}$$

The first term on the right side of (8) represents for the second-order power that is stored in the decoupling capacitors and the rest terms in the right side of (8) are the power naturally generated by the controller itself and is controlled to store within the decoupling circuit. The second order and self-created power components (4th, 6th, 8th, …) with different value of *m* are shown in Fig. 4. Practically, the waveforms of voltage (current) of decoupling capacitor (inductor) is generated by a controller in the closed loop system, thus to reduce the control complexity

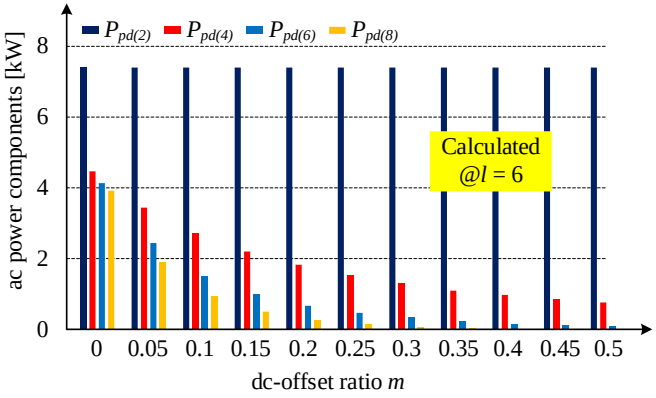

Fig. 4. AC power components of the decoupling circuit calculated at l = 6, C_t = 16 μF, and C_b = 86 μF.

caused by the endless chains of (3) and (6), the orders higher than eight will be ignored since the amplitude of which are negligible. It can also be seen from Fig. 4 that second-order power in the proposed approach is independent from *m* since it is designed same as OBC rating, and the higher dc-offset ratio *m* will lead to lower other self-created ac power in the circuit (higher order ac power of 4th, 6th, 8th, …), this has not been investigated in the previous literatures. If second-order power of the grid in (2) are equal to that from (8) to achieve the ideal decoupling purpose, thus:

$$\left[l-1+2\cdot m\cdot(l+1)\right]\cdot C_t = \frac{V_g\cdot I_g}{\omega\cdot V_{ac(2)}\cdot V_{Link}} \tag{11}$$

Since decoupling capacitors are designed to absorb second-order power of the grid, the calculation of which can be done by setting *m* to zero to reduce the complexity. The relationship of top and bottom capacitors is therefore obtained by:

$$(l-1)\cdot C_t = C_b - C_t = \frac{2\cdot V_g\cdot I_g}{\omega\cdot V_{Link}^2} = \frac{2\cdot P_g}{\omega\cdot V_{Link}^2} \tag{12}$$

The relationship of $C_{bot} - C_{top} \geq 70$ uF is therefore obtained based on (12) with P_g = 7.4kW and V_{Link} = 820V. In the proposed method, the bottom capacitor with higher dc voltage component and capacitance value absorbs a higher amount of second-order power compared to the top capacitor which has lower dc voltage component and capacitance value.

The equivalent capacitance of dc-link as a function of switching frequency and desired ripple is expressed by:

$$C_{eq} = \frac{P_g\cdot D}{V_{Link}\cdot\Delta V_{Link,sw}\cdot f_s} \tag{13}$$

where *D* is a duty cycle of the PFC circuit, $\Delta V_{Link,sw}$ is the dc-link voltage ripple at switching frequency, and f_s is the switching frequency of the PFC circuit.

The above equivalent capacitance is also obtained based on each decoupling capacitor by:

$$C_{eq} = \frac{C_b\cdot C_t}{C_b + C_t} = \frac{\left(C_t + \dfrac{2\cdot P_g}{\omega\cdot V_{Link}^2}\right)\cdot C_t}{2\cdot C_t + \dfrac{2\cdot P_g}{\omega\cdot V_{Link}^2}} \tag{14}$$

This article has been accepted for publication in IEEE Transactions on Transportation Electrification. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TTE.2023.3299988

Therefore, minimum capacitance of top capacitor can be obtained from (13) and (14) by:

$$C_{t,\min} = \sqrt{\left(\frac{P_g}{\omega \cdot V_{Link}^2} - C_{eq}\right)^2 + C_{eq} \cdot \frac{2 \cdot P_g}{\omega \cdot V_{Link}^2}} - \left(\frac{P_g}{\omega \cdot V_{Link}^2} - C_{eq}\right) \tag{15}$$

The required capacitances as a function of switching frequency are shown in Fig. 5. In this project, f_s and $\Delta V_{Link,sw}$ is set to 50kHz and 8V, respectively. The minimum capacitance of top and bottom capacitors are therefore obtained by 16uF and 86uF, respectively, yielding l_{min} = 5.4.

The comparison of decoupling capacitors between the proposed method and previous research is shown in Fig. 6. It can be observed that AC power decoupling has larger capacitance due to zero dc voltage component [19] – [21]. The line-frequency decoupling approach with balancing capacitors has large capacitance since its equivalent capacitance is high, which is calculated same as the right side of (12). Moreover, due to balancing capacitance approach, each capacitor must be twice of the equivalent capacitance worsening the required capacitance value [14] - [17]. Authors in [15] used the unequal capacitance to increase the robustness of controller under nonideal grid. However, its unbalancing strategy is opposite from our proposed strategy in such a way that bottom capacitor in [15] has smaller capacitance value than top capacitor. This strategy is however not beneficial because it reduces the power decoupling capability, as seen in (8). Moreover, equivalent capacitance given in [15] is same as [16] – [18] which is much larger than this paper.

The relationship between peak 2nd harmonic current of the decoupling inductor as a function of *m* and *l* is described in (16), which is obtained from (6) and (10), and is shown in Fig. 7.

$$i_{L,pd(2)} = \frac{-(l+1) \cdot C_t \cdot 2 \cdot V_g \cdot I_g \cdot \cos(2 \cdot \omega \cdot t + \theta_2)}{\left[l - 1 + 2 \cdot m \cdot (l+1)\right] \cdot C_t \cdot V_{Link}} \tag{16}$$

It can be observed that with same decoupling capacitors, the peak current of decoupling inductor reduces as *m* and *l* increase. However, with a given second-order power and dc-link voltage, m must be designed so that the peak voltage of the bottom capacitor does not exceed dc-link voltage. The selection of decoupling capacitors is a challenging task since their voltages consist of both dc and low-frequency ac components. The dc-voltage rating of the decoupling capacitor is selected based on its peak voltage which is assumed to be dc-link voltage as the

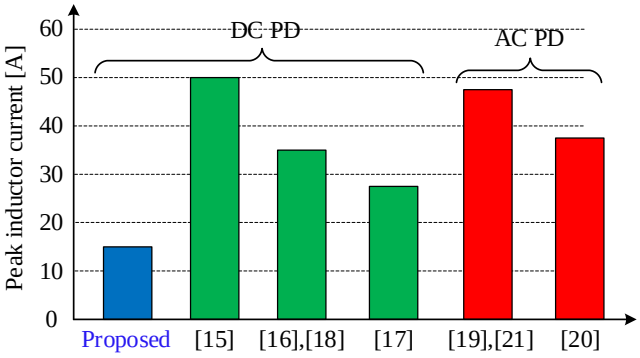

Fig. 9. Decoupling inductor current comparison

worst case in this paper, while ac voltage rating depends on *m*. Lower value of m leads to higher ac voltage rating and vice versa. Since film capacitor is used for decoupling purpose, the dc voltage rating of which is usually several times higher than its ac voltage rating. Fig. 8 shows the dc and ac components of the decoupling capacitors. In this paper, considering the availability and margins, the actual value of decoupling capacitors used for experiment are C_{top} = 15uF and C_{bot} = 100uF, l = 6.25. The dc-link voltage is design maximum at 820V, thus film capacitor BLH505K901A062 with ac voltage rating of 230V_{rms} is selected considering its low-profile benefit. Therefore, *m* can be theoretically designed between 0.05 to 0.25 considering 10% margin for ac voltage rating. However, in practical *m* is designed at its maximum possible value of 0.25 to minimize the self-created power and inductor current, as seen in Fig. 4.

The comparisons of the decoupling inductor current (peak) between the proposed method and other counterparts are shown in Fig. 9. It can be observed that, the proposed method has lowest inductor current due to lower top capacitance value. The unbalance strategy in [15] has another disadvantage is that its inductor current is very high due to higher top capacitance value.

III. Modelling and Control Algorithm

This section describes the proposed control algorithm for the system including PFC stage and HSC-PD circuit. A small-signal model of HSC-PD will be presented, after that, the implementation of two parallel controllers is explained to realize the best compromise between the PFC stage and the PD circuit.

1) Modeling HSC-PD circuit

HSC-PD circuit in Fig. 2 can be considered as a buck converter with input voltage and output voltage are V_{Link} and $v_{C,b}$, respectively. Hence, the voltage across top capacitor $v_{C,t}$ will be naturally obtained as a result of these two input and output voltages. Top switch S_t is the main switch of the converter, and its duty cycle is controlled to generate the desired output voltage, while the bottom switch S_b is switched complementarily with S_t. The converter operates under continuous conduction mode. The average model of HSC-PD with current and voltage is defined as:

$$\begin{cases} \bar{v}_{cp}(t) = d(t)\cdot \bar{v}_{ap}(t) \\ \bar{i}_a(t) = d(t)\cdot \bar{i}_c(t) \end{cases} \tag{17}$$

The average voltage and current are functions of duty cycle '*d*' and termed as the averaged PWM switch model. The linearization of PWM switch model and ignoring second-order terms will result in the small signal PWM switch model under CCM as:

$$\begin{cases} V_{cp} + \hat{v}_{cp}(t) = D\cdot V_{ap} + \hat{d}(t)\cdot V_{ap} + D\cdot \hat{v}_{ap}(t) \\ I_a + \hat{i}_a(t) = D\cdot I_c + \hat{d}(t)\cdot I_c + D\cdot \hat{i}_c(t) \end{cases} \tag{18}$$

The small signal circuit model of the HSC-PD circuit is therefore obtained, as shown in Fig. 10, which is used for the design and development of the controller. The transfer function for duty cycle-to-inductor current (19) and duty cycle-to-output voltage (20) is obtained by considering $\hat{v}_{Link}(s)$ = 0. Here, the output voltage is the ac ripple component in the output dc voltage of HSC-PD circuit. The duty cycle to output voltage transfer function of HSC-PD circuit is similar to [16] and capacitor voltage possessing the same ac component.

$$G_{PDi}(s) = \frac{\hat{i}_{Lpd}(s)}{\hat{d}_{pd}(s)} = \frac{(l+1)\cdot C_t \cdot V_{Link}\cdot s}{L_{pd}\cdot(l+1)\cdot C_t \cdot s^2 + 1} \tag{19}$$

$$G_{PDv}(s) = \frac{\hat{v}_{ac(n)}(s)}{\hat{d}_{pd}(s)} = \frac{V_{Link}}{L_{pd}\cdot(l+1)\cdot C_{top}\cdot s^2 + 1} \tag{20}$$

From (19) and (20), current-to-output voltage transfer function of HSC-PD circuit is obtained as

$$G_{PDiv}(s) = \frac{\hat{v}_{ac(n)}(s)}{\hat{i}_{Lpd}(s)} = \frac{1}{s\cdot(l+1)\cdot C_t} \tag{21}$$

2) Proposed control algorithm

PI-controller is the most commonly used for the dc reference regulation without steady-state error in synchronously rotating dq frame. PR controller are employed for the reference tracking in stationary frame αβ [28]**.** The PI controller in synchronously rotating dq frame is equivalent to the PR controller in stationary αβ frame [29], however, this holds true mainly for the fundamental frequency components. Considering this, the PR controller requires lesser computation burden as there is no transformation required. PI- controller is capable of tracking the dc reference corresponding to the

This article has been accepted for publication in IEEE Transactions on Transportation Electrification. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TTE.2023.3299988

fundamental freuqncy only. Therefore, the PR controller is required in the feedback control loop for multi-frequency control considering the double-line frequency and fourth line frequency compensation.

The proposed control loop in Fig.11 is the amalgamation of PFC-stage controller and PD controller offering multifrequency compensation with an additional duty-based feedforward control. The top part of the control structure is the PFC stage consisting of a PI-based outer voltage control loop followed by co-ordinate transformation and a PI-based inner-current control loop in a stationary frame. The bottom part of the control structure consists of the PR-based multifrequency control in the rotating synchronous frame and duty-based feedforward control in the inner current control loop. The top and bottom controller structure is employed as an independent parallel control loop with the same bandwidth response for the inner current control loop.

The PFC stage controller responsible for the regulation of dc-link voltage. The dc voltage error fed to PI controller of the outer voltage control loop providing the equivalent dc current. After the co-ordinate transformation, the ac grid current error passed through the PI controller of the inner current control loop to generate reference duty cycle for the switches.

$$G_{PI}(s) = K_p + \frac{K_i}{s} \tag{22}$$

The design of the PFC-stage controller must be in accordance with the HSC-PD controller to achieve the optimized performance of the system. The proposed active power decoupling control technique is intended to reduce the equivalent capacitance. However, the value of capacitance and ripple in the voltage are correlated. Reduction in dc capacitance leads to an increase in the voltage fluctuation at the dc-bus. It is crucial during the transients under load change and change in input power. Therefore, the outer voltage loop of PFC is required to have a higher bandwidth compared to the conventional PFC scheme to regulate dc-link voltage faster through current reference. Considering the above-mentioned issue and criteria, the cut-off frequency of the inner current loop is chosen to be $f_{c_inner} = \frac{f_{sw}}{10}$ and the cut-off frequency of the outer voltage loop is chosen to be at least 2 times of grid frequency $f_{c_outer} \geq f_{grid} * 2$. In [17] and [18] the outer voltage loop cut-off frequency is between 200-300Hz, and higher capacitance values are used. The lower capacitance values used in this paper and the outer voltage control loop is designed with slightly higher bandwidth to accommodate that effect. The frequency response using the bode plot is demonstrated in Fig. 12 for the PFC controller including both the voltage control loop as well as the current control loop. As mentioned above, the cut-off frequency for the outer voltage control loop is $f_{c_outer} = 370Hz$ with 90^0 phase margins. The inner current control loop is designed with cut-off frequency of 7 kHz and 75^0 phase margins.

The multi-frequency decoupling control is implemented with unequal dc offset for the designed HSC-PD circuit having an unequal capacitor. PR controller had been the choice of controller for the multi-frequency control as it possesses the infinite gain at the desired frequency that provides the zero steady-state error. The PR controller transfer function is given by (23) with a damping constant near the resonance frequency for system stability. PR-controller is used to compensate for the multi-frequency harmonic components specially double-line and four-line frequency components in the capacitor voltage. The multi-even-harmonic component is generated using current reference for the inductor in PD circuit.

$$G_{PR}(s) = K_p + \frac{2 \cdot K_r \cdot \omega_c \cdot s}{s^2 + 2 \cdot s \cdot \omega_c + \omega_0^2} \tag{23}$$

Nevertheless, the implementation of the PR controller in the digital environment is an issue because of the programming complexity for a real experimental system. The implementation of the PR controllers on the digital processor requires dicretization and two times delay corresponding to the discretization of the transfer function. The PR-controller is implemented using the second-order generalized integrator (SOGI) in the digital environment [30] possesses complex

This article has been accepted for publication in IEEE Transactions on Transportation Electrification. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TTE.2023.3299988

structure and delay. The discretization method significantly impacts the Stability and performance of the PR controller [31]. Therefore, needed a special attention to avoid instability by restraining the actual performace of PR. The frequency response is comparatively not good compared to the integral control action of the PI-controller.

In this paper, the co-ordinate transformation $\alpha\beta/dq$ is proposed in Fig.11 to change n-order-line-frequency (n=2,4,6,..) to DC signal for the implementation of the PR controller. The integral control action is employed to generate equivalent d-axis and q-axis signals and further pass through dq/αβ transformation with infinite DC gain instead of limit gain in [28]. The implementation of the integral control action is simpler and ultimately results in the reduced DSP memory utilization and calculation weights, consequently, making it cost-effective as digital processor cost depends on memory and computing capability. The unbalanced $\alpha\beta/dq$ transformation [32] is used instead of conventional $\alpha\beta/dq$ transformation for easier implementation. The conventional $\alpha\beta/dq$ need 90° delay to α input signal to generate β axis signal through OGM - Orthogonal (imaginary) term generation method. The difference is unbalanced $\alpha\beta/dq$ transformation has a half gain and a negative term that have no significance.

The outer voltage loop of HSC-PD should have to be designed with larger bandwidth as compared to PFC stage outer voltage loop. The outer voltage loop bandwidth of the HSC-PD circuit has a dominant effect on the system performance. The smaller bandwidth compared to the PFC stage lead to a very high voltage overshoot at dc-link. Furthermore, the bandwidth similar to the PFC stage has a better response considering overshoot at dc-link, however, leads to an oscillation in dc voltage and grid current. This ultimately results in the system unstability. Therefore, the larger outer voltage

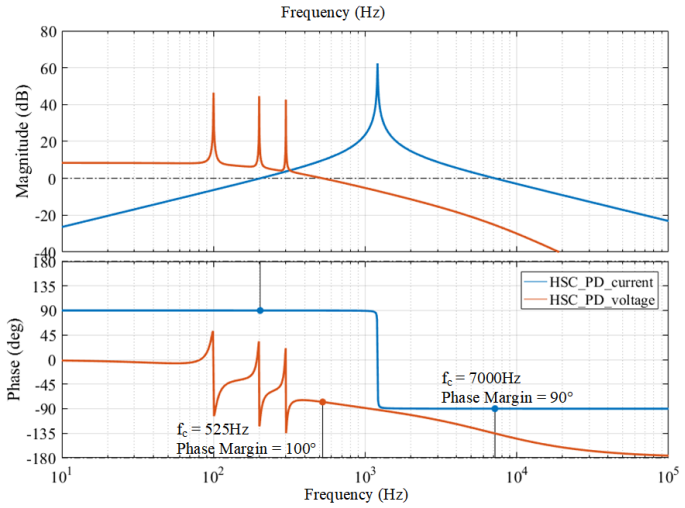

Fig. 13. Frequency response of HSC-PD circuit.

loop bandwidth of the HSC-PD circuit is desirable to achieve a faster response with a minimized overshoot at dc-link voltage. The inner current loop of HSC-PD should have a cut-off frequency at $f_{c_inner} = \frac{f_{sw}}{10}$ and resonant gain should be tuned to have lower response than the PFC stage but still get enough gain to attenuate ripple on DC-Link. The frequency response of HSC-PD circuit in Fig.13 is investigated using bode-plot for current control loop as well as voltage control loop. The current control loop has a cut-off frequency of 7000Hz and 90^0 phase margins. The voltage control loop has three resonant frequencies to compensate the double-line (100Hz), fourth line (200Hz) and sixth (300Hz) frequency harmonics with cut off frequency of 525Hz and 100^0 phase margins. The higher cut-off frequency of outer voltage. Finally, the overall comparison

of the proposed HSC-PD with other counterparts is shown in Table I.

IV. Experimental Results

The experimental results of the 7.4kW interleaved totem-pole PFC with HSC-PD in Fig.14 are demonstrated in this section to verify the above analysis and System design parameters summarized in Table II. The grid current, grid voltage, dc-link voltage, and decoupling inductor current at full load condition are shown in Fig. 15(a). Grid current and voltage are controlled in-phase with measured power factor of 0.9986. THD of the grid current is low of 3.6% due to interleaved approach even though each inductor current has a significantly higher THD of 5%, as shown in Fig. 15(b).

1) Decoupling capacitor and inductor performance

The decoupling capacitor voltages measured at half and full loads are shown in Fig. 16. The voltages across decoupling capacitor are fluctuating with the same frequency but 180° phase-shift. Dc-offset votlages of the bottom and top capacitors are set to 25% and 75% of the V_{Link}, resepctively, resulting in m = 0.25. DC-link voltage is flat with low ripple of 12.6V at full load meaning that the PD circuit functions well with low

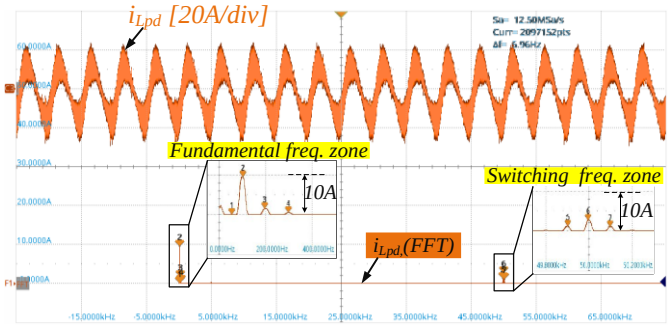

Fig. 17. Decoupling inductor current and its FFT analysis.

dc-link capacitance, and the 2nd harmonic is almost cancelled in both cases 50% and 100% of load. The ac components of the decoupling capacitors voltage at 50% of load has lower magnetude than that of the 100% of load.

The FFT analysis of the decoupling inductor current is shown in Fig. 17. There are two different harmonics zones; the fundermantal frequency zone around 50Hz, and the other harmonic zone is at around swtiching frequency of 50kHz. It can be seen from Fig. 17 that, the amplitude of 2nd harmonic is dominant over other components, verified the theoretical analysis, as shown in Fig. 4.

A step load changes from half to full load is shown in Fig. 18. In general, the transient of HSC-PD capacitors and inductor is smooth. The dc-link voltage drops within a short period of time at the transient because it is regulated by conventional dual-loop controller of the totem-pole PFC circuit without any effort to support the fast transient in addition to low equivalent dc-link capacitance and non-ideal grid in our facility. However, it worth to mention that fast dynamic response is not typically a critical requirement in OBC application since the battery voltage or battery current changes very gradually over an extended charging period. Therefore, the design in this paper does not specifically target this performance aspect.

The method based on conventional PR-controller in [15] and the proposed methods are both implemented on a DSP TMS320F28377D microprocessor, and the experimental comparison of the computation times for the two methods is shown in Fig.19. The results clearly highlight the computational efficiency of the proposed method, which outperforms the conventional approach with a faster calculation time of 389ns.

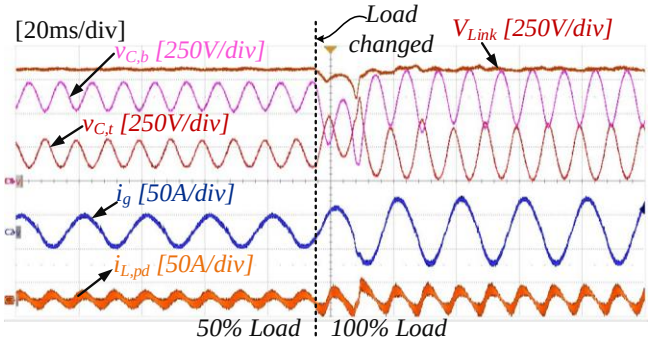

Fig. 18. Transient response of the step load changed from 50% to 100% of load.

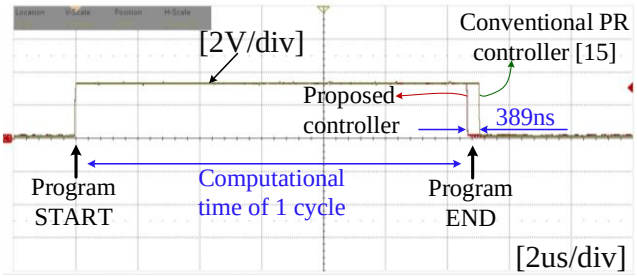

Fig. 19. Computation times for the practical implementation of both the conventional and proposed methods on a DSP TMS320F28377D.

2) Comparisons between the proposed HSC-PD and conventional E-cap method

The measured efficiency of the conventional totem pole PFC with E-cap and the proposed abroad with HSC-PD is shown in Fig. 20, full-load efficiency drops about 0.5% with PD due to additional losses of the HSC-PD circuit. The dropped efficiency is more significant under light load condition because the additional switching loss and core loss of the HSC-PD circuit are more dominant other conduction losses. It is however worth to mention that, in OBC applications the

This article has been accepted for publication in IEEE Transactions on Transportation Electrification. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TTE.2023.3299988

TABLE III
SELECTED DEVICES FOR HSC-PD AND CONVENTIONAL E-CAP METHOD

Component	HSC-PD	E-cap
Capacitor	23x BLH505K901A062	148x 450BXW68MEFR18X25
Switch	2x NTHL040N120SC1	
Gate driver IC Power supply	2x UCC5320SCD 2x PDS2-S12-S24-M-TR	
Core	1x CH400060	

converter operates under heavy load most of the time during one charging cycle.

The loss distribution of the converter at the full load is shown in Fig. 21. Due to hard-switching condition, switching loss of main switches of the interleaved totem-pole PFC is the most dominant loss. The HSC-PD contributes 20.5% to the total loss of the converter at full-load condition. Within the HSC-PD, the switching loss and inductor core loss dominant over the conduction loss due to low current rating of the decoupling circuit.

Furthermore, with the selected components are presented in Table III, total cost and volume of the proposed HSC-PD are 1.9 and 2.2 times lower than that of the conventional E-cap method, respectively, as demonstrated in Fig. 22. Therefore, while acknowledging a marginal reduction in efficiency, the substantial cost and volume savings, complemented by improved reliability, underscore the advantageous trade-off of our proposed HSC-PD approach. This underlines the HSC-PD's potential as a viable alternative to traditional methods, paving the way for more compact and cost-effective OBC.

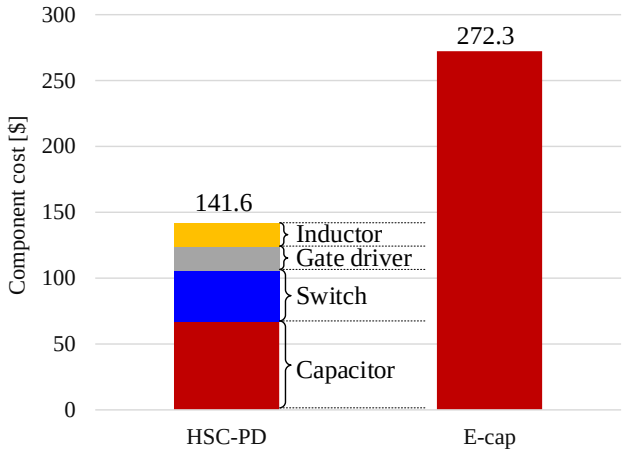

Fig. 22. Cost and volume comparison between the proposed HSC-PD and E-cap: (a) cost; (b) volume. (Cost is based on digikey.com accessed Jan. 2023)

3) Inrush current and precharge resistor

In OBC application, precharge circuit, which typically consits of one relay and one precharge resistor, is usually used at the input side to limit the inrush current when the OBC is connected to the grid, as seen in Fig. 23(a). The equivalent circuit of the converter when OBC is connected to the grid without and with precharge resistor is shown in Fig. 23(b) and Fig. 23(c), respectively. Assumming grid voltage is fixed, the rating of precharge resistor is mostly based on dc-link capacitance so that the higher dc-link capacitance the higher power needed of the precharge resistor. Therefore, in case of

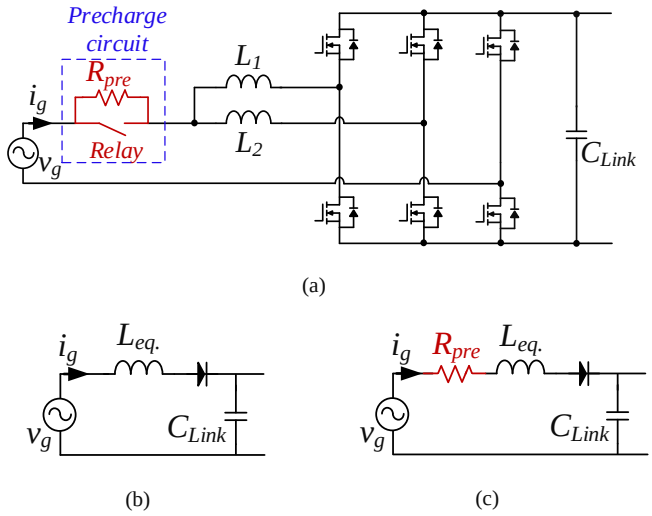

Fig. 23. Precharge circuit and equivalent circuit of AC/DC converter during start-up: (a) interleaved totem-pole PFC with precharge circuit; (b) equivalent PFC circuit during start-up without precharge resistor; (c) equivalent PFC circuit during start-up with precharge resistor.

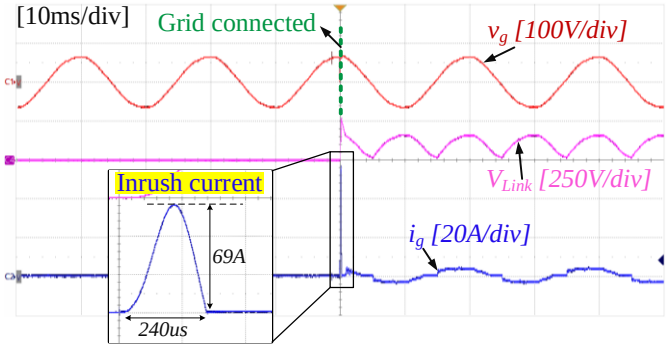

Fig. 24. Experimental waveforms of the inrush current when connecting the HSC-PD based PFC circuit with low dc-link capacitance to the grid without precharge resistor.

This article has been accepted for publication in IEEE Transactions on Transportation Electrification. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TTE.2023.3299988

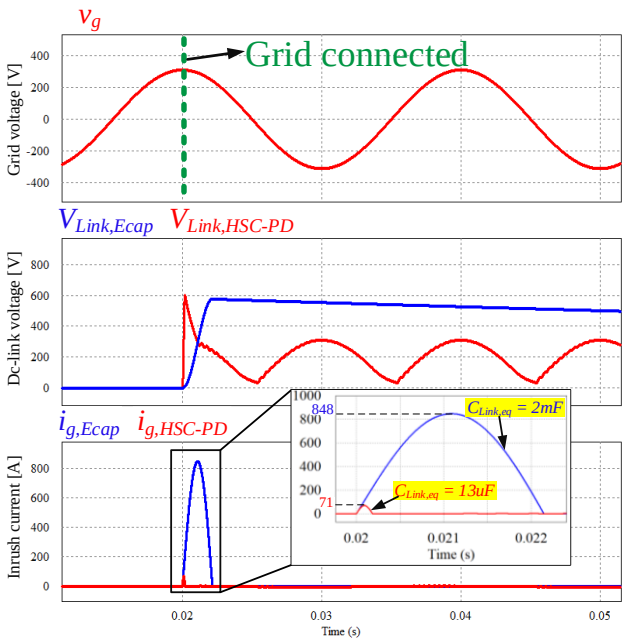

Fig. 25. Inrush currents comparison between conventional PFC with large E-cap and proposed HSC-PD based PFC with low capacitance F-cap.

using PD circuit, the precharge resistor can be significantly reduced compared to that of the conventional rectifier with large E-cap, reducing volume and cost.

Fig. 24 shows the input inrush current of the totempole PFC using HSC-PD circuit. The inrush current is within the acceptable magnetute and short interval due to small dc-link capacitance. The experiment with conventional totempole using large dc-link capaciance with E-cap could not be performed without prechage circuit due to safety issue. However, the simulation results of the inrush current in two cases are shown in Fig. 25. It can be seen that the conventional rectifier with large dc-link capacitor has significantly larger inrush current compared to that of the proposed converter.

VI. Conclusions

In this paper, a new method for designing and controlling a Half-bridge Split Capacitor based Power Decoupling circuit (HSC-PD) is presented with the dominant of bottom capacitor over the top one. The proposed design approach is demonstrated to have the following addvantage over the previous works:

1) Smaller capacitance value of each decoupling capacitors
2) Smaller equivalent dc-link capcitance
3) Reducing the required ac voltage rating of the film capacitor, which is critical in high voltage applications such as 800V OBC due to the low availability and costly of the high ac voltage rating film capacitor.
4) Smaller decoupling inductor current

Moreover, the small signal model of the HSC-PD is presented, and the modified the feedback control of the HSC-PD is proposed based on the co-ordinate transformation αβ/dq, which reduces the memory utilization and calculation effort of the DSP microcontroller compared to the conventional PR implementation. In addition, the effect of dc-link capacitance to precharge resistor power rating is investigated, showing the additional advantage of proposed method. Finally, experimental results of the 7.4kW 820V interleaved totem-pole PFC with HSC-PD are given to demonstrate the superiorities of the proposed method.

While our proposed HSC-PD scheme presents several significant advantages, it does come with its own unique set of challenges. These include a marginal decrease in efficiency due to the incorporation of additional circuit elements, increased complexity in PCB and control design, potential limitations for applications requiring prolonged hold-up times due to low dc-link capacitance value, and meticulous selection requirements for capacitors, especially considering their current rating due to low capacitance of the top capacitor. These issues offer ample opportunities for further refinement and optimization in future research.

This work was supported in part by the European Union's Horizon 2020 Research and Innovation Program through the Marie Skłodowska-Curie Innovative Training Networks (ITN) (TESLA) under Grant 811232; and in part by the Minsiterio de Ciencia e Innovación (MICIN), Spanish Government, through the Research and Development Project under Grant PID2019-103982RB-C41 (funded by MICIN/AEI/10.13039/501100011033).

ABSTRACT This article describes the use of dielectric rods to reconfigure combline filters both with respect to center frequency and bandwidth. In this context, a new filter topology is developed in order to maximize the achievable reconfiguration range. The design of a prototype is discussed in detail, clearly demonstrating the feasibility of center frequency and bandwidth reconfiguration, with the same filter structure, while maintaining an equiripple return loss. In addition to theory, a combline filter prototype is also fabricated, tuned and measured in several configurations showing excellent agreement with simulations, thereby fully validating both the basic concept and the design procedure.

INDEX TERMS Band-pass filter, combline filters, dielectric tuners, reconfigurability, tunable filters.

I. INTRODUCTION

The current evolution trend in communication equipment requirements, for both ground and space applications, is towards an ever increasing use of bandwidth. However, the total available bandwidth is limited, so that the frequency spectrum that is allocated to each application is now fully regulated at world wide level [1]. To meet this challenge, modern communication systems are currently being developed with the ability of providing multi-channel communication systems, where each channel uses different center frequency and bandwidth [2].

In this context therefore, the possibility of developing microwave components, and filters in particular, that are agile in frequency has recently become a very important area of research [3], [4], [5]. Filters (and multiplexers) have always been considered key components for the front-end of communication equipment for both ground and space applications [6]. As a consequence, a very significant research effort has been devoted in the last decade to the development of filters and multiplexers that can be reconfigured both in terms of center frequency and bandwidth [7], [8].

The simplest approach to change the center frequency of a filter structure based on coupled cavities, is to change the size of the cavities. A number of different approaches that explore this possibility have indeed been reported in the technical literature. For instance, a compressible bellow or a conductive elastomer lid on the top of two dual-mode cavities has been demonstrated in [9]. A different concept has also been proposed in [10] discussing a contact-less corrugated plunger. Furthermore, one more approach is presented in [11], where the cavity size is changed by activating or deactivating an array of conductive lines located on the cavity wall. An additional approach has also been introduced in [12], for the reconfiguration of both center frequency and bandwidth by moving, at the same time, both end walls of a cylindrical cavity. Two more contributions can also be found in the technical literature, where the filter tunability is obtained by rotating a specially designed piece of dielectric material that is located inside the resonant cavities of the filter [13], [14].

Furthermore, in [15] a copper coated polyflon sheet is used to cover the top of a metallic cavity, and a piezoelectric

actuator is used to modify the cavity dimensions. Another approach is described in [16], where tuning disks are actuated using thermal MEMS. Several papers have also discussed capacitive coupling between resonator and tuning discs or posts. In [17] and [18], for instance, a floating capacitance between the disk and the post is modified using a MEMS-based capacitance or a varactor. One more approach is described in [19] where GaAs and MEMS capacitors are proposed. In [20], another tuning solution is adopted, namely, a varactor diode connected to the open end of a coaxial post resonator.

Another very common approach to tune filters based on waveguide cavities is to use metallic tuning elements or screws. This approach has been demonstrated with directly-coupled rectangular waveguide filters [21], and dual-mode filters [22]. Classical combline filter topologies can also be tuned with metallic screws, as it is shown in [23] and [24]. More recently, metal screws have also been used within re-entrant coaxial resonators, for tuning the frequency response while keeping the bandwidth constant [25]. However, the use of metallic tuning elements (or screws) for remotely reconfigurable filter implementations, can introduce a number of complications, namely:

- The tuning element or screw must be securely fastened to the filter body in order to operate correctly.
- The penetration of the tuning screw must be controlled very accurately to ensure the correct filter performance.
- The presence of metallic tuning elements may have a negative effect on the high power and passive intermodulation (PIM) performance of the filter.

Alternative solutions, based on the use of a single rotating mechanism driving all metal tuning elements, have been recently developed for E-plane filters [26], and coaxial filters [27]. These solutions have a simplified mechanical assembly, and also allow to keep a constant bandwidth in the achievable frequency tuning ranges. This is achieved using a clever design for the coupling elements of the filter. However, these new topologies can only produce filters with fixed bandwidth (approximately 2%), with a return loss of 15 dB.

In addition to metallic tuners, however, dielectric tuners have also been used more recently to tune microwave filters. In [28] and [29], their potential use for tuning standard rectangular waveguide filters is validated through full-wave simulations and measurements. A very recent work on the practical demonstration of dielectric tuners in inductive waveguide filters is discussed in [30]. It is important to note, at this point, that the results discussed in [30] are only applicable to rectangular waveguide filters based on *distributed* resonators. The present work, in contrast, intends to demonstrates the use of dielectric tuners in combline filters, where the resonators can essentially be considered as *lumped-element* resonators. In the context of combline filters, dielectric tuners were first used within resonators, in [31] and [32], for implementing tunable filters in terms of center frequency only (keeping constant the filter bandwidth). Additional initial results for the same tunable responses (only in terms of center frequency) have also been discussed in [33], where dielectric tuners are used in coupling windows to preserve the same filter bandwidth.

In this context, therefore, the objective of this paper is to significantly extend the initial results presented in [33]. The additional novel material discussed in this paper is as follows:

- In addition to Alumina, we also study the use of Zirconia, and we compare the key performance of the two dielectric materials.
- A new filter structure is then designed to take advantage of the superior performance of Zirconia.
- Furthermore, we show that both simulation and measurements indicate that Zirconia has a good quality factor, that is comparable to other established topologies using either metallic or dielectric tuners.
- In addition to changing the center frequency, we show how the same structure can also be used to change the bandwidth of the filter. In particular, we show that the combline filter can be reconfigured to maintain a constant absolute bandwidth throughout the frequency tuning range. Alternatively, the bandwidth of the filter can be increased up to twice the initial value.
- We show that the relation between the variation of the penetration of the tuning elements and the filter center frequency remains approximately linear. As a consequence, the prediction of the filter center frequency is greatly simplified.
- We discuss how the use of dielectric tuners eliminates the need for keeping a very good electrical contact with the body of the filter, thereby eliminating a common source of insertion loss and PIM.
- In addition to simulations, we also show the measured results of a prototype built using Zirconia, and we demonstrate successfully how the same filter structure can be reconfigured both in terms of center frequency and bandwidth.
- Furthermore, we show how the out of band performance of tunable filter can be improved with the integration of a simple lowpass filter. In this context, we also discuss the achievable improvements and limitations of this approach.
- In addition, we also study the high power behavior of our tunable filter, and discuss the possible trade-offs between power handling and tuning range.
- Finally, we discuss how the structure we propose opens the possibility of using low-accuracy, computer-controlled actuators to implement remotely controlled reconfiguration of the filter.

This article is organized as follows: In section II, the design of a frequency-tunable filter using dielectric rods made of Alumina is discussed in detail. We then discuss in section III the use of Zirconia as an alternative dielectric material, and derive a new set of initial filter dimensions. After that, we discuss in section IV the complete design of a filter that can be tuned both in terms of frequency and bandwidth.

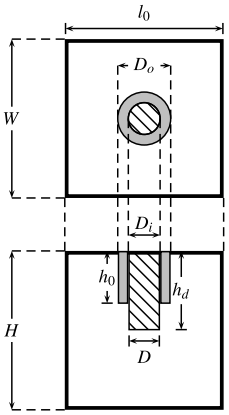

FIGURE 1. Cavity configuration where the dielectric tuner is inserted in the hollow post (top view and side view [33]).

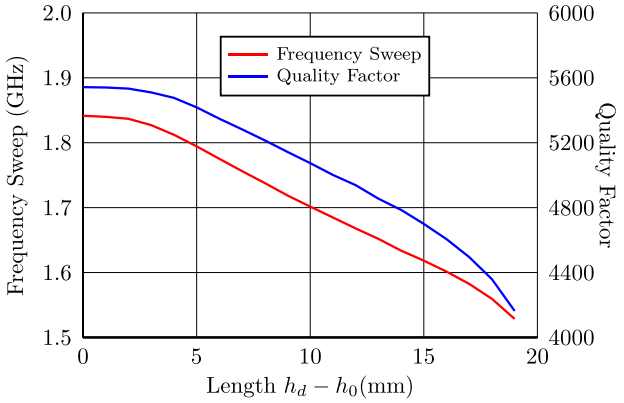

FIGURE 2. Frequency tuning range (left side scale) and Q_u factor (right side scale) provided by the structure in Fig. 1 as a function of the length of the dielectric rod exceeding the hollow post ($h_d - h_0$).

The details in the manufacturing process and the measured results are shown in sections V. In Section VI we discuss how the out-of-band response of the reconfigurable filter can be controlled. In Section VII we study the multipactor behavior of our filter. Section VIII describes the remote operation of the reconfigurable filter prototype. Finally, Section IX concludes the paper with a summary of the results achieved.

II. FREQUENCY-TUNABLE FILTER WITH ALUMINA DIELECTRIC TUNERS

In this section, we briefly recall, for the sake of completeness, the design of the frequency tunable filter based on Alumina tuners already discussed in [33], providing, at the same time, new information concerning the dimensions of the structure, and the evaluation of losses and Q-factors.

A. RESONATOR DESIGN CONSIDERATIONS

The resonators are the basic elements of any coupled cavity filter. It is common practice to initiate the design procedure by optimizing the structure of the resonator to operate in the desired resonant mode and frequency range. The selection of the adequate resonator topology is indeed a fundamental step because it has a strong effect on the unloaded quality factor (Q_u), filter size, cost, and power handling capability of the complete filter.

Different cavity configurations for the resonators have been studied in [33], and the most suitable design has been chosen (see Fig. 1). Once the basic shape of the resonator has been defined, metallic screws are normally placed in the vicinity of the open-ended post to create a variable capacitance to tune the resonance at the desired frequency.

There are, however, several issues associated with the use of metallic tuning screws. Namely, the metallic screws must be securely fastened to the body of the filter. As a consequence, remote tuning becomes problematic. Additionally, even if a remote tuning mechanism could be developed, the structure would be extremely sensitive to the position of the metallic tuning screw, so that a practical (low-cost) solution for an actuator-controlled remote tuning would be very difficult to implement. Finally, metallic tuning screws can also introduce significant losses in the filter structure if repeated tuning is required. In our basic resonator, we have therefore replaced the traditional metal screws with dielectric tuners.

Additionally, as we can see in Fig. 1, a hollow metallic post has been chosen instead a solid one [32]. This has been done because a hollow post provides a support for the movement of the dielectric tuning element. Another reason for choosing this configuration is the almost-linear variation of the frequency with the tuner penetration. Using this configuration, we can, in fact, obtain the desired starting value of the resonant frequency using the metallic post, and we can then have an extended tuning range inserting a dielectric rod inside the cavity using the hollow post as a support.

The dimensional parameters of the basic resonator in Fig. 1 are: $l_0 = H = 50\,\text{mm}$ and $W = 40\,\text{mm}$. The outer and inner diameters of the hollow post are $D_o = 16\,\text{mm}$ and $D_i = 12\,\text{mm}$, respectively. The height of the hollow post is $h_0 = 32.290\,\text{mm}$. h_d is the height of the dielectric tuner, the diameter of which is $D = 11.8\,\text{mm}$ (slightly less than D_i).

Fig. 2 shows the variation in center frequency with the tuner penetration. The linear pattern is clearly evident. Fig. 2 shows also the unloaded quality factor Q_u as a function of the dielectric post penetration. The values for the Q_u are quite high ranging from 4200 for deep penetrations up to near 5600 for penetrations not exceeding the hollow post h_0. It is interesting to note that the equivalent structure with a metallic tuner has a quality factor of 2758 at the lowest frequency compared with the Q value of 4200 using the dielectric tuner. Furthermore, we have verified that, with the resonator we have designed, we can indeed tune the resonance in the entire frequency range of interest.

B. DESIGN CONSIDERATIONS OF INPUT AND OUTPUT COUPLING

In the context of tunable filters, it is very crucial to maintain the correct input/output coupling throughout the frequency tuning range in order to maintain constant bandwidth and

return loss levels. The Q_{ext} value is computed from the desired filter center frequency (f_0) and bandwidth (BW) using the following classical expression [6]:

$$Q_{\text{ext}} = \frac{f_0}{M_{S1}^2 BW} \tag{1}$$

where M_{S1} is the coupling matrix element corresponding to the input coupling of the filter.

From equation (1), we can now deduce the following:

1) For lower f_0 and constant BW a higher input coupling is required. Therefore, lower frequencies are more challenging for tunable filters.
2) For wider BW a lower Q_{ext} (higher input coupling) is also required. Therefore wider BW are more challenging for tunable filters.

As initially discussed in [33], we propose to use the structure shown in Fig. 3, where the resonator post and the input coupling post are attached to opposite walls. This geometrical configuration allows for a stronger electric coupling, thus providing the required coupling strength. The input coupling post shares the same mechanism as the tunable resonator: a dielectric rod is inserted inside the hollow post. This arrangement does indeed provide a variable capacitive coupling that depends on the penetration of the dielectric rod.

The dimensions of the structure in Fig. 3 have been chosen to be consistent with the dimensions of the basic resonator, namely, $l_0 = H = 50\,\text{mm}$ and $W = 40\,\text{mm}$, where the height of the hollow resonator and the coupling structure are $h_0 = 26.172\,\text{mm}$ and $h_i = 26.82\,\text{mm}$, respectively. The input coaxial feed is located at $h_c = 19.140\,\text{mm}$. The value of h_i is optimized to obtain the input coupling value that is required at the highest frequency, when the dielectric rod is fully inserted in the metallic post (Fig. 3). The inner conductor of the coaxial input is connected to the first metallic post at a height $h_c = 19.140\,\text{mm}$ which is 7.68 mm shorter than h_i. This has been done in order to ensure the proper mechanical robustness of the input structure. The outer diameter of the input/output metallic post is set at $d_0 = 8\,\text{mm}$. The inner diameter is $d_i = 6\,\text{mm}$ and the rod inserted inside has a diameter of 5.95 mm. A gap s equal to 2.0 mm has been left between the input post and the resonator post. The lowest coupling value is obtained when the dielectric rod is totally confined inside the metallic hollow post having height $h_{\text{id1}} = 25\,\text{mm}$.

A key point to be emphasized at this stage is that the input coupling in our combline cavity loads significantly the first resonator. This leads to a reduction in the height of the resonator post (please note that $h_0 = 26.172\,\text{mm}$ in Fig. 3, whereas $h_0 = 32.290\,\text{mm}$ in Fig. 1). This, in turn, allows for an enhanced range in the frequency tuning of the input resonator.

Fig. 4 shows the experiment carried out using the structure in Fig. 3. From this result, we can now see that, using (1), the Q_{ext} value required to maintain the $RL = 25\,\text{dB}$ at 1.842 GHz is around 18.5 while at 1.542 GHz (for $BW = 75\,\text{MHz}$), the Q_{ext} value required is 15.5. Fig. 4 confirms that our structure can provide the required coupling values in the frequency range of interest. Moreover, the variation of Q_{ext} slightly degrades the quality factor of the cavity (from 4280 to 3922), as also shown in Fig. 4.

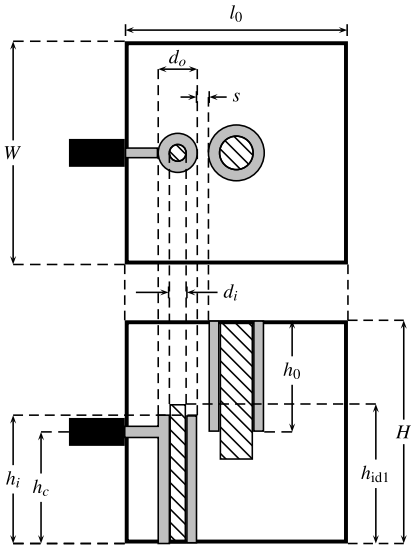

FIGURE 3. Input cavity configuration with the most significant geometrical parameters.

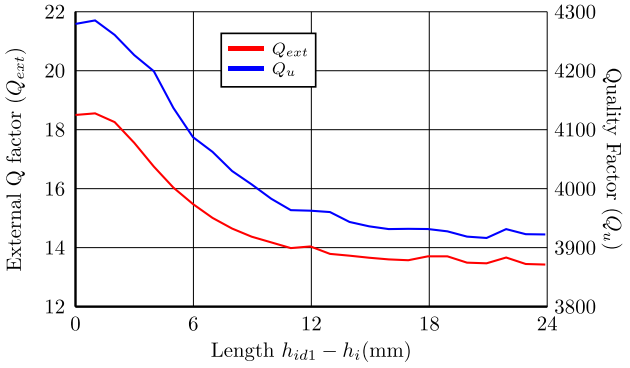

FIGURE 4. Q_{ext} (left side scale) and Q_u (right side scale) variation of the proposed solution. The x-axis shows the length of the dielectric rod exceeding the hollow post ($h_{\text{id1}} - h_i$).

An additional interesting point is that our simulations indicate that inserting the dielectric rod in the input coupling post lowers the resonant frequency of the cavity (it has been observed that it changes from 1.813 GHz for $h_{\text{id1}} - h_i = 0\,\text{mm}$ to 1.746 GHz for $h_{\text{id1}} - h_i = 24\,\text{mm}$). This is indeed a clear indication that confirms the capacitive nature of the input coupling.

C. DESIGN CONSIDERATIONS OF INTER-RESONATOR COUPLING

Generally speaking, a very common solution to implement the inter resonator coupling in combline filters is to use coupling windows (see for instance [34]). Metallic or dielectric tuning elements (or screws) are then located inside the coupling windows (2mm thick) to tune the coupling to the desired value (see the red inset in Fig. 5). However, our study

shows that using coupling windows and tuning elements is not adequate for the application under investigation. The reason is that the coupling value variations that can be achieved are insufficient for our application.

The solution that we propose in this paper consists of using a short hollow metallic post having an outer diameter of $d_0 = 8\,\text{mm}$, and an inner diameter of $d_i = 6\,\text{mm}$, with a dielectric tuner (of diameter 5.95 mm) inside, located on the wall opposite to the resonator post, in the middle between resonators (see the blue inset in Fig. 5). The rest of the dimensional variables (for the cavity resonator and dielectric tuner) are kept the same as the ones given in section II-A. The results in Fig. 5 show the coupling range obtained by full-wave simulation. The extraction of the coupling values has been carried out with two resonators weakly coupled to the input/output ports and strongly coupled to each other, as described in [6]. Another advantage of this solution is that the initial coupling value is then established with the height of the hollow metallic post $h_c = 11\,\text{mm}$. Another feature of this solution is that without a coupling window, the dielectric rod has more room to penetrate in the filter cavity, thus implementing a stronger coupling between resonators, as well as a wider range of coupling values. This is indeed confirmed by a comparison of the results shown in Fig. 5.

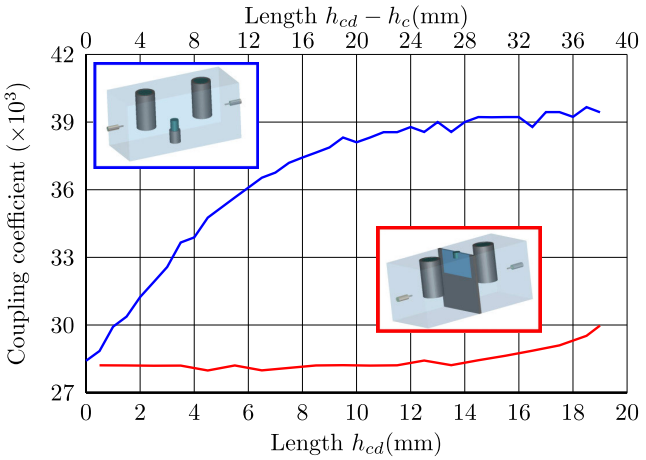

FIGURE 5. Inter-resonator coupling using a metallic post without a coupling window (upper side scale). The length of the hollow post holding the tuner is $h_c = 11$ mm. Length h_{cd} is the height of the dielectric tuner. Inter-resonator coupling using an iris with a dielectric tuning screw (lower side scale). h_{cd} is the height of the dielectric tuner. Blue line: response of coupling using a dielectric post. Red line: response of coupling using an iris.

D. COMPLETE FILTER GEOMETRY

The results that have been shown so far can effectively be used to establish the initial dimension of our filter structure.

The filter transfer function we want to implement is a fourth-order Chebyshev function. The desired specifications are as follows:

- Center frequency must be tunable from $f_{0,\min} = 1.542\,\text{GHz}$ up to $f_{0,\max} = 1.842\,\text{GHz}$.
- Bandwidth $BW = 75\,\text{MHz}$ constant throughout the whole range of frequencies.
- Return loss: $RL > 25\,\text{dB}$.

and must be achieved while maintaining a constant bandwidth and return loss performance. This means that the filter tuning range, as defined in [35], [36], and [37], for instance, is:

$$\frac{f_{0,\max} - f_{0,\min}}{f_C} \times 100 \approx 18\% \tag{2}$$

where f_C is given by:

$$\frac{f_{0,\max} + f_{0,\min}}{2} = 1.692\,GHz \tag{3}$$

and the relative bandwidth at f_C is $\approx$ 4.4%. Which means that the filter must be tuned over a frequency range that is approximately equal to four times the bandwidth (that is $\approx$ 400% in terms of BW).

It is now interesting to note that, if we use the tunability range definition proposed in [5] and [22], we obtain directly:

$$\frac{f_{0,\max} - f_{0,\min}}{BW} \times 100 \approx 400\% \tag{4}$$

It is important to note that our definition of tunability does not intend to define the quality of a filter. The objective of the definition is simply to measure the tuning range in terms of the number of bandwidths. This second definition is, therefore, the one we will use in the reminder of this paper since we believe that it is more appropriate for tunable filters with constant bandwidth.

The procedure we have followed to actually design the filter is based on the group delay computation described in [6]. A lumped element model is used to obtain the reference values for the different stages. The dimensions of the real structure are obtained through optimization in a stage-by-stage procedure using CST Studio Suite (v.2022, Dassault Systémes) [38] in low precision (and without considering mechanization effects). The precision has been controlled by adjusting the computational variables, namely, the threshold of the convergence criteria, the number of passes/checks and the number of cells per max model box. Finally, with the space mapping technique described in [39], the final dimensions of the real structure are obtained using CST Studio Suite (v.2022, Dassault Systémes) for the high precision full-wave electromagnetic simulations.

Fig. 6 shows the 2D side view of the structure of the proposed filter. The final prototype consists of a single housing of dimensions $W \times H \times l$, with $W = 40\,\text{mm}$, $H = 50\,\text{mm}$ and $l = 200\,\text{mm}$, being W the width of the waveguide housing (transversal dimension not shown in Fig. 6). The resonators are located at $l_1 = 50\,\text{mm}$ and $l_2 = 50\,\text{mm}$. The height values of the hollow metal supports for the dielectric resonators and coupling structures are $h_1 = h_4 = 26.819\,\text{mm}$, $h_2 = h_3 = 30.651\,\text{mm}$, $h_i = 26.952\,\text{mm}$, $hc_1 = hc_3 = 19.681\,\text{mm}$, $hc_2 = 13.351\,\text{mm}$, respectively. All four hollow metal supports for the resonators have the same outer and inner diameter of $D_o = 16\,\text{mm}$ and $D_i = 12\,\text{mm}$, respectively. The outer diameter of all hollow metal

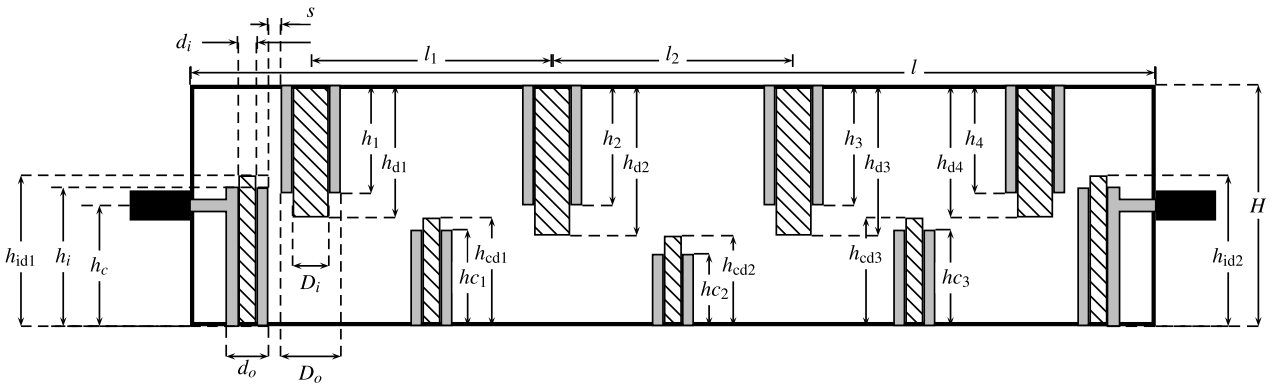

FIGURE 6. Side view of the filter structure. The filter is symmetric and the most relevant dimensions used in the design are shown.

supports for the coupling posts is $d_0 = 8$ mm, and the inner diameter is $d_i = 6$ mm. The gap s has been set to 2.0 mm to facilitate manufacturing. The coaxial connector (of external and internal diameters equal to 4.06 mm and 1.28 mm, respectively, with dielectric constant 2.1) is placed at a height of $h_c = 24.528$ mm for the input/output excitation.

It is important to point out at this stage that the starting values for the resonators, input and output couplings and inter-resonator couplings are simply obtained by optimizing the height of hollow metallic support cylinders, while keeping the dielectric rods inside the support structures. The Alumina dielectric rods, with a dielectric constant of 9.9 and loss tangent of 0.0002, are then pushed out of the hollow support posts in order to tune the filter at a lower center frequency. For this purpose, the diameters of the tuners used in the resonator and coupling structures are 11.8 mm and 5.95 mm, respectively. They are slightly smaller than the inner diameters of the corresponding hollow metal supports.

The two extreme cases for the tuning range have been obtained with the penetrations of the Alumina tuners shown in Table 1. The simulated filter performance for these two cases is shown in Fig. 7. The inset in Fig. 7 shows a detailed view of the insertion losses at the lower and upper end of the tuning range. The structure has been simulated considering the losses due to aluminum for all metal parts, and the losses for the dielectric tuning rods (Alumina). The simulations have been carried out with two different full-wave 3D simulators, namely, HFSS (Ansoft) and CST Studio Suite, in order to validate the accuracy of the results obtained. Moreover, the quality factor has been estimated using the simulation results including all losses.

As we can see, the proposed structure maintains the same filter characteristics for a tuning range of 300 MHz. The insertion loss is better than 0.06 dB when the filter is tuned at $f_{0,\min} = 1542$ MHz, giving an estimated quality factor approximately equal to 5982. When the response is tuned at $f_{0,\max} = 1842$ MHz, on the other hand, the insertion losses are better than 0.05 dB with a quality factor approximately equal to 7430.

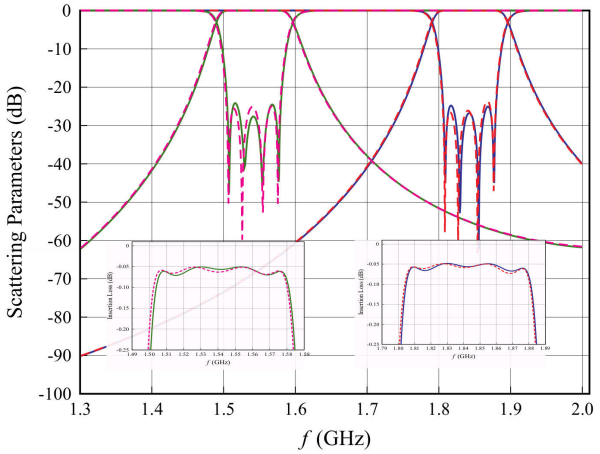

FIGURE 7. Electrical response of the filter for two extreme cases of the tuning range (the upper frequency case requires the lowest penetrations of the tuners and the lower frequency case requires the deepest penetrations). Solid lines: simulation with CST. Dashed lines: simulation with HFSS (Insertion loss response in corresponding inset figure).

III. ZIRCONIA VS ALUMINA TUNERS

In the previous section, we have shown how the structure that we propose can effectively be used to build combline filters that can be tuned in center frequency using tuning rods made of Alumina. In this section we explore the use of an alternative dielectric, namely, Zirconium Dioxide ($Y_2O_3 - ZrO_2$), or simply Zirconia. This material has, in fact, already been proposed for a number of microwave applications.

In [40], for instance, the performance of Zirconia thick films in high Q structures has been studied. Moreover, [41] has carried out comparative studies of Yttrium-stabilized Zirconia and Alumina coatings. Furthermore, the use of Zirconia in wideband filter applications has also been recently shown in [42]. The Zirconia we have use has the dielectric constant $\epsilon_r = 28$, and loss tangent $\tan\delta = 0.001$.

A. RESONATOR RESULTS

Having changed the dielectric material, we need also to redesign the basic resonator. The dimensions of the center

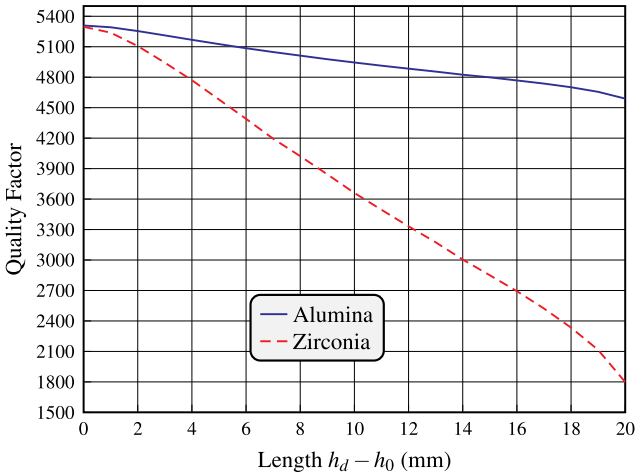

FIGURE 9. Q_u factor in terms of the penetration of the dielectric rod exceeding the hollow post ($h_d - h_0$) according to Fig. 1.

resonator post are calculated following the same procedure already discussed. The resulting cavity dimensions (shown in Fig. 1) are $l_0 = 44.8$ mm, $H = 48$ mm and $W = 35$ mm. The hollow resonator post is set to $h_0 = 27.5$ mm in order to place the initial resonant frequency (the highest one of the new design) at $f_0 = 2.175$ GHz.

One point that is now important is to make sure that the use of a higher dielectric constant does not introduce radiation loss. Radiation could, in fact, occur because the metallic posts loaded with Zirconia are actually sections of circular waveguide. If their cutoff is near the resonant frequency of the cavity, they could effectively extract energy from the filter. The diameter that we have used for the dielectric rod is $D = 9.91$ mm. The hollow post has an inner diameter $D_i = 10$ mm. The resulting cutoff frequency is 3.39 GHz, which is well above the maximum operating frequency of our filter. Another important consideration in this context is that all the hollow posts are located along the center line of the filter. As a consequence, due to symmetry, the excitation of the modes inside the hollow posts is theoretically reduced to zero. The above considerations confirm that the structure we have chosen does not suffer from losses due to radiation.

One advantage introduced by the use of Zirconia is that the tuning range is considerably extended with respect to Alumina, as shown in Fig. 8. However, a significant effect in the unloaded quality factor is observed, as shown in Fig. 9.

B. RESULTS FOR INTER RESONATOR COUPLING

In this new design, we have used a different approach to fix the initial inter-resonator coupling. The correct coupling value has, in fact, been obtained optimizing the distance between the consecutive resonator posts (l_1 and l_2 variables in Fig. 6), rather than the height of the hollow inter-resonator post. However, a hollow metallic post of $= 5$ mm in height has been maintained to provide mechanical support for the dielectric rods. An additional advantage of using Zirconia is that it provides a much stronger (and relatively linear) variation of the coupling coefficient, as compared to the one in Fig. 5. To simplify the manufacturing, the outer and inner diameters of the metallic posts are chosen to be $D_0 = 12$ mm and $D_i = 10$ mm (the same as in the resonators). A distance between two resonator posts of $l_1 = 44$ mm is, in this case, required to obtain the initial coupling coefficient value equal to 0.0185.

Furthermore, a dielectric rod of the diameter $D = 9.91$ mm is inserted inside the hollow post. It is important to note that, for the sake of comparison, we have used for this study the two types of dielectric rods (Zirconia and Alumina) with the same dimensions. The results of this experiment clearly show significantly wider coupling range values with Zirconia, as shown in Fig. 10.

C. RESULTS FOR INPUT/OUTPUT COUPLING

We re-designed next the input coupling structure in Fig. 3. The resulting dimensions are $H = 48$ mm, $l_0 = 44$ mm and $W = 35$ mm. The height of the hollow resonator post and the input coupling structure are $h_0 = 24.2$ mm and $h_i = 22.35$ mm, respectively. The coaxial input probe has been placed at the height $h_c = 21$ mm. The hollow post now

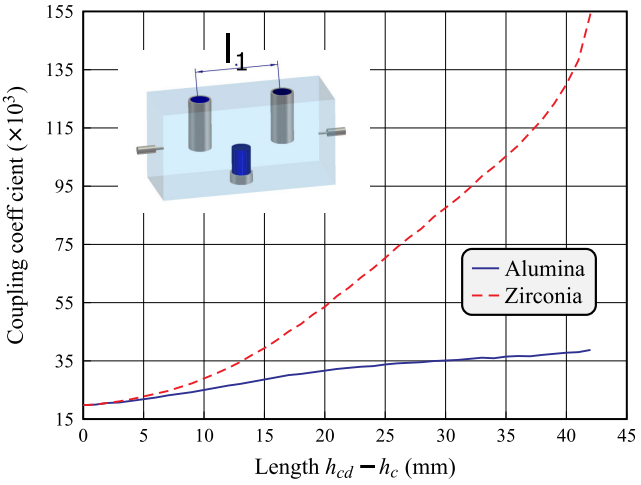

FIGURE 10. Coupling coefficient variation for two possible cases: experiment with Alumina (solid line) and the proposed solution using Zirconia (dashed line). Distance l_1 in the inset has been moved to obtain the initial coupling value at the left of the graph. Both coupling coefficients are plotted versus the penetration of the dielectric tuner exceeding the hollow post ($h_{cd} - h_c$).

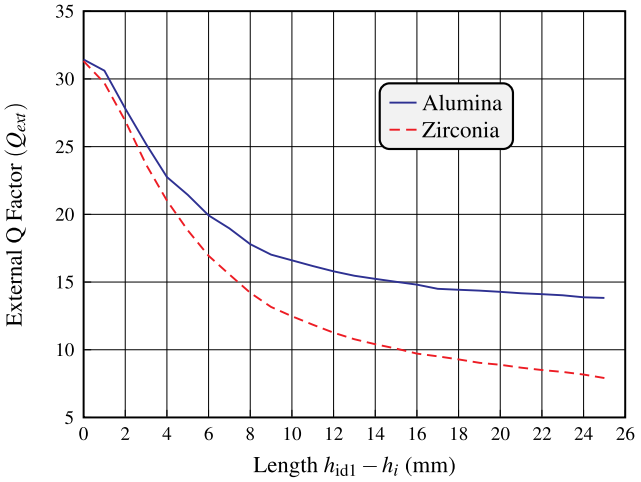

FIGURE 11. Q_{ext} variation for two possible cases: experiment with Alumina (solid line) and the proposed solution inserting Zirconia (dashed line). Both curves are plotted versus the penetration of the dielectric rod exceeding the hollow post ($h_{id1} - h_i$).

has outer and inner diameters equal to $d_o = 12$ mm and $d_i = 10$ mm, respectively. The dielectric rods of Alumina and Zirconia are inserted to explore the variation in the input coupling value. A gap s equal to 2 mm has been left between the coupling post and the resonator post.

In order to start the experiment, the dielectric rod is totally confined inside the metallic hollow post having height equal to $h_{id1} = 22$ mm. The simulations we have performed indicates that the structure provides a $Q_{ext} = 32.8$. This is indeed the value required to design the initial case (highest center frequency of 2.175 GHz and lower bandwidth of 50 MHz). As expected, Zirconia can achieve a significantly wider range of Q_{ext} with respect to the h_{id1}, as shown in Fig. 11.

IV. TUNABLE FILTER IN FREQUENCY AND BANDWIDTH

Using the information obtained with respect to the behavior of Zirconia, we have next re-designed the filter structure using the same procedure already described for the Alumina case in Fig. 6. The novel prototype consists of a single housing (see Fig. 6) of dimensions $W \times H \times l$ with $W = 35$ mm, $H = 48$ mm and $l = 177.8$ mm.

As previously discussed in section III-B, in this case we have optimized the length between consecutive resonators to obtain the initial values for the inter resonator couplings. This leads to the initial values $l_1 = 41.82$ mm and $l_2 = 46.12$ mm. The height of the hollow resonator posts are set to $h_1 = h_4 = 24.45$ mm and $h_2 = h_3 = 26.82$ mm. All inter-resonator coupling hollow posts have equal height of $hc_1 = hc_2 = hc_3 = 5$ mm that also act as the support structures for the dielectric tuners. In order to simplify the structure, all the hollow metallic posts used for either inter resonator couplings and input/output couplings are set to the same outer diameter of $d_o = D_o = 12$ mm. All inner diameters are set to $d_i = D_i = 10$ mm, which allows the same size dielectric rod ($D = 9.91$ mm) to be utilized for all the tuning elements.

The input coupling post having the height of $h_i = 22.37$ mm has been excited with a coaxial probe at the height of $h_c = 21$ mm. The gap s has been set to 2mm to simplify manufacturing. The coaxial connector for the input and output excitation is the same used in section II.

In order to provide an accurate prediction of the filter performance, the structure has been simulated taking into account the metal losses in the aluminum for the hollow posts and the housing. Dielectric losses are also taken into account in all rods used for the resonators and for the coupling structures. It is important to note that the filter structures discussed in this paper are reconfigurable also in bandwidth in addition to center frequency. For this last filter, for instance, the lower and upper limits of the bandwidth are $BW = 50$ MHz and $BW = 100$ MHz, respectively. This means that the filter can be tuned to achieve any bandwidth value between 50 MHz to 100 MHz throughout the complete center frequency tuning range while maintain an equiripple return loss $RL > 25$ dB in all cases. The specifications for the initial design of this fully reconfigurable filter are as follows:

Case 1:

- Center frequency must be tunable from $f_{0,\min} = 1.475$ GHz up to $f_{0,\max} = 2.175$ GHz.
- Bandwidth $BW = 50$ MHz constant throughout the whole range of frequencies.
- Return losses: $RL > 25$ dB.

and must be achieved while maintaining a constant 50MHz bandwidth and return loss performance. This means that the filter tuning range (as defined in [5] and [22]) is

$$\frac{f_{0,\max} - f_{0,\min}}{BW} \times 100 = 1400\% \tag{5}$$

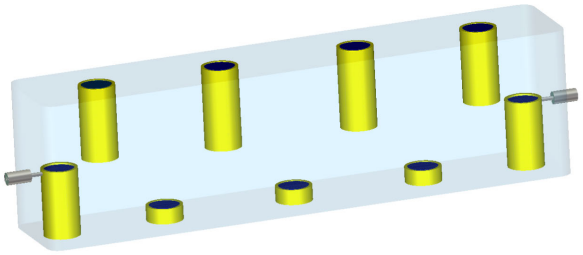

FIGURE 12. 3-D model of the combline filter with tunable frequency and bandwidth.

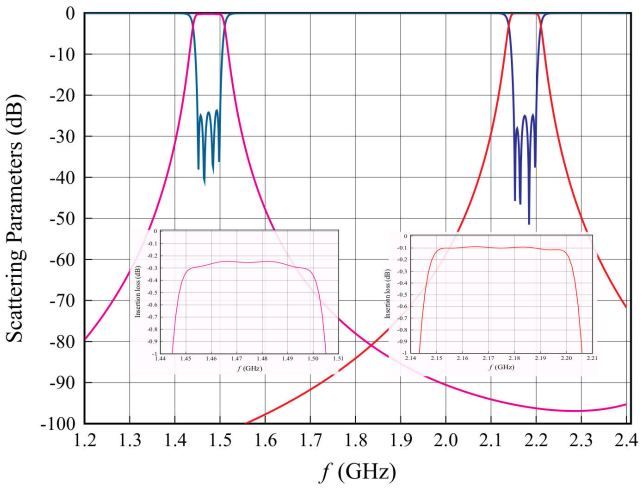

FIGURE 13. Simulation response of the filter for two extreme cases of the tuning range (the upper frequency case requires the lowest penetrations of the tuners, and the lower frequency case requires the deeper penetrations) while keeping the initial 50 MHz bandwidth. Blue line: Simulated S_{11} at 2175 MHz. Red line: Simulated S_{21} at 2175 MHz. Midnight Blue line: Simulated S_{11} at 1475 MHz. Magenta line: Simulated S_{21} at 1475 MHz (Insertion loss in corresponding inset figure).

Case 2:

- Center frequency must be tunable from $f_{0,\min} = 1.60\,\text{GHz}$ up to $f_{0,\max} = 1.92\,\text{GHz}$.
- Bandwidth $BW = 100\,\text{MHz}$ constant throughout the whole range of frequencies.
- Return losses: $RL > 25\,\text{dB}$.

This means that the filter tuning range (as defined in [5] and [22]) is

$$\frac{f_{0,\max} - f_{0,\min}}{BW} \times 100 = 320\% \tag{6}$$

Fig. 12 shows the final structure of the filter. As we can see, for case 2 ($BW = 100\,\text{MHz}$) the frequency tuning range is smaller than for case 1 ($BW = 50\,\text{MHz}$). This is due to the loading effect of the dielectric tuners, which need to be pushed out of the hollow posts in the coupling elements to obtain a wider bandwidth ($BW = 100\,\text{MHz}$), thus reducing the maximum frequency value that can be achieved. The penetration of the Zirconia tuners is summarized in Table 2 for the lower and higher cases of the lowest (50 MHz) and highest (100 MHz) filter bandwidths.

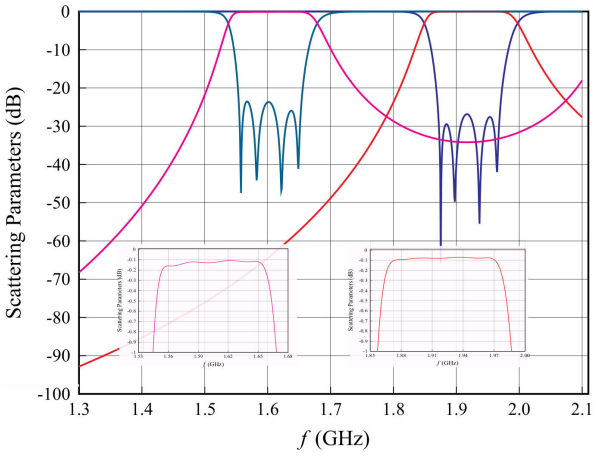

FIGURE 14. Simulation response of the filter for two extreme cases of the tuning range (the upper frequency case requires the lowest penetrations of the tuners, and the lower frequency case requires the deeper penetrations) while keeping the 100 MHz bandwidth. Blue line: Simulated S_{11} at 1920 MHz. Red line: Simulated S_{21} at 1920 MHz. Midnight Blue line: Simulated S_{11} at 1600 MHz. Magenta line: Simulated S_{21} at 1600 MHz (Insertion loss response in corresponding inset figure).

Fig. 13 shows the simulated performance obtained by changing the filter center frequency while maintaining a constant bandwidth of 50 MHz. Fig. 14, on the other hand, shows the simulated performance obtained maintaining a constant bandwidth of 100 MHz. It is worth noting at this stage that our simulations predicted the in-band insertion loss of 0.3 dB for 50 MHz and 0.25 dB for 100 MHz. These theoretical values are in good agreement with the experimental results of the manufactured prototype shown next.

V. EXPERIMENTAL RESULTS AND DISCUSSION

The manufacturing drawings of the filter prototype have been obtained using SolidWorks (from Dassault Systémes SolidWorks Corp.). The structure is composed of one body and two covers. Fig. 15 shows the 3D model of the filter.

As shown in Fig. 15, an additional 10 mm length of hollow metallic post is added to the external surface of both top and bottom covers. This has been done to provide mechanical support to the dielectric rods. Furthermore, a Teflon screw has been added in the orthogonal direction, to hold the dielectric rods in the desired tuning position. It is important to note at this point that, due to the use of milling, all concave corners of the filter body now have a curvature radius equal to 2 mm. The filter is made in Aluminum without silver plating.

Fig. 16 shows the internal topology of the filter before assembly. Furthermore, Fig. 17 shows the prototype of the filter assembles using dielectric tuners made of Zirconia. The filter has been tested using a vector network analyzer (VNA), after being properly calibrated following a standard TRL procedure. The filter is initially tuned at the higher center frequency of 2175 MHz with the lowest $BW = 50\,\text{MHz}$. Then, as it has already been discussed, the bandwidth of the

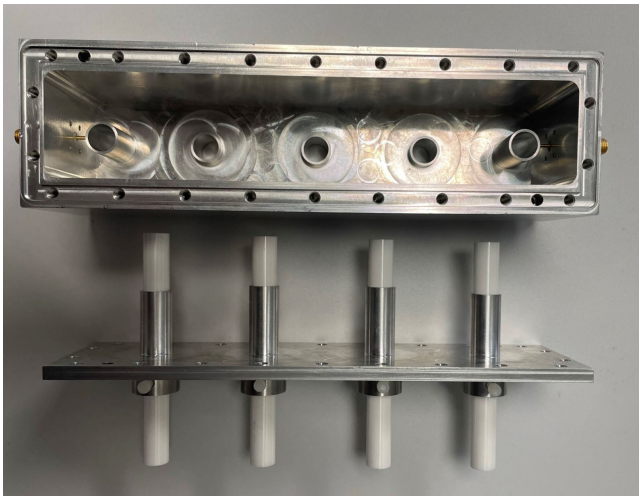

FIGURE 16. Filter structure before assembly.

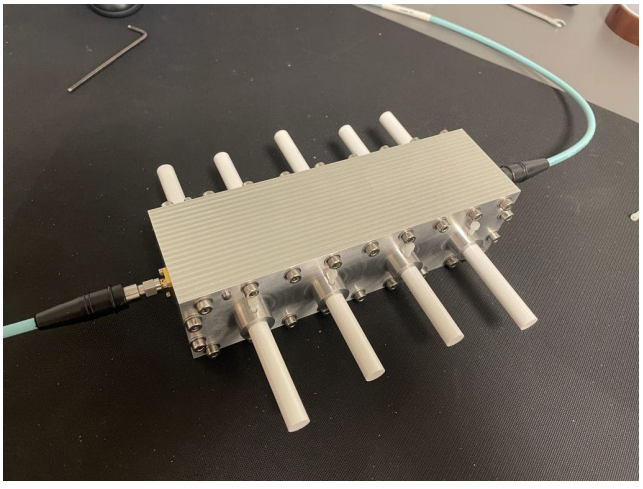

FIGURE 17. Final assembled filter prototype on the test bench.

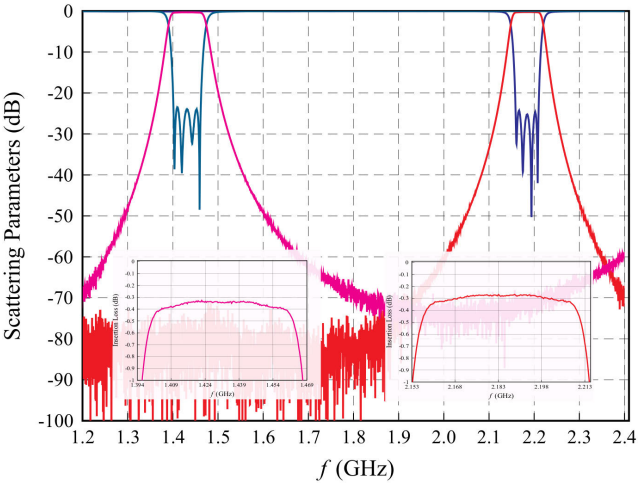

FIGURE 18. Measured response of the filter for two extreme cases of the tuning range while keeping the initial 50 MHz bandwidth. Blue line: Measured S_{11} at 2180 MHz. Red line: Measured S_{21} at 2180 MHz. Midnight Blue line: Measured S_{11} at 1433 MHz. Magenta line: Measured S_{21} at 1433 MHz (Insertion loss response in corresponding inset figure).

bandpass response can be tuned to any value between 50 MHz and 100 MHz, in the corresponding frequency ranges. As a proof of concept, the two extreme cases (i.e. $BW = 50$ MHz and $BW = 100$ MHz) have been demonstrated. In the first case, the filter center frequency can be tuned while keeping a constant bandwidth equal to 50 MHz, as shown in Fig. 18. The achieved frequency tuning range is 1494%, namely, from 1433 MHz to 2180 MHz. The response of the filter has an insertion loss level better than 0.35 dB throughout the complete tuning range, as shown in the inset of Fig. 18.

The next measurement has been performed expanding the bandwidth up to 100 MHz (double of the initial bandwidth). In this case, the filter can achieve a tuning range of 320%, starting from 1600 MHz down to 1920 MHz. As shown in Fig. 19, the measured results show a return loss level always better than 25 dB, and insertion loss values below 0.22 dB through the whole tuning range.

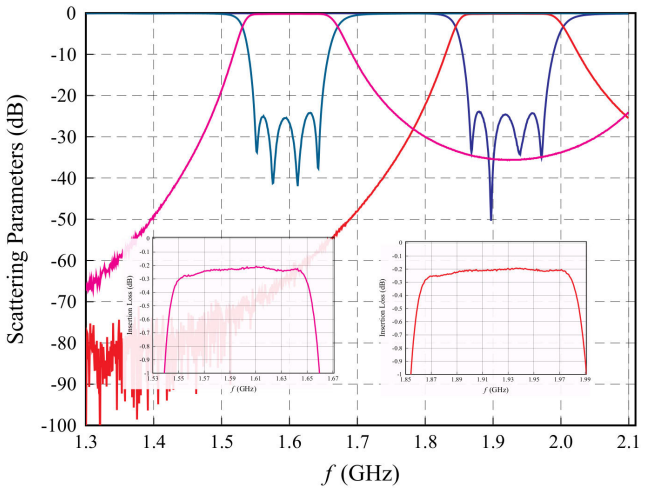

FIGURE 19. Measured response of the filter for two extreme cases of the tuning range while keeping the initial 100 MHz bandwidth. Blue line: Measured S_{11} at 1920 MHz. Red line: Measured S_{21} at 1920 MHz. Midnight Blue line: Measured S_{11} at 1600 MHz. Magenta line: Measured S_{21} at 1600 MHz (Insertion loss response in corresponding inset figure).

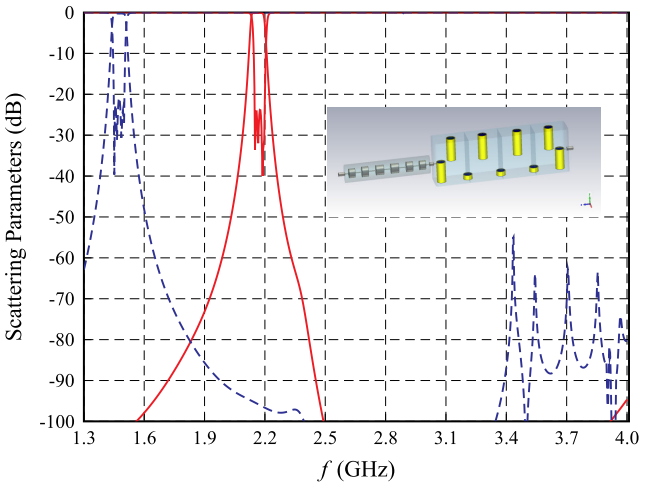

FIGURE 20. Simulated response of the integrated structure with LPF for two extreme cases of the tuning range while keeping the initial 50 MHz bandwidth. Red line: Simulated response at 2175 MHz. Blue dashed line: Simulated response at 1475 MHz. (Lowpass filter + Bandpass filter integrated structure in corresponding inset figure).

One important aspect to evaluate the performance of our filter structure is the achieved quality factor. To this end, the Q factor has been evaluated and compared using the insertion loss of the measured and simulated responses [43]. The results obtained are shown in Table. 3. The frequency range used is $1475 - 2175$ MHz. The extracted Q factor from measurement appears to be in agreement with the simulated estimations. It is important to note at this point that the prototype has been manufactured using aluminum. The Q factor of the filter can be further improved using silver plating, as can be seen in [44].

VI. OUT-OF-BAND PERFORMANCE

One of the key characteristics of any microwave filter is the out-of-band performance. However, the specific requirements that a filter must satisfy are normally dictated by the intended application. In this context, therefore, since the main objective of this paper is to discuss the proof-of-concept for a filter structure that can be reconfigured both in terms of center frequency and bandwidth, we are not aiming at satisfying a specific set of requirements. Nevertheless, since the out-of-band performance is indeed an important aspect, we discuss in this section a number of examples of how the spurious performance of our filter can be easily controlled with the help of simple, standard lowpass filters (LPFs).

Generally speaking, the out of band performance of a filter is limited by the appearance of spurious responses that can be due to the harmonics of the resonators, or to the excitation of higher order modes. For the reconfigurable filter discussed in this paper, the out-of-band response is intrinsically linked to the filter bandwidth. In fact, increasing the bandwidth, will inevitably reduce the spurious free range above the filter passband.

As a first illustrative example, we have designed a simple six-pole stepped-impedance coaxial lowpass filter, with a cutoff frequency of 2.3 GHz [45]. Fig. 20 shows the structure of the LPF integrated with the reconfigurable filter, and the simulated response for the case in which the bandwidth is set to the minimum value of 50 MHz. As we can see, adding a simple LPF of sixth order, we have obtained more than 60 dB of rejection up to 4 GHz.

As a second example, we have set the bandpass of our reconfigurable filter to 100 MHz, and we have designed an eight-pole coaxial LPF with a cutoff frequency of 2.02 GHz. Fig. 21 shows the structure and the simulated response. As expected, the LPF does improve the out-of-band response.

As a final example, we have demonstrated the combined case of an integrated lowpass filter with all the frequency and bandwidth scenarios. In this example, we have varied the bandwidths from 50 to 100 MHz. In this case, we have used an eight-pole LPF with a cutoff frequency set at 2.23 GHz. As we can see from Fig. 22, also in this case, a simple LPF can be used to improve the out-of-band response. In this case, however, the minimum frequency to which the filter can be tuned is limited to 1750 MHz, instead of 1600 MHz for 100 MHz bandwidth, as shown in Fig. 22.

The dimensions of the LPFs used in these three illustrations are given in Table 4. In all the lowpass filters discussed, the internal air spaces are filled with Teflon (relative permittivity value of 2.2). The input and output connector dimensions are identical to the ones of the filter described in subsection II-D.

VII. MULTIPACTION ANALYSIS

The power handling capability of microwave filters is a key issue for many applications and, as it is well-known, it must be evaluated in detail for each specific new structure that

TABLE 3. Q-values extracted from measurements and simulations.

Bandwidth (MHz)	Q-values extracted from measurements			Q-values extracted from simulations

is being developed. We, therefore, discuss in this section the results of a multipactor breakdown analysis for our reconfigurable filter [46]. It is important to note, however, that multipaction discharge can only happen in vacuum. As a consequence, we do not anticipate any power restrictions for ground applications.

To continue, it is important to note that, early in the design process of any filter, it is critical to evaluate and assess the power-handling phenomena of the structure being designed. In this context, the following are some key considerations relevant to multipaction:

- Coupling windows are very often critical for multipactor breakdown. As a consequence, structures without coupling windows can improve the power performance.
- The critical areas of the filter structure, namely, where the maximum electric field is located, must be identified so that a minimum gap can be used to avoid breakdown [47].
- Furthermore, since our filter structure uses both aluminum and dielectrics, the secondary emission yield (SEY) profile of the dielectric material is assumed to be the same as that of aluminum [48].
- The multipaction analysis requires the precise evaluation of the electromagnetic fields in the critical areas. The critical areas must therefore be identified, and a dense local meshing must be used to ensure the accuracy of the simulations using CST Studio Suite.

To continue, the parameters we used for the multipactor analysis, as required by the ECSS-E-HB-20-01A– Multipactor handbook [49], are as follows:

A. ALUMINUM

- SEY_{max}: 2.92.
- SEY_0: 0.8.
- E_1(eV), Impact energy: 17 eV.
- E_{max}(eV), Impact energy @ SEY_{max}: 276 eV.

B. POWER LOOP

- Precision: 0.1 dB.
- Initial Power: 500 W.
- Maximum Power: $1e + 06$ W.
- The initial number of electrons: 2000.

The power threshold has been estimated using SPARK3D v2022 (Aurora Software and Testing S.L.U., CST/3DS). The frequencies at which the multipaction threshold have been evaluated are three, namely, the center frequency and the ones at the edges of the bandwidth. The maximum peak power that we obtained for different cases in the tuning range is shown in Table 5. As we can see in Table 5, the filter structure is able to support a continuous wave of around 3656.12 W at the highest center frequency, as shown in row 1 of Table 5 for a 50 MHz bandwidth. However, as expected, there is significant degradation of power handling in the lower tuning frequency of 1475 MHz. When the filter is tuned to a bandwidth of 100 MHz, a similar pattern can be observed, as shown in the second section of Table 5.

It is therefore evident that there is a relation between the maximum power and the minimum tuning frequency. As an illustrative example, for instance, if we assume that the maximum required power is 100 W CW, the filter can be tuned from 2175 MHz to 1720 MHz (for 50 MHz bandwidth) and from 1920 MHz to 1645 MHz (for 100 MHz bandwidth).

Finally, it is important to note that, if higher power and a wider tuning range are required, enclosure of the filter structure in a pressurized environment would allow to use the full tuning range that the structure can offer.

VIII. REMOTE FILTER OPERATION

One important feature of the family of filters described in this paper, is that the use of dielectric tuners opens the possibility of developing remotely operated reconfigurable filters based on the use of low-cost, computer-controlled linear actuators.

In particular, this feature can be appreciated noting that, using the data in Table 2 for the central dielectric coupling rod movements, we obtain 13 μm/MHz for the 50 MHz bandwidth, and 57 μm/MHz for the 100 MHz bandwidth case.

These values are indeed perfectly compatible with commercial computer-controlled, low-cost linear actuators. Furthermore, it is important to note that, even though each tuner needs to be operated independently, developing the appropriate software, the complete filter performance can be controlled with a single command.

IX. CONCLUSION

In this paper, we have explored novel configurations to develop fully reconfigurable combline filters. The solution that we propose is based on the use of dielectric tuners. All resonators and all couplings can be tuned independently. The main advantage of using dielectrics is that it greatly reduces the sensitivity of the filter performance with respect to the position of the tuners. As a result, the use of a low-cost computer-controlled linear actuator becomes now an attractive possibility for the implementation of remotely reconfigurable combline filters. The out-of-band performance of our filter is also discussed, showing how a simple low-pass filter can be used to satisfy specific requirements. Furthermore, the multipaction power threshold of the structure has been studied, clearly showing that there is a trade-off between the maximum power and the minimum tuning frequency in vacuum. In conclusion, with the results presented in this paper, we have firmly established the proof of concept of a novel family of combline filters that is reconfigurable over a wide range of both bandwidth and center frequency. It is our opinion that the structure that we propose, may prove to be a significant contribution to the development of future reconfigurable payloads for both ground and space applications.

ABHISHEK SHARMA (Student Member, IEEE) was born in New Delhi, India, in 1992. He received the bachelor's degree in electronics and communication from the Technical University of Uttar Pradesh, India, in 2014, and the master's degree in microwave and optical communication from the Department of Electronics and Communication, Delhi Technological University (formerly DCE), India, in 2017. He is currently pursuing the Ph.D. degree with the Microwave Applications Group (GAM-ITEAM), Universitat Politècnica de València (UPV), Valencia, Spain, like an Early Stage Researcher of the TESLA Network.

From 2017 to 2019, he was an RF Design Engineer with the Microwave Component Division of Bharat Electronics Ltd., under the Ministry of Defence, India, where he participated in the design of TR modules for active phased arrays and radars. During the Ph.D. studies, he developed novel compact solutions for reconfigurable waveguide filters and multiplexers. His research interests include high-power filter design, reconfigurable filters, transmit-receive modules, and RF subsystems and radars.

SANTIAGO COGOLLOS (Member, IEEE) was born in Valencia, Spain, in 1972. He received the "Ingeniero Superior de Telecomunicación" and "Doctor Ingeniero de Telecomunicación" degrees from Universitat Politècnica de València (UPV), Valencia, in 1996 and 2002, respectively.

In 2000, he joined the Communications Department, UPV, where he was an Assistant Lecturer, from 2000 to 2001; a Lecturer, from 2001 to 2002; an Associate Professor, from 2002 to 2022; and became a Full Professor, in 2022. He has collaborated with the European Space Research and Technology Centre of the European Space Agency in the development of modal analysis tools for payload systems in satellites. In 2005, he held a postdoctoral research position involved in the area of new synthesis techniques in filter design with the University of Waterloo, Waterloo, ON, Canada. His research interests include applied electromagnetics, mathematical methods for electromagnetic theory, analytical and numerical methods for the analysis of microwave structures, and the design of waveguide components for space applications.

VICENTE E. BORIA (Fellow, IEEE) was born in Valencia, Spain, in May 1970. He received the Ingeniero de Telecomunicacin (Hons.) and Doctor Ingeniero de Telecomunicacin degrees from the Universidad Politècnica de València (UPV), Valencia, in 1993 and 1997, respectively. In 1993, he joined the Departamento de Comunicaciones, UPV, where he has been a Full Professor, since 2003. In 1995 and 1996, he was a Spanish Trainee with the European Space Research and Technology Centre, European Space Agency (ESTEC-ESA), Noordwijk, The Netherlands, where he was involved in the area of EM analysis and design of passive waveguide devices. He has authored or coauthored ten chapters in technical textbooks, 200 papers in refereed international technical journals, and more than 250 papers in international conference proceedings. His current research interests include the analysis and automated design of passive components, left-handed and periodic structures, and the simulation and measurement of power effects in passive waveguide systems. He has been a member of the IEEE Microwave Theory and Techniques Society (IEEE MTT-S) and the IEEE Antennas and Propagation Society (IEEE AP-S) since 1992. He is also a member of the European Microwave Association (EuMA) and the Technical Committees of the IEEE-MTT International Microwave Symposium and the European Microwave Conference. He serves as an Editorial Board Member of the *International Journal of RF and Microwave Computer-Aided Engineering*. He has been the Chair for the 48th European Microwave Conference held in Madrid, Spain. He acts as a regular reviewer for the most relevant IEEE and IET technical journals on the areas of interest. He was an Associate Editor of the IEEE MICROWAVE AND WIRELESS COMPONENTS LETTERS from 2013 to 2018 and the *IET of Electronics Letters* from 2015 to 2018. He serves as a Subject Editor for *Microwave Journal* and the *IET of Electronics Letters*.

MARCO GUGLIELMI (Life Fellow, IEEE) was born in Rome, Italy, in December 1954. He received the "Laurea in Ingegneria Elettronica" degree from the University of Rome "La Sapienza," Rome, in 1979, the M.S. degree in engineering from the University of Bridgeport, Bridgeport, CT, USA, in 1982, and the Ph.D. degree in electrophysics from Polytechnic University, Brooklyn, NY, USA, in 1986. He also attended the Scuola di Specializzazione in Elettromagnetismo Applicato, University of Rome "La Sapienza," in 1980. From 1984 to 1986, he was an Academic Associate with Polytechnic University, where he was an Assistant Professor, from 1986 to 1988. From 1988 to 1989, he was an Assistant Professor at the New Jersey Institute of Technology, Newark, NJ, USA. In 1989, he joined the RF System Division, European Space Agency, European Space Research and Technology Centre (ESTEC), Noordwijk, The Netherlands, as a Senior Microwave Engineer, where he was in charge of the development of microwave filters and electromagnetic simulation tools. In 2001, he was appointed as the Head of the Technology Strategy Section, ESTEC, where he contributed to the development of management processes and tools for the formulation of a European Strategy for Space Technology Research and Development. In 1981, he was awarded a Fulbright Scholarship in Rome and a Halsey International Scholarship Program (HISP) from the University of Bridgeport. In 2014, he retired from the European Space Agency and is currently an Invited Senior Researcher at the Universidad Politècnica de València (UPV), Valencia, Spain. He has been elevated to the grade of a fellow of the IEEE "For Contributions to Multimode Equivalent Networks and Microwave Filter Design," in January 2013.

Abstract - This paper presents a new voltage mode Tow-Thomas biquad circuit. The proposed circuit employs three voltage differencing transconductance amplifier(VDTA) as active element together with two capacitors only as passive elements. This configuration provides independent tunability of centre frequency(w), quality factor(Q) and gain by properly setting the transconductance values of the VDTAs. The synthesis of the filter has been done using gpdk 180nm technology in Cadence virtuoso environment.

Keywords**:** VDTA, Current Conveyors, OTA, Biquad fiters, Tow-Thomas,Transconductance

1. Introduction

The TT biquad, known as the Tow-Tomas biquad, is a widely used filter implementation topology that has gained significant popularity [1]. Various active elements, including operational transconductance amplifiers (OTAs), current conveyors (CCs), and differential voltage current conveyors (DVCCs), have been employed in different realizations of this structure [1]. A recent development in this area involves the implementation of a new circuit using voltage differencing current conveyors (VDCCs) [2]. The field of microelectronics has witnessed notable advancements, leading to the introduction of novel circuit principles for active building blocks, aiming to enhance the performance of existing elements such as OTAs and CCs in fast analog signal processing. One of these recent advancements is the voltage differencing transconductance amplifier (VDTA) [3].

The VDTA consists of a current source controlled by the voltage difference between two input voltages and a multiple-output transconductance amplifier. It offers electronic tuning capabilities through its transconductance gains. In the VDTA, the differential input voltage (Vp, Vn) is converted to current at terminal Z by the first transconductance gain. The voltage drop at terminal Z is then converted to current at terminals X+ and X- (negative of X+) by the second transconductance gain. Both transconductance gains can be electronically controlled using external bias currents [5].

In this study, a voltage mode TT biquad filter is designed using VDTAs, incorporating an optimal number of active and passive elements. This circuit configuration enables high cut-off frequency and independent tunability.

2. Voltage Differencing Transconductance Amplifier (VDTA)

The circuit symbol for VDTA is depicted in Figure 1, illustrating input terminals labeled as p and n, and output terminals labeled as Z, X+, and X-. It is important to note that all these terminals demonstrate a high impedance characteristic.

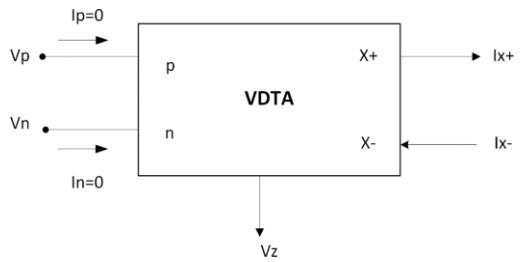

Fig. 1: VDTA block diagram

Considering ideal VDTA, the terminal relations can be characterized by the following matrix:

$$\begin{bmatrix} I_z \\ I_{x+} \\ I_{x-} \end{bmatrix} = \begin{bmatrix} g_{mf} & -g_{mf} & 0 \\ 0 & 0 & g_{ms} \\ 0 & 0 & -g_{ms} \end{bmatrix} \begin{bmatrix} V_p \\ V_n \\ V_z \end{bmatrix} \quad (1)$$

In the given matrix, the parameters g_mf and g_ms represent the tunable transconductance gains of the first and second stage respectively, and they are influenced by external currents supplied to the VDTA. The output current (Iz) is produced by converting the difference between the input voltages (Vp –Vn) using the transconductance gain g_mf. Different methods have been utilized for the realization of VDTA. Figure 2 [5] depicts the implementation of the VDTA.

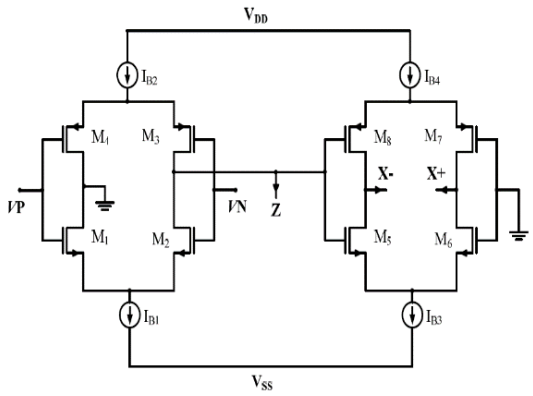

Fig. 2: VDTA Internal Architecture

The transconductance parameters derived through this structure are shown as:

$$g_{mf} = \left(\frac{g_1 g_2}{g_1 + g_2}\right) + \left(\frac{g_3 g_4}{g_3 + g_4}\right) \quad (2)$$

$$g_{ms} = \left(\frac{g_5 g_6}{g_5 + g_6}\right) + \left(\frac{g_7 g_8}{g_7 + g_8}\right) \quad (3)$$

where

$g_i = \sqrt{\frac{\mu C_{ox} W_i I_{Bi}}{L_i}}$ is the transconductance value.

In the equation above, I_Bi represents the bias current, μ denotes the effective carrier mobility, Cox corresponds to the gate-oxide capacitance, and W_i/L_i represents the effective channel length ratio of the i-th MOS transistor (where i = 1, 2, ..., 8).

2.1. VDTA-C Tow Thomas Biquad Filter

The figure provided in Fig. 3 illustrates the suggested arrangement of the multifunction voltage mode VDTA-C TT biquad filter. It enables the acquisition of both band-pass and low-pass filter responses concurrently. It may be noted that no resistors have been used in this configuration and the capacitors are grounded.

The analysis of the proposed circuit configuration yields the following output transfer function for band-pass filter:

$$T_{BP}(s) = \frac{V_{BP}}{V_{in}} = \frac{-\left(\frac{g_{mf1}}{C_1}\right)s}{s^2 + s\left(\frac{g_{ms1}}{C_1}\right) + \left(\frac{g_{mf3}\, g_{mf2}}{C_1 C_2}\right)} \quad (4)$$

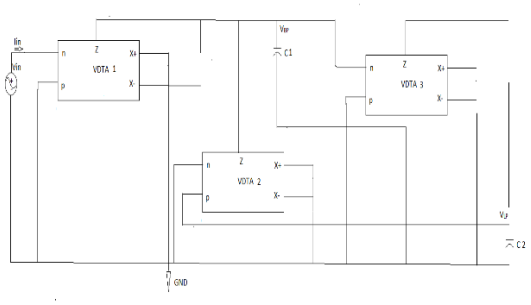

Fig. 3: VDTA-C based voltage mode Tow – Thomas biquad filter

Similarly, the transfer function of a low-pass filter can be derived as follows:

$$T_{LP}(s) = \frac{V_{LP}}{V_{in}} = \frac{\left(\frac{g_{mf1}\, g_{mf3}}{C_1 C_2}\right)}{s^2 + s\left(\frac{g_{ms1}}{C_1}\right) + \left(\frac{g_{mf3}\, g_{mf2}}{C_1 C_2}\right)} \quad (5)$$

The filter parameters namely the pole frequency (ω0), Bandwidth (BW) and quality factor (Q), can be mathematically expressed as follows:

$$\omega_0 = \sqrt{\frac{g_{mf3}\, g_{mf2}}{C_1 C_2}} \quad (6)$$

$$BW = \frac{g_{ms1}}{C_1} \quad (7)$$

$$Q = \sqrt{\frac{C_1\ g_{mf2}}{C_2 g_{mf3}}} \quad (8)$$

The DC gain for low pass response is given by:

$$H_{LP} = \frac{g_{mf1}}{g_{mf2}} \quad (9)$$

where g_mf1 and g_ms1 are first and second stage transconductance gain of VDTA1 and g_mf2 〖,g〗_mf3 are first stage transconductance gains of VDTA2 and VDTA3 block respectively.

In the case of a low-pass filter, it is possible to adjust the pole frequency and DC gain independently without any mutual interference, as demonstrated by equations (6), (7), and (9). Similarly, for a band-pass filter, we have observed the ability to independently tune the pole frequency and center frequency gain.

3. Simulation Results

The proposed circuit is simulated using gpdk 180 nm CMOS process in the Cadence virtuoso environment. The implementation of VDTA is done using given MOS transistor aspect ratio in Table 1. The supplied value of biasing is 150μA and at the supply voltage Vdd = +0.9V and Vss =-0.9V. The cutoff frequency is obtained as 10MHz using capacitor values as, C1 = C2 = 15pF. A sinusoidal

waveform of amplitude 1V and 100 KHZ is applied to the given circuit. The ideal Simulation results show that this choice yields transconductance values of VDTA as g_mf = g_ms= = 636.3 μA/V and the parasitic capacitance at the Z terminal is specified as Cp = 0.15 pF. The DC transfer characteristic is shown in the Fig. 4.

Table 1

MOS- Transistor Aspect Ratios (W/L) of VDTA

S.No	Transistors	L (*μm*)	W (*μm*)
1	M_1 - M_2 - M_5 - M_6	0.36	3.6
2	M_3 - M_4 - M_7 - M_8	0.36	16.64

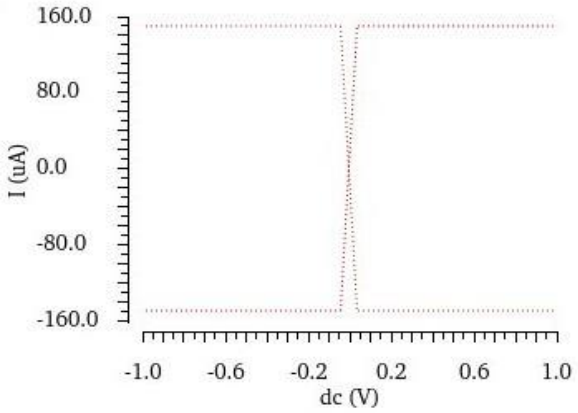

Fig. 4: DC characteristics of VDTA

The frequency response of band-pass and low pass filter is shown in Fig. 5. The phase response of band-pass filter is also obtained and can be seen in Fig. 6. The transient response of the filter is also obtained as shown in Fig. 7.

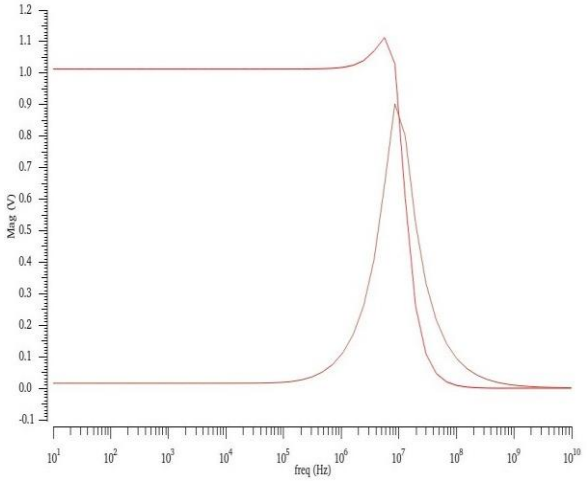

Fig. 5: Frequency response of TT Biquad filter

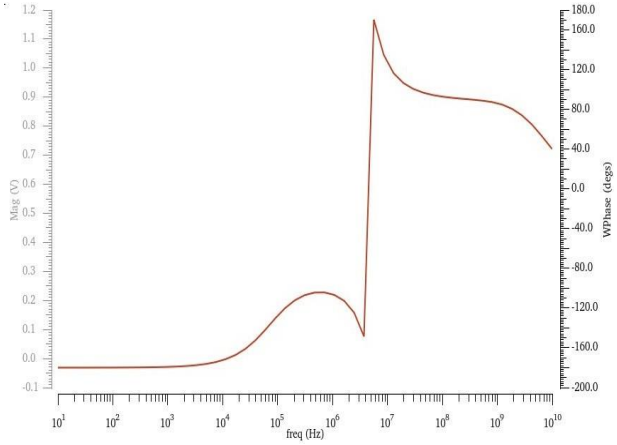

Fig. 6: Phase response of Band Pass Filter

Since the inverse configuration is obtained, we are aving 180 dergree phase change as we can see from the phase response and also from the transient response as seen in fig 8.

Table 2 - Comparision of TT biquad circuit based on number of components used

Active elements	No. of blocks	Resistors	Capacitor	Gain Control
OTA	3	6	2	Yes
OTRA	2	4	2	Yes
CCII	3	4	2	Yes
DVCC	3	3	2	No
VDCC	2	5	2	Yes
VDTA (Proposed)	3	0	2	Yes

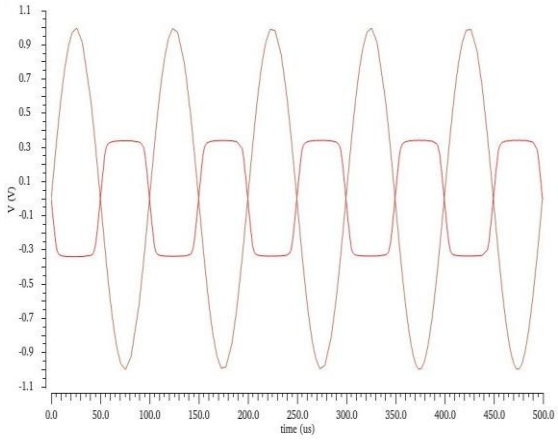

Fig. 7: Transient response of Band Pass Filter

4. Conclusion

The VDTA-C Tow-Thomas biquad presented in this paper makes use of an optimal combination of active and passive elements. Table 2 presents a comparison of various voltage mode TT biquad filter configurations, considering different numbers of active building blocks and passive elements.Noted point is that resistor is not used in this proposed configuration. The independent tunability is also demonstrated and the high frequency performance is required which can be seen in simulation results obtained from Cadence Virtuoso environment.

Water surface profile prediction in non-prismatic compound channel using support vector machine (SVM)

Vijay Kaushik[1*] and Munendra Kumar[1]

Abstract

The process of estimating the level of water surface in two-stage waterways is a crucial aspect in the design of flood control and diversion structures. Human activities carried out along the course of rivers, such as agricultural and construction operation, have the potential to modify the geometry of floodplains, leading to the formation of compound channels with non-prismatic floodplains, thus possibly exhibiting convergent, divergent, or skewed characteristics. In the current investigation, the Support Vector Machine (SVM) technique is employed to approximate the water surface profile of compound channels featuring narrowing floodplains. Some models are constructed by utilizing significant experimental data obtained from both contemporary and previous investigations. Water surface profiles in these channels can be estimated through the utilization of non-dimensional geometric and flow parameters, including: converging angle, width ratio, relative depth, aspect ratio, relative distance, and bed slope. The results of this study indicate that the SVM-generated water surface profile exhibits a high degree of concordance with both the empirical data and the findings from previous research, as evidenced by its R^2 value of 0.99, RMSE value of 0.0199, and MAPE value of 1.263. The findings of this study based on statistical analysis demonstrate that the SVM model developed is dependable and suitable for applications in this particular domain, exhibiting superior performance in forecasting water surface profiles.

Keywords Non-prismatic compound channel, Non-dimensional parameter, Support vector machine (SVM), Water surface profile

1 Introduction

With growing population across the world, increasingly more people are living in and exploring the areas along rivers, leading to serious problems related to natural flooding, which often results in heavy life losses, in addition to economic damage. Trend analyses have shown that the proportion of both global losses and deaths attributable to flood disasters continue to rise rapidly (Berz, 2000). Given that flooding occurs when the volume of water flowing through a channel is greater than the channel's capacity, predicting the flow rate of natural streams is crucial for flood prevention. As a means to reduce casualties and salvage assets as much as possible, accurate flow parameter prediction in flood circumstances, therefore, has aroused the attention of academics and engineers over recent years, with various techniques and methodologies devised to precisely gauge and anticipate river discharge, velocity distribution, shear stress distribution, and water surface level in the event of overbank floods. Compound channels are a prevalent river feature during the period of overbank flows. The hydrodynamics of a river's discharge can induce alterations to the morphology of floodplains, leading to the development of a two-stage channel system that

exhibits either converging or diverging characteristics. The transfer of energy from main channels to flood zones is comparatively higher in a composite waterway with narrowing flood zones, and thereby rendering the replication of flows in such a channel is a challenging task. Although the flow models of straight and meandering prismatic two-stage channels have been investigated by some researchers, including Sellin (1964), Myers and Elsawy (1975), Knight et al. (2010), and Khatua et al. (2012), very little is known about non-prismatic compound channels. When a channel is shaped like a converging or diverging path, the floodplain flow would increase and the floodplain flow would decrease (James & Brown, 1977). After investigating compound channels with symmetrically descending floodplains, Bousmar and Zech (2002), Bousmar et al. (2004), Rezaei (2006), and Rezaei and Knight (2009) discovered additional losses of head as well as the transfer of momentum from main channels to floodplains. Proust et al., (2006) have surveyed asymmetric geometry at a faster convergence rate, finding that there were more mass transfers and more head losses at a large convergence angle of 22 degrees. Flows in curved, two-stage converging and diverging channels were investigated by Chlebek et al. (2010), who found that when floodplains expand, the velocity gradient would rise and the head losses would increase, owing to mass and momentum transfer. There are discernible variations in the flow distribution between main channels and floodplains as a result of varying flow forces in each segment. Rezaei and Knight (2011) have explored the depth-averaged velocity, local velocity distributions, and boundary shear stress distributions in compound channels with nonprismatic floodplains in a range of convergence degrees, discovering an increase in velocity near the main channel walls, especially during the second half of the convergence reach; in addition, the effects of the lateral flows that enter main channels were observed at a high relative depth, as shown with the depth-averaged velocities. Overbank flows in compound channels with non-prismatic floodplains were studied by Yonesi et al. (2013), who found that when the depth ratio is increased or the roughness ratio is decreased, the velocity gradient between main channels and floodplains may be reduced at the divergence stretch's middle and end sections. As the divergence angle becomes greater, so does the velocity gradient. The proportion of the split discharge is affected by the roughness ratio and the depth ratio. Furthermore, the shear stress gradient would increase with higher roughness of floodplains. Naik and Khatua (2016) have developed a multivariable regression model to forecast the water surface profile for compound channels with non-prismatic floodplains. Their proposed model matches actual facts and other researchers' conclusions well. In non-prismatic compound channels, high-flow features have received little attention, and more data are needed for prediction of water surface profiles. To recreate precise profiles, more tests shall be conducted on non-prismatic compound channels with converging floodplains.

Building profile models for water surface by using different approaches makes it difficult to analyze dependencies among components, and these models would get complicated and time-consuming. This cuts in half the time needed for experiments and labour-intensive calculations. Support vector machine (SVM), gene expression programming (GEP), artificial neural networks (ANN), fuzzy neural networks (ANFIS), and M5 tree decision models are all often used to estimate flows in composite channels (Parsaie et al., 2017b). Unlike other soft computing algorithms like ANN and SVM, GEP can really produce mathematical relationships (Karimi et al., 2015), although GEP-based river engineering has been neglected (Azamathulla et al., 2013; Pradhan & Khatua, 2017). Parsaie et al. (2015) have used the support vector machine (SVM) method to forecast discharges in a compound open channel, finding that SVM can deliver the maximum accuracy, as illustrated by the error indices. By employing various analytical techniques, including the single channel method (SCM), coherence method (COHM), and divided channel method (DCM), Parsaie et al. (2016) have forecasted the discharges of a compound open channel. To enhance the precision of the flow discharge prediction, they have also devised a radian basis neural network (RBF). Finally, they found that the DCM featuring a horizontally separated boundary between subsections exhibited a correlation of determination (R^2) of 0.76, with more precise results acquired in analytical methods. The evaluation of the MLP model's outcomes exhibited a higher degree of precision ($R^2 = 0.95$) than the RBF ($R^2 = 0.85$) and other analytical methodologies. In another study, Parsaie and Haghiabi (2017) employed certain analytical techniques, specifically artificial neural network (ANN) and multivariate adaptive regression splines (MARS), to predict the discharge capacity of compound open channels, finding that the divided channel method yielded a coefficient of determination (R^2) value of 0.76 and a root mean square error (RMSE) value of 0.162, exhibiting superior performance over other analytical methods evaluated. Their research further revealed that the precision of the applied soft computing models surpassed that of analytical methods by delivering an R^2 value of 0.97 and an RMSE value of 0.03, indicating that the MARS model has a higher level of accuracy than the MLP model. In an exploration conducted by Parsaie et al. (2017a) to evaluate the precision of various empirical techniques, including the Single

Channel Method (SCM), Divided Channel Method (DCM), and Coherence Method (CM), in approximating the flow discharges in a heterogeneous compound channel roughness, they found that if assuming the virtual perpendicular line as the boundary line between sub-sections, DCM could result in a coefficient of determination greater than 0.90, demonstrating its effective performance through empirical approaches. By using the most important characteristics, such as the width ratio, relative flow depth, aspect ratio, Reynolds number, and Froude number, Khuntia et al. (2018) created an artificial neural network (ANN) model to forecast boundary shear stress distribution in straight compound channels, revealing that back-propagation neural network (BPNN) models could function effectively over wide parameter spaces. Das and Khatua (2018b) designed a numerical model that relies on the momentum balance principle to forecast water surface elevations of compound channels with the converging floodplains. The numerical model was solved with the finite difference method in MATLAB, and the simulation results demonstrated a high level of concurrence with the experimental datasets. In addition, the model could yield the lowest level of errors in terms of such metrics as the mean absolute error, mean absolute percentage error, and root mean square error. To calculate flow magnitudes and velocities in the upper and lower main channels, Das et al. (2018) have enhanced the conventional independent subsection method (ISM) framework, which features the establishment of four distinct subsections that are delineated by both vertical and horizontal division lines. These lines correspond to the vertical interface between the primary channel and floodplains, as well as the horizontal interface between upper and lower main channels. The computation results demonstrate that the method possesses the ability to accurately forecast the discharge distributions in both floodplains and main channels. Das and Khatua (2018a) have conducted experiments on symmetric compound channels in diverging and converging floodplains with various relative flow depths, in order to examine the resistance characteristics of overbank flows in non-prismatic sections. A multivariable regression model was constructed, with consideration given to the geometric and hydraulic parameters previously mentioned, for the purpose of estimating the Manning's roughness coefficient in non-prismatic compound channels. This model demonstrated favourable outcomes in comparison to the alternative methodologies across diverse experimental channels and field data, exhibiting reduced errors. Das et al. (2019) have developed a formula for calculating the flow rate in a system of compound channels with both divergent and convergent branches. Das et al. (2020) employed artificial neural network (ANN) and adaptive neuro-fuzzy inference system (ANFIS) techniques to forecast the discharge in compound channels featuring converging and diverging sections. The discharge was influenced by several significant input parameters, including the friction factor ratio, hydraulic radius ratio, relative flow depth, and bed slope. The ANFIS model demonstrated a favourable level of performance in comparison to the ANN model, as evidenced by a high coefficient of determination of 0.86 and a low root mean square error of 0.005. In order to estimate the water surface profile in converging compound channels by using non-dimensional variables, Naik et al. (2022) suggested a unique equation based on GEP. Yonesi et al., (2022) have modelled the discharges of compound open channels with non-prismatic floodplains (CCNPF) by utilizing some soft computation models, such as multivariate adaptive regression splines (MARS) and group method of data handling (GMDH). The outcomes were subsequently compared with the data from multilayer perceptron neural networks (MLPNN). The statistical error indices indicate that the developed models can deliver sufficient accuracy in estimating the flow discharge in CCNPF. Additionally, an analysis of the architecture of advanced GMDH and MARS models revealed that the following parameters exerted the most significant influence on the modelling and estimation of discharges: roughness, area, hydraulic radius, flow aspect ratio, depth, and angle of convergence or divergence of floodplain. In a study conducted by Bijanvand et al. (2023), soft computing models such as the Multi-Layer Perceptron Neural Network (MLPNN), Group Method of Data Handling (GMDH), Neuro Fuzzy Group Method of Data Handling (NF-GMDH) and Support Vector Machine (SVM) were utilised to predict water surface elevation of compound channels with converging and diverging floodplains. In this research, the SVM model exhibited superior performance in the testing phase, as evidenced by the statistical indicators; the utilization of the adaptive fuzzy methodology in the development of the Group Method of Data Handling (GMDH) model resulted in a noteworthy enhancement of precision, as evidenced by the statistical metrics during the testing phase; The optimal performance of the activation and kernel functions in the construction of the MLPNN model and the SVM was found to be associated with the sigmoid and radial tangent functions. In their study, Kaushik and Kumar (2023a) utilized machine learning techniques to forecast the water surface profile of a compound channel with a converging floodplains based on a combination of geometric and flow variables. The results indicate that the proposed artificial neural network (ANN) model could deliver a high degree of accuracy in forecasting the water surface profile, as compared to gene expression

programming (GEP), support vector machine (SVM), and previously established techniques. Moreover, Kaushik and Kumar (2023b) have also employed gene expression programming to formulate a novel equation for compound channels with converging floodplains. Expressed in terms of nondimensional geometric and flow variables, the equation can be used to estimate the boundary shear force conveyed by floodplains. Finally, it is found that the anticipated proportion of the floodplain-supported shear force as identified through GEP exhibits a satisfactory level of concurrence with the empirical evidence.

This study will employ Support Vector Machine (SVM) modelling technique to predict the water surface profile of non-prismatic compound channels with converging floodplains. This study, along with other researches on similar channel configurations, utilizes experimental datasets to investigate the impacts of diverse non-dimensional geometric and flow parameters on water surface elevations. Other different methods were previously utilized by other researchers to compute the water surface profile in non-prismatic compound channels; and they will be subjected to effectiveness or error analysis to assess the accuracy of the model proposed in this study.

2 Materials and methodologies

2.1 Data sources

Numerous explorations have been conducted on the distribution of shear force, transfer of momentum, and discharge mechanisms of compound channels with non-prismatic floodplains. This study will utilize the data from Rezaei (2006) and Naik and Khatua (2016), as well as the experiments of this paper's author. Table 1 showcases the data pertaining to the experimental channel dimensions of composite waterway with diverse geometric characteristics.

2.2 The experimental setup

The investigations for this study were conducted at a hydraulic laboratory of the Department of Civil Engineering at Delhi Technological University, India, with the experimental procedures operated in a masonry flume 12 m long, 1 m wide, and 0.8 m deep. A cross-sectional compound configuration was established with brick masonry in the flume, and the main channel was 0.5 m in width and 0.25 m in depth. The section of the channel to exhibit convergence was constructed with brick masonry. The maintenance of the geometry was achieved through the utilization of a converging angle of 4° in the channel. The compound channel under investigation exhibited a non-prismatic geometry, with a converging length of 3.6 m. The state of subcritical flow was measured under various circumstances within the two-stage channel, which featured a longitudinal bed slope of 0.001. Manning's n value was estimated based on the data obtained from both in-bank and over-bank flows in the flooded areas and primary channel. The water supply was recycled through a mechanism that pumps

Table 1 Channel dimensions used (Kaushik & Kumar, 2023a)

Verified test channel	Type of channel	Angle of convergent (θ)	Longitudinal slope (S)	Cross-sectional geometry	Total channel width (B) (m)	Main channel width (b) (m)	Main channel depth (h) (m)	Converging length (L) (m)	Aspect ratio (δ)
Channel 1 Rezaei (2006)	Converging	11.31°	0.002	Rectangular	1.2	0.398	0.05	2	7.96
Channel 2 Rezaei (2006)	Converging	3.81°	0.002	Rectangular	1.2	0.398	0.05	6	7.96
Channel 3 Rezaei (2006)	Converging	1.91°	0.002	Rectangular	1.2	0.398	0.05	6	7.96
Channel 1 Naik and Khatua (2016)	Converging	5°	0.0011	Rectangular	0.9	0.5	0.1	2.28	5

water from an underground sump to a reservoir located in the experimental channel. The flow originating from the conduit was accumulated within a volumetric receptacle equipped with a V-shaped notch; subsequently, it returned to the sump situated below. Figure 1 presents an exposition of the geometric characteristics and a sectional view of the composite waterway.

The experimental setup designed for the proposed research is depicted in Fig. 2 for its top view. A tailgate was implemented at the terminal point of the flume to regulate the profile of water surface and enforce a predetermined flow depth within the flume segment. The height of the water surface was determined with a point gauge, which could achieve an accuracy of 0.1 mm. An Acoustic Doppler Velocimeter (ADV) was employed to identify velocity distributions in three dimensions. The data obtained via the Acoustic Doppler Velocimeter (ADV) was subject to filtration in the Horizon ADV software. The lateral distributions of boundary shear stress were measured with a Preston tube of an outer diameter of 5 mm at the identical sections where the velocity distributions were examined. The pressure difference

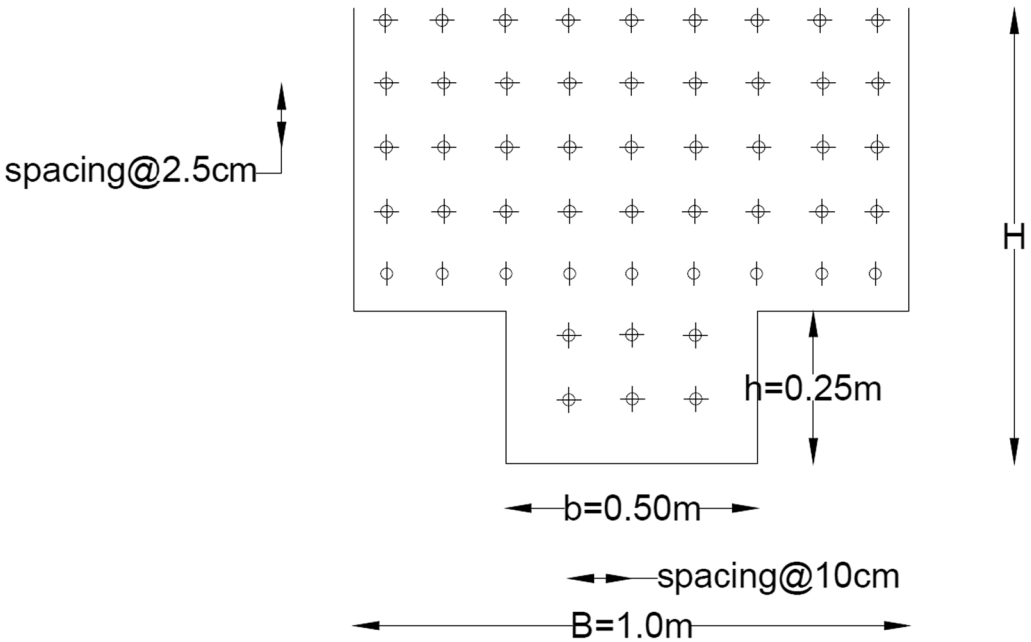

Fig. 1 Cross section of the compound channel

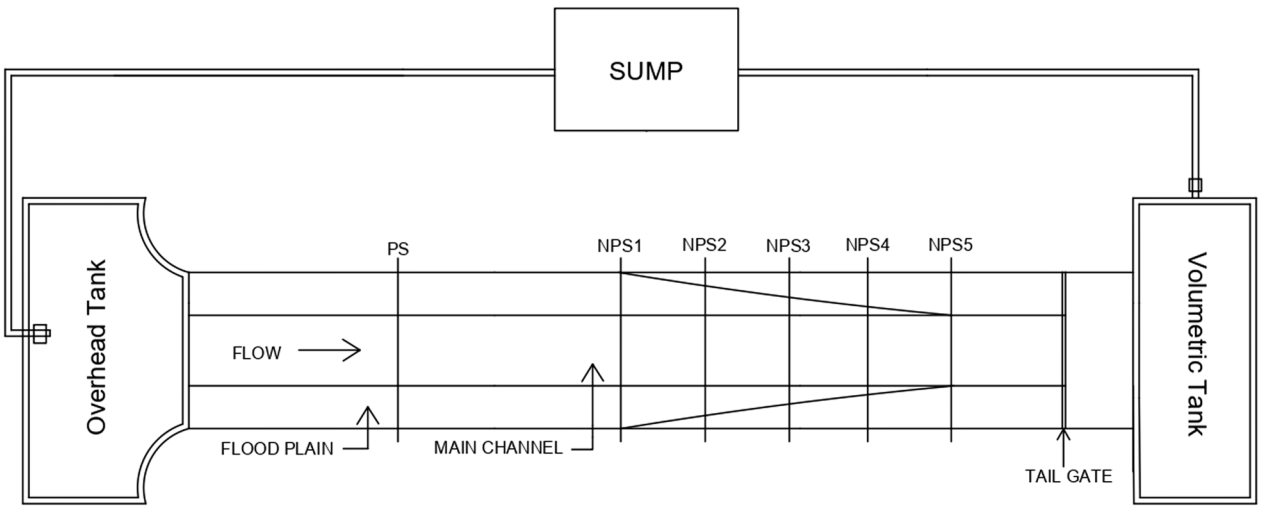

Fig. 2 Plan view of the experimental setup

was measured with a digital manometer. The utilization of Patel (1965) calibration equations was subsequently employed to compute the shear stress values. Measurements of local boundary shear stress and velocity were conducted along the wetted perimeter at intervals of 2.5 cm and 10 cm in the vertical and horizontal directions, respectively, as depicted in Fig. 1.

2.3 Theoretical background

For river specialists, the ability to make reliable projections of the contour of the top of the water during flood flows is essential for constructing drainage canals, flood defence systems, river training works, and floodplain management. As flood flow conditions in natural rivers are unpredictable, it may be difficult to acquire accurate and complete field data. Understanding the water surface profile in composite channels, especially those including both prismatic and non-prismatic floodplains, requires extensive laboratory experiments. Naik and Khatua (2016) have utilized multivariate analyses based on Eqs. (1–21) for forecasting the water surface profile in a converging compound channel, and Naik et al. (2022) have used the GEP approach based on Eq. (22).

$$\Psi = 1.06\alpha^{0.22} \tag{1}$$

$$\Psi = 1.16\alpha^{0.22} \tag{2}$$

$$\Psi = 1.21\alpha^{0.29} \tag{3}$$

$$\Psi = 0.07\alpha + 1.78 \tag{4}$$

$$\Psi = 0.05\alpha + 1.28 \tag{5}$$

$$\Psi = 0.13\alpha + 1.25 \tag{6}$$

$$\Psi = -0.14X_r + 1.22 \tag{7}$$

$$\Psi = -0.15X_r + 1.32 \tag{8}$$

$$\Psi = -0.22X_r + 1.37 \tag{9}$$

$$\Psi = -0.15X_r + 2.01 \tag{10}$$

$$\Psi = -0.16X_r + 1.45 \tag{11}$$

$$\Psi = -0.21X_r + 1.67 \tag{12}$$

$$\Psi = -1.22 + 2.27\alpha^{0.22} + 0.18X_r \tag{13}$$

$$\Psi = -1.21 + 2.28\alpha^{0.22} + 0.19X_r \tag{14}$$

$$\Psi = -0.58 + 1.63\alpha^{0.29} + 0.18X_r \tag{15}$$

$$\Psi = -0.66 + 0.29\alpha + 0.12X_r \tag{16}$$

$$\Psi = 0.86 + 0.29\alpha + 0.11X_r \tag{17}$$

$$\Psi = 0.86 + 0.29\alpha + 0.12X_r \tag{18}$$

$$\Psi^*(\theta) = \frac{Actual\Psi}{Eq.(12)} \tag{19}$$

$$\frac{Actual\Psi}{Eq.(12)} = e^{0.0017\theta} \tag{20}$$

$$\Psi = e^{0.0017\theta}\left(-1.21 + 2.25\alpha^{0.22} + 0.18X_r\right) \tag{21}$$

$$\Psi = \left[\frac{3.72 + \delta\beta + S\beta}{3.72 - S - 0.12\alpha} + \frac{9.63 - \alpha\delta}{(5.73 + \theta) \times \left(\delta^2\beta + 2\delta X_r\right)} - 14.75\delta S - \alpha\delta S\right] \tag{22}$$

A predictive model was formulated to estimate the configuration of the water's free surface in a composite waterway in convergent flooded areas. As anticipated, the fluid flow exhibits non-uniform behaviour within the non-prismatic region prior to its entry into the straight zone. The surface of both the primary waterway and the flooded zones showcases a consistently smooth texture. The mean value of Manning's n for the aforementioned smooth surfaces is 0.013. When assessing the water surface configuration of composite waterways in the narrowing floodplains, several significant factors shall be considered, including but not limited to: the width ratio (α), relative depth ratio (β), aspect ratio (δ), converging angle (θ), relative distance (X_r), and longitudinal bed slope (S_o).

The requisite equation in a dimensionless form can be formulated as follows:

$$\Psi = F(\alpha, \beta, \delta, \theta, X_r, S_o) \tag{23}$$

2.4 SVM model

The Support Vector Regression (SVR) algorithm is a commonly employed machine learning technique for the purpose of regression analysis. The method in question operates on the principles analogous to those of support vector machines (SVMs) for the classification purpose, albeit with the objective of forecasting a continuous output variable on the basis of input variables. The fundamental concept underlying Support Vector Regression (SVR) is to identify a function that can effectively map input variables to output variables, with minimal errors incurred, while also satisfying a predetermined margin. The process of attaining this objective involves the conversion of the input variables into a space of higher dimensions via a kernel function. Subsequently, the regression line that optimizes the margin while maintaining the error under a predetermined tolerance level is determined (Parsaie et al., 2015). SVR exhibits a notable benefit in its capacity to effectively manage non-linear associations between input and output variables. This feature is facilitated by such kernel functions as polynomial, radial basis function (RBF), and sigmoid function, which enable the capture of intricate relationships between variables. Support Vector Regression (SVR) has been effectively utilized in diverse domains, including finance, transportation, and medical imaging. It is of utmost significance to meticulously choose and adjust the kernel functions and other associated parameters, in order to attain optimal performance. One common method for transforming a linear classifier into a non-linear classifier utilizes a non-linear function to map the input space x into a feature space F. An alternative approach involves the utilization of a non-linear function for mapping. The separating function in space F can be expressed as below (Parsaie et al., 2015):

$$f(x) = w^T \varphi(x) + b \tag{24}$$

Within the subspace, the statistical methodology denoted by the algebraic function f (x, w) can be described as follows:

$$w = \sum_{i=1}^{n} \alpha_i x_i \tag{25}$$

$$f(x, w) = \sum_{j=1}^{n} \alpha_i x_i \varphi_i(x) + b \tag{26}$$

$$f(x) = \sum_{i=1}^{n} \alpha_i x_i^T x + b \tag{27}$$

In the feature space F, these expressions take the following forms:

$$f(x) = \sum_{i=1}^{n} \alpha_i \varphi(x_i)^T \varphi(x) + b 0 \le \alpha_i \le C \tag{28}$$

$$k(x, x\prime) = \varphi(x)^T \varphi(x\prime) \tag{29}$$

$$f(x) = \sum_{i=1}^{n} \alpha_i k(x, x_i) + b \tag{30}$$

This study finds that among the numerous kernel functions present in SVM, the radial basis kernel function is the most efficacious. Conversely, alternative kernel functions exist that can be utilized to provide assistance in a broad sense.

Linear kernel: $k\left(x_i, x_j\right) = x_i^T x_j$
Polynomial kernel: $k\left(x_i, x_j\right) = \left(\gamma x_i^T x_j + r\right)^d, \gamma > 0$
RBF kernel: $k\left(x_i, x_j\right) = \exp(-\gamma \left\| x_i - x_j \right\|)^2, \gamma > 0$
Sigmoid kernel: $k\left(x_i, x_j\right) = \tan h(\gamma x_i^T x_j + r), \gamma > 0$

The SVM model employs parameters C, γ, r, and d. The efficacy of the Support Vector Machine (SVM) model is contingent upon the calibre of the selected settings for the said parameters, in addition to the kernel parameters. The selection of values for parameters C, γ, and r plays a crucial role in regulating the complexity of the regression model. However, the process of determining the optimal parameters would be further complicated by the intricate nature of their selection. The kernel functions are utilized to reduce the dimensionality of the input space and facilitate classification. The Support Vector Machine (SVM) model is further refined through its exposure to data sets, a process that is analogous to the refinement of other neural network models. This study utilized a reliable and high-quality experimental dataset to evaluate the water surface profile of composite waterways with convergent floodplains. Prior to building the SVM model, the data were partitioned into a training set and a testing set at a 70:30 ratio in MATLAB R (2019).

2.5 Statistical measures

To further test the accuracy of the developed SVM model, various metrics of error analysis, such as the coefficient of determination (R^2), mean absolute error (MAE), mean absolute percentage error (MAPE), and root mean squared error (RMSE), are measured by using the following equations (Kaushik & Kumar, 2023a, 2023b):

$$R^2 = \frac{\sum_{i=1}^{N} (a_i - \overline{a})^2 (p_i - \overline{p})^2}{\sum_{i=1}^{N} (a_i - \overline{a})^2 \sum_{i=1}^{N} (p_i - \overline{p})^2} \tag{31}$$

$$\mathrm{MAE} = \frac{1}{N}\sum_{i=1}^{N}|p_i - a_i| \tag{32}$$

$$\mathrm{MAPE}(\%) = \frac{1}{N}\sum_{i=1}^{N}\left(\frac{|p_i - a_i|}{a_i} \times 100\right) \tag{33}$$

$$\mathrm{RMSE} = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(p_i - a_i)^2} \tag{34}$$

The above equations utilize the actual and predicted values, which are denoted by a and p, respectively. Additionally, the means of the actual and predicted values, represented by $\bar{a}$ and $\bar{p}$, respectively, are also utilized in the computation. The total number of datasets is denoted by N.

3 Results and discussion

In Fig. 3, the surface profile of water in a non-prismatic composite channel is depicted for various relative flow depths in conjunction with the channel length. In the straight segment of the waterway, the water level remains constant. However, in the convergent section, particularly in the latter half of the transition, the velocity of the flow would become faster, and the water level would be decreased. The flow in the lower section of the waterway exhibits a degree of consistency, albeit with some variations. Figure 4 illustrates the variation of the non-dimensional water surface profile (Ψ) in relation to the width ratio, relative depth, aspect ratio, and relative distance at a convergence angle of $\theta = 4°$ and relative flow depths ranging from $\beta = 0.10$ to 0.60. An increase in flow depth would result in a wider width ratio, which would in turn broaden the water surface profile. The water surface always changes in the same way as the width ratio, even at extreme convergence angles. For a wide range of convergent angles, the water surface would rise in a way not linearly connected to the depths at which the two flows are interacting with each other. The water surface profile across the non-prismatic compound channel exhibits a decreasing aspect ratio as the water traverses various sections of the channel. The influence of distance on two-dimensional representations of the water surface would diminish with increased separations between the spots. This demonstrates that the velocity head would quickly rise up as the potential head is lowered and the transition converges. Given sharper angles of convergence in floodplains, the decline is very dramatic.

Figure 5 shows a scatter plot to compare the predicted and actual values for the SVM model. The close proximity of the values to the line verifies an excellent agreement, remarkably indicating the SVM model's ability to

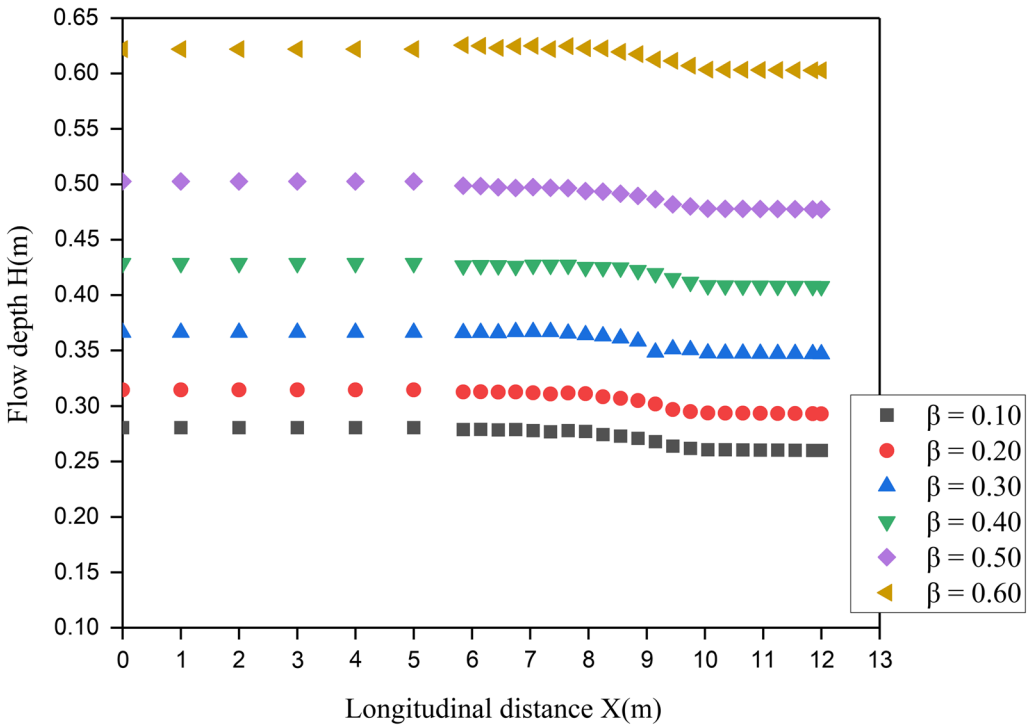

Fig. 3 Water surface profile of the two-stage waterway

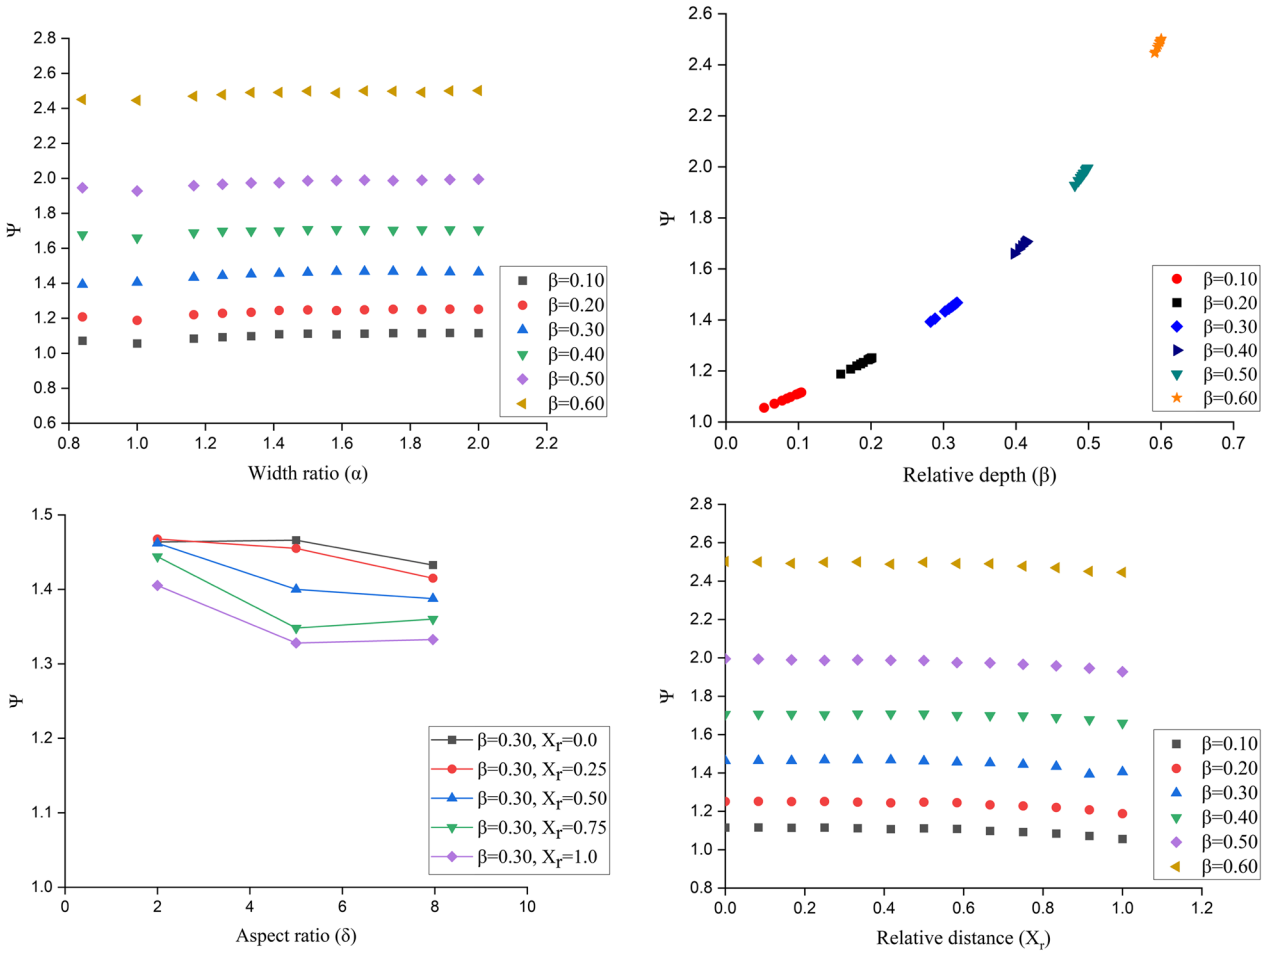

Fig. 4 Variation of non-dimensional water surface profile with various non-dimensional parameters

deliver accurate predictions. The fact that this model may offer analytical, non-parametric equations that can be used in real-world situations makes it much more useful. When making forecasts, the value of the SVM approach would yield more promising results, since the projected values are extremely near to the best-fitting line. Table 2 showcases the statistical metrics used to assess the performance of the SVM model, including R^2, MSE, RMSE, MAE, and MAPE. As shown in the table, SVM ($R^2 = 0.99$ and RMSE = 0.0199) predicts a better water surface profile in non-prismatic compound channels than other approaches, such as those proposed by Naik et al. (2022) and Naik and Khatua (2016). SVM is found to be the most suitable approach for predicting the surface water profile of composite waterways with the narrowing floodplains, with a mean absolute percentage error (MAPE) of 1.263, which is better that that of other methods.

4 Conclusion

This study demonstrates the applicability of Support Vector Machine (SVM), a machine learning technique, in detecting the elevation of water surface of two-stage channels with the narrowing floodplains. The proposed models are derived from high-quality laboratory datasets, which feature dimensionless geometric and flow characteristics and pertain to composite waterways that exhibit diverse convergent angles and relative flow depths. Several findings and implications are drawn from this study.

Certain parameters, such as the width ratio, relative flow depth, aspect ratio, angle of convergent, relative longitudinal distance, and longitudinal bed slope, appear to influence the proposed model. The phenomenon of decreasing flow depths along the channel length is attributable to the converged geometry of the channel. In fact, this trend has been observed across various floodplain

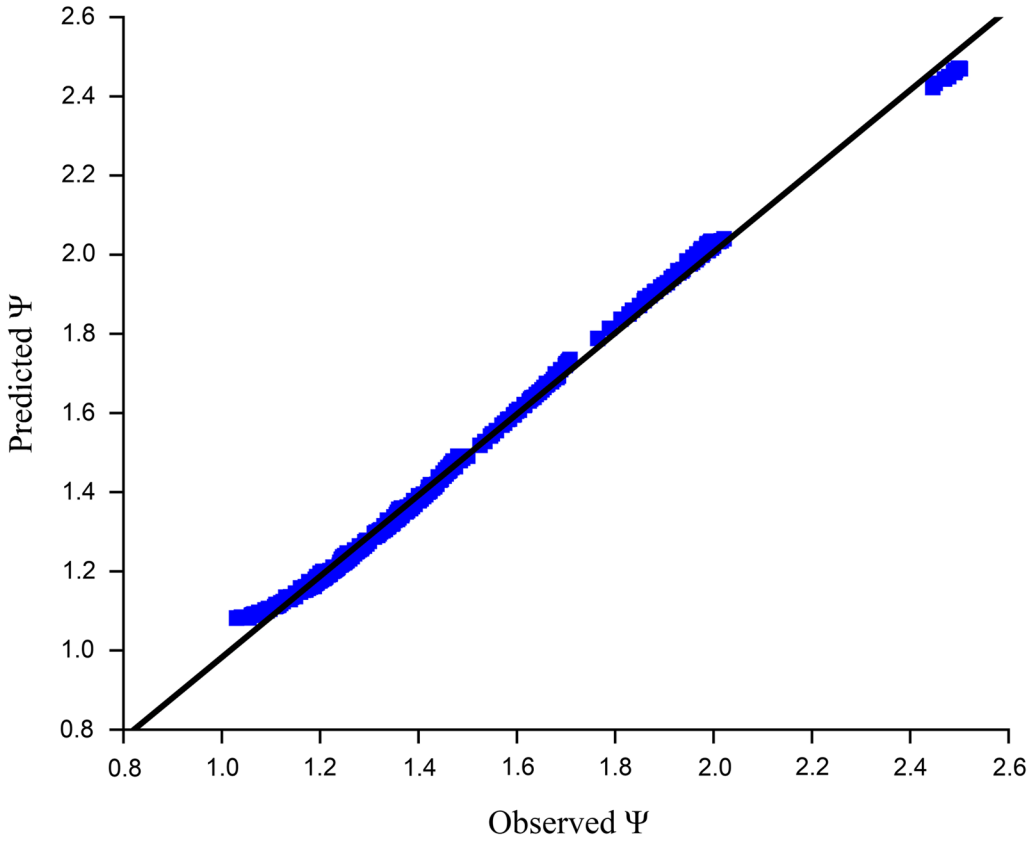

Fig. 5 Comparison between the predicted Ψ and the observed Ψ

convergence angles and at higher relative depths. It is also revealed that the non-dimensional profile of water surface exhibits an upward trend with hiking width ratio and relative depth, while showing a downward trend in terms of the aspect ratio and relative distance. The alteration of water surface's elevation in two-stage waterways exhibits the similar trend across the spectrum of narrowing angles, as demonstrated in other previous investigations. By exploring the correlation between the elevation of water surface and the non-dimensional geometric and hydraulic features of a narrowing composite waterway, this study identified non-linear correlations among the parameters. The models generated in this study deliver superior performance in terms of R^2, MAE, RMSE, and MAPE metrics over previous methodologies, such as those proposed by Naik and Khatua (2016) and Naik et al. (2022). These findings validate that the Support Vector Machine (SVM) approach can yield a satisfactory estimation of the water surface profile in composite waterways, as determined by the assessment metrics. The SVM model proposed in this study exhibits superior performance over other models, as evidenced by its R value of 0.99, RMSE value of 0.0199, and MAPE value of 1.263. These results prove the models' satisfactory performance and practical usefulness across the range of non-dimensional factors examined in this study. The utilization of statistical regression as the sole methodology is considered obsolete and should be improved. The aforementioned process is operated with a technique that could translate knowledge into a feature space of high dimensionality. Subsequently, various methods can be employed to identify interrelated fragments of information within this framework. The comprehensive mapping results in categorized linkages. The physical,

Table 2 Error analysis of SVM-predicted Ψ against previously developed methods

process-oriented research in riverine hydraulics has predicted that various parameters have an impact on energy losses, velocity, and discharge. The challenges in obtaining reliable hydraulic data in riverine environments pose significant obstacles to in-depth research in this field.
